Recall that a family $\{\hat{K}(t) : t \in \mathbb{R}\}$ of operators on a Hilbert space $\mathcal{L}$ is said to be **strongly continuous** provided each $\hat{K}(t)$ has domain $\mathcal{L}$ and, for all $\psi \in \mathcal{L}$, the function $\mathbb{R} \to \mathcal{L}$ given by $t \mapsto \hat{K}(t)\psi$ is continuous. If, furthermore, $\hat{K}(0) = \hat{1}$ and each $\hat{K}(t)$ is bounded, then we call $\{\hat{K}(t) : t \in \mathbb{R}\}$ a **quantum system** on $\mathcal{L}$. In that case, we sometimes consider a family of vectors $\{\psi(t) : t \in \mathbb{R}\}$ such that

$$\psi(t) = \hat{K}(t)\psi(0).$$

A quantum system $\mathcal{U} = \{\hat{U}(t) : t \in \mathbb{R}\}$ on $\mathcal{L}$ is said to be **unitary** provided each operator $\hat{U}(t)$ is unitary. If, furthermore,

$$\hat{U}(t)\hat{U}(t') = \hat{U}(t + t')$$

for all $t, t' \in \mathbb{R}$, then we say that $\mathcal{U}$ is **conservative**.

The boundedness condition in our general definition of a quantum system is somewhat artificial, but convenient for our purposes. Our main concern is with conservative systems, and these have been thoroughly studied in various contexts and from various perspectives. For a detailed

introduction to conservative systems as quantum stochastic systems, see Ref. 9, Chap. 1. Let us recall some well-known properties of conservative systems (introducing some notation that will be convenient in the proof of Theorem 3.5).

Suppose that $\mathcal{U}$ is conservative. Stone's theorem asserts that there exists a unique Hermitian operator $\hat{H}$ on $\mathcal{L}$ such that

$$U(t)=\exp(-i\hat{H}t).$$

We call $\hat{H}$ the **Hamiltonian** for $\mathcal{U}$. Conversely, every Hermitian operator on $\mathcal{L}$ is the Hamiltonian of a conservative quantum system. The bijective correspondence $\hat{H}\leftrightarrow\mathcal{U}$ allows us to characterize conservative quantum systems by the Schrödinger equation

$$i\frac{d}{dt}\psi(t)=\hat{H}\psi(t).$$

For the sake of rigor, we must mention that, as a definition,

$$\exp(-i\hat{H}t):=\int_{-\infty}^{\infty}e^{-its}dE(s),$$

where E is the spectral family for $\hat{H}$. The notation on the right-hand side is as in Ref. 10, Chap. 7. It may be worth explaining what this equation tells us. Introducing some notation that will be of use in the proof of Theorem 3.5, let us consider an integer m, and write $\hat{E}_m$ for the orthogonal projection on $\mathcal{L}$ associated with E and the half-open interval $[m,m+1)$. [Intuitively, we might think of $\hat{E}_m$ as the projection to the subspace $\hat{E}_m\mathcal{L}$ of $\mathcal{L}$ spanned by those ''eigenvectors'' whose ''eigenvalues'' are at least m and less than $m+1$. The operator $\hat{H}$ restricts to an operator on each subspace $\hat{E}_m\mathcal{L}$. Vaguely, we might think of $\hat{E}_m$ as a kind of ''eigenspace,'' whose associated ''eigenvalue'' is spread across the interval $[m,m+1)$.] Any vector in $\mathcal{L}$ is a sum of vectors belonging to the spaces $\hat{E}_m\mathcal{L}$, so the unitary operator $\exp(-i\hat{H}t)$ is determined by the condition that it restricts to an operator on $\hat{E}_m\mathcal{L}$ given by

$$\exp(-i\hat{H}t)\psi=\sum_{l=0}^{\infty}\frac{(-i\hat{H}t)^l}{l!}\psi$$

for all $\psi\in\hat{E}_m\mathcal{L}$. (The series converges because $\hat{H}$ restricts to a bounded operator on $\hat{E}_m\mathcal{L}$.)

Stone's theorem may be found in Ref. 10, Theorem 7.38. The bijectivity of the correspondence $\hat{H}\leftrightarrow\mathcal{U}$ is given in Ref. 15, Theorem 7.37. See also Ref. 9, Theorem 13.1.

Given a quantum system $\mathcal{K}_\infty=\{\hat{K}_\infty(t):t\in\mathbb{R}\}$ on $\mathcal{L}_\infty$, and quantum systems $\mathcal{K}_n=\{\hat{K}_n(t):t\in\mathbb{R}\}$ on $\mathcal{L}_n$ for sufficiently large $n\in\mathcal{N}$, we say that $(\mathcal{K}_n)_n$ **converges** to $\mathcal{K}_\infty$ provided

$$\hat{K}_\infty(t)=\lim_{n\in\mathcal{N}}\hat{K}_n(t)$$

for all $t\in\mathbb{R}$. Obviously, $(\mathcal{K}_n)_n$ converges to at most one quantum system on $\mathcal{L}_\infty$. When $(\mathcal{K}_n)_n$ converges to $\mathcal{K}_\infty$, we call $\mathcal{K}_\infty$ the **limit** of $(\mathcal{K}_n)_n$, and we write $\mathcal{K}_\infty=\lim_{n\in\mathcal{N}}\mathcal{K}_n$.

Remark 3.1: Let $\mathcal{K}_\infty=\{\hat{K}_\infty(t):t\in\mathbb{R}\}$ and $\mathcal{K}_n=\{\hat{K}_n(t):t\in\mathbb{R}\}$, respectively, be quantum systems on $\mathcal{L}_\infty$ and on each $\mathcal{L}_n$. Write $\psi_\infty(t)=\hat{K}_\infty(t)\psi_\infty(0)$ and $\psi_n(t)=\hat{K}_n(t)\psi_n(0)$. Then we have a limit of quantum systems $\mathcal{K}_\infty=\lim_{n\in\mathcal{N}}\mathcal{K}_n$ if and only if, given any initial state vectors $\psi_\infty(0)$ in $\mathcal{L}_\infty$ and $\psi_n(0)$ in each $\mathcal{L}_n$ with $\psi_\infty(0)=\lim_{n\in\mathcal{N}}(\psi_n(0))$, and writing $\psi_\infty(t)=\hat{K}_\infty(t)\psi_\infty(0)$ and $\psi_n(t)=\hat{K}_n(t)\psi_n(0)$, we have $\psi_\infty(t)=\lim_{n\in\mathcal{N}}\psi_n(t)$ for all $t\in\mathbb{R}$.

Proof: This is obvious. □

In particular, Remark 3.1 tells us that if the limit holds for the quantum systems and for the initial vectors, then the limit holds for all the time-evolved vectors. In case this seems counter-intuitive, we point out that, if $\psi_n(t)$ is to be a "good approximation" to $\psi_\infty(t)$, one should first fix t, and then choose n.

Theorem 3.2: *Any quantum system on $\mathcal{L}_\infty$ is the limit of a sequence of quantum systems on the spaces $\mathcal{L}_n$.*

Proof: Let $\mathcal{K}_\infty=\{\hat{K}_\infty(t):t\in\mathbb{R}\}$ be a quantum system on $\mathcal{L}_\infty$. For each $t\in\mathbb{R}$, and $j,k\in\mathbb{N}$, we define

$$K_{j,k}(t):=\langle\beta_{j,\infty}|\hat{K}_\infty(t)\beta_{k,\infty}\rangle.$$

Let $\hat{K}_n(t)$ be the operator in $\mathcal{L}_n$ constructed from the matrix entries $K_{j,k}(t)$ as in the proof of Theorem 2.4. Let $\mathcal{K}_n=\{\hat{K}_n(t):t\in\mathbb{R}\}$. Using the condition that $\mathcal{K}_\infty$ is strongly continuous, it is easy to check that each $\mathcal{K}_n$ is strongly continuous. □

Proposition 3.3: *Let $\hat{H}_\infty$ and each $\hat{H}_n$ be bounded Hermitian operators on $\mathcal{L}_\infty$ and $\mathcal{L}_n$, respectively, and suppose that the norms $\|\hat{H}_n\|$ are bounded. Let $\mathcal{U}_\infty$ and each $\mathcal{U}_n$ be the conservative systems with Hamiltonians $\hat{H}_\infty$ and $\hat{H}_n$, respectively. Then $\mathcal{U}_\infty=\lim_{n\in\mathcal{N}}\mathcal{U}_n$ if and only if $\hat{H}_\infty=\lim_{n\in\mathcal{N}}\hat{H}_n$.*

Proof: Write $\mathcal{U}_\infty=\{\hat{U}_\infty(t):t\in\mathbb{R}\}$ and $\mathcal{U}_n=\{\hat{U}_n(t):t\in\mathbb{R}\}$. For $m\in\mathbb{N}$, let

$$\hat{K}_{m,\infty}(t):=\sum_{k=0}^{m}\frac{(-i\hat{H}_\infty t)^k}{k!}\quad\text{and}\quad\hat{K}_{m,n}(t):=\sum_{k=0}^{m}\frac{(-i\hat{H}_n t)^k}{k!}.$$

Then $\hat{U}_\infty(t)=\lim_{m\to\infty}\hat{K}_{m,\infty}(t)$ and $\hat{U}_n(t)=\lim_{m\to\infty}\hat{K}_{m,n}(t)$.

