The infinite dimensional part of the limit Dirac–Ramond–Taubes operator is built of the following operator and its adjoint. If we consider a local orthonormal basis e_i of V_g which depends only on g, we have

$$\overline{\partial}_{\infty,l}=\sum_{i,n>0} c(n)\nabla_{X_{n,l}(e_i)_.}\wedge\overline{X}_{-n,l}(e_i) \tag{3.12}$$

for a family of deterministics constants $c(n)$ for a family of deterministic constant satisfying $\Sigma c(n)^2<\infty$ and we take the sum over an orthogonal basis of the orthogonal of the Lie algebra of H. This operator is clearly invariant under the H-action, because the set of he_ih^{-1} is still an orthogonal basis of the orthogonal of the Lie algebra of H. It acts over $\Lambda_H(\Xi_l)$. Namely, if $n\neq 0$, $X_{n,l}(e_i)_.\langle ge_j\alpha,g_{\text{flat},.}\rangle=\int_0^1\langle ge_j\alpha_s,g\exp[2i\pi ns]e_ids\rangle$, if e_i belongs to the orthogonal of Lie H, which is quickly decreasing because α_s is chosen smooth. This means that the infinitesimal variation of dB_s under $X_{n,l}(e_i)_.$ is $\exp[2i\pi ns]e_ids$ if e_i belongs to the orthogonal of the Lie algebra of H.

The adjoint of $\overline{\partial}_{\infty,l}$, denoted by $\overline{\partial}^*_{\infty,l}$ is defined by the following formula:

$$\overline{\partial}^*_{\infty,l}=\sum_{i,n<0} i_{X_{-n,l}(e_i)}c(n)(-\nabla_{X_{n,l}(e_i)_.}+\operatorname{div}X_{n,l}(e_i)_.). \tag{3.13}$$

We put

$$D_{\infty,l}=\overline{\partial}_{\infty,l}+\overline{\partial}^*_{\infty,l}. \tag{3.14}$$

This operator is clearly invariant under the H-action and defined over $\Lambda_H(\Xi_l)$. Namely, a vector field $X_{n,l}(e_i)_.$ is transformed under the H-action into $X_{n,l}(he_ih^{-1})$.

The finite dimensional part of the limit Dirac–Ramond–Taubes operator is constructed as follow. We add a finite dimensional $\overline{\partial}_{f,l}$ operator,

$$\overline{\partial}_{f,l}=\sum_{f_j} X_{0,l}(f_j)_.\wedge\nabla_{X_0(f_j)_.} \tag{3.15}$$

with the notations of (2.20), which operates over the bundle $B(V_g)\otimes\Xi_l$.

We compute its adjoint: with the notations of Eq. (2.26), we have

$$\overline{\partial}^*_{f,l}=\sum_j -\nabla_{X_0(f_j')_.}i_{X_0(f_j)_.}+\operatorname{div}X_0(f_j')_.i_{X_0(f_j)_.}. \tag{3.16}$$

In order to summarize, there are two parts in the limit Dirac–Ramond–Taubes operator,

$$D_l=\overline{\partial}_{f,l}+\overline{\partial}_{f,l}+\overline{\partial}_{\infty,l}+\overline{\partial}^*_{\infty,l}. \tag{3.17}$$

There is a finite dimensional part which acts over the bundle $B(V_g)\otimes\Xi_l$ and and infinite dimensional part which acts over the Brownian bridge paths in the fiber of the linear bundle V_g.

The limit model inherites a natural limit circle action. The form $\overline{X}_{n,l}(e_i)_.$ behaves as q^n as we have seen after (2.20).

Let us compute the behavior under the limit action of the circle of the considered limit functional $\int_0^1\langle ge_i\exp[2i\pi ns],dg_{\text{flat},s}\rangle$ for e_i a section of V_g which depends only on g. For that, let us study the action of the circle of the functional $\int_0^1\langle g_{\epsilon,s}e_i\exp[2i\pi ns]ds,dg_{\epsilon,s}\rangle/\epsilon$ which tends in law to $\int_0^1\langle ge_i\exp[2i\pi ns],dg_{\text{flat},s}\rangle$. But

$$\int_0^1\langle g_{\epsilon,s-t}e_i\exp[2i\pi n(s-t)],dg_{s-t,\epsilon}\rangle=\int_0^1\langle g_{\epsilon,s}e_i\exp[2i\pi ns],dg_{\epsilon,s}\rangle. \tag{3.18}$$

If we put $F(g_{\epsilon,.})=\int_0^1\langle g_{\epsilon,s}e_i\exp[2i\pi ns],dg_{\epsilon,s}\rangle$, we have then

$$F(qg_{\epsilon,.})=q^nF(g_{\epsilon,.}) \tag{3.19}$$

for an element q of the circle. This means that F behaves as q^n by himself under the natural action of the circle over the loop group. Therefore, $\int_0^1 \langle g e_i \exp[2i\pi ns], dg_{\text{flat},s}\rangle$ behaves as q^n by himself under the limit circle action which arises by limit of the circle action over the loop group.

Let us compute the behavior of this functional under the H-action: $g_{\epsilon,s}\exp[2i\pi ns]e_i$ is transformed in $g_{\epsilon,s}\exp[2i\pi ns]e_i h$ and $g_{\epsilon,s}$ is transformed into $g_{\epsilon,s}h$. This shows that the functional F is invariant under the H action, and therefore that the limit functional is invariant under the H-action. The core $\Lambda_H(\Xi_l)$ is invariant under the limit circle action.

Let us recall what is the Witten genus of G/H: we consider the Atiyah–Singer genus of G/H which gives the Index of the Dirac operator over G/H, because G/H is supposed spin. It is too equal to $\text{Todd}(G/H)\wedge\text{ch}(\xi')$, where $\text{Todd}(G/H)$ is the Todd genus of the Kaehlerian manifold G/H. We consider the symmetric tensor algebra of $T(G/H)\otimes C$, where a tensor product of length j is counted with the power q^{nj}, where q is the generic element of S^1. The Witten genus is given by the following formula:

$$Wi(G/H)=\int_{G/H}\hat{A}(G/H)\wedge\text{ch}\otimes_{n>0}S_{q^n}(T(G/H)\otimes C) \tag{3.20}$$

(see Refs. 6, 3, 7, 8). It is given by the characterisic series (see Ref. 8, p. 83 modulo some normalizing factors)

$$Q(x)=\frac{x/2}{\sinh(x/2)}\prod_{n>0}\frac{1}{(1-q^n\exp[x])(1-q^n\exp[-x])}. \tag{3.21}$$

It is a formal series in q. So the Witten genus has to be seen as a formal series in q.

In the sequel, we will suppose that $c(n)\neq 0$ for $n>0$.

The operator D_l commutes with the limit circle action over $\Lambda_H(\Xi_l)$. We can define its ''formal'' equivariant index,

$$\text{Ind}_q D_l=\text{Tr}_{\text{Ker}\,D_l^+}q-\text{Tr}_{\text{Ker}\,D_l^-}q. \tag{3.22}$$

D_l^+ is the restriction of D_l to $\Lambda_H^+(\Xi_l)$, where $\Lambda_H^+(\Xi_l)$ is the subset of elements of $\Lambda_H(\Xi_l)$, where we choose an even power of $\overline{X}_{-n,l}(e_i)_.$, and $\Lambda_H^-(\Xi_l)$ is the subset of $\Lambda_H(\Xi_l)_.$, where we have an odd power of $\overline{X}_{-n,l}(e_i)_.$.

Theorem III.2: The equivariant Index of the limit Dirac–Ramond–Taubes operator over $\Lambda_H(\Xi_l)$ is equal to the Witten genus of G/H.

Proof: Let us compute $\Delta_l=D_l^2$. The infinite dimensional part and the finite dimensional part of the limit Dirac operator anticommute. Therefore, we have

$$\Delta_l=(\overline{\partial}_{f,l}+\overline{\partial}^*_{f,l})^2+(\overline{\partial}_{\infty,l}+\overline{\partial}^*_{\infty,l})^2=\Delta_{f,l}+\Delta_{\infty,l}. \tag{3.23}$$

To the polarization given, is associated a class of holomorphic bosons; they are combinations in the Wick products, $:\int_0^1\langle g e_j\exp[2i\pi n_j s], dg_{\text{flat},s}\rangle:$ where $n_j>0$. Let $N_{B,c}(\text{anti})$ be the second quantized operator of $c(n)^2$ which counts the number of antiholomorphic bosons and let $N_{F,c}$ be the second quantized operator of $c(n)^2$ which counts the number of fermions of the type $\overline{X}_{-n,l}(e_i)$ with $n>0$. We have[32]

$$\Delta_{\infty,l}=N_{B,c}(\text{anti})+N_{F,c}. \tag{3.24}$$

Namely, in the Gaussian space $B_.$, we do the infinitesimal transformation by $\exp[2i\pi ns]e_i$, where e_i belongs to the orthogonal of $\text{Lie}\,H$. Therefore $\Delta_{\infty,l}$ has a set of eigenvectors, which can be seen following Taubes as a countable set of finite dimensional bundles over G. Moreover, $\overline{\partial}_{f,l}+\overline{\partial}^*_{f,l}$ transforms a section of each bundle into a section of the same finite dimensional bundle. D_l has,

therefore, a self-adjoint extension which is compatible with the self-adjoint extension of Δ_l. Moreover, these constructions are compatible with the natural H-action over the limit model.

This implies that we can compute the elements which are H-invariants of the kernel of Δ_l as follows: we take first the kernel of $\Delta_{\infty,l}$, and the elements which are H-invariant under the natural H-action over it. This gives a countable set of finite dimensional bundles over G/H.

$\overline{\partial}_{f,l}+\overline{\partial}^{*}_{f,l}$ acting over H-invariant elements of the kernel of $\Delta_{\infty,l}$ tensorized by H-invariant sections of $\Lambda(n_{-}(g))\otimes p^{*}\xi'$ can be seen as homotopic to the Dirac operator over G/H tensorized by the previous countable sets of these finite dimensional bundles over G/H. The kernel of the Bosonic number operator is constitute of the holomorphic bosons since $c(n)\neq 0$, or in others words of linear combinations of Wick products, $\int_0^1 \langle g e_j \exp[2i\pi n_j s], dg_{\text{flat},s}\rangle$, with $n_j>0$. This last quantity behaves under the natural circle action as $q^{\sum n_j}$. This explains that only positive n appear in the expression of the equivariant index of D_l acting over $\Lambda_H(\Xi_l)$. The index formula (see Ref. 26) gives

$$\mathrm{Ind}_q(D_l)=\int_{G/H}\hat{A}(G/H)\wedge ch\otimes_{n>0}S_{q^n}(T(G/H)\otimes C). \tag{3.25}$$

◇

Remark: If we do not suppose that G/H is spin, we get for any complex auxiliary line bundle ξ, the equivariant index formula,

$$\mathrm{Ind}_q D_l=\int_{G/H}\mathrm{Todd}(G/H)\wedge \mathrm{ch}\,\xi'\wedge \mathrm{ch}\otimes_{n>0}S_{q^n}(T(G/H)\otimes C). \tag{3.26}$$

Let $B(x_i;\delta_i)$ be a finite cover of G/H, such that for all i, there exists a small ball B_i included in $B(x_i;\delta_i)$ such that the intersection of B_i with $B(x_j;\delta_j)$ is empty for $j\neq i$. We consider the open subset $p^{-1}B(x_i;\delta_i)$ of G. It constitutes a finite open cover of G.

Let $g_.$ be a loop. We consider a smooth function f_i from $R^{+}\to[0,\infty]$ which behaves has $1/(-\delta_i''+r)^{+n}$ for a big integer n when $r\to\delta_{i,+}''$, and which is infinite if $r<\delta_i''$ for a convenient δ_i'', and which is equal to zero outside a bounded set. We consider the functional,

$$G_i'(g_.)=\int_H d\pi(h)\int_0^1 f_i(d(g_s,hg_i)ds \tag{3.27}$$

for some $g_i\in p^{-1}(x_i)$. We multiply this by a functional of the type (2.16) such that it is equal to infinite over a small neighborhood for the uniform norm of $p^{-1}B(x_i;\delta_i)$ and it is equal to 0 outside a small neighborhood of the same set for the uniform distance in the Holderian loop space. Let us call the functional which is got by this procedure $G_i(g_.)$. Let us introduce a function h from $[0,\infty]\to[0,1]$ which is equal to 1 if $r>C$ and which is equal to zero in a neighborhood of 0.

We introduce the functional

$$F(g_.)=h\left(\sum G_i(g_.)\right). \tag{3.28}$$

This functional is clearly invariant by rotation, invariant under the H-action. It checks clearly the hypothesis (2.15) and is equal to outside a neighborhood of the constants loops in G, and is equal to 1 in a neighborhood of the constant loops in G.

Moreover,

$$P[F(g_{\epsilon,.})\neq 1]\leqslant C\exp\left[-\frac{C}{\epsilon^2}\right] \tag{3.29}$$

by the exponential inequality.

We put

$$F_i(g_.)=h(G_i(g_.)). \tag{3.30}$$

Let us suppose that $F_i(g_.)\neq 0$. $g_.$ lies in a small neighborhood for the uniform topology over the Hoelderian loop space of $p^{-1}B(x_i;\delta_i)$, if δ_i'' is chosen enough well. This neighborhood is invariant under the H-action and under the natural circle action over the loop group. Let $\tau_{i,\xi_\infty}(g_.)$ be the section of the bundle ξ_∞ given by the trivialization which is given after (2.12) by 1. Since the connection form is invariant by rotation, $\tau_{i,\xi_\infty}(g_.)$ is invariant under rotation. It is too invariant under the H-action. Namely the connection form (2.14) is invariant under the H-action. Let us precise a bit this statement: we consider the set $B(g;\delta'')$ where $g\in p^{-1}(x_i)$ for the uniform distance over the Hoelder loop space. We introduce following (2.12) the path in the loop space:

$$l_g(g_.)(t)_s=\exp[t(g_s-g)] \tag{3.31}$$

joining the loop $g_.$ to the constant loop g, and after we go to g to any fixed given element g' of $p^{-1}(x_i)$. [Recall the notation of (2.11).] If we multiply $g_.$ by h, we consider the ball $B(gh;\delta'')$ for the uniform distance over the Hoelder loop space, and the path $l_{hg}(hg_.)(t)_s=\exp[t(hg_s-hg)]$ with the notations of (2.11) and any given curve in $p^{-1}(x_i)$ joining gh to the given element g' of $p^{-1}(x_i)$. Since $-p^*R$ is in fact a basical form over G/H, the extra integral from curves in $p^{-1}x_i$ which appears in the transition functional gives a contribution which is equal to 0. This explains why the section $\tau_{i,\xi_\infty}(g_.)$ is invariant under the H-action.

We consider a section τ_{ξ_∞} of ξ_∞ such that

$$\sup_{\epsilon\leqslant 1}\sum_{n,i} E[|\nabla_{X_n(e_i)_.}\tau_{\xi_\infty}(g_{\epsilon,.})|^{2m}]<\infty. \tag{3.32}$$

It is possible by a small refinement of lemma II.1 to find such a section. By using an argument similar to Ref. 12, the second remark after Theorem II.10, it is possible to show that these sections are dense in the space of the L^2 section of ξ_∞ if ϵ is small enough.

Let us introduce a set of expressions. We consider as functionals

$$\xi(A)=\prod \int_0^1 \langle g_{\epsilon,s}e_i\exp[2i\pi ns],\delta g_{\epsilon,s}\rangle, \tag{3.33}$$

where e_i is a fixed element of Lie(G) and i and n describes the finite set A and δ denotes the Itô integral. We consider as form $X_{-n}(e_i)_.$ for the e_i element of an orthogonal basis of the orthogonal of the Lie algebra of H, i and the negative integers $-n$ describing the finite set B. We consider $X_n(e_i)_.$ for e_i belonging to the Lie algebra of G and the negative integers describing a finite set C. We consider the wedge product of all and we get an expression called $X_-(B,C)_.$. The different conventions of signs with (2.20) result that here we consider forms.

At a last step, we consider forms $X_0(f_i')$ for f_i' describing a finite set C of f_i'. [Let us recall that in (2.20), $X_0(f_j)$ considered as a vector corresponds to $X_0(f_j')$ considered as a form.] We choose a wedge product of these forms and we call it $X_0(D_.)$.

We consider as core $\Lambda_{H,\epsilon}(\Xi)$ the space of section of Ξ defined by

$$\tau_\Xi(g_{\epsilon,.})=\sum \lambda(A,B,C,D,i)F_i(g_{\epsilon,.})\xi(A,i)X_-(B,C,i)_.\wedge X_0(D,i)_.\otimes\tau_{i,\xi_\infty}(g_{\epsilon,.})$$

$$+(1-F(g_{\epsilon,.}))\sum F_{I,J,K}(g_{\epsilon,.})(X_I)_.\wedge Y_{J,.}\otimes\tau_{\xi_\infty,K}. \tag{3.34}$$

$\lambda(A,B,C,D,i)$ are constants, where the second sum in (3.34) is defined as in (2.20) and $\tau_{\xi_\infty}(g_{\epsilon,.})$ satisfies (3.33). $F_{I,J,K}(g_{\epsilon,.})$ is a cylindrical functional.

This core is invariant under the H-action and not under the natural circle action over the loop group. Namely, it is not clear that $X_{n,\epsilon}(e_i)_.$ is invariant under rotation. For that, we average under the circle the vector $X_{n,\epsilon}(e_i)_.$. It is not clear that it remains an independent family. But if $g_{\epsilon,.}$ is a small loop, it remains an independent family. For that, we introduce some cuttofs as it was done in Ref. 10, p. 270. If $\sup_{s,t}|g_{\epsilon,s}g_{\epsilon,t}^{-1}-e|$ remains small, the averaged vector fields are still an independent family of vectors. We introduce the mollifer of Ref. 10, p. 270, which is invariant by rotation and invariant under the H action because $\sup_{s,t}|g_{\epsilon,s}g_{\epsilon,t}^{-1}-e|$ is invariant under the H-action in order to conclude. We localize the core $\Lambda_{H,\epsilon}(\Xi)$ by using this others restrictions, and by using the average vector fields which are invariant by rotations, and which are independent, and which are supposed orthogonal by modifying a bit the metric.

We define Bismut's dilatation B_ϵ which acts over $\xi(A)$ by

$$B_\epsilon \xi(A)=\prod_{(i,n)\in A}\int_0^1 \frac{\langle g_{\epsilon,s}e_i \exp[2i\pi ns], dg_{\epsilon,s}\rangle}{\epsilon^{\alpha_i}}, \tag{3.35}$$

where $\alpha_i=1$ if e_i belongs to the orthogonal of the Lie algebra as H and $\alpha_i=1/2$ if e_i belongs to the Lie algebra of H. Bismut's dilatation acts over wedge products $X_-(C,D)$ by multiplying each elements of the wedge product of the type $X_n(e_i)$ with e_i belonging to the Lie algebra of H by ϵ.

Definition III.3: Bismut's dilatation over $\Lambda_{H,\epsilon}(\Xi)$ is defined by

$$B_\epsilon \tau_\Xi(g_{\epsilon,.})=\sum F_i(g_{\epsilon,.})\lambda(A,B,C,D,i)B_\epsilon\xi(A,i)B_\epsilon(X_-(B,C,i))\wedge X_0(D,i)\otimes\tau_{i,\xi_\infty}(g_{\epsilon,.})$$
$$+\left(1-F(g_.\epsilon,.)\right)\sum F_{I,J,K}(X_{I.})\wedge Y_{J_.}\otimes\tau_{\xi_\infty,K}. \tag{3.36}$$

Lemma III.4: Bismut's dilatation are well defined over $\Lambda_{H,\epsilon}(\Xi)$.

Proof: We suppose in order to simplify that $\epsilon=1$.

Since there is a small neighborhood O_i of $p^{-1}x_i$ for the uniform distance for the Hoelder loop space such that the intersection of O_i with the set $\{F_j(g_{\epsilon,.})\neq 0\}$ is empty, the result will follow the following property: if

$$i_{O_i}\sum_{A,B,C,D}\lambda(A,B,C,D,i)\xi(A,i)X_-(B,C,i)\wedge X_0(D,i)\otimes\tau_{i,\xi_\infty}(g_{\epsilon,.})=0, \tag{3.37}$$

then $\lambda(A,B,C,D,i)=0$.

We can find a mollifer functional $\tilde{F}_i$ which belongs to all the Sobolev spaces and of the type studied before such that $\tilde{F}_i(g)\neq 0$ for some $g\in p^{-1}x_i$ and such that the set $\{\tilde{F}_i(g_.)\neq 0\}$ is included in O_i.

Let us introduce the random variables $\zeta(i,n)=\int_0^1\langle e_i\cos[2\pi ns], dB_s\rangle$ for $n\geqslant 0$ and $\zeta(i,n)=\int_0^1\langle e_i\sin[2\pi ns], dB_s\rangle$ for $n<0$.

We suppose in order to simplify the exposure that the diffusion $g_.$ starts from e. We consider the measure over $G\times R^N$ μ,

$$F\to E[\tilde{F}_i(g_.)f(g_1,\zeta(.,.)], \tag{3.38}$$

where we consider $|n|\leqslant n_0$. We can suppose that $\tilde{F}_i(e)\neq 0$. Let us show that μ has an absolutely continuous part which has a strictly positive density in (e,ζ) for some convenient ζ. This will show the result. It is enough to show the following property: let us replace formally dB_s by $h_s\,ds$ with the L^2 topology over $h_.$. g_1 is replaced by $g_1(h_.)$ and $\zeta(.,.)$ by $\zeta(.,.)(h_.)$. The property says that the application Ψ: $h_.\to(g_1(h_.),\zeta(.,.)(h_.))$ is a submersion for a small $h_.$ such that $g_1(h_.)=e$. By the positivity theorem of Ref. 33 (see Ref. 34 for an abstract version), the density part of μ in $(e,\zeta(.,.)(h_.))$ is strictly positive.

If we do not suppose that n can be equal to zero, it is clearly a submersion in $h_\cdot=0$. The only problem in order that Ψ is a submersion in $h=0$ is $n=0$. But, we can perturb a little bit $h_\cdot$ in order to get a submersion, because there are multiple iterated integrals which appear in the expression of $g_1(h_\cdot)$. Let us precise a little bit this statement, after plunging the Lie group in an orthogonal matrix group. Let us denote by $Dg_s(h_\cdot)(h'_\cdot)$ the expression of the derivative of $g_s(h_\cdot)$ in the direction $h'_\cdot$. It is the solution of the differential equation,

$$dDg_s(h_\cdot)(h'_\cdot)=Dg_s(h_\cdot)(h'_\cdot)h_s ds+g_s(h_\cdot)h'_s ds. \tag{3.39}$$

We can solve this equation by the method of variation of constants. We get

$$Dg_1(h_\cdot)(h'_\cdot)=\int_0^1 g_s(h_\cdot)h'_s g_s^{-1}(h_\cdot)ds g_1(h_\cdot). \tag{3.40}$$

It is enough to choose a small h such that $s\to g_s(h_\cdot).g_s^{-1}(h_\cdot)$ is not proportional to $s\to\cos[2\pi ns]$ and to $s\to\sin[2\pi ns]$ for $|n|\leqslant n_0$ such that $g_1(h)=e$. ◇

We would like to compute the limit of $B_\epsilon\tau_\Xi(g_{\epsilon,\cdot})$ when $\epsilon\to 0$ in order to justify the appellation ''limit model'' which was used previously.

Definition III.5: We say that a sequence of sections $\tau_\xi(g_{\epsilon,\cdot},\epsilon)$ of the type

$$\tau_\Xi(g_{\epsilon,\cdot},\epsilon)=\sum_{B,C,D,i} F_{I,J,K}(g_{\epsilon,\cdot},\epsilon)X_-(B,C,i)_\cdot\wedge X_0(D,i)_\cdot\otimes\tau_{\xi_\infty,K}(g_{\epsilon,0}) \tag{3.41}$$

tends in law to the section $\tau_{\Xi_l}(g_{\text{flat},\cdot})$ of the limit model defined by

$$\tau_{\xi_l}(g_{\text{flat},\cdot})=\sum_{B,C,D,i}\xi_{(B,C,D,i)}g_{\text{flat},\cdot}\overline{X}_{-,l}(B,C,i)_\cdot\wedge\overline{Y}_{0,l}(D,i)_\cdot\otimes\tau_{\xi'}(g) \tag{3.42}$$

if the family of random variables $F_{B,C,D,i}(g_{\epsilon,\cdot},\epsilon)$ in $L^2(N)$ tends in law to the family of random variable $\xi_{B,C,D,i}(g_{\text{flat},\cdot})$ and if $E[\Sigma|F_{I,J,K}(g_{\epsilon,\cdot},\epsilon)|^2]$ remains bounded.

In this definition, it is supposed that the random variables $F_{A,B,C,i}(g_{\epsilon,\cdot},\epsilon)$ tends in law to zero if there is in $X_-(B,C,i)_\cdot$ a $X_n(e_i)_\cdot$ considered as vector or a $\overline{X}_{-n,l}(e_i)_\cdot$ considered as a form at the limit (with $n>0$) associated to an element e_i of the Lie algebra of H.

Proposition III.6: If $\tau_\Xi(g_{\epsilon,\cdot})$ is a section of Ξ of the type (3.34), $B_\epsilon\tau_\Xi(g_{\epsilon,\cdot})$ tends in law to a section of the limit model τ_{Ξ_l}.

Proof: It will result from the following observation. The contribution which is normalized at which comes from the loop close of the constant loops can be handled by the following remark: in law, when $\epsilon\to 0$,

$$g_{\epsilon,\cdot}=g\exp[\epsilon B_s+O(\epsilon^2)] \tag{3.43}$$

for a Brownian bridge $B_\cdot$ over the Lie algebra of G (see Refs. 35 and 36).

This shows that, in law,

$$B_\epsilon\xi(A)\to\prod_{i,n\in A}\int_0^1\langle ge_i\exp[2i\pi ns],dg_{\text{flat},s}\rangle \tag{3.44}$$

if all the e_i belong to the orthogonal of the Lie algebra of H and tends to 0 in law in the others cases. ◇

We consider the core $\Lambda_{H,\epsilon}(\Xi)$ as the set of sections in (3.34), where the contributions which are far from the constant loops are equal to 0. So this core is a space of sections over a small neighborhood of the constant loops in the loop group which is invariant under the circle action and

invariant under the H-action. Since the contribution outside the constant loops vanishes, it is natural to introduce a deformation of the infinite dimensional Dirac–Ramond–Taubes operator near the constant loops.

We define the regularized Dirac–Ramond–Taubes operator over the core $\Lambda_{H,\epsilon}(\Xi)$ by

$$D_\epsilon = \overline{\partial}_{\epsilon,\infty} + \overline{\partial}^*_{\epsilon,\infty}, \tag{3.45}$$

where

$$\overline{\partial}_{\epsilon,\infty} = \sum_{n>0,i} X_{-n}(e_i)_\cdot \wedge \nabla_{X_{n,\epsilon}(e_i)_\cdot} + \sum_{f_j} X_0(f'_j)_\cdot \wedge \nabla_{X_0(f_j)_\cdot}, \tag{3.46}$$

and where

$$\begin{aligned}\overline{\partial}^*_{\epsilon,\infty} = &\sum_{n<0,i} -\nabla_{X_{n,\epsilon}(e_i)_\cdot} i_{X_n(e_i)_\cdot} + \operatorname{div} X_{n,\epsilon}(e_i)_\cdot i_{X_n(e_i)_\cdot} \\ &+ \sum_j -\nabla_{X_0(f'_j)_\cdot} i_{X_0(f_j)_\cdot} + \operatorname{div} X_0(f'_j)_\cdot i_{X_0(f_j)_\cdot}.\end{aligned} \tag{3.47}$$

Let us remark that D_ϵ operates over the core $\Lambda_{H,\epsilon}(\Xi)$. Namely,

$$\begin{aligned}&X_{m,\epsilon}(e_j)_\cdot \cdot \int_0^1 \langle g_{\epsilon,s} \exp[2i\pi ns] e_i, dg_{\epsilon,s}\rangle \\ &= O(1/n) + C(\epsilon,m) \\ &\quad \times \int_0^1 \langle g_{\epsilon,s} \exp[2i\pi ns] e_i, g_{\epsilon,s} \exp[2i\pi ms] e_j\rangle \\ &= O(1/n) + C(\epsilon,m,n)\,\delta_{m,n}.\end{aligned} \tag{3.48}$$

The problem is that this operator is not invariant under rotation. For that, we average the vector fields $X_{n,\epsilon}(e_i)_\cdot$ under the natural circle action. The problem is that the averaged vector fields do not constitute an independent family in general. But it remains an independent family, because we work over a small neighborhood of the constant loops. We have the following theorem:

Theorem III. 7: When $\epsilon \to 0$, we have in law if $\tau_\Xi(g_{\epsilon,\cdot})$ is a section belonging to $\Lambda'_{H,\epsilon}(\Xi)$,

$$D_\epsilon B_\epsilon \tau_\Xi(g_{\epsilon,\cdot}) \to D_l \tau_{\Xi_l} \tag{3.49}$$

for some $c(n) \neq 0$, $\tau_\Xi(g_{\epsilon,\cdot})$ and τ_{Ξ_l} being given as in Proposition III.6.

Proof: We remark first that the contribution of the derivatives of $F_i(g_{\epsilon,\cdot})$ vanishes as it was seen previously.

There is the contribution of the covariant $\tau_{i,\xi_\infty}(g_{\epsilon,\cdot})$. If $n \neq 0$, $\nabla_{X_{n,e_i(e_i)_\cdot}} \tau_{i,\xi_\infty}(g_{\epsilon,\cdot})$ tends clearly to 0 because $X_{n,\epsilon}(e_i) \to 0$. If $n=0$, we remark that ξ_∞ restricts over G to $p^*\xi'$, and the connection forms over the first bundle over the loop group restricts over the connection form over G. Let us look at formula (2.15). The distinguished path $l_{g'}(\epsilon,\cdot)(t)$ tends to the distinguished path joining g to the given element g' of $p^{-1}(x_i)$. Therefore,

$$A_{g'}(g_{\epsilon,\cdot})(X_0(e_i)_\cdot) \to A_{g'}(e_i g), \tag{3.50}$$

where A_i is the connection form associated to $p^*\xi'$ over $p^{-1}B(x_i;\delta)$. Therefore the expression which comes to the covariant derivative of $\tau_{i,\xi_\infty}(g_{\epsilon,\cdot})$ pass to the limit.

The treatment of the covariant derivative of $B_\epsilon(X_-(B,C,i)_\cdot)$ and $X_0(D,i)_\cdot$ is trivial, with the chosen connections.

The treatment of $\operatorname{div} X_{n,\epsilon}(e_i)_.$ is given at Lemma III.1. It remains to remark that $\operatorname{div} X_{n,\epsilon}(e_i)_.$ if e_i belongs to Lie H at the limit does not appear, because there is an interior product in D_ϵ, $i_{X_n(e_i)_.}$, and that the corresponding forms are multiplied by ϵ and disappear at the limit.

It remains to consider

$$X_{n,\epsilon}(e_i)_.\,.B_\epsilon\xi(A) \tag{3.51}$$

or equivalently,

$$X_{n,\epsilon}(e_i)_.\,.\int_0^1\langle g_{\epsilon,s}\exp[2i\pi ms]e_j,\delta g_{\epsilon,s}\rangle/\epsilon. \tag{3.52}$$

Let us consider first $n\neq 0$ and e_j belonging to the orthogonal of Lie H. It tends in law, too,

$$\int_0^1\langle g\exp[2i\pi ns]e_j,g\exp[2i\pi ms]e_i\rangle \tag{3.53}$$

which is the derivative of $\int_0^1\langle g\exp[2i\pi ms]e_j,dg_{\mathrm{flat},s}\rangle$ along $X_{n,l}(e_i)_.$.

If $n\neq 0$ and e_j belongs to Lie H, $X_{n,\epsilon}(e_i)_.=O(\epsilon)$ and

$$X_{n,\epsilon}(e_i)_.\,.\int_0^1\langle g_{\epsilon,s}\exp[2i\pi ms]e_j,\delta g_{\epsilon,s}\rangle/\sqrt{\epsilon}=O(\epsilon^{1/2})) \tag{3.54}$$

and tends to zero, which is the derivative of the limit of this expression, which is 0.

If $n=0$ and if e_j belongs to the orthogonal of the Lie algebra of H,

$$\begin{aligned}X_0(e_i)_.\,.\int_0^1\langle g_{\epsilon,s}\exp[2i\pi ms]e_j,\delta g_{\epsilon,s}\rangle/\epsilon&\\ =\int_0^1\langle g_{\epsilon,s}e_i\exp[2i\pi ms]e_j,\delta g_{\epsilon,s}\rangle/\epsilon&\\ +\int_0^1\langle g_{\epsilon,s}\exp[2i\pi ms]e_j,\delta g_{\epsilon,s}(e_i)\rangle/\epsilon,&\end{aligned} \tag{3.55}$$

which tends in law to

$$\begin{aligned}\int_0^1\langle ge_i\exp[2i\pi msd]e_j,gdB_s\rangle&\\ +\int_0^1\langle g\exp[2i\pi ms]e_j,ge_idB_s\rangle=0&\end{aligned} \tag{3.56}$$

which is the derivative of

$$\int_0^1\langle g\exp[2i\pi ms]e_j,dg_{\mathrm{flat},s}\rangle=\int_0^1\langle\exp[2i\pi ms]e_j,dB_.\rangle$$

in the direction ge_i.

We have considered the limit in law of each component of the section $\tau_\Xi(g_{\epsilon,.})$, but the collections of each components converges in law.

The last property of Proposition III.5. is clearly checked. ◇

Remark: It is enough to suppose the G/H spin, by extending the Clifford multiplication over small loops as it was done in Ref. 10, (2.10), because we work over a small neighborhood of the constant loops.

Remark: The previous argument should justify, but not prove the following assertion: over $(LG)/H$, there is a Dirac–Ramond–Taubes operator, and its ''renormalized'' equivariant index is equal to the Witten genus of G/H. The contribution of the others fixed points should be treated by looking at the ''homeomorphism'' $g_\cdot \to \exp[e_\cdot] g_\cdot$.

(Received 13 October 1998; accepted for publication 24 December 1998)

It is shown that the Gel'fand–Tsetlin realization of irreducible representations of the A_n algebra is directly connected with a linear exactly integrable system in the n-dimensional space. General solutions for this system is explicitly given.
 [DOI: 10.1063/1.1285005]

I. INTRODUCTION

Almost 50 years ago Gel'fand and Tsetlin (GZ) discovered the explicit form of irreducible representations of the classical semisimple Lie algebras such as A_n, B_n, and D_n.[1] Their purely algebraic arguments were based on the possibility of the consequent embedding of one algebra into another. Under such kind of embedding the number of necessary additional ''quantum numbers'' is equal to the number of arising Cazimir operators.

In the present paper we consider GZ results from another point of view in order to connect them with some exactly integrable system of finite difference equations or with its continuous limit which has a form of partial differential equations in the n-dimensional space. The key point is that we propose the operator realization of the generators of the simple roots $X_i^{\pm}$ and Cartan elements h_i of the A_n algebra. The selection rules used by us (the assumed form of operators) are of course initiated by GZ results.

As a consequence of the commutation relations between $3n$ elements of the A_n algebra ($2n$ generators of its simple roots $X_i^{\pm}$ and n elements h_i of its Cartan subalgebra)

$$[X_i^+, X_j^-] = \delta_{i,j} h_i, \quad [h_i, X_j^{\pm}] = \pm k_{j,i} X_j^{\pm}, \tag{1}$$

in some specific form of their realization arises a discrete system of equations for n unknown functions depending on n arguments. This system allows the exact integration. Finally, the particular solution of this system under some additional requirements of irreducibility overgoes to the matrix elements the famous GZ paper.

It is more suitable to perform continuous limit not from the limiting procedure from discrete variables but by independently considering (1) on the level of Poisson brackets. Then we can use the Darboux theorem for resolving the arising functional group. (We use the old sense of this term, see, e.g., the book of Eisenhart.[2]) In this way it is possible to obtain the GZ expressions in the classical region. This method is much simpler technically and may be used as an additional hint for introducing and understanding the algebraic GZ formulas:

Such a general approach to the problem of constructing the irreducible representations of the Lie algebras was proposed many years ago in Ref. 3 but up to now has not been used (to the best of our knowledge).

We begin our discussion in Secs. II and III with the simplest cases of A_1 and A_2 algebras, discribing in detail all necessary steps of calculations. In Sec. IV we consider the general case of A_n algebra. In Sec. V we summarize the results of the paper and discuss the perspectives of the further investigations.

II. THE CASE OF $A_1 \simeq$ SU(2) AND U(2)

Every section will be divided into two parts; the classical case (the functional group level) and proper algebraic construction (''quantum case''). As it was remarked in the Introduction, the classical results may be used as good hint in further algebraic (quantum) calculations.

A. The functional algebra case

The functional U(2) algebra contains four elements $X^{\pm},H,I$ connected among themselves by Poisson brackets,

$$\{I,X^{\pm}\}=\{I,H\}=0, \quad \{X^{+},X^{-}\}=H, \quad \{H,X^{\pm}\}=\pm 2X^{\pm}. \tag{2}$$

In correspondence with the Darboux theorem[2] out of the elements of the U(2) functional group (2) it is possible to construct a pair of canonically conjugated variables M,m, $\{M,m\}=1$ and two cyclic variables $I,L\equiv X^{+}X^{-}+\frac{1}{4}H^{2}$ which have zero Poisson brackets among themselves and with all the other elements of the U(2) functional group (clearly, up to an arbitrary canonical transformation). Let us choose $M=H$ and $m=\frac{1}{4}\ln(X^{+}/X^{-})+f(H)$. With the help of the Poisson brackets (2) it is not difficult to see that thus constructed M,m are really canonically conjugate variables. Resolving these relations with respect to the functional group elements leads to following realization of the functional group elements in terms of the canonical conjugated coordinate m and momenta M and the two cyclic momenta L_1,L_2,

$$\begin{gathered} X^{+}=\tfrac{1}{2}e^{2m}(L_1-M), \quad X^{-}=\tfrac{1}{2}e^{-2m}(M-L_2), \quad H=M, \\ K^{1}\equiv I=L_1+L_2, \quad K^{2}=\frac{1}{4}\left(\frac{L_1-L_2}{2}\right)^{2}. \end{gathered} \tag{3}$$

By direct calculations it is not difficult to verify that (3) is indeed a realization of the functional group (2). If we want to restrict ourselves with the case of A_1 algebra it is necessary to put $I=0$.

B. Algebraic case

As always, to pass from the classical expressions to the quantum ones it is necessary to order in some way the operators involved and replace the Poisson brackets by commutators. Equations (3) give us a hint about the very tempting possibility to rewrite them as

$$\begin{gathered} X^{+}=\tfrac{1}{2}e^{m}(L_1-M)e^{m}, \quad X^{-}=\tfrac{1}{2}e^{-m}(M-L_2)e^{-m}, \\ H=M-\frac{L_1+L_2}{2}, \quad Q=L_1+L_2, \quad L=\frac{1}{2}\left(\frac{(L_1-L_2)^{2}}{2}-1\right) \end{gathered} \tag{4}$$

and consider now M,m as generators of the Heisenberg algebra ($[M,m]=1$, $[M,1]=0$, $[m,1]=0$, and L_1,L_2 commute with all of the generators involved in (4)). Keeping in mind the following operator relation for the Heisenberg algebra, $e^{\pm x}pe^{\mp x}=p\mp 1$, we conclude that the generators, defined in (4) satisfy the commutation relations (2) of U(2) algebra (of course with square brackets instead of the curly ones).

Two Cazimir operators under realization (4) take on the constant values

$$K^{(1}=L_1+L_2, \quad K^{(2}=X^+X^-+X^-X^+ +\frac{1}{2}H^2=\left(\frac{(L_1-L_2)^2}{2}-1\right), \tag{5}$$

which proves the irreducibility of the constructed representation.

III. $A_2 \simeq$ SU(3) AND U(3) CASES

In this case the problem consists in resolving the system of commutation relations

$$[X_1^+,X_1^-]=h_1, \quad [X_1^+,X_2^-]=0, \quad [h_1,X_1^\pm]=\pm 2X_1^\pm, \quad [h_1,X_2^\pm]=\mp X^\pm,$$

$$[X_1^+,X_2^-]=0, \quad [X_2^+,X_2^-]=h_2, \quad [h_2,X_2^\pm]=\pm 2X_2^\pm, \quad [h_2,X_1^\pm]=\mp X_1^\pm. \tag{6}$$

Algebra representation theory insures us that this is equivalent to the construction of some representation (possibly a reducible one) of the A_2 algebra.

The ''selection rules'' of the GZ paper allow us to try to find a solution of this problem in the following form:

$$\begin{gathered} X_1^+=\tfrac{1}{2}e^m(L_1-M)e^m, \quad X_2^+=e^{l_1}f^1e^{l_1}+e^{l_2}f^2e^{l_2}, \\ h_1=M-\frac{L_1+L_2}{2}, \\ X_1^-=\tfrac{1}{2}e^{-m}(M-L_2)e^{-m}, \quad X_2^-=e^{-l_1}\overline{f^1}e^{-l_1}+e^{-l_2}\overline{f^2}e^{-l_2}, \\ h_2=-\frac{M}{2}+L_1+L_2-\frac{N_1+N_2+N_3}{2}, \end{gathered} \tag{7}$$

where all ''structural'' functions $f^{1,2},\overline{f^{1,2}}$ depend only on momentum (capital letters) variables. We intentionally preserve the order of operators to avoid rewriting the same formulas for several times.

A. Classical case

In this case it is necessary to understand all of the above relations at the functional group level. The commutators have to be replaced by the Poisson brackets understood as usually,

$$\{A,B\}=\sum_1^3\left(\frac{\partial A}{\partial p_i}\frac{\partial B}{\partial x_i}-\frac{\partial A}{\partial x_i}\frac{\partial B}{\partial p_i}\right), \quad x_i=(m,l_1,l_2), \quad p_i=(M,L_1,L_2).$$

Now all of the objects are commutative and the order of the factors in (7) is unimportant. As a consequence of the vanishing Poisson brackets $\{X_1^+,X_2^-\}=\{X_2^+,X_1^-\}=0$, we obtain the explicit dependence of structural functions on momentum M. Namely,

$$\begin{gathered} X_1^+=\tfrac{1}{2}e^m(L_1-M)e^m, \quad X_2^+=e^{l_1}f^1e^{l_1}+e^{l_2}(M-L_2)f^2e^{l_2}, \\ X_{12}^+\equiv[X_1^+,X_2^+]=e^m\{e^{l_1}f^1e^{l_1}-e^{l_2}(L_1-M)f^2e^{l_2}\}e^m, \\ h_1=M-\frac{L_1+L_2}{2}, \quad h_2=-\frac{M}{2}+L_1+L_2-\frac{N_1+N_2+N_3}{2}, \end{gathered} \tag{8}$$

$$X_{12}^-\equiv[X_2^-,X_1^-]=e^{-m}\{e^{-l_1}(L_1-M)\overline{f^1}e^{-l_1}-e^{l_2}\overline{f^2}e^{-l_2}\}e^{-m},$$

$$X_1^-=\tfrac{1}{2}e^{-m}(M-L_2)e^{-m}, \quad X_2^-=e^{-l_1}(L_1-M)\overline{f^1}e^{-l_1}+e^{-l_2}\overline{f^2}e^{-l_2}. \tag{9}$$

Keeping in mind the above arguments, we have preserved the order of factors essential for the consideration in the next subsection. Moreover, we have presented also the explicit form of the generators of the composed roots $X_{12}^{\pm}$, which will be necessary below for constructing of the Cazimir operators. The additional constant in h_2 will be explained a little bit later. In the case of the A_2 algebra this constant is equal to zero.

The remaining Poisson bracket $\{X_2^+, X_2^-\}=h_2$, unused up to now, has as its consequence the system of equations for structural functions. Technically, all these operations are simple and we represent only the result,

$$(f^1\overline{f^1})_{L_1}-(f^2\overline{f^2})_{L_2}=-\tfrac{1}{4},\quad -(L_1 f^1\overline{f^1})_{L_1}+(L_2 f^2\overline{f^2})_{L_2}=\frac{L_1+L_2}{2}-\frac{N_1+N_2+N_3}{4}, \tag{10}$$

$$f^2_{L_1}\overline{f^1}+f^2\overline{f^1}_{L_2}=0,\quad f^1_{L_2}\overline{f^2}+f^1\overline{f^2}_{L_1}=0. \tag{11}$$

By shifts of independent variables $L_1\to L_1+(N_1+N_2+N_3)/3$ and $L_2\to L_2+(N_1+N_2+N_3)/3$ the constant term from the second Eq. (10) may be taken away. This corresponds to the transition from the algebra U(3) to SU(3).

From now on we can divide our problem into two parts and formulate it more precisely. First of all, we want to prove that the linear system of Eqs. (10) is exactly integrable and to give its general solution. In the case of arbitrary A_n algebra it will be the linear system of equations in partial derivatives for n unknown functions in the n-dimensional space. Secondly, we can solve this system under additional restrictions, which follow from (11), and in this way to obtain once again the GZ formulas for matrix elements of irreducible representations of the A_n algebra.

In this section we present the solution of the second part of the problem. The functional group possesses two cyclic variables (Cazimir operators on the algebra representation level), which may be constructed as the traces of the second and third degree of the following matrix:

$$K=\begin{pmatrix} h^1 & X_1^- & X_{12}^- \\ X_1^+ & h^2-h^1 & X_2^- \\ X_{12}^+ & X_2^+ & -h^2 \end{pmatrix},$$

where $h^1=(2h_1+h_2)/3=(M/2)$, and $h^2=(h_1+2h_2)/3=(L_1+L_2)/2$. Explicit forms of Cazimir operators of the second- and the third-order are as follows:

$$\begin{aligned} K^{(2}&=X_{12}^+X_{12}^-+X_1^+X_1^-+X_2^+X_2^-+(h^1)^2-h^1h^2+(h^2)^2\\ &=(L_1-L_2)(f^1\overline{f^1}+f^2\overline{f^2})+\tfrac{1}{4}(L_1^2+L_1L_2+L_2^2),\end{aligned}$$

$$\begin{aligned} K^{(3}&=X_{12}^+X_1^-X_2^-+X_{12}^-X_1^+X_2^+-h^1X_2^+X_2^-+h^2X_1^+X_1^-+(h^1-h^2)X_{12}^+X_{12}^-+h^1h^2(h^1+h^2)\\ &=\tfrac{1}{2}\{(L_1-L_2)(L_1f^1\overline{f^1}+L_2f^2\overline{f^2})+\tfrac{1}{4}L_1L_2(L_1+L_2).\end{aligned}$$

Equating the Cazimir operators to constant values, we obtain additional system of linear algebraic equations for the functions $x\equiv f^1\overline{f^1}$, $y\equiv f^2\overline{f^2}$, which is consistent with (10), (11),

$$x+y=\frac{\sigma_2-(L_1^2+L_1L_2+L_2^2)}{4(L_1-L_2)^2},\quad L_2x+L_1y=\frac{\sigma_3-L_1L_2(L_1+L_2)}{4(L_1-L_2)^2}.$$

The solution of the last system is given as follows:

$$f^1\overline{f^1}=\frac{P_3(L_1)}{4(L_1-L_2)^2},\quad f^2\overline{f^2}=\frac{-P_3(L_2)}{4(L_1-L_2)^2}, \tag{12}$$

where $P_3(z)=(z-N_1)(z-N_2)(z-N_3)$ and $N_1+N_2+N_3=0$ in the case of A_2 algebra. We emphasize that solution (12) is only a particular solution of system (10), but not of the general one.

B. General solution of the linear system

To stress the symmetry properties of (10), we rewrite it in the variables $X^1\equiv f^1\overline{f^1}, X^2\equiv -f^2\overline{f^2}, x_1\equiv L_1, x_2\equiv L_2$, keeping only the homogeneous part of it,

$$X^1_{x_1}+X^2_{x_2}=0, \quad (x_1X^1)_{x_1}+(x_2X^2)_{x_2}=0. \tag{13}$$

The system (13) is a particular case of the following system for n unknown functions X^i in n-dimensional coordinate space x_i,

$$\sum_{i=1}^{n}(x_i^kX^i)_{x_i}=0, \ \ k=0,1,2,...,n-1 \tag{14}$$

the particular case (13) corresponds to the choice $n=2$ in (14).

Now we would like to demonstrate the direct way for obtaining the general solution of (13). Multiplying the first equation of the system (13) correspondingly by x_1, x_2 and subtracting it from the second equation we obtain

$$((x_2-x_1)X^2)_{x_2}+X^1=0, \quad ((x_1-x_2)X^1)_{x_1}+X^2=0.$$

Introducing new unknown functions $Y^{1,2}\equiv(x_1-x_2)^2X^{1,2}$, we transform the system (13) to the form

$$(x_2-x_1)(Y^2)_{x_2}+Y^1-Y^2=0, \quad (x_1-x_2)(Y^1)_{x_1}+Y^2-Y^1=0,$$

from which we conclude that $(Y^1)_{x_1}=(Y^2)_{x_2}$. At last, differentiating the first equation with respect to x_1 and the second one with respect to x_2, we present each of them in the integrable form,

$$\frac{\partial \ln Y^2_{x_1}}{\partial x_2}=\frac{1}{x_2-x_1}, \quad \frac{\partial \ln Y^1_{x_2}}{\partial x_1}=\frac{1}{x_1-x_2}. \tag{15}$$

Finally, the general solution of the system (13) takes the form,

$$\begin{aligned}(x_1-x_2)^2X^1&=\Phi(x_2)_{x_2}(x_1-x_2)+\Theta(x_1)+\Phi(x_2),\\ (x_1-x_2)^2X^2&=\Theta(x_1)_{x_1}(x_2-x_1)+\Phi(x_2)+\Theta(x_1),\end{aligned} \tag{16}$$

where $\Theta(x_1),\Phi(x_2)$ are arbitrary functions of a single argument.

C. Algebraic cases $A_2\simeq$ SU(3) and U(3)

In this section we will consider a realization of (8), where the pairs M,m,L_1,l_1,L_2,l_2 are the elements of the three independent mutually commutative Heisenberg algebras $[M,m]=1$, $[L_1,l_1]=1$, $[L_2,l_2]=1$. The involved structural functions are supposed to depend only on the momentum operators M,L_1,L_2,N_1,N_2,N_3.

Explicit dependence of the structural functions upon the momentum M arises immediately, if we take into account commutation relations $[X_1^+,X_2^-]=[X_2^+,X_1^-]=0$.

Commutation relation $[X_2^+,X_2^-]=h_2$, after using the well-known from the theory of the Heisenberg algebra relations $\exp(\pm x)p\exp(\mp x)=p\mp 1$ is equivalent to the system of equations in finite differences, which will be convenient to write in the following notation:

$$F^{(1}_{\pm}=f^{(1}(L_1\pm 1,L_2)\overline{f}^{(1}(L_1\pm 1,L_2),$$

$$F^{(2}_{\pm}=f^{(2}(L_1,L_2\pm 1)\overline{f}^{(2}(L_1,L_2\pm 1),$$

$$F^{(1}_{+}-F^{(1}_{-}+F^{(2}_{+}-F^{(2}_{-}=-\tfrac{1}{2},$$

$$-(L_1+1)F^{(1}_{+}+(L_1-1)F^{(1}_{-}-(L_2-1)F^{(2}_{-}+(L_2+1)F^{(2}_{+}=L_1+L_2-\frac{N_1+N_2+N_3}{2}, \tag{17}$$

$$\begin{aligned} &f^{(2}(L_1-1,L_2)\overline{f}^{(1}(L_1,L_2-1)=f^{(2}(L_1+1,L_2)\overline{f}^{(1}(L_1,L_2+1),\\ &f^{(1}(L_1,L_2-1)\overline{f}^{(2}(L_1-1,L_2)=f^{(1}(L_1,L_2+1)\overline{f}^{(2}(L_1+1,L_2). \end{aligned} \tag{18}$$

In the continuous limit (17) coincides with (10), and (18) coincides with (11).

The Cazimir operators may be constructed as traces of the first, second, and third degrees of the K matrix as in the previous subsection. But in this case it is necessary to take into account noncommutativity of operators involved. In this way we obtain their explicit expressions,

$$K^{(1}=\frac{N_1+N_2+N_3}{2},$$

$$\begin{aligned} K^{(2}&=X^+_{12}X^-_{12}+X^-_{12}X^+_{12}+X^+_1X^-_1+X^-_1X^+_1+X^+_2X^-_2+X^-_2X^+_2+2((h^1)^2-h^1h^2+(h^2)^2),\\ K^{(3}&=X^-_2X^+_{12}X^-_1+X^+_1X^-_{12}X^+_2-\tfrac{1}{2}h^1\{X^+_2X^-_2\}+\tfrac{1}{2}h^2\{X^+_1X^-_1\}\\ &\quad+\tfrac{1}{2}(h^1-h^2-2)\{X^+_{12}X^-_{12}\}+h^1h^2(h^1+h^2)+(h^1+h^2)-((h^1)^2-h^2h^1+(h^2)^2). \end{aligned} \tag{19}$$

Equating Cazimir's operators to constant values, we obtain the additional and consistent with (17), (18) equations,

$$\begin{aligned} F^{(1}_{+}+F^{(1}_{+}+F^{(2}_{+}+F^{(2}_{-}=&\frac{\sigma_2-(L_1^2+L_1L_2+L_2^2)}{2(L_1-L_2)}\left[\frac{(L_2-1)(L_1+L_2+4)}{4}-(L_1+1)(L_2+1)\right]F^{(1}_{+}\\ &+\frac{(L_2+1)(L_1+L_2+4)}{4}F^{(1}_{-}-\frac{(L_1+1)(L_1+L_2+4)}{4}F^{(2}_{-}\\ &+\left[(L_2+1)(L_1+1)-\frac{(L_1-1)(L_1+L_2+4)}{4}\right]F^{(2}_{+}\\ =&\sigma_3+\frac{1}{8}L_1L_2(L_1+L_2)+\frac{5}{8}(L_1+L_2)+\frac{1}{4}(L_1+L_2)^2. \end{aligned} \tag{20}$$

In connection with the last system the following comments will be appropriate. (17) is the system of the two equations for two unknown functions $F^{(1,2}$ with shifted ± 1 arguments. In this sense it is a closed one. (18) and (20) may be considered as additional to (17) conditions, by which are necessary to choose from the general solution only those that correspond to the realization of the irreducible (Cazimir operators are fixed) representations of the A_2 algebra.

As in the previous section, here two problems arises; to find a general solution of the system (17) and, as the second step, to satisfy additional conditions which follow from (18) and (20).

Here we present a solution of the second part of the above formulated problem. Combining the first equation of (17) with the first equation from (20), we immediately obtain

$$F_+^{(1}+F_-^{(2}=-\frac{1}{4}+\frac{\sigma_2-(L_1^2+L_1L_2+L_2^2)}{4(L_1-L_2)},\quad F_+^{(1}+F_+^{(2}=\frac{1}{4}+\frac{\sigma_2-(L_1^2+L_1L_2+L_2^2)}{4(L_1-L_2)}.$$

For unknown functions, $v\equiv(L_1-L_2-2)(F_-^{(1}-F_+^{(2})$, $u\equiv(L_1-L_2+2)(F_+^{(1}-F_-^{(2})$, we obtain the linear system from the remaining equations,

$$v-u=\tfrac{3}{2}(L_1+L_2),$$

$$(L_1-L_2+2)v+(L_1-L_2-2)u=\frac{(L_1+L_2+4)(\sigma_2-(L_1^2+L_1L_2+L_2^2))}{4}+L_1L_2(L_1+L_2)$$
$$+2(L_1^2+L_1L_2+L_2^2)+2(L_1+L_2)+\sigma_3,$$

with the explicit solution,

$$4(L_1-L_2-1)(L_1-L_2+1)F^{(1}=P_3(L_1),\quad 4(L_1-L_2-1)(L_1-L_2+1)F^{(2}=P_3(L_2),\quad (21)$$

where $P_3(z)=(z-N_1)(z-N_2)(z-N_3)$.

The square roots of $F^{(1},F^{(2}$ are exactly the matrix elements of Gel'fand–Tsetlin realization of U(3) algebra.

IV. GENERAL CASE OF ARBITRARY *n*

A. The algebra representation level

Let us assume that the generators of the simple roots and Cartan elements of elements of $U(n+1)$ algebra may be represented in the form

$$X_s^+=\sum_{k=1}^{s} e^{l_k^s}g_k^s e l_k^s,\quad X_s^-=\sum_{k=1}^{s} e^{-l_k^s}\overline{g}_k^s e^{-l_k^s},\qquad (22)$$

$$h_s=-\frac{1}{2}\sum_{r=1}^{s-1}L_r^{s-1}+\sum_{k=1}^{s}L_k^s-\frac{1}{2}\sum_{l=1}^{s+1}L_l^{s+1},\quad 1\leqslant s\leqslant n,$$

where nonzero commutators of operators involved are only those

$$[L_k^s,l_l^t]=\delta_{st}\delta_{kl}I$$

and structural functions are the functions only of the following arguments: $g_k^s\equiv g_k^s(L^{s+1},L^s,L^{s-1})$, $\overline{g}_k^s\equiv\overline{g}_k^s(L^{s+1},L^s,L^{s-1})$. The reader may identify without any difficulties L^1 with M,L^2 with L_1,L_2 and at last L^3 with N_1,N_2,N_3. We will assume also that structural functions may be represented in factorizable form

$$g_k^s\equiv F_k^s(L^{s+1};L^s)f_k^s(L^s;L^{s-1}),\quad \overline{g}_k^s\equiv\overline{F}_k^s(L^{s+1};L^s)\overline{f}_k^s(L^s;L^{s-1}),$$

and

$$(F_k^{s-1})^2=(\overline{F}_k^{s-1})^2=\frac{\Pi_{r=1}^s(L_k^{s-1}-L_r^s)}{\Phi(L^{s-1})},$$

where function Φ is translation invariant with respect to the shift of all of its arguments L_k^{s-1}.

The last proposition we will prove by induction.

It is obvious that under such kinds of restrictions commutation relation between generators of Cartan subalgebra h_l and generators of the simple roots $X_k^{\pm}$ are correctly satisfied. It is also clear that the generators $X_s^{\pm}$ commute with all generators $X_k^{\mp}$ with $k \leqslant (s-2)$ because they act on essentially different arguments. And finally, commutation relations

$$[X_s^{\pm}, X_{s-1}^{\mp}] = 0$$

allow us to reconstruct in explicit form the dependence of structural functions $f_k^s, \overline{f_k^s}$ on arguments L_k^{s-1}.

As a direct consequence of the last commutation relations we obtain

$$f_k^s(L^s;\ldots,L_r^{s-1}-1,\ldots)\overline{F_r^s}^{s-1}(\ldots,L_k^s-1,\ldots;L^{s-1}) = f_k^s(L^s;\ldots,L_r^{s-1}+1,\ldots)\overline{F_r^s}^{s-1}(\ldots,L_k^s+1,\ldots;L^{s-1}),$$

$$\overline{f_k^s}(L^s;\ldots,L_r^{s-1}-1,\ldots)F_r^{s-1}(\ldots,L_k^s-1,\ldots;L^{s-1}) = \overline{f_k^s}(L^s;\ldots,L_r^{s-1}+1,\ldots)F_r^{s-1}(\ldots,L_k^s+1,\ldots;L^{s-1}).$$

The last relations must be satisfied for all possible values of the indices k and r. Keeping in mind the explicit form of the structural functions $F_k^{s-1} = \overline{F_k^s}^{s-1}$, proposed above, we can resolve the last equations in the form,

$$g_k^s = F_k^s(L^{s+1};L^s)\sqrt{\prod_{r=1}^{s-1}(L_k^s - L_r^{s-1})},\quad \overline{g_k^s} = \overline{F_k^s}(L^{s+1};L^s)\sqrt{\prod_{r=1}^{s-1}(L_k^s - L_r^{s-1})}. \tag{23}$$

Up to now we have not satisfied the only commutation relation

$$[X_s^+, X_s^-] = h_s. \tag{24}$$

This equation contains a ''diagonal'' part (which does not contain the coordinates of Heisenberg subalgebras l_i) and a nondiagonal one (in above sense). It is suitable to write the emerged equation for the diagonal part in the following notations:

$$X_k^{\pm s} = F_k^s(L^{s+1};\ldots,L_k^s \pm 1,\ldots)\overline{F_k^s}(L^{s+1};\ldots,L_k^s \pm 1\ldots),$$

$$\sum_{k=1}^{s}\prod_{r=1}^{s-1}(L_k^s + 1 - L_r^{s-1})X_k^{+s} - \sum_{k=1}^{s}\prod_{r=1}^{s-1}(L_k^s - 1 - L_r^{s-1})X_k^{(-s}$$

$$= -\frac{1}{2}\sum_{r=1}^{s-1}L_r^{s-1} + \sum_{k=1}^{s}L_k^s - \frac{1}{2}\sum_{j=1}^{s+1}L_j^{s+1}. \tag{25}$$

The left-hand side of this equation may be represented as linear combination of $s-1$ symmetrical functions, constructed out of $(s-1)$ momentum variables L_r^{s-1}. The right-hand side of (25) contains only terms of the first and zero degree with respect to such functions. Thus, as a corollary of (25), we obtain the system of s equations in finite differences for determining s unknown functions X_k^s,

$$\sum_{k=1}^{s}[(L_k^s+1)^{s-1}X_k^{+s} - (L_k^s-1)^{s-1}X_k^{-s}] = \sum_{k=1}^{s}L_k^s - \frac{1}{2}\sum_{j=1}^{s+1}L_j^{s+1},$$

$$\sum_{k=1}^{s}[(L_k^s+1)^{s-2}X_k^{+s} - (L_k^s-1)^{s-2}X_k^{-s}] = \frac{1}{2}, \tag{26}$$

$$\sum_{k=1}^{s}\left[(L_k^s+1)^i X_k^{+s}-(L_k^s-1)^i X_k^{-s}\right]=0 \quad 0\leqslant i\leqslant(s-3).$$

The zero value of ''nondiagonal'' part of (24) is equivalent to additional conditions which structural functions must satisfy

$$\begin{aligned}&F_k^s(L^{s+1};\ldots,L_j^s-1,\ldots)\overline{F_j^s}(L^{s+1};\ldots,L_k^s-1,\ldots)=F_k^s(L^{s+1};\ldots,L_j^s+1,\ldots)\overline{F_j^s}(L^{s+1};\ldots,L_k^s+1,\ldots),\\&\overline{F_k^s}(L^{s+1};\ldots,L_j^s-1,\ldots)F_j^s(L^{s+1};\ldots,L_k^s-1,\ldots)=\overline{F_k^s}(L^{s+1};\ldots,L_j^s+1,\ldots)F_j^s(L^{s+1};\ldots,L_k^s+1,\ldots).\end{aligned}\tag{27}$$

From (27) we see that the solution $F_j^s=\overline{F_j^s}$ is possible and the functions X_k^s (as the solutions of (25)) must satisfy the additional conditions,

$$X_k^s(L^{s+1};\ldots,L_j^s-1,\ldots)X_j^s(L^{s+1};\ldots,L_k^s-1,\ldots)=X_k^s(L^{s+1};\ldots,L_j^s+1,\ldots)X_j^s(L^{s+1};\ldots,L_k^s+1,\ldots).\tag{28}$$

Putting $s=2$, the reader can easily obtain from general equations of the present subsection all results of the previous section, in particular, Eqs. (17). At this point we interrupt our consideration for a moment in order to represent a general solution of the continuous version of Eq. (26).

B. General solution of the linear system in the continuous limit

The continuous limit of the homogeneous part of the system (26) in variables $X^i\equiv F_i^n$, $x_i\equiv L_i^n$ has the form

$$\sum_{i=1}^{n}(x_i^k X^i)_{x_i}=0, \quad k=0,1,\ldots, \ n-1.\tag{29}$$

We do not know the simple regular methods of the direct resolution of (29). The way of solving of this problem known to us for the particular case $n=3$ is given in the Appendix. Here we represent the final result and the proof of its validity.

General solution of the system (29) is given by the formula

$$X^s=\left(\frac{\Theta}{\Pi'^n_{k=1}(x_i-x_k)}\right)_{x_1\ldots x_{s-1}x_{s+1}\ldots x_n},\tag{30}$$

where the function Θ satisfies the equation $\Theta_{x_1\ldots x_n}=0$ (here the differentiation is performed with respect to all independent coordinates of the problem!).

The following result from the theory of symmetrical functions will be necessary for us to prove that (30) is indeed a solution of (29),

$$\sum_{i=1}^{n}\frac{x_i^r}{\Pi'^n_{k=1}(x_i-x_k)}=(0,1,S^{r-n+1}).$$

In the parentheses in the right-hand side different possibilities are given. The first one (0) takes place if r is strictly less then $n-1$; the second one occurs if $r=n-1$ and the third possibility corresponds to the case when r is strictly more the $n-1$ and S^k is some symmetrical function of the kth degree.

It is possible to understand the above proposition without any calculations. Indeed, the written sum is a symmetrical function. After reducing it to the common denominator we obtain the ratio of two n-dimensional polynomial functions, one of which (the denominator) is exactly the Wandermond determinant (an only function which is antisymmetrical with respect to permutation of

each pair of coordinates). Hence the numerator must also be antisymmetrical polynomial (since the ratio is symmetric!). This is impossible if r is less then $n-1$ (the degree of the numerator in this case is less than the degree of the Wandermond determinant).

After these comments let us consider an arbitrary equation from the system (30). We have consequently

$$\sum_{s=1}^{n}\left(x_s^r\left(\frac{\Theta}{\Pi'^{n}_{k=1}(x_s-x_k)}\right)_{x_1\cdots x_{s-1}x_{s+l}\cdots x_n}\right)_{x_s}=\left(\sum_{s=1}^{n}\frac{x_s^r}{\Pi'^{n}_{k=1}(x_s-x_k)}\Theta\right)_{x_1\cdots x_n}=0.$$

In the case when r is strictly less than $n-1$ the sum by itself equals zero; in the case when $r=(n-1)$ the sum is equal to unity but the condition for the function Θ equates to zero the corresponding equation of the system.

Thus, our proposition is proven and (30) is indeed a general solution of the linear system (29).

C. Continuation of the discussion

Now we can present the solution of inhomogeneous system (27) together with the additional conditions (28). We begin with the continuous case, using the notations of the previous subsection. In this case system (27) takes the form,

$$2\sum_{i=1}^{n}(x_i^{n-1}X^i)_{x_i}=-\frac{1}{2}\sum_{j=1}^{n+1}y_j+\sum_{i=1}^{n}x_i 2\sum_{i=1}^{n}(x_i^{n-2}X^i)_{x_i}=\frac{1}{2},$$
$$\sum_{i=1}^{n}(x_i^rX^i)_{x_i}=0,\quad 0\leqslant r\leqslant n-3. \tag{31}$$

Keeping in mind the solution for the particular case $n=2$ (21) we will try to find a solution of the last system in the form,

$$X^i=\frac{1}{4}\left(\frac{P_{n+1}(x_i)}{\Pi'^{n}_{k=1}(x_i-x_k)}\right)_{x_1\cdots x_{i-1}x_{i+1},\cdots x_n}\equiv\frac{1}{4}\frac{P_{n+1}(x_i)}{\Pi'^{n}_{k=1}(x_i-x_k)^2}, \tag{32}$$

where $P_{n+1}(x_i)=\Pi_{j=1}^{n+1}(x_i-y_j)$. Substituting (32) into each Eq. (31) we consequently check all equations,

$$\sum_{i=1}^{n}(x_i^rX^i)_{x_i}=\frac{1}{4}\left(\frac{x^rP_{n+1}(x_i)}{\Pi'^{n}_{k=1}(x_i-x_k)}\right)_{x_1,\cdots x_n},$$

where in the last expression it is necessary to perform the differentiation on all coordinates.

In connection with the facts from the theory of the symmetrical functions, mentioned in the previous subsection, the sum under the symbol of differentiation in the case $(0\leqslant r\leqslant(n-3))$ is nothing else but the linear combination of the symmetrical functions with the degree not greater than $n-1$. After differentiating with respect to all coordinates such functions vanish. By the same reason only the term with the highest power of polynomial gives contribution different from zero in the case when $(r=n-2)$ and the terms $x_i^{n+1}-(\Sigma_{j=1}^{n+1}y_j)x_i^n$ in the case when $r=n-1$. Numerical values for corresponding sums, which can be calculated without big difficulties, shows that the first pair of Eqs. (31) is also satisfied. It is not difficult to check that the solution (32) satisfies additional conditions (28).

In the algebraic case situation is very similar. To show this let us introduce the operation of the discrete differentiation, defined as

$$\Delta_i f(x_1,\ldots,x_n)=\frac{f(\ldots x_i+1,\ldots)-f(\ldots,x_i-1,\ldots)}{2}.$$

Operations Δ_i and Δ_j are obviously mutually commutative and satisfy the linear condition in the following sense:

$$\Delta_i(f^1+f^2)=\Delta_i f^1+\Delta_i f^2,\ \ \Delta_i c f=c\Delta_i f,$$

if c is some function independent of the x_i coordinate.

In this notations general solution of homogeneous system (26) has the form

$$X^i=(\Delta_1\cdots\Delta_{i-1}\Delta_{i+1}\cdots\Delta_n)\frac{\Theta}{\Pi'^n_{k=1}(L^n_i-L^n_k)},\tag{33}$$

where the function Θ is an arbitrary solution of the equation in finite differences

$$(\Delta_1\cdots\Delta_n)\Theta=0.$$

Solution of the inhomogeneous system (26) satisfying additional conditions (28) is given by

$$F^i=(\Delta_1\cdots\Delta_{i-1}\Delta_{i+1}\cdots\Delta_n)\frac{P_{n+1}(L^n_i)}{\Pi'^n_{k=1}(L^n_i-L^n_k)},\ \ P_{n+1}(x)=\prod_{j=1}^{n+1}(x-L^{n+1}_j).\tag{34}$$

We omit the proofs of the last propositions because it does not change in essential points in comparison with the continuous case. This fact is extremely interesting and remarkable and it will take some time to comprehend it.

V. OUTLOOK AND POSSIBLE PERSPECTIVES

In the present paper we have presented some new (unknown before or may be forgotten at the present moment) linear integrable systems in the space of arbitrary n dimensions. This system is invariant with respect to transformations from the whole group of permutations of n symbols. Particular solutions of this system are in the deep connection with the algebra A_n and matrix elements of its irreducible representations, discovered many years ago by Gel'fand and Tsetlin.[1] This fact allows us to reproduce the GZ result by a new method and moreover, to make them more understandable. Remarkably, under our formulation of the problem it was sufficient to perform calculations only on the functional group level. But to give any explanation or comment of this fact we are now not ready.

By some reasons (which are not clear for us at this moment) the quasiclassical approach gives a functionally correct quantum result. We hope that the method proposed in this paper can be generalized to the case of arbitrary semisimple algebra, relating the used parameterization with the properties of the Weyl discrete group of corresponding semisimple algebra.

We hope also that by a method of the present paper it will be possible to find new realizations of quantum and deformed algebras.

ACKNOWLEDGMENTS

The author is indebted to the Instituto de Investigaciones en Matemáticas Aplicadas y en Sistemas, UNAM, Mexico for the beautiful condition of his work. Permanent company and discussions with N. M. Atakishiyev, S. M. Chumakov, K. B. Wolf, and P. Winternitz allowed the author to finish this paper in a short amount of time.

APPENDIX

The initial system in the case $n=3$ has the form

$$X^1_{x_1}+X^2_{x_2}+X^3_{x_3}=0,$$

$$(x_1X^1)_{x_1}+(x^k_iX^i)_{x_i}+(x_3X^3)_{x_3}=0, \tag{35}$$

$$(x^2_1X^1)_{x_1}+(x^2_2X^2)_{x_2}+(x^2_3X^3)_{x_3}=0.$$

Multiplying the first equation by x_2x_3, the second one by $-(x_2+x_3$ and summing them with the third one we obtain

$$((x_3-x_2)(x_3-x_1)X^3)_{x_3}+\frac{(x_1-x_2)(x_1-x_3)X^1}{(x_1-x_3)}+\frac{(x_2-x_1)(x_2-x_3)X^2}{(x_2-x_3)}=0.$$

Let us introduce the new unknown functions $\overline{X^i}\equiv\Pi'^n_{k=1}(x_i-x_k)X^i$ and rewrite the last equation (together with those which arise from it after obvious permutations of the indexes), we come to a system

$$\overline{X^1}_{x_1}+\frac{\overline{X^2}}{(x_2-x_1)}+\frac{\overline{X^3}}{(x_3-x_1)}=0,$$

$$\overline{X^2}_{x_2}+\frac{\overline{X^1}}{(x_1-x_2)}+\frac{\overline{X^3}}{(x_3-x_2)}=0, \tag{36}$$

$$\overline{X^3}_{x_3}+\frac{\overline{X^1}}{(x_1-x_3)}+\frac{\overline{X^2}}{(x_2-x_3)}=0.$$

The next transformation $\tilde{X}^i=\equiv\Pi'^n_{k=1}(x_i-x_k)\tilde{X}^i$ would be possible to realize independently on the first step, but the form of the system (36) will be necessary for further consideration and for this reason we represent it above. In the new variables we obtain

$$(x_1-x_2)(\tilde{X}^2_{x_2}+\tilde{X}^1_{x_1})+2(\tilde{X}^2-\tilde{X}^1)=0,$$

$$(x_2-x_3)(\tilde{X}^3_{x_3}+\tilde{X}^2_{x_2})+2(\tilde{X}^3-\tilde{X}^2)=0, \tag{37}$$

$$(x_1-x_2)(\tilde{X}^1_{x_1}+\tilde{X}^3_{x_3})+2(\tilde{X}^1-\tilde{X}^3)=0.$$

After excluding unknown $\tilde{X}^3$ from the two last equations and introducing $v\equiv\tilde{X}^2_{x_3}$ and $u\equiv\tilde{X}^1_{x_3}$ we obtain the system of two equations,

$$v_{x_2}-u_{x_1}-\frac{2v}{x_2-x_3}-\frac{2u}{x_3-x_1}=0,\quad v_{x_2}+u_{x_1}+\frac{2v}{x_1-x_2}-\frac{2u}{x_1-x_2}=0.$$

Finally excluding the unknown u we obtain an equation for v in the integrable form,

$$v_{x_1x_2}=v_{x_1}\left(\frac{1}{x_2-x_1}+\frac{1}{x_2-x_3}\right).$$

Returning back, after some algebraic manipulations we obtain the general solution of the initial system in the form

$$\overline{X^1}=\Theta_{x_2x_3}+\frac{\Theta_{x_3}}{x_1-x_2}+\frac{\Theta_{x_2}}{x_1-x_3}+\frac{\Theta}{(x_1-x_2)(x_1-x_3)},$$

$$\overline{X^2}=\Theta_{x_1x_3}+\frac{\Theta_{x_3}}{x_1-x_2}+\frac{\Theta_{x_1}}{x_2-x_3}+\frac{\Theta}{(x_2-x_1)(x_2-x_3)},$$

$$\overline{X^3}=\Theta_{x_2x_1}+\frac{\Theta_{x_2}}{x_3-x_1}+\frac{\Theta_{x_1}}{x_3-x_2}+\frac{\Theta}{(x_3-x_2)(x_3-x_1)}, \tag{38}$$

where $\Theta=\Theta^1(x_2x_3)+\Theta^2(x_1x_3)+\Theta^3(x_1x_2)$ and Θ^i are arbitrary functions of two independent arguments. So it is possible to state that Θ is an arbitrary solution of the equation

$$\Theta_{x_1x_2x_3}=0.$$

Of course, (38) is equivalent to one represented in the main text and used as an initial guess to find the general solution in the form (30).

(Received 30 June 2000; accepted for publication 8 November 2000)

A few years ago, some of us devised a method to obtain integrable systems in $(2+1)$-dimensions from the classical non-Abelian pure Chern–Simons action via the reduction of the gauge connection in Hermitian symmetric spaces. In this article we show that the methods developed in studying classical non-Abelian pure Chern–Simons actions can be naturally implemented by means of a geometrical interpretation of such systems. The Chern–Simons equation of motion turns out to be related to time evolving two-dimensional surfaces in such a way that these deformations are both locally compatible with the Gauss–Mainardi–Codazzi equations and completely integrable. The properties of these relationships are investigated together with the most relevant consequences. Explicit examples of integrable surface deformations are displayed and discussed. © *2001 American Institute of Physics.* [DOI: 10.1063/1.1339831]

I. INTRODUCTION

Many authors have extensively studied the deep relations among completely integrable systems and the basic equations of the differential geometry, like the Frenet formulas defining curves embedded in $\mathbf{R}^3$, or their analogous formulas for the surfaces, the Gauss–Weingarten (GW) equations, and the corresponding integrability conditions, i.e., the Gauss–Mainardi–Codazzi (GMC) equations (see for instance Refs. 1–3). In these approaches the main idea is to add to a generic differential geometry setting certain auxiliary conditions, containing from the beginning the properties of the completely integrable systems.

A slightly different situation occurs in the study of the so-called Darboux system,[4,5] which naturally arises in looking for classes of orthogonal curvilinear coordinates in Euclidean spaces and whose integrability has been detected in Ref. 6. Such a system has been investigated mainly in connection with the topological field theory.[7] On the other hand, some years ago some of us proposed a simple method to obtain completely integrable systems in $(2+1)$-dimensions, from classes of non-Abelian Chern–Simons (CS) field theories, taking values in Hermitian symmetric spaces.[8] In this context completely integrable systems are seen as particular gauge choices in which the theory is formulated. Moreover, linear spectral problems are naturally related to the geometrical constraints imposed on the target space. From this point of view, integrable systems arise as special reductions, which break the general covariance and the gauge invariance of the original field theory, but preserve a residual symmetry in order to allow the Lax representation and the complete integrability, although the solvability is lost.

In the present work we show that this approach can be naturally implemented by resorting to a geometrical interpretation of the completely integrable systems mentioned above. Precisely, we

[a]Permanent address: Institute of Physics and Technology, 480082, Alma-Ata-82, Kazakhstan. Electronic mail: cnlpmyra@satsun.sci.kz

show, as the CS equation of motion can describe, time evolving two-dimensional surfaces in such a way that the deformation is not only locally compatible with the GMC equation, but completely integrable as well. The nature and the properties of such relationships are investigated together with the most important consequences. Furthermore, explicit examples of integrable deformations of surfaces are displayed.

The article is organized as follows. Section II contains some results on the CS theory. In Sec. III the fundamental terminology and notations related to the theory of two-dimensional surfaces are reviewed. In Sec. IV the general formulation of deformation of two-dimensional surfaces is presented. Section V is devoted to the analysis of certain spin models in $(2+1)$-dimensions. Section VI is addressed the bilinear representations of the spin systems fields and the trihedral moving frame. Sections VII and VIII are concerned with the deformations of surfaces from integrable $(2+1)$-dimensional spin systems and equations of the nonlinear Schrödinger type, respectively. In Secs. IX and X some solutions and special surfaces associated with spin system vortices are considered. Finally, in Sec. XI some concluding remarks are reported.

II. CHERN–SIMONS THEORY AND COMPLETELY INTEGRABLE SYSTEMS

Here we shall review some preliminaries concerning the CS theory and we show how one can connect them to the completely integrable systems in $(2+1)$ dimensions. We are dealing with the field theory defined by the action

$$S[J]=\frac{k}{4\pi}\int_M \mathrm{Tr}\left(J\wedge dJ+\frac{2}{3}J\wedge J\wedge J\right), \tag{1}$$

where J is a one-form gauge connection taking values in a simple Lie algebra $\hat{g}$ on an oriented closed three-manifold M, and k is a coupling constant which should be quantized in a quantum theory.[9] The related classical equation of motion is the zero-curvature condition,

$$F\equiv dJ+J\wedge J=0. \tag{2}$$

The action (1) is manifestly invariant under general coordinate transformations (preserving orientation and volumes). Moreover, under a generic gauge map $G:M\to\hat{G}$ the gauge connection transforms as $J\to G^{-1}JG+G^{-1}\,dG$. Correspondingly, the action (1) changes as $S[J]\to S[J]+2\pi k\,W(G)$, where

$$W(J)=\frac{1}{24\pi^2}\int_M \mathrm{Tr}(G^{-1}\,dG\wedge G^{-1}\,dG\wedge G^{-1}\,dG) \tag{3}$$

is the winding number of the map G and takes integer values, because of the result $\pi_3(\hat{G})=\mathbf{Z}$ from the homotopy theory.[10] This is a topological field theory in the sense that it possesses quantum observables, which are independent of the metric and are related to the Jones polynomials of the knot theory.[11] From other points of view, the action (1) has been used as an effective interaction for quasiparticles and vortices in two space-dimensional systems, of interest in the physics of high temperature superconductivity,[12] and in the context of the low-dimensional gravity models (see Ref. 13 and references therein). In the static self-dual reductions the system of equations (2) becomes the two-dimensional Toda field theory,[14] the static reductions of the Ishimori model, or of the Davey–Stewartson equation.[15]

In Ref. 8 the general action (1) was reduced assuming that the Lie algebra $\hat{g}$ admits a $\mathbf{Z}_2$ graduation, in such a way the form J splits in two parts, taking values on an isotropy subalgebra and a complement linear space, respectively. The former component will play the role of a gauge field with the isotropy group as a gauge group; the latter could be considered as a sort of coupled ''matter'' field. At any point of the corresponding coset space we can introduce in a natural way a Riemannian torsion-free connection.[10] Furthermore, the three-manifold M is trivialized into $\Sigma\times\mathbf{R}$, where Σ is a Riemann surface endowed with a set of local complex coordinates $z=x^1$

$+ix^2$, and $\mathbf{R}$ is interpreted as the time axis. Thus the connection J can be further decomposed into time- and space-like components. In the simplest SU(2)/U(1)$\sim CP^1\sim S^2$ case the connection takes the form

$$J=\begin{pmatrix} iv_\mu & -q_\mu^* \\ q_\mu & -iv_\mu \end{pmatrix} dx^\mu,$$

which can be rewritten in terms of complex forms

$$v\,dz=\tfrac{1}{2}(v_1-iv_2)dz, \quad \psi_- dz=\tfrac{1}{2}(q_1-iq_2)dz, \quad \psi_+ d\bar{z}=\tfrac{1}{2}(q_1+iq_2)d\bar{z}.$$

This allows us to write the action (1) as follows:

$$S=-\frac{k}{\pi}\int_{\Sigma\times\mathbf{R}}\left\{\frac{1}{2}\varepsilon^{\lambda\mu\nu}v_\lambda\partial_\mu v_\nu+\frac{i}{2}(\psi_+^* D_0\psi_+-\psi_+(D_0\psi_+)^*-\psi_-^* D_0\psi_-+\psi_-(D_0\psi_-)^*)\right.$$
$$\left.-iq_0^*(D\psi_+-\bar{D}\psi_-)+iq_0(D\psi_+-\bar{D}\psi_-)^*\right\}dx^0\,dx^1\,dx^2, \tag{4}$$

where $D_0=\partial_0-2iv_0$, $D=\partial_z-2iv$, $\bar{D}=\partial_{\bar{z}}-2iv^*$ (* denotes the complex conjugation). The first-order Lagrangian involved in (4) is constrained by the torsion-free condition

$$D\psi_+-\bar{D}\psi_-=0, \tag{5}$$

and by what we call the Gauss–Chern–Simons (GCS) law

$$\partial_z v^*-\partial_{\bar{z}}v=-i(|\psi_+|^2-|\psi_-|^2), \tag{6}$$

enforced by the Lagrangian multipliers q_0 and v_0, respectively. Of course, here we are looking in a different way to a subset of the equations of motion (2), in which the general covariance is broken. Indeed, only the isotropic U(1) invariance is left. Furthermore, by exploiting the local isomorphism between so(3) and su(2) realized by the adjoint representation of the connection

$$J^{(\mathrm{ad})}=\begin{pmatrix} 0 & -v_0 & -\mathrm{Re}(q_0) \\ v_0 & 0 & -\mathrm{Im}(q_0) \\ \mathrm{Re}(q_0) & \mathrm{Im}(q_0) & 0 \end{pmatrix} dx^0$$
$$+\begin{pmatrix} 0 & -2\,\mathrm{Re}(v) & -\mathrm{Re}(\psi_++\psi_-) \\ 2\,\mathrm{Re}(v) & 0 & -\mathrm{Im}(\psi_++\psi_-) \\ \mathrm{Re}(\psi_++\psi_-) & \mathrm{Im}(\psi_++\psi_-) & 0 \end{pmatrix} dx^1$$
$$+\begin{pmatrix} 0 & 2\,\mathrm{Im}(v) & -\mathrm{Im}(\psi_+-\psi_-) \\ -2\,\mathrm{Im}(v) & 0 & -\mathrm{Re}(\psi_+-\psi_-) \\ \mathrm{Im}(\psi_+-\psi_-) & \mathrm{Re}(\psi_+-\psi_-) & 0 \end{pmatrix} dx^2,$$

we are able to introduce the so-called moving trihedral frame $\{\mathbf{e}_i\}$ in $\mathbf{R}^3$,[10] which satisfies the orthonormal conditions

$$\mathbf{e}_i\cdot\mathbf{e}_j=\delta_{ij}, \quad \mathbf{e}_i\wedge\mathbf{e}_j=\varepsilon_{ijk}\mathbf{e}_k, \tag{7}$$

and changes accordingly to

$$\partial_\mu\mathbf{e}_i=(J_\mu)_{ik}^{(\mathrm{ad})}\mathbf{e}_k, \quad \mu=0,1,2, \quad i=1,2,3. \tag{8}$$

Its integrability is assured by the zero-curvature condition, namely by Eq. (2). For instance, assigning to $\mathbf{e}_3$ the special role of unimodular normal vector to a given surface $\mathcal{S}$, whose tangent plane is defined by the vectors $(\mathbf{e}_1,\mathbf{e}_2)$, the equations (8) for $\mu=1,2$ and $i=1,2,3$ can be seen as the Gauss–Weingarten equations of such a surface. Moreover, the mapping $\mathbf{e}_3:\mathcal{S}\to S^2$ is the well-known Gauss map. Furthermore, the corresponding integrability equations, rewritten as

$$\partial_1 J_2^{(\mathrm{ad})}-\partial_2 J_1^{(\mathrm{ad})}+[J_1^{(\mathrm{ad})},J_2^{(\mathrm{ad})}]=0,$$

are the Gauss–Codazzi–Mainardi equations for a surface S immersed in $\mathbf{R}^3$. They are the real form of Eqs. (5) and (6). The U(1) invariance of such equations is readily interpreted as the invariance under local rotations of the tangent plane at the surface $\mathcal{S}$. This identification is one of the motivations of the present article and it will be fully developed from the geometrical point of view in the next sections. Here we would like to show how to use effectively the remaining equations in (8) for $\mu=0$ and $i=1,2,3$ and the corresponding integrability conditions. In particular, we ask if structures related to the integrable systems can be detected in the above general picture. Then, since we show that it is the case, we are allowed to introduce a completely integrable dynamics for the trihedral frame and, by consequence, we can infer an integrable dynamics for the corresponding surfaces.

First, we can rewrite Eqs. (5) and (6) by introducing the quantities

$$V=\begin{pmatrix} v^* & \\ & v \end{pmatrix},\quad \Psi_\pm=\begin{pmatrix} & \psi_\pm \\ -\psi_\pm^* & \end{pmatrix},\quad B=\frac{i}{2}\sigma_3(\Psi_- -\Psi_+).$$

Indeed, the torsionless condition (5) and its complex conjugate can be written as

$$\begin{pmatrix} \partial_z & \\ & \partial_{\bar z} \end{pmatrix} B+\frac{i}{2}(\partial_{\bar z}-\partial_z)\Psi_- +V\Psi_- -\Psi_+ V=0,$$

while combining the GCS law (6) and its complex conjugate yields

$$\mathrm{Tr}\left\{\sigma_3\left[\begin{pmatrix} \partial_z & \\ & \partial_{\bar z} \end{pmatrix} V+B\Psi_- -\Psi_+ B\right]\right\}=0.$$

These equations involve independent components in the basis of the complex 2×2 matrices, and we have no information about the identity component σ_0. So the last two equations provide

$$L_+\left[\frac{i}{2}(\partial_{\bar z}-\partial_z)+V+B\right]-\left[\frac{i}{2}(\partial_{\bar z}-\partial_z)+V+B\right]L_-=f\sigma_0, \tag{9}$$

$$L_\pm=\begin{pmatrix} \partial_z & \\ & \partial_{\bar z} \end{pmatrix}-\Psi_\pm, \tag{10}$$

where f is an arbitrary function. Equation (10) has the form of the two-dimensional principal Zakharov–Shabat spectral operator[16] of elliptic type. Moreover, putting $f\equiv 0$ in Eq. (9), we obtain the so-called space part of the Bäcklund transformations associated with $L_\pm$, defining the first-order Bäcklund-gauge operator

$$\hat B=\frac{i}{2}(\partial_{\bar z}-\partial_z)+V+B.$$

This means that $\hat B$ maps solutions between the two linear problems

$$L_-\phi_-=0\Rightarrow L_+B\phi_-=L_+\phi_+=0. \tag{11}$$

The previous considerations tell us that in the above formalism the Gauss–Codazzi–Mainardi equations are expressed in terms of products of first-order differential operators, which have a precise meaning in the theory of the completely integrable systems. Of course, in this context an essential role is played by the second (evolution) linear operator of the Lax pair, in order to introduce a compatible time evolution. The latter, generally speaking, is nonlinear, while the corresponding equations from the CS theory still contains the arbitrary functions interpreted as Lagrangian multipliers in the action (4). Indeed, the corresponding equations read

$$D_0\psi_+ = \bar{D}q_0, \quad D_0\psi_- = Dq_0, \tag{12}$$

$$\partial_0 v - \partial_z v_0 = i(q_0\psi_+^* - q_0^*\psi_-), \tag{13}$$

and their complex conjugated. However, we can exploit the freedom in the choice of q_0 and v_0 in order to fix the evolution of $\psi_\pm$ and v in the x^0 variable. In fact, let us take

$$q_0 = 2i\left[\left(\bar{D} - \frac{i}{2}(\partial_{\bar{z}}\omega - i\partial_{\bar{z}}\chi)\right)\psi_+ + \left(D - \frac{i}{2}(\partial_z\omega + i\partial_z\chi)\right)\psi_-\right], \tag{14}$$

where we require that the real functions χ and ω satisfy the supplementary conditions

$$\partial_z\partial_{\bar{z}}\chi = -4(|\psi_+|^2 - |\psi_-|^2), \quad \partial_z\partial_{\bar{z}}\omega = 0. \tag{15}$$

Furthermore, by introducing an irrotational field $\mathbf{A} = (\partial_z\Lambda, \partial_{\bar{z}}\Lambda, \partial_0\Lambda)$ (Λ is an arbitrary real function) in such a way that

$$v = \frac{1}{4}\partial_z\Lambda - \frac{i}{8}\partial_z\chi, \quad v_0 = \frac{1}{4}(\partial_0\Lambda + u_0), \quad \psi_\pm = \Psi_\pm \exp\left(\frac{i}{2}\Lambda\right),$$

the ''time evolutions'' (12) become

$$i\partial_0\Psi_\pm + 2(\partial_z^2 + \partial_{\bar{z}}^2)\Psi_\pm + \tfrac{1}{2}u_0^\pm\Psi_\pm - i(\partial_{\bar{z}}\omega\partial_{\bar{z}} + \partial_z\omega\partial_z)\Psi_\pm = 0, \tag{16}$$

where we have suitably defined in terms of u_0, χ, and ω the scalar fields $u_0^\pm$, which obey the consistency conditions arising from (13),

$$\partial_z\partial_{\bar{z}}u_0^\pm = 8(\partial_z^2 + \partial_{\bar{z}}^2)|\Psi_\pm|^2. \tag{17}$$

Thus, to summarize, the gauge fixing conditions (14) and (15) destroy the arbitraryness contained in the equations (12) in favor of a formally decoupled pair of Davey–Stewartson equations (16) and (17). Actually, between the two pairs of fields $(\Psi_\pm, u_0^\pm)$ there still exists the coupling provided by the torsionless condition (5), which in the new variables takes the form

$$(\partial_{\bar{z}} + \tfrac{1}{4}\partial_{\bar{z}}\chi)\Psi_- = (\partial_z + \tfrac{1}{4}\partial_z\chi)\Psi_+. \tag{18}$$

As we discussed above, Eq. (18) is in essence the space part of the Bäcklund transformations. Starting from a known solution, say (Ψ_-, u_0^-), and fixing ω, one can reconstruct the function χ, and solving (18) for Ψ_+, finally we find u_0^+ from (17). Furthermore, we observe that the gauge choice (14)–(15) is equivalent to fix the second operator of the Lax pair, denoted here by $M_\pm = \partial_{x^0} + \Sigma_{k=0}^2 M_\pm^{(k)}[i/2(\partial_{\bar{z}} - \partial_z)]^{2-k}$, where $M_\pm^{(k)}$ are specific matrices. $M_\pm$ provide the system (16)–(17) and (18) by the compatibility relations

$$[L_\pm, M_\pm] = 0, \quad M_+\hat{B} - \hat{B}M_- = 0.$$

Moreover, by using a suitable particular eigenfunction ϕ_-^0 of Eq. (11), it is well-known (see Refs. 17, 18) that one can construct a new spectral problem of the form

$$L_-^I=(\phi_-^0)^{-1}L_-\phi_-^0=\partial_{x^1}+iS\partial_{x^2},\quad M_-^I=(\phi_-^0)^{-1}M_-\phi_-^0,$$

where

$$S=i(\phi_-^0)^{-1}\sigma_3\phi_-^0$$

is an element of SU(2)/U(1) coset space and the corresponding eigenfunction is $\phi_-^I=(\phi_-^0)^{-1}\phi_-$. The resulting integrable system is known as Ishimori model and it describes the evolution of a classical spin in a background generated by the density of the topological charge. Since this equation will be discussed in the next sections, we do not give other details about it. But here we want to stress that such a system is an alternative integrable restriction of the possible configurations of the CS field, exactly as the Davey–Stewartson equation does. Furthermore, one can purpose the question does the spin field S have something to do with the trihedral frame introduced above. The consequences arising from the identification of S with one of the unimodular vector fields $\mathbf{e}_i$ is the main subject of the next sections.

III. SURFACES IN R^3

To introduce our terminology and notations and to make the exposition self-contained, we recall some basic facts from the theory of two-dimensional surfaces. So, we consider a smooth surface in a three-dimensional Euclidean space $\mathbf{R}^3$. Let x,y be the local coordinates on the surface. At the same time, the surface can be described by the position vector $(x_1,x_2,x_3)=\mathbf{r}(x,y)$, where the x_i are coordinates of $\mathbf{R}^3$. The surface is uniquely defined within rigid motions by the two fundamental forms

$$I=E\,dx^2+2F\,dx\,dy+G\,dy^2 \tag{19}$$

and

$$II=L\,dx^2+2M\,dx\,dy+N\,dy^2, \tag{20}$$

where E,F,G,L,M,N can be defined by

$$E=\mathbf{r}_x\cdot\mathbf{r}_x=g_{11},\quad F=\mathbf{r}_x\cdot\mathbf{r}_y=g_{12}=g_{21},\quad G=\mathbf{r}_y\cdot\mathbf{r}_y=g_{22}, \tag{21}$$

$$L=\mathbf{n}\cdot\mathbf{r}_{xx}=b_{11},\quad M=\mathbf{n}\cdot\mathbf{r}_{xy}=b_{12}=b_{21},\quad N=\mathbf{n}\cdot\mathbf{r}_{yy}=b_{22}. \tag{22}$$

In Eqs. (21) and (22),

$$\mathbf{n}(x,y)=\frac{\mathbf{r}_x\wedge\mathbf{r}_y}{|\mathbf{r}_x\wedge\mathbf{r}_y|}=\frac{\mathbf{r}_x\wedge\mathbf{r}_y}{\sqrt{g}} \tag{23}$$

is introduced, where $g=\det(g_{ij})=EG-F^2=|\mathbf{r}_x\wedge\mathbf{r}_y|^2$, is the normal vector field at each point of the surface. Then the triple $(\mathbf{r}_x,\mathbf{r}_y,\mathbf{n})$ represents a local frame of $\mathbf{R}^3$, the changes of which are characterized by the GW equations

$$\mathbf{r}_{xx}=\Gamma_{11}^1\mathbf{r}_x+\Gamma_{11}^2\mathbf{r}_y+L\mathbf{n}, \tag{24}$$

$$\mathbf{r}_{xy}=\Gamma_{12}^1\mathbf{r}_x+\Gamma_{12}^2\mathbf{r}_y+M\mathbf{n}, \tag{25}$$

$$\mathbf{r}_{yy}=\Gamma_{22}^1\mathbf{r}_x+\Gamma_{22}^2\mathbf{r}_y+N\mathbf{n}, \tag{26}$$

$$\mathbf{n}_x=p_{11}\mathbf{r}_x+p_{12}\mathbf{r}_y, \tag{27}$$

$$\mathbf{n}_y=p_{21}\mathbf{r}_x+p_{22}\mathbf{r}_y, \tag{28}$$

where the Christoffel symbols of the second kind are defined by g_{ij} ($g^{ij}=(g_{ij})^{-1}$) as

$$\Gamma^i_{jk}=\frac{1}{2}g^{il}\left(\frac{\partial g_{lk}}{\partial x^j}+\frac{\partial g_{jl}}{\partial x^k}-\frac{\partial g_{jk}}{\partial x^l}\right), \tag{29}$$

with $i,j,k=1,2$ and

$$p_{ij}=-b_{ik}g^{kj}. \tag{30}$$

The principal curvatures k_1,k_2 are the eigenvalues of the Weingarten operator

$$\Lambda=\begin{pmatrix}E & F\\ F & G\end{pmatrix}^{-1}\begin{pmatrix}L & M\\ M & N\end{pmatrix}, \tag{31}$$

which for the mean and the Guassian curvature implies

$$H=\frac{k_1+k_2}{2}=\mathrm{Tr}(\Lambda)=\frac{EN+LG-2MF}{2(EG-F^2)}, \tag{32}$$

$$K=k_1k_2=\det(\Lambda)=\frac{LN-M^2}{EG-F^2}. \tag{33}$$

One of the global characteristics of surfaces is the integral curvature

$$\chi=\frac{1}{2\pi}\int K\sqrt{g}\,dx\,dy, \tag{34}$$

which for compact oriented surfaces is the integer

$$\chi=2(1-\Delta), \tag{35}$$

where Δ is the genus of the surface. The compatibility conditions of the GW Eqs. (24)–(28) furnish the GMC equations, which in two dimensions read

$$R_{1,2,1,2}=K,\quad \frac{\partial b^{ij}}{\partial x^k}-\frac{\partial b_{ik}}{\partial x^j}=\Gamma^s_{ik}b_{js}-\Gamma^s_{ij}b_{ks}, \tag{36}$$

where $i,j=1,2$, $b^j_i=g^{jl}b_{il}$, and the curvature tensor, defined in the standard way,

$$R^l_{ijk}=\frac{\partial\Gamma^l_{ij}}{\partial x^k}-\frac{\partial\Gamma^l_{ik}}{\partial x^j}+\Gamma^s_{ij}\Gamma^l_{ks}-\Gamma^s_{ik}\Gamma^l_{js}, \tag{37}$$

has only one (i.e., $R^1_{2,1,2}$) independent component. For our purposes it is convenient to employ the triad of orthonormal vectors,

$$\mathbf{e}_1=\frac{\mathbf{r}_x}{\sqrt{E}},\quad \mathbf{e}_2=\mathbf{n},\quad \mathbf{e}_3=\mathbf{e}_1\wedge\mathbf{e}_2. \tag{38}$$

In terms of these vectors the GW Eqs. (24)–(28) take the form

$$\mathbf{e}_{jx}=\mathbf{X}\wedge\mathbf{e}_j,\quad \mathbf{e}_{jy}=\mathbf{Y}\wedge\mathbf{e}_j, \tag{39}$$

where

$$\mathbf{X}=\tau\mathbf{e}_1+\sigma\mathbf{e}_2+k\mathbf{e}_3,\quad \mathbf{Y}=m_1\mathbf{e}_1+m_2\mathbf{e}_2+m_3\mathbf{e}_3, \tag{40}$$

and

$$k=\frac{L}{\sqrt{E}},\quad \sigma=\frac{2EF_x-EE_y-FE_x}{2E\sqrt{g}},\quad \tau=\frac{ME-LF}{\sqrt{gE}}, \tag{41}$$

$$m_1=\frac{NE-MF}{\sqrt{gE}},\quad m_2=\frac{FE_y-EG_x}{2E\sqrt{g}},\quad m_3=\frac{M}{\sqrt{E}}. \tag{42}$$

Similarly, we can rewrite the GMC Eqs. (36) in the following form:

$$A_y-B_x+[A,B]=0, \tag{43}$$

with

$$A=\begin{pmatrix} 0 & k & -\sigma \\ -k & 0 & \tau \\ \sigma & -\tau & 0 \end{pmatrix},\quad B=\begin{pmatrix} 0 & m_3 & -m_2 \\ -m_3 & 0 & m_1 \\ m_2 & -m_1 & 0 \end{pmatrix}. \tag{44}$$

Then, the GMC equation turns out to be equivalent to the set of equations for the coefficients of the first and second fundamental forms. This system, which is in general nonintegrable, reduces to integrable partial differential equations for certain particular surfaces.[10]

IV. DEFORMATIONS OF SURFACES IN (2+1)-DIMENSIONS: THE GENERAL FORMULATION

It is well-known that in some cases deformations of surfaces can be associated with integrable equations.[1–3] Here we are interested in the deformation of the two-dimensional surfaces discussed in Sec. III. In other words, we have to deal with the motion of such surfaces. To this aim, let us introduce the vector field

$$\mathbf{r}_t=a_1\mathbf{r}_x+a_2\mathbf{r}_y+a_3\mathbf{n}, \tag{45}$$

where the a_i are some real functions. It is easy to show that the evolution of the local trihedral frame is given by

$$\mathbf{e}_{jt}=\mathbf{T}\wedge\mathbf{e}_j, \tag{46}$$

$$\mathbf{T}=\omega_1\mathbf{e}_1+\omega_2\mathbf{e}_2+\omega_3\mathbf{e}_3, \tag{47}$$

ω_j being real functions. Summarizing, the changes of the local frame are provided by

$$\mathbf{e}_{jx}=\mathbf{X}\wedge\mathbf{e}_j,\quad \mathbf{e}_{jy}=\mathbf{Y}\wedge\mathbf{e}_j,\quad \mathbf{e}_{jt}=\mathbf{T}\wedge\mathbf{e}_j, \tag{48}$$

where the vectors **X** and **Y** are defined by (40). This system is analogous to the system (8) in Sec. II.

The system (48) represents the simplest form of the (2+1)-dimensional GW equations.

By introducing the matrix

$$C=\begin{pmatrix} 0 & \omega_3 & -\omega_2 \\ -\omega_3 & 0 & \omega_1 \\ \omega_2 & -\omega_1 & 0 \end{pmatrix}, \tag{49}$$

and using the matrices A and B [see (44)], the compatibility conditions of Eqs. (48) entail

$$A_y - B_x + [A,B] = 0, \tag{50}$$

$$A_t - C_x + [A,C] = 0, \tag{51}$$

$$B_t - C_y + [B,C] = 0. \tag{52}$$

Of the nine funcions $k, \sigma, \tau, m_i, \omega_i$ involved in A, B, and C, only three are independent. In fact, we can express the functions m_i, ω_i in terms of k, σ, τ, and their derivatives. This point will be discussed later.

A. Some geometrical invariants and integrals of motion as a consequence of the geometrical formalism

The formalism developed above yields some important invariants having a pure geometrical nature. Indeed, in terms of the triad vectors these geometrical invariants take the form

$$K_1^{(t)} = \int \mathbf{e}_1 \cdot (\mathbf{e}_{1x} \wedge \mathbf{e}_{1y}) dx\, dy, \quad K_2^{(t)} = \int \mathbf{e}_2 \cdot (\mathbf{e}_{2x} \wedge \mathbf{e}_{2y}) dx\, dy,$$

$$K_3^{(t)} = \int \mathbf{e}_3 \cdot (\mathbf{e}_{3x} \wedge \mathbf{e}_{3y}) dx\, dy. \tag{53}$$

In a similar way we can write down the other two classes of invariants with respect to x and y directions, respectively. These geometrical invariants can be interpreted as ''topological charges.'' However, three of them, namely $K_i^{(t)}$ $(i = 1,2,3)$ behave as integrals of motion of the $(2+1)$-dimensional geometrical models under consideration. This will be elucidated in the next sections. These invariants can be related to the topological Chern index of a curvature two-form on a two-dimensional space.[19]

V. INTEGRABLE SPIN MODELS IN (2+1)-DIMENSIONS

Now let us dwell upon the problem of finding or building up integrable deformations of $(2+1)$-dimensional surfaces. Among several possibilities, within the geometrical formalism previously presented, we shall consider multidimensional integrable spin (field) systems (MISS) to recognize integrable deformations of surfaces.

A. The spin model

A few words on MISS. At present there exist many integrable spin systems in $(2+1)$-dimensions (see, for example, Refs. 20–25). A well-known prototype of these systems is the Ishimori model (IM).[20] A more general $(2+1)$-dimensional integrable spin model is described by the pair of equations

$$\mathbf{S}_t + \mathbf{S} \wedge \{(b+1)\mathbf{S}_{\xi\xi} - b\mathbf{S}_{\eta\eta}\} + b u_\eta \mathbf{S}_\eta + (b+1) u_\xi \mathbf{S}_\xi = 0, \tag{54}$$

$$u_{\xi\eta} = \mathbf{S} \cdot (\mathbf{S}_\xi \wedge \mathbf{S}_\eta), \tag{55}$$

where ξ, η are real or complex variables, b is a real constant, $\mathbf{S} = (S_1, S_2, S_3)$ is the spin (field) vector, $\mathbf{S}^2 = 1$, and u is a scalar function. These equations, which are called M-XX equations (about our conditional notations, see e.g., Refs. 21–25), are one of the $(2+1)$-dimensional integrable generalizations of the isotropic Landau–Lifshitz (LL) equation

$$\mathbf{S}_t = \mathbf{S} \wedge \mathbf{S}_{xx}. \tag{56}$$

In $(1+1)$-dimensions, Eqs. (54) and (55) reduce to the LL equation. In fact, assuming that the variables $\mathbf{S}, u$ are, for example, independent of η, then Eqs. (54) and (55) reproduce Eq. (56) within a simple scale transformation.

We notice that Eqs. (54) and (55) are not the only integrable generalization of the LL equation in $(2+1)$-dimensions. Actually, other integrable generalizations exist, such as the IM or the model defined by

$$\mathbf{S}_t=(\mathbf{S}\wedge\mathbf{S}_y+u\mathbf{S})_x, \tag{57}$$

$$u_x=-\mathbf{S}\cdot(\mathbf{S}_x\wedge\mathbf{S}_y). \tag{58}$$

These equations, which are called M-I equations (see Ref. 21) are again completely integrable. Some properties of these equations are studied in Refs. 21–23.

1. The Lax representation

Equations (54) and (55) can be solved by the inverse spectral transform (IST) method. The applicability of the IST method to Eqs. (54) and (55) is based on the equivalence of these equations to the compatibility condition of the following linear equations [the Lax representation (LR)]

$$\Phi_{Z^+}=S\Phi_{Z^-}, \tag{59}$$

$$\Phi_t=2i[S+(2b+1)I]\Phi_{Z^-Z^-}+W\Phi_{Z^-}, \tag{60}$$

where $Z^{\pm}=\xi\pm\eta$ and

$$W=2i\left\{(2b+1)(F^++F^-S)+(F^+S+F^-)+(2b+1)SS_{Z^-}+\frac{1}{2}S_{Z^-}+\frac{1}{2}SS_{Z^+}\right\},$$

$$S=\begin{pmatrix} S_3 & rS^- \\ rS^+ & -S_3 \end{pmatrix}, \quad S^{\pm}=S_1\pm iS_2, \quad S^2=EI, \quad E=\pm 1, \quad r^2=\pm 1,$$

$$F^+=2iu_{Z^-}, \quad F^-=2iu_{Z^+}.$$

In fact, from the condition $\Phi_{Z^+t}=\Phi_{tZ^+}$ we deduce

$$iS_t+\tfrac{1}{2}[S,(b+1)S_{\xi\xi}-bS_{\eta\eta}]+ibu_{\eta}S_{\eta}+i(b+1)u_{\xi}S_{\xi}=0, \tag{61}$$

$$u_{\xi\eta}=\frac{1}{4i}\,\mathrm{Tr}(S[S_{\xi},S_{\eta}]), \tag{62}$$

which is the matrix form of Eqs. (54) and (55).

2. Special cases

Equations (54) and (55) contain both well-known and less-known integrable cases in $(2+1)$- and $(1+1)$-dimensions. Below we shall report some of them.

(i) If $b=0$, Eqs. (54) and (55) yield

$$\mathbf{S}_t+\mathbf{S}\wedge\mathbf{S}_{\xi\xi}+w\mathbf{S}_{\xi}=0, \tag{63}$$

$$w_{\eta}-\mathbf{S}\cdot(\mathbf{S}_{\xi}\wedge\mathbf{S}_{\eta})=0, \tag{64}$$

where $w=u_{\xi}$. This system, which is known as the M-VIII model,[24] is one of the simplest spin systems in $(2+1)$-dimensions integrable by IST. It affords a different type of solutions (solitons, vortices, etc.). In particular, vortex solutions of Eqs. (63)–(64) can be derived from vortex solutions of the spin system (54)–(55) discussed in Sec. IX (for $b=0$).

(ii) Let us introduce the coordinates $x=\xi-\eta$, $y=\alpha(\xi+\eta)$, and put $b=-\frac{1}{2}$. Then, the spin system (54)–(55) reduces to the IM

$$\mathbf{S}_t+\mathbf{S}\wedge(\mathbf{S}_{xx}+\alpha^2\mathbf{S}_{yy})+u_x\mathbf{S}_y+u_y\mathbf{S}_x=0, \tag{65}$$

$$u_{xx}-\alpha^2u_{yy}=-2\alpha^2\mathbf{S}\cdot(\mathbf{S}_x\wedge\mathbf{S}_y). \tag{66}$$

The IM is the first integrable spin (field) system in the plane which can be solved by the IST method. The IM was studied by many authors from different points of view (e.g., Refs. 16, 17, 20, 23, 26).

(iii) By setting $b=0$, $\eta=t$, Eqs. (54) and (55) reduce to the following $(1+1)$-dimensional spin system:

$$\mathbf{S}_t+\mathbf{S}\wedge\mathbf{S}_{\xi\xi}+w\mathbf{S}_\xi=0, \tag{67}$$

$$w_t+\tfrac{1}{2}(\mathbf{S}_\xi^2)_\xi=0. \tag{68}$$

This integrable model describes the nonlinear dynamics of compressible magnets.[27] It is the first (and, to the best of our knowledge, at present the unique) example of an integrable spin system governing the nonlinear interactions of spin $(\mathbf{S})$ and lattice (u) subsystems in $(1+1)$-dimensions.

VI. BILINEAR REPRESENTATIONS

One of the powerful tools in the soliton theory is the Hirota method. Now we show how to construct the bilinear representations of the fields of the spin system by using geometry. First, let e_{ji} be the components of the unit vector $\mathbf{e}_j$, i.e., $\mathbf{e}_j=(e_{j1},e_{j2},e_{j3})$. We can take the following representation for the components of the vector $\mathbf{e}_1$:

$$e_1^+=e_{11}+ie_{12}=\frac{2\bar{f}g}{\bar{f}f+\bar{g}g},\quad e_{13}=\frac{\bar{f}f-\bar{g}g}{\bar{f}f+\bar{g}g}, \tag{69}$$

where f and g are complex functions of (x,y,t). Then, the consistency of the system (48) implies

$$e_2^+=e_{21}+ie_{22}=\frac{\bar{f}^2+g^2}{\bar{f}f+\bar{g}g},\quad e_{23}=i\frac{fg-\bar{f}\bar{g}}{\bar{f}f+\bar{g}g}, \tag{70}$$

$$e_3^+=e_{31}+ie_{32}=\frac{\bar{f}^2-g^2}{\bar{f}f+\bar{g}g},\quad e_{33}=-\frac{fg+\bar{f}\bar{g}}{\bar{f}f+\bar{g}g}, \tag{71}$$

with

$$k=-i\frac{D_x(g\circ f-\bar{g}\circ\bar{f})}{\bar{f}f+\bar{g}g},\quad m_3=-i\frac{D_y(g\circ f-\bar{g}\circ\bar{f})}{\bar{f}f+\bar{g}g}, \tag{72}$$

$$\sigma=-\frac{D_x(g\circ f+\bar{g}\circ\bar{f})}{\bar{f}f+\bar{g}g},\quad m_2=-\frac{D_y(g\circ f+\bar{g}\circ\bar{f})}{\bar{f}f+\bar{g}g}, \tag{73}$$

$$\tau=i\frac{D_x(\bar{f}\circ f+\bar{g}\circ g)}{\bar{f}f+\bar{g}g},\quad m_1=i\frac{D_y(\bar{f}\circ f+\bar{g}\circ g)}{\bar{f}f+\bar{g}g}, \tag{74}$$

$$\omega_3=-i\frac{D_t(g\circ f-\bar{g}\circ\bar{f})}{\bar{f}f+\bar{g}g},\quad \omega_2=-\frac{D_t(g\circ f+\bar{g}\circ\bar{f})}{\bar{f}f+\bar{g}g}, \tag{75}$$

$$\omega_1 = i\frac{D_t(\overline{f}\circ f + \overline{g}\circ g)}{\overline{f}f + \overline{g}g}. \tag{76}$$

The Hirota operators D_x, D_y, and D_t are defined by

$$D_x^l D_y^m D_t^n f(x,y,t)\circ g(x,y,t) = (\partial_x - \partial_{x'})^l (\partial_y - \partial_{y'})^m (\partial_t - \partial_{t'})^n f(x,y,t)\circ g(x',y',t')\big|_{x=x',y=y',t=t'}.$$

Now we write the bilinear representation for the spin vector and for the derivatives of the potential u, identifying $\mathbf{S}$ and $\mathbf{e_1}$. Taking into account (69), we find

$$S^+ = S_1 + iS_2 = \frac{2\overline{f}g}{\overline{f}f + \overline{g}g}, \quad S_3 = \frac{\overline{f}f - \overline{g}g}{\overline{f}f + \overline{g}g}. \tag{77}$$

This is the general representation for the components of the spin vector for all the spin systems. However, for the potential, the bilinear forms for every spin system should be different. In the following we shall consider some examples.

A. The Ishimori model

In this case we have

$$\tau = \frac{1}{2}u_y, \quad m_1 = \frac{1}{2\alpha^2}u_x. \tag{78}$$

Hence, from (74) we get

$$u_y = -2i\frac{D_x(\overline{f}\circ f + \overline{g}\circ g)}{\overline{f}f + \overline{g}g}, \quad u_x = -2i\alpha^2\frac{D_y(\overline{f}\circ f + \overline{g}\circ g)}{\overline{f}f + \overline{g}g}. \tag{79}$$

On the other hand, from (74) it also follows that

$$\tau_x = \alpha^2 m_{1y}, \tag{80}$$

so that

$$m_1 = \alpha^{-2}\partial_y^{-1}\tau_x. \tag{81}$$

B. The isotropic M-I equation

Let us take

$$\tau = 0, \quad m_1 = u. \tag{82}$$

Then, from (74) and (82) we obtain

$$D_x(\overline{f}\circ f + \overline{g}\circ g) = 0, \quad u = -i\frac{D_y(\overline{f}\circ f + \overline{g}\circ g)}{\overline{f}f + \overline{g}g}. \tag{83}$$

C. The spin system (54)–(55)

Let us start from

$$\tau=\frac{1}{2}u_{\xi},\quad m_1=-\frac{1}{2}u_{\eta}. \tag{84}$$

Then we have

$$u_{\xi}=-2i\frac{D_{\xi}(\bar{f}\circ f+\bar{g}\circ g)}{\bar{f}f+\bar{g}g},\quad u_{\eta}=2i\frac{D_{\eta}(\bar{f}\circ f+\bar{g}\circ g)}{\bar{f}f+\bar{g}g},$$

and

$$\tau_{\eta}=-m_{1\xi}, \tag{85}$$

$$m_1=-\partial_{\xi}^{-1}\tau_{\eta}. \tag{86}$$

An important consequence of these results is the possibility to determine the time evolution of the potential (and/or its derivatives). For instance, for the IM the time evolution of the derivatives of the potential are given by

$$\frac{1}{2}(u_y)_t-\omega_{3x}+\sigma\omega_1-\tau\omega_2=0, \tag{87}$$

$$\frac{1}{2\alpha^2}(u_x)_t-\omega_{1y}+m_3\omega_3-m_2\omega_3=0. \tag{88}$$

VII. DEFORMATIONS OF SURFACES BY INTEGRABLE SPIN SYSTEMS IN (2+1) DIMENSIONS

As we said above, examples of surface integrable deformations can be found out by identifying the tangent unit vector $\mathbf{e}_1$ with the spin vector, i.e.,

$$\mathbf{e}_1\equiv\mathbf{S}. \tag{89}$$

In such a way, the spin model (54)–(55) takes the form

$$\mathbf{e}_{1t}+\mathbf{e}_1\wedge\{(b+1)\mathbf{e}_{1\xi\xi}-b\mathbf{e}_{1\eta\eta}\}+bu_{\eta}\mathbf{e}_{1\eta}+(b+1)u_{\xi}\mathbf{e}_{1\xi}=0, \tag{90}$$

$$u_{\xi\eta}=\mathbf{e}_1\cdot(\mathbf{e}_{1\xi}\wedge\mathbf{e}_{1\eta}). \tag{91}$$

The functions m_i,ω_i can be expressed in terms of the three independent functions k,τ,σ. Using the GW Eq. (48), Eqs. (90)–(91) can be written as

$$\mathbf{e}_{1t}=\omega_3\mathbf{e}_2-\omega_2\mathbf{e}_3, \tag{92}$$

$$u_{\xi\eta}=\sigma m_3-km_2, \tag{93}$$

where

$$\omega_2=b[m_{3\eta}-m_2^2-u_{\eta}m_2]-(b+1)[k_{\xi}+\sigma\tau+u_{\xi}\sigma], \tag{94}$$

$$\omega_3=(b+1)[\sigma_{\xi}-k\tau-ku_{\xi}]-b[m_{2\eta}-m_1m_3+u_{\eta}m_3]. \tag{95}$$

Now by choosing m_1 according to the special reduction (84), the remaining functions m_2 and m_3 are given by

$$m_2=\frac{\sigma m_3-u_{\xi\eta}}{k}, \quad m_3=\frac{\sigma\tau u_{\xi\eta}+(a_2/2)u_\xi-a_3}{a_1+\sigma^2\tau}, \tag{96}$$

where

$$a_1=k^2\tau-k\sigma_\xi+\sigma k_\xi, \quad a_2=-k^3-\sigma^2 k,$$
$$a_3=k^2\sigma_\eta-\sigma k k_\eta+k u_{\xi\xi\eta}-k_\xi u_{\xi\eta}. \tag{97}$$

By virtue of these formulas we derive the function ω_1 from (50)–(52).

Thus, all the unknown functions m_i,ω_i are defined via the three functions k,τ,σ only and their derivatives. This is the consequence of the identification of the motion of surface with the spin system (90)–(91). This means that the motion of surface is fully determined by these three functions. Since the spin model (90)–(91) is integrable, we can conclude that the deformation of the surface characterized by Eqs. (50)–(52) is integrable.

VIII. DEFORMATIONS OF SURFACES RELATED TO THE (2+1)-DIMENSIONAL NLS-TYPE EQUATION

One of the most remarkable consequences of the geometrical formalism previously outlined is that it allows to find the equivalent counterpart of the spin system (54)–(55). To show this property, let us introduce two complex functions q,p according to the following expressions:

$$q=a_1e^{ib_1}, \quad p=a_2e^{ib_2}, \tag{98}$$

where a_j,b_j are real functions. Now let us choose the functions a_j,b_j in such a way that

$$a_1^2=\frac{1}{4}k^2+\frac{|\alpha|^2}{4}(m_3^2+m_2^2)-\frac{1}{2}\alpha_R k m_3-\frac{1}{2}\alpha_I k m_2, \tag{99}$$

$$b_1=\partial_x^{-1}\left\{-\frac{\gamma_1}{2ia_1'^2}-(\bar{A}-A+D-\bar{D})\right\}, \tag{100}$$

$$a_2^2=\frac{1}{4}k^2+\frac{|\alpha|^2}{4}(m_3^2+m_2^2)+\frac{1}{2}\alpha_R k m_3-\frac{1}{2}\alpha_I k m_2, \tag{101}$$

$$b_2=\partial_x^{-1}\left\{-\frac{\gamma_2}{2ia_2'^2}-(A-\bar{A}+\bar{D}-D)\right\}, \tag{102}$$

where

$$\gamma_1=i\left\{\frac{1}{2}k^2\tau+\frac{|\alpha|^2}{2}(m_3 k m_1+m_2k_y)-\frac{1}{2}\alpha_R(k^2m_1+m_3k\tau+m_2k_x)\right.$$
$$\left.+\frac{1}{2}\alpha_I[k(2k_y-m_{3x})-k_x m_3]\right\}, \tag{103}$$

$$\gamma_2=-i\left\{\frac{1}{2}k^2\tau+\frac{|\alpha|^2}{2}(m_3 k m_1+m_2k_y)+\frac{1}{2}\alpha_R(k^2m_1+m_3k\tau+m_2k_x)\right.$$
$$\left.+\frac{1}{2}\alpha_I[k(2k_y-m_{3x})-k_x m_3]\right\}. \tag{104}$$

In this case, q,p satisfy the $(2+1)$-dimensional equations of the nonlinear Schrödinger (NLS) type[27]

$$iq_t+(1+b)q_{\xi\xi}-bq_{\eta\eta}+vq=0, \tag{105}$$

$$ip_t-(1+b)p_{\xi\xi}+bp_{\eta\eta}-vp=0, \tag{106}$$

$$v_{\xi\eta}=-2\{(1+b)(pq)_{\xi\xi}-b(pq)_{\eta\eta}\}. \tag{107}$$

These equations are the geometrical equivalent counterpart of the spin system (54)–(55). Therefore, the spin system and the $(2+1)$-dimensional NLS equations (105)–(107) turn out to be mutually geometrical equivalent.

A. Gauge equivalence

Now we prove that the spin system (54)–(55) and Eqs. (105)–(107) are not only equivalent in the geometrical sense, but are also gauge equivalent. To this purpose, let us perform the gauge transformation $\Psi=g\Phi$, where the function Φ is the solution of Eqs. (59)–(60) and g is a 2×2 matrix such that

$$S=g^{-1}\sigma_3 g, \tag{108}$$

and

$$g_{Z^+}g^{-1}-\sigma_3 g_{Z^-}g^{-1}=\begin{pmatrix}0 & q\\ p & 0\end{pmatrix}. \tag{109}$$

Under this transformation the function Ψ obeys the following set of linear equations

$$\Psi_{Z^+}=\sigma_3\Psi_{Z^-}+B_0\Psi, \tag{110}$$

$$\Psi_t=4iC_2\Psi_{Z^-Z^-}+2C_1\Psi_{Z^-}+C_0\Psi, \tag{111}$$

where B_0,C_j are given by

$$B_0=\begin{pmatrix}0 & q\\ p & 0\end{pmatrix},\quad C_2=\begin{pmatrix}b+1 & 0\\ 0 & b\end{pmatrix},$$

$$C_1=\begin{pmatrix}0 & iq\\ ip & 0\end{pmatrix},\quad C_0=\begin{pmatrix}c_{11} & c_{12}\\ c_{21} & c_{22}\end{pmatrix}, \tag{112}$$

and the functions c_{ij} $(i,j=1,2)$ fulfill the equations

$$c_{12}=i[(4b+3)q_{Z^-}+q_{Z^+}],\quad c_{21}=-i[(4b+1)p_{Z^-}+p_{Z^+}], \tag{113}$$

$$c_{11Z^-}-c_{11Z^+}=i[(4b+3)(pq)_{Z^-}+(pq)_{Z^+}], \tag{114}$$

$$c_{22Z^-}+c_{22Z^+}=i[(4b+1)(pq)_{Z^-}+(pq)_{Z^+}], \tag{115}$$

with $v=i(c_{22}-c_{11})$ [see (105)–(107)].

The compatibility condition of Eqs. (110)–(111) gives the equations (105)–(107). This means that the spin model (54)–(55) and the NLS—type equations (105)–(107) are gauge equivalent. Moreover, it is easy to check that if g satisfies Eq. (109), then S given by (108) satisfies Eqs. (54)–(55) with

$$u=-2\ln\det g. \tag{116}$$

B. Reductions

Equations (105)–(107), as its and equivalent spin system (54)–(55), contain several integrable cases, namely

(i) $b=0$. Equations (105)–(107) yield the equations[27]

$$iq_t+q_{\xi\xi}+vq=0, \tag{117}$$

$$ip_t-p_{\xi\xi}-vp=0, \tag{118}$$

$$v_\eta=-2(pq)_\xi. \tag{119}$$

(ii) $a=b=-\frac{1}{2}$. Then, we give the Davey–Stewartson (DS) equations[27]

$$iq_t+q_{xx}+\alpha^2q_{yy}+vq=0, \tag{120}$$

$$ip_t-p_{xx}-\alpha^2p_{yy}-vq=0, \tag{121}$$

$$v_{xx}-\alpha^2v_{yy}=2\{(pq)_{xx}+\alpha^2(pq)_{yy}\}, \tag{122}$$

where $x=\xi-\eta, y=\alpha(\xi+\eta)$.

(iii) Putting $b=0, \eta=t$, Eqs. (105)–(107) reduce to the $(1+1)$-dimensional Ma[28]–Yajima–Oikawa[29] equations,

$$iq_t+q_{\xi\xi}+vq=0, \tag{123}$$

$$ip_t-p_{\xi\xi}-vp=0, \tag{124}$$

$$v_t+2(pq)_\xi=0, \tag{125}$$

which are known to be integrable.

IX. SOLUTIONS OF THE SPIN SYSTEM

It could be of interest to study Eqs. (54)–(55) by the IST method. However, to look for some special solutions, it is convenient to exploit the Hirota bilinear method. To this aim, let us build up the bilinear form of (54)–(55) for the compact case.

We obtain

$$S^+=S_1+iS_2=\frac{2\overline{f}g}{\overline{f}f+\overline{g}g}, \quad S_3=\frac{\overline{f}f-\overline{g}g}{\overline{f}f+\overline{g}g}, \tag{126}$$

$$u_\xi=-2i\frac{D_\xi(\overline{f}\circ f+\overline{g}\circ g)}{\overline{f}f+\overline{g}g}, \quad u_\eta=2i\frac{D_\eta(\overline{f}\circ f+\overline{g}\circ g)}{\overline{f}f+\overline{g}g}, \tag{127}$$

where S_j $(j=1,2,3)$ are the components of spin vector $\mathbf{S}$, $S^\pm=S_1\pm iS_2$, and u is the scalar potential.

Hence, from (116) we get

$$u(\xi,\eta,t)=-2\ln(|f|^2+|g|^2). \tag{128}$$

Substituting formulas (126) and (127) into the spin system (54)–(55), we obtain the bilinear equations

$$[iD_t-(b+1)D_\xi^2+bD_\eta^2](\overline{f}\circ g)=0, \tag{129}$$

$$[iD_t-(b+1)D_\xi^2+bD_\eta^2](\overline{f}\circ f-\overline{g}\circ g)=0, \tag{130}$$

$$\{D_\xi D_\eta+D_\eta D_\xi\}(\overline{f}f+\overline{g}g)\circ(\overline{f}f+\overline{g}g)=0. \tag{131}$$

Equation (131) coincides with the compatibility condition $u_{\xi\eta}=u_{\eta\xi}$.

Now we can construct some special solutions of Eqs. (54)–(55). In particular, to construct vortex solutions, we start from Eqs. (129)–(130) and assume that

$$f=f(\xi,t), \quad g=g(\xi,t). \tag{132}$$

Then Eq. (131) is satisfied automatically. At the same time, Eqs. (129)–(130) are fulfilled if

$$if_t+(b+1)f_{\xi\xi}=0, \quad ig_t+(b+1)g_{\xi\xi}=0. \tag{133}$$

Consequently, we are led to the following multivortex solutions:

$$g_N=\sum_{j=0}^{N}\sum_{m+2n=j}\frac{a_j}{m!n!}\left(\frac{2}{b+1}\right)^{m/2}\xi^m(2it)^n, \tag{134}$$

$$f_N=\sum_{j=0}^{N-1}\sum_{m+2n=j}\frac{b_j}{m!n!}\left(\frac{2}{b+1}\right)^{m/2}\xi^m(2it)^n, \tag{135}$$

where a_j and b_j are arbitrary complex constants, and m,n are nonnegative integer numbers. In particular, the one-vortex solution can be derived by choosing

$$f=b_0, \quad g=a_1'\xi+a_0, \tag{136}$$

where $a_1'=a_1(2/(b+1))^{1/2}$.

So, the one-vortex solution is static. To find a dynamic solution, we have to consider the N-vortex solution using the forms

$$f(\xi,t)=b_0\prod_{j=1}^{N}[\xi-p_j(t)], \tag{137}$$

$$g(\xi,t)=a_0\prod_{j=1}^{N}[\xi-q_j(t)], \tag{138}$$

where p_j and q_j denote the positions of the zeros of f and g, and a_0,b_0 are constants. The evolution of p_j and q_j is

$$p_{jt}=-i(b+1)\sum_{k[n0]=j}^{N}\frac{1}{p_j-p_k}, \tag{139}$$

$$q_{jt}=-i(b+1)\sum_{k\neq j}^{N}\frac{1}{q_j-q_k}, \tag{140}$$

where $j,k=1,2,\ldots,N$. These equations are related to the Calogero–Moser system.

X. SPECIAL SURFACES CORRESPONDING TO VORTEX SOLUTIONS OF THE SPIN SYSTEM

This section is devoted to the construction of explicit surfaces. To this aim, let us start from the one-vortex solution of the spin system (54)–(55). By choosing for simplicity $E=1$, Eqs. (41)–(42) become

$$k=L, \quad \sigma=\frac{F_x}{\sqrt{g}}, \quad \tau=\frac{M-LF}{\sqrt{g}}, \tag{141}$$

$$m_1=\frac{N-MF}{\sqrt{g}}, \quad m_2=-\frac{G_x}{2\sqrt{g}}, \quad m_3=M. \tag{142}$$

On the other hand, from (38) and (89) we get

$$\mathbf{r}_x(\xi,\eta,t)=\mathbf{S}(\xi,\eta,t). \tag{143}$$

Now let us consider by way of example the surface associated with the one-vortex solution of the Ishimori system, whose components are

$$S_3=\frac{1-b^2|\Xi|^2}{1+b^2|\Xi|^2}, \quad S^+=2be^{i\delta}\frac{\Xi}{1+b^2|\Xi|^2},$$

$$u=2(\ln(b)+\ln[1+b^2|\Xi|^2]),$$

where Ξ denotes the complex variable $\Xi=2a\exp(i\gamma)(x+iy)+1$, a,b, γ, and δ being real constants.

Then, by resorting to the formula $e_1=r_x/\sqrt{E}$ (with $E\equiv 1$), we can integrate to yield the following components for the position vector:

$$r_1=\frac{\hat{c}\ln(1+b^2|\Xi|^2)}{a\,b}-\frac{\sqrt{2}\arctan\left[b\sqrt{\frac{2}{\Omega}}(a\,x+c)\right](\tilde{c}-2\,a\,\hat{s}y)}{a\sqrt{\Omega}},$$

$$r_2=\frac{\hat{s}\ln(1+b^2|\Xi|^2)}{a\,b}-\frac{\sqrt{2}\arctan\left[b\sqrt{\frac{2}{\Omega}}(a\,x+c)\right](2\,a\,\hat{c}y+\tilde{s})}{a\sqrt{\Omega}}, \tag{144}$$

$$r_3=-x+\frac{2\sqrt{2}\arctan\left[b\sqrt{\frac{2}{\Omega}}(a\,x+c)\right]}{a\,b\sqrt{\Omega}},$$

where for the sake of clarity we have introduced the second degree polynomial $\Omega=2+b^2[1+2a^2y^2-\cos(2\gamma)+4a\sin(\gamma)y]$ and the constants $c=\cos(\gamma)$, $s=\sin(\gamma)$, $\hat{c}=\cos(\gamma+\delta)$, $\hat{s}=\sin(\gamma+\delta)$, $\tilde{c}=-\cos(\delta)+\cos(2\gamma+\delta)$, and $\tilde{s}=-\sin(\delta)+\sin(2\gamma+\delta)$. Furthermore, we have put identically equal to zero any arbitrary function of integration in y only.

From them, with the help of the various formulas given in Sec. III, we obtain the coefficients of the I-fundamental form,

$$E=1, \quad F=\frac{4\,b\,(s+a\,y)\,(b\,(c+a\,x)\sqrt{\Omega}+\sqrt{2}\,(1+b^2|\Xi|^2)\,At[x,y])}{(1+b^2|\Xi|^2)\,\Omega^{3/2}},$$

$$G=\frac{2\,(4\,b^2\,(s+a\,y)^2\,\Omega+8\,(1+b^2\,|\Xi|^2)\,At[x,y]^2)}{(1+b^2\,|\Xi|^2)\,\Omega^2},$$

where $At[x,y]=\arctan[\,b\,\sqrt{2/\Omega}\,(a\,x+c)]$, and analogously for the II-fundamental form,

$$\sqrt{g}L=\frac{8\,a\,b\,[-(b^3\,(c+a\,x)\,(s+a\,y)^2\,\sqrt{\Omega})+\sqrt{2}\,(1+b^2\,|\Xi|^2)\,At[x,y]]}{(1+b^2\,|\Xi|^2)^2\,\Omega^{3/2}},$$

$$\sqrt{g}M=\frac{-4\,a\,b^2\,(s+a\,y)}{(1+b^2\,|\Xi|^2)^2},$$

$$\sqrt{g}N=\frac{8\,a\,b(2\sqrt{2}(1+b^2|\Xi|^2)\,\sqrt{\Omega}\;At[x,y]+8\,b\,(c+a\,x)\,(1+b^2\,|\Xi|^2)\;At[x,y]^2+b^3\,(c+a\,x)\,(s+a\,y)^2\,\Omega\,(2+\Omega))}{(1+b^2|\,\Xi|^2)^2\,\Omega^3},$$

where g in the metric factor $\sqrt{g}$ is expressed by

$$g=\frac{8}{(1+b^2\,|\Xi|^2)^2\,\Omega^3}\{\,b^2\,(s+a\,y)^2\,\Omega-2\,b^2\,(c+a\,x)^2+(1+b^2\,|\Xi|^2)\,\Omega)$$
$$-4\sqrt{2}\,b^3\,(c+a\,x)\,(s+a\,y)^2\,(1+b^2\,|\Xi|^2)\,\sqrt{\Omega}\,At[x,y]+4\,(1+b^2\,|\Xi|^2)^2\,At[x,y]^2\}.$$

The Gauss curvature K and the mean curvature H are given by [see (32) and (33)] are given by

$$K=\frac{8\,a^2\,b^2}{(1+b^2\,\Xi^2)^4\,\Omega^{9/2}}\{-b^2\,(s+a\,y)^2\,\Omega^{3/2}\,(\Omega^3+4\,b^4\,(c+a\,x)^2\,(s+a\,y)^2\,(2+\Omega))$$
$$+4\sqrt{2}b^3(c+ax)(s+ay)^2(1+b^2|\Xi|^2)\Omega^2At[x,y]-16(1+b^2|\Xi|^2)$$
$$\times[2\,b^4\,(c+a\,x)^2\,(s+a\,y)^2-(1+b^2|\Xi|^2)]\sqrt{\Omega}\,At[x,y]^2$$
$$+32\sqrt{2}b(c+ax)(1+b^2|\Xi|^2)^2At[x,y]^3\},$$

$$H=\frac{4ab}{(1+b^2\,|\Xi|^2)^3\Omega^{7/2}\sqrt{g}}\{b^3\,(c+a\,x)\,(s+a\,y)^2\,\Omega^{3/2}[(1+b^2\,|\Xi|^2)\,(2+\Omega)$$
$$+4\,(2\,b^2\,(s+a\,y)^2+\Omega)]+2\,\sqrt{2}\,(1+b^2\,|\Xi|^2)\,\Omega\,(1-4\,b^2\,(s+a\,y)^2+b^2\,|\Xi|^2$$
$$+2\,b^2\,(s+a\,y)^2\,\Omega)\,At[x,y]+8\,b\,(c+a\,x)\,(1+b^2\,|\Xi|^2)$$
$$\times(1+2\,b^2\,(s+a\,y)^2+b^2\,|\Xi|^2)\,\sqrt{\Omega}\,At[x,y]^2-16\sqrt{2}\,(1+b^2\,|\Xi|^2)^2\,At[x,y]^3\},$$

respectively.

An example of a surface associated with the one-vortex solution of the Ishimori system is drawn in Fig 1.

XI. CONCLUSIONS

In this article we have established some notable connections among the purely topological CS theory, deformations of surfaces, and integrable equations in $(2+1)$-dimensions. However, many questions remain open and deserve further investigation, such as, for example, the search for other integrable classes of deformations of surfaces, the determination of the Hamiltonian structure, and the possible interpretation of the solutions from a physical point of view. To this regard, in particular we have found the surface associated with the exact vortex solutions of the $(2+1)$-dimensional spin system. We notice that another approach exists to study integrable $(2+1)$-dimensional deformations of surfaces, i.e., the method developed mainly by Konopelchenko, Taimanov, and co-workers.[3,30] The essential tool of their procedure is the use of a generalized

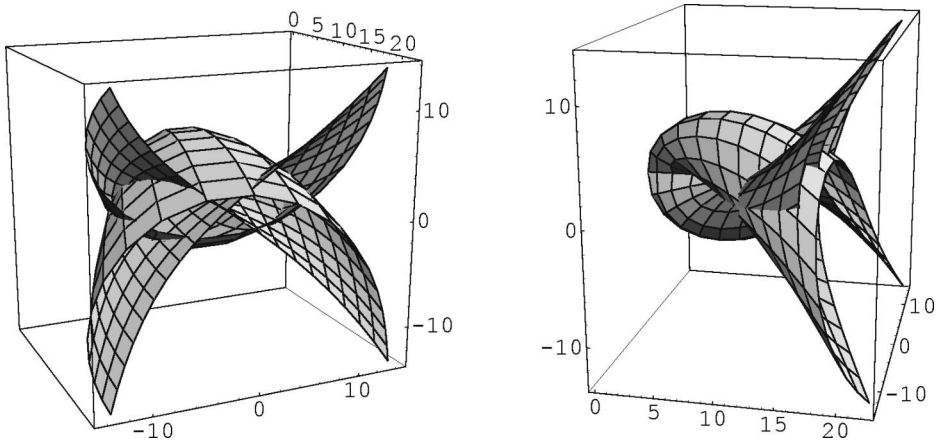

FIG. 1. We drew the same surface from two different points of view. The parameters used in Eq. (144) are $a=1$, $b=0.1$, $\gamma=\delta=0$.

Weierstrass representation for a conformal immersion of surfaces into R^3 or R^4, together with a linear problem related to this representation. The method devised in Refs. 3, 30 allows one to express integrable deformations of surfaces via hierarchies of integrable equations, such as the Nizhnik–Veselov–Novikov, the DS equations, and so on. We think that our approach and that described in Ref. 3 should be pursued in parallel, with the purpose to achieve possible complementary results on the link between integrable deformations of surfaces and completely integrable partial differential equations. Finally, we have shown that the non-Abelian Chern–Simons field theory can be interpreted in a more classical geometrical setting. From this aspect, by a suitable choice of the configuration space of the fields and under certain assumptions on the gauge conditions, notable equations of the mathematical physics arise. In this case, since large classes of solutions are known, our results could be useful in the studies of related problems in the low-dimensional classical and quantum physics, where the peculiar properties of the Chern–Simons interaction are involved.[14,15,31–33]

A method of construction of harmonic functions for the system of anyons on a plane is given. Spectra of angular momentum are derived. Anyonic statistics implies a restriction of the range of angular momentum which is stronger in comparison to the bosonic and fermion case. © *2001 American Institute of Physics.* [DOI: 10.1063/1.1339220]

I. INTRODUCTION

We consider the system of N anyons on a plane, with the statistical parameter $\nu \in [0,2)$. The configuration space of the system is $Q_N = C^N \backslash D_N / \Sigma_N$ (we identify the plane with the complex plane C, D_N denotes the fat diagonal, and Σ_N is the symmetric group). The fundamental group of this space is the so called braid group $B_N = \pi_1(Q_N)$.[1–4] Wave functions describing this system will be referred to as the ν-equivariant functions, that is functions which transform according to one-dimensional unitary irreducible representations of the corresponding braid group B_N, labeled uniquely by ν.

In the theory of anyons on a (complex) plane it is convenient to separate the motion of the system into the mass center and the relative part. Because the mass center part corresponds to a simply connected space we will deal only with the relative one. The relative part of the motion is orthogonal to the mass center part because the former is generated by differences of positions of particles. It is obvious that the space of the relative part has complex dimension $M := N-1$.

Anyonic harmonic functions (it means those satisfying the Laplace equation and being ν-equivariant) are very important in the anyon theory. For example, solutions of the stationary Schrödinger equation for free anyons or anyons in a homogeneous harmonic oscillator potential can be written by means of products of homogeneous anyonic harmonic functions and suitable special functions depending only on the length of the relative radius. So the relative angular momentum depends only on the harmonic factor, the other factor does not affect the value of angular momentum. Solutions for the system was given in the papers of Refs. 5, 6 by means of homogeneous holomorphic functions, but more general formulas we obtain replacing them by homogeneous harmonic functions.

It is well known [3,4] that the relative part of ν-equivariant functions can be presented as

$$V^{\nu}(u) F_{\mathrm{sym}}(u,u^*) \tag{1}$$

or

$$V^{2-\nu}(u^*) F_{\mathrm{sym}}(u,u^*), \tag{2}$$

where

a)Electronic mail: milewski@euler.mat.univ.szczecin.pl

$$u=(u_1,\ldots,u_M), \quad u^*=(u_1^*,\ldots,u_M^*) \tag{3}$$

are orthonormal system of holomorphic (resp., antiholomorphic) coordinates of the relative motion space,

$$V(u)=\prod_{k<l}(z_l-z_k) \tag{4}$$

is the Vandermonde determinant of positions of particles $(z_k, k=1,2,\ldots,N)$, expressed by the relative coordinates, and $F_{\mathrm{sym}}(u,u^*)$ is a power series of variables u,u^*, symmetric with respect to transpositions of particles.

Our aim in the present paper is the construction of anyonic harmonic functions, that is such ν-equivariant functions $H(u,u^*)$ of the form of Eqs. [(1)–(2)], which satisfy the Laplace equation:

$$\sum_{k=1}^{M}\frac{\partial}{\partial u_k}\frac{\partial}{\partial u_k^*}H=0. \tag{5}$$

In Sec. II we propose the construction of such functions, in Sec. III we deal with the angular momentum, in Sec. IV we give an example, and in Sec. V, some general remarks and conclusions.

II. CONSTRUCTION OF ANYONIC HARMONIC FUNCTIONS

We start with the following evident commutation relations:

$$\left[\frac{\partial}{\partial u_k},\frac{\partial}{\partial u_l}\right]=0, \tag{6}$$

$$\left[\frac{\partial}{\partial u_k},u_l^*\right]=0, \tag{7}$$

$$\left[\frac{\partial}{\partial u_k},\frac{\partial}{\partial u_l^*}\right]=0. \tag{8}$$

They imply that despite the fact that the Laplace Equation (5) is of the second order, we can treat it as a first order partial differential equation with respect to the antiholomorphic variables. This equation is linear, and its coefficients are operators $\partial/\partial u_k$, which are constant with respect to antiholomorphic variables. Thus the solutions are given in a full analogy with the case of equations with constant number coefficients,

$$\sum_{k=1}^{M}a_k\frac{\partial}{\partial x_k}p(x)=0. \tag{9}$$

The solution can be written in the form

$$p(x)=P(x_1a_2-x_2a_1,x_1a_3-x_3a_1,\ldots,x_{M-1}a_M-x_Ma_{M-1}), \tag{10}$$

with P being an arbitrary function of the class C_1. It suggests we look for the solutions of Eq. (5) in the form

$$H(u,u^*)=P\left(u_1^*\frac{\partial}{\partial u_2}-u_2^*\frac{\partial}{\partial u_1},u_1^*\frac{\partial}{\partial u_3}-u_3^*\frac{\partial}{\partial u_3{}_1},\ldots,u_{M-1}^*\frac{\partial}{\partial u_M}-u_M^*\frac{\partial}{\partial u_{M-1}}\right)\tilde{f}(u), \tag{11}$$

where $\tilde{f}$ depends only upon holomorphic variables u. Moreover, we admit in our consideration only a polynomial form of the functions P, to avoid detailed discussion of domains, etc.

The right-hand side of Eq. (11) is the result of acting of the differential operator $P(u_1^*(\partial/\partial u_2) - u_2^*(\partial/\partial u_1),\ldots]$ on holomorphic function $\tilde{f}(u)$.

To impose the fractional statistics ν, we take the function $\tilde{f}(u)$ in the form

$$\tilde{f}(u) = f(u)V^{\nu}(u), \tag{12}$$

where $f(u)$ is a polynomial. The condition of hard core for anyons implies that H should vanish at the fat diagonal.[3] Thus, it cannot exhibit any pole there. It follows that the polynom f should be divisible by V^n, where n is the total degree of the polynom P. Moreover, (Eq. (1) implies that either both $P[u_1^*(\partial/\partial u_2) - u_2^*(\partial/\partial u_1),\ldots]$ and $f(u)$ are symmetric with respect to transpositions of particles, or both are antisymmetric.

For homogeneous polynomials P and f the function H is a bihomogeneous one, which means that H is an eigenfunction of holomorphic and antiholomorphic homogeneity degree operators:

$$\hat{n}_h = \sum_k u_k \frac{\partial}{\partial u_k}, \quad \hat{n}_a = \sum_k u_k^* \frac{\partial}{\partial u_k^*}, \tag{13}$$

i.e.,

$$\hat{n}_h H = n_h H, \quad \hat{n}_a H = n_a H. \tag{14}$$

We have therefore the following formulas:

$$H(u,u^*) = P_{\mathrm{sym}}\left(u_1^* \frac{\partial}{\partial u_2} - u_2^* \frac{\partial}{\partial u_1},\ldots\right)(f_{\mathrm{sym}}(u)V^{\nu+2k}(u)), \tag{15}$$

$$H(u,u^*) = P_{\mathrm{antisym}}\left(u_1^* \frac{\partial}{\partial u_2} - u_2^* \frac{\partial}{\partial u_1},\ldots\right)(f_{\mathrm{sym}}(u)V^{\nu+2k-1}(u)), \tag{16}$$

or

$$H(u,u^*) = P_{\mathrm{sym}}\left(u_1 \frac{\partial}{\partial u_2^*} - u_2 \frac{\partial}{\partial u_1^*},\ldots\right)(f_{\mathrm{sym}}(u^*)V^{2-\nu+2k}(u^*)), \tag{17}$$

$$H(u,u^*) = P_{\mathrm{antisym}}\left(u_1 \frac{\partial}{\partial u_2^*} - u_2 \frac{\partial}{\partial u_1^*},\ldots\right)(f_{\mathrm{sym}}(u^*)V^{1-\nu+2k}(u^*)), \tag{18}$$

where f_{sym} is a symmetric bihomogeneous polynomial indivisible by V. In all of Eqs. (15)–(18), the degree of polynomial P_{sym} (P_{antisym}) is less than the exponent of Vandermonde determined (the hardcore condition). Equations (15)–(18) provide general formulas for anyonic harmonic functions for arbitrary N, and constitute the basis for the following considerations. We proceed to demonstrate some special cases in more detail.

III. ANGULAR MOMENTUM OF ANYON SYSTEM

Let us consider the operators

$$\hat{l} = \hat{n}_h + \hat{n}_a \tag{19}$$

and

$$\hat{m} = \hat{n}_h - \hat{n}_a. \tag{20}$$

Clearly, $\hat{m}$ is the operator of the two-dimensional angular momentum, and a bihomogeneous function $H(u,u^*)$ is its eigenfunction, with eigenvalue $m=n_h-n_a$.

The operator $\hat{l}$ has the meaning of the total degree of homogeneity $l=n_h+n_a$ and bears some resemblance to the quantum number of the square of angular momentum in the three-dimensional theory. Namely, we are going to demonstrate that it provides some bounds to the range of m.

We start with the observation that in the three-dimensional case the (z-projection of) the angular momentum m varies with the step 1, whereas in our case m varies with the step 2, for fixed value of the total homogeneity degree l. It is an immediate consquence of Eqs. (19), (20), which follow from the fact that our system is two-dimensional.

Let us consider in particular harmonic functions of the form

$$H_I=P\left(u_k^*\frac{\partial}{\partial u_l}-u_l^*\frac{\partial}{\partial u_k}\right)(V^{n+\nu}(u)f(u)), \tag{21}$$

where P is a polynomial of degree n, which is symmetric (antisymmetric) for n even (odd), and f is a holomorphic homogeneous symmetric polynomial. The total homogeneity degree and the angular momentum of the function are given by

$$l_I=(n+\nu)\binom{N}{2}+d(f), \quad m_I=l_I-2n, \tag{22}$$

where $d(f)$ is the homogeneity degree of the polynomial f. Note that $\binom{N}{2}$ is equal to the homogeneity degree of the Vandermonde determinant $V(u)$. For given l_I we obtain the minimal value of m_I for $n=(n_I)_{\max}$,

$$(n_I)_{\max}=\left[\frac{l_I-\binom{N}{2}\nu}{\binom{N}{2}}\right], \tag{23}$$

where the square bracket denotes the integer part,

$$(m_I)_{\min}=l_I-2(n_I)_{\max}>0. \tag{24}$$

Bounds (23) and (24) follow from the fact that ν is genuinely nonintegral. Namely, it is easy to observe that $P[u_k^*(\partial/\partial u_l)-u_l^*\partial/\partial u_k)$ in Eq. (21) generates poles when the degree of P is bigger than $(n_I)_{\max}$. In other words, the spectrum of the angular momentum m_I is

$$l_I-2(n_I)_{\max}, \quad l_I-2(n_I)_{\max}+2, \ldots l_I-2, \quad l_I. \tag{25}$$

For harmonic functions of the form

$$H_{II}=P\left(u_k\frac{\partial}{\partial u_l^*}-u_l\frac{\partial}{\partial u_k^*}\right)(V^{n+2-\nu}(u^*)f(u^*)), \tag{26}$$

we obtain in a similar way the spectrum of the angular momentum m_{II}:

$$-(l_{II}-2(n_{II})_{\max}), -(l_I-2(n_{II})_{\max}+2), \ldots -(l_{II}-2), -l_{II}, \tag{27}$$

where l_{II} is the total homogeneity degree of the function (26), and

$$(n_{II})_{\max}=\left[\frac{l_{II}-\binom{N}{2}(2-\nu)}{\binom{N}{2}}\right], \tag{28}$$

$$(m_{II})_{\max}=-(l_{II}-2(n_{II})_{\max})<0. \tag{29}$$

Thus in the case of boson ($\nu=0$) or fermion ($\nu=1$) statistics, the angular momentum m varies in the range from $-l$ to l with the step 2 (for the two-dimensional system). For fractional statistics we obtain some bounds the range of m under fixed l, given by Eqs. (23), (24) and Eqs. (28), (29).

When considering purely fractional statistics ($\nu\neq 0$ and $\nu\neq 1$), we should distinguish between two cases: the generic $N(N-1)\nu\notin Z$, and the special one $N(N-1)\nu\in Z$.

The consideration given above imply that for the generic case the spectra of the total homogeneity degree l_I and l_{II} are mutually different. In this case the equality $l_I=l_{II}$ cannot be satisfied because the difference l_I-l_{II} is not an integer. In special cases a series of positive values [Eq. (25)] of angular momentum m_I joins with suitable series of negative values m_{II} [Eq. (27)] such that $l_I=l_{II}$.

We conclude that in the generic case the spectrum of the angular momentum m for fixed l is either positive or negative, whereas in special cases it encompasses both positive and negative values.

IV. THE CASE OF THREE ANYONS. EXAMPLES

Now we discuss the case of three anyons. The complex dimension of the relative space is $M=2$, so that P depends only upon a single argument, e.g., $u_1^*(\partial/\partial u_2)-u_2^*(\partial/\partial u_1)$ (cf. Eq. (11)]. Thus we take

$$P(x)=x^n. \tag{30}$$

For the sake of definiteness, we restrict our further discussion to Eq. (15). Other cases follow correspondingly.

The Vandermonde determinant for three anyons in Fourier coordinates:[7]

$$u_k=\frac{1}{\sqrt{3}}\sum_{l=1}^{3} e^{2\pi ikl/3}z_l, \quad k=0,1,2, \tag{31}$$

is given, up to a multiplicative constant, by the formula

$$V(u)=u_2^3-u_1^3. \tag{32}$$

So Eq. (15) yields $H(u,u^*)=[u_1^*(\partial/\partial u_2)-u_2^*(\partial/\partial u_1)]^n[f(u)(u_2^3-u_1^3)^r]$, where $r\geqslant n$; $[r]=[\nu]$ with $[x]$ denoting the integer part of x. For simplicity we put $f(u)=u_1^k u_2^l$, which is not symmetric generally, and then we get a formula for symmetric polynomials.

The case $n=0$ in Eq. (30) corresponds to the constant function $P=1$, so the multivalued function H is locally holomorphic.

In the case $n=1$ (the antiholomorphic homogenity rank is equal to 1, we have

$$\left(u_1^*\frac{\partial}{\partial u_2}-u_2^*\frac{\partial}{\partial u_1}\right)[(u_1^k u_2^l(u_2^3-u_1^3)^r)]=(lu_1u_1^*-ku_2u_2^*)u_1^{k-1}u_2^{l-1}(u_2^3-u_1^3)^r + 3r(u_2^2u_1^*+u_1^2u_2^*)u_1^k u_2^l(u_2^3-u_1^3)^{r-1}. \tag{33}$$

In particular, we have a very simple form of harmonics for $k,l=0$, which reads as

$$(u_2^2u_1^*+u_1^2u_2^*)(u_2^3-u_1^3)^{r-1}. \tag{34}$$

The case $n=2$ yields

$$\begin{aligned}
&\left(u_1^*\frac{\partial}{\partial u_2}-u_2^*\frac{\partial}{\partial u_1}\right)^2[(u_1^ku_2^l(u_2^3-u_1^3)^r)]\\
&\quad=-(k+l)u_1^*u_2^*u_1^{k-1}u_2^{l-1}(u_2^3-u_1^3)^r\\
&\qquad+(lu_1u_1^*-ku_2u_2^*)[(l-1)u_1u_1^*-(k-1)u_2u_2^*]u_1^{k-2}u_2^{l-2}(u_2^3-u_1^3)^r\\
&\qquad+6r(u_2^2u_1^*+u_1^2u_2^*)(lu_1u_1^*-ku_2u_2^*)u_1^{k-1}u_2^{l-1}(u_2^3-u_1^3)^{r-1}\\
&\qquad+6r(u_2u_1^{*2}+u_1u_2^{*2})u_1^ku_2^l(u_2^3-u_1^3)^{r-1}\\
&\qquad+9r(r-1)(u_2^2u_1^*+u_1^2u_2^*)^2u_1^ku_2^l(u_2^3-u_1^3)^{r-2}.
\end{aligned}$$

It shows that the number of terms increases rapidly with n.

Now let us consider the spectrum of the angular momentum operator for the relative part of anyonic harmonic functions of the three anyon system. The total homogeneity rank of the function of the form (42) is

$$l_I=3(n+\nu)+k, \tag{35}$$

and of the form (43),

$$l_{II}=3(n+2-\nu)+k, \tag{36}$$

where k is the homogeneity rank of $f(u)$, $(f(u^*))$.

The permutation group S_3 acts on variables u_0,u_1,u_2 in the standard way as on functions of z_1,z_2,z_3:

$$(\sigma f)(z_1,z_2,z_3)=f(z_{\sigma(1)},z_{\sigma(2)},z_{\sigma(3)}). \tag{37}$$

This action is trivial on u_0, and

$$\sigma_1u_1=u_2,\quad \sigma_1u_2=u_1,\quad \sigma_2u_1=\epsilon^2u_2,\quad \sigma_2u_2=\epsilon u_1, \tag{38}$$

where $\epsilon=e^{2\pi i/3}$. The relative space is a carrying space of the irreducible representation $\Gamma_{\{1,2\}}$ of the group S_3. In the coordinate (u_1,u_2) the matrix elements are

$$\Gamma_{\{1,2\}}(\sigma_1)=\begin{bmatrix}0&1\\1&0\end{bmatrix},\quad \Gamma_{\{1,2\}}(\sigma_2)=\begin{bmatrix}0&\epsilon^2\\\epsilon&0\end{bmatrix}. \tag{39}$$

The symmetrization $S=\frac{1}{6}\Sigma\sigma$ of the monomial $u_1^{n_1}u_2^{n_2}$ is equal 0 for n_1-n_2 indivisible by 3:

$$S(u_1^{n_1}u_2^{n_2})=\tfrac{1}{6}(1+\epsilon^{n_1-n_2}+\epsilon^{n_2-n_1})u_1^{n_1}u_2^{n_2}+(1+\epsilon^{n_1-n_2}+\epsilon^{n_2-n_1})u_2^{n_1}u_1^{n_2}. \tag{40}$$

So the basis of the holomorphic relative symmetric polynomials is formed by such functions:

$$u_1^{n_1}u_2^{n_2}+u_1^{n_2}u_2^{n_1},\quad n_1\geqslant n_2, \tag{41}$$

where the difference n_1-n_2 is divisible by three. In a similar way one can show that $u_1^*(\partial/\partial u_2-u_2^*(\partial/\partial u_1)$ is an antisymmetric operator. So general formulas for the relative part of harmonic functions for a three anyon system of the type (15.) can be written in the form

$$H_I(u,u^*)=\left(u_1^*\frac{\partial}{\partial u_2}-u_2^*\frac{\partial}{\partial u_1}\right)^n(u_2^3-u_1^3)^{n+\nu}f(u), \tag{42}$$

where $f(u)$ is a relative holomorphic symmetric polynomial.

The other formula of the type (18) is given in such a way,

$$H_{II}(u,u^*)=\left(u_1\frac{\partial}{\partial u_2^*}-u_2\frac{\partial}{\partial u_1^*}\right)^n(u_2^{*3}-u_1^{*3})^{n+2-\nu}f(u^*), \tag{43}$$

where $f(u^*)$ is a relative antiholomorphic symmetric polynomial.

The dimension of the space X_k (X_k^*) of homogeneous relative holomorphic (antiholomorphic) symmetric polynomials of degree k is equal to $d(k)$, where

$$d(6n+a)=n+1 \quad \text{for } a=0,2,3,4,5 \text{ and } d(6n+1)=n. \tag{44}$$

The pairs (l_I,m_I) and (l_{II},m_{II}) in general are degenerate. The degree of the degeneration of the pair (l_I,m_I) or (l_{II},m_{II}) is equal to the dimension $d(k)$ of the space X_k.

Now let us consider two examples—one for the generic case: $\nu=\frac{1}{7}$, $l_I=8\frac{3}{7}$, the nearest value of l_{II} to $8\frac{3}{7}$ is $l_{II}=8\frac{4}{7}$, and one for the special case $\nu=\frac{1}{6}$, $l_I=l_{II}=l=8\frac{1}{2}$.

The spectrum of the angular momentum for $\nu=\frac{1}{7}$ and for $8\frac{3}{7}$ the spectrum of the angular momentum is

$$m_I=4\,\tfrac{3}{7},\quad 6\,\tfrac{3}{7},\quad 8\,\tfrac{3}{7}, \tag{45}$$

and for $\nu=\frac{1}{7}$, $l_{II}=8\frac{4}{7}$ the spectrum of the angular momentum is

$$m_{II}=-8\,\tfrac{4}{7},\quad -6\,\tfrac{4}{7}. \tag{46}$$

For the special case $\nu=\frac{1}{6}$, $l_I=l_{II}=l=8\frac{1}{2}$ the spectrum of angular momentum is given as

$$m_{II}=-8\,\tfrac{1}{2},\quad -6\,\tfrac{1}{2},4\,\tfrac{1}{2},\ 6\,\tfrac{1}{2},\quad 8\,\tfrac{1}{2}. \tag{47}$$

V. CONCLUSIONS

The construction of anyonic harmonic functions for the system of N anyons on the plane has been given. The separation of holomorphic and antiholomorphic variables allows us to reduce the Laplace equation to a homogeneous linear first order partial differential equation with constant operatorial coefficients. The solution of the problem is given by Eqs. (15)–(18).

We have already reported another approach to the construction presented above.[8,9] The anyonic harmonic functions are presented there in terms of covariant derivatives. It is related to the fact that the differential operators in these papers are acting upon polynomials $f(u)$ instead of multivalued functions $\tilde{f}(u)$:

$$\frac{\partial\tilde{f}}{\partial u_k}=V^\nu\left(\nu\frac{\partial \ln V}{\partial u_k}+\frac{\partial}{\partial u_k}\right)f. \tag{48}$$

As the result the derivation presented here is formally equivalent to that given before, but is remarkably simpler, since it avoids a double change of gauge transformation.

The angular momentum of an anyonic harmonic function H is quantized with step 2 for fixed total homogeneity degree $l=d(H)$. This observation follows from the fact that the system is two-dimensional. The angular momentum for boson or fermion statistics is constrained to the range $-l,-l+2,\ldots,l$. The case of intrinsically fractional statistics imposes a further restriction of this range specified by the formulas in Eqs. (25), (27). This effect follows from the fact that

bosonic or fermionic harmonic functions are polynoms and thus any differentiation cannot lead to poles on the fat diagonal. Contrary for an intrinsically fractional statistic, an appropriately large number of differentiations yields unavoidably poles on the fat diagonal which is inconsistent with the hard-core requirement.

This formalism can be adapted for more general systems. For example, for a system of many kinds of anyons on a plane with different statistical parameters or for a system of distinguishable particles with hard cores on a plane.

Stability of nonconservative hyperbolic systems and relativistic dissipative fluids

Omar E. Ortiz
Facultad de Matemática, Astronomía y Física, Universidad Nacional de Córdoba, Ciudad Universitaria, (5000) Córdoba, Argentina

(Received 25 August 2000; accepted for publication 6 November 2000)

A stability theorem for general quasi-linear symmetric hyperbolic systems (not necessarily conservation laws) is proved in this work. The key assumption is the ''stability eigenvalue condition,'' which requires all the eigenvalues of the constant coefficient system symbol to have negative real part for nonzero Fourier frequency, decaying no faster than $|\omega|^2$ when $|\omega|\to 0$. The decay of the solution to zero, as time grows to infinity, is proved when the space dimension is bigger than or equal to 3. As an application of the general theorem, stability is proved for the equations describing relativistic dissipative fluids. © *2001 American Institute of Physics.*

I. INTRODUCTION

It is the purpose of this work to prove the linear and nonlinear stability of stationary constant solutions to the Cauchy problem in the whole space of a general quasi-linear symmetric hyperbolic system of equations. It is also the purpose of this work to present a concrete, physically relevant application of the stability result, namely to the systems of equations describing dissipative relativistic fluids.

The Cauchy problems considered are those of the form

$$\partial_t u=\sum_{j=1}^{d}\,[A_{0j}+\varepsilon A_{1j}(x,t,u,\varepsilon)]\partial_j u+[B_0+\varepsilon B_1(x,t,u,\varepsilon)]u+F(x,t),$$
$$u(x,0)=f(x). \tag{1}$$

Here $x\in\mathbf{R}^d$, $t\geqslant 0$, and $u(x,t)$ and $f(x)$ take values in $\mathbf{R}^n$. Partial differentiation with respect to t and x_j are denoted by ∂_t and ∂_j, respectively. The assumptions on the coefficients, source, and initial data to be used in the theorems throughout the article are given below after introducing some notation.

As usual, for $u,v\in\mathbf{C}^n$, and $A\in\mathbf{C}^{n\times n}$,

$$\langle u,v\rangle=\sum_{j=1}^{n}\,u_j^*\,v_j,\quad |u|=\langle u,u\rangle^{1/2}\quad\text{and}\quad |A|=\max_u\{|Au|:|u|=1\}$$

denote the inner product, Euclidean norm, and corresponding matrix norm. For vector functions u,v of the space variables, $\|u\|_1$, (u,v), $\|u\|=(u,u)^{1/2}$, and $\|u\|_{H^p}$ denote the L_1-norm, L_2-inner product, L_2-norm, and the H^p-Sobolev norm, respectively.

For the squared L_1-norm in space and time the following notation will be used

$$K_F(T):=\left[\int_0^T\int_{\mathbf{R}^d}|F(x,t)|\,dx\,dt\right]^2.$$

Given multi-indices $\alpha=(\alpha_1,\alpha_2,\ldots,\alpha_d)$ and $\beta=(\beta_1,\beta_2,\ldots,\beta_n)$ the following notation will be used for partial derivatives

$$\partial_x^\alpha=\partial_1^{\alpha_1}\cdots\ \partial_d^{\alpha_d},\quad \text{and}\quad |\alpha|=\alpha_1+\cdots+\alpha_d,$$

and

$$\partial_u^\beta=\left(\frac{\partial}{\partial u_1}\right)^{\beta_1}\cdots\left(\frac{\partial}{\partial u_n}\right)^{\beta_n}\quad \text{and}\quad |\beta|=\beta_1+\cdots+\beta_n.$$

Assumption 1: The constant matrices A_{0j} and B_0 are real and symmetric. The matrices A_{1j} are also real and symmetric.

The following is an assumption on the regularity of the coefficients, source, and initial data.

Assumption 2: (a) Given $C>0$, there are constants $k_{A,C}$ and $k_{B,C}$ such that, for $j=1,2,\ldots,d$,

$$|A_{1j}(x,t,u,\varepsilon)|\leqslant k_{A,C}|u(x,t)|$$

and

$$|B(x,t,u,\varepsilon)|\leqslant k_{B,C}|u(x,t)|,$$

provided that $|u|\leqslant C$.

(b) Given $C>0$, for every $p=0,1,2,\ldots$ there is a constant $K(C,p)$ such that

$$|\partial_x^\alpha\partial_u^\beta A_{1j}(x,t,u,\varepsilon)|+|\partial_x^\alpha\partial_u^\beta\partial_t A_{1j}(x,t,u,\varepsilon)|\leqslant K(C,p)$$

and

$$|\partial_x^\alpha\partial_u^\beta B_1(x,t,u,\varepsilon)|+|\partial_x^\alpha\partial_u^\beta\partial_t B_1(x,t,u,\varepsilon)|\leqslant K(C,p),$$

provided that $|u|\leqslant C$, and for all multi-indices α and β with $|\alpha|+|\beta|=p$.

(c) The source F is such that

$$K_F(\infty)<\infty\quad \textit{and}\quad \int_0^\infty \|F(\cdot,t)\|_{H^p}^2\,dt<\infty,\ \ p=0,1,2,\ldots.$$

(d) The initial data function f satisfies

$$f\in L_1(\mathbf{R}^d,\mathbf{R}^n)\cap H^p(\mathbf{R}^d,\mathbf{R}^n),\ \ for\ \ p=0,1,2,\ldots.$$

The first two assumptions are just the usual assumptions for short time existence theorems plus adequate decay rates in time. The third assumption, given later, is the one that implies global in time existence and stability, and is not necessary for local existence. We introduce notation for the first-order partial differential operators and associated symbol first:

$$P_0=\sum_{j=1}^d A_{0j}\partial_j\quad \text{and}\quad P_1=\sum_{j=1}^d A_{1j}(x,t,u,\varepsilon)\partial_j.$$

The symbol of the constant coefficient system, (1) with $\varepsilon=0$, is given by

$$\hat{P}_0(i\omega)+B_0=\sum_{j=1}^d i\omega_j A_{0j}+B_0,\quad \text{for}\ \ \omega\in\mathbf{R}^d. \tag{2}$$

Assumption 3: The symbol of the constant coefficient system satisfies the ''stability eigenvalue condition,'' i.e., there are positive constants ω_0, μ, *and* δ *such that all eigenvalues* $\lambda(\omega)$ *of (2) satisfy*

(a) $\mathrm{Re}\,\lambda(\omega)\leqslant -\mu|\omega|^2$, *for* $|\omega|\leqslant\omega_0$;
(b) $\mathrm{Re}\,\lambda(\omega)\leqslant -\delta$, *for* $|\omega|>\omega_0$.

Let $\hat{u}(\omega,t)$ denote the Fourier transform of $u(x,t)$. The following splitting in high and low frequencies of u will be useful:

$$u(x,t)=u^I(x,t)+u^{II}(x,t),\quad \text{where}\quad \hat{u}^I(\omega,t)=\begin{cases}\hat{u}(\omega,t) & \text{if } |\omega|\leqslant\omega_0,\\ 0 & \text{if } |\omega|>\omega_0.\end{cases} \tag{3}$$

This article presents a generalization of the work by Kreiss *et al.*,[1] where stability is proved for a wide class of systems of conservation laws. The symmetric hyperbolic systems studied in the present work are more general since they are not required to be systems of conservation laws. This generalization requires the dimension of space to be bigger than or equal to 3. In this article the initial data function is explicitly included in the estimates, as opposed to absorbing it in the source by means of a transformation as done by Kreiss *et al.*

This work also extends previous stability results[2] by including noncompact domains. This extension is necessary for some physical applications such as the theories of relativistic dissipative fluids.[3] Stability of the Cauchy problem of these fluid theories, under periodic boundary conditions, was shown in a previous work.[4]

Sections II and III of this work follow the paper by Kreiss *et al.*[1] In Sec. II the estimates for the solution of the linear equation [Eq. (1) with coefficients independent of u] are found and linear stability is proved. In Sec. III the linear estimates together with Sobolev's inequalities are used to prove global existence and stability in the nonlinear case. A proof of the following theorem is given.

Theorem 1: *Consider the Cauchy problem for the nonlinear equation (1), let Assumptions 1–3 hold, and let the dimension of space be* $d\geqslant 3$. *Then there exists* $\varepsilon_0>0$ *such that for* $|\varepsilon|\leqslant\varepsilon_0$ *the solution* u *is* C^∞ *and exists globally in time. Furthermore, the Cauchy problem is stable in the sense that*

$$\lim_{t\to\infty}|u(\cdot,t)|_\infty=0.$$

In Sec. IV the stability theorem is applied to an example of physical relevance, namely that of the general theories of relativistic dissipative fluids. Most of the effort done in Sec. IV is devoted to proving that these fluid theories comply with the stability eigenvalue condition required by Assumption 3.

Along this work C_l and $C_l(p)$, $l=1,2,\ldots$, will denote positive constants that may depend on P_0, B_0, and p when indicated, but are independent of P_1, B_1, ε, F, and f.

II. ESTIMATES AND LINEAR STABILITY

Consider the Cauchy problem for the linear, symmetric hyperbolic system of equations

$$\begin{aligned}\partial_t u&=\sum_{j=1}^{d}[A_{0j}+\varepsilon A_{1j}(x,t,\varepsilon)]\partial_j u+[B_0+\varepsilon B_1(x,t,\varepsilon)]u+F(x,t),\\ u(x,0)&=f(x).\end{aligned} \tag{4}$$

The first step to prove global existence and stability is to obtain estimates for the constant coefficient problem. Application of the Fourier–Laplace transformation to the constant coefficient system, (4) with $\varepsilon=0$, gives

$$[sI-\hat{P}_0(i\omega)-B_0]\tilde{u}(\omega,s)=\hat{f}(\omega)+\tilde{F}(\omega,s), \quad s=\eta+i\xi, \quad \eta>0. \tag{5}$$

Here $\tilde{u}(\omega,s)=\mathcal{L}_{t\to s}[\mathcal{F}_{x\to\omega}u(x,t)]$ and $\hat{f}(\omega)=\mathcal{F}_{x\to\omega}f(x)$.

Recall the decomposition (3) of u in low and high frequencies.

A. Estimates for u^I (low frequencies)

Assumption 3(a) implies $B_0\leqslant 0$, Then

$$[\hat{P}_0(i\omega)+B_0]+[\hat{P}_0(i\omega)+B_0]^{\dagger}=2B_0\leqslant 0,$$

where the symmetry was used. Consequently $|e^{(\hat{P}_0+B_0)t}|\leqslant 1$ and Kreiss' matrix theorem[5] can be applied. There are two constants C_1 and C_2 such that for each ω there is a transformation $S(\omega)$ such that

$$S^{-1}(\hat{P}_0+B_0)S=\begin{pmatrix}\lambda_1 & b_{12} & \cdots & b_{1n}\\ & \lambda_2 & \cdots & b_{2n}\\ & & \ddots & \vdots\\ 0 & & & \lambda_n\end{pmatrix}$$

with $|S^{-1}|+|S|\leqslant C_1$ and $|b_{ij}|\leqslant C_2|\mathrm{Re}\,\lambda_i|$, $1\leqslant i<j\leqslant n$. Therefore, it can be proved that

$$|[(\eta+i\xi)I-(\hat{P}_0+B_0)]^{-1}|^2\leqslant C_3\sum_j \frac{1}{(\eta-\mathrm{Re}\,\lambda_j)^2+(\xi-\mathrm{Im}\,\lambda_j)^2}.$$

By Assumption 3(a), $\eta-\mathrm{Re}\,\lambda_j\geqslant-\mu|\omega|^2$ when $|\omega|\leqslant\omega_0$. Then integration of the previous inequality gives

$$\int_{-\infty}^{\infty}|[(\eta+i\xi)I-(\hat{P}_0+B_0)]^{-1}|^2d\xi\leqslant\frac{C_4}{|\omega|^2}. \tag{6}$$

Lemma 1: Let u solve the constant coefficient Cauchy problem (4) with $\varepsilon=0$. If Assumptions 1, 2(c), 2(d), and 3(a) hold, and the dimension of space is $d\geqslant 3$, then for every $p=0,1,2,\ldots$ there exists a constant $C_0(p)$, which is independent of T, F, and f such that

$$\int_0^T\|u^I(\cdot,t)\|_{H^p}^2dt\leqslant C_0(p)[\|f\|_1^2+K_F(T)].$$

Proof: Equation (5) implies

$$|\tilde{u}|^2\leqslant 2|(sI-\hat{P}_0-B_0)^{-1}|^2|\hat{f}|^2+2|(sI-\hat{P}_0-B_0)^{-1}|^2|\tilde{F}|^2. \tag{7}$$

Notice that $|\hat{f}|^2\leqslant\|f\|_1^2$ and

$$|\tilde{F}|^2\leqslant\left|\int_0^{\infty}\int_{\mathbf{R}^d}e^{-i\langle\omega,x\rangle}e^{-\eta t}F(x,t)dxdt\right|^2\leqslant\left(\int_0^{\infty}\int_{\mathbf{R}^d}e^{-\eta t}|F(x,t)|dxdt\right)^2\leqslant K_F(\infty),$$

so that Parseval's relation,

$$\int_0^{\infty}e^{-2\eta t}\|u^I\|^2dt=\frac{1}{(2\pi)^{d+1}}\int_{|\omega|\leqslant\omega_0}\int_{-\infty}^{\infty}|\tilde{u}(\omega,\eta+i\xi)|^2d\xi\,d\omega,$$

together with estimates (6) and (7) imply

$$\int_0^\infty e^{-2\eta t}\|u^I\|^2 dt \leq C_4[\|f\|_1^2 + K_F(\infty)] \int_{|\omega|\leq\omega_0} \frac{d\omega}{|\omega|^2}.$$

As the dimension of space is $d \geq 3$, the integral of $|\omega|^{-2}$ is finite, and as the right-hand side is independent of η, the inequality also holds in the limit $\eta \to 0^+$. Thus,

$$\int_0^\infty \|u^I\|^2 dt \leq C_5[\|f\|_1^2 + K_F(\infty)]. \tag{8}$$

The space derivatives $\partial_x^\alpha u$ satisfy the same constant coefficient partial differential equation (PDE) as u. Therefore

$$|\widetilde{\partial_x^\alpha u}(\omega,s)| \leq |\omega|^{|\alpha|} |\tilde{u}(\omega,s)| \leq \omega_0^{|\alpha|} |\tilde{u}(\omega,s)|$$

and Eq. (8) imply

$$\int_0^\infty \|u^I\|_{H^p}^2 dt \leq \frac{1}{(2\pi)^{d+1}} \sum_{|\alpha|\leq p} \int_0^\infty \int_{|\omega|\leq\omega_0} |\widetilde{\partial_x^\alpha u}(\omega, \eta + i\xi)|^2 d\omega d\xi \leq C_0(p)[\|f\|_1^2 + K_F(\infty)]. \tag{9}$$

Finally, as the values of $u^I(x,t)$ for $t \leq T$ do not depend on the values of $F(x,t)$ for $t > T$, ∞ can be replaced by a finite time T in the previous estimate. This concludes the proof.

Consider now the Cauchy problem for the variable coefficient system (4). In this case the following assumption is needed.

Assumption 2(a′):

$$\sum_j \int_0^\infty \|A_{1j}(\cdot,t,\varepsilon)\|^2 \, dt + \int_0^\infty \|B_1(\cdot,t,\varepsilon)\|^2 \, dt \leq K_1 < \infty.$$

An estimate for the solution u in the variable coefficient case can be obtained, for $p \geq 1$, from the estimate (9) by redefining the source term to include the variable coefficients

$$G(x,t) = F(x,t) + \varepsilon \sum_j A_{1j}(x,t,\varepsilon)\partial_j u(x,t) + \varepsilon B_1(x,t,\varepsilon)u(x,t). \tag{10}$$

Notice that

$$\begin{aligned} K_G(\infty) &\leq 3K_F(\infty) + 3\varepsilon^2 \left(\int_0^\infty \int_{\mathbf{R}^d} \sum_j |A_{1j}||\partial_j u| dx \, dt \right)^2 \\ &\quad + 3\varepsilon^2 \left(\int_0^\infty \int_{\mathbf{R}^d} |B_1||u| dx \, dt \right)^2 \\ &\leq 3K_F(\infty) + 3\varepsilon^2 K_1 \int_0^\infty \|u\|_{H^1}^2 dt. \end{aligned}$$

Thus, application of (9) with F replaced by G gives

$$\begin{aligned} \int_0^\infty \|u^I\|_{H^p}^2 dt &\leq C_0(p)\|f\|_1^2 + 3C_0(p)K_F(\infty) + 6\varepsilon^2 C_0(p)K_1 \int_0^\infty \|u^I\|_{H^1}^2 dt \\ &\quad + 6\varepsilon^2 C_0(p)K_1 \int_0^\infty \|u^{II}\|_{H^1}^2 dt, \end{aligned}$$

where $u=u^I+u^{II}$ was used. Then, choosing ε small enough and repeating the argument for replacing ∞ by a finite time T, we have proved the following.

Lemma 2: Let u solve (4). If Assumptions 1, 2(a′), 2(c), 2(d), and 3(a) hold, and the dimension of space is $d\geqslant 3$, *then for* $p=1,2,\ldots,$

$$\int_0^T \|u^I\|_{H^p}^2 dt \leqslant 2C_0(p)\left[\|f\|_1^2+3K_F(T)+6\varepsilon^2 K_1\int_0^T \|u^{II}\|_{H^1}^2 dt\right], \tag{11}$$

where $C_0(p)$ *is the same constant of Lemma 1 and* ε *is assumed to be small enough so that* $6\varepsilon^2 C_0(p)K_1\leqslant \frac{1}{2}$.

B. Estimates for u^{II} (high frequencies)

Given $u\in L_2(\mathbf{R}^d,\mathbf{R}^n)$ [respectively $u\in H^p(\mathbf{R}^d,\mathbf{R}^n)$] and using the decomposition in low and high frequencies for u given by (3), the decomposition $L_2=L_2^I\oplus L_2^{II}$ (respectively $H^p=H^{pI}\oplus H^{pII}$) is defined so that $u^I\in L_2^I$ and $u^{II}\in L_2^{II}$.

It was shown in a previous work[2] that if the system (4) satisfies Assumption 3(b), then there exists a constant C_6 and a time independent pseudo-differential operator S, acting on $L_2^{II}(\mathbf{R}^d,\mathbf{R}^n)$ and depending on P_0+B_0 only, with the following properties.

(a) S is self-adjoint and bounded, i.e., $\|S\|_{L_2^{II}}\leqslant C_6$.

(b) $I+S$ is positive definite with $\|I+S\|_{L_2^{II}}+\|(I+S)^{-1}\|_{L_2^{II}}\leqslant C_6$.

(c) $2\,\mathrm{Re}(I+S)(P_0+B_0)\leqslant -\delta(I+S)$.

(d) S is a smoothing operator, i.e., its symbol satisfies $|\hat{S}(\omega)|=C_6/|\omega|$, for $|\omega|\geqslant\omega_0$.

The action of S is extended to L_2 by defining $S=I$ on L_2^I. It is clear from the properties above that there exists a constant C_7 such that the operator $H=I+S$ has the following properties.

(*i*) H is self-adjoint and bounded, i.e., $\|H\|\leqslant C_7$.
(*ii*) H is positive definite with $\|H\|+\|H^{-1}\|\leqslant C_7$.
(*iii*) $2\,\mathrm{Re}\,H(P_0+B_0)\leqslant -\delta H$ when restricted to L_2^{II}.
(*iv*) $|(u,H\partial_j v)-(u,\partial_j v)|\leqslant C_7\|u\|\,\|v\|$, for all $u\in L_2$, $v\in H^1$, and $j=1,2,\ldots,d$.

The last property follows from Parseval's relation and property (d) of S.

New inner products and norms in L_2 and H^p are defined using H:

$$(u,v)_H=(u,Hv),\quad (u,v)_{p,H}=\sum_{|\alpha|\leqslant p}(\partial_x^\alpha u,H\partial_x^\alpha v),$$

and

$$\|u\|_H=(u,u)_H^{1/2},\quad \|u\|_{p,H}=(u,u)_{p,H}^{1/2}.$$

Properties (*i*) and (*ii*) of H imply the equivalence

$$\frac{1}{C_7}\|u\|_{H^p}\leqslant\|u\|_{p,H}\leqslant C_7\|u\|_{H^p},\quad \text{for } p=0,1,2,\ldots. \tag{12}$$

The estimate for u^{II} will be obtained in the H-norm:

$$\begin{aligned}\frac{d}{dt}\|u^{II}\|_H^2 &= 2\,\mathrm{Re}(u^{II},u_t^{II})_H\\ &= 2\,\mathrm{Re}(u^{II},u_t)_H\\ &= 2\,\mathrm{Re}(u^{II},[P_0+B_0]u)_H+2\varepsilon\,\mathrm{Re}(u^{II},P_1u)_H\\ &\quad +2\varepsilon\,\mathrm{Re}(u^{II},B_1u)_H+2\,\mathrm{Re}(u^{II},F)_H.\end{aligned} \tag{13}$$

Let us estimate the four terms above separately. Using the property (iii) of H we obtain

$$\begin{aligned} 2\,\mathrm{Re}(u^{II},[P_0+B_0]u)_H &= 2\,\mathrm{Re}(u^{II},[P_0+B_0]u^{II})_H \\ &\leqslant (u^{II},2\,\mathrm{Re}H[P_0+B_0]u^{II}) \\ &\leqslant -\delta\|u^{II}\|_H^2. \end{aligned}$$

The second term in (13) can be separated as

$$2\varepsilon\,\mathrm{Re}(u^{II},P_1u)_H = 2\varepsilon\,\mathrm{Re}(u^{II},P_1u^I)_H + 2\varepsilon\,\mathrm{Re}(u^{II},P_1u^{II})_H.$$

However,

$$\begin{aligned} |2\,\mathrm{Re}(u^{II},P_1u^I)_H| &\leqslant 2\|u^{II}\|\,\|HP_1u^I\| \\ &\leqslant 2\,C_7\|u^{II}\|\left\|\sum_j A_{1j}\partial_j u^I\right\| \\ &\leqslant 2\,C_7\,|A_1|_\infty\omega_0\|u^I\|\,\|u^{II}\|, \end{aligned}$$

where $|A_1|_\infty=\Sigma_j|A_{1j}|_\infty$ and $\|\partial_j u^I\|\leqslant\omega_0\|u^I\|$. Also,

$$P_1u^{II}=\sum_j \partial_j(A_{1j}u^{II})-\left(\sum_j \partial_jA_{1j}\right)u^{II}.$$

Symmetry of A_{1j} and properties (i) and (iv) of H imply

$$\begin{aligned} |2\,\mathrm{Re}(u^{II},P_1u^{II})_H| &\leqslant |2\,\mathrm{Re}\sum_j (u^{II},\partial_j[A_{1j}u^{II}])_H| + \left|2\left(u^{II},\left[\sum_j \partial_jA_{1j}\right]u^{II}\right)_H\right| \\ &\leqslant \sum_j |2\,\mathrm{Re}(u^{II},\partial_j[A_{1j}u^{II}])| + 2\sum_j C_7\|u^{II}\|\|A_{1j}u^{II}\| \\ &\quad + 2\|u^{II}\|\left\|H\left(\sum_j \partial_jA_{1j}\right)u^{II}\right\| \\ &\leqslant \sum_j |(u^{II},[\partial_jA_{1j}]u^{II})| + 2C_7|A_1|_\infty\|u^{II}\|^2 \\ &\quad + 2C_7|DA_1|_\infty\|u^{II}\|^2 \\ &\leqslant 2[C_7|A_1|_\infty+(1+C_7)|DA_1|_\infty]\|u^{II}\|^2, \end{aligned}$$

where $|DA_1|_\infty=\Sigma_j|\partial_jA_{1j}|_\infty$. Therefore the estimate

$$\begin{aligned} |2\varepsilon\,\mathrm{Re}(u^{II},P_1u)_H| &\leqslant \{\rho+2|\varepsilon|[C_7|A_1|_\infty+(1+C_7)|DA_1|_\infty]\}\|u^{II}\|^2 \\ &\quad +(\varepsilon^2/\rho)C_7{}^2|A_1|_\infty^2\omega_0^2\|u^I\|^2 \end{aligned}$$

holds for any $\rho>0$. By property (i) of H

$$\begin{aligned} |2\varepsilon\,\mathrm{Re}(u^{II},B_1u)_H| &\leqslant 2|\varepsilon|C_7|B_1|_\infty\|u^{II}\|\,\|u^I\| \\ &\leqslant \rho\|u^{II}\|^2+(\varepsilon^2/\rho)C_7{}^2|B_1|_\infty^2\,\|u^I\|^2. \end{aligned}$$

Also,

$$|2\,\mathrm{Re}(u^{II},F)_H| \leqslant \rho\|u^{II}\|^2 + (C_7{}^2/\rho)\|F\|^2.$$

The last four estimates and the equivalence (12) for $p=0$ imply

$$\frac{d}{dt}\|u^{II}\|_H^2 = \{-\delta + 3\rho C_7{}^2 + 2|\varepsilon| C_7{}^2[C_7|A_1|_\infty + (1+C_7)|DA_1|_\infty]\}\,\|u^{II}\|_H^2$$

$$+\varepsilon^2\frac{C_7}{\rho}(\omega_0^2|A_1|_\infty^2 + |B_1|_\infty^2)\,\|u^I\|^2 + \frac{C_7{}^2}{\rho}\|F\|^2.$$

Thus, choosing $\rho = \delta(18C_7{}^2)^{-1}$ and calling

$$\varepsilon_1 = \delta\{12C_7{}^2[C_7|A_1|_\infty + (1+C_7)|DA_1|_\infty]\}^{-1}$$

we have proved the following.

Lemma 3: Let u be a solution of (4), and let Assumptions 1, 2(b), 2(c), and 3(b) hold. Then there exists ε_1 such that

$$\frac{d}{dt}\|u^{II}\|_H^2 = -\frac{2}{3}\,\delta\,\|u^{II}\|_H^2 + \varepsilon^2 C_{A,B}\|u^I\|^2 + C_0\|F\|^2, \quad \text{if } |\varepsilon| \leqslant \varepsilon_1. \tag{14}$$

Here $C_{A,B}$ depends on P_0+B_0, $|A_1|_\infty$ and $|B_1|_\infty$, and C_0 depends on P_0+B_0 only.

This result can be generalized to include derivatives. Applying ∂_x^α to (4), it becomes

$$\partial_t(\partial_x^\alpha u) = \sum_j\,(A_{0j}+\varepsilon A_{1j})\partial_j\partial_x^\alpha u + (B_0+\varepsilon B_1)\partial_x^\alpha u + \varepsilon R^\alpha + \partial_x^\alpha F,$$

$$\partial_x^\alpha u(x,0) = \partial_x^\alpha f, \tag{15}$$

where $R^\alpha = \Sigma_j[\partial_x^\alpha(A_{1j}\partial_j u) - A_{1j}\partial_j\partial_x^\alpha u] + \partial_x^\alpha(B_1 u) - B_1\partial_x^\alpha u$ is made of lower order terms only, i.e., derivatives of A_{1j}, B_1 and u up to order $|\alpha|$.

Lemma 4: Let u be a solution of (4), and let Assumptions 1, 2(a′), 2(b), 2(c), and 3(b) hold. Then, if $|\varepsilon| \leqslant \varepsilon_1(A,B,p)$, we get for $p=1,2,\ldots$

$$\frac{d}{dt}\|u^{II}\|_{p,H}^2 = -\frac{2}{3}\,\delta\,\|u^{II}\|_{p,H}^2 + \varepsilon^2 C_{A,B,p}\|u^I\|_{H^p}^2 + C_0\|F\|_{H^p}^2. \tag{16}$$

Here, $\varepsilon_1(A,B,p)$ and $C_{A,B,p}$ are constants that depend P_0+B_0 and the L_∞-norms of A_{1j} and B_1 and their derivatives up to order p, but are independent of F. C_0 depends on P_0+B_0 only.

Proof: For $|\alpha| \leqslant p$, Lemma 3 can be applied to the system (15), thinking of $\partial_x^\alpha F + \varepsilon R^\alpha$ as the source term. This gives

$$\frac{d}{dt}\|\partial_x^\alpha u^{II}\|_H^2 = -\frac{2}{3}\,\delta\|\partial_x^\alpha u^{II}\|_H^2 + \varepsilon^2 C_{A,B}\|\partial_x^\alpha u^I\|^2 + 2\varepsilon^2 C_0\|R^\alpha\|^2 + 2C_0\|\partial_x^\alpha F\|^2.$$

All terms in R^α are proportional to a derivative of u of order less than or equal to $|\alpha|$. Addition of all the inequalities with $|\alpha| \leqslant p$ gives

$$\frac{d}{dt}\|u^{II}\|_{p,H}^2 = -\frac{2}{3}\,\delta\|u^{II}\|_{p,H}^2 + \varepsilon^2 C_{A,B}\|u^I\|^2 + 2\varepsilon^2 C_0\tilde{C}_{A,B,p}\|u^I + u^{II}\|_{H^p}^2 + 2C_0\|F\|_{H^p}^2.$$

Here $\tilde{C}_{A,B,p}$ depends on the L_∞-norms of A_{1j} and B_1 and their derivatives up to order p. Using the equivalence (12) and defining an appropriate $\varepsilon_1=\varepsilon_1(\tilde{C}_{A,B,p})$ the lemma follows.

C. Linear stability

Global existence for the linear problem shown in this section is well known. As a simple application of the estimates for the low and high frequency parts of the solution obtained earlier, linear stability is shown here. The fundamental estimates, Lemmas 1 and 3, will be the base for the nonlinear stability, too.

Theorem 2: *Assume that u solves the linear system (4), Assumptions 1, 2(a′), 2(b), 2(c), 2(d), and 3 hold, and the dimension of space is* $d\geqslant 3$. *Then, for any* $p=1,2,3,\ldots$ *there are positive constants* $C_0(p)$ *and* $\varepsilon_0(A,B,p)$ *such that*

$$\int_0^\infty (\|u\|^2_{H^{p+1}}+\|\partial_t u\|^2_{H^p})dt\leqslant C_0(p)\left[\|f\|_1^2+\|f\|^2_{H^{p+1}}+K_F(\infty)+\int_0^\infty \|F\|^2_{H^{p+1}}dt\right], \tag{17}$$

provided that $|\varepsilon|\leqslant\varepsilon_0(A,B,p)$. $C_0(p)$ *depends only on* P_0+B_0 *and* p, *while* $\varepsilon_0(A,B,p)$ *depends also on the constants* K_1 *of Assumption 2(a′) and* $K(0,0)$, $K(0,1),\ldots,K(0,p+1)$ *of Assumption 2(b). Furthermore,*

$$\lim_{t\to\infty}|u(\cdot,t)|_\infty=0.$$

Proof: Denote

$$y_1(t)=\|u^I(\cdot,t)\|^2_{H^p},\quad y_2(t)=\|u^{II}(\cdot,t)\|^2_{p,H}.$$

The results of Lemmas 2 and 4 can be written as

$$\int_0^\infty y_1 dt\leqslant C_8(p)\left[\|f\|_1^2+K_F(\infty)+\varepsilon^2 C_0(p)K_1\int_0^\infty \|u^{II}\|^2_{H^1}dt\right] \tag{18}$$

and

$$\frac{dy_2}{dt}\leqslant -\frac{2}{3}\delta y_2+\varepsilon^2\tilde{C}_{A,B,p}y_1+C_0\|F\|^2_{H^p}.$$

This last estimate is equivalent to

$$y_2(t)\leqslant y_2(0)e^{-(2/3)\,\delta t}+C_0\int_0^t e^{-(2/3)\,\delta(t-\tau)}\|F(\cdot,\tau)\|^2_{H^p}d\tau$$

$$+\varepsilon^2\tilde{C}_{A,B,p}\int_0^t e^{-(2/3)\,\delta(t-\tau)}y_1(\tau)d\tau. \tag{19}$$

Notice that

$$\int_0^\infty\int_0^t e^{-a(t-\tau)}f(\tau)d\tau dt=\int_0^\infty\int_\tau^\infty e^{-a(t-\tau)}f(\tau)dtd\tau=\frac{1}{a}\int_0^\infty f(\tau)d\tau.$$

Using this identity, the estimate (19) implies

$$\int_0^\infty y_2(t)dt\leqslant\frac{3}{2\delta}y_2(0)+\frac{3C_0}{2\delta}\int_0^\infty\|F(\cdot,\tau)\|^2_{H^p}dt+\varepsilon^2\frac{3\tilde{C}_{A,B,p}}{2\delta}\int_0^\infty y_1(\tau)d\tau. \tag{20}$$

The equivalence of norms, Eq. (12), implies

$$\int_0^\infty \|u\|_{H^p}^2 dt \leqslant 2\int_0^\infty y_1 dt + 2C_7 \int_0^\infty y_2 dt.$$

Thus (18) and (20) imply, for $|\varepsilon| \leqslant \tilde{\varepsilon}_0$,

$$\int_0^\infty \|u\|_{H^p}^2 dt \leqslant C_9(p)\left[\|f\|_1^2 + \|f\|_{H^p}^2 + K_F(\infty) + \int_0^\infty \|F\|_{H^p}^2 dt\right]. \tag{21}$$

Here $\tilde{\varepsilon}_0 = \tilde{\varepsilon}_0(\tilde{C}_{A,B,p}, K_1)$. To estimate $\partial_t u$ and its space derivatives we apply ∂_x^α to Eq. (4) and take the norm. Adding all the estimates for $|\alpha| \leqslant p$ we obtain

$$\|\partial_t u\|_{H^p}^2 \leqslant C_{10}(p)\|u\|_{H^{p+1}}^2 + \varepsilon^2 \tilde{C}_{A,B,p}\|u\|_{H^{p+1}}^2 + C(p)\|F\|_{H^p}^2.$$

Finally, integrating this last estimate and using (21) for $p+1$ we get the desired estimate (17), with ε_0 conveniently defined. The stability follows from the convergence of the integral in (17). More precisely,

$$|u(\cdot,T)|_\infty^2 \leqslant C\int_T^\infty (\|u\|_{H^{p+1}}^2 + \|\partial_t u\|_{H^p}^2) dt \to 0, \text{ when } T \to \infty,$$

for $p > d/2$.

III. NONLINEAR STABILITY

A proof of Theorem 1 is given in this section. The construction of the estimates for the nonlinear solution is based on the estimates of Lemmas 1 and 3 and Sobolev's inequalities.

Proof of Theorem 1: Local (in time) existence is well known for quasi-linear symmetric hyperbolic systems; let u denote such a solution to the problem (1) for a given initial data function f and source F. It will be shown that, for ε small enough, the ''energy''

$$\|f\|_{H^{p+1}}^2 + \int_0^{t_1} (\|u\|_{H^{p+1}}^2 + \|\partial_t u\|_{H^p}^2) dt, \quad p = d+3,$$

remains bounded by a constant M sufficiently large, even when $t_1 \to \infty$; thus the solution exists globally. Suppose this is not the case. Then there exists a time $T(M,\varepsilon)$ such that

$$\|f\|_{H^{p+1}}^2 + \int_0^T (\|u\|_{H^{p+1}}^2 + \|\partial_t u\|_{H^p}^2) dt = M. \tag{22}$$

In what follows C_M^l, $l = 1,2,\ldots$, will denote constants that may depend on M, $P_0 + B_0$, and the constants in Assumption 2, but not on ε or T.

Recall that, for all $f(t) \in H^1([0,T], \mathbf{R})$,

$$\max_{0 \leqslant t \leqslant T} |f(t)|^2 \leqslant \min_{0 \leqslant t \leqslant T} |f(t)|^2 + \int_0^T [|f(t)|^2 + |f'(t)|^2] dt.$$

Sobolev's Lemma and (22) imply, for $|\alpha| + (d/2) < p$,

$$|\partial_x^\alpha u|_{\infty,T}^2 = \sup_{0 \leqslant t \leqslant T} |\partial_x^\alpha u(\cdot,t)|_\infty^2 \leqslant C\left[\|f\|_{H^p}^2 + \int_0^T (\|u\|_{H^p}^2 + \|\partial_t u\|_{H^p}^2) dt\right] \leqslant CM, \tag{23}$$

where C is a constant independent of ε, T, and M.

To apply the estimates obtained for the linear case we rewrite (1) as

$$\begin{aligned} \partial_t u &= (P_0+B_0)u+\varepsilon\sum_{j=1}^{d} A'_{1j}(x,t,\varepsilon)\partial_j u+B'_1(x,t,\varepsilon)u+F(x,t), \\ u(x,0) &= f(x), \end{aligned} \tag{24}$$

with

$$A'_{1j}(x,t,\varepsilon)=A_{1j}(x,t,u(x,t),\varepsilon)$$

and

$$B'_1(x,t,\varepsilon)=B_1(x,t,u(x,t),\varepsilon).$$

Application of Lemma 1, with F replaced by $G=F+\varepsilon\Sigma_{j=1}^{d}A'_{1j}\partial_j u+\varepsilon B'_1 u$, gives

$$\int_0^T \|u^I(\cdot,t)\|^2_{H^{p+1}}dt\leqslant C_{11}(p)[\|f\|_1^2+K_G(T)].$$

Notice that, using (23) and Assumption 2(a),

$$\begin{aligned} K_G(T) &= 3\Bigg\{K_F(T)+\varepsilon^2 k^2_{A,CM}\Bigg(\sum_{j=1}^{d}\int_0^T\int_{\mathbf{R}^d}|u|\,|\partial_j u|dxdt\Bigg)^2 \\ &\quad +\varepsilon^2 k^2_{B,CM}\Bigg(\sum_{j=1}^{d}\int_0^T\int_{\mathbf{R}^d}|u|^2dxdt\Bigg)^2\Bigg\} \\ &\leqslant 3K_F(T)+\varepsilon^2 C_M^1. \end{aligned}$$

Thus,

$$\int_0^T \|u^I(\cdot,t)\|^2_{H^{p+1}}dt\leqslant C_{11}(p)[\|f\|_1^2+3K_F(T)+\varepsilon^2 C_M^1]. \tag{25}$$

The estimate of u^{II} is constructed in the H-norm. Lemma 3 applied to (24) gives

$$\frac{d}{dt}\|u^{II}\|_H^2\leqslant -\frac{2}{3}\,\delta\|u^{II}\|_H^2+\varepsilon^2 C_M^3\|u^I\|^2+C_{12}\|F\|^2. \tag{26}$$

To estimate the derivatives of u^{II} we first apply ∂_x^α, $1\leqslant|\alpha|\leqslant p+1$, to (24),

$$\partial_t\partial_x^\alpha u=(P_0+B_0)\partial_x^\alpha u+\varepsilon\sum_{j=1}^{d}A'_{1j}\partial_j\partial_x^\alpha u+\varepsilon\,\partial_x^\alpha(B'_1u)+\partial_x^\alpha F+\varepsilon R^\alpha, \tag{27}$$

with

$$R^\alpha=\sum_{j=1}^{d}R_j^\alpha=\sum_{j=1}^{d}[\partial_x^\alpha(A'_{1j}\partial_j u)-A'_{1j}\partial_j\partial_x^\alpha u].$$

The chain rule implies that each R_j^α is a sum of terms of the form

$$r_j(x,t,\alpha,\sigma)\partial_x^{\sigma_1}u\cdots\partial_x^{\sigma_r}u, \tag{28}$$

where, for all $|\alpha|\leqslant p+1$,

$$|\sigma_1|+\cdots+|\sigma_r|\leqslant p+2,\ |\sigma_l|\leqslant p+1,\ l=1,\ldots,r,$$

and $r_j(x,t,\alpha,\sigma)$ are partial derivatives $\partial_x^\beta\partial_u^\gamma A_{1j}$, $|\beta|+|\gamma|\leqslant p+1$. On the one hand, all factors $\partial_x^{\sigma_l}u$ in (28), with the exception of at most one of them, can be bounded in the infinite norm, otherwise there would be two factors with

$$|\sigma_l|+\frac{d}{2}\geqslant p,\ |\sigma_m|+\frac{d}{2}\geqslant p,$$

and, consequently,

$$p+2+d\geqslant|\sigma_l|+|\sigma_m|+d\geqslant 2p,$$

which would contradict the choice $p=d+3$. On the other hand, the factors $r_j(x,t,\alpha,\sigma)$ can be bounded in terms of the constants $K(CM,0),K(CM,1),\ldots,K(CM,p+1)$ of Assumption 2(b). Therefore,

$$\|R^\alpha\|^2\leqslant C_M^4\|u\|^2_{H^{|\alpha|}}.$$

Similarly,

$$\|\partial_x^\alpha(B_1'u)\|\leqslant C_M^5\|u\|^2_{H^{|\alpha|}}.$$

Lemma 3 applied to (27), with F replaced by $\partial_x^\alpha F+\varepsilon R^\alpha+\partial_x^\alpha(B_1'u)$, gives

$$\frac{d}{dt}\|\partial_x^\alpha u^{II}\|_H^2\leqslant-\frac{2}{3}\,\delta\|\partial_x^\alpha u^{II}\|_H^2+\varepsilon^2C_M^6\|\partial_x^\alpha u^I\|^2+C_{13}\|\partial_x^\alpha F+\varepsilon R^\alpha+\varepsilon\partial_x^\alpha(B_1'u)\|^2.$$

So, adding these estimates for $1\leqslant|\alpha|\leqslant p+1$ to (26), and using the bounds for R^α and $\partial_x^\alpha(B_1'u)$ and the equivalence (12) we obtain

$$\frac{d}{dt}\|u^{II}\|^2_{p+1,H}\leqslant-\frac{1}{3}\,\delta\|\partial_x^\alpha u^{II}\|_H^2+\varepsilon^2C_M^7\|u^I\|^2_{H^{p+1}}+C_{14}\|F\|^2_{H^{p+1}}.$$

Integration like in the proof of Theorem 2, plus the equivalence (12), gives

$$\int_0^T\|u^{II}\|^2_{p+1,H}dt\leqslant C_{15}\left(\|f\|_1^2+\|f\|^2_{H^{p+1}}+\int_0^T\|F\|^2_{H^{p+1}}dt\right)+\varepsilon^2C_M^8.$$

Equivalence (12) together with (25) give

$$\int_0^T\|u\|^2_{H^{p+1}}dt\leqslant C_{16}(p)\left[\|f\|_1^2+\|f\|^2_{H^{p+1}}+K_F(T)+\int_0^T\|F\|^2_{H^{p+1}}dt\right]+\varepsilon^2C_M^9 \tag{29}$$

if $|\varepsilon|\leqslant\varepsilon_2(M)$.

The differential equation (1) will be used now to estimate $\partial_t u$ in the H^p-norm. Notice that

$$\|\partial_x^\alpha\partial_t u\|^2\leqslant 3\|(P_0+B_0)\partial_x^\alpha u\|^2+3\varepsilon^2\|\partial_x^\alpha[(P_1+B_1)u]\|^2+3\|\partial_x^\alpha F\|^2.$$

The highest derivative of u in each of the first two terms is of order $|\alpha|+1$. The second term can be treated as we did before with R^α. The addition of the resulting estimates for $0\leqslant|\alpha|\leqslant p$ gives

$$\|\partial_t u\|^2_{H^p}\leqslant C_{17}(p)\|u\|^2_{H^{p+1}}+3\|F\|^2_{H^p}+\varepsilon^2C_M^{10}\|u\|^2_{H^{p+1}},$$

and, using (29),

$$\|f\|^2_{H^{p+1}}+\int_0^T(\|u\|^2_{H^{p+1}}+\|\partial_t u\|^2_{H^p})dt\leqslant C_{18}(p)\left[\|f\|^2_1+\|f\|^2_{H^{p+1}}+K_F(\infty)+\int_0^\infty\|F\|^2_{H^{p+1}}dt\right]+\varepsilon^2 C_M^{11}.$$

Therefore, choosing

$$M=1+C_{18}(p)\left[\|f\|^2_1+\|f\|^2_{H^{p+1}}+K_F(\infty)+\int_0^\infty\|F\|^2_{H^{p+1}}\,dt\right],$$

and if $|\varepsilon|\leqslant\varepsilon_0(M)$ with $\varepsilon_0(M)$ conveniently defined, we arrive at a contradiction and the time T cannot exist. Then the solution exists globally in time and standard arguments show that it is C^∞. Stability is shown as in the proof of Theorem 2.

IV. STABILITY OF RELATIVISTIC DISSIPATIVE FLUIDS

As an application of the stability theorem given in the Introduction, stability of the standard theories of dissipative relativistic fluids[3,6,7] is shown in this section. Stability for these theories has already been shown,[4] but only on compact domains with periodic boundary conditions.

The dynamical equations in these theories constitute a symmetric hyperbolic system of equations with zeroth-order dissipation. The Cauchy problem will be considered on the Minkowski space–time—$\mathbf{R}^4$ with a flat Lorentzian metric, and the stability shown for constant equilibrium solutions.

Calling $v(x,t)$ the vector of dynamical fields in the theory ($v:\mathbf{R}^3\times\mathbf{R}\to\mathbf{R}^n$) the system of equations, when written on Cartesian coordinates $\{x_i,t\}$, $i=1,2,3$, takes the form[4]

$$\begin{aligned}N(v)\partial_t v&=\sum_{j=1}^3 A_j(v)\partial_j v+B(v)v,\\ v(x,0)&=g(x).\end{aligned}\tag{30}$$

Here N is a symmetric, positive definite matrix, the matrices A_j are symmetric, and B is symmetric and negative semi-definite (at least when evaluated at constant equilibrium).

If v_0 is a constant solution of (30), the smallness parameter ε is introduced so that

$$g(x)=v_0+\varepsilon f(x)\quad\text{and}\qquad v(x,t)=v_0+\varepsilon\,u(x,t).$$

Thus, the coefficient matrices in (30) can be written as

$$A_j(v)=A_{0j}+\varepsilon A_{1j}(u,\varepsilon),\quad A_{0j}=A_j(v_0),$$

$$B(v)=B_0+\varepsilon B_1(u,\varepsilon),\quad B_0=B(v_0).$$

All the coefficients are assumed to be C^∞ functions of v, therefore it is clear that all the matrices A_{1j} and B_1 vanish at least linearly with u. The matrix B_0 is the one introducing dissipation into the system, and it is a physical requirement that this matrix is negative semi-definite. The Cauchy problem for the variable u is like the problem (1) with vanishing source function. The presence of the matrix $N(u)$ in front of the time derivative does not change the character of the problem, and though, for simplicity, the stability was proved for the case $N=I$, the estimates can be built also with a general N and the stability result holds.

The regularity assumptions on the coefficients and initial data, Assumptions 1 and 2, are physically reasonable and will be assumed to be satisfied. The requirement that the initial data are

functions on L_2 implies that the only equilibrium solution to be considered is $v_0=0$. This is, in turn, the only physically relevant equilibrium solution when the Cauchy problem is considered in the whole space, in the sense that it is the only constant solution with finite total energy.

The only critical condition that needs verification so that the stability theorem can be applied is Assumption 3. This is an assumption on the eigenvalues λ of the symbol of the constant coefficient system. This system can be written as

$$N_0\partial_t u=\sum_{j=0}^{3} A_{0j}\partial_j u+B_0 u.$$

The Fourier transformed system is

$$N_0\partial_t \hat{u}(\omega,t)=[\hat{P}_0(i\omega)+B_0]\hat{u}(\omega,t).$$

The eigenvalue problem for the symbol, in the presence of N_0, is

$$[\hat{P}_0(i\omega)+B_0]a(\omega)=\lambda(\omega)N_0 a(\omega). \tag{31}$$

Here $a(\omega)$ is an eigenvector, normalized so that $\langle a(\omega),N_0 a(\omega)\rangle=1$, with eigenvalue $\lambda(\omega)$.

In the previous work,[4] the first part of Assumption 3 was proved to follow from a condition previously required in the literature to characterize equilibrium states. This condition can be written as the injectivity of a linear map, and the result in Ref. 4 can be written as follows.[8]

Lemma 5: If for all complex numbers z and unit frequency vectors $\hat{\omega}$, the linear map

$$zN_0+\hat{P}(i\hat{\omega}):\ker(B_0)\to\mathbf{C}^n \tag{32}$$

is injective, then for all $\omega_0>0$ there exists $\delta>0$ such that $\mathrm{Re}\{\lambda(\omega)\}\leqslant-\delta$, *for all* $|\omega|\geqslant\omega_0$.

It will be shown in this section that the second part of Assumption 3 also follows from the injectivity condition of Lemma 5.

To simplify notation the work will be carried out in a basis of $\mathbf{C}^n$ where N_0 becomes the identity and B_0 becomes block diagonal. To see that such a basis exists notice that, as N_0 is symmetric and positive definite, there exists a constant, nonsingular matrix R_0 such that $N_0=R_0^{\dagger}R_0$. On the one hand, the eigenvalue problem (31) is equivalent to

$$(R_0^{-1})^{\dagger}[\hat{P}_0(i\omega)+B_0]R_0^{-1}b(\omega)=\lambda(\omega)b(\omega),$$

with $b(\omega)=R_0 a(\omega)$ denoting the eigenvector, which satisfies $\langle b(\omega),b(\omega)\rangle=1$. On the other hand, the injectivity condition of Lemma 5 is equivalent to the following: The map

$$zI+\tilde{P}_0(i\hat{\omega}):\ker(\tilde{B}_0)\to\mathbf{C}^n$$

is injective for all $z\in\mathbf{C}$ and unit $\hat{\omega}$; where $\tilde{P}_0(i\hat{\omega})=(R_0^{-1})^{\dagger}\hat{P}_0(i\hat{\omega})R_0^{-1}$, and $\tilde{B}_0=(R_0^{-1})^{\dagger}B_0R_0^{-1}$. One further change of basis, with a unitary matrix U_0, takes $\tilde{B}_0$ to block diagonal form

$$B=U_0^{\dagger}\tilde{B}_0U_0=\begin{pmatrix}B_{11} & 0\\ 0 & 0\end{pmatrix}, \tag{33}$$

where B_{11} is symmetric and negative definite. The eigenvalue problem becomes

$$[iA(\hat{\omega})+B]c(\omega)=\lambda(\omega)c(\omega), \tag{34}$$

where $A(\hat{\omega})$ is a self-adjoint matrix given by

$$A(\hat{\omega}) = -iU_0^{\dagger}(R_0^{-1})^{\dagger}\hat{P}_0(i\hat{\omega})R_0^{-1}U_0 = U_0^{\dagger}(R_0^{-1})^{\dagger}\left(\sum_{j=1}^{d}\hat{\omega}_j A_{0j}\right)R_0^{-1}U_0,$$

$c(\omega) = U_0 R_0 a(\omega)$, and B is given by (33). The injectivity condition now reads as follows.

Assumption 4: For all complex numbers z and unit frequency vectors $\hat{\omega}$, the linear map

$$zI + iA(\hat{\omega}):\ker(B) \to \mathbf{C}^n$$

is injective.

Using the block structure of B to block also $A(\hat{\omega})$ and the eigenvector, the eigenvalue problem can be written as

$$\begin{pmatrix} i|\omega|A_{11}(\hat{\omega}) + B_{11} & i|\omega|A_{12}(\hat{\omega}) \\ i|\omega|A_{12}^{\dagger}(\hat{\omega}) & i|\omega|A_{22}(\hat{\omega}) \end{pmatrix}\begin{pmatrix} u(\omega) \\ v(\omega) \end{pmatrix} = \lambda(\omega)\begin{pmatrix} u(\omega) \\ v(\omega) \end{pmatrix}. \tag{35}$$

The eigenvalues $\lambda(\omega)$ are continuous functions of ω and therefore they separate into two disjoint sets when $|\omega|$ is small; the set of eigenvalues that approach the eigenvalues of B_{11}, and the set of those that approach zero. Moreover, there exists $\omega_1 > 0$ such that, for $|\omega| \leqslant \omega_1$, the whole symbol can be transformed to block diagonal form by a smooth transformation (to simplify notation the dependence on $\hat{\omega}$ will be omitted in what follows):

$$S^{-1}\begin{pmatrix} i|\omega|A_{11} + B_{11} & i|\omega|A_{12} \\ i|\omega|A_{12}^{\dagger} & i|\omega|A_{22} \end{pmatrix}S = \begin{pmatrix} P_{11} & 0 \\ 0 & P_{22} \end{pmatrix}, \tag{36}$$

where

$$P_{11} = B_{11} + i|\omega|A_{11} - |\omega|^2 A_{12}A_{12}^{\dagger}B_{11}^{-1} + \mathcal{O}(|\omega|^3),$$

$$P_{22} = i|\omega|A_{22} + |\omega|^2 A_{12}^{\dagger}B_{11}^{-1}A_{12} + \mathcal{O}(|\omega|^3),$$

and where the transformation

$$S = \begin{pmatrix} I & S_{12} \\ S_{21} & S_{22} \end{pmatrix},$$

with

$$S_{12} = -i|\omega|B_{11}^{-1}A_{12} + \mathcal{O}(|\omega|^2),$$

$$S_{21} = i|\omega|A_{12}^{\dagger}B_{11}^{-1} + \mathcal{O}(|\omega|^2),$$

$$S_{22} = I + \mathcal{O}(|\omega|^2),$$

is a smooth function of ω for $|\omega| \leqslant \omega_1$.

The eigenvalues of (36) are the same ones of (35). The eigenvalues of P_{11} are the ones close to those of B_{11}. For these eigenvalues there exist $\delta > 0$ and $\omega_2 > 0$ ($\omega_2 \leqslant \omega_1$) such that $\mathrm{Re}\,\lambda \leqslant -\delta < 0$ for $|\omega| \leqslant \omega_2$. Assumption 3 is certainly true for these eigenvalues.

In what follows the eigenvalues $\lambda(\omega)$ of P_{22}, which are the ones approaching zero, and their eigenvectors will be studied.

Lemma 6: There exists $\omega_3 > 0$ such that the functions $\lambda(\omega)/|\omega|$ are continuous functions of $(|\omega|, \hat{\omega})$ for $|\omega| \leqslant \omega_3$.

Proof: Consider the matrix $P_{22}(\omega)/|\omega|$:

$$\frac{P_{22}(\omega)}{|\omega|} = iA_{22}(\hat{\omega}) + |\omega| M_{22}(|\omega|, \hat{\omega}). \tag{37}$$

Here A_{22} is a smooth function of $\hat{\omega}$, and M_{22} is a smooth function of $(|\omega|, \hat{\omega})$ for $|\omega| > 0$ that stays bounded when $|\omega| \to 0$. As

$$\| |\omega| M_{22}(|\omega|, \hat{\omega}) | \to 0 \quad \text{when} \quad |\omega| \to 0,$$

perturbation theory says that each eigenvalue of (37) is of the form

$$\frac{\lambda(\omega)}{|\omega|} = i\alpha(\hat{\omega}) + \gamma(|\omega|, \hat{\omega}). \tag{38}$$

Here $\alpha(\hat{\omega})$, an eigenvalue of $A_{22}(\hat{\omega})$, is a continuous function of $\hat{\omega}$, and γ is a continuous function of its arguments that vanishes at least as a rational power of $|\omega|$ when $|\omega| \to 0$. This proves the lemma.

An important property of the eigenvectors in (35) is proved next.

Lemma 7: Assumption 4 implies that there exist $c > 0$ *and* $\omega_0 > 0$ *such that, for all* $|\omega| \leqslant \omega_0$, $|u(\omega)| \geqslant c|\omega|$.

Proof: If $|\lambda|$ does not vanish when $|\omega| \to 0$, the lemma is clearly true since $\mathrm{Re}\,\lambda = \langle u, B_{11} u \rangle$. Consider the case $|\lambda| \to 0$ when $|\omega| \to 0$ (eigenvalues of P_{22}).

The equation (35) can be written as

$$\left(\frac{\lambda}{|\omega|} I - iA - \frac{1}{|\omega|} B \right) \begin{pmatrix} u \\ 0 \end{pmatrix} = \left(-\frac{\lambda}{|\omega|} I + i\hat{A} \right) \begin{pmatrix} 0 \\ v \end{pmatrix}. \tag{39}$$

Let us define

$$F(|\omega|, \hat{\omega}, y) = (zI + iA) \begin{pmatrix} 0 \\ y \end{pmatrix}, \quad \text{with} \quad z = -\frac{\lambda(\omega)}{|\omega|}, \quad \text{and} \quad |y| = 1.$$

The injectivity assumption (Assumption 4) implies that $|F|$ is a strictly positive function, and Lemma 6 implies that, for $|\omega| \leqslant \omega_3$, the function $|F|$ is continuous on all its arguments. Therefore, as $(|\omega|, \hat{\omega}, y)$ moves on a compact set, there exist $\tilde{c} > 0$ such that $|F(|\omega|, \hat{\omega}, y)| \geqslant \tilde{c}$. As $|u|$ goes to zero when $|\omega|$ goes to zero (otherwise $|\mathrm{Re}\,\lambda|$ would not go zero), $|v|$ stays close to one and we can divide (39) by $|v|$ to obtain

$$\left| \left(\frac{\lambda}{|\omega|} I - iA - \frac{1}{|\omega|} B \right) \frac{1}{|v|} \begin{pmatrix} u \\ 0 \end{pmatrix} \right| = |F(|\omega|, \hat{\omega}, v/|v|)| \geqslant \tilde{c},$$

and consequently

$$\left| (\lambda I - i|\omega| A - B) \begin{pmatrix} u \\ 0 \end{pmatrix} \right| \geqslant \tilde{c} |\omega| |v|. \tag{40}$$

Now assume the lemma is false. Thus for all $c > 0$ and $\omega_0 > 0$, there exists ω, with $|\omega| < \omega_0$, such that $|u(\omega)| < c|\omega|$. Then, it follows from (40) that

$$|B_{11}||u(\omega)| \geqslant \tilde{c}|\omega| \sqrt{1 - |u(\omega)|^2} - |\lambda(\omega)||u(\omega)| - |\omega||A||u(\omega)|,$$

$$> (\tilde{c}\sqrt{1 - c^2|\omega|^2} - c|\lambda(\omega)| - c|A||\omega|)|\omega|,$$

which, as $|\lambda(\omega)| \to 0$ when $|\omega| \to 0$, gives a contradiction for $c = \tilde{c}/2|B_{11}|$ and $\omega_0 \leqslant \omega_3$ small enough so that

$$\tilde{c}\sqrt{1-c^2|\omega|^2}-c|\lambda(\omega)|-c|A||\omega|>\frac{\tilde{c}}{2}.$$

This concludes the proof.

Corollary 1: For $|\omega|\leqslant\omega_0$, *the eigenvalues of* P_{22} *satisfy* $\mathrm{Re}\,\lambda\leqslant-\mu|\omega|^2$ *with* $\mu>0$.

Proof: Left multiply (35) by the eigenvector and take the real part to obtain

$$\mathrm{Re}\,\lambda(\omega)=\langle u,B_{11}u\rangle\leqslant-\beta|u(\omega)|^2\leqslant-\beta c^2|\omega|^2,$$

where $\beta>0$ exists because B_{11} is negative definite and Lemma 7 was used. Corollary 1 holds with $\mu=\beta c^2$.

We can summarize the results of Lemma 5 and Corollary 1 in the following.

Theorem 3: *If Assumption 4 holds, there are positive constants* ω_0, δ, *and* μ *such that all eigenvalues* $\lambda(\omega)$ *of the symbol satisfy*

$$\mathrm{Re}\,\lambda(\omega)\leqslant\begin{cases}-\mu|\omega|^2, & \text{or } -\delta, \quad \text{if } |\omega|\leqslant\omega_0,\\ -\delta, & \text{if } |\omega|\geqslant\omega_0.\end{cases}$$

This says that the physically based Assumption 4 implies that Assumption 3 holds for the general dissipative relativistic fluids. Therefore Theorem 1 applies and the constant solutions of these theories are stable.

[8] The injectivity condition required by Kreiss *et al.*[4] is the one given here when z is pure imaginary. It is not hard to prove though, using anti-Hermiticity of $\hat{P}(i\hat{\omega})$, that the injectivity condition also holds for general complex z.

Painlevé–Calogero correspondence revisited

Kanehisa Takasaki[a)]

(Received 26 April 2000; accepted for publication 20 December 2000)

We extend the work of Fuchs, Painlevé and Manin on a Calogero-like expression of the sixth Painlevé equation (the ''Painlevé–Calogero correspondence'') to the other five Painlevé equations. The Calogero side of the sixth Painlevé equation is known to be a nonautonomous version of the (rank one) elliptic model of Inozemtsev's extended Calogero systems. The fifth and fourth Painlevé equations correspond to the hyperbolic and rational models in Inozemtsev's classification. Those corresponding to the third, second and first are not included therein. We further extend the correspondence to the higher rank models, and obtain a ''multi-component'' version of the Painlevé equations. © *2001 American Institute of Physics.*

I. INTRODUCTION

The so called Painlevé equations are the following six equations discovered by Painlevé[1] and Gambier:[2]

$$(\mathrm{P_{VI}}) \quad \frac{d^2\lambda}{dt^2} = \frac{1}{2}\left(\frac{1}{\lambda}+\frac{1}{\lambda-1}+\frac{1}{\lambda-t}\right)\left(\frac{d\lambda}{dt}\right)^2 - \left(\frac{1}{t}+\frac{1}{t-1}+\frac{1}{\lambda-t}\right)\frac{d\lambda}{dt} + \frac{\lambda(\lambda-1)(\lambda-t)}{t^2(t-1)^2}\left(\alpha+\frac{\beta t}{\lambda^2}+\frac{\gamma(t-1)}{(\lambda-1)^2}+\frac{\delta t(t-1)}{(\lambda-t)^2}\right),$$

$$(\mathrm{P_V}) \quad \frac{d^2\lambda}{dt^2} = \left(\frac{1}{2\lambda}+\frac{1}{\lambda-1}\right)\left(\frac{d\lambda}{dt}\right)^2 - \frac{1}{t}\frac{d\lambda}{dt} + \frac{\lambda(\lambda-1)^2}{t^2}\left(\alpha+\frac{\beta}{\lambda^2}+\frac{\gamma t}{(\lambda-1)^2}+\frac{\delta t^2(\lambda+1)}{(\lambda-1)^3}\right),$$

$$(\mathrm{P_{IV}}) \quad \frac{d^2\lambda}{dt^2} = \frac{1}{2\lambda}\left(\frac{d\lambda}{dt}\right)^2 + \frac{3}{2}\lambda^3 + 4t\lambda^2 + 2(t^2-\alpha)\lambda + \frac{\beta}{\lambda},$$

$$(\mathrm{P_{III}}) \quad \frac{d^2\lambda}{dt^2} = \frac{1}{\lambda}\left(\frac{d\lambda}{dt}\right)^2 - \frac{1}{t}\frac{d\lambda}{dt} + \frac{\lambda^2}{4t^2}\left(\alpha+\frac{\beta t}{\lambda^2}+\gamma\lambda+\frac{\delta t^2}{4\lambda^3}\right),$$

$$(\mathrm{P_{II}}) \quad \frac{d^2\lambda}{dt^2} = 2\lambda^3 + t\lambda + \alpha,$$

$$(\mathrm{P_I}) \quad \frac{d^2\lambda}{dt^2} = 6\lambda^2 + t.$$

a)Electronic mail: takasaki@math.h.kyoto-u.ac.jp

The third equation P_{III} is slightly modified; the original equation can be reproduced by the simple change of variables $(t,\lambda)\to(t^2,t\lambda)$. It is well known that these equations are characterized by the absence of ''movable singularities'' other than poles.

Fuchs[3] proposed two more approaches to the sixth equation P_{VI}. One approach is the concept of isomonodromic deformations. In this approach, P_{VI} is interpreted as a differential equation describing isomonodromic deformations of a linear ordinary differential equation on the Riemann sphere. This is the origin of many subsequent researches. Another approach relates P_{VI} to an incomplete elliptic integral. Painlevé[4] took the second approach, and derived a new expression of P_{VI} in term of the Weierstrass $\wp$-function. This work of Painlevé is briefly reviewed in Okamoto's work on affine Weyl group symmetries of P_{VI}.[5]

Manin[6] revived the almost forgotten work of Fuchs and Painlevé after nearly ninety years. Manin's remarkable idea is to use the elliptic modulus τ, rather than t, as an independent variable. The outcome is a Hamiltonian system with a Hamiltonian of the normal form $\mathcal{H}=p^2/2+V(q)$, where the potential is a linear combination of the Weierstrass $\wp$-function and its shift by three half periods. This is a nonautonomous system, because the Hamiltonian depends on the ''time'' τ through the τ-dependence of the $\wp$-function.

Levin and Olshanetsky[7] pointed out that Manin's equation resembles the so called Calogero–Moser systems, i.e., the various extensions[8] of the integrable many-body systems first discovered by Calogero.[9] More precisely, the Hamiltonian $\mathcal{H}$ is identical to a special case (the rank-one elliptic model) of Inozemtsev's extensions[10,11] of the Calogero–Moser systems. Levin and Olshanetsky called this relation the ''Painlevé–Calogero correspondence.''

One will naturally ask if this correspondence can be extended to the other Painlevé equations. Manin himself raised this problem in his paper. Olshanetsky[12] conjectured that a degenerate version of Inozemtsev's elliptic model will emerge therein.

In this paper we aim to answer this question affirmatively. A guiding principle is the degeneration relation of the six Painlevé equations.[13] This relation can be schematically expressed as follows:

$$\begin{array}{ccccccc} P_{VI} & \to & P_V & \to & P_{IV} & & \\ & & \downarrow & & \downarrow & & \\ & & P_{III} & \to & P_{II} & \to & P_I \end{array}$$

This diagram means, for instance, that P_V can be derived from P_{VI} by a degeneration process, which amounts to confluence of singular points of the aforementioned linear ordinary differential equation in the isomonodromic approach. We shall trace this process carefully on the ''Calogero side,'' and find a P_V-version of Manin's equation. In principle, one can thus find an analog of Manin's equation for all the six Painlevé equations (though, actually, one can resort to a more direct approach that bypasses the complicated degeneration process).

Remarkably (or rather naturally?), all the six equations on the Calogero side turn out to become a (nonautonomous) Hamiltonian system with a Hamiltonian of the normal form $\mathcal{H}=p^2/2+V(q)$. Furthermore, the Hamiltonians on the Calogero side of P_V and P_{IV} coincide with the Hamiltonians of the (rank one) hyperbolic and rational models in Inozemtsev's classification[10] (which were discovered by Levi and Wojciechowski[14] before Inozemtsev's work). Those corresponding to the other three Painlevé equations are not included therein, but may be thought of as a further degeneration of the hyperbolic and rational models.

One can further proceed to the higher rank models, and ask if there is still a Painlevé–Calogero correspondence. We shall show that this is also the case. The Painlevé side of the correspondence is a kind of multi-dimensional extension of the Painlevé equations. They are obviously different from another multi-dimensional extension called the ''Garnier systems.''[13] For this reason, we call our multi-dimensional extension a *multi-component* version of the Painlevé equations.

This paper is organized as follows. Section II is a brief review of the work of Fuchs, Painlevé and Manin. In Sec. III we deal with P_V, P_{IV} and P_{III}. The degeneration process is discussed in

detail for the case of P_V. The direct approach is illustrated for the case of P_{IV} and P_{III}. In Sec. IV we show a reformulation of the foregoing calculations in the Hamiltonian formalism. The status of P_{II} and P_I is also clarified therein. Section V is devoted to the higher rank Inozemtsev Hamiltonians and the multi-component Painlevé equations. Section VI is for concluding remarks. Part of the technical details are gathered in the Appendices.

II. PAINLEVÉ–CALOGERO CORRESPONDENCE FOR P_{VI}

We here briefly review the work of Fuchs, Painlevé and Manin.

Fuchs rewrites P_{VI} into the following form:

$$t(1-t)\mathcal{L}_t\int_\infty^\lambda \frac{dz}{\sqrt{z(z-1)(z-t)}} = \sqrt{\lambda(\lambda-1)(\lambda-t)}\left[\alpha+\frac{\beta t}{\lambda^2}+\frac{\gamma(t-1)}{(\lambda-1)^2}+\left(\delta-\frac{1}{2}\right)\frac{t(t-1)}{(\lambda-t)^2}\right]. \tag{1}$$

Here $\mathcal{L}_t$ is the linear differential operator (Picard–Fuchs operator)

$$\mathcal{L}_t = t(1-t)\frac{d^2}{dt^2}+(1-2t)\frac{d}{dt}-\frac{1}{4}, \tag{2}$$

which also appears in the Picard–Fuchs equation of complete elliptic integrals. In this respect, P_{VI} may be thought of as an inhomogeneous (and nonlinear) analog of the Picard–Fuchs equation.

Painlevé and Manin make use of a parametrization of the elliptic curve,

$$y^2 = z(z-1)(z-t), \tag{3}$$

by the Weierstrass $\wp$-function. Let $\wp(u)$ be the $\wp$-function with primitive periods 1 and τ:

$$\wp(u)=\wp(u|1,\tau)=\frac{1}{u^2}+\sum_{(m,n)\neq(0,0)}\left(\frac{1}{(u+m+n\tau)^2}-\frac{1}{(m+n\tau)^2}\right). \tag{4}$$

The parametrization is now given by

$$z=\frac{\wp(u)-e_1}{e_2-e_1},\quad y=\frac{\wp'(u)}{2(e_2-e_1)^{3/2}}, \tag{5}$$

where $e_n=\wp(\omega_n)$, $n=1,2,3$ are the values of $\wp(u)$ at the three half period points $\omega_1=1/2$, $\omega_2=-(1+\tau)/2$, $\omega_3=\tau/2$.

Manin's excellent idea is to do a simultaneous change of the dependent variable $\lambda\to q$ by

$$\lambda=\frac{\wp(q)-e_1}{e_2-e_1}, \tag{6}$$

and the independent variable $t\to\tau$ by

$$t=\frac{e_3-e_1}{e_2-e_1}. \tag{7}$$

Manin presents the beautiful formula

$$\frac{d\tau}{dt}=\frac{\pi i}{t(t-1)(e_2-e_1)}, \tag{8}$$

for the Jacobian of the latter, which plays a key role in his calculations. P_{VI} is thereby mapped to the equation

$$(2\pi i)^2 \frac{d^2 q}{d\tau^2} = \sum_{n=0}^{3} \alpha_n \wp'(q+\omega_n), \tag{9}$$

where the parameters on the right hand side are connected with the parameters of P_{VI} as $\alpha_0 = \alpha$, $\alpha_1 = -\beta$, $\alpha_2 = \gamma$, $\alpha_3 = -\delta + 1/2$. This equation is equivalent to the Hamiltonian system,

$$2\pi i \frac{dq}{d\tau} = \frac{\partial \mathcal{H}}{\partial p}, \quad 2\pi i \frac{dp}{d\tau} = -\frac{\partial \mathcal{H}}{\partial q}, \tag{10}$$

with the Hamiltonian

$$\mathcal{H} = \frac{p^2}{2} - \sum_{n=0}^{3} \alpha_n \wp(q+\omega_n). \tag{11}$$

III. CORRESPONDENCE FOR P_V, P_{IV} AND P_{III}

A. Degeneration of P_{VI} to P_V

The degeneration of P_{VI} to P_V is achieved by rescaling the time variable and the parameters as

$$t = 1 + \epsilon \tilde{t}, \quad \alpha = \tilde{\alpha}, \quad \beta = \tilde{\beta}, \quad \gamma = \frac{\tilde{\gamma}}{\epsilon} - \frac{\tilde{\delta}}{\epsilon^2}, \quad \delta = \frac{\tilde{\delta}}{\epsilon^2}, \tag{12}$$

and letting $\epsilon \to 0$ while leaving $\tilde{\alpha}, \ldots, \tilde{\gamma}$ and $\tilde{t}$ finite.[13]

The building blocks of Fuchs' equation (1) turn out to survive this scaling limit as follows.

(1) The Picard–Fuchs operator:

$$t(1-t)\mathcal{L}_t \to \tilde{t}^2 \frac{d^2}{d\tilde{t}^2} + \tilde{t}\frac{d}{d\tilde{t}} = \left(\tilde{t}\frac{d}{d\tilde{t}}\right)^2.$$

(2) The sum $\alpha + \cdots$ of four terms on the right hand side:

$$\alpha + \frac{\beta t}{\lambda^2} + \frac{\gamma(t-1)}{(\lambda-1)^2} + \left(\delta - \frac{1}{2}\right)\frac{t(t-1)}{(\lambda-t)^2} \to \tilde{\alpha} + \frac{\tilde{\beta}}{\lambda^2} + \frac{\tilde{\gamma}\tilde{t}}{(\lambda-1)^2} + \frac{\tilde{\delta}\tilde{t}^2(\lambda+1)}{(\lambda-1)^3}.$$

(3) The square root on the right hand side:

$$\sqrt{\lambda(\lambda-1)(\lambda-t)} \to \sqrt{\lambda}(\lambda-1).$$

(4) The incomplete elliptic integral:

$$\int_\infty^\lambda \frac{dz}{\sqrt{z(z-1)(z-t)}} \to \int_\infty^\lambda \frac{dz}{\sqrt{z}(z-1)}.$$

In particular, the degeneration of P_{VI} to P_V is associated with the degeneration of the elliptic curve to a rational curve,

$$y^2 = z(z-1)(z-t) \to y^2 = z(z-1)^2, \tag{13}$$

or, equivalently, the degeneration of the torus $\mathbb{C}/(\mathbb{Z} + \tau\mathbb{Z})$ to the cylinder $\mathbb{C}/\mathbb{Z}$.

Thus, rewriting $\tilde{\alpha}$, $\tilde{\beta}$, $\tilde{\gamma}$, $\tilde{\delta}$ and $\tilde{t}$ to α, β, γ, δ and t, we obtain the following equation as a P_V-version of Fuchs' equation:

$$\left(t\frac{d}{dt}\right)^2\int_\infty^\lambda \frac{dz}{\sqrt{z}(z-1)}=\sqrt{\lambda}(\lambda-1)\left(\alpha+\frac{\beta}{\lambda^2}+\frac{\gamma t}{(\lambda-1)^2}+\frac{\delta t^2(\lambda+1)}{(\lambda-1)^3}\right). \tag{14}$$

B. Analog of Manin's equation for P_V

As a counterpart of the q-variable for P_{VI}, we now consider

$$q=\int_\infty^\lambda \frac{dz}{\sqrt{z}(z-1)}. \tag{15}$$

If one prefers to be more faithful to Manin's parametrization, one should rather define q as

$$q=\frac{1}{2\pi i}\int_\infty^\lambda \frac{dz}{\sqrt{z}(z-1)},$$

because $2(e_2-e_1)^{1/2}\to 2\pi i$ as $\mathrm{Im}\,\tau\to+\infty$ (see Appendix B). Since there is no substantial difference, let us take the first definition that is slightly simpler for calculations.

Let us rewrite (14) in terms of q. The integral can be readily calculated as

$$q=\log\left(\frac{\sqrt{\lambda}-1}{\sqrt{\lambda}+1}\right), \tag{16}$$

so that the inverse relation can be written as

$$\sqrt{\lambda}=-\coth(q/2). \tag{17}$$

Terms on the right hand side of (14) can be calculated as follows:

$$\sqrt{\lambda}(\lambda-1)=-\frac{\cosh(q/2)}{\sinh^3(q/2)},$$

$$\sqrt{\lambda}(\lambda-1)\frac{1}{\lambda^2}=-\frac{\sinh(q/2)}{\cosh^3(q/2)},$$

$$\sqrt{\lambda}(\lambda-1)\frac{1}{(\lambda-1)^2}=-\frac{1}{2}\sinh(q),$$

$$\sqrt{\lambda}(\lambda-1)\frac{(\lambda+1)}{(\lambda-1)^3}=-\frac{\lambda^{3/2}+\lambda^{1/2}}{(\lambda-1)^2}=-\frac{1}{4}\sinh(2q).$$

The differential equation for q eventually takes the form

$$\left(t\frac{d}{dt}\right)^2 q=-\frac{\partial V(q)}{\partial q}, \tag{18}$$

where

$$V(q)=-\frac{\alpha}{\sinh^2(q/2)}-\frac{\beta}{\cosh^2(q/2)}+\frac{\gamma t}{2}\cosh(q)+\frac{\delta t^2}{8}\cosh(2q). \tag{19}$$

This gives a P_V-version of Manin's equation. Note that this equation can be readily converted to a Hamiltonian system with the Hamiltonian $\mathcal{H}=p^2/2+V(q)$.

Remark: A very similar change of dependent variable for P_V is discussed in the book of Iwasaki *et al.*[15]

C. Idea of direct approach

Although the degeneration process can be continued to the other Painlevé equations, we now present a more direct approach. Note that the integrand is connected with the coefficient of $(d\lambda/dt)^2$ in the original Painlevé equation by the following very simple relation:

$$\frac{1}{\sqrt{z(z-1)(z-t)}} = \exp\left[-\int \frac{1}{2}\left(\frac{1}{z} + \frac{1}{z-1} + \frac{1}{z-t}\right) dz \right],$$

$$\frac{1}{\sqrt{z}(z-1)} = \exp\left[-\int \left(\frac{1}{2z} + \frac{1}{z-1}\right) dz \right].$$

If this is a correct prescription, one will be able to define the q-variable for P_{III} and P_{II} directly without the cumbersome degeneration process. This is indeed the case, as we shall show below.

D. q-variable for P_{IV}

Since the expected integrand is given by

$$\exp\left(-\int \frac{dz}{2z} \right) = \frac{1}{\sqrt{z}}, \tag{20}$$

we define

$$q = \int^{\lambda} \frac{dz}{\sqrt{z}} = 2\sqrt{\lambda}. \tag{21}$$

This can be solved for λ as

$$\lambda = \left(\frac{q}{2}\right)^2. \tag{22}$$

Honest calculations show that all derivative terms of P_{IV} can be absorbed by the second derivative of q:

$$\frac{d^2q}{dt^2} = \frac{1}{\sqrt{\lambda}} \frac{d^2\lambda}{dt^2} - \frac{1}{2\lambda\sqrt{\lambda}} \left(\frac{d\lambda}{dt}\right)^2$$

$$= \frac{1}{\sqrt{\lambda}} \left(\frac{3}{2}\lambda^3 + 4t\lambda^2 + 2(t^2 - \alpha)\lambda + \frac{\beta}{\lambda} \right). \tag{23}$$

Substituting $\lambda = (q/2)^2$ gives the second order differential equation,

$$\frac{d^2q}{dt^2} = -\frac{\partial V(q)}{\partial q}, \tag{24}$$

with the potential

$$V(q) = -\frac{1}{2}\left(\frac{q}{2}\right)^6 - 2t\left(\frac{q}{2}\right)^4 - 2(t^2 - \alpha)\left(\frac{q}{2}\right)^2 + \beta\left(\frac{q}{2}\right)^{-2}. \tag{25}$$

E. q-variable for P_{III}

The integrand is expected to be given by

$$\exp\left(-\int \frac{dz}{z}\right)=\frac{1}{z}. \tag{26}$$

We consider

$$q=\int^{\lambda}\frac{dz}{z}=\log\lambda, \tag{27}$$

and its inversion

$$\lambda=e^{q}. \tag{28}$$

All derivatives terms of P_{III} are now absorbed by the second derivative of q with respect to $\log t$:

$$\left(t\frac{d}{dt}\right)^2 q=\frac{t^2}{\lambda}\frac{d^2\lambda}{dt^2}+\frac{t}{\lambda}\frac{d\lambda}{dt}-\frac{t^2}{\lambda^2}\left(\frac{d\lambda}{dt}\right)^2$$

$$=\frac{\alpha\lambda}{4}+\frac{\beta t}{4\lambda}+\frac{\gamma\lambda^2}{4}+\frac{\delta t^2}{4\lambda^2}. \tag{29}$$

Substituting $\lambda=e^{q}$ gives the second order equation,

$$\left(t\frac{d}{dt}\right)^2 q=-\frac{\partial V(q)}{\partial q}, \tag{30}$$

with the potential

$$V(q)=-\frac{\alpha}{4}e^{q}+\frac{\beta t}{4}e^{-q}-\frac{\gamma}{8}e^{2q}+\frac{\delta t^2}{8}e^{-2q}. \tag{31}$$

F. Summary

Let us summarize the results of this section.

Theorem 1: *The foregoing change of variable $\lambda\to q$ maps P_V, P_{IV} and P_{III} to a second order differential equation for the new dependent variable q. These equations are equivalent to a non-autonomous Hamiltonian system with a Hamiltonian of the normal form $\mathcal{H}=p^2/2+V(q)$.*
(P_V) *The Hamiltonian system takes the form*

$$t\frac{dq}{dt}=\frac{\partial\mathcal{H}}{\partial p},\quad t\frac{dp}{dt}=-\frac{\partial\mathcal{H}}{\partial q}, \tag{32}$$

with the Hamiltonian

$$\mathcal{H}=\frac{p^2}{2}-\frac{\alpha}{\sinh^2(q/2)}-\frac{\beta}{\cosh^2(q/2)}+\frac{\gamma t}{2}\cosh(q)+\frac{\delta t^2}{8}\cosh(2q). \tag{33}$$

(P_{IV}) *The Hamiltonian system takes the form*

$$\frac{dq}{dt}=\frac{\partial\mathcal{H}}{\partial p},\quad \frac{dp}{dt}=-\frac{\partial\mathcal{H}}{\partial q}, \tag{34}$$

with the Hamiltonian

$$\mathcal{H}=\frac{p^2}{2}-\frac{1}{2}\left(\frac{q}{2}\right)^6-2t\left(\frac{q}{2}\right)^4-2(t^2-\alpha)\left(\frac{q}{2}\right)^2+\beta\left(\frac{q}{2}\right)^{-2}. \tag{35}$$

(P_{III}) *The Hamiltonian system takes the form*

$$t\frac{dq}{dt}=\frac{\partial\mathcal{H}}{\partial p},\quad t\frac{dp}{dt}=-\frac{\partial\mathcal{H}}{\partial q}, \tag{36}$$

with the Hamiltonian

$$\mathcal{H}=\frac{p^2}{2}-\frac{\alpha}{4}e^q+\frac{\beta t}{4}e^{-q}-\frac{\gamma}{8}e^{2q}+\frac{\delta t^2}{8}e^{-2q}. \tag{37}$$

Remark:

(1) The Hamiltonians for P_V and P_{IV} coincide with those of the hyperbolic and rational models of Inozemtsev,[10] Levi and Wojciechowski.[14] The Hamiltonian for P_{III} has no counterpart in their work, but nowadays can be found in the literature.[16]
(2) The foregoing construction of the q-variable does not literally work for P_{II} and P_I, because there is no $(d\lambda/dt)^2$ term. The status of these equations will be clarified in the next section from a different point of view.

IV. HAMILTONIAN FORMALISM OF CORRESPONDENCE

A. Hamiltonians of Painlevé equations

All the six Painlevé equations are known to be expressed in the Hamiltonian form

$$\frac{d\lambda}{dt}=\frac{\partial H}{\partial\mu},\quad \frac{d\lambda}{dt}=-\frac{\partial H}{\partial\lambda},$$

with a suitable choice of the canonical conjugate variable μ and the Hamiltonian H.[17] This expression is by no means unique; we here consider the following Hamiltonians.[13] These Hamiltonians are referred to as the ''polynomial Hamiltonians'' because they are polynomials in λ and μ:

$$(P_{VI})\quad H=\frac{\lambda(\lambda-1)(\lambda-t)}{t(t-1)}\left[\mu^2-\left(\frac{\kappa_0}{\lambda}+\frac{\kappa_1}{\lambda-1}+\frac{\theta-1}{\lambda-t}\right)\mu+\frac{\kappa}{\lambda(\lambda-1)}\right],$$

$$(P_V)\quad H=\frac{\lambda(\lambda-1)^2}{t}\left[\mu^2-\left(\frac{\kappa_0}{\lambda}+\frac{\theta_1}{\lambda-1}-\frac{\eta_1 t}{(\lambda-1)^2}\right)\mu+\frac{\kappa}{\lambda(\lambda-1)}\right],$$

$$(P_{IV})\quad H=2\lambda\left[\mu^2-\left(\frac{\lambda}{2}+t+\frac{\kappa_0}{\lambda}\right)\mu+\frac{\theta_\infty}{2}\right],$$

$$(P_{III})\quad H=\frac{\lambda^2}{t}\left[\mu^2-\left(\eta_\infty+\frac{\theta_0}{\lambda}-\frac{\eta_0 t}{\lambda^2}\right)\mu+\frac{\eta_\infty(\theta_0+\theta_\infty)}{2\lambda}\right],$$

$$(P_{II})\quad H=\frac{\mu^2}{2}-\left(\lambda^2+\frac{t}{2}\right)\mu-\left(\alpha+\frac{1}{2}\right)\lambda,$$

$$(P_I)\quad H=\frac{\mu^2}{2}-2\lambda^3-t\lambda.$$

Here $\kappa_0, \kappa_1, \theta$, etc. are constants that are connected with the parameters $\alpha, \beta, \gamma, \delta$ of the Painlevé equations by simple algebraic relations:

$$(\mathrm{P_{VI}}) \quad \alpha = \frac{(\kappa_0+\kappa_1+\theta-1)^2}{2} - 2\kappa, \quad \beta = -\frac{\kappa_0^2}{2}, \quad \gamma = \frac{\kappa_1^2}{2}, \quad \delta = \frac{1-\theta^2}{2};$$

$$(\mathrm{P_V}) \quad \alpha = \frac{(\kappa_0+\theta_1)^2}{2} - 2\kappa, \quad \beta = -\frac{\kappa_0^2}{2}, \quad \gamma = \eta_1(\theta_1+1), \quad \delta = -\frac{\eta_1^2}{2};$$

$$(\mathrm{P_{IV}}) \quad \alpha = 2\theta_\infty - \kappa_0 + 1, \quad \beta = -2\kappa_0^2;$$

$$(\mathrm{P_{III}}) \quad \alpha = -4\eta_\infty\theta_\infty, \quad \beta = 4\eta_0(\theta_0+1), \quad \gamma = 4\eta_\infty^2, \quad \delta = -4\eta_0^2.$$

B. How to find canonical transformations

The goal of this section is to show that the Painlevé–Calogero correspondence is, in fact, a (time-dependent) canonical transformation of two Hamiltonian systems. By this, we mean that the functional relation between λ and q can be extended to (λ,μ) and (q,p) so as to satisfy the equation

$$\mu\, d\lambda - H dt = \text{constant} \cdot (p\, dq - \mathcal{H}\, dT) + \text{exact form}, \tag{38}$$

with a suitably redefined time variable T (such as the logarithmic time $\log t$ in $\mathrm{P_V}$ and $\mathrm{P_{III}}$). The constant factor on the right hand side is inserted simply for convenience; if necessary, one can normalize the constant to 1 by suitably rescaling p, q, $\mathcal{H}$ and T. For this reason, we call this type of coordinate transformation a ''canonical'' transformation even if the constant factor is not equal to 1.

Let us illustrate, in the case of $\mathrm{P_{VI}}$, how to find such a canonical transformation. Suppose that λ and μ be a solution of $\mathrm{P_{VI}}$ in the aforementioned Hamiltonian formalism, and that q be a corresponding solution of Manin's equation. The canonical equation for λ takes the form

$$\frac{d\lambda}{dt} = \frac{\lambda(\lambda-1)(\lambda-t)}{t(t-1)}\left(2\mu - \frac{\kappa_0}{\lambda} - \frac{\kappa_1}{\lambda-1} - \frac{\theta-1}{\lambda-t}\right).$$

This equation can be solved for μ:

$$\mu = \frac{t(t-1)}{2\lambda(\lambda-1)(\lambda-t)}\frac{d\lambda}{dt} + \frac{1}{2}\left(\frac{\kappa_0}{\lambda} + \frac{\kappa_1}{\lambda-1} + \frac{\theta-1}{\lambda-t}\right).$$

Our task is to rewrite the right hand side in terms of p and q. We first consider $d\lambda/dt$. Differentiating (6) against t gives

$$\frac{d\lambda}{dt} = \left(\frac{\wp'(q)}{e_2-e_1}\frac{dq}{d\tau} + f_\tau(q)\right)\frac{d\tau}{dt},$$

where we have introduced the functions

$$f(u) = \frac{\wp(u)-e_1}{e_2-e_1}, \quad f_\tau(u) = \frac{\partial f(u)}{\partial \tau}. \tag{39}$$

The derivative $dq/d\tau$ can be read off from the canonical equation for q:

$$\frac{dq}{d\tau} = \frac{1}{2\pi i}\frac{\partial \mathcal{H}}{\partial p} = \frac{p}{2\pi i}.$$

As for the Jacobian $d\tau/dt$, Manin's formula (8) is available. One can thus express $d\lambda/dt$ as a function of p, q and τ. The other part of the foregoing expression of μ contains λ only, which can be readily converted to a function of q and τ by (6). We thus obtain the following expression of μ:

$$\mu = \frac{e_2-e_1}{\wp'(q)}p + \frac{2\pi i(e_2-e_1)^2}{\wp'(q)^2}f_\tau(q) + \frac{e_2-e_1}{2}\left(\frac{\kappa_0}{\wp(q)-e_1} + \frac{\kappa_1}{\wp(q)-e_2} + \frac{\theta-1}{\wp(q)-e_3}\right). \tag{40}$$

We now move the point of view, and think of (6) and (40) as defining a coordinate transformation $(\lambda,\mu)\to(q,p)$. This gives a canonical transformation that we have sought for the following.

Theorem 2: *(6) and (40) define a canonical transformation that connects the Hamiltonian form of* P_{VI} *and Manin's Hamiltonian system. The canonical coordinates and the Hamiltonians of the two systems obey the equation*

$$\mu\, d\lambda - H dt = p\, dq - \mathcal{H}\frac{d\tau}{2\pi i} + \text{exact form}. \tag{41}$$

C. Proof of Theorem 2

The total differential of (6) gives

$$d\lambda = \frac{\wp'(q)}{e_2-e_1}dq + f_\tau(q)d\tau,$$

so that $\mu\, d\lambda$ can be expressed as

$$\begin{aligned}\mu\, d\lambda &= \left(\frac{e_2-e_1}{\wp'(q)}p + \frac{2\pi i(e_2-e_1)^2}{\wp'(q)^2}f_\tau(q)\right)\left(\frac{\wp'(q)}{e_2-e_1}dq + f_\tau(q)d\tau\right) \\ &\quad + \frac{1}{2}\left(\frac{\kappa_0}{\lambda} + \frac{\kappa_1}{\lambda-1} + \frac{\theta-1}{\lambda-t}\right)d\lambda \\ &= p\, dq + (\mathrm{A}) + (\mathrm{B}) + (\mathrm{C}),\end{aligned}$$

where

$$(\mathrm{A}) = \frac{2\pi i(e_2-e_1)}{\wp'(q)}f_\tau(q)dq,$$

$$(\mathrm{B}) = \left(\frac{e_2-e_1}{\wp'(q)}p + \frac{2\pi i(e_2-e_1)^2}{\wp'(q)^2}f_\tau(q)\right)f_\tau(q)d\tau,$$

$$(\mathrm{C}) = \frac{1}{2}\left(\frac{\kappa_0}{\lambda} + \frac{\kappa_1}{\lambda-1} + \frac{\theta-1}{\lambda-t}\right)d\lambda.$$

As we shall prove in Appendix A, (A) can be further rewritten as

$$(\mathrm{A}) = \left[\frac{\wp(q+\omega_3)}{4\pi i} - \pi\left(\frac{f_\tau(q)}{f'(q)}\right)^2\right]d\tau + \text{exact form}, \tag{42}$$

where $f'(u)$ denotes the u-derivative of $f(u)$:

$$f'(u)=\frac{\partial f(u)}{\partial u}=\frac{\wp'(u)}{e_2-e_1}. \tag{43}$$

For (B) and (C), we have

$$(\mathrm{B})=\left[\frac{f_\tau(q)}{f'(q)}p+2\pi i\left(\frac{f_\tau(q)}{f'(q)}\right)^2\right]d\tau,$$

$$(\mathrm{C})=\frac{\theta-1}{2(\lambda-t)}dt+\frac{1}{2}(\kappa_0\log\lambda+\kappa_1\log(\lambda-1)+(\theta-1)\log(\lambda-t))$$

$$=\frac{\theta-1}{2(\lambda-t)}dt+\text{exact form}.$$

Thus we find that

$$\mu\,d\lambda-H dt=p\,dq-\tilde{\mathcal{H}}\frac{d\tau}{2\pi i}+\text{exact form}, \tag{44}$$

where

$$\tilde{\mathcal{H}}=2\pi i\frac{dt}{d\tau}\left(H-\frac{\theta-1}{2(\lambda-t)}\right)-2\pi i\left[\frac{\wp(q+\omega_3)}{4\pi i}+\frac{f_\tau(q)}{f'(q)}p+\pi i\left(\frac{f_\tau(q)}{f'(q)}\right)^2\right]. \tag{45}$$

Our task is to prove that the transformed Hamiltonian $\tilde{\mathcal{H}}$ coincides, modulo irrelevant terms, with the Hamiltonian of Manin's equation. Here ''irrelevant'' means that the term is a function of t only. Such a ''nondynamical'' term can be absorbed by the ''exact form'' part of the foregoing relation of 1-forms, thereby being negligible.

Let us evaluate the contribution of $2\pi i(dt/d\tau)H$. By Manin's formula (8) of $d\tau/dt$, and also by the identity

$$\lambda(\lambda-1)(\lambda-t)=\frac{\wp'(q)^2}{4(e_2-e_1)^3},$$

we can rewrite $2\pi i(dt/d\tau)H$ as follows:

$$2\pi i\frac{dt}{d\tau}H=\frac{\wp'(q)^2}{2(e_2-e_1)^2}\left[\mu^2-\left(\frac{\kappa_0}{\lambda}+\frac{\kappa_1}{\lambda-1}+\frac{\theta-1}{\lambda-t}\right)\mu+\frac{\kappa}{\lambda(\lambda-1)}\right]$$

$$=\frac{\wp'(q)^2}{2(e_2-e_1)^2}\left[\mu-\frac{1}{2}\left(\frac{\kappa_0}{\lambda}+\frac{\kappa_1}{\lambda-1}+\frac{\theta-1}{\lambda-t}\right)\right]^2$$

$$+\frac{\wp'(q)^2}{2(e_2-e_1)^2}\left[-\frac{1}{4}\left(\frac{\kappa_0}{\lambda}+\frac{\kappa_1}{\lambda-1}+\frac{\theta-1}{\lambda-t}\right)^2+\frac{\kappa}{\lambda(\lambda-1)}\right].$$

The first term on the right hand side is equal to

$$\frac{1}{2}\left(p+2\pi i\frac{f_\tau(q)}{f'(q)}\right)^2=\frac{p^2}{2}+2\pi i\frac{f_\tau(q)}{f'(q)}p+\left(2\pi i\frac{f_\tau(q)}{f'(q)}\right)^2,$$

by which the terms proportional to $f_\tau(q)/f'(q)$ and its square in the definition of $\tilde{\mathcal{H}}$ are cancelled out. The transformed Hamiltonian $\tilde{\mathcal{H}}$ can now be expressed as

$$\widetilde{\mathcal{H}}=\frac{p^2}{2}-\frac{\wp'(q)^2}{2(e_2-e_1)^2}-\frac{(\theta-1)t(t-1)(e_2-e_1)}{\lambda-t}+\frac{\wp'(q)}{2(e_2-e_1)^2}\left[-\frac{1}{4}\left(\frac{\kappa_0}{\lambda}+\frac{\kappa_1}{\lambda-1}+\frac{\theta-1}{\lambda-t}\right)^2+\frac{\kappa}{\lambda(\lambda-1)}\right]. \tag{46}$$

Note that this is already of the normal form $p^2/2+\widetilde{V}(q)$ with the potential

$$\widetilde{V}(q)=-\frac{\wp'(q)^2}{2(e_2-e_1)^2}-\frac{(\theta-1)t(t-1)(e_2-e_1)}{\lambda-t}+\frac{\wp'(q)}{2(e_2-e_1)^2}\left[-\frac{1}{4}\left(\frac{\kappa_0}{\lambda}+\frac{\kappa_1}{\lambda-1}+\frac{\theta-1}{\lambda-t}\right)^2+\frac{\kappa}{\lambda(\lambda-1)}\right]. \tag{47}$$

What remains is to express $\widetilde{V}(q)$ as an explicit function of q. To this end, we substitute the factor $\wp'(q)^2/2(e_2-e_1)^2$ by $2(e_2-e_1)\lambda(\lambda-1)(\lambda-t)$, and rewrite the main part of $\widetilde{V}(q)$ as a linear combination of λ, $1/\lambda$, $1/(\lambda-1)$ and $1/(\lambda-t)$. This leads to the following expression of $\widetilde{V}(q)$:

$$\widetilde{V}(q)=-\frac{(\kappa_0+\kappa_1+\theta-1)^2-4\kappa}{2}(e_2-e_1)\lambda-\frac{\kappa_0^2}{2}\cdot\frac{(e_2-e_1)t}{\lambda}-\frac{\kappa_1^2}{2}\cdot\frac{(e_2-e_1)(1-t)}{\lambda-1}-\frac{(\theta-1)^2+1}{2}\cdot\frac{(e_2-e_1)t(t-1)}{\lambda-t}-\frac{1}{2}\wp(q+\omega_3)+\text{function of } t \text{ only}.$$

The final piece of the ring is the general formula

$$\wp(u+\omega_j)=e_j+\frac{(e_j-e_k)(e_j-e_l)}{\wp(u)-e_j}, \tag{48}$$

where (j,k,l) is a cyclic permutation of (1,2,3). This implies that

$$\frac{(e_2-e_1)t}{\lambda}=\wp(q+\omega_1)-e_1,$$

$$\frac{(e_2-e_1)(1-t)}{\lambda-1}=\wp(q+\omega_2)-e_2,$$

$$\frac{(e_2-e_1)t(t-1)}{\lambda-t}=\wp(q+\omega_3)-e_3,$$

so that

$$\widetilde{V}(q)=-\frac{(\kappa_0+\kappa_1+\theta-1)^2-4\kappa}{2}\wp(q)-\frac{\kappa_0^2}{2}\wp(q+\omega_1)-\frac{\kappa_1^2}{2}\wp(q+\omega_2)-\frac{\theta^2}{2}\wp(q+\omega_3)+\text{function of } \tau \text{ only}. \tag{49}$$

Apart from the last term which is negligible, this potential is indeed the same as Manin's potential $V(q)$ (recall the algebraic relations connecting the constants κ_0, etc. and the parameters of P_{VI}). This completes the proof of the theorem. Q.E.D.

D. Canonical transformation for P_V

This heuristic method for constructing a canonical transformation can be applied to the other Painlevé equations. Here we consider the case of P_V.

Let λ be a solution of P_V, μ the canonical conjugate variable, and q the corresponding solution of (18). The canonical equation for λ can be written as

$$\frac{d\lambda}{dt}=\frac{\lambda(\lambda-1)^2}{t}\left(2\mu-\frac{\kappa_0}{\lambda}-\frac{\theta_1}{\lambda-1}+\frac{\eta_1 t}{(\lambda-1)^2}\right).$$

This equation can be solved for μ as

$$\mu=\frac{1}{2\lambda(\lambda-1)^2}t\frac{d\lambda}{dt}+\frac{1}{2}\left(\frac{\kappa_0}{\lambda}+\frac{\theta_1}{\lambda-1}-\frac{\eta_1 t}{(\lambda-1)^2}\right).$$

By differentiating (17) against t and using the canonical equation $t\,dq/dt=\partial\mathcal{H}/\partial p=p$, we obtain the identity

$$t\frac{d\lambda}{dt}=\sqrt{\lambda}(\lambda-1)p,$$

which can be used to rewrite the expression of μ as

$$\mu=\frac{p}{2\sqrt{\lambda}(\lambda-1)}+\frac{1}{2}\left(\frac{\kappa_0}{\lambda}+\frac{\theta_1}{\lambda-1}-\frac{\eta_1 t}{(\lambda-1)^2}\right). \tag{50}$$

We now reinterpret (17) and (50) as defining a coordinate transformation $(\lambda,\mu)\to(q,p)$. This indeed turns out to give a canonical transformation that we have sought for the following.

Theorem 3: *(17) and (50) define a canonical transformation that connects* P_V *and the* P_V*-version of Manin's Hamiltonian system. The canonical coordinates and the Hamiltonians of the two systems obey the equation*

$$\mu\,d\lambda-H\,dt=\frac{1}{2}\left(p\,dq-\mathcal{H}\frac{dt}{t}\right)+\text{exact form}. \tag{51}$$

Proof: Since $d\lambda$ and dq are connected by the relation

$$d\lambda=\sqrt{\lambda}(\lambda-1)dq,$$

$\mu\,d\lambda$ can be expressed as

$$\begin{aligned}\mu\,d\lambda&=\frac{1}{2}pdq+\frac{1}{2}\left(\frac{\kappa_0}{\lambda}+\frac{\theta_1}{\lambda-1}-\frac{\eta_1 t}{(\lambda-1)^2}\right)d\lambda\\&=\frac{1}{2}p\,dq-\frac{\eta_1}{2(\lambda-1)}dt+\frac{1}{2}d\left(\kappa_0\log\lambda+\theta_1\log(\lambda-1)+\frac{\eta_1 t}{\lambda-1}\right),\end{aligned}$$

so that

$$\mu\, d\lambda - H\, dt = \frac{1}{2}\left(p\, dq - \widetilde{\mathcal{H}}\frac{dt}{t}\right) + \text{exact form}, \tag{52}$$

where

$$\widetilde{\mathcal{H}} = 2Ht + \frac{\eta_1 t}{\lambda - 1}. \tag{53}$$

We can rewrite $\widetilde{\mathcal{H}}$ to a normal form as

$$\begin{aligned}\widetilde{\mathcal{H}} &= 2\lambda(\lambda-1)^2\left[\mu - \frac{1}{2}\left(\frac{\kappa_0}{\lambda} + \frac{\theta_1}{\lambda-1} - \frac{\theta_1 t}{(\lambda-1)^2}\right)\right]^2 \\ &\quad + 2\lambda(\lambda-1)^2\left[-\frac{1}{4}\left(\frac{\kappa_0}{\lambda} + \frac{\theta_1}{\lambda-1} - \frac{\eta_1 t}{(\lambda-1)^2}\right)^2 + \frac{\kappa}{\lambda(\lambda-1)}\right] + \frac{\eta_1 t}{\lambda-1} \\ &= \frac{p^2}{2} + \widetilde{V}(q),\end{aligned} \tag{54}$$

where

$$\begin{aligned}\widetilde{V}(q) &= -\frac{\lambda(\lambda-1)^2}{2}\left(\frac{\kappa_0}{\lambda} + \frac{\theta_1}{\lambda-1} - \frac{\eta_1 t}{(\lambda-1)^2}\right)^2 + 2\kappa(\lambda-1) + \frac{\eta_1 t}{\lambda-1}. \\ &= -\left(\frac{\kappa_0}{2} + \frac{\theta_1^2}{2} + \kappa_1\theta_1 - 2\kappa\right)\frac{1}{\sinh^2(q/2)} + \frac{\kappa_0^2}{2}\,\frac{1}{\cosh^2(q/2)} \\ &\quad + \frac{\eta_1(\theta_1+1)t}{2}\cosh(q) - \frac{\eta_1^2 t^2}{2}\cosh(2q) + \text{function of } t \text{ only}.\end{aligned} \tag{55}$$

Apart from the last negligible term, this coincides with the potential $V(q)$ in the statement of the theorem. Q.E.D.

E. Canonical transformation for P_{IV}

We now consider the case of P_{IV}.

Let λ be a solution of P_{IV}, μ the canonical conjugate variable, and q the corresponding solution of (24). The canonical equation for λ can be written as

$$\frac{d\lambda}{dt} = 4\lambda\mu - (\lambda^2 + 2t\lambda + 2\kappa_0),$$

which can be solved for μ as

$$\mu = \frac{1}{4\lambda}\frac{d\lambda}{dt} + \frac{1}{4}\left(\lambda + 2t + \frac{2\kappa_0}{\lambda}\right).$$

By (22) and the canonical equation $dq/dt = \partial\mathcal{H}/\partial p = p$, we have the identity

$$\frac{d\lambda}{dt} = \sqrt{\lambda}\frac{dq}{dt} = \sqrt{\lambda}p,$$

so that

$$\mu = \frac{p}{4\sqrt{\lambda}} + \frac{1}{4}\left(\lambda + 2t + \frac{2\kappa_0}{\lambda}\right). \tag{56}$$

Theorem 4: *(22) and (55) define a canonical transformation that connects* P_{IV} *and the* P_{IV}*-version of Manin's Hamiltonian system. The canonical coordinates and Hamiltonians of the two systems obey the equation*

$$\mu\, d\lambda - H\, dt = \tfrac{1}{4}(p\, dq - \mathcal{H}\, dt) + \text{exact form}. \tag{57}$$

Proof: Since $d\lambda$ and dq are connected by the relation

$$d\lambda = \sqrt{\lambda}\, dq,$$

$\mu\, d\lambda$ can be expressed as

$$\begin{aligned}\mu\, d\lambda &= \frac{1}{4}p\, dq + \frac{1}{4}\left(\lambda + 2t + \frac{2\kappa_0}{\lambda}\right)d\lambda \\ &= \frac{1}{4}p\, dq - \frac{1}{2}\lambda\, dt + \frac{1}{4}d\left(\frac{\lambda^2}{2} + 2t\lambda + 2\kappa_0 \log\lambda\right),\end{aligned}$$

so that

$$\mu\, d\lambda - H\, dt = \tfrac{1}{4}(p\, dq - \tilde{\mathcal{H}}\, dt) + \text{exact form}, \tag{58}$$

where

$$\tilde{\mathcal{H}} = 4H + 2\lambda. \tag{59}$$

We can rewrite the transformed Hamiltonian $\tilde{\mathcal{H}}$ to a normal form as

$$\begin{aligned}\tilde{\mathcal{H}} &= 8\lambda\left[\mu - \frac{1}{2}\left(\frac{\lambda}{2} + t + \frac{\kappa_0}{\lambda}\right)\right]^2 + 8\lambda\left[-\frac{1}{4}\left(\frac{\lambda}{2} + t + \frac{\kappa_0}{\lambda}\right)^2 + \frac{\theta_\infty}{2}\right] + 2\lambda \\ &= \frac{p^2}{2} + \tilde{V}(q),\end{aligned} \tag{60}$$

where

$$\begin{aligned}\tilde{V}(q) &= -2\lambda\left(\frac{\lambda}{2} + t + \frac{\kappa_0}{\lambda}\right)^2 + 4\theta_\infty\lambda + 2\lambda \\ &= -\frac{1}{2}\lambda^3 - 2t\lambda^2 - 2(t^2 + \kappa_0 - 2\theta_\infty - 1)\lambda - 2\kappa_0^2\lambda^{-1} \\ &\quad + \text{function of } t \text{ only}.\end{aligned} \tag{61}$$

Substituting $\lambda = (q/2)^2$ gives the potential $V(q)$ modulo an irrelevant term. Q.E.D.

F. Canonical transformations for P_{III}

The situation of P_{III} is somewhat similar to P_V.

Let λ, again, be a solution of $\mathrm{P}_{\mathrm{III}}$, λ the canonical conjuage variable, and q be the corresponding solution of (30). The canonical equation for λ takes the form

$$\frac{d\lambda}{dt} = \frac{\lambda^2}{t}\left(2\mu - \eta_\infty - \frac{\theta_0}{\lambda} + \frac{\eta_0 t}{\lambda^2}\right),$$

which can be solved for μ as

$$\mu = \frac{t}{2\lambda^2}\frac{d\lambda}{dt} + \frac{1}{2}\left(\eta_\infty + \frac{\theta_0}{\lambda} - \frac{\eta_0 t}{\lambda^2}\right).$$

By differentiating (28) and using the canonical equation $t\,dq/dt = \partial\mathcal{H}/\partial p = p$, the t-derivative of λ can be written as

$$t\frac{d\lambda}{dt} = \lambda p,$$

so that we obtain

$$\mu = \frac{p}{2\lambda} + \frac{1}{2}\left(\eta_\infty + \frac{\theta_0}{\lambda} - \frac{\eta_0 t}{\lambda^2}\right). \tag{62}$$

This relation, again, can be used to define a canonical transformation.

Theorem 5: *(28) and (62) define a canonical transformation that connects* $\mathrm{P}_{\mathrm{III}}$ *and the* $\mathrm{P}_{\mathrm{III}}$*-version of Manin's Hamiltonian system. The canonical coordinates and the Hamiltonians of the two systems obey the equation*

$$\mu\,d\lambda - H dt = \frac{1}{2}\left(p\,dq - \mathcal{H}\frac{dt}{t}\right) + \text{exact form}. \tag{63}$$

Proof: Since $d\lambda$ and dq are connected by the relation

$$d\lambda = \lambda\,dq,$$

$\mu\,d\lambda$ can be written as

$$\begin{aligned}\mu\,d\lambda &= \frac{1}{2}p\,dq + \frac{1}{2}\left(\eta_\infty + \frac{\theta_0}{\lambda} - \frac{\eta_0 t}{\lambda^2}\right)d\lambda \\ &= \frac{1}{2}p\,dq - \frac{\eta_0}{2\lambda}dt + \frac{1}{2}d\left(\eta_\infty\lambda + \theta_0\log\lambda + \frac{\eta_0 t}{\lambda}\right),\end{aligned}$$

so that

$$\mu\,d\lambda - H\,dt = \frac{1}{2}\left(p\,dq - \tilde{\mathcal{H}}\frac{dt}{t}\right) + \text{exact form}, \tag{64}$$

where

$$\tilde{\mathcal{H}} = 2Ht + \frac{\eta_0 t}{\lambda}. \tag{65}$$

We can convert the transformed Hamiltonian $\tilde{\mathcal{H}}$ to a normal form as

$$\tilde{\mathcal{H}}=2\lambda^2\left[\mu-\frac{1}{2}\left(\eta_\infty+\frac{\eta_0}{\lambda}-\frac{\eta_0 t}{\lambda^2}\right)\right]^2$$
$$+2\lambda^2\left[-\frac{1}{2}\left(\eta_\infty+\frac{\eta_0}{\lambda}-\frac{\eta_0 t}{\lambda^2}\right)^2+\frac{\eta_\infty(\theta_0+\theta_\infty)}{2\lambda}\right]+\frac{\eta_0 t}{\lambda}$$
$$=\frac{p^2}{2}+\tilde{V}(q), \tag{66}$$

where

$$\tilde{V}(q)=-\frac{\lambda^2}{2}\left(\eta_\infty+\frac{\theta_0}{\lambda}-\frac{\eta_0 t}{\lambda^2}\right)^2+\eta_\infty(\theta_0+\theta_\infty)\lambda+\frac{\eta_0 t}{\lambda}$$
$$=\eta_\infty\theta_\infty e^q+\eta_0(\theta_0+1)te^{-q}-\frac{\eta_\infty^2}{2}e^{2q}-\frac{\eta_0^2 t^2}{2}e^{-2q}$$
$$+\text{function of } t \text{ only}. \tag{67}$$

Thus, apart from the last irrelevant term, $\tilde{V}(q)$ coincides with the potential $V(q)$ in the statement of the theorem. Q.E.D.

G. Status of P_{II} and P_I

Let us turn to P_{II} and P_I. The Hamiltonian of P_I is already of the normal form $\mathcal{H}=p^2/2+V(q)$ with $\lambda=q$, $\mu=p$ and $H=\mathcal{H}$. Although this is not the case for P_{II}, one can directly find a canonical transformation that converts the Hamiltonian H to a normal form.

Theorem 6: *A* P_{II}*-version of Manin's Hamiltonian system is defined by the Hamiltonian*

$$\mathcal{H}=\frac{p^2}{2}-\frac{1}{2}\left(q^2+\frac{t}{2}\right)^2-\alpha q. \tag{68}$$

This system is connected with P_{II} *by the canonical transformation,*

$$\lambda=q, \quad \mu=p+\lambda^2+\frac{t}{2}. \tag{69}$$

The canonical coordinates and the Hamiltonians of the two systems obey the equation

$$\mu\, d\lambda-H\, dt=p\, dq-\mathcal{H}\, dt+\text{exact form}. \tag{70}$$

Proof: The foregoing relation between (λ,μ) and (q,p) implies that

$$\mu\, d\lambda=p\, dq+\left(\lambda^2+\frac{t}{2}\right)d\lambda=p\, dq-\frac{\lambda}{2}dt+d\left(\frac{\lambda^3}{3}+\frac{t\lambda}{2}\right),$$

so that

$$\mu\, d\lambda-H\, dt=p\, dq-\tilde{\mathcal{H}}\, dt+\text{exact form}, \tag{71}$$

where

$$\begin{aligned}\widetilde{\mathcal{H}} &= H + \frac{\lambda}{2} \\ &= \frac{1}{2}\left[\mu - \left(\lambda^2 + \frac{t}{2}\right)\right]^2 - \frac{1}{2}\left(\lambda^2 + \frac{t}{2}\right)^2 - \left(\alpha + \frac{1}{2}\right)\lambda + \frac{\lambda}{2} \\ &= \frac{p^2}{2} - \frac{1}{2}\left(q^2 + \frac{t}{2}\right)^2 - \alpha q. \end{aligned} \tag{72}$$

This is nothing but the Hamiltonian in the statement of the theorem. Q.E.D.

V. MULTI-COMPONENT PAINLEVÉ EQUATIONS

A. Inozemtsev Hamiltonians of higher rank

The rank l version of Inozemtsev's Hamiltonians have l coordinates $q_1,\dots,q_l$ and canonical conjugate momenta $p_1,\dots,p_l$. The Hamiltonians of the elliptic, hyperbolic and rational models take the following form:[10,11,14]

- Elliptic model:

$$\mathcal{H} = \sum_{j=1}^{l}\left(\frac{p_j^2}{2} + \sum_{n=0}^{3} g_n^2 \wp(q_j + \omega_n)\right) + g_4^2 \sum_{j\neq k} (\wp(q_j - q_k) + \wp(q_j + q_k)).$$

- Hyperbolic model:

$$\begin{aligned}\mathcal{H} = \sum_{j=1}^{l}&\left(\frac{p_j^2}{2} + \frac{g_0^2}{\sinh^2(q_j/2)} + \frac{g_1^2}{\cosh^2(q_j/2)} + g_2^2\cosh(q_j) + g_3^2\cosh(2q_j)\right) \\ &+ g_4^2 \sum_{j\neq k}\left(\frac{1}{\sinh^2((q_j - q_k)/2)} + \frac{1}{\sinh^2((q_j + q_k)/2)}\right).\end{aligned}$$

- Rational model:

$$\mathcal{H} = \sum_{j=1}^{l}\left(\frac{p_j^2}{2} + g_0^2 q_j^6 + g_1^2 q_j^4 + g_2^2 q_j^2 + g_3^2 q_j^{-2}\right) + g_4^2 \sum_{j\neq k}\left(\frac{1}{(q_j - q_k)^2} + \frac{1}{(q_j + q_k)^2}\right).$$

Here g_0, g_1, g_2, g_3 and g_4 are coupling constants. The Painlevé–Calogero correspondence for P_{III}, P_{II} and P_I suggests the existence of further degeneration of these models.

Our goal in this section is to extend the Painlevé–Calogero correspondence to these higher rank models. Since a complete exposition will become inevitably lengthy, we shall illustrate the elliptic and hyperbolic models in detail, leaving the other cases rather sketchy. The strategy is as follows: The point of departure is the Hamiltonian of Inozemtsev's rank l elliptic model. This gives rise to a rank l version of Manin's equation. Starting with this nonautonomous Hamiltonian system, we seek an analog of the degeneration process for the Painlevé equations. We can thus obtain six types of nonautonomous Hamiltonian systems. At each stage of the degeneration process, we confirm that the nonautonomous Hamiltonian system on the Calogero side can be mapped, by a canonical transformation, to a multicomponent analog of the Painlevé equation of the corresponding type.

B. Elliptic model and multi-component P_{VI}

We now consider the nonautonomous Hamiltonian system,

$$2\pi i \frac{dq_j}{d\tau} = \frac{\partial \mathcal{H}}{\partial p_j}, \quad 2\pi i \frac{dp_j}{d\tau} = -\frac{\partial \mathcal{H}}{\partial q_j}, \tag{73}$$

defined by the Hamiltonian of Inozemtsev's elliptic model. This is a rank l version of Manin's equation. This nonautonomous system is known to describe a family of isomonodromic deformations on the torus.[18]

An honest generalization of the canonical transformation for the case of $l=1$ leads to a multi-component version of P_{VI} as follows.

Theorem 7: *The time-dependent canonical transformation defined by*

$$\lambda_j=\frac{\wp(q_j)-e_1}{e_2-e_1},$$

$$\mu_j=\frac{e_2-e_1}{\wp'(q)}p_j+\frac{2\pi i(e_2-e_1)^2}{\wp'(q_j)^2}f_\tau(q_j)+\frac{e_2-e_1}{2}\left(\frac{\kappa_0}{\wp(q_j)-e_1}+\frac{\kappa_1}{\wp(q_j)-e_2}+\frac{\theta-1}{\wp(q_j)-e_3}\right), \tag{74}$$

and

$$t=\frac{e_3-e_1}{e_2-e_1}. \tag{75}$$

maps (73) to the Hamiltonian system,

$$\frac{d\lambda_j}{dt}=\frac{\partial H}{\partial\mu_j},\quad \frac{d\mu_j}{dt}=-\frac{\partial H}{\partial\lambda_j}, \tag{76}$$

with the Hamiltonian

$$H=\sum_{j=1}^{l}\frac{\lambda_j(\lambda_j-1)(\lambda_j-t)}{t(t-1)}\left[\mu_j^2-\left(\frac{\kappa_0}{\lambda_j}+\frac{\kappa_1}{\lambda_j-1}+\frac{\theta-1}{\lambda_j-t}\right)\mu_j+\frac{\kappa}{\lambda_j(\lambda_j-1)}\right]+\frac{g_4^2}{2t(t-1)}\sum_{j\neq k}\left[\frac{\lambda_j(\lambda_j-1)(\lambda_j-t)+\lambda_k(\lambda_k-1)(\lambda_k-t)}{8(\lambda_j-\lambda_k)^2}-2(\lambda_j+\lambda_k)\right]. \tag{77}$$

Proof: The method of proof for the case of $l=1$ can be applied to the present case as well, yielding the equality

$$\sum_{j=1}^{l}p_j\,dq_j-\mathcal{H}\frac{d\tau}{2\pi i}=\sum_{j=1}^{l}\mu_j\,d\lambda_j-\tilde{H}\,dt+\text{exact form}, \tag{78}$$

where

$$\tilde{H}=\sum_{j=1}^{l}\frac{\lambda_j(\lambda_j-1)(\lambda_j-t)}{t(t-1)}\left[\mu_j^2-\left(\frac{\kappa_0}{\lambda_j}+\frac{\kappa_1}{\lambda_j-1}+\frac{\theta-1}{\lambda_j-t}\right)\mu_j+\frac{\kappa}{\lambda_j(\lambda_j-1)}\right]+\frac{g_4^2}{2t(t-1)(e_2-e_1)}\sum_{j\neq k}(\wp(q_j-q_k)+\wp(q_j+q_k)). \tag{79}$$

What remains is to express the ''two-body potential'' part in terms of λ_j. To this end, let us recall the addition formula,

$$\wp(u-v)+\wp(u+v)=-2\wp(u)-2\wp(v)+\frac{\wp'(u)^2+\wp'(v)^2}{2(\wp(u)-\wp(v))^2}, \tag{80}$$

of the $\wp$-function. Applying it to the case where $(u,v)=(\lambda_j,\lambda_k)$, and substituting

$$\wp(q_j)=e_1+(e_2-e_1)\lambda_j,$$

$$\wp(q_k)=e_1+(e_2-e_1)\lambda_k,$$

$$\wp'(q_j)^2=\frac{(e_2-e_1)^3}{4}\lambda_j(\lambda_j-1)(\lambda_j-t),$$

$$\wp'(q_k)^2=\frac{(e_2-e_1)^3}{4}\lambda_k(\lambda_k-1)(\lambda_k-t),$$

we can rewrite the two-body potential terms as

$$\begin{aligned}\wp(q_j-q_k)+\wp(q_j+q_k)&=-2(e_1+(e_2-e_1)\lambda_j)-2(e_1+(e_2-e_1)\lambda_k)\\&\quad+\frac{(e_2-e_1)^3}{8}\cdot\frac{\lambda_j(\lambda_j-1)(\lambda_j-t)+\lambda_k(\lambda_k-1)(\lambda_k-t)}{(e_1+(e_2-e_1)\lambda_j-e_1-(e_2-e_1)\lambda_k)^2}\\&=-4e_1-2(e_2-e_1)(\lambda_j+\lambda_k)\\&\quad+\frac{e_2-e_1}{8}\cdot\frac{\lambda_j(\lambda_j-1)(\lambda_j-t)+\lambda_k(\lambda_k-1)(\lambda_k-t)}{(\lambda_j-\lambda_k)^2}.\end{aligned}\tag{81}$$

The first term $-4e_1$ is nondynamical, thereby negligible (i.e., can be absorbed by the ''exact form'' part). Removing these terms from $\tilde{H}$, we obtain the Hamiltonian H. Q.E.D.

C. Degeneration of elliptic model to hyperbolic model

The degeneration of the elliptic model is achieved by letting Im $\tau\to+\infty$. Like the degeneration process from P_{VI} to P_V, this is a kind of scaling limit, namely, the coupling constants g_n and the elliptic modulus τ have to be suitably rescaled. To this end, we have to understand the asymptotic behavior of the constants e_1, e_2, e_3 and the $\wp$-function in the limit as Im $\tau\to+\infty$. All necessary data are collected in Appendix B. For instance, the asymptotic expression of e_1, e_2 and e_3 imply that

$$t=1+\frac{e_3-e_2}{e_2-e_1}=1+16\pi^2e^{\pi i\tau}+O(e^{2\pi i\tau}).\tag{82}$$

This is indeed consistent with the scaling rule $t=1+\epsilon\tilde{t}$ in the degeneration process of P_{VI} to P_V.

Having these data, we now rescale the coupling constants and the elliptic modulus as

$$g_0^2=\tilde{g}_0^2,\quad g_1^2=\tilde{g}_1^2,\quad g_2^2=\frac{\tilde{g}_2^2}{\epsilon}+\frac{\tilde{g}_3^2}{\epsilon^2},\quad g_3^3=\frac{\tilde{g}_3^2}{\epsilon^2},\quad g_4^2=\tilde{g}_4^2,\tag{83}$$

and

$$16e^{\pi i\tau}=\epsilon\tilde{t},\tag{84}$$

and consider the limit as $\epsilon\to0$ while leaving $\tilde{g}_n$ and $\tilde{t}$ finite. Note that letting $\epsilon\to0$ amounts to letting Im $\tau\to+\infty$.

The asymptotic expression of $\wp(u)$ and $\wp(u+\omega_n)$ in Appendix B shows that the potential $V(q)$ of the elliptic model behaves as

$$V(q)=\sum_{j=1}^{l}\left(\frac{\tilde{g}_0^2\pi^2}{\sin^2(\pi q_j)}+\frac{\tilde{g}_1^2\pi^2}{\cos^2(\pi q_j)}+\frac{\tilde{g}_2^2\pi^2\tilde{t}}{2}\cos(2\pi q_j)-\frac{\tilde{g}_3^2\pi^2\tilde{t}^2}{8}\cos(4\pi q_j)\right)$$
$$+\tilde{g}_4^2\sum_{j\neq k}\left(\frac{1}{\sin^2(\pi(q_j-q_k))}+\frac{1}{\sin^2(\pi(q_j+q_k))}\right)$$
$$+\text{function of }\epsilon\text{ and }\tilde{t}\text{ only}+O(\epsilon).$$

Thus, removing negligible terms, we obtain the following Hamiltonian in the limit

$$\tilde{\mathcal{H}}=\sum_{j=1}^{l}\left(\frac{p_j^2}{2}+\frac{\tilde{g}_0^2\pi^2}{\sin^2(\pi q_j)}+\frac{\tilde{g}_1^2\pi^2}{\cos^2(\pi q_j)}+\frac{\tilde{g}_2^2\pi^2\tilde{t}}{2}\cos(2\pi q_j)-\frac{\tilde{g}_3^2\pi^2\tilde{t}^2}{8}\cos(4\pi q_j)\right)$$
$$+\tilde{g}_4^2\sum_{j\neq k}\left(\frac{1}{\sin^2(\pi(q_j-q_k))}+\frac{1}{\sin^2(\pi(q_j+q_k))}\right).\tag{85}$$

The asymptotic expression of t determines the equation of motion in the limit. In fact, since

$$\frac{d\tau}{dt}=\frac{\pi}{t(t-1)(e_2-e_1)}=\frac{\pi i}{(1+\epsilon\tilde{t})(-\epsilon\tilde{t})(-\pi^2+O(\epsilon))}$$

and

$$2\pi i\frac{d}{d\tau}=2\pi i\frac{dt}{d\tau}\frac{d\tilde{t}}{dt}\frac{d}{dt}=(2\pi^2\tilde{t}+O(\epsilon^2))\frac{d}{dt},$$

we find that the equations of motion take the following form:

$$2\pi^2\tilde{t}\frac{dq_j}{d\tilde{t}}=\frac{\partial\tilde{\mathcal{H}}}{\partial p_j},\quad 2\pi^2\tilde{t}\frac{dp_j}{d\tilde{t}}=-\frac{\partial\tilde{\mathcal{H}}}{\partial q_j}.\tag{86}$$

The final step is to rescale the variables and the Hamiltonian as

$$q_j\to\frac{q_j}{2\pi i},\quad p_j\to\pi i q_j,\quad \tilde{\mathcal{H}}\to-\pi^2\tilde{\mathcal{H}},\tag{87}$$

and to rename $\tilde{t}$ and $\tilde{\mathcal{H}}$ to t and $\mathcal{H}$. Let us also define the new constants

$$\alpha=-\frac{\tilde{g}_0^2}{2},\quad \beta=\frac{\tilde{g}_1^2}{2},\quad \gamma=-\frac{\tilde{g}_2^2}{2},\quad \delta=\frac{\tilde{g}_3^2}{2},\tag{88}$$

which are to be identified with the four parameters of P_V. The outcome is the nonautonomous Hamiltonian system

$$t\frac{dq_j}{dt}=\frac{\partial\mathcal{H}}{\partial p_j},\quad t\frac{dp_j}{dt}=-\frac{\partial\mathcal{H}}{\partial q_j},\tag{89}$$

with the Hamiltonian

$$\mathcal{H}=\sum_{j=1}^{l}\left(\frac{p_j^2}{2}-\frac{\alpha}{\sinh^2(q_j/2)}-\frac{\beta}{\cosh^2(q_j/2)}+\frac{\gamma t}{2}\cosh(q_j)+\frac{\delta t^2}{8}\cosh(2q_j)\right)$$
$$+g_4^2\sum_{j\neq k}\left(\frac{1}{\sinh^2((q_j-q_k)/2)}+\frac{1}{\sinh^2((q_j+q_k)/2)}\right). \tag{90}$$

This gives a rank l version of the nonautonomous Hamiltonian system on the Calogero side of P_V. Note that the Hamiltonian is essentially the same as the Hamiltonian of Inozemtsev's hyperbolic model, except that the effective coupling constants are now time-dependent.

Remark: The foregoing prescription of scaling limit of the coupling constants and the elliptic modulus is reminiscent of ''renormalization'' in quantum field theories. In this analogy, one can interpret the equations of motion of the Hamiltonian system as ''renormalization group equations,'' in which $\tilde{t}$ plays the role of a ''mass scale'' parameter.

D. Canonical transformation to multi-component P_V

Again, an honest generalization of the canonical transformation for the case of $l=1$ leads to a multi-component version of P_V.