Let $\epsilon>0$. Consider vectors $\phi\in\mathcal{S}$ and $\psi_\infty\in\mathcal{L}_\infty$ and $\psi_n\in\mathcal{L}_n$ such that $\psi_\infty=\lim_n\psi_n$. Write $\phi_n=\mathrm{res}_n(\phi)$. Let A be an upper bound for $\|\phi\|$ and $\|\phi_n\|$. Let B be an upper bound for $\|\hat{H}_\infty\|$ and $\|\hat{H}_n\|$. Let C be an upper bound for $\|\psi_\infty\|$ and $\|\psi_n\|$. Choose m such that

$$2AC\sum_{k=m}^{\infty}|Bt|^k/k!\leqslant\epsilon.$$

Then $\|\hat{U}_\infty(t)-K_{m,\infty}(t)\|\leqslant\epsilon/2AC\geqslant\|\hat{U}_n(t)-K_{m,n}(t)\|$ for sufficiently large n. Hence

$$|\langle\phi|\hat{U}_\infty(t)-\hat{K}_{m,\infty}(t)|\psi_\infty\rangle-\langle\phi_n|\hat{U}_n-\hat{K}_{m,n}(t)|\psi_n\rangle|\leqslant\epsilon.$$

If $\hat{H}_\infty=\lim_n\hat{H}_n$, then, by Remark 2.3, $\hat{K}_{m,\infty}=\lim_n\hat{K}_{m,n}$, hence $\hat{U}_\infty(t)\psi_\infty=\lim_{n\in\mathcal{N}}\hat{U}_n(t)\psi_n$.

Conversely, suppose that $\hat{U}_\infty(t)\psi_\infty=\lim_{n\in\mathcal{N}}\hat{U}_n(t)\psi_n$. Given t, we can put $\epsilon=t^2/2$ (and then choose m), where

$$|\langle\phi|\hat{K}_{m,\infty}(t)\psi_\infty\rangle-\langle\phi_n|\hat{K}_{m,n}(t)\psi_n\rangle|=O(t^2)$$

for sufficiently large n. Equating coefficients of t (the sums $\Sigma_{k=0}^{m}|\hat{H}_n t|^k/k!$ and the similar sum for $\hat{H}_\infty$ are bounded by $e^{B|t|}$), we obtain $\hat{H}_\infty\psi_\infty=\lim_n\hat{H}_n\psi_n$. □

Corollary 3.4: Let $\mathcal{U}_\infty$ be a conservative system on $\mathcal{L}_\infty$ with bounded Hamiltonian $\hat{H}_\infty$. Then there exist conservative systems $\mathcal{U}_n$ on $\mathcal{L}_n$ with bounded Hamiltonians $\hat{H}_n$ such that $\mathcal{U}_\infty=\lim_{n\in\mathcal{N}}\mathcal{U}_n$ and $\hat{H}_\infty=\lim_{n\in\mathcal{N}}\hat{H}_n$.

Proof: This is immediate from Corollary 2.5 and Proposition 3.3. □

Theorem 3.5: *Any conservative system on $\mathcal{L}_\infty$ is the limit of a sequence of conservative systems on the spaces $\mathcal{L}_n$.*

Proof: Let $\mathcal{U}_\infty=\{\hat{U}_\infty(t):t\in\mathbb{R}\}$ be a conservative system on $\mathcal{L}_\infty$, let $\hat{H}_\infty$ be the Hamiltonian for $\mathcal{U}_\infty$, and let E be the spectral family for $\hat{H}_\infty$. For each $m\in\mathbb{Z}$, let $\hat{E}_m$ be the orthogonal projection as above, and let $\mathcal{L}_{m,\infty}=\hat{E}_m\mathcal{L}_\infty$. The Hermitian operator $\hat{H}_\infty$ restricts to a Hermitian operator $\hat{H}_{m,\infty}$ on $\mathcal{L}_{m,\infty}$. Let $\mathcal{U}_{m,\infty}=\{\hat{U}_{m,\infty}(t):t\in\mathbb{R}\}$ be the conservative system on $\mathcal{L}_{m,\infty}$ with Hamiltonian $\hat{H}_{m,\infty}$. Any vector $\psi_\infty\in\mathcal{L}_\infty$ has a unique decomposition as a sum

$$\psi_\infty=\sum_{m\in\mathbb{Z}}\psi_{m,\infty}$$

where each $\psi_{m,\infty}\in\mathcal{L}_{m,\infty}$. We have $\hat{H}_\infty\psi_{m,\infty}=\hat{H}_{m,\infty}\psi_{m,\infty}$ and

$$\hat{U}_\infty(t)\psi_\infty=\sum_{m\in\mathbb{Z}}\hat{U}_{m,\infty}(t)\psi_{m,\infty}.$$

It is easy to see that there exists an enumerated orthonormal basis $\mathcal{B}_\infty=\{\beta_{j,\infty}:j\in J_\infty\}$ such that each $\beta_{j,\infty}$ belongs to one of the subspaces $\mathcal{L}_{m,\infty}$. The enumerated orthonormal sets $\mathcal{B}_n$, as in Sec. II, may be chosen such that each $J_n\subseteq J_\infty$. For each $m\in\mathbb{Z}$, let

$$J_\infty(m):=\{j\in J_\infty:\beta_{j,\infty}\in\mathcal{L}_{m,\infty}\}\quad\text{and}\quad J_n(m):=J_n\cap J_\infty(m).$$

Let $\mathcal{L}_{m,n}$ be the subspace of $\mathcal{L}_n$ spanned by the vectors $\beta_{j,n}$ such that $j\in J_n(m)$. Any vector $\chi_n\in\mathcal{L}_n$ has a unique decomposition as a sum

$$\chi_n=\chi_n^\perp+\sum_{m\in\mathbb{Z}}\chi_{m,n},$$

where $\chi_n^\perp\in\mathcal{L}_n^\perp$, and each $\chi_{m,n}\in\mathcal{L}_{m,n}$. For $j,k\in J_\infty$, let

$$H_{j,k}=\langle\beta_{j,\infty}|\hat{H}_\infty\beta_{k,\infty}\rangle.$$

Note that $H_{j,k}=\overline{H_{k,j}}$, and $H_{j,k}=0$ unless $j,k\in J_\infty(m)$ for some $m\in\mathbb{Z}$. Let $\hat{H}_{m,n}$ be the Hermitian operator on $\mathcal{L}_{m,n}$ such that

$$H_{j,k}=\langle\beta_{j,n}|\hat{H}_{m,n}\beta_{k,n}\rangle$$

for $j,k\in J_n(m)$. Let $\mathcal{U}_{m,n}=\{\hat{U}_{m,n}(t):t\in\mathbb{R}\}$ be the conservative system on $\mathcal{L}_{m,n}$ with Hamiltonian $\hat{H}_{m,n}$. Let $\hat{H}_n$ be the Hermitian operator on $\mathcal{L}_n$ such that $\hat{H}_n\chi_n^\perp=0$ and $\hat{H}_n\chi_{m,n}=\hat{H}_{m,n}\chi_{m,n}$. Let $\mathcal{U}_n=\{\hat{U}_n(t):t\in\mathbb{R}\}$ be the conservative system on $\mathcal{L}_n$ with Hamiltonian $\hat{H}_n$. Then

$$\hat{U}_n(t)\chi_n=\chi_n^\perp+\sum_{m\in\mathbb{Z}}\hat{U}_{m,n}(t)\chi_{m,n}.$$

We are to show that $\hat{U}_\infty(t)=\lim_{n\in\mathcal{N}}\hat{U}_n(t)$ for all $t\in\mathbb{R}$.

For each $n\in\mathcal{N}$, let $\psi_n\in\mathcal{L}_n$, and suppose that $\psi_\infty=\lim_{n\in\mathcal{N}}\psi_n$. Write

$$\psi_\infty=\sum_{j=0}^{\infty}c_{j,\infty}\beta_{j,\infty}\quad\text{and}\quad\psi_n=\psi_n^\perp+\sum_{j=0}^{\infty}c_{j,n}\beta_{j,n}$$

as in Sec. II. Fix $t\in\mathbb{R}$, and let $\theta_\infty=\hat{U}_\infty(t)\psi_\infty$ and $\theta_n=\hat{U}_n\psi_n$. We are to show that $\theta_\infty=\lim_n\theta_n$. Write

$$\theta_\infty = \sum_{j=0}^{\infty} d_{j,\infty}\beta_{j,\infty} \quad \text{and} \quad \theta_n = \theta_n^\perp + \sum_{j=0}^{\infty} d_{j,n}\beta_{j,n}$$

as we did for ψ_∞ and ψ_n. The norms $\|\theta_n\| = \|\psi_n\|$ are bounded. So, by Theorem 2.2, we are to show that $d_{j,\infty} = \lim_n d_{j,n}$ for all $j \in J_\infty$. Fix $j \in J_\infty$, and let m be such that $j \in J_\infty(m)$. We have

$$d_{j,\infty} = \sum_{k \in J_\infty(m)} \langle \beta_{j,\infty} | \hat{U}_{m,\infty}(t) \beta_{k,\infty} \rangle c_{k,\infty}.$$

The equation still holds with the symbol n instead of the symbol ∞. Replacing $\hat{H}_\infty$ with the Hermitian operator $\hat{E}_m \hat{H}_\infty = \hat{H}_\infty \hat{E}_m$ does not change $\hat{H}_{m,\infty}$ or $\hat{H}_{m,n}$, so it does not change $\hat{U}_{m,\infty}$ or $\hat{U}_{n,m}$. So it does not change $d_{j,\infty}$ or $d_{j,n}$. Therefore, we may assume that $\hat{H}_{m',\infty} = 0$ for all integers $m' \neq m$. Hence $\hat{H}_{m',n} = 0$ for all $m' \neq m$ and all $n \in \mathcal{N}$. But now $\hat{H}_\infty$ is bounded, indeed $\|\hat{H}_\infty\| \leqslant |m| + 1$. Furthermore, the operators $\hat{H}_n$ are constructed from $\hat{H}_\infty$ just as the operators $\hat{K}'_n$ were constructed from $\hat{K}_\infty$ in the proof of Theorem 2.4. So $\hat{H}_\infty = \lim_{n \in \mathcal{N}} \hat{H}_n$. Thanks to Proposition 3.3, the argument is now complete. □

Corollary 3.6: Any unitary operator on $\mathcal{L}_\infty$ is the limit of a sequence of unitary operators on the spaces $\mathcal{L}_n$.

Proof: Given a unitary operator $\hat{U}_\infty$ on $\mathcal{L}_\infty$, then by Ref. 10 Exercise 7.50, there exists a conservative system $\{\hat{U}_\infty(t) : t \in \mathbb{R}\}$ such that $\hat{U}_\infty = \hat{U}_\infty(1)$. Theorem 3.5 now gives the assertion. □

A more direct way to demonstrate Corollary 3.6 is to adapt the proof of Theorem 2.4, using the Gram–Schmidt process to modify the columns of the matrices $(K_{j,k})_{j,k \in J_n}$. The argument is fairly routine, although it is complicated by the need to make some arbitrary choices when the Gram–Schmidt process terminates prematurely.

The existence results above can be interpreted as saying that, in principle, any ''continuum'' system (of a particular kind) is the limit of a sequence of ''discrete'' systems (of the same kind). The next result provides one way of actually recognizing that a given ''continuum'' system is the limit of a given sequence of ''discrete'' systems.

Proposition 3.7: Let $\mathcal{U}_\infty = \{\hat{U}_\infty(t) : t \in \mathbb{R}\}$ be a conservative system on $\mathcal{L}_\infty$, and for each $n \in \mathcal{N}$, let $\mathcal{U}_n = \{\hat{U}_n(t) : t \in \mathbb{R}\}$ be a conservative system on $\mathcal{L}_n$. Let $\hat{H}_\infty$ and $\hat{H}_n$, respectively, be the Hamiltonians. Let $\mathcal{B}_\infty$ and $\mathcal{B}_n$ be as in Sec. II. Suppose that, for each $j \in J_\infty$, there exists a real $\lambda_{j,\infty}$ such that

$$\hat{H}_\infty \beta_{j,\infty} = \lambda_{j,\infty} \beta_{j,\infty}.$$

Suppose also that, for sufficiently large n, there exist reals $\lambda_{j,n}$ such that

$$\hat{H}_n \beta_{j,n} = \lambda_{j,n} \beta_{j,n}.$$

Then $\mathcal{U}_\infty = \lim_{n \in \mathcal{N}} \mathcal{U}_n$ if and only if $\lambda_{j,\infty} = \lim_{n \in \mathcal{N}} \lambda_{j,n}$ for all $j \in J_\infty$.

Proof: This follows quickly from Theorem 2.2. □

Proposition 3.7 yields an alternative (and very easy) proof of Theorem 3.5 in the special case of a conservative system on $\mathcal{L}_\infty$ with a diagonalizable Hamiltonian.

IV. SOME EXAMPLES OF CONTINUUM LIMITS OF DISCRETE SYSTEMS

In all the examples to follow, we shall apply Proposition 3.7 to show that the given ''continuum'' system is the limit of the given sequence of ''discrete'' systems. Each of the inductive resolutions is a sample-point inductive resolution, as in Ref. 6, Examples 2.A–2.F. Sample-point inductive resolutions are examined also in Ref. 7.

Example 4.A: The circular rotor. The rotor, in one dimension, is a model for a particle moving freely on a circle. Classically, the energy is proportional to the square of the angular momentum.

Let $\mathcal{S}$ be the space of smooth functions $\phi:\mathbb{R}\to\mathbb{C}$ such that ϕ has period unity and ϕ is square-integrable on a bounded domain. The inner product on $\mathcal{S}$ is given by integration over an interval of length unity. Making a suitable choice of units, the Hamiltonian $\hat{H}_\infty$ of the rotor has domain $\mathcal{S}$ and satisfies

$$\hat{H}_\infty\phi(x)=-d^2\phi(x)/dx^2$$

for $\phi\in\mathcal{S}$ and $x\in\mathbb{R}$. The completion $\mathcal{L}_\infty$ of $\mathcal{S}$ has an orthonormal basis $\mathcal{B}_\infty=\{\beta_{j,\infty}:j\in\mathbb{N}\}$ given by

$$\beta_{j,\infty}(x)=\begin{cases}\sqrt{2}\cos(\pi jx) & \text{if } j \text{ is even,}\\ \sqrt{2}\sin(\pi(j+1)x) & \text{if } j \text{ is odd.}\end{cases}$$

It is easy to check that $\mathcal{B}_\infty$ diagonalizes $\mathcal{H}_\infty$, indeed, $\hat{H}_\infty\beta_{j,\infty}=\lambda_{j,\infty}\beta_{j,\infty}$, where

$$\lambda_{j,\infty}=\begin{cases}\pi^2j^2 & \text{if } j \text{ is even,}\\ \pi^2(j+1)^2 & \text{if } j \text{ is odd.}\end{cases}$$

Let $\mathcal{N}$ be the set of positive odd integers. For each $n\in\mathcal{N}$, let $\mathcal{L}_n$ be the n-dimensional inner product space consisting of the functions $\mathbb{Z}\to\mathbb{C}$ with period n. The inner product on $\mathcal{L}_n$ is given by summation over n consecutive integers. We replace the differential operator $-d^2/dx^2$ with a difference operator $\hat{H}_n$ where

$$\hat{H}_n\psi(X)=n^2(-\psi(X-1)+2\psi(X)-\psi(X+1))$$

for $\psi\in\mathcal{L}_n$ and $X\in\mathbb{Z}$. Given an integer j with $0\leqslant j\leqslant n-1$, we put

$$\beta_{j,n}(X)=\begin{cases}\sqrt{2/n}\cos(\pi jX/n) & \text{if } j \text{ is even,}\\ \sqrt{2/n}\sin(\pi(j+1)X/n) & \text{if } j \text{ is odd.}\end{cases}$$

It is easy to check that $\{\beta_{j,n}:0\leqslant j\leqslant n-1\}$ is an orthonormal basis for $\mathcal{L}_n$ diagonalizing $\hat{H}_n$. Writing $\hat{H}_n\beta_{j,n}=\lambda_{j,n}\beta_{j,n}$, then

$$\lambda_{j,n}=\begin{cases}2n^2(1-\cos(2\pi jX/n)) & \text{if } j \text{ is even,}\\ 2n^2(1-\cos(2\pi(j+1)X/n)) & \text{if } j \text{ is odd.}\end{cases}$$