Theorem 8: *The time-dependent canonical transformation defined by*

$$\sqrt{\lambda_j}=-\coth(q_j/2),$$
$$\mu_j=\frac{p_j}{2\sqrt{\lambda_j}(\lambda_j-1)}+\frac{1}{2}\left(\frac{\kappa_0}{\lambda_j}+\frac{\theta_1}{\lambda_j-1}-\frac{\eta_1 t}{(\lambda_j-1)^2}\right), \tag{91}$$

maps (89) to the Hamiltonian system,

$$\frac{d\lambda_j}{dt}=\frac{\partial H}{\partial\mu_j},\quad \frac{d\mu_j}{dt}=-\frac{\partial H}{\partial\lambda_j}, \tag{92}$$

with the Hamiltonian

$$H=\sum_{j=1}^{l}\frac{\lambda_j(\lambda_j-1)^2}{t}\left[\mu_j^2-\left(\frac{\kappa_0}{\lambda_j}+\frac{\theta_1}{\lambda_j-1}-\frac{\eta_1 t}{(\lambda_j-1)^2}\right)\mu_j+\frac{\kappa}{\lambda_j(\lambda_j-1)}\right]$$
$$+\frac{g_4^2}{2t}\sum_{j\neq k}\frac{2(\lambda_j-1)(\lambda_k-1)(\lambda_j+\lambda_k)}{(\lambda_j-\lambda_k)^2}. \tag{93}$$

Proof: The method of proof for the case of $l=1$ can be used as it is. The outcome is the equality

$$\sum_{j=1}^{l}p_j\,dq_j-\mathcal{H}\frac{dt}{t}=2\left(\sum_{j=1}^{l}\mu_j\,d\lambda_j-H\,dt\right)+\text{exact form}, \tag{94}$$

where

$$H=\sum_{j=1}^{l}\frac{\lambda_j(\lambda_j-1)^2}{t}\left[\mu_j^2-\left(\frac{\kappa_0}{\lambda_j}+\frac{\theta_1}{\lambda_j-1}-\frac{\eta_1 t}{(\lambda_j-1)^2}\right)\mu_j+\frac{\kappa}{\lambda_j(\lambda_j-1)}\right]$$
$$+\frac{g_4^2}{2t}\sum_{j\neq k}\left(\frac{1}{\sinh^2((q_j-q_k)/2)}+\frac{1}{\sinh^2((q_j+q_k)/2)}\right). \tag{95}$$

The two-body potential part can be rewritten by use of the identity

$$\frac{1}{\sinh^2(u-v)}+\frac{1}{\sinh^2(u+v)}=4\frac{\cosh(2u)\cosh(2v)-1}{(\cosh(2u)-\cosh(2v))^2}. \tag{96}$$

Substituting $u=q_j/2$, $v=q_k/2$, and also using the equality $\cosh(q_j)=(\lambda_j+1)/(\lambda_j-1)$, we find that

$$\frac{1}{\sinh^2((q_j-q_k)/2)}+\frac{1}{\sinh^2((q_j+q_k)/2)}=\frac{2(\lambda_j-1)(\lambda_k-1)(\lambda_j+\lambda_k)}{(\lambda_j-\lambda_k)^2}, \tag{97}$$

which gives the two-body potential term in H. Q.E.D.

E. Other models

The degeneration process can be further continued, and leads to four more models that correspond to a multi-component version of P_{IV}, P_{III}, P_{II} and P_I. Since the details of derivation are more or less parallel, we show the final results only. The Hamiltonian of each model, like those in the foregoing cases, becomes a sum of l copies of the one-component Hamiltonian and Calogero-like two-body potential terms.

1. Rational model and multi-component P_{IV}

This model can be derived from the hyperbolic model by degeneration. The degeneration process consists of putting the variables and the parameters as

$$t=1+2\epsilon\tilde{t}, \quad q_j=\pi i+\epsilon^{1/2}\tilde{q_j}, \quad p_j=\frac{\tilde{p_j}}{2\epsilon^{1/2}}, \tag{98}$$

and

$$\alpha=\frac{1}{8\epsilon^4}, \quad \beta=\frac{\tilde{\beta}}{4}, \quad \gamma=\frac{1}{4\epsilon^4}, \quad \delta=-\frac{1}{8\epsilon^4}+\frac{\tilde{\alpha}}{2\epsilon^2}, \tag{99}$$

and letting $\epsilon\to 0$ while leaving the ''renormalized'' quantities $\tilde{t}$, etc. finite.

The equations of motion of this model takes the canonical form

$$\frac{dq_j}{dt}=\frac{\partial\mathcal{H}}{\partial p_j}, \quad \frac{dp_j}{dt}=-\frac{\partial\mathcal{H}}{\partial q_j}, \tag{100}$$

with the Hamiltonian

$$\mathcal{H}=\sum_{j=1}^{l}\left[\frac{p_j^2}{2}-\frac{1}{2}\left(\frac{q_j}{2}\right)^6-2t\left(\frac{q_j}{2}\right)^4-2(t^2-\alpha)\left(\frac{q_j}{2}\right)^2+\beta\left(\frac{q_j}{2}\right)^{-2}\right]$$
$$+g_4^2\sum_{j\neq k}\left(\frac{1}{(q_j-q_k)^2}+\frac{1}{(q_j+q_k)^2}\right). \tag{101}$$

The canonical transformation defined by

$$\lambda_j=\left(\frac{q_j}{2}\right)^2, \quad \mu_j=\frac{p_j}{4\sqrt{\lambda_j}}+\frac{1}{4}\left(\lambda_j+2t+\frac{2\kappa_0}{\lambda_j}\right), \tag{102}$$

maps the foregoing nonautonomous system to the Hamiltonian system,

$$\frac{d\lambda_j}{dt}=\frac{\partial H}{\partial\mu_j}, \quad \frac{d\mu_j}{dt}=-\frac{\partial H}{\partial\lambda_j}, \tag{103}$$

with the Hamiltonian

$$H=\sum_{j=1}^{l} 2\lambda_j^2\left[\mu_j^2-\left(\frac{\lambda_j}{2}+t+\frac{\kappa_0}{\lambda}\right)\mu_j+\frac{\theta_0}{2}\right]+\frac{g_4^2}{4}\sum_{j\neq k}\frac{2(\lambda_j+\lambda_k)}{(\lambda_j-\lambda_k)^2}. \tag{104}$$

2. Exponential-hyperbolic model and multi-component $\mathrm{P_{III}}$

This model, too, can be derived from the hyperbolic model by degeneration. This degeneration is achieved by the putting the variables and the parameters as

$$q_j=-\tilde{q}_j-\log\frac{\epsilon}{4},\quad p_j=-\tilde{p}_j, \tag{105}$$

and

$$\alpha=\frac{\tilde{\alpha}}{4\epsilon}+\frac{\tilde{\gamma}}{8\epsilon^2},\quad \beta=-\frac{\tilde{\gamma}}{8\epsilon^2},\quad \gamma=\frac{\tilde{\beta}\epsilon}{4},\quad \delta=\frac{\tilde{\delta}\epsilon^2}{8}, \tag{106}$$

and letting $\epsilon\to 0$.

The equations of motion of this model takes the canonical form

$$t\frac{dq_j}{dt}=\frac{\partial\mathcal{H}}{\partial p_j},\quad t\frac{dp_j}{dt}=-\frac{\partial\mathcal{H}}{\partial q_j}, \tag{107}$$

with the Hamiltonian

$$\mathcal{H}=\sum_{j=1}^{l}\left(\frac{p_j^2}{2}-\frac{\alpha}{4}e^{q_j}+\frac{\beta t}{4}e^{-q_j}-\frac{\gamma}{8}e^{2q_j}+\frac{\delta t^2}{8}e^{-2q_j}\right)$$
$$+g_4^2\sum_{j\neq k}\frac{1}{\sinh^2((q_j-q_k)/2)}. \tag{108}$$

The canonical transformation defined by

$$\lambda_j=e^{q_j},\quad \mu_j=\frac{p_j}{2\lambda_j}+\frac{1}{2}\left(\eta_\infty+\frac{\theta_0}{\lambda_j}-\frac{\eta_0 t}{\lambda_j^2}\right), \tag{109}$$

maps the foregoing nonautonomous system to the Hamiltonian system,

$$\frac{d\lambda_j}{dt}=\frac{\partial H}{\partial\mu_j},\quad \frac{d\mu_j}{dt}=-\frac{\partial H}{\partial\lambda_j}, \tag{110}$$

with the Hamiltonian

$$H=\sum_{j=1}^{l}\frac{\lambda_j^2}{t}\left[\mu_j^2-\left(\eta_\infty+\frac{\theta_0}{\lambda_j}-\frac{\eta_0 t}{\lambda_j^2}\right)\mu_j+\frac{\eta_\infty(\theta_0+\theta_\infty)}{2\lambda_j}\right]+\frac{g_4^2}{2t}\sum_{j\neq k}\frac{4\lambda_j\lambda_k}{(\lambda_j-\lambda_k)^2}. \tag{111}$$

3. Second rational model and multi-component $\mathrm{P_{II}}$

This model can be derived from *both* the rational model and the exponential-hyperbolic model by degeneration. For the degeneration from the rational model, we write the variables and the parameters as

$$t=\frac{-1+4^{-1/3}\epsilon^4\tilde{t}}{\epsilon},\quad \frac{q_j}{2}=\frac{1+2^{-1/3}\epsilon^2\tilde{q}_j}{\epsilon^{3/2}},\quad p_j=\frac{4^{2/3}\tilde{p}_j}{\epsilon^{1/2}},\tag{112}$$

and

$$\alpha=-2\tilde{\alpha}-\frac{1}{2\epsilon^6},\quad \beta=-\frac{1}{2\epsilon^{12}},\tag{113}$$

and let $\epsilon\to 0$. The degeneration from the exponential-hyperbolic model is similarly achieved by putting

$$t=1+2\epsilon^2\tilde{t},\quad q_j=2\epsilon\tilde{q}_j,\quad p_j=\frac{\tilde{p}_j}{\epsilon},\tag{114}$$

and

$$\alpha=-\frac{1}{2\epsilon^6},\quad \beta=\frac{1+4\epsilon^3\tilde{\alpha}}{2\epsilon^6},\quad \gamma=\frac{1}{4\epsilon^6},\quad \delta=-\frac{1}{4\epsilon^6},\tag{115}$$

and again letting $\epsilon\to 0$.

The equations of motion of this model takes the canonical form

$$\frac{dq_j}{dt}=\frac{\partial\mathcal{H}}{\partial p_j},\quad \frac{dp_j}{dt}=-\frac{\partial\mathcal{H}}{\partial q_j},\tag{116}$$

with the Hamiltonian

$$\mathcal{H}=\sum_{j=1}^{l}\left[\frac{p_j^2}{2}-\frac{1}{2}\left(q_j^2+\frac{t}{2}\right)^2-\alpha q_j\right]+g_4^2\sum_{j\neq k}\frac{1}{(q_j-q_k)^2}.\tag{117}$$

The canonical transformation defined by

$$\lambda_j=q_j,\quad \mu_j=p_j+\lambda_j^2+\frac{t}{2},\tag{118}$$

maps the foregoing nonautonomous system to the Hamiltonian system,

$$\frac{d\lambda_j}{dt}=\frac{\partial H}{\partial\mu_j},\quad \frac{d\mu_j}{dt}=-\frac{\partial H}{\partial\lambda_j},\tag{119}$$

with the Hamiltonian

$$H=\sum_{j=1}^{l}\left[\frac{\mu_j^2}{2}-\left(\lambda_j^2+\frac{t}{2}\right)\mu_j-\left(\alpha+\frac{1}{2}\right)\lambda_j\right]+g_4^2\sum_{j\neq k}\frac{1}{(\lambda_j-\lambda_k)^2}.\tag{120}$$

4. Multi-component $\mathrm{P_I}$

This model can be derived from the second rational model, and takes the *same* form on both the Painlevé and Calogero sides. The degeneration process is achieved by putting

$$t=\frac{-6+\epsilon^{12}\tilde{t}}{\epsilon^{10}},\quad q_j=\frac{1+\epsilon^6\tilde{q}_j}{\epsilon^5},\quad p_j=\frac{\tilde{p}_j}{\epsilon},\quad \alpha=4\epsilon^{15},\tag{121}$$

and letting $\epsilon\to 0$. The equations of motion takes the canonical form

$$\frac{dq_j}{dt}=\frac{\partial H}{\partial p_j},\quad \frac{dp_j}{dt}=-\frac{\partial H}{\partial q_j}, \tag{122}$$

with the Hamiltonian

$$H=\sum_{j=1}^{l}\left(\frac{p_j^2}{2}-2q_j^3-tq_j\right)+g_4^2\sum_{j\neq k}\frac{1}{(q_j-q_k)^2}. \tag{123}$$

VI. CONCLUDING REMARKS

We have shown that the Painlevé–Calogero correspondence persists for all the six Painlevé equations and their multi-component generalizations. The Calogero side of this correspondence is a nonautonomous version of Inozemtsev's elliptic model and its various degenerations. Those for P_V and P_{IV} are a nonautonomous version of Inozemtsev's hyperbolic and rational models. The others corresponding to P_{III}, P_{II} and P_I are further degenerations of the hyperbolic and rational models. The pattern of degeneration on the Calogero side repeats the degeneration diagram,

$$\begin{array}{ccccc} P_{VI} & \rightarrow & P_V & \rightarrow & P_{IV} \\ & & \downarrow & & \downarrow \\ & & P_{III} & \rightarrow & P_{II} \quad \rightarrow \quad P_I \end{array}$$

of the Painlevé equations.

This picture applies to the autonomous systems as well. Actually, such degeneration relations in the autonomous case have been more or less well known to experts of Calogero–Moser systems (see the Introduction of van Diejen's paper[16]). The autonomous systems are defined by a Hamiltonian of the same form with the time-dependent coupling constants being replaced by absolute constants (except for the elliptic model, in which case an independent time variable is introduced). Those in the position of the first row of the degeneration diagram are, of course, Inozemtsev's elliptic, hyperbolic and rational models (see Sec. V). Those in the position of P_{III} and P_{II} are defined by the following Hamiltonians:

- Exponential-hyperbolic model:
$$\mathcal{H}=\sum_{j=1}^{l}\left(\frac{p_j^2}{2}+g_0^2e^{q_j}+g_1^2e^{2q_j}+g_2^2e^{-q_j}+g_3^2e^{-2q_j}\right)+g_4^2\sum_{j\neq k}\frac{1}{\sinh^2((q_j-q_k)/2)}.$$
- Second rational model:
$$\mathcal{H}=\sum_{j=1}^{l}\left(\frac{p_j^2}{2}+g_0^2q_j^4+g_1^2q_j^3+g_2^2q_j^2+g_3^2q_j\right)+g_4^2\sum_{j\neq k}\frac{1}{(q_j-q_k)^2}.$$

The Hamiltonian in the position of P_I is redundant in the automonous case, because it is a specialization, rather than a degeneration, of the last Hamiltonian.

Note that the Hamiltonian of the second rational model is a *quartic* perturbation of the usual (A_l type) rational Calogero Hamiltonian. According to the recent work of Caseiro, Françoise and Sasaki,[19] such a quartic (integrable) perturbation always exists for any rational Calogero–Moser system. Inozemtsev's rational model, which is a *sextic* perturbation of the D_l type rational Calogero–Moser system, might admit a similar interpretation.

Back to the Painlevé equations, the extended Painlevé–Calogero correspondence raises many interesting problems. A central issue will be to find an isomonodromic description of the multi-component Painlevé equations. If such an isomonodromic description does exist, it should be related to a new geometric structure.

APPENDIX A: PROOF OF (42)

Let us introduce the two auxiliary functions:

$$g(u)=\frac{f_\tau(u)}{f'(u)},\quad h(u)=\frac{\vartheta'(u+\omega_1)}{\vartheta(u+\omega_1)}, \tag{A1}$$

associated with the function

$$f(u)=\frac{\wp(u)-e_1}{e_2-e_1} \tag{A2}$$

and the standard elliptic theta function,

$$\vartheta(u)=\sum_{n=-\infty}^{\infty}\exp(\pi i\tau n^2+2\pi i n u). \tag{A3}$$

Lemma 1: $g(u)$ *is a meromorphic function on the* u*-plane with additive quasi-periodicity,*

$$g(u+1)=g(u),\quad g(u+\tau)=g(u)-1. \tag{A4}$$

All poles are of the first order and contained in the lattice $\omega_3+\mathbb{Z}+\tau\mathbb{Z}$*. Furthermore,* $g(u)$ *has zeros at* $u=0$ *and* $u=\omega_1$.

Proof: Since $f(u)$ is a doubly periodic function with primitive periods 1 and τ, $f'(u)$ and $f_\tau(u)$ transform as

$$f'(u+1)=f'(u),\quad f'(u+\tau)=f'(u),$$

$$f_\tau(u+1)=f_\tau(u),\quad f_\tau(u+\tau)=f_\tau(u)-f'(u),$$

under the shift by 1 and τ. This implies the additive quasi-periodicity of $g(u)$. Furthermore, by the construction, $g(u)$ is a meromorphic function on the u-plane, and all possible poles are of the first order and located at the points of $\omega_k+\mathbb{Z}+\tau\mathbb{Z}$. Let us examine the behavior of $g(u)$ at the representative points $u=\omega_0,\omega_1,-\omega_2,\omega_3$:

- As $u\to\omega_0=0$,

$$f(u)=\frac{1}{(e_2-e_1)u^2}+O(1),$$

thereby

$$f'(u)=-\frac{2}{(e_2-e_1)u^3}+O(1),\quad f_\tau(u)=-\frac{e_{2,\tau}-e_{1,\tau}}{(e_2-e_1)^2u^2}+O(1),$$

so that $g(u)$ has rather a zero at $u=0$:

$$g(u)=O(u). \tag{A5}$$

- As $u\to\omega_1=\frac{1}{2}$,

$$f(u)=\frac{1}{e_2-e_1}(\wp(\omega_1)-e_1+\wp'(\omega_1)(u-\omega_1)+O((u-\omega_1)^2))$$

$$= O((u-\omega_1)^2),$$

thereby

$$f'(u) = O(u-\omega_1), \quad f_\tau(u) = O((u-\omega_1)^2),$$

so that $g(u)$ has another zero at $u=\omega_1$:

$$g(u) = O(u-\omega_1). \tag{A6}$$

- As $u \to -\omega_2 = \frac{1}{2} + \tau/2$,

$$f(u) = \frac{1}{e_2-e_1}(\wp(-\omega_2) - e_1 + \wp'(-\omega_2)(u+\omega_2) + O((u+\omega_2)^2))$$
$$= O((u+\omega_2)^2),$$

thereby

$$f'(u) = O(u+\omega_2), \quad f_\tau(u) = O(u+\omega_2),$$

so that $g(u)$ behaves as

$$g(u) = O(1). \tag{A7}$$

- As $u \to \omega_3 = \tau/2$,

$$f(u) = \frac{1}{e_2-e_1}(\wp(\omega_3) - e_1 + \wp'(\omega_3)(u-\omega_3) + O((u-\omega_3)^2))$$
$$= t + O((u-\omega_3)^2),$$

thereby

$$f'(u) = O(u-\omega_3), \quad f_\tau(u) = O(1),$$

so that $g(u)$ turns out to have a pole of the first order at $u=\omega_3$:

$$g(u) = 0((u-\omega_3)^{-1}). \tag{A8}$$

The behavior of $g(u)$ at the other points of $\omega_n + \mathbb{Z} + \tau\mathbb{Z}$ can be deduced from these results by the additive quasi-periodicity of $g(u)$. Q.E.D.

Lemma 2: $h(u)$ is a meromorphic function on the u-plane with additive quasi-periodicity,

$$h(u+1) = h(u), \quad h(u+\tau) = h(u) - 2\pi i. \tag{A9}$$

All poles are of the first order and contained in the lattice $\omega_3 + \mathbb{Z} + \tau\mathbb{Z}$. Furthermore, $h(u)$ has zeros at $u=0$ and $u=\omega_1$.

Proof: Let us recall the fundamental properties of $\vartheta(u)$:

- $\vartheta(u)$ is an entire function on the u-plane with zeros of the first order at the lattice points $\omega_2 + m + n\tau$ $(m,n \in \mathbb{Z})$.
- $\vartheta(u)$ is quasi-periodic,

$$\vartheta(u+1) = \vartheta(u), \quad \vartheta(u+\tau) = e^{-\pi i\tau - 2\pi i u}\vartheta(u).$$

- $\theta(u)$ and $\vartheta(u+1/2)$ are even under the reflection $u \to -u$.

All the properties of $h(u)$ in the statement of the lemma are an immediate consequence of these properties of $\vartheta(u)$. Q.E.D.

Lemma 3: The function $f(u)$ satisfies the equation

$$2\pi i \frac{f_\tau(u)}{f'(u)} = \frac{\vartheta'(u+\omega_1)}{\vartheta(u+\omega_1)}, \tag{A10}$$

where the prime stands for $\partial/\partial u$.

Proof: The foregoing properties of $g(u)$ and $h(u)$ imply the following:

- $2\pi i g(u)-h(u)$ is a doubly periodic meromorphic function with primitive period 1 and τ.
- All poles of $2\pi i g(u)-h(u)$ are of the first order and contained in the lattice $\omega_3+\mathbb{Z}+\tau\mathbb{Z}$.
- $2\pi i g(u)-h(u)$ has zeros at $u=0$ and $u=\omega_1$.

The first two properties imply that $2\pi i g(u)-h(u)$ is a constant. By the last one, this constant has to be zero. We thus find that $2\pi i g(u)-h(u)=0$. Q.E.D.

Lemma 4: $\vartheta(u)$ satisfies the equation

$$(\log \vartheta(u+\omega_1))''=-\wp(u+\omega_3)+\text{function of } \tau \text{ only.} \tag{A11}$$

Proof: The aforementioned complex analytic properties of $\vartheta(u)$ imply the following:

- $(\log \vartheta(u+\omega_1))''$ is a doubly periodic meromorphic function with primitive period 1 and τ.
- All poles of this meromorphic function are contained in the lattice $\omega_3+\mathbb{Z}+\tau\mathbb{Z}$.
- As $u\to-\omega_3$, this function behaves as

$$(\log \vartheta(u+\omega_1))''=-\frac{1}{(u+\omega_3)^2}+O(1).$$

The function $-\wp(u+\omega_3)$, too, has these properties. Accordingly, their difference is a constant function on the u-plane, namely, a function of τ only. Q.E.D.

We now return to the proof of (42). By the third lemma, we have the identity

$$2\pi i\frac{f_\tau(u)}{f'(u)}du=\frac{\vartheta'(u+\omega_1)}{\vartheta(u+\omega_1)}du=\frac{d\vartheta(u+\omega_1)}{\vartheta(u+\omega_1)}-\frac{\partial\vartheta(u+\omega_1)/\partial\tau}{\vartheta(u+\omega_1)}d\tau. \tag{A12}$$

On the other hand, the well known ''heat equation,''

$$4\pi i\frac{\partial\vartheta(u)}{\partial\tau}=\vartheta(u)'', \tag{A13}$$

implies that

$$\frac{\partial\vartheta(u+\omega_1)/\partial\tau}{\vartheta(u+\omega_1)}=\frac{1}{4\pi}\frac{\vartheta(u+\omega_1)''}{\vartheta(u+\omega_2)}=\frac{1}{4\pi i}\left[(\log\vartheta(u+\omega_1))''+\left(\frac{\vartheta'(u+\omega_1)}{\vartheta(u+\omega_1)}\right)^2\right].$$

By the third and fourth lemmas, the last line can be rewritten as

$$\frac{1}{4\pi i}\left[-\wp(u+\omega_3)+\left(2\pi i\frac{f_\tau(u)}{f'(u)}\right)^2\right]+\text{function of } \tau \text{ only,}$$

so that

$$2\pi i\frac{f_\tau(u)}{f'(u)}du=\frac{1}{4\pi i}\left[\wp(u+\omega_3)-\left(2\pi i\frac{f_\tau(u)}{f'(u)}\right)^2\right]d\tau+\text{exact form.} \tag{A14}$$

Substituting $u=q$ gives (42).

APPENDIX B: ASYMPTOTICS OF ELLIPTIC FUNCTIONS

The asymptotic behavior of the $\wp$-function $\wp(u)$, the shifted $\wp$-functions $\wp(u+\omega_k)$ and the constants $e_k=\wp(\omega_k)$, in the limit as $\mathrm{Im}\,\tau\to+\infty$, can be deduced from the well known formula

$$\wp(u)=\sum_{n=-\infty}^{\infty}\frac{\pi^2}{\sin^2(\pi(u+n\tau))}-\frac{\pi^2}{3}-\sum_{n=1}^{\infty}\frac{2\pi^2}{\sin^2(\pi n\tau)}. \tag{B1}$$

Let us first consider the asymptotic behavior of $\wp(u)$ itself. The constant $(n=0)$ term in the first sum is of order 1 and the n-th term is of order $e^{2n\pi i\tau}$. Similarly, the n-th term in the second sum is of order $e^{2n\pi i\tau}$. Therefore

$$\wp(u)=\frac{\pi^2}{\sin^2(\pi u)}-\frac{\pi^2}{3}+O(e^{2\pi i\tau}). \tag{B2}$$

A similar estimate leads to the following asymptotic expression for the shifted $\wp$-functions:

$$\begin{aligned}\wp(u+\omega_1)&=\frac{\pi^2}{\cos^2(\pi u)}-\frac{\pi^2}{3}+O(e^{2\pi i\tau}),\\ \wp(u+\omega_2)&=-\frac{\pi^2}{3}+8\pi^2\cos(2\pi u)e^{\pi i\tau}+O(e^{2\pi i\tau}),\\ \wp(u+\omega_3)&=-\frac{\pi^2}{3}-8\pi^2\cos(2\pi u)e^{2\pi i\tau}+O(e^{2\pi i\tau}).\end{aligned} \tag{B3}$$

In fact, the degeneration process of the elliptic model requires us to know the asymptotic expression of $\wp(u+\omega_2)+\wp(u+\omega_3)$ to the order $e^{2\pi i\tau}$. This can be achieved by the following calculations:

$$\begin{aligned}\wp(u+\omega_2)+\wp(u+\omega_3)&=\sum_{n=-\infty}^{\infty}\frac{\pi^2}{\cos^2\left(u+\frac{\tau}{2}+n\tau\right)\sin^2\left(u+\frac{\tau}{2}+n\tau\right)}-\frac{2\pi^2}{3}-\sum_{n=1}^{\infty}\frac{4\pi^2}{\sin^2(\pi n\tau)}\\ &=-\frac{2\pi^2}{3}-32\pi^2\cos(2\pi u)e^{2\pi i\tau}+16\pi^2e^{2\pi i\tau}+O(e^{3\pi i\tau}).\end{aligned} \tag{B4}$$

We now consider the constants e_k. For instance, e_1 can be written as

$$\begin{aligned}e_1&=\sum_{n=-\infty}^{\infty}\frac{\pi^2}{\cos^2(\pi n\tau)}-\frac{\pi^2}{3}-\sum_{n=1}^{\infty}\frac{2\pi^2}{\sin^2(\pi n\tau)}\\ &=\frac{2}{3}\pi^2+\sum_{n=1}^{\infty}\frac{2\pi^2}{\cos^2(\pi n\tau)}-\sum_{n=1}^{\infty}\frac{2\pi^2}{\sin^2(\pi n\tau)}.\end{aligned} \tag{B5}$$

The constant $2\pi^2/3$ becomes the leading term; the leading $(n=1)$ terms of the last two series give the next-leading term of the order $e^{2\pi i\tau}$. e_2 and e_3 can be similarly analyzed. Thus the following asymptotic formulas are obtained:

$$\begin{aligned}e_1&=\frac{2\pi^2}{3}+16\pi^2e^{2\pi i\tau}+O(e^{4\pi i\tau}),\\ e_2&=-\frac{\pi^2}{3}+8\pi^2e^{\pi i\tau}+O(e^{2\pi i\tau}),\\ e_3&=-\frac{\pi^2}{3}-8\pi^2e^{\pi i\tau}+O(e^{2\pi i\tau}).\end{aligned} \tag{B6}$$

In particular, $e_2-e_1\to-\pi^2$, as expected.

JOURNAL OF MATHEMATICAL PHYSICS VOLUME 42, NUMBER 3 MARCH 2001

On the problem of algebraic completeness for the invariants of the Riemann tensor: I

E. Zakhary and J. Carminati[a)]
School of Computing and Mathematics, Deakin University, Waurn Ponds, Victoria 3217, Australia

(Received 25 April 2000; accepted for publication 18 December 2000)

We present a new determining set, CZ, of Riemann invariants which possesses the minimum degree property. From an analysis on the possible independence of CZ, we are led to the division of all space–times into two distinct, invariantly characterized, classes: a general class $\mathcal{M}_{G^+}$, and a special, singular class $\mathcal{M}_S$. For each class, we provide an independent set of invariants ($\mathcal{I}_{G^+} \subset \mathrm{CZ}$ and $\mathcal{I}_S \subset \mathrm{CZ}$, respectively) which, with the results of a sequel paper, will be shown to be algebraically complete. © *2001 American Institute of Physics.*
[DOI: 10.1063/1.1348027]

I. INTRODUCTION

In the literature, there are many papers devoted to the study of the scalar invariants of the Riemann tensor. The motivation behind this study has been, primarily, the coordinate invariant characterization of certain geometrical properties of space–times. For example, it has been shown that these invariants play an important role in the study of curvature singularities, classification of the Weyl and Ricci tensors and more fundamentally in the problem of the equivalence of two space–time metrics.

It is well known that, in general, there are 14 (algebraically) independent, second-order, invariants formed from the Riemann tensor R_{abcd}. This is simply a consequence of the fact that the 20 independent components of R_{abcd} can be reduced to 14 using the 6-parameter group freedom of the Lorentz transformations. Alternatively, the 14 independent algebraic invariants can be considered to be made up of the 4 independent eigenvalues of each of the Weyl and Ricci tensors together with the 6 parameters specifying the Lorentz transformation between the Weyl and Ricci canonical tetrads.[1,2] However, there is no guidance as to how these invariants may be constructed.

In the literature, there are different definitions of ''complete.'' Our definition of an ''algebraically complete'' set is motivated by the folllowing questions: How much algebraically independent information that is in the Riemann tensor is present in its polynomial invariants, and what is the minimum number of invariants of lowest possible degree, needed so that this maximum amount of information is contained? Accordingly, we define an ''algebraically complete'' set of Riemann invariants $\mathcal{I}=\{I_1, I_2, \ldots, I_n\}$ as one having the following properties: (i) any other invariant can be expressed in an algebraic relation (not necessarily equal to a polynomial) which determines that invariant for all Petrov or Segre types, with some or all of $I_1, I_2, \ldots, I_n$ and their complex conjugates, and (ii) no invariant $I_i \in \mathcal{I}$ can <u>always</u> (i.e., for all Petrov or Segre types) be expressed in an algebraic relation, which determines I_i, with the remaining invariants in $\mathcal{I}$. Note that this definition would essentially lead to that given by Zakhary and McIntosh.[3] Any set of invariants which satisfies property (i) will be called ''determining'' and any set which satisfies property (ii) is said to be ''not always dependent.'' Hence, a set $\mathcal{I}$ is said to be ''always dependent'' if there exists an invariant $I_i \in \mathcal{I}$ such that I_i can always be expressed in an algebraic relation which determines (for all Petrov or Segre types) I_i, with the remaining invariants in $\mathcal{I}$.

TABLE I. Equivalent invariants in Sneddon's set.

CZ	$\mathcal{K}$
R	R
w_1	$[A^2]=[\Psi^2]$
w_2	$\det A=\det \Psi$
r_1	$[B]=[K]$
r_2	$\Delta=\det \Gamma$
r_3	$[B^2]=[K^2]$
m_1	$[AB]=[\Psi K]=\overline{[C]}$
m_2	$[A^2B]=[\Psi^2K]=\overline{[D]}$
m_3	$[AB^2]=[\Psi K^2]=\overline{[BC]}$
m_4	$[AC]=[\Psi\Gamma\overline{\Psi\Gamma}]$
m_5	$[AD]=[\Psi\Gamma\overline{\Psi^2\Gamma}]=\overline{[A^2C]}$
m_6	$[A^2D]=[\Psi^2\Gamma\overline{\Psi^2\Gamma}]$

For simplicity, in the remainder of this article, we will use the term ''dependent'' to mean ''always dependent'' and use the term ''independent'' to mean ''not always dependent,'' when referring to a set of invariants.

Recently, Bonanos[4] and Sneddon[5–7] have studied the problem of completeness for a set of Riemann tensor invariants. Bonanos studied invariants formed from contractions with only Ψ_{ABCD} and the Plebanski spinor $\chi_{ABCD}=\Phi_{(AB}{}^{\dot{C}\dot{D}}\Phi_{CD)\dot{C}\dot{D}}$ but not with $\overline{\Psi}_{\dot{A}\dot{B}\dot{C}\dot{D}}$, while Sneddon examined the problem, in general, in a comprehensive study using rotor calculus. It is interesting to compare our work with theirs.

First, we note that *algebraically complete* is different from *complete* in the usual classical sense which is the one that both Bonanos and Sneddon use (it is more restrictive than ours in that in the construction of a complete set, they include an invariant in a set if it is not equal to some *polynomial* of the already existing elements in the set. On the other hand, in terms of our definition, an invariant is independent of a ''base'' set if it cannot be expressed for all Segre and Petrov types in an *algebraic* relation with the elements of that set). On this matter, we believe that our definition is more appropriate for relativity. Second, our primary concern is always with how much algebraic information that is in the Riemann tensor is present in its polynomial invariants. As will be shown below, no set of curvature invariants formed from contractions with only Ψ_{ABCD} and $\Phi_{AB}{}^{\dot{C}\dot{D}}$ can contain all of the possible algebraic information that is in R_{abcd}. It is essential that contraction ''mixing'' between Ψ_{ABCD} and $\overline{\Psi}_{\dot{A}\dot{B}\dot{C}\dot{D}}$ be included. This is also evident from Sneddon's work. We conclude that Bonanos' set cannot be algebraically complete. On the other hand, Sneddon's set $\mathcal{K}$ is complete in the usual classical sense. However, within the context of this work, his set is unnecessarily large (consisting of the equivalent of 38 real invariants) and of too high degree (going up to overall degree 11). This could make his set unwieldy to work with in many practical applications (the general expansion of some of the high-degree invariants would lead to extremely large expressions). What we will show in this and a sequel paper is that for a determining set, we need at most the equivalent of 18 real invariants with a maximum overall degree of 6. Also, our proposed set of invariants is essentially contained in $\mathcal{K}$, and in Table I we list the equivalence.

As an additional point, it is important to note that there are space–times where the set of all polynomial invariants does not contain all of the information that is in R_{abcd}. An illustrative example will be given below.

Prior to 1991, there were a number of sets of 14 invariants in the literature claiming to be independent.[8–16] However, none of these sets can be algebraically complete.[14,17] This suggests that such a set should contain more than 14 invariants and hence, in general, be redundant. Some of the members of this set would then be connected by a number of algebraic relations for different Petrov or Segre types, with no one relation holding for all types. Also, Carminati and

McLenaghan,[17] for the first time, pointed out two highly desirable properties of an algebraically complete set, namely (a) it must consist of invariants of the lowest possible degree, and (b) it must be the smallest set which contains the maximum number (less than or equal to 14) of independent invariants for any Petrov or Segre type. In this article, we intend to construct a determining set of invariants subject to property (a) while attempting to satisfy properties (ii) and (b). However, we note that our construction process would generally lead to a set having a reduced number of elements but not necessarily the minimum number, since we are satisfying property (a) as well. Theoretically, it could be possible to have a determining or algebraically complete set with a smaller number of invariants if higher degree scalars were to be introduced. This issue still remains unresolved. Priority will be given to property (a).

As will be evident from the backsolving method presented in this and a sequel paper, given particular values for our invariants, multiple solutions will result (as a consequence of taking roots of algebraic equations) for the curvature components. This is not an issue in the process of establishing the determining nature of the proposed set of invariants since we are trying to establish sufficiency. In practical terms, one is not concerned with explicitly applying this process but rather to invariantly express (if possible) certain geometrical properties [like alignment between principal null directions (PND's) of the Weyl and Ricci tensor, or electric and magnetic characteristics of the Weyl tensor, etc.] with the use of just the polynomial invariants of the Riemann tensor for a given particular space–time.

This is the first of two papers dedicated to eventually establishing an algebraically complete set of second-order Riemann invariants for each canonically different space–time. In this paper, we will show that the set CM, as proposed by Carminati and McLenaghan, is not algebraically complete. Further, although the set of invariants as proposed by Zakhary and McIntosh (ZM)[3] is algebraically complete (as shown later) for the general class, $\mathcal{M}_{G^+}$, we will also show that it fails for the special singular class, $\mathcal{M}_S$ (as described below), since it is missing an essential invariant. Our main purpose in this paper is to propose a new determining set of invariants CZ that contains that missing invariant, possesses the minimum degree property (a), and simultaneously attempts to satisfy properties (ii) and (b). The possible independence of the invariants of this set is analyzed[18,19] and as a consequence we are led to the division of all space–times into two distinct, invariantly characterized, classes: a general class $\mathcal{M}_{G^+}$, and a singular class $\mathcal{M}_S$. For each class, we provide an independent set of invariants ($\mathcal{I}_{G^+} \subset \mathrm{CZ}$ and $\mathcal{I}_S \subset \mathrm{CZ}$, respectively) which, with the results of a sequel paper, will be shown to be algebraically complete.

The CZ set consists of the following invariants, using the notation (but different definitions of the invariants) of Carminati and McLenaghan:

$$R := g^{ab} g^{cd} R_{acdb},$$

$$w_1 := \frac{1}{6} \Psi_{ABCD} \Psi^{ABCD},$$

$$w_2 := \frac{1}{6} \Psi_{ABCD} \Psi^{CD}{}_{EF} \Psi^{EFAB},$$

$$r_1 := \frac{1}{3} \Phi_{AB\dot{A}\dot{B}} \Phi^{AB\dot{A}\dot{B}},$$

$$r_2 := \frac{1}{6} \Phi_{AB\dot{A}\dot{B}} E^{AB\dot{A}\dot{B}},$$

$$r_3 := \frac{1}{12} E_{AB\dot{A}\dot{B}} E^{AB\dot{A}\dot{B}},$$

TABLE II. Relations between sets.

CZ	ZM	CM

$$m_1 := \Psi_{ABCD}\Phi^{CD}{}_{\dot{C}\dot{D}}\Phi^{AB\dot{C}\dot{D}},$$

$$m_2 := \Psi^{EF}{}_{(AB}\Psi_{CD)EF}\Phi^{AB}{}_{\dot{C}\dot{D}}\Phi^{CD\dot{C}\dot{D}},$$

$$m_3 := \Psi_{ABCD}\Phi^{AE\dot{A}\dot{B}}\Phi^{B}{}_{E\dot{A}\dot{C}}\Phi^{CF\dot{C}\dot{D}}\Phi^{D}{}_{F\dot{D}\dot{B}},$$

$$m_4 := \Psi^{AB}{}_{CD}\Phi^{CD}{}_{\dot{A}\dot{B}}\overline{\Psi}^{\dot{A}\dot{B}}{}_{\dot{C}\dot{D}}\Phi_{AB}{}^{\dot{C}\dot{D}},$$

$$m_5 := \Psi_{(AB}{}^{CD}\Psi_{EF)CD}\overline{\Psi}_{\dot{A}\dot{B}\dot{C}\dot{D}}\Phi^{AB\dot{C}\dot{D}}\Phi^{EF\dot{A}\dot{B}},$$

$$m_6 := \Psi^{AB}{}_{CD}\Psi^{CD}{}_{EF}\Phi^{EF}{}_{\dot{A}\dot{B}}\overline{\Psi}^{\dot{A}\dot{B}}{}_{\dot{C}\dot{D}}\overline{\Psi}^{\dot{C}\dot{D}}{}_{\dot{E}\dot{F}}\Phi_{AB}{}^{\dot{E}\dot{F}},$$

where $E^{AB}{}_{\dot{C}\dot{D}} := 2\Phi^{A}{}_{E\dot{F}(\dot{C}}\Phi^{BE\dot{F}}{}_{\dot{D})}$.

For future reference, we give, in Table II, the relations between the various sets. In Tables III and IV below,[20,3] we summarize the syzygies for the different Petrov and Segre types of the Weyl and Ricci tensors, respectively.

TABLE III. The Weyl Syzygies.

Petrov Types	Syzygies
I	—
II, D	$w_1^3=w_2^2$
III, N, O	$w_1=w_2=0$

TABLE IV. The Ricci Syzygies.

Ricci Degeneracy	Segre Types	Syzygies
{1111}	[1,111], $[Z\bar{Z}11]$	—
{112}	[1,1(11)], [(1,1)11], $[Z\bar{Z}(11)]$, [211]	$r_2^2(4r_1^3-6r_1r_3+r_2^2)=r_3^2(3r_1^2-4r_3)$
{22}	[(1,1)(11)], [2(11)]	$r_2=r_3=0$
{13}	[1,(111)], [(1,11)1], [(21)1], [31]	$r_2^2=r_1^3$, $r_3=r_1^2$
{4}	[(31)], [(211)], [(1,111)]	$r_1=r_2=r_3=0$

II. AN INDEX THEOREM

Before proceeding with the analysis of our invariants, we shall need to establish a result on the general structure of any invariant formed from the Weyl and Ricci spinors:

$$\Psi_{ABCD}=\Psi_0\iota_A\iota_B\iota_C\iota_D-4\Psi_1o_{(A}\iota_B\iota_C\iota_{D)}+6\Psi_2o_{(A}o_B\iota_C\iota_{D)}-4\Psi_3o_{(A}o_Bo_C\iota_{D)}+\Psi_4o_Ao_Bo_Co_D,$$

$$\Phi_{AB\dot{A}\dot{B}}=\Phi_{00}\iota_A\iota_B\bar{\iota}_{\dot{A}}\bar{\iota}_{\dot{B}}-2\Phi_{01}\iota_A\iota_B\bar{\iota}_{(\dot{A}}\bar{o}_{\dot{B})}+\Phi_{02}\iota_A\iota_B\bar{o}_{\dot{A}}\bar{o}_{\dot{B}}-2\Phi_{10}o_{(A}\iota_{B)}\bar{\iota}_{\dot{A}}\bar{\iota}_{\dot{B}}+4\Phi_{11}\iota_{(A}o_{B)}\bar{\iota}_{(\dot{A}}\bar{o}_{\dot{B})}$$
$$-2\Phi_{12}\iota_{(A}o_{B)}\bar{o}_{\dot{A}}\bar{o}_{\dot{B}}+\Phi_{20}o_Ao_B\bar{\iota}_{\dot{A}}\bar{\iota}_{\dot{B}}-2\Phi_{21}o_Ao_B\bar{\iota}_{(\dot{A}}\bar{\iota}_{\dot{B})}+\Phi_{22}o_Ao_B\bar{o}_{\dot{A}}\bar{o}_{\dot{B}}.$$

Index Theorem: Let a, b, c be non-negative integers and let $\boldsymbol{\Psi}^a\bar{\boldsymbol{\Psi}}^b\boldsymbol{\Phi}^c$ represent any of the complete contractions (invariant) of a copies of the Weyl spinor, b copies of its complex conjugate and c copies of the Ricci spinor. Then any term in the expansion of this invariant has the form

$$\Psi_0^{a_0}\Psi_1^{a_1}\Psi_2^{a_2}\Psi_3^{a_3}\Psi_4^{a_4}\bar{\Psi}_0^{b_0}\bar{\Psi}_1^{b_1}\bar{\Psi}_2^{b_2}\bar{\Psi}_3^{b_3}\bar{\Psi}_4^{b_4}\Phi_{00}^{c_{00}}\Phi_{01}^{c_{01}}\Phi_{02}^{c_{02}}\Phi_{10}^{c_{10}}\Phi_{11}^{c_{11}}\Phi_{12}^{c_{12}}\Phi_{20}^{c_{20}}\Phi_{21}^{c_{21}}\Phi_{22}^{c_{22}}$$

where $a_0,\ldots,a_4,b_0,\ldots,b_4,c_{00},\ldots,c_{22}$ are non-negative integers which must satisfy the following conditions:

$$a_0+a_1+a_2+a_3+a_4=a,$$

$$b_0+b_1+b_2+b_3+b_4=b,$$

$$c_{00}+c_{01}+c_{02}+c_{10}+c_{11}+c_{12}+c_{20}+c_{21}+c_{22}=c,$$

$$a_1+2a_2+3a_3+4a_4+c_{10}+c_{11}+c_{12}+2c_{20}+2c_{21}+2c_{22}=2a+c,$$

$$b_1+2b_2+3b_3+4b_4+c_{01}+2c_{02}+c_{11}+2c_{12}+c_{21}+2c_{22}=2b+c.$$

The proof of this result is readily established by counting the number of contracting pairs of dotted and undotted indices.

When applying the index theorem, note the following:

(1) If $\Phi_{ij}=0$ (or $\Psi_i=0$), we set $c_{ij}=0$ (or $a_i=b_i=0$).
(2) If an invariant does not include Ψ_i's, we set all $b_i=0$ and $b=0$.
(3) If $\Phi_{ij}=1$ (or $\Psi_i=1$), we do not set $c_{ij}=0$ (or $a_i=b_i=0$).
(4) If $\Phi_{ij}=\Phi_{kl}$, we do not set $c_{ij}=c_{kl}$.

To illustrate this theorem's use, consider the Segre type [(3,1)] in the canonical frame where the only nonzero Ricci components are $\Phi_{12}=\Phi_{21}=1$. In this case, we set $c_{ij}=0$, except c_{12} and c_{21}. For an invariant of the form $\mathbf{\Psi}\overline{\mathbf{\Psi}}\mathbf{\Phi}^2$, $a=b=1$ and $c=2$. Hence, the index theorem implies the following:

$$a_0+a_1+a_2+a_3+a_4=1,$$

$$b_0+b_1+b_2+b_3+b_4=1,$$

$$c_{12}+c_{21}=2,$$

$$a_1+2a_2+3a_3+4a_4+c_{12}+2c_{21}=4,$$

$$b_1+2b_2+3b_3+4b_4+2c_{12}+c_{21}=4.$$

These equations allow only three solutions:

$$\{c_{12}=0,c_{21}=2,a_2=1,a_0=a_1=a_3=a_4=0,b_0=1,b_1=b_2=b_3=b_4=0\},$$

$$\{c_{12}=1,c_{21}=1,a_1=1,a_0=a_2=a_3=a_4=0,b_1=1,b_0=b_2=b_3=b_4=0\},$$

$$\{c_{12}=2,c_{21}=0,a_0=1,a_1=a_2=a_3=a_4=0,b_2=1,b_0=b_1=b_3=b_4=0\}.$$

This agrees with the expression of m_4 which contains exactly the correct three terms. In fact, $m_4=4(\Psi_0\overline{\Psi}_2\Phi_{21}^2+2\Psi_1\overline{\Psi}_1\Phi_{12}\Phi_{21}+\Psi_2\overline{\Psi}_0\Phi_{12}^2)$.

III. PROPERTIES OF THE CZ SET

We have carried out a detailed study[21] of the possible canonical frames for the different Segre types using Hall's approach.[22] Our analysis is somewhat more detailed than Hall's in that we give more explicit descriptions of the canonical forms together with the remaining tetrad freedom for each case. The details of this work will be published in a sequel paper. For our current purposes, we will only need canonical frames for the Segre types [1,111], [1,1(11)], [(2,11)] and [2,11].

In this section, we shall construct the CZ set so that it possesses the minimum degree property (a) and attempts to satisfy properties (i), (ii) and (b). To begin with, we will look at Ricci tensors that are of Segre Type [1,111]. The canonical frame is completely fixed by the Ricci tensor and described by $\Phi_{00}=\Phi_{22}\neq 0$, Φ_{11}, $\Phi_{02}=\Phi_{20}\neq 0$, $\Phi_{01}=\Phi_{12}=0$, with $4\Phi_{11}^2\neq(\Phi_{00}\pm\Phi_{02})^2$.

We will now show that the set of invariants $\mathcal{I}_G=\{R,w_1,w_2,r_1,r_2,r_3,m_1,m_2,m_3\}$ is algebraically complete, for this Segre type, by completely backsolving for the curvature components in terms of the invariants where, in terms of equivalent real invariants, the number of nonzero curvature components equals the number of invariants. We begin with the backsolving for the Ricci components Φ_{ab}. In our canonical frame, the Ricci invariants are

$$r_1=\tfrac{2}{3}(\Phi_{00}^2+\Phi_{02}^2+2\Phi_{11}^2),$$

$$r_2=2\Phi_{11}(\Phi_{00}^2-\Phi_{02}^2),$$

$$r_3=\tfrac{1}{3}(\Phi_{00}^4-2\Phi_{00}^2\Phi_{02}^2+8\Phi_{00}^2\Phi_{11}^2+8\Phi_{02}^2\Phi_{11}^2+\Phi_{02}^4).$$

The Jacobian of this system is $\frac{64}{9}J$, where

$$J=\Phi_{00}\Phi_{02}(\Phi_{00}+\Phi_{02}+2\Phi_{11})(\Phi_{00}+\Phi_{02}-2\Phi_{11})(\Phi_{00}-\Phi_{02}+2\Phi_{11})(\Phi_{00}-\Phi_{02}-2\Phi_{11}),$$

and consequently is always nonzero. Thus it follows that the Ricci invariants r_1,r_2,r_3 are always backsolvable for Φ_{ab}. We note that

FIG. 1. Quadratic-degree invariants.

$$J^2=\tfrac{27}{16}(r_3^2(3r_1^2-4r_3)-r_2^2(4r_1^3-6r_1r_3+r_2^2)),$$

and that $J=0$, which can be alternatively written as $4(r_1^2-r_3)^3=(2r_1^3-3r_1r_3+r_2^2)^2$ (similar to the condition $w_1^3=w_2^2$), is the condition for the Ricci spinor to be algebraically special.

To facilitate the backsolving of the Weyl components Ψ_i, we make the following substitutions:

$$\Psi_0=x+y,\quad \Psi_1=u+v,\quad \Psi_3=u-v,\quad \Psi_4=x-y.$$

The Weyl and mixed invariants then take the form

$$w_1=\tfrac{1}{3}(x^2-y^2-4u^2+4v^2+3\Psi_2^2),$$

$$w_2=2\Psi_2u^2-2\Psi_2v^2-\Psi_2^3-2u^2x+4yuv-2v^2x+\Psi_2x^2-\Psi_2y^2,$$

$$m_1=2\Psi_2\Phi_{00}^2-8\Psi_2\Phi_{11}^2+4\Phi_{00}\Phi_{02}x+2\Psi_2\Phi_{02}^2,$$

$$\begin{aligned}m_2=&-2\Psi_2^2\Phi_{02}^2+8\Psi_2^2\Phi_{11}^2-2\Psi_2^2\Phi_{00}^2+\tfrac{16}{3}\Phi_{11}^2v^2-\tfrac{4}{3}\Phi_{02}^2v^2-\tfrac{4}{3}\Phi_{00}^2v^2-\tfrac{16}{3}\Phi_{11}^2u^2+\tfrac{4}{3}\Phi_{02}^2u^2\\&+\tfrac{4}{3}\Phi_{00}^2u^2-8\Phi_{00}v^2\Phi_{02}-8\Phi_{00}u^2\Phi_{02}-\tfrac{8}{3}\Phi_{11}^2x^2+\tfrac{8}{3}\Phi_{11}^2y^2+\tfrac{2}{3}\Phi_{02}^2x^2-\tfrac{2}{3}\Phi_{02}^2y^2+\tfrac{2}{3}\Phi_{00}^2x^2\\&-\tfrac{2}{3}\Phi_{00}^2y^2+8\Psi_2\Phi_{00}\Phi_{02}x,\end{aligned}$$

$$m_3=8\Psi_2\Phi_{11}^2\Phi_{00}^2-16\Phi_{02}\Phi_{00}\Phi_{11}^2x+4\Psi_2\Phi_{00}^2\Phi_{02}^2+8\Psi_2\Phi_{02}^2\Phi_{11}^2-2\Psi_2\Phi_{00}^4-2\Psi_2\Phi_{02}^4.$$

We begin by noting that the system $\{m_1,m_3\}$ which contains only the Weyl variables x and Ψ_2 has Jacobian equal to $-8J$ which is nonzero. Hence, we may regard x and Ψ_2 as (locally) implicit functions of m_1 and m_3 and Φ_{ab} (which in turn are determined by the Ricci invariants). Next, we solve w_1 for u^2 and use this equation to eliminate u from m_2. We can always solve this resulting equation for v^2, since its coefficient is nonzero. Finally, after solving w_2 for $4yuv$ and squaring, we substitute the solutions for u^2 and v^2 into this expression to obtain a polynomial equation of degree 6 in y with the coefficients being polynomials in x, Ψ_2, Φ_{ab}, and invariants. This polynomial can always be solved for y, since the coefficient of y^6 is $J/\Phi_{00}\Phi_{02}\neq 0$. Thus complete backsolving has been achieved.

Next, we will show that the set $\mathcal{I}_G$ is of the lowest possible degree. We begin by listing all (inequivalent and excluding complex conjugates and trivially dependent invariants which have separable product contractions) invariants at the various degree levels. This is done diagramatically as follows. A straight line between quantities indicates a contraction between undotted spinor indices and a dashed line indicates a contraction between dotted indices (see Fig. 1–4).

By direct calculation, it can be readily shown that all of the quadratic, cubic and quartic scalars represented in Fig. 1-3, constitute an equivalent set to $\mathcal{I}_4$

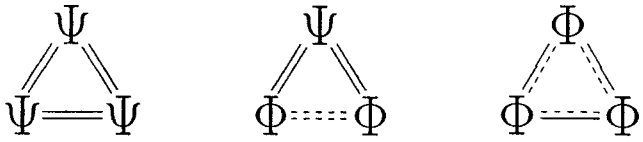

FIG. 2. Cubic-degree invariants.

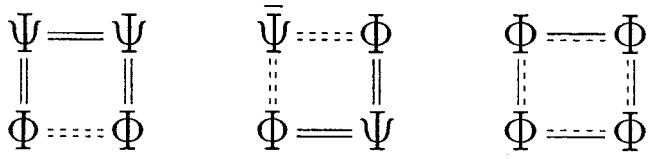

FIG. 3. Independent quartic-degree invariants.

$=\{R,w_1,w_2,r_1,r_2,r_3,m_1,m_2,m_4\}$. It is also easy to show that all the remaining quartic scalars represented in Fig. 4 are either identically zero or dependent on the remaining ones. Now we observe that this set $\mathcal{I}_4$, differs from $\mathcal{I}_G$ in that it contains m_4 but does not contain m_3 and therefore $\mathcal{I}_4$ contains the equivalent of 13 independent real invariants (less information than $\mathcal{I}_G$ since m_4 is real whereas m_3 is complex, in general). Thus, we conclude that the set $\mathcal{I}_4$, which is constructed using the minimum degree property, and contains all of the information in all scalars up to and including quartic degree, cannot contain all possible information for this Segre type, whereas $\mathcal{I}_G$ does. Next, we note that adding one more real invariant of degree five to $\mathcal{I}_4$ will not make it algebraically complete (in general). This can be shown as follows. First, all real, nontrivial invariants of degree five must be of the form $\Psi\bar{\Psi}\Phi^3$ and they are equivalent[7] (if independent of $\mathcal{I}_4$). Consider one such invariant to be $m:=\Psi_A{}^B{}_{DE}\Phi^{DE}{}_{\dot{A}}{}^{\dot{B}}\bar{\Psi}_{\dot{B}}{}^{\dot{C}}{}_{\dot{D}\dot{E}}\Phi_B{}^{C\dot{D}\dot{E}}\Phi_C{}^{A}{}_{\dot{C}}{}^{\dot{A}}$. For Segre type [1,111] and Petrov type **N**, we have, by direct calculation, $m^2=Em_4$, where E is a polynomial in Weyl and Ricci components. Hence, in the special case that $m_4=0$ (which is possible), we have $m=0$ but $m_3\neq 0$. This means that with one real condition, two real invariants vanish. Thus we conclude that m_4 and m cannot replace m_3 in general.

Since $\mathcal{I}_G$ is obtained from $\mathcal{I}_4$ by removing m_4 and adding m_3 and the addition of a real invariant of degree five to $\mathcal{I}_4$ is not sufficient, it follows that the set $\mathcal{I}_G$ must satisfy the minimum degree property (a).

We have thus far established the fact that an algebraically complete set satisfying property (a) must contain all of the invariants (or their equivalent at each corresponding degree level) in $\mathcal{I}_G$. Now, let us address the following key question: ''*Is* $\mathcal{I}_G$ *algebraically complete for all Segre Types*?'' To answer this question, we need to consider the Segre Type [(2,11)].

For Segre Type [(2,11)], the canonical frame is fixed (up to a 2-p null rotation plus a spatial rotation) by the Ricci tensor and described by $\Phi_{00}=\Phi_{01}=\Phi_{02}=\Phi_{11}=\Phi_{12}=0,\Phi_{22}=1$.

Case 1: $\Psi_0\neq 0$: In this case, we can make Ψ_0 real and $\Psi_1=0$. Hence, the elements of $\mathcal{I}_G$ (except R) are given by

$$w_1=\tfrac{1}{3}(\Psi_0\Psi_4+3\Psi_2^2),$$

$$w_2=\Psi_0\Psi_2\Psi_4-\Psi_0\Psi_3^2+3\Psi_2^3,$$

$$r_1=0,$$

$$r_2=0,$$

$$r_3=0,$$

$$m_1=0,$$

$$m_2=0,$$

$$m_3=0.$$

It is clear that we do not have sufficient curvature information in the invariants of $\mathcal{I}_G$ (there are the equivalent of seven real unknowns, Ψ_0, Ψ_2, Ψ_3, Ψ_4, to be solved for, whereas $\mathcal{I}_G$

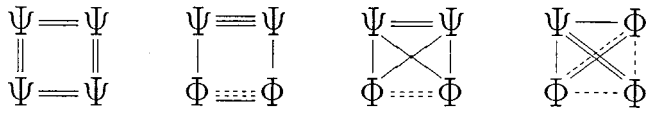

FIG. 4. Dependent quartic-degree invariants.

contains only the nontrivial invariants w_1, w_2, excluding R). We conclude that we need the equivalent of three more real invariants. Using the index theorem, it follows that any further curvature information must come from an invariant which contains contractions with $\bar{\mathbf{\Psi}}$ as well as $\mathbf{\Psi}$ and $\mathbf{\Phi}$ (i.e. a, b and c must be nonzero in the contraction $\mathbf{\Psi}^a\bar{\mathbf{\Psi}}^b\mathbf{\Phi}^c$).

Guided by criteria (a), (b) and (ii), it follows that we must include the two invariants m_4 and m_5 to obtain the new set $\mathcal{I}_{G^+}=\mathcal{I}_G\cup\{m_4,m_5\}$ so that complete backsolving is possible in this case. This is established as follows. The necessary inclusion of m_4 follows immediately from the application of the Index theorem and properties (a), (b) and (ii). Hence, all of the information in the scalars up to and including quartic degree has now been included. Thus we must next consider degree five. In this case, the inclusion of m_5 is justified as follows. First, by appealing to the Index theorem, the required invariant must be of the form $\mathbf{\Psi}^2\bar{\mathbf{\Psi}}\mathbf{\Phi}^2$.

In Fig. 5, we list all (inequivalent and excluding complex conjugates and trivially dependent invariants which have separable product contractions) degree five invariants of this form. By direct calculation, it follows that the second invariant, in the list below, is equivalent to the product of lower degree invariants. Also, we find that the first and third invariants are both equivalent to m_5. Note that we are still maintaining the minimum degree requirement. In this case, we have $m_4=\Psi_0^2$ and $m_5=2\Psi_0^2\Psi_2$. Now, complete backsolving is possible since m_4 determines Ψ_0, m_5 determines Ψ_2, w_1 determines Ψ_4, and w_2 determines Ψ_3. There remains to consider whether it is possible to remove the invariant m_3 retaining only the invariant m_5. In fact, this is impossible since by a direct calculation it follows that the invariant m_5 always vanishes for Petrov type **N** while m_3 does not, and m_3 is generally needed in the backsolving for these cases. It now follows that the CM set cannot be algebraically complete.

Case 2: $\Psi_0=0$, & $\Psi_1\neq 0$: In this case, we can make Ψ_1 real and $\Psi_2=0$. Hence, the elements of $\mathcal{I}_{G^+}$ (except R) are given by

$$w_1=-\tfrac{4}{3}\Psi_1\Psi_3,$$

$$w_2=-\Psi_1^2\Psi_4,$$

$$r_1=0,$$

$$r_2=0,$$

$$r_3=0,$$

$$m_1=0,$$

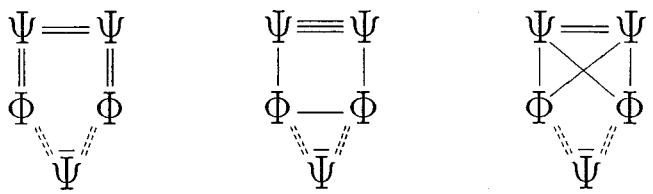

FIG. 5. Fifth-degree invariants of the form $\Psi^2\bar{\Psi}\Phi^2$.

$$m_4 = 0,$$

$$m_5 = 0.$$

In this case, we do not have sufficient curvature information in the invariants of $\mathcal{I}_{G^+}$ (there are the equivalent of five real unknowns, Ψ_1, Ψ_3, Ψ_4, to be solved for, whereas $\mathcal{I}_{G^+}$ contains only the nontrivial invariants w_1, w_2, excluding R). We conclude that we need the equivalent of one more real invariant, since we can view the above system as determining Ψ_3 and Ψ_4 in terms of Ψ_1 and invariants. Using the Index theorem, it follows that any further curvature information must come from an invariant which must be of sixth degree or higher and of the form $\mathbf{\Psi}^2 \overline{\mathbf{\Psi}}^2 \mathbf{\Phi}^2$ for sixth degree. We choose to include the new real invariant m_6. Since in this case $m_6 = 4\Psi_1^4$, complete backsolving is possible because m_6 determines Ψ_1. Also, the inclusion of m_6 maintains the minimum degree property since $\mathcal{I}_{G^+}$ has the minimum degree property. We now have arrived at the proposed determining set $\mathrm{CZ} = \mathcal{I}_{G^+} \cup \{m_6\}$. It follows from this that the set $\mathrm{ZM} = \mathcal{I}_{G^+}$ is not determining and hence is not algebraically complete. We note that m_6 cannot replace m_4 since the invariant m_6 always vanishes for Petrov type **N** while m_4 does not, and m_4 is generally needed in the backsolving for these cases.

Again, we stress that the set CZ is of the lowest possible degree. This does not mean that CZ is unique, since other invariants, at the same degree level, may be substituted for some of the invariants in our set.

As a consequence of our analysis in this and a sequel paper, on the possible independence of CZ, we are led to the partitioning of all space–times into two disjoint classes: a special class $\mathcal{M}_S$ and a general class $\mathcal{M}_{G^+}$ containing the remaining space–times. The space–times in $\mathcal{M}_S$ are invariantly characterized by the conditions given in Table V. Thus, all the mixed invariants of $\mathcal{I}_{G^+}$ are dependent, hence the need for m_6. Specifically, $\mathcal{M}_S$ consists of special cases within some Segre types (see Table VI) and splits into two groups **A** and **B**.[23]

For $\mathcal{M}_S$, $\mathcal{I}_S = \{R, w_1, w_2, r_1, m_6\}$ is an independent set of invariants. It will be shown in a sequel paper that $\mathcal{I}_S$ is also determining, and hence it follows that $\mathcal{I}_S$ is algebraically complete for $\mathcal{M}_S$.

Next, we will now show that the set $\mathcal{I}_{G^+}$ is independent for $\mathcal{M}_{G^+}$. First, it is clear that any mixed invariant m_i cannot replace any of the Ricci invariants r_i or Weyl invariants w_i. This follows from consideration of conformally flat spaces and Einstein spaces. Second, the invariants in $\mathcal{I}_G$ are independent since they are all needed for the Segre type [1,111] as shown before. Hence, it remains to show that m_4 or m_5 or any ''parts'' of these invariants cannot replace any (''parts'')

TABLE VI. Space–times for the class $\mathcal{M}_S$.

Group	Subclasses of Segre types	
	Segre type	Restrictions in the Ricci canonical frame
Group A: $r_1 \neq 0$	[1,1(11)]	$\Psi_0=\Phi_{11}=\Psi_4=0$ with $\Psi_1\overline{\Psi}_1+\Psi_3\overline{\Psi}_3\neq 0$
	$[Z\overline{Z}(11)]$	$\Psi_0=\Phi_{11}=\Psi_4=0$ with $\Psi_1\overline{\Psi}_1+\Psi_3\overline{\Psi}_3\neq 0$
	[(1,1)11]	$\Psi_0=\Phi_{11}=\Psi_4=0$ with $\Psi_1\Psi_3\neq 0$
Group B: $r_1=0$	[(2,11)]	$\Psi_0=0$ with $\Psi_1\neq 0$

of the invariants in $\mathcal{I}_G$. The invariant m_4 cannot replace any parts of m_1 or m_2 because these three invariants are all needed (essential)[3] for the Segre type [(1,1)11] as will be shown in the sequel paper. Since, for the Segre type [31], $m_4=0$ for some special cases, while $m_3\neq 0$, then m_4 cannot replace m_3. For the invariant m_5, it cannot replace m_1 or m_3 or parts of these invariants, since m_5 vanishes identically for Petrov type N while m_1 and m_3 do not, in general (and they are both needed in general for backsolving). For Segre type [(1,1)(11)], $3r_1m_5=\overline{m}_1m_2$,[3] and therefore $m_5=0$ if $m_1=0$. Hence, m_5 cannot replace m_2, for this Segre type, since $m_1=0$ does not imply $m_2=0$, in general, and m_2 is generally needed in the backsolving. Details will be given in the sequel paper. Finally, no part of m_5 can replace m_4 since they are both (entirely) needed for Segre type [(211)], as shown above. This completes the proof that $\mathcal{I}_{G^+}$ is independent for $\mathcal{M}_{G^+}$

In a sequel paper, we will show that the set $\mathcal{I}_{G^+}$ is determining (and hence algebraically complete) for the class $\mathcal{M}_{G^+}$. As regards the set CZ, it is possible that m_6 could replace $m_2\overline{m}_2$ or $m_5\overline{m}_5$, or both (this is the only possible redundancy that could exist) but as yet we have been unable to resolve this issue. Hence, we cannot claim, at this stage, that CZ is independent, but it will be shown, at least, that it is determining for the set of all space–times.

As previously mentioned, there are some space–times where the information in R_{abcd} is not contained in the set CZ. In these cases, it follows that the missing information cannot be contained in any other invariants. An example of such space–times is Segre type [2,11] with $\Psi_0=\Psi_1=0$ in the canonical frame where the only nonzero Φ_{ab} are $\Phi_{02}=\Phi_{20}$, Φ_{11}, $\Phi_{22}=\pm 1$. In this case, there is no remaining tetrad freedom as the Ricci tensor determines the frame completely. Applying the Index theorem, for any invariant, we obtain $a_2+a_3+a_4=a$, $b_2+b_3+b_4=b$, $c_{02}+c_{11}+c_{20}+c_{22}=c$, $2a_2+3a_3+4a_4+c_{11}+2c_{20}+2c_{22}=2a+c$, $2b_2+3b_3+4b_4+2c_{02}+c_{11}+2c_{22}=2b+c$. This gives $a_3+2a_4+b_3+2b_4+2c_{22}=0$ and hence, $a_3=a_4=b_3=b_4=c_{22}=0$. This means that no invariant will ever contain Ψ_3, Ψ_4, $\overline{\Psi}_3$ or $\overline{\Psi}_4$ and hence there will always be missing information in the Riemann invariants of any degree.

IV. CONCLUSION

A set, CZ, of second-order Riemann invariants has been presented. This set has been constructed so that it is determining, possessing the minimum degree property while attempting to include a minimum number of independent invariants. An analysis on the possible independence of CZ leads to the division of all space–times into two distinct, invariantly characterized, classes: a general class $\mathcal{M}_{G^+}$, and a very special, singular class $\mathcal{M}_S$. Explicitly, in this paper, we have shown that CZ is the union of two sets $\mathcal{I}_S$ and $\mathcal{I}_{G^+}$. The set $\mathcal{I}_S$ has been shown to be independent for the class $\mathcal{M}_S$ while $\mathcal{I}_{G^+}$ has been shown to be independent for the class $\mathcal{M}_{G^+}$. In a sequel paper, we will show that $\mathcal{I}_S$ and $\mathcal{I}_{G^+}$ are also determining and hence algebraically complete for their respective classes $\mathcal{M}_S$ and $\mathcal{M}_{G^+}$. An Index theorem has also been introduced to assist in establishing our results. Finally, an illustrative example has been given to show that in some space–times, no set of second-order invariants can contain all of the information in the Riemann tensor. In such cases, ''complete backsolving'' is not possible. Interestingly, this can only occur for those Segre types in which the Ricci tensor possesses a null eigenvector. In our sequel paper, we will explicitly list all such space–times and show that in these cases there is a geometric

common theme, that being, of alignment between the repeated PND of the Weyl tensor with the null eigenvector of the Ricci tensor. We suspect that some space–times within such classes will, in general, prove to be more difficult to distinguish as inequivalent.

ACKNOWLEDGMENT

Clifford algebra as quantum language

We suggest Clifford algebra as a useful simplifying language for present quantum dynamics. Clifford algebras arise from representations of the permutation groups as they arise from representations of the rotation groups. Aggregates using such representations for their permutations obey *Clifford statistics*. The vectors supporting the Clifford algebras of permutations and rotations are plexors and spinors, respectively. Physical spinors may actually be plexors describing quantum ensembles, not simple individuals. We use Clifford statistics to define quantum fields on a quantum space–time, and to formulate a quantum dynamics-field-space–time unity that evades the compactification problem. The quantum bits of history regarded as a quantum computation seem to obey a Clifford statistics. © *2001 American Institute of Physics.* [DOI: 10.1063/1.1353183]

I. SPINORS AND PLEXORS

Pauli represented electron rotations in SO(3) with elements of the Clifford algebra of a **3**, and Dirac represented Lorentz transformation in SO(1, 3) with elements of the Clifford algebra of a **4**. (In what follows, all representations and their homomorphisms are projective, and may be double valued, unless they are stated to be linear or vector representations, which are single valued. **1**, **2**, **3**,... represent real quadratic spaces of dimension 1, 2, 3,... and of signature specified in context.)

It is unlikely that they knew that Wiman[1] and Schur[2] had represented permutations in the permutation group S_N (also called ''the symmetric group,'' no doubt because its elements are not symmetric) with elements of the Clifford algebra of $(N-1)\mathbf{1}$. A vector space (or module) on which these Clifford algebras are faithfully represented as endomorphism algebra (or ring) are called spinors for the orthogonal groups and *plexors* for the permutation groups. Plexors and spinors are isomorphic mathematical objects of different physical meaning. Spinors arise in one-body quantum physics, plexors in N-body quantum physics with $N>3$.

In the first years of quantum theory, physicists overlooked spinors because they do not occur in the tensor product of vectors. We then proceeded to overlook plexors until Nayak and Wilczek[3] for much the same reason.

Clifford representation of the permutation groups. We write the free Clifford algebra over a quadratic space V as

$$\mathrm{Cliff}(V)=\mathbf{2}^V \tag{1}$$

and the spinor space S of V defined by the isomorphism $\mathbf{2}^V\cong S\otimes S^\dagger$, as

$$S=\sqrt{\mathbf{2}^V}=\sqrt{2}^V. \tag{2}$$

a)Electronic mail: gt1570a@prism.gatech.edu

We construct a reducible Clifford representation R of the permutation group S_N by associating the ath individual of the N-ad being permuted with a first-degree Clifford unit $i_a \in \mathbf{2}^{N1}$, for $a = 1,...,N$, obeying Clifford relations

$$i_a i_b + i_b i_a = 2\delta_{ab}. \tag{3}$$

For quantum applications we define an adjoint † on $\mathbf{2}^V$ by

$$i_a^\dagger = i_a. \tag{4}$$

Then R represents each swap $(ab) \in S_N$ (for $a<b$) by the Clifford difference $R(ab) = i_b - i_a$:

$$R: S_N \to \mathbf{2}^{N1}, \quad (ab) \mapsto i_a - i_b. \tag{5}$$

It is straightforward to see that R is a (projective!) representation of S_N. The i_a make up an orthonormal basis for the first-degree subspace $\mathcal{V} = \mathrm{Cliff}_1(N,0) \subset \mathrm{Cliff}(N,0)$. Let us call R the *orthonormal* Clifford representation of S_N.

R', a useful variant of R, replaces Eq. (3) by

$$i_a i_b + i_b i_a = 2t_{ab}, \tag{6}$$

where

$$t_{ab} = \frac{N+1}{N-1}\delta_{ab} - \frac{2}{N-1}. \tag{7}$$

The form t_{ab} is the inner product between two unit vectors i_a, i_b from the center of a regular $N-1$-simplex $\sigma^{N-1} \subset (N-1)\mathbf{1}$ to its N vertices $i_1,\ldots,i_N$. The i_a of Eq. (6) can be identified with the N simplex vertices permuted. We therefore call R' the *simplicial* representation of S_N. It is isomorphic to a representation given less symmetrically by Schur (1911). The R' image of S_N is an irreducible group of Clifford-algebra elements $\tilde{S}(N)$ that is a (universal) covering group $\tilde{S}_N$ of the discrete group S_N. [Schur (1911) would call $\tilde{S}(N)$ a ''representation group'' of S_N, but today this seems apt to be confused with a group representation.]

The concept of rotation presupposes physical concepts of angle and length. The concept of permutation does not. It presupposes the more primal concept of identity. Therefore permutation groups can enter theoretical physics at finer levels of resolution and higher energies than rotation groups. Plexors may be more basic than spinors.

Representations of permutation groups, and hence plexors, enter quantum physics by two specially deep routes, statistics and dynamics.

II. CLIFFORD STATISTICS

A *statistics* describes how we compose individual quantum elements into an aggregate quantum system. Such a transition from the individual to the collective is sometimes called ''second quantization,'' merely because it introduces new operators, but is better called quantification. Quantification has little to do with quantization and is thousands of years older.

A quantification or statistics is often defined by giving a representation of each permutation group S_N. A *Clifford statistics* represents permutations doubly by Clifford algebra elements of degree 1.[4–8] A *cliffordon* is a quantum whose aggregates have Clifford statistics. A *squadron* is a quantum assembly of cliffordons.

The operators representing operations on a squadron of cliffordons, including the observables of the squadron, form the Clifford algebra of the one-cliffordon mode space. Modes of the squadron are plexors of its Clifford algebra, representable by elements of a minimal left ideal of the algebra.

A statistics is *Abelian* (or central, or scalar, respectively) as its representation of the permutation group is. The Bose and Fermi statistics are Abelian, and the Maxwell, Clifford, and braid statistics are non-Abelian. Read and Moore[9] suggested non-Abelian statistics for quasiparticles of the fractional quantum Hall effect. Nayak and Wilczek[3] recognized this as a Clifford statistics in the first application of the Schur[2] theory to physics. While anyonic and braid statistics are confined to two dimensions, Clifford statistics works in any dimensionality.

A. Spinors describe aggregates

When a spinor of SO_N describes one quantum individual with N possible modes, a plexor of S_N describes a complex of at least N isomorphic individuals. Thus our belated encounter with Schur[2] disabuses us of a long-held notion that spinors represent simpler entities than vectors, a notion that has blocked important research directions. Spinors represent aggregates.[10]

This deserves to be said three times, differently.

B. Spinors describe aggregates

That spinors describe aggregates in quantum theory was already implicit in Cartan's theory of spinors. Cartan starts from a complex vector space $\mathcal{V}$ with a symmetric quadratic form g. The complex space $\mathcal{V}$ can be decomposed (in many ways) into two maximal null subspaces $\mathcal{V}_\pm$ as $\mathcal{V}=\mathcal{V}_+\otimes\mathcal{V}_-$. (A *null space* is one composed entirely of null vectors.) A Cartan spinor—relative to such a decomposition!—is an element of the Grassmann algebra $\bigvee\mathcal{V}_+$. The spinor space $\mathcal{S}$ then has dimension

$$\mathrm{Dim}\,\mathcal{S}=2^{\lceil (D-1)/2\rceil}, \tag{8}$$

where $\mathrm{Dim}\,\mathcal{V}=D=2\,\mathrm{Dim}\,\mathcal{V}_+$ and $\lceil N\rceil$ is the greatest integer $n\leqslant N$. Quantum theory interprets $\mathcal{V}_\pm$ as mode spaces for a fermion and the Grassmann algebra $\bigvee\mathcal{V}_+$ as the algebra of an aggregate of such fermions. Thus Cartan spinors describe fermionic quantum aggregates, not elementary individuals.

C. Spinors describe aggregates

The fact that a vector v can be expressed through a spinor ψ bilinearly as $v^\mu=\psi^\dagger\sigma^\mu\psi$ is sometimes cited to indicate that the vector is less elementary. This is a categorical error. The relation $v^\mu=\psi^\dagger\sigma^\mu\psi$ indicates that a spinor, like an aggregate of vectors, carries enough information to define a vector. But a vector cannot define a spinor. Therefore the vectorial object is a subobject of the spinorial object, not conversely.

Some have called Dirac's spinor space a ''square root of space–time,'' because v^μ is quadratic in ψ^α. More accurately, a spinor space $\mathcal{S}$ is the square root of the Clifford algebra $\mathcal{C}=2^{\mathcal{X}}\cong\mathcal{S}\otimes\mathcal{S}^\dagger$ over space–time; or half thereof, after reduction:

$$\mathcal{S}=\sqrt{2}^{\mathcal{X}}. \tag{9}$$

$\mathrm{Dim}\,\mathcal{S}$ is never less than $\mathrm{Dim}\,\mathcal{X}$, and is exponentially greater for high dimension.

Since plexors describe aggregates, plexor theory can be a quantum substitute for set theory. We apply it to quantum dynamics next.

III. CLIFFORD DYNAMICS

A *dynamics*, too, can be defined by a permutation. First we give a fixed set $\mathcal{V}$ of elementary processes that the system under study can undergo. Then we give a permutation

$$D:\mathcal{V}\to\mathcal{V}. \tag{10}$$

For any elementary process $s \in \mathcal{V}$, we interpret Ds as the immediate successor of s in the dynamical development defined by D. We write the group of such permutations of $\mathcal{V}$ as $S(\mathcal{V})$.

It is customary to avoid messy boundary questions by imagining experiments that have gone on forever and will continue forever. We shall use periodic boundary conditions. Now the experimental space–time region ultimately closes on itself, outside the interesting part of the experiment. This is no more fantastic than the infinite domain and it permits us to work in a finite-dimensional algebra.

A permutation D partitions its domain $\mathcal{V}$ into a congruence of orbits. These are the threads that tie the dynamical elements together. They do not intersect. The intersecting geodesics and the light cones of space–time must arise when we project orbits from eight dimensions down to the four dimensions of space-time. They arise from and describe a quantum entanglement that occurs in the dynamical development.

Then a possible quantum concept of a dynamics mode D is an operator D in the algebra of a representation of $S(\mathcal{V})$, e.g., in the algebra of the covering group $\tilde{S}(\mathcal{V})$. Since S_N is not simple in general, and distinguishes a basis in SO_N, we do not found our theory on this concept. Instead we imbed S_N in the simple group SO_N as the axis-permuting elements, and represent SO_N. We still interpret the operator D as defining a dynamical succession.

Everything we know about a system is in the record of our dynamical operations on the system. A good language for quantum dynamics is then a language of great expressive power.

As syntax for the dynamics language, abstract † algebra is not sufficient. It deals only with how to combine actions in series and parallel, by multiplication and addition, and how to reverse their internal chronological order, by forming the adjoint. It omits space–time fine structure, which is supplied in standard quantum theory by classical constructions prior to the definition of the algebra. How to express space–time concepts within the algebra is part of the problem of marrying quantum theory with gravity theory. We use a high-dimensional Clifford algebra to express quantum space–time.

The statistics and the dynamics roads to the permutation group join when we postulate that ordinary dynamical processes are aggregates too, namely of elementary dynamical processes. In the standard field theory the general process is composed of operations that go on everywhere in the system all the time, described by the Hamiltonian or Lagrangian density. Space–time is how the parts of the dynamics are interconnected.

Any quantum-dynamical theory must give the statistics of its elementary quantum-dynamical processes. In standard physics they are tagged with space–time coordinates, so they are distinguishable and implicity obey Maxwell–Boltzmann statistics.

A. Plexic dynamics

To learn the structure of the dynamical process, we dissect it into its atomic constituents and reassemble it out of them. Evidently these elements of dynamics must still have the nature of dynamical processes themselves. The dynamics is built out of elementary dynamical actions χ, represented by arrows joining states. The simplest classical concept of dynamics is a topological dynamics D.[11] This is usually presented as a map $D:S \to S$ of a set of states S into itself. Instead we deal only with dynamical actions and not with states. We define the dynamics as a mapping D sending each arrow χ to its dynamical successor D_χ.

A theory that puts states of being prior to modes of action is called ontic, the reverse *praxic*. Praxism is an acute case of the pragmatism of Charles Peirce and William James and the operationalism of Einstein and Heisenberg. Here we dissect dynamical operations into micro-operations as James proposed to analyze experience into microexperiences.

This praxic concept of classical dynamics introduces our two principals: a set X of atomic actions $\chi \in X$, and a semigroup $S(X)$ of possible dynamical developments

$$D:X \to X. \tag{11}$$

Dynamical developments are 1-1 mappings or permutations of $X \to X$.

To formulate a quantum dynamics we ''quantize'' the structure (11). That is, we replace classical variables described by sample spaces with corresponding quantum variables described by full matrix algebras. Our prime variable is not space–time, as Einstein proposed, but the dynamical law. Anandan[12] has proposed (like Newton) that dynamical law is variable and Smolin[13,14] that it evolves. We sharpen this assumption and take the dynamical law as the only independent variable, on which all others depend.

The individual elementary quantum process making up the dynamics we call the chronon χ. Its mode space $\mathcal{X}$ and algebra Endo($\mathcal{X}$) replace the set X of atomic actions. Its operator algebra $\mathcal{A}(\mathcal{X}) := \mathrm{Endo}\,\mathcal{X}$ replaces and synthesizes the commutative Boolean algebra of X and the arrow semigroup of ordered pairs $X \times X$. The nearest classical analog of a chronon is not a space–time point, which has no natural dynamical successor, but a tangent or cotangent vector (x, v) or (x,p), which does. These form an eight-dimensional manifold, not a four-dimensional one.

To describe an aggregate of chronons we need a statistics for the chronon.

Neither Fermi, Bose, nor Maxwell statistics will do. A dynamics is a permutation. A Fermi aggregate, like a classical set, is invariant under any permutation of its elements. It cannot represent its dynamics by its permutations. Nor can a Bose aggregate.

And Maxwell statistics are reducible.

Evidently chronons, to be permuted effectively, must be distinguishable, like classical space–time points, which are implicitly supposed to have Maxwell statistics.

In nature the ambient dynamics has modes with spin 1/2.

The simplest statistics that supports two-valued representations of S_N is the *Clifford statistics*. The operator algebra of this aggregate is a Clifford algebra $\mathcal{C} = \mathrm{Cliff}(\mathcal{V}I)$ generated by individual unit modes i_a obeying Eq. (3). The difference of two units $C(ab) = i_a - i_b$ represents their swap (ab). We identify the individual mode space $\mathcal{V}I$ with the first-degree subspace $\mathcal{C}_1 \subset \mathcal{C}$. Here there is no doubt that the spinor represents an aggregate, namely the aggregate that the permutations permute.

Schur[2] and Nayak and Wilczek[3] use complex coefficients throughout. They represent some swaps by sums $i_a + i_b$ and others by differences $i_a - i_b$, depending on an arbitrary choice of $N-1$ generating swaps. It is not possible to represent all swaps (ab) by sums $i_a + i_b$. But their representation is isomorphic to the simplex representation (7), of all swaps by differences.

Choosing Clifford statistics for chronons expresses the distinguishability of events and the existence of spin 1/2. The grade of a Clifford element gives the minimal number of swaps or chronons in its factorization, corresponding roughly to classical phase-space volume.

In the quantum theory of a variable dynamics D, we distinguish between the dynamics D and some dynamics operator D that describes D maximally, just as we distinguish between a hydrogen atom H and a mode vector ψ maximally describing H. A Hamiltonian is a kind of dynamics operator of the continuum limit.

Standard quantum theory uses modes in a complex † space $\mathcal{V}$ whose † defines a nonsingular sesquilinear form $\psi\dagger\phi$. Gauge invariance requires that the gauge generators be anti-Hermitian, and the gauge group structure requires that some of them be nilpotent. Only in an indefinite sesquilinear space can a nilpotent other than the trivial 0 be anti-Hermitian. Therefore † is usually indefinite, and the quantum theories that work in Hilbert spaces, with their definite *, are not sufficiently relativistic for physics.

B. Field theory under the microscope

Clifford statistics also resolves a question that has beset quantum space–time physics from its inception. What is the algebra of quantum fields on a quantum space–time? When we first asked this question[15] we imagined that the q bits of the space–time quantum computer all commuted, and had serious difficulties with this question. Now that they all anticommute it answers itself.

First the problem. In classical physics, the field fiber $\mathcal{F}$ of field values and the Minkowski manifold $\mathcal{M}$ of space–time points are combined (at least locally) by exponentiation into a space

$$\Phi = \mathcal{F}^{\mathcal{M}} \tag{12}$$

of fields, each field $f \in \mathcal{F}^{\mathcal{M}}$ being a function $f:\mathcal{M}\to\mathcal{F}$.

Question: How do we define the exponential F^M when the classical spaces $\mathcal{F}$ and $\mathcal{M}$ have been replaced by operator algebras describing quantum field and space–time entities?

Answer: Take the logarithms of the algebras. This reduces the computation of the exponential to the computation of products, an already solved problem.

We expand on this answer a bit.

One's first guess for the algebra F^M is apt to be the algebra of linear morphisms $M\to F$, but this reduces merely to the tensor product $M^\dagger\otimes F$ when M and F are algebras, and represents merely a pair of one M quantum and one F quantum. This is to be expected, since M and F describe individuals, not aggregates, and a mapping from one individual to another is merely one ordered pair.

For a better answer, one must express algebraically the fact that $\mathcal{M}$ is a plenum, not a point. All the points of $\mathcal{M}$ are actual, not mutually exclusive possibilities.

This is just the case for the Clifford statistics, which permutes entities that are all present at once. We designate a real free Clifford algebra $\mathcal{C}$ over a quadratic space $\mathcal{X}$ with endomorphisms algebra $\mathcal{A}=\mathrm{Endo}(\mathcal{X})$ by

$$\mathcal{C}=\mathbf{2}^{\mathcal{X}}=\sqrt{\mathbf{2}}^{\mathcal{A}}=\mathrm{Cliff}\,\mathcal{X}. \tag{13}$$

This makes $\mathcal{A}$ a logarithm of $\mathcal{C}$ and tells us how to define any quantum exponential of $\mathcal{C}$:

$$\mathcal{C}^{\mathcal{M}}:=(\sqrt{\mathbf{2}}^{\mathcal{A}})^{\mathcal{M}}:=(\sqrt{\mathbf{2}})^{\mathcal{A}\otimes\mathcal{M}}=\mathrm{Cliff}(\mathcal{X}\otimes\mathcal{Y}), \tag{14}$$

where $\mathcal{M}=\mathrm{Endo}(\mathcal{Y})$.

It is not hard to see that the observed field algebras do have logarithm algebras, using the Chevalley[16] representation of spinors within their Clifford algebra.

Definitions: An *octad* is a squadron of eight cliffordons with neutral quadratic form. An octad space is a real neutral quadratic space

$$\mathbf{8}=\mathbf{4}\oplus\overline{\mathbf{4}} \tag{15}$$

of eight dimensions, where the bar indicates a reversal of metric, $\dagger\to-\dagger$. An *octon* is a hypothetical quantum whose mode space is **8**. An *octadic space* is a real neutral quadratic space whose dimension is a multiple of 8: The general octadic space is

$$\mathcal{O}=\mathbf{8}\oplus\ldots\oplus\mathbf{8}=N\mathbf{8} \tag{16}$$

with $N>0$ terms.

C. Examples

The tangent–cotangent space to Minkowskian space–time $\mathcal{M}$ is the octad space $\mathbf{8}=\mathbb{M}\oplus\overline{\mathbb{M}^\dagger}$, where $\mathbb{M}:=\mathbf{1}\oplus\overline{\mathbf{3}}$ is the Minkowski tangent space. The irreducible spinor spaces of **8** are again octad spaces (Chevalley triality).

The Clifford algebra of an octadic space, with its neutral quadratic form, is algebra-isomorphic to the Clifford algebra of a space of the same dimension with a definite quadratic form.

Octad lemma: An octadic chronon algebra $\mathbf{2}^{N\mathbf{S}}$ factors as a Maxwell–Boltzmann ensemble of N octads each with algebra $\mathbf{2}^{\mathbf{S}}$.

$$\mathbf{2}^{N\mathbf{S}}=\mathbf{2}^{\mathbf{S}}\otimes\ldots\otimes\mathbf{2}^{\mathbf{S}}\quad(N\ \text{terms}) \tag{17}$$

In the limit $N\to\infty$, this Maxwell–Boltzmann ensemble includes a Bose–Einstein aggregate of octads.

It is easy to see that this Bose–Einstein aggregate admits condensation into an eight-dimensional symplectic manifold isomorphic to the tangent bundle to space–time. A field of operators on space–time is a similar condensation of a squadron of octads as $N\to\infty$, $\hbar\to 0$.

This is a great simplification. The group of a bundle is never simple; the base couples to the fiber without reverse coupling. In Galilean relativity the base was time, while in field theory the base is space–time, but the illness is the same, and the cure too: relativization. In Eq. (14) the field and the space–time are unified in the simple space–time-field entity $\mathcal{S}$. When we first attempted to express field theory in terms of q bits or chronons[15] we imagined an absolute split between field fiber and space–time base. Now the field/space–time split appears to be a factorization of a field-space–time unity $\mathcal{S}$. It is as relative as the factorization of space–time into space/time.

IV. QUANTIFICATION OPERATORS

Each of the usual statistics, Fermi, Bose, and Maxwell, has an operator-valued form $Q^\dagger$ and dual form Q that defines how infinitesimal actions on the individual can act on the aggregate.

In each statistics the individual I has a mode vector space $\mathcal{V}(I)$ and operator algebra $\mathcal{A}(I)$. The aggregate has a mode vector space $\mathcal{V}(S)$ and operator algebra $\mathcal{A}(S)$. Let $d\mathcal{A}$ be the infinitesimal Lie algebra of $\mathcal{A}$ with Lie product $[\alpha,\beta]:=\alpha\beta-\beta\alpha$. The quantification operator $Q^\dagger$ is a linear morphism

$$Q^\dagger:\mathcal{V}(I)\to\mathcal{A}(S),\qquad \psi\mapsto Q^\dagger\psi, \tag{18}$$

transforming a mode vector (or a ket) $\psi\in\mathcal{V}(I)$ for the individual to an operator $Q^\dagger\psi\in\mathcal{A}(S)$ for the aggregate. The operators $\psi^\dagger Q$ generate $\mathcal{A}(S)$ † algebraically. The mapping

$$\langle\ldots\rangle:d\mathcal{A}(I)\to d\mathcal{A}(S),\qquad w\mapsto\hat{w}=Q^\dagger wQ \tag{19}$$

is a Lie-algebra homomorphism.

We call the Q with these properties, when it exists, the *quantification operator* of the statistics. If w represents an additive quantity or infinitesimal transformation of the individual, we call $Q^\dagger wQ$ the *quantified w* for the quantified system. The quantification operators of Fermi, Bose, and Maxwell statistics map individual mode vectors ψ into annihilation operators $Q^\dagger\psi$, and individual quantities q into additive total quantities $Q^\dagger qQ$. Clifford statistics also has a quantification operator $Q^\dagger$, which maps mode vectors into swaps instead of creation operators.

The Clifford quantification operator Q_0 obeys the Clifford law

$$(\forall v\in\mathcal{V})(Q_0^\dagger v)^2=\|v\|. \tag{20}$$

We chose the sign in Eq. (3) so that the mapping (19) is a Lie algebra homomorphism, preserving the commutation relations of the individual within those of the aggregate, as for Fermi and Bose statistics. This is just the familiar fact that the commutators $L_{ab}=i_{[ab]}$ generate a representation of the orthogonal group.

We write the quantification operators for Clifford, Fermi, and Bose statistics as Q_0, Q_1, and Q_2. The numerical subscripts count the independent imaginaries in the coefficient field $\mathbb{R}$, $\mathbb{C}$, and $\mathbb{H}$ of the classical group of the statistics. We write Q_M for the Maxwell–Boltzmann quantifiation operator. We call the most important aggregates (Maxwell) *sequences*, (Bose) *sibs*, (Fermi) *sets* and (Clifford) *squadrons* for brevity. We call the Clifford composite a *squadron* to remind us that it is an essentially *quantum* structure. There are classical sets and classical sibs, but no classical squadrons. Clifford statistics, like anyonic and other multivalued statistics, involves quantum superposition more deeply than the single-valued composites such as the sequence, sib, or set.

For example if L is a component of individual angular momentum, then for Fermi quantification $Q=Q_1$ and Bose quantification $Q=Q_2$, $Q^\dagger LQ$ is the total angular momentum of the aggregate. These quantifications *totalize* the operator on which they act.

The Maxwell quantification operator Q_M does not totalize. The quantified operator $Q_M^\dagger L Q_M$ represents the L of only the last individual in the sequence, not the total ω. Totals have somewhat more complicated expressions in Maxwell statistics.

Clifford quantification, like Fermi and Bose, totalizes.

Clifford statistics relates a quadratic space $\mathcal{V}$, its endomorphism algebra $\mathcal{A}$, its Clifford algebra $\mathcal{C}$, and its spinor space $\mathcal{S}$, by the commutative diagram

$$\begin{array}{ccc} & \overset{\text{Endo}}{} & \\ \mathcal{V} & \rightarrow & \mathcal{A} \\ Sq\downarrow & \searrow \text{Cliff} & Sq\downarrow \\ & \overset{\text{Endo}}{} & \\ \mathcal{S} & \rightarrow & \mathcal{C} \end{array} \tag{21}$$

When we apply Clifford statistics to dynamics, $\mathcal{V}$ is the mode space $\mathcal{X}$ for a chronon. The composite system described by a spinor of $\mathcal{S}$ consists of all the chronons transpiring in the experimental space–time region. The algebra $\mathcal{A}$ consists of endomorphisms of $\mathcal{V}$. The Clifford algebra $\mathcal{C}$ consists of descriptions D of the global dynamics of the squadron.

The real Clifford algebra $\mathcal{C}=\text{Cliff}(\mathcal{V},\mathbb{R})$ of Clifford statistics is the endomorphism algebra of an underlying spinor module $\mathcal{S}$ over one of the five rings $\mathbb{R}$, $\mathbb{C}$, $\mathbb{H}$, $2\mathbb{R}$, $2\mathbb{H}$, depending on the dimension and signature of ν according to the spinorial chessboard.[17]

Clifford statistics can readily simulate Bose and Fermi statistics with pseudobosons and pseudofermions. In Eq. (17), Clifford statistics exactly simulates an aggregate of octads obeying mutual Maxwell–Boltzmann statistics and internal Clifford statistics at the same time.

The most striking difference between the Clifford statistics and Fermi statistics cannot be read from their algebras. Orthogonal ψ's anticommute in both statistics, and every fermionic algebra is algebra isomorphic to a neutral Clifford algebra, but fermions are identical and cliffordons are not. An algebra does not define its interpretation. The exchange of two fermions is represented by factor exchange, one stipulates, and hence by -1, which is projectively equivalent to the identity. The exchange of cliffordons 1 and 2, however, is represented by i_1-i_2. Cliffordon swaps, far from being trivial, scalar, or central, may generate the entire aggregate action algebra.

V. CHRONON DYNAMICS

We hypothesize that the dynamics of a suitably isolated physical system is a squadron of elementary dynamical processes or chronons, and that the ambient vacuum breaks its Clifford algebra $\mathcal{C}$ down into many mutually commuting local octadic Clifford algebras as in Eq. (17).

We construct a simple finite-dimensional Clifford algebra $\mathcal{C}=\check{\mathcal{A}}$ that approaches (or ''contracts to'' (cf. Ref. 18) the Minkowski manifold algebra, the associative algebra $\mathcal{A}=\mathcal{A}(x^\mu,\partial_\mu)$ of coordinates x and derivations ∂ of space–time differential geometry. $\mathcal{A}$ may be regarded as a generalization of the Heisenberg algebra of x and p and a variant of the Bose–Einstein algebra. Expanding it into a Clifford algebra is mathematically akin to approximating bosonic fields with fermionic ones, the process of bosonization.

Since $\mathcal{A}$ is infinite dimensional, the dimensions of $\mathcal{C}$ and its orthogonal group are huge, like the number of phase-space cells in the experiment, which is likely $\gg 10^{20}$ for atomic experiments, and approach infinity in the contraction to the continuum.

Chronons and the basic Clifford variables i_a that represent them are prelocal in the extreme, since they all anticommute. Nevertheless they are the raw material of our universe, we propose.

This only apparently clashes with quasilocality, due to Eq. (17).

A. Localization

We begin construction with an octadic chronon space $\mathbf{8}N$ and its Clifford algebra $\mathcal{C}$.

We decompose $\mathcal{C}$ into N mutually commuting octad algebras of independent local variables $\gamma_\mu(n)$ obeying local commutation relations

$$\{\gamma_\nu(n),\gamma_\mu(m)\}=t_{\nu\mu}\delta_{nm}. \tag{22}$$

We define the Lorentz algebra and group of such a Clifford algebra by the usual expression for the angular momentum of a spin aggregate,

$$\check{L}_{\nu\mu}:=\frac{1}{2}\sum_{n=1}^{N}\sum_{\beta=0}^{1}\gamma_{\mu\nu}(n,\beta). \tag{23}$$

We assume that p_μ and x^μ for the N squadrons are, like $L_{\mu\nu}$, additively composed of terms from each squadron, corresponding to how the displacement $\Delta x=\int_C \mathrm{d}x(\tau)$ along a curve $C{:}x=x(\tau)$ is an integral over C of a contribution from each differential element $\mathrm{d}x(\tau)$:

$$\Delta x^\mu=\sum_{n,\beta}\delta x^\mu(n,\beta),\quad \Delta p_\mu=\frac{1}{2N}\sum_{n,\beta}\delta p_\mu(n,\beta). \tag{24}$$

Here we use $\hbar=c=л=1$.

Suppose each tetrad has contributions

$$\delta x^\mu=2^{-1/2}\gamma^\mu,\quad \delta p_\mu=2^{-1/2}\gamma^\uparrow\gamma_\mu,\quad \delta i=\gamma^\uparrow. \tag{25}$$

The unit of x is $л$ and the unit of p is $\hbar/л$, while i is dimensionless.

Then for each tetrad

$$\begin{aligned}[\delta x^\nu,\delta p_\mu]&=\delta i\,\delta_{\nu\mu},\\ [\delta i,\delta x^\mu]&=+2\,\delta p^\mu,\\ [\delta i,\delta p_\mu]&=-2\,\delta x_\mu.\end{aligned} \tag{26}$$

The first equation of (26) makes $\gamma^\uparrow$ the expansion of Heisenberg's i, much as Hestenes[19] proposed. Presumably this builds in a violation of parity.

The second and third equations tell us that the expanded i generates the symplectic symmetry between x and p, as Segal[20] proposed. On the chronon scale, this violates Heisenberg's commutation relations seriously. In the standard quantum theory i is central.

We recover the Heisenberg commutation relations as a contraction of the Clifford relations by summation and a subsequent correlation:

$$\begin{aligned}\check{x}^\mu&=\sum_{n,\beta}\delta x^\mu(n,\beta),\\ \check{p}_\mu&=\frac{1}{2N}\sum_{n,\beta}\delta p_\mu(n,\beta),\\ \check{i}&=\sum_{n,\beta}\delta i(n,\beta).\end{aligned} \tag{27}$$

Here and in what follows, the breve on a variable, like $\check{i}$ Eq. (27) is a semantic annotation rather than a syntactic one. It declares that the accented variable is an expansion of the standard unaccented one, and reduces to it upon contraction. It thus tells us how to measure the variable in the contracted domain of experience. If one set of physical concepts successfully covers both domains, as in quantum theory and relativity, for example, we drop such labels.

Feynman[21] proposed that the space–time coordinate-difference operator is the sum of many mutually commuting tetrads of Dirac vectors:

$$\Delta x^{\mu} = \text{const} \sum \gamma^{\mu}(n) \tag{28}$$

as a quantum form of the proper-time Heisenberg–Dirac equation $\mathrm{d}x^{\mu}/\mathrm{d}r = \gamma^{\mu}(\tau)$. Feynman's proposal returns in Eq. (27) as a result of the octad lemma. Each of his γ's represents one chronon i^{a} in a large octadic squadron.

B. Correlation

We now have far too many *i*'s: one for every tetrad. In the standard physics there is only one imaginary *i* and one Clifford vector γ^{μ} for the whole system. We correlate all the δi so that they are effectively one *i*, and all the tetrads $\gamma^{\mu}(n)$ so that they are effectively one tetrad γ^{μ}. We suppose that the vacuum Bose–Einstein condensation establishes this correlation. The local departure of $\breve{i}$ from its global mean *i* is presumably a Higgs operator.

To be sure, the tetrads of the tetrad lemma obey Maxwell statistics, not Bose. But the mode space of Maxwell statistics is the direct sum of the spaces of all the tensorial statistics, including Fermi and Bose and parastatistics. Any Bose projection is *a fortiori* a Maxwell projection.

We require a projection operator $P \in \mathcal{C}$ expressing this alleged Bose–Einstein correlation, projecting onto the symmetric subspace.

We have constructed this symmetrizer elsewhere. The symmetric subspace of $\mathcal{S}$ is $P\mathcal{S}$, the *P* image of $\mathcal{S}$. The restrictions of the $\breve{i}(n)$ to $P\mathcal{S}$ are all equal to $P\breve{i}P$, the restriction of $\breve{i}$ to $\mathcal{S}$, with $\breve{i}$ given by Eq. (27).

It is then straightforward to see that this restriction of $\breve{i}$ is a square root of the restriction of -1 to *P*:

$$(P\breve{i}P)^{2} = -P. \tag{29}$$

It remains to be seen whether the variable $P\breve{i}P$ is sufficiently close to being central in processes close to the vacuum. If so then it can pass for the physical *i* of quantum mechanics in such processes.

The Clifford elements

$$L_{\mu\nu} = \sum_{\beta,\tau} [i_{\mu,\beta,\tau}, i_{\nu,\beta,\tau}] \tag{30}$$

are infinitesimal generators of the connected Lorentz group $\mathcal{L}$ of this model. The operators *x* and *p* constructed by Eq. (27) are covariant under the connected Lorentz group $\mathcal{L}$.

VI. RELATIVISTIC DYNAMICS OPERATOR

To recover Maxwell statistics in the classical space–time limit we were forced to order the octads with a ''proper time'' index τ. This permits us to formulate an ''octad-cycling'' dynamics operator D_o that advances τ by unity and so is a scalar invariant, unlike the Hamiltonian, which increases *t* and is one component of a vector.

A covariant development in proper time is generated by *a rest mass operator* just as a coordinate-time development is generated by a Hamiltonian energy operator. A covariant proper-time dynamics with a second-order mass operator is used by Schwinger among others. The present theory is a kind of ''quantum square-root'' of such theories.

D_o is then an ordered product of eight disjoint cycles of length *N* according to Clifford statistics. Defining $\Delta i_{\mu,\beta,\tau} := (i_{\mu,\beta,\tau+1} - i_{\mu,\beta,\tau})$, we write this basic dynamics operator as

$$D_o = \overleftarrow{\prod_{\beta}} \; \overleftarrow{\prod_{\mu}} \; \overleftarrow{\prod_{\tau}} \; \Delta i_{\mu,\beta,\tau}. \tag{31}$$

In the τ ordering, $\Delta i_{\mu,\beta,\tau}$ is to be treated as a whole with one index τ, not divided between τ and $\tau+1$. Each cycle of Eq. (31) swaps the μ, β chronon of octad τ with the μ, β chronon of octad $\tau+1$ according to the orthonormal statistics (5).

Now two apparently separate conceptual streams, special relativity and combinatorics, merge almost unexpectedly.

The octadic chronon dynamics D_o is Lorentz invariant. The proof is straightforward. It rests on the familiar fact that the Dirac top gamma $\gamma^{\uparrow}=``\gamma^5"$ is invariant under the connected Lorentz group. This confluence gives us renewed hope for a chronon dynamics.

D_o has several easily constructed brothers that are also Lorentz invariant and also shift tetrads or octads forward in τ by small steps.

D_o is still unsatisfactory for many reasons. Above all, it does not define the Minkowskian metrical structure of space–time. In a simple theory, Poincaré invariance of the ambient dynamics operator D is not enough. D must also define the space–time metric.

Physically, we must know the momentum of a moving particle to predict its next position sharply. This means a coupling among the eight components of space–time–energy–momentum. The dynamics D_0 is an uncoupled development. Lorentz-invariant couplings are now under study.

VII. SIMPLIFYING THE STANDARD MODEL

The simplification of the space–time structure of the standard model that we have performed so far suggests that we can simplify its internal structure as well by dissolving the separation between field variables and space–time variables. This was the goal of our earlier Fermi quantizations of space–time, and it comes closer in the present Clifford quantization.

The standard theory needs internal variables to describe hypercharge, isospin, color, and family because it assumes that the immediate neighborhood of any event is exactly Minkowskian. *At any one point all gauge vectors can be transformed to zero by a gauge transformation.*

In the case of gravity this assumption of the standard model specializes to Einstein's equivalence principle. We call this italicized proposition the *generalized equivalence principle* when we intend to include gravity among the gauge fields.

We have supposed that the field variables actually describe finite quasilocal defects of size $л$ in the vacuum condensate. In the continuum limit $л\to 0$, these vanish, and surrogate variables have to be invented. Variables that describe the condensate in maximal quantum detail, with $л\neq 0$, should suffice to describe its defects.

This approach to simplification avoids the compactification problem that plagues theories of the Kaluza kind. It replaces mysteriously small extra dimensions by physically small neighborhoods. The same chronon variables i^a that combine to form the external x's and ∂'s, also combine into the internal γ's and τ's, the fields, and the Lagrangian, a contraction of the dynamics operator. In the condensate many of these degrees of freedom are frozen. A high-energy interaction thaws and excites some of them. We require that the same i's give us the external modes when they sing in unison and the internal modes when they sing polyphonically.

VIII. DISCUSSION

The revolutions of the past hundred years of physics have simplified certain algebras. Several nonsimple algebras still wait to be simplified, notably the Heisenberg algebra of quantum theory, the algebra of the field bundle, and the algebra of dynamics. These couple to each other so that the next revolution must likely simplify them all at once. The result will be a nonlocal quantum theory.

We have given one obvious simplification of these algebras, postulating a dynamics operator D that contracts to the standard Hamiltonian and Lagrangian in a suitable limit but consists of many elementary quantum actions, chronons. The key unifying element is the Clifford statistics for the chronon.

This leads us to a quantum correspondent for the standard gauge principle: Remote comparisons are effected by a succession of quantum swaps. It also suggests a host of relativistic candidates for the dynamics operator D.

Some of these results were presented at the American Physical Society Centennial Meeting, Atlanta, 25 March 1999.[22]

Magnetic fields and factored two-spheres

J. S. Dowker[a)]
Theory Group, Department of Physics, Imperial College, Blackett Laboratory, Prince Consort Road, London, England

(Received 14 September 1999; accepted for publication 7 February 2000)

A magnetic monopole is placed at the center of a ball whose surface S^2 is tiled by the symmetry group, Γ, of a regular solid. The quantum mechanics on the two-dimensional quotient S^2/Γ is developed and the monopole charge is found to be quantized in an expected manner. The heat-kernel and ζ-functions are evaluated and the Casimir energy is computed. Numerical approaches to the calculation of the derivative of the Barnes ζ-function are presented. © *2001 American Institute of Physics.* [DOI: 10.1063/1.1345501]

I. INTRODUCTION

In previous work,[1] we have discussed quantum field theory on orbifold factors of spheres S^n/Γ, where Γ is a discrete subgroup of the orthogonal group, $O(n+1)$. In this paper we wish to present an extension in the two-dimensional case $(n=2)$ to the situation where there is a uniform radial magnetic field passing through the surface of the sphere. This can be thought of as due to a magnetic monopole at the center of a ball in an embedding R^3. The motivation is partly to investigate the interplay between a magnetic field and a nontrivial topology/geometry induced by identification. Specifically we would be interested in what happens to the Dirac quantization in topologically interesting or singular manifolds (orbifolds). There is also continuing statistical mechanical interest in magnetic fields and two-dimensional domains.

The quotient group is the complete symmetry group of a regular solid and can be generated by reflections in the three (concurrent) planes of symmetry of the solid. The elements fall into two sets depending on whether they contain an even or an odd number of reflections. The even subset forms the rotational subgroup denoted now by $\Gamma \in \mathrm{SO}(3)$. The odd subset is denoted by Γ_1'. If γ' is any fixed element of Γ' then as γ runs over Γ, $\gamma\gamma'$ exhausts Γ_1'. In particular we can choose $\gamma'=\sigma$ where σ is a reflection in a symmetry plane and so the complete group is

$$\Gamma' = \Gamma \cup \Gamma_1' = \Gamma \cup \Gamma\sigma. \tag{1}$$

The standard classification of finite subgroups (reflection groups) is given by Meyer,[2] and we use his notation. The general construction of the quotients, S^2/Γ', which in this case are certain geodesic triangles on S^2 is sketched later. The vertices of these triangles are singular points. Joining them to the origin of the ambient $\mathbb{R}^3$ produces singular strings and our analysis can be extended to this three-dimensional setting.[3] The two-dimensional models that we study can be thought of as toy models for more general ''textures'' in higher dimensions as laid down by Kibble [see, e.g., Ref. 4].

Our main interest is in setting up the general framework and then applying it to some specific calculations such as the evaluation of vacuum energies. This will involve a certain amount of technical manipulation, especially with the properties of the Barnes ζ-function. This function appears quite commonly, particularly in spherically symmetric situations and in the presence of magnetic fields or harmonic oscillators and we expect that our methods will have an applicability beyond the immediate one here.

A very brief summary of our findings is given in Sec. XIII.

II. MODES AND GROUP ACTIONS ON THE FULL SPHERE

As modes on the full sphere, we can take the angular part of the Schrödinger equation solutions derived long ago by Tamm[5] and Fierz.[6] It would be more rigorous to use a fibre bundle formulation (Greub and Petry,[7] Wu and Yang[8]) or geometric quantization[9,10] but this is unnecessary for our purposes. For definiteness, we employ the modes denoted by $(Y_{qm})_a$ in Wu and Yang, corresponding to the string running down the negative z-axis. The modes are, up to normalization, the SU(2) representation matrices $\mathcal{D}^{(l)*}_{m,-q}(\phi,\theta,-\phi)$ with $l=|q|,|q+1|\ldots,-l\leqslant m\leqslant l$.[11] $2q$ is the monopole number with $q\equiv eg/\hbar$, and $2q\in\mathbb{Z}$. If the string runs up the positive z-axis, the modes are $\mathcal{D}^{(l)*}_{m,-q}(\phi,\theta,\phi)$.

The corresponding eigenvalues of H_{S^2}, the angular part of $-(\nabla-ie\mathbf{A})^2$, are

$$\lambda_l=l(l+1)-q^2=(l+\tfrac{1}{2})^2-\tfrac{1}{4}-q^2 \tag{2}$$

with degeneracy $2l+1$.

It is helpful to give the explicit form of the angular eigenfunctions in spherical polar coordinates,

$$Y^{(l)}_{qm}(\theta,\phi)=N_{qlm}\sin^{|q+m|}(\theta/2)\cos^{|q-m|}(\theta/2)P^{|q+m|,|q-m|}_{l-(q|q+m|+|q-m|)/2}(\cos\theta)e^{i(q+m)\phi}, \tag{3}$$

where N_{qlm} is a normalization constant and the $P^{\alpha,\beta}_n(x)$ are Jacobi polynomials. In the Wu–Yang formalism these are the solutions (sections) in the upper hemisphere. In the lower hemisphere the potential is taken to have a string along the positive z-axis. The two sets of solutions are related on the equator by the factor $\exp(i2q\phi)$. Making this single valued gives the quantization condition on q, in this approach.

The basic means of finding the modes is to write $H_{S^2}\psi=\lambda\psi$ explicitly as a differential equation in spherical polar coordinates,

$$\frac{1}{\sin\theta}\frac{\partial}{\partial\theta}\sin\theta\frac{\partial\psi}{\partial\theta}+\frac{1}{\sin^2\theta}\frac{\partial^2\psi}{\partial\phi^2}+i\frac{2q}{1+\cos\theta}\frac{\partial\psi}{\partial\phi}-q^2\frac{1-\cos\theta}{1+\cos\theta}\psi=\lambda\psi, \tag{4}$$

and solve it assuming the separation $\psi(\theta,\phi)=\exp(iu\phi)P(\cos\theta)$. Using this method we can suppose initially that q is arbitrary which leads to the same solutions as in (3) but which are characterized by two integers $u\in\mathbb{Z}^+$ and $v\in\mathbb{Z}$.[5] The relationship to the SU(2) labels l and m is given by

$$l=u+\tfrac{1}{2}(|q+m|+|q-m|),\quad v=m-q \tag{5}$$

and thus it would appear that we could have any value of q as long as u and v are integers (with suitable $l,m\in\mathbb{R}$). However, in this case the solutions would not be single-valued and all the solutions would vanish on the string axis. Setting $2q\in\mathbb{Z}$ gives the same values of l and m as before.

As usual, when one tries to adapt wave functions to some symmetry (here Γ') there is the problem that the magnetic potential, $\mathbf{A}$, might not possess the same symmetry so that compensating gauge transformations are necessary. Peierls[12] calls this process ''umeichen.'' It is a well known situation, with extensive discussion,[13] which we have encountered in an earlier calculation on the tetrahedron,[14] an orbifold factor of the plane. A similar procedure has also been applied to factors of the Poincaré half-plane.

In the present case, under the action of Γ', the string is rotated and reflected and has to be brought back to its original position if we are to implement the identification in S^2/Γ' consistently. The equation that contains the relevant information is the behavior of the modes under arbitrary rotations-reflections. For the moment we deal with the easier, pure rotational case, $g\in\mathrm{SO}(3)$. Then the behavior is an elementary consequence of the SU(2) group combination law and one has explicitly (Wu and Yang,[8] Frenkel and Hraskó[15]),

$$Y^{(l)}_{qm'}(g^{-1}\hat{\mathbf{r}}) = e^{iq\Lambda_g(\hat{\mathbf{r}})} Y^{(l)}_{qm}(\hat{\mathbf{r}}) \mathcal{D}^{(l)}_{mm'}(g), \quad g \in \mathrm{SO}(3). \tag{6}$$

The exponential factor is the compensating gauge rotation with

$$\Lambda_g(\hat{\mathbf{r}}) = \alpha(g) + \gamma(g) - \Omega_g, \tag{7}$$

where α, β, and γ are the Euler angles of the rotation g and Ω_g is the solid angle subtended by the geodesic triangle on the (unit) sphere cut out by $-\mathbf{r}$, the string axis, $\mathbf{n}$ (here the negative z-axis) and the rotated string axis, $g\mathbf{n}$,

$$\Omega_g(\hat{\mathbf{r}}) = \Omega(g\mathbf{n}, \mathbf{n}; \mathbf{r}), \quad \mathbf{r} = (\hat{\mathbf{r}}, r).$$

(Our conventions regarding rotations and actions are generally those of Brink and Satchler.[16]) The gradient of Ω gives the gauge transformation between the potentials of the two strings.

An alternative expression for Λ is (Wu and Yang[8])

$$\Lambda_g(\hat{\mathbf{r}}) = \phi_g - \phi - A_g, \tag{8}$$

where A_g is the angle at $-\hat{\mathbf{r}}$ in the above mentioned triangle on S^2 and $g^{-1}\hat{\mathbf{r}} = (\theta_g, \phi_g)$

In order that (6) be consistently iterated, it is necessary that the group combination (cocycle) condition,

$$\Lambda_{gh}(\hat{\mathbf{r}}) = \Lambda_g(\hat{\mathbf{r}}) + \Lambda_h(g^{-1}\hat{\mathbf{r}}), \tag{9}$$

should hold, and this can be checked directly from (7). The geometrical details are to be found in the useful article by Frenkel and Hraskó.[15]

The magnetic rotation operator, T_g, is defined, on scalars, by the action

$$(T_g\psi)(\mathbf{r}) = e^{-iq\Lambda_g(\hat{\mathbf{r}})} \psi(g^{-1}\mathbf{r}), \tag{10}$$

or, equivalently,

$$\langle \mathbf{r} | T_g = e^{-iq\Lambda_g(\hat{\mathbf{r}})} \langle g^{-1}\mathbf{r} |. \tag{11}$$

In the present spherical case, because of (9), the magnetic rotations provide a true, as opposed to a ray, representation of the *double* of SO(3) [denoted $\mathrm{SO}^{\bullet}(3)$] in the sense that

$$T_{gh} = T_g T_h$$

and

$$T_E = (-1)^{2q}\mathbf{1}, \tag{12}$$

where E is a 2π rotation. This is not unexpected considering that for q a half odd-integer all the monopole harmonics have half odd-integer angular momentum. $\mathrm{SO}^{\bullet}(3)$ is isomorphic to SU(2).

Magnetic rotations on the plane[17] also provide true representations but not so *translations*, unless the flux through a fundamental domain is quantized.[18]

We record the action of T_g on the modes which is easily obtained from (10) and (6),

$$T_g Y^{(l)}_{qm'}(\hat{\mathbf{r}}) = Y^{(l)}_{qm}(\hat{\mathbf{r}}) \mathcal{D}^{(l)}_{mm'}(g). \tag{13}$$

III. PARITY AND REFLECTIONS

The singularity (string) preserving magnetic parity operator on monopole wave functions is defined by the action,[15]

$$(\Pi\psi)(\mathbf{r}) = e^{-iq\Omega(-\mathbf{n},\mathbf{n};\mathbf{r})} \psi(-\mathbf{r}) \tag{14}$$

under the inversion $\iota:\mathbf{r}\to-\mathbf{r}$.

On the modes we have, as an easy calculation shows

$$\Pi Y^{(l)}_{qm}=(-1)^l Y^{(l)}_{-qm}. \tag{15}$$

The parity operator can be used to extend the magnetic rotation operator T to include reflections. The reflection, σ, in the plane with normal $\mathbf{t}$ can be written as a rotation through π about the axis $\mathbf{t}$ combined with the parity inversion ι. This can be written as $\sigma=g_\pi\iota=\iota g_\pi$. The extension of T to reflections is thus defined by

$$T_\sigma\psi=T_{ig_\pi}\psi=T_\iota T_{g_\pi}\psi=\Pi T_{g_\pi}\psi.$$

From (10) and (14),

$$(T_\sigma\psi)(\mathbf{r})=e^{-iq\Omega_\sigma(\hat{\mathbf{r}})+iq\pi}(R_{g_\pi}\psi)(-\mathbf{r}), \tag{16}$$

and on the modes,

$$(T_\sigma Y^{(l)}_{qm'})(\hat{\mathbf{r}})=(-1)^l Y^{(l)}_{-qm}(\hat{\mathbf{r}})\mathcal{D}^{(l)}_{mm'}(g_\pi). \tag{17}$$

IV. CONSTRUCTION OF THE DOMAINS S^2/Γ'

It is convenient now to formalize briefly what we mean by the space S^2/Γ' where Γ' is a finite subgroup of O(3). A region of the sphere $\mathcal{F}\in S^2$ is called a fundamental domain for Γ if it satisfies the following criteria:

(i) $\mathcal{F}$ is open in S^2,
(ii) $\mathcal{F}\cap\gamma\mathcal{F}=\varnothing$, $\forall\,\gamma\in\Gamma'-\{id\}$,
(iii) $S^2=\cup_{\gamma\in\Gamma'}\overline{\gamma\mathcal{F}}$.

We also assume that $\mathcal{F}$ is connected.

Physically, $\mathcal{F}\cup\partial\mathcal{F}$ represents the space on which our theory is defined, and all the copies of $\mathcal{F}$ on S^2 must be physically equivalent.

The space S^2/Γ' is the the sphere S^2 with the points $\mathbf{r}$ and $\gamma\mathbf{r}$ identified for all $\gamma\in\Gamma'$. If Γ' acts freely on S^2, i.e., there are no fixed points, then S^2/Γ' is closed and can be taken to be $\mathcal{F}$ with identified boundary. If there are fixed points, these will be contained in $\partial\mathcal{F}$ and can be considered as boundary singular points of S^2/Γ'.

When Γ is purely rotational the fixed points form a discrete set of which there are two, or three, in $\partial\mathcal{F}$. For the extended, reflection groups, as already indicated, the boundary $\partial\mathcal{F}$ is constructed from the intersections of two or three reflection planes with the sphere. Thus there are transformations that map $\mathcal{F}$ into adjacent domains and which leave part of the boundary of $\mathcal{F}$ fixed. The conclusion here is that, unlike the rotational case, the boundary $\partial\mathcal{F}$ is a real boundary and the physical manifold is termed a Möbius triangle.

V. PROJECTION TO S^2/Γ

Still restricting to purely rotational Γ, we will now formally project everything down to S^2/Γ in a more or less standard fashion.

In order that a function $\tilde{\psi}(\mathbf{r})$ on S^2 project down consistently to S^2/Γ, it is necessary that it satisfy the magnetic periodicity condition,

$$T_g\cdot\tilde{\psi}(\mathbf{r})=a(g^\bullet)\tilde{\psi}(\mathbf{r}),\quad g\in\Gamma^\bullet, \tag{18}$$

where $a(g^\bullet)$ forms a one-dimensional representation of $\Gamma^\bullet$, the double of Γ, and labels the projection. For ease we have put $\mathbf{r}$ in place of $\hat{\mathbf{r}}$. We show later that there is a minimal choice for $a(g^\bullet)$.

If q is integral, there is no need to introduce the group doubles. However, if one does, there is a simple duplication, which is easily dealt with in practice as we can show with the following, somewhat superfluous, constructions.

Since the action of $\Gamma^\bullet$ covers the sphere S^2 twice, we introduce the trivial double covering, $S^{2^\bullet}$, of two identical copies of S^2, with $S^{2^\bullet}/\Gamma^\bullet = S^2/\Gamma$.

The modes themselves do not change sign on a 2π rotation, even when l is half odd-integral, and neither does the wave function. So $\psi^\bullet(\mathbf{r}) = \psi^\bullet(E\mathbf{r})$, where E is a 2π rotation, and therefore, $\tilde{\psi}(\mathbf{r}) = \psi^\bullet(\mathbf{r})$.

We then have, somewhat non-rigorously, for the function, $\psi(\mathbf{r})$, on $S^{2^\bullet}/\Gamma^\bullet$ the numerical equality

$$\psi(\mathbf{r}) = \psi^\bullet(\mathbf{r}), \tag{19}$$

where we do not distinguish between the projected and original coordinates, both being denoted by $\mathbf{r}$. The $\mathbf{r}$ on the right belongs to the fundamental domain of $\Gamma^\bullet$ on $S^{2^\bullet}$, which is, of course, isomorphic to that of Γ on S^2. Then,

$$T_{g^\bullet}\psi(\mathbf{r}) = a(g^\bullet)\psi(\mathbf{r}). \tag{20}$$

The heat-kernel on S^2, written in mode form,

$$K_{S^2}(\mathbf{r},\mathbf{r}';\tau) = \sum_{l=|q|}^{\infty} e^{-\lambda_l \tau}\,\mathrm{Tr}[\mathbf{Y}_q^{(l)}(\mathbf{r})\mathbf{Y}_q^{(l)\dagger}(\mathbf{r}')], \tag{21}$$

propagates arbitrary wave functions on S^2 and satisfies the important switching relation

$$K_S(\mathbf{r},g^{-1}\mathbf{r}';\tau) = e^{-iq\Lambda_g(\mathbf{r}')-iq\Lambda_{g^{-1}}(\mathbf{r})}K_S(g\mathbf{r};\mathbf{r}';\tau),$$

which realizes in coordinate representation the operator rotational symmetry,

$$T_g K_{S^2} = K_{S^2} T_g$$

[see (11)].

The heat-kernel that propagates wave functions on $S^{2^\bullet}/\Gamma^\bullet$ obeying (20) is, by general theory,

$$K_{S^{2^\bullet}/\Gamma^\bullet}(\mathbf{r},\mathbf{r}') = \sum_{g^\bullet \in \Gamma^\bullet} a(g^\bullet) T_{g^{\bullet -1}} K_{S^2}(\mathbf{r},\mathbf{r}'), \tag{22}$$

which is referred to as the preimage form of this propagator in terms of that on $S^{2^\bullet}$.

The double group $\Gamma^\bullet$ can be decomposed,

$$\Gamma^\bullet = \Gamma \cup E\Gamma,$$

and the sum over $\Gamma^\bullet$ reduced to a sum over the subset Γ,

$$K_{S^{2\bullet}/\Gamma^\bullet}(\mathbf{r},\mathbf{r}') = \sum_{g\in\Gamma} (a(g)T_{g^{-1}} + a(Eg)T_{(Eg)^{-1}})K_{S^{2\bullet}}(\mathbf{r},\mathbf{r}'). \tag{23}$$

We know, (12), that $T_E = (-1)^{2q}\mathbf{1}$ and so from (20), $a(E) = (-1)^{2q}$. Hence $a(E)T_E = \mathbf{1}$ and so

$$K_{S^{2\cdot}/\Gamma\cdot}(\mathbf{r},\mathbf{r}')=2\sum_{g\in\Gamma}a(g)T_{g^{-1}}K_{S^{2}\cdot}(\mathbf{r},\mathbf{r}'), \tag{24}$$

which means we can finally write what was almost obvious from the start, the preimage sum,

$$K_{S^2/\Gamma}(\mathbf{r},\mathbf{r}')=\sum_{g\in\Gamma}a(g)T_{g^{-1}}K_{S^2}(\mathbf{r},\mathbf{r}'). \tag{25}$$

The factor of 2 is a normalization (volume) factor between $S^{2\cdot}$ and S^2, $K_{S^{2\cdot}}=2K_{S^2}$.

This result shows that we can effectively ignore the complication of the double group and just proceed with Γ as usual.

Given an arbitrary field $\tilde{\phi}(\mathbf{r})$ on S^2, a quasiperiodic field on S^2 and hence, via (19), a field on S^2/Γ is constructed by the projection

$$\psi(\mathbf{r})=\frac{1}{|\Gamma|}\sum_{g\in\Gamma}a(g)T_{g^{-1}}\tilde{\phi}(\mathbf{r}). \tag{26}$$

In particular the projected (i.e., adapted) modes are

$$Y^{\Gamma(l)}_{qm}(\mathbf{r})=\frac{1}{\sqrt{|\Gamma|}}\sum_{g\in\Gamma}a(g)(T_{g^{-1}}Y^{(l)}_{qm})(\mathbf{r})=\sqrt{|\Gamma|}Y^{(l)}_{qm'}(\mathbf{r})P_{m'm}, \tag{27}$$

where, using (13),

$$P_{m'm}=\frac{1}{|\Gamma|}\sum_{g\in\Gamma}a(g)\mathcal{D}^{(l)}_{m'm}(g^{-1}) \tag{28}$$

is a Hermitian projection matrix, $P^2=P$. Since the eigenvalues of P are 0 and 1, this shows that in a suitable, i.e., diagonal, basis the projected eigenfunctions are a subset of the unprojected ones, a general result and independent of the magnetic field.

Depending on whether q and l are integral or half odd-integral together, the representations a and $\mathcal{D}$ of the doubled elements, $E\gamma$, have the same or opposite sign as those of γ and we can see explicitly that it is adequate to restrict the sum in (28) to Γ, as we have done.

Let us pursue this a little further to make sure everything is satisfactory. It is much more elegant to express everything in abstract form but we will retain the coordinate representation. The discussion is a textbook one in applied group theory.

From (27), using periodicity, one easily derives the integral

$$\int_{S^2/\Gamma}Y^{\Gamma(l)}_{qm}{}^{*}(\mathbf{r})Y^{\Gamma(l)}_{qm'}(\mathbf{r})d\mathbf{r}=P_{mm'}.$$

Diagonalizing A, $A=UDU^{-1}$, introduces the linear combinations $Y^{(\Gamma)}U$, which, from (27) equals $\sqrt{|\Gamma|}YUD$ showing that certain linear combinations of the modes on S^2 vanish and others do not, after adaptation which takes on the nature of a filtering process. We write for the nonzero combinations,

$$\mathcal{Y}^{(l)}_{q\alpha}=\sqrt{|\Gamma|}Y^{(l)}_{qm}U_{m\alpha}, \tag{29}$$

which form a complete, orthogonal set on S^2/Γ.

The factors of $\sqrt{|\Gamma|}$ have been chosen to give suitably normalized eigenfunctions on S^2/Γ so that

$$K_{S^2/\Gamma}(\mathbf{r},\mathbf{r}';\tau)=\sum_{l=|q|}^{\infty} e^{-\lambda_l \tau}\,\mathrm{Tr}[\mathcal{Y}_q^{(l)}(\mathbf{r})\mathcal{Y}_q^{(l)\dagger}(\mathbf{r}')]. \tag{30}$$

The matrix U reduces the l-representation of $\Gamma^\bullet$ into irreducible ones and, from (28), the range of α, i.e., the degeneracy, is the number of times the irreducible a-representation occurs in this decomposition.

VI. EFFECT OF FIXED POINTS

The standard theory of coverings applies when the covering group acts freely. This is not so in the present case and the result is a singular space—an orbifold. We can still maintain the standard covering terminology, as we already have done when referring to fundamental domains, in an obvious way by firstly removing the fixed points, so that the standard theory applies, and then extending the action of the covering group, Γ, to these points.

We now investigate the implications of the periodicity condition (18) when extended to the fixed point set of Γ. For any $\gamma\in\Gamma$ there are two fixed points on the sphere, $\pm\mathbf{r}_\gamma$. Going back to the mathematical result (6), we see that the monopole modes on the full sphere satisfy the *identity*,

$$Y_{qm'}^{(l)}(\pm\mathbf{r}_\gamma)=e^{iq\Lambda_\gamma(\pm\mathbf{r}_\gamma)}Y_{qm}^{(l)}(\pm\mathbf{r}_\gamma)\mathcal{D}_{mm'}^{(l)}(\gamma), \tag{31}$$

where γ is the rotation about $\pm\mathbf{r}_\gamma$, obviously.

Using the relation (29) we can determine the action of the magnetic rotation operator T_γ on the $\mathcal{Y}$,

$$T_\gamma\mathcal{Y}(\mathbf{r})=\sqrt{|\Gamma|}(T_\gamma Y)(\mathbf{r})U=e^{-iq\Lambda_\gamma(\mathbf{r})}\sqrt{|\Gamma|}Y(\gamma^{-1}\mathbf{r})U=e^{iq\Lambda_\gamma(\mathbf{r})}\mathcal{Y}(\gamma^{-1}\mathbf{r})$$

as expected. However we also have, from (27),

$$T_\gamma\mathcal{Y}(\mathbf{r})=a(\gamma)\mathcal{Y}(\mathbf{r})$$

and therefore

$$e^{-iq\Lambda_\gamma(\mathbf{r})}\mathcal{Y}(\gamma^{-1}\mathbf{r})=a(\gamma)\mathcal{Y}(\mathbf{r})$$

and of course

$$e^{-iq\Lambda_\gamma(\mathbf{r})}\psi(\gamma^{-1}\mathbf{r})=a(\gamma)\psi(\mathbf{r}).$$

If there were no fixed points there would be no problem to discuss. However if $\mathbf{r}=\mathbf{r}_\gamma$ is fixed by γ we have the consistency condition,

$$e^{iq\Lambda_\gamma(\mathbf{r}_\gamma)}\psi(\mathbf{r}_\gamma)=a(\gamma)\psi(\mathbf{r}_\gamma),$$

$$e^{-iq\Lambda_\gamma(\mathbf{r}_\gamma)}\mathcal{Y}(\mathbf{r}_\gamma)=a(\gamma)\mathcal{Y}(\mathbf{r}_\gamma). \tag{32}$$

This says that the phase is undetermined at the fixed points. If the fixed point is removed there is no problem. We are then effectively working arbitrarily close to the fixed point and all the points $\gamma\mathbf{r}$, $\gamma\in\Gamma$, belong to different images of the fundamental domain. When the fixed point is put back and the limit $\mathbf{r}\to\mathbf{r}_\gamma$ taken, all these images coalesce and the phase becomes indeterminate, unless something special happens such as $e^{-iq\Lambda_\gamma(\mathbf{r}_\gamma)}$ equaling $a(\gamma)$ or if the wave function has a node at $\mathbf{r}_\gamma$. We analyze this situation further.

Since Γ can be generated by a set of cyclic rotations, it is helpful first to take the case when Γ is cyclic, C_k, about the z-axis. Everything in (28) is then explicit. Let the generator of C_k be $\hat{\gamma}$, ($\hat{\gamma}^k=\mathbf{1}$). Also let the generator of the double group $\mathbb{Z}^\bullet$ be $\gamma^\bullet$ with $(\gamma^\bullet)^k=E$ and $(\gamma^\bullet)^{2k}=\mathbf{1}$. E is the 2π doubling rotation.

The representations $a(g^{\bullet})$ are

$$a((\gamma^{\bullet})^{p})=e^{2\pi ipr/k}, \quad p=0,1,...,2k-1, \tag{33}$$

where, for integral q, the label r, is in the range 0 to $k-1$, while for half-odd integral q, $r=(2s+1)/2$ with $0\leqslant s\leqslant k-1$.

$\mathcal{D}^{(l)}_{mm'}(g^{\bullet})$ is diagonal

$$\mathcal{D}^{(l)}_{mm'}((\gamma^{\bullet})^{p})=e^{-2\pi ipm/k}\delta_{mm'}, \quad -l\leqslant m, \ \ m'\leqslant l, \tag{34}$$

and $P_{mm'}$ is easily found,

$$P_{mm'}=\frac{1}{k}\,\frac{1-e^{2\pi i(m+r)}}{1-e^{2\pi i(m+r)/k}}\,\delta_{mm'}. \tag{35}$$

This expression vanishes unless $m+r$ is 0 mod k, in which case it equals unity making the filtering obvious.

It is comforting to check things by looking at the explicit forms of some modes. For $q=0$, the modes $Y^{(l)}_{m}$ are ordinary spherical harmonics. At the north pole only the $m=0$ component survives which then forces r to be zero and (32) is trivially satisfied since $a(\gamma)=1$.

One can proceed generally but let us use the modes exhibited in Wu and Yang, Sec. VII. For $q=1/2$ we see that only the $m=-1/2$ survives at the north pole making $r=1/2$ and now to check (32) we need the expression for Λ. For a rotation through ω about the z-axis, from (7) or (8), $\Lambda=-\omega$, and again the check works. For $q=1$, the nonzero mode corresponds to $r=1$.

In general one finds that $r=q$ and looking at the ϕ dependence of the modes, $Y^{(l)}_{mq}$, (3), i.e., $\exp(i(m+q)\phi)$, we see that the modes $Y^{\Gamma(l)}$ are periodic as ϕ increases by $2\pi/k$ and so, therefore, is the wave function.

It should be noted that if (8) is used, the azimuthal angle of the north pole changes by ω even though it is a fixed point. The string's location may be unchanged, but a nonzero compensating gauge transformation is still required.

It is clear geometrically that the same results will hold if C_k is cyclic about any axis so that it is consistent to set

$$a(\gamma)=e^{-iq\Lambda_{\gamma}(\mathbf{r}_{\gamma})}, \tag{36}$$

for any Γ. The consequence of replacing $\mathbf{r}_{\gamma}$ by $-\mathbf{r}_{\gamma}$ is discussed in the next section.

The minimal choice (36) clearly corresponds to untwisted fields in the sense that the more general form,

$$a(\gamma)=e^{-iq\Lambda_{\gamma}(\mathbf{r}_{\gamma})}b(\gamma), \tag{37}$$

where $b(\gamma)$ is some nontrivial representation of $\Gamma^{\bullet}$, encodes physics over and above the magnetic monopole, such as Aharonov–Bohm fluxes through the fixed points. In this latter case, (18) implies that the wave function vanishes at the fixed points.

VII. CHARGE QUANTIZATION ON ROTATIONAL DOMAINS

We now have expressions for the modes and heat-kernel on S^2/Γ in the rotational case and have tacitly assumed that all integer values of $2q$ are allowed. However $2q$ need only form a subset of the integers. A geometric, Dirac-type argument will first be used to calculate this subset.

Choose a fundamental domain $\mathcal{F}$ which does not contain the string. Let $L\subset\mathcal{F}$ be a piecewise continuous loop in $\mathcal{F}$ and construct the parallel propagator,

$$\mathcal{I}[L]=e^{ie\int_L A}=e^{-iq\Omega}, \tag{38}$$

where A is the potential one-form, Ω is the area within L. This follows from the explicit form of the monopole potential. As L shrinks to a point in $\mathcal{F}$, $\mathcal{I}[L]$ clearly tends to unity as the area vanishes. Now L also describes a loop with (oriented) area $-(|\mathcal{F}|-\Omega)$ in S^2/Γ, since S^2/Γ is closed for rotational Γ (except for the fixed points which we can ignore for these purposes as a set of measure zero). Thus if we let L expand to fill the boundary $\partial\mathcal{F}\subset S^2$, the propagator will also take the value 1. This requires that $q|\mathcal{F}|$ be a multiple of 2π which gives the possible values of the magnetic charge as

$$q=|\Gamma|\frac{n}{2}, \quad n\in\mathbb{Z}, \tag{39}$$

the expected value since the magnetic charge per closed domain, $\overline{q}\equiv q/|\Gamma|$, equals the Dirac value, $n/2$.

If the string passes through $\mathcal{F}$ there is an extra phase $-4\pi q$ in (38) which makes no difference to the final result.

For the cyclic group, C_k, according to (33), and (36),

$$a(\gamma^{\bullet p})=e^{2\pi ipq/\nu}=(-1)^{np} \tag{40}$$

so all the $a(\gamma)$ are ± 1.

A further restriction occurs if C_k is a subgroup of a point group Γ, for then

$$a(\gamma^{\bullet})=e^{i\pi|\Gamma|n/k},$$

but, by observation, for a noncyclic point group, all $|\Gamma|/k$ are even and the $a(\gamma)$ are unity. Furthermore the monopole charge q is integral and there are no spinor modes.

The quantization (39) or (36), will now be derived in another way. The consistency condition (32) must hold for both fixed points of γ. Geometry shows, if orientation effects are taken correctly into account, that $\Lambda_\gamma(-\mathbf{r}_\gamma)=-\Lambda_\gamma(\mathbf{r}_\gamma)$. This also follows from the mode transformation (31) and the behavior under parity (14), which involves $q\to -q$.

The two definitions of $a(\gamma)$ require

$$q=\frac{k_\gamma}{2}n_\gamma \tag{41}$$

for some integer n_γ, where k_γ is the order of the cyclic subgroup generated by γ. Since $\Lambda_\gamma(\mathbf{r}_\gamma)=2\pi/n_\gamma$, all the $a(\gamma)$ are ± 1.

If Γ is not cyclic, the minimum requirement of (41) is $q=(K/2)p$, where $p\in\mathbb{Z}$ and K is the LCM of all the n_γ. Looking at the character tables of the double point groups it is easily checked that it is not possible to reconcile the tabulated ± 1 representations $a(\gamma^{\bullet})$ with (41) unless all the $a(\gamma^{\bullet})$ are unity, implying that p is even or $q=(2K/2)p'$ for $p'\in\mathbb{Z}$. But $2K$ is nothing but the group order Γ leading to (39) for all n. Q.E.D.

VIII. INTEGRATED KERNELS AND ZETA FUNCTIONS

Special interest attaches itself to the integrated kernel,

$$\begin{aligned} K_\Gamma(\tau)&\equiv\int_{S^2/\Gamma}K_{S^2/\Gamma}(\mathbf{r},\mathbf{r};\tau)d\mathbf{r}\\ &=\sum_{g\in\Gamma}a(g)\int_{S^2/\Gamma}(T_{g^{-1}}K_{S^2})(\mathbf{r},\mathbf{r};\tau)d\mathbf{r}\\ &=\frac{1}{|\Gamma|}\sum_{g\in\Gamma}a(g)\int_{S^2}(T_{g^{-1}}K_{S^2})(\mathbf{r},\mathbf{r};\tau)d\mathbf{r}. \end{aligned} \tag{42}$$

It is convenient to write everything in terms of the covering S^2 quantities because we can use the mode form (21) in (42) to obtain

$$K_\Gamma(\tau)=\sum_{l=|q|}^{\infty} d_\Gamma(l)e^{-\lambda_l\tau} \tag{43}$$

with

$$d_\Gamma(l)=\frac{1}{|\Gamma|}\sum_g a(g)\chi^{(l)}(g^{-1}), \tag{44}$$

where we have used the orthogonality of the S^2 monopole modes and $\chi^{(l)}(g)$ is the usual $\mathrm{SO}^\bullet(3)\sim\mathrm{SU}(2)$ character of g. In particular,

$$\int_{S^2}\mathrm{Tr}[(T_g\mathbf{Y}_{ql})(\mathbf{r})\mathbf{Y}^\dagger_{ql}(\mathbf{r})]d\mathbf{r}=\chi_l(g). \tag{45}$$

Algebraically we can see that the degeneracy, $d_\Gamma(l)$, is the number of times the irreducible representation ''a'' occurs in the l-representation. Since degeneracies are real $a(g)$ in (44) and in the following equations, can be replaced by its real part, $\mathrm{Re}\,a(g)$, although in the present case the minimal $a(g)=\pm1$.

(44) shows that the summand in $d_\Gamma(l)$, is a class function so that we can make a convenient geometrical decomposition of the traced kernel, as in our earlier work.[1] The preimage sum, i.e., the sum over Γ, is firstly replaced by a sum over conjugacy classes, $\{g\}$,

$$d_\Gamma(l)=\frac{2l+1}{|\Gamma|}+\frac{1}{|\Gamma|}\sum_{\{g\}} a(g)|\{g\}|\chi^{(l)}(g)$$

with g being a typical element in $\{g\}$.

We now recall that the elements of a class correspond to rotations through one fixed angle about a set of conjugate axes. For a given set of such axes, one corresponding class can be considered to be the primitive class, all others associated with these axes then being generated by this one. Thus the sum over all classes can be rewritten as a sum over primitive classes and powers of these. Let k be the generic order of the rotation associated with the generic primitive class $\{\hat g\}$ so that $\hat g^k=id$. Then $|\{\hat g\}|$ is just the number, n_k, of conjugate k-fold axes and we can write

$$d_\Gamma(l)=\frac{2l+1}{|\Gamma|}+\frac{1}{|\Gamma|}\sum_{\hat g} n_k\sum_{p=1}^{k-1} a^p(\hat g)\chi^{(l)}(\hat g^p) \tag{46}$$

which is the same as when there is no magnetic field, apart from the restriction $l\geqslant|q|$ and one sees again that the cyclic groups, C_k, form the basic building blocks. This can be made explicit as follows. In the case that Γ is just C_k, one has from (46)

$$d_k(l)=\frac{1}{k}\sum_{p=0}^{k-1} a^p(\hat g)\chi^{(l)}(\hat g^p)=\frac{2l+1}{k}+\frac{1}{k}\sum_{p=1}^{k-1} a^p(\hat g)\chi^{(l)}(\hat g^p) \tag{47}$$

so that, substituting back,

$$d_\Gamma(l)=\frac{d_1(l)}{|\Gamma|}\left(1-\sum_{\hat g} n_k\right)+\frac{1}{|\Gamma|}\sum_{\hat g} kn_kd_k(l), \tag{48}$$

where $d_1(l)=2l+1$ is the full sphere degeneracy.

Having now the degeneracies and the eigenvalues, we can turn to the explicit construction of the integrated heat-kernel (43) and its Mellin transform, the ζ-function,

$$\zeta_\Gamma(s)=\sum_l \frac{d_\Gamma(l)}{\lambda_l^s}. \tag{49}$$

The eigenvalues are given by (2) and we face the old problem of computing spherical spectral quantities. We will approach this by firstly looking at a ''linearized'' system, one whose eigenvalues are $l+1/2$. The corresponding heat-kernel, denoted $\tilde{K}_\Gamma(\tau)$, can be considered as that for the pseudo-operator $(H_{S^2}+1/4+q^2)^{1/2}$ and will allow us to find the ζ-function for the eigenvalues $(l+1/2)^2$ quickly and that for the λ_l of (2), more elaborately. The expressions are also of some statistical mechanical interest if τ is interpreted as an inverse temperature.

From (43), we have the linearized, or square root, kernel

$$\tilde{K}_\Gamma(\tau)=\sum_{l=|q|}^{\infty} d_\Gamma(l)e^{-(l+1/2)r} \tag{50}$$

with degeneracies given by (44).

In accordance with (48), it is sufficient to consider the cyclic group case, $K_k(\tau)$ and $\zeta_k(s)$.

Since the cyclic axis is immaterial, we choose it to lie along the z-axis and could use the expressions in the previous section since $d_k(l)$ is $\mathrm{Tr}\,\mathbf{P}$, where $\mathbf{P}$ is given by (35) with $r=q$. Therefore,

$$\tilde{K}_k(\tau)=\frac{1}{k}\sum_{l=|q|}^{\infty}\sum_{m=-l}^{l} e^{-(l+1/2)r}\frac{1-e^{2\pi i(m+q)}}{1-e^{2\pi i(m+q)/k}}. \tag{51}$$

The summations can be relabeled using (5) and performed, but it is perhaps more elegant to substitute (44) into (43) and do the l-summation first, as in Ref. 1.

Remembering the charge quantization condition, (40), the degeneracies are

$$d_k(l,q)=\frac{1}{k}\sum_{p=0}^{k-1}\cos(\pi np)\frac{\sin((2l+1)\pi p/k)}{\sin(\pi p/k)},\quad q=nk/2, \tag{52}$$

where n is even or odd. If n is even, the degeneracies are identical to the case when $q=0$, $d_k(l,q)=d_k(l,0)$.

We now introduce the generating function

$$h_k(\sigma,q)=\sum_{l=|q|}^{\infty} d_k(l,q)\sigma^l \tag{53}$$

closely connected with the traced heat-kernel, (43), if $\sigma=e^{-\tau}$. For n even the only effect of the monopole is to make the series start at $l=|q|$. However it is better to continue with the summations. We have, for both integral and half odd-integral q,

$$
\begin{aligned}
h_k(\sigma,q)&=\frac{1}{k}\sum_{l=|q|}^{\infty}\sum_{p=0}^{k-1}\cos(\pi np)\,\frac{\sin(2l+1)\pi p/k)}{\sin(\pi p/k)}\,\sigma^l\\
&=\frac{1}{k}\sum_{p=0}^{k-1}\cos(\pi np)\sum_{l=|q|}^{\infty}\frac{\sin(2l+1)\pi p/k}{\sin(\pi p/k)}\,\sigma^l\\
&=\sigma^q\frac{(q+\sigma+2q(1-\sigma))}{k(1-\sigma)^2}+\frac{1}{k}\sum_{p=1}^{k-1}\cos(\pi np)\sum_{l=|q|}^{\infty}\frac{\sin(2l+1)\pi p/k)}{\sin(\pi/k)}\,\sigma^l\\
&=\sigma^q\left(\frac{1}{1-\sigma}\,\frac{1+\sigma^k}{1-\sigma^k}+\frac{2q}{k(1-\sigma)}\right)
\end{aligned}
\tag{54}
$$

and so the corresponding heat-kernel is related in the simple way,

$$
\tilde{K}^q_k(\tau)=e^{-q\tau}\left(\tilde{K}_k(\tau)+\frac{2q}{k}\tilde{K}_\infty(\tau)\right) \tag{55}
$$

to the monopole-less ($q=0$) expression,[1]

$$
\tilde{K}_k(\tau)=\frac{\coth(k\tau/2)}{2\sinh(\tau/2)}.
$$

The decomposition into conjugacy classes, (48), shows that this relation will follow through for all groups Γ,

$$
\tilde{K}^q_\Gamma(\tau)=e^{-q\tau}(\tilde{K}_\Gamma(\tau)+2\overline{q}\tilde{K}_\infty(\tau)), \tag{56}
$$

where $\overline{q}$ is the charge per domain and $\tilde{K}_\Gamma(\tau)$ has been determined in Ref. 1,

$$
\tilde{K}_\Gamma(\tau)=\frac{\cosh(d_0\tau/2)}{2\sinh(d_1\tau/2)\sinh(d_2\tau/2)}. \tag{57}
$$

Here d_0, d_1, and d_2 are integer invariants associated with the reflection group having Γ as its rotation subgroup.

The zeta function corresponding to the linear heat kernel is easily determined as the Mellin transform of (57). In fact we shall find it more useful to consider the slightly more general zeta function defined by

$$
\begin{aligned}
\zeta^q_\Gamma(s,a)&=\frac{1}{\Gamma(s)}\int_0^\infty\tau^{s-1}e^{\tau/2-a\tau}\tilde{K}^q_\Gamma(\tau)d\tau\\
&=\zeta_2(s,a+q|d_1,d_2)+\zeta_2(s,a+q+d_0|d_1,d_2)+\overline{q}\zeta_H(s,a+q),
\end{aligned}
\tag{58}
$$

where ζ_H is the Hurwitz zeta function, and ζ_2 is the two-dimensional Barnes zeta function defined for $s>2$ by,[19]

$$
\zeta_2(s,a|d_1,d_2)=\sum_{n_1,n_2=0}^{\infty}\frac{1}{(a+n_1d_1+n_2d_2)^s}. \tag{59}
$$

ζ_H is actually a one-dimensional Barnes ζ-function.

To conclude this section we shall present some properties of the Barnes zeta function needed later.

The function $\zeta_2(s,a|d_1,d_2)$ has simple poles at $s=1,2$ whose residues can be written in terms of generalized Bernoulli polynomials,

$$\mathrm{Res}_{s\to r}\zeta_2(s,a|d_1,d_2)=\frac{(-1)^r}{d_1d_2}B^{(2)}_{2-r}(a|d_1,d_2) \tag{60}$$

for $r=1,2$. Here we have used the more standard notation as in Erdelyi.[20] The values of the Barnes ζ-function at negative integers are also given in terms of generalized Bernoulli polynomials. For $n\in\mathbb{Z}^+$ we have,

$$\zeta_2(-n,a|d_1,d_2)=\frac{1}{(n+1)(n+2)d_1d_2}B^{(2)}_{2+n}(a|d_1,d_2) \tag{61}$$

The explicit generalized Bernoulli polynomials required in this paper are

$$\begin{aligned}
B^{(2)}_0(a|d_1,d_2)&=1,\\
B^{(2)}_1(a|d_1,d_2)&=a-\tfrac{1}{2}(d_1+d_2),\\
B^{(2)}_2(a|d_1,d_2)&=a^2-(d_1+d_2)a+\tfrac{1}{6}(d_1^2+3d_1d_2+d_2^2),\\
B^{(2)}_3(a|d_1,d_2)&=a^3-\tfrac{3}{2}(d_1+d_2)a^2+\tfrac{1}{2}(d_1^2+3d_1d_2+d_2^2)a-\tfrac{1}{4}(d_1^2d_2+d_1d_2^2).
\end{aligned} \tag{62}$$

Finally we present a useful Bernoulli identity which will be used to simplify some expressions later on,

$$B^{(2)}_n(d_1+d_2-a|d_1,d_2)=(-1)^nB^{(2)}_n(a|d_1,d_2). \tag{63}$$

IX. EXTENSION TO REFLECTION GROUPS

Before showing how to deal with the eigenvalues (2), we extend the analysis to orbifolds S^2/Γ' where Γ' is a finite reflection group—the complete symmetry group of a regular solid as outlined in Sec. I. The domain of interest is a Möbius triangle on S^2.

As shown in Sec. III, under reflection, the magnetic charge, q, changes sign and the projection has to take this into account. The rotational projection is given by (22) and (27) and all that is necessary is to combine this with the group decomposition (1). We start by writing down the projected modes

$$W^{(l)}_{qm}(\mathbf{r})=Y^{\Gamma(l)}_{qm}(\mathbf{r})+a(\sigma)T_\sigma Y^{\Gamma(l)}_{-qm}(\mathbf{r}), \tag{64}$$

where σ is a reflection, say in one of the symmetry planes, so that $a(\sigma)=\pm1$. We can choose either sign.

Note the extended periodicity condition

$$T_{\gamma'}W^{(l)}_{qm}(\mathbf{r})=a(\gamma)a(\sigma)W^{(l)}_{-qm}(\mathbf{r}),\quad \gamma'=\gamma\sigma,$$

which shows that the wave function on the domain $\gamma'\mathcal{F}$ has monopole charge $-q$ if that on $\mathcal{F}$ has charge q.

The group decomposition of Γ' gives

$$S^2=\Big(\bigcup_{\gamma\in\Gamma}\overline{\gamma\mathcal{F}}\Big)\cup\Big(\bigcup_{\gamma\in\Gamma'_1}\overline{\gamma'\mathcal{F}}\Big)=\bigcup_{\gamma\in\Gamma}\overline{\gamma(\mathbf{1}+\sigma)\mathcal{F}},$$

and we see that the only possible theory using images requires that adjacent domains on the sphere have opposite numerical monopole charge.[23] The charge is q on $\gamma\mathcal{F}$ and $-q$ on $\gamma'\mathcal{F}$ for all $\gamma\in\Gamma,\gamma'\in\Gamma'_1$.

For the theory to be consistent, we must at least show that the fundamental domains with charge q and $-q$ define equivalent physical theories. There are two points. The first is that the

sign of the charge is arbitrary, being essentially a matter of definition for the observer. The second point is that any physically significant quantities will depend only on $F_{\mu\nu}F^{\mu\nu}\sim q^2$. Our theory therefore has the possibility of being consistent and we now derive the values of q for which it is consistent.

Across the boundaries of the fundamental domains we have $\mathbf{B}\to-\mathbf{B}$ and $\mathbf{A}\to-\mathbf{A}$. For consistency we should define these vector quantities to vanish on the reflecting boundaries. Consider now the parallel propagator, (38), where the loop $L\in\mathcal{F}$. Since we have defined $\mathbf{A}$ to vanish on $\partial\mathcal{F}$ we have $\mathcal{I}[\partial\mathcal{F}]=1$. Thus for an arbitrary loop approaching the boundary we require trivial parallel transport just as in the pure rotational case. This gives the *possible* values of q as

$$q=|\Gamma'|\frac{n'}{2}=|\Gamma|n', \quad n'\in\mathbb{Z}, \tag{65}$$

so q is integral and there are no spinor modes.

The existence of fixed points imposes certain conditions. The situation is more restricting than in the pure rotational case because the fixed points form a continuous set, the boundary of our domain, $\mathcal{F}$. Let σ be a reflection ($\sigma^2=\mathbf{1}$). The fixed point set, $\mathcal{P}$, is the intersection of the reflecting plane with the S^2, i.e., a great circle. Extending the periodicity condition (18) to Γ' we see that ψ would have to satisfy

$$e^{-iq\Omega_\sigma(\mathbf{r})+iq\pi}\psi(\mathbf{r})=a(\sigma)\psi(\mathbf{r}), \quad \forall\,\mathbf{r}\in\mathcal{P}. \tag{66}$$

Since $\Omega_\sigma(\mathbf{r})$ is not constant on $\mathcal{P}$, this equation cannot be satisfied on all of $\mathcal{P}$ unless one of $q=0$, $\psi|_{\mathcal{P}}=0$, $\mathbf{n}\perp\mathcal{P}$ or $\mathbf{n}\in\mathcal{P}$ is true. Applying this argument to the two, or three, reflection generators removes the last two possibilities and we are left with either $q=0$ or $\psi|_{\mathcal{P}}=0$ (or both).

The fact that the magnetic charge, q, has to be of opposite sign on adjacent domains under the action of Γ' for the image method to work indicates, crudely, that q is zero on the boundary and suggests that our construction satisfies the restrictions following from (66).

Developing this nonrigorous analysis, since the magnetic field $\mathbf{B}$ vanishes on the reflecting boundaries we must insist that the monopole modes take the value $W^{(l)}_{0m}$ on the boundaries. Thus the consistency Eq. (66) is satisfied. Let γ be an arbitrary rotation in Γ. The rotational consistency (32) is satisfied for all γ since q is an integer multiple of $|\Gamma|$ and, as already stated, $a(\gamma)=1$, $\forall\gamma$. It would thus appear that all the values of q in (65) produce a consistent theory.

For clarity we restate that the mode labeled by qlm takes the values

$$\begin{gathered} W^{(l)}_{qm} \ \text{ on } \ \Gamma\mathcal{F}, \\ W^{(l)}_{-qm} \ \text{ on } \ \Gamma'_1\mathcal{F}, \\ W^{(l)}_{0m} \ \text{ on } \ \partial(\Gamma\mathcal{F})\sim-\partial(\Gamma'_1\mathcal{F}). \end{gathered} \tag{67}$$

The modes (64) can be used to define a heat-kernel analogous to the rotational case. We skip straight to the linear heat-kernel which may be written

$$\tilde{K}^q_{\Gamma'}(\tau)=\int_{S^2/\Gamma'}\sum_{l=q}^{\infty}e^{-(l+1/2)\tau}\mathrm{Tr}[\mathbf{W}^{(l)}_q(\mathbf{r})\mathbf{W}^{(l)\dagger}_q(\mathbf{r})]d\mathbf{r}.$$

Here $\mathbf{W}^{(l)}_q$ is the vector of solutions $W^{(l)}_{qm}$. We can extend this integral to all S^2 just as we did in Eq. (42), in the rotational case (this is not entirely trivial but it is possible using the invariance of the theory under $q\to-q$),

$$\tilde{K}^q_{\Gamma'}(\tau)=\frac{1}{|\Gamma'|}\int_{S^2}\sum_{l=q}^{\infty}e^{-(l+1/2)\tau}\mathrm{Tr}[\mathbf{W}^{(l)}_q(\mathbf{r})\mathbf{W}^{(l)\dagger}_q(\mathbf{r})]d\mathbf{r}.$$

The next step is to the use the explicit rotational modes (27) or (29) [with $a(g)=1$], Eqs. (13) and (17), and the invariance of the heat kernel under charge reversal. The result is

$$\tilde{K}^q_{\gamma'}(\tau)=\tfrac{1}{2}\tilde{K}^q_\Gamma(\tau)+\frac{a(\sigma)}{|\Gamma'|}\sum_{\gamma'\in\Gamma_1}\int_{S^2}\sum_{l=q}^{\infty}e^{-(l+1/2)}\,\mathrm{Tr}[(T_{\gamma'}\mathbf{Y}^{(l)}_{-q})(\mathbf{r})\mathbf{Y}^{(l)\dagger}_q(\mathbf{r})]d\mathbf{r}. \tag{68}$$

This equation actually represents two heat kernels for the cases $a(\sigma)=\pm 1$. For $a(\sigma)=-1$ we shall use the term ''Dirichlet'' and write $K^q_D(\tau)$. For $a(\sigma)=+1$ we use the term ''Neumann'' and write $K^q_N(\tau)$. These names are used in analogy to the case with no monopole field, $q=0$. In this case $W^{(l)}_{0m}$ is, by construction, a solution on the whole sphere [see (67)] and must satisfy $T_{\gamma'}W^{(l)}_{0m}=a(\sigma)W^{(l)}_{0m}$ everywhere. On the reflecting boundaries, $a(\sigma)=-1$ requires $W^{(l)}_{0m}$ to vanish, i.e., Dirichlet boundary conditions, and $a(\sigma)=+1$ requires the normal derivative of $W^{(l)}_{0m}$ to vanish, i.e., Neumann boundary conditions.

We now turn to some specific calculations of the heat kernels. Using (45) we can write the second term in (68) as,

$$\frac{a(\sigma)}{|\Gamma'|}\int_{S^2}\sum_{l=q}^{\infty}\sum_{\gamma'\in\Gamma_1}\chi_l(\gamma')e^{-(l+1/2)r}. \tag{69}$$

Our first calculation is for the reflection group Γ' with rotational subgroup C_k. In this case Γ'_1 consists of k reflection planes with a common invariant axis, and with angle $2\pi/k$ between adjacent planes. If we take one plane to be the $z-x$ plane then we can write $\Gamma'_1=\{\Pi g_\pi\hat{\gamma}^p|p=0,1,2,\ldots,k-1\}$ where Π is parity, g_π is a rotation by angle π about the y axis, and $\hat{\gamma}$ is a rotation by angle $2\pi/k$ about the z-axis. Using the explicit result

$$\mathcal{D}^{(l)}_{mm'}(g_\pi)=(-1)^{l-m}\delta^m_{-m'} \tag{70}$$

and Eqs. (15), (34) we find $\chi_l(\gamma')=1$ for all $\gamma'\in\Gamma'_1$ and all l. Thus (69) is trivial to calculate in this case, and from (68), (55) we find[23]

$$\tilde{K}^q_D(\tau)=e^{-q\tau}\frac{e^{-k\tau/2}}{4\sinh(\tau/2)\sinh(k\tau/2)}+\frac{q}{2k}\frac{e^{-q\tau}}{\sinh(\tau/2)}, \tag{71}$$

$$\tilde{K}^q_N(\tau)=e^{-q\tau}\frac{e^{k\tau/2}}{4\sinh(\tau/2)\sinh(k\tau/2)}+\frac{q}{2k}\frac{e^{-q\tau}}{\sinh(\tau/2)}. \tag{72}$$

The first term in each of these expressions is simply $\exp(-q\tau)$ times the monopoleless heat kernel.[1] Notice that the extra monopole contribution is the same in both heat kernels.

We can also calculate the heat kernels for the group Γ' with dihedral rotational subgroup D_k. We take Γ'_1 as σD_k where σ is a reflection in the $x-y$ plane, and D_k is the dihedral group with the k-fold cyclic group about the z axis, and a rotation by π about the y axis. Using (34) and (70), we find $\chi_l(\gamma')=1$ for elements $\gamma'\in\Gamma'_1$ involving the rotation by angle π about y. These elements are $|\Gamma|$ in number and contribute to (69) the expression

$$\frac{a(\sigma)}{8}\frac{e^{-q\tau}}{\sinh(\tau/2)}. \tag{73}$$

The remaining elements can be written $\Pi g_\pi\hat{\gamma}^p$, where g_π is a rotation by π about the z axis, and Π, $\hat{\gamma}$ are as defined above. Using (15) and (34) we find the transformation matrix $(-1)^{l+m}\delta^m_{m'}\exp(-i2\pi mp/k)$. This transformation is nontrivial and we have to construct a sum similar to (51).

For technical variety we use the relations (5) so that the sum can be written,

$$\frac{a(\sigma)}{4}e^{-\tau/2}\sum_{u=0}^{\infty}\sum_{t=-\infty}^{\infty}(-1)^{kt}(-e)^{-\tau(u+(|tk+q|+|tk-q|)/2)}=a(\sigma)e^{-q\tau}\frac{\cosh(k\tau/2)}{8\cosh(\tau/2)\sinh(k\tau/2)}. \tag{74}$$

Adding together (73) and (74), and using (55) gives the results from (68),

$$\tilde{K}_D^q(\tau)=e^{-q\tau}\frac{e^{-(k+1)\tau/2}}{4\sinh(2\tau/2)\sinh(k\tau/2)}+\frac{q}{4k}\frac{e^{-q\tau}}{\sinh(\tau/2)}, \tag{75}$$

$$\tilde{K}_N^q(\tau)=e^{-q\tau}\frac{e^{(k+1)\tau/2}}{4\sinh(2\tau/2)\sinh(k\tau/2)}+\frac{q}{4k}\frac{e^{-q\tau}}{\sinh(\tau/2)}. \tag{76}$$

Again the first terms are simply $\exp(-q\tau)$ times the $q=0$ case.

For all the heat kernels derived above the extra monopole contribution is simply given by

$$\frac{q}{|\Gamma'|}\frac{e^{-q\tau}}{\sinh(\tau/2)}. \tag{77}$$

Since we may construct the heat kernel for an arbitrary reflection group from the heat kernels calculated above,[2] the simplicity of (77) leads us to conclude that in the general case,[23]

$$\tilde{K}_D^q(\tau)=e^{-q\tau}\frac{e^{-d_0\tau/2}}{4\sinh(d_1\tau/2)\sinh(d_2\tau/2)}+\overline{q}'\frac{e^{-q\tau}}{\sinh(\tau/2)}, \tag{78}$$

$$\tilde{K}_N^q(\tau)=e^{-q\tau}\frac{e^{-d_0\tau/2}}{4\sinh(d_1\tau/2)\sinh(d_2\tau/2)}+\overline{q}'\frac{e^{-q\tau}}{\sinh(\tau/2)}. \tag{79}$$

These two equations are the culmination of this section.

The first terms in these heat kernels are just $\exp(-q\tau)$ times the $q=0$ expressions,[1] and we have defined the monopole charge per reflection domain

$$\overline{q}'=\frac{q}{|\Gamma'|}.$$

Equation (68) predicts that the linear Dirichlet and Neumann heat kernels should add up to give the rotational linear heat kernel (56), and this is seen to be true (in performing this sum we must use the relation $\overline{q}=2\overline{q}'$ for the same value of q).

The linear zeta functions for $\tilde{K}_D^q$ and $\tilde{K}_N^q$ are calculated using Eq. (58) with $\tilde{K}_\Gamma^q(\tau)$ suitably replaced. In terms of the Barnes zeta function we find,

$$\zeta_D^q(s,a)=\zeta_2(s,a+q+d_0|d_1,d_2)+\overline{q}'\zeta_H(s,a+q), \tag{80}$$

$$\zeta_N^q(s,a)=\zeta_2(s,a+q|d_1,d_2)+\overline{q}'\zeta_H(s,a+q). \tag{81}$$

It should be remembered that although we may add these two zeta functions to produce the rotational zeta function, the physical theories are completely different due to the changing sign of the magnetic field. Thus the procedure can only be regarded as a formal trick.

X. GENERAL ZETA FUNCTION AND ITS DERIVATIVE

Equations (58), (80), and (81) give zeta functions for the eigenvalues $(l+a)^2$ if s is replaced with $2s$. In general we need the zeta functions for the more general eigenvalues $\lambda_l=(l+a)^2-\alpha^2$, with suitable constants a and α. For example we may add curvature coupling and mass terms to the Hamiltonian H_{S^2}. In this case the eigenvalue equation is,

$$(H_{S^2}+\xi R+m^2)Y_{qm}^{(l)}=\lambda_l Y_{qm}^{(l)}$$

and we find $a=1/2$, $\alpha^2=q^2+(1/4-2\xi)-m^2$ ($R=2$ on the unit two-sphere). It is assumed that α^2 is positive. To analyze these general zeta functions we use similar methods to those found in Ref. 21; For brevity we shall just write $\zeta(s)$ to represent a general zeta function. For $s>1$, we have the explicit mode sum

$$\zeta(s)=\sum_{l=|q|}^{\infty}\frac{d(l)}{[(l+a)^2-\alpha^2]^s}. \tag{82}$$

The function $d(l)$ is the degeneracy of the eigenvalue λ_l for some linear zeta function (i.e., rotational, Dirichlet or Neumann). If we assume that $|\alpha|<|q|+a$ we can perform a binomial expansion on the summand which leads to a continuation of $\zeta(s)$ given by

$$\zeta(s)=\sum_{r=0}^{\infty}\alpha^{2r}\frac{\Gamma(s+r)}{r!\Gamma(s)}\zeta^q(2s+2r,a). \tag{83}$$

In the the above equation $\zeta^q(s,a)$ is intended to be any one of the rotational, Dirichlet, or Neumann zeta functions defined by Eqs. (58), (80), and (81), respectively.

In order to tie in with Ref. 21 we generalize to the case where $\zeta^q(s)$ represents an arbitrary zeta function on a d-dimensional space with simple poles (only) at $s=1,2,...,d$. This is the situation encountered in Ref. 21, where $\zeta^q(s)$ would just be a d-dimensional Barnes function $\zeta_d(s,a|\mathbf{d})$ (of course the label q is defunct in the general case). Near the poles we define,

$$\zeta^q(s+r,a)=\frac{N_r}{s}+R_r+O(s),\quad s\to 0,$$

for $r=1,2,...,d$. For our three cases (with $d=2$) the residues N_r for $r=1,2$ can be calculated from the specific forms of the zeta functions and (60).

The important fact is that the series (83) reduces to a finite sum when s is a negative integer. Thus we concentrate on these values of s and find for $n\in\mathbb{Z}^+$,

$$(-\alpha^2)^{-n}\zeta(-n)=\sum_{r=0}^{n}(-\alpha^2)^{-r}\binom{n}{r}\zeta^q(-2r,a)+\frac{1}{2}\sum_{r=1}^{u}\alpha^{2r}\frac{n!(r-1)!}{(r+n)!}N_{2r}. \tag{84}$$

The number u in the above is defined as $[d/2]$ where d is the dimension of the space under consideration. The derivative of the zeta function at $s=-n$ can also be calculated from (83),

$$\begin{aligned}(-\alpha^2)^{-n}\zeta'(-n)=&2\sum_{r=0}^{n}\binom{n}{r}(-\alpha^2)^{-r}\zeta^{q\prime}(-2r,a)-\sum_{r=0}^{n}\binom{n}{r}(-\alpha^2)^{-r}(\psi(n+1)-\psi(r+1))\zeta^q\\&\times(-2r,a)-\sum_{r=1}^{u}\alpha^{2r}\frac{n!(r-1)!}{(r+n)!}\left\{R_{2r}+\frac{1}{2}N_{2r}(\psi(r)-\psi(n+1))\right\}\\&+\sum_{r=u+1}^{\infty}\alpha^{2r}\frac{n!(r-1)!}{(r+n)!}\zeta^q(2r,a),\end{aligned} \tag{85}$$

where $\psi(z)=\Gamma'(z)/\Gamma(z)$ is the logarithmic derivative of the gamma function.

The problem now rests on the evaluation of the infinite sum on the last line of this expression. We show that this sum can be written in finite terms. It is expected that the sum will be finite since we expect $\zeta'(-n)$ to be finite, and all other terms on the right-hand side are finite. A word of caution is that in singular situations, there is the possibility that logarithmic terms, $\log\tau$, may

appear in the asymptotic expansion of the heat-kernel. If this were so, more care would have to be taken over the evaluation of the determinants. However no such terms occur here.

Using the integral representation (58) extended to the arbitrary zeta function $\zeta^q(s,a)$, we may write the last line in (85) as,

$$2n!\sum_{n=u+1}^{\infty}\alpha^{2r}\frac{r!}{(r+n)!(2r)!}\int_0^\infty \tau^{2r-1}e^{\tau/2-a\tau}\widetilde{K}^q(\tau)d\tau, \tag{86}$$

where $\widetilde{K}^q(\tau)$ is the linear heat kernel associated with $\zeta^q(s,a)$. Since (86) is assumed finite we may take the sum inside the integral. Thus our problem can be reduced to evaluating the sequence of sums,

$$T_n(\tau)=n!\sum_{r=1}^{\infty}\frac{r!\,\tau^{2r}}{(2r)!(r+n)!}.$$

Using the simple result $\sqrt{\pi}(2r)!=2^{2r}r!\Gamma(r+1/2)$ and changing the summation variable to $r'=r+n$ gives the result

$$T_n(\tau)=n!\sqrt{\pi}\left(\frac{1}{2}\tau\right)^{1/2-n}I_{-n-1/2}(\tau)-\sum_{r=0}^{n}\binom{n}{r}(2r)!(-\tau^2)^{-r},$$

where $I_\nu(x)$ is the modified Bessel function.

To find a closed form for $T_n(\tau)$ we employ a useful integral representation given in Ref. 22; For $\nu>0$,

$$\Gamma\left(\frac{1}{2}+\nu\right)I_{-\nu}(x)=\frac{2}{\sqrt{\pi}}\left(\frac{1}{2}x\right)^{\nu}\left[\int_{-1}^{1}e^{-xt}(1-t^2)^{\nu-1/2}dt+\sin(\pi\nu)\int_1^\infty e^{-xt}(t^2-1)^{\nu-1/2}dt\right].$$

Setting $\nu=n+1/2$ in this expression we may expand the integrand factors $(1-t^2)^n$ using the binomial theorem leaving simple exponential integrals. After a little work we find,

$$T_n(\tau)=\sum_{r=0}^{n}\binom{n}{r}(-1)^r\left\{(-\tau^2)^{-n}(2\tau)^r(2n-r)!\frac{1}{2}(e^\tau+(-1)^\tau e^{-\tau})-(2r)!\,\gamma t^{-2r}\right\}. \tag{87}$$

Having found a suitable expression for T_n we can now go back to (86) and write it in the new form,

$$\int_0^\infty\left\{2T_n(\alpha\tau)-\sum_{r=1}^{u}(\alpha\tau)^{2r}\frac{n!(r-1)!}{(r+n)!(2r-1)!}\right\}\tau^{s-1}e^{\tau/2-a\tau}\widetilde{K}^q(\tau)d\tau. \tag{88}$$

We have introduced into the integral a regulator τ^s (the expression that we want is given for the value $s=0$). The continuation variable s has been introduced so that we may evaluate the integrals of the individual terms in the sum definition (87) of T_n, and of the sum subtracted from it, *before* we perform the sums. We assume that s is large enough so that all the individual integrals are well defined. In fact this requires $s>2n$. Performing the integrations leaves

$$(-\alpha^2)^{-n}\sum_{r=0}^{n}\binom{n}{r}(2\alpha)^{\tau}(2n-r)!\Gamma(s+r-2n)\{\zeta^q(s+r-2n,a+\alpha)$$

$$+(-1)^r\zeta^q(s+r-2n,a-\alpha)\}-2\sum_{r=0}^{n}(-\alpha^2)^{-r}\binom{n}{r}(2r)!$$

$$\times\Gamma(s-2r)\zeta^q(s-2r,a)-\sum_{r=1}^{u}\alpha^{2r}\frac{n!(r-1)!\Gamma(s+2r)}{(r+n)!(2r-1)!}\zeta^q(s+2r,a). \tag{89}$$

As $s\to 0$ all of these terms diverge, although taking all terms together we must get a finite result, i.e., all poles must cancel as $s\to 0$. This cancellation of the poles leads to the equation,

$$(-\alpha^2)^{-n}\sum_{r=0}^{n}\binom{n}{r}(2\alpha)^r\{\zeta^q(r-2n,a-\alpha)+(-1)^r\zeta^q(r-2n,a+\alpha)\}$$

$$-2\sum_{r=0}^{n}(-\alpha^2)^{-r}\binom{n}{r}\zeta^q(-2r,a)-\sum_{r=1}^{u}\alpha^{2r}\frac{n!(r-1)!}{(r+n)!}N_{2r}=0. \tag{90}$$

Comparing Eqs. (90) and (84) we see that the pole cancellation is precisely the statement,

$$\zeta(-n)=\frac{1}{2}\sum_{r=0}^{n}\binom{n}{r}(2\alpha)^r\{\zeta^q(r-2n,a-\alpha)+(-1)^r\zeta^q(r-2n,a+\alpha)\}. \tag{91}$$

This expression contains equally terms with arguments $a+\alpha$ and $a-\alpha$. We shall say that $\zeta(-n)$ is ''symmetric.'' It is a generalization to general n of the symmetric expression for $n=0$ found in Ref. 21. The methods used in this reference do not produce a suitable pole cancellation to give a symmetric result for $\zeta(-n)$.

The finite remainder part of (89) as $s\to 0$ is given by the expression,

$$(-\alpha^2)^{-n}\sum_{r=0}^{n}\binom{n}{r}(2\alpha)^r\{\zeta^{q\prime}(r-2n,a-\alpha)+(-1)^r\zeta^{q\prime}(r-2n,a+\alpha)\}-2\sum_{r=0}^{n}(-\alpha^2)^{-r}\binom{n}{r}\zeta^{q\prime}$$

$$\times(-2r,a)-\sum_{r=1}^{u}\alpha^{2r}\frac{n!(r-1)!}{(r+n)!}R_{2r}+(-\alpha^2)^{-n}\sum_{r=0}^{n}\binom{n}{r}(2\alpha)^r\psi(2n-r+1)$$

$$\times\{\zeta^q(r-2n,a-\alpha)+(-1)^r\zeta^q(r-2n,a+\alpha)\}-2\sum_{r=0}^{n}(-\alpha^2)^{-r}\binom{n}{r}\psi(2r+1)\zeta^q(-2r,a)$$

$$-\sum_{r=1}^{u}\alpha^{2r}\frac{n!(r-1)!}{(r+n)!}\psi(2r)N_{2r}.$$

Inserting this expression into (85), and adding zero in the form of $\psi(2n+1)$ times (90) gives

$$\zeta'(-n)=\sum_{r=0}^{n}\binom{n}{r}(2\alpha)^r\{\zeta^{q\prime}(r-2n,a-\alpha)+(-1)^r\zeta^{q\prime}(r-2n,a+\alpha)\}-\sum_{r=1}^{n}\binom{n}{r}(2\alpha)^r\sigma_r$$
$$\times\{\zeta^q(r-2n,a-\alpha)+(-1)^r\zeta^q(r-2n,a+\alpha)\}-\sum_{r=0}^{n-1}(-\alpha^2)^{n-r}\binom{n}{r}(2\psi(2r+1)$$
$$-\psi(r+1)+\psi(n+1)-2\psi(2n+1))\zeta^q(-2r,a)-(-1)^n$$
$$\times\sum_{r=1}^{u}\alpha^{2(r+n)}\frac{n!(r-1)!}{2(r+n)!}(2\psi(2r)-\psi(r)+\psi(n+1)-2\psi(2n+1))N_{2r}. \tag{92}$$

The quantities σ_r in the above equation are defined as the sums,

$$\sigma_r=\sum_{k=0}^{r-1}\frac{1}{2n-k}.$$

Equation (92) is not symmetric in the sense that, unlike (91), it does not depend only on the quantities $a\pm\alpha$. If we assume that the sum over the residues is a true feature of $\zeta'(-n)$, as it is for $\zeta'(0)$ in Ref. 21, then we are still left with a sum over $\zeta^q(-2r,a)$. We will now rewrite this sum in a more natural, i.e., symmetric, form.

To this end we introduce the intermediate zeta function, $\overline{\zeta}(s)$, on the space $\overline{\mathcal{M}}=\mathbb{R}^{2n}\times S^2/\Gamma$, which is given by

$$\overline{\zeta}(s)=\frac{\Gamma(s-n)}{(4\pi)^n\Gamma(s)}\zeta(s-n). \tag{93}$$

Combining this with (83) gives an expansion for $\overline{\zeta}(s)$,

$$\overline{\zeta}(s)=\sum_{r=0}^{\infty}\alpha^{2r}\frac{\Gamma(s+r)}{r!\Gamma(s)}\overline{\zeta^q}(2s+2r,a), \tag{94}$$

where we have defined the new linear zeta function via

$$\overline{\zeta^q}(s,a)=\frac{\Gamma\left(\frac{1}{2}s-n\right)}{(4\pi)^n\Gamma\left(\frac{1}{2}s\right)}\zeta^q(s-2n,a). \tag{95}$$

The dimension of $\overline{\mathcal{M}}$ is $\overline{d}=2n+d$ (remember, for our monopole case $d=2$). We see from (95) that $\overline{\zeta^q}(s)$ has poles at $s=2,4,...,2n$ and $s=2n+1,2n+2,...,\overline{d}$. The residues are given by the formulas,

$$\overline{N}_{2r}=\frac{2(-1)^r}{(4\pi)^n(r-1)!(n-r)!}\zeta^q(2r-2n,a),\quad r=1,2,...,n, \tag{96}$$

$$\overline{N}_{2n+r}=\frac{\Gamma\left(\frac{1}{2}r\right)}{(4\pi)^n\Gamma\left(\frac{1}{2}r+n\right)}N_r,\quad r=1,2,...,d. \tag{97}$$

The purpose of making these new definitions is the functional similarity between (83) and (94). This implies that results like (91) and (92) should exist for $\overline{\zeta}(s)$ in terms of $\overline{\zeta^q}(s)$. The

important point is that we know that $\zeta'(0)$ can be written as a symmetric part and a sum over the residues of $\zeta^q(s,a)$, either from Ref. 21, or setting $n=0$ in (92). Thus we might expect $\overline{\zeta'}(0)$ to consist of a symmetric part and a sum over the residues of $\overline{\zeta^q}(s,a)$. Differentiating (93) and setting $s=0$ gives,

$$\overline{\zeta'}(0)=\frac{(-1)^n}{(4\pi)^n n!}(\zeta'(-n)+(\psi(n+1)-\psi(1))\zeta(-n)). \tag{98}$$

Now $\zeta(-n)$ is symmetric in terms of $\zeta^q(s,a\pm\alpha)$ and extends easily to a symmetric form for $\overline{\zeta^q}(s,a)$ using (95). Thus by our reasoning we expect $\zeta'(-n)$ to contain a sum over the residues $\overline{N}_r$. This is exactly what we find, and the final result, in this section, is the *symmetrical* expression,[23]

$$\begin{aligned}\zeta'(-n)=&\sum_{r=0}^{n}\binom{n}{r}(2\alpha)^r\{\zeta^{q\prime}(r-2n,a-\alpha)+(-1)^r\zeta^{q\prime}(r-2n,a+\alpha)\}\\&-\sum_{r=1}^{n}\binom{n}{r}(2\alpha)^r\sigma_r\{\zeta^q(r-2n,a-\alpha)+(-1)^r\zeta^q(r-2n,a+\alpha)\}\\&-(-1)^n(4\pi)^n n!\sum_{r=1}^{\overline{u}}\frac{\alpha^{2r}}{\tau}\rho_r\overline{N}_{2r},\end{aligned} \tag{99}$$

with the definitions $\overline{u}=[\overline{d}/2]$ and

$$\rho_r=\psi(2r-2n+1)-\frac{1}{2}\psi(r-n+1)-\left(\psi(2n+1)-\frac{1}{2}\psi(n+1)\right)=\sum_{k=0}^{r-1}\frac{2}{2k+1}-\sum_{k=0}^{n-1}\frac{1}{2k+1}.$$

The conclusion of these manipulations is that, despite the apparent awkwardness of the binomial expansion, (83), to obtain the required ζ-function, the quantities that we want are given in finite terms, (91), (92), (99), and involve only relatively standard functions such as generalized Bernoulli polynomials introduced via the Barnes ζ-function.

XI. VACUUM ENERGY CALCULATIONS

Simply as an example of the use of the preceding expressions, we evaluate some vacuum (Casimir) energies on S^2/Γ'.

Let $\zeta^q(s,a)$ represent one of the rotational, Dirichlet or Neumann linear zeta functions as in the previous section. Then $\zeta^q(s,a)$ can be extended to the odd-dimensional space–time $\mathbb{R}\times S^2/\Gamma$ (or $\mathbb{R}\times S^2/\Gamma'$) by defining a new zeta function $\zeta(s)$ given by (with $a=1/2$),

$$\zeta(s)=\frac{\Gamma(s-1/2)}{(4\pi)^{1/2}\Gamma(s)}\zeta^q(2s,1/2). \tag{100}$$

This zeta function corresponds to the rather artificial case of a conformally coupled field in three dimensions with mass q^2. [For a scalar field conformally coupled in N dimensions we have $4\xi=(N-2)/(N-1)$. In fact we only require that $\alpha^2=0$ or equivalently $m^2=q^2+(1/4-2\xi)$.] The vacuum energy associated with this physical situation is defined by the simple formula[24]

$$E=-\frac{1}{2}\mu_r\frac{d}{ds}\left(\frac{\mu}{\mu_r}\right)^{2s}\zeta(s)\bigg|_{s=0}. \tag{101}$$

In this equation μ is an arbitrary mass scale and $\mu_r=1/r$ is the mass scale associated with the sphere radius r (which has the value $r=1$). Equation (101) is in fact just half the logarithmic determinant. Inserting Eq. (100) into (101) gives the simpler expression

$$E=\tfrac{1}{2}\zeta^q(-1,1/2), \tag{102}$$

which is finite and independent of μ (we have set $r=1$ again).

The vacuum energy on the space $\mathbb{R}\times\mathbb{R}^{2n}\times S^2/\Gamma(')$ can also be found and gives E proportional to $\zeta^q(-1-2n,\frac{1}{2})$. The calculation for general n is entirely equivalent to the $n=0$ case, which we now calculate.

Using the definitions (80), (80) and Eq. (61), we find from (102) the Dirichlet and Neumann vacuum energies,

$$E_{\{{}^D_N\}}=\pm\frac{d_0}{48|\Gamma'|}(d_0^2-d_1^2-d_2^2)+\frac{\overline{q}'}{24}\left(3d_0^2-d_1^2+\frac{1}{2}\pm 6d_0q-2q^2\right).$$

The constant (q independent) terms are exactly the same as those calculated in Ref. 1 for $q=0$, as required. Adding together the Dirichlet and Neumann vacuum energies gives the rotational vacuum energy

$$E_\Gamma=\frac{\overline{q}}{24}(3d_0^2-d_1^2-d_2^2-2q^2),$$

where we have used the relation $\overline{q}=2\overline{q}'$ for fixed q. This vacuum energy necessarily vanishes for $q=0$, as proven in Ref. 1. We now list the vacuum energies $E_{\{{}^D_N\}}$ for all possible reflection groups Γ',

$$O^*:\quad \pm\frac{29}{256}+\frac{\overline{q}'}{48}(383\pm 108q-4q^2),$$

$$Y^*:\quad \pm\frac{89}{384}+\frac{\overline{q}'}{48}(1079\pm 90q-4q^2),$$

$$O]T:\quad \pm\frac{11}{192}+\frac{\overline{q}'}{48}(167\pm 36q-4q^2),$$

$$D_n]C_n:\quad \mp\frac{1}{96}+\frac{\overline{q}'}{48}(4n^2-1\pm 6nq-4q^2),$$

$$D_n^*(n\ \text{even}),\ D_{2n}]D_n(n\ \text{ odd}):\quad \pm\frac{(n+1)(2n-3)}{192n}\frac{\overline{q}'}{48}(4(n+1)(n+2)-9\pm 6(n+1)q-4q^2).$$

Those for the corresponding rotational subgroups are obtained by adding the D and N values.

We now go on to calculate the vacuum energy on the even-dimensional space $\mathbb{R}^{2n}\times S^2/\Gamma(')$. Using Eqs. (93), (98), and (101) we find the expression,

$$E=\frac{(-1)^{n+1}\mu_r}{2(4\pi)^n n!}\left(\zeta'(-n)+\left[\ln\left(\frac{\mu}{\mu_r}\right)^2+\psi(n+1)-\psi(1)\right]\zeta(-n)\right). \tag{103}$$

Here $\zeta(s)$ is the general zeta function defined via Eqs. (82) and (83).

An infinite contribution has been (arbitrarily) dropped to arrive at (103), the logarithmic term being a relic of this divergence. Since $\zeta(0)$ is not zero for any of the three monopole theories, we

conclude from (103) that the vacuum energy is explicitly dependent on the arbitrary scale μ. However for simplicity we shall assume $\mu=\mu_r=1$ for the rest of this section. Our concern in this paper is not with realistic quantum field theory considerations.

Equations (91) and (92) imply that the calculation for increasing n merely requires the evaluation of more and more zeta functions and their derivatives. Thus we shall concentrate on the simplest case $n=0$ corresponding to $S^2/\Gamma(')$ itself. This will also allow us to compare with the results for $q=0$ studied in Ref. 21.

We consider the case of a massless field with minimal coupling, that is $m^2=0$ and $\xi=0$. Thus we have $a=1/2$ and $2\alpha=\sqrt{4q^2+1}$ (we shall still write α when convenient). From the definitions (80), (81), and Eqs. (91), (61), we find for Dirichlet and Neumann boundary conditions,

$$\zeta_{\{N\}}^{D}(0)=\frac{1}{12}+\frac{1}{6|\Gamma'|}(d_0(d_0-1)+1\pm 6d_0q+18q^2).$$

These expressions reduce to those found earlier for $q=0$.[21] For the rotational case we simply add the Dirichlet and Neumann results to give

$$\zeta_{\Gamma}(0)=\frac{1}{6}+\frac{1}{6|\Gamma|}(d_0(d_0-1)+1+18q^2).$$

To calculate the vacuum energy we have still to calculate $\zeta'(0)$. Considering Eq. (92) with $n=0$ requires the evaluation of the residue N_2. For both Dirichlet and Neumann zeta functions we find from (60) and (62) the value $N_2=2/|\Gamma'|$. Using the derivative of the Hurwitz zeta function in Ref. 20 then gives the zeta function derivatives

$$\begin{aligned}\zeta_D'(0)=&\zeta_2'\left(0,\frac{1}{2}+q-\alpha+d_0\right)+\zeta_2'\left(0,\frac{1}{2}+q+\alpha+d_0\right)\\&+\overline{q}'\ln\left\{\Gamma\left(\frac{1}{2}+q-\alpha\right)\Gamma\left(\frac{1}{2}+q+\alpha\right)\right\}-\overline{q}'\ln(2\pi)-\frac{1+4q^2}{2|\Gamma'|},\end{aligned}\tag{104}$$

$$\begin{aligned}\zeta_N'(0)=&\zeta_2'\left(0,\frac{1}{2}+q-\alpha\right)+\zeta_2'\left(0,\frac{1}{2}+q+\alpha\right)\\&+\overline{q}'\ln\left\{\Gamma\left(\frac{1}{2}+q-\alpha\right)\Gamma\left(\frac{1}{2}+q+\alpha\right)\right\}-\overline{q}'\ln(2\pi)-\frac{1+4q^2}{2|\Gamma'|}.\end{aligned}\tag{105}$$

(The rotational zeta function derivative is just the sum of these two.) The triangle inequality $|x|+|y|\geqslant\sqrt{x^2+y^2}(x,y\in\mathbb{R})$ implies that $1/2+q\geqslant\alpha$. The equality is only met for $q=0$, and in this case we have to remove the singularity in the first term $\zeta_2'(0,1/2+q-\alpha|d_1,d_2)$ of the Dirichlet zeta function as in (21) (we shall do this later). For $q>0$ all terms in (105) and (104) are well defined.

There is no known analytic form for the derivatives of the Barnes zeta functions appearing in (105) and (104), and so we have to calculate them numerically. To do this we obviously need a continuation of the Barnes zeta function which is open to easy numerical computation. In Ref. 21 several efficient continuations are presented which are valid for positive integer values of d_1 and d_2. However as we shall show in the next section, it is useful to have an expression which is valid for all d_1, $d_2\in\mathbb{R}^+$. We shall now derive such an expression.

Our starting point is the Plana sum formula which we display here,[25]

$$\sum_{n=a}^{b}f(n)=\frac{1}{2}(f(a)+f(b))+\int_a^b f(t)dt+i\int_0^\infty\frac{f(a+it)-f(a-it)-f(b+it)+f(b-it)}{e^{2\pi t}-1}dt.\tag{106}$$

To be valid $f(t)$ must be an analytic function in the region of the complex t plane $a \leqslant \mathrm{Re}(t) \leqslant b$, and the integrals must exist. Applying (106) twice to the sum definition (59) of the Barnes zeta function gives immediately, for $s>2$,

$$\zeta_2(s,a|d_1,d_2)=\frac{1}{2}d_1^{-s}\zeta_H\left(s,\frac{a}{d_1}\right)+\frac{1}{d_2(s-1)}d_1^{-s}\zeta_H\left(s-1,\frac{a}{d_1}\right)$$
$$+i\int_0^\infty\frac{dt}{e^{2\pi t}-1}\left\{\frac{1}{2}((a+id_2t)^{-s}-(a-id_2t)^{-s})+\frac{1}{d_1(s-1)}((a+id_2t)^{1-s}\right.$$
$$\left.-(a-id_2t)^{1-s})\right\}+\int_0^\infty\frac{du}{e^{2\pi u}-1}\int_0^\infty\frac{dt}{e^{2\pi t}-1}\{(a+id_1u-id_2t)^{-s}$$
$$+(a-id_1u+id_2t)^{-s}-(a+id_{21}u+id_2t)^{-s}-(a-id_1u-id_2t)^{-s}\}. \qquad (107)$$

It is simple to verify that we are meeting the conditions required for the validity of the sum formula. In order to get rid of the single integrals in (107) we use the Plana sum definition of the Hurwitz zeta function which is, from (106),

$$\zeta_H(s,a)=\frac{1}{2}a^{-s}+\frac{a^{1-s}}{s-1}+i\int_0^\infty\frac{dt}{e^{2\pi t}-1}\{(a+it)^{-s}-(a-it)^{-s}\}. \qquad (108)$$

The integral part of this expression is equivalent to the integrals appearing in (107).

To simplify the double integral in (107) we first perform a change of variables from t, u to $d_1u\pm d_2t$. Following this, we use the easily proven formula,

$$(x+iy)^s+(x-iy)^s=2\cos(s\tan^{-1}y/x),$$

which is valid for $\mathrm{Re}(x)\geqslant 0$. After a little work we find the more convenient form for the double integral,

$$\frac{2}{d_1d_2}\int_0^\infty dw\,\frac{G(w)}{e^{2\pi w}-1}\,\frac{\cos(s\tan^{-1}(w/a))}{(a^2+w^2)^{s/2}}. \qquad (109)$$

All the nontrivial d_1, d_2 dependence has been absorbed into the function $G(w)$ which is independent of s and has the explicit form,

$$G(w)=(e^{2\pi w}-1)\left\{\int_0^w\frac{dy}{(e^{\delta_1 y}-1)(e^{\delta_2(w-y)}-1)}-\int_0^\infty\frac{dy}{(e^{\delta_1 y}-1)(e^{\delta_2(w+y)}-1)}\right.$$
$$\left.-\int_0^\infty\frac{dy}{(e^{\delta_1(w+y)}-1)(e^{\delta_2 y}-1)}\right\}, \qquad (110)$$

where we have defined $\delta_i=2\pi/d_i$, $i=1,2$. This function is symmetric under the interchange of d_1, d_2 as one would expect. The factor $(e^{2\pi w}-1)$ has been included into the definition to ensure that $G(w)$ is finite as $w\to 0$.

All the integrals in the definition of $G(w)$ are divergent at their lower limits, and the first integral is also divergent at its upper limit. However one can check that the combination is well defined. In fact by expanding the integrands at their limits of integration we find that for small $\epsilon>0$,

$$G(w)=(e^{2\pi w}-1)\left\{\int_{\epsilon}^{w-\omega}\frac{dy}{(e^{\delta_1 y}-1)(e^{\delta_2(w-y)}-1)}-\int_{\epsilon}^{\infty}\frac{dy}{(e^{\delta_1 y}-1)(e^{\delta_2(w+y)}-1)}\right.$$
$$\left.-\int_{\epsilon}^{\infty}\frac{dy}{(e^{\delta_1(w+y)}-1)(e^{\delta_2 y}-1)}\right\}+O(\epsilon).$$

Thus $G(w)$ is easy to calculate numerically, with the error being of order ϵ. We may also make ϵ the lower limit of the integration over w in (109). Since the integrand with respect to w is finite at the lower limit, the error incurred will still be $O(\epsilon)$.

The full expression for our continuation of the Barnes zeta function, after dealing with both the single and double integrals in (107), is

$$\zeta_2(s,a|d_1,d_2)=-\frac{1}{4}a^{-s}-\frac{a^{2-s}}{d_1d_2(s-1)(s-2)}-\frac{(d_1+d_2)a^{1-s}}{2d_1d_2(s-1)}+\frac{1}{2}d_1^{-s}\zeta_H\left(s,\frac{a}{d_1}\right)$$
$$+\frac{1}{2}d_2^{-s}\zeta_H\left(s,\frac{a}{d_2}\right)+\frac{1}{d_1d_2(s-1)}\left\{d_1^{2-s}\zeta_H\left(s-1,\frac{a}{d_1}\right)+d_2^{2-s}\zeta_H\left(s-1,\frac{a}{d_2}\right)\right\}$$
$$+\frac{2}{d_1d_2}\int_0^{\infty}\frac{G(w)dw}{e^{2\pi w}-1}\frac{\cos(s\tan^{-1}(w/a))}{(a^2+w^2)^{s/2}}. \tag{111}$$

Although this formula was derived for $s>2$, it is actually a continuation to all values of (complex) s except at the points $s=1,2$ where there are simple poles. It is easy to check that these poles are correct in that their residues match those given in (60). From (111) we can calculate the derivative of the Barnes zeta function at $s=0$,[23]

$$\zeta_2'(0,a|d_1,d_2)=-\frac{1}{4}\ln a-\frac{1}{2}\left(1-\frac{a}{d_1}-\frac{a}{d_2}\right)\ln(2\pi)+\frac{1}{2}a\ln a\left(\frac{1}{d_1}+\frac{1}{d_2}\right)-\frac{a^2}{2d_1d_2}\left(\frac{5}{2}+\ln a\right)$$
$$+\left(\frac{1}{2}-\frac{a}{d_1}\right)\left(\frac{1}{2}-\frac{a}{d_2}\right)\ln\frac{a^2}{d_1d_2}+\left(\frac{1}{2}-\frac{a}{d_1}\right)\ln\Gamma\left(\frac{a}{d_2}\right)+\left(\frac{1}{2}-\frac{a}{d_2}\right)\ln\Gamma\left(\frac{a}{d_1}\right)+\frac{d_1^2+d_2^2}{12d_1d_2}$$
$$+\frac{1}{d_1d_2}\int_0^{\infty}\frac{dw}{e^{2\pi w}-1}(2G(w)-d_1^2w\ln(a^2+d_1^2w^2)-d_2^2w\ln(a^2+d_2^2w^2)). \tag{112}$$

Here we have used (108) again to convert derivatives of the Hurwitz zeta function $\zeta_H(s,a)$ at $s=-1$ into integrals suitable for numerical evaluation.

The expression (112) can be used directly in equation (105) and (104). Figures 1–4 show plots of $E=-\zeta'(0)/2$ for small values of $\overline{q}$. The lines on the graphs for T, O, and Y are for labeling only. The graphs for C_k and D_k are plotted for all k, although at the moment we are only concerned with the integral values $k=1,2,...$ marked with crosses. On each graph the value $\overline{q}$ of the charge per rotational domain is always twice the reflection value $\overline{q}'$ so as to give the same value of q.

The graphs with $\overline{q}=q=0$ are exactly the same as those calculated in Ref. 21. To plot the graphs in this case we have had to remove the divergence in the first Barnes zeta function derivative in (105). This is due to a zero mode appearing in the spectrum of the operator H_{S^2}. The divergence is logarithmic and can be removed by defining the so called Γ-modular form ρ_2 defined by[19,21]

$$\lim_{a\to 0}\zeta_2'(0,a|d_1,d_2)=-\ln a-\ln\rho_2.$$

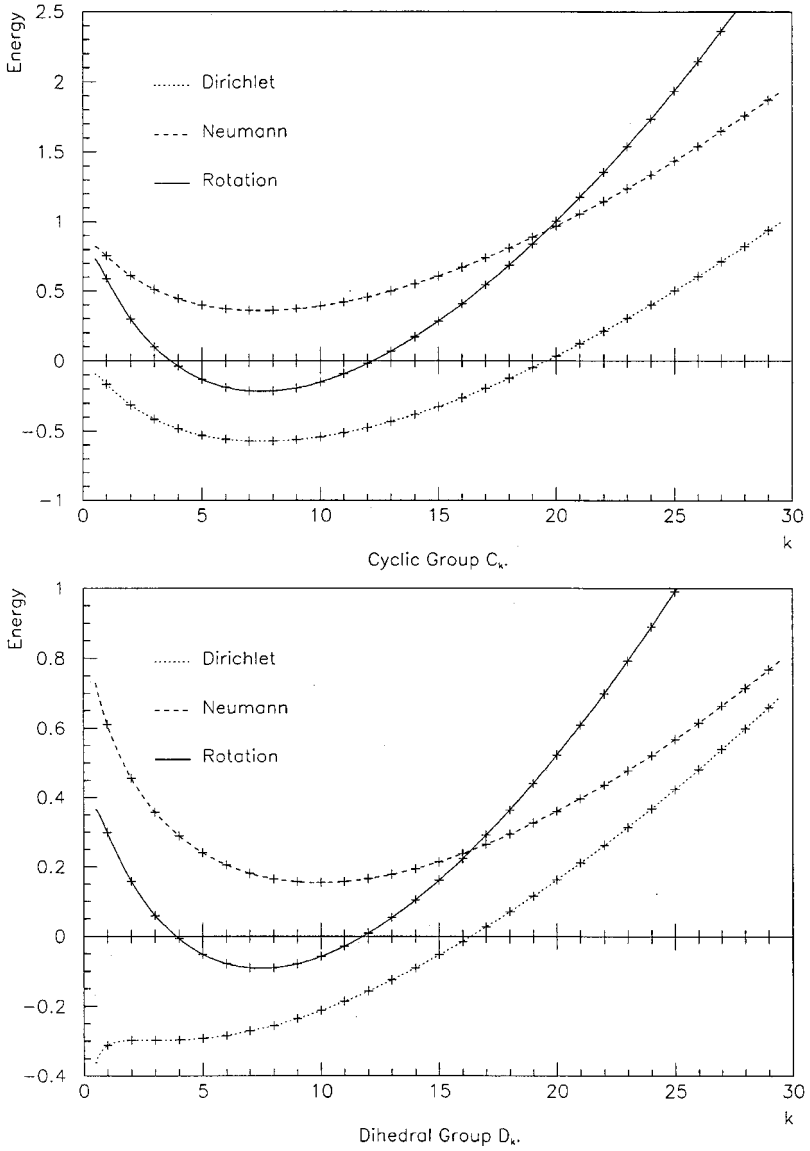

FIG. 1. Vacuum energies for C_k and D_k with $\overline{q}'=0$.

The leading term $-\ln a$ on the right-hand side is the divergent zero mode contribution which must be removed. The form ρ_2 has been calculated in terms of the multiple gamma function by Barnes.[19,26] The Γ-modular form can be more easily calculated by using the simply proved relation,

$$\zeta_2(s,a|d_1,d_2)=a^{-s}+d_1^{-s}\zeta_H\left(s,1+\frac{a}{d_1}\right)+d_2^{-s}\zeta_H\left(s,1+\frac{a}{d_2}\right)+\zeta_2(s,a+d_1+d_2|d_1,d_2).$$

Differentiating this with respect to s at $s=0$, and taking the limit $a\to 0$ leaves the expression

$$-\ln\rho_2=\tfrac{1}{2}\ln(d_1d_2)-\ln(2\pi)+\zeta_2'(0,d_0+1|d_1,d_2).$$

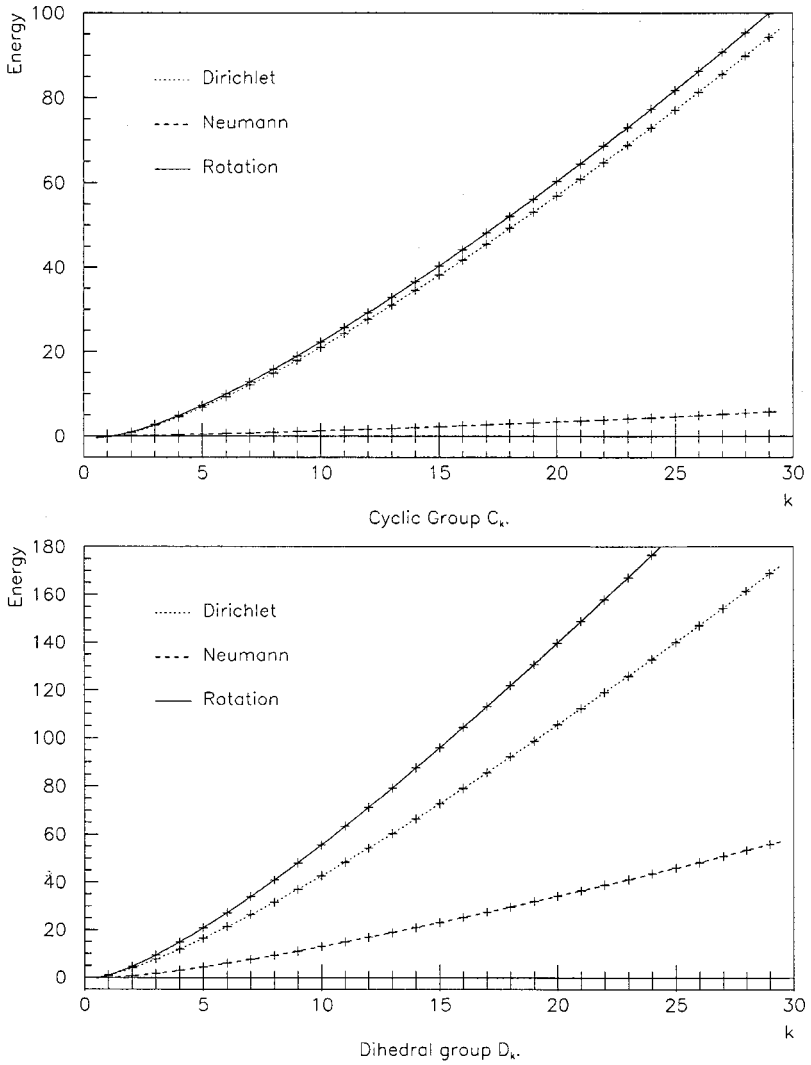

FIG. 2. Vacuum energies for C_k and D_k with $\overline{q}=1/2$.

For $q>0$, the zero mode that we have just removed for $q=0$ is still almost zero. This is the reason why the vacuum energy for the Dirichlet zeta function increases more rapidly with $\overline{q}$ than in the Neumann case.

XII. THEORY FOR A SPHERICAL SLICE

By a spherical slice of width β we mean the space $S_\beta=\{(\theta,\phi)\,|\,\theta\in[0,\pi],\ \phi\in[0,\beta]\}$ with the points $(\theta, 0)$ and (θ, β) identified [here (θ, ϕ) are the spherical polar coordinates on the sphere which shall be used throughout this section]. One might also term this space a ''periodic lune.''

The starting point for the monopole theory on S_β is the solution to the explicit differential Eq. (4) with arbitrary q. As mentioned in the discussion surrounding the differential equation the solutions are characterized by integers u, v, and are given by Eqs. (3) and (5). We shall now show that it is possible to define consistent monopole theories on S_β corresponding to the rotational, Dirichlet and Neumann cases already given. The rotational case is considered first.

Define k by $k=2\pi/\beta$ and let $\hat{\gamma}$ denote a rotation by angle β about the z axis. Due to the identification of points in S_β at $\phi=0,\beta$, we will proceed conventionally and take the wave

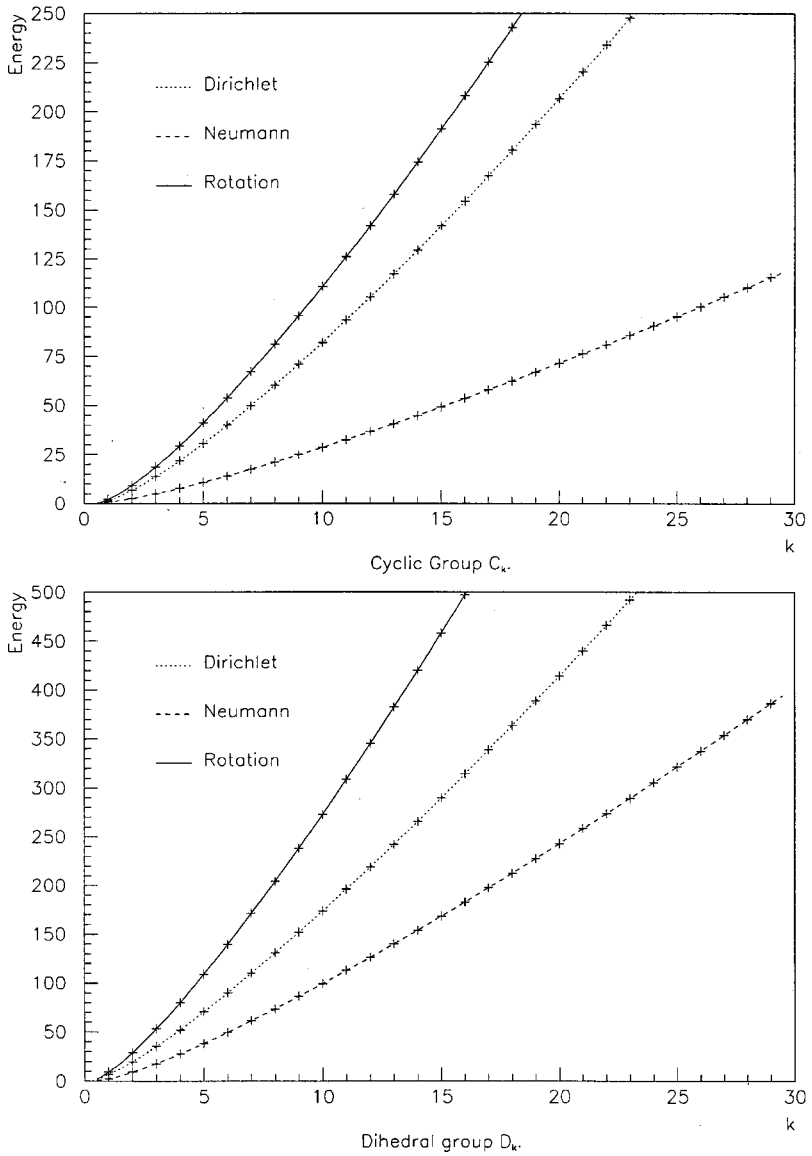

FIG. 3. Vacuum energies for C_k and D_k with $\overline{q}'=1$.

function to be single valued, i.e., to have period β. Also, for rapidity, the monopole charge quantization will be obtained by requiring the connecting function $\exp(i2q\phi)$ to have period β. This yields

$$q=\frac{k}{2}n, \quad n\in\mathbb{Z}. \tag{113}$$

Corresponding to these values of q we find $a(\hat{\gamma})=(-1)^n$. If k is an integer then S_β is a fundamental domain for the group C_k (generated by $\hat{\gamma}$), and the relation $|C_k|=k$ gives an equivalence between the quantization conditions (39) and (113). Thus we see that the quantization condition for arbitrary k is a generalization of the previous theory for C_k (with integer k). From single valuedness, $\varphi(\theta,\beta)=\varphi(\theta,0)$, for the monopole harmonics (5), we see from the explicit ϕ dependence that,

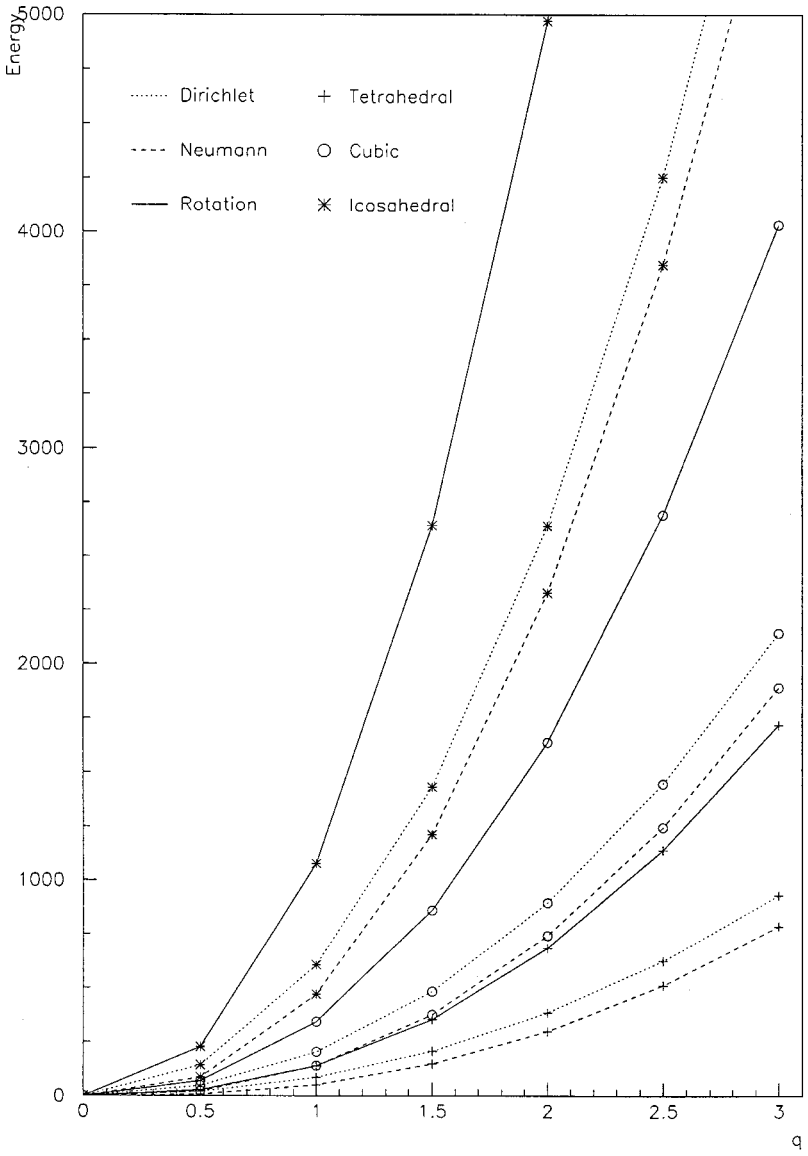

FIG. 4. Vacuum energies for groups T, O, and Y as functions of $\overline{q}'$.

$$m = jk - q, \quad j \in \mathbb{Z}. \tag{114}$$

In this more general setting it would appear that we can always choose n to be odd, whereas before this was only possible for k odd also. From (5) we find the possible values of l,

$$l = u + \frac{k}{2}(|j| + |n-j|), \quad u \in \mathbb{Z}^+, j \in \mathbb{Z}.$$

The eigenvalues λ appearing in the mode Eq. (4) are still given by $l(l+1) - q^2$. As in Sec. VII we shall calculate the linear heat kernel for the eigenvalues $(l+1/2)$.

Using the values of q, l, and m above gives the sum form for the linear heat kernel analogous to (51), with (5),

$$\tilde{K}_k^q(\tau)=e^{-\tau/2}\sum_{u=0}^{\infty}\sum_{j=-\infty}^{\infty}e^{-r(u+k(|j|+|j+n|)/2)}. \tag{115}$$

Evaluating this sum gives exactly the result found before, Eq. (56), except that now k is not an integer, and q need not be an integer multiple of k. A corollary of this result is that (56) is also valid for the case when $\Gamma=C_k$ with k and $2q$ odd integers. The zeta function defined by Eq. (58) is also correct for $d_1=1$, $d_2=k$ and hence we conclude that the vacuum energies calculated in the previous section are valid for *arbitrary* k.

For the Dirichlet and Neumann theories defined in section 8 we consider the slice $S_{\beta/2}$ and two reflection planes P_0 and P_1 which leave $\phi=0$ and $\phi=\beta/2$ invariant respectively. Following the same arguments as in section 8 gives the values of the monopole charge

$$q=kn', \tag{116}$$

which is equivalent to Eq. (65). Taking γ' in (64) to be a reflection in P_0 and using (17) gives the modes $W_{qm}^{(l)}$ as the combinations,

$$W_{qm}^{(l)}(\theta,\phi)=Y_{qm}^{(l)}(\theta,\phi)+a(\sigma)Y_{q-m}^{(l)}(\theta,\phi).$$

Here $Y_{qm}^{(l)}$ are those defined in (3) with the string along the negative z axis, and $a(\sigma)=\pm1$ as before (the reflection in P_0 is expressed simply as $\phi\to-\phi$).

The ϕ dependent part of the modes $W_{qm}^{(l)}$ is given by

$$W_{qm}^{(l)}\sim e^{iq\phi}\times\begin{cases}\cos(m\phi), & a(\sigma)=+1\\ \sin(m\phi), & a(\sigma)=-1\end{cases}.$$

Reflection in P_0 is equivalent to $\phi\to-\phi$ and we see explicitly that this transforms $W_{qm}^{(l)}(\theta,0)$ into $a(\sigma)W_{-qm}^{(l)}(\theta,0)$ as required. Reflection in P_1 is equivalent to $\phi\to\beta-\phi$ and results in the condition on m,

$$m=kj, \quad j\in\mathbb{Z}^+. \tag{117}$$

For the Dirichlet case $a(\sigma)=-1$ the $m=0$ mode is in fact zero and has to be removed. Comparing (117) with (114) (with $n=2n'$ even) we see that the only difference between the rotation and reflection cases is that in the reflection case the values of m are restricted to positive integers.

The linear heat kernel for the Neumann case $a(\sigma)=+1$ is given by

$$\tilde{K}_N^q(\tau)=e^{-\tau/2}\sum_{u=0}^{\infty}\sum_{j=0}^{\infty}e^{-r(u+k(|j+n'|+|j-n'|)/2)}. \tag{118}$$

Explicit evaluation of the sum gives exactly the heat kernel as before, Eq. (55). The Dirichlet case involves subtracting the $j=0$ term from (71) and yields the previous expression (75). Thus the zeta functions are given exactly as before and we conclude that the vacuum energy calculated for C_k is in fact valid for all k.

To extend the results of D_k to arbitrary k we consider the slice of the upper hemisphere $S'_\beta=\{(\theta,\phi)\,|\,\theta\in[0,\pi/2],\ \phi\in[0,\beta]\}$ with again $k=2\pi/\beta$. This is a fundamental domain for D_k when k is an integer. The theory then follows as for the C_k extension above, but we must include in this case a rotation about the x axis by angle π. This rotation can be thought of as a reflection in the plane P_0 followed by a reflection in the x–y plane, which we call P_2. The theory for S_β above is adapted to the reflection P_0 and thus we see that P_2 is the essential extra detail here.

The reflection P_2 is equivalent to the transformation $\theta\to\pi-\theta$ which does not affect the ϕ dependence of the modes $Y_{qm}^{(l)}(\theta,\phi)$. Since the extension to arbitrary k is entirely linked with the

ϕ dependence, we conclude that all the heat kernels, zeta functions and vacuum energies for D_k can be extended to arbitrary k. The values of the monopole charge in the reflection case are calculated using the theory of Sec. IX as

$$q = 2kn', \quad n' \in \mathbb{Z},$$

which is the generalization of (65) with $|\Gamma'| = 4k$.

XIII. SUMMARY AND DISCUSSION

We have thoroughly adapted Dirac's monopole theory to the orbifold, S^2/Γ, for the cases that Γ contains only rotations and when Γ is generated by reflections. In the former case we imposed rotational (periodic) boundary conditions on the monopole solutions. In the latter we had a choice of boundary conditions defined so as to reproduce Dirichlet and Neumann conditions for no monopole charge, $q=0$. We found that it was the monopole charge $\overline{q} = q/|\Gamma|$ through S^2/Γ that was Dirac quantized with $2\overline{q} \in \mathbb{Z}$.

After all the formalities of the theory had been tidied we explicitly calculated the vacuum energies on the orbifolds S^2/Γ and $\mathbb{R}\times S^2/\Gamma$. Formal expressions are given for the generalization to the spaces $\mathbb{R}^{2n}\times S^2/\Gamma$ and $\mathbb{R}\times\mathbb{R}^{2n}\times S^2/\Gamma$. Finally we provided an extension of the monopole theory to arbitrary slices of the sphere and hemisphere. In this case the flux through the spherical region is still quantized, although now the overall monopole charge q is not, in general, an integer or half odd-integer.

We feel that the scalar theory has been developed essentially to its analytical limit on the factored sphere. The next step would be the extension to $\mathbb{R}^3/\Gamma$ for Γ a reflection or rotation group. This requires modes of the full Hamiltonian which are given by

$$Y^{(l)}_{qm}(\theta,\phi) J_\nu(kr)\sqrt{k/r}, \quad \nu = \sqrt{(l+1/2)^2 - q^2}$$

with eigenvalues k^2. Since the radial dependence does not involve m, the underlying facts of the theory (modes on factored space, charge quantization, etc.) are the same as in the spherical case. However the heat-kernel calculation, and hence the ζ-function, is completely different. Due to the complicated index, $\sqrt{(l+1/2)^2-q^2}$, closed forms do not seem possible and asymptotic methods are needed. One could always arbitrarily add a term q^2/r to the (total) Hamiltonian and then a closed form would exist. This fact suggests that there is some significance to this modification.

The spinor theory on the factored sphere S^2/Γ has been considered by Chang.[27] He found a consistent theory only for $\Gamma = C_k$ with k odd. For $q \neq 0$ we claim that the same restriction still holds. This follows from the lack of half odd-integral solutions to the scalar monopole problem for $\Gamma \neq C_k$.

A possible extension of the scalar calculation would be to consider if (high temperature) Bose–Einstein condensation occurs. The general theory has been laid down by Toms[28] See also Kirsten and Toms.[29] Basically, all that is required is to ensure that the ζ-function for the theory, and its derivative, are finite at zero as the chemical potential approaches a critical value. On the two-sphere we can use the calculations of $\zeta(-n)$ and $\zeta'(-n)$ given in Sec. X to study the theory on $\mathbb{R}^{2n}\times S^2$. In fact we could also discuss $\mathbb{R}^{2n}\times S^d$.

(Received 31 July 2000; accepted for publication 4 December 2000)

A complete and rigorous determination of the possible ground states for *D*-wave pairing Bose condensates is presented, using a geometrical invariant theory approach to the problem. The order parameter is argued to be a vector, transforming according to a ten-dimensional real representation of the group $G=\mathbf{O}_3\otimes\mathbf{U}_1\times\langle\mathcal{T}\rangle$. We determine the equalities and inequalities defining the orbit space of this linear group and its symmetry strata, which are in a one-to-one correspondence with the possible distinct phases of the system. We find 15 allowed phases (besides the unbroken one), with different symmetries, that we thoroughly determine. The group–subgroup relations between bordering phases are pointed out. The perturbative sixth degree corrections to the minimum of a fourth degree polynomial *G*-invariant free energy, calculated by Mermin, are also determined. © *2001 American Institute of Physics.* [DOI: 10.1063/1.1345871]

I. INTRODUCTION

Superfluidity and superconductivity are justified on the basis of the macroscopic condensation of Bose quasiparticles. The classical Bardeen, Cooper, and Schrieffer (BCS) theory for superconductivity dates to 1957. Soon after, a BCS-type transition was proposed for the Fermi system ^{3}He by Anderson and Morel.[1] Cooper pair formation was thought to occur in an $L\neq 0$ state, to take into account the hard core nature of ^{3}He atom interaction. The superfluid phases were actually observed,[2] and the nature of *p*-wave pairing is now well established for ^{3}He. The theory of $L\neq 0$ superfluids is relevant for ''unconventional'' superconductivity too. The high temperature superconducting (HTS) oxides are anomalous in their non-Fermi liquid normal state properties and in many cases share with heavy fermion superconductors unconventional *d*-wave pairing behavior.[3,4] In fact, experiments probing the phase and the nodes of the gap show a sign reversal of the order parameter, compatible with the *d*-wave scenario. Nevertheless, other experiments on the same HTS compounds point in the direction of a significant *s*-wave component. In the presence of external magnetic fields, defects, and interface phenomena there is also evidence of a mixed pairing symmetry (see, e.g., the Introduction of Ref. 5, and references therein). Such a

controversial experimental situation is reflected in the fact that the underlying microscopic mechanism inducing superconductivity in HTS materials is still unclear and is one of today's major challenges.[6,7]

Such a situation has motivated the efforts at studying the macroscopic properties of unconventional superconductors through the Landau theory of phase transitions[8] and the identification of the order parameter symmetry has become a preliminary task in the construction of viable models describing the attractive nature of the pairing interaction.

Direct experimental evidence of an order parameter unconventional structure lies on multiple phase transitions. The heavy fermion compounds $U_{1-x}Th_xBe_{13}$ display four different superconducting phases in the $T-x$ phase diagram and UPt_3 displays three superconducting phases in a $T-H$ phase diagram.[3] Furthermore, from power-law temperature behavior of thermodynamic and transport properties (e.g., specific heat, magnetic penetration depth), a nontrivial node structure for the gap function may be inferred, compatible with high L-pairing. That is the case also for HTS oxides, for which, at present, clear proofs are lacking of the existence of more than one superconducting state.

Actually, it must be pointed out that, unlike superfluid ^{3}He, which is an isotropic fermion system, Bloch electrons in a superconductor crystal lattice exhibit, in general, a reduced finite symmetry; in addition, the existence of imperfections, even in the cleanest samples, can partly destroy the gap node structure at low energy. So, the very fact that the experimental observation cannot at present completely unravel the node structure of the gap function, reinforces the necessity of classifying all the possible symmetry breaking schemes.

Moreover, the role of Fermi isotropic space beyond a zeroth-order approximation in phenomenological theories is still supported by some recent studies: In HTS oxides, low symmetrical crystal fields (tetragonal and orthorombic), as well as spontaneous strain, have weak influence on the temperature of the superconducting phase transition[9] or on the penetration depth.[10] So, even if the spectrum of the interactions which are responsible for the pairing (whatever there origins may be) must be anisotropic in the crystal, it is worth analyzing the possibility that they act in a way not directly dependent on the crystal structure (like in isotropic space).

The possible ground states of a high L superfluid was the object of intense investigations during the 1960s and the 1970s. From the solution of the state equations, Anderson and Morel[1] and Mermin[11] identified five different phases, through the minimization of a fourth degree Landau potential. Schakel and Bias[12] analyzed the problem using only group theoretical arguments. Capel and Schakel,[13] taking advantage of the results in Ref. 12, computed the possible ground states of condensates driven by p-waves. They also investigated the consequences of lowering the residual symmetry by means of strong spin–orbit interactions. Since, in this case, the Cooper pair is in a $J=2$ state $(S=1, L=1)$, the order parameter is represented by a traceless symmetric tensor. The same holds true for an $(S=0, L=2)$ state order parameter, so their results may be directly applied to D-wave pairing. According to the authors of Ref. 13, eleven different phases are allowed. Their analysis, however, is questionable, since time reversal symmetry cannot be neglected in the theory of condensate states and the use of a fourth degree polynomial Landau free energy strongly limits the number of phases that would be allowed by the symmetry of the system.

Our aim is to give a definitive answer to the classification of possible symmetry breaking patterns in D-wave pairing Bose condensate, in the framework of the Landau theory of phase transitions. In this paper, we shall mainly be concerned with the mathematical aspects of the problem, which will be solved making use of the geometrical invariant theory approach, proposed in Ref. 14. The strategy is to exploit a set of basic invariant polynomials of the symmetry group of the system, as fundamental variables in the description of the phase space of the system and in the minimization procedure of the free energy.[15] In the realization of this program, we shall meet some substantial computational difficulties, which will be overcome by means of innovative procedures.

II. THE GEOMETRICAL INVARIANT THEORY APPROACH TO SPONTANEOUS SYMMETRY BREAKING

Let us briefly recall some basic elements of the geometrical invariant theory approach, or orbit space approach (see Ref. 16, and references therein) to the determination of possible patterns of spontaneous symmetry breaking.

Let $x \in \mathbf{R}^n$ be a vector order parameter, transforming linearly and orthogonally under the compact real symmetry group G, and let $\Phi(\alpha;x)$ be the G-invariant free energy, expressed in terms, also, of state variables α. The points $x_0(\alpha)$, where the function $\phi_\alpha(x)=\Phi(\alpha;x)$ takes on its absolute minimum, determine the stable phase of the system, whose residual symmetry is defined by the isotropy subgroup of G at x_0, G_{x_0}. Owing to its G-invariance, the free energy is a constant along each G-orbit, so each of its stationary points is degenerate along the G-orbit through it. Since the isotropy subgroups of G at points of the same orbit are conjugate in G, only the conjugate class, $[G_{x_0}]$, of G_{x_0} in G, i.e., the *orbit type* (or *symmetry*) of the orbit through x_0, is physically relevant.

The set of all G-orbits, endowed with the quotient topology and differentiable structure, forms the *orbit space*, $\mathbf{R}^n/G$, of G and the subset of all the G-orbits with the same orbit type forms a *stratum* of $\mathbf{R}^n/G$. Phase transitions take place when, by varying the values of the α's, the point $x_0(\alpha)$ is shifted to an orbit lying on a different stratum.

If $\Phi(\alpha;x)$ is a sufficiently general function of the α's, by varying these parameters, the point $x_0(\alpha)$ can be shifted to any stratum of $\mathbf{R}^n/G$. So, *the strata are in a one-to-one correspondence with the symmetry phases allowed by the G-invariance of the free energy*. On the contrary, extra restrictions on the form of the free energy function, not coming from G-symmetry requirements (e.g., the assumption that the free energy is a polynomial of low degree), can limit the number of allowed phases for the system in its ground state.

Being constant along each G-orbit, the free energy may be conveniently thought of as a function defined in the orbit space of G. This fact can be formalized using some basic results of invariant theory. In fact, the G-invariant polynomial functions separate the G-orbits, meaning that, for any two distinct orbits, there is at least a polynomial G-invariant function assuming different values on them. Moreover, every G-invariant polynomial can be built as a real polynomial function of a *finite* set, $\{p_1(x),\ldots,p_q(x)\}$, of basic polynomial invariants (*integrity basis of the ring of G-invariant polynomials*). Thus, the elements of an integrity basis can be conveniently used as coordinates of the orbit space points. They need not, for general compact groups, be algebraically independent, but can, and will, be chosen to be homogeneous polynomials in x. The number of algebraically independent elements in a *minimal* set of basic polynomial invariants is $n-\nu$, where ν is the dimension of a generic (principal) orbit of G. Information on the number and degrees of a minimal set of basic invariants, and the degrees of the algebraic relations (*syzygies*) among them, can be inferred from the Mölien function of G.

Let us call q_0 the number of independent elements of the set $\{p\}$. The range of the *orbit map*, $x \mapsto p(x)=(p_1(x),\ldots,p_q(x)) \in \mathbf{R}^q$, yields a realization of the orbit space of the linear group G, as a connected semialgebraic surface, i.e., a subset of $\mathbf{R}^q$, determined by algebraic equations and inequalities. The orbit space of G will, therefore, be identified with a closed and connected region, $\hat{S}$, of a q_0-dimensional algebraic surface, delimited by lower dimensional semialgebraic surfaces.

If an integrity basis has been determined, the equations and inequalities defining the orbit space of a compact group can be obtained from a simple recipe. It has been shown, in fact, that the orbit space of a reductive linear group can be identified with the semialgebraic variety formed by the points $p \in \mathbf{R}^q$, satisfying the following conditions:[14,17]

(i) p lies on the surface, Z, defined by the syzygies.

(ii) The $q \times q$ matrix $\hat{P}(p)$, defined by the relations

$$\hat{P}_{ab}(p(x))=\sum_{j=1}^{n} \partial_j p_a(x)\partial_j p_b(x), \quad \forall x \in \mathbf{R}^n \tag{1}$$

is positive semidefinite and has rank $\leqslant q_0$ at p.

The minimum of $\Phi(\alpha;x)$ can be computed as a *constrained* minimum of the function, $\hat{\Phi}(\alpha;p)$, $p\in\hat{S}$, defined by

$$\hat{\Phi}(\alpha;p(x))=\Phi(\alpha;x), \quad \forall x\in\mathbf{R}^n. \tag{2}$$

It has also been shown[14] that the state equation

$$\partial\Phi(\alpha;x)/\partial x_j=0, \quad j=1,...,n,$$

determining the extremal points of $\Phi(\alpha;x)$, is equivalent to the following equation in orbit space:

$$\sum_{b=1}^{q}\hat{P}_{ab}(p)\partial_b\hat{\Phi}(\alpha;p)=0, \quad a=1,...,q, \quad p\in\hat{S}. \tag{3}$$

Like all semialgebraic sets, the orbit space of G presents a natural *stratification*. It can, in fact, be considered as the disjoint union of a *finite number* of semialgebraic subsets of decreasing dimensions (*geometrical strata*), each geometrical stratum being in the border of a higher dimensional one, but for the highest dimensional stratum, which is unique (*principal stratum*). The *geometrical strata* are the connected components of the *symmetry strata*. The symmetries of two bordering strata are related by a group–subgroup relation and the orbit type of the lower dimensional stratum is larger.

In order to determine the minimum of $\hat{\Phi}(\alpha;p)$, $p\in\hat{S}$, as a constrained minimum, one needs the relations defining the geometrical strata of $\mathbf{R}^n/G$. These can be obtained from positivity and rank conditions on the matrix $\hat{P}(p)$ and from the syzygies, as already stated.

The geometrical and symmetry strata are determined in the following way. Let $\hat{W}^{(d)}$ denote the (generally nonconnected) d dimensional algebraic subset of Z, defined by the relation

$$\hat{W}^{(d)}=\{p\in Z|\operatorname{rank}(\hat{P}(p))=d, \ \hat{P}(p)\geqslant 0\}, \tag{4}$$

then, the geometrical d dimensional strata are the connected components of $\hat{W}^{(d)}$ and each d dimensional symmetry stratum, $\hat{S}^{(d,\alpha)}$, $\alpha=1,...$, is the union of all the geometrical d dimensional strata, $\hat{W}^{(d,\alpha,r)}$, $r=1,...k_\alpha$, with the same orbit type, $[G^{(d,r)}]$. A representative in $[G^{(d,r)}]$ can be obtained as the isotropy subgroup at an arbitrarily chosen point $x^{(d,r)}$ of the image in $\mathbf{R}^n$, $W^{(d,r)}$, of the geometric stratum $\hat{W}^{(d,r)}$. The point $x^{(d,r)}$ can be obtained as a solution of the equation $p(x)=p^{(d,r)}$, where $p^{(d,r)}$ is an arbitrarily chosen point in $\hat{W}^{(d,r)}$. Note that for $p^{(0)}\in\hat{S}$, all the solutions, x, of the equation $\tilde{p}(x)=\tilde{p}^{(0)}$ form a unique G-orbit. The equation has no solutions for $p^{(0)}\notin\hat{S}$.

In the following, we shall classify and characterize all the allowed symmetry phases and possible phase transitions between contiguous phases, for D-wave phase condensates in isotropic space. In particular, in Sec. III we shall identify the linear symmetry group, G, of these systems and a minimal set of basic polynomial invariants of G. In Sec. IV, we shall determine the geometrical features of the orbit space of G, i.e., its stratification (including connection properties and bordering relations of the strata) and the orbit types of its strata. In Sec. V, using an innovative method, we shall provide relatively simple expressions for the equalities and inequalities determining each stratum. These are essential for establishing the connection properties of the strata and make much easier the determination of the minima of a specific free energy function. A simple example of the determination of the minima of a general fourth degree G-invariant polynomial and their stability against sixth-order perturbations will be given in Sec. V.

III. SYMMETRY OF THE ALLOWED *D*-WAVE CONDENSATE STATES IN ISOTROPIC SPACE

The formation of *D*-wave condensate ground states breaks the symmetry of the isotropic three-dimensional space, which corresponds to the group $\mathbf{O}_3 \otimes \mathbf{U}_1 \times \langle \mathcal{T} \rangle$, where $\mathbf{O}_3$ is the complete rotation group, $\mathbf{U}_1$ is the gauge group, and $\langle \mathcal{T} \rangle$ is the group generated by the time reversal operator $\mathcal{T}$. Also, here and in the following, we shall denote by $\langle g_1,\ldots,g_n \rangle$ the group generated by the set $\{g_1,\ldots,g_n\}$.

The symmetry of the allowed *D*-wave condensate ground states is defined by the relative values of the complex coefficients in the decomposition of the gap function, Δ, in terms of spherical harmonics with $L=2$:

$$\Delta(\theta,\phi)=\sum_{m=-2}^{2} D_m Y_2^m(\theta,\phi).$$

The set of functions $\{Y_2^m, Y_2^{m*}\}$ yields a basis of a ten-dimensional (10 D) space, hosting a real representation of the symmetry group $\mathbf{O}_3 \otimes \mathbf{U}_1 \times \langle \mathcal{T} \rangle$. A general element, γ, of the group will be denoted by a triple

$$\gamma=(\rho, e^{i\phi}, \epsilon),$$

where, $\rho \in \mathbf{O}_3$, $0 \leqslant \phi < 2\pi$ and $\epsilon = -1$, or $+1$ according to whether a time reflection is involved in the transformation, or not. In the following, we shall also use the shortened notations ρ for $(\rho,1,1)$, $U_1(\phi)$ for $(\mathbf{1}_3, U_1(\phi),1)$, and $\mathcal{T}$ for $(\mathbf{1}_3,1,-1)$.

The action of G can be transferred to a real irreducible action on the 10 D vector formed by the coefficients $\{D_2,\ldots,D_{-2},D_{-2}^*,\ldots,D_2^*\}$. The representation of G thus obtained can be realized in the 10 D real vector space generated by a couple of two independent, real, second rank, symmetric, traceless tensors, $X_{ij}^{(1)}$ and $X_{ij}^{(2)}$, $i, j=1, 2, 3$, which can be considered as the real and imaginary parts of a complex 3×3 matrix ψ, whose elements will be written in terms of five complex coordinates, z_j:

$$z_j = x_j + i x_{5+j}, \quad j=1,\ldots,5, \quad x_i \in \mathbf{R}, \tag{5}$$

$$\psi = \frac{1}{\sqrt{2}} \begin{pmatrix} z_2 + \dfrac{z_5}{\sqrt{3}} & z_1 & z_4 \\ z_1 & -z_2 + \dfrac{z_5}{\sqrt{3}} & z_3 \\ z_4 & z_3 & -\dfrac{2z_5}{\sqrt{3}} \end{pmatrix}. \tag{6}$$

The coordinates D_α are connected to the z_j by the following relations:

$$D_2 = -\frac{iz_1+z_2}{\sqrt{2}}, \quad D_1 = \frac{iz_3+z_4}{\sqrt{2}}, \quad D_0 = z_5, \quad D_{-1} = \frac{iz_3-z_4}{\sqrt{2}}, \quad D_{-2} = \frac{iz_1-z_2}{\sqrt{2}}. \tag{7}$$

The matrix ψ transforms in the following way under a general transformation, $\gamma=(\rho,\phi,\epsilon) \in G$:

$$\gamma \cdot \psi = e^{i\phi} \rho \psi' \rho^T, \tag{8}$$

where $\psi' = \psi$ or ψ^*, according to whether $\epsilon = +1$ or -1 and the apex T denotes transposition. As a consequence, the group G acts as a group of linear, real, *orthogonal* transformations on the vector order parameter $x = (x_1, \ldots, x_{10}) \in \mathbf{R}^{10}$.

The kernel of the representation of G just defined is the group generated by the space reflection, so it will not be restrictive to assume that the symmetry group is

$$G = \mathbf{SO}_3 \otimes \mathbf{U}_1 \times \langle \mathcal{T} \rangle$$

and, when referring to G, in the following, we shall always mean this linear group acting in the vector space $\mathbf{R}^{10}$.

The group G has a trivial principal isotropy subgroup (the isotropy subgroup of generic points of $\mathbf{R}^{10}$), thus the principal G-orbits have the same dimensions, four, as G and its *orbit space*, $\mathbf{R}^{10}/G$, has dimensions $q_0 = 10 - 4 = 6$.

The Mölien function of $G, M_G(\eta)$, can be calculated in the form of an invariant Haar integral over G (see, for instance, Refs. 18 and 19):

$$M_G(\eta) = \int_G \frac{\mathrm{d}\mu(g)}{\det(\mathbf{1} - \eta g)}, \quad |\eta| < 1,$$

where $\mu(g)$ is a normalized invariant measure on the group G, the integration is over the whole group G, and $g \in G$. In terms of the Euler angles ϕ_1, θ, ϕ_2 and of the gauge angle α, the integral can be written in the form of a sum over the two connected components of G,

$$M_G(\eta) = \frac{1}{16\pi^2} \int_0^{2\pi} \mathrm{d}\phi_1 \int_0^{2\pi} \mathrm{d}\phi_2 \int_0^{\pi} \sin\theta \, \mathrm{d}\theta \times \left\{ \int_0^{2\pi} \frac{\mathrm{d}\alpha}{2\pi} \prod_{k=-2}^{2} [(1 - \eta e^{i(k\chi + \alpha)}) \times (1 - \eta e^{i(k\chi - \alpha)})]^{-1} + \prod_{k=-2}^{2} [(1 - \eta e^{ik\chi})(1 + \eta e^{ik\chi})]^{-1} \right\}, \tag{9}$$

where $\{e^{ik\chi}\}_{-2 \leqslant k \leqslant 2}$ are the distinct eigenvalues of the 10 D rotation matrix and $\cos\chi$ is a function of the Euler angles:

$$\cos\chi = \tfrac{1}{2}[\cos\theta + \cos(\phi_1 + \phi_2) + \cos\theta \cos(\phi_1 + \phi_2) - 1]. \tag{10}$$

It has to be noted that, in principle, the denominators in (9) are polynomials in $\sin\chi$ and $\cos\chi$; but, by definition, they are also even functions of χ, so they can be expressed as polynomials only in $\cos\chi$.

An explicit calculation of the integrals (see Appendix A) leads to

$$M_G(\eta) = \frac{1 + \eta^8 + \eta^{10} + \eta^{12} + \eta^{20}}{(1 - \eta^2)(1 - \eta^4)^2 (1 - \eta^6)^2 (1 - \eta^8)}, \tag{11}$$

a relation that can also be written in the following equivalent suggestive form:

$$M_G(\eta) = \frac{1 - \eta^{16} - \eta^{18} - \eta^{20} - \eta^{22} - \eta^{24} + \eta^{26} + \eta^{28} + \eta^{30} + \eta^{32} + \eta^{34} - \eta^{50}}{(1 - \eta^2)(1 - \eta^4)^2 (1 - \eta^6)^2 (1 - \eta^8)^2 (1 - \eta^{10})(1 - \eta^{12})}. \tag{12}$$

Any G-invariant homogeneous polynomial of degree 20 in $x \in \mathbf{R}^{10}$ can be written as a polynomial in $p_1(x), \ldots, p_9(x)$; Eqs. (11) and (12) yield the following indications, whose validity has been checked through direct calculations.

(1) A minimal integrity basis (IB) for the linear group G contains nine elements, $\{p_1, \ldots, p_9\}$ with degrees $(d_1, \ldots, d_9) = (2, 4, 4, 6, 6, 8, 8, 10, 12)$.

(2) The invariants p_i are connected by five independent syzygies of degrees 16, 18, 20, 22, and 24. The group is, therefore, *noncoregular*.

(3) It is possible to find a *nonminimal homogeneous* IB, $\{\xi_1,\ldots,\xi_6,\theta_1,\ldots,\theta_4\}$, with degrees (2, 4, 4, 6, 6, 8, 8, 10, 12, 20), such that any invariant polynomial, F, can be written in the form[20]

$$F=Q_0(\xi)+\sum_{i=1}^{4} Q_i(\xi)\,\theta_i, \tag{13}$$

where the Q's, are polynomials in the *algebraically independent* polynomial invariants $(\xi_1,\ldots,\xi_6)$.

A possible choice for the IBs $\{p\}$ and $\{\xi,\ \theta\}$ is the following:

$$\begin{gathered}
p_1=\mathrm{Tr}(\psi\psi^*)=\Sigma_{i=1}^{10}x_i^2,\\
p_2=\mathrm{Tr}[(\psi\psi^*)^2],\quad p_6=\Re[\mathrm{Tr}(\psi^2)\mathrm{Tr}(\psi^2\psi^*)\mathrm{Tr}(\psi^{*3})],\\
p_3=|\mathrm{Tr}(\psi^2)|^2,\quad p_7=\Re[\mathrm{Tr}(\psi^{*2})(\mathrm{Tr}(\psi^2\psi^*))^2],\\
p_4=|\mathrm{Tr}(\psi^3)|^2,\quad p_8=\Re[\mathrm{Tr}(\psi^2\psi^*)\mathrm{Tr}(\psi^3)(\mathrm{Tr}(\psi^{*2}))^2],\\
p_5=|\mathrm{Tr}(\psi^2\psi^*)|^2,\quad p_9=\Re[(\mathrm{Tr}(\psi^2))^3(\mathrm{Tr}(\psi^{*3}))^2].
\end{gathered} \tag{14}$$

and

$$\begin{gathered}
\xi_i=p_i,\quad i=1,\ldots,5,\quad \xi_6=p_6+p_7,\\
\theta_1=p_6-p_7,\quad \theta_2=p_8,\quad \theta_3=p_9,\quad \theta_4=(p_6-p_7)p_9.
\end{gathered} \tag{15}$$

Thus, the most general nonequilibrium polynomial Landau potential, $\hat{\Phi}(\alpha;p)$, can be written in the form

$$\hat{\Phi}=Q_0+Q_1p_7+Q_2p_8+Q_3p_9+Q_4p_7p_9. \tag{16}$$

Using the above-mentioned definitions, the explicit form of the syzygies and of the $\hat{P}$-matrix elements can be obtained through the following simple procedure.

After defining the *weight* of an element, p_i, of the IB to be equal to the degree, d_i, of the homogeneous polynomial $p_i(x)$, and the degree of $\Pi_i p_i^{n_i}$ as $\Sigma_i n_i d_i$, one writes down the most general homogeneous polynomial, $\hat{\Theta}^{(d)}(\xi,\theta)$, of the relevant weight, d, in the weighted variables ξ_i, $i=1,\ldots,6$ and θ_i, $i=1,\ldots,4$. With the definitions $\theta_0=1$, $d_0=0$, the polynomial $\hat{\Theta}^{(d)}(\xi,\theta)$ can be written in the compact form

$$\hat{\Theta}^{(d)}(\xi,\theta)=\sum_{j=0}^{3}\delta_{N_j,d}A^{(j,d)}_{n_i,\ldots,n_6}\theta_j\prod_{k=1}^{6}\xi^{n_k},$$

where $N_j=\Sigma_{i=1}^{6}n_id_i-d_j$, $\delta_{N_{j,d}}$ is a Kronecker symbol and the A's are real coefficients to be determined through the following conditions:

(i) In the case of the syzygies $\hat{s}_d(\xi,\theta)$, $d=16,\ 18,\ 20,\ 22,\ 24$: The expression $\hat{s}_d(\xi(x),\theta(x))$ has to vanish identically in x.

(ii) In the case of the matrix elements $\hat{P}_{a,b}(\xi,\theta)$, $a,b=1,\ldots,9$, $d=d_a+d_b-2$: The expression $\hat{P}_{ab}(\xi(x),\theta(x))=\Sigma_{i=1}^{10}\partial_i p_a(x)\partial_i p_b(x)$ has to be an identity in x.

The explicit expressions of the syzygies are reported in Appendix B and the elements of the matrix $\hat{P}(p)$ in Appendix C. In the following we shall always use the minimal IB $\{p\}$.

On the algebraic surface, Z, defined by the syzygies in the nine-dimensional space of the p's, the 9×9 symmetric matrix $\hat{P}(p)$ has rank $\leqslant 6$, as it has to be, since the orbit space is six dimensional.

IV. THE ORBIT SPACE OF THE LINEAR GROUP *G*

As recalled in Sec. I, the orbit space of G can be identified with the range of the orbit map $x\mapsto p(x)$, which is the same as the set of values of $p\in Z$, that render the matrix $\hat{P}(p)$ positive semidefinite.

The analytic conditions determining the geometrical strata, $\hat{W}^{(d,\alpha,r)}$, are not difficult to specify, in principle, but, in the case of the higher dimensional strata, their explicit expressions (as sets of equalities and inequalities in the p's) become difficult to obtain, too large to be written down extensively and uneasy to handle, if they are derived only from rank and positivity conditions of the matrix $\hat{P}(p)$. An elegant way to bypass this difficulty is the following.

One starts with the relatively easy determination of the *geometrical* strata of dimensions $\leqslant 2$ [i.e., the connected components of the sets $\hat{W}^{(d)}$, $d=1$, 2, defined in (4)], starting from the positivity and rank properties of the matrix $\hat{P}(p)$ and from the syzygies. The subsequent step consists in the identification of the orbit type of each geometrical stratum. This allows one to identify the connected components, $\hat{W}^{(d,\alpha,r)}$, $r=1,...$, with the same orbit type, $[G^{d,\alpha}]$, and belonging, therefore, to the same *symmetry* stratum, $\hat{S}^{(d,\alpha)}$. There is a unique zero-dimensional stratum, corresponding to the point $p=p(0)=0$, whose symmetry is $[G]$. It will be ignored in the following. All the groups $G^{(2,\alpha)}$ turn out to be finite groups of low order ($\leqslant 8$).

The determination of the higher dimensional strata bordered by a given two-dimensional stratum, $\hat{S}^{(2,\alpha)}$, can be obtained starting from the identification of their orbit types, which are necessarily contained in the orbit type of $\hat{S}^{(2,\alpha)}$. The task is easily accomplished by selecting, out of the set of maximal subgroups of $G^{(2,\alpha)}$, those which are isotropy subgroups of G. To this end, the following criterion can be used. Let H be one of the maximal subgroups of a $G^{(d,\alpha)}$ and denote by V_H the linear subspace formed by all the points $x\in\mathbf{R}^{10}$, which are stable under H. Then, H is an isotropy subgroup of G, if and only if the following condition is satisfied:

$$\operatorname*{Max}_{x\in V_H}\operatorname{rank}(P(x))<d.$$

If this condition is satisfied, when x spans V_H, the point $p(x)\in\mathbf{R}^9$ spans the topological closure of a stratum $\hat{S}^{(d',\alpha')}$ and

$$\dim(\hat{S}^{(d',\alpha')})=\operatorname*{Max}_{x\in V_H}\operatorname{rank}(P(x)).$$

To get the full set of higher dimensional strata, the last part of the procedure just described has to be repeated for each newly determined stratum.

The derivation of the equalities and inequalities determining each of the higher dimensional strata requires a more sophisticated method,[21] which we shall explain and exploit in Sec. V.

Before resuming the results obtained with the realization of the program just presented, let us note that, owing to the linearity of G, its isotropy subgroups coincide at the points $x\in\mathbf{R}^{10}$ and κx, $0\neq\kappa\in\mathbf{R}$. Thus, also taking into account the homogeneity of the polynomials $p_i(x)$, the points $(p_1,...,p_9)$ and $(1,p_2/p_1^{d_2/2},...,p_9/p_1^{d_9/2})$ lie on the same stratum and the equalities and inequalities defining the strata can be written as homogeneous relations in the weighted variables p_i. It will be useful, therefore, to introduce the definitions

$$\tilde{p}_i=p_i/p_1^{d_i/2},\quad \tilde{p}=(\tilde{p}_2,...,\tilde{p}_9). \tag{17}$$

TABLE I. Relations defining 1 D geometrical strata, $\hat{S}^{(1,A)}=\hat{W}^{(1,A)}$ in orbit space. For $2\leqslant i\leqslant 9$, $\tilde{p}_i=p_i/(p_1^{d_i/2})$, d_i denotes the degree of the polynomial $p_i(x)$ in the order parameter x and the values, $p^{(1,A)}$, taken on by $\tilde{p}$ on $\hat{W}^{(1,A)}$ are listed in the columns from 2 to 9.

A	$\tilde{p}_2$	$\tilde{p}_3$	$\tilde{p}_4$	$\tilde{p}_5$	$\tilde{p}_6$	$\tilde{p}_7$	$\tilde{p}_8$	$\tilde{p}_9$
1	1	0	0	0	0	0	0	0
2	1/2	1	1/6	1/6	1/6	1/6	1/6	1/6
3	1/2	1	0	0	0	0	0	0
4	1/3	0	1/3	0	0	0	0	0
5	1/2	0	0	0	0	0	0	0

The relations determining the one- and two-dimensional strata can be easily obtained by selecting those solutions, $\overline{p}$, of the condition rank $(\hat{P}(p))=1$ and, respectively, rank $(\hat{P}(p))=2$, at which the matrix $\hat{P}(\overline{p})$ is positive semidefinite. In this way, one obtains five connected components, $\hat{W}^{(1,A)}$,$A=1,...,5$, of $\hat{W}^{(1)}$ and seven connected components, $\hat{W}^{(2,A)}$, $A=1_+, 1_-, 2, 3_+, 3_-, 4, 5$, of $\hat{W}^{(2)}$. The parametric equations defining these semialgebraic sets are listed in Tables I and II.

In order to identify the distinct 1 D and 2 D symmetry strata, for each connected component $\hat{W}^{(d,A)}$, $d=1,2$, we have picked up a point $p^{(d,A)}$ and, for each $p^{(d,A)}$, a ''simple'' solution, $x^{(d,A)}$, of the equation $\tilde{p}(x)=\tilde{p}^{d,A}$. Then, at each point $x^{(d,A)}$ we have determined, and compared for conjugation, the isotropy subgroup of G,$G^{(d,A)}$. These subgroups turn out to be nonconjugate in G, but for $G^{(2,1_+)}$, which is conjugate to $G^{(2,1_-)}$, and $G^{(2,3_+)}$, which is conjugate to $G^{(2,3_-)}$. Thus, there are five distinct 1 D and five 2 D symmetry strata, $\hat{S}^{(d,\alpha)}$, with orbit-types $[G^{(d,\alpha)}]$, $d=1,2$, $\alpha=1,...,5$.

After choosing an element, H, in each class $[G^{(d,\alpha)}]$, it is easy to determine the subspace $V_H\subset\mathbf{R}^{10}$, formed by the vectors which are H-invariant.

The results we have obtained are listed in Tables III and IV and the bordering relations among the strata are illustrated in Fig. 1. The definitions of the rotation matrices appearing in the tables and in the following text are recalled in Appendix D. We have used standard notations for the corresponding geometrical transformations (see, e.g, Ref. 22).

V. RELATIONS DEFINING THE STRATA WITH DIMENSIONS ⩾3

In order to derive the relations defining the higher dimensional strata we shall exploit the following results,[21] which we shall briefly recall, without proof. Let H be an isotropy subgroup of G, $S_{[H]}$ and $\hat{S}_{[H]}$ the associated strata in $\mathbf{R}^{10}$ and $\mathbf{R}^{10}/G$ respectively, and let $\mathrm{Stab}(H,G)$ be the stabilizer of H in G:

TABLE II. Parametric equations defining the geometrical strata, $\hat{W}^{(2,A)}$ (A is listed in the head row) in orbit space. For $2\leqslant i\leqslant 9$, $\tilde{p}_i=p_i/(p_1^{d_i/2})$ and d_i denotes the degree of the polynomial $p_i(x)$, in the order parameter x, and $\epsilon=\pm 1$.

$\tilde{p}\backslash A$	1_ϵ	2	3_ϵ	4	5
$\tilde{p}_2$	$(2+\xi^2)/6$	1/2	$(2+\xi^2)/6$	1/2	ξ

(3,1)	III	4	$\langle C_{2x},C_{2x}\mathcal{T}\rangle$	$(it_1,t_2,0,0,t_3)$	$(t_1-t_2,0,t_3\sqrt{2},0,-t_1-t_2)$
(3,2)	$\cdots$	4	$\langle C_{2x},C_{2z}\rangle$	$(0,v_1,0,0,v_2)$	$(-v_1,0,v_2\sqrt{2},0,-v_1)$
(4,1)	$\cdots$	2	$\langle C_{2x}\mathcal{T}\rangle$	(it_1,t_2,t_3,it_4,t_5)	$(t_1-t_2,it_3+it_4,t_5\sqrt{2},it_3-it_4,-t_1-t_2)$
(4,2)	$\cdots$	2	$\langle C_{2z}\rangle$	$(v_1,v_2,0,0,v_3)$	$(-iv_1-v_2,0,v_3\sqrt{2},0,iv_1-v_2)$
(6,1)	$\cdots$	1	$\{1\}$	(v_1,v_2,v_3,v_4,v_5)	$(-iv_1-v_2,iv_3+v_4,v_5\sqrt{2},iv_3-v_4,iv_1-v_2)$

$$\mathrm{Stab}(H,G)=\{g\in G\,|\,gHg^{-1}=H\}.$$

We have denoted by V_H the linear subspace formed by the H-invariant vectors of $\mathbf{R}^{10}$:

$$V_H=\{x\in\mathbf{R}^{10}\,|\,hx=x,\forall h\in H\},\tag{18}$$

and we shall denote by $V_H^{(H)}$ the subset of V_H formed by the points at which the isotropy subgroup of G is H:

$$V_H^{(H)}=\{x\in\mathbf{R}^{10}\,|\,G_x=H\}.\tag{19}$$

TABLE IV. Strata of dimensions $\geqslant 3$, bordering each stratum $\hat{S}^{(d,r)}$ (d denotes the dimension of the stratum and r is an enumeration index). From left to right, the columns refer to the enumeration numbers, (d,r), of the lower bordering stratum, $\hat{S}^{(d,r)}$, its orbit type, $[G^{(d,r)}]$, the maximal conjugacy classes of subgroups of $[G^{(d,r)}]$, $[H]_M$, the order, $|H_M|$, of H_M and the indices, (d',r'), of the corresponding strata, if any. The definitions of the group elements are recalled in Appendix D.

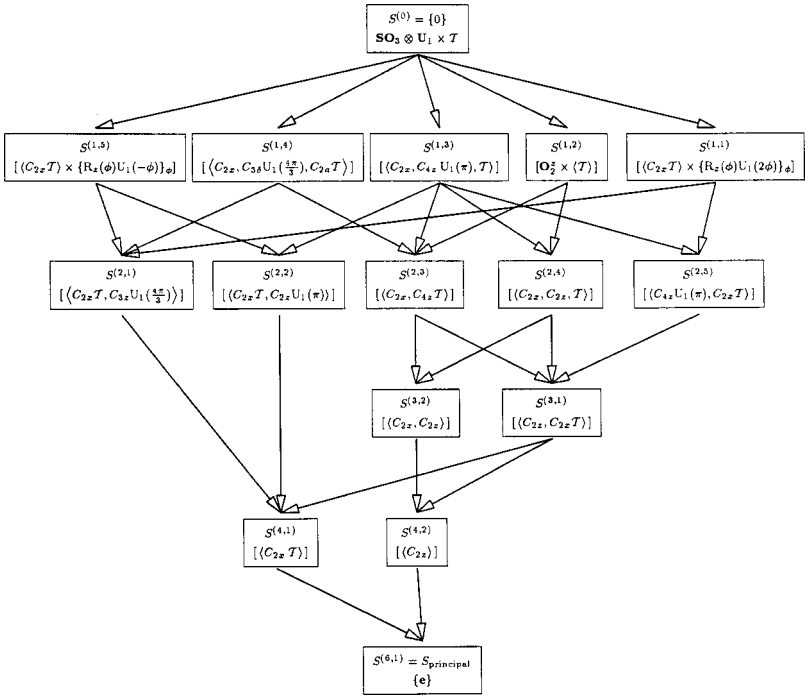

FIG. 1. Possible phase transitions between bordering strata, connected by continuous sequences of one or more arrows. The group elements are defined in Appendix D.

The set $V_H^{(H)}$ is the intersection of V_H with the stratum of orbit-type $[H]$.

The group $\mathrm{Stab}(H,G)$ acts linearly on V_H; let us call $\tilde{H}$ the linear group defined by this action. The $\tilde{H}$-orbit through $x \in V_H$ is the intersection of the G-orbit through x with V_H. There is, therefore, a one-to-one correspondence between the G-orbits lying in the closure of $\hat{S}_{[H]}$ and the $\tilde{H}$ orbits. This correspondence can be restricted to a one-to-one correspondence between the interior points of the closure of $\hat{S}_{[H]}$ and the points of the principal stratum of $V_H/\tilde{H}$. If $\hat{S}_{[H]}$ is connected, the one-to-one correspondence is between the principal stratum of $V_H/\tilde{H}$ and $\hat{S}_{[H]}$, otherwise the inverse image of $\hat{S}_{[H]}$ in the correspondence reduces to the points of the principal stratum of $V_H/\tilde{H}$, corresponding to $\tilde{H}$-orbits through points of $V_H^{(H)}$. Thus an IB, $\{\lambda\}$, of $\tilde{H}$ can be used to parametrize the points of $\hat{S}_{[H]}$:

$$p = p(\lambda).$$

The range of the parameters λ will be determined by the positivity conditions of the $\hat{P}$ matrix associated to the IB $\{\lambda\}$, $\hat{P}^{(H)}(\lambda)$, and convenient additional conditions obtained from positivity and rank conditions of $\hat{P}(p)$, if $\hat{S}_{[H]}$ is not connected. To this end it will be worth noting that, for $p \in \hat{S}_{[H]}$, the matrix $\hat{P}(p)$ can be written in the following form:

$$\hat{P}(p(\lambda)) = J^T(\lambda)\hat{P}^{(H)}(\lambda)J(\lambda), \tag{20}$$

where, $J(\lambda)$ is the Jacobian matrix

$$J_{ai}(\lambda) = \frac{\partial p_a(\lambda)}{\partial \lambda_i}. \tag{21}$$

Owing to a well-known theorem in matrix theory, from (20) one obtains the following upper limit:

$$\mathrm{rank}(\hat{P}(p(\lambda))) \leqslant \mathrm{rank}(J(\lambda)). \tag{22}$$

In the following, we shall use this approach to derive rational parametric equations for all the strata of $\hat{S}$ with dimensions three and four. The results obtained in this way, starting from each of the strata of dimensions $\geqslant 2$, are summarized in Table IV and in the lower part of Table III.

A. Stratum $\hat{S}^{(3,1)}$

The stabilizer in G of the group $H=G^{(3,1)}=\langle C_{2z}, C_{2x}\mathcal{T}\rangle$, is the group $\mathrm{Stab}(H)=\langle C_{2x}, C_{2a}, U_1(\pi), \mathcal{T}\rangle$.

An easy calculation shows that the space V_H is defined by the equations $x_i=0$, $i=1, 3, 4, 7, 8, 9, 10$. The elements of $\tilde{H}$ act on the x_i, $i=2, 5, 6,$ by changing the signs of one or two or all of these coordinates, so, an IB of $\tilde{H}$ can be chosen to be

$$\lambda_1=x_5^2, \quad \lambda_2=x_2^2, \quad \lambda_3=x_6^2 \tag{23}$$

and the expression of the p's in terms of the λ's turns out to be the following:

$$\begin{aligned}
p_1&=\lambda_1+\lambda_2+\lambda_3,\\
p_2&=(3\lambda_1^2+6\lambda_1\lambda_2+3\lambda_2^2+2\lambda_1\lambda_3+18\lambda_2\lambda_3+3\lambda_3^2)/6,\\
p_3&=(\lambda_1+\lambda_2-\lambda_3)^2,\\
p_4&=\lambda_1(\lambda_1-3\lambda_2+3\lambda_3)^2/6,\\
p_5&=\lambda_1(\lambda_1-3\lambda_2-\lambda_3)^2/6,\\
p_6&=\lambda_1(\lambda_1-3\lambda_2-\lambda_3)(\lambda_1+\lambda_2-\lambda_3)(\lambda_1-3\lambda_2+3\lambda_3)/6,\\
p_7&=\lambda_1(\lambda_1-3\lambda_2-\lambda_3)^2(\lambda_1+\lambda_2-\lambda_3)/6,\\
p_8&=\lambda_1(\lambda_1-3\lambda_2-\lambda_3)(\lambda_1+\lambda_2-\lambda_3)^2(\lambda_1-3\lambda_2+3\lambda_3)/6,\\
p_9&=\lambda_1(\lambda_1+\lambda_2-\lambda_3)^3(\lambda_1-3\lambda_2+3\lambda_3)^2/6,
\end{aligned} \tag{24}$$

with

$$\lambda_1, \lambda_2, \lambda_3 > 0. \tag{25}$$

For values of the λ's satisfying (25), the values of the p's defined in (24) render $\hat{P}(p)$ everywhere positive semidefinite and of rank three. We can conclude, therefore, that they yield parametric equations for the three-dimensional (3D) stratum $\hat{S}^{(3,1)}$. Being the continuous image of a connected set, the stratum is *connected*.

By eliminating the parameters λ's from (24) and (25), one obtains the following relations:

$$\begin{aligned}
p_4&=9(2p_1{}^2-2p_2-p_3)(2p_1{}^2-2p_2+2p_1\sqrt{p_3}+p_3)^2\tau,\\
p_5&=(2p_1{}^2-2p_2-p_3)(2p_1{}^2-6p_2-2p_1\sqrt{p_3}-p_3)^2\tau,\\
p_6&=-3\sqrt{p_3}(2p_1{}^2-2p_2-p_3)(2p_1{}^2-6p_2-2p_1\sqrt{p_3}-p_3)(2p_1{}^2-2p_2+2p_1\sqrt{p_3}+p_3)\tau,
\end{aligned}$$

$$p_7 = -\sqrt{p_3}(2{p_1}^2 - 2p_2 - p_3)(2{p_1}^2 - 6p_2 - 2p_1\sqrt{p_3} - p_3)^2\tau,$$

$$p_8 = 3p_3(2{p_1}^2 - 2p_2 - p_3)(2{p_1}^2 - 6p_2 - 2p_1\sqrt{p_3} - p_3)(2{p_1}^2 - 2p_2 + 2p_1\sqrt{p_3} + p_3)\tau,$$

$$p_9 = -9\sqrt{p_3^3}(2{p_1}^2 - 2p_2 - p_3)(2{p_1}^2 - 2p_2 + 2p_1\sqrt{p_3} + p_3)^2\tau, \tag{26}$$

$$\begin{cases} 0 < p_3 < p_1^2, \\ 2p_1^2 + p_3 < 6p_2 < 3(2p_1^2 - p_3), \end{cases} \tag{27}$$

where

$$\tau^{-1} = 64(p_1 + \sqrt{p_3})^3, \tag{28}$$

and the square root of p_3 has to be intended in an algebraic sense.

B. Stratum $\hat{S}^{(3,2)}$

The stabilizer in G of the group $H = G^{(3,2)} = \langle C_{2x}, C_{2x} \rangle$, is a group of ∞ order: Stab(H) $= \langle C_{4x}, C_{4z}, \mathcal{T} \rangle \times \mathbf{U}_1$.

The space V_H is defined by the equations $x_i = 0$, $i = 1, 3, 4, 6, 8, 9$. The transformation properties of the coordinates x_i, $i = 2, 5, 7, 10$, under the transformations of $\tilde{H}$ can be conveniently described in the following way. Let us define:

$$\eta_1 = x_2 + ix_5 + i(x_7 + ix_{10}), \quad \eta_2 = x_2 - ix_5 + i(x_7 - ix_{10}), \tag{29}$$

then

(i) under a gauge transformation, $U_1(\phi)$:$(\eta_1, \eta_2) \to (e^{i\phi}\eta_1, e^{i\phi}\eta_2)$;
(ii) under time reversal $\mathcal{T}$:$(\eta_1, \eta_2) \to (\eta_2^*, \eta_1^*)$;
(iii) under a transformation C_{4x}:$(\eta_1, \eta_2) \to (e^{i\pi/3}\eta_2, e^{-i\pi/3}\eta_1)$;
(iv) under a transformation C_{4z}:$(\eta_1, \eta_2) \to (-\eta_2, -\eta_1)$.

The group $\tilde{H}$ is coregular and admits the following minimal IB:

$$\lambda_1 = (|\eta_1|^2 + |\eta_2|^2)/2 = {x_2}^2 + {x_5}^2 + {x_7}^2 + {x_{10}}^2,$$

$$\lambda_2 = (|\eta_1|^2 - |\eta_2|^2)^2/16 = (x_5x_7 - x_2x_{10})^2, \tag{30}$$

$$\lambda_3 = \Re[(\eta_1\eta_2^*)^3] = ({x_2}^2 - {x_5}^2 + {x_7}^2 - {x_{10}}^2)({x_2}^4 - 14{x_2}^2{x_5}^2 + {x_5}^4 + 2{x_2}^2{x_7}^2 - 2{x_5}^2{x_7}^2 + {x_7}^4$$
$$- 24x_2x_5x_7x_{10} - 2{x_2}^2{x_{10}}^2 + 2{x_5}^2{x_{10}}^2 - 14{x_7}^2{x_{10}}^2 + {x_{10}}^4).$$

It has to be noted that the invariant $(\Im[(\eta_1\eta_2^*)^3])^2$ can be expressed as a polynomial in $\lambda_1, \lambda_2, \lambda_3$.

The corresponding $\hat{P}$-matrix turns out to be

$$\begin{pmatrix} 4\lambda_1 & 8\lambda_2 & 12\lambda_3 \\ 8\lambda_2 & 4\lambda_1\lambda_2 & 0 \\ 12\lambda_3 & 0 & 36\lambda_1(\lambda_1^2 - 4\lambda_2)^2 \end{pmatrix} \tag{31}$$

and the p's can be expressed in terms of the λ's in the following form:

$$p_1 = \lambda_1,$$

$$p_2 = (3\lambda_1^2 - 4\lambda_2)/6,$$

$$
\begin{aligned}
p_3&=\lambda_1^2-4\lambda_2,\\
p_4&=(\lambda_1^3+12\lambda_1\lambda_2-\lambda_3)/12,\\
p_5&=(\lambda_1^3-4\lambda_1\lambda_2-\lambda_3)/12,\\
p_6&=(\lambda_1^4-16\lambda_2^2-\lambda_1\lambda_3)/12,\\
p_7&=(\lambda_1^4-8\lambda_1^2\lambda_2+16\lambda_2^2-\lambda_1\lambda_3)/12,\\
p_8&=(\lambda_1^5-8\lambda_1^3\lambda_2+16\lambda_1\lambda_2^2-\lambda_1^2\lambda_3-4\lambda_2\lambda_3)/12,\\
p_9&=(\lambda_1^6-12\lambda_1^4\lambda_2+48\lambda_1^2\lambda_2^2-64\lambda_2^3-\lambda_1^3\lambda_3-12\lambda_1\lambda_2\lambda_3)/12,
\end{aligned}
\tag{32}
$$

where the parameters λ have to satisfy the conditions:

$$
\begin{cases}
\lambda_1>0,\\
0<4\lambda_2<\lambda_1^2,\\
\lambda_3^2<(\lambda_1^2-4\lambda_2)^3.
\end{cases}
\tag{33}
$$

For values of the λ's satisfying (33), the values of the p's defined in (32) render $\hat{P}(p)$ everywhere positive semidefinite and of rank three. We can conclude, therefore, that they yield parametric equations for the 3D stratum $\hat{S}^{(3,1)}$. Being the continuous image of a connected set, the stratum is *connected*.

By eliminating the parameters λ from (32) and (33) one obtains the following relations:

$$
\begin{aligned}
p_2&=(2p_1^2+p_3)/6,\\
p_5&=(-p_1^3+p_1p_3+3p_4)/3,\\
p_6&=(-4p_1^4+5p_1^2p_3-p_3^2+12p_1p_4)/12,\\
p_7&=(-4p_1^4+3p_1^2p_3+p_3^2+12p_1p_4)/12,\\
p_8&=(-4p_1^5+5p_1^3p_3-p_1p_3^2+12p_1^2p_4-6p_3p_4)/6,\\
p_9&=(-16p_1^6+24p_1^4p_3-9p_1^2p_3^2+p_3^3+48p_1^3p_4-36p_1p_3p_4)/12
\end{aligned}
\tag{34}
$$

and

$$
\begin{cases}
p_1>0,\\
0<p_3<p_1^2,\\
p_3^3<[12p_4-(4p_1^2-3p_3)p_1]^2
\end{cases}
.
\tag{35}
$$

C. Stratum $\hat{S}^{(4,1)}$

The stabilizer in G of the group $H=G^{(4,1)}=\langle C_{2x},\mathcal{T}\rangle$, is the group $\mathrm{Stab}(H,G)=\mathbf{O}_2^x\times\langle U_1(\pi),\mathcal{T}\rangle$.

The space V_H is defined by the equations $x_i=0$, $i=1, 4, 7, 8, 10$. The transformation properties of the coordinates, x_i, $i=2, 3, 5, 6, 9$ of V_H are easily derived from (8) and can be put in the following advantageous form. Let us define

$$\eta_1=\frac{\sqrt{3}x_2+x_5}{2},\quad \eta_2=x_3+i\frac{x_2-\sqrt{3}x_5}{2},\quad \eta_3=x_6-ix_9, \tag{36}$$

then,

(i) under a proper rotation, $O_2^x(\phi):(\eta_1,\eta_2,\eta_3)\to(\eta_1,e^{-2i\phi}\eta_2,e^{i\phi}\eta_3)$;
(ii) under a gauge transformation, $U_1(\pi):(\eta_1,\eta_2,\eta_3)\to(-\eta_1,-\eta_2,-\eta_3)$;
(iii) under a transformation $C_{2z}:(\eta_1,\eta_2,\eta_3)\to(\eta_1,-\eta_2^*,\eta_3^*)$;
(iv) under time reversal $\mathcal{T}:(\eta_1,\eta_2,\eta_3)\to(\eta_1,\eta_2,-\eta_3)$.

The group $\tilde{H}$ is not coregular and admits the following minimal IB:

$$\lambda_1=3|\eta_1|^2=\tfrac{3}{4}(\sqrt{3}x_2+x_5)^2,$$

$$\lambda_2=|\eta_2|^2=\tfrac{1}{4}(x_2^2+4x_3^2-2\sqrt{3}x_2x_5+3x_5^2),$$

$$\lambda_3=|\eta_3|^2=x_6^2+x_9^2, \tag{37}$$

$$\lambda_4=\sqrt{3}\,\eta_1\mathfrak{I}(\eta_2\eta_3^2)=\frac{\sqrt{3}}{4}(\sqrt{3}x_2+x_5)(x_2x_6^2-\sqrt{3}x_5x_6^2-4x_3x_6x_9-x_2x_9^2+\sqrt{3}x_5x_9^2),$$

$$\lambda_5=[\mathfrak{I}(\eta_2\eta_3^2)]^2=\tfrac{1}{4}(x_2x_6^2-\sqrt{3}x_5x_6^2-4x_3x_6x_9-x_2x_9^2+\sqrt{3}x_5x_9^2)^2$$

with the syzygy

$$\lambda_4^2-\lambda_1\lambda_5=0 \tag{38}$$

and the $\hat{P}$ matrix

$$\begin{pmatrix} 12\lambda_1 & 0 & 0 & 6\lambda_4 & 0 \\ 0 & 4\lambda_2 & 0 & 2\lambda_4 & 4\lambda_5 \\ 0 & 0 & 4\lambda_3 & 4\lambda_4 & 8\lambda_5 \\ 6\lambda_4 & 2\lambda_4 & 4\lambda_4 & 4\lambda_1\lambda_2\lambda_3+\lambda_1\lambda_3^2+2\lambda_3(4\lambda_2+\lambda_3)\lambda_4 & 2\lambda_3(4\lambda_2+\lambda_3)\lambda_4 \\ 0 & 4\lambda_5 & 8\lambda_5 & 2\lambda_3(4\lambda_2+\lambda_3)\lambda_4 & 4\lambda_3(4\lambda_2+\lambda_3)\lambda_5 \end{pmatrix}. \tag{39}$$

The conditions $\hat{P}(\lambda)\geqslant 0$ and rank $(\hat{P}(\lambda))=4$, added to (38), yield the following restrictions on the acceptable range for the λ's:

$$\begin{cases} \lambda_1,\lambda_2,\lambda_3\geqslant 0, \\ 0\leqslant\lambda_5<\lambda_2\lambda_3^2, \\ \lambda_1+\lambda_5>0. \end{cases} \tag{40}$$

The p's can be expressed in terms of the λ's in the following form:

$$p_1=(\lambda_1+3\lambda_2+3\lambda_3)/3,$$

$$p_2=(\lambda_1^2+6\lambda_1\lambda_2+9\lambda_2^2+14\lambda_1\lambda_3+18\lambda_2\lambda_3+9\lambda_3^2+24\lambda_4)/18,$$

$$p_3=(\lambda_1+3\lambda_2-3\lambda_3)^2/9,$$

$$p_4=(4\lambda_1^3-72\lambda_1^2\lambda_2+324\lambda_1\lambda_2^2-36\lambda_1^2\lambda_3+324\lambda_1\lambda_2\lambda_3+81\lambda_1\lambda_3^2$$
$$+108\lambda_1\lambda_4-972\lambda_2\lambda_4-486\lambda_3\lambda_4+729\lambda_5)/648,$$

$$p_5=(4\lambda_1^3-72\lambda_1^2\lambda_2+324\lambda_1\lambda_2^2+12\lambda_1^2\lambda_3-108\lambda_1\lambda_2\lambda_3+9\lambda_1\lambda_3^2 -36\lambda_1\lambda_4+324\lambda_2\lambda_4-54\lambda_3\lambda_4+81\lambda_5)/648, \tag{41}$$

$$p_6=(\lambda_1+3\lambda_2-3\lambda_3)(4\lambda_1^3-72\lambda_1^2\lambda_2+324\lambda_1\lambda_2^2-12\lambda_1^2\lambda_3+108\lambda_1\lambda_2\lambda_3 -27\lambda_1\lambda_3^2+36\lambda_1\lambda_4-324\lambda_2\lambda_4+162\lambda_3\lambda_4-243\lambda_5)/1944,$$

$$p_7=(\lambda_1+3\lambda_2-3\lambda_3)(4\lambda_1^3-72\lambda_1^2\lambda_2+324\lambda_1\lambda_2^2+12\lambda_1^2\lambda_3-108\lambda_1\lambda_2\lambda_3 +9\lambda_1\lambda_3^2-36\lambda_1\lambda_4+324\lambda_2\lambda_4-54\lambda_3\lambda_4+81\lambda_5)/1944,$$

$$p_8=(\lambda_1+3\lambda_2-3\lambda_3)^2(4\lambda_1^3-72\lambda_1^2\lambda_2+324\lambda_1\lambda_2^2-12\lambda_1^2\lambda_3+108\lambda_1\lambda_2\lambda_3 -27\lambda_1\lambda_3^2+36\lambda_1\lambda_4-324\lambda_2\lambda_4+162\lambda_3\lambda_4-243\lambda_5)/5832,$$

$$p_9=(\lambda_1+3\lambda_2-3\lambda_3)^3(4\lambda_1^3-72\lambda_1^2\lambda_2+324\lambda_1\lambda_2^2-36\lambda_1^2\lambda_3+324\lambda_1\lambda_2\lambda_3 +81\lambda_1\lambda_3^2+108\lambda_1\lambda_4-972\lambda_2\lambda_4-486\lambda_3\lambda_4+729\lambda_5)/17\,496.$$

For values of the λ's satisfying (38) and (40), the values of the p's defined in (41) render $\hat{P}(p)$ everywhere positive semidefinite and of rank four. We can conclude, therefore, that they yield parametric equations for the four-dimensional (4D) stratum $\hat{S}^{(4,1)}$. Being the continuous image of a connected set, the stratum is *connected*.

For $\lambda_1\neq 0$ $[\lambda_5\neq 0]$, the syzygy can be solved with respect to $\lambda_5[\lambda_1]$ and the expression one obtains can be substituted into (41), so, in this region, $(\lambda_1,\ldots,\lambda_4)[(\lambda_2,\ldots,\lambda_5)]$ play the role of local coordinates for the manifold underlying the stratum. Since, owing to (40), λ_1 and λ_5 cannot vanish simultaneously, the whole stratum is covered by two rational charts of local coordinates.

The elimination of the parameters λ from (41) and (40) leads to cumbersome relations, which are not worth writing down.

D. Stratum $\hat{S}^{(4,2)}$

The stabilizer in G of the isotropy subgroup $H=G^{(4,2)}=\langle C_{2z}\rangle$, is the group $\mathrm{Stab}(H)=\mathbf{O}_2^z\times\mathbf{U}_1$.

The space V_H is defined by the equations $x_i=0$, $i=3,4,8,9$. The transformation properties of the coordinates, x_i, $i=1, 2, 5, 6, 7, 10$ of V_H can be put in the following advantageous form. Let us define

$$\eta_1=x_5+ix_{10},\quad \eta_2=\frac{x_7+ix_6+i(x_2+ix_1)}{\sqrt{2}},\quad \eta_3=\frac{x_7+ix_6-i(x_2+ix_1)}{\sqrt{2}}, \tag{42}$$

then,

(i) under a proper rotation, $O_2^z(\phi)$: $(\eta_1,\eta_2,\eta_3)\to(\eta_1,e^{-2i\phi},e^{-2i\phi}\eta_3)$;
(ii) under a gauge transformation, $U_1(\phi)$: $(\eta_1,\eta_2,\eta_3)\to(e^{i\phi}\eta_1,e^{-i\phi}\eta_2,e^{i\phi}\eta_3)$;
(iii) under a transformation C_{2x}: $(\eta_1,\eta_2,\eta_3)\to(\eta_1,\eta_3^*,\eta_2^*)$;
(iv) under time reversal $\mathcal{T}$: $(\eta_1,\eta_2,\eta_3)\to(\eta_1^*,-\eta_3,-\eta_2)$.

A minimal IB of $\tilde{H}$, which is coregular, can be chosen to be

$$\lambda_1=\Sigma_{j=1}^3|\eta_j|^2=x_1^2+x_2^2+x_5^2+x_6^2+x_7^2+x_{10}^2,$$

$$\lambda_2=|\eta_1|^2=x_5^2+x_{10}^2, \tag{43}$$

$$\lambda_3=(|\eta_2|^2-|\eta_3|^2)^2/4=(x_2x_6-x_1x_7)^2,$$

$$\lambda_4=2\Re(\eta_1^2\eta_2\eta_3^*)=-x_1^2x_5^2-x_2^2x_5^2+x_5^2x_6^2+x_5^2x_7^2-4x_1x_5x_6x_{10}-4x_2x_5x_7x_{10}+x_1^2x_{10}^2+x_2^2x_{10}^2-x_6^2x_{10}^2-x_7^2x_{10}^2.$$

The $\hat{P}$ matrix relative to the IB $\{\lambda\}$ has the following form:

$$\hat{P}(\lambda)=4\begin{pmatrix}\lambda_1 & \lambda_2 & 2\lambda_3 & 2\lambda_4\\ \lambda_2 & \lambda_2 & 0 & \lambda_4\\ 2\lambda_3 & 0 & (\lambda_1-\lambda_2)\lambda_3 & 0\\ 2\lambda_4 & \lambda_4 & 0 & \lambda_2(\lambda_1^2-\lambda_1\lambda_2-4\lambda_3)\end{pmatrix}. \tag{44}$$

The conditions $\hat{P}(\lambda)>0$ and rank $(\hat{P}(p))=4$ yield the following restrictions on the acceptable values of the λ's:

$$\begin{cases}0<\lambda_2<\lambda_1\\ 0<4\lambda_3<(\lambda_1-\lambda_2)^2\\ \lambda_4^2<\lambda_2^2[(\lambda_1-\lambda_2)^2-4\lambda_3]\end{cases}. \tag{45}$$

The expressions of the p's in terms of the λ's turn out to be the following:

$$p_1=\lambda_1,$$

$$p_2=(3\lambda_1^2-2\lambda_1\lambda_2+2\lambda_2^2+12\lambda_3-2\lambda_4)/6,$$

$$p_3=\lambda_1^2-2\lambda_1\lambda_2+2\lambda_2^2-4\lambda_3-2\lambda_4,$$

$$p_4=\lambda_2(9\lambda_1^2-18\lambda_1\lambda_2+10\lambda_2^2-36\lambda_3+6\lambda_4)/6,$$

$$p_5=(5\lambda_1^2\lambda_2-14\lambda_1\lambda_2^2+10\lambda_2^3-4\lambda_2\lambda_3-4\lambda_1\lambda_4+6\lambda_2\lambda_4)/6, \tag{46}$$

$$p_6=(6\lambda_1^3\lambda_2-17\lambda_1^2\lambda_2^2+14\lambda_1\lambda_2^3-2\lambda_2^4-24\lambda_1\lambda_2\lambda_3+20\lambda_2^2\lambda_3-3\lambda_1^2\lambda_4+2\lambda_1\lambda_2\lambda_4+4\lambda_2^2\lambda_4+12\lambda_3\lambda_4-2\lambda_4^2)/6,$$

$$p_7=(4\lambda_1^3\lambda_2-11\lambda_1^2\lambda_2^2+6\lambda_1\lambda_2^3+2\lambda_2^4-16\lambda_1\lambda_2\lambda_3+28\lambda_2^2\lambda_3-5\lambda_1^2\lambda_4+10\lambda_1\lambda_2\lambda_4-4\lambda_2^2\lambda_4+4\lambda_3\lambda_4+2\lambda_4^2)/6,$$

$$p_8=(3\lambda_1^4\lambda_2+2\lambda_1^3\lambda_2^2-36\lambda_1^2\lambda_2^3+52\lambda_1\lambda_2^4-20\lambda_2^5-24\lambda_1^2\lambda_2\lambda_3-8\lambda_1\lambda_2^2\lambda_3+80\lambda_2^3\lambda_3+48\lambda_2\lambda_3^2-6\lambda_1^3\lambda_4+16\lambda_1^2\lambda_2\lambda_4-16\lambda_1\lambda_2^2\lambda_4+8\lambda_2^3\lambda_4+24\lambda_1\lambda_3\lambda_4-16\lambda_2\lambda_3\lambda_4-4\lambda_1\lambda_4^2+12\lambda_2\lambda_4^2)/6,$$

$$p_9=(33\lambda_1^4\lambda_2^2-132\lambda_1^3\lambda_2^3+168\lambda_1^2\lambda_2^4-72\lambda_1\lambda_2^5+4\lambda_2^6-264\lambda_1^2\lambda_2^2\lambda_3+528\lambda_1\lambda_2^3\lambda_3-144\lambda_2^4\lambda_3+528\lambda_2^2\lambda_3^2-9\lambda_1^4\lambda_4+36\lambda_1^3\lambda_2\lambda_4-60\lambda_1^2\lambda_2^2\lambda_4+48\lambda_1\lambda_2^3\lambda_4-12\lambda_2^4\lambda_4+72\lambda_1^2\lambda_3\lambda_4-144\lambda_1\lambda_2\lambda_3\lambda_4+96\lambda_2^2\lambda_3\lambda_4-144\lambda_3^2\lambda_4-12\lambda_1^2\lambda_4^2+24\lambda_1\lambda_2\lambda_4^2+12\lambda_2^2\lambda_4^2+48\lambda_3\lambda_4^2-4\lambda_4^3)/6.$$

In the range of values for the λ's defined in (45), the values of the p's defined in (46) render $\hat{P}(p)$ everywhere positive semidefinite and of rank four. We can conclude, therefore, that they yield parametric equations for the four dimensional stratum $\hat{S}^{(4,2)}$. Being the continuous image of a connected set, the stratum is *connected*.

The elimination of the parameters λ from (46) and (45) leads to cumbersome relations, which are not worthwhile writing down.

E. Principal stratum $\hat{S}^{(6,1)}$

Implicit equations for the principal stratum are yielded in $\mathbf{R}^9$ by the syzygies relating the invariants p_i, $i=1,...,9$, which can be easily obtained from the syzygies (B1)–(B5), using (15). At the points of $\hat{S}_p=\hat{S}^{(6,1)}$ the matrix $\hat{P}(p)$ has to be positive semidefinite and its rank has to be 6.

The method used for the singular strata does not help to obtain parametric equations for $\hat{S}_p$ and to attain the goal one has to resort to less elegant and more pedantic procedures. A possibility is to use the invariants of an IB of the subgroup $\mathbf{SO}_3$ of G as parameters in terms of which to express the p's, but in this case, great care has to be paid to the determination of the range of the parameters that render one-to-one correspondence with the points $p\in\hat{S}_p$.

The Mölien function for the subgroup $\mathbf{SO}_3$ of G can be obtained as a byproduct of the calculation of the Mölien function for G (see Appendix A):

$$M_{\mathbf{SO}_3}(\eta)=\frac{1+\eta^4+\eta^8}{(1-\eta^2)^3(1-\eta^3)^4}, \tag{47}$$

which, after multiplying numerator and denominator by $(1-\eta^4)$, becomes

$$M_{\mathbf{SO}_3}(\eta)=\frac{1-\eta^{12}}{(1-\eta^2)^3(1-\eta^3)^4(1-\eta^4)}. \tag{48}$$

Equations (47) and (48) indicate that a minimal IB for the subgroup $\mathbf{SO}_3$ of G is formed by eight invariants, with degrees (2, 2, 2, 3, 3, 3, 3, 4) related by only one syzygy of degree 12. A possible choice is the following:

$$\begin{aligned}
&\lambda_1=\mathrm{Tr}(\psi\psi^*), \quad \lambda_5=\Im[\mathrm{Tr}(\psi^3)],\\
&\lambda_2=\Re[\mathrm{Tr}(\psi^2)], \quad \lambda_6=\Re[\mathrm{Tr}(\psi^2\psi^*)],\\
&\lambda_3=\Im[\mathrm{Tr}(\psi^2)], \quad \lambda_7=\Im[\mathrm{Tr}(\psi^2\psi^*)],\\
&\lambda_4=\Re[\mathrm{Tr}(\psi^3)]), \quad \lambda_8=\mathrm{Tr}(\psi\psi^*\psi\psi^*).
\end{aligned} \tag{49}$$

Only the first seven elements of the basis are algebraically independent. The explicit expression of the syzygy relating the λ's is reported in Appendix B [see (B7)].