Let $\mathcal{U}_\infty$ be the conservative system on $\mathcal{L}_\infty$ with Hamiltonian $\hat{H}_\infty$. For each $n\in\mathcal{N}$, let $\mathcal{U}_n$ be the conservative system on $\mathcal{L}_n$ with Hamiltonian $\hat{H}_n$. Of course, it is heuristically ''obvious'' that $\mathcal{U}_\infty$ is some kind of ''limit'' of $\mathcal{U}_n$, but in order to formulate this observation mathematically, we must realize $(\mathcal{L}_n)_n$ as an inductive resolution of $\mathcal{L}_\infty$. We define $\mathrm{res}_n:\mathcal{S}\to\mathcal{L}_n$ such that

$$\mathrm{res}_n(\phi)(X)=\phi(X/n)/\sqrt{n}$$

for $\phi\in\mathcal{S}$ and $X\in\mathbb{Z}$ with $-n/2<X<n/2$. It is easy to check that the sequence $(\mathcal{L}_n)_n$, equipped with the sequence $(\mathrm{res}_n)_n$, is indeed an inductive resolution of $\mathcal{L}_\infty$. (In fact, this is the precisely the one-dimensional case of Ref. 6, Example 2.F.) Given $j\in\mathbb{N}$, then, for all $n>j$, we have $\beta_{j,n}=\mathrm{res}_n(\beta_{j,\infty})$. Therefore, $\beta_{j,\infty}=\lim_{n\in\mathcal{N}}\beta_{j,n}$. Since $\lambda_{n,\infty}=\lim_{n\in\mathcal{N}}\lambda_{j,n}$, Proposition 3.7 tells us that

$$\mathcal{U}_\infty=\lim_{n\in\mathcal{N}}\mathcal{U}_n.$$

Example 4.B: The one-dimensional box. For each $j\in\mathbb{N}$ and $x\in[-\frac{1}{2},\frac{1}{2}]$, we write

$$\beta_{j,\infty}(x)=\begin{cases}\sqrt{2}\cos(\pi(j+1)x) & \text{if } j \text{ is even,}\\ \sqrt{2}\sin(\pi(j+1)x) & \text{if } j \text{ is odd.}\end{cases}$$

Let $\mathcal{L}_\infty$ be the Hilbert space with orthonormal basis $\{\beta_{j,\infty}: j\in\mathbb{N}\}$. Let $\mathcal{S}$ be the dense subspace of $\mathcal{L}_\infty$ consisting of the smooth functions $[-\frac{1}{2},\frac{1}{2}]\to\mathbb{C}$. The box, in one dimension, is the conservative system $\mathcal{U}_\infty$ whose Hamiltonian $\hat{H}_\infty$ has domain $\mathcal{S}$ and is given by

$$\hat{H}_\infty\phi(x)=-d^2\phi(x)/dx^2$$

for $\phi\in\mathcal{S}$. Evidently $\hat{H}_\infty\beta_{j,\infty}=\lambda_{j,\infty}\beta_{j,\infty}$ where $\lambda_{j,\infty}=\pi^2(j+1)^2$.

Again, let $\mathcal{N}$ be the set of positive odd integers. Let $\mathcal{L}_n$ be the n-dimensional inner product space consisting of the complex-valued functions on the integers X lying in the interval $-n/2<X<n/2$. As in the previous example, we replace the differential operator $-d^2/dx^2$ with a difference operator $\hat{H}_n$, but this time the sample-points indexed by $(1-n)/2$ and $(n-1)/2$ are to be interpreted as end-points (they are no longer interpreted as being adjacent). Writing $n=2l+1$, we put

$$\hat{H}_n\psi(X)=\begin{cases}n^2(2\psi(-l)-\psi(1-l)) & \text{if } X=-l,\\ n^2(-\psi(X-1)+2\psi(X)-\psi(X+1)) & \text{if } -l<X<l,\\ n^2(-\psi(l-1)+2\psi(l)) & \text{if } X=l.\end{cases}$$

The operator $\hat{H}_n$ is diagonalized by the orthonormal basis $\mathcal{B}_n=\{\beta_{j,n}: 0\leqslant j\leqslant n-1\}$ of $\mathcal{L}_n$, where

$$\beta_{j,n}(X)=\begin{cases}\sqrt{\dfrac{2}{n-1}}\cos\left(\dfrac{\pi(j+1)X}{n+1}\right) & \text{if } j \text{ is even,}\\ \sqrt{\dfrac{2}{n+1}}\sin\left(\dfrac{\pi(j+1)X}{n+1}\right) & \text{if } j \text{ is odd.}\end{cases}$$

In fact, $\hat{H}_n\beta_{j,n}=\lambda_{j,n}\beta_{j,n}$ where $\lambda_{j,n}=2(1-\cos(\pi(j+1)/(n+1)))$.

We realize $(\mathcal{L}_n)_n$ as an inductive resolution of $\mathcal{L}_\infty$ by defining $\mathrm{res}_n:\mathcal{S}\to\mathcal{L}_n$ by the same formula as in Example 4.A. A straightforward calculation yields, for all $j\in\mathbb{N}$, all $x\in[-\frac{1}{2},\frac{1}{2}]$ and all sequences $(X_n)_n$ of integers such that $x=\lim_{n\in\mathcal{N}}X_n/\sqrt{n}$, the point-wise convergence condition

$$\beta_{j,\infty}(x)=\lim_{n\in\mathcal{N}}\sqrt{n}\beta_{j,n}(X_n/n).$$

The norms $\|\beta_{j,n}\|$ are all unity, and, in particular, they are bounded. In Ref. 7, Theorem 3.1, it was proved that point-wise convergence of vectors with bounded norms implies convergence; in particular,

$$\beta_{j,\infty}=\lim_{n\in\mathcal{N}}\beta_{j,n}.$$

Observing that each $\lambda_{j,\infty}=\lim_{n\in\mathcal{N}}\lambda_{j,n}$, we again conclude from Proposition 3.7 that

$$\mathcal{U}_\infty=\lim_{n\in\mathcal{N}}\mathcal{U}_n.$$

Example 4.C: The Harper function harmonic oscillator. In this example and the next, we review some results from Refs. 11 and 12, and we show how that material can be streamlined using Proposition 3.7. Recall that $L^2(\mathbb{R})$ has an orthonormal basis $\{h_{j,\infty}: j\in\mathbb{N}\}$ consisting of the functions $h_{j,\infty}:\mathbb{R}\to\mathbb{C}$, called the **Hermite–Gaussians**, which are given by

$$h_{j,\infty}(x) = C_j e^{-x^2/2} H_j(x),$$

where H_j is the Hermite polynomial of degree j, and C_j is a positive real normalization constant. The **continuum harmonic oscillator** is defined to be the conservative system $\mathcal{U}_\infty = \{\hat{U}_\infty(t) : t \in \mathbb{R}\}$ whose Hamiltonian $\hat{H}_\infty$ is given by $\hat{H}_\infty \psi(x) = (-d^2/dx^2 + x^2)\psi(x)$, or equivalently, $\hat{H}_\infty h_{j,\infty} = (2k+1) h_{j,\infty}$. Thus

$$\hat{U}_\infty(t) h_{j,\infty} = e^{-(2j+1)it} h_{j,\infty}.$$

Let $\mathcal{N}$ be an infinite set of positive integers such that $\sqrt{n_2/n_1} \in \mathbb{Z}$ for all $n_1, n_2 \in \mathcal{N}$ with $n_1 \leqslant n_2$. (At one point in the discussion, we shall make use of this peculiar hypothesis on $\mathcal{N}$, but the assertions probably hold for any infinite set $\mathcal{N}$ of positive integers.) Given an element $n \in \mathcal{N}$, let $\mathcal{L}_n$ be the n-dimensional inner product space consisting of the functions $\mathbb{Z} \to \mathbb{C}$ with period n. We realize $(\mathcal{L}_n)_n$ as an inductive resolution of $L^2(\mathbb{R})$ by defining restriction maps $\mathrm{res}_n : \mathcal{S}(\mathbb{R}) \to \mathcal{L}_n$ such that

$$\mathrm{res}_n(\phi)(X) = (n/2\pi)^{-1/4} \phi((n/2\pi)^{-1/2} X)$$

for $\phi \in \mathcal{S}(\mathbb{R})$ and $X \in \mathbb{Z}$. After Harper,[13] Namias,[1] Pei–Yeh[3] and others, we define the **Harper function harmonic oscillator** to be the conservative system $\mathcal{U}_n$ on $\mathcal{L}_n$ with Hamiltonian $\hat{H}_n$ such that

$$\hat{H}_n \psi(X) = \frac{n}{2\pi}(-\psi(X-1) + (4 - 2\cos(2\pi i X/n))\psi(X) - \psi(X+1))$$

for $\psi \in \mathcal{L}_n$ and $X \in \mathbb{Z}$. The definition and enumeration of the Harper functions $\beta_{0,n}, \beta_{1,n}, \ldots$ may be found in Ref. 3; see also Refs. 11 and 12. The Harper functions comprise an orthonormal basis for $\mathcal{L}_n$, they are eigenvectors of $\hat{H}_n$, and by Ref. 12, Theorem 2.5,

$$h_{j,\infty} = \lim_{n \in \mathcal{N}} \beta_{j,n}$$

for all $j \in \mathcal{N}$. (It is here that the peculiar hypothesis on $\mathcal{N}$ is used.) Combining this result with Ref. 12, Lemmas 3.1 and 3.9, it is easy to show that the eigenvalue $\lambda_{j,n}$ of $\hat{H}_n$ associated with $\beta_{j,n}$ satisfies

$$2j+1 = \lim_{n \in \mathcal{N}} \lambda_{j,n}.$$

Proposition 3.7 now yields

$$\mathcal{U}_\infty = \lim_{n \in \mathcal{N}} \mathcal{U}_n.$$

As suggested in Ref. 7, Sec. 3, the peculiar hypothesis on $\mathcal{N}$ can perhaps be relaxed using results that were not available when Ref. 12 was written.