The $\hat{P}$ matrix relative to the IB $\{\lambda_1,\ldots,\lambda_8\}$ is the following and for values of the λ's satisfying the syzygy (B7), it has rank seven:

$$\hat{P}_{1i}=2d_i^{(\lambda)}\lambda_i, \quad d^{(\lambda)}=(2,2,2,3,3,3,3,4), \quad i=1,...,8,$$

$$\hat{P}_{22}=4\lambda_1, \quad \hat{P}_{45}=0,$$

$$\hat{P}_{23}=0, \quad \hat{P}_{46}=\tfrac{1}{2}(2\lambda_1\lambda_2+\lambda_2^2-\lambda_3^2),$$

$$\hat{P}_{24}=6\lambda_6, \quad \hat{P}_{47}=-(\lambda_1-\lambda_2)\lambda_3,$$

$$\hat{P}_{25}=6\lambda_7, \quad \hat{P}_{48}=2(2\lambda_1\lambda_4+\lambda_2\lambda_6-\lambda_3\lambda_7),$$

$$\hat{P}_{26}=2(\lambda_4+2\lambda_6), \quad \hat{P}_{55}=\tfrac{3}{4}(6\lambda_1^2-\lambda_2^2-\lambda_3^2-6\lambda_8),$$

$$\hat{P}_{27}=2(\lambda_5-2\lambda_7),\quad \hat{P}_{56}=(\lambda_1+\lambda_2)\lambda_3,$$

$$\hat{P}_{28}=4\lambda_1\lambda_2,\quad \hat{P}_{57}=\tfrac{1}{2}(2\lambda_1\lambda_2-\lambda_2^2+\lambda_3^2),$$

$$\hat{P}_{33}=4\lambda_1,\quad \hat{P}_{58}=2(2\lambda_1\lambda_5+\lambda_3\lambda_6+\lambda_2\lambda_7),$$

$$\hat{P}_{34}=-6\lambda_7,\quad \hat{P}_{66}=\tfrac{1}{12}(2\lambda_1^2+8\lambda_1\lambda_2+5\lambda_2^2+5\lambda_3^2+6\lambda_8),$$

$$\hat{P}_{35}=6\lambda_6,\quad \hat{P}_{67}=\tfrac{2}{3}\lambda_1\lambda_3,$$

$$\hat{P}_{36}=2(\lambda_5+2\lambda_7),\quad \hat{P}_{68}=-\tfrac{2}{3}(3\lambda_2\lambda_4+3\lambda_3\lambda_5-14\lambda_1\lambda_6+2\lambda_2\lambda_6+2\lambda_3\lambda_7),$$

$$\hat{P}_{37}=-2(\lambda_4-2\lambda_6),\quad \hat{P}_{77}=\tfrac{1}{12}(2\lambda_1^2-8\lambda_1\lambda_2+5\lambda_2^2+5\lambda_3^2+6\lambda_8),$$

$$\hat{P}_{38}=4\lambda_1\lambda_3,\quad \hat{P}_{78}=\tfrac{2}{3}(3\lambda_3\lambda_4-3\lambda_2\lambda_5-2\lambda_3\lambda_6+14\lambda_1\lambda_7+2\lambda_2\lambda_7),$$

$$\hat{P}_{44}=\tfrac{3}{4}(6\lambda_1^2-\lambda_2^2-\lambda_3^2-6\lambda_8),\quad \hat{P}_{88}=-\tfrac{8}{3}(3\lambda_1^3-2\lambda_4^2-2\lambda_5^2+2\lambda_6^2+2\lambda_7^2-9\lambda_1\lambda_8).\tag{50}$$

The connection between the p's and the λ's can be immediately obtained from their very definitions:

$$p_1=\lambda_1,$$

$$p_2=\lambda_8,$$

$$p_3=\lambda_2^2+\lambda_3^2,$$

$$p_4=\lambda_4^2+\lambda_5^2,$$

$$p_5=\lambda_6^2+\lambda_7^2,\tag{51}$$

$$p_6=\lambda_2\lambda_4\lambda_6+\lambda_3\lambda_5\lambda_6-\lambda_3\lambda_4\lambda_7+\lambda_2\lambda_5\lambda_7,$$

$$p_7=\lambda_2\lambda_6^2+2\lambda_3\lambda_6\lambda_7-\lambda_2\lambda_7^2,$$

$$p_8=\lambda_2^2\lambda_4\lambda_6-\lambda_3^2\lambda_4\lambda_6+2\lambda_2\lambda_3\lambda_5\lambda_6+2\lambda_2\lambda_3\lambda_4\lambda_7-\lambda_2^2\lambda_5\lambda_7+\lambda_3^2\lambda_5\lambda_7,$$

$$p_9=\lambda_2^3\lambda_4^2-3\lambda_2\lambda_3^2\lambda_4^2+6\lambda_2^2\lambda_3\lambda_4\lambda_5-2\lambda_3^3\lambda_4\lambda_5-\lambda_2^3\lambda_5^2+3\lambda_2\lambda_3^2\lambda_5^2.$$

As already noted, there is not one-to-one correspondence between the points $\lambda=(\lambda_1,\ldots,\lambda_8)$, lying on the surface determined by the syzygy (B7) and rendering positive semidefinite and of rank seven the $\hat{P}$ matrix associated with the integrity basis $\{\lambda\}$, and the points p of the principal stratum of $\mathbf{R}^{10}/G$. In fact, the action of the group G in $\mathbf{R}^{10}$ induces a linear action of G on the variables λ_i. With the definitions

$$\eta_1=\lambda_2+i\lambda_3,\quad \eta_2=\lambda_4+i\lambda_5,\quad \eta_3=\lambda_6+i\lambda_7,\tag{52}$$

the variables λ and η have the following transformation properties:

(i) λ_1 and λ_8 are invariant under the whole group;
(ii) under gauge transformations, $U_1(\phi)$: $(\eta_1,\eta_2,\eta_3)\rightarrow(e^{2i\phi}\eta_1,e^{3i\phi}\eta_2,e^{i\phi}\eta_3)$;
(iii) under time reversal $\mathcal{T}$: $(\eta_1,\eta_2,\eta_3)\rightarrow(\eta_1^*,\eta_2^*,\eta_3^*)$.

The one-to-one correspondence problem can be solved by finding a criterion enabling one to select a unique point in each orbit of the action of G in the λ space. To this end, let us make some preliminary remarks:

(i) A direct check shows that for $\eta_1=0$ and general values of η_2 and η_3 the rank of $\hat{P}(p(\lambda))$ is six.

(ii) Using (22) one easily realizes that $\mathrm{rank}(\hat{P}(p(\lambda)))<\mathrm{rank}(J(\lambda))<6$, for $\lambda_3=\lambda_5=\lambda_7=0$.

Now, let us choose any orbit, $\overline{\Omega}$, in the principal stratum of $\mathbf{R}^{10}/G$, i.e., a $\overline{p}\in\hat{S}_p$, and let $\overline{\lambda}$ be such that $p(\overline{\lambda})=\overline{p}$. At least one of the parameters $\overline{\eta}_i$, $i=1, 2, 3$, has to be different from zero. Let us say that $\overline{\eta}_i$, is the first one, in lexicographic order (in a lexicographic ordering, $(v_1,\ldots,v_k)>(v_1',\ldots,v_k')$ means that the first nonvanishing component v_i-v_i', $i=1,\ldots,k$, is positive). Then, on $\overline{\Omega}$ there will be a point $\overline{\lambda}'$, such that $\overline{\eta}_i'$ is real and positive; this point can be attained from $\overline{\lambda}$ by means of a convenient gauge transformation. Since at least a $\overline{\eta}_j$, $j=1, 2, 3$, has to be $\neq 0$, this means $\overline{\imath}<3$. At this point we still have at our disposal time reversal transformations to fix the sign of the imaginary part of one of the $\overline{\eta}_i, i>\overline{\imath}$ [recall that at least one of the $\Im(\overline{\eta}_j)$ has to be $\neq 0$]. So, if $\overline{J}$ is such that $\Im(\overline{\eta}_{\overline{J}})$ is the first (in lexicographic order) nonvanishing imaginary part of the $\overline{\eta}$'s, we can choose $\Im(\overline{\eta}_{\overline{J}})>0$.

After introducing a lexicographic order in the real vector spaces generated by the vectors formed, respectively, with the real and imaginary parts of the η's, the criterion that we have devised can be resumed in the following simple additional conditions on these vectors:

$$\lambda_3=0,\quad (\lambda_2,\lambda_4,\lambda_6)>0,\quad (\lambda_3,\lambda_5,\lambda_7)>0,\quad \lambda_5=0 \ \text{ for } \ \lambda_2=0. \tag{53}$$

Using these conditions, the expressions (51) of the p's can be simplified as follows:

$$\begin{gathered} p_1=\lambda_1,\quad p_6=\lambda_2(\lambda_4\lambda_6+\lambda_5\lambda_7),\\ p_2=\lambda_8,\quad p_7=\lambda_2(\lambda_6^2-\lambda_7^2),\\ p_3=\lambda_2^2,\quad p_8=\lambda_2^2(\lambda_4\lambda_6-\lambda_5\lambda_7),\\ p_4=\lambda_4^2+\lambda_5^2,\quad p_9=\lambda_3(\lambda_4^2-\lambda_5^2),\\ p_5=\lambda_6^2+\lambda_7^2, \end{gathered} \tag{54}$$

where the λ's are required to satisfy the syzygy (B7), the conditions rendering the matrix $\hat{P}(p)$ positive semidefinite and of rank six and $(\lambda_5,\lambda_7)>0$.

VI. AN EXAMPLE: MINIMA OF A GENERAL FOURTH DEGREE LANDAU POLYNOMIAL

As a simple example, we have also calculated the minimum of a general fourth degree polynomial free energy

$$\hat{\Phi}^{(4)}(p)=\frac{\alpha_0}{2}p_1^2+\sum_{j=1}^{3}\alpha_j p_j,\quad \alpha_i\in\mathbf{R},\quad i=0,\ldots,3, \tag{55}$$

with the additional assumptions that it is bounded below and has a local maximum at the origin $(\alpha_1<0)$. In (55) the α's are phenomenological parameters.

Recalling the definition $\tilde{p}_i=p_i/p_1^{d_i/2}$, the polynomial $\hat{\Phi}^{(4)}(p)$ can be put in the following form:

TABLE V. Absolute minimum, $\hat{\Phi}^{(4)}_{\min}=-\alpha_1^2/(2\delta)$, of a general, bounded below, *G*-invariant fourth degree polynomial, $\hat{\Phi}^{(4)}(\alpha,p)=\alpha_0 p_1^2/2+\Sigma_{j=1}^3\,\alpha_j p_j$, $\alpha_1<0$, and hosting strata, $S^{(d,r)}$, as functions of the coefficients α. The denomination of the strata is the same as in Table III.

α range	δ	(d,r)
$\mathcal{R}_1$: Max$(0-3\alpha_0/2,-6\alpha_3)<\alpha_2$	$\alpha_0+2\alpha_2/3$	(1,4)
$\mathcal{R}_2$: $-6\alpha_3>\alpha_2>$Max$(-\alpha_0-2\alpha_3,2\alpha_3)$	$\alpha_0+\alpha_2+2\alpha_3$	(1,2), (1,3), (2,4)
$\mathcal{R}_3$: $-\alpha_0/2<\alpha_2<$Min$(0,2\alpha_3)$	$\alpha_0+2\alpha_2$	(1,1)
$\mathcal{R}_{13}$: $0=\alpha_2<$Min(α_0,α_3)	α_0	(1,1), (1,4), (1,5), (2,1), (3,1), (4,1)
$\mathcal{R}_{12}$: Max$(-3\alpha_0/2,0)<\alpha_2=-6\alpha_3$	$\alpha_0-4\alpha_3$	(1,2), (1,3), (1,4), (2,3), (2,4), (3,2)
$\mathcal{R}_{23}$: $-\alpha_0/2<\alpha_2=2\alpha_3<0$	$\alpha_0+4\alpha_3$	(1,1), (1,2), (1,3), (2,4), (2,5)
$\mathcal{R}_{123}$: $\alpha_2=\alpha_3=0<\alpha_0$	α_0	All, except (0,1)

$$\hat{\Phi}^{(4)}(p)=\frac{p_1^2}{2}\Delta+\alpha_1 p_1, \tag{56}$$

where we have defined

$$\Delta=\alpha_0+2\alpha_2\tilde{p}_2+2\alpha_3\tilde{p}_3. \tag{57}$$

Since, owing to its definition (14), p_1 ranges over the whole non-negative real numbers, in the orbit space, the polynomial $\hat{\Phi}^{(4)}(p)$ is bounded below (in the assumption $\alpha_1<0$) if and only if the minimum of Δ, δ, evaluated in the section $p_1=1$ of the orbit space, is positive. Being the minimum of the right-hand side of (56), thought of as a function only of $p_1\geqslant 0$, equal to $-\alpha_1/(2\Delta)$, the absolute minimum of $\hat{\Phi}^{(4)}(p)|_{p\in S}$ is $-\alpha_1^2/(2\delta)$. In this way, the determination of the minimum of $\hat{\Phi}^{(4)}(p)$ is reduced to the calculation of δ.

The absolute minimum of δ in each singular stratum can be easily computed using the equations of the strata. For the principal stratum the determination of the minimum of the restriction of $\hat{\Phi}^{(4)}$ to the surface $p_1=1$ as a constrained minimum is difficult and it is easier to solve Eq. (2) and to check subsequently if the solutions lie in the principal stratum. A comparison of the values of the minima in the different strata, in order to determine the absolute minimum, leads to the results summarized in Table V and illustrated in Fig. 2, where the denomination of the strata introduced in the text has been used. Owing to the low degree of the polynomial defining $\hat{\Phi}^{(4)}\times(p)$ in (55), and the consequent low number of free parameters α, the absolute minimum exhibits strong degeneracy, particularly for special values of the α's. If these special values are excluded, spontaneous breaking of the symmetry can generate only five distinct phases out of fifteen permitted in the *G*-symmetry; some of them are unstable. For no nontrivial values of (α_2,α_3) does the absolute minimum lie on the stratum $S^{(2,2)}$.

For general values of the α's, our results are in agreement with Mermin's ones.[11] Let us add a few words about the perturbative stability of the three degenerate phases in the region $\mathcal{R}_2$ (see Table V). For $(\alpha_0,\alpha_2,\alpha_3)\in\mathcal{R}_2$, the addition to the free energy, $\Phi^{(4)}$, of a ''small'' perturbation, consisting in an invariant polynomial of degree six:

$$\Theta^{(6)}=\alpha_4 p_4+\alpha_5 p_5, \tag{58}$$

splits the three degenerate minima determined by the fourth degree term.[23] This is easy to check, at least in the additional assumption that the perturbation leaves the absolute minimum in one of the strata corresponding to the degenerate phases. In fact, at the first perturbative order, one obtains from Tables I and II the following shifts, $\Theta^{(6)}_{(d,r)}$, in the values of the sixth-order free energy at the points where $\Phi^{(4)}(p)$ takes on its degenerate absolute minimum under consideration:

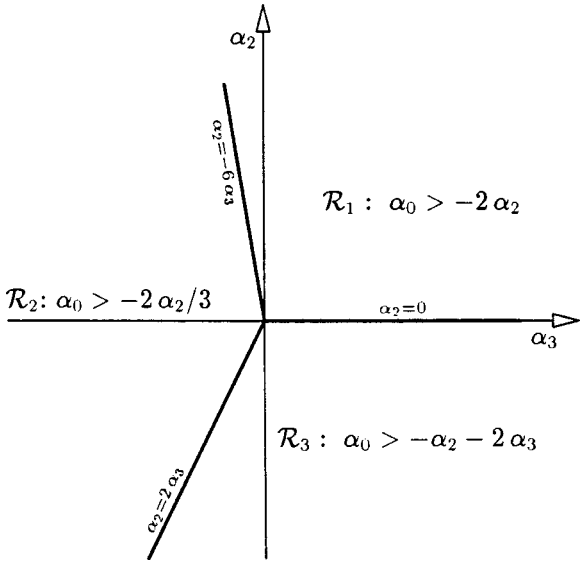

FIG. 2. Localization of the absolute minimum of a fourth degree G-invariant polynomial, $\hat{\Phi}^{(4)}(\alpha,p)=\alpha_0 p_1^2/2+\Sigma_{j=1}^{3}\alpha_j p_j$, $\alpha_1<0$, as a function of its coefficients. For values of $(\alpha_0,\alpha_2,\alpha_3)$ in $\mathcal{R}_1$ or in $\mathcal{R}_2$ or in $\mathcal{R}_3$, the absolute minimum lies, respectively, in the strata $S^{(1,4)}$ or $\{S^{(1,2)},S^{(1,3)},S^{(2,4)}\}$ (degenerate minimum) or $S^{(1,1)}$. For particular values of the α's, see Table IV.

$$\Theta^{(6)}_{(1,2)}=\frac{\alpha_1^3}{\delta^3}\,\frac{\alpha_4+\alpha_5}{6},\quad \Theta^{(6)}_{(1,3)}=0,\quad \Theta^{(6)}_{(2,4)}=\frac{\alpha_1^3}{\delta^3}(\alpha_4+\alpha_5)\xi, \tag{59}$$

where $0<\xi<1/6$.

Since $-\alpha_1/\delta>0$, the absolute minimum will be perturbatively stable on $\hat{S}^{(1,2)}$ or, respectively, $\hat{S}^{(1,3)}$, depending on whether $\alpha_4+\alpha_5$ is negative or positive.

As stressed in Sec. I, the above-mentioned difficulties can be overcome if one puts less restrictive upper limits to the degree of the polynomial describing the free energy. It is trivial, for instance, to realize that the following class of bounded below polynomial functions[16] have a vanishing maximum at the origin of $\mathbf{R}^{10}$ and display an absolute minimum at the arbitrarily chosen point $\overline{p}\in\hat{S}$:

$$\sum_{i=1}^{9}\alpha_i[(p_i-\overline{p}_i)^{2n_i}-\overline{p}_i^{2n_i}], \tag{60}$$

where the α's are positive constants and the n's are positive integers.

The physical implications of our results and the derivation of a more realistic form of the free energy will be discussed in forthcoming papers. We shall limit ourselves, here, to note that, the D-wave content in terms, e.g., of d- or extended s-waves (mentioned in Sec. I) can be directly read off the fourth column of Table III for each of the possible symmetry phases of the system under consideration.

VII. CONCLUSIONS

Through a detailed and rigorous analysis, we have determined and characterized the possible ground states of D-wave condensates in isotropic space, which are relevant both in high T_c superconductivity and in ^{3}He phase transitions. The problem has been formulated and solved in the framework of geometric invariant theory, which, as noted long ago,[14] is the natural mathemati-

cal setting in which to deal with minimization of invariant potentials, which are plagued by degeneracy problems. This enabled us to complete and/or correct results previously obtained by other authors, using different methods.

Until now, the kind of approach we have used had only been applied to relatively simple models, with coregular symmetry groups, in condensed matter[24] and in elementary particle physics.[25] In this paper, we have fully characterized the geometry of the orbit space of the linear group $\mathbf{SO}_3 \otimes \mathbf{U}_1 \times \langle \mathcal{T} \rangle$, acting in the space $\mathbf{R}^{10}$, a highly nontrivial group, with a noncoregular minimal integrity basis, formed by nine elements with degrees up to 12. For this group we have determined the explicit form of the elements of an integrity basis and of the syzygies relating these elements, the equations and inequalities determining the orbit space and its stratification and the corresponding isotropy subgroups chains. The minima of a general fourth degree polynomial invariant free energy have been recalculated and the sixth degree polynomial perturbative corrections to its absolute minimum have been determined. Some of our conclusions have been compared with previous results obtained by other authors.

To overcome some computational difficulties in the full characterization of the stratification of the orbit space, difficulties originating from the high dimensionality of the problem, we had to devise a sophisticated procedure, allowing us to obtain *rational* parametric equations also for the higher dimensional singular strata. The procedure is absolutely general and is reminiscent, but in a different context and in higher dimensions, of classical techniques for parametrizing plane algebraic curves.[26]

APPENDIX A: CALCULATION OF MÖLIEN FUNCTIONS

In this Appendix, we shall explicitly calculate the two integrals, I_1 and I_2, appearing in the expression of $M_G(\eta)$ [see (9)]:

$$I_1 = \frac{1}{32\pi^3} \int_0^{2\pi} \mathrm{d}\phi_1 \int_0^{2\pi} \mathrm{d}\phi_2 \int_0^{\pi} \sin\theta \, \mathrm{d}\theta \int_0^{2\pi} \frac{\mathrm{d}\alpha}{f_1(\cos\chi, \alpha)},$$

$$I_2 = \frac{1}{16\pi^2} \int_0^{2\pi} \mathrm{d}\phi_1 \int_0^{2\pi} \mathrm{d}\phi_2 \int_0^{\pi} \frac{\sin\theta \, \mathrm{d}\theta}{f_2(\cos\chi)}, \tag{A1}$$

where

$$f_1(\cos\chi, \alpha) = \prod_{k=-2}^{2} [(1 - \eta e^{i(k\chi + \alpha)})(1 - \eta e^{i(k\chi - \alpha)})],$$

$$f_2(\cos\chi) = \prod_{k=-2}^{2} [(1 - \eta e^{ik\chi})(1 + \eta e^{ik\chi})] \tag{A2}$$

and $\cos\chi$ is defined in (10).

Using as new integration variables ϕ_2, $u = \cos(\phi_1 + \phi_2)$, and $v = \cos\chi$, the integral over ϕ_2 can be immediately performed and one remains with

$$
\begin{aligned}
I_1 &= \frac{1}{2\pi^2}\int_0^{2\pi} d\alpha \int_{-1}^{1} \frac{dv}{f_1(v,\alpha)} \int_v^1 \frac{du}{(1+u)\sqrt{1-u^2}} \\
&= \frac{1}{2\pi^2}\int_0^{2\pi} d\alpha \int_{-1}^{1} \frac{dv}{f_1(v,\alpha)} \frac{\sqrt{1-v^2}}{1+v} \\
&= \frac{1}{2\pi^2}\int_0^{2\pi} d\alpha \int_0^{2\pi} d\chi \frac{\sin^2(\chi/2)}{f_1(\cos\chi,\alpha)}
\end{aligned} \tag{A3}
$$

and, analogously,

$$
I_2 = \frac{1}{\pi}\int_0^{2\pi} d\chi \frac{\sin^2(\chi/2)}{f_2(\cos\chi)}. \tag{A4}
$$

After defining

$$
\zeta_1 = e^{i\chi}, \quad \zeta_2 = e^{i\alpha}, \tag{A5}
$$

the remaining integrals can be conveniently thought of as integrals on unit circles of complex planes of the variables ζ_1 and ζ_2,

$$
\begin{aligned}
I_1 &= -\frac{1}{8\pi^2\eta^4} \oint \frac{d\zeta_2}{(\zeta_2-\eta)(\zeta_2\eta-1)} \oint d\zeta_1 F_1(\zeta_1,\zeta_2,\eta), \\
I_2 &= \frac{1}{4\pi i\eta^4(\eta^2-1)} \oint d\zeta_1 F_2(\zeta_1,\eta),
\end{aligned} \tag{A6}
$$

where

$$
\begin{aligned}
&F_1(\zeta_1,\zeta_2,\eta) \\
&= \frac{\zeta_1^4(\zeta_1-1)^2}{\left(\zeta_1^2-\frac{\eta}{\zeta_2}\right)(\zeta_1^2-\zeta_2\eta)\left(\zeta_1-\frac{\eta}{\zeta_2}\right)(\zeta_1-\zeta_2\eta)\left(\zeta_1-\frac{\zeta_2}{\eta}\right)\left(\zeta_1-\frac{1}{\zeta_2\eta}\right)\left(\zeta_1^2-\frac{\zeta_2}{\eta}\right)\left(\zeta_1^2-\frac{1}{\zeta_2\eta}\right)},
\end{aligned} \tag{A7}
$$

$$
F_2(\zeta_1,\eta) = \frac{\zeta_1^4(\zeta_1-1)^2}{(\zeta_1^2-\eta^2)(\zeta_1^4-\eta^2)\left(\zeta_1^2-\frac{1}{\eta^2}\right)\left(\zeta_1^4-\frac{1}{\eta^2}\right)}.
$$

Using the Cauchy theorem and recalling that $|\eta|<1$, the calculation reduces to a computation of residues at the internal poles to the unit circles. So, one ends up with the following expressions for I_1 and I_2:

$$
\begin{aligned}
I_1 &= \frac{1+3\eta^8+2\eta^{10}+3\eta^{12}+\eta^{20}}{2(1-\eta^2)^3(1-\eta^4)^2(1-\eta^8)(1-\eta+\eta^2)^2(1+\eta+\eta^2)^2}, \\
I_2 &= \frac{1-\eta^2+\eta^4}{2(1-\eta^2)^3(1-\eta^4)(1-\eta+\eta^2)(1+\eta+\eta^2)}.
\end{aligned} \tag{A8}
$$

The sum of I_1 and I_2 gives to the expression of $M_G(\eta)$ reported in (11).

As a by-product of the calculation, one finds also the following expression for the Mölien function of the subgroup $\mathbf{SO}_3$ of G:

$$M_{\mathbf{SO}_3}(\eta)=\frac{1}{8\pi^2}\int_0^{2\pi}\mathrm{d}\phi_1\int_0^{2\pi}\mathrm{d}\phi_2\int_0^{\pi}\mathrm{d}\theta\sin\theta f_1(\cos\chi,0)$$
$$=-\frac{1}{4\pi i\,\eta^4(1-\eta^2)}\oint\mathrm{d}\zeta_1 F_1(\zeta_1,1,\eta)$$
$$=\frac{1+\eta^4+\eta^8}{(1-\eta^2)^3(1-\eta^3)^4}. \tag{A9}$$

APPENDIX B: SYZYGIES

1. Explicit form of the syzygies for the group *G*

The ten elements of the nonminimal IB $\{\xi,\theta\}$ defined in (14) and (15) are related by the following syzygies:

$$\theta_1^2=\tfrac{1}{192}[36\xi_1^6\xi_3-144\xi_1^4\xi_2\xi_3+180\xi_1^2\xi_2^2\xi_3-72\xi_2^3\xi_3-36\xi_1^4\xi_3^2+108\xi_1^2\xi_2\xi_3^2-72\xi_2^2\xi_3^2+9\xi_1^2\xi_3^3$$
$$-18\xi_2\xi_3^3-80\xi_1^3\xi_3\xi_4+144\xi_1\xi_2\xi_3\xi_4+24\xi_1\xi_3^2\xi_4+48\xi_3\xi_4^2+144\xi_1^3\xi_3\xi_5-144\xi_1\xi_2\xi_3\xi_5$$
$$+72\xi_1\xi_3^2\xi_5-288\xi_3\xi_4\xi_5-144\xi_3\xi_5^2-96\xi_1^2\xi_3\xi_6-24\xi_3^2\xi_6+192\xi_6^2$$
$$+24\theta_1(8\xi_1^2-12\xi_2-\xi_3)\xi_3+96\theta_2(\xi_1\xi_3-4\xi_5)-16\theta_3\xi_3], \tag{B1}$$

$$\theta_1\theta_2=-\tfrac{1}{2}(\xi_3\xi_4\xi_6+\theta_1\xi_3\xi_4-2\theta_2\xi_6+2\theta_3\xi_5), \tag{B2}$$

$$\theta_2^2=\tfrac{1}{768}[-36\xi_1^6\xi_3^2+144\xi_1^4\xi_2\xi_3^2-180\xi_1^2\xi_2^2\xi_3^2+72\xi_2^3\xi_3^2+36\xi_1^4\xi_3^3-108\xi_1^2\xi_2\xi_3^3+72\xi_2^2\xi_3^3-9\xi_1^2\xi_3^4$$
$$+18\xi_2\xi_3^4+80\xi_1^3\xi_3^2\xi_4-144\xi_1\xi_2\xi_3^2\xi_4-24\xi_1\xi_3^3\xi_4-48\xi_3^2\xi_4^2-44\xi_1^3\xi_3^2\xi_5+144\xi_1\xi_2\xi_3^2\xi_5$$
$$-72\xi_1\xi_3^3\xi_5+1056\xi_3^2\xi_4\xi_5+144\xi_3^2\xi_5^2+96\xi_1^2\xi_3^2\xi_6+24\xi_3^3\xi_6-384\xi_3\xi_6^2+24\theta_1\xi_3$$
$$\times(-8\xi_1^2\xi_3+12\xi_2\xi_3+\xi_3^2-16\xi_6)-96\theta_2\xi_3(\xi_1\xi_3-4\xi_5)+16\theta_3(\xi_3^2+24\xi_6)-384\theta_4], \tag{B3}$$

APPENDIX C: EXPLICIT FORM OF THE $\hat{P}$ MATRIX FOR THE GROUP G

For

$$(d_1,\ldots,d_9)=(2,4,4,6,6,8,8,10,12), \qquad \text{(C1)}$$

the explicit form of the $\hat{P}$ matrix related to the integrity basis $\{p\}$ of the group G is the following:

$$P_{1,i}=2d_ip_i, \quad i=1,...,9,$$

$$P_{2,2}=-\tfrac{8}{3}(3p_1{}^3-9p_1p_2-2p_4+2p_5),$$

$$P_{2,3}=8p_1p_3,$$

$$P_{2,4}=4(2p_1p_4+p_6),$$

$$P_{2,5}=\tfrac{4}{3}(14p_1p_5-3p_6-2p_7),$$

$$P_{2,6}=-\tfrac{2}{3}(3p_3p_4-3p_3p_5-26p_1p_6+2p_8),$$

$$P_{2,7}=-\tfrac{4}{3}(2p_3p_5-17p_1p_7+3p_8),$$

$$P_{2,8}=-\tfrac{2}{3}(2p_3p_6-3p_3p_7-32p_1p_8+3p_9),$$

$$P_{2,9}=4(p_3p_8+5p_1p_9),$$

$$P_{3,3}=16p_1p_3,$$

$$P_{3,4}=24p_6,$$

$$P_{3,5}=8(p_6+2p_7),$$

$$P_{3,6}=4(p_3p_4+3p_3p_5+2p_1p_6+2p_8),$$

$$P_{3,7}=8(2p_3p_5+p_1p_7+p_8),$$

$$P_{3,8}=4(2p_3p_6+3p_3p_7+4p_1p_8+p_9),$$

$$P_{3,9}=24(p_3p_8+p_1p_9),$$

$$P_{4,4}=3(6p_1^2-6p_2-p_3)p_4,$$

$$P_{4,5}=2(2p_1p_6+p_8),$$

$$P_{4,6}=\tfrac{1}{2}(4p_1p_3p_4+24p_4p_5+18p_1^2p_6-18p_2p_6-3p_3p_6+2p_9),$$

APPENDIX D: EXPLICIT FORM OF THE GENERATORS OF THE ISOTROPY SUBGROUPS OF SO_3

In this Appendix are collected the definitions of the groups and of the elements and the generators of the subgroups of $\mathbf{SO}_3$, involved in the body of the paper, in the tables and in the figures.

1. Generators or group elements

$$C_{2x}=\begin{pmatrix}1&0&0\\0&-1&0\\0&0&-1\end{pmatrix},\quad C_{2z}=\begin{pmatrix}-1&0&0\\0&-1&0\\0&0&1\end{pmatrix},\quad C_{3z}=\begin{pmatrix}-\frac{1}{2}&\frac{\sqrt{3}}{2}&0\\-\frac{\sqrt{3}}{2}&-\frac{1}{2}&0\\0&0&1\end{pmatrix},$$

$$C_{4z}=\begin{pmatrix}0&1&0\\-1&0&0\\0&0&1\end{pmatrix},\quad C_{4x}=\begin{pmatrix}1&0&0\\0&0&1\\0&-1&0\end{pmatrix},\quad C_{2a}=\begin{pmatrix}0&1&0\\1&0&0\\0&0&-1\end{pmatrix},\tag{D1}$$

$$C_{3\delta}=\begin{pmatrix}0&1&0\\0&0&1\\1&0&0\end{pmatrix},\quad R_z(\phi)=\begin{pmatrix}\cos(\phi)&\sin(\phi)&0\\-\sin(\phi)&\cos(\phi)&0\\0&0&1\end{pmatrix},$$

$$R_x(\phi)=\begin{pmatrix}1&0&0\\0&\cos(\phi)&\sin(\phi)\\0&-\sin(\phi)&\cos(\phi)\end{pmatrix}.$$

2. Groups

By $\mathbf{SO}_3$ and $\mathbf{O}_3$ we denote the proper and, respectively, the complete 3D rotation group and, by $\mathbf{O}_2^{\alpha}$, $\alpha=x,z$ the following $\mathbf{O}_2$ subgroups of $\mathbf{SO}_3$: $\mathbf{O}_2^x=\{\mathrm{R}_x(\phi)\}_{0\leqslant\phi<2\pi}\cup\{C_{2z}\mathrm{R}_x(\phi)\}_{0\leqslant\phi<2\pi}$ and $\mathbf{O}_2^z=\{\mathrm{R}_z(\phi)\}_{0\leqslant\phi<2\pi}\cup\{C_{2x}\mathrm{R}_z(\phi)\}_{0\leqslant\phi<2\pi}$.

(Received 13 September 2000; accepted for publication 5 January 2001)

In this article we continue our analysis of Schrödinger operators on arbitrary graphs given as certain Laplace operators. In the present article we give the proof of the composition rule for the scattering matrices. This composition rule gives the scattering matrix of a graph as a generalized star product of the scattering matrices corresponding to its subgraphs. We perform a detailed analysis of the generalized star product for arbitrary unitary matrices. The relation to the theory of transfer matrices is also discussed. © *2001 American Institute of Physics.*

I. INTRODUCTION

Potential scattering for one-particle Schrödinger operators on the line possesses a remarkable property concerning its (on-shell) scattering matrix given as a 2×2 matrix-valued function of the energy. Let the potential V be given as the sum of two potentials V_1 and V_2 with disjoint support. Then the scattering matrix for V at a given energy is obtained from the two scattering matrices for V_1 and V_2 at the same energy by a certain nonlinear, noncommutative but associative composition rule. This fact has been discovered independently by several authors (see, e.g., Refs. 1–7) and is an easy consequence of the multiplicative property of the transfer matrix of the Schrödinger equation (see e.g., Ref. 8). It has also been well known in the theory of mesoscopic systems and multichannel conductors (see, e.g., Refs. 9–18). In higher space dimensions a similar rule is not known. However, for large separation between the supports of the potentials the scattering matrix at a given energy is asymptotically related to the scattering matrices for V_1 and V_2 at the same energy.[19,20]

To the best of our knowledge the composition rule for 2×2 scattering matrices was first observed in network theory by Redheffer,[2,3] who called it the star product. In an earlier article[21] we extended this result to quasi-one-dimensional quantum systems—Schrödinger operators on graphs. Such systems are nowadays a subject of intensive study (see, e.g., Refs. 22–27). Some other related works are quoted in Ref. 21. In Refs. 28–31 differential operators with Neuman boundary conditions on ''fat graphs'' were considered, i.e., on thin domains in $\mathbb{R}^d$ which asymptotically shrink to a graph.

There is also a large amount of literature on linear difference operators on graphs. The motivation for the study of such operators comes from the graph theory, where the spectra of these operators are known to be related to topological properties of the graph.[32–34] Scattering theory for such operators was developed in Refs. 35 and 36.

In Ref. 21 we considered the (continuous) Laplace operator on graphs with an arbitrary number n of open ends (i.e., channels) and with arbitrary boundary conditions at the edges resulting in a self-adjoint operator. We formulated and proved necessary and sufficient conditions

a)Electronic mail: kostrykin@t-online.de,kostrykin@ilt.fhg.de
b)Electronic mail: schrader@physik.fu-berlin.de

for such operators to be self-adjoint. We provided an explicit expression for the resulting unitary $n\times n$ scattering matrix in terms of the boundary conditions, the lengths of the internal lines, and the given energy. Furthermore, we generalized Redheffer's star product to what we called the generalized star product. This is a nonlinear, noncommutative but associative composition rule for unitary matrices not necessarily of equal rank and resulting in a unitary matrix.

Under special circumstances there is an alternative way to describe the generalized star product. Fix $p\geqslant 1$ and consider the group $\mathsf{U}(p,p)$ with its natural multiplication. As a set this group is isomorphic to some subgroup of $\mathsf{U}(2p)$. This nonlinear set isomorphism is well known in the case $p=1$ (see, e.g., Ref. 37) and can be easily generalized to the case of arbitrary $p>1$. Under this isomorphism the multiplication in $\mathsf{U}(p,p)$ induces new nonlinear multiplication $*_p$ in this subgroup of $\mathsf{U}(2p)$, which is our generalized star product. The operation $*_p$ can be extended by continuity to the whole $\mathsf{U}(2p)$. The set $\mathsf{U}(2p)$ with $*_p$ as multiplication is no longer a group, but only a semigroup.

Employing this generalized star product in Ref. 21 we provided a formal proof based on the quantum mechanical superposition principle to show how the scattering matrix at the same energy for the whole graph can be obtained from the scattering matrices of two subgraphs obtained by cutting the graph in any way in two. Again for the special case of two-channel scattering matrices, like potential scattering on the line, this formal argument is well known (see, e.g., Ref. 17). In this article we will provide a rigorous proof of this composition rule. It is interesting to note that in this general case the composition rule cannot be reduced to the multiplicative property of the transfer matrix of the Schrödinger equation on the graph.

Such composition rules are important in the study of the electric conduction in multi-terminal mesoscopic systems. By the Landauer–Büttiker theory the electric conduction in mesoscopic systems is directly related to the transmission probability and thus to the scattering matrix.[38–41] A good introduction into the theory of electronic transport in such systems is given in the book[17] by S. Datta. The formal arguments leading to the composition rule for the scattering matrices are presented on pp. 125–126 of Ref. 17.

The composition rules are also very useful in the study of statistical properties of large random or periodic systems. Examples of such systems can be found, e.g., in Refs. 42, 24, and 25. In Refs. 8 and 43–45 we proved that in arbitrary dimensions the scattering phase (or more generally of the spectral shift function) per interaction volume equals (up to a factor π) the difference of the integrated densities of states for the free and interaction theories, respectively. In the strictly one-dimensional situation (Schrödinger operators on the line) the Lyapunov exponent is known to be related to the logarithmic density of transmission probability.[46–48,8] Due to the Ishii-Pastur-Kotani theorem (see, e.g., Ref. 49) the vanishing of the transmission amplitude for almost all values of energy implies localization (i.e., the spectrum must be purely point) (see also the related works Refs. 9–16):

Certain Laplace operators on (infinite) periodic graphs were previously considered in Refs. 24 and 25. There are also some attempts to consider differential operators on regular graphs with random boundary conditions or on random graphs with deterministic boundary conditions (see, e.g., Ref. 42). Some other examples can be found also in Ref. 50, Chap. 3. A difference Laplace operator on the edges of aperiodic tilings was considered in Ref. 51. Such systems provide a main field of application for our composition rule which will be discussed in a forthcoming publication.

The article is organized as follows. In Sec. II we recall the general quantum scattering theory on graphs as given in Ref. 21. In Sec. III we recall the definition of the generalized star product and study some its properties. In particular we show that this product applies to arbitrary unitary matrices. In Sec. IV we give a rigorous proof of the composition rule for scattering matrices on arbitrary finite graphs. Section V is devoted to the special case of graphs having an even number $2p$ of external lines. If the new graph is obtained by gluing of exactly p lines, then it has again $2p$ external lines. We consider the question whether in this case the composition rule for the scattering matrices can be reduced to the multiplication rule of the corresponding transfer matrices. In general for $p>1$ the answer is negative. We formulate a necessary and sufficient condition, which

guarantees that the composition rule for the scattering matrices is equivalent to the standard multiplication of transfer matrices.

After completing the work we received the preprint[52] by M. Harmer where, among other questions, the composition rule for the scattering matrices is also considered. The results there partially recover our Theorem IV.1 below.

We are indebted to P. Kuchment for sending us the preliminary version of the preprint[29] and also for pointing out the works of R. Carlson.[26,27,53]

II. THE LAPLACIAN ON A GRAPH AND ITS SCATTERING MATRIX

In this section we will recall the definition of Schrödinger operators on an arbitrary but finite graph and the construction of their scattering matrices.[21]

We consider an arbitrary graph Γ with a finite number $n \geqslant 1$ of external and a finite number $m \geqslant 0$ of internal lines (edges). More precisely this means that outside of a finite domain the graph is isomorphic to the union of n positive half-lines. Any internal line ends at two, not necessary different, vertices and has a finite length. We assume that any vertex of Γ has nonzero degree, i.e., for any vertex there is at least one edge (internal or external) with which it is incident.

Let the set $\mathcal{E}$ label the external and the set $\mathcal{I}$ the internal lines of the graph. We assume that the sets $\mathcal{E}$ and $\mathcal{I}$ are ordered in an arbitrary but fixed way. To each $e \in \mathcal{E}$ we associate the infinite interval $[0,\infty)$ and to each $i \in \mathcal{I}$ the finite directed interval $[0,a_i]$, where $a_i > 0$ is the length of this line. With this association the graph becomes directed, such that the initial vertex of an edge of length a corresponds to $x=0$ and the terminal vertex corresponds to $x=a$. The external lines are assumed to be directed in the positive direction of half-lines.

We define the Hilbert space $\mathcal{H}=L^2(\Gamma)$ as

$$\mathcal{H}=\mathcal{H}_{\mathcal{E}} \oplus \mathcal{H}_{\mathcal{I}}, \quad \mathcal{H}_{\mathcal{E}}=\bigoplus_{e \in \mathcal{E}} \mathcal{H}_e, \quad \mathcal{H}_{\mathcal{I}}=\bigoplus_{i \in \mathcal{I}} \mathcal{H}_i,$$

where $\mathcal{H}_e=L^2(0,\infty)$ and $\mathcal{H}_i=L^2(0,a_i)$. Elements of $\mathcal{H}$ are written as column vectors

$$\psi=(\{\psi_e\}_{e \in \mathcal{E}},\{\psi_i\}_{i \in \mathcal{I}})^T=(\psi_{\mathcal{E}},\psi_{\mathcal{I}})^T, \quad \psi_e \in M\mathcal{H}_e, \quad \psi_i \in \mathcal{H}_i. \tag{2.1}$$

Similarly we define the Sobolev space $W^{2,2}(\Gamma)$ as

$$W^{2,2}(\Gamma)=\bigoplus_{e \in \mathcal{E}} W^{2,2}(0,\infty) \oplus \bigoplus_{i \in \mathcal{I}} W^{2,2}(0,a_i),$$

where $W^{2,2}(0,\infty)$ and $W^{2,2}(0,a_i)$ are the usual Sobolev spaces of square integrable functions whose distributional second derivatives are also square integrable (see, e.g., Ref. 54). Let $[\,]: W^{2,2}(\Gamma) \to \mathbb{C}^{2(n+2m)}$ be the surjective linear map which associates to each ψ the element $[\psi]$ given as

$$[\psi]=\begin{pmatrix} (\{\psi_e(0)\}_{e \in \mathcal{E}},\ \{\psi_i(0)\}_{i \in \mathcal{I}},\ \{\psi_i(a_i)\}_{i \in \mathcal{I}})^T \\ (\{\psi_e'(0)\}_{e \in \mathcal{E}},\ \{\psi_i'(0)\}_{i \in \mathcal{I}},\ \{-\psi_i'(a_i)\}_{i \in \mathcal{I}})^T \end{pmatrix}=\begin{pmatrix} \underline{\psi} \\ \underline{\psi}' \end{pmatrix}$$

again viewed as a column vector with the same ordering as in ψ, i.e., with the ordering given by the ordering of $\mathcal{E}$ and $\mathcal{I}$.

In Ref. 21 we showed that for any two $(n+2m)\times(n+2m)$ complex matrices A and B with AB^* being Hermitian and the $(n+2m)\times 2(n+2m)$ matrix (A,B) having maximal rank equal to $n+2m$, one can define the self-adjoint Laplace operator $\Delta(A,B,\underline{a})$ in $\mathcal{H}$ corresponding to the boundary condition

$$A\underline{\psi}+B\underline{\psi}'=0. \tag{2.2}$$

Here $\underline{a}=(a_1,\ldots,a_m)^T\in\mathbb{R}_+^m$, $m=\#(\mathcal{I})$. Furthermore, any self-adjoint extension of the Laplacian on the given graph is given by $\Delta(A,B,\underline{a})$ with some matrices A and B satisfying the properties stated above. If $\mathcal{I}=\varnothing$, we simply write $(\Delta(A,B)$ instead of $\Delta(A,B,\cdot)$.

Before we turn to the scattering theory for $\Delta(A,B,\underline{a})$ we recall some well-known facts from scattering theory in two Hilbert spaces $\mathfrak{h}_1$ and $\mathfrak{h}_2$ (see, e.g., Ref. 55). Let H_1 and H_2 be self-adjoint operators in the Hilbert spaces $\mathfrak{h}_1$ and $\mathfrak{h}_2$, respectively. Let $\mathcal{J}$ be a bounded operator from $\mathfrak{h}_1$ into $\mathfrak{h}_2$. The two-space wave operators are defined as the strong limits

$$\Omega^{\pm}(H_2,H_1;\mathcal{J})=\operatorname*{s-lim}_{t\to\mp\infty} e^{iH_2t}\mathcal{J}e^{-iH_1t}P_{\mathrm{ac}}(H_1),$$

where $P_{\mathrm{ac}}(H)$ denotes the projection onto the absolute continuous subspace of H. We consider the sets $\mathfrak{N}_{\pm}$ of elements $g\in\mathfrak{h}_2$ for which $\lim_{t\to\mp\infty}\|\mathcal{J}^*e^{iH_2t}P_{\mathrm{ac}}(H_2)g\|=0$. The wave operators $\Omega^{\pm}$ are called $\mathcal{J}$-complete if $\mathfrak{h}_2=\overline{\mathrm{Ran}(\Omega^{\pm})}\oplus\mathfrak{N}_{\pm}$. For details we refer to, e.g., to Chap. 3 of Ref. 56.

Now we consider a graph $\Gamma_{\mathcal{E}}$ consisting of the external lines of the original graph Γ. On the graph $\Gamma_{\mathcal{E}}$ we consider the operator $-\Delta(A_{\mathcal{E}}=0,B_{\mathcal{E}}=\mathbb{I})$ corresponding to Neumann boundary conditions. Let $\mathcal{J}:\mathcal{H}\to\mathcal{H}_{\mathcal{E}}$ be given as $\mathcal{J}\psi=\psi_{\mathcal{E}}$ according to the notation (2.1). In particular $\mathcal{J}$ is identity if $m=0$. Since we actually deal with finite-dimensional perturbations by the Kato-Rosenblum theorem (see, e.g., Ref. 56, Theorem 6.2.3 and Corollary 6.2.4) the wave operators $\Omega^{\pm}(-\Delta(A,B,\underline{a}),-\Delta(A_{\mathcal{E}}=0,B_{\mathcal{E}}=\mathbb{I});\mathcal{J})$ exist and are $\mathcal{J}$-complete. Thus the scattering operator

$$S(-\Delta(A,B,\underline{a}),-\Delta(A_{\mathcal{E}}=0,B_{\mathcal{E}}=\mathbb{I};\mathcal{J})=(\Omega^-)^*\Omega^+:\mathcal{H}_{\mathcal{E}}\to\mathcal{H}_{\mathcal{E}} \tag{2.3}$$

is unitary and its layers $S_{A,B,\underline{a}}(\lambda):\mathbb{C}^n\to\mathbb{C}^n$ [in the direct integral representation with respect to $-\Delta(A_{\mathcal{E}}=0,B_{\mathcal{E}}=\mathbb{I})$] are also unitary for almost all energies $\lambda\in\mathbb{R}_+$.

The resulting scattering matrix is related to the scattering wave function for the operator $-\Delta(A,B,\underline{a})$ at energy $\lambda>0$ as follows. The function $\psi^k(\cdot,\lambda)$ indexed by $k\in\mathcal{E}$ and with components

$$\psi_j^k(x,\lambda)=\begin{cases} S_{jk}(\lambda)e^{i\sqrt{\lambda}x} & \text{for } j\in\mathcal{E}, j\neq k,\\ e^{-i\sqrt{\lambda}x}+S_{kk}(\lambda)e^{i\sqrt{\lambda}x} & \text{for } j\in\mathcal{E}, j=k,\\ \alpha_{jk}(\lambda)e^{i\sqrt{\lambda}x}+\beta_{jk}(\lambda)e^{-i\sqrt{\lambda}x} & \text{for } j\in\mathcal{J},\end{cases} \tag{2.4}$$

solves the Schrödinger equation with the operator $-\Delta(A,B,\underline{a})$ for energy $\lambda>0$.

Recall that in potential scattering for one-particle Schrödinger operators the wave operators give precise meaning to the scattering wave functions, i.e., solutions of the Schrödinger equation at positive energy $\lambda>0$. Similarly the wave operators $\Omega^{\pm}(-\Delta(A,B,\underline{a}),-\Delta(A_{\mathcal{E}}=0,B_{\mathcal{E}}=\mathbb{I});\mathcal{J})$ determine the ''external part'' of the scattering wave function, i.e., $\psi_j^k(x,\lambda)$ for $j\in\mathcal{E}$. The completeness of usual wave operators means that any solution of the Schrödinger equation at energy $\lambda>0$ can be uniquely represented as a superposition of the scattering wave functions. Similarly, in the present context the $\mathcal{J}$-completeness of the wave operators $\Omega^{\pm}(-\Delta(A,B,\underline{a}),-\Delta(A_{\mathcal{E}}=0,B_{\mathcal{E}}=\mathbb{I});\mathcal{J})$ means that the external part of any solution for the Schrödinger equation with the operator $-\Delta(A,B,\underline{a})$ at energy $\lambda>0$ can uniquely be represented as a linear combination of the external parts of the scattering wave functions (2.4).

The scattering matrix $S_{A,B,\underline{a}}(\lambda)$ as well as the $m\times n$ matrix amplitudes $\alpha_{A,B,\underline{a}}(\lambda)$ and $\beta_{A,B,\underline{a}}(\lambda)$ are determined as solutions to the equation

$$Z_{A,B,\underline{a}}(\lambda)\begin{pmatrix} S(\lambda)\\ \alpha(\lambda)\\ \beta(\lambda)\end{pmatrix}=-A(-i\sqrt{\lambda}B)\begin{pmatrix}\mathbb{I}\\0\\0\end{pmatrix}, \tag{2.5}$$

where

$$Z_{A,B,\underline{a}}(\lambda)=AX_{\underline{a}}(\lambda)+i\sqrt{\lambda}BY_{\underline{a}}(\lambda) \tag{2.6}$$

is the $(n+2m)\times(n+2m)$ matrix with

$$X_{\underline{a}}(\lambda)=\begin{pmatrix} \mathbb{I} & 0 & 0 \\ 0 & \mathbb{I} & \mathbb{I} \\ 0 & e^{i\sqrt{\lambda}\underline{a}} & e^{-i\sqrt{\lambda}\underline{a}} \end{pmatrix}$$

and

$$Y_{\underline{a}}(\lambda)=\begin{pmatrix} \mathbb{I} & 0 & 0 \\ 0 & \mathbb{I} & -\mathbb{I} \\ 0 & -e^{i\sqrt{\lambda}\underline{a}} & e^{-i\sqrt{\lambda}\underline{a}} \end{pmatrix}.$$

Here $e^{\pm i\sqrt{\lambda}\underline{a}}$ stands for the $m\times m$ diagonal matrix with elements

$$(e^{\pm i\sqrt{\lambda}\underline{a}})_{jk}=e^{\pm i\sqrt{\lambda}\underline{a}_j}\delta_{jk}, \quad j,k\in\mathcal{J}.$$

If $\det Z_{A,B,\underline{a}}(\lambda)\neq 0$, the scattering matrix $S(\lambda)=S_{A,B,\underline{a}}(\lambda)$ as well as the $m\times n$ matrices $\alpha(\lambda)=\alpha_{A,B,\underline{a}}(\lambda)$ and $\beta(\lambda)=\beta_{A,B,\underline{a}}(\lambda)$ can be uniquely determined by solving the equation (2.5) in the form

$$\begin{pmatrix} S(\lambda) \\ \alpha(\lambda) \\ \beta(\lambda) \end{pmatrix} = -Z_{A,B,\underline{a}}(\lambda)^{-1}(A-i\sqrt{\lambda}B)\begin{pmatrix} \mathbb{I} \\ 0 \\ 0 \end{pmatrix}. \tag{2.7}$$

We denote by $\Sigma_{A,B,\underline{a}}=\{\lambda>0|\det Z_{A,B,\underline{a}}(\lambda)=0\}$ the set of exceptional points for which $Z_{A,B,\underline{a}}(\lambda)$ is not invertible.

Let ϕ be an arbitrary measurable function on the graph Γ. The subset supp ϕ of all edges of the graph Γ will be called the *support* of the function ϕ if $\phi\neq 0$ a.e. on supp ϕ.

In Ref. 21 we proved the following.

Theorem II.1: *For any boundary condition* (A, B) *and arbitrary* $\underline{a}\in\mathbb{R}_+^m$ *the set* $\Sigma_{A,B,\underline{a}}$ *equals the set* $\sigma_{A,B,\underline{a}}$ *of all positive eigenvalues of* $-\Delta(A,B,\underline{a})$. *This set is discrete and has no finite accumulation points in* $\mathbb{R}_+$. *The eigenfunctions of* $-\Delta(A,B,\underline{a})$ *have support on the internal lines of the graph. For all* $\lambda\in\Sigma_{A,B,\underline{a}}$ *the equation (2.5) is still solvable and determines* $S_{A,B,\underline{a}}(\lambda)$ *uniquely*.

Given an arbitrary $n\times n$ unitary matrix U and an energy $\lambda_0>0$ we can find boundary conditions A,B defining a self-adjoint operator $-\Delta(A,B)$ on a single-vertex graph (i.e., with $m=0$) with n external lines such that the corresponding scattering matrix is given as $S_{A,B}(\lambda_0)=U$. The proof of this fact can be found in Ref. 57. For other inverse problems on graphs we refer to Refs. 58 and 53.

Recall that by definition the operator $\Delta(A,B,\underline{a})$ is real if it commutes with complex conjugation, i.e., for any $\psi\in\mathcal{D}(\Delta(A,B,\underline{a}))$ the function $\overline{\psi}$ also belongs to $\mathcal{D}(\Delta(A,B,\underline{a}))$ and $\Delta(A,B,\underline{a})\psi=\overline{\Delta(A,B)\overline{\psi}}$. Equivalently, this means that any $\psi\in\mathcal{D}(\Delta(A,B,\underline{a}))$ [i.e., $\psi\in W^{2,2}(\Gamma)$ satisfying $A\psi+B\psi'=0$] also satisfies the equation $\overline{A}\overline{\psi}+\overline{B}\overline{\psi}'=0$. Thus, $\Delta(A,B,\underline{a})$ is real iff $\mathrm{Ker}(A,B)=\mathrm{Ker}(\overline{A},\overline{B})$. The last condition is satisfied iff there is an invertible matrix C_1 such that $A=C_1\overline{A}$, $B=C_1\overline{B}$ or alternatively there is an invertible matrix C_2 such that both C_2A and C_2B are real. We recall that $\Delta(A,B,\underline{a})=\Delta(CA,CB,\underline{a})$ for any invertible C (see Ref. 21).

In Ref. 21, Corollary 3.2, we have proved the following.

Theorem II.2: *For arbitrary* $\underline{a}\in\mathbb{R}_+^m$, $\lambda>0$, *and all boundary conditions A, B defining the self-adjoint operator* $\Delta(A,B,\underline{a})$

$$S_{\overline{A},\overline{B},\underline{a}}(\lambda)^T=S_{A,B,\underline{a}}(\lambda). \tag{2.8}$$

In particular, if the operator $\Delta(A,B,\underline{a})$ *is real, then* $S_{A,B,\underline{a}}(\lambda)=S_{A,B,\underline{a}}(\lambda)^T$ *for all* $\lambda>0$.

Here we give an alternative proof.

Proof: From the self-adjointness of the operator $\Delta(A,B,\underline{a})$ it follows that the matrix $A+i\sqrt{\lambda}B$ is invertible for all $\lambda>0$ (see Ref. 21). The relation (2.5) implies that

$$\begin{pmatrix} S_{A,B,\underline{a}}(\lambda) \\ \alpha_{A,B,\underline{a}}(\lambda) \\ e^{-i\sqrt{\lambda}\underline{a}}\beta_{A,B,\underline{a}}(\lambda) \end{pmatrix} = -(A+i\sqrt{\lambda}B)^{-1}(A-i\sqrt{\lambda}B)\begin{pmatrix} \mathbb{I} \\ \beta_{A,B,\underline{a}}(\lambda) \\ e^{i\sqrt{\lambda}\underline{a}}\alpha_{A,B,\underline{a}}(\lambda) \end{pmatrix}.$$

Similarly, for the operator $\Delta(\overline{A},\overline{B},\underline{a})$ we have

$$\begin{pmatrix} S_{\overline{A},\overline{B},\underline{a}}(\lambda) \\ \alpha_{\overline{A},\overline{B},\underline{a}}(\lambda) \\ e^{-i\sqrt{\lambda}\underline{a}}\beta_{\overline{A},\overline{B},\underline{a}}(\lambda) \end{pmatrix} = -(\overline{A}+i\sqrt{\lambda}\overline{B})^{-1}(\overline{A}-i\sqrt{\lambda}\overline{B})\begin{pmatrix} \mathbb{I} \\ \beta_{\overline{A},\overline{B},\underline{a}}(\lambda) \\ e^{i\sqrt{\lambda}\underline{a}}\alpha_{\overline{A},\overline{B},\underline{a}}(\lambda) \end{pmatrix}.$$

Taking the complex conjugate and multiplying by $(A+i\sqrt{\lambda}B)^{-1}(A-i\sqrt{\lambda}B)$ from the left we obtain

$$\begin{pmatrix} \mathbb{I} \\ \overline{\beta_{\overline{A},\overline{B},\underline{a}}(\lambda)} \\ e^{-i\sqrt{\lambda}\underline{a}}\overline{\alpha_{\overline{A},\overline{B},\underline{a}}(\lambda)} \end{pmatrix} = -(A+i\sqrt{\lambda}B)^{-1}(A-i\sqrt{\lambda}B)\begin{pmatrix} \overline{S_{\overline{A},\overline{B},\underline{a}}(\lambda)} \\ \overline{\alpha_{\overline{A},\overline{B},\underline{a}}(\lambda)} \\ e^{i\sqrt{\lambda}\underline{a}}\overline{\beta_{\overline{A},\overline{B},\underline{a}}(\lambda)} \end{pmatrix}.$$

We multiply this relation by $S_{\overline{A},\overline{B}}(\lambda)^T$ from the right and make use of the unitarity of the scattering matrix in the form $\overline{S_{\overline{A},\overline{B}}(\lambda)}S_{\overline{A},\overline{B}}(\lambda)^T=\mathbb{I}$, thus obtaining

$$\begin{pmatrix} S_{\overline{A},\overline{B},\underline{a}}(\lambda)^T \\ \overline{\beta_{\overline{A},\overline{B},\underline{a}}(\lambda)}S_{\overline{A},\overline{B},\underline{a}}(\lambda)^T \\ e^{-i\sqrt{\lambda}\underline{a}}\overline{\alpha_{\overline{A},\overline{B},\underline{a}}(\lambda)}S_{\overline{A},\overline{B},\underline{a}}(\lambda)^T \end{pmatrix} = -(A+i\sqrt{\lambda}B)^{-1}(A-i\sqrt{\lambda}B)\begin{pmatrix} \mathbb{I} \\ \overline{\alpha_{\overline{A},\overline{B},\underline{a}}(\lambda)}S_{\overline{A},\overline{B},\underline{a}}(\lambda)^T \\ e^{i\sqrt{\lambda}\underline{a}}\beta_{\overline{A},\overline{B},\underline{a}}(\lambda)S_{\overline{A},\overline{B},\underline{a}}(\lambda)^T \end{pmatrix}.$$

Equivalently, this relation can be written in a form analogous to (2.5),

$$Z_{A,B,\underline{a}}(\lambda)\begin{pmatrix} S_{\overline{A},\overline{B},\underline{a}}(\lambda)^T \\ \overline{\beta_{\overline{A},\overline{B},\underline{a}}(\lambda)}S_{\overline{A},\overline{B},\underline{a}}(\lambda)^T \\ \overline{\alpha_{\overline{A},\overline{B},\underline{a}}(\lambda)}S_{\overline{A},\overline{B},\underline{a}}(\lambda)^T \end{pmatrix} = -(A-i\sqrt{\lambda}B)\begin{pmatrix} \mathbb{I} \\ 0 \\ 0 \end{pmatrix}. \tag{2.9}$$

In Ref. 21 we proved that equation (2.5) has a solution for all $\lambda>0$. If $\lambda>0$ is not an eigenvalue of the operator $\Delta(A,B,\underline{a})$, then it has a unique solution. If $\lambda>0$ is an eigenvalue of $\Delta(A,B,\underline{a})$, this solution is nonunique, but still determines the scattering matrix uniquely. Therefore, from comparison of (2.5) and (2.9) the relation (2.8) follows. If $\Delta(A,B,\underline{a})$ is real, by the remark preceding the theorem we can choose the matrices A and B to be real. From this and from (2.8) the second claim of the theorem follows. □

We note that the comparison of (2.5) with (2.9) also gives the relations

$$\alpha_{A,B,\underline{a}}(\lambda)=\overline{\beta_{\overline{A},\overline{B},\underline{a}}(\lambda)}S_{A,B,\underline{a}}(\lambda)^T,$$

$$\beta_{A,B,\underline{a}}(\lambda)=\overline{\alpha_{\overline{A},\overline{B},\underline{a}}(\lambda)}S_{A,B,\underline{a}}(\lambda)^T,$$

III. THE GENERALIZED STAR PRODUCT

Let $U^{(1)}$ and $U^{(2)}$ be arbitrary $n_1\times n_1$ and $n_2\times n_2$ unitary matrices, respectively. Let p be some integer satisfying $1\leqslant p<(n_1+n_2)/2$, $p\leqslant n_j$, $j=1$, 2, and V be an arbitrary $p\times p$ unitary matrix. We write $U^{(1)}$ and $U^{(2)}$ in a 2×2-block form

$$U^{(1)}=\begin{pmatrix} U_{11}^{(1)} & U_{12}^{(1)} \\ U_{21}^{(1)} & U_{22}^{(1)} \end{pmatrix}, \quad U^{(2)}=\begin{pmatrix} U_{11}^{(2)} & U_{12}^{(2)} \\ U_{21}^{(2)} & U_{22}^{(2)} \end{pmatrix}, \tag{3.1}$$

where $U_{22}^{(1)}$ and $U_{11}^{(2)}$ are $p\times p$ matrices, $U_{11}^{(1)}$ is an $(n_1-p)\times(n_1-p)$ matrix, $U_{22}^{(2)}$ is an $(n_2-p)\times(n_2-p)$ matrix, etc. The unitarity condition for $U^{(1)}$ then reads

$$U_{11}^{(1)*}U_{11}^{(1)}+U_{21}^{(1)*}U_{21}^{(1)}=\mathbb{I},$$

$$U_{12}^{(1)*}U_{12}^{(1)}+U_{22}^{(1)*}U_{22}^{(1)}=\mathbb{I},$$

$$U_{11}^{(1)*}U_{12}^{(1)}+U_{21}^{(1)*}U_{22}^{(1)}=0,$$

$$U_{12}^{(1)*}U_{11}^{(1)}+U_{22}^{(1)*}U_{21}^{(1)}=0,$$

and similarly for $U^{(2)}$.

*Definition III.1: The unitary matrix $U^{(1)}$ is called V-***compatible** *with the unitary matrix $U^{(2)}$ if the $p\times p$ matrix $VU_{22}^{(1)}V^*U_{11}^{(2)}$ does not have* 1 *as an eigenvalue. For the case $V=\mathbb{I}$ the matrix $U^{(1)}$ is simply called* **compatible** *with $U^{(2)}$ (for given $p\geqslant 1$).*

Note that the compatibility of the matrices is not a symmetric relation, i.e., if $U^{(1)}$ is V-compatible with $U^{(2)}$, then $U^{(2)}$ need not be V-compatible with $U^{(1)}$.

Obviously, if $U^{(1)}$ is V-compatible with $U^{(2)}$, then also the matrix $V^*U_{11}^{(2)}VU_{22}^{(1)}$ does not have 1 as an eigenvalue. Indeed, let us assume the converse, i.e., let there be nonzero $c\in\mathbb{C}^p$ such that $V^*U_{11}^{(2)}VU_{22}^{(1)}c=c$ and thus

$$VU_{22}^{(1)}V^*U_{11}^{(2)}VU_{22}^{(1)}c=VU_{22}^{(1)}c.$$

Since $VU_{22}^{(1)}c\neq 0$ the matrix $VU_{22}^{(1)}V^*U_{11}^{(2)}$ has 1 as an eigenvalue, which is a contradiction. From this it also follows that if $U^{(1)}$ is not V-compatible with $U^{(2)}$, then the matrix $V^*U_{11}^{(2)}VU_{22}^{(1)}$ has 1 as an eigenvalue.

From the unitarity conditions it follows that

$$0\leqslant U_{11}^{(1)*}U_{11}^{(1)}=\mathbb{I}-U_{21}^{(1)*}U_{21}^{(1)}\leqslant\mathbb{I},$$

$$0\leqslant U_{22}^{(1)*}U_{22}^{(1)}=\mathbb{I}-U_{12}^{(1)*}U_{12}^{(1)}\leqslant\mathbb{I},$$

and thus $\|U_{11}^{(1)}\|\leqslant 1, \|U_{22}^{(1)}\|\leqslant 1$. Similar inequalities hold for $U_{11}^{(2)}$ and $U_{22}^{(2)}$. Therefore $\|VU_{22}^{(1)}V^*U_{11}^{(2)}\|\leqslant 1$. Strict inequality holds whenever $\|U_{22}^{(1)}\|<1$ or $\|U_{11}^{(2)}\|<1$ and then $U^{(1)}$ is V-compatible with $U^{(2)}$ and $U^{(2)}$ is V-compatible with $U^{(1)}$ for all unitary $p\times p$ matrices V.

In general, if $U^{(1)}$ is V-compatible with $U^{(2)}$, then it is easy to see that the following $p\times p$ matrices exist:

$$\begin{aligned} K_1&=(\mathbb{I}-VU_{22}^{(1)}V^*U_{11}^{(2)})^{-1}V=V(\mathbb{I}-U_{22}^{(1)}V^*U_{11}^{(2)}V)^{-1}, \\ K_2&=(\mathbb{I}-V^*U_{11}^{(2)}VU_{22}^{(1)})^{-1}V^*=V^*(\mathbb{I}-U_{11}^{(2)}VU_{22}^{(1)}V^*)^{-1}. \end{aligned} \tag{3.2}$$

An easy calculation establishes the following relations

$$\begin{aligned} K_1&=V+VU_{22}^{(1)}V^*U_{11}^{(2)}K_1=V+VU_{22}^{(1)}K_2U_{11}^{(2)}V=V+K_1U_{22}^{(1)}V^*U_{11}^{(2)}V, \\ K_2&=V^*+V^*U_{11}^{(2)}VU_{22}^{(1)}K_2=V^*+V^*U_{11}^{(2)}K_1U_{22}^{(1)}V^*=V^*+K_2U_{11}^{(2)}VU_{22}^{(1)}V^*. \end{aligned} \tag{3.3}$$

Note that formally one has the power series expansion

$$K_1=\sum_{m=0}^{\infty}(VU_{22}^{(1)}V^*U_{11}^{(2)})^mV,$$

$$K_2=\sum_{m=0}^{\infty}(V^*U_{11}^{(2)}VU_{22}^{(1)})^mV^*,$$

which is rigorous if $\|U_{22}^{(1)}\|<1$ or $\|U_{11}^{(2)}\|<1$. These power series expansions combined with the superposition principle were used in Ref. 21 to give a formal proof that the composition rule for scattering matrices was given by the generalized star product.

With these preparations the generalized star product $U=U^{(1)}*_VU^{(2)}$ of the unitary matrices $U^{(1)}$ and $U^{(2)}$ is defined as follows. Write the $(n_1+n_2-2p)\times(n_1+n_2-2p)$ matrix U in a 2×2 block form as

$$U=\begin{pmatrix}U_{11} & U_{12}\\ U_{21} & U_{22}\end{pmatrix},$$

where U_{11} is an $(n_1-p)\times(n_1-p)$ matrix, U_{22} is an $(n_2-p)\times(n_2-p)$ matrix, etc. These matrices are now defined as

$$\begin{aligned}U_{11}&=U_{11}^{(1)}+U_{12}^{(1)}K_2U_{11}^{(2)}VU_{21}^{(1)},\\ U_{22}&=U_{22}^{(2)}+U_{21}^{(2)}K_1U_{22}^{(1)}V^*U_{12}^{(2)},\\ U_{12}&=U_{12}^{(1)}K_2U_{12}^{(2)},\\ U_{21}&=U_{21}^{(2)}K_1U_{21}^{(1)}.\end{aligned}\tag{3.4}$$

In particular for an arbitrary $n\times n$ unitary matrix U and all p such that $1\leqslant p<n$ the $2p\times2p$ matrices $\mathbb{E}=\left(\begin{smallmatrix}0 & \mathbb{I}\\ \mathbb{I} & 0\end{smallmatrix}\right)$ serve as units for the $*_V$-product when $V=\mathbb{I}$,

$$\begin{pmatrix}0 & \mathbb{I}\\ \mathbb{I} & 0\end{pmatrix}*_VU=U_{*V}\begin{pmatrix}0 & \mathbb{I}\\ \mathbb{I} & 0\end{pmatrix}=U.$$

Further, we will need the following Perron–Frobenius-type result which, for the sake of generality, will be formulated to cover also the infinite-dimensional case:

Lemma III.2: Let a compact operator A on a separable Hilbert space $\mathfrak{h}$ be a contraction, i.e. $\|A\|\leqslant1$. Suppose that $\lambda=l$ is an eigenvalue of A. Then

(i) *every $c\in\mathfrak{h}$ such that $Ac=c$ also satisfies $A^*c=c$ and hence also $A^*Ac=AA^*c=c$,* and
(ii) *the geometric and algebraic multiplicities of the eigenvalue $\lambda=1$ are equal.*

Proof: The claim (*i*) is an easy consequence of the singular values decomposition (see, e.g., Ref. 59, p. 155). Thus we have $\mathrm{Ker}(A-1)=\mathrm{Ker}(A^*-1)=(\mathrm{Ran}(A-1))^{\perp}$. The claim (*ii*) now follows from the fact that the geometric and algebraic multiplicities of an eigenvalue λ are unequal iff $\mathrm{Ran}(A-\lambda)\cap\mathrm{Ker}(A-\lambda)$ is nontrivial. □

Also, we will make use of the following.

Lemma III.3: Let A and B be linear compact operators on a separable Hilbert space $\mathfrak{h}$ such that $\|A\|\leqslant1$, $\|B\|\leqslant1$, and $ABb=b$ for some $b\in\mathfrak{h}$. Then $B^*Bb=b$.

Proof: Without loss of generality we may assume that $\|b\|_{\mathfrak{h}}=1$. By Lemma III.2

$$B^*A^*ABb=b.\tag{3.5}$$

Therefore, by well-known inequalities for the singular values of compact operators (see, e.g., Ref. 60) we have

$$1 \leqslant s(AB) \leqslant s(A)s(B) \leqslant \|A\|\|B\| \leqslant 1,$$

where $s(K)$ denotes the maximal singular value of a compact operator K, i.e., the maximal eigenvalue of the self-adjoint non-negative operator K^*K. This gives $s(AB)=s(A)=s(B)=1$. From $s(A)=s(B)=1$ it follows that $\lambda=1$ is a maximal eigenvalue of A^*A and B^*B. By the min-max principle (see, e.g., Ref. 61, Theorem XIII.2) any $c \in \mathfrak{h}$, $\|c\|_{\mathfrak{h}}=1$ maximizing $(c,K^*Kc) \leqslant 1$, satisfies $K^*Kc=c$. Moreover, if $(c,K^*Kc)=1$ with some $\|c\|_{\mathfrak{h}} \leqslant 1$, then $K^*Kc=c$ and $\|c\|_{\mathfrak{h}}=1$. Therefore, since

$$(Bb,A^*ABb)=(b,B^*A^*ABb)=1,$$

we obtain

$$A^*ABb=Bb \tag{3.6}$$

and $\|Bb\|=1$. The relations (3.5) and (3.6) imply that $B^*Bb=B^*A^*ABb=b$. □

Suppose now that the unitary matrix $U^{(1)}$ is not V-compatible with $U^{(2)}$. In this case the linear subspaces of $\mathbb{C}^p$

$$\mathcal{C}=\mathrm{Ker}(\mathbb{I}-VU_{22}^{(1)}V^*U_{11}^{(2)}, \quad \tilde{\mathcal{C}}=\mathrm{Ker}(\mathbb{I}-U_{22}^{(1)}V^*U_{11}^{(2)}V),$$

$$\mathcal{B}=\mathrm{Ker}(\mathbb{I}-V^*U_{11}^{(2)}VU_{22}^{(1)}), \quad \tilde{\mathcal{B}}=\mathrm{Ker}(\mathbb{I}-U_{11}^{(2)}VU_{22}^{(1)}V^*)$$

are nontrivial. By Lemma III.2 we also have

$$\mathcal{C}=\mathrm{Ker}(\mathbb{I}-U_{11}^{(2)*}VU_{22}^{(1)*}V^*), \quad \tilde{\mathcal{C}}=\mathrm{Ker}(\mathbb{I}-V^*U_{11}^{(2)*}VU_{22}^{(1)*}),$$

$$\mathcal{B}=\mathrm{Ker}(\mathbb{I}-U_{22}^{(1)*}V^*U_{11}^{(2)*}V), \quad \tilde{\mathcal{B}}=\mathrm{Ker}(\mathbb{I}-VU_{22}^{(1)*}V^*U_{11}^{(2)*}).$$

Obviously $\tilde{\mathcal{C}}=V^*\mathcal{C}$ and $\tilde{\mathcal{B}}=V\mathcal{B}$. Since V is unitary this implies $\dim\tilde{\mathcal{C}}=\dim\mathcal{C}$ and $\dim\tilde{\mathcal{B}}=\dim\mathcal{B}$. Furthermore, we have the following.

Lemma III.4: The subspaces $\mathcal{B}$ and $\mathcal{C}$ have equal dimensions, $\dim\mathcal{B}=\dim\mathcal{C}$. *Moreover,*

(i) $\mathcal{B}=\mathrm{lin\ span}\{V^*U_{11}^{(2)}c, c\in\mathcal{C}\}=\mathrm{lin\ span}\{U_{22}^{(1)*}V^*c, c\in\mathcal{C}\}$,

$\mathcal{C}=\mathrm{lin\ span}\{VU_{22}^{(1)}b, b\in\mathcal{B}\}=\mathrm{lin\ span}\{U_{11}^{(2)*}Vb, b\in\mathcal{B}\}$,

and

$\tilde{\mathcal{B}}=\mathrm{lin\ span}\{U_{11}^{(2)}V\tilde{c}, \tilde{c}\in\tilde{\mathcal{C}}\}=\mathrm{lin\ span}\{VU_{22}^{(1)*}\tilde{c}, \tilde{c}\in\tilde{\mathcal{C}}\}$,

$\tilde{\mathcal{C}}=\mathrm{lin\ span}\{U_{22}^{(1)}V^*\tilde{b}, \tilde{b}\in\tilde{\mathcal{B}}\}=\mathrm{lin\ span}\{V^*U_{11}^{(2)*}\tilde{b}, \tilde{b}\in\tilde{\mathcal{B}}\}$,

(ii) $U_{21}^{(2)}c=0$ *for all* $c\in\mathcal{C}$,

(iii) $U_{12}^{(1)}b=0$ *for all* $b\in\mathcal{B}$,

(iv) $U_{21}^{(1)*}\tilde{c}=0$ *for all* $\tilde{c}\in\tilde{\mathcal{C}}$,

(v) $U_{12}^{(2)*}\tilde{b}=0$ *for all* $\tilde{b}\in\tilde{\mathcal{B}}$.

Proof: Let $c_i\in\mathbb{C}^p$, $i=1,...,k\leqslant p(k\geqslant 1)$, be a (not necessarily orthogonal) basis in $\mathcal{C}$. For all $i=1,...,k$ we have

$$(\mathbb{I}-VU_{22}^{(1)}V^*U_{11}^{(2)})c_i=0. \tag{3.7}$$

Multiplying these equations by $V^*U_{11}^{(2)}$ from the left we obtain

$$(\mathbb{I}-V^*U_{11}^{(2)}VU_{22}^{(1)}V^*U_{11}^{(2)}c_i=0.$$

Thus

$$\text{lin span}\{V^*U_{11}^{(2)}c, \quad c\in\mathcal{C}\}\subseteq\mathcal{B}. \tag{3.8}$$

By Lemma III.3 it follows from (3.7) that

$$U_{11}^{(2)*}U_{11}^{(2)}c_i=c_i, \quad i=1,...,k. \tag{3.9}$$

Hence,

$$\dim \text{ lin span}\{V^*U_{11}^{(2)}c, \quad c\in\mathcal{C}\}=\dim\ \mathcal{C} \tag{3.10}$$

and therefore by (3.8) $\dim\mathcal{C}\leqslant\dim\mathcal{B}$.

Let $b_i\in\mathbb{C}^p$, $i=1,...,k'\leqslant p$ be some basis in $\mathcal{B}$. We have

$$(\mathbb{I}-V^*U_{11}^{(2)}VU_{22}^{(1)})b_i=0 \tag{3.11}$$

for all $i=1,...,k'$. Multiplying these equations by $VU_{22}^{(1)}$ we obtain

$$(\mathbb{I}-VU_{22}^{(1)}V^*U_{11}^{(2)})VU_{22}^{(1)}b_i=0,$$

and thus

$$\text{lin span}\{VU_{22}^{(1)}b, \quad b\in\mathcal{B}\}\subseteq\mathcal{C}. \tag{3.12}$$

Again by Lemma III.3 it follows from (3.11) that

$$U_{22}^{(1)*}U_{22}^{(1)}b_i, \quad i=1,...,k'. \tag{3.13}$$

Thus

$$\dim \text{ lin span}\{VU_{22}^{(1)}b, \quad b\in\mathcal{B}\}=\dim\mathcal{B} \tag{3.14}$$

and therefore by (3.12) $\dim\mathcal{B}\leqslant\dim\mathcal{C}$. So we have proved that $\dim\mathcal{B}=\dim\mathcal{C}$. The inclusion (3.8) and the equality (3.10) imply that

$$\text{lin span}\{V^*U_{11}^{(2)}c, \quad c\in\mathcal{C}\}=\mathcal{B}.$$

The inclusion (3.12) and the equality (3.14) imply that

$$\text{lin span}\{VU_{22}^{(1)}b, b\in\mathcal{B}\}=\mathcal{C}.$$

The proof of the relations

$$\mathcal{B}=\text{lin span}\{U_{22}^{(1)*}V^*c, \quad c\in\mathcal{C}\},$$

$$\mathcal{C}=\text{lin span}\{U_{11}^{(2)*}Vb, \quad b\in\mathcal{B}\}$$

is similar and will therefore be omitted.

We turn to the proof of (ii)–(v). By the unitarity of $U^{(2)}$ from (3.9) it follows that $U_{21}^{(2)*}U_{21}^{(2)}c_i=0$. Since $\text{Ker}\,A^*A=\text{Ker}\,A$ for any linear operator A we obtain the claim (*ii*). By the unitarity of $U^{(1)}$ from (3.13) it follows that $U_{12}^{(1)*}U_{12}^{(1)}b_i=0$, which proves the claim (*iii*).

As already noted the vectors c_i and b_i also satisfy

$$(\mathbb{I}-U_{11}^{(2)*}VU_{22}^{(1)*}V^*)c_i=0, \quad (\mathbb{I}-U_{22}^{(1)*}V^*U_{11}^{(2)*}V)b_i=0.$$

A final application of Lemma III.3 yields

$$VU_{22}^{(1)}U_{22}^{(1)*}V^*c_i=c_i, \quad V^*U_{11}^{(2)}U_{11}^{(2)*}Vb_i=b_i,$$

which by the unitarity of $U^{(1)}$, $U^{(2)}$ and V implies (*iv*) and (v), which completes the proof of the lemma. □

Lemma III.5:

(i) *The matrices* $\mathbb{I}-VU_{22}^{(1)}V^*U_{11}^{(2)}$ *and* $\mathbb{I}-U_{11}^{(2)*}VU_{22}^{(1)*}V^*$ *map* $\mathcal{C}^\perp$ *bijectively onto itself.*

(ii) *The matrices* $\mathbb{I}-V^*U_{11}^{(2)}VU_{22}^{(1)}$ *and* $\mathbb{I}-U_{22}^{(1)*}V^*U_{11}^{(2)*}V$ *map* $\mathcal{B}^\perp$ *bijectively onto itself.*

(iii) *The matrices* $\mathbb{I}-U_{22}^{(1)}V^*U_{11}^{(2)}V$ *and* $\mathbb{I}-V^*U_{11}^{(2)*}VU_{22}^{(1)*}$ *map* $\tilde{\mathcal{C}}^\perp$ *bijectively onto itself.*

(iv) *The matrices* $\mathbb{I}-U_{11}^{(2)}VU_{22}^{(1)}V^*$ *and* $\mathbb{I}-VU_{22}^{(1)*}V^*U_{11}^{(2)*}$ *map* $\tilde{\mathcal{B}}^\perp$ *bijectively onto itself.*

Proof: Since V is unitary by the definitions of $\tilde{\mathcal{B}}$ and $\tilde{\mathcal{C}}$ it suffices to prove (*i*) and (*ii*). By the definition of $\mathcal{C}$ we have that

$$(c,VU_{22}^{(1)}V^*U_{11}^{(2)}c_\perp)=(U_{11}^{(2)*}VU_{22}^{(1)*}V^*c,c_\perp)=(c,c_\perp)=0$$

for any $c\in\mathcal{C}$ and any $c_\perp\in\mathcal{C}^\perp$. Thus $(\mathbb{I}-VU_{22}^{(1)}V^*U_{11}^{(2)})c_\perp\in\mathcal{C}^\perp$ for all $c_\perp\in\mathcal{C}^\perp$. Conversely, by Lemma III.2 for any $c_\perp\in\mathcal{C}^\perp$ there is a unique $d\in\mathcal{C}^\perp$ which satisfies the equation $(\mathbb{I}-VU_{22}^{(1)}V^*U_{11}^{(2)})d=c_\perp$. This proves the claim (*i*). The claim (*ii*) is proved similarly. □

Theorem III.6: *If at least one of the off-diagonal blocks of the matrices* $U^{(1)}$ *and* $U^{(2)}$ (*i.e.*, $U_{12}^{(1)}$, $U_{21}^{(1)}$, $U_{12}^{(2)}$, *or* $U_{21}^{(2)}$ *is of maximal rank, then the matrix* $U^{(1)}$ *is* V*-compatible with* $U^{(2)}$ *for all unitary* $p\times p$ *matrices* V.

Proof: We recall that for $p\leqslant n_1/2$ the $(n_1-p)\times p$ matrix $U_{12}^{(1)}$ is not of maximal rank ($=\min\{n_1-p,p\}$) iff there is a vector $b\in\mathbb{C}^p$ such that $U_{12}^{(1)}b=0$. For $p\geqslant n_1/2$ the matrix $U_{12}^{(1)}$ is not of maximal rank iff there is a vector $c\in\mathbb{C}^p$ such that $U_{12}^{(1)*}c=0$.

Let us suppose that the matrix $U^{(1)}$ is not V-compatible with $U^{(2)}$. Then by Lemma III.4 it follows that all off-diagonal blocks of $U^{(1)}$ and $U^{(2)}$ are not of maximal rank. □

Actually we have also the following result. Let a unitary $n\times n$ matrix U be written in the block form

$$U=\begin{pmatrix} U_{11} & U_{12} \\ U_{21} & U_{22} \end{pmatrix},$$

where U_{11} is an $(n-p)\times(n-p)$ matrix, U_{22} is a $p\times p$ matrix, etc. with p being an arbitrary integer such that $1\leqslant p<n$.

Lemma III.7: The matrices U_{12} *and* U_{21} *are simultaneously either of maximal rank or not of maximal rank.*

Proof: Let us suppose that $p\leqslant n/2$. Then the $(n-p)\times p$ matrix U_{12} is not of maximal rank iff there is a nonzero vector $b\in\mathbb{C}^p$ such that $U_{12}b=0$. From the unitarity of U it follows that

$$U_{11}^*U_{12}+U_{21}^*U_{22}=0, \quad U_{22}^*U_{22}+U_{12}^*U_{12}=\mathbb{I},$$

and therefore

$$U_{21}^*U_{22}b=0, \quad U_{22}^*U_{22}b=b.$$

Thus $U_{22}b\neq 0$ and $U_{22}b\in\operatorname{Ker}U_{21}^*$. From this it follows that the $(n-p)\times p$ matrix U_{21}^* is not of maximal rank, and thus the $p\times(n-p)$ matrix U_{21} is also not of maximal rank.

Now let us suppose that $n>p\geqslant n/2$. Then the matrix U_{12} is not of maximal rank iff there is a nontrivial vector $b\in\mathbb{C}^{n-p}$ such that $U_{12}^*b=0$. Again from the unitarity we have

$$U_{21}U_{11}^*+U_{22}U_{12}^*=0, \quad U_{11}U_{11}^*+U_{12}U_{12}^*=\mathbb{I},$$

and therefore

$$U_{21}U_{11}^{*}b=0, \quad U_{11}U_{11}^{*}b=b.$$

Thus, the $p\times(n-p)$ matrix U_{21} is not of maximal rank. □

We will show now that the *-product can be extended to arbitrary, not necessarily V-compatible, unitary matrices. We will prove that the operators

$$U_{21}^{(2)}K_1=U_{21}^{(2)}(\mathbb{I}-VU_{22}^{(1)}V^{*}U_{11}^{(2)})^{-1}V$$

and

$$U_{12}^{(1)}K_2=U_{12}^{(1)}(\mathbb{I}-V^{*}U_{11}^{(2)}VU_{22}^{(1)})^{-1}V^{*}$$

are actually well defined. From Lemma III.5 it follows (see Ref. 62, Section 1.5.3) that

$$P_{\mathcal{C}^{\perp}}(\mathbb{I}-VU_{22}^{(1)}V^{*}U_{11}^{(2)})^{-1} \quad \text{and} \quad P_{\mathcal{B}^{\perp}}(\mathbb{I}-V^{*}U_{11}^{(2)}VU_{22}^{(1)})^{-1}$$

are well defined. From (*ii*) and (*iii*) of Lemma III.4 it follows that $\mathcal{C}\subseteq\operatorname{Ker}U_{21}^{(2)}$ and $\mathcal{B}\subseteq\operatorname{Ker}U_{12}^{(1)}$ and thus

$$U_{21}^{(2)}(\mathbb{I}-VU_{22}^{(1)}V^{*}U_{11}^{(2)})^{-1}=U_{21}^{(2)}P_{\mathcal{C}^{\perp}}(\mathbb{I}-VU_{22}^{(1)}V^{*}U_{11}^{(2)})^{-1}$$

and

$$U_{12}^{(1)}(\mathbb{I}-V^{*}U_{11}^{(2)}VU_{22}^{(1)})^{-1}=U_{12}^{(1)}P_{\mathcal{B}^{\perp}}(\mathbb{I}-V^{*}U_{11}^{(2)}VU_{22}^{(1)})^{-1}$$

are well defined. Similarly one can show that the operators

$$U_{21}^{(2)}V(\mathbb{I}-U_{22}^{(1)}V^{*}U_{11}^{(2)}V)^{-1} \quad \text{and} \quad U_{12}^{(1)}V^{*}(\mathbb{I}-U_{11}^{(2)}VU_{22}^{(1)}V^{*})^{-1}$$

are also well defined. With this we obtain that the relations (3.4) indeed also define the generalized star product of two noncompatible unitary matrices. Moreover, we have

$$\begin{gathered}U_{21}^{(2)}(\mathbb{I}-VU_{22}^{(1)}V^{*}U_{11}^{(2)})^{-1}c=0, \quad U_{12}^{(1)}(\mathbb{I}-V^{*}U_{11}^{(2)}VU_{22}^{(1)})^{-1}b=0,\\ U_{21}^{(2)}V(\mathbb{I}-U_{22}^{(1)}V^{*}U_{11}^{(2)}V)^{-1}\tilde{c}=0, \quad U_{12}^{(1)}V^{*}(\mathbb{I}-U_{11}^{(2)}VU_{22}^{(1)}V^{*})^{-1}\tilde{b}=0\end{gathered} \tag{3.15}$$

for all $c\in\mathcal{C}$, $b\in\mathcal{B}$, $\tilde{c}\in\tilde{\mathcal{C}}$, and $\tilde{b}\in\tilde{\mathcal{B}}$.

Theorem III.8: *For arbitrary unitary matrices $U^{(1)}$, $U^{(2)}$, and V the matrix $U=U^{(1)}*_{V}U^{(2)}$ is unitary.*

This theorem was proved in Appendix C of Ref. 21 in the case when $U^{(1)}$ is V-compatible with $U^{(2)}$. For the general case the proof is given in the Appendix.

Analogously one can prove associativity of the generalized star product. More precisely, let $U^{(3)}$ be a unitary $n_3\times n_3$ and V' a unitary $p'\times p'$ matrix with $p'\leqslant n_2$, $p'\leqslant n_3$. If $p+p'\leqslant n_1$, then

$$U^{(1)}*_{V}(U^{(2)}*_{V'}U^{(3)})=(U^{(1)}*_{V}U^{(2)})*_{V'}U^{(3)}$$

holds.

Theorem III.9: *The generalized star product is a continuous operation in each of its two arguments, i.e., for any unitary matrices $U^{(1)}$, $U^{(2)}$, $U^{(3)}$, and V such that $U^{(2)}$ and $U^{(3)}$ have equal size there is a constant $C>0$ depending on $U^{(1)}$ and V only such that*

$$\|U^{(1)}*_{V}U^{(2)}-U^{(1)}*_{V}U^{(3)}\|\leqslant C\|U^{(2)}-U^{(3)}\|,$$

where the norm $\|\cdot\|$ is an arbitrary matrix norm. A similar estimate holds with respect to the first argument.

In Ref. 21 we proved that the scattering matrix of a self-adjoint Laplacian on an arbitrary graph is a continuous function of $\lambda>0$. Theorem III.9 together with the composition rule given in Sec. IV below allows us to give an alternative proof of this fact. We will not dwell on the details here.

In the sequel we will use the notion of the Moore–Penrose pseudoinverse (see, e.g., Ref. 63). Recall that for any (not necessarily square) matrix M its pseudoinverse $M^\star$ is uniquely defined by the Penrose equations

$$MM^\star M=M, M^\star MM^\star=M^\star,$$

$$(M^\star M)^*=M^\star M, (MM^\star)^*=MM^\star.$$

One also has

$$M^{\star *}=M^{**},$$

$$\text{Ran}\ \ M^\star=\text{Ran}\ \ M^*,$$

$$\text{Ker}\ \ M^\star=\text{Ker}\ \ M^*,$$

and $MM^\star=P_{\text{Ran}M}$, $M^\star M=P_{\text{Ran}M^*}$, where $P_{\mathcal{H}}$ denotes the orthogonal projection onto the linear subspace $\mathcal{H}$. Moreover $0^\star=0$. If M is a square matrix of maximal rank, then $M^\star=M^{-1}$.

Let U again be an arbitrary unitary $n\times n$ matrix written in the block form with some $1\leqslant p<n$.

Lemma III.10: If $\text{Ker}\,U_{12}=\{0\}$, *then* $\text{Ker}\,(U_{21}-U_{22}U_{12}^\star U_{11})^*=\{0\}$.

Proof: Assume the converse, i.e., let there be $c\in\mathbb{C}^p$, $c\neq 0$, such that

$$(U_{21}-U_{22}U_{12}^\star U_{11})^*c=0,$$

or, equivalently,

$$U_{21}^*c-U_{11}^*U_{12}^{\star *}U_{22}^*c=0.$$

We multiply this equation by U_{21} from the left and use the unitarity of U which in particular implies

$$U_{21}U_{21}^*+U_{22}U_{22}^*=\mathbb{I}.$$

This yields

$$c-U_{22}U_{22}^*c-U_{21}U_{11}^*U_{12}^{\star *}U_{22}^*c=0. \tag{3.16}$$

Again by unitarity we have $U_{21}U_{11}^*=-U_{22}U_{12}^*$. Recall that

$$U_{12}^*U_{12}^{\star *}=(U_{12}^\star U_{12})^*=(\mathbb{I}-P_{\text{Ker}\,U_{12}})^*=\mathbb{I}$$

by the hypothesis of the lemma. Thus, from (3.16) it follows that $c=0$. □

Now we turn to a discussion of the inverse of a unitary $2p\times 2p$ matrix U with respect to the generalized star product $*_p$, i.e., the existence of the unitary matrices U^L and U^R such that

$$U^L*_pU=U*_pU^R=\mathbb{E},$$

where $\mathbb{E}$ is the $2p\times 2p$ matrix $\left(\begin{smallmatrix}0 & \mathbb{I}\\ \mathbb{I} & 0\end{smallmatrix}\right)$ (in the $p\times p$ block notation). We will not discuss general necessary and sufficient conditions for the existence of U^L and U^R, but simply restrict ourselves to a special case. We will prove the following.

Theorem III.11: *Let U be an arbitrary $2p\times 2p (p\geqslant 1)$ unitary matrix. Let at least one of the $p\times p$ matrices U_{12} and U_{21} be of maximal rank $(=p)$. Then there exists a unique unitary $2p\times 2p$ matrix U' such that*

$$U'*_p U = U*_p U' = \mathbb{E}. \tag{3.17}$$

Proof: By Lemma III.7 both matrices U_{12} and U_{21} have maximal rank. We will discuss only the second of the relations (3.17). In block notation this relation has the form

$$\begin{aligned} &U_{11}+U_{12}(\mathbb{I}-U'_{11}U_{22})^{-1}U'_{11}U_{21}=0,\\ &U'_{22}+U'_{21}(\mathbb{I}-U_{22}U'_{11})^{-1}U_{22}U'_{12}=0,\\ &U_{12}(\mathbb{I}-U'_{11}U_{22})^{-1}U'_{12}=\mathbb{I},\\ &U'_{21}(\mathbb{I}-U_{22}U'_{11})^{-1}U_{21}=\mathbb{I}. \end{aligned} \tag{3.18}$$

By Theorem III.6 the matrix U must be compatible with U' such that $(\mathbb{I}-U'_{11}U_{22})^{-1}$ and $(\mathbb{I}-U_{22}U'_{11})^{-1}$ are both well defined. We multiply the first of the relations (3.18) by U_{12}^{-1} from the left. Next we multiply the resulting expression by $\mathbb{I}-U'_{11}U_{22}$, thus obtaining

$$U'_{11}(U_{21}-U_{22}U_{12}^{-1}U_{11}) = -U_{12}^{-1}U_{11}.$$

By Lemma III.10 we have that $U_{21}-U_{22}U_{12}^{-1}U_{11}$ is invertible and thus

$$U'_{11} = -U_{12}^{-1}U_{11}(U_{21}-U_{22}U_{12}^{-1}U_{11})^{-1}. \tag{3.19}$$

From the third relation in (3.18) we obtain

$$U'_{12}=(\mathbb{I}-U'_{11}U_{22})U_{12}^{-1}=U_{12}^{-1}+U_{12}^{-1}U_{11}(U_{21}-U_{22}U_{12}^{-1}U_{11})^{-1}U_{22}U_{12}^{-1}.$$

The fourth relation in (3.18) gives

$$U'_{21}=U_{21}^{-1}(\mathbb{I}-U_{22}U'_{11})=(U_{21}-U_{22}U_{12}^{-1}U_{11})^{-1}. \tag{3.20}$$

The second relation in (3.18) determines U'_{22}.

It remains to prove that U' is unitary. By the unitarity of the matrix U we have

$$(U_{21}^*-U_{11}^*U_{12}^{*-1}U_{22}^*)(U_{21}-U_{22}U_{12}^{-1}U_{11})=\mathbb{I}+U_{11}^*U_{12}^{*-1}U_{12}^{-1}U_{11}.$$

Therefore

$$(U_{21}^*-U_{11}^*U_{12}^{*-1}U_{22}^*)^{-1}[\mathbb{I}+U_{11}^*U_{12}^{*-1}U_{12}^{-1}U_{11}](U_{21}-U_{22}U_{12}^{-1}U_{11})^{-1}=\mathbb{I},$$

and thus by (3.19) and (3.20) we obtain

$$U_{11}'^*U'_{11}+U_{21}'^*U'_{21}=\mathbb{I}.$$

The relations $U_{12}'^*U'_{12}+U_{22}'^*U'_{22}=\mathbb{I}$, $U_{11}'^*U'_{12}+U_{21}'^*U'_{22}=0$, and $U_{12}'^*U'_{11}+U_{22}'^*U'_{21}=0$ can be proved similarly.

The left inverse is constructed similarly and by means of the obvious relation

$$(U_{21}-U_{22}U_{12}^{-1}U_{11})^{-1}U_{22}U_{12}^{-1}=U_{21}^{-1}U_{22}(U_{21}-U_{22}U_{12}^{-1}U_{11})^{-1}U_{22}U_{12}^{-1}$$

is easily shown to be equal to the right inverse. □

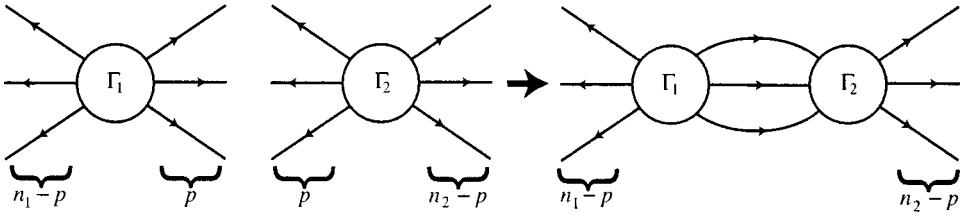

FIG. 1. Gluing of two graphs.

Corollary III.12: *Let* G *be the set of all* $2p\times 2p$ *unitary matrices with* $p\times p$ *blocks* U_{12} *and* U_{21} *both being of maximal rank, endowed with the generalized star product* $*_p$ *as a multiplication and* $\mathbb{E}$ *as a unit. Then* G *is a group isomorphic to* $\mathsf{U}(p,p)$.

The proof will follow from the arguments given in Sec. V. In particular, the group isomorphism between G and $\mathsf{U}(p,p)$ is given by the formulas (5.9) and (5.13). We note that this isomorphism generalizes the well-known *set* isomorphism between the group $\mathsf{SU}(1,1)$ and a subgroup of $\mathsf{SU}(2)$.

The set of *all* $2p\times 2p$ unitary matrices endowed with the generalized star product $*_p$ as a multiplication and $\mathbb{E}$ as a unit is no longer a group but only a semigroup.

IV. COMPOSITION RULE FOR THE SCATTERING MATRICES

Now we apply the generalized star product to prove the composition rule for the scattering matrices on graphs. For this we only need the special case $V=\mathbb{I}_p$, the $p\times p$ unit matrix, and so we introduce the notation $*_p := *_{V=\mathbb{I}_p}$. Let Γ_1 and Γ_2 be two graphs with $n_1\geqslant 1$ and $n_2\geqslant 1$ external lines, respectively, labeled by $\mathcal{E}_1$ and $\mathcal{E}_2$, i.e., $\#(\mathcal{E}_1)=n_1$, $\#(\mathcal{E}_2)=n_2$ and an arbitrary number of internal lines with given fixed lengths (see Fig. 1). Furthermore, at all vertices we have local boundary conditions giving Laplace operators $\Delta(\Gamma_1)$ on Γ_1 and $\Delta(\Gamma_2)$ on Γ_2 and the scattering matrices $S_1(\lambda)$ and $S_2(\lambda)$. Let now $\mathcal{E}_1^0$ and $\mathcal{E}_2^0$ be subsets of $\mathcal{E}_1$ and $\mathcal{E}_2$ respectively having an equal number $1\leqslant p\leqslant \min\{n_1,n_2\}$ of elements. Also let $\varphi_0:\mathcal{E}_1^0\to\mathcal{E}_2^0$ be a one-to-one map. Finally, to each $k\in\mathcal{E}_1^0$ we associate a number $a_k>0$. With these data we can now form a graph Γ by connecting the external line $k\in\mathcal{E}_1^0$ with the line $\varphi_0(k)\in\mathcal{E}_2^0$ to form a line of length a_k. In other words any interval $[0_k,\infty_k)$, $k\in\mathcal{E}_1^0$ belonging to Γ_1 and the interval $[0_{\varphi_0(k)},\infty_{\varphi_0(k)}]$ belonging to Γ_2 is replaced by the finite interval $[0_k,a_k]$ with 0_k being associated to the same vertex in Γ_1 as previously and a_k being associated to the same vertex in Γ_2 as $0_{\varphi_0(k)}$ before in the sense of the discussion at the end of the previous section. Recall that the graphs need not be planar. Thus Γ has $n=n_1+n_2-2p$ external lines indexed by elements in $(\mathcal{E}_1\backslash\mathcal{E}_1^0)\cup(\mathcal{E}_2\backslash\mathcal{E}_2^0)$ and p internal lines indexed by elements in $\mathcal{E}_1^0$ in addition to those of Γ_1 and of Γ_2. We denote this set by $\mathcal{I}_{12}$ such that the set of all internal lines of the graph Γ is given by $\mathcal{I}=\mathcal{I}_1\cup\mathcal{I}_2\cup\mathcal{I}_{12}$. There are no new vertices in addition to those of Γ_1 and Γ_2 so the boundary conditions on Γ_1 and Γ_2 define boundary conditions on Γ resulting in a Laplace operator $\Delta(\Gamma)$. Suppose that the indices of $\mathcal{E}_1^0$ in $\mathcal{E}_1$ come after the indices in $\mathcal{E}_1\backslash\mathcal{E}_1^0$ (in an arbitrary but fixed order) [see (3.1)]. Via the map φ_0 we may identify $\mathcal{E}_2^0$ with $\mathcal{E}_1^0$ so let these indices now come first in $\mathcal{E}_2$, but again in the same order. Finally, let the diagonal $n_2\times n_2$ matrix $V(\underline{a})$ be given as

$$V(\underline{a})=\begin{pmatrix}\exp i\sqrt{\lambda}\underline{a} & 0\\ 0 & \mathbb{I}\end{pmatrix},$$

where $\exp(i\sqrt{\lambda}\underline{a})$ again is the diagonal $p\times p$ matrix given by the p new lengths a_k, $k\in\mathcal{E}_2^0$.

Recall that by Theorem II.1 all eigenfunctions of the operator $-\Delta(\Gamma)$ have the form

$$\psi=\begin{cases}0, & j\in\mathcal{E},\\ \alpha_j e^{i\sqrt{\lambda}x}+\beta_j e^{-i\sqrt{\lambda}x}, & j\in\mathcal{I},\end{cases}$$

where the coefficients α_j and β_j satisfy the homogeneous equation

$$Z_{A,B,\underline{a}}(\lambda)\begin{pmatrix}0\\ \alpha\\ \beta\end{pmatrix}=0, \quad \alpha=\{\alpha_j\}_{j=1}^m, \quad \beta=\{\beta_j\}_{j=1}^m$$

with the matrix $Z_{A,B,\underline{a}}(\lambda)$ defined by (2.6). We define the linear subspace $\mathcal{L}_{12}(\lambda)$ of $\mathbb{C}^{n+2m}$ as a set of all vectors $(0,\alpha,\beta)^T$ for which $\alpha_j=\beta_j=0$ for all $j\in\mathcal{I}_{12}$,

$$\mathcal{L}_{12}(\lambda)=\{l=(0,\alpha,\beta)^T\in \operatorname{Ker} Z_{A,B,\underline{a}}(\lambda)\subset\mathbb{C}^{n+2m}\,|\,\alpha_j=\beta_j \forall j\in\mathcal{I}_{12}\}. \tag{4.1}$$

Obviously for $\lambda\notin\sigma_{A,B,\underline{a}}$ this subspace is trivial, i.e., $\mathcal{L}_{12}(\lambda)=\{0\}$. Let $\Upsilon(\Gamma,\mathcal{I}_{12})\subset\mathbb{R}$ be the set of those eigenvalues of $-\Delta(\Gamma)$ for which $\operatorname{Ker} Z_{A,B,\underline{a}}(\lambda)\ominus\mathcal{L}_{12}(\lambda)$ is nontrivial. Obviously the eigenfunctions corresponding to the eigenvalues from $\Upsilon(\Gamma,\mathcal{I}_{12})$ have nontrivial overlap with $\mathcal{I}_{12}$, i.e., $\operatorname{supp}\phi\cap\mathcal{I}_{12}$ has nonzero measure.

Let $\Xi(\Gamma_1,\Gamma_2)\subset\mathbb{R}_+$ be the set of those $\lambda>0$ for which $\operatorname{Ker}(V(\underline{a})S_{22}^{(1)}(\lambda)V(\underline{a})S_{11}^{(2)}(\lambda)-1)$ is nontrivial.

Theorem IV.1: *With the above notations* $\Xi(\Gamma_1,\Gamma_2)=\Upsilon(\Gamma,\mathcal{I}_{12})\cap\mathbb{R}_+$. *The composition rule*

$$S(\lambda)=S_1(\lambda)*_pV(\underline{a})S_2(\lambda)V(\underline{a}) \tag{4.2}$$

holds for all $\lambda\in\mathbb{R}_+$. *If* $\lambda\in\Upsilon(\Gamma,\mathcal{I}_{12})$ *and* $\lambda>0$, *then its multiplicity equals*

$$\dim\operatorname{Ker}(-\Delta(\Gamma_1)-\lambda)+\dim\operatorname{Ker}(-\Delta(\Gamma_2-\lambda)+\dim\operatorname{Ker}(V(\underline{a})S_{22}^{(1)}(\lambda)V(\underline{a})S_{11}^{(2)}(\lambda)-).$$

In particular, if the eigenvalue $\lambda>0$ *is such that* $\lambda\notin\Upsilon(\Gamma,\mathcal{I}_{12})$, *then its multiplicity equals*

$$\dim\operatorname{Ker}(-\Delta(\Gamma_1)-\lambda)+\dim\operatorname{Ker}(-\Delta(\Gamma_2)-\lambda).$$

Here $\dim\operatorname{Ker}(-\Delta(\Gamma_1)-\lambda)$ denotes the multiplicity of the eigenvalue λ regardless whether it is embedded into the absolutely continuous spectrum or not.

Note that by Lemma III.2 $\dim\operatorname{Ker}(V(\underline{a})S_{22}^{(1)}(\lambda)V(\underline{a})S_{11}^{(2)}(\lambda)-1)$ equals the algebraic multiplicity of the eigenvalue $\mu=1$ of $V(\underline{a})S_{22}^{(1)}(\lambda)V(\underline{a})S_{11}^{(2)}(\lambda)$.

If by cutting p internal lines of an arbitrary graph Γ with local boundary conditions, the graph will be decomposed into two disjoint subgraphs Γ_1 and Γ_2, by Theorem IV.1 the scattering matrix S_Γ can be obtained from the scattering matrices S_{Γ_1} and S_{Γ_2} at the same energy. Thus, using (4.2) iteratively the scattering matrix associated to any graph can be obtained from the scattering matrices associated to its subgraphs each having one vertex only. In fact, pick one vertex and choose all the internal lines connecting to all other vertices. This leads to two graphs and the rule (4.2) may be applied. Iterating this procedure L times, where L is the number of vertices, gives the desired result.

Proof of Theorem IV.1: We split the proof into several steps.

(1) First we suppose that $S_1(\lambda)$ is compatible with $V(\underline{a})S_2(\lambda)V(\underline{a})$ and prove that the composition rule (4.2) holds. Let $\psi_j^k(x,\lambda;\Gamma_l)$, $j\in\mathcal{E}_l\cup\mathcal{I}_l$ for any $k\in\mathcal{E}_l$ be the solution of the Schrödinger equation with the operator $-\Delta(\Gamma_l)$, $l=1,2$ [see (2.4)] at energy λ. Let $\Psi_l(x,\lambda)$ be $n_l\times n_l$ matrices

$$[\Psi_l(x,\lambda)]_{jk}=\psi_j^k(x,\lambda;\Gamma_l), \quad j,k\in\mathcal{E}_l, \quad l=1,2, \tag{4.3}$$

such that

$$\Psi_l(x,\lambda)=e^{-i\sqrt{\lambda}x}\mathbb{I}+e^{i\sqrt{\lambda}x}S_l(\lambda), \quad l=1,2. \tag{4.4}$$

Observe that $e^{-i\sqrt{\lambda}x}$ and $e^{i\sqrt{\lambda}x}$ are linearly independent functions and therefore the scattering matrices may uniquely be recovered from $\Psi_l(x,\lambda)$. The columns of $\Psi_l(x,\lambda)$ define the external part of solutions of the Schrödinger equation for $-\Delta(\Gamma_l)$ at energy λ. We are looking for a square matrix

$$\Psi(x,\lambda)=e^{-i\sqrt{\lambda}x}\mathbb{I}+e^{i\sqrt{\lambda}x}S(\lambda)$$

such that its $(n_1-p)+(n_2-p)=n_1+n_2-2p$ columns defines the external parts of a solution to the Schrödinger equation for $-\Delta(\Gamma)$. Here the indices are assumed to be arranged such that the first indices are those of $\mathcal{E}_1\backslash\mathcal{E}_1^0$ followed by the indices of $\mathcal{E}_2\backslash\mathcal{E}_2^0$. The aim is to obtain $\Psi(x,\lambda)$ from $\Psi_1(x,\lambda)$, $\Psi_2(x,\lambda)$, and the lengths $\underline{a}=\{a_s\}_{s\in\mathcal{I}_{12}}$ of the new internal lines $\mathcal{I}_{12}$. By the above observation this will determine the scattering matrix $S(\lambda)$. The strategy will be to find new solutions of the Schrödinger equations for $-\Delta(\Gamma_l)$ with incoming plane waves $(e^{-i\sqrt{\lambda}x})$ in the channels $k\in\mathcal{E}_l\backslash\mathcal{E}_l^0$ which agree suitably in the channels $k\in\mathcal{E}_1^0$ and $\varphi_0(k)\in\mathcal{E}_2^0$.

With the conventions made above we write

$$\begin{aligned}S_1(\lambda)&=\begin{pmatrix}S_1^{(n_1-p)\times(n_1-p)}(\lambda) & S_1^{(n_1-p)\times p}(\lambda)\\ S_1^{p\times(n_1-p)}(\lambda) & S_1^{p\times p}(\lambda)\end{pmatrix},\\ S_2(\lambda)&=\begin{pmatrix}S_2^{p\times p}(\lambda) & S_2^{p\times(n_2-p)}(\lambda)\\ S_2^{(n_2-p)\times p}(\lambda) & S_2^{(n_2-p)\times(n_2-p)}(\lambda)\end{pmatrix},\end{aligned}\tag{4.5}$$

where the superscripts denote the sizes of the blocks. For arbitrary $p\times(n_1-p)$ matrices C_1 and C_2, respectively, consider the $n_1\times(n_1-p)$ and $n_2\times(n_1-p)$ matrices

$$\begin{aligned}\Phi_1(x,\lambda;C_1)&=e^{-i\sqrt{\lambda}x}\begin{pmatrix}\mathbb{I}\\ C_1\end{pmatrix}+e^{i\sqrt{\lambda}x}S_1(\lambda)\begin{pmatrix}\mathbb{I}\\ C_1\end{pmatrix},\\ \Phi_2(x,\lambda;C_2)&=e^{-i\sqrt{\lambda}x}\begin{pmatrix}C_2\\ 0\end{pmatrix}+e^{i\sqrt{\lambda}x}S_2(\lambda)\begin{pmatrix}C_2\\ 0\end{pmatrix}.\end{aligned}\tag{4.6}$$

Here $\mathbb{I}$ stands for the $(n_1-p)\times(n_1-p)$ unit matrix and 0 stands for the $(n_2-p)\times(n_1-p)$ zero matrix. Obviously, the columns of $\Phi_l(x,\lambda;C_l)$ are the external parts of linear combinations of the columns of $\Psi_l(x,\lambda;\Gamma_l)$, and thus define the external parts of solutions of the Schrödinger equations for the operators $-\Delta(\Gamma_l)$, $l=1,2$. Note that $\Phi_1(x,\lambda;C_1)$ has an incoming plane wave in any of the channels $k\in\mathcal{E}_1\backslash\mathcal{E}_1^0$ and $\Phi_2(x,\lambda;C_2)$ has no incoming plane wave in all channels $k\in\mathcal{E}_2\backslash\mathcal{E}_2^0$.

Now we make the coordinate transformations $x\to a_k-x$ on the lines $\varphi_0(k)\in\mathcal{E}_2^0(k\in\mathcal{E}_1^0)$. The reason for this is as follows. Under the gluing process $\Gamma_1,\Gamma_2\to\Gamma$ (see Fig. 1) the two half-lines corresponding to $k\in\mathcal{E}_1^0$ and $\varphi_0(k)\in\mathcal{E}_2^0$ are replaced by the interval $[0,a_k]$, giving the new lines in $\mathcal{I}_{12}$. This may be realized by identifying a point P on the half-line corresponding to $k\in\mathcal{E}_1^0$ and with coordinate $x(0\leqslant x\leqslant a_k)$ with the point Q on the half-line corresponding to $\varphi_0(k)\in\mathcal{E}_2^0$ with coordinate a_k-x. In particular, $x=a_k$ on the k-line corresponds to $x=0$ on the $\varphi_0(k)$-line and vice versa. Applying this transformation to $\Phi_2(x,\lambda;C_2)$ we obtain in this new coordinate system

$$\Phi_2^{(a)}(x,\lambda;C_2)=\begin{pmatrix}e^{-i\sqrt{\lambda}(\underline{a}-x)} & 0\\ 0 & e^{-i\sqrt{\lambda}x}\end{pmatrix}+\begin{pmatrix}C_2\\ 0\end{pmatrix}+\begin{pmatrix}e^{-i\sqrt{\lambda}(\underline{a}-x)} & 0\\ 0 & e^{-i\sqrt{\lambda}x}\end{pmatrix}S_2(\lambda)\begin{pmatrix}C_2\\ 0\end{pmatrix}.$$

We now require that $\Phi_1(x,\lambda;C_1)$ and $\Phi_2^{(a)}(x,\lambda;C_2)$ agree on the lines labeled by $\mathcal{I}_{12}$. This will fix C_1 and C_2. Indeed, we then obtain

$$e^{-i\sqrt{\lambda}x}C_1+e^{i\sqrt{\lambda}x}S_1^{p\times(n_1-p)}(\lambda)+e^{i\sqrt{\lambda}x}S_1^{p\times p}(\lambda)C_1=e^{-i\sqrt{\lambda}(\underline{a}-x)}C_2+e^{i\sqrt{\lambda}(\underline{a}-x)}S_2^{p\times p}(\lambda)C_2.$$

By the linear independence of the functions $e^{i\sqrt{\lambda}x}$ and $e^{-i\sqrt{\lambda}x}$ it follows that

$$\begin{aligned} C_1 &= e^{i\sqrt{\lambda}\underline{a}} S_2^{p\times p}(\lambda) C_2, \\ S_1^{p\times p}(\lambda) C_1 + S_1^{p\times(n_1-p)}(\lambda) &= e^{-i\sqrt{\lambda}\underline{a}} C_2, \end{aligned} \tag{4.7}$$

and thus

$$\begin{aligned} C_2 &= [\mathbb{I} - e^{i\sqrt{\lambda}\underline{a}} S_1^{p\times p}(\lambda) e^{i\sqrt{\lambda}\underline{a}} S_2^{p\times p}(\lambda)]^{-1} e^{i\sqrt{\lambda}\underline{a}} S_1^{p\times(n_1-p)}(\lambda), \\ C_1 &= e^{i\sqrt{\lambda}\underline{a}} S_2^{p\times p}(\lambda) [\mathbb{I} - e^{i\sqrt{\lambda}\underline{a}} S_1^{p\times p}(\lambda) e^{i\sqrt{\lambda}\underline{a}} S_2^{p\times p}(\lambda)]^{-1} e^{i\sqrt{\lambda}\underline{a}} S_1^{p\times(n_i-p)}(\lambda). \end{aligned} \tag{4.8}$$

Since for any invertible A and U the identities $UA^{-1} = (AU^{-1})^{-1}$ and $A^{-1}U = (U^{-1}A)^{-1}$ hold, we have

$$\begin{aligned} [\mathbb{I} - e^{i\sqrt{\lambda}\underline{a}} S_1^{p\times p}(\lambda) e^{i\sqrt{\lambda}\underline{a}} S_2^{p\times p}(\lambda)]^{-1} e^{i\sqrt{\lambda}\underline{a}} &= [e^{-i\sqrt{\lambda}\underline{a}} - S_1^{p\times p}(\lambda) e^{i\sqrt{\lambda}\underline{a}} S_2^{p\times p}(\lambda)]^{-1} \\ &= e^{i\sqrt{\lambda}\underline{a}} [\mathbb{I} - S_1^{p\times p}(\lambda) e^{i\sqrt{\lambda}\underline{a}} S_2^{p\times p}(\lambda) e^{i\sqrt{\lambda}\underline{a}}]^{-1}. \end{aligned}$$

Since $S_1(\lambda)$ is assumed to be compatible with $V(\underline{a}) S_2(\lambda) V(\underline{a})$ the inverses in (4.8) are well defined.

Similar to (4.5) and according to the ordering convention made previously we write the scattering matrix $S(\lambda)$ for the graph Γ in the block form

$$S(\lambda) = \begin{pmatrix} S^{(n_1-p)\times(n_1-p)}(\lambda) & S^{(n_1-p)\times(n_2-p)}(\lambda) \\ S^{(n_2-p)\times(n_1-p)}(\lambda) & S^{(n_2-p)\times(n_2-p)}(\lambda) \end{pmatrix},$$

where the superscripts denote again the sizes of the blocks. Since $\Phi_1(x,\lambda;C_1)$ has an incoming plane wave in any of the first n_1-p channels $k \in \mathcal{E}_1 \backslash \mathcal{E}_1^0$, Eqs. (4.8) allow one to determine $S^{(n_1-p)\times(n_1-p)}(\lambda)$ and $S^{(n_1-p)\times(n_2-p)}(\lambda)$:

$$\begin{aligned} S^{(n_1-p)\times(n_1-p)}(\lambda) &= S_1^{(n_1-p)\times(n_1-p)}(\lambda) + S_1^{(n_1-p)\times p}(\lambda) C_1 \\ &= S_1^{(n_1-p)\times(n_1-p)}(\lambda) + S_1^{(n_1-p)\times p}(\lambda) e^{i\sqrt{\lambda}\underline{a}} S_2^{p\times p}(\lambda) \\ &\quad \times e^{i\sqrt{\lambda}\underline{a}} \cdot [\mathbb{I} - S_1^{p\times p}(\lambda) e^{i\sqrt{\lambda}\underline{a}} S_2^{p\times p}(\lambda) e^{i\sqrt{\lambda}\underline{a}}]^{-1} S_1^{p\times(n_1-p)}(\lambda), \end{aligned}$$

$$\begin{aligned} S^{(n_2-p)\times(n_1-p)}(\lambda) &= S_2^{(n_2-p)\times p}(\lambda) C_2 \\ &= S_2^{(n_2-p)\times p}(\lambda) e^{i\sqrt{\lambda}\underline{a}} \cdot [\mathbb{I} - S_1^{p\times p}(\lambda) e^{i\sqrt{\lambda}\underline{a}} S_2^{p\times p}(\lambda) e^{i\sqrt{\lambda}\underline{a}}]^{-1} S_1^{p\times(n_1-p)}(\lambda). \end{aligned}$$

To determine the remaining blocks of the scattering matrix $S(\lambda)$ instead of (4.6) we consider the $n_1\times(n_2-p)$ and $n_2\times(n_2-p)$ matrices

$$\begin{aligned} \tilde{\Phi}_1(x,\lambda;\tilde{C}_1) &= e^{-i\sqrt{\lambda}x} \begin{pmatrix} 0 \\ \tilde{C}_1 \end{pmatrix} + e^{i\sqrt{\lambda}x} S_1(\lambda) \begin{pmatrix} 0 \\ \tilde{C}_1 \end{pmatrix}, \\ \tilde{\Phi}_2(x,\lambda;\tilde{C}_2) &= e^{-i\sqrt{\lambda}x} \begin{pmatrix} \tilde{C}_2 \\ \mathbb{I} \end{pmatrix} + e^{i\sqrt{\lambda}x} S_2(\lambda) \begin{pmatrix} \tilde{C}_2 \\ \mathbb{I} \end{pmatrix}, \end{aligned} \tag{4.9}$$

with arbitrary $p\times(n_2-p)$ matrices $\tilde{C}_1$ and $\tilde{C}_2$. Again $\tilde{\Phi}_l(x,\lambda;\tilde{C}_l)$ are the external parts of some solutions of the Schrödinger equations with the operators $-\Delta(\Gamma_l)$, $l=1,2$. Now $\tilde{\Phi}_1(x,\lambda;\tilde{C}_1)$ has no incoming plane waves in the channels $k\in\mathcal{E}_1\setminus\mathcal{E}_1^0$, but $\tilde{\Phi}_2(x,\lambda;\tilde{C}_2)$ has an incoming plane wave in any of the channels $k\in\mathcal{E}_2\setminus\mathcal{E}_2^0$.

Repeating the arguments used above we obtain the following matching conditions for $\tilde{C}_1$ and $\tilde{C}_2$:

$$\begin{aligned}\tilde{C}_2&=e^{i\sqrt{\lambda}\underline{a}}S_1^{p\times p}\tilde{C}_1,\\ S_2^{p\times p}(\lambda)\tilde{C}_2+S_2^{p\times(n_2-p)}(\lambda)&=e^{-i\sqrt{\lambda}\underline{a}}\tilde{C}_1,\end{aligned}\tag{4.10}$$

and thus

$$\tilde{C}_1=[\mathbb{I}-e^{i\sqrt{\lambda}\underline{a}}S_2^{p\times p}(\lambda)e^{i\sqrt{\lambda}\underline{a}}S_1^{p\times p}(\lambda)]^{-1}e^{i\sqrt{\lambda}\underline{a}}S_2^{p\times(n_2-p)}(\lambda),$$

$$\tilde{C}_2=e^{i\sqrt{\lambda}\underline{a}}S_1^{p\times p}(\lambda)[\mathbb{I}-e^{i\sqrt{\lambda}\underline{a}}S_2^{p\times p}(\lambda)e^{i\sqrt{\lambda}\underline{a}}S_1^{p\times p}(\lambda)]^{-1}e^{i\sqrt{\lambda}\underline{a}}S_2^{p\times(n_2-p)}(\lambda).$$

Since $S_1(\lambda)$ is compatible with $V(\underline{a})S_2(\lambda)V(\underline{a})$ the inverses are again well defined. From this and from (4.9) it follows that

$$\begin{aligned}S^{(n_2-p)\times(n_2-p)}(\lambda)&=S_2^{(n_2-p)\times(n_2-p)}(\lambda)+S_2^{(n_2-p)\times p}(\lambda)\tilde{C}_2\\&=S_2^{(n_2-p)\times(n_2-p)}(\lambda)+S_2^{(n_2-p)\times p}(\lambda)e^{i\sqrt{\lambda}\underline{a}}S_1^{p\times p}(\lambda)\\&\quad\cdot[\mathbb{I}-e^{i\sqrt{\lambda}\underline{a}}S_2^{p\times p}(\lambda)e^{i\sqrt{\lambda}\underline{a}}S_1^{p\times p}(\lambda)]^{-1}e^{i\sqrt{\lambda}\underline{a}}S_2^{p\times(n_2-p)}(\lambda),\end{aligned}$$

$$\begin{aligned}S^{(n_1-p)\times(n_2-p)}(\lambda)&=S_1^{(n_1-p)\times p}(\lambda)\tilde{C}_1\\&=S_1^{(n_1-p)\times p}(\lambda)\cdot[\mathbb{I}-e^{i\sqrt{\lambda}\underline{a}}S_2^{p\times p}(\lambda)e^{i\sqrt{\lambda}\underline{a}}S_1^{p\times p}(\lambda)]^{-1}e^{i\sqrt{\lambda}\underline{a}}S_2^{p\times(n_2-p)}(\lambda).\end{aligned}$$

By the definition of the generalized star product (3.4) we obtain (4.2).

(2) Now suppose that $\lambda\in\Xi(\Gamma_1,\Gamma_2)$. We prove that the composition rule (4.2) remains valid. Also $\lambda\in\Upsilon(\Gamma,\mathcal{I}_{12})$ and the multiplicity of λ equals

$$\dim\mathrm{Ker}(-\Delta(\Gamma_1)-\lambda)+\dim\ker(-\Delta(\Gamma_2)-\lambda)+\dim\mathrm{Ker}(V(\underline{a})S_{22}^{(1)}(\lambda)V(\underline{a})S_{11}^{(2)}(\lambda)-1).\tag{4.11}$$

The assumption $\lambda\in\Xi(\Gamma_1,\Gamma_2)$ implies that

$$\mathbb{I}-S_1^{p\times p}(\lambda)e^{i\sqrt{\lambda}\underline{a}}S_2^{p\times p}(\lambda)e^{i\sqrt{\lambda}\underline{a}}$$

and

$$\mathbb{I}-e^{i\sqrt{\lambda}\underline{a}}S_2^{p\times p}(\lambda)e^{i\sqrt{\lambda}\underline{a}}S_1^{p\times p}(\lambda)$$

have nontrivial kernels. This implies that the homogeneous form of the equations (4.7) and (4.10),

$$\begin{aligned}C_1&=e^{i\sqrt{\lambda}\underline{a}}S_2^{p\times p}(\lambda)C_2,\\S_1^{p\times p}(\lambda)C_1&=e^{-i\sqrt{\lambda}\underline{a}}C_2,\end{aligned}\tag{4.12}$$

and

$$\begin{aligned}\widetilde{C}_2 &= e^{i\sqrt{\lambda}\underline{a}} S_1^{p\times p}(\lambda)\widetilde{C}_1,\\ S_2^{p\times p}(\lambda)\widetilde{C}_2 &= e^{-i\sqrt{\lambda}\underline{a}}\widetilde{C}_1,\end{aligned} \tag{4.13}$$

respectively, have nontrivial solutions. It is easy to prove that the inhomogeneous equations (4.7) and (4.10) still have solutions in this case. Consider, for instance, the equation (4.7), which is equivalent to

$$C_2 = e^{i\sqrt{\lambda}\underline{a}} S_1^{p\times(n_1-p)}(\lambda) + e^{i\sqrt{\lambda}\underline{a}} S_1^{p\times p}(\lambda) e^{i\sqrt{\lambda}\underline{a}} S_2^{p\times p}(\lambda) C_2.$$

By the Fredholm alternative this equation has a nontrivial solution iff

$$S_1^{p\times(n_1-p)}(\lambda)^* e^{-i\sqrt{\lambda}\underline{a}} b = 0 \tag{4.14}$$

for any $0 \neq b \in \mathbb{C}^p$ satisfying

$$S_2^{p\times p}(\lambda)^* e^{-i\sqrt{\lambda}\underline{a}} S_1^{p\times p}(\lambda)^* e^{-i\sqrt{\lambda}\underline{a}} b = b.$$

By Lemma III.3 with $A = S_2^{p\times p}(\lambda)^*$ and $B = e^{-i\sqrt{\lambda}\underline{a}} S_1^{p\times p}(\lambda)^* e^{-i\sqrt{\lambda}\underline{a}}$ we have

$$e^{i\sqrt{\lambda}\underline{a}} S_1^{p\times p}(\lambda) S_1^{p\times p}(\lambda)^* e^{-i\sqrt{\lambda}\underline{a}} b = b. \tag{4.15}$$

From the unitarity of $V(\underline{a})S_1(\lambda)V(\underline{a})$, which states in particular that

$$e^{i\sqrt{\lambda}\underline{a}} S_1^{p\times p}(\lambda) S_1^{p\times p}(\lambda)^* e^{-i\sqrt{\lambda}\underline{a}} + e^{i\sqrt{\lambda}\underline{a}} S_1^{p\times(n_1-p)}(\lambda) S_1^{p\times(n_1-p)}(\lambda)^* e^{-i\sqrt{\lambda}\underline{a}} = \mathbb{I},$$

and from (4.15) it follows that

$$e^{i\sqrt{\lambda}\underline{a}} S_1^{p\times(n_1-p)}(\lambda) S_1^{p\times(n_1-p)}(\lambda)^* e^{-i\sqrt{\lambda}\underline{a}} b = 0.$$

Since $\operatorname{Ker} C^*C = \operatorname{Ker} C$ for any operator C we obtain (4.14). Equation (4.10) is discussed similarly.

From (4.6) and (4.9) it follows that the Schrödinger equation with the operator $-\Delta(\Gamma)$ for given value of the spectral parameter $\lambda > 0$ has (nonunique) solutions which have the form

$$\begin{aligned}\Phi_1(x,\lambda;C_1) &= e^{-i\sqrt{\lambda}x}\begin{pmatrix}0\\ C_1\end{pmatrix} + e^{i\sqrt{\lambda}x} S_1(\lambda)\begin{pmatrix}0\\ C_1\end{pmatrix},\\ \Phi_2(x,\lambda;C_2) &= e^{-i\sqrt{\lambda}x}\begin{pmatrix}C_2\\ 0\end{pmatrix} + e^{i\sqrt{\lambda}x} S_2(\lambda)\begin{pmatrix}C_2\\ 0\end{pmatrix},\end{aligned} \tag{4.16}$$

and

$$\begin{aligned}\widetilde{\Phi}_1(x,\lambda;\widetilde{C}_1) &= e^{-i\sqrt{\lambda}x}\begin{pmatrix}0\\ \widetilde{C}_1\end{pmatrix} + e^{i\sqrt{\lambda}x} S_1(\lambda)\begin{pmatrix}0\\ \widetilde{C}_1\end{pmatrix},\\ \widetilde{\Phi}_2(x,\lambda;\widetilde{C}_2) &= e^{-i\sqrt{\lambda}x}\begin{pmatrix}\widetilde{C}_2\\ 0\end{pmatrix} + e^{i\sqrt{\lambda}x} S_2(\lambda)\begin{pmatrix}\widetilde{C}_2\\ 0\end{pmatrix},\end{aligned} \tag{4.17}$$

where C_1 and C_2 ($\widetilde{C}_1$ and $\widetilde{C}_2$) solve (4.12) [(4.13), respectively]. Note that $C_1 = \widetilde{C}_1$ and $C_2 = \widetilde{C}_2$. On the lines in the set $\mathcal{I}_{12}$ the quantity Φ_1 coincides with Φ_2 and $\widetilde{\Phi}_1$ and $\widetilde{\Phi}_2$. We will now prove that

$$S_1^{(n_1-p)\times p}(\lambda)C_1=0, \quad S_2^{(n_2-p)\times p}(\lambda)C_2=0. \tag{4.18}$$

Thus, the functions (4.16) and (4.17) are zero on all external lines of the graph Γ and their support has nontrivial overlap with the interval lines $\mathcal{I}_{12}$.

From (4.12) it follows that $C_1=e^{i\sqrt{\lambda}a}S_2^{p\times p}(\lambda)e^{i\sqrt{\lambda}a}S_1^{p\times p}(\lambda)C_1$. By Lemma III.3 we have

$$S_1^{p\times p}(\lambda)*S_1^{p\times p}(\lambda)C_1=C_1.$$

By unitarity it follows that

$$S_1^{(n_1-p)\times p}(\lambda)*S_1^{(n_1-p)\times p}(\lambda)C_1=0$$

and thus $S_1^{(n_1-p)\times p}(\lambda)C_1=0$. The second relation in (4.18) is proved similarly.

Now we note that from (4.12) and (4.13) it follows that

$$\text{Rank } C_1=\text{Rank } C_2= \dim \text{Ker}(e^{i\sqrt{\lambda}a}S_2^{p\times p}(\lambda)e^{i\sqrt{\lambda}a}S_1^{p\times p}(\lambda)-1).$$

The columns of (4.16) correspond to linear-independent eigenfunctions of $-\Delta(\Gamma)$ for the eigenvalue λ. There are precisely $\dim \text{Ker}(e^{i\sqrt{\lambda}a}S_2^{p\times p}(\lambda)e^{i\sqrt{\lambda}a}S_1^{p\times p}(\lambda)-1)$ such eigenfunctions and the supports of all of them have nontrivial overlap with the internal lines $\mathcal{I}_{12}$.

(3) Let $\lambda\in\Upsilon(\Gamma,\mathcal{I}_{12})\cap\mathbb{R}_+$ and let

$$\dim(\text{Ker } Z_{A,B,a}(\lambda)\ominus\mathcal{L}_{12}(\lambda))=k, \tag{4.19}$$

where the linear subspace $\mathcal{L}_{12}(\lambda)$ is defined by (4.1). This means that there are precisely k eigenfunctions of $-\Delta(\Gamma)$ which disappear if we cut the internal lines $\mathcal{I}_{12}$. We will prove that $\lambda\in\Xi(\Gamma_1,\Gamma_2)$ and that

$$\dim \text{Ker}(V(a)S_{22}^{(1)}(\lambda)V(a)S_{11}^{(2)}(\lambda)-1)=k, \tag{4.20}$$

which in turn implies that

$$\begin{aligned}\dim \text{Ker}(-\Delta(\Gamma)-\lambda)&=\dim \text{Ker}(-\Delta(\Gamma_1)-\lambda)+\dim \text{Ker}(-\Delta(\Gamma_2)-\lambda)\\&\quad+\dim \text{Ker}(V(a)S_{22}^{(1)}(\lambda)V(a)S_{11}^{(2)}(\lambda)-1).\end{aligned}$$

From the existence of the above-mentioned eigenfunctions it follows that these eigenfunctions can be constructed by means of superposition and matching of the solutions (4.4) of the Schrödinger equation for the operators $-\Delta(\Gamma_1)$ and $-\Delta(\Gamma_2)$ at energy $\lambda>0$. For any vectors $C_1,C_2\in\mathbb{C}^p$ the functions

$$\phi_1(x,\lambda,C_1)=e^{-i\sqrt{\lambda}x}\begin{pmatrix}0\\C_1\end{pmatrix}+e^{i\sqrt{\lambda}x}S_1(\lambda)\begin{pmatrix}0\\C_1\end{pmatrix},$$

$$\phi_2(x,\lambda,C_2)=e^{-i\sqrt{\lambda}x}\begin{pmatrix}C_2\\0\end{pmatrix}+e^{i\sqrt{\lambda}x}S_2(\lambda)\begin{pmatrix}C_2\\0\end{pmatrix},$$

define the external parts of solutions of the Schrödinger equations for the operators $-\Delta(\Gamma_l)$, $l=1,2$. Since the eigenfunctions are supported on internal lines of the graph Γ (Theorem II.1) the vectors C_1 and C_2 must satisfy

$$S_1^{(n_1-p)\times p}(\lambda)C_1=0, \quad S_2^{p\times(n_2-p)}(\lambda)C_2=0$$

FIG. 2. The graph from Example IV.2.

such that $\phi_1(x,\lambda,C_1)$ vanishes in any of the channels $k\in\mathcal{E}_1\backslash\mathcal{E}_1^0$ and $\phi_2(x,\lambda,C_2)$ vanishes in all channels $k\in\mathcal{E}_2\backslash\mathcal{E}_2^0$. Making the coordinate transformation $x\to\underline{a}-x$ on the lines $\varphi_0(k)\in\mathcal{E}_2^0(k\in\mathcal{E}_1^0)$ and requiring that $\phi_1(x,\lambda,C_1)$ and $\phi_2(\underline{a}-x,\lambda,C_2)$ agree on the lines labeled by $\mathcal{I}_{12}$, we obtain

$$C_1=e^{i\sqrt{\lambda}\underline{a}}S_2^{p\times p}(\lambda)C_2,$$

$$S_1^{p\times p}(\lambda)C_1=e^{-i\sqrt{\lambda}\underline{a}}C_2,$$

or equivalently

$$\begin{aligned} e^{i\sqrt{\lambda}\underline{a}}S_2^{p\times p}(\lambda)e^{i\sqrt{\lambda}\underline{a}}S_1^{p\times p}(\lambda)C_1&=C_1,\\ C_2&=e^{i\sqrt{\lambda}\underline{a}}S_1^{p\times p}(\lambda)C_1. \end{aligned} \tag{4.21}$$

Linear-independent solutions of (4.21) correspond to linear-independent eigenfunctions of $-\Delta(\Gamma)$ and vise versa. Thus the condition (4.19) implies (4.20). This completes the proof of the theorem. □

Note that if Γ is simply the disjoint union of Γ_1 and Γ_2, i.e., if no connections are made (corresponding to $p=0$ and $n=n_1+n_2$), then $S(\lambda)$ is just the direct sum of $S_1(\lambda)$ and $S_2(\lambda)$. Also $V^*S(\lambda)V=S_{2n}^{\text{free}}(\lambda)*_V S(\lambda)$ for any scattering matrix with n open ends and any unitary $n\times n$ matrix V, where

$$S_{2n}^{\text{free}}(\lambda)=\begin{pmatrix}0 & \mathbb{I}\\ \mathbb{I} & 0\end{pmatrix}.$$

Similarly $S(\lambda)*_V S_{2n}^{\text{free}}(\lambda)=VS(\lambda)V^*$.

Example IV.2: Consider an arbitrary self-adjoint Laplacian $\Delta(A,B)$ with local boundary conditions on the graph depicted in Fig. 2, where the distance between the two vertices is a. The composition rule (4.2) with

$$V(a)=\begin{pmatrix}e^{i\sqrt{\lambda}a} & 0\\ 0 & 1\end{pmatrix}.$$

easily gives

$$\begin{aligned} S_{11}&=S_{11}^{(1)}+S_{12}^{(1)}S_{11}^{(2)}S_{21}^{(1)}(1-S_{22}^{(1)}S_{11}^{(2)}e^{2ia\sqrt{\lambda}})^{-1},\\ S_{22}&=S_{22}^{(2)}+S_{22}^{(1)}S_{21}^{(2)}S_{12}^{(2)}(1-S_{22}^{(1)}S_{11}^{(2)}e^{2ia\sqrt{\lambda}})^{-1},\\ S_{12}&=S_{12}^{(1)}S_{12}^{(2)}(1-S_{22}^{(1)}S_{11}^{(2)}e^{2ia\sqrt{\lambda}})^{-1},\\ S_{21}&=S_{21}^{(2)}S_{21}^{(1)}(1-S_{22}^{(1)}S_{11}^{(2)}e^{2ia\sqrt{\lambda}})^{-1}, \end{aligned} \tag{4.22}$$

where the S-matrices are written in the form analogous to (3.1)

$$S^{(1)}=\begin{pmatrix}S_{11}^{(2)} & S_{12}^{(1)}\\ S_{21}^{(1)} & S_{22}^{(1)}\end{pmatrix},\quad S^{(2)}=\begin{pmatrix}S_{11}^{(2)} & S_{12}^{(2)}\\ S_{21}^{(2)} & S_{22}^{(2)}\end{pmatrix},$$

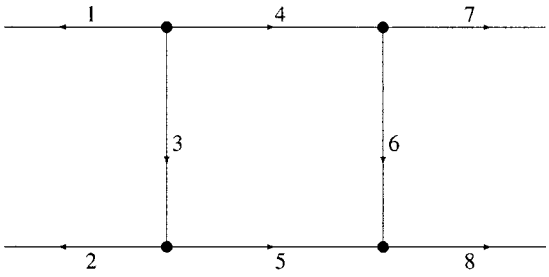

FIG. 3. The graph from Example IV.3. The arrows show the positive direction for every edge. The edges 3 and 6 have the length *a* and the edges 4 and 5 the length *b*.

leaving out the λ *dependence. These relations are equivalent to the well-known factorization formula*[2–4,1,5–7] *applied to the Laplacian on a line with boundary conditions posed at* $x=0$ *and* $x=a$.

Example IV.3: Consider the graph depicted in Fig. 3 where the length of the edges 3 and 6 equals a and the length of the edges 4 and 5 equals b. Let the boundary conditions be given as

$$\begin{aligned}
&\psi_1(0)=\psi_3(0)=\psi_4(0),\\
&\psi_2(0)=\psi_3(a)=\psi_5(0),\\
&\psi_1'(0)+\psi_3'(0)+\psi_4'(0)=0,\\
&\psi_2'(0)+\psi_5'(0)-\psi_3'(a)=0,\\
&\psi_4(b)=\psi_6(0)=\psi_7(0),\\
&\psi_5(b)=\psi_6(a)=\psi_8(0),\\
&-\psi_4'(b)+\psi_6'(0)+\psi_7'(0)=0,\\
&-\psi_5'(b)-\psi_6'(a)+\psi_8'(0)=0.
\end{aligned} \tag{4.23}$$

Obviously they define a self-adjoint operator which we denote by $\Delta(a,b)$. *The scattering matrix corresponding to this operator [as defined by (2.3) and (2.4)] will be denoted by* $S_{a,b}(\lambda)$. *To determine this* 4×4 *matrix we first consider the graph depicted in Fig. 4 where the length of the edge 3 is supposed to be equal a. The boundary conditions (4.23) determine the self-adjoint operator. The corresponding scattering matrix we denote by* $S_a(\lambda)$. *From (2.7) it follows that*

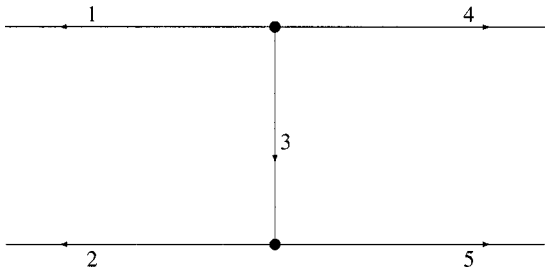

FIG. 4. The graph from Example IV.3. The arrows show the positive direction for every edge.

$$S_a(\lambda)=(e^{i\sqrt{\lambda}a}-9e^{-i\sqrt{\lambda}a})^{-1}$$
$$\times\begin{pmatrix} e^{i\sqrt{\lambda}a}+3e^{-i\sqrt{\lambda}a} & -4 & 2(e^{i\sqrt{\lambda}a}-3e^{-i\sqrt{\lambda}a}) & -4 \\ -4 & e^{i\sqrt{\lambda}a}+3e^{-i\sqrt{\lambda}a} & -4 & 2(e^{i\sqrt{\lambda}a}-3e^{-i\sqrt{\lambda}a}) \\ 2(e^{i\sqrt{\lambda}a}-3e^{-i\sqrt{\lambda}a}) & -4 & e^{i\sqrt{\lambda}a}+3e^{-i\sqrt{\lambda}a} & -4 \\ -4 & 2(e^{i\sqrt{\lambda}a}-3e^{-i\sqrt{\lambda}a}) & -4 & e^{i\sqrt{\lambda}a}+3e^{-i\sqrt{\lambda}a} \end{pmatrix}. \tag{4.24}$$

By Theorem IV.1 the scattering matrix $S_{a,b}(\lambda)$ is given by

$$S_{a,b}(\lambda)=S_a(\lambda)*_2V(\underline{b})S_a(\lambda)V(\underline{b}), \tag{4.25}$$

where

$$V(\underline{b})=\mathrm{diag}(e^{i\sqrt{\lambda}b},e^{i\sqrt{\lambda}b},1,1),\quad \underline{b}=(b,b)\in\mathbb{R}^2.$$

We now compute the 2×2 matrices K_1 and K_2 entering the definition (3.4) *of the generalized star product, thus obtaining*

$$K_1^{-1}=K_2^{-1}=(e^{i\sqrt{\lambda}a}-9e^{-i\sqrt{\lambda}a})^{-2}L,$$

$$(L)_{11}=(L)_{22}=e^{2i\sqrt{\lambda}a}(1-e^{2i\sqrt{\lambda}b})+9e^{-2i\sqrt{\lambda}a}(9-e^{2i\sqrt{\lambda}b})-2(9+11e^{2i\sqrt{\lambda}b}),$$

$$(L)_{12}=(L)_{21}=8e^{2i\sqrt{\lambda}b}(e^{i\sqrt{\lambda}a}+3e^{-i\sqrt{\lambda}a}).$$

From this it follows that

$$\det K_1^{-1}=\det K_2^{-1}=(e^{i\sqrt{\lambda}a}-9e^{-i\sqrt{\lambda}a})^{-4}\cdot e^{-4i\sqrt{\lambda}a}[\xi(\xi\eta^2-64)(\xi-8)^2$$
$$+16\eta(-256-128\xi+44\xi^2-3\xi^3)],$$

where $\xi=\exp\{2i\sqrt{\lambda}a\}-1$ and $\eta=\exp\{2i\sqrt{\lambda}b\}-1$. Obviously these determinants vanish if $e^{2i\sqrt{\lambda}a}=e^{2i\sqrt{\lambda}b}=1$. One can show that there are no other zeros. Note that the embedded eigenvalues of the operator $-\Delta(a,b)$ are determined by the equation $e^{2i\sqrt{\lambda}a}=e^{2i\sqrt{\lambda}b}=1$ such that for incommensurable a and b there are no embedded eigenvalues.

For $e^{2i\sqrt{\lambda}a}=e^{2i\sqrt{\lambda}b}=1$ the matrix $S_a(\lambda)$ is not compatible with $V(\underline{b})S_a(\lambda)V(\underline{b})$ and

$$K_1^{-1}=K_2^{-1}=\frac{1}{2}\begin{pmatrix} 1 & \pm1 \\ \pm1 & 1 \end{pmatrix},$$

where ±1 corresponds to $\exp\{i\sqrt{\lambda}a\}=\pm1$. Obviously $\mathrm{Ker}\,K_1^{-1}=\mathrm{Ker}\,K_2^{-1}$ is the subspace spanned by the vector $(1,\mp1)^T$. Further,

$$(S_a(\lambda))_{12}\begin{pmatrix} 1 \\ \mp1 \end{pmatrix}=\frac{1}{2}\begin{pmatrix} 1 & \pm1 \\ \pm1 & 1 \end{pmatrix}\begin{pmatrix} 1 \\ \mp1 \end{pmatrix}=0$$

and

$$V(\underline{b})S_a(\lambda)V(\underline{b}))_{12}\begin{pmatrix} 1 \\ \mp1 \end{pmatrix}=\frac{1}{2}e^{i\sqrt{\lambda}b}\begin{pmatrix} 1 & \pm1 \\ \pm1 & 1 \end{pmatrix}\begin{pmatrix} 1 \\ \mp1 \end{pmatrix}=0.$$

Thus, as proved in Sec. III, the generalized star product is well defined also in the case when the matrix $S_a(\lambda)$ is not compatible with $V(\underline{b})S_a(\lambda)V(\underline{b})$.

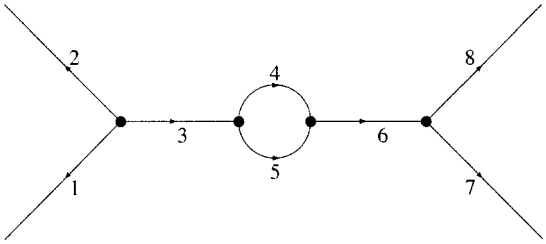

FIG. 5. The graph from Example IV.3. The arrows show the positive direction for every edge. The edges 3 and 6 have the length a and the edges 4 and 5 the length b.

Example IV.4: Consider the graph depicted in Fig. 5 where the length of the edges 3 and 6 equals a and the length of the edges 4 and 5 equals b. Let the boundary conditions be given by

$$\psi_1(0)=\psi_2(0)=\psi_3(0),$$

$$\psi_4(0)=\psi_5(0)=\psi_3(a),$$

$$\psi_1'(0)+\psi_2'(0)+\psi_3'(0)=0,$$

$$\psi_4'(0)+\psi_5'(0)-\psi_3'(a)=0,$$

$$\psi_4(b)=\psi_5(b)=\psi_6(0),$$

$$\psi_6(a)=\psi_7(0)=\psi_8(0),$$

$$-\psi_4'(b)-\psi_5'(b)+\psi_6'(0)=0,$$

$$-\psi_6'(a)+\psi_7'(0)+\psi_8'(0)=0.$$

Obviously they define a self-adjoint operator which we denote by $\Delta(a,b)$. The scattering matrix corresponding to this operator [as defined by (2.3) and (2.4)] will be denoted by $S_{a,b}(\lambda)$. To determine this 4×4 matrix we first consider the graph depicted in Fig. 4 where the length of the edge 3 is supposed to be equal a. The boundary conditions (4.23) determine the self-adjoint operator. The corresponding scattering matrix $S_a(\lambda)$ can be obtained from (4.24) by means of the permutation of its lines and columns thus giving

$$S_a(\lambda)=(e^{i\sqrt{\lambda}a}-9e^{-i\sqrt{\lambda}a})^{-1}$$
$$\times\begin{pmatrix} e^{i\sqrt{\lambda}a}+3e^{-i\sqrt{\lambda}a} & 2(e^{i\sqrt{\lambda}a}-3e^{-i\sqrt{\lambda}a}) & -4 & -4 \\ 2(e^{i\sqrt{\lambda}a}-3e^{-i\sqrt{\lambda}a}) & e^{i\sqrt{\lambda}a}+3e^{-i\sqrt{\lambda}a} & -4 & -4 \\ -4 & -4 & e^{i\sqrt{\lambda}a}+3e^{-i\sqrt{\lambda}a} & 2(e^{i\sqrt{\lambda}a}-3e^{-i\sqrt{\lambda}a}) \\ -4 & -4 & 2(e^{i\sqrt{\lambda}a}-3e^{-i\sqrt{\lambda}a}) & e^{i\sqrt{\lambda}a}+3e^{-i\sqrt{\lambda}a} \end{pmatrix}.$$

By Theorem IV.1 the scattering matrix $S_{a,b}(\lambda)$ is given by

$$S_{a,b}(\lambda)=S_a(\lambda)*_2V(\underline{b})S_a(\lambda)V(\underline{b}), \tag{4.26}$$

where

$$V(\underline{b})=\mathrm{diag}(e^{i\sqrt{\lambda}b},e^{i\sqrt{\lambda}b},1,1), \quad \underline{b}=(b,b).$$

We now compute the 2×2 *matrices* K_1 and K_2 *entering the definition* (3.4) *of the generalized star product, thus obtaining*

$$K_1^{-1}=K_2^{-1}=(e^{i\sqrt{\lambda}a}-9e^{-i\sqrt{\lambda}a})^2L,$$

$$(L)_{11}=(L)_{22}=e^{2i\sqrt{\lambda}a}(1-5e^{2i\sqrt{\lambda}b})+9e^{-2i\sqrt{\lambda}a}(9-5e^{2i\sqrt{\lambda}b})-18(1-e^{2i\sqrt{\lambda}}),$$

$$(L)_{12}=(L)_{21}=-4e^{2i\sqrt{\lambda}b}(e^{2i\sqrt{\lambda}a}-9e^{-2i\sqrt{\lambda}a}).$$

From this it follows that

$$\begin{aligned}\det K_1^{-1}=\det K_2^{-1}=(e^{i\sqrt{\lambda}a}-9e^{-i\sqrt{\lambda}a})^{-4}[&e^{4i\sqrt{\lambda}a}(1-10e^{2i\sqrt{\lambda}b}+9e^{4i\sqrt{\lambda}b})\\&+9^3e^{-4i\sqrt{\lambda}a}(9-10e^{2i\sqrt{\lambda}b}+e^{4i\sqrt{\lambda}b})-36e^{2i\sqrt{\lambda}a}(1-6e^{2i\sqrt{\lambda}b}+5e^{4i\sqrt{\lambda}b})\\&-18^2e^{-2i\sqrt{\lambda}a}(9-14e^{2i\sqrt{\lambda}b}+5e^{4i\sqrt{\lambda}b})+18(27-86e^{2i\sqrt{\lambda}b}+59e^{4i\sqrt{\lambda}b})].\end{aligned}$$

Obviously these determinants vanish if $e^{2i\sqrt{\lambda}b}=1$. *One can show that there are no other zeros. Note that the embedded eigenvalues of the operator* $-\Delta(a,b)$ *are determined by the equation* $e^{2i\sqrt{\lambda}b}=1$.

For $e^{2i\sqrt{\lambda}b}=1$ *the matrices* $S_a(\lambda)$ *and* $V(\underline{b})S_a(\lambda)V(\underline{b})$ *are not compatible and*

$$K_1^{-1}=K_2^{-1}=-4\,\frac{e^{2i\sqrt{\lambda}a}-9e^{-2i\sqrt{\lambda}a}}{(e^{i\sqrt{\lambda}a}-9e^{-i\sqrt{\lambda}a})^2}\begin{pmatrix}1&1\\1&1\end{pmatrix}.$$

Obviously $\operatorname{Ker}K_1^{-1}=\operatorname{Ker}K_2^{-1}$ *is the subspace spanned by the vector* $(1,-1)^T$. *Further,*

$$(S_a(\lambda))_{12}\begin{pmatrix}1\\-1\end{pmatrix}=-4\begin{pmatrix}1&1\\1&1\end{pmatrix}\begin{pmatrix}1\\-1\end{pmatrix}=0$$

and

$$(V(\underline{b})S_a(\lambda)V(\underline{b}))_{12}\begin{pmatrix}1\\-1\end{pmatrix}=-4e^{i\sqrt{\lambda}b}\begin{pmatrix}1&1\\1&1\end{pmatrix}\begin{pmatrix}1\\-1\end{pmatrix}=0.$$

Thus, as proved in Sec. III, the generalized star product is well defined also in the case when the matrices $S_a(\lambda)$ *and* $V(\underline{b})S_a(\lambda)V(\underline{b})$ *are not compatible.*

As already discussed in Ref. 21, multiple application of (4.2) to an arbitrary graph allows one by complete induction on the number of vertices to calculate its scattering matrix from the scattering matrices corresponding to single-vertex graphs. If these single-vertex graphs contain no tadpoles, i.e., internal lines starting and ending at the same vertex, then (4.2) give a complete explicit construction of the scattering matrix in terms of the scattering matrices for single vertex graphs. In the case when a resulting single-vertex graph contains tadpoles we proceed as follows. Let the graph Γ have one vertex, n external lines, and m tadpoles of lengths a_i. To calculate the scattering matrix of Γ we insert an extra vertex on each of the internal lines (for definiteness, say, at $x=a_i/2$). At these new vertices we impose trivial boundary conditions corresponding to continuous differentiability at this point. With these new vertices we may now repeat our previous procedure. Thus in the end we arrive at graphs with one vertex only and no tadpoles.

V. SPECIAL CASE $n_1=n_2=2p$: TRANSFER MATRICES

This section is devoted to the construction of the transfer matrix for Schrödinger operators on graphs with an even number of external lines. The transfer matrix formalism for general Schrödinger operators on the line is well known (see, e.g., Ref. 49). Its relation to the scattering matrix is discussed in, e.g., Refs. 9 and 8.

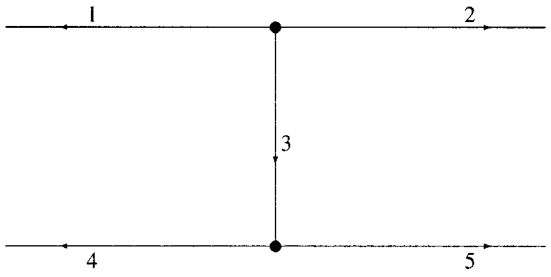

FIG. 6. The same graph as in Fig. 4 but with different ordering of the external lines.

We start with the simplest example of a Laplace operator on the graph with $n=2$ and $m=0$ (see Fig. 6) which is equivalent to a Schrödinger operator on the line with point interaction. The boundary conditions given by the relation

$$\begin{pmatrix} \psi_2(0) \\ \psi_2'(0) \end{pmatrix} = e^{i\mu} \begin{pmatrix} a & b \\ c & d \end{pmatrix} \begin{pmatrix} \psi_1(0) \\ -\psi_1'(0) \end{pmatrix}, \tag{5.1}$$

where the matrix

$$\begin{pmatrix} a & b \\ c & d \end{pmatrix} \in \mathsf{SL}(2,\mathbb{R}),$$

and μ is real, lead to self-adjoint Laplacians (see Refs. 21 and 64–67). Conversely, from the viewpoint of the von Neumann extension theory (see, e.g., Ref. 54) relation (5.1) describes almost all [with respect to the Haar measure on $\mathsf{U}(2)$] self-adjoint Laplacians $\Delta(A,B)$. If $\exp\{2i\mu\}=1$, the operator $\Delta(A,B)$ is real, i.e., commutes with complex conjugation. In particular, the choice $a-1=d-1=b=0$, $\exp\{2i\mu\}=1$ corresponds to the δ-potential of strength c (see, e.g., Ref. 68).

By definition the transfer matrix is a 2×2 matrix $M(\lambda)\in \mathsf{U}(1)\times\mathsf{SL}(2,\mathbb{R})$ satisfying

$$M(\lambda)\begin{pmatrix} \psi_1(0) \\ \psi_1'(0) \end{pmatrix} = \begin{pmatrix} \psi_2(0) \\ -\psi_2'(0) \end{pmatrix}. \tag{5.2}$$

In fact, in the case at hand it is given explicitly as follows:

$$M(\lambda) = e^{i\mu} \begin{pmatrix} a & b \\ c & d \end{pmatrix}$$

If $\exp\{2i\mu\}=1$, the matrix $M(\lambda)$ is unimodular, i.e., $M(\lambda)\in\mathsf{SL}(2;\mathbb{R})$.

The transfer matrix possesses the following equivalent description. Any solution of the Schrödinger equation with the operator $-\Delta(A,B)$ for the energy $\lambda>0$ has the form

$$u_1(x) = a_1 e^{i\sqrt{\lambda}x} + b_1 e^{-i\sqrt{\lambda}x},$$

$$u_2(x) = a_2 e^{i\sqrt{\lambda}x} + b_2 e^{-i\sqrt{\lambda}x}.$$

From this and (5.2) it follows that there is a matrix $\Lambda(\lambda)\in\mathsf{U}(1)\times\mathsf{SU}(1,1)\subset\mathsf{U}(1)\times\mathsf{SL}(2;\mathbb{C})$ (with the inclusion in the group-theoretical sense) such that

$$\Lambda(\lambda)\begin{pmatrix} a_1 \\ b_1 \end{pmatrix} = \begin{pmatrix} b_2 \\ a_2 \end{pmatrix} \tag{5.3}$$

and

$$M(\lambda)=\begin{pmatrix} 1 & 1 \\ i\sqrt{\lambda} & -i\sqrt{\lambda} \end{pmatrix}\Lambda(\lambda)\begin{pmatrix} 1 & 1 \\ i\sqrt{\lambda} & -i\sqrt{\lambda} \end{pmatrix}^{-1}.$$

For $\lambda>0$ the matrix $\Lambda(\lambda)$ is related to the scattering matrix

$$S_{A,B}(\lambda)=\begin{pmatrix} R(\lambda) & T_1(\lambda) \\ T_2(\lambda) & L(\lambda) \end{pmatrix}$$

by the relation

$$\Lambda(\lambda)=\begin{pmatrix} \dfrac{1}{T_2(\lambda)} & -\dfrac{R(\lambda)}{T_2(\lambda)} \\ \dfrac{L(\lambda)}{T_2(\lambda)} & \dfrac{T_1(\lambda)}{|T_2(\lambda)|^2} \end{pmatrix},$$

where

$$T_1(\lambda)=2e^{i\mu}(a-ib\sqrt{\lambda}+ic/\sqrt{\lambda}+d)^{-1},$$

$$T_2(\lambda)=2e^{-i\mu}(a-ib\sqrt{\lambda}+ic/\sqrt{\lambda}+d)^{-1},$$

$$R(\lambda)=(a-ib\sqrt{\lambda}+ic/\sqrt{\lambda}+d)^{-1}(a-ib\sqrt{\lambda}-ic/\sqrt{\lambda}-d),$$

$$L(\lambda)=(a-ib\sqrt{\lambda}+ic/\sqrt{\lambda}+d)^{-1}(-a-ib\sqrt{\lambda}-ic/\sqrt{\lambda}+d),$$

Note that $T_1(\lambda)=T_2(\lambda)$ for all $\lambda>0$ if the operator $\Delta(A,B)$ is real, i.e., $\exp\{2i\mu\}=1$. This is in analogy with Schrödinger operators on the line with potentials which are necessarily real (see, e.g., Refs. 69 and 70).

The factorization rule from Example IV.2 can now be written in the form

$$\Lambda(\lambda)=\Lambda^{(1)}(\lambda)U(a)\Lambda^{(2)}(\lambda)U(a)^{-1}, \tag{5.4}$$

where

$$U(a)=\begin{pmatrix} e^{-i\sqrt{\lambda}a} & 0 \\ 0 & e^{i\sqrt{\lambda}a} \end{pmatrix}.$$

The relation (5.4) is the special case of the well-known factorization formula[1–7] applied to the Laplacian on a line with point interaction.

It is easy to realize that the transfer matrix cannot be defined for *arbitrary* boundary conditions. For instance, the Dirichlet $[\psi_2(0+)=\psi_1(0+)=0]$ or Neuman $[\psi_2'(0+)=\psi_1'(0+)=0]$ or mixed $[\psi_2(0+)+k_2\psi_2'(0+)=\psi_1(0+)+k_1\psi_1'(0+)=0]$ boundary conditions introduce the decoupling $\Delta(A,B)=\Delta_1\oplus\Delta_2$, where Δ_j, $j=1,2$, are the Laplacians on $L^2(0,\infty)$ with corresponding boundary conditions. Recall, however, that the scattering matrix is well defined even in these cases. The composition rule (4.22) (see Example IV.2) remains valid.

Now we consider an arbitrary graph Γ with an even number of external lines $n=2p$. We enumerate the external lines in an arbitrary but fixed order. The external part of an arbitrary solution of the Schrödinger equation with $-\Delta(A,B)$ at the energy $\lambda>0$ has the form

$$u_j(x)=a_je^{i\sqrt{\lambda}x}+b_je^{-i\sqrt{\lambda}x}, \quad j=1,...,n. \tag{5.5}$$

We define the transfer matrix

$$\Lambda(\lambda)\begin{pmatrix} a_1 \\ \vdots \\ a_p \\ b_1 \\ \vdots \\ b_p \end{pmatrix} = \begin{pmatrix} b_{p+1} \\ \vdots \\ b_n \\ a_{p+1} \\ \vdots \\ a_n \end{pmatrix}. \tag{5.6}$$

To prove that $\Lambda(\lambda)$ is correctly defined it suffices to show that for arbitrary constants (a_j, b_j), $j = 1,\ldots,p$, there is a solution to the Schrödinger equation with the operator $-\Delta(A,B)$ whose external part has the form (5.5) and this solution is unique up to its internal part. The external part of any solution to the Schrödinger equation with the operator $-\Delta(A,B)$ is a linear combination of the columns of the matrix-valued function

$$\Psi(x,\lambda) = e^{-i\sqrt{\lambda}x}\mathbb{I} + e^{i\sqrt{\lambda}x}S(\lambda). \tag{5.7}$$

Thus, the columns of (5.7) have to satisfy (5.6), i.e.,

$$\Lambda(\lambda)\begin{pmatrix} S_{11}(\lambda) & S_{12}(\lambda) \\ \mathbb{I} & 0 \end{pmatrix} = \begin{pmatrix} 0 & \mathbb{I} \\ S_{21}(\lambda) & S_{22}(\lambda) \end{pmatrix},$$

where the $p \times p$ block notation is adopted. Writing $\Lambda(\lambda)$ as

$$\Lambda(\lambda) = \begin{pmatrix} \Lambda_{11}(\lambda) & \Lambda_{12}(\lambda) \\ \Lambda_{21}(\lambda) & \Lambda_{22}(\lambda) \end{pmatrix}$$

we obtain

$$\begin{gathered} \Lambda_{11}(\lambda)S_{11}(\lambda) + \Lambda_{12}(\lambda) = 0, \\ \Lambda_{11}(\lambda)S_{12}(\lambda) = \mathbb{I}, \\ \Lambda_{21}(\lambda)S_{11}(\lambda) + \Lambda_{22}(\lambda) = S_{21}(\lambda), \\ \Lambda_{21}(\lambda)S_{12}(\lambda) = S_{22}(\lambda). \end{gathered} \tag{5.8}$$

Let us suppose that $\det S_{12}(\lambda) \neq 0$. Then

$$\Lambda_{11}(\lambda) = S_{12}(\lambda)^{-1}, \Lambda_{12}(\lambda) = -S_{12}(\lambda)^{-1}S_{11}(\lambda),$$

$$\Lambda_{21}(\lambda) = S_{22}(\lambda)S_{12}(\lambda)^{-1}, \Lambda_{22}(\lambda) = S_{21}(\lambda) - S_{22}(\lambda)S_{12}(\lambda)^{-1}S_{11}(\lambda).$$

Thus, we proved that for $\det S_{12}(\lambda) \neq 0$ the transfer matrix exists and has the form

$$\Lambda(\lambda) = \begin{pmatrix} S_{12}(\lambda)^{-1} & -S_{12}(\lambda)^{-1}S_{11}(\lambda) \\ S_{22}(\lambda)S_{12}(\lambda)^{-1} & S_{21}(\lambda) - S_{22}(\lambda)S_{12}(\lambda)^{-1}S_{11}(\lambda) \end{pmatrix}. \tag{5.9}$$

Also, its definition (5.6) immediately leads to the following factorization formula,

$$\Lambda(\lambda) = \Lambda^{(1)}(\lambda)U(\underline{a})\Lambda^{(2)}(\lambda)U(\underline{a})^{-1}, \tag{5.10}$$

where the diagonal unitary matrix $U(\underline{a})$ is given by

$$U(\underline{a})=\begin{pmatrix} e^{-i\sqrt{\lambda}\underline{a}} & 0 \\ 0 & e^{i\sqrt{\lambda}\underline{a}} \end{pmatrix}.$$

Note that formal arguments based on the superposition principle leading to (5.10) have appeared earlier in Ref. 17. As for related results we mention that in Ref. 71 it was shown that the transfer matrix of a Schrödinger operator on the line with a matrix-valued potential can be written in the form (5.9).

Lemma V.1: If $\det S_{12}(\lambda)\neq 0$, *then* $\Lambda(\lambda)\in \mathsf{U}(p,p)$.

Proof: Obviously the coefficients $a_1,\ldots,a_n,b_1,\ldots,b_n$ in (5.5) satisfy the relation

$$\begin{pmatrix} a_1 \\ \vdots \\ a_n \end{pmatrix}=S(\lambda)\begin{pmatrix} b_1 \\ \vdots \\ b_n \end{pmatrix}.$$

From the unitarity of the scattering matrix it follows that

$$|a_1|^2+\cdots+|a_n|^2=|b_1|^2+\cdots+|b_n|^2,$$

or, equivalently,

$$|a_1|^2+\cdots+|a_p|^2-|b_1|^2-|b_p|^2=|b_{p+1}|^2+\cdots+|b_n|^2-|a_{p+1}|^2-\cdots-|a_n|^2.$$

This relation and (5.6) complete the proof of the lemma. □

Let us summarize the above results of the present section:

Theorem V.2: *If* $\det S_{12}(\lambda)\neq 0$, *then the transfer matrix* $\Lambda(\lambda)\in \mathsf{U}(p,p)$ *as given by* (5.9) *exists such that for an arbitrary* $(a_1,\ldots,a_p,b_1,\ldots,b_p)\in\mathbb{C}^n$ *there is a solution of the Schrödinger equation with* $-\Delta(A,B)$ *at the energy* $\lambda>0$ *whose external part has the form* (5.5) *and the coefficients* $(b_{p+1},\ldots,b_n,a_{p+1},\ldots,a_n)\in\mathbb{C}^n$ *are given by* (5.6). *The composition rule for the scattering matrices* (4.2) *is equivalent to the multiplication formula* (5.10) *for the transfer matrices.*

In addition for real operators we have the following.

Theorem V.3: *If the operator* $\Delta(A,B,\underline{a})$ *is real and if in addition* $\det S_{12}(\lambda)\neq 0$, *then* $\Lambda(\lambda)\in \mathsf{SU}(p,p)\subset \mathsf{SL}(2p;\mathbb{C})$.

Proof: From the well-known determinant formula for block matrices (see, e.g., Ref. 72, Section II.5)

$$\det\begin{pmatrix} A_{11} & A_{12} \\ A_{21} & A_{22} \end{pmatrix}=\det A_{11}\det(A_{22}-A_{21}A_{11}^{-1}A_{12}), \tag{5.11}$$

which follows from the decomposition

$$\begin{pmatrix} A_{11} & A_{12} \\ A_{21} & A_{22} \end{pmatrix}=\begin{pmatrix} A_{11} & 0 \\ A_{21} & \mathbb{I} \end{pmatrix}\begin{pmatrix} \mathbb{I} & A_{11}^{-1}A_{12} \\ 0 & A_{22}-A_{21}A_{11}^{-1}A_{12} \end{pmatrix},$$

it follows that

$$\det\Lambda(\lambda)=\frac{\det S_{21}(\lambda)}{\det S_{12}(\lambda)}.$$

By Theorem II.2 we have $S_{12}(\lambda)^T=S_{21}(\lambda)$ and thus $\det\Lambda(\lambda)=1$. □

We turn now to a discussion of the assumption $\det S_{12}(\lambda)\neq 0$. For the scattering matrix of the graph depicted in Fig. 4 with the boundary conditions (4.23) (see Example IV.3) $\det(S_a(\lambda))_{12}=0$ for all $\lambda>0$.

Theorem V.4: *Suppose that* $\det S_{12}(\lambda)=0$. *Then the transfer matrix* $\Lambda(\lambda)$ *exists such that for arbitrary*

$$(a_1,\ldots,a_p,b_1,\ldots,b_p)\in \mathrm{Ran}\begin{pmatrix}\mathbb{I} & 0\\ 0 & P_{(\mathrm{Ker}\, S_{12}(\lambda))^\perp}\end{pmatrix}\subset\mathbb{C}^n$$

there is a solution of the Schrödinger equation with $-\Delta(A,B,\underline{a})$ *at energy* $\lambda>0$ *whose external part has the form (5.5) and the coefficients* $(b_{p+1},\ldots,b_n,a_{p+1},\ldots,a_n)\in\mathbb{C}^n$ *are given by* (5.6).

Proof: The external part of any solution to the Schrödinger equation with the operator $-\Delta(A,B,\underline{a})$ satisfying the conditions of the theorem is a linear combination of the columns of the matrix-valued function

$$\Psi(x,\lambda)\begin{pmatrix}\mathbb{I} & 0\\ 0 & P_{(\mathrm{Ker}\, S_{12}(\lambda))^\perp}\end{pmatrix}, \tag{5.12}$$

where $\Psi(x,\lambda)$ is given by (5.7). Thus, the columns of (5.12) have to satisfy (5.6), i.e.,

$$\begin{pmatrix}\Lambda_{11}(\lambda) & \Lambda_{12}(\lambda)\\ \Lambda_{21}(\lambda) & \Lambda_{22}(\lambda)\end{pmatrix}\begin{pmatrix}S_{11}(\lambda) & S_{12}(\lambda)P_{(\mathrm{Ker}\, S_{12}(\lambda))^\perp}\\ \mathbb{I} & 0\end{pmatrix}=\begin{pmatrix}0 & P_{(\mathrm{Ker}\, S_{12}(\lambda))^\perp}\\ S_{21}(\lambda) & S_{22}(\lambda)P_{(\mathrm{Ker}\, S_{12}(\lambda))^\perp}\end{pmatrix}.$$

The solution of this equation can be wiritten in the form

$$\Lambda_{11}(\lambda)=S_{12}(\lambda)^\star,\Lambda_{12}(\lambda)=-S_{12}(\lambda)^\star S_{11}(\lambda),$$

$$\Lambda_{21}(\lambda)=S_{22}(\lambda)S_{12}(\lambda)^\star,\Lambda_{22}=S_{21}(\lambda)-S_{22}(\lambda)S_{12}(\lambda)^\star S_{11}(\lambda),$$

where $\star$ stands for the Penrose–Moore pseudoinverse. □

Note that any vector of the form $(c,0)^T$ with $c\in\mathrm{Ker}\, S_{12}(\lambda)$ satisfies $\Lambda(\lambda)\binom{c}{0}=0$. Thus $\det\Lambda(\lambda)=0$.

Inspection of the proof of Theorem V.4 shows that the transfer matrix cannot be extended to a subspace larger than

$$\mathrm{Ran}\begin{pmatrix}\mathbb{I} & 0\\ 0 & P_{(\mathrm{Ker}\, S_{12}(\lambda))^\perp}\end{pmatrix}.$$

If $\det\Lambda^{(1)}(\lambda)=\det\Lambda^{(2)}(\lambda)=0$, then $\mathrm{Ran}\, U(\underline{a})\Lambda^{(2)}(\lambda)U(\underline{a})$ and $\mathrm{Ker}\,\Lambda^{(1)}(\lambda)$ may have a nontrivial overlap and therefore the multiplication formula (5.10) does not hold in this case.

Example V.5: Consider the graph depicted in Fig. 4 with the boundary conditions from Example IV.3. For all $\lambda\in\mathbb{R}_+$ *such that* $e^{2i\sqrt{\lambda}a}=1$ *we have that* $\mathrm{Ker}\, S_{12}(\lambda)$ *is nontrivial and*

$$P_{\mathrm{Ker}\, S_{12}(\lambda)}=\frac{1}{2}\begin{pmatrix}1 & \mp 1\\ \mp 1 & 1\end{pmatrix},$$

$$P_{(\mathrm{Ker}\, S_{12}(\lambda))^\perp}=\frac{1}{2}\begin{pmatrix}1 & \pm 1\\ \pm 1 & 1\end{pmatrix},$$

where ± 1 *corresponds to* $\exp\{i\sqrt{\lambda}a\}=\pm 1$. *Suppose that*

$$(a_1,a_2,b_1,b_2)^T\notin\mathrm{Ran}\begin{pmatrix}\mathbb{I} & 0\\ 0 & P_{(\mathrm{Ker}\, S_{12}(\lambda))^\perp}\end{pmatrix},$$

or, equivalently,

FIG. 7. The graph with $n=2$ and $m=0$.

$$(a_1,a_2,b_1,b_2)^T \in \mathrm{Ran}\begin{pmatrix} 0 & 0 \\ 0 & P_{\mathrm{Ker}\, S_{12}(\lambda)} \end{pmatrix}.$$

In particular, we can choose

$$a_1=a_2=0, \quad b_1=1, \quad b_2=\mp 1.$$

It is easy to check that there is no solution to the Schrödinger equation with these boundary conditions.

Example V.6: Consider the graph depicted in Fig. 7 with the boundary conditions as in Example IV.4. $\mathrm{Ker}\, S_{12}(\lambda)$ *is nontrivial for all* $\lambda \in \mathbb{R}_+$ *and*

$$P_{\mathrm{Ker}\, S_{12}(\lambda)}=\frac{1}{2}\begin{pmatrix} 1 & -1 \\ -1 & 1 \end{pmatrix}, \quad P_{(\mathrm{Ker}\, S_{12}(\lambda))^\perp}=\frac{1}{2}\begin{pmatrix} 1 & 1 \\ 1 & 1 \end{pmatrix}.$$

Suppose again that

$$(a_1,a_2,b_1,b_2)^T \notin \mathrm{Ran}\begin{pmatrix} \mathbb{I} & 0 \\ 0 & P_{(\mathrm{Ker}\, S_{12}(\lambda))^\perp} \end{pmatrix}$$

and choose

$$a_1=a_2=0, \quad b_1=1, \quad b_2=1.$$

Again it is easy to check that there is no solution to the Schrödinger equation with these boundary conditions.

The statement converse to Theorem V.2 immediately follows from Theorem V.4.

Theorem V.7: *If the transfer matrix* $\Lambda(\lambda)$ *exists in the sense of Theorem V.2, then* $\det S_{12}(\lambda)\neq 0$ *and the corresponding scattering matrix is given by*

$$S(\lambda)=\begin{pmatrix} -\Lambda_{11}(\lambda)^{-1}\Lambda_{12}(\lambda) & \Lambda_{11}(\lambda)^{-1} \\ \Lambda_{22}(\lambda)-\Lambda_{21}(\lambda)\Lambda_{11}(\lambda)^{-1}\Lambda_{12}(\lambda) & \Lambda_{21}(\lambda)\Lambda_{11}(\lambda)^{-1} \end{pmatrix}. \tag{5.13}$$

Proof: Suppose that $\det S_{12}(\lambda)=0$. Then by Theorem V.4 we get $\det \Lambda(\lambda)=0$, which is a contradiction. Thus, $\det S_{12}(\lambda)\neq 0$ and therefore by Theorem V.2 $\det \Lambda(\lambda)\neq 0$. The representation (5.13) follows from (5.8). □

APPENDIX: PROOF OF THEOREM III.8

Here we give the proof of Theorem III.8 which claims that for arbitrary unitary matrices $U^{(1)}$, $U^{(2)}$, and V the matrix $U=U^{(1)}*_V U^{(2)}$ defined by (3.4) is unitary. As already noted in Ref. 21 it suffices to prove only the relations

$$U_{11}^* U_{11}+U_{21}^* U_{21}=\mathbb{I},$$

$$U_{11}^* U_{12}+U_{21}^* U_{22}=0. \tag{A1}$$

The remaining relations,

$$U_{12}^{*}U_{12}+U_{22}^{*}U_{22}=\mathbb{I},$$

$$U_{12}^{*}U_{11}+U_{22}^{*}U_{21}=0, \tag{A2}$$

follow immediately from (A1). To see this for an arbitrary unitary matrix U we define an involutive map $U\mapsto U^{\tau}$ given as

$$U=\begin{pmatrix} U_{11} & U_{12} \\ U_{21} & U_{22} \end{pmatrix}\mapsto U^{\tau}=\begin{pmatrix} U_{22} & U_{21} \\ U_{12} & U_{11} \end{pmatrix}.$$

Direct calculations show that the following ''transposition law,''

$$U^{\tau}=U^{(2)^{\tau}}*_{V^{*}}U^{(1)^{\tau}} \tag{A3}$$

holds whenever $U=U^{(1)}*_{V}U^{(2)}$. Assume that (A1) holds for arbitrary unitary U. Replacing the matrix U by U^{τ} given by (A3) transforms the relations (A1) into (A2).

By the definition of the generalized star product (3.4) and by the unitarity of $U^{(1)}$ the first of the relations (A1) is equivalent to

$$\begin{aligned} &-U_{21}^{(1)*}U_{21}^{(1)}+U_{21}^{(1)*}V^{*}U_{11}^{(2)*}K_{2}^{*}U_{12}^{(1)*}U_{11}^{(1)}+U_{11}^{(1)*}U_{12}^{(1)}K_{2}U_{11}^{(2)}VU_{21}^{(1)} \\ &\quad+U_{21}^{(1)*}V^{*}U_{11}^{(2)*}K_{2}^{*}U_{12}^{(1)*}U_{12}^{(1)}K_{2}U_{11}^{(2)}VU_{21}^{(1)}+U_{21}^{(1)*}K_{1}^{*}U_{21}^{(2)*}U_{21}^{(2)}K_{1}U_{21}^{(1)}=0. \end{aligned} \tag{A4}$$

Since the opposite case was already considered in Ref. 21, we further assume that the matrix $U^{(1)}$ is not V-compatible with $U^{(2)}$. From Theorem III.6 it follows that all off-diagonal blocks $U_{12}^{(1)}$, $U_{21}^{(1)}$, $U_{12}^{(2)}$, and $U_{21}^{(2)}$ are not of maximal rank and thus $\operatorname{Ker}U_{21}^{(1)}$ is nontrivial. Let d_i, $1\leqslant i\leqslant k=\dim\ \operatorname{Ker}U_{21}^{(1)}$, be an arbitrary basis in $\operatorname{Ker}U_{21}^{(1)}$. From the unitary of the matrix $U^{(1)}$ we get $U_{12}^{(1)*}U_{11}^{(1)}d_i=0$ for all $1\leqslant i\leqslant k$. Thus

$$\begin{aligned} &[-U_{21}^{(1)*}U_{21}^{(1)}+U_{21}^{(1)*}V^{*}U_{11}^{(2)*}K_{2}^{*}U_{12}^{(1)*}U_{11}^{(1)}+U_{11}^{(1)*}U_{12}^{(1)}K_{2}U_{11}^{(2)}VU_{21}^{(1)} \\ &\quad+U_{21}^{(1)*}V^{*}U_{11}^{(2)*}K_{2}^{*}U_{12}^{(1)*}U_{12}^{(1)}K_{2}U_{11}^{(2)}VU_{21}^{(1)}+U_{21}^{(1)*}K_{1}^{*}U_{21}^{(2)*}U_{21}^{(2)}K_{1}U_{21}^{(1)}]d_i=0 \end{aligned}$$

for all $1\leqslant i\leqslant k$. Hence to prove (A4) it remains to show that

$$\begin{aligned} &[-U_{21}^{(1)*}U_{21}^{(1)}+U_{21}^{(1)*}V^{*}U_{11}^{(2)*}K_{2}^{*}U_{12}^{(1)*}U_{11}^{(1)}+U_{11}^{(1)*}U_{12}^{(1)}K_{2}U_{11}^{(2)}VU_{21}^{(1)} \\ &\quad+U_{21}^{(1)*}V^{*}U_{11}^{(2)*}K_{2}^{*}U_{12}^{(1)*}U_{12}^{(1)}K_{2}U_{11}^{(2)}VU_{21}^{(1)}+U_{21}^{(1)*}K_{1}^{*}U_{21}^{(2)*}U_{21}^{(2)}K_{1}U_{21}^{(1)}]d=0. \end{aligned} \tag{A5}$$

for any $d\in(\operatorname{Ker}U_{21}^{(1)})^{\perp}=\operatorname{Ran}U_{21}^{(1)*}$. Therefore we set $d=U_{21}^{(1)*}\tilde{d}$, where $\tilde{d}\in\mathbb{C}^{p}$ is an arbitrary vector. Thus, the relation (A5) holds whenever

$$\begin{aligned} &[-U_{21}^{(1)*}U_{21}^{(1)}U_{21}^{(1)*}+U_{21}^{(1)*}V^{*}U_{11}^{(2)*}K_{2}^{*}U_{12}^{(1)*}U_{11}^{(1)}U_{21}^{(1)*}+U_{11}^{(1)*}U_{12}^{(1)}K_{2}U_{11}^{(2)}VU_{21}^{(1)}U_{21}^{(1)*} \\ &\quad+U_{21}^{(1)*}V^{*}U_{11}^{(2)*}K_{2}^{*}U_{12}^{(1)*}U_{12}^{(1)}K_{2}U_{11}^{(2)}VU_{21}^{(1)}U_{21}^{(1)*}+U_{21}^{(1)*}K_{1}^{*}U_{21}^{(2)*}U_{21}^{(2)}K_{1}U_{21}^{(1)}U_{21}^{(1)*}]\tilde{d}=0 \end{aligned} \tag{A6}$$

for all $\tilde{d}\in\mathbb{C}^{p}$.

First we note that by Lemma III.4 (*iv*) the relation (A6) holds for all $\tilde{d}\in\tilde{\mathcal{C}}$. Therefore it suffices to prove that (A6) holds for all $\tilde{d}\in\tilde{\mathcal{C}}^{\perp}$. Observe that in this case by Lemma III.4 (*i*) and by the unitarity of the matrices $U^{(1)}$ and $U^{(2)}$ we have

$$U_{12}^{(1)*}U_{11}^{(1)}U_{21}^{(1)*}\tilde{d}=-U_{12}^{(1)*}U_{12}^{(1)}U_{22}^{(1)*}\tilde{d}=-U_{22}^{(1)*}\tilde{d}+U_{22}^{(1)*}U_{22}^{(1)}U_{22}^{(1)*}\tilde{d}\in\mathcal{B}^{\perp},$$

$$U_{11}^{(2)}VU_{21}^{(1)}U_{21}^{(1)*}\tilde{d}=U_{11}^{(2)}V\tilde{d}-U_{11}^{(2)}VU_{22}^{(1)}U_{22}^{(1)*}\tilde{d}\in\tilde{B}^{\perp}, \tag{A7}$$

$$U_{21}^{(1)}U_{21}^{(1)*}\tilde{d}=\tilde{d}-U_{22}^{(1)}U_{22}^{(1)*}\tilde{d}\in\tilde{\mathcal{C}}^{\perp}.$$

To prove the first relation in (A7) it suffices to show that for any $\tilde{d}\in\tilde{\mathcal{C}}^{\perp}$ and any $b\in\mathcal{B}$

$$-(b,U_{22}^{(1)*}\tilde{d})+(b,U_{22}^{(1)*}U_{22}^{(1)}U_{22}^{(1)*}\tilde{d})=-(U_{22}^{(1)}b,\tilde{d})+(U_{22}^{(1)}U_{22}^{(1)*}U_{22}^{(1)}b,\tilde{d})=0. \tag{A.8}$$

By the definition of $\mathcal{B}$ and by Lemma III.3 $U_{22}^{(1)*}U_{22}^{(1)}b=b$ for any $b\in\mathcal{B}$ which proves (A8). To prove the second relation in (A7) it suffices to show for any $\tilde{d}\in\tilde{\mathcal{C}}^{\perp}$ and any $\tilde{b}\in\tilde{\mathcal{B}}$

$$(\tilde{b},U_{11}^{(2)}V\tilde{d})-(\tilde{b},U_{11}^{(2)}VU_{22}^{(1)}U_{22}^{(1)*}\tilde{d})=(V^{*}U_{11}^{(2)}\tilde{b},\tilde{d})-(U_{22}^{(1)}U_{22}^{(1)*}V^{*}U_{11}^{(2)*}\tilde{b},\tilde{d})=0. \tag{A9}$$

By Lemma III.4 (*i*) $V^{*}U_{11}^{(2)}\tilde{b}\in\tilde{\mathcal{C}}$. By the definition of $\tilde{\mathcal{C}}$ and by Lemma III.3 $U_{22}^{(1)}U_{22}^{(1)*}\tilde{c}=\tilde{c}$ for any $\tilde{c}\in\tilde{\mathcal{C}}$ which proves (A9). This also proves that

$$(\tilde{c},\tilde{d})-(\tilde{c},U_{22}^{(1)}U_{22}^{(1)*}\tilde{d})=(\tilde{c},\tilde{d})-(U_{22}^{(1)}U_{22}^{(1)*}\tilde{c},\tilde{d})=0$$

for all $\tilde{d}\in\tilde{\mathcal{C}}^{\perp}$ and all $\tilde{c}\in\tilde{\mathcal{C}}$ from which the third relation in (A7) follows.

From Lemma III.5 and the definition (3.2) of the matrices K_1 and K_2 it follows that

$$\begin{aligned}
&(i)\quad K_1 \text{ maps } \tilde{\mathcal{C}}^{\perp} \text{ onto } \mathcal{C}^{\perp} \text{ bijectively},\\
&(ii)\quad K_1^{*} \text{ maps } \mathcal{C}^{\perp} \text{ onto } \tilde{\mathcal{C}}^{\perp} \text{ bijectively},\\
&(iii)\quad K_2 \text{ maps } \tilde{\mathcal{B}}^{\perp} \text{ onto } \mathcal{B}^{\perp} \text{ bijectively},\\
&(iv)\quad K_2^{*} \text{ maps } \mathcal{B}^{\perp} \text{ onto } \tilde{\mathcal{B}}^{\perp} \text{ bijectively},
\end{aligned} \tag{A10}$$

Noting that $U_{12}^{(1)*}U_{12}^{(1)}b_{\perp}=b_{\perp}-U_{22}^{(1)*}U_{22}^{(1)}b_{\perp}\in\mathcal{B}^{\perp}$ and $U_{21}^{(2)*}U_{21}^{(2)}c_{\perp}=c_{\perp}-U_{11}^{(2)*}U_{11}^{(2)}c_{\perp}\in\tilde{\mathcal{C}}^{\perp}$ due to (A7) and (A10) we can write the lhs of (A6) in the form

$$\begin{aligned}
U_{21}^{(1)*}[&-\mathbb{I}-V^{*}U_{11}^{(2)*}K_2U_{22}^{(1)*}-U_{22}^{(1)}K_2U_{11}^{(2)}V+V^{*}U_{11}^{(2)*}K_2^{*}K_2U_{11}^{(2)}V\\
&-V^{*}U_{11}^{(2)*}K_2^{*}U_{22}^{(1)*}U_{22}^{(1)}K_2U_{11}^{(2)}V+K_1^{*}K_1-K_1^{*}U_{11}^{(2)*}U_{11}^{(2)}K_1]U_{21}^{(2)*}U_{21}^{(2)}\tilde{d}.
\end{aligned} \tag{A11}$$

Similar to Ref. 21 one can easily prove that for any $\tilde{b}_{\perp}\in\tilde{\mathcal{B}}^{\perp}$ and $\tilde{c}_{\perp}\in\tilde{\mathcal{C}}^{\perp}$ the following relations hold:

$$K_1^{*}K_1\tilde{c}_{\perp}=\tilde{c}_{\perp}+U_{22}^{(1)}K_2U_{11}^{(2)}V\tilde{c}_{\perp}+V^{*}U_{11}^{(2)*}K_2^{*}U_{22}^{(1)*}\tilde{c}_{\perp}+V^{*}U_{11}^{(2)*}K_2^{*}U_{22}^{(1)*}U_{22}^{(1)}K_2U_{11}^{(2)}V\tilde{c}_{\perp}.$$

$$K_1^{*}U_{11}^{(2)*}U_{11}^{(2)}K_1\tilde{c}_{\perp}=V^{*}(\mathbb{I}+U_{11}^{(2)*}K_2^{*}U_{22}^{(1)*}V^{*})U_{11}^{(2)*}U_{11}^{(2)}(\mathbb{I}+VU_{22}^{(1)}K_2U_{11}^{(2)})V\tilde{c}_{\perp},$$

$$K_2^{*}K_2\tilde{b}_{\perp}=\tilde{b}_{\perp}+K_2^{*}U_{22}^{(1)*}V^{*}U_{11}^{(2)*}+U_{11}^{(2)}VU_{22}^{(1)}K_2\tilde{b}_{\perp}+K_2^{*}U_{22}^{(1)*}V^{*}U_{11}^{(2)*}U_{11}^{(2)}VU_{22}^{(1)}K_2\tilde{b}_{\perp}.$$

Inserting these relations in (A11) with the choice $\tilde{c}_\perp = U_{21}^{(2)*} U_{21}^{(2)} \tilde{d}$ and $\tilde{b}_\perp = U_{11}^{(2)} V \tilde{c}_\perp$ we obtain that it vanishes, thus completing the proof of the first relation in (A1). The proof of the second relation in (A1) is similar and will therefore be omitted.

In this paper we apply the chiral spinorial approach to the description of spin $\frac{3}{2}$ particles. Chiral components of rank 3 spinor fields are considered to be the dynamical variables of the theory. The free Lagrangian is built from the same principles as in the case of spin 1 and spin 2 particles: chiral symmetry at the free field level and chiral symmetry breakdown at the interaction level. We show how the chiral spinorial approach provides an unambiguous Lagrangian approach for massless spin $\frac{3}{2}$ particles. This approach provides a fairly rich set of effective Lagrangians for the interaction of spin $\frac{3}{2}$ particles. © *2001 American Institute of Physics.* [DOI: 10.1063/1.1316061]

I. INTRODUCTION

The usual way to describe a massive (or massless) spin $\frac{3}{2}$ field is to use the Rarita–Schwinger[1] (RS) spinor-vector $\Phi^{\mu}_{,a}$ field (four vector indices $\mu=0,1,2,3$ and four spinor indices $a=1,2,3,4$) which satisfies the equations

$$(i\partial\!\!\!/-m)_{ab}\Phi_{\mu,b}=0, \tag{1.1}$$

$$\gamma^{\mu}_{ab}\Phi_{\mu,b}=0, \tag{1.2}$$

$$\partial^{\mu}\Phi_{\mu,a}=0. \tag{1.3}$$

The RS theory can be obtained as a consequence of the more general Bargmann–Wigners[2] (BW) approach, which assigns to a massive particle of spin s, a spinorial symmetric field of rank $2s$, obeying a Dirac equation in each index.

This paper deals with the extension to particles of spin $\frac{3}{2}$, of our chiral spinorial approach.[3,4] We show in this paper that our method provides an ambiguity free approach to the description of spin $\frac{3}{2}$ particles.

In our approach we use a set of 8 chiral fields which are built from the rank 3 spinor field. These chiral fields are treated as independent field variables. We have in this way, a set of eight Dirac-type equations. The fact that we have a larger number of equations than the BW method, means that we are able to describe particles with more degrees of freedom than Bargmann and Wigner did. We shall come back to this point in a future paper.

Besides the enlargement of the number of degrees of freedom our method relies upon a Lagrangian from which we can derive all equations of motion. These equations can be written either in terms of the chiral fields or alternatively, in terms of tensor fields. Within this Lagrangian approach one can easily discuss internal and discrete symmetries such as C, P, and T.

In this paper we shall see that RS equations follow from chiral invariance at the free field level and chiral asymmetry at the interaction level. In this way we have extended to spin $\frac{3}{2}$ the description used by us to particles of spin 1 (Ref. 3) and spin 2.[4]

The chiral spinorial method is also useful in the construction of effective interactions.[5] In this approach the interactions are represented as effective Lagrangians involving the coupling of the eight chiral components, with matter fields and the other fields.

The plan of this paper is the following: in Sec. II we review the BW method and discuss some aspects of this theory. We have pointed out in this section some ambiguities of this approach for spin $\frac{3}{2}$ particles.

In Sec. III we define the chiral components and show how they can be written in terms of vector–spinor and tensor–spinor fields.

Chiral invariance is defined in Sec. IV. The free field Lagrangian is required to be chiral invariant. This is enough to fix the first order derivative Lagrangian for spin $\frac{3}{2}$ particles. The chiral invariant Lagrangian is shown to lead to the right equations for massless $\frac{3}{2}$ particles in Sec. V. This is done through the use of the set of equations for the chiral components.

In Sec. VI we show that in the massive case our Lagrangian leads to a Lagrangian approach for the Rarita–Schwinger equation. The Lagrangian is written in terms of the vector–spinor and tensor–spinor fields which are now treated as independent field variables.

The approach developed here is particularly useful in phenomenological applications. In Sec. VII we show how this method will lead to a large number of Lagrangians for the interaction of spin $\frac{3}{2}$ particles to other particles.

We end this paper by drawing some conclusions in Sec. VIII.

II. SPINORS AND THE BARGMANN–WIGNER APPROACH

We take the generally accepted view that particles of spin s can be described by a rank $2s$ spinor field $\psi_{a_1 a_2 \cdots a_{2s}}(x)$. In the case of spin 1 and 2 particles this is a departure of the usual approach that relies upon the use of vector and tensor fields. For particles of spin $\frac{3}{2}$ the basic field is a rank 3 spinor field $\psi_{a_1 a_2 a_3}(x)$.

The problem with this approach is that we deal with a field having too many degrees of freedom. In fact, in the case of the spin $\frac{3}{2}$ particles we are dealing with a field with 64 components, and so we have 64 degrees of freedom.

How to we deal with so many degrees of freedom? Some of these degrees of freedom are fields which can be expressed in terms of more fundamental fields. One expects some relations among them. There might also be constraints upon these fields.

These relations, or constraints, can be obtained from three equations proposed by Bargmann and Wigner:[2]

$$i\partial\!\!\!/ \otimes 1 \otimes 1\,\psi = m\psi, \tag{2.1a}$$

$$1 \otimes i\partial\!\!\!/ \otimes 1\,\psi = m\psi, \tag{2.1b}$$

$$1 \otimes 1 \otimes i\partial\!\!\!/\,\psi = m\psi. \tag{2.1c}$$

where m is the mass of the Bargmann–Wigner field, which is associated to the mass of the spin $\frac{3}{2}$ particles.

The first problem with the Bargmann–Wigner equations is that they cannot be obtained from a Lagrangian density. BW method is not based on a Lagrangian approach.

The second problem with the BW method is that for a general 64 component spinor field three equations are not enough to impose all restrictions and relations among the components. It is enough however for symmetric spinors. We shall come to this point later.

Finally, we would like to stress the fact that the Bargmann–Wigner method fails in the case of zero mass particles.

We shall see that the chiral spinorial method proposed by us provides a better description for particles of spin $\frac{3}{2}$, since we are able to cure all these three problems associated with the BW method.

In order to understand the problems discussed before let us reduce the number of degrees of freedom to 40 by imposing the symmetry of ψ into two indices. This can be achieved by means of a decomposition of the field ψ in terms of the symmetric matrices $(\gamma^\mu C)$ and $(\sigma^{\mu\nu}C)$. We write

$$\psi_{a_1a_2a_3}(x)=\psi_{a_1a_3a_2}(x)=D_1\mathbf{\Phi}_{\mu,a_1}(x)(\gamma^\mu C)_{a_2a_3}+D_2\mathcal{G}_{\mu\nu,a_1}(x)(\sigma^{\mu\nu}C)_{a_2a_3} \tag{2.2a}$$

or

$$\psi_{a_2a_3a_1}(x)=\psi_{a_2a_1a_3}(x)=D_1\mathbf{\Phi}_{\mu,a_2}(x)(\gamma^\mu C)_{a_3a_1}+D_2\mathcal{G}_{\mu\nu,a_2}(x)(\sigma^{\mu\nu}C)_{a_3a_1} \tag{2.2b}$$

or

$$\psi_{a_3a_1a_2}(x)=\psi_{a_3a_2a_1}(x)=D_1\mathbf{\Phi}_{\mu,a_3}(x)(\gamma^\mu C)_{a_1a_2}+D_2\mathcal{G}_{\mu\nu,a_3}(x)(\sigma^{\mu\nu}C)_{a_1a_2}. \tag{2.2c}$$

where $\mathcal{G}_{\mu\nu,a}$ is a tensor-spinor field and $\mathbf{\Phi}_{\mu,a}$ is the RS vector–spinor field. Clearly each of the above decompositions takes into account the symmetry in only two indices.

A decomposition that takes into account the symmetry in all indices is

$$\begin{aligned}\psi_{a_1a_2a_3}(x)=\psi_{a_2a_3a_1}(x)=\psi_{a_3a_1a_2}(x)=\cdots=d_1\{&\varphi_{\mu,a_1}(x)(\gamma^\mu C)_{a_2a_3}+\varphi_{\mu,a_2}(x)(\gamma^\mu C)_{a_3a_1}\\&+\varphi_{\mu,a_3}(x)(\gamma^\mu C)_{a_1a_2}\}+d_2\{G_{\mu\nu,a_1}(x)(\sigma^{\mu\nu}C)_{a_2a_3}\\&+G_{\mu\nu,a_2}(x)(\sigma^{\mu\nu}C)_{a_3a_1}+G_{\mu\nu,a_3}(x)(\sigma^{\mu\nu}C)_{a_1a_2}\}.\end{aligned} \tag{2.3}$$

For a totally symmetric tensor the BW equations reduces to just one equation since for a symmetric ψ we have the identity

$$(i\partial\!\!\!/\otimes 1\otimes 1)\psi=(1\otimes i\partial\!\!\!/\otimes 1)\psi=(1\otimes 1\otimes i\partial\!\!\!/)\psi. \tag{2.4}$$

For a symmetric spinor we are left with just one equation. One equation is not enough to impose all relations and constraints expected for the $\mathbf{\Phi}_{\mu,a}$ and $\mathcal{G}_{\mu\nu,a}$ fields. There is, however, a way of getting around this problem. It amounts, in fact, to the use of a simple trick. We use the partially symmetric decomposition in the BW equations and then assume that ψ is totally symmetric.

Let us consider the simple example of $\psi_{a_1a_2a_3}$ as given by decomposition (2.2a). Since C^{-1}, $C^{-1}\gamma^5$, and $C^{-1}\gamma^5\gamma^\mu$ are antisymmetric matrices, the following projections are obviously zero:

$$\mathrm{Tr}(C^{-1}_{a_1a_2}\cdot\psi_{a_1a_2a_3})=0,$$

$$\mathrm{Tr}((C^{-1}\gamma^5)_{a_1a_2}\cdot\psi_{a_1a_2a_3})=0,$$

$$\mathrm{Tr}((C^{-1}\gamma^5\gamma^\mu)_{a_1a_2}\cdot\psi_{a_1a_2a_3})=0.$$

Let us use in the above equations the nonsymmetrical decomposition (2.2a). We will be led to the following independent conditions:

$$\gamma^\mu_{a_1a_2}\mathbf{\Phi}_{\mu,a_2}=0, \tag{2.5}$$

$$\mathbf{\Phi}^\mu_{a_1}=2i\frac{D_2}{D_1}(\gamma_\nu)_{a_1a_2}\mathcal{G}^{\mu\nu}_{a_2}. \tag{2.6}$$

The first constraint, (2.5), is just one of the Rarita–Schwinger (RS) equations for the spinor–vector $\mathbf{\Phi}^\mu_{,a}$. The use of the second constraint (2.6), and of the BW equations (2.1b) gives rise, after further extra manipulations, to the other two RS equations:

$$(i\partial\!\!\!/ - m)_{ab}\mathbf{\Phi}_{\mu,b} = 0 \tag{2.7}$$

and

$$\partial^{\mu}\mathbf{\Phi}_{\mu,a} = 0. \tag{2.8}$$

Clearly we will obtain the same results if we use expressions (2.2b) or (2.2c) for ψ and take the appropriate projections.

The conclusion is that the way of getting the RS equations from the BW method, works but is a tricky method. We use an asymmetric decomposition but assume that the field is a symmetric one.

Finally let us relate the superposition coefficients φ_{μ} and $G_{\mu\nu}$ of the totally symmetric decomposition (2.3) of ψ, to the coefficients $\mathbf{\Phi}^{\mu}$ and $\mathcal{G}^{\mu\nu}$. We get

$$2D_1\mathbf{\Phi}^{\mu}_{,a_1} = d_1\{2\varphi^{\mu}_{,a_1} + (\gamma^{\alpha}\gamma^{\mu})_{a_1a_2}\varphi_{\alpha,a_2}\} + d_2(\sigma^{\alpha\beta}\gamma^{\mu})_{a_1a_2}G_{\alpha\beta,a_2}, \tag{2.9}$$

$$2D_2\mathcal{G}^{\mu\nu}_{,a_1} = d_1(\gamma^{\alpha}\sigma^{\mu\nu})_{a_1a_2}\varphi_{\alpha,a_2} + 4d_2G_{\mu\nu,a_1} + d_2(\sigma^{\alpha\beta}\sigma^{\mu\nu})_{a_1a_2}G_{\alpha\beta,a_2}. \tag{2.10}$$

III. CHIRAL COMPONENTS

Let us analyze the relativistic equations for spin $\frac{3}{2}$ particles by using the spinorial approach. Within the spinorial approach we treat chiral components as independent field variables. For spin $\frac{1}{2}$ particles we define two chiral components as

$$\psi_R = \tfrac{1}{2}(1+\gamma^5)\psi$$

$$\psi_L = \tfrac{1}{2}(1-\gamma^5)\psi.$$

For the rank 3 spinor field ψ, one can introduce, in close analogy with the spin $\frac{1}{2}$ case, the chiral components:

$$\begin{aligned}
\psi^{RRR}_{a_1a_2a_3} &= \tfrac{1}{2}(1+\gamma^5)\otimes\tfrac{1}{2}(1+\gamma^5)\otimes\tfrac{1}{2}(1+\gamma^5)\psi,\\
\psi_{RRL} &= \tfrac{1}{2}(1+\gamma^5)\otimes\tfrac{1}{2}(1+\gamma^5)\otimes\tfrac{1}{2}(1-\gamma^5)\psi,\\
\psi_{RLR} &= \tfrac{1}{2}(1+\gamma^5)\otimes\tfrac{1}{2}(1-\gamma^5)\otimes\tfrac{1}{2}(1+\gamma^5)\psi,\\
\psi_{LRR} &= \tfrac{1}{2}(1-\gamma^5)\otimes\tfrac{1}{2}(1+\gamma^5)\otimes\tfrac{1}{2}(1+\gamma^5)\psi,\\
\psi_{LLR} &= \tfrac{1}{2}(1-\gamma^5)\otimes\tfrac{1}{2}(1-\gamma^5)\otimes\tfrac{1}{2}(1+\gamma^5)\psi,\\
\psi_{LRL} &= \tfrac{1}{2}(1-\gamma^5)\otimes\tfrac{1}{2}(1+\gamma^5)\otimes\tfrac{1}{2}(1-\gamma^5)\psi,\\
\psi_{RLL} &= \tfrac{1}{2}(1+\gamma^5)\otimes\tfrac{1}{2}(1-\gamma^5)\otimes\tfrac{1}{2}(1-\gamma^5)\psi,\\
\psi_{LLL} &= \tfrac{1}{2}(1-\gamma^5)\otimes\tfrac{1}{2}(1-\gamma^5)\otimes\tfrac{1}{2}(1-\gamma^5)\psi,
\end{aligned} \tag{3.1}$$

where by definition

$$\psi = \psi_{RRR} + \psi_{RRL} + \psi_{RLR} + \psi_{LRR} + \psi_{LLR} + \psi_{LRL} + \psi_{RLL} + \psi_{LLL}\,. \tag{3.2}$$

To each possible expansions of the spinor ψ, there corresponds a set of chiral components: there is a set of equations obtained from a nonsymmetric decomposition and another set obtained from the symmetrized decomposition. We shall analyze both sets of equations. We shall see that the method works in both cases.

The chiral components defined in (3.1) assumes, after inserting the nonsymmetrized expression in (3.1), the following form:

$$
\begin{aligned}
\psi^{RRR}_{a_1a_2a_3} &= D_2(\mathcal{G}_{\mu\nu R})_{a_2}(\sigma^{\mu\nu}C)_{Ra_3a_1},\\
\psi_{RRL} &= D_1(\mathbf{\Phi}_{\mu R})(\gamma^{\mu}C)_L,\\
\psi_{RLR} &= D_2(\mathcal{G}_{\mu\nu L})(\sigma^{\mu\nu}C)_R,\\
\psi_{LRR} &= D_1(\mathbf{\Phi}_{\mu R})(\gamma^{\mu}C)_R,\\
\psi_{LLR} &= D_1(\mathbf{\Phi}_{\mu L})(\gamma^{\mu}C)_R,\\
\psi_{LRL} &= D_2(\mathcal{G}_{\mu\nu R})(\sigma^{\mu\nu}C)_L,\\
\psi_{RLL} &= D_1(\mathbf{\Phi}_{\mu L})(\gamma^{\mu}C)_L,\\
\psi_{LLL} &= D_2(\mathcal{G}_{\mu\nu L})(\sigma^{\mu\nu}C)_L,
\end{aligned}
\tag{3.3}
$$

where in (3.3), we have introduced the more compact following notation:

$$
\begin{aligned}
&\tfrac{1}{2}(1\pm\gamma^5)_{a_1a_2}\mathbf{\Phi}_{\mu a_2} = (\mathbf{\Phi}_{\mu})^{Ra_1}_{L},\\
&\tfrac{1}{2}(1\pm\gamma^5)\mathcal{G}_{\mu\nu} = (\mathcal{G}_{\mu\nu})^{R}_{L},\\
&(\tfrac{1}{2}(1\pm\gamma^5)\gamma^{\mu}C)_{a_1a_2} = (\gamma^{\mu}C)^{R}_{L},\\
&(\tfrac{1}{2}(1\pm\gamma^5)\sigma^{\mu\nu}C) = (\sigma^{\mu\nu}C)^{R}_{L}.
\end{aligned}
\tag{3.4}
$$

We will refer to the chiral components (3.3) as to the nonsymmetrized chiral components. One can see that the chiral components provides a way of separating the vector–spinor from the tensor–spinor contributions.

The chiral components defined in (3.1) assumes after inserting the symmetrized expansion of ψ into (3.1) and having in mind the notation (3.4), the following form:

$$
\begin{aligned}
\psi^{RRR}_{a_1a_2a_3} &= d_2\{(G_{\mu\nu R})_{a_1}(\sigma^{\mu\nu}C)_{Ra_2a_3}+(G_{\mu\nu R})_{a_2}(\sigma^{\mu\nu}C)_{Ra_3a_1}+(G_{\mu\nu R})_{a_3}(\sigma^{\mu\nu}C)_{Ra_1a_2}\},\\
\psi^{RRL}_{a_1a_2a_3} &= d_1\{(\varphi_{\mu R})_{a_1}(\gamma^{\mu}C)_{Ra_2a_3}+(\varphi_{\mu R})_{a_2}(\gamma^{\mu}C)_{La_3a_1}\}+d_2(G_{\mu\nu L})_{a_3}(\sigma^{\mu\nu}C)_{Ra_1a_2},\\
\psi^{RLR}_{a_1a_2a_3} &= d_1\{(\varphi_{\mu R})_{a_1}(\gamma^{\mu}C)_{La_2a_3}+(\varphi_{\mu R})_{a_3}(\gamma^{\mu}C)_{Ra_1a_2}\}+d_2(G_{\mu\nu L})_{a_2}(\sigma^{\mu\nu}C)_{Ra_3a_1},\\
\psi^{LRR}_{a_1a_2a_3} &= d_1\{(\varphi_{\mu R})_{a_2}(\gamma^{\mu}C)_{Ra_3a_1}+(\varphi_{\mu R})_{a_3}(\gamma^{\mu}C)_{La_1a_2}\}+d_2(G_{\mu\nu L})_{a_1}(\sigma^{\mu\nu}C)_{Ra_2a_3},\\
\psi^{LLR}_{a_1a_2a_3} &= d_1\{(\varphi_{\mu L})_{a_1}(\gamma^{\mu}C)_{La_2a_3}+(\varphi_{\mu L})_{a_2}(\gamma^{\mu}C)_{Ra_3a_1}\}+d_2(G_{\mu\nu R})_{a_3}(\sigma^{\mu\nu}C)_{La_1a_2},\\
\psi^{LRL}_{a_1a_2a_3} &= d_1\{(\varphi_{\mu L})_{a_1}(\gamma^{\mu}C)_{Ra_2a_3}+(\varphi_{\mu L})_{a_3}(\gamma^{\mu}C)_{La_1a_2}\}+d_2(G_{\mu\nu R})_{a_2}(\sigma^{\mu\nu}C)_{La_3a_1},
\end{aligned}
\tag{3.5}
$$

$$\psi^{RLL}_{a_1a_2a_3} = d_1\{(\varphi_{\mu L})_{a_2}(\gamma^\mu C)_{La_3a_1} + (\varphi_{\mu L})_{a_3}(\gamma^\mu C)_{Ra_1a_2}\} + d_2(G_{\mu\nu R})_{a_1}(\sigma^{\mu\nu}C)_{La_2a_3},$$

$$\psi^{LLL}_{a_1a_2a_3} = d_2\{(G_{\mu\nu L})_{a_1}(\sigma^{\mu\nu}C)_{La_2a_3} + (G_{\mu\nu L})_{a_2}(\sigma^{\mu\nu}C)_{La_3a_1} + (G_{\mu\nu L})_{a_3}(\sigma^{\mu\nu}C)_{La_1a_2}\}.$$

Chiral components (3.5) will be named symmetrized chiral components.

Our next step will be to write the free Lagrangian for the chiral components.

IV. CHIRAL TRANSFORMATION AND CHIRAL INVARIANCE

Let us turn now to the construction of the free field Lagrangian. If one imposes the requirement of Lorentz invariance and requires further that the Lagrangian be first order, the Lagrangian density will be written under the general form

$$\mathcal{L}_0 = a_1\overline{\psi}(i\partial\!\!\!/\otimes 1\otimes 1)\psi + a_2\overline{\psi}(1\otimes i\partial\!\!\!/\otimes 1)\psi + a_3\overline{\psi}(1\otimes 1\otimes i\partial\!\!\!/)\psi. \tag{4.1}$$

For spin $\frac{1}{2}$ particles, chiral transformation is defined as the following transformation of the field:

$$\psi \to \psi^{\text{chi}} = e^{i\theta\gamma^5}\psi = (\cos\theta + i\gamma^5\sin\theta)\psi. \tag{4.2}$$

The natural extension of (4.2) will be the following general chiral transformation:

$$\psi \to \psi^{\text{chi}} = e^{i\theta_1\gamma^5}\otimes e^{i\theta_2\gamma^5}\otimes e^{i\theta_3\gamma^5}\psi. \tag{4.3}$$

Under this general chiral transformation, the chiral components will be transformed as

$$\begin{aligned}
\psi_{RRR} &\to \psi^{\text{chi}}_{RRR} = e^{i(\theta_1+\theta_2+\theta_3)}\psi_{RRR},\\
\psi_{RRL} &\to \psi^{\text{chi}}_{RRL} = e^{i(\theta_1+\theta_2-\theta_3)}\psi_{RRL},\\
\psi_{RLR} &\to \psi^{\text{chi}}_{RLR} = e^{i(\theta_1-\theta_2+\theta_3)}\psi_{RLR},\\
\psi_{LRR} &\to \psi^{\text{chi}}_{LRR} = e^{i(-\theta_1+\theta_2+\theta_3)}\psi_{LRR},\\
\psi_{LLR} &\to \psi^{\text{chi}}_{LLR} = e^{i(-\theta_1-\theta_2+\theta_3)}\psi_{LLR},\\
\psi_{LRL} &\to \psi^{\text{chi}}_{LRL} = e^{i(-\theta_1+\theta_2-\theta_3)}\psi_{LRL},\\
\psi_{RLL} &\to \psi^{\text{chi}}_{RLL} = e^{i(\theta_1-\theta_2-\theta_3)}\psi_{RLL},\\
\psi_{LLL} &\to \psi^{\text{chi}}_{LLL} = e^{i(-\theta_1-\theta_2-\theta_3)}\psi_{LLL}.
\end{aligned} \tag{4.4}$$

As far as the chiral components are concerned, chiral transformation stands for phase transformations. Each chiral component transforms under a different phase.

In order to get a chiral invariant Lagrangian, we are left with just one among the following three options:

$$a_1 = a_2 = 0 \Rightarrow \theta_1 = \theta_2 = 0$$

or

$$a_1 = a_3 = 0 \Rightarrow \theta_1 = \theta_3 = 0$$

or

$$a_2 = a_3 = 0 \Rightarrow \theta_2 = \theta_3 = 0.$$

In the third case, that will be considered, from now on, the chiral invariant Lagrangian is

$$\mathcal{L}_0 = \overline{\psi}(i\not{\partial} \otimes 1 \otimes 1)\psi, \tag{4.5}$$

which is invariant under the chiral transformation

$$\psi \rightarrow \psi^{\text{chi}} = e^{i\theta_1 \gamma^5} \otimes 1 \otimes 1 \psi. \tag{4.6}$$

Our proposal for treating massless spin $\frac{3}{2}$ particles is, in close analogy with spin $\frac{1}{2}$ particles,[3,4] to treat all chiral components as independent field variables. In this way we consider all chiral components as dynamical variables. It is simple to check that the substitution of (3.2) into (4.5) leads to the following Lagrangian density:

$$\begin{aligned}\mathcal{L} = {} & \overline{\psi}_{RRR}(\ )\psi_{RLL} + \overline{\psi}_{RRL}(\ )\psi_{RLR} + \overline{\psi}_{RLR}(\ )\psi_{RRL} + \overline{\psi}_{LRR}(\ )\psi_{LLL} \\ & + \overline{\psi}_{LLR}(\ )\psi_{LRL} + \overline{\psi}_{LRL}(\ )\psi_{LLR} + \overline{\psi}_{RLL}(\ )\psi_{RRR} + \overline{\psi}_{LLL}(\ )\psi_{LRR},\end{aligned} \tag{4.7}$$

where ( ) stands for the operator $i\not{\partial} \otimes 1 \otimes 1$.

Treating all chiral components as independent field variables, one gets from (4.7) the following equations of motion:

$$\begin{aligned}
&(i\not{\partial} \otimes 1 \otimes 1)\psi_{RLL} = 0, \\
&(i\not{\partial} \otimes 1 \otimes 1)\psi_{RLR} = 0, \\
&(i\not{\partial} \otimes 1 \otimes 1)\psi_{RRL} = 0, \\
&(i\not{\partial} \otimes 1 \otimes 1)\psi_{LLL} = 0, \\
&(i\not{\partial} \otimes 1 \otimes 1)\psi_{LRL} = 0, \\
&(i\not{\partial} \otimes 1 \otimes 1)\psi_{LLR} = 0, \\
&(i\not{\partial} \otimes 1 \otimes 1)\psi_{RRR} = 0, \\
&(i\not{\partial} \otimes 1 \otimes 1)\psi_{LRR} = 0.
\end{aligned} \tag{4.8}$$

We write the equations of motion (4.8) for the symmetric and nonsymmetric decompositions of the chiral components. The nonsymmetrized chiral components leads to the following set of equations:

$$\begin{aligned}
&(\tfrac{1}{2}(1-\gamma^5)\gamma^\mu \not{\partial} C)_{a_3 a_1}(\mathbf{\Phi}_{\mu_L^R})_{a_2} = 0, \\
&(\tfrac{1}{2}(1+\gamma^5)\gamma^\mu \not{\partial} C)(\mathbf{\Phi}_{\mu_L^R}) = 0, \\
&(\tfrac{1}{2}(1-\gamma^5)\sigma^{\mu\nu} \not{\partial} C)(\mathcal{G}_{\mu\nu_L^R}) = 0, \\
&(\tfrac{1}{2}(1+\gamma^5)\sigma^{\mu\nu} \not{\partial} C)(\mathcal{G}_{\mu\nu_L^R}) = 0.
\end{aligned} \tag{4.9}$$

From the above equations it follows that

$$(\gamma^{\mu}\partial\!\!\!/ C)_{a_3a_1}\mathbf{\Phi}_{\mu,a_2}=0, \tag{4.10}$$

$$(\sigma^{\mu\nu}\partial\!\!\!/ C)_{a_3a_1}\mathcal{G}_{\mu\nu,a_2}=0. \tag{4.11}$$

Multiplying (4.10) successively by $(C^{-1})_{a_1a_3}$ and $(C^{-1}\gamma^{\alpha}\gamma^{\beta})_{a_1a_3}$, we obtain after some additional trivial manipulations, the massless Rarita–Schwinger equations for the vector spinor $\mathbf{\Phi}^{\mu}_{,a}$.

The symmetrized decomposition of the spinor field will result in the following set of equations:

$$\begin{aligned}
&(\partial\!\!\!/ G_{\mu\nu}{}^{R}_{L})_{a_1}(\sigma^{\mu\nu}C^{R}_{L})_{a_2a_3}-(G_{\mu\nu}{}^{R}_{L})_{a_2}(\sigma^{\mu\nu}{}^{R}_{L}\partial\!\!\!/ C)_{a_3a_1}+(G_{\mu\nu}{}^{R}_{L})_{a_3}(\partial\!\!\!/(\sigma^{\mu\nu}C)^{R}_{L})_{a_1a_2}=0,\\
&d_1\{(\partial\!\!\!/\varphi_{\mu}{}^{R}_{L})_{a_1}(\gamma^{\mu}C^{R}_{L})_{a_2a_3}-(\varphi_{\mu}{}^{R}_{L})_{a_2}[(\gamma^{\mu})^{R}_{L}\partial\!\!\!/ C]_{a_3a_1}\}+d_2(G_{\mu\nu}{}^{R}_{L})_{a_3}(\partial\!\!\!/(\sigma^{\mu\nu}C)^{R}_{L})_{a_1a_2}=0,\\
&d_1\{(\partial\!\!\!/\varphi_{\mu}{}^{R}_{L})_{a_1}(\gamma^{\mu}C^{R}_{L})_{a_2a_3}+(\varphi_{\mu}{}^{R}_{L})_{a_3}[\partial\!\!\!/(\gamma^{\mu}C)^{R}_{L}]_{a_1a_2}\}-d_2(G_{\mu\nu}{}^{L}_{R})_{a_2}[(\sigma^{\mu\nu})^{R}_{L}\partial\!\!\!/ C]_{a_3a_1}=0,\\
&d_1\{-(\varphi_{\mu}{}^{R}_{L})_{a_2}[(\gamma^{\mu})^{R}_{L}\partial\!\!\!/ C]_{a_3a_1}+(\varphi_{\mu}{}^{R}_{L})_{a_3}[\partial(\gamma^{\mu}C)^{R}_{L}{}_{a_1a_2}+d_2(\partial\!\!\!/ G_{\mu\nu}{}^{L}_{R})_{a_1}(\sigma^{\mu\nu}C)^{R}_{L}{}_{a_2a_3}=0.
\end{aligned} \tag{4.12}$$

From (4.12) it follows that

$$\begin{aligned}
&d_1\{(\partial\!\!\!/)_{a_1a'_1}\varphi_{\mu a'_1}(\gamma^{\mu}C)_{a_2a_3}-\varphi_{\mu a_2}(\gamma^{\mu}\partial\!\!\!/ C)_{a_3a_1}+\varphi_{\mu a_3}(\partial\!\!\!/\gamma^{\mu}C)_{a_1a_2}\}\\
&\quad+d_2\{(\partial\!\!\!/)_{a_1a'_1}G_{\mu\nu a'_1}(\sigma^{\mu\nu}C)_{a_2a_3}+G_{\mu\nu a_3}(\partial\!\!\!/\sigma^{\mu\nu}C)_{a_1a_2}-G_{\mu\nu a_2}(\sigma^{\mu\nu}\partial\!\!\!/ C)_{a_3a_1}\}=0.
\end{aligned} \tag{4.13}$$

Now, the multiplication of (4.13) by C^{-1}, $C^{-1}\gamma^{\eta}$, and $C^{-1}\gamma^{\eta}\gamma^{\lambda}$ gives rise to three equations in φ^{μ}, $G^{\mu\nu}$ and derivatives of these fields. We get

$$\partial^{\mu}\mathbf{\Phi}_{\mu}=0, \tag{4.14a}$$

$$\partial^{\mu}\mathcal{G}_{\mu\nu}=0, \tag{4.14b}$$

$$g^{\alpha\beta}\partial^{\mu}\mathbf{\Phi}_{\mu}-\partial^{\alpha}\mathbf{\Phi}^{\beta}-\partial^{\beta}\mathbf{\Phi}^{\alpha}=0. \tag{4.14c}$$

It is easy to check that the equations (4.14a), (4.14b), (4.14c) will lead us, remembering also condition (2.5) for $\mathbf{\Phi}^{\mu}$ (trivially satisfied in the symmetrized version), to the RS massless equations.

Chiral components remove the ambiguity in the Lagrangian approach to spin $\frac{3}{2}$ massless particles. We have a well-defined Lagrangian, built from first principles, and it does not matter which decomposition one uses.

As we shall see in the next section the chiral spinorial approach is the only anomaly free framework for massless particles.

V. MASSIVE SPIN $\frac{3}{2}$ PARTICLES

We know that at some level chiral invariance is broken. For example, a mass term breaks chiral invariance. We propose then that the Lagrangian in the massive case, be of the form

$$\mathcal{L}=\overline{\psi}(i\partial\!\!\!/\otimes 1\otimes 1)\psi-m\overline{\psi}\psi. \tag{5.1}$$

By making the variation over the field $\overline{\psi}$ we will get just one equation for the field ψ, that is,

$$i\partial\!\!\!/\otimes 1\otimes 1\psi=m\psi. \tag{5.2}$$

Let us consider first the explicitly symmetric expansion of ψ. The advantage of this symmetric expression is that we can deduce all properties and equations for φ_μ and $G_{\mu\nu}$ from just one Dirac-type equation. In this case it does not matter which of the three equations (2.1) one uses. We take equation (2.1a).

From (5.2) it follows the following equations for φ_μ and $G_{\mu\nu}$:

$$\partial_\mu\{d_1(2\varphi^{\mu}_{,a_1}+(\gamma^\alpha\gamma^\mu)_{a_1a_2}\varphi_{\alpha,a_2})+d_2(\sigma^{\alpha\beta}\gamma^\mu)_{a_1a_2}G_{\alpha\beta,a_2}\}=0, \tag{5.3}$$

$$\begin{aligned} &i\{d_1(\gamma^\mu\partial^\nu\varphi_\mu-\gamma^\mu\gamma^\rho\gamma^\nu\partial_\rho\varphi_\mu)+d_2(\sigma^{\alpha\beta}\partial^\nu G_{\alpha\beta}-\sigma^{\alpha\beta}\gamma^\rho\gamma^\nu)\partial_\rho G_{\alpha\beta}\}+4d_2\partial_\rho G^{\nu\rho}\\ &\quad=md_1\{2\varphi^\nu+(\gamma^\alpha\gamma^\nu)\varphi_\alpha\}+md_2(\sigma^{\alpha\beta}\gamma^\nu)G_{\alpha\beta}, \end{aligned} \tag{5.4}$$

$$\begin{aligned} &i\{d_1[\partial^\lambda(2\varphi^\eta+\gamma^\mu\gamma^\eta\varphi_\mu)+\partial^\eta(2\varphi^\lambda+\gamma^\mu\gamma^\lambda\varphi_\mu)-\partial_\alpha g^{\lambda\eta}(2\varphi^\alpha+\gamma^\mu\gamma^\alpha\varphi_\mu)]\\ &\quad+d_2[\partial^\lambda(\sigma^{\mu\nu}\gamma^\eta)-\partial^\eta(\sigma^{\mu\nu}\gamma^\lambda)-\partial_\alpha g^{\lambda\eta}(\sigma^{\mu\nu}\gamma^\alpha)]G_{\mu\nu}\}\\ &\quad=md_1\gamma^\mu(g^{\lambda\eta}-\gamma^\lambda\gamma^\eta)\varphi_\mu+md_2\{-4iG^{\eta\lambda}-(\sigma^{\mu\nu}\gamma^\lambda\gamma^\eta)G_{\mu\nu}+g^{\lambda\eta}\sigma^{\mu\nu}G_{\mu\nu}\} \end{aligned} \tag{5.5}$$

[spinor indices omitted in (5.3), (5.4), and (5.5)].

The equations (5.3), (5.4), and (5.5) can be rewritten in a simpler form if one uses properties (2.9) and (2.10). These alternative expressions are

$$\partial^\mu\mathbf{\Phi}_\mu=0, \tag{5.6}$$

$$-2D_2\partial_\alpha\mathcal{G}^{\alpha\nu}=mD_1\mathbf{\Phi}^\nu, \tag{5.7}$$

$$D_1(\partial^\lambda\mathbf{\Phi}^\eta-\partial^\eta\mathbf{\Phi}^\lambda-g^{\lambda\eta}\partial_\alpha\mathbf{\Phi}^\alpha)=2mD_2\mathcal{G}^{\lambda\eta}. \tag{5.8}$$

As a consequence of the above equations we establish that the spinor vector $\mathbf{\Phi}^\mu_{,a}$, obeys a Dirac-type equation

$$(i\partial\!\!\!/-m)_{a_1a_2}\mathbf{\Phi}^\mu_{,a_2}=0. \tag{5.9}$$

So that, the symmetric expansion (2.3) gives rise to a vector spinor $\mathbf{\Phi}^\mu_{,a}$ which satisfies the RS equations.

Let us turn now to the nonsymmetric decomposition of the ψ field. At first sight it might appear that we cannot get Rarita–Schwinger equation from just one Dirac-type equation [like Eq. (5.2)]. We can get RS equations if one uses decomposition (2.2b). Decompositions (2.2a) and (2.2c) will lead to RS equations by using (2.1b) and (2.1c). That is, for each decomposition we need to use a different equation.

As a final remark we would like to comment on the massless case. We can show explicitly that the $m=0$ limit of (5.3)–(5.5) do not lead to the Rarita–Schwinger equations. In this case the only alternative is to use our previous equations for the chiral components.

VI. SIMPLER LAGRANGIANS IN THE MASSIVE CASE

The usual RS Lagrangian involving the spinor–vector $\mathbf{\Phi}^\mu$, is built in a somehow artificial manner.[6] That is, it is constructed in such a way as to give rise to the equations and constraints satisfied by the vector-spinor field.

We should see that the chiral approach lead naturally to an unambiguous Lagrangian formulation. The difference from the usual approaches is that our Lagrangians are written in terms of $\mathcal{G}^{\mu\nu}_a$ and $\mathbf{\Phi}^\mu_a$ which are then treated as dynamical variables.

If one wants to write simpler Lagrangians in terms of the fields $\mathbf{\Phi}^\mu_{,a}$ and $\mathcal{G}^{\mu\nu}_{,a}$, all we have to do is to substitute ψ given in (2.2b) into Lagrangian (5.1). Doing so we get

$$\mathcal{L}=4D_1^*D_2\overline{\mathbf{\Phi}}_{\mu,a}(\partial_\alpha\mathcal{G}^{\alpha\mu}_{,a}-\partial_\alpha\mathcal{G}^{\mu\alpha}_{,a})+4D_2^*D_1\overline{\mathcal{G}}_{\mu\nu,a}(\partial^\nu\mathbf{\Phi}^\mu_{\ a}-\partial^\mu\mathbf{\Phi}^\nu_{\ a})$$
$$+4D_1^*D_1m\overline{\mathbf{\Phi}}^\mu_{,a}\mathbf{\Phi}_{\mu,a}+8D_2^*D_2m\overline{\mathcal{G}}^{\mu\nu}_{,a}\mathcal{G}_{\mu\nu,a}. \tag{6.1}$$

Considering $\mathbf{\Phi}^\mu_{,a}$ and $\mathcal{G}^{\mu\nu}_{,a}$ as independent field variables, we get the following Euler-Lagrange equations:

$$2D_2\partial_\mu\mathcal{G}^{\mu\nu}_{,a}=-mD_1\mathbf{\Phi}^\nu_{,a}, \tag{6.2}$$

$$2mD_2\mathcal{G}^{\mu\nu}_{,a}=D_1(\partial^\mu\mathbf{\Phi}^\nu_{\ a}-\partial^\nu\mathbf{\Phi}^\mu_{\ a}). \tag{6.3}$$

Now, by construction, $\mathcal{G}^{\mu\nu}_{\ a}$ is antisymmetric in its vector indices, from this fact and Eq. (6.2) it follows that

$$\partial^\mu\mathbf{\Phi}_{\mu,a}=0. \tag{6.4}$$

Now, if one considers Eqs. (6.2)–(6.4) together with the conditions (2.5) and (2.6) satisfied by $\mathbf{\Phi}^\mu_{,a}$ and $\mathcal{G}^{\mu\nu}_{,a}$, we can see that $\mathbf{\Phi}^\mu_{,a}$ obeys Dirac equation

$$(i\not\partial-m)_{a_1a_2}\mathbf{\Phi}^\mu_{a_2}=0. \tag{6.5}$$

Equations (2.5), (6.4), and (6.5) for the vector–spinor $\mathbf{\Phi}^\mu_{,a}$, are exactly the RS equations.

Now let us use the symmetrized expansion (2.3) of ψ. The results are a little bit different. To illustrate this point, we consider just the massless case, and use the expression (4.5).

Substituting ψ by the decomposition (2.3) in (4.5), we obtain the following expression for the massless Lagrangian:

$$\mathcal{L}=i\{-2d_1^*d_1(2\overline{\varphi}_\mu\not\partial\varphi^\mu+\overline{\varphi}^\mu\not\partial\gamma^\alpha\gamma^\mu\varphi_\alpha+\overline{\varphi}_\mu\gamma^\alpha\gamma^\mu\not\partial\varphi_\alpha-\overline{\varphi}_\mu\gamma^\alpha\not\partial\gamma^\mu\varphi_\alpha)$$
$$-2d_1^*d_2(\overline{\varphi}_\mu\not\partial\sigma^{\alpha\beta}\gamma^\mu G_{\alpha\beta}+\overline{\varphi}_\mu\sigma^{\alpha\beta}\gamma^\mu\not\partial G_{\alpha\beta}-\overline{\varphi}_\mu\sigma^{\alpha\beta}\not\partial\gamma^\mu G_{\alpha\beta}+8i\overline{\varphi}_\mu\partial^\alpha G_\alpha{}^\mu)$$
$$-2d_2^*d_1(\overline{G}_{\mu\nu}\not\partial\gamma^\alpha\sigma^{\mu\nu}\varphi_\alpha+\overline{G}_{\mu\nu}\gamma^\alpha\sigma^{\mu\nu}\not\partial\varphi_\alpha-\overline{G}_{\mu\nu}\gamma^\alpha\not\partial\sigma^{\mu\nu}\varphi_\alpha+4i\overline{G}_{\mu\nu}(\partial^\nu\varphi^\mu-\partial^\mu\varphi^\nu))$$
$$-2d_2^*d_2(4\overline{G}_{\mu\nu}\not\partial G^{\mu\nu}+\overline{G}_{\mu\nu}\not\partial\sigma^{\alpha\beta}\sigma^{\mu\nu}G_{\alpha\beta}+\overline{G}_{\mu\nu}\sigma^{\alpha\beta}\sigma^{\mu\nu}\not\partial G_{\alpha\beta}-\overline{G}_{\mu\nu}\sigma^{\alpha\beta}\not\partial\sigma^{\mu\nu}G_{\alpha\beta})\}, \tag{6.6}$$

where φ^μ stands for $\varphi^\mu_{,a}$ (for example), and the obvious summed spinor indices were omitted.

Considering $\varphi^\mu_{,a}$ and $G^{\mu\nu}_{,a}$ as independent field variables, we write the Euler–Lagrange equations and obtain two equations. We give here the ''translated'' expression of this two equations, obtained using ''the dictionary'' equations (2.9) and (2.10), in order to have simpler, but equivalent, equations than the original ones. We have

$$D_1\not\partial_{a_1a_2}\mathbf{\Phi}^\mu_{a_2}-4iD_2\partial_\alpha\mathcal{G}^{\mu\alpha}_{,a_1}=0, \tag{6.7}$$

$$D_2\not\partial_{a_1a_2}\mathcal{G}^{\mu\nu}_{a_2}+iD_1(\partial^\nu\mathbf{\Phi}^\mu_{a_1}-\partial^\mu\mathbf{\Phi}^\nu_{a_1})=0. \tag{6.8}$$

Clearly the conditions (2.5) and (2.6) with respect to $\mathbf{\Phi}^\mu$ and $\mathcal{G}^{\mu\nu}$ are understood. Having this last point in mind, it is easy to show that in fact (6.7) is a consequence of (6.8), and therefore we have only one independent equation relating $\mathbf{\Phi}^\mu$ and $\mathcal{G}^{\mu\nu}$ in this case. This symmetric approach gives rise to too few equations for too many fields. We need to fix or to impose extra conditions in order to reduce this number of degrees of freedom. Having in mind the results obtained using a nonsymmetric expansion for ψ, we propose to separate equations (6.7) and (6.8) into two vanishing parts:

$$D_1 \not\partial_{a_1 a_2} \mathbf{\Phi}^{\mu}_{a_2} = 4iD_2 \partial_\alpha \mathcal{G}^{\mu\alpha}_{a_1} = 0, \tag{6.9}$$

$$D_2 \not\partial_{a_1 a_2} \mathcal{G}^{\mu\nu}_{a_2} = iD_1 (\partial^\mu \mathbf{\Phi}^{\nu}_{a_1} - \partial^\nu \mathbf{\Phi}^{\mu}_{a_1}). \tag{6.10}$$

Now, as a consequence of the two last equations and the condition (2.5) we have

$$\partial^\mu \mathbf{\Phi}_{\mu,a} = 0.$$

We get in this way the RS equations, for the spinor vector $\mathbf{\Phi}^{\mu}_{,a}$. We can justify the method used here only when one looks back to Sec. IV. There we have made use of the chiral components.

VII. EFFECTIVE INTERACTIONS

In previous papers[5,7] we have constructed effective interactions for particles of arbitrary spin. In Ref. 5 we have made the description of a particle of spin s by using a symmetric rank $2s$ spinor (BW method) and by using this field we obtain interactions making contractions of the spinor indices. For example, an interaction involving one spin $\frac{3}{2}$ particle and three spin $\frac{1}{2}$ particles, can be written as

$$\overline{\psi}_{a_1 a_2 a_3} (\eta^C)_{a_1} \eta_{a_2} \eta_{a_3}, \tag{7.1}$$

η^C is a charge conjugated spin $\frac{1}{2}$ spinor.

An interaction term involving spin $\frac{3}{2}$ with spin 1 and spin $\frac{1}{2}$ particles can be written in this approach as

$$\overline{\psi}_{a_1 a_2 a_3} \psi_{a_1 a_2} \eta_{a_3} \tag{7.2}$$

or

$$\overline{\psi}_{a_1 a_2 a_3} \psi_{a_1 a_3} \eta_{a_2}. \tag{7.3}$$

If we rememember[3] the decomposition (7.4) for a spin 1 field:

$$\psi_{a_1 a_2} = C_1 A_\alpha (\gamma^\alpha C)_{a_1 a_2} + C_2 F_{\alpha\beta} (\sigma^{\alpha\beta} C)_{a_1 a_2} \tag{7.4}$$

the interaction term (7.2) involving particles of spin $\frac{3}{2}$, 1 and $\frac{1}{2}$ may be written as

$$-D_1^* C_1 A_\alpha \overline{\mathbf{\Phi}}_{\mu,a_2} (\gamma^\alpha \gamma^\mu)_{a_2 a_3} \eta_{a_3} - D_2^* C_1 A_\alpha \overline{\mathcal{G}}_{\mu\nu,a_2} (\gamma^\alpha \sigma^{\mu\nu})_{a_2 a_3} \eta_{a_3},$$

$$-D_1^* C_2 F_{\alpha\beta} \overline{\mathbf{\Phi}}_{\mu,a_2} (\sigma^{\alpha\beta} \gamma^\mu)_{a_2 a_3} \eta_{a_3} - D_2^* C_2 F_{\alpha\beta} \overline{\mathcal{G}}_{\mu\nu,a_2} (\sigma^{\alpha\beta} \sigma^{\mu\nu})_{a_2 a_3} \eta_{a_3}. \tag{7.5}$$

The chiral method introduces some improvements for the construction of effective interactions. We have now a richer set of alternative Lagrangians. Furthermore, we are now able to separate vector–spinor and tensor–spinor parts. For example, in the case of the nonsymmetric decomposition of the rank 3 spinor $\psi_{a_1 a_2 a_3}$, we have

$$(\overline{\psi}_{RRL} + \overline{\psi}_{LRR} + \overline{\psi}_{LLR} + \overline{\psi}_{RLL})_{a_1 a_2 a_3} = -D_1^* \overline{\Phi}_{\mu,a_2} (C^{-1} \gamma^\mu)_{a_3 a_1}, \tag{7.6}$$

whereas the combination associated to $\overline{\mathcal{G}}_{\mu\nu}$ is

$$(\overline{\psi}_{RRR} + \overline{\psi}_{LRL} + \overline{\psi}_{RLR} + \overline{\psi}_{LLL})_{a_1 a_2 a_3} = -D_2^* \overline{\mathcal{G}}_{\mu\nu,a_2} (C^{-1} \sigma^{\mu\nu})_{a_3 a_1}. \tag{7.7}$$

In expression (7.6) we have just the vector spinor $\mathbf{\Phi}^{\mu}_{a}$ whereas in (7.7) we have just the tensor spinor $\mathcal{G}^{\mu\nu}_{a}$.

The interaction resulting from (7.6) for spin $\frac{1}{2}$ particles is, from (7.1):

$$D_1^*(\overline{\eta}_{a_2}\gamma^{\mu}_{a_2a_3}\eta_{a_3})(\overline{\Phi}_{\mu,a_2}\eta_{a_2}). \tag{7.8}$$

We are also able to separe the purely vector, vector–tensor and purely tensor parts of the expansion of the field ψ by using the chiral components.

The purely vector part is given by the interaction Lagrangian

$$\begin{aligned}&(\overline{\psi}_{RRL}+\overline{\psi}_{LRR}+\overline{\psi}_{LLR}+\overline{\psi}_{RLL})_{a_1a_2a_3}(\psi_{RL}+\psi_{LR})_{a_1a_2}\eta_{a_3}\\&\quad=-D_1^*C_1A_{\alpha}\overline{\mathbf{\Phi}}_{\mu,a_2}(\gamma^{\alpha}\gamma^{\mu})_{a_2a_3}\eta_{a_3}.\end{aligned} \tag{7.9}$$

The interaction between vector field A_{μ} and tensor components ($\mathcal{G}_{\mu\nu,a}$) is given by the following interaction terms:

$$\begin{aligned}&(\overline{\psi}_{RRR}+\overline{\psi}_{LRL}+\overline{\psi}_{RLR}+\overline{\psi}_{LLL})_{a_1a_2a_3}(\psi_{RL}+\psi_{LR})_{a_1a_2}\eta_{a_3}\\&\quad=-D_2^*C_1A_{\alpha}\overline{\mathcal{G}}_{\mu\nu,a_2}(\gamma^{\alpha}\sigma^{\mu\nu})_{a_2a_3}\eta_{a_3}\end{aligned} \tag{7.10}$$

and between the tensor field $F_{\mu\nu}$ and the vector spinor $\mathbf{\Phi}_{\mu}$ by the Lagrangian

$$\begin{aligned}&(\overline{\psi}_{RRL}+\overline{\psi}_{LRR}+\overline{\psi}_{LLR}+\overline{\psi}_{RLL})_{a_1a_2a_3}(\psi_{RR}+\psi_{LL})_{a_1a_2}\eta_{a_3}\\&\quad=-D_1^*C_2F_{\alpha\beta}\overline{\mathbf{\Phi}}_{\mu,a_2}(\sigma^{\alpha\beta}\gamma^{\mu})_{a_2a_3}\eta_{a_3},\end{aligned} \tag{7.11}$$

whereas the purely tensor interaction is associated to the following chiral components interaction:

$$(\overline{\psi}_{RRR}+\overline{\psi}_{LRL}+\overline{\psi}_{RLR}+\overline{\psi}_{LLL})_{a_1a_2a_3}(\psi_{RR}+\psi_{LL})_{a_1a_2}\eta_{a_3}=-D_2^*C_2F_{\alpha\beta}\overline{\mathcal{G}}_{\mu\nu,a_2}(\sigma^{\alpha\beta}\sigma^{\mu\nu})_{a_2a_3}\eta_{a_3}. \tag{7.12}$$

We can also introduce effective interactions involving just one, or more chiral components. That is, at the interaction level the different chiral components might interact with different strengths. This means that at the interaction level we might have left–right asymmetry. For example, if one couples just the ψ_{RRL} spin $\frac{3}{2}$ component with three spin $\frac{1}{2}$ particles we get the only nonzero term:

$$\begin{aligned}&(\overline{\psi}_{RRL})_{a_1a_2a_3}(\eta_R^C)_{a_1}(\eta_L)_{a_2}(\eta_R)_{a_3}\\&\quad=-D_1^*\overline{\Phi}_{\mu,a}\tfrac{1}{2}(1-\gamma^5)_{aa_1}\eta_{a_1}\overline{\eta}_{a_2}(\tfrac{1}{2}(1-\gamma^5)\gamma^{\mu})_{a_2a_3}\eta_{a_3}.\end{aligned} \tag{7.13}$$

Clearly the consequence of such an interaction term is that there will be parity violation.

VIII. CONCLUSIONS

In this paper we have expanded even further the idea that chirality is a basic notion in the description of particles of arbitrary spin. We have shown that a consistent description of spin $\frac{3}{2}$ particles can be achieved by using our chiral spinorial method.

Our approach is different from others in the sense that we take the interaction of spin $\frac{1}{2}$ particles as a guide to other interactions. That is, at the free field level one imposes chiral invariance as a guide to establish the Lagrangian.

Another important distinction from other approaches is that we treat all eight chiral components as independent field variables. This allows us to get a consistent Lagrangian method for massless spin $\frac{3}{2}$ particles.

The extension of this Lagrangian to the massive case is straightforward. In the massive case, we have shown how the description here proposed (using the prescription that the chiral components be treated as independent field variables) lead to the same results as in the case of RS theory. It is important to stress here the main distinction between our approach and RS theory. In our case there is a Lagrangian, the equations of motion for all chiral components are very similar to each other, the discrete symmetries can be analyzed and the zero mass limit can be properly treated.

For the massive case we have shown that our Lagrangian provides a way of getting Rarita–Schwinger equations by using three different methods.

At the free field level we show that the chiral approach lead to an unambiguous Lagrangian for the description of spin $\frac{3}{2}$ particles. This is the only consistent Lagrangian method for massless particles.

As far as interactions of spin $\frac{3}{2}$ particles are concerned, our approach provides a very simple method for the construction of effective interactions. We get, by treating the chiral components as independent variables, a large number of effective Lagrangians. Some of them might be useful in phenomenological applications.

High-frequency asymptotics for Maxwell's equations in anisotropic media Part I: Linear geometric and diffractive optics

Josselin Garnier[a)]
Centre de Mathématiques Appliquées, Ecole Polytechnique, 91128 Palaiseau Cedex, France

(Received 28 October 1999; accepted for publication 10 January 2001)

This paper is devoted to the derivation of the equations that govern the propagation of pulses in noncentrosymmetric crystals. The method is based upon high-frequency expansions techniques for Maxwell's equations. By suitable choices of the scalings we are able to derive two classical models: Geometric optics and diffractive optics (Schrödinger-type equations). In the so-called geometric regime we recover the standard results on the propagation of pulses in crystals (dispersion equation, polarization states, group velocity). In the diffractive regime we exhibit original results and give a closed-form expression for the diffraction operator which reads as an anisotropic operator. Given this expression we identify a critical configuration where the diffraction reduces to a one-dimensional second-order operator instead of the standard transverse Laplacian. © *2001 American Institute of Physics.* [DOI: 10.1063/1.1354639]

I. INTRODUCTION

Many crystals and liquid crystals have optical properties which depend on the direction of propagation and the polarization of light. A precise understanding of light propagation in such anisotropic media is important for both theoretical and practical applications. Indeed this problem is theoretically interesting in that it exhibits many optical phenomena such as polarizations effects, optical rotation, and conical refraction.[1] It is also practically relevant since anisotropic media are essential components for many optical devices such as prism polarizers, birefringent filters, and Pockels cells.[2] Anisotropic media are also used for phase-matched frequency conversion.[3] The aim of this paper is to describe the effects of the anisotropy of the medium so as to derive evolution equations for the slowly varying envelopes of fields. Such results have been already obtained using more or less ad hoc methods (see Ref. 4 and references therein). In particular a modern method of solving optical problems is based on the integral formulation of the field equation and the determination of the Green function.[5] The method requires an explicit representation of the Green function which is obtained by the use of a Fourier transform. Then applying stationary phase method one gets the asymptotic form of the Green function. This method is efficient for linear media, but it is not well-adapted for addressing nonlinear problems since the use of Fourier transforms, and thus the derivation of an explicit form of the solution, are then prohibited.

We shall use a technique based on high-frequency expansions of the fields which has already been successfully applied to systems of linear, semilinear and quasilinear hyperbolic partial differential equations (see Ref. 6 and references therein). This technique is more robust than the Green function approach in the sense that the approximate solutions are not derived by an asymptotic analysis of an explicit solution, but through a direct asymptotic analysis of Maxwell's equations. This high-frequency asymptotics method can deal with boundary conditions and—more important—it can handle nonlinearities. Applying this technique to Maxwell's equations in anisotropic media allows us to get evolution equations for the field envelopes in both the scales

[a)]Telephone: 01.69.33.46.30; Fax: 01.69.33.30.11. Electronic mail: garnier@cmapx.polytechnique.fr

corresponding to geometric optics and diffractive optics. We are then able to write equations which recover the classical results and also exhibit original results such as the explicit form of the anisotropic second-order operator which plays the role of the transverse Laplace operator in the standard Schrödinger equation.

The theoretical derivations of the equations and the physically relevant applications are quite long, but they can be divided into two parts. In this paper we restrict ourselves to linear propagation. Nonlinear propagation is addressed in the companion paper[7] that requires the results derived here below. The framework for high-frequency expansions of the solutions of Maxwell's equations follows from the appearance of the small parameter δ which has the order of magnitude of the carrier wavelength of light divided by the next smallest characteristic length present in the problem. If we consider the propagation along the z axis of a broadband and divergent pulse with carrier frequency ω, then there exists a wave number $k=k(\omega)$ such that the electric field $\mathcal{E}$ can be expanded as a series of slowly varying functions modulated by a rapid phase $\phi=kz-\omega t$

$$\mathcal{E}(t,x,y,z)=\frac{1}{2}\left(\sum_{j=0}^{\infty}\delta^j\mathbf{E}_j(\delta t,\delta x,\delta y,\delta z)e^{i(kz-\omega t)}+cc\right), \tag{1}$$

where *cc* is a shorthand for ''complex conjugate.'' We are particularly interested in determining the leading profile $\mathbf{E}_0$, the so-called slowly varying envelope of the field. We shall derive the evolution equation for $\mathbf{E}_0$ by using the fact that it reads as the compatibility condition for the existence of the expansion (1). We shall see that for propagation length (z) of order δ^{-1} times the wavelength, which corresponds to the scales of the so-called geometric optics, evolution equations read as transport equations with constant velocity. Further, in the moving pulse-time frame (moving according to the velocity exhibited by the geometric transport equations), we can study the evolution of the field for propagation lengths of order δ^{-2} times the wavelength, which corresponds to the scales of the so-called diffractive optics. The evolution of the slowly varying envelope of the field is then governed by a Schrödinger-type equation.

The paper is organized as follows. First we describe the general configuration at hand in Sec. II. Sections III–V are devoted to an extensive study of the linear propagation of pulses in biaxial crystals. We finally apply these results to specific configurations and discuss some applications in the last sections of this paper.

II. FORMULATION AND SCALING

We aim at focusing on the derivation of the propagation equation, so we consider simple boundary conditions. We refer to Refs. 8 and 9 for extensive treatments of very general boundary conditions. In this paper the plane $\Sigma:=\{(x',y,z)\in\mathbb{R}^3,z=0\}$ is the boundary surface that separates the semi-infinite vacuum $\mathbb{R}^3_-:=\{(x,y,z)\in\mathbb{R}^3,z<0\}$ on the left and a biaxial crystal on the right $\mathbb{R}^3_+:=\{(x,y,z)\in\mathbb{R}^3,z>0\}$. We consider an incident beam incoming from the left whose propagation axis is perpendicular to the boundary surface Σ and is collinear to the z axis.

We assume absence of free charges or currents ($\mathbf{j}=0$, $\rho=0$), and that the crystal is nonmagnetic so that its magnetic permeability $\mu\equiv\mu_0$. Inside the domain $\mathbb{R}^3_+$, the electric field $\mathcal{E}$ and magnetic induction $\mathcal{B}$ obey the Maxwell equations

$$\partial_t\mathcal{B}+\mathbf{rot}\,\mathcal{E}=0,$$

$$\mu_0\partial_t\mathcal{D}-\mathbf{rot}\,\mathcal{B}=0,$$

where $\mathcal{D}$ is the electric induction which contains the physic interaction between light and matter and can be expressed in terms of $\mathcal{E}$. The magnetic field $\mathcal{H}$ is simply given by $\mathcal{B}=\mu_0\mathcal{H}$. By differentiating the second equation with respect to time t and substituting into the first one, the magnetic induction is eliminated so that we get the equation which governs the evolution of the electric field

$$\mathbf{rot}\,\mathbf{rot}\,\mathcal{E}=-\mu_0\partial_t^2\mathcal{D}. \tag{2}$$

Equation (2) is insufficient to determine the electric field and has to be supplemented by a constitutive equation showing how the field is related to the properties of the medium. Assuming that the wave intensity is small enough so that the response of the medium is linear, the electric induction reads

$$\mathcal{D}=\varepsilon_0\mathcal{E}+\mathcal{P} \tag{3}$$

$$\mathcal{P}=\varepsilon_0\chi^{(1)}*\mathcal{E}=\varepsilon_0\int_{-\infty}^{t}dt_1\chi^{(1)}(t-t_1)\mathcal{E}(t_1), \tag{4}$$

where $\mathcal{P}$ is the polarization of the medium. We assume that the electromagnetic wave is far enough from all absorption lines of the medium so that we can neglect absorption and the tensor $\chi^{(1)}$ is real and symmetric. ε_0 and μ_0 are, respectively, the dielectric constant and magnetic permeability of vacuum. These constant quantities are related to the light velocity c by the identity $\varepsilon_0\mu_0c^2=1$.

In order to deal with a well-posed problem we must state boundary conditions in time and space domains. The boundary condition at the boundary surface Σ is imposed by the continuity of the tangential components of the magnetic and electric fields. If we know the total field $\mathcal{S}_{\text{tot}}$ in vacuum just in the limit slab $z=0^-$, then the electric field $\mathcal{E}$ within the crystal in $z=0^+$ should satisfy $\mathcal{E}\times\mathbf{n}=\mathcal{S}_{\text{tot}}\times\mathbf{n}$, where $\mathbf{n}$ is the outgoing normal direction $(0, 0, -1)$. Unfortunately we do not know *a priori* the total source, which divides into the sum of the incoming wave and the reflected wave. It is much more appropriate to consider as a boundary condition the incoming wave condition which is a well-adapted condition for almost normally incident pulses. The boundary conditions then read as the following equation over the interface Σ:

$$(\mathcal{E}-c\mathcal{B}\times\mathbf{n})\times\mathbf{n}=2\mathcal{S}\times\mathbf{n}, \tag{5}$$

where $\mathcal{S}$ is the source corresponding to the field of the incoming pulse given at the interface Σ by

$$\mathcal{S}(x,y,t)=\begin{pmatrix}\mathcal{S}_x(x,y,t)\\ \mathcal{S}_y(x,y,t)\\ 0\end{pmatrix}.$$

Last we assume that all unknown quantities are vanishing at time $t\leqslant 0$

$$\mathcal{E},\mathcal{B},\mathcal{D}(t=0)=0 \quad \text{in } \mathbb{R}^3_+.$$

The source is assumed to be a modulation of a high-frequency signal whose carrier wavelength is λ_0, or the superposition of a finite number of such modes. From the characteristic spatial (resp. temporal) variations of the envelope of the source we can also define a length scale R_0 (resp. a time scale T_0). In order to make comparison we associate to the time scale T_0 the corresponding length scale $L_0:=cT_0$. Our study will take place in the framework where the dimensionless parameter $\delta=\min\{\lambda_0/R_0,\lambda_0/L_0\}$ is small. Note that this assumption prevents from addressing the cases of ultrashort pulses (whose duration is of the order of a few femtoseconds) and of ultrafocused beams (whose radius is of the order of a few micrometers). The most interesting case is then the configuration where R_0 and L_0 are of the same order: $\lambda_0\ll R_0\sim L_0$, since it is the case that contains all physical phenomena and the other configurations $\lambda_0\ll R_0\ll L_0$ and $\lambda_0\ll L_0\ll R_0$ can be deduced from the first one by straightforward approximations. Setting $\delta=\lambda_0/R_0$, $\tilde{x}=x/\lambda_0$, $\tilde{y}=y/\lambda_0$, $\tilde{z}=z/\lambda_0$, and $\tilde{t}=ct/\lambda_0$, the dimensionless Maxwell equation reads as:

$$\tilde{\mathbf{rot}}\,\tilde{\mathbf{rot}}\,\mathcal{E}=-\tilde{\mu}_0\partial_t^2\mathcal{D},$$

where $\tilde{\mu}_0=\mu_0 c^2$. If we denote $\tilde{\varepsilon}_0=\varepsilon_0$ and $\tilde{c}=1$, then we still have the conservation relation $\tilde{\mu}_0\tilde{\varepsilon}_0\tilde{c}^2=1$. The source $\mathcal{S}$ has a high-frequency expansion of the form

$$\mathcal{S}(\tilde{x},\tilde{y},\tilde{t})=\frac{1}{2}\sum_{\omega_f\in\Omega_{\mathcal{S}}}\begin{pmatrix} v_x^f(\delta\tilde{t},\delta\tilde{x},\delta\tilde{y}) \\ v_y^f(\delta\tilde{t},\delta\tilde{x},\delta\tilde{y}) \\ 0 \end{pmatrix} e^{-i\omega_f\tilde{t}}+cc. \tag{6}$$

$\Omega_{\mathcal{S}}$ is the collection (with finite cardinality) of the high carrier frequencies ω_f of the modes that the source contains. These carrier frequencies are now of order 1. $\mathbf{v}^f$ is the slowly varying envelope of the mode with carrier frequency ω_f, and the typical scale of the variations of the smooth function $(T,X,Y)\mapsto\mathbf{v}^f(T,X,Y)$ is of order 1. Note that a dimensionless propagation distance $\tilde{z}$ of the order of δ^{-1} corresponds to a physical distance of the order of R_0. Further a dimensionless propagation distance $\tilde{z}$ of the order of δ^{-2} corresponds to a physical distance of the order of R_0^2/λ_0 which is the well-known Rayleigh distance.

From now on we drop the tildes. We assume *a priori* that the electric field, the electric induction and the polarization can be expanded in a power series of the small parameter δ and in a series with respect to a set of rapid phases $k^f z-\omega_f t$:

$$\mathcal{E}=\frac{1}{2}\sum_{(\omega_f,k^f)\in H}(\mathbf{E}^f(\delta t,\delta x,\delta y,\delta z)e^{i(k^f z-\omega_f t)}+cc), \tag{7a}$$

$$\mathbf{E}^f(T,X,Y,Z)=\sum_{j=0}^{\infty}\delta^j\mathbf{E}_j^f(T,X,Y,Z), \tag{7b}$$

where $\mathbf{E}^f$ is the slowly varying envelope of the mode whose rapid phase is (ω_f,k^f). The functions $\mathbf{E}_j^f$ are smooth in all their arguments. H denotes the set of the rapid phases (ω_f,k^f) which are contained in the field $\mathcal{E}$. Finally note that the slow variables will be denoted throughout the paper by capital letters (say T), while the fast variables, or microscopic, will be represented by lower case letters (say t).

III. LINEAR POLARIZATION

A. Geometry

We introduce the geometric framework. We first define a reference frame (x, y, z) associated with the pulse where the carrier wave vector of the incoming pulse is collinear to the z axis. We then introduce a reference frame (1, 2, 3) associated with the optic axis of the crystal, where $\mathbf{e}_3$ is the main optic axis. The description of the carrier wave vector in the crystal reference frame is given in Fig. 1. θ stands for the angle between the wave vector $\mathbf{k}_0$ and the main optic axis. ϕ is the angle between the projection of the wave vector onto the plane $(\mathbf{e}_1,\mathbf{e}_2)$ and the axis collinear to $\mathbf{e}_1$. In such a configuration the transition matrix between the reference frames (x, y, z) and (1, 2, 3) is

$$U:=\begin{pmatrix} \cos\theta\cos\phi & -\sin\phi & \sin\theta\cos\phi \\ \cos\theta\sin\phi & \cos\phi & \sin\theta\sin\phi \\ -\sin\theta & 0 & \cos\theta \end{pmatrix}.$$

The matrix U is unitary and satisfies $U^{-1}=U^T$. Throughout the paper we use the notation M^T for the transpose of a matrix M. If $\mathbf{v}$ is a row vector (resp. line vector), $\mathbf{v}^T$ stands for the line vector (resp. row vector) whose coefficients are v_j.

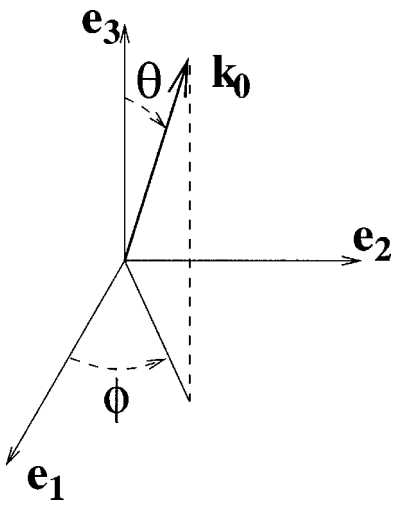

FIG. 1. Description of the wave vector in the crystallographic reference frame.

B. Linear susceptibility

The linear susceptibility is defined as the Fourier transform of the $\chi^{(1)}$ tensor[10]

$$\hat{\chi}^{(1)}(\omega) := \int_0^\infty dt_1 \chi^{(1)}(t_1) e^{i\omega t_1}.$$

Time integration starts from 0 to satisfy the causality property. In the crystallographic reference frame (1, 2, 3) the linear susceptibility is diagonal and reads:

$$\hat{\chi}^{(1)}_{123} = \begin{pmatrix} \chi_1 & 0 & 0 \\ 0 & \chi_2 & 0 \\ 0 & 0 & \chi_3 \end{pmatrix},$$

so that in the reference frame (x, y, z) the tensor $\hat{\chi}^{(1)}_{xyz}$ is $U^{-1}\hat{\chi}^{(1)}_{123}U$

$$\hat{\chi}^{(1)}_{xyz} = \begin{pmatrix} \chi_4 \cos^2\theta + \chi_3 \sin^2\theta & \frac{\sin(2\phi)}{2}(\chi_2 - \chi_1)\cos\theta & \frac{\sin(2\theta)}{2}(\chi_4 - \chi_3) \\ \frac{\sin(2\phi)}{2}(\chi_2 - \chi_1)\cos\theta & \chi_1 \sin^2\phi + \chi_2 \cos^2\phi & \frac{\sin(2\phi)}{2}(\chi_2 - \chi_1)\sin\theta \\ \frac{\sin(2\theta)}{2}(\chi_4 - \chi_3) & \frac{\sin(2\phi)}{2}(\chi_2 - \chi_1)\sin\theta & \chi_4 \sin^2\theta + \chi_3 \cos^2\theta \end{pmatrix}, \quad (8)$$

where $\chi_4 = \chi_1 \cos^2\phi + \chi_2 \sin^2\phi$. In the following χ is a shorthand for the matrix $\hat{\chi}^{(1)}_{xyz} + I_d$.

C. Expansion of the linear polarization

The linear induction is $\mathcal{D} = \varepsilon_0 \mathcal{E} + \mathcal{P}$. If $\mathcal{E} = \frac{1}{2}(\mathbf{E}(\delta t, \delta \mathbf{x}) e^{i(kz - \omega t)} + cc)$ and if we denote by $T = \delta t$ the slowly varying time variable, then the contribution of the linear induction to the Maxwell equation (2) can be expanded as

$$-\mu_0 \partial_t^2 \mathcal{D} = \tfrac{1}{2}(\mathbf{D}_0(\mathbf{E}) + \delta \mathbf{D}_1(\mathbf{E}) + \delta^2 \mathbf{D}_2(\mathbf{E}) + O(\delta^3)) e^{i(kz - \omega t)} + cc, \quad (9)$$

where the $\mathbf{D}_j(\mathbf{E})$ are linear functions of $\mathbf{E}$ given by

$$\mathbf{D}_0(\mathbf{E})=\frac{\omega^2}{c^2}\chi\mathbf{E},\quad \mathbf{D}_1(\mathbf{E})=\frac{i}{c^2}(\omega^2\chi)'\,\partial_T\mathbf{E},\quad \mathbf{D}^2(\mathbf{E})=-\frac{1}{2c^2}(\omega^2\chi)''\,\partial_T^2\mathbf{E}, \tag{10}$$

and the primes indicate partial derivatives with respect to ω.

Proof: If $\mathcal{E}=\frac{1}{2}(\mathbf{E}(\delta t,\delta\mathbf{x})e^{i(kz-\omega t)}+cc)$, then by expanding the linear induction as powers of δ we get

$$\mathcal{D}=\tfrac{1}{2}(\mathbf{D}(\delta t,\delta\mathbf{x})e^{i(kz-\omega t)}+cc),$$

$$\mathbf{D}=\varepsilon_0\mathbf{E}+\varepsilon_0\sum_{j=0}^{\infty}\frac{\delta^j(-1)^j}{j!}\left(\int_0^{\infty}dt'\,t'^j\,\chi^{(1)}(t')e^{i\omega t'}\right)\partial_T^j\mathbf{E}.$$

We introduce the derivatives of the linear susceptibility:

$$\hat{\chi}^{(1,j)}(\omega)=\frac{\partial^j\hat{\chi}^{(1)}}{\partial\omega^j}(\omega)=\int_0^{\infty}dt_1(it_1)^j\chi^{(1)}(t_1)e^{i\omega t_1},$$

so that the above expression reduces

$$\mathbf{D}=\varepsilon_0\mathbf{E}+\varepsilon_0\sum_{j=0}^{\infty}\frac{\delta^j i^j}{j!}\hat{\chi}^{(1,j)}(\omega)\partial_T^j\mathbf{E}.$$

If only the coefficients of order smaller than δ^2 are retained, then the contribution of the linear polarization to the Maxwell equation reads

$$-\mu_0\partial_t^2\mathcal{D}=\frac{1}{2}\left\{\frac{\omega^2}{c^2}(I_d+\hat{\chi}^{(1)})\mathbf{E}+i\delta\frac{\omega}{c^2}(\omega\hat{\chi}^{(1,1)}+2\hat{\chi}^{(1)})\partial_T\mathbf{E}\right.$$
$$\left.-\delta^2\frac{1}{c^2}\left(\frac{1}{2}\omega^2\hat{\chi}^{(1,2)}+2\omega\hat{\chi}^{(1,1)}+\hat{\chi}^{(1)}\right)\partial_T^2\mathbf{E}+O(\delta^3)\right\}e^{i(kz-\omega t)}+cc,$$

which establishes the desired result since $\chi=I_d+\hat{\chi}^{(1)}$. □

Notice that an expansion of the field of the form $\mathcal{E}=\frac{1}{2}\mathbf{E}(\delta t,\delta\mathbf{x})e^{i(kz-\omega t)}+cc$ provides an expansion of the contribution of the linear induction of the form $\frac{1}{2}(\mathbf{D}_0(\mathbf{E})+\delta\mathbf{D}_1(\mathbf{E})+\delta^2\mathbf{D}_2(\mathbf{E})+\cdots)e^{i(kz-\omega t)}+cc$. If one desires similar forms in both expansions, then it is sufficient to consider an expansion of the field of the form $\mathcal{E}=\frac{1}{2}(\mathbf{E}_0+\delta\mathbf{E}_1+\delta^2\mathbf{E}_2+\cdots)(\delta t,\delta\mathbf{x})e^{i(kz-\omega t)}+cc$. This remark will appear determining in the establishing of a suitable ansatz for the solution of the Maxwell equation which is discussed in the next section.

IV. ELECTROMAGNETIC PROPAGATION IN ANISOTROPIC MEDIA

A. Principle of the high-frequency expansion

We aim at outlining the principle of the high-frequency expansion method. It can be applied if the source can be expanded as (6). Then we proceed to *a priori* expansions of the field inside the crystal of the form (7). In linear media the set of the frequencies ω which are contained in H is imposed by the source and is equal to $\Omega_{\mathcal{S}}$. In nonlinear media the generation of harmonics should be taken into account so that the set H could be much larger than in the linear case.

The establishing of the propagation equations for the slowly varying envelopes obeys the following scheme. The form (7) is substituted into Eq. (2): **rot rot** $\mathcal{E}=-\mu_0\partial_t^2\mathcal{D}$. We get the expansion with respect to δ by applying formulas (9) and (11) for the right-hand side of Eq. (2) (contribution of the linear induction) and the left-hand side of Eq. (2) (**rot rot** $\mathcal{E}$), respectively. Collecting the terms with similar orders in δ and the same rapid phases (ω_f,k^f), we get a family

of equations. These equations can be decomposed into independent systems of equations parametrized by the rapid phases. The system corresponding to a rapid phase (ω_f, k^f) reads as a closed form system for the coefficients $\mathbf{E}_j^f$ of the series expansion of the envelope $\mathbf{E}^f$. This means that the envelopes of the different modes propagate independently. Note that in nonlinear media there may be coupling between the propagation equations of the modes. Considering the system for the mode with rapid phase (ω_f, k^f), we shall show on the one hand that a dispersion equation on (ω_f, k^f) appears as a compatibility condition for the existence of the high-frequency expansion (7a), and on the other hand that the form of the leading order term $\mathbf{E}_0^f$ is imposed by a compatibility condition for the existence of the series expansion (7b).

The form (7) is an ansatz, that is to say an *a priori* form of the solution which is valid in a given domain, here for $z \lesssim \delta^{-1}$. As an ansatz it satisfies basic properties. First it is compatible with the boundary conditions and the source. Second it is self-similar with respect to the operators that are encountered in the Maxwell equation. Indeed we have already established in Sec. III C that applying the operator corresponding to the right-hand side of the Maxwell equation to a an expansion of the kind (7) provides the same form. We are going to see in the next section devoted to the action of the **rot rot** operation that the expansion (7) is also self-similar with respect to this operator.

B. Expansion of the rot rot $\mathcal{E}$ term

If $\mathcal{E}$ is of the form $\mathcal{E}=\frac{1}{2}(\mathbf{E}(\delta t, \delta x, \delta y, \delta z)e^{i(kz-\omega t)}+cc)$, then **rot rot** $\mathcal{E}$ can be expanded as powers of δ. Denoting by $T=\delta t$, $X=\delta x$, $Y=\delta y$, and $Z=\delta z$ the slowly varying variables we find that

$$\mathbf{rot\,rot}\,\mathcal{E}=\tfrac{1}{2}(\mathbf{R}_0(\mathbf{E})+\delta\mathbf{R}_1(\mathbf{E})+\delta^2\mathbf{R}_2(\mathbf{E}))e^{i(kz-\omega t)}+cc, \tag{11}$$

where the mappings $\mathbf{R}_j(\mathbf{E})$ are given by

$$\mathbf{R}_0(\mathbf{E})=\begin{pmatrix} k^2E_x \\ k^2E_y \\ 0 \end{pmatrix}, \tag{12a}$$

$$\mathbf{R}_1(\mathbf{E})=\begin{pmatrix} ik\partial_X E_z-2ik\partial_Z E_x \\ ik\partial_Y E_z-2ik\partial_Z E_y \\ ik\partial_X E_x+ik\partial_Y E_y \end{pmatrix}, \tag{12b}$$

$$\mathbf{R}_2(\mathbf{E})=\begin{pmatrix} -\partial_Y^2E_x-\partial_Z^2E_x+\partial_X\partial_Y E_y+\partial_X\partial_Z E_z \\ -\partial_X^2E_y-\partial_Z^2E_y+\partial_X\partial_Y E_x+\partial_Y\partial_Z E_z \\ -\partial_X^2E_z-\partial_Y^2E_z+\partial_X\partial_Z E_x+\partial_Y\partial_Z E_y \end{pmatrix}. \tag{12c}$$

Note that (11) actually holds true as an identity, and not only as an expansion. Furthermore $\mathbf{R}_2(\mathbf{E})$ is simply the standard ''**Rot Rot E**'' when the spatial derivatives are taken with respect to the slow variables (X, Y, Z).

C. Dispersion equation

Let us first assume that the input pulse has a single carrier frequency ω. By substituting the ansatz (7) into Eq. (2) and collecting the coefficients with power δ^0, we get by applying the identities (9) and (11) that $\mathbf{R}_0(\mathbf{E}_0)=\mathbf{D}_0(\mathbf{E}_0)$

$$k^2J\mathbf{E}_0=\omega^2c^{-2}\chi\mathbf{E}_0, \tag{13}$$

where J is the matrix

$$J=\begin{pmatrix}1&0&0\\0&1&0\\0&0&0\end{pmatrix}. \tag{14}$$

The projection of Eq. (13) onto the z axis implies

$$E_{0z}=-\chi_{zz}^{-1}(\chi_{zx}E_{0x}+\chi_{zy}E_{0y}),$$

and substituting this identity into Eq. (13) we get that (E_{0x},E_{0y}) should fulfill

$$k^2\begin{pmatrix}E_{0x}\\E_{0y}\end{pmatrix}=\frac{\omega^2}{c^2}M\begin{pmatrix}E_{0x}\\E_{0y}\end{pmatrix},$$

where M is the 2×2 matrix

$$M=\begin{pmatrix}\chi_{xx}-\dfrac{\chi_{xz}\chi_{zx}}{\chi_{zz}} & \chi_{xy}-\dfrac{\chi_{xz}\chi_{zy}}{\chi_{zz}}\\ \chi_{yx}-\dfrac{\chi_{yz}\chi_{zx}}{\chi_{zz}} & \chi_{yy}-\dfrac{\chi_{yz}\chi_{zy}}{\chi_{zz}}\end{pmatrix}.$$

Note that, since χ is symmetric, M is also symmetric. The existence of a nonzero field $\mathbf{E}_0$ with carrier wave number k is equivalent to the Fresnel equation expressing the determinant of the system (13) equaling 0

$$\det(M-n^2I_d)=0. \tag{15}$$

The relationship $k=n\omega c^{-1}$ describes the normal waves that can propagate in the media with dielectric tensor χ. Eq. (15) also reads in terms of χ_1, χ_2, and χ_3 as

$$n^4-Sn^2+P=0,$$

$$S=\frac{(\chi_1\chi_2+\chi_3\chi_4)\sin^2\theta+\chi_3(\chi_1+\chi_2)\cos^2\theta}{\chi_3\cos^2\theta+\chi_4\sin^2\theta},$$

$$P=\frac{\chi_1\chi_2\chi_3}{\chi_3\cos^2\theta+\chi_4\sin^2\theta}.$$

The sum $n_a^2+n_b^2$ is equal to S and the product $n_a^2n_b^2$ is equal to P. Since S and P are positive it is easy to check that the Fresnel equation (15) has two positive solutions n_a and n_b. Consequently there exist two possible polarizations $\mathbf{s}_a$ and $\mathbf{s}_b$ so that $\mathbf{s}_a$ and $\mathbf{s}_b$ are unit vectors and $(n_a\omega c^{-1},\mathbf{s}_a)$ and $(n_b\omega c^{-1},\mathbf{s}_b)$ are solutions of Eq. (13). Furthermore the vectors (s_{ax},s_{ay}) and (s_{bx},s_{by}) are orthogonal. We define the dispersion relationship, the group velocity and the dispersion coefficient of the waves as follows:

$$k_m(\omega):=\frac{\omega n_m(\omega)}{c},\quad v_m(\omega):=\left(\frac{\partial k_m}{\partial\omega}\right)^{-1},\quad \sigma_m(\omega):=k_m\frac{\partial^2k_m}{\partial\omega^2},\quad m=a,b. \tag{16}$$

Accordingly, if the polarization of the incoming pulse has components on both the x and y axis, then it should be decomposed into the sum of a type a and type b waves. We shall discuss this decomposition precisely in the next section. Further, if the incoming pulse is a superposition of

several modes with different carrier frequencies, then for each carrier frequency ω_f the above results can be applied, so that each mode should be decomposed into the sum of a type a and type b waves.

Note that the occurrence of the case $n_a=n_b$ corresponds to very particular configurations. If the three indices χ_1, χ_2, and χ_3 are distinct (biaxial crystals), then the only cases for which $n_a=n_b$ are (assuming for instance $\chi_1>\chi_2>\chi_3$): $\phi=0$ or π and $\theta=\pm\theta_c(\omega)$, where

$$\sin^2\theta_c=\frac{\chi_1/\chi_2-1}{\chi_1/\chi_3-1}, \tag{17}$$

which defines the two optic axes of the biaxial crystal. If χ_3 is different from $\chi_1=\chi_2$ (uniaxial crystals), then the only cases for which $n_a=n_b$ are $\theta=0$ or π, and any ϕ. This defines the optic axis of the uniaxial crystal. Of course in isotropic medium $\chi_1=\chi_2=\chi_3$ one has $n_a=n_b$, but this trivial case will not be addressed in this paper.

Section V is devoted to an extensive study of the propagation of the pulse in anisotropic media in the general case when $n_a\neq n_b$. These results are then applied to the case of uniaxial crystals in Sec. VI. In Secs. VII–VIII we study the critical cases when $n_a=n_b$. Finally in Sec. IX we give some more results about the case when the crystal is biaxial but two of the crystal indices χ_j are close to each other.

D. Boundary condition

This condition reads as (5). We first eliminate the magnetic induction by differentiating with respect to time

$$(\partial_t\mathcal{E}+c\,\mathbf{rot}\,\mathcal{E}\times\mathbf{n})\times\mathbf{n}=2\partial_t\mathcal{S}\times\mathbf{n}.$$

If we assume that the source $\mathcal{S}$ can be expanded as (6), and accordingly that the field $\mathcal{E}$ inside the crystal is of the form (7), then collecting the coefficients with power δ^0 and high carrier frequency ω_f establishes the continuity conditions which impose that the components parallel to the boundary surface of the input field $\mathcal{S}$ and of the field $\mathcal{E}$ should be equal, while there are no condition for the normal components. Consequently, the type m mode ($m=a,b$) with carrier frequency ω_f should be at $z=0^+$

$$\mathbf{E}^f_{0,m}(\delta t,\delta x,\delta y,z=0^+)=c_{tr,m}(\omega_f)\mathbf{v}^f(\delta t,\delta x,\delta y),$$

where the transmission matrices $c_{tr,m}$ are

$$c_{tr,m}(\omega)=\frac{2}{1+n_m(\omega)}\frac{1}{s_{mx}^2+s_{my}^2}\begin{pmatrix} s_{mx}^2 & s_{mx}s_{my} & 0\\ s_{mx}s_{my} & s_{my}^2 & 0\\ s_{mx}s_{mz} & s_{my}s_{mz} & 0\end{pmatrix}.$$

Note that, if the input field at frequency ω_f is linearly polarized along the $(s_{ax},s_{ay},0)$-axis, then the field inside the crystal is purely type a. Moreover $c_{tr,m}(s_{mx},s_{my},0)^T=(2/[1+n_m(\omega)])\mathbf{s}_m$.

V. THE GEOMETRIC AND DIFFRACTIVE REGIMES IN THE GENERAL CASE

In this section we assume that the input pulse has only one carrier frequency ω and that the dispersion equation has two distinct solutions $n_a\neq n_b$. In such a configuration, the input pulse can be decomposed into a type a wave and a type b wave which propagate independently. We shall express our results in the case when the input pulse is linearly polarized according to the $(s_{ax},s_{ay},0)$. The generalization to any polarization is then straightforward by application of the superposition principle. The case when $n_a=n_b$ require a specific study since the rapid phases of the type a and type b waves are equal, so their propagations may be coupled. This study will be carried out in Secs. VII and VIII.

A. Geometric optics

We assume in this section that the input pulse with carrier frequency ω is linearly polarized according to the $(s_{ax}(\omega),s_{ay}(\omega),0)$-axis

$$\mathcal{S}=\tfrac{1}{2}v(\delta x,\delta y,\delta t)(s_{ax},s_{ay},0)^T e^{-i\omega t}+cc. \tag{18}$$

Consequently we adopt the ansatz (7) with $H=\{(\omega,k_a(\omega))\}$

$$\mathcal{E}=\frac{1}{2}\left(\sum_{j=0}^{\infty}\delta^j\mathbf{E}_j(\delta t,\delta x,\delta y,\delta z)\right)e^{i(k_a(\omega)z-\omega t)}+cc. \tag{19}$$

We denote $T=\delta t,\ X=\delta x,\ Y=\delta y,\ Z=\delta z,$ and k_a is a shorthand for $k_a(\omega)$.

Proposition 1. If the source $\mathcal{S}$ can be expanded as (18), then the leading order term $\mathbf{E}_0$ of the slowly varying envelope is linearly polarized along the $\mathbf{s}_a$-axis and satisfies the transport equation:

$$u_{ax}\partial_X E_0+u_{ay}\partial_Y E_o-\partial_Z E_0-v_a(\omega)^{-1}\partial_T E_0=0, \tag{20}$$

starting from $\mathbf{E}_0(T,X,Y,Z=0)=2/[1+n_a(\omega)]v(T,X,Y)$, *where* $\mathbf{u}_a=(s_{ax}s_{az}/(s_{ax}^2+s_{ay}^2),s_{ay}s_{az}/(s_{ax}^2+s_{ay}^2),-1)^T$. The solution of the above transport equation reads

$$E_0(T,X,Y,Z)=\frac{2}{1+n_a(\omega)}v(T-Z/v_a(\omega),X+u_{ax}Z,Y+u_{ay}Z).$$

It corresponds to the framework of the geometric optics, where the slowly varying envelope propagates without deformation with the group velocity. Note that the group velocity $v_a(\omega)$ and $v_b(\omega)$ are different. This phenomenon is called walk-off in the classical literature. It means that an input pulse will break into the sum of a type a and type b waves which propagate without interaction at different velocities. Furthermore the rays along which the waves propagate are not parallel. The Poynting vector of a type a wave is collinear to the vector $\mathbf{u}_a$ which means that the energy flow does not propagate along the direction of the carrier wave vector $\mathbf{k}_a$ which is collinear to the z axis. This is the so-called angular walk-off phenomenon. Finally note that $\mathbf{u}_a$ is orthogonal to the polarization vector $\mathbf{s}_a$: $\mathbf{u}_a.\mathbf{s}_a=0$, and that the three vectors $\mathbf{s}_a$, $\mathbf{u}_a$, and $\mathbf{k}_a$ lie in the same plane.

Proof: Let us substitute the ansatz (19) into Eq. (2) and collect the coefficients of each power of δ.

Order δ^0. The equations obtained at order δ^0 give the dispersion relationship and the fact that $\mathbf{E}_0=E_0\mathbf{s}_a$ (see Sec. IV C).

Order δ^1. The identity $\mathbf{R}_0(\mathbf{E}_1)+\mathbf{R}_1(\mathbf{E}_0)=\mathbf{D}_0(\mathbf{E}_1)+\mathbf{D}_1(\mathbf{E}_0)$ reads

$$\frac{\omega^2}{c^2}\chi\mathbf{E}_1+\frac{i}{c^2}(\omega^2\chi)'\partial_T\mathbf{E}_0=k_a^2J\mathbf{E}_1+ik_a\begin{pmatrix}\partial_X E_{0z}-2\partial_Z E_{0x}\\ \partial_Y E_{0z}-2\partial_Z E_{0y}\\ \partial_X E_{0x}+\partial_Y E_{0y}\end{pmatrix}, \tag{21}$$

where J is the matrix (14). We project this equation onto the vector $\mathbf{s}_a$. Since the matrix χ is symmetric, Eq. (13) implies

$$(\mathbf{s}_a^T)\chi-k_a^2(\mathbf{s}_a^T)J\equiv 0, \tag{22}$$

so that the terms in $\mathbf{E}_1$ cancel. Furthermore $\mathbf{E}_0=E_0\mathbf{s}_a$, so that it remains

$$\frac{i}{c^2}((\mathbf{s}_a^T)(\omega^2\chi)'\mathbf{s}_a)\partial_T E_0=2ik_a(s_{ax}s_{az}\partial_X E_0+s_{ay}s_{az}\partial_Y E_0-(s_{ax}^2+s_{ay}^2)\partial_Z E_0). \tag{23}$$

Besides, differentiating with respect to ω the equation $(\omega^2/c^2)\chi\mathbf{s}_a=k_a^2J\mathbf{s}_a$ yields

$$\frac{1}{c^2}(\omega^2\chi)\mathbf{s}_a+\frac{\omega^2}{c^2}\chi\mathbf{s}_a=k_a^2J\mathbf{s}_a+2k_ak_a'J\mathbf{s}_a\,. \tag{24}$$

Left-multiplying this equation by $\mathbf{s}_a$, the terms in $\mathbf{s}_a'$ cancel by (22), so it comes

$$c^{-2}((\mathbf{s}_a^T)(\omega^2\chi)'\mathbf{s}_a)=2k_ak_a'(s_{ax}^2+s_{ay}^2).$$

Substituting into (23) finally establishes Eq. (20). □

B. Diffractive optics

Eq. (20) describes the propagation of the envelope of the pulse for distances z of the order of δ^{-1}. The propagation is a pure transport without deformation. Consequently no evolution is noticeable in the moving reference frame $(\delta(t-z/v_a),\delta(x+u_{ax}z),\delta(y+u_{ay}z))$ when one looks at z of the order of δ^{-1}. We are now considering longer propagation distances z of the order of the Rayleigh distance δ^{-2} and we adopt the following ansatz:

$$\mathcal{E}=\frac{1}{2}\left(\sum_{j=0}^{\infty}\delta^j\mathbf{E}_j(\delta(t-z/v_a),\delta(x+u_{ax}z),\delta(y+u_{ay}z),\delta^2z)\right)e^{i(k_az-\omega t)}+cc. \tag{25}$$

We denote $T=\delta(t-z/v_a)$, $X=\delta(x+u_{ax}z)$, $Y=\delta(y+u_{ay}z)$ and the long scale variation of the envelope will be characterized by the variable $\zeta=\delta^2z$.

Proposition 2. If the source $\mathcal{S}$ can be expanded as (18), then the leading order term of the slowly varying envelope is linearly polarized along the $\mathbf{s}_a$-axis and satisfies in the moving frame the Schrödinger equation

$$\begin{aligned}&2ik_a\partial_\zeta E_0+c_{a,xx}\partial_X^2E_0+c_{a,yy}\partial_Y^2E_0+2c_{a,xy}\partial_X\partial_YE_0-\sigma_a\partial_T^2E_0\\&\quad+2k_a(u_{ax}'\partial_T\partial_XE_0+u_{ay}'\partial_T\partial_YE_0)=0,\end{aligned} \tag{26}$$

starting from $E_0(T,X,Y,\zeta=0)=(2/[1+n_a(\omega)])v(T,X,Y)$, where the prime stands for the partial derivative with respect to ω. The diffraction coefficients are given by

$$c_{a,xx}(\omega)=\frac{n_a^2}{n_b^2-n_a^2}\left(\frac{\chi_{zy}}{\chi_{zz}}+2u_{ay}\right)^2+\frac{n_a^2s_{ax}^2}{\chi_{zz}(s_{ax}^2+s_{ay}^2)}+\frac{s_{ay}^2}{(s_{ax}^2+s_{ay}^2)^2},$$

$$c_{a,xy}(\omega)=-\frac{n_a^2}{n_b^2-n_a^2}\left(\frac{\chi_{zy}}{\chi_{zz}}+2u_{ay}\right)\left(\frac{\chi_{zx}}{\chi_{zz}+2u_{ax}}\right)+\frac{n_a^2s_{ax}s_{ay}}{\chi_{zz}(s_{ax}^2+s_{ay}^2)}-\frac{s_{ax}s_{ay}}{(s_{ax}^2+s_{ay}^2)^2},$$

$$c_{a,yy}(\omega)=\frac{n_a^2}{n_b^2-n_a^2}\left(\frac{\chi_{zx}}{\chi_{zz}}+2u_{ax}\right)^2+\frac{n_a^2s_{ay}^2}{\chi_{zz}(s_{ax}^2+s_{ay}^2)}+\frac{s_{ax}^2}{(s_{ax}^2+s_{ay}^2)^2}.$$

This proposition gives the equation which governs the propagation of the envelope of the field in the framework of the slowly varying envelope. We get here the result that the envelope in the moving framework satisfies a Schrödinger-type equation with an anisotropic diffraction operator, and that coupled time–space derivatives of the envelope are coming into the equation.

It thus appears that there exists a disagreement between the propagation equations which are proposed in standard references,[4] where the diffraction effect is represented as an isotropic Laplace operator with respect to the transverse coordinates, and our Eq. (26) where the diffraction effect reads as an anisotropic second order operator. We aim here at underlying the point where we feel the departure comes from. The direction of the polarization vector is assumed to be constant during propagation in previous derivations of the evolution equations. We have shown in this paper that this hypothesis holds true for the leading term $\mathbf{E}_0$, but it is wrong when considering

the corrective term $\mathbf{E}_1$. We feel that the departure between the results essentially originates from the improper assumption about the constancy of the direction of the polarization vector.

The crossed space–time derivatives essentially originate from the fact that the Poynting vector of a monochromatic pulse is collinear to $\mathbf{u}_a(\omega)$ whose direction depends on the frequency ω. Accordingly the different frequencies of a broadband pulse (or equivalently a short pulse) do not propagate exactly in the same direction which involves this additive ''dispersion.''

PROOF: We substitute the ansatz (25) into Eq. (2) and we collect the coefficients with the same power of δ. In the expressions (12b) and (12c) of $\mathbf{R}_1$ and $\mathbf{R}_2$ we must take care to replace $\partial_Z(.)$ by $-v_a^{-1}\partial_T(.)+u_{ax}\partial_X(.)+u_{ay}\partial_Y(.)$ and to take into account the new slow variable ζ.

Order δ^1. Once rewritten in terms of the new variables, the transport equation (20) becomes trivial. Furthermore, since

$$((\omega^2\chi)'\mathbf{s}_a)_z=(\omega^2\chi\mathbf{s}_a)_z'-(\omega^2\chi\mathbf{s}_a')_z=0-\omega^2(\chi_{zx}s_{ax}'+\chi_{zy}s_{ay}'+\chi_{zz}s_{az}'),$$

the projection of Eq. (21) onto the z axis establishes that

$$E_{1z}=-\chi_{zz}^{-1}(\chi_{zx}E_{1x}+\chi_{zy}E_{1y})+\frac{ik_ac^2}{\omega^2\chi_{zz}}(\partial_XE_{0x}+\partial_YE_{0y})+i\left(\frac{\chi_{zx}}{\chi_{zz}}s_{ax}'+\frac{\chi_{zy}}{\chi_{zz}}s_{ay}'+s_{az}'\right)\partial_TE_0. \tag{27}$$

Substituting into the projections of Eq. (21) onto the axes x and y

$$\left(\frac{\omega^2}{c^2}M-k_a^2I_d\right)\begin{pmatrix}E_{1x}\\E_{1y}\end{pmatrix}=ik_a\begin{pmatrix}-s_{ay}\\s_{ax}\end{pmatrix}\left(\left(-\frac{\chi_{yz}}{\chi_{zz}}-2u_{ay}\right)\partial_XE_0+\left(\frac{\chi_{xz}}{\chi_{zz}}+2u_{ax}\right)\partial_YE_0\right)$$
$$+i\left(\left(\frac{\omega^2}{c^2}M-k_a^2I_d\right)\begin{pmatrix}s_{ax}'\\s_{ay}'\end{pmatrix}-2k_ak_a'\begin{pmatrix}s_{ax}\\s_{ay}\end{pmatrix}\right)\partial_TE_0. \tag{28}$$

Since the vectors (s_{ax},s_{ay}) and $(-s_{ay},s_{ax})$ are orthogonal, there exist two scalars A_a and B_a such that

$$\begin{pmatrix}E_{1x}\\E_{1y}\end{pmatrix}=A_a\begin{pmatrix}s_{ax}\\s_{ay}\end{pmatrix}+B_a\begin{pmatrix}-s_{ay}\\s_{ax}\end{pmatrix}, \tag{29}$$

and two scalars C_a and D_a such that

$$\left(\frac{\omega^2}{c^2}M-k_a^2I_d\right)\begin{pmatrix}-s_{ay}\\s_{ax}\end{pmatrix}=C_a\begin{pmatrix}s_{ax}\\s_{ay}\end{pmatrix}+D_a\begin{pmatrix}-s_{ay}\\s_{ax}\end{pmatrix}.$$

Since $\binom{s_{ax}}{s_{ay}}$ is an eigenvector of $\omega^2c^{-2}M$ with eigenvalue k_a^2, left-multiplying this equation by $\binom{s_{ax}}{s_{ay}}$ yields: $0=C_a(s_{ax}^2+s_{ay}^2)$ so $C_a=0$. Thus $\binom{-s_{ay}}{s_{ax}}$ is an eigenvector of $\omega^2c^{-2}M$ with eigenvalue $D_a+k_a^2$, and by definition of the eigenvalues this proves that $D_a=k_b^2-k_a^2$. Eq. (28) now reads

$$B_a=i\frac{s_{ax}s_{ay}'-s_{ay}s_{ax}'}{s_{ax}^2+s_{ay}^2}\partial_TE_0+\frac{ik_a}{k_b^2-k_a^2}\left(\left(-\frac{\chi_{yz}}{\chi_{zz}}-2u_{ay}\right)\partial_XE_0+\left(\frac{\chi_{xz}}{\chi_{zz}}+2u_{ax}\right)\partial_YE_0\right). \tag{30}$$

Order δ^2. Collecting the coefficients of order δ^2 we get:

$$\mathbf{R}_0(\mathbf{E}_2)+\mathbf{R}_1(\mathbf{E}_1)+\mathbf{R}_2(\mathbf{E}_0)=\mathbf{D}_0(\mathbf{E}_2)+\mathbf{D}_1(\mathbf{E}_1)+\mathbf{D}_2(\mathbf{E}_0).$$

Projecting onto the vector $\mathbf{s}_a$ the terms in $\mathbf{E}_2$ cancel and it remains

$$\mathbf{s}_a.\mathbf{R}_1(\mathbf{E}_1)+\mathbf{s}_a.\mathbf{R}_2(\mathbf{E}_0)=\mathbf{s}_a.\mathbf{D}_1(\mathbf{E}_1)+\mathbf{s}_a.\mathbf{D}_2(\mathbf{E}_0). \tag{31}$$

We now compute the four terms of this identity.

(i) Computation of $\mathbf{S}_a.\mathbf{D}_1(\mathbf{E}_1)$.
By definition:

$$\mathbf{S}_a.\mathbf{D}_1(\mathbf{E}_1)=ic^{-2}(\mathbf{s}_a^T)(\omega^2\chi)'\partial_T\mathbf{E}_1.$$

From (22) this expression simplifies

$$\mathbf{s}_a.\mathbf{D}_1(\mathbf{E}_1)=2ik_ak_a'\partial_T(s_{ax}E_{1x}+s_{ay}E_{1y})-i(\mathbf{s}_a'^T)(\omega^2c^{-2}\chi-k_a^2J)\partial_T\mathbf{E}_1. \tag{32}$$

Differentiating Eq. (21) with respect to time and multiplying by $\mathbf{s}_a'^T$ establishes

$$\begin{aligned}&(\mathbf{s}_a'^T)(\omega^2c^{-2}\chi-k_a^2J)\partial_T\mathbf{E}_1\\&\quad=i(\mathbf{s}_a'^T)(\omega^2c^{-2}\chi-k_a^2J)\mathbf{s}_a'\partial_T^2E_0+ik_a(s_{ax}^2+s_{ay}^2)(u_{ax}'\partial_T\partial_XE_0+u_{ay}'\partial_T\partial_YE_0).\end{aligned}$$

On the one hand, differentiating Eq. (24) with respect to ω and multiplying by $\mathbf{s}_a^T$

$$\begin{aligned}&c^{-2}(\mathbf{s}_a^T)(\omega^2\chi)''\mathbf{s}_a+2c^{-2}(\mathbf{s}_a^T)(\omega^2\chi)'\mathbf{s}_a'\\&\quad=4k_ak_a'(s_{ax}s_{ax}'+s_{ay}s_{ay}')+2((k_a')^2+k_ak_a'')(s_{ax}^2+s_{ay}^2).\end{aligned}$$

On the other hand, multiplying Eq. (24) by $\mathbf{s}_a'^T$

$$c^{-2}(\mathbf{s}_a'^T)(\omega^2\chi)'\mathbf{s}_a+\omega^2c^{-2}(\mathbf{s}_a'^T)\chi\mathbf{s}_a'=k_a^2((s_{ax}')^2+(s_{ay}')^2)+2k_ak_a'(s_{ax}'s_{ax}+s_{ay}'s_{ay}).$$

Multiplying by 2 the last identity and subtracting the last two identities establish:

$$c^{-2}(\mathbf{s}_a^T)(\omega^2\chi)''\mathbf{s}_a=2(\mathbf{s}_a'^T)(\omega^2c^{-2}\chi-k_a^2J)\mathbf{s}_a'+2((k_a')^2+k_ak_a'')(s_{ax}^2+s_{ay}^2).$$

Finally, substituting into (32)

$$\begin{aligned}\mathbf{s}_a.\mathbf{D}_1(\mathbf{E}_1)=&2ik_ak_a'\partial_T(s_{ax}E_{1x}+s_{ay}E_{1y})+k_a(s_{ax}^2+s_{ay}^2)(u_{ax}'\partial_T\partial_XE_0+u_{ay}'\partial_T\partial_YE_0)\\&+(-((k_a')^2+k_ak_a'')(s_{ax}^2+s_{ay}^2)+2^{-1}c^{-2}(\mathbf{s}_a^T)(\omega^2\chi)''\mathbf{s}_a)\partial_T^2E_0.\end{aligned} \tag{33}$$

(ii) Computation of $\mathbf{s}_a.\mathbf{D}_2(\mathbf{E}_0)$.
By definition and using the fact that $\mathbf{E}_0$ reads $\mathbf{s}_aE_0$

$$\mathbf{s}_a.\mathbf{D}_2(\mathbf{E}_0)=-2^{-1}c^{-2}(\mathbf{s}_a^T)(\omega^2\chi)''\mathbf{s}_a\partial_T^2E_0. \tag{34}$$

(iii) Computation of $\mathbf{s}_a.\mathbf{R}_2(\mathbf{E}_0)$.
Computing $\mathbf{s}_a.\mathbf{R}_2(\mathbf{E}_0)$ is easy

$$\begin{aligned}\mathbf{s}_a.\mathbf{R}_2(\mathbf{E}_0)=&\frac{-s_{ay}^2}{s_{ax}^2+s_{ay}^2}\partial_X^2E_0+\frac{2s_{ax}s_{ay}}{s_{ax}^2+s_{ay}^2}\partial_X\partial_YE_0+\frac{-s_{ax}^2}{s_{ax}^2+s_{ay}^2}\partial_Y^2E_0\\&-2ik_a(s_{ax}^2+s_{ay}^2)\partial_\xi E_0-\frac{s_{ax}^2+s_{ay}^2}{v_a^2}\partial_T^2E_0.\end{aligned} \tag{35}$$

(iv) Computation of $\mathbf{s}_a.\mathbf{R}_1(\mathbf{E}_1)$.
We first compute $\mathbf{s}_a.\mathbf{R}_1(\mathbf{E}_1)$ by taking into account (27)

$$\mathbf{s}_a.\mathbf{R}_1(\mathbf{E}_1)=ik_a\left[\left(-\frac{\chi_{zy}}{\chi_{zz}}-2u_{ay}\right)\partial_X+\left(\frac{\chi_{zx}}{\chi_{zz}}+2u_{ax}\right)\partial_Y\right](s_{ax}E_{1y}-s_{ay}E_{1x})$$
$$-\frac{k_a^2c^2}{\omega^2\chi_{zz}}(s_{ax}^2\partial_X^2E_0+2s_{ax}s_{ay}\partial_X\partial_YE_0+s_{ay}^2\partial_Y^2E_0)+2i\frac{k_a}{v_a}\partial_T(s_{ax}E_{1x}+s_{ay}E_{1y})$$
$$-k_a\left(\frac{\chi_{zx}}{\chi_{zz}}s'_{ax}+\frac{\chi_{zy}}{\chi_{zz}}s'_{ay}+s'_{az}\right)(s_{ax}\partial_T\partial_XE_0+s_{ay}\partial_T\partial_YE_0).$$

Using the representation (29) and the identity (30)

$$\mathbf{s}_a.\mathbf{R}_1(\mathbf{E}_1)=-\left[\frac{n_a^2(s_{ax}^2+s_{ay}^2)}{n_b^2-n_a^2}\left(\frac{\chi_{zy}}{\chi_{zz}}+2u_{ay}\right)^2+\frac{n_a^2s_{ax}^2}{\chi_{zz}}\right]\partial_X^2E_0-\left[\frac{n_a^2(s_{ax}^2+s_{ay}^2)}{n_b^2-n_a^2}\left(\frac{\chi_{zx}}{\chi_{zz}}+2u_{ax}\right)^2\right.$$
$$\left.+\frac{n_a^2s_{ay}^2}{\chi_{zz}}\right]\partial_Y^2E_0+2\left[\frac{n_a^2(s_{ax}^2+s_{ay}^2)}{n_b^2-n_a^2}\left(\frac{\chi_{zx}}{\chi_{zz}}+2u_{ax}\right)\left(\frac{\chi_{zy}}{\chi_{zz}}+u_{ay}\right)\right.$$
$$\left.-\frac{n_a^2s_{ax}s_{ay}}{\chi_{zz}}\right]\partial_X\partial_YE_0+2i\frac{k_a}{v_a}\partial_T(s_{ax}E_{1x}+s_{ay}E_{1y})-k_a\left(\frac{\chi_{zx}}{\chi_{zz}}s'_{ax}+\frac{\chi_{zy}}{\chi_{zz}}s'_{ay}+s'_{az}\right)$$
$$\times(s_{ax}\partial_T\partial_XE_0+s_{ay}\partial_T\partial_YE_0). \tag{36}$$

By collecting the expressions (33)–(36) of the four terms which are coming into the identity (31), we conclude that Eq. (26) holds true. □

C. Anomalous diffraction for biradial waves in biaxial crystals

We examine in this section the propagation in biaxial crystals in the particular configuration $\theta=\theta_r(\omega)$ and $\phi=0$ or π where

$$\sin^2\theta_r=\frac{1-\chi_2/\chi_1}{1-\chi_3/\chi_1},$$

where we have assumed that $\chi_1>\chi_2>\chi_3$. Computing all relevant quantities we have found that the eigenindices are $n_a^2=\chi_2$ and $n_b^2=\chi_1\chi_3/(\chi_1+\chi_3-\chi_2)$. The corresponding unit polarization vectors are

$$\mathbf{s}_a=(\cos\beta_r,0,\sin\beta_r)^T,$$

where the angle β_r is given by

$$\tan\beta_r=-\frac{\sqrt{(\chi_2-\chi_3)(\chi_1-\chi_2)}}{\chi_1+\chi_3-\chi_2}.$$

The diffraction coefficients are:

$$c_{a,xx}=1,\quad c_{a,xy}=0,\quad c_{a,yy}=0,$$

$$c_{b,xx}=\frac{\chi_1\chi_3}{(\chi_1+\chi_3-\chi_2)^2},\quad c_{b,xy}=0,\quad c_{b,yy}=\frac{\chi_1+\chi_3}{\chi_1+\chi_3-\chi_2}.$$

The striking point is that the diffraction operator for the type a wave is degenerate, in the sense that there is no diffraction in the y direction. The a wave is polarized along the y axis and satisfies the Schrödinger equation

$$2ik_a\partial_\zeta E_{0y}+\partial_X^2 E_{0y}-\sigma_a\partial_T^2 E_{0y}=0.$$

Such an anomalous behavior is consistent with the results derived in Ref. 11 where the authors show that the asymptotic form of the Green function is proportional to $z^{-1/2}$ instead of the standard z^{-1}-decay. This phenomenon is made transparent from our results, since the solution of a Schrödinger equation with a d-dimensional second-order operator spreads out as $z^{-d/2}$. This configuration could involve an interesting application in nonlinear optics. Consider high-intensity pulses so that the nonlinearity of the medium should be taken into account. Choose a carrier frequency such that the phase matching condition for the second-harmonic generation is not fulfilled. We may then expect that the main nonlinear term reads as a cubic Kerr effect, so that the field should satisfy (neglecting group velocity dispersion):

$$2ik_a\partial_\zeta E_{0y}+\partial_X^2 E_{0y}+\gamma|E_{0y}|^2E_{0y}=0.$$

This one-dimensional nonlinear Schrödinger equation possesses the complete integrability property, which implies that stable solitons should be generated and propagate over large distances. This configuration will be studied in the companion paper.[7]

VI. UNIAXIAL CRYSTALS

We assume in this section that the dielectric tensor $\chi^{(1)}$ corresponds to the uniaxial case, that is to say $\chi_1=\chi_2:=\chi_o$ and $\chi_3=\chi_e$, with $\chi_e\neq\chi_o$. The results derived in the above sections can then be rewritten in simpler terms. In the general framework $\theta\neq 0$ there are two distinct eigenindices, the so-called ordinary and extraordinary refractive indices

$$n_o(\omega)=\chi_o(\omega)^{1/2},\quad n_e(\omega)=\left(\frac{\chi_o(\omega)\chi_e(\omega)}{\cos^2\theta\chi_e(\omega)+\sin^2\theta\chi_o(\omega)}\right)^{1/2}. \tag{37}$$

These configurations correspond to an ordinary wave and an extraordinary wave, respectively. The unit polarization vector of an ordinary wave is simply $\mathbf{s}_o=(0,1,0)^T$, while the polarization vector of an extraordinary wave lies in the plane (xz) and is given by $\mathbf{s}_e(\omega)=(\cos\beta,0,\sin\beta)^T$, where the angle $\beta(\omega)$ is

$$\tan\beta(\omega)=\frac{\cos\theta\sin\theta(\chi_e(\omega)-\chi_o(\omega))}{\cos^2\theta\chi_e(\omega)+\sin^2\theta\chi_o(\omega)}.$$

A. Ordinary wave

The vector $\mathbf{u}_o$ which gives the direction of the rays along which the wave propagates in the geometric framework is simply $\mathbf{u}_o=(0,0,-1)^T$. The diffraction coefficients are $c_{o,xy}=0$, $c_{o,xx}=c_{o,yy}=1$, and $\mathbf{u}_o'=\mathbf{0}$, so that the propagation equation in the moving frame $(\delta(t-z/v_o),\delta x,\delta y,\delta^2 z))$ reads as the standard Schrödinger equation:

$$2ik_o\partial_\zeta E_{0y}+\partial_X^2 E_{0y}+\partial_Y^2 E_{0y}-\sigma_o\partial_T^2 E_{0y}=0.$$

An ordinary wave propagates according to the usual rules which govern the propagation of waves in linear isotropic media.

B. Extraordinary wave

The Poynting vector is $\mathbf{u}_e=(\tan\beta,0,-1)^T$. Thus β is the walk-off angle, that is to say the angle between the carrier wave vector $\mathbf{k}$ and the Poynting vector. The transverse diffraction coefficient $c_{e,xy}$ is zero while

$$c_{e,xx}(\omega)=\frac{\chi_o\chi_e}{(\cos^2\theta\chi_e+\sin^2\theta\chi_o)^2},\quad c_{e,yy}(\omega)=\frac{\chi_o}{\cos^2\theta\chi_e+\sin^2\theta\chi_o}.$$

Furthermore $u'_{e,x}=(\tan\beta)'$ and $u'_{e,y}=0$. The extraordinary wave $E_0=\mathbf{s}_e.\mathbf{E}_0$ in the moving frame $(\delta(t-z/v_e),\delta(x+\tan\beta z),\delta y,\delta^2 z)$ thus satisfies the equation

$$2ik_e\partial_\zeta E_0+c_{e,xx}\partial_X^2E_0+c_{e,yy}\partial_Y^2E_0+2k_e(\tan\beta)'\partial_T\partial_XE_0-\sigma_e\partial_T^2E_0=0.$$

In a negative crystal $\chi_o>\chi_e$ we have $c_{e,xx}<c_{e,yy}$, which proves that diffraction effects are more important along the y axis than along the x axis. Note that, as $\theta\to0$, we have $n_e\to n_o$ while the coefficients $c_{e,xx}$ and $c_{e,yy}$ converge to χ_o/χ_e. But as pointed out in Sec. V B, this extrapolation is not correct since terms of order δ are inversely proportional to n_o-n_e and consequently tend to infinity. At the limit $\theta\to0$ new terms of order 1 must be introduced. This will be done in the next section. Finally note that the expressions of the diffraction coefficients $c_{m,\dots}$, $m=o,e$, are compatible with the asymptotic form of the Green function in the case of a uniaxial medium given by Lax and Nelson.[12]

VII. CRITICAL CONFIGURATION IN UNIAXIAL CRYSTALS

As demonstrated in Sec. IV C, if $\chi_1=\chi_2:=\chi_o$ and $\chi_3:=\chi_e$ there exists a family of critical configurations characterized by $\theta=0$ and any ϕ for which the indices n_a and n_b are both equal to $\sqrt{\chi_o}$. We assume in this section that the crystal is uniaxial and tailored so that its principal axis and the propagation axis z of the input pulse are collinear. In such a configuration there is no distinction between ordinary and extraordinary waves, and the field is transverse (there is no component E_{0z}). Further the propagations of the components E_{0x} and E_{0y} which used to be independent in the configuration $\theta\neq0$ are now coupled since they have the same rapid phase $(\omega,n_o\omega/c)$. To deal with this coupling we consider a general form for the source

$$\mathcal{S}=\tfrac{1}{2}(v_x(\delta x,\delta y,\delta t),v_y(\delta x,\delta y,\delta t),0)^Te^{-i\omega t}+cc. \tag{38}$$

The dispersion relationship, group velocity coefficient and dispersion are similar to those of a standard ordinary wave and given by (37).

A. Geometric optics

We adopt the ansatz (7) with $H=\{(\omega,k_o(\omega))\}$

$$\mathcal{E}=\frac{1}{2}\left(\sum_{j=0}^{\infty}\delta^j\mathbf{E}_j(\delta t,\delta x,\delta y,\delta z)\right)e^{i(k_o(\omega)z-\omega t)}+cc.$$

We denote $T=\delta t$, $X=\delta x$, $Y=\delta y$, $Z=\delta z$, and $k_o=k_o(\omega)$.

Proposition 3: If the source $\mathcal{S}$ can be expanded as (38), then the leading order term $\mathbf{E}_0$ of the slowly varying envelope is transverse. It has the same polarization as the incoming pulse, and it satisfies the transport equation

$$\partial_Z\mathbf{E}_0+v_o^{-1}\partial_T\mathbf{E}_0=0, \tag{39}$$

starting from $\mathbf{E}_0(T,X,Y,Z=0)=(2/[1+n_o(\omega)])\mathbf{v}(T,X,Y)$.

In the geometric optics framework, this proposition demonstrates that the leading order terms of the components of the wave with perpendicular polarizations propagate without interaction according to the standard law of ordinary waves.

B. Diffractive optics

Equation (39) describe the propagation of the slowly varying envelope of the wave over propagation distance z of the order of δ^{-1}. It appears that the envelope is transported without deformation. Accordingly, if one considers the envelope in the moving reference frame $(\delta(t-z/v_o),\delta x,\delta y)$, then no evolution is noticeable as far as $z\sim\delta^{-1}$. It is therefore, necessary to address the problem of long-range propagation, over distances z of the order of δ^{-2}. The corresponding ansatz is the following:

$$\mathcal{E}=\frac{1}{2}\left(\sum_{j=0}^{\infty}\delta^j\mathbf{E}_j(\delta(t-z/v_o),\delta x,\delta y,\delta^2 z)\right)e^{i(k_o(\omega)z-\omega t)}+cc. \tag{40}$$

We denote $T=\delta(t-z/v_o)$, $X=\delta x$, $Y=\delta y$ and the long-range scale is represented by the slow variable $\zeta=\delta^2 z$.

Proposition 4: If the source $\mathcal{S}$ can be expanded as (38), then the leading order term $\mathbf{E}_0$ of the slowly varying envelope is elliptically polarized in the plane (x, y) and it obeys the coupled system of Schrödinger equations in the moving frame:

$$2ik_o\partial_\zeta E_{0x}+\rho\partial_X^2E_{0x}+\partial_Y^2E_{0x}+(\rho-1)\partial_X\partial_YE_{0y}-\sigma_o\partial_T^2E_{0x}=0, \tag{41a}$$

$$2ik_o\partial_\zeta E_{0y}+\partial_X^2E_{0y}+\rho\partial_Y^2E_{0y}+(\rho-1)\partial_X\partial_YE_{0x}-\sigma_o\partial_T^2E_{0y}=0, \tag{41b}$$

starting from $\mathbf{E}_0(T,X,Y,Z=0)=(2/[1+n_o(\omega)])\mathbf{v}(T,X,Y)$, *where* $\rho(\omega):=\chi_o(\omega)/\chi_e(\omega)$.

Note that the result of this proposition was reported in Ref. 13, which is as far as we know the only paper which provides an explicit form for the diffraction operator in an anisotropic medium. Nevertheless Ref. 13 only addressed the propagation of pulses along the principal axis of a uniaxial crystal, while our formulas are valid for more general configurations and systems (41a) and (41b) is just a particular application. As in the diffractive regime of the propagation of an extraordinary wave in the framework $\theta\neq0$, we find an anisotropic diffraction operator. Further systems (41a) and (41b) puts into evidence a coupling between the linear Schrödinger type equations satisfied by the components of the field which are polarized along the x and y axes, respectively. This coupling shows itself in crossed second-order spatial derivatives which act onto the orthogonally polarized components. Accordingly, if the input wave is linearly polarized, then the spatial spectrum of the orthogonally polarized output field will present a dark cross which is known as the Maltese cross.

C. Almost-critical configuration $\theta=\delta\eta$

The condition $\theta=0$ is very stringent. It seems hardly possible to reach such a perfect level in realistic experimental configurations. It is consequently relevant to address the problem of the influence of a small perturbation of the ideal case $\theta=0$ by considering that the main optic axis of the crystal is collinear to the propagation axis up to a term of order δ. The second motivation of this section is to make smooth the transition between the results of the cases $\theta\neq0$ and $\theta=0$, since it appears at first glance that there is discontinuity. As we shall see in this section, this apparent disagreement is involved by the fact that the transition is continuous at $\theta=0$ when considering a change of θ at rate δ. Accordingly we set $\theta=\delta\eta$. In the geometric optics framework, one finds the very same equations as in the case $\eta=0$. In the diffractive optics framework, one finds the following perturbed Schrödinger equations:

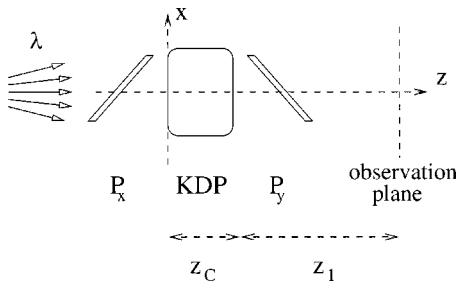

FIG. 2. Experimental setup of a Pockels cell.

$$2ik_o\partial_\zeta E_{0x}+\rho\partial_X^2E_{0x}+\partial_Y^2E_{0x}+(\rho-1)\partial_X\partial_YE_{0y}-\sigma_o\partial_T^2E_{0x}$$
$$=\eta^2k_o^2(\rho-1)E_{0x}-i\eta k_o(\rho-1)(2\partial_XE_{0x}+\partial_YE_{0y}), \tag{42a}$$

$$2ik_o\partial_\zeta E_{0y}+\partial_X^2E_{0y}+\rho\partial_Y^2E_{0y}+(\rho-1)\partial_X\partial_YE_{0x}-\sigma_o\partial_T^2E_{0y}=-i\eta k_o(\rho-1)\partial_YE_{0x}. \tag{42b}$$

These equations involve an interesting application that we discuss in the next section.

D. Application: Detection of the optic axis of a crystalline medium

This section is devoted to a useful and straightforward application of the propagation equations derived here above. We aim at determining the optic axis of a uniaxial crystal by a simple and efficient method. The technique which is described here below is widely used to bring into alignment Pockels cells in experimental setups. We consider the experimental configuration presented in Fig. 2. A linearly polarized divergent light beam emerging from a polarizer P_x is normally incident onto a plane parallel crystal plate of thickness z_c. The optic axis of the crystal is assumed to be almost collinear to the propagation axis z, and we are looking for the angle mismatch η between these axes.

We consider in this section long pulses with carrier wavelength λ so that the time-dependence of the envelope is much slower than its transverse spatial dependence and can be neglected. We take the Fourier transform with respect to the transverse spatial coordinates

$$\hat{\mathbf{E}}_0=\int\mathbf{E}_0e^{-i(k_xx+k_yy)}dxdy.$$

Inside the crystal plate the field evolution is ruled by the systems (42a) and (42b) which reduces to a system of ordinary differential equations (we drop the 0-index)

$$2ik_o\partial_z\hat{E}_x=\rho k_x^2\hat{E}_x+k_y^2\hat{E}_x+(\rho-1)k_xk_y\hat{E}_y+(\rho-1)\eta k_o((\eta k_o-2k_x)\hat{E}_x-k_y\hat{E}_y),$$

$$2ik_o\partial_z\hat{E}_y=k_x^2\hat{E}_y+\rho k_y^2\hat{E}_y+(\rho-1)k_xk_y\hat{E}_x-(\rho-1)\eta k_ok_y\hat{E}_x,$$

that can be solved exactly by a straightforward exponentiation. The input field is linearly polarized along the x axis by the P_x polarizer, and the P_y polarizer eliminates the x component of the output field. Consequently the spectral intensity of the output field is

$$|\hat{E}_y|^2(z_c,k_x,k_y)=F\left((k_x-\eta k_o)\sqrt{\frac{(\rho-1)z_c}{4k_o}},\quad k_y\sqrt{\frac{(\rho-1)z_c}{4k_o}}\right)|\hat{E}_x|^2(0,k_x,k_y), \tag{43a}$$

$$F(u,v)=4u^2v^2\,\mathrm{sinc}^2(u^2+v^2), \tag{43b}$$

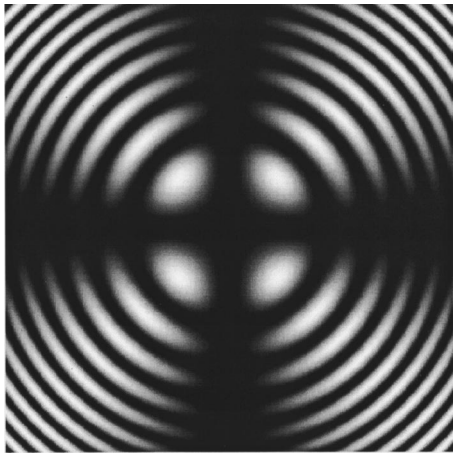

FIG. 3. Interference pattern from uniaxial crystal plate cut perpendicular to the optic axis, between two crossed polarizers. Function $(u,v)\mapsto F(u,v)$ over the domain $(-4,4)\times(-4,4)$.

where $\mathrm{sinc}(s)=\sin(s)/s$. The function F is plotted in Fig. 3. From z_c to $z_{\mathrm{obs}}:=z_c+z_1$ the pulse propagates in vacuum, so in the far field configuration $(z_1\gg\lambda)$ the intensity distribution $|E_y|^2(z_{\mathrm{obs}},x,y)$ is proportional to the power spectral density of the near field:

$$|E_y|^2(z_{\mathrm{obs}},x_o,y_o)=\frac{1}{\lambda^2 z_1^2}|\hat{E}_y|^2\left(z_c,\frac{2\pi x_o}{\lambda z_1},\frac{2\pi y_o}{\lambda z_1}\right).$$

Substituting Eq. (43a) into this identity yields

$$|E_y|^2(z_{\mathrm{obs}}x_o,y_o)=\frac{1}{\lambda^2 z_1^2}F\left(\left(\frac{x_o}{z_1}+\eta n_o\right)\sqrt{\frac{(\rho-1)\pi z_c}{2n_o\lambda}},\quad\frac{y_o}{z_1}\sqrt{\frac{(\rho-1)\pi z_c}{2n_o\lambda}}\right)|\hat{E}_x|^2(0,k_x,k_y).$$

Conclusion. If the optic axis of the crystal is perfectly collinear to the propagation axis of the beam, then the far field intensity presents a centered dark cross. If there exists an angle mismatch η between the optic axis and the propagation axis, then the cross is shifted by the quantity $\Delta x_o=\eta n_o z_1$.

VIII. CONICAL REFRACTION IN BIAXIAL CRYSTAL

As pointed out in Sec. IV C, if $\chi_1>\chi_2>\chi_3$ are distinct, then a simple study of the matrix χ shows that there exists only one case when $n_a=n_b$, which corresponds to the configuration when $\phi=0$ and $\theta=\pm\theta_c(\omega)$ where $\theta_c(\omega)$ is defined by (17). In such a configuration $n_a=n_b=\chi_2^{1/2}$, and the two mutually orthogonal polarization vectors are:

$$\mathbf{s}_a=(\cos\beta_c,0,\sin\beta_c)^T,\quad \mathbf{s}_b=(0,1,0)^T,$$

where the angle $\beta_c(\omega)$ between the polarization vector $\mathbf{s}_a$ and the propagation axis z is given by

$$\tan\beta_c=-\sqrt{\left(1-\frac{\chi_2}{\chi_1}\right)\left(\frac{\chi_2}{\chi_3}-1\right)}.$$

Substituting the ansatz (19) into Eq. (2) and collecting the coefficients of each power of δ, we get the following result.

Proposition 5: If we denote the projections of the field $\mathbf{E}_0$ *onto the vectors* $\mathbf{s}_a$ *and* $\mathbf{s}_b$ *by* $E_{0a}=\mathbf{s}_a\cdot\mathbf{E}_0$ *and* $E_{0b}=\mathbf{s}_b\cdot\mathbf{E}_0$, *then the scalar fields* E_{0a} *and* E_{0b} *satisfy the coupled equations*

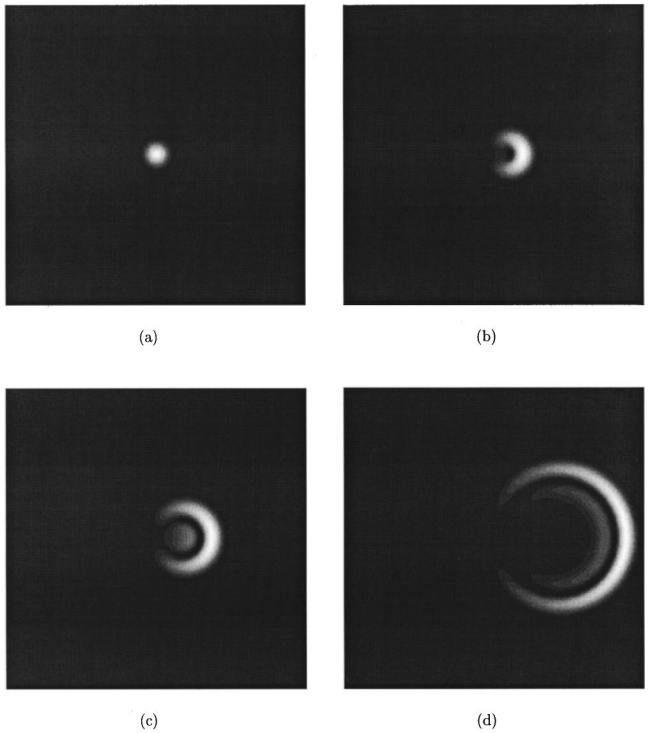

FIG. 4. Conical refraction of a Gaussian pulse polarized along the x axis for different values of Z. $Z=0$ (a), $Z=4.13$ (b), $Z=8.26$ (c), and $Z=20.65$ (d). Here $\cos\beta_c=0.9$ or equivalently $(\tan\beta_c)/2=0.24$.

$$v_a^{-1}\partial_T E_{0_a}+\partial_Z E_{0a}-\tan\beta_c\partial_X E_{0a}=\frac{\tan\beta_c}{2\cos\beta_c}\partial_Y E_{ob}, \tag{44a}$$

$$v_a^{-1}\partial_T E_{0b}+\partial_Z E_{0b}=\frac{\sin\beta_c}{2}\partial_Y E_{0a}, \tag{44b}$$

starting from $E_{0a}(T,X,Y,Z=0)=(2/[1+n_a(\omega)])v_x(T,X,Y)$ *and* $E_{0b}(T,X,Y,Z=0)=(2/[1+n_a(\omega)])v_y(T,X,Y)$.

Taking the spatial Fourier transform with respect to the transverse coordinates (X,Y), the solution field reads

$$\begin{pmatrix}\hat{E}_{0a}\\ \hat{E}_{0b}\end{pmatrix}(Z,T,k_x,k_y)=\frac{2e^{ik_xZ'}}{1+n_a}\left[\cos(k_rZ')\begin{pmatrix}1&0\\0&1\end{pmatrix}\right.$$
$$\left.+i\sin(k_rZ')\frac{1}{k_r}\begin{pmatrix}k_x & \dfrac{k_y}{\cos\beta_c}\\ k_y\cos\beta_c & -k_x\end{pmatrix}\right]\hat{\mathbf{v}}(T-Z/v_a,k_x,k_y),$$

where $k_r=\sqrt{k_x^2+k_y^2}$ and $Z'=Z(\tan\beta_c)/2$. The evolution of an input Gaussian field is plotted in Fig. 4. Let us study the field in the framework $|Z'|>1$ but not so large so as to be allowed to neglect the diffractive terms (i.e., $\delta^{-1}\leqslant z\ll\delta^{-2}$). In the physical space, using the stationary phase method, we get that the field is concentrated on the circle with center Z' and radius Z' if the input field is localized around 0. In other words the wave surface has the shape of a cone. This conical refraction is a well-known phenomena which was predicted in 1832 by Hamilton and observed thereafter by Lloyd. Historical references and an elementary study of conical refraction can be found in Ref. 1. More advanced treatments are devoted to the subject.[14,15] In particular Warnick and Arnold[16] predicts additional fringes by computing the asymptotic form of the Green func-

tion. These results can be exhibited in our framework quite easily. Let us denote by $(\cos\gamma,\sin\gamma,0)$ the unit polarization vector of the source $\mathbf{v}$, and by R_0 the radius of the input beam. If (X,Y) is farther than R_0 from the cone $(X-Z')^2+Y^2=Z'^2$, then we have $|E_0|^2(Z,X,Y)=o(Z^{-1})$. If (X,Y) is close to the cone $(X-Z')^2+Y^2=Z'^2$ by less than R_0, then denoting $X=Z'+Z'\cos\alpha$ and $Y=Z'\sin\alpha$

$$|E_0|^2(Z,X,Y)\simeq\frac{Z_0}{Z}\left(\cos\left(\frac{\alpha}{2}\right)\cos(\gamma)\cos(\beta_c)+\sin\left(\frac{\alpha}{2}\right)\sin(\gamma)\right)^2\left(1+\cos^2\left(\frac{\alpha}{2}\right)\tan^2(\beta_c)\right),$$

where Z_0 is a characteristic distance proportional to $R_0/\tan\beta_c$. If Z is so large that it reaches values of order δ^{-1} (i.e., z reaches values of order δ^{-2}), then one should take into account the second-order derivatives, which makes the evolution of the field more complicated. The strategy is still the same as in the other configurations. It consists in looking at the evolution of the field at the long scale $\delta^2 z$ around the points defined by the transport equation, that is to say the cone defined by $(x-z(\tan\beta_c)/2)^2+y^2=(z(\tan\beta_c)/2)^2$. This specific study will be carried out elsewhere. Nevertheless, we would like to add the following comment that gives a new insight into the phenomena that govern conical refraction. In the moving reference frame $(\delta(t-z/v_a),\delta(x+z(\tan\beta_c)/2),\delta y,\delta z)$ Eqs. (44a) and (44b) read as

$$\partial_Z E_{0a}=\frac{\tan\beta_c}{2}\partial_X E_{0a}+\frac{\tan\beta_c}{2\cos\beta_c}\partial_Y E_{0b}, \tag{45a}$$

$$\partial_Z E_{0b}=\frac{\sin\beta_c}{2}\partial_Y E_{0a}-\frac{\tan\beta_c}{2}\partial_X E_{0b}. \tag{45b}$$

Composing these equations establishes that the modes E_{0m} for $m=a$ and b obey the standard wave equations with uniform ''velocity'' $(\tan\beta_c)/2$

$$\partial_Z^2 E_{0a}=\frac{\tan^2\beta_c}{4}(\partial_X^2+\partial_Y^2)E_{0_a}, \tag{46a}$$

$$\partial_Z^2 E_{0b}=\frac{\tan^2\beta_c}{4}(\partial_X^2+\partial_Y^2)E_{0b}, \tag{46b}$$

where Z plays the role of the usual time. The initial conditions are imposed by $E_{0m}(Z=0)$ and $\partial_Z E_{0m}(Z=0)$. As is well-known the solution of the wave equation $u_{tt}=c^2\Delta u$ satisfies the Huygens principle which states that, if the Laplacian acts on a space with odd dimension d, then the solution $u(x,t)$ depends only on the initial data at $t=0$ for $x_0\in\{x_0\in\mathbb{R}^d,|x_0-x|=ct\}$. Thus an initial delta-like pulse at $t=0$, $x=0$ will give rise at time t to a pulse concentrated on the circle with center 0 and radius ct. This property does not hold true for even dimension, since the solution $u(x,t)$ then depends on the initial data at $t=0$ in the cone $x_0\in\{x_0\in\mathbb{R}^d,|x_0-x|\leqslant t\}$. In the standard wave equation, the space has dimension $d=3$ and the Huygens principle is satisfied. In our case, Z plays the role of t and $d=2$, which proves that complex structure inside the main cone can be generated during the propagation. We refer to the standard literature on the wave equation for a description of the different phenomena that can arise.[17,18]

IX. TRANSITION BETWEEN UNIAXIAL AND BIAXIAL CONFIGURATIONS

We assume in this section that the crystal is tailored so that its principal axis and the propagation axis z of the input pulse are collinear. Furthermore the susceptibilities χ_1 and χ_2 are close to each other so that they can be written as: $\chi_1=\chi_o$ and $\chi_2=\chi_o-\delta^2\eta_\chi$, where η_χ is of order 1. Accordingly the tensor χ in the (x,y,z)-frame reads as

$$\chi=\chi^0-\delta^2\eta_x M_\phi, \quad \chi^0:=\begin{pmatrix}\chi_o & 0 & 0\\ 0 & \chi_o & 0\\ 0 & 0 & \chi_e\end{pmatrix}, \quad M_\phi=N_\phi\oplus 0, \quad N_\phi:=\begin{pmatrix}\sin^2\phi & \cos\phi\sin\phi\\ \cos\phi\sin\phi & \cos^2\phi\end{pmatrix}.$$

In such a configuration the dispersion equation is the same as in the uniaxial case considered in Sec. VII since the mismatch only appears at order δ^2. Thus the two eigenindices are equal to $\chi_o^{1/2}$, the group velocity coefficient and dispersion are similar to those of a standard ordinary wave and given by (37), and the leading order term $\mathbf{E}_0$ of the field is transverse. Further the propagations of the components E_{0x} and E_{0y} are coupled. To deal with this coupling we consider the general form (38) for the source. The weak biaxial property (of order δ^2) does not involve any modification of the transport equations which govern the propagation of the wave in the geometric scales with respect to the uniaxial case. We thus consider the scales of diffractive optics and we adopt the ansatz (40).

Proposition 6: If the source $\mathcal{S}$ can be expanded as (38), then the leading order term $\mathbf{E}_0$ of the slowly varying envelope is transverse and it satisfies the coupled Schrödinger equations:

$$2ik_o\partial_\zeta E_{0x}+\rho\partial_X^2 E_{0x}+\partial_Y^2 E_{0x}+(\rho-1)\partial_X\partial_Y E_{0y}-\sigma_o\partial_T^2 E_{0x}=k_o^2\eta_\chi(M_\phi\mathbf{E}_0)_x, \tag{47a}$$

$$2ik_o\partial_\zeta E_{0y}+\partial_X^2 E_{0y}+\rho\partial_Y^2 E_{0y}+(\rho-1)\partial_X\partial_Y E_{0x}-\sigma_o\partial_T^2 E_{0y}=k_o^2\eta_\chi(M_\phi\mathbf{E}_0)_y, \tag{47b}$$

starting from $\mathbf{E}_0(T,X,Y,\zeta=0)=(2/[1+n_o(\omega)])\mathbf{v}(T,X,Y)$, *where* $\rho=\chi_o/\chi_e$.

Taking the spatial Fourier transform with respect to the transverse coordinates (X, Y), the systems (47a) and (47b) reduces to a system of ordinary differential equations. If the initial pulse is polarized along the x axis, and if we retain only the component of the output pulse which is y polarized, then we have

$$|\hat{E}_y(z_c,k_x,k_y)|^2=F_\phi\left(k_x\sqrt{\frac{(\rho-1)z_c}{4k_o}},k_y\sqrt{\frac{(\rho-1)z_c}{4k_o}},\frac{\eta_\chi k_o z_c}{4}\right)|\hat{E}_x(0,k_x,k_y)|^2,$$

$$F_\phi(u,v,\eta)=(2uv+\eta\sin(2\phi))^2 \times\operatorname{sinc}^2\left(\sqrt{(u^2+v^2)^2+\eta^2+2\eta((v^2-u^2)\cos(2\phi)+2uv\sin(2\phi))}\right),$$

where $\operatorname{sinc}(s)=\sin(s)/s$. Figure 5 plots the function $(u,v)\mapsto F_\phi(u,v,\eta)$ for different values of the parameters ϕ and η. Comparisons with experimental observations show excellent agreement. See Figure 14.26 in Ref. 1 for an observation of Fig. 5(f), Figures 465 to 466 in Ref. 19 for observations of Figs. 5(d) and Fig. 5(e), and Fig. 5.30 in Ref. 20 for another observation of Fig. 5(e). In particular Fig. 5(f) is the theoretical counterpart of the cover of the sixth edition of the book ''Principles of Optics'' by Born and Wolf![1] Let us briefly discuss the main properties of the functions F_ϕ. If the initial polarization vector is collinear to one of the axis of the crystal ($\phi=0$ or π), then F_0 has a factor u^2v^2, which shows that there is a centered dark cross, whatever η. If the initial polarization vector is collinear to the bisecting line of the axes of the crystal ($\phi=\pi/4$), then we have

$$F_{\pi/4}(u,v,\eta)=(2uv+\eta)^2\operatorname{sinc}^2\left(\sqrt{(u^2+v^2)^2+\eta^2+4\eta uv}\right), \tag{48}$$

which shows that the transmission at the center gets nonzero when η increases and may even be 1 at some particular values (see Fig. 5). Indeed, whatever ϕ, the transmission at $u=v=0$ is $F_\phi(0,0,\eta)=\sin(\eta)^2\sin(2\phi)^2$. If $\phi=0$, it is always 0, but if $\phi=\pi/4$, it is equal to $\sin(\eta)^2$ which is maximal and equal to 1 when $\eta=\pi/2 \bmod \pi$. This implies that a plane wave is fully transmitted in this configuration.

The results derived in this section provide the principle and the precise characterization of electro-optic switching devices of the family of Pockels cells.[2] Indeed, the experimental setup

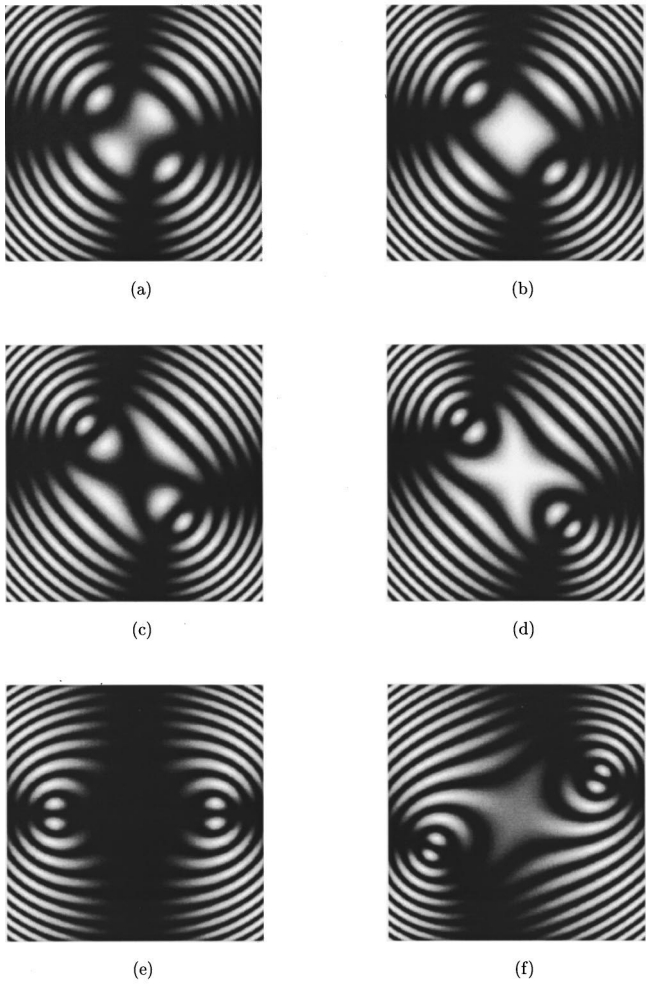

FIG. 5. Interference patterns from biaxial crystal plates between two crossed polarizers. Functions $(u,v)\mapsto F_\phi(\eta,u,v)$ over the domain $(-4,4)\times(-4,4)$ for different values of η and ϕ. $\eta=\pi/4$ and $\phi=\pi/4$ (a), $\eta=\pi/2$ and $\phi=\pi/4$ (b), $\eta=\pi$ and $\phi=\pi/4$ (c), $\eta=3\pi/2$ and $\phi=\pi/4$ (d), $\eta=2\pi$ and $\phi=\pi$ (e), and $\eta=5\pi/2$ and $\phi=7\pi/8$ (f). The case $\eta=0$ (and any ϕ) is plotted in Fig. 3.

depicted in Fig. 2 corresponds to the case $\eta_\chi=0$. Applying an electric field between two faces of the potassium dihydrogen phosphate (KDP) crystal plate involves an alteration of the distribution of the electric charges of the atoms and molecules which constitute the crystal, which affect the optical properties of the medium. The theory of electro-optics is well-known, and we refer for instance to Ref. 21, Section 87, for a survey. In the case of point group $\bar{4}2m$ to which KDP crystal belongs, it is known that the crystals become biaxial while they are uniaxial in the absence of external electric field, that is to say η_χ takes nonzero values which are imposed by the applied electric field. By applying the tension from 0 to the value corresponding to $\eta_\chi=2\pi/(k_o(\omega)z_c)$, the transmittivity goes from 0 to 1 for an input plane wave with carrier frequency ω. Finally note also that the transfer function $(u,v)\mapsto F_{\pi/4}(u,v,\pi/2)$ possesses a flat top hat. This configuration could then be used as a spatial filter as well.

X. CONCLUSION

In this paper we have derived the equations which govern the linear propagation of the slowly varying envelopes of pulses in a bulk medium presenting anisotropic properties. The strategy mainly consists in two steps. We first consider the Maxwell equations in the scales of optic

geometric, that is to say for propagation distance of the same order as the radius of the beam or the duration of the pulse times the light velocity. In this framework the propagation equations read as transport equations, which actually give the propagation of the rays according to the law of geometric optics. Second we revisit the Maxwell equations in the moving frame indicated by the above-derived transport equations. In the scales of the geometric optics, the propagation equations are then trivial, which allows to consider larger propagation distances, of the order of the Rayleigh distance or the dispersion distance. In this framework the propagation equations read as Schrödinger-type equations, which actually give the propagations of the slowly varying envelope according to the law of diffractive optics.

By applying this methodology we have put into evidence that we can deal with many situations. We have recovered well-known results, but we have also exhibited closed form expressions for the diffraction operator which has led to original results regarding an anomalous diffraction in a very particular configuration. Another advantage of this method is that it can still be applied when we take into account the nonlinear susceptibility of the medium. This generalization is addressed in the companion paper.[7]

(Received 28 October 1999; accepted for publication 10 January 2001)

This paper is devoted to the derivation of the equations that govern the propagation and frequency conversion of pulses in noncentrosymmetric crystals. The method is based upon high-frequency expansions techniques for hyperbolic quasi-linear and semilinear equations. In the so-called geometric regime we recover the standard results on the frequency conversion of pulses in nonlinear crystals. In the diffractive regime we show that the anisotropy of the diffraction operator involves remarkable phenomena. In particular the phase matching angle of a divergent pulse depends on the distance between the waist and the crystal plate. Finally we detect a configuration where the beam propagation in a biaxial crystal involves the generation of spatial solitons thanks to an anomalous one-dimensional diffraction. [DOI: 10.1063/1.1354640]

I. INTRODUCTION

In 1961 Franken *et al.*[1] observed radiation at a double frequency when a ruby laser beam was directed into a quartz crystal. Unfortunately, because of phase mismatch of the fundamental and converted waves, the efficiency of conversion proved to be very low (about $10^{-10}\%$). The so-called phase matching condition which should be fulfilled for the second harmonic generation $\omega+\omega \mapsto 2\omega$ reads as $2\mathbf{k}(\omega)=\mathbf{k}(2\omega)$, or equivalently $n(2\omega)=n(\omega)$, where n is the refractive index. In the optical transparency region of isotropic crystals, and in anisotropic crystals for waves of identical polarizations, this condition is never fulfilled because of normal dispersion ($n(\omega) < n(2\omega)$). The use of anomalous dispersion is prohibited because the energy absorption is then very high. In 1962 Giordmaine[2] and Maker[3] simultaneously and independently proposed an ingenious method of matching the phase velocities of the fundamental and converted waves. The technique is based on the difference between the refractive indices of the waves with different polarizations in an anisotropic crystal. It is now current to reach efficiency of conversion of several ten percents.[4]

Anisotropy is a necessary condition for a medium to have a nonzero second order nonlinearity.[5] The χ^2-tensor is zero for any centrosymmetric crystal. The study of sum-frequency generation thus takes place in anisotropic media. The aim of this paper is to describe the effects of the anisotropy of the medium and to take a rigorous account of it in the study of the nonlinear regime and especially the frequency conversion phenomenon. The case of plane waves has been carefully studied in Ref. 6. We aim at deriving evolution equations for the slowly varying envelopes of broadband and divergent pulses by using a technique based on high-frequency expansions of the fields.[7]

The derived equations find practical applications in the framework of frequency conversion of high-power laser beams. Indeed the phase matching condition for efficient frequency doubling and tripling of laser beams is very drastic,[4] and it is therefore, necessary to detect the principal axis of the crystal with great precision. The standard process consists in observing the main output

direction of the frequency converted pulse of a divergent pulse. This work was originally triggered by the experimental observation that the direction of the frequency converted pulse of a fundamental Gaussian pulse depends on the distance between the waist of the fundamental pulse and the crystal, even with a perfectly normal incidence. The departures for different distances exceed the high-precision level required for reaching the expected conversion performance. The results derived in this paper predict the phenomenon and allow to compute the direction of the phase matching angle as a function of the direction of the frequency converted pulse and the distance between the waist of the fundamental pulse and the crystal.

The results of this paper are also necessary for a careful treatment of the propagation and frequency conversion of partially coherent pulses. Indeed incoherent light with short coherence time is of interest for smoothing techniques for uniform irradiation in plasma physics.[8] If propagation of incoherent light in isotropic linear media is now rather well understood, the evolution of the statistical properties of incoherent pulses in anisotropic and/or nonlinear media has been insufficiently examined.[9] A high level of irradiation uniformity is required for both direct and indirect drive for Inertial Confinement Fusion.[8] This criterion can be reached by implementing active smoothing methods, such as Induced Spatial Incoherence with echelons,[10] Smoothing by Spectral Dispersion (SSD),[11] Smoothing by multimode Optical Fiber (SOF).[12] All these methods involve the illumination on the target with an intensity which is a time varying speckle pattern, so that the time integrated intensity averages towards a flat profile. As an unavoidable drawback the optical smoothing techniques also involve phase modulations in the amplifiers and frequency converters (SSD), or even intensity modulations (SOF).

The framework for high-frequency expansions of the solutions of Maxwell's equations follows from the appearance of the small parameter δ which has the order of magnitude of the carrier wavelength of light divided by the next smallest characteristic length present in the problem. If we assume that the carrier wavelength is 1, then we have seen in Ref. 13 that for propagation length of order δ^{-1}, which corresponds to the scales of the so-called geometric optics, evolution equations read as transport equations with constant velocity. Further, in the moving pulse-time frame (moving according to the velocity exhibited by the geometric transport equations), for propagation length of order δ^{-2}, which corresponds to the scales of diffractive optics, the evolution of the field is governed by a Schrödinger equation.

The first nonlinear effect we discuss in this paper is the sum frequency generation. A nonlinear χ^2-type function applied to expressions of the form $\Sigma_f \mathbf{E}_f^{\delta}(\delta t, \delta \mathbf{x}) \exp i(k^f z - \omega_f t)$ will produce harmonics, that is to say expression with phase $(k^{f_1} + k^{f_2})z - (\omega_{f_1} + \omega_{f_2})t$. If the couples (ω_f, k^f) satisfy the dispersion relation, then the natural harmonic phases generally do not, due to the dispersive property of the material. The set of harmonics which satisfy the dispersion relation is generally very small (sometimes empty), because they need to fulfill a very drastic phase matching condition.

We must also take care that the strength of interaction and, therefore, the scale for interaction depends on the amplitude of the wave. If the amplitude of the wave is δ^{α}, then a p-wave interaction process will be noticeable for propagation length of order $\delta^{-(p-1)\alpha}$. Since we are mainly concerned in this paper with second-order nonlinearity, it means that the nonlinear effect will appear for propagation length of the order of $\delta^{-\alpha}$. Accordingly $\alpha = 1$ will correspond to nonlinear geometric optics and $\alpha = 2$ to nonlinear diffractive optics.

The paper is organized as follows. First we describe the general configuration at hand in Sec. II. Section III is devoted to the derivations of the dispersion relation, the phase matching and the suitable expanded form of the solution of the Maxwell equations. We address in Secs. IV and V the frequency conversion in birefringent crystals. In Sec. VI we derive the propagation equation of the slowly varying envelope of the field when the phase-matching conditions for frequency generation are not fulfilled. In Sec. VII we study a particular configuration which should allow the generation and propagation of spatial solitons.

II. FORMULATION AND SCALING

We consider an incident beam incoming from the left onto a nonmagnetic nonlinear crystal that occupies the domain $\mathbb{R}^3_+ := \{(x,y,z) \in \mathbb{R}^3, z>0\}$. The propagation axis is perpendicular to the boundary surface $\Sigma := \{(x,y,z) \in \mathbb{R}^3, z=0\}$ and is collinear to the z axis. The evolution of the electric field $\mathcal{E}$ is governed by the Maxwell equation

$$\mathbf{rot}\ \mathbf{rot}\ \mathcal{E} = -\mu_0 \partial_t^2 \mathcal{D}, \tag{1}$$

where the electric induction divides into the sum $\mathcal{D} = \mathcal{D}_l + \mathcal{P}_{nl}$ of a linear and a nonlinear part

$$\mathcal{D}_l = \varepsilon_0 \mathcal{E} + \varepsilon_0 \chi^{(1)} * \mathcal{E}, \tag{2}$$

$$\mathcal{P}_{nl} = \varepsilon_0 \chi^{(2)} * (\mathcal{E},\mathcal{E}) + \varepsilon_0 \chi^{(3)} * (\mathcal{E},\mathcal{E},\mathcal{E}) + \cdots, \tag{3}$$

$$\chi^{(j)} * (\mathcal{E},\ldots,\mathcal{E}) = \int_{-\infty}^{t} dt_1 \cdots \int_{-\infty}^{t} dt_j \chi^{(j)}(t-t_1,\ldots,t-t_j) : \mathcal{E}(t_1)\cdots\mathcal{E}(t_j). \tag{4}$$

ε_0 and μ_0 are, respectively, the dielectric constant and magnetic permeability of vacuum. The electromagnetic wave is assumed to be far enough from all absorption lines of the medium so that we can neglect absorption and the tensors $\chi^{(j)}$ are real.

The boundary condition at the surface Σ is imposed by the continuity of the tangential components of the magnetic and electric fields. The source $\mathcal{S}$ corresponding to the electric field of the incoming pulse at the interface Σ is assumed to be a modulation of a high-frequency signal whose carrier wavelength is λ_0, or the superposition of a finite number of such modes. From the characteristic spatial (resp. temporal) variations of the source we can also define a length scale R_0 (resp. a time scale T_0, associated with the length $L_0 := cT_0$). Our study will take place in the framework where the dimensionless parameter $\delta := \min\{\lambda_0/R_0, \lambda_0/L_0\}$ is small. As pointed out in the introduction, the order of magnitude $\overline{\mathcal{S}}$ of the source also plays a crucial role in that it determines the strength of the nonlinear interaction. Let us denote by $\overline{\chi_1}$ (resp. $\overline{\chi_2}$) the typical value taken by the Fourier transforms of the components of the $\chi^{(1)}$-tensor (resp. $\chi^{(2)}$-tensor) evaluated at frequency $2\pi c/\lambda_0$. The characteristic nonlinear amplitude is defined by $\overline{E_{nl}} := \overline{\chi_1}/\overline{\chi_2}$. Our study takes place in the framework of weakly nonlinear waves, which reads as $\overline{\mathcal{S}}/\overline{E_{nl}} \ll 1$. This ratio may be related to the small parameter δ through a new parameter $\alpha > 0$ such that $\overline{\mathcal{S}}/\overline{E_{nl}} = \delta^\alpha$. Setting $\tilde{x} = x/\lambda_0$, $\tilde{y} = y/\lambda_0$, $\tilde{z} = z/\lambda_0$, $\tilde{t} = ct/\lambda_0$, $\tilde{\mathcal{D}} = \mathcal{D}/(\varepsilon_0 \overline{E_{nl}})$, and $\tilde{\mathcal{E}} = \mathcal{E}/\overline{E_{nl}}$ the dimensionless Maxwell equation reads as

$$\tilde{\mathbf{rot}}\ \tilde{\mathbf{rot}}\ \tilde{\mathcal{E}} = -\tilde{\mu}_0 \partial_{\tilde{t}}^2 \tilde{\mathcal{D}},$$

where $\tilde{\mu}_0 = \varepsilon_0 \mu_0 c^2 = 1$. The source $\tilde{\mathcal{S}}$ has a high-frequency expansion of the form

$$\tilde{\mathcal{S}}(\tilde{x},\tilde{y},\tilde{t}) = \frac{1}{2}\delta^\alpha \sum_{\omega_f \in \Omega_s} \begin{pmatrix} v_x^f(\delta\tilde{t},\delta\tilde{x},\delta\tilde{y}) \\ v_y^f(\delta\tilde{t},\delta\tilde{x},\delta\tilde{y}) \\ 0 \end{pmatrix} e^{-i\omega_f \tilde{t}} + cc, \tag{5}$$

where *cc* is a shorthand for ''complex conjugate.'' $\Omega_{\mathcal{S}}$ is the collection of the high-carrier frequencies ω_f. $\mathbf{v}^f$ is the slowly varying envelope of the mode with carrier frequency ω_f. Note that a dimensionless propagation distance $\tilde{z}$ of the order of δ^{-1} corresponds to a physical distance of the order of R_0, while a dimensionless distance $\tilde{z}$ of the order of δ^{-2} corresponds to a physical distance of the order of R_0^2/λ_0 which is the well-known Rayleigh distance.

From now on we drop the tildes. We assume *a priori* that the electric field can be expanded in a power series of the small parameter δ and in a series with respect to a set of rapid phases $k^f z - \omega_f t$

$$\mathcal{E}=\tfrac{1}{2}\delta^{\alpha}\sum_{(\omega_f,k^f)\in H}(\mathbf{E}^f(\delta t,\delta x,\delta y,\delta z)e^{i(k^f z-\omega_f t)}+cc), \tag{6a}$$

$$\mathbf{E}^f(T,X,Y,Z)=\sum_{j=0}^{\infty}\delta^j\mathbf{E}_j^f(T,X,Y,Z), \tag{6b}$$

where $\mathbf{E}^f$ is the slowly varying envelope of the mode whose rapid phase is (ω_f,k^f). The functions $\mathbf{E}_j^f$ are smooth in all their arguments. H denotes the set of the rapid phases (ω_f,k^f) which are contained in the field $\mathcal{E}$. In case of linear medium[13] the modes propagate without interaction and the set of high frequencies $\{\omega_f,\exists k^f$ such that $(\omega_f,k^f)\in H\}$ is equal to Ω_S. In case of nonlinear medium, the generation of new phases (the so-called harmonics) is expected so that the series (6) may contain much more terms than in the source (5).

III. PROPAGATION IN A BIREFRINGENT CRYSTAL

We introduce the geometric framework. We first define a reference frame (x,y,z) associated with the pulse whose carrier wave vector $\mathbf{k}_0$ is collinear to the z axis. We then introduce a reference frame (1, 2, 3) associated with the optic axis of the crystal, where $\mathbf{e}_3$ is the main optic axis. We denote by θ the angle between the wave vector and the main optic axis. ϕ is the angle between the projection of the carrier wave vector onto the plane $(\mathbf{e}_1,\mathbf{e}_2)$ and the axis collinear to $\mathbf{e}_1$. The transition matrix between the reference frames (x,y,z) and (1, 2, 3) is denoted by U.

A. Principle of the high-frequency expansion

We present the principle of the high-frequency expansion method. It can be applied if the source can be expanded as (5). We proceed to *a priori* expansions of the field inside the crystal of the kind (6) with $\alpha>0$ (weak nonlinearity). In linear media (or equivalently for evanescent sources $\alpha\gg 1$) all nonlinear phenomena can be neglected, and the set of the frequencies ω which are contained in H is imposed by the source and is equal to Ω_S. Otherwise the generation of harmonics should be taken into account so that the set H could be much larger than in the linear case.

The establishing of the propagation equations for the slowly varying envelopes obeys the following scheme. The form (6) is substituted into Eq. (1). Collecting the terms with similar orders in δ and the same rapid phases (ω_f,k^f), we get a family of equations. These equations can be decomposed into coupled systems of equations parametrized by the rapid phases. In linear media these systems are independent so that the envelopes of the different modes propagate independently,[13] but in nonlinear media there are coupling between the propagation equations of the envelopes. If the form (6) is suitable, then the derived systems should have unique solutions. Actually we shall show the two following statements. First, the rapid phases must satisfy dispersion relations which read as compatibility conditions for the existence of the high-frequency expansion (6a). Second, the leading order terms $\mathbf{E}_0^f$ are determined by compatibility conditions for the existence of the series expansion (6b).

The form (6) is an ansatz, that is to say an *a priori* form of the solution which is valid in a given domain, here for $z\lesssim\delta^{-1}$. It is compatible with the boundary conditions and the source. It is self-similar with respect to the operators that are encountered in the Maxwell equation. This fact was established in Ref. 13 for the linear operators, and we shall see in the following that the expansion (6) is also self-similar with respect to the nonlinear operators.

B. Expansions of the linear terms

The linear susceptibility is defined as the Fourier transform of the tensor $\chi^{(1)}$ defined by (2). It is a diagonal matrix $\hat{\chi}^{(1)}_{123}$ in the frame (1, 2, 3), while in the reference frame (x,y,z) the tensor $\hat{\chi}^{(1)}_{xyz}$ is $U^{-1}\hat{\chi}^{(1)}_{123}U$. In the following χ is a shorthand for the matrix $\hat{\chi}^{(1)}_{xyz}+I_d$. If $\mathcal{E}$ is of the form $\mathcal{E}=\frac{1}{2}\delta^{\alpha}(\mathbf{E}(\delta t,\delta x,\delta y,\delta z)e^{i(kz-\omega t)}+cc)$, then the contribution of the linear induction to the Max-

well equation (1) and the **rot rot** $\mathcal{E}$ term can be expanded as powers of δ. Denoting by $T=\delta t$, $X=\delta x$, $Y=\delta y$, and $Z=\delta z$ the slowly varying variables, we have on the one hand

$$-\mu_0\partial_t^2\mathcal{D}_l=\tfrac{1}{2}\delta^\alpha(\mathbf{D}_0(\mathbf{E})+\delta\mathbf{D}_1(\mathbf{E})+\delta^2\mathbf{D}_2(\mathbf{E})+O(\delta^3))e^{i(kz-\omega t)}+cc, \tag{7}$$

where the $\mathbf{D}_j(\mathbf{E})$ are linear functions of $\mathbf{E}$ given by

$$\mathbf{D}_0(\mathbf{E})=\frac{\omega^2}{c^2}\chi\mathbf{E},\quad \mathbf{D}_1(\mathbf{E})=\frac{i}{c^2}(\omega^2\chi)'\partial_T\mathbf{E},\quad \mathbf{D}_2(\mathbf{E})=-\frac{1}{2c^2}(\omega^2\chi)''\partial_T^2\mathbf{E}, \tag{8}$$

and the primes stand for partial derivatives with respect to ω. On the other hand the **rot rot** $\mathcal{E}$ term writes

$$\textbf{rot rot}\ \mathcal{E}=\tfrac{1}{2}\delta^\alpha(\mathbf{R}_0(\mathbf{E})+\delta\mathbf{R}_1(\mathbf{E})+\delta^2\mathbf{R}_2(\mathbf{E}))e^{i(kz-\omega t)}+cc, \tag{9}$$

where the mappings $\mathbf{R}_j(\mathbf{E})$ are sums of partial derivatives of E with respect to space coordinates of order j that are given in Ref. 13.

C. Dispersion relations for the rapid phases

We aim at showing here that the rapid phases (ω_f,k^f) of the set H should fulfill the so-called dispersion equation. By substituting the ansatz (6) into Eq. (1) and collecting the coefficients with power δ^α and phases (ω_f,k^f), we get by applying the identities (7) and (9) that the leading order term $\mathbf{E}_0^f$ should satisfy

$$\mathbf{R}_0(\mathbf{E}_0^f)=\mathbf{D}_0(\mathbf{E}_0^f), \tag{10}$$

similarly as in the linear case. This is of course expected, since the weakness of the amplitude of the pulse (of order δ^α with $\alpha>0$) prevents nonlinear terms from coming into the leading part of the expansion with respect to δ.

As established in Ref. 13 there exist two positive solutions n_a and n_b and two polarizations $\mathbf{s}_a$ and $\mathbf{s}_b$ so that $\mathbf{s}_a$ and $\mathbf{s}_b$ are unit vectors and $(n_a\omega c^{-1},\mathbf{s}_a)$ and $(n_b\omega c^{-1},\mathbf{s}_b)$ are solutions of Eq. (10). We define the dispersion relationship, the group velocity and the dispersion coefficient of the waves as follows:

$$k_m(\omega):=\frac{\omega n_m(\omega)}{c},\quad v_m(\omega):=\left(\frac{\partial k_m}{\partial\omega}\right)^{-1},\quad \sigma_m(\omega):=k_m\frac{\partial^2 k_m}{\partial\omega^2},\quad m=a,b, \tag{11}$$

and we denote by β_m the angle between the polarization vector $\mathbf{s}_m$ and the z axis

$$\cos^2(\beta_m(\omega))=s_{mx}^2(\omega)+s_{my}^2(\omega).$$

In order to fulfill condition (10), the set $(\omega_f,k^f,\mathbf{E}_0^f)$ must satisfy one of the three following alternatives:

(i) Either $k^f=k_a(\omega_f)$ and the components of $\mathbf{E}_0^f$ parallel to $\mathbf{s}_a(\omega_f)$ may be nonvanishing;
(ii) either $k^f=k_b(\omega_f)$ and the components of $\mathbf{E}_0^f$ parallel to $\mathbf{s}_b(\omega_f)$ may be nonvanishing;
(iii) or $k^f\notin\{k_a(\omega_f),k_b(\omega_f)\}$, and then necessarily $\mathbf{E}_0^f\equiv 0$.

Note that the third option simply means that modes which are not phase-matched cannot have an envelope of order δ^α.

We can now give a suitable description of the set H of the rapid phases. The set H in the general nonlinear framework should at least contain the rapid phases that were exhibited in the linear framework for a given source $\mathcal{S}$ that is to say

$$H_{\mathcal{S}}=H_{a,\mathcal{S}}\cup H_{b,\mathcal{S}},$$

where $H_{a,\mathcal{S}}$ and $H_{b,\mathcal{S}}$ are the subsets of the rapid phases which satisfy either the a dispersion relation or the b relation

$$H_{m,\mathcal{S}}=\{(\omega,k) \text{ such that } \omega\in\Omega_{\mathcal{S}} \text{ and } k=k_m(\omega)\}.$$

In a nonlinear medium the generation of new frequencies is expected. The choice of the ansatz should take into account this phenomenon and that is why the set H of all possible rapid phases reads as the extended formulation

$$H=\left\{(\omega,k) \text{ such that } \exists j_1,\ldots,j_n\in\mathbb{Z},(\omega_i,k^i)\in H_{\mathcal{S}},\omega=\sum_{j=1}^{n} j_i\omega_i, \text{ and } k=\sum_{j=1}^{n} j_i k_i\right\}.$$

The rapid phases $(\omega,k)\in H$ for which $\omega\notin\Omega_{\mathcal{S}}$ correspond to the so-called harmonic modes. Since the pairs (ω_f,k^f) are algebraic sums of adapted rapid phases which originate from $H_{\mathcal{S}}$, and since the media we usually consider have a normal dispersion, there is only two types of phase matching (assuming that $n_a<n_b$):

(i) Type I: Both fundamental modes are of type a and the harmonic mode is of type b with $\omega_h=\omega_p+\omega_q$ and $k_a(\omega_q)+k_a(\omega_p)=k_b(\omega_h)$;
(ii) Type II: One of the fundamental modes is of type a and the other one of type b, while the harmonic mode is also of type b with $\omega_h=\omega_p+\omega_q$ and $k_a(\omega_p)+k_b(\omega_q)=k_b(\omega_h)$.

Only the rapid phases of H which satisfy one of the two phase matching conditions may possess a nonvanishing zeroth-order component $\mathbf{E}_0^f$. That is why the physically relevant modes are those for which the rapid phases belong to H_{ac}

$$H_{ac}=\{(\omega,k)\in H \text{ such that } k=k_a(\omega) \text{ or } k=k_b(\omega)\}.$$

The leading order terms for the other harmonic phases $(\omega_f,k^f)\in H\backslash H_{ac}$ are at most of order $\delta^{2\alpha}$, that is to say $\mathbf{E}^f\sim\delta^\alpha\mathbf{E}_\alpha^f+O(\delta^{\alpha+1})$. Nevertheless it is necessary to take into account the harmonic modes that are not phase-matched so as to close the propagation equations. To complete this section we would like to add that the phase matching condition is only required to be fulfilled at order 1. A phase matching condition satisfied up to a term of order δ: $k_b(\omega_h)-k^p-k^q\sim O(\delta)$ or $k_b(\omega_h)-k^p-k^q\sim O(\delta)$, is a sufficient condition for an harmonic phase to possess an envelope with a nonvanishing leading order term $\mathbf{E}_0^h$. We shall encounter such situations in the forthcoming sections.

D. Boundary condition

If we assume that the source $\mathcal{S}$ can be expanded as (5), and accordingly that the field $\mathcal{E}$ inside the crystal is of the form (6), then collecting the coefficients with power δ^α and high carrier frequency ω_f establishes the continuity conditions which impose that the components parallel to the boundary surface of the input field $\mathcal{S}$ and of the field $\mathcal{E}$ should be equal, while there are no condition for the normal components. Since $\alpha>0$ these conditions are the same as in the linear configuration, so the type m mode $(m=a,b)$ with carrier frequency ω_f should be at $z=0^+$

$$\mathbf{E}_{0,m}^f(\delta t,\delta x,\delta y,z=0^+)=\frac{2}{1+n_m(\omega)}\frac{1}{s_{mx}^2+s_{my}^2}\begin{pmatrix} s_{mx}^2 & s_{mx}s_{my} & 0\\ s_{mx}s_{my} & s_{my}^2 & 0\\ s_{mx}s_{mz} & s_{my}s_{mz} & 0\end{pmatrix}\mathbf{v}^f(\delta t,\delta x,\delta y).$$

E. Poynting vector and diffraction operator in the linear framework

In this section we remember the reader with the main results of Ref. 13 in the case when the nonlinear polarization is neglected. The following results hold true when the two eigenindices (n_a,n_b) are different from each other. Note that the occurrence of the case $n_a=n_b$ corresponds to

very particular configurations which were thoroughly studied in Ref. 13. In the framework of frequency conversion, these configurations are not interesting since we aim at using the existence of two different dispersion relations for the modes to fulfill the phase matching conditions. The input wave break into the sum of modulations of high-frequency signals, which also divide into two modes which all propagate independently. For each high frequency ω and mode $m=a,b$, the Poynting vector of the mode is collinear to

$$\mathbf{u}_m(\omega)=\left(\frac{s_{mx}s_{mz}}{s_{mx}^2+s_{my}^2},\frac{s_{my}s_{mz}}{s_{mx}^2s_{my}^2},-1\right)^T. \tag{12}$$

In the reference frame $(\delta t,\delta x,\delta y,\delta z)$ the slowly varying envelope E_m^ω of the mode satisfies the transport equation $\partial_Z E_m^\omega+\mathcal{T}_m(\omega)E_m^\omega=0$ where

$$\mathcal{T}_m(\omega)=-u_{mx}(\omega)\partial_X-u_{my}(\omega)\partial_Y+v_m(\omega)^{-1}\partial_T. \tag{13}$$

In the moving reference frame $(\delta(t-z/v_m),\delta(x+u_{mx}z),\delta(y+u_{my}z),\delta^2 z)$ the slowly varying envelope E_m^ω of the mode satisfies a Schrödinger-type equation with respect to the long scale variable $\zeta=\delta^2 z$

$$2ik_m(\omega)\partial_\zeta E_m^\omega+\mathcal{L}_m(\omega)E_m^\omega+\mathcal{K}_m(\omega)E_m^\omega=0, \tag{14}$$

where the diffraction operator $\mathcal{L}_m(\omega)$ is anisotropic (see Ref. 13 for the complete expressions of the $c_{m,\ldots}$)

$$\mathcal{L}_m(\omega)=c_{m,xx}(\omega)\partial_X^2+2c_{m,xy}(\omega)\partial_X\partial_Y+c_{m,yy}(\omega)\partial_Y^2, \tag{15}$$

and the dispersion operator $\mathcal{K}_m(\omega)$ contains crossed space–time derivatives

$$\mathcal{K}_m(\omega)=-\sigma_m(\omega)\partial_T^2+2k_m(\omega)(\partial_\omega u_{mx})(\omega)\partial_T\partial_X+2k_m(\omega)(\partial_\omega u_{my})(\omega)\partial_T\partial_Y. \tag{16}$$

F. Second-order nonlinear polarization

The nonlinear susceptibility is the Fourier transform of the tensor $\chi^{(2)}$ defined by (3)

$$\hat{\chi}^{(2)}(\omega_1,\omega_2):=\int_0^\infty dt_1\int_0^\infty dt_2\chi^{(2)}(t_1,t_2)e^{i\omega_1 t_1+i\omega_2 t_2}.$$

Time integration starts from 0 to satisfy the causality property. We introduce the projector Θ_{ω_c,k^c} acting on fields of the form $\mathcal{A}=\frac{1}{2}\Sigma_{(\omega_f,k^f)\in H}\mathbf{A}_\delta^f e^{i(k^f z-\omega_f t)}+cc$ by

$$\Theta_{\omega_c,k^c}(\mathcal{A})=\mathbf{A}_\delta^c \text{ if } (\omega_c,k^c)\in H, \text{ and } 0 \text{ otherwise.}$$

The (ω_h,k^h) component of the nonlinear polarization in the crystallographic frame then reads as

$$\Theta_{\omega_h,k^h}(\mathcal{P}_{nl})=\frac{\epsilon_0}{2}\sum_{p,q,\omega_p+\omega_q=\omega_h,k^p+k^q=k^h}\hat{\chi}^{(2)}(\omega_p,\omega_q):(\mathbf{E}^p,\mathbf{E}^q).$$

For frequencies ω_p and ω_q and for types m_1 and m_2 in $\{a,b\}$ we denote by $\mathbf{s}_{m_1,m_2}(\omega_p,\omega_q)$ the vector

$$\mathbf{s}_{m_1,m_2}(\omega_p,\omega_q):=\hat{\chi}^{(2)}(\omega_p,\omega_q):(\mathbf{s}_{m_1}(\omega_p),\mathbf{s}_{m_2}(\omega_q)). \tag{17}$$

We list in the following the processes which can give rise to the generation of new frequencies:

(i) Type I conversion.
Let us denote $\omega_h=\omega_p+\omega_q$, $k^p=k_a(\omega_p)$, $k^q=k_a(\omega_q)$, and $k^h=k^p+k^q$. Then $\mathcal{E}^p+\mathcal{E}^q$ is of the form $\frac{1}{2}E^p\mathbf{s}_a(\omega_p)e^{i(k^pz-\omega_pt)}+\frac{1}{2}E^q\mathbf{s}_a(\omega_q)e^{i(k^qz-\omega_qt)}+cc$. In the (xyz)-reference frame the nonlinear polarization reads $\mathcal{P}_{nl,xyz}=U^{-1}\mathcal{P}_{nl,123}U$ and the (ω_h,k^h) component is

$$\Theta_{\omega_h,k^h}(\mathcal{P}_{nl,xyz})=\epsilon_0\mathbf{s}_{a,a}(\omega_p,\omega_q)E^pE^q. \tag{18}$$

(i) Type II conversion.
Let us denote $\omega_h=\omega_p+\omega_q$, $k^p=k_a(\omega_p)$, $k^q=k_b(\omega_q)$, and $k^h=k^p+k^q$. Then $\mathcal{E}^p+\mathcal{E}^q$ is of the form $\frac{1}{2}E^p\mathbf{s}_a(\omega_p)e^{i(k^pz-\omega_pt)}+\frac{1}{2}E^q\mathbf{s}_b(\omega_q)e^{i(k^qz-\omega_qt)}$. In the (xyz)-reference frame the nonlinear polarization reads $\mathcal{P}_{nl,xyz}=U^{-1}\mathcal{P}_{nl,123}U$ and the (ω_h,k^h) component is

$$\Theta_{\omega_h,k^h}(\mathcal{P}_{nl,xyz})=\epsilon_0\mathbf{s}_{a,b}(\omega_p,\omega_q)E^pE^q. \tag{19}$$

In the case of the class $\overline{4}2m$ which contains in particular potassium dihydrogen phosphate (KDP) crystal, the $\chi^{(2)}$-tensor has only six nonvanishing components which are equal to the coefficient $2d$: $\hat{\chi}^{(2)}_{123}=\hat{\chi}^{(2)}_{132}=\hat{\chi}^{(2)}_{213}=\hat{\chi}^{(2)}_{231}=\hat{\chi}^{(2)}_{312}=\hat{\chi}^{(2)}_{321}=2d$. The vectors $\mathbf{s}_{o,o}$ and $\mathbf{s}_{o,e}$ then read as

$$\mathbf{s}_{o,o}=2d\begin{pmatrix}\sin\theta\sin(2\phi)\\0\\-\cos\theta\sin(2\phi)\end{pmatrix},\quad \mathbf{s}_{o,e}=2d\begin{pmatrix}\cos(2\phi)\sin(\beta-2\theta)\\-\sin(2\phi)\sin(\beta-\theta)\\\cos(2\phi)\cos(\beta-2\theta)\end{pmatrix}.$$

IV. TYPE I PHASE-MATCHING

We assume that the incoming pulse consists of two modes with carrier frequencies ω_p and ω_q which are linearly polarized along the $\mathbf{s}_a(\omega_p)$-axis and $\mathbf{s}_a(\omega_q)$-axis, respectively

$$\mathcal{S}=\tfrac{1}{2}\delta^\alpha(v^p(\delta x,\delta y,\delta t)\mathbf{s}_a(\omega_p)e^{-i\omega_pt}+v^q(\delta x,\delta y,\delta t)\mathbf{s}_a(\omega_q)e^{-i\omega_qt})+cc. \tag{20}$$

The type I phase matching conditions are assumed to be satisfied for the sum $\omega_p+\omega_q=\omega_h$

$$k_a(\omega_p)+k_a(\omega_q)=k_b(\omega_h). \tag{21}$$

We also assume that the pair $(\omega_h,k_b(\omega_h))$ is the only adapted harmonic phase, that is to say the phase matching condition is not fulfilled for a subtraction or a sum between ω_p, ω_q, and ω_h different from $\omega_h=\omega_p+\omega_q$. As a consequence $H_{ac}=\{(\omega_p,k^p),(\omega_q,k^q),(\omega_h,k^h)\}$ where $k^p=k_a(\omega_p)$, $k^q=k_a(\omega_q)$, and $k^h=k_b(\omega_h)$. The adapted ansatz is accordingly

$$\mathcal{E}=\mathcal{E}^p+\mathcal{E}^q+\mathcal{E}^h+\mathcal{R}, \tag{22a}$$

$$\mathcal{E}^f=\frac{1}{2}\,\delta^\alpha\left(\sum_{j=0}^{\infty}\delta^j\mathbf{E}^f_j(\delta t,\delta x,\delta y,\delta z)\right)e^{i(k^fz-\omega_ft)}+cc, \tag{22b}$$

where $\mathcal{R}$ indicates a series of harmonic modes whose leading order coefficients $\mathbf{E}^f_0$ are vanishing. The parameter α will then play a crucial part since the order of magnitude of the input pulse imposes the distance scale at which the nonlinear effects become noticeable.

A. Geometric optics $\alpha=1$

We denote $T=\delta t$, $X=\delta x$, $Y=\delta y$, $Z=\delta z$.

Proposition 1: If the source can be expanded as (20), then the fundamental modes are of type a for the carrier frequencies ω_p and ω_q while the harmonic mode at frequency ω_h is of type b. By denoting $E^p_0=\mathbf{s}_a(\omega_p).\mathbf{E}^p_0$, $E^q_0=\mathbf{s}_a(\omega_q).\mathbf{E}^q_0$, and $E^h_0=\mathbf{s}_b(\omega_h).\mathbf{E}^h_0$ the projections of the modes onto their respective unit polarization vectors, the slowly varying envelopes E^f_0 satisfy the following coupled equations:

$$\partial_Z E_0^p + \mathcal{T}_a(\omega_p)(E_0^p) = \frac{i\omega_p d^{(I)}}{n_a(\omega_p)\cos^2(\beta_a(\omega_p))} E_0^q * E_0^h, \tag{23a}$$

$$\partial_Z E_0^q + \mathcal{T}_a(\omega_q)(E_0^q) = \frac{i\omega_q d^{(I)}}{n_a(\omega_q)\cos^2(\beta_a(\omega_q))} E_0^p * E_0^h, \tag{23b}$$

$$\partial_Z E_0^h + \mathcal{T}_b(\omega_h)(E_0^h) = \frac{i\omega_h d^{(I)}}{n_b(\omega_h)\cos^2(\beta_b(\omega_h))} E_0^p E_0^q, \tag{23c}$$

starting from $E_0^p(T,X,Y,Z=0) = (2/[1+n_a(\omega_p)])v^p(T,X,Y)$, $E_0^q(T,X,Y,Z=0) = (2/[1+n_a(\omega_q)])v^q(T,X,Y)$ *and* $E_0^h(T,X,Y,Z=0) = 0$, *where the transport operator* $\mathcal{T}_m(\omega)$ *is given by* (13) *and*

$$d^{(I)} = \frac{\mathbf{s}_a(\omega_p).\mathbf{s}_{a,b}(\omega_q,\omega_h)}{2c}.$$

Proof: The strategy is formally the same as in linear configurations. We substitute the ansatz (22a) and (22b) with $\alpha = 1$ into Eq. (1) and we collect the coefficients with the same power of δ and the same carrier frequency. At order δ we find the dispersion relation and phase matching conditions discussed in Sec. III C. At order δ^2, we project the equation onto the three axes.
For the frequency ω_p (resp. $-\omega_p$), denoting $k^p = k_a(\omega_p)$

$$\mathbf{R}_0(\mathbf{E}_1^p) + \mathbf{R}_1(\mathbf{E}_0^p) = \mathbf{D}_0(\mathbf{E}_1^p) + \mathbf{D}_1(\mathbf{E}_0^p) + \mu_0\omega_p^2\Theta_{\omega_p,k^p}(\mathcal{P}_{nl}(\mathcal{E}_0,\mathcal{E}_0)), \tag{24}$$

where we retain only the terms of order δ in $\mathcal{P}_{nl}$, which are the ones that give a contribution of the nonlinear polarization of order δ^2. Further in the nonlinear term $\mathcal{P}_{nl}(\mathcal{E}_0,\mathcal{E}_0)$ we only retain the coefficients with rapid phase $+(k^p z - \omega_p t)$. Only the frequencies ω_h and $-\omega_q$ can generate ω_p (resp. $-\omega_h$ and ω_q for $-\omega_p$). We, therefore, compute the sum of a type a wave at frequency $-\omega_q$ with a type b wave at frequency ω_h. By applying (19) we get in the reference frame (x,y,z):

$$\Theta_{\omega_p,k^p}(\mathcal{P}_{nl}(\mathcal{E}_0,\mathcal{E}_0)) = \epsilon_0\mathbf{s}_{a,b}(\omega_q,\omega_h)E_0^q * E_0^h.$$

The projection of Eq. (24) onto $\mathbf{s}_a(\omega_p)$ then provides the compatibility condition which reads as Eq. (23a).

For the frequency ω_q, the situation is similar. We get Eq. (23b) with an expression of $d^{(I)}$ which is $d^{(I)'} = (\mathbf{s}_a(\omega_q).\mathbf{s}_{a,b}(\omega_p,\omega_h))/(2c)$, and using the symmetry properties of $\hat{\chi}^{(2)}$[14] it is easy to prove that $d^{(I)'} = d^{(I)}$.

For the frequency ω_h, denoting $k^h = k_b(\omega_h)$:

$$\mathbf{R}_0(\mathbf{E}_1^h) + \mathbf{R}_1(\mathbf{E}_0^h) = \mathbf{D}_0(\mathbf{E}_1^h) + \mathbf{D}_1(E_0^h) + \mu_0\omega_h^2\Theta_{\omega_h,k^h}(\mathcal{P}_{nl}(\mathcal{E}_0,\mathcal{E}_0)), \tag{25}$$

where we retain only the terms of order δ in $\mathcal{P}_{nl}$, which are the ones that give a contribution of the nonlinear polarization of order δ^2. Further in the nonlinear term $\mathcal{P}_{nl}(\mathcal{E}_0,\mathcal{E}_0)$ we only retain the coefficients with rapid phase $+(k^h z - \omega_h t)$. Only the frequencies ω_p and ω_q can generate ω_h (resp. $-\omega_p$ and $-\omega_q$ for $-\omega_h$). We therefore compute the sum of a type a wave at frequency ω_p with a type a wave at frequency ω_q. By applying (18), we get in the reference frame (x,y,z)

$$\Theta_{\omega_h,k^h}(\mathcal{P}_{nl,xyz}) = \epsilon_0\mathbf{s}_{a,a}(\omega_p,\omega_q)E_0^p E_0^q.$$

The projection of Eq. (25) onto $\mathbf{s}_b(\omega_h)$ then provides the compatibility condition which reads as Eq. (23c) with $d^{(I)''} = (\mathbf{s}_b(\omega_h).\mathbf{s}_{a,a}(\omega_p,\omega_q))/(2c)$, and using the symmetry properties of $\hat{\chi}^{(2)}$ it is easy to prove that $d^{(I)''} = d^{(I)}$. □

B. Approximate phase matching

In the above section we have considered a perfect phase matching condition. This condition is indeed very stringent and should be fulfilled at the leading order. Nevertheless it is barely possible in realistic experimental configurations to reach such a level of perfection. It is therefore relevant to address the case of a slight perturbation of the ideal case $\theta=\theta_{pm}$ where θ_{pm} is the angle which satisfies (21). We consider in this section that the phase matching condition is fulfilled up to a term of order δ and we set $\theta=\theta_{pm}+\delta\eta$. The corresponding propagation equations read

$$\partial_Z E_0^p+\mathcal{T}_a(\omega_p)E_0^p=\frac{i\omega_p d^{(I)}}{n_a(\omega_p)\cos^2(\beta_a(\omega_p))}E^{q*}\tilde{E}_0^h,$$

$$\partial_Z E_0^q+\mathcal{T}_a(\omega_q)E_0^q=\frac{i\omega_q d^{(I)}}{n_a(\omega_q)\cos^2(\beta_a(\omega_q))}E_0^{p*}E_0^h,$$

$$\partial_Z E_0^h+\mathcal{T}_b(\omega_h)E_0^h=\frac{i\omega_h d^{(I)}}{n_b(\omega_h)\cos^2(\beta_b(\omega_h))}E_0^pE_0^q+i\eta_k E_0^h,$$

where $\eta_k=\eta[\partial k_b(\omega_h)/\partial\theta]|_{\theta=\theta_{pm}}$. By setting $\tilde{E}_0^h=E_0^h e^{-i\eta_k Z}$, this system reduces:

$$\partial_Z E_0^p+\mathcal{T}_a(\omega_p)E_0^p=\frac{i\omega_p d^{(I)}}{n_a(\omega_p)\cos^2(\beta_a(\omega_p))}E_0^{q*}\tilde{E}_0^h e^{i\eta_k Z},$$

$$\partial_Z E_0^q+\mathcal{T}_a(\omega_q)E_0^q=\frac{i\omega_q d^{(I)}}{n_a(\omega_q)\cos^2(\beta_a(\omega_q))}E_0^{p*}\tilde{E}_0^h e^{i\eta_k Z},$$

$$\partial_Z \tilde{E}_0^h+\mathcal{T}_b(\omega_h)\tilde{E}_0^h=\frac{i\omega_h d^{(I)}}{n_b(\omega_h)\cos^2(\beta_b(\omega_h))}E_0^pE_0^q e^{-i\eta_k Z}.$$

It appears that it is necessary to add a phase $-\eta_k Z$ to the harmonic field so as to make the frequency conversion equations into a standard form. It shows that the rapid phase of the harmonic is imposed by the product of the phases of the fundamental modes: $\exp i((k^p+k^q)z-(\omega_p+\omega_q)t)$, which is different from the ''natural'' type b phase $\exp i(k_b(\omega_h)z-\omega_h t)$, with $\omega_h=\omega_p+\omega_q$.

C. Diffractive optics $\alpha=2$

In this configuration the nonlinear effects are weaker, of the order of $\delta^{2\alpha}=\delta^4$, so that they can show themselves only after a longer propagation distance z of the order of δ^{-2}. The technique is the same as for the derivations of the propagation equations in the linear framework. The final result is expressed in terms of the original variables x,y,z,t:

Proposition 2: Let us assume that the input field $\mathcal{S}$ consists of two modes with carrier frequencies ω_p and ω_q which are linearly polarized along the $\mathbf{s}_a(\omega_p)$-axis and $\mathbf{s}_a(\omega_q)$-axis, respectively. Then the fundamental modes are of type a and the harmonic mode is of type b ($\omega_h=\omega_p+\omega_q$). We denote $k^p=k_a(\omega_p)$, $k^q=k_a(\omega_q)$, $k^h=k_b(\omega_h)$, $\eta_k=k^h-k^p-k^q$, and $\tilde{\mathbf{E}}^h=\mathbf{E}^h e^{-i\eta_k z}$. We introduce the projections of the envelopes of the modes onto their respective unit polarization vectors: $E^p=\mathbf{s}_a(\omega_p).\mathbf{E}^p$, $E^q=\mathbf{s}_a(\omega_q).\mathbf{E}^q$, and $\tilde{E}^h=\mathbf{s}_b(\omega_h).\tilde{\mathbf{E}}^h$. The system which governs the propagation and conversion is:

$$\partial_z E^p+\mathcal{T}_a(\omega_p)E^p-\frac{i}{2k^p}\mathcal{L}_a(\omega_p)E^p-\frac{i}{2k^p}\mathcal{K}_a(\omega_p)E^p=\frac{i\omega_p d^{(I)}}{n_a(\omega_p)\cos^2(\beta_a(\omega_p))}E^{q*}\tilde{E}^h e^{i\eta_k z},$$

$$\partial_z E^q+\mathcal{T}_a(\omega_q)E^q-\frac{i}{2k^q}\mathcal{L}_a(\omega_q)E^q-\frac{i}{2k^q}\mathcal{K}_a(\omega_q)E^q=\frac{i\omega_q d^{(I)}}{n_a(\omega_q)\cos^2(\beta_a(\omega_q))}E^{p*}\tilde{E}^h e^{i\eta_k z},$$

$$\partial_z \tilde{E}^h + \mathcal{T}_b(\omega_h)\tilde{E}^h - \frac{i}{2k^h}\mathcal{L}_b(\omega_h)\tilde{E}^h - \frac{i}{2k^h}\mathcal{K}_b(\omega_h)\tilde{E}^h = \frac{i\omega_h d^{(I)}}{n_b(\omega_h)\cos^2(\beta_b(\omega_h))}E^p E^q e^{-i\eta_k z},$$

where the transport operator $\mathcal{T}_m$ and the diffraction-dispersion operators $\mathcal{L}_m$ and $\mathcal{K}_m$ are given by (13), (15), and (16), respectively (where small letters should be substituted for capital letters).

V. TYPE II PHASE-MATCHING

We assume that the source can be expanded as

$$\mathcal{S} = \frac{1}{2}\delta^2 \begin{pmatrix} v_x(\delta x, \delta y, \delta t)e^{-i\omega_q t} \\ v_y(\delta x, \delta y, \delta t)e^{-i\omega_p t} \\ 0 \end{pmatrix} + cc, \tag{26}$$

and that the type II phase matching condition is almost satisfied by the sum $\omega_p + \omega_q = \omega_h$:

$$k_b(\omega_h) - k_a(\omega_p) - k_b(\omega_q) = O(\delta).$$

We also assume that the pair $(\omega_h, k_b(\omega_h))$ is the only adapted harmonic phase, that is to say the phase matching condition is not fulfilled for a subtraction or a sum between ω_p, ω_q, and ω_h different from $\omega_h = \omega_p + \omega_q$, so that the suitable ansatz is (22a) and (22b) with $H_{ac} = \{(\omega_p, k^p), (\omega_q, k^q), (\omega_h, k^h)\}$ where $k^p = k_a(\omega_p)$, $k^q = k_b(\omega_q)$, and $k^h = k_b(\omega_h)$. The main result is obtained by using the very same techniques as in the previous sections so that we only state it in the original variables *x,y,z,t*. We denote the phase mismatch by $\eta_k := k^h - k^p - k^q$.

Proposition 3. Let us assume that the input field $\mathcal{S}$ consists of two modes with carrier frequencies ω_p and ω_q which are linearly polarized along the y axis and x axis, respectively. Then the modes of the field $\mathcal{E}$ are ordinary for the fundamental ω_p and extraordinary for the fundamental ω_q and harmonic $\omega_h = \omega_p + \omega_q$. By introducing $\tilde{\mathbf{E}}^h = \mathbf{E}^h e^{-i\eta_k z}$ and denoting $E^p = \mathbf{s}_a(\omega_p).\mathbf{E}^p$, $E^q = \mathbf{s}_b(\omega_q \mathbf{E}^q)$. and $\tilde{E}^h = \mathbf{s}_b(\omega_h).\tilde{\mathbf{E}}^h$ the projections of the envelopes of the modes onto their respective unit polarization vectors, the system which governs the propagation and conversion is:

$$\partial_z E^p + \mathcal{T}_a(\omega_p)E^p - \frac{i}{2k^p}\mathcal{L}_a(\omega_p)E^p - \frac{i}{2k^p}\mathcal{K}_a(\omega_p)E^p = \frac{i\omega_p d^{(II)}}{n_a(\omega_p)\cos^2(\beta_a(\omega_p))}E^{q*}\tilde{E}^h e^{i\eta_k z},$$

$$\partial_z E^q + \mathcal{T}_b(\omega_q)E^q - \frac{i}{2k^q}\mathcal{L}_b(\omega_q)E^q - \frac{i}{2k^q}\mathcal{K}_b(\omega_q)E^q = \frac{i\omega_q d^{(II)}}{n_b(\omega_q)\cos^2(\beta_b(\omega_q))}E^{p*}\tilde{E}^h e^{i\eta_k z},$$

$$\partial_z \tilde{E}^h + \mathcal{T}_b(\omega_h)\tilde{E}^h - \frac{i}{2k^h}\mathcal{L}_b(\omega_h)\tilde{E}^h - \frac{i}{2k^h}\mathcal{K}_b(\omega_h)\tilde{E}^h = \frac{i\omega_h d^{(II)}}{n_b(\omega_h)\cos^2(\beta_b(\omega_h))}E^p E^q e^{-i\eta_k z},$$

where

$$d^{(II)} = \frac{\mathbf{s}_a(\omega_p).\mathbf{s}_{b,b}(\omega_q, \omega_h)}{2c}.$$

VI. PROPAGATION FAR FROM PHASE-MATCHING

In the two previous sections we have examined the two cases corresponding to phase-matching for sum-frequency generation. In this section we consider the general situation where the phase-matching condition is not fulfilled so as to derive the propagation equation of the fundamental wave, and also some information for the different harmonic waves. Such a work has been performed by Leblond[15] who considered the propagation of a pulse along the principal axis of a uniaxial crystal. In this section we consider the general case of biaxial crystals in the configuration when the two eigenindices are different from each other. We assume a source of the form

$$\mathcal{S}=\tfrac{1}{2}\delta v(\delta x,\delta y,\delta t)(s_{ax}(\omega),s_{ay}(\omega),0)^T e^{-i\omega t}+cc, \tag{27}$$

and we shall see that the suitable ansatz for the scales corresponding to diffractive optics is:

$$\mathcal{E}=\mathcal{E}^{0\omega}+\mathcal{E}^{1\omega}+\mathcal{E}^{2\omega}+\mathcal{R}, \tag{28a}$$

$$\mathcal{E}^{l\omega}=\frac{1}{2}\delta\sum_{j=0}^{\infty}\delta^j\mathbf{E}_j^{l\omega}(\delta(t-z/v_a),\delta(x+u_{ax}z),\delta(y+u_{ay}z),\delta^2 z)e^{il(k_a(\omega)z-\omega t)}+cc, \tag{28b}$$

where $\mathcal{R}$ is a sum of harmonic waves whose leading order term is of order δ^3 or smaller, and v_a, $\mathbf{u}_a$ are shorthands for $v_a(\omega)$, $\mathbf{u}_a(\omega)$, respectively.

Proposition 4: If we assume that the input field $\mathcal{S}$ consists of one mode with carrier frequency ω which is linearly polarized along the $\mathbf{s}_a(\omega)$-axis, then the slowly varying envelope of the field $\mathcal{E}$ is of type a and $E_0=\mathbf{s}_a(\omega).\mathbf{E}_0^{1\omega}$ satisfies the nonlinear Schrödinger equation

$$2ik_a\partial_\zeta E_0+\mathcal{L}_a(\omega)E_0+\mathcal{K}_a(\omega)E_0+P_3(E_0)=0, \tag{29}$$

starting from $E_0(T,X,Y,\zeta=0)=(2/[1+n_a(\omega)])v(T,X,Y)$, *where* $P_3(E_0)=(\gamma_1+\gamma_2)|E_0|^2E_0+\mathbf{s}_a.\hat{\chi}^{(2)}(0,\omega)(\mathbf{E}_1^{0\omega^*},\mathbf{E}_0^{1\omega})$,

$$\gamma_1=\tfrac{3}{4}\mathbf{s}_a(\omega).\hat{\chi}^{(3)}(\omega,\omega,-\omega):(\mathbf{s}_a(\omega),\mathbf{s}_a(\omega),\mathbf{s}_a(\omega)),$$

$$\gamma_2=\tfrac{1}{2}\mathbf{s}_a(\omega).\hat{\chi}^{(2)}(2\omega,-\omega):((n_a^2(\omega)J-\chi(2\omega))^{-1}\mathbf{s}_{a,a}(\omega,\omega),\mathbf{s}_a(\omega)),$$

where J is the 3×3 matrix whose entries are vanishing but $J_{11}=J_{22}=1$. The second harmonic is of order δ^2 and its leading order term $\mathbf{E}_1^{2\omega}$ is given by (30). The zero harmonic is of order δ^2 and its leading order term $\mathbf{E}_1^{0\omega}$ is given by (32). All other harmonic are of order smaller than δ^3.

Note that far from phase matching, the second harmonic does not propagate with its natural phase velocity and group velocity, but with those of the fundamental. But it is smaller by an order of magnitude. The same holds true for the zero-harmonic term. By ''zero-harmonic'' we mean an electromagnetic wave whose wavelength is of the order of δ^{-1}.

Proof:

(i) Computation of the leading order term at 2ω.
Collecting the terms of order δ^2 at frequency 2ω provides an explicit representation for $\mathbf{E}_1^{2\omega}$:

$$\mathbf{E}_1^{2\omega}=\tfrac{1}{2}(n_a^2(\omega)J-\chi(2\omega))^{-1}\hat{\chi}^{(2)}(\omega,\omega):(\mathbf{E}_0^{1\omega},\mathbf{E}_0^{1\omega}). \tag{30}$$

Note that the matrix $n_a^2(\omega)J-\chi(2\omega)$ is invertible since we assume that there is no phase-matching for second harmonic generation.

(ii) Computation of the leading order term at 0ω.
Collecting the terms of order δ^4 at frequency 0ω yields:

$$\mathbf{R}_2(\mathbf{E}_1^{0\omega})=\mathbf{D}_2(\mathbf{E}_1^{0\omega})-c^{-2}\partial_T^2\mathbf{P}_2,$$

where $\mathbf{P}_2$ is given by

$$\mathbf{P}_2=\hat{\chi}^{(2)}(\omega,-\omega)(\mathbf{E}_0^{1\omega},\mathbf{E}_0^{1\omega^*}).$$

Note that $\mathbf{D}_2(\mathbf{E}_1^{0\omega})=-c^{-2}\chi(0\omega)\partial_T^2\mathbf{E}_1^{0\omega}$. The computation of $\mathbf{E}_1^{0\omega}$ is formally identical as for the second-harmonic wave, that is to say the zero-harmonic wave is obtained by applying an inversion operator [here $(\mathbf{R}_2-\mathbf{D}_2)^{-1}$] to a functional of the leading-order term of the fundamental wave (here $-c^{-2}\partial_T^2\mathbf{P}_2$). But the inversion is a little more elaborate, since it requires to apply the Green function of a linear nondispersive Maxwell equation. We give in what follows an explicit formulation of this inversion. First denote by **Rot** the standard ''**rot**'' operator operating on the macroscopic variables (X,Y,Z). Consider the

problem of finding the solution $\mathbf{E}$ of the following Maxwell equation with a source:

$$\mathbf{Rot}\ \mathbf{Rot}\ \mathbf{E}=-c^{-2}\chi(0\omega)\partial_T^2\mathbf{E}-c^{-2}\partial_T^2\mathbf{P},$$

where $\mathbf{P}(T,X,Y,Z)$ is the polarization induced by the source. Taking the Fourier transform with respect to time and space

$$(|\mathbf{K}|^2 I_d-\mathbf{K}\otimes\mathbf{K}-\nu^2c^{-2}\chi(0\omega))\hat{\mathbf{E}}(\nu,\mathbf{K})=\nu^2c^{-2}\hat{\mathbf{P}}(\nu,\mathbf{K}), \tag{31}$$

where ν is the frequency, $\mathbf{K}$ the wave number, and $\mathbf{S}\otimes\mathbf{U}$ is the matrix whose entries are S_iU_j. We denote by N_a and N_b the two solutions of the Fresnel equation associated with the tensor $\chi(0\omega)$:

$$\det(N^2I_d-N^2|\mathbf{K}|^2\mathbf{K}\otimes\mathbf{K}-\chi(0\omega))=0,$$

and by $\mathbf{S}_a$ and $\mathbf{S}_b$ the corresponding unit eigenvectors. The Green function $\hat{g}(\nu,\mathbf{K})$ corresponding to Eq. (31) is defined by the equation

$$\hat{\mathbf{E}}(\nu,\mathbf{K})=\hat{g}(\nu,\mathbf{K})\hat{\mathbf{P}}(\nu,\mathbf{K}).$$

It was shown by Lax and Nelson that the Green function can be written in the form[16]

$$\hat{g}(\nu,\mathbf{K})=\frac{\nu^2}{c^2}\left(\frac{e_a}{|\mathbf{K}|^2/N_a^2-\nu^2/c^2-io}+\frac{e_b}{|\mathbf{K}|^2/N_b^2-\nu^2/c^2-io}\right)-\frac{\mathbf{K}\otimes\mathbf{K}}{\mathbf{K}^T\chi(0\omega)\mathbf{K}},$$

$$e_m=\frac{\mathbf{S}_m\otimes\mathbf{S}_m}{\mathbf{S}_m^T\chi(0\omega)\mathbf{S}_m}.$$

If $\nu<0$, then the term $-io$ should be replaced by $+io$. We then introduce the auxiliary function $\hat{G}$ which is the projection of $\hat{g}$ onto the characteristic equation satisfied by $\mathbf{P}_2$

$$\hat{G}(\nu,K_x,K_y)=\hat{g}(\nu,K_x,K_y,K_xu_{ax}(\omega)+K_yu_{ay}(\omega)-\nu/v_a(\omega)),$$

$$G(T,X,Y)=\frac{1}{(2\pi)^3}\int\hat{G}(\nu,K_x,K_y)e^{i(K_xX+K_yY-\nu T)}dXdYdT.$$

We finally define the convolution operator Ψ which associates to any pair of vector-valued functions $\mathbf{A}_1(T,X,Y)$ and $\mathbf{A}_2(T,X,Y)$ the vector-valued function

$$\Psi*(\mathbf{A}_1,\mathbf{A}_2)(T,X,Y):=\int G(T-s,X-u,Y-v)[\hat{\chi}^{(2)}(\omega,-\omega):(\mathbf{A}_1,\mathbf{A}_2)(s,u,v)]dsdudv.$$

The leading order term $\mathbf{E}_1^{0\omega}(T,X,Y,\zeta)$ of the zero-harmonic wave can then be expressed for every ζ as the application of the Ψ-operator to the pair $(\mathbf{E}_0^{1\omega}(.,.,.,\zeta),\mathbf{E}_0^{1\omega^*}(.,.,.,\zeta))$:

$$\mathbf{E}_1^{0\omega}(T,X,Y,\zeta)=\Psi*(\mathbf{E}_0^{1\omega}(.,.,.,\zeta),\mathbf{E}_0^{1\omega^*}(.,.,.,\zeta))(T,X,Y). \tag{32}$$

(iii) Equation for the corrective term at ω.
Collecting the terms of order δ^2 at frequency ω we get an explicit form for the first corrective term $\mathbf{E}_1^{1\omega}$ of the fundamental wave. No nonlinear term is coming to at this order, so the expression is identical to the linear framework (see Ref. 13).

(iv) Equation for the leading order term at ω.
Collecting the terms of order δ^3 at frequency ω we get

$$\mathbf{R}_2(\mathbf{E}_0^{1\omega})+\mathbf{R}_1(\mathbf{E}_1^{1\omega})+\mathbf{R}_0(\mathbf{E}_2^{1\omega})=\mathbf{D}_2(\mathbf{E}_0^{1\omega})+\mathbf{D}_1(\mathbf{E}_1^{1\omega})+\mathbf{D}_0(\mathbf{E}_2^{1\omega})-c^{-2}\mathbf{P}_3,$$

where the contribution of the nonlinear polarization is:

$$\mathbf{P}_3=(\tfrac{3}{4})\hat{\chi}^{(3)}(\omega,\omega,-\omega):(\mathbf{E}_0^{1\omega},\mathbf{E}_0^{1\omega},\mathbf{E}_0^{1\omega^*})+\hat{\chi}^{(2)}(2\omega,-\omega):(\mathbf{E}_1^{2\omega},\mathbf{E}_0^{1\omega^*})$$
$$+\hat{\chi}^{(2)}(0\omega,\omega):(\mathbf{E}_1^{0\omega},\mathbf{E}_0^{1\omega}).$$

Projecting onto $\mathbf{s}_a(\omega)$ we get

$$\mathbf{s}_a(\omega).\mathbf{R}_2(\mathbf{E}_0^{1\omega})+\mathbf{s}_a(\omega).\mathbf{R}_1(\mathbf{E}_1^{1\omega})=\mathbf{s}_a(\omega).\mathbf{D}_2(\mathbf{E}_0^{1\omega})+\mathbf{s}_a(\omega).\mathbf{D}_1(\mathbf{E}_1^{1\omega})-c^{-2}\mathbf{s}_a(\omega).\mathbf{P}_3.$$

Substituting the expression of $\mathbf{E}_1^{1\omega}$ establishes the result.

Note that the long-scale variable ζ plays the role of a parameter in the expression (32) of $\mathbf{E}_1^{0\omega}$. Consequently Eq. (29) reads as a simple first-order evolution equation with respect to the ζ-variable for the envelope E_0. This provides a simple numerical scheme to compute $E_0(.,.,.,\zeta+\Delta\zeta)$ from $E_0(.,.,.,\zeta)$.

VII. SPATIAL SOLITON PROPAGATION IN BIAXIAL CRYSTALS

We examine in this section the propagation in biaxial crystals of the modulation of a high-frequency signal with frequency ω in the particular configuration $\theta=\theta_r(\omega)$ and $\phi=0$ or π where

$$\sin^2\theta_r(\omega)=\frac{1-\chi_2(\omega)/\chi_1(\omega)}{1-\chi_3(\omega)/\chi_1(\omega)}.$$

Computing all relevant quantities according to the general formulas we have found in particular that the type a eigenindex and unit polarization eigenvector are $n_a^2(\omega)=\chi_2(\omega)$ and $\mathbf{s}_a(\omega)=(0,1,0)^T$, respectively (for the type b we refer to Ref. 13). The diffraction coefficients for the a-mode are $c_{a,xx}(\omega)=1$, $c_{a,xy}(\omega)=0$, and $c_{a,yy}(\omega)=0$, while the dispersion operator reads $\mathcal{K}_a(\omega)=-\sigma_a(\omega)\partial_T^2$. The striking point is that the diffraction operator for the type a wave is degenerate, in the sense that there is no diffraction in the y-direction. Let us assume that the carrier frequency ω of the input pulse is such that the phase matching condition for the second-harmonic generation is not fulfilled. For the sake of simplicity we first restrict ourselves to one of the three following classes:[17]

(1) triclinic class with point group $\overline{1}$, such as Mica or Al_2SiO_5;
(2) monoclinic class with point group $2/m$, such as $AgAuTe_4$ or $PbSiO_3$;
(3) orthorhombic class with point group mmm, such as $CaCl_2$, or Al_2BeO_4 (also called alexandrite).

The crystals of these classes are biaxial and have a vanishing $\chi^{(2)}$-tensor. This simplification allows us to get rid of the $\chi^{(2)}$-cascaded terms and to deal with a simple $\chi^{(3)}$-component which then reads as a simple Kerr effect. The result is the following:

Proposition 5. In cases 1, 2, 3, if we assume that the input field $\mathcal{S}$ consists of one mode with carrier frequency ω which is linearly polarized along the y axis, then the slowly varying envelope of the field $\mathcal{E}$ is polarized along the y axis and $E_0=(0,1,0).\mathbf{E}_0^{1\omega}$ satisfies the nonlinear Schrödinger equation

$$2ik_a\partial_\zeta E_0+\partial_X^2E_0-\sigma_a\partial_T^2E_0+\gamma|E_0|^2E_0=0, \tag{33}$$

starting from $E_0(T,X,Y,\zeta=0)=(2/[1+n_a(\omega)])v(T,X,Y)$, where $\gamma=(\frac{3}{4})\hat{\chi}^{(3)}_{2222}(-\omega,\omega,\omega)$.

The removal of the time variable is involved by the assumption that there is no modulation of the input pulse at the time scale δ^{-1}, which is typically of the order of the picosecond, but only at scale δ^{-2}, which is typically of the order of the nanosecond. Then the slowly varying envelope of the field satisfies the standard one-dimensional Schrödinger equation

$$2ik_a\partial_\zeta E_0+\partial_X^2E_0+\gamma|E_0|^2E_0=0. \tag{34}$$

The one-dimensional nonlinear Schrödinger equation possesses the complete integrability property, which implies that stable solitons should be generated and propagate over large distances. If a pulse is focused onto a crystal plate according to the incident angle and polarization described here above, then in the x-transverse direction the profile of the pulse will not diffract and keep its original form while in the transverse y-direction the pulse will break into a soliton (or eventually

several solitons) and radiation whose amplitude will decay as standard one-dimensional waves do in linear media, that is to say at rate $z^{-1/2}$. The incident pulse must at least fulfill a well-known power criterion so that a soliton can be generated[18]

$$\int_{-\infty}^{\infty} |E_0| dx \geqslant 1.279 \gamma^{-1/2},$$

which simply means that the incident pulse should be sufficient focused so that its power $\int |E_0|^2 dx$ be concentrated on a small segment. Nevertheless one should still remain in the domain where Eq. (33) holds true, which is basically the paraxial approximation.

In case of biaxial crystals with nonvanishing $\chi^{(2)}$-tensor the result is qualitatively the same, in the sense that the diffraction operator still reads as a one-dimensional second-order derivative, but $\chi^{(2)}$-cascaded terms make the nonlinear term more complicated. We aim in the following proposition at generalizing Proposition 5 to any biaxial crystal.

Proposition 6. For any biaxial crystal in the configuration $\theta=\theta_r$ and $\phi=0$, if we assume that the input field $\mathcal{S}$ consists of one mode with carrier frequencies ω which is linearly polarized along the y axis, then the slowly varying envelope of the field $\mathcal{E}$ is polarized along the y axis and $E_0=(0,1,0).\mathbf{E}_0$ satisfies the nonlinear Schrödinger equation

$$2ik_a \partial_\zeta E_0 + \partial_X^2 E_0 - \sigma_a \partial_T^2 E_0 + P_3(E_0) = 0, \tag{35}$$

where $P_3(E_0)=(\gamma_1+\gamma_2)|E_0|^2E_0+\Sigma_{j,l=1}^3 \gamma_{3_{jl}} \Phi_{jl}(|E_0|^2(.,.,.,\zeta))E_0$, *with*

$$\gamma_1 = \tfrac{3}{4}\hat{\chi}^{(3)}_{2222}(\omega,\omega,-\omega),$$

$$\gamma_2 = \frac{1}{2}\sum_{j=1}^{3} \hat{\chi}^{(2)}_{2j2}(2\omega,-\omega)[(n_a^2(\omega)J-\chi(2\omega))^{-1}\chi^{(2)}_{.22}(\omega,\omega)]_j,$$

$$\gamma_{3_{jl}} = \hat{\chi}^{(2)}_{2j2}(0,\omega)\hat{\chi}^{(2)}_{l22}(\omega,-\omega),$$

$$\Phi_{jl}(I(.,.,.))(T,X,Y) = \sum_{j',l'=1}^{3} U_{jj'}U_{ll'} \int G_{j'l'}(T-s,X-u,Y-v) I(s,u,v) ds du dv.$$

G is the Green function whose Fourier transform is $\hat{G}(\nu,K_x,K_y)=\hat{g}(\nu,K_x,K_y,-\nu/v_a(\omega))$ *with*:

$$\hat{g}(\nu,\mathbf{K}) = \frac{\nu^2}{c^2}\left(\frac{e_a}{|\mathbf{K}|^2/n_a(0\omega)^2-\nu^2/c^2-io} + \frac{e_b}{|\mathbf{K}|^2/n_b^2(0\omega)-\nu^2/c^2-io}\right) - \frac{\mathbf{K}\otimes\mathbf{K}}{\mathbf{K}^T\chi(0\omega)\mathbf{K}},$$

$$e_m = \frac{\mathbf{s}_m(0\omega)\otimes\mathbf{s}_m(0\omega)}{(\mathbf{s}_m(0\omega)^T)\chi(0\omega)\mathbf{s}_m(0\omega)},$$

where $n_m(0\omega)$ *and* $\mathbf{s}_m(0\omega)$ *are the eigenindices and unit eigenvectors of the Fresnel equation corresponding to the tensor* $\chi(0\omega)$ *at angles* $\theta_r(\omega)$, $\phi=0$

$$(n^2 I_d - n^2|\mathbf{K}|^{-2}\mathbf{K}\otimes\mathbf{K} - \chi(0\omega,\theta_r(\omega),0))\mathbf{s}=0.$$

All terms in P_3 are proportional to $|E_0|^2E_0$ or a product of three terms proportional to E_0. Note that the only coefficient of the $\chi^{(3)}$-tensor which plays a role is $\hat{\chi}^{(3)}_{2222}(\omega,\omega,-\omega)$. The coefficients of the $\chi^{(2)}$-tensor which play a role are the ones with at least two indices equal to 2. In case of orthorhombic class with point group 222, the only non-vanishing coefficients of the $\chi^{(2)}$-tensor are the ones with three different indices. Consequently all components of P_3 vanish but $\gamma_1|E_0|^2E_0$ so that we get back the result of Proposition 5.

VIII. SPATIAL SPECTRUM OF THE SECOND HARMONIC PULSE

In this section we aim at giving the explanation of a recent experimental observation. The framework is the following. In the context of Inertial Confinement Fusion, many high-power laser beams are focused onto a spherical target composed of a mixture of deuterium–tritium so as to compress it and to obtain density and pressure conditions which involve thermonuclear burning. The laser energy production is based on the amplification of an infrared pulse in glass amplifiers, which are the only ones capable to deliver an energy of the order of 1 to 2 megajoules. Nevertheless it is necessary to frequency convert the pulse in the ultraviolet (UV) domain so as to optimize the plasma-laser interaction between the laser beams and the inertial confinement-fusion (ICF) target. Thus the frequency tripling performance conditions the feasibility of the project. Two successive KDP crystals, which can be produced in large dimensions, are used for the frequency doubling and summing operations. In order to get a high tripling rate, it is necessary to adjust the positions of the KDP crystals in the laser chain with very high accuracy, since a precision of the order of 15 μrad is required. The method consists in focusing a fundamental beam and to detect the main output angle of the second harmonic pulse (''test'' configuration), which should correspond to the optimal frequency conversion angle. However it appears that the direction of the frequency converted pulse of a fundamental Gaussian pulse depends on the distance between the waist of the fundamental pulse and the crystal. The departures for different distances far exceed the high precision level required for reaching the expected conversion performance for applications to ICF. It is, therefore, necessary to give a precise account of this unexpected phenomenon.

We assume that the fundamental pulse has Gaussian shape in the waist plane $z=0$. We denote by z_0 the distance from the waist plane to the crystal plate, and by z_c the thickness of the plate. If w_0 is the beam radius in the waist plane, A_0 is its maximal amplitude, and **e** is its unit polarization vector, then in the plane just before the plate the input field writes

$$\hat{\mathbf{E}}(z=z_0^-,k_x,k_y)=A_0\pi w_0^2\exp\left(-\frac{(k_x^2+k_y^2)w_0^2}{4}-i\frac{(k_x^2+k_y^2)z_0}{2k}\right)\mathbf{e},$$

where k is the free wave number and we have performed a Fourier transform with respect to the transverse coordinates $(x,y)\mapsto(k_x,k_y)$. By continuity of the tangential components of the electric field, the field just inside the plate is the sum of an ordinary wave and an extraordinary wave

$$\hat{E}_{o,\omega}(z=z_0^+,k_x,k_y)=A_0\pi w_0^2 e_y\exp\left(-\frac{(k_x^2+k_y^2)w_0^2}{4}-i\frac{(k_x^2+k_y^2)n_o(\omega)z_0}{2k_o(\omega)}\right),$$

$$\hat{E}_{e,\omega}(z=z_0^+,k_x,k_y)=\frac{A_0\pi w_0^2 e_x}{\cos(\beta(\omega))}\exp\left(-\frac{(k_x^2+k_y^2)w_0^2}{4}-i\frac{(k_x^2+k_y^2)n_e(\omega)z_0}{2k_e(\omega)}\right).$$

For the type I configuration we consider the case $e_x=0$, $e_y=1$. For the type II configuration we choose an equiphotonic repartition $e_x=1/\sqrt{2}$, $e_y=1/\sqrt{2}$.

A. Type I conversion

Applying Proposition 2 the system which governs the second harmonic generation in the type I configuration is:

$$\partial_z E_{o,\omega}-\frac{i}{2k_o(\omega)}\partial_x^2 E_{o,\omega}-\frac{i}{2k_o(\omega)}\partial_y^2 E_{o,\omega}=\frac{i2\omega d^{(I)}}{n_o(\omega)}E_{o,\omega}^* E_{e,2\omega}e^{i\eta_k z},$$

$$\partial_z E_{e,2\omega}-\eta\partial_x E_{e,2\omega}-\frac{ic_x(2\omega)}{2k_e(2\omega)}\partial_x^2 E_{e,2\omega}-\frac{ic_y(2\omega)}{2k_e(2\omega)}\partial_y^2 E_{e,2\omega}=\frac{i2\omega d^{(I)}}{n_e(2\omega)\cos^2\beta(2\omega)}E_{o,\omega}^2 e^{-i\eta_k z},$$

where $\eta_k=k_e(2\omega)-2k_o(\omega)$, $\eta=\tan\beta(2\omega)$, and

$$c_x(2\omega)=\frac{\chi_o(2\omega)\chi_e(2\omega)}{(\cos^2(\theta)\chi_e(2\omega)+\sin^2(\theta)\chi_o(2\omega))^2},\quad c_y(2\omega)=\frac{\chi_o(2\omega)}{\cos^2(\theta)\chi_e(2\omega)+\sin^2(\theta)\chi_o(2\omega)}.$$

We assume that the frequency conversion rate is low. Taking the Fourier transform with respect to the spatial transverse coordinates $(x,y)\mapsto(k_x,k_y)$:

$$\partial_z\hat{E}_{o,\omega}+\frac{ik_x^2}{2k_o(\omega)}\hat{E}_{o,\omega}+\frac{ik_y^2}{2k_o(\omega)}\hat{E}_{o,\omega}=0, \tag{36a}$$

$$\partial_z\hat{E}_{e,2\omega}+ik_x\eta\hat{E}_{e,2\omega}+\frac{ik_x^2c_x(2\omega)}{2k_e(2\omega)}\hat{E}_{e,2\omega}+\frac{ik_y^2c_y(2\omega)}{2k_e(2\omega)}\hat{E}_{e,2\omega}=id^I_{e,2\omega}\hat{E}_{o,\omega}*\hat{E}_{o,\omega}e^{i(2k_o-k_e)z}, \tag{36b}$$

where $*$ stands for the convolution operation. It is easy to find the explicit form of $\hat{E}_{o,\omega}$ from Eq. (36a) by a simple exponentiation, and convoluting this expression with itself

$$\hat{E}_{o,\omega}*\hat{E}_{o,\omega}(z_0+z,k_x,k_y)=\frac{A_0\pi w_0^2}{\frac{w_0^2}{2}+i\frac{n_o(\omega)z_0+z}{k_o(\omega)}}\exp-\frac{k_x^2+k_y^2}{2}\left(\frac{w_0^2}{4}+i\frac{n_o(\omega)z_0+z}{2k_o(\omega)}\right).$$

In order to compute $|\hat{E}_{e,2\omega}|$ we set:

$$\hat{E}_{e,2\omega}=\hat{E}_{e,2\omega}\exp iz\left(k_x\eta+\frac{k_x^2c_x(2\omega)}{2k_e(2\omega)}+\frac{k_y^2c_y(2\omega)}{2k_e(2\omega)}\right),$$

whose modulus is equal to the modulus of $\hat{E}_{e,2\omega}$ and which satisfies

$$\partial_z\overline{E}_{e,2\omega}=id^{II}_{e,2\omega}\hat{E}_{o,\omega}*\hat{E}_{o,\omega}\exp iz\left(k_x\eta+\frac{k_x^2c_x(2\omega)}{2k_e(2\omega)}+\frac{k_y^2c_y(2\omega)}{2k_e(2\omega)}+2k_o(\omega)-k_e(2\omega)\right).$$

The right-hand side is known, so by a simple exponentiation we get that, up to a multiplicative constant

$$|\hat{E}_{e,2\omega}|^2(z_0+z_c,k_x,k_y)=e^{-\gamma(k_x,k_y)k_ow_0^2}|E_i(-\gamma(k_x,k_y)(z_1+iz_c))-E_i(-\gamma(k_x,k_y)z_1)|^2, \tag{37}$$

where E_i is the integral exponential function: $E_i(x):=\int_1^\infty[\exp(-xt)/t]dt$ and

$$z_1=\frac{k_o(\omega)w_0^2}{2}+iz_0n_0(\omega),$$

$$\gamma(k_x,k_y)=k_x\eta+k_x^2\left(\frac{c_x(2\omega)}{2k_e(2\omega)}-\frac{1}{4k_o(\omega)}\right)+k_y^2\left(\frac{c_y(2\omega)}{2k_e(2\omega)}-\frac{1}{4k_o(\omega)}\right)+2k_o(\omega)-k_e(2\omega).$$

A study of the function (37) proves that the locations of the minima of the spectral intensity (which are experimentally detectable with high precision) do not depend on the waist distance z_0.

B. Type II conversion

We still assume that the frequency conversion rate is low. Taking the Fourier transform for the spatial transverse coordinates and applying Proposition 3, the system which governs the second harmonic generation in the type II configuration is:

$$\partial_z \hat{E}_{o,\omega} + \frac{ik_x^2}{2k_o(\omega)}\hat{E}_{o,\omega} + \frac{ik_y^2}{2k_o(\omega)}\hat{E}_{o,\omega} = 0, \tag{38a}$$

$$\partial_z \hat{E}_{e,\omega} + ik_x\eta_1\hat{E}_{e,\omega} + \frac{ik_x^2 c_x(\omega)}{2k_e(\omega)}\hat{E}_{e,\omega} + \frac{ik_y^2 c_y(\omega)}{2k_e(\omega)}\hat{E}_{e,\omega} = 0, \tag{38b}$$

$$\partial_z \hat{E}_{e,2\omega} + ik_x\eta_2\hat{E}_{e,2\omega} + \frac{ik_x^2 c_x(2\omega)}{2k_e(2\omega)}\hat{E}_{e,2\omega} + \frac{ik_y^2 c_y(2\omega)}{2k_e(2\omega)}\hat{E}_{e,2\omega} = \frac{2i\omega d^{(II)}}{n_e(2\omega)\cos^2\beta(2\omega)}\hat{E}_{o,\omega} * \hat{E}_{e,\omega}e^{-i\eta_k z}, \tag{38c}$$

where $\eta_k = k_e(2\omega) - k_e(\omega) - k_o(\omega)$, $\eta_1 = \tan\beta(\omega)$, and $\eta_2 = \tan\beta(2\omega)$. The calculations are identical to the ones performed in the type I configuration. One first compute the closed-form expressions of the fields $\hat{E}_{o,\omega}$ and $\hat{E}_{e,\omega}$ from Eqs. (38a) and (38b). These expressions are then substituted into the right-hand side of Eq. (38c) which can then be solved. We have found that, up to a multiplicative constant

$$|\hat{E}_{e,2\omega}|(2k\theta_x, 2k\theta_y) = \left| \int_0^{z_c} \frac{1}{(\bar{\alpha} + iC_x z)^{1/2}} \exp k \frac{A_x(\theta_x)z^2 + i\bar{\alpha}B_x(\theta_x)z - \bar{\alpha}^2\theta_x^2}{\bar{\alpha} + iC_x z} \times \frac{1}{(\bar{\alpha} + iC_y z)^{1/2}} \exp k \frac{A_y(\theta_y)z^2 + i\bar{\alpha}B_y(\theta_y)z - \bar{\alpha}^2\theta_y^2}{\bar{\alpha} + iC_y z} \times \exp(-i\eta_k z)\, dz \right|, \tag{39}$$

where $\bar{\alpha} = z_r + iz_0$, $z_r = kw_0^2/2$, $k = 2\pi/\lambda = \omega/c$, and

$$A_x(\theta_x) = \theta_x^2\left(\frac{c_x(\omega)}{n_o(\omega)n_e(\omega)} - \frac{c_x(2\omega)}{n_e(2\omega)}C_x\right) + \theta_x\left(\frac{\eta_1}{n_o(\omega)} - 2\eta_2 C_x\right) - \frac{\eta_1^2}{4},$$

$$B_x(\theta_x) = \theta_x^2\left(\frac{c_x(2\omega)}{n_e(2\omega)} - 2C_x\right) + \theta_x(2\eta_2 - \eta_1),$$

$$C_x = \frac{1}{2}\left(\frac{1}{n_o(\omega)} + \frac{c_x(\omega)}{n_e(\omega)}\right),$$

$$A_y(\theta_y) = \theta_y^2\left(\frac{c_y(\omega)}{n_o(\omega)n_e(\omega)} - \frac{c_y(2\omega)}{n_e(2\omega)}C_y\right),$$

$$B_y(\theta_x) = \theta_y^2\left(\frac{c_y(2\omega)}{n_e(2\omega)} - 2C_y\right),$$

$$C_y = \frac{1}{2}\left(\frac{1}{n_o(\omega)} + \frac{c_y(\omega)}{n_e(\omega)}\right).$$

In the type II configuration the positions of the minima of the spectral intensity depend on the waist distance z_0.

IX. CONCLUSION

In this paper we have derived the equations which govern the evolutions of the slowly varying envelopes of pulses in a bulk medium presenting anisotropic properties and nonlinear suscepti-

bilities. In case of phase-matching we have derived the equations that govern the frequency conversion of the source. In case of no phase matching we have derived the nonlinear Schrödinger-type equation that governs the evolution of the pulse. We have shown that the diffraction operator is anisotropic, and that the nonlinear term may be more complicated than the standard Kerr effect due to $\chi^{(2)}$-cascaded effects. We have in particular detected a configuration where stable solitons should be naturally generated since the equation then reads as the standard one-dimensional Schrödinger equation with Kerr nonlinearity. As a natural extension of this work we may also think at the propagation of partially coherent light in a linear or nonlinear anisotropic medium. Indeed the intensity profiles of the speckle spots along the propagation axis are imposed by the diffraction. So an anisotropic diffraction should involve interesting and original characteristics of the speckle spots.

(Received 24 August 2000; accepted for publication 22 December 2000)

We prove that the inertia operator A of a rigid body is generically determined, up to a scalar multiple, by the curve Ω in $\mathbf{R}^3$ that describes its angular velocity in the body. The precise condition is that Ω not be contained in a two-dimensional subspace of $\mathbf{R}^3$. We derive two indirect methods to compute A from the values of Ω over an arbitrary interval, and a direct method to compute A from the second- and fourth-order moments of Ω. The direct method utilizes moment identities derived from symmetries in Euler's equation. © *2001 American Institute of Physics.*

I. INTRODUCTION

In this section we review some of the kinematics and dynamics of rigid bodies as presented in Ref. 1. Consider a rigid body whose center of mass is fixed at $\mathbf{0}\in\mathbf{R}^3$, and let F be an orthonormal frame at $\mathbf{0}$ fixed relative to the body. At time t during the motion, F is an orthonormal frame $B(t)=(b_1(t),b_2(t),b_3(t))$ relative to ambient space $\mathbf{R}^3$. Suppose that $B(0)$ is the standard basis of $\mathbf{R}^3$. Identifying triples of column vectors with 3×3 matrices, $B(t)$ lies in the rotation group $SO(3)$, and $B(0)$ is the identity I. Relative to the standard basis, the position at time t of a point fixed relative to the body is then $q(t)=B(t)q(0)$, where $q(0)\in\mathbf{R}^3$ is the position at time 0. For $u\in\mathbf{R}^3$ define the skew-symmetric operator $\alpha(u):\mathbf{R}^3\to\mathbf{R}^3$ by $\alpha(u)v=u\times v$, $v\in\mathbf{R}^3$ where $\times$ is the cross product. The *angular velocity in the body* is the function $\Omega:\mathbf{R}\to\mathbf{R}^3$ defined by

$$\dot{B}=B\alpha(\Omega). \tag{1}$$

The *angular velocity in space* is $\omega=B\Omega$ and Eq. (1) implies that

$$\dot{\omega}=B\dot{\Omega}. \tag{2}$$

Inertial motion of the body is described by *Euler's equation*[2]

$$A\dot{\Omega}=(A\Omega)\times\Omega, \tag{3}$$

where A is the symmetric positive-definite 3×3 matrix that represents the inertia operator with respect to the standard basis (the inertia operator is defined from the mass distribution of the body). It follows from Eq. (1) and (3) that the *kinetic energy* $E=\frac{1}{2}\Omega^T A\Omega$ and the *angular momentum in space* $\mathbf{m}=BA\Omega$ are constant. Write $m=\|\mathbf{m}\|$. Evidently $\Omega^T A^2\Omega=m^2$, and $\omega^T\mathbf{m}=2E$. Notice that Ω is analytic, since it is bounded and its derivative is an analytic function of Ω. Suppose from now on that the rigid body is not fixed, namely q is a nonconstant function of t. Then $E,m>0$.

There is an extensive classical literature including Refs. 2–4 that addresses the problem of computing the solution Ω of Euler's equation from A and the initial value of Ω. For the remainder of this paper we consider the inverse problem of computing A from a solution Ω. For future investigations we record the fact that Euler's equation describes uniform speed parametrized geodesics on the rotation group with a left-invariant Riemmanian metric induced by the inertia operator, and that it can be generalized to describe geodesics on Lie groups[1] and Riemannian manifolds.[5] An important objective of this paper, and one motivation for our detailed derivations of three distinct methods to compute the inertia operator, is to develop techniques for investigating more inverse problems in these more general contexts.

II. DEGENERACY

Let $\Omega : \mathbf{R} \to \mathbf{R}^3$ be a solution of Euler's equation (3). Call Ω *degenerate* when its range is contained in a two-dimensional subspace of $\mathbf{R}^3$. Otherwise Ω is *nondegenerate*. The distinction turns out to be useful in determining A from Ω in Sec. III. Euler's equation is invariant with respect to SO(3) in the sense that for any $O \in \mathrm{SO}(3)$, $\tilde{\Omega} = O\Omega$ satisfies Euler's equation where A is replaced by $\tilde{A} = OAO^T$. Evidently $\tilde{\Omega}$ is degenerate if and only if Ω is degenerate. Choose $O \in \mathrm{SO}(3)$ such that

$$OAO^T = \mathrm{diag}(I_1, I_2, I_3), \tag{4}$$

where $0 < I_1 \leqslant I_2 \leqslant I_3$ are the eigenvalues of A (Arnold lists the eigenvalues in the opposite order).

Proposition 1: The function Ω is degenerate if and only if $m^2/2E \in \{I_1, I_2, I_3\}$. If Ω is nondegenerate then $\|\dot{\Omega}\|$ is bounded below by a positive number and Ω is periodic.

Proof: It suffices to prove these assertions for $\tilde{\Omega}$. Define $\alpha_j \equiv I_j - m^2/(2E)$, $j = 1,2,3$. Since the range of $\tilde{\Omega}$ is contained in both the energy ellipsoid $\epsilon_E \equiv \{ x \in \mathbf{R}^3 : I_1 x_1^2 + I_2 x_2^2 + I_3 x_3^2 = 2E \}$ and the momentum (or co-adjoint) ellipsoid $\epsilon_m \equiv \{ x \in \mathbf{R}^3 : I_1^2 x_1^2 + I_2^2 x_2^2 + I_3^2 x_3^2 = m^2 \}$, it is contained in $\epsilon_h \equiv \{ x \in \mathbf{R}^3 : \alpha_1 I_1 x_1^2 + \alpha_2 I_2 x_2^2 + \alpha_3 I_3 x_3^2 = 0 \}$ and $I_1 \leqslant m^2/2E \leqslant I_3$. If $m^2/2E \in \{I_1, I_3\}$ then $\tilde{\Omega}$ is degenerate since it is constant. If $I_1 < m^2/2E = I_2 < I_3$ then the range of $\tilde{\Omega}$ is contained in the union $\{ x \in \mathbf{R}^3 : \sqrt{-\alpha_1 I_1}\, x_1 = \sqrt{\alpha_3 I_3}\, x_3 = 0 \} \cup \{ x \in \mathbf{R}^3 : \sqrt{-\alpha_1 I_1}\, x_1 = \sqrt{\alpha_3 I_3}\, x_3 = 0 \}$ of two two-dimensional subspaces of $\mathbf{R}^3$. Therefore, since $\tilde{\Omega}$ is analytic, its range is entirely contained in one of these two subspaces and it is degenerate (the orbits consist of two fixed points and four heteroclinic connections between them). To complete the proof, observe that if $m^2/2E \notin \{I_1, I_2, I_3\}$ then the ellipsoids ϵ_E and ϵ_m intersect transversally. Hence their intersection is diffeomorphic to the disjoint union of two circles and Euler's equation implies that $\|\dot{\Omega}\|$ is bounded below by a positive number. Furthermore, the range of $\tilde{\Omega}$ is contained in a half-space $H \subset \mathbf{R}^3$. Therefore, $\tilde{\Omega}$ is nondegenerate and periodic.

III. *A* FROM Ω: METHODS 1 AND 2

Consider the problem of determining the inertia matrix A from the solution Ω of Euler's equation (3). Clearly A is at most determined up to a positive scalar multiple. When this happens we say A is *almost-determined* by Ω.

Theorem 2: *A is almost-determined by Ω if and only if Ω is nondegenerate.*

Proof: Assume Ω is degenerate. Then there is a nonzero $v \in \mathbf{R}^3$ such that $v^T \Omega = v^T \dot{\Omega} = 0$. Define a symmetric positive definite matrix $A_v = A + vv^T$. Then Ω satisfies Eq. (3) with A replaced by A_v, and A_v is not a scalar multiple of A. This proves the only if part. To prove the if part choose any $s_2 > s_1$ and define three matrices and one vector

$$M_\Omega = \int_{s_1}^{s_2} \Omega(t)\, \Omega(t)^T\, dt, \quad M_\omega = \int_{s_1}^{s_2} \omega(t)\, \omega(t)^T\, dt,$$

$$M_{\mathbf{m}}=\int_{s_1}^{s_2}\Omega(t)\,\mathbf{m}^T B(t)\,dt, \quad u_\omega=\int_{s_1}^{s_2}\omega(t)dt.$$

Then $M_{\mathbf{m}}$ is linear in $\mathbf{m}$, and A and $\mathbf{m}$ satisfy

$$M_\Omega A=M_{\mathbf{m}}, \tag{5}$$

$$M_\omega \mathbf{m}=2E\,u_\omega. \tag{6}$$

Proposition 3: If Ω is nondegenerate then the matrices M_Ω and M_ω are nonsingular.

Proof: Suppose that M_Ω is singular and choose a nonzero vector $w\in\mathbf{R}^3$ such that $w^T M_\Omega w=0$. Then $w^T\Omega(t)\,\Omega(t)^T w=0$ for all $t\in[s_1,s_2]$, namely $\|\Omega(t)^T w\|=0$. Then $\Omega(t)$ lies in the plane V orthogonal to w for all $t\in[s_1,s_2]$ and hence for all $t\in\mathbf{R}$ since Ω is analytic, therefore Ω is degenerate. To show that M_ω is nonsingular it suffices to show that the range of ω is not contained in any two-dimensional subspace of $\mathbf{R}^3$. Assume to the contrary that the range of $\omega([s_1,s_2])$ is contained in a two-dimensional subspace V of $\mathbf{R}^3$ and hence in the line $V\cap\{x: x^T\mathbf{m}=2E\}$. By Proposition 1 $\|\dot\Omega\|=\|\dot\omega\|$ is bounded below by a positive number, thus the range of ω is unbounded. This is impossible since $\|\omega\|=\|\Omega\|$ and $\|\Omega\|$ is bounded above and the proposition is proved.

Define $C(t), t\in[s_1,s_2]$ by the nonautonomous linear differential equation $\dot C=C\alpha(\Omega)$ and initial value $C(s_1)=I$. Then $B(t)=B(s_1)C(t)$, $\omega(t)=B(s_1)C(t)\Omega(t)$, $u_\omega=B(s_1)\int_{s_1}^{s_2}C(t)\Omega(t)dt$, and Eq. (6) implies that

$$\left(\int_{s_1}^{s_2}C(t)\Omega(t)\Omega(t)^T C(t)^T dt\right)B(s_1)^T\mathbf{m}=2E\int_{s_1}^{s_2}C(t)\Omega(t)dt.$$

Proposition 3 implies that $B(s_1)^T\mathbf{m}$ is determined up to a positive scalar multiple by Ω, hence $\mathbf{m}^T B(t)$ and $M_{\mathbf{m}}$ are also determined up to a positive scalar multiple. Finally, Eq. (5) and Proposition 3 show that A is determined up to a positive scalar multiple from Ω. This proves Theorem 2 and provides a constructive method (Method 1) for almost-determining A from Ω.

Method 1 requires Ω to be observed on a continuous interval $[s_1,s_2]$, and may be difficult to apply in cases where Ω is known only on finite subsets of $[s_1,s_2]$. When sampling is coarse or noise contaminated, solving the ordinary differential equation for C is especially problematic. Notice also that Method 1 uses the associations between t and $\Omega(t)$: It is not enough to observe the image of Ω over $[s_1,s_2]$. Alternatively, we can apply Theorem 2 in a less direct way to almost-determine A as follows. Let Ω be a nondegenerate solution of Eq. (3), and let $s_2>s_1$. Denote the space of symmetric 3×3 matrices by S, and define a quadratic form $Q: S\to\mathbf{R}$ by

$$Q(D)=\int_{s_1}^{s_2}\|D\dot\Omega(t)-(D\Omega(t))\times\Omega(t)\|^2 dt, \quad D\in S.$$

Corollary 4: Q has co-rank 1 and A is a null-eigenvector of Q. So Q defines A up to a positive scalar multiple.

Proof: Clearly $A\in S$ and $Q(A)=0$. Let $D\in S$ with $Q(D)=0$. It suffices to show that there exists $\mu\in\mathbf{R}$ such that $D=\mu A$. Choose $\epsilon>0$ such that $A_\epsilon=A+\epsilon D$ is positive definite. Clearly $Q(A_\epsilon)=0$, hence Ω satisfies Eq. (3) with inertia matrix A_ϵ over the interval $[s_1,s_2]$ and thus over $\mathbf{R}$ since Ω is analytic. Theorem 2 implies that there exists $\lambda>0$ such that $A_\epsilon=\lambda A$. Therefore $D=\mu A$ where $\mu=(\lambda-1)/\epsilon$ and the corollary is proved.

The quadratic form Q is determined by values of Ω and $\dot\Omega$ over $[s_1,s_2]$, thus Corollary 4 gives another method (Method 2) to almost-determine A from Ω. We observe that (i) Q can be approximated by sampling $(\Omega,\dot\Omega)$ uniformly over $[s_1,s_2]$, (ii) the associations between t and $(\Omega(t),\dot\Omega(t))$ are not needed, (iii) when observations of $(\Omega,\dot\Omega)$ are contaminated by noise, the

effects in the formula for Q are approximately additive, and (iv) Method 2 does not require the intermediate step of solving an ODE for $C(t)$. These observations suggest that Method 2 may be more robust and practical than Method 1. However, Method 2 requires us to know $\dot{\Omega}$. It may be difficult to accurately estimate $\dot{\Omega}$ from values of Ω that are coarsely sampled or noise contaminated. These difficulties are overcome (to some degree) by using a method, based on moments of Ω (Method 3 in Sec. VIII), to almost-determine A. It turns out that moments of orders 0, 2, and 4 give most of the needed information, and it seems these quantities can be reliably estimated from uniform samples of Ω over $[s_1,s_2]$ (without regard to their time association). To simplify the discussion we assume that the moments of Ω are calculated over an entire orbit of the motion: The more general case of sampling over $[s_1,s_2]$ is a straightforward extension. Even so, the analysis is lengthy and not as clean as for Methods 1 and 2. We also note that genericity assumptions are required for Sec. VIII.

IV. MOMENTS

Let Ω be a periodic solution of Euler's equation (3), of period $T>0$.

Definition 5: Given a monomial $\mu:\mathbf{R}^3\to\mathbf{R}$ the associated moment Ω^μ is defined to be

$$\int_0^T \mu\circ\Omega(t)dt.$$

The moment Ω^μ associated with the monomial $\mu=x_{i_1}x_{i_2}\ldots x_{i_d}$ is denoted by $\Omega^{i_1i_2\cdots i_d}$. The degree d of the monomial μ is said to be the order of the moment Ω^μ.

We shall see that the moments satisfy many interesting identities involving the inertia matrix A. As before, we frequently use conservation of energy

$$E=\tfrac{1}{2}\Omega^T A\Omega \tag{7}$$

and conservation of squared length of angular momentum

$$m^2=\|A\Omega\|^2. \tag{8}$$

Assume that the eigenspaces of A are one-dimensional, namely that the I_j are distinct where $j=1,2,3$. Then any orthogonal matrix O satisfying (4) maps eigenvectors of A to nonzero multiples of standard basis elements of $\mathbf{R}^3$. Furthermore, O is *almost-unique* in the sense that, if $O'\in O(3)$ diagonalizes A then $O'=DO$, where D is a diagonal matrix whose diagonal entries are ± 1.

Let Ω be nondegenerate. Write $\alpha_j\equiv I_j-m^2/2E$. Theorem 1 says $\alpha_j\neq 0$ for $j=1,2,3$ and, because the I_j are distinct, $\alpha_1<0,\alpha_2<\alpha_3$. Moments of Ω may be called *empirical*: They can be inferred from observations of the trajectory of the rigid body. Moments of $\tilde{\Omega}\equiv O\Omega$, where $O\in \mathrm{SO}(3)$ satisfies (4), are said to be *almost-canonical* (they are not quite canonical because O is not quite unique). Empirical moments are linear combinations of almost-canonical moments (and vice versa) with coefficients polynomial in entries of O. In order to obtain identities there are some simple things we can try with almost-canonical moments. First, integration of Eqs. (7) and (8) gives

$$I_1\tilde{\Omega}^{11}+I_2\tilde{\Omega}^{22}+I_3\tilde{\Omega}^{33}=2TE, \tag{9}$$

$$I_1^2\tilde{\Omega}^{11}+I_2^2\tilde{\Omega}^{22}+I_3^2\tilde{\Omega}^{33}=Tm^2. \tag{10}$$

Solving Eqs. (9) and (10) gives

$$\tilde{\Omega}^{22}=\frac{2\alpha_3 TE-I_1(I_3-I_1)\tilde{\Omega}^{11}}{I_2(I_3-I_2)}, \tag{11}$$

$$\tilde{\Omega}^{33}=\frac{-2\alpha_2 TE+I_1(I_2-I_1)\tilde{\Omega}^{11}}{I_3(I_3-I_2)}. \tag{12}$$

From Eqs. (11) and (12) we obtain the following bounds on $\tilde{\Omega}^{11}$ in terms of E, m^2, T and the I_j:

$$\frac{2\alpha_2 TE}{I_1(I_2-I_1)}<\tilde{\Omega}^{11}<\frac{2\alpha_3 TE}{I_1(I_3-I_1)}. \tag{13}$$

This begs the question of how to calculate $\tilde{\Omega}^{11}$. This can be done by quadrature, as in Secs. V and VI, where we also consider third-order moments. Before doing that, we say some things about fourth-order moments. Multiplying Eqs. (7) and (8) by $\tilde{\Omega}_i^2$ and integrating gives

$$I_1\tilde{\Omega}^{1111}+I_2\tilde{\Omega}^{1122}+I_3\tilde{\Omega}^{1133}=2E\tilde{\Omega}^{11}, \tag{14}$$

$$I_1\tilde{\Omega}^{1122}+I_2\tilde{\Omega}^{2222}+I_3\tilde{\Omega}^{2233}=2E\tilde{\Omega}^{22}, \tag{15}$$

$$I_1\tilde{\Omega}^{1133}+I_2\tilde{\Omega}^{2233}+I_3\tilde{\Omega}^{3333}=2E\tilde{\Omega}^{33}, \tag{16}$$

$$I_1^2\tilde{\Omega}^{1111}+I_2^2\tilde{\Omega}^{1122}+I_3^2\tilde{\Omega}^{1133}=m^2\tilde{\Omega}^{11}, \tag{17}$$

$$I_1^2\tilde{\Omega}^{1122}+I_2^2\tilde{\Omega}^{2222}+I_3^2\tilde{\Omega}^{2233}=m^2\tilde{\Omega}^{22}, \tag{18}$$

$$I_1^2\tilde{\Omega}^{1133}+I_2^2\tilde{\Omega}^{2233}+I_3^2\tilde{\Omega}^{3333}=m^2\tilde{\Omega}^{33}. \tag{19}$$

The system of equations (14)–(18) has rank 5. We now need to consider the cases $\alpha_2<0$ and $\alpha_2>0$ separately.

V. THE CASE $\alpha_2<0$

Suppose $\alpha_2<0$. Then $x_3\neq 0$ for $x\in\epsilon_E\cap\epsilon_m$. Solving Eqs. (7) and (8), x lies on at least one of eight arcs $x_{\sigma_1,\sigma_2,\sigma_3}$ given parametrically by

$$x_{\sigma_1,\sigma_2,\sigma_3}(v)=\begin{bmatrix}\sigma_1\sqrt{\dfrac{I_3v^2(I_3-I_2)+2\alpha_2E}{I_1(I_2-I_1)}}\\ \sigma_2\sqrt{\dfrac{-2\alpha_1E-I_3v^2(I_3-I_1)}{I_2(I_2-I_1)}}\\ \sigma_3 v\end{bmatrix}, \quad v\in[\beta_L,\beta_U], \tag{20}$$

where $\sigma_j=\pm$, $j=1,2,3$, $\beta_L=\sqrt{-2\alpha_2E/(I_3(I_3-I_2))}$, and $\beta_U=\sqrt{-2\alpha_1E/(I_3(I_3-I_1))}$. Then $0<\beta_L<\beta_U$, and

$$x_{\sigma_1,\sigma_2,\sigma_3 1}(v)\neq 0 \quad \text{for} \quad v\in(\beta_L,\beta_U], \quad x_{\sigma_1,\sigma_2,\sigma_3 1}(\beta_L)=0, \tag{21}$$

$$x_{\sigma_1,\sigma_2,\sigma_3 2}(v)\neq 0 \quad \text{for} \quad v\in[\beta_L,\beta_U), \quad x_{\sigma_1,\sigma_2,\sigma_3 2}(\beta_U)=0, \tag{22}$$

$$x_{\sigma_1,\sigma_2,\sigma_3 3}(v)\neq 0 \quad \text{for} \quad v\in[\beta_L,\beta_U]. \tag{23}$$

Since the image C of $\tilde{\Omega}$ is diffeomorphic to a circle, C is a union of arcs. By Eq. (23) and because C is connected, σ_3 is fixed. Given σ_3, there are at most four such arcs in C, corresponding to choices of σ_1,σ_2. Inspection of Eqs. (21) and (22) show that, in order for C to be connected, all four arcs are needed: C is the track sum of

$$x_{+,+,\sigma_3}(v),\quad x_{+,-,\sigma_3}(\beta_U-\beta_L-v),\quad x_{-,-,\sigma_3}(v),\quad x_{-,+,\sigma_3}(\beta_U-\beta_L-v),$$

where $v\in[\beta_L,\beta_U]$. By Eq. (3) $I_3\dot{\tilde{\Omega}}_3(v)=-(I_2-I_1)\tilde{\Omega}_1(v)\tilde{\Omega}_2(v)\neq 0$ for $v\in(\beta_L,\beta_U)$, and so $\tilde{\Omega}^\mu=[I_3/(I_2-I_1)]\int_{\beta_L}^{\beta_U}P(v)dv$, where

$$P=\frac{\mu(x_1,x_2,x_3)+\mu(x_1,-x_2,x_3)+\mu(-x_1,-x_2,x_3)+\mu(-x_1,x_2,x_3)}{x_1x_2}$$

and $x\equiv x_{+,+,\sigma_3}(v)$. From this formula the moments $\tilde{\Omega}^\mu$ can be evaluated by quadrature. The following result follows directly from the form of P.

Proposition 6: Write $\mu=x_1^{a_1}x_2^{a_2}x_3^{a_3}$. *If* a_1 *or* a_2 *is odd then* $\tilde{\Omega}^\mu=0$. *Otherwise*

$$\tilde{\Omega}^\mu=\frac{4I_3}{I_2-I_1}\int_{\beta_L}^{\beta_U}x_1(v)^{a_1-1}x_2(v)^{a_2-1}x_3(v)^{a_3}\,dv\neq 0.$$

This result provides the following examples of zeroth-, first-, and second-order almost-canonical moment identities.

Example 7: If μ *is the monomial of degree* 0 *whose value is* 1 *everywhere then the corresponding moment is the period*

$$T=4I_3\sqrt{I_1I_2}\int_{\sqrt{-2\alpha_2E/I_3(I_3-I_2)}}^{\sqrt{-2\alpha_1E/I_3(I_3-I_1)}}\times\frac{1}{\sqrt{(2\alpha_2E+I_3v^2(I_3-I_2))(-2\alpha_1E-I_3v^2(I_3-I_1))}}\,dv.$$

Example 8: $\tilde{\Omega}^1=\tilde{\Omega}^2=0$, *and*

$$\tilde{\Omega}^3=4I_3\sqrt{I_1I_2}\,\mathrm{sign}(\tilde{\Omega}_3)\int_{\sqrt{-2\alpha_2E/I_3(I_3-I_2)}}^{\sqrt{-2\alpha_1E/I_3(I_3-I_1)}}\times\frac{v}{\sqrt{(2\alpha_2E+I_3v^2(I_3-I_2))(-2\alpha_1E-I_3v^2(I_3-I_1))}}\,dv\neq 0.$$

Example 9: $\tilde{\Omega}^{12}=\tilde{\Omega}^{23}=\tilde{\Omega}^{31}=0$, *and the* $\tilde{\Omega}^{ii}$ *are nonzero. In particular*

$$\tilde{\Omega}^{11}=\frac{4I_3}{I_2-I_1}\sqrt{\frac{I_2}{I_1}}\int_{\sqrt{-2\alpha_2E/I_3(I_3-I_2)}}^{\sqrt{-2\alpha_1E/I_3(I_3-I_1)}}\sqrt{\frac{2\alpha_2E+I_3v^2(I_3-I_2)}{-2\alpha_1E-I_3v^2(I_3-I_1)}}dv>0,$$

and the two remaining nonzero second-order almost-canonical moments can be calculated algebraically in terms of $\tilde{\Omega}^{11}$ *as in Sec. IV. Alternatively, we can calculate either* $\tilde{\Omega}^{22}$ *or* $\tilde{\Omega}^{33}$ *by quadrature and solve algebraically for the other nonzero second-order moments.*

Theorem 10: *There are ten third-order almost-canonical moments, all except three are zero, and these are given by* $(\tilde{\Omega}^{113},\tilde{\Omega}^{223},\tilde{\Omega}^{333})=\tilde{\Omega}^3Q/((I_3-I_1)(I_3-I_2))$ *where* $Q=((I_3-I_2)\alpha_3/I_1,(I_3-I_1)\alpha_3/I_2,(-I_3(\alpha_1+\alpha_2)+I_1\alpha_2+I_2\alpha_1)/I_3)$.

Proof: We multiply both sides of Eq. (7) and (8) by $\tilde{\Omega}_3$ and integrate to obtain

$$I_1\tilde{\Omega}^{113}+I_2\tilde{\Omega}^{223}+I_3\tilde{\Omega}^{333}=2E\tilde{\Omega}^3, \tag{24}$$

$$I_1^2\tilde{\Omega}^{113}+I_2^2\tilde{\Omega}^{223}+I_3^2\tilde{\Omega}^{333}=m^2\tilde{\Omega}^3. \tag{25}$$

We integrate

$$\tilde{\Omega}_1\dot{\tilde{\Omega}}_2+\dot{\tilde{\Omega}}_1\Omega_2=\frac{I_2-I_3}{I_1}\tilde{\Omega}_2^2\tilde{\Omega}_3+\frac{I_3-I_1}{I_2}\tilde{\Omega}_1^2\tilde{\Omega}_3$$

(from Euler's Equation) and use $\tilde{\Omega}(0)=\tilde{\Omega}(T)$ to obtain

$$\frac{I_2-I_3}{I_1}\tilde{\Omega}^{223}+\frac{I_3-I_1}{I_2}\tilde{\Omega}^{113}=0, \tag{26}$$

and then solve the system (24), (25), (26) to complete the proof.

Theorem 11: *There are fifteen almost-canonical fourth-order moments. All of these are zero except for* $\tilde{\Omega}^{1111},\tilde{\Omega}^{1122},\tilde{\Omega}^{1133},\tilde{\Omega}^{2222},\tilde{\Omega}^{2233},\tilde{\Omega}^{3333}$. *These are positive and they satisfy a nondegenerate system of six linear equations whose matrix coefficients are rational functions of the* I_j *and whose right-hand sides are linear separately in* E,m^2, *and the second-order almost-canonical moments* $\tilde{\Omega}^{jj}, j=1,2,3$.

Proof: We integrate

$$\tilde{\Omega}_2\tilde{\Omega}_3\dot{\tilde{\Omega}}_1+\tilde{\Omega}_3\tilde{\Omega}_1\dot{\tilde{\Omega}}_2+\tilde{\Omega}_1\tilde{\Omega}_2\dot{\tilde{\Omega}}_3=-\frac{I_3-I_2}{I_1}\tilde{\Omega}_2^2\tilde{\Omega}_3^2+\frac{I_3-I_1}{I_2}\tilde{\Omega}_1^2\tilde{\Omega}_3^2-\frac{I_2-I_1}{I_3}\tilde{\Omega}_1^2\tilde{\Omega}_2^2,$$

[from Eq. (3)] to obtain

$$-\frac{I_3-I_2}{I_1}\tilde{\Omega}^{2233}+\frac{I_3-I_1}{I_2}\tilde{\Omega}^{1133}-\frac{I_2-I_1}{I_3}\tilde{\Omega}^{1122}=0. \tag{27}$$

The proof is complete since the determinant of the coefficient matrix of the system (14), (15), (16), (17), (18), (27) equals $3I_1I_2I_3(I_2-I_1)(I_3-I_1)(I_3-I_2)$, which is positive.

Comparing Theorem 11 with Example 9 we obtain

Corollary 12: The second- and fourth-order almost-canonical moments are independent of the choice of O. *They are determined algebraically by* E,m^2,T, *the* I_j, $j=1,2,3$, *and any one of* $\tilde{\Omega}^{ii}$, $j=1,2,3$.

VI. THE CASE $\alpha_2>0$

When $\alpha_2>0$, $x_1\neq 0$ for $x\in\epsilon_E\cap\epsilon_m$, and x lies on at least one of eight arcs $x_{\sigma_1,\sigma_2,\sigma_3}$ given by

$$x_{\sigma_1,\sigma_2,\sigma_3}(v)=\begin{bmatrix}\sigma_1 v\\ \sigma_2\sqrt{\dfrac{2\alpha_3E-I_1v^2(I_3-I_1)}{I_2(I_3-I_2)}}\\ \sigma_3\sqrt{\dfrac{I_1v^2(I_2-I_1)-2\alpha_2E}{I_3(I_3-I_2)}}\end{bmatrix}, \tag{28}$$

where the $\sigma_j=\pm$. The arguments of Sec. V then adapt as follows: $v\in[\beta_L,\beta_U]$ where

$$\beta_L = \sqrt{\frac{2\alpha_2 E}{I_1(I_2 - I_1)}}, \quad \beta_U = \sqrt{\frac{2\alpha_3 E}{I_1(I_3 - I_1)}}.$$

In this case

$$x_{\sigma_1,\sigma_2,\sigma_3 1}(v) \neq 0 \quad \text{for} \quad v \in [\beta_L, \beta_U], \tag{29}$$

$$x_{\sigma_1,\sigma_2,\sigma_3 2}(v) \neq 0 \quad \text{for} \quad v \in [\beta_L, \beta_U), \quad x_{\sigma_1,\sigma_2,\sigma_3 2}(\beta_U) = 0, \tag{30}$$

$$x_{\sigma_1,\sigma_2,\sigma_3 3}(v) \neq 0 \quad \text{for} \quad v \in (\beta_L, \beta_U], \quad \text{and} \quad x_{\sigma_1,\sigma_2,\sigma_3 3}(\beta_L) = 0. \tag{31}$$

As before, the image C of $\tilde{\Omega}$ is a union of arcs, but this time σ_1 is fixed. Given σ_1, we argue as before, but using Eqs. (30) and (31), that C is parametrized by four arcs, namely the track sum of

$$x_{\sigma_1,+,+}(v), \quad x_{\sigma_1,-,+}(\beta_U - \beta_L - v), \quad x_{\sigma_1,-,-}(v), \quad x_{\sigma_1,-,+}(\beta_U - \beta_L - v),$$

where $v \in [\beta_L, \beta_U]$. By Eq. (3) $I_1 \tilde{\Omega}_1(v) = (I_3 - I_2)\tilde{\Omega}_2(v)\tilde{\Omega}_3(v) \neq 0$ for $v \in (\beta_L, \beta_L)$, and so

$$\tilde{\Omega}^\mu = \frac{I_1}{I_3 - I_2} \int_{\beta_L}^{\beta_U} P(v)\, dv,$$

where

$$P = \frac{\mu(x_1, x_2, x_3) + \mu(x_1, -x_2, x_3) + \mu(-x_1, -x_2, x_3) + \mu(-x_1, x_2, x_3)}{x_1 x_2}$$

and $x \equiv x_{\sigma_1,+,+}(v)$. The following result is analogous to Proposition (6).

Proposition 13: Write $\mu = x_1^{a_1} x_2^{a_2} x_3^{a_3}$. *If* a_2 or a_3 *is odd then* $\tilde{\Omega}^\mu = 0$. *Otherwise*

$$\tilde{\Omega}^\mu = \frac{4I_1}{I_3 - I_2} \int_{\beta_L}^{\beta_U} x_1(v)^{a_1} x_2(v)^{a_2 - 1} x_3(v)^{a_3 - 1} dv \neq 0.$$

Example 14: The moment that corresponds to the monomial of degree 0 ($which = 1$) *is the period*

$$T = 4I_1 \sqrt{I_2 I_3} \int_{\sqrt{2\alpha_2 E / I_1(I_2 - I_1)}}^{\sqrt{2\alpha_3 E / I_1(I_3 - I_1)}} \times \frac{1}{\sqrt{(-2\alpha_2 E + I_1 v^2(I_2 - I_1))(2\alpha_3 E - I_1 v^2(I_3 - I_1))}} dv.$$

Example 15: Let $\tilde{\Omega}^j$ *be the first-order moments corresponding to* x_j *where* $j = 1,2,3$. *Then* $\tilde{\Omega}^2 = \tilde{\Omega}^3 = 0$, *and* $\tilde{\Omega}^1 \neq 0$.

Example 16: Let $\tilde{\Omega}^{ij}$ *be the second-order moments corresponding to* $x_1^i x_2^j$. *Then* $\tilde{\Omega}^{12} = \tilde{\Omega}^{23} = \tilde{\Omega}^{31} = 0$, *and the* $\tilde{\Omega}^{ii}$ *are nonzero. As in Example 9, it suffices to calculate a single* $\tilde{\Omega}^{ii}$ *by quadrature. The other nonzero second-order moments are then determined algebraically.*

Example 17: Of the ten almost-canonical third-order moments, the nonzero ones are $\tilde{\Omega}^{111}, \tilde{\Omega}^{122}, \tilde{\Omega}^{133}$, *which can be calculated algebraically from* $\tilde{\Omega}^1$, E, m^2, *and the* I_j, *by imitating the proof of Theorem 10.*

Example 18: Of the fifteen almost-canonical moments of order 4, the nonvanishing ones are the same as in Theorem 11. The proofs of Theorem 11 and Corollary 12 are valid in the present case where $\alpha_2 > 0$.

VII. *G* AND NULL VECTORS: THE GENERIC CASE

Given $\overline{O} \in O(3)$ write $\overline{A} = \overline{O} A \overline{O}^T$, and $\overline{\Omega}(t) = \overline{O}\Omega(t)$. The transformations $A \mapsto \overline{A}$, $\Omega \mapsto \overline{\Omega}$ leave Eq. (3) invariant and, using $\overline{O}$, moments $\overline{\Omega}^\mu$ of $\overline{\Omega}$ can be calculated from empirical moments. Suppose $\overline{O} \in O(3)$ diagonalizes the symmetric matrix

$$E^{[2]} \equiv \begin{bmatrix} \Omega^{11} & \Omega^{12} & \Omega^{13} \\ \Omega^{12} & \Omega^{22} & \Omega^{23} \\ \Omega^{13} & \Omega^{23} & \Omega^{33} \end{bmatrix}$$

of empirical second-order moments, namely $\overline{O} E^{[2]} \overline{O}^T$ is diagonal. Suppose that the eigenvalues of $E^{[2]}$ are distinct, and let $\mathbf{e}_j$ denote the jth standard basis vector of $\mathbf{R}^3$. Examples 9 and 16 imply that $\overline{O} = \Pi O$ where $\Pi(\mathbf{e}_j) = \pm \mathbf{e}_{\pi(j)}$, $j = 1,2,3$, and π is a permutation of $\{1,2,3\}$. The eigenvalues of $E^{[2]}$ are the nonvanishing second-order almost-canonical moments $\tilde{\Omega}^{jj}$, and $\overline{A} = \mathrm{diag}(\overline{I}_1, \overline{I}_2, \overline{I}_3)$. where $\overline{I}_{\pi(j)} \equiv I_j$. Write $\overline{I} \equiv [\overline{I}_1\, \overline{I}_2\, \overline{I}_3]^T$. Equations (9), (14), (15), (16) are invariant with respect to permutations of coordinates in monomials. Substitution of Eq. (9) in the right-hand sides of (14), (15), (16) shows that $\overline{I}$ is a null-vector of $G \equiv TF^{[4]} - F^{[2]} F^{[2]T}$, where

$$F^{[4]} \equiv \begin{bmatrix} \overline{\Omega}^{1111} & \overline{\Omega}^{1122} & \overline{\Omega}^{1133} \\ \overline{\Omega}^{1122} & \overline{\Omega}^{2222} & \overline{\Omega}^{2233} \\ \overline{\Omega}^{1133} & \overline{\Omega}^{2233} & \overline{\Omega}^{3333} \end{bmatrix}, \quad F^{[2]} \equiv \begin{bmatrix} \overline{\Omega}^{11} \\ \overline{\Omega}^{22} \\ \overline{\Omega}^{33} \end{bmatrix}.$$

In the same way, with (10), (17), (18), (19) in place of (9), (14), (15), (16), $\overline{I}^{(2)} \equiv [\overline{I}_1^2\, \overline{I}_2^2\, \overline{I}_3^2]^T$ is also a null-vector of the symmetric matrix G. Because $\{\overline{I}, \overline{I}^{(2)}\}$ is linearly independent, G is either trivial or rank 1.

Theorem 19: *G has rank 1, with non-null eigenvector*

$$w \equiv \left[\frac{\overline{I}_2 - \overline{I}_3}{\overline{I}_1} \quad \frac{\overline{I}_3 - \overline{I}_1}{\overline{I}_2} \quad \frac{\overline{I}_1 - \overline{I}_2}{\overline{I}_3} \right]^T.$$

Proof: Given $v \in \mathbf{R}^3$ define $f(t) = v_1 \overline{\Omega}_1(t)^2 + v_2 \overline{\Omega}_2(t)^2 + v_3 \overline{\Omega}_3(t)^2$, where $t \in [0,T]$. Let $g: [0,T] \to \mathbf{R}$ be identically 1. Cauchy–Schwarz for $f, g \in L^2[0,T]$ says

$$(F^{[2]T} v)^2 < T v^T F^{[4]} v \tag{32}$$

unless f is a scalar multiple of g. Let v be a nonzero null-vector of G. By Eq. (32) f is constant, and by Eq. (3)

$$0 = v^T \begin{bmatrix} \overline{\Omega}_1(t) \dot{\overline{\Omega}}_1(t) \\ \overline{\Omega}_2(t) \dot{\overline{\Omega}}_2(t) \\ \overline{\Omega}_3(t) \dot{\overline{\Omega}}_3(t) \end{bmatrix} = 2 \overline{\Omega}_1(t) \overline{\Omega}_2(t) \overline{\Omega}_3(t) v^T w$$

for $t\in[0,T]$. By Eq. (20), and the corresponding equation (28) for the other case, $\overline{\Omega}_1\overline{\Omega}_2\overline{\Omega}_3 = \tilde{\Omega}_1\tilde{\Omega}_2\tilde{\Omega}_3$ vanishes for only finitely many parameter values. Therefore v is orthogonal to w. Because w is nonzero it is not a null-vector of G. However it is an eigenvector, because it is orthogonal to the null-vectors $\overline{I}, \overline{I^{(2)}}$, and G is symmetric.

Remark 20: The eigenvalue of w is

$$-R\frac{\overline{I}_3^2\overline{I}_1^2(\overline{I}_3-\overline{I}_1)^2+\overline{I}_2^2\overline{I}_3^2(\overline{I}_2-\overline{I}_3)^2+\overline{I}_1^2\overline{I}_2^2(\overline{I}_1-\overline{I}_2)^2}{3\overline{I}_1^2\overline{I}_2^2\overline{I}_3^2(\overline{I}_1-\overline{I}_2)(\overline{I}_2-\overline{I}_3)(\overline{I}_3-\overline{I}_1)}$$

where $R\equiv\overline{I}_2\overline{I}_3(\overline{I}_2-\overline{I}_3)\overline{\Omega}^{22}\overline{\Omega}^{33}+\overline{I}_3\overline{I}_1(\overline{I}_3-\overline{I}_1)\overline{\Omega}^{33}\overline{\Omega}^{11}+\overline{I}_1\overline{I}_2(\overline{I}_1-\overline{I}_2)\overline{\Omega}^{11}\overline{\Omega}^{22}$.

VIII. METHOD 3: *A* FROM MOMENTS

Let Ω be a nondegenerate solution of Eq. (3) of period $T>0$. In Sec. III A is almost-determined by the restriction of Ω to an interval $[s_1,s_2]$ of positive length. It turns out that in generic cases we can obtain a similar result using moments of Ω of order $\leqslant 4$, together with a small amount of auxiliary information. First we explain what is meant by *generic*.

Definition 21: The symmetric positive-definite matrix A is generic *when its eigenvalues* I_j *are distinct for* $j=1,2,3$. *When A is generic a solution* Ω *of Eq. (3) is* generic *provided the matrix* $E^{[2]}$ *of Sec. VII has distinct eigenvalues.*

Let Ω be generic. In Secs. VI and V we see that either Ω_3 or Ω_1 has constant sign on $[0,T]$, but not both: The *index* of Ω is defined to be 3 or 1 accordingly.

Theorem 22: *For* Ω *generic, A is almost-determined by the index of* Ω *and the moments of* Ω *of orders* 0,1,2,4.

Proof: As in Sec. VII, the matrix $E^{[2]}$ of second-order moments determines O up to conjugation with a permutation matrix Π. As in Sec. VII, the corresponding permutation of $\{1,2,3\}$ is denoted by π. Examining first-order moments with Examples 15, 8, choose π so that $\pi(\iota)=\iota$ where ι is the index of Ω. Second- and fourth-order moments determine a rank 1 symmetric matrix G. By Theorem 19 any non-null eigenvector $\hat{w}$ of G has all coordinates nonzero. Choose $\hat{w}$ so that $\hat{w}_\iota<0$. Furthermore, the permutation π of $\{1,2,3\}\backslash\{\iota\}$ is uniquely determined by the condition

$$\hat{w}_{\pi(2)}>0. \tag{33}$$

Knowing π, return to Sec. VII and rechoose $\overline{O}$ so that Π becomes a diagonal matrix with entries ± 1. Define w and choose $\hat{w}$ as before, but with the new $\overline{O}$. Then $\overline{I}_j=I_j$ for $j=1,2,3$, and w becomes

$$\left[\frac{I_2-I_3}{I_1}\ \frac{I_3-I_1}{I_2}\ \frac{I_1-I_2}{I_3}\right]^T=\sigma\hat{w}, \tag{34}$$

where $\sigma>0$. For $j=1,2$, set $v_j=\hat{w}_j/\hat{w}_3$. The v_j are determined by the index and the moments. Since $I_1<I_2<I_3$,

$$v_1>0,\ v_2<0. \tag{35}$$

Proposition 23: Suppose that $J\in\mathbf{R}^3$ *satisfies*

$$\left[\frac{J_2-J_3}{J_1}\ \frac{J_3-J_1}{J_2}\ \frac{J_1-J_2}{J_3}\right]^T=\sigma\hat{w}, \tag{36}$$

where $\sigma>0$ *is unknown, and* $J_j>0$ *for* $j=1,2,3$. *Then J is a positive scalar multiple of I.*

Proof: Since $\hat{w}_1<0,\hat{w}_2>0,\hat{w}_3<0$, we have

$$0<J_1<J_2<J_3.$$

Define $\Delta_1,\Delta_2>0$ by $J_2=(1-\Delta_2)J_3$ and $J_1=(1-\Delta_1-\Delta_2)J_3$. Then $\Delta_1+\Delta_2<1$. Substituting for the J_j in Eq. (36), and eliminating σ,

$$\frac{\Delta_2}{\Delta_1(1-\Delta_1-\Delta_2)}=v_1, \tag{37}$$

$$-\frac{\Delta_1+\Delta_2}{\Delta_1(1-\Delta_2)}=v_2. \tag{38}$$

Consider the possible solutions for $\Delta\equiv(\Delta_1,\Delta_2)$ of the simultaneous equations (37) and (38). We consider two cases.

Case 1: When $v_1+v_2\neq 0$ there are at most two possible solutions, namely

$$\Delta=\left(\frac{\sqrt{-v_1v_2(1+v_1+v_2)}}{v_1v_2},\frac{(1+v_1+v_2)v_2-\sqrt{-v_1v_2(1+v_1+v_2)}}{(v_1+v_2)v_2}\right), \tag{39}$$

and

$$\Delta=\left(-\frac{\sqrt{-v_1v_2(1+v_1+v_2)}}{v_1v_2},\frac{(1+v_1+v_2)v_2+\sqrt{-v_1v_2(1+v_1+v_2)}}{(v_1+v_2)v_2}\right). \tag{40}$$

Since Eqs. (35) and (39) imply that $\Delta_1<0$, hence Eq. (40) is the only possible solution.

Case 2: When $v_1+v_2=0$ there is at most one solution, namely

$$\Delta=\left(\frac{1}{v_1},\frac{v_1-1}{2v_1}\right).$$

In both cases there is at most one solution Δ (corresponding to $J=I$). This proves the proposition.

Proposition 23 implies that Eq. (34) determines $[I_1\,I_2\,I_3]$ up to positive scalar multiple. Since O is determined up to multiplication by a scalar matrix with entries ± 1, A is almost-determined. This completes the proof of Theorem 22 and provides Method 3, for almost-determining A from qualitative information about Ω (the index) and moments of Ω of orders 0,1,2,4.

A constructive algorithm is proposed for the investigation of symmetries of partial differential equations. The algorithm is used to present classical Lie symmetries of systems of two nonlinear reaction diffusion equations. © *2001 American Institute of Physics.* [DOI: 10.1063/1.1331318]

I. INTRODUCTION

Mathematical models which ultimately involve the analysis of coupled systems of nonlinear diffusion equations are often discussed in the literature. The Schrödinger equation in m-dimensional space is an obvious example from mathematical physics while activator-inhibitor reactions,[1] predator-prey systems, and $\lambda-\omega$ reaction systems[2] are common examples from mathematical biology. These systems are very complex in nature and admit fundamental particular solutions (for example, traveling waves and spiral waves) which have a clear group-theoretical interpretation and which can be obtained using the classical Lie approach. The existence of such solutions suggests an important role for both the classical and nonclassical symmetry analysis of systems of reaction diffusion equations. However, to the best of our knowledge, a comprehensive group analysis has not been undertaken previously although analyses of some special cases do exist.

In this article we discuss symmetries of equations in the general form

$$\frac{\partial u}{\partial t}-A\sum_i \frac{\partial^2 u}{\partial x_i^2}-f(u)=0, \tag{1}$$

where $u\in\mathbb{R}^n$, $f\in\mathbb{R}^n$, $(x,t)\in\mathbb{R}^m\times\mathbb{R}$ and A is a $n\times n$ constant non singular matrix. Actually we restrict ourselves to the case $n=2$ but all results present in Sec. II and the main part of results of Sec. III are valid for arbitrary n.

We note that Eq. (1) with $m=n=1$, $f\equiv 0$ was the subject of a group analysis by Sophus Lie.[3] In addition, classical Lie symmetries of Eq. (1), with $n=m=1$, were investigated by Ovsiannikov[4] whose results were completed by Dorodnitsyn[5] and then generalized to the case $m=2,3$ by Dorodnitsyn, Kniazeva and Svirishchevski.[6] The related conditional (nonclassical) symmetries were described by Fushchych and Serov[7] and Clarkson and Mansfield.[8] The classical symmetries are summarized in Table I.

Here Greek letters denote arbitrary parameters and are the translation, X_0; Galilei, G_α $(\alpha=0,1)$; scale, $\hat{D}_\mu$ $(\mu=0,1,\ldots,4)$ and conformal, $\hat{A}_s$ $(\sigma=0,1,2)$ generators respectively, where

$$X_0=\alpha\frac{\partial}{\partial t}+\beta\frac{\partial}{\partial x},\quad G_\alpha=t\frac{\partial}{\partial x}-\frac{1}{2}xu\frac{\partial}{\partial u}+\frac{1}{2}\delta_{\alpha 1}tx\frac{\partial}{\partial u},\quad \hat{D}_0=2t\frac{\partial}{\partial t}+x\frac{\partial}{\partial x},$$

TABLE I. Symmetries of the scalar diffusion equation with source

$f(u)$	Infinitesimals generator, X
arbitrary	X_0
0	$X_0+\nu G_0+\mu\hat{D}_0+\lambda\hat{A}_0+\sigma u\frac{\partial}{\partial u}+\psi_0\frac{\partial}{\partial u}$
1	$X_0+\nu G_1+\mu\hat{D}_1+\lambda\hat{A}_1+\sigma(u-t)\frac{\partial}{\partial u}+\psi_0\frac{\partial}{\partial u}$
u	$X_0+\nu G_0+\mu\hat{D}_2+\alpha\hat{A}_2+\sigma u\frac{\partial}{\partial u}+\psi_1\frac{\partial}{\partial u}$
$u^n,\ n\neq 1$	$X_0+\mu\hat{D}_3$
e^u	$X_0+\mu\hat{D}_4$
$f=u\ln u$	$X_0+\nu e^t\left(\frac{\partial}{\partial x}-\frac{1}{2}xu\frac{\partial}{\partial u}\right)+\mu e^t u\frac{\partial}{\partial u}$

$$\hat{D}_1=\hat{D}_0+2t\frac{\partial}{\partial u},\quad \hat{D}_2=\hat{D}_0+2tu\frac{\partial}{\partial u},\quad \hat{D}_3=\hat{D}_0-\frac{2}{n-1}u\frac{\partial}{\partial u},\tag{2}$$

$$\hat{D}_4=D_0-2\frac{\partial}{\partial u},\quad \hat{A}_\mu=\frac{1}{2}t\hat{D}_\mu-\frac{1}{4}(x^2+2t)(1-\delta_{\mu 1}t)u\frac{\partial}{\partial u}.$$

In addition, $\delta_{\mu\nu}$ is the Kronecker symbol and $\psi_n(n=0,1)$ is an arbitrary solution of the linear diffusion equation $(\partial/\partial t-\partial^2/\partial x^2)\psi_n=n\psi_n$.

A systematic investigation of the symmetries of the general Eq. (1) with $m>1$ and $n>1$ has so far not been considered in detail, although partial results are available in Refs. 2 and 9–11. In a recent paper[12] Lie symmetries of a subclass of systems (1) for $n=2$ and arbitrary m were investigated. In this subclass the matrix A was diagonal but not a multiple of the unit matrix. We shall demonstrate that the results[12] are incomplete.

It is the aim here to undertake such an investigation for the most general case of an *arbitrary* 2×2 matrix A. In this way we present a complete description of Lie symmetries of all possible systems (1) including the cases of the unit matrix A. This latter case corresponds to the most rich of symmetries with many interesting applications. In particular, we find all nonlinear Schrödinger equations admitting nontrivial Lie symmetries since these equations can also be represented in the form (1) with an *antidiagonal* matrix A, as is demonstrated in Sec. VII. Moreover, we find new symmetries of (1) also in the subclass studied in Ref. 12.

The additional main aim of this article is to present the novel use of a rather conventional algorithm for investigation of symmetries of a special class of partial differential equations which includes (1) as a particular case. More precisely we will show that the classical Lie approach (refer to, for example, Refs. 13 and 11) when applied to systems (1) admits a rather simple formulation in terms of commutator algebra which may also be applied to extended classes of partial differential equations. Furthermore, the algorithm may be used to determine nonclassical (or conditional) symmetries of (1). It will be shown that for $n>1$ there is a proliferation of symmetries, including for the case when $f(u)$ is linear, which do not have origins in symmetries of Table I for the one dimensional scalar diffusion equation with source.

II. AN ALGORITHM FOR THE DETERMINING EQUATIONS OF SYMMETRY FOR THE SYSTEM (1)

We require form invariance of the system of reaction diffusion equations (1) with respect to the one-parameter group of transformations:

$$t\to t'(t,x,\varepsilon),\quad x\to x'(t,x,\varepsilon),\quad u\to u'(t',x',\varepsilon),\tag{3}$$

where ε is a group parameter. In other words, we require that $u'(t',x',\varepsilon)$ satisfies the same equation as $u(t,x)$:

$$L'u'=f(u'), \quad L'=\frac{\partial}{\partial t'}-A\sum_i \frac{\partial_i^2}{\partial x_i'^2}. \tag{4}$$

From the infinitesimal transformations,

$$\begin{gathered} t\to t'=t+\Delta t=t+\varepsilon\eta, \quad x_a\to x_a'=x_a+\Delta x_a=x_a+\varepsilon\xi^a, \\ u_a\to u_a'=u_a+\Delta u_a=u_a+\varepsilon\pi_a, \end{gathered} \tag{5}$$

we obtain the following representation for the operator L':

$$L'=\left[1+\varepsilon\left(\eta\frac{\partial}{\partial t}+\xi^a\frac{\partial}{\partial x_a}\right)\right]L\left[1-\varepsilon\left(\eta\frac{\partial}{\partial t}+\xi^a\frac{\partial}{\partial x_a}\right)\right]+O(\varepsilon^2). \tag{6}$$

Using the classical Lie algorithm it is possible to find the determining equations for the functions η,ξ_a and π_a which specify the generator X of the symmetry group:

$$X=\eta\frac{\partial}{\partial t}+\xi^a\frac{\partial}{\partial x_a}-\pi^b\frac{\partial}{\partial u_b}, \tag{7}$$

where a summation from 1 to m and from 1 to n is assumed over repeated indices a and b, respectively. This system will not be reproduced here, but we note that three of the equations are

$$\frac{\partial\eta}{\partial u_a}=0, \quad \frac{\partial\xi^a}{\partial u_b}=0, \quad \frac{\partial^2\pi^a}{\partial u_c\partial u_b}=0. \tag{8}$$

So from (8) η and ξ^a are functions of t and x_a and π^a is linear in u_a. Thus,

$$\pi^a=-\pi^{ab}u_b-\omega^a, \tag{9}$$

where π^{ab} and ω^a are functions of t and $x=(x_1,x_2,\ldots,x_m)$.

From (4) it is possible to deduce all the remaining determining equations. Indeed, substituting (5), and (9) into (6), using (1), and neglecting the terms of order ε^2 we find that

$$[Q,L]u-L\omega=\pi f+\frac{\partial f}{\partial u_a}(-\pi^{ab}u_b-\omega^a), \quad Q=\eta\frac{\partial}{\partial t}+\xi^a\frac{\partial}{\partial x_a}+\pi \tag{10}$$

and π is a matrix whose elements π^{ab} are defined by the relation (9).

To guarantee that Eq. (10) is compatible with (1) and does not impose new nontrivial conditions for u in addition to (1) it is necessary to suppose that the commutator $[Q,L]$ admits the representation

$$[Q,L]=\Lambda L+\varphi(t,x), \tag{11}$$

where Λ and φ are $n\times n$ matrices dependent on (t,x_a).

Substituting (11) into (10) the following determining equations for f are obtained:

$$(\Lambda^{kb}-\pi^{kb})f^b+\varphi^{kb}u^b-(L\omega)^k=-(\omega^a+\pi^{ab}u_b)\frac{\partial f^k}{\partial u^a}. \tag{12}$$

Thus, to find all nonlinearities f^k generating Lie symmetries for Eq. (1) it is necessary to solve the operator equation (11) for L, Q given in (4) and (10) and to determine the corresponding

matrices Λ, π, φ and functions η and ξ. In the second step the nonlinearities f^a may be found by solving the system of first-order equations (12) with their known coefficients.

Equation (11) is a straightforward generalization of the invariance condition for the *linear* system of diffusion equations (1) with $f(u)=0$, so that $[Q,L]=\Lambda L$, which may readily be solved. By means of this ''linearization'' the problem of investigating symmetries of systems of nonlinear diffusion equations is reduced to the rather simple application of elements of matrix calculus in order to classify nonequivalent solutions of the determining equations.

We notice that this approach is valid for the extended class of equations $Lu=f(u)$ where L is a linear differential operator with constant coefficients and where $u\in\mathbb{R}^n$. We note also that calculations of the nonclassical (conditional) symmetries for the system (1) may be reduced to the solution of the determining equations (12) where now Λ, π, φ, η and ξ are defined as solutions of the following relationship,

$$[Q,L]=\Lambda L+\varphi(t,x)+\mu(t,x)Q, \tag{13}$$

and where $\mu(t,x)$ is an unknown function of the independent variables.

III. THE SYMMETRY OPERATORS AND THEIR SIMPLIFICATION

We now determine the general solutions for matrices Λ, φ, π and also the functions ξ, η, π which satisfy (12) and (11).

Evaluating the commutator in (11) and equating the coefficients for linearly independent differential operators we obtain the five determining equations:

$$2A\xi^a_b=-\delta_{ab}(\Lambda A+[A,\pi]),\quad \dot\eta_a=0,\quad \dot\eta=\Lambda, \tag{14}$$

$$\dot\xi^a-2A\pi_a-A\xi^a_{nn}=0,\quad \varphi=A\pi_{nn}-\dot\pi. \tag{15}$$

Here the dots denote derivatives with respect to t and subscripts denote derivatives with respect to the spatial variables, so, for example, $\eta_a=\partial\eta/\partial x_a$.

From (14) Λ is proportional to the unit matrix, $\Lambda=\lambda I$ and from (14) $[A,\pi]=0$. Indeed, choosing $a=b$ we obtain

$$\pi-A^{-1}\pi A=(2\xi^a_a-\lambda)I. \tag{16}$$

The trace of the left hand side of (16) is equal to zero, and so $2\xi^a_a-\lambda\equiv 0$ and $A\pi-\pi A=0$.

Equations (14) and (15) contain matrices which commute, and so they may easily be integrated using, for example, the method of characteristics. The general solution of (14) and (15) is

$$\xi^a=C^{[ab]}x_b+\dot d x^a+g^a,\quad \eta=-2d,$$

$$\pi=\frac{1}{2}A^{-1}\left(\frac{\ddot d}{2}x^2+\dot g^a x^a\right)+C,\quad \Lambda=-2\dot d I, \tag{17}$$

$$\varphi=\frac{m}{2}\ddot d-\dot C-\frac{1}{2}A^{-1}\left(\frac{\dddot d}{2}x^2+\ddot g^a x^a\right),$$

where d and g^a are arbitrary functions of t and C is a t-dependent matrix commuting with A.

By considering the x dependence of functions (17) it is convenient to represent still unknown functions ω_a, occurring in (12), as

$$\omega_a=\omega^a_2x^2+\omega^{ab}_1x_b+\omega^a_0+\mu^a, \tag{18}$$

where $\omega_2^a, \omega_1^{ab}, \omega_0^a$ are functions of t, and μ^a is a function of t and x. Without loss of generality we suppose that all terms on the right hand side of (18) are linearly independent. Then comparing with (12) and (17) the functions μ^k have to satisfy

$$(L\mu)^k = \lambda^{kb}\mu^b + \xi_0^k + \xi_1^{kb}x_b + \xi_2^k x^2, \tag{19}$$

where λ^{kb} are constants and $\xi_0^k, \xi_1^{kb}, \xi_2^k$ are functions of t.

The final step is to substitute (17) and (19) into (12) and equate coefficients for all different powers of x_a. As a result we obtain the system of equations

$$\ddot{d}(A^{-1})^{kb}f^b + \dddot{d}(A^{-1})^{kb}u^b - \ddot{d}(A^{-1})^{ab}u^b\frac{\partial f^k}{\partial u^a} = 4\left(\dot{\omega}_2^k + \xi_2^k - \omega_2^b\frac{\partial f^k}{\partial u_b}\right), \tag{20}$$

$$\dot{g}^a(A^{-1})^{kb}f^b + \ddot{g}^a(A^{-1})^{kb}u^b - \dot{g}^a(A^{-1})^{kb}u^b\frac{\partial f^k}{\partial u^a} = 2\left(\dot{\omega}_1^{ka} + \xi_1^{ka} - \omega_1^{ba}\frac{\partial f^k}{\partial u_a}\right), \tag{21}$$

$$2\dot{d}f^k - C^{kb}f^b - \left(\dot{C}^{kb} + \frac{m}{2}\ddot{d}\,\delta^{kb}\right)u^b + (\omega_0^a + C^{ab}u^b)\frac{\partial f^k}{\partial u_a} = \dot{\omega}_0^k - 2mA^{kb}\omega_2^b + \xi_0^k, \tag{22}$$

$$\frac{\partial f^k}{\partial u_b}\mu^b = \lambda^{kb}\mu^b. \tag{23}$$

Thus, the general form of symmetry group generators for Eq. (1) is given by relations (7), (17), and (18) where $d, g^a, C^{ab}, \omega_0^k, \omega_1^{kb}, \omega_2^a, \mu^a$ are functions of t to be specified using Eqs. (20)–(23). These results are valid for Eq. (1) with arbitrary $n\times n$ constant nonsingular matrix A.

In the following we restrict ourselves to the case of 2×2 matrix A. The related Eq. (1) is reduced to the form

$$\begin{aligned}
&\frac{\partial}{\partial t}u_1 - \sum_i \frac{\partial^2}{\partial x_i^2}(A^{11}u_1 + A^{12}u_2) = f^1,\\
&\frac{\partial}{\partial t}u_2 - \sum_i \frac{\partial^2}{\partial x_i^2}(A^{21}u_1 + A^{22}u_2) = f^2,
\end{aligned} \tag{24}$$

where A^{11}, A^{12}, A^{21} and A^{22} are elements of matrix A, and f^1 and f^2 are functions of u_1, u_2 to be specified.

First we present all nonequivalent matrices A which have to be considered in the analysis. The *ad hoc* nonequivalent versions of Eq. (24) correspond to the following matrices A:

$$\text{(Ia) } A = \begin{pmatrix} 1 & 0 \\ 0 & 1 \end{pmatrix}; \quad \text{(Ib) } A = \begin{pmatrix} 1 & 0 \\ 0 & a \end{pmatrix}; \quad \text{(II) } A = \begin{pmatrix} b & -c \\ c & b \end{pmatrix}; \quad \text{(III) } A = \begin{pmatrix} 1 & 0 \\ e & 1 \end{pmatrix}, \tag{25}$$

where a, b, c and e are arbitrary parameters, $a \neq 0,1$. All 2×2 matrices can be reduced to one of the forms (25) using linear and scale transformations of the dependent variables. Moreover, without loss of generality it is possible to set $c=1$ and $e=1$.

The analysis of symmetries of systems of nonlinear diffusion equations present in Ref. 12 was restricted to the case when matrix A had the form Ib. We consider here the most general case, that is, all possible forms of the matrix A given by relations (25). We present now an outline of the approach used to solve the system (20)–(23)and begin by noticing the following.

(i) Except for the functions μ_a depending on t, x and the constant matrix A^{-1}, all quantities in the determining equations belong to one of two classes. Either the quantities depend on u

but are independent of t, or, alternatively, the quantities depend on t but are independent of u. This enables us to separate variables and so decouple the equations.

(ii) To simplify calculations it is convenient to use the equivalence transformations

$$u^a \to (u')^a = \lambda^{ab} u^b + \sigma^a, \quad f^a \to (f')^a = \lambda^{ab} f^b, \tag{26}$$

where λ^{ab} is an invertable constant matrix and σ^a are constants. Such transformations leave Eq. (1) form invariant and so make it possible to reduce A^{-1} (and other matrices used in the analysis) to canonical forms (25).

(iii) Many solutions of (20)–(23) are such that f is linear in u. Such possibilities are considered separately.

An important *a priori* simplification of the determining equations can be obtained by considering the compatibility of (20)–(23).

Lemma 1: Let Eqs. (20) and (22) be compatible and f^k be nonlinear in u. Then, up to equivalence transformations (26), the functions d and ω_2^k have to satisfy one of the following relations:

$$\dddot{d} = 0, \quad \omega_2^1 = 0, \quad \dot{\omega}_2^k = \mu \omega_2^k - \xi_2^k + \mu \ddot{d}, \quad \text{or} \quad \dddot{d} = \mu \ddot{d}, \quad \omega_2^1 = \omega_2^2 = 0, \tag{27}$$

where $\mu \neq 0$, ν_1 and ν_2 are constants, at least one of constants ν_α is nonzero, and nontrivial ω_2^k are linearly independent of $\ddot{d}$.

The proof of Lemma 1 depends on the analysis of the consequences of differentiating Eq. (20) first, with respect to u_c, and then with respect to u_a, and further considering the conditions for consistency of the resulting system. Details of this analysis are straightforward and are omitted here.

An analogous result with a similar proof is valid for Eq. (21) which generates the following restrictions:

$$\ddot{g}_a = 0, \quad \omega_1^{1b} = 0, \quad \dot{\omega}_1^{2b} = \nu \omega_1^{2b} - \xi_1^{2b}, \quad \text{or} \quad \ddot{g}_a = \nu \dot{g}_a, \quad \omega_1^{1b} = \omega_1^{2b} = 0. \tag{28}$$

These conditions are compatible with (20) and (21) only when

$$\dot{d} = d_3 t + d_4, \quad g^a = g_3^a t + g_4^a, \quad \omega_1^{2b} = \nu^b \omega_2^2, \tag{29}$$

$$\dot{d} = d_1 \exp(\nu t) + d_2, \quad g^a = g_1^a \exp(\nu t) + g_2^a, \quad \omega_1^{2b} = \nu^b \omega_2^2, \tag{30}$$

where ν, ν^a, g_k^a, d_k, $k = 1,...,4$, are constant.

Let μ^α be trivial. Then substituting these into (20)–(22) we find that

$$(A^{-1})^{kb} f_b = (A^{-1})^{ab} u_b \frac{\partial f^k}{\partial u^a}, \quad d_3 \neq 0 \quad \text{or/and} \quad g_3^a \neq 0, \tag{31}$$

$$[-2(d_3 t + d_4)\delta^{kb} + C^{kb}] f^b + \left(\frac{m}{2} d_3 \delta_{kb} + \dot{C}^{kb} \right) u^b = \dot{\omega}_0^k - 2mA^{k2} \omega_2^2 - (\omega_0^a - C^{ab} u^b) \frac{\partial f^k}{\partial u^a}, \tag{32}$$

$$\omega_2^2 \left(\mu \delta_{k2} - \frac{\partial f^k}{\partial u_2} \right) = 0, \tag{33}$$

or alternatively, the system which includes (33) and the two following equations,

$$(A^{-1})^{kb} (f^b + \mu u^b) = (A^{-1})^{ab} u_b \frac{\partial f^k}{\partial u^a}, \quad \mu \neq 0, \quad d_1 \neq 0 \quad \text{or} \quad g_1 \neq 0, \tag{34}$$

$$[(2d_1\exp(\mu t)+d_2)\,\delta^{kb}+C^{kb}]f^b+\left(\frac{1}{2}\mu d_1\exp(\nu t)\,\delta^{kb}+\dot{C}^{kb}\right)u^b$$

$$=\dot{\omega}_0^k-2A^{k2}\omega_2^2-(\omega_0^a-C^{ab}u_b)\frac{\partial f^k}{\partial u^a}. \tag{35}$$

Thus, the investigation of symmetries for systems of diffusion equations depends on solving the determining equations (31)–(33) and (34), (35), (33). These include arbitrary parameters d_k, and μ, arbitrary functions of t, i.e., ω_0^a,ω_2^a, and an arbitrary matrix C^{ab} which commutes with A and also depends on t. The form of C is given as follows.

Lemma 2: A necessary condition of compatibility of system (31)–(33) is that the matrix function C^{ab} has the form

$$C^{ab}=\phi_0F^{ab}+\phi_1B^{ab}+\nu(\delta^{ab}-F^{ab}) \tag{36}$$

where F^{ab}, B^{ab} are constants and ϕ_0, ϕ_1 are functions of t satisfying the conditions

$$F^{ak}B^{kb}-B^{ak}F^{kb}=\alpha B^{ab}+\beta F^{ab},$$
$$\dot{\phi}_0=k_0\phi_0+k_1\phi_1+k_2,\quad \dot{\phi}_1=n_0\phi_0+n_1\phi_1+n_2. \tag{37}$$

Here α, β, ν, k_0, k_1, k_2, n_0, n_1 and n_2 are arbitrary constants.

Proof is straightforward but rather cumbersome, so we present its sketch only.

An arbitrary 2×2 matrix C whose elements are C^{ab} can be expanded as

$$C=C_0I+C_1\sigma_1+C_2\sigma_2+C_3\sigma_3, \tag{38}$$

where

$$I=\begin{pmatrix}1&0\\0&1\end{pmatrix},\quad \sigma_1=\begin{pmatrix}0&1\\1&0\end{pmatrix},\quad \sigma_2=\begin{pmatrix}0&-1\\1&0\end{pmatrix},\quad \sigma_3=\begin{pmatrix}1&0\\0&-1\end{pmatrix}, \tag{39}$$

and C_0, C_1, C_2 and C_3 are functions of t. Let k $(1\leqslant k\leqslant 4)$ of these functions be linearly independent. Then equating in (32) the coefficients for these functions we obtain k systems of equations for f^a.

Considering the case $k=4$ it is possible to convince ourselves that the related overdetermined systems are incompatible. For $k=3$ the compatibility condition for (32) reduces to the form (36). Then equating coefficients for independent functions ϕ_0 and ϕ_1 in (32) we come to systems of equations for f^a, which are compatible provided relations (36) and (37) are satisfied.

Substituting (27) and (28) into (32) we obtain

$$\phi_0\left[F^{kb}(f^b+k_0u^b)-F^{ab}u_b\frac{\partial f^k}{\partial u_a}+n_0B^{kb}u^b\right]+\phi_1\left[B^{kb}(f^b+n_1u^b)-B^{ab}u_b\frac{\partial f^k}{\partial u^a}+k_1F^{kb}u^b\right]$$
$$+\nu\left[(\delta^{kb}-F^{kb})F^b-(\delta^{ab}-F^{ab})u_b\frac{\partial f^k}{\partial u_a}\right]+(n_2F^{kb}+k_2B^{ab})u_b-2(d_3t+d_4)f^k+\frac{1}{2}d_3u^k$$
$$=-\dot{\omega}_0^k+2m\,\delta_{k2}A^{k2}\omega_2^2+2\omega_0^a\frac{\partial f^k}{\partial u^a}. \tag{40}$$

This equation has to be imposed together with (31) provided $g_3^a\neq0$ or $d_3\neq0$. Moreover, different combinations of values of these parameters correspond to different systems of determining equations. We specify the following five cases:

$$d_3=0,\quad g_3^a=0,\quad \phi_0\not\equiv0,\quad \omega_2^2=\omega_1^{2b}=0,\quad \omega_0^a=\text{const},\quad n_2=k_2=0,$$

$$d_3=0,\quad g_3^a=0,\quad \phi_0\equiv 0,\quad \omega_2^2=\omega_1^{2b}=0,\quad \omega_0^a=\text{const},\quad n_2=k_2=0,$$

$$d_3=0,\quad g_3^a\neq 0,\quad \omega_2^2=\omega_1^{2b}=0,\quad \omega_0^a=\text{const},$$

$$d_3\neq 0,\quad \omega_2^2=\omega_1^{2b}=0,\quad \omega_0^a=\text{const},$$

$$\omega_2^2\neq 0,\quad \omega_1^{2b}\neq 0.$$

In this way the system of equations (31)–(33) may be solved explicitly using the method of characteristics to determine f^k and their corresponding symmetries. A similar approach can be used for the alternative system (34) and (35) and for the case when μ^α are not trivial. In the last case very strong restrictions are imposed on f^k by relation (23) which has only few solutions.

IV. NON-LINEARITIES AND SYMMETRIES

We will not give the detailed calculations but present the general solution of relations (20)–(23). In the following tables we present the results of the symmetry analysis for the case where f^k is nonlinear in u.

First we present the list of nonlinearities of the most general form which are defined up to arbitrary functions (Table II). To make this we specify matrices B which commute with A (25) according to the following categories:

$$\begin{aligned}
&\text{(I) } B=\begin{pmatrix}1&0\\0&d\end{pmatrix},\quad A^{-1}=\begin{pmatrix}1&0\\0&a^{-1}\end{pmatrix}\ \text{if}\ a\neq 1;A^{-1}\ \text{is arbitrary if}\ a=1;\\
&\text{(II) } B=\begin{pmatrix}d&-1\\1&d\end{pmatrix},\quad A^{-1}=\frac{1}{b^2+c^2}\begin{pmatrix}b&c\\-c&b\end{pmatrix},\\
&\text{(IIIa) } B=\begin{pmatrix}0&0\\1&0\end{pmatrix},\quad A^{-1}=\begin{pmatrix}1&0\\-c&1\end{pmatrix},\\
&\text{(IIIb) } B=\begin{pmatrix}1&0\\1&1\end{pmatrix},\quad A^{-1}=\begin{pmatrix}1&0\\-e&1\end{pmatrix}.
\end{aligned}\tag{41}$$

Here $R=\sqrt{u_1^2+u_2^2},\theta=\arctan(u_2/u_1)$, the Greek letters in the right column of Table II denote arbitrary coefficients while D_μ, G_a^i and $\overline{G_a^i}, X_A, Y_a, \hat{B}$ are various types of dilatation, Galilei and special transformation generators as follows:

$$\begin{aligned}
&D_0=2t\frac{\partial}{\partial t}+x_a\frac{\partial}{\partial x_a},\quad D_1=D_0-\frac{2}{k}\hat{B},\quad D_2=D_0+\frac{2}{k}\left(\frac{\partial}{\partial u_2}+nu_1\frac{\partial}{\partial u_1}\right),\\
&D_3=D_0-\frac{2}{k}\left(\frac{\partial}{\partial u_1}-nu_1\frac{\partial}{\partial u_2}\right),\quad D_4=D_0-\frac{2}{k}\omega_a\frac{\partial}{\partial u_a},\\
&G_a=t\frac{\partial}{\partial x_a}-\frac{1}{2}x_a(A^{-1})^{nb}u_b\frac{\partial}{\partial u_n},\quad \hat{G}_a=e^{nt}\left(\frac{\partial}{\partial x_a}-\frac{1}{2}nx_a(A^{-1})^{nb}u_b\frac{\partial}{\partial u_n}\right),\\
&X_0=\alpha\frac{\partial}{\partial t}+\beta_a\frac{\partial}{\partial x_a}+\nu^{[a,b]}x_a\frac{\partial}{\partial x_b},\quad \nu^{[a,b]}=-\nu^{[b,a]},\\
&Y_1=ntu_1\frac{\partial}{\partial u_2}+u_2\frac{\partial}{\partial u_2},\quad Y_2=u_1\frac{\partial}{\partial u_1}+n\frac{\partial}{\partial u_2},\quad Y_3=e^{st}\left(u_1\frac{\partial}{\partial u_1}+n\frac{\partial}{\partial u_2}\right),
\end{aligned}\tag{42}$$

In Table IV, columns 4 and 5 refer to both the nonlinearities specified as cases 9 and 10. However, the conditions marked by * are related to case 9 only and the symmetries marked by ** correspond only to case 10.

Here $\kappa=$constant, $\Delta=k_0n_1-n_0k_1$, $\delta=\frac{1}{4}(k_0-n_1)^2+k_1n_0$, $\hat{\mathcal{F}}_\alpha=\mathcal{F}_\alpha^{ab}u_b\,\partial/\partial u_a$, $\hat{F}=F^{ab}u_b\,\partial/\partial u_a$ and:

$$Y_{13}=\exp(nt)\left(\cos(pt)u_1\frac{\partial}{\partial u_1}-\sin(pt)\frac{\partial}{\partial u_2}\right),\quad Y_{14}=\exp(nt)\left(ptu_1\frac{\partial}{\partial u_1}+\frac{\partial}{\partial u_2}\right).$$

V. LINEAR SYSTEMS

Consider now the linear case when f^1 and f^2 have the form $f^a=\Lambda^{ab}u_b+\lambda_a$. In contrast to the one-dimensional cases we find nontrivial possibilities corresponding to the noncommutation of the matrices A and Λ where we specify A in formulas (25).

In Table V the following notation has been employed:

$$\delta=bc-\tfrac{1}{4}(a-d)^2,$$

$$X_5=X_0+\nu\left(u_1\frac{\partial}{\partial u_1}+u_2\frac{\partial}{\partial u_2}\right)+\lambda D_0+\psi^a_\Lambda\frac{\partial}{\partial u_a}+\mu\left(t^2\frac{\partial}{\partial t}+tx_a\frac{\partial}{\partial x_a}-\frac{1}{4}x^2(A^{-1})^{ab}u_b\frac{\partial}{\partial u_a}\right.$$
$$\left.-\frac{m}{2}t\left(u_1\frac{\partial}{\partial u_1}+u_2\frac{\partial}{\partial u_2}\right)+t^2\lambda^{ab}u_b\frac{\partial}{\partial u_a}\right).$$

Note that symbols X_0 and D_0 has been defined in (42) and (25) and, further, ψ_Λ is an arbitrary solution of the homogeneous equation

$$\left(\frac{\partial}{\partial t}-\sum_{i=1}^{m}\frac{\partial^2}{\partial x_1^2}\right)\psi^j_\Lambda=\Lambda^{jk}\psi^k_\Lambda.$$

VI. EQUIVALENCE TRANSFORMATIONS

The solutions of the determining equations presented in Tables II–V are defined up to the equivalence transformations (26) which do not change the shape of Eqs. (1) for *arbitrary* f^k. However, for some *particular* f^k, it is possible to indicate more extended groups of equivalence transformations which include (26) as a subgroup. Here we discuss such transformations.

The most extended equivalence groups appear for the case of linear f^k presented in Table V. Let the related solutions have the following general form:

$$f^k=\Lambda^{kb}u^b, \tag{45}$$

where Λ^{kb} is a matrix which commutes with $(A^{-1})^{kb}$. So there exists an additional equivalence transformation

$$u_a \to \exp\left(-t\hat{\Lambda}^{cb} u_b \frac{\partial}{\partial u_c} u_a \right) = \exp(-t\hat{\Lambda}^{ab}) u_b , \tag{46}$$

where $\hat{\Lambda}^{cb}$ is a matrix which commutes with A^{ab} and Λ^{ab}. The transformed equation has the form (45) where $f'^k = (\Lambda^{kb} - \hat{\Lambda}^{kb}) u_b$. In particular, we can choose $\hat{\Lambda}^{kb} = \Lambda^{kb}$ and reduce the related f^k to zero.

For A diagonal there exists also the following equivalence transformation

$$u_1 \to u_1 \exp(-kt), \quad u_2 \to u_2 + nt, \tag{47}$$

$$u_1 \to u_1 - tu_2 + \frac{t^2}{2} p, \quad u_2 \to u_2 - tp, \tag{48}$$

$$u_1 \to u_1 + \frac{pt^2}{2}, \quad u_2 \to u_2 + pt. \tag{49}$$

Moreover, (48) is valid only for the case when A is proportional to the unit matrix.

Solutions present in Table V are defined up to equivalence transformations (26) and (46)–(49).

Using the transformation

$$u_1 \to \exp(nt) u_1, \quad u_2 \to \exp\left(-\frac{qn}{r} \right) u_2,$$

it is possible to reduce to zero the parameter n in Table III, item 1 (we will refer to this case as [T3.1]). The transformations $u_1 \to u_1, u_2 \to u_2 + \nu t + \mu x^2$ enable us to make zero parameters C_1 and C_2 in the cases when f^1 and f^2 have the form $f^1 = \varphi_1 + C_1, f^2 = \varphi_2 + C_2$ where φ_1 and φ_2 are given functions of u_1. Such transformations can be applied in the cases [T3.10] and [T3.8] (in the last case it is necessary to change roles of u_1 and u_2).

Transformations $u_2 \to \exp(-nt) u_2$ and $u_2 \to \exp(-bt) u_2$ give rise to new n and b in solutions 2 and 3 from Table IV, respectively. The transformation

$$u_1 \to u_1 \exp(-st), \quad u_2 \to u_2 + \frac{sr}{k} t$$

reduces to zero parameter s in nonlinearities [T3.6].

Consider further the scale transformation

$$u_1 \to \mu u_1, \quad u_2 \to \nu u_2, \quad t \to \lambda t \quad x \to \sqrt{\lambda} x. \tag{50}$$

Under obvious conditions for the parameters defining the functions f_1 and f_2 transformations (50) enable the reduction of nonzero coefficients p and q to zero coefficients for solutions 1, 8, and 9 from Table IV.

We see that using equivalence transformations it is possible to make ''cosmetic'' improvements to the solutions found for f^k. These transformations were not used systematically because they do not change the principal classes of solutions. Also in some cases their use would complicate the presentation of the results in standard form and make them less convenient for applications.

VII. DISCUSSION

In this article we have found all possible versions of systems of diffusion equations that admit a nontrivial Lie symmetry. These results can be used to construct mathematical models with required symmetry properties in, for example, physics, biology, and chemistry.

In the case when the matrix A is proportional to the unit matrix I Eq. (24) admits nontrivial symmetries for *all* f^1, f^2 given in Tables II–IV. In other words in this case we have obtained the richest spectrum of possible symmetries. If A is not proportional to I, the number of symmetries is sufficiently reduced by the requirement of commutativity of A^{-1} with the chosen matrices B and F in (43).

In the particular case when matrix A has the form Ib from (25) our results can be compared with those of Ref. 12. Our results are quite similar. However, a number of our solutions, namely, seven of those presented in Table IV, case 1 (which correspond to symmetries Z_N), solutions [T4.3] for $b=k=q=0$, [T5.2], [T3.8] for $p\neq 0$, [T3.11], and all solutions [T4.4] [T4.5], and [T4.7] are missing in Ref. 12. In addition, [T2.17] is presented in Ref. 12 incorrectly (see Table V, item 9 here).

Consider the examples of reaction diffusion equations mentioned earlier in Sec. I.

(i) The activator-inhibitor reaction equations[1] are given by

$$\dot{u}_1-\frac{\partial^2 u_1}{\partial x^2}=\frac{u_1^2}{u_2}-bu_1,\quad \dot{u}_2-a\frac{\partial^2 u_2}{\partial x^2}=u_1^2-u_2,$$

and these are a particular case of Eq. (24) with the nonlinearities given in [T2.5] with $d=2,k=0,\varphi_1=u_1^2/u_2-b,\varphi_2=u_1^2/u_2-1$, and so admits the symmetry

$$X=X_0+\alpha\left(u_1\frac{\partial}{\partial u_1}+2u_2\frac{\partial}{\partial u_2}\right).$$

(ii) The primitive predator-prey system can be defined by[1]

$$\dot{u}_1-D\frac{\partial^2 u_1}{\partial x_2}=-u_1u_2,\quad \dot{u}_2-\lambda D\frac{\partial^2 u_2}{\partial x^2}=u_1u_2.$$

This is a particular case of (24) with nonlinearities [T2.1] where $d=1,k=1,\varphi_2=-\varphi_1=u_2/u_1$, and so it admits the symmetry

$$X=X_0+\alpha\left(D_0-2u_1\frac{\partial}{\partial u_1}-2u_2\frac{\partial}{\partial u_2}\right).$$

(iii) The $\lambda-\omega$ reaction-diffusion system

$$\dot{u}_1=D\Delta u_1+\lambda(R)u_1-\omega(R)u_2,\quad \dot{u}_2=D\Delta u_2+\omega(R)u_1+\lambda(R)u_2, \tag{51}$$

where $R^2=u_1^2+u_2^2$ and Δ is the Laplacian operator, has symmetries that were analyzed in paper Ref. 2. Again we recognize that this system is a particular case of (24) with nonlinearities [T2.6] with $n=0$. Hence it admits the five-dimensional Lie algebra generated by

$$X=X_0+\alpha\left(u_1\frac{\partial}{\partial u_2}-u_2\frac{\partial}{\partial u_1}\right), \tag{52}$$

which is in accordance with results of Ref. 2 for the case when functions λ and ω are arbitrary. Moreover, using Table III, case [T3.2] we find that for the cases when

$$\lambda=\kappa_1R^r,\quad \omega=\kappa_2R^r, \tag{53}$$

Eq. (51) admits additional symmetry with respect to scaling transformations given by the operator

$$X=X_0+\alpha\left(u_1\frac{\partial}{\partial u_2}-u_2\frac{\partial}{\partial u_1}\right)+\nu D_5. \tag{54}$$

(iv) The nonlinear Schrödinger equation in m-dimensional space, is given by

$$\left(i\frac{\partial}{\partial t} - \sum_{i=1}^{m} \frac{\partial^2}{\partial x_i^2} \right) \psi = F(\psi, \psi^*)\psi, \tag{55}$$

also is a particular case of (24). If we denote

$$u_1 = \frac{1}{2}(\psi + \psi^*), \quad u_2 = \frac{1}{2i}(\psi - \psi^*), \tag{56}$$

then (55) reduces to the form (24) with $A = -\sigma_2$ and

$$f^1 = \frac{1}{2}(F^* + F)u_2 + \frac{1}{2i}(F - F^*)u_1, \quad f^2 = \frac{1}{2i}(F - F^*)u_2 - \frac{1}{2}(F + F^*)u_1. \tag{57}$$

In other words, any solution given in Table III–V with matrices belonging to classes I ($d = 0$) and II gives rise to the nonlinearity

$$F = \frac{1}{R^2}(u_2 f^1 - u_1 f^2 + i(u_2 f^2 + f^1 u^1)) \tag{58}$$

for the nonlinear Schrödinger equation (55) that admits a nontrivial Lie symmetry. In the cases [T3.7] with $n = 0$, [T3.2] for $s = l = q = 0$, $r \neq 4/m$ and $r = 4/m$, and [T4.8] for $k_1 = n_1 = k_0 = 0$, $p = q$, we recognize the well-known nonlinearities[11]

$$F = F(\psi^* \psi), \quad F = (\psi^* \psi)^k, \quad F = (\psi^* \psi)^{2/m}, \quad F = \ln(\psi^* \psi), \tag{59}$$

which correspond to extended symmetries. Our analysis makes it possible to describe all other possible versions of the nonlinear Schrödinger equation with a nontrivial symmetry. We plan to discuss these elsewhere.

Higher symmetries of the linear and nonlinear Schrödinger equations were investigated in Ref. 14; extended supersymmetries were studied in Ref. 15 The nonlinear Schrödinger equations and Eqs. (24) for diagonal A with *ad hoc* required symmetry with respect to the (extended) Galilei group were analyzed in Refs. 11 and 16. We notice that the algorithm used in the present article reduces such an analysis to routine and simple calculations. For example, to find all systems (1) *with arbitrary n* which are invariant with respect to the Galilei group it is sufficient to solve the system of homogeneous linear equations (31), which is easily integrated for any given invertable matrix A.

In the present article we have restricted ourselves to a complete description of all possible nonlinearities which generate Lie symmetry of Eq. (1). We have not analyzed nonclassical symmetries that may be found with using condition (13) nor have any symmetry reductions been presented. These problems will be a subject of further investigations. Finally, we remark that some of the results of this article have been presented in Ref. 17.

Statistical turbulence suppression by a strong magnetic field: A Feynman path integral argument

Luiz C. L. Botelho
Departamento de Física, Universidade Federal Rural do Rio de Janeiro, 23851-970—Itaguaí, RJ, Brazil

(Received 27 December 1999; accepted for publication 1 September 2000)

We show the suppression of the randomness of the magnetohydrodynamic flux (modeled by the Navier–Stokes equation) in the presence of a random stirring by a Feynman path integral one-loop and low viscosity argument. Additionally, we show exactly the above supressing turbulence phenomenon in the context of Beltrami fluxes. © *2001 American Institute of Physics.* [DOI: 10.1063/1.1319858]

I. INTRODUCTION

One of the long-standing unsolved problems in turbulent magnetohydrodynamics going back to L. Landau (Ref. 1, p. 238) is to produce quantitative arguments for the charged fluid motion turbulence suppression by the presence of a strong magnetic field. In this article, we propose to present in Sec. II such an argument by using our Feynman path integral formulation for turbulence[2] at a low viscosity (turbulent) regime in the context of a background one-loop (Gaussian) approximation. Additionally, we show in Sec. III the above cited suppressing phenomena in the exactly soluble (nonperturbative) path integral context of Beltrami fluxes.

II. THE ONE-LOOP CASE

Let us start our analysis by considering the Navier–Stokes equation for a charged fluid flux in the presence of an uniform magnetic field $\mathbf{B}$ in the z direction and a uniform electric field $\mathbf{E}$ in the plane (x,y):

$$\frac{\partial \mathbf{V}(\mathbf{r},t)}{\partial t}+(\mathbf{V}\cdot\boldsymbol{\nabla})\mathbf{V}(\mathbf{r},t)=\left(e\mathbf{E}+\frac{1}{c}(\mathbf{V}(\mathbf{r},t)\times\mathbf{B})\right)+\nu\Delta\mathbf{V}(\mathbf{r},t)-(\mathbf{grad}P)(\mathbf{r},t)+\mathbf{F}^{\mathrm{ext}}(\mathbf{r},t). \quad (1)$$

Here, the random stirring force (caused by the fluid flux turbulent regime in the statistical-Langevin approach[2]) is such that it satisfies the white-noise Gaussian statistics with disorder strength $D>0$:

$$\langle (F^{\mathrm{ext}})_i(\mathbf{r},t)(F^{\mathrm{ext}})_j(\mathbf{r}',t')\rangle = D\,\delta_{ij}\delta^{(3)}(\mathbf{r},\mathbf{r}')\,\delta(t-t'). \quad (2)$$

It is worthwhile to remark that the presence of such external random fluctuations are considered in this statistical framework with the same conceptual role as used in the usual Langevin–Einstein approach for the study of Brownian motion. It is still missing a turbulence theory for first principles, leading to the master Eq. (1) with Eq. (2).

Now a functional integral shift[2] leads to the exact characteristic functional path integral expression for the random (turbulence) process defined by the magnetohydrodynamic (incompressible) fluid flux Eq. (1) after taking into account the fluid incompressibility condition on the fluid motion $\mathrm{div}\,\mathbf{V}(\mathbf{r},t)=0$ and disregarding the transverse part of the term $((\mathbf{V}\cdot\nabla)\mathbf{V})^{\mathrm{tr}}$ coming from the above mentioned incompressibility condition (see Ref. 2). We obtain, thus, the following Burger magnethydrodynamical turbulent path integral as the main object of our study:

$$Z[\mathbf{J}(\mathbf{r},t)]=\frac{1}{Z[0]}\int D^F[\mathbf{V}(\mathbf{r},t)]\exp\left\{-\frac{1}{2D}\int_{-\infty}^{+\infty}d^3\mathbf{r}\int_{-\infty}^{\infty}dt\left[\frac{\partial}{\partial t}\mathbf{V}-\nu\Delta\mathbf{V}+((\mathbf{V}\cdot\boldsymbol{\nabla})\mathbf{V})\right.\right.$$
$$\left.\left.-\left(e\mathbf{E}+\frac{1}{c}(\mathbf{V}(\mathbf{r},t)\times\mathbf{B})\right)\right]^2(\mathbf{r},t)\right\}\exp\left\{i\int_{-\infty}^{+\infty}d^3\mathbf{r}\int_{-\infty}^{\infty}dt\mathbf{J}(\mathbf{r},t)\cdot\mathbf{V}(\mathbf{r},t)\right\}. \quad (3)$$

Note that the square brackets in the above equation are the usual R^3-norm.

In order to show the randomness suppression of the fluid flux motion in the plane (x,y) normal to the magnetic field B at its strong field limit regime $B\to\infty$, we consider the background flux decomposition

$$\mathbf{V}(\mathbf{r},t)=\boldsymbol{\phi}+\sqrt{D}\mathbf{v}(\mathbf{r},t), \quad (4)$$

where the background flux $\boldsymbol{\phi}$ satisfies the steady-isotropic Ohm's law flux condition $(i=1,2,3)$

$$eE_i=-\frac{1}{c}\varepsilon_{ijk}\phi_jB\delta_{k3}. \quad (5)$$

As for the usual pertubative arguments in quantum field theories (Refs. 2 and Ref. 3, p. 29), we consider the usual one-loop Gaussian approximation for the path integral (3) with the following result:

$$S^{(\varepsilon)}_{\text{one loop}}[\mathbf{v}(\mathbf{r},t)]=\int d^3\mathbf{r}dt(v_1(\mathbf{r},t),v_2(\mathbf{r},t),v_3(\mathbf{r},t)$$

$$\begin{bmatrix} -\left(\frac{\partial}{\partial t}+\phi_i\frac{\partial}{\partial x_i}\right)^2+\frac{B^2}{c^2}+\nu^2\Delta^2 & \frac{2B}{c}\left(\frac{\partial}{\partial t}+\phi^i\frac{\partial}{\partial x_i}\right)+\frac{2\nu}{c}B\Delta & 0 \\ -\frac{2B}{c}\left(\frac{\partial}{\partial t}+\phi^i\frac{\partial}{\partial x_i}\right)-\frac{2}{c}(\nu+\varepsilon)B\Delta & -\left(\frac{\partial}{\partial t}+\phi_i\frac{\partial}{\partial x_i}\right)^2+\frac{B^2}{c^2}+\nu^2\Delta^2 & 0 \\ 0 & 0 & -\left(\frac{\partial}{\partial t}+\phi_i\frac{\partial}{\partial x_i}\right)^2 \end{bmatrix}$$

$$(v_1(\mathbf{r},t),v_2(\mathbf{r},t),v_3(\mathbf{r},t))^T, \quad (6)$$

where we have given a small ε-parameter to the viscosity term in the (2,1) entry of the Gaussian weight matrix associated to our mathematical one-loop theory [defined by just disregarding the nonlinear (cubic and quartic) terms]. Note that this parameter keeps the important interaction viscosity and magnetic field nonzero at this one-loop order.

Let us show the vanishing of the two-point correlation flux at the limit of the very strong magnetic field $B\to\infty$ in the plane (x,y) within the turbulent regime, which is defined phenomenologically in our approach by considering ν such that $B^2/c^2\Lambda^4\gg\nu^2$ and, by its turn, forces us to neglect the term $\nu^2(\Delta\mathbf{v})^2$ in relation to other terms in the matrix entry terms.

Let us use the following matrix inversion formulas to obtain the explicit expression for the flux two-point correlation functions,

$$\begin{bmatrix} a & b & 0 \\ -b+\delta & a & 0 \\ 0 & 0 & c \end{bmatrix}^{-1} = \begin{bmatrix} +\left(\dfrac{a}{a^2-b(-b+\delta)}\right) & -\left(\dfrac{b}{a^2-b(-b+\delta)}\right) & 0 \\ -\left(\dfrac{-b+\delta}{a^2-b(-b+\delta)}\right) & \left(\dfrac{a}{a^2-b(b+\delta)}\right) & 0 \\ 0 & 0 & +\left(\dfrac{1}{c}\right) \end{bmatrix}, \tag{7a}$$

where in momentum frequency space we have explicitly the following matrix entries:

$$\begin{aligned} a &= (w+\mathbf{k}\cdot\boldsymbol{\phi})^2+\frac{B^2}{c^2}, \\ b &= i\frac{2B}{c}(w+\mathbf{k}\cdot\boldsymbol{\phi})^2-\frac{2\nu}{c}B|\mathbf{k}|^2, \\ c &= (w+\mathbf{k}\cdot\boldsymbol{\phi})^2, \\ \delta &= -2\varepsilon\frac{B}{c}|\mathbf{k}|^2. \end{aligned} \tag{7b}$$

Since we are going to remove the parameter ε at the end of our calculations, we can safely use the approximation $\sqrt{b^2-\delta b}=b\sqrt{1-\delta/b^2}\cong b(1-\frac{1}{2}(\delta/b)=b-\delta/2$ in Eq. (7a).

We thus obtain the following structure for the (1,1) entry of the inverse matrix Eq. (7a):

$$\frac{a}{a^2+b^2-b\delta}=\frac{1}{2}\left(\frac{1}{a-i\sqrt{b^2-b\delta}}+\frac{1}{a+i\sqrt{b^2-b\delta}}\right)\cong\frac{1}{2}\left(\frac{1}{a+\frac{1}{2}i\delta-ib}+\frac{1}{a-\frac{1}{2}i\delta+ib}\right). \tag{7c}$$

As a consequence of Eq. (7c) we have the result below for the $x-x$ two-point correlation function in our one-loop approximation:

$$\begin{aligned} \langle v_1(\mathbf{r},t),v_1(\mathbf{r}',t')\rangle = \int_{|\mathbf{k}|<\Lambda} d^3\mathbf{k}\exp[i\mathbf{k}((\mathbf{r}-\mathbf{r}')-\boldsymbol{\phi}(t-t'))]\frac{1}{2}\int_{-\infty}^{+\infty}d\overline{w}e^{-i\overline{w}(t-t')} \\ \times\left\{\left(\frac{1}{\overline{w}^2+(2B/c)\overline{w}+(B^2/c^2-\frac{1}{2}i\delta+(2i\nu/c)B|\mathbf{k}|^2)}\right)\right. \\ \left.+\left(\frac{1}{\overline{w}^2-(2B/c)\overline{w}+(B^2/c^2-\frac{1}{2}i\delta-(2i\nu/c)B|\mathbf{k}|^2)}\right)\right\}. \end{aligned} \tag{8}$$

The first frequency $\overline{w}$-integral Eq. (8) may easily be evaluated by means of the residue theorem applied in the (causal) lower half-plane region $\mathrm{Im}(\overline{w})<0$ {after removing the regularizing parameter $\varepsilon\to 0$ [see Eq. (6)]}:

$$\overline{w}-\text{integral} = \lim_{\varepsilon\to 0}\left(\frac{2\pi\{-\exp[-i(-B/c-\sqrt{((2\nu-\varepsilon)/c)B}|\mathbf{k}|(-\sqrt{2}/2+i\sqrt{2}/2))(t-t')]\theta(t-t')\}}{2(-|\mathbf{k}|(\sqrt{(2\nu-\varepsilon)B/c})\sqrt{2}/2+i|\mathbf{k}|(\sqrt{2}/2)(\sqrt{(2\nu-\varepsilon)B/c}))}\right) \tag{9a}$$

or

$$\langle v_1(\mathbf{r},t),v_1(\mathbf{r}',t')\rangle$$

$$= -2\pi i \frac{\exp((iB/c)(t-t'))\times\theta(t-t')}{\sqrt{(2\nu/c)B}|(\mathbf{r}-\mathbf{r}')-\boldsymbol{\phi}(t-t')|(-\sqrt{2}/2+i(\sqrt{2}/2))}$$

$$\times\left[\frac{1}{2i}\left(\frac{1}{i(-|(\mathbf{r}'-\mathbf{r})-\boldsymbol{\phi}(t-t')-\sqrt{(2\nu/c)B}(\sqrt{2}/2)(t-t')\sqrt{(2\nu/c)B}(t-t'))}\right.\right.$$

$$\left.\left.-\text{complex conjugate}\right)\right]. \tag{9b}$$

Note that we have considered only the residue at the pole $w_+ = -B/c + |\mathbf{k}|\sqrt{[(2\nu-\varepsilon)/c]B} - i\sqrt{2/2}|\mathbf{k}|\sqrt{((2\nu-\varepsilon/c)B}$ in the lower half-plane which by its turn leads straightforwardly to the causal Fourier transform Eq. (9a) vanishing at $t\to\infty$. Now it is easy to see that at the large $B\to\infty$ limit with ν very small *but fixed*, the integral Eq. (9) vanishes. A similar result holds true for the second term of the $\overline{w}$-integral Eq. (8) and produces, thus, the suppression of the randomness at the limit of $B\to\infty$ within our one-loop leading small viscosity approximation, namely,

$$\lim_{B\to\infty}\langle v_1(\mathbf{r},t)v_1(\mathbf{r}',t')\rangle\to 0. \tag{10}$$

Analogously

$$\lim_{B\to\infty}\langle v_1(\mathbf{r},t)v_2(\mathbf{r}',t')\rangle = \lim_{B\to\infty}\langle v_2(\mathbf{r},t)v_2(\mathbf{r}',t)\rangle = 0. \tag{11}$$

However, the flux randomness in the B direction in this context is given exactly by the nonvanishing result (with $\Lambda\to\infty$)

$$\langle v_3(\mathbf{r},t),v_3(\mathbf{r},t)\rangle = \delta^{(3)}((\mathbf{r}-\mathbf{r}')-\boldsymbol{\phi}(t-t'))\frac{e^{-\nu(t-t')}}{\nu}\theta(t-t'). \tag{12}$$

At this point, it is very important to remark that the zero viscosity (full tubulent) regime is a *singular* limit never reached in our approach, a result opposite to those of the instanton calculations of Ref. 4.

Let us comment that our argument is not a theorem and is entirely based on a formal perturbative one-loop approximation for the path integral Eq. (3). Next-loop corrections for Eq. (3) are still an open problem in our framework since the usual renormalization program borrowed from relativistic quantum fields does not make sense in the turbulence context[5] (the usual power counting analysis and unitary conditions are meaningless here). Anyway, it is possible to evaluate ''next-loop corrections'' by introducing a cutoff $|\mathbf{k}|<\Lambda$ and the nonlinear terms in the functional integral weight in Eq. (3). An alternative proposal to analyze Eq. (3) is to devise scaling-decimation (nonperturbative) smearing of short wavelength modes in the momentum space as usually implemented in critical phenomena.[6]

Finally, let us make a strict mathematical comment. It is well known from the rigorous mathematical literature that the Navier–Stokes (NS) equation with completely delta-correlated noise in space cannot be studied rigorously in the sense that it is not possible to prove that it has a solution which is a random field. However, let us conjecture that the *integral equation* version of the NS equation may overcome the estimative problems involved in such unsuccessful mathematical attempts, namely,[2]

$$A_i[\mathbf{v}(\mathbf{r},t)] = B_i[\mathbf{F}(\mathbf{r},t)] \tag{13}$$

with

$$A_i[\mathbf{v}]=v_i(\mathbf{r},t)-\int_0^\infty ds\int_{R^3}d^3\mathbf{r}'O_{ijk}(\mathbf{r}-\mathbf{r}',t-t')\times(V_iV_k)(\mathbf{r}',t') \tag{14}$$

and

$$B_i[\mathbf{F}]=\int_0^\infty ds\int_{R^3}d^3\mathbf{r}'H_{(1)}(\mathbf{r}-\mathbf{r}',t-t')F_i(\mathbf{r}',t'). \tag{15}$$

Here the kernels O_{ijk} and $H_{(1)}$ are given respectively by

$$\begin{aligned} O_{ijk}(z,\xi)&=-\frac{1}{2}\left(\frac{\partial\overline{O}_{ik}}{\partial z_{\not j}}+\frac{\partial\overline{O}_{i\not j}}{\partial z_k}\right)(z,\xi),\\ \widetilde{O}_{pq}(z,\xi)&=\delta_{pq}\theta(\xi)H_0(|z|,\xi)+\frac{\partial^2}{\partial z_p\partial z_q}\left(\frac{2\nu\xi}{|z|}\int_0^{|z|}H_0(|z'|,\xi)dz'\right), \end{aligned} \tag{16}$$

$$H_{(0)}(|z|,\xi)=\frac{1}{(4\pi\nu|\xi)^{3/2}}\exp\left(-\frac{|z^2|}{4\pi\nu\xi}\right) \tag{17}$$

$$H_{(1)}(|z|,\xi)=\theta(\xi)H_{(0)}(|z|,\xi). \tag{18}$$

Anyway, we took the philosophy that the functional integral Eq. (3) is the main passive object to be analyzed mathematically (that functional integral should define the NS random equation!). It is very worthwhile to remark that the differential nonlinear NS equation does not make sense in principle for fluid configurations which are distributional objects as it must be expected with completely delta-correlated noise in space as we have shown in this article.

Note that in this path integral framework, the usual nonrandom NS equation is correctly obtained from the minimum functional point limit $D\to 0$ in Eq. (3). The objects that satisfy the differential Navier–Stokes equation with randomness are now the n-point correlation functions

$$\lim_{\mathbf{J}\to 0}\{\delta^N Z[\mathbf{J}(\mathbf{r},t)]/\delta J_1(\mathbf{r}_1,t_1)\cdots\delta J_N(\mathbf{r}_N,t_N)\}=\langle v_1(\mathbf{r}_1,t_1)\cdots v_N(\mathbf{r}_N,t_N)\rangle\times(-1)^N. \tag{19}$$

At this point we call to the reader's attention that this infinite-coupled set of classical equations must be shown to have a rigorous mathematical solution instead of the formal mathematical object in Eq. (1).

As a final comment on our perturbative argument presented here, let us point out that in the case *of not neglecting the term* $\nu^2\Delta^2$ in Eq. (7a), Eq. (8) now takes the following form (with $\Lambda=\infty$ and $\varepsilon=0$!):

$$\begin{aligned} \langle v_1(\mathbf{r},t)v_1(\mathbf{r}',t')\rangle=&\int_{-\infty}^{+\infty}d^3\mathbf{k}e^{i[\mathbf{k}((\mathbf{r}-\mathbf{r}')-\phi(t-t'))]}\times\frac{1}{2}\int_{-\infty}^{+\infty}d\overline{w}e^{-i\overline{w}(t-t')}\\ &\times\left\{\left(\frac{1}{\overline{w}^2+(2B/c)\,\overline{w}+(B^2/c^2+\nu^2|\mathbf{k}|^4+(2i\nu/c)\,B|\mathbf{k}|^2)}\right)\right.\\ &\left.\times\left(\frac{1}{\overline{w}^2-(2B/c)\overline{w}+(B^2/c^2+\nu^2|\mathbf{k}|^4-(2i\nu/c)\,B|\mathbf{k}|^2)}\right)\right\}. \end{aligned} \tag{20}$$

The same analysis implemented to Eq. (9) may be applied and leads to the same qualitative formal result. For instance, we have the behavior at large B

$$\lim_{B\to\infty}\int_{-\infty}^{+\infty} d\overline{w} e^{-\overline{w}(t-t')}\left(\frac{1}{\overline{w}^2+(2B/c)\overline{w}+(B^2/c^2+\nu^2|\mathbf{k}|^4-(2i\nu/c)B|\mathbf{k}|^2)}\right)$$
$$\times \lim_{B\to\infty}\exp\left\{-it\left(-\frac{B}{c}-\nu k^2\left(1+\frac{4B^2}{\nu^2c^2|\mathbf{k}|^4}\right)^{1/4}\left(i\frac{\sqrt{2}}{2}-\frac{\sqrt{2}}{2}\right)\right)\right\}$$
$$\simeq \lim_{B\to\infty}\exp\left\{-\left[\nu|\mathbf{k}|^2 t\frac{\sqrt{2}}{2}\left(1+\frac{4B^2}{\nu^2c^2|\mathbf{k}|^4}\right)^{1/4}\right]\right\}\sim 0, \tag{21}$$

which again indicates the randomness suppression at the limit of a very strong magnetic field for a charged fluid under the presence of an eletromagnetic field (laser) for any value of ν (including the case of physical turbulence phenomenologically modeled with very small ν).

III. A SOLUBLE MODEL OF TURBULENCE SUPPRESSION IN TURBULENT MAGNETOHYDRODYNAMICS

The celebrated Landau conjecture on the suppressing of turbulence (or randomness in the statistical approach) by a strong magnetic field, analyzed in Sec. II within the context of the path integral approximations stated there, can be displayed exactly in the following reduced degrees of freedom model of Beltrami fluxes in a turbulent regime defined analitically by $\mathrm{rot}\mathbf{v}(\mathbf{r},t)=\lambda\mathbf{v}(\mathbf{r},t)$.[7]

Let us, thus, start with the magnetohydrodynamical Navier–Stokes Eq. (1) in the following suitable form for Beltrami fluxes:

$$\frac{\partial\mathbf{v}(\mathbf{r},t)}{\partial t}+\left\{\frac{1}{2}\,\mathrm{grad}[(\mathbf{v}\cdot\mathbf{v})(\mathbf{r},t)]-(\mathbf{v}\times\mathrm{rot}\cdot\mathbf{v})(\mathbf{r},t)\right\}$$
$$=-\,\mathrm{grad}\,P(\mathbf{r},t)+\nu\Delta\mathbf{v}(\mathbf{r},t)+\mathbf{F}^{\mathrm{ext}}(\mathbf{r},t)+\frac{1}{c}(\mathbf{v}(\mathbf{r},t)\times\mathbf{B}). \tag{22}$$

It is important to remark that the wave vectors of the Beltrami hydrodynamical motions have eddies of a fixed scale $|\mathbf{k}|=\lambda$, as consequence of a Fourier (wave vector) transformation of the Beltrami condition.[7]

Let us, thus, suppose that the random stirring force in Eq. (23) satisfies the *spatially nonlocal* Gaussian statistics

$$\langle(F^{\mathrm{ext}})_i(\mathbf{r},t);(F^{\mathrm{ext}})_j(\mathbf{r}',t')\rangle_{|\mathbf{k}|=\lambda}=\lambda^2\delta_{ij}((\Delta^{-1})\delta(\mathbf{r}-\mathbf{r}')\delta(t-t'). \tag{23}$$

At this point, we remark that we assume implicity the same vector constraint $|\mathbf{k}|=\lambda$ in our random stirring equation (24), namely the exact expression for the right-hand side of Eq. (24) is given below:

$$\langle(F^{\mathrm{ext}})_i(\mathbf{r},t);(F^{\mathrm{ext}})_j(\mathbf{r}',t)\rangle=\frac{\delta_{ij}\cdot\lambda\cdot\mathrm{Sen}(\lambda|\mathbf{r}-\mathbf{r}'|)}{2\pi|\mathbf{r}-\mathbf{r}'|}\cdot\delta(t-t'). \tag{24}$$

At this point in our study, we consider the already mentioned Beltrami flux condition and its direct consequences, namely,

$$\lambda^2\mathbf{v}(\mathbf{r},t)=\mathrm{rot}(\mathrm{rot}\,\mathbf{v}(\mathbf{r},t))=-\Delta\mathbf{v}(\mathbf{r},t), \tag{25}$$

$$(\mathbf{v}\times\mathrm{rot}\,\mathbf{v})(\mathbf{r},t)=(\mathbf{v}\times\lambda\mathbf{v})(\mathbf{r},t)=0, \tag{26}$$

in order to replace the Navier–Stokes Eq. (23) by the exactly soluble Langevin-type fluid flux stirred by the external force $\mathbf{\Omega}^{\mathrm{ext}}(\mathbf{r},t)=\mathrm{rot}(\mathbf{F}^{\mathrm{ext}})(\mathbf{r},t)$:

$$\frac{\partial \mathbf{v}(\mathbf{r},t)}{\partial t}=(-\nu\lambda^2)\mathbf{v}(\mathbf{r},t)+\frac{1}{\lambda}\mathbf{\Omega}^{\mathrm{ext}}(\mathbf{r},t)+\frac{1}{c\lambda}(\mathbf{B}\cdot\mathbf{\Delta})\mathbf{v}(\mathbf{r},t). \tag{27}$$

Here the new external stirring $\mathbf{\Omega}^{\mathrm{ext}}(\mathbf{r},t)$ satisfies a Gaussian process with the following two-point correlation function (again with $|\mathbf{k}|=\lambda$!):

$$\langle \Omega_{\mathrm{l}}^{\mathrm{ext}}(\mathbf{r},t);\Omega_{\mathrm{l}'}^{\mathrm{ext}}(\mathbf{r}',t')\rangle=\lambda^2\delta^{\mathrm{ll}'}\delta^{(3)}(\mathbf{r}-\mathbf{r})\,\delta(t-t')-\lambda^2\partial_{\mathrm{l}}^{(r)}\partial_{\mathrm{l}'}^{(r')}(\Delta_r^{-1}\delta(\mathbf{r}-\mathbf{r}'))\,\delta(t-t'). \tag{28}$$

Now a simple functional integral shift leads to the following exactly soluble Feynman path integral for our Beltrami magnetohydrodynamic reduced model:

$$Z[\mathbf{j}(\mathbf{r},t)=\frac{1}{Z(0)}\times\int D^F[\mathbf{v}(\mathbf{r},t)]\exp\left\{-\frac{1}{2}\int_{-\infty}^{+\infty}dr^3\int_0^{\infty}dt\left[\frac{\partial\mathbf{v}}{\partial t}-\frac{1}{\lambda c}(\mathbf{B}\cdot\nabla)\mathbf{v}+\nu\lambda^2\mathbf{v}\right]^2(\mathbf{r},t)\right\}$$
$$\times\exp\left\{i\int_{-\infty}^{+\infty}d^3\mathbf{r}\int_0^{\infty}dt(\mathbf{j}\cdot\mathbf{v})(\mathbf{r},t)\right\}. \tag{29}$$

It is worthwhile remarking that we have used incompressible constraint $\partial_i^{(r)}v^i(\mathbf{r},t)=0$ to obtain that the spatially nonlocal piece of Eq. (29) does not contribute to the final path integral weight in Eq. (30).

Now the Fourier transformed expression for the correlation functions associated to the Beltrami magnetohydrodynamical model Eq. (30) are given exactly by (note again the wave vector constraint $|\mathbf{k}|=\lambda$ in the model formulas!)

$$\langle v_i(\mathbf{r},t)v_j(\mathbf{r}',t')\rangle=\delta_{ij}\times\frac{e^{-\nu\lambda^2|t-t'|}}{\nu\lambda^2}\times\left\{\int_{|\mathbf{k}|=\lambda}d^3\mathbf{k}e^{i\mathbf{k}[(\mathbf{r}-\mathbf{r}')-\mathbf{B}/c\lambda\,(t-t')|]}\right\}$$
$$=2\,\delta_{ij}\left(\frac{e^{\nu\lambda^2|t-t'|}}{\nu\lambda}\right)\frac{\mathrm{sen}[\lambda(|\mathbf{r}-\mathbf{r}')-(\mathbf{B}/c\lambda)\,(t-t')|)]}{|(\mathbf{r}-\mathbf{r}')-(\mathbf{B}/c\lambda)\,(t-t')|}. \tag{30}$$

It is a direct consequence of the exact expression of Eq. (29) that for the limit of strong magnetic field $|\mathbf{B}|\to\infty$, we get the vanishing of the correlation functions [Eq. (29)] and, thus, the exactly randomness suppression in our Beltrami magnetohydrodynamical model Eq. (28) and corroborate the Landau conjecture (Ref. 1) and the correctness of our one-loop calculations presented in the bulk of this article [Eqs. (10) and (11)].

APPENDIX: THE ONE-LOOP ACTION

In this Appendix we show for completeness the Gaussian one-loop approximation for Eq. (3). Let us consider the complete functional integral weight

$$W[\mathbf{v}(\mathbf{r},t)]=\frac{1}{2D}\left[\frac{\partial v^i}{\partial t}+v^j\frac{\partial}{\partial x_j}v^i+(-\nu\Delta v^i)-eE^i-\frac{1}{c}\varepsilon^{ijk}v^jB^k\right]^2. \tag{A1}$$

By making the background field decomposition [Eq. (5)] on the manifold $\{\mathbf{v}(\mathbf{r},t)\}$ define the domain of the functional integral [Eq. (3)], one easily obtains the following result:

$$W[\mathbf{v}(\mathbf{r},t)]=\left(\frac{\partial v^i}{\partial t}\right)^2+\left(\phi_j\frac{\partial}{\partial x_j}v^i\right)^2+\nu^2(\Delta v^i)^2+\left(-\frac{1}{c}\varepsilon^{ijk}v^jB^k\right)^2+2\left(\frac{\partial v^i}{\partial t}\right)\left(\phi_j\frac{\partial}{\partial x_j}v^i\right)+2\left(\frac{\partial}{\partial t}v^i\right)$$
$$\times(-\nu\Delta v^i)+2\left(\frac{\partial v^i}{\partial t}\right)\left(-\frac{1}{c}\varepsilon^{ijk}v^jB^k\right)+2\phi_j\frac{\partial}{\partial\lambda_j}v^i(-\nu\Delta v^i)$$
$$+2\phi_j\frac{\partial}{\partial x_j}v^i\left(-\frac{1}{c}\varepsilon^{ijk}v^jB^k\right)+\frac{2\nu}{c}\Delta v^i\varepsilon_{ijk}v^jB^k+\text{nonquadratic terms.} \tag{A2}$$

Since under the integration on $R^3\times R$ the terms below are zero and since $\lim_{t\to\pm\infty}v^i(\mathbf{r},t)=\lim_{|\mathbf{r}|\to+\infty}v^i(\mathbf{r},t)=0$, namely

$$\int_{-\infty}^{+\infty}dt\int_{-\infty}^{+\infty}d^3\mathbf{r}\left(\frac{\partial v^i}{\partial t}\Delta v_i\right)(\mathbf{r},t)=\int_{-\infty}^{+\infty}d^3r\Delta\left(\int_{-\infty}^{+\infty}\frac{1}{2}\frac{\partial}{\partial t}(v^iv_i)=0\right), \tag{A3}$$

$$\int_{-\infty}^{+\infty}dt\int_{-\infty}^{+\infty}d^3\mathbf{r}\left(\left(\phi_j\frac{\partial}{\partial x_j}v^i\right)(\Delta v_i)\right)(\mathbf{r},t)=\int_{-\infty}^{+\infty}dt\int_{-\infty}^{+\infty}d^3\mathbf{r}\phi_jv^i\left(\left(\frac{\partial}{\partial x_j}v^i\right)\right)$$
$$=\int_{-\infty}^{+\infty}dt\int_{-\infty}^{+\infty}d^3\mathbf{r}\phi_j\Delta v^i\frac{\partial}{\partial x_j}v_i=0. \tag{A4}$$

Besides, we have kept a small ε-regularization of the important interaction term among viscosity and the magnetic field:

$$2\left(\frac{\nu}{c}\Delta v^i\right)(\varepsilon^{ijk}v^jB^k)\leftrightarrow\frac{2\nu}{c}\Delta v^i\cdot v_2B-\frac{2(\nu+\varepsilon)}{c}\Delta v^2\cdot v_1B. \tag{A5}$$

As a result we obtain the result shown in Eq. (6) under the form of an operator valued 3×3 matrix defining the Gaussian one-loop approximation of the full path integral weight Eq. (A1).

(Received 24 July 2000; accepted for publication 20 December 2000)

We give a general formulation of the algorithm of Fokas and Ablowitz, which then allows us to obtain transformations for nth order ordinary differential equations, to equations of the same order but perhaps of higher degree. Previously this algorithm has been used to obtain transformations for the six second order equations defining new transcendental functions discovered by Painlevé and co-workers, either to other equations in the Painlevé classification or to equations of second order and second degree. As an example of our approach we consider a new fourth order ordinary differential equation due to Cosgrove which is believed to define a new transcendent. We obtain transformations relating this equation to other fourth order ordinary differential equations, of degrees $\geqslant 2$. All of these transformations, as well as the corresponding higher degree differential equations, all of which have the Painlevé property, are new. © *2001 American Institute of Physics.*

I. INTRODUCTION

As is well known, the six Painlevé equations ($P_I,\ldots,P_{VI}$) have for many years been the subject of much intensive research. One particular aspect of that research, of interest to many authors, has been the discovery of transformations relating a particular Painlevé equation either to itself (with possibly different values for any parameters appearing as coefficients), or to another second order ordinary differential equation (ODE). With this aim in mind, Fokas and Ablowitz[1] developed an algorithmic approach to obtaining transformations for second order ODEs in the Painlevé classification, either to second order ODEs linear in the second derivative (and so in the same Painlevé classification) or to ODEs of second order and second degree. In Ref. 1 the first of these two cases was investigated for P_{II}–P_V, and the second for P_{VI}. The second case has been investigated for P_I–P_{VI} in Refs. 2 and 3.

In the present article we give a general formulation of this algorithm, allowing us to obtain transformations for nth order ODEs of the form

$$V^{(n)}=F(V^{(n-1)},V^{(n-2)},\ldots,V;x), \tag{1}$$

where F is rational in $V^{(n-1)},\ldots,V$ with coefficients dependent on x, to ODEs of the same order but perhaps of higher degree. Thus we see that this algorithm can be applied to ODEs of order higher than 2, and can be used to obtain transformations to ODEs of degree greater than 2. As an example we apply this approach to a fourth order ODE recently found by Cosgrove, and which is believed to define a new transcendent.[4] We obtain transformations to a variety of fourth order ODEs, of degrees $\geqslant 2$. These transformations and the corresponding ODEs, all of which have the Painlevé property, are all new. We also indicate further possible extensions of this algorithm.

II. THE FOKAS–ABLOWITZ ALGORITHM

Given an ODE of the form (1), we seek a transformation to an ODE in U, also of order n, defined by the relation

$$(dV^2+eV+f)U-(V'+aV^2+bV+c)=0, \tag{2}$$

where a, b, c, d, e and f are all functions of x only. Taking $n-1$ derivatives of this expression yields a polynomial in $U,\ldots,U^{(n-1)}$ and $V,\ldots,V^{(n)}$. Using (1) to replace $V^{(n)}$, and the jth derivative of (2) to replace $V^{(j+1)}$, $j=0,\ldots,n-2$, then gives a polynomial (say of degree N) in V with coefficients in $U,\ldots,U^{(n-1)}$,

$$\sum_{i=0}^{N}\alpha_i V^i=0. \tag{3}$$

In (3) each α_i is at most linear in $U^{(n-1)}$; in the case where F is a polynomial function of $V^{(n-1)},\ldots,V$, only α_0, α_1 and α_2 can depend on $U^{(n-1)}$.

In the general case, when $N>1$, we thus obtain V as an algebraic function of $U,\ldots,U^{(n-1)}$, and substitution into (2) then gives an ODE in U of order n related to (1) by the transformation (2). We could alternatively eliminate V between (2) and (3) by differentiating (3) and using (2) to replace V' in order to obtain a second polynomial in V, whose coefficients now also depend on $U^{(n)}$, and then successively eliminating leading order coefficients between this and (3), until we obtain an expression linear in V. Solving this for V and substituting back into (3)—or into one of the polynomials obtained during the elimination process—then gives an ODE in U of order n and of higher degree; the expression for V defines the inverse of (2).

However, of more interest than this general case is the case where, for certain choices of the coefficients a, b, c, d, e and f, the polynomial (3) reduces to a polynomial of degree less than N, say M,

$$\sum_{i=0}^{M}A_i V^i=0. \tag{4}$$

This occurs either when some leading order coefficients in (3) vanish, or when (3) factorizes, or both. We can explore the second of these cases by seeking a factorization of (3),

$$\sum_{i=0}^{N}\alpha_i V^i-\left(\sum_{i=0}^{N-M}g_i V^i\right)\left(\sum_{i=0}^{M}A_i V^i\right)=0, \tag{5}$$

where the coefficients A_i are functions of $U,\ldots,U^{(n-1)}$ and x, and the coefficients g_i are functions of x only, and $g_{N-M}=1$. [We proceed similarly if considering the factorization of (3) in the case where some leading order coefficients vanish.]

In the relation (5), we solve the coefficients of $V^N,\ldots,V^{N-M}$ for $A_M,\ldots,A_0$ (so $A_M=\alpha_N$). We then set the remaining coefficients of V identically to zero (as polynomials in $U,\ldots,U^{(n-1)}$) in order to determine g_i and any constraints on a, b, c, d, e and f. Provided that we are able to obtain a consistent solution, we then obtain a lower degree polynomial (4). In the case where $M=1$, V is easily determined from (4); substitution into (2) then gives an ODE of order n. In the case where $M>1$ we obtain the corresponding nth order ODE in U in the same way as discussed previously in the general case (3). [We note that obtaining an ODE of order n requires that at least one A_i in (4) depends on $U^{(n-1)}$; thus, for example, in the case where F is polynomial we must have $M=N-2$ or $N-1$.]

The above is a general statement of the algorithm presented in Refs. 1–3 for the case $n=2$ (second order) and $M=1$ or 2 (transformations to second order ODEs of degree 1 or 2). We note

that the requirement that all g_i are functions of x only is stronger than that usually made; we return to this point in the conclusions. We now consider the application of the above algorithm to a fourth order ODE.

III. APPLICATION TO COSGROVE'S EQUATION

We now consider a fourth order ODE due to Cosgrove,[4,5]

$$E[V] \equiv V'''' + 12VV'' + 6(V')^2 + \tfrac{32}{3}V^3 + p(V'' + 4V^2) - qX = 0, \tag{6}$$

where p and q are both constant. This ODE is of considerable interest, since it is believed to define a new transcendent.[4] Hierarchies of ODEs and partial differential equations (in $1+1$ and $2+1$ dimensions) related to the above ODE, together with their underlying linear problems, can be found in Refs. 6 and 7. Further generalizations can be found in Ref. 8.

Seeking a transformation for (6) as described above leads to a quintic in V [(3) with $N=5$],

$$\sum_{i=0}^{5} \alpha_i V^i = 0, \tag{7}$$

with α_0, α_1 and α_2 linear in U''', and with

$$\alpha_5 = 24(a - dU)^4. \tag{8}$$

Our analysis now consists of seeking lower degree polynomials (4). We consider two cases, according as to whether $\alpha_5 = 0$ or $\alpha_5 \neq 0$. We give full details in the first case, but for the second, for reasons of brevity, we restrict ourselves to writing down the final transformations (2) and the coefficients of the lower degree polynomial (4), i.e., we do not write down the inverse mapping giving V in terms of U, U', U''' and U''''.

A. Case 1: $\alpha_5 = 0$

In this case we have $a = d = 0$, for which values α_4 also vanishes, and (7) reduces to a cubic,

$$\sum_{i=0}^{3} \alpha_i V^i = 0, \tag{9}$$

with α_0 and α_1 linear in U''', and with

$$\alpha_3 = \tfrac{32}{3}. \tag{10}$$

Again rather than consider this general case, related to (6) by the transformation

$$U = \frac{V' + bV + c}{eV + f}, \tag{11}$$

wherein all coefficients are arbitrary, it is more interesting to seek a transformation to an ODE in U defined by a lower degree polynomial in V. Since in (9) we have $\alpha_3 \neq 0$, the only possibility is to seek a factorization of (9), i.e., to consider (5) with $N=3$ and $M=1$ or 2.

For $M=1$ we seek a factorization as

$$\sum_{i=0}^{3} \alpha_i V^i - (V^2 + gV + h)\left(\frac{32}{3}V + B\right) = 0, \tag{12}$$

from which we quickly determine B. However, requiring that the remaining coefficients of V in (12) (i.e., of V and V^0) vanish identically requires that $e = f = 0$. Thus we are unable to obtain a linear factor [see (11)].

For $M=2$ we seek a factorization as

$$\sum_{i=0}^{3}\alpha_i V^i-(V+g)\left(\frac{32}{3}V^2+BV+C\right)=0, \tag{13}$$

and again we easily determine B and C. We are then left with the coefficient of V^0, which we make vanish identically as a polynomial in U, U', U'' and U'''. One of the coefficients of this polynomial is $eg-f$, from which we see that if $e=0$ then we must also have $f=0$. Thus we must have $e\neq 0$. In this case we can assume (using a Möbius transformation) that $e=1$ and $b=0$. We thus obtain that $g=f$. From other coefficients in this polynomial we find that $c=f'$, and also that f defines a second solution of Cosgrove's equation, since $f=-w$ satisfies $E[w]=0$. In summary, we have a transformation

$$U=\frac{(V-w)'}{V-w}, \tag{14}$$

corresponding to which we have the quadratic in V

$$AV^2+BV+C=0, \tag{15}$$

where

$$A=\tfrac{32}{3}, \tag{16}$$

$$B=\tfrac{2}{3}(6p+27U^2+16w+18U'), \tag{17}$$

$$C=p(U'+U^2+4w)+U^4-6U^2w+(32/3)w^2+6U^2U' \tag{18}$$

$$+3(U')^2+12Uw'+4UU''+12w''+U'''', \tag{19}$$

and where w also satisfies (6). Elimination between (14) and (15) leads to an expression for V in terms of U [the inverse of (14)],

$$\begin{aligned}V=&[U''''+12w''+2UU''-12Uw''+10U'U''-2U^2U''+24U'w'+32ww'-12U^2w'\\&+6U(U')^2-24UU'w-8U^3U'-32Uw^2-6U^3w-2U^5+p(U''+8w'-12Uw-2U^3)]/\\&[2(2pU+9U^3+16Uw-12UU'-16w'-6U'')],\end{aligned} \tag{20}$$

and substitution into (15) then yields an ODE in U of fourth order and second degree, with coefficients depending on w, a second solution of Cosgrove's equation.

B. Case 2: $\alpha_5\neq 0$

In this case we assume that not both of a and d vanish, and we seek a factorization of the quintic (7). We quickly find that there is no factorization for $M=1$ and $M=2$. (Note also that for these choices of M, no A_i can depend on U'''.)

This then leaves us with the cases $M=3$ and $M=4$.

1. M=3

We seek a factorization of our quintic as

$$\sum_{i=0}^{5}\alpha_i V^i-(V^2+gV+h)[24(a-dU)^4V^3+BV^2+CV+D]=0, \tag{21}$$

from which we quickly obtain B, C, and D. We are then left with the coefficients of V and V^0 (polynomials in U, U', U'' and U'''), which we make vanish identically.

We find that if $d=0$, then both e and f must also vanish. We must therefore have $d\neq 0$, in which case we may assume (by use of a Möbius transformation) that $d=1$ and $a=0$. In this case we obtain $g=e$ and $h=f$, and $c=(be+e')/2$.

We then find that $b(e^2-4f)+(1/2)(e^2-4f)'=0$, and so our analysis splits into two cases: $e^2-4f=0$, and $e^2-4f\neq 0$.

Case 1: In this first case, we have $f=e^2/4$, and we find that our two remaining coefficients in the transformation (2), b and e, satisfy a pair of coupled ODEs. The second of these coefficients, e, defines a second solution of Cosgrove's equation; setting $e=-2w$, we find that $E[w]=0$. The coefficient b is then determined by the ODE

$$b'''-4bb''-3(b')^2+6b^2b'-b^4+(12w+p)(b'-b^2)+12w'b-4(3w''+8w^2+2pw)=0. \tag{22}$$

This equation is a special case of Chazy Class XII (N=2);[9] setting

$$b=\lambda(x)y(\zeta)+\mu(x), \quad \zeta=\zeta(x), \tag{23}$$

where $\zeta'=2\lambda$, $\mu=(3\lambda')/(2\lambda)$, and $\Lambda=\lambda'/\lambda$ satisfies the Riccati equation $\Lambda'-(1/2)\Lambda^2-(1/5)(12w+p)=0$, obtains

$$\dddot{y}-2y\ddot{y}-\tfrac{3}{2}(\dot{y})^2+\tfrac{3}{2}y^2\dot{y}-\tfrac{1}{8}y^4+\gamma=0, \tag{24}$$

wherein this last $\gamma(\zeta)$ is defined by

$$\gamma(\zeta(x))=\frac{1}{10\lambda^4}\left(\frac{9}{80}p^2-\frac{73}{10}pw-\frac{119}{5}w^2-\frac{21}{2}w''\right), \tag{25}$$

and $\dot{}$ denotes differentiation w.r.t. ζ. We recall[9,10] that the most general equation in this class with the Painlevé property (when put in canonical form) is

$$\dddot{y}-2y\ddot{y}-\tfrac{3}{2}(\dot{y})^2+\tfrac{3}{2}y^2\dot{y}-\tfrac{1}{8}y^4+\alpha y+\beta=0, \tag{26}$$

where α and β are two arbitrary functions of ζ. Thus we see that our Eq. (22) is equivalent to a special case of this last equation, with $\alpha=0$ and with β defined in terms of a solution of Cosgrove's equation. Equation (24) can be linearized [as can (26)] by the transformation $y=-2\dot{u}/u$.[9] Thus our Eq. (22) is linearizable.

Our final results in this case are therefore that we have a transformation defined by

$$U=\frac{(V-w)'+b(V-w)}{(V-w)^2}, \tag{27}$$

where w is a second solution of Cosgrove's equation, and where b satisfies (22), a linearizable equation with coefficients defined in terms of w. Corresponding to this transformation we have a cubic in V,

$$AV^3+BV^2+CV+D=0, \tag{28}$$

where

$$A=24U^4, \tag{29}$$

$$B=6U^2(5-10bU-12U^2w+6U'), \tag{30}$$

$$C=\tfrac{2}{3}(16-72bU+3pU^2+75b^2U^2-54U^2w+180bU^3w+108U^4w^2 \tag{31}$$

$$-30b'U^2+18U'-78bUU'-108U^2U'w+9(U')^2+12UU''), \tag{32}$$

$$D=\tfrac{1}{3}(12p+54b^2-9pbU-45b^3U+64w+36bUw-6pU^2w \tag{33}$$

$$-150b^2U^2w+18U^2w^2-180bU^3w^2-72U^4w^3-36b'+75bb'U \tag{34}$$

$$+60b'U^2w+3pU'+51b^2U'+156bUU'w+108U^2U'w^2-27b'U' \tag{35}$$

$$-18(U')^2w+36Uw'-15b''U-21bU''-24UU''w+3U'''). \tag{36}$$

Elimination of V between (27) and (28) then gives a fourth order ODE in U of degree three, with coefficients depending on w and b.

Case 2: We now assume $e^2-4f\neq 0$. We solve for b as $b=-(e^2-4f)'/(2(e^2-4f))$. In the resulting equations in e and f we make the change of variables $e=-(w+r)$ and $f=wr$ (so $w\neq r$), and we then find that both w and r satisfy Cosgrove's equation. Our final result in this case is that we have a transformation defined by

$$U=\frac{(rV'-r'V)+(wr'-w'r)+(Vw'-V'w)}{(r-V)(w-r)(V-w)}, \tag{37}$$

where both w and r are also solutions of Cosgrove's equation. In fact this transformation is a symmetric mapping of three different solutions (V, w and r) of Cosgrove's equation; we note also that the numerator consists of the the sum of the Wronskians of these three solutions. Corresponding to this transformation we have a cubic in V,

$$AV^3+BV^2+CV+D=0; \tag{38}$$

we give the coefficients A, B, C, D in Appendix A. Elimination of V between (37) and (38) then gives a fourth order ODE in U of degree three, with coefficients depending on w and r. [We could also, of course, obtain an ODE with coefficients depending on V and w, or V and r, by appropriate elimination between Cosgrove's equation (in r or w respectively) and the transformation (37).]

2. M=4

We now seek a factorization of our quintic as

$$\sum_{i=0}^{5}\alpha_iV^i-(V+g)[24(a-dU)^4V^4+BV^3+CV^2+DV+E]=0, \tag{39}$$

from which we easily obtain B, C, D and E. We are then left with the coefficient of V^0 (a polynomial in U, U', U'' and U'''), which we make vanish identically.

We find that we must have $f-eg+dg^2=0$. We consider this condition in the two cases $d=0$ or $d\neq 0$. We consider first the case $d=0$.

Case 1: We assume that $d=0$. We then have $f-eg=0$. When $e=0$, we find we must have $f=0$, which cannot be allowed. Thus we have $e\neq 0$, in which case (using a Möbius transformation) we may assume $e=1$ and $b=0$. We then solve for g as $g=f$. We then find $c=f'-af^2$, and that f defines a second solution of Cosgrove's equation; setting $f=-w$, we find that $E[w]=0$.

Thus our final results in this case are that we have a transformation defined by

$$U=\frac{(V-w)'+a(V^2-w^2)}{(V-w)}, \tag{40}$$

where w also satisfies Cosgrove's equation, and a is arbitrary. Corresponding to this transformation we have the quartic in V,

$$AV^4+BV^3+CV^2+DV+E=0, \tag{41}$$

where

$$A=24a^4, \tag{42}$$

$$B=6a^2(5-10aU+4a^2w-6a'), \tag{43}$$

$$\begin{aligned}C=&\tfrac{2}{3}(16+3pa^2-72aU+75a^2U^2+45a^2w-30a^3Uw-24a^4w^2-18a'+78aa'U\\&-54a^2a'w+9a'^2+30a^2U'-60a^3w'+12aa''),\end{aligned} \tag{44}$$

$$\begin{aligned}D=&\tfrac{1}{3}(12p-9paU+54U^2-45aU^3+32w+6pa^2w-36aUw-30a^2U^2w-18a^2w^2\\&+120a^3Uw^2-48a^4w^3-3pa'-51a'U^2-36a'w+42aa'Uw+36a^2a'w^2+18(a')^2w\\&+36U'-75aUU'+30a^2U'w-27a'U'-108aw'+150a^2Uw'-60a^3ww'+114aa'w'\\&-21a''U+24aa''w-15aU''+30a^2w''-3a'''),\end{aligned} \tag{45}$$

$$\begin{aligned}E=&\tfrac{1}{3}(3pU^2+3U^4+12pw-3paUw-18U^2w+21aU^3w+32w^2+36aUw^2-48a^2U^2w^2\\&-18a^2w^3+24a^3Uw^3-3pa'w+15a'U^2w-54aa'Uw^2+36a^2a'w^3+3pU'+18U^2U'\\&+3aUU'w-18a^2U'w^2-9a'U'w+9(U')^2-6paw'+36Uw'-36aU^2w'-36aww'\\&-6a^2Uww'+36a^3w^2w'-48a'Uw'+54aa'ww'-36aU'w'+36a^2(w')^2-3a''Uw\\&-18a''w'+12UU''-9aU''w+36w''-24aUw''+18a^2ww''-18a'w''-3a'''w+3U'''\\&-6aw'''),\end{aligned} \tag{46}$$

Elimination of V between (40) and (41) then gives a fourth order ODE in U of degree four, with coefficients depending on w and a. We note that in the case $a=0$ the transformation (40) becomes the transformation (14) and the quartic (41) becomes the quadratic (15).

Case 2: We now assume $d\neq 0$. We can then assume (using a Möbius transformation) that $d=1$ and $a=0$. We then have (see earlier) that $f=eg-g^2$. We then obtain that $(e-2g)(c-bg-g')=0$. However, taking $e=2g$ leads in any case to $(c-bg-g')=0$, and so we restrict our attention to the choice $c=bg+g'$. We then obtain that w defined by $g=-w$ is also a solution of Cosgrove's equation.

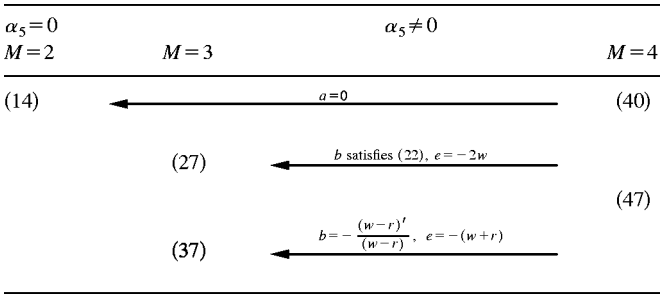
Our final results in this case are then that we have a transformation defined by

$$U=\frac{(V-w)'+b(V-w)}{V^2-w^2+e(V-w)}, \tag{47}$$

where w also satisfies Cosgrove's equation, and b and e are arbitrary. Corresponding to this transformation we have a quartic in V,

$$AV^4+BV^3+CV^2+DV+E=0; \tag{48}$$

TABLE I. Relations between transformations obtained.



we give the coefficients A, B, C, D, E in Appendix B. Elimination of V between (47) and (48) then gives a fourth order ODE in U of degree six, with coefficients depending on w, b and e. We note that taking $e=-2w$, and assuming that b satisfies (22), gives the transformation (27) together with the factorization of our quartic to yield the corresponding cubic factor (28) of (7). We note also that taking $b=-(w-r)'/(w-r)$ and $e=-(w+r)$, where r is also assumed to satisfy Cosgrove's equation, gives the transformation (37) together with the factorization of our quartic to yield the corresponding cubic factor (38) of (7).

We summarize relations between the different transformations obtained in this article in Table I. We see that there are two transformations from which the other three can be derived.

IV. CONCLUSIONS AND OUTLOOK

The Fokas–Ablowitz algorithm was originally phrased to obtain transformations for second order ODEs, to second order ODEs of degrees one or two. Here we have given a general formulation which can be applied to ODEs of order higher than 2, and which allows us to obtain transformations to ODEs of the same order but which may be of degree greater than 2. We have applied this to Cosgrove'e equation, an ODE believed to define a new transcendent, and which is therefore of as fundamental importance as the Painlevé equations themselves. This ODE has an underlying linear problem of third order,[6–8] and is likely to be the subject of much future research. We have obtained a variety of transformations relating this equation to other fourth order ODEs, of degrees $\geqslant 2$. These transformations and the corresponding ODEs, all of which have the Painlevé property, are all new. Of the transformations obtained, (40) and (47) can be understood to be master transformations, for transformations of the form (2), since all of our other transformations (14), (27) and (37) can be obtained from these two (see Table I). We note that all of our transformations hold also in the case $q=0$, in which case we may take the coefficient functions w and r to be any corresponding solution of Cosgrove's equation (hyperelliptic, elliptic, rational or zero; see Ref. 4).

In order to obtain further transformations for Eq. (6), we could consider a factorization (5) where the coefficients g_i are not restricted to be functions of x only, or we could alternatively consider generalizing the ansatz (2).

Let us consider generalizing the factorization (5). We note first that the aim of this factorization is to obtain restrictions on the coefficients a, b, c, d, e and f of the transformation (2) such that we obtain a lower degree polynomial (4) in V. That is, it is assumed that without any such restrictions on the coefficients of the transformation (2), the polynomial (3) is irreducible. The case where the polynomial (3) happens to factorize without making any restrictions on the coefficients of the transformation (2) is to be considered separately, with each factor then being used in the role played by Eq. (3). This possibility does not occur for (7).

Let us now consider the process of imposing restrictions on a, b, c, d, e and f such that (3) factorizes. In our description of this factorization process, we stated that the functions g_i are to be taken as functions of x only. This is a stronger requirement than is usually made (see, for example, Refs. 2 and 3). We now consider this factorization process more generally. The first factor can

always be assumed to be monic, and we can always proceed as described to obtain the coefficients A_i of the second factor. We are then left with the remaining coefficients of V, which must be made to vanish identically. At this stage some restriction needs to be made on the coefficients $g_0,\ldots,g_{N-M-1}$; we assumed that they depend only on x. However, more general assumptions can be made. For example, they could be assumed to be functions of $x,U,U',\ldots,U^{(n-2)}$; each coefficient of the terms $V^{N-M-1},\ldots,V^0$ is then to be made to vanish identically as a polynomial in $U^{(n-1)}$. We have checked that under such an assumption, no further results are obtained for Cosgrove's equation. Of course, more general assumptions can always be made, e.g., that each g_i be a polynomial in $U^{(n-1)}$ of some specified degree, or that each g_i be rational in $U^{(n-1)}$, again of some specified form.

In order to generalize the ansatz (2), we could, for example, seek transformations to fourth order ODEs defined by a relation of the form

$$U=\frac{(V')^2+(\Sigma_{i=0}^{2}a_iV^i)V'+\Sigma_{i=0}^{4}b_iV^i}{(\Sigma_{i=0}^{2}c_iV^i)V'+\Sigma_{i=0}^{4}d_iV^i}, \tag{49}$$

where all a_i, b_i, c_i and d_i are functions of x. This relation was used in Ref. 11 to obtain, for each of the Painlevé equations, transformations to previously unknown second order second degree equations having the Painlevé property. Furthermore, since we are now considering higher order equations with the Painlevé property, one might expect that the ansatz used for the form of the transformation could now be further generalized so as to include higher derivatives. Thus an obvious choice when considering fourth order ODEs with the Painlevé property would be an ansatz whereby U is expressed as a function linear in V''' and rational in V'', V' and V, with coefficients dependent on x, e.g., we may take

$$U=\frac{V'''+(\Sigma_{i=0}^{1}a_iV^i)V''+b_0(V')^2+(\Sigma_{i=0}^{2}c_iV^i)V'+\Sigma_{i=0}^{4}d_iV^i}{(\Sigma_{i=0}^{1}e_iV^i)V''+f_0(V')^2+(\Sigma_{i=0}^{2}g_iV^i)V'+\Sigma_{i=0}^{4}h_iV^i}. \tag{50}$$

Further generalizations, to the case where this function is a rational function of V''', can then be considered (and similarly when U depends on V, V' and V'' only). In cases such as these we then need to eliminate V between the expression for U and the original ODE in V (here Cosgrove's equation). Given the recent interest in higher order equations having the Painlevé property, and the corresponding interest in finding transformations for these, there seems to be much scope for future research.

JOURNAL OF MATHEMATICAL PHYSICS VOLUME 42, NUMBER 4 APRIL 2001

Conservation laws of semidiscrete Hamiltonian equations

Roman Kozlov[a)]
Department of Mathematical Sciences, NTNU, N-7491, Trondheim, Norway

(Received 27 April 2000; accepted for publication 12 January 2001)

Many evolution partial differential equations (PDEs) can be cast into Hamiltonian form. Conservation laws of these equations are related to one-parameter Hamiltonian symmetries admitted by the PDEs [P. J. Olver, *Applications of Lie Groups to Differential Equations* (Springer, New York, 1986)]. In this paper we consider symmetries and Noether's theorem for semidiscrete Hamiltonian equations which are obtained by space discretization of Hamiltonian PDEs. Using symmetries, one can find conservation laws of these equations. Several applications including a transfer equation and the Korteweg–de Vries equation are presented. © *2001 American Institute of Physics.* [DOI: 10.1063/1.1353184]

I. INTRODUCTION

Many partial differential equations (PDEs) possess conservation laws. Solutions of the equations of nondissipative continuum mechanics can often be presented as solutions of the Euler–Lagrange equations for the relevant functional. Conservation laws of such equations are given by Noether's theorem[1] if the admitted symmetries are known. The first discrete analog of Noether's theorem was presented by Maeda,[2,3] who considered transformations which do not change the independent variables and hence the mesh. Discrete versions of Noether's theorem for transformations which may also involve the independent variables have been developed by Dorodnitsyn.[4–6]

However, there are evolution equations without appropriate or natural Lagrangian formulation. For these equations one may prefer to use the Hamiltonian viewpoint. Much work has been done recently in preserving the structure and conservation laws of Hamiltonian PDEs under discretization. One approach is based on using the Hamiltonian formulation of PDEs on multisymplectic structures, which generalized the classical Hamiltonian structure by assigning a distinct symplectic operator for each space direction and time.[7] Variational integrators[8] generalize Veselov-type[9,10] discretizations of PDEs in variational form. They conserve the corresponding discrete multisymplectic form as well as the discrete momentum mappings corresponding to symmetries which do not transform the mesh. Different symplectic ordinary differential equation (ODE) solvers can also be used to build up multisymplectic integrators for PDEs[11–13] which preserve multisymplectic structure and may preserve some conservation laws.

In this paper we consider the Hamiltonian formulation of evolution equations based on the Poisson bracket approach. Conservation laws of these equations are related to one-parameter Hamiltonian symmetries admitted by the PDEs.[14,15] We introduce a discrete Poisson bracket, which provides us an infinite dimensional system of semidiscrete equations. Our main interest is to find conservation laws of such systems with the help of Noether's theorem in the Hamiltonian formulation. It will transpire that Noether's theorem can be carried over from the continuous case to the semidiscrete case so that one can use Hamiltonian symmetries of semidiscrete equations to find their conservation laws. As one can expect not all symmetries and conservation laws can be preserved under discretization of the bracket.

It is not known how to find all symmetries of a set of discrete equations. An overview of different methods and references can be found, for example, in Refs. 16 and 17. Some Lie point

[a)]Electronic mail: Roman.Kozlov@math.ntnu.no

symmetries of the original continuous equations can be preserved under discretization. These symmetries are realized by the same vector field in the continuous and discrete cases.[5] Discrete equations can also have symmetries which have no continuous counterparts. Because our main interest is to see what happens to conservation laws of continuous equations under space discretization we do not consider symmetries which disappear in the continuous limit.

In the paper we consider semidiscrete Hamiltonian equations and their conservation laws. The space discretization of Hamiltonian PDEs can be viewed as a first step of discretization that leads from a PDE to a difference scheme. Therefore the consideration of semidiscrete Hamiltonian equations can explain how space discretizations affect the conservation laws.

The paper is organized as follows: In Sec. II we consider continuous and semidiscrete Hamiltonian equations. Symmetries and their connection with conservation laws are reviewed in Sec. III, where we construct the ideal of the Lie–Bäcklund operators on a uniform space mesh and present the Hamiltonian form of Noether's theorem. Section IV contains applications. Finally, we summarize the results of the paper in Sec. V.

II. HAMILTONIAN EQUATIONS

In what follows (except Sec. III B) we will consider the case of one dependent variable u and two independent variables: time t and space coordinate x. We assume that the solutions are sufficiently smooth all variational derivatives tend to zero as $u\to 0$ and that u and a number of space derivatives of u tend to zero as $|x|\to\infty$. For simplicity we suppose that the solution decays fast enough so that all integrals in the continuous case and all sums in the semidiscrete case make sense. All integrals are assumed to be taken over the whole real line.

A. Hamiltonian partial differential equations

Many evolution partial differential equations of the form

$$u_t = K(x,u^{(n)}), \tag{2.1}$$

where $u^{(n)}=(u,u_1,u_2,\ldots,u_n)$ represents u and a finite set of derivatives of u with respect to space coordinate x, can be represented in the Hamiltonian form

$$u_t = \mathcal{D}\left(\frac{\delta \mathcal{H}}{\delta u}\right), \quad \mathcal{H}[u]=\int H(x,u^{(n)})\mathrm{d}x \tag{2.2}$$

with the help of the Hamiltonian functional $\mathcal{H}[u]$, variational operator $\delta\cdot/\delta u$, and a linear operator $\mathcal{D}$.[14] Denote by $\mathcal{F}$ the space of functionals of the type

$$\int P(t,x,u^{(m)})\mathrm{d}x, \quad m\in\mathbb{N}.$$

The operator $\mathcal{D}$ is required to be Hamiltonian, i.e., it forms the Poisson bracket

$$\{P,\mathcal{L}\}=\int \frac{\delta \mathcal{P}}{\delta u}\mathcal{D}\left(\frac{\delta \mathcal{L}}{\delta u}\right)\mathrm{d}x \tag{2.3}$$

satisfying the conditions of *skew-symmetry*

$$\{\mathcal{P},\mathcal{L}\}=-\{\mathcal{L},\mathcal{P}\} \tag{2.4}$$

and the *Jacobi identity*

$$\{\{\mathcal{P},\mathcal{L}\},\mathcal{R}\}+\{\{\mathcal{R},\mathcal{P}\},\mathcal{L}\}+\{\{\mathcal{L},\mathcal{R}\},\mathcal{P}\}=0 \tag{2.5}$$

for all functionals $\mathcal{P},\mathcal{L},\mathcal{R}\in\mathcal{F}$.

The variational derivative of a functional can be found by the action of the Euler operator on the integrand

$$\frac{\delta \mathcal{H}}{\partial u}=E(H), \quad E=\frac{\partial \cdot}{\partial u}-D_x\left(\frac{\partial \cdot}{\partial u_1}\right)+D_x^2\left(\frac{\partial \cdot}{\partial u_2}\right)+\cdots+(-1)^n D_x^n\left(\frac{\partial \cdot}{\partial u_n}\right)+\cdots, \tag{2.6}$$

where D_x is the total differentiation operator:

$$D_x=\frac{\partial}{\partial x}+u_1\frac{\partial}{\partial u}+u_2\frac{\partial}{\partial u_1}+\cdots+u_{n+1}\frac{\partial}{\partial u_n}+\cdots. \tag{2.7}$$

Example 2.1: Let us illustrate the above-described approach on Korteweg–de Vries equation[14,18]

$$u_t=uu_x+u_{xxx}. \tag{2.8}$$

The Korteweg–de Vries equation can be presented in the Hamiltonian form (2.2) in several ways.[14] One of them is the following:

$$\mathcal{D}=D_x, \quad \mathcal{H}=\int\left(\frac{u^3}{6}-\frac{u_x^2}{2}\right)\mathrm{d}x. \tag{2.9}$$

Example 2.2: The same bracket can be used to cast the transfer equation

$$u_t=h''(u)u_x \tag{2.10}$$

in the the Hamiltonian form with the Hamiltonian functional

$$\mathcal{H}=\int h(u)\mathrm{d}x. \tag{2.11}$$

B. Semidiscrete Hamiltonian equations

Given a Hamiltonian PDE, it is desirable to discretize both the Poisson bracket and the Hamiltonian functional so that we preserve Poisson structure.

To do so let us introduce a two-dimensional mesh which is uniform (regular) in space and continuous in time. We denote the mesh points as $\{x_i(t)\}$, $i=0,\pm1,\pm2,...,t\geqslant 0$ and define the mesh by two conditions:

$$\begin{cases}\Omega_1=(x_{i+1}(t)-x_i(t))-(x_i(t)-x_{i-1}(t))=0, & i=0,\pm1,\pm2,..., \quad t\geqslant 0,\\ \Omega_2=x_i(t+\tau)-x_i(t)=0, & i=0,\pm1,\pm2,..., \quad t,\tau\geqslant 0.\end{cases} \tag{2.12}$$

We will use the short notation $\Omega=0$ for this mesh. The first equation means that for any fixed time the space mesh is uniform. The second equation requires that we consider only vertical mesh lines in the time–space plane. Figure 1 shows the type of the mesh we specified.

At the mesh points we introduce discrete space derivatives $\underset{h}{u_1}=\underset{+h}{D}u, \underset{h}{u_2}=\underset{-h\,h}{D}u_1$, $\underset{h}{u_{2k+1}}=\underset{+h\,h}{D}u_{2k}$, $\underset{h}{u_{2k+2}}=\underset{-h\,h}{D}u_{2k+1}$, $k=1,2,...$, where $\underset{+h}{D}$ and $\underset{-h}{D}$ are the right and left discrete differentiation operators. They can be defined with the help of the right shift S_+ and left shift S_- operators

$$S_+f(x)=f(x+h), \quad S_-f(x)=f(x-h) \tag{2.13}$$

as

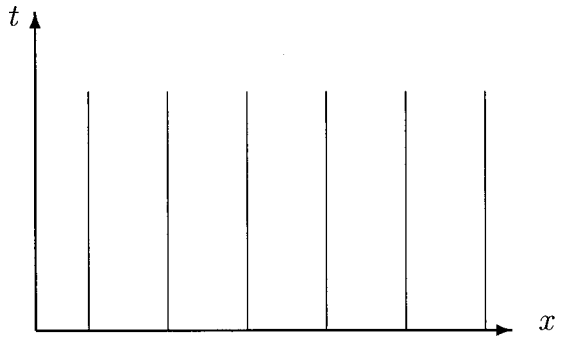

FIG. 1. The uniform mesh for the semidiscrete equations.

$$\underset{+h}{D}=\frac{S_+-1}{h},\quad \underset{-h}{D}=\frac{1-S_-}{h}. \tag{2.14}$$

We will consider the space of discrete derivatives $\underset{h}{u}^{(n)}=(u,\underset{h}{u}_1,\underset{h}{u}_2,\ldots,\underset{h}{u}_n)$ and corresponding functionals of the form

$$\underset{h}{\mathcal{P}}=\sum_{\Omega} \underset{h}{P}(t,x,h,\underset{h}{u}^{(n)})h, \tag{2.15}$$

where the summation is taken over all space points of the mesh Ω. We denote the space of such functionals as $\underset{h}{\mathcal{F}}$.

We assume that the Hamiltonian operator $\mathcal{D}$ can be approximated by an operator $\underset{h}{\mathcal{D}}$ such that the discrete bracket

$$\{\underset{h}{\mathcal{P}},\underset{h}{\mathcal{L}}\}_h=\sum_{\Omega} \frac{\delta \underset{h}{\mathcal{P}}}{\delta u}\underset{h}{\mathcal{D}}\left(\frac{\delta \underset{h}{\mathcal{L}}}{\delta u}\right)h \tag{2.16}$$

defines a Poisson bracket for functionals from $\underset{h}{\mathcal{F}}$. This means that $\{\cdot,\cdot\}_h$ is *skew-symmetric* and satisfies the Jacobi identity. We can choose some approximation $\underset{h}{\mathcal{H}}$ of the Hamiltonian functional $\mathcal{H}$ and get a set of Hamiltonian semidiscrete equations

$$\dot{u}=\underset{h}{\mathcal{D}}\left(\frac{\delta \underset{h}{\mathcal{H}}}{\delta u}\right), \tag{2.17}$$

which approximate Eq. (2.1) on the mesh (2.12).

Using the bracket notation, we can express a total time derivative of a functional $\underset{h}{\mathcal{P}}\in\underset{h}{\mathcal{F}}$ as

$$\frac{\mathrm{d}}{\mathrm{d}t}\underset{h}{\mathcal{P}}=\frac{\partial}{\partial t}\underset{h}{\mathcal{P}}+\{\underset{h}{\mathcal{P}},\underset{h}{\mathcal{H}}\}_h. \tag{2.18}$$

Definition: For a given Hamiltonian operator $\underset{h}{\mathcal{D}}$ a distinguished functional is a functional $\underset{h}{\mathcal{C}}(x,h,\underset{h}{u}^{(n)})$ such that

$$\underset{h}{\mathcal{D}}\left(\frac{\delta \underset{h}{\mathcal{C}}}{\delta u}\right)=0.$$

It follows that a functional is distinguished if and only if its Poisson bracket with every other functional is trivial:

$$\{\underset{h}{\mathcal{C}},\underset{h}{\mathcal{H}}\}_h=0 \quad \text{for any} \quad \underset{h}{\mathcal{H}}\in\mathcal{F}.$$

Example 2.3: Let us consider the bracket based on the central difference derivative operator

$$\underset{h}{D_0}=\frac{S_+-S_-}{2h}, \tag{2.19}$$

defined with the help of the right and left shift operators (2.13). It is easy to check that the bracket is *skew-symmetric* and satisfies the Jacobi identity. This bracket has two linearly independent distinguished functionals

$$\underset{h}{\mathcal{C}_1}=\sum_{i=-\infty}^{\infty} u_i h, \quad \underset{h}{\mathcal{C}_2}=\sum_{i=-\infty}^{\infty} (-1)^i u_i h. \tag{2.20}$$

In the continuous limit the first distinguished functional gives the only distinguished functional of the continuous bracket (2.3) generated by the total differentiation operator D_x (the continuous counterpart of $\underset{h}{D_0}$):

$$\underset{h}{\mathcal{C}_1}\to\int u\,\mathrm{d}x \quad \text{as} \quad h\to 0.$$

The second distinguished functional disappears in the continuous limit: $\underset{h}{\mathcal{C}_2}\to 0$ as $h\to 0$.

Alternatively, we can present the distinguished functionals as

$$\underset{h}{\tilde{\mathcal{C}}_1}=\sum_{i=-\infty}^{\infty} u_{2i} h, \quad \underset{h}{\tilde{\mathcal{C}}_2}=\sum_{i=-\infty}^{\infty} u_{2i+1} h.$$

These expressions indicate that conservations of mass for even and odd points of the mesh hold independently.

Remark: Approximating the first-order differential operator D_x by the second-order difference operator (2.19), we introduce stable spurious solutions into the semidiscrete framework. The resulting semidiscrete equations (2.17) possess two linearly independent solutions

$$u_i=C_1, \quad i\in\mathbb{Z}, \quad C_1=\text{const}, \tag{2.21}$$

$$u_i=C_2(-1)^i, \quad i\in\mathbb{Z}, \quad C_2=\text{const}. \tag{2.22}$$

However, the underlying Hamiltonian PDE possesses only the solution (2.21). The other solution is introduced into the semidiscrete equations by the space discretization.

Imposing the requirement $u_i \to 0$ as $i \to \infty$ for the solution and the initial data, we exclude all steady spurious solutions (except the trivial one $u_i \equiv 0$, $i \in \mathbb{Z}$) from the semidiscrete framework.

Example 2.4: We can choose a higher order approximation of the operator D_x (up to $O(h^4)$):

$$\hat{\mathcal{D}}_h = \frac{1}{3}(4\mathcal{D}_{0h} - \mathcal{D}_{02h}) = \frac{-S_+^2 + 8S_+ - 8S_- + S_-^2}{12h}, \tag{2.23}$$

The discrete bracket (2.16) based on $\hat{\mathcal{D}}_h$ has four linearly independent distinguished functionals:

$$\hat{\mathcal{C}}_{1h} = \sum_{i=-\infty}^{\infty} u_i h, \quad \hat{\mathcal{C}}_{2h} = \sum_{i=-\infty}^{\infty} (-1)^i u_i h,$$
$$\hat{\mathcal{C}}_{3h} = \sum_{i=-\infty}^{\infty} (4-\sqrt{15})^i u_i h, \quad \hat{\mathcal{C}}_{4h} = \sum_{i=-\infty}^{\infty} (4+\sqrt{15})^i u_i h. \tag{2.24}$$

Note that the functionals $\hat{\mathcal{C}}_{1h}$ and $\hat{\mathcal{C}}_{2h}$ are the same as in the previous example.

As a higher order approximation for the first-order operator D_x the operator (2.23) introduces steady spurious solutions. We do not investigate them since this operator will not be used further.

C. Discrete Euler operator

It is useful to have some practical formula to compute the variation derivatives of the discrete functionals. A discrete analog of the Euler operator (2.6) was introduced in order to study variations of discrete Lagrangian problems.[4–6] For Hamiltonian functionals of the form

$$\mathcal{H}_h = \sum_{\Omega} H(x,h,u,u_{1h},u_{2h},\ldots,u_{nh})h \tag{2.25}$$

the variational derivative can be found with the help of the discrete Euler operator E_h:

$$\frac{\delta \mathcal{H}_h}{\delta u} = E_h H, \tag{2.26}$$

where

$$E_h = \frac{\partial \cdot}{\partial u} - D_{-h}\left(\frac{\partial \cdot}{\partial u_{1h}}\right) + D_{+h-h}D_{+h-h}\left(\frac{\partial \cdot}{\partial u_{2h}}\right) + \cdots + (-1)^n (D_{-h})^{(n \bmod 2)} (D_{+h-h}D_{+h-h})^{\lfloor n/2 \rfloor}\left(\frac{\partial \cdot}{\partial u_{nh}}\right). \tag{2.27}$$

The function $\lfloor \cdot \rfloor$ denotes the integer part and $\cdot \bmod 2$ the remainder of the division by 2.

Another approach can be used for the Hamiltonian functionals of the form

$$\mathcal{H}_h = \sum_{i=-\infty}^{\infty} H[u_i]h = \sum_{i=-\infty}^{\infty} H(x_i,h,u_{i-m},\ldots,u_i,\ldots,u_{i+n})h \tag{2.28}$$

for some $m,n \in \mathbb{N}$. The variation derivative of the functional with respect to u_i is

$$\begin{aligned}\underset{h}{E}H &= \frac{\partial H[u_{i-n}]}{\partial u_i} + \cdots + \frac{\partial H[u_i]}{\partial u_i} + \cdots + \frac{\partial H[u_{i+m}]}{\partial u_i} \\ &= \left(\frac{\partial H[u_i]}{\partial u_{i+n}}\right)_{-n} + \cdots + \left(\frac{\partial H[u_i]}{\partial u_i}\right) + \cdots + \left(\frac{\partial H[u_i]}{\partial u_{i-m}}\right)_{m} \\ &= \sum_{k=-m}^{n} \left(\frac{\partial H[u_i]}{\partial u_{i+k}}\right)_{-k}, \end{aligned} \tag{2.29}$$

where $(\cdot)_k$ denotes that the quantity inside bracket is shifted on k steps. Thus in this case we get the following presentation of the discrete Euler operator:

$$\underset{h}{E} = \sum_{k=-m}^{n} \left(\frac{\partial \cdot}{\partial u_{i+k}}\right)_{-k}. \tag{2.30}$$

III. SYMMETRIES AND CONSERVATION LAWS

A. Invariance of semidiscrete equations

Let $\underset{h}{Z}$ be the space of sequences of variables $(t,x,h,u,\underset{h}{u_1},\underset{h}{u_2},\ldots)$ and $\underset{h}{\mathcal{A}}$ be the space of analytic functions of a finite number of variables z from $\underset{h}{Z}$.