Example 4.D: The Harper function fractional Fourier transform. We continue to use the notation from Example 4.C. After Namias, the **continuum FRFT** is defined to be the conservative system $\mathcal{F}_\infty = \{\hat{F}^t_\infty : t \in \mathbb{R}\}$ such that

$$\hat{F}^t_\infty h_{j,\infty} = e^{2\pi i j t} h_{j,\infty}.$$

As Namias observed, the continuum FRFT and the continuum harmonic oscillator are related by the equality

$$\hat{U}_\infty(t)=e^{-it}\hat{F}_\infty^{-t/\pi}.$$

Note that $\hat{F}^{1/4}$ is the usual Fourier transform. The **Harper function FRFT** comes in two versions, the **import** version $\mathcal{I}_n=\{\hat{I}_n^t:t\in\mathbb{R}\}$ and the **domestic** version $\mathcal{D}_n=\{\hat{D}_n^t:t\in\mathbb{R}\}$. The import version, defined by

$$\hat{I}_n^t\beta_{j,n}=e^{2\pi ijt}\beta_{j,n},$$

is perhaps rather artificial (its eigenvalues being ''imported'' from the continuum FRFT), but it has the virtue that $\hat{F}_n^{1/4}$ is the usual discrete Fourier transform. The domestic version, defined by

$$\hat{U}_n(t)=e^{-it}\hat{D}_n^{-t/\pi},$$

has the virtue that it has an explicit Hamiltonian, namely $(\hat{H}_n-1)/2$. By Proposition 3.7,

$$\mathcal{F}_\infty=\lim_{n\in\mathcal{N}}\mathcal{I}_n=\lim_{n\in\mathcal{N}}\mathcal{D}_n.$$

Example 4.E: The Kravchuk function harmonic oscillator. We retain the notation from Examples 4.C and 4.D, except that we now let $\mathcal{N}$ be any set of positive integers. Given $n\in\mathcal{N}$, let us write $n=2l+1$, and let $\mathcal{X}_n$ be the set consisting of the X such that $l+X$ and $l-X$ are both natural numbers. We write $L(\mathcal{X}_n)$ to denote the n-dimensional inner product space consisting of the complex-valued functions on $\mathcal{X}_n$. As in Ref. 7, Secs. 4 and 5, we realize $(L(\mathcal{X}_n))_n$ as an inductive resolution of $L^2(\mathbb{R})$ by defining $\mathrm{res}_n:\mathcal{S}(\mathbb{R})\to L(\mathcal{X}_n)$ such that

$$\mathrm{res}_n(\phi)(X)=l^{-1/4}\phi(l^{-1/2}X)$$

for $\phi\in\mathcal{S}(\mathbb{R})$ and $X\in\mathcal{X}_n$. Recall (or see Ref. 7, Sec. 5) that the Kravchuk functions $h_{j,n}$ comprise an orthonormal basis $\{h_{j,n}:0\leqslant j\leqslant n-1\}$ for $L(\mathcal{X}_n)$. The Kravchuk functions are discrete analog of the Hermite–Gaussians, and arise from a binomial weight function in place of a Gaussian weight function. By Ref. 7, Theorem 5.1,

$$h_{j,\infty}=\lim_{n\in\mathcal{N}}h_{j,n}$$

for all $j\in\mathbb{N}$. After Ref. 14, the **Kravchuk function harmonic oscillator** is defined to be the conservative system $\hat{K}_n=\{\hat{K}_n(t):t\in\mathbb{R}\}$ on $\mathcal{L}_n$ such that

$$\hat{H}_n(t)h_{j,n}=e^{-(2j+1)it}h_{j,n}.$$

By Proposition 3.7,

$$\mathcal{U}_\infty=\lim_{n\in\mathcal{N}}\mathcal{K}_n.$$

Example 4.F: The Kravchuk function fractional Fourier transform. We retain the notation from the previous three examples, $\mathcal{N}$ being any infinite set of positive integers. After Ref. 2, the **Kravchuk function FRFT** is defined to be the conservative system $\mathcal{F}_n=\{\hat{F}_n^t:t\in\mathbb{R}\}$ such that

$$\hat{F}_n^t h_{j,n}=e^{2\pi ijt}h_{j,n}.$$

Equivalently, $\mathcal{F}_n$ may be defined by

$$\hat{K}_n(t)=e^{-it}\hat{F}_n^{-t/\pi}.$$

By Proposition 3.7,

$$\mathcal{F}_\infty = \lim_{n \in \mathcal{N}} \mathcal{F}_n .$$

Comment: Advantages of the Kravchuk function FRFT over the Harper function FRFT. In applications of the Harper function FRFT, one must select either the import version, whose eigenvalues are integer powers of $e^{2\pi i t}$, but whose Hamiltonian is not known explicitly, or else one must select the domestic version, whose Hamiltonian is $(\hat{H}_n - 1)/2$, but whose eigenvalues are not known explicitly. Either way, the eigenvectors—the Harper functions—lack a known explicit formula, and have to be calculated numerically. The eigenvectors of the Kravchuk function FRFT $\mathcal{F}_n$ are integer powers of $e^{2\pi i t}$. As can be gleaned from Refs. 2 and 5, the Hamiltonian for $\mathcal{F}_n$ has a very simple description in terms of the n-dimensional irreducible representation of the Lie algebra su(2) (see also Ref. 4). The eigenvectors of $\mathcal{F}_n$—the Kravchuk functions—are given by a complicated but explicit formula.

V. SOME QUESTIONS AND REMARKS ON CONVERGENCE OF SPECTRA

An alternative description of a conservative system is provided by the spectral measure associated with the Hamiltonian. Throughout this section, we consider conservative systems $\mathcal{U}_\infty = \{\hat{U}_\infty(t) : t \in \mathbb{R}\}$ on $\mathcal{L}_\infty$ and $\mathcal{U}_n = \{\hat{U}_n(t) : t \in \mathbb{R}\}$ on each $\mathcal{L}_n$. Let $\hat{H}_\infty$ and $\hat{H}_n$ be the Hamiltonians for $\mathcal{U}_\infty$ and $\hat{U}_n$, respectively. If $\mathcal{U}_\infty = \lim_{n \in \mathcal{N}} \mathcal{U}_n$, how is the spectral measure for the Hermitian operator $\mathcal{H}_\infty$ related to the spectral measure for the operators $\mathcal{H}_n$? Or, more simply, how is the spectrum $\sigma(\hat{H}_\infty)$ (or the essential or residual spectrum) related to the spectra $\sigma(\hat{H}_n)$?

On the one hand, it would be desirable to have techniques for investigating the spectrum (or spectral measure) of an infinite-dimensional system by examining limiting properties of the spectra of finite-dimensional approximations. On the other hand, finite-dimensional systems are themselves of interest. (As a vague principle, any closed system of finite extent in space can have only finitely many independent nondecaying states.) Finite-dimensional systems are not always more amenable than infinite-dimensional systems (difference equations often have richer solutions than their analogous differential equations.) In connection with example 4.E, it is worth remembering that De Moivre, having established the correspondence between the Gaussian distribution and the binomial distribution, then employed the Gaussian as an approximation to the binomial. Continuum approximation to discrete phenomena has pervaded statistical techniques ever since. It is to be expected that results relating $\sigma(\hat{H}_\infty)$ and $\sigma(\hat{H}_n)$ could be usefully applied in either direction.

As regards practical methods for relating the spectra of discrete and continuum systems, the results in this article are simply not in competition with those in Ref. 8. We do not know whether or not their results can be extended to our more general context. (It should be mentioned that the examples considered in Sec. 4 are all, essentially, in the situation they considered.) The following result indictates that the questions above do have answers, and that our approach can be developed to yield alternative and more general methods.

Proposition 5.1: Suppose that $\mathcal{U}_\infty = \lim_n \mathcal{U}_n$. Suppose also that $\hat{H}_\infty$ and each $\hat{H}_n$ are bounded, and that the norms $\|\hat{H}_n\|$ are bounded. Then every point $\lambda \in \sigma(\hat{H}_n)$ is the limit $\lambda = \lim_n \lambda_n$ of points $\lambda_n \in \sigma(\hat{H}_n)$.