Let us consider the infinite set of semidiscrete equations

$$\dot{u} = F(z), \quad F \in \underset{h}{\mathcal{A}} \tag{3.1}$$

defined at points of some two-dimensional mesh Ω. This equation is written on the finite number of points (stencil) of the difference mesh

$$\Omega(h_+, z) = 0, \quad h_+ = x_+ - x = (S_+ - 1)x, \tag{3.2}$$

which may be uniform or nonuniform. Then we say that the semidiscrete equation (3.1) on mesh (3.2) admits the group G if

$$\begin{cases} \dot{u} = F(z), \\ \Omega(h_+, z) = 0 \end{cases} \tag{3.3}$$

is an invariant manifold of the group G.

Symmetries of the systems of equation (3.3) are transformations generated by vector fields of the form

$$X = \xi^t(z)\frac{\partial}{\partial t} + \xi^x(z)\frac{\partial}{\partial x} + \eta(z)\frac{\partial}{\partial u}, \tag{3.4}$$

where $\xi^t,\ \xi^x,\ \eta \in \underset{h}{\mathcal{A}}$, which leave the system invariant. The infinitesimal criterion for invariance of Eq. (3.3) under a transformation generated by the operator (3.4) is given by the following conditions:

$$\mathbf{pr}\, X(\dot{u} - F(z))|_{\dot{u}=F,\Omega=0} = 0, \tag{3.5}$$

$$\mathbf{pr}\, X(\Omega)|_{\dot{u}=F,\Omega=0} = 0; \tag{3.6}$$

where the operator X is prolonged on all variables appearing in the system of Eq. (3.3)

$$\mathbf{pr}\,X = X + \zeta_1^t \frac{\partial}{\partial \dot{u}} + \underset{h}{\zeta_1^x} \frac{\partial}{\partial \underset{h}{u_1}} + \underset{h}{\zeta_2^x} \frac{\partial}{\partial \underset{h}{u_2}} + \cdots . \tag{3.7}$$

On the space-uniform grid (2.12) the coefficients of the prolonged operator are calculated through the prolongation formulas

$$\begin{gathered}\zeta_1^t = D_t(\eta) - \dot{u} D_t(\xi^t) - u_1 D_t(\xi^x), \quad \underset{h}{\zeta_1^x} = \underset{+h}{D}(\eta) - S_+(\dot{u}) \underset{+h}{D}(\xi^t) - \underset{h}{u_1} \underset{+h}{D}(\xi^x), \\ \underset{h}{\zeta_2^x} = \underset{-h+h}{D\,D}(\eta) - 2\underset{h}{u_2} \underset{+h}{D}(\xi^x) - \frac{1}{h} S_+(\dot{u}) \underset{+h}{D}(\xi^t) + \frac{1}{h} S_-(\dot{u}) \underset{-h}{D}(\xi^t), \ldots .\end{gathered} \tag{3.8}$$

These formulas are continuous for the time derivative $\dot{u}$[14,18–20] and discrete for the space derivatives.[5] Note that $u_1 = D_x(u)$ is the ''continuous'' derivative. It needs to be in some discrete representation, e.g., $\underset{h}{\tilde{D}_0}(u)$, which will be introduced in the following.

To check out the invariance one has to act by the prolonged operator $\mathbf{pr}\,X$ on the equation of system (3.3) and verify that the obtained expressions are annihilated on Eq. (3.3) and its difference consequences.

Conditions (3.5) and (3.6) require the invariance of the equations and of the mesh, correspondingly. For the mesh (2.12) the last condition can be split into two:

$$\underset{-h+h}{D\,D}(\xi^x)\big|_{\dot{u}=F,\Omega=0} = 0 \tag{3.9}$$

and

$$D_t(\xi^x)\big|_{\dot{u}=F,\Omega=0} = 0. \tag{3.10}$$

The bracket $\{\cdot,\cdot\}_h$ requires a space-uniform mesh that implies condition (3.9), which means the conservation of the space mesh uniformity under the group transformation.[21] Condition (3.10) has a clear geometrical meaning, it enforces that a vertical line of the time–space plane $x_i = \text{const}$, passing through a mesh point x_i, will remain vertical under the transformation. Let us note that in general the group transformation corresponding to the operator (3.4) destroys grid geometry.

Operators of the form (3.4) are called Lie–Bäcklund symmetries (they are also called *generalized* symmetries). An important subclass of the Lie–Bäcklund symmetries (3.4) is constituted by Lie point symmetries. They are given by the vector fields with coefficients ξ^t, ξ^x and η depending only on dependent and independent variables

$$X = \xi^t(t,x,u) \frac{\partial}{\partial t} + \xi^x(t,x,u) \frac{\partial}{\partial x} + \eta(t,x,u) \frac{\partial}{\partial u}. \tag{3.11}$$

Such symmetries are given by the same vector fields in the continuous and discrete cases.

Example 3.1: Groups satisfying invariance conditions.

If we require conditions (3.9) and (3.10) to be true for Lie point symmetries (3.11) independently of the considered equations, we find, as an example, that the transformations with generators

$$X = (ax + b) \frac{\partial}{\partial x} + \xi^t(t,x,u) \frac{\partial}{\partial t} + \eta(t,x,u) \frac{\partial}{\partial u}, \tag{3.12}$$

where a and b are constant, keep the mesh invariant.

Remark: In example 3.1 we require the mesh to be strongly invariant. For weak invariance of the semidiscrete equations we need the conditions (3.5), (3.9), and (3.10) to be satisfied on the

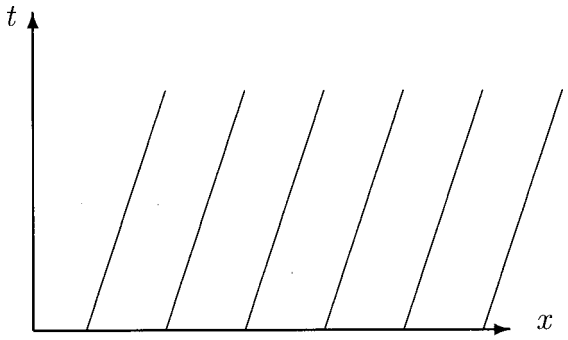

FIG. 2. Mesh deformation under the action of Galilean transformation.

solutions of the equations. Therefore a set of operators which keep equations invariant is broader than the set of operators which keep the mesh invariant independently of the considered equations.

Example 3.2: A group not satisfying invariance conditions.

Galilean transformation is central in models of Newton mechanics and is admitted by many equations. For example, the transfer equation (also known as nonviscous Burgers equation)

$$u_t = u u_x \tag{3.13}$$

and Korteweg–de Vries equation (2.8) are invariant with respect to the Galilean transformation

$$\begin{aligned} x^* &= x + t\alpha, \\ t^* &= t, \\ u^* &= u - \alpha, \end{aligned} \tag{3.14}$$

where α is a transformation parameter. Galilean transformation corresponds to the operator

$$X = t\frac{\partial}{\partial x} - \frac{\partial}{\partial u}.$$

The transformation does not keep vertical lines of the mesh [condition (3.10)]. Figure 2 shows that the vertical lines of the two-dimensional mesh (2.12) (see Fig. 1) become inclined under the transformation.

B. Factorization of the operators

In this point we overview factorization of operators both in continuous and discrete cases. The factorizations will be used to transfer the admitted symmetries into the canonical form. For simplicity we consider the space (x,u), where u is dependent variable and x is independent one.

(a) It is known that the Taylor group generated by the total differentiation operator D_x (2.7) provides a transition to the quotient algebra of the Lie–Bäcklund operators.[20] The operators $\xi(z)D_x$, where $\xi(z)$ is an analytic function of a finite number of variables in the space $(x,u,u_1,u_2,\ldots)$, form the ideal in the Lie algebra of operators

$$X = \xi(z)\frac{\partial}{\partial x} + \eta(z)\frac{\partial}{\partial u} + \cdots. \tag{3.15}$$

Thus instead of operator (3.15) one can consider the operator $\overline{X}$ in the canonical form

$$\overline{X}=X-\xi D_x=\overline{\eta}\frac{\partial}{\partial u}+\cdots, \quad \overline{\eta}=\eta-\xi u_x. \tag{3.16}$$

The representatives of this quotient algebra have independent variables as invariants and the extension formulas for them have simple and convenient form.

(b) Similar factorization can be done in the discrete case. Following Refs. 5 and 22 we consider the Lie–Bäcklund operator in the space $\underset{h}{Z}=(x,h,u,\underset{h}{u_1},\underset{h}{u_2},\ldots,\underset{h}{u_n},\ldots)$:

$$X=\xi(z)\frac{\partial}{\partial x}+\eta(z)\frac{\partial}{\partial u}+\underset{h}{\zeta_1}\frac{\partial}{\partial \underset{h}{u_1}}+\underset{h}{\zeta_2}\frac{\partial}{\partial \underset{h}{u_2}}+\cdots+h\underset{+h}{D}(\xi)\frac{\partial}{\partial h}, \tag{3.17}$$

where

$$\begin{gathered}\zeta_1=\underset{+h}{D}(\eta)-\underset{h}{u_1}\underset{+h}{D}(\xi), \quad \zeta_2=\underset{-h}{D}(\zeta_1)-\underset{h}{u_2}\underset{-h}{D}(\xi),\ \ldots,\\ \zeta_{2k+1}=\underset{+h}{D}(\zeta_{2k})-\underset{h}{u_{2k+1}}\underset{+h}{D}(\xi), \quad \zeta_{2k+2}=\underset{-h}{D}(\zeta_{2k+1})-\underset{h}{u_{2k+2}}\underset{-h}{D}(\xi),\ \ldots.\end{gathered} \tag{3.18}$$

Proposition 3.1: (*Dorodnitsyn*—Refs. 5 *and* 22) *The set of Lie–Bäcklund operators defined on the same uniform mesh forms a Lie algebra with multiplication*

$$[X_1,X_2]=X_1X_2-X_2X_1.$$

Let us consider the special operation of left multiplication of a Lie–Bäcklund operator by an analytic function $\underset{h}{\tilde{\xi}}(z)\in\mathcal{A}$:

$$\tilde{\xi}^*X=\overline{\tilde{\xi}\xi}\frac{\partial}{\partial x}+\overline{\tilde{\xi}\eta}\frac{\partial}{\partial u}+\left(\underset{+h}{D}(\tilde{\xi}\eta)-\underset{h}{u_1}\underset{+h}{D}(\tilde{\xi}\xi)\right)\frac{\partial}{\partial \underset{h}{u_1}}+\cdots+\underset{+h}{D}(\tilde{\xi}\xi)\frac{\partial}{\partial h}. \tag{3.19}$$

The first coordinates in the operator $\tilde{\xi}^*X$ are multiplied by $\tilde{\xi}(z)$ and the remaining coordinates are constructed according to the prolongation formulas (3.18).

Two representations for the operator of the Taylor group in the mesh space $\underset{h}{Z}$ were proposed in Refs. 5 and 22. They are the exact representations of the operator of total differentiation D_x in the space of difference variables

$$\begin{gathered}D^+=\frac{\partial}{\partial x}+\underset{+h}{\tilde{D}}(u)\frac{\partial}{\partial u}+\ldots, \quad \underset{+h}{\tilde{D}}=\sum_{n=1}^{\infty}\frac{(-h)^{n-1}}{n}\underset{+h}{D^n},\\ D^-=\frac{\partial}{\partial x}+\underset{-h}{\tilde{D}}(u)\frac{\partial}{\partial u}+\ldots, \quad \underset{-h}{\tilde{D}}=\sum_{n=1}^{\infty}\frac{h^{n-1}}{n}\underset{-h}{D^n},\end{gathered} \tag{3.20}$$

where $\underset{+h}{D}$ and $\underset{-h}{D}$ are right and left difference derivative operators on a uniform mesh.

It was shown in Refs. 5 and 22 that in the discrete case one can use ideals $\tilde{\xi}(z)*D^+$ and $\tilde{\xi}(z)*D^-$ for factorization of the operators (3.17). It is important to notice that every difference equation on a regular mesh admits the operators D^+ and D^-, which do not change the mesh, and that the representation (3.20) is true only for uniform meshes.

Another exact representation of the Taylor group operator in the mesh space $\underset{h}{Z}$ can be found with the help the central difference derivative (2.19). It is known that the finite transformations of a continuous groups have a one-to-one relation with infinitesimal transformations. This relation is expressed by a finite system of Lie equations for pointwise groups and by the unique recurrent sequence of coefficients of formal series for Lie–Bäcklund groups.[20] For both group types the solution of the system can be presented in the form of an exponential map. A finite transformation of any coordinate $z^i \in \underset{h}{Z}$ is generated by a vector field X,

$$(z^i)* = \exp(aX)(z^i) = \sum_{k=0}^{\infty} \frac{a^k}{k!} X^k(z^i).$$

Let us now invert the series, finding an infinitesimal transformation $aX(z^i)$ from the finite transformation $\exp(aX)(z^i)$:

$$aX(z^i) = \ln(\exp(aX))(z^i).$$

Taking the parameter value $a=h$, we can reconstruct the tangent field from the finite transformation of the Taylor group

$$\exp(a\underset{h}{\tilde{D}}_0)|_{a=h} = S_+$$

using the presentation of the right shift operator in terms of powers of $\underset{h}{D}_0$:

$$S_+ = h\underset{h}{D}_0 + \sqrt{1+h^2\underset{h}{D}_0^2} = h\underset{h}{D}_0 + \sum_{k=0}^{\infty} C_k^{1/2} h^{2k} \underset{h}{D}_0^{2k},$$

found from the relation

$$\underset{h}{D}_0 = \frac{S_+ - (S_+)^{-1}}{2h}.$$

We get

$$\underset{h}{\tilde{D}}_0 = \frac{1}{h}\sinh^{-1}(h\underset{h}{D}_0) = \frac{1}{h}\ln(h\underset{h}{D}_0 + \sqrt{1+h^2\underset{h}{D}_0^2}).$$

Using

$$\sinh^{-1}(x) = \ln(x+\sqrt{1+x^2}) = \sum_{k=0}^{\infty} \alpha_{2k+1} x^{2k+1}$$

with the expansion coefficients

$$\alpha_{2k+1}=(-1)^k\frac{1}{2}\frac{3}{4}\cdots\frac{2k-1}{2k}\frac{1}{2k+1}=\frac{(-1)^k}{2k+1}\frac{(2k-1)!!}{2^k k!},$$

where $(2k-1)!!=1\cdot 3\cdot 5\cdots(2k-1)$, we obtain the discrete representation of the operator D_x:

$$\underset{h}{\tilde{D}}_0=\sum_{k=0}^{\infty}\alpha_{2k+1}h^{2k}\underset{h}{D}_0^{2k+1}. \tag{3.21}$$

Finally, the infinitesimal operator of the Taylor group on $\underset{h}{Z}$ can be written as follows:

$$D^0=\frac{\partial}{\partial x}+\underset{h}{\tilde{D}}_0(u)\frac{\partial}{\partial u}+\underset{h}{\tilde{D}}_0(\underset{h}{u}_1)\frac{\partial}{\partial \underset{h}{u}_1}+\cdots+\underset{h}{\tilde{D}}_0(\underset{h}{u}_n)\frac{\partial}{\partial \underset{h}{u}_n}+\cdots, \tag{3.22}$$

where we used commutativity of the operators $\underset{+h}{D}$, $\underset{-h}{D}$ and $\underset{h}{D}_0$ on the uniform grid. One can also see that the operator D^0 satisfies conditions (3.18), i.e., the group generated by this operator is a nontrivial Lie–Bäcklund group.

Remark: The operators D^+ and D^- given in Eq. (3.20) use Newton series interpolation to the right and to the left, correspondingly. In the opposite directions they represent extrapolation. The operator D^0 represents interpolation on the whole real line.

Lemma 3.2: For any Lie–Bäcklund operators X and $\tilde{\xi}*D^0$, $\tilde{\xi}\in\underset{h}{\mathcal{A}}$ *defined on the same uniform mesh it is true that*

$$[\tilde{\xi}*D^0,X]=[\tilde{\xi}*D^0(\xi)-X(\tilde{\xi})]*D^0. \tag{3.23}$$

The proof of this Lemma is identical to the proof of the same result for the operators D^+ and D^-.[22] The Lemma provides us with the following result:

Theorem 3.3: The set of operators of the form

$$X_*=\tilde{\xi}(z)*D^0=\tilde{\xi}(z)\frac{\partial}{\partial x}+\tilde{\xi}(z)\underset{h}{\tilde{D}}_0(u)\frac{\partial}{\partial u}+\cdots \tag{3.24}$$

with arbitrary coefficients $\tilde{\xi}(z)$ *forms an ideal in the Lie algebra of all Lie–Bäcklund operators* $\{X\}$ *on the uniform grid.*

Consequently, instead of the Lie algebra of operators (3.17) we could consider the quotient algebra by the ideal $\tilde{\xi}(z)*D^0$. Although we can also use ideal $\tilde{\xi}(z)*D^+$ or $\tilde{\xi}(z)*D^-$ for factorization of the operators in the mesh space, the presence of the operator D_0 in the bracket suggests us to choose the ideal $\tilde{\xi}(z)*D^0$. As we will later see this choice is motivated by applications.

As representatives of the quotient algebra we shall consider the operators with the coordinate $\xi=0$:

$$\overline{X}=\overline{\eta}\frac{\partial}{\partial u}+\cdots,\quad \overline{\eta}=\eta-\xi\underset{h}{\tilde{D}}_0(u). \tag{3.25}$$

Let us note that the independent variable is invariant for the canonical operator (3.25). Furthermore it follows that the step of the mesh h is also invariant.

C. Conservation laws

For the system of Hamiltonian equations (2.17) considered on the grid (2.12) we have the following types of the conservation laws:

(1) If there are any distinguished functionals for the bracket (2.16), then they are conserved quantities. The distinguished functionals can be viewed as functionals corresponding to the symmetry $X_0 \equiv 0$.

(2) Hamiltonian form of Noether's theorem.

For the bracket based on the central difference derivative $\underset{h}{D}_0$ we can factorize the symmetries

$$X = \xi^t \frac{\partial}{\partial t} + \xi^x \frac{\partial}{\partial x} + \eta \frac{\partial}{\partial u} \tag{3.26}$$

by a combination of the discrete factorization (3.25) in space and continuous factorization (3.16) in time

$$\overline{X} = \overline{\eta} \frac{\partial}{\partial u}, \quad \overline{\eta} = \eta - \xi^t \underset{h}{\mathcal{D}} \left(\frac{\delta \underset{h}{\mathcal{H}}}{\delta u} \right) - \xi^x \underset{h}{\tilde{D}}_0(u), \tag{3.27}$$

where we substituted the expression for $\dot{u}$ from Eq. (2.17).

Definition: The Hamiltonian vector field associated with a functional $\underset{h}{\mathcal{P}}$ is the unique smooth vector field X_P satisfying

$$X_P(\underset{h}{\mathcal{F}}) = \{\underset{h}{\mathcal{F}}, \underset{h}{\mathcal{P}}\}_h. \tag{3.28}$$

In coordinate form it can be presented as the operator

$$X_P = \underset{h}{\mathcal{D}} \left(\frac{\delta \underset{h}{\mathcal{P}}}{\delta u} \right) \frac{\partial}{\partial u}. \tag{3.29}$$

Some symmetries (3.4) are given as Hamiltonian vector fields or are equivalent to Hamiltonian vector fields under factorization (3.27).

The Hamiltonian formulation of Noether's theorem provides the connection between symmetries and conservation laws.

Theorem 3.4: *For a Hamiltonian system of semidiscrete evolution equations (2.17) a Hamiltonian vector field X_P determines a generalized symmetry of the system if and only if there is an equivalent functional $\underset{h}{\tilde{\mathcal{P}}} = \underset{h}{\mathcal{P}} - \underset{h}{\mathcal{C}}$, differing only from $\underset{h}{\mathcal{P}}$ by a time-dependent distinguished functional $\underset{h}{\mathcal{C}}(t,x,h,u^{(n)})$, such that $\underset{h}{\tilde{\mathcal{P}}}$ determines a conservation law.*

The proof of this theorem is identical to that in the continuous case[14] and we will not reproduce it here.

Remark: The total derivative of the Hamiltonian is equal to its partial derivative

$$\frac{\mathrm{d}}{\mathrm{d}t} \underset{h}{\mathcal{H}} = \frac{\partial}{\partial t} \underset{h}{\mathcal{H}} + \{\underset{h}{\mathcal{H}}, \underset{h}{\mathcal{H}}\}_h = \frac{\partial}{\partial t} \underset{h}{\mathcal{H}} \tag{3.30}$$

because $\{\underset{h}{\mathcal{H}},\underset{h}{\mathcal{H}}\}_h=0$. Thus $\underset{h}{\mathcal{H}}$ is a conservation law if it is time independent. It is interesting to note that conservation of the time-independent Hamiltonian functional can be viewed as invariance of the equations with respect to time translation. Equations generated by time-independent Hamiltonian functionals are also time independent, that is they are invariant with respect to the operator

$$X_t=\frac{\partial}{\partial t}.$$

In the canonical form this operator can be presented as

$$\overline{X_t}=\dot{u}\frac{\partial}{\partial u}=\underset{h}{\mathcal{D}}\left(\frac{\delta\underset{h}{\mathcal{H}}}{\delta u}\right)\frac{\partial}{\partial u},$$

which shows that the Hamiltonian functional generates a symmetry and according to Theorem 3.4 it is a conservation law.

IV. EXAMPLES OF SEMIDISCRETE EQUATIONS WITH CONSERVATION LAWS

In this section we present several examples which demonstrate how Hamiltonian symmetries can be used to find conservation laws of the semidiscrete equations.

Example 4.1: Linear semidiscrete equations with infinitely many conservation laws.

Let us consider the Hamiltonian functional

$$\underset{h}{\mathcal{H}}=\sum_{\Omega} H[u]h,\quad H[u]=\frac{1}{2}(c_0u^2+c_1\underset{h}{u_1^2}+c_2\underset{h}{u_2^2}+\cdots+c_n\underset{h}{u_n^2}) \tag{4.1}$$

and the Poisson bracket based on the central difference derivative (2.19). They provide us the infinite set of ODEs

$$\dot{u}_i=c_0\frac{u_{i+1}-u_{i-1}}{2h}-c_1\frac{u_{i+2}-2u_{i+1}+2u_{i-1}-u_{i-2}}{2h^3}+\cdots+(-1)^n\underset{h}{c_n}\underset{h}{D_0}(\underset{h}{u_{2n}}) \tag{4.2}$$

with $i=0,\pm1,\pm2,\ldots$. In the continuous limit these equations correspond to the PDE

$$u_t=c_0u_1-c_1u_3+\cdots+(-1)^nc_nu_{2n+1}$$

for a function $u(t,x)$, $x\in\mathbb{R}$.

From the first glance we see that these equations conserve the distinguished functionals $\underset{h}{\mathcal{C}_1}$ and $\underset{h}{\mathcal{C}_2}$ given in Eq. (2.20) and the Hamiltonian functional (4.1). In addition to these evident conserved functionals we can construct conservation laws corresponding to the following symmetries:

(1) The admitted Hamiltonian operator

$$X_1=\frac{\partial}{\partial u} \tag{4.3}$$

corresponds to the functional

$$\underset{h}{\mathcal{P}_1}=\sum_{i=-\infty}^{\infty}x_iu_ih.$$

Because

$$\frac{\mathrm{d}}{\mathrm{d}t}\underset{h}{\mathcal{P}_1}=-c_0\sum_{i=-\infty}^{\infty}u_ih=-c_0\underset{h}{\mathcal{C}_1}$$

we obtain the conservation law

$$\underset{h}{\mathcal{P}_1}+tc_0\underset{h}{\mathcal{C}_1}=\sum_{i=-\infty}^{\infty}x_iu_ih+tc_0\sum_{i=-\infty}^{\infty}u_ih. \tag{4.4}$$

In the continuous limit we have

$$\underset{h}{\mathcal{P}_1}+tc_0\underset{h}{\mathcal{C}_1}\to\int xu\,\mathrm{d}x+tc_0\int u\,\mathrm{d}x.$$

(2) The symmetry

$$X_2=x\frac{\partial}{\partial u}$$

is admitted if $c_0=0$. It provides us the conservation law

$$\underset{h}{\mathcal{P}_2}=\frac{1}{2}\sum_{i=-\infty}^{\infty}x_i^2u_ih, \tag{4.5}$$

which goes into $\frac{1}{2}\int x^2u\,\mathrm{d}x$ in the continuous limit.

(3) The symmetry

$$X_3=x^2\frac{\partial}{\partial u} \tag{4.6}$$

is also admitted in the case $c_0=0$. Although it is not a Hamiltonian operator, the linear combination

$$X_3+\frac{h^2}{3}X_1=\left(x^2+\frac{h^2}{3}\right)\frac{\partial}{\partial u}$$

is. It is generated by the functional

$$\underset{h}{\mathcal{P}_3}=\frac{1}{3}\sum_{i=-\infty}^{\infty}x_i^3u_ih, \tag{4.7}$$

which lets us find the conservation law $\underset{h}{\mathcal{P}_3}+2tc_1\underset{h}{\mathcal{C}_1}$ which in the limit $h\to0$ becomes $\frac{1}{3}\int x^3u\,\mathrm{d}x+2tc_1\int u\,\mathrm{d}x$.

(4) Another Lie point symmetry admitted by the set of equations (4.2) is the translation in space presented by the operator

$$X_4=\frac{\partial}{\partial x}. \tag{4.8}$$

This operator is not canonical. Applying the factorization (3.27), we obtain the canonical symmetry

$$\overline{X}_4 = \underset{h}{\widetilde{D}}_0(u)\frac{\partial}{\partial u},$$

which is generated by the functional $\underset{h}{\mathcal{P}}_4$ satisfying

$$\underset{h}{D}_0\left(\frac{\delta \underset{h}{\mathcal{P}}_4}{\delta u}\right) = \underset{h}{\widetilde{D}}_0(u).$$

Further, with the help of the expression (3.21) we get

$$\left.\frac{\delta \underset{h}{\mathcal{P}}_4}{\delta u}\right|_i = \sum_{k=0}^{\infty} \alpha_{2k+1} h^{2k} \underset{h}{D}_0^{2k} u_i = \sum_{k=0}^{\infty} \alpha_{2k+1} \frac{(S_+ - S_-)^{2k}}{2^{2k}} u_i . \tag{4.9}$$

Applying

$$(S_+ - S_-)^{2k} = \sum_{j=0}^{2k} (-1)^j \frac{(2k)!}{j!(2k-j)!} S_{2(k-j)} = \sum_{p=-k}^{k} (-1)^{k-p} \frac{(2k)!}{(k-p)!(k+p)!} S_{2p},$$

where $S_i = S_{\mathrm{sign}(i)}^{|i|}$ represents a shift of indexes operator, to (4.9) and changing the order in the double sum, we arrive at

$$\left.\frac{\delta \underset{h}{\mathcal{P}}_4}{\delta u}\right|_i = \sum_{p=-\infty}^{\infty} b_{2p} S_{2p}(u_i) = \sum_{p=-\infty}^{\infty} b_{2p} u_{i+2p}, \tag{4.10}$$

where

$$b_{2p} = \sum_{k=|p|}^{\infty} \alpha_{2k+1} \frac{(-1)^{k-p}}{2^{2k}} \frac{(2k)!}{(k-p)!(k+p)!} = (-1)^p \sum_{k=|p|}^{\infty} \frac{1}{2k+1} \frac{1}{2^{2k}} \frac{((2k-1)!!)^2}{(k-p)!(k+p)!} \tag{4.11}$$

Let us note that $b_{-2p} = b_{2p}$.

Lemma 4.1: The series (4.11) defining coefficients b_{2p} for $p \in \mathbb{Z}$ are convergent.

Proof: Substituting $(k-p)!(k+p)! \geqslant (k!)^2$ into Eq. (4.11), we get

$$|b_{2p}| \leqslant \sum_{k=|p|}^{\infty} \frac{1}{2k+1} \frac{1}{2^{2k}} \left(\frac{(2k-1)!!}{k!}\right)^2 = \sum_{k=|p|}^{\infty} \frac{1}{2k+1} \left(\frac{(2k)!}{(2^k k!)^2}\right)^2 .$$

We use the bounds on the factorial provided by the Stirling's expansion

$$n^n \exp(-n)\sqrt{2\pi n} < n! < n^n \sqrt{2\pi n} \exp\left(-n + \frac{1}{12n}\right) \quad \text{for } n \in \mathbb{N}$$

to obtain the inequality

$$\frac{1}{2k+1}\left(\frac{(2k)!}{(2^k k!)^2}\right)^2 < \frac{1}{\pi k(2k+1)} \exp\left(\frac{1}{12}k\right) \quad \text{for } k \in \mathbb{N}$$

that ensures us that the series defining b_{2p} converges, moreover it can be shown that $|b_{2p}| \sim 1/|p|$ as $p \to \infty$.

A number of the first coefficients b_{2p} is given in Table I.

TABLE I. Some coefficients b_{2p}.

b_0	$b_{\pm 2}$	$b_{\pm 4}$	$b_{\pm 6}$	$b_{\pm 8}$	$b_{\pm 10}$	$b_{\pm 12}$	$b_{\pm 14}$
1.1662	−0.1070	0.0344	−0.0164	0.0095	−0.0061	0.0043	−0.0031

At this point we can construct the functional corresponding to the Hamiltonian symmetry $\overline{X}_4$. It is the conservation law of equations (4.2)

$$\mathop{\mathcal{P}_4}_h=\frac{1}{2}\sum_{i=-\infty}^{\infty} b_0u_i^2h+\sum_{p=1}^{\infty} b_{2p}\sum_{i=-\infty}^{\infty} u_iu_{i+2p}h=\frac{1}{2}\sum_{i=-\infty}^{\infty} u_i\sum_{p=-\infty}^{\infty} b_{2p}u_{i+2p}h. \tag{4.12}$$

For convergence of Eq. (4.12) it is essential that $u_i\to 0$ as $i\to\pm\infty$ fast enough.

Lemma 4.2: It is true that

$$\mathop{\mathcal{P}_4}_h\to\frac{1}{2}\int u^2\mathrm{d}x+O(h^2)\quad \text{as}\quad h\to 0.$$

Proof: Let us compare the functional $\mathop{\mathcal{P}_4}_h$ with the functional $1/2\sum_{i=-\infty}^{\infty} u_i^2h$:

$$\mathop{\mathcal{P}_4}_h-\frac{1}{2}\sum_{i=-\infty}^{\infty} u_i^2h=\frac{1}{2}\sum_{i=-\infty}^{\infty} u_i\left(\sum_{p=-\infty}^{\infty} b_{2p}u_{i+2p}-u_i\right)h$$

$$=\frac{1}{2}\sum_{i=-\infty}^{\infty} u_i\left(\sum_{k=0}^{\infty}\alpha_{2k+1}h^{2k}\mathop{D_0^{2k}}_h-1\right)u_ih=\frac{1}{2}\sum_{i=-\infty}^{\infty} u_i\sum_{k=1}^{\infty}\alpha_{2k+1}h^{2k}\mathop{D_0^{2k}}_h u_ih$$

$$=\frac{1}{2}\sum_{i=-\infty}^{\infty} u_i(\alpha_3h^2u''(x_i)+O(h^4))h=\frac{h^2}{2}\sum_{i=-\infty}^{\infty}\alpha_3u_iu''(x_i)h+O(h^4)=-\frac{h^2}{12}\int uu''\,dx+O(h^4).$$

On the other hand we have

$$\frac{1}{2}\sum_{i=-\infty}^{\infty} u_i^2h=\frac{1}{2}\int u^2\,\mathrm{d}x+O(h^2),$$

which combined with the previous result gives the statement of the lemma.

Let us note that in physical applications the integral (4.12) is referred as linear momentum.

(5) Equations (4.2) also admit the operators

$$Y_k=\mathop{D_0^{2k+1}}_h(u)\frac{\partial}{\partial u},\quad k=0,1,2,\ldots. \tag{4.13}$$

These operators are true Lie–Bäcklund symmetries, i.e., symmetries which are not equivalent to Lie point symmetries (3.11). All these operators are Hamiltonian with generating functionals

$$\underset{h}{\mathcal{R}}_k=\frac{1}{2}\sum_{i=-\infty}^{\infty} u_i D_0^{2k}(u_i)h=\frac{(-1)^k}{2}\sum_{i=-\infty}^{\infty}(\underset{h}{D}_0^k u_i)^2 h, \quad k=0,1,2,\ldots. \tag{4.14}$$

The functionals $\underset{h}{\mathcal{R}}_k$ are the conservation laws of (4.2), which in the continuous limit correspond to

$$\mathcal{R}_k=\frac{(-1)^k}{2}\int u_k^2\,dx, \quad k=0,1,2,\ldots.$$

It is interesting to note that the operators Y_k form the canonical operator $\overline{X}_4$ and that functionals $\underset{h}{\mathcal{R}}_k$ form the momentum functional (4.12) as the infinite series:

$$\overline{X}_4=\sum_{k=0}^{\infty}\alpha_{2k+1}h^{2k}Y_k, \quad \underset{h}{\mathcal{P}}_4=\sum_{k=0}^{\infty}\alpha_{2k+1}h^{2k}\underset{h}{\mathcal{R}}_k.$$

Example 4.2: In Examples 2.1 and 2.2 we saw that the Korteweg–de Vries equation and the transfer equation (2.10) can be rewritten as Hamiltonian PDEs. Let us now provide Hamiltonian semidiscretizations of these. We can take the operator $\underset{h}{D}_0$ for the discrete bracket and approximate the Hamiltonian functionals as

$$\underset{h}{\mathcal{H}}_1=\sum_{i=-\infty}^{\infty}\left(\frac{u_i^3}{6}-\frac{1}{2}\left(\frac{u_{i+1}-u_i}{h}\right)^2\right)h \tag{4.15}$$

and

$$\underset{h}{\mathcal{H}}_2=\sum_{i=-\infty}^{\infty}h(u_i)h, \tag{4.16}$$

leading to the semidiscrete equations

$$\dot{u}_i=\frac{u_{i+1}^2-u_{i-1}^2}{4h}+\frac{u_{i+2}-2u_{i+1}-2u_{i-1}-u_{i-2}}{2h^3} \tag{4.17}$$

and

$$\dot{u}_i=\frac{h'(u_{i+1})-h'(u_{i-1})}{2h}, \tag{4.18}$$

which approximate the original equations to order $O(h^2)$.

Some of the symmetries admitted by the original continuous equations[18] carry over to the semidiscretized equations. The invariance of Eqs. (4.17) and (4.18) on a uniform mesh with respect to translation in space provides us the conservation law (4.12). The equations also preserve the distinguished functionals (2.20) and their own Hamiltonian functionals.

That each of the above-found conservation laws is conserved can, of course, be proved directly. The advantage of the approach we used is that it is constructive and gives not only conservation laws, which we can expect (distinguished and Hamiltonian functionals), but also conservation laws of the form we would probably not try to find by ad hoc methods [see discrete momentum (4.12)]. We sum up the considered symmetries and their generating functionals in Table II.

TABLE II. Some symmetries and their generating functionals for the bracket given by the central difference derivative. The functionals (up to some distinguished functional) are conservation laws of the Hamiltonian semidiscrete equations constructed with the help of this bracket.

Operator	Operator in canonical form	Functional	Continuous limit of functional
	$0\,\frac{\partial}{\partial u}$	$\sum_{i=-\infty}^{\infty} u_i h, \quad \sum_{i=-\infty}^{\infty} (-1)^i u_i h$	$\int u\,\mathrm{d}x, \quad 0$
$\frac{\partial}{\partial t}$	$D_{0\,h}\left(\frac{\partial \mathcal{H}_h}{\delta u}\right)\frac{\partial}{\partial u}$	$\mathcal{H}_h$	$\mathcal{H}$
	$\frac{\partial}{\partial u}$	$\sum_{i=-\infty}^{\infty} x_i u_i h$	$\int xu\,\mathrm{d}x$
	$x\,\frac{\partial}{\partial u}$	$\frac{1}{2}\sum_{i=-\infty}^{\infty} x_i^2 u_i h$	$\frac{1}{2}\int x^2 u\,\mathrm{d}x$
	$\left(x^2+\frac{h^2}{3}\right)\frac{\partial}{\partial u}$	$\frac{1}{3}\sum_{i=-\infty}^{\infty} x_i^3 u_i h$	$\frac{1}{3}\int x^3 u\,\mathrm{d}x$
$\frac{\partial}{\partial x}$	$\sum_{k=0}^{\infty} \alpha_{2k+1} h^{2k} D_{0\,h}^{2k+1}(u)\,\frac{\partial}{\partial u}$	$\frac{1}{2}\sum_{i=-\infty}^{\infty} u_i \sum_{p=-\infty}^{\infty} b_{2p} u_{i+2p} h$	$\frac{1}{2}\int u^2\,\mathrm{d}x$
	$D_{0\,h}^{2k+1}(u)\,\frac{\partial}{\partial u}, \quad k=0,1,\ldots$	$\frac{(-1)^k}{2}\sum_{i=-\infty}^{\infty} (D_{0\,h}^k u_i)^2 h$	$\frac{(-1)^k}{2}\int u_k^2\,\mathrm{d}x$

V. CONCLUSIONS

In the paper we presented the Hamiltonian form of Noether's theorem for semidiscrete equations. The approach was illustrated on discretizations of Hamiltonian PDEs which preserve the Poisson bracket and some conservation laws of the original continuous equations. Using the connection between symmetries and conservation laws, we can point to two reasons why some conservation laws get lost after Poisson structure preserving space discretization. First, the symmetry can be lost because it is not admitted by the semidiscrete system on a uniform mesh (see Example 3.2). Second, there is a difference between continuous and discrete differentiation and some relations, which hold in the limit $h\to 0$, may not be true for finite steps h. One can easily see on the discrete Leibniz rule for the central discrete derivative

$$D_{0\,h}(FG)=\frac{G_+ + G_-}{2}D_{0\,h}(F)+\frac{F_+ + F_-}{2}D_{0\,h}(G)$$

or

$$D_{0\,h}(FG)=GD_{0\,h}(F)+FD_{0\,h}(G)+\frac{h^2}{2}(D\,D\,G)D_{0\,h}(F)+\frac{h^2}{2}(D\,D\,F)D_{0\,h}(G)$$

why some symmetries can be Hamiltonian in the continuous case, but lose this property under space discretization.

Although the necessity to have a discrete bracket satisfying *skew-symmetry* and Jacobi identity imposes limitations on the applications of the presented approach, extensions are possible in several ways. The results of the paper can be extended on the case of several dependent variables or several space variables. Work is in progress on conservation laws of the semidiscretized Schrödinger and wave equations, which can be presented as Hamiltonian equations with the help of the canonical bracket.[23] It is interesting to examine semidiscrete equations with periodic solutions, where the set of semidiscrete equations is finite. For such equations one can find first integrals

preserving time discretizations using first integral preserving discretization methods for Hamiltonian ODEs.[24–27] Note that, in general, it is impossible to preserve symplectic structure and all first integrals simultaneously.[28]

The present approach might also be applied to equations which have Lagrangian formulation. The consideration of semidiscrete equations with the Lagrangian formulation can take an intermediate position between the well-known continuous case and fully discrete case.[4–6] It can probably explain whether space or time discretization is the reason why particular conservation laws get lost under a discretization.

ACKNOWLEDGMENTS

The author would like to thank C. J. Budd for stimulating discussions on Hamiltonian equations, in particular for pointing out that some semidiscrete equations can be cast into the Hamiltonian form. The author is grateful to V. A. Dorodnitsyn and P. C. Moan who read the preliminary version of the paper for helpful comments. In this paper we study the Bianchi VIII cosmological dynamical system. Our aim is to show that this system is nonintegrable. To show this we use an extension of Ziglin theory made by Morales-Ruiz and Ramis. © *2001 American Institute of Physics.* [DOI: 10.1063/1.1351885]

I. INTRODUCTION

In certain cases cosmological models and relativistic systems can be represented as finite dimensional dynamical systems, i.e., as a set of ordinary differential equations. Such representation must be considered a great advantage. Usually the original model is represented as a coupled system of partial nonlinear differential equations arising from the field theory. Having a finite dimensional dynamical system, we have at hand a very rich theory and elaborated tools for its investigations.

It has to be mentioned, however, that dynamical systems of cosmological (or relativistic) origin have many special features which distinguish them from a ''typical'' dynamical system we meet in dynamical astronomy, classical mechanics or physics (see Ref. 1). These differences lead sometimes to controversies and long discussions. A good example is connected with the Bianchi IX [B(IX) or the Mixmaster] model and the presence of chaos in it. The numerically computed maximal Lapunov exponent for this system was equal to zero or different from zero depending on the time parametrization. Because an approximation of the Mixmaster model by a discrete map has strong chaotic properties,[2] it was natural to expect such behavior in the original system. However, as it was proved,[3] there exists no recurrence in the system and, thus, no form of standard deterministic chaos is present in it. Nevertheless, there were attempts to show that the dynamics of B(IX) contains some features characteristic for chaotic behavior. For example, in Refs. 4 and 5 one can find results of interesting numerical works where ''parametrization independent'' characteristics of chaos were used. Let us note, however, that this approach does not make big progress in understanding the system. The point is that in the cited works a certain approximation of the Mixmaster model was investigated, not the Mixmaster model itself. Moreover, one notices several notions used in these investigations which have no precise meaning.

A strict proof of the specific character of chaos in the Mixmaster system seems to be very difficult. That is why several authors tried to show that this system is not integrable. It must be mentioned that ''integrability'' here was understood differently by different authors. Several authors tested if the model passes the standard Painlevé integrability test in the form of the ARS

algorithm.[6] In this approach the Mixmaster system is extended to a complex dynamical system. In Refs. 7 and 8 it was indicated that B(IX) model passes this test. This result was revised,[9] however, without any strict conclusions concerning integrability. Further studies[10] showed that the B(IX) model does not pass the so-called perturbative Painlevé test. The authors of this article suggest the existence of ''some chaotic regimes'' in the system, but, as the result of Cushman and Sniatycki shows, this claim without explanation of what ''chaotic regimes'' means is meaningless. The strongest result to this end was obtained in Ref. 11 where the authors show the existence of movable critical essential singularities in the B(IX) model. This kind of investigation connects a complicated behavior of the system with singularities of its solutions on the complex time plane. It should be mentioned, however, that the relation between Painlevé's test and integrability, in particular with complete integrability of Hamiltonian systems, is far from being clear.

The strongest and mathematically precise result concerning the Mixmaster model was obtained by J. J. Morales-Ruiz and J.-P. Ramis on the basis of their theory connecting Ziglin's method and differential Galois theory.[12] We state this result briefly. The Mixmaster model can be formulated as a Hamiltonian system. There exists a four dimensional invariant manifold $\mathcal{T}$ on which the system can be integrated explicitly. Solutions of the system restricted to $\mathcal{T}$ are known as Taub solutions. Studying variational equations around a selected Taub solution J. J. Morales-Ruiz proved that the Mixmaster model, considered as a complex Hamiltonian system, is not completely integrable (with meromorphic first integrals) in the sense of Liouville–Arnold theorem. As the system is homogeneous the meromorphic first integrals can be replaced by rational first integrals.

We make a few remarks about these results. First, it was not excluded that this system possesses one additional rational integral or is completely integrable in terms of nonrational integrals. Moreover, it can possess an additional integral only on the physically interesting zero energy level, or it can be integrable on it. Thus, by no means, does the result of Morales-Ruiz and Ramis close the subject.

In the sequel, when speaking about a completely integrable Hamiltonian system, we assume that all integrals are meromorphic.

In this article we apply Morales-Ruiz and Ramis approach to prove the nonintegrability of the Bianchi VIII model. To this end we study its dynamics carefully. We show that this system contains a four dimensional subsystem which is completely integrable. We demonstrate how to find an explicit form of solutions of this subsystem. Next, we consider particular solutions lying on the zero level of the Hamiltonian, and we investigate the normal variational equations for these solutions. Using the Kovacic algorithm, we determine the differential Galois group of these equations, and we prove the nonintegrability of the Bianchi VIII model.

II. DIFFERENTIAL GALOIS EXTENSION OF ZIGLIN THEORY

The fundamental papers of Ziglin[13,14] gave a formulation of a very basic theorem about the nonintegrability of analytic Hamiltonian systems. The idea of the Ziglin approach lies in a deep connection between properties of solutions on the complex time plane and the existence of first integral. This idea takes its origins from works of S. W. Kovalevskaya and A. M. Lapunov. Ziglin works found many continuations and many important applications (see, e.g., Refs. 15–27).

Here we give only the definitions needed for a formulation of the theorem we used to prove our main result.

We consider a complex Hamiltonian system with n degrees of freedom. It is defined on a complex analytic symplectic manifold M of complex dimension $2n$, and is given by a holomorphic Hamiltonian $\mathrm{H}: M \to \mathbb{C}$. The Hamiltonian vector field associated with H is denoted by X_{H}.

Let us assume that we know a nonequilibrium solution $z=\varphi(t)$, $t \in \mathbb{C}$, of Hamilton's equations of motion generated by X_{H} which is the maximal analytical continuation of a certain local solution. We associate a Riemannian surface Γ with it. Next, we consider the variational equations along $\varphi(t)$, and we restrict them to the normal bundle of Γ. These reduced variational equations are called the normal variational equations (NVE).

In the Ziglin approach the fundamental role is played by the monodromy group of NVE. Continuation along a close path γ with the base point $t_0 \in \mathbb{C}$ of a local fundamental solution of

NVE gives rise to a new fundamental solution of NVE defined in the same neighborhood of t_0. As NVE are linear and our system is Hamiltonian, there exists an element G_γ of symplectic group $\mathrm{Sp}(2(n-1),\mathbb{C})$ which transforms one solution to the other. In fact, G_γ depends on the homotopy class of γ, and map $\gamma \to G_\gamma$ gives a representation of the first homotopy group $\pi_1(\Gamma)$ of Γ in $\mathrm{Sp}(2(n-1),\mathbb{C})$. The image of this representation is called the monodromy group associated with NVE.

The Ziglin theory bases on two implications:

(i) If the considered Hamiltonian system possesses a first integral, then NVE also possess a first integral.
(ii) If NVE possess a first integral, then there exists a nonconstant function invariant with respect to the action of the monodromy group.

Now, it is clear that the existence of first integrals puts certain constraints onto the monodromy group and this fact was used by Ziglin to formulate his theorems.

J. J. Morales-Ruiz and J. P. Ramis modify the Ziglin approach in two respects. First, instead of answering the question of what restrictions to the monodromy group are imposed by the existence of certain numbers of independent first integrals, they ask what the consequences of complete integrability are. Next, instead of working with the monodromy group of NVE, they use the differential Galois group associated with NVE. This last group is bigger than the monodromy group and this fact makes a proof of complete nonintegrability easier. For a definition of differential Galois group, Liouvillian solutions and differential Galois theory (see Refs. 28–32).

We prove the main result of this article using the following theorem.

Theorem 1 (Morales-Ruiz, 1999): *Assume that there exist n first integrals of X_H which are meromorphic, in involution and functionally independent in a neighborhood of Γ. Then the identity component of the differential Galois group of NVE is Abelian.*

The main difficulty in application of the above theorem is connected with determination of the identity component of the differential Galois group of NVE. In fact, little is known about how to determine it for given equations. However, in our case, as it will be shown, we can reduce the investigated NVE to a second order linear equation with rational coefficients. This allows us to apply the Kovacic algorithm.[33] We describe it in the Appendix with some improvements compared to Refs. 34–36. Our description is self-contained and it can be useful in the study of other nonintegrability problems.

III. BIANCHI CLASS A HAMILTONIAN SYSTEMS

Homogeneous cosmological models are given by a four dimensional manifold $\mathcal{M}^4$ with a pseudo-Riemannian metric ds^2 satisfying Einstein equations. Homogeneity of a model means that metric ds^2 is invariant with respect to a certain three dimensional Lie group G acting on $\mathcal{M}^4$. It is assumed that orbits of this action are three dimensional. The most important are those models where the orbits of G action are spacelike, i.e., the metric restricted to an orbit is negative define. In such case $\mathcal{M}^4$ has the structure of Cartesian product of the form $\mathcal{M}^4=\mathbb{R}\times\mathcal{M}^3$ where $\mathcal{M}^3$ is an orbit of action of G. Vector fields X_i, $i=1,2,3$, which generate the action of group G, form a three dimensional Lie algebra. A simple classification of real three dimensional Lie algebras was done by Bianchi in 1897. It depends on a scalar $a\in\mathbb{R}$ and a vector (n_1,n_2,n_3), where $n_i\in\{+1,-1,0\}$ for $i=1,2,3$ in the following way:

$$[X_1,X_2]=n_3X_3,\ [X_2,X_3]=n_1X_1-aX_2,\ [X_3,X_1]=n_2X_2+aX_1.$$

Table I presents Bianchi classification. This classification, as well as the corresponding cosmological models, are naturally divided into two classes: to class A belong those models for which $a=0$, and to class B those for which $a\neq 0$. For a homogeneous model Einstein equations reduce to a certain dynamical system. In the case of a model belonging to class A this dynamical system is Hamiltonian. The Hamiltonian function for this system can be written in the following form:

TABLE I. Bianchi classification of three-dimensional Lie algebras.

Type	a	n_1	n_2	n_3	Type	a	n_1	n_2	n_3
I	0	0	0	0	III	1	1	-1	0
II	0	1	0	0	IV	1	1	0	0
VI_0	0	1	-1	0	V	1	0	0	0
VII_0	0	1	1	0	VI_a	$a\neq 1$	1	-1	0
VIII	0	1	1	-1	VII_a	$a\neq 0$	1	1	0
IX	0	1	1	1					

$$\mathrm{H}=g^{ij}p_ip_j+\frac{1}{2}\sum_{1\leqslant i<j\leqslant 3}n_iq_in_jq_j-\frac{1}{4}\sum_{i=1}^{3}(n_iq_i)^2, \tag{III.1}$$

where

$$[g^{ij}]=\begin{bmatrix}-q_1^2 & q_1q_2 & q_1q_3\\ q_2q_1 & -q_2^2 & q_2q_3\\ q_3q_1 & q_3q_2 & -q_3^2\end{bmatrix}.$$

From the physical interpretation it follows that variables q_i are non-negative. Thus our Hamiltonian system is defined on T^*Q, where $Q=\mathbb{R}_+^3$, where $\mathbb{R}_+$ is the positive real axis.

IV. PROPERTIES OF BIANCHI VIII HAMILTONIAN SYSTEM

From now on we will consider only the case of the Bianchi VIII model when $(n_1,n_2,n_3)=(1,1,-1)$. For short we called it a B(VIII) model.

For our investigation it is important to find a particular solution for the system. To this end we select an invariant set.

Lemma 1: For the B(VIII) *model a four dimensional manifold,*

$$\mathcal{T}=\{(q_1,q_2,q_3,p_1,p_2,p_3)\in T^*Q\,|\,q_1=q_2,\quad p_1=p_2\},$$

is invariant.

Proof: We make a symplectic change of variables

$$[q_1,q_2,q_3,p_1,p_2,p_3]^T=A[Q_1,Q_2,Q_3,P_1,P_2,P_3]^T,$$

where

$$A=\frac{1}{2}\begin{bmatrix}2 & 2 & 0 & 0 & 0 & 0\\ -2 & 2 & 0 & 0 & 0 & 0\\ 0 & 0 & 2 & 0 & 0 & 0\\ 0 & 0 & 0 & 1 & 1 & 0\\ 0 & 0 & 0 & -1 & 1 & 0\\ 0 & 0 & 0 & 0 & 0 & 2\end{bmatrix}. \tag{IV.1}$$

In the new variables the Hamiltonian of the B(VIII) model has the form

$$\mathrm{H}=-P_1^2Q_2^2-Q_1^2(1+P_2^2)-2Q_1P_1(Q_2P_2-Q_3P_3)+Q_2Q_3(2P_2P_3-1)-\tfrac{1}{4}Q_3^2(1+4P_3^2),$$

and thus Hamilton's equations read

$$\begin{aligned}
\dot{Q}_1 &= -2[P_1Q_2^2 + Q_1(Q_2P_2 - Q_3P_3)],\\
\dot{Q}_2 &= -2[Q_2(Q_1P_1 - Q_3P_3) + Q_1^2P_2],\\
\dot{Q}_3 &= 2Q_3[Q_1P_1 + Q_2P_2 - Q_3P_3],\\
\dot{P}_1 &= 2[Q_1(1+P_2^2) + P_1(Q_2P_2 - Q_3P_3)],\\
\dot{P}_2 &= Q_3(1-2P_2P_3) + 2P_1(Q_2P_1 + Q_1P_2),\\
\dot{P}_3 &= Q_2 + \tfrac{1}{2}Q_3 - 2P_3(Q_1P_1 + Q_2P_2 - Q_3P_3).
\end{aligned} \tag{IV.2}$$

Manifold $\mathcal{T}$ is defined in the new variables as

$$\mathcal{T} = \{(Q_1,Q_2,Q_3,P_1,P_2,P_3) \in T^*Q \,|\, Q_1 = 0, \quad P_1 = 0\}.$$

Direct inspection of the first and fourth equations in (IV.2) shows that indeed $\mathcal{T}$ is invariant. □

$\mathcal{T}$ is called Taub manifold and solutions lying on it are called Taub solutions. It is important to notice that the B(VIII) system restricted to $\mathcal{T}$ is integrable.

Lemma 2: The B(VIII) *model restricted to manifold* $\mathcal{T}$ *is a completely integrable Hamiltonian system*.

Proof: The B(VIII) model restricted to manifold $\mathcal{T}$ is given by the following system of differential equations:

$$\begin{aligned}
\dot{Q}_2 &= 2Q_2(Q_3P_3),\\
\dot{Q}_3 &= 2Q_3(Q_2P_2 - Q_3P_3),\\
\dot{P}_2 &= Q_3(1-2P_2P_3),\\
\dot{P}_3 &= Q_2 + \tfrac{1}{2}Q_3 - 2P_3(Q_2P_2 - Q_3P_3).
\end{aligned} \tag{IV.3}$$

Direct inspection shows that these equations are Hamiltonian with respect to the standard symplectic structure of $\mathbb{R}^4$, and that the Hamiltonian reads

$$\mathrm{H}_{\mathcal{T}} := \mathrm{H}_{|\mathcal{T}} = Q_2Q_3(2P_2P_3 - 1) - \tfrac{1}{4}Q_3^2(1+4P_3^2).$$

It is easy to verify that the function

$$F := Q_2Q_3 - (Q_2P_2)^2$$

is a first integral of system (IV.3). As $\mathrm{dH}_{\mathcal{T}} \wedge dF \not\equiv 0$, first integral $\mathrm{H}_{\mathcal{T}}$ and F are functionally independent. Thus system (IV.3) is completely integrable. □

There does not exist a direct ''recipe'' which allows us to obtain an explicit form of solutions of an integrable system. In fact, in general, it is a difficult task. Below, we demonstrate how to obtain an explicit form of a solution of system (IV.3). To this end, we first introduce noncanonical variables defined as follows:

$$z_i := \frac{\dot{q}_i}{q_i}, \quad i = 1,2,3.$$

In variables $(q_1,q_2,q_3,z_1,z_2,z_3)$ Bianchi class A models have the following form

$$\dot{q}_i = q_i z_i, \quad \dot{z}_i = (n_j q_j - n_k q_k)^2 - n_i^2 q_i^2,$$

where (i,j,k) runs all even permutations of $\{1,2,3\}$. In new variables Hamiltonian (III.1) reads

$$4\mathrm{H} = \sum_{1 \leqslant i < j \leqslant 3} (z_i z_j + 2 n_i n_j q_i q_j) - \sum_{i=1}^{3} (n_i q_i)^2.$$

Next we perform only for the B(VIII) model. We make a transformation

$$x := (q_1, q_2, q_3, z_1, z_2, z_3) \to X := (Q_1, Q_2, Q_3, Z_1, Z_2, Z_3),$$

given by $x = AX$, where matrix A is defined by (IV.1). The explicit form of equations of motion is the following:

$$\dot{Q}_1 = \tfrac{1}{2}(Q_1 Z_2 + Q_2 Z_1),$$

$$\dot{Q}_2 = \tfrac{1}{2}(Q_1 Z_1 + Q_2 Z_2),$$

$$\dot{Q}_3 = Q_3 Z_3,$$

$$\dot{Z}_1 = -4 Q_1 (2 Q_2 + Q_3),$$

$$\dot{Z}_2 = 2 Q_3 (2 Q_2 + Q_3),$$

$$\dot{Z}_3 = 4 Q_1^2 - Q_3^2,$$

and the first integral H reads

$$4\mathrm{H} = -4 Q_1^2 - Q_3 (4 Q_2 + Q_3) + Z_2 Z_3 + \tfrac{1}{4}(Z_2^2 - Z_1^2).$$

Now, invariant set $\mathcal{T}$ is defined as follows:

$$\mathcal{T} = \{(Q_1, Q_2, Q_3, Z_1, Z_2, Z_3) \,|\, Q_1 = 0, \quad Z_1 = 0\},$$

and the B(VIII) system restricted to $\mathcal{T}$ has the form

$$\dot{Q}_2 = \tfrac{1}{2} Q_2 Z_2, \tag{IV.4}$$

$$\dot{Q}_3 = Q_3 Z_3, \tag{IV.5}$$

$$\dot{Z}_2 = 2 Q_3 (2 Q_2 + Q_3), \tag{IV.6}$$

$$\dot{Z}_3 = -Q_3^2. \tag{IV.7}$$

This system possesses two functionally independent first integrals

$$H_{\mathcal{T}} = -Q_3 (4 Q_2 + Q_3) + Z_2 Z_3 + \tfrac{1}{4} Z_2^2, \quad G = Q_3^2 + Z_3^2.$$

Equations (IV.5) and (IV.7) form a closed subset which can be easily integrated explicitly if one takes into account that $Q_3^2 + Z_3^2$ is its first integral. The solution has the form

$$Q_3(t) = \frac{2Ak\mathrm{e}^{At}}{1 + k^2 \mathrm{e}^{2At}}, \quad Z_3(t) = A \frac{1 - k^2 \mathrm{e}^{2At}}{1 + k^2 \mathrm{e}^{2At}}, \tag{IV.8}$$

where $A \geqslant 0$ [because, as we already stated, the original phase space of the B(VIII) model is $T^*\mathbb{R}^3_+$], and $k \in \mathbb{R}$ are constants of integration. Thus, the main difficulty lies in explicit integrations of the subsystem formed by Eqs. (IV.4) and (IV.6). However, let us notice that, using first integral $\mathrm{H}_{\mathcal{T}}$, we can rewrite Eq. (IV.6) in the form

$$\dot{Z}_2 = \tfrac{1}{4} Z_2^2 + Z_3(t) Z_2 + Q_3(t)^2 - B, \tag{IV.9}$$

where B is the value of integral $\mathrm{H}_{\mathcal{T}}$. This is the Ricatti equation, and now the main difficulty of solving it lies in finding its particular solution. Equation (IV.9) depends on three parameters and thus we have to find a particular solution which is valid for all values of the parameters. It must be noted that there is no universal method for finding a particular solution of a Ricatti equation. However, in our case we can try to find it as a function of $Z_3(t)$. Direct calculations show that

$$U(t) = -2Z_3(t) + 2\sqrt{A^2 + B}$$

is a desired particular solution. In the above formula we assumed that $A^2 + B \geqslant 0$ because we look for real solutions, and we take the positive value of the square root. Now, using the standard procedure (see, e.g., Ref. 37), we obtain a general solution of (IV.9) in the form

$$Z_2(t) = Z(t)^{-1} + U(t), \tag{IV.10}$$

where

$$Z(t) = C \exp[-t\sqrt{A^2 + B}] - \frac{1}{4\sqrt{A^2 + B}},$$

and where C is an integration constant. Finally, integrating Eq. (IV.4) we obtain

$$Q_2(t) = D \frac{(1 + k^2 \exp 2tA) \exp[t(\sqrt{A^2 + B} - A)]}{(4C\sqrt{A^2 + B} - \exp[t\sqrt{A^2 + B}])^2}, \tag{IV.11}$$

where D is an integration constant.

Integrating system (IV.4)–(IV.7) we introduced five constants (A, B, C, D, k). However, only four of them can be independent. In fact, Eqs. (IV.8), (IV.10) and (IV.11) give a solution of system (IV.4)–(IV.7) if and only if the following condition is fulfilled:

$$2C(A^2 + B)^{3/2} = kAD. \tag{IV.12}$$

For further investigation we select only nonequilibrium solutions. As it is easy to verify Eqs. (IV.8), (IV.10) and (IV.11), define an equilibrium if and only if

$$A = B = 0, \quad \text{or} \quad A = D = C = 0, \quad \text{or} \quad k = D = A^2 + B = 0.$$

In our further investigations we plan to study those solutions which lie on the zero energy level. More precisely, we are interested in all real nonequilibrium solutions which lie on the invariant set $\mathrm{H}^{-1}(0) \cap \mathcal{T}$. For these solutions we have $B = 0$. Summarizing, all real nonequilibria solutions of system (IV.4)–(IV.7) which lie on the Taub manifold are given by (IV.8), (IV.10) and (IV.11) with $(A, B, C, D, k) \in \mathcal{P}$, where

$$\mathcal{P} := \{(A, B, C, D, k) \in \mathbb{R}_+ \times \mathbb{R}^4 \,|\, A > 0, \ B = 0, \ 2CA^2 = kD\}. \tag{IV.13}$$

V. NORMAL VARIATIONAL EQUATIONS

We can extend the B(VIII) Hamiltonian system to a complex one, i.e., as the phase space we can take $\mathbb{C}^6$. Moreover, we can take time as a complex variable. Solutions found in the previous section naturally extend to the complex time.

Let us take a solution $(Q_2(t),Q_3(t),Z_2(t),Z_3(t))$ which lies on invariant manifold $\mathcal{T}$, and let us write variational equations associated with this solution. They have the following form:

$$\frac{\mathrm{d}}{\mathrm{d}t}\eta=\Lambda(t)\eta, \quad \eta\in\mathbb{C}^6,$$

where

$$\Lambda(t)=\frac{1}{2}\begin{bmatrix} Z_2(t) & 0 & 0 & Q_2(t) & 0 & 0 \\ 0 & Z_2(t) & 0 & 0 & Q_2(t) & 0 \\ 0 & 0 & 2Z_3(t) & 0 & 0 & 2Q_3(t) \\ \tilde{Q}(t) & 0 & 0 & 0 & 0 & 0 \\ 0 & 8Q_3(t) & 8Q(t) & 0 & 0 & 0 \\ 0 & 0 & -4Q_3(t) & 0 & 0 & 0 \end{bmatrix},$$

and $Q(t)=-8(2Q_2(t)+Q_3(t))$, $\tilde{Q}(t)=Q_2(t)+Q_3(t)$. From the definition of this manifold it follows that variations normal to $\mathcal{T}$ correspond to (η_1,η_4), and thus the normal variational equations are the following:

$$\frac{\mathrm{d}}{\mathrm{d}t}\eta_1=\frac{1}{2}Z_2(t)\eta_1+\frac{1}{2}Q_2(t)\eta_4,$$

$$\frac{\mathrm{d}}{\mathrm{d}t}\eta_4=-4[2Q_2(t)+Q_3(t)]\eta_1.$$

We transform this system to one equation of second order. To this end we determine η_4 from the first equation and we substitute it in the second. After simple calculations we obtain

$$\ddot{\xi}+a(t)\dot{\xi}+b(t)\xi=0, \tag{V.1}$$

where

$$a(t)=-Z_2(t), \quad b(t)=4Q_2(t)^2-Q_3(t)^2+\tfrac{1}{4}Z_2(t)^2,$$

and $\xi:=\eta_1$.

VI. MAIN RESULT

Generally, for a Taub solution given by (IV.8), (IV.10) and (IV.11) we do not know how to decide whether the identity component of the differential Galois group is Abelian or not. The reason is connected with the fact that we do not know how to transform Eq. (V.1) to an equation with rational coefficients. However, when such solution lies on the zero energy level $\mathrm{H}^{-1}(0)$ [it is equivalent to taking $(A,B,C,D,k)\in\mathcal{P}$ in (IV.8), (IV.10) and (IV.11)] then it is rational with respect to variable $z=\exp[At]$. This suggests making transformation $t\to z$ in (V.1). In order to minimize the number of parameters we distinguish two cases $k\neq 0$ and $k=0$, and we define

$$z(t):=\begin{cases} k\exp[At] & \text{for } k\neq 0, \\ \exp[At] & \text{for } k=0. \end{cases}$$

Let us note that the above transformation (which is a covering of the Riemannian surface) does not change the identity component of the differential Galois group of NVE. Now, after transformation $t\to z$ Eq. (V.1) has the form

$$\xi''+p(z)\xi'+q(z)\xi=0,$$

where

$$p(z)=\frac{A+a(t(z))}{Az},\quad q(z)=\frac{b(t(z))}{A^2z^2}.$$

Finally, putting

$$w:=\xi\exp\frac{1}{2}\int p(\tau)\,\mathrm{d}\tau,$$

we transform NVE to the reduced form

$$w''-r(z)w=0, \tag{VI.1}$$

where

$$r(z)=\frac{1}{2}\frac{dp(z)}{dz}+\frac{1}{4}p(z)^2-q(z).$$

For $k=0$ (in this case necessarily $C=0$) we have

$$r(z)=-\frac{c^2}{z^6}-\frac{1}{4z^2},\quad \text{where } c=\frac{2D}{A}. \tag{VI.2}$$

When $k\neq 0$ then

$$r(z)=\frac{s(z)}{z^2(z-c)^4},\quad c=4kAC, \tag{VI.3}$$

where

$$s(z)=-\tfrac{1}{4}(1+4c^2)z^4-cz^3+\tfrac{1}{2}c^2z^2-c^3z-c^2(1+\tfrac{1}{4}c^2).$$

We prove now that NVEs with $r(z)$ given by (VI.2) and (VI.3) have no Liouvillian solution.

Lemma 3: For $c\neq 0$ Eq. (VI.1) *with $r(z)$ given by* (VI.2) *has no Liouvillian solution.*

Proof: Let us use the Kovacic algorithm presented in the Appendix. We have $\Gamma'=\{0\}$, $\Gamma=\{0,\infty\}$, $\mathrm{ord}(0)=6$, $\mathrm{ord}(\infty)=2$, thus $m^+=6$ and $\gamma_2=\gamma=1$. Conditions 3, 4, 5 in the first step in the Appendix give $L=\{1\}$. It follows that we have $n=1$ and we proceed to the second step. Point 3 in this step gives $E_\infty=\{\frac{1}{2}\}$, and in point 5 we easily determine that $a_0=\mathrm{i}c$, $b_0=0$, and thus $E_0=\{\frac{3}{2}\}$. There is only one element in Cartesian product $E_0\times E_\infty$, namely $e=(e_0,e_\infty)=(\frac{3}{2},\frac{1}{2})$, and for it we have $d(e)=-1\notin\mathbb{N}_0$. Thus the equation considered has no Liouvillian solution. □

Lemma 4: For $c\neq 0$ Eq. (VI.1) *with $r(z)$ given by* (VI.3) *has no Liouvillian solution.*

Proof: As in the previous lemma we apply the Kovacic algorithm. We have $\Gamma'=\{0,c\}$, $\Gamma=\{0,c,\infty\}$, $\mathrm{ord}(0)=2$, $\mathrm{ord}(c)=4$, $\mathrm{ord}(\infty)=2$, thus $m^+=4$ and $\Gamma_2=\{0,\infty\}$, $\gamma_2=\gamma=2$. Conditions 3–5 in the first step give $L=\{1,2\}$. The partial fraction expansion for $r(z)$ has the form

$$r(z)=-\frac{4+c^2}{4c^2z^2}-\frac{2(2+c^2)}{c^3z}-\frac{(1+c^2)^2}{(z-c)^4}+\frac{2(1-c^4)}{c(z-c)^3}-\frac{2+(1+c^2)^2}{c^2(z-c)^2}+\frac{2(2+c^2)}{c^3(z-c)},$$

thus

$$\alpha_0=-\frac{4+c^2}{4c^2},\quad \Delta_0=\frac{2\mathrm{i}}{c}.$$

The Laurent series expansion of $r(z)$ at infinity has the form

$$r(z)=-\frac{1+4c^2}{4z^2}+O\left(\frac{1}{z^3}\right),$$

and thus

$$\alpha_\infty=-\tfrac{1}{4}-c^2,\quad \Delta_\infty=2\mathrm{i}c.$$

Now, we put $n=1$ and we go to the second step. We have

$$E_0=\left\{\frac{1}{2}\pm\frac{\mathrm{i}}{c}\right\},\quad E_\infty=\left\{\frac{1}{2}\pm\mathrm{i}c\right\}.$$

For pole $z=c$ we can find that

$$[\sqrt{r}]_c=\frac{\pm\mathrm{i}(1+c^2)}{(x-c)^2},\quad \text{thus}\quad a_c=-\mathrm{i}(1+c^2),$$

$$r-[\sqrt{r}]_c^2=\frac{2(1-c^4)}{c(z-c)^3}+O\left(\frac{1}{(z-c)^2}\right),\quad \text{thus}\quad b_c=2\,\frac{1-c^4}{c}.$$

From these calculations we find

$$E_c=\left\{1\pm\mathrm{i}\frac{1-c^2}{c}\right\}.$$

As $c\in\mathbb{R}\setminus\{0\}$, for $e\in E_0\times E_c\times E_\infty$ we have

$$\mathrm{Re}\sum_{p\in\Gamma}e_p=2\quad\text{and}\quad \mathrm{Re}\,d(e)=-1;$$

thus, it never happens that $d(e)\in\mathbb{N}_0$. It follows that we have to start from the second step of the algorithm with $n=2$. Now, we have

$$E_0=\{2(1-\Delta_0)+2j\Delta_0\,|\,j=0,1,2\}\cap\mathbb{Z}=2,$$

$$E_\infty=\{2(1-\Delta_\infty)+2j\Delta_\infty\,|\,j=0,1,2\}\cap\mathbb{Z}=2,$$

and $E_c=4$. Thus for unique $e=(2,4,2)$ we have $d(e)=-2\notin\mathbb{N}_0$, and we can conclude that the equation has no Liouvillian solution. □

Using the above two lemmas we prove the following.

Theorem 2: *The Hamiltonian system describing the* B(VIII) *model is not completely integrable in a neighborhood of a nonequilibrium Taub solution lying on the level* $\mathrm{H}^{-1}(0)$.

Proof: In fact, let us take a solution given by (IV.8), (IV.10) and (IV.11) with $(A,B,C,D,k)\in\mathcal{P}$. If $k=0$, then, by Lemma 3, NVE has no Liouvillian solution. Thus the identity component of the differential Galois group of NVE is $\mathrm{SL}(2,\mathbb{C})$, and from Theorem 1 it follows that the B(VIII) model is not completely integrable in a neighborhood of the selected solution. For $k\neq0$ we repeat the same arguments using Lemma 4. This ends the proof. □

VII. REMARKS AND COMMENTS

We proved that the B(VIII) model is not completely integrable in a neighborhood of an arbitrary nonequilibrium Taub solution lying on the zero level of the Hamiltonian. The method applied gives the nonintegrability result for all such solutions (note that they form a family parametrized by three parameters). As the theory used formulates only the necessary conditions for nonintegrability, one can expect that for specific values of parameters these conditions are not satisfied. For the system studied above it is not the case. It will be interesting and important to find examples where such phenomenon occurs. In fact, the applied theory gives only very limited insight into dynamical reasons of the nonintegrability, see Ref. 12. Thus, having examples for which this theory does not yield the nonintegrability for some parameters values we can numerically investigate a neighborhood of the particular solution. It seems that the obtained local phase portrait should show which dynamical phenomena are not ''sensed'' by the applied theory.

Let us stress that to relate the algebraic features of the system to geometry of its orbits is the main open problem in this domain.

ACKNOWLEDGMENTS

We thank J.-A. Weil (Université de Limoges, France) for his pertinent comments concerning our presentation of the Kovacic algorithm. We thank J. J. Morales Ruiz (Universitat Politécnica de Catalunya) for his helpful remarks. We thank also Zbroja for her linguistic help and patience. For the first two authors this work was supported by program Jumelage.

The second author thanks N. Belili (Université d'Evreux, France) and D. Gutkin (Université Paris 13, France) for some Maple computations.

APPENDIX: KOVACIC ALGORITHM

The Kovacic algorithm gives an answer to the question if a linear second order differential equation with rational coefficients

$$w''+pw'+qw=0, \quad p, q\in\mathbb{C}(z), \quad '\equiv\frac{d}{dz}, \tag{A1}$$

possesses a Liouvillian solution. For definitions, details and proofs related to differential algebra, Refs. 29, 33, and 36. It is important that an answer to this question is connected with properties of the identity component of the differential Galois group of (A1).

It is known that when Eq. (A1) possesses a nonzero Liouvillian solution then all its solutions are Liouvillian. Making a change of variables

$$y=w\exp\frac{1}{2}\int p,$$

we transform (A1) to the reduced form

$$y''=ry, \tag{A2}$$

where

$$r=\tfrac{1}{2}p'+\tfrac{1}{4}p^2-q.$$

The new equation has the same identity component of differential Galois group as (A1). The logarithmic derivative $\omega:=y'/y$ of a solution y of Equation (A2) satisfies the Riccati equation

$$\omega'+\omega^2=r, \tag{A3}$$

and, according to Lie–Kolchin's theorem, Eq. (A2) has a Liouvillian solution if and only if the corresponding Riccati equation (A3) has an algebraic solution. Moreover, the degree n of the minimal polynomial for this algebraic solution belongs to

$$L_{\max} := \{1,2,4,6,12\}.$$

The differential Galois group G of (A2) is an algebraic subgroup of $\mathrm{SL}(2,\mathbb{C})$ and its identity component G^0 is of one of the following forms

Case 1: G^0 is triangularizable; for this case Eq. (A2) is reducible and has a solution of the form $y=\exp\int\omega$, where $\omega\in\mathbb{C}(z)$, i.e., Riccati equation (A3) has a rational solution $(n=1)$.

Case 2: G^0 is imprimitive; for this case Eq. (A2) has a solution of the form $y=\exp\int\omega$, where ω is algebraic over $\mathbb{C}(z)$ of degree 2, i.e., Riccati equation (A3) has an algebraic solution of degree $n=2$.

Case 3: G^0 is primitive and finite; for this case all solutions of Eq. (A2) are algebraic and Riccati equation (A3) has an algebraic solution of degree $n\in\{4,6,12\}$.

Case 4: $G^0=\mathrm{SL}(2,\mathbb{C})$ and Eq. (A2) has no Liouvillian solution, i.e. Riccati equation (A3) has no algebraic solution.

Now, we present the algorithm. First, we fix notation. The set of non-negative integers is denoted by $\mathbb{N}_0$. We define on $L_{\max}$ function h in the following way:

$$h(1)=1,\quad h(2)=2,\quad h(4)=3,\quad h(6)=2,\quad h(12)=1.$$

We write $r\in\mathbb{C}(z)$ in the form

$$r=\frac{s}{t},\quad s,t\in\mathbb{C}[z],$$

where s and t are relatively prime and t is monic. The algorithm consists of three steps.

First step

(1) Let $\Gamma' := \{c\in\mathbb{C}\mid t(c)=0\}$, $\Gamma := \Gamma'\cup\{\infty\}$. The order $\mathrm{ord}(c)$ of $c\in\Gamma'$ is equal to the multiplicity of c as a root of t; the order of infinity is defined by

$$\mathrm{ord}(\infty) := \max(0,4+\deg s-\deg t).$$

(2) Define

$$m^+ := \max_{c\in\Gamma}\mathrm{ord}(c).$$

For $i\in\mathbb{N}_0$ let

$$\Gamma_i := \{c\in\Gamma\mid \mathrm{ord}(c)=i\},$$

$$\Gamma_i' := \Gamma_i\setminus\{\infty\},\quad \gamma_i := \mathrm{card}\,\Gamma_i,\quad \text{and}\quad \gamma := \gamma_2+\sum_{\substack{\text{odd } k\\ 3\leqslant k\leqslant m^+}}\gamma_k.$$

(3) Define $L'\subset L_{\max}$ by the following rules:

$$1\in L'\Leftrightarrow \gamma=\gamma_2,$$

$$2\in L'\Leftrightarrow \gamma\geqslant 2,$$

$$4,6,12\in L'\Leftrightarrow m^+\leqslant 2.$$

(4) For each $c\in\Gamma_1\cup\Gamma_2$ find the Laurent series expansion of r around c in the form

$$r=\frac{\alpha_c}{(z-c)^2}+\frac{\beta_c}{z-c}+O(1),$$

for $c\in\Gamma_1'\cup\Gamma_2'$, and

$$r=\frac{\alpha_\infty}{z^2}+\frac{\beta_\infty}{z^3}+O\left(\frac{1}{z^4}\right),$$

for $c=\infty$. Put $\Delta_c:=\sqrt{1+4\alpha_c}$.

(5) If $m^+>2$, then $L=L'$. If $m^+\leqslant 2$ and $\forall c\in\Gamma_1\cup\Gamma_2\ \Delta_c\in\mathbb{Q}$, then $L=L'$ else $L=L'\setminus\{4,6,12\}$.

(6) If $L=\varnothing$, then go to **End** else assign n to the smallest element of L.

Second step

(1) If $\infty\in\Gamma_0$, then $E_\infty:=\{h(n)k\mid k=0,\ldots,n\}$.

(2) For each $c\in\Gamma_1$, define set $E_c:=\{nh(n)\}$.

(3) When $n=1$, for each $c\in\Gamma_2$, define the set

$$E_c:=\left\{\frac{1}{2}(1\pm\Delta_c)\right\}.$$

(4) When $n\geqslant 2$, for each $c\in\Gamma_2$, define the set

$$E_c:=\left\{\frac{h(n)}{2}(n-(n-2j)\Delta_c)\;\middle|\; j=0,\ldots,n\right\}\cap\mathbb{Z}.$$

If at least one set E_c is empty then go to **Continue**.

(5) When $n=1$, for each $c\in\Gamma_{2k}$, with $k\geqslant 2$, compute rational function $[\sqrt{r}]_c$ defined up to sign by the following conditions:

- for $c\in\Gamma_{2k}'$

$$[\sqrt{r}]_c=\frac{a_c}{(z-c)^k}+\sum_{2\leqslant j\leqslant k-1}\frac{s_{j,c}}{(z-c)^j},$$

$$r-[\sqrt{r}]_c^2=\frac{b_c}{(z-c)^{k+1}}+O\left(\frac{1}{(z-c)^k}\right),$$

- for $c=\infty$

$$[\sqrt{r}]_\infty=a_\infty z^{k-2}+\sum_{0\leqslant j\leqslant k-3}s_{j,\infty}z^j,$$

$$r-[\sqrt{r}]_\infty^2=-b_\infty z^{k-3}+O(z^{k-4}).$$

Now define the set E_c by

$$E_c:=\left\{\frac{1}{2}\left(k+\varepsilon\frac{b_c}{a_c}\right)\;\middle|\;\varepsilon=\pm 1\right\},$$

and function

$$\text{sign: } E_c\to\{+1,-1\},$$

$$\operatorname{sign}\left(\frac{1}{2}\left(k+\varepsilon\frac{b_c}{a_c}\right)\right):=\begin{cases}\varepsilon & \text{if} \quad b_c\neq 0,\\ +1 & \text{if} \quad b_c=0.\end{cases}$$

(6) When $n=2$ for each $c\in\Gamma_k$, with $k\geqslant 3$, define the set E_c by $E_c:=\{k\}$.

Third step

(1) For each $e=\{e_c\}_{c\in\Gamma}$ in Cartesian product $E:=\Pi_{c\in\Gamma}E_c$ compute

$$d(e)=n-\frac{1}{h(n)}\sum_{c\in\Gamma}e_c.$$

(2) Select elements e for which

(a) $d(e)\in\mathbb{N}_0$, and
(b) when $n=2$ or $n=6$, then e has an even number of components which are odd integers, and
(c) when $n=4$, then e has at least two components which are not divisible by 3 and the sum of all components which are not divisible by 3 is divisible by 3.

If no such element exists, then go to **Continue**.

(3) For each selected element e put

$$\theta=\frac{1}{h(n)}\sum_{c\in\Gamma'}\frac{e_c}{z-c}+\delta_n^1\sum_{\substack{c\in\Gamma_{2k}\\ k>1}}\operatorname{sign}(e_c)[\sqrt{r}]_c,$$

where δ_n^1 is the Kronecker symbol.

(4) For each (e,θ) decide if there exists a monic polynomial P of degree $d=d(e)$ satisfying the following system of equations,

$$P_n=-P,$$

$$P_{i-1}=-P_i'-\theta P_i-(i+1)(n-i)rP_{i+1},\quad \text{for}\quad n\geqslant i\geqslant 0,$$

$$P_{-1}=0,$$

and if so find it (in the above formulas P_i' denotes the derivative of P_i with respect to z).

Output: If a pair (θ,P) is found, then equation $y''=ry$ possesses the Liouvillian solution $\eta=\exp\int\omega$ where ω is a solution of the following irreducible algebraic equation

$$\sum_{i=1}^{n}\frac{P_i}{(n-i)!}\omega^i=0,$$

else

Continue: if n is not the greatest element in L then assign to n the next value in L and go to **Second step** else

End: equation $y''=ry$ has no Liouvillian solution.

1. Comments

A formulation of the Kovacic algorithm given in Ref. 38 is alternative to its original form and to that presented previously. It seems that it is much more convenient for computer implementation. However, for differential equations with simple structure of singularities, and depending on parameters it seems that the previous form of the algorithm is well suited. Let us note also that, as it was explained in Ref. 38, the polynomial P which appears in the point 4 of the third step satisfies a linear differential equation of order $n+1$ (this equation is isomorphic, as a differential operator, of the nth symmetric power of the investigated equation).

In the original formulation of the algorithm[23] consisting in fact, of three separated algorithms corresponding to cases 1, 2 and 3, each of them repeats similar steps. In Ref. 36 one can find a modification of the original formulation unifying and improving three algorithms in one. This form is very convenient for applications. However, there are errors in the algorithm. In fact, for

$$r(z)=-\frac{3}{16z^2}-\frac{2}{9(z-1)^2}+\frac{3}{16z(z-1)},$$

the equation $y''=r(z)y$ has a Liouvillian solution (see Ref. 33, Example 1, p. 23), but algorithm in Ref. 36 finds no such solution. Our analysis showed that there are three errors. Namely, we have the following.

(1) Conditions 5 in the first step of the algorithm (see Ref. 36, p. 215) are wrong. These conditions do not appear in earlier published versions of the algorithm[34,35]. However, when correctly stated they are important—they are necessary conditions for the existence of an algebraic solution (case 3). Their meaning is the following. If case 3 occurs, then poles $c\in\Gamma'$ have order not greater than 2 and for all $c\in\Gamma'$ we have $\Delta_c\in\mathbb{Q}$. Moreover, $c=\infty$ has order not greater then 2. This is equivalent to $\Sigma_{c\in\Gamma_1'\cup\Gamma_2'}\beta_c=0$. Finally, as it was shown in Ref. 33 (p. 11),

$$\alpha_\infty=\sum_{c\in\Gamma_2'}\alpha_c+\sum_{c\in\Gamma_1'\cup\Gamma_2'}c\beta_c.$$

Thus, the proper necessary condition is $\Delta_\infty\in\mathbb{Q}$.

(2) In the third step condition 2(b), $n=4$ in Ref. 36 (p. 216) is not correct. In fact, for

$$r(z)=-\frac{5z^2+27}{36(z^2-1)^2},$$

the equation $y''=r(z)y$ has an algebraic solution and case $n=4$ occurs (see Ref. 33, Example 2, p. 25). Applying the algorithm of Ref. 36 we find for $n=4$, $e=(4,4,4)\in E_1\times E_{-1}\times E_\infty$. For this e we have $d(e)=0$, but, according to the mentioned condition, we have to reject it from further calculations. However, exactly for this e, using the original algorithm we find the desired solution. This error appears also in the earlier version of the algorithm.[34,35]

(3) In the third step there is an additional condition for $n=4$ in 2(b). Namely, at least two components of e are divisible by 3. The example in the previous point shows that it is not a correct condition. In the earlier version of the algorithm the mentioned condition reads ''... at least two components of e are not multiples of 3,'' and this is the correct condition.

Let us explain how the proper condition for components of vectors e in the third step can be deduced. For $n=2$, 4 and 6 we can choose the fundamental solution (ξ,η) of the equation $y''=ry$ in such a way that $u_n^{h(n)}\in\mathbb{C}(z)$, where $u_2:=\xi\eta$, $u_4:=\eta^4+8\eta\xi^3$, and $u_6:=\xi\eta^5-\xi^5\eta$. Moreover, from the structure of differential Galois groups for the respective cases it follows that $u_n\notin\mathbb{C}(z)$ for $n=2$, 4 and 6. Thus writing

$$u_n^{h(n)}=\prod_{c\in\Gamma'}(z-c)^{e_c},\quad e_c\in\mathbb{Z},$$

we deduce that for $n=2$ and $n=6$ at least one e_c for $c\in\Gamma'$ is an odd integer, and for $n=4$ at least one e_c is not divisible by 3. Moreover, we have

$$d(e)=n-\frac{1}{h(n)}\sum_{c\in\Gamma}e_c,\quad e_c\in\mathbb{Z},$$

and this implies the necessary conditions in the presented algorithm.

Finally let us notice that in Ref. 39 necessary conditions for the existence of a Liouvillian solution of third and second order linear differential equations were formulated. This article gives also a clear explanation of the origin of arithmetic conditions which appear in the present formulation of the algorithm.

Reduction of dispersionless coupled Korteweg–de Vries equations to the Euler–Darboux equation

Yoshimasa Matsuno[a)]
Department of Applied Science, Faculty of Engineering, Yamaguchi University, Ube 755-8611, Japan

(Received 4 January 2000; accepted for publication 5 December 2000)

A quasilinear hyperbolic system of two first-order equations is introduced. The system is linearized by means of the hodograph transformation combined with Riemann's method of characteristics. In the process of linearization, the main step is to explicitly express the characteristic velocities in terms of the Riemann invariants. The procedure is shown to be performed by quadrature only for specific combinations of the parameters in the system. We then apply the method developed here to the dispersionless versions of the typical coupled Korteweg–de Vries (cKdV) equations including the Broer–Kaup, Ito, Hirota–Satsuma, and Bogoyavlenskii equations and show that these equations are transformed into the classical Euler–Darboux equation. A more general quasilinear system of equations is also considered with application to the dispersionless cKdV equations for the Jaulent–Miodek and Nutku–Öğuz equations. © *2001 American Institute of Physics.* [DOI: 10.1063/1.1345500]

I. INTRODUCTION

In the development of soliton theory, a large number of nonlinear evolution equations have been found that can be solved by means of the inverse scattering transform (IST).[1–3] A remarkable feature of the IST is that it enables us to reduce essentially nonlinear problems to linear ones and this fact makes it possible to solve the initial value problem of a wide class of nonlinear evolution equations. The equations solved by the IST are now called soliton equations. Although the IST provides a general scheme for solving soliton equations, it is difficult to construct solutions analytically for arbitrary initial conditions. Exceptions are soliton solutions which can be obtained by purely algebraic means.

If one neglects dispersive terms, however, soliton equations are considerably simplified and they may sometimes be solved analytically without recourse to the IST. For a certain class of initial conditions, the solutions thus obtained would become multivalued functions after a finite time due to the effect of nonlinearity, namely wave-breaking occurs which usually accompanies shocks. While the properties of the solutions for the original dispersive equations in the small dispersion limit generally differ from those of the corresponding dispersionless equations, the latter provides useful information on wave characteristics such as the wave profile prior to wave-breaking and the time and location of shock formation.

The purpose of this paper is to show that typical dispersionless soliton equations are reducible to the linear equations whose solutions have been studied in detail. In particular, we are concerned here with the dispersionless coupled Korteweg–de Vries (cKdV) equations. It is demonstrated by means of the hodograph transformation combined with Riemann's method of characteristics that these equations can be transformed into either the Euler–Darboux (ED) equation or the Euler–Poisson–Darboux (EPD) equation which is a special case of the ED equation. The method of exact solution for both equations is now well known, mainly due to the original work of Riemann. This paper is organized as follows. In Sec. II, a quasilinear hyperbolic system of two first-order

[a)]Electronic mail: matsuno@po.cc.yamaguchi-u.ac.jp

equations is introduced in two independent variables which are closely related to the dispersionless cKdV equations. The characteristic velocities and associated Riemann invariants are defined for this system. We regard the Riemann invariants as new independent variables and use the hodograph method to transform the quasilinear system of equations into a linear system of equations with respect to the time and space variables. Tsarev's method for solving the hodograph equations is also discussed. Then, we calculate the Riemann invariants by elementary integration and derive the conditions under which the characteristic velocities are represented explicitly by the Riemann invariants. In Sec. III, we exemplify various types of dispersionless cKdV equations which include the dispersionless versions of the Broer–Kaup, Ito, Hirota–Satsuma, and Bogoyavlenskii equations. It is shown that all these equations are transformed into the ED or EPD equations. In Sec. IV, we extend the method developed in Sec. II to a more general class of quasilinear system of equations and use it to linearize the dispersionless equations for the Jaulent-Miodek and Nutku–Öğuz equations. Section V is devoted to concluding remarks. In Appendix A, we derive an infinite number of conservation laws for the quasilinear system of equations considered in Sec. II. In Appendix B, the periodic-wave and soliton solutions for Ito's cKdV equation are presented which will suggest a hint for constructing general multisoliton solutions.

II. QUASILINEAR HYPERBOLIC SYSTEM

Let us introduce the following quasilinear system of first-order equations:

$$u_t = \alpha u u_x + \beta v v_x, \tag{2.1a}$$

$$v_t = \gamma v u_x + \delta u v_x, \tag{2.1b}$$

where $u=u(x,t)$ and $v=v(x,t)$ are real functions of x and t and α, β, γ, and δ are real parameters. We assume that $\beta \neq 0$ since the case $\beta=0$ decouples the equation for u from (2.1a). The notations $u_t=\partial u/\partial t, u_x=\partial u/\partial u_x$, etc. are used for convenience. The system of Eqs. (2.1) can be written compactly in a vector form as

$$\mathbf{u}_t = A\mathbf{u}_x, \quad \mathbf{u}=\begin{pmatrix} u \\ v \end{pmatrix}, \quad A=(A_{ij})=\begin{pmatrix} \alpha u & \beta v \\ \gamma v & \delta u \end{pmatrix}. \tag{2.2}$$

We consider here the hyperbolic system which is defined by the condition

$$\Delta \equiv (\alpha-\delta)^2 u^2 + 4\beta\gamma v^2 > 0. \tag{2.3}$$

As will be seen in Sec. III, typical dispersionless cKdV equations are reduced to (2.1) by appropriate change of dependent variables. In Appendix A, an infinite number of conservation laws are derived for Eq. (2.1).

A. Riemann invariants

In order to solve (2.1), we use the hodograph transformation combined with Riemann's method of characteristics. Although the method is well-known,[4,5] we shall summarize it in a form relevant to the present problem. The characteristic velocity c is defined by the solution of the following characteristic equation,

$$\det(A_{ij} - \delta_{ij} c) = 0, \tag{2.4}$$

where δ_{ij} is Kronecker's delta. Introducing A into (2.4), one obtains

$$c^{\pm} = \tfrac{1}{2}[(\alpha+\delta)u \pm \sqrt{(\alpha-\delta)^2 u^2 + 4\beta\gamma v^2}], \tag{2.5}$$

with the $\pm$ signs ordered vertically. The condition of hyperbolicity (2.2) assures that $c^{\pm}$ are real and distinct. Let $\mathbf{l}^{+}=(l_1^{+},l_2^{+})$ denotes a left eigenvector of A associated with the eigenvalue c^{+}, i.e., $\mathbf{l}^{+}\cdot A=c^{+}\mathbf{l}^{+}$. It then follows from (2.2) that $\mathbf{l}^{+}\cdot\mathbf{u}_t=\mathbf{l}^{+}\cdot A\mathbf{u}_x=c^{+}\mathbf{l}^{+}\cdot\mathbf{u}_x$. In terms of the components l_1^{+},l_2^{+}, this relation becomes

$$l_1^{+}\frac{du}{dt}+l_2^{+}\frac{dv}{dt}=0, \tag{2.6}$$

where $du/dt=u_t+(dx/dt)u_x=u_t-c^{+}u_x(dx/dt=-c^{+})$. If we rewrite (2.6) as $du/dv=-l_2^{+}/l_1^{+}$ and express l_1^{+} and l_2^{+} in terms of u and v, we can regard this equation as an ordinary differential equation for u with v being an independent variable. Its solution defines the Riemann invariant ϕ,

$$\phi(u,v)=\xi=\text{const. on}\frac{dx}{dt}=-c^{+}. \tag{2.7}$$

Similarly, one finds for c^{-},

$$l_1^{-}\frac{du}{dt}+l_2^{-}\frac{dv}{dt}=0, \tag{2.8}$$

where $\mathbf{l}^{-}=(l_1^{-},l_2^{-})$ is a left eigenvector corresponding to c^{-}. This equation yields another Riemann invariant ψ,

$$\psi(u,v)=\eta=\text{const. on}\frac{dx}{dt}=-c^{-}. \tag{2.9}$$

The Riemann invariants (2.7) and (2.9) play roles analogous to integrals for systems of ordinary differential equations.

B. Hodograph transformation

The hodograph transformation reverses the roles of the dependent and independent variables. In the present case, we regard x and t as functions of u and v. However, if we use (2.7) and (2.9), we can express u and v by the Riemann invariants ξ and η. Hence, it is more convenient to choose ξ and η as new independent variables, i.e., $x=x(\xi,\eta),t=t(\xi,\eta)$. Then, on the characteristic curve $dx/dt=-c^{+}$ ($\xi=$const.), one obtains $dx=x_{\eta}d\eta$ and $dt=t_{\eta}d\eta$. Introducing these relations into the equation $dx/dt=-c^{+}$ gives

$$x_{\eta}=-c^{+}t_{\eta}. \tag{2.10}$$

Similarly, on the characteristic curve $dx/dt=-c^{-}$ ($\eta=$const.), one obtains

$$x_{\xi}=-c^{-}t_{\xi}. \tag{2.11}$$

We can eliminate x from (2.10) and (2.11) to obtain the second-order linear equation for t,

$$t_{\xi\eta}=\frac{c_{\eta}^{-}}{c^{+}-c^{-}}t_{\xi}-\frac{c_{\xi}^{+}}{c^{+}-c^{-}}t_{\eta}. \tag{2.12}$$

Also, it is possible to find a single equation for x as

$$x_{\xi\eta}=\frac{c^{+}c_{\eta}^{-}}{c^{-}(c^{+}-c^{-})}x_{\xi}-\frac{c^{-}c_{\xi}^{+}}{c^{+}(c^{+}-c^{-})}x_{\eta}. \tag{2.13}$$

Note that to solve the above system of equations, one must express the characteristic velocities $c^{\pm}$ in terms of ξ and η explicitly. As will be shown in Sec. II C, this is always possible *in principle* for the system of equations with two dependent variables. However, in order to perform this procedure only by quadrature, certain conditions must be imposed on the parameters in (2.1). Equations (2.12) and (2.13) will play a central role in the reduction of the dispersionless cKdV equations.

Lastly, we shall introduce a new method developed by Tsarev.[6] Let w_1 and w_2 be the solutions of the following system of linear equations with $c^{\pm}$ being given functions of ξ and η,

$$\frac{w_{1,\eta}}{w_1-w_2}=\frac{c^+_\eta}{c^+-c^-},\ \frac{w_{2,\xi}}{w_1-w_2}=\frac{c^-_\xi}{c^+-c^-}, \tag{2.14}$$

and consider the system of linear algebraic equations for x and t, $x+c^+t=w_1$ and $x+c^-t=w_2$. Then, a direct calculation shows that the solutions for t and x given by

$$t=\frac{w_1-w_2}{c^+-c^-},\quad x=-\frac{c^-w_1-c^+w_2}{c^+-c^-}, \tag{2.15}$$

satisfy the system of Eqs. (2.10) and (2.11). We can derive from (2.14) a single linear equation for w_1,

$$w_{1,\xi\eta}=\frac{c^+_\eta}{c^+-c^-}w_{1,\xi}+\left(\frac{c^+_{\xi\eta}}{c^+_\eta}-\frac{c^+_\xi}{c^+-c^-}\right)w_{1,\eta}, \tag{2.16}$$

and for w_2,

$$w_{2,\xi\eta}=\left(\frac{c^-_{\xi\eta}}{c^-_\xi}+\frac{c^-_\eta}{c^+-c^-}\right)w_{2,\xi}-\frac{c^-_\xi}{c^+-c^-}w_{2,\eta}. \tag{2.17}$$

The Tsarev system of Eqs. (2.16) and (2.17) sometimes considerably simplifies the problem of finding solutions even when Eqs. (2.12) and (2.13) for t and x become too complicated to be solved analytically (see Secs. III and IV).

C. Calculation of the Riemann invariants

Following the method developed in Sec. II B, we shall now calculate the Riemann invariants and express the characteristic velocities in these terms. Three different cases arise according to values of the coefficients in (2.1).

(1) Case 1: $\alpha\neq\delta,\ \gamma\neq 0,\ \alpha-\gamma-\delta\neq 0$:

In this case, we first define the constant parameters a and b by

$$a=\frac{\beta}{\alpha-\gamma-\delta},\quad b=\frac{4\beta\gamma}{(\alpha-\delta)^2}. \tag{2.18}$$

In the following analysis, we consider the case $b/a\leqslant 1$, i.e., $4\gamma(\alpha-\gamma-\delta)\leqslant(\alpha-\delta)^2$.

For $c^+=\frac{1}{2}[(\alpha+\delta)u+\sqrt{\Delta}]$, one finds $\mathbf{l}^+=(l_1^+,l_2^+)=(1,-\{(\alpha-\delta)u-\sqrt{\Delta}\}/2\gamma v)$. Then, the equation that defines the Riemann invariant follows from (2.6) as

$$\frac{du}{dv}=\frac{1}{2\gamma v}\{(\alpha-\delta)u-\sqrt{\Delta}\}. \tag{2.19}$$

If we introduce a new dependent variable $\tilde{u}$ by $u=v\tilde{u}$, we can integrate (2.19) and obtain the Riemann invariants. The result is expressed compactly as follows:

$$(\sqrt{u^2+bv^2}+u)(\sqrt{u^2+bv^2}-\rho_1 u)^{\rho_1}v^{\rho_2}(u^2+av^2)^{\rho_3}=\xi, \tag{2.20a}$$

with

$$\rho_1=-\sqrt{1-\frac{b}{a}},\quad \rho_2=\mathrm{sgn}(\alpha-\delta)-1,\quad \rho_3=\frac{1}{2}\mathrm{sgn}(\alpha-\delta)-\frac{\gamma}{|\alpha-\delta|}+\frac{1}{2}\sqrt{1-\frac{b}{a}}. \tag{2.20b}$$

The corresponding Riemann invariant for $c^-=\frac{1}{2}[(\alpha+\delta)u-\sqrt{\Delta}]$ reads in the form

$$(\sqrt{u^2+bv^2}-u)(\sqrt{u^2+bv^2}+\rho_1 u)^{\rho_1}v^{\rho_2}(u^2+av^2)^{\rho_3}=\eta. \tag{2.21}$$

Now, we like to express $c^{\pm}$ in terms of the Riemann invariants. For this purpose, we divide (2.20a) by (2.21) and put $\sqrt{u^2+bv^2}=uz$ to define new variable z. We then find the equation that determines z,

$$\frac{z+1}{z-1}\left[\frac{z-\rho_1}{z+\rho_1}\right]^{\rho_1}=\frac{\xi}{\eta}. \tag{2.22}$$

By solving (2.22) together with (2.20) and (2.21), we can express u and v in terms of ξ and η. The expressions of $c^{\pm}$ then follow from (2.5). Equation (2.22) will become a transcendental equation for z. However, if the ratio b/a is chosen such that the factor ρ_1 becomes a rational number, (2.22) reduces to an algebraic equation for z. Of particular interest is the case for which the solutions of the algebraic equation can be obtained by quadrature. As is well-known, this situation occurs if the order of the algebraic equation is less than or equal to four. The corresponding values of b/a and ρ_1 are then given by

$$\frac{b}{a}=\frac{4\gamma(\alpha-\gamma-\delta)}{(\alpha-\delta)^2}=1,\frac{8}{9},\frac{3}{4},-3,-8,\quad \rho_1=0,-\frac{1}{3},-\frac{1}{2},-2,-3. \tag{2.23}$$

(2) Case 2: $\alpha\neq\delta,\ \gamma=0$:

This special case is particularly simple. Indeed, the characteristic velocities and corresponding Riemann invariants become

$$c^+=\alpha u,\quad c^-=\delta u, \tag{2.24}$$

$$u^2+\frac{\beta}{\alpha-\delta}v^2=\xi,\quad -\frac{\beta}{\alpha-\delta}v^2=\eta, \tag{2.25}$$

and $c^{\pm}$ are now written in the form

$$c^+=\alpha\sqrt{\xi+\eta},\quad c^-=\delta\sqrt{\xi+\eta}. \tag{2.26}$$

(3) Case 3: $\alpha=\delta,\gamma\neq 0$:

In this case, it follows from (2.5) that

$$c^{\pm}=\alpha u\pm\sqrt{\beta\gamma}v,\quad (\beta\gamma>0), \tag{2.27}$$

and the corresponding Riemann invariants are

$$u+\sqrt{\frac{\beta}{\gamma}}v=\xi,\quad -u+\sqrt{\frac{\beta}{\gamma}}v=\eta. \tag{2.28}$$

In terms of ξ and η, $c^{\pm}$ are expressed as

$$c^{\pm}=\tfrac{1}{2}(\alpha\pm|\gamma|)\xi+\tfrac{1}{2}(\alpha\mp|\gamma|)\eta. \tag{2.29}$$

D. Remark

Under certain condition, the equation for u is decoupled completely from that of v. To see this, we differentiate (2.1a) by t and use (2.1a) and (2.1b) to obtain

$$u_{tt}=\alpha^2(u^2u_x)_x+\beta(\alpha+\delta)(uv_{xx}+uv_x^2)+\beta(\alpha+2\gamma+\delta)vu_xv_x+\beta\gamma^2v^2u_{xx}. \tag{2.30}$$

Hence, if we put

$$\alpha+\delta=0,\ \gamma=0. \tag{2.31}$$

Equation (2.30) reduces to a second-order nonlinear equation for u,

$$u_{tt}=\alpha^2(u^2u_x)_x. \tag{2.32}$$

Exact solutions of Eq. (2.32) have been given by Zabusky[7] in his study of the vibrations of nonlinear string. A more general class of equations of the form $u_{tt}=(f(u)u_x)_x, f\in C^2(\mathbf{R})$, $f>0, f'\neq 0$ has been studied by Ames *et al.*[8]

III. REDUCTION OF DISPERSIONLESS COUPLED KDV EQUATIONS

In this section, we demonstrate that various types of dispersionless cKdV equations are transformed into second-order linear equations by employing the technique developed in Sec. II. In particular, we show that the resulting linear equations are reduced to the following ED equation:

$$f_{\xi\eta}=\frac{1}{\xi+\eta}(pf_\xi+qf_\eta),\quad f=f(\xi,\eta), \tag{3.1}$$

where p and q are arbitrary real constants. When $p=q$, this equation is called the Euler–Poisson–Darboux (EPD) equation. The method of exact solution for Eq. (3.1) is now established which originated from the work of Riemann. It consists of constructing the so-called Riemann–Green function which is defined by the solution of the boundary value problem of the adjoint equation to the ED equation.[9,10] The Riemann–Green function for Eq. (3.1) is actually given by the hypergeometric function (or the Legendre function in the case of the EPD equation). It is also remarked that a number of particular solutions of (3.1) have been obtained by investigating the symmetry group of the equation.[11,12]

We first define the dispersionless cKdV equation associated with the cKdV equation of the form $u_t=F(u,u_x,\ldots,v,v_x,\ldots), v_t=G(u,u_x,\ldots,v,v_x,\ldots)$, where F and G are real functions. Let us introduce new independent variables $T=\epsilon t$ and $X=\epsilon x$, where ϵ is a small parameter and rewrite the partial derivatives as $\partial/\partial t=\epsilon\partial/\partial T$ and $\partial/\partial x=\epsilon\partial/\partial X$. We substitute these into the cKdV equation and then take the limit $\epsilon\to 0$. Retaining the leading term in ϵ, we obtain the dispersionless cKdV equation. In the following analysis, we use the variables t and x in place of T and X, respectively.

A. Broer–Kaup equation

The first example that we consider here is the Broer–Kaup equation[13,14] given by

$$u_t+uu_x+h_x=0, \tag{3.2a}$$

$$h_t+u_x+(uh)_x\pm u_{xxx}=0. \tag{3.2b}$$

In accordance with the definition, the dispersionless Broer–Kaup equation can be written as

$$u_t=uu_x+2vv_x, \tag{3.3a}$$

$$v_t=\tfrac{1}{2}vu_x+uv_x, \tag{3.3b}$$

where we have put $h=-1+v^2$ and replaced t by $-t$. Comparing (3.3) with (2.1), one can see that (3.3) is a special case of (2.1) with

$$\alpha=1,\ \ \beta=2,\ \ \gamma=\tfrac{1}{2},\ \ \delta=1. \tag{3.4}$$

This choice of the parameters belongs to the case 3 in Sec. II C. The characteristic velocities and corresponding Riemann invariants are found from (2.27) and (2.28) as

$$c^{\pm}=u\pm v, \tag{3.5}$$

$$u+2v=\xi,\ \ -u+2v=\eta. \tag{3.6}$$

Using (3.6), $c^{\pm}$ are expressed in terms of ξ and η as

$$c^{+}=\tfrac{3}{4}\xi-\tfrac{1}{4}\eta,\ \ c^{-}=\tfrac{1}{4}\xi-\tfrac{3}{4}\eta. \tag{3.7}$$

The linear equations for t and x follow from (2.12) and (2.13). They read in the form,

$$t_{\xi\eta}=-\frac{3}{2(\xi+\eta)}(t_{\xi}+t_{\eta}), \tag{3.8}$$

$$x_{\xi\eta}=-\frac{3}{2(\xi+\eta)}\left(\frac{3\xi-\eta}{\xi-3\eta}x_{\xi}+\frac{\xi-3\eta}{3\xi-\eta}x_{\eta}\right). \tag{3.9}$$

Although Eq. (3.8) for t is an EPD equation, i.e., Eq. (3.1) with $p=q=-\frac{3}{2}$, that for x is not reduced to (3.1). However, following Tsarev's procedure summarized in Sec. II B, the reduction to the ED equation is possible. Indeed, if we introduce w_1 and w_2 by the relations

$$w_1=x+(\tfrac{3}{4}\xi-\tfrac{1}{4}\eta)t,\ \ w_2=x+(\tfrac{1}{4}\xi-\tfrac{3}{4}\eta)t, \tag{3.10}$$

the equations for these variables are derived immediately from (2.16) and (2.17) with $c^{\pm}$ given by (3.7). The result is

$$w_{1,\xi\eta}=-\frac{1}{2(\xi+\eta)}(w_{1,\xi}+3w_{1,\eta}), \tag{3.11}$$

$$w_{2,\xi\eta}=-\frac{1}{2(\xi+\eta)}(3w_{2,\xi}+w_{2,\eta}). \tag{3.12}$$

B. Ito equation

The second example is Ito's cKdV equation,[15]

$$u_t=6uu_x+2vv_x+u_{xxx}, \tag{3.13a}$$

$$v_t=2(uv)_x. \tag{3.13b}$$

The dispersionless Ito equation is written as

$$u_t=6uu_x+2vv_x, \tag{3.14a}$$

$$v_t=2(uv)_x. \tag{3.14b}$$

The above system of equations is equivalent to (2.1) with the choice of the parameters

$$\alpha=6,\quad \beta=2,\quad \gamma=2,\quad \delta=2. \tag{3.15}$$

Note that this corresponds to the case 1 in Sec. II C. The parameters a, b and ρ_1,ρ_2,ρ_3 defined, respectively, by (2.18) and (2.20b) become $a=b=1$ and $\rho_1=\rho_2=\rho_3=0$. It then follows from (2.5), (2.20), and (2.21) that

$$c^{\pm}=4u\pm 2\sqrt{u^2+v^2}, \tag{3.16}$$

$$\sqrt{u^2+v^2}+u=\xi,\quad \sqrt{u^2+v^2}-u=\eta. \tag{3.17}$$

Therefore,

$$c^{+}=3\xi-\eta,\quad c^{-}=\xi-3\eta. \tag{3.18}$$

Introducing (3.18) into (2.12), (2.13), (2.16), and (2.17), we find that the linear equations for t,x,w_1, and w_2 take exactly the same forms as those corresponding to the dispersionless Broer–Kaup equation described in Sec. II A. This fact would suggest the close relationship between dispersionless Broer–Kaup and dispersionless Ito equations. In fact, assuming that the Riemann invariants for both equations are proportional to each other, we put $4(\sqrt{u^2+v^2}+u)=\tilde{u}+2\tilde{v}$ and $4(\sqrt{u^2+v^2}-u)=-\tilde{u}+2\tilde{v}$ and rewrite (3.14) in terms of $\tilde{u}$ and $\tilde{v}$. We then find that $\tilde{u}$ and $\tilde{v}$ satisfy the dispersionless Broer–Kaup Eq. (3.3).

Remark: The Ito equation has been proven to be completely integrable, i.e., it exhibits an infinite number of conservation laws commuting each other with respect to an appropriate Poisson bracket.[15] Nevertheless, to the best of our knowledge, the multisoliton solutions have not as yet been explicitly constructed. In Appendix B, we shall present a periodic-wave and one-soliton solutions of the Ito equation which will suggest a hint in studying the structure of the multisoliton solutions.

C. Hirota–Satsuma equation

The third example is the Hirota–Satsuma equation,[16]

$$u_t=\tfrac{1}{2}(6uu_x+u_{xxx})+2vv_x, \tag{3.19a}$$

$$v_t=-3uv_x-v_{xxx}. \tag{3.19b}$$

The dispersionless Hirota–Satsuma equation takes the form

$$u_t=3uu_x+2vv_x, \tag{3.20a}$$

$$v_t=-3uv_x. \tag{3.20b}$$

The above system of equations is a special case of (2.1) with

$$\alpha=3,\quad \beta=2,\ \gamma=0,\quad \delta=-3, \tag{3.21}$$

which belongs to the case 2 in Sec. II C.

It follows from (2.24) and (2.25) that

$$c^{+}=3u,\quad c^{-}=-3u, \tag{3.22}$$

$$u^2+\frac{v^2}{3}=\xi,\quad -\frac{v^2}{3}=\eta. \tag{3.23}$$

Hence, $c^{\pm}$ may be expressed as

$$c^+=3\sqrt{\xi+\eta},\quad c^-=-3\sqrt{\xi+\eta}. \tag{3.24}$$

The linear equations for t and x reduce to the standard EPD equations. The final result is given as follows:

$$t_{\xi\eta}=-\frac{1}{4}\frac{1}{\xi+\eta}(t_\xi+t_\eta), \tag{3.25}$$

$$x_{\xi\eta}=\frac{1}{4}\frac{1}{\xi+\eta}(x_\xi+x_\eta). \tag{3.26}$$

Remark: The coefficients given by (3.21) satisfy the condition (2.31). It then follows from (2.32) that the equation for u is transformed into a single second-order nonlinear equation of the form $u_{tt}=9(u^2u_x)_x$.

D. Bogoyavlenskii equation

The last example is a cKdV equation proposed by Bogoyavlenskii,[17] which is

$$u_t=6uu_x+6v_x-u_{xxx}, \tag{3.27a}$$

$$v_t=-2uv_x+2v_{xxx}. \tag{3.27b}$$

The dispersionless version of this system of equations reduces, after replacing v by $v^2/6$, to

$$u_t=6uu_x+2vv_x, \tag{3.28a}$$

$$v_t=-2uv_x, \tag{3.28b}$$

which is a special case of Eq. (2.1) with

$$\alpha=6,\quad \beta=2,\ \gamma=0,\ \delta=-2. \tag{3.29}$$

Since this class belongs to case 2 in Sec. II C, one immediately finds from (2.20) and (2.25) the expressions

$$c^+=6u,\quad c^-=-2u, \tag{3.30}$$

$$u^2+\tfrac{1}{4}v^2=\xi,\quad -\tfrac{1}{4}v^2=\eta. \tag{3.31}$$

Hence, $c^\pm$ are written in the form

$$c^+=6\sqrt{\xi+\eta},\quad c^-=-2\sqrt{\xi+\eta}. \tag{3.32}$$

The linear equations for t and x are readily derived from (2.12) and (2.13) and they become the EP equation as follows:

$$t_{\xi\eta}=-\frac{1}{8(\xi+\eta)}(t_\xi+3t_\eta), \tag{3.33}$$

$$x_{\xi\eta}=\frac{1}{8(\xi+\eta)}(3x_\xi+x_\eta). \tag{3.34}$$

E. Remark

Here, we shall briefly discuss on a class of nonintegrable cKdV equations that reduces to the system of Eqs. (2.2). A variant of the famous Boussinesq system in the theory of shallow-water waves belongs to this class. In an appropriate dimensionless form, it reads[18]

$$h_t+(uh)_x=0, \tag{3.35a}$$

$$u_t+uu_x+h_x+h_{xxx}=0. \tag{3.35b}$$

If we put $h=v^2$, replace t by $-t$ and then take the dispersionless limit, we can see that the above system of equations reduces to the dispersionless Broer–Kaup Eq. (3.3). This example shows that the nonintegrability of the cKdV equation does not necessarily imply the nonintegrability of the corresponding dispersionless equation. This fact is almost trivial. Indeed, we can construct many examples of nonintegrable cKdV equations that reduce to the system of Eqs. (2.2) in the dispersionless limit. Our concern is rather the opposite problem, i.e., whether the integrable cKdV equations are always reducible to the integrable equations of the ED type or not in the dispersionless limit. The analysis developed in this section gives an affirmative answer as long as the typical integrable cKdV equations are concerned.

IV. EXTENSION

Here, we shall briefly discuss the following quasilinear system of equations which generalizes the system of Eqs. (2.1):

$$u_t=(\alpha_1u+\alpha_2v)u_x+(\beta_1u+\beta_2v)v_x, \tag{4.1a}$$

$$v_t=(\gamma_1u+\gamma_2v)u_x+(\delta_1u+\delta_2v)v_x, \tag{4.1b}$$

where $\alpha_j,\beta_j,\gamma_j$, and $\delta_j(j=1,2)$ are real parameters. Under certain conditions, the linear transformation of u and v makes it possible to transform (4.1) into (2.1). However, we exclude this special case below. Although we could develop the discussion analogous to that which has been done in Sec. II, we shall not enter into specific detail here. Instead, we will perform the reduction of (4.1) to the ED equation in two explicit examples.

A. Jaulent–Miodek equation

The Jaulent–Miodek equation[19] reads in the form

$$U_t+U_{xxx}+\tfrac{3}{2}QQ_{xxx}+\tfrac{9}{2}Q_xQ_{xx}-6UU_x-6UQQ_x-\tfrac{3}{2}U_xQ^2=0, \tag{4.2a}$$

$$Q_t+Q_{xxx}-6UQ_x-6U_xQ-\tfrac{15}{2}Q_xQ^2=0. \tag{4.2b}$$

The dispersionless Jaulent–Miodek equation now becomes

$$u_t=(u+v)u_x+uv_x, \tag{4.3a}$$

$$v_t=2vu_x+(u+v)v_x, \tag{4.3b}$$

where we have introduced new variables u and v by $U=\frac{1}{6}(u-(v/2))$ and $Q^2=v/3$, respectively. As is readily seen, the above system of equations is a special case of (4.1) with $\alpha_1=\alpha_2=1,\beta_1=1,\beta_2=0,\gamma_1=0,\gamma_2=2,\delta_1=\delta_2=1$. The characteristic velocities and corresponding Riemann invariants are easily calculated following the procedure developed in Sec. II. They are given by

$$c^+=u+v+\sqrt{2uv},\quad c^-=u+v-\sqrt{2uv}, \tag{4.4}$$

$$\sqrt{2u}+\sqrt{v}=\xi,\quad \sqrt{2u}-\sqrt{v}=\eta. \tag{4.5}$$

In terms of the Riemann invariants, $c^{\pm}$ are rewritten as

$$c^{+}=\tfrac{5}{8}\xi^2-\tfrac{1}{4}\xi\eta+\tfrac{1}{8}\eta^2,\quad c^{-}=\tfrac{1}{8}\xi^2-\tfrac{1}{4}\xi\eta+\tfrac{5}{8}\eta^2, \tag{4.6}$$

The equations for t and x now take the form,

$$t_{\xi\eta}=\frac{1}{2(\xi^2-\eta^2)}[(-\xi+5\eta)t_{\xi}-(5\xi-\eta)t_{\eta}], \tag{4.7}$$

$$x_{\xi\eta}=\frac{1}{2}\frac{(5\xi^2-2\xi\eta+\eta^2)(-\xi+5\eta)}{(\xi^2-2\xi\eta+5\eta^2)(\xi^2-\eta^2)}x_{\xi}-\frac{1}{2}\frac{(\xi^2-2\xi\eta+5\eta^2)(5\xi-\eta)}{(5\xi^2-2\xi\eta+\eta^2)(\xi^2-\eta^2)}x_{\eta}. \tag{4.8}$$

Although the reduction to the ED equation is difficult to perform in the t and x variables, Tsarev's method is applied successfully to transform (4.3) into the ED equation. Indeed, it is easy to show from (2.16), (2.17), and (4.6) that the variables $w_1=x+c^{+}t$ and $w_2=x+c^{-}t$ satisfy the following second-order equations of the ED type:

$$w_{1,\xi\eta}=-\frac{1}{2(\xi+\eta)}(w_{1,\xi}+3w_{1,\eta}), \tag{4.9}$$

$$w_{2,\xi\eta}=-\frac{1}{2(\xi+\eta)}(3w_{2,\xi}+w_{2,\eta}). \tag{4.10}$$

Remark: Levi *et al.*[20] introduced the system of equations

$$q_t=\tfrac{1}{4}(q_{xx}-3rq_x+3qr^2-3q^2)_x, \tag{4.11a}$$

$$r_t=\tfrac{1}{4}(r_{xx}+3rr_x+r^3-6rq)_x, \tag{4.11b}$$

which is the first member of the Lax hierarchy of the Broer–Kaup equation. If we take the dispersionless limit and then put $q=-2/3u$ and $r^2=\frac{4}{3}v$ in (4.11), the dispersionless equations for u and v reduce to (4.3). Note also that Eqs. (4.9) and (4.10) are the same equations as (3.11) and (3.12), respectively. One can see that the Lax hierarchy of the Broer–Kaup equation is mathematically equivalent to the Lax hierarchy of the Jaulent–Miodek equation.

B. Nutku–Öğuz equation

The Nutku–Öğuz equation[21] is written as

$$u_t=2\lambda uu_x+vv_x+(uv)_x+u_{xxx}, \tag{4.12a}$$

$$v_t=2\mu vv_x+uu_x+(uv)_x+v_{xxx}, \tag{4.12b}$$

where λ and μ are real constants satisfying the condition $\lambda+\mu=1$. Note that the above system of equations decouple for $\lambda=\mu=1/2$ and hence we consider the case $\lambda\neq\mu$ below. The dispersionless version of (4.12) becomes

$$u_t=(2\lambda u+v)u_x+(u+v)v_x, \tag{4.13a}$$

$$v_t=(u+v)u_x+\{u+2(1-\lambda)v\}v_x. \tag{4.13b}$$

The characteristic velocities and corresponding Riemann invariants are given by

$$c^{\pm}=[(\lambda+\tfrac{1}{2})u+(-\lambda+\tfrac{3}{2})v\pm\kappa(u+v)],\quad \kappa=\sqrt{\lambda^2-\lambda+\tfrac{5}{4}}, \tag{4.14}$$

$$u+(-\lambda+\tfrac{1}{2}+\kappa)v=\xi,\quad u+(-\lambda+\tfrac{1}{2}-\kappa)v=\eta. \tag{4.15}$$

Thus, $c^{\pm}$ are written in terms of ξ and η as

$$c^{+}=(\lambda+\tfrac{1}{2}+\kappa)\xi,\quad c^{-}=(\lambda+\tfrac{1}{2}-\kappa)\eta. \tag{4.16}$$

If we define new variables $\tilde{\xi}$ and $\tilde{\eta}$ according to $\tilde{\xi}=(\lambda+\frac{1}{2}+\kappa)\xi$ and $\tilde{\eta}=-(\lambda+\frac{1}{2}-\kappa)\eta$, the equations for x and t become

$$t_{\tilde{\xi}\tilde{\eta}}=-\frac{1}{\tilde{\xi}+\tilde{\eta}}(t_{\tilde{\xi}}+t_{\tilde{\eta}}), \tag{4.17a}$$

$$x_{\tilde{\xi}\tilde{\eta}}=\frac{\tilde{\xi}}{\tilde{\eta}(\tilde{\xi}+\tilde{\eta})}x_{\tilde{\xi}}+\frac{\tilde{\eta}}{\tilde{\xi}(\tilde{\xi}+\tilde{\eta})}x_{\tilde{\eta}}. \tag{4.17b}$$

The equation for x is not reducible to the ED equation. However, as seen from (4.16), each characteristic velocity depends only on a single Riemann invariant. In view of this observation, the Tsarev system of Eqs. (2.14) turns out to be the trivial equations $w_{1,\eta}=w_{2,\xi}=0$, which are integrated immediately to give the solutions $w_1=f_1(\xi)$ and $w_2=f_2(\eta)$, where f_1 and f_2 are arbitrary functions. The expressions (2.15) then yield the general solutions of Eq. (4.17) as follows:

$$t=\frac{f_1(\tilde{\xi})+f_2(\tilde{\eta})}{\tilde{\xi}+\tilde{\eta}}, \tag{4.18a}$$

$$x=-\frac{\tilde{\eta}f_1(\tilde{\xi})+\tilde{\xi}f_2(\tilde{\eta})}{\tilde{\xi}+\tilde{\eta}}. \tag{4.18b}$$

By direct calculation, one can easily confirm that (4.18) does indeed satisfy (4.17).

V. CONCLUDING REMARKS

In this paper, we demonstrated that a class of dispersionless cKdV equations can be linearized in the form of the EP or EPD equations by means of the hodograph transformation. In the process of linearization, the main step is to express the characteristic velocities in terms of the Riemann invariants. Although the Riemann invariants always exist for quasilinear hyperbolic systems of equations such as (2.2) and (4.1) with two dependent variables, the explicit expressions for the characteristic velocities are obtainable by quadrature only for special combinations of the parameters (Sec. II C). The present analysis shows that the procedure mentioned above can be performed completely in the case of the dispersionless versions for typical two-component cKdV equations (Secs. III and IV). It should be kept in mind that the cKdV equations exemplified here possess the completely integrable Hamiltonian structures. It will therefore be an interesting problem to apply the method developed in this paper to other types of integrable two-component nonlinear dispersive systems of equations and to investigate the relationship between the integrability of the original equations and the reducibility of the corresponding dispersionless equations to the ED or EPD equations.

APPENDIX A: CONSERVATION LAWS FOR EQ. (2.1)

We show that the system of Eqs. (2.1) exhibits an infinite number of conservation laws. By inspection, one can see that the conservation laws are represented by the integral of homogeneous polynomials of u and v as follows:

$$I_{2n}=\sum_{j=0}^{n} C_j^{(2n)}\int_{-\infty}^{\infty} u^{2(n-j)}v^{2j}dx,\quad (n=1,2,\dots), \tag{A1}$$

$$I_{2n+1}=\sum_{j=0}^{n} C_j^{(2n+1)}\int_{-\infty}^{\infty} u^{2(n-j)+1}v^{2j}dx,\quad (n=0,1,\dots). \tag{A2}$$

Here the integrand of $I_{2n}(I_{2n+1})$ is a polynomial of u and v of order $2n(2n+1)$.

We now derive the recursion relations that determine the coefficients $C_j^{(2n)}$ and $C_j^{(2n+1)}$.

1. Recursion relation for $C_j^{(2n)}$

Differentiating (A1) by t and using (2.1), we obtain, with integration by parts under appropriate boundary conditions, the relation

$$\frac{dI_{2n}}{dt}=\sum_{j=1}^{n}\left[\frac{2j\{2(\delta-\alpha)(n-j)-2\gamma j+\delta\}}{2(n-j)+1}C_j^{(2n)}+2\beta(n-j+1)C_{j-1}^{(2n)}\right]\times\int_{-\infty}^{\infty}u^{2(n-j)+1}v^{2j-1}v_x dx. \tag{A3}$$

Hence, the quantities I_{2n} are conserved if the following recursion relations hold for $C_j^{(2n)}$:

$$\frac{2j\{2(\delta-\alpha)(n-j)-2\gamma j+\delta\}}{2(n-j)+1}C_j^{(2n)}+2\beta(n-j+1)C_{j-1}^{(2n)}=0,\quad (j=1,2,\dots,n). \tag{A4}$$

Under the conditions

$$D_j^{(2n)}\equiv 2(\delta-\alpha)(n-j)-2\gamma j+\delta\neq 0,\quad (j=1,2,\dots,n), \tag{A5}$$

the coefficients $C_j^{(2n)}$ are determined successively by the relations,

$$C_j^{(2n)}=-\frac{\beta\{2(n-j)+1\}(n-j+1)}{j\{2(\delta-\alpha)(n-j)-2\gamma j+\delta\}}C_{j-1}^{(2n)},\quad (j=1,2,\dots,n), \tag{A6}$$

with $C_0^{(2n)}$ being an arbitrary constant.

If $D_j^{(2n)}=0$ for certain $j(=k)(k\leqslant n)$, then (A1) has the form

$$I_{2n}=\sum_{j=k}^{n} C_j^{(2n)}\int_{-\infty}^{\infty} u^{2(n-j)}v^{2j}dx,\quad (n=1,2,\dots), \tag{A7}$$

where $C_k^{(2n)}$ can be taken arbitrary and $C_j^{(2n)}\,(k+1\leqslant j\leqslant n)$ are determined by (A6).

2. Recursion relation for $C_j^{(2n+1)}$

Under the conditions,

$$D_j^{(2n+1)}\equiv 2(\delta-\alpha)(n-j)-2\gamma j-\alpha+2\delta\neq 0,\quad (j=0,1,\dots,n), \tag{A8}$$

one can determine $C_j^{(2n+1)}$ by the recursion relations,

$$C_j^{(2n+1)}=-\frac{\beta\{2(n-j)+3\}(n-j+1)}{j\{2(\delta-\alpha)(n-j)-2\gamma j-\alpha+2\delta\}}C_{j-1}^{(2n+1)},\quad (j=1,2,\dots,n), \tag{A9}$$

starting with an arbitrary constant $C_0^{(2n+1)}$.

If $D_j^{(2n+1)}=0$ for certain $j(=k)(k\leqslant n)$, then (A2) has the form

$$I_{2n+1}=\sum_{j=k}^{n} C_j^{(2n+1)}\int_{-\infty}^{\infty} u^{2(n-j)+1}v^{2j}dx,\quad (n=1,2,\dots), \tag{A10}$$

where $C_k^{(2n+1)}$ can be taken as arbitrary and $C_j^{(2n+1)}\,(k+1\leqslant j\leqslant n)$ are determined by (A9).

3. Examples

The conservation laws for the dispersionless cKdV equations discussed in Sec. II are constructed by using (A6) and (A9). We shall write down the first four of them for each equation.

a. Dispersionless Broer–Kaup Eq. (3.3)

$$I_1=\int_{-\infty}^{\infty} u dx,\quad I_2=\int_{-\infty}^{\infty} v^2 dx,\quad I_3=\int_{-\infty}^{\infty} uv^2 dx,\quad I_4=\int_{-\infty}^{\infty}(u^2v^2+v^4)dx. \tag{A11}$$

b. Dispersionless Ito Eq. (3.14)

$$\begin{gathered} I_1=\int_{-\infty}^{\infty} u dx,\quad I_2=\int_{-\infty}^{\infty}(u^2+v^2)dx,\\ I_3=\int_{-\infty}^{\infty}(u^3+uv^2)dx,\quad I_4=\int_{-\infty}^{\infty}\left(u^4+\frac{6}{5}u^2v^2+\frac{1}{5}v^4\right)dx. \end{gathered} \tag{A12}$$

c. Dispersionless Hirota–Satsuma Eq. (3.20)

$$\begin{gathered} I_1=\int_{-\infty}^{\infty} u dx,\quad I_2=\int_{-\infty}^{\infty}\left(u^2+\frac{2}{3}v^2\right)dx,\\ I_3=\int_{-\infty}^{\infty}\left(u^3+\frac{2}{3}uv^2\right)dx,\quad I_4=\int_{-\infty}^{\infty}\left(u^4+\frac{4}{5}u^2v^2+\frac{4}{15}v^4\right)dx. \end{gathered} \tag{A13}$$

d. Dispersionless Bogoyavlenskii Eq. (3.28)

$$\begin{gathered} I_1=\int_{-\infty}^{\infty} u dx,\quad I_2=\int_{-\infty}^{\infty}(u^2+v^2)dx,\\ I_3=\int_{-\infty}^{\infty}\left(u^3+\frac{3}{5}uv^2\right)dx,\quad I_4=\int_{-\infty}^{\infty}\left(u^4+\frac{2}{3}u^2v^2+\frac{1}{3}v^4\right)dx. \end{gathered} \tag{A14}$$

APPENDIX B: PERIODIC-WAVE AND SOLITON SOLUTIONS OF ITO'S CKDV EQUATION

In accordance with the exact solutions of Ito's cKdV and related equations, several references are now available.[22] Here, we shall derive the periodic-wave and soliton solutions and discuss their properties.

1. Periodic-wave solution

We shall first seek a periodic-wave solution of the Ito Eq. (3.13) of the form,

$$u=u(\zeta),\quad v=v(\zeta),\quad \zeta=x-ct,\quad (c>0). \tag{B1}$$

Introducing (B1) into Eq. (3.13) and integrating once, we obtain

$$-cu-u''-3u^2-v^2=k_1,\quad \left(u''=\frac{d^2u}{d\zeta^2}\right), \tag{B2}$$

$$-cv-2uv=k_2, \tag{B3}$$

where k_1 and k_2 are integration constants. In the following analysis, we assume that $k_2\neq 0$. Equation (B2) is once more integrated after eliminating v by (B3) to give

$$\frac{1}{2}(u')^2+u^3+\frac{c}{2}u^2-\frac{k_2^2}{4}\frac{1}{u+\frac{c}{2}}=-k_1u-k_3, \tag{B4}$$

with k_3 being an integration constant. It follows from (B3) that $u=-(cv+k_2)/2v$. If we substitute this expression into (B4) and define the new dependent variable g according to $v=-k_2g/c$, (B4) is transformed into the equation

$$\frac{(g')^2}{g}=\frac{4k_2^2}{c^3}g^4-\frac{4k_1}{c}(1-g)g^2-\frac{8k_3}{c^2}g^3-c(1-g)^2. \tag{B5}$$

Furthermore, we introduce the new independent variable η by

$$\frac{d\eta}{d\zeta}=\sqrt{\frac{4k_2^2g}{c^3}}, \tag{B6}$$

to recast (B5) into the form

$$\left(\frac{dg}{d\eta}\right)^2=(g-g_1)(g-g_2)(g-g_3)(g-g_4), \tag{B7}$$

where $g_j(j=1-4)$ are determined by the relations

$$\sum_{j=1}^{4}g_j=-\frac{c^2k_1}{k_2^2}+\frac{2ck_3}{k_2^2},\quad \sum_{j<k}g_jg_k=-\left(\frac{c^2k_1}{k_2^2}+\frac{c^4}{4k_2^2}\right),$$

$$\sum_{j<k<l}g_jg_kg_l=-\frac{c^4}{2k_2^2},\quad \prod_{j=1}^{4}g_j=-\frac{c^4}{4k_2^2}. \tag{B8}$$

The periodic-wave solution of (B7) is now given explicitly by Jacobi's elliptic functions $sn(\mu\eta,k)$ and $cn(\mu\eta,k)$ as follows:

$$g(\eta)=\frac{g_3-\lambda g_4\,\mathrm{sn}^2(\mu\eta,k)}{1-\lambda\,\mathrm{sn}^2(\mu\eta,k)}=\frac{g_3-\lambda g_4+\lambda g_4\,\mathrm{cn}^2(\mu\eta,k)}{1-\lambda+\lambda\,\mathrm{cn}^2(\mu\eta,k)}, \tag{B9}$$

where

$$\lambda=\frac{g_2-g_3}{g_2-g_4},\quad k^2=\frac{(g_2-g_3)(g_1-g_4)}{(g_1-g_3)(g_2-g_4)},$$
$$\mu^2=\tfrac{1}{4}(g_1-g_3)(g_2-g_4),\quad (g_4<g_3<g_2<g_1), \tag{B10}$$

and we have used the formula $\mathrm{sn}^2(\mu\eta,k)=1-\mathrm{cn}^2(\mu\eta,k)$. It follows from (B6) that

$$\zeta(\eta)=\int_0^{\eta}\sqrt{\frac{c^3}{4k_2^2 g(\eta')}}d\eta', \tag{B11}$$

where we have assumed $\zeta(0)=0$. Thus, the periodic-wave solution of Eq. (B7) is represented parametrically by (B9) and (B11). With g thus obtained, v is given by $v=-k_2 g/c$ and u is derived from (B3).

Remark: For appropriate choices of the integration constants k_1,k_2, and k_3, the real solutions of (B8) will exist which satisfy the condition $g_4<g_3<g_2<g_1$. If these constants take the values $k_1=-c^2\kappa_1, k_2=-c^2/\sqrt{\kappa_2}, k_3=c^3/(2\kappa_2), (\kappa_2>0)$ with κ_1 and κ_2 being arbitrary constants, the right-hand side of (B7) simplifies to $(g-1)(g^3-\kappa_1\kappa_2 g^2-(\kappa_2/4)g+(\kappa_2/4))$. Hence, $g_1=1$ and g_2,g_3, and g_4 are obtained by solving the cubic equation $g^3-\kappa_1\kappa_2 g^2-(\kappa_2/4)g+(\kappa_2/4)=0$. One can show that for certain ranges of κ_1 and κ_2, the real solutions of this equation exist which satisfy the condition $g_4<g_3<g_2<1$. Furthermore, if we put $\kappa_1=v_0^2/c^2$ and $\kappa_2=c^2/v_0^2$ to reduce this equation to $(g-1)(g^2-(c^2/4v_0^2))=0$, the periodic-wave solution derived here degenerates into the soliton solution as shown below.

2. Soliton solution

The soliton solution is simply obtained from the periodic-wave solution by taking an appropriate limit. First of all, we note that the relevant boundary conditions for the soliton solution should be $u,u',u''\to 0, g\to v_0(>0)$ as $|\zeta|\to\infty$. These conditions completely fix the integration constants k_1,k_2, and k_3. Indeed, it readily follows from (B2), (B3), and (B4) that

$$k_1=-v_0^2,\quad k_2=-v_0 c,\quad k_3=\frac{v_0^2 c}{2}. \tag{B12}$$

Substituting (B12) into (B8), we find

$$g_1=g_2=1,\quad g_3=-g_4=\frac{c}{2v_0}. \tag{B13}$$

To assure the positivity of μ^2 in (B10), we impose the condition $c/2v_0<1$. Then, the parameters in (B10) are reduced, with use of (B13), to

$$\lambda=\frac{1-\dfrac{c}{2v_0}}{1+\dfrac{c}{2v_0}},\quad k=1,\quad \mu=\frac{1}{2}\sqrt{1-\frac{c^2}{4v_0^2}}. \tag{B14}$$

In view of the relation $\mathrm{cn}^2(\mu\eta,1)=\mathrm{sech}^2\mu\eta=2/(\cosh 2\mu\eta+1)$, (B9) reduces to

$$g(\eta)=1-\frac{\dfrac{2v_0}{c}\left(1-\dfrac{c^2}{4v_0^2}\right)}{\cosh\left[\sqrt{1-\dfrac{c^2}{4v_0^2}}\,\eta\right]+\dfrac{2v_0}{c}}. \tag{B15}$$

Lastly, we substitute (B15) into (B11) and perform the integration, and we obtain

$$\zeta=\sqrt{\frac{c^2}{4v_0^2-c^2}}\left[\left(1+\frac{c}{2v_0}\right)\Pi\left(\phi,\frac{1}{1-\dfrac{c}{2v_0}},\frac{1}{\sqrt{2}}\right)+\frac{2v_0}{c}\left(1-\frac{c^2}{4v_0^2}\right)F\left(\phi,\frac{1}{\sqrt{2}}\right)\right], \tag{B16}$$

where

$$\phi=\sin^{-1}\sqrt{\left(1-\frac{c}{2v_0}\right)\frac{\cosh\left[\sqrt{1-\frac{c^2}{4v_0^2}}\eta\right]-1}{\cosh\left[\sqrt{1-\frac{c^2}{4v_0^2}}\eta\right]+\frac{c}{2v_0}}}. \tag{B17}$$

Here, F and Π are elliptic integrals of the first and third kinds defined, respectively, by

$$F(\phi,k)=\int_0^{\phi}\frac{d\alpha}{\sqrt{1-k^2\sin^2\alpha}},\quad \Pi(\phi,\nu,k)=\int_0^{\phi}\frac{d\alpha}{(1-\nu\sin^2\alpha)\sqrt{1-k^2\sin^2\alpha}}. \tag{B18}$$

Thus, (B15) and (B16) give a parametric representation of the solution of $v(=v_0 g)$. As seen from (B11) and (B15), ζ is a monotonically increasing function of η. In particular, $\zeta\to\sqrt{(c/4v_0^2)}\,\eta$ when $\eta\to\infty$. The solution u is then found from (B3) and (B12) as

$$u=\frac{v_0\left(1-\frac{c^2}{4v_0^2}\right)}{\cosh\left[\sqrt{1-\frac{c^2}{4v_0^2}}\eta\right]+\frac{c}{2v_0}}. \tag{B19}$$

If we denote the amplitude of u by a, we see from (B19) that $a\equiv u(0)=v_0(1-(c/2v_0))$. Hence, the propagation velocity c of the soliton is related to the soliton amplitude by the relation $c=2(v_0-a)$.

(Received 23 October 1998; accepted for publication 15 February 2000)

In this paper we study the dynamics of self-gravitating ellipsoids in n dimensions, from the point of view of the Poisson structure of the dual of a suitable Lie algebra. When $n=3$ this was done by Rosenteel. In this setting we describe explicitly the ring of invariant functions. In the two-dimensional case we apply a technique due to Pedersen to find globally defined Darboux coordinates on the coadjoint orbits. Finally we derive a characterization of tensors coming from potentials, and use it to exhibit the dynamical equations of the ellipsoid in the Hamiltonian form. © *2001 American Institute of Physics.* [DOI: 10.1063/1.1316059]

I. INTRODUCTION

It was Rosensteel who pioneered[1] the Lie theoretical approach to the study of the dynamics of self-gravitating ellipsoids. His main idea was to view the dual of the Lie algebra $\mathrm{gcm}(3)=\mathrm{sym}(3)\ltimes \mathrm{gl}(3)$ as the phase space of these systems. In Sec. II we generalize this theory defining a n-dimensional ellipsoid introducing the Lie algebra $\mathrm{sym}(n)\times \mathrm{gl}(n)$ as the phase space for dynamical systems defined by ellipsoids in an arbitrary number of dimensions n. In Sec. III global Darboux coordinates are given explicitly for the two-dimensional problem. In Sec. IV the main result is the characterization of matrices of functions on the coordinates I_{ik} coming from a potential, then as a corollary we prove that the gravitational potential of a self-gravitating Riemman ellipsoid comes from potential in the sense we defined it.

II. CLASSIFICATION OF PHYSICAL ORBITS AND STRUCTURE OF THE ALGEBRA OF INVARIANTS

In this section we introduce the Lie algebra $\mathrm{sym}(n)\times \mathrm{gl}(n)$ as the phase space for dynamical systems defined by ellipsoids in an arbitrary number of dimensions n. The reduced phase space will then be the orbits under the coadjoint action. In general these orbits are the sets where the functions invariant under the coadjoint action take constant values. So it is important to classify the orbits and elucidate the structure of the algebra of functions invariant under the coadjoint action. This is what will be done in this section. For $n=3$ this has been done by Rosensteel.[1] Our results for general n include as special case his classification of orbits there, and his identification of orbits as level sets of the Kelvin circulation. It is interesting that the structure of the ring of invariants is a little more complicated when n is even than when n is odd.

Recall that $\mathrm{sym}(n)$ is the space of $n\times n$ real symmetric matrices, $\mathrm{gl}(n)$ is the group of $n\times n$ invertible matrices, and $\mathrm{gl}_+(n)$ is the subgroup of elements whose determinants are >0. Let $G=\mathrm{sym}(n)\times \mathrm{gl}_+(n)$ denote the group with multiplication law given by

$$(x,g)*(y,h)=(x+\psi_g(y),gh).$$

Lemma 1: The Lie algebra $\mathcal{G}$ of G is isomorphic with the space of matrices

a)Electronic mail: jcarrero@pdvsa.com

$$\begin{pmatrix} a & b \\ 0 & -a^t \end{pmatrix} \quad (a \in \mathrm{gl}(n), \quad b \in \mathrm{sym}(n)).$$

Proof: Immediate. □

Lemma 2: The following bilinear form on $\mathrm{sp}(n)\times\mathrm{sp}(n)$ is nondegenerate:

$$<,>:\mathrm{sp}(n)\times\mathrm{sp}(n)\to\mathbf{R}$$

$$<a,b>=\mathrm{tr}(ab).$$

In particular, this gives an identification $\mathrm{sp}(n)^*\sim\mathrm{sp}(n)$

Proof: Immediate. □

If we write (b,a) for the elements in $\mathcal{G}$, the adjoint action of G on $\mathcal{G}$ is given by

$$\mathrm{Ad}_{(x,g)}(b,a)=(gbg^t-\{a^g x+(a^g x)^t\},a^g).$$

Also the coadjoint action of G on $\mathcal{G}^*$ is given by

$$\mathrm{Ad}^*_{(x,g)}(c,a)=(\check{g}cg^{-1},a^g+x\check{g}cg^{-1}).$$

As was discussed in Ref. 1, the orbits in $\mathcal{G}^*$ related to physical phenomena are those where c is positive definite. This is the reason of defining the space $\mathcal{G}^+$ as

$$\mathcal{G}^+=\{(c,a)\in\mathcal{G}^*|c \text{ positive definite}\}.$$

Lemma 3: $\mathcal{G}^+$ is an open set in $\mathcal{G}^*$, invariant under the coadjoint action. Let $(c,a)\in\mathcal{G}^*$. Then $O_{(c,a)}$ contains an element of the form (I,a'), for some $a'\in gl(n)$, I being the identity matrix.

Proof: The result is a consequence of a classical theorem of Sylvester. □

From now on all the orbits that we consider, $O_{(c,a)}$ are orbits of elements in $\mathcal{G}^+$.

Theorem 4: If $n=2k+1$, every $O_{(c,a)}$ has a unique element $(I,\tilde{H})$, where

$$\tilde{H}=\begin{pmatrix} \begin{pmatrix} 0 & \lambda_1 \\ -\lambda_1 & 0 \end{pmatrix} & & & \\ & \ddots & & \\ & & \begin{pmatrix} 0 & \lambda_n \\ -\lambda_n & 0 \end{pmatrix} & \\ & & & 0 \end{pmatrix}$$

$$(\lambda_1\geqslant\lambda_2\geqslant\ldots\geqslant\lambda_n\geqslant 0).$$

If $n=2k$, it contains an element of the form

$$\tilde{H}=\begin{pmatrix} \begin{pmatrix} 0 & \lambda_1 \\ -\lambda_1 & 0 \end{pmatrix} & & \\ & \ddots & \\ & & \begin{pmatrix} 0 & \lambda_n \\ -\lambda_n & 0 \end{pmatrix} \end{pmatrix}$$

$$(\lambda_1\geqslant\lambda_2\geqslant\ldots\geqslant\lambda_n).$$

Proof: This is a consequence of the theory of compact Lie groups. We refer to Ref. 2, Theorem 4.12.2. □

Corollary 5: If $\lambda_1>\lambda_2>\ldots>\lambda_n>0$ then $O_{(c,a)}\simeq G/\mathrm{SO}(2)\times\mathrm{SO}(2)\times\ldots\times\mathrm{SO}(2)$.

Let $\mathcal{H}$ be the (CSA) of $\mathrm{SO}(n)$ given in Theorem 4. $\mathcal{W}$ the normalizer of $\mathcal{H}$ in $\mathrm{SO}(n)$, modulo its centralizer. It was proved by Chevalley[3] that the algebra of polynomials on $\mathrm{SO}(n)$ which are $\mathrm{SO}(n)$-invariant is isomorphic, via restriction to $\mathcal{H}$, with the algebra of polynomials on $\mathcal{H}$ that are $\mathcal{W}$-invariant. Let $I(\mathcal{H})$ denote this ring. Since every G orbit in $\mathcal{G}^+$ meets $\mathcal{H}$ in a $\mathcal{W}$ orbit in $\mathcal{H}$, it is clear that an invariant function on $\mathcal{G}^+$ is uniquely determined by its restriction to $\mathcal{H}$. Our aim now is to determine the ring of invariant functions on $\mathcal{G}^+$ whose restriction to $\mathcal{H}$ is all of $I(\mathcal{H})$. Let us denote this ring by $I(\mathcal{G}^+)$. It is interesting to note that unlike the theorem of Chevalley in the semisimple case, we need to go to the rational functions on $\mathcal{G}^+$ for $n=2k+1$, and algebraic functions on $\mathcal{G}^+$ for $n=2k$, to obtain all elements of $I(\mathcal{G}^+)$.

We begin with the determination of $\mathcal{W}$ and $I(\mathcal{H})$.

Lemma 6: $\mathcal{W}$ has the following determination.

(1) If $n=2k+1$, $\mathcal{W}$ consists of the group of all permutations of $(\lambda_1,\ldots,\lambda_k)$ followed by arbitrary changes of signs of the λ's.
(2) If $n=2k$, $\mathcal{W}$ consists of the group of all permutations of $(\lambda_1,\ldots,\lambda_n)$ followed by an even number of changes of sign of the λ's.

Proof: A proof is given in Ref. 2. □

Remark 7: It is very important to notice that when $n=2k$, $\mathcal{W}$ does not have arbitrary sign changes, because the only orthogonal matrix fixing $\gamma_s s\neq i$ and $\gamma_i\rightarrow-\gamma_i$ is the matrix K_i given in case $n=2k+1$ with last column and row deleted. However this matrix is not in $\mathrm{SO}(n)$ because its determinant is -1. The stabilizer of $\mathcal{H}$ in $O(n)$, the full orthogonal group, is the subgroup $\mathcal{W}'$ consisting in all the permutations followed by arbitrary sign changes. Therefore when n is odd $\mathcal{W}=\mathcal{W}'$ but when n is even $\mathcal{W}\subset\mathcal{W}'$, a normal subgroup.

Lemma 8: If $n=2k$, the ring of polynomial functions on $\mathcal{H}$, invariant under $\mathcal{W}$ is generated by

$$\sum_{1\leqslant i\leqslant k}\lambda_i^2,\quad \sum_{1\leqslant i\leqslant k}\lambda_i^4,\quad \ldots,\quad \sum_{1\leqslant i\leqslant k}\lambda_i^{2(k-1)},\quad \lambda_1,\ldots,\lambda_n.$$

If $n=2k+1$, it is generated by

$$\sum_{1\leqslant i\leqslant k}\lambda_i^2,\quad \sum_{1\leqslant i\leqslant k}\lambda_i^4,\quad \ldots,\quad \sum_{1\leqslant i\leqslant k}\lambda_i^{2(k-1)},\quad \sum_{1\leqslant i\leqslant k}\lambda_i^{2k}.$$

Proof: Let $\mathcal{W}'$ the group consisting in all permutations followed by arbitrary sign changes. Then $[\mathcal{W}',\mathcal{W}]=2$ and therefore $\mathcal{W}$ is normal in $\mathcal{W}'$. This can be proved as follows: when $n=2k+1$, $\mathcal{W}=\mathcal{W}'$, so there is nothing to prove. When $n=2k$ we take an element $\sigma\in\mathcal{W}'$, which has an odd number of sign changes; then $\mathcal{W}'=\mathcal{W}\cup\sigma\mathcal{W}$. Take an arbitrary polynomial $f(\lambda_1,\ldots,\lambda_k)$ invariant under $\mathcal{W}'$. Since S_n is a subgroup of $\mathcal{W}'$ all λ's can be interchanged, so f is symmetric. f has to be also invariant under arbitrary sign changes, what implies that $f=g(\lambda_1^2,\ldots,\lambda_k^2)$ showing that f is a polynomial in

$$\sum_{1\leqslant i\leqslant k}\lambda_i^2,\quad \sum_{1\leqslant i<j\leqslant k}\lambda_i^2\lambda_j^2,\ldots,\lambda_1^2,\ldots,\lambda_k^2. \tag{1}$$

Therefore when n is odd, the ring of polynomial invariants is generated by the polynomials in (1), because $\mathcal{W}=\mathcal{W}'$. Suppose n is even. Let s be any element of $\mathcal{W}'\setminus\mathcal{W}$. Since $\mathcal{W}$ is normal of index 2 in $\mathcal{W}'$, f^s is also $\mathcal{W}$-invariant. Write

$$f=\frac{f+f^s}{2}+\frac{f-f^s}{2}=f_1+f_2,$$

f_1 is $\mathcal{W}$ invariant and s-invariant. So it is $\mathcal{W}'$-invariant and so is a polynomial in (1). But $f_2^s = -f_2$ and hence $f_2^t = -f_2$ for any t that changes the sign of a single λ. So $f_2 = 0$ when $\lambda_j = 0$, showing that $\lambda_j | f_2$, hence that $\lambda_1, \ldots, \lambda_k | f_2$. So $f_2 = \lambda_1, \ldots, \lambda_k g(\lambda_1, \ldots, \lambda_k)$, where g is $\mathcal{W}'$-invariant and hence a polynomial in (1). Therefore f is a polynomial in

$$\sum_{1 \leqslant i \leqslant k} \lambda_i^2, \quad \sum_{1 \leqslant i < j \leqslant k} \lambda_i^2 \lambda_j^2, \ldots, \lambda_1, \ldots, \lambda_k.$$

To complete the proof we use the fact that if $x_1, \ldots, x_n$ are any set of variables, for any $r \leqslant N$,

$$\sum_{i_1 < \cdots < i_r} x_{i_1}, \ldots, x_{i_r}$$

is a polynomial in

$$\sum_i x_i, \sum_i x_i^2, \ldots, \sum_i x_i^r.$$

□

Theorem 9: For $m \geqslant 1$ the functions $f_m(a,c)$, given by the formula

$$f_m(a,c) = tr(((a^{c^{1/2}})_{sk})^{2m}) = \frac{1}{2^{2m}} \mathrm{tr}((cac^{-1} - a^t)^{2m})$$

are well defined and invariant under $\mathrm{ad}^*(G)$. Moreover for all m, f_m is a rational function in (c,a); and for $H \in \mathcal{H}$, $f_M(I,H) = \mathrm{tr}(H^{2m}) = (-1)^m \Sigma_{1 \leqslant i \leqslant k} \lambda_i^{2m}$.

Proof: This is a straightforward calculation. □

Theorem 10: For n odd, $I(\mathcal{G}^+)$ is the ring of invariant functions on $\mathcal{G}^*$ is generated by

$$f_1, f_2, \ldots, f_k, \quad k = \left[\frac{n}{2}\right].$$

Proof: By Theorem 9 the functions f_m restricted to $\mathcal{H}$ agree with the generators of the ring of invariant on $\mathcal{H}$. This proves the result. □

Remark 11: As we just proved in Theorem (10), when n is odd, the ring of invariant functions $I(\mathcal{G}^+)$ contains typically rational functions and not polynomials in (c,a) because of the presence of c^{-1}. When n is even the situation is quite different because the ring of invariants on $\mathcal{H}$ carries the additional polynomial $\lambda_1, \ldots, \lambda_k$. This polynomial gives rise to an additional function, the Pfaffian, which although a polynomial on $so(n)$, is not even rational on $\mathcal{G}^*$.

Let $n = 2k$, H a skew-symmetric $n \times n$ matrix. The Pfaffian of H is by definition

$$\mathrm{Pf}\{H\} = \frac{1}{k! 2^k} \sum \pm h_{(i_1 i_2)} \ldots h_{(i_{k-1} i_k)} \quad (H = (h_{ij})).$$

When $H \in \mathcal{H}$, $\mathrm{Pf}\{H\} = \lambda_1, \ldots, \lambda_k$. Also $\mathrm{Det}(H) = (\mathrm{Pf}\{H\})$.[2,4] We extend Pf to all $n \times n$ matrices by writing for any $n \times n$ matrix A,

$$\pi(A) = \mathrm{Pf}(\tfrac{1}{2}(A - A^t)).$$

Clearly π is a polynomial function, homogeneous of degree k, but has no general invariant properties. π is unique up to a sign since

$$\pi(A)^2 = \det(\tfrac{1}{2}(A - A^t))^2.$$

Lemma 12: Let $n=2k$. The invariant function Pf on $\mathcal{G}^+$ that coincides with Pf on SO(n) is given by

$$\mathrm{Pf}(c,a)=\pi(ca)\det(c)^{-1/2}=\pi(ac^{-1})\det(c)^{1/2}.$$

Proof: Direct computation. □

Theorem 13: For $n=2k$, the ring $I(\mathcal{G}^+)$ of invariant functions is generated by

$$f_1,\ldots,f_{k-1},\mathrm{Pf}.$$

In general Pf is not rational.

Proof: As we have seen in previous lemma the ring generated by the functions

$$f_1,\ldots,f_{k-1},\mathrm{Pf}$$

restricts to $I(\mathcal{H})$. It only remains to show that Pf is not a rational expression. Assume Pf $=P/Q$, then

$$\det(c)^{1/2}=\frac{P(c,a)}{Q(c,a)\pi(ac^{-1})}$$

is a rational function of c which is absurd. □

Theorem 14: The simultaneous level sets of the generators of $I(\mathcal{G}^+)$ are precisely the G-orbits in $\mathcal{G}^+$.

Proof: By Chevalley's theorem for SO(n), the $\mathcal{W}$-invariant functions on $\mathcal{H}$ separates the $\mathcal{W}$-orbits. Hence $I(\mathcal{G}^+)$ separate the G-orbits in $\mathcal{G}^+$. □

Proposition 15: For $n=3$, the square of the Kelvin circulation generates the ring $I(\mathcal{G}^+)$. It is defined as $f_1=\frac{1}{2}\mathrm{tr}(a^2)-\mathrm{tr}(cac^{-1}a^t)$.

Proof: By Theorem 10 the number of invariant functions is equal to $[n/2]$. Write the expression for f_1 and compare with the square of the lengths of the Kelvin circulation given in Ref. 1. □

The Riemann disks, the two-dimensional analogs of the Riemann S-type ellipsoids, where introduced by Weinberg in Refs. 5 and 6. There he considers this Riemann disks as models of galactic bar. The disks are compose of a two-dimensional fluid specified by a surface σ, and a pressure P, which acts only in the plane of the fluid. The surface density of the Riemann disk is obtained by collapsing a homogeneous ellipsoid with density ρ and principal axes $a\geqslant b\geqslant c$ and it is proved that the potential function in this case is given by the very simple formula

$$V=\frac{\pi G\sigma_0}{a}[A(\lambda)(x^2-a^2)+B(\lambda)(y^2-b^2)]$$

also the velocity field in the rotating frame may be written

$$u_x=\frac{a}{b}\Lambda y,\quad u_y=\frac{a}{b}\Lambda x.$$

Then he points out that with this form of u, each stream line is an ellipse similar to the boundary of the disk, and each fluid element conserves its density and pressure. Notice that this corresponds exactly with the orbits for the two-dimensional ellipsoids we defined here abstractly.

III. SYMPLECTIC STRUCTURE AND GLOBAL DARBOUX COORDINATES FOR COADJOINT ORBITS OF SO(2)⋉GL$_+$(2)

In this section we find global Darboux coordinates for the coadjoint orbits of sym(2)⋉gl$_+$(2) on the dual of its Lie algebra. If we denote by O any one of these orbits, then Darboux theorem

says that: for each point of O there is a local chart (σ,U), $\sigma=(q_1,\ldots,q_n;p_1,\ldots,p_n)$ such that the 2-form ω, defining the symplectic structure, restricted to U has the simple form

$$\omega|_U=\sum_{u=1}^{n} dp_u\wedge dq_u.$$

However, even locally, it is extremely difficult to find such coordinates for most of the symplectic manifolds known. Pedersen showed that for simply connected exponential solvable Lie groups, it is indeed possible to find such Darboux coordinates, not locally but globally defined. In his paper[7] he proves that such coordinates exist and develops a technique to find these coordinates. Even though our group is not solvable, we could adapt his proof to our case so that one can find explicit Darboux coordinates in the case of *physical orbits*.

Theorem 16: For every $(c,a)\in\mathcal{G}^+$, there exist global coordinates on $O_{(c,a)}$ so that $O_{(c,a)}$ is diffeomorphic to $\mathbf{R}^6$. Coordinates given by the map

$$\sigma:\ \hat{G}\sim O_{(c,a)}\to\mathbf{R}^6,$$

$$\left(\begin{pmatrix} u & v\\ v & w\end{pmatrix},\begin{pmatrix} e^{\alpha} & \gamma\\ 0 & e^{\beta}\end{pmatrix}\right)\to(u,v,w;\alpha,\beta,\gamma),$$

$$\hat{G}=\mathrm{sym}(2)\ltimes B_+(2).$$

Proof: The proof is immediate from Corollary 5 and the Iwasawa decomposition of $\mathrm{gl}_+(2)$ using the fact that in this case the stabilizer is isomorphic to $\mathrm{SO}(2)$. □

As was proved by Kirillov,[8] $O_{(c,a)}$ is a symplectic manifold. We are going to use the identification just given, $O_{(c,a)}\sim\hat{G}$, to compute its symplectic structure. First we would like to recall how this ''canonical'' symplectic structure is defined for coadjoint orbits of connected Lie groups.

For $g\in\mathcal{G}^*$ we define the skewsymmetric bilinear form $B_g:\ \mathcal{G}\times\mathcal{G}\to\mathbf{R}$ by $B_g(X,Y)=<g,[X,Y]>$. The radical of B_g is the Lie algebra $\mathcal{G}_g$ of the stabilizer G_g of g, and therefore we can define a symplectic form $\hat{B}_g:\ \mathcal{G}/\mathcal{G}_g\times\mathcal{G}/\mathcal{G}_g\to\mathbf{R}$ by factoring through $\mathcal{G}_g$.

Let $\omega=\omega_O$ be the canonical symplectic form on O. We recall how ω is defined: For $l\in O$, let $\alpha_l:\mathcal{G}/\mathcal{G}_g\to T_l(O)$ be the canonical vector space isomorphism, i.e., $\alpha_l(\dot{X})\varphi(l)=(d/dt)\,\varphi(\exp tX.l)|_{t=0}$, where $\dot{X}=X+\mathcal{G}_g$ and $\varphi\in\mathbf{C}^{\infty}(C)$. Then ω_l is defined to be the transport by α_l of $\hat{B}_l$, i.e., $\omega_l(\alpha_l(\hat{X}),\alpha(\hat{Y}))=B_l(X,Y)$. The form ω is then defined by moving ω_l by the elements of G to the points of O. Let us now return to our special situation where $\mathrm{gl}_l=\mathrm{SO}(2)$ and we have

$$\hat{G}\to O_l,\quad \hat{g}\to\hat{g}.l.$$

So if $\hat{\mathcal{G}}$ is the Lie algebra of $\hat{G}$, α_l is an isomorphism of $\hat{\mathcal{G}}$ with $T_l(O)$. Thus ω_l lifts to a symplectic form $\hat{\omega}$ on $\hat{G}$ characterized by

(1) $\hat{\omega}$ is invariant under left translations of $\hat{G}$;
(2) $\hat{\omega}_e(\hat{X},\hat{Y})=l([\hat{X},\hat{Y}]),\ \hat{X},\hat{Y}\in\hat{\mathcal{G}}$.

We have thus come down from G to $\hat{G}$; although G is not solvable, $\hat{G}$ is solvable, even exponential. For $\hat{\mathcal{G}}$ the elements are of the form

$$(s,b)\quad \left(s=\begin{pmatrix} u & v\\ v & w\end{pmatrix},\quad b=\begin{pmatrix} x & z\\ 0 & y\end{pmatrix}\right).$$

So we have a basis

$$S_1, S_2, S_3; B_1, B_2, B_3$$

for $\hat{\mathcal{G}}$ given by

$$S_1 = \left(\begin{pmatrix} 1 & 0 \\ 0 & 0 \end{pmatrix}, 0 \right), \quad S_2 = \left(\begin{pmatrix} 0 & 1 \\ 0 & 0 \end{pmatrix}, 0 \right), \quad S_3 = \left(\begin{pmatrix} 0 & 1 \\ 1 & 0 \end{pmatrix} \right),$$

$$B_1 = \left(0, \begin{pmatrix} 1 & 0 \\ 0 & 0 \end{pmatrix} \right), \quad B_2 = \left(0, \begin{pmatrix} 0 & 0 \\ 0 & 1 \end{pmatrix} \right), \quad B_3 = \left(0, \begin{pmatrix} 0 & 1 \\ 0 & 0 \end{pmatrix} \right).$$

The commutation rules are

$$[S_i, S_j] = 0, \quad [B_1, B_2] = 0, \quad [B_1, B_3] = B_3, \quad [B_2, B_3] = -B_3,$$

$$[B_1, S_1] = 2S_1, \quad [B_1, S_2] = 0, \quad [B_1, S_3] = S_3,$$

$$[B_2, S_1] = 0, \quad [B_2, S_2] = 2S_2, \quad [B_2, S_3] = S_3,$$

$$[B_3, S_1] = 0, \quad [B_3, S_2] = S_3, \quad [B_3, S_3] = 2S_1.$$

These are straightforward to check.

The element l we shall take to be $(I, r\left(\begin{smallmatrix} 0 & -1 \\ 1 & 0 \end{smallmatrix}\right))$. So

$$<(s,b), l> = 2r \operatorname{tr}\left(b \begin{pmatrix} 0 & -1 \\ 1 & 0 \end{pmatrix} \right) + \operatorname{tr}(s) = 2rz + u + w,$$

where

$$b = \begin{pmatrix} x & z \\ 0 & y \end{pmatrix}, \quad s = \begin{pmatrix} u & w \\ w & v \end{pmatrix}.$$

Thus

$$l: \ S_1 \to 1, S_2 \to 1, S_3 \to 0, B_1 \to 0, B_2 = 0, B_3 \to 2r.$$

Moreover, at the identity element of $\hat{G}$,

$$S_1 = \frac{\partial}{\partial u}, \quad S_2 = \frac{\partial}{\partial v}, \quad S_3 = \frac{\partial}{\partial w},$$

$$B_1 = \frac{\partial}{\partial \alpha}, \quad B_2 = \frac{\partial}{\partial \beta}, \quad B_3 = \frac{\partial}{\partial \gamma}.$$

Theorem 17: In the coordinate system given in Theorem 16. $\hat{\omega}_e$ is equal to

$$\hat{\omega}_e = -(2r\, d\beta \wedge d\gamma + 2r\, d\gamma \wedge d\alpha + 2\, du \wedge d\alpha + 2\, dv \wedge d\beta + 2\, dw \wedge d\gamma).$$

Proof: Follows from the previous relations and the definition of $\hat{\omega}_e$. □

Theorem 18: The 2-form $\hat{\omega}$ on $\hat{G}$ is equal to

$$\begin{aligned} \omega = & -2e^{-2\alpha} du \wedge d\alpha - 2\gamma^2 e^{-2(\alpha+\beta)} dv \wedge d\alpha - 2(\gamma^2 e^{-2(\alpha+\beta)} + e^{2\beta}) dv \wedge d\beta \\ & + 2\gamma e^{-2(\alpha+\beta)} dv \wedge d\gamma - 2e^{-(2\alpha+\beta)} dw \wedge d\gamma - 2r\gamma e^{-\alpha} d\alpha \wedge d\beta \\ & + 2re^{-\alpha} d\alpha \wedge d\gamma - 2re^{-\alpha} d\beta \wedge d\gamma - 4\gamma e^{-(2\alpha+\beta)} d\alpha \wedge dw - 2\gamma e^{-(2\alpha+\beta)} d\beta \wedge dw. \end{aligned}$$

Proof: Since $\hat{\omega}$ is the left invariant extension of $\hat{\omega}_e$, Theorem 17 shows that

$$\hat{\omega} = -2r[d\beta]\wedge[d\gamma] + 2r[d\alpha]\wedge[d\gamma] + 2[d\alpha]\wedge[du] + 2[d\beta]\wedge[dv] + 2[d\gamma]\wedge[dw].$$

Now if we compute the left invariant 1-form that extend $d\alpha_e, \ldots, dw_e$ we get the result. □

We shall use Pedersen's[7] technique in the explicit construction of the global Darboux coordinates. If we denote by $\hat{\mathcal{S}} = \mathrm{sym}(2)$, view as a normal subgroup of $\mathcal{G}$, then the functions on $\hat{\mathcal{G}}/\hat{\mathcal{S}}$ are precisely those that are functions of α,β,γ only. We denote by $\mathcal{E}^O$ the space of all smooth functions on $\hat{G}/\hat{\mathcal{S}}$, i.e., smooth functions on α,β,γ. Our aim is to study $C^\infty(\hat{G})$ as a Poisson algebra under the Poisson bracket $\{.,.\}$ determined by $\hat{\omega}$. From classical results in symplectic manifolds we know that if $a_1, \ldots, a_n$ be a chart on a symplectic manifold M with symplectic form ω, and $\omega(\partial/\partial a_j, \partial/\partial a_k) = \omega_{jk}$ $(1 \leqslant j,k \leqslant n)$ then

$$\{a_j, a_k\} = \omega^{kj} \quad (1 \leqslant j,k \leqslant n),$$

where (ω^{kj}) is the inverse matrix of (ω_{kj}).

We now return to $\mathcal{G}$.

Theorem 19: In the coordinates $u,v,w,\alpha,\beta,\gamma$ the matrix of $\hat{\omega}$ is

$$\begin{pmatrix} 0 & \tilde{A} \\ -\tilde{A}^t & \tilde{B} \end{pmatrix},$$

where

$$\tilde{A} = \begin{pmatrix} -2e^{-2\beta} & 0 & \\ -2\gamma^2 e^{-2(\alpha+\beta)} & -2(e^{-2\beta} + \gamma^2 e^{-2(\alpha+\beta)}) & 0 \\ 4\gamma e^{-(2\alpha+\beta)} & 2\gamma e^{-(2\alpha+\beta)} & -2e^{-(2\alpha+\beta)} \end{pmatrix},$$

$$\tilde{B} = \begin{pmatrix} 0 & -2r\gamma e^{-\alpha} & 0 & -2re^{-\alpha} \\ 2r\gamma e^{\alpha} & 0 & -2re^{-\alpha} & \\ -2re^{-\alpha} & 2re^{-\alpha} & 0 & \end{pmatrix}.$$

Its inverse has the form

$$\begin{pmatrix} A & B \\ -B^t & 0 \end{pmatrix},$$

where A,B,C are 3×3 matrices. In particular

$$\{\alpha,\beta\} = \{\beta,\gamma\} = \{\gamma,\alpha\} = 0.$$

Proof: The matrix of ω has the form

$$\begin{pmatrix} 0 & X \\ -X^t & Y \end{pmatrix},$$

where X and Y are 3×3 matrices; and as $\hat{\omega}$ is invertible, X is invertible. Its inverse is

$$\begin{pmatrix} X^{-1t} Y X^{-1} & -X^{-1t} \\ X^{-1} & 0 \end{pmatrix}$$

as an easy calculation shows. □

We shall now give a brief description of Pedersen's work[7] and proceed to apply it in this case. Recall the isomorphism

$$\hat{G}\sim O, \quad \hat{g}\to \hat{g}.l$$

where

$$l=\left(I, r\begin{pmatrix} 0 & -1 \\ 1 & 0 \end{pmatrix}\right).$$

Let $\mathcal{E}^O(\hat{G})$ be the space of smooth functions on $\hat{G}/\hat{\mathcal{S}}$, i.e., smooth functions of α,β,γ. By theorem 19 this is an Abelian Lie algebra under $\{.,.\}$.

Following Pedersen we introduce $\mathcal{E}^1(\hat{G})$, the space of quantizable functions on $\hat{G}$, namely the space of smooth functions f on $\mathcal{G}$ such that

$$\{f,g\}\in \mathcal{E}^O(\mathcal{G}) \quad (g\in \mathcal{E}^O(\hat{G})).$$

Thus $\mathcal{E}^1(\hat{G})$ is the normalizer of $\mathcal{E}^O(\hat{G})$ with respect to $\{.,.\}$; consequently it is also a Lie algebra under $\{.,.\}$. Pederson now constructs a Lie algebra isomorphism

$$\delta:\ \mathcal{E}^1(\hat{G})\tilde{\to}\mathrm{Diff}^1(\hat{G}/\hat{\mathcal{S}}),$$

where $\mathrm{Diff}^1(\hat{G}/\hat{\mathcal{S}})$ is the Lie algebra of smooth differential operators in α,β,γ of degree $\leqslant 1$. It follows there will be elements

$$P_\alpha, P_\beta, P_\gamma \in \mathcal{E}^1(\hat{G})$$

such that

$$\delta(P_\alpha)=\frac{\partial}{\partial\alpha}, \quad \delta(P_\beta)=\frac{\partial}{\partial\beta}, \quad \delta(P_\gamma)=\frac{\partial}{\partial\gamma}.$$

Then we will have

$$\{P_\alpha, P_\beta\}=\{P_\beta, P_\gamma\}=\{P_\gamma, P_\alpha\}=0,$$

$$\{P_\alpha, \alpha\}=\{P_\beta, \beta\}=\{P_\gamma, \gamma\}=1,$$

$$\{P_\alpha, \beta\}=\{P_\alpha, \gamma\}=0,$$

etc. These relations then show that

$$\hat{\omega}=dP_\alpha\wedge d\alpha+dP_\beta\wedge d\beta+dP_\gamma\wedge d\gamma.$$

In other words

$$\alpha,\beta,\gamma,P_\alpha,P_\beta,P_\gamma$$

will be the global Darboux coordinates we are after.

It remains to describe the Pedersen isomorphism. Recall that

$$\mathcal{G}=\mathcal{S}\oplus\hat{b}(2), \quad \hat{b}(2)=\mathrm{Lie}(B_+(2)).$$

Let us now associate to $X\in\hat{b}$ the functions ψ^X on $\hat{G}$ by

$$\psi^X(\hat{g}) = <X, \hat{g}.l>.$$

Pedersen associates to ψ^X the differential operators $D(X)$ acting on functions on $\mathcal{G}/\hat{\mathcal{S}} \sim B_+(2)$

$$(D(X))(b) = \frac{d}{dt} u(\exp(-tX.b))|_{t=0};$$

thus

$$\delta(\psi^X) = D(X).$$

If φ is a smooth function on $\hat{G}/\hat{\mathcal{S}}$, Pedersen associates to φ the operator M_φ of multiplication by φ

$$\delta(\varphi) = M_\varphi, \quad M_\varphi u = \varphi u.$$

Since ψ^X and φ are functions on $\hat{G}$, $\{\psi^X, \varphi\}$ makes sense and it is not difficult to check that

$$\{\psi^X, \varphi\} = X\varphi,$$

$$[D(X), M_\varphi] = M_{X\varphi}.$$

The first relation shows that $\psi^X \in \mathcal{E}^1(\hat{G})$. Pedersen shows actually that the ψ^X and φ generate $\mathcal{E}^1(\hat{G})$ as an $\mathcal{E}^0(\hat{G})$-module and that δ defines a Lie algebra isomorphism

$$\delta: \ \mathcal{E}^1(\hat{G}) \tilde{\rightarrow} \mathrm{Diff}(\alpha, \beta, \gamma).$$

To construct the Darboux coordinates in our case it is not even necessary to assume Pedersen's theorem; it is enough to compute

$$\psi^{B_1}, \psi^{B_2}, \psi^{B_3}, D(B_1), D(B_2), D(B_3),$$

where $\{B_1, B_2, B_3\}$ is the basis of $\hat{b}(2)$ introduced earlier, and determine $P_\alpha, P_\beta, P_\gamma$.

We begin with $\gamma(B_j)$.

Lemma 20: We have

$$D(B_1) = -\frac{\partial}{\partial \alpha} - \gamma \frac{\partial}{\partial \gamma},$$

$$D(B_2) = -\frac{\partial}{\partial \beta},$$

$$D(B_3) = -e^\beta \frac{\partial}{\partial \gamma}.$$

Proof: We have, for any smooth function u of α, β, γ

$$(D(X)u)(b) = \frac{d}{dt} u(\exp(-tX.b))|_{t=0}$$

apply this formula when $X = B_1, B_2, B_3$ to get the result. □

Let

$$X=\begin{pmatrix}\xi & \zeta\\ 0 & \tau\end{pmatrix},\quad b=\begin{pmatrix}e^{\alpha} & \gamma\\ 0 & e^{\beta}\end{pmatrix},\quad s=\begin{pmatrix}u & w\\ w & v\end{pmatrix}.$$

Lemma 21: The function ψ^X is given by the formula

$$\psi^X(s,b)=2re^{-\alpha}(\xi\gamma+\zeta e^{\beta}-\tau\gamma)+2[(\xi u+\xi w)e^{-2\alpha}-\gamma e^{-(2\alpha+\beta)}(\xi w+\zeta v)$$
$$-\tau w\gamma e^{-(2\alpha+\beta)}+\tau v e^{-2\beta}(\gamma^2e^{-2\alpha}+1)].$$

Proof: We have

$$b^{-1}Xb=\begin{pmatrix}e^{-\alpha} & -\gamma e^{-(\alpha+\beta)}\\ 0 & e^{-\beta}\end{pmatrix}\begin{pmatrix}\xi & \zeta\\ 0 & \tau\end{pmatrix}\begin{pmatrix}e^{\alpha} & \gamma\\ 0 & e^{\beta}\end{pmatrix}=\begin{pmatrix}\xi & e^{-\alpha}(\xi\gamma+\zeta e^{\beta}-\tau\gamma)\\ 0 & \tau\end{pmatrix},$$

$$Xs\check{b}b^{-1}=\begin{pmatrix}\xi u+\zeta w & \xi w+\zeta v\\ \tau w & \tau v\end{pmatrix}\begin{pmatrix}e^{-2\alpha} & -\gamma e^{-(2\alpha+\beta)}\\ -\gamma e^{-(2\alpha+\beta)} & \gamma^2e^{-2(\alpha+\beta)}+e^{-2\beta}\end{pmatrix}.$$

From which the formula for ψ^X is immediate. □

Lemma 22: We have

$$\psi^{B_1}=2r\gamma e^{-\alpha}+2ue^{-2\alpha}-2\gamma we^{-(2\alpha+\beta)},$$

$$\psi^{B_2}=-2r\gamma e^{-\alpha}-2w\gamma e^{-(2\alpha+\beta)}+2ve^{-2\beta}(\gamma^2e^{-2\beta}+1),$$

$$\psi^{B_3}=2re^{\beta-\alpha}+2we^{-2\alpha}-2\gamma ve^{-(2\alpha+\beta)}.$$

Proof: Immediate. □

Lemma 23: Let

$$P_{\alpha}=-2r\gamma e^{-\alpha}-2ue^{-2\alpha}+2\gamma we^{-(2\alpha+\beta)}+\gamma e^{-\beta}(2we^{-2\alpha}-2\gamma ve^{-(2\alpha+\beta)}+2re^{\beta-\alpha}),$$

$$P_{\beta}=2r\gamma e^{-\alpha}+2w\gamma e^{-(2\alpha+\beta)}-2ve^{-2\beta}(\gamma^2e^{-2\beta}+1),$$

$$P_{\gamma}=-e^{-\beta}(2re^{\beta-\alpha}+2we^{-2\alpha}-2\gamma ve^{-(2\alpha+\beta)}),$$

then

$$\delta(P_{\alpha})=\frac{\partial}{\partial\alpha},\quad \delta(P_{\beta})=\frac{\partial}{\partial\beta},\quad \delta(P_{\gamma})=\frac{\partial}{\partial\gamma}.$$

Proof: From Lemmas 22 and 20 we get

$$\delta(-\psi^{B_1}+\gamma e^{-\beta}\psi^{B_3})=\frac{\partial}{\partial\alpha},$$

$$\delta(-\psi^{B_2})=\frac{\partial}{\partial\beta},$$

$$\delta(-e^{-\beta}\psi^{B_3})=\frac{\partial}{\partial\gamma}.$$

□

From this we get the following lemma.

Lemma 24: We have

$$\hat{\omega} = dP_\alpha \wedge d\alpha + dP_\beta \wedge d\beta + dP_\gamma \wedge d\gamma.$$

Proof: This is a straightforward computation. □

Theorem 25: The coordinates

$$\alpha, \beta, \gamma, P_\alpha, P_\beta, P_\gamma$$

are global Darboux coordinates on $\hat{G} \sim O$.

Proof: Immediate. □

IV. STRUCTURE OF POTENTIALS AND HAMILTONIAN FORM FOR ELLIPSOIDAL DYNAMICS

The equations of motion for a self-gravitating ellipsoid have been described in Ref. 1. They make sense for n-dimensional ellipsoids and take the following form. Let

$$\mathbf{I} = (I_{ij}), \quad \mathbf{S} = (S_{kl})$$

be, respectively, the inertia and shear tensor (in the laboratory frame). The motion of the ellipsoid is completely determined by the time evolution of **I** and **S**.

Let **T** the kinetic energy tensor. Then

$$\mathbf{T} = \tfrac{1}{2}\mathbf{S}^t\mathbf{I}^{-1}\mathbf{S}$$

and the differential equations are

$$\begin{aligned} \dot{\mathbf{I}} &= \mathbf{S} + \mathbf{S}^t \\ \dot{\mathbf{S}} &= 2\mathbf{T} + \mathbf{P} + \Pi, \end{aligned} \tag{2}$$

where $\Pi = p.v.\mathbf{1}$, $p =$ total pressure, $v =$ volume of the ellipsoid and **P** the gravitational tensor

$$\mathbf{P} = (P_{ij}).$$

We shall show in this section that Eqs. (2) can be expressed in the Hamiltonian form, i.e., for a suitable function H on the phase space,

$$\begin{aligned} \dot{I}_{ij} &= \{H, I_{ij}\}, \\ \dot{S}_{ij} &= \{H, S_{ij}\}. \end{aligned} \tag{3}$$

The main result that does this is Theorem 41. For the case $n = 3$ it was proved by Rosensteel.[1] It depends on a study of the conditions under which we may assert that a tensor $A = (a_{ij})$ is of the form

$$a_{ij} = \{V, S_{ij}\}$$

for a functions V of the I_{ik} that is SO(n)-invariant. Theorem 34 does this. Theorem 34 and its corollary Theorem 36 appear to be new. The method of proof of Rosensteel[1] was somewhat different from the one given here.

Lemma 26: The Poisson bracket of S_{ij} and I_{ij} is given by

$$\{I_{ij}, S_{rk}\} = -(\delta_{ik}I_{rj} + \delta_{jk}I_{ri}),$$

$$\{I_{ij}, I_{rk}\} = 0,$$

$$\{S_{ij},S_{rk}\}=\delta_{ik}S_{jr}-\delta_{rj}S_{ik}.$$

Proof: Refer to Ref. 1. □

Let's define the kinetic energy tensor

$$\mathbf{T}=\tfrac{1}{2}(S^tI^{-1}S),\quad T_{ij}=\tfrac{1}{2}S_{ki}I^{km}S_{mj}=T_{ji}. \tag{4}$$

Proposition 27: The following relations are satisfied:

$$\{T,I_{kl}\}=S_{kl}+S^t_{lk}, \tag{5}$$

$$\{T,S_{kl}\}=2T_{kl}. \tag{6}$$

Proof: This is a direct computation. □

It is now necessary to determine which matrices $A=(A_{ij})$ of functions of the I_{ij} can be written in the form $(\{V,S_{kl}\})$ for some rotation invariant function V of the I_{ij}.

Definition 28: Let $M_V=(\{V,S_{lj}\})$. A matrix, $A=(A_{lj})$, of functions on the coordinates $I_{ik}i\leqslant k$, is said to come from a potential if there exits a SO(n)-invariant function of the I_{ik} such that $A=M_V$, i.e., $A_{lj}=\{V,S_{lj}\}$ for all l,j.

Proposition 29: Let $V(I_{lk})=\mathrm{tr}(I^p)$, where I is the matrix whose components are the functions I_{ij} on $\mathcal{G}^*$; then $M_V=-2pI^p$.

Proof: The identity follows immediately from the formula

$$V=\sum_{i_1,\ldots,i_p} I_{i_1i_2}I_{i_2i_3},\ldots,I_{i_pi_1}.$$

□

Corollary 30: The matrix I comes from a potential.

Proof: Take $V=(-1/2)\,\mathrm{tr}(I)$ and apply the previous lemma. □

Lemma 31: Let $V_1,V_2,\ldots,V_n$ be SO(n)-invariant functions of the I_{ik}. Then for any smooth function $\Phi(V_1,\ldots,V_n)$ of the V_i the following equation is true:

$$M_{\Phi(V_1,\ldots,V_n)}=\sum_{1\leqslant i\leqslant n}\frac{\partial\Phi}{\partial V_i}M_{V_i}.$$

Proof:

$$M_{\Phi(V_1,\ldots,V_n)}=(\{\Phi(V_1,\ldots,V_n),S_{kl}\}).$$

Using the fact that $\{.,S_{kl}\}$ is a derivation we get

$$\{\Phi(V_1,\ldots,V_n),S_{kl}\}=\frac{\partial\Phi}{\partial V_1}\{V_1,S_{kl}\}+\ldots+\frac{\partial\Phi}{\partial V_n}\{V_n,S_{kl}\}.$$

This proves the lemma. □

Lemma 32: Let V be a function of the I_{ik}, invariant under SO(n). Then for all $g\in\mathrm{SO}(n)$,

$$(M_V)^g=g^tMg.$$

Proof: Notice that $(M_V)^g_{kl}=\{V,S_{kl}\}^g=\{V^g,S^g_{kl}\}=\{V,S^g_{kl}\}$. Using the pairing $<.,.>$ the lemma follows. □

For any smooth function F on the set of positive definite matrices define

$$\tilde{F}(a_1,\ldots,a_n)=F(\mathrm{diag}(a_1^2,\ldots,a_n^2)).$$

If $M=(F_{ij})$ is a matrix of such functions, we define

$$\tilde{M}=\widetilde{(F_{ij})}.$$

Finally let

$$\mathcal{D}=(D_{ij})$$

be the matrix of vector fields in the variables $a_1,\ldots,a_n$, with

$$D_{ij}=\delta_{ij}a_i\frac{\partial}{\partial a_i}(\text{no summation}).$$

Lemma 33: For any $\mathrm{SO}(n)$-invariant smooth function V on the set of positive definitive matrices,

$$\tilde{M}_V=\mathcal{D}\tilde{V}=\left(-\delta_{ij}a_i\frac{\partial}{\partial a_i}\tilde{V}\right).$$

Proof: Since both sides are smooth it is enough to verify this on the open set where the a_i are distinct. Moreover it is enough to do this locally.

Write

$$V_p(s)=\mathrm{tr}(s^p),\quad p=1,2,\ldots,n.$$

If V is $\mathrm{SO}(n)$-invariant, locally on U we have a representation

$$V(s)=\varphi(V_1(s),\ldots,V_n(s)),$$

where φ is smooth. Then

$$\tilde{M}_V=\sum_p\left(\frac{\widetilde{\partial\varphi}}{\partial V_p}\right)\tilde{M}_{V_p},$$

on the other hand, by Proposition 29

$$\tilde{M}_{V_p}(a_1,\ldots,a_n)=-2p\ \mathrm{diag}(a_1^{2p},\ldots,a_n^{2p})=(D_{ij}\tilde{V}_p(a_1,\ldots,a_n)),$$

hence

$$\tilde{M}_V=\sum_p\left(\frac{\widetilde{\partial\varphi}}{\partial V_p}\right)\tilde{M}_{V_p}=\sum_p\left(\frac{\widetilde{\partial\varphi}}{\partial V_p}\right)\mathcal{D}\tilde{V}=\mathcal{D}\varphi(\tilde{V}_1,\ldots,\tilde{V}_n)=\mathcal{D}\tilde{V}.$$

This proves the lemma. □

Theorem 34: Suppose

$$M=(M_{ij})$$

is a tensor of smooth functions on the open set of positive definite matrices with the following properties:

(1) $M^g=g^tMg\ \ (g\in\mathrm{SO}(n))$.
(2) There exist a smooth $\mathrm{SO}(n)$-invariant function V on the open positive definite matrices such that

$$\tilde{M}=\mathcal{D}\tilde{M}.$$

Then

$$M = M_V .$$

In particular M comes from a potential.

Remark 35: These conditions are obviously necessary. This theorem is very useful since it reduces the verification to the diagonal matrices.

Proof: By the lemma above,

$$\tilde{M} = \tilde{M}_V .$$

Since both M and M_V have the transformation properties (1), it follows that they are both uniquely determined by they restriction to the space of diagonal matrices. Since the restriction of M and M_V to the diagonal space are equal, we must have $M = M_V$. □

Theorem 36: Let f be a scalar smooth SO(n)-invariant function. Then the tensor

$$f.I = (\delta_{ij} f)$$

comes from a potential if and only if it is a function of the determinant. More precisely, if

$$f(s) = h((\det(s))^{1/2}),$$

then

$$f.I = M_g ,$$

where

$$g(s) = k((\det(s)^{\frac{1}{2}}), \quad k(x) = -\int^x \frac{h(t)}{t} dt.$$

Proof: Assume first that f is a smooth function of det. We can thus write

$$f(s) = h((\det)^{1/2}),$$

where h is a smooth function of a single variable $x > 0$. Select a function $k(x)$ $(x > 0)$, smooth, such that

$$h(x) = -xk'(x),$$

for instance

$$k(x) = -\int_1^x \frac{h(t)}{t} dt.$$

If

$$g(s) = k((\det(s))^{\frac{1}{2}})$$

we claim that

$$f.I = M_g .$$

In view of Theorem 36 it is enough to prove that

$$f(\mathrm{diag}(a_1^2,\ldots,a_n^2)) = -a_i \frac{\partial}{\partial a_i} g(\mathrm{diag}(a_1^2,\ldots,a_n^2)).$$

But

$$\begin{aligned} -a_i \frac{\partial}{\partial a_i} g(\mathrm{diag}(a_1^2,\ldots,a_n^2)) &= -a_i \frac{\partial}{\partial a_i} k(\mathrm{diag}(a_1,\ldots,a_n)) = -a_i k'(a_1,\ldots,a_n) \\ &\quad \times (a_1,\ldots,\hat{a}_i,\ldots,a_n) = -(a_1,\ldots,a_n)k'(a_1,\ldots,a_n) \\ &= h(a_1,\ldots,a_n) = f(\mathrm{diag}(a_1^2,\ldots,a_n^2)). \end{aligned}$$

We must now prove the converse. So we assume that for all $i=1,\ldots,n$

$$f(\mathrm{diag}(a_1^2,\ldots,a_n^2)) = -a_i \frac{\partial}{\partial a_i} g(\mathrm{diag}(a_1^2,\ldots,a_n^2))$$

for some smooth function g in the positive definite matrices.

Write

$$F(a_1,\ldots,a_n) = f(\mathrm{diag}(a_1^2,\ldots,a_n^2)), \quad G(a_1,\ldots,a_n) = -g(\mathrm{diag}(a_1^2,\ldots,a_n^2)).$$

Then

$$F(a_1,\ldots,a_n) = -a_i \frac{\partial G}{\partial a_1} \quad (1 \leqslant i \leqslant n, a_i > 0).$$

If we go to variables $b_1,\ldots,b_n$ where $b_1 = a_1 \ldots a_n$, $b_j = a_j$, $2 \leqslant j \leqslant n$, then

$$a_1 \frac{\partial G}{\partial a_1} = (a_1 \ldots a_n) \frac{\partial G}{\partial b_1},$$

$$a_j \frac{\partial G}{\partial a_j} = (a_1 \ldots a_n) \frac{\partial G}{\partial b_1} + a_j \frac{\partial G}{\partial b_j} \quad (2 \leqslant j \leqslant n).$$

As all the $a_j(\partial G/\partial a_j)$ are equal to F, we must have

$$\frac{\partial G}{\partial b_j} = 0, \quad 2 \leqslant j \leqslant n.$$

Hence G is a function of b_1 only, say

$$G(b_1,\ldots,b_n) = h(b_1) = h(a_1 \ldots a_n).$$

But then

$$F(a_1,\ldots,a_n) = a_1 h'(a_1,\ldots,a_n) a_2,\ldots,a_n = (a_1 \ldots a_n) h'(a_1 \ldots a_n).$$

Showing that F depends only on $a_1,\ldots,a_n$. So f is a function of det only. □

We begin by applying Theorem 34 to show that the gravitational potential tensor of an ellipsoid comes from a potential, and determine this potential. We observe that for any point $(c,a) \in \mathcal{G}^*$ (a symmetric) the corresponding ellipsoid is given by the equation

$$x^t a^{-1} x = 1.$$

For an ellipsoid with mass density $\rho(x)$, the analogue of the gravitational potential tensor is

$$P_{ij}(a)=k\int_{\Gamma}\int_{\Gamma'}\frac{\rho(x)\rho(x')(x_i-x_i')(x_j-x_j')}{\|x-x'\|^n}d^nx\,d^nx', \tag{7}$$

where k is a constant >0 and

$$\Gamma=\{x|x^ta^{-1}x\leqslant 1\},\quad \Gamma'=\{x'|x'^ta^{-1}x'\leqslant 1\}.$$

For a homogeneous ellipsoid, $\rho=$mass/volume. Hence, as the volume is $\det(a)^{\frac{1}{2}}$, we get for homogeneous ellipsoids

$$P_{ij}(a)=k.\det(a)^{-1}\int_{\Gamma}\int_{\Gamma'}\frac{(x_i-x_i')(x_j-x_j')}{\|x-x'\|^n}d^nx\,d^nx'.$$

Proposition 37: The following properties are valid for the tensor (P_{ij}):

(1) For any $g\in O(n)$, $P^g_{ij}(a)=(P_{ij}(g^tag))=g^tP_{ij}(a)g$,
(2) $P_{ij}(\mathrm{diag}(a_1^2,\ldots,a_n^2))=0\ (i\neq j)$,
(3) $P_{ij}(\mathrm{diag}(a_1^2,\ldots,a_n^2))=k(a_1^2,\ldots,a_n^2)^{-1}\int_{\Gamma}\int_{\Gamma'}\frac{(x_i-x_i')^2}{\|x-x'\|^3}d^nx\,d^nx'$.

Proof: All this properties are easy to verify. □

Theorem 38: Let $V=[1/(n-2)]\,\mathrm{tr}(P_{ij})$, where P_{ij} is the tensor defined as in Eq. (7). Then $P=(P_{ij})$ comes from a potential V, i.e.,

$$P_{ij}=\{V,S_{ij}\}.$$

Proof: Take $V=[1/(n-2)]\,\mathrm{tr}(P)$. We shall show that

$$M_V=P.$$

In view of Theorem 34 and Proposition 37 we must show that

$$P_{ij}(\mathrm{diag}(a_1^2,\ldots,a_n^2))=-a_i\frac{\partial}{\partial a_i}V(\mathrm{diag}(a_1^2,\ldots,a_n^2)).$$

But this equation follows after a change of variables on the region of integration. □

Remark 39: Even for $n=3$ *this proof is different from that on Ref. 1.*

Theorem 40: Finally,

$$\delta_{ij}\det{}^{1/2}=-\{\det{}^{1/2},S_{ij}\}.$$

Proof: We use Theorem 36. In the notation there $k(x)=x$, so $h(x)=-x$, proving what we want. □

We are thus able to prove that Eqs. (2) have the Hamiltonian form.

Theorem 41: Let

$$H=T+V-p.v,\quad V=\frac{1}{n-2}\mathrm{tr}(P)$$

then the equations of motion

$$\dot I=S_{ij}+S_{ji},\quad \dot S_{ij}=2T_{ij}+P_{ij}+p.v\,\delta_{ij}$$

can be written as

$$\dot{I}_{ij}=\{H,I_{ij}\},\quad \dot{S}_{ij}=\{H,S_{ij}\}.$$

Proof: We have

$$\{H,I_{ij}\}=\{T,I_{ij}\}+\{V-p.v,I_{ij}\}$$

the second term is 0 because it is a function of the I_{ij} only. The first is $S_{ij}+S_{ji}$ by Proposition 27. Further

$$\{H,S_{ij}\}=\{T,S_{ij}\}+\{V,S_{ij}\}-p\{v,S_{ij}\}.$$

The first term is $2T_{ij}$ by Proposition 27. The second term is P_{ij} by Theorem 38. Finally

$$\{p.v,S_{ij}\}=p\{\det^{1/2},S_{ij}\}=-p.\det^{1/2}\delta_{ij}=-\delta_{ij}p.v.$$

Hence

$$\{H,S_{ij}\}=2T_{ij}+P_{ij}+p.v\,\delta_{ij}.$$

□

Rosensteel, in case $n=3$, defines additional potential tensors that depend on the surface energy tensor

$$\mathcal{G}_{ij}=\frac{1}{2}\gamma_S\int_{\partial v}x_i.\boldsymbol{\nabla}.\mathbf{n}n_j\,dS,$$

where ∂E denotes the boundary of the ellipsoid, $\mathbf{n}$ denotes the outward normal vector. γ_S is the surface tension and dS denote the area element. Rosenkilde[9] has showed that $\mathcal{G}_{ij}$ is a symmetric tensor and simplifies to

$$\mathcal{G}_{ij}=\frac{1}{2}\gamma_S\int_{\partial v}(\delta_{ij}-n_in_j)dS.$$

It has been shown[1] that the matrix $(\mathcal{G}_{ij})$ also comes from a potential given by $V^{\Sigma}=\mathrm{tr}(\mathcal{G})$. We do not treat this case here.

Last remark: It is not clear at this moment what is, if there is any, correct physical interpretation for the energy functions and tensors defined here. This topic should be the subject of further studies.

(Received 15 June 2000; accepted for publication 21 November 2000)

We present a systematic study of static solutions of the vacuum Einstein equations with negative cosmological constant which asymptotically approach the generalized Kottler (''Schwarzschild–anti-de Sitter'') solution, within (mainly) a conformal framework. We show connectedness of conformal infinity for appropriately regular such spacetimes. We give an explicit expression for the Hamiltonian mass of the (not necessarily static) metrics within the class considered; in the static case we show that they have a finite and well-defined Hawking mass. We prove inequalities relating the mass and the horizon area of the (static) metrics considered to those of appropriate reference generalized Kottler metrics. Those inequalities yield an inequality which is opposite to the conjectured generalized Penrose inequality. They can thus be used to prove a uniqueness theorem for the generalized Kottler black holes if the generalized Penrose inequality can be established. [DOI: 10.1063/1.1340869]

I. INTRODUCTION

Consider the families of metrics

$$ds^2=-\left(k-\frac{2m}{r}-\frac{\Lambda}{3}r^2\right)dt^2+\left(k-\frac{2m}{r}-\frac{\Lambda}{3}r^2\right)^{-1}dr^2+r^2\,d\Omega_k^2,\quad k=0,\pm 1, \tag{I.1}$$

$$ds^2=-(\lambda-\Lambda r^2)dt^2+(\lambda-\Lambda r^2)^{-1}\,dr^2+|\Lambda|^{-1}\,d\Omega_k^2,\quad k=\pm 1,\quad k\Lambda>0,\quad \lambda\in\mathbb{R}, \tag{I.2}$$

where $d\Omega_k^2$ denotes a metric of constant Gauss curvature k on a two-dimensional manifold ${}^2M$. (Throughout this work we assume that ${}^2M$ is compact.) These are well-known static solutions of the vacuum Einstein equation with a cosmological constant Λ; some subclasses of (I.1) and (I.2) have been discovered by de Sitter[1] [(I.1) with $m=0$ and $k=1$], by Kottler[2] [Eq. (I.1) with an arbitrary m and $k=1$], and by Nariai[3] [Eq. (I.2) with $k=1$]. As discussed in detail in Sec. V D, the parameter $m\in\mathbb{R}$ is related to the Hawking mass of the foliation $t=\text{const}$, $r=\text{const}$. We will refer to those solutions as the generalized Kottler and the generalized Nariai solutions. The constant Λ is an arbitrary real number, but in this paper we will mostly be interested in $\Lambda<0$, and this assumption will be made unless explicitly stated otherwise. There has been recently renewed interest in the black hole aspects of the generalized Kottler solutions.[4–7] The object of this paper is to initiate a systematic study of static solutions of the vacuum Einstein equations with a negative cosmological constant.

The first question that arises here is that of asymptotic conditions one wants to impose. In the present paper we consider metrics which tend to the generalized Kottler solutions, leaving the

asymptotically Nariai case to future work. We present the following three approaches to asymptotic structure, and study their mutual relationships: three-dimensional conformal compactifications, four-dimensional conformal completions, and a coordinate approach. We show that under rather natural hypotheses the conformal boundary at infinity is connected.

The next question we address is that of the definition of mass for such solutions, *without assuming staticity* of the metrics. We review again the possible approaches that occur here: a naive coordinate approach, a Hamiltonian approach, a ''Komar-type'' approach, and the Hawking approach. We show that the Hawking mass converges to a finite value for the metrics considered here, and we also give conditions on the conformal completions under which the ''coordinate mass,'' or the Hamiltonian mass, are finite. Each of those masses come with different normalization factor, whenever all are defined, except for the Komar and Hamiltonian masses which coincide. We suggest that the correct normalization is the Hamiltonian one.

Returning to the static case, we recall that appropriately behaved vacuum black holes with $\Lambda=0$ are completely described by the parameter m appearing above,[8–10] and it is natural to enquire whether this remains true for other values of Λ. In fact, for $\Lambda<0$, Boucher, Gibbons, and Horowitz[11] have given arguments suggesting uniqueness of the anti-de Sitter solution within an appropriate class. As a step towards a proof of a uniqueness theorem in the general case we derive, under appropriate hypotheses (1) lower bounds on (loosely speaking) the area of cross sections of the horizon, and (2) upper bounds on the mass of static vacuum black holes with negative cosmological constant. When these inequalities are combined the result goes precisely the opposite way as a (conjectured) generalization of the Geroch–Huisken–Ilmanen–Penrose inequality[12–17] appropriate to spacetimes with nonvanishing cosmological constant. In fact, such a generalization was obtained by Gibbons[18] along the lines of Geroch,[13] and of Jang and Wald,[19] i.e., under the very stringent assumption of the global existence and smoothness of the inverse mean curvature flow, see Sec. VI. We note that it is far from clear that the arguments of Huisken and Ilmanen,[14,15] or those of Bray,[16,17] which establish the original Penrose conjecture can be adapted to the situation at hand. If this were the case, a combination of this inequality with the results of the present work would give a fairly general uniqueness result. In any case this part of our work demonstrates the usefulness of a generalized Penrose inequality, if it can be established at all.

To formulate our results more precisely, consider a static spacetime $(M,{}^4g)$ which might—but does not have to—contain a black hole region. In the asymptotically flat case there exists a well-established theory (see Ref. 20, or Ref. 10, Secs. 2 and 6 and references therein) which, under appropriate hypotheses, allows one to reduce the study of such spacetimes to the problem of finding all suitable triples (Σ,g,V), where (Σ,g) is a three-dimensional Riemannian manifold and V is a *non-negative* function on Σ. Further V is required to vanish precisely on the boundary of Σ, when nonempty:

$$V\geqslant 0, \quad V(p)=0\Leftrightarrow p\in\partial\Sigma. \tag{I.3}$$

Finally g and V satisfy the following set of equations on Σ:

$$\Delta V=-\Lambda V, \tag{I.4}$$

$$R_{ij}=V^{-1}D_iD_jV+\Lambda g_{ij} \tag{I.5}$$

($\Lambda=0$ in the asymptotically flat case). Here R_{ij} is the Ricci tensor of the (''three-dimensional'') metric g. We shall not attempt to formulate the conditions on $(M,{}^4g)$ which will allow one to perform such a reduction [some of the aspects of the relationship between (Σ,g,V) and the associated spacetime are discussed in Sec. III B], but we shall directly address the question of properties of solutions of (I.4)–(I.5). Our first main result concerns the topology of $\partial\Sigma$ (cf. Theorem IV.1, Sec. IV; compare Refs. 21 and 22):

Theorem I.1: Let $\Lambda<0$, consider a set (Σ,g,V) which is C^3 conformally compactifiable in the sense of Definition III.1 below, suppose that (I.3)–(I.5) hold. Then the conformal boundary at infinity $\partial_\infty\Sigma$ of Σ is connected.

Our second main result concerns the Hawking mass of the level sets of V, cf. Theorem V.2, Sec. V D:

Theorem I.2: Under the conditions of Theorem I.1, the Hawking mass m of the level sets of V is well defined and finite.

It is natural to enquire whether there exist static vacuum spacetimes with complete spacelike hypersurfaces and no black hole regions; it is expected that no such solutions exist when $\Lambda<0$ and $\partial_\infty\Sigma\neq S^2$. We hope that points (2) and (3) of the following theorem can be used as a tool to prove their nonexistence.

Theorem I.3: Under the conditions of Theorem I.1, suppose further that $\partial\Sigma=\varnothing$, and that the scalar curvature R' of the metric $g'=V^{-2}g$ is constant on $\partial_\infty\Sigma$. Then

(1) If $\partial_\infty\Sigma$ is a sphere, then the Hawking mass m of the level sets of V is nonpositive, vanishing if and only if there exists a diffeomorphism $\psi:\Sigma\to\Sigma_0$ and a positive constant λ such that $g=\psi^*g_0$ and $V=\lambda V_0\circ\psi$, with (Σ_0, g_0, V_0) corresponding to the anti-de Sitter space–time.
(2) If $\partial_\infty\Sigma$ is a torus, then the Hawking mass m is strictly negative.
(3) If the genus g_∞ of $\partial_\infty\Sigma$ is higher than or equal to 2, we have

$$m<-\frac{1}{3\sqrt{-\Lambda}}, \tag{I.6}$$

with $m=m(V)$ normalized as in Eq. (VI.7).

A mass inequality similar to that in point (1) above has been established in Ref. 11, and in fact we follow their technique of proof. However, our hypotheses are rather different. Further, the mass here is *a priori* different from the one considered in Ref. 11; in particular it is not clear at all whether the mass defined as in Ref. 11 is also defined for the metrics we consider, cf. Secs. III C and V A below.

We note that metrics satisfying the hypotheses of point (2) above, with arbitrarily large (strictly) negative mass, have been constructed in Ref. 23.

As a straightforward corollary of Theorem I.3 one has

Corollary I.4: Suppose that the generalized positive energy inequality $m\geqslant m_{\mathrm{crit}}(g_\infty)$ holds in the class of three-dimensional manifolds (Σ,g) which satisfy the requirements of point (1) of Definition III.1 with a connnected conformal infinity $\partial_\infty\Sigma$ of genus g_∞, and, moreover, the scalar curvature R of which satisfies $R\geqslant 2\Lambda$. Then

(1) If $m_{\mathrm{crit}}(g_\infty=0)=0$, then the only solution of Eqs. (I.4)–(I.5) satisfying the hypotheses of point (1) of Theorem I.3 are data for anti-de Sitter space–time.
(2) If $m_{\mathrm{crit}}(g_\infty>1)=-1/(3\sqrt{-\Lambda})$, then there exist no solutions of Eqs. (I.4)–(I.5) satisfying the hypotheses of point (3) of Theorem I.3.

When $\partial_\infty\Sigma=S^2$ one expects that the inequality $m\geqslant 0$, with m being the mass defined by spinorial identities can be established using Witten-type techniques (cf. Refs. 24 and 25), regardless of whether or not $\partial\Sigma=\varnothing$. (On the other hand, it follows from Ref. 26 that when $\partial_\infty\Sigma\neq S^2$ there exist no asymptotically covariantly constant spinors which can be used in the Witten argument.) This might require imposing some further restrictions on, e.g., the asymptotic behavior of the metric. To be able to conclude in this case that there are no static solutions without horizons, or that the only solution with a connected nondegenerate horizon is the anti-de Sitter one, requires working out those restrictions, and showing that the Hawking mass of the level sets of V coincides with the mass occuring in the positive energy theorem.

When horizons occur, our comparison results for mass and area read as follows.

Theorem I.5: Under the conditions of Theorem I.1, suppose further that the genus g_∞ of $\partial_\infty\Sigma$ satisfies $g_\infty\geqslant 2$, and that the scalar curvature R' of the metric $g'=V^{-2}g$ is constant on $\partial_\infty\Sigma$. Let $\partial_1\Sigma$ be any connected component of $\partial\Sigma$ for which the surface gravity κ defined by Eq. (VII.1) is largest, and assume that

$$0<\kappa\leqslant\sqrt{-\frac{\Lambda}{3}}. \tag{I.7}$$

Let m_0, respectively A_0, be the Hawking mass, respectively the area of $\partial\Sigma_0$, for that generalized Kottler solution (Σ_0,g_0,V_0), with the same genus g_∞, the surface gravity κ_0 of which equals κ. Then

$$m\leqslant m_0, \quad A_0(g_{\partial_1\Sigma}-1)\leqslant A(g_\infty-1), \tag{I.8}$$

where A is the area of $\partial_1\Sigma$ and $m=m(V)$ is the Hawking mass of the level sets of V. Further $m=m_0$ if and only if there exists a diffeomorphism $\psi:\Sigma\to\Sigma_0$ and a positive constant λ such that $g=\psi^* g_0$ and $V=\lambda V_0\circ\psi$.

The asymptotic conditions assumed in Theorems I.3 and I.5 are somewhat related to those of Refs. 27–29, 11. The precise relationships are discussed in Secs. III B and III C. Let us simply mention here that the condition that R' is constant on $\partial_\infty\Sigma$ is the (local) higher genus analog of the (global) condition in Refs. 28 and 29 that the group of conformal isometries of I coincides with that of the standard conformal completion of the anti-de Sitter space–time; the reader is referred to Proposition III.6 in Sec. III B for a precise statement.

We note that the hypothesis (I.7) is equivalent to the assumption that the generalized Kottler solution with the same value of κ has nonpositive mass; cf. Sec. II for a discussion. We emphasize, however, that we do not make any *a priori* assumptions concerning the sign of the mass of (Σ,g,V). Our methods do not lead to any conclusions for those values of κ which correspond to generalized Kottler solutions with positive mass.

With $m=m(V)$ normalized as in Eq. (VI.7), the inequality $m\leqslant m_0$ takes the following explicit form:

$$m\leqslant\frac{(\Lambda+2\kappa^2)\sqrt{\kappa^2-\Lambda}+2\kappa^3}{3\Lambda^2}, \tag{I.9}$$

while $A(g_\infty-1)\geqslant A_0(g_{\partial_1\Sigma}-1)$ can be explicitly written as

$$A(g_\infty-1)\geqslant 4\pi(g_{\partial_1\Sigma}-1)\left[\frac{\kappa+\sqrt{\kappa^2-\Lambda}}{\Lambda}\right]^2. \tag{I.10}$$

[The right-hand sides of Eqs. (I.9) and (I.10) are obtained by straightforward algebraic manipulations from (II.1) and (II.10).]

It should be pointed out that in Ref. 30 a lower bound for the area has also been established. However, while the bound there is sharp only for the generalized Kottler solutions with $m=0$, our bound is sharp for all Kottler solutions. On the other hand, in Ref. 30 it is not assumed that the space–time is static.

If the generalized Penrose inequality (which we discuss in some detail in Sec. VI) holds,

$$2M_{\mathrm{Haw}}(u)\geqslant\sum_{i=1}^{k}\left((1-g_{\partial_i\Sigma})\left(\frac{A_{\partial_i\Sigma}}{4\pi}\right)^{1/2}-\frac{\Lambda}{3}\left(\frac{A_{\partial_i\Sigma}}{4\pi}\right)^{3/2}\right) \tag{I.11}$$

(with the $\partial_i\Sigma$'s, $i=1,\ldots,k$, being the connected components of $\partial\Sigma$, the $A_{\partial_i\Sigma}$'s—their areas, and the $g_{\partial_i\Sigma}$'s—the genera thereof) we obtain uniqueness of solutions:

Corollary I.6: Suppose that the generalized Penrose inequality (I.11) holds in the class of three-dimensional manifolds (Σ,g) with scalar curvature R satisfying $R\geqslant 2\Lambda$, which satisfy the requirements of point (1) of Definition III.1 with a connnected conformal infinity $\partial_\infty\Sigma$ of genus $g_\infty>1$, and which have a compact connected boundary. Then the only static solutions of Eqs. (I.4)–(I.5) satisfying the hypotheses of Theorem I.5 are the corresponding generalized Kottler solutions.

II. THE GENERALIZED KOTTLER SOLUTIONS

We recall some properties of the solutions (I.1). Those solutions will be used as reference solutions in our arguments, so it is convenient to use a subscript 0 when referring to them. As already mentioned, we assume $\Lambda<0$ unless indicated otherwise. For $m_0\in\mathbb{R}$, let r_0 be the largest positive root of the equation[31]

$$V_0^2\equiv k-\frac{2m_0}{r}-\frac{\Lambda}{3}r^2=0. \tag{II.1}$$

We set

$$\Sigma_0=\{(r,v)|r>r_0,v\in{}^2M\},\quad g_0=\left(k-\frac{2m_0}{r}-\frac{\Lambda}{3}r^2\right)^{-1}dr^2+r^2\,d\Omega_k^2, \tag{II.2}$$

where, as before, $d\Omega_k^2$ denotes a metric of constant Gauss curvature k on a smooth two-dimensional compact manifold ${}^2M$. We denote the corresponding surface gravity by κ_0. [Recall that the surface gravity of a connected component of a horizon $N[X]$ is usually defined by the equation

$$(X^\alpha X_\alpha)_{,\mu}|_{N[X]}=-2\kappa X_\mu, \tag{II.3}$$

where X is the Killing vector field which is tangent to the generators of $N[X]$. This requires normalizing X; here we impose the normalization[32] that $X=\partial/\partial t$ in the coordinate system of (I.1).] We set

$$W_0(r)\equiv g_0^{ij}D_iV_0D_jV_0=\left(\frac{m_0}{r^2}-\frac{\Lambda r}{3}\right)^2. \tag{II.4}$$

When $m_0=0$ we note the relationship

$$W_0=-\frac{\Lambda}{3}(V_0^2-k), \tag{II.5}$$

which will be useful later on, and which holds regardless of the topology of ${}^2M$.

Suppose, now, that $k=-1$, and that m_0 is in the range

$$m_0\in[m_{\rm crit},0], \tag{II.6}$$

where

$$m_{\rm crit}\equiv-\frac{1}{3\sqrt{-\Lambda}}. \tag{II.7}$$

Here $m_{\rm crit}$ is defined as the smallest value of m_0 for which the metrics (I.1) can be extended across a Killing horizon.[5,7] Let us show that Eq. (II.6) is equivalent to

$$r_0\in\left[\frac{1}{\sqrt{-\Lambda}},\sqrt{-\frac{3}{\Lambda}}\right]. \tag{II.8}$$

In order to simplify notation it is useful to introduce

$$\frac{1}{l^2}\equiv-\frac{\Lambda}{3}. \tag{II.9}$$

Now, the equation $V_0(l/\sqrt{3})=0$ implies $m=m_{\rm crit}$. Next, an elementary analysis of the function r^3/l^2-r-2m_0 (recall that $k=-1$ in this section) shows that (1) V has no positive roots for $m<m_{\rm crit}$; (2) for $m=m_{\rm crit}$ the only positive root is $l/\sqrt{3}$; (3) if r_0 is the largest positive root of the equation $V_0(r_0)=0$, then for each $m_0>m_{\rm crit}$ the radius $r_0(m_0)$ exists and is a differentiable function of m_0. Differentiating the equation $r_0V_0(r_0)=0$ with respect to m_0 gives

$$\left(\frac{3r_0^2}{l^2}+k\right)\frac{\partial r_0}{\partial m_0}=\left(\frac{3r_0^2}{l^2}-1\right)\frac{\partial r_0}{\partial m_0}=2.$$

It follows that for $r\geqslant l/\sqrt{3}$ the function $r_0(m_0)$ is a monotonically increasing function on its domain of definition $[m_{\rm crit},\infty)$, which establishes our claim.

We note that the surface gravity κ_0 is given by the formula

$$\kappa_0=\sqrt{W_0(r_0)}=\frac{m_0}{r_0^2}+\frac{r_0}{l^2}, \tag{II.10}$$

which gives

$$\frac{\partial\kappa_0}{\partial m_0}=\frac{1}{r_0^2}+\left(\frac{1}{l^2}-\frac{2m_0}{r_0^3}\right)\frac{\partial r_0}{\partial m_0}.$$

Equation (II.10) shows that κ_0 vanishes when $m_0=m_{\rm crit}$.[33] Under the hypothesis that $m_0\leqslant 0$, it follows from what has been said above (a) that $\partial\kappa_0/\partial m_0$ is positive; (b) that we have

$$\kappa_0\in\left[0,\sqrt{-\frac{\Lambda}{3}}\right], \tag{II.11}$$

when (II.6) holds, and (c) that, under the current hypotheses on k and Λ, (II.6) is equivalent to (II.11) for the metrics (I.1). While this can probably be established directly, we note that it follows from Theorem I.5 that (II.11) is equivalent to (II.6) without having to assume that $m_0\leqslant 0$.

In what follows we shall need the fact that in the above ranges of parameters the relationship $V_0(r)$ can be inverted to define a smooth function $r(V_0):[0,\infty)\to\mathbb{R}$. Indeed, the equation $(dV_0/dr)(r_{\rm crit})=0$ yields $r_{\rm crit}^3=3m_0/\Lambda$; when $k=-1$, $\Lambda<0$, and when (II.6) holds one finds $V_0(r_{\rm crit})\leqslant 0$, with the inequality being strict unless $m=m_{\rm crit}$. Therefore, $V_0(r)$ is a smooth strictly monotonic function in $[r_0,\infty)$, which implies in turn that $r(V_0)$ is a smooth strictly monotonic function on $(0,\infty)$; further $r(V_0)$ is smooth up to 0 except when $m=m_{\rm crit}$.

III. ASYMPTOTICS

A. Three-dimensional formalism

As a motivation for the definition below, consider one of the metrics (I.1) and introduce a new coordinate $x\in(0,x_0]$ by

$$\frac{r^2}{l^2}=\frac{1-kx^2}{x^2} \tag{III.1}$$

with x_0 defined by substituting r_0 at the left-hand side of (III.1). It then follows that

$$g=l^2x^{-2}\left[(1-kx^2)^{-1}\left(1-\frac{2mx^3}{l\sqrt{1-kx^2}}\right)^{-1}dx^2+(1-kx^2)d\Omega_k^2\right].$$

Thus the metric

$$g' \equiv (l^{-2}x^2)g$$

is smooth up to boundary metric on the compact manifold with boundary $\overline{\Sigma}_0 \equiv [0,x_0]\times {}^2M$. Furthermore, xV_0 can be extended by continuity to a smooth up to boundary function on $\overline{\Sigma}_0$, with $xV_0=1$. This justifies the following definition.

Definition III.1: Let Σ be a smooth manifold (all manifolds are assumed to be Hausdorff, paracompact, and orientable throughout), with perhaps a compact boundary which we denote by $\partial\Sigma$ when non empty.[34] Suppose that g is a smooth metric on Σ, and that V is a smooth nonnegative function on Σ, with $V(p)=0$ if and only if $p\in\partial\Sigma$.

(1) (Σ,g) will be said to be C^i, $i\in\mathbb{N}\cup\{\infty\}$, conformally compactifiable or, shortly, compactifiable, if there exists a C^{i+1} diffeomorphism χ from $\Sigma\backslash\partial\Sigma$ to the interior of a compact Riemannian manifold with boundary $(\overline{\Sigma}\approx\Sigma\cup\partial_\infty\Sigma,\overline{g})$, with $\partial_\infty\Sigma\cap\Sigma=\varnothing$, and a C^i function $\omega:\overline{\Sigma}\to\mathbb{R}^+$ such that

$$g=\chi^*(\omega^{-2}\overline{g}). \tag{III.2}$$

We further assume that $\{\omega=0\}=\partial_\infty\Sigma$, with $d\omega$ nowhere vanishing on $\partial_\infty\Sigma$, and that $\overline{g}$ is of C^i differentiability class on $\overline{\Sigma}$.

(2) A triple (Σ,g,V) will be said to be C^i, $i\in\mathbb{N}\cup\{\infty\}$, compactifiable if (Σ,g) is C^i compactifiable, and if $V\omega$ extends by continuity to a C^i function on $\overline{\Sigma}$,

(3) with

$$\lim_{\omega\to 0} V\omega > 0. \tag{III.3}$$

We emphasize that Σ itself is allowed to have a boundary on which V vanishes,

$$\partial\Sigma=\{p\in\Sigma\,|\,V(p)=0\}$$

If that is the case we will have

$$\partial\overline{\Sigma}=\partial\Sigma\cup\partial_\infty\Sigma.$$

The conditions above are not independent when the ''static field equations'' [Eqs. (I.4)–(I.5)] hold:

Proposition III.2: Consider a triple (Σ,g,V) satisfying Eqs. (I.3)–(I.5).

(1) The condition that $|d\omega|_{\overline{g}}$ has no zeros on $\partial_\infty\Sigma$ follows from the remaining hypotheses of point 1 of Definition III.1, when those hold with $i\geqslant 2$.

(2) Suppose that (Σ,g) is C^i compactifiable with $i\geqslant 2$. Then $\lim_{\omega\to 0}V\omega$ exists. Further, one can choose a (uniquely defined) conformal factor so that ω is the $\overline{g}$ distance from $\partial_\infty\Sigma$. With this choice of conformal factor, when (III.3) holds a necessary condition that (Σ,g,V) is C^i compactifiable is that

$$(4\overline{R}_{ij}-\overline{R}\overline{g}_{ij})\overline{n}^i\overline{n}^j|_{\partial_\infty\Sigma}=0, \tag{III.4}$$

where $\overline{n}$ is the field of unit normals to $\partial_\infty\Sigma$.

(3) (Σ,g,V) is C^∞ compactifiable if and only if (Σ,g) is C^∞ compactifiable and Eqs. (III.3) and (III.4) hold.

Remarks: (1) When (Σ,g) is C^∞ compactifiable but Eq. (III.4) does not hold, the proof below shows that $V\omega$ is of the form $\alpha_0+\alpha_1\omega^2\log\omega$, for some smooth up-to-boundary functions α_0 and α_1. This is perhaps not so surprising because the nature of the equations satisfied by g and V

suggests that both $\overline{g}$ and $V\omega$ should be polyhomogeneous, rather than smooth. (''Polyhomogeneous'' means that $\overline{g}$ and $V\omega$ are expected to admit asymptotic expansions in terms of powers of ω and $\log\omega$ near $\partial_\infty\Sigma$ under some fairly weak conditions on their behavior at $\partial_\infty\Sigma$; cf., e.g., Ref. 36 for precise definitions and related results.) From this point of view the hypothesis that (Σ,g) is C^∞ compactifiable is somewhat unnatural and should be replaced by that of polyhomogeneity of $\overline{g}$ at $\partial_\infty\Sigma$.

(2) One can prove appropriate versions of point (3) above for (Σ,g)'s which are C^i compactifiable for finite i. This seems to lead to lower differentiability of $1/V$ near $\partial_\infty\Sigma$ as compared to $\overline{g}$, and for this reason we shall not discuss it here.

(3) We leave it as an open problem whether or not there exist solutions of (I.3)–(I.5) such that (Σ,g) is smoothly compactifiable, such that V can be extended by continuity to a smooth function on $\overline{\Sigma}$, while (III.3) does not hold.

(4) We note that (III.4) is a conformally invariant condition because ω and $\overline{g}$ are uniquely determined by g. However, it is not conformally covariant, in the sense that if $\overline{g}$ is conformally rescaled, then (III.4) will not be of the same form in the new rescaled metric. It would be of interest to find a form of (III.4) which does not have this drawback.

(5) The result above has counterparts for one-point compactifications in the asymptotically flat case (cf., e.g., the theorem in the Appendix of Ref. 35.)

Proof: Let $\alpha\equiv V\omega$. After suitable identifications we can without loss of generality assume that the map χ in (III.2) is the identity. Equations (I.4)–(I.5) together with the definition of $\overline{g}=\omega^2 g$ lead to the following:

$$\overline{\Delta}\alpha-3\frac{\overline{D}^i\omega\overline{D}_i\alpha}{\omega}+\left(\frac{\overline{\Delta}\omega}{\omega}+\frac{\overline{R}}{2}\right)\alpha=0, \tag{III.5}$$

$$\overline{D}_i\overline{D}_j\alpha-\frac{\overline{D}^k\omega\overline{D}_k\alpha}{\omega}\overline{g}_{ij}=\left(\overline{R}_{ij}+2\frac{\overline{D}_i\overline{D}_j\omega}{\omega}-\left(\frac{\overline{\Delta}\omega}{\omega}+\frac{\overline{R}}{2}\right)\overline{g}_{ij}\right)\alpha. \tag{III.6}$$

We have also used $R=2\Lambda$ which, together with the transformation law of the curvature scalar under conformal transformations, implies

$$\omega^2\overline{R}=6|d\omega|^2_{\overline{g}}+2\Lambda-4\omega\overline{\Delta}\omega. \tag{III.7}$$

In all the equations here barred quantities refer to the metric $\overline{g}$. Point (1) of the proposition follows immediately from Eq. (III.7).

To avoid factors of $-\Lambda/3$ in the remainder of the proof we rescale the metric g so that $\Lambda=-3$. Next, to avoid annoying technicalities we shall present the proof only for smoothly compactifiable (Σ,g), i.e., for $i=\infty$; the finite i cases can be handled using the results in Ref. 36, Appendix A and Ref. 37, Appendix A. Suppose, thus, that $i=\infty$. As shown in Ref. 38, Lemma 2.1 we can choose ω and $\overline{g}$ so that ω coincides with the $\overline{g}$ distance from $\partial_\infty\Sigma$ in a neighborhood of $\partial_\infty\Sigma$; we shall use the symbol x to denote this function. In this case we have

$$\overline{\Delta}\omega=\overline{p}, \tag{III.8}$$

where $\overline{p}$ is the mean curvature of the level sets of $\omega=x$. Further $|d\omega|^2_{\overline{g}}=1$ so that (III.8) together with (III.7) give $\overline{R}=-4\overline{p}/x$, in particular $\overline{p}|_{x=0}=0$. We can introduce Gauss coordinates (x^1,x^A) near $\partial_\infty\Sigma$ in which $x^1=x\in[0,x_0)$, while the $(x^A)=v$'s form local coordinates on $\partial_\infty\Sigma$, with the metric taking the form

$$\overline{g}=dx^2+\overline{h},\quad \overline{h}(\partial_x,\cdot)=0. \tag{III.9}$$

To prove point (2), from Eq. (III.6) we obtain

$$\omega\overline{D}^i\omega\overline{D}^j\omega\overline{D}_i(\omega^{-1}\overline{D}_j\alpha)=\overline{D}^i\omega\overline{D}^j\omega\left(\overline{R}_{ij}+2\frac{\overline{D}_i\overline{D}_j\omega}{\omega}-\left(\frac{\overline{\Delta}\omega}{\omega}+\frac{\overline{R}}{2}\right)\overline{g}_{ij}\right)\alpha. \tag{III.10}$$

Equations (III.8)–(III.10) lead to

$$x\partial_x(x^{-1}\partial_x\alpha)=\left(\overline{R}_{xx}-\frac{\overline{R}}{4}\right)\alpha. \tag{III.11}$$

At each $v\in\partial_\infty\Sigma$ this is an ODE of Fuchsian type for $\alpha(x,v)$. Standard results about such equations show that for each v the functions $x\to\alpha(x,v)$ and $x\to\partial_x\alpha(x,v)$ are bounded and continuous on $[0,x_0)$. Integrating (III.11) one finds

$$\partial_x\alpha=x\beta(v)+\left(\overline{R}_{xx}-\frac{\overline{R}}{4}\right)\alpha(0,v)x\ln x+O(x^2\ln x), \tag{III.12}$$

where $\beta(v)$ is a (v-dependent) integration constant. By hypothesis there exist no points at $\partial_\infty\Sigma$ such that $\alpha(0,v)=0$, Eqs. (III.11) and (III.12) show that $\partial_x^2\alpha$ blows up at $x=0$ unless (III.4) holds, and point (2) follows.

We shall only sketch the proof of point (3): Standard results about Fuchsian equations show that solutions of Eq. (III.11) will be smooth in x whenever $[\overline{R}_{xx}-(\overline{R}/4)](x=0,v)$ vanishes throughout $\partial_\infty\Sigma$. A simple bootstrap argument applied to Eq. (III.6) with $(ij)=(1A)$ shows that α is also smooth in v. Commuting Eq. (III.6) with $(x\partial_x)^i\partial_v^\beta$, where β is an arbitrary multi-index, and iteratively repeating the reasoning outlined above establishes smoothness of α jointly in v and x. □

A consequence of condition (3) of Definition III.1 is that the function

$$V'\equiv V^{-1},$$

when extended to $\overline{\Sigma}$ by setting $V'=0$ on $\partial_\infty\Sigma$, can be used as a compactifying conformal factor, at least away from $\partial\Sigma$: If we set

$$g'=V^{-2}g,$$

then g' is a Riemannian metric smooth up to boundary on $\overline{\Sigma}\setminus\partial\Sigma$. In terms of this metric Eqs. (I.4)–(I.5) can be rewritten as

$$\Delta' V'=3V'W+\Lambda V, \tag{III.13}$$

$$R'_{ij}=-2VD'_iD'_jV'. \tag{III.14}$$

Here R'_{ij} is the Ricci tensor of the metric g', D' is the Levi-Civita covariant derivative associated with g', while Δ' is the Laplace operator associated with g'. Taking the trace of (III.14) and using (III.13) we obtain

$$R'=-6W-2\Lambda V^2, \tag{III.15}$$

where

$$W\equiv D_iVD^iV. \tag{III.16}$$

Defining

$$W'\equiv g'^{ij}D'_iV'D'_jV'=(V')^2W, \tag{III.17}$$

Eq. (III.15) can be rewritten as

$$6W' = -2\Lambda - R'(V')^2. \tag{III.18}$$

If (Σ, g, V) is C^2 compactifiable then R' is bounded in a neighborhood of $\partial_\infty\Sigma$, and since V blows up at $\partial_\infty\Sigma$ it follows from Eq. (III.15) that so does W, in particular W is strictly positive in a neighborhood of $\partial_\infty\Sigma$. Further Eq. (III.18) implies that the level sets of V are smooth manifolds in a neighborhood of $\partial_\infty\Sigma$, diffeomorphic to $\partial_\infty\Sigma$ there.

Equations (I.4)–(I.5) are invariant under a rescaling $V \to \lambda V$, $\lambda \in \mathbb{R}^*$. This is related to the possibility of choosing freely the normalization of the Killing vector field in the associated space–time. Similarly the conditions of Definition III.1 are invariant under such rescalings with $\lambda > 0$. For various purposes—e.g., for the definition (VII.1) of surface gravity—it is convenient to have a unique normalization of V. We note that if (Σ, g, V) corresponds to a generalized Kottler solution (Σ_0, g_0, V_0), then (I.1) and (II.4) together with (III.16) give $6W'_0 = -2\Lambda(1-k(V'_0)^2) + O((V'_0)^3)$ so that from (III.15) one obtains

$$R'_0|_{\partial_\infty\Sigma} = -2\Lambda k. \tag{III.19}$$

We have the following:

Proposition III.3: Consider a C^i-compactifiable triple (Σ, g, V), $i \geqslant 3$, satisfying equations (I.4)–(I.5).

(1) We have
$$^2\mathcal{R}'|_{x=0} = \tfrac{1}{3}R'|_{x=0}, \tag{III.20}$$
where $^2\mathcal{R}'$ is the scalar curvature of the metric induced by $g' \equiv V^{-2}g$ on the level sets of V, and R' is the Ricci scalar of g'.

(2) If R' is constant on $\partial_\infty\Sigma$, replacing V by a positive multiple thereof if necessary we can achieve
$$R'|_{\partial_\infty\Sigma} = -2\Lambda k, \tag{III.21}$$
where $k = 0$, 1 or -1 according to the sign of the Gauss curvature of the metric induced by g' on $\partial_\infty\Sigma$.

Remark: When $k = 0$ Eq. (III.21) holds with an arbitrary normalization of V.

Proof: Consider a level set $\{V = \text{const}\}$ of V which is a smooth hypersurface in $\overline{\Sigma}$, with unit normal n_i, induced metric h_{ij}, scalar curvature $^2\mathcal{R}$, second fundamental form p_{ij} defined with respect to an inner pointing normal, mean curvature $p = h^{ij}p_{ij} = h^k_i h^m_j D_{(k}n_{m)}$; we denote by q_{ij} the trace-free part of p_{ij}: $q_{ij} = p_{ij} - 1/2 h_{ij}p$. Let R_{ijk}, respectively, R'_{ijk}, be the Cotton tensor of the metric g_{ij}, respectively, g'_{ij}; by definition

$$R_{ijk} = 2(R_{i[j} - \tfrac{1}{4}Rg_{i[j})_{;k]}, \tag{III.22}$$

where square brackets denote antisymmetrization with an appropriate combinatorial factor (1/2 in the equation above), and a semicolon denotes covariant differentiation. We note the useful identity due to Lindblom[39]

$$R'_{ijk}R'^{ijk} = V^6 R_{ijk}R^{ijk} = 8(VW)^2 q_{ij}q^{ij} + V^2 h^{ij}D_i W D_j W. \tag{III.23}$$

When (Σ, g, V) is C^3 compactifiable the function $R'_{ijk}R'^{ijk}$ is uniformly bounded on a neighborhood of $\overline{\Sigma}$, which gives

$$(VW)^2 q_{ij}q^{ij} \leqslant C \tag{III.24}$$

in that same neighborhood, for some constant C. Equations (III.24) and (III.17) give

$$|q|_g = O((V')^3). \tag{III.25}$$

Let q'_{ij} be the trace-free part of the second fundamental form p'_{ij} of the level sets of V' with respect to the metric g'_{ij}, defined with respect to an inner pointing normal; we have $q'_{ij} = q_{ij}/V$, so that

$$|q'|_{g'} = O((V')^2). \tag{III.26}$$

Throughout we use $|\cdot|_k$ to denote the norm of a tensor field with respect to a metric k.

Let us work out some implications of (III.26); Eqs. (III.13)–(III.15) lead to

$$\left(\Delta' + \frac{R'}{2}\right) V' = 0. \tag{III.27}$$

Equations (III.17) and (III.18) show that dV' is nowhere vanishing on a suitable neighborhood of $\partial_\infty \Sigma$. We can thus introduce coordinates there so that $V' = x$. If the remaining coordinates are Lie dragged along the integral curves of ∂_x the metric takes the form

$$g' = (W')^{-1}\, dx^2 + h', \quad h'(\partial_x, \cdot) = 0. \tag{III.28}$$

Equations (III.27)–(III.28) give then

$$p' = -\frac{1}{2\sqrt{W'}}\left(\frac{\partial W'}{\partial x} + R'x\right) = \frac{x}{12\sqrt{W'}}\left(4R' - x\frac{\partial R'}{\partial x}\right), \tag{III.29}$$

and in the second step we have used (III.18). Here $p' = \sqrt{W'}\partial_x(\sqrt{\det h'})/\sqrt{\det h'}$ is the mean curvature of the level sets of x measured with respect to the inner pointing normal $n' = \sqrt{W'}\partial_x$. Equation (III.14) implies

$$R'_{ij} n'^i n'^j = -2Vn'^i n'^j D'_i D'_j V' = -2\frac{D'^i V' D'^j V'}{V'W'} D'_i D'_j V' = -\frac{D'^i V' D'_i W'}{V'W'} = \frac{-\partial_x W'}{x}$$

in the coordinate system of Eq. (III.28). From (III.18) we get

$$R'_{ij} n'^i n'^j = \frac{R'}{3} + O(x). \tag{III.30}$$

From the Codazzi–Mainardi equation,

$$(-2R'_{ij} + R' g'_{ij}) n'^i n'^j = {}^2\mathcal{R}' + q'_{ij} q'^{ij} - \tfrac{1}{2} p'^2, \tag{III.31}$$

where ${}^2\mathcal{R}'$ is the scalar curvature of the metric induced by g' on $\partial_\infty \Sigma$, one obtains

$$(-2R'_{ij} + R' g'_{ij}) n'^i n'^j = {}^2\mathcal{R}' + O(x), \tag{III.32}$$

where we have used (III.26) and (III.29). This, together with Eq. (III.30), establishes Eq. (III.20). In particular $R'|_{\partial_\infty \Sigma}$ is constant if and only if ${}^2\mathcal{R}'$ is, and R' at $x = 0$ has the same sign as the Gauss curvature of the relevant connected component of $\partial_\infty \Sigma$. Under a rescaling $V \to \lambda V$, $\lambda > 0$, we have $W \to \lambda^2 V$; Eq. (III.15) shows that $R' \to \lambda^2 R'$, and choosing λ appropriately establishes the result. □

We do not know whether or not there exist smoothly compactifiable solutions of Eqs. (I.4)–(I.5) for which R' is not locally constant at $\partial_\infty \Sigma$, it would be of interest to settle this question.

B. Four-dimensional conformal approach

Consider a space–time $(M,{}^4g)$ of the form $M=\mathbb{R}\times\Sigma$ with the metric ${}^4g$

$$ {}^4g=-V^2\,dt^2+g,\quad g(\partial_t,\cdot)=0,\quad \partial_t V=\partial_t g=0. \tag{III.33}$$

By definition of a space–time ${}^4g$ has Lorentzian signature, which implies that g has signature $+3$; it then naturally defines a Riemannian metric on Σ which will still be denoted by g. Equations (I.4)–(I.5) are precisely the vacuum Einstein equations with cosmological constant Λ for the metric ${}^4g$. It has been suggested that an appropriate[28,29] framework for asymptotically anti-de Sitter space–times is that of conformal completions introduced by Penrose.[40] The work of Friedrich[41] has confirmed that it is quite reasonable to do that, by showing that a large class of space–times (not necessarily stationary) with the required properties exist; some further related results can be found in Refs. 42 and 43. In this approach one requires that there exists a space–time with boundary $(\overline{M},{}^4\overline{g})$ and a positive function $\Omega:\overline{M}\to\mathbb{R}^+$, with Ω vanishing precisely at $\mathrm{I}\subset\partial\overline{M}$, and with $d\Omega$ without zeros on I, together with a diffeomorphism $\Xi:M\to\overline{M}\backslash I$ such that

$$ {}^4g=\Xi^*(\Omega^{-2}\,{}^4\overline{g}). \tag{III.34}$$

The vector field $X=\partial_t$ is a Killing vector field for the metric (III.33) on M, and it is well known (cf., e.g., Ref. 44, Appendix B) that X extends as smoothly as the metric allows to I; we shall use the same symbol to denote that extension. We have the following trivial observation.

Proposition III.4: Assume that (Σ,g,V) is smoothly compactifiable, then $M=\mathbb{R}\times\Sigma$ with the metric (III.33) has a smooth conformal completion with I diffeomorphic to $\mathbb{R}\times\partial_\infty\Sigma$. Further $(M,{}^4g)$ satisfies the vacuum equations with a cosmological constant Λ if and only if Eqs. (I.4)–(I.5) hold.

The implication the other way around requires some more work.

Theorem III.5: Consider a space–time $(M,{}^4g)$ of the form $M=\mathbb{R}\times\Sigma$, with a metric ${}^4g$ of the form (III.33), and suppose that there exists a smooth conformal completion $(\overline{M},{}^4\overline{g})$ with nonempty I. Then

(1) X is timelike on I; in particular it has no zeros there;
(2) The hypersurfaces $t=\text{const}$ extend smoothly to I;
(3) (Σ,g,V) is smoothly compactifiable;
(4) there exists a (perhaps different) conformal completion of $(M,{}^4g)$, still denoted by $(\overline{M},{}^4\overline{g})$, such that $\overline{M}=\mathbb{R}\times\overline{\Sigma}$, where $(\overline{\Sigma},\overline{g})$ is a conformal completion of (Σ,g), with $X=\partial_t$ and with

$$ {}^4\overline{g}=-\alpha^2\,dt^2+\overline{g},\quad \overline{g}(\partial_t,\cdot)=0,\quad X(\alpha)=\mathcal{L}_X\overline{g}=0. \tag{III.35}$$

Remark: The new completion described in point (4) above will coincide with the original one if and only if the orbits of X are complete in the original completion.

Proof: As the isometry group maps M to M, it follows that X has to be tangent to I. On M we have ${}^4\overline{g}(X,X)>0$ hence ${}^4\overline{g}(X,X)\geqslant 0$ on I, and to establish point (1) we have to exclude the possibility that ${}^4\overline{g}(X,X)$ vanishes somewhere on I.

Suppose, first, that $X(p)=0$ for a point $p\in I$. Clearly X is a conformal Killing vector of ${}^4\overline{g}$. We can choose a neighborhood U of I so that X is strictly timelike on $U\backslash I$. There exists $\epsilon>0$ and a neighborhood $O\subset U$ of p such that the flow $\phi_t(q)$ of X is defined for all $q\in O$ and $t\in[-\epsilon,\epsilon]$. The ϕ_t's are local conformal isometries, and therefore map timelike vectors to timelike vectors. Since X vanishes at p the ϕ_t's leave p invariant. It follows that the ϕ_t's map causal curves through p into causal curves through p; therefore they map $\partial J^+(p)$ into itself. This implies that X is tangent to $\partial J^+(p)$. However this last set is a null hypersurface, so that every vector tangent to it is spacelike or null, which contradicts timelikeness of X on $\partial J^+(p)\cap U\neq\varnothing$. It follows that X has no zeros on I.

Suppose, next, that $X(p)$ is lightlike at p. There exists a neighborhood of p and a strictly positive smooth function ψ such that X is a Killing vector field for the metric ${}^4\overline{g}\psi^2$. Now the staticity condition

$$X_{[\alpha}\nabla_{\beta}X_{\gamma]}=0 \tag{III.36}$$

is conformally invariant, and therefore also holds in the ${}^4\overline{g}$ metric. We can thus use the Carter–Vishweshvara lemma[45,46] to conclude that the set $N=\{q\in\overline{M}|X(q)\neq 0\}\cap\partial\{{}^4\overline{g}(X,X)<0\}\neq\varnothing$ is a null hypersurface. By hypothesis there exists a neighborhood U of I in $\overline{M}$ such that $N\cap M\cap U=\varnothing$, hence $N\subset I$. This contradicts the fact[40] that the conformal boundary of a vacuum space–time with a strictly negative cosmological constant Λ is timelike. It follows that X cannot be lightlike on I either, and point (1) is established.

To establish point (2), we note that Eq. (III.36) together with point (1) show that the one-form

$$\lambda\equiv\frac{1}{{}^4\overline{g}_{\alpha\beta}X^{\alpha}X^{\beta}}\,{}^4\overline{g}_{\mu\nu}X^{\mu}\,dx^{\nu}$$

is a smooth closed one-form on a neighborhood O of I, hence on any simply connected open subset of O there exists a smooth function $\overline{t}$ such that $\lambda=d\overline{t}$. Now (III.33) shows that the restriction of λ to M is dt, which establishes our claim. From now on we shall drop the bar on $\overline{t}$, and write t for the corresponding time function on $\overline{M}$.

Let

$$\overline{\Sigma}=\overline{M}\cap\{t=0\},\quad \chi=\Xi|_{t=0},\quad \omega=\Omega|_{t=0},$$

where Ξ and Ω are as in (III.34); from Eq. (III.34) one obtains

$$g=\chi^*(\omega^{-2}\overline{g}),$$

which shows that $(\overline{\Sigma},\overline{g})$ is a conformal completion of (Σ,g). We further have $V^2\omega^2={}^4g(X,X)|_{t=0}\omega^2={}^4\overline{g}(X,X)|_{t=0}$, which has already been shown to be smoothly extendible to I^+ and strictly positive there, which establishes point (3).

There exists a neighborhood V of $\overline{\Sigma}$ in $\overline{M}$ on which a new conformal factor Ω can be defined by requiring $\Omega|_{t=0}=\omega$, $X(\Omega)=0$. Redefining ${}^4\overline{g}$ appropriately and making suitable identifications so that Ξ is the identity, Eq. (III.34) can then be rewritten on V as

$${}^4\overline{g}=-(V\Omega)^2\,dt^2+\Omega^2 g. \tag{III.37}$$

All the functions appearing in Eq. (III.37) are time independent. The new manifold $\overline{M}$ defined as $\overline{\Sigma}\times\mathbb{R}$ with the metric (III.37) satisfies all the requirements of point (4), and the proof is complete. □

In addition to the conditions described above, in Refs. 28 and 29 it was proposed to further restrict the geometries under consideration by requiring the group of conformal isometries of I to be the same as that of the anti-de Sitter space–time, namely the universal covering group of $O(2,3)$; cf. also Ref. 43 for further discussion. While there are various ways of adapting this proposal to our setup, we simply note that the requirement on the group of conformal isometries to be $O(2,3)$ or a covering thereof implies that the metric induced on I is locally conformally flat. Let us then see what are the consequences of the requirement of local conformal flatness of ${}^Ig$ in our context; this last property is equivalent to the vanishing of the Cotton tensor of the metric ${}^Ig$ induced by ${}^4\overline{g}$ on I. As has been discussed in detail in Sec. III A, we can choose the conformal factor Ω to coincide with V^{-1}, in which case Eq. (III.37) reads

$${}^4g'\equiv{}^4g/V^2=-dt^2+V^{-2}g=-dt^2+g', \tag{III.38}$$

with $g' \equiv V^{-2} g$ already introduced in Sec. III A. It follows that

$$ {}^I g \equiv {}^4 g'|_I = -dt^2 + h', \tag{III.39}$$

where h' is the metric induced on $\partial_\infty \Sigma \equiv I \cap \overline{\Sigma}$ by g'. Let ${}^I R_{ij}$ denote the Ricci tensor of ${}^I g$; from (III.39) we obtain

$$ {}^I R_{it} = 0, \quad {}^I R_{AB} = {}^2 \mathcal{R}_{AB}, \tag{III.40}$$

where ${}^2 \mathcal{R}_{AB}$ is the Ricci tensor of h'. In particular the xxA component of the Cotton tensor ${}^I R_{ijk}$ of ${}^I g$ satisfies

$$ {}^I R_{xxA} = -\frac{{}^2 \mathcal{R}_{,A}}{4}. $$

Point (1) of Proposition III.3, see Eq. (III.20), shows that the requirement of conformal flatness of ${}^I g$ implies that R' is constant on $\partial_\infty \Sigma$. Conversely, it is easily seen from (III.40) that a locally constant R'—or equivalently ${}^2 \mathcal{R}$—on $\partial_\infty \Sigma$ implies the local conformal flatness of ${}^I g$. We have therefore proved:

Proposition III.6: Let (Σ, g, V) be C^i conformally compactifiable, $i \geqslant 3$, and satisfy (I.3)–(I.5). The conformal boundary $\mathbb{R} \times \partial_\infty \Sigma$ of the space–time $(M = \mathbb{R} \times \Sigma, {}^4 g)$, ${}^4 g$ given by (III.33), is locally conformally flat if and only if the scalar curvature R' of the metric $V^{-2} g$ is locally constant on $\partial_\infty \Sigma$. This is equivalent to requiring that the metric induced by $V^{-2} g$ on $\partial_\infty \Sigma$ has locally constant Gauss curvature.

C. A coordinate approach

An alternative approach to the conformal one discussed above is by introducing preferred coordinate systems. As discussed in Ref. 27, Appendix D, coordinate approaches are often equivalent to conformal approaches when sufficiently strong hypotheses are made. We stress that this equivalence is a delicate issue when finite degrees of differentiability are assumed, as arguments leading from one approach to the other often involve constructions in which some differentiability is lost.

In any case, the coordinate approach has been used by Boucher, Gibbons, and Horowitz[11] in their argument for uniqueness of the anti-de Sitter metric within a certain class of static space–times. More precisely, in Ref. 11 one considers metrics which are asymptotic to generalized Kottler metrics with $k=1$ in the following strong sense: if g_0 denotes one of the metrics (I.1) with $k=1$, then one assumes that there exists a coordinate system (t, r, x^A) such that

$$\begin{aligned} g = g_0 &+ O(r^{-2}) dt^2 + O(r^{-6}) dr^2 + O(r) \,(\text{remaining differentials not involving } dr) \\ &+ O(r^{-1}) \,(\text{remaining differentials involving } dr). \end{aligned} \tag{III.41}$$

We note that in the uniqueness assertions of Ref. 11 one makes appeal to the positive energy theorem to conclude. Now we are not aware of a version of such a theorem which would hold without some further hypotheses on the behavior of the metric. For example, in such a theorem one is likely to require that the derivatives of the metric also fall off at some sufficiently high rates. In any case the argument presented in Ref. 11 seems to implicitly assume that the asymptotic behavior of g^{tt} described above is preserved under differentiation, so that the corrections terms in (III.41) give a vanishing contribution when calculating $|dV|_g^2 - |dV_0|_{g_0}^2$ and passing to the limit $r \to \infty$, with g_0—the anti-de Sitter metric. While it might well be possible that Eqs. (I.4)–(I.5) force the metrics satisfying (III.41) to have sufficiently good asymptotic properties to be able to justify this, or to apply a positive energy theorem,[47] this remains to be established.[48]

It is far from being clear whether or not a general metric of the form (III.41) has any well-behaved conformal completions. For example, the coordinate transformation (III.1) together

with a multiplication by the square of the conformal factor $\omega = x$ brings the metric (III.41) to one which can be continuously extended to the boundary, but if only (III.41) is assumed then the resulting metric will not be differentiable up to boundary on the compactified manifold in general. There could, however, exist coordinate systems which lead to better conformal behavior when Eqs. (I.4)–(I.5) are imposed.

In any case, it is natural to ask whether or not a metric satisfying the requirements of Sec. III A will have a coordinate representation similar to (III.41). A partial answer to this question is given by the following result; see Ref. 27 for a related discussion. While the conclusions in Ref. 27 appear to be weaker than ours, it should be stressed that in Ref. 27 staticity of the space–times under consideration is not assumed.

Proposition III.7: Let (Σ, g, V) be a C^i compactifiable solution of Eqs. (I.4)–(I.5), $i \geqslant 3$. Define a C^{i-2} function $\widetilde{k} = \widetilde{k}(x^A)$ on $\partial_\infty \Sigma$ by the formula

$$R'|_{\partial_\infty \Sigma} = -2\Lambda \widetilde{k}. \tag{III.42}$$

(1) Rescaling V by a positive constant if necessary, there exists a coordinate system (r, x^A) near $\partial_\infty \Sigma$ in which we have

$$V^2 = \frac{r^2}{l^2} + \widetilde{k}, \tag{III.43}$$

$$g = \left(\frac{r^2}{l^2} + \widetilde{k} - \frac{2\mu}{r} \right)^{-1} dr^2 + O(r^{-3}) dr\, dx^A + r^2 \check{h}_{AB} + O(r^{-1})) dx^A\, dx^B \tag{III.44}$$

(recall that $l^2 = -3\Lambda^{-1}$), for some r-independent smooth two-dimensional metric $\check{h}_{AB}$ with Gauss curvature equal to $\widetilde{k}$ and for some function $\mu = \mu(r, x^A)$. Further

$$\check{h}^{AB} g_{AB} = 2 \left(r^2 - \frac{\mu_\infty}{r} + O(r^{-2}) \right), \tag{III.45}$$

where $\check{h}^{AB}$ denotes the matrix inverse to $\check{h}_{AB}$ while

$$\mu_\infty \equiv \lim_{r \to \infty} \mu = \frac{l^3}{12} \left. \frac{\partial R'}{\partial x} \right|_{x=0}. \tag{III.46}$$

(2) If one moreover assumes that R' is locally constant on $\partial_\infty \Sigma$, then Eq. (III.44) can be improved to

$$g = \left(\frac{r^2}{l^2} + k - \frac{2\mu}{r} \right)^{-1} dr^2 + (r^2 \check{h}_{AB} + O(r^{-1})) dx^A\, dx^B, \tag{III.47}$$

with $\check{h}_{AB}$ having constant Gauss curvature $k = 0, \pm 1$ according to the genus of the connected component of $\partial_\infty \Sigma$ under consideration.

Remarks: (1) The function $(x, x^A) \to \mu(r = 1/x, x^A)$ is of differentiability class C^{i-3} on $\overline{\Sigma}$, with the function $(x, x^A) \to (\mu/r)(r = 1/x, x^A)$ being of differentiability class C^{i-2} on $\overline{\Sigma}$.

(2) In Eqs. (III.44) and (III.47) the error terms $O(r^{-j})$ satisfy

$$\partial_r^s \partial_{A_1} \cdots \partial_{A_t} O(r^{-j}) = O(r^{-j-s})$$

for $0 \leqslant s+t \leqslant i-3$.

(3) We emphasize that the function $\tilde{k}$ defined in Eq. (III.42) could *a priori* be x^A dependent. In such a case neither the definition of coordinate mass of Sec. V A nor the definition of Hamiltonian mass of Sec. V B apply.

(4) It seems that to be able to obtain (III.41), in addition to the hypothesis that R' is locally constant on $\partial_\infty \Sigma$ one would at least need the quantity appearing at the right-hand side of Eq. (III.46) to be locally constant on $\partial_\infty \Sigma$ as well. We do not know whether this is true in general; we have not investigated this question as this is irrelevant for our purposes.

Proof: Consider, near $\partial_\infty \Sigma$, the coordinate system of Eq. (III.28), from Eqs. (III.29) and (III.18) we obtain

$$\partial_x (\ln \sqrt{\det h'_{AB}}) = -2\tilde{k}x - \frac{3\mu_\infty}{l} x^2 + O(x^3), \tag{III.48}$$

l as in (II.9), $\tilde{k}$ as in (III.42), μ_∞ as in (III.46). This, together with Eq. (III.26), leads to

$$\frac{\partial h'_{AB}}{\partial x} = -2x\tilde{k} h'_{AB} + O(x^2) \Rightarrow h'_{AB} = (1-\tilde{k}x^2) l^2 \check{h}_{AB} + O(x^3),$$

where $\check{h}_{AB} \equiv (1/l^2)\, h'_{AB}|_{x=0}$. Proposition III.3 shows that $\tilde{k}$ is proportional to the Gauss curvature of $\check{h}_{AB}$. It follows now from (III.18) that

$$g = x^{-2} g' = \frac{l^2}{x^2}\left(1 - \frac{R' l^2 x^2}{6}\right)^{-1} dx^2 + \left\{ \frac{(1-\tilde{k}x^2)}{x^2} h'_{AB}|_{x=0} + O(x^3) \right\} dx^A\, dx^B.$$

The above suggests to introduce a coordinate r via the formula[49]

$$\frac{r^2}{l^2} = \frac{1-\tilde{k}x^2}{x^2}. \tag{III.49}$$

Suppose, first, that $\tilde{k}$ is locally constant on $\partial_\infty \Sigma$, then $\tilde{k}$ equals $k = 0, \pm 1$ according to the genus of the connected component of $\partial_\infty \Sigma$ under consideration, and one finds

$$\begin{aligned} g &= \left(\frac{r^2}{l^2} + k\right)^{-1} \left\{ 1 + \frac{l^2}{r^2}\left(k - \frac{R' l^2 x^2}{6}\right) \right\}^{-1} dr^2 + \left(\frac{r^2}{l^2} h'_{AB}|_{x=0} + O(r^{-1})\right) dx^A\, dx^B \\ &= \left(\frac{r^2}{l^2} + k - \frac{2\mu}{r}\right)^{-1} dr^2 + \left(\frac{r^2}{l^2} h'_{AB}|_{x=0} + O(r^{-1})\right) dx^A\, dx^B, \end{aligned}$$

where the ''mass aspect'' function $\mu = \mu(r, x^A)$ is defined as

$$\mu \equiv -\frac{r}{2}\left(1 + k\frac{l^2}{r^2}\right)\left(k - \frac{R' l^2 x^2}{6}\right) = -\frac{r}{2}\left(k - \frac{R' l^2}{6} + \frac{k^2 l^2}{r^2}\right) = \frac{r l^2}{2}\left(\frac{1}{6}(R' - R'|_{x=0}) - \frac{k^2}{r^2}\right). \tag{III.50}$$

This establishes Eqs. (III.43) and (III.47). When $\tilde{k}$ is not locally constant an identical calculation using the coordinate r defined in Eq. (III.49) establishes Eq. (III.44)—the only difference is the

occurrence of nonvanishing error terms in the $dr\,dx^A$ part of the metric, introduced by the angle dependence of $\tilde{k}$. It follows from Eq. (III.50)—or from the $\tilde{k}$ version thereof when $\tilde{k}$ is not locally constant—that

$$\mu=\frac{l^3}{12}\frac{\partial R'}{\partial x}\bigg|_{x=0}+O(r^{-1}),$$

which establishes Eq. (III.46). Equation (III.45) is obtained by integration of Eq. (III.48). □

IV. CONNECTEDNESS OF $\partial_\infty\Sigma$

The class of manifolds considered so far could in principle contain Σ's for which neither $\partial_\infty\Sigma$ nor $\partial\Sigma$ are connected. Under the hypothesis of staticity the question of connectedness of $\partial\Sigma$ is open; we simply note here the existence of dynamical (nonstationary) solutions of Einstein–Maxwell equations with a nonconnected black hole region with positive cosmological constant Λ.[50,51] As far as $\partial_\infty\Sigma$ is concerned, we have the following:

Theorem IV.1: Let (Σ,g,V) be a C^i compactifiable solution of Eqs. (I.4)–(I.5), $i\geqslant 3$. Then $\partial_\infty\Sigma$ is connected.

Proof: Consider the manifold $M=\mathbb{R}\times\Sigma$ with the metric (III.33); its conformal completion $\overline{M}=\mathbb{R}\times\overline{\Sigma}$ with the metric ${}^4g/V^2$ is a stably causal manifold with boundary. We wish to show that it is also globally hyperbolic in the sense of Ref. 4, namely that (1) it is strongly causal and (2) for each $p,q\in M$ the set $J^+(p)\cap J^-(q)$ is compact. The existence of the global time function t clearly implies strong causality, so it remains to verify the compactness condition. Now a path $\Gamma(s)=(t(s),\gamma(s))\in\mathbb{R}\times\Sigma$ is an achronal null geodesic from $p=(t(0),\gamma(0))$ to $q=(t(1),\gamma(1))$ if and only if $\gamma(s)$ is a minimizing geodesic between $\gamma(0)$ and $\gamma(1)$ for the ''optical metric'' $V^{-2}g$. Compactness of $J^+(p)\cap J^-(q)$ is then equivalent to compactness of the $V^{-2}g$ distance balls; this latter property will hold when $(\Sigma\cup\partial_\infty\Sigma,V^{-2}g)$ is a geodesically complete manifold (with boundary) by (an appropriate version of) the Hopf–Rinow theorem.

Let us thus show that $(\Sigma,V^{-2}g)$ is geodesically complete. Suppose, first, that $\partial\Sigma=\varnothing$; the hypothesis that Σ has compact interior together with the fact that V tends to infinity in the asymptotic regions implies that $V\geqslant V_0>0$ for some constant V_0. This shows that $(\Sigma,V^{-2}g)$ is a compact manifold with boundary $\partial_\infty\Sigma$, and the result follows. (When the metric induced by $V^{-2}g$ on $\partial_\infty\Sigma$ has positive scalar curvature connectedness of $\partial_\infty\Sigma$ can also be inferred from Ref. 21.)

Consider, next, the case $\partial\Sigma\neq\varnothing$. It is well known that $|dV|_g$ is a nonzero constant on every connected component of $\partial\Sigma$ [cf. the discussion around Eq. (VII.2)]; therefore we can introduce coordinates near $\partial\Sigma$ so that $V=x$, with the metric taking the form

$$V^{-2}g=x^{-2}((dx)^2+h_{AB}(x,x^A)dx^A\,dx^B), \tag{IV.1}$$

where the x^A's are local coordinates on $\partial\Sigma$. It is elementary to show now from (IV.1) that $(\Sigma\cup\partial_\infty\Sigma,V^{-2}g)$ is a complete manifold with boundary, as claimed.

When (Σ,g) is smoothly compactifiable we can now use Theorem 2.1 of Ref. 4 to infer connectedness of $\partial_\infty\Sigma$, compare Ref. 22, Corollary, Sec. III. For compactifications with finite differentiability we argue as follows: For small s let λ be the mean curvature of the sets $\{x=s\}$, where x is the coordinate of Eq. (III.9). In the coordinate system used there the unit normal to those sets pointing away from $\partial_\infty\Sigma$ equals $x\partial_x$; if (Σ,g,V) is C^3 compactifiable the tensor field $\overline{h}$ appearing in Eq. (III.9) will be C^1 so that[52]

$$\lambda=\frac{1}{\sqrt{\det g}}\partial_i(\sqrt{\det g}n^i)=\frac{x^3}{\sqrt{\det\overline{h}}}\partial_x(x^{-2}\sqrt{\det\overline{h}})=-2+O(x).$$

It follows that for s small enough the sets $\{x=s,t=\tau\}$ are trapped, with respect to the inward pointing normal, in the space–time $\mathbb{R}\times\Sigma$ with the metric (III.33). Suppose that $\partial_\infty\Sigma$ were not

connected, then those (compact) sets would be outer trapped with respect to every other connected component of $\partial_\infty\Sigma$. This is, however, not possible by the usual global arguments, cf., e.g., Refs. 53 and 54 or Ref. 37, Sec. 4 for details. □

V. THE MASS

A. A coordinate mass M_c

There exist several proposals how to assign a mass M to a space–time which is asymptotic to an anti-de Sitter space–time.[27,29,55,18,56] It seems that the simplest way to do that (as well as to extend the definition to the generalized Kottler context considered here) proceeds as follows: consider a metric defined on a coordinate patch covering the set

$$\Sigma_{\text{ext}}\equiv\{t=t_0, r\geqslant R, (x^A)\in {}^2M\} \tag{V.1}$$

(which we will call an ''end''), and suppose that in this coordinate system the functions $g_{\mu\nu}$ are of the form (I.1) plus lower order terms

$$\begin{gathered} g_{tt}=-\left(k-\frac{2m}{r}-\frac{\Lambda}{3}r^2\right)+\frac{o(1)}{r}, \quad g_{rr}=\left(k-\frac{2m}{r}-\frac{\Lambda}{3}r^2+\frac{o(1)}{r}\right)^{-1}, \\ g_{t\mu}=o(1), \quad \mu\neq t, \quad g_{r\mu}=o(1), \quad \mu\neq r, \quad g_{AB}-r^2h_{AB}=o(r^2), \end{gathered} \tag{V.2}$$

for some constant m, and for some constant curvature (t and r independent) metric $h_{AB}\,dx^A\,dx^B$ on ${}^2M$. Then we define the coordinate mass M_c of the end Σ_{ext} to be the parameter m appearing in (I.1). This procedure gives a unique prescription of how to assign a mass to a metric and a coordinate system on Σ_{ext}.

There is an obvious coordinate dependence in this definition when $k=0$: Indeed, in that case a coordinate transformation $r\to\lambda r$, $t\to t/\lambda$, $d\Omega_k^2\to\lambda^{-2}\,d\Omega_k^2$, where λ is a positive constant, does not change the asymptotic form of the metric, while m gets replaced by $\lambda^{-3}m$. When ${}^2M$ is compact this freedom can be removed, e.g., by requiring that the area of ${}^2M$ with respect to the metric $d\Omega_k^2$ be equal to 4π, or to 1, or to some other chosen constant. For $k=\pm 1$ this ambiguity does not arise because in this case such rescalings will change the asymptotic form of the metric, and are therefore not allowed.

It is far from being clear that the above definition will assign the same parameter M_c to every coordinate system satisfying our requirements: if that is the case, to prove such a statement one might perhaps need to further require that the coordinate derivatives of the coordinate components of g in the above described coordinate system have some appropriate decay properties; further one might perhaps have to replace the $o(1)$'s by $o(r^{-\sigma})$'s or $O(r^{-\sigma})$'s, for some appropriate σ's, perhaps as in (III.41); this is however irrelevant for our discussion at this stage.

A possible justification of this definition proceeds as follows: when ${}^2M=S^2$ and $\Lambda=0$ it is widely accepted that the mass of Σ_{ext} equals m, because m corresponds to the active gravitational mass of the gravitational field in a quasi-Newtonian limit. (It is also known in this case that the definition is coordinate independent.[57,58]) For $\Lambda\neq 0$ and/or ${}^2M\neq S^2$ one calls m the mass by analogy.

Consider, then, the metric (III.33), with V and g as in (III.43)–(III.44); suppose further that the limit

$$\mu_\infty\equiv\lim_{r\to\infty}\mu$$

exists and is a constant. To achieve the form of the metric ${}^4g$ just described one needs to replace the coordinate r of (III.43)–(III.44) with a new coordinate ρ defined as

$$r^2+k=\rho^2+k+\frac{\mu_\infty}{\rho}.$$

This leads to

$$
{}^4g = -\left(\frac{\rho^2}{l^2} + k + \frac{\mu_\infty}{\rho}\right) dt^2 + \left(\frac{\rho^2}{l^2} + k + \frac{\mu_\infty}{\rho} + O\left(\frac{1}{\rho^2}\right)\right)^{-1} d\rho^2
$$
$$
+ O(\rho^{-3}) d\rho\, dx^A + (\rho^2 \check{h}_{AB} + O(\rho^{-1})) dx^A\, dx^B, \tag{V.3}
$$

and therefore

$$
M_c \equiv -\frac{\mu_\infty}{2} = -\frac{l^3}{24} \left.\frac{\partial R'}{\partial x}\right|_{x=0}, \tag{V.4}
$$

where the second equality above follows from (III.46). We note that the approach described above does not give a definition of mass when $\lim_{r\to\infty}\mu$ does not exist, or is not a constant function on $\partial_\infty \Sigma$.

The above described dogmatic approach suffers from various shortcomings. First, when ${}^2M \neq S^2$, the arguments given are compatible with M_c being any function $M_c(m,\Lambda)$ with the property that $M_c(m,0)=m$. Next, the transition from $\Lambda \neq 0$ to $\Lambda = 0$ has dramatic consequences as far as global properties of the corresponding space–times are concerned, and one can argue that there is no reason why the function $M_c(m,\Lambda)$ should be continuous at zero. For example, according to Ref. 27, Eq. (III.8c), the mass of the metric (I.1) with ${}^2M = S^2$ should be $16\pi m l$, with l as in (II.9), which blows up when Λ tends to zero with m being held fixed. Finally, when ${}^2M \neq S^2$ the Newtonian limit argument does not apply because the metrics (I.1) with $\Lambda = 0$ and ${}^2M \neq S^2$ do not seem to have a Newtonian equivalent. In particular there is no reason why M_c should not depend upon the genus g_∞ of ${}^2M$ as well.

All the above arguments make it clear that a more fundamental approach to the definition of mass would be useful. It is common in field theory to define energy by Hamiltonian methods, and this is the approach we shall pursue in the next section.

B. The Hamiltonian mass M_{Ham}

The Hamiltonian approach allows one to define the energy from first principles. For a solution of the field equations, we can simply take as the energy the numerical value of the Hamiltonian. It must be recognized, however, that the Hamiltonians might depend on the choice of the phase space, if several such choices are possible, and they are defined only up to an additive constant on each connected component of the phase space. They also depend on the choice of the Hamiltonian structure, if more than one such structure exists.

Let us start by briefly recalling the results of the analysis of Ref. 59, based on the Hamiltonian approach of Kijowski and Tulczyjew,[60,61] see also Ref. 62. One assumes that a manifold M on which an (unphysical) background metric b is given, and one considers metrics ${}^4g$ which asymptote to b in the relevant asymptotic regions of M. We stress that the background metric is only a tool to prescribe the asymptotic boundary conditions, and does not have any physical significance. Let X be any vector field on M and let Σ be any hypersurface in M. By a well known procedure the motion of Σ along the flow of X can be used to construct a Hamiltonian dynamical system in an appropriate phase space of fields over Σ; the reader is referred to Refs. 60–63 for a geometric approach to this question. In Ref. 59 it is also assumed that X is a Killing vector field of the background metric; this is certainly not necessary (cf., e.g., Ref. 63 for general formulas), but is sufficient for our purposes, as we are going to take X to be equal to $\partial/\partial t$ in the coordinate system of Eq. (III.33). In the context of metrics which asymptote to the generalized Kottler metrics at large r, a rigorous functional description of the spaces involved has not been carried out so far, and lies outside the scope of this paper. Let us simply note that one expects, based on the results in Refs. 41, 42, and 63, to obtain a well-defined Hamiltonian system in this context. Therefore the formal calculations of Ref. 59 lead one to expect that on an appropriate space of fields, such that

the associated physical space–time metrics ${}^4g$ asymptote to the background metric b at a suitable rate, the Hamiltonian $H(X,\Sigma)$ will coincide with (or, at worse, will be closely related to) the one given by the formula derived in Ref. 59:

$$H(X,\Sigma)=\frac{1}{2}\int_{\partial\Sigma}\mathbb{U}^{\alpha\beta}\,dS_{\alpha\beta}, \tag{V.5}$$

where the integral over $\partial\Sigma$ should be understood as the limit as R tends to infinity of integrals of coordinate spheres $t=0$, $r=R$ on $\Sigma_{\rm ext}$. Here $dS_{\alpha\beta}$ is defined as

$$\frac{\partial}{\partial x^\alpha}\lrcorner\frac{\partial}{\partial x^\beta}\lrcorner \mathrm{d}x^0\wedge\cdots\wedge\mathrm{d}x^n,$$

with $\lrcorner$ denoting contraction, and $\mathbb{U}^{\alpha\beta}$ is given by

$$\mathbb{U}^{\nu\lambda}=\mathbb{U}^{\nu\lambda}{}_\beta X^\beta+\frac{1}{8\pi}\left(\sqrt{|\det g_{\rho\sigma}|}g^{\alpha[\nu}-\sqrt{|\det b_{\rho\sigma}|}b^{\alpha[\nu}\right)\delta^{\lambda]}_\beta X^\beta{}_{;\alpha}, \tag{V.6}$$

$$\mathbb{U}^{\nu\lambda}{}_\beta=\frac{2|\det b_{\mu\nu}|}{16\pi\sqrt{|\det g_{\rho\sigma}|}}g_{\beta\gamma}\left(e^2 g^{\gamma[\nu}g^{\lambda]\kappa}\right)_{;\kappa}. \tag{V.7}$$

Here, and *throughout this section*, g stands for the space–time metric ${}^4g$ unless explicitly indicated otherwise. Further, a semicolon denotes covariant differentiation *with respect to the background metric* b, while $e\equiv\sqrt{|\det g_{\rho\sigma}|}/\sqrt{|\det b_{\mu\nu}|}$. Some comments concerning Eq. (V.6) are in order: in Ref. 59 the starting point of the analysis is the Hilbert Lagrangian for vacuum Einstein gravity, $L=\sqrt{-\det g_{\mu\nu}}(g^{\alpha\beta}R_{\alpha\beta}/16\pi)$. As the normalization factors play an important role in giving a correct definition of mass, we recall that the factor $1/16\pi$ is determined by the requirement that the theory has the correct Newtonian limit (units $G=c=1$ are used throughout). With our signature $(-+++)$ the Einstein equations with a cosmological constant read

$$R_{\mu\nu}-\frac{g^{\alpha\beta}R_{\alpha\beta}}{2}g_{\mu\nu}=-\Lambda g_{\mu\nu},$$

so that one needs to repeat the analysis in Ref. 59 with L replaced by $(\sqrt{-\det g_{\mu\nu}}/16\pi)(g^{\alpha\beta}R_{\alpha\beta}-2\Lambda)$. The general expression for the Hamiltonian (V.5) in terms of X^μ, $g_{\mu\nu}$, and $b_{\mu\nu}$ ends up to coincide with that obtained with $\Lambda=0$, which can be seen either by direct calculations, or by the Legendre transformation arguments of Ref. 59, end of Sec. 3, together with the results in Ref. 62. Note that Eq. (V.6) does not exactly coincide with that derived in Ref. 59, as the formulas there do not contain the term $-\sqrt{|\det b_{\rho\sigma}|}b^{\alpha[\nu}\delta^{\lambda]}_\beta X^\beta{}_{;\alpha}$. However, this term does not depend on the metric g, and such terms can be freely added to the Hamiltonian because they do not affect the variational formula that defines a Hamiltonian. From an energy point of view such an addition corresponds to a choice of the zero point of the energy. We note that in our context $H(X,\Sigma)$ would not converge if the term $-\sqrt{|\det b_{\rho\sigma}|}b^{\alpha[\nu}\delta^{\lambda]}_\beta X^\beta{}_{;\alpha}$ were not present in (V.6).

In order to apply this formalism in our context, we let b be any t-independent metric on $M=\mathbb{R}\times\Sigma$ such that (with $0\neq\Lambda=-3/l^2$)

$$b=-\left(k+\frac{r^2}{l^2}\right)dt^2+\left(k+\frac{r^2}{l^2}\right)^{-1}dr^2+r^2\check{h} \tag{V.8}$$

on $\mathbb{R}\times\Sigma_{\rm ext}\approx\mathbb{R}\times[R,\infty)\times{}^2M$, for some $R\geqslant 0$, where $\check{h}=\check{h}_{AB}\,dx^A\,dx^B$ denotes a metric of constant Gauss curvature $k=0,\pm1$ on the two-dimensional connected compact manifold ${}^2M$.

Let us return to the discussion in Sec. V A concerning the freedom of rescaling the coordinate r by a positive constant λ. First, if k in Eq. (V.8) is any constant different from zero, then there

exists a (unique) rescaling of r and t which brings k to one, or to minus one. Next, if $k=0$ we can—without changing the asymptotic form of the metric—rescale the coordinate r by a positive constant λ, the coordinate t by $1/\lambda$, and the metric $\check{h}$ by λ^{-2}, so that there is still some freedom left in the coordinate system above; a unique normalization can then be achieved by asking, e.g., that the area

$$A_\infty \equiv \int_{^2M} d^2\mu_{\check{h}} \tag{V.9}$$

equals 4π—this will be the most convenient normalization for our purposes. Here $d^2\mu_{\check{h}}$ is the Riemannian measure associated with the metric $\check{h}$. We wish to point out that *regardless* of the value of k, the Hamiltonian $H(X,\Sigma)$ is *independent* of this scaling: this follows immediately from the fact that $\mathbb{U}^{\alpha\beta}$ behaves as a density under linear coordinate transformations. An alternative way of seeing this is that in the new coordinate system X equals $\lambda\partial/\partial t$, which accounts for a factor $1/\lambda$ in the transformation law of the coordinate mass, as discussed at the beginning of Sec. V A. The remaining factor $1/\lambda^2$ needed there is accounted for by a change of the area of $\partial_\infty\Sigma$ under the rescaling of the metric $\check{h}$ which accompanies that of r.

In order to evaluate H it is useful to introduce the following b-orthonormal frame:

$$e_{\hat{0}} = \left(k+\frac{r^2}{l^2}\right)^{-1/2}\partial_t, \quad e_{\hat{1}} = \left(k+\frac{r^2}{l^2}\right)^{1/2}\partial_r, \quad e_{\hat{A}} = \frac{1}{r}\check{e}_{\hat{A}}, \tag{V.10}$$

where $\check{e}_{\hat{A}}$ is an ON frame for the metric $\check{h}$. The connection coefficients, defined by the formula $\nabla_{e_{\hat{a}}} e_{\hat{b}} = \omega^{\hat{c}}{}_{\hat{b}\hat{a}} e_{\hat{c}}$, read

$$\omega_{\hat{0}\hat{1}\hat{0}} = -\frac{r}{l^2}\left(k+\frac{r^2}{l^2}\right)^{-1/2}, \quad \omega_{\hat{1}\hat{2}\hat{2}} = \omega_{\hat{1}\hat{3}\hat{3}} = -\frac{1}{r}\left(k+\frac{r^2}{l^2}\right)^{1/2},$$

$$\omega_{\hat{2}\hat{3}\hat{3}} = \begin{cases} -\dfrac{\coth\theta}{r}, & k=-1, \\ 0, & k=0, \\ -\dfrac{\cot\theta}{r}, & k=1. \end{cases} \tag{V.11}$$

Those connection coefficients which are not obtained from the above ones by permutations of indices are zero; we have used a coordinate system θ,φ on ^2M in which $\check{h}$ takes, locally, the form $d\theta^2+\sinh^2\theta\, d\varphi^2$ for $k=-1$, $d\theta^2+d\varphi^2$ for $k=0$, and $d\theta^2+\sin^2\theta\, d\varphi^2$ for $k=1$. We also have

$$X^{\hat{0}} = \sqrt{k+\frac{r^2}{l^2}} = \frac{r}{l}+O(r^{-1}), \quad e_{\hat{1}}(X^{\hat{0}}) = X^{\hat{0}}{}_{;\hat{1}} = -X_{\hat{0};\hat{1}} = X_{\hat{1};\hat{0}} = \frac{r}{l^2}, \tag{V.12}$$

all the remaining $X^{\hat{\mu}}$'s and $X_{\hat{\mu};\hat{\nu}}$'s are zero. Let the tensor field $e^{\mu\nu}$ be defined by the formula

$$e^{\mu\nu} \equiv g^{\mu\nu} - b^{\mu\nu}. \tag{V.13}$$

We shall use hatted indices to denote the components of a tensor field in the frame $e_{\hat a}$ defined in (V.10), e.g., $e^{\hat\alpha\hat c}$ denotes the coefficients of $e^{\mu\nu}$ with respect to that frame:

$$e^{\mu\nu}\partial_\mu\otimes\partial_\nu = e^{\hat\alpha\hat c} e_{\hat\alpha}\otimes e_{\hat c}\,.$$

Suppose that the metric ${}^4g$ is such that the $e^{\hat\alpha\hat c}$'s tend to zero as r tends to infinity. By a Gram–Schmidt procedure we can find a frame $f_{\tilde a}$, $\tilde a=0,\dots,3$, orthonormal *with respect to the metric* g, such that f_0 is proportional to e_0, and such that the $e_{\hat a}$ components of $f_0-e_0,\dots, f_3-e_3$ tend to zero as r tends to infinity:

$$f_{\tilde a} = f_{\tilde a}{}^{\hat a} e_{\hat a} \to_{r\to\infty} \delta^{\hat a}_{\tilde a} e_{\hat a}\,. \tag{V.14}$$

From (V.5) and (V.14) we expect that

$$H(X,\Sigma) = \lim_{R\to\infty}\int_{\Sigma\cap\{r=R\}} r^2 \mathbb{U}^{\hat1\hat0}\, d^2\mu_r\,, \tag{V.15}$$

where $d^2\mu_r$ is the Riemannian measure induced on $\Sigma\cap\{r=R\}$ by ${}^4g$. We wish to analyze when the above limit exists; we have

$$r^2\mathbb{U}^{\hat1\hat0}{}_\beta X^\beta = r^2\mathbb{U}^{\hat1\hat0}{}_{\hat0}X^{\hat0} \approx \frac{r^3}{l}\mathbb{U}^{\hat1\hat0}{}_{\hat0}\,,$$

hence we need to keep track of all the terms in $\mathbb{U}^{\hat1\hat0}{}_{\hat0}$ which decay as r^{-3} or slower. Similarly one sees from Eqs. (V.12) that only those terms in

$$\Delta^{\hat\alpha\hat\nu} \equiv \sqrt{|\det g_{\hat\rho\hat\sigma}|}\, g^{\hat\alpha\hat\nu} - \sqrt{|\det b_{\hat\rho\hat\sigma}|}\, b^{\hat\alpha\hat\nu}$$

which are $O(r^{-3})$, or which are decaying slower, will give a nonvanishing contribution to the term involving the derivatives of X in the integral (V.15). This suggests to consider metrics ${}^4g$ such that

$$e^{\hat\mu\hat\nu} = o(r^{-3/2}), \quad e_{\hat\rho}(e^{\hat\mu\hat\nu}) = o(r^{-3/2}). \tag{V.16}$$

The boundary conditions (V.16) ensure that one needs to keep track only of those terms in $\mathbb{U}^{\hat1\hat0}$ which are linear in $e^{\hat\mu\hat\nu}$ and $e_{\hat\rho}(e^{\hat\mu\hat\nu})$, when $\mathbb{U}^{\hat1\hat0}$ is Taylor expanded around b. For a generalized Kottler metric (I.1) we have

$$e^{\hat0\hat0} \approx e^{\hat1\hat1} \approx -\frac{2ml^2}{r^3}, \quad e_{\hat1}(e^{\hat0\hat0}) \approx e_{\hat1}(e^{\hat1\hat1}) \approx \frac{6ml}{r^3}, \tag{V.17}$$

with the remaining $e^{\hat\mu\hat\nu}$'s and $e_{\hat\sigma}(e^{\hat\mu\hat\nu})$'s vanishing, so that Eqs. (V.16) are satisfied. Under (V.16) one obtains

$$g_{\hat a\hat c} = \eta_{\hat a\hat c} - \eta_{\hat a\hat r}\eta_{\hat c\hat s}e^{\hat r\hat s} + o(r^{-3}),\ \sqrt{|\det g_{\mu\nu}|} = \sqrt{|\det b_{\mu\nu}|}\,(1+\tfrac12(e^{\hat0\hat0}-e^{\hat1\hat1}-e^{\hat A\hat A})+o(r^{-3})), \tag{V.18}$$

$$\begin{aligned}\mathbb{U}^{\hat1\hat0}{}_{\hat0} &= -\frac{1}{16\pi}(2e_{;\hat1}+e^{\hat1\hat\imath}{}_{;\hat\imath}-e^{\hat0\hat0}{}_{;\hat1}) + o(r^{-3})\\ &= \frac{1}{16\pi}\left(e_{\hat1}(e^{\hat A\hat A}) + \frac{1}{l}(e^{\hat A\hat A}-2e^{\hat1\hat1}) - \frac{1}{r}\check D_{\hat A}e^{\hat1\hat A}\right) + o(r^{-3}),\end{aligned}$$

$$\frac{1}{8\pi}\Delta^{\alpha[\hat{1}}X^{\hat{0}]}{}_{;\alpha}=\frac{1}{16\pi}(\Delta^{\hat{1}\hat{1}}-\Delta^{\hat{0}\hat{0}})X^{\hat{0}}{}_{;\hat{1}}=\frac{r}{16\pi l^2}(\Delta^{\hat{1}\hat{1}}-\Delta^{\hat{0}\hat{0}})+o(r^{-3})$$

$$=-\frac{r}{16\pi l^2}e^{\hat{A}\hat{A}}+o(r^{-3}). \tag{V.19}$$

The indices $\hat{\imath}$ run from 1 to 3 while the indices $\hat{A}$ run from 2 to 3; $\breve{D}_{\hat{A}}$ denotes the covariant derivative on ${}^2M$, and $\breve{D}_{\hat{A}}e^{\hat{1}\hat{A}}$ is understood to be the covariant derivative associated with the metric $\breve{h}$ of a vector field on ${}^2M$, with repeated $\hat{A}$ indices being summed over. In Eq. (V.18) $\eta_{\hat{\mu}\hat{\nu}}=\mathrm{diag}(-1,+1,+1,+1)$, while the $g_{\hat{\mu}\hat{\nu}}$'s are the components of the tensor $g_{\hat{\mu}\hat{\nu}}$ in a co-frame dual to (V.10). Inserting all this into (V.15) one is finally led to the simple expression

$$M_{\mathrm{Ham}}\equiv H\left(\frac{\partial}{\partial t},\{t=0\}\right)=\lim_{R\to\infty}\frac{r^3}{16\pi l^2}\int_{\Sigma\cap\{r=R\}}\left(r\frac{\partial e^{\hat{A}\hat{A}}}{\partial r}-2e^{\hat{1}\hat{1}}\right)d^2\mu_{\breve{h}}. \tag{V.20}$$

In particular if ${}^4g$ is the generalized Kottler metric (I.1) one obtains [cf. Eq. (V.17)]

$$M_{\mathrm{Ham}}=\frac{A_\infty m}{4\pi}, \tag{V.21}$$

A_∞ defined in (V.9). If ${}^2M=T^2$ with area normalized to 4π we obtain $M_{\mathrm{Ham}}=m$. For $k=\pm 1$ it follows from the Gauss–Bonnet theorem that $A_\infty=4\pi|1-g_\infty|$, where g_∞ is the genus of ${}^2M$, hence

$$M_{\mathrm{Ham}}=|1-g_\infty|m. \tag{V.22}$$

This gives again $M_{\mathrm{Ham}}=m$ for ${}^2M=S^2$, but this will not be true anymore for ${}^2M$'s of higher genus. We believe that the Hamiltonian approach is the one which provides *the* correct definition of mass in field theories, and therefore Eqs. (V.21)–(V.22) are the ones which provide the correct normalization of mass.

Let us finally consider static metrics ${}^4g$ of the form (III.33), and suppose that the hypotheses of point (2) of Proposition III.7 hold. We can then use the coordinates of that proposition to calculate M_{Ham}, and obtain

$$M_{\mathrm{Ham}}=-\frac{1}{8\pi}\int_{\partial_\infty\Sigma}\mu_\infty\, d^2\mu_{\breve{h}}. \tag{V.23}$$

If we further assume that μ_∞ is constant on $\partial_\infty\Sigma$, Eq. (V.23) gives

$$M_{\mathrm{Ham}}=-\frac{\mu_\infty}{2}=M_c$$

for ${}^2M=S^2$ and for an appropriately normalized T^2, while

$$M_{\mathrm{Ham}}=-|1-g_\infty|\frac{\mu_\infty}{2}=|1-g_\infty|M_c$$

for higher genus $\partial_\infty\Sigma$'s. Here M_c is the coordinate mass as defined in Sec. V A.

C. A generalized Komar mass

Recall that the Komar mass is a number which can be assigned to every stationary, asymptotically flat metric the energy-momentum tensor of which decays sufficiently rapidly:

$$M_K = \lim_{R\to\infty} \frac{1}{8\pi} \int_{S_{R,T}} \sqrt{|\det g_{\alpha\beta}|}\, \nabla^\mu X^\nu \, dS_{\mu\nu}, \tag{V.24}$$

where $X^\mu \partial_\mu$ is the Killing vector field which asymptotes to $\partial/\partial t$ in the asymptotically flat region, and the $S_{R,T} \equiv \{t=T, r=R\}$'s are coordinate spheres in that region. The normalization factor $1/(8\pi)$ has been chosen so that M_K reproduces the familiar mass parameter m when Schwarzschild metrics are considered. For metrics considered here with $\Lambda \neq 0$ the integral (V.24) diverges when $X^\mu \partial_\mu = \partial/\partial t$ and when the $S_{R,T}$'s are taken to be coordinate spheres in the region $\Sigma_{\rm ext}$ where the metric exhibits the generalized Kottler asymptotics. An obvious way to generalize M_K to the situation considered in this paper is to remove the divergent part of the integral using a background metric b:

$$M_K = \lim_{R\to\infty} \frac{1}{8\pi} \int_{S_{R,T}} (\sqrt{|\det g_{\alpha\beta}|}\, \nabla^\mu X^\nu - \sqrt{|\det b_{\alpha\beta}|}\, \overline{\nabla}^\mu X^\nu) dS_{\mu\nu}. \tag{V.25}$$

Here $\overline{\nabla}$ denotes a covariant derivative with respect to the background metric. More precisely, let $\Sigma_{\rm ext}$, b, $\check{h}$, etc., be as in Eq. (V.8), and consider time-independent metrics g which in the coordinate system of Eq. (V.8) are of the form (III.33) with

$$V^2 = \frac{r^2}{l^2} + \tilde{k} - \frac{2\beta}{r} + o\left(\frac{1}{r}\right), \quad \partial_r\left(V^2 - \frac{r^2}{l^2} - \tilde{k} + \frac{2\beta}{r}\right) = o\left(\frac{1}{r^2}\right), \quad g^{rr} = l^2 + \tilde{k} - \frac{2\gamma}{r} + o\left(\frac{1}{r}\right),$$

$$\sqrt{|\det g_{\alpha\beta}|} = \left(r^2 + \frac{2\delta l^2}{r} + o\left(\frac{1}{r}\right)\right) \sqrt{|\det \check{h}_{AB}|}, \tag{V.26}$$

for some r-independent differentiable functions $\tilde{k} = \tilde{k}(x^A)$, $\beta = \beta(x^A)$, $\gamma = \gamma(x^A)$, and $\delta = \delta(x^A)$ defined on a coordinate neigbhorhood of $\partial_\infty \Sigma$. [The conditions (V.26) roughly reflect the behavior of the metric in the coordinate system of Proposition III.7.] Under (V.26) the limit as R tends to infinity in the definition (V.25) of M_K exists, and one finds

$$\begin{aligned} M_K &= \lim_{R\to\infty} \frac{1}{4\pi} \int_{S_{R,T}} (\sqrt{|\det g_{\alpha\beta}|}\, g^{r\mu} g^{\nu t} \partial_{[\mu} g_{\nu]t} - \sqrt{|\det b_{\alpha\beta}|}\, b^{r\mu} b^{\nu t} \partial_{[\mu} b_{\nu]t}) dx^2\, dx^3 \\ &= \lim_{R\to\infty} \frac{1}{8\pi} \int_{S_{R,T}} (\sqrt{|\det g_{\alpha\beta}|}\, g^{rr} g^{tt} \partial_r g_{tt} - \sqrt{|\det b_{\alpha\beta}|}\, b^{rr} b^{tt} \partial_r b_{tt}) dx^2 dx^3 \\ &= \frac{1}{4\pi} \int_{\partial_\infty \Sigma} (3\beta - 2\gamma + 2\delta) d^2\mu_{\check{h}}. \end{aligned} \tag{V.27}$$

It turns out that the value of M_K so obtained depends on the background metric chosen. [Our definition of background, Eq. (V.8), is tied to the choice of a particular coordinate system, so another way of stating this is that the number M_K as defined so far is assigned to a metric *and* to a coordinate system, in a manner somewhat similar to the coordinate mass of Sec. V A.] Indeed, given any differentiable function $\alpha(x^A)$ there exists a neighborhood of $\partial_\infty \Sigma$ on which a new coordinate $\hat{r}$ can be introduced by the formula

$$\frac{\hat{r}^2}{l^2} - 2\frac{\alpha}{\hat{r}} = \frac{r^2}{l^2}. \tag{V.28}$$

We can then choose the new background to be

$$b=-\left(k+\frac{\hat{r}^2}{l^2}\right)dt^2+\left(k+\frac{\hat{r}^2}{l^2}\right)^{-1}d\hat{r}^2+\hat{r}^2\check{h},$$

and obtain a new M_K which will in general *not* coincide with the old one. [It is noteworthy that the coordinate transformation (V.28) with the associated change of background do *not* change the value of the Hamiltonian mass M_{Ham}.] For example, if α is constant, using hats to denote the corresponding functions appearing in the metric expressed in the new coordinate system we obtain

$$\hat{\beta}=\beta+\alpha,\quad \hat{\gamma}=\gamma+3\alpha,\quad \hat{\delta}=\delta-2\alpha\Rightarrow\hat{M}_K=M_K-\frac{7\alpha A_\infty}{4\pi},$$

where A_∞ is the area of $\partial_\infty\Sigma$ with respect to the metric $\check{h}$. It turns out that one can remove this coordinate dependence in an appropriate class of metrics, tailoring the prescription in such a way that Eq. (V.27) reproduces, up to a genus dependent factor, the coordinate mass M_c. In order to do that we shall suppose that the metric ${}^4g$ satisfies the hypotheses of point (2) of Proposition III.7 (in particular $\tilde{k}=k=0,\pm1$ according to the genus of the connected component of $\partial_\infty\Sigma$ under consideration), and we let the background be associated with a coordinate system (ρ,x^A) with ρ given by (III.43). It follows from Eqs. (V.3) and (III.45) that in this coordinate system it holds

$$\sqrt{|\det g_{\alpha\beta}|}=r^2+o\left(\frac{1}{r}\right),\tag{V.29}$$

where we have used the generic symbol r to denote the coordinate ρ. We then impose (V.29) as a restriction on the coordinate system in which the generalized Komar mass M_K has to be calculated. When this condition is imposed we obtain from (V.3) and (V.23)

$$M_K=-\frac{1}{8\pi}\int_{\partial_\infty\Sigma}\mu_\infty d^2\mu_{\check{h}}=M_{\mathrm{Ham}}.$$

We have thus proved

Proposition V.1: Consider a metric ${}^4g$ satisfying the hypotheses of point (2). of Proposition III.7, then the generalized Komar mass (V.25) associated to a background metric (V.8) such that (V.29) holds equals the Hamiltonian mass (V.20).

Proposition V.1 is the $\Lambda<0$ analogue of the theorem of Beig,[64] that for static $\Lambda=0$ vacuum metrics which are asymptotically flat in spacelike directions the ADM mass and the Komar masses coincide. Our treatment here is inspired by, and somewhat related to, the analysis of Ref. 43.