Proof: The condition $\lambda \in \sigma(\hat{H}_\infty)$ is equivalent to the condition that there exists a sequence $(\phi_m)_m$ of vectors in $\mathcal{L}_\infty$ such that $\|\phi_m\| = 1$ and $\|(\hat{H}_\infty - \lambda)\phi_m\| \to 0$ as $m \to \infty$ (see, for instance, Ref. 15, Theorem 5.10). Since $\mathcal{S}$ is dense in $\mathcal{L}_\infty$, we may insist that each $\phi_m \in \mathcal{S}$. Let $\epsilon > 0$, and fix m such that $\|(\hat{H}_\infty - \lambda)\phi_m\| \leqslant \epsilon/2$. By Proposition 3.3, the convergence hypothesis on $\mathcal{U}_\infty$ is equivalent to the condition that $\hat{H}_\infty = \lim_n \hat{H}_n$. Noting that $\lim_n \|\mathrm{res}_n(\phi_m)\| = 1$, and putting $\psi_n = \mathrm{res}_n(\phi_m)/\|\mathrm{res}_n(\phi_m)\|$, we have $\|(\hat{H}_n - \lambda)\psi_n\| \leqslant \epsilon$ for sufficiently large n. By a well-known criterion for existence of spectral points in an interval (see Ref. 12, Theorem 5.9), $\sigma(\hat{H}_n) \cap [\lambda - \epsilon, \lambda + \epsilon] \neq \varnothing$. □

Corollary 5.2: In the situation of Proposition 5.1, suppose that the limits $\lim_n \mu_n$ *of points* $\mu_n \in \sigma(\hat{H}_n)$ *comprise a discrete subset of* $\mathbb{R}$. *Then* $\hat{H}_n$ *is diagonalizable.* □

It seems probable that the boundedness condition in Proposition 5.1 can be removed by using a refinement of the argument (and the rider to Stone's theorem as recorded in Ref. 9, Theorem 13.1). A more systematic option would be to wait for that to become a corollary of a result expressing the condition $\mathcal{U}_\infty = \lim_n \mathcal{U}_n$ in terms of the spectral measures. We end with a few comments in this direction. Consider an interval I in $\mathbb{R}$. Write $\overline{I}$ and I° for the closure and the interior. Let $E_{I,\infty}$ and $E_{I,n}$ be the corresponding projections to $\mathcal{L}_\infty$ and $\mathcal{L}_n$ associated with $\hat{H}_\infty$ and $\mathcal{H}_n$. To see that convergence of the sequence $(\hat{H}_n)_n$ does not imply convergence of the sequence $(E_{I,n})_n$, let a be an end-point of I, and let $\hat{H}_n = (a + (-2)^n)\hat{1}$.

Question 5.A: Are the following conditions equivalent?

(1) $\mathcal{U}_\infty = \lim_n \mathcal{U}_n$.
(2) *If* $\psi_\infty = \lim_n \psi_n$ *with* $\psi_n \in E_{I,n}\mathcal{L}_n$, *then* $\psi_\infty \in E_{\overline{I},n}\mathcal{L}_\infty$.
(3) *If* $\psi_\infty = \lim_n \psi_n$ *with* $\psi_\infty \in E_{I^\circ,n}\mathcal{L}_\infty$ *and* $\|\psi_\infty\| = \lim_n \|\psi_n\|$, *then* $\lim_n \|(\hat{1} - \hat{E}_{I,n})\psi_n\| = 0$.

(Received 8 April 2001; accepted for publication 28 June 2001)

We consider a family of four-dimensional nonlinear sigma models based on an O(5) symmetric group, whose fields take their values on the 4-sphere S^4. An SO(4)-subgroup of the model is gauged. The solutions of the model are characterized by two distinct topological charges, the Chern–Pontryagin charge of the gauge field and the degree of the map, i.e., the winding number, of the S^4 field. The one-dimensional equations arising from the variation of the action density subjected to spherical symmetry are integrated numerically. Several properties of the solutions thus constructed are pointed out. The only solution with *unit* Chern–Pontryagin charge are the usual BPST instantons with zero S^4 winding number, while solutions with *unit* S^4 winding number have zero Chern–Pontryagin charge.
 [DOI: 10.1063/1.1396636]

I. INTRODUCTION

The model considered in this work is described by the Lagrangian on $\mathbb{R}^4$

$$\mathcal{L}=\frac{\lambda_0}{24}|F_{\mu\nu}^{[\alpha\beta]}|^2+\frac{\lambda_1}{2}|D_\mu\phi^a|^2+\frac{\lambda_2}{24}|D_\mu\phi^a\times D_\nu\phi^b|^2$$

$$+\frac{\lambda_3}{72}|D_\mu\phi^a\times D_\nu\phi^b\times D_\rho\phi^c|^2+V(\phi^5,\cos\omega), \tag{1}$$

in terms of the S^4 valued fields $\phi^a=(\phi^\alpha,\phi^5)$ $(\alpha=1,2,3,4)$ satisfying the constraint

$$\phi^a\phi^a=1,$$

and the SO(4) gauge connection $A_\mu^{[\alpha\beta]}$ with curvature $F_{\mu\nu}^{[\alpha\beta]}$. The covariant derivatives in (1) are defined by

$$D_\mu\phi^\alpha=\partial_\mu\phi^\alpha+A_\mu^{[\alpha\beta]}\phi^\beta,\quad D_\mu\phi^5=\partial_\mu\phi^5. \tag{2}$$

(The brackets $[\cdots]$ imply antisymmetrization of indices throughout.)

The Lagrangian (1) differs from that of the various models considered in Ref. 1, in the physically important respect that the kinetic term *quadratic* in the S^4 field ϕ^a, which was absent

there,[1] is present here. Without a *quadratic* kinetic term, it is not possible to infer from *finite action conditions*, that that the matter field (in this case the S^4 valued field) becomes asymptotically a constant and hence consistent with *vacuum* field. It would then be impossible to interpret the resulting topologically stable finite action solution as an instanton. As a result of the Derrick scaling requirement, the system (1) features also a kinetic term *sextic* in the S^4 valued field. (1) differs from that in Ref. 1 also in the presence of the generic potential $V(\phi^5,\cos\omega)$

$$V(\phi^5,\omega)=\lambda(\cos\omega-\phi^5)^n, \quad 0\leqslant\omega\leqslant\pi, \quad n=\text{integer}, \tag{3}$$

whose role it is to fix the asymptotic value of the field ϕ^a, rather like the pion-mass potential in the usual three-dimensional O(4) Skyrme[2] model. Like in that case,[2] this term serves only the purpose of fixing the asymptotics, and will be considered only in this limited context. Moreover, anticipating our conclusions in Sec. II A, namely that only for $\omega=0$ is it possible to construct finite action solutions, the relevant $V(\phi^5,\omega=0)$ is

$$V(\phi^5,\omega=0)=\lambda(1-\phi^5), \tag{4}$$

in analogy with the pion-mass[2] potential. Notwithstanding, in Sec. II B we have described a model differing from (1) and characterized by nonzero ω (in particular $\omega=\pi/2$), which can support topologically stable finite action solutions. As will be seen there, the Lagrangian of such a model does not feature the usual YM term and is therefore not studied further here.

Our topologically stable finite action solutions are interpreted as instantons, although the latter are not always characterized by the second Chern–Pontryagin density, but also by the $S^4\to S^4$ degree of the S^4 valued field (which may or may not be integer).

By adapting the methods formulated in Ref. 3 used in establishing the topological lower bounds given by the degree of the map $S^4\to S^4$, a suitable such lower bound can be established for the action (1), for all positive values of λ_1, λ_2, λ_3, and λ_0. This will be established in Sec. II. In Sec. III, the system (1) will be subjected to spherical symmetry, and thenceforth we will restrict to the study of the ensuing one-dimensional equations numerically. The results of our numerical work is presented in Sec. IV, and Sec. V is devoted to the summary and discussion of our results.

In the work of Ref. 1, which employs the above model (1) with $\lambda_1=\lambda_3=0$, it was found that the action of the main SO(4) gauged O(5) model decreased with the Skyrme coupling λ_2 and exhibited a bifurcation at a value very close to and above the action of the (pure) Yang–Mills (YM) instanton.[4] Thus beyond a critical value of the coupling λ_2, the system did not support a finite action solution, and more importantly the action could be made smaller by decreasing λ_2. Our main aim in the present work is the verification of these two properties of the solutions when $\lambda_1>0$ and $\lambda_3>0$. We have found that these properties of the solution persist, namely that instantons can be constructed for values of λ_2 (holding λ_3 constant) up to some value λ_2^{cr}, and for values of λ_3 (holding λ_2 constant) up to some value λ_3^{cr}. Also, the actions of these instantons decrease with λ_2 and λ_3, respectively, consistently with the Derrick scaling requirement. We find surprisingly that the action at $\lambda_2=0$ is nonzero, inspite of the vanishing of the topological lower bound at that point. We defer discussion of the possible physical significance of these properties to Sec. V.

Another objective here is to probe the nature of the topological lower bounds. In Ref. 1, we were exclusively concerned with lower bounds stated in terms of the degree of the map of the S^4 valued field, such that the corresponding solutions supported *vanishing* Chern–Pontryagin charge. Here we attempt to construct numerically, instantons with *nonzero* Pontryagin charge when the S^4 field is nontrivial. We do not find such solutions and offer an analytic argument to support their nonexistence.

The boundary conditions employed for the S^4 valued field are

$$\lim_{r\to 0}\phi^5=-1, \quad \lim_{r\to\infty}\phi^5=\cos\omega, \tag{5}$$

but we will be restricting our numerical investigations to the $\omega=0$ case. For the gauge field we will adopt the vacuum behaviors

$$\lim_{r\to 0} A_\mu = 0, \quad \lim_{r\to\infty} A_\mu = qg\,\partial_\mu g^{-1}. \tag{6}$$

$q=0$ leads to zero Pontryagin charge. Pure-gauge $q=1$, and half-pure-gauge $q=\frac{1}{2}$, both lead to nonzero Pontryagin charges. The half-pure-gauge case $q=\frac{1}{2}$ pertains to $\omega\neq 0$, which we do not study numerically. The pure-gauge cases $q=0$ and $q=1$ both pertain to $\omega=0$, and are studied numerically. It turns out that instantons with nontrivial (S^4 valued) matter field can only be constructed for the $q=0$ case.

II. LOWER BOUNDS

The work in this section follows very closely that in Ref. 3 and that in Sec. II of Ref. 1. The analysis in Refs. 3 and 1 was adapted to the definition of topological charges presenting lower bounds on the actions, of systems supporting asymptotics with $\omega=0$ in (5). Here, we extend this analysis to include values of $0\leqslant\omega\leqslant\pi$. In the generic case therefore, we would expect solutions with a *fractional* analogue of the Baryon number in three dimensions,[5] while in the limiting case[1,3] $\omega=0$ this will be the degree of the map of the S^5 valued field taking an *integer* value.

We start with the definition of the winding number density

$$\varrho_0 = \frac{1}{64\pi^2}\varepsilon_{\mu\nu\rho\sigma}\varepsilon^{abcde}\partial_\mu\phi^a\partial_\nu\phi^b\partial_\rho\phi^c\partial_\sigma\phi^d\phi^e, \tag{7}$$

which is inadequate for our purposes here since it is *gauge variant*, and its *gauge invariant* version

$$\varrho_G = \frac{1}{64\pi^2}\varepsilon_{\mu\nu\rho\sigma}\varepsilon^{abcde}D_\mu\phi^a\,D_\nu\phi^b\,D_\rho\phi^c\,D_\sigma\phi^d\,\phi^e, \tag{8}$$

whose volume integral cannot be evaluated by stating the asymptotic conditions, i.e., it is not useful as a topological charge density.

The volume integral of (7) can indeed be evaluated by stating the asymptotic conditions (5), such that for $\omega=0$ the value of this integral is integer, and is fractional for $\omega\neq 0$. The normalization ensures that in the spherically symmetric case this is the unit charge, or winding number. The task is to define a suitable density which is (a) gauge invariant, and (b) its volume integral equals the volume integral of the density ϱ_0 (7).

To this end we find the relation between the two densities (7) and (8), in suitable form, such that *all gauge-variant terms appear as total divergences*. Thus,

$$\begin{aligned}\varrho_G = \varrho_0 + \partial_\mu(\phi^5\partial_\nu\Omega_{\nu\mu} + \tilde{\Omega}_\mu) + \frac{3}{64\pi^2}\varepsilon_{\mu\nu\rho\sigma}\varepsilon^{\alpha\beta\gamma\delta} \\ \times[\phi^\alpha D_\nu\phi^\beta D_\mu\phi^5 F^{\gamma\delta}_{\rho\sigma} - \tfrac{1}{8}\phi^5(1-\tfrac{1}{3}(\phi)^2)F^{\alpha\beta}_{\mu\nu}F^{\gamma\delta}_{\rho\sigma}],\end{aligned} \tag{9}$$

where

$$\Omega_{\nu\mu} = \frac{3}{64\pi^2}\varepsilon_{\mu\nu\rho\sigma}\varepsilon^{\alpha\beta\gamma\delta}A_\sigma\phi^\alpha(2\partial_\rho\phi^\beta + (A_\rho\phi)^\beta), \tag{10}$$

$$\tilde{\Omega}_\mu = \frac{3}{128\pi^2}\varepsilon_{\mu\nu\rho\sigma}\varepsilon^{\alpha\beta\gamma\delta}\left\{\phi^5\left(1-\frac{1}{3}(\phi)^2\right)A^{\gamma\delta}_\nu\left[\partial_\rho A^{\alpha\beta}_\sigma - \frac{2}{3}(A_\rho A_\sigma)^{\alpha\beta}\right]\right\}. \tag{11}$$

The volume integral of the (gauge-variant) total divergence terms in (9) can, after conversion to two surface integrals, be evaluated using the asymptotic values (5) and (6). If these surface

integrals vanished, then the volume integral of the remaining gauge-invariant terms could be expressed in terms of the volume integral of ϱ_0, namely the (integral or fractional) winding number, leading to the definition of a gauge-invariant topological charge density.

This can be checked by substituting the spherically symmetric Ansatz (31) and (32) in (10) and (11). One then sees immediately that the density (10) vanishes asymptotically by symmetry, while the density (11) yields a nonvanishing contribution to the corresponding surface integral, which depends on the asymptotic parameter ω. Thus the definition of the charge density to be given below is ω-dependent.

Making use of the relation

$$\tfrac{1}{4}\varepsilon_{\mu\nu\rho\sigma}\varepsilon^{\alpha\beta\gamma\delta}F^{\alpha\beta}_{\mu\nu}F^{\gamma\delta}_{\rho\sigma}=\varepsilon_{\mu\nu\rho\sigma}\varepsilon^{\alpha\beta\gamma\delta}\partial_\mu\{A^{\gamma\delta}_\nu[\partial_\rho A^{\alpha\beta}_\sigma-\tfrac{2}{3}(A_\rho A_\sigma)^{\alpha\beta}]\} \tag{12}$$

one can add and subtract the gauge-invariant density

$$\cos\omega(\cos\omega-\tfrac{1}{3}\cos^2\omega)\varepsilon_{\mu\nu\rho\sigma}\varepsilon^{\alpha\beta\gamma\delta}F^{\alpha\beta}_{\mu\nu}F^{\gamma\delta}_{\rho\sigma}$$

to (9), such that the nonvanishing surface contribution of $\tilde{\Omega}_\mu$ is cancelled. After some rearrangement, the natural definition for the charge density ϱ pertaining to a system characterized by the asymptotic parameter ω is

$$\varrho=\varrho_G-\frac{3}{64\pi^2}\varepsilon_{\mu\nu\rho\sigma}\varepsilon^{\alpha\beta\gamma\delta}\Big\{\phi^\alpha D_\nu\phi^\beta D_\mu\phi^5 F^{\gamma\delta}_{\rho\sigma}-\frac{1}{8}\Big[\phi^5\Big(1-\frac{1}{3}(\phi)^2\Big)-\cos\omega\Big(\cos\omega-\frac{1}{3}\cos^2\omega\Big)\Big]F^{\alpha\beta}_{\mu\nu}F^{\gamma\delta}_{\rho\sigma}\Big\}, \tag{13}$$

which is the manifestly gauge-invariant definition that is employed in establishing (Bogomol'nyi type) lower bounds, and which is equivalent to the definition

$$\varrho=\varrho_0+\partial_\mu(\phi^5\partial_\nu\Omega_{\nu\mu}+\hat{\Omega}_\mu), \tag{14}$$

in which $\Omega_{\nu\mu}$ is defined by (10) while $\hat{\Omega}_\mu$ is

$$\hat{\Omega}_\mu=\frac{3}{128\pi^2}\varepsilon_{\mu\nu\rho\sigma}\varepsilon^{\alpha\beta\gamma\delta}\Big\{\Big[\phi^5\Big(1-\frac{1}{3}(\phi)^2\Big)-\cos\omega\Big(\cos\omega-\frac{1}{3}\cos^2\omega\Big)\Big]\times A^{\gamma\delta}_\nu\Big[\partial_\rho A^{\alpha\beta}_\sigma-\frac{2}{3}(A_\rho A_\sigma)^{\alpha\beta}\Big]\Big\}. \tag{15}$$

For the spherically symmetric fields (31) and (32), $x_\mu\hat{\Omega}_\mu$ vanishes asymptotically, and since we already know that $\Omega_{\nu\mu}$ vanishes asymptotically, we see that the volume integral of (14) equals the (generic fractional) winding number. The (topological charge) density is gauge-invariant, and its volume integral is just the winding number of the S^4 valued field.