D. The Hawking mass $M_{\mathrm{Haw}}(\psi)$

Let ψ be a function defined on the asymptotic region Σ_{ext}, with Σ_{ext} defined as in (V.1), such that the level sets of ψ are smooth compact surfaces diffeomorphic to each other (at least for ψ large enough), with $\psi\to_{r\to\infty}\infty$. Following Hawking,[65] Gibbons [Ref. 18, Eq. (17)] assigns a mass $M_{\mathrm{Haw}}(\psi)$ to such a foliation via the formula

$$M_{\mathrm{Haw}}(\psi)\equiv\lim_{\epsilon\to0}\frac{\sqrt{A_{1/\epsilon}}}{32\pi^{3/2}}\int_{\{\psi=1/\epsilon\}}\left({}^2\mathcal{R}-\frac{1}{2}p^2-\frac{2}{3}\Lambda\right)dA,\tag{V.30}$$

where A_α is the area of the connected component under consideration of the level set $\{\psi=\alpha\}$.

By considering simple examples in Minkowski space–times it can be seen that this definition is ψ dependent. However, when ${}^2M=S^2$, $\Lambda=0$, and the coordinate system on Σ_{ext} is such that the ADM mass m_{ADM} (which equals m_H as defined in Sec. V B) of Σ_{ext} is well defined (see Refs. 58

and 57), then $M_{\mathrm{Haw}}(\psi)$ will be independent of ψ, in the class of ψ's singled out by the condition that the level sets of ψ approach round spheres at a suitable rate. No results of this kind are known when $\Lambda \neq 0$.

The definition (V.30) applied to the function $\psi = r$ and the metric (I.1) with $k \neq 0$ gives

$$M_{\mathrm{Haw}} = m|1-g_\infty|^{3/2}.$$

We have also used the Gauss–Bonnet theorem to calculate $\sqrt{A_{1/\epsilon}}$. Thus the definition (V.30) differs from the coordinate one by the somewhat unnatural factor $|1-g_\infty|^{3/2}$. It is not clear why such a factor should be included in the definition of mass.

Consider, next, the metrics (III.33) with V and g given by (III.43)–(III.44). Let $\psi = V$; from the Codazzi–Mainardi Eq. (III.31), Eq. (I.5), and the definition (III.16) of W we obtain, for V large enough so that $|dV| > 0$,

$$\begin{aligned} {}^2R - \frac{1}{2}p^2 - \frac{2}{3}\Lambda &= (-2R_{ij} + Rg_{ij})n^i n^j - |q_{ij}|_g^2 - \frac{2}{3}\Lambda \\ &= -2\frac{D^i V D^j V}{VW} D_i D_j V - |q_{ij}|_g^2 - \frac{2}{3}\Lambda \\ &= -\frac{D^i V D_i W}{VW} - |q_{ij}|_g^2 - \frac{2}{3}\Lambda. \end{aligned}$$

In the coordinate system of Eq. (III.28), where $V = 1/x$, one is led to

$${}^2R - \frac{1}{2}p^2 - \frac{2}{3}\Lambda = x^3\frac{\partial W}{\partial x} - \frac{2}{3}\Lambda + O(x^6) = -\frac{x^3}{6}\frac{\partial R'}{\partial x} + O(x^6),$$

and we have used (III.25) and (III.15). From $A_{1/\epsilon} \approx x^{-2} A'_{\partial_\infty \Sigma}$ we finally obtain

$$M_{\mathrm{Haw}}(V) = -\frac{\sqrt{A'_{\partial_\infty \Sigma}}}{32\pi^{3/2}} \int_{\partial_\infty \Sigma} \frac{1}{6}\frac{\partial R'}{\partial x} d^2\mu_{h'} = -\frac{\sqrt{A'_{\partial_\infty \Sigma}}}{32\pi^{3/2}} \int_{\partial_\infty \Sigma} l\frac{n'(R')}{6} d^2\mu_{h'}, \tag{V.31}$$

where $d^2\mu_{h'}$ is the Riemannian area element induced by g' on $\partial_\infty \Sigma$, and n' denotes the inward-pointing g'-unit normal to $\partial_\infty \Sigma$. We have thus proved the following result.

Theorem V.2: Let a triple (Σ, g, V) satisfying Eqs. (I.3)–(I.5) be C^i compactifiable, $i \geqslant 3$. Then the Hawking mass $M_{\mathrm{Haw}}(V)$ of the V-foliation is finite and well defined; it is given by the formula (V.31), with R'—the curvature scalar of the metric $g' = V^{-2}g$.

We can relate $M_{\mathrm{Haw}}(V)$ to the coordinate mass M_c if we assume in addition that the latter is well defined; recall that this required R' and $\partial_x R'$ to be constant on $\partial_\infty \Sigma$. In this case Eq. (V.4) gives

$$M_{\mathrm{Haw}}(V) = \left(\frac{A'_{\partial_\infty \Sigma}}{4\pi l^2}\right)^{3/2} M_c. \tag{V.32}$$

From Eq. (III.20) we have ${}^2\mathcal{R}'|_{x=0} = 2k/l^2$, and the Gauss–Bonnet theorem implies

$$\int_{\partial_\infty \Sigma} {}^2\mathcal{R}'\, d^2\mu_{h'} = \frac{2k}{l^2} A'_{\partial_\infty \Sigma} = 8\pi(1-g_\infty),$$

so that when $g_\infty \neq 1$ we obtain

$$M_{\mathrm{Haw}}(V) = |1-g_\infty|^{3/2} M_c. \tag{V.33}$$

We emphasize that $M_{\mathrm{Haw}}(V)$ is finite and well defined even when the conditions of Sec. V A, which we have set forth to define M_c, are not met.

Similarly, the Hamiltonian mass M_{Ham}, associated to the background singled out by the coordinate system of Proposition III.7, can be defined when R' is constant on $\partial_\infty\Sigma$. (This holds regardless of whether or not $\partial_x R'$ is constant on $\partial_\infty\Sigma$.) Proceeding as above, making use of Eqs. (III.42)–(III.47), one is led to

$$\begin{aligned} &g_\infty \neq 1 \Rightarrow M_{\mathrm{Haw}}(V) = |1-g_\infty|^{1/2} M_{\mathrm{Ham}}, \\ &g_\infty = 1, \quad A'_\infty = 4\pi l^2 \Rightarrow M_{\mathrm{Haw}}(V) = M_{\mathrm{Ham}}. \end{aligned} \tag{V.34}$$

VI. THE GENERALIZED PENROSE INEQUALITY

We recall here an argument of Geroch,[13] as extended by Jang and Wald,[19] and Gibbons,[18] for the validity of the Penrose inequality:[66]

Proposition VI.1: Assume we are given a three dimensional manifold (Σ, g) with connected boundary $\partial\Sigma$ such that:

(1) $R \geqslant 2\Theta$ for some strictly negative constant Θ.
(2) There exists a smooth, global solution of the inverse mean curvature flow without critical points, i.e., there exists a surjective function $u:\Sigma \to [0,\infty)$ such that du has no zeros and
$$\begin{aligned} &u|_{\partial\Sigma} = 0, \\ &\nabla_i \left(\frac{\nabla^i u}{|du|} \right) = |du|. \end{aligned} \tag{VI.1}$$
(3) The level sets of u
$$N_s = \{u(x) = s\}$$
are compact.
(4) The boundary $\partial\Sigma = u^{-1}(0)$ of Σ is minimal.
(5) The Hawking mass of the level sets of u as defined in (V.30) exists.

Then

$$2M_{\mathrm{Haw}}(u) \geqslant (1-g_{\partial\Sigma}) \left(\frac{A_{\partial\Sigma}}{4\pi} \right)^{1/2} - \frac{\Theta}{3} \left(\frac{A_{\partial\Sigma}}{4\pi} \right)^{3/2}. \tag{VI.2}$$

Here $A_{\partial\Sigma}$ is the area of $\partial\Sigma$ and $g_{\partial\Sigma}$ is the genus thereof.

Remarks: (1) The Proposition above can be applied to solutions of (I.4) and (I.5) with $\Theta = \Lambda$: in this case we have $R = 2\Lambda$; further Eq. (I.5) multiplied by V and contracted with two vectors tangent to $\partial\Sigma$ shows that the boundary $\{V=0\}$ is totally geodesic and hence minimal.

(2) Equation (VI.2) is sharp—the inequality there becomes an equality for the generalized Kottler metrics.

Proof: Let A_s denote the area of N_s, and define

$$\sigma(s) = \sqrt{A_s} \int_{N_s} \left({}^2R_s - \frac{1}{2} p_s^2 - \frac{2}{3}\Theta \right) d^2\mu_s, \tag{VI.3}$$

where ${}^2R_s$ is the scalar curvature of the metric induced on N_s, $d^2\mu_s$ is the Riemannian volume element associated to that same metric, and p_s is the mean curvature of N_s. The hypothesis that du is nowhere vanishing implies that all the objects involved are smooth in s. At $s=0$ we have

$$\sigma(0) = \sqrt{A_{\partial\Sigma}} \int_{\partial\Sigma} ({}^2R_0 - \tfrac{2}{3}\Theta) d^2\mu_0 = \sqrt{A_{\partial\Sigma}} (8\pi(1-g_{\partial\Sigma}) - \tfrac{2}{3}\Theta A_{\partial\Sigma}). \tag{VI.4}$$

On the other hand, $\lim_{s\to\infty}\sigma(s)=32\pi^{3/2}M_{\mathrm{Haw}}(u)$. The generalization in Ref. 18 of the classical calculation of Ref. 13 gives

$$\frac{\partial\sigma}{\partial s}\geqslant 0. \tag{VI.5}$$

This implies $\lim_{s\to\infty}\sigma(s)\geqslant\sigma(0)$, which gives (VI.2). □

To be able to carry out the above argument one had to assume that du had no zeros, which implies in particular that $\partial_\infty\Sigma$ is connected with $g_{\partial\Sigma}=g_\infty$. It is not known whether or not the other hypotheses of Proposition VI.1, or the conditions of Definition III.1 together with Eqs. (I.3)–(I.5), force $\partial\Sigma$ to be connected. If they do not, one is tempted to conjecture that the right inequality should be

$$2M_{\mathrm{Haw}}(u)\geqslant\sum_{i=1}^{k}\left((1-g_{\partial_i\Sigma})\left(\frac{A_{\partial_i\Sigma}}{4\pi}\right)^{1/2}-\frac{\Theta}{3}\left(\frac{A_{\partial_i\Sigma}}{4\pi}\right)^{3/2}\right). \tag{VI.6}$$

Here the $\partial_i\Sigma$'s, $i=1,\ldots,k$, are the connected components of $\partial\Sigma$, $A_{\partial_i\Sigma}$ is the area of $\partial_i\Sigma$, and $g_{\partial_i\Sigma}$ is the genus thereof. This would be the inequality one would obtain from the Geroch–Gibbons argument if it could be carried through for u's which are allowed to have critical points, on manifolds with $\partial_\infty\Sigma$ connected but $\partial\Sigma$ not necessarily connected.

We note that when $\Lambda=0$ there is a version of the proof of Proposition VI.1 due to Huisken and Ilmanen in which du is allowed to have zeros (with $\partial\Sigma$ connected).[67] Note that at points where du vanishes Eq. (VI.1) does not make sense classically, and has to be understood in a proper way. Further the monotonicity calculation of Ref. 13 breaks down at critical level sets of u, as those do not have to be smooth submanifolds. Nevertheless (when $\Lambda=0$) existence of appropriate functions u (perhaps with critical points) together with the monotonicity of σ can be established[14,15] when $\partial\Sigma$ is an outermost (necessarily connected) minimal sphere. It is conceivable that the argument of Huisken and Ilmanen can be modified to include the case $\Lambda\neq 0$. One of the difficulties here is to handle the possibly changing genus of the level sets of u.

Let us discuss some of the consequences of the (hypothetical) Eq. (VI.6). To proceed further it is convenient to introduce a mass parameter m defined as follows:

$$m=\begin{cases} M_{\mathrm{Haw}}, & \partial_\infty\Sigma=S^2,\\ M_{\mathrm{Haw}}, & \partial_\infty\Sigma=T^2, \text{ with the normalization } A'_\infty=4\pi l^2,\\ \dfrac{M_{\mathrm{Haw}}}{|g_{\partial_\infty\Sigma}-1|^{3/2}}, & g_{\partial_\infty\Sigma}>1. \end{cases} \tag{VI.7}$$

Strictly speaking, we should write $m(u)$ if $M_{\mathrm{Haw}}(u)$ is used above, $m(V)$ if $M_{\mathrm{Haw}}(V)$ is used, etc.; we shall do this when confusions are likely to occur. For generalized Kottler metrics the mass $m=m(u)$ so defined coincides with the mass parameter appearing in (I.1) when u is the radial solution $u=u(r)$ of the problem (VI.1); $m(V)$ coincides with the coordinate mass M_c for the metrics considered here when M_c is defined, cf. Eq. (V.32).

Note, first, that if all connected components of the horizon have spherical or toroidal topology, then the lower bound (VI.6) is strictly positive. For example, if $\partial\Sigma=T^2$, and $\partial_\infty\Sigma=T^2$ as well we obtain

$$2m\geqslant\frac{1}{l^2}\left(\frac{A_{\partial\Sigma}}{4\pi}\right)^{3/2}.$$

On the other hand, if $\partial\Sigma=T^2$ but $g_{\partial_\infty\Sigma}>1$ from Eq. (VI.6) one obtains

$$2m \geqslant \frac{1}{l^2|g_\infty - 1|}\left(\frac{A_{\partial\Sigma}}{4\pi}\right)^{3/2}.$$

Let us return to the case where Eqs. (I.3)–(I.5) hold;[68] we can then use the Galloway–Schleich–Witt–Woolgar inequality[4]

$$\sum_{i=1}^{k} g_{\partial_i\Sigma} \leqslant g_\infty . \tag{VI.8}$$

It implies that if $\partial_\infty\Sigma$ has spherical topology, then all connected components of the horizon must be spheres. Similarly, if $\partial_\infty\Sigma$ is a torus, then all components of the horizon are spheres, except perhaps for at most one which could be a torus. It follows that to have a component of the horizon which has genus higher than one we need $g_\infty > 1$ as well.

When some—or all—connected components of the horizon have genus higher than one the right-hand side of Eq. (VI.6) might become negative. Minimizing the generalized Penrose inequality (VI.6) with respect to the areas of the horizons gives the following interesting inequality:

$$M_{\mathrm{Haw}}(u) \geqslant -\frac{1}{3\sqrt{-\Lambda}} \sum_i |g_{\partial_i\Sigma} - 1|^{3/2}, \tag{VI.9}$$

where the sum is over those connected components $\partial_i\Sigma$ of $\partial\Sigma$ for which $g_{\partial_i\Sigma} \geqslant 1$. Equation (VI.9), together with the elementary inequality $\Sigma_{i=1}^N |\lambda_i|^{3/2} \leqslant (\Sigma_{i=1}^N |\lambda_i|)^{3/2}$, lead to

$$m \geqslant -\frac{1}{3\sqrt{-\Lambda}}. \tag{VI.10}$$

The Geroch–Gibbons argument establishing the inequality (VI.4) when a suitable u exists can also be *formally* carried through when $\partial\Sigma = \varnothing$. In this case one still considers solutions u of the differential equation that appears in Eq. (VI.1), however the Dirichlet condition on u at $\partial\Sigma$ is replaced by a condition on the behavior of u near some chosen point $p_0 \in \Sigma$. If the level set of u around p_0 approach distance spheres centered at p_0 at a suitable rate, then $\sigma(s)$ tends to zero when the N_s's shrink to p_0, which together with the monotonicity of σ leads to the positive energy inequality:

$$M_{\mathrm{Haw}}(u) \geqslant 0. \tag{VI.11}$$

It should be emphasized that the Horowitz–Myers solutions[23] with negative mass show that this argument breaks down when $g_\infty = 1$.

When $\partial_\infty\Sigma = S^2$ one expects that (VI.11), with $M_{\mathrm{Haw}}(u)$ replaced by the spinorially defined mass (which might perhaps coincide with $M_{\mathrm{Haw}}(u)$, but this remains to be established), can be proved by Witten-type techniques, compare Refs. 24 and 25. On the other hand it follows from Ref. 26 that when $\partial_\infty\Sigma \neq S^2$ there exist no asymptotically covariantly constant spinors which can be used in the Witten argument. The Geroch–Gibbons argument has a lot of ''ifs'' attached in this context, in particular if $\partial_\infty\Sigma \neq S^2$ then some level sets of u are necessarily critical and it is not clear what happens with σ when a jump of topology from a sphere to a higher genus surface occurs. We note that the area of the horizons does not occur in (VI.10) which, when $g_{\partial_\infty\Sigma} > 1$, suggests that the correct inequality is actually (VI.10) rather than (VI.11).

VII. MASS AND AREA INEQUALITIES

A. Preliminaries

Let (Σ,g,V) satisfy (I.3)–(I.5) together with the topological, the differential, and the asymptotic requirements spelled out in the statements of Theorems I.3 or I.5. (Lemma VII.3 below actually holds under more general conditions.) We first introduce the surface gravity κ of $\partial\Sigma$ to be the corresponding restriction of the function $\sqrt{W}$ defined by (III.16):

$$\kappa \equiv |dV|_g|_{\partial\Sigma}, \tag{VII.1}$$

where we have normalized V so that Eq. (III.21) holds, cf. Proposition III.3. By the strong maximum principle (Ref. 69, Lemma 3.4) W is nowhere vanishing on $\partial\Sigma$. Moreover, it is well known [and easily seen using Eq. (I.5)] that κ is locally constant on $\partial\Sigma$:

$$0 = n^j D_i D_j V|_{V=0} = \frac{D^j V}{\sqrt{W}} D_i D_j V|_{V=0} = \frac{1}{2\sqrt{W}} D_i W|_{V=0}. \tag{VII.2}$$

Here n^i is the unit normal to $\partial\Sigma$, where V vanishes. It is convenient to introduce the notion of a *reference solution* (RS): this is a generalized Kottler solution with the same genus g_∞ as (Σ,g,V). Moreover, if $\partial\Sigma\neq\emptyset$, the surface gravity κ of the RS is chosen to be equal to the maximum of the surface gravities of (Σ,g,V). On the other hand, if $\partial\Sigma=\emptyset$, the mass of the RS will be specified suitably below, in the proof of (I.3). It should be stressed, that we are *not* comparing manifolds and/or metrics, but we are only using the resulting scalar functions V and W:

We only consider RS with mass m_0 in the range (II.6) (if $\partial\Sigma\neq\emptyset$, this property follows from the restriction (I.7) on κ). Let $r(\cdot)$ be the function $V_0\to r(V_0)$ constructed at the end of Sec. II, composing r with V we obtain functions $r(V(\cdot))$ and $W_0(r(V(\cdot)))$ defined on Σ. By an abuse of notation we shall still denote those functions by r and W_0.

Remark: In the same manner, we can define a RS from other solutions with the property that W is a function of V only. (In Lemma VII.3 below we will also include the Nariai case.)

Following Ref. 70 we define $\psi(V)$ to be that unique solution of the equation

$$\psi^{-1}\frac{d\psi}{dV} = -VW_0^{-1}\frac{m_0}{r^3} \tag{VII.3}$$

which goes[71] to 1 as V goes to ∞. (In particular $\psi\equiv 1$ when $m_0=0$.) Here $r=r(V)$ is again the function defined at the end of Sec. II. Standard results on ODE's show that solutions of (VII.3) have no zeros unless identically vanishing, and that

$$\Psi \equiv \psi\circ V$$

can be extended by continuity to a smooth function on $\overline{\Sigma}$, still denoted by Ψ, which satisfies

$$\Psi>0, \quad \Psi|_{\partial_\infty\Sigma}=1.$$

We also define

$$\tilde{g}_{ij} = V^{-2}\Psi^4 g_{ij}, \quad \tilde{W}=\Psi^{-4}W, \quad \tilde{W}_0=\Psi^{-4}W_0. \tag{VII.4}$$

We proceed with a computation which is required in Lemma VII.1 as well as in Lemma VII.2. Consider a level set $\{V=\text{const}\}$ of V which is a smooth hypersurface in $\overline{\Sigma}$, with unit normal n_i, induced metric h_{ij}, scalar curvature ${}^2\mathcal{R}$, second fundamental form p_{ij} defined with respect to an inner pointing normal, mean curvature $p=h^{ij}p_{ij}$; we denote by q_{ij} the trace-free part of p_{ij}: $q_{ij}=p_{ij}-\frac{1}{2}h_{ij}p$. Using Eq. (II.4), the Eq. (I.4) with $g=g_0$ and $V=V_0$, together with the relation $dV_0/dr=\sqrt{W_0}/V_0$ we obtain

$$V^{-1}\frac{dW_0}{dV}=-\frac{2}{3}\Lambda-\frac{4m_0}{r^3}. \tag{VII.5}$$

To obtain (VII.6) we use, in this order, the definitions (VII.4), the Eqs. (I.4)–(I.5), Eqs. (VII.5) and (VII.3), and the Codazzi–Mainardi equation:

$$\begin{aligned}V^{-1}\tilde{W}^{-1}D^iVD_i(\tilde{W}-\tilde{W}_0)&=V^{-1}W^{-1}D^iV(D_iW)-V^{-1}\frac{dW_0}{dV}-4V^{-1}\Psi^{-1}\frac{d\Psi}{dV}(W-W_0)\\&=(2R_{ij}-Rg_{ij})n^in^j+\frac{2}{3}\Lambda+\frac{4m_0}{r^3}-\frac{4m_0}{r^3}(1-W_0^{-1}W)\\&=-{}^2\mathcal{R}-q_{ij}q^{ij}+\frac{1}{2}p^2+\frac{2}{3}\Lambda+\frac{4m_0}{r^3}-\frac{4m_0}{r^3}(1-W_0^{-1}W).\end{aligned} \tag{VII.6}$$

Lemma VII.1: Under the conditions of Theorem I.1, suppose further that the scalar curvature R' of the metric $g'=V^{-2}g$ is constant on $\partial_\infty\Sigma$. Let V be normalized so that (III.21) holds, with $A'_\infty=4\pi l^2$ when $\partial_\infty\Sigma=T^2$. If m is the Hawking mass parameter defined as in (VI.7), then

$$\int_{\partial_\infty\Sigma}D'_i(\tilde{W}-\tilde{W}_0)dS'^i=-\left(\frac{2\Lambda}{3}\right)^2A'_{\partial_\infty\Sigma}(m-m_0), \tag{VII.7}$$

where dS'^i denotes the outer-oriented area element of the metric $g'=V^{-2}g$, and $A'_{\partial_\infty\Sigma}$ is the area of $\partial_\infty\Sigma$ with respect to that metric.

Proof: Using

$$D'^i(\tilde{W}-\tilde{W}_0)n'_i=\frac{1}{\sqrt{W'}}D_i(\tilde{W}-\tilde{W}_0)D^iV \tag{VII.8}$$

and (VII.6), the left-hand side of (VII.7) reads

$$\int_{\partial_\infty\Sigma}\frac{V\tilde{W}}{\sqrt{W'}}\left[-{}^2\mathcal{R}-q_{ij}q^{ij}+\frac{1}{2}p^2+\frac{2}{3}\Lambda+\frac{4m_0}{r^3}-\frac{4m_0}{r^3}(1-W_0^{-1}W)\right]d^2\mu_{g'}, \tag{VII.9}$$

where $d^2\mu_{g'}$ is the two-dimensional surface measure associated with the metric g'. Chasing through the definitions one finds that $V\tilde{W}/\sqrt{W'}\approx\sqrt{-(\Lambda/3)}V^3$ near $\partial_\infty\Sigma$. From the definition of V_0 we further have $r\approx\sqrt{-(3/\Lambda)}V$, again near $\partial_\infty\Sigma$, so that $\lim_{V\to\infty}V\tilde{W}/(\sqrt{W'}r^3)=(-\Lambda/3)^2$. It follows that the second to last term in (VII.9) gives a contribution

$$\left(\frac{2\Lambda}{3}\right)^2A'_{\partial_\infty\Sigma}m_0, \tag{VII.10}$$

where $A'_{\partial_\infty\Sigma}$ denotes the g' area of the connected component of $\partial_\infty\Sigma$ under consideration. Equation (III.15) and its equivalent with W replaced by W_0 show that $(1-W_0^{-1}W)\to_{V\to\infty}0$ so that the last term drops out from (VII.9). Furthermore, by Eq. (III.25) we have $(V\tilde{W}/\sqrt{W'})\,q_{ij}q^{ij}=O(V^{-3})\to_{V\to\infty}0$, and it remains to analyze the contribution of $-V\tilde{W}({}^2\mathcal{R}-\frac{1}{2}p^2-\frac{2}{3}\Lambda)/\sqrt{W'}$ to the integral (VII.7). To do this, note that

$$A_{1/\epsilon}\equiv A(\{V=1/\epsilon\})=\int_{V'=\epsilon}d^2\mu_g=\int_{V'=\epsilon}V^2\,d^2\mu_{g'}\approx\epsilon^{-2}A'_{\partial_\infty\Sigma},$$

where $d^2\mu_g$ is the induced measure on $\partial_\infty\Sigma$ associated with the metric g. It follows that

$$
\begin{aligned}
&-\int_{V'=\epsilon}\frac{V\tilde{W}}{\sqrt{W'}}\left({}^2\mathcal{R}-\frac{1}{2}p^2-\frac{2}{3}\Lambda\right)d^2\mu_{g'}\\
&\quad\approx-\sqrt{-\frac{\Lambda}{3}}\frac{1}{\epsilon}\int_{V'=\epsilon}\left({}^2\mathcal{R}-\frac{1}{2}p^2-\frac{2}{3}\Lambda\right)d^2\mu_g\\
&\quad\approx-\sqrt{-\frac{\Lambda}{3}}\sqrt{\frac{A_{1/\epsilon}}{A'_{\partial_\infty\Sigma}}}\int_{V'=\epsilon}\left({}^2\mathcal{R}-\frac{1}{2}p^2-\frac{2}{3}\Lambda\right)d^2\mu_g\to_{\epsilon\to 0}-\left(\frac{2\Lambda}{3}\right)^2A'_{\partial_\infty\Sigma}m,
\end{aligned}
\tag{VII.11}
$$

where

$$
m\equiv\lim_{\epsilon\to 0}\frac{1}{4}\left(-\frac{\Lambda A'_{\partial_\infty\Sigma}}{3}\right)^{-3/2}\sqrt{A_{1/\epsilon}}\int_{\{V=1/\epsilon\}}\left({}^2\mathcal{R}-\frac{1}{2}p^2-\frac{2}{3}\Lambda\right)dA. \tag{VII.12}
$$

To finish the proof we need to show that m in (VII.12) is indeed the Hawking mass as defined in Eq. (VI.7). In the torus case this follows immediately from the normalization condition $A'_\infty=4\pi l^2$; for the remaining topologies this can be seen as follows: if V is normalized so that (III.21) holds, then (III.20) implies ${}^2\mathcal{R}'|_{x=0}=-\frac{2}{3}\Lambda k$. When $g_\infty\neq 1$ the Gauss–Bonnet theorem gives

$$
8\pi|1-g_\infty|=\left|\int {}^2\mathcal{R}'\,d^2\mu_{g'}\right|=-\tfrac{2}{3}\Lambda A'_{\partial_\infty\Sigma},
$$

which shows that the mass defined by Eq. (VII.12) coincides with that of (VI.7). □

For the subsequent lemma, recall from Theorem I.3 that $\partial_1\Sigma$ refers to the component of Σ with the largest surface gravity.

Lemma VII.2: Under the conditions of Theorem I.1, we have

$$
\int_{\partial_1\Sigma}\tilde{W}^{-1/2}\tilde{D}_i(\tilde{W}-\tilde{W}_0)d\tilde{S}^i=8\pi\left[(g_{\partial_1\Sigma}-1)-\frac{A_{\partial_1\Sigma}}{A_0}(g_\infty-1)\right]. \tag{VII.13}
$$

Proof: We integrate (VII.6) over $\partial_1\Sigma$. We note that Eq. (I.5) multiplied by V and contracted with two vectors tangent to $\partial\Sigma$ shows that $\partial\Sigma$ is totally geodesic; equivalently, $q_{ij}=0$. We introduce ${}^2\mathcal{R}_0=\frac{2}{3}\Lambda+(4m_0/r_0^3)$, the scalar curvature of the metric $d\Omega_k^2$. Using (VII.6) and the Gauss–Bonnet theorem, the left-hand side of (VII.13) can be written as

$$
\int_{\partial_1\Sigma}\left(-{}^2\mathcal{R}+\frac{2}{3}\Lambda+\frac{4m_0}{r_0^3}\right)dA=\int_{\partial_1\Sigma}(-{}^2\mathcal{R}+{}^2\mathcal{R}_0)dA=8\pi(g_{\partial_1\Sigma}-1)+{}^2\mathcal{R}_0A_{\partial_1\Sigma}. \tag{VII.14}
$$

Equation (VII.13) is then obtained by eliminating ${}^2\mathcal{R}_0$ from (VII.14), using the Gauss–Bonnet theorem for the generalized Kottler metrics: $8\pi(1-g_\infty)={}^2\mathcal{R}_0A_0$. □

The following elliptic equation for $\tilde{W}-\tilde{W}_0$ will be the crucial ingredient in the proof of the theorems. It is also useful for Lemma VII.3.

$$
(\tilde{\Delta}-a)(\tilde{W}-\tilde{W}_0)=\tfrac{1}{4}\tilde{W}^{-1}\tilde{R}_{ijk}\tilde{R}^{ijk}+\tfrac{3}{4}\tilde{W}^{-1}\tilde{D}_i(\tilde{W}-\tilde{W}_0)\tilde{D}^i(\tilde{W}-\tilde{W}_0), \tag{VII.15}
$$

with

$$a=\frac{5}{3r^3}m_0\Lambda V^4 W_0^{-2}\tilde{W}, \tag{VII.16}$$

$\tilde{\Delta}$ being the Laplace operator of the metric $\tilde{g}_{ij}$, and $\tilde{R}_{ijk}$—the Cotton tensor of $\tilde{g}_{ij}$. This equation is obtained by specializing[72] Eq. (V.4) of Ref. 70 (which has been used in that paper in the context of a uniqueness proof for static perfect fluid solutions) to the present case with $8\pi\rho=-8\pi p=\Lambda$.

It is important to stress that Eq. (VII.15), as it stands, makes only sense on the set $\{dV\neq 0\}$, because of the factors $\tilde{W}^{-1}$ appearing there. However, it follows from Eq. (I.4) that the set $\{dV=0\}$ has no interior: indeed, if dV vanishes on a connected open set then V is constant there, which is compatible with Eq. (I.5) only if V vanishes there. This contradicts our hypothesis that V vanishes only on $\partial\Sigma$. Hence Eq. (VII.15) holds on an open dense set of Σ. Since the left-hand side of Eq. (VII.15) is a smooth function on $\Sigma\backslash\partial\Sigma$, the right-hand side thereof is smoothly extendible by continuity to a smooth function on $\Sigma\backslash\partial\Sigma$, and Eq. (VII.15) holds everywhere on this set with the right-hand side being understood in the sense explained here.

Lemma VII.3: Let $\Lambda\in\mathbb{R}$, and let (Σ,g,V) be a solution of (I.3)–(I.5) such that

(a) either $W\equiv W_0$ for W_0 defined from the generalized Kottler or from the Nariai solution (I.2), or
(b) (Σ,g) is locally conformally flat.

Suppose further that Σ is a union of compact boundary-less level sets of V. Then

(1) Every connected component $\mathcal{V}$ of the set $\{p\in\Sigma\,|\,dV(p)\neq 0\}$ ''corresponds to'' one of the generalized Kottler solutions (I.1), or to one of the generalized Nariai solutions (I.2), or is flat. More precisely, there exists an interval $J\subset\mathbb{R}$, a two-dimensional compact Riemannian manifold $({}^2M,d\Omega_k^2)$, with $d\Omega_k^2$ an (r-independent) metric of constant Gauss curvature $k=0,\pm 1$, and a diffeomorphism $\psi:\mathcal{V}\to J\times{}^2M$ such that, transporting g and V to $J\times{}^2M$ using ψ, we have:

(i) Either there exists a constant $\lambda>0$ such that $V=\lambda V_0$ and
$$g=V_0^{-2}\,dr^2+r^2\,d\Omega_k^2,\quad r\in J,\quad V_0^2=k-\frac{2m}{r}-\frac{\Lambda}{3}r^2, \tag{VII.17}$$
(ii) or, when $k\Lambda>0$, there exists a constant $\lambda\in\mathbb{R}$ ($\lambda>0$ if $\Lambda>0$) such that
$$g=V^{-2}\,dz^2+|\Lambda|^{-1}\,d\Omega_k^2,\quad z\in J,\quad V^2=\lambda-\Lambda z^2, \tag{VII.18}$$
(iii) or, when $k=\Lambda=0$, there exists a constant $\lambda>0$ such that $V=\lambda z$ and
$$g=dz^2+d\Omega_k^2,\quad z\in J. \tag{VII.19}$$
(In each case the interval J is constrained by the condition that V and V^2 be non-negative).

(2) Under condition (a). above, if Σ is connected and if W_0 (considered as a function of V) has no zeros in the interval where V takes its values,
$$\forall p\in\Sigma\quad W_0(V(p))\neq 0, \tag{VII.20}$$
then $\mathcal{V}=\Sigma$, thus Eqs. (VII.18) or (VII.17) hold globally on Σ.

Remarks:

(1) Here we do not make any hypotheses on the sign of Λ.
(2) The result is local, in particular it is sufficient to be able to invert $r_0(V_0)$ locally on the range of the values of V under consideration to obtain $W_0(V)$.
(3) The set (Σ,g,V) corresponding to the metric (VII.19) arises from a boost Killing vector in suitably identified Minkowski space–time.
(4) We note that the set $\mathcal{V}$ could be empty, as is the case for $\mathbb{R}\times T^3$ with the obvious flat metric. Our analysis does not say anything about the metric on regions where dV vanishes.

(5) We note that the generalized Kottler and the generalized Nariai metrics also arise naturally in the generalized Birkhoff theorem, see Refs. 73 and 74, and also Ref. 75 for a very clear treatment in the $\Lambda>0$ case.
(6) The lemma can easily be reformulated by taking any conformally flat solution of (I.4)-(I.5) as a reference solution. The condition of conformal flatness is required to ensure that (VII.15) holds and excludes, in particular, the Horowitz–Myers solutions with a toroidal I^+ (Ref. 23) as RS.

Proof: The proof is an adaptation of an argument of Ref. 76 to the current setting. Suppose that $W=W_0$ for some W_0; Eq. (VII.15) shows then that $\tilde{R}_{ijk}\tilde{R}^{ijk}$ vanishes, so that (Σ,g) is locally conformally flat. It then follows that condition (b). holds in both cases.

We start by removing from Σ some undesirable points: set

$$\Sigma_{\text{sing}}\equiv\{p\in\Sigma\,|\,\text{the connected component of the set } \{q|V(q)=V(p)\} \text{ containing } p \text{ contains a point } r \text{ such that } dV(r)=0.\},$$

$$\Sigma'\equiv\Sigma\backslash\Sigma_{\text{sing}}.$$

Σ_{sing} is a closed subset of Σ, so that Σ' is still a manifold. It follows from Sard's theorem that $\Sigma'\neq\varnothing$. We note that Σ' still satisfies all the hypotheses of the lemma, except perhaps for being connected. By construction all the level sets of V are noncritical in Σ'. (Recall that a level set $\{V=c\}$ of V is noncritical if dV is nowhere vanishing on $\{V=c\}$.)

Let $\mathcal{U}$ to be any connected component of Σ'. Compactness of the level sets of V implies[77] that $\mathcal{U}$ is diffeomorphic to $I\times{}^2M$, for some two-dimensional compact connected manifold ${}^2M$ and some interval $I\subset\mathbb{R}$, with V equal to c on $\{c\}\times{}^2M$, $c\in I$, and that on $\mathcal{U}$ the function V can be used as a coordinate. Further we can introduce on ${}^2M$ a finite number of coordinate patches with coordinates x^A, $A=1,2$, so that on $\mathcal{U}$ the metric takes the form

$$g=W^{-1}\,dV^2+h_{AB}\,dx^A\,dx^B. \tag{VII.21}$$

Let, as before, $q_{AB}\,dx^A\,dx^B$ be the trace free part of the extrinsic curvature tensor of the level sets of V—in the coordinate system of (VII.21)

$$q_{AB}=\sqrt{W}\left(\frac{\partial h_{AB}}{\partial V}-\frac{1}{2}h^{CD}\frac{\partial h_{CD}}{\partial V}h_{AB}\right). \tag{VII.22}$$

Equations (VII.22) and (III.23) imply that q_{AB} vanishes hence $\partial h_{AB}/\partial V$ is pure trace, that $W=W(V)$, and that $\det\gamma_{AB}$ is a product of a function of V with a function of the remaining coordinates. We thus have

$$h=W(V)^{-1}\,dV^2+r(V)^2\,d\Omega^2 \tag{VII.23}$$

for some positive function $r(V)$, where $d\Omega^2$ is a V-independent metric on ${}^2M$. Next, from (I.5) and from the Codazzi–Mainardi equations (VII.24),

$$R'_{1a}=-D'_ap'+D'_bp'^b_a=-\tfrac{1}{2}D'_ap'+D'_bq'^b_a \tag{VII.24}$$

[here we are using the adapted coordinate system of Eq. (III.28) with $x^1=x$ and with the indices $a,b=2,3$ corresponding to the remaining coordinates; further D' denotes the Levi–Civita derivative associated with the metric h'], respectively (III.31), applied to ${}^2M\subset\mathcal{U}$, we find that the mean curvature p of all level surfaces, respectively, their Ricci scalars, are constant. Hence $({}^2M,d\Omega^2)$ is a space of constant curvature, and scaling r appropriately we can without loss of generality assume that the Gauss curvature k of the metric $d\Omega^2$ equals $0,\pm1$, as appropriate to the genus of ${}^2M$. We define

$$L=\frac{dW}{dV}+2\Lambda V. \tag{VII.25}$$

Evaluating (I.4) for the metric (VII.23), we find

$$\frac{dr}{dV}=-\frac{rL}{4W}. \tag{VII.26}$$

Equations (I.4)–(I.5) for the metric (VII.23) are equivalent to (VII.25)–(VII.26) together with

$$2W\left(\Lambda-\frac{k}{r^2}\right)=L\left(V^{-1}W-\frac{L}{8}\right), \tag{VII.27}$$

$$W\frac{dL}{dV}=\frac{3}{4}L^2+(V^{-1}W-\Lambda V)L. \tag{VII.28}$$

These equations arise, e.g., by adapting Eqs. (3.16) and (3.17) of Ref. 70 to the present case (namely by setting $8\pi\rho=-8\pi p=\Lambda$, $L_1=L$ and $C^2=k$, and allowing the constant k to take negative values). Suppose, first, that there exists V_* such that $L(V_*)=0$. Equation (VII.28) shows then that $L\equiv 0$, and from (VII.27) one obtains

$$\Lambda=\frac{k}{r^2}. \tag{VII.29}$$

If $k=0$ then Λ vanishes as well; further r is constant by Eq. (VII.26) and can therefore be absorbed into $d\Omega^2$. Integrating Eq. (VII.25) one finds that there exists a strictly positive constant λ such that $W=\lambda^2$, defining a coordinate z by the equation $z=V/\lambda$ proves point (iii) on $\mathcal{U}$. Next, if $k\neq 0$ Eq. (VII.29) gives $k\Lambda>0$ as desired, together with $r^2=-1/|\Lambda|$. Integrating Eq. (VII.25) one obtains $W=\Lambda(\lambda-V^2)$, for some constant $\lambda\in\mathbb{R}$. Introducing the coordinate z via the equation $V^2=\lambda-\Lambda z^2$ establishes point (1ii). on $\mathcal{U}$.

In the case of L without zeros we obtain, from (VII.25), (VII.26), and (VII.28), that $(d/dV)(V\sqrt{W}/rL)=0$, which implies that there exists a nonvanishing constant α such that

$$L=\alpha V\frac{\sqrt{W}}{r}. \tag{VII.30}$$

Using (VII.26) one is led to

$$\frac{dV}{dr}=-\frac{4\sqrt{W}}{\alpha V}. \tag{VII.31}$$

Next we define

$$m(V)=-\frac{\alpha}{4}r^2\sqrt{W}+\frac{\Lambda r^3}{3}; \tag{VII.32}$$

from (VII.25), (VII.30), and (VII.31) we obtain $dm/dV=0$, i.e., m is a constant. Equation (VII.27) gives $V^2=(16/\alpha^2)[k-(2m/r)-(\Lambda/3)r^2]$. Equation (VII.26) shows that we can use r as a coordinate, and Eq. (VII.31) implies that the metric is of the desired form (VII.17). This establishes point (1i) on $\mathcal{U}$.

Let $\mathcal{V}$ be the connected component of $\{dV\neq 0\}\subset\Sigma$ that contains $\mathcal{U}$. To establish point (1) of the lemma we need to show that $\mathcal{V}=\mathcal{U}$. We claim that $\mathcal{U}$ is open in V—and hence in Σ—which can be seen as follows: Let $p\in\mathcal{U}$, we thus have $dV(q)\neq 0$ for all q such that $V(p)=V(q)$. By

Eq. (VII.23) $|dV|_g=\sqrt{W}$ is constant on the intersection with $\mathcal{U}$ of the level set $V^{-1}(V(p))$ of V through p, so that $\inf_{V^{-1}(V(p))\cap\mathcal{U}}|dV|_g>0$, which easily implies that all nearby level sets in $\mathcal{U}\subset\Sigma'$ are noncritical.

Let us show now that $\mathcal{U}$ is closed in $\mathcal{V}$. To see that, consider a sequence $p_i\in\mathcal{U}$ such that $p_i\to p\in V$. By definition of $\mathcal{V}$ the function $|dV|_g$ has no zeros on V, hence $dV(p)\neq 0$. Now it follows from (III.23) that $|dV|_g$ is locally constant on smooth subsets of level sets of V, which easily implies (a) that the connected component of $V^{-1}(V(p))$ containing p is smooth and (b) that $|dV|_g$ is nowhere vanishing there. Compactness of the level sets of V implies that all the connected components of level sets intersecting a neighborhood of p are noncritical, and hence are in Σ'. It then follows that $p\in\mathcal{U}$.

We have thus shown that $\mathcal{U}$ is both open and closed in $\mathcal{V}$; connectedness of $\mathcal{V}$ shows that $\mathcal{U}=\mathcal{V}$, and point (1) is established.

To prove point (2), we note that the equality $W(p)=W_0(V(p))$ together with Eq. (VII.20) shows that V has no critical points on Σ; as Σ is connected the set $\mathcal{V}$ of point (1) coincides with Σ, and point (2) follows from point (1). □

B. Proofs

Proof of Theorem I.3: Suppose that $\partial\Sigma=\varnothing$. We first consider as RS a generalized Kottler solution with $m=0$ [see Eq. (II.5)]: This leads to

$$\Psi\equiv 1,\quad \widetilde{W}_0(V_0)=-\frac{\Lambda}{3}(V_0^2-k). \tag{VII.33}$$

We further normalize V as in Proposition III.3, so that by (III.15), (III.19), and (III.21) we have $\widetilde{W}-\widetilde{W}_0\to_{r\to\infty}0$. (Actually when $\partial_\infty\Sigma=T^2$, the normalization of V does not play any role, as we make claims only about the sign of m in this case.) Equation (VII.15) together with the maximum principle shows that

$$\widetilde{W}-\widetilde{W}_0\leqslant 0\quad \text{on } \Sigma, \tag{VII.34}$$

$$n'^i D'_i(\widetilde{W}-\widetilde{W}_0)|_{\partial_\infty\Sigma}\geqslant 0, \tag{VII.35}$$

where n' is the *outer* pointing g'-unit normal to $\partial_\infty\Sigma$. Further, equality is attained in (VII.34) or in (VII.35) if and only if $W\equiv W_0$ (Ref. 69, Theorems 3.5 and 3.6). Thus Lemma VII.1 together with Eq. (VII.35) shows that $m\leqslant 0$. Assume now that $m=0$ in the case $\partial_\infty\Sigma=S^2$; as an indirect argument, we also assume that $m=0$ in the T^2 case, or that $m\geqslant m_{\text{crit}}$ in the remaining cases. In the sphere or torus case from the strong maximum principle we obtain

$$W\equiv W_0. \tag{VII.36}$$

In the higher genus cases we consider (VII.15) again but take here as RS a generalized Kottler solution with the same mass as the given one, $m_0=m$. Equations (VII.34)–(VII.35) hold again; then Lemma VII.1 shows that equality must hold in (VII.35). Applying the maximum principle again yields Eq. (VII.36). We note that both point (a) as well as the structural hypotheses of Lemma VII.3 hold under the hypotheses of Theorem I.3. Equation (VII.36) and the discussion of Sec. II show that point (2) of that lemma applies, so that the given solution must be a member of the generalized Kottler family with m in the range (II.6) (the generalized Nariai metrics are excluded as they do not satisfy the asymptotic hypotheses of Theorem I.3). In the case $\partial_\infty\Sigma=S^2$ point (1) readily follows. In the remaining cases none of these solutions has the topology required in Theorem I.3, which gives a contradiction and establishes Theorem I.3. □

Proof of Theorem I.5: By choice of the RS we have $(\widetilde{W}-\widetilde{W}_0)|_{\partial\Sigma}=0$. We normalize V again so that $\lim_{\to\infty}(\widetilde{W}-\widetilde{W}_0)=0$ holds, cf. Proposition III.3 and Eq. (III.15). Negativity of m_0 implies

that a in (VII.15) is non-negative. The maximum principle applied to Eq. (VII.15) gives $\tilde{W}-\tilde{W}_0\leqslant 0$ on Σ, with equality being achieved somewhere if and only if $W\equiv W_0$. Moreover, as in the proof of point (2) the boundary version of the strong maximum principle (Ref. 69, Theorem 3.6) implies that $n^{i\prime}D_i'(\tilde{W}-\tilde{W}_0)>0$ on $\partial_\infty\Sigma$ unless $W=W_0$. Lemma VII.1 allows us to conclude that either $m<m_0$ or $W\equiv W_0$. In that last case point (2) of Lemma VII.3 implies that (Σ,g,V) corresponds to a generalized Kottler solution. In any case there holds $m\leqslant m_0$.

To prove the area inequality in (I.8) requires some care as the metric $\tilde{g}$ defined in Eq. (VII.4) is singular at Σ, so that standard maximum principle arguments such as Ref. 69, Theorem 3.6 do not apply. We proceed as follows. By choice of W_0 we have $\tilde{W}=\tilde{W}_0$ on $\partial_1\Sigma$. Further, Eq. (VII.2) shows that $n^iD_i(\tilde{W}-\tilde{W}_0)$ vanishes there. De l'Hospital's rule, the nonvanishing of dV at $\partial\Sigma$, and the requirement $\tilde{W}-\tilde{W}_0\leqslant 0$ lead to

$$n^jn^iD_iD_j(\tilde{W}-\tilde{W}_0)|_{\partial\Sigma}=\lim_{V\to 0}\frac{D^iVD_i(\tilde{W}-\tilde{W}_0)}{V}\leqslant 0.$$

It follows that the left-hand side of Eq. (VII.13) is nonpositive, which establishes the second part of (I.8). □

Proof of Corollary I.6: Assume that $\partial\Sigma$ is connected and that (VI.2) holds; we want to show that (I.8) implies an inequality inverse to (VI.2). In order to do this, note first that by (I.8) the mass m is nonpositive, and Eq. (VI.2) implies that $g_{\partial\Sigma}>1$. It is useful to introduce a genus-rescaled area radius $r_{\partial\Sigma}$ by the formula

$$r_{\partial\Sigma}=\sqrt{\frac{A_{\partial\Sigma}}{4\pi(g_{\partial\Sigma}-1)}}.$$

In terms of this object, the inequality (VI.2) reads

$$2m|g_\infty-1|^{3/2}+\left(r_{\partial\Sigma}+\frac{\Lambda}{3}r_{\partial\Sigma}^3\right)|g_{\partial\Sigma}-1|^{3/2}\geqslant 0. \tag{VII.37}$$

It follows that $r_{\partial\Sigma}+(\Lambda/3)r_{\partial\Sigma}^3\geqslant 0$, and the Galloway–Schleich–Witt–Woolgar inequality[4] $g_{\partial\Sigma}\leqslant g_\infty$ implies

$$2m+r_{\partial\Sigma}+\frac{\Lambda}{3}r_{\partial\Sigma}^3\geqslant 0. \tag{VII.38}$$

Let us denote by r_0 the $r_{\partial\Sigma}$ corresponding to the relevant generalized Kottler solution:

$$r_0=\sqrt{\frac{A_0}{4\pi(g_{\partial_\infty\Sigma}-1)}}.$$

The inequality (VII.38) is actually an equality for the generalized Kottler solutions, therefore it holds that $2m_0+r_0+(\Lambda/3)r_0^3=0$. We have $r_0\geqslant 1/\sqrt{-\Lambda}$ from (II.8), and $m\leqslant m_0$, $r_{\partial\Sigma}\geqslant r_0$ from (I.8), so that

$$\begin{aligned}2m+r_{\partial\Sigma}+\frac{\Lambda}{3}r_{\partial\Sigma}^3&=2m+r_{\partial\Sigma}+\frac{\Lambda}{3}r_{\partial\Sigma}^3-2m_0-r_0-\frac{\Lambda}{3}r_0^3\\&=2(m-m_0)+(r_{\partial\Sigma}-r_0)\left[1+\frac{\Lambda}{3}(r_{\partial\Sigma}^2+r_{\partial\Sigma}r_0+r_0^2)\right]\\&\leqslant(r_{\partial\Sigma}-r_0)(1+\Lambda r_0^2)\leqslant 0.\end{aligned} \tag{VII.39}$$

It follows from Eqs. (VII.38)–(VII.39) that $r_{\partial\Sigma}=r_0$, $m=m_0$, and the rigidity part of Theorem I.5 establishes Corollary I.6. □

[31] See Ref. 5 for an exhaustive analysis, and explicit formulae for the roots of Eq. (II.1).
[32] When $^2M=T^2$ a unique normalization of X needs a further normalization of $d\Omega_k^2$, cf. Secs. V A and V B for a detailed discussion of this point.
[33] The methods of Ref. 78 show that in this case the space–times with metrics (I.1) can be extended to black hole space–times with a degenerate event horizon, thus a claim to the contrary in Ref. 5 is wrong. It has been claimed without proof in Ref. 7 that I^+, as constructed by the methods of Ref. 78, can be extended to a larger one, say $\hat{I}^+$, which is connected. Recall that the claim would imply that $\partial I^-(\hat{I}^+)=\varnothing$ (see Fig. 2 in Ref. 7), thus the space–time would not contain an event horizon with respect to $\hat{I}^+$. Regardless of whether such an extended $\hat{I}^+$ exists or not, we wish to point out the following: (a) there will still be degenerate *event* horizons as defined with respect to any connected component of I^+; (b) regardless of how null infinity is added there will exist *degenerate Killing horizons* in those space–times; (c) there will exist an *observer* horizon associated to the world line of any observer which moves along the orbits of the Killing vector field in the asymptotic region. It thus appears reasonable to give those space–times a black hole interpretation in any case.
[34] We use the convention that a manifold with boundary Σ contains its boundary as a point set.

[47] Recall that in the asymptotically flat case one can derive an asymptotic expansion for stationary metrics from rather weak hypotheses on the leading order behavior of the metric (Refs. 79–81). See especially Refs. 82 and 83, where the Lichnerowicz theorem is proved without any hypotheses on the asymptotic behavior of the metric, under the condition of geodesic completeness of space–time.
[48] The key point of the argument in Ref. 11 is to prove that the coordinate mass is negative. When $\partial_\infty \Sigma = S^2$, and the asymptotic conditions are such that the positive energy theorem applies, one can conclude that the initial data set under consideration must be coming from one in anti-de Sitter space-times *provided* one shows that the coordinate mass coincides with the mass which occurs in the positive energy theorem. To our knowledge such an equality has not been proved so far for metrics with the asymptotics (III.41), or else.
[49] We note that $\tilde{k}$ is of differentiability class lower by two orders as compared to the metric itself, which leads to a loss of three derivatives when passing to a new coordinate system in which r is defined by Eq. (III.49). One can actually introduce a coordinate system closely related to (III.49) with a loss of only one degree of differentiability of the metric by using the techniques of Ref. 36, Appendix A, but we shall not discuss this here.

[65] S. Hawking, J. Math. Phys. **9**, 598 (1968).
[66] The argument we review has been used by Gibbons in Ref. 18 to obtain a somewhat different inequality, in which the genus factors are not present. The inequality proposed in Ref. 18 is violated for generalized Kottler metrics with $g_\infty \geqslant 3$.
[67] Bray's proof (Ref. 17) of the inequality (VI.6) with $\Theta=0$, but $\partial\Sigma$, not necessarily connected, uses a completely different technique; in particular it makes appeal to the positive energy theorem which does not hold in the class of manifolds considered here.
[68] The discussion that follows actually applies to all (Σ,g)'s that can be isometrically embedded into a globally hyperbolic space–time M in which the null convergence condition holds; further the image of Σ should be a partial Cauchy surface in M. Finally the intersection of Σ with I should be compact. The global hyperbolicity here, and the notion of Cauchy surfaces, is understood in the sense of manifolds with boundary, see Ref. 4 for details.

[70] R. Beig and W. Simon, Commun. Math. Phys. **144**, 373 (1992).
[71] Using the asymptotic behavior of $V(r)$ and $r(V)$ it is not too difficult to show that solutions of (VII.3) are uniformly bounded on $[0,\infty)$, and approach a non-zero constant at infinity unless identically vanishing. Since solutions of (VII.3) are defined up to a multiplicative constant, we can choose this constant so that our normalization holds.
[72] The assumption of spherical symmetry of the level sets of the reference solution made in Ref. 69 is not needed to obtain Eq. (VII.16).

(Received 5 September 2000; accepted for publication 12 December 2000)

We investigate the so-called magnification relations of gravitational lensing models. We show that multidimensional residue integrals provide a simple explanation for the existence of these relations, and an effective method of computation. We illustrate the method with several examples, thereby deriving new magnification relations for galaxy lens models and microlensing (point mass lensing). © *2001 American Institute of Physics.* [DOI: 10.1063/1.1347394]

I. INTRODUCTION

Gravitational lensing has proven to be not only important astrophysically, but intriguing mathematically as well. Mathematical investigations of gravitational lens theory have yielded important results and insights,[1–6] employing techniques and results from such disparate areas as catastrophe theory, differential geometry and Morse theory. In this paper, we illustrate how another seemingly unrelated subject, multidimensional residue calculus, applies to gravitational lensing, and specifically we explain the origin of certain ''magnification relations'' that have been discussed in the lensing literature.[7–10] We additionally demonstrate that calculations of these magnification relations are enormously simplified using residue techniques, and illustrate the method by deriving several new results.

This paper is organized as follows. In the remainder of this section, we introduce the relevant terminology of gravitational lensing, and describe the magnification relations. In Sec. II, we express the problem in terms of residue calculations at the image positions, and thereby relate it to a residue at infinity. Using one-dimensional residue calculus, we derive trace formulas for the magnification relations for a subset of lens models. In Sec. III, we consider a more general class of lens models, and describe how to perform the necessary multidimensional residue integrals. In Sec. IV, we apply this formalism and derive previously known results, as well as new results. In Sec. V, we summarize our results and discuss implications. The material discussed in Secs. II–IV may be unfamiliar to astronomers, and so we provide a simple procedure which may be applied to models to obtain their magnification relations, without requiring a detailed understanding of the underlying mathematics.

A. Gravitational lensing terminology

Numerous excellent introductions to gravitational lensing have been written, e.g., Refs. 1, 2; here we briefly summarize some of the results and terminology relevant to our discussion. The effects of gravitational lensing can perhaps best be understood by considering the time delay of trajectories connecting the lensed source to the observer.[1] The time delay is a simple sum of two terms, a ''geometrical'' piece, and a ''gravitational'' piece. Let ϕ_N be the three-dimensional (3-D) Newtonian potential, and $\psi=(2/Dc^2)\int \phi_N\, dl$ the projected 2-D potential, where D is a function of

[a)]Electronic address: endall@astrophys.ucsd.edu
[b)]Electronic address: jrabin@euclid.ucsd.edu

cosmology and the source and lens redshifts. Just as $\nabla^2\phi_N = 4\pi G\rho$, similarly $\nabla_\perp^2\psi \propto 4\pi G\Sigma$, where $\Sigma = \int \rho\, dl$ is the surface density. In the thin-screen, small deflection limit, the time delay can be written as

$$\tau = \tau_0(\tfrac{1}{2}|\vec{\Theta} - \vec{\beta}|^2 - \psi), \tag{1}$$

where the normalization τ_0 depends upon cosmology and the lens and source redshifts, $\vec{\Theta}$ is the image location on the sky and $\vec{\beta}$ is the location the source would have had, had not the lens intervened. Light rays follow null geodesics, which can be shown to obey Fermat's principle.[2] Plotting time delay as a function of the two angular coordinates on the sky, Fermat's principle demands that images arise at the stationary points of this time delay surface. Setting the gradient of the time delay to zero gives the so-called ''lens equations,'' the (real) solutions of which are the image positions. Since the time delay surface can have multiple stationary points, multiple images of a single source can arise, and the image multiplicity can depend on the source position relative to the lens. The curves on the source plane separating regions of different image multiplicity are called caustics. As a source crosses over a caustic, its image multiplicity generically changes by two, as a pair of images either merge together and annihilate, or are created and move apart. The magnification μ, which relates differential area elements of the unlensed source to area elements of the lensed images, is simply the inverse of the Jacobian J of the mapping from image coordinates $\vec{\Theta}$ to source coordinates $\vec{\beta}$. Since the orientation of an image can be inverted relative to the unlensed source, the magnification can have either sign. Much of the lensing literature adopts the convention of positive magnifications (i.e., defining $\mu = 1/|J|$); in this paper we always take the magnification to be signed, i.e., $\mu = 1/J$.

B. Lens models

Two astrophysically important types of lenses are compact objects (like stars or MACHOs) and galaxies. The former class are effectively point masses, and so have lensing potentials proportional to the Green's function for the 2-D Laplacian, i.e., $\psi = m \log r$ where m is proportional to the mass of the point lens. Only the weak-field regime is observationally relevant, so the potentials linearly superpose for multiple point masses (as long as they are not appreciably separated along the line of sight). Galaxies have more complicated, extended mass distributions with correspondingly complicated lens potentials. In principle, one may decompose the potential into eigenfunctions of the 2-D Laplacian,[11]

$$\psi = \sum_{m,n} (a_{mn}\cos m\theta + b_{mn}\sin m\theta) r^n. \tag{2}$$

This has the advantage that each term in the expansion relates to a corresponding multipole in the expansion of the surface density. In practice, it is necessary to truncate the series due to the limited observational constraints. Since galaxies are believed to have roughly ''isothermal'' $\rho \sim r^{-2}$ profiles, such truncated series generally consist of variations on the singular isothermal sphere (SIS) potential $\psi = br$. Two examples considered by Kochanek[11] are the SIS+elliptical potential $\psi = br(1 + \gamma\cos 2\theta)$ and the SIS+external shear $\psi = br + (\gamma/2)\, r^2 \cos 2\theta$. Another variation[12] is the singular isothermal ellipse (SIE) $\psi = bR = b\sqrt{x^2 + y^2/q^2}$ with axis ratio q. Other, more elaborate and more physically justified models have been employed in the lensing literature; here we will focus on simple models such as the above to avoid obfuscating the general method with heavy algebra. In Table I we list the models considered in this paper.

Given a model for the lens, the lensed images of a given source may be found by solving the lens equations as described above. For simple potentials, the solutions are often analytic. For example, consider the the SIS+external shear model. The stationarity equations become

TABLE I. Model lens potentials and results. The lth lens has mass m_l and position $\vec{\Theta}_l$. For the galaxy potentials, with only one lens, we choose coordinates centered on the lens and oriented along the ellipticity or shear axes. Here, the image position $\vec{\Theta}=(x,y)=(r\cos\theta, r\sin\theta)$ and source position $\vec{\beta}=(x_s,y_s)=(s\cos\theta_s,\ s\sin\theta_s)$. We use the complex notation (Ref. 3) $z=x+iy$, and similarly for z_s, z_l. Also, $R=\sqrt{x^2+y^2/q^2}$ is an elliptical radial coordinate, γ is the strength of the shear and q is the axis ratio. We reiterate that these results are physically meaningful only when all solutions to the lens equations are real.

Model	ψ	$\Sigma_i \mu_i$	$\Sigma_i \mu_i z_i$
point masses	$\Sigma_l m_l \log\lvert\vec{\Theta}-\vec{\Theta}_l\rvert$	1	$z_s+\Sigma_l \frac{m_l}{\bar{z}_s-\bar{z}_l}$
point masses+shear	$\psi_{\rm pm}+\frac{\gamma}{2}r^2\cos 2\theta$	$1/(1-\gamma^2)$	$\frac{1}{(1-\gamma^2)^2}(z_s+\gamma\bar{z}_s)$
SIE	bR	2	$2z_s$
SIS+elliptical	$br+\gamma br\cos 2\theta$	1	$z_s+2\gamma\bar{z}_s-\frac{\bar{z}_s^3}{32b^2\gamma^2}$
SIS+shear	$br+\frac{\gamma}{2}r^2\cos 2\theta$	$2/(1-\gamma^2)$	$\frac{2}{(1-\gamma^2)^2}(z_s+\gamma\bar{z}_s)$
SIE+shear	$bR+\frac{\gamma}{2}r^2\cos 2(\theta-\theta_\gamma)$	$2/(1-\gamma^2)$	$\frac{2}{(1-\gamma^2)^2}(z_s+\gamma e^{2i\theta_\gamma}\bar{z}_s)$

$$\frac{\partial\tau}{\partial r}=r-s\cos(\theta-\theta_s)-b-\gamma r\cos 2\theta=0, \tag{3}$$

$$\frac{1}{r}\frac{\partial\tau}{\partial\theta}=s\sin(\theta-\theta_s)+\gamma r\sin 2\theta=0, \tag{4}$$

where (r,θ) is the image position in polar coordinates, and (s,θ_s) is the source position. From this it is easy to show that the quantity $u=e^{i\theta}$ satisfies the fourth degree polynomial equation,

$$\gamma b u^4+\left(\gamma s v+\frac{s}{v}\right)u^3-\left(sv+\frac{\gamma s}{v}\right)u+\gamma b=0, \tag{5}$$

with $v=e^{i\theta_s}$. As a quartic equation in u, this can be solved analytically, and from u the image coordinates (r,θ) follow simply. For many models, it is possible to eliminate all but one variable in a similar fashion and thereby obtain analytic solutions, but for more realistic models, the lens equations must be solved numerically.

C. Magnification relations

As mentioned above, there are in general multiple lensed images for a given source. These images lie at the discrete positions satisfying the lens equations for a given source position, and the images have different magnifications and orientations. If we restrict ourselves to purely real solutions of the lens equations (i.e., the physically observable images) then the number of images changes when the source crosses over a caustic. The number of solutions, of course, does not change, but instead generically a pair of complex solutions become real (for a source crossing into a caustic) or a real pair become complex (for a source crossing out of a caustic).[5] For certain lens models, such as the simple potentials described above, there may exist certain parameter ranges such that *all* solutions to the lens equations are real. In such cases, it has been shown that there exist interesting and surprising relations among the image positions and magnifications. First, Witt and Mao[7] considered lensing by a binary microlensing system, involving two point masses, and derived the following result: when the image multiplicity is maximized, the sum of the signed magnifications of all the images is always 1. That is, $\Sigma_i \mu_i=1$, independent of quantities such as

the lens masses, separation, or source position (as long as the source is inside a caustic). This is quite an astonishing result, as the individual image magnifications can vary wildly as the source position changes, and even diverge as the source crosses a caustic. Witt and Mao derived this result by using resultants to obtain a monic polynomial equation satisfied by μ, and noted that the sum of the roots is given by the subleading coefficient. Rhie,[8] using similar reasoning, showed that a similar result is true for an arbitrary number of point mass lenses. Dalal[9] extended this work to galaxy potentials like those described above. Again, the magnification relations were obtained by using elimination theory (e.g., Gröbner bases) to obtain monic polynomial equations in μ; the ''total magnification'' was then given by the subleading coefficient. We summarize these results in Table I.

Subsequently, Witt and Mao[10] showed that for a particular class of power-law models, there exist additional magnification relations, involving not only μ but the image positions as well. They derived this result by separating the coupled lens equations into disjoint x and y equations, and then relating μ to the coefficients. Just as previous work had derived expressions for $\Sigma_i \mu_i$, Witt and Mao found expressions for $\Sigma_i \mu_i x_i^k$ and $\Sigma_i \mu_i y_i^k$. They called these the ''kth moments,'' and we adopt their terminology here. For example, they found that the first moment $\Sigma_i \mu_i \vec{\Theta}_i = 2\vec{\beta}$ for the SIE model.

The general pattern seen in previous work is that both the total magnification and the higher moments can be expressed in terms of the model parameters, and that progressively higher moments have progressively more complicated forms involving more of the parameters. The expressions' independence of certain parameters suggests some sort of invariant, but clearly not a topological invariant since certain models seemed not to obey any magnification relations whatsoever. Indeed, the origin of the magnification relations and their absence in certain models has been a mystery. In this paper, we provide an explanation of these relations, and additionally find a method easier than elimination theory to derive them.

D. Residue integrals

As noted above, the lens equations have multiple discrete solutions, both real and complex. While only the real solutions have a physical meaning, it is instructive to consider the complex solutions as well. In this paper, we will henceforth treat the image coordinates $\vec{\Theta}$ as complex variables. We are interested in the sum over these discrete points of various quantities, such as the signed magnification, or magnification times position, etc. From complex analysis, we know that one may relate a sum over discrete points to an integral over a contour encircling those points, by choosing an integrand which has poles at those points. For lensed images, which are stationary points of the time delay, there is an obvious class of integrands, namely rational functions of the form

$$f(x,y) = \frac{g(x,y)}{\partial_x \tau \, \partial_y \tau}. \tag{6}$$

There are complications, which we discuss later, due to the fact that the integrals here are multidimensional; however, the analogy to the one-dimensional case should be clear. We need only find the appropriate function g such that f will have a residue equaling the quantity we wish to sum over the images, and choose a contour large enough to enclose all the images. Now, converting a discrete sum to a contour integral would not seem to be much progress, however we can use another idea from one-dimensional complex analysis. Recall that by inverting coordinates (mapping the origin to infinity and vice versa) one can see that the sum of the residues of poles inside the contour is equal to the sum of the residues of poles outside the contour, but with opposite sign. In our case, we are summing over all the finite solutions, so the only pole outside the contour is at infinity. This is the essence of the method described in this paper: we relate the sum over the images to the behavior of the time delay at infinity, and we simply evaluate the residue at the

point(s) at infinity. The validity of the resulting magnification relations does not depend on the image coordinates being real, although of course their physical applicability does.

The methods presented in this paper apply when the lens equations are polynomial in the image variables. Lens equations containing algebraic functions, such as nth roots, can be put in this form by introducing an additional variable for each algebraic function along with the polynomial equation it satisfies. For example, if $\sqrt{x^3+1}$ appears, we introduce z satisfying $z^2=x^3+1$. In principle, these extra variables can then be eliminated to return to two equations in two variables. In Sec. II we discuss ''trace methods,'' which are based on ordinary one-dimensional complex analysis and apply when the lens equations can be conveniently reduced to one polynomial equation in one variable. In Sec. III we discuss residue methods which can be applied directly to two polynomial equations in two image variables. In Sec. IV we illustrate with specific examples. Possible extensions of our methods are discussed in Sec. V.

II. TRACE METHODS

Our method in this section is useful when all but one variable can be conveniently eliminated from the lens equations, e.g., Eq. (5). Of course, this is always possible in principle, but it may require computer implementation of Gröbner basis algorithms in practice. Thus, we assume that the x-coordinates of the images are the roots x_i of a polynomial equation of degree n,

$$f(x)=\sum_{i=0}^{n} a_i x^i=0. \tag{7}$$

We assume that the signed magnification $\mu(x)$ of an image at x is given by a rational function,

$$\mu=\frac{p(x)}{q(x)}, \tag{8}$$

where the denominator has no common roots with $f(x)$. This will necessarily be the case if the coordinates are chosen generically, since there will then be at most one image at a given x-coordinate, whose magnification must be a single-valued algebraic function of x. We wish to calculate the total magnification,

$$M=\sum_i \mu(x_i)\equiv \mathrm{Tr}\,\mu, \tag{9}$$

where the ''trace'' notation will be explained below. Generically, the roots x_i of $f(x)$ will be distinct; since M is determined by continuity when some roots coincide we will always consider the generic case.

Let $A=\mathbb{C}[x]$ be the ring of polynomials in x with complex coefficients. We call two polynomials g and h equivalent, writing $g\sim h$, if they differ by a polynomial multiple of $f(x)$. This sorts the polynomials into equivalence classes, and we denote the class containing g by $[g]$ and the set of all equivalence classes by A_f. This is of use for our problem because all polynomials in a given class take the same values at the x_i and therefore have the same trace. Addition and multiplication of classes are well-defined by $[g]+[h]=[g+h]$, $[g][h]=[gh]$, and A_f is itself a ring.

Now we observe that each class $[g]\in A_f$ contains a representative which has degree (at most) $n-1$. Indeed, the relation $f\sim 0$ implies

$$a_n x^n \sim -\sum_{i=0}^{n-1} a_i x^i, \tag{10}$$

and this can be used to eliminate all terms of degree n or greater from a polynomial g. The resulting polynomial is unique, being determined by its values at the n roots x_i. It follows that A_f is in fact a vector space of dimension n over $\mathbb{C}$.

Now consider, instead of polynomials, the set R of rational functions of x which are defined at the zeros of $f(x)$, and call two elements equivalent if their difference is $f(x)$ times another element. Then all elements of a class have the same trace, and the set R_f of equivalence classes is again a ring. In fact, it is isomorphic to A_f. An isomorphism is obtained by associating to a class $[g]$ in A_f the obvious class $[g]$ in R_f. To see that this mapping is invertible, we must find a polynomial representative g of an arbitrary class $[h]$ in R_f. To do so, simply let $g(x)$ be the unique polynomial of degree $n-1$ satisfying $g(x_i)=h(x_i)$ for all i. Then $g-h$ is a rational function vanishing at every x_i, so when expressed in lowest terms its numerator must be a multiple of $f(x)$. Therefore $g\in[h]$.

At this point we can explain the ''trace'' terminology for the sum over the roots x_i.[13] The vector space A_f has a basis consisting of (the classes of) the n polynomials δ_i of degree $n-1$ defined by $\delta_i(x_j)=\delta_{ij}$. Fix an element $g\in A_f$ and consider the linear operator on A_f given by multiplication by g. In the given basis, the matrix of this operator is diagonal, with entries $g(x_i)$. Hence the trace of this matrix, which is independent of the basis and coincides with the trace of the operator, is simply $\mathrm{Tr}\, g=\Sigma_i g(x_i)$. For example, consider $\mathrm{Tr}\, x$, which just gives the sum of the roots. Choosing the basis $\{1,x,x^2,\ldots,x^{n-1}\}$ for A_f, the matrix of the operator of multiplication by x has only one nonzero diagonal entry, $-a_{n-1}/a_n$, arising from the relation $x\cdot x^{n-1}\sim -(a_{n-1}/a_n)x^{n-1}+\cdots$. This recovers the standard result for the sum of the roots of a polynomial and shows how our method generalizes others based on that result.[7–10]

Returning to the problem of computing the total magnification, we see that $M=\mathrm{Tr}\,\mu=\mathrm{Tr}[\mu]$ can be computed using any element in its equivalence class. For example, we can choose the unique polynomial representative of degree $n-1$. Of course, we do not determine this polynomial from its values $\mu(x_i)$, since we do not know the x_i explicitly. Instead, we seek a polynomial solution of degree $n-1$ to the condition (8) defining $[\mu]$,

$$[\mu q(x)]=[p(x)]. \tag{11}$$

This is solved by using Eq. (10) to reduce the degree of each side to $n-1$, and then equating coefficients.

To compute the trace we use a formula due to Euler, which we derive by means of the residue theorem for complex contour integrals. A purely algebraic proof is not difficult,[14] but our derivation shows the relevance of residue methods and motivates the multivariable generalization which we describe in the following section. Consider the contour integral,

$$\frac{1}{2\pi i}\oint \frac{f'(x)\mu}{f(x)}dx, \tag{12}$$

where the contour is a large circle in the complex plane enclosing all the zeros x_i of $f(x)$. The integrand has a pole of residue $\mu(x_i)$ at x_i, and consequently the integral is $\mathrm{Tr}\,\mu$. However, we can also regard the contour as encircling the point at infinity and evaluate the integral in terms of the residue there, introducing if we wish the new variable $u=1/x$ to move the point at infinity to the origin. Furthermore, the integral is unchanged if $f'(x)\mu$ is replaced by any member of its equivalence class. By choosing the polynomial representative of degree $n-1$ we need only evaluate

$$\frac{1}{2\pi i}\oint \frac{x^k}{f(x)}dx=\frac{\delta_{k,n-1}}{a_n},\quad 0\leqslant k\leqslant n-1. \tag{13}$$

This proves Euler's formula,

$$\mathrm{Tr}\,\mu=\frac{\text{coefficient in degree } n-1 \text{ of } f'(x)\mu}{\text{coefficient in degree } n \text{ of } f(x)}, \tag{14}$$

where it is understood that the polynomial representative of degree $n-1$ is meant in the numerator. This makes it clear that the total magnification is determined by the leading behavior of $f(x)$ and $f'(x)\mu$ at infinity.

As an example, we consider a generalization of the SIS+elliptical potential ($n=1$ multipole) with an arbitrary harmonic, $\psi = br + \gamma br\cos m\theta$. As an aid to clarity, we shall depart from conventional notation, and instead rewrite the lens equations so that the variables are x,y, and parameters are denoted $a,b,c,\ldots$. In this case we define $x=e^{i\theta}$, $y=r$, $a=\gamma$, $b=b$, $c=s$, $d=e^{i\theta_s}$. The lens equations then take the form

$$f(x) = mabx^{2m} + c\,d^{-1}x^{m+1} - c\,dx^{m-1} - mab = 0, \tag{15}$$

$$2(y-b) - c(xd^{-1} + dx^{-1}) - ab(x^m + x^{-m}) = 0, \tag{16}$$

with the magnification satisfying

$$[m^2 ab(x^m + x^{-m}) + c(xd^{-1} + dx^{-1})]\mu = 2y. \tag{17}$$

Eliminating y results in

$$[m^2 abx^{2m} + c\,d^{-1}x^{m+1} + c\,dx^{m-1} + m^2 ab]\mu = abx^{2m} + cd^{-1}x^{m+1} + 2bx^m + c\,dx^{m-1} + ab. \tag{18}$$

Dividing through by x and replacing x^{-1} in the resulting equation with a polynomial equivalent via the relation $x^{-1}f(x) \sim 0$ produces

$$\begin{aligned}[2m^2 abx^{2m-1} + (m+1)c\,d^{-1}x^m - (m-1)c\,dx^{m-2}]\mu \\ \sim 2abx^{2m-1} + (1+m^{-1})c\,d^{-1}x^m + 2bx^{m-1} + (1-m^{-1})c\,dx^{m-2},\end{aligned} \tag{19}$$

where the left side is precisely in the Euler form $f'(x)\mu$. Then we immediately have the total magnification invariant as

$$M = \mathrm{Tr}\,\mu = \frac{2ab}{mab} = \frac{2}{m}. \tag{20}$$

It is no harder to verify that the total magnification is the same for a potential containing an arbitrary finite sum of harmonics $\Sigma_{k=1}^{m} b_k r\cos k\theta$; the highest harmonic determines M. Other models are amenable to this method as well.

In principle one can compute moments by this method, by replacing μ with $x^k\mu$ in the relevant equations, but we have preferred the residue methods of the next section for moment computations.

III. RESIDUE METHODS: THEORY

Let us review the key steps in our contour integral derivation of Euler's formula in the previous section. First, we expressed the total magnification as a complex contour integral of a function having poles at the image locations. Second, we converted this to an integral around the point at infinity. This amounts to viewing the complex plane as a subset of the Riemann sphere, or complex projective space $\mathbb{CP}^1$. Our change of variables $u=1/x$ connects two coordinate charts on $\mathbb{CP}^1$ centered at the origin and at infinity. Finally, we evaluated the residue at infinity, making it clear that the total magnification depends on the behavior of the integrand at infinity.

These steps all have multivariable analogs. In fact, there is a well-developed, if little-known, residue theory for meromorphic differential forms in several complex variables. This makes it possible to compute directly the total magnification and moments for lens models without reducing to one-variable lens equations. The theory is particularly effective in the situation of two

variables, and we describe it in this case. References include Refs. 15–18. An application to chemical reaction rate equations appears in Ref. 19, but we are not aware of other physical applications in the literature.

We consider a meromorphic two-form,

$$\omega = \frac{g(x,y)\,dx\,dy}{P_1(x,y)P_2(x,y)}, \tag{21}$$

on $\mathbb{C}^2$, which we view as a subset of the compact complex projective space $\mathbb{CP}^2$. Here P_1, P_2 are polynomials having finitely many common zeros (the image locations) of multiplicity one (as is generically the case), and g is also a polynomial. Such a form can be integrated over a 2-cycle, a compact two-dimensional real submanifold of $\mathbb{CP}^2$. Since ω is closed ($d\omega = 0$), the integral depends only on the homology class of the cycle. For example, in a small neighborhood of a common zero of the P_i, we can integrate over the ''torus'' T:$\{|P_1| = |P_2| = \epsilon\}$, defining the residue of ω at this zero:

$$\mathrm{Res}\,\omega = \left(\frac{1}{2\pi i}\right)^2 \int_T \omega. \tag{22}$$

[The standard orientation of T is that specified by the nonvanishing 2-form $d(\arg P_1)\,d(\arg P_2)$. That is, T is oriented so that $dP_1\,dP_2/(2\pi i)^2 P_1 P_2$ has a positive integral.] We will always denote by J the naive Jacobian of the mapping $(x,y) \mapsto [P_1(x,y), P_2(x,y)]$, namely,

$$J = \frac{\partial(P_1,P_2)}{\partial(x,y)} = \begin{vmatrix} \partial_x P_1 & \partial_y P_1 \\ \partial_x P_2 & \partial_y P_2 \end{vmatrix}. \tag{23}$$

This coincides with the physical Jacobian relating corresponding area elements in the source and image planes if x,y are rectangular coordinates, and P_1, P_2 are the corresponding lens equations, but requires a correction factor otherwise. The first key fact we need is that the residue at a nondegenerate zero (one where J does not vanish), located say at the origin, is given by[18]

$$\mathrm{Res}\,\frac{g\,dx\,dy}{P_1 P_2} = \frac{g(0)}{J(0)}, \tag{24}$$

which is equal to the magnification of the corresponding image if g is chosen appropriately ($g = 1$ for rectangular coordinates). Moments of magnification can be computed by including additional monomial factors in $g(x,y)$.

Next we need the Global Residue Theorem,[18] which states that the sum of all the residues of a meromorphic form, such as ω, on any compact manifold, such as $\mathbb{CP}^2$, vanishes. Note that this sum is over the common zeros of the P_i only, so that points where only one polynomial vanishes do not contribute; also the points summed over may depend on the choice of the factorization $P_1 P_2$ of the denominator of ω. The theorem makes it possible to replace the sum over the residues at the common zeros in $\mathbb{C}^2$ by minus the sum of residues at points at infinity in $\mathbb{CP}^2$. This is the fundamental explanation for the existence of magnification relations in general: compactness relates the sum of finite residues to the behavior of the lens equations at infinity, indeed to a finite number of terms in an expansion around infinity. It remains to explain how to locate the common zeros at infinity and compute their residues.

$\mathbb{CP}^2$ is conveniently described by homogeneous coordinates $[X,Y,U] \neq [0,0,0]$, where $[\lambda X, \lambda Y, \lambda U]$ is identified with $[X,Y,U]$ for all complex $\lambda \neq 0$. The points with $U \neq 0$ can be represented in the form $[x,y,1]$ and are viewed as the subset $\mathbb{C}^2$ of finite points. The polynomials $P_i(x,y)$ correspond to homogeneous polynomials $P_i^h(X,Y,U) \equiv U^{\deg P_i} P_i(X/U, Y/U)$. Their common zeros at infinity are those having $U = 0$. These also lie in coordinate charts diffeomorphic to

$\mathbb{C}^2$, described by $[1,y,u]$ or $[x,1,u]$. In these charts they can be treated just as are ''finite'' zeros. The meromorphic form ω is homogenized so as to have total degree zero, that is,

$$\omega^h = \frac{g(X/U,Y/U)\,d(X/U)\,d(Y/U)}{P_1(X/U,Y/U)P_2(X/U,Y/U)} = \frac{g^h U^{\deg P_1+\deg P_2-\deg g-3}(U\,dX\,dY - X\,dU\,dY - Y\,dX\,dU)}{P_1^h P_2^h}. \tag{25}$$

When $n \equiv \deg g - \deg P_1 - \deg P_2 + 3 > 0$, the denominator of ω^h takes the form $U^n P_1^h P_2^h$. This creates a subtlety in that the above theory applies to a chosen factorization of the denominator into two factors. Thus, we may factor it as $(U^n P_1^h)(P_2^h)$ and treat these as the two factors in applying the residue theorem. The common zeros then consist of all (finite and infinite) common zeros of the P_i^h, together with any zeros of P_2^h alone at infinity. The latter might have been overlooked in a naive application of the theorem. In the examples we will consider in detail, no such additional zeros exist, but we will point out a case where they do.

Unfortunately, the zeros at infinity are rarely nondegenerate, and their residues cannot be computed using Eq. (24). Instead, they typically lie at singular points of the curves $P_i = 0$, that is, at least one curve has multiple branches meeting at this point.[20] There is a classical method, dating back to Newton, for finding the branches of an algebraic curve $P(x,y)=0$ at a singular point, taken to be the origin. The branches are given as Puiseux series, or fractional power series, of the form

$$y = \sum_{i=0}^{\infty} a_i x^{\alpha_i}, \tag{26}$$

where the exponents α_i form an increasing sequence of rational numbers whose denominators eventually stabilize. The possibilities for the leading exponent α_0 are determined by requiring that at least two terms in the polynomial $P(x,a_0x^{\alpha_0})$ have the same degree, while the remaining terms have a higher degree. Then a_0 is found by demanding the vanishing of the terms of minimal degree. An elegant graphical method for identifying the possible exponents α_0 is provided by the Newton polygon, or diagram.[17,21] For each monomial $x^a y^b$ appearing in $P(x,y)$, plot the point (a,b) in the coordinate plane. Begin at the lowest of the leftmost points (minimize a, then minimize b) and draw a polygonal path with vertices at a subset of the points, terminating at the leftmost of the lowest points (minimize b, then minimize a), and choosing each successive segment to have the smallest possible slope (steepest possible negative slope). This is the Newton diagram of the polynomial $P(x,y)$. The points lying on any segment of the Newton diagram represent terms in P which will have minimal degree if α_0 is chosen as the negative reciprocal of the slope of that segment. The next term in the Puiseux series can be found by applying the same procedure to $P(x,a_0x^{\alpha_0}+\tilde{y})$, and so on. One term is often enough for computing the total magnification; higher moments require more terms in general. The denominators of the exponents stabilize at the stage where the Newton diagram has only a single segment. The curve $P(x,y)=0$ has at least as many branches at the origin as there are segments in the Newton diagram, and has more if there are multiple solutions to the equations for the coefficients a_i.

Consider one particular branch X of the curve $P_1(x,y)=0$ at a singular point, given by a Puiseux series $y = a_0x^{m/n} + \cdots$, with m,n relatively prime. On this branch draw a small circle C around the origin; its projection on the x-plane must wind n times around the origin. Now construct a 2-torus δC by ''thickening'' C: at any point p of C take a plane transverse to X and a small circle in this plane with center p. As p moves around C this circle sweeps out the torus δC. We may construct such a torus for each branch of the curve. These are called Leray tori, and the ''thickening'' operator δ is the Leray coboundary.

Our objective is to compute the residue integral $\int_T \omega$ at the origin. We can work entirely within a small ball B around the origin. The residue depends on the homology class of T in $H_2(B-\{P_1P_2=0\})$. As we explain in the Appendix, this class is, up to sign, the sum of the

classes of the Leray tori constructed on the branches of *either* of the curves $P_1=0$ or $P_2=0$. Therefore the residue is the sum of the integrals of ω over either set of Leray tori, with appropriate orientation.

The integral over a Leray torus δC lying on a branch of $P_1(x,y)=0$ given by a Puiseux series $y=p(x)$ is computed using the Leray residue formula. We give this formula under the assumption that $\partial_y P_1$ does not vanish on the given branch, which amounts to assuming that $y=p(x)$ is a branch of an irreducible factor of P_1 which appears to the first power only (the analog of a simple rather than multiple pole). The general formula can be found in Ref. 16. Our case reads as

$$\frac{1}{2\pi i}\int_{\delta C}\frac{g\,dx\,dy}{P_1P_2}=-\int_C\left.\frac{g\,dx}{P_2\,\partial_y P_1}\right|_{y=p(x)}, \tag{27}$$

which is proved as follows. To integrate over δC, we can integrate first over the circles in the planes transverse to C, then over C itself. Since these circles are centered at $P_1=0$, we can change variables from x,y to x,P_1 by means of $dP_1\,dx=-dx\,dy\,\partial_y P_1$ and then integrate over P_1 by means of the one-variable residue theorem. The evaluation of the residue at $P_1=0$ by substituting $y=p(x)$ leaves another one-variable residue integral to be performed. For this one must keep in mind that the cycle C may wind around the origin several times in the x-plane.

The Leray residue formula holds with obvious notational and possible sign changes if the Leray torus lies on a branch of $P_2(x,y)=0$, or if we choose to eliminate x rather than y in favor of a P_i.

IV. RESIDUE METHODS: EXAMPLES

In this section we apply the residue methods just developed to various lens models. The first is a generalized $n=2$ multipole model with potential $\psi=br+(\gamma/2)r^2\cos m\theta$. We again redefine notation to clarify the computation, writing the variables as x,y and the parameters as $a,b,c,\ldots$. Let $x=e^{i\theta}$, $y=r$, $a=\gamma$, $b=b$, $c=s$, $d=e^{i\theta_s}$. The lens equations then take the form

$$P_1=c\,d^{-1}x^{m+1}-c\,dx^{m-1}+\frac{m}{2}ay(x^{2m}-1)=0, \tag{28}$$

$$P_2=2(y-b)x^m-c\,d^{-1}x^{m+1}-c\,dx^{m-1}-ay(x^{2m}+1)=0. \tag{29}$$

Because x,y are not rectangular coordinates, there is an extra Jacobian factor in the magnification, and we find

$$\mu=\frac{4yx^{2m-1}}{J}. \tag{30}$$

Consequently the total magnification is given by the residue sum,

$$M=\sum_{\text{images}}\operatorname{Res}\frac{4yx^{2m-1}dx\,dy}{P_1P_2}. \tag{31}$$

The residue theorem relates this to the sum of the residues at points at infinity in $\mathbb{CP}^2$, which are found from the homogeneous forms of the P_i:

$$P_1^h=c\,d^{-1}X^{m+1}\,U^m-c\,dX^{m-1}\,U^{m+2}+\frac{m}{2}aY(X^{2m}-U^{2m}), \tag{32}$$

$$P_2^h=2X^m(YU^m-bU^{m+1})-c\,d^{-1}X^{m+1}\,U^m-c\,dX^{m-1}\,U^{m+2}-aY(X^{2m}+U^{2m}). \tag{33}$$

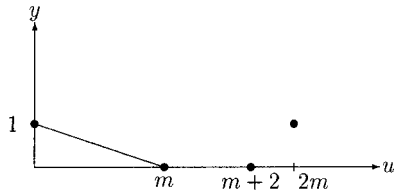

FIG. 1. The Newton diagram for $P_1^{X=1}$ in the $n=2$ multipole model. The degree of a monomial in y (u) is plotted vertically (horizontally). The case $m=3$ is shown.

The common roots at infinity are those with $U=0$, and there are two: $[X,Y,U]=[1,0,0]$, and $[0,1,0]$. The total magnification is minus the sum of the residues at these points of

$$\frac{4Y\,X^{2m-1}U^{2m+2}\,d(X/U)\,d(Y/U)}{P_1^h P_2^h}. \tag{34}$$

Consider first the point $[1,0,0]$, which we examine in the affine chart $[X,Y,U]=[1,y,u]$, where

$$P_1^{X=1}=c\,d^{-1}u^m-c\,du^{m+2}+\frac{m}{2}ay(1-u^{2m}), \tag{35}$$

$$P_2^{X=1}=2u^m(y-bu)-c\,d^{-1}u^m-c\,du^{m+2}-ay(1+u^{2m}), \tag{36}$$

and we need the residue at the origin of $4yu^{2m-1}\,du\,dy/P_1^{X=1}P_2^{X=1}$.

The Newton diagram for P_1 is shown in Fig. 1; there is a single branch on which to leading order $y\sim u^m$, as is easily verified by solving $P_1^{X=1}=0$ for y. The Leray formula evaluates the residue as the one-variable residue of

$$-\frac{4yu^{2m-1}\,du}{P_2^{X=1}\partial_y P_1^{X=1}}, \tag{37}$$

where $y\sim u^m$. But it is easily seen that the leading behavior of this 1-form near $u=0$ is $u^{2m-1}\,du$, so that there is no pole and no residue for $m>0$.

We examine the remaining root $[0,1,0]$ in the chart $[X,Y,U]=[x,1,u]$ where

$$P_1^{Y=1}=c\,d^{-1}x^{m+1}\,u^m-c\,dx^{m-1}u^{m+2}+\frac{m}{2}a(x^{2m}-u^{2m}), \tag{38}$$

$$P_2^{Y=1}=2x^mu^m(1-bu)-c\,d^{-1}x^{m+1}\,u^m-c\,dx^{m-1}\,u^{m+2}-a(x^{2m}+u^{2m}), \tag{39}$$

and we compute

$$\mathrm{Res}\,\frac{4x^{2m-1}u^{2m-1}\,dx\,du}{P_1^{Y=1}P_2^{Y=1}}. \tag{40}$$

The Newton diagram for $P_1^{Y=1}$ is shown in Fig. 2, and gives the leading behavior $u=lx+\cdots$. With this behavior, the lowest-order terms of $P_1^{Y=1}$ vanish iff $l^{2m}=1$, so that there are $2m$ branches with $l_p=\exp(ip\pi/m)$, $p=1,\ldots,2m$.

With the Leray formula, the total magnification becomes

$$\sum_{u=l_p x+\cdots} -\mathrm{Res}\,\frac{4x^{2m-1}u^{2m-1}\,dx}{P_2^{Y=1}\,\partial_u P_1^{Y=1}}. \tag{41}$$

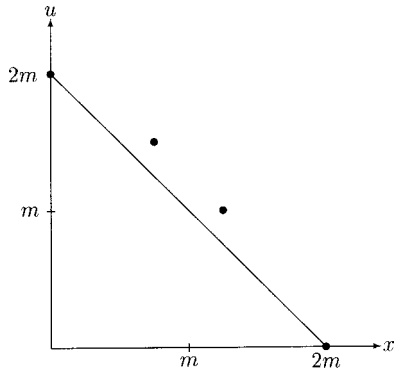

FIG. 2. The Newton diagram for $P_1^{Y=1}$ in the $n=2$ multipole model.

The leading terms are readily identified, and indeed the behavior is as dx/x, with residue

$$\sum_{p=1}^{2m} \frac{2}{m^2 a(l_p^m - a)} = \frac{2}{m^2 a} \sum_{p=1}^{2m} \frac{1}{(-1)^p - a} = \frac{4}{m(1-a^2)}. \tag{42}$$

In terms of the original parameters of the model,

$$M = \frac{4}{m(1-\gamma^2)}, \tag{43}$$

an attractive generalization of the known result[9] for $m=2$.

Once the branches of the P_i have been identified, it is easy to modify the calculation to compute moments rather than total magnification. For example, let us compute the first x-moment, $\mathrm{Tr}\, x\mu$. (We continue to use the Tr notation for the sum over the images.) Since $x=e^{i\theta}$ in terms of the physical variables of this model, from the real and imaginary parts of the result we can obtain the moments weighted by $\cos\theta$ and $\sin\theta$, in the case that all images are real. In homogeneous coordinates this simply gives an additional factor X/U in the residue in Eq. (34). At the point $[1,0,0]$ this adds a factor $1/u$ to the one-variable residue (37), changing the behavior to $u^{2m-2}\,du$. There is still no contribution for $m \geqslant 1$. At the point $[0,1,0]$, there is an extra factor $x/u = l^{-1} + \cdots$ in the residue (41), changing the contribution to

$$\sum_p \frac{2}{m^2 a l_p (l_p^m - a)} = \frac{2}{m^2 a} \sum_{p=1}^{2m} \frac{e^{-ip\pi/m}}{(-1)^p - a}, \tag{44}$$

which can be evaluated in closed form if desired.

From the real part of $\mathrm{Tr}\, yx\mu$ we can obtain the moment of $r\cos\theta$, the physical x-coordinate of the image. This leads to a factor YX/U^2, which worsens the singularity at $[0,1,0]$ to a double pole, requiring an additional term in the Puiseux expansion to obtain the residue. The result, for the true external shear model $m=2$, is

$$\mathrm{Tr}\, \mu r\cos\theta = -\frac{2x_s}{(1-\gamma)(1-\gamma^2)}. \tag{45}$$

This example illustrates the general situation. Higher moments produce extra monomial factors in the residue expression. In general this will worsen the singular behavior at points at infinity, although this may not occur for certain branches, such as those at $[0,1,0]$ in the example of $\mathrm{Tr}\, x\mu$. This will have two effects: points which do not contribute to the total magnification generally will

contribute to higher moments, and more terms in the Puiseux expansions will be required for higher moments. Both effects will result in higher moments being given by more complex expressions, with more model parameters contributing.

We turn to a second example, the Singular Isothermal Ellipse (SIE) potential.[10,12] For this model $\psi = bR = b\sqrt{x^2+y^2q^{-2}}$, where x,y are rectangular coordinates and b,q are parameters. The lens equations are

$$\tau_x = x - x_s - \frac{bx}{R} = 0, \tag{46}$$

$$\tau_y = y - y_s - \frac{by}{q^2 R} = 0, \tag{47}$$

and the magnification is given by

$$\mu^{-1} = \begin{vmatrix} \tau_{xx} & \tau_{xy} \\ \tau_{xy} & \tau_{yy} \end{vmatrix}. \tag{48}$$

Algebraic manipulation leads to the polynomial equations,

$$p_1 = q^2 x\tau_y - y\tau_x = q^2 x(y-y_s) - y(x-x_s) = 0, \tag{49}$$

$$p_2 = R^2\tau_x^2 - 2bRx\tau_x = (x-x_s)^2(x^2+y^2q^{-2}) - b^2x^2 = 0. \tag{50}$$

However, these equations have the extraneous solution $(x,y)=(0,0)$, which does not satisfy the original lens equations. This can be eliminated by substituting $y=wx$, and adopting the modified equations,

$$P_1 = p_1/q^2 x = wx - y_s - \eta w x + \eta w x_s, \tag{51}$$

$$P_2 = p_2/x^2 = b^2 - (x-x_s)^2(1+\eta w^2), \tag{52}$$

where we have set $\eta = q^{-2}$. Relating the naive Jacobian J of the P_i with respect to x,w to the Hessian of τ gives the magnification in the new variables,

$$\mu = \frac{2x(x-x_s)(1+\eta w^2)}{J}. \tag{53}$$

The moments of the magnification with respect to x are given by

$$\mathrm{Tr}\, x^k \mu = \sum \mathrm{Res} \frac{2x^{k+1}(x-x_s)(1+\eta w^2)\, dx\, dw}{P_1 P_2}. \tag{54}$$

In homogeneous coordinates we have

$$P_1^h = (1-\eta)XW - y_s U^2 + \eta x_s WU, \tag{55}$$

$$P_2^h = b^2 U^4 - (X - x_s U)^2(U^2 + \eta W^2), \tag{56}$$

and we need to compute

$$\mathrm{Tr}\, \mu x^k = \sum \mathrm{Res} \frac{2X^{k+1}U^{2-k}(X-x_sU)(U^2+\eta W^2)\, d(X/U)\, d(W/U)}{P_1^h P_2^h}. \tag{57}$$

There are two common zeros of the P_i^h at infinity, namely $[X,W,U]=[1,0,0]$, $[0,1,0]$, and in the corresponding affine charts we have

$$P_1^{X=1}=(1-\eta)w-y_s u^2+\eta x_s w u, \tag{58}$$

$$P_2^{X=1}=b^2u^4-(1-x_s u)^2(u^2+\eta w^2), \tag{59}$$

$$P_1^{W=1}=(1-\eta)x-y_s u^2+\eta x_s u, \tag{60}$$

$$P_2^{W=1}=b^2u^4-(x-x_s u)^2(u^2+\eta). \tag{61}$$

The residues at these zeros may be computed via the Leray formula applied to the branches of either P_1 or P_2; we have done both computations and the latter seems slightly simpler. In each case the branches can be determined directly without appealing to the Newton diagrams. At $[0,1,0]$, the equation $P_2^{W=1}=0$ is solved by

$$x=x_s u\pm b\,\eta^{-1/2}u^2\left(1+\frac{u^2}{\eta}\right)^{-1/2}, \tag{62}$$

giving one branch for each choice of sign. The contribution to $\mathrm{Tr}\,\mu x^k$ from one branch is

$$\mathrm{Res}\frac{2x^{k+1}(x-x_s u)(u^2+\eta)\,dx\,du}{u^{k+1}P_1^{W=1}P_2^{W=1}}. \tag{63}$$

Applying the Leray formula gives

$$\mathrm{Res}\frac{2x^{k+1}(x-x_s u)(u^2+\eta)\,du}{u^{k+1}P_1^{W=1}\,\partial_x P_2^{W=1}}, \tag{64}$$

which simplifies to

$$\mathrm{Res}\frac{x^{k+1}\,du}{u^{k+1}[x-y_s u^2-\eta(x-x_s u)]}=x_s^k, \tag{65}$$

where only the first term in the series expansion of x was required. The two branches at this point thus contribute $2x_s^k$ to the moment of x^k.

At the remaining point $[1,0,0]$, $P_2^{X=1}=0$ is solved by

$$w=\pm\frac{iu}{\sqrt{\eta}}\sqrt{1-\frac{b^2u^2}{(1-x_s u)^2}}=\pm\frac{iu}{\sqrt{\eta}}\left(1-\frac{1}{2}b^2u^2+\cdots\right), \tag{66}$$

and we need

$$\mathrm{Res}\frac{2(1-x_s u)(u^2+\eta w^2)\,du\,dw}{u^{k+1}P_1^{X=1}P_2^{X=1}}, \tag{67}$$

summed over the two branches. Integrating over w using the Leray residue formula and simplifying yields

$$\mathrm{Res}\frac{(u^2+\eta w^2)\,du}{\eta w u^{k+1}(1-x_s u)[(1-\eta)w+\eta x_s w u-y_s u^2]}, \tag{68}$$

where $u^2+\eta w^2=b^2u^4+\cdots$. Since $w\sim u$, there is no pole for $k<2$: the total magnification and first moment are simply given by the contributions from [0,1,0]. There is an additional contribution to the second moment given by $-2b^2/(1-\eta^2)=2b^2q^2/(1-q^2)$, which agrees with the result of Ref. 10.

We have verified the results of Witt and Mao[10] through the third moment. Those authors noted that the moments of x were independent of y_s to this order, and that ''this seems remarkable'' in view of the dependence of μ on this parameter. The explanation is that the term y_su^2 in $P_1^{X=1}$ does not contribute to the residue for low moments; indeed it *does* contribute to the residues for the third moment but its contribution cancels between the two branches. The fourth and higher moments do depend on y_s.

Last, we note that it is entirely straightforward, and no more work, to generalize the calculation to include an arbitrarily oriented external shear term. The first moment, for example, takes the form

$$\mathrm{Tr}\,\mu x=\frac{2}{(1-\gamma^2)^2}(x_s+\gamma_1x_s+\gamma_2y_s),\quad \mathrm{Tr}\,\mu y=\frac{2}{(1-\gamma^2)^2}(y_s+\gamma_2x_s-\gamma_1y_s), \tag{69}$$

where $\gamma_1\equiv\gamma\cos 2\theta_\gamma$, $\gamma_2\equiv\gamma\sin 2\theta_\gamma$, and θ_γ is the orientation angle of the shear (see Table I).

As our final example we consider microlensing due to a collection of N coplanar point masses. We adopt Witt's complex notation, writing $z=x+iy$ for the position of an image and w for the position of the source. The lenses have masses m_i and positions z_i. The lens equations are

$$z-w-\sum_{i=1}^{N}\frac{m_i}{\overline{z}-\overline{z}_i}=0, \tag{70}$$

and its complex conjugate; when we complexify the coordinates x,y of an image, z and $\overline{z}$ become independent variables and the conjugate equation becomes an independent condition as well. The observable (real) images are those for which $\overline{z}$ is the conjugate of z. Clearing denominators, we set

$$P_1=(z-w)\prod_i(\overline{z}-\overline{z}_i)-\sum_i m_i\prod_{j\neq i}(\overline{z}-\overline{z}_j), \tag{71}$$

$$P_2=(\overline{z}-\overline{w})\prod_i(z-z_i)-\sum_i m_i\prod_{j\neq i}(z-z_j). \tag{72}$$

For the magnification we find

$$\mu=J^{-1}\prod_i(z-z_i)(\overline{z}-\overline{z}_i), \tag{73}$$

where $J=\partial(P_1,P_2)/\partial(z,\overline{z})$. For the kth moment of magnification, we must compute

$$\mathrm{Tr}\,\mu z^k=\mathrm{Res}\frac{z^k\,\Pi_i(z-z_i)(\overline{z}-\overline{z}_i)\,dz\,d\overline{z}}{P_1P_2}. \tag{74}$$

The homogeneous polynomials are

$$P_1^h=(Z-wU)\prod_i(\overline{Z}-\overline{z}_iU)-\sum_i m_iU^2\prod_{j\neq i}(\overline{Z}-\overline{z}_jU), \tag{75}$$

$$P_2^h=(\overline{Z}-\overline{w}U)\prod_i(Z-z_iU)-\sum_i m_iU^2\prod_{j\neq i}(Z-z_jU). \tag{76}$$

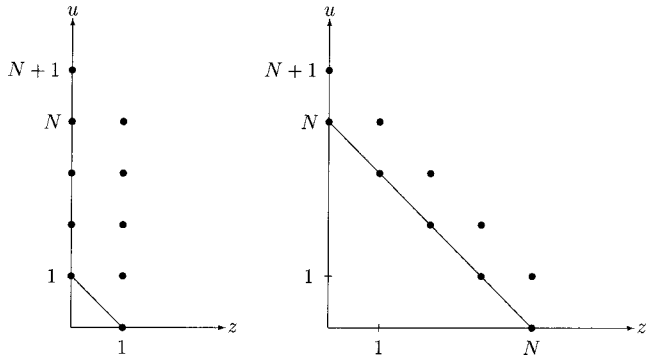

FIG. 3. The Newton diagrams for $P_1^{\overline{Z}=1}$ (left) and $P_2^{\overline{Z}=1}$ (right) for N point masses. The case $N=4$ is shown.

Setting $U=0$, we obtain $P_1^h=Z\overline{Z}^N$, $P_2^h=\overline{Z}Z^N$, so there are two common zeros at infinity, $[Z,\overline{Z},U]=[1,0,0],[0,1,0]$. However, we can say more: each of these zeros has multiplicity N. Since the homogeneous polynomials each have degree $N+1$, the number of finite common zeros will be $(N+1)^2-2N=N^2+1$, in agreement with previous results.[3]

Dehomogenizing the polynomials at these points, we find

$$P_1^{\overline{Z}=1}=(z-wu)\prod_i (1-u\overline{z_i})-u^2\sum_i m_i\prod_{j\neq i}(1-u\overline{z_j}), \tag{77}$$

$$P_2^{\overline{Z}=1}=(1-\overline{w}u)\prod_i (z-uz_i)-u^2\sum_i m_i\prod_{j\neq i}(z-uz_j), \tag{78}$$

$$P_1^{Z=1}=(1-wu)\prod_i (\overline{z}-u\overline{z_i})-u^2\sum_i m_i\prod_{j\neq i}(\overline{z}-u\overline{z_j}), \tag{79}$$

$$P_2^{Z=1}=(\overline{z}-\overline{w}u)\prod_i (1-uz_i)-u^2\sum_i m_i\prod_{j\neq i}(1-uz_j). \tag{80}$$

Because of the complex conjugation symmetry of these expressions, it suffices to examine the branches of, say, $P_i^{\overline{Z}=1}$ to deduce the others. The Newton diagrams of these are shown in Fig. 3. In each case, the Puiseux series are ordinary power series. For P_1 there is a single branch $u=z/w+\cdots$, while for P_2 there are N branches $u=z/z_i-(m_i/z_i^3)z^2+\cdots$.

It is now straightforward to compute the residues,

$$\mathrm{Res}\,\frac{Z^kU^{2-k}\Pi_i(Z-z_iU)(\overline{Z}-\overline{z_i}U)\,d(Z/U)\,d(\overline{Z}/U)}{P_1^hP_2^h}, \tag{81}$$

and determine the moments. The first two are $M=\mathrm{Tr}\,\mu=1$, and $\mathrm{Tr}\,z\mu=w+\Sigma_i[m_i/(\overline{w}-\overline{z_i})]$. The single branch contributes w^k to the kth moment, while the contribution of the N branches becomes progressively more complicated.

We have also considered a generalization of the model to include external shear. This brings the lens equations to the form[3]

$$z-w-\gamma\overline{z}-\sum_{i=1}^N\frac{m_i}{\overline{z}-\overline{z_i}}=0, \tag{82}$$

and its complex conjugate. Defining P_i^h as before, their zeros at infinity are $[1,0,0]$ and $[\gamma,1,0]$ for P_1^h, and $[0,1,0]$ and $[1,\gamma,0]$ for P_2^h. For $\gamma \neq 0,1$ there are no common zeros at infinity. Factoring the denominator of ω^h as $(U^n P_1^h)(P_2^h)$, the residue theorem gives the sum over the finite common roots as minus the sum of residues at the infinite roots of P_2^h. We find, for example, the total magnification $1/(1-\gamma^2)$, and the first moment,

$$\mathrm{Tr}\, z\mu = \frac{w+\gamma\overline{w}}{(1-\gamma^2)^2}. \tag{83}$$

Note that the first moment's dependence upon the lens' positions has vanished.

V. DISCUSSION

We have introduced in this paper a new framework for analyzing gravitational lens models. The use of residue integrals makes clear the origin of the magnification relations, and facilitates their computation for a wide class of model potentials. We have also applied this method to a series of models, confirmed and extended previous results, and provided new magnification relations for several models. Although multidimensional residue calculus may be unfamiliar to readers from astronomy, one may follow a simple procedure to perform the necessary integrals. Basically, the procedure is as follows.

(1) From the stationarity equations, construct two polynomials P_1, P_2 that simultaneously vanish at (and only at) the image positions.
(2) Define the ''Jacobian'' $J_P = \det[\partial(P_1,P_2)/\partial(x,y)]$, and define $g(x,y) = J_P(x,y)\mu(x,y)$ where μ is the magnification.
(3) Change to homogeneous coordinates: $(x,y) \to (X,Y,U)$ with $x = X/U, y = Y/U$ and homogenize the polynomials by multiplying each by the factor $U^{\deg P}$. Also, multiply g by $U^{\deg P_1 + \deg P_2}$.
(4) From the homogenized g, P_1, P_2, construct the 2-form $(g/P_1P_2)d(X/U)d(Y/U)$, and factor the denominator into two groups; usually, the grouping P_1, P_2 suffices. (Henceforth P_1, P_2 shall refer to the two groups, not the original polynomials.) If the denominator contains explicit factors of U then redefine one of the polynomials, say P_2, to contain these additional factors.
(5) For $U=0$, find the points (X,Y) where P_1, P_2 simultaneously vanish; these are the roots at infinity.
(6) Pick one of the polynomials—say P_1—and determine the behavior of $P_1 = 0$ in the vicinity of each common root. First define coordinates for the neighborhood of the root. For example, if the root is $Y=0$, $U=0$, then a good choice would be $(X,Y,U) = (1,y,u)$. As discussed, there are in general multiple branches of $P_1 = 0$ meeting at the root at infinity, each parametrized by a Puiseux series $y = \Sigma_i a_i u^{\alpha_i}$. The α_i's can be determined from the Newton diagram, and by substituting in the specified α_i's one may solve for the coefficients a_i. Usually, only the first one or two terms in the series are necessary.
(7) Construct the quantity

$$\frac{g(u, a_1 u^{\alpha_1} + a_2 u^{\alpha_2} + \cdots)}{\dfrac{\partial P_1}{\partial y}(u, a_1 u^{\alpha_1} + \cdots) P_2(u, a_1 u^{\alpha_1} + \cdots)},$$

and pick out the term $\sim u^{-1}$. The coefficient of u^{-1} is the contribution for this branch; summing over all the branches gives the residue for each root.
(8) Repeat this procedure for all the roots at infinity, and sum their residues. Negating this quantity gives the sum of the residues at finite poles (the images).

The above is of course just a rough outline; in Sec. III we describe the method in full detail. Following this procedure, the results listed in Table I can be reproduced with minimal effort.

As we have discussed, the methods presented in this paper apply when the two lens equations are polynomial in the two image variables. When algebraic functions of the image variables appear, we introduce new variables and equations to bring the whole set to polynomial form. In principle, the extra variables can be eliminated to return to a pair of polynomial equations to which our residue methods apply. A simple example of this was seen in our discussion of the SIE potential. In principle, however, the residue methods apply directly to any number of polynomial equations in the same number of variables. We have not investigated whether this can be turned into a practical computational scheme for dealing with algebraic functions. One would first require an analysis like that in the Appendix, determining the homology class of the torus T defining the residue integral. The Leray residue formula holds quite generally, but is less explicit without the machinery of algebraic curves and Puiseux series which we exploited in the two-variable case. Details can be found in Refs. 15, 16. We do not know how to extend our methods to equations involving transcendental functions.

Dalal[9] and Witt and Mao[10] have considered the applicability of such magnification relations to real gravitational lenses. For galaxies, Dalal[9] has shown that these relations can be an aid in fitting models to lensed objects, or can be used to rule out models *a priori*. Witt and Mao[10] have shown, however, that reliance upon simple galaxy models can be misleading, when applied to realistic galaxy potentials. This limits the applicability of magnification relations to making statements about models, as opposed to statements about the lenses themselves. For this reason, some authors have aimed at deriving magnification results that apply to generic lens models. For example, Petters[22] determines lower bounds on the total magnification using Morse theoretic methods. The residue integral method introduced here allows explicit results, for relatively little effort, by focusing on a specific class of models. The applicability of the derived relations then depends upon the validity of the model.

For microlensing, there is no doubt about the accuracy of the point mass model, and as such our derived magnification relations may be considered exact. The limitation of our results is that they have physical relevance only when the maximum number of images is attained. It is currently an open question whether there exist parameter ranges for which all solutions are real, e.g., Ref. 23. Nevertheless, such magnification relations have already proven themselves to have astrophysical value. Witt and Mao[7] have already shown how the total signed magnification (''zeroth moment'') can be used for binary microlensing to set lower limits on the overall unsigned magnification, useful for example for detecting source blending. Although the multiple images of a microlensing event cannot as yet be resolved, precluding the present-day experimental verification of our prediction regarding the first moment, we are hopeful that the future advent of space-based interferometers will allow our microlensing formulas to be tested observationally.

ACKNOWLEDGMENTS

The authors would like to thank Wyn Evans, Geza Gyuk, Eduard Looijenga, Peter Teichner, Adrian Wadsworth, Nolan Wallach, and John Wavrik for many helpful discussions. This work was supported in part by the U.S. Dept. of Energy under Grant No. DEFG0390ER40546, and in part by the ARCS Foundation.

APPENDIX: THE HOMOLOGY CLASS OF THE TORUS *T*

Here we explain why the torus T defining the local residue at a singular point, taken to be the origin, is homologous to the sum of the Leray tori constructed from the branches of *either* of the polynomials $P_i(x,y)$, and how to determine the correct orientations. We are grateful to Eduard Looijenga and Peter Teichner for explaining the topology to us. See also Sec. 2.2 of Dimca.[24]

We are working locally in a closed ball B around the origin, and we denote by X the zero locus $P_1P_2=0$ within B. The various tori define homology classes in $H_2(B-X)$. It is known that X is topologically a cone with vertex the origin and base $X\cap\partial B$, which is a linked collection of topological circles.[17,24] Denote the several branches of X as X_i, and the Leray torus built on a given branch as δC_i. Let σ_{ij} be a path running from the origin to ∂B along X_i, and returning to

the origin along branch X_j. A subset of these paths forms a basis for the relative homology group $H_1(X,\partial B)$. Furthermore, by Alexander duality,[16] an element of $H_2(B-X)$ is uniquely determined by its linking numbers with these paths (indeed, with those in a basis alone). [The linking number $l(c^1,c^2)$ of a 1-cycle with a 2-cycle in a 4-ball is the intersection number of c^1 with any 3-manifold having boundary c^2.]

The Leray tori have linking numbers,

$$l(\sigma_{ij},\delta C_k)=\delta_{ik}-\delta_{jk}. \tag{A1}$$

Indeed, the intersection of σ_{ij} with a solid torus bounded by δC_k is the intersection of σ_{ij} with C_k, which is one point if the outward segment of σ_{ij} lies on branch X_k, and one point (with opposite orientation) if the returning segment does.

The sum $\Sigma_{P_1}\delta C_k$ of Leray tori built on branches of $P_1=0$ therefore has linking number with σ_{ij} equal to $+1$ if X_i is a branch of P_1 and X_j is a branch of P_2, -1 if *vice versa*, and 0 if X_i and X_j are branches of the same polynomial. The sum $\Sigma_{P_2}\delta C_k$ has the negatives of these linking numbers and therefore represents the same homology class but with opposite orientation.

It remains to show that T has the linking numbers of $\Sigma_{P_1}\delta C_k$. A solid torus bounded by T is given by $\{|P_1|\leqslant\epsilon,|P_2|=\epsilon\}$. This meets any branch X_k of $P_1=0$ given by a Puiseux series $y=p(x)$ in the locus $|P_2(x,p(x))|=\epsilon$ on X_k. This set is topologically a circle around the origin, having intersection number $+1$ with a path radially outward from the origin. The solid torus meets no branch of $P_2=0$. Therefore, radially outward (inward) paths on any branch of P_1 contribute $+1$ (-1) to intersection numbers with this solid torus, while paths on branches of P_2 contribute nothing. This duplicates the linking numbers of $\Sigma_{P_1}\delta C_k$.

The orientation for T used in this argument is indeed the standard one prescribed in Sec. III. Using the Leray residue formula to evaluate

$$\left(\frac{1}{2\pi i}\right)^2\int_T\frac{dP_1\,dP_2}{P_1P_2} \tag{A2}$$

produces a positive contribution from every branch of P_1.

(Received 14 September 2000; accepted for publication 13 November 2000)

In view of the geometrical importance of spaces with constant scalar curvature, a systematic study of spherically symmetric such space–time manifolds with respect to the eigenvalues of the Ricci tensor is made. The cases of two double or one quadruple eigenvalue are treated exhaustively. In the generic case of one double and two single eigenvalues, no conformally flat solutions, and only solutions with one arbitrary function of one variable are found. We also give all four-dimensional decomposable s.s. spaces with constant curvature scalar. © *2001 American Institute of Physics.* [DOI: 10.1063/1.1339218]

I. INTRODUCTION

In this paper we study spherically symmetric solutions (s.s.s.) of the equation

$$R = R_0, \tag{1}$$

where R is the Ricci scalar of the four-dimensional pseudo-Riemannian metric $g_{\alpha\beta}$, and R_0 is a constant. The case $R_0 = 0$ was treated in a previous communication.[1] As expressed there, our original interests in s.s.s. of Eq. (1) was directed to their use as counterexamples for the validity of Birkhoff's theorem for a large class of gravitational theories derivable from a variational principle.[2] Equation (1), through the use of a scalar multiplier, is also derivable from a variational principle. The Lagrangian is given by

$$\sqrt{-g}(R-R_0)^2\phi,$$

where the scalar field ϕ acts as a multiplier and remains completely undetermined. Any solution of Eq. (1) with $R_0 = -4\Lambda$ solves also the field equations following from the Lagrangian $(-g)^{1/2}[R+2\Lambda+(8\Lambda)^{-1}R^2]$, where Λ is the cosmological constant. Moreover, any conformally flat solution of Eq. (1) with $R_0 = -4\Lambda$ satisfies the field equations following from the Lagrangian:

$$(-g)^{1/2}[R+2\Lambda+aR^2+3((8\Lambda)^{-1}-a)R^{\beta}_{\alpha}R^{\alpha}_{\beta}],$$

where $R_{\alpha\beta}$ is the contracted curvature (Ricci) tensor and a an arbitrary constant. Because Eq. (1) admits a multiplicity of solutions, as shown in this paper, no such field equation admits Birkhoff's theorem.

We were further motivated to look into the s.s.s. of Eq. (1) because they contain, as a subset, all s.s.s. of the Einstein–Maxwell field equations with a cosmological constant, and of the Yang–Kilmister (gauge-)theory of gravitation.[3] In this context, the solutions of the Bach–Treder-equation augmented with a cosmological constant term may be mentioned, because for them $R = R_0$ is implied.[4–6]

TABLE I.

	Quadruple	Quadruple	Two double	Two double	One triple, one single	One double, two single canonical form	One double, two single canonical form
	$2C-R=0$	$2C-R\neq 0$	$2C-R=0$	$2C-R\neq 0$		(2)	(3)
$C=0$		De Sitter metric			(26a, b) Einstein cosmos (28a, b) (30a, c) (31) (incomplete) (79)	(no solution found)	(no solution found)
$C\neq 0$	(21)	(23)	(18)	(9) (14) (16a, b)	(no solution found)	(39a) with (41), (42),(44); (39b, c, d) with (41), and (47a, b, c); (52) with (30a, b), (31b, c); (54b, c, d) (56a, b, c) (57b, d)	(10) with (11); (63) with (65a, b, c); (72) with (68); (78a, b, c)

The prime interest in Eq. (1), however, is that this equation points to the possibility of a geometrization of many physical systems in the sense that their basic equations, or subcases of them, appear as special cases of (1). To name some: nonlinear wave equations as in the ϕ^4-theory and the 1-dimensional Landau–Ginzburg theory of superconduction, the Lane–Emden equation of stellar interiors and the Thomas–Fermi equation, particular cases of Boltzman's equation and the time-independent Schrödinger equation for special potentials. It is also known that, in Euclidean space, soliton equations may be derived by embedding 2-surfaces with the property (1); an example is given by surfaces with constant negative curvature: the corresponding Gauss–Codazzi equation is equivalent to the sine-Gordon equation.[7–9] Also for the Korteweg-de Vries equation a geometrical interpretation with the help of a surface of constant, nonvanishing Gaussian curvature has been suggested.[10]

The generic solution of Eq. (1) contains, at most, one arbitrary function of two variables and two further arbitrary functions of one variable each. In paper I, for $R_0=0$, we explicitly gave the general s.s.s. of Eq. (1) for certain specific values of the conformal invariant $C:=[3/4C_{\alpha\beta\gamma\delta}C^{\alpha\beta\gamma\delta}]^{1/2}$, e.g., for $C=0$, where $C_{\alpha\beta\gamma\delta}$ denotes the conformal curvature tensor, and implicitly reduced the problem to a linear equation. (For s.s. metrics $C=0$ and $C_{\alpha\beta\gamma\delta}=0$ are equivalent.) In the present case, $R_0\neq 0$, we have not been able to achieve as much, although we do obtain classes of solutions depending on one or even two arbitrary functions of one variable. This is due to the fact that none of the canonical forms of the metric considered in Sec. II linearizes Eq. (1) nor reduces it to a nonlinear partial differential equation whose solutions are known completely. Nevertheless, as in paper I, we display the general solution of Eq. (1) for metrics the Ricci tensor of which has a quadruple or two double eigenvalues. Also, all four-dimensional decomposable s.s. spaces with a constant curvature scalar are found.

After introducing, in Sec. II, the canonical forms for the metric we are using, in Sec. III we first deal with decomposable spaces. In Sec. IV we discuss all the metrics obtained by us with a degenerate eigenvalue structure of the corresponding Ricci tensor R_α^β. In Sec. V, s.s.s. of Eq. (1) with the most general eigenvalue structure of R_α^β are given. In Sec. VI a different canonical form for the metric is used in order to obtain further solutions. Those s.s.s. of the Yang–Kilmister theory found here are identified in Sec. VII. In Sec. VIII a brief discussion of the generation of s.s.s. of Eq. (1) from others or from s.s.s. of $R=0$ by conformal mappings is given. Our results are summarized in Table I and discussed in Sec. IX.

II. CANONICAL FORMS OF s.s. METRIC

As in paper I we use, alternatively, the canonical forms

$$ds^2=z^2(u,v)[2e^{w(u,v)}\,du\,dv-d\Omega^2] \tag{2}$$

and

$$ds^2=c^2(r,t)dt^2-a^4(r,t)[dr^2+r^2\,d\Omega^2], \tag{3a}$$

with $d\Omega^2:=d\theta^2+\sin^2\theta\,d\varphi^2$ for describing metrics with a Ricci tensor R_α^β of a nondegenerate eigenvalue structure. A canonical form equivalent to (3a) is

$$ds^2=c^2(\rho,t)dt^2-b^4(\rho,t)[d\rho^2+d\Omega^2]. \tag{3b}$$

Any s.s. metric can be brought into either form (2) or Eq. (3a).

For metrics the Ricci tensor of which has two double eigenvalues the following canonical forms are especially suited:[11]

$$ds^2=F(u,r)du^2+2\,du\,dr-r^2d\Omega^2, \tag{4}$$

with $R-2C\neq 0$ and

$$ds^2=F(u,r)du^2+2\,du\,dr-b_0^2d\Omega^2, \tag{5}$$

$$ds^2=2e^{2\alpha(u,v)}\,du\,dv-u^2d\Omega^2, \tag{6}$$

and the canonical form obtained from Eq. (6) by interchange of u and v. For both forms (5) and (6) $R-2C=0$ holds; b_0 is a constant.

We keep to the canonical forms (2)–(6) unless another form, obviously transformable into one of these forms, is more convenient for an explicit integration of (1). Such a transformation may not always be obtainable explicitly.

The equivalence problem arising from the use of different canonical forms is circumvented by a classification of the s.s.s. of Eq. (1) with regard to the eigenvalue structure of R_α^β and to the conformal invariant C.

Starting from the canonical form (2) we calculate the curvature invariants R and C. For convenience we repeat the resulting partial differential equations for $z(u,v)$ and $w(u,v)$ given in paper I, i.e.,

$$e^{-w}w_{,uv}+1-z^2C=0, \tag{7a}$$

$$z_{,uv}+\frac{1}{6}z^3e^w\left(C-\frac{1}{2}R\right)=0. \tag{7b}$$

III. DECOMPOSABLE SPHERICALLY SYMMETRIC SPACE–TIMES

Before entering the general discussion we shall first deal with a case of special geometric interest, the decomposable s.s.s. of Eq. (1). Two main subcases exist.

A. Two 2-dimensional subspaces

Here we take the canonical form

$$ds^2=2e^{w(u,v)}\,dv\,dv-b_0^2d\Omega^2. \tag{2′}$$

A constant Ricci scalar R_0 for (2′) can occur if and only if the $u-v$-space is of constant Gaussian curvature,

$$k=\frac{1}{b_0^2}-\frac{R_0}{2}. \tag{8}$$

Standard forms for such solutions of Eq. (1) are, for $k=1/a_0^2$,

$$ds^2=\left(1+\frac{uv}{4a_0^2}\right)^{-2}du\,dv-b_0^2d\Omega^2, \tag{9a}$$

and, for $k=-1/a_0^2$,

$$ds^2=\left(1-\frac{uv}{4a_0^2}\right)^{-2}du\,dv-b_0^2d\Omega^2. \tag{9b}$$

The case $k=0$ is represented by the canonical form

$$ds^2=du\,dv-b_0^2d\Omega^2.$$

Other canonical forms for the u, v-subspace of the metric (9a) are, for example,

$$d\sigma^2=dt^2-\sin^2(t/a_0)dr^2$$

or

$$d\sigma^2=\sinh^2(r/a_0)dt^2-dr^2.$$

However, the coordinates t, r chosen above cover only part of the range $-\infty<u<\infty$, $-\infty<v<\infty$, $vid.uv>0$ and $0<uv<4a_0^2$, respectively. From Eq. (6) we conclude $C=1/2R_0$ for the metrics (9). The Ricci tensor has two double (or one quadruple) eigenvalues $\lambda_{1,2}=\pm 1/a_0^2$, $\lambda_{3,4}=-1/b_0^2$. Moreover, the corresponding Riemannian space is symmetric. Equation (9) admits a two-dimensional isotropy group and a six-dimensional isometry group.[12] The metrics (9a) and (9b) have been discussed repeatedly[13] as solutions of Einstein's field equations with cosmological constant Λ and/or a constant nonsingular electromagnetic field. They also satisfy the field equations following from the Lagrangian:

$$(-g)^{1/2}[R+\Lambda+aR^2-(2a+R_0^{-1})R_\alpha^\beta R_\beta^\alpha],$$

to which a matter Lagrangian describing a constant, nonsingular electromagnetic field may be added. Wynne's solutions[14] of types XI, XII, XIII, XIV and XVI solving the field equations derived from the Lagrangian $R_\beta^\alpha R_\alpha^\beta+aR^2$ belong to this set.

B. One 1-dimensional and one 3-dimensional subspace

Here we use the canonical forms

$$ds^2=dt^2-A(r)dr^2-r^2\,d\Omega^2 \tag{10a}$$

and

$$ds^2=B(t)dt^2-t^2\,d\Omega^2-dr^2. \tag{10b}$$

Using the formulas of Takeno[15] one can show that a constant Ricci scalar R_0 occurs if and only if

$$A(r)=\left(1-\frac{R_0}{6}r^2+a_0/r\right)^{-1}, \tag{11a}$$

$$B(t)=\left(-1+\frac{R_0}{6}t^2+b_0/t\right)^2. \tag{11b}$$

For $a_0\neq 0$ ($b_0\neq 0$) the 3-dimensional subspace is not a space of constant curvature; $a_0=0$ leads to the Einstein cosmos. $b_0=0$, after a coordinate transformation, leads to the line element

$$ds^2=2\,du\,dv-\frac{6}{R_0}\cosh^2\left[\left(\frac{R_0}{12}\right)^{1/2}(u+v)\right]d\Omega^2. \tag{12}$$

For the decomposable spaces (10) and (11) the conformal invariant is given by

$$C=3a_0/2r^3 \quad \text{or} \quad 3b_0/2t^3, \quad \text{respectively.} \tag{13}$$

The eigenvalues of R^{α}_{β} for metric (10a) with (11a) are

$$\lambda_1=0,\ \lambda_2=\frac{R_0}{3}-\frac{a_0}{r^3},\ \lambda_3=\lambda_4=\frac{R_0}{3}+\frac{a_0}{2r^3}.$$

IV. s.s.s. WITH DEGENERATE EIGENVALUE STRUCTURE OF R^{β}_{α}

In general, the Ricci tensor of a s.s. spacetime admits one double and two single eigenvalues.

A. Two double eigenvalues

We first deal with the case of the metric not being conformally flat, i.e., $C\neq 0$. Two further subcases arise

1. $2C-R=0$

Here both canonical forms (5) and (6) must be considered. For (5), the general s.s.s. of Eq. (1) is given by

$$F(u,r)=a(u)+b(r)r+\left(\frac{1}{b_0^2}-\frac{R_0}{2}\right)r^2, \tag{14}$$

with arbitrary functions $a(u),b(u)$.

Among the metrics (5) with (14) we find the decomposable spaces (9) considered before, i.e., for $a(u)=\pm 1$, $b(u)=0$.

The eigenvalues of the Ricci tensor are

$$\lambda_{1,2}=\frac{R_0}{2}-\frac{1}{b_0^2},\ \lambda_{3,4}=1/b_0^2. \tag{15}$$

For the canonical form (6) the most general s.s.s. of Eq. (1) is given by

$$ds^2=z^2(u)\left\{\frac{4\,du\,dv}{(u-v)^2\left[1-\frac{R_0}{2}z^2(u)\right]}-d\Omega^2\right\}, \tag{16a}$$

with $z(u)$ arbitrary.

In this case the eigenvalues of R^{β}_{α} are

$$\lambda_{1,2}=\frac{R_0}{2}-\frac{1}{z^2(u)},\quad \lambda_{3,4}=\frac{1}{z^2(u)}. \tag{17}$$

Obviously, the interchange of u and v leads to another set of solutions,

$$ds^2=z^2(v)\left\{\frac{4\,du\,dv}{(u-v)^2\left[1-\frac{R_0}{2}z^2(v)\right]}-d\Omega^2\right\}. \tag{16b}$$

2. $2C-R\neq 0$

Here we must use the canonical form (4). The general s.s.s. of Eq. (1), in this case, then is given by

$$ds^2=\left(1-\frac{2m(u)}{r}+\frac{e^2(u)}{r^2}-\frac{\Lambda}{3}r^2\right)du^2+2\,du\,dr-r^2d\Omega^2, \tag{18}$$

where $e\cdot m\neq 0$ and

$$R_0=4\Lambda,\quad C=\frac{6m(u)}{r^3}-6\frac{e^2(u)}{r^4}, \tag{19}$$

$m(u),e(u)$ arbitrary functions.

The eigenvalues of R^β_α are

$$\lambda_{1,2}=\Lambda+e^2/r^4,\quad \lambda_{3,4}=\Lambda-e^2/r^4. \tag{20}$$

The solutions (18) include the Reissner–Nordström metric with cosmological term.

For conformally flat metrics, $C=0$, the canonical form (4) is the only possibility. However, from Eq. (19), in this case, we must have $m=e=0$ and thus Eq. (20) implies a quadruple eigenvalue of R^β_α. Hence, there are no conformally flat s.s.s. of Eq. (1) with two distinct double eigenvalues.

B. One quadruple eigenvalue

We follow the same subdivision as before.

1. $2C-R=0$

From Eqs. (14) and (15) we obtain

$$ds^2=[a(u)+b(u)r-r^2/b_0^2]du^2-2\,du\,dr-\frac{1}{b_0^2}d\Omega^2, \tag{21}$$

with the quadruple eigenvalue $\lambda=1/b_0^2$.

On the other hand we obtain from Eqs. (16a), (16b) and (17),

$$ds^2=-z_0^2\left[\frac{4\,du\,dv}{(u-v)^2}-d\Omega^2\right], \tag{22}$$

with the quadruple eigenvalues $\lambda=1/z_0^2$.

A coordinate transformation $u=2^{-1/2}(r-t)$, $v=2^{-1/2}(r+t)$ leads to

$$ds^2=\left(\frac{z_0}{t}\right)^2[dt^2-dr^2-t^2\,d\Omega^2].$$

Both (21) and (22) are decomposable spaces of type (9b), i.e., with negative Gaussian curvature $k=-2/b_0^2$ $(k=-1/z_0^2)$.

2. $2C-R\neq 0$

From Eqs. (18) and (20) we obtain

$$ds^2=\left(1-\frac{2m(u)}{r}-\frac{1}{3}\Lambda r^2\right)du^2+2\,dv\,dr-r^2\,d\Omega^2, \tag{23}$$

with $m\cdot\Lambda\neq 0$ and the quadruple eigenvalue $\lambda=\Lambda$.

The only conformally flat s.s.s. of Eq. (1) with the quadruple eigenvalue of R_α^β is the DeSitter metric (mentioned at the end of Sec. IV A) following from (23) by putting $m=0$, $\Lambda\neq 0$.

C. One triple and one single eigenvalue

In this case we were only able to find conformally flat solutions. For the canonical form (2), $C=0$ means

$$ds^2=z^2\left[\frac{4\,du\,dv}{(u-v)^2}-d\Omega^2\right], \tag{24}$$

and Eq. (1) then leads to

$$(u-v)^2z_{,uv}-\tfrac{1}{6}R_0z^3=0. \tag{25a}$$

In place of z we introduce a new dependent variable ϕ by $z=(u-v)\phi$. Equation (25a) is replaced by

$$\phi_{,uv}-\frac{R_0}{6}\phi^3+\frac{1}{(u-v)}[\phi_{,v}-\phi_{,u}]=0. \tag{25b}$$

We were able to find solutions of this equation with the following three special assumptions.

1. $\phi=A(u)\cdot B(v)$

A particular solution of Eq. (25b) is given by

$$A(u)=(a_0+a_1u+a_2u^2)^{-1/2},$$

$$B(v)=(a_0+a_1v+a_2v^2)^{-1/2},$$

where $4a_0a_2-a_1^2=2/3R_0$ must hold. The corresponding metric can be transformed into the forms

$$ds^2=2dUdV-\frac{6}{|R_0|}\sinh^2\left(\sqrt{\frac{|R_0|}{12}}(U-V)\right)d\Omega^2, \tag{26a}$$

for $R_0<0$, and

$$ds^2=2\,dU\,dV-\frac{6}{R_0}\sin^2\left(\sqrt{\frac{R_0}{12}}(U-V)\right)d\Omega^2, \tag{26b}$$

for $R_0>0$.

Both (26a) and (26b) are equivalent to the Einstein cosmos. The corresponding eigenvalues of the Ricci tensor, for (26a) and (26b) are

$$\lambda_1=0,\quad \lambda_2=\lambda_3=\lambda_4=R_0/3. \tag{27}$$

2. $\phi=\phi(u+v)$

This case always leads to a triple (or, possibly, quadruple) eigenvalue of R^{β}_{α}. Eq. (25b) reduces to

$$\phi''-\frac{R_0}{6}\phi^3=0. \tag{25c}$$

Solutions of Eq. (25c) with 0, 1 and 2 arbitrary parameters were given in Ref. 20, Sec. III. Examples in terms of Jacobian elliptic functions are, for $R_0<0$,

$$ds^2=\frac{12}{|R_0|}cn^2\left(u+v,\pm\frac{1}{\sqrt{2}}\right)\left[2\,du\,dv-\frac{(u-v)^2}{2}d\Omega^2\right], \tag{28a}$$

and, for $R_0>0$,

$$ds^2=\frac{12}{R_0}nc^2\left(u+v,\pm\frac{1}{\sqrt{2}}\right)\left[2\,du\,dv-\frac{(u-v)^2}{2}d\Omega^2\right]. \tag{28b}$$

The corresponding eigenvalues of the Ricci tensor are given by

$$\begin{aligned}\lambda_1&=\frac{|R_0|}{4}\left[-1-cn^{-4}\left(u+v,\pm\frac{1}{\sqrt{2}}\right)\right].\\ \lambda_2=\lambda_3=\lambda_4&=\frac{|R_0|}{12}\left[-3+cn^{-4}\left(u+v,\pm\frac{1}{\sqrt{2}}\right)\right],\end{aligned} \tag{29a}$$

and

$$\begin{aligned}\lambda_1&=\frac{R_0}{4}\left[1+nc^{-4}\left(u+v,\pm\frac{1}{\sqrt{2}}\right)\right],\\ \lambda_2=\lambda_3=\lambda_4&=\frac{R_0}{12}\left[3-nc^{-4}\left(u+v,\pm\frac{1}{\sqrt{2}}\right)\right],\end{aligned} \tag{29b}$$

respectively.

The only solution of this type with a quadruple eigenvalue is generated by $\phi=\sqrt{12/R_0}(u+v)^{-1}$ and this, according to Sec. IV B, is again the DeSitter space–time.

3. $\phi=(uv)^{-1/2}G(\ln(uv))$

A straightforward calculation shows that, again, a triple eigenvalue of R^{β}_{α} occurs. In this case, Eq. (25b) reduces to

$$\frac{d^2G}{(d\ln\eta)^2}-\frac{1}{4}G-\frac{R_0}{6}G^3=0, \tag{25d}$$

where $\eta:=u\cdot v$ and $G=G(\ln\eta)$ which was also solved in Ref. 16. The metric can be written, alternatively, in the forms

$$ds^2=\frac{2}{uv}G^2(\ln(uv))\left[2\,du\,dv-\frac{(u-v)^2}{2}d\Omega^2\right] \tag{30a}$$

and

$$ds^2=4G^2(U+V)\left[dU\,dV-\sinh^2\left(\frac{U-V}{2}\right)d\Omega^2\right], \tag{30b}$$

where $U:=\ln u$, $V:=\ln v$. The singular solution of (25d), i.e.,

$$G(\ln\eta)=\pm\left(\frac{3}{2R_0}\right)^{1/2}, \tag{31a}$$

leads back to (26b) for $R_0>0$.

On the other hand, the 2-parameter solutions of Eq. (25d) taken from Ref. 20, Sec. III, lead to new solutions of Eq. (1). They are given by

$$G(\ln\eta)=\alpha\left[-\frac{\varepsilon}{3}+\varepsilon\wp\left(\frac{1}{2}\ln\eta+\beta,g_2,g_3\right)\right]^{-1/2}, \tag{31b}$$

where $\wp(x)$ is the Weierstraß function with

$$g_2=\frac{4}{3}(1-R_0\alpha^2),\quad g_3=-\frac{8}{27}+\frac{4}{9}\varepsilon R_0\alpha^2,\quad \varepsilon=\pm1,$$

and α and β are arbitrary constants. Equation (31b) holds for an arbitrary sign of R_0. While we can go to the limit $R_0=0$ in (31b), this cannot be done with the further 2-parameter solution,

$$G(\ln\eta)=\sqrt{\frac{3}{R_0}}\left[-\frac{1}{3}+\wp\left(\frac{1}{2}\ln\eta+\beta,g_2,g_3\right)\right], \tag{31c}$$

where now $g_3=4/27-1/3g_2$ whereas g_2 and β are arbitrary constants. For (31c) $R_0>0$ must hold. The metric (30b) with (31b) or (31c) is conformally related to the metric (26a) (cf. Sec. VIII).

It is also possible to express the solutions of Eq. (25d) by Jacobian elliptic functions (cf. Ref. 20, Appendix E).

V. s.s.s. OF $R=R_0$ WITH GENERIC EIGENVALUE STRUCTURE OF R^{β}_{α}: CANONICAL FORM (2) OF THE METRIC

If the conformal invariant C is eliminated from Eqs. (7a) and (7b) we obtain the equation

$$z_{,uv}+\frac{1}{6}z(e^w+w_{,uv})-\frac{R_0}{12}z^3e^w=0. \tag{32}$$

In contrast to the case $R_0=0$ of paper I, for $w(u,v)$ arbitrarily given, Eq. (32) is a nonlinear partial differential equation for $z(u,v)$.

All the classes of solutions of Eqs. (32) found by us were obtained by assuming the following particular relation between the functions w and z:

$$e^w=z^a(u,v)g^2(u\pm v), \tag{33}$$

with integer a, while g satisfies the equation (37) whose solutions are (38a,...,e). The metric corresponding to (33) is

$$ds^2=2g^2(u\pm v)z^{a+2}(u,v)du\,dv-z^2(u,v)d\Omega^2, \tag{34}$$

while Eq. (32) with (33) goes over into

$$0=\left(1+\frac{a}{6}\right)zz_{,uv}-\frac{a}{6}z_{,u}z_{,v}\pm\frac{1}{3}z^2(\ln g)''+\frac{g^2}{6}\left[z^{a+2}-\frac{R_0}{2}z^{a+4}\right]. \tag{35}$$

The conformal invariant is given by

$$C=z^{-2}+z^{-(a+2)}g^{-2}\{\pm 2(\ln g)''+a(\ln z)_{,uv}\}. \tag{36}$$

If the additional restriction

$$(\ln g)''=\delta_0 g^2 \tag{37}$$

is introduced, we obtain from (35) and (37),

$$\left(1+\frac{a}{6}\right)zz_{,uv}-\frac{a}{6}z_{,u}z_{,v}\pm\frac{\delta_0}{3}g^2z^2+\frac{1}{6}g^2\left[z^{a+2}-\frac{R_0}{2}z^{a+4}\right]=0. \tag{35$'$}$$

For $\delta_0=0$, Eq. (37) is solved by

$$g=g_0e^{c_1(u\pm v)}, \tag{38a}$$

and for $\delta_0\neq 0$ by

$$\delta_0 g^2=(u\pm v+\delta_1)^{-2}, \tag{38b}$$

$$\delta_0 g^2=-\frac{c_1}{2}\cosh^{-2}\left(\sqrt{\frac{c_1}{2}}(u\pm v)+\delta_1\right), \tag{38c}$$

$$\delta_0 g^2=\frac{c_1}{2}\sinh^{-2}\left(\sqrt{\frac{c_1}{2}}(u\pm v)+\delta_1\right), \tag{38d}$$

$$\delta_0 g^2=\frac{c_1}{2}\cos^{-2}\left(\sqrt{\frac{c_1}{2}}(u\pm v)+\delta_1\right). \tag{38e}$$

As far as the corresponding metrics (34) are concerned, the choice $g_0=1$, $c_1=0$ in (38a) and $c_1=\pm 1$ in (38c) and (38d) is no restriction of generality. Thus the following metrics will occur:

$$ds^2=z^2[2z^a\,du\,dv-d\Omega^2], \tag{39a}$$

$$ds^2=z^2\left[2\frac{z^a}{\delta_0}\frac{du\,dv}{(u\pm v)^2}-d\Omega^2\right], \tag{39b}$$

$$ds^2=z^2\left[2\frac{z^a}{\delta_0}\frac{du\,dv}{\cosh^2\dfrac{u\pm v}{\sqrt{2}}}-d\Omega^2\right] \tag{39c}$$

and

$$ds^2=z^2\left[2\frac{z^a}{\delta_0}\frac{du\,dv}{\sinh^2\dfrac{u\pm v}{\sqrt{2}}}-d\Omega^2\right] \tag{39d}$$

and

$$ds^2=z^2\left[2\frac{z^a}{\delta_0}\frac{du\,dv}{\cos^2\frac{u\pm v}{\sqrt{2}}}-d\Omega^2\right]. \tag{39e}$$

For the solution of (35′) two essentially different cases can be distinguished.

A. $a=-6$

In this case (35′) reduces to a first-order nonlinear partial differential equation. By introducing $\varphi:=z^2$ as a new dependent variable, Eq. (35′) goes over into

$$\varphi_{,u}\varphi_{,v}+\tfrac{1}{3}g^2[\pm 4\delta_0\varphi^2+2\varphi^{-1}-R_0]=0. \tag{40}$$

By introducing, in place of φ, the variable

$$\chi(u,v)=\int^{\varphi}dx\,\frac{\sqrt{x}}{\sqrt{\mp 4\delta_0 x^3+R_0x-2}}, \tag{41}$$

Eq. (40) can be transformed into

$$\chi_{,u}\chi_{,v}=\mp\tfrac{1}{3}g^2. \tag{40′}$$

The integral in (41) can be evaluated in terms of elliptic integrals of the first and third kind of Legendre's canonical forms.[17] The problem of solving (35′) thus is reduced to finding solutions of Eq. (40′) for g^2 given by Eqs. (38a)–(38d). Then $z(u,v)$ can be determined as an implicit function of $u\pm v$ from Eq. (41).

(α) Let us start with (38a), that is $g=1$, $\delta_0=0$. Then

$$\chi=\frac{2}{\sqrt{3}}\sqrt{uv} \tag{42}$$

solves (40a) with the + sign on the right hand side. Apart from integration constants which are irrelevant for the corresponding metric (39a) this is the most general solution for which $\chi=A(u)\cdot B(v)$. Another solution is given by

$$\chi=\frac{1}{\sqrt{3}}(u\pm v). \tag{43}$$

In this case the integral in (41) can be carried through. We obtain

$$\chi=\frac{\varphi}{R_0}\sqrt{R_0-2\varphi^{-1}}-R_0^{3/2}\ln\frac{\sqrt{R_0-2\varphi^{-1}}-\sqrt{R_0}}{\sqrt{R_0-2\varphi^{-1}}+\sqrt{R_0}}, \tag{44a}$$

if $R_0>0$, and

$$\chi=\frac{\varphi}{R_0}\sqrt{R_0-2\varphi^{-1}}-2|R_0|^{3/2}\arctan\sqrt{\frac{R_0}{|R_0|}-2\frac{\varphi^{-1}}{|R_0|}}, \tag{44b}$$

if $R_0<0$. The three different eigenvalues of R_α^β corresponding to the solution (42) are given by:

$$\lambda_1=R_0-2\varphi^{-1}-\frac{1}{\sqrt{3}}\varphi\frac{\sqrt{R_0-2\varphi^{-1}}}{\sqrt{uv}},$$

$$\lambda_2 = -(2/3)\varphi^{-1}, \tag{45}$$

$$\lambda_3 = \lambda_4 = \frac{4}{3}\varphi^{-1} + \frac{1}{2\sqrt{3}}\varphi\frac{\sqrt{R_0 - 2\varphi^{-1}}}{\sqrt{uv}},$$

while the conformal invariant is

$$C = R_0 - 2\varphi^{-1} - \frac{1}{2}\sqrt{3}\varphi\frac{\sqrt{R_0 - 2\varphi^{-1}}}{\sqrt{uv}}. \tag{46}$$

(β) It is not difficult to obtain solutions of Eq. (40a) for the other values (38b)–(38d) of g^2. The solutions of Eq. (40a) corresponding to (38c), (38e), (38b) are, respectively,

$$\chi = \pm\frac{2}{\sqrt{-3\delta_0}}\arctan\left[\exp\sqrt{\frac{c_1}{2}}(u+v-\eta_0)\right], \tag{47a}$$

$$\chi = \frac{1}{2\sqrt{3\delta_0}}\ln\tan\left(\frac{\pi}{4} + \sqrt{\frac{|c_1|}{2}}(u+v-\eta_0)\right), \tag{47b}$$

$$\chi = \frac{1}{\sqrt{3\delta_0}}\ln(u+v-\eta_0). \tag{47c}$$

B. $a \neq -6$

In this case the substitution $z := \varphi^{1+a/6}$ transforms Eq. (35′) into

$$\left(1+\frac{a}{6}\right)^2\varphi_{,uv} + g^2\left[\pm\frac{1}{3}\delta_0\varphi + \frac{1}{6}\varphi^{1/6\,a^2+a+1} - \frac{R_0}{12}\varphi^{1/6\,a^2+4/3\,a+3}\right] = 0. \tag{48}$$

The canonical form of the metric now is

$$ds^2 = 2g^2(u \pm v)\varphi^{1/6(a+6)(a+2)}\,du\,dv - \varphi^{2+a/3}d\Omega^2. \tag{49}$$

For $g=1$, $a=0$, Eq. (48) reduces to the 2-dimensional nonlinear wave equation of the ϕ^4-theory,

$$\varphi_{,uv} + \left(\pm\frac{1}{3}\delta_0 + \frac{1}{6}\right)\varphi - \frac{R_0}{12}\varphi^3 = 0. \tag{50}$$

All known exact s.s. solutions of the ϕ^4-theory thus lead to spaces with constant curvature scalar (cf. Refs. 18–20).

(α) Again, we deal with the most simple case $g=1$, $\delta_0=0$ first, i.e., with (38a). The ansatz $\varphi = \varphi(Au+Bv)$, $AB \neq 0$ reduces Eq. (48) to an ordinary differential equation the integral of which is given by

$$\pm(Au+Bv+E) = \int^{\varphi}\frac{d\varphi}{\sqrt{2D + \dfrac{72}{AB(6+a)^2}\left[\dfrac{R_0}{2}\dfrac{\varphi^{((a+4)^2+8)/6}}{(a+4)^2+8} - \dfrac{\varphi^{((a+3)^2+3)/6}}{(a+3)^2+3}\right]}}. \tag{51}$$

For $a=0,-2,-3,-4$ the integral can be evaluated in terms of elliptical functions (cf. Appendix A). Specifically, for $a=0$ (and $g=1\cong\delta_0=0$) with $\varphi=\varphi(Au+Bv)$, Eq. (48) reduces to

$$\varphi'' + (6AB)^{-1}\left[\varphi - \frac{R_0}{2}\varphi^3\right] = 0. \tag{52}$$

Equation (51) is of the same type as Eq. (25d) solutions of which we presented in Eqs. (31a)–(31c). It is the 1-dimensional *Landau–Ginzburg* equation of a superconductor without an external magnetic field. While the functions appearing are the same the metrics are different, though. For $a=0$, from Eq. (39a),

$$ds^2 = \varphi^2(2\,du\,dv - d\Omega^2), \tag{53}$$

results which is not conformally flat in contradistinction to the metric, Eqs. (30), with (30a)–(30c). The singular solution with $\varphi=(2/R_0)^{1/2}$ admits two double eigenvalues; it was already found in Sec. III as a decomposable space [Eq. (9), $k=0$], and is among the metrics (5) with (14) discussed in Sec. IV. Solutions of (51) in terms of Jacobian elliptical functions were given by us in Appendix E of Ref. 20.

(β) Coming now to the values (38b)–(38d) for g^2 we must solve, for $a=0$, as the first particular case:

$$g^{-2}(u\pm v)\varphi_{,uv} + \left(\frac{1}{6} \pm \frac{\delta_0}{3}\right)\varphi - \frac{R_0}{12}\varphi^3 = 0. \tag{54a}$$

In Eqs. (B1), (B3), (B6) of Appendix B we display 1-parameter solutions of Eq. (54a) for certain fixed values of δ_0 and by assuming $\varphi=\varphi(u\pm v)$.

For the case (38b), $\delta_0=\mp 3/2$, and the corresponding metric (with the correct signature) is

$$ds^2 = \varphi^2\left[\frac{4}{3}\frac{du\,dv}{(u\pm v)^2} - d\Omega^2\right], \tag{54b}$$

with

$$\varphi = [1/2\sqrt{-R_0} + c_1(u\pm v)^{-1/3}]^{-1},$$

where $R_0 \leqslant 0$. For (38c) and (38d) we have $\delta_0=\mp 1/2$ and the solutions

$$ds^2 = \frac{6}{R_0}\cosh^2\frac{(u-v)}{\sqrt{2}}\left[\frac{2\,du\,dv}{\cosh^2\dfrac{u-v}{\sqrt{2}}} - d\Omega^2\right] \tag{54c}$$

and

$$ds^2 = \frac{6}{|R_0|}\cos^2\frac{u-v}{\sqrt{2}}\left[\frac{2\,du\,dv}{\cos^2\dfrac{u-v}{\sqrt{2}}} - d\Omega^2\right], \tag{54d}$$

where $R_0 \neq 0$.

Both metrics (54c) and (54d) have been met before in Eqs. (12) and (26b) (Einstein cosmos); they lead to degenerate eigenvalues of R_α^β.

For the particular value $a=-2$ we obtain from Eq. (48),

$$g^{-2}\varphi_{,uv} + \frac{3}{4}\left(\pm\delta_0 - \frac{R_0}{4}\right)\varphi + \frac{3}{8}\varphi^{-1/3} = 0. \tag{55}$$

Again, from Appendix B, we obtain the following solutions of (55) for the values (38b)–(38d) of g^2 if $\varphi=\varphi(u+v)$,

$$\varphi=\left[\pm\left(-\frac{6}{R_0}\right)^{1/2}+\tilde{c}_1(u\pm v+\delta_1)^{1/2}\right]^{3/2}, \tag{56a}$$

$$\varphi=\left[\frac{3}{5}\left(\mp 2\,\delta_0+\frac{R_0}{2}\right)\right]^{-3/4}\cosh^{-3/2}[\sigma(u\pm v)+\delta_1], \tag{56b}$$

and

$$\varphi=\left[\frac{3}{5}\left(\mp 2\,\delta_0+\frac{R_0}{2}\right)\right]^{-3/4}\cos^{-3/2}[\sigma(u\pm 4)+\delta_1], \tag{56c}$$

with

$$\sigma:=\left[-\frac{1}{5}\left(1\mp\frac{R_0}{4\,\delta_0}\right)\right]^{1/2}.$$

The corresponding metric, for (56a), is

$$ds^2=\frac{6}{|R_0|}\,\frac{du\,dv}{(u-v+\delta_1)^2}-\left[-\sqrt{\frac{6}{|R_0|}}+\tilde{c}_1(u+v+\delta_1)^{1/2}\right]^2 d\Omega^2, \tag{57}$$

for $R_0<0$.

If $\tilde{c}_1=c_1(12/|R_0|)^{1/4}$, $\delta_1=c_1^{-2}(3/|R_0|)^{1/2}$ the metric (57) can be transformed into

$$ds^2=\left(c_1-\sqrt{\frac{|R_0|}{6}}\,r\right)^4 dt^2-\frac{dr^2+r^2\,d\Omega^2}{\left(c_1-\sqrt{\frac{|R_0|}{6}}\,r\right)^2}.$$

For (56b) and (56c) we obtain metrics of the form

$$ds^2=4|\delta_0|\cosh^{-2}\left[\sqrt{\frac{c_1}{2}}(u\pm v)+\delta_1\right](2\,du\,dv-b_0^2\,d\Omega^2)$$

and

$$ds^2=4\,\delta_0\cos^{-2}\left[\sqrt{\frac{c_1}{2}}(u\pm v)+\delta_1\right](2\,du\,dv-b_0^2\,d\Omega^2),$$

i.e., essentially come back to the metric (52).

VI. s.s.s. of $R=R_0$ WITH GENERIC EIGENVALUE STRUCTURE OF R_α^β: CANONICAL FORM (3) OF THE METRIC

We now use a slightly altered form of the canonical form (3) of the metric,

$$ds^2=(\psi/\chi)^2\,dt^2-(\chi/r)^4[dr^2+r^2\,d\Omega^2], \tag{58}$$

with $\psi=\psi(r,t)$, $\chi=\chi(r,t)$.

We note that the change of radial coordinate $\rho=r^{-1}$ leads to

$$ds^2=(\psi/\chi)^2\,dt^2-\chi^4[d\rho^2+\rho^2\,d\Omega^2],$$

where now $\psi=\psi(\rho,t)$, $\chi=\chi(\rho,t)$.

While working with (58) permits us to find more s.s.s. of Eq. (1), we ought to check, in each case, if the solution is different from those given in Sec. V. In principle, (58) can be transformed into (2).

A straightforward calculation of the Ricci scalar R_0 and the conformal invariant gives

$$\psi''+\psi\left[3\chi''/\chi+\frac{R_0}{2}(\chi/r)^4\right]-\frac{6}{5}r^{-4}\chi[\psi^{-1}(\chi^5)^{\cdot\cdot}+(\chi^5)^{\cdot}(\psi^{-1})^{\cdot}]=0 \tag{59}$$

and

$$\begin{aligned} r^{-4}\chi^4 C=&-\chi^3[(\chi^{-3})''+3r^{-1}(\chi^{-3})'+2(\chi^{-3})' \\ &+2(\chi^{-3})'\psi^{-1}\psi']-3r^{-1}\psi^{-1}\psi'-\psi^{-1}\psi'', \end{aligned} \tag{60}$$

where $\psi':=d\psi/dr$, $\dot{\psi}:=d\psi/dt$.

Equations (59) and (60) hold for any s.s. metric as ψ and χ are arbitrary functions of two variables. In order to obtain solutions of (59) for given R_0 we add particular assumptions. Two main cases are discussed.

A.

$$\chi=\chi(r). \tag{61}$$

Now, Eq. (59) reduces to a linear equation for $\psi(r,t)$ and arbitrarily given $\chi(r)$. In principle we are thus led to s.s.s. of Eq. (1) with two free functions of the variable r and two more free functions of t. In fact, however, we succeeded in integrating (59) only for two subcases. In place of (59) we consider the system

$$\frac{\partial^2\psi(r,t)}{\partial r^2}+f(r)\psi(r,t)=0, \tag{62a}$$

$$\chi''-\frac{1}{3}f(r)\chi+\frac{R_0}{6}r^{-4}\chi^5=0, \tag{62b}$$

for $\psi(r,t)$ and $\chi(r)$ and discuss two choices for $f(r)$.

1. $f(r)=0$

From (62a),

$$\psi(r,t)=\omega(t)r+\nu(t). \tag{63}$$

One of the free functions $\omega(t),\nu(t)$ can be transformed to one in the metric (58), while $\chi(r)$ satisfies

$$\chi''+\frac{R_0}{6}r^{-4}\chi^5=0, \tag{64}$$

which is the *generalized Lane–Emden equation* of type $(0,R_0/6,-3,5)$. Its solutions (cf. Ref. 20) are given by

$$\chi=\left(\frac{3}{2R_0}\right)^{1/4}r^{1/2}, \tag{65a}$$

$$\chi = r d^{1/2}\left[1+\frac{1}{18}R_0\, d^2 r^2\right]^{-1/2}, \tag{65b}$$

and

$$\chi = c_1 r^{1/2}\left[-\frac{\varepsilon}{3}+\epsilon\wp\left(\mp\frac{1}{2}\ln r + c_2, g_2, g_3\right)\right]^{-1/2}, \tag{65c}$$

where in the Weierstraß function $\wp$ $g_2 = 4/3(1+c_1^2 R_0)$, $g_3 = -8/27 - 4/9\varepsilon c_1^2 R_0$, $\varepsilon^2 = 1, d, c_1, c_2$ arbitrary constants.

The singular solution (65a) is equivalent to the decomposable spaces (9) of Sec. III. The spatial sections of the metric (58) with (65a) are 3-spaces of constant curvature. The conformal invariant of this 1-parameter solution equals

$$C = 3\, d^{-2} r^{-2} + d^{-2} r^{-1}\left[1-\left(\frac{R_0\, d^2 r^2}{18}\right)^2\right]\omega(t)[\omega(t) r + \nu(t)]^{-1}. \tag{66}$$

2. $f(r) = 3\lambda(\lambda-1)r^{-2} + 1/2 R_0 \sigma^4 r^{4(\lambda-1)}$

A comparison of Eq. (62a) with this particular value of $f(r)$ with the differential equation

$$\frac{\partial^2 \psi}{\partial r^2} + \psi\left[\frac{1/4 - p^2\gamma^2}{r^2} + \delta^2\gamma^2 r^{2\gamma-2}\right] = 0, \tag{67}$$

for the Bessel functions, leads to the following solution:

$$\psi = r^{1/2}[\omega(t) I_p(\delta r^{\pm 2(4p^2+3)-1/2}) + \nu(t)\mathcal{N}_p(\delta r^{\pm 2(4p^2+3)^{-1/2}})], \tag{68}$$

where

$$\delta := \pm\sqrt{\frac{R_0}{2}}\,\frac{\sigma^2}{2}\sqrt{4p^2+3}, \quad p = \frac{\sqrt{1+12\lambda-12\lambda^2}}{2(2\lambda-1)}, \qquad \lambda \neq 1/2, \quad R_0 \gtrless 0. \tag{69}$$

Equation (62b) in this case looks difficult to solve:

$$r^4\chi'' - \left[\lambda(\lambda-1)r^2 + \frac{R_0}{6}\sigma^4 r^{4\lambda}\right]\chi + \frac{R_0}{6}\chi^5 = 0. \tag{70}$$

However, a particular solution,

$$\chi = \sigma r^{\lambda}, \tag{71}$$

with arbitrary λ is easily obtained.

The corresponding metric is

$$ds^2 = \psi^2\left(\frac{1}{\rho}, t\right)\sigma^{-2}\rho^{2\lambda}\, dt^2 - \sigma^2\rho^{-2\lambda}[d\rho^2 + \rho^2\, d\Omega^2], \tag{72}$$

with $\rho = r^{-1}$.

The conformal invariant belonging to (68) and (71) and calculated from Eq. (60) is

$$C = \frac{R_0}{2} + 3\sigma^{-4}(1-2\lambda)r^{2(1-2\lambda)}\left[\lambda - r + r\,\frac{\psi'}{\psi}\right].$$

The case $\lambda = 1/2$ excluded in (67), (68) again leads to the decomposable spaces (9) of Sec. III.

B. $\chi = \psi = A(r)B(t)$

For this case we obtain from Eqs. (59) and (60), respectively,

$$8r^4A^{-5}A'' + R_0B^4 - 3(B^4)^{\cdot\cdot} = 0 \tag{73}$$

and

$$C = -r^4B^{-4}A^{-2}[(A^{-2})'' + 3r^{-1}(A^{-2})'\,]. \tag{74}$$

By separation of variables, from Eq. (73),

$$A'' - \lambda_0/8r^{-4}A^5 = 0 \tag{75}$$

and

$$\ddot{y} - (R_0/3)y - \lambda_0/3 = 0, \tag{76}$$

where $y := B^4$ has been introduced. Equation (75) again is the generalized Lane–Emden equation (64); thus the solutions given in Eqs. (65a)–(65c) apply as well here if R_0 there is replaced by $-\lambda_0 \cdot 3/4$. Equation (76) is linear.

The corresponding metrics are conformal to decomposable spaces,

$$ds^2 = y(t)\left\{\frac{dt^2}{y(t)} - r^{-4}A^4(r)[dr^2 + r^2\,d\Omega^2]\right\}. \tag{77}$$

More precisely, the solutions corresponding to (65a) and (65c) are conformal to decomposable spaces of type (9) of Sec. III, i.e.,

$$ds^2 = dt^2 - \frac{9}{8}|\lambda_0|y(t)[d\rho^2 + d\Omega^2] \tag{78a}$$

and

$$ds^2 = dt^2 - y(t)\left[-\frac{\varepsilon}{3} + \varepsilon\wp(\pm\rho/2 + c_2, g_2, g_3)\right]^{-2}(d\rho^2 + d\Omega^2), \tag{78b}$$

where $\rho = \ln r$.

On the other hand (65b) leads to

$$ds^2 = y(t)\left\{\frac{dt^2}{y(t)} - \frac{dr^2 + r^2\,d\Omega^2}{[1 - \lambda_0/24r^2]^2}\right\} \tag{79}$$

which is conformally flat and gives a Ricci tensor with a triple eigenvalue. It thus belongs to the class of metrics (24) of Sec. IV C.

If $\lambda_0 = 0$ in Eqs. (75) and (76), we obtain $\chi = A_0 + B_0 r$ in place of Eq. (65a) and the metrics

$$ds^2 = dt^2 - (A_0r^{-1} + B_0)^4\left\{\begin{array}{l}\sinh\left(\sqrt{\dfrac{R_0}{3}}t + c_2\right)\\[2ex] \sin\left(\sqrt{\dfrac{|R_0|}{3}}t + c_2\right)\end{array}\right\}(dr^2 + r^2\,d\Omega^2). \tag{78c}$$

Finally, we mention a solution of Eq. (1) corresponding to the metric (78) but with coordinates r and t interchanged:

$$ds^2=-dr^2+y(r)[A(t)]^4(dt^2-d\Omega^2), \tag{80}$$

where

$$y=\begin{cases} c_1\sinh\left(\sqrt{\dfrac{|R_0|}{3}}r+c_2\right), & \text{if } R_0<0 \\ c_1\sin\left(\sqrt{\dfrac{R_0}{3}}r+c_2\right), & \text{if } R_0>0 \end{cases} \tag{81a}$$

and

$$A(t)=d_1\sin\left(\frac{t}{2}+d_2\right). \tag{81b}$$

VII. s.s.s. OF THE KILMISTER–YANG THEORY OF GRAVITATION

Kilmister and Yang have suggested the following field equations for a theory of gravitation:[3]

$$R_{\alpha[\beta;\gamma]}=0. \tag{82}$$

They are equivalent to[21]

$$C^{\kappa}_{\alpha\beta\gamma;\kappa}=0, \quad R=R_0=\text{const.} \tag{83}$$

If we write $d^{\alpha}_{\beta\gamma}:=C^{\kappa\alpha}{}_{\beta\gamma;\kappa}$ then, for a s.s. metric, the only nonvanishing components of $d^{\alpha}_{\beta\gamma}$ are

$$d^0_{01}=2d^2_{12}=2d^3_{13}=-C^{01}_{01,1}-3C^{01}_{01}\Gamma_{84}12^2 \tag{84a}$$

and

$$d^1_{01}=-2d^2_{02}=-2d^3_{03}=-C^{01}_{01,0}-3C^{01}_{01}\Gamma^2_{02}. \tag{84b}$$

For the further calculation we use Takeno's canonical form of the s.s. metric[15] with two redundant functions, that is,

$$ds^2=E\,dt^2-A\,dr^2+2D\,dr\,dt-B\,d\Omega^2. \tag{85}$$

Integration of $d^{\alpha}_{\beta\gamma}=0$ then leads to

$$C=c_0B(r,t)^{-3/2} \tag{86a}$$

where C is the conformal invariant and c_0 an arbitrary constant. Thus, for the canonical form (2),

$$C=c_0z^{-3}, \tag{86b}$$

while for (3) or (58), respectively,

$$C=c_0a^{-6}, \quad C=r^3\chi^{-6}, \tag{86c}$$

must hold in addition to (1) if the s.s. metric is to be a solution of Eq. (82). Equations (86) allow an easy inspection of the solutions of Eq. (1) presented in the previous sections. Of course all Einstein spaces and all conformally flat solutions with constant Ricci scalar are solutions of the Kilmister–Yang equations (82).[22] In paper I we have given the most general conformally flat

solution with $R=0$. Thus, it is of interest only, which solutions of Eq. (1) with $C\neq 0$ conform to Eqs. (86b) or (86c). Of all the solutions presented only the following three classes are solutions of the Yang–Kilmister equations:

$$ds^2=\left[a(u)+b(u)r+\left(\frac{1}{b_0^2}-\frac{R_0}{2}\right)r^2\right]du^2+2\,du\,dr-b_0^2\,d\Omega^2, \tag{87}$$

i.e., the s.s.s. of (1) with two double eigenvalues given in (14); the solution given by Ni,[23]

$$ds^2=dt^2-\left(1-\frac{a_0}{r}+b_0r^2\right)^{-1}dr^2-r^2\,d\Omega^2, \tag{88}$$

and the metric obtained from (88) by interchanging t and r,

$$ds^2=\left(-1+\frac{R_0}{6}t^2+\frac{b_0}{t}\right)^{-1}dt^2-t^2\,d\Omega^2.$$

The last two were found as decomposable spaces in Sec. III.

VIII. GENERATION OF SOLUTIONS BY CONFORMAL MAPPING

From the very start we used the fact that, locally, every s.s.s. metric is conformal to a decomposable s.s. space, built from two 2-dimensional subspaces. If in place of (2),

$$\overset{\star}{g}=z^2g, \tag{89}$$

is written, then Eqs. (7a) and (7b) can be recast into the form

$$e^{-w}z_{,uv}+\frac{1}{6}zC-\frac{\overset{\star}{R}}{12}z^3=0, \tag{90a}$$

$$\overset{\star}{C}-z^{-2}C=0, \tag{90b}$$

$$R-2C=0, \tag{90c}$$

where $R^\star, C^\star$ belong to the metric $g^\star$ while R, C are formed by g. If Eq. (90a) admits a solution $z(u,v)$ for arbitrarily given function $w(u,v)$ and fixed $R^\star=\text{const}$, then every s.s.s. of (1) is conformal to a s.s. metric,

$$ds^2=2e^{w(u,v)}\,du\,dv-d\Omega^2. \tag{91}$$

This is the local version, in the case of spherical symmetry of the problem of Yamabe for compact Riemannian manifolds, whether a conformal metric exist for which the scalar curvature is constant.[24,25] Now, Eq. (90a) is nonlinear and existence proofs for local (and global) solutions are available only for a number of very restricted choices of $w(u,v)$ such as, for example, $w=\text{const}$.[26]

In particular, Eq. (90a) can be used to generate s.s.s. of $R^\star=R_0$ from s.s. metrics with $R=0$, $R=R_0\neq 0$ and R not a constant, respectively. An example for the first case is given by Sec. IV C [$w=-2\log(u-v)$]; another one by solution (54b). On the other hand, $w=0$ leads to the metrics (53) of Sec. V B, with $R=1$. Finally, the rather peculiar choice of

$$w=\log 2-2\log(u-v)-\log\left[1-\frac{R_0}{2}z^2(u)\right]$$

with the arbitrary function $z(u)$ leads from $R=R_0z^2(u)$ to the class of metrics (16a) of Sec. IV A solving (1).

IX. DISCUSSION

In our investigation of s.s.s. with a constant Ricci scalar we obtained a number of explicitly given solutions depending on two free functions of one variable, at most. As far as we know, all s.s. metrics with a constant nonvanishing Ricci scalar presented in the literature are contained within the classes found in this paper and collected in Table I.

However, in contradistinction to the case $R_0=0$ of paper I we have found no way of transforming the relevant differential equation into a linear one for the case of metrics whose Ricci tensor has a nondegenerate eigenvalue structure. This explains, why, in this generic case, the solutions exhibited depend on just one arbitrary function of one variable and integration constants, or just on integration constants alone. Moreover, we have not been able to explicitly give a solution with nonvanishing conformal invariant and a triple eigenvalue of R_α^β nor a conformally flat solution with a generic eigenvalue structure, or to prove their nonexistence. However, we have exhausted all s.s.s. of Eq. (1) for which R_α^β has two double or one quadruple eigenvalue and all s.s. decomposable space–times. The set of solutions found in the other cases is general enough to be helpful for the construction of counterexamples to Birkhoff's theorem within large classes of gravitational theories. On the other hand, there exists a large class of gravitational theories which, for vanishing matter, coincides with the Einstein vacuum field equations, and which therefore admit a Birkhoff theorem just like Einstein's theory.[27]

Space–time manifolds with constant curvature have been investigated with the help of Killing–Yano symmetry;[28] they also occur in studies of conformal vector fields[29] and Kaehler metrics.[30] Also in this context it may well be an advantage to have a reservoir of exact solutions to play with, as presented here.

Their also exist investigations using constant scalar curvature within gauge theory,[31] supergravity,[32] and supergeometry.[33] However, the extension of the present investigation to higher-dimensional spaces is not as straightforward as one might expect. As listed in Appendix C, the equation replacing (7b) will contain an additional nonlinearity if the space–time-dimension $n>4$.

The case of plane symmetry which, in paper I, was completely solved can be dealt with only partial success for $R_0\neq 0$. If $R_0-2C=0$, the general solution of Eqs. (64a) and (64b) of paper I is given by

$$ds^2=\frac{16}{R_0}\frac{du\,dv}{(u+v)^2}-(u+v)^2(dx^2+dy^2). \tag{92}$$

For $2C-R_0\neq 0$ $z(u,v)$ is arbitrary while $w(u,v)$ must satisfy

$$w_{,uv}-\frac{R_0}{2}z^2e^w=-6\frac{z_{,uv}}{z}. \tag{93}$$

Even the case of conformally flat metrics resists *complete* integration. The cases of constant z or w are easily solved.

ACKNOWLEDGMENTS

Part of the early work on this paper was done while one of the authors (H. G.) was on sabbatical leave at Temple University, and while the other one (P. H.) held a guest professorship at the University of Goettingen. In its early stages, this research was supported in part by a grant

and a travel grant of the National Science Foundation. Our thanks go also both to the Physics Departments of Temple University and the University of Goettingen, and to Deutsche Forschungsgemeinschaft. One of us (H. G.) would also like to thank Folkert Mueller-Hoissen for providing helpful references.

APPENDIX A

The evaluation of Eq. (51). For $a=0$ we obtain the standard elliptic integral,

$$\int \frac{d\varphi}{\sqrt{2D+(6AB)^{-1}\left[\frac{R_0}{4}\varphi^4-\varphi^2\right]}},$$

which falls into one of the categories 251.00–259.00 of Ref. 17.

For $a=-2$ the substitution $u=\varphi^{2/3}$ leads to the integral

$$\int \frac{u^{1/2}\,du}{\sqrt{2D+9(8AB)^{-1}\left[\frac{R_0}{6}u^3-u\right]}},$$

i.e., to the cases 253.13–15 of Ref. 17. $a=-3$ with $u=\varphi^{+1/2}$ results in an integral

$$\int \frac{u\,du}{\sqrt{2D+8(3AB)^{-1}\left[\frac{R_0}{6}u^3-u\right]}},$$

of type 232.19–20 of Ref. 17 and, finally, $a=-4$ with $u=\varphi^{2/3}$ leads to

$$\int \frac{u^{1/2}\,du}{\sqrt{9R_0(8AB)^{-1}\left(u-\frac{2}{R_0}\right)^2+2D-9(2ABR_0)^{-1}}}.$$

APPENDIX B

Solutions to Eq. (54a). We list the following 1-parameter solutions of the relevant equations

$$\varphi=\left[-\varepsilon_1\varepsilon_2\frac{2}{3-n}\left(\frac{a}{b}\right)^2\right]^{1/(n-1)}\cosh^{2/(n-1)}(\sigma\eta+\delta_1), \tag{B1}$$

with

$$\sigma:=\left[\varepsilon_1 a^2\frac{(n-1)^2}{2(3-n)}\right]^{1/2}, \quad \varepsilon_1^2=\varepsilon_2^2=1,$$

solves

$$\cosh^2(\sigma\eta+\delta_1)\frac{d^2\varphi}{d\eta^2}+\varepsilon_1 a^2\varphi+\varepsilon_2 b^2\varphi^n=0, \tag{B2}$$

if $n\neq 3, a, b$ constants with $ab\neq 0$, δ_1 an integration constant,

$$\varphi=\left[\mp\varepsilon_1\varepsilon_2\frac{2}{3-n}\left(\frac{a}{b}\right)^2\right]^{1/(n-1)}\begin{Bmatrix}\cos^{2/(n-1)}(\sigma\eta+\delta_1)\\ \sinh^{2/(n-1)}(\sigma\eta+\delta_1)\end{Bmatrix}, \tag{B3}$$

with

$$\sigma:=\left[-\varepsilon_1 a^2\frac{(n-1)^2}{2(3-n)}\right]^{1/2},\quad \varepsilon_1^2=\varepsilon_2^2=1,$$

and the $\mp$ signs refer to cos and sinh, respectively, solves

$$\begin{Bmatrix}\cos^2(\sigma\eta+\delta_1)\\ \sinh^2(\sigma\eta+\delta_1)\end{Bmatrix}\frac{d^2\varphi}{d\eta^2}+\varepsilon_1 a^2\varphi+\varepsilon_2 b^2\varphi^n=0. \tag{B4}$$

Furthermore,

$$\varphi=\left[\pm|3+n|\left(-\frac{\varepsilon_2 b^2}{2(1+n)}\right)^{1/2}+\tilde{c}_1\eta^{(1-n)/(3+n)}\right]^{2/(1-n)}, \tag{B5}$$

solves

$$\eta^2\frac{d^2\varphi}{d\eta^2}+2\frac{1+n}{(3+n)^2}\varphi+\varepsilon_2 b^2\varphi^n=0, \tag{B6}$$

if $n\neq -3$, $\tilde{c}_1$ integration constant.

For $n=3$ we note the following results:

$$\varphi=[-\varepsilon_2 b^{-2}]^{1/2}\cosh(\eta+\delta_1), \tag{B7}$$

solves

$$\cosh^2\eta\frac{d^2\varphi}{d\eta^2}+\varepsilon_2 b^2\varphi^3=0, \tag{B8}$$

while

$$\varphi=[\varepsilon_2 b^{-2}]^{1/2}\cos(\eta+\delta_1), \tag{B9}$$

solves

$$\cos^2\eta\frac{d^2\varphi}{d\eta^2}+\varepsilon_2 b^2\varphi^3=0. \tag{B10}$$

APPENDIX C

Using the formulas given by Takeno[15] it is easy to see that, by a suitable change of the constant factor in the conformal invariant C (in the sense that it now depend on n), Eq. (7a) stays unchanged. On the other hand, in place of Eq. (7b) we get

$$z_{,uv}+\frac{1}{2(n-1)}z^3e^w\left(C-\frac{1}{2}R\right)+\frac{n-4}{4}(2z^{-1}z_u z_v+e^w z)=0. \tag{C1}$$

Complete asymptotic expansions of the Fermi–Dirac integrals $\mathcal{F}_p(\eta)=1/\Gamma(p+1)\int_0^\infty[\epsilon^p/(1+e^{\epsilon-\eta})]d\epsilon$

(Received 23 October 2000; accepted for publication 2 January 2001)

The complete asymptotic expansions, that is to say expansions which include any exponentially small terms lying beyond all orders of the asymptotic power series, are calculated for the Fermi–Dirac integrals. We present two methods to accomplish this, the first in the complex plane utilizing Mellin transforms and Hankel's representation of the gamma function, and the second on the real line using the known asymptotic expansions of the confluent hypergeometric functions. The complete expansions of $\mathcal{F}_p(\eta)$ are then used to investigate the effect that these traditionally neglected exponentially small terms have on physical systems. It is shown that for a 2 dimensional nonrelativistic ideal Fermi gas, the subdominant exponentially small series becomes dominant. © *2001 American Institute of Physics.* [DOI: 10.1063/1.1350634]

I. INTRODUCTION

If one adheres to the conventional definition of the asymptotic series for a function given by Poincaré, all terms in the series are algebraic in the asymptotically small variable ϵ. This implies that transcendental exponentially small terms are not captured by the series in the limit $\epsilon\to 0$, and hence these transcendentally small terms have traditionally been neglected in asymptotics. These small terms are said to lie beyond all orders of the asymptotic expansion. By neglecting such terms in the asymptotic expansion of a given function, it is clear that the resultant series cannot give an exact representation of this function. It has been demonstrated however, most notably by Dingle[1] via his derivations of integral representations of the remainder terms of a wide class asymptotic series, that asymptotic series are capable of being precisely interpreted. Thus it became apparent in the late 1950s that the definition of Poincaré needed to be replaced. This led Dingle[1] to define the *complete asymptotic expansion* of a function $f(x)$ as an expansion constructed from asymptotic series, which formally exactly obeys—throughout a certain phase sector—all those relations satisfied by $f(x)$ which do not involve any finite numerical value of x. Dingle found that in practice a suitably rigorous analysis would yield, in a certain phase sector, the complete asymptotic expansion of a function, including any transcendentally small terms which may be present. Dingle's definition suggested that if methods were developed whereby the divergent sequence of late terms in an asymptotic expansion could be interpreted, then asymptotic expansions could become an exact representation of a function. The construction of such methods was pioneered by Dingle[1] with his theory of terminants, and has been further developed by Berry *et al.* in their work on *hyperasymptotics*.[2,3]

There has been an increasing amount of research undertaken in recent years which demonstrates the practical importance of obtaining complete asymptotic expansions as opposed to Poincaré expansions. For example, problems in crystal growth, viscous flow, quantum tunnelling, and optics[2,3] have demonstrated the physical manifestations of the terms lying beyond all orders in a complete asymptotic expansion; and work on ordinary differential equations and such problems as

a)Electronic mail: frankel@physics.unimelb.edu.au

the Generalized Euler–Jacobi inversion formula[2] has reinforced their application to fundamental problems in classical analysis.

Our aim in this paper is to demonstrate that the transcendentally small terms appearing in a complete asymptotic expansion are capable of producing important physical effects, that can be manifest even when the expansion is truncated at an early order. In particular, we develop the complete asymptotic expansion of $\mathcal{F}_p(\eta)$, a function which is of fundamental importance in the statistical mechanics of Fermi systems. We then use this to demonstrate that exponentially small terms dominate the low temperature expansions of the thermodynamic functions of an ideal Fermi gas, when the number of spatial dimensions is even. We investigate the particular case of a two dimensional ideal Fermi gas in detail, and show that using our complete expansions we recover the exact result obtained by May[4] in which closed form solutions were obtained for the integrals occurring in the number equation, and internal energy.

As has been discussed by Dingle,[1,5] the commonly accepted Sommerfeld method of asymptotically expanding the Fermi–Dirac integrals (see, e.g., Refs. 6, 7), does not yield the complete asymptotic expansion and thus leads to erroneous conclusions regarding the exponentially small terms. For general p, the complete asymptotic expansion of $\mathcal{F}_p(\eta)$ consists of an asymptotic power series, as well as a subdominant exponentially small series which is traditionally neglected. In the particular case when p is an odd half integer, this exponentially small series vanishes identically, and so the usual assertion accompanying the Sommerfeld treatment that exponentially small terms are being neglected is, in this case, incorrect. When p is an integer, however, the asymptotic power series truncates into a finite sum, and the exponentially small terms then become dominant. This will be shown to be the cause of the aforementioned behavior of the even dimensional Fermi gas.

Although the complete asymptotic expansion of $\mathcal{F}_p(\eta)$ is known,[1,5] albeit not well known, we feel that our proofs being simultaneously both perspicuous, and rigorous and complete, elucidate the construction of this seemingly esoteric yet fundamentally important expansion. We present the derivations from two alternative angles. The first method is performed using contour integration, and highlights the mechanisms producing the various idiosyncrasies displayed by the expansion of $\mathcal{F}_p(\eta)$. We begin with the standard Mellin/inverse Mellin transform method, and use this to obtain a representation of $\mathcal{F}_p(\eta)$ along Hankel's contour. By paying careful attention to the various limits involved, we then show how the Hankel contour representation of $\mathcal{F}_p(\eta)$ is related to Hankel's representation of the gamma function. The second method makes use of standard hypergeometric theory, and the known asymptotic expansions of the confluent hypergeometric functions, and provides an expedient alternative construction.

II. THE COMPLETE ASYMPTOTIC EXPANSION OF $\mathcal{F}_p(\eta)$ USING MELLIN TRANSFORMS

We define $\mathcal{F}_p(\eta)$, following Dingle,[5] via

$$\mathcal{F}_p(\eta)=\frac{1}{\Gamma(p+1)}\int_0^\infty \frac{\epsilon^p}{1+e^{\epsilon-\eta}}d\epsilon. \tag{2.1}$$

We seek the complete asymptotic expansion for $\mathcal{F}_p(\eta)$ for the case of large positive real η, and $p>-1$.

To obtain a contour integral representation of $\mathcal{F}_p(\eta)$, we express it as the inverse Mellin transform of it's Mellin transform,[5,1] which results in

$$\mathcal{F}_p(\eta)=\frac{1}{2\pi i}\int_{c-i\infty}^{c+i\infty}\frac{\pi e^{\eta s}\,ds}{s^{p+1}\sin(\pi s)},\quad 0<c<1. \tag{2.2}$$

By changing the sign of s in (2.2) and closing the contour to the right, we arrive at

$$\mathcal{F}_p(\eta)=\frac{1}{2i}\int_{\infty}^{(0+)}\frac{e^{-\eta s}\,ds}{(-s)^{p+1}\sin(\pi s)}, \tag{2.3}$$

where the integration is performed over Hankel's contour, viz. the contour begins at infinity in the first quadrant, encircles the origin in the positive direction and proceeds to infinity in the fourth quadrant in such a manner as to avoid enclosing any of the poles on the negative real axis.[8]

To proceed further, we shrink the curve onto the positive real axis from both above and below, indenting the curve around the simple poles at $s=1, 2, 3, \ldots$, and also about the origin which will either be a pole if p is an integer or both a pole and a branch point if p is a noninteger. In either case we can choose $-s=se^{-i\pi}$ on the top of the curve to ensure that the generally many valued function $(-s)^{-p-1}$ becomes definite. We choose the indentations of the curve around the simple poles, both above and below the real axis, to be semi-circles of radius ρ, centered at the poles. We denote the contour of the indentation at the simple pole $s=n$ above the real axis by $above_\rho(n)$, and that below the real axis by $below_\rho(n)$. The indentation around the origin is taken to be along the curve Ω_δ, where we define Ω_δ to be the circle of radius $\delta<1$ centered at the origin and traversed in the positive direction.[9]

The essence of the derivation that follows is to split up the $\int_\infty^{(0+)}$ integral so that we can deal with the simple poles, and the problem of the origin separately. Having dealt with the simple poles we will be left with integrals whose integrand is only nonanalytic at the origin, and we will then be in a position to identify these remaining pieces with Hankel's representation of the gamma function. To begin then, we split up (2.3) as follows:

$$\begin{aligned}\int_{\infty}^{(0+)}\frac{e^{-\eta s}\,ds}{2i(-s)^{p+1}\sin(\pi s)}=&\sum_{n=1}^{\infty}\int_{n+1-\rho}^{n+\rho}\frac{e^{-\eta s}\,ds}{2ie^{-i\pi(p+1)}s^{p+1}\sin(\pi s)}+\int_{1-\rho}^{\delta}\frac{e^{-\eta s}\,ds}{2ie^{-i\pi(p+1)}s^{p+1}\sin(\pi s)}\\&+\sum_{n=1}^{\infty}\int_{above_\rho(n)}\frac{e^{-\eta s}\,ds}{2ie^{-i\pi(p+1)}s^{p+1}\sin(\pi s)}\\&+\sum_{n=1}^{\infty}\int_{n+\rho}^{n+1-\rho}\frac{e^{-\eta s}\,ds}{2ie^{i\pi(p+1)}s^{p+1}\sin(\pi s)}+\int_{\delta}^{1-\rho}\frac{e^{-\eta s}\,ds}{2ie^{i\pi(p+1)}s^{p+1}\sin(\pi s)}\\&+\sum_{n=1}^{\infty}\int_{below_\rho(n)}\frac{e^{-\eta s}\,ds}{2ie^{i\pi(p+1)}s^{p+1}\sin(\pi s)}\\&+\int_{\Omega_\delta}\frac{e^{-\eta s}\,ds}{2i(-s)^{p+1}\sin(\pi s)}.\end{aligned} \tag{2.4}$$

The first and third lines of (2.4) are the contributions from along the real line from above and below, respectively.

We now take the limit $\rho\to 0$. The contribution of the indentations around the simple poles becomes

$$\frac{(e^{i\pi(p+1)}+e^{-i\pi(p+1)})}{2i}\sum_{l=1}^{\infty} i\pi\,\mathrm{Res}(e^{-\eta s}s^{-p-1}\mathrm{cosec}(\pi s)|s=l)=\cos(\pi p)\mathcal{F}_p(-\eta), \tag{2.5}$$

where $\mathrm{Res}(f(s)|s=l)$ signifies the residue of $f(s)$ at $s=l$, and where we have used

$$\mathcal{F}_p(-\eta)=\sum_{\nu=1}^{\infty}\frac{(-1)^{\nu+1}}{\nu^{p+1}}e^{-\nu\eta},\quad \eta>0. \tag{2.6}$$

For the contributions along the real axis we obtain

$$-\frac{\left[e^{i\pi(p+1)}-e^{-i\pi(p+1)}\right]}{2i}\lim_{\rho\to 0}\left[\sum_{l=1}^{\infty}\int_{l+\rho}^{l+1-\rho}\frac{e^{-\eta s}}{s^{p+1}\sin(\pi s)}ds+\int_{\delta}^{l-\rho}\frac{e^{-\eta s}}{s^{p+1}\sin(\pi s)}ds\right]$$

$$=\sin(\pi p)\mathcal{P}\int_{\delta}^{\infty}\frac{e^{-\eta s}ds}{s^{p+1}\sin(\pi s)}. \tag{2.7}$$

$\mathcal{P}$ signifies the Cauchy principal value of the integral.

Since $\delta<1$, we can substitute into the Ω_δ integral, the result[10]

$$\frac{\pi s}{\sin(\pi s)}=\sum_{\nu=0}^{\infty}2\tau_{2\nu}s^{2\nu},\quad |s|<1, \tag{2.8}$$

where

$$\tau_n\equiv\sum_{\nu=1}^{\infty}\frac{(-1)^{\nu+1}}{\nu^n}=(1-2^{1-n})\zeta(n), \tag{2.9}$$

and $\zeta(n)$ is the Riemann zeta function.

Adding these pieces together we see that (2.3) can be written in the following more illuminating form:

$$\mathcal{F}_p(\eta)=\cos(\pi p)\mathcal{F}_p(-\eta)+\sin(\pi p)\mathcal{P}\int_{\delta}^{\infty}\frac{e^{-\eta s}ds}{s^{p+1}\sin(\pi s)}$$

$$+\frac{i}{2\pi}\sum_{\nu=0}^{\infty}\frac{2\tau_{2\nu}}{\eta^{2\nu-p-1}}\int_{\Omega_\delta}(-s)^{2\nu-p-2}e^{-s}\,ds. \tag{2.10}$$

It is to be noted that no asymptotic analysis has yet been performed. In order to obtain the complete asymptotic expansion of $\mathcal{F}_p(\eta)$ for arbitrary $p>-1$, we need to asymptotically expand the contribution from (2.7).

In the special case when p is an integer, it will be noticed that the contribution from (2.7) vanishes, and it should be obvious that this is merely a result of the fact that $(-s)^{-p-1}$ is in fact single valued in this case. Also, the Ω_δ integral then simply yields the residues at the origin for the finite number of terms in which the integrand is meromorphic, and vanishes for the remainder of the terms since their integrands are analytic. Hence for integer p the asymptotic expansions to be derived will agree precisely with the exact results. This observation is in agreement with Dingle's definition of a complete asymptotic expansion, which requires that the correct asymptotic expansion should agree with exact result for those special special values of p in which direct integration of $\mathcal{F}_p(\eta)$ is possible.

If p is a noninteger, then the contribution from (2.7) must be asymptotically expanded. However, nothing in the following argument relies on p being a noninteger, and it is equally true for integer p; $p\in Z$ just happens to be a particularly simple special case of the general result to be now derived.

Consider then

$$\mathcal{P}\int_{\delta}^{\infty}\frac{e^{-\eta s}ds}{s^{p+1}\sin(\pi s)}, \tag{2.11}$$

and note that $s^{-p-1}e^{-\eta s}\to 0$ as $s\to\infty$. The dominant contribution obviously comes from the neighborhood of $s=\delta<1$. We develop the desired asymptotic power series then, by substituting

(2.8) into (2.11), and integrating term by term. By making this substitution we are essentially ignoring the poles of $\mathrm{cosec}(\pi s)$ at $s=1, 2, 3, \ldots$, and thus the resulting integrals are no longer of the Cauchy principle value type. We thus obtain

$$\mathcal{F}_p(\eta)\sim\sum_{\nu=0}^{\infty}\frac{2\tau_{2\nu}}{\eta^{2\nu-p-1}}\frac{i}{2\pi}\left[\int_{\Omega_\delta}(-t)^{2\nu-p-2}e^{-t}dt-2i\sin(\pi p)\int_{\delta}^{\infty}(-t)^{2\nu-p-2}e^{-t}dt\right]+\cos(\pi p)\mathcal{F}_p(-\eta). \tag{2.12}$$

The term in parentheses in the above power series will be recognized as the function $-2i\sin[(2\nu-p-1)\pi]\Gamma(2\nu-p-1)$,[11] viz. it is simply Hankel's expression for the gamma function. Inserting this result into (2.12), we arrive at

$$\mathcal{F}_p(\eta)\sim\sum_{\nu=0}^{\infty}2\tau_{2\nu}\frac{\sin[(2\nu-p-1)\pi]}{\pi}\Gamma(2\nu-p-1)\eta^{p+1-2\nu}+\cos(\pi p)\mathcal{F}_p(-\eta), \tag{2.13}$$

or upon utilizing the reflection formula for the gamma function,

$$\mathcal{F}_p(\eta)\sim\sum_{\nu=0}^{[(p+1)/2]}\frac{2\tau_{2\nu}}{\Gamma(p+2-2\nu)}\eta^{p+1-2\nu}+\frac{\sin(\pi p)}{\pi}\sum_{[(p+3)/2]}^{\infty}2\tau_{2\nu}\Gamma(2\nu-p-1)\times\eta^{p+1-2\nu}+\cos(\pi p)\mathcal{F}_p(-\eta), \tag{2.14}$$

$[x]$ represents the integer part of the real number x.

Expressed in this form, the behavior of $\mathcal{F}_p(\eta)$ in the special cases p an integer and p an odd half integer become obvious. The beauty of this derivation lies in the fact that it was not necessary to treat the integer and noninteger cases separately, and that it makes manifest the mechanism accounting for the structural differences of the expansions in these two cases, namely the single valued or many valuedness of the integrand, respectively.

III. THE COMPLETE ASYMPTOTIC EXPANSION OF $\mathcal{F}_p(\eta)$ USING CONFLUENT HYPERGEOMETRIC FUNCTIONS

The complete asymptotic expansion of $\mathcal{F}_p(\eta)$ can be obtained in a more expedient and less complicated, although less enlightening fashion by simply using the known asymptotic expansions for the confluent hypergeometric functions. By splitting the range of integration in (2.1) into $[0,\eta]$ and $[\eta,\infty]$, and inserting the binomial expansions of $(1+e^{x-\eta})^{-1}$ we obtain

$$\Gamma(p+1)\mathcal{F}_p(\eta)=\sum_{k=0}^{\infty}(-1)^k\int_0^{\eta}e^{-k(\eta-x)}x^p dx+\sum_{k=1}^{\infty}(-1)^{k+1}\int_{\eta}^{\infty}e^{-k(x-\eta)}x^p dx. \tag{3.1}$$

We then change the variable of integration to $t\equiv\pm(\eta-x)/\eta$ in the first and second summands, respectively, thus obtaining

$$\Gamma(p+1)\mathcal{F}_p(\eta)=\sum_{k=0}^{\infty}(-1)^k\eta^{p+1}\int_0^1 e^{(-\eta k)t}t^{1-1}(1-t)^{p+2-1-1}dt+\sum_{k=1}^{\infty}(-1)^{k+1}\eta^{p+1}\int_0^{\infty}e^{-(\eta k)t}t^{1-1}(1+t)^{p+2-1-1}dt. \tag{3.2}$$

The integrals in the first and second summands are then recognized as $[1/(p+1)]M(1,p+2,-\eta k)$ and $U(1,p+2,\eta k)$, respectively, where $M(a,b,z)\equiv{}_1F_1(a;b;z)\equiv\Phi(a,b,z)$ and

$U(a,b,z)\equiv z^{-a}\,{}_2F_0(a;1+a-b;-1/z)\equiv\Psi(a,b,z)$ are the two independent solutions of Kummer's equation discussed in Ref. 10. Hence $\mathcal{F}_p(\eta)$ can be written in terms of these confluent hypergeometric functions as

$$\mathcal{F}_p(\eta)=\frac{\eta^{p+1}}{\Gamma(p+2)}+\sum_{k=1}^{\infty}(-1)^{k+1}\frac{\eta^{p+1}}{\Gamma(p+1)}\left[U(1,p+2,\eta k)-\frac{1}{p+1}M(1,p+2,-\eta k)\right]. \tag{3.3}$$

To derive the complete asymptotic expansion for $\mathcal{F}_p(\eta)$ we then substitute into (3.3) the known asymptotic expansions for $M(1,p+2,-\eta k)$ and $U(1,p+2,\eta k)$,[10]

$$\frac{1}{p+1}M(1,p+2,-\eta k)\sim\sum_{n=0}^{\infty}\frac{(-p)_n}{k^{n+1}}\eta^{-n-1}-\frac{\Gamma(p+1)}{\eta^{p+1}}(-1)^{-p}\frac{e^{-\eta k}}{k^{p+1}}, \tag{3.4}$$

$$U(1,p+2,\eta k)\sim\sum_{n=0}^{\infty}(-1)^n\frac{(-p)_n}{k^{n+1}}\eta^{-n-1}, \tag{3.5}$$

where $(a)_n$ is Pochammer's symbol, defined by[10]

$$\begin{aligned}(a)_0&=1,\\ (a)_n&=a(a+1)(a+2)\cdots\ (a+n-1)=\frac{\Gamma(a+n)}{\Gamma(a)}.\end{aligned} \tag{3.6}$$

Interchanging the order of summation in the resultant double sum we thus obtain

$$\begin{aligned}\mathcal{F}_p(\eta)\sim&\frac{\eta^{p+1}}{\Gamma(p+2)}+\sum_{n=0}^{\infty}(-1)^n\frac{(-p)_n}{\Gamma(p+1)}\eta^{p-n}\sum_{k=1}^{\infty}\frac{(-1)^{k+1}}{k^{n+1}}\\ &-\sum_{n=0}^{\infty}\frac{(-p)_n}{\Gamma(p+1)}\eta^{p-n}\sum_{k=1}^{\infty}\frac{(-1)^{k+1}}{k^{n+1}}+(-1)^{-p}\sum_{k=1}^{\infty}\frac{(-1)^{k+1}}{k^{p+1}}e^{-\eta k}.\end{aligned} \tag{3.7}$$

Making use of (2.6) and (2.9) this becomes

$$\mathcal{F}_p(\eta)\sim(-1)^{-p}\mathcal{F}_p(-\eta)+\frac{\eta^{p+1}}{\Gamma(p+2)}+\sum_{n=1}^{\infty}2\tau_{2n}\left[\frac{-(-p)_{2n-1}}{\Gamma(p+1)}\right]\eta^{p+1-2n}. \tag{3.8}$$

Since $\mathcal{F}_p(\eta)$ and the above power series are real for real p and η, taking the real part of the above equation results in the correct exponential series in (2.14), $\cos(\pi p)\mathcal{F}_p(-\eta)$. We also note, using (3.6), that

$$\left[\frac{-(-p)_{2n-1}}{\Gamma(p+1)}\right]=\frac{1}{\Gamma(p+2-2n)}. \tag{3.9}$$

Hence we arrive at the following expression which is entirely equivalent to (2.13) and (2.14):

$$\mathcal{F}_p(\eta)\sim\cos(\pi p)\mathcal{F}_p(-\eta)+\sum_{\nu=0}^{\infty}\frac{2\tau_{2\nu}}{\Gamma(p+2-2\nu)}\eta^{p+1-2\nu}. \tag{3.10}$$

This method is certainly far more expedient than the previous method since all the genuine asymptotic analysis has already been performed for us in the tabulation of the complete asymptotic expansions of the functions U and M.

IV. LOW TEMPERATURE BEHAVIOR OF AN ARBITRARY DIMENSIONAL FERMI GAS

We proceed now to use our complete asymptotic expansion of $\mathcal{F}_p(\eta)$ to investigate the statistical mechanics of an ideal Fermi gas in d spatial dimensions. We will see that in even dimensions, the subdominant series in (3.10) produces very important physical effects in the expansions of the thermodynamic functions.

For an ideal nonrelativistic spin 1/2 Fermi gas at temperature T in d dimensions, the internal energy, U, and average number density, n, are expressed in terms of $\mathcal{F}_p$ via

$$n=\frac{2}{\lambda_T^d}\frac{1}{\Gamma\left(\frac{d}{2}+1\right)}\left(\frac{\epsilon_F}{kT}\right)^{d/2}=\frac{2}{\lambda_T^d}\mathcal{F}_{d/2-1}(\beta\mu), \tag{4.1}$$

$$\frac{U}{N\epsilon_{\mathrm{F}}}=\frac{d}{2}\Gamma(d/2+1)\left(\frac{kT}{\epsilon_{\mathrm{F}}}\right)^{d/2+1}\mathcal{F}_{d/2}(\beta\mu), \tag{4.2}$$

where ϵ_{F} is the Fermi energy, $\mu(T)$ is the chemical potential, k is Boltzmann's constant, $\lambda_T \equiv\sqrt{2\pi\hbar/mkT}$, and $\beta\equiv 1/kT$. The dependence of ϵ_{F} on n and d is stated implicitly in (4.1).

The convergent power series expansion of $\mathcal{F}_p(\eta)$, (2.6), can be used to examine the behavior of U and n for negative $\beta\mu$, i.e., in the classical region. We focus on the degenerate region in which $\beta\mu$ is large and positive. Using (2.14), we find in this case that n and U have the following expansions.

$$\frac{n\lambda_T^d}{2}\sim\sum_{\nu=0}^{[d/4]}\frac{2\tau_{2\nu}}{\Gamma(d/2+1-2\nu)}(\beta\mu)^{d/2-2\nu}-\sin(d\pi/2)\sum_{\nu=[(d+4)/4]}^{\infty}2\tau_{2\nu}\frac{\Gamma(2\nu-d/2)}{\pi}$$
$$\times(\beta\mu)^{d/2-2\nu}-\cos(d\pi/2)\sum_{\nu=1}^{\infty}\frac{(-1)^{\nu+1}}{\nu^{d/2}}e^{-\nu\beta\mu},\quad(\beta\mu)\to\infty \tag{4.3}$$

$$\frac{U}{N\epsilon_{\mathrm{F}}}\left(\frac{\epsilon_{\mathrm{F}}}{kT}\right)^{d/2+1}\frac{1}{\frac{d}{2}\Gamma(d/2+1)}\sim\sum_{\nu=0}^{[(d+2)/4]}\frac{2\tau_{2\nu}}{\Gamma(d/2+2-2\nu)}(\beta\mu)^{d/2+1-2\nu}+\sin(d\pi/2)$$
$$\times\sum_{\nu=[(d+6)/4]}^{\infty}2\tau_{2\nu}\frac{\Gamma(2\nu-d/2-1)}{\pi}(\beta\mu)^{d/2+1-2\nu}$$
$$+\cos(d\pi/2)\sum_{\nu=1}^{\infty}\frac{(-1)^{\nu+1}}{\nu^{d/2+1}}e^{-\nu\beta\mu},\quad(\beta\mu)\to\infty. \tag{4.4}$$

From these expansions we see clearly that n and U behave quite differently depending on whether the number of spatial dimensions is odd or even. For an odd number of dimensions the exponentially small series vanishes and we simply obtain a conventional asymptotic power series. For an even number of dimensions, however, the asymptotic power series truncates, and the exponentially small series thus dominates.

It is instructive to compare the expansions of n and U for the physically important cases $d=2$ and 3. The number density n goes like

$$d=2,\qquad\frac{n\lambda_T^2}{2}\sim\beta\mu+\sum_{\nu=1}^{\infty}\frac{(-1)^{\nu+1}}{\nu}e^{-\nu\beta\mu}, \tag{4.5}$$

$$d=3,\qquad\frac{n\lambda_T^3}{2}\sim\sum_{\nu=0}^{\infty}\frac{2\tau_{2\nu}}{\Gamma(5/2-2\nu)}(\beta\mu)^{3/2-2\nu}. \tag{4.6}$$

For the energy we obtain

$$d=2, \qquad \frac{U}{N\epsilon_{\mathrm{F}}}\left(\frac{\epsilon_{\mathrm{F}}}{kT}\right)^2 \sim \frac{(\beta\mu)^2}{2}+\frac{\pi^2}{6}-\sum_{\nu=1}^{\infty}\frac{(-1)^{\nu+1}}{\nu^2}e^{-\nu\beta\mu}, \tag{4.7}$$

$$d=3, \qquad \frac{U}{N\epsilon_{\mathrm{F}}}\left(\frac{\epsilon_{\mathrm{F}}}{kT}\right)^{5/2} \sim \frac{8}{9\sqrt{\pi}}\sum_{\nu=0}^{\infty}\frac{2\tau_{2\nu}}{\Gamma(7/2-2\nu)}(\beta\mu)^{5/2-2\nu}. \tag{4.8}$$

The $d=3$ result is simply the standard result first obtained by Sommerfeld,[7] but it is interesting to note that in this case the subdominant exponential series vanishes identically. The usual statement that this result neglects terms $O(e^{-\beta\mu})$, e.g., Ref. 6, is therefore incorrect. When $d=2$ it is the power series in (4.3) and (4.4) which vanish identically, leaving only a finite sum and the exponentially small series. Thus the subdominant exponentially small series which should have been neglected in strict adherence to Poincaré's definition has become dominant. We shall now investigate the physical effects of this dominance of the exponentially small series in the two dimensional Fermi gas in greater detail.

V. THE TWO DIMENSIONAL FERMI GAS

In 2 spatial dimensions we have seen that only the first term in the power series of the large $\beta\mu$ expansion of n is nonzero, and thus that the exponentially small series is dominant.

To obtain suitable asymptotic expansions in the ultra degenerate limit, $kT/\epsilon_F \ll 1$, for U and the heat capacity at constant volume, C_v, we invert (4.5) for $\beta\mu$ and substitute this into (4.7).

Inversion of (4.5) leads to an asymptotic expansion for the chemical potential,

$$\mu(T)=\epsilon_{\mathrm{F}}\left[1-\frac{e^{-\beta\epsilon_{\mathrm{F}}}}{\beta\epsilon_{\mathrm{F}}}-\frac{e^{-2\beta\epsilon_{\mathrm{F}}}}{2\beta\epsilon_{\mathrm{F}}}+O\left(\frac{e^{-3\beta\epsilon_{\mathrm{F}}}}{\beta\epsilon_{\mathrm{F}}}\right)\right]. \tag{5.1}$$

The first correction term to the chemical potential away from the Fermi energy is seen to be exponentially small in β, so that even as the system moves away from absolute zero the chemical potential stays essentially fixed at the Fermi energy. This demonstrates that this system is loath to move away from a perfect Fermi sphere configuration as T increases.

Substituting (5.1) into (4.7) we obtain

$$\begin{aligned} U=\frac{N\epsilon_{\mathrm{F}}}{2}\Bigg[1+\frac{\pi^2}{3}\left(\frac{kT}{\epsilon_{\mathrm{F}}}\right)^2-2\left(\frac{kT}{\epsilon_{\mathrm{F}}}+\left[\frac{kT}{\epsilon_{\mathrm{F}}}\right]^2\right)e^{-\epsilon_{\mathrm{F}}/kT} \\ -\left(\frac{kT}{\epsilon_{\mathrm{F}}}+\frac{1}{2}\left[\frac{kT}{\epsilon_{\mathrm{F}}}\right]^2\right)e^{-2(\epsilon_{\mathrm{F}}/kT)}\Bigg]+O\left(\frac{kT}{\epsilon_F}e^{-3\epsilon_F/kT}\right). \end{aligned} \tag{5.2}$$

Note that all the algebraic factors multiplying the exponential terms are in fact polynomials; they have not been truncated. Differentiating (5.2) we obtain the heat capacity at constant volume C_v,

$$\frac{C_v}{Nk}=\frac{\pi^2}{3}\frac{kT}{\epsilon_{\mathrm{F}}}-\left(\frac{\epsilon_F}{kT}+2+2\frac{kT}{\epsilon_{\mathrm{F}}}\right)e^{-\epsilon_{\mathrm{F}}/kT}-\left(\frac{\epsilon_{\mathrm{F}}}{kT}+1+\frac{1}{2}\frac{kT}{\epsilon_{\mathrm{F}}}\right)e^{-2(\epsilon_{\mathrm{F}}/kT)}+O\left(\frac{\epsilon_{\mathrm{F}}}{kT}e^{-3(\epsilon_{\mathrm{F}}/kT)}\right). \tag{5.3}$$

We see that to first order C_v vanishes linearly as $T\to 0$, as one would expect for a Fermi gas, just as in the 3 dimensional case. The interesting thing to note however is that unlike the 3 dimensional case, the small T behavior of C_v in 2 dimensions contains transcendental rather than algebraic correction terms. This lack of algebraic corrections to C_v is testament to the physical effects that the transcendentally small terms in a complete asymptotic expansion can have.

The results obtained here using the complete asymptotic expansion of $\mathcal{F}_p(\eta)$ are also seen to be in agreement with the closed form solutions obtained by May.[4] The reason for this is rather

obvious from the derivation in Sec. II, since it was pointed out there that in the case of integer p, our result for the asymptotic expansion of $\mathcal{F}_p(\eta)$ is actually the exact solution of the integral. In effect the complete asymptotic expansion thus simultaneously performs the Sommerfeld treatment, as well as an exact treatment for the case of integer p. By using the complete asymptotic expansions we are thus able to recover Sommerfeld's asymptotic result for $d=3$, and May's exact result for $d=2$. This provides a concrete physical example of the usefulness of obtaining the complete asymptotic expansions for a given function, as opposed to the traditional algebraic series.

(Received 19 September 2000; accepted for publication 17 November 2000)

A unified framework is provided in which Lie and covariant differentiation may be considered as special cases of a new operation, called ''*D* differentiation.'' The present article develops *D* differentiation of tensor fields, whereas the extension to spinor fields, called ''$\tilde{D}$ differentiation,'' is presented in a companion article. The concept of ''generalized curvature'' of *D* differentiation is introduced, and a bundle formulation of *D* differentiation is obtained. © *2001 American Institute of Physics.* [DOI: 10.1063/1.1343091]

I. INTRODUCTION

In previous articles,[1–4] we investigated the problem of defining the Lie derivative $\tilde{\mathcal{L}}_{\mathbf{X}}\psi$ and the covariant derivative $\tilde{\nabla}_{\mathbf{X}}\psi$ of a spinor field ψ in full generality. We thus considered the operator $\tilde{\mathcal{L}}_{\mathbf{X}}$ when the differentiating vector field X is not restricted to being a Killing vector of the metric ($\mathcal{L}_{\mathbf{X}}g\neq 0$); analogously, we took into account, for $\tilde{\nabla}_{\mathbf{X}}$, the possibility of a metric-incompatible connection ($\nabla_{\mathbf{X}}g\neq 0$). Note that, here as in Ref. 2, we denote Lie (respectively, covariant) differentiation of a tensor field by $\mathcal{L}$ (respectively, ∇), and of a spinor field by $\tilde{\mathcal{L}}$ (respectively, $\tilde{\nabla}$).

In the first stage of this work,[1,2] we proposed a definition for $\tilde{\mathcal{L}}_{\mathbf{X}}\psi$ and for $\tilde{\nabla}_{\mathbf{X}}\psi$ based on heuristic analogies with tensor calculus. Then, we provided a bundle formalism[4] for the covariant derivative. In both treatments, we concentrated mainly on covariant differentiation, and obtained as by-products, results for Lie differentiation by making use of a ''translation rule'' exploiting similarities between Lie and covariant differentiation.[1,4]

In the present sequence of two articles, we are going to reanalyze Lie and covariant differentiation from the point of view of unifying them in one single operation, called ''*D* differentiation.'' This will put their respective properties in perspective, and justify the ''translation rule'' employed in Refs. 1 and 4. For the sake of clarity, we shall consider here exclusively *D* differentiation of tensor fields. The extension to spinor fields, under the name of ''$\tilde{D}$ differentiation,'' will appear in a companion article.[5]

We shall begin, in Sec. II, by constructing *D* differentiation, and determining its expression in coordinates. This operation will not require the presence of either a metric or a connection on the manifold M under consideration. If, however, M possesses a metric g, it will be possible to introduce a modified kind of *D* differentiation, denoted by ${}^{\mathbf{g}}D$, which preserves the metric.

Examples of *D* and modified *D* differentiation will then be given in Sec. III. It will be proved that both Lie and covariant differentiation are special cases of *D* differentiation. This observation will be the fundamental justification for the above-mentioned ''translation rule'' employed in Refs. 1 and 4. Furthermore, a special subclass of *D* differentiation, called ''restricted *D* differentiation,'' will be singled out and given special attention.

In Sec. IV, the concept of ''generalized curvature'' of *D* differentiation will be introduced. As

a)Electronic mail: djh@ucc.ie

the name suggests, it will play, for D differentiation, the role that curvature (in the traditional sense) plays for covariant differentiation. This investigation will shed light on the construction of $\tilde{D}$ differentiation of spinor fields in the companion article.[5]

A reformulation of D differentiation in terms of fiber bundles will then be obtained, in two stages, in Secs. V and VI. Its purpose will be twofold: first, it will provide a geometrical interpretation of D differentiation, and second, it will yield the appropriate language for the extension to spinor fields in Ref. 5.

II. CONSTRUCTION OF *D* DIFFERENTIATION

As explained in Sec. I, all our consideration will be based on a type of differentiation, called D differentiation, which is general enough to contain, as special cases, Lie and covariant differentiation, as well as other kinds described in the following. All throughout, we shall assume that M is a smooth (C^∞) manifold of dimension n. Moreover, the set of smooth functions, vector fields, and tensor fields defined on M will be denoted by $\mathcal{F}$, $\mathcal{X}$, and $\mathcal{T}$, respectively. A local basis of $\mathcal{X}$ will be written as $\{\vec{e}_{(\mathbf{i})}:1\leqslant i\leqslant n\}$, and $\{\underrightarrow{e}^{(\mathbf{i})}:1\leqslant i\leqslant n\}$ will be its dual basis. The Einstein summation convention will be adopted systematically.

The general operation of D differentiation associates with each vector field X of $\mathcal{X}$ an operator $D_{\mathbf{X}}:\mathcal{T}\to\mathcal{T}$ satisfying the axioms

$$D_{\mathbf{X}}(T+U)=D_{\mathbf{X}}T+D_{\mathbf{X}}U, \tag{2.1}$$

$$D_{\mathbf{X}}(kT)=kD_{\mathbf{X}}T, \tag{2.2}$$

$$D_{\mathbf{X}}(T\otimes U)=(D_{\mathbf{X}}T)\otimes U+T\otimes(D_{\mathbf{X}}U), \tag{2.3}$$

$$D_{\mathbf{X}}\text{ preserves tensor rank,} \tag{2.4}$$

$$D_{\mathbf{X}}\text{ commutes with tensor contractions,} \tag{2.5}$$

$$D_{\mathbf{X}}f=X(f)=\mathrm{d}f(X), \tag{2.6}$$

for all T, U in $\mathcal{T}$, all f in $\mathcal{F}$, and all constants k. By virtue of these conditions, the action of D differentiation on a tensor field of arbitrary rank is entirely determined[6] by its action on vector fields. Therefore, we shall henceforth restrict attention to vector fields, leaving the case of tensors to the reader.

For all vector fields X and Y, let $D_{\mathbf{X}}Y$ be given by

$$D_{\mathbf{X}}Y=D_{\mathbf{X}}(Y^{\mathbf{i}}\vec{e}_{(\mathbf{i})}) \tag{2.7}$$

$$=\{X(Y^{\mathbf{i}})+\Lambda^{\mathbf{i}}{}_{\mathbf{j}}(X)Y^{\mathbf{j}}\}\vec{e}_{(\mathbf{i})}, \tag{2.8}$$

where $\Lambda^{\mathbf{i}}{}_{\mathbf{j}}(X)$ is a collection of n^2 functions that characterize each particular operator of D differentiation. To ensure that the right-hand side of (2.8) is independent of the basis $\{\vec{e}_{(\mathbf{i})}\}$ chosen, $\Lambda^{\mathbf{i}}{}_{\mathbf{j}}(X)$ must transform in a very special manner under a change of basis. To determine the transformation rule for $\Lambda^{\mathbf{i}}{}_{\mathbf{j}}(X)$, we note that, under the frame change

$$\vec{e}\,'_{(\mathbf{i})}=\vec{e}_{(\mathbf{j})}N^{\mathbf{j}}{}_{\mathbf{i}}, \tag{2.9}$$

for a given matrix N, vector components transform as

$$X'^{\mathbf{i}}=M^{\mathbf{i}}{}_{\mathbf{j}}X^{\mathbf{j}},\quad MN=I, \tag{2.10}$$

so that the requirement of frame independence of the right-hand side of (2.8) may be written

$$\{X(Y^{\mathbf{i}})+\Lambda^{\mathbf{i}}{}_{\mathbf{j}}(X)Y^{\mathbf{j}}\}\vec{e}_{(\mathbf{i})}=\{X(M^{\mathbf{a}}{}_{\mathbf{k}}Y^{\mathbf{k}})+\Lambda'^{\mathbf{a}}{}_{\mathbf{b}}(X)M^{\mathbf{b}}{}_{\mathbf{k}}Y^{\mathbf{k}}\}\vec{e}_{(\mathbf{i})}N^{\mathbf{i}}{}_{\mathbf{a}} \tag{2.11}$$

for all X and Y. Elementary algebra then yields $\Lambda'(X)$ in terms of $\Lambda(X)$ as

$$\Lambda'^{\mathbf{i}}{}_{\mathbf{j}}(X)=M^{\mathbf{i}}{}_{\mathbf{a}}\Lambda^{\mathbf{a}}{}_{\mathbf{b}}(X)N^{\mathbf{b}}{}_{\mathbf{j}}-X(M^{\mathbf{i}}{}_{\mathbf{a}})N^{\mathbf{a}}{}_{\mathbf{j}} \tag{2.12}$$

$$=M^{\mathbf{i}}{}_{\mathbf{a}}\Lambda^{\mathbf{a}}{}_{\mathbf{b}}(X)N^{\mathbf{b}}{}_{\mathbf{j}}-(dM^{\mathbf{i}}{}_{\mathbf{a}})(X)N^{\mathbf{a}}{}_{\mathbf{j}}. \tag{2.13}$$

So far, no assumption has been made on the relationship between $D_{\mathbf{X}}$ and $D_{\mathbf{fX}}$, for an arbitrary function f. This information is enciphered in the relationship between $\Lambda^{\mathbf{i}}{}_{\mathbf{j}}(X)$ and $\Lambda^{\mathbf{i}}{}_{\mathbf{j}}(fX)$, and we shall postulate, consistently with (2.12) and (2.13), that there exists a tensor $A^{\mathbf{i}}{}_{\mathbf{j}}{}^{\mathbf{a}}{}_{\mathbf{b}}\vec{e}_{(\mathbf{i})}\otimes\underset{\rightarrow}{e}{}^{(\mathbf{j})}\otimes\vec{e}_{(\mathbf{a})}\otimes\underset{\rightarrow}{e}{}^{(\mathbf{b})}$, characterizing each particular operator D, such that

$$\Lambda^{\mathbf{i}}{}_{\mathbf{j}}(X+Y)=\Lambda^{\mathbf{i}}{}_{\mathbf{j}}(X)+\Lambda^{\mathbf{i}}{}_{\mathbf{j}}(Y) \tag{2.14}$$

$$\Lambda^{\mathbf{i}}{}_{\mathbf{j}}(fX)=f\Lambda^{\mathbf{i}}{}_{\mathbf{j}}(X)-A^{\mathbf{i}}{}_{\mathbf{j}}{}^{\mathbf{a}}{}_{\mathbf{b}}\vec{e}_{(\mathbf{a})}(f)X^{\mathbf{b}} \tag{2.15}$$

$$=f\Lambda^{\mathbf{i}}{}_{\mathbf{j}}(X)-A^{\mathbf{i}}{}_{\mathbf{j}}(\mathrm{d}f,X), \tag{2.16}$$

in which $A^{\mathbf{i}}{}_{\mathbf{j}}$ is an abbreviation for

$$A^{\mathbf{i}}{}_{\mathbf{j}}:=A^{\mathbf{i}}{}_{\mathbf{j}}{}^{\mathbf{a}}{}_{\mathbf{b}}\vec{e}_{(\mathbf{a})}\otimes\underset{\rightarrow}{e}{}^{(\mathbf{b})}. \tag{2.17}$$

In terms of D, the expressions (2.14) and (2.15) read

$$D_{\mathbf{X+Y}}Z=D_{\mathbf{X}}Z+D_{\mathbf{Y}}Z, \tag{2.18}$$

$$D_{\mathbf{fX}}Z=fD_{\mathbf{X}}Z-A^{\mathbf{i}}{}_{\mathbf{j}}(\mathrm{d}f,X)Z^{j}\vec{e}_{(\mathbf{i})}, \tag{2.19}$$

for all X, Y, Z, and f.

For future reference, it is useful to note that, because of (2.14) and (2.15), it is now possible to express $\Lambda^{\mathbf{i}}{}_{\mathbf{j}}(X)$ as a function of the components of X as follows:

$$\Lambda^{\mathbf{i}}{}_{\mathbf{j}}(X)=\Lambda^{\mathbf{i}}{}_{\mathbf{j}}(X^{\mathbf{k}}\vec{e}_{(\mathbf{k})}) \tag{2.20}$$

$$=X^{\mathbf{k}}\Lambda^{\mathbf{i}}{}_{\mathbf{j}}(\vec{e}_{(\mathbf{k})})-A^{\mathbf{i}}{}_{\mathbf{j}}{}^{\mathbf{a}}{}_{\mathbf{b}}\vec{e}_{(\mathbf{a})}(X^{\mathbf{b}}) \tag{2.21}$$

$$=\lambda^{\mathbf{i}}{}_{\mathbf{jk}}X^{\mathbf{k}}-A^{\mathbf{i}}{}_{\mathbf{j}}{}^{\mathbf{a}}{}_{\mathbf{b}}\vec{e}_{(\mathbf{a})}(X^{\mathbf{b}}), \tag{2.22}$$

where, in the last step, we have introduced the symbols $\lambda^{\mathbf{i}}{}_{\mathbf{jk}}$ given by

$$\lambda^{\mathbf{i}}{}_{\mathbf{jk}}:=\Lambda^{\mathbf{i}}{}_{\mathbf{j}}(\vec{e}_{(\mathbf{k})}). \tag{2.23}$$

The transformation law (2.12) for $\Lambda^{\mathbf{i}}{}_{\mathbf{j}}(X)$ translates then into the following one for $\lambda^{\mathbf{i}}{}_{\mathbf{jk}}$:

$$\lambda'^{\mathbf{i}}{}_{\mathbf{jk}}=M^{\mathbf{i}}{}_{\mathbf{a}}\lambda^{\mathbf{a}}{}_{\mathbf{bc}}N^{\mathbf{b}}{}_{\mathbf{j}}N^{\mathbf{c}}{}_{\mathbf{k}}-M^{\mathbf{i}}{}_{\mathbf{a}}N^{\mathbf{b}}{}_{\mathbf{j}}A^{\mathbf{a}}{}_{\mathbf{b}}{}^{\mathbf{c}}{}_{\mathbf{d}}\vec{e}_{(\mathbf{c})}(N^{\mathbf{d}}{}_{\mathbf{k}})+M^{\mathbf{i}}{}_{\mathbf{a}}\vec{e}_{(\mathbf{c})}(N^{\mathbf{a}}{}_{\mathbf{j}})N^{\mathbf{c}}{}_{\mathbf{k}}. \tag{2.24}$$

Moreover, after substitution of (2.22) into (2.8), the explicit form for $D_{\mathbf{X}}Y$ in terms of the components of X and Y becomes

$$D_{\mathbf{X}}Y=\{X(Y^{\mathbf{i}})+\lambda^{\mathbf{i}}{}_{\mathbf{jk}}X^{\mathbf{k}}Y^{\mathbf{j}}-A^{\mathbf{i}}{}_{\mathbf{j}}{}^{\mathbf{a}}{}_{\mathbf{b}}Y^{\mathbf{j}}\vec{e}_{(\mathbf{a})}(X^{\mathbf{b}})\}\vec{e}_{(\mathbf{i})}. \tag{2.25}$$

The decompositions (2.22) and (2.25) will play an important role in the study of examples and properties of D differentiation in Secs. III and IV.

For the preceding developments, D differentiation has not required the presence of any metric on the manifold. Some authors (e.g., Ref. 7), however, have introduced a modified version of the Lie derivative, which involves the metric. (The purpose of that modification was to shed light on Ref. 8.) This construction may be adapted to D differentiation in general, and we shall present these considerations hereafter.

Let g denote the covariant metric on M:

$$g := g_{\mathbf{ij}} \underset{\rightarrow}{e}^{(\mathbf{i})} \otimes \underset{\rightarrow}{e}^{(\mathbf{j})}. \tag{2.26}$$

The definition (2.8), extended to a twice-covariant tensor, yields then the D derivative of g as

$$D_{\mathbf{X}} g = \{X(g_{\mathbf{ij}}) - \Lambda_{\mathbf{ij}}(X) - \Lambda_{\mathbf{ji}}(X)\} \underset{\rightarrow}{e}^{(\mathbf{i})} \otimes \underset{\rightarrow}{e}^{(\mathbf{j})} \tag{2.27}$$

$$= \{X(g_{\mathbf{ij}}) - 2\Lambda_{(\mathbf{ij})}(X)\} \underset{\rightarrow}{e}^{(\mathbf{i})} \otimes \underset{\rightarrow}{e}^{(\mathbf{j})}, \tag{2.28}$$

in which parentheses around indices indicate symmetrization, and the symbols $\Lambda_{\mathbf{ij}}$ are defined by

$$\Lambda_{\mathbf{ij}} = g_{\mathbf{ik}} \Lambda^{\mathbf{k}}{}_{\mathbf{j}}. \tag{2.29}$$

As a result of (2.28), given a vector field X, it is not true in general that $D_{\mathbf{X}} g = 0$. On the other hand, if, from $D_{\mathbf{X}}$, one constructs a new operator (denoted by ${}^{\mathbf{g}}D_{\mathbf{X}}$) as

$${}^{\mathbf{g}}D_{\mathbf{X}} Y = \{X(Y^{\mathbf{i}}) + {}^{\mathbf{g}}\Lambda^{\mathbf{i}}{}_{\mathbf{j}}(X) Y^{\mathbf{j}}\} \vec{e}_{(\mathbf{i})}, \tag{2.30}$$

with

$${}^{\mathbf{g}}\Lambda^{\mathbf{i}}{}_{\mathbf{j}}(X) := g^{\mathbf{ik}}\, {}^{\mathbf{g}}\Lambda_{\mathbf{kj}}(X) \tag{2.31}$$

$$:= g^{\mathbf{ik}} \{\Lambda_{[\mathbf{kj}]}(X) + \tfrac{1}{2} X(g_{\mathbf{kj}})\} \tag{2.32}$$

$$= g^{\mathbf{ik}} \{\Lambda_{[\mathbf{kj}]} + \tfrac{1}{2} d g_{\mathbf{kj}}\}(X), \tag{2.33}$$

where $2\Lambda_{[\mathbf{kj}]} := \Lambda_{\mathbf{kj}} - \Lambda_{\mathbf{jk}}$, then it is obvious that ${}^{\mathbf{g}}D_{\mathbf{X}} g = 0$, whatever X might be. In other words, given a vector field X and an operator of D differentiation that does not satisfy $D_{\mathbf{X}} g = 0$, it is always possible to construct the new operator ${}^{\mathbf{g}}D_{\mathbf{X}}$, which does satisfy ${}^{\mathbf{g}}D_{\mathbf{X}} g = 0$.

In order to determine the relationship between ${}^{\mathbf{g}}\Lambda^{\mathbf{i}}{}_{\mathbf{j}}(fX)$ and ${}^{\mathbf{g}}\Lambda^{\mathbf{i}}{}_{\mathbf{j}}(X)$, we return to (2.32), and use (2.15) and (2.29), to obtain

$$2\,{}^{\mathbf{g}}\Lambda^{\mathbf{i}}{}_{\mathbf{j}}(fX) = g^{\mathbf{iu}} \{\Lambda_{\mathbf{uj}}(fX) - \Lambda_{\mathbf{ju}}(fX) + (fX)(g_{\mathbf{uj}})\} \tag{2.34}$$

$$= \Lambda^{\mathbf{i}}{}_{\mathbf{j}}(fX) - g^{\mathbf{iu}} g_{\mathbf{jv}} \Lambda^{\mathbf{v}}{}_{\mathbf{u}}(fX) + fX(g_{\mathbf{uj}}) g^{\mathbf{iu}} \tag{2.35}$$

$$= \{f\Lambda^{\mathbf{i}}{}_{\mathbf{j}}(X) - A^{\mathbf{i}}{}_{\mathbf{j}}{}^{\mathbf{a}}{}_{\mathbf{b}} \vec{e}_{(\mathbf{a})}(f) X^{\mathbf{b}}\} - g^{\mathbf{iu}} g_{\mathbf{jv}} \{f\Lambda^{\mathbf{v}}{}_{\mathbf{u}}(X) - A^{\mathbf{v}}{}_{\mathbf{u}}{}^{\mathbf{a}}{}_{\mathbf{b}} \vec{e}_{(\mathbf{a})}(f) X^{\mathbf{b}}\} + fX(g_{\mathbf{uj}}) g^{\mathbf{iu}} \tag{2.36}$$

$$= f \cdot \{\Lambda^{\mathbf{i}}{}_{\mathbf{j}}(X) - g^{\mathbf{iu}} g_{\mathbf{jv}} \Lambda^{\mathbf{v}}{}_{\mathbf{u}}(X) + X(g_{\mathbf{uj}}) g^{\mathbf{iu}}\} - 2\,{}^{\mathbf{g}}A^{\mathbf{i}}{}_{\mathbf{j}}{}^{\mathbf{a}}{}_{\mathbf{b}} \vec{e}_{(\mathbf{a})}(f) X^{\mathbf{b}} \tag{2.37}$$

$$= f 2\,{}^{\mathbf{g}}\Lambda^{\mathbf{i}}{}_{\mathbf{j}}(X) - 2\,{}^{\mathbf{g}}A^{\mathbf{i}}{}_{\mathbf{j}}(df, X), \tag{2.38}$$

with

$$2\,{}^{\mathbf{g}}A^{\mathbf{i}}{}_{\mathbf{j}}{}^{\mathbf{a}}{}_{\mathbf{b}} := A^{\mathbf{i}}{}_{\mathbf{j}}{}^{\mathbf{a}}{}_{\mathbf{b}} - g^{\mathbf{iu}} g_{\mathbf{jv}} A^{\mathbf{v}}{}_{\mathbf{u}}{}^{\mathbf{a}}{}_{\mathbf{b}} = A^{\mathbf{i}}{}_{\mathbf{j}}{}^{\mathbf{a}}{}_{\mathbf{b}} - A_{\mathbf{j}}{}^{\mathbf{ia}}{}_{\mathbf{b}}, \tag{2.39}$$

$$2\,{}^{\mathbf{g}}A^{\mathbf{i}}{}_{\mathbf{j}} := A^{\mathbf{i}}{}_{\mathbf{j}} - g^{\mathbf{iu}} g_{\mathbf{jv}} A^{\mathbf{v}}{}_{\mathbf{u}} = A^{\mathbf{i}}{}_{\mathbf{j}} - A_{\mathbf{j}}{}^{\mathbf{i}}. \tag{2.40}$$

These considerations show that, given an operation $D_{\mathbf{X}}$, the modified operator ${}^{\mathbf{g}}D_{\mathbf{X}}$ is also an operation of type D, and (2.39), (2.40) enable one to construct the tensors $A^{\mathbf{i}}{}_{\mathbf{j}}{}^{\mathbf{a}}{}_{\mathbf{b}}$ and $A^{\mathbf{i}}{}_{\mathbf{j}}$ of ${}^{\mathbf{g}}D_{\mathbf{X}}$ in terms of those of $D_{\mathbf{X}}$. The modified operation ${}^{\mathbf{g}}D_{\mathbf{X}}$ will be seen, in the following section, to have a simple interpretation when particularized to covariant and Lie differentiation.

Remark: From the fact that $D_{\mathbf{X}}$ is a derivation, it follows[6] that, for all vector fields X and Y, the Lie derivative and $D_{\mathbf{X}}$ are related by

$$D_{\mathbf{X}} Y = \mathcal{L}_{\mathbf{X}} Y + S(Y), \tag{2.41}$$

where S is a vector-valued one-form (depending on X). Therefore, in some sense, studying general D differentiation amounts to investigating Lie differentiation and properties of the tensor S appearing in (2.41).

This is, however, not the point of view that we wish to adopt. We are going to construct a geometrical framework where all differentiations of D type will appear *on the same footing*, without giving particular emphasis to special cases. This is quite different from (2.41), which singles out Lie differentiation as the type in terms of which all other representatives of D differentiation are expressed.

III. EXAMPLES OF *D* DIFFERENTIATION

D differentiation contains, as special cases, some of the differential operators commonly used in differential geometry. The most important ones for our purposes are covariant differentiation $\nabla_{\mathbf{X}}$ and Lie differentiation $\mathcal{L}_{\mathbf{X}}$. Moreover, the modified version ${}^{\mathbf{g}}\mathcal{L}_{\mathbf{X}}$ of Lie differentiation introduced[7] for the investigation of Lie differentiation of *spinor* fields, also falls in the category of D differentiation. We are now going to consider each of these operators in turn, and relate them to D differentiation.

The coordinate expression for ∇, namely

$$\nabla_{\mathbf{X}} Y = \{X(Y^{\mathbf{i}}) + \gamma^{\mathbf{i}}{}_{\mathbf{j}}(X) Y^{\mathbf{j}}\} \vec{e}_{(\mathbf{i})} \tag{3.1}$$

$$= \{X(Y^{\mathbf{i}}) + \Gamma^{\mathbf{i}}{}_{\mathbf{jk}} X^{\mathbf{k}} Y^{\mathbf{j}}\} \vec{e}_{(\mathbf{i})}, \tag{3.2}$$

in which $\gamma^{\mathbf{i}}{}_{\mathbf{j}}$ and $\Gamma^{\mathbf{i}}{}_{\mathbf{jk}}$ denote the connection forms and the connection coefficients, enables one, after comparison with (2.8), (2.25), to identify $\Lambda^{\mathbf{i}}{}_{\mathbf{j}}$ and $\lambda^{\mathbf{i}}{}_{\mathbf{jk}}$ with $\gamma^{\mathbf{i}}{}_{\mathbf{j}}$ and $\Gamma^{\mathbf{i}}{}_{\mathbf{jk}}$, respectively. Furthermore, it also shows that $A^{\mathbf{i}}{}_{\mathbf{j}}$ and $A^{\mathbf{i}}{}_{\mathbf{j}}{}^{\mathbf{a}}{}_{\mathbf{b}}$ vanish for ∇. Covariant differentiation is thus that particular D differentiation characterized by

$${}_{\nabla}\Lambda^{\mathbf{i}}{}_{\mathbf{j}}(X) = \gamma^{\mathbf{i}}{}_{\mathbf{j}}(X), \quad {}_{\nabla}\lambda^{\mathbf{i}}{}_{\mathbf{jk}} = \Gamma^{\mathbf{i}}{}_{\mathbf{jk}}, \tag{3.3}$$

$${}_{\nabla}A^{\mathbf{i}}{}_{\mathbf{j}} = 0, \quad {}_{\nabla}A^{\mathbf{i}}{}_{\mathbf{j}}{}^{\mathbf{a}}{}_{\mathbf{b}} = 0, \tag{3.4}$$

where a prefixed subscript specifies that covariant differentiation is understood. In this context, the laws (2.13), (2.24) reduce to the well-known transformation laws for the connection forms and the connection coefficients.

To recognize Lie differentiation, one must recall its coordinate expression employed in Ref. 2:

$$\mathcal{L}_{\mathbf{X}} Y = \{X(Y^{\mathbf{i}}) - L^{\mathbf{i}}{}_{\mathbf{j}}(X) Y^{\mathbf{j}}\} \vec{e}_{(\mathbf{i})}, \tag{3.5}$$

$$L^{\mathbf{i}}{}_{\mathbf{j}}(X) := \vec{e}_{(\mathbf{j})}(X^{\mathbf{i}}) + D^{\mathbf{i}}{}_{\mathbf{jk}} X^{\mathbf{k}}, \tag{3.6}$$

where the symbols $D^{\mathbf{i}}{}_{\mathbf{jk}}$ denote the commutation coefficients of the basis:

$$D^{\mathbf{k}}{}_{\mathbf{ij}} \vec{e}_{(\mathbf{k})} = [\vec{e}_{(\mathbf{i})}, \vec{e}_{(\mathbf{j})}]. \tag{3.7}$$

It follows from (3.5) that, for Lie differentiation, the appropriate $\Lambda^{\mathbf{i}}{}_{\mathbf{j}}$ reads

$$\mathcal{L}\Lambda^{\mathbf{i}}{}_{\mathbf{j}}(X) = -L^{\mathbf{i}}{}_{\mathbf{j}}(X). \tag{3.8}$$

A simple calculation based on (2.17), (2.22), (3.6), (3.8) yields then

$$\mathcal{L}\lambda^{\mathbf{i}}{}_{\mathbf{jk}} = -D^{\mathbf{i}}{}_{\mathbf{jk}}, \quad \mathcal{L}A^{\mathbf{i}}{}_{\mathbf{j}} = \vec{e}_{(\mathbf{j})} \otimes \underset{\rightarrow}{e}{}^{(\mathbf{i})}, \quad \mathcal{L}A^{\mathbf{i}}{}_{\mathbf{j}}{}^{\mathbf{a}}{}_{\mathbf{b}} = \delta^{\mathbf{i}}{}_{\mathbf{b}}\delta^{\mathbf{a}}{}_{\mathbf{j}}, \tag{3.9}$$

which fully characterize Lie differentiation within the class of D derivatives. Note that, as a result of (3.9), one has $\mathcal{L}_{\mathbf{f}\mathbf{X}} \neq f\mathcal{L}_{\mathbf{X}}$, in contrast with what happens for covariant differentiation.

Furthermore, a comparison of (3.3) and (3.8) reveals the origin of the ''translation rule''

$$\gamma^{\mathbf{i}}{}_{\mathbf{j}}(X) \rightarrow -L^{\mathbf{i}}{}_{\mathbf{j}}(X) \tag{3.10}$$

employed in Ref. 1 to ''convert'' statements about covariant differentiation into analogous ones for Lie differentiation: Both operations ∇ and $\mathcal{L}$ are special cases of D differentiation, and their symbols $\Lambda^{\mathbf{i}}{}_{\mathbf{j}}(X)$ are interchanged under the substitution (3.10). In Ref. 1, the conversion (3.10) was performed in the context of differentiation of spinors; here we see its counterpart for tensors.

All this applies to D differentiation proper. In Sec. II, however, we also introduced, from D differentiation, a modified operation ${}^{\mathbf{g}}D$, which has the characteristic that ${}^{\mathbf{g}}D_{\mathbf{X}}g = 0$, where g is the metric. In the special case of covariant differentiation, the modified operation ${}^{\mathbf{g}}\nabla$ reads, by virtue of (2.30), (2.33), (3.3)

$${}^{\mathbf{g}}\nabla_{\mathbf{X}}Y = \{X(Y^{\mathbf{i}}) + {}^{\mathbf{g}}_{\nabla}\Lambda^{\mathbf{i}}{}_{\mathbf{j}}(X)Y^{\mathbf{j}}\}\vec{e}_{(\mathbf{i})} \tag{3.11}$$

with

$${}^{\mathbf{g}}_{\nabla}\Lambda^{\mathbf{i}}{}_{\mathbf{j}}(X) = g^{\mathbf{ik}}\{\gamma_{[\mathbf{kj}]} + \tfrac{1}{2}\mathrm{d}g_{\mathbf{kj}}\}(X). \tag{3.12}$$

The general construction (2.33) guarantees that ${}^{\mathbf{g}}\nabla_{\mathbf{X}}g = 0$, which is the main reason why one introduces the modified connection ${}_{\nabla}{}^{\mathbf{g}}\Lambda^{\mathbf{i}}{}_{\mathbf{j}}(X)$. However, light is shed on (3.12) by pursuing the matter a little further. We begin by using the Cartan equation

$$\mathrm{d}g_{\mathbf{kj}} = \gamma_{\mathbf{kj}} + \gamma_{\mathbf{jk}} + h_{\mathbf{kj}}, \tag{3.13}$$

where $h_{\mathbf{kj}}$ denotes the nonmetricity one-forms:

$$h_{\mathbf{kj}}(X) := (\nabla_{\mathbf{X}}g)(\vec{e}_{(\mathbf{k})}, \vec{e}_{(\mathbf{j})}) = (\nabla_{\mathbf{X}}g)_{\mathbf{kj}}. \tag{3.14}$$

After substitution of (3.14) in (3.12), the latter implies

$${}^{\mathbf{g}}_{\nabla}\Lambda^{\mathbf{i}}{}_{\mathbf{j}}(X) = g^{\mathbf{ik}}(\gamma_{\mathbf{kj}} + \tfrac{1}{2}h_{\mathbf{kj}}) \tag{3.15}$$

$$= \gamma^{\mathbf{i}}{}_{\mathbf{j}} + \tfrac{1}{2}h^{\mathbf{i}}{}_{\mathbf{j}}, \tag{3.16}$$

so that (3.11) becomes

$${}^{\mathbf{g}}\nabla_{\mathbf{X}}Y = \nabla_{\mathbf{X}}Y + \tfrac{1}{2}h^{\mathbf{i}}{}_{\mathbf{j}}(X)Y^{\mathbf{j}}\vec{e}_{(\mathbf{i})} \tag{3.17}$$

$$= \nabla_{\mathbf{X}}Y + \tfrac{1}{2}(\nabla_{\mathbf{X}}g)^{\mathbf{i}}{}_{\mathbf{j}}Y^{\mathbf{j}}\vec{e}_{(\mathbf{i})}. \tag{3.18}$$

As one can see, the new covariant derivative ${}^{\mathbf{g}}\nabla_{\mathbf{X}}$ is obtained from the original one $\nabla_{\mathbf{X}}g$ by the adjunction of a linear transformation generated by $\frac{1}{2}\nabla_{\mathbf{X}}g$. The reason for the presence of that particular linear transformation becomes clear when ${}^{\mathbf{g}}\nabla_{\mathbf{X}}$ is applied to the metric g itself, rather than to a general vector field Y. A similar treatment to that leading to (3.18) yields then

$$ {}^{\mathbf{g}}\nabla_{\mathbf{X}} g = \nabla_{\mathbf{X}} g - \nabla_{\mathbf{X}} g = 0, \tag{3.19} $$

which confirms the interpretation suggested by (3.16), namely that, in the case of covariant differentiation ∇, the modified version ${}^{\mathbf{g}}\nabla_{\mathbf{X}}$ corresponds to covariant differentiation with respect to the metric-compatible part of the connection.

Let us now follow the same line of reasoning in the case of Lie differentiation. By virtue of (2.30), (2.33), (3.8), the modified operator ${}^{\mathbf{g}}\mathcal{L}_{\mathbf{X}}$ reads

$$ {}^{\mathbf{g}}\mathcal{L}_{\mathbf{X}} Y = \{ X(Y^{\mathbf{i}}) + {}_{\mathcal{L}}{}^{\mathbf{g}}\Lambda^{\mathbf{i}}{}_{\mathbf{j}}(X) Y^{\mathbf{j}} \} \vec{e}_{(\mathbf{i})}, \tag{3.20} $$

with

$$ {}_{\mathcal{L}}{}^{\mathbf{g}}\Lambda^{\mathbf{i}}{}_{\mathbf{j}}(X) = g^{\mathbf{ik}} \{ -L_{[\mathbf{kj}]} + \tfrac{1}{2} \mathrm{d} g_{\mathbf{kj}} \}(X). \tag{3.21} $$

Furthermore, as a result of (2.38), (2.40), and (3.9), ${}_{\mathcal{L}}{}^{\mathbf{g}}\Lambda^{\mathbf{i}}{}_{\mathbf{j}}(fX)$ is related to ${}_{\mathcal{L}}{}^{\mathbf{g}}\Lambda^{\mathbf{i}}{}_{\mathbf{j}}(X)$ by

$$ {}_{\mathcal{L}}{}^{\mathbf{g}}\Lambda^{\mathbf{i}}{}_{\mathbf{j}}(fX) = f\, {}_{\mathcal{L}}{}^{\mathbf{g}}\Lambda^{\mathbf{i}}{}_{\mathbf{j}}(X) - {}_{\mathcal{L}}{}^{\mathbf{g}}A^{\mathbf{i}}{}_{\mathbf{j}}(\mathrm{d}f, X), \tag{3.22} $$

where ${}_{\mathcal{L}}{}^{\mathbf{g}}A^{\mathbf{i}}{}_{\mathbf{j}}$ is given by

$$ 2\, {}_{\mathcal{L}}{}^{\mathbf{g}}A^{\mathbf{i}}{}_{\mathbf{j}} = \vec{e}_{(\mathbf{j})} \otimes \underset{\rightarrow}{e}{}^{(\mathbf{i})} - g^{\mathbf{iu}} g_{\mathbf{jv}} \vec{e}_{(\mathbf{u})} \otimes \underset{\rightarrow}{e}{}^{(\mathbf{v})}. \tag{3.23} $$

The last line may be simplified by introducing the two operations $\sharp$ and $\flat$ of metric dualization, as follows.

Let X be a vector field. Then, the one-form $X^{\flat}$, which g associates with X, is defined by

$$ (X^{\flat})(Y) := g(X,Y) = g_{\mathbf{ij}} X^{\mathbf{i}} Y^{\mathbf{j}}, \tag{3.24} $$

for all vector fields Y. The operator $\sharp$ is the inverse of $\flat$, and maps one-forms to vectors. With that notation, (3.23) becomes

$$ 2\, {}_{\mathcal{L}}{}^{\mathbf{g}}A^{\mathbf{i}}{}_{\mathbf{j}} = \vec{e}_{(\mathbf{j})} \otimes \underset{\rightarrow}{e}{}^{(\mathbf{i})} - (\underset{\rightarrow}{e}{}^{(\mathbf{i})})^{\sharp} \otimes (\vec{e}_{(\mathbf{j})})^{\flat}. \tag{3.25} $$

The main reason for introducing the modified version ${}^{\mathbf{g}}\mathcal{L}$ of Lie differentiation lies in the fact that, for an arbitrary X, ${}^{\mathbf{g}}\mathcal{L}_{\mathbf{X}} g$ vanishes (by construction), whereas $\mathcal{L}_{\mathbf{X}} g \neq 0$ in general. If one attempts to extend Lie differentiation to spinor fields, it is the fact that, in general, $\mathcal{L}_{\mathbf{X}} g \neq 0$ which creates difficulties. Therefore, one of the approaches[7] to spinorial Lie differentiation consists in extending ${}^{\mathbf{g}}\mathcal{L}$ to spinors, not $\mathcal{L}$ itself. The present article being devoted solely to tensors, we shall not elaborate further on Lie differentiation of spinor fields. The interested reader will find details in Ref. 5, where we shall investigate the spinorial analog of the material presented here.

Remark: In the case of covariant and Lie differentiation, the tensors $A^{\mathbf{i}}{}_{\mathbf{j}}$ appearing in (2.16) are very simple. By virtue of (3.4) and (3.9), it is possible to write both under the form

$$ \underset{\mathcal{L}}{\nabla} A^{\mathbf{i}}{}_{\mathbf{j}} = \alpha \vec{e}_{(\mathbf{j})} \otimes \underset{\rightarrow}{e}{}^{(\mathbf{i})}. \tag{3.26} $$

with $\alpha = 0$ or 1 according to whether the differentiation is of covariant or Lie type. This observation prompts us to give special attention to the subclass of D differentiation characterized by an arbitrary value of the constant α in (3.26), not just 0 or 1. Such kinds of D will be called ''restricted D derivatives,'' and they will be identified by a subscript R, as

$$ {}_{\mathbf{R}}A^{\mathbf{i}}{}_{\mathbf{j}} = \alpha \vec{e}_{(\mathbf{j})} \otimes \underset{\rightarrow}{e}{}^{(\mathbf{i})} \tag{3.27} $$

for an arbitrary α.

It must be emphasized that the class of restricted D derivatives contains much more than Lie and covariant differentiation because, even if (for instance) $\alpha=1$, the corresponding D derivative only reduces to Lie differentiation when the coefficients $\lambda^{\mathbf{i}}_{\mathbf{jk}}$ of (2.23) are given by (3.9). In other words, although restricted D differentiation uses the particular value (3.27) for the tensors ${}_{\mathbf{R}}A^{\mathbf{i}}_{\mathbf{j}}$, it nevertheless leaves the coefficients $\lambda^{\mathbf{i}}_{\mathbf{jk}}$ of (2.23) entirely unconstrained, but compatible with (2.24).

Note that the modified covariant derivative ${}^{\mathbf{g}}\nabla$ of (3.11), (3.12) also falls within the category of restricted D differentiation (with $\alpha=0$), as follows from (2.40) and (3.4). However, such is not the case for the modified Lie derivative ${}^{\mathbf{g}}\mathcal{L}$ of (3.20), (3.21), as shown by (3.23). This is why, when defining general D differentiation, we adopted the very weak assumption (2.15).

It is clear from (2.22) that (2.15) may be interpreted as the requirement that $\Lambda^{\mathbf{i}}_{\mathbf{j}}(X)$ be a general linear combination of the components $X^{\mathbf{k}}$ of X and all the directional derivatives $\vec{e}_{(\mathbf{a})}(X^{\mathbf{b}})$ of these components along the basic vectors $\vec{e}_{(\mathbf{a})}$. On the other hand, for restricted D differentiation (3.27), the relationship (2.16) between ${}_{\mathbf{R}}\Lambda^{\mathbf{i}}_{\mathbf{j}}(fX)$ and ${}_{\mathbf{R}}\Lambda^{\mathbf{i}}_{\mathbf{j}}(X)$ particularizes as

$$ {}_{\mathbf{R}}\Lambda^{\mathbf{i}}_{\mathbf{j}}(fX)=f\,{}_{\mathbf{R}}\Lambda^{\mathbf{i}}_{\mathbf{j}}(X)-\alpha\vec{e}_{(\mathbf{j})}(f)X^{\mathbf{i}}, \tag{3.28}$$

which implies, by (2.22),

$$ {}_{\mathbf{R}}\Lambda^{\mathbf{i}}_{\mathbf{j}}(X)=\lambda^{\mathbf{i}}_{\mathbf{jk}}X^{\mathbf{k}}-\alpha\vec{e}_{(\mathbf{j})}(X^{\mathbf{i}}). \tag{3.29}$$

Furthermore, the translation of (3.28) in terms of the operation D reads

$$ {}_{\mathbf{R}}D_{\mathbf{f}\,\mathbf{X}}Y=f\,{}_{\mathbf{R}}D_{\mathbf{X}}Y-\alpha X\,\mathrm{d}f(Y). \tag{3.30}$$

By providing the examples of covariant and Lie differentiation, as well as the modified versions of these operations, we have shown that the class of D derivatives (even the restricted subclass ${}_{\mathbf{R}}D$) unifies enough nontrivial material to justify its study. In Sec. IV, we are going to investigate some of the properties of D differentiation. Later, a geometrical interpretation of D differentiation will be developed.

IV. GENERALIZED CURVATURE OF *D* DIFFERENTIATION

As mentioned earlier, covariant and Lie differentiation satisfy the strikingly different properties $\nabla_{\mathbf{f}\,\mathbf{X}}=f\nabla_{\mathbf{X}}$ and $\mathcal{L}_{\mathbf{f}\,\mathbf{X}}\neq f\mathcal{L}_{\mathbf{X}}$. Another important difference is that

$$ \mathcal{L}_{\mathbf{X}}\mathcal{L}_{\mathbf{Y}}-\mathcal{L}_{\mathbf{Y}}\mathcal{L}_{\mathbf{X}}-\mathcal{L}_{[\mathbf{X},\mathbf{Y}]}=0, \tag{4.1}$$

whereas, in general,

$$ \nabla_{\mathbf{X}}\nabla_{\mathbf{Y}}-\nabla_{\mathbf{Y}}\nabla_{\mathbf{X}}-\nabla_{[\mathbf{X},\mathbf{Y}]}\neq 0. \tag{4.2}$$

This suggests that we study the same kind of operation for D differentiation. More precisely, let us define

$$ {}_{\mathbf{D}}\mathcal{R}(X,Y,Z):=(D_{\mathbf{X}}D_{\mathbf{Y}}-D_{\mathbf{Y}}D_{\mathbf{X}}-D_{[\mathbf{X},\mathbf{Y}]})Z, \tag{4.3}$$

for all vector fields X, Y, Z. It is at once obvious that

$$ {}_{\mathcal{L}}\mathcal{R}=0, \quad {}_{\nabla}\mathcal{R}=\text{curvature operator} \tag{4.4}$$

for Lie and covariant differentiation.

Owing to the properties of D, the mapping $Z\mapsto{}_{\mathbf{D}}\mathcal{R}(X,Y,Z)$ is a linear transformation, which enables us to reformulate (4.3) as

$$ {}_{\mathbf{D}}\mathcal{R}(X,Y,\cdot)={}_{\mathbf{D}}\Omega^{\mathbf{i}}_{\mathbf{j}}(X,Y)\vec{e}_{(\mathbf{i})}\otimes\underset{\rightarrow}{e}{}^{(\mathbf{j})}, \tag{4.5}$$

for a certain family of functions ${}_{\mathbf{D}}\Omega^{\mathbf{i}}{}_{\mathbf{j}}(X,Y)$. In the context of linear transformations, the interpretation of the tensor product appearing in (4.5) is

$$ {}_{\mathbf{D}}\mathcal{R}(X,Y,Z) = {}_{\mathbf{D}}\Omega^{\mathbf{i}}{}_{\mathbf{j}}(X,Y)\vec{e}_{(\mathbf{i})}\underset{\rightarrow}{e}{}^{(\mathbf{j})}(Z) \tag{4.6} $$

$$ = {}_{\mathbf{D}}\Omega^{\mathbf{i}}{}_{\mathbf{j}}(X,Y)Z^{\mathbf{j}}\vec{e}_{(\mathbf{i})}\,. \tag{4.7} $$

The expression of ${}_{\mathbf{D}}\Omega^{\mathbf{i}}{}_{\mathbf{j}}$, which generalizes to D differentiation what is, in the special case of covariant differentiation, the family of curvature two-forms, is tedious to evaluate in terms of the coefficients $\lambda^{\mathbf{i}}{}_{\mathbf{jk}}$ and the tensors $A^{\mathbf{i}}{}_{\mathbf{j}}{}^{\mathbf{a}}{}_{\mathbf{b}}$ of (2.15). This expression is established by employing repeatedly the definition (2.8) of D differentiation, the coordinate expansion (2.22), and the definition (3.7) of the commutation coefficients the basis, with the result

$$ \begin{aligned} {}_{\mathbf{D}}\Omega^{\mathbf{i}}{}_{\mathbf{j}}(X,Y) = {}& X^{\mathbf{a}}Y^{\mathbf{b}}{}_{D}R^{\mathbf{i}}{}_{\mathbf{jab}} + \{X^{\mathbf{a}}\vec{e}_{(\mathbf{u})}(Y^{\mathbf{b}}) - Y^{\mathbf{a}}\vec{e}_{(\mathbf{u})}(X^{\mathbf{b}})\}{}_{\mathbf{D}}S^{\mathbf{i}}{}_{\mathbf{ja}}{}^{\mathbf{u}}{}_{\mathbf{b}} \\ & + \{\vec{e}_{(\mathbf{u})}(X^{\mathbf{a}})\vec{e}_{(\mathbf{v})}(Y^{\mathbf{b}}) - \vec{e}_{(\mathbf{u})}(Y^{\mathbf{a}})\vec{e}_{(\mathbf{v})}(X^{\mathbf{b}})\}{}_{D}T^{\mathbf{i}}{}_{\mathbf{jab}}{}^{\mathbf{uv}}, \end{aligned} \tag{4.8} $$

where

$$ {}_{\mathbf{D}}R^{\mathbf{i}}{}_{\mathbf{jab}} = \vec{e}_{(\mathbf{a})}(\lambda^{\mathbf{i}}{}_{\mathbf{jb}}) - \vec{e}_{(\mathbf{b})}(\lambda^{\mathbf{i}}{}_{\mathbf{ja}}) + \lambda^{\mathbf{i}}{}_{\mathbf{ra}}\lambda^{\mathbf{r}}{}_{\mathbf{jb}} - \lambda^{\mathbf{i}}{}_{\mathbf{rb}}\lambda^{\mathbf{r}}{}_{\mathbf{ja}} - \lambda^{\mathbf{i}}{}_{\mathbf{jr}}D^{\mathbf{r}}{}_{\mathbf{ab}} + A^{\mathbf{i}}{}_{\mathbf{j}}{}^{\mathbf{r}}{}_{\mathbf{s}}\vec{e}_{(\mathbf{r})}(D^{\mathbf{s}}{}_{\mathbf{ab}}), \tag{4.9} $$

$$ {}_{\mathbf{D}}S^{\mathbf{i}}{}_{\mathbf{ja}}{}^{\mathbf{u}}{}_{\mathbf{b}} = A^{\mathbf{i}}{}_{\mathbf{j}}{}^{\mathbf{r}}{}_{\mathbf{b}}D^{\mathbf{u}}{}_{\mathbf{ra}} + A^{\mathbf{i}}{}_{\mathbf{r}}{}^{\mathbf{u}}{}_{\mathbf{b}}\lambda^{\mathbf{r}}{}_{\mathbf{ja}} - A^{\mathbf{i}}{}_{\mathbf{j}}{}^{\mathbf{u}}{}_{\mathbf{r}}D^{\mathbf{r}}{}_{\mathbf{ba}} - A^{\mathbf{r}}{}_{\mathbf{j}}{}^{\mathbf{u}}{}_{\mathbf{b}}\lambda^{\mathbf{i}}{}_{\mathbf{ra}} - \vec{e}_{(\mathbf{a})}(A^{\mathbf{i}}{}_{\mathbf{j}}{}^{\mathbf{u}}{}_{\mathbf{b}}), \tag{4.10} $$

$$ {}_{\mathbf{D}}T^{\mathbf{i}}{}_{\mathbf{jab}}{}^{\mathbf{uv}} = A^{\mathbf{i}}{}_{\mathbf{j}}{}^{\mathbf{u}}{}_{\mathbf{b}}\delta^{\mathbf{v}}{}_{\mathbf{a}} + A^{\mathbf{i}}{}_{\mathbf{r}}{}^{\mathbf{u}}{}_{\mathbf{a}}A^{\mathbf{r}}{}_{\mathbf{j}}{}^{\mathbf{v}}{}_{\mathbf{b}}\,. \tag{4.11} $$

These equations become a little less unmanageable for restricted D differentiation (3.27), and read

$$ \begin{aligned} {}_{\mathbf{R}}\Omega^{\mathbf{i}}{}_{\mathbf{j}}(X,Y) = {}& X^{\mathbf{a}}Y^{\mathbf{b}}{}_{\mathbf{R}}R^{\mathbf{i}}{}_{\mathbf{jab}} + \alpha\{X^{\mathbf{a}}\vec{e}_{(\mathbf{u})}(Y^{\mathbf{b}}) - Y^{\mathbf{a}}\vec{e}_{(\mathbf{u})}(X^{\mathbf{b}})\}\{\delta^{\mathbf{i}}{}_{\mathbf{b}}(D^{\mathbf{u}}{}_{\mathbf{ja}} + \lambda^{\mathbf{u}}{}_{\mathbf{ja}}) \\ & - \delta^{\mathbf{u}}{}_{\mathbf{j}}(D^{\mathbf{i}}{}_{\mathbf{ba}} + \lambda^{\mathbf{i}}{}_{\mathbf{ba}})\} + (\alpha - \alpha^{2})\{\vec{e}_{(\mathbf{j})}(X^{\mathbf{r}})\vec{e}_{(\mathbf{r})}(Y^{\mathbf{i}}) - \vec{e}_{(\mathbf{j})}(Y^{\mathbf{r}})\vec{e}_{(\mathbf{r})}(X^{\mathbf{i}})\}, \end{aligned} \tag{4.12} $$

with

$$ {}_{\mathbf{R}}R^{\mathbf{i}}{}_{\mathbf{jab}} = \vec{e}_{(\mathbf{a})}(\lambda^{\mathbf{i}}{}_{\mathbf{jb}}) - \vec{e}_{(\mathbf{b})}(\lambda^{\mathbf{i}}{}_{\mathbf{ja}}) + \lambda^{\mathbf{i}}{}_{\mathbf{ra}}\lambda^{\mathbf{r}}{}_{\mathbf{jb}} - \lambda^{\mathbf{i}}{}_{\mathbf{rb}}\lambda^{\mathbf{r}}{}_{\mathbf{ja}} - \lambda^{\mathbf{i}}{}_{\mathbf{jr}}D^{\mathbf{r}}{}_{\mathbf{ab}} + \alpha\vec{e}_{(\mathbf{j})}(D^{\mathbf{i}}{}_{\mathbf{ab}}). \tag{4.13} $$

We are now ready to investigate the question of the uniqueness of the operator of D differentiation that yields a vanishing ${}_{\mathbf{D}}\Omega^{\mathbf{i}}{}_{\mathbf{j}}(X,Y)$ for all X and Y in (4.8). Equivalently, we wish to decide to what extent the requirement

$$ D_{\mathbf{X}}D_{\mathbf{Y}}Z - D_{\mathbf{Y}}D_{\mathbf{X}}Z - D_{[\mathbf{X},\mathbf{Y}]}Z = 0, \tag{4.14} $$

for all X, Y, Z, determines D uniquely. As we shall see, (4.14) admits several nontrivial D operators, even of the restricted class (3.27).

Let us, initially, return to (4.12). For ${}_{\mathbf{R}}\Omega^{\mathbf{i}}{}_{\mathbf{j}}(X,Y)$ to vanish identically for all X and Y, one must have, as a necessary condition,

$$ \alpha - \alpha^{\mathbf{2}} = 0, \tag{4.15} $$

which implies that either $\alpha = 0$ or $\alpha = 1$. If $\alpha = 0$, then the second term on the right-hand side of (4.12) disappears automatically, whereas (4.13) becomes

$$ 0 = {}_{\mathbf{R}}R^{\mathbf{i}}{}_{\mathbf{jab}} = \vec{e}_{(\mathbf{a})}(\lambda^{\mathbf{i}}{}_{\mathbf{jb}}) - \vec{e}_{(\mathbf{b})}(\lambda^{\mathbf{i}}{}_{\mathbf{ja}}) + \lambda^{\mathbf{i}}{}_{\mathbf{ra}}\lambda^{\mathbf{r}}{}_{\mathbf{jb}} - \lambda^{\mathbf{i}}{}_{\mathbf{rb}}\lambda^{\mathbf{r}}{}_{\mathbf{ja}} - \lambda^{\mathbf{i}}{}_{\mathbf{jr}}D^{\mathbf{r}}{}_{\mathbf{ab}}\,. \tag{4.16} $$

The right-hand side of (4.16) is the usual expression of the Riemann tensor in terms of the connection coefficients $\lambda^{\mathbf{i}}{}_{\mathbf{jk}}$. Therefore, when $\alpha = 0$, the requirement (4.14) determines that D

differentiation be covariant differentiation with a flat connection. This, however, does not mean that the resulting D derivative is trivial, because the connection may still exhibit torsion or nonmetricity (or both).

On the other hand, when $\alpha=1$, the second term on the right-hand side of (4.12) no longer disappears automatically, but determines $\lambda^{\mathbf{i}}{}_{\mathbf{jk}}$ as

$$\lambda^{\mathbf{i}}{}_{\mathbf{jk}}=-D^{\mathbf{i}}{}_{\mathbf{jk}}, \tag{4.17}$$

which has been observed in (3.9) to identify Lie differentiation. Furthermore, when (4.17) holds, (4.13) vanishes identically, for $\alpha=1$, as a consequence of the Jacobi identity

$$[[\vec{e}_{(\mathbf{a})},\vec{e}_{(\mathbf{b})}],\vec{e}_{(\mathbf{j})}]+[[\vec{e}_{(\mathbf{b})},\vec{e}_{(\mathbf{j})}],\vec{e}_{(\mathbf{a})}]+[[\vec{e}_{(\mathbf{j})},\vec{e}_{(\mathbf{a})}],\vec{e}_{(\mathbf{b})}]=0. \tag{4.18}$$

The conclusion that we have reached is thus that, among all the operators ${}_{\mathbf{R}}D$ of restricted D differentiation, the only two operators satisfying (4.14) are either covariant differentiation in a flat manifold with, possibly, torsion and nonmetricitry (which is often called a ''tele-parallel'' space), or Lie differentiation. In the case of Lie differentiation, our result should not be confused with the well-known theorem[6]

$$[\mathcal{L}_{\mathbf{X}}Z,\mathcal{L}_{\mathbf{Y}}Z]=\mathcal{L}_{[\mathbf{X},\mathbf{Y}]}Z, \tag{4.19}$$

because (4.19) follows, as proved in Ref. 6, from

$$\mathcal{L}_{\mathbf{X}}Y=[X,Y] \tag{4.20}$$

and the Jacobi identity, whereas we have assumed the analog (4.14) of (4.19) for restricted D differentiation, and derived Lie differentiation as one of the possibilities. Obviously, (4.20) is special to the Lie derivative, and was not assumed to be a general property of D differentiation. Indeed, the analog of (4.20) for D differentiation is (2.25), and becomes, for the restricted class ${}_{\mathbf{R}}D$,

$${}_{\mathbf{R}}D_{\mathbf{X}}Y=\{X(Y^{\mathbf{i}})-\alpha Y(X^{\mathbf{i}})+\lambda^{\mathbf{i}}{}_{\mathbf{jk}}X^{\mathbf{k}}Y^{\mathbf{j}}\}\vec{e}_{(\mathbf{i})}, \tag{4.21}$$

which is different from (4.20), unless $\alpha=1$ and $\lambda^{\mathbf{i}}{}_{\mathbf{jk}}=-D^{\mathbf{i}}{}_{\mathbf{jk}}$.

Owing to the fact that the operator D of restricted type (3.27) fails to be uniquely determined by (4.14), it is also true, *a fortiori*, that D differentiation of general type is not determined by (4.14). It remains, at present, an open question to characterize the subclass of general D differentiation for which ${}_{\mathbf{D}}\Omega^{\mathbf{i}}{}_{\mathbf{j}}=0$. For our purposes, which are centered around covariant and Lie differentiation (of spinor fields, ultimately), it is not necessary to answer this question, because both covariant and Lie differentiation fall into the category of restricted D differentiation. As remarked in Sec. III, modified covariant differentiation ${}^{\mathbf{g}}\nabla$ belongs to D differentiation of restricted type as well. Moreover, modified Lie differentiation ${}^{\mathbf{g}}\mathcal{L}$, albeit not a member of the class of restricted D differentiation, does not lead to an identically vanishing $\Omega^{\mathbf{i}}{}_{\mathbf{j}}$, as one establishes by combining (3.23) with (4.8)–(4.11).

Our investigation of D differentiation has been conducted, up to now, in the language of tensors. Further light is shed on the construction by a reformulation in terms of fiber bundles. This will be done, in two stages, in Secs. V and VI.

V. BUNDLE FORMULATION OF *D* DIFFERENTIATION

The reason for recasting D differentiation in the framework of fiber bundles is twofold: first, we wish to provide a more geometrical interpretation of D differentiation, and second, bundles facilitate the extension of D differentiation to spinor fields, as we shall show in the companion article.[5] The initial stage of this reformulation, developed in the present section, will employ the

tangent bundle *TM* to the manifold *M*, as well as the principal bundle *PLM* of linear frames over *M*. A more powerful language, using the tangent bundle *TTM* to *TM*, will enable us to obtain further geometrical insight in Sec. VI.

Let P be a point of M, and X be a vector field over M. Consequently $X_{\mathbf{P}}$, the value of X at P, is a certain vector of the tangent space $T_{\mathbf{P}}M$ to M. Let $\varphi_{\mathbf{t}}(P)$ denote the integral curve of X passing through P at $t=0$. Let finally $y_{\mathbf{P}}$ denote a vector of $T_{\mathbf{P}}M$. Then, one may construct from $y_{\mathbf{P}}$ a vector field ${}^{\mathbf{D}}Y$, defined above $\varphi_{\mathbf{t}}(P)$, by requiring

$$0 = D_{\mathbf{X}}{}^{\mathbf{D}}Y, \tag{5.1}$$

$${}^{\mathbf{D}}Y_{\mathbf{P}} = y_{\mathbf{P}}. \tag{5.2}$$

In other words, one solves (5.1) for ${}^{\mathbf{D}}Y$, with initial condition (5.2). The vector field ${}^{\mathbf{D}}Y$ will be said to be ''*D*-transported'' along X. (This terminology is an obvious generalization of the phrases ''parallel-transported'' and ''Lie transported,'' which apply to covariant and Lie differentiation.)

To determine the explicit expression of ${}^{\mathbf{D}}Y$ in coordinates, we begin by selecting a field of bases $\{\vec{e}_{(\mathbf{i})}\}$ over M, so that $\{\vec{e}_{(\mathbf{i})\mathbf{P}}\}$ is a basis of $T_{\mathbf{P}}M$. The vector field ${}^{\mathbf{D}}Y$ may therefore be written, at the point $\varphi_{\mathbf{t}}(P)$, as

$${}^{\mathbf{D}}Y_{\varphi_{\mathbf{t}}(\mathbf{P})} = {}^{\mathbf{D}}Y^{\mathbf{i}}_{\varphi_{\mathbf{t}}(\mathbf{P})}\vec{e}_{(\mathbf{i})\varphi_{\mathbf{t}}(\mathbf{P})}. \tag{5.3}$$

In the neighborhood of P, namely on the portion of the integral curve $\varphi_{\mathbf{t}}(P)$ near $t=0$, (5.3) becomes

$${}^{\mathbf{D}}Y_{\varphi_{\mathbf{t}}(\mathbf{P})} = \{{}^{\mathbf{D}}Y^{\mathbf{i}}_{\mathbf{P}} + tX_{\mathbf{P}}({}^{\mathbf{D}}Y^{\mathbf{i}}) + o(t^2)\}\vec{e}_{(\mathbf{i})\varphi_{\mathbf{t}}(\mathbf{P})}. \tag{5.4}$$

By virtue of the hypothesis (5.1) that ${}^{\mathbf{D}}Y$ is *D*-transported, the quantities $X_{\mathbf{P}}({}^{\mathbf{D}}Y^{\mathbf{i}})$ of (5.4) may be replaced by their expressions coming from (2.8), with the result

$${}^{\mathbf{D}}Y_{\varphi_{\mathbf{t}}(\mathbf{P})} = \{{}^{\mathbf{D}}Y^{\mathbf{i}}_{\mathbf{P}} - t\Lambda^{\mathbf{i}}{}_{\mathbf{j}}(X_{\mathbf{P}}){}^{\mathbf{D}}Y^{\mathbf{j}}_{\mathbf{P}} + o(t^2)\}\vec{e}_{(\mathbf{i})\varphi_{\mathbf{t}}(\mathbf{P})} \tag{5.5}$$

$$= \{y^{\mathbf{i}}_{\mathbf{P}} - t\Lambda^{\mathbf{i}}{}_{\mathbf{j}}(X_{\mathbf{P}})y^{\mathbf{j}}_{\mathbf{P}}\}\vec{e}_{(\mathbf{i})\varphi_{\mathbf{t}}(\mathbf{P})} + o(t^2), \tag{5.6}$$

where, in the last step, use has been made of the initial condition (5.2).

The expression (5.6) enables one to calculate (at first order in t) the extension ${}^{\mathbf{D}}Y$ of the vector $y_{\mathbf{P}}$ over the integral curves of X. On the other hand, if Y is a vector field on M, then $Y_{\mathbf{P}}$ may be used as the vector $y_{\mathbf{P}}$ in the above, and ${}^{\mathbf{D}}Y_{\varphi\mathbf{t}(\mathbf{P})}$ reads, by (5.6):

$${}^{\mathbf{D}}Y_{\varphi_{\mathbf{t}}(\mathbf{P})} = \{Y^{\mathbf{i}}_{\mathbf{P}} - t\Lambda^{\mathbf{i}}{}_{\mathbf{j}}(X_{\mathbf{P}})Y^{\mathbf{j}}_{\mathbf{P}}\}\vec{e}_{(\mathbf{i})\varphi_{\mathbf{t}}(\mathbf{P})} + \cdots. \tag{5.7}$$

Therefore, when dealing with a vector field Y, one has at one's disposal two objects that may be compared with one another, namely $Y_{\varphi_{\mathbf{t}}(\mathbf{P})}$ and ${}^{\mathbf{D}}Y_{\varphi_{\mathbf{t}}(\mathbf{P})}$. Let $\Delta_{\varphi_{\mathbf{t}(\mathbf{P})}}(X,Y)$ be the difference of these two quantities:

$$\Delta_{\varphi_{\mathbf{t}}(\mathbf{P})}(X,Y) := Y_{\varphi_{\mathbf{t}}(\mathbf{P})} - {}^{\mathbf{D}}Y_{\varphi_{\mathbf{t}}(\mathbf{P})} \tag{5.8}$$

$$= \{Y^{\mathbf{i}}_{\varphi_{\mathbf{t}}(\mathbf{P})} - Y^{\mathbf{i}}_{\mathbf{P}} + t\Lambda^{\mathbf{i}}{}_{\mathbf{j}}(X_{\mathbf{P}})Y^{\mathbf{j}}_{\mathbf{P}}\}\vec{e}_{(\mathbf{i})\varphi_{\mathbf{t}}(\mathbf{P})} + \cdots \tag{5.9}$$

$$= \{[Y^{\mathbf{i}}_{\mathbf{P}} + tX_{\mathbf{p}}(Y^{\mathbf{i}})] - Y^{\mathbf{i}}_{\mathbf{P}} + t\Lambda^{\mathbf{i}}{}_{\mathbf{j}}(X_{\mathbf{P}})Y^{\mathbf{j}}_{\mathbf{P}}\}\vec{e}_{(\mathbf{i})\varphi_{\mathbf{t}}(\mathbf{P})} + \cdots \tag{5.10}$$

$$= t(D_{\mathbf{X}}Y)_{\mathbf{P}} + \cdots. \tag{5.11}$$

As a consequence, we have established that

$$(D_{\mathbf{X}}Y)_{\mathbf{P}}=\lim_{\mathbf{t}\to\mathbf{0}}\frac{1}{t}\Delta_{\varphi_{\mathbf{t}}(\mathbf{P})}(X,Y) \tag{5.12}$$

$$=\lim_{\mathbf{t}\to\mathbf{0}}\frac{1}{t}\{Y_{\varphi_{\mathbf{t}}(\mathbf{P})}-{}^{D}Y_{\varphi_{\mathbf{t}}(\mathbf{P})}\}, \tag{5.13}$$

which yields a geometrical interpretation of D differentiation in terms of D transport of Y along the integral curves of X.

To go one step further, let us introduce the tangent bundle TM to the manifold M. We denote by π the projection from TM to M. In TM, the fiber $\pi^{-1}(P)$ above a point P of M is the tangent space $T_{\mathbf{P}}M$ to M at P, which is isomorphic to $\mathbf{R}^n$.

The vector $y_{\mathbf{P}}$ of $T_{\mathbf{P}}M$ employed previously may then be reinterpreted as a particular point of the fiber $\pi^{-1}(P)$ of TM above P. Moreover, the mapping (near $t=0$)

$$t\mapsto{}^{\mathbf{D}}Y_{\varphi_{\mathbf{t}}(\mathbf{P})}=\{y^{\mathbf{i}}_{\mathbf{P}}-t\Lambda^{\mathbf{i}}{}_{\mathbf{j}}(X_{\mathbf{P}})y^{\mathbf{j}}_{\mathbf{P}}\}\vec{e}_{(\mathbf{i})\varphi_{\mathbf{t}}(\mathbf{P})} \tag{5.14}$$

$$=\{\delta^{\mathbf{i}}_{\mathbf{j}}-t\Lambda^{\mathbf{i}}{}_{\mathbf{j}}(X_{\mathbf{P}})\}y^{\mathbf{j}}_{\mathbf{P}}\vec{e}_{(\mathbf{i})\varphi_{\mathbf{t}}(\mathbf{P})} \tag{5.15}$$

describes a curve in TM, which will be denoted by ${}^{\mathbf{D}}_{\mathbf{TM}}\varphi_{\mathbf{t}}(y_{\mathbf{P}})$, and will be called the ''D lift'' of the integral curve $\varphi_{\mathbf{t}}(P)$ of X to TM through $y_{\mathbf{P}}$. It follows from (5.15) that, when a field of bases has been selected, ${}^{\mathbf{D}}_{\mathbf{TM}}\varphi_{\mathbf{t}}(y_{\mathbf{P}})$ reads

$${}^{\mathbf{D}}_{\mathbf{TM}}\varphi_{\mathbf{t}}(y_{\mathbf{P}}=y^{\mathbf{i}}_{\mathbf{P}}\vec{e}_{(\mathbf{i})\mathbf{P}})=G^{\mathbf{i}}_{\mathbf{j}}(t,X)y^{\mathbf{j}}_{\mathbf{P}}\vec{e}_{(\mathbf{i})\varphi_{\mathbf{t}}(\mathbf{P})}, \tag{5.16}$$

with

$$G^{\mathbf{i}}_{\mathbf{j}}(t,X):=\delta^{\mathbf{i}}_{\mathbf{j}}-t\Lambda^{\mathbf{i}}{}_{\mathbf{j}}(X_{\mathbf{P}}). \tag{5.17}$$

In (5.16), the object $y^{\mathbf{j}}_{\mathbf{P}}$ and $G^{\mathbf{i}}_{\mathbf{j}}(t,X)$ may be considered, respectively, as a column matrix and a square matrix of $GL(n)$, which reflects the fact that the fiber bundle TM has its fibers isomorphic to $\mathbf{R}^n$, and admits $GL(n)$ as its structure group. In the same context, the mapping

$$t\mapsto{}^{\mathbf{D}}_{\mathbf{GL(n)}}\varphi_{\mathbf{t}}(X):=G^{\mathbf{i}}_{\mathbf{j}}(t,X), \tag{5.18}$$

may be interpreted, given a field of bases $\{\vec{e}_{(\mathbf{i})}\}$, as the D lift to $GL(n)$ of the integral curve $\varphi_{\mathbf{t}}(P)$ of X.

What has been done to D-transport a vector $y_{\mathbf{P}}$ of $T_{\mathbf{P}}M$ along the integral curve $\varphi_{\mathbf{t}}(P)$ of a vector field X may also be applied to a set of n vectors forming a basis at P. In order to see this more clearly, one needs to introduce the principal bundle PLM of linear frames above M.

The fiber of PLM above a point P of M is constituted by all the possible bases of $T_{\mathbf{P}}M$. In other words, each particular point of the fiber above P is one particular basis of $T_{\mathbf{P}}M$. More precisely, let $\{\vec{e}_{(\mathbf{i})}\}$ denote again a field of bases over M. Let $\vec{e}_{(\underline{\mathbf{m}})\mathbf{P}}$ denote a particular point of the fiber above P, namely a particular basis of $T_{\mathbf{P}}M$, where we have underlined the index to distinguish $\vec{e}_{(\underline{\mathbf{m}})\mathbf{P}}$ from a member of the field of bases $\{\vec{e}_{(\mathbf{i})}\}$ at P. Because $\vec{e}_{(\underline{\mathbf{m}})\mathbf{P}}$ and $\{\vec{e}_{(\mathbf{i})\mathbf{P}}\}$ are bases of the same tangent space $T_{\mathbf{P}}M$, one may write

$$\vec{e}_{(\underline{\mathbf{m}})\mathbf{P}}:=E^{i}_{(\underline{\mathbf{m}})\mathbf{P}}\vec{e}_{(\mathbf{i})\mathbf{P}}, \tag{5.19}$$

where the scalars $E^{\mathbf{i}}_{(\underline{\mathbf{m}})\mathbf{P}}$ represent the components of $\vec{e}_{(\underline{\mathbf{m}})\mathbf{P}}$ in the basis $\{\vec{e}_{(\mathbf{i})\mathbf{P}}\}$, and form a $GL(n)$ matrix. [This reflects the fact that the fibres of PLM are isomorphic to $GL(n)$.]

Each of the vectors $\vec{e}_{(\underline{\mathbf{m}})\mathbf{P}}$ of (5.19) may now be D-transported along the integral curve $\varphi_{\mathbf{t}}(P)$ of a given vector field X, just as we did with the vector $y_{\mathbf{P}}$ in (5.16), (5.17), which yields a new basis ${}^{\mathbf{D}}\vec{e}_{(\underline{\mathbf{m}})\varphi_{\mathbf{t}}(\mathbf{P})}$, at the point $\varphi_{\mathbf{t}}(P)$, defined by

$$^{\mathbf{D}}\vec{e}_{(\underline{\mathbf{m}})\varphi_{\mathbf{t}}(\mathbf{P})}=G^{\mathbf{i}}{}_{\mathbf{j}}(t,X)E^{j}{}_{(\underline{\mathbf{m}})\mathbf{P}}\vec{e}_{(\mathbf{i})\varphi_{\mathbf{t}}(\mathbf{P})}, \tag{5.20}$$

with $G^{\mathbf{i}}{}_{\mathbf{j}}$ as in (5.17). Therefore, the mapping

$$t\mapsto{}^{\mathbf{D}}_{\mathbf{PLM}}\varphi_{\mathbf{t}}(\vec{e}_{(\underline{\mathbf{m}})\mathbf{P}}=E^{\mathbf{i}}_{(\underline{\mathbf{m}})\mathbf{P}}\vec{e}_{(\mathbf{i})\mathbf{P}}):=G^{\mathbf{i}}{}_{\mathbf{j}}(t,X)E^{j}_{(\underline{\mathbf{m}})\mathbf{P}}\vec{e}_{(\mathbf{i})\varphi_{\mathbf{t}}(\mathbf{P})} \tag{5.21}$$

may be interpreted as the D lift to the bundle PLM of the integral curve $\varphi_{\mathbf{t}}(P)$ of X through P.

As soon as one has at one's disposal the D lift to PLM of the integral curves of an arbitrary vector field X, it becomes possible to complete the circle, and rederive the formula (2.8) for D differentiation, which was our starting point. To this end, we employ Weyl's method, which exploits the fact that PLM and TM are associated bundles.

Let the field of frames $\{\vec{e}_{(\mathbf{i})}\}$ be fixed over M, and let P be a point of M. A vector $y_{\mathbf{P}}$ of $T_{\mathbf{P}}M$ is a linear combination of $\{\vec{e}_{(\mathbf{i})}\}$:

$$y_{\mathbf{P}}=y^{\mathbf{m}}_{\mathbf{P}}\vec{e}_{(\mathbf{m})\mathbf{P}}. \tag{5.22}$$

Given that $\vec{e}_{(\mathbf{m})\mathbf{P}}$ is a point in the fibre of PLM above P, one may apply (5.20), with $E^{\mathbf{j}}{}_{(\underline{\mathbf{m}})\mathbf{P}}=\delta^{\mathbf{j}}{}_{\mathbf{m}}$, to evaluate the D transport of $\vec{e}_{(\mathbf{m})\mathbf{P}}$ from P to $\varphi_{\mathbf{t}}(P)$ in PLM:

$$^{D}\vec{e}_{(\underline{\mathbf{m}})\varphi_{\mathbf{t}}(\mathbf{P})}=G^{\mathbf{i}}{}_{\mathbf{j}}(t,X)\,\delta^{\mathbf{j}}{}_{\mathbf{m}}\vec{e}_{(\mathbf{i})\varphi_{\mathbf{t}}(\mathbf{P})} \tag{5.23}$$

$$=G^{\mathbf{i}}{}_{\mathbf{m}}(t,X)\vec{e}_{(\mathbf{i})\varphi_{\mathbf{t}}(\mathbf{P})}. \tag{5.24}$$

Weyl's method consists in defining the D transport of $y_{\mathbf{P}}$ from P to $\varphi_{\mathbf{t}}(P)$ as the vector of $T_{\varphi_{\mathbf{t}}(\mathbf{P})}M$ that has, in $^{\mathbf{D}}\vec{e}_{(\underline{\mathbf{m}})\varphi_{\mathbf{t}}(\mathbf{P})}$, the same components as $y_{\mathbf{P}}$ has in $\vec{e}_{(\mathbf{m})\mathbf{P}}$. Consequently, we put

$$^{\mathbf{D}}y_{\varphi_{\mathbf{t}}(\mathbf{P})}:=y^{\mathbf{m}}_{\mathbf{P}}G^{\mathbf{i}}{}_{\mathbf{m}}(t,X)\vec{e}_{(\mathbf{i})\varphi_{\mathbf{t}}(\mathbf{P})}. \tag{5.25}$$

This is as far as one can go with a vector $y_{\mathbf{P}}$. If, however, $y_{\mathbf{P}}$ is the value $Y_{\mathbf{P}}$ of the field Y at P, one has two vectors at one's disposal at $\varphi_{\mathbf{t}}(P)$, and one may compare them as in (5.8):

$$\Delta_{\varphi_{\mathbf{t}}(\mathbf{P})}(X,Y):=Y_{\varphi_{\mathbf{t}}(\mathbf{P})}-{}^{D}Y_{\varphi_{\mathbf{t}}(\mathbf{P})} \tag{5.26}$$

$$=\{Y^{\mathbf{i}}_{\varphi_{\mathbf{t}}(\mathbf{P})}-Y^{\mathbf{j}}_{\mathbf{P}}G^{\mathbf{i}}{}_{\mathbf{j}}(t,X)\}\vec{e}_{(\mathbf{i})\varphi_{\mathbf{t}}(\mathbf{P})}+\cdots, \tag{5.27}$$

where (5.25) has been employed. A calculation similar to that leading from (5.8) to (5.11), using the definition (5.17) of $G^{\mathbf{i}}{}_{\mathbf{j}}$, yields then the expected result

$$\lim_{\mathbf{t}\to\mathbf{0}}\frac{1}{t}\Delta_{\varphi_{\mathbf{t}}(\mathbf{P})}(X,Y)=(D_{\mathbf{X}}Y)_{\mathbf{P}}. \tag{5.28}$$

It might seem that, in the present section, we have obtained no new results, and that, therefore, the reformulation of D differentiation in terms of the tangent bundle TM and the bundle PLM of linear forms was unnecessary. This, however, is not the case: In the companion article[5] about Lie and covariant differentiation of spinor fields, we shall exploit to a considerable extent the fact that a spinor field over M is a linear combination of the field of spinor frames over M, just as, above, a vector field was considered as a linear combination of the field of bases. The bundle of spinor frames will thus play, *mutatis mutandis*, the same role as the bundle PLM of linear frames. It will then be possible to adapt, quite simply, to spinor fields, the construction of D differentiation, and thus of Lie and covariant differentiation as special cases.

In addition to the TM and PLM bundle interpretations of D differentiation, another bundle formulation will prove enlightening, namely one involving the bitangent bundle TTM to the manifold, i.e., the tangent bundle to TM. Its construction will be presented in Sec. VI.

VI. BUNDLE FORMULATION OF GENERALIZED *D* DIFFERENTIATION

Let the manifold M admit a set of charts $\{\Phi_{\mathbf{i}}\}$. In the future, we shall assume that all our developments take place in a neighborhood of a point P of M entirely covered by one single chart, so that the index i of $\Phi_{\mathbf{i}}$ may be omitted.

Let the coordinates in M be denoted by $x^{\mathbf{i}}$. With a slight abuse of notation, we shall thus write

$$\Phi(P)=x^{\mathbf{i}}. \tag{6.1}$$

Let Γ denote a curve in M, with parameter t, passing through the point P at $t=0$:

$$\Gamma:\mathbf{R}\to M:t\mapsto\Gamma(t). \tag{6.2}$$

The derivative operator along Γ at $t=0$ is a vector belonging to $T_{\mathbf{P}}M$, which we write as

$$v_{\mathbf{P}}:=\left.\frac{d}{dt}\right|_{\mathbf{\Gamma}}^{\mathbf{t=0}}. \tag{6.3}$$

This operator acts on real-valued functions defined on M.

Let TM be the tangent bundle to M. A point of the fiber $\pi^{-1}(P)$ above P is a vector $v_{\mathbf{P}}$ of $T_{\mathbf{P}}M$. Consequently, the chart Φ' describing TM may be taken as

$$\Phi':TM\to\mathbf{R}^{\mathbf{2n}}:\Phi'(v_{\mathbf{P}}):=(\Phi(P),v^{\mathbf{j}}_{\mathbf{P}}) \tag{6.4}$$

$$=(x^{\mathbf{i}}_{\mathbf{P}},v^{\mathbf{j}}_{\mathbf{P}}), \tag{6.5}$$

where the components $v^{\mathbf{j}}_{\mathbf{P}}$ express $v_{\mathbf{P}}$ in a given field of bases $\{\vec{e}_{(\mathbf{i})\mathbf{P}}\}$:

$$v_{\mathbf{P}}=v^{\mathbf{j}}_{\mathbf{p}}\vec{e}_{(\mathbf{j})\mathbf{P}}. \tag{6.6}$$

Let Γ' denote a curve in TM, with parameter t', passing though the point $v_{\mathbf{P}}$ at $t'=0$:

$$\Gamma':\mathbf{R}\to TM:t'\mapsto\Gamma'(t'). \tag{6.7}$$

The derivative operator along Γ' at $t'=0$ is a vector of $T_{\mathbf{v_p}}TM$, which will be denoted by a boldface letter, as

$$\mathbf{u}_{\mathbf{v_p}}:=\left.\frac{d}{dt'}\right|_{\mathbf{\Gamma'}}^{\mathbf{t'=0}}. \tag{6.8}$$

This operator acts on real-valued functions defined on TM. (When there will be no danger of confusion, the subscript $v_{\mathbf{P}}$ will often be omitted, as well as the primes over t and Γ; sometimes the point $t'=0$ will also be omitted.)

One may then construct the *bitangent* bundle TTM, namely the tangent bundle to TM. The fiber $\pi'^{-1}(v_{\mathbf{P}})$ of TTM above a point $v_{\mathbf{P}}$ of TM is constituted by all the vectors of the tangent space $T_{\mathbf{v_p}}TM$. Furthermore, vector fields over TM are cross sections of TTM, just as vector fields over M are cross sections of TM. Vector fields over TM will be denoted by boldface capitals (for instance $\mathbf{X}$) to distinguish them from vector fields over M (such as X).

A special kind of vector $\mathbf{u}_{\mathbf{v_p}}$ of $T_{\mathbf{v_p}}TM$ will play an important role in our forthcoming constructions. It is based on the concept of a *fiber curve* in TM.

Let Γ' be a curve in TM, as in (6.7). If Γ' lies entirely in the fiber $\pi^{-1}(P)$ above P, in a neighborhood of $t'=0$, then Γ' will be called a *fiber curve* in that neighborhood. Moreover, the derivative operator $\mathbf{u}_{\mathbf{v_p}}$ of (6.8) will be called a *fiber vector*. Such vectors have a particular characteristic, when expressed in components, which we are now going to determine.

Let f be a function on TM. The coordinate expression ${}^{\mathbf{c}}f$ of f, defined by

$$^{\mathbf{c}}f = f \circ \Phi'^{-1}, \tag{6.9}$$

where Φ' is given by (6.5), is thus a function of $x^{\mathbf{i}}$ and $v^{\mathbf{j}}$. Therefore, a vector $\mathbf{u}_{\mathbf{w_P}}$ at $w_{\mathbf{P}}$ acts on f as

$$\mathbf{u}_{\mathbf{w_P}}[f] = \mathbf{u}^{\mathbf{i}}_{\mathbf{w_P}} \frac{\partial\, ^{\mathbf{c}}f}{\partial x^{\mathbf{i}}}(x^{\mathbf{k}} = x^{\mathbf{k}}_{\mathbf{P}}, v^l = w^l_{\mathbf{P}}) + \mathbf{u}^{\mathbf{j}}_{\mathbf{w_P}} \frac{\partial\, ^{\mathbf{c}}f}{\partial v^{\mathbf{j}}}(x^{\mathbf{k}} = x^{\mathbf{k}}_{\mathbf{P}}, v^l = w^l_{\mathbf{P}}), \tag{6.10}$$

for some scalars $\mathbf{u}^{\mathbf{i}}_{\mathbf{w_P}}$ and $\mathbf{u}^{\mathbf{j}}_{\mathbf{w_P}}$, which implies that

$$\left\{ \frac{\partial}{\partial x^{\mathbf{i}}}, \frac{\partial}{\partial v^{\mathbf{j}}} \right\}$$

forms a basis of $T_{\mathbf{v_P}}TM$. More generally, if $\{\vec{e}_{(\mathbf{i})\mathbf{P}}\}$ is an arbitrary basis (not necessarily holonomic) of $T_{\mathbf{P}}M$, one may extend it to act on functions defined on TM, the extension being denoted by $\{\vec{\mathbf{e}}_{(\mathbf{i})\mathbf{w_P}}\}$:

$$\vec{\mathbf{e}}_{(\mathbf{i})\mathbf{w_P}}[^{\mathbf{c}}f(x^{\mathbf{i}}, v^{\mathbf{j}})] := \vec{e}_{(\mathbf{i})}[^{\mathbf{c}}f(x^{\mathbf{i}}, v^{\mathbf{j}} = w^{\mathbf{j}}_{\mathbf{P}})]. \tag{6.11}$$

In other words, $\vec{\mathbf{e}}_{(\mathbf{i})\mathbf{w_P}}$ acts on $^{\mathbf{c}}f$ as $\vec{e}_{(\mathbf{i})\mathbf{P}}$ acts on the function obtained from $^{\mathbf{c}}f$ by fixing its fiber coordinates at the values $w^{\mathbf{j}}_{\mathbf{P}}$. A generic vector of $T_{\mathbf{v_P}}TM$ may thus be written

$$\mathbf{u}_{\mathbf{w_P}} = \mathbf{u}^{\mathbf{i}}_{\mathbf{w_P}} \vec{\mathbf{e}}_{(\mathbf{i})\mathbf{w_P}} + \mathbf{u}^{\mathbf{j}}_{\mathbf{w_P}} \left. \frac{\partial}{\partial v^{\mathbf{j}}} \right|_{\mathbf{v}^{\mathbf{k}} = \mathbf{w}^{\mathbf{k}}_{\mathbf{P}}}, \tag{6.12}$$

which generalizes (6.10).

If the curve Γ' along which $\mathbf{u}_{\mathbf{w_P}}$ differentiates is a fiber curve, the variables $x^{\mathbf{i}}$ of the coordinate expression $^{\mathbf{c}}\Gamma' = \Phi' \circ \Gamma'$ of Γ' remain constant, and the first term on the right-hand side of (6.12), when acting on a function $^{\mathbf{c}}f$, vanishes. As a consequence, a fiber vector $^{\mathbf{F}}\mathbf{u}_{\mathbf{w_P}}$ is of the form

$$^{\mathbf{F}}\mathbf{u}_{\mathbf{w_P}} = {}^{\mathbf{F}}\mathbf{u}^{\mathbf{j}}_{\mathbf{w_P}} \left. \frac{\partial}{\partial v^{\mathbf{j}}} \right|_{\mathbf{v}^{\mathbf{k}} = \mathbf{w}^{\mathbf{k}}_{\mathbf{P}}}, \tag{6.13}$$

for some scalars $^{\mathbf{F}}\mathbf{u}^{\mathbf{j}}_{\mathbf{w_P}}$.

The concept of a fiber vector leads to that of the *fiber lift* of a vector of $T_{\mathbf{P}}M$, which will play a fundamental role in what follows. Given two vectors $u_{\mathbf{P}}$ and $w_{\mathbf{P}}$ of $T_{\mathbf{P}}M$, let Γ' be the curve in TM defined by

$$\Gamma' : \mathbf{R} \to TM : t' \mapsto w_{\mathbf{P}} + t' u_{\mathbf{P}}. \tag{6.14}$$

It is clear that $\Gamma(0) = w_{\mathbf{P}}$ and that Γ' is a fiber curve. Therefore, the vector of $T_{\mathbf{w_P}}TM$ which is tangent to Γ' at $t' = 0$ is a fiber vector, and it will be written

$$\mathbf{u}^{\dagger}_{\mathbf{w_P}} = \left. \frac{d}{dt'} \right|^{\mathbf{t}' = \mathbf{0}}_{\mathbf{\Gamma}'}. \tag{6.15}$$

The vector $\mathbf{u}^{\dagger}_{\mathbf{w_P}}$ will be called the *fiber lift* of $u_{\mathbf{P}}$ to the point $w_{\mathbf{P}}$ of TM. Henceforth, a vector and its fiber lift will always be denoted by the same letter, the vector of $T_{\mathbf{P}}M$ in italics, and the lift in boldface (with a dagger).

By considering a function f on TM, and evaluating the differentiation that appears on the right-hand side of (6.15), one establishes that the fiber lift of a vector $u_{\mathbf{P}}$ decomposed as

$$u_{\mathbf{P}}=u^{\mathbf{i}}_{\mathbf{P}}\vec{e}_{(\mathbf{i})\mathbf{P}} \tag{6.16}$$

reads, in the language of (6.11) and (6.12),

$$\mathbf{u}^{\dagger}_{\mathbf{w_P}}=u^{\mathbf{j}}_{\mathbf{P}}\frac{\partial}{\partial v^{\mathbf{j}}}\bigg|_{\mathbf{v^k=w^k_P}}. \tag{6.17}$$

In order to geometrize the operation of D differentiation, we still need another type of lift, called the *generalized lift*. To introduce it, we proceed in a similar fashion as for the fiber lift, with, however, the fundamental difference that it is only possible to obtain the generalized lift of a vector *field* over M, but not of an isolated vector of $T_{\mathbf{P}}M$. To emphasize this difference, we shall denote the vector field to be lifted as X, instead of employing the symbol $u_{\mathbf{P}}$ as in (6.16).

Thus let X be a vector field over M, and let $w_{\mathbf{P}}$ be a vector of $T_{\mathbf{P}}M$. We saw, in Sec. V, how to obtain, from the integral curves $\varphi_{\mathbf{t}}$ of X, a family of curves $\overset{\mathbf{D}}{\mathbf{TM}}\varphi_{\mathbf{t}}$ in TM, which was called the D lift of $\varphi_{\mathbf{t}}$ to TM. By virtue of (5.16), (5.17), the curve passing through $w_{\mathbf{P}}$ at $t=0$ reads

$$t\mapsto\overset{\mathbf{D}}{\mathbf{TM}}\varphi_{\mathbf{t}}(w_{\mathbf{P}})=\{\delta^{\mathbf{i}}_{\mathbf{j}}-t\Lambda^{\mathbf{i}}_{\mathbf{j}}(X_{\mathbf{P}})\}w^{\mathbf{j}}_{\mathbf{P}}\vec{e}_{(\mathbf{i})\varphi_{\mathbf{t}}(\mathbf{P})}. \tag{6.18}$$

Owing to the fact that this curve lies in TM and passes through $w_{\mathbf{P}}$ at $t=0$, its tangent at $t=0$ is a vector of $T_{\mathbf{w_P}}TM$. This vector is called the *generalized lift* of X at the point $w_{\mathbf{P}}$ of TM, and is denoted by

$$\mathbf{X}^{\ddagger}_{\mathbf{w_P}}=\frac{d}{dt}\bigg|^{\mathbf{t=0}}_{\overset{\mathbf{D}}{\mathbf{TM}}\varphi_{\mathbf{t}}(\mathbf{w_P})}. \tag{6.19}$$

When the definition (6.19) of $\mathbf{X}^{\ddagger}_{\mathbf{w_P}}$ is combined with the expression (6.18) for the curve $\overset{\mathbf{D}}{\mathbf{TM}}\varphi_{\mathbf{t}}(w_{\mathbf{P}})$, the generalized lift becomes

$$\mathbf{X}^{\ddagger}_{\mathbf{w_P}}=X^{\mathbf{i}}_{\mathbf{P}}\mathbf{e}_{(\mathbf{i})\mathbf{w_P}}-\Lambda^{\mathbf{j}}_{\mathbf{i}}(X_{\mathbf{P}})w^{\mathbf{i}}_{\mathbf{P}}\frac{\partial}{\partial v^{\mathbf{j}}}\bigg|_{\mathbf{v^k=w^k_P}}. \tag{6.20}$$

The restricted proof of this result for the special case where the basis $\{\vec{e}_{(\mathbf{i})\mathbf{P}}\}$ is the holonomic one $\{\partial/\partial x^{\mathbf{i}}\}$ is simple. One considers a function f defined on TM, which, in coordinates, is expressed by (6.9). Moreover, the coordinate expression of the curve (6.18) along which $\mathbf{X}^{\ddagger}_{\mathbf{w_P}}$ differentiates reads (in a neighborhood of $t=0$)

$$t\mapsto(x^{\mathbf{i}}+tX^{\mathbf{i}}_{\mathbf{P}},\{\delta^{\mathbf{j}}_{\mathbf{k}}-t\Lambda^{\mathbf{j}}_{\mathbf{k}}(X_{\mathbf{P}})\}w^{\mathbf{k}}_{\mathbf{P}}). \tag{6.21}$$

Consequently, the definition (6.19) of $\mathbf{X}^{\ddagger}_{\mathbf{w_P}}$ becomes, when applied to f,

$$\mathbf{X}^{\ddagger}_{\mathbf{w_P}}[f]=\frac{d}{dt}\bigg|_{\mathbf{t=0}}f(x^{\mathbf{i}}+tX^{\mathbf{i}}_{\mathbf{P}},w^{\mathbf{j}}_{\mathbf{P}}-t\Lambda^{\mathbf{j}}_{\mathbf{k}}(X_{\mathbf{P}})w^{\mathbf{k}}_{\mathbf{P}}) \tag{6.22}$$

$$=X^{\mathbf{i}}_{\mathbf{P}}\frac{\partial f(x,v)}{\partial x^{\mathbf{i}}}\bigg|_{\mathbf{v^k=w^k_P}}-\Lambda^{\mathbf{j}}_{\mathbf{i}}(X_{\mathbf{P}})w^{\mathbf{i}}_{\mathbf{P}}\frac{\partial f(x,v)}{\partial v^{j}}\bigg|_{\mathbf{v^k=w^k_P}}, \tag{6.23}$$

which is the holonomic version of (6.20).

With this machinery at our disposal, we are in the position to define a new operation $\mathbf{D}$, called *generalized D differentiation*, which, from two vector fields X and Y over M, enables one to construct the vector field $\mathbf{D}_{\mathbf{X}}Y$ over TM. To emphasize that the vector field resulting from X and Y is a field over TM, rather than over M, we have employed a boldface letter $\mathbf{D}$ to denote it. (Generalized D differentiation will turn out to be deeply related to D differentiation, as we shall show.)

Let P be a point of M, and let $\varphi_{\mathbf{t}}(P)$ be the integral curve of the field X passing through P at $t=0$. Then, for every t fixed, the value $Y_{\varphi_{\mathbf{t}}(\mathbf{P})}$ of the field Y at the point $\varphi_{\mathbf{t}}(P)$ belongs to the fiber $\pi^{-1}(\varphi_{\mathbf{t}}(P))$ of TM above $\varphi_{\mathbf{t}}(P)$. One may thus apply the mapping $\overset{\mathbf{D}}{\mathbf{TM}}\varphi_{-\mathbf{t}}$ of (5.16) to $Y_{\varphi_{\mathbf{t}}(\mathbf{P})}$, and the result is an element of the fiber above $\varphi_{-\mathbf{t}}(\varphi_{\mathbf{t}}(P))=P$. Consequently, the mapping

$$t\mapsto \overset{\mathbf{D}}{\mathbf{TM}}\varphi_{-\mathbf{t}}(Y_{\varphi_{\mathbf{t}}(\mathbf{P})}) \tag{6.24}$$

is a curve in TM, lying in the fiber of TM above P (in the neighborhood of $t=0$). Therefore, the tangent to this curve is a fiber vector, and we define

$$(\mathbf{D}_{\mathbf{X}}Y)_{\mathbf{Y_P}} := \left.\frac{d}{dt}\right|^{\mathbf{t=0}}_{\overset{\mathbf{D}}{\mathbf{TM}}\varphi_{-\mathbf{t}}(Y_{\varphi_{\mathbf{t}}(\mathbf{P})})} . \tag{6.25}$$

To evaluate $\mathbf{D}_{\mathbf{X}}Y$ in coordinates, let us return to the definition (5.16), (5.17), of the mapping $\overset{\mathbf{D}}{\mathbf{TM}}\varphi_{-\mathbf{t}}$. One readily obtains then, at first order in t,

$$\overset{\mathbf{D}}{\mathbf{TM}}\varphi_{-\mathbf{t}}(Y_{\varphi_{\mathbf{t}}(\mathbf{P})}) = \{Y^{\mathbf{i}}_{\varphi_{\mathbf{t}}(\mathbf{P})} + t\Lambda^{\mathbf{i}}{}_{\mathbf{j}}(X_{\mathbf{P}})Y^{\mathbf{j}}_{\mathbf{P}}\}\vec{e}_{(\mathbf{i})\varphi_{-\mathbf{t}}(\varphi_{\mathbf{t}}(\mathbf{P}))} \tag{6.26}$$

$$= \{Y^{\mathbf{i}}_{\mathbf{P}} + tX_{\mathbf{P}}[Y^{\mathbf{i}}] + t\Lambda^{\mathbf{i}}{}_{\mathbf{j}}(X_{\mathbf{P}})Y^{\mathbf{j}}_{\mathbf{P}}\}\vec{e}_{(\mathbf{i})\mathbf{P}} \tag{6.27}$$

$$= \{Y^{\mathbf{i}}_{\mathbf{P}} + t(D_{\mathbf{X}}Y)^{\mathbf{i}}_{\mathbf{P}}\}\vec{e}_{(\mathbf{i})\mathbf{P}}, \tag{6.28}$$

where, in the last line, we have used the definition (2.8) of the D derivative. From (6.16), (6.17), (6.25), and (6.28), one easily establishes that

$$(\mathbf{D}_{\mathbf{X}}Y)_{\mathbf{Y_P}} = (D_{\mathbf{X}}Y)^{\mathbf{j}}_{\mathbf{P}}\left.\frac{\partial}{\partial v^{\mathbf{j}}}\right|_{\mathbf{v^k=Y^k_P}} \tag{6.29}$$

$$= (D_{\mathbf{X}}Y)^{\dagger}_{\mathbf{Y_P}}, \tag{6.30}$$

which establishes the relationship between generalized D differentiation and D differentiation, thus providing a geometrical interpretation of the latter in the language of fiber bundles.

Another relationship, this time between $\mathbf{D}$ and the generalized lift, sheds light on all this construction. To express it, one needs to recall that, given a mapping f from a manifold to itself, it is always possible to construct[6] the tangent mapping Tf, which transforms the tangent space $T_{\mathbf{P}}M$ at a point P into the tangent space $T_{\mathbf{f(P)}}M$ at $f(P)$. Furthermore, if Y is a vector field over M, it is also a cross section of TM, so that Y may be considered as a particular mapping from M to TM. Therefore, the tangent mapping TY transforms TM into TTM, and it follows that $(TY)(X_{\mathbf{P}})$, for any vector field X, belongs to TTM.

After these preparations, the operation $\mathbf{D}$ may be reformulated as

$$(\mathbf{D}_{\mathbf{X}}Y)_{\mathbf{Y_P}} = (TY)(X_{\mathbf{P}})_{\mathbf{Y_P}} - \mathbf{X}^{\ddagger}_{\mathbf{Y_P}}, \tag{6.31}$$

which shows the connection between $\mathbf{D}$ and the generalized lift $\mathbf{X}^{\ddagger}_{\mathbf{w_P}}$. The proof of (6.31) is simple, and only a few indications will suffice.

One begins by evaluating the tangent mapping TY, and calculates how the first term on the right-hand side of (6.31) acts on a function f. Then, one uses (6.20) for the generalized lift $\mathbf{X}^{\ddagger}_{\mathbf{w_P}}$. One thus constructs the complete right-hand side of (6.31) acting of f, and one observes that this action is identical to that of the right-hand side of (6.30).

We now have at our disposal various interpretations of the operation of D differentiation. It remains to put them all in perspective, which will be done in the conclusion.

VII. CONCLUSION

The purpose of this work has been to introduce a new operator of differentiation, called D differentiation, which contains, among others types, Lie and covariant differentiation. Our considerations have been restricted to D differentiation of tensor fields, but may be extended to spinor fields, as will be done in the companion article.[5]

We began, in Sec. II, by constructing D differentiation, and ascertaining that the definition is independent of the basis chosen on the manifold M. We also introduced a modified version of D differentiation, which is compatible with the metric g on M in the sense that, although $D_{\mathbf{X}}g$, in general, does not vanish for an arbitrary vector field X, the modified operation ${}^{\mathbf{g}}D$ satisfies ${}^{\mathbf{g}}D_{\mathbf{X}}g=0$ for all X.

In Sec. III, we established that Lie and covariant differentiation are special cases of a particular kind of D differentiation, called ''restricted'' D differentiation, defined in (3.27). We also saw that modified D differentiation ${}^{\mathbf{g}}D$, when specialized to D being covariant differentiation, falls into the category of restricted D differentiation as well. (It may then be interpreted as the covariant derivative with respect to the metric-compatible part of the connection.) On the other hand, modified D differentiation, in the case of Lie differentiation, does not belong to the subtype of restricted D differentiation.

The concept of ''generalized curvature'' of D differentiation was introduced in Sec. IV. We mainly discussed which kinds of D differentiation are compatible with an identically vanishing generalized curvature.

Finally, D differentiation was reformulated, in two stages, in terms of fiber bundles in Secs. V and VI. In the first stage, we defined the D transport of a vector y along the integral curves $\varphi_{\mathbf{t}}$ of a vector field X. This led to the concept of the lift of $\varphi_{\mathbf{t}}$ to the tangent bundle TM and to the bundle PLM of frames over M. Weyl's method enabled us then to obtain D differentiation from the bundle PLM.

In the second stage, we intoduced the notion of generalized D differentiation, which, from two vector fields X and Y over M, enables one to construct the vector field $\mathbf{D}_{\mathbf{X}}Y$, over the bundle TM. We proved that D differentiation is simply related to generalized D differentiation, through the concept of generalized lift of a vector field X over M to a vector field $\mathbf{X}^{\dagger}$ over TM. In addition to providing a geometrical interpretation of D differentiation, these bundle formulations constitute the appropriate language for the extension of our considerations to spinor fields in Ref. 5.

ACKNOWLEDGMENTS

The formulation of generalized D differentiation presented in Sec. VI was stimulated by the concepts of generalized Lie derivative and lift to the bitangent bundle employed in Refs. 7 and 9 in the context of spinor fields. More precisely, we realized that D differentiation could be given an enlightening interpretation by adapting and generalizing to D differentiation what had been done in Refs. 7 and 9 for Lie differentiation. It is a pleasure to thank Professor M. Godina for drawing our attention to Ref. 9. P. Campbell and T. Philbin are also gratefully acknowledged for interesting and useful discussions.

(Received 29 July 1999; accepted for publication 22 December 2000)

We describe all possible ''natural'' deformations of the metaplectic representation of the Lie superalgebras $\mathfrak{osp}(1,2n)$ and of its natural extension and show in particular that in most cases for the metaplectic representation itself, it is rigid. [DOI: 10.1063/1.1350637]

I. INTRODUCTION

As was shown by Flato and coworkers (see, e.g., Refs. 1, 2, 3), in anti-de Sitter space, massless particles are composite of two singletons, i.e., of the two representations of the universal covering of $SO_0(3,2)$ which decompose the metaplectic representation, the latter being actually an irreductible representation of the supersymmetry $\mathfrak{osp}(1,4)$. In view of the deformation philosophy of Flato (see, e.g., Ref. 4) it is therefore important to study deformations of the metaplectic representation, and of its natural extension, the so-called extended metaplectic representation. In order to make the problem amenable, we shall restrict our study to some natural categories of representations, essentially the following three: first, representations having the same weight structure as the initial one; second, representations which are still diagonal with respect to the Cartan subalgebra $\mathfrak{h}$; third (keeping in mind that both the metaplectic representation and its natural extension are representations of the Weyl algebra) representations of the second kind which are still representations of the Weyl algebra.

A main result of the present paper is the *rigidity of the metaplectic representation* in all these categories of representations [Theorem (4.7)]. So, in the $\mathfrak{osp}(1,4)$-supersymmetry framework, the metaplectic representation, i.e., the Di and Rac singletons, appears to be a completely isolated and really unique object. This result is also true for $\mathfrak{osp}(1,2n)$, for any $n\geqslant 2$. For $\mathfrak{osp}(1,2)$, the metaplectic representation is rigid in the first and third category, but not in the second one [Remarks (3.16) and (3.17)].

Now, what about the *extended metaplectic representation*? We start with the $\mathfrak{osp}(1,2)$-case, which is a necessary step and obtain a complete classification of all possible deformations which do exist in the three categories (Sec. III). Using these results we give, in the case of $\mathfrak{osp}(1,4)$, a complete description of the cohomology groups involved, corresponding to deformations in the three categories [Proposition (4.1) and Theorem (4.4)]. As a consequence, we show the *rigidity* in the first category, and give a complete classification of all deformations in the third [Proposition (4.2)]; infinitesimally, deformations in the second category belong to the third. Finally, we note that the results obtained in the case of $\mathfrak{osp}(1,4)$ generalize easily to $\mathfrak{osp}(1,2n), n\geqslant 2$ [Remark (4.8)]; as a consequence, there do not exist (nontrivial) deformations with unchanged weight structure, in contradistinction with the $\mathfrak{osp}(1,2)$-case, which happens to be very singular, probably due to its low dimension.

[a)]We dedicate this paper to the memory of Moshé Flato, our teacher, a permanent source of inspiration, and above all an irreplaceable friend.

[c)]Electronic mail: Georges.Pinczon@u-bourgogne.fr

The results, and proofs, of the paper are given in details for the extended metaplectic representation. The results concerning the metaplectic representation itself are given in Remarks (3.16) and (3.17) for $\mathfrak{osp}(1,2)$, together with some applications to maximal primitive quotients of the enveloping algebra, and in Remark (4.6) in the case of $\mathfrak{osp}(1,4)$; we did not detail the proofs in that case because they are essentially a repetition (with some simplifications) of the arguments given in the extended metaplectic case. Also, we have not given the proofs in the case of $\mathfrak{osp}(1,2n), n \geqslant 2$, because they can be obtained by induction and application of exactly the same arguments as in the $\mathfrak{osp}(1,4)$-case, with some simplifications [$\mathfrak{osp}(1,4)$ is actually the most complicated case!].

II. DEFINITIONS AND NOTATIONS

In this section we recall some notions and notations from deformation theory; for more details, we refer to Refs. 5, 6, 7. Given a Lie superalgebra $\mathfrak{g}=\mathfrak{g}_{\bar{0}}\oplus\mathfrak{g}_{\bar{1}}$ and a representation π of $\mathfrak{g}$ in a space $\mathcal{H}=\mathcal{H}_{\bar{0}}\oplus\mathcal{H}_{\bar{1}}$, if we denote by $\mathcal{L}(\mathcal{H})=\mathcal{L}(\mathcal{H})_{\bar{0}}\oplus\mathcal{L}(\mathcal{H})_{\bar{1}}$ the space of linear maps from $\mathcal{H}$ into itself endowed with its natural Lie superalgebra structure, there is a representation R of $\mathfrak{g}$ in $\mathcal{L}(\mathcal{H})$ defined by

$$R_X(T)=\pi(X)\circ T-(-1)^{\deg X.\deg T}T\circ\pi(X)=[\pi(X),T].$$

For this representation, the spaces of cocycles Z^1 and of coboundaries B^1 are (respectively)

$$Z^1(\mathfrak{g},\mathcal{L}(\mathcal{H}))=\{F:\mathfrak{g}\to\mathcal{L}(\mathcal{H})\,|\deg F=0,\ F([X,Y])=R_X(F_Y)-(-1)^{\deg X.\deg Y}R_Y(F_X)\},$$

$$B^1(\mathfrak{g},\mathcal{L}(\mathcal{H}))=\{F_X=R_X(T), T\in\mathcal{L}(\mathcal{H})_{\bar{0}}\}.$$

Note that the corresponding cohomology $H^1(\mathfrak{g},\mathcal{L}(\mathcal{H}))=Z^1(\mathfrak{g},\mathcal{L}(\mathcal{H}))/B^1(\mathfrak{g},\mathcal{L}(\mathcal{H}))$ is 0-degree cohomology in the terminology of Ref. 7. Cocycles are canonically associated with extensions of π by itself, i.e., with representations on $\mathcal{H}\oplus\mathcal{H}$ of the type $\tilde{\pi}_X=\left(\begin{smallmatrix}\pi_X & C_X\\ 0 & \pi_X\end{smallmatrix}\right)$. Indeed such a formula defines a representation if and only if $C\in Z^1(\mathfrak{g},\mathcal{L}(\mathcal{H}))$, and this representation splits into the direct sum $\pi\oplus\pi$ if and only if $C\in B^1(\mathfrak{g},\mathcal{L}(\mathcal{H}))$ (see Refs. 5, 7 for more details). But they are also associated with deformations (or formal representations) of π, defined by $\pi^\lambda=\pi+\Sigma_{n\geqslant 1}\lambda^n C_n$, where C_n are 0-degree linear maps from $\mathfrak{g}$ into $\mathcal{L}(\mathcal{H})$, and λ is a formal parameter. In fact, π^λ can be interpreted as a $\mathbb{C}[[\lambda]]$-linear representation of $\mathfrak{g}$ in the space $\mathcal{L}(\mathcal{H})[[\lambda]]$ (see Ref. 6). If π^λ is a deformation of π, then $C_1\in Z^1(\mathfrak{g},\mathcal{L}(\mathcal{H}))$; if moreover $C_1\in B^1(\mathfrak{g},\mathcal{L}(\mathcal{H}))$, then π^λ is equivalent to a deformation without a λ-term and the λ^2-term is a cocycle. We recall that π^λ and π'^λ are equivalent if they are intertwined by a $T^\lambda=\mathrm{Id}+\Sigma_{n\geqslant 1}\lambda^n T^n, T^n\in\mathcal{L}(\mathcal{H})_{\bar{0}}$. Clearly, if $H^1(\mathfrak{g},\mathcal{L}(\mathcal{H}))=\{0\}$, then π^λ can be reduced to π by a sequence of equivalences, and we shall say that π is rigid. So, in order to study deformations of π, the first step is the computation of $H^1(\mathfrak{g},\mathcal{L}(\mathcal{H}))$. To do that, it is often useful to extend the cocycles $C\in Z^1(\mathfrak{g},\mathcal{L}(\mathcal{H}))$ to the enveloping algebra $\mathcal{U}(\mathfrak{g})$; this is easily done using the corresponding extension $\tilde{\pi}$, which can obviously be extended to a representation of $\mathcal{U}(\mathfrak{g})$, so C can be extended to $\mathcal{U}(\mathfrak{g})$, and then it satisfies

$$C(1)=0,\ \text{and}\ \ C(uv)=\pi(u)\circ C(v)+C(u)\circ\pi(v),\ \ u,v\in\mathcal{U}(\mathfrak{g}).$$

If C is the coboundary defined by $T\in\mathcal{L}(\mathcal{H})$ we have $C(u)=\pi(u)\circ T-T\circ\pi(u)=[\pi(u),T], u\in\mathcal{U}$. Let $Z(\mathfrak{g})$ be the center of $\mathcal{U}(\mathfrak{g})$ and assume that π is Schur-irreducible, i.e., if $[\pi(X),T]=0$, with $T\in\mathcal{L}(\mathcal{H})_{\bar{0}}, \forall X\in\mathfrak{g}$, then $T=\lambda\,\mathrm{Id}_{|\mathcal{H}}$ (this is true for instance if π is irreducible by Quillen's lemma); if C is a coboundary, one has $C(Q)=0, \forall Q\in Z(\mathfrak{g})_{\bar{0}}$. For a general cocycle C, the identity $C(Q\cdot X)=C(X\cdot Q), Q\in Z(\mathfrak{g})_{\bar{0}}, X\in\mathfrak{g}$, gives $[\pi(X),C(Q)]=0$, so $C(Q)=\lambda(Q)\mathrm{Id}_{\mathcal{H}}, \lambda(Q)\in\mathbb{C}$; if we can find Q such that $\lambda(Q)\neq 0$, then, obviously, C is a nontrivial cocycle.

We now state a lemma which will prove very useful.

Lemma (2.1): Let $\mathfrak{h}$ *be an Abelian subalgebra of* $\mathfrak{g}$ *such that* $\mathfrak{h}\subset\mathfrak{g}_{\bar{0}}$. *Assume that* $\mathfrak{g}$ *splits as* $\mathfrak{g}=\oplus_{\alpha\in\Delta\subset\mathfrak{h}^*}\mathfrak{g}^{\alpha}$ *into weight spaces under* $ad\,\mathfrak{h}$; *let* π *be a representation of* $\mathfrak{g}$ *in* $\mathcal{H}$ *and assume that* $\mathcal{H}$ *splits as* $\mathcal{H}=\oplus_{p\in\mathcal{P}\subset\mathfrak{h}^*}\mathcal{H}^p$ *into weight spaces under* $\pi(\mathfrak{h})$. *Let* $C\in Z^1(\mathfrak{g},\mathcal{L}(\mathcal{H}))$. *Then if* $C(\mathfrak{h})(\mathcal{H}^p)\subset\mathcal{H}^p,\forall p\in\mathcal{P}$, *we have* $C(\mathfrak{g}^{\alpha})(\mathcal{H}^p)\subset\mathcal{H}^{p+\alpha},\forall p\in\mathcal{P},\alpha\in\Delta$.

Remark (2.2): Obviously, Lemma (2.1) can be applied if $C\in Z^1(\mathfrak{g},\mathcal{L}(\mathcal{H}))^{\mathfrak{h}}$, the subspace of cocycles which vanish on $\mathfrak{h}$.

Proof: Let $X\in\mathfrak{g}^{\alpha}$. Relation $[H,X]=\alpha(H)X,\forall H\in\mathfrak{h}$, shows that $\pi(X)(\mathcal{H}^p)\subset\mathcal{H}^{p+\alpha}$. We decompose $C=A+B$, with $A(\mathfrak{g}^{\alpha})(\mathcal{H}^p)\subset\mathcal{H}^{p+\alpha}$, $\forall p$, α, and $B(\mathfrak{g}^{\alpha})(\mathcal{H}^p)\subset\oplus_{r\neq p+\alpha}\mathcal{H}^r$. It is easily seen that $A\in Z^1(\mathfrak{g},\mathcal{L}(\mathcal{H}))$, and $B\in Z^1(\mathfrak{g},\mathcal{L}(\mathcal{H}))^{\mathfrak{h}}$. Then, if $X\in\mathfrak{g}^{\alpha},B([H,X])=[\pi(H),B(X)]=\alpha(H)B(X)$, so we deduce that $B(X)(\mathcal{H}^p)\subset\mathcal{H}^{p+\alpha},\forall p$, and then, from the definition of B, that $B=0$. □

Finally we want to stress that, when dealing with a Z_2-graded associative algebra A, we are using the notation $[a,b]$ for the super-bracket $[a,b]=ab-(-1)^{\deg a\cdot\deg b}ba$ while, for the Lie bracket, we write $[a,b]_{\mathcal{L}}=ab-ba$.

III. DEFORMATION OF THE EXTENDED METAPLECTIC REPRESENTATION OF $\mathfrak{g}=\mathfrak{osp}(1,2)$

Throughout this section, $\mathfrak{g}=\mathfrak{osp}(1,2),\mathfrak{g}_{\bar{0}}=\mathfrak{sl}(2)$. As in Ref. 8, we introduce a basis H, F, G for $\mathfrak{g}_{\bar{0}}$, and $E_{\pm}$ for $\mathfrak{g}_{\bar{1}}$, with commutation rules:

$$[H,F]=F,[H,G]=-G,[H,E_{\pm}]=\pm\tfrac{1}{2}E_{\pm},F=[E_+,E_+],G=-[E_-,E_-],$$

$$H=[E_+,E_-],[F,E_-]=-E_+ \text{ and } [G,E_+]=-E_-.$$

[3.1] Let $\mathcal{U}(\mathfrak{g})$ and $\mathcal{U}(\mathfrak{g}_{\bar{0}})$ be the respective enveloping algebras, and $Z(\mathfrak{g}),Z(\mathfrak{g}_{\bar{0}})$ their centers. Then $Z(\mathfrak{g})=\mathbb{C}[Q],Z(\mathfrak{g}_{\bar{0}})=\mathbb{C}[Q_0]$, where $Q_0=GF+H+H^2$, and $Q=Q_0-\frac{1}{2}[E_+,E_-]_{\mathcal{L}}$. If $\theta=\frac{1}{4}+[E_+,E_-]_{\mathcal{L}}$, it is shown in Ref. 8 (see also Ref. 9) that $\mathcal{U}(\mathfrak{g})$ is exactly the algebra with generators $E_{\pm}$ and θ and relations $[E_+,E_-]_{\mathcal{L}}=-\frac{1}{4}+\theta$, with θ anticommuting with $E_{\pm}$. Then $Q=-\frac{1}{16}+\theta^2$ and $Q_0=-\frac{3}{16}+\frac{1}{2}\theta+\theta^2$. $\mathcal{U}\theta$ is a two sided primitive ideal of $\mathcal{U}$, and the quotient $\mathcal{U}/\mathcal{U}\theta$ is the Weyl algebra W_1, i.e., the algebra with generators $E_{\pm}$ and relations $[E_+,E_-]_{\mathcal{L}}=-\frac{1}{4}$. The Weyl algebra has a natural Schur-irreducible representation on $\mathcal{H}=\mathbb{C}[z^{-1},z]$ defined by $\pi(E_+)=\frac{1}{2}(d/dz),\pi(E_-)=-\frac{1}{2}z$; using $W_1=\mathcal{U}/\mathcal{U}\theta$, we deduce a representation of $\mathfrak{g}$ on $\mathbb{C}[z^{-1},z]$, that we also denote by π. One has $\pi(H)=-\frac{1}{2}z(d/dz)-\frac{1}{4}$, $\pi(F)=\frac{1}{2}(d^2/dz^2)$, $\pi(G)=-\frac{1}{2}z^2$, $\pi(Q)=-\frac{1}{16}$ and $\pi(Q_0)=-\frac{3}{16}$. We call π the extended metaplectic representation (we shall explain why later).

At this stage, we shall interpret π as an extension of two irreducible representations of $\mathfrak{g}$: if $\mathcal{H}^+=\mathbb{C}[z]$ and $\mathcal{H}^-=(1/z)\mathbb{C}[1/z]$, then $\mathcal{H}^+$ is a subrepresentation of $\mathcal{H}$ that we denote π^+. In the notations of Ref. 7, π^+ is an irreducible representation of type $[-\frac{1}{4}]\downarrow$; let now π^- be the representation induced by π on $\mathcal{H}/\mathcal{H}^+$: then π^- is an irreducible representation of type $[\frac{1}{4}]\uparrow$, so that π^- is exactly the contragedient of π^+. There is an exact sequence: $0\to(\mathcal{H}^+,\pi^+)\to(\mathcal{H},\pi)\to(\mathcal{H}/\mathcal{H}^+,\pi^-)\to 0$, so π is an extension of π^+ by π^- (see Ref. 7). The restriction $\pi_{|\mathfrak{g}_{\bar{0}}}$ decomposes as $\pi_{\bar{0}}\oplus\pi_{\bar{1}}$ on $\mathcal{H}=\mathcal{H}_{\bar{0}}\oplus\mathcal{H}_{\bar{1}}$, the grading being defined by parity. We get two extensions: $0\to(\mathcal{H}_{\bar{0}}^+,\pi_{\bar{0}}^+)\to(\mathcal{H}_{\bar{0}},\pi_{\bar{0}})\to(\mathcal{H}_{\bar{0}}/\mathcal{H}_{\bar{0}}^+,\pi_{\bar{0}}^-)\to 0$ and $0\to(\mathcal{H}_{\bar{1}}^+,\pi_{\bar{1}}^+)\to(\mathcal{H}_{\bar{1}},\pi_{\bar{1}})\to(\mathcal{H}_{\bar{1}}/\mathcal{H}_{\bar{1}}^+,\pi_{\bar{1}}^-)\to 0$, and $\pi_{\bar{0}}^+=(-\frac{1}{4})\downarrow,\pi_{\bar{1}}^+=(-\frac{3}{4})\downarrow,\pi_{\bar{0}}^-=(\frac{3}{4})\uparrow,\pi_{\bar{1}}^-=(\frac{1}{4})\uparrow$. All these extensions are nontrivial.

Let now $\mathcal{F}=\mathbb{C}[[z,z^{-1}]]$ be the space of formal Laurent series, graded as $\mathcal{F}=\mathcal{F}_{\bar{0}}\oplus\mathcal{F}_{\bar{1}}$ by parity; we can extend π to a representation (denoted by the same symbol) of $\mathfrak{g}$ on $\mathcal{F}$. Note that $\mathcal{F}^+=\mathbb{C}[[z]]$ is a subrepresentation, that we denote by π^+. We define a scalar product by $\langle z^n,z^n\rangle=n!,\langle z^{-n},z^{-n}\rangle=1/(n-1)!$ if $n>0,\{z^n,n\in\mathbb{Z}\}$ being an orthogonal set, and denote by $\mathbf{H}$ the Hilbert space of series $f=\Sigma_{n\in\mathbb{Z}}a_nz^n\in\mathcal{F}$ such that $\Sigma_{n\geqslant 1}[|a_{-n}|^2/(n-1)!]<+\infty$ and $\Sigma_{n\geqslant 0}n!|a_n|^2<+\infty$. Let $\mathbf{H}^+=\mathcal{F}^+\cap\mathbf{H}$. If $f\in\mathbf{H}^+$, the two series $\Sigma\sqrt{n!}a_n$ and $\Sigma z^n/\sqrt{n!}$ are in l^2, so, by Schwarz inequality, one has

$$\left|\sum_{n\geqslant 0} a_n z^n\right| \leqslant \left[\sum_{n\geqslant 0} n!|a_n|^2\right]^{1/2}\left[\sum_{n\geqslant 0}\frac{z^{2n}}{n!}\right]^{1/2} = e^{|z|^2/2}\|f\|_{\mathbf{H}}.$$

In other words, $f(z)=\Sigma_{n\geqslant 0}a_n z^n$ is actually an entire function. Convergence in $\mathbf{H}^+$ implies pointwise convergence, and it is easily seen that $\mathbf{H}^+$ is exactly the space of entire functions such that $\int e^{-|z|^2}|f(z)|^2 dxdy<+\infty$; the scalar product on $\mathbf{H}^+$ is exactly $\langle f|g\rangle = 1/\pi\int e^{-|z|^2} f(z)\overline{g(z)}dxdy$.

We denote by $\mathbf{G}$ the twofold metaplectic covering of $SU(1,1)$: $\mathfrak{g}_0^-$ is its Lie algebra. $\mathbf{K}$ being the maximal compact subgroup of $\mathbf{G}$ we have the following.

Proposition (3.1): There exists a continuous representation U of $\mathbf{G}$ on $\mathbf{H}$ such that the space of $\mathbf{K}$-finite vectors of U is $\mathcal{H}$, and $dU_{|_{\mathcal{H}}}=\pi_{|_{\mathfrak{g}_0^-}}$.

Proof: Let $\pi^+=\pi^+_{|_{\mathfrak{g}_0^-}}$. The condition $\pi^+(F)^*=-\pi^+(G)$ is satisfied on $\mathcal{H}^+$, so by Nelson's criteria,[10] there exists a unitary representation U^+ of $\mathbf{G}$ in $\mathbf{H}^+$ such that $\mathcal{H}^+$ is the space of $\mathbf{K}$-finite vectors of U^+, and $dU^+|_{\mathcal{H}^+}=\pi^+$ (*a priori*, U^+ is a representation of the universal covering $\tilde{\mathbf{G}}$, but due to the weight structure, it is in fact a representation of $\mathbf{G}$). Now, let $\pi^-=\pi^-_{|_{\mathfrak{g}_0^-}}$, on $\mathcal{H}/_{\mathcal{H}^+}$; again, the condition $\pi^-(F)^*=-\pi^-(G)$ is satisfied, so there exists a unitary representation U^- of $\mathbf{G}$ in $\mathbf{H}/\mathbf{H}^+$ such that, if we identify the spaces $\mathcal{H}/\mathcal{H}^+$ and $\mathcal{H}^-$, $\mathcal{H}^-$ is the space of $\mathbf{K}$-finite vectors of U^- and $dU^-_{|_{\mathcal{H}^-}}=\pi^-$. In what follows, we identify the Hilbert spaces $\mathbf{H}/\mathbf{H}^+$ and $\mathbf{H}^-=\{f=\Sigma_{n\geqslant 1}a_n z^{-n}\in\mathcal{F}|\Sigma_{n\geqslant 1}[|a_{-n}|^2/(n-1)!]<\infty\}$, so U^- is a representation of $\mathbf{G}$ on $\mathbf{H}^-$. Let $Z_n(z)=z^n/\sqrt{n!}, Z_{-n}(z)=\sqrt{(n-1)!}z^{-n}, n\geqslant 0$; one has

$$\pi(F)Z_n=\tfrac{1}{2}\sqrt{n(n-1)}Z_{n-2},$$

$$\pi(G)Z_n=-\tfrac{1}{2}[\sqrt{(n+1)(n+2)}Z_{n+2}+\delta_{n+1,0}Z_1+\delta_{n+2,0}Z_0],\quad \forall n\in\mathbb{Z}.$$

So the representation π of $\mathfrak{g}_0^-$ on $\mathcal{H}=\mathcal{H}^+\oplus\mathcal{H}^-$ can be written as $\pi=\begin{pmatrix}\pi^+ & \xi\\ 0 & \pi^-\end{pmatrix}$, with an extension cocycle $\xi\in Z^1(\mathfrak{g}_0^-,\mathcal{L}(\mathcal{H}^-,\mathcal{H}^+))$ (see Ref. 5) defined by $\xi_H=\xi_F=0$, and $\xi_G(Z_n)=-\frac{1}{2}[\delta_{n+1,0}Z_1+\delta_{n+2,0}Z_0]$; it is obvious that $\xi(X), X\in\mathfrak{g}_0^-$, is always a continuous linear map from $\mathbf{H}^-$ into $\mathbf{H}^+$, so, by Ref. 5, there exists a representation U of $\mathbf{G}$ in $\mathbf{H}$ such that $dU|_{\mathcal{H}}=\pi_{|_{\mathfrak{g}_0^-}}$. □

Remark (3.2): Still identifying the spaces $\mathbf{H}/\mathbf{H}^+$ and $\mathbf{H}^-$, as in the proof of Proposition (3.1), we see that $U=\begin{pmatrix}U^+ & \tau\\ 0 & U^-\end{pmatrix}$ is an extension of U^+ by U^-, with extension cocycle τ (see Ref. 5), and actually a nontrivial extension (because its differential is a nontrivial extension). One has $U^+=U_0^+\oplus U_1^+=(-\frac{1}{4})\downarrow\oplus(-\frac{3}{4})\downarrow$, so U^+ is equivalent to the usual metaplectic representation of $\mathbf{G}$, which is obtained from the well-known harmonic oscillator representation of $\mathbf{G}$; moreover, one has $U^-=U_0^-\oplus U_1^-=(\frac{3}{4})\uparrow\oplus(\frac{1}{4})\uparrow$, so that U is a nontrivial (and therefore nonunitary) extension of the metaplectic representation of $\mathbf{G}$ by its own contragedient: this explains the name ''extended metaplectic representation.''

To end this subsection, we briefly explicit an isomorphism between U^+ and the usual metaplectic representation. Let $\phi_n(x)=H_n(x)e^{-x^2/2}/\pi^{1/4}2^{n/2}\sqrt{n!}$, with $H_n=(-1)^n e^{x^2}(d^n/dx^n)\times(e^{-x^2})$, be the orthonormal basis of Hermite functions in $L^2(\mathbb{R})$. Now $\theta_n(x)=\int(x+it)^n e^{-t^2/2}dt$ satisfies $\theta_{n+2}=x\theta_{n+1}-(n+1)\theta_n$; so, from Ref. 11, one has $\theta_n=\sqrt{2\pi}H_n(x/\sqrt{2})2^{-n/2}$ and $H_n(x)=2^n/\sqrt{\pi}\int(x+it)^n e^{-t^2}dt$. Hence $\phi_n(x)=e^{-x^2/2}/\pi^{3/4}\int Z_n(\sqrt{2}(x+it))e^{-t^2}dt$. Define an operator T by $T(f)=e^{-x^2/2}/\pi^{3/4}\int f(\sqrt{2}(x+it))e^{-t^2}dt$, $f\in\mathcal{H}^+$. One has $T(Z_n)=\phi_n$, so T extends to a unitary operator from $\mathbf{H}^+$ onto $L^2(\mathbb{R})$. It is easy to check that T maps the operator z (resp., d/dz) of $\mathbf{H}^+$ onto the operator $(1/\sqrt{2})(x-d/dx)$ [resp., $1/\sqrt{2}(x+d/dx)$] of $L^2(\mathbb{R})$, so it intertwines U^+ and the usual metaplectic representation of $\mathbf{G}$.

[3.2] In this subsection we shall deform the extended metaplectic representation π defined in subsection [3.1]. Note that π can be considered as a representation of $\mathfrak{g}$, hence also of $\mathfrak{g}_0^-$, but also as a representation of the Weyl algebra W_1. So we have to specify in what category of representations we want to deform π.

[*3.2.1*] We shall first deform π as a representation of the Lie algebra $\mathfrak{g}_0^-$ and assume that the weight structure of π is unchanged by the deformation. So if $\mathfrak{h}=\mathbb{C}H$ is the Cartan subalgebra, we have to compute $H^1(\mathfrak{g}_0^-,\mathcal{L}(\mathcal{H}))^{\mathfrak{h}}$.

Proposition (3.3): One has $\dim H^1(\mathfrak{g}_0^-,\mathcal{L}(\mathcal{H}))^{\mathfrak{h}}=2$; *any cocycle is equivalent to a cocycle such that* $C(H)=C(G)=0$, *and* $C(F)=(\alpha P+\beta\,\mathrm{Id})\pi(G)^{-1}$, *where* P *is the parity operator.*

Proof: If $C\in Z^1(\mathfrak{g}_0^-,\mathcal{L}(\mathcal{H}))^{\mathfrak{h}}$, we deduce from Lemma (2.1) that $C(G)(\mathcal{H}_n)\subset\mathcal{H}_{n+2}(\mathcal{H}_n=\mathbb{C}z^n)$, so, up to a coboundary, we can assume that $C(G)=0$. $\forall X\in\mathfrak{g}_0^-$ we deduce from $C(Q_0X)=C(XQ_0)$ and $\pi(Q_0)=-\frac{3}{16}$ that $[\pi(X),C(Q_0)]=0$, so $C(Q_0)_{|_{\mathcal{H}_d}}=\alpha_d\,\mathrm{Id}_{\mathcal{H}_d},\alpha_d\in\mathbb{C}$, $d=\overline{0,1}$. If C is a coboundary, then $C(Q_0)=\pi(G)C(F)=0$, and since G is invertible, we get $C=0$. If $C(Q_0)\neq 0$,C cannot be a coboundary, and using $C(Q_0)=\pi(G)C(F)$, we deduce $C(F)_{|_{\mathcal{H}_d}}=\alpha_d\pi(G)^{-1}_{|_{\mathcal{H}_d}}$, $d=\overline{0,1}$. Now define $\alpha=\frac{1}{2}(\alpha_0^-\alpha_1^-)$, and $\beta=\frac{1}{2}(\alpha_0^-+\alpha_1^-)$. We get $C(F)=(\alpha\cdot P+\beta\,\mathrm{Id})\pi(G)^{-1}$. It is easy to check that these formulas define a cocycle. □

Let us now construct deformations associated with the cocycles of Proposition (3.3). Note that if C and C' are two such cocycles, one has $[C(X),C'(Y)]=0$, for every $X,Y\in\mathfrak{g}_0^-$. Thus if C_n is a sequence of such cocycles, then $\pi^\lambda=\pi+\Sigma_{n\geqslant 1}\lambda^nC_n$ defines a deformation of π. Using Lemma (2.1) and a sequence of equivalences, it is easily seen that any deformation of π such that the weight structure is unchanged (i.e., the cochains vanish on $\mathfrak{h}$) is equivalent to a deformation of the type described above, so we have the following.

Proposition (3.4): (1) *Any deformation of* π, *considered as a representation of* $\mathfrak{g}_0^-$, *with unchanged weight structure, is equivalent to a deformation* $\pi^\lambda_{f,g}$ *defined, given two formal series* $f(\lambda)$ *and* $g(\lambda)$ *such that* $f(0)=g(0)=0$, *by* $\pi^\lambda_{f,g}(H)=\pi(H)$, $\pi^\lambda_{f,g}(G)=\pi(G)$, $\pi^\lambda_{f,g}(F)=\frac{1}{2}(d^2/dz^2)-2(f(\lambda)P+g(\lambda))\cdot 1/z^2$. *One has* $\pi^\lambda_{f,g}(Q_0)=-\frac{3}{16}+(f(\lambda)P+g(\lambda))$; *as deformations* $\pi^\lambda_{f,g}\simeq\pi^\lambda_{f',g'}$, *if and only if* $f=f'$ *and* $g=g'$.

(2) *If* $\tilde{\pi}^\lambda$ *is a deformation of* π, *with unchanged weight structure, there exist* $f(\lambda),g(\lambda)\in\mathbb{C}[[\lambda]]$, *such that* $f(0)=g(0)=0$, *and* $\tilde{\pi}^\lambda(Q_0)=-\frac{3}{16}+(f(\lambda)P+g(\lambda))$; *as a deformation,* $\tilde{\pi}^\lambda\simeq\pi^\lambda_{f,g}$.

Proof: We have to prove the two last claims. Let $\pi^\lambda=\pi^\lambda_{f,g}$, and $\pi'^\lambda=\pi^\lambda_{f',g'}$. Assume that $T^\lambda\pi^\lambda=\pi'^\lambda T^\lambda$, with $T^\lambda=\mathrm{Id}+\Sigma_{n\geqslant 1}\lambda^nT_n$; since $\pi^\lambda(H)=\pi'^\lambda(H)=\pi(H)$, one has $[\pi(H),T^\lambda]=0$, so $T^\lambda(z^p)=t_p(\lambda)\cdot z^p$, with $t_p(0)=1$. Applying $T^\lambda\pi^\lambda(Q_0)=\pi'^\lambda(Q_0)T^\lambda$ on z^p, one gets $(-1)^pf(\lambda)+g(\lambda)=(-1)^pf'(\lambda)+g'(\lambda)$, so $g=g'$, and $f=f'$.

We know that $\tilde{\pi}^\lambda$ is equivalent to some $\pi^\lambda_{f,g}$; since $[Q_0,H]=0$, one has $\tilde{\pi}^\lambda(Q_0)(z^p)=q(\lambda)\cdot z^p$. Let $T^\lambda\tilde{\pi}^\lambda(Q_0)=\pi^\lambda_{f,g}(Q_0)T^\lambda$. As before, one sees that $T(z^p)=t_p(\lambda)\cdot z^p$, with $t_p(0)=1$, and $t_p(\lambda)q(\lambda)\cdot z^p=[-\frac{3}{16}+(-1)^pf(\lambda)+g(\lambda)]t_p(\lambda)z^p$, hence the formula for $\tilde{\pi}^\lambda(Q_0)$. □

Remark (3.5): A deformation of π with unchanged weight structure, when not trivial, can never be a representation of the Weyl algebra, because in the Weyl algebra, one has $Q_0=-\frac{3}{16}$. We shall see in the next section when it is possible to extend from $\mathfrak{g}_0^-$ to $\mathfrak{g}$.

[*3.2.2*] Here we deform π as a *representation of the superalgebra* $\mathfrak{g}$. We begin by assuming that the weight structure is unchanged (i.e., the cochains vanish on $\mathfrak{h}$), as was done in the case of $\mathfrak{g}_0^-$. So we have to compute $Z^1(\mathfrak{g},\mathcal{L}(\mathcal{H}))^{\mathfrak{h}}$.

Proposition (3.6): $\mathrm{Dim}\,Z^1(\mathfrak{g},\mathcal{L}(\mathcal{H}))^{\mathfrak{h}}=1$. *A nontrivial cocycle is defined by* $C(H)=C(E_-)=0$ *and* $C(E_+)=P\pi(E_-)^{-1}$, *where* P *is the parity operator.*

Proof: For simplicity, we write $X=\pi(X)$, for $X\in\mathfrak{g}$. Define the operators $E^\lambda_\pm$ by $E^\lambda_+=E_+ +\lambda P\cdot E_-^{-1}$ and $E^\lambda_-=E_-$. We get $[E^\lambda_+,E^\lambda_-]_{\mathcal{L}}=-\frac{1}{4}+2\lambda P$, and P anticommutes with E^λ_+ and E^λ_-. Therefore, from the definition of $\mathcal{U}(\mathfrak{g})$ by generators and relations (see Sec. [3.1]), there exists a formal representation π^λ of $\mathfrak{g}$ such that $\pi^\lambda(E_\pm)=E^\lambda_\pm$ and one has, $\forall X\in\mathfrak{g}$, $\pi^\lambda(X)=\pi(X)+\lambda C(X)+\lambda^2D(X)$ with $C\in Z^1(\mathfrak{g},\mathcal{L}(\mathcal{H}))^{\mathfrak{h}}$. Now $\pi^\lambda(H)=[E^\lambda_+,E^\lambda_-]=\pi(H)$, so that $C(H)=C(E_-)=0$ and $C(E_+)=P\cdot E_-^{-1}$. This proves that the above definition of C gives indeed an element of $Z^1(\mathfrak{g},\mathcal{L}(\mathcal{H}))^{\mathfrak{h}}$.

To prove the first assertion above, we take some $C \in Z^1(\mathfrak{g}, \mathcal{L}(\mathcal{H}))^\mathfrak{h}$. Since $C(H)=0$, by Lemma (2.1), one has $C(E_-)(\mathcal{H}_n) \subset \mathcal{H}_{n+1}$ ($\mathcal{H}_n = \mathbb{C}z^n$), so, up to a coboundary, we can assume that $C(E_-)=0$. From Sec. II, one has $C(Q)=\alpha\,\mathrm{Id}_\mathcal{H}$, and from the proof of Proposition (3.3), $C(Q_0)_{|_{\mathcal{H}_d}} = \alpha_d \cdot \mathrm{Id}_{\mathcal{H}_d}$, $d = \overline{0,1}$. Since $Q = Q_0 - \frac{1}{2}[E_+, E_-]_\mathcal{L}$, we deduce $C([E_+, E_-]_\mathcal{L})_{|_{\mathcal{H}_d}} = 2(\alpha_d - \alpha)\cdot \mathrm{Id}_{\mathcal{H}_d}$. But $H=[E_+, E_-]$, so $C(H)=[C(E_+), E_-]=0$ gives $C(E_+)E_- = -E_- C(E_+)$. Therefore $C(E_+)E_{-|_{\mathcal{H}_d}} = (\alpha_d - \alpha_d)\mathrm{Id}_{\mathcal{H}_d}$. But since E_- anticommutes with $(\frac{1}{4} + [E_+, E_-]_\mathcal{L})$ (see Sec. [3.1]), one has $E_- C([E_+, E_-]_\mathcal{L}) = -C([E_+, E_-]_\mathcal{L})E_-$. Applying on $f \in \mathcal{H}_0^-$, we get $(\alpha_0^- - \alpha)E_- f = -(\alpha_1^- - \alpha)E_- f$, and then $C(E_+)E_- = (\alpha_0^- - \alpha)P$, so $C(E_+) = (\alpha_0^- - \alpha)PE_-^{-1}$. □

We shall now classify our deformations up to equivalence. First, for $f \in \mathbb{C}[[\lambda]]$ and $f(0)=0$, we define a deformation π_f^λ by $\pi_f^\lambda(E_-) = \pi(E_-)$ and $\pi_f^\lambda(E_+) = \pi(E_+) + f(\lambda)P\pi(E_-)^{-1}$. It is indeed a deformation because, as in the proof of Proposition (3.6), $[\pi_f^\lambda(E_+), \pi_f^\lambda(E_-)]_\mathcal{L} = -\frac{1}{4} + 2f(\lambda)P$, and P anticommutes with $\pi_f^\lambda(E_\pm)$. One has $\pi_f^\lambda(H) = H$, so the weight structure is unchanged, as wanted. Moreover, one has $\pi_f^\lambda(Q_0) = -\frac{3}{16} + f(\lambda)P + 4f(\lambda)^2$, and $\pi_f^\lambda(Q) = -\frac{1}{16} + 4f(\lambda)^2$, using formulas given in (3.1). As in the proof of Proposition (3.4), it is easily proved that $\pi_f^\lambda \simeq \pi_{f'}^\lambda$ if and only if $f = f'$.

Proposition (3.7): Any deformation $\tilde{\pi}^\lambda$ of π, considered as a representation of $\mathfrak{g}$, with unchanged weight structure, is equivalent to some π_f^λ. In addition $\tilde{\pi}^\lambda(Q_0) = -\frac{3}{16} + f(\lambda)P + 4f(\lambda)^2$, and $\tilde{\pi}^\lambda(Q) = -\frac{1}{16} + 4f(\lambda)^2$.

We shall need the following technical lemma.

Lemma (3.8): Given $C_\pm \in \mathcal{L}(\mathcal{H})$ such that $[\pi(E_+), C_-]_\mathcal{L} + [C_+, \pi(E_-)]_\mathcal{L}$ anticommutes with $E_\pm$, and $[\pi(E_+), C_-] + [\pi(E_-), C_+] = 0$, there exists a cocycle $C \in Z^1(\mathfrak{g}, \mathcal{L}(\mathcal{H}))^\mathfrak{h}$ such that $C(E_\pm) = C_\pm$.

Proof: Define $\widetilde{E_\pm} = \begin{pmatrix} \pi(E_\pm) & C_\pm \\ 0 & \pi(E_\pm) \end{pmatrix} \in \mathcal{L}(\mathcal{H} \oplus \mathcal{H})$. Then $[\widetilde{E_+}, \widetilde{E_-}]_\mathcal{L} = -\frac{1}{4} + \tilde{T}$, where $\tilde{T}$ anticommutes with $\widetilde{E_\pm}$, so (see Sec. [3.1]), there exists a representation ρ of $\mathcal{U}(\mathfrak{g})$ on $\mathcal{H} \oplus \mathcal{H}$ such that $\rho(E_\pm) = \tilde{E}_\pm$ and one has $\rho(u) = \begin{pmatrix} \pi(u) & C(u) \\ 0 & \pi(u) \end{pmatrix}$ where C is a cocycle which satisfies $C(E_\pm) = C_\pm$. Since $H = [E_+, E_-]$, one has $C(H) = [\pi(E_+), C(E_-)] + [\pi(E_-), C(E_+)] = 0$. □

We now prove Proposition (3.7). From Sec. [3.1], we see that $\tilde{\pi}^\lambda$ is completely defined if one knows $\widetilde{E_\pm^\lambda} = \tilde{\pi}^\lambda(E_\pm)$, which have to satisfy $[\widetilde{E_+^\lambda}, \widetilde{E_-^\lambda}]_\mathcal{L} = -\frac{1}{4} + T^\lambda$, with T^λ anticommuting with $\widetilde{E_\pm^\lambda}$, and $[\widetilde{E_+^\lambda}, \widetilde{E_-^\lambda}] = H$.

Let $\widetilde{E_\pm^\lambda} = \pi(E_\pm) + \lambda C_\pm + o(\lambda^2)$. We know that there exists a cocycle $C \in Z^1(\mathfrak{g}, \mathcal{L}(\mathcal{H}))^\mathfrak{h}$ such that $C_\pm = C(E_\pm)$; by Proposition (3.6), C is equivalent to $\gamma_1 C_0$, where $\gamma_1 \in \mathbb{C}$, and C_0 is the cocycle of Proposition (3.6). Then, using an equivalence, we can replace $C_\pm$ by $\gamma_1 C_0(E_\pm)$. So we get new operators, that we still denote by $\tilde{E}_\pm^\lambda$, and which can be written as

$$\widetilde{E_+^\lambda} = \pi(E_+) + \lambda\gamma_1 P\pi(E_-)^{-1} + \lambda^2 D_+ + o(\lambda^3),$$

$$\widetilde{E_-^\lambda} = \pi(E_-) + \lambda^2 D_- + o(\lambda^3).$$

Now $D_\pm$ satisfies the assumptions of Lemma (3.8), so there exists $D \in Z^1(\mathfrak{g}, \mathcal{L}(\mathcal{H}))^\mathfrak{h}$ such that $D(E_\pm) = D_\pm$. By Proposition (3.6), D is equivalent to $\gamma_2 C_0, \gamma_2 \in \mathbb{C}$. So, via an equivalence of the form $(\mathrm{Id} + \lambda^2 T)$, we can replace $D_\pm$ by $\gamma_2 C_0(E_\pm)$ and get new operators, still denoted by $\widetilde{E_\pm^\lambda}$, which can be written as

$$\widetilde{E_+^\lambda} = \pi(E_+) + \lambda\gamma_1 P\pi(E_-)^{-1} + \lambda^2\gamma_2 P\pi(E_-)^{-1} + \lambda^3 J_+ + o(\lambda^4),$$

$$\widetilde{E_-^\lambda} = \pi(E_-) + \lambda^3 J_- + o(\lambda^4).$$

We can now repeat the argument for $J_\pm$, and so on. Eventually we obtain that, by equivalence, our operators $\widetilde{E_\pm^\lambda}$ can be written as

$$\widetilde{E_+^\lambda}=\pi(E_+)+\sum_{n\geqslant 1}\lambda^n\gamma_n P\pi(E_-)^{-1}=\pi(E_+)+f(\lambda)P\pi(E_-)^{-1}\ \text{ and }\ \widetilde{E_-^\lambda}=\pi(E_-),$$

which shows that $\tilde{\pi}^\lambda$ is equivalent to π_f^λ. Finally we obtain $\tilde{\pi}^\lambda(Q_0)=\pi_f^\lambda(Q_0)$ and $\tilde{\pi}^\lambda(Q)=\pi_f^\lambda(Q)$ as in the proof of Proposition (3.4).

Remark (3.9): (1) The deformations $\tilde{\pi}^\lambda$ of Proposition (3.7), when nontrivial, can never be representations of the Weyl algebra W_1 (where $Q=-\frac{1}{16}$).

(2) One has $\tilde{\pi}^\lambda(Q_0)=-\frac{3}{16}+f(\lambda)P+4f(\lambda)^2$, so $\tilde{\pi}^\lambda|_{\mathfrak{g}_0^-}$ is equivalent to $\pi_{f,4f^2}^\lambda$ by Proposition (3.4). In particular, $\pi_{f,g}^\lambda$ extends from $\mathfrak{g}_0^-$ to $\mathfrak{g}$ if and only if $g=4f^2$.

[3.3] From Sec. [3.2], we see that it is impossible to deform π nontrivially if one assumes that the weight structure and the Weyl structure are preserved. In this section, we study deformations of π, considered as a representation of $\mathfrak{g}$, such that the Weyl structure is preserved, i.e., which are still representations of the Weyl algebra. We then have to release our assumption about the weight structure: we shall assume only that our deformation is still H-diagonal on $\mathcal{H}=\oplus_{n\in\mathbb{Z}}\mathcal{H}_n$, $\mathcal{H}_n=\mathbb{C}z^n$, but the weights may change (and in fact will change, as we shall see). Writing such a deformation as $\pi^\lambda=\pi+\Sigma_{n\geqslant 1}\lambda^n C_n$, we must have $C_n([E_+,E_-]_{\mathcal{L}})=0$, $\forall n$, and $C_n(H)\times(\mathcal{H}_p)\subset\mathcal{H}_p,\forall_p$. The corresponding cohomology is defined by

$$Z_W^1(\mathfrak{g},\mathcal{L}(\mathcal{H}))=\{C\in Z^1(\mathfrak{g},\mathcal{L}(\mathcal{H}))\,|\,C([E_+,E_-]_{\mathcal{L}})=0,\ \text{and}\ C(H)(\mathcal{H}_p)\subset\mathcal{H}_p,\forall p\in\mathbb{Z}\},$$

$B_W^1(\mathfrak{g},\mathcal{L}(\mathcal{H}))=B^1(\mathfrak{g},\mathcal{L}(\mathcal{H}))^{\mathfrak{h}}$ (easy to check), and $H_W^1=Z_W^1/B_W^1$.

Proposition (3.10): $\dim H_W^1(\mathfrak{g},\mathcal{L}(\mathcal{H}))=1$, *a nontrivial cocycle being defined by* $C(E_+)=\pi(E_-)^{-1}$, $C(E_-)=0$, *and one has* $C(H)=2\,\mathrm{Id}_{\mathcal{H}}$.

Proof: Again, we write $X=\pi(X),X\in\mathfrak{g}$, to simplify notations, and define two operators: $\tilde{E}_+^\lambda=E_++\lambda E_-^{-1}$, $\tilde{E}_-^\lambda=E_-$; one has $[\tilde{E}_+^\lambda,\tilde{E}_-^\lambda]=-\frac{1}{4}$ so that we can extend this to a formal representation of the Weyl algebra W_1. Since $W_1=\mathcal{U}(\mathfrak{g})/\mathcal{U}(\mathfrak{g})\theta$ (see Sec. [3.1]), it is actually a formal representation of $\mathfrak{g}$, which deforms π, so there exists $C\in Z^1(\mathfrak{g},\mathcal{L}(\mathcal{H}))$ such that $C(E_+)=E_-^{-1}$ and $C(E_-)=0$. One has $C(H)=C([E_+,E_-])=2\mathrm{Id}_{\mathcal{H}}$, so $C\in Z_W^1(\mathfrak{g},\mathcal{L}(\mathcal{H}))$.

Let us now consider a general $C\in Z_W^1(\mathfrak{g},\mathcal{L}(\mathcal{H}))$. Using Lemma (2.1), one has $C(E_-)\times(\mathcal{H}_n)\subset\mathcal{H}_{n+1}$, for every n, so up to a coboundary, we can assume that $C(E_-)=0$. By Lemma (2.1), one has $C(E_+)(z^n)=c_nz^{n-1}$, but since $C([E_+,E_-]_{\mathcal{L}})=[C(E_+),E_-]_{\mathcal{L}}=0$, and $E_-z^n=-\frac{1}{2}z^{n+1}$, we deduce that $c_{n+1}=c_n,\forall n$, so finally $C(E_+)=cE_-^{-1},c\in\mathbb{C}$. Since $C(H)=2c\,\mathrm{Id}_{\mathcal{H}}$, C is a coboundary if and only if $c=0$. □

Proposition (3.11): Let π^λ *be a deformation of* π, *as a representation of* $\mathfrak{g}$, *such that the Weyl structure is preserved* [*and that* $\pi^\lambda(H)$ *is still diagonal on* $\oplus_n\mathcal{H}_n$]. *Then* π^λ *is equivalent to a deformation* π_{Wf}^λ *defined, for* $f\in\mathbb{C}[[\lambda]]$ *with* $f(0)=0$, *by* $\pi_{Wf}^\lambda(E_+)=\pi(E_+)+f(\lambda)\pi(E_-)^{-1}$ *and* $\pi_{Wf}^\lambda(E_-)=\pi(E_-)$. *One has* $\pi^\lambda(H)=\pi_{Wf}^\lambda(H)=\pi(H)+2f(\lambda)\cdot\mathrm{Id}_{\mathcal{H}},\pi^\lambda(Q_0)=\pi_{Wf}^\lambda(Q_0)=-\frac{3}{16},\pi^\lambda(Q)=\pi_{Wf}^\lambda(Q)=-\frac{1}{16}$. *Two deformations* π_{Wf}^λ *and* $\pi_{Wf'}^\lambda$ *are equivalent if and only if* $f=f'$.

We need the following lemma, which is proved exactly as Lemma (3.8).

Lemma (3.12): Let $C_\pm\in\mathcal{L}(\mathcal{H})$, *we assume that* $[\pi(E_+),C_-]_{\mathcal{L}}-[\pi(E_-),C_+]_{\mathcal{L}}=0$, *and moreover that* $([\pi(E_+),C_-]+[\pi(E_-),C_+])(\mathcal{H}_n)\subset\mathcal{H}_n$; *then there exists* $C\in Z_W^1(\mathfrak{g},\mathcal{L}(\mathcal{H}))$ *such that* $C(E_\pm)=C_\pm$.

We can now prove Proposition (3.11). It is clear that π^λ is completely defined from $\tilde{E}_\pm^\lambda=\pi^\lambda(E_\pm)$, which must satisfy $[\tilde{E}_+^\lambda,\tilde{E}_-^\lambda]_{\mathcal{L}}=-\frac{1}{4}$, and $[\tilde{E}_+^\lambda,\tilde{E}_-^\lambda](\mathcal{H}_n)\subset\mathcal{H}_n$. Let $\pi^\lambda=\pi+\lambda C+O(\lambda^2)$; then $C\in Z_W^1(\mathfrak{g},\mathcal{L}(\mathcal{H}))$. Therefore, by Proposition (3.10), up to an equivalence, we can assume that $\pi^\lambda=\pi+\gamma_1C_0+O(\lambda^2)$, where C_0 is the cocycle defined in Proposition (3.10), and $\gamma_1\in\mathbb{C}$. So our operators $\tilde{E}_\pm^\lambda$ can be written as $\tilde{E}_+^\lambda=\pi(E_+)+\lambda\gamma_1\pi(E_-)^{-1}+\lambda^2D_++O(\lambda^3)$, and $\tilde{E}_-^\lambda=\pi(E_-)+\lambda^2D_-+O(\lambda^3)$. Now Lemma (3.12) can be applied to $D_\pm$: there exists $D\in Z_W^1(\mathfrak{g},\mathcal{L}(\mathcal{H}))$ such that $D(E_\pm)=D_\pm$; by Proposition (3.10), D is equivalent to a cocycle $\gamma_2C_0,\gamma_2\in\mathbb{C}$, so, by an equivalence of the form $(\mathrm{Id}+\lambda^2T)$, we can assume that $\tilde{E}_+^\lambda=\pi(E_+)$

$+\lambda\gamma_1\pi(E_-)^{-1}+\lambda^2\gamma_2\pi(E_-)^{-1}+\lambda^3 J_+ + O(\lambda^4)$, and $\tilde{E}^\lambda_- = \pi(E_-)+\lambda^3 J_- + O(\lambda^4)$. We can repeat the same argument for $J_\pm$, and so on. Finally, up to an equivalence, we can write $\tilde{E}^\lambda_+ = \pi(E_+) + f(\lambda)\pi(E_-)^{-1}$, and $\tilde{E}^\lambda_- = \pi(E_-)$, so π^λ is equivalent to π^λ_{Wf}. It is easy to check that $\pi^\lambda(H) = \pi^\lambda_{Wf}(H) = \pi(H) + 2f(\lambda)\mathrm{Id}_{\mathcal{H}}$, and since the Weyl structure is preserved, one has $\pi^\lambda(Q_0) = -\frac{3}{16}$ and $\pi^\lambda(Q) = -\frac{1}{16}$. If π^λ_{Wf} and $\pi^\lambda_{Wf'}$ are equivalent, they have the same weight, so $f = f'$. □

[3.4] In this section, we shall compute those deformations of π, considered as a representation of $\mathfrak{g}$, which are still H-diagonal. This overlaps with Secs. [3.2] and [3.3], and we shall now show how the results of these two sections combine to describe the deformations we are dealing with. The cohomology associated with our problem is defined by

$$Z^1_H(\mathfrak{g},\mathcal{L}(\mathcal{H})) = \{C \in Z^1(\mathfrak{g},\mathcal{L}(\mathcal{H})) \,|\, C(H)(\mathcal{H}_n)\subset\mathcal{H}_n, \forall n\},$$

$$B^1_H(\mathfrak{g},\mathcal{L}(\mathcal{H})) = B^1(\mathfrak{g},\mathcal{L}(\mathcal{H}))^{\mathfrak{h}} \text{ (easy to check), and } H^1_H(\mathfrak{g},\mathcal{L}(\mathcal{H})) = Z^1_H/B^1_H.$$

$$\text{Obviously } H^1(\mathfrak{g},\mathcal{L}(\mathcal{H}))^{\mathfrak{h}} \subset H^1_H(\mathfrak{g},\mathcal{L}(\mathcal{H})) \text{ and } H^1_W(\mathfrak{g},\mathcal{L}(\mathcal{H})) \subset H^1_H(\mathfrak{g},\mathcal{L}(\mathcal{H})).$$

Proposition (3.13): $H^1_H(\mathfrak{g},\mathcal{L}(\mathcal{H})) = H^1(\mathfrak{g},\mathcal{L}(\mathcal{H}))^{\mathfrak{h}} \oplus H^1_W(\mathfrak{g},\mathcal{L}(\mathcal{H}))$.

Proof: Let $C \in Z^1_H(\mathfrak{g},\mathcal{L}(\mathcal{H}))$. By Lemma (2.1), $C(E_-)(\mathcal{H}_n)\subset\mathcal{H}_{n+1}$, so, up to a coboundary, we can assume that $C(E_-)=0$. Exactly as in the proof of Proposition (3.6) we now obtain $C([E_+,E_-]_{\mathcal{L}})_{|\mathcal{H}_d} = 2(\alpha_d-\alpha)\mathrm{Id}_{\mathcal{H}_d}, \alpha_d, \alpha \in \mathbb{C}$. Since E_- anticommutes with $(\frac{1}{4}+[E_+,E_-]_{\mathcal{L}})$, we deduce $E_- C([E_+,E_-]_{\mathcal{L}}) = -C([E_+,E_-]_{\mathcal{L}})E_-$, and thus $\alpha_1^- - \alpha = -(\alpha_0^- - \alpha)$. If we write $C(H)z^n = h_n \cdot z^n$, from $[H,E_-] = -\frac{1}{2}E_-$, we deduce $[C(H),E_-]=0$, and then $h_{n+1}=h_n, \forall n$, so $C(H)z^n = h\cdot z^n$. Since $H=[E_+,E_-]$, we obtain $[C(E_+),E_-] = h\cdot\mathrm{Id}$ and so $C([E_+,E_-]_{\mathcal{L}}) = [C(E_+),E_-]_{\mathcal{L}} = 2(\alpha_0^- - \alpha)\cdot P$, hence $C(E_+)E_- = (h/2)\mathrm{Id} + (\alpha_0^- - \alpha)\cdot P$. We conclude that $C(E_+) = (a\mathrm{Id}+bP)\cdot E_-^{-1}, C(E_-)=0$. Now if C_1 and C_2 are defined by $C_1(E_-)=C_2(E_-)=0$ and $C_1(E_+)=E_-^{-1}, C_2(E_+)=P\cdot E_-^{-1}$, then by Propositions (3.6) and (3.10), $C_1 \in Z^1_W(\mathfrak{g},\mathcal{L}(\mathcal{H}))$, $C_2 \in Z^1(\mathfrak{g},\mathcal{L}(\mathcal{H}))^{\mathfrak{h}}$, so we have proved that $H^1_H = H^{1\mathfrak{h}} + H^1_W$. But if C belongs to their intersection, we pick a representative of the cohomology class satisfying $C(E_+) = cE_-^{-1}$, $c\in\mathbb{C}$, $C(E_-)=0$ [Proposition (3.10)]: then $C(H) = 2c\mathrm{Id}$, but since the class is in $H^1(\mathfrak{g},\mathcal{L}(\mathcal{H}))^{\mathfrak{h}}$, one has $c=0$, and thus $C=0$. □

We now construct deformations of π corresponding to the cocycles of Proposition (3.13). Define $E^\lambda_+ = \pi(E_+) + (f(\lambda)+g(\lambda)P)\pi(E_-)^{-1}$ and $E^\lambda_- = \pi(E_-)$ for $f,\ g \in \mathbb{C}[[\lambda]]$ with $f(0) = g(0) = 0$. Then $[E^\lambda_+, E^\lambda_-] = -\frac{1}{4} + 2g(\lambda)P$ and $[E^\lambda_+, E^\lambda_-] = \pi(H) + 2f(\lambda)$. Since P anticommutes with $\pi(E_\pm)$, there exists a deformation $\tilde{\pi}^\lambda_{f,g}$ of π such that $\tilde{\pi}^\lambda_{f,g}(E_\pm) = E^\lambda_\pm$ and we have $\tilde{\pi}^\lambda_{f,g}(H) = \pi(H) + 2f(\lambda)$, so H is still diagonal, with translated eigenvalues. One finds $\tilde{\pi}^\lambda_{f,g}(Q_0) = -\frac{3}{16} + g(\lambda)P + 4g(\lambda)^2$, and $\tilde{\pi}^\lambda_{f,g}(Q) = -\frac{1}{16} + 4g(\lambda)^2$. In particular, when $f=0$, $\tilde{\pi}_{0,g} = \pi^\lambda_g$, and when $g=0$, $\tilde{\pi}_{f,0} = \pi^\lambda_{Wf}$, we recover the deformations obtained in Secs. [3.2] and [3.3]. The proof of the next result is so similar to the proofs of Propositions (3.7) or (3.11) that we shall not repeat the arguments.

Proposition (3.14): Let π^λ be a deformation of a representation π of $\mathfrak{g}$; we assume that $\pi^\lambda(H)$ is still diagonal on $\oplus_{n\in\mathbb{Z}}\mathcal{H}_n$. Then there exist $f, g \in \mathbb{C}[[\lambda]]$ with $f(0)=g(0)=0$ such that π^λ is equivalent to $\tilde{\pi}^\lambda_{f,g}$. One has $\pi^\lambda(H) = \pi(H) + f(\lambda)$, $\pi^\lambda(Q_0) = -\frac{3}{16} + g(\lambda)P + 4g(\lambda)^2$, and $\pi^\lambda(Q) = -\frac{1}{16} + 4g(\lambda)^2$. Given a second deformation π'^λ, of the same type, with associated f' and g', then $\pi^\lambda \simeq \pi'^\lambda$ if and only if $f=f'$, and $g=g'$.

Remark (3.15): Given two functions $f(\lambda)$, and $g(\lambda)$, analytic for $|\lambda|<R$, such that $f(0) = g(0) = 0$, let us consider $\pi^\lambda = \tilde{\pi}^\lambda_{f,g|_{\mathfrak{g}_0^-}}$; it can be checked easily that the integrability conditions of (Ref. 6, Proposition 9) are satisfied, so π^λ is the differential of a deformation U^λ of U, as representations of the universal covering $\tilde{\mathbf{G}}$ of $\mathbf{G} = SU(1,1)$.

Remark (3.16): Define $\Delta_\pm$ by $\Delta_\pm(h)=1/z(h(z)\pm h(-z))$. Then $E^\lambda_+=\pi(E_+)+(f(\lambda)+g(\lambda)P)\pi(E_-)^{-1}=\frac{1}{2}(d/dz)-(f(\lambda)-g(\lambda))\Delta_+-(f(\lambda)+g(\lambda))\Delta_-$. Since $\Delta_{\pm|_{\mathcal{H}^{\bar{1}}_0}}=0$, this expression can be useful to solve the equation $E^\lambda_+(h)=0$.

Take for instance $f-g=\alpha\lambda$, $f+g=\beta\lambda$, $\alpha, \beta\in\mathbb{C}$. We obtain a family of representations of $\mathfrak{g}$ and it is easy to check that all $\mathfrak{h}$-diagonal modules appear, either directly, or as subquotients of that family (see Ref. 5 for the classification of such modules), by solving the equation $E^\lambda_+(h)=0$.

We shall give some details in the special case $\alpha=0$ and $\beta=1$, denoting by π^λ the corresponding representations. One has $\pi^\lambda(E_+)=\frac{1}{2}(d/dz)-\lambda\Delta_-$, $\pi^\lambda(E_-)=-\frac{1}{2}z$, $\pi^\lambda(H)=-\frac{1}{2}z(d/dz)-\frac{1}{4}+\lambda$, $\pi^\lambda(\theta)=\lambda P$, and $\pi^\lambda(Q)=\lambda^2-\frac{1}{16}$. Note that $\pi^\lambda(g)(\mathcal{H}_+)\subset\mathcal{H}_+$. Let $\rho^\lambda=\pi^\lambda_{|\mathcal{H}^+}$, and V_μ, $\mu\in\mathbb{C}$, be the $\mathfrak{g}$-Verma module with dominant weight μ. Then $\rho^\lambda\simeq V_{\lambda-1/4}$, so ρ^λ provides an explicit construction of all Verma modules, as a deformation of $\rho^0=V_{-1/4}$, which is the metaplectic representation.

There is an interesting direct consequence. First we recall some results of Ref. 8. The minimal primitive ideals of $\mathcal{U}=\mathcal{U}(\mathfrak{g})$ were determined in Ref. 8; they are the ideals $I_\nu=\mathcal{U}(Q-\nu)$, for $\nu\neq-\frac{1}{16}$, and the singular ideal $I=\mathcal{U}\theta$ (which is not generated by its intersection with the center of $\mathcal{U}$). The corresponding primitive quotients are the algebras $\mathcal{B}_\nu=\mathcal{U}/I_\nu$, $\nu\neq-\frac{1}{16}$, and, in the singular case, the Weyl algebra $W_1=\mathcal{U}/I$. Now ρ^λ is a faithful representation of $\mathcal{B}_{\lambda^2-1/16}$, $\lambda\neq0$, and ρ^0 is a faithful representation of the Weyl algebra. This is useful when $\lambda\neq0$, because one can deduce a very explicit description of the algebra $\mathcal{B}_{\lambda^2-1/16}$ as the algebra generated by the two operators $\rho^\lambda(E_+)=\frac{1}{2}(d/dz)-\lambda\Delta_-$ and $\rho^\lambda(E_-)=-\frac{1}{2}z$, acting on $\mathcal{H}_+=\mathbb{C}[z]$. As a consequence, $\mathcal{B}_{\lambda^2-1/16}$ can be described by generators and relations as the algebra generated by three elements $E^\lambda_\pm$ and P satisfying $[E^\lambda_+,E^\lambda_-]=-\frac{1}{4}+\lambda P$, $E_\pm P=-PE_\pm$, and $P^2=\mathrm{Id}$. When $\lambda=0$, these relations define an algebra which is an extension of the Weyl algebra by a parity and was introduced in Ref. 9, where it was shown that it is a quasi-simple and primitive algebra. It is not a quotient of the enveloping algebra of $\mathfrak{osp}(1,2)$, but rather a quotient of the enveloping algebra of $\mathfrak{sl}(2,1)$ (see Ref. 9).

Remark (3.17): For the metaplectic representation itself, i.e. $\pi_{|\mathcal{H}^+}$, one can define a cocycle $C\in Z^1_H(\mathfrak{g},\mathcal{L}(\mathcal{H}^+))$ by $C(E_+)=\Delta_-$, and $C(E_-)=0$. It is not difficult to prove [adapting the proof of Proposition (3.13)], that $H^1_H(\mathfrak{g},\mathcal{L}(\mathcal{H}^+))=\mathbb{C}\cdot C$, and $H^1(\mathfrak{g},\mathcal{L}(\mathcal{H}^+))^{\mathfrak{h}}=\{0\}$.

IV. DEFORMATIONS OF THE EXTENDED METAPLECTIC REPRESENTATION OF $\mathfrak{g}=\mathfrak{osp}(1,4)$

Throughout this section, $\mathfrak{g}$ is the Lie superalgebra $\mathfrak{osp}(1,4)$.

[4.1] Let us briefly recall some well-known facts about $\mathfrak{g}$ and the corresponding Weyl algebra W_2. The latter is the algebra generated by $E_\pm$, $E'_\pm$ with relations $[E_+,E_-]_\mathcal{L}=[E'_+,E'_-]_\mathcal{L}=-\frac{1}{4}$, $[E_\pm,E'_\pm]_\mathcal{L}=0$. The extended metaplectic representation π of W_2 is defined on $\mathcal{H}=\mathbb{C}[z,z',z^{-1},z'^{-1}]$ by $\pi(E_+)=\frac{1}{2}(\partial/\partial z)$, $\pi(E_-)=-\frac{1}{2}z$, $\pi(E'_+)=\frac{1}{2}(\partial/\partial z')$, $\pi(E'_-)=-\frac{1}{2}z'$.

It is a Schur-irreducible representation built from irreducible subquotients, which is obtained as follows: let $\mathcal{H}_{++}=\mathrm{span}\{z^n,z'^{n'},n,n'\geqslant0\}$, $\mathcal{H}_{-+}=\mathrm{span}\{z^{-n}z'^{n'},n>0,n'\geqslant0\}$, $\mathcal{H}_{+-}=\mathrm{span}\{z^nz'^{-n'},n\geqslant0,n'>0\}$, and $\mathcal{H}_{--}=\mathrm{span}\{z^{-n},z'^{-n'},n,n'>0\}$. Then $\mathcal{H}_{++}$, $\mathcal{H}_{-+}\oplus\mathcal{H}_{++}$, $\mathcal{H}_{+-}\oplus\mathcal{H}_{++}$, $\mathcal{H}_{-+}\oplus\mathcal{H}_{++}\oplus\mathcal{H}_{+-}$ are submodules. $\mathcal{H}_{++}$ is irreducible, and isomorphic with the metaplectic representation, the quotients $(\mathcal{H}_{-+}\oplus\mathcal{H}_{++})/\mathcal{H}_{++}$ and $(\mathcal{H}_{+-}\oplus\mathcal{H}_{++})/\mathcal{H}_{++}$ are irreducible, and so does the quotient $\mathcal{H}/(\mathcal{H}_{-+}\oplus\mathcal{H}_{++}\oplus\mathcal{H}_{+-})$, which is isomorphic with the contragedient to the metaplectic representation. All the extensions involved are nontrivial. So the extended metaplectic representation is, by definition, a triplet.

Now, we introduce $\mathfrak{g}=\mathfrak{osp}(1,4)$ as the sub-Lie superalgebra of W_2, generated, as a Lie superalgebra, by $\{E_\pm,E'_\pm\}$; one has $\mathfrak{g}=\mathfrak{g}_{\bar{0}}\oplus\mathfrak{g}_{\bar{1}}$, where $\mathfrak{g}_{\bar{1}}=\mathrm{span}\{E_\pm,E'_\pm\}$, and $\mathfrak{g}_{\bar{0}}=[\mathfrak{g}_{\bar{1}},\mathfrak{g}_{\bar{1}}]$. $\mathfrak{g}_{\bar{0}}$ acts on $\mathfrak{g}_{\bar{1}}$ by the adjoint action ad, and the form defined on $\mathfrak{g}_{\bar{1}}$ by $\langle X|Y\rangle=[X,Y]_\mathcal{L}$ is invariant. It is easy to see that ad is an isomorphism from $\mathfrak{g}_{\bar{0}}$ onto $\mathfrak{sp}(4)$. Let $\mathcal{U}(\mathfrak{g})$ be the enveloping algebra of $\mathfrak{g}$. The preceding construction shows that W_2 is a quotient of $\mathcal{U}(\mathfrak{g})$. Note that $\mathfrak{g}\subset W_2$, and also $\mathfrak{g}\subset\mathcal{U}(\mathfrak{g})$, which may lead to some misunderstanding if these inclusions are not properly inter-

preted: For instance E_+ and E'_+ commute when realized as elements of W_2, but do not commute when realized as elements of $\mathcal{U}(\mathfrak{g})$! Since W_2 is a quotient of $\mathcal{U}(\mathfrak{g})$, π is also a representation of $\mathcal{U}(\mathfrak{g})$. It has some interesting properties.

First, let $\rho=\pi_{|\mathfrak{g}_0^-}$ and $\rho^+=\rho_{|\mathcal{H}_{++}}$. Then ρ^+ decomposes, under parity, into $\rho^+=\rho_0^+\oplus\rho_1^+$, and one has: $\rho_0^+\simeq \mathrm{Rac}=D(\frac{1}{2},0)$, $\rho_1^+\simeq Di=D(1,\frac{1}{2})$, the two singleton representations (see Ref. 3, and also Refs. 1, 2) which appear in the usual metaplectic representation. Second, let $\mathfrak{l}$ (resp $\mathfrak{l}'$) be the sub-Lie superalgebra of $\mathfrak{g}$ with basis $E_\pm$, $H=[E_+,E_-]$, $F=[E_+,E_+]$, and $G=-[E_-,E_-]$ (resp., $E'_\pm$, $H'=[E'_+,E'_-]$, $F'=[E'_+,E'_+]$, and $G'=-[E'_-,E'_-]$). Then $\mathfrak{l}$ and $\mathfrak{l}'$ are isomorphic to $\mathfrak{osp}(1,2)$. Let $V_{n'}$ (resp., V'_n) be the subspace of $\mathcal{H}$ with basis $\{z^n\cdot z'^{n'}, n\in\mathbb{Z}\}$ (resp., $\{z^n\cdot z'^{n'}, n'\in\mathbb{Z}\}$), then $V_{n'}$ is stable under $\pi_{|\mathfrak{l}}$ (resp., V'_n is stable under $\pi_{|\mathfrak{l}'}$), and $\pi_{|\mathfrak{l}}$ (resp., $\pi_{|\mathfrak{l}'}$) acting on $V_{n'}$ (resp., V'_n) is isomorphic to the extended metaplectic representation. Obviously, $\mathcal{H}=\oplus_{n'\in\mathbb{Z}}V_{n'}=\oplus_{n\in\mathbb{Z}}V'_n$. Third, define $Z_+=-2[E'_+,E_-]$, $Z_-=-2[E_+,E'_-]$, $T=\frac{1}{2}[Z_+,Z_-]=-[E_+,E_-]+[E'_+,E'_-]$, $U=-([E_+,E_-]+[E'_+,E'_-])$. Then $\mathfrak{h}=\mathbb{C}T\oplus\mathbb{C}U=\mathbb{C}H\oplus\mathbb{C}H'$ is a Cartan subalgebra of $\mathfrak{g}$, and the subalgebra $\mathfrak{k}$ with basis $\{Z_\pm,T,U\}$ is isomorphic to $\mathfrak{sl}(2)\oplus\mathbb{C}$. One has

$$\pi(Z_+)=z\frac{\partial}{\partial z'},\quad \pi(Z_-)=z'\frac{\partial}{\partial z},\quad \pi(T)=\frac{1}{2}\left(z\frac{\partial}{\partial z}-z'\frac{\partial}{\partial z'}\right),\quad \pi(U)=\frac{1}{2}\left(z\frac{\partial}{\partial z}+z'\frac{\partial}{\partial z'}+1\right).$$

Now the subspace Ξ_r of $\mathcal{H}$ with basis $\{z^n,z'^{n'}, n+n'=r\}$ is stable under $\pi_{|\mathfrak{k}}$, and when acting on Ξ_r, $\pi_{|\mathfrak{k}}$ is an extension of a finite dimensional representation by two (up and down) representations. Obviously, $\mathcal{H}=\oplus_{r\in\mathbb{Z}}\Xi_r$, and $\mathcal{H}_{++}$ is the space of $\mathfrak{k}$-finite vectors of $\mathcal{H}$.

[4.2] Consider deformations of π which preserve the Weyl structure, and which are still $\mathfrak{h}$-diagonal on $\oplus_{n,n'\in\mathbb{Z}}\mathcal{H}_{n,n'}$, $\mathcal{H}_{n,n'}=\mathbb{C}z^nz'^{n'}$. The corresponding cohomology is $Z^1_W(\mathfrak{g},\mathcal{L}(\mathcal{H}))=\{C\in Z^1(\mathfrak{g},\mathcal{L}(\mathcal{H}))|C(\mathfrak{h})\mathcal{H}_{n,n'}\subset\mathcal{H}_{n,n'}$ and $C([E_\pm,E'_\pm]_\mathcal{L})=C([E_+,E_-]_\mathcal{L})=C([E'_+,E'_-]_\mathcal{L})=0\}$, $B^1_W(\mathfrak{g},\mathcal{L}(\mathcal{H}))=B^1(\mathfrak{g},\mathcal{L}(\mathcal{H}))^\mathfrak{h}$ (easy to check), and $H^1_W(\mathfrak{g},\mathcal{L}(\mathcal{H}))=Z^1_W/B^1_W$.

Proposition (4.1): $\dim H^1_W(\mathfrak{g},\mathcal{L}(\mathcal{H}))=2$. *Any cocyle is equivalent to a cocycle defined, for* $\alpha,\beta\in\mathbb{C}$, *by* $C(E_-)=C(E'_-)=0$, $C(E_+)=\alpha\pi(E_-)^{-1}$, $C(E'_+)=\beta\pi(E'_-)^{-1}$, *and one has* $C(H)=2\alpha\,\mathrm{Id}_\mathcal{H}$, $C(H')=2\beta\,\mathrm{Id}_\mathcal{H}$.

Proof: Let $C\in Z^1_W(\mathfrak{g},\mathcal{L}(\mathcal{H}))$. By Lemma (2.1), $C(E_-)(\mathcal{H}_{n,n'})\subset\mathcal{H}_{n+1,n'}$, so up to a coboundary, we can assume that $C(E_-)=0$. Then $C(E'_-)(\mathcal{H}_{n,n'})\subset\mathcal{H}_{n,n'+1}$, and $C([E_-,E'_-]_\mathcal{L})=0$ leads to $[E_-,C(E'_-)]_\mathcal{L}=0$. Therefore $C(E'_-)z^nz'^{n'}=c_{n'}z^nz'^{n'+1}$, $\forall n$, n', $c_{n'}\in\mathbb{C}$, so there exists T such that $Tz^nz'^{n'}=t_{n'}z^nz'^{n'}$, and $C(E'_-)=[\pi(E'_-),T]$. But $[\pi(E_-),T]=0$, so, up to a coboundary, we can assume that $C(E_-)=C(E'_-)=0$. Since $C(\mathfrak{l})(V_{n'})\subset V_{n'}$, and $C(\mathfrak{l}')(V'_n)\subset V'_n$, $\forall n$, n', Proposition (3.10) gives $C(E_+)_{|V_{n'}}=c_{n'}\pi(E_-)^{-1}_{|V_{n'}}$ and $C(E'_+)_{|V_{n'}}=c'_n\pi(E'_-)^{-1}_{|V_{n'}}$, with $c_{n'}$, $c'_n\in\mathbb{C}$. In the Weyl algebra, one has $[E_+,E'_-]_\mathcal{L}=[E'_+,E_-]_\mathcal{L}=0$, so $[\pi(E'_-),C(E_+)]_\mathcal{L}=[\pi(E_-),C(E'_+)]_\mathcal{L}=0$. Acting on $z^nz'^{n'}$ we obtain $c_{n'}=c_{n'+1}$, and $c'_n=c'_{n+1}$, $\forall n$, n', so $C(E_+)=\alpha\pi(E_-)^{-1}$, $\alpha\in\mathbb{C}$, and $C(E'_+)=\beta\pi(E'_-)^{-1}$, $\beta\in\mathbb{C}$. To check that such a cocycle does exist, define $E^\lambda_+=\pi(E_+)+\lambda\alpha\pi(E_-)^{-1}$, $E^\lambda_-=\pi(E_-)$, $E'^\lambda_+=\pi(E'_+)+\lambda\beta\pi(E'_-)^{-1}$, and $E'^\lambda_-=\pi(E'_-)$. Then $[E^\lambda_+,E^\lambda_-]=-\frac{1}{4}$, $[E'^\lambda_+,E'^\lambda_-]=-\frac{1}{4}$, $[E^\lambda_\pm,E'^\lambda_\pm]=0$, so there exists a formal representation π^λ of the Weyl algebra such that $\pi^\lambda(E_\pm)=E^\lambda_\pm$, $\pi^\lambda(E'_\pm)=E'^\lambda_\pm$. Since the Weyl algebra is a quotient of $\mathcal{U}(\mathfrak{osp}(1,4))$, π^λ is a representation of $\mathfrak{g}$, and clearly a deformation of π. Writing $\pi^\lambda=\pi+\lambda C+\cdots$, we obtain the wanted cocycle. It cannot be a coboundary if α, or $\beta\neq0$ [see, e.g., Proposition (3.10)]. □

Exactly as at the end of the proof of Proposition (4.1), given $f,g\in\mathbb{C}[[\lambda]]$ with $f(0)=g(0)=0$, we can define a deformation of π by

$$\pi^\lambda_{f,g}(E^\lambda_+)=\pi(E_+)+f(\lambda)\pi(E_-)^{-1},\quad \pi^\lambda_{f,g}(E'_+)=\pi(E'_+)+g(\lambda)\pi(E'_-)^{-1},$$

$$\pi^\lambda_{f,g}(E_-)=\pi(E_-),\quad \pi^\lambda_{f,g}(E'_-)=\pi(E'_-).$$

One has $\pi^{\lambda}_{f,g}(H)=\pi(H)+2f(\lambda)\mathrm{Id}_{\mathcal{H}}$, and $\pi^{\lambda}_{f,g}(H')=\pi(H')+2g(\lambda)\mathrm{Id}_{\mathcal{H}}$. By Proposition (3.10), two such deformations are equivalent if and only if the associated formal series are the same. By a proof completely similar to that of Proposition (3.11), we obtain the following.

Proposition (4.2): Let π^{λ} be a deformation of π such that the Weyl structure is preserved, and $\mathfrak{h}$ is still diagonal on $\oplus_{n,n'\in Z}\mathcal{H}_{n,n'}$. Then π^{λ} is equivalent to some $\pi^{\lambda}_{f,g}$.

Remark (4.3): It is straightforward to compute the submodules of the representation $\pi^{\lambda}=\pi^{\lambda}_{f,g}$, e.g., when $f=\lambda\alpha$, $g=\lambda$, $\alpha\in\mathbb{C}$: it is enough to solve $\pi^{\lambda}(E_+)(h)=\pi^{\lambda}(E_-)(h)=0$. We shall not detail the complete results, but indicate only that, generically, π^{λ} is irreducible, and does not belong to the classes of irreducible classified up to now. In degenerate cases, π^{λ} is an extension of two irreducible representations, which are also new, and in the most degenerate cases, π^{λ} is isomorphic to the extended metaplectic representation, i.e., the representation with which we started

[4.3] We now turn to the more general problem of deformation which are still $\mathfrak{h}$-diagonal [as was done in Sec. [3.4] for $\mathfrak{osp}(1,2)$]. A subproblem is the case of deformations with unchanged weight structure. The corresponding cohomologies are defined by

$$Z^1_{\mathfrak{h}}(\mathfrak{g},\mathcal{L}(\mathcal{H}))=\{C\in Z^1(\mathfrak{g},\mathcal{L}(\mathcal{H}))\,|\,C(\mathfrak{h})(\mathcal{H}_{n,n'})\subset\mathcal{H}_{n,n'}\},\quad \mathcal{H}_{n,n'}=\mathbb{C}z^n z'^{n'},$$

$$Z^1(\mathfrak{g},\mathcal{L}(\mathcal{H}))^{\mathfrak{h}}=\{C\in Z^1(\mathfrak{g},\mathcal{L}(\mathcal{H}))\,|\,C(\mathfrak{h})=0\},\quad B^1_{\mathfrak{h}}(\mathfrak{g},\mathcal{L}(\mathcal{H}))=B^1(\mathfrak{g},\mathcal{L}(\mathcal{H}))^{\mathfrak{h}},$$

$$H^1_{\mathfrak{h}}(\mathfrak{g},\mathcal{L}(\mathcal{H}))=Z^1_{\mathfrak{h}}(\mathfrak{g},\mathcal{L}(\mathcal{H}))/B^1_{\mathfrak{h}}(\mathfrak{g},\mathcal{L}(\mathcal{H})),$$

and

$$H^1(\mathfrak{g},\mathcal{L}(\mathcal{H}))^{\mathfrak{h}}=Z^1(\mathfrak{g},\mathcal{L}(\mathcal{H}))^{\mathfrak{h}}/B^1(\mathfrak{g},\mathcal{L}(\mathcal{H}))^{\mathfrak{h}}.$$

It is clear that $H^1(\mathfrak{g},\mathcal{L}(\mathcal{H}))^{\mathfrak{h}}$ and $H^1_W(\mathfrak{g},\mathcal{L}(\mathcal{H}))$ are contained in $H^1_{\mathfrak{h}}(\mathfrak{g},\mathcal{L}(\mathcal{H}))$. In the case of $\mathfrak{osp}(1,2)$, the last one was the direct sum of the first two, both of them being one dimensional and we constructed interesting deformations, with modified Casimir values [see, e.g., Propositions (3.13), (3.14) and Remark (3.16)]. The situation is very different here, for $\mathfrak{g}=\mathfrak{osp}(1,4)$, as shown by the next result.

Theorem (4.4): *$H^1(\mathfrak{g},\mathcal{L}(\mathcal{H}))^{\mathfrak{h}}=\{0\}$, and $H^1_{\mathfrak{h}}(\mathfrak{g},\mathcal{L}(\mathcal{H}))=H^1_W(\mathfrak{g},\mathcal{L}(\mathcal{H}))$.*

Remark (4.5): Theorem (4.4) shows that all deformations with unchanged weight structure are trivial. First order $\mathfrak{h}$-diagonal deformations are representations of the Weyl algebra, and there is no analog to the representations constructed in Remark (3.16).

Proof of Theorem (4.4): Starting with $C\in Z^1_{\mathfrak{h}}(\mathfrak{g},\mathcal{L}(\mathcal{H}))$, one has $C(E_-)(\mathcal{H}_{n,n'})\subset\mathcal{H}_{n+1,n'}$ by Lemma(2.1). So, up to a coboundary, we can assume that $C(E_-)=0$. We shall now prove that we can also assume, by a good choice of the coboundary, that $C(E'_-)=0$.

First, since $C(G')(\mathcal{H}_{n,n'})\subset\mathcal{H}_{n,n'+2}$, and $[E_-,G']=0$, so that $[E_-,C(G')]=0$, we can assume, up to a coboundary, that $C(G')=0$. Let $C(E'_-)z^n z'^{n'}=c_{n,n'}z^n z'^{n'+1}$. From $[G,E'_-]=0$, so that $[G,C(E'_-)]=0$, we deduce $c_{2p,n'}=c_{0,n'}$, and $c_{2p+1,n'}=c_{1,n'}$, so we can write $C(E'_-)z^{2p}z'^{n'}=c_{n'}z^{2p}z'^{n'+1}$, and $C(E'_-)z^{2p+1}z'^{n'}=d_{n'}z^{2p+1}z'^{n'+1}$. Now $[E'_-,E'_-]=-G'$, so that $[E'_-,C(E'_-)]=0$ and we get $c_{n'}=(-1)^{n'}c_0$, and $d_{n'}=(-1)^{n'}d_0$. Define T by $T(z^n z'^{n'})=z^n z'^{n'}$, if n' is even, and 0 if n' is odd. The coboundary $D=[\cdot,T]$ satisfies $D(E_-)=0$, and $D(E'_-)(z^n z'^{n'})=((-1)^{n'+1}/2)z^n z'^{n'+1}$. So the cocycle $\tilde{C}=C+2c_0D$ satisfies $\tilde{C}(E_-)=0$, $\tilde{C}(E'_-)z^n z'^{n'}=0$, if n is even, and $\tilde{C}(E'_-)z^n z'^{n'}=(d_0-c_0)(-1)^{n'}z^n z'^{n'+1}$, if n is odd. Let $d=d_0-c_0$.

It is clear that $\tilde{C}(\mathfrak{l}')(V'_n)\subset V'_n$, and, as a cocycle of $\mathfrak{l}'=\mathfrak{osp}(1,2)$, $\tilde{C}$ belongs to $Z^1_H(\mathfrak{l}',\mathcal{L}(V'_n))$, and V'_n is the extended metaplectic representation, so Proposition (3.13) can be applied. There are two cases: since $\tilde{C}(E'_-)=0$ on V'_{2p}, one has $\tilde{C}(E'_+)z^{2p}z'^{n'}=(\beta_{2p}+(-1)^{n'-1}\gamma_{2p})z^{2p}z'^{n'-1}$. But we can also use the cocycle $\hat{C}=C+2d_0D$, with $\hat{C}(E'_-)$ vanishing on V'_{2p+1}, to deduce

$$\tilde{C}(E'_+)z^{2p+1}z'^{n'}=(\hat{C}-2dD)(E'_+)z^{2p+1}z'^{n'}$$
$$=(\beta_{2p+1}+(-1)^{n'-1}\gamma_{2p+1}-(-1)^{n'}dn')z^{2p+1}z'^{n'-1}.$$

Now we use $[[E_-,E'_+],E'_-]=\frac{1}{2}E_-$, so that $[[E_-,E'_+],\tilde{C}(E'_-)]-[E'_-,\tilde{C}([E_-,E'_+])]=0$. Note that $\tilde{C}([E_-,E'_+])=[E_-,\tilde{C}(E'_+)]$. By a straightforward computation, acting on $z^{2p}z'^{n'}$, and then on $z^{2p+1}z'^{n'}$, we deduce $d=-2(\gamma_{2p}+\gamma_{2p+1})=2(\gamma_{2p+1}+\gamma_{2p+2})$, so that $\gamma_n=(-1)^n\,[\gamma_0+nd/2]$.

In order to decompose $\tilde{C}$ into $Z^{1\mathfrak{h}}+Z^1_W$ we have to evaluate $\tilde{C}(H')=[\tilde{C}(E'_+),E'_-]$ and $\tilde{C}(H)=[\tilde{C}(E_+),E_-]$. Acting on $z^{2p}z'^{n'}$ and $z^{2p+1}z'^{n'}$ we get $\tilde{C}(H')z^nz'^{n'}=-\beta_nz^nz'^{n'}$. Again Proposition (3.13) can be applied to $\tilde{C}_{|\mathfrak{l}}$ considered as an element of $Z^1_H(\mathfrak{l},\mathcal{L}(V_{n'}))$, so $\tilde{C}(E_+)z^nz'^{n'}=(\alpha_{n'}+(-1)^{n-1}\delta_{n'})z^{n-1}z'^{n'}(\alpha_{n'},\delta_{n'}\in\mathbb{C})$. Hence $\tilde{C}(H)z^nz'^{n'}=-\alpha_{n'}z^nz'^{n'}$. Since $[H,E'_-]=[H',E_-]=0$, we obtain $\alpha_{n'}=\alpha$ and $\beta_n=\beta(\alpha,\beta\in\mathbb{C})$ for every n, n'. Therefore $\tilde{C}$ can be written as the sum of a cocycle D in Z^1_W [according to Proposition (4.1)] and of $C_1=\tilde{C}-D$ in $Z^{1\mathfrak{h}}$, D being defined by $D(E_+)z^nz'^{n'}=\alpha z^{n-1}z'^{n'}$, $D(E'_+)z^nz'^{n'}=\beta z^nz'^{n'-1}$ and $D(E_-)=D(E'_-)=0$.

There remains to show that $\tilde{C}-D=0$ in order to prove $H^1_{\mathfrak{h}}=H^1_W$ and thus $H^{1\mathfrak{h}}=\{0\}$. Exactly as for (γ_n), using the relation $[[E'_-,E_+],E_-]=-\frac{1}{2}E'_-$, we have $d=2(-1)^{n'}(\delta_{n'}+\delta_{n'+1})$ and so $\delta_{n'}=(-1)^{n'}\,[\delta_0-n'(d/2)]$. Lengthy but straightforward calculations yield

$$C_1([E_+,E'_+])z^nz'^{n'}=-\tfrac{1}{2}[(-1)^nn'(\delta_{n'}+\delta_{n'-1})+(-1)^{n'}n(\gamma_n+\gamma_{n-1})$$
$$+(-1)^nnn'd]z^{n-1}z'^{n'}.$$

Since $[[E_+,E'_+],E_+]=0$, one has $[[E_+,E'_+],C_1(E_+)]-[E_+,C_1([E_+,E'_+])]=0$, so that $2\delta_0+d(n^2-2n+\frac{1}{2})=0$. Therefore $d=\delta_0=0$ and C_1 satisfies $C_1(E_-)=C_1(E'_-)=C_1(E_+)=0$ and $C_1(E'_+)z^nz'^{n'}=(-1)^{n+n'}\gamma z^nz'^{n'-1}$. Then $C_1([E_+,E'_+])=0$ and from $[[E_+,E'_+],[E_+,E'_-]]=-\frac{1}{2}[E'_+,E'_+]$ it follows that $C_1([E'_+,E'_+])=0$. So (acting on $z^nz'^{n'}$) $\gamma=0$. Thus $C_1=0$. □

Remark (4.6): The preceding results suggest that the metaplectic representation $\rho=\pi_{|\mathcal{H}_{++}}$ is rigid (in the category of $\mathfrak{h}$-diagonal deformations). This is indeed the case.

Theorem (4.7): $H^1_{\mathfrak{h}}(\mathfrak{g},\mathcal{L}(\mathcal{H}_{++}))=\{0\}$.

Proof: We start with $C\in Z^1_{\mathfrak{h}}(\mathfrak{g},\mathcal{L}(\mathcal{H}_{++}))$, following (with the same notations) the proof of Theorem (4.4), we can suppose, up to a coboundary, that C satisfies, $C(E_-)=0$, $C(E'_-)z^{2p}z'^{n'}=0$, $C(E'_-)z^{2p+1}z'^{n'}=(-1)^{n'}dz^{2p+1}z'^{n'+1}$ with $d\in\mathbb{C}$. Denoting by V'^{+}_n the subspace $V'_n\cap\mathcal{H}_{++}$, one has $C_{|\mathfrak{l}'}\in Z^1_H(\mathfrak{l}',\mathcal{L}(V'^{+}_n))$. Using Remark (3.17), $C(E'_+)$ on V'^{+}_n is given by $C(E'_+)z^{2p}z'^{n'}=\beta_{2p}(1+(-1)^{n'-1})z^{2p}z'^{n'-1}$ and $C(E'_+)z^{2p+1}z'^{n'}=[\beta_{2p+1}(1+(-1)^{n'-1})-dn'(-1)^{n'}]z^{2p+1}z'^{n'-1}$ if $n'\geqslant 1$ [$C(E'_+)z^nz'^{n'}$ vanishes if $n'=0$]. Considering $C_{|\mathfrak{l}}$ as an element of $Z^1_H(\mathfrak{l},\mathcal{L}(V^+_{n'}))$, we have $C(E_+)z^nz'^{n'}=\alpha_{n'}(1+(-1)^{n-1})z^{n-1}z'^{n'}$, if $n\geqslant 1$, and $C(E_+)z^nz'^{n'}=0$ if $n=0$. Again [see the proof of Theorem (4.4)] we have $\beta_n=(-1)^n\,[\beta_0+n(d/2)]$; since $[E_-,H']=0$ and $[E'_-,H]=0$, we have $\beta_n=\beta$ and $\alpha_{n'}=\alpha(\alpha,\beta\in\mathbb{C})$ for every n, $n'\in\mathbb{N}$, so that $\beta=d=0$. Now from the relation $[[E'_-,E_+],E_-]=-\frac{1}{2}E'_-$, acting on $z^nz'^{n'}$ with n even, we get, $\alpha=(-1)^{n'+1}(d/4)$, so $\alpha=0$. □

Remark (4.8): Theorems (4.4) and (4.7) are valid for $\mathfrak{osp}(1,2n)$, $n\geqslant 2$. The proofs are obtained by induction and the application of arguments completely similar to (and even simpler than) the arguments for $\mathfrak{osp}(1,4)$.

We study integral-difference collision operators with a truncated Gaussian equilibrium distribution function. We prove that the number of eigenvalues in an arbitrary small vicinity of zero goes to infinity when the truncation parameter goes to infinity. © *2001 American Institute of Physics.* [DOI: 10.1063/1.1354643]

I. INTRODUCTION

We continue the study[1–3] of operators of the form

$$\mathcal{K}_\varphi : u(x) \mapsto \int_{-\infty}^{\infty} \frac{u(x)\varphi(s) - u(s)\varphi(x)}{|x-s|}\, ds, \tag{1}$$

acting originally in the Hilbert space $L_2(\mathbf{R}, dx)$. Here $\varphi(x)$ is the so-called equilibrium distribution function, having the following properties induced by its physical nature as a probability distribution:

$$\varphi(x) \geqslant 0; \quad \int_{-\infty}^{\infty} \varphi(x)\, dx = 1.$$

Such operators appear as collision operators in nonequilibrium statistical physics models.[4,5] In our previous papers[1–3] we have investigated spectral properties of operators $\mathcal{K}_\varphi$ under some additional conditions on function $\varphi(x)$. In particular, in the case when $\varphi(x)$ has compact support, the spectral analysis of the operator $\mathcal{K}_\varphi$ may be essentially reduced to the spectral analysis of the operator,

$$K_\varphi : u(x) \mapsto \int_{-1}^{1} \frac{u(x)\varphi(s) - u(s)\varphi(x)}{|x-s|}\, ds, \tag{2}$$

acting in the Hilbert space $L_2[-1,1]$. The spectral analysis of the operator K_φ is based on the following useful representation:[2,3]

$$K_\varphi = \varphi \circ K_0 - (K_0 \varphi), \tag{3}$$

where operator K_0 is defined as

$$K_0 : u \mapsto \int_{-1}^{1} \frac{u(x) - u(s)}{|x-s|}\, ds, \tag{4}$$

and $(K_0\varphi)$ stands for the operator of multiplication by function $K_0\varphi(x)$. The spectral problem for operator K_0 happened to be exactly solvable.[1] The eigenvalues are

a)Electronic mail: imelniko@ulb.ac.be

$$\mu_0=0; \quad \mu_n=2\sum_{j=1}^{n}\frac{1}{j}, \quad n=1,2,..., \tag{5}$$

and the correspondent eigenfunctions are Legendre polynomials $p_n(x)$.

However, physically important Gaussian equilibrium distributions have infinite support and there are not many results known concerning the spectral analysis of the corresponding collision operator. In our paper[3] we have considered a family of operators K_{φ_a} with a truncated Gaussian equilibrium distribution function,

$$\varphi(x)=C_a e^{-x^2}, \quad C_a^{-1}=\int_{-a}^{a} e^{-x^2}\,dx=\sqrt{\pi}\,\mathrm{erf}(a), \tag{6}$$

on the interval $[-a,a]$. We have proved[3] analytically that the first two eigenvalues λ_1, λ_2 of operator K_a go to zero $\sim a^{-1}$ when $a\to\infty$ and have confirmed it numerically for several other lower eigenvalues. In the present paper we shall prove analytically that zero becomes a point of spectral concentration when $a\to\infty$, i.e., the number of the eigenvalues in an arbitrary small vicinity of zero increases unlimitedly as $a\to\infty$.

II. RESULT

We study a family of operators,

$$K_{\varphi_a}: u(x)\mapsto\int_{-a}^{a}\frac{u(x)\varphi(s)-u(s)\varphi(x)}{|x-s|}\,ds, \tag{7}$$

on the interval $[-a,a]$ with the equilibrium distribution function $\varphi(x)$ given by Eq. (6). As we have shown in our paper,[3] a simple change of variables makes the spectral problem for operator K_{φ_a} equivalent to the spectral problem for the operator

$$K_a: u(x)\mapsto\int_{-1}^{1}\frac{u(x)\varphi_a(s)-u(s)\varphi_a(x)}{|x-s|}\,ds, \tag{8}$$

on the interval $[-1, 1]$, where

$$\varphi_a(x):=C_a e^{-a^2x^2}. \tag{9}$$

It is more convenient to study the spectral properties of our operator in the form (8).

We use notations

$$\langle u,v\rangle:=\int_{-1}^{1}u(x)\overline{v}(x)\,\frac{dx}{\varphi_a(x)},$$

for the inner product in space $L_2([-1,1],dx/\varphi_a(x))$ and

$$(u,v):=\int_{-1}^{1}u(x)\overline{v}(x)\,dx,$$

for the inner product in the space $L_2([-1,1],dx)$.

Let us denote by $E_a[-M,M]$ the spectral measure of the operator K_a on the interval $[-M,M]\subset\mathbf{R}$. By $\mathcal{H}_a=L_2([-1,1],dx/\varphi_a(x))$ we denote Hilbert space, where operator K_a acts as a self-adjoint operator.[1] The main result of this paper is the following.

Theorem: *For any* $M>0$,

$$\dim(E_a[-M,M]\mathcal{H}_a)\to\infty, \quad \text{as} \quad a\to\infty. \tag{10}$$

This theorem means that the number of eigenvalues (counted with multiplicity) of the operator K_a (and, consequently, of the operator K_{φ_a}) in an arbitrary small vicinity of zero increases to infinity when the truncation parameter a goes to infinity. Indeed, as it is shown in our previous papers,[2,3] the spectrum of the operators K_{φ_a} is purely discrete for all $a<\infty$. Hence, the increase of the spectral measure on the interval $[-M,M]$ can be caused only by the increase of the number of the eigenvalues (counted with multiplicity) on this interval. Therefore zero is a point of spectral concentration for the limit operator $\mathcal{K}_\infty=\lim_{a\to\infty} K_{\varphi_a}$.

We shall prove this theorem using the bilinear form approach. In order to prove our theorem it is enough[6,7] to construct for all $N>0$ a linear set $F_N^a\subset D(K_a)$, $\dim F_N^a=N$, such that for any $M>0$ there exists $a_0(N,M)$ such that for all $a>a_0(N,M)$ inequality,

$$|\langle K_a u,u\rangle|\leqslant M\langle u,u\rangle, \tag{11}$$

is true for all $u\in F_N^a$.

We construct F_N^a as a linear span,

$$F_N^a:=\bigvee_{k=0}^{N-1} u_k, \quad u_k(x):=p_k(x)\varphi_a^{1/2}(x),$$

where $p_k(x)$ are Legendre polynomials normalized in space $L_2([-1,1],dx)$ [the eigenfunctions of operator K_0 given by Eq. (4)].[1] Functions $u_k(x)$ are orthogonal in the space $L_2([-1,1], dx/\varphi_a(x))$, therefore $\dim F_N^a=N$ for all a.

Any function $u\in F_N^a$ can be represented as $u(x)=\Sigma_{k=0}^{N-1}\alpha_k u_k(x)$. Obviously,

$$\langle u,u\rangle=\sum_{k=0}^{N-1}\sum_{l=0}^{N-1}\alpha_k\overline{\alpha_l}(p_k,p_l)=\sum_{k=0}^{N-1}|\alpha_k|^2. \tag{12}$$

On the other hand, using representation (3), we have

$$\langle K_a u,u\rangle=(K_0 u,u)-\langle (K_0\varphi_a)u,u\rangle. \tag{13}$$

Let us first estimate the term

$$\begin{aligned}
|\langle (K_0\varphi_a)u,u\rangle| &= \left|\sum_{k=0}^{N-1}\sum_{l=0}^{N-1}\alpha_k\overline{\alpha_l}(K_0(\varphi_a)p_k,p_l)\right| \\
&= \left|\sum_{k=0}^{N-1}\sum_{l=0}^{N-1}\alpha_k\overline{\alpha_l}\int_{-1}^{1}\int_{-1}^{1}dx\,ds\,p_k(x)p_l(x)\,\frac{\varphi_a(x)-\varphi_a(s)}{|x-s|}\right| \\
&= \left|\sum_{k=0}^{N-1}\sum_{l=0}^{N-1}\alpha_k\overline{\alpha_l}\int_{-1}^{1}\int_{-1}^{1}dx\,ds\left[\frac{\varphi_a(x)p_k(x)p_l(x)}{|x-s|}-\frac{\varphi_a(x)p_k(s)p_l(s)}{|x-s|}\right]\right| \\
&= \left|\sum_{k=0}^{N-1}\sum_{l=0}^{N-1}\alpha_k\overline{\alpha_l}(\varphi_a,K_0(p_k p_l))\right|,
\end{aligned}$$

with a simple change of variables between x and s in the second term. Let us estimate terms $(\varphi_a,K_0(p_k p_l))$. As $p_k,p_l\in F_N^a$, then $k,l\leqslant N-1$, therefore the product of these Legendre polynomials is a polynomial of the power not higher than $2N-2$. Therefore one can represent

$$p_k(x)p_l(x)=\sum_{m=0}^{2N-2}\gamma_{kl}^m p_m(x),$$

where

$$\gamma_{kl}^m := \int_{-1}^{1} p_k(x)p_l(x)p_m(x)dx < \infty,$$

for all k,l,m. Therefore

$$|(\varphi_a, K_0(p_k p_l))| = \left| \sum_{m=0}^{2N-2} \gamma_{kl}^m (\varphi_a, K_0 p_m) \right| = \left| \sum_{m=0}^{2N-2} \gamma_{kl}^m \mu_m (\varphi_a, p_m) \right|.$$

Using the Laplace method[8] we find the asymptotics

$$(\varphi_a, p_m) = C_a \int_{-1}^{1} p_m(x) e^{-a^2 x^2} dx = C_a \sqrt{\pi} p_m(0) a^{-1}(1 + O(a^{-1})), \text{ as } a \to \infty.$$

Obviously $C_a < C_1$ for $a > 1$. Thus, we got the estimate at $a \to \infty$,

$$\left| \sum_{k=0}^{N-1} \sum_{l=0}^{N-1} \alpha_k \overline{\alpha_l} (\varphi_a, K_0(p_k p_l)) \right|$$
$$\leqslant 2C_1 \sum_{m=0}^{2N-2} \mu_m |p_m(0)| \max_{0 \leqslant k \leqslant N-1} \max_{0 \leqslant l \leqslant N-1} |\gamma_{kl}^m| \left| \sum_{k=0}^{N-1} \sum_{l=0}^{N-1} \alpha_k \overline{\alpha_l} \right| a^{-1}(1 + O(a^{-1})).$$

Obviously

$$|\alpha_k \overline{\alpha_l}| \leqslant \frac{(|\alpha_k| + |\alpha_l|)^2}{2};$$

therefore

$$\left| \sum_{k=0}^{N-1} \sum_{l=0}^{N-1} \alpha_k \overline{\alpha_l} \right| \leqslant 2N^2 \max_{0 \leqslant k \leqslant N-1} |\alpha_k|^2 \leqslant 2N^2 \sum_{k=0}^{N-1} |\alpha_k|^2.$$

Finally we have obtained the estimate

$$|((K_0 \varphi_a)u, u)| = \left| \sum_{k=0}^{N-1} \sum_{l=0}^{N-1} \alpha_k \overline{\alpha_l} (\varphi_a, K_0(p_k p_l)) \right|$$
$$\leqslant A(N) a^{-1} \sum_{k=0}^{N-1} |\alpha_k|^2 (1 + O(a^{-1})), \tag{14}$$

where the coefficient,

$$A(N) := 4C_1 N^2 \sum_{m=0}^{2N-2} \mu_m |p_m(0)| \max_{0 \leqslant k \leqslant N-1} \max_{0 \leqslant l \leqslant N-1} |\gamma_{kl}^m|,$$

does not depend on a and finite for any $N < \infty$.

Now let us estimate the term

$$(K_0 u, u) = \sum_{k=0}^{N-1} \sum_{l=0}^{N-1} \alpha_k \overline{\alpha_l} (K_0(p_k \varphi_a^{1/2}), p_l \varphi_a^{1/2}).$$

We have

$$(K_0(p_k\varphi_a^{1/2}),p_l\varphi_a^{1/2})=\int_{-1}^{1}dx\,p_l(x)\varphi_a^{1/2}(x)\int_{-1}^{1}ds\,\frac{p_k(x)\varphi_a(x)-p_k(s)\varphi_a(s)}{|x-s|}.$$

We split the domain of integration into two parts, one where $|x-s|<a^{-1/2}$, and the other one where $|x-s|\geqslant a^{-1/2}$. Then we can write

$$(K_0(p_k\varphi_a^{1/2}),p_l\varphi_a^{1/2})=\mathcal{I}_1+\mathcal{I}_2, \tag{15}$$

$$\mathcal{I}_1:=C_a\int\int_{|x-s|<a^{-1/2}}p_l(x)e^{-a^2x^2/2}\,\frac{p_k(x)e^{-a^2x^2/2}-p_k(s)e^{-a^2s^2/2}}{|x-s|}\,ds\,dx;$$

$$\mathcal{I}_2:=C_a\int\int_{|x-s|\geqslant a^{-1/2}}p_l(x)e^{-a^2x^2/2}\,\frac{p_k(x)e^{-a^2x^2/2}-p_k(s)e^{-a^2s^2/2}}{|x-s|}\,ds\,dx;$$

and estimate integrals $\mathcal{I}_1$ and $\mathcal{I}_2$ separately.

For $\mathcal{I}_1$ we have

$$|\mathcal{I}_1|\leqslant C_a\max_{x\in[-1,1]}|p_l(x)|\int\int_{|x-s|\leqslant a^{-1/2}}e^{-a^2x^2/2}\left|\frac{1}{x-s}\int_s^x(p_k(t)e^{-a^2t^2/2})'\,dt\right|ds\,dx$$

$$\leqslant C_a\max_{x\in[-1,1]}|p_l(x)|\max_{x\in[-1,1]}|(p_k(x)e^{-a^2x^2/2})'|\int\int_{|x-s|\leqslant a^{-1/2}}e^{-a^2x^2/2}\,ds\,dx. \tag{16}$$

One can estimate

$$\max_{x\in[-1,1]}|(p_k(x)e^{-a^2x^2/2})'|\leqslant\max_{x\in[-1,1]}|p_k'(x)|+a^2\max_{x\in[-1,1]}|p_k(x)|\max_{x\in[-1,1]}|xe^{-a^2x^2/2}|$$

$$=\max_{x\in[-1,1]}|p_k'(x)|+ae^{-1/2}\max_{x\in[-1,1]}|p_k(x)|. \tag{17}$$

Now we estimate

$$\int\int_{|s-x|\leqslant a^{-1/2}}e^{-a^2x^2/2}\,ds\,dx\leqslant\int_{-1}^{1}ds\int_{a-a^{-1/2}}^{s+a^{1/2}}dx\,e^{-a^2x^2/2}=\mathcal{I}_3+\mathcal{I}_4, \tag{18}$$

where

$$\mathcal{I}_3=\int_{2a^{-1/2}\leqslant|s|\leqslant1}ds\int_{s-a^{-1/2}}^{s+a^{1/2}}dx\,e^{-a^2x^2/2};$$

$$\mathcal{I}_4=\int_{-2a^{-1/2}}^{2a^{-1/2}}ds\int_{s-a^{-1/2}}^{s+a^{1/2}}dx\,e^{-a^2x^2/2}.$$

Everywhere in the domain of integration of $\mathcal{I}_3$ we have $|x|\geqslant a^{-1/2}$; therefore

$$\mathcal{I}_3\leqslant 2a^{-1/2}\max_{|x|\geqslant a^{-1/2}}e^{-a^2x^2/2}=2a^{-1/2}e^{-a/2}. \tag{19}$$

On the other hand,

$$\mathcal{I}_4\leqslant\int_{-2a^{-1/2}}^{2a^{-1/2}}ds\int_{-a^{-1/2}}^{a^{1/2}}dx\,e^{-a^2x^2/2}=4a^{-1/2}\int_{-a^{-1/2}}^{a^{1/2}}dxe^{-a^2x^2/2}.$$

Using the Laplace method[8] we get the asymptotics

$$\int_{-a^{-1/2}}^{a^{1/2}} dx\, e^{-a^2x^2/2} = a^{-1}\sqrt{\pi/2}(1+O(a^{-1/2})), \quad \text{as } a\to\infty;$$

therefore

$$\mathcal{I}_4 \leqslant a^{-3/2} 4\sqrt{\pi/2}(1+O(a^{-1/2})), \quad \text{as } a\to\infty. \tag{20}$$

Combining Eqs. (16)–(20) we get at $a\to\infty$:

$$|\mathcal{I}_1| \leqslant a^{-1/2} C_1 4\sqrt{\pi/2} e^{-1/2} \max_{x\in[-1,1]} |p_l(x)| \max_{x\in[-1,1]} |p_k(x)| (1+O(a^{-1/2})). \tag{21}$$

Now let us estimate $\mathcal{I}_2$:

$$|\mathcal{I}_2| \leqslant a^{1/2} C_a \int_{-1}^{1}\int_{-1}^{1} dx\, ds |p_l(x) e^{-a^2x^2/2}(p_k(x)e^{-a^2x^2/2} - p_k(s)e^{-a^2x^2/2})|$$

$$\leqslant a^{1/2} 2 C_a \max_{x\in[-1,1]} |p_l(x)| \max_{x\in[-1,1]} |p_k(x)| \int_{-1}^{1} e^{-a^2x^2/2}\, dx.$$

Again using the Laplace method[8] we have the asymptotics

$$\int_{-1}^{1} e^{-a^2x^2/2}\, dx = \sqrt{\pi} a^{-1}(1+O(a^{-1/2})), \quad \text{as } a\to\infty,$$

and therefore

$$|\mathcal{I}_2| \leqslant a^{-1/2} 2 C_1 \sqrt{\pi} \max_{x\in[-1,1]} |p_l(x)| \max_{x\in[-1,1]} |p_k(x)| (1+O(a^{-1})). \tag{22}$$

From Eqs. (15), (21), and (22) we see now that at $a\to\infty$,

$$|(K_0(p_k\varphi_a^{1/2}), p_l\varphi_a^{1/2})| \leqslant a^{-1/2} 2 C_1 \sqrt{\pi}(1+\sqrt{2}e^{-1/2}) \max_{x\in[-1,1]} |p_l(x)| \max_{x\in[-1,1]} |p_k(x)| (1+O(a^{-1}));$$

therefore at $a\to\infty$,

$$|(K_0 u, u)| = \left| \sum_{k=0}^{N-1} \sum_{l=0}^{N-1} \alpha_k \overline{\alpha_l} (K_0(p_k\varphi_a^{1/2}), p_l\varphi_a^{1/2}) \right|$$

$$\leqslant B(N) a^{-1/2} \sum_{k=0}^{N-1} |\alpha_k|^2 (1+O(a^{-1})), \tag{23}$$

where the coefficient

$$B(N) := 4N^2 C_1 \sqrt{\pi}(1+\sqrt{2}e^{-1/2}) \max_{0\leqslant k\leqslant N-1} \max_{x\in[-1,1]} |p_k(x)|^2$$

does not depend on a and finite for any $N<\infty$. Formulas (12)–(14), (23) mean that for any $N>0$, and $M>0$; and any function $u(x)=\Sigma_{k=0}^{N-1}\alpha_k u_k(x) \in F_N^a$, inequality (11) is satisfied for sufficiently large a, $a>a_0(N,M)$. Taking into account the normalization of the Legendre polynomials $p_k(x)$ in $L_2([-1,1],dx)$, we get a very rough estimate, $a_0(N,M) \leqslant N^6 M^{-2} 16\pi C_1^2 (1+\sqrt{2e^{-1/2}})^2$. The theorem is proved.

III. CONCLUSIONS

In the present paper we have proved that zero becomes a point of spectral concentration for collision operators with a truncated Gaussian equilibrium distribution function when the truncation parameter a goes to infinity. Nevertheless, other spectral properties of the limit operator are still unknown. In particular, it would be very interesting to clarify if the discrete spectrum of the truncated operators condenses into continuous one when $a \to \infty$.

As concerns physical conclusions, they have been discussed in our previous paper.[3]

$\perp$-order automorphisms of Hilbert space effect algebras: The two-dimensional case

Lajos Molnár[a] and Zsolt Páles[b]

It is well known that the $\perp$-order automorphisms of the effect algebra of a Hilbert space of dimension not less than three are implemented by unitary or antiunitary operators. The aim of this paper is to show that the same assertion also holds true in the two-dimensional case. © *2001 American Institute of Physics.*
[DOI: 10.1063/1.1352052]

Let H be a (real or complex) Hilbert space. The effect algebra of H is the operator interval $[0,I]$ of all positive (self-adjoint, bounded linear) operators on H which are bounded by the identity I. Effect algebras play a very important role in the mathematical foundations of quantum mechanics (see, e.g., Ref. 1). It is well known that if the dimension of H is at least three, then the $\perp$-order automorphisms of $[0,I]$ (which are the bijective transformations of the effect algebra that preserve the order $\leqslant$ in both directions and also preserve the orthocomplementation $\perp: E \mapsto I - E$) are implemented by unitary or antiunitary operators on H (see Ref. 1, Sec. V 5 and Ref. 2). In fact, the proof is usually based on the fundamental theorem of projective geometry which holds true only in spaces of dimension not less than three. Because of the importance of effect algebras, it is a natural problem to clarify the situation in the two-dimensional case. In fact, Cassinelli *et al.* faced this issue in their paper[2] (it is trivial that the corresponding assertion fails to hold in one dimension). Moreover, in their recent work,[3] Lahti *et al.* showed that if the considered automorphism is induced via the functional calculus by a Borel function of the interval $[0,1]$, then it is necessarily the identity. The aim of this paper is to present the complete solution of the problem.

We have the following result.

Theorem: *Let H be a two-dimensional (real or complex) Hilbert space and let $[0,I]$ be the effect algebra of H. Let $\phi:[0,I]\to[0,I]$ be a bijective transformation with the property that*

$$E \leqslant F \Leftrightarrow \phi(E) \leqslant \phi(F) \quad \text{and} \quad \phi(I-E) = I - \phi(E)$$

hold for every $E,F \in [0,I]$. Then there exists an either unitary or antiunitary operator U on H such that

$$\phi(E) = UEU^* \quad (E \in [0,I]).$$

Proof: Several times in the proof we shall use the following easy observation: If A, B are positive (self-adjoint) operators, $B \leqslant A$, and A is of rank one, then $B = \lambda A$ for some scalar $\lambda \geqslant 0$.

We recall that every bijection of the effect algebra of a Hilbert space which preserves the order in both directions necessarily preserves the projections as well as their ranks in both directions (see [Ref. 1, Theorem 5.8, p. 219]). Clearly, we have $\phi(0)=0$, $\phi(I)=I$.

In what follows, let P be any rank-one projection on H and let Q be its orthogonal complement. Pick $\lambda \in [0,1]$. Since $0 \leqslant \phi(\lambda P) \leqslant \phi(P)$, it follows that $\phi(\lambda P) = f_P(\lambda)\phi(P)$ for some

[a]Electronic mail: molnarl@math.klte.hu
[b]Electronic mail: pales@math.klte.hu

scalar $f_P(\lambda)\in[0,1]$. Clearly, $f_P:[0,1]\to[0,1]$ is a strictly monotone increasing bijection (observe that ϕ^{-1} has the same properties as ϕ). If $\lambda\in[0,1]$, then from the inequality

$$\phi(Q)\leqslant\phi(\lambda P+Q)\leqslant I=\phi(P)+\phi(Q)$$

we obtain

$$0\leqslant\phi(\lambda P+Q)-\phi(Q)\leqslant\phi(P).$$

This implies that

$$\phi(\lambda P+Q)=h_P(\lambda)\phi(P)+\phi(Q)$$

for some scalar $h_P(\lambda)\in[0,1]$. Similiary to the case of f_P, $h_P:[0,1]\to[0,1]$ is a strictly monotone increasing bijection. We show that $h_P=f_P$. Indeed, since

$$f_P(\lambda)\phi(P)=\phi(\lambda P)\leqslant\phi(\lambda P+Q)=h_P(\lambda)\phi(P)+\phi(Q),$$

it follows that $f_P\leqslant h_P$. Considering the inverse ϕ^{-1} of ϕ, it is easy to see that

$$\phi^{-1}(\lambda\phi(P))=f_P^{-1}(\lambda)P$$

and

$$\phi^{-1}(\lambda\phi(P)+\phi(Q))=h_P^{-1}(\lambda)P+Q.$$

Therefore, just as mentioned previously, we can deduce that $f_P^{-1}\leqslant h_P^{-1}$. Since the functions $f_P,h_P:[0,1]\to[0,1]$ are monotone increasing we then conclude that $f_P=h_P$. From the inequality

$$\begin{aligned}f_P(\lambda)\phi(P)=\phi(\lambda P)\leqslant\phi(\lambda I)=\phi(\lambda P+\lambda Q)\leqslant\phi(\lambda P+Q)\\ =h_P(\lambda)\phi(P)+\phi(Q)=f_P(\lambda)\phi(P)+\phi(Q)\end{aligned}$$

we infer that

$$0\leqslant\phi(\lambda I)-f_P(\lambda)\phi(P)\leqslant\phi(Q)$$

and this implies that

$$\phi(\lambda I)=f_P(\lambda)\phi(P)+k_P(\lambda)\phi(Q)$$

for some scalar $k_P(\lambda)\in[0,1]$. Since $\phi(P),\phi(Q)$ run through the set of all pairs of mutually orthogonal rank-one projections, it now follows that $\phi(\lambda I)$ is diagonizable with respect to every basis. This gives us that $\phi(\lambda I)$ is a scalar operator, that is, $\phi(\lambda I)=f(\lambda)I$ for some scalar $f(\lambda)\in[0,1]$. Clearly, $f:[0,1]\to[0,1]$ is a strictly monotone increasing bijection. Since

$$f_P(\lambda)\phi(P)=\phi(\lambda P)\leqslant\phi(\lambda I)=f(\lambda)I\leqslant\phi(\lambda P+Q)=f_P(\lambda)\phi(P)+\phi(Q),$$

it follows that $f=f_P=h_P$. So, we have

$$\phi(\lambda P)=f(\lambda)\phi(P)$$

and

$$\phi(\lambda P+Q)=f(\lambda)\phi(P)+\phi(Q).$$

The argument leading to this conclusion can also be applied to get

$$\phi(\lambda Q)=f(\lambda)\phi(Q)$$

and

$$\phi(P+\lambda Q)=\phi(P)+f(\lambda)\phi(Q).$$

For any $\lambda,\mu\in[0,1]$ we have

$$f(\lambda)\phi(P)=\phi(\lambda P)\leqslant\phi(\lambda P+\mu Q)\leqslant\phi(\lambda P+Q)=f(\lambda)\phi(P)+\phi(Q)$$

and

$$f(\mu)\phi(Q)=\phi(\mu Q)\leqslant\phi(\lambda P+\mu Q)\leqslant\phi(P+\mu Q)=\phi(P)+f(\mu)\phi(Q).$$

From the first inequality we infer that

$$\phi(\lambda P+\mu Q)=f(\lambda)\phi(P)+\alpha\phi(Q)$$

for some $\alpha\in[0,1]$, while from the second one we have

$$\phi(\lambda P+\mu Q)=\beta\phi(P)+f(\mu)\phi(Q)$$

for some $\beta\in[0,1]$. Comparing these equalities we get

$$\phi(\lambda P+\mu Q)=f(\lambda)\phi(P)+f(\mu)\phi(Q) \tag{1}$$

for every $\lambda,\mu\in[0,1]$.

Observe that f has the following symmetry property: $f(\lambda)+f(1-\lambda)=1$. Indeed, this follows from the equality $\phi(\lambda I)+\phi((1-\lambda)I)=I$.

Our next claim is to obtain a functional equation for f. In order to do this, we recall the following notation from Ref. 4. If E is an effect on a Hilbert space and φ is a unit vector, then let

$$\lambda(E,P_\varphi)=\sup\{\lambda\in[0,1]:\lambda P_\varphi\leqslant E\},$$

where P_φ is the orthogonal projection onto the subspace generated by φ. Suppose that $E\in[0,I]$. Then (Ref. 4, Theorem 4) tells us that

$$\lambda(E,P_\varphi)=\begin{cases}\|E^{-1/2}\varphi\|^{-2}, & \text{if } \varphi\in\mathrm{ran}(E^{1/2})\\ 0, & \text{else}\end{cases}.$$

Fix mutually orthogonal rank-one projections P, Q on H. Pick $\mu\in]0,1[$ and let $E=\mu P+Q$. Take any rank-one projection R on H which is neither equal to nor orthogonal to P. Similarly to the second step of the proof (Ref. 2, Lemma 3), it is easy to verify that

$$\lambda(E,R)=\frac{\mu}{\mu+(1-\mu)\mathrm{tr}\,PR}.$$

Indeed, if r is a unit vector in the range of R, then using the above-mentioned result from Ref. 4, we compute

$$\lambda(E,R)=\|((1/\sqrt{\mu})P+Q)r\|^{-2}=\frac{1}{(1/\mu)\|Pr\|^2+\|Qr\|^2}=\frac{\mu}{\|Pr\|^2+\mu\|Qr\|^2}$$

$$=\frac{\mu}{\mu\|Pr\|^2+\mu\|Qr\|^2+(1-\mu)\|Pr\|^2}=\frac{\mu}{\mu+(1-\mu)\|Pr\|^2}=\frac{\mu}{\mu+(1-\mu)\mathrm{tr}\,PR}.$$

By the definition of $\lambda(E,R)$, it is clear that

$$f(\lambda(E,R)) = \sup\{f(\lambda) : \lambda R \leqslant E\} = \sup\{f(\lambda) : \phi(\lambda R) \leqslant \phi(E)\}$$
$$= \sup\{f(\lambda) : f(\lambda)\phi(R) \leqslant \phi(E)\} = \lambda(\phi(E), \phi(R)).$$

Since $\phi(E) = \phi(\mu P + Q) = f(\mu)\phi(P) + \phi(Q)$, it follows that

$$f\left(\frac{\mu}{\mu + (1-\mu)\operatorname{tr} PR}\right) = \frac{f(\mu)}{f(\mu) + (1-f(\mu))\operatorname{tr}\phi(P)\phi(R)}.$$

As the quantities $\operatorname{tr} PR$ and $\operatorname{tr}\phi(P)\phi(R)$ do not depend on μ, it follows from this equality that $\operatorname{tr}\phi(P)\phi(R)$ can be uniquely expressed as a function of $\operatorname{tr} PR$. Denoting $g(\operatorname{tr} PR) = \operatorname{tr}\phi(P)\phi(R)$, we get a bijective function $g:]0,1[\to]0,1[$ for which

$$f\left(\frac{\mu}{\mu + (1-\mu)\nu}\right) = \frac{f(\mu)}{f(\mu) + (1-f(\mu))g(\nu)} \quad (\mu, \nu \in]0,1[)$$

holds true. Replacing μ by $1-\mu$ and ν by $1-\nu$ we have the following more aesthetic equality:

$$f\left(\frac{1-\mu}{1-\mu\nu}\right) = \frac{1-f(\mu)}{1-f(\mu)g(\nu)} \quad (\mu, \nu \in]0,1[). \tag{2}$$

Here we have used the fact that g has the same symmetry property as f. This follows from the following equality:

$$g(1-\operatorname{tr} PR) = g(\operatorname{tr} P - \operatorname{tr} PR) = g(\operatorname{tr}(P(I-R))) = \operatorname{tr}\phi(P)\phi(I-R) = \operatorname{tr}\phi(P)(I-\phi(R)) = \operatorname{tr}\phi(P)$$
$$-\operatorname{tr}\phi(P)\phi(R) = 1 - g(\operatorname{tr} PR).$$

Now, we turn to the solution of the functional equation (2). Our corresponding result is formulated in the following separate statement.

Proposition: Let $f,g:]0,1[\to]0,1[$ be functions. Suppose that f is a strictly monotone increasing bijection and that $f(1-x) = 1-f(x)$ and $g(1-y) = 1-g(y)$ hold for every $x,y \in]0,1[$. If

$$f\left(\frac{1-x}{1-xy}\right) = \frac{1-f(x)}{1-f(x)g(y)} \quad (x,y \in]0,1[), \tag{3}$$

then f and g are the identities on $]0,1[$.

Proof: The function f being continuous, Eq. (3) implies the continuity of g.

Observe that, with the notation

$$\alpha(t) := \frac{1}{1+e^t} \quad (t \in \mathbb{R}),$$

$$\beta(x) := \ln\frac{x}{1-x} \quad (x \in]0,1[),$$

$$\gamma(y) := \ln(1-y) \quad (y \in]0,1[),$$

we have the following identity:

$$\frac{1-x}{1-xy} = \frac{1}{1+\exp\left(\ln\frac{x}{1-x} + \ln(1-y)\right)} = \alpha(\beta(x) + \gamma(y))$$

for all $x,y \in]0,1[$. Therefore, Eq. (3) can be rewritten as

$$f\circ\alpha(\beta(x)+\gamma(y))=\alpha(\beta\circ f(x)+\gamma\circ g(y)) \quad (x,y\in]0,1[). \tag{4}$$

Substituting $x=\beta^{-1}(u)$ and $y=\gamma^{-1}(v)$ into Eq. (4) and applying the inverse function of α to both sides of Eq. (4), we get

$$\alpha^{-1}\circ f\circ\alpha(u+v)=\beta\circ f\circ\beta^{-1}(u)+\gamma\circ g\circ\gamma^{-1}(v) \tag{5}$$

for all $u\in\mathbb{R}$ and $v\in]-\infty,0[$. Thus the functions

$$F:=\alpha^{-1}\circ f\circ\alpha, \quad G:=\beta\circ f\circ\beta^{-1}, \quad H:=\gamma\circ g\circ\gamma^{-1}$$

satisfy the following so-called Pexider equation:

$$F(u+v)=G(u)+H(v) \quad (u\in\mathbb{R}, v\in]-\infty,0[).$$

Then, by known results of the theory of functional equations (cf. Ref. 5 or 6) and by the continuity of F, G, H, it follows that there exist constants $a,b,c\in\mathbb{R}$ such that

$$F(w)=cw+a+b \quad (w\in\mathbb{R}),$$

$$G(u)=cu+a \quad (u\in\mathbb{R}), \tag{6}$$

$$H(v)=cv+b \quad (v\in]-\infty,0[). \tag{7}$$

Using Eq. (6) and the definition of G, we get that $\beta\circ f(x)=c\beta(x)+a$, whence

$$f(x)=\frac{x^c}{x^c+e^{-a}(1-x)^c} \quad (x\in]0,1[).$$

Similarly, the definitions of H and γ, and Eq. (7) yield

$$g(y)=1-e^b(1-y)^c \quad (y\in]0,1[).$$

The function f being strictly increasing, G is also increasing whence we get that $c>0$. Thus f satisfies the identity $f(1-x)=1-f(x)$ if and only if $a=0$. The analogous identity for g is valid if and only if $b=0$, $c=1$. Therefore $f(x)=g(x)=x$ for all $x\in]0,1[$. □

Returning to the proof of our theorem, since the above-mentioned function g is the identity, we have $\mathrm{tr}\,PQ=\mathrm{tr}\,\phi(P)\phi(Q)$ for any rank-one projections P, Q on H. Hence, using Wigner's theorem on symmetry transformations we obtain that there exists an either unitary or antiunitary operator U on H such that

$$\phi(P)=UPU^*$$

for every rank-one projection P on H. As f is also the identity, from Eq. (1) we infer that

$$\phi(\lambda P+\mu Q)=\lambda\phi(P)+\mu\phi(Q)=\lambda UPU^*+\mu UQU^*=U(\lambda P+\mu Q)U^*,$$

which means that $\phi(E)=UEU^*$ holds for every effect E on H.

This completes the proof of our theorem. □

On one class of exact Poisson structures

Radosław Przybysz[a)]

(Received 9 August 2000; accepted for publication 1 December 2000)

We discuss some properties of a natural class of Poisson structures on Euclidean spaces and abstract manifolds. In particular it is proved that such structures are always exact and may be reconstructed from their Casimir functions. It is shown that in low dimensions they give the whole class of exact Poisson structures. The dimension of Poisson homology of these structures is computed in terms of the Milnor number of their Casimir functions. We also analyze some concrete examples of such structures in low dimensions and show that their centers are generated by Casimir functions. © *2001 American Institute of Physics.*

I. INTRODUCTION

Let M denote an affine algebraic variety and $F(M)$ denote an associative algebra of functions on M.

Definition 1: (cf. Refs. 1 and 2). A Poisson bracket on M is a bilinear mapping $\{\cdot,\cdot\}:F(M)\times F(M)\to F(M)$, *satisfying the following conditions:*

$$\text{antisymmetry}\quad \{f,g\}=-\{g,f\} \tag{1a}$$

$$\text{Leibniz rule}\quad \{f,gh\}=\{f,g\}h+\{f,h\}g, \tag{1b}$$

$$\text{Jacobi identity}\quad \{\{f,g\},h\}+\{\{g,h\},f\}+\{\{h,f\},g\}=0. \tag{1c}$$

For any field K of characteristic zero, let $K_n=K[x_1,\ldots,x_n]$ be the algebra of polynomials of n variables with coefficients in K (actually we will work only with fields of real or complex numbers).

We will be concerned with one class of Poisson brackets on K^n, which was introduced in (Ref. 3).

Definition 2: A Jacobian bracket on K^n *is defined as a bilinear map* $\{\cdot,\cdot\}:K_n\times K_n\to K_n$,

$$\{f,g\}=uJ(f,g,P_1,\ldots,P_{n-2}), \tag{2}$$

where $u,P_i\in K_n$, $i=1,\ldots,n-2$, *and* J *stands for the usual Jacobian* $J(h_1,\ldots,h_n)=\det(\partial h_i/\partial x_j)$.

As we will see in Sec. II, this formula actually defines a Poisson bracket on K^n. In the sequel we will establish some general properties of such brackets and explicate some results from (Refs. 3 and 4).

A Poisson structure defined by a Jacobian bracket will be called simply a Jacobian Poisson structure (JPS).

For the fields of real and complex numbers, the same formula defines a Poisson structure on $C^\infty(K^n)$. The polynomial context is chosen for simplicity.

II. PROPERTIES OF JACOBIAN BRACKETS

Let us denote by $\chi(M)$ the vector space of vector fields being the sections of tangent bundle $T(M)\to M$, by $\chi^k(M)$ the space of k-vectors and by $\Omega^k(M)$ the space of differential k-forms on M, endowed with exterior differentiation $d:\Omega^k(M)\to\Omega^{k+1}(M)$. If the manifold M is endowed with a volume form Ω, then we can define the operation,

$$\Phi_k:\chi^k(M)\to\Omega^{n-k}(M), \tag{3}$$

$$\Phi_k:v\mapsto i(v)\Omega, \tag{4}$$

and using above we can define[5] $D=\Phi_{k-1}^{-1}\circ d\circ\Phi_k:\chi^k(M)\to\chi^{k-1}(M)$.

It will be convenient for further use to rewrite the bracket (2) in terms of a Poisson bivector. Let Λ denote the Poisson structure defined by the Jacobian Poisson bracket. Then

$$\Lambda=\omega^{ij}\frac{\partial}{\partial x^i}\wedge\frac{\partial}{\partial x^j}, \tag{5}$$

$$\omega^{ij}=\epsilon^{ijk_1\ldots k_{n-2}}\frac{\partial P_1}{\partial x^{k_1}}\cdots\frac{\partial P_{n-2}}{\partial x^{k_{n-2}}}, \tag{6}$$

$$\{f,g\}=\Lambda(df,dg)=\omega^{ij}\frac{\partial f}{\partial x^i}\frac{\partial g}{\partial x^j}. \tag{7}$$

Theorem 1: (cf. Ref. 3). *Any Jacobian bracket is a Poisson bracket.*

Proof: An antisymmetry and Leibniz rule follow directly from well-known properties of determinants. Proving the Jacobi identity requires more work.

One could obtain the Jacobi identity for a Jacobian Poisson bracket as a particular case of generalized Jacobi identity for the Nambu bracket,[6] but we prefer to give a short direct proof, which as we believe is illuminating.

A nontrivial case is if polynomials $P_1,\ldots,P_{n-2}$ are functionally independent,[7] otherwise the Jacobian bracket vanishes identically. Because the Jacobi identity is invariant with respect to changes of coordinates, we can prove it locally in a convenient system of local coordinates. Now when $P_1,\ldots,P_{n-2}$ are functionally independent, we can always choose locally a frame for which they are local coordinates, i.e., $\partial P_i/\partial x^j=\delta_{ij}$ for $i,j=1,\ldots,n-2$. Then the formula (6) gives that $\{f,g\}=\partial_{n-1}f\partial_n g-\partial_{n-1}g\partial_n f$, where $\partial_i f=\partial f/\partial x^i$. The rest of the proof now becomes trivial. □

In order to formulate the next important property of Jacobian brackets we need one general definition.

Definition 3 (Ref. 5): A Poisson structure Λ is called exact if $D(\Lambda)=0$.

Theorem 2: *Any Poisson structure defined by the Jacobian bracket is exact.*

Proof: As in Theorem 1 the proper choice of coordinate system simplifies the proof. Indeed, after choosing the coordinate system exactly as in Theorem 1, obviously $\omega^{ij}=\epsilon^{ij}$ is a constant tensor and

$$D(\Lambda)=\Phi^{-1}\circ d\circ\Phi^2(\Lambda)=\partial_j\omega^{ij}\partial_i-\partial_i\omega^{ij}\partial_j=2\partial_j\omega^{ij}\partial_i=2\partial_j\epsilon^{ij}\partial_i=0, \tag{8}$$

which finishes the proof. □

Remark 1: The property of exactness may be interpreted in terms of the modular vector field introduced in Ref. 8. Indeed, from the discusion in Ref. 8 it follows that our $D(\Lambda)$ actually coincides with the modular vector field of Poisson manifold (M,Λ). This, in turn, means that under the property of exactness, Ω is an invariant density for the flows of all Hamiltonian vector fields on M, i.e., $L_{X_f}\Omega=0$, where L_{X_f} denotes the Lie derivative with respect to X_f—Hamiltonian

vector field of $f \in \mathbf{C}^\infty(M)$, $(X_f := \{f, \cdot\})$, *and in such a case the Poisson manifold* (M, Λ) *is said to be unimodular.*[8] *Thus, we see that JPS on affine spaces are unimodular.*

It is obvious that functions $P_1, \ldots, P_{n-2}$ are Casimirs of the corresponding Jacobian Poisson bracket (2), i.e., $\{f, P_i\} = 0$, $\forall f \in K_n$, $i = 1, \ldots, n-2$.

It turns out that the existence of sufficiently many functionally independent Casimirs is a characteristic property of corresponding Jacobian Poisson structures.

Theorem 3: *A Poisson structure on* K^n *which has* $n-2$ *functionally independent Casimirs, is always a Jacobian Poisson structure.*

For simplicity of notation, we only present the proof for $n = 4$. The general case is completely analogous.

Proof: For $n = 4$, we have two Casimirs; let us name them P and Q. If our coordinates are x^1, x^2, x^3, x^4, then we have

$$\{x^i, P\} = \omega^{ij}\, \partial_j P = 0, \quad \{x^i, Q\} = \omega^{ij}\, \partial_j Q = 0; \quad i = 1,2,3,4.$$

First we observe that in this set of eight equations no more than five are linearly independent, because we always have

$\partial_i P\{x^i, P\} = 0$,
$\partial_i Q\{x^i, Q\} = 0$,
$\partial_i P\{x^i, Q\} + \partial_j Q\{x^j, P\} = 0$.

Actually the rank of the matrix of this system is exactly five. As a result we can take one of nonzero ω^{ij} as a parameter, and then, a standard procedure for solving linear equations gives us that components ω^{ij} are proportional to $\epsilon^{ijkl}\, \partial_k P\, \partial_l Q$, which exactly means that this is a Jacobian Poisson structure.

□

III. LOW-DIMENSIONAL ANALYSIS

In low dimensions we can establish further interesting properties of JPS. First of all it turns out that sometimes the exactness is an intrinsic property of JPS. More precisely, the converse of Theorem 2 holds true for dimension 3. Actually there are two curious facts about Poisson structures on K^3.

Theorem 4: *For any bivector* Λ *on* K^3, *the condition of its exactness* $[D(\Lambda) = 0]$ *implies a Jacobi identity.*

Proof: We will use one general formula from the calculus of bivectors (presented, e.g., in Ref. 3) which states that for any two bivector fields Λ_1, Λ_2 one has

$$D(\Lambda_1 \wedge \Lambda_2) = [\Lambda_1, \Lambda_2]_S + D(\Lambda_1) \wedge \Lambda_2 - \Lambda_1 \wedge D(\Lambda_2), \tag{9}$$

where $[\cdot, \cdot]_S$ denotes the Schouten bracket.[9]

In particular,

$$D(\Lambda \wedge \Lambda) = [\Lambda, \Lambda]_S + 2D(\Lambda) \wedge \Lambda. \tag{10}$$

Since for the dimension reasons $\Lambda \wedge \Lambda = 0$ on K^3, it becomes clear that $D(\Lambda) = 0$ implies $[\Lambda, \Lambda]_S = 0$, which is exactly equivalent to Jacobi identity.

□

Theorem 5: *For* $n = 3$, *an exact polynomial Poisson structure is always a Jacobian Poisson structure.*

Proof: Without losing generality we can consider Poisson bivectors with components given by homogeneous polynomials of the same degree. This enables us to obtain the proof by merely ''counting of parameters.'' We make no attempt to obtain coordinate free proofs because such counting of parameters is also helpful for dealing with the higher dimensional case.

In order to avoid complicated notations we present a proof for quadratic Poisson structures; the case of higher degree is completely similar.

Any quadratic Poisson structure on K^3 is of the form

$$\Lambda = c^{ij}_{st} x^s x^t \partial_i \wedge \partial_j ; \quad c^{ij}_{st} = -c^{ji}_{st}, \ c^{ij}_{st} = c^{ij}_{ts}, \tag{11}$$

and then using (9) we obtain

$$D(\Lambda) = 2c^{ij}_{st} \partial_j (x^s x^t) \partial_i = 4c^{is}_{st} x^t \partial_i , \tag{12}$$

and finally we have that $D(\Lambda)=0$ iff

$$c^{is}_{st} = 0, \quad i,t = 1,2,3. \tag{13}$$

As it follows from Theorem 4, we need not analyze conditions on c^{is}_{st} imposed by the Jacobi identity, so we work with conditions (13) alone.

Let us write down Λ explicitly, replacing (x^1,x^2,x^3) with (x,y,z),

$$\begin{aligned}\Lambda = &(c^{12}_{11}x^2 + c^{12}_{22}y^2 + c^{12}_{33}z^2 + 2c^{12}_{12}xy + 2c^{12}_{13}xz + 2c^{12}_{23}yz)\frac{\partial}{\partial x}\wedge\frac{\partial}{\partial y}\\ &+ (c^{23}_{11}x^2 + c^{23}_{22}y^2 + c^{23}_{33}z^2 + 2c^{23}_{12}xy + 2c^{23}_{13}xz + 2c^{23}_{23}yz)\frac{\partial}{\partial y}\wedge\frac{\partial}{\partial z}\\ &+ (c^{31}_{11}x^2 + c^{31}_{22}y^2 + c^{31}_{33}z^2 + 2c^{31}_{12}xy + 2c^{31}_{13}xz + 2c^{31}_{23}yz)\frac{\partial}{\partial z}\wedge\frac{\partial}{\partial x}.\end{aligned} \tag{14}$$

Any quadratic Jacobian Poisson bracket is defined by some homogenous polynomial of degree 3. Let P denote such a function, and Λ_P be the corresponding Jacobian Poisson structure. It is convenient to represent P in the form

$$P = 2c^{12}_{12}xyz + \tfrac{1}{3}c^{23}_{11}x^3 + \tfrac{1}{3}c^{31}_{22}y^3 + \tfrac{1}{3}c^{12}_{33}z^3 + c^{23}_{22}xy^2 + c^{23}_{33}xz^2 + c^{31}_{11}yx^2 + c^{31}_{33}yz^2 + c^{12}_{11}zx^2 + c^{12}_{22}zy^2. \tag{15}$$

Then clearly,

$$\begin{aligned}\Lambda_P = &(c^{12}_{11}x^2 + c^{12}_{22}y^2 + c^{12}_{33}z^2 + 2c^{12}_{12}xy + 2c^{23}_{33}xz + 2c^{31}_{33}yz)\frac{\partial}{\partial x}\wedge\frac{\partial}{\partial y}\\ &+ (c^{23}_{11}x^2 + c^{23}_{22}y^2 + c^{23}_{33}z^2 + 2c^{31}_{11}xy + 2c^{12}_{11}xz + 2c^{12}_{12}yz)\frac{\partial}{\partial y}\wedge\frac{\partial}{\partial z}\\ &+ (c^{31}_{11}x^2 + c^{31}_{22}y^2 + c^{31}_{33}z^2 + 2c^{23}_{22}xy + 2c^{12}_{12}xz + 2c^{12}_{22}yz)\frac{\partial}{\partial z}\wedge\frac{\partial}{\partial x}.\end{aligned} \tag{16}$$

Now it is easy to see that $\Lambda = \Lambda_P$ precisely when

$$c^{12}_{12} = c^{23}_{23} = c^{31}_{13}, \ c^{12}_{11} = c^{23}_{13}, \ c^{31}_{11} = c^{23}_{12}, \ c^{12}_{22} = c^{31}_{23}, \ c^{23}_{22} = c^{31}_{12}, \ c^{23}_{33} = c^{12}_{13}, \ c^{31}_{33} = c^{12}_{23}. \tag{17}$$

These relations evidently coincide with the conditions of exactness (13).

□

Remark 2: Analogs of these results do not hold in dimensions bigger than 4 as it may be seen by ''counting of parameters.'' Nevertheless they may hold for bivectors with components given by polynomials of low degree. For quadratic PS on $\mathbf{R}^4$ *this may be derived from the results of Ref. 5.*

Interesting examples of Jacobian Poisson structures are given by well-known Sklyanin brackets[4] defined as follows:

$$\{x^\alpha, x^0\} = 2J^{\beta\gamma}x^\beta x^\gamma, \quad \{x^\alpha, x^\beta\} = -2x^0 x^\gamma, \tag{18}$$

where $J^{\alpha\beta}=J^{\alpha}-J^{\beta}$; J^{α},J^{β} are some complex numbers, $\alpha,\beta=1,2,3$.

Thus Sklyanin brackets give examples of quadratic Poisson structures on $\mathbf{C}^4$ (cf. Ref. 5) and it is easy to observe that they are Jacobian Poisson brackets. Indeed if one takes in (2) $P=\Sigma_{i=0}^{3}a_i(x^i)^2$, $Q=\Sigma_{j=0}^{3}b_i(x^j)^2$ then the Jacobian Poisson structure generated by P and Q coincides with (18) if $J^{\alpha\beta}=(a_{\alpha}-a_{\beta})/a_0$ and $a_{\gamma}b_0-a_0b_{\gamma}=1/2$, for every $\alpha,\beta,\gamma=1,2,3$.

In Ref. 4 it was shown that the center of the Sklyanin bracket admits a complete description. We will generalize this fact to an arbitrary Jacobian Poisson bracket on K^n.

In order to give a complete description of the center let us denote by $K\{x^1,\ldots,x^n\}$ the algebra of convergent power series with coefficients from K.

Theorem 6: *For arbitrary n, the center of Jacobian Poisson bracket* (2) *in $K\{x^1,\ldots,x^n\}$ is the subalgebra generated by $P_1,\ldots,P_{n-2}$.*

Proof: The general case may be obtained by induction. For the sake of brevity we present a proof for dimension 4. The crucial point is that for the Jacobian Poisson bracket the rank $rk(\omega^{ij})=2$ for every dimension.

The Jacobian Poisson structure in dimension 4 has the form

$$\Lambda=\epsilon^{ijpq}\frac{\partial P}{\partial x^p}\frac{\partial Q}{\partial x^q}\partial_i\wedge\partial_j, \tag{19}$$

where $P=P_1$ and $Q=P_2$.

For any polynomial f, this structure defines a vector field $X_f\in\chi(M)$:

$$X_f=\Lambda(df,\cdot)=\{f,\cdot\}=\omega^{ij}\partial_i f\partial_j. \tag{20}$$

If g is another polynomial, then

$$(dg)(X_f)=(X_f)g=\Lambda(df,dg)=\{f,g\}. \tag{21}$$

Let $X_{x^i}\equiv X_i$ and let h be a Casimir. It is obvious that $(dh)(X_i)=0$, for $i=1,2,3,4$. We want to show that h is some algebraic function of Casimirs P and Q. Let us put $dh=h_1\,dx^1+h_2\,dx^2+h_3\,dx^3+h_4\,dx^4$. In the next step we want to find functions h_i solving the set of equations $(dh)(X_i)=0$, for $i=1,2,3,4$. Because only two of the vectors X_i are linearly independent $(rk(\omega^{ij})=2)$, we can choose two functions, for example h_3, h_4, as parameters, and we will obtain

$$h_1=\frac{1}{\omega^{12}}(\omega^{23}h_3+\omega^{24}h_4), \tag{22}$$

$$h_2=-\frac{1}{\omega^{12}}(\omega^{13}h_3+\omega^{14}h_4), \tag{23}$$

$$\omega^{ij}=\epsilon^{ijkl}\,\partial_k P\,\partial_l Q:=\epsilon^{ijkl}P_kQ_l. \tag{24}$$

For convenience we will rewrite these formulas as

$$\begin{pmatrix}\omega^{12}h_1\\ \omega^{12}h_2\\ \omega^{12}h_3\\ \omega^{12}h_4\end{pmatrix}=\begin{pmatrix}\omega^{23}h_3+\omega^{24}h_4\\ -\omega^{13}h_3-\omega^{14}h_4\\ \omega^{12}h_3\\ \omega^{12}h_4\end{pmatrix}=\begin{pmatrix}(Q_4h_3-Q_3h_4)P_1+(P_3h_4-P_4h_3)Q_1\\ (Q_4h_3-Q_3h_4)P_2+(P_3h_4-P_4h_3)Q_2\\ (Q_4h_3-Q_3h_4)P_3+(P_3h_4-P_4h_3)Q_3\\ (Q_4h_3-Q_3h_4)P_4+(P_3h_4-P_4h_3)Q_4\end{pmatrix}. \tag{25}$$

Finally, if we set

$$\alpha=\frac{1}{\omega^{12}}(Q_4h_3-Q_3h_4),\quad \beta=\frac{1}{\omega^{12}}(P_3h_4-P_4h_3), \tag{26}$$

then it is immediate that

$$dh=\alpha\, dP+\beta\, dQ, \tag{27}$$

which implies that h may be represented as an analytic function of P and Q.[7]

□

Remark 3: Some properties of Sklyanin structures may be extended to a more general class of Poisson structures. Let us say that a Poisson structure is of the Sklyanin type, if the bracket of any two variables is a function of the remaining $(n-2)$ *variables. For example, for quadratic structures, we have*

$$\{x^i,x^j\}=J^{ij}_{mn}x^m x^n, \tag{28}$$

where we use the usual summation convention and assume that both m and n avoid values i and j.

Counting of parameters suggests that all such structures on $\mathbf{R}^5$ may be defined by some Jacobian brackets, for example, by taking the Jacobian Poisson structure with polynomials P_i being proper Pham polynomials.[10]

For a quadratic structure like above, the proper choice of functions in dimension 5 is

$$P_1=\sum_{i=1}^{5} a_i x^i, \quad P_2=\sum_{i=1}^{5} b_i (x^i)^2, \quad P_3=\sum_{i=1}^{5} c_i (x^i)^2. \tag{29}$$

Then we obtain

$$\{x^i,x^j\}=\sum_{k,l,m} \epsilon^{ijklm} a_k b_l c_m x^l x^m. \tag{30}$$

IV. QUASI-HOMOGENEOUS POISSON STRUCTURES

It turns out that affine Poisson structures with certain homogeneity have especially nice properties. Below we give a precise definition and present two results about such structures.

Let us say that a collection $\mathbf{w}=(w_1,\ldots,w_n)$ of positive rational numbers w_i is a system of weights for variables $x_1,\ldots,x_n$. The $\mathbf{w}$-degree of a monomial $e=x_1^{k_1}\cdot\ldots x_n^{k_n}$ is defined as $\Sigma w_i k_i$. Recall that polynomial $P\in K_n$ is called quasi-homogeneous of $\mathbf{w}$-degree d if all monomials entering in P have the same $\mathbf{w}$-degree equal to d.[10]

Definition 4: A Poisson structure is called a quasi-homogeneous Poisson structure of $\mathbf{w}$*-degree d if components* ω^{ij} *of the corresponding bivector are quasi-homogeneous polynomials of the same* $\mathbf{w}$*-degree* $d+w_i+w_j$.

Let us also introduce the so-called Euler vector field $X_E=\Sigma w_i x^i \partial_i$ associated with weights $(w_1,\ldots,w_n)$. Then it is easy to check that for a quasi-homogeneous Poisson structure of $\mathbf{w}$-degree d one has $L_{X_E}\Lambda=d\Lambda$. Moreover, for homogeneous Poisson structures (all $w_i=1$) we obtain a useful decomposition theorem generalizing the decomposition theorem of Liu and Xu.[5]

Theorem 7: *If* Λ *is a homogeneous Poisson structure of degree d on* K^n*, then it may be decomposed as* $\Lambda=\Lambda_0-[1/(d+n-2)]X_\Lambda\wedge X_E$*, where* Λ_0 *is an exact Poisson structure,* $X_\Lambda=D(\Psi)$ *and* $X_E=\Sigma_i x^i\partial_i$.

Proof: First let us consider the general quasi-homogeneous case when $X_E=\Sigma w_i x^i\partial_i$ and let $\Lambda=\Lambda_0-(1/c)X_\Lambda\wedge X_E$ for some $c\in K$ with exact Λ_0. Then since $D(\Lambda_0)=0$ we will get

$$D\left(\Lambda-\frac{1}{c}X_\Lambda\wedge X_E\right)=X_\Lambda-\frac{1}{c}([X_E,X_\Lambda]+D(X_E)X_\Lambda-D(X_\Lambda)X_E) \tag{31}$$

$$=\frac{1}{c}\left(c-d+w_i+w_j-\sum_{k=1}^{n} w_k\right)X_\Lambda=0. \tag{32}$$

This equality may only hold when $w_i=w_j$ for every i,j. This means that only a homogeneous case is possible and then we can take $w_i=1$, which directly leads to $c=d+n-2$.

□

As is well known, Poisson structures may be restricted to level surfaces of Casimirs. It turns out that applying this procedure to a quasi-homogeneous Jacobian Poisson structure one comes to an interesting connection with singularity theory.

Let us consider a Jacobian Poisson structure (2) given by $(n-2)$ functionally independent polynomials $P_1,\ldots,P_{n-2}\in K_n$ each of which is quasi-homogeneous with respect to the same system of weights **w**. It is easy to see that in such case their common zero-set $X=\{P_1=\cdots=P_{n-2}=0\}$ in $\mathbf{C}^n$ is a so-called two-dimensional complete intersection with an isolated singularity at the origin of $\mathbf{C}^n$.[10] The Jacobian Poisson structure Λ_P (2) naturally defines a Poisson structure $\tilde{\Lambda}_P$ on the ring of regular functions on X which is just $A=\mathbf{C}_n/(P_1,\ldots,P_{n-2})$.[11] For this reduced structure $\tilde{\Lambda}_P$ one can define its Poisson homology in the usual way.[9]

In particular its zero-dimensional Poisson homology $H_0^\pi(X,\tilde{\Lambda}_P)$ is isomorphic to the factor space $A/\{A,A\}$, where $\{A,A\}$ defines the ideal in A generated by all pairwise brackets of elements of A.

Our last result shows that Poisson homology of $\tilde{\Lambda}_P$ is related to some important topological characteristic of X.

Recall that the Milnor number of a complete intersection germ X of complex dimension two is defined as $\dim H^2(X_\epsilon\cap B_\delta^{2n},\mathbf{Z})$, where X_ϵ is a small nonsingular deformation of X and B_δ^{2n} is a small ball centered at the origin.[12]

Theorem 8: *For any two-dimensional quasi-homogeneous complete intersection* $X=\{P_1=\cdots=P_{n-2}=0\}$ *in* $\mathbf{C}^n$, *the dimension of zero-dimensional Poisson homology*[9] *of* $\tilde{\Lambda}_P$ *on* X *is equal to the Milnor number of* X *at the origin.*

Proof: For simplicity we present a proof for $n=3$. As is known, the Milnor number μ always can be computed in a purely algebraic way.[10]

In particular for a hypersurface in three dimensions the Milnor number is equal to the dimension of local algebra of the singular point,[12] i.e., $\mu=\dim\mathbf{C}_3/(\partial_1P,\partial_2P,\partial_3P)$.

A simple algebraic verification shows that the theorem will be proved if we establish the following equality between ideals in $\mathbf{C}_3$:

$$\{\mathbf{C}_3,\mathbf{C}_3\}+(P)=(\partial_1P,\partial_2P,\partial_3P). \tag{33}$$

The fact that $\{\mathbf{C}_3,\mathbf{C}_3\}+(P)\supset(\partial_1P,\partial_2P,\partial_3P)$ is obvious since $\{x^i,x^j\}=\epsilon^{ijk}\partial_kP$, $\partial_iP\in\{\mathbf{C}_3,\mathbf{C}_3\}$.

The reverse inclusion is not true in general, but in the quasi-homogeneous case it may be proven using the Euler formula $P=(1/d)\,\Sigma_i x^i w_i\,\partial_iP$ and repeated application of the Leibniz rule.

Indeed, it is sufficient to prove that the bracket of arbitrary two monomials lies in the Jacobian ideal $(\partial_1P,\partial_2P,\partial_3P)$. For that one can proceed by induction over a **w**-degree of monomials and consider a bracket of the form $\{xe,ye'\}$ where e, e' are arbitrary monomials of the **w**-degree not exceeding a given number r which are all supposed to have brackets in the Jacobian ideal. Now we get $\{x^ie,x^je'\}=\{x^i,x^j\}ee'+\{e,e'\}x^ix^j+\{x^i,e'\}x^je+\{e,x^j\}x^ie'$. Apparently every member on the right hand side of the equation fulfils the induction assumption, which ends the proof.

□

In higher dimensions one makes use of the general formula $\mu=\dim(\mathbf{C}_n)^{n-2}/(\partial_1Q,\ldots,\partial_nQ)$, where $(\mathbf{C}_n)^{n-2}$ is the module of $n-2$ columns of polynomials from $\mathbf{C}_n$, ∂_iQ stands for column obtained by taking the i-th partial derivative of the column $Q=(P_1,\ldots,P_{n-2})^T$, and $(\partial_1Q,\ldots,\partial_nQ)$ denotes the submodule in $(\mathbf{C}_n)^{n-2}$ generated by columns ∂_iQ.[10]

The structure of the proof remains the same but computations become much more involved.

In conclusion we would like to notice that the natural problem of computing Poisson homology of JPS on the whole affine space seems to be very difficult. Using examples and technique presented in Ref. 13 it is possible to construct quadratic JPS on $\mathbf{R}^4$ with nontrivial second and third Poisson homology groups, but we were not able to calculate these groups explicitly. Some related results may be found in Ref. 14.

An asymptotic expansion for the hypergeometric function ${}_2F_1(a,b;c;x)$

(Received 23 October 2000; accepted for publication 12 January 2001)

Watson's treatise expresses the ordinary Bessel function as a limit of a hypergeometric function, where the first two parameters go to infinity, while simultaneously the argument goes to zero. We have extended Watson's method of proof to derive an asymptotic expression for the hypergeometric function to second order in the inverse of the first two parameters, with the ordinary Bessel function as its leading-order term. We show, as an example, that the use of this new result is pivotal in showing the correspondence between quantal and classical results of the differential cross section in Coulomb excitation. © *2001 American Institute of Physics.* [DOI: 10.1063/1.1353185]

I. INTRODUCTION

The hypergeometric function ${}_2F_1(a,b;c;x)$[1,2] plays an important role in the solution of many physical problems. It is found, for example, in the quantal formulation of the differential cross section for excitation of atomic systems by the Coulomb field of charged particles.[3–6]

Historically, there have been two main approaches to modeling the electromagnetic interaction of two particles. In the *semiclassical approach*,[7] which has its roots in the classical study of radiation emitted by interacting charged particles,[8] the projectile is assumed to follow a classical hyperbolic trajectory, which determines the scattering angle, while the excitation of the target is caused by the resulting time-varying electric and magnetic fields. Results obtained through this technique provide both an intuitive physical picture of the scattering process and also serve as approximations to the quantal results for low-energy collisions.

In the *quantal approach*, and assuming the validity of first-order time-independent perturbation theory, the scattering process is described as a transition of the projectile between two Coulomb-distorted plane-wave states, while the target simultaneously undergoes a change in state. Both of these approaches have been reviewed by Alder *et al.*[5] and Biedenharn and Brussaard.[4]

In both approaches, expanding the interaction in multipoles and neglecting the penetration of the projectile into the target results, for each multipole order L, in a problem which factors into two parts—one solely dependent on the properties of the target in question, which controls the strength of the interaction, and a differential excitation function $\mathrm{d}f(\theta,\eta_i,\xi)/\mathrm{d}\Omega$, which determines the angular distribution of the scattered projectile. The angle θ is the deflection angle of the scattered particle, and the dimensionless Sommerfeld parameter η_i is defined by

$$\eta_i=\frac{Z_1Z_2e^2}{\hbar v_i}=Z_1Z_2\sqrt{\frac{M}{(E_i/\mathrm{Ry})}}, \tag{1.1}$$

where Z_1 and Z_2 are the charge numbers of the projectile and the atomic system, v_i their relative velocities, M the reduced mass of the system, in electron-mass units, and E_i is the initial kinetic energy of relative motion measured in rydbergs (13.8 eV). The dimensionless adiabaticity parameter ξ is defined by

a)Electronic mail: mchidich@math.uwaterloo.ca

$$\xi = \eta_f - \eta_i = \eta_i \left[\left(1 - \frac{E_{if}}{E_i} \right)^{-1/2} - 1 \right]$$
$$= Z_1 Z_2 \sqrt{\frac{M}{(E_i/\mathrm{Ry})}} \left[\left(1 - \frac{E_{if}}{E_i} \right)^{-1/2} - 1 \right], \tag{1.2}$$

where the indices i and f refer to the initial and the final state, respectively, and $E_{if} = E_i - E_f$.

While, in general, the excitation function $\mathrm{d}f/\mathrm{d}\Omega$ can be expressed only as an infinite sum, in the special case where the organ of interaction is the dipole component of the electrostatic interaction ($E1$), the excitation functions in both the semiclassical and quantal derivations are soluble in terms of Bessel[7] and hypergeometric[9] functions, respectively.

By applying appropriate analytic continuations, we show, in Sec. III A, that the differential excitation function for θ bounded away from zero is left in terms of hypergeometric functions of the form

$$ {}_2F_1(\alpha \pm i\eta_i, \beta \mp i\eta_f; 1 \mp i\xi; t), \tag{1.3}$$

where α and β are integers and

$$t = \frac{\xi^2}{\xi^2 + 4\eta_i \eta_f \sin^2(\theta/2)}. \tag{1.4}$$

The usual procedure for obtaining a classical limit of a quantal result is to let η_i, $\eta_f \to \infty$ and assume ξ is finite.[4] Since our variable t becomes small as $\eta_i, \eta_f \to \infty$ and ξ is kept finite, it would seem to be the appropriate form of the quantal expression for investigating this correspondence between the semiclassical and quantal results directly.

Actually, demonstrating this result proves to be much more difficult than first thought, since it requires taking limits of hypergeometric functions whose first two parameters go to infinity, while the argument t goes to zero simultaneously. Further complicating the problem is the fact that, in many cases, the leading and first-order terms all cancel out in the subexpressions and a quadratic factor in η promotes the second-order correction terms in the asymptotic expressions to significance as $\eta \to \infty$.

For this reason, we have derived an asymptotic expansion for Gauss' hypergeometric function to second order in the inverses of the first two parameters and used the resulting expression to evaluate the limit.

The limiting case $E_i \to E_{if}$, in atomic collisions, needs special consideration and will be dealt with in a forthcoming paper. In this particular case, the parameters η_f, $\xi \to \infty$ simultaneously, whereas the parameter η_i remains finite and the argument $t \to 1$.

We used the symbolic computation program MAPLE VI[10] to help us with the algebraic manipulations in this work.

II. ASYMPTOTIC EXPANSION OF HYPERGEOMETRIC FUNCTION

Equation 5.7(1) of Watson's treatise[12] expresses the ordinary Bessel function as a limit of a hypergeometric function.

$$J_\nu(z) = \lim_{\lambda,\mu\to\infty} \frac{\left(\frac{1}{2}z\right)^\nu}{\Gamma(\nu+1)} {}_2F_1\left(\lambda, \mu; \nu+1; -\frac{z^2}{4\lambda\mu}\right). \tag{2.1}$$

${}_2F_1(a,b;c;x)$ is Gauss' hypergeometric function defined by

$$ {}_2F_1(a,b;c;x) = \sum_{n=0}^{\infty} \frac{(a)_n (b)_n}{n!(c)_n} x^n, \tag{2.2}$$

in the circle of convergence of this series ($|x|<1$) and by analytic continuation elsewhere.

We will extend Watson's method of proof to derive an asymptotic expression for the hypergeometric function with this result as its leading-order (constant) term. We believe this result has not been discussed before.

Expanding the right-hand side of the equation through the Gauss hypergeometric series (2.2) gives a summation whose $(m+1)$th term is

$$\frac{(-)^m(\frac{1}{2}z)^{\nu+2m}}{m!\Gamma(\nu+m+1)}\prod_{r=1}^{m-1}[(1+r\delta)(1+r\eta)], \tag{2.3}$$

where $\delta=\lambda^{-1}$ and $\eta=\mu^{-1}$. As is discussed in Ref. 11, Sec. 5.7, for $|\delta|<\delta_0<2|z|^{-1}$ and $\eta<\eta_0<2|z|^{-1}$, this term is smaller than the $(m+1)$th term in the absolutely convergent hypergeometric series, which represents

$$\frac{(\frac{1}{2}z)^{\nu}}{\Gamma(\nu+1)}\,{}_2F_1\left(\frac{1}{\delta_0},\frac{1}{\eta_0};\nu+1;\frac{z^2\delta_0\eta_0}{4}\right). \tag{2.4}$$

Since the Weierstrass test shows that the terms of this series are uniformly smaller than the terms of a convergent series of constants, for small enough δ and η in any circle around $z=0$, the series to which this term belongs is uniformly convergent for large enough λ and μ.

To extract higher-order corrections from this system, we require the product

$$\prod_{r=1}^{m-1}(1+r\delta)=(1+\delta)(1+2\delta)(1+3\delta)\cdots(1+(m-1)\delta) \tag{2.5}$$

in powers of δ. The constant term of this expression is obviously 1. The coefficient of the linear term is the sum of all possible integers between 1 and $(m-1)$, namely $m(m-1)/2$. The coefficient of the second-order term is zero for $m<2$ or the sum of all possible distinct products of two distinct integers between 1 and $(m-1)$ for $m\geqslant 2$. To derive a closed-form expression for this, we will first derive a closed-form expression for the sum of all possible multiplications of two (not necessarily distinct) integers between 1 and $(m-1)$. To obtain this, we use the following matrix.

$$\begin{array}{ccccc} 1\times1 & 1\times2 & 1\times3 & \cdots & 1\times(m-1) \\ 2\times1 & 2\times2 & 2\times3 & \cdots & 2\times(m-1) \\ \vdots & \vdots & \vdots & \ddots & \vdots \\ (m-1)\times1 & (m-1)\times2 & (m-1)\times3 & \cdots & (m-1)\times(m-1) \end{array}. \tag{2.6}$$

We can use the result

$$\sum_{k=1}^{n}k=n(n+1)/2$$

to take the sum of each column and again to take the sum of all of the columns

$$[\tfrac{1}{2}m(m-1)+2\times\tfrac{1}{2}m(m-1)+\cdots+(m-1)\times\tfrac{1}{2}m(m-1)]=[\tfrac{1}{2}m(m-1)]^2=\tfrac{1}{4}m^2(m-1)^2. \tag{2.7}$$

In fact, this argument can be generalized by induction to products of any length

$$\sum_{k_1=1}^{m-1}\sum_{k_2=1}^{m-1}\cdots\sum_{k_n=1}^{m-1} k_1k_2\cdots k_n=\frac{1}{2}m(m-1)\sum_{k_1=1}^{m-1}\sum_{k_2=1}^{m-1}\cdots\sum_{k_{n-1}=1}^{m-1} k_1k_2\cdots k_{n-1}$$
$$=\left[\frac{1}{2}m(m-1)\right]^n. \tag{2.8}$$

This summation overcounts terms for our purposes, since it counts each product twice (once as $a\times b$ and once as $b\times a$) and also includes the squares, which are not obtained in our expansion. We therefore modify this expression somewhat and write

$$S=\frac{1}{2}\left[\left(\frac{m(m-1)}{2}\right)^2-\sum_{k=1}^{m-1}k^2\right]$$
$$=\frac{1}{2}\left[\left(\frac{m(m-1)}{2}\right)^2-\frac{m(m-1)(2m-2)}{6}\right]$$
$$=\frac{1}{24}m(m-1)(m-2)(3m-1), \tag{2.9}$$

which has the convenient property that it is 0 for $m<2$, thus eliminating the need to handle these cases separately.

Consequently, we now have an asymptotic expression for the $(m\text{-}1)$th term, viz.,

$$\frac{(-)^m(\frac{1}{2}z)^{\nu+2m}}{m!\Gamma(\nu+m+1)}\left[1+\frac{1}{2}m(m-1)\delta+\frac{1}{24}m(m-1)(m-2)(3m-1)\delta^2\right]$$
$$\times[1+\tfrac{1}{2}m(m-1)\eta+\tfrac{1}{24}m(m-1)(m-2)(3m-1)\eta^2]$$
$$=\frac{(-)^m\left(\frac{1}{2}z\right)^{\nu+2m}}{m!\Gamma(\nu+m+1)}\left[1+\frac{1}{2}m(m-1)(\delta+\eta)+\tfrac{1}{24}m(m-1)\right.$$
$$\left.\times(m-2)(3m-1)(\delta^2+\eta^2)+\frac{1}{4}m^2(m-1)^2\delta\eta\right], \tag{2.10}$$

and all that remains is to find a closed-form summation for each term in this expansion. The constant term is the one presented in Ref. 11, viz.,

$$\sum_{m=0}^{\infty}\frac{(-)^m(\frac{1}{2}z)^{\nu+2m}}{m!\Gamma(\nu+m+1)}=J_\nu(z). \tag{2.11}$$

To obtain the linear term, we notice that

$$\frac{1}{8}z^2J_{\nu+2}(z)=\frac{1}{2}\sum_{m=0}^{\infty}\frac{(-)^m(\frac{1}{2}z)^{\nu+4+2m}}{m!\Gamma(\nu+2+m+1)}$$
$$=\frac{1}{2}\sum_{n=2}^{\infty}\frac{(-)^n(\frac{1}{2}z)^{\nu+2n}}{(n-2)!\Gamma(\nu+n+1)}$$
$$=\frac{1}{2}\sum_{n=0}^{\infty}n(n-1)\frac{(-)^n(\frac{1}{2}z)^{\nu+2n}}{n!\Gamma(\nu+n+1)}, \tag{2.12}$$

where we have made use of the fact that the first two terms of the sum are 0 to extend the summation down to $n=0$. In obtaining the second-order terms, we use the generalized form of Eq. (2.12), namely,

$$(-)^k\left(\frac{1}{2}z\right)^k J_{\nu+k}(z)=\sum_{m=0}^{\infty}\frac{(-)^k\left(\frac{1}{2}z\right)^{\nu+2k+2m}}{m!\Gamma(\nu+k+m+1)}$$

$$=\sum_{n=0}^{\infty} n(n-1)\cdots(n-k+1)\frac{(-)^n\left(\frac{1}{2}z\right)^{\nu+2n}}{n!\Gamma(\nu+n+1)}. \tag{2.13}$$

Since the polynomials $\{1,m,m(m-1),m(m-1)(m-2),\cdots\}$ comprise a basis of all polynomials, we can sum the standard Bessel function expansion, with terms prefixed by any polynomial in the summation index, by expanding that polynomial over this basis and using the identity (2.13) to sum the sums from each component separately. Applying this to our present situation and writing $3m-1=8+3(m-3)$, we obtain

$$\frac{1}{24}\sum_{m=0}^{\infty} m(m-1)(m-2)(3m-1)\frac{(-)^m(\frac{1}{2}z)^{\nu+2m}}{m!\Gamma(\nu+m+1)}=-\frac{1}{24}z^3J_{\nu+3}(z)+\frac{1}{128}z^4J_{\nu+4}(z). \tag{2.14}$$

As well, using the identity $m(m-1)=2+4(m-2)+(m-2)(m-3)$, we get

$$\frac{1}{4}\sum_{m=0}^{\infty} m^2(m-1)^2\frac{(-)^m(\frac{1}{2}z)^{\nu+2m}}{m!\Gamma(\nu+m+1)}=\frac{1}{8}z^2J_{\nu+2}(z)-\frac{1}{8}z^3J_{\nu+3}(z)+\frac{1}{64}z^4J_{\nu+4}(z). \tag{2.15}$$

Combining the above gives the expansion

$$\frac{(\frac{1}{2}z)^{\nu}}{\Gamma(\nu+1)}{}_2F_1\left(\lambda,\mu;\nu+1;-\frac{z^2}{4\lambda\mu}\right)\sim J_{\nu}(z)+\frac{z^2}{8}J_{\nu+2}(z)\left(\frac{1}{\lambda}+\frac{1}{\mu}\right)$$
$$+\left[-\frac{1}{24}z^3J_{\nu+3}(z)+\frac{1}{128}z^4J_{\nu+4}(z)\right]\left(\frac{1}{\lambda^2}+\frac{1}{\mu^2}\right)$$
$$+\left[\frac{1}{8}z^2J_{\nu+2}(z)-\frac{1}{8}z^3J_{\nu+3}(z)+\frac{1}{64}z^4J_{\nu+4}(z)\right]\left(\frac{1}{\lambda\mu}\right), \tag{2.16}$$

for λ and μ large.

III. EXAMPLE: COULOMB EXCITATION AND HYPERGEOMETRIC FUNCTIONS

In the quantal expression for the E1 differential excitation function, we are bombarded with hypergeometric functions of the form

$${}_2F_1(\alpha+i\eta_i,\beta-i\eta_f;1-i\xi;t)={}_2F_1(\alpha+i\eta,\beta-i(\eta+\xi);1-i\xi;t), \tag{3.1}$$

or those of the form

$$ {}_2F_1(\alpha - i\eta_i, \beta + i\eta_f; 1 + i\xi; t) = {}_2F_1(\alpha - i\eta, \beta + i(\eta + \xi); 1 + i\xi; t). \tag{3.2} $$

In this section, we will use the variable name $\eta = \eta_i$ and express η_f as $\eta + \xi$, where convenient.

The hypergeometric function of form (3.1) may be converted to one of form (3.2) by making the substitution $\eta \to -\eta$ and $\xi \to -\xi$. For this reason, we will concern ourselves with expanding only the form (3.1) and will perform this transformation afterwards to handle form (3.2).

If we define $\lambda = \alpha + i\eta_i$ and $\mu = \beta - i\eta_f$, we may apply the asymptotic expression of Sec. II to these functions as $\eta \to \infty$. We define z by

$$ t = -\frac{z^2}{4\lambda\mu} \Rightarrow z = 2i\sqrt{\lambda\mu t}. \tag{3.3} $$

An additional complication arises, because z is a nonconstant function of η. Thus, in addition to the limiting process associated with the expansion of the hypergeometric function, there are additional terms associated with the variation in z as $\eta \to \infty$. We start by expanding z to second order in powers of η^{-1}:

$$ z = 2i\left[(\alpha + i\eta_i)(\beta - i\eta_f) \frac{\xi^2}{\xi^2 + 4\eta_i\eta_f \sin^2\left(\frac{\theta}{2}\right)} \right]^{1/2} \sim z_0 \left\{ 1 + c_1 \frac{1}{\eta} + c_2 \frac{1}{\eta^2} \right\}, \tag{3.4} $$

where

$$ \varepsilon = \frac{1}{\sin\left(\frac{\theta}{2}\right)}, \tag{3.5} $$

$$ z_0 = i|\xi|\varepsilon, \tag{3.6} $$

$$ c_1 = -\frac{i}{2}(\alpha - \beta), \tag{3.7} $$

$$ c_2 = \frac{(\alpha + \beta)^2 - 4i\xi\beta - \xi^2\varepsilon^2}{8}. \tag{3.8} $$

We want to expand the Bessel functions in the coefficients of the asymptotic expression of the hypergeometric function evaluated at z in powers of η^{-1}. Using the differentiation formula (9.1.30) of Ref. 2 and expanding the function $z^{-\nu}J_\nu(z)$ as a Taylor series about z_0, we find

$$ z^{-\nu}J_\nu(z) \sim z_0^{-\nu}J_\nu(z_0) - c_1 z_0^{-\nu+1}J_{\nu+1}(z_0)\frac{1}{\eta} - \left\{ c_2 z_0^{-\nu+1}J_{\nu+1}(z_0) + \frac{c_1^2}{2}[z_0^{-\nu+1}J_{\nu+1}(z_0) - z_0^{-\nu+2}J_{\nu+2}(z_0)] \right\}\frac{1}{\eta^2}. \tag{3.9} $$

Similarly, differentiating the Bessel function in the second coefficient gives

$$ \frac{\mathrm{d}}{\mathrm{d}z}[z^{-\nu+2}J_{\nu+2}(z)] = 4z^{-\nu+1}J_{\nu+2}(z) - z^{-\nu+2}J_{\nu+3}(z), \tag{3.10} $$

whence the linear approximation

$$z^{-\nu+2}J_{\nu+2}(z)=z_0^{2-\nu}J_{\nu+2}(z_0)+[4z_0^{-\nu+1}J_{\nu+2}(z_0)-z_0^{-\nu+2}J_{\nu+3}(z_0)]z_0c_1\frac{1}{\eta}. \tag{3.11}$$

Expanding the coefficients of the third and fourth term (beyond zeroth order) introduces only higher-order terms in η^{-1}. It suffices to use the ''constant'' approximation and evaluate them at z_0.

We now have the asymptotic expression

$$\begin{aligned}\frac{2^{-\nu}}{\Gamma(\nu+1)}{}_2F_1(\lambda,\mu;1+\nu;t)\sim{}&z_0^{-\nu}J_\nu(z_0)-c_1z_0^{-\nu+1}J_{\nu+1}(z_0)\frac{1}{\eta}\\&-\left\{c_2z_0^{-\nu+1}J_{\nu+1}(z_0)+\frac{c_1^2}{2}[z_0^{-\nu+1}J_{\nu+1}(z_0)-z_0^{-\nu+2}J_{\nu+2}(z_0)]\right\}\frac{1}{\eta^2}\\&+\left(\frac{1}{\lambda}+\frac{1}{\mu}\right)\{z_0^{2-\nu}J_{\nu+2}(z_0)-c_1[3z_0^{-\nu+2}J_{\nu+2}(z_0)-z_0^{-\nu+3}J_{\nu+3}(z_0)]\}\\&+\left(\frac{1}{\lambda^2}+\frac{1}{\mu^2}\right)\left\{-\frac{1}{24}z_0^{3-\nu}J_{\nu+3}(z_0)+\frac{1}{128}z_0^{4-\nu}J_{\nu+4}(z_0)\right\}+\left(\frac{1}{\lambda\mu}\right)\\&\times\left\{\frac{1}{8}z_0^{2-\nu}J_{\nu+2}(z_0)-\frac{1}{8}z_0^{3-\nu}J_{\nu+3}(z_0)+\frac{1}{64}z_0^{4-\nu}J_{\nu+4}(z_0)\right\}.\end{aligned} \tag{3.12}$$

Finally, we must expand the asymptotic variables λ and μ themselves in powers of η^{-1},

$$\frac{1}{\lambda}=\frac{1}{\alpha+i\eta}\sim-\frac{i}{\eta}+\frac{\alpha}{\eta^2}, \tag{3.13}$$

$$\frac{1}{\mu}=\frac{1}{\beta-i(\eta+\xi)}\sim\frac{i}{\eta}+\frac{\beta-i\xi}{\eta^2}, \tag{3.14}$$

$$\frac{1}{\lambda}+\frac{1}{\mu}\sim\frac{\alpha+\beta-i\xi}{\eta^2},\quad \frac{1}{\lambda^2}+\frac{1}{\mu^2}\sim-\frac{2}{\eta^2},\quad \frac{1}{\lambda\mu}\sim\frac{1}{\eta^2}. \tag{3.15}$$

With these expansions, the asymptotic expression becomes

$$\begin{aligned}{}_2F_1(\alpha+i\eta,\beta-i(\eta+\xi);1-i\xi;t)\sim{}&\Gamma(1-i\xi)\left(\frac{z_0}{2}\right)^{i\xi}\left\{J_{-i\xi}(z_0)-c_1z_0J_{1-i\xi}(z_0)\frac{1}{\eta}\right.\\&+\left[-c_2z_0J_{1-i\xi}(z_0)-\frac{c_1^2}{2}[z_0J_{1-i\xi}(z_0)-z_0^2J_{2-i\xi}(z_0)]\right.\\&\left.\left.+\frac{\alpha+\beta-i\xi+1}{8}z_0^2J_{2-i\xi}(z_0)-\frac{1}{24}z_0^3J_{3-i\xi}(z_0)\right]\frac{1}{\eta^2}\right\}.\end{aligned} \tag{3.16}$$

For the purposes of comparing with the semiclassical results, we express this asymptotic expansion in terms of the modified Bessel functions $I_\nu(z)$ (relation 9.6.3 of Ref. 2), and we obtain

$$
\begin{aligned}
&{}_2F_1(\alpha+i\eta,\beta-i(\eta+\xi);1-i\xi;t)\\
&\quad\sim\Gamma(1-i\xi)\left(\frac{x_0}{2}\right)^{i\xi}\Bigg\{I_{-i\xi}(x_0)-\frac{1}{2}i(\alpha-\beta)x_0I_{1-i\xi}(x_0)\frac{1}{\eta}\\
&\qquad-\Bigg\{\left[\frac{1}{12}(x_0^2-\xi^2-1-3\alpha(\alpha-1)-3\beta(\beta-1))+\frac{i\xi}{4}(\beta-\alpha)(\beta-\alpha-1)\right]x_0I_{1-i\xi}(x_0)\\
&\qquad+\left[\frac{1}{24}(3\alpha(\alpha-1)+3\beta(\beta-1)-6\alpha\beta+1)+\frac{i\xi}{24}\right]x_0^2I_{-i\xi}(x_0)\Bigg\}\frac{1}{\eta^2}\Bigg\},
\end{aligned}
\tag{3.17}
$$

where $x_0=|\xi|\varepsilon=|\xi|\sin(\theta/2)^{-1}$. Recurrence relations have been used to express all of the modified Bessel functions in terms of $I_{1-i\xi}$ and $I_{-i\xi}$.

Classical limit of the electric dipole differential excitation function. We begin our discussion with the excitation function expression,[9,12] but make explicit the distinction between the repulsive and attractive cases by writing ξ as $\mp|\xi|$. We can convert the repulsive case ($\eta_i>0$) to the attractive case ($\eta_i<0$) by simply switching the signs of η_i, η_f, and ξ. The total effect of this transformation is to replace the factor of $\exp(-\pi|\xi|)$, for repulsive potentials, by a factor of $\exp(+\pi|\xi|)$ for attractive potentials,

$$
\mathrm{d}f_{E1}=\frac{8\pi^3\eta_i\eta_f}{9\xi^2}\frac{e^{\mp\pi|\xi|}}{\sinh(\pi\eta_i)\sinh(\pi\eta_f)}\,\mathrm{d}/\mathrm{d}x\left(-x\frac{\mathrm{d}}{\mathrm{d}x}|\,{}_2F_1(-i\eta_i,-i\eta_f;1;x)|^2\right),
\tag{3.18}
$$

where

$$
x=-\frac{4\eta_i\eta_f}{\xi^2}\sin^2\left(\frac{\theta}{2}\right).
\tag{3.19}
$$

We will henceforth omit the subscripts and write ${}_2F_1(\ldots)$ simply as $F(\cdots)$. Expanding out the derivatives, and making use of the analytic continuations 15.3.15 and 15.3.6 of Ref. 2, we are left with

$$
\begin{aligned}
\mathrm{d}f_{E1}=&\frac{16\pi^3}{9}\frac{(\eta_i\eta_f)^2te^{\pm\pi|\xi|}}{\xi^2\sinh(\pi\eta_i)\sinh(\pi\eta_f)}\times\Bigg\{\frac{|\Gamma(i\xi)|^2}{|\Gamma(1+i\eta_i)|^2\Gamma(1+i\eta_f)|^2}[\mathrm{Im}(e1-e3)-\mathrm{Re}(e4)]\\
&+\mathrm{Im}\left(\frac{t^{-i\xi}\Gamma^2(i\xi)}{\Gamma^2(1-i\eta_i)\Gamma^2(1+i\eta_f)}(e2-e5)\right)-\mathrm{Re}\left(\frac{t^{-i\xi}\Gamma^2(i\xi)}{\Gamma^2(1-i\eta_i)\Gamma^2(1+i\eta_f)}(e6)\right)\\
&+t\Bigg[\frac{|\Gamma(i\xi)|^2}{|\Gamma(1+i\eta_i)|^2\Gamma(1+i\eta_f)|^2}[\mathrm{Im}(e3)+\mathrm{Re}(e4)]+\mathrm{Im}\left(\frac{t^{-i\xi}\Gamma^2(i\xi)}{\Gamma^2(1-i\eta_i)\Gamma^2(1+i\eta_f)}(e5)\right)\\
&+\mathrm{Re}\left(\frac{t^{-i\xi}\Gamma^2(i\xi)}{\Gamma^2(1-i\eta_i)\Gamma^2(1+i\eta_f)}(e6)\right)\Bigg]\Bigg\},
\end{aligned}
\tag{3.20}
$$

where

$$
\begin{aligned}
e1=&-\eta_iF(1+i\eta_i,1-i\eta_f;1-i\xi;t)F(1-i\eta_i,i\eta_f;1+i\xi;t)\\
&+\eta_fF(1+i\eta_i,1-i\eta_f;1-i\xi;t)F(-i\eta_i,1+i\eta_f;1+i\xi;t),
\end{aligned}
\tag{3.21}
$$

$$
\begin{aligned}
e2=&-\eta_fF(1+i\eta_i,1-i\eta_f;1-i\xi;t)F(i\eta_i,1-i\eta_f;1-i\xi;t)\\
&+\eta_iF(1+i\eta_i,1-i\eta_f;1-i\xi,t)F(1+i\eta_i,-i\eta_f;1-i\xi;t),
\end{aligned}
\tag{3.22}
$$

$$e3 = -\eta_i F(1+i\eta_i,2-i\eta_f;1-i\xi;t)F(1-i\eta_i,i\eta_f;1+i\xi;t) + \eta_f F(2+i\eta_i,1-i\eta_f;1-i\xi;t)F(-i\eta_i,1+i\eta_f;1+i\xi;t), \tag{3.23}$$

$$e4 = \eta_i\eta_f[F(1+i\eta_i,2-i\eta_f;1-i\xi;t)F(1-i\eta_i,i\eta_f;1+i\xi;t) + F(2+i\eta_i,1-i\eta_f;1-i\xi;t)F(-i\eta_i,1+i\eta_f;1+i\xi;t) - 2F(1-i\eta_i,1+i\eta_f;1+i\xi;t)F(1+i\eta_i,1-i\eta_f;1-i\xi;t)], \tag{3.24}$$

$$e5 = -\eta_f F(1+i\eta_i,2-i\eta_f;1-i\xi;t)F(i\eta_i,1-i\eta_f;1-i\xi;t) + \eta_i F(2+i\eta_i,1-i\eta_f;1-i\xi;t)F(1+i\eta_i,-i\eta_f;1-i\xi;t), \tag{3.25}$$

$$e6 = \eta_f^2 F(1+i\eta_i,2-i\eta_f;1-i\xi;t)F(i\eta_i,1-i\eta_f;1-i\xi;t) + \eta_i^2 F(2+i\eta_i,1-i\eta_f;1-i\xi;t)F(1+i\eta_i,-i\eta_f;1-i\xi;t) - 2\eta_i\eta_f F^2(1+i\eta_i,1-i\eta_f;1-i\xi;t), \tag{3.26}$$

t being given by Eq. (1.4).

Using the asymptotic expression (3.17), we see that as $\eta\to\infty$

$$A\,\mathrm{Im}(e1-e3)\to Cx_0\,\mathrm{Re}[I_{1-i\xi}(x_0)I_{i\xi}(x_0)], \tag{3.27}$$

$$\mathrm{Im}(B(e2-e5))\to -Cx_0\,\mathrm{Im}[iI_{1-i\xi}(x_0)I_{-i\xi}(x_0)], \tag{3.28}$$

$$A\,\mathrm{Re}(e4)\to -C\left[\frac{1}{2}x_0^2|I_{i\xi}(x_0)|^2+\frac{1}{2}x_0^2|I_{1+i\xi}(x_0)|^2-x_0\,\mathrm{Re}(I_{i\xi}(x_0)I_{1-i\xi}(x_0) - \xi x_0\,\mathrm{Im}(I_{i\xi}(x_0)I_{1-i\xi}(x_0))\right], \tag{3.29}$$

$$\mathrm{Re}(B(e6))\to -C[\xi^2\,\mathrm{Re}(I_{-i\xi}^2(x_0))-\tfrac{1}{2}x_0^2\,\mathrm{Re}(I_{-i\xi}^2(x_0))-\tfrac{1}{2}x_0^2\,\mathrm{Re}(I_{1-i\xi}^2(x_0)) + \xi x_0\,\mathrm{Re}(iI_{-i\xi}(x_0)I_{1-i\xi}(x_0))+x_0\,\mathrm{Re}(I_{-i\xi}(x_0)I_{1-i\xi}(x_0))], \tag{3.30}$$

where

$$A=\frac{|\Gamma(i\xi)|^2}{|\Gamma(1+i\eta_i)|^2|\Gamma(1+i\eta_f)|^2}, \tag{3.31}$$

$$B=\frac{t^{-i\xi}\Gamma^2(i\xi)}{\Gamma^2(1-i\eta_i)\Gamma^2(1+i\eta_f)}, \tag{3.32}$$

$$C=\frac{|\Gamma(1+i\xi)|^4}{\xi^2|\Gamma(1+i\eta_i)|^2|\Gamma(1+i\eta_f)|^2}, \tag{3.33}$$

and relation 6.1.31 of Ref. 2 defines

$$|\Gamma(1+i\eta)|^2=\frac{\pi\eta}{\sinh(\pi\eta)}. \tag{3.34}$$

This leaves the result

$$\mathrm{d}f_{E1}\rightarrow\frac{4\pi^3}{9}\frac{\varepsilon^2 e^{\pm|\xi|}}{\sinh^2(\pi|\xi|)}\times\left\{\frac{1}{2}x_0^2[|I_{i\xi}(x_0)|^2-\mathrm{Re}(I^2_{-i\xi}(x_0))+|I_{1-i\xi}(x_0)|^2-\mathrm{Re}(I^2_{1-i\xi}(x_0))]\right.$$
$$\left.+\mathrm{sgn}(\xi)x_0[\mathrm{Re}(iI_{-i\xi}(x_0)I_{1-i\xi}(x_0))-\mathrm{Im}(I_{i\xi}(x_0)I_{1-i\xi}(x_0))]+\xi^2\,\mathrm{Re}(I^2_{-i\xi}(x_0))\right\}. \tag{3.35}$$

To simplify this expression, we make use of the complex-number identity

$$\mathrm{Re}(z^2)=\mathrm{Re}^2(z^*)-\mathrm{Im}^2(z^*). \tag{3.36}$$

Thus, using relations (9.6.2) and (9.6.26) of Ref. 2, we obtain

$$\mathrm{d}f_{E1}\rightarrow\frac{4\pi^3}{9}\frac{\xi^2\varepsilon^2 e^{\pm\pi|\xi|}}{\sinh^2(\pi|\xi|)}\{(\varepsilon^2-1)\mathrm{Im}^2(I_{i\xi}(|\xi|\varepsilon))[\varepsilon\,\mathrm{Im}(I_{1-i\xi}(|\xi|\varepsilon))-\mathrm{sgn}(\xi)\mathrm{Re}(I_{i\xi}(|\xi|\varepsilon))]^2\}$$
$$=\frac{4\pi}{9}\xi^2\varepsilon^2 e^{\pm\pi|\xi|}\{(\varepsilon^2-1)K^2_{i\xi}(|\xi|\varepsilon)+\varepsilon^2K'^2_{i\xi}(|\xi|\varepsilon)\}, \tag{3.37}$$

as $\eta\rightarrow\infty$. $K_\nu(z)$ is the modified Bessel function of the second kind and $K'_\nu(z)$ is its derivative with respect to its argument and $\varepsilon=\sin(\theta/2)^{-1}$. This last expression is the semiclassical result quoted by Alder *et al.* [see Eqs. (II A.29) and (II E.57) of Ref. 3].

(Received 15 November 2000; accepted for publication 4 January 2001)

We present new exact solutions (in $3+1$ and $2+1$ dimensions) of relativistic wave equations (Klein–Gordon and Dirac) in external electromagnetic fields of special form. These fields are combinations of Aharonov–Bohm solenoid field and some additional electric and magnetic fields. In particular, as such additional fields, we consider longitudinal electric and magnetic fields, some crossed fields, and some special nonuniform fields. The solutions obtained can be useful to study the Aharonov–Bohm effect in the corresponding electromagnetic fields. © *2001 American Institute of Physics.* [DOI: 10.1063/1.1353182]

I. INTRODUCTION

The Aharonov–Bohm (AB) effect[1] plays an important role in quantum theory refining the status of electromagnetic potentials in this theory. First this effect was discussed in relation to a study of interaction between a nonrelativistic charged particle and an infinitely long and infinitesimally thin magnetic solenoid field (further the AB field) (a similar effect was discussed earlier by Ehrenberg and Siday[2]). It was discovered that particle wave functions vanish at the solenoid line. In spite of the fact that the magnetic field vanishes out of the solenoid, the phase shift in the wave functions is proportional to the corresponding magnetic flux.[3] A nontrivial particle scattering by the solenoid is interpreted as a possibility for quantum particles to ''feel'' potentials of the corresponding electromagnetic field. Indeed, potentials of the AB field do not vanish out of the solenoid. AB scattering for spinning particles was considered in Refs. 4 and 5 using exact solutions of the Dirac equation in the AB field. A number of theoretical works and convincing experiments were done to clarify the AB effect and to prove its existence (see, e.g., Refs. 6–9).

Progress in the study of the AB effect may be related to revealing new situations, where the effect takes place. For example, one can consider more complicated configurations of electromagnetic fields, different regimes of particle motions, different dimensions, and so on. To study these new possibilities one has to have exact solutions of the corresponding quantum equations in these configurations of electromagnetic fields. In this relation, we ought to mention exact solutions of the Schrödinger equation in a superposition of the AB field and a uniform magnetic field.[10] The latter solutions were analyzed in Refs. 11–13 from AB effect point of view. The corresponding coherent states were constructed in Ref. 12. Klein–Gordon and Dirac equations for particles moving in a superposition of the AB field, Coulomb field, and magnetic monopole field were found and analyzed in Refs. 14 and 15.

In this article we present new exact solutions (in $3+1$ and $2+1$ dimensions) of relativistic wave equations (Klein–Gordon and Dirac) in external electromagnetic fields of special form. These fields are combinations of the AB field and different types of electric and magnetic fields. In Sec. II we consider the AB field combined with longitudinal electromagnetic fields. In Sec. III superpositions of the AB, longitudinal, and crossed fields are studied. In Secs. IV and V we present solutions in the AB field combined with some nonuniform fields. Here we also discuss

[a]On leave from Tomsk State University and Tomsk Institute of High Current Electronics, Russia.
[b]Electronic mail: gitman@fma.if.usp.br
[c]Also at: Tomsk Institute of High Current Electronics, Russia.

some relevant solutions in $2+1$ dimensional quantum electro dynamics (QED). Special functions and their properties, which are used in the article, are present in the Appendix.

Most of works, in which the AB effect was studied, are based on the use of exact solutions of the Schrödinger equation in the AB field.[1] Consider the latter a field in $3+1$ dimensions. If the magnetic solenoid is placed along the axis $z=x^3$, then the AB field can be given by potentials [we denote these potentials as $A^{(0)}_\mu(x)$, $x=(x^\mu,\mu=0,1,2,3)$] of the form

$$A^{(0)}_1=\frac{\Phi}{2\pi r^2}x^2,\quad A^{(0)}_2=-\frac{\Phi}{2\pi r^2}x^1,\quad A^{(0)}_0=A^{(0)}_3=0,\quad r^2=(x^1)^2+(x^2)^2. \tag{1.1}$$

The AB magnetic field has the form $\mathbf{H}^{(0)}=(0,0,H^{(0)})$, where $H^{(0)}$ is singular at $r=0$,

$$H^{(0)}=\Phi\,\delta(x^1)\,\delta(x^2). \tag{1.2}$$

The AB field creates a finite magnetic flux Φ along the axis z. It is convenient to define a quantity μ, which characterizes the magnetic flux Φ and is related to the latter as follows:

$$\Phi=(l_0+\mu)\Phi_0,\quad \Phi_0=2\pi c\hbar/|e|,\quad 0\leqslant\mu<1, \tag{1.3}$$

where l_0 is integer, and $e=-|e|$ is the charge of the electron. In what follows, we call μ the mantissa of the magnetic flux Φ. By definition μ is a positive fractional part of the magnetic flux if the latter is measured in units of quanta Φ_0. Cylindrical coordinates r,φ ($x^1=r\cos\varphi$, $x^2=r\sin\varphi$) are preferable for AB field consideration. In these coordinates

$$\frac{|e|}{c\hbar}A^{(0)}_1=\frac{l_0+\mu}{r}\sin\varphi,\quad \frac{|e|}{c\hbar}A^{(0)}_2=-\frac{l_0+\mu}{r}\cos\varphi. \tag{1.4}$$

In the present article, we are going to consider particle motion in electromagnetic fields A_μ that are a combination of the AB field and some additional fields with potentials $A^{(1)}_\mu$,

$$A_\mu=A^{(0)}_\mu+A^{(1)}_\mu. \tag{1.5}$$

Electromagnetic potentials enter in relativistic wave equations only via the operators of momenta $P_\mu=i\hbar\partial_\mu-(e/c)A_\mu$. Doing the transformation $\Psi(x)=e^{-il_0\varphi}\tilde{\Psi}(x)$ of wave functions, we can eliminate l_0 dependence of AB potentials in equations for $\tilde{\Psi}(x)$. Indeed, such equations already contain momentum operators of the form

$$\begin{gathered}e^{il_0\varphi}P_\mu e^{-il_0\varphi}=i\hbar\partial_\mu-\frac{e}{c}(\tilde{A}^{(0)}_\mu+A^{(1)}_\mu),\\ \frac{|e|}{ch}\tilde{A}^{(0)}_1=\frac{\mu}{r}\sin\varphi,\quad \frac{|e|}{ch}\tilde{A}^{(0)}_2=-\frac{\mu}{r}\cos\varphi,\quad \tilde{A}^{(0)}_0=\tilde{A}^{(0)}_3=0.\end{gathered} \tag{1.6}$$

Thus, all the matrix elements of any axial-symmetric operators depend on the mantissa of the magnetic flux only.

II. AHARONOV–BOHM FIELD COMBINED WITH LONGITUDINAL ELECTROMAGNETIC FIELDS

Here we consider particle motion in a superposition of the AB field and of some longitudinal electromagnetic fields. We call electric $\mathbf{E}$ and magnetic $\mathbf{H}$ fields longitudinal ones whenever they are parallel and are directed along the AB solenoid (along the axis z),

$$\mathbf{E}=E\mathbf{n},\quad \mathbf{H}=H\mathbf{n},\quad \mathbf{n}^2=1,\quad \mathbf{n}=(0,0,1). \tag{2.1}$$

It follows from Maxwell equations that in this case the functions E and H must obey the conditions

$$\begin{aligned} &E=E(x^0,x^3)=\partial_0 A_3-\partial_3 A_0, \quad A_0=A_0(x^0,x^3), \quad A_3=A_3(x^0,x^3), \\ &H=H(x^1,x^2)=\partial_2 A_1-\partial_1 A_2, \quad A_1=A_1(x^1,x^2), \quad A_2=A_2(x^1,x^2), \end{aligned} \tag{2.2}$$

where $A_0(x^0,x^3)$, $A_1(x^1,x^2)$, $A_2(x^1,x^2)$, $A_3(x^0,x^3)$ are arbitrary functions of the indicated arguments. Exact solutions of the relativistic wave equations in such fields (in the absence of the AB field) were studied in Refs. 16 and 17. As we show in the following, whenever the AB field is present, then exact solutions of the relativistic wave equations can be found only in the axially symmetric case with the magnetic field having the form $H=H(r)$. Thus, potentials of additional fields, which are considered in the present section, have the following form: $A_0^{(1)}=A_0^{(1)}(x^0,x^3)$, $A_3^{(1)}=A_3^{(1)}(x^0,x^3)$ arbitrary and

$$A_1^{(1)}=\frac{c\hbar}{|e|}\frac{A(r)}{r}\sin\varphi, \quad A_2^{(1)}=-\frac{c\hbar}{|e|}\frac{A(r)}{r}\cos\varphi, \quad H(r)=\frac{c\hbar}{|e|}\frac{A'(r)}{r}, \tag{2.3}$$

where $A(r)$ is an arbitrary function of r.

A. Classical description of radial motion

To interpret quantum numbers of wave functions, it is often useful to have a classical picture of the problem. That is why we present here a classical analysis of the particle motion in fields under consideration.

Consider classical trajectories that do not intersect the axis z, thus they do not ''feel'' the existence of the AB field. For such trajectories, the quantity P_r^2 is an integral of motion ($c^2P_r^2$ is said to be radial energy),

$$P_r^2=P_1^2+P_2^2=\hbar^2k_1^2, \quad m_0^2c^2+P_r^2=P_0^2-P_3^2, \tag{2.4}$$

where P_μ is the classical kinetic momentum (a classical analog of the operators P_μ) and m_0 is the rest mass. L_z is an integral of motion as well (L is the angular momentum),

$$L_z=\tilde{L}_z-\hbar(l_0+\mu)=\hbar(l-l_0), \quad \tilde{L}_z=x^1P^2-x^2P^1-\hbar A(r)=\hbar(l+\mu). \tag{2.5}$$

Here l is arbitrary (l will be an integer in quantum theory).

As will be seen in the following, exact solutions of relativistic wave equations can be found whenever the functions $A(r)$ in Eq. (2.3) have the form

$$(1) \quad A(r)=0, \tag{2.6}$$

$$(2) \quad A(r)=\frac{\gamma r^2}{2}, \quad \gamma>0, \tag{2.7}$$

$$(3) \quad A(r)=\gamma r, \quad \gamma>0. \tag{2.8}$$

The first case corresponds to the absence of an additional electromagnetic field, the second one corresponds to the additional constant uniform magnetic field H along the solenoid ($\gamma=|eH|/c\hbar$), and the third one corresponds to the additional constant magnetic field $H(r)=b/r$, ($\gamma=|eb|/c\hbar$). Consider classical motion in these cases.

(1) For $A(r)=0$, the momenta P_1 and P_2 are integrals of motion. Then the radial motion (the motion in x^1,x^2 plane) is parametrized by the proper time τ and can be presented as

$$x^1=\frac{P^1}{m_0c}\tau+x^1_{(0)}, \quad x^2=\frac{P^2}{m_0c}\tau+x^2_{(0)}, \tag{2.9}$$

where $x^1_{(0)}$, $x^2_{(0)}$ are integration constants. In this case

$$\tilde{L}_z=\hbar(l+\mu)=x^1_{(0)}P^2-x^2_{(0)}P^1. \tag{2.10}$$

Consider the quantity

$$\Delta R=P_r^{-1}(x^1_{(0)}P^2-x^2_{(0)}P^1)=\frac{l+\mu}{k_1}. \tag{2.11}$$

One can show that $|\Delta R|$ characterizes a minimal distance between the trajectory (2.9) and the axis x^3. All the classical trajectories are divided in two groups according to the sign of $l+\mu$. Trajectories with $l+\mu>0$ can be called right ones and those with $l+\mu<0$ can be called left ones. The reason is the following: Looking from the positive z direction, one can see that a minimal angle rotation from the vector $\mathbf{r}=(x^1,x^2,x^3)$ to the particle momentum is counterclockwise for the right trajectories and clockwise for left ones.

(2) For $A(r)=\gamma r^2/2$, the radial motion has the form

$$\begin{gathered} x^1=R\cos\kappa+x^1_{(0)}, \quad x^2=R\sin\kappa+x^2_{(0)}, \\ \kappa=\omega_0\tau+\varphi_0, \quad \omega_0=\frac{\gamma}{m}, \quad m=\frac{m_0c}{\hbar}. \end{gathered} \tag{2.12}$$

Here R, φ_0, $x^1_{(0)}$, $x^2_{(0)}$ are integration constants. The trajectories (2.12) are circles of radius R with centers having coordinates $x^1_{(0)}$, $x^2_{(0)}$,

$$(x^1-x^1_{(0)})^2+(x^2-x^2_{(0)})^2=R^2. \tag{2.13}$$

One can easily find

$$\begin{gathered} P_r=\hbar\gamma R, \quad l+\mu=\frac{\gamma}{2}(R^2-R_0^2), \quad (x^1_{(0)})^2+(x^2_{(0)})^2=R_0^2, \\ l+\mu\leqslant\frac{\gamma R^2}{2}=\frac{P_r^2}{2\hbar^2\gamma}=\frac{k_1^2}{2\gamma}. \end{gathered} \tag{2.14}$$

We can see that classical trajectories with $l\geqslant-\mu$ embrace the solenoid, and ones with $l<-\mu$ do not. In quantum theory these conditions are $l\geqslant 0$ and $l<0$, respectively. The quantity ΔR characterizes a minimal distance between the trajectory (2.12) and the solenoid,

$$\Delta R=|R-R_0|=\frac{2|l+\mu|}{\gamma(R+R_0)}. \tag{2.15}$$

(3) Consider finally $A(r)=\gamma r$. Here the radial motion depends essentially on values of constants a, ε,

$$a=\frac{P_r}{\hbar\gamma}=\frac{k_1}{\gamma}>0, \quad \varepsilon=(l+\mu). \tag{2.16}$$

For $\varepsilon=1$, the classical motion is possible only if $a>1$. For $\varepsilon=-1$, the classical motion is possible if $a>0$. Whenever $a\geqslant 1$ we get unbounded motion for r. For $0<a<1$, $\varepsilon=-1$, this motion is bounded. In the following we present the radial motion in s parametrization,

$$
\begin{gathered}
a>1:\ \ r=\frac{|l+\mu|(a\cosh s+\varepsilon)}{\gamma(a^2-1)},\quad \tau=\frac{|l+\mu|(a\sinh s+\varepsilon s)}{\gamma^2(a^2-1)^{3/2}},\\
\varphi-\varphi_0=\frac{s}{\sqrt{a^2-1}}+2\varepsilon\arctan\left(\sqrt{\frac{a-\varepsilon}{a+\varepsilon}}\tanh\frac{s}{2}\right),\\
a=1,\quad \varepsilon=-1:\ \ 2\gamma r=|l+\mu|(s^2+1),\quad 2\gamma^2\tau=|l+\mu|m\left(\frac{s^3}{3}+s\right),\\
\varphi-\varphi_0=s-2\arctan s,\\
a<1,\quad \varepsilon=-1:\ \ r=\frac{|l+\mu|(1-a\cos s)}{\gamma(1-a^2)},\quad \tau=\frac{|l+\mu|m(s-a\sin s)}{\gamma^2(1-a^2)^{3/2}},\\
\varphi-\varphi_0=s\left(\frac{1}{\sqrt{1-a^2}}-1\right)-2\arctan\left(\frac{a\sin s}{1+\sqrt{1-a^2}-a\cos s}\right).
\end{gathered}
\tag{2.17}
$$

In all the cases under consideration, the minimal distance between a trajectory and the solenoid is defined by

$$
\Delta R=\frac{|l+\mu|}{\gamma|a-\varepsilon|}. \tag{2.18}
$$

Thus, the quantity l has a clear classical interpretation.

B. Klein–Gordon equation in longitudinal fields

Here we consider solutions of the Klein–Gordon equation

$$
(P_\mu P^\mu-m_0^2c^2)\Psi(x)=0 \tag{2.19}
$$

in the superposition of the external fields (1.1) and (2.3). In this case, the operators (2.4) are integrals of motion. Whenever an additional field is axial-symmetric one (2.3), then the operator (2.5) is an integral of motion as well. Thus, we subject solutions of Eq. (2.19) to the following additional conditions:

$$
\hbar^{-2}(P_1^2+P_2^2)\Psi(x)=k_1^2\Psi(x),\quad \hbar^{-2}(P_0^2-P_3^2)\Psi(x)=(m^2+k_1^2)\Psi(x). \tag{2.20}
$$

Then such solutions can be presented in the form $\Psi(x)=\psi(x^1,x^2)\Phi(x^0,x^3)$, where the functions ψ and Φ obey

$$
\hbar^{-2}(P_1^2+P_2^2)\psi(x^1,x^2)=k_1^2\psi(x^1,x^2), \tag{2.21}
$$

$$
\hbar^{-2}(P_0^2-P_3^2)\Phi(x^0,x^3)=(m^2+k_1^2)\Phi(x^0,x^3). \tag{2.22}
$$

The AB field does not enter in Eq. (2.22). This equation can be solved for a large class of electromagnetic fields. All the corresponding solutions of Eq. (2.22) are described in detail in Refs. 16 and 17, that is why we do not present them here.

Let us turn to Eq. (2.21). As was mentioned previously, exact solutions of this equation can be found only in the superposition of the AB field and fields (2.6)–(2.8). In all these cases, the operator L_z is an integral of motion, thus we can search for solutions which are eigenvectors for the latter operator. In cylindrical coordinates, we get

$$L_z\psi(r,\varphi)=-i\hbar\partial_\varphi\psi(r,\varphi)=\hbar(l-l_0)\psi(r,\varphi),\quad \psi(r,\varphi)=\frac{\exp[i(l-l_0)\varphi]}{\sqrt{2\pi}}\psi(r). \tag{2.23}$$

Whenever additional fields have the structure (2.3), the radial function $\psi(r)$ obeys

$$\hat{R}\psi(r)=k_1^2\psi(r),\quad \hat{R}=\left(\frac{l+\mu+A(r)}{r}\right)^2-\frac{1}{r}\frac{\mathrm{d}}{\mathrm{d}r}-\frac{\mathrm{d}^2}{\mathrm{d}r^2}. \tag{2.24}$$

C. Solutions of the radial equation in the absence of additional fields

Consider Eq. (2.24) for $A(r)=0$,

$$\frac{\mathrm{d}^2\psi}{\mathrm{d}r^2}+\frac{1}{r}\frac{\mathrm{d}\psi}{\mathrm{d}r}+\left[k_1^2-\frac{(l+\mu)^2}{r^2}\right]\psi=0. \tag{2.25}$$

A general solution of the equation can be written via Bessel functions $J_\nu(x)$, (Ref. 18, 8.402),

$$\psi(r)=\psi_{k_1,l}(r)=c_1J_\nu(k_1r)+c_2J_{-\nu}(k_1r),\quad \nu=|l+\mu|. \tag{2.26}$$

Solutions, which are bounded for all $r\geqslant 0$, must have $c_2=0$. In this case $\psi_{k_1,l}$ form an orthogonal and complete set of functions $(k_1,k_1'>0)$,

$$\int_0^\infty J_\nu(k_1'r)J_\nu(k_1r)r\,\mathrm{d}r=k_1^{-1}\delta(k_1-k_1'),\quad \int_0^\infty J_\nu(k_1r')J_\nu(k_1r)k_1\,\mathrm{d}k_1=\frac{\delta(r-r')}{r}. \tag{2.27}$$

Suppose $l=0,-1$, $\mu\neq 0$ (note that in this case the corresponding classical trajectories pass maximally close to the solenoid). Then we have a special case. Here there are solutions of the form (2.26) with $c_1=0$, $c_2\neq 0$ (of course they are unbounded), which obey relations (2.27). Moreover, there are solutions (2.26) with both $c_1\neq 0$ and $c_2\neq 0$, which are unbounded and not orthogonal,

$$\int_0^\infty J_\nu(k_1'r)J_{-\nu}(k_1r)r\,\mathrm{d}r=\frac{2\sin\nu\pi}{\pi(k_1'^2-k_1^2)}\left(\frac{k_1'}{k_1}\right)^\nu,\quad k_1>k_1',\quad |\nu|<1. \tag{2.28}$$

However, these solutions are quadratically integrable [due to (2.27)] and form a complete set of functions (in fact, an overcomplete set). Besides, Eq. (2.25) has solutions of the form

$$\psi(r)=K_\nu(qr),\quad k_1^2=-q^2, \tag{2.29}$$

where $K_\nu(r)$ are Macdonald functions (Ref. 18, 8.407). These functions have a finite norm ($\delta=\arg q$)

$$\int_0^\infty K_\nu^*(qr)K_\nu(qr)r\,\mathrm{d}r=\frac{\pi\sin 2\nu\delta}{2|q|^2\sin\nu\pi\sin 2\delta},\quad |\nu|<1,\quad -\pi/2<\delta<\pi/2\quad (\mathrm{Re}\,q>0). \tag{2.30}$$

But they are not orthogonal with respect to q,

$$\int_0^\infty K_\nu(q'r)K_\nu(qr)r\,\mathrm{d}r=\frac{\pi(q^{2\nu}-q'^{2\nu})}{2(q^2-q'^2)\sin\nu\pi},\quad |\nu|<1. \tag{2.31}$$

In particular, for $\nu=0$, we get

$$\int_0^\infty K_0^*(qr)K_0(qr)r\ \mathrm{d}r=\frac{\delta}{|q|^2\sin 2\delta},\quad \int_0^\infty K_0(q'r)K_0(qr)r\ \mathrm{d}r=\frac{\ln q-\ln q'}{q^2-q'^2}. \tag{2.32}$$

The above-mentioned peculiarities are related to the loss of hermicity of the operator $\hat{R}$ for $l=0,-1$, $\mu\neq 0$. A similar problem was discussed in Ref. 19.

D. Uniform magnetic field

Here we consider a superposition of AB field (1.1) and a uniform magnetic field (2.7). It is useful to introduce dimensionless operators a_k, a_k^+, $k=1,2$ by the following relations:

$$\begin{gathered}\hbar\sqrt{2\gamma}a_1=-iP_1-P_2,\quad \hbar\sqrt{2\gamma}a_1^+=iP_1-P_2,\quad \gamma=\frac{|eH|}{c\hbar},\\ \hbar\sqrt{2\gamma}a_2=-iP_1+P_2+\hbar\gamma(x^1+ix^2),\quad \hbar\sqrt{2\gamma}a_2^+=iP_1+P_2+\hbar\gamma(x^1-ix^2).\end{gathered} \tag{2.33}$$

Considering coordinates and momenta in these relations as classical quantities, we can get a representation for the classical motion (2.12) in terms of a_1 and a_2,

$$a_1=\sqrt{\frac{\gamma}{2}}\mathrm{Re}^{-i\kappa},\quad a_2=\sqrt{\frac{\gamma}{2}}(x_0^1+ix_0^2),\quad (x_0^1+ix_0^2)=R_0e^{i\delta}. \tag{2.34}$$

The following operator relations take place:

$$P_r^2=P_1^2+P_2^2=\hbar^2\gamma(a_1^+a_1+a_1a_1^+),\quad 2L_z=\hbar(a_1^+a_1+a_1a_1^+-a_2^+a_2-a_2a_2^+). \tag{2.35}$$

We introduce also a dimensionless coordinate ρ instead of r,

$$\rho=\frac{\gamma r^2}{2},\quad \mathrm{d}x^1\,\mathrm{d}x^2=\frac{1}{\gamma}\mathrm{d}\rho\ \mathrm{d}\varphi. \tag{2.36}$$

On the classical trajectories (2.12) ρ evolves as

$$2\rho=\gamma[R^2+R_0^2+2RR_0\cos(\kappa-\delta)]. \tag{2.37}$$

Being written in terms of the variables ρ,φ, the operators a_k,a_k^+ take the form

$$\begin{gathered}a_1=\sqrt{\rho}e^{-i\varphi}[(l_0+\mu+\rho-i\partial_\varphi)/2\rho+\partial_\rho],\\ a_1^+=\sqrt{\rho}e^{i\varphi}[(l_0+\mu+\rho-i\partial_\varphi)/2\rho-\partial_\rho],\\ a_2=-\sqrt{\rho}e^{i\varphi}[(l_0+\mu-\rho-i\partial_\varphi)/2\rho-\partial_\rho],\\ a_2^+=-\sqrt{\rho}e^{-i\varphi}[(l_0+\mu-\rho-i\partial_\varphi)/2\rho+\partial_\rho].\end{gathered} \tag{2.38}$$

Using the commutation relations for the momentum operators

$$P_\mu P_\nu-P_\nu P_\mu=-i\frac{e\hbar}{c}F_{\mu\nu},\quad F_{\mu\nu}=\partial_\mu A_\nu-\partial_\nu A_\mu, \tag{2.39}$$

and definition of the magnetic field (1.2), we arrive at the following commutation relations for the operators a_k,a_k^+ :

$$[a_1,a_1^+]=1+f,\quad [a_2,a_2^+]=1-f,\quad [a_1,a_2]=-f,\quad [a_1,a_2^+]=0,$$
$$f=(\Phi/H)\,\delta(x^1)\,\delta(x^2)=2\,\frac{\Phi}{\Phi_0}\,\delta(\rho)=2(l_0+\mu)\,\delta(\rho). \tag{2.40}$$

These commutation relations contain a singular dimensionless function f. Whenever the AB field is absent ($f=0$), then the operators a_k,a_k^+ form two mutual commuting sets of creation and annihilation operators. It is not true in the presence of the AB field. However, as will be seen further, these operators behave as creation and annihilation ones when acting on functions that tend to zero (sufficiently rapidly) as $\rho\to 0$. Being written in the coordinates ρ,φ, the operators (2.35) have the form

$$P_r^2=2\gamma\hbar^2 Q,\quad L_z=-i\hbar\partial_\varphi,\quad Q=\frac{(l_0+\mu+\rho-i\partial_\varphi)^2}{4\rho}-\partial_\rho-\rho\partial_\rho^2. \tag{2.41}$$

In the case under consideration, the radial equation (2.24) reads

$$\overline{Q}\psi(\rho)=\left(\overline{n}+\frac{1}{2}\right)\psi(\rho),\quad \overline{Q}=\frac{(l+\mu+\rho)^2}{4\rho}-\partial_\rho-\rho\partial_\rho^2,\quad k_1^2=2\gamma\left(\overline{n}+\frac{1}{2}\right). \tag{2.42}$$

Bounded and quadratically integrable solutions of this equation are expressed via the Laguerre functions (A1) (see the Appendix). There are two types of solutions of the latter equation, we denote them as $\psi^{(j)}(\rho)$, $j=1,2$ (two types of states). The first one $j=1$ corresponds to $l\geqslant 0$ (classical trajectories embrace the solenoid),

$$\psi^{(1)}(\rho)=I_{n+\mu,n-l}(\rho),\quad 0\leqslant l\leqslant n,\quad n=0,1,2,\ldots,\quad \overline{n}=n+\mu. \tag{2.43}$$

The second type of solutions with $j=2$ corresponds to $l<0$ (classical trajectories do not embrace the solenoid),

$$\psi^{(2)}(\rho)=I_{n-l-\mu,n}(\rho),\quad l<0,\quad \overline{n}=n. \tag{2.44}$$

In these two cases radial momentum spectra are different,

$$(k_1^{(1)})^2=2\gamma(n+\mu+\tfrac{1}{2}),\quad 0\leqslant l\leqslant n,$$
$$(k_1^{(2)})^2=2\gamma(n+\tfrac{1}{2}),\quad l<0,\quad n=0,1,2,\ldots\ . \tag{2.45}$$

The spectrum for $j=2$ (which is a part of the total spectrum) corresponds exactly to the spectrum of a spinless particle in a uniform magnetic field (without the AB field). The spectrum for $j=1$ is shifted by $2\gamma\mu$ with respect to the one for $j=2$. It is important to note that the presence of the AB field partially lifts the degeneracy of the total spectrum in the quantum number l.

It is convenient to define effective quantum numbers $\overline{l}$ and $\overline{n}$ by

$$\overline{n}=n+\mu(2-j)=\begin{cases} n+\mu, & j=1,\quad \overline{l}=l+\mu,\quad \overline{l}\leqslant\overline{n} \\ n, & j=2,\quad n=0,1,2,\ldots\ . \end{cases} \tag{2.46}$$

Using these numbers, we introduce the functions

$$\psi_{n,l}^{(1)}(\rho,\varphi)=(-1)^{n-l}\frac{\exp[i(l-l_0)\varphi]}{\sqrt{2\pi}}I_{\overline{n},\overline{n}-\overline{l}}(\rho), \tag{2.47}$$

$$\psi^{(2)}_{n,l}(\rho,\varphi)=(-1)^n\frac{\exp[i(l-l_0)\varphi]}{\sqrt{2\pi}}I_{\overline{n}-\overline{l},\overline{n}}(\rho).$$

According to Eq. (A4), these functions can be expressed via the Laguerre polynomials. Thus, the orthonormality relation can be proved

$$\int_0^\infty \mathrm{d}\rho\int_0^{2\pi}\mathrm{d}\varphi\ \psi^{(j')}_{n',l'}{}^{*}(\rho,\varphi)\psi^{(j)}_{n,l}(\rho,\varphi)=\delta_{l.l'}\delta_{n,n'}. \tag{2.48}$$

The set of the Laguerre functions

$$I_{\alpha+n,n}(x),\quad n=0,1,2\ldots,\quad \alpha>-1 \tag{2.49}$$

is complete in the space of quadratically integrable functions of $x\geqslant 0$,

$$\sum_{n=0}^{\infty} I_{\alpha+n,n}(x)I_{\alpha+n,n}(y)=\delta(x-y). \tag{2.50}$$

Then the set $\psi^{(j)}_{n,l}(\rho,\varphi)$ is complete in the space of quadratically integrable functions of ρ,φ, ($\rho>0,0\leqslant\varphi\leqslant 2\pi$).

Using relations (A6)–(A11), one can get the action of the operators (2.38) on the functions $\psi^{(j)}_{n,l}(\rho,\varphi)$,

$$\begin{aligned} a_1\psi^{(j)}_{n,l}(\rho,\varphi)&=\sqrt{\overline{n}}\psi^{(j)}_{n-1,l-1}(\rho,\varphi),\quad a_1^+\psi^{(j)}_{n,l}(\rho,\varphi)=\sqrt{\overline{n+1}}\psi^{(j)}_{n+1,l+1}(\rho,\varphi),\\ a_2\psi^{(j)}_{n,l}(\rho,\varphi)&=\sqrt{\overline{n-l}}\psi^{(j)}_{n,l+1}(\rho,\varphi),\quad a_2^+\psi^{(j)}_{n,l}(\rho,\varphi)=\sqrt{\overline{n-l+1}}\psi^{(j)}_{n,l-1}(\rho,\varphi). \end{aligned} \tag{2.51}$$

These formulas show that the functions $\psi^{(1)}_{n,l}$ may be created by an action of the operators a_k^+ on $\psi^{(1)}_{0,0}$, and the functions $\psi^{(2)}_{n,l}$ may be created by an action of the operators a_k^+ on $\psi^{(2)}_{0,-1}$. Namely,

$$\psi^{(1)}_{n,l}=\sqrt{\frac{\Gamma(1+\mu)}{\Gamma(1+\overline{n})\Gamma(1+\overline{n}-\overline{l})}}(a_2^+)^{n-l}(a_1^+)^n\psi^{(1)}_{0,0}, \tag{2.52}$$

$$\psi^{(2)}_{n,l}=\sqrt{\frac{\Gamma(2-\mu)}{\Gamma(1+\overline{n})\Gamma(1+\overline{n}-\overline{l})}}(a_1^+)^n(a_2^+)^{n-l-1}\psi^{(2)}_{0,-1}. \tag{2.53}$$

It is natural to interpret $\psi^{(1)}_{0,0}$ as a vacuum state for the states $\psi^{(1)}_{n,l}$, and to interpret $\psi^{(2)}_{0,-1}$ as a vacuum state for the states $\psi^{(2)}_{n,l}$. Thus, for $\mu\neq 0$, we have two vacuum states in the problem. For $\mu=0$, the situations changes. By virtue of Eq. (A18)

$$I_{n,n-l}=(-1)^l I_{n-l,n}\rightarrow\psi^{(1)}_{n,l}=(-1)^l\psi^{(2)}_{n,l},\quad \mu=0, \tag{2.54}$$

and for any $l<n$, the function $\psi^{(1)}_{0,0}$ is connected to $\psi^{(2)}_{0,-1}$ as

$$a_2^+\psi^{(1)}_{0,0}=\psi^{(2)}_{0,-1},\quad a_2\psi^{(2)}_{0,-1}=\psi^{(1)}_{0,0}. \tag{2.55}$$

Thus, we have only one vacuum in the problem, one energy spectrum (2.45), and all the wave functions are created from the vacuum $\psi^{(1)}_{0,0}$.

One ought to stress that all the states obey the property $\psi^{(j)}_{n,l}(\rho=0,\varphi)=0$, which means that the scalar particle has zero probability to be found in the solenoid area. In fact, the existence of this property allows us to speak about the AB effect.

Definitions (2.51) can formally be considered for any values of indices n, l. In particular, we can consider the following relations:

$$a_1^+\psi^{(2)}_{n,-1}=\sqrt{n+1}\,\psi^{(2)}_{n+1,0}=(-1)^{n+1}(1+n)\sqrt{\frac{\Gamma(1+n)}{2\pi\Gamma(2-\mu+n)}}\exp\left[-il_0\varphi-\frac{\rho}{2}\right]\rho^{-\mu/2}L^{-\mu}_{n+1}(\rho),$$

$$\begin{aligned}a_1\psi^{(1)}_{n,0}&=\sqrt{n+\mu}\,\psi^{(1)}_{n-1,-1}\\&=(-1)^n(n+\mu)\sqrt{\frac{\Gamma(1+n)}{2\pi\Gamma(1+\mu+n)}}\exp\left[-i(1+l_0)\varphi-\frac{\rho}{2}\right]\rho^{-(1-\mu)/2}L^{\mu-1}_{n}(\rho),\\ a_2^+\psi^{(1)}_{n,0}&=\sqrt{n+1}\,\psi^{(1)}_{n,-1}\\&=(-1)^{n+1}(1+n)\sqrt{\frac{\Gamma(1+n)}{2\pi\Gamma(1+\mu+n)}}\exp\left[-i(1+l_0)\varphi-\frac{\rho}{2}\right]\rho^{-(1-\mu)/2}L^{\mu-1}_{n+1}(\rho),\end{aligned}\tag{2.56}$$

$$a_2\psi^{(2)}_{n,-1}=\sqrt{1-\mu+n}\,\psi^{(2)}_{n,0}=(-1)^n(1-\mu+n)\sqrt{\frac{\Gamma(1+n)}{2\pi\Gamma(2-\mu+n)}}\exp\left[-il_0\varphi-\frac{\rho}{2}\right]\rho^{-\mu/2}L^{-\mu}_{n}(\rho).$$

However, the functions $\psi^{(1)}_{n,-1}$, $\psi^{(2)}_{n,0}$ do not present any physical solutions of the problem, they are not in the set (2.47). Thus, in the general case $\mu\neq 0$, the action of the operators a_k^+, a_k on wave functions may lead them out of a class of physical solutions. The functions (2.56) are singular at $r=0$ (for $\mu\neq 0$), however they still remain quadratically integrable.

Thus, we see that $l=0,-1$ is a special case. Here there appear unbounded (but quadratically integrable) solution $\psi^{(1)}_{n,-1}$, $\psi^{(2)}_{n,0}$. Whenever $\mu\to 0$, these states either coincide with the corresponding states in the pure magnetic field or disappear. The states $\psi^{(1)}_{n,0}, \psi^{(2)}_{n,0}, \psi^{(1)}_{n,-1}, \psi^{(2)}_{n,-1}$ are not mutually orthogonal in spite of the fact that they belong to different eigenvalues of the operator P_r^2.

Equation (2.42) has additional solutions in the case $l=0,-1$. According to Eq. (A20) they have the form

$$\psi(\rho)=\psi_{\lambda\alpha}(\rho),\quad \alpha=\begin{cases}\mu, & l=0,\\ & 2\overline{n}=2\lambda+l+\mu-1,\\ 1-\mu, & l=-1,\end{cases}\tag{2.57}$$

where the functions $\psi_{\lambda\alpha}(\rho)$ are defined by Eqs. (A28) and (A29). Solutions (2.57) with any different complex λ are orthogonal and have finite norms according to the properties (A38)–(A40). These solutions are singular at $r=0$. For $l=0$ such solutions exist even in the pure magnetic field. Their existence is related to the loss of hermicity of the operator P_r^2.

E. Nonuniform magnetic field

Here we consider the radial equation (3.2.8) for $A(r)=\gamma r$,

$$\frac{\mathrm{d}^2\psi}{\mathrm{d}r^2}+\frac{1}{r}\frac{\mathrm{d}\psi}{\mathrm{d}r}-\left(\frac{l+\mu+\gamma r}{r}\right)^2\psi+(\gamma a)^2\psi=0,\quad P_r^2=(\hbar\gamma a)^2,\quad k_1^2=(\gamma a)^2.\tag{2.58}$$

The constant a is defined in Eq. (2.16).

For $a\neq 1$ bounded solutions of this equation are expressed via the the Laguerre functions (A1) as

$$\psi(r)=\psi_{n,l}(r)=I_{\alpha+n,n}(x),\quad x=2\sqrt{1-a^2}\,\gamma r,\tag{2.59}$$

$$\alpha=2|l+\mu|, \quad 1+\alpha+2n=-\frac{2(l+\mu)}{\sqrt{1-a^2}}.$$

For $a>1$, there are solutions for any l (in complete accordance with the classical theory). In this case the Laguerre functions have imaginary arguments and complex indices.

For $a<1$, bounded solutions of the form (2.59) exist only for $l<0$ (also in accordance with the classical theory). Besides, in such a case

$$a^2=1-\frac{\alpha^2}{(1+\alpha+2n)^2}, \quad n=0,1,2,\ldots, \qquad x=\frac{2\alpha\gamma r}{1+\alpha+2n}. \tag{2.60}$$

Thus, n must be integer and a is quantized. Here the functions (2.59) can be expressed via the Laguerre polynomials by means of Eqs. (A4) and (A19).

For $a=1$, bounded solutions of the form (2.59) exist only for $l<0$, these functions can be expressed via the Bessel functions,

$$\psi(r)=J_\alpha(2\sqrt{\alpha\gamma r}), \quad a=1, \quad l<0. \tag{2.61}$$

One can see with the help of Eq. (A22) that the solutions (2.61) follow from Eq. (2.59) as $a\to 1$.

All the bounded solutions vanish at $r=0$.

It is interesting to note that there exist unbounded (but quadratically integrable solutions) of Eq. (2.58) for $l=0,-1$. For any complex a, the latter solutions are defined as

$$\psi(r)=\psi_{\lambda,\alpha}(2\sqrt{1-a^2}\gamma r), \quad a\neq 1, \quad \lambda=-\frac{l+\mu}{\sqrt{1-a^2}}, \quad \mathrm{Re}\sqrt{1-a^2}>0,$$
$$\psi(r)=K_\alpha(2\sqrt{\alpha\gamma r}), \quad a=1. \tag{2.62}$$

Here $K_\alpha(x)$ are Macdonald functions. The existence of such solutions is related to the loss of hermicity of the operator P_r^2.

F. Solutions of the Klein–Gordon equation that are not related to radial momentum conservation

As was demonstrated previously, selecting the radial momentum (2.21) as an integral of motion, we can separate variables and then consider two independent problems: a two-dimensional motion of the charge in the magnetic field (2.21) (the latter field includes the AB field), and a two-dimensional motion of the charge in an electric field, the latter problem does not depend on the AB field. However, there is a wide class of exact solutions, which are not eigenvectors for the radial momentum operator. They correspond to a superposition of the AB field and longitudinal running electric fields (potentials of such fields depend on $u^0=x^0-x^3$ only). Thus, here we will use light cone variables u^0,u^3,

$$u^0=x^0-x^3, \quad u^3=x^0+x^3. \tag{2.63}$$

Then the above-mentioned longitudinal running electric fields have the following potentials and strengths:

$$A_0^{(1)}=A_3^{(1)}=\tfrac{1}{2}B(u^0), \quad E=B'(u^0), \tag{2.64}$$

where $B(u^0)$ is an arbitrary function of u^0. Consider operators $\tilde{P}_0, \tilde{P}_3, \tilde{p}_3$,

$$2\tilde{P}_0 = P_0 - P_3, \quad 2\tilde{P}_3 = P_0 + P_3, \quad \tilde{P}_0 = i\hbar \frac{\partial}{\partial u^0},$$
$$\tilde{p}_3 = i\hbar \frac{\partial}{\partial u^3}, \quad \tilde{P}_3 = \tilde{p}_3 + \frac{\hbar g(u^0)}{2}, \quad g = \frac{|e|B(u^0)}{c\hbar}. \tag{2.65}$$

The operator $\tilde{p}_3$ commutes with the one L_z and both are integrals of motion. Thus, we can demand for solutions of Eq. (2.19) to be eigenvectors for these operators,

$$\tilde{p}_3 \Psi(x) = \frac{\hbar\lambda}{2}\Psi(x), \quad L_z\Psi(x) = \hbar(l - l_0)\Psi(x). \tag{2.66}$$

Such solutions have the form

$$\Psi(x) = [\lambda + g(u^0)]^{-1/2}\Phi(r,t)\exp i\left[(l-l_0)\varphi - m^2 t(u^0) - \frac{\lambda u^3}{2}\right],$$
$$t(u^0) = \frac{1}{2}\int \frac{du^0}{\lambda + g(u^0)}, \tag{2.67}$$

where the function $\Phi(r,t)$ obeys

$$\hat{R}_1\Phi(r,t) = 0, \quad \hat{R}_1 = i\partial_t + \partial_r^2 + \frac{\partial_r}{r} - \frac{[\overline{l} + A(r)]^2}{r^2}, \quad \overline{l} = l + \mu. \tag{2.68}$$

We recall that $A(r)$ was defined in Eq. (2.3).

Consider first the case $A(r) = 0$. Here we find a propagation function for Eq. (2.68) in the form [$J_\nu(x)$ are the Bessel functions]

$$G_0(r,r',t) = \frac{1}{2t} J_{|\overline{l}|}\left(\frac{rr'}{2t}\right) e^{iQ_0}, \quad Q_0 = \frac{r^2 + r'^2}{4t} - \frac{(|\overline{l}| + 1)\pi}{2},$$
$$\hat{R}_1|_{A=0} G_0(r,r',t) = 0, \quad \lim_{t\to 0} G_0(r,r',t) = \frac{1}{r}\delta(r - r'). \tag{2.69}$$

The case $A(r) = \rho = \gamma r^2/2$ can be considered in the same manner. Here the propagation function has the form

$$G(\rho,\rho',t) = \frac{1}{2\sin\tau} J_{|\overline{l}|}\left(\frac{\sqrt{\rho\rho'}}{\sin\tau}\right) e^{iQ}, \quad Q = \frac{\rho + \rho'}{\sin\tau} - \frac{(|\overline{l}| + 1)\pi}{2} - \overline{l}\,\tau,$$
$$\hat{R}_1 G(\rho,\rho',t) = 0, \quad \lim_{t\to 0} G(\rho,\rho',t) = \delta(\rho - \rho'), \quad \tau = \gamma t(u^0). \tag{2.70}$$

The functions $G_0(r,r',t)$ and $G(\rho,\rho',t)$ solve the Cauchy problem. For example,

$$\Phi(\rho,t) = \int_0^\infty G(\rho,\rho',t)\Phi(\rho')\,d\rho', \tag{2.71}$$

where $\Phi(\rho)$ is an arbitrary functions [an initial date for $\Phi(\rho,t)$].

For the field (2.8), the corresponding propagation function is quite complicated.[20]

G. Exact solutions of the Dirac equation

Here we are going to study the Dirac equation

$$(\gamma^{\mu}P_{\mu}-m_0c)\Psi(x)=0 \tag{2.72}$$

in the superposition of the AB field and field (2.1). We use a standard representation (see, e.g., Ref. 17) for γ matrices. In the case under consideration, we look for solutions with a definite radial momentum. The corresponding bispinors $\Psi(x)$ can be written in a block form

$$\Psi(x)=Q\begin{pmatrix}\psi_1(x^1,x^2)[m+F-ik_1\sigma_2]\\ \psi_2(x^1,x^2)[(m-F)\sigma_3-ik_1\sigma_1]\end{pmatrix}\upsilon\tilde{\Phi}(x^0,x^3),\quad F=\hbar^{-1}(P_0+P_3), \tag{2.73}$$

where υ is an arbitrary spinor; $\sigma_k(k=1,2,3)$ are Pauli matrices; the function $\tilde{\Phi}(x^0,x^3)$ obeys

$$\left[\hbar^{-2}(P_0^2-P_3^2)+i\frac{|e|E}{c\hbar}\right]\tilde{\Phi}(x^0,x^3)=0, \tag{2.74}$$

where $E=E(x^0,x^3)$ is electric field strength (2.2), and functions ψ_1,ψ_2 obey the following equations:

$$(P_1+iP_2)\psi_1(x^1,x^2)=\hbar k_1\psi_2(x^1,x^2),\quad (P_1-iP_2)\psi_2(x^1,x^2)=\hbar k_1\psi_1(x^1,x^2). \tag{2.75}$$

The presence of the arbitrary spinor υ in solutions (2.73) indicates that Eq. (2.72) does not fix the spin orientation. This orientation can be fixed by a choice of a spin operator.[16,17] One has to stress that Eq. (2.74) does not contain the AB field. All possible exact solutions of this equation were presented in Refs. 16 and 17, thus here we do not repeat these results.

Fields (2.3) are axially symmetric, thus J_z is an integral of motion in such a case (J is the total angular momentum operator). Let us consider solutions that are eigenvectors for this operator,

$$J_z\Psi=\hbar\left(l-l_0-\frac{1}{2}\right)\Psi,\quad J_z=L_z+\frac{\hbar}{2}\Sigma_3,\quad l=0,\pm1,\pm2,\ldots \tag{2.76}$$

[$\Sigma=\mathrm{diag}(\sigma,\sigma)$]. We obey equations (2.76) choosing

$$\psi_1(x^1,x^2)=\frac{\exp[i(l-l_0-1)\varphi]}{\sqrt{2\pi}}\psi_1(r),\quad \psi_2(x^1,x^2)=-i\frac{\exp[i(l-l_0)\varphi]}{\sqrt{2\pi}}\psi_2(r), \tag{2.77}$$

where the functions $\psi_k(r)$ satisfy a set of first-order differential equations

$$\left(\frac{\overline{l}+A(r)}{r}+\frac{\mathrm{d}}{\mathrm{d}r}\right)\psi_2(r)=k_1\psi_1(r),\quad \left(\frac{\overline{l}-1+A(r)}{r}-\frac{\mathrm{d}}{\mathrm{d}r}\right)\psi_1(r)=k_1\psi_2(r). \tag{2.78}$$

Consider solutions of the latter equations for fields (2.6)–(2.8).

For $A(r)=0$, we deal with the pure AB field. For $l\neq0$, all bounded solutions of Eq. (2.78) have the form

$$\psi_1(r)=J_{|\overline{l}-1|}(k_1r),\quad \psi_2(r)=\varepsilon J_{|\overline{l}|}(k_1r),\quad \varepsilon=\mathrm{sign}\,l, \tag{2.79}$$

where $J_{\mu}(x)$ are the Bessel functions. These solutions vanish at $r=0$. For $l=0,\mu\neq0$, the system of equations (2.78) has no bounded solutions. In such a case, a general solution of this system has the form

$$\psi_1(r)=c_1J_{\mu-1}(k_1r)+c_2J_{1-\mu}(k_1r),\quad \psi_2(r)=c_1J_{\mu}(k_1r)-c_2J_{-\mu}(k_1r), \tag{2.80}$$

where c_1, c_2 are arbitrary constants. In spite of the fact that these solutions are unbounded they still are quadratically integrable (as in the scalar case). Moreover, for any complex k_1 ($\mathrm{Re}\, k_1 > 0$) there exist unbounded solutions with a finite norm, they are expressed via the Macdonald functions,

$$\psi_1(r) = K_{1-\mu}(k_1 r), \quad \psi_2(r) = -K_\mu(k_1 r), \quad 0 < \mu < 1. \tag{2.81}$$

Similar to the scalar case, we can conclude that the operator $\gamma^\mu P_\mu$ is not self-conjugate anymore for $l=0$, $\mu \neq 0$. In contrast to the scalar case, there are no quadratically integrable unbounded solutions for $l=-1$, as well as for $l=0$, $\mu=0$.

Consider now the case of the uniform magnetic field (2.7). Using the operators (2.38), we can write Eq. (2.75) as

$$a_1 \psi_2(\rho,\varphi) = -i\sqrt{\bar{n}}\,\psi_1(\rho,\varphi), \quad a_1^+ \psi_1(\rho,\varphi) = i\sqrt{\bar{n}}\,\psi_2(\rho,\varphi), \quad k_1 = \sqrt{2\gamma\bar{n}}, \quad \rho = \frac{\gamma r^2}{2}.$$

Their solutions have the form [see Eqs. (2.51) and (2.47)]

$$\psi_1(\rho,\varphi) = \psi^{(j)}_{n-1,l-1}(\rho,\varphi), \quad \psi_2(\rho,\varphi) = -i\psi^{(j)}_{n,l}(\rho,\varphi). \tag{2.82}$$

As in the scalar case, there are two types of states (with $j=1,2$). These states are bounded at $l \neq 0$; they vanish at $r=0$. The states (2.82) are unbounded at $l=0$ but they still are quadratically integrable. Besides, there are unbounded solutions with finite norms for any complex $\bar{n}$. Such solutions are expressed via the functions $\psi_{\lambda,a}(x)$ [the latter are defined by Eqs. (A28) and (A29)] as

$$\psi_1(r) = \bar{n}^{3/4}\psi_{\lambda-1/2,1-\mu}(\rho), \quad \psi_2(r) = \bar{n}^{1/4}\psi_{\lambda,\mu}(\rho), \quad 2\bar{n} = 2\lambda + \mu - 1. \tag{2.83}$$

Thus, we see that the operator $\gamma^\mu P_\mu$ is not self-conjugate for $l=0, \mu \neq 0$ as well. All the above-mentioned singular solutions vanish or become nonsingular as $\mu \to 0$.

One ought also remark that ψ_1 (which correspond to $j=2$) from Eq. (2.82) vanish at $n=0$. Thus, the complete wave function (2.73) is an eigenvector for the operator Σ_3,

$$\Sigma_3 \Psi = -\Psi. \tag{2.84}$$

That means that in such states the electron spin has only one orientation, namely, opposite to the magnetic field.

Consider finally the case of nonuniform magnetic field (2.8). For $l \neq 0, a \neq 1$, the corresponding bounded solutions (they also vanish at $r=0$) have the form

$$\psi_1(r) = I_{n-1,n+1-2\bar{l}}(x), \quad \psi_2(r) = -I_{n,n-2\bar{l}}(x), \quad l > 0,$$

$$\psi_1(r) = I_{n+1-2\bar{l},n-1}(x), \quad \psi_2(r) = -I_{n-2\bar{l},n}(x), \quad l < 0, \tag{2.85}$$

$$x = 2\sqrt{1-a^2}\,\gamma r, \quad 1 - 2\bar{l} + 2n = \frac{1-2\bar{l}}{\sqrt{1-a^2}}, \quad \bar{l} = l + \mu,$$

where $I_{n,m}(x)$ are the Laguerre functions (A1), and we use the notation (2.16). Whenever $a^2 > 1$, any $l \neq 0$ are admissible in complete agreement with classical theory. Whenever $a^2 < 1$, only $l < 0$ are admissible. In such a case n is an integer and the functions (2.85) are expressed via the Laguerre polynomials according to Eq. (A19). At the same time, the following quantization takes place:

$$a^2=1-\frac{(1+2|\overline{l}|)^2}{(1+2|\overline{l}|+2n)^2},\quad n=0,1,2,\ldots. \tag{2.86}$$

For $a=1$, $l\neq 0$, the only bounded states can be found for $l<0$. They are expressed via the Bessel functions,

$$\psi_1(r)=J_{2|\overline{l}|+2}(2\sqrt{(1+2|\overline{l}|)\gamma r}),\quad \psi_2(r)=-J_{2|\overline{l}|}(2\sqrt{(1+2|\overline{l}|)\gamma r}). \tag{2.87}$$

Solutions (2.87) follow from Eq. (2.85) as $a\to 1$. That fact can be confirmed by the use of the limit (A22).

$l=0$ is a special case. Here there are only unbounded solutions. Some of them are quadratically integrable. Whenever $a^2>1$, such solutions have the form

$$\begin{aligned}\psi_1(r)&=c_1I_{n+1-2\mu,n-1}(x)+c_2I_{n-1,n+1-2\mu}(x),\\ \psi_2(r)&=-c_1I_{n-2\mu,n}(x)-c_2I_{n,n-2\mu}(x),\end{aligned} \tag{2.88}$$

where c_k are arbitrary constants, and for $a=1$ these solutions read

$$\psi_1(r)=J_{2-2\mu}(z),\quad \psi_2(r)=-J_{-2\mu}(z),\quad 0<\mu<\tfrac{1}{2},$$

$$\psi_1(r)=K_{2-2\mu}(z),\quad \psi_2(r)=K_{2\mu}(z),\quad \tfrac{1}{2}<\mu<1,\quad z=2\sqrt{|1-2\mu|\gamma r}. \tag{2.89}$$

Quadratically integrable solutions exist for $a^2<1$ as well. For example, for $0<\mu<\frac{1}{2}$ they have the form (2.88), where $c_2=0$. In such a case a^2 is quantized

$$a^2=1-\frac{(1-2\mu)^2}{(1-2\mu+2n)^2},\quad n=0,1,2,\ldots. \tag{2.90}$$

Moreover, for any complex a^2 (provided $\mathrm{Re}\sqrt{1-a^2}>0$) there exist unbounded solutions with a finite norm. They read

$$\psi_1(r)=a\,\psi_{\lambda,2(1-\mu)}(x),\quad \psi_2(r)=(1+\sqrt{1-a^2})\psi_{\lambda,2\mu}(x),\quad \lambda=\frac{1-2\mu}{2\sqrt{1-a^2}}. \tag{2.91}$$

All the above-mentioned solutions obey Eq. (2.84) for $n=0$.

Finally we present solutions, which do not have an analog in the Klein–Gordon case discussed in Sec. II F. These solutions are not eigenvectors of the radial momentum operator. With this aim in view we present Dirac wave functions in the following form:

$$\Psi(x)=\Psi_{(-)}(x)+\Psi_{(+)}(x),\quad \Psi_{(\pm)}(x)=P_{(\pm)}\Psi(x),\quad 2P_{(\pm)}=1\pm(\alpha\mathbf{n}), \tag{2.92}$$

where $\mathbf{n}$ is a unit vector, $\alpha=(\alpha_k=\gamma^0\gamma^k), k=1,2,3$, and $P_{(\pm)}$ are projection operators, $P_{(+)}+P_{(-)}=1$, $P_{(\pm)}^2=P_{(\pm)}$, $P_{(+)}P_{(-)}=P_{(-)}P_{(+)}=0$. Then we can always present $\Psi_{(\pm)}(x)$ in the following block form:

$$\Psi_{(+)}(x)=\begin{pmatrix}v(x)\\(\sigma\mathbf{n})v(x)\end{pmatrix},\quad \Psi_{(-)}(x)=\begin{pmatrix}u(x)\\-(\sigma\mathbf{n})u(x)\end{pmatrix}, \tag{2.93}$$

with $u(x)$, $v(x)$ being arbitrary spinors. Without loss of generality we can always choose $\mathbf{n}=(0,0,1)$. The Dirac equation (2.72) demands $u(x)$, $v(x)$ to obey

$$2\tilde{P}_0u=[m_0c-(\sigma\mathbf{B})\sigma_3]v,\quad 2\tilde{P}_3v=[m_0c+(\sigma\mathbf{B})\sigma_3]u, \tag{2.94}$$

$$2\tilde{P}_0 = P_0 - P_3, \quad 2\tilde{P}_3 = P_0 + P_3, \quad \mathbf{B} = (P_1, P_2, 0).$$

Suppose we consider external fields, for which the operator $\tilde{P}_3$ (2.65) is an integral of motion, and suppose we are looking for solutions that are eigenvectors of the latter operator. Then in accordance with Eq. (2.66)

$$2\tilde{P}_3 = \hbar(\lambda + g), \quad c\hbar g = |e|(A_0^{(1)} + A_3^{(1)}). \tag{2.95}$$

It follows from Eq. (2.94) that the spinor υ can be restored by the one u,

$$\hbar(\lambda + g)\upsilon = [m_0 c + (\sigma\mathbf{B})\sigma_3]u. \tag{2.96}$$

For external fields under consideration, the operator $\mathbf{B}$ commutes with $\lambda + g$, thus we get a closed equation for u,

$$2\hbar(\lambda + g)\tilde{P}_0 u = [m_0 c - (\sigma\mathbf{B})\sigma_3][m_0 c + (\sigma\mathbf{B})\sigma_3]u. \tag{2.97}$$

Considering eigenvectors for the operator J_z (2.76) in axial-symmetric external fields (2.3), we can write

$$u(x) = \begin{pmatrix} e^{-i\varphi}u_1(r,t) \\ u_{-1}(r,t) \end{pmatrix} \exp i\left[(l - l_0)\varphi - \frac{m^2}{2}\int \frac{du^0}{\lambda + g(u^0)} - \frac{\lambda u^3}{2}\right], \tag{2.98}$$

where the functions $u_\zeta(r,t)$, $\zeta = \pm 1$ obey the equations

$$\hat{R}_1^\zeta u_\zeta(r,t) = 0, \quad \hat{R}_1^\zeta = i\partial_t + \partial_r^2 + \frac{\partial_r}{r} - \frac{\left[l - \frac{1+\zeta}{2} + A(r)\right]^2}{r^2} - \zeta\frac{A'(r)}{r}, \tag{2.99}$$

which can be solved similar to the one (2.68).

III. SUPERPOSITION OF THE AHARONOV–BOHM, LONGITUDINAL, AND CROSSED FIELDS

We consider here the Klein–Gordon and Dirac equations in some superpositions of the AB field, longitudinal, and crossed fields. In fact, there are only two types of such fields, which admit exact solutions of these equations.

To define the first type of the fields, we introduce curvilinear coordinates u^μ by the relations

$$u^0 = x^0 - x^3, \quad u^1 = q(u^0)r^2, \quad u^2 = \varphi, \quad u^3 = x^0 + x^3 - u^0 u^1, \quad q(u^0) = [(u^0)^2 + a]^{-1}, \tag{3.1}$$

where a is a constant. In these coordinates, covariant components $A_\mu^{(1)}$ of electromagnetic potentials are given as

$$\begin{aligned} &\frac{|e|A_0^{(1)}}{c\hbar} = q(u^0)[f_1(u^1) + au^1 g_1(u^0)], \quad A_1^{(1)} = 0, \\ &\frac{|e|A_2^{(1)}}{c\hbar} = f_2(u^1) + u^1 g_2(u^0), \quad \frac{|e|A_3^{(1)}}{c\hbar} = \frac{g_1(u^0)}{2}. \end{aligned} \tag{3.2}$$

Here $g_s(u^0)$, $f_s(u^1)$ $(s = 1,2)$ are arbitrary functions of indicated arguments. The corresponding additional (to the AB field) electromagnetic field is given by its components in cylindrical reference frame

$$\frac{|e|E_r}{c\hbar}=\frac{|e|H_\varphi}{c\hbar}=qr[2q(f_1'+ag_1)+u^0g_1'],\quad \frac{|e|E_z}{c\hbar}=-g_1',$$
$$\frac{|e|E_\varphi}{c\hbar}=-\frac{|e|H_r}{c\hbar}=-qr[g_2'-2qu^0(g_2+f_2')],\quad \frac{|e|H_z}{c\hbar}=2q(g_2+f_2'). \tag{3.3}$$

Exact solutions in the field (3.3) were studied in Refs. 21 and 17.

In the case under consideration, the operators L_z (or J_z in the Dirac equation case) and $\tilde{P}_3$ (2.65) are integrals of motion. We are going to study solutions that are eigenvectors for such operators. Let us impose the following constraint on the functions $g_s(u^0)$, $f_s(u^1)$ $(s=1,2)$,

$$u^1(g_2^2-ag_1^2-b)+2g_2f_2-2g_1f_1=0,\quad b=\text{const}. \tag{3.4}$$

Then we can separate the variables u^0 and u^1 and present Klein–Gordon wave functions in the form

$$\Psi=\sqrt{\frac{q}{P}}e^{-i\Gamma}\psi(u^1),\quad P=\lambda+g_1(u^1),$$
$$\Gamma=\frac{\lambda}{2}u^3-(l-l_0)\varphi+\int[m^2+2q(2k_1+\overline{l}g_2)]\frac{du^0}{2P}. \tag{3.5}$$

The functions $\psi(u^1)$ obey

$$\psi''+\frac{1}{u^1}\psi'+R(u^1)\psi=0,\quad R(u^1)=\frac{2k_1+\lambda f_1}{2u^1}-\frac{a\lambda^2+b}{4}-\frac{(\overline{l}+f_2)^2}{4(u^1)}. \tag{3.6}$$

In the same case, Dirac wave functions have the form

$$\Psi=\frac{\sqrt{q}}{P}e^{-i\Gamma}KW[(1+\sigma_3)\psi_1(u^1)+(1-\sigma_3)\psi_{-1}(u^1)]\upsilon, \tag{3.7}$$

where υ is an arbitrary constant spinor, and

$$K=\begin{pmatrix} m+P-\sigma_3(\sigma\mathbf{F}) \\ (m-P)\,\sigma_3-(\sigma\mathbf{F})\end{pmatrix},\quad \mathbf{F}=\mathbf{e}_r\,qr(2i\partial_{u^1}-u^0P)+\mathbf{e}_\varphi\left(\frac{\overline{l}+f_2}{r}+qrg_2\right),$$
$$W=\cos\delta+i\sigma_3\sin\delta,\quad \delta=\int\frac{qg_2}{P}du^0. \tag{3.8}$$

The scalar functions $\psi_\zeta(u^1)(\zeta=\pm1)$ obey a set of independent equations

$$\psi_\zeta''+\frac{1}{u^1}\psi_\zeta'+\left[R(u^1)+\zeta\frac{f_2'}{2u^1}\right]\psi_\zeta=0. \tag{3.9}$$

Explicit solutions of Eqs. (3.6) and (3.9) can be written for

$$f_1(u^1)=\alpha u^1+\frac{\beta}{u^1},\quad f_2(u^1)=\gamma u^1,\quad \alpha,\,\beta,\,\gamma=\text{const}. \tag{3.10}$$

In such a case Eqs. (3.6) and (3.9) are reduced to the one (2.58). Solutions of the latter equation we have studied previously.

Let us return to the constraint (3.4). If $\beta\neq 0$, then $g_1=0, g_2=\text{const}$, and b can be found from Eq. (3.4) to be $b=g_2^2+2\gamma g_2$. If $\beta=0$, then g_1, g_2 are related by

$$(g_2+\alpha)^2=a\left(g_1+\frac{\gamma}{a}\right)^2+\alpha^2-\frac{\gamma^2}{a}+b. \tag{3.11}$$

Thus, one of the constants remains arbitrary. We see that there exist a wide class of fields, which admit exact solutions.

To define the second type of fields, which admit exact solutions, we introduce curvilinear coordinates u^μ by

$$u^0=x^0-x^3, \quad u^1=\frac{r^2}{u^0}, \quad u^2=\varphi, \quad u^3=x^0+x^3-\frac{r^2}{2u^0}. \tag{3.12}$$

Covariant components of electromagnetic potentials in the coordinates (3.12) are given by

$$\frac{|e|A_0^{(1)}}{c\hbar}=\frac{f_1(u^1)}{u^0}, \quad A_1^{(1)}=0, \quad \frac{|e|A_2^{(1)}}{c\hbar}=f_2(u^1), \quad A_3^{(1)}=0, \tag{3.13}$$

where $f_s(u^1)$ $(s=1,2)$ are arbitrary functions of u^1. The corresponding electromagnetic field is given by its components in the cylindrical reference frame

$$E_r=H_\varphi=\frac{2c\hbar r}{|e|(u^0)^2}f_1', \quad E_\varphi=-H_r=-\frac{2c\hbar r}{|e|(u^0)^2}f_2', \quad H_z=\frac{2c\hbar}{|e|u^o}f_2', \quad E_z=0. \tag{3.14}$$

In the absence of the AB field, exact solutions in such a field were studied in Refs. 22 and 17.

Here integrals of motion are the same as in the previous case. Klein–Gordon wave functions can be written in the form

$$\Psi=\frac{1}{\sqrt{u^0}}\psi(u^1)\exp\left\{-i\left[\frac{\lambda}{2}u^3-i(l-l_0)\varphi+m^2u^0+k_1\ln u^0\right]\right\}. \tag{3.15}$$

The functions $\psi(u^1)$ obey

$$\psi''+\frac{1}{u^1}\psi'+R(u^1)\psi=0, \quad R(u^1)=\frac{\lambda^2}{16}+\frac{k_1+2\lambda f_1}{4u^1}-\frac{(\overline{l}+f_2)^2}{4(u^1)^2}. \tag{3.16}$$

Dirac wave function can be presented in the form (3.7) and (3.8) with the following modifications:

$$P=\lambda, \quad q=\frac{1}{u^0}, \quad \mathbf{F}=\mathbf{e}_r\,\frac{r}{u^0}\left(2i\partial_1-\frac{\lambda}{2}\right)+\mathbf{e}_\varphi\frac{\overline{l}+f_2}{r}. \tag{3.17}$$

Besides, the functions $\psi_\zeta(u^1)$ have to obey Eq. (3.9) with $R(u^1)$ defined by Eq. (3.16). Solutions of the latter equations are available for $f_s(u^1)$ in the form (3.10). Thus, we have again returned to Eq. (2.58).

IV. SUPERPOSITION OF THE AHARONOV–BOHM FIELD AND SOME NONUNIFORM FIELDS

Consider now additional fields, which are given by potentials of the form

$$A_0^{(1)}=\frac{c\hbar}{|e|}f_1(r), \quad A_1^{(1)}=\frac{c\hbar}{|e|}\frac{A(r)}{r}\sin\varphi, \quad A_2^{(1)}=-\frac{c\hbar}{|e|}\frac{A(r)}{r}\cos\varphi, \quad A_3^{(1)}=\frac{c\hbar}{|e|}f_2(r). \tag{4.1}$$

Here $f_1(r), f_2(r), A(r)$ are arbitrary functions of r. The corresponding electromagnetic field components in cylindrical reference frame have the form

$$E_r=-\frac{c\hbar}{|e|}f_1'(r),\quad H_\varphi=\frac{c\hbar}{|e|}f_2'(r),\quad H_z=\frac{c\hbar}{|e|}\frac{A'(r)}{r},\quad E_\varphi=E_z=H_r=0. \tag{4.2}$$

Exact solutions of relativistic wave equations in such fields were studied in Refs. 23, and 17. Here we present exact solutions of the equations in the superposition of these fields and the AB field.

Stationary solutions of Klein–Gordon equation that are eigenvectors for the operators p_0, p_3, L_z can be written as

$$\Psi(x)=e^{-i\Gamma}\psi(r),\quad \Gamma=k_0x^o+k_3x^3-(l-l_0)\varphi. \tag{4.3}$$

Functions $\psi(r)$ obey

$$\psi''(r)+\frac{1}{r}\psi'(r)+R(r)\psi(r)+0,\quad R(r)=(k_0+f_1)^2-(k_3+f_2)^2-\frac{(\overline{l}+A)^2}{r^2}-m^2. \tag{4.4}$$

The corresponding solutions of the Dirac equation have the form $\Psi(x)=e^{-i\Gamma}M\psi$, where the matrix M reads $M=\mathrm{diag}(e^{-i\varphi},i,e^{-i\varphi},i)$, and the bispinor $\psi=(\psi_k)(k=1,2,3,4)$ obeys

$$\left[k_0+f_1-m\gamma^0-\frac{1}{r}\left(\overline{l}+A-\frac{1}{2}\right)\alpha_1-i\left(\frac{d}{dr}+\frac{1}{2r}\right)\alpha_2+(k_3+f_2)\alpha\right]\psi=0. \tag{4.5}$$

In some particular cases the latter equation can be reduced to the one (2.78) and thus solved explicitly. All such cases are described in Refs. 23, and 17.

V. AHARONOV–BOHM FIELD IN 2+1 QED

Consider Dirac equation in $2+1$ dimensions (see e.g., Refs. 24 and 25) ($x=(x^\mu)$, $\mu=0,1,2$, $\gamma^0=\sigma_3$, $\gamma^1=i\sigma_2$, $\gamma^3=-i\sigma_1$),

$$(\gamma^\mu P_\mu-m_0c)\,\Psi(x)=0,\quad \Psi(x)=\begin{pmatrix}\Psi_1(x)\\ \Psi_2(x)\end{pmatrix}. \tag{5.1}$$

For components of the spinor $\Psi(x)$ we get the following equations:

$$(P_0-m)\Psi_1+(P_1-iP_2)\Psi_2=0,\quad (P_0+m)\Psi_2+(P_1+iP_2)\Psi_1=0. \tag{5.2}$$

These equations can be solved exactly for a superposition of the AB field and an additional field described in the following. Potentials (1.6) of the latter field are given as

$$\frac{|e|}{c\hbar}A_0^{(1)}=B(r),\quad \frac{|e|}{c\hbar}A_1^{(1)}=\frac{A(r)}{r}\sin\varphi,\quad \frac{|e|}{c\hbar}A_2^{(1)}=-\frac{A(r)}{r}\cos\varphi, \tag{5.3}$$

where $A(r), B(r)$ are arbitrary functions of r. This field is an analog of field (4.1) in $3+1$ dimensions. Potentials $A_0^{(0)}$, $A_1^{(0)}$, $A_2^{(0)}$ of the AB field in $2+1$ dimensions are still given by the formulas (1.1). The operators

$$p_0=i\hbar\frac{\partial}{\partial x^0},\quad J_3=-i\hbar\frac{\partial}{\partial\varphi}+\frac{\hbar}{2}\sigma_3 \tag{5.4}$$

are integrals of motions in the external field under consideration. Thus, we can impose the following conditions on the spinor Ψ:

$$p_0\Psi=\hbar k_0\Psi,\quad J_3\Psi=\hbar\left(l-l_0-\tfrac{1}{2}\right)\Psi. \tag{5.5}$$

A solution of Eqs. (5.1) and (5.5) has the form

$$\Psi(x)=e^{-i\Gamma}\begin{pmatrix} e^{-i\varphi}\psi_1(r)\\ i\psi_2(r)\end{pmatrix},\quad \Gamma=k_0x^0-(l-l_0)\varphi, \tag{5.6}$$

where the functions $\psi_k(r)$ $(k=1,2)$ obey

$$\begin{aligned}\psi_1'(r)&=\frac{\overline{l}-1+A(r)}{r}\psi_1(r)-(k_0+B(r)+m)\psi_2(r),\\ \psi_2'(r)&=(k_0+B(r)-m)\psi_1(r)-\frac{\overline{l}+A(r)}{r}\psi_2(r).\end{aligned} \tag{5.7}$$

Explicit solutions of these equations can be found in three particular cases:

$$(1)\quad A(r)=B(r)=0, \tag{5.8}$$

$$(2)\quad A(r)=\rho=\frac{\gamma r^2}{2},\quad \gamma>0,\quad B(r)=0, \tag{5.9}$$

$$(3)\quad A(r)=\gamma r,\quad B(r)=\frac{b}{r},\quad \gamma>0. \tag{5.10}$$

In the following we consider each case in detail.

Case (5.8) corresponds to the pure AB field. For $l\neq 0$, there exist bounded solutions of the form

$$\begin{aligned}\psi_1(r)&=\sqrt{k_0+m}\;J_{|\overline{e}-1|}(kr),\quad k=\sqrt{k_0^2-m^2},\\ \psi_2(r)&=\varepsilon\sqrt{k_0+m}\,J_{|\overline{e}|}(kr),\quad \varepsilon=\operatorname{sign} l.\end{aligned} \tag{5.11}$$

Here $J_l(x)$ are Bessel functions. Solutions (5.11) vanish at $r=0$. They are orthogonal and normalized.

For $l=0$, $\mu\neq 0$, bounded solutions do not exist. However, there are unbounded at $r=0$ solutions. Some of them have the form

$$\begin{aligned}\psi_1(r)&=\sqrt{k_0+m}\;[c_1J_{\mu-1}(kr)+c_2J_{1-\mu}(kr)],\\ \psi(r)&=\sqrt{k_0-m}\;[c_1J_{\mu}(kr)-c_2J_{-\mu}(kr)].\end{aligned} \tag{5.12}$$

Here c_1,c_2 are arbitrary constants. Solutions (5.12) are still orthogonal and normalized. Another set of unbounded solutions (they are expressed via the Macdonald functions) reads

$$\begin{aligned}\psi_1(r)&=\sqrt{m+k_0}K_{1-\mu}(\sqrt{m^2-k_0^2}r),\quad \operatorname{Re}\sqrt{m^2-k_0^2}>0,\\ \psi_2(r)&=-\sqrt{m-k_0}K_{\mu}(\sqrt{m^2-k_0^2}r).\end{aligned} \tag{5.13}$$

As we see they are defined even for some complex k_0. It is interesting to remark that the latter solutions have finite norms.

The case (5.9) corresponds a combination of AB and uniform constant magnetic fields. Here we can introduce operators a_k^+,a_k $(k=1,2)$ by relations (2.33). Using the substitution

$$\psi_1(x)=e^{-ik_0x^0}\psi_1(\rho,\varphi),\quad \psi_2(x)=ie^{-ik_0x^0}\psi_2(\rho,\varphi), \tag{5.14}$$

we present (5.2) in the following form:

$$(k_0-m)\psi_1(\rho,\varphi)-\sqrt{2\gamma}a_1\psi_2(\rho,\varphi)=0,\quad (k_0+m)\psi_2(\rho,\varphi)-\sqrt{2\gamma}a_1^+\psi_1(\rho,\varphi)=0. \tag{5.15}$$

Now we can use the functions (2.47) and the relations (2.41).

Consider first states with $k_0^2\neq m^2$, $l\neq 0$. As in $3+1$ dimensions, these states can be divided in two types ($j=1,2$),

$$\psi_1(\rho,\varphi)=\sqrt{k_0+m}\,\psi^{(j)}_{n-1,\,l-1},\quad \psi_2(\rho,\varphi)=\sqrt{k_0-m}\,\psi^{(j)}_{n,l},\quad k_0^2=m^2+2\gamma\overline{n}, \tag{5.16}$$

where $\overline{n}$ was defined in Eq. (2.46). Solutions (5.16) vanish at $r=0$.

If $k_0^2\neq m^2$, $l=0$, $\mu\neq 0$, then solutions, which are formally defined by Eq. (5.16), are unbounded at $r=0$. However, they are still orthogonal and normalized. For $l=0$, $\mu\neq 0$, $k_0^2=m^2+\gamma(2\lambda+\mu-1)$ (λ is arbitrary complex), there exist other unbounded solutions. They have the form (5.6), with

$$\psi_1(r)=(k_0+m)\psi_{\lambda-1/2,\,1-\mu}(\rho),\quad \psi_2(r)=\sqrt{2\gamma}\psi_{\lambda,\mu}(\rho), \tag{5.17}$$

where the functions $\psi_{\lambda,\mu}(x)$ are defined by Eqs. (A28) and (A29). These solutions are orthogonal and normalized as well.

Consider now states with $k_0^2=m^2$. Suppose $k_0=m$; then a general solution of Eq. (5.7) reads

$$\begin{gathered}\psi_1(r)=Nf_l(\rho)+ce^{\rho/2}\rho^{[\overline{l}-1]/2},\quad \psi_2(r)=gNe^{-\rho/2}\rho^{-\overline{l}/2},\\ f_l(\rho)=e^{\rho/2}\rho^{[\overline{l}-1]/2}\int_\rho^\infty e^{-x}x^{-\overline{l}}dx,\quad g=\sqrt{\frac{\gamma}{2m^2}},\end{gathered} \tag{5.18}$$

where N, c are arbitrary constants. For $\mu\neq 0$ only some states with $l=0$ have a finite norm. Namely the states

$$\begin{gathered}\psi_1(r)=N\rho^{(\mu-1)/2}e^{\rho/2}\int_\rho^\infty e^{-x}x^{-\mu}\,dx,\quad \psi_2(r)=gN\,e^{-\rho/2}\rho^{-\mu/2},\\ N=\sqrt{\frac{\Gamma(1+\mu)\sin\mu\pi}{\pi[1+\mu\psi(1)-\mu\psi(1+\mu)+\mu g^2]}},\quad \int_0^\infty[\psi_1^2(r)+\psi_2^2]d\rho=1,\end{gathered} \tag{5.19}$$

where $\psi(x)$ is the logarithmic derivative of Γ-function (Ref. 18, 8.360). All the above-mentioned solutions are singular at $r=0$. One can see that $\lim_{\mu\to 0}N=0$. Thus, in $2+1$ dimensions, in pure magnetic field, the Dirac equation does not have solutions with $k_0=m$, in contrast to the corresponding $3+1$-dimensional case. For $\mu\neq 0$ (in the presence of the AB field) such solutions appear even in $2+1$ dimensions.

Suppose $k_0=-m$. Then, the functions

$$\psi_1(r)=0,\quad \psi_2(r)=[\Gamma(1-\overline{l})]^{-1/2}\rho^{-\overline{l}/2}e^{-\rho/2},\quad \int_0^\infty[\psi_1^2(r)+\psi_2^2]d\rho=1 \tag{5.20}$$

present solutions for $l\leqslant 0$. One can see that Eq. (5.20) is a particular case of Eq. (5.16). For $l<0$, the states (5.20) vanish at $r=0$. For $l=0$, $\mu\neq 0$, they are singular at $r=0$. If $\mu=0$, then this singularity disappears, however the states do not tend to zero as $r\to 0$.

Let us finally turn to case (5.10). Here it is enough to consider $b\neq 0$ only. Indeed, suppose $b=0$; then doing the change of functions ($\psi\to f$)

$$\psi_1(r)=\sqrt{k_0+m}\,f_1(r),\quad \psi_2(r)=\sqrt{k_0-m}f_2(r), \tag{5.21}$$

we can transform Eq. (5.7) to the form (2.78) with $k_1=\sqrt{k_0^2-m^2}$. Solutions of Eq. (2.78) are given by formulas (2.85)–(2.89). Thus, in the following we consider the case $b\neq 0$ only. We introduce the following notation:

$$g_1=\sqrt{|2\overline{l}-1|+2b},\quad g_{-1}=\sqrt{|2\overline{l}-1|-2b},\quad \varepsilon=\pm 1=\operatorname{sign} l. \tag{5.22}$$

Thus solutions of Eq. (5.7) have the form

$$\begin{gathered}\psi_1(r)=c_1 I_{\alpha+s,s}(y)+c_2 I_{\alpha+s-1,s+1}(y),\quad \psi_2(r)=c_3 I_{\alpha+s,s}(y)+c_4 I_{\alpha+s-1,s+1}(y),\\ y=2\sqrt{m^2+\gamma^2-k_0^2}\,r,\quad \alpha=1+g_1g_{-1},\quad 2+2s+g_1g_{-1}=\frac{2bk_0-(2\overline{l}-1)\gamma}{\sqrt{m^2+\gamma^2-k_0^2}},\end{gathered} \tag{5.23}$$

where

$$\begin{aligned}c_1&=(g_\varepsilon-\varepsilon g_{-\varepsilon})\sqrt{(2\overline{l}-1)k_0-2b\gamma-mg_1g_{-1}}=\frac{(g_\varepsilon-\varepsilon g_{-\varepsilon})}{(g_\varepsilon+\varepsilon g_{-\varepsilon})}c_3,\\ c_2&=-(g_\varepsilon+\varepsilon g_{-\varepsilon})\sqrt{(2\overline{l}-1)k_0-2b\gamma+mg_1g_{-1}}=\frac{(g_\varepsilon+\varepsilon g_{-\varepsilon})}{(g_\varepsilon-\varepsilon g_{-\varepsilon})}c_4,\end{aligned} \tag{5.24}$$

and relations (A6)–(A11) for the Laguerre functions $I_{n,m}$ were used. It follows from Eq. (5.22) that both g_1 and g_{-1} are real and positive for $(2\overline{l}-1)^2>4b^2$. If $(2\overline{l}-1)^2<4b^2$, then one of these quantities is real and positive and another one is imaginary. Suppose $(2\overline{l}-1)^2>4b^2$. Then for the energies $k_0^2<m^2+\gamma^2$ there exist bound states. In the latter case s is a positive integer and k_0^2 is quantized according to the last equation (5.23).

Another observation: For any b there exist a number l such that

$$1>g_1^2g_{-1}^2=(2\overline{l}-1)^2-4b^2>0. \tag{5.25}$$

For example, $b=0$ corresponds to $l=0$. Then one can choose two values for α,

$$\alpha_1=1+g_1g_{-1},\quad \alpha_2=1-g_1g_{-1}. \tag{5.26}$$

In both cases the solutions (5.23) have singularity at $r=0$ but still have finite norms.

APPENDIX

(1) The Laguerre functions $I_{n,m}(x)$ are defined by

$$I_{n,m}(x)=\sqrt{\frac{\Gamma(1+n)}{\Gamma(1+m)}}\,\frac{\exp(-x/2)}{\Gamma(1+n-m)}x^{(n-m)/2}\Phi(-m,n-m+1;x). \tag{A1}$$

Here $\Phi(\alpha,\gamma;x)$ is the confluent hypergeometric function in a standard definition (see Ref. 18, 9.210). For $\gamma\neq -s$, where s is an integer and non-negative, the latter function can be presented by a series

$$\Phi(\alpha,\gamma;x)=\sum_{k=0}^{\infty}\frac{(\alpha)_k}{(\gamma)_k}\frac{x^k}{k!}=\frac{\Gamma(\gamma)}{\Gamma(\alpha)}\sum_{k=0}^{\infty}\frac{\Gamma(\alpha+k)}{\Gamma(\gamma+k)}\frac{x^k}{k!}. \tag{A2}$$

This series converges for any complex x. For any complex α, the Pochhammer symbols $(\alpha)_k$ are defined as follows:

$$2(\alpha)_k=\alpha(\alpha+1)\ldots(\alpha+k-1)=\frac{\Gamma(\alpha+k)}{\Gamma(\alpha)}. \tag{A3}$$

(2) Let m be a non-negative integer number; then the Laguerre functions are related to Laguerre polynomials $L_n^{\alpha}(x)$ (Ref. 18, 8.970, 8.972.1) by

$$I_{n,m}(x)=\sqrt{\frac{\Gamma(1+m)}{\Gamma(1+n)}}\exp(-x/2)x^{(n-m)/2}L_m^{n-m}(x),\quad m=0,1,2,\ldots, \tag{A4}$$

$$L_n^{\alpha}(x)=\frac{1}{n!}e^x x^{-\alpha}\frac{d^n}{dx^n}e^{-x}x^{n+\alpha}=\sum_{k=0}^{n}\binom{n+\alpha}{n-k}\frac{(-x)^k}{k!}=\binom{n+\alpha}{n}\Phi(-n,1+\alpha;x). \tag{A5}$$

Here n are non-negative integer numbers such that

$$\binom{\alpha}{n}=\frac{\Gamma(1+\alpha)}{\Gamma(1+n)\Gamma(1+\alpha-n)}=\frac{\alpha(\alpha-1)\ldots(\alpha-n+1)}{n!}.$$

(3) Using well-known properties of the confluent hypergeometric function (Ref. 18, 9.212; 9.213; 9.216), one can easily get both relations for the Laguerre functions

$$2\sqrt{x(n+1)}I_{n+1,m}(x)=(n-m+x)I_{n,m}(x)-2xI'_{n,m}(x), \tag{A6}$$

$$2\sqrt{x(m+1)}I_{n,m+1}(x)=(n-m-x)I_{n,m}(x)+2xI'_{n,m}(x), \tag{A7}$$

$$2\sqrt{xn}I_{n-1,m}(x)=(n-m+x)I_{n,m}(x)+2xI'_{n,m}(x), \tag{A8}$$

$$2\sqrt{xm}I_{n,m-1}(x)=(n-m-x)I_{n,m}(x)-2xI'_{n,m}(x), \tag{A9}$$

$$2\sqrt{nm}I_{n-1,m-1}(x)=(n+m-x)I_{n,m}(x)-2xI'_{n,m}(x), \tag{A10}$$

$$2\sqrt{(n+1)(m+1)}I_{n+1,m+1}(x)=(n+m+2-x)I_{n,m}(x)+2xI'_{n,m}(x), \tag{A11}$$

and a differential equation for these functions

$$4x^2I''_{n,m}(x)+4xI'_{n,m}(x)-[x^2-2x(1+n+m)+(n-m)^2]I_{n,m}(x)=0. \tag{A12}$$

Suppose $I_{n,m}(x)$ and $I_{m,n}(x)$ are linearly independent. Then, a general solution I of this equation has the form $I=AI_{n,m}(x)+BI_{m,n}(x)$. However, whenever condition (A18) holds, $I_{n,m}(x)$ and $I_{m,n}(x)$ are dependent. Formulas (A6)–(A11) and Eq. (A12) are valid for any complex n, m, x. One has to be careful applying formulas (A8)–(A10) for $n,m=0$. A straightforward calculation, which uses Eqs. (A1) and (A2), gives

$$\lim_{n\to 0}\sqrt{n}I_{n-1,m}(x)=-\frac{\sin m\pi}{\pi}\sqrt{\Gamma(1+m)}x^{-(1+m)/2}\exp(x/2),\quad \lim_{m\to 0}\sqrt{m}I_{n,m-1}(x)=0. \tag{A13}$$

A combination of Eqs. (A6)–(A9) results in the following relations:

$$2\sqrt{x}I'_{n,m}(x)=\sqrt{n}I_{n-1,m}(x)-\sqrt{n+1}I_{n+1,m}(x)=\sqrt{m+1}I_{n,m+1}(x)-\sqrt{m}I_{n,m-1}(x), \tag{A14}$$

$$\sqrt{x(n+1)}I_{n+1,m}(x)-(n-m+x)I_{n,m}(x)+\sqrt{xn}I_{n-1,m}(x)=0, \tag{A15}$$

$$\sqrt{x(m+1)}I_{n,m+1}(x)-(n-m-x)I_{n,m}(x)+\sqrt{xm}I_{n,m-1}(x)=0. \tag{A16}$$

(4) Using properties of the confluent hypergeometric function, one can get a representation

$$I_{n,m}(x)=\sqrt{\frac{\Gamma(1+n)}{\Gamma(1+m)}}\frac{\exp(x/2)}{\Gamma(1+n-m)}x^{(n-m)/2}\Phi(1+n,1+n-m;-x), \tag{A17}$$

and a relation (Ref. 18, 9.214)

$$I_{n,m}(x)=(-1)^{n-m}I_{m,n}(x), \quad n-m \ \text{integer}. \tag{A18}$$

(5) An asymptotic formula takes place

$$\Phi(a,c;x)\approx\frac{\Gamma(c)}{\Gamma(a)}e^{x}x^{a-c}, \quad \mathrm{Re}\,x\to\infty. \tag{A19}$$

Thus we obtain the following asymptotic behavior of $I_{n,m}(x)$ whenever m is not an integer:

$$I_{n,m}(x)=-\frac{\sin m\pi}{\pi}\sqrt{\Gamma(1+n)\Gamma(1+m)}x^{-(n+m+2)/2}\exp\,(x/2), \quad \mathrm{Re}\,x\to\infty, \tag{A20}$$

and

$$I_{n,m}(x)=(-1)^{m}\frac{x^{(n+m)/2}\exp(-x/2)}{\sqrt{\Gamma(1+n)\Gamma(1+m)}}, \quad \mathrm{Re}\,x\to\infty, \tag{A21}$$

whenever m is integer.

(6) One can prove the following asymptotic formula:

$$\lim_{p\to\infty} I_{p+\alpha,p+\beta}\left(\frac{x^2}{4p}\right)=J_{\alpha-\beta}(x), \tag{A22}$$

where $J_\nu(x)$ are Bessel functions.

(7) Taking into account Eqs. (A20) and (A21), one can see that only the functions $I_{\alpha+n,n}(x)$ with non-negative integer n and $\alpha>-1$ are quadratically integrable on the interval $(0,\infty)$. Such functions obey the orthonormality relation

$$\int_0^\infty I_{\alpha+n,n}(x)I_{\alpha+m,m}(x)\mathrm{d}x=\delta_{m,n}, \tag{A23}$$

which follows from the corresponding properties of the Laguerre polynomials (Ref. 18, 7.414.3). In such a case, the relation

$$I_{\alpha+n,n}(x)=\sqrt{\frac{n!}{\Gamma(n+\alpha+1)}}e^{-x/2}x^{\alpha/2}L_n^{\alpha}(x) \tag{A24}$$

follows from (A4).

(8) Consider a class of functions, which are closely related to Laguerre functions, and which appear often in various problems of mathematical physics.

As follows from Eq. (A12), the Laguerre functions are solutions of the following eigenvalue problem:

$$R_\alpha\psi=\lambda\psi, \quad R_\alpha=\frac{\alpha^2}{4x}+\frac{x}{4}-\frac{\mathrm{d}}{\mathrm{d}x}-x\frac{\mathrm{d}^2}{\mathrm{d}x^2}, \quad 0<x<\infty, \quad \alpha=\mathrm{const}. \tag{A25}$$

A general solution of this problem has the form

$$\psi(x)=aI_{n,m}(x)+bI_{m,n}(x),\quad \alpha=n-m,\quad 2\lambda=n+m+1, \tag{A26}$$

where a, b are arbitrary constants. In the general case functions $\psi(x)$ vanish as $x\to\infty$ only if one of the numbers n or m is positive and an integer. However, one can provide such a behavior for any n,m, choosing some special values of a, b. Consider the functions

$$\psi_{\lambda,\alpha}(x)=x^{-1/2}W_{\lambda,\alpha/2}(x),\quad \psi_{\lambda,\alpha}(x)=\psi_{\lambda,-\alpha}(x), \tag{A27}$$

where $W_{\lambda,\mu}(x)$ are Whittaker functions (Ref. 18, 9.220.4). The functions $\psi_{\lambda,\alpha}(x)$ can be expressed via the confluent hypergeometric functions

$$\psi_{\lambda,\alpha}(x)=e^{-x/2}\left[\frac{\Gamma(-\alpha)x^{\alpha/2}}{\Gamma\left(\frac{1-\alpha}{2}-\lambda\right)}\Phi\left(\frac{1+\alpha}{2}-\lambda,1+\alpha;x\right)+\frac{\Gamma(\alpha)x^{-\alpha/2}}{\Gamma\left(\frac{1+\alpha}{2}-\lambda\right)}\Phi\left(\frac{1-\alpha}{2}-\lambda,1-\alpha;x\right)\right], \tag{A28}$$

or, using (A1), via the Laguerre functions

$$\psi_{\lambda,\alpha}(x)=\frac{\sqrt{\Gamma(1+n)\Gamma(1+m)}}{\sin(n-m)\pi}(\sin n\pi I_{n,m}(x)-\sin m\pi I_{m,n}(x)),$$
$$\alpha=n-m,\quad 2\lambda=1+n+m,\quad n=\lambda-\frac{1-\alpha}{2},\quad m=\lambda-\frac{1+\alpha}{2}. \tag{A29}$$

By the help of (A6)–(A16), the following properties of the functions $\psi_{\lambda,\alpha}(x)$ can be established:

$$\psi_{\lambda,\alpha}(x)=\sqrt{x}\psi_{\lambda-1/2,\alpha-1}(x)+\frac{1+\alpha-2\lambda}{2}\psi_{\lambda-1,\alpha}(x), \tag{A30}$$

$$\psi_{\lambda,\alpha}(x)=\sqrt{x}\psi_{\lambda-1/2,\alpha+1}(x)+\frac{1-\alpha-2\lambda}{2}\psi_{\lambda-1,\alpha}(x), \tag{A31}$$

$$2x\psi'_{\lambda,\alpha}(x)=(2\lambda-1-x)\psi_{\lambda,\alpha}(x)+\tfrac{1}{2}(2\lambda-1-\alpha)(2\lambda-1+\alpha)\psi_{\lambda-1,\alpha}(x), \tag{A32}$$

$$2x\psi'_{\lambda,\alpha}(x)=(\alpha-x)\psi_{\lambda,\alpha}(x)+(2\lambda-1-\alpha)\sqrt{x}\psi_{\lambda-1/2,\alpha+1}(x) \tag{A33}$$

$$=(x-2\lambda-1)\psi_{\lambda,\alpha}-2\psi_{\lambda+1,\alpha}. \tag{A34}$$

As a consequence of these properties we get

$$A_\alpha\psi_{\lambda,\alpha}(x)=\frac{2\lambda-1+\alpha}{2}\psi_{\lambda-1/2,\alpha-1}(x),\quad A^+_\alpha\psi_{\lambda-1/2,\alpha-1}(x)=\psi_{\lambda,\alpha}(x),$$
$$A_\alpha=\frac{x+\alpha}{2\sqrt{x}}+\sqrt{x}\frac{\mathrm{d}}{\mathrm{d}x},\quad A^+_\alpha=\frac{x+\alpha-1}{2\sqrt{x}}-\sqrt{x}\frac{\mathrm{d}}{\mathrm{d}x}. \tag{A35}$$

The operator R_α can be expressed via the operators A_α, A^+_α,

$$R_\alpha=A^+_\alpha A_\alpha+\frac{1-\alpha}{2},\quad R_{\alpha-1}=A_\alpha A^+_\alpha-\frac{\alpha}{2}. \tag{A36}$$

Since Eq. (A29) is a particular case of Eq. (A26), then $\psi_{\lambda,\alpha}(x)$ are also eigenfunctions for the operator R_α.

Using well-known asymptotics of the Whittaker function (Ref. 18, 9.227), we get

$$\psi_{\lambda,\alpha}(x)\sim x^{\lambda-1/2}e^{-x/2},\quad x\to\infty,\quad \psi_{\lambda,\alpha}(x)\sim\frac{\Gamma(|\alpha|)}{\Gamma\left(\frac{1+|\alpha|}{2}-\lambda\right)}x^{-|\alpha|/2},\quad \alpha\neq 0,\quad x\sim 0. \tag{A37}$$

The functions $\psi_{\lambda,0}(x)$ have a logarithmic singularity at $x\sim 0$. It is important to stress that the functions $\psi_{\lambda,\alpha}(x)$ are correctly defined and infinitely differentiable for $0<x<\infty$ and for any complex λ,α. In this respect one can mention that the Laguerre functions are not defined for negative integer n, m. In particular cases, when one of the numbers n, m is non-negative and an integer, the functions $\psi_{\lambda,\alpha}(x)$ coincide (up to a constant factor) with Laguerre functions. Thus, $\psi_{\lambda,\alpha}(x)$ are eigenfunctions (of the operator R_α), which vanish at $x\to\infty$.

According to Eq. (A37), the functions $\psi_{\lambda,\alpha}(x)$ are quadratically integrable on the interval $0<x<\infty$ whenever $|\alpha|<1$. It is not true for $|\alpha|\geqslant 1$. The corresponding integrals can be calculated (Ref. 18, 7.611),

$$\int_0^\infty \psi_{\lambda,\alpha}(x)\psi_{\lambda',\alpha}(x)\,dx=\frac{\pi}{(\lambda'-\lambda)\sin\alpha\pi}\left\{\left[\Gamma\left(\frac{1+\alpha-2\lambda'}{2}\right)\Gamma\left(\frac{1-\alpha-2\lambda}{2}\right)\right]^{-1}-\left[\Gamma\left(\frac{1-\alpha-2\lambda'}{2}\right)\Gamma\left(\frac{1+\alpha-2\lambda}{2}\right)\right]^{-1}\right\},\quad |\alpha|<1, \tag{A38}$$

$$\int_0^\infty |\psi_{\lambda,\alpha}(x)|^2\,dx=\frac{\pi}{\sin\alpha\pi}\,\frac{\psi\left(\frac{1+\alpha-2\lambda}{2}\right)-\psi\left(\frac{1-\alpha-2\lambda}{2}\right)}{\Gamma\left(\frac{1+\alpha-2\lambda}{2}\right)\Gamma\left(\frac{1-\alpha-2\lambda}{2}\right)},\quad |\alpha|<1, \tag{A39}$$

$$\int_0^\infty |\psi_{\lambda,0}(x)|^2\,dx=\frac{\psi'\left(\frac{1}{2}-\lambda\right)}{\Gamma^2\left(\frac{1}{2}-\lambda\right)},\quad \int_0^\infty \left|\psi_{n+1/2,0}(x)\right|^2\,dx=\Gamma^2(1+n). \tag{A40}$$

Here $\psi(x)$ is the logarithmic derivative of the Γ function (Ref. 18, 8.360).

For $|\alpha|\geqslant 1$, the situation is the following: the only quadratically integrable eigenfunctions of the operator R_α are Laguerre functions, they also form a complete set. The functions $\psi_{\lambda,\alpha}(x)$ are orthogonal whenever arguments of the Γ function in Eq. (A38) are integers and negative. That corresponds to n, m integer and non-negative. Thus, that is again the case of Laguerre functions according to Eq. (A29). If $|\alpha|<1$, then, in the general case, the functions $\psi_{\lambda,\alpha}(x)$ and $\psi_{\lambda',\alpha}(x)$, $\lambda'\neq\lambda$, are not orthogonal, as follows from Eq. (A38). That is a reflection of the fact that R_α is no longer a self-conjugate operator for such values of α.

Department of Physics, Washington University, St. Louis, Missouri 63130

(Received 20 November 2000; accepted for publication 8 February 2001)

The Ising limit is a correlated limit in which two bare Lagrangian parameters, the coupling constant g and the *negative* mass squared $-m^2$, both approach infinity with the ratio $-m^2/g=\alpha>0$ held fixed. In a conventional Hermitian parity-symmetric scalar quantum field theory, with interaction term $g|\phi|^N/N$, the renormalized mass of the asymptotic theory is finite in this limit, and the limiting theory exhibits universality in N. For a non-Hermitian $\mathcal{PT}$-symmetric but parity-violating Lagrangian, with interaction term $-g(i\phi)^N/N$, the renormalized mass diverges in the same correlated limit. Nevertheless, the asymptotic theory still has interesting properties. In particular, the one-point Green's function approaches the value $-i\alpha^{1/(N-2)}$ independently of the space–time dimension D for $D<2$. Moreover, while the Ising limit of a conventional theory is dominated by a dilute instanton gas, the corresponding correlated limit of this $\mathcal{PT}$-symmetric theory is dominated by a constant-field configuration with corrections determined by a weak-coupling expansion in which the expansion parameter is proportional to an inverse power of g. We thus observe a weak-coupling/strong-coupling duality: the Ising limit itself is a strong-coupling limit, but the expansion about this limit takes the form of a conventional weak-coupling expansion. A possible generalization to dimensions $D<4$ is briefly discussed.

I. $\mathcal{PT}$-SYMMETRIC QUANTUM FIELD THEORY

Conventional field-theoretic Hamiltonians possess two crucial symmetries, the continuous symmetry of the proper Lorentz group and the discrete symmetry of Hermiticity. While Lorentz invariance is a physical requirement, Hermiticity is a useful but rather mathematical constraint. However, assuming Lorentz invariance and positivity of the spectrum of the Hamiltonian one can prove the $\mathcal{PCT}$ theorem and thereby establish the physical discrete symmetry of $\mathcal{PCT}$ invariance. Recent papers have investigated the consequences of imposing only the physical symmetries of Lorentz invariance and $\mathcal{PCT}$ invariance in constructing a Hamiltonian. The constraint of $\mathcal{PCT}$ invariance is weaker than Hermiticity, so Hamiltonians having this property need not be Hermitian. In quantum mechanics and in scalar quantum field theory the $\mathcal{C}$ operator is unity, so $\mathcal{PCT}$ symmetry reduces to $\mathcal{PT}$ symmetry. While it has not yet been proved, there is strong analytical and

numerical evidence supporting the conjecture that, except when $\mathcal{PT}$ symmetry is spontaneously broken, the energy levels of many such Hamiltonians are all real and positive. The reality and positivity of the spectrum are apparently a consequence of the $\mathcal{PT}$ symmetry of H. Hamiltonians having $\mathcal{PT}$ symmetry have been studied in quantum mechanics[1–14] and in quantum field theory.[15–20]

A simple example of such a quantum-mechanical Hamiltonian is $H=p^2+ix^3$. Hamiltonians of this form may be regarded as *complex deformations* of conventional Hermitian Hamiltonians. To illustrate this deformation we consider the Hamiltonian $H=p^2-(ix)^N$, where $N\geqslant 2$ is a real number that is *not necessarily an integer*. When $N=2$, we have the harmonic oscillator Hamiltonian, whose spectrum is real and positive. As N increases from 2, the entire spectrum of the Hamiltonian smoothly deforms as a function of N and remains real and positive for all values of $N>2$. Thus, these theories are in effect the analytic continuation of conventional quantum mechanics into the complex plane.

These non-Hermitian theories exhibit some remarkable properties. Most interesting is that the expectation value of the operator x in quantum mechanics and the field ϕ in the corresponding quantum field theory is *nonzero* when $N>2$. This is true even for the p^2-x^4 Hamiltonian that one obtains at $N=4$, and it is also true for the $-g\phi^4$ scalar quantum field theory. The $-g\phi^4$ quantum field theory is particularly surprising because it has a positive real spectrum and exhibits a nonzero value of $\langle\phi\rangle$, and in four-dimensional space–time has a dimensionless coupling constant, is renormalizable, and is asymptotically free (and thus nontrivial). It may thus provide a useful setting to describe the Higgs particle.[19]

In this article we investigate the Euclidean scalar quantum field theory in dimensions $D<2$ defined by the Lagrangian density

$$\mathcal{L}=\frac{1}{2}(\nabla\phi)^2+\frac{1}{2}m^2\phi^2-\frac{g}{N}(i\phi)^N \quad (N>2). \tag{1.1}$$

Our purpose here is to study this theory in the correlated limit in which two bare Lagrangian parameters, the coupling constant g and the *negative* mass squared $-m^2$, both approach infinity with the ratio

$$-m^2/g\equiv\alpha>0 \tag{1.2}$$

held fixed. In a conventional parity-symmetric scalar quantum field theory this limit is called the *Ising limit*. In this limit the renormalized mass of the asymptotic theory is finite. Moreover, the limiting theory exhibits universal properties that will be discussed in Sec. II. For the non-Hermitian $\mathcal{PT}$-symmetric Lagrangian Eq. (1.1) the renormalized mass diverges in this same limit. We will show, however, that the asymptotic theory exhibits intriguing properties. Of considerable interest is the fact that the one-point Green's function G_1 approaches the finite value $-i\alpha^{1/(N-2)}$. Furthermore, while the Ising limit of a parity-symmetric quantum field theory is dominated by a dilute instanton gas, the corresponding correlated limit of a $\mathcal{PT}$-symmetric quantum field theory lacking parity symmetry is dominated by a constant-field configuration with corrections determined by a weak-coupling expansion in which the lines represent propagators of the conventional weak-coupling form and the vertices are proportional to an inverse power of g.

This article is organized as follows. In Sec. II we review the Ising limit of a Hermitian parity-invariant self-interacting scalar quantum field theory and consider this same correlated limit in a $\mathcal{PT}$-symmetric quantum field theory. In Sec. III we examine Hermitian and non-Hermitian $\mathcal{PT}$-symmetric quantum field theories in the correlated limit of Eq. (1.2) for the special case of $D=0$. In Sec. IV we investigate the one-dimensional case of Eq. (1.1) in this correlated limit by using the correspondence between one-dimensional field theory and quantum mechanics. Finally, in Sec. V we study this correlated limit for a D-dimensional quantum field theory where $D<2$ and make some observations concerning the case $D\geqslant 2$.

II. CONVENTIONAL ISING LIMIT OF SCALAR QUANTUM FIELD THEORY

The *Ising limit* of a scalar quantum field theory is defined as follows. Given the Lagrangian density for a D-dimensional Euclidean space quantum field theory,

$$\mathcal{L}=\frac{1}{2}(\nabla\phi)^2+\frac{1}{2}m^2\phi^2+\frac{g}{N}|\phi|^N \quad (N>2), \tag{2.1}$$

take the limit as the bare coupling constant $g\to\infty$ but demand that the renormalized mass M (the pole of the two-point Green's function) remain fixed and finite. To satisfy this constraint the value of the bare mass squared m^2 must approach $-\infty$ so that the ratio $-m^2/g=\alpha$ is fixed. Thus, the Ising limit is a correlated limit. In this limit the renormalized Green's functions of Eq. (2.1) approach universal N-independent values.[21]

The terminology ''Ising limit'' is taken from statistical mechanics. The Ising model of statistical mechanics describes systems in which there are two equally likely spin states. By analogy, in the correlated limits $g\to\infty$ and $m^2\to-\infty$ the potential $\frac{1}{2}m^2\phi^2+(g/N)|\phi|^N$ develops a deep symmetric double well. In one Euclidean space–time dimension (quantum mechanics) the Lagrangian density $\mathcal{L}$ represents a particle that is equally likely to be in one of two possible states, the left well or the right well.

The Ising limit is a strong-coupling phenomenon and is not accessible by a conventional perturbative treatment. However, a nonperturbative semiclassical analysis in quantum mechanics can be used to calculate the amplitude for the particle to tunnel from one well to the other. This tunneling amplitude is exponentially small. The well is symmetric, so the splitting between the lowest energy state and the first excited state is also exponentially small and is proportional to this tunneling amplitude. The renormalized mass M is the difference between the energy of the (odd-parity) first excited state and the energy of the (even-parity) ground state. The Ising limit exists because M can remain fixed even though the double-well potential becomes infinitely deep and all of its energy levels approach negative infinity. The symmetry of the double well is crucial; if it were not symmetric, the renormalized mass could not remain finite as g and $-m^2$ become large.

To determine the dimensionless renormalized Green's functions of a D-dimensional Euclidean quantum field theory in the Ising limit, we follow a routine procedure. First, we construct the vacuum persistence amplitude in the presence of an external source:

$$\mathcal{Z}[J]=\int \mathcal{D}\phi\,\exp\left(-\int d^Dx\,[\mathcal{L}-J(x)\phi(x)]\right). \tag{2.2}$$

The connected unrenormalized n-point Green's functions are then usually obtained by repeated functional differentiation of $\mathcal{W}[J]\equiv\ln\mathcal{Z}[J]$ with respect to the source J:

$$G_n(x_1,x_2,x_3,\ldots,x_n)=\frac{\delta}{\delta J(x_1)}\frac{\delta}{\delta J(x_2)}\frac{\delta}{\delta J(x_3)}\cdots\frac{\delta}{\delta J(x_n)}\ln(\mathcal{Z}[J])\bigg|_{J=0}. \tag{2.3}$$

(If the Lagrangian is symmetric under $\phi\to-\phi$, then Green's functions having an odd number n of legs vanish.) In the Ising limit, as opposed to perturbation theory, the simpler objects to calculate are the n-point correlation functions

$$W_n(x_1,x_2,\ldots,x_n)\equiv\frac{1}{\mathcal{Z}}\int \mathcal{D}\phi\,\phi(x_1)\phi(x_2)\ldots\phi(x_n)\exp\left(-\int d^Dx\,\mathcal{L}\right), \tag{2.4}$$

and the G_n are then obtained by subtracting the disconnected parts according to the formulas for the cumulants according to

$$G_1(x_1)=W_1(x_1),$$

$$G_2(x_1,x_2)=W_2(x_1,x_2)-W_1(x_1)W_1(x_2), \tag{2.5}$$

$$G_3(x_1,x_2,x_3)=W_3(x_1,x_2,x_3)-W_1(x_1)W_2(x_2,x_3)-W_1(x_2)W_2(x_1,x_3)$$
$$-W_1(x_3)W_2(x_1,x_2)+2W_1(x_1)W_1(x_2)W_1(x_3),$$

and so on.

Second, we construct the one-particle-irreducible (1PI) connected Green's functions Γ_n. These are obtained by functional differentiation with respect to the classical field $\phi(x)$ of the effective action,

$$\Gamma[\phi]=\mathcal{W}[J]-\int d^Dx'\,[\phi(x')-G_1]J(x'), \tag{2.6}$$

where $\phi(x)$ is the expectation value of the field in the presence of the source $J(x)$:

$$\phi(x)=\frac{\delta\mathcal{W}[J]}{\delta J(x)}. \tag{2.7}$$

In an abbreviated notation, or in momentum space, the first few Γ_n are

$$\Gamma_1=G_1(G_2)^{-1},$$

$$\Gamma_2=-(G_2)^{-1}-G_1G_3(G_2)^{-3}, \tag{2.8}$$

$$\Gamma_3=G_3(G_2)^{-3}-G_1G_4(G_2)^{-4}+3G_1(G_3)^2(G_2)^{-5}.$$

One effect of these relations is to amputate the legs of the n-point unrenormalized Green's function by multiplying by $(G_2)^{-n}$.

Third, we construct the dimensionless renormalized 1PI Green's functions $\tilde{\Gamma}_n^{\mathrm{ren}}$. To do so we perform a (finite) wave-function renormalization by multiplying by $(\sqrt{Z})^n$, where Z is the wave-function renormalization constant. The *dimensionless* renormalized Green's functions are then obtained by multiplying by the appropriate power of the renormalized mass. Normally Z is defined as the residue of the pole of the two-point Green's function. However, in this article we use the simpler *intermediate renormalization scheme* in which the renormalization is performed in momentum space with the Green's functions evaluated at zero momentum on the external legs. In this scheme the value of Z is just the two-point Green's function in momentum space multiplied by the square of the renormalized mass.

The dimensionless renormalized 1PI Green's functions $\tilde{\Gamma}_n^{\mathrm{ren}}$ are the coefficients in the Taylor expansion of the renormalized effective action. In the Ising limit of the parity-symmetric Lagrangian density in Eq. (2.1) these coefficients are known analytically in the cases $D=0$ and $D=1$. In those cases the dimensionless renormalized $2n$-point momentum-space Green's functions $\tilde{\Gamma}_{2n}^{\mathrm{ren}}$ at zero external momentum have the form[21]

$$\tilde{\Gamma}_{2n}^{\mathrm{ren}}|_{D=0}=-\frac{n!}{2n(2n-1)},$$
$$\tilde{\Gamma}_{2n}^{\mathrm{ren}}(0,0,\ldots,0)|_{D=1}=-\frac{2^n\Gamma(n-\frac{1}{2})}{4\Gamma(\frac{1}{2})}. \tag{2.9}$$

Note that these results are independent of N; thus, apart from dimensional dependence, the Ising limit is evidently universal.

In this article we examine the Ising limit for the class of scalar quantum field theories defined in Eq. (1.1). While these theories are similar to those in Eq. (2.1), they do not possess parity symmetry. For such theories we will show that in this limit the Green's functions exhibit a remarkably simple structure even though in this limit the renormalized mass now diverges. Of course, when N is not an even integer, the spectrum of a quantum field theory whose interaction term is ϕ^N is not bounded below. Moreover, the functional-integral representation for the vacuum persistence amplitude

$$\mathcal{Z}=\int \mathcal{D}\phi \exp\left(-\int d^D x\, \mathcal{L}\right) \tag{2.10}$$

does not exist. However, for the strange looking non-Hermitian Lagrangian density in Eq. (1.1), which was discussed in detail in Ref. 15, it appears that for $N\geqslant 2$, the energy levels are all real and positive and that for this Lagrangian density the functional integral in Eq. (2.10) exists. (Note that for $N\geqslant 3$ the functional integral must be performed along a complex contour that begins *below* the negative-real axis and ends *below* the positive-real axis in the complex-ϕ plane. More precisely, the contour approaches infinity within asymptotic wedges whose opening angles are determined by the criterion that the functional integral in Eq. (2.10) exist. These wedges are described in detail in Ref. 15.) The $\mathcal{PT}$-symmetric Lagrangian density (1.1) is interesting because it provides a simple model of a quantum field theory with a broken symmetry. When $N=2$ the Lagrangian density represents a free theory, but as N increases from this value, the theory exhibits remarkable properties. For example, by direct calculation one can show that the value of $\langle\phi\rangle$ is nonzero (it has a negative-imaginary value) even if N is an even integer.[15]

III. CORRELATED LIMIT FOR $D=0$

In this section we discuss the Ising limit in the special case $D=0$. The vacuum persistence amplitude $\mathcal{Z}$ and correlation functions W_n are then expressible in terms of conventional Riemann integrals.

A. The parity-symmetric case

For the parity-symmetric theory the n-point correlation functions are

$$W_n=\frac{\int_{-\infty}^{\infty} dt\, t^n \exp(-\frac{1}{2}m^2t^2-(g/N)\,t^N)}{\int_{-\infty}^{\infty} dt \exp(-\frac{1}{2}m^2t^2-(g/N)\,t^N)}, \tag{3.1}$$

where N is an even integer greater than 2. Note that W_n vanishes when n is odd.

To evaluate the integrals in Eq. (3.1) in the limit of large g and $-m^2$, we substitute $-m^2=\alpha g$, where α is a positive constant, and use Laplace's method.[22] The Laplace points are the roots of $(d/dt)\,(\frac{1}{2}\alpha t^2-(1/N)\,t^N)=\alpha t-t^{N-1}=0$. Clearly, one Laplace point is always $t=0$, and expanding about this point gives the usual weak-coupling Feynman perturbation series. However, as $g\to\infty$, the contribution from this point vanishes exponentially relative to contributions from other Laplace points. Two real Laplace points located at $t=\pm\alpha^{1/(N-2)}$ dominate the asymptotic behavior of the integral representation for W_n. We thus obtain the leading asymptotic behavior

$$W_{2n}\sim\alpha^{2n/(N-2)} \quad (g\to\infty). \tag{3.2}$$

We then construct the connected Green's functions from the correlation functions W_n by using the zero-dimensional version of the cumulants in Eq. (2.5):

$$\begin{aligned} G_1&=W_1,\\ G_2&=W_2-(W_1)^2, \end{aligned} \tag{3.3}$$

$$G_3 = W_3 - 3W_1W_2 + 2(W_1)^3,$$

and so on. In the symmetric case these equations simplify enormously because $W_{2n+1}=0$.

We recover the first result in Eq. (2.9) by substituting Eq. (3.2) into Eq. (3.3) and then following the renormalization procedure described in Sec. II: we amputate the external legs, and then multiply by the appropriate power of the renormalized mass M, where $G_2 = M^{-2}$, to make the Green's functions dimensionless. In zero dimensions the wave-function renormalization constant Z can be chosen to be unity. Note that the dimensionless renormalized Green's functions in (2.9) are pure numbers independent of both N and α.

B. The parity-nonsymmetric case

Now consider the zero-dimensional version of the theory in Eq. (1.1). For this theory the n-point correlation functions W_n are

$$W_n = \frac{\int_{-\infty}^{\infty} dt\, t^n \exp[-\frac{1}{2}m^2t^2 + (g/N)(it)^N]}{\int_{-\infty}^{\infty} dt \exp[-\frac{1}{2}m^2t^2 + (g/N)(it)^N]}. \tag{3.4}$$

To evaluate W_n we split the range of integration in each of these integrals into two contributions:

$$\int_{-\infty}^{\infty} dt\, t^n \cdots = \int_{-\infty}^{0} dt\, t^n \cdots + \int_{0}^{\infty} dt\, t^n \cdots = 2\begin{pmatrix} \mathrm{Re(if}\ n\ \mathrm{even)} \\ i\ \mathrm{Im(if}\ n\ \mathrm{odd)} \end{pmatrix} \int_{0}^{\infty} dt\, t^n \cdots . \tag{3.5}$$

This integral exists if $1 < \mathrm{Re}\, N < 3$.

Note that W_n is an analytic function of N for $N \geqslant 0$ because the region inside of which the integration path in Eq. (3.4) lies *is an implicit function of N*. Indeed, as N ranges through real values, the paths of integration of the two integrals in Eq. (3.5) lie inside wedge-shaped regions that *rotate in opposite directions*.[23] It is convenient to take the paths of integration to lie at the center of the wedges. In this case, the path of integration of the first integral connects complex ∞ to 0 in the t plane along the straight line

$$\text{path 1:} \quad \arg t = -\pi/2 - \pi/N. \tag{3.6}$$

The second integration path runs from 0 to complex ∞ along

$$\text{path 2:} \quad \arg t = -\pi/2 + \pi/N. \tag{3.7}$$

The opening angle of each wedge is π/N.

When $N=2$ the wedges are centered about the positive and negative real axes and the opening angle of the wedges is 90°. In this case path 1 connects $-\infty$ to 0 and path 2 connects 0 to ∞ along the real-t axis. Here, W_n is *real* and parity symmetry is unbroken. As N increases, path 1 rotates anticlockwise and path 2 rotates clockwise. Integration along the real axis is no longer allowed when $N \geqslant 3$. The two paths slope downward at 45° angles when $N=4$. For all $N>2$ we find that $W_{2n+1} \neq 0$, demonstrating that parity symmetry is broken.

Now we discuss the Ising limit. To analyze the asymptotic behavior of the integrals in Eq. (3.4) we examine the expression

$$L(t) = \frac{1}{2}m^2t^2 - \frac{g}{N}(it)^N \quad (N>2). \tag{3.8}$$

The saddle points determining the asymptotic behavior are the zeros of $L'(t) = m^2t - ig(it)^{N-1}$. Remember that both g and $-m^2$ are large such that the ratio $\alpha = -m^2/g$ is fixed. There are many roots of $L'(t)=0$: First there is a root at $t=0$, which is the perturbative root, corresponding to

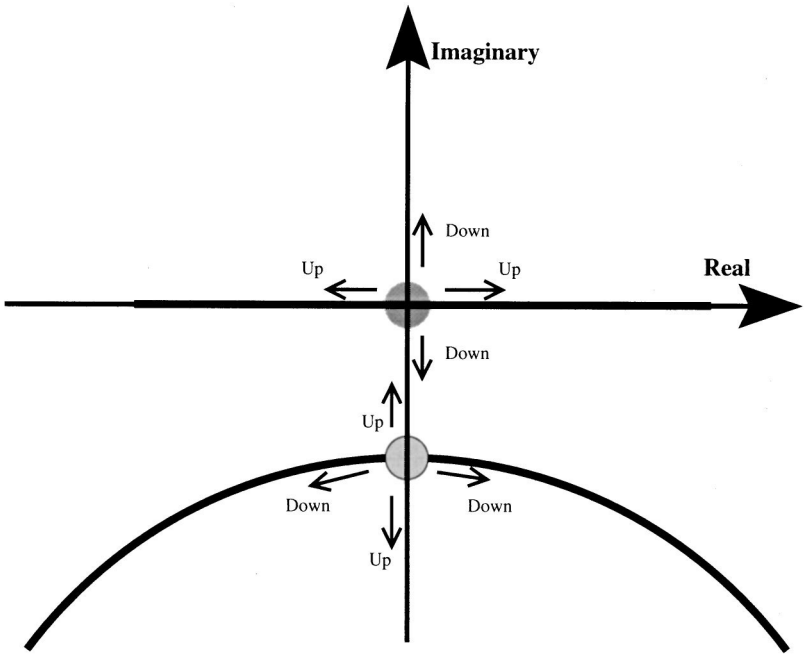

FIG. 1. Position of relevant saddle points and paths of stationary phase for the evaluation of Eq. (3.4) in the Ising limit.

expansions in powers of g. Second, there is a ring of roots surrounding the origin. The most important of these roots, and the one that determines the Ising limit of the theory, lies on the negative imaginary axis:

$$t_0 = -i\alpha^{1/(N-2)}. \tag{3.9}$$

To find the directions of the saddle points we calculate the second derivative of L: $L''(t) = m^2 + g(N-1)(it)^{N-2}$. Thus, $L''(0) = m^2$ and $L''(t_0) = -(N-2)m^2$, which is positive because m^2 is negative and $N > 2$. Hence, the down directions for the saddle point at $t = 0$ go vertically along the imaginary axis. The down directions for the saddle point t_0 are locally horizontal (see Fig. 1). As we trace the down paths away from the saddle point t_0 they curve downward and align with the directions in Eqs. (3.6) and (3.7). This verifies that t_0 is the saddle point that we should use.

It is straightforward to find the leading asymptotic behavior of the integrals in Eq. (3.4). The Gaussian corrections cancel and we obtain the leading-order result

$$W_n \sim (t_0)^n. \tag{3.10}$$

However, when we substitute this result into the formulas in Eq. (3.3), we find that except for G_1, each of the Green's functions *vanishes* to leading order. This happens because the sum of the numerical coefficients in each cumulant except the first is zero. (This does not happen in the parity-symmetric case because $W_n \equiv 0$ for odd n.)

Therefore, we are obliged to perform the asymptotic analysis to higher order. For example, to obtain the first nonvanishing contribution to G_2 we must calculate W_1 and W_2 to one order beyond the Gaussian approximation; to obtain G_3 we must calculate W_1, W_2, and W_3 to two orders beyond the Gaussian approximation; to obtain G_4 we must calculate W_1, W_2, W_3, and W_4 to three orders beyond the Gaussian approximation; and so on. To perform this calculation we need the kth derivative of $L(t)$ in (3.8):

$$L^{(k)}(t)=-\frac{i^k g\Gamma(N)}{\Gamma(N-k+1)}(it)^{N-k} \quad (k\geqslant 3). \tag{3.11}$$

Substituting the saddle point $t=t_0$ gives

$$L^{(k)}(t_0)=-\frac{i^k g\Gamma(N)}{\Gamma(N-k+1)}\alpha^{(N-k)/(N-2)} \quad (k\geqslant 3). \tag{3.12}$$

The expression for W_n then has the form

$$W_n\sim\frac{\int dt\, t^n \exp[\Sigma_{k=2}^{\infty}-(1/k!)\,L^{(k)}(t_0)(t-t_0)^k]}{\int dt \exp[\Sigma_{k=2}^{\infty}-(1/k!)\,L^{(k)}(t_0)(t-t_0)^k]}. \tag{3.13}$$

Note that $L(t_0)$ cancels from the numerator and denominator. Next, we make the translation $s=t-t_0$ and the scaling $s=v\epsilon\alpha^{1/(N-2)}$, where $\epsilon^2=\alpha^{-N/(N-2)}/[g(N-2)]$. The result is

$$W_n\sim(t_0)^n\frac{\int dv\,(1+iv\epsilon)^n e^{-(1/2)v^2}\exp\left[\Sigma_{k=3}^{\infty}\dfrac{v^k i^k\Gamma(N)\epsilon^{k-2}}{k!\Gamma(N+1-k)(N-2)}\right]}{\int dv\, e^{-(1/2)v^2}\exp\left[\Sigma_{k=3}^{\infty}\dfrac{v^k i^k\Gamma(N)\epsilon^{k-2}}{k!\Gamma(N+1-k)(N-2)}\right]}. \tag{3.14}$$

We expand the integrands in the numerator and denominator as series in powers of ϵ and perform the Gaussian integrals. We then substitute the result into Eq. (3.3) to obtain the small-ϵ leading asymptotic approximations to the unrenormalized connected Green's functions G_n:

$$\begin{aligned} G_1&\sim t_0,\\ G_2&\sim-(t_0)^2\epsilon^2, \end{aligned} \tag{3.15}$$

and

$$G_n\sim-(t_0)^n\epsilon^{2n-2}(N-1)(N-2)^{n-2}\Gamma\left[\frac{(n-2)(N-1)}{N-2}\right]\Big/\,\Gamma\left(\frac{n-2}{N-2}\right) \tag{3.16}$$

for $n>2$. To obtain the analogs of the first of Eqs. (2.9) we construct the coefficients of the effective action. Using the relations given in Eq. (2.8) we obtain

$$\begin{aligned} \Gamma_1&\sim-(t_0)^{-1}\epsilon^{-2},\\ \Gamma_2&\sim-(t_0)^{-2}\epsilon^{-2}(N-2), \end{aligned} \tag{3.17}$$

and so on. The general formula is

$$\Gamma_n\sim-(t_0)^{-n}\epsilon^{-2}\frac{1}{(N-2)}\left[\frac{(N-n-1)\Gamma(N)}{\Gamma(N-n+1)}+\delta_{n,2}\right]. \tag{3.18}$$

We construct the *dimensionless* renormalized coefficients $\tilde{\Gamma}_n^{\mathrm{ren}}$ by multiplying Γ_n by the appropriate power of the renormalized mass $M^2=1/G_2=-(\epsilon t_0)^{-2}=\alpha g(N-2)$ according to $\tilde{\Gamma}_n^{\mathrm{ren}}=\Gamma_n(M^2)^{-n/2}$. Thus, we have the result

$$\tilde{\Gamma}_n^{\mathrm{ren}}\sim-\epsilon^{n-2}\frac{i^n}{(N-2)}\left[\frac{(N-n-1)\Gamma(N)}{\Gamma(N-n+1)}+\delta_{n,2}\right], \tag{3.19}$$

independent of t_0. This is the analog of the first of Eqs. (2.9) for the $\mathcal{PT}$-symmetric theory.

IV. CORRELATED LIMIT FOR THE SCHRÖDINGER EQUATION

The Lagrangian in Eq. (1.1) is a field-theoretic generalization of the quantum-mechanical theory described by the non-Hermitian Hamiltonian

$$H=\frac{1}{2}p^2+\frac{1}{2}x^2-\frac{g}{N}(ix)^N. \tag{4.1}$$

This Hamiltonian is $\mathcal{PT}$-symmetric because under parity reflection $\mathcal{P}$: $p\to -p$ and $x\to -x$ and under time reversal, which is an antiunitary operation, $\mathcal{T}$: $p\to -p$, $x\to x$, and $i\to -i$. The Ising substitution $m^2=-\alpha g$ gives the Schrödinger equation

$$-\frac{1}{2}\psi''(x)+\left[-\frac{1}{2}\alpha g x^2-\frac{g}{N}(ix)^N-E\right]\psi(x)=0, \tag{4.2}$$

where $\alpha>0$. The eigenvalue problem is posed on a path in the complex-x plane whose endpoints lie in complex wedges similar to the wedges discussed earlier for the complex path integral. See Refs. 1 and 2.

We seek the large-g behavior of (4.2). In this limit the energy E scales like g because the potential scales like g (this will be verified shortly). Thus, we make the substitution

$$E=\lambda g. \tag{4.3}$$

We now can study $Q(x)=-\frac{1}{2}\alpha x^2-(1/N)(ix)^N-\lambda$ in the resulting Schrödinger equation

$$-\tfrac{1}{2}\psi''(x)+gQ(x)\psi(x)=0. \tag{4.4}$$

For large g it is the turning points [the zeros of $Q(x)$] that determine the physics of the problem. More precisely, it is the lowest-lying pair of turning points that control the physics. Near this pair of turning points, the polynomial $Q(x)$ can be approximated by a parabola. To construct the parabola, we locate the point on the imaginary axis midway between the pair of turning points by differentiating $Q(x)$ and setting $Q'(x)=-\alpha x-i(ix)^{N-1}=0$. The value of x on the negative imaginary axis that solves this equation is $x_0=-i\alpha^{1/(N-2)}$. At this value of x, we see that $Q(x)$ vanishes if

$$\lambda=\frac{N-2}{2N}\alpha^{N/(N-2)}, \tag{4.5}$$

which justifies the scaling of E used in (4.3).

Next, we expand the Schrödinger equation (4.4) around the point x_0 by substituting

$$x=-i\alpha^{1/(N-2)}+\epsilon t \quad \text{and} \quad \lambda=\frac{N-2}{2N}\alpha^{N/(N-2)}+\delta. \tag{4.6}$$

Here, we treat ϵ and δ as small parameters, whose size will be determined below. We obtain

$$-\frac{1}{2\epsilon^2}\psi''(t)+g\left[-\frac{N-2}{2}\alpha\epsilon^2t^2+i\frac{(N-1)(N-2)}{6}\alpha^{(N-3)/(N-2)}\epsilon^3t^3-\delta\right]\psi(t)=0. \tag{4.7}$$

The requirement of dominant balance[22] implies that we must choose

$$\epsilon=g^{-1/4} \quad \text{and} \quad \delta=\beta g^{-1/2}, \tag{4.8}$$

where $\beta=\mathrm{O}(1)$ is a constant. To leading order the resulting Schrödinger equation reads

$$-\frac{1}{2}\psi''(t)+\left[-\frac{N-2}{2}\alpha t^2+i\frac{(N-1)(N-2)}{6}\alpha^{(N-3)/(N-2)}g^{-1/4}t^3-\beta\right]\psi(t)=0. \tag{4.9}$$

As $g\to\infty$ this equation becomes the eigenvalue problem for the harmonic oscillator, whose nth eigenvalue is $\beta=(n+1/2)\sqrt{(N-2)\alpha}$, where $n=0,1,2,\ldots$ is an integer. Thus, for the Schrödinger equation (4.2) the nth eigenvalue in the Ising limit is

$$E_n=\frac{N-2}{2N}\alpha^{N/(N-2)}g+(n+1/2)\sqrt{(N-2)\alpha g}\quad(n=0,1,2,\ldots) \tag{4.10}$$

with higher-order corrections of order g^0.

From this formula we can determine the renormalized mass M_{R}:

$$M_{\mathrm{R}}\equiv E_1-E_0=\sqrt{(N-2)\alpha g}. \tag{4.11}$$

Observe that unlike the conventional Ising limit, the renormalized mass *diverges* as $g\to\infty$. Thus, the unrenormalized two-point Green's function, which behaves like M_{R}^{-2}, vanishes as $g\to\infty$ like $1/g$, in agreement with the result in (3.15) for the zero-dimensional case.

We can determine the one-point Green's function G_1 by calculating the expectation value of x in the ground-state wave function. Specifically,

$$G_1\equiv\frac{\int dx\, x[\psi_0(x)]^2}{\int dx\,[\psi_0(x)]^2}, \tag{4.12}$$

where we obtain the ground-state wave function ψ_0 by setting $g=\infty$ in (4.9). Because ψ_0 is a Gaussian in t and $x=x_0+\epsilon t$ from (4.6), we immediately have

$$G_1=x_0=-i\alpha^{1/(N-2)}. \tag{4.13}$$

This result is identical to that obtained in (3.15) for $D=0$.

To calculate G_1 to first order we need to solve $-\frac{1}{2}\psi''(s)+[-\frac{1}{2}+\frac{1}{2}s^2+i\eta s^3]\psi(s)=0$ as a perturbation series

$$\psi(s)=e^{-s^2/2}[1+\eta f(s)+\mathrm{O}(\eta^2)].$$

We find that $f(s)=-i(s+s^3/3)$. Finally, we use this result in the integral (4.12) to obtain

$$G_1=-i\alpha^{1/(N-2)}\left(1+\frac{N-1}{4\sqrt{N-2}}\alpha^{-(N+2)/(2N-4)}g^{-1/2}\right). \tag{4.14}$$

V. CORRELATED LIMIT FOR GENERAL $D<2$

In this section we use functional-integral techniques to study the Ising limit in a scalar Euclidean quantum field theory of space-time dimension $D<2$. We first focus on the calculation of the one-point Green's function:

$$G_1\equiv\frac{\int\mathcal{D}\phi\,\phi(0)\exp(-\int d^Dx\,\mathcal{L})}{\int\mathcal{D}\phi\exp(-\int d^Dx\,\mathcal{L})}, \tag{5.1}$$

where $\mathcal{L}$ is given in (1.1). Making the substitution in (1.2) and letting $x=s/\sqrt{g}$ gives

$$G_1=\frac{\int\mathcal{D}\phi\,\phi(0)\exp(-g^{1-D/2}S[\phi])}{\int\mathcal{D}\phi\exp(-g^{1-D/2}S[\phi])}, \tag{5.2}$$

where

$$S[\phi]=\int d^D s\left[\frac{1}{2}(\nabla\phi)^2-\frac{1}{2}\alpha\phi^2-\frac{1}{N}(i\phi)^N\right]\quad(N>2). \tag{5.3}$$

If we assume that $D<2$, then as $g\to\infty$ we can use saddle-point methods to determine the behavior of G_1 in (5.2) as $g\to\infty$ because the coefficient of $S[\phi]$ is large. We begin by taking the functional derivative of $S[\phi]$. The saddle points are determined by the equation

$$\frac{\delta}{\delta\phi(t)}S[\phi]=-\nabla^2\phi(t)-\alpha\phi(t)-i[i\phi(t)]^{N-1}=0. \tag{5.4}$$

The solution to this equation is a saddle point at $\phi=0$ and a ring of saddle points centered about 0. The dominant saddle point is the one on the negative imaginary axis:

$$\phi_0=-i\alpha^{1/(N-2)}. \tag{5.5}$$

The complex contour can be connected to this saddle point. If we substitute the value of ϕ_0, we get

$$G_1\sim-i\alpha^{1/(N-2)}\quad(g\to\infty). \tag{5.6}$$

We now calculate all higher-order corrections. To do so we substitute

$$\phi(s)=\phi_0+\eta(s)=-i\alpha^{1/(N-2)}+\eta(s), \tag{5.7}$$

$\eta(s)$ is treated as small; that is, $\eta(s)\ll 1$. To illustrate the procedure, we expand the functional S in (5.3) to third order in powers of $\eta(s)$. The result is

$$S_3[\eta]=\int d^D s\left[\frac{N-2}{2N}\alpha^{N/(N-2)}+\frac{1}{2}(\nabla\eta)^2+\frac{N-2}{2}\alpha\eta^2+\frac{(N-1)(N-2)}{6}\alpha^{(N-3)/(N-2)}i\eta^3\right]. \tag{5.8}$$

We can now rewrite (5.2) in the form

$$G_1=-i\alpha^{1/(N-2)}+\frac{\int\mathcal{D}\eta\,\eta(0)\exp(-g^{1-D/2}S_3[\eta])}{\int\mathcal{D}\eta\exp(-g^{1-D/2}S_3[\eta])}. \tag{5.9}$$

The constant term in S_3, which is proportional to the volume of Euclidean space-time, cancels from the exponentials in the numerator and the denominator in (5.9). We expand the cubic term in the exponential as a power series in η^3 and keep the first nontrivial term. In the denominator, the term proportional to η^3 vanishes by oddness, but in the numerator we must retain the cubic term because in this case the leading term vanishes for the same reason:

$$G_1\sim-i\alpha^{1/(N-2)}-i\frac{(N-1)(N-2)}{6}\alpha^{(N-3)/(N-2)}g^{1-D/2}\times\frac{\int\mathcal{D}\eta\,\eta(0)\int d^D t\,\eta^3(t)\exp(-g^{1-D/2}S_{\text{free}}[\eta])}{\int\mathcal{D}\eta\exp(-g^{1-D/2}S_{\text{free}}[\eta])}, \tag{5.10}$$

where $S_{\text{free}}[\eta]=\frac{1}{2}\int d^D s\,[(\nabla\eta)^2+(N-2)\alpha\eta^2]$.

We can evaluate this ratio of functional integrals *exactly*. To do so we introduce an external source function $J(s)$ in the integral in the numerator:

$$G_1 \sim -i\alpha^{1/(N-2)} - i\frac{(N-1)(N-2)}{6}\alpha^{(N-3)/(N-2)}g^{-3+3D/2} \times \frac{\delta}{\delta J(0)}\int d^D t\left[\frac{\delta}{\delta J(t)}\right]^3 \frac{\int \mathcal{D}\eta \exp(-g^{1-D/2}S_J[\eta])}{\int \mathcal{D}\eta \exp(-g^{1-D/2}S_{\text{free}}[\eta])}\Bigg|_{J=0}, \tag{5.11}$$

where $S_J[\eta] = \int d^D s\,(\frac{1}{2}([\nabla\eta(s)]^2 + \frac{1}{2}\alpha(N-2)[\eta(s)]^2 - J(s)\eta(s))$.

Next, we evaluate the Gaussian integral in the numerator by completing the square. Upon doing so, the integral in the denominator cancels and what remains is the formula

$$G_1 \sim -i\alpha^{1/(N-2)} - i\frac{(N-1)(N-2)}{6}\alpha^{(N-3)/(N-2)}g^{-3+3D/2} \times \frac{\delta}{\delta J(0)}\int d^D t\left[\frac{\delta}{\delta J(t)}\right]^3 \exp\left(\frac{1}{2}g^{1-D/2}\int\int dr\,ds\,J(r)J(s)\Delta(r,s)\right)\Bigg|_{J=0}, \tag{5.12}$$

where Δ is the coordinate-space propagator satisfying the Euclidean coordinate space Green's function equation

$$[\nabla^2 + \alpha(N-2)]\Delta(r,s) = \delta(r-s). \tag{5.13}$$

The final step is to expand the exponential containing the external source and to perform the indicated differentiations. The result is

$$G_1 \sim -i\alpha^{1/(N-2)} - i\frac{(N-1)(N-2)}{2}\alpha^{(N-3)/(N-2)}g^{-1+D/2}\int dr\,\Delta(r,0)\Delta(0,0). \tag{5.14}$$

This expression has a graphical interpretation: A propagator connects the origin to the point r, where there is a tadpole. The momentum-space propagator is $\tilde{\Delta}(p) = 1/[p^2 + \alpha(N-2)]$, so that

$$\Delta(r,s) = (2\pi)^{-D}\int d^D p\, e^{ip(r-s)}\frac{1}{p^2+\alpha(N-2)}. \tag{5.15}$$

Thus, $\tilde{\Delta}(0) = \int dr\,\Delta(r,0) = 1/\alpha(N-2)$ and $\Delta(0,0) = \Gamma(1-D/2)(4\pi)^{-D/2}[\alpha(N-2)]^{-1+D/2}$. The final result for G_1 is

$$G_1 \sim -i\alpha^{1/(N-2)}\left[1 + \frac{N-1}{2}[g(N-2)]^{-1+D/2}(4\pi)^{-D/2}\Gamma\left(1-\frac{D}{2}\right)\alpha^{(D/2)\,-\,N/(N-2)}\right], \tag{5.16}$$

which agrees exactly with (3.15) for the case $D=0$ and (4.14) for the case $D=1$.

The procedure we have used to calculate G_1 can be generalized to calculate any of the Green's functions G_n by taking advantage of the graphical methods developed above. For the two-point Green's function we immediately obtain

$$G_2(x,y) \sim g^{-1+D/2}\Delta(x\sqrt{g}, y\sqrt{g}) \tag{5.17}$$

to leading order, which in momentum space gives

$$G_2(p) \sim \frac{1}{p^2 + (N-2)\alpha g}. \tag{5.18}$$

From this equation we see that to leading order the renormalization constant $Z=1$ and that the renormalized mass M_{R} is given by

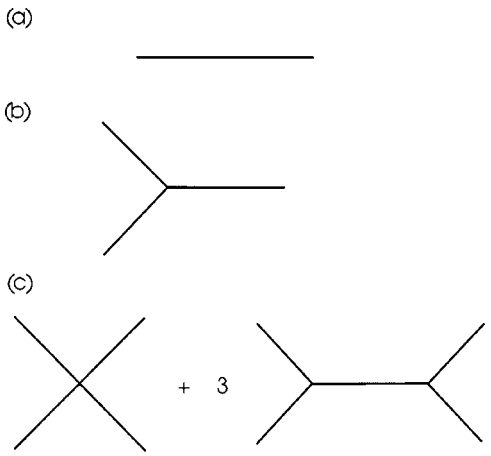

FIG. 2. Tree graphs contributing to G_2 through G_4 in the Ising limit.

$$M_{\mathrm{R}}^2=(N-2)\alpha g. \tag{5.19}$$

Observe that this result is independent of the dimension D and agrees with the result for $D=0$ and also with that in (4.11) for $D=1$, which was derived by quite different techniques. Figure 2 shows the tree graphs contributing to G_2 through G_4.

In fact, we find that the results in Eqs. (3.15) and (3.16) are valid for any dimension $D<2$, provided that they are interpreted as momentum space Green's functions evaluated at zero momentum on all external legs. The parameter ϵ^2 is, however, dimensional for $D\neq 0$. Equations (3.18) and (3.19) for the 1PI Green's functions are also valid with the same understanding.

Thus, we observe a form of universality; the expressions for the Green's functions are the same for all D and only depend on N, the exponent in the interaction term. This is quite different from the usual statement of universality, in which the Green's functions are independent of N but do depend on the value of D. However, Eq. (3.19) is D dependent insofar as the parameter ϵ must be replaced by its dimensionless version, given by

$$\tilde{\epsilon}^2=\frac{\alpha^{(D/2)\,-\,N/(N-2)}}{[(N-2)g]^{1-D/2}}. \tag{5.20}$$

This is the natural small parameter governing the asymptotic expansion, as in Eq. (5.16).

In the calculations performed so far it has been assumed implicitly that $D<2$. Indeed, D cannot exceed 2 if α is taken to be fixed, as in the original definition of the Ising limit in Eq. (1.2). However, if the restriction that α be fixed is relaxed and α is allowed to grow with g in such a way that $\tilde{\epsilon}$ in Eq. (5.20) remains small, then our results for the Green's functions in this modified Ising limit remain valid in the larger range $2<D<4$. Unfortunately, we still cannot extend the range of these results to the physically important case $D=4$.

Nevertheless, in the range of dimension $0\leqslant D<4$ with $D\neq 2$ we have the following picture. The scalar theory in this Ising-like regime is very simple. The only remnant of the theory is a renormalized mass M_{R}, which approaches infinity, and a one-point Green's function, which is the expectation value of the scalar field. The higher Green's functions are all negligible in this regime. If these results could be extended to $D=4$, we would have the equivalent of the Higgs phenomenon without requiring the existence of a (so-far unobserved) finite-mass Higgs particle.

(Received 12 June 2000; accepted for publication 12 February 2001)

The Casimir energy of a semi-circular cylindrical shell is calculated by making use of the zeta function technique. This shell is obtained by crossing an infinite circular cylindrical shell by a plane passing through the symmetry axes of the cylinder and by considering only half of this configuration. All the surfaces, including the cutting plane, are assumed to be perfectly conducting. The zeta functions for scalar massless fields obeying the Dirichlet and Neumann boundary conditions on the semi-circular cylinder are constructed exactly. The sum of these zeta functions gives the zeta function for the electromagnetic field in question. The relevant plane problem is considered also. In all the cases the final expressions for the corresponding Casimir energies contain the pole contributions which are the consequence of the edges or corners in the boundaries. This implies that further renormalization is needed in order for the finite physical values for vacuum energy to be obtained for given boundary conditions. © *2001 American Institute of Physics.*

I. INTRODUCTION

When calculating the ground state energy of a quantum field (the Casimir energy) the main problem is to single out a finite part of the vacuum energy which is initially divergent. Usually for this purpose a subtraction procedure is used with preliminary regularization of the divergent expressions (for example, by introducing ultraviolet cutoff). However, in quantum field theory treated with allowance for nontrivial boundary conditions or in the space–time with curvature, a complete renormalization procedure is not formulated explicitly. Therefore, for any specific problem the subtraction procedure should be invented anew. As a result, one succeeds in calculating the Casimir energy only in the problems with known spectra or at least implicitly known spectra. Practically it implies the boundary conditions of high symmetry[1,2] (parallel plates, sphere, cylinder).

In studies of the Casimir energy the zeta function technique,[3,4] which is also referred to as the zeta regularization or zeta renormalization, is widely used. In fact, the use of the zeta functions, as well as other regularizations, gives only regularized quantities for ground state energy, for effective potential and so on. The necessity to renormalize the expressions obtained in this way certainly remains. However, in some problems the zeta technique gives at once a finite result. Usually the latter is considered to be a renormalized physical answer though generally it is not the case.[5]

When using the zeta regularization in one or another problem, it is desirable to know beforehand whether the finite result can be obtained in this way. In order to answer this question the general analysis of the divergences in the problem at hand should be accomplished. This can be done by calculating the heat kernel coefficients[6] depending on the geometry of the manifold under

[a)]Electronic mail: nestr@thsun1.jinr.ru
[b)]Electronic mail: lambiase@sa.infn.it
[c)]Electronic mail: scarpetta@sa.infn.it

consideration. For a large class of situations these coefficients have been obtained.[7] However, there are a number of problems (for example, boundaries with edges or corners) for which no general results regarding the heat trace are known.

In this situation it is undoubtedly worth carrying out, in the framework of the zeta function technique, the calculations of the Casimir energy for new configurations, the cases being interesting with both finite result and with pole contributions left in the final expression for the vacuum energy.

In the present article we address the calculation of the Casimir energy for boundaries with edges; more precisely, the vacuum energy of electromagnetic field will be calculated for a semi-circular cylindrical shell by making use of the relevant zeta functions. This shell is obtained by crossing an infinite circular cylindrical shell by a plane passing through the symmetry axes of the cylinder. All the surfaces, including the infinite cutting plane, are assumed to be perfectly conducting. Obviously it is sufficient to consider only a half of this configuration (left or right) which we shall refer to as a semi-circular cylindrical shell or, for the sake of shortening, as a semi-circular cylinder. The internal boundary value problem for this configuration is nothing other as a semi-cylindrical waveguide. In the theory of waveguides[8] it is well known that a semi-circular waveguide has the same eigenfrequencies as the cylindrical one but without degeneracy (without doubling) and safe for one frequency series (see later in this work). Notwithstanding the very close spectra, the zeta function technique does not give a finite result for a semi-circular cylinder unlike for a circular one. First the Casimir energy of an infinite perfectly conducting cylindrical shell was calculated in Ref. 9 by introducing ultraviolet cutoff and recently this result was derived by zeta function technique[10] (see also Refs. 11–13). As far as we know the asymmetric boundaries such as a semi-circular cylinder have not been considered in the Casimir problem.

The article is organized as follows. In Sec. II the electromagnetic spectra are considered in detail for cylindrical and semi-cylindrical shells. The general solution of the Maxwell equations for boundary conditions chosen is expressed in terms of two scalar functions, longitudinal components of the electric and magnetic Hertz vectors. These scalar functions are the eigenfunctions of the two-dimensional transverse Laplace operator and obey the Dirichlet and Neumann boundary conditions on the conducting surfaces. In Sec. III the spectral zeta function is constructed for the Dirichlet boundary value problem. To this end, the technique is used which has been elaborated before for representing the spectral zeta function, with given eigenfrequency equations, in terms of contour integral. When carrying out the analytic continuation of the zeta function into the physical region, the uniform asymptotic expansion for the modified Bessel functions is used. In the same way, in Sec. IV the zeta function is constructed for a scalar field obeying the Neumann boundary conditions given on the surface of a semi-circular cylindrical shell. Section V is concerned with the complete zeta function for an electromagnetic field with boundary conditions on the semi-circular cylinder. Transition to the relevant two-dimensional problem is also considered here. In the Conclusion (Sec. VI) the results obtained are summarized, and the origin of the pole singularities of the zeta functions at hand and their relation to the respective boundary value problem are briefly discussed.

II. EIGENMODES OF ELECTROMAGNETIC FIELD FOR CIRCULAR AND SEMI-CIRCULAR CYLINDERS

The construction of the solutions to the Maxwell equations with boundary conditions given on closed surfaces proves to be nontrivial problem. Mainly it is due to the vector character of the electromagnetic field.[8,14,15] In the case of cylindrical symmetry the electric $\mathbf{E}$ and magnetic $\mathbf{H}$ fields are expressed in terms of the electric ($\mathbf{\Pi}'$) and magnetic ($\mathbf{\Pi}''$) Hertz vectors having only one nonzero component

$$\mathbf{\Pi}' = \mathbf{e}_z \Phi(r,\varphi)\, e^{\pm i k_z' z}, \tag{2.1}$$

$$\mathbf{\Pi}'' = \mathbf{e}_z \Psi(r,\varphi)\, e^{\pm i k_z'' z}. \tag{2.2}$$

Here the cylindrical coordinate system r,φ,z is used with z axes directed along the cylinder axes. The common time-dependent factor $e^{i\omega t}$ is dropped. The scalar functions $\Phi(r,\varphi)$ and $\Psi(r,\varphi)$ are the eigenfunctions of the two-dimensional transverse Laplace operator and meet, respectively, the Dirichlet and Neumann conditions on the boundary $\partial\Gamma$

$$(\nabla_\perp^2+\gamma'^2)\Phi(r,\varphi)=0, \quad \Phi(r,\varphi)|_{\partial\Gamma}=0, \tag{2.3}$$

$$(\nabla_\perp^2+\gamma''^2)\Psi(r,\varphi)=0, \quad \left.\frac{\partial\Psi(r,\varphi)}{\partial n}\right|_{\partial\Gamma}=0, \tag{2.4}$$

where $\nabla_\perp^2$ is the transverse part of the Laplace operator

$$\nabla_\perp^2=\frac{\partial^2}{\partial r^2}+\frac{1}{r}\frac{\partial}{\partial r}+\frac{1}{r^2}\frac{\partial^2}{\partial\varphi^2} \tag{2.5}$$

and

$$\gamma'^2=\omega^2-k_z'^2, \quad \gamma''^2=\omega^2-k_z''^2. \tag{2.6}$$

First we consider a cylindrical shell. In this case the functions $\Phi(r,\varphi)$ and $\Psi(r,\varphi)$ should be 2π-periodic in angular variable φ. As a result the Dirichlet boundary value problem (2.3) has the following unnormalized eigenfunctions (E-modes):

$$\Phi_{nm}(r,\varphi)=\begin{matrix}\sin\\ \cos\end{matrix}(n\varphi)\begin{cases}J_n(\gamma'_{nm}r), & r<a,\\ H_n^{(1)}(\overline{\gamma}'_{nm}r), & r>a,\end{cases} \tag{2.7}$$

where a is the cylinder radius, $J_n(x)$ are the Bessel functions, $H_n^{(1)}(x)$ are the Hankel functions of the first kind, and γ'_{nm}, $\overline{\gamma}'_{nm}$ stand for the roots of the frequency equations

$$J_n(\gamma'_{nm}a)=0, \quad H_n^{(1)}(\overline{\gamma}'_{nm}a)=0,$$
$$n=0,1,2,\ldots, \quad m=1,2,\ldots. \tag{2.8}$$

For the Neumann boundary value problem (2.4) we have the H-modes

$$\Psi_{nm}(r,\varphi)=\begin{matrix}\sin\\ \cos\end{matrix}(n\varphi)\begin{cases}J_n(\gamma''_{nm}r), & r<a,\\ H_n^{(1)}(\overline{\gamma}''_{nm}r), & r>a,\end{cases} \tag{2.9}$$

where γ''_{nm} and $\overline{\gamma}''_{nm}$ are the roots of the equations

$$\left.\frac{d}{dr}J_n(\gamma''_{nm}r)\right|_{r=a}=0, \quad \left.\frac{d}{dr}H^{(1)}(\overline{\gamma}''_{nm}r)\right|_{r=a}=0,$$
$$n=0,1,2,\ldots, \quad m=1,2,\ldots. \tag{2.10}$$

As usual, it is assumed that for $r>a$ the eigenfunctions should satisfy the radiation condition.

It is important to note that each root

$$\gamma'_{nm}, \quad \overline{\gamma}'_{nm}, \quad \gamma''_{nm}, \quad \overline{\gamma}''_{nm}, \quad n\geqslant 1, \quad m\geqslant 1, \tag{2.11}$$

is doubly degenerate since, according to Eqs. (2.7) and (2.9), there are two eigenfunctions which are proportional to either $\sin(n\varphi)$ or $\cos(n\varphi)$. The eigenfunctions for the roots with $n=0$

$$\gamma'_{0m}, \quad \overline{\gamma}'_{0m}, \quad \gamma''_{0m}, \quad \overline{\gamma}''_{0m}, \quad m=1,2,\ldots, \tag{2.12}$$

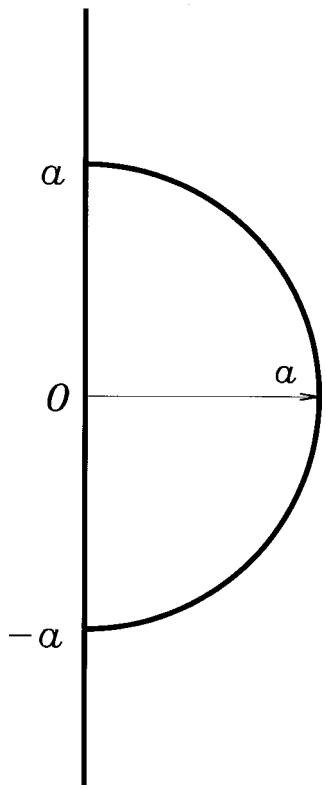

FIG. 1. The cross section of an infinite semi-circular cylindrical shell of radius a. All the surfaces (bold-faced lines) are assumed to be perfectly conducting. At the same time this picture presents the two-dimensional (plane) version of the problem under consideration, i.e., the semi-circular boundaries for massless fields defined on the plane.

are independent on φ, and the degeneracy disappears.

For given Hertz vectors $\mathbf{\Pi}'$ and $\mathbf{\Pi}''$ the electric and magnetic fields are constructed by the formulas

$$\begin{aligned} &\mathbf{E}=\boldsymbol{\nabla}\times\boldsymbol{\nabla}\times\mathbf{\Pi}', \quad \mathbf{H}=-i\omega\boldsymbol{\nabla}\times\mathbf{\Pi}' \quad (E\text{-modes}),\\ &\mathbf{E}=i\omega\boldsymbol{\nabla}\times\mathbf{\Pi}'', \quad \mathbf{H}=\boldsymbol{\nabla}\times\boldsymbol{\nabla}\times\mathbf{\Pi}'' \quad (H\text{-modes}). \end{aligned} \tag{2.13}$$

It has been proved[16] that the superposition of these modes gives the general solution to the Maxwell equations in the problem under consideration. An essential merit of using the Hertz polarization vectors is that in this approach the necessity to satisfy the gauge conditions does not arise.

Let us consider a waveguide which is obtained by cutting the infinite cylindrical shell by a plane passing through the symmetry axes of the cylinder (see Fig. 1). All the surfaces are assumed to be perfectly conducting. In this case the boundary value problems (2.3) and (2.4) for the Hertz electric ($\mathbf{\Pi}'$) and magnetic ($\mathbf{\Pi}''$) vectors have the following eigenfunctions:

$$\Phi_{nm}(r,\varphi)=\sin(n\varphi)\begin{cases} J_n(\gamma'_{nm}r), & r<a,\\ H_n^{(1)}(\overline{\gamma}'_{nm}r), & r>a, \end{cases} \tag{2.14}$$

$$n=1,2,\ldots, \quad m=1,2,\ldots$$

and

$$\Psi_{nm}(r,\varphi)=\cos(n\varphi)\begin{cases} J_n(\gamma''_{nm}r), & r<a, \\ H_n^{(1)}(\overline{\gamma}''_{nm}r), & r>a, \end{cases} \tag{2.15}$$

$$n=0,1,2,\ldots, \quad m=1,2,\ldots .$$

The frequencies γ'_{nm}, $\overline{\gamma}'_{nm}$, γ''_{nm}, and $\overline{\gamma}''_{nm}$ are determined by the same equations (2.8) and (2.10). However, the new spectral problem has two essential distinctions: (i) the frequencies (2.11) are now nondegenerate, and (ii) two series of eigenfrequencies

$$\gamma'_{0m}, \quad \overline{\gamma}'_{0m}, \quad m=1,2,\ldots, \tag{2.16}$$

are absent. At first sight one could expect that such a change of the spectrum cannot influence drastically the ultraviolet behavior of the relevant spectral density. However, as it will be shown below, the zeta function for a semi-circular cylinder, unlike for a circular one, does not provide a finite answer for the Casimir energy in the problem in question.

In view of all the above-mentioned the zeta function for the electromagnetic field obeying the boundary conditions on the surface of the semi-circular cylinder is the sum of two zeta functions for scalar massless fields satisfying the Dirichlet and Neumann conditions on the lateral of this cylinder.

III. ZETA FUNCTION FOR DIRICHLET BOUNDARY VALUE PROBLEM

First we consider the Dirichlet boundary conditions. We shall proceed from the following representation for the zeta function in terms of a contour integral for given frequency equations (2.8) with $n=1,2,\ldots$,

$$\zeta^{\mathrm{D}}_{\mathrm{cyl}}(s)=\frac{1}{2\pi i}\int_{-\infty}^{\infty}\frac{dk_z}{2\pi}\sum_{n=1}^{\infty}\oint_C d\gamma\,(\gamma^2+k_z^2)^{-s/2}\frac{d}{d\gamma}\ln\frac{J_n(\gamma a)H_n^{(1)}(\gamma a)}{J_n(\infty)H_n^{(1)}(\infty)}. \tag{3.1}$$

The contour C consists of the imaginary axis $(-i\infty,i\infty)$ and a semi-circle of an infinite radius in the right half-plane of a complex variable γ. The details of obtaining this integral representation can be found in Refs. 10, 11, 17, and 18. Contribution into Eq. (3.1) of integration along a semi-circle of infinite radius vanishes. Therefore upon integration over k_z this formula acquires the form

$$\zeta^{\mathrm{D}}(s)=C(s)\sum_{n=1}^{\infty}\int_0^{\infty}dy\,y^{1-s}\frac{d}{dy}\ln[2yI_n(y)K_n(y)] \tag{3.2}$$

with

$$C(s)=\frac{a^{s-1}}{2\sqrt{\pi}\Gamma\left(\frac{s}{2}\right)\Gamma((3-s)/2)}. \tag{3.3}$$

In order to accomplish the analytic continuation of (3.2) into the physical region including the point $s=-1$, we shall use the uniform asymptotic expansion for the modified Bessel functions[19]

$$\ln[2ynI_n(ny)K_n(ny)]=\ln(yt)+\frac{t^2}{8n^2}(1-6t^2+5t^4)$$
$$+\frac{t^4}{64n^4}(13-284t^2+1062t^4-1356t^6+565t^8)+O(n^{-6}), \tag{3.4}$$

where $t=1/\sqrt{1+y^2}$. Following the usual procedure applied in the analogous calculations,[20–23] we add and subtract in the integrand in Eq. (3.2) the first two terms of the asymptotic expansion (3.3). After that we combine all the terms there in the following way:

$$\zeta_{\rm cyl}^{\rm D}(s)=C(s)[Z_1(s)+Z_2(s)+Z_3(s)], \tag{3.5}$$

$$Z_1(s)=\frac{1}{2}\sum_{n=1}^{\infty} n^{1-s}\int_0^{\infty} dy\, y^{1-s}\frac{d}{dy}\ln\left(\frac{y^2}{1+y^2}\right), \tag{3.6}$$

$$Z_2(s)=\frac{1}{8}\sum_{n=1}^{\infty} n^{-1-s}\int_0^{\infty} dy\, y^{1-s}\frac{d}{dy}[t^2(1-6\,t^2+5\,t^4)], \tag{3.7}$$

$$Z_3(s)=\sum_{n=1}^{\infty} n^{1-s}\int_0^{\infty} dy\, y^{1-s}\frac{d}{dy}\left[\ln(2yn\,I_n(yn)K_n(ny))-\ln\frac{y}{\sqrt{1+y^2}}-\frac{t^2(1-6t^2+5t^4)}{8n^2}\right]. \tag{3.8}$$

Analytic continuation of the function $Z_1(s)$ into vicinity of the point $s=-1$ can be accomplished in the same way as it has been done in Ref. 18. Therefore we write here only the final result of this continuation

$$Z_1(s)=\frac{1}{2}\zeta(s-1)\Gamma\left(\frac{3-s}{2}\right)\sum_{m=1}^{\infty}\frac{\Gamma(m-(1-s)/2)}{m\Gamma(m)}. \tag{3.9}$$

The integral in Eq. (3.6) converges when $-1<\mathrm{Re}\,s<3$, and the sum over n is finite for $\mathrm{Re}\,s>0$. Thus, the regions, where the integral and the sum exist, overlap, and this formula can be used for constructing the analytic continuation needed. For this aim we substitute the sum by the Riemann zeta function

$$\sum_{n=1}^{\infty} n^{-1-s}=\zeta(s+1) \tag{3.10}$$

and define the integral as an analytic function by making use of the formula[24]

$$\int_0^{\infty} dy\, y^{1-s}\frac{d}{dy}t^{2(\rho-1)}=(1-\rho)\frac{\Gamma((3-s)/2)\Gamma(\rho-(3-s)/2)}{\Gamma(\rho)},\quad 3-2\,\mathrm{Re}\,\rho<\mathrm{Re}\,s<3. \tag{3.11}$$

In view of the poles of the gamma functions on the right-hand side of this relation, the integral on the left-hand side of it is well defined, as a function of the complex variable s, only in the region indicated in Eq. (3.11). Doing the analytic continuation of this integral we define it outside this region also by this equation, keeping in mind that the gamma functions involved should be treated as the analytic functions over all the plane of the complex variable s safe for the known poles. This gives

$$Z_2(s)=\frac{1}{8}\zeta(s+1)\Gamma\left(\frac{3-s}{2}\right)\Gamma\left(\frac{1+s}{2}\right)\left[-1+3(1+s)-\frac{5}{8}(3+s)(1+s)\right]. \tag{3.12}$$

In order to investigate the convergence of the integral entering in Eq. (3.7) it makes sense to substitute in the integrand the logarithmic function by expansion (3.3). After that it is easy to be convinced that the integral under consideration converges when $-3<\mathrm{Re}\,s<3$. The sum over n in

this formula is finite for $\mathrm{Re}\, s > -2$. Hence, the function $Z_3(s)$ is an analytic function without singularities in the domain $-2 < \mathrm{Re}\, s < 3$. It is quiet enough for our purpose, and the analytic continuation is unnecessary.

Summarizing we conclude that Eqs. (3.3), (3.5), (3.8), (3.9), and (3.12) afford the analytic continuation needed and define the zeta function $\zeta^{\mathrm{D}}(s)$ as an analytic function in the region including the point $s=-1$.

Now we are able to calculate the value of the zeta function $\zeta^{\mathrm{D}}(s)$ at the point $s=-1$. For the coefficient $C(s)$ in Eq. (3.3) we have

$$C(-1) = -\frac{1}{4\pi a^2}. \tag{3.13}$$

From Eq. (3.9) it follows that

$$Z_1(-1) = \frac{1}{2} \lim_{s\to -1} \zeta(s-1) \left[\Gamma\left(\frac{1+s}{2}\right) + \sum_{m=2}^{\infty} \frac{1}{m(m-1)} \right]. \tag{3.14}$$

With allowance for the relations

$$\Gamma(x) = \frac{1}{x} - \gamma + O(x), \quad \sum_{m=2}^{\infty} \frac{1}{m(m-1)} = 1, \quad \zeta(-2) = 0, \tag{3.15}$$

where γ is the Euler constant, $\gamma = 0.577\,215\ldots$, one derives

$$\begin{aligned} Z_1(-1) &= \lim_{s\to -1} \frac{1}{2} [\zeta(-2) + \zeta'(-2)(s+1) + O((s+1)^2)] \left[\frac{2}{s+1} - \gamma + O(s+1) \right] \\ &= \zeta'(-2) = -0.030\,448. \end{aligned} \tag{3.16}$$

Using the values of the Riemann zeta function and its derivative at the origin,

$$\zeta(0) = -\tfrac{1}{2}, \quad \zeta'(0) = -\tfrac{1}{2}\ln(2\pi),$$

and taking into account the behavior of the gamma function near zero [see Eq. (3.15)] we deduce from Eq. (3.12)

$$\begin{aligned} Z_2(-1) &= \frac{1}{8} \lim_{s\to -1} [\zeta(0) + \zeta'(0)(s+1) + O((s+1)^2)] \left[\frac{2}{s+1} - \gamma + \mathcal{O}(s+1) \right] \cdot \left[-1 + \frac{7}{4}(s+1) \right] \\ &= -\frac{7}{32} - \frac{\gamma}{16} + \frac{1}{8}\ln(2\pi) + \frac{1}{8} \frac{1}{s+1} \Big|_{s\to -1}. \end{aligned} \tag{3.17}$$

When calculating $Z_3(-1)$ we shall use Eq. (3.8) for several first values of n, $n \leqslant n_0$, and for $n > n_0$ we substitute the asymptotic expansion (3.4) into (3.8) with the result

$$Z_3^{\mathrm{as}}(s)=\frac{1}{64}\left(\sum_{n=n_0+1}^{\infty} n^{-3-s}\right)\int_0^{\infty} dy\, y^{1-s}\frac{d}{dy}[t^4(13-284\,t^2+1062\,t^4-1356\,t^6+565\,t^8)]$$

$$=\frac{1}{64}\left(\sum_{n=n_0+1}^{\infty} n^{-3-s}\right)\Gamma\left(\frac{3-s}{2}\right)\left[-13\,\Gamma\left(\frac{3+s}{2}\right)+142\,\Gamma\left(\frac{5+s}{2}\right)\right.$$

$$\left.-\frac{532}{3}\Gamma\left(\frac{7+s}{2}\right)+\frac{113}{2}\Gamma\left(\frac{9+s}{2}\right)-\frac{113}{24}\Gamma\left(\frac{11+s}{2}\right)\right]. \tag{3.18}$$

The value of n_0 should be chosen so as to provide the accuracy needed. This algorithm with $n_0=6$ gives for $Z_3(-1)$

$$Z_3(-1)=0.022\,806. \tag{3.19}$$

Summing up Eqs. (3.16), (3.17), and (3.19) we obtain

$$\zeta^{\mathrm{D}}(-1)=-\frac{1}{4\pi a^2}\left(-\frac{7}{32}+0.022\,806-\frac{\gamma}{16}+\frac{1}{8}\ln(2\pi)+\zeta'(-2)+\frac{1}{8}\frac{1}{s+1}\bigg|_{s\to -1}\right)$$

$$=\frac{1}{a^2}\left(0.000\,523-0.009\,947\frac{1}{s+1}\bigg|_{s\to -1}\right). \tag{3.20}$$

Thus the zeta function $\zeta^{\mathrm{D}}(s)$ has a pole at the point $s=-1$, therefore it does not give the finite (renormalized) value for the respective Casimir energy

$$E^{\mathrm{D}}=\tfrac{1}{2}\zeta^{\mathrm{D}}(-1). \tag{3.21}$$

It implies that further renormalization is required.

IV. ZETA FUNCTION FOR NEUMANN BOUNDARY VALUE PROBLEM

When constructing the zeta function for the boundary value problem (2.4) with $\partial\Gamma$ being a semi-circular infinite cylinder, we shall again proceed from the frequency equations [now from Eq. (2.10)]. It should be taken into account that all these roots are not degenerate. Therefore we can write analogously to Eq. (3.1)

$$\zeta^{\mathrm{N}}(s)=\frac{1}{2\pi i}\int_{-\infty}^{\infty}\frac{dk_z}{2\pi}\sum_{n=0}^{\infty}{}'\ \oint_C d\gamma\,(\gamma^2+k_z^2)^{-s/2}\frac{d}{d\gamma}\ln\frac{J_n'(\gamma a)H_n^{(1)\,\prime}(\gamma a)}{J_n'(\infty)H_n^{(1)\,\prime}(\infty)}. \tag{4.1}$$

The contour C is the same as in Eq. (3.1) and the prime on the Bessel and Hankel functions denotes differentiation with respect to the entire argument.

The product of the derivatives of the modified Bessel functions $I_n'(z)K_n'(z)$ has the following asymptotics when n is fixed and $|z|$ is large:[19]

$$I_n'(z)K_n'(z)=-\frac{1}{2z}\left[1+\frac{4n^2-3}{2(2z)^2}+\frac{(4n^2-1)(4n^2-45)}{8(2z)^4}+O(z^{-6})\right]. \tag{4.2}$$

Taking this into account in calculation of the denominator in Eq. (4.1), we obtain for $\zeta^{\mathrm{N}}(s)$ upon integration over k_z

$$\zeta^{\mathrm{N}}(s)=C(s)\sum_{n=0}^{\infty}{}'\ \int_0^{\infty} dy\, y^{1-s}\frac{d}{dy}\ln[-2yI_n'(y)K_n'(y)] \tag{4.3}$$

with the same function $C(s)$ as in Eq. (3.3).

Further we shall use the uniform asymptotic expansion for the derivatives of the Bessel functions:[19]

$$\ln[-2ynI_n'(ny)K_n'(ny)]=-\ln(yt)+\frac{t^2}{8n^2}(-3+10t^2-7t^4)+\frac{t^4}{n^4}\left(-\frac{27}{64}+\frac{109}{16}t^2-\frac{733}{32}t^4+\frac{441}{16}t^6-\frac{707}{64}t^8\right)+\mathcal{O}(n^{-6}). \tag{4.4}$$

In order to render the integral in the term with $n=0$ in Eq. (4.3) convergent we add and subtract the second term from the asymptotics (4.4). For $n\geqslant 1$ in Eq. (4.3) we add and subtract in respective intagrands the first two terms of the asymptotic expansion (4.4). After that we combine all the terms in the following way:

$$\zeta^{\mathrm{N}}(s)=C(s)[V_0(s)+V_1(s)+V_2(s)+V_3(s)], \tag{4.5}$$

$$V_0(s)=\int_0^\infty dy\, y^{1-s}\frac{d}{dy}\left\{\ln[-2yI_0'(y)K_0'(y)]-\frac{t^2}{8}(-3+10t^2-7t^4)\right\}, \tag{4.6}$$

$$V_1(s)=-\frac{1}{2}\sum_{n=1}^\infty n^{1-s}\int_0^\infty dy\, y^{1-s}\frac{d}{dy}\ln\left(\frac{y^2}{1+y^2}\right)=-Z_1(s), \tag{4.7}$$

$$V_2(s)=\frac{1}{8}\left(\sum_{n=1}^\infty n^{-1-s}+1\right)\int_0^\infty dy\, y^{1-s}\frac{d}{dy}[t^2(-3+10\,t^2-7\,t^4)], \tag{4.8}$$

$$V_3(s)=\sum_{n=1}^\infty n^{1-s}\int_0^\infty dy\, y^{1-s}\frac{d}{dy}\left\{\ln[-2ynI_n'(ny)K_n'(ny)]+\ln(yt)-\frac{t^2}{8n^2}(-3+10t^2-7t^4)\right\}. \tag{4.9}$$

Taking into account the behavior of the product $I_0'(y)K_0'(y)$ at the origin and at infinity,

$$\begin{aligned}-2yI_0'(y)K_0'(y)&=y+\tfrac{1}{8}(-1+4y-4\ln 2+\ln y)y^3+O(y^5\ln y),\\ -2yI_0'(y)K_0'(y)&=1-\frac{3}{8y^2}+\frac{45}{128y^4}+O(y^{-6}),\end{aligned} \tag{4.10}$$

it is easy to show that Eq. (4.6) defines $V_0(s)$ as an analytic function in the region $-3<\mathrm{Re}\,s<1$. Under this condition the integration by parts can be done here:

$$V_0(s)=-(1-s)\int_0^\infty dy\, y^{-s}\left\{\ln[-2yI_0'(y)K_0'(y)]-\frac{t^2}{8}(-3+10t^2-7t^4)\right\}. \tag{4.11}$$

The function $V_1(s)$ differs only in the sign of the function $Z_1(s)$ from the preceding section. The integral in Eq. (4.7) is convergent when $-1<\mathrm{Re}\,s<3$. The sum over n in this formula is finite when $\mathrm{Re}\ s>0$. Thus the regions, where the integral and the sum exist, overlap and this formula can be used for constructing the analytic continuation needed by making use of the substitutions (3.10) and (3.11). Substituting the sum in Eq. (4.8) by the Riemann zeta function and doing the integration according to Eq. (3.11) one obtains

$$V_2(s)=\frac{1}{8}[\zeta(1+s)+1]\Gamma\left(\frac{3-s}{2}\right)\Gamma\left(\frac{1+s}{2}\right)\left[3-5(1+s)+\frac{7}{8}(1+s)(3+s)\right]. \tag{4.12}$$

The convergence of the integral in Eq. (4.9) can be determined in the same line as it has been done for the function $Z_3(s)$ in the preceding section. This integral converges when $-3<\mathrm{Re}\,s<3$, and the sum encountered here is finite for $\mathrm{Re}\,s>-2$. Hence there is no need to do analytic continuation for $V_3(s)$.

Finally the zeta function $\zeta^{\mathrm{N}}(s)$ for the massless scalar field obeying the Neumann boundary conditions on a semi-circular cylinder is determined explicitly by Eqs. (4.5), (4.7), (4.11), and (4.12) in a finite domain of the complex plane s containing the closed interval of the real axis $-1\leqslant \mathrm{Re}\,s\leqslant 0$.

Now we turn to the calculation of the value of the function $\zeta^{\mathrm{N}}(s)$ at the point $s=-1$. Integration in Eq. (4.11) gives

$$V_0(-1)=-2\int_0^\infty dy\, y\left\{\ln[-2yI_0'(y)K_0'(y)]+\frac{3}{8}t^2\right\}+\frac{13}{16}$$
$$=2\cdot 0.475\,215+0.8123=1.763\,93. \tag{4.13}$$

From Eqs. (4.7) and (3.16) it follows that

$$V_1(-1)=-Z_1(-1)=-\zeta'(-2)=0.030\,44. \tag{4.14}$$

Developing the functions $\zeta(1+s)$ and $\Gamma((1+s)/2)$ in Eq. (4.12) near the point $s=-1$ one obtains

$$V_2(-1)=\frac{1}{8}[\zeta(0)+\zeta'(0)(s+1)+1+O((s+1)^2)]\cdot\left[\frac{2}{1+s}-\gamma+O(s+1)\right]\left[3-\frac{13}{4}(s+1)\right]$$
$$=-\frac{13}{32}-\frac{3}{16}\gamma+\frac{3}{4}\zeta'(0)+\frac{3}{8}\frac{1}{s+1}\bigg|_{s\to -1}. \tag{4.15}$$

When calculating $V_3(s)$ for $s=-1$ numerically we cannot use the method applied in the preceding section because it now requires us to take into account the next terms in the uniform asymptotic expansion (4.4). Instead of this we calculate numerically the first 30 terms in the sum (4.9) with the result[25]

$$V_3(-1)=-0.043\,66. \tag{4.16}$$

Substituting in Eq. (4.9) the logarithm by its uniform asymptotic expansion (4.4) we derive a rough estimation for $V_3(s)$ without numerical integration

$$V_3^{\mathrm{as}}(s)=\zeta(3+s)\int_0^\infty dy\, y^{1-s}\frac{d}{dy}\left[t^4\left(-\frac{27}{64}+\frac{109}{16}t^2-\frac{733}{32}t^4+\frac{441}{16}t^6-\frac{707}{64}t^8\right)\right]$$
$$=\zeta(3+s)\Gamma\left(\frac{3-s}{2}\right)\left[\frac{27}{64}\Gamma\left(\frac{3+s}{2}\right)-\frac{109}{32}\Gamma\left(\frac{5+s}{2}\right)+\frac{733}{192}\Gamma\left(\frac{7+s}{2}\right)-\frac{441}{384}\Gamma\left(\frac{9+s}{2}\right)\right.$$
$$\left.+\frac{707}{7680}\Gamma\left(\frac{11+s}{2}\right)\right]. \tag{4.17}$$

For $s=-1$ it gives

$$V_3^{\mathrm{as}}(-1)=-\frac{839}{2^6\cdot 3\cdot 5}\zeta(2)=-\frac{839}{960}\frac{\pi^2}{6}=-1.437\,60, \tag{4.18}$$

which is very far from Eq. (4.16) having only the right sign.

Summing up V_i, $i=0,1,2,3$, with allowance for Eq. (3.13) we arrive at the final result

$$\zeta^{\mathrm{N}}(-1)=-\frac{1}{4\pi a^2}\left[\frac{13}{32}+0.950\,43-\zeta'(-2)-\frac{3}{16}\gamma-\frac{3}{8}\ln(2\pi)-0.043\,66+\frac{3}{8}\frac{1}{s+1}\bigg|_{s\to-1}\right]$$
$$=\frac{1}{a^2}\left(-0.043\,45-0.0298\frac{1}{s+1}\bigg|_{s\to-1}\right). \tag{4.19}$$

Thus both the zeta functions for Dirichlet and Neumann boundary conditions have the pole at the point $s=-1$. Hence an additional renormalization is needed in order for a finite physical value of the relevant Casimir energies to be obtained.

V. VACUUM ENERGY OF ELECTROMAGNETIC FIELD WITH BOUNDARY CONDITIONS ON A SEMI-CIRCULAR CYLINDER

Analysis of the spectral problem for the electromagnetic field with boundary conditions on a semi-circular cylinder (see Sec. II) implies that the zeta function for this field is the sum of two zeta functions calculated in the preceding sections:

$$\zeta^{\mathrm{EM}}(s)=\zeta^{\mathrm{D}}(s)+\zeta^{\mathrm{N}}(s). \tag{5.1}$$

Substitution of Eqs. (3.20) and (4.17) into Eq. (5.1) gives

$$\zeta^{\mathrm{EM}}(-1)=-\frac{1}{4\pi a^2}\left[\frac{1}{4}+0.950\,43-\frac{\gamma}{4}-\frac{1}{4}\ln(2\pi)-0.043\,66+\frac{1}{2}\frac{1}{s+1}\bigg|_{s\to-1}\right]$$
$$=\frac{1}{a^2}\left(-0.044\,01-0.039\,78\frac{1}{s+1}\bigg|_{s\to-1}\right). \tag{5.2}$$

In both the zeta functions $\zeta^{\mathrm{D}}(s)$ and $\zeta^{\mathrm{N}}(s)$ the pole terms have the same sign. As a result the pole contribution in the sum (5.1) retains. Thus, the situation here proves to be analogous to that when calculating, in the framework of zeta technique, the vacuum energy for spheres in spaces of even dimensions.[21–23]

As was noted earlier, we have derived the exact expressions for the zeta functions in question which determine these functions as analytic functions of the complex variable s in a finite region of the plane s containing the closed interval of the real axis $-1\leqslant \mathrm{Re}\, s\leqslant 0$. It enables one to construct in a straightforward way the spectral zeta functions for relevant boundary value problem on the plane by making use of the relation[18]

$$\zeta_{\text{s-cir}}(s)=2\sqrt{\pi}\frac{\Gamma((s+1)/2)}{\Gamma(s/2)}\zeta_{\text{s-cyl}}(s), \tag{5.3}$$

where $\zeta_{\text{s-cir}}$ is the Dirichlet or the Neumann zeta function for a semi-circle, and $\zeta_{\text{s-cyl}}$ is the respective zeta function for semi-circular cylinder. We shall use this relation for calculating the values $\zeta^{\mathrm{D}}_{\text{s-cir}}(-1)$ and $\zeta^{\mathrm{N}}_{\text{s-cir}}(-1)$ which determine the vacuum energy of the massless scalar fields defined on the half-plane and obeying, respectively, the Dirichlet or Neumann boundary conditions on a semi-circle (see Fig. 1).

For $\zeta^{\mathrm{D}}_{\text{s-cir}}(-1)$ we get from Eqs. (5.3), (3.4), and (3.2)

$$\zeta^{\mathrm{D}}_{\text{s-cir}}(-1)=-\frac{1}{\pi a}\sum_{i=1}^{3}Z_i(0). \tag{5.4}$$

When $s=0$ integration in Eq. (3.6) can be done explicitly with the result

$$Z_1(0)=-\zeta(-1)\int_0^\infty dy\,\ln\frac{y}{\sqrt{1+y^2}}=\frac{1}{12}\left(-\frac{\pi}{2}\right)=-\frac{\pi}{24}. \tag{5.5}$$

From Eq. (3.12) it follows that

$$Z_2(0)=\frac{\pi}{128}\left(\frac{1}{s}\bigg|_{s\to 0}+\gamma\right). \tag{5.6}$$

Numerical integration in Eq. (3.8) with $s=0$ gives

$$Z_3(0)=-0.003\,04. \tag{5.7}$$

Summing up Eqs. (5.5)–(5.7) we arrive at the result

$$\zeta^{\mathrm{D}}_{\text{s-cir}}(-1)=\frac{1}{a}\left(\frac{1}{24}-\frac{\gamma}{128}+0.000\,97-\frac{1}{128}\frac{1}{s}\bigg|_{s\to 0}\right)=\frac{1}{a}\left(0.038\,127-\frac{1}{128}\frac{1}{s}\bigg|_{s\to 0}\right). \tag{5.8}$$

Following the same way one can write

$$\zeta^{\mathrm{N}}_{\text{s-cir}}(-1)=-\frac{1}{\pi a}\sum_{n=0}^{3}V_i(0). \tag{5.9}$$

Using Eq. (4.11) one gets

$$V_0(0)=-\int_0^\infty dy\left\{\ln[-2yI_0'(y)K_0'(y)]+\frac{3}{8}t^2\right\}-\frac{\pi}{64}=0.475\,175-\frac{\pi}{64}. \tag{5.10}$$

From Eqs. (4.7) and (5.5) it follows that

$$V_1(0)=-Z_1(0)=\frac{\pi}{24}. \tag{5.11}$$

Equation (4.12) gives

$$V_2(0)=\frac{5\pi}{128}\left(1+\gamma+\frac{1}{s}\bigg|_{s\to 0}\right). \tag{5.12}$$

For $V_3(0)$ numerical integration in Eq. (4.9) with $s=0$ gives

$$V_3(0)=-0.005\,659. \tag{5.13}$$

Finally, we have

$$\begin{aligned}\zeta^{\mathrm{N}}_{\text{s-cir}}(-1)&=\frac{1}{a}\left[-0.151\,32-\frac{5}{128}\left(\gamma+\frac{5}{3}\right)+0.001\,80-\frac{5}{128}\frac{1}{s}\bigg|_{s\to 0}\right]\\&=\frac{1}{a}\left(-0.237\,103-0.0124\frac{1}{s}\bigg|_{s\to 0}\right).\end{aligned} \tag{5.14}$$

Both the functions $\zeta^{\mathrm{D}}_{\text{s-cir}}(s)$ and $\zeta^{\mathrm{N}}_{\text{s-cir}}(s)$ have the pole at the point $s=-1$ with the coefficients of the same (negative) sign. For electromagnetic field defined on a plane the boundary conditions reduce to the Neumann conditions. Hence the relevant zeta function is $\zeta^{\mathrm{N}}_{\text{s-cir}}(s)$.

VI. CONCLUSION

In this article the spectral zeta functions are constructed for massless scalar fields obeying the Dirichlet and Neumann boundary conditions on a semi-circular infinite cylinder. Proceeding from this, the zeta function for electromagnetic field is also derived for such a configuration. In all three cases, the final expressions for the relevant Casimir energy contains the pole contribution. Hence for obtaining the physical result an additional renormalization is needed.

It is essential that for the zeta functions $\zeta(s)$ the exact formulas are derived which determine these functions in a finite region of the complex variable s but not at the vicinity of one point $s=-1$. This allowed one to get in a straightforward way the zeta functions for the two-dimensional (plane) version of the boundary value problem at hand, i.e., the zeta functions for scalar fields defined on a half-plane and obeying the Dirichlet and Neumann boundary conditions on a semi-circle. In this case the final expression for the vacuum energy contains the pole contributions also.

Notwithstanding the spectrum of a semi-circular cylinder is very close to the spectrum of circular one, the zeta function technique does not give a finite value for vacuum energy in the first case and does for the second configuration. In a recent paper[26] the divergences found in our consideration are attributed to the existence of edges or corners in the boundaries under investigation.

Closing, it is worth noting that, as far as we know, such boundary conditions with asymmetric geometry (semi-circular cylinder) has been considered in the Casimir problem for the first time.

Perturbation theory and the energy spectrum of normal Fermi systems

A. Ya. Povzner[a] and Yu. A. Kukharenko

(Received 31 May 2000; accepted for publication 17 January 2001)

This paper is a study in a possible steady-state perturbation theory for arbitrary excited multiply degenerate states of a normal Fermi system in the statistical limit. An operator technique has been developed to transform the relevant Hamiltonian into an operator that is a function of occupation number operators only. The perturbation theory equations have been proved to be solvable in the space of quasinormal form operators and their formal solutions have been derived. It is shown that the operator series of perturbation theory can be transformed to a linked cluster expansion with the nonphysical powers of volume eliminated. Elimination of nonphysical terms is effected without use of the diagrams technique. © *2001 American Institute of Physics.* [DOI: 10.1063/1.1357199]

I. INTRODUCTION

The perturbation theory for the energy of the ground state for a normal Fermi system was developed by Brueckner,[1] Goldstone,[2] and Hugenholtz[3] (see also Refs. 4–7) using diagram techniques. The main difficulty this procedure encounters is to transform a diagram series to a linked cluster expansion, which allows the contributions with nonphysical powers of volume to be eliminated. Van-Hove[8] examined the overall structure of the relevant perturbation theory series for the resolvent of the Schrödinger equation whose singular points are intimately related to the power spectrum.

The present paper is concerned with an operator technique in steady-state perturbation theory for calculating the entire spectrum of the perturbed Hamiltonian in the case in which the spectrum is strongly degenerate using the normal Fermi system as an example. The principal result is a (formal) proof of the statement that an invertible operator S can be found to transform the Hamiltonian of a normal Fermi system $H=H_0+\epsilon H_1$ to the form $\hat{E}=S^{-1}HS$, where the operator $\hat{E}$ is a functional of occupation number operators for eigenstates of the undisturbed Hamiltonian H_0. This operator technique was developed by one of us.[9] However, insuperable difficulties were encountered in the way of a solution for the equations involved owing to the small denominators. Our use of Keldysh's diagram technique to describe excited states[10] did not succeed in solving the problem fully either because of secular divergences that remained unsuppressed.

We prove that the resulting operator equations of the steady-state perturbation theory are solvable in the space of quasinormal form operators and construct their formal solutions. We show that the perturbation theory operator series can be transformed to a linked cluster expansion with the contributions involving nonphysical powers of the volume eliminated. Our development of the perturbation theory relies, not on the usual expansion into a series in the interaction parameter, but on a more general iterative scheme that avoids squares and higher powers of integrals defined in the principal value sense.

II. ITERATIVE SCHEME

The Hamiltonian H under discussion has the following momentum representation:

$$H=\sum_{\sigma}\int d\overline{p}\frac{p^2}{2m}a_{\sigma}^{+}(\overline{p})a_{\sigma}(\overline{p})$$
$$+\varepsilon\frac{1}{2}\sum_{\sigma_1\sigma_2}\int d\overline{p_1}d\overline{p_2}d\overline{q}U(\overline{q})a_{\sigma_1}^{+}(\overline{p_1}+\overline{q})a_{\sigma_2}^{+}(\overline{p_2}-\overline{q})\times a_{\sigma_2}(\overline{p_2})a_{\sigma_1}(\overline{p_1})$$
$$\equiv H_0+\epsilon H_1. \tag{1}$$

This is defined for a set of N identical Fermi particles that are contained in a cube of volume $V=(2L)^3$. The limit $N/V\to n$ is assumed to exist and the equations are considered in the limit $N\to\infty$. The operators $a_{\sigma}(\overline{p}),a_{\sigma}^{+}(\overline{p'})$ anticommute to the delta-function and are Fourier transforms of secondary-quantized wave functions of the particle in the functions $\varphi_{\overline{p}}(\overline{x})=[1/(2\pi)^{3/2}]\cdot e^{i(\overline{p},\overline{x})}$, normalized to the delta-function. We define a linear space Π_λ as the space of eigenvectors of H_0 belonging to the eigenvalue λ. When $[H_0,\hat{E}]=H_0\hat{E}-\hat{E}H_0=0$ and $\varphi\in\Pi_\lambda$, one has $\hat{E}\varphi\subset\Pi_\lambda$, i.e., $\hat{E}\Pi_\lambda\subset\Pi_\lambda$. For this reason, when

$$S^{-1}HS=\hat{E} \text{ and } [H_0,\hat{E}]=0, \tag{2}$$

then the spectrum of H is known when the spectrum of $\hat{E}$ is defined on all Π_λ spaces. This remark shows that the solution of the problem under discussion must be sought by looking for a transform S that satisfies the requirements: $S^{-1}(H_0+\varepsilon H_1)S=\hat{E}, [H_0,\hat{E}]=0$, since the space Π_λ for H_0 is identical, as will be seen in what follows, with that of eigenvectors of operators that are functions of $a_{\sigma}^{+}(p)a_{\sigma}(\overline{p})$.

The basic device to solve the problem is to replace (2) with the equation

$$(H_0+\varepsilon H_1)(1+\varepsilon S_1+\varepsilon^2S_2+\cdots)=(1+\varepsilon S_1+\varepsilon^2S_2+\cdots)(H_0+\varepsilon\hat{E}_1+\varepsilon^2\hat{E}_2+\cdots), \tag{3}$$

where

$$S=1+\varepsilon S_1+\varepsilon^2S_2+\cdots,\quad \hat{E}=H_0+\varepsilon\hat{E}_1+\varepsilon^2\hat{E}_2+\cdots, \tag{4}$$

with the additional requirement.

$$[H_0,\hat{E}_n]=0,\quad n=1,2,\ldots. \tag{5}$$

Introducing the notations

$$H_{0n}=H_0+\varepsilon\hat{E}_1+\cdots+\varepsilon^n\hat{E}_n,\quad H_{11}=H_1-E_1,\quad H_{1k}=-\hat{E}_k\quad (k\geqslant 2), \tag{6}$$

rewriting (3) in the form

$$(H_{0n-1}+\varepsilon H_{11}+\varepsilon^2H_{12}+\cdots\varepsilon^nH_{1n}-\varepsilon^n\overline{E_n})(I+\varepsilon S_1+\cdots+\varepsilon^{n-1}S_{n-1}+\varepsilon^nS_n+\cdots+)$$
$$=(I+\varepsilon S_1+\cdots+\varepsilon^{n-1}S_{n-1}+\varepsilon^nS_n)(H_{0n-1}+\varepsilon^n\hat{E}_n), \tag{7}$$

and equating the coefficients of ε^n in (7), we obtain the following recurrence equation:

$$[H_{0n},S_n]+\sum_{k=1}^{n-1}H_{1k}S_{n-k}=\hat{E}_n,\quad [H_0,\hat{E}_n]=0\quad n\geqslant 2. \tag{8}$$

We now state the requirements for (8) to be solvable. Consider the linear space Π and the linear space T of operators defined on Π. We define the operator $A_0 \in T$ and the linear space $T_0 \subset T$ of operators that are permutable with this A_0. Suppose an operator B is given, and it is required to find operators S and M that satisfy equations like (8)

$$[A_0, S] = B + M, \quad [A_0, M] = 0, \quad \text{i.e.,} \quad M \in T_0. \tag{9}$$

Specify a linear operator P on T that transforms each element $\tau \in T$ to an element $P\tau \in T_0$, i.e., which is commutable with this A_0 and satisfies the following requirements: (a) $P^2 = P$; (b) $[A_0, PS] = 0$, $S \in T$; (c) if $PB = 0$ then Eq. (9) is solvable and a solution S exists such that $PS = 0$; (d) if $[A_0 S] = 0$, i.e., $S \in T_0$, then $PS = S$; (e) if $PH = h$ and $PS = 0$, then $P(hS) = 0$. Not all of these requirements are independent.

To solve (9), it is sufficient to define an operator P on T that satisfies (a)–(e), because, since $B = PB + QB$, where $Q = 1 - P$, then by assuming $M = -PB$ we obtain the result that Eq. (9) becomes $[A_0, S] = QB$, which is solvable in virtue of (c). Below we construct an operator P that satisfies (a)–(e) for (8).

III. QUASINORMAL FORMS

In the framework of secondary quantization any operator $\hat{A}$ can be written in a normal form[11]

$$\hat{A} = \sum_{n=1}^{\infty} \hat{A}_{nn},$$

$$\hat{A}_{nn} = \int dp_1 \cdots dp_n dp_1' \cdots dp_n' A_{nn}(p_1 \cdots p_n, p_1' \cdots p_n') a^+(p_1') \cdots a^+(p_n') a(p_n) \cdots a(p_1), \tag{10}$$

where $p' \equiv (\overline{p}, \sigma)$, $\int dp \equiv \int \prod_n d\overline{p}_j$. Since $a(p_i)$ and $a^+(p_i')$ are generalized operator functions,[12] one asks how their product in (10) is to be interpreted when p_i and p_i' are identical. They can produce a finite contribution in the statistical limit, even though an integration region of zero measure corresponds to the requirement $p_i = p_i'$. For such products to make sense, we shall understand (10) to be limits as $V \to \infty$ for the integral sums corresponding to a cube of volume V

$$\hat{A}_{nn}(V) \left(\frac{8\pi^3}{V} \right)^{2n} \sum_{\substack{p_1 \cdots p_n \\ p_1 \cdots p_p}} A_{nn}(p_1 \cdots p_n, p_1') a^+(p_1') \cdots a^+(p_n') a(p_n) \cdots a(p_1), \tag{11}$$

where $\overline{p} = (2\pi/L)\overline{n}$, $\overline{n}$ being a vector of integer components (n_1, n_2, n_3) taking on values between $-\infty$ and $+\infty$ which enumerates the nodes of a lattice with a cell of volume $\Delta\overline{p} = (2\pi/L)^3$ in the momentum space. We now carry out the following operation on (11):

(1) Decompose (11) in all different ways into subsums in which the arguments of a set of $a^+(p)$ operators are pairwise identical with those of the same number of $a(p)$ operators, all the other arguments along with those of the pairwise identical operators being different (it is only when the last requirement is satisfied that the decomposition is defined uniquely);
(2) Use commutation relations to juxtapose operators whose arguments are identical (that operation will be called pairing);
(3) Replace $a^+(p)a(p)$ with $[V/(2\pi)^3]\hat{n}_p$, where $\hat{n}_p = a_p^+ a_p$ is the occupation number operator for single-particle states with momentum $\overline{p}$ and spin σ; the operators a_p and a_p^+ anticommute to unity and are Fourier transforms of secondary-quantized functions of the particle $\hat{\psi}_\sigma(x), \hat{\psi}_\sigma^+(x)$ in functions $\varphi_p^v(\overline{x}) = (1/\sqrt{V}) e^{i(\overline{p}, \overline{x})}$ normalized to unity in volume V [although $\varphi_\sigma^\vartheta(\overline{x})$ and a_p vanish as $V \to \infty$, the operator $\hat{n}_p$ exists in the statistical limit];
(4) Pass to the limit $V \to \infty$ in each subsum.

As a result, (11) becomes

$$\hat{A}_{nn}=\sum_{m\geqslant 0,k\geqslant 0,m+k=n}\hat{A}_{m,kk};\hat{A}_{m,kk}=\int dq_1\cdots dq_m dp_1\cdots dp_k dp_1'\cdots dp_k'$$
$$\times A_{m,kk}(q_1\cdots q_m,p_1\cdots p_k,p_1'\cdots p_k')\hat{n}_{q_1}\cdots\hat{n}_{q_m}a^+(p_1')\cdots a^+(p_k')a(p_k)\cdots a(p_1). \quad (12)$$

All coefficient functions $A_{m,kk}(q_1\cdots q_m,p_1\cdots p_k,p_1'\cdots p_k')$ in (12) contain factors, which are functions $\sigma(q_1\cdots q_m,p_1\cdots p_k,p_1'\cdots p_k')$ vanishing when two arguments are identical; the function σ prohibit further pairing. Thus, one can consider all arguments different and all operators commutative in the integrals derived by pairing, because all pairings have been carried out. One especially important fact is that the integrals (12) contain a term that is a function of operators $\hat{n}_p$ only:

$$\hat{A}_{m,00}=\int dq_1\cdots dq_m A_{m,00}(q_1\cdots q_m)\hat{n}_{q_1}\cdots n_{q_m}, \quad (13)$$

which contains $n!$ integrals (11) in which all $a^+(p')$ are paired to all the $a(p)$. Operators like (13) will be called n-forms. Operators of the type $\hat{A}_{m,kk}$ with $k\geqslant 1$ will be called quasinormal forms. We thus obtain the result that any operator can be reduced to a sum of n-forms and quasinormal forms

$$\hat{A}=\sum_{m=1}^{\infty}\hat{A}_{m,00}+\sum_{m=0}^{\infty}\sum_{n=1}^{\infty}\hat{A}_{m,nn}. \quad (14)$$

The decomposition will be illustrated by using a simple example

$$\hat{A}_{11}=\int dp_1 dp_1' A_{11}(p_1p_1')a^+(p_1')a(p_1)$$
$$=\lim_{V\to\infty}\left(\frac{8\pi^3}{V}\right)^2\sum_{p_1p_1'}A_{11}(p_1p_1')a^+(p_1')a(p_1)$$
$$=\lim_{V\to\infty}\left\{\left(\frac{8\pi^3}{V}\right)^2\sum_{p_1\neq p_1'}A_{11}(p_1p_1')a^+(p_1')a(p_1)+\left(\frac{8\pi^3}{V}\right)^2\sum_{p_1=p_1'}A_{11}(p_1p_1)\frac{V}{(2\pi)^3}\hat{n}_{p_1}\right\}$$
$$=\int dp_1 A_{11}(p_1p_1)\hat{n}_{p_1}+\int dp_1 dp_1' A_{11}(p_1p_1')\sigma(p_1p_1')a^+(p_1')a(p_1)$$
$$\equiv\hat{A}_{1,00}+\hat{A}_{0,11}. \quad (15)$$

We shall make a remark that will be important for the subsequent argument: When an operator $\hat{A}$ commutes with the total momentum operator, then the coefficient functions in its normal form (10), $A_{nn}(p_1\cdots p_n,p_1'\cdots p_n')$, contain $\delta(\overline{p_1}+\cdots+\overline{p_n}-\overline{p_1'}-\cdots-\overline{p_n'})$. When we pass to the integral sum (11), that delta-function should be replaced with $[V/(2\pi)^3]\delta^{kr}_{\overline{p_1}+\cdots+\overline{p_n},\overline{p_1'}+\cdots+\overline{p_n'}}$, where $\delta^{kr}_{\overline{p},\overline{p'}}$ is the Kronecker delta. This will have the consequence that the coefficients in the n-form (13) in which all operators with momentums involved in the delta-function are paired, namely, the, $A_{n,00}(q_1\cdots q_n)$ will involve the factor $V/(2\pi)^3$ which is proportional to the volume. Products of such operators will obviously contain a factor with higher powers of the volume.

IV. SOLVING THE EQUATIONS

We attack Eq. (8) by considering the T-space of operators like (14). The space T_0 will be defined as the set of all operators τ that satisfy the requirement $[H_0,\tau]=0$. We are going to show

that T_0 consists of n-forms, i.e., of all operators like (13) that are functions of occupation number operators only. This can be seen as follows. From $[H_0,\hat{A}_{m,nn}]=0$ it follows that:

$$\int dq_1\cdots dq_m dp_1\cdots dp_n dp_1'\cdots dp_n' A_{m,nn}(q_1\cdots q_m,p_1\cdots p_n,{}_1p_1'\cdots p_n') \times\left(\sum_{k=1}^{n}\frac{\overline{p}_k^2}{2m}-\sum_{k=1}^{n}\frac{\overline{p}_k'^2}{2m}\right)\hat{n}_{q_1}\cdots\hat{n}_{q_m}a^+(p_n')a(p_n)\cdots a(p_1)=0.$$

In that case, however, $A_{m,nn}(q_1\cdots q_m,p_1\cdots p_n,p_1'\cdots p_n')$ must vanish throughout the entire space $p_1\cdots p_n,p_1'\cdots p_n'$, because $\Sigma_{k=1}^{n}[(\overline{p}_k^2/2m)-(\overline{p}_k'^2/2m)]$ vanishes only on a set of zero measure in that space. For this reason the operator $\hat{A}_{m,nn}$ which commutes with H_0 cannot be different from zero, unless it has the form (13), i.e., when $n=0$. We now introduce a linear operator P into T assuming $P\hat{A}=\Sigma_{m=1}^{\infty}\hat{A}_{m,00}$ by definition. Assume further that $Q=1-P$, hence $Q\hat{A}=\Sigma_{m=0}^{\infty}\Sigma_{n=1}^{\infty}\hat{A}_{m,nn}$. Thus, P separates an n-form in A, i.e., a sum of operators that are functions of $\hat{n}_p$ only, which are obtained by pairing from $\hat{A}$, while Q separates a quasinormal operator in $\hat{A}$, i.e., an operator each term of which involves products of $a^+(p')$ and $a(p)$ with different arguments after pairing. It follows that $PQ\hat{A}=0$. We now are going to verify that the operator P thus defined on T satisfies all of (a)–(e) for the case $A_0\equiv H_0$. Verification of (a), (b), (d), and (e) is trivial. It remains to show that (c) holds, i.e., to show that (9) with $A_0\equiv H_0$ is solvable. We have in fact proved a stronger statement, namely, that (8), i.e., equations of the type $[H_{0n},S_n]=B_n+M_n$, are solvable. We have constructed a space T_0 based on operators that commute with $A_0\equiv H_0$; however, since $\hat{E}_n$ has been assumed to commute with H_0, that very space T_0 corresponds to the operator $A_0=H_{0n}$ for any n. Consequently, P is independent of n. We begin by considering the equation

$$[H_{01},S_1]+H_1=\hat{E}_1,\quad \lfloor H_0,\hat{E}_1\rfloor=0. \tag{16}$$

We assume

$$\hat{E}_1=PH_1=\frac{1}{2}\sum_{\sigma_1\sigma_2}\frac{V}{(2\pi)^3}\int d\overline{p}_1 d\overline{p}_2 U(0).\hat{n}_{\overline{p}_1\sigma_1}\hat{n}_{\overline{p}_2\sigma_2} -\frac{1}{2}\sum_{\sigma_2}\frac{V}{(2\pi)^3}\int d\overline{p}_1 d\overline{p}_2 U(\overline{p}_1-\overline{p}_2).\hat{n}_{\overline{p}_1\sigma_1}\hat{n}_{\overline{p}_2\sigma_2}, \tag{17}$$

in order to be able to eliminate the n-form on the right-hand side of (16), so that we have to solve an equation whose right-hand side is quasinormal:

$$[H_{01},S_1]=-QH_1\equiv-\frac{1}{2}\sum_{\sigma_1\sigma_2}\int d\overline{p}_1 d\overline{p}_2 d\overline{q}U(\overline{q})\sigma(\overline{p}_1,\overline{p}_2,\overline{q})a_{\sigma_1}^+(\overline{p}_1+\overline{q}) \times a_{\sigma_1}^+(\overline{p}_2-\overline{q})a_{\sigma_2}(\overline{p}_2)a_{\sigma_1}(\overline{p}_1), \tag{18}$$

and in which the operator $H_{01}=H_0+\varepsilon\hat{E}_1$ is already known.

The integral (18) does not involve operators having pairwise identical arguments, because it is the limit of an integral sum with all pairings eliminated.

Making use of

$$[H_{01},UV]=[H_{01},U]V+U[H_{01},V] \quad \text{and} \quad [\hat{n}_p,a^+(p')]=\frac{(2\pi)^3}{V}\delta(p-p')a^+(p),$$

$$[\hat{n}_p,a(p')]=-\frac{(2\pi)^3}{V}\delta(p-p')a(p), \tag{19}$$

we calculate the commutator H_{01} with the right-hand side of (18)

$$[H_{01},QH_1]\equiv\frac{-1}{2}\sum_{\sigma_1\sigma_2}\int d\overline{p_1}d\overline{p_2}d\overline{q}\hat{\omega}_{01}(\overline{p_1},\overline{p_2},\overline{q},\sigma_1\sigma_2)U(\overline{q})\sigma(\overline{p_1},\overline{p_2},\overline{q})$$
$$\times a^+_{\sigma_1}(\overline{p_1}+\overline{q})a^+_{\sigma_2}(\overline{p_2}-\overline{q})a_{\sigma_2}(\overline{p_2})a_{\sigma_1}(\overline{p_1}), \tag{20}$$

where

$$\hat{\omega}_{01}(\overline{p_1},\overline{p_2},\overline{q},\sigma_1\sigma_2)=\frac{\overline{p_1}^2}{2m}+\frac{\overline{p_2}^2}{2m}-\frac{(\overline{p_1}\overline{q})^2}{2m}-\frac{(\overline{p_2}-q)^2}{2m}-\int d\overline{p}[U(\overline{p_1}-\overline{p})\hat{n}_{\overline{p}\sigma_1}+U(\overline{p_2}-\overline{p})\hat{n}_{\overline{p}\sigma_2}$$
$$-U(\overline{p_1}+q-\overline{p})\hat{n}_{\overline{p}\sigma_1}-U(\overline{p_2}-q-\overline{p})\hat{n}_{\overline{p}\sigma_2}]. \tag{21}$$

From (20) it follows that one of the solutions of (18) is

$$S_1=-\frac{1}{2}\sum_{\sigma_1\sigma_2}\oint d\overline{p_1}d\overline{p_2}d\overline{q}\frac{U(\overline{q})\sigma(\overline{p_1}\overline{p_2}\overline{q})}{\hat{\omega}_{01}(\overline{p_1}\overline{p_2}\overline{q},\sigma_1\sigma_2)}a^+_{\sigma_1}(\overline{p_1}+\overline{q})a^+_{\sigma_2}(\overline{p_2}-\overline{q})a_{\sigma_2}(\overline{p_2})a_{\sigma_1}(\overline{p_1}), \tag{22}$$

where $\oint$ denotes the principal value of the (multiple) integral in the sense of Cauchy. It is important to note that S_1 is a quasinormal operator and that $PS_1=0$. Equation (16) is thus proved to be solvable. It can now be discussed how the general equation (8) is to be solved. Suppose the quasinormal operators $S_1,S_2\cdots S_{n-1}$ are known. We begin by defining $\hat{E}_n=\Sigma_{k=1}^{n-1}PH_{1k}S_{n-k}=PH_1S_{n-1}$ because $P\hat{E}_kS_{n-k}=0$ in virtue of $PS_{n-k}=0$. The result is

$$[H_{0n},S_n]+\sum_{k=1}^{n-1}QH_{1k}S_{n-k}=0, \quad n\geqslant 2, \tag{23}$$

in which H_{0n} is known. The quasinormal operator $\Sigma_1^{n-1}QH_{1k}S_{n-k}$ contains terms $\hat{A}_{m,kk}$ in the form (12) with $k\geqslant 2$. The commutator H_{0n} with $\hat{A}_{m,kk}$ leads to the appearance, in the coefficient functions $A_{m,kk}(q_1\cdots q_m,p_1\cdots p_k,p_1'\cdots p_k')$, of the factor $\hat{\omega}_{0n}(p_1\cdots p_n,p_1'\cdots p_n')$ which is a function of occupation number operators only. It thus appears that one of the solutions of (23) is a quasinormal operator S_n containing the same terms as the operator $\Sigma_1^{n-1}QH_{1k}S_{n-k}$, but whose coefficient functions are

$$-\frac{P}{\hat{\omega}_{0n}(p_1\cdots p_n,p_1'\cdots p_n')}A_{m,kk}(q_1\cdots q_m,p_1\cdots p_k,p_1'\cdots p_k'),$$

where P means that the integrals are understood in the sense of the principal value. Consequently, Eq. (23) and the set of equations (8) have been proved to be solvable.

V. ELIMINATION OF CONTRIBUTIONS INVOLVING NONPHYSICAL POWERS OF VOLUME

We shall examine the structure of solutions of (23). To do this we write them in matrix form in the representation of occupation numbers $|n\rangle\equiv|\cdots n_p\cdots\rangle$

$$\langle n|S_1|n'\rangle = \frac{-1}{\hat{\omega}_{01}(n)}\langle n|H_{11}|n'\rangle;$$

$$\langle n|S_2|n'\rangle = \frac{1}{\hat{\omega}_{02}(n)}\sum_{n''}\langle n|H_{11}|n''\rangle\frac{1}{\hat{\omega}_{01}(n)}\langle n''|H_{11}|n'\rangle;$$

$$\langle n|S_3|n'\rangle = -\frac{1}{\hat{\omega}_{03}(n)}\sum_{\substack{n'',n'''\\ n''\neq n'}}\langle n|H_{11}|n''\rangle\frac{1}{\hat{\omega}_{02}(n'')}\langle n''|H_{11}|n'''\rangle\frac{1}{\hat{\omega}_{01}(n''')}\langle n'''|H_{11}|n'\rangle$$
$$-\frac{1}{\hat{\omega}_{03}(n)}E_2(n)\frac{1}{\hat{\omega}_{01}(n)}\langle n|H_{11}|n'\rangle;$$

$$\langle n|S_4|n'\rangle = \frac{1}{\hat{\omega}_{04}(n)}\sum_{\substack{n'',n''',n''''\\ n''\neq n',n''\neq n'}}\langle n|H_{11}|n''\rangle\frac{1}{\hat{\omega}_{03}(n'')}\langle n''|H_{11}|n'''\rangle$$
$$\times\frac{1}{\hat{\omega}_{02}(n''')}\langle n'''|H_{11}|n''''\rangle\frac{1}{\hat{\omega}_{01}(n'''')}\langle n''''|H_{11}|n'\rangle+\frac{1}{\hat{\omega}_{04}(n)}\sum_{n''}\langle n|H_{11}|n''\rangle$$
$$\times\frac{1}{\hat{\omega}_{03}(n'')}E_2(n'')\frac{1}{\hat{\omega}_{01}(n'')}\langle n''|H_{11}|n'\rangle+\frac{1}{\hat{\omega}_{04}(n)}E_2(n)\frac{1}{\hat{\omega}_{02}(n)}\sum_{n''}\langle n|H_{11}|n''\rangle$$
$$\times\frac{1}{\hat{\omega}_{01}(n'')}\langle n''|H_{11}|n'\rangle-\frac{1}{\hat{\omega}_{04}(n)}E_3(n)\frac{1}{\hat{\omega}_{01}(n)}\langle n|H_{11}|n'\rangle;\cdots 6. \tag{24}$$

Here, $1/\hat{\omega}_{0k}(n)$ is the symbolic form of the ''division by commutator'' operator, the inequalities in sums over intermediate states n'',n''',n'''' being due to Q in (23). In all of (24) we understand that $n\neq n'$, and the relation $\langle n|H_{11}|n\rangle=0$ has been used. One can see from (24) that the matrix elements $\langle n|S_2|n'\rangle$ do not contain factors that are diagonal elements of the operators in the representation of occupation numbers. In contrast to this, the second term in $\langle n|S_3|n'\rangle$ contains a diagonal factor, $E_2(n)$. The factor is proportional to the volume and gives a contribution proportional to the square of the volume when $\hat{S}_3$ is substituted into $\hat{E}_4$. We note however that the first term in $\langle n|S_3|n'\rangle$ in (24) contains a term with $n'''=n$, which exactly compensates the term with $E_2(n)$. As a result, we have

$$\langle n|S_3|n'\rangle = \frac{-1}{\hat{\omega}_{03}(n)}\sum_{\substack{n'',n'''\\ n''\neq n',n''\neq n}}\langle n|H_{11}|n''\rangle\frac{1}{\hat{\omega}_{02}(n'')}\langle n''|H_{11}|n'''\rangle\frac{1}{\hat{\omega}_{01}(n''')}\langle n'''|H_{11}|n'\rangle. \tag{25}$$

The expression (25) does not involve diagonal factors. We can see in a similar manner that the first term in $\langle n|S_4|n'\rangle$ contains terms with $n'''=n$, with $n''''=n''$ and with $n''''=n$ which compensate the second, third and fourth terms, respectively, in $\langle n|S_4|n'\rangle$; these terms contain the diagonal factors $E_2(n''),E_2(n),E_3(n)$. Accordingly, we derive an expression for $\langle n|S_4|n'\rangle$ with no diagonal factors

$$\langle n|S_4|n'\rangle = \frac{1}{\hat{\omega}_{04}(n)}\sum_{\substack{n'',n''',n''''\\ n''\neq n,n'''\neq n',n'''\neq n'',\\ n''''\neq n,n''\neq n'}}\langle n|H_{11}|n''\rangle\frac{1}{\hat{\omega}_{03}(n'')}\langle n''|H_{11}|n'''\rangle$$
$$\times\frac{1}{\hat{\omega}_{02}(n)}\langle n'''|H_{11}|n''''\rangle\frac{1}{\hat{\omega}_{01}(n'''')}\langle n''''|H_{11}|n'\rangle. \tag{26}$$

Continuing this process, which is in a sense similar to the separation of Van-Hove diagonal fragments,[8] we arrive at the conclusion that the matrix elements of S_k can be transformed so as to involve no diagonal factors. Accordingly, substituting $\langle n'|S_{k-1}|n\rangle$ into

$$E_k(n)=\sum_{n'}\langle n|H_{11}|n'\rangle\langle n'|S_{k-1}|n\rangle, \quad k\geqslant 2, \tag{27}$$

We see that (27) does not contain diagonal factors and that the matrix element E_k is proportional to the first power of the volume, namely, the desired result.

We shall prove these statements by induction. Suppose that for all $m\leqslant k$, where k is any given natural number, the following relation holds:

$$\langle n_m|S_m|n'\rangle=\frac{(-1)^m}{\hat{\omega}_{0m}(n_m)}\overrightarrow{\sum_{n_l\cdots n_{m-1}}}\langle n_m|H_{11}|n_{m-1}\rangle\frac{1}{\hat{\omega}_{0,m-1}(n_{m-1})}\langle n_{m-1}|H_{11}|n_{m-2}\rangle$$
$$\times\frac{1}{\hat{\omega}_{0,m-2}(n_{m-2})}\cdots\frac{1}{\hat{\omega}_{01}(n_1)}\langle n_1|H_{11}|n'\rangle, \tag{28}$$

where $\rightarrow$ at the sign of summation means that all indices $n_1\cdots n_m, n'$ are different, hence (28) involves no diagonal factors. We now prove that matrix elements of S_{k+1} have the same form. From (23)

$$\langle n|S_{k+1}|n'\rangle=\frac{-1}{\hat{\omega}_{0,k+1}(n)}\Bigg(\sum_{n_k}\langle n|H_{11}|n_k\rangle\langle n_k|S_k|n'\rangle-E_2(n)\langle n|S_{k-1}|n'\rangle-E_3(n)\langle n|S_{k-2}|n'\rangle$$
$$-\cdots-E_k(n)\langle n|S_1|n'\rangle\Bigg). \tag{29}$$

Using (28), we can write the sum over n_k contained in (29) in the form

$$\sum_{n_k}\langle n|H_{11}|n_k\rangle\langle n_k|S_k|n'\rangle=(-1)^k\overrightarrow{\sum_{n_1\cdots n_k}}\langle n|H_{11}|n_k\rangle$$
$$\times\frac{1}{\hat{\omega}_{0k}(n_k)}\langle n_k|H_{11}|n_{k-1}\rangle\frac{1}{\hat{\omega}_{0,k-1}(n_{k-1})}\langle n_{k-1}|H_{11}|n_{k-2}\rangle$$
$$\times\frac{1}{\hat{\omega}_{0,k-2}(n_{k-2})}\cdots\frac{1}{\hat{\omega}_{01}(n_1)}\langle n_1|H_{11}|n'\rangle. \tag{30}$$

The arrow here means that all indices $n_1\cdots n_k, n'$ are different. Now we separate in (30) successively those terms in which $n=n_{k-1}$, $n=n_{k-2}$, $n=n_1$. These terms will cancel with those containing the factors $E_2(n),E_3(n),\cdots E_k(n)$ on substituting (30) into (29). We finally find that the matrix element $\langle n|S_{k+1}|n'\rangle$ can be written in a form similar to (28)

$$\langle n|S_{k+1}|n'\rangle=\frac{(-1)^{k+1}}{\hat{\omega}_{0,k+1}(n)}\overrightarrow{\sum_{n_1\cdots n_k}}\langle n|H_{11}|n_k\rangle\frac{1}{\hat{\omega}_{0k}(n_k)}\langle n_k|H_{11}|n_{k-1}\rangle$$
$$\times\frac{1}{\hat{\omega}_{0,k-1}(n_{k-1})}\cdots\frac{1}{\hat{\omega}_{01}(n_1)}\langle n_1|H_{11}|n'\rangle, \tag{31}$$

where the arrow at the summation sign means that all indices $n, n_1 \cdots n_k, n'$ are different, hence (31) involves no diagonal factors, which is the desired result. The perturbation theory developed here for calculating excited multiply degenerate states is thus efficient enough for the many-body problem.

VI. CONCLUSION

As can be seen from (3), the operator S transforms eigenfunctions of the perfect gas Hamiltonian H_0 into the exact eigenfunctions of the interacting particle Hamiltonian H. The spectrum of the system is coincident with that of the operator $\hat{E}$, hence can be enumerated by occupation numbers for perfect gas states. As demonstrated in Ref. 9 (see also Ref. 10), the calculation of a statistical sum with $\hat{E}$ leads to an expression for free energy in the form of a functional of the Ballian–Dominicis distribution function of thermodynamical quasiparticles,[13] the entropy of the system being expressible in terms of the distribution function of quasiparticles through the same relation as is the case for perfect gas.

We wish to emphasize the fact that all results derived in this study hold only for normal systems in the statistical limit, i.e., for macroscopic systems with continuous spectra and without the long-range order. In that case the multiple degeneration of the power spectrum does not affect results in the statistical limit and does not prevent us from establishing a one-to-one correspondence between exact wave functions of the system of interacting particles and the wave functions of perfect gas enumerated by single-particle occupation numbers.

ACKNOWLEDGMENTS

This paper presents a study conducted during several years and repeatedly reported at seminars in the Physical Institute and Mathematical Institute of the Russian Academy of Sciences, and the Moscow State University. We are grateful to all those taking part in these seminars for helpful discussions. Special thanks go to D. N. Zubarev, D. A. Kirsnits, Yu. L. Klimontovich, E. G. Maksimov, N. M. Plakida, V. A. (Received 17 November 2000; accepted for publication 15 February 2001)

We study a quantum mechanical potential introduced previously as a conditionally exactly solvable (CES) model. Besides an analysis following its original introduction in terms of the point canonical transformation, we also present an alternative supersymmetric construction of it. We demonstrate that from the three roots of the implicit cubic equation defining the bound-state energy eigenvalues, there is always only one that leads to a meaningful physical state. Finally we demonstrate that the present CES interaction is, in fact, an exactly solvable Natanzon-class potential. [DOI: 10.1063/1.1362286]

I. INTRODUCTION

Exactly solvable models have attracted much attention since the early years of quantum mechanics. Some solvable potentials have become standard examples of textbooks, but a lot more have been discovered by various approaches. Systematic work has been done to generate and classify these potentials using the factorization method,[1] algebraic methods[2] and more recently, in terms of supersymmetric quantum mechanics (SUSYQM).[3] These approaches were found to be interrelated with each other.[4–6]

The most general family of solvable potentials is the six-parameter Natanzon class,[7] which contains potentials with solutions expressible in terms of a single (confluent) hypergeometric function. A rather important subclass of this is that of the shape-invariant potentials,[7–9] to which the most well-known potentials (such as the harmonic oscillator, Coulomb, Pöschl–Teller, etc.) potentials belong. Altogether 12 such potentials have been identified,[5,9] but some of these actually represent different forms of the same potentials, and their separate discussion is justified only for historical reasons. An important recent development was the introduction of SUSYQM, which can be considered a reinterpretation of the factorization method,[1] and which links basically isospectral potentials in a pairwise manner. Shape-invariant potentials are defined in terms of SUSYQM: The functional form of the SUSYQM partner potentials has to be the same, and only the parameters appearing in them can be different.

SUSYQM has been found to be rather useful in generating new solvable potentials as SUSYQM partners from known solvable ones. A rather wide potential class is obtained as the SUSYQM partner of Natanzon potentials, but these are not Natanzon potentials themselves (except in the case of shape invariance), since their solution is written as the linear combination of several (confluent) hypergeometric functions.[10] There are also further solvable potentials which are solved by functions other than the (confluent) hypergeometric type. Examples for this are the square well[11] and the exponential potential, which are solved by Bessel functions.

A different concept of solvability characterizes quasiexactly solvable (QES) potentials.[12] In

[a)]Electronic mail: znojil@ujf.cas.cz

this case only part of the eigenstates can be obtained, by requiring termination of a recursion relation defining the eigenfunctions in a polynomial form.

The most recent concept of solvability is related to conditionally exactly solvable (CES) potentials. The first models coined CES potentials[13,14] were characterized by the fact that the coupling constant of some potential term had to be fixed to a numerical constant value in order to obtain their solutions. These potentials were introduced by the point canonical transformation method.[15] Here we present the analysis of one of these CES potentials.[14] Our motivation is to clarify some inconsistencies in their treatment, and to determine their place in other classification schemes of solvable models. (We note that another class of CES potentials was also introduced using the techniques of SUSYQM,[16,17] but we do not extend our analysis on this class.)

In Sec. II we give a reinterpretation of the potential of Ref. 14 in a supersymmetric context, and derive the bound-state energies determined implicitly by a cubic equation. In Sec. III the procedure is placed in a more general context of methods based on variable transformations, and the potential is identified as an exactly solvable member of the Natanzon potential class.

II. THE MODEL OF DUTT, KHARE, AND VARSHNI

We start by presenting the potentials introduced by Dutt *et al.*[14] as CES models. The two potentials defined on the full axis $x\in(-\infty,\infty)$ can be written in a common form as

$$V^{(g_0,g_1,g_2,g_3)}(x)=\frac{g_0}{e^x z(x)}+\frac{g_1}{z(x)}+\frac{g_2}{z^2(x)}+\frac{g_3}{z^4(x)}, \tag{2.1}$$

with $z(x)=(1+e^{-2x})^{1/2}\in(1,\infty)$. The explicit form of these potentials[14] is

$$V_1^{(\mathrm{DKV})}(x)=V^{(0,-B,A,-3/4)}(x),\quad V_2^{(\mathrm{DKV})}(x)=V^{(-B,0,A,-3/4)}(x). \tag{2.2}$$

These potentials depend on two parameters (A and B) which define the potential shape. The coupling constant of the third potential term has to be fixed to a constant value ($-3/4$) in order to obtain exact solution of these models. This is why the authors of Ref. 14 identified these potentials as CES ones.

One can easily demonstrate that the two potentials, in fact, are equivalent in the sense that

$$V^{(0,-B,A,-3/4)}(x)=V^{(-D,0,C,-3/4)}(-x)+\epsilon, \tag{2.3}$$

where

$$\epsilon=-A+3/4,\quad C=-A+3/2,\quad D=B. \tag{2.4}$$

Thus, in what follows it is sufficient to deal with only one of the potentials, so we pick $V_1^{(\mathrm{DKV})}(x')$ for our analysis.

A. Conventional approach via the point canonical transformation

In Ref. 14 potentials (2.2) were introduced using the point canonical transformation method,[15] by which a Schrödinger-type differential equation can be transformed into another equation of this type, applying an invertible parametrization $r=r(x)$. With this change of variables, dating back to Liouville[18] a given asymptotically free equation

$$\left[-\frac{\mathrm{d}^2}{\mathrm{d}r^2}+U(r)\right]\chi(r)=-\kappa^2\chi(r) \tag{2.5}$$

can be transformed into an apparently different bound state problem

$$\left[-\frac{\mathrm{d}^2}{\mathrm{d}x^2}+V(x)\right]\psi(x)=-k^2\psi(x). \tag{2.6}$$

After we denote the derivative by a prime $[x'(r)$, etc.], an extremely elementary correspondence between the potentials and/or energies is obtained,

$$U(r)+\kappa^2=[x'(r)]^2\{V[x(r)]+k^2\}+\left(\frac{3}{4}\frac{x''(r)}{x'(r)}\right)^2-\frac{1}{2}\frac{x'''(r)}{x'(r)}. \tag{2.7}$$

Obviously, the ''old'' energy eigenvalues are related to the parameters of the ''new'' potential, and vice versa. The formal definition of the new wave functions is also virtually trivial,

$$\psi(x)=(x'[r(x)])^{1/2}\chi[r(x)]. \tag{2.8}$$

In any situation of practical interest one may just pick up a suitable exactly solvable (ES) problem (2.5) and quickly derive its partner (2.6). Setting out from two shape-invariant[8] ES potentials defined on the positive half axis, Dutt *et al.*[14] used the variable transformation $x=\ln(\sinh r)$ to obtain potentials (2.2). The particular initial potentials and their energies were

$$U_1(r)=-2b\frac{\cosh r}{\sinh r}+a(a-1)\frac{1}{\sinh^2 r},\quad \kappa^2=\kappa_m^2=(a+n)^2+b^2/(a+n)^2 \tag{2.9}$$

[with $b>(a+n_{\max})^2$] and

$$U_2(r)=-(2a+1)b\frac{\cosh r}{\sinh^2 r}+[a(a+1)+b^2]\frac{1}{\sinh^2 r},\quad \kappa^2=\kappa_n^2=(a-n)^2 \tag{2.10}$$

(with $b>a>n_{\max}$).

Recalling the bound-state wave functions of potentials $U_j(r)$, the solutions to potentials $V_j^{(\mathrm{DKV})}(x)$ in (2.2) readily follow from Eq. (2.8). Without the loss of generality we can consider the $j=1$ case and recall the solutions of $U_1(r)$ (see, e.g., Refs. 9 and 5) in terms of Jacobi polynomials,

$$\chi(z)=(z-1)^{-(1/2)(a+n-s)}(z+1)^{-(1/2)(a+n+s)}P_n^{(-a-n+s,-a-n-s)}(z),\quad s=b/(a+n) \tag{2.11}$$

with $z=z(r)=\coth r$. Using this function in (2.8), substituting it into the Schrödinger equation, and matching parameters a and b with A and B appearing in $V_1^{(\mathrm{DKV})}(x)$ in (2.2), we find $B=2b$ and

$$A=n^2+1/2+(2n+1)\,a+b^2/(a+n)^2. \tag{2.12}$$

This equation will ultimately determine the energy eigenvalues of quantum number n, through a cubic equation as described also in Ref. 14. We postpone the analysis of this formula to Sec. II C, where our new results concerning the energy spectrum of the $V_j^{(\mathrm{DKV})}(x)$ potentials are presented. Before that, we present an alternative interpretation of the same problem in terms of a supersymmetric framework.

B. Supersymmetric construction

An interesting SUSY reinterpretation of the solvability of Schrödinger equations has been described by Nag *et al.*[19] They have employed the two Dutra's models[13] in order to illustrate their main idea. Unfortunately, the spectrum of states in the latter potentials can only be determined purely numerically.[20] Strictly speaking, the potentials do not belong to the CES class.[21,22] At best, only their incomplete (=quasiexact) non-numerical solution can be obtained at certain *exceptional* energies and couplings.[21,23] Within the SUSY methodical framework, they seem less suitable for illustrative purposes.

We shall now obtain the spectrum of the potential $V_1^{(\mathrm{DKV})}(x)$ in (2.2) in a manifestly supersymmetric fashion. Before doing this we recall that in supersymmetric quantum mechanics[9] a pair of Hamiltonians $H_\pm$ defined by

$$H_\pm = -\frac{\mathrm{d}^2}{\mathrm{d}x^2} + V_\pm(x) = -\frac{\mathrm{d}^2}{\mathrm{d}x^2} + W^2(x) \pm W'(x) \tag{2.13}$$

are isospectral except for the zero energy ground state, which, for unbroken supersymmetry, exists only for one of the partner potentials, $V_-(x)$. The ground-state solution of H_- is related to the $W(x)$ superpotential through

$$W(x) = -\frac{\mathrm{d}}{\mathrm{d}x}\ln\psi_0^{(-)}(x). \tag{2.14}$$

One can also extend the concept of superpotential to the excited states of $V_-(x)$, simply using $\psi_n^{(-)}(x)$ in (2.14). In this case $W(x)$ has singularities at the nodes of $\psi_n^{(-)}(x)$, and one can talk about singular superpotentials.[9] [Note that such singularities cannot occur using the nodeless ground-state wave function $\psi_0^{(-)}(x)$.] Despite these singularities of $W(x)$, it can be shown[9] that $V_-(x)$ will be singularity free in this case too, and these will appear only for the partner potential $V_+(x)$. Our purpose is, however, to discuss only $V_-(x)$, which we identify with $V_1^{(\mathrm{DKV})}(x)$ in Eq. (2.2), in a supersymmetric form, therefore we shall avoid the problems arising due to the singularities of $W(x)$.

For this purpose, let us consider the superpotential

$$W(z) = \frac{B_1}{z} - \frac{1}{2z^2} - C_0 + \sum_{i=1}^{n} \frac{g_i'(z)}{g_i(z)}, \tag{2.15}$$

where $z = (1+\mathrm{e}^{-2x})^{1/2}$ as in (2.2) and (2.1), and $g_i(z)$ is given by

$$g_i(z) = \frac{1}{1+g_i z}, \quad C_0 = \epsilon_0^{1/2}, \tag{2.16}$$

where ϵ_n is related to the (negative) bound-state energies of potential $V_1^{(\mathrm{DKV})}(x)$ via $\epsilon_n = -E_n$. Note that the zero-energy wave function $\psi_0^{(-)}(x) = N_0 \exp[-\int W(x)\mathrm{d}x]$ is always normalizable for our choice of $W(x)$, irrespective of the values of g_i. It may be noted that if we had omitted the last term in (2.15), i.e.,

$$W_0(z) = \frac{B_1}{z} - \frac{1}{2z^2} - C_0, \tag{2.17}$$

we would have obtained only the ground state. Insertion of the last term containing the sum ensures that we would get the excited states also.

It is straightforward to show that $W(z)$ can be written in the form

$$W(z) = \frac{B_1 - \Sigma_{i=1}^n g_i}{z} - \frac{1}{2z^2} + C_0' + \frac{\Sigma_{i=1}^n (g_i^2 - 1)}{(1+g_i z)}, \tag{2.18}$$

where we have defined $C_0' = n - C_0$.

Using (2.18) we obtain

$$W^2(x)-W'(x)=\left[\left(B_1-\sum_{i=1}^{n} g_i\right)^2-C_0'-\sum_{i=1}^{n}(g_i^2-1)+1\right]\Big/ z^2$$
$$+\left[2\left(B_1-\sum_{i=1}^{n} g_i\right)C_0'+2\left(B_1-\sum_{i=1}^{n} g_i\right)\left(\sum_{i=1}^{n}(g_i^2-1)\right)-\left(B_1-\sum_{i=1}^{n} g_i\right)\right.$$
$$\left.+2g_i(g_i^2-1)\right]\Big/ z-\frac{3}{4z^4}+\sum_{i=1}^{n}\frac{1}{1+g_iz}\left[-2\left(B_1-\sum_{i=0}^{n} g_i\right)(g_i^2-1)g_i-g_i^2(g_i^2\right.$$
$$\left.-1)+2C_0'(g_i^2-1)-(g_i^4-1)+\sum_{j\neq i}\frac{(g_j^2-1)(g_i^2-1)g_i}{g_i-g_j}\right]+(C_0')^2. \tag{2.19}$$

We now make the following identification

$$W^2(x)-W'(x)=V_1^{(\mathrm{DKV})}(x)-E, \tag{2.20}$$

where E is the energy of the states in potential $V_1^{(\mathrm{DKV})}(x)$.

Then it follows that

$$-2\left(B_1-\sum_{i=1}^{n} g_i\right)g_i-g_i^2+2C_0'-(g_i^2+1)+2\sum_{i\neq j}\frac{(g_j^2-1)g_i}{g_i-g_j}=0, \tag{2.21}$$

$$2\left(B_1-\sum_{i=1}^{n} g_i\right)C_0'+2\left(B_1-\sum_{i=1}^{n} g_i\right)\left(\sum_{i=1}^{n}(g_i^2-1)\right)-\left(B_1-\sum_{i=1}^{n} g_i\right)+2\sum_{i=1}^{n} g_i(g_i^2-1)=-B, \tag{2.22}$$

$$\left(B_1-\sum_{i=1}^{n} g_i\right)^2-C_0'-\sum_{i=1}^{n}(g_i^2-1)+1=A, \tag{2.23}$$

$$(C_0')^2=-E. \tag{2.24}$$

Multiplying (2.21) by g_i and summing over i we obtain

$$-2\left(B_1-\sum_{i=1}^{n} g_i\right)\sum_{i=1}^{n} g_i-2\sum_{i=1}^{n} g_i^3+2\sum_{i=1}^{n} C_0'g_i-(2n-1)\sum_{i=1}^{n} g_i=0. \tag{2.25}$$

From (2.22) and (2.25) we get

$$B_1=\frac{B}{1+2C_0}=\frac{B}{1+2\epsilon_0^{1/2}}. \tag{2.26}$$

It can be verified by insertion that the wave functions $\psi_n^{(-)}(x)=N\exp[-\int W(x)\mathrm{d}x]$ are normalizable. Equations (2.21) and (2.23) also imply that

$$A=\frac{(B/2)^2}{\left(n+\frac{1}{2}+\epsilon_n^{1/2}\right)^2}+n^2+n+1+(2n+1)\epsilon_n^{1/2}, \tag{2.27}$$

where in obtaining the above-mentioned relation we have taken $C_0'=-\epsilon_n^{1/2}$. We can summarize that our supersymmetric construction reproduces exactly the results obtained in Ref. 14. Once we take $a=\epsilon_n^{1/2}$ it proves equivalent to Eq. (2.12) of Sec. II A.

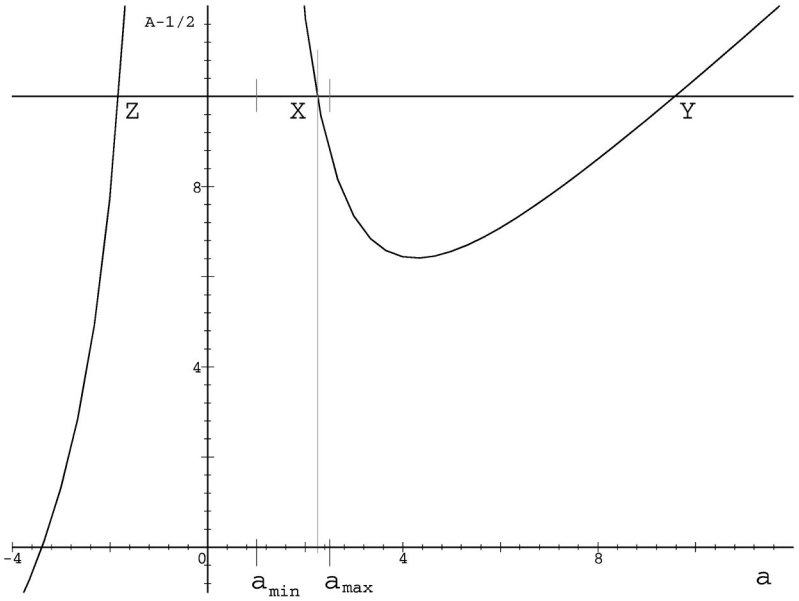

FIG. 1. Graphical solution of Eq. (2.12).

C. The allowed bound-state energies

Let us now continue with the analysis of the energy eigenvalues based on formula (2.12) and its equivalent form (2.27) obtained in two different ways. The key element of our approach is the strict observation of the constraints imposed on the parameters by the boundary conditions of the wave functions. By this we mean both the solutions of the ''old'' potential $U_1(r)$ (2.9) and those of the ''new'' one $V_1^{(\mathrm{DKV})}(x)$ (2.2).

The appropriate physical boundary condition for (2.11) near the threshold $r\to 0$ is standard, though a bit counterintuitive.[21,24] Its implementation implies that we have to choose $a>1/2$. Then, after the transition from r to x we get the wave functions still safely normalizable near the left infinity $x\to-\infty$. Similarly, our explicit wave functions remain asymptotically normalizable near the right infinities $r\to\infty$ and $x\to+\infty$ if and only if we have $a+n<b/(a+n)$. This means that the eligible quantum numbers $n=0,1,\ldots,M$ have to be such that $0\leqslant M<b^{1/2}-a$, i.e.,

$$(n+1/2)^2<(a+n)^2<b. \tag{2.28}$$

As mentioned in Sec. II A, for transition to the ''new'' potential $V_1^{(\mathrm{DKV})}(x)$ we have to reparametrize $g_1=-B\equiv-2b$ and define the ''new'' CES energy in terms of the ''old'' ES coupling, $k=a-1/2>0$. The second CES coupling $A>2(n+1/2)^2+3/4$ is then defined by (2.12), which is equivalent to (2.27) in Sec. II B. The n dependence of the ''new'' energy $a=a(n)=k_n+1/2>1/2$ is fully consistent with the n independence of the coupling A. For each level the CES potential $V(x)$ is a map of a *different* ES potential $U(r)$. The energies are determined by the cubic algebraic equation. In order to make this definition unique we have to tell which one of the three roots of Eq. (2.12) is ''physical.'' In Ref. 14 we find advice that ''from the three roots we can discard two by demanding that the spectrum must reduce to the standard one for $B=0$.'' Such a vague recipe is misleading since it is in manifest contradiction with the above-mentioned normalizability condition (2.28) which implies that $b=B/2>1/4$ cannot lie too close to zero.

The problem is not too difficult to disentangle. Equation (2.12) has very transparent graphical interpretation in terms of the intersection of the left-hand side horizontal line with the right-hand side curve with three branches. The latter shape is a sum of a growing linear term with a spike oriented upwards. Figure 1 indicates how one gets a triplet of roots in the $n=0$ ground state at

$b=6.25$ and $A=10.25$. Always, only one of them is compatible with the normalizability condition (2.28) and lies in the ''admissible'' interval $(0.5,2.5)$.

The general rule is that we always have to pick up the middle root as physical. Let us give a proof of this assertion. First we rename $b=\beta^2$ and rescale our three roots, $Z=[a_1(n)+n]/\beta < X=[a_2(n)+n]/\beta < Y=[a_3(n)+n]/\beta$. As long as $a(n)\in(1/2,\beta-n)$ we may rewrite Eq. (2.12) in the significantly simplified form

$$\tau=\mu X+\frac{1}{X^2}$$

(and, similarly for Y and Z) with abbreviations

$$\tau=\tau(A,b,n)\equiv\frac{A+n^2+n-1/2}{b},\quad 0<\mu=\frac{2n+1}{\beta}<2.$$

The leftmost root Z will always be negative and can be discarded immediately. Knowing that the acceptable root X is constrained, $X\in(T,1)$, $T=(n+1/2)/\beta\in(0,1)$, it is now sufficient to prove that the third root Y *always* violates our condition (2.28),

$$[X\in(T,1)\ \&\ T\in(0,1)]\Rightarrow Y>1. \tag{2.29}$$

For this purpose we eliminate τ and get the quadratic equation

$$\mu=\frac{X+Y}{X^2Y^2}.$$

We can skip the negative alternative and have the unique definition of the root Y,

$$Y=\frac{1+(1+4\mu X^3)^{1/2}}{2\,\mu X^2}.$$

As a smooth function of $\mu\in(0,2)$ and $X\in(T,1)$ it satisfies our rule (2.29) *everywhere* within a two-dimensional domain containing all points with $\mu<1$ and *not containing* any point of the sign-changing boundary. This is demonstrated quite easily. The boundary curve can be implicitly defined as a set $X=\xi(\mu)$,

$$1+(1+4\mu\,\xi^3)^{1/2}=2\,\mu\,\xi^2.$$

Only on it the sign of $Y-1$ can change. This set is a part of the curve defined by the square of the latter equation,

$$\mu\,\xi^2=\xi+1.$$

In the graphical language it is trivial to find that for the positive $\xi>0$ the right-hand side straight line intersects the left-hand side parabola in a point which is a decreasing function of μ. Hence, the curve touches the boundary of our open simplex of normalizability (with $\mu\in(0,2)$ and $X<1$) in a single point $(\mu=2,\xi=1)$. Q.E.D.

III. INTERPRETATION OF THE POTENTIAL

The potentials of Ref. 14 derived in two different ways in Sec. II can be placed into a more general context by realizing that both the point canonical transformation method[15] presented in Sec. II A and the supersymmetric construction of Sec. II B can be formulated in terms of a rather general approach based on the change of variables.[25,7,5] In this section we specify these connections with the formulation of Ref. 5, which can be considered a simplified treatment of the general Natanzon-class potentials.[7]

Following the discussion of Ref. 5 one considers the Schrödinger equation

$$\frac{\mathrm{d}^2\psi}{\mathrm{d}x^2}+(E-V(x))\psi(x)=0 \tag{3.1}$$

and assumes that its solutions can be written in the form

$$\psi(x)=f(x)F(z(x)), \tag{3.2}$$

where $F(z)$ satisfies a second-order differential equation

$$\frac{\mathrm{d}^2F}{\mathrm{d}z^2}+Q(z)\frac{\mathrm{d}F}{\mathrm{d}z}+R(z)F(z)=0. \tag{3.3}$$

The function $F(z)$ can be any special function of mathematical physics, e.g., the (confluent) hypergeometric function,[26] or any other function satisfying a second-order differential equation of the type (3.3). Simple calculation shows[5] that the function $E-V(x)$ can be written as

$$E-V(x)=\frac{z'''(x)}{2z'(x)}-\frac{3}{4}\left(\frac{z''(x)}{z'(x)}\right)^2+(z'(x))^2\left[R(z(x))-\frac{1}{2}\frac{\mathrm{d}Q(z)}{\mathrm{d}z}-\frac{1}{4}Q^2(z(x))\right], \tag{3.4}$$

where the only unknown element is the function $z(x)$, which basically governs the change of variables connecting the two differential equations (3.1) and (3.3). Expressing $f(x)$ in (3.2) in terms of $z(x)$ and $Q(z)$, the solutions of the Schrödinger equation can be written[5] as

$$\psi(x)\sim(z'(x))^{-1/2}\exp\left(\frac{1}{2}\int^{z(x)}Q(z)\mathrm{d}z\right)F(z(x)). \tag{3.5}$$

We are left with the task of finding such a functional form of $z(x)$ which takes our Schrödinger equation (3.4) into an exactly and *completely* solvable problem.

Obviously, the transformation employed in Sec. II A (i.e., the point canonical transformation[15] or the Liouvillean method[18]) is a special case of the above-mentioned construction. Taking, in a way explained in detail in Ref. 27

$$Q(z)=0, \quad R(z)=-\kappa^2-U(z), \tag{3.6}$$

Eq. (3.4) reduces to the inverted version of Eq. (2.7) (with r and $-k^2$ there replaced with z and E here). Similarly, (3.5) also reduces to the equivalent of (2.8), where $\chi(r)$ is playing the role of $F(z)$.

From here the approaches applied in Refs. 25 and 5 and in the point canonical transformation[15] emphasize somewhat different strategies of deriving solvable potentials within the Natanzon potential class.[7] In Refs. 25 and 5 the main point is to identify some term on the right-hand side of Eq. (3.4), to account for the constant (i.e., the energy) term on the left-hand side. With this, a differential equation of the type

$$\left(\frac{\mathrm{d}z}{\mathrm{d}x}\right)^2\phi(z)=C \tag{3.7}$$

was obtained (see also Ref. 28), and this determined the function $z(x)$ describing the variable transformation. In some cases the $z(x)$ function could not be determined explicitly from (3.7), only the inverse $x(z)$ function, therefore a number of solvable models obtained this way turned out to be ''implicit'' potentials.[29,30] On the other hand, following the point canonical transformation method,[15] the $z(x)$ function is always available in an explicit form, however, it is not guaranteed that any $z(x)$ function would lead to a Schrödinger-like equation in which all the n dependence can be absorbed into the constant (energy) term. Equation (2.12) might turn out to have Sturm–Liouvillean form, where n typically appears in coordinate-dependent terms. Simply stated, the

approach of Ref. 5 focuses on having the energy in a simple form, even at the expense of leaving the solutions in a complicated (implicit) form, while in the point canonical transformation the preference is having the solutions in an explicit form, rather than getting the energy expression in a simple way. We stress that despite this difference, the two approaches are interrelated, and are special cases of deriving Natanzon-class potentials. We shall come back to this point later on.

A. Conventional construction

Let us now see how potential $V_1^{(\mathrm{DKV})}(x)$ in Eq. (2.2) can be obtained from the method described in Ref. 5. For this, $F(z)$ should be identified with a Jacobi polynomial: $F(z)=P_n^{(\alpha,\beta)}(z)$. Equation (4.2) in Ref. 5 is an explicit form for $E-V(x)$ in this case:

$$\begin{aligned} E-V(x)=&\frac{z'''(x)}{2z'(x)}-\frac{3}{4}\left(\frac{z''(x)}{z'(x)}\right)^2+\frac{(z'(x))^2}{1-z^2(x)}n(n+\alpha+\beta+1)\\ &+\frac{(z'(x))^2}{(1-z^2(x))^2}\left[\frac{1}{2}(\alpha+\beta+2)-\frac{1}{4}(\beta-\alpha)^2\right]\\ &+\frac{(z'(x))^2z(x)}{(1-z^2(x))^2}\,\frac{1}{2}(\beta-\alpha)(\beta+\alpha)+\frac{(z'(x))^2z^2(x)}{(1-z^2(x))^2}\left[\frac{1}{4}-\left(\frac{\alpha+\beta+1}{2}\right)^2\right]. \end{aligned} \tag{3.8}$$

As discussed in Ref. 5, one selects differential equations of the type (3.7) for $z(x)$ to get constant terms on the right-hand side of (3.8). In Ref. 5 the first two nontrivial terms were picked, leading to the PI and PII potential classes, typical representations of which are, for example, $U_2(r)$ and $U_1(r)$ in Eqs. (2.10) and (2.9), respectively. The defining differential equation of these is $(z')^2(1-z^2)^{-1}=C$ and $(z')^2(1-z^2)^{-2}=C$. Later in Ref. 30 the third ''PIII'' possibility, $z(z')^2(1-z^2)^{-2}=C$, was also discussed, resulting in an ''implicit potential.'' All these potentials are exactly solvable Natanzon-class potentials, furthermore, those discussed in Ref. 5 also have the property of shape invariance.

The fourth possibility,

$$z^2(z')^2(1-z^2)^{-2}=C \tag{3.9}$$

was not discussed in detail in Ref. 5, only the generic form of the solution was mentioned. However, it turns out that the function $z(x)=(1+\exp(2C^{1/2}x+D))^{1/2}$ satisfies (3.9), and it leads to the same variable transformation as that discussed in Ref. 14, if the $C^{1/2}=-1$ and $D=0$ choice is made. The actual form of (3.4) is now (in the ''PIV'' case)

$$\begin{aligned} E_n-V(x)=&-\left(n+\frac{\alpha+\beta+1}{2}\right)^2+\frac{1}{2}(\beta-\alpha)(\beta+\alpha)z^{-1}(x)+\frac{3}{4}z^{-4}(x)\\ &+\left[\left(n+\frac{\alpha+\beta+1}{2}\right)^2-\left(\frac{\alpha+\beta}{2}\right)^2-\frac{3}{4}-\frac{1}{4}(\beta-\alpha)^2\right]z^{-2}(x). \end{aligned} \tag{3.10}$$

This leads to a solvable potential if the n dependence can be canceled in the coordinate-dependent (i.e., potential) terms by a suitable change of the parameters. Comparing (3.10) with (2.2) we get

$$A=-\left[\left(n+\frac{\alpha+\beta+1}{2}\right)^2-\left(\frac{\alpha+\beta}{2}\right)^2-\frac{3}{4}-\frac{1}{4}(\beta-\alpha)^2\right], \tag{3.11}$$

$$B=\tfrac{1}{2}(\beta-\alpha)(\beta+\alpha), \tag{3.12}$$

and

$$E_n = -\left(n + \frac{\alpha+\beta+1}{2}\right)^2. \tag{3.13}$$

Obviously, α and β depend on n and also on the potential parameters A and B. Substituting (3.13) in (3.11) and combining it with (3.12) we arrive at (2.12), the equation defining the energy eigenvalues in the two approaches of Sec. II.

The bound-state wave functions are found to be

$$\psi(x) \sim z^{1/2}(x)(z(x)+1)^{\beta_n/2}(z(x)-1)^{\alpha_n/2}P_n^{(\alpha_n,\beta_n)}(z(x)), \tag{3.14}$$

which (apart from some misprints), corresponds to Eqs. (15), (16), and (18) in Ref. 14, if we substitute $\alpha_n = B/(2c) - c$ and $\beta_n = -B/(2c) - c$.

B. Supersymmetric connection

In the knowledge of the bound-state wave functions, constructing the superpotential $W(x)$ is a simple matter using Eq. (2.14). From (3.14) with $n=0$ one obtains

$$W(x) = \frac{1}{2}(\alpha_0+\beta_0+1) + \frac{\alpha_0-\beta_0}{2z(x)} - \frac{1}{2z^2(x)}. \tag{3.15}$$

In order to get closer to the methods described in Sec. II B, we also introduce the singular superpotentials obtained in a similar way to the wave functions with $n>0$. The Jacobi polynomial appearing in these functions is best expressed in a product form

$$P_n^{(\alpha_n,\beta_n)}(z) \sim \Pi_{i=1}^{n}(z-c_i), \tag{3.16}$$

where the c_i are at the roots (nodes) of the polynomial. Obviously, the logarithmic derivative of this product will reduce to a sum form

$$\frac{\mathrm{d}}{\mathrm{d}x}(\ln P_n^{(\alpha_n,\beta_n)}(z)) = \frac{\mathrm{d}z}{\mathrm{d}x}\frac{\mathrm{d}}{\mathrm{d}z}\sum_{i=1}^{n}\ln(z-c_i) = (z^{-1}-z)\sum_{i=1}^{n}\frac{1}{z-c_i}. \tag{3.17}$$

Here we used the differential equation (3.9) to express z' in terms of z. This explains the sum appearing in the superpotential (2.18) in Sec. II B. A similar construction can readily be presented for the superpotential used in Ref. 19 describing the potential of Ref. 13 in a supersymmetric framework. The polynomial there is of the Hermite type.

C. Relation to the Natanzon potentials

Our discussion in the present section was based on the approach of Ref. 5, which is general enough to incorporate both the conventional and the supersymmetric formulation of potential (2.2) in a relatively straightforward way. One can, however, put the whole subject into an even more general framework, that of the Natanzon potentials.[7] Although the discussion could have been presented using the formalism of this potential class, we decided to follow the easier route of Ref. 5 for several reasons. First, the general formalism was too heavy for demonstrative purposes, and second, its relation to the machinery of supersymmetric quantum mechanics[3,9] is less transparent. However, to conclude this section we present the essential facts about Natanzon potentials, and their relevance to the potentials we investigated.

The general families of the Natanzon[7] and Natanzon confluent[31] potentials are characterized by the feature that their solutions are expressed in terms of a single (confluent) hypergeometric function. The general Natanzon potential depends on six parameters, three of which (f, h_0, and h_1) appear explicitly in

$$V(x)=-\frac{z'''(x)}{2z'(x)}+\frac{3}{4}\left(\frac{z''(x)}{z'(x)}\right)^2+\frac{fz(x)(z(x)-1)+h_0(1-z(x))+h_1z(x)}{\mathcal{R}(z(x))}, \tag{3.18}$$

while three others (a, c_0, and c_1) enter implicitly through the $z(x)$ function determined by the differential equation

$$z'(x)\equiv\frac{dz}{dx}=\frac{2z(1-z)}{(\mathcal{R}(z))^{1/2}} \tag{3.19}$$

with

$$\mathcal{R}(z)=az(x)(z(x)-1)+c_0(1-z(x))+c_1z(x). \tag{3.20}$$

The construction of Ref. 5, when specified for the Jacobi polynomials (a special case of the hypergeometric function[26]) can easily be recognized as a particular reformulation of this change of variable method. (See also Ref. 32 and the Appendix of Ref. 28.) The energy spectrum is determined[7] by the implicit equation

$$2n+1=(f+1-aE_n)^{1/2}-(h_0+1-c_0E_n)^{1/2}-(h_1+1-c_1E_n)^{1/2}\equiv\alpha_n-\beta_n-\delta_n, \tag{3.21}$$

while the bound-state wave functions are written as

$$\psi(x)\sim\mathcal{R}^{1/4}(z(x))(1-z(x))^{\delta_n/2}(z(x))^{\beta_n/2}F(-n,\alpha_n-n;\beta_n+1;z(x)). \tag{3.22}$$

The form of (3.22) is again reminiscent of the construction of Ref. 5, while (3.21) is close to the implicit energy formula obtained for the potential of Ref. 14 in the point canonical transformation formalism.

Equations similar to those mentioned previously are valid for the Natanzon confluent potential class[31] too.

It is instructive to examine the role of the $3+3$ parameters appearing in the Natanzon potentials, as it is related to the concept of conditionally exact solvability. For the most commonly occurring potentials (like the shape-invariant ones[8]), the three parameters determining the $z(x)$ function via (3.19) and (3.20), usually only one appears, and even that one is a trivial scaling parameter of the coordinate and/or the energy scale. (Trivial coordinate shifts can also appear through them.) Usually they play a nontrivial role only in the case of some ''implicit'' potentials.[29]

The other three parameters appearing in (3.18) set the potential shape, and determine the relative strength of the individual potential terms. In most potentials only one or two of these parameters appear. The two parameters appearing in potential (2.2), A and B are of this type. (There could be one more parameter setting the length scale, but it is set to 1 in this case.) Obviously, when there are three potential terms, as in (2.2), and only two parameters, then the relative strength of the three potential terms cannot be arbitrary, and has to be constrained. This is why the third term of (2.2) is a numerical constant, i.e., $-3/4$. It is the presence of this numerical constant which earned potentials in Refs. 13 and 14 the name ''conditionally exactly solvable.'' In fact, based on the structure of their eigenfunctions, the potentials appearing in Ref. 14 are of the Natanzon type,[7] while those in Ref. 13 belong to the Natanzon confluent class.[31] There are, however, further considerations regarding normalizability and regularity, which might impose restrictions on the solvability of certain potentials. Not surprisingly, these may play a more important role in the case of the less ''trivial'' potentials.[33]

Finally, we note that the other class of CES potentials[16,17] has a completely different nature, and does not belong to the Natanzon class, rather it has features typical for SUSY partners of general Natanzon-class potentials. This again confirms our finding that the concept of conditionally exact solvability is not an alternative of exact solvability, rather it classifies potentials according to different principles.

IV. CONCLUSIONS

We analyzed the potentials introduced originally in Ref. 14 as conditionally exactly solvable (CES) potentials via the method of point canonical transformation. Our results concerned the following three areas.

(i) We gave a supersymmetric reinterpretation of this potential class.
(ii) We examined the cubic formula which determines implicitly the energy eigenvalues of the problem. We rigorously took into account boundary conditions of the eigenfunctions, and corrected certain inaccuracies presented in Ref. 14. We demonstrated that from the three roots of the cubic equation there is only one (the middle one) which can lead to physically acceptable eigenstates.
(iii) We interpreted this potential in the general framework of the Natanzon potential class, and demonstrated that this CES potential, in fact, belongs to this class, and therefore it is a *bona fide* exactly solvable problem.

Berry's phase for compact Lie groups

E. Strahov[a)]
Department of Physics, Technion–Israel Institute of Technology, Haifa, 32000 Israel

(Received 21 August 2000; accepted for publication 2 February 2001)

The methods of Kähler geometry are applied to generalize the results of Berry obtained for $SU(2)$ (namely, the existence of a geometrical part in the adiabatic phase) to any compact Lie group. We obtain explicit expressions for Berry's geometric phases, Berry's connections, and Berry's curvatures in terms of parameters of the corresponding Lie algebra valued Hamiltonian. It is demonstrated that the parameter space of the Hamiltonian in the general theory is essentially a homogeneous Kähler manifold. The fundamental Kähler potentials of this manifold completely determine Berry's phase. A general approach is exemplified by the Lie algebra Hamiltonians corresponding to $SU(2)$ and $SU(3)$ evolution groups. [DOI: 10.1063/1.1358879]

I. INTRODUCTION

A number of branches of physics make use of the geometric properties of Kähler coset spaces (a definition may be found in Kobayashi and Nomizu, Vol. 2[1]). For instance, in quantum field theory the Kähler coset spaces give rise to a broad class of supersymmetric nonlinear sigma models discussed in Zumino,[2] Alvarez-Gaumé and Freedman,[3] and Bando, Kuramoto, Maskawa, and Uehara[4] (among others). In quantization of dynamical systems with curved phase space with a nontrivial global geometry Kähler cosets serve as a model of such curved phase space (e.g., Beresin,[5] Bar-Moshe, and Marinov[6,7]). Kähler geometry is also used in relativity theory (for a review see Flaherty[8]).

In this work I show how geometric properties of Kähler coset spaces may be used in the ordinary nonrelativistic quantum mechanics. Knowledge of the fundamental Kähler potentials of these cosets enables me to generalize the result of Berry obtained for $SU(2)$ to essentially any compact Lie group.

Berry[9] was the first to discover the relation between the adiabatic phase acquired by the wave function under a slow variation of the Hamiltonian parameters and the geometry of the parameter space. Specifically, it has been demonstrated that the adiabatic phase includes a part of a pure geometrical origin (the geometric phase factor). Simon[10] has shown that the geometrical meaning of the geometric phase is the holonomy in a Hermitian line bundle over the parameter space of the Hamiltonian, and that the adiabatic theorem[11] (see also Messiah[12]) gives rise to a connection with such a bundle. When the parameter dependence of the Hamiltonian is determined by a closed curve C on the parameter space, the Berry geometrical factor Ω is expressed by the integral (Simon,[10] Berry[9])

$$\Omega(C)=\int_S F. \tag{1}$$

Here S is any oriented surface in the parameter space with $\partial S=C$, and F is a two-form given on this parameter space. As a consequence of Stokes' theorem the two-form F may be expressed in terms of the Berry vector potential[9] (or Berry's connection).

a)Electronic mail: strahov@physics.technion.ac.il

However, explicit forms for the geometric phase factor Ω [Eq. (1)] and for the Berry connection in terms of the (local) coordinates of the parameter space have since been obtained only for a number of simple cases. The spin precession in a slowly time-dependent magnetic field when the parameter space is a two-dimensional sphere, and the Berry connection is expressed in terms of the spherical coordinates is the simplest example. After a suitable reparametrization of the time variable the Hamiltonian H for this case may be chosen as

$$H(s)=\mathbf{n}(s)\cdot\mathbf{J},|\mathbf{n}(s)|=1, \tag{2}$$

where $\mathbf{J}$ is the spin operator, and the vector $\mathbf{n}=(\sin\theta\cos\phi,\sin\theta\sin\phi,\cos\theta)$. [It has been shown by Jakšić and Segert[13] that any two-level system may be described by the Hamiltonian (2) (with $\mathbf{J}=\boldsymbol{\sigma},\boldsymbol{\sigma}=(\sigma_1,\sigma_2,\sigma_3)$ are Pauli matrices) after a corresponding reparametrization of the time variable.] The corresponding Berry connection A_s induced by the adiabatic evolution of the spin state is

$$A_s=\frac{l}{2}(1-\cos\theta)\dot{\phi},\quad l=0,\pm1,\pm2\ldots\ . \tag{3}$$

The Berry geometrical phase is defined by Eq. (1), where the two-form F is

$$F=\frac{l}{2}\sin\theta d\phi\wedge d\theta,\quad l=0,\pm1,\pm2\ldots\ . \tag{4}$$

In this example the evolution operator acting on the spin state belongs to an irreducible representation of the $SU(2)$ group, the Hamiltonian $H(s)$ [Eq. (2)] determines a smooth curve in the Lie algebra $su(2)$, and the parameter space is the homogeneous space of the group $SU(2)$, $S^2=SU(2)/U(1)$.

It is my goal in the present paper to consider cases when the adiabatic evolution is determined by one-parameter Hamiltonians belonging to more complicated than $su(2)$ Lie algebras. I shall concentrate on one-parameter Hamiltonians which lead to compact evolution operators, and determine closed smooth curves in the semi-simple Lie algebras of arbitrary ranks. The aim is to generalize equations, Eq. (3), Eq. (4), and to find explicit expressions for Berry connections and Berry curvatures in terms of the coordinates of the corresponding parameter spaces.

This paper is organized as follows. Section II begins with an introduction of the relevant Lie algebra notations. We first obtain that the adiabatic phase is a scalar product of two vectors in the root space of the Lie algebra under consideration. We reveal that it is not always the case that the adiabatic phase depends on one integer only [as in the case of $su(2)$ Lie algebra, Eqs. (3), (4)]. Rather, it is dependent on a set of integers with a number equal to the rank of the Lie algebra [e.g., in the case of $su(2)$ the rank is equal to one; thus only one integer suffices]. We note that these integers determine irreducible representation in which quantum states form a basis.

In Sec. III we discuss the familiar example of Berry for $SU(2)$ while introducing the technique which enables generalization to any compact Lie group. In Sec. IV we introduce a complex parametrization of the parameter space by a Mackey-type decomposition for any element of the evolution group G. Applicability of this procedure is restricted to the cases when the parameter space of the Hamiltonian is a homogeneous Kähler manifold $\mathsf{G/H}$. Since in the cases under consideration this restriction is always satisfied, it becomes possible to apply this method to find explicit expressions for the adiabatic phase and the Berry potential in terms of the coordinates of the parameter space (Sec. V). We discover that the Berry potentials may be expressed in terms of the fundamental Kähler potentials of the homogeneous Kähler manifold $\mathsf{G/H}$. The Bando, Kuramoto, Maskawa, and Uehara[4] method is used to express the fundamental Kähler potentials in terms of the coordinates of the parameter space. Thus, the explicit expressions for the Berry connections in terms of the complex parameters are found. This result will be formulated as a theorem in Sec. V. It will be demonstrated in Sec. VI that the action of the group G on the Kähler manifold $\mathsf{G/H}$ induces the gauge transformation of the Berry potentials. Once explicit forms for

the Berry connections are obtained, the Berry curvature and the Berry geometrical phase are easily derived (Sec. VI). We illustrate the general procedure on a specific case of the $SU(3)$ group (Sec. VII). The paper is concluded in Sec. VIII.

II. PRELIMINARIES AND NOTATIONS

Assume that a matrix irreducible representation of a compact semi-simple Lie group G of order n and rank r is given. Let $\mathcal{G}$ be the Lie algebra of G in which $\mathcal{H}\in\mathcal{G}$ denotes its Cartan subalgebra. A canonical Cartan–Weyl basis $\{h_j, e_\alpha, e_{-\alpha}\}$ in $\mathcal{G}$ is introduced, where $j=1,\ldots,r \equiv \operatorname{rank}\mathcal{G}$, and $\{\alpha\}\in\mathbf{\Delta}^+_{\mathcal{G}}$ are the positive roots of $\mathcal{G}$. (The definitions and properties of semi-simple Lie algebras and Lie groups may be found in Gilmore.[14]) The number of the positive roots is $n_+=\frac{1}{2}[n-r]$. The canonical basis of the Lie algebra $\mathcal{G}$ may be chosen so that the commutation relations will be written in the following standard form:

$$\begin{gathered}[h_i h_j]=0 \quad , \quad [h_i, e_\alpha]=\alpha_i e_\alpha, \\ [e_\alpha, e_{-\alpha}]=\sum_{j=1}^{r} \alpha_i h_i \quad , \quad [e_\alpha, e_\beta]=\chi(\alpha,\beta) e_{\alpha+\beta}.\end{gathered} \tag{5}$$

Here $\chi(\alpha,\beta)$ is a function on the root lattice which vanishes if $\alpha+\beta\notin\Delta^+_{\mathcal{G}}$. Choosing primitive roots $\boldsymbol{\gamma}_j$, $j=1,\ldots,r$, the fundamental weights $\boldsymbol{\omega}_j$, $j=1,\ldots,r$ are determined from the equation

$$(\boldsymbol{\omega}_i\cdot\boldsymbol{\gamma}_i)=\frac{\delta_{ij}}{2}(\boldsymbol{\gamma}_i\cdot\boldsymbol{\gamma}_i). \tag{6}$$

For any unitary irreducible group representation its dominant weight $\mathbf{l}$ is given by a sum of the fundamental weights with non-negative integer coefficients:

$$\mathbf{l}=\sum_{j=1}^{r} l_j\boldsymbol{\omega}_j=\sum_{j=1}^{r} \tilde{l}_j\mathbf{x}_j, \tag{7}$$

where $(\tilde{l}_1,\ldots,\tilde{l}_r)$ are the coordinates of the dominant weight $\mathbf{l}$ in the root space of the Lie algebra in which an orthogonal coordinate system is chosen. (Here and afterwards boldface is used to denote vectors in the root space of the Lie algebra.) The set $\{\mathbf{x}_j, j=1,\ldots,r\}$ denotes the unit basis vector of this coordinate system.

We are interested in the cyclic adiabatic evolution of the weight eigenket $\psi_{\mathbf{l}}$ which is defined by the following equation:

$$h_j\psi_{\mathbf{l}}=\tilde{l}_j\psi_{\mathbf{l}}, \quad j=1,\ldots,r. \tag{8}$$

(For convenience we are dealing with the weight eigenket $\psi_{\mathbf{l}}$, corresponding to the dominant weight $\mathbf{l}$ here. The adiabatic evolution of an eigenket corresponding to an arbitrary weight may be considered in the same manner.) This adiabatic evolution will be determined by the Schrödinger equation with a Lie algebra valued Hamiltonian $b(s)\in\mathcal{G}$ given in the irreducible representation $(l_1,\ldots, l_r)$ of $\mathcal{G}$:

$$i\dot{\psi}(s)=\tau b(s)\psi(s), \quad \psi(0)=\psi_{\mathbf{l}}. \tag{9}$$

[The physical time t is replaced here by the scale time $s=t/\tau, s\in[0,1]$. The adiabatic limit is $\tau\to\infty$. The Hamiltonian $b(s)$ is assumed to depend smoothly on $s\in[0,1]$.] The cyclic evolution means that $b(s)$ takes the same values at the ends of the segment $[0,1]$. In order for the initial state $\psi_{\mathbf{l}}$ defined by Eq. (8) to be an eigenstate of the Hamiltonian $b(s)$, we demand that $b(0)=b(1)\in\mathcal{H}$.

The problem (9) can be written in terms of the Cartan–Maurer one-form:

$$dg\,g^{-1}=-i\tau b(s)ds,\quad g(s)\in \mathsf{G},\quad b(s)\in\mathcal{G}. \tag{10}$$

Here $g(s)$ is the evolution operator in the irreducible representation $(l_1,\ldots,l_r)$ of the Lie group G, $\psi(s)=g(s)\psi_{\mathbf{l}}$ and $g(0)=e$ is the unit element of the compact group G. Geometrically, the given Lie algebra Hamiltonian $b(s)$ determines a closed smooth curve in the Lie algebra $\mathcal{G}$ which begins and ends in the Cartan subalgebra $\mathcal{H}$ of $\mathcal{G}$. To solve Eq. (10) means to find the corresponding curve on the group manifold G.

For any given s the Hamiltonian $b(s)\in\mathcal{G}$ may be reduced to the Cartan subalgebra $\mathcal{H}$,

$$b(s)=g_1(s)\beta(s)g_1^{-1}(s),\quad \beta(s)\in\mathcal{H}. \tag{11}$$

It is useful to assume that the Cartan subalgebra element β does not depend on the parameter $s\in[0,1]$, i.e., the eigenvalues of the Hamiltonian $b(s)$ are constants on the segment under consideration. For example, the $su(2)$ Lie algebra Hamiltonian given by Eq. (2) has two constant eigenvalues ± 1 if $\mathbf{J}=\boldsymbol{\sigma}$, $(\sigma_1,\sigma_2,\sigma_3)$ are Pauli matrices. When $b(s)$ determines the closed curve that begins and ends in $\mathcal{H}$, $g_1(0)=g_1(1)=e$.

We look for an unknown group element as the following product:

$$g(s)=g_2(s)h(s),\quad h(s)\in\mathsf{H},\quad g_2(s)\in\mathsf{G}. \tag{12}$$

Inserting (12) to Eq. (10) we obtain

$$dh(s)h^{-1}(s)=-i\tau g_2^{-1}(s)g_1(s)\beta(s)g_1^{-1}(s)g_2(s)-dg_2(s)g_2^{-1}(s). \tag{13}$$

In the adiabatic limit $(\tau\to\infty)$ we neglect by the second part of the right-hand side of Eq. (13). It gives as a zeroth-order approximation,

$$h^{(0)}(s)=\exp(-i\tau\beta s),\quad \beta=\sum_{j=1}^{r}\beta^j h_j, \tag{14}$$

$$g_2^{(0)}(s)=g_1(s)h^{(1)}(s),\quad h^{(1)}(s)\in\mathsf{H}. \tag{15}$$

The element $h^{(1)}(s)$ (which is arbitrary in the zeroth-order approximation) should be chosen in such a way that the form $dg_2(s)g_2^{-1}(s)$ will be as minimal as possible. Then we find

$$h^{(1)}(s)=\exp(-i\mathcal{Q}(s)),\quad \mathcal{Q}(s)=\sum_{j=1}^{r}\mathcal{Q}^j(s)h_j, \tag{16}$$

$$\mathcal{Q}^j(s)=-i\int_0^s \mathrm{Tr}\left(g_1^{-1}(\tilde{s})\frac{dg_1(\tilde{s})}{d\tilde{s}}h_j\right)d\tilde{s}. \tag{17}$$

Equations (12), (14), (15), (16), (17) determine evolution operator $g(s)$ in the adiabatic limit:

$$g(s)=g_1(s)\exp(-i\tau\beta s)\exp(-i\mathcal{Q}(s)). \tag{18}$$

After a cyclic adiabatic evolution $(s=1)$, the eigenket $\psi_{\mathbf{l}}$ is transformed according to the formula

$$\psi_{\mathbf{l}}\rightsquigarrow g(1)\psi_{\mathbf{l}}=\exp(-i\tau\beta)\exp(-i\mathcal{Q}(1))\psi_{\mathbf{l}}, \tag{19}$$

where we have taken into account that $g_1(1)=e$. Let us introduce the r-dimensional vectors in the root space of the Lie algebra $\mathcal{G}$:

$$\boldsymbol{\beta}=\sum_{j=1}^{r}\beta^j\mathbf{x}_j,\quad \mathbf{Q}=\sum_{j=1}^{r}\mathcal{Q}^j(1)\mathbf{x}_j. \tag{20}$$

Using Eq. (8) and explicit forms for the elements β [Eq. (14)] and $\mathcal{Q}$ [Eq. (16)] we finally obtain that the adiabatic phase factor Θ acquired by the quantum state $\psi_{\mathbf{l}}$ is given by the scalar product of the dominant weight vector $\mathbf{l}$ [Eq. (7)] on the sum of the vectors $\mathbf{Q}$ and $\boldsymbol{\beta}$:

$$\psi_{\mathbf{l}} \to \exp(-i\Theta)\psi_{\mathbf{l}}, \quad \Theta = \mathbf{l}\cdot\boldsymbol{\beta} + \mathbf{l}\cdot\boldsymbol{\mathcal{Q}}. \tag{21}$$

While the first term in the above expression for the adiabatic phase Θ is associated with the dynamical phase, the second term $\mathbf{l}\cdot\boldsymbol{\mathcal{Q}}$ is the geometrical phase Ω, defined as

$$\Omega \equiv \mathbf{l}\cdot\boldsymbol{\mathcal{Q}}. \tag{22}$$

As we can see from Eq. (21), the Berry geometrical phase depends on integers $l_1, \ldots, l_r$ which determine the dominant weight $\mathbf{l}$ [Eq. (7)], and characterize the irreducible representation of the evolution group under consideration.

III. GEOMETRICAL PHASE FOR *SU*(2)

Let us discuss a familiar example of Berry[9] for a spin in a time-dependent magnetic field using the machinery that admits generalization to any compact Lie group. The Hamiltonian of Berry's example is given by

$$b(s) = \mu \mathbf{B}(s)\cdot\mathbf{J}, \tag{23}$$

where $\mathbf{B}(s) = B\mathbf{n}(s)$ is the vector of the magnetic field, μ is the particle magnetic momentum, and $\mathbf{J}$ is the angular momentum. This example can be understood as a case when the Hamiltonian $b(s)$ takes values on a closed curve in the Lie algebra of the $SU(2)$. The generators of the group $SU(2)$ are the Pauli matrices:

$$\sigma_1 = \begin{pmatrix} 0 & 1 \\ 1 & 0 \end{pmatrix}; \quad \sigma_2 = \begin{pmatrix} 0 & -i \\ i & 0 \end{pmatrix}; \quad \sigma_3 = \begin{pmatrix} 1 & 0 \\ 0 & -1 \end{pmatrix}. \tag{24}$$

The elements of the canonical basis of the Lie algebra $SU(2)$ in the fundamental (spinor) representation are

$$E_1 = \frac{1}{2}(\sigma_1 + i\sigma_2); \quad E_2 = \frac{1}{2}(\sigma_1 - i\sigma_2); \quad H = \frac{1}{\sqrt{2}}\sigma_3. \tag{25}$$

Correspondingly, the canonical commutation relations for the $SU(2)$ Lie algebra have the following form:

$$[e_1, e_2] = \sqrt{2}h, \quad [h, e_1] = \sqrt{2}e_1, \quad [h, e_2] = -\sqrt{2}e_2. \tag{26}$$

The rank of the Lie algebra $SU(2)$ is equal to one, $r=1$. The root space is one-dimensional, R^1, with two opposite roots $\pm\boldsymbol{\alpha} = \pm\sqrt{2}\mathbf{x}$, and the primitive root is $\boldsymbol{\gamma} = \boldsymbol{\alpha}$. The fundamental weight $\boldsymbol{\omega}$ is determined by Eq. (6), $\boldsymbol{\omega} = \frac{1}{2}\boldsymbol{\alpha}$. An arbitrary irreducible representation is defined by the dominant weight,

$$\mathbf{l} = l\boldsymbol{\omega} = \frac{l}{\sqrt{2}}\mathbf{x}, \quad l = 0, \pm 1, \pm 2, \ldots . \tag{27}$$

Consider the cyclic adiabatic evolution of the eigenket $\psi_{\mathbf{l}}$ which is the eigenvector of the following eigenvalue problem:

$$h\psi_{\mathbf{l}}=\frac{l}{\sqrt{2}}\psi_{\mathbf{l}},\quad l=0,\pm 1,\pm 2,\ldots\ . \tag{28}$$

The above equation means that the state $\psi_{\mathbf{l}}$ corresponds to the dominant weight $\mathbf{l}$. In accordance with Eq. (21) after the cyclic adiabatic evolution the state $\psi_{\mathbf{l}}$ acquires the geometrical phase factor Ω [Eq. (22)]. The geometric part of the adiabatic phase is determined by a scalar product of the dominant weight [Eq. (27)], and the vector $\boldsymbol{\mathcal{Q}}$ in the root space with the components given by Eq. (17). Thus, in order to obtain the geometrical phase we have to express the trace in Eq. (17) in terms of the Hamiltonian parameters. This trace depends on parameters of $g_1(s)$ only [see the decomposition of the Hamiltonian, Eq. (11)]. The parametrization of $g_1(s)\in SU(2)/U(1)$ should be introduced in such a way that the explicit calculation of the trace in Eq. (17) would be as simple as possible.

The desired (complex) parametrization of a representative $g_1(s)$ of the coset space $SU(2)/U(1)$ is obtained by the following decomposition:

$$g_1(s)=g_1(z(s),\overline{z}(s))=u(z)g_-(z,\overline{z}),\quad u(z)=\exp(ze_1). \tag{29}$$

The element $g_-(z,\overline{z})$ in the above expression is represented as the product,

$$g_-(z,\overline{z})=\exp(y(z,\overline{z})e_2)\exp(\kappa(z,\overline{z})h). \tag{30}$$

The explicit forms for the functions $y(z,\overline{z}),\kappa(z,\overline{z})$ are obtained from the condition that the element $g_1(z(s),\overline{z}(s))$ should be unitary. It gives

$$y(z,\overline{z})=-\frac{\overline{z}}{1+z\overline{z}},\quad \kappa(z,\overline{z})=\frac{1}{\sqrt{2}}\ln(1+z\overline{z}). \tag{31}$$

The explicit expression for the group element $g_1(z(s),\overline{z}(s))$ enables us to calculate the trace in the integral of Eq. (17):

$$\mathrm{Tr}\left(g_1^{-1}(s)\frac{dg_1(s)}{ds}h\right)=\dot{\overline{z}}\frac{\partial}{\partial\overline{z}}\kappa(z,\overline{z})-\dot{z}\frac{\partial}{\partial z}\kappa(z,\overline{z}). \tag{32}$$

In the above equation we have denoted $\dot{z}\equiv dz(s)/ds$,$\dot{\overline{z}}\equiv d\overline{z}(s)/ds$. The Berry connection A_s may be introduced and expressed in terms of the complex coordinates of the coset space $SU(2)/U(1)$:

$$A_s=\frac{il}{2}\left(\frac{\dot{z}\overline{z}-z\dot{\overline{z}}}{1+z\overline{z}}\right). \tag{33}$$

Using Stokes' theorem we determine the Berry geometrical phase factor [Eq. (22)]:

$$\Omega=-il\int\int\frac{dz\wedge d\overline{z}}{(1+z\overline{z})^2},\quad l=0,\pm 1,\pm 2,\ldots\ . \tag{34}$$

In order to compare Eq. (34) with the original Berry result[9] for the spin procession in the time-dependent magnetic field, use the stereographic projection of the two-dimensional sphere with the unit radius:

$$|z|=\cot\theta/2,\quad \arg z=\varphi. \tag{35}$$

Then the geometrical phase factor is equal to

$$\Omega=\frac{l}{2}\int\int\sin\theta\, d\theta\wedge d\varphi,\quad l=0,\pm 1,\pm 2,\ldots\ . \tag{36}$$

It is this result that was obtained by Berry.[9]

For a generalization to more complicated evolution groups the following two observations are important. First, the geometric phase is determined by the torus function $\kappa(z,\overline{z})$ only, appearing in the decomposition Equations (29), (30). The second is that the torus function $\kappa(z,\overline{z})$ is the Kähler potential of the Kähler manifold $SU(2)/U(1)$.

IV. COMPLEX PARAMETRIZATION OF THE HAMILTONIAN PARAMETER SPACE

The given Lie algebra valued Hamiltonian $b(s)\in\mathcal{G}$ varies adiabatically through a circuit C in the parameter space which is the homogeneous group manifold G/H. Indeed, $b(s)$ depends on s only through the group element $g_1(s)$ [Eq. (11)]. The Hamiltonian $b(s)$ decomposition, Eq. (11), is invariant under $g_1(s)\rightarrow g_1(s)h_1$, $\forall h_1\in\mathsf{H}$, so $g_1(s)$ must be chosen as a representative of the corresponding equivalence class. Thus, there is a gauge freedom in the diagonalization process [Eq. (11)], and the Cartan subgroup $\mathsf{H}\in\mathsf{G}$ is the group of the gauge transformations. Geometrically, G is described as a principal fiber bundle with the Cartan subgroup H as the standard fiber and G/H is the base coset space. According to Borel's theorem,[15] the necessary and sufficient condition for the coset space G/H (where G is a compact semi-simple group, and H is a closed subgroup of G) to be a homogeneous Kähler manifold is that H be the centralizer of a torus in G. A torus means a direct product of any $U(1)$ subgroup of H and the centralizer means a subgroup which consists of all G elements commutative with that torus elements. As it may be seen from Sec. II, in the case under consideration conditions of the Borel theorem are satisfied (H is a Cartan subgroup commuting with a torus), so the Hamiltonian parameter is a homogeneous Kähler manifold. Then the complex parametrization on G/H may be introduced, and the explicit expression for the geometrical factor Ω may be found in terms of the (complex) coordinates of the parameter space G/H.

The desired complex parametrization of the homogeneous group manifold G/H is introduced by the complex parametrization of the group element g_1, which determines decomposition of the Hamiltonian $b(s)$ [Eq. (11)]. Namely, given the canonical basis, the Lie algebra $\mathcal{G}$ is split into three subalgebras, $\mathcal{G}=\mathcal{H}\oplus\mathcal{B}_+\oplus\mathcal{B}_-$, ($\mathcal{B}_+,\mathcal{B}_-$ are called Borel subalgebras), corresponding to three subsets of the basis elements $\{e_{-\alpha}\},\{h_j\},\{e_\alpha\}$. Respectively, the Lie algebra $\mathcal{B}_+(\mathcal{B}_-)$ generates a nilpotent Borel subgroup $\mathsf{B}_+(\mathsf{B}_-)\subset\mathsf{G}^c$ (G^c means the complexification of the group G). The element g_1 has a unique (left) Mackey decomposition,

$$g_1=ug_-,\quad u\in\mathsf{B}_+,\quad g_-\in\mathsf{G}/\mathsf{B}_+. \tag{37}$$

(Note that in order to get u for any given g_1 one has to impose the condition that $g_-=u^{-1}g_1$ has no part in B_+. That would determine u completely.) The complex parameters which can be introduced in G/H correspond to the positive roots of $\mathcal{G}$,

$$u(z)=\exp\left(\sum_{\alpha\in\Delta_{\mathcal{G}}^+} z^\alpha e_\alpha\right),\quad z^\alpha\in\mathcal{C}. \tag{38}$$

$u(z)$ is an element of a nilpotent group and its matrix representions are polynomials of z^α. The local form (38) for $u(z)$ is valid in a neighborhood of the point $z^\alpha=0$, i.e., the origin of the coordinate system in G/H. The origin is related to the choice of coordinates. A transition to other domains of G/H covering the Kähler manifold G/H may be performed by the group transformation.

Given $u(z)$, $g_-(z,\overline{z})$ will acquire the following form:

$$g_-(z,\overline{z})=v^+(z,\overline{z})k(z,\overline{z}),\quad v(z,\overline{z})\in\mathsf{B}_+,\quad k(z,\overline{z})\in\mathsf{H}. \tag{39}$$

The elements $v^+(z,\overline{z})$, $k(z,\overline{z})$ are expressed as exponentials of the corresponding Lie algebra elements:

$$v^+(z,\overline{z})=\exp\left(\sum_{\alpha\in\Delta_{\mathcal{G}}^+} y^\alpha(z,\overline{z})e_{-\alpha}\right),\quad k(z,\overline{z})=\exp\left(\sum_{i=1}^{r}\kappa^i(z,\overline{z})h_i\right). \tag{40}$$

For a particular $u(z)\in \mathsf{B}_+$ the functions $y^\alpha(z,\overline{z})$ and $\kappa^i(z,\overline{z})$ may be determined when the group element g_1 is unitary:

$$g_1^+=g_1^{-1}\rightarrow v^+kk^+v=(u^+u)^{-1}. \tag{41}$$

v is obtained from the (right) Mackey decomposition of $(u^+u)^{-1}$, and the explicit forms for the functions $y_\alpha(z,\overline{z})$ may be found. As soon as v is given, one turns to the calculation of k from the equation

$$kk^+=(vu^+uv^+)^{-1}\in \mathsf{H}. \tag{42}$$

The functions $\kappa^i(z,\overline{z})$ are especially important as we shall see below. It will be shown in Sec. IV that the functions $\kappa^i(z,\overline{z})$ completely determine the Berry potentials when G is a compact evolution group, and the Hamiltonian parameter space is $\mathsf{G/H}$. These functions are linearly related with the fundamental Kähler potentials $K^i(z,\overline{z})$ of the Kähler manifold $\mathsf{G/H}$ under considerations:

$$K^i(z,\overline{z})=-2\sum_{j=1}^{r}\kappa^j(z,\overline{z})\mathrm{Tr}(h_j\eta_i). \tag{43}$$

The formula (43) was obtained by Itoh, Kugo, and Kunimoto.[16] Here η_i are the projection matrices introduced by Bando, Kuratomo, Maskawa, and Uehara.[4] The projection matrices exist in any matrix representation of G and correspond to elements of the Cartan subalgebra $h_j\in\mathcal{H}$. The basic properties of the projection matrices are[4]

$$\eta_j=\eta_j^+\quad \eta_j^2=\eta_j\quad \eta_j\hat{h}_k=\hat{h}_k\eta_j,\quad \forall j,k=1,\ldots,r,$$

$$\eta_j\hat{e}_{-\alpha}\eta_j=\hat{e}_{-\alpha}\eta_j,\quad \eta_j\hat{e}_\alpha\eta_j=\eta_j\hat{e}_\alpha. \tag{44}$$

(The overcaret stands for the matrix representation.) All η_j are commuting with each other. For any representation of G, where $\hat{h}_j$ are diagonal, all η_j are also diagonal. The explicit forms of η_j satisfying Eq. (44) may be found (Bando, Kuratomo, Maskawa, and Uehara[4]). For the irreducible representation under consideration the functions $\kappa^j(z,\overline{z}),j=1,\ldots,r$ may be expressed linearly in terms of the fundamental Kähler potentials $K^j(z,\overline{z}),j=1,\ldots,r$ [Eq. (43)]. In its turn a suitable method of construction of the fundamental Kähler potentials is given by Bando, Kuratomo, Maskawa, and Uehara[4] (see also Itoh, Kugo, and Kunitomo[16]). A number of particular examples is considered by Marinov and Bar-Moshe[6,7] in relation to the geometric quantization on homogeneous compact Kähler manifolds.

A technique for constructing the fundamental Kähler potentials may be described as follows. Once the projection matrices η_j are obtained from Eqs. (44), the projected determinant is defined for any matrix M as

$$\det{}_{\eta_j}M\equiv\det(\eta_jM\eta_j+I-\eta_j). \tag{45}$$

For any projection matrix η_j, a fundamental Kähler potential $K^j(z,\overline{z})$ is constructed from the fundamental represenation for the element $u(z)$ [Eq. (38)] of the nilpotent Borel subgroup B_+,

$$K^j(z,\overline{z})\equiv\ln\det{}_{\eta_j}(u(z)^+u(z)). \tag{46}$$

Note that the fundamental Kähler potential $K^j(z,\overline{z})$ is not a global function on $\mathsf{G/H}$, except for cases where $\mathsf{G/H}$ has a trivial topology. However, the manifold $\mathsf{G/H}$ may be covered with com-

plex coordinate neighborhoods. A transition from one neighborhood to another may be given by the group transformation. If the group G acts holomorphically on G/H, $z\to gz, \forall g\in \mathsf{G}$, the fundamental Kähler potentials (45) are transformed as

$$K^j(gz,\overline{gz})=K^j(z,\overline{z})+\Phi^j(z,g)+\overline{\Phi^j(z,g)}, \tag{47}$$

where $\Phi^j(z,g)$ are locally holomorphic functions of z^α, $\alpha=1,\ldots,(n-r)/2$. These functions must satisfy the following cocycle condition:

$$\Phi^j(z,g_2g_1)=\Phi^j(g_2z,g_1)+\Phi^j(z,g_2), \quad \forall g_1,g_2\in \mathsf{G}, \tag{48}$$

which results from the group property $z\to g_2(g_1z)=(g_2g_1)z$.

V. EXPRESSION OF BERRY'S CONNECTION IN TERMS OF THE FUNDAMENTAL KÄHLER POTENTIALS

With all the preliminary steps completed, we are in a position to formulate the main result of this work.

Theorem: Suppose that the cyclic adiabatic evolution of the dominant weight eigenket $\psi_{\mathbf{l}}$ defined by Eq. (8) is determined by the Schrödinger equation [Eq. (9)]. Let the Hamiltonian parameter space be a compact homogeneous Kähler manifold G/H, where G is the compact evolution group, and H its Cartan subgroup. Then the geometrical phase factor Ω acquired by the quantum state $\psi_{\mathbf{l}}$ is

$$\Omega=\int_0^1 A_s\,ds, \tag{49}$$

where the Berry connection A_s is completely determined in terms of the fundamental Kähler potentials of the parameter space G/H. Explicitly, when the local complex parametrization $\{z^\alpha,\overline{z^\alpha},\alpha=1,\ldots,(n-r)/2\}$ on G/H is introduced,

$$A_s=\mathbf{l}\cdot\mathbf{A}(z,\overline{z}), \quad \mathbf{A}(z,\overline{z})=\mathcal{L}_{z,\overline{z}}\boldsymbol{\kappa}(z,\overline{z}). \tag{50}$$

$\mathbf{A}(z,\overline{z})$ and $\boldsymbol{\kappa}(z,\overline{z})$ are the vectors in the root space of the Lie algebra of G given in the orthonormal basis $\{\mathbf{x}_j,j=1,\ldots,r\}$,

$$\boldsymbol{\kappa}(z,\overline{z})=\sum_{j=1}^{r}\kappa^j(z,\overline{z})\mathbf{x}_j, \quad \mathbf{A}(z,\overline{z})=\sum_{j=1}^{r}A^j(z,\overline{z})\mathbf{x}_j. \tag{51}$$

$\mathcal{L}_{z,\overline{z}}$ is the (Hermitian) differential operator:

$$\mathcal{L}_{z,\overline{z}}=i\sum_{\alpha,\overline{\alpha}=1}^{(n-r)/2}(\dot{z}^\alpha\partial_\alpha-\dot{z}^{\overline{\alpha}}\partial_{\overline{\alpha}}), \tag{52}$$

where $\dot{z}\equiv dz(s)/ds$, $z^{\overline{\alpha}}\equiv\overline{z^\alpha}$, $\partial_\alpha\equiv\partial/dz^\alpha$, $\partial_{\overline{\alpha}}\equiv\partial/dz^{\overline{\alpha}}$. The real functions $\kappa^j(z,\overline{z})$ define the Cartan subgroup element $k(z,\overline{z})\in \mathsf{H}$ [Eq. (40)] under (left) Mackey decomposition of a representative of the coset space G/H [Eqs. (37)–(40)]. These functions are linearly connected with the fundamental Kähler potentials $K^j(z,\overline{z})$ [Eq. (43)].

Proof: The geometric phase Ω is given by the scalar product of the dominant weight $\mathbf{l}$ and the vector $\boldsymbol{\mathcal{Q}}$ [Eq. (21)]. The coordinates of the vector $\boldsymbol{\mathcal{Q}}$ in the root space of the Lie algebra $\mathcal{G}$ corresponding to the evolution group G are determined by Eq. (17). When the local complex parametrization on the coset space G/H is introduced, the components $\mathcal{Q}^j$ of the vector $\boldsymbol{\mathcal{Q}}$ may be represented as a sum of two integrals:

$$\mathcal{Q}^j = -i \sum_{\alpha,\bar{\alpha}=1}^{(n-r)/2} \left\{ \int_C \mathrm{Tr}(g_1^{-1}\partial_\alpha g_1 h_j) dz^\alpha + \int_C \mathrm{Tr}(g_i^{-1}\partial_{\bar{\alpha}} g_1 h_j) dz^{\bar{\alpha}} \right\}. \tag{53}$$

The group element $g_1(z,\bar{z})$ which is the representative of the coset space G/H is decomposed (see Sec. III) as

$$g_1(z,\bar{z}) = u(z) v^+(z,\bar{z}) k(z,\bar{z}), \tag{54}$$

where $u(z) \in \mathsf{B}_+$, $v^+(z,\bar{z}) \in \mathbf{B}_-$, $k(z,\bar{z}) \in \mathsf{H}$ are given by Eqs. (38), (40). Let us recall that

$$k(z,\bar{z}) = \exp\left(\sum_{j=1}^{r} \kappa^j(z,\bar{z}) h_j \right).$$

It may be shown (see, for example, Itoh, Kugo, and Kunimoto[16]) that

$$\mathrm{Tr}\,(g_1^{-1}\partial_\alpha g_1 h_j) = -\partial_\alpha \kappa^j(z,\bar{z}), \quad \mathrm{Tr}(g_1^{-1}\partial_{\bar{\alpha}} g_1 h_j) = \partial_{\bar{\alpha}} \kappa^j(z,\bar{z}). \tag{55}$$

Indeed, noting that

$$\partial_{\bar{\alpha}} g_1(z,\bar{z}) = u(z)\partial_{\bar{\alpha}}(v^+(z,\bar{z}) k(z,\bar{z})), \tag{56}$$

we find that

$$\mathrm{Tr}\,(g_1^{-1}\partial_\alpha g_1 h_j) = \mathrm{Tr}(h_j (v^+(z,\bar{z}))^{-1} \partial_{\bar{\alpha}}(v^+(z,\bar{z}))) + \sum_{i=1}^{r} \partial_\alpha(\kappa^i(z,\bar{z}))\mathrm{Tr}(h_i h_j). \tag{57}$$

The expression $(v^+(z,\bar{z}))^{-1}\partial_{\bar{\alpha}}(v^+(z,\bar{z}))$ produces only terms belonging to the Borel subalgebra $\mathcal{B}_-$. As a consequence, the first term in the above equation equals zero. Using the orthogonality condition for the Cartan subalgebra canonic basis elements,

$$\mathrm{Tr}(h_i h_j) = \delta_{ij}, \tag{58}$$

we obtain

$$\mathrm{Tr}\,(g_1^{-1}\partial_{\bar{\alpha}} g_1 h_j) = \partial_{\bar{\alpha}} \kappa^j(z,\bar{z}). \tag{59}$$

In order to prove the first equation in (55) we use

$$\begin{aligned} g_1^{-1}\partial_\alpha g_1 = g_1^+ \partial_\alpha (g_1^+)^{-1} &= k^+ v u^+ \partial_\alpha ((u^+)^{-1} v^{-1} (k^+)^{-1}) \\ &= k^+ v \partial_\alpha (v^{-1}(k^+)^{-1}). \end{aligned} \tag{60}$$

Afterwards, we proceed with the proof as in the previous case.

From Eqs. (53), (55) we find

$$\mathcal{Q}^j = i \sum_{\alpha,\bar{\alpha}=1}^{(n-r)/2} \int_0^1 (\dot{z}^\alpha \partial_\alpha - \dot{z}^{\bar{\alpha}} \partial_{\bar{\alpha}}) \kappa^j(z,\bar{z}) ds \equiv \int_0^1 A^j(z,\bar{z}) ds. \tag{61}$$

Thus, the vector in the root space of $\mathcal{G}$,

$$\mathbf{A}(z,\bar{z}) = i \sum_{\alpha,\bar{\alpha}=1}^{(n-r)/2} (\dot{z}^\alpha \partial_\alpha - \dot{z}^{\bar{\alpha}} \partial_{\bar{\alpha}}) \boldsymbol{\kappa}(z,\bar{z}) \equiv \mathcal{L}_{z,\bar{z}} \boldsymbol{\kappa}(z,\bar{z}), \tag{62}$$

is introduced; the Berry connection and the Berry geometrical phase are determined by Eqs. (49), (50) respectively. □

In the next section we use this result to demonstrate that the holomorphic action of the evolution group G on the Hamiltonian parameter space G/H induces the gauge transformation of the Berry potentials. In addition, the Berry curvature and the Berry geometrical phase will be obtained.

VI. GAUGE TRANSFORMATION AND BERRY CURVATURE

Consider the transformation of the vector $\mathbf{A}(z,\overline{z})$ (in the root space) under the holomorphic action of the group G on the homogeneous Kähler G/H. As soon as the fundamental Kähler potentials $K^j(z,\overline{z}), j=1,\ldots,r$ are transformed in accordance with Eq. (47), the vector $\boldsymbol{\kappa}(z,\overline{z})$ changes in a similar fashion, i.e.,

$$\boldsymbol{\kappa}(z,\overline{z})\to\boldsymbol{\kappa}(gz,\overline{gz})=\boldsymbol{\kappa}(z,\overline{z})+\boldsymbol{\phi}(g,z)+\overline{\boldsymbol{\phi}(g,z)}. \tag{63}$$

Indeed, given the decomposition of the coset space representative [Eqs. (37)–(40)], the action of an arbitrary group element $g_2\in\mathsf{G}$ on the coset space G/H is defined (by Coleman, Wess, and Zumino[17]) as

$$g_2u(z)=u(g_2z)g_-(z,g_2), \tag{64}$$

and g_2z is a rational function of z. Once the nonlinear realization of the group action on the coset space G/H is determined [Eq. (64)], the transformation law (63) may be proved using the Mackey-type decomposition of the product $g_1\cdot g_2$ [where $g_1\in\mathsf{G/H}$ is given by Eqs. (37)–(40)] (for further details see Itoh, Kugo, and Kunimoto.[16] The change of the real vector $\boldsymbol{\kappa}(z,\overline{z})$ [Eq. (63)] under the holomorphic action of the group on its coset space leads to the gauge transformation of the vector $\mathbf{A}(z,\overline{z})$:

$$\mathbf{A}(z,\overline{z})=\mathcal{L}_{z,\overline{z}}\boldsymbol{\kappa}(z,\overline{z})\to\mathbf{A}(gz,\overline{gz})=\mathbf{A}(z,\overline{z})+d\mathbf{W}(z,\overline{z}), \tag{65}$$

where the real vector $\mathbf{W}(z,\overline{z})$ is defined in terms of the vectors $\boldsymbol{\phi}(g,z),\overline{\boldsymbol{\phi}(g,z)}$:

$$\mathbf{W}(z,\overline{z})\equiv i(\boldsymbol{\phi}(g,z)-\overline{\boldsymbol{\phi}(g,z)}). \tag{66}$$

Respectively, the Abelian Berry connection A_s defined by Eq. (50) is transformed as

$$\begin{gathered}A_s(z,\overline{z})\to A_s(gz,\overline{gz})=A_s(z,\overline{z})+dW(z,\overline{z}),\\ W(z,\overline{z})\equiv\mathbf{l}\cdot\mathbf{W}(z,\overline{z}).\end{gathered} \tag{67}$$

Note that the expression (49) for Ω may be rewritten as

$$\Omega=\sum_{\alpha=1}^{(n-r)/2}\int_C A_\alpha(z,\overline{z})dz^\alpha+\sum_{\alpha=1}^{(n-r)/2}\int_C A_{\overline{\alpha}}(z,\overline{z})dz^{\overline{\alpha}}, \tag{68}$$

where

$$\begin{gathered}A_\alpha(z,\overline{z})\equiv i\partial_\alpha(\mathbf{l}\cdot\boldsymbol{\kappa}(z,\overline{z})),\\ A_{\overline{\alpha}}(z,\overline{z})\equiv-i\partial_{\overline{\alpha}}(\mathbf{l}\cdot\boldsymbol{\kappa}(z,\overline{z})).\end{gathered} \tag{69}$$

Under the holomorphic action of the group G on the homogeneous Kähler manifold G/H, $A_\alpha(z,\overline{z})$, $A_{\overline{\alpha}}(z,\overline{z})$ transform as

$$A_\alpha(z,\overline{z})\to A_\alpha(gz,\overline{gz})=A_\alpha(z,\overline{z})+i\partial_\alpha(\mathbf{l}\cdot\boldsymbol{\phi}(g,z)),$$

$$A_{\bar{\alpha}}(z,\bar{z}) \to A_{\bar{\alpha}}(gz,\overline{gz}) = A_{\bar{\alpha}}(z,\bar{z}) - i\partial_{\bar{\alpha}}(\mathbf{l}\cdot\bar{\boldsymbol{\phi}}(g,z)). \tag{70}$$

Using the Stokes theorem, we obtain the expression for the Berry geometrical factor in terms of the surface integral,

$$\Omega = \int_S F, \quad F = \sum_{\alpha,\beta=1}^{(n-r)/2} \frac{\partial^2 K^{(\mathbf{l})}(z,\bar{z})}{\partial z^\alpha \partial \bar{z}^\beta} dz^\alpha \wedge d\bar{z}^\beta, \tag{71}$$

where

$$K^{(\mathbf{l})}(z,\bar{z}) = 2(\mathbf{l}\cdot\boldsymbol{\kappa}(z,\bar{z})), \tag{72}$$

and S is any oriented surface in the parameter space G/H with $\partial S = C$. As it may be seen from Eqs. (63), (71), the Berry curvature F is invariant under the gauge transformation [Eq. (67)] induced by the holomorphic group action on the parameter space G/H.

A simple way to calculate the vector $\boldsymbol{\kappa}(z,\bar{z})$ which determines the Berry connection and the Berry curvature is to use Eq. (43). This formula connects the vector $\boldsymbol{\kappa}(z,\bar{z})$ with the fundamental Kähler potentials given by Eqs. (44)–(46).

VII. *SU*(3) ADIABATIC EVOLUTION

The Cartan subgroup of the $SU(3)$ group is $U(1)\times U(1)$, so the Berry geometrical phase factor will be determined by the geometry of the Flag manifold $SU(3)/U(1)\times U(1)$. The canonical basis of $SU(3)$ Lie algebra is introduced with the help of the eight Gell-Mann generators:

$$\lambda_1 = \begin{pmatrix} 0 & 1 & 0 \\ 1 & 0 & 0 \\ 0 & 0 & 0 \end{pmatrix}, \quad \lambda_2 = \begin{pmatrix} 0 & -i & 0 \\ i & 0 & 0 \\ 0 & 0 & 0 \end{pmatrix}, \quad \lambda_3 = \begin{pmatrix} 1 & 0 & 0 \\ 0 & -1 & 0 \\ 0 & 0 & 0 \end{pmatrix},$$

$$\lambda_4 = \begin{pmatrix} 0 & 0 & 1 \\ 0 & 0 & 0 \\ 1 & 0 & 0 \end{pmatrix}, \quad \lambda_5 = \begin{pmatrix} 0 & 0 & -i \\ 0 & 0 & 0 \\ i & 0 & 0 \end{pmatrix}, \quad \lambda_6 = \begin{pmatrix} 0 & 0 & 0 \\ 0 & 0 & 1 \\ 0 & 1 & 0 \end{pmatrix}, \tag{73}$$

$$\lambda_7 = \begin{pmatrix} 0 & 0 & 0 \\ 0 & 0 & -i \\ 0 & i & 0 \end{pmatrix}, \quad \lambda_8 = \frac{1}{\sqrt{3}} \begin{pmatrix} 1 & 0 & 0 \\ 0 & 1 & 0 \\ 0 & 0 & -2 \end{pmatrix}.$$

Then the elements of the canonical Cartan–Weyl basis in the fundamental three-dimensional representation are given by

$$E_{12} = 1/2(\lambda_1 + i\lambda_2); \quad E_{23} = 1/2(\lambda_6 + i\lambda_7); \quad E_{13} = 1/2(\lambda_4 + i\lambda_5);$$

$$E_{21} = 1/2(\lambda_1 - i\lambda_2); \quad E_{32} = 1/2(\lambda_6 - i\lambda_7); \quad E_{31} = 1/2(\lambda_4 - i\lambda_5); \tag{74}$$

$$H_1 = \frac{\sqrt{3}}{2}\lambda_3 + \frac{\lambda_8}{2}; \quad H_2 = -\frac{\lambda_3}{2} + \frac{\sqrt{3}}{2}\lambda_8.$$

The rank of the Lie algebra $SU(3)$ is equal to two, $r=2$. The root space is two-dimensional, R^2, and the canonical commutation relations determining the positive root vectors are

$$[h_1, e_{12}] = \frac{3}{\sqrt{6}} e_{12}; \quad [h_2, e_{12}] = -\frac{1}{\sqrt{2}} e_{12};$$

$$[h_1,e_{13}]=\frac{3}{\sqrt{6}}e_{13};\quad [h_2,e_{13}]=\frac{1}{\sqrt{2}}e_{13};\tag{75}$$

$$[h_1,e_{23}]=0;\quad [h_2,e_{23}]=-\sqrt{2}e_{23}.$$

From the commutation relations (75) we find six nonzero root vectors,

$$\pm\boldsymbol{\alpha_1}=\pm\left(\frac{3}{\sqrt{6}};-\frac{1}{\sqrt{2}}\right),\quad \pm\boldsymbol{\alpha_2}=\pm\left(\frac{3}{\sqrt{6}};\frac{1}{\sqrt{2}}\right),\quad \pm\boldsymbol{\alpha_3}=(0;-\sqrt{2}).\tag{76}$$

The root diagram is a hexagon, the two primitive roots are $\boldsymbol{\gamma_1}=\boldsymbol{\alpha_3}$, $\boldsymbol{\gamma_2}=\boldsymbol{\alpha_2}$. The fundamental weights are found to be

$$\boldsymbol{\omega_1}=\left(\frac{1}{\sqrt{6}};-\frac{1}{\sqrt{2}}\right),\quad \boldsymbol{\omega_2}=\left(\frac{2}{\sqrt{6}};0\right).\tag{77}$$

An arbitrary irreducible representation is defined by the (two-dimensional) dominant weight vector:

$$\mathbf{l}=l_1\boldsymbol{\omega_1}+l_2\boldsymbol{\omega_2},\quad l_1,l_2=0,\pm1,\pm2,\ldots\ .\tag{78}$$

The coordinates of this vector in the root space are

$$\tilde{l}_1=\frac{l_1}{\sqrt{6}}+\frac{2l_2}{\sqrt{6}},\quad \tilde{l}_2=-\frac{l_1}{\sqrt{2}}.\tag{79}$$

The eigenket $\psi_{\mathbf{l}}$ is an eigenvector of both Cartan Lie algebra elements h_1,h_2 with eigenvalues $\tilde{l}_1,\tilde{l}_2$. It follows from the Theorem (Sec. V) that in order to find the geometric phase factor Ω acquired by the dominant weight vector eigenket $\psi_{\mathbf{l}}$, one should determine the two-component vector $\mathbf{k}(z,\overline{z})$ in the root space of the Lie algebra $su(3)$. As it may be seen from Eq. (43) the components of this vector in the orthogonal basis of the root space are linear combinations of the fundamental Kähler potentials $K^1(z,\overline{z}),K^2(z,\overline{z})$ of the homogeneous Kähler manifold $SU(3)/U(1)\times U(1)$. The fundamental Kähler potentials $K^1(z,\overline{z}),K^2(z,\overline{z})$ are constructed using Eq. (46), where the element $u(z)$ is taken in the fundamental 3×3 representation:

$$u(z)\equiv\exp(z_1E_{12}+z_2E_{23}+z_3E_{13})=\begin{pmatrix}1 & z_1 & z_3^+\\ 0 & 1 & z_2\\ 0 & 0 & 1\end{pmatrix}.\tag{80}$$

We have denoted $z^{\pm}=z_3\pm\frac{1}{2}z_1z_2$, and the projection matrices found from Eqs. (44) are

$$\eta_1=\begin{pmatrix}0 & 0 & 0\\ 0 & 1 & 0\\ 0 & 0 & 1\end{pmatrix},\quad \eta_2=\begin{pmatrix}0 & 0 & 0\\ 0 & 0 & 0\\ 0 & 0 & 1\end{pmatrix}.\tag{81}$$

Knowing $u(z),\eta_1,\eta_2$ in the fundamental representation, the fundamental Kähler potentials are calculated, and we obtain

$$K^1(z,\overline{z})=\ln(1+z_1\overline{z_1}+z_3^-\overline{z_3^-}),\quad K^2(z,\overline{z})=\ln(1+z_2\overline{z_2}+z_3^+\overline{z_3^+}).\tag{82}$$

Finding the coefficients $\mathrm{Tr}(h_j\eta_i)$ (in the fundamental represenation $h_1\equiv H_1,h_2\equiv H_2$), we get the components of the vector $\boldsymbol{\kappa}(z,\overline{z})$ in the root space of $su(3)$ algebra:

$$\kappa^1(z,\bar{z})=\frac{\sqrt{6}}{4}K^1(z,\bar{z}),\quad \kappa^2(z,\bar{z})=\frac{1}{\sqrt{2}}K^2(z,\bar{z})-\frac{1}{2\sqrt{2}}K^1(z,\bar{z}). \tag{83}$$

[Note that the expressions for the components of the vector $\boldsymbol{\kappa}(z,\bar{z})$ in terms of the complex coordinates, Eqs. (82), (83), may be obtained also by the (left) Mackey decomposition of the coset space representative g_1, Eqs. (37)–(40)].

For the case of $SU(3)$ evolution group the Berry connection A_s given by Eq. (50) is (84):

$$A_s=\mathcal{L}_{z,\bar{z}}\{\mathbf{l}\cdot\boldsymbol{\kappa}(z,\bar{z})\},\quad \mathbf{l}\cdot\boldsymbol{\kappa}(z,\bar{z})=\frac{1}{2}[(l_1+l_2)K^1(z,\bar{z})-l_1K^2(z,\bar{z})],$$
$$\mathcal{L}=\sum_{\alpha,\bar{\alpha}=1}^{3}\left(\dot{z}^{\alpha}\frac{\partial}{\partial z^{\alpha}}-\dot{z}^{\bar{\alpha}}\frac{\partial}{\partial z^{\bar{\alpha}}}\right), \tag{84}$$

and the Berry curvature F [Eq. (71)] is

$$F=\sum_{\alpha,\bar{\beta}=1}^{3}\frac{\partial^2K^{(\mathbf{l})}(z,\bar{z})}{\partial z^{\alpha}\,\partial z^{\bar{\beta}}}dz^{\alpha}\wedge dz^{\bar{\beta}}, \tag{85}$$

where the real function $K^{(\mathbf{l})}(z,\bar{z})$ is a linear combination of the fundamental Kähler potentials $K_1(z,\bar{z})$, $K_2(z,\bar{z})$ with the integer coefficients:

$$K^{(\mathbf{l})}(z,\bar{z})=(l_1+l_2)K^1(z,\bar{z})-l_1K^2(z,\bar{z}),\quad l_1,l_2=0,\pm1,\pm2\ldots\ . \tag{86}$$

Note that a common approach to the $SU(3)$ group evolution is to use the Euler coordinates that are similar to the Euler angle parameters of $SU(2)$. Such a method has been used by Byrd,[18] Arvind, Mallesh, and Mukunda,[19] and Khanna, Mukhopadhaya, Simon, and Mukunda[20] in connection with the evolution of a three-level system. While the geometric phase factor for this case has been found, none of them noticed that in cases under their consideration there exists an intimate relation between the geometric phase factors, Berry connections and Berry curvature and the fundamental Kähler potentials of parameter spaces.

VIII. CONCLUSIONS

In this paper we have considered the adiabatic evolution determined by a compact Lie group taken in an arbitrary irreducible representation. It has been demonstrated that the parameter space of the Hamiltonian is essentially a homogeneous Kähler manifold and its fundamental Kähler potentials completely determine Berry geometrical phase. Besides, we have shown that the Berry geometrical factor and the Berry connections depend on a set of integers a number of which equals to the rank of the corresponding Lie algebra. These integers determine irreducible representation in which quantum states form a basis.

Chaotic and irreversible properties of quantum scattering systems

Clasine van Winter[a)]
Department of Mathematics and Department of Physics and Astronomy, University of Kentucky, Lexington, Kentucky 40506

(Received 27 October 2000; accepted for publication 15 November 2000)

Recent results for a free particle are generalized to N-particle quantum systems. Chaotic and irreversible behavior occurs in scattering states that belong to a certain Hilbert space K^2 with a preferred time direction pointing to the future. At positive times the time evolution of positive observables exhibits quantum analogs of sensitive dependence on initial conditions, topological transitivity, and existence of a dense set of periodic points. A mixture of states in K^2 can be described in terms of a density operator with thermodynamical entropy that increases to its least upper bound when the time tends to infinity. © *2001 American Institute of Physics.* [DOI: 10.1063/1.1345872]

I. INTRODUCTION

This paper is devoted to the quantum mechanics of N particles with two-body interactions that give rise to scattering. The objective is to generalize recent work on entropy increase[1] and chaotic observables[2] for a free particle. It is shown that chaotic and irreversible behavior occurs if wave functions belong to a certain Hilbert space K^2 with a preferred time direction pointing to the future.

It is assumed that the interaction between any two particles is reasonably smooth and tends to zero sufficiently fast when the distance between particles tends to infinity. As a result there are scattering states in which the N-particle system separates into bound clusters that eventually move away from one another and in the remote future are infinitely far apart. Associated with each mode of separation are wave operators that intertwine between the exact time evolution and the time evolution of bound clusters moving freely relative to one another. The intertwining property is true for long- as well as for short-range interactions. It is the feature that enables previous results for free particles to be generalized. For a function f to belong to K^2, it must be a wave function of a scattering state, hence it must be orthogonal to any bound states of the scattering system. Moreover, it must satisfy analyticity conditions generalizing the ones in Refs. 1 and 2.

The wave function for the motion of N particles relative to their center of mass is an element of $L^2(\mathbb{R}^{3N-3})$. Henceforth we refer to L^2. There is an orthogonal projection $\Pi: L^2 \to \Pi L^2$ onto scattering states. Let H be the Hamiltonian of the relative motion. In the Schrödinger picture the time evolution takes $f \in L^2$ into $f(t) := \exp(-iHt)f$. If $f \in K^2$, then $f(t) \in K^2$ if $t \geqslant 0$, but not necessarily if $t < 0$. This causes a time asymmetry that is essential in this paper. Unless stated otherwise, it is assumed throughout the following that $t \geqslant 0$.

The quantities with chaotic properties are operators representing observables in the Heisenberg picture. Given an operator A on L^2, the Heisenberg picture lets

$$A(t) := \exp(iHt)A \exp(-iHt)$$

act on time-independent wave functions f. The space K^2 has a central role in that we focus on

[a)]Deceased.

positive self-adjoint operators A on ΠL^2 with the property that $A^{1/2}$ maps K^2 into ΠL^2. Quadratic form techniques developed in Ref. 2 determine a topology for such operators A. The result is a topological space X with the property that $A(t) \in X$ if $A \in X$ and $t \geqslant 0$.

Once a topology is in place, we can formulate conditions for chaos. To this end, we follow Devaney's definition of chaos in classical dynamical systems.[3] Hence we investigate

(S) sensitive dependence on initial conditions,

(T) topological transitivity,

(P) existence of a dense set of periodic points.

Precise statements are provided by Theorems S, T, and P in Sec. VIII. Formally, these chaos theorems are the same as in Ref. 2, but they are of wider scope because a more general time evolution is being considered. The proof in the present paper can be reduced to the previous proof. This is an analog of the fact that chaos in classical dynamical systems is invariant under homeomorphisms.[3]

The chaos theorems show that the outcome of experiments is unpredictable, yet retains elements of regularity. As an illustration, let us consider a fixed operator $A \in X$ and compare this with $Z \in X$. To do so, we choose finite sets of wave functions $f_i, g_i \in K^2 (i = 1,2,...,j)$, then perform experiments to determine the matrix elements $\langle f_i|A|g_i\rangle$ and $\langle f_i|Z|g_i\rangle$. Suppose for each i the two matrix elements differ by less than the experimental error. We repeat the experiments at a later time with the same A, Z, and f_i, g_i. According to Theorem S, the expectation values $\langle f_i|A(t)|f_i\rangle$ and $\langle f_i|Z(t)|f_i\rangle$ may differ by any constant δ times $\|f_i\|^2$. Given any operator $B \in X$, Theorem T says that $\langle f_i|Z(t)|g_i\rangle$ may equal $\langle f_i|B|g_i\rangle$ within experimental errors, for each $i (i = 1,2,...,j)$. In this sense the space of chaotic operators is indecomposable. The system is not random, however. By Theorem P, the operator $Z(t)$ may be semiperiodic in the sense that τ exists such that $Z(t + n\tau) = Z(t)$ if $t \geqslant 0$, $n = 0,1,2,...$. This means that $\langle f_i|Z(t)|g_i\rangle$ is close to $\langle f_i|A|g_i\rangle$ at all times $t = n\tau$, for every i. The proofs of the theorems show that there are operators Z with these erratic behaviors in any neighborhood of any operator $A \in X$.

Chaos as defined in this paper is related to irreversible behavior because either phenomenon occurs if wave functions belong to the space K^2. First suppose that ρ is a positive operator in the trace class on ΠL^2. To study chaos, we use the Heisenberg picture with time-dependent observables $A(t)$. Irreversible behavior calls for the Schrödinger picture with time-dependent density operators $\rho(t)$ determined by

$$\rho(t) := \exp(-iHt)\rho \exp(iHt). \tag{1.1}$$

Following von Neumann, we define the quantum-mechanical entropy of $\rho(t)$ by

$$S[\rho(t)] := -\operatorname{Tr} \rho(t) \ln \rho(t). \tag{1.2}$$

Because H is self-adjoint, the entropy $S[\rho(t)]$ does not depend on the time t. Hence there is no irreversible behavior at this level.

Now assume that $t \geqslant 0$ and that the range of ρ belongs to K^2. The operator $\rho(t)$ then determines an operator $\tilde{\rho}(t)$ in the trace class on K^2. The time evolution on K^2 is represented by a semigroup $\{U(t)|0 \leqslant t < \infty\}$, not by a unitary group such as $\{\exp(-iHt)|-\infty < t < \infty\}$. This eliminates a major paradox of statistical mechanics, but, since $U(t)$ is an isometry on K^2, is not sufficient to produce entropy increase.

For further progress, we need to refer to an unbounded positive operator J introduced in Sec. V. A function $f \in \Pi L^2$ belongs to K^2 if and only if $Jf \in \Pi L^2$. In terms of the inner product $(\cdot, \cdot)$ on ΠL^2, the inner product $\langle \cdot, \cdot \rangle$ on K^2 is defined according to

$$\langle f,g\rangle = (f,g) + (Jf, Jg). \tag{1.3}$$

If Tr denotes the trace on ΠL^2 and $\langle \mathrm{Tr} \rangle$ the trace on K^2,

$$\langle \mathrm{Tr}\, \tilde{\rho}(t) \rangle = \mathrm{Tr}\, \rho(t) + \mathrm{Tr}\, J\rho(t)J. \tag{1.4}$$

This expression brings to mind a discussion by Mackey (Ref. 4; Ref. 5, Chap. 9) in which he showed that taking a factor of a classical dynamical system with invertible time evolution may give rise to a system with increasing entropy. The transformation $\rho(t) \to \sigma(t)$ with

$$\sigma(t) := \rho(t) + J\rho(t)J \quad (t \geqslant 0) \tag{1.5}$$

can be viewed as a quantum analog of taking a factor in the sense of Mackey. It is shown in Sec. XIII that $S[\sigma(t)]$ is not constant in time and increases to its least upper bound as $t \to \infty$. The irreversible feature at the heart of the proof is easy to visualize by looking at a scattering event. In the distant past the system was separated into clusters that approached the center of mass. In the remote future scattered clusters will move away from it. This history gives rise to Eqs. (13.7) and (13.8), generalizing corresponding relations in Ref. 1. As a result the proof that $S[\sigma(t)]$ increases is the same as in Ref. 1.

If ρ is of rank 1, it can be shown as in Ref. 1 that the entropy $S[\sigma(t)]$ is a monotone increasing function of t. It is an open problem whether $S[\sigma(t)]$ may exhibit fluctuations if ρ is of higher rank. The latter case is difficult to assess due to the fact that there are positive operators in the trace class on ΠL^2 that cannot occur as density operators σ because they are not generated by positive operators ρ. This problem is discussed in some detail in Ref. 1.

Let us write $\sigma(t) = L\rho(t)$. This defines a linear operator L taking $\rho(t)$ with finite $\langle \mathrm{Tr}\, \tilde{\rho}(t) \rangle$ into the trace class on ΠL^2. According to Sec. XIV, L is invertible and L^{-1} can be constructed explicitly. Given a bounded operator T on L^2, there is an operator TL^{-1} such that

$$\mathrm{Tr}\, T\rho(t) = \mathrm{Tr}(TL^{-1})\sigma(t). \tag{1.6}$$

In combination with the fact that $\mathrm{Tr}\sigma(t)$ does not depend on t, Eq. (1.6) indicates that $\sigma(t)$ can be used as a density operator to evaluate expectation values of observables.

The transformation $\rho(t),\ T \to \sigma(t),\ TL^{-1}$ can be viewed as a new example of the Λ-transformation advocated by Prigogine and co-workers[6,7] to show that irreversible behavior originates at the microscopic level. There is an overview of the Prigogine program in Ref. 1. Further references follow in Sec. XVI.

Section II describes our coordinate systems for N-body problems. Section III summarizes fundamental concepts in scattering theory. Section IV is devoted to a Hilbert space of analytic functions that serves as a building block to construct the space of wave functions K^2 in Sec. V. The topological space X is introduced in Sec. VI. An essential point about X is that operators $A(t) \in X$ are related to bounded operators $\tilde{A}(t)$ on K^2. Hence the time evolution on K^2 is investigated in Sec. VII. Devaney's definition of chaos is reviewed in Sec. VIII. Theorems S, T, and P in Sec. VIII state that the time evolution of operators $A \in X$ has chaotic properties that can be viewed as quantum transcriptions of Devaney's chaos conditions for maps on metric spaces. To prove the theorems, one needs to construct nets $\{Z_\tau\} \in X$ $(\tau \geqslant 0)$ that tend to $A \in X$ as $\tau \to \infty$, yet give rise to time evolutions $\{Z_\tau(t)\}$ with erratic behaviors. Section VIII sketches the construction, but formal proofs are omitted because they are the same as in Ref. 2. The time evolution on K^2 is reminiscent of K flows, often quoted as prototypes of chaotic systems. It is discussed in Sec. IX how the relation has helped to shape the present paper. Other chaos concepts are mentioned in Sec. X, including the notion of quantum chaos.

Comparing the trace classes on ΠL^2 and K^2, Sec. XI shows how the density operator ρ determines $\tilde{\rho}$. Constructing σ can be viewed as taking a partial trace of $\tilde{\rho}$. It is shown in Sec. XII that $\mathrm{Tr}\ \sigma(t)$ is constant and that $\mathrm{Tr}\ \sigma^2(t)$ is a decreasing function of t, provided $t \geqslant 0$. The entropy $S[\sigma(t)]$ increases to its least upper bound by Sec. XIII. The proof is the same as in Ref. 1. Section XIV describes how the usual density operator ρ can be reconstructed when σ is known. The density operator $\sigma(t)$ can be used to calculate expectation values of observables according to Sec.

XV. Section XVI relates the transformation $\rho(t)\to\sigma(t)$ to the Λ-transformation in many papers by Prigogine and co-workers. In certain cases applying Λ can be interpreted as taking a factor of a classical dynamical system. That this step may lead to a system with increasing entropy was the reason for us to introduce $\sigma(t)$ and the entropy $S[\sigma(t)]$.

II. COORDINATE SYSTEMS

Consider a system of n particles with masses m_j $(j=1,2,...,n)$ located at $\mathbf{X}_j$. Suppose the Schrödinger operator has the form

$$i\frac{\partial}{\partial t}=-\sum_{j=1}^{n}(2m_j)^{-1}\Delta(\mathbf{X}_j)+\sum_{i<j}V_{ij}(\mathbf{X}_i-\mathbf{X}_j).$$

It is convenient to introduce a standard notation that separates the relative and center-of-mass motions.

The total mass of particles $1,2,...,k$ is

$$M_k:=\sum_{j=1}^{k}m_j.$$

The center of mass of this set is located at

$$\boldsymbol{\eta}_k:=(M_k)^{-1}\sum_{j=1}^{k}m_j\mathbf{X}_j \quad (k=1,2,...,n).$$

The vector from $\boldsymbol{\eta}_k$ to $\mathbf{X}_{k+1}$ is

$$\boldsymbol{\xi}_k:=\mathbf{X}_{k+1}-\boldsymbol{\eta}_k=(M_k)^{-1}\sum_{j=1}^{k}m_j(\mathbf{X}_{k+1}-\mathbf{X}_j) \quad (k=1,2,...,n-1).$$

Imagine a particle of mass M_k at $\boldsymbol{\eta}_k$ and a particle of mass m_{k+1} at $\mathbf{X}_{k+1}$. The reduced mass is

$$\mu_k:=(M_{k+1})^{-1}M_k m_{k+1} \quad (k=1,2,...,n-1).$$

Hence we define

$$\mathbf{x}_k:=(2\mu_k)^{1/2}\boldsymbol{\xi}_k$$

$$=(M_kM_{k+1})^{-1/2}(2m_{k+1})^{1/2}\sum_{j=1}^{k}m_j(\mathbf{X}_{k+1}-\mathbf{X}_j) \quad (k=1,2,...,n-1),$$

$$\mathbf{x}_n:=(2M_n)^{1/2}\boldsymbol{\eta}_n=(2/M_n)^{1/2}\sum_{j=1}^{n}m_j\mathbf{X}_j.$$

It is easy to verify that

$$-\sum_{j=1}^{n}(2m_j)^{-1}\Delta(\mathbf{X}_j)=-\sum_{j=1}^{n}\Delta(\mathbf{x}_j). \tag{2.1}$$

If there were only j particles, the system could be described in terms of the coordinates $\mathbf{x}_k$ with $k=1,2,...,j-1$ plus the center -of-mass coordinate $\boldsymbol{\eta}_j$. If $i<j$, then $\mathbf{X}_i-\mathbf{X}_j$ does not depend on $\boldsymbol{\eta}_j$. Hence there exist constants d_{ij}^{k} such that

$$V_{ij}(\mathbf{X}_i-\mathbf{X}_j)=V_{ij}\left(\sum_{k=1}^{j-1} d_{ij}^k\mathbf{x}_k\right) \quad (i<j).$$

Now consider n multiparticle clusters. Denote the mass of cluster c by N_c and assume that the center of mass is located at $\mathbf{Y}_c$ $(c=1,2,...,n)$. Introduce internal coordinates in cluster c as in the previous paragraphs, but denote these by $\mathbf{y}_c$, where c is a cluster subscript, not a particle subscript. The interaction within cluster c depends on $\mathbf{y}_c$ only. The kinetic energy of cluster c relative to its center of mass is represented by $-\Delta(\mathbf{y}_c)$. The total kinetic energy is

$$-\sum_{c=1}^{n}\Delta(\mathbf{y}_c)-\sum_{c=1}^{n}(2N_c)^{-1}\Delta(\mathbf{Y}_c).$$

Now apply to N_c, $\mathbf{Y}_c$ $(c=1,2,...,n)$ the coordinate transformation that took m_j, $\mathbf{X}_j$ $(j=1,2,...,n)$ into $\mathbf{x}_k$ $(k=1,2,...,n)$. Denoting the new variables by $\mathbf{x}_k$ as before takes the kinetic energy of the relative motion of the clusters into $-\Sigma_{j=1}^{n-1}\Delta(\mathbf{x}_j)$. The interaction between clusters b and c depends on $\mathbf{y}_b,\mathbf{y}_c$, and some or all of the $\mathbf{x}_j$ $(j=1,2,...,n-1)$, but not on the overall center-of-mass coordinate $\mathbf{x}_n$. Thus we find that

$$i\frac{\partial}{\partial t}=-\sum_{c=1}^{n}\Delta(\mathbf{y}_c)+\sum_{c=1}^{n}V_{cc}(\mathbf{y}_c)-\sum_{j=1}^{n-1}\Delta(\mathbf{x}_j)+\sum_{b<c}V_{bc}(\mathbf{y}_b,\mathbf{y}_c,\mathbf{x}_1,\ldots,\mathbf{x}_{n-1})-\Delta(\mathbf{x}_n). \quad (2.2)$$

In an obvious notation, V_{cc} and V_{bc} are interactions within cluster c and between clusters b and c, respectively. The operator $-\Delta(\mathbf{x}_n)$ represents the kinetic energy of the center of mass. To simplify the notation, we combine the vectors $\mathbf{y}_c$ $(c=1,2,,...,n)$ into a vector $\mathbf{y}$ and the vectors $\mathbf{x}_j$ $(j=1,2,...,n-1)$ into a vector $\mathbf{x}$. This takes the relative Hamiltonian for cluster c into

$$H_c(\mathbf{y}):=-\Delta(\mathbf{y}_c)+V_{cc}(\mathbf{y}_c).$$

The relative kinetic energy of the clusters is denoted by

$$-\Delta(\mathbf{x}):=-\sum_{j=1}^{n-1}\Delta(\mathbf{x}_j).$$

In this notation the Hamiltonian for the relative motion is

$$H:=\sum_c H_c(\mathbf{y})-\Delta(\mathbf{x})+\sum_{b<c}V_{bc}(\mathbf{x},\mathbf{y}).$$

There are many ways to separate a system of N particles into clusters. By Eq. (2.1) all choices transform the kinetic energy into the negative Laplace operator. This indicates that the transformations between various sets of coordinates are orthogonal and allows us to use different coordinates in different parts of the same problem. Moreover, in case there are $n-1$ intercluster coordinates $\mathbf{x}$ as in Eq. (2.2), the transformation from $(2m_j)^{1/2}\mathbf{X}_j$ to $\mathbf{y}$, $\mathbf{x}$, $\mathbf{x}_n$ is orthogonal, so that

$$d^{3N}X=\prod_{j=1}^{N}(2m_j)^{-1/2}d^{3N-3n}y\,d^{3n-3}x\,d^3x_n.$$

The mass factor is a constant which should be taken into account if one wishes to calculate actual physical values of matrix elements. In the present context, however, an overall numerical factor is of no consequence. Hence we ignore the mass factor and work with normalized functions of $\mathbf{y}$, $\mathbf{x}$, $\mathbf{x}_n$. In fact, since all cluster decompositions arrive at the same center-of-mass coordinate $\mathbf{x}_n$ equal to $(2/M_N)^{1/2}\Sigma_{j=1}^{N}m_j\mathbf{X}_j$, the transformations among the relative coordinates $\mathbf{y}$, $\mathbf{x}$ are orthogonal,

even if we change cluster decompositions. In studying the relative motion, it is therefore sufficient to work in terms of the usual inner product $(\cdot,\cdot)$ and norm $\|\cdot\|$ of $L^2(\mathbb{R}^{3N-3})$-functions depending on $\mathbf{x}$, $\mathbf{y}$.

III. SCATTERING THEORY

This section reviews concepts from scattering theory[8–10] that are used throughout the paper.

Consider a specific decomposition into n clusters, hence $(3n-3)$-dimensional relative motion $-\Delta(\mathbf{x})$, and assume that each multiparticle cluster Hamiltonian $H_c(\mathbf{y})$ has a normalized eigenvector $\psi_c(\mathbf{y})$ with eigenvalue E_c. Denote the product $\Pi_c \psi_c(\mathbf{y})$ by $\psi(\mathbf{y})$ and the sum $\Sigma_c E_c$ by E. The vector $\mathbf{y}$ must have $3N-3n$ components. Since $\psi(\mathbf{y})$ is normalized by assumption, the operator Ψ on $L^2(\mathbb{R}^{3N-3})$ defined by

$$\Psi f(\mathbf{x},\mathbf{y}) := \psi(\mathbf{y}) \int f(\mathbf{x},\mathbf{z})\overline{\psi}(\mathbf{z}) d^{3N-3n}z \tag{3.1}$$

is an orthogonal projection. If $f \in L^2(\mathbb{R}^{3N-3})$ belongs to the domain of H,

$$H\Psi f(\mathbf{x},\mathbf{y}) = \left[E - \Delta(\mathbf{x}) + \sum_{b<c} V_{bc}(\mathbf{x},\mathbf{y}) \right] \Psi f(\mathbf{x},\mathbf{y}). \tag{3.2}$$

For a more general notation, we consider all possible cluster decompositions of N particles and in each decomposition allow all possible bound-state wave functions ψ. We refer to the possibilities as scattering channels and label these by a subscript α. The bound-state wave function in channel α is denoted by ψ_α. It is a function of $\mathbf{y}_\alpha$. Typically, ψ_α is a product of several cluster functions ψ_c. The projection operator determined by ψ_α as in Eq. (3.1) is denoted by Ψ_α. The operators $\Sigma_{b<c} V_{bc}$ and $E-\Delta(\mathbf{x})$ in Eq. (3.2) are replaced by V_α and

$$H_\alpha := E_\alpha - \Delta(\mathbf{x}_\alpha). \tag{3.3}$$

Hence

$$H\Psi_\alpha f = (H_\alpha + V_\alpha)\Psi_\alpha f.$$

If all interaction terms V_α are of short range, there exist wave operators $\Omega_{\alpha\pm}$ satisfying

$$\lim_{t \to \mp\infty} \|\exp(iHt)\exp(-iH_\alpha t)\Psi_\alpha f - \Omega_{\alpha\pm} f\| = 0. \tag{3.4}$$

As a result of this definition, $\Omega_{\alpha\pm}$ annihilates the orthogonal complement of the range of Ψ_α,

$$\Omega_{\alpha\pm}(1-\Psi_\alpha)f = 0.$$

A sufficient condition for $\Omega_{\alpha\pm}$ to exist is that each term $V_{ij}(\mathbf{X}_i - \mathbf{X}_j)$ in the sum V_α is of the form $V_{ij} = V_2 + V_p$, where $V_2 \in L^2(\mathbb{R}^3)$ and $V_p \in L^p(\mathbb{R}^3)$ with some p satisfying $2<p<3$ (Ref. 9, Theorem X1.34). Another sufficient condition is that $\epsilon>0$ exists such that

$$(1+|\mathbf{X}|^2)^{\epsilon+1/2} V_{ij}(\mathbf{X}) = V_{3/2} + V_\infty,$$

where $V_{3/2} \in L^{3/2}(\mathbb{R}^3)$ and $V_\infty \in L^\infty(\mathbb{R}^3)$, see Ref. 9, Theorem X1.35. Generally speaking, these conditions are satisfied if $V_{ij}(\mathbf{X})$ does not have serious singularities and at infinity tends to 0 like $|\mathbf{X}|^{-1-\delta}$ with some $\delta>0$.

If $V_{ij}(\mathbf{X})$ behaves at infinity like $|\mathbf{X}|^{-\mu}$ with $\mu \leqslant 1$, the interaction is said to be of long range. In this case the limits in Eq. (3.4) do not exist, but it may be possible to construct modified wave operators provided the factor $\exp(-iH_\alpha t)$ in Eq. (3.4) is replaced by one that better characterizes the time evolution of scattered clusters at large separations.[11] If $\sqrt{3}-1<\mu\leqslant 1$ and V_{ij} satisfies

suitable smoothness conditions, modified wave operators exist for any number of particles.[10,12] Even in cases where $\mu \leqslant \sqrt{3}-1$, there are results for two particles.[13] For such very slowly decaying interactions, modified wave operators have been shown to exist in larger systems[10,12] provided cluster wave functions $\psi(\mathbf{y})$ go to 0 sufficiently rapidly as $|\mathbf{y}| \to \infty$.

Whether the interaction is of short or long range, henceforth we simply refer to wave operators and denote these quantities by $\Omega_{\alpha\pm}$. They all satisfy the intertwining relation

$$\exp(-iHt)\Omega_{\alpha\pm} = \Omega_{\alpha\pm} \exp(-iH_\alpha t). \tag{3.5}$$

Denoting the orthogonal projection onto the range of $\Omega_{\alpha\pm}$ by $\Pi_{\alpha\pm}$, we have

$$\Omega_{\alpha\pm}^* \Omega_{\alpha\pm} = \Psi_\alpha, \quad \Omega_{\alpha\pm}\Omega_{\alpha\pm}^* = \Pi_{\alpha\pm}.$$

Since

$$\Omega_{\beta\pm}^* \Omega_{\alpha\pm} = \delta_{\alpha\beta}\Psi_\alpha, \tag{3.6}$$

the projections $\Pi_{\alpha+}$ commute and have mutually orthogonal ranges. The same applies to the projections $\Pi_{\alpha-}$. Summing over channels, we define the projections

$$\Pi_\pm := \sum_\alpha \Pi_{\alpha\pm}.$$

The sum has finitely many terms or converges strongly.

Let B be the projection onto any bound states of the N-particle system. If the wave operators exist, BL^2 is orthogonal to $\Pi_\pm L^2$. If

$$BL^2 + \Pi_+ L^2 = BL^2 + \Pi_- L^2 = L^2,$$

the scattering is said to be asymptotically complete. Under various smoothness assumptions on the interaction, asymptotic completeness has been proved for short-range interactions[14,15] and for long-range interactions[12] with $\sqrt{3}-1 < \mu \leqslant 1$. In two-particle problems asymptotic completeness is even known to be true in cases in which $\mu \leqslant \sqrt{3}-1$.[13]
Examples show that the existence of wave operators is not sufficient for asymptotic completeness.[16]

The important point in the following is the intertwining relation (3.5). It provides the link between time evolutions with and without interaction. In the present paper we can use operators $\Omega_{\alpha+}$ throughout. This gives rise to an operator J_+ and space K_+^2. Alternatively, we can use operators $\Omega_{\alpha-}$ giving rise to J_- and K_-^2. The restriction $t \geqslant 0$ applies in either case. If the projections Π_+ and Π_- are equal, the spaces K_+^2 and K_-^2 are isometrically isomorphic, operators $A_+^{1/2}(t)$ acting on K_+^2 are unitarily equivalent to operators $A_-^{1/2}(t)$ acting on K_-^2, and each operator $\sigma_+(t)$ defined in terms of J_+ by Eq. (1.4) is unitarily equivalent to an operator $\sigma_-(t)$ defined in terms of J_-. This will become clear once the operators $J_\pm$ are defined in Sec. V.

Since the theories with subscripts $+$ and $-$ run parallel, we omit the subscripts in the following, writing

$$\Omega_\alpha \Omega_\alpha^* = \Pi_\alpha, \quad \Pi = \sum_\alpha \Pi_\alpha.$$

Thus Ω_α is either $\Omega_{\alpha+}$ or $\Omega_{\alpha-}$, and similarly for the other operators. The projection Π is the projection onto scattering states meant in Sec. I. If asymptotic completeness holds, $\Pi_+ = \Pi_-$, so that Π is uniquely determined.

Recall that L^2 stands for $L^2(\mathbb{R}^{3N-3})$. If in channel α the system is separated into n clusters, a $(3n-3)$-dimensional coordinate $\mathbf{x}_\alpha$ refers to the relative motion of the clusters. The wave function of the clusters depends on a $(3N-3n)$-dimensional coordinate $\mathbf{y}_\alpha$. For any $f \in \Pi L^2$,

$$\exp(-iHt)f=\exp(-iHt)\sum_{\alpha}\ \Omega_{\alpha}\Omega_{\alpha}^{*}f=\sum_{\alpha}\ \Omega_{\alpha}\exp(-iH_{\alpha}t)\Omega_{\alpha}^{*}f. \tag{3.7}$$

Since $\Omega_{\alpha}^{*}f$ belongs to the range of Ψ_{α}, there must be a function f_{α} such that

$$\Omega_{\alpha}^{*}f=\psi_{\alpha}(\mathbf{y}_{\alpha})f_{\alpha}(\mathbf{x}_{\alpha}). \tag{3.8}$$

To calculate f_{α}, it suffices to multiply $\Omega_{\alpha}^{*}f$ by $\overline{\psi}(\mathbf{y}_{\alpha})$ and integrate with respect to $\mathbf{y}_{\alpha}$. Due to Eqs. (3.3) and (3.8)

$$\exp(-iH_{\alpha}t)\Omega_{\alpha}^{*}f=\exp(-iE_{\alpha}t)\psi_{\alpha}(\mathbf{y}_{\alpha})\exp[i\Delta(\mathbf{x}_{\alpha})t]f_{\alpha}(\mathbf{x}_{\alpha}).$$

In the following we mainly use the momentum representation. Hence we replace $\exp[i\Delta(\mathbf{x}_{\alpha})t]f_{\alpha}(\mathbf{x}_{\alpha})$ by $\exp(-ik_{\alpha}^{2}t)f_{\alpha}(\mathbf{k}_{\alpha})$. For f to belong to K^{2}, the functions $f_{\alpha}(\mathbf{k}_{\alpha})$ have to satisfy analyticity conditions introduced in Sec. IV.

IV. ANALYTIC FUNCTIONS

This section discusses functions $f(\mathbf{k})\in L^{2}(\mathbb{R}^{\nu})$ that are meant as prototypes of Fourier transforms of functions $f_{\alpha}(\mathbf{x}_{\alpha})$ in Eq. (3.8). We follow Ref. 1 closely, but in the process generalize previous results for $L^{2}(\mathbb{R}^{3})$ so that they become valid on $L^{2}(\mathbb{R}^{\nu})$.

Denoting $|\mathbf{k}|$ by k, we introduce $\nu-1$ spherical coordinates ω and replace $f(\mathbf{k})$ by $f(k,\omega)$. Hence $k^{(\nu-1)/2}f(k,\omega)$ is an element of $L^{2}(\mathbb{R}^{+}\times S^{\nu-1})$.

The Mellin transform

$$M_{\nu}f(k,\omega)=f^{\#}(u,\omega)$$

defined by

$$f^{\#}(u,\omega):=(2\pi)^{-1/2}\int_{0}^{\infty}k^{(\nu-1)/2}f(k,\omega)k^{iu-1/2}\,\mathrm{d}k$$

is a unitary map taking $L^{2}(\mathbb{R}^{+}\times S^{\nu-1})$ onto the space $L^{2}(\mathbb{R}\times S^{\nu-1})$ consisting of functions $f^{\#}(u,\omega)$ with inner product

$$(f^{\#},g^{\#})=\int_{S^{\nu-1}}\int_{-\infty}^{\infty}f^{\#}(u,\omega)\overline{g^{\#}}(u,\omega)\mathrm{d}u\,\mathrm{d}\omega.$$

The inverse Mellin transform is determined by

$$k^{(\nu-1)/2}f(k,\omega)=(2\pi)^{-1/2}\int_{-\infty}^{\infty}f^{\#}(u,\omega)k^{-iu-1/2}\,\mathrm{d}u.$$

If we define $z:=\ln k$ and

$$F(z,\omega):=e^{\nu z/2}f(e^{z},\omega),$$

it follows that

$$F(z,\omega)=(2\pi)^{-1/2}\int_{-\infty}^{\infty}f^{\#}(u,\omega)e^{-izu}\,\mathrm{d}u.$$

For starters we now assume that $f^{\#}(u,\omega)\in C_{0}^{\infty}(\mathbb{R}\times S^{\nu-1})$. This guarantees that F belongs to the domain of $\partial/\partial z$. Applying $i\partial/\partial z$ to F corresponds to multiplying $f^{\#}$ by u. Because $\partial/\partial z=k\partial/\partial k$,

$$i\frac{\partial}{\partial z}F(z,\omega)=k^{\nu/2}\left[ik\frac{\partial}{\partial k}+i\nu/2\right]f(k,\omega). \tag{4.1}$$

The operator in square brackets is among our major concepts. To give it a more transparent form, we examine the dilation operator D_ν, which is the self-adjoint operator on $L^2(\mathbb{R}^\nu)$ that acts on C_0^∞-functions $f(\mathbf{k})\in L^2(\mathbb{R}^\nu)$ as

$$D_\nu=\frac{i}{2}(\mathbf{k}\cdot\nabla_k+\nabla_k\cdot\mathbf{k}).$$

The differential operator D_ν is equal to $i\mathbf{k}\cdot\nabla_k+i\nu/2$. The components of $\mathbf{k}$ are of the form $k_j=k\cos\theta_j(\omega)$, with some set of functions $\theta_j(\omega)$ $(j=1,2,...,\nu)$. Hence

$$k\partial/\partial k=\sum_{j=1}^{\nu}k\frac{\partial k_j}{\partial k}\partial/\partial k_j=\sum_{j=1}^{\nu}k_j\partial/\partial k_j=\mathbf{k}\cdot\nabla_k.$$

It follows that the operator in square brackets in Eq. (4.1) is the dilation operator D_ν. Multiplying Eq. (4.1) by $k^{-1/2}$ gives

$$k^{(\nu-1)/2}D_\nu f(k,\omega)=(2\pi)^{-1/2}\int_{-\infty}^{\infty}uf^{\#}(u,\omega)k^{-iu-1/2}\,du.$$

Following Ref. 1, we now extend multiplication by u on $C_0^\infty(\mathbb{R}\times S^{\nu-1})$ to a self-adjoint operator u on $L^2(\mathbb{R}\times S^{\nu-1})$, then use the operator u so defined to extend the differential operator D_ν to the self-adjoint operator $D_\nu=M_\nu^{-1}uM_\nu$ on $L^2(\mathbb{R}^\nu)$. The spectra of u and D_ν are absolutely continuous and run from $-\infty$ to ∞.

The self-adjoint operator D_ν determines $\exp(\phi D_\nu)$. Taking $\phi=-\pi/2$ we define

$$J_\nu:=\exp(-\pi D_\nu/2)=M_\nu^{-1}\exp(-\pi u/2)M_\nu \tag{4.2}$$

and let the domain of J_ν be the set of all $f\in L^2(\mathbb{R}^\nu)$ with the property that $f^{\#}(u,\omega)\exp(-\pi u/2)$ belongs to $L^2(\mathbb{R}\times S^{\nu-1})$. The operator J_ν so defined is self-adjoint and positive. Henceforth the domain of J_ν is denoted by K_ν^2. Hence K_ν^2 is the set of all $f\in L^2(\mathbb{R}^\nu)$ with the property that $J_\nu f\in L^2(\mathbb{R}^\nu)$.

Functions in K_ν^2 have certain analyticity properties. This can be seen by examining the set of all functions $f(ke^{i\phi},\omega)$ which are analytic in the sector $-\pi/2<\phi<0$ for almost every $\omega\in S^{\nu-1}$ and have the property that

$$\int_{S^{\nu-1}}\int_0^\infty|(ke^{i\phi})^{(\nu-1)/2}f(ke^{i\phi},\omega)|^2dk\,d\omega$$

is bounded uniformly in the sector.[17,18] Functions in this set have mean-square boundary values $f(k,\omega)$ and $f(ke^{-i\pi/2},\omega)$. Under the inner product

$$\langle f,g\rangle=\int_{S^{\nu-1}}\int_0^\infty[f(k,\omega)\overline{g}(k,\omega)+f(ke^{-i\pi/2},\omega)\overline{g}(ke^{-i\pi/2},\omega)]k^{\nu-1}\,dk\,d\omega \tag{4.3}$$

the set is a Hilbert space which we denote by G_ν^2.

At this point we can adapt the reasoning for $\nu=3$ in Refs. 1 and 2 to general ν. On the basis of known properties[17,18] of Mellin transforms of functions in G_ν^2, it can be shown that $f\in L^2(\mathbb{R}^\nu)$ belongs to K_ν^2 if and only if $f(k,\omega)$ is the boundary value at $\phi=0$ of a function $f(ke^{i\phi},\omega)$ in G_ν^2. Moreover, for $-\pi/2\leqslant\phi\leqslant0$,

$$e^{\phi D_\nu}f(k,\omega)=e^{i\nu\phi/2}f(ke^{i\phi},\omega). \tag{4.4}$$

We now define an inner product $\langle \cdot, \cdot \rangle$ on K^2_ν by

$$\langle f,g\rangle := (f,g) + (J_\nu f, J_\nu g)$$

$$= \int_{S^{\nu-1}} \int_{-\infty}^{\infty} (1+e^{-\pi u}) f^{\#}(u,\omega)\overline{g^{\#}}(u,\omega)\mathrm{d}u\,\mathrm{d}\omega.$$

The term $(J_\nu f, J_\nu g)$ is equal to the second term on the right-hand side in Eq. (4.3). The fact that G^2_ν is a Hilbert space can now be used to show that K^2_ν is complete under the inner product $\langle \cdot, \cdot \rangle$, hence a Hilbert space.

If $-\pi/2 < \phi < 0$, then $\exp(-ik^2 e^{2i\phi}t)$ is bounded if and only if $t \geqslant 0$. Hence $f \in G^2_\nu$ yields $\exp(-ik^2e^{2i\phi}t) f \in G^2_\nu$ if $t \geqslant 0$, but not necessarily if $t<0$. In terms of boundary values at $\phi = 0$, it follows that $f \in K^2_\nu$ yields $\exp(-ik^2 t) f \in K^2_\nu$ if $t \geqslant 0$, but not necessarily if $t<0$. This is the reason why we assume that $t \geqslant 0$, unless stated otherwise. Due to Eq. (4.4) with $\phi = -\pi/2$,

$$J_\nu \exp(-ik^2 t) f(k,\omega) = \exp(ik^2 t) J_\nu f(k,\omega), \tag{4.5}$$

provided $f \in K^2_\nu$ and $t \geqslant 0$. Taking $\phi = -\pi/4$ gives

$$J^{1/2}_\nu \exp(-ik^2 t) f(k,\omega) = \exp(-k^2 t) J^{1/2}_\nu f(k,\omega). \tag{4.6}$$

V. THE SPACE OF WAVE FUNCTIONS

The time evolution of $f \in \Pi L^2$ can be represented by Eq. (3.7). In the momentum representation Eq. (3.8) takes the form

$$\Omega^*_\alpha f = \psi_\alpha(\mathbf{K}'_\alpha) f_\alpha(\mathbf{k}_\alpha), \tag{5.1}$$

where $\mathbf{k}'_\alpha$ and $\mathbf{k}_\alpha$ are the variables conjugate to $\mathbf{y}_\alpha$ and $\mathbf{x}_\alpha$, respectively. If channel α refers to a separation into n clusters, the vector $\mathbf{k}_\alpha$ has $3n-3$ components. We let $3n-3$ be the number ν in Sec. IV and assume that $f_\alpha(\mathbf{k}_\alpha)$ belongs to K^2_ν, but we change the notation and now refer to operators D_α and J_α and a space K^2_α. Using the notation $\|\cdot\|$ for norms on L^2-spaces, we denote the norm on K^2_α by $|||\cdot|||$. Thus, if $f_\alpha \in K^2_\alpha$, then $\langle f_\alpha, f_\alpha \rangle$ is denoted by $|||f_\alpha|||^2$.

Let K^2 be the set of $f \in \Pi L^2$ with the property that $\Sigma_\alpha |||f_\alpha|||^2 < \infty$. If $f \in K^2$, then

$$\left\| \sum_{\alpha=m}^{n} \Omega_\alpha J_\alpha \Omega^*_\alpha f \right\|^2 = \sum_{\alpha=m}^{n} \|\psi_\alpha J_\alpha f_\alpha\|^2 \leqslant \sum_{\alpha=m}^{n} |||f_\alpha|||^2.$$

Since $\Sigma^n_{\alpha=m} |||f_\alpha|||^2$ tends to 0 as $m,n \to \infty$, the sum $\Sigma_{\alpha \leqslant n} \Omega_\alpha J_\alpha \Omega^*_\alpha f$ tends to a limit as $n \to \infty$. We denote the limit by Jf. This defines the operator

$$J := \sum_\alpha \Omega_\alpha J_\alpha \Omega^*_\alpha \tag{5.2}$$

on ΠL^2 with domain K^2.

It is easy to verify that J is symmetric. We claim that the operator J with domain K^2 is self-adjoint on ΠL^2. To prove this, it is sufficient to show that $(J \pm i) f$ runs through ΠL^2 when f runs through K^2. By the definition of J,

$$(J \pm i) f = \sum_\alpha \Omega_\alpha (J_\alpha \pm i) \Omega^*_\alpha f.$$

Recall that $\Omega^*_\alpha f = \psi_\alpha f_\alpha$, where f_α belongs to a certain $L^2(\mathbb{R}^\nu)$-space. The operator J_α on $L^2(\mathbb{R}^\nu)$ is self-adjoint. Its domain is the set $K^2_\alpha \in L^2(\mathbb{R}^\nu)$. Hence $(J_\alpha \pm i)\psi_\alpha f_\alpha$ runs through $\psi_\alpha L^2(\mathbb{R}^\nu)$

when f_α runs through K_α^2. In the process, $\Omega_\alpha(J_\alpha \pm i)\Omega_\alpha^* f$ runs through $\Omega_\alpha \Omega_\alpha^* L^2$. When f runs through K^2, each f_α runs through its set K_α^2, hence $(J\pm i)f$ runs through $\Sigma_\alpha \Omega_\alpha \Omega_\alpha^* L^2$, as we wanted to show.

Now that we know that J is self-adjoint, we can be more specific about the convergence properties of the sum Σ_α in Eq. (5.2). If f runs through K^2,

$$\sum_{\alpha \leqslant n} \Omega_\alpha J_\alpha \Omega_\alpha^* f \pm i f$$

runs through a dense set in ΠL^2. It follows that K^2 is a core for $\Sigma_{\alpha \leqslant n} \Omega_\alpha J_\alpha \Omega_\alpha^*$, for every n. By Ref. 19, Theorem VIII.25

$$\lim_{n\to\infty} \left\| \left(\sum_{\alpha \leqslant n} \Omega_\alpha J_\alpha \Omega_\alpha^* \pm i \right)^{-1} f - (J \pm i)^{-1} f \right\| = 0 \tag{5.3}$$

for every $f \in \Pi L^2$. The sets $(J\pm i)^{-1}\Pi L^2$ are both equal to the domain of J, which can therefore be identified without prior knowledge of K^2. Instead of looking at $\Sigma_\alpha |||f_\alpha|||^2$ to define K^2, we can construct J via Eq. (5.3). Then we can let K^2 be the set of $f \in \Pi L^2$ with the property that $Jf \in \Pi L^2$. Either way J is self-adjoint on ΠL^2 with domain K^2, hence the two definitions of K^2 are equivalent.

Given J, the relation (1.3) defines an inner product on K^2. Denoting $\langle f, f\rangle$ by $|||f|||^2$, we proceed to show that the set K^2 is complete under the $|||\cdot|||$ norm.

Let $\{f_n\}$ $(n=1,2,...)$ be a sequence in K^2 with the property that $|||f_m - f_n||| \to 0$ as $m,n \to \infty$. Then $\|f_m - f_n\| \to 0$ and $\|Jf_m - Jf_n\| \to 0$, hence there are elements f and g in ΠL^2 such that $\|f_n - f\| \to 0$ and $\|Jf_n - g\| \to 0$. Since J is self-adjoint, J is closed. Hence f must belong to the domain of J and $Jf = g$. In other words, $f \in K^2$ and

$$|||f_n - f|||^2 = \|f_n - f\|^2 + \|Jf_n - Jf\|^2 \to 0.$$

This shows that a sequence $\{f_n\}$ in K^2 that converges in the $|||\cdot|||$-norm has a limit f in K^2. Equipped with the $|||\cdot|||$ norm, the set K^2 is a Hilbert space with inner product $\langle \cdot, \cdot \rangle$. It is easily verified that

$$\langle f, g\rangle = ([1+J^2]^{1/2} f, [1+J^2]^{1/2} g).$$

The adjoint on K^2 of an operator $S: K^2 \to K^2$ is denoted by $S^\dagger$. We continue to denote the adjoint on L^2 of an operator $T: L^2 \to L^2$ by T^*. Hence

$$\langle Sf, g\rangle = \langle f, S^\dagger g\rangle, \quad (Tf, g) = (f, T^* g).$$

The domains of operators S and T are denoted by $\mathrm{Dom}(S)$ and $\mathrm{Dom}(T)$, respectively.

If $f \in K^2$ and $t \geqslant 0$, then $\exp(-iHt)f \in K^2$. Indeed, with Eq. (3.3) for H_α, it follows from the intertwining relation (3.5) and Eq. (5.2) that

$$\begin{aligned} J \exp(-iHt) f &= \sum_\alpha \Omega_\alpha J_\alpha \exp(-iH_\alpha t) \Omega_\alpha^* f \\ &= \sum_\alpha \Omega_\alpha \exp(iH_\alpha t) \exp(-2iE_\alpha t) J_\alpha \Omega_\alpha^* f \\ &= \exp(iHt) \sum_\alpha \Omega_\alpha \exp(-2iE_\alpha t) J_\alpha \Omega_\alpha^* f. \end{aligned}$$

Defining

$$W(t) := \sum_\alpha \Omega_\alpha \exp(-2iE_\alpha t)\Omega_\alpha^*$$

gives

$$J\exp(-iHt)f = \exp(iHt)W(t)Jf. \tag{5.4}$$

The operator $W(t)$ is unitary on ΠL^2 and commutes with $\exp(-iHt)$. It follows that $\|J\exp(-iHt)f\| = \|Jf\|$, hence $|||\exp(-iHtf\|| = |||f|||$.

In much the same way as we defined the operator J, we can introduce the square root

$$J^{1/2} = \sum_\alpha \Omega_\alpha J_\alpha^{1/2}\Omega_\alpha^*.$$

If $f \in K^2$, it follows with Eq. (4.6) that

$$J^{1/2}\exp(-iHt)f = W^{1/2}(t)\sum_\alpha \Omega_\alpha \exp(-k_\alpha^2 t)J_\alpha^{1/2}\Omega_\alpha^* f. \tag{5.5}$$

The norm of this vector decreases as t increases.

We note for future reference that

$$\langle \exp(-iHt)f, g\rangle = \sum_\alpha \langle \exp(-ik_\alpha^2 t - iE_\alpha t)f_\alpha, g_\alpha\rangle, \tag{5.6}$$

where the left-hand side is an inner product on K^2, the terms on the right-hand side are inner products on spaces K_α^2.

Recall that Ω_α denotes either $\Omega_{\alpha+}$ or $\Omega_{\alpha-}$. Thus Eq. (5.2) actually defines operators

$$J_\pm := \sum_\alpha \Omega_{\alpha\pm} J_\alpha \Omega_{\alpha\pm}^*$$

giving rise to spaces $K_\pm^2$ with inner products $\langle\cdot,\cdot\rangle_\pm$. Now consider

$$\Theta := \sum_\alpha \Omega_{\alpha-}\Omega_{\alpha+}^*.$$

This operator commutes with $\exp(-iHt)$. Due to Eq. (3.6)

$$\Theta J_+ \Theta^* = J_-, \quad \Theta^* J_- \Theta = J_+.$$

If $\Pi_+ = \Pi_- = \Pi$, then $\Theta\Theta^* = \Theta^*\Theta = \Pi$, so that Θ is a unitary operator on ΠL^2. Under this assumption $\Theta K_+^2 = K_-^2$ and

$$\begin{aligned}\langle f,g\rangle_+ &= (f,g) + (J_+ f, J_+ g)\\ &= (\Theta f, \Theta g) + (\Theta J_+ \Theta^*\Theta f, \Theta J_+ \Theta^*\Theta g)\\ &= (\Theta f, \Theta g) + (J_-\Theta f, J_-\Theta g) = \langle \Theta f, \Theta g\rangle_-.\end{aligned}$$

Hence K_+^2 and K_-^2 are isometrically isomorphic. If $f \in K_+^2$ and $A^{1/2}(t)f \in \Pi L^2$, then $\Theta A^{1/2}(t)\Theta^*\Theta f \in \Pi L^2$. Thus if the expectation value of $A(t)$ is chaotic when wave functions belong to K_+^2, the expectation value of $\Theta A(t)\Theta^*$ is chaotic when wave functions belong to K_-^2.

Following Eq. (1.5) we write

$$\sigma_+(t)=\rho(t)+J_+\rho(t)J_+ .$$

If Θ is unitary, it follows that

$$\Theta\sigma_+(t)\Theta^*=\Theta\rho(t)\Theta^*+J_-\Theta\rho(t)\Theta^*J_- .$$

Hence the pair ρ, J_+ determines the same entropy as the pair $\Theta\rho\Theta^*, J_-$.

VI. THE OPERATOR TOPOLOGY

The operator J and the space K^2 are important for our purposes because the chaotic and irreversible behavior that we want to discuss, occurs precisely when states belong to K^2. The quantities with chaotic time evolution are positive self-adjoint operators A such that $A^{1/2}$ maps K^2 into ΠL^2. If A is not bounded, it may happen that (Af, g) is not well defined. Hence for $f,g \in K^2$, matrix elements of A are expressed in the form

$$\langle f|A|g\rangle := (A^{1/2}f, A^{1/2}g). \tag{6.1}$$

These are the quantities meant in Sec. I.

Because the operator J and the space K^2 have essential properties in common with the corresponding quantities in Refs. 1 and 2, many previous results can be copied unchanged. In this section we review the steps to construct a topology for the operators A that will later be shown to have chaotic time evolutions. As mentioned before, the domain of an operator T is denoted by $\mathrm{Dom}(T)$. The restriction to K^2 of an operator $T:\Pi L^2 \to \Pi L^2$ is denoted by $T\restriction K^2$.

Let T be a positive self-adjoint operator on ΠL^2 such that $\mathrm{Dom}(T^{1/2}) \supseteq K^2$. Consider the quadratic form

$$q[f,g] := (T^{1/2}f, T^{1/2}g) \tag{6.2}$$

on ΠL^2 with form domain $\mathrm{Dom}(q)=K^2$.

Since $T^{1/2}\restriction K^2$ is symmetric, the form is closed or closable. Denote the closure by $\overline{q}$ and its form domain by $\mathrm{Dom}(\overline{q})$. The form $\overline{q}$ determines a positive self-adjoint operator A on ΠL^2 with domain $\mathrm{Dom}(A) \subset \mathrm{Dom}(\overline{q})$ and $\mathrm{Dom}(A^{1/2}) = \mathrm{Dom}(\overline{q})$. For every $f,g \in \mathrm{Dom}(\overline{q})$,

$$\overline{q}[f,g] = (A^{1/2}f, A^{1/2}g).$$

Since K^2 is a core for $\overline{q}$, the set K^2 is a core for $A^{1/2}$.

The above-mentioned propositions follow from two representation theorems for quadratic forms,[20] see Chap. VI, Sec. II. That K^2 is a core for $A^{1/2}$ implies that $A^{1/2}=(A^{1/2}\restriction K^2)^*$. The theorems depend on the fact that $T^{1/2}\restriction K^2$ is closable, but do not make comparisons between any extensions of $T^{1/2}\restriction K^2$ and $A^{1/2}\restriction K^2$ to domains larger than K^2. As long as $f,g \in K^2$,

$$(T^{1/2}f, T^{1/2}g) = (A^{1/2}f, A^{1/2}g).$$

For the purpose of calculating expectation values of observables in states $f,g \in K^2$, all positive self-adjoint operators T with the same $T^{1/2}\restriction K^2$ are equivalent. Henceforth we select the particular operator A that is singled out by the representation theorems. We denote by Γ the set of all positive self-adjoint operators A on ΠL^2 with the property that K^2 is a core for $A^{1/2}$. On Γ one can define a sum as well as multiplication by a positive constant. Hence Γ is a cone, which includes all bounded positive operators on ΠL^2.

We now choose $A \in \Gamma$ and focus on the quadratic form

$$q[f,g] := (A^{1/2}f, A^{1/2}g)$$

with form domain $\mathrm{Dom}(q)=K^2$. Since A is a special case of the operator T in Eq. (6.2), the form is closed or closable. It is shown in Ref. 2 that $(1+J^2)^{-1/2}A^{1/2}$ is a bounded linear operator on K^2. Hence the operator $\tilde{A}$ defined by

$$\tilde{A}:=[(1+J^2)^{-1/2}A^{1/2}]^{\dagger}(1+J^2)^{-1/2}A^{1/2} \tag{6.3}$$

is a bounded positive operator on K^2 satisfying

$$(A^{1/2}f,A^{1/2}g)=\langle \tilde{A}f,g\rangle \tag{6.4}$$

for every $f,g\in K^2$.

Let us denote by Γ_q the set of positive closable forms on ΠL^2 with form domain K^2. The representation theorems do not require that $q\in\Gamma_q$ be given in terms of an operator $T^{1/2}$ as in Eq. (6.2). Any $q\in\Gamma_q$ determines $A\in\Gamma$ and $A\in\Gamma$ determines $\tilde{A}$. Hence $q\in\Gamma_q$ is of the form $\langle\tilde{A}f,g\rangle$ with some $\tilde{A}$.

Now consider a positive operator $\tilde{T}$ on K^2 with the property that the form $\langle\tilde{T}f,g\rangle$ on ΠL^2 with form domain K^2 is closable. Since $\langle\tilde{T}f,g\rangle$ must exist for every $f,g\in K^2$, the operator $\tilde{T}$ must be bounded on K^2. The form $\langle\tilde{T}f,g\rangle$ determines A and A determines the bounded linear operator $\tilde{A}$ on K^2 satisfying

$$\langle\tilde{T}f,g\rangle=\langle\tilde{A}f,g\rangle$$

for every $f,g\in K^2$. This requires that $\tilde{T}=\tilde{A}$. Hence the set Γ_q is associated with a set $\tilde{\Gamma}$ consisting of uniquely determined operators $\tilde{A}$. There is an invertible function $A=\gamma(\tilde{A})$ mapping $\tilde{\Gamma}$ onto Γ.

In order that we can define chaos, we need a topology on Γ. We begin with the topology on $\tilde{\Gamma}$ induced by the weak topology for bounded linear operators on K^2. This turns $\tilde{\Gamma}$ into a topology space $\tilde{X}$ with the property that a net $\{\tilde{Z}_\tau\}\in\tilde{X}(\tau\geqslant 0)$ tends to $\tilde{A}\in\tilde{X}$ as $\tau\to\infty$ if and only if $\langle\tilde{Z}_\tau f,g\rangle$ tends to $\langle\tilde{A}f,g\rangle$ for every fixed $f,g\in K^2$. Via the map γ, it follows that

$$\lim_{\tau\to\infty}(Z_\tau^{1/2}f,Z_\tau^{1/2}g)=(A^{1/2}f,A^{1/2}g). \tag{6.5}$$

Conversely, if Eq. (6.5) is true for every $f,g\in K^2$, then $\tilde{Z}_\tau$ tends to $\tilde{A}$ in $\tilde{X}$.

Since Eq. (6.5) says that the expectation value of Z_τ tends to the expectation value of A as $\tau\to\infty$, it represents a convergence concept that is suitable for our purpose. It implies that both γ and its inverse γ^{-1} are continuous. Given the topology of $\tilde{X}$ and the fact that γ maps $\tilde{\Gamma}$ onto Γ, there is one and only one topology on Γ that makes γ and γ^{-1} continuous. Details about the open sets that determine this topology are in Ref. 2. With the topology that recognizes Eq. (6.5) as convergence on Γ, the set Γ becomes a topological space denoted by X. This is our space of observables A.

By a transcription of Eq. (6.5), a net $\{Z_\tau\}\in X$ tends to $A\in X$ as $\tau\to\infty$ if and only if $f,g\in K^2$ and $\epsilon>0$ determine $T>0$ such that

$$|(A^{1/2}f,A^{1/2}g)-(Z_\tau^{1/2}f,Z_\tau^{1/2}g)|<\epsilon \quad \text{if} \quad \tau>T.$$

We denote this relation by $\lim_{\tau\to\infty}Z_\tau=A$.

VII. THE TIME EVOLUTION

Given an operator $A\in X$, our goal is to show that there exist nets $\{Z_\tau\}$ $(\tau\geqslant 0)$ that tend to A as $\tau\to\infty$ while the $Z_\tau(t)$ with $t>0$ have the special properties required by the chaos theorems S, T, and P in Sec. VIII. For the proof we construct nets $\{\tilde{Z}_\tau\}$ that tend to $\tilde{A}$. These determine $Z_\tau=\gamma(\tilde{Z}_\tau)$ as desired. To control $\tilde{Z}_\tau(t)$, we need to know how the time evolution acts on K^2. To

simplify the notation, we denote $\exp(-iHt)$ by $U(t)$. Whether f is viewed as an element of ΠL^2 or K^2, the time evolution takes f into $f(t)=U(t)f$. The adjoint of $U(t)$ on ΠL^2 is denoted by $U^*(t)$. It acts as $\exp(iHt)$. The adjoint of $U(t)$ on K^2 is denoted by $U^\dagger(t)$. This operator differs from $U^*(t)$. Due to Eq. (5.4)

$$\langle U(t)f,U(t)g\rangle=\langle f,g\rangle, \tag{7.1}$$

so that $U(t)$ is an isometry on K^2. As a result the set $U(t)K^2$ is a subspace of K^2 which is closed in the K^2-norm. If $Q(t)$ denotes the orthogonal projection of K^2 onto $U(t)K^2$, it follows from general properties of isometries (Ref. 2. see Chap. V, Sec. 2) that

$$U(t)U^\dagger(t)=Q(t). \tag{7.2}$$

To investigate $U^\dagger(t)$ and the projection $Q(t)$, we decompose $U(t)$ according to Eq. (3.7) and take advantage of the close connection between the space G^2_ν and the Hardy space H^2 of the lower half-plane.[17] When $ke^{i\phi}$ varies in the sector $-\pi/2<\phi<0$, then $(ke^{i\phi})^2$ runs through the lower half-plane. Hence we define

$$v+iw:=k^2e^{2i\phi},\quad F(v+iw,w):=2^{-1}(ke^{i\phi})^{(\nu-2)/2}f_\nu(ke^{i\phi},\omega),$$

and similarly for $G(v+iw,\omega)$ in terms of g_ν. If $f_\nu,g_\nu\in G^2_\nu$,

$$\langle f_\nu,g_\nu\rangle=\int_{S^{\nu-1}}\int_{-\infty}^{\infty}F(v-i0,\omega)\tilde{G}(\nu-i0,\omega)\mathrm{d}v\ \mathrm{d}\omega.$$

The Fourier transform of F is

$$\hat{f}_\nu(s,\omega)=(2\pi)^{-1/2}\int_{-\infty}^{\infty}\exp(ivs)F(v-i0,\omega)\mathrm{d}v.$$

The function $F(v+iw,\omega)$ belongs to the space H^2 of the $(v+iw)$-variable if and only if $f_\nu\in G^2_\nu$. By the Paley–Wiener theorem[21] $\hat{f}_\nu(s,\omega)=0$ if $s<0$, for almost every $\omega\in S^{\nu-1}$.

Since the Fourier transform is unitary,

$$\langle f_\nu,g_\nu\rangle=\int_{S^{\nu-1}}\int_0^{\infty}\hat{f}_\nu(s,\omega)\overline{\hat{g}}_\nu(s,\omega)\mathrm{d}s\ \mathrm{d}\omega. \tag{7.3}$$

We derived this relation assuming that $f_\nu,g_\nu\in G^2_\nu$. Now recall that $f_\nu(k,\omega)\in K^2_\nu$ if and only if $f_\nu(k,\omega)$ is the boundary value of $f_\nu(ke^{i\phi},\omega)\in G^2_\nu$. Whether f_ν and g_ν are viewed as elements of G^2_ν or K^2_ν, the inner product $\langle f_\nu,g_\nu\rangle$ is the same. Hence there is a unitary map taking $f_\nu(k,\omega)\in K^2_\nu$ into $\hat{f}_\nu(s,\omega)\in L^2(\mathbb{R}^+\times S^{\nu-1})$ and Eq. (7.3) applies whenever $f_\nu,g_\nu\in K^2_\nu$.

The time evolution multiplies $f_\nu\in K^2_\nu$ by $\exp(-ik^2t)$ and $f_\nu(ke^{i\phi},\omega)\in G^2_\nu$ by $\exp(-ik^2e^{2i\phi}t)$. In the process $F(v+i0,\omega)$ is multiplied by $\exp(-ivt)$, taking $\hat{f}_\nu(s,\omega)$ into

$$(2\pi)^{-1/2}\int_{-\infty}^{\infty}\exp(ivs-ivt)F(v-i0,\omega)dv=\hat{f}_\nu(s-t,\omega).$$

It follows that

$$\begin{aligned}\langle\exp(-ik^2t)f_\nu,g_\nu\rangle&=\int_{S^{\nu-1}}\int_t^{\infty}\hat{f}_\nu(s-t,\omega)\overline{\hat{g}}_\nu(s,\omega)\mathrm{d}s\ \mathrm{d}\omega\\&=\langle f_\nu,[\exp(-ik^2t)]^\dagger g_\nu\rangle=\int_{S^{\nu-1}}\int_0^{\infty}\hat{f}_\nu(s,\omega)\overline{\hat{g}}_\nu(s+t,\omega)\mathrm{d}s\ \mathrm{d}\omega.\end{aligned} \tag{7.4}$$

Replacing ν by the appropriate channel subscript α, we may use Eq. (5.6) on the right-hand side in Eq. (7.4). For $f,g\in K^2$ it follows that

$$\begin{aligned}\langle U(t)f,g\rangle &= \sum_\alpha \int_{S_\alpha}\int_t^\infty \exp(-iE_\alpha t)\hat{f}_\alpha(s-t,\omega)\overline{\hat{g}}_\alpha(s,\omega)\mathrm{d}s\,\mathrm{d}\omega \\ &= \langle f,U^\dagger(t)g\rangle \\ &= \sum_\alpha \int_{S_\alpha}\int_0^\infty \hat{f}_\alpha(s,\omega)\exp(-iE_\alpha t)\overline{\hat{g}}_\alpha(s+t,\omega)\mathrm{d}s\,\mathrm{d}\omega. \end{aligned} \tag{7.5}$$

Replacing f by $U^\dagger(t)f$ gives

$$\langle Q(t)f,g\rangle = \sum_\alpha \int_{S_\alpha}\int_t^\infty \hat{f}_\alpha(s,\omega)\overline{\hat{g}}_\alpha(s,\omega)\mathrm{d}s\,\mathrm{d}\omega.$$

Since $Q(t)$ is an orthogonal projection

$$\|\|Q(t)f\|\|^2 = \sum_\alpha \int_{S_\alpha}\int_t^\infty |\hat{f}_\alpha(s,\omega)|^2\mathrm{d}s\,\mathrm{d}\omega.$$

This is a nonincreasing function of t which tends to 0 as $t\to\infty$.

The family $\{U(t)|0\leqslant t<\infty\}$ is a semigroup of operators on K^2. As in Ref. 2, it follows from the semigroup property and Eq. (7.2) that

$$Q(s)U(t) = \begin{cases} U(t) & \text{if } 0\leqslant s\leqslant t \\ U(t)Q(s-t) & \text{if } 0\leqslant t<s, \end{cases} \tag{7.6}$$

$$Q(s)Q(t) = Q(\max s,t). \tag{7.7}$$

If $A\in\Gamma$, it can be shown as in Ref. 2 that the quadratic form

$$q_t[f,g] := (A^{1/2}U(t)f, A^{1/2}U(t)g) = \langle U^\dagger(t)\tilde{A}U(t)f,g\rangle$$

with form domain K^2 is closable, and hence determines an operator $A_t\in\Gamma$. Moreover, A_t is equal to the self-adjoint operator $U^*(t)AU(t)$ with domain $U^*(t)\mathrm{Dom}(A)$. It follows that $U^*(t)AU(t)\in\Gamma$. We denote this operator by $A(t)$. It represents the observable A in the Heisenberg picture. Given a form $q[f,g]\in\Gamma_q$, we can extract $A\in\Gamma$, then construct $A(t)\in\Gamma$. Or we can replace f, g by $U(t)f, U(t)g$ to find q_t, then determine $A_t\in\Gamma$. Since the two procedures give the same result, the Heisenberg picture can be used without ambiguity. The operator in $\tilde{\Gamma}$ determined by $A(t)\in\Gamma$ is

$$\tilde{A}(t) := U^\dagger(t)\tilde{A}U(t).$$