Not surprisingly the definition (13) for the two most prominent cases $\varrho(\omega=0)$ and $\varrho(\omega=\pi/2)$, simplifies somewhat. After some manipulations one has

$$\varrho(0)=\varrho_G+\frac{3}{64\pi^2}\varepsilon_{\mu\nu\rho\sigma}\varepsilon^{\alpha\beta\gamma\delta}\Big[\phi^5 D_\mu\phi^\alpha D_\nu\phi^\beta F^{\gamma\delta}_{\rho\sigma}+\frac{1}{12}((\phi^5)^3-1)F^{\alpha\beta}_{\mu\nu}F^{\gamma\delta}_{\rho\sigma}\Big], \tag{16}$$

$$\varrho\Big(\frac{\pi}{2}\Big)=\varrho_G+\frac{3}{64\pi^2}\varepsilon_{\mu\nu\rho\sigma}\varepsilon^{\alpha\beta\gamma\delta}\phi^5\Big[D_\mu\phi^\alpha D_\nu\phi^\beta F^{\gamma\delta}_{\rho\sigma}+\frac{1}{12}(\phi^5)^2F^{\alpha\beta}_{\mu\nu}F^{\gamma\delta}_{\rho\sigma}\Big]. \tag{17}$$

In Secs. II A and II B we shall analyze models whose actions are bounded from below by the topological charges corresponding to (16), pertaining to $\omega=0$, and (17), pertaining to $\omega=\pi/2$.

A. Model with $\omega=0$

The relevant gauge-invariant charge density in this case is (16). The first term, ϱ_G can be reproduced as a consequence of the inequality

$$\left|\kappa_1 D_\mu\phi^a-\frac{\kappa_3^3}{3!}\varepsilon_{\mu\nu\rho\sigma}\varepsilon^{abcde}D_{[\nu}\phi^b D_{[\rho}\phi^c D_{\sigma]]}\phi^d\phi^e\right|^2\geqslant 0,$$

leading to

$$\kappa_1^2|D_\mu\phi^a|^2+\kappa_3^6|D_{[\nu}\phi^b D_{[\rho}\phi^c D_{\sigma]]}\phi^d|^2\geqslant\kappa_1\kappa_3^3\varrho_G, \tag{18}$$

where κ_1 and κ_3 are constants with the dimension of length. The next term in (16),

$$\varepsilon_{\mu\nu\rho\sigma}\varepsilon^{\alpha\beta\gamma\delta}\phi^5 D_\mu\phi^\alpha D_\nu^\beta F_{\rho\sigma}^{\gamma\delta},$$

is reproduced by the inequality

$$\left|\kappa_0^2 F_{\mu\nu}^{\alpha\beta}-\frac{\kappa_2^2}{2!^2}\varepsilon_{\mu\nu\rho\sigma}\varepsilon^{\alpha\beta\gamma\delta}\phi^5 D_{[\rho}\phi^\gamma D_{\sigma]}\phi^\delta\right|^2\geqslant 0,$$

expanding which and adding the appropriate positive terms to the left-hand side yields

$$\kappa_0^4|F_{\mu\nu}^{\alpha\beta}|^2+\kappa_2^4|D_{[\mu}\phi^a D_{\nu]}\phi^b|^2\geqslant\kappa_0^2\kappa_2^2\varepsilon_{\mu\nu\rho\sigma}\varepsilon^{\alpha\beta\gamma\delta}\phi^5 D_\rho\phi^\gamma D_\sigma\phi^\delta F_{\mu\nu}^{\alpha\beta}. \tag{19}$$

Finally the last term in (16) can be reproduced by adding the two inequalities

$$(\phi^5)^2\left|\phi^5 F_{\mu\nu}^{\alpha\beta}-\frac{1}{2!^2}F_{\rho\sigma}^{\gamma\delta}\right|^2\geqslant 0,$$

$$\left|F_{\mu\nu}^{\alpha\beta}+\frac{1}{2!^2}F_{\rho\sigma}^{\gamma\delta}\right|^2\geqslant 0,$$

and then adding suitable positive quantities to the right-hand side to yield

$$\overline{\kappa}_4^4|F_{\mu\nu}^{\alpha\beta}|^2\geqslant\frac{1}{3!}\overline{\kappa}_4^4\varepsilon_{\mu\nu\rho\sigma}\varepsilon^{\alpha\beta\gamma\delta}[(\phi^5)^2-1]F_{\mu\nu}^{\alpha\beta}F_{\rho\sigma}^{\gamma\delta}. \tag{20}$$

The constants κ_0, in κ_1, κ_3, and $\overline{\kappa}_0$ in (18), (19), and (20), all have the dimension of length.

Adding (18), (19), and (20), we end up with an inequality whose left-hand side, up to some redefinitions, is precisely the system (1), without the potential term V. This Lagrangian is bounded from below by the right-hand side, which will be a topological bound if the latter coincides with the topological charge density (16) (up to a constant multiple). This turns out to be the case, provided that the constants κ_0, in κ_1, κ_3, and $\overline{\kappa}_0$ satisfy the following constraints:

$$\kappa_0^2\kappa_2^2=3\kappa_1\kappa_3^3,\quad 2\overline{\kappa}_0^4=3\kappa_1\kappa_3^3, \tag{21}$$

with the constant multiplying ϱ (16), equal to $\kappa_1\kappa_3^3$. Thus the action (before redefining the constants) is bounded from below as

$$S\geqslant\kappa_1\kappa_3^3 N, \tag{22}$$

where N is the winding number. The action S is the four-volume integral of the Lagrange density

$$\hat{\mathcal{L}}=(\kappa_0^4+\overline{\kappa}_0^4)|F_{\mu\nu}^{[\alpha\beta]}|^2+\kappa_1^2|D_\mu\phi^a|^2+\kappa_2^4|D_\mu\phi^a\times D_\nu\phi^b|^2+\kappa_3^6|D_\mu\phi^a\times D_\nu\phi^b\times D_\rho\phi^c|^2, \tag{23}$$

subject to the restrictions (21), which is up to some redefinitions coincides with (1) without the potential term V.

It is seen from (22) that the condition that this lower bound be nontrivial is that neither one of κ_1 and κ_3 should vanish. It could be thought that this means κ_2 can be set equal to zero without violating this bound, but from the first member of the constraint equations (21) we see that this is impossible. We conclude therefore that the lower bound remains valid only as long as all the constants $(\kappa_0,\kappa_1,\kappa_2,\kappa_3,)$, and hence also the couplings $(\lambda_0,\lambda_1,\lambda_2,\lambda_3,)$, remain positive and nonzero.

As will be shown in Sec. III, the constants λ_0 and λ_1 can be scaled away leaving only two independent coupling constants λ_2 and λ_3, both of which have to be positive and greater than zero if the lower bound (22) is to be preserved.

Before proceeding to the next section, we note that the Lagrangian (1) is not unique in being bounded from below by the topological charge density (16). Rather, it is the simplest system motivated by the requirements that it features the YM term and the *quadratic* kinetic term of the scalar field. An inspection of the spherically symmetric restriction of the YM term, Eq. (33) below, implies the finite action condition on the gauge field function $a(r)$

$$\lim_{r\to\infty} a(r)=\pm 1,$$

which in the language of the asymptotic conditions (6) means that $q=0$ and $q=1$, respectively. In the first case, the Pontryagin charge vanishes, while in the second case it is equal to 1.

B. Model with $\omega=\pi/2$

The relevant gauge-invariant charge density in this case is (17). Unlike in the previous section however, here we do not proceed straightforwardly to construct the simplest density which is bounded from below by (17).

The reason is that when $\omega\neq 0$ (as in the case case at hand with $\omega=\pi/2$) the gauge group SO(4) breaks down to SO(3) at infinity. This can easily be seen by rotating the asymptotic field ϕ^α $(\alpha=1,2,3,4)$ of length $|\phi^\alpha(\infty)|=\sin\omega$, to the constant vector field along the x_4 axis, by means of an appropriate SO(4) gauge transformation. The effect of this transformation on the so(4) gauge connection is, that it develops a line singularity along the x_4 axis, and its nonvanishing components then take their values in the residual so(3). We do not give the details of the passage to this Dirac gauge here, because this has been given in detail previously in Refs. 6 and 7, in the context of the SO(4)×U(1) gauged Higgs model. The analysis here is identical to that in Refs. 6 and 7, with the 4 component field ϕ^α here replacing the Higgs field $\Phi=\gamma_5\gamma_\mu\hat{x}_\mu$ of Refs. 6 and 7. Indeed this is the case for all d-dimensional $(d\geqslant 3)$SO(d) Higgs models with d-vector Higgs fields,[8] of which the most familiar is the Wu–Yang monopole in $d=3$.

The relevant information that follows from the preceding discussion is, that the asymptotic connection field $\tilde{A}^{ab}_\mu=(\tilde{A}^{ab}_i,\tilde{A}^{ab}_4)$, $(a=\alpha,5)$ in the Dirac gauge decays exactly as $1/r$, and its only nonvanishing component is

$$\tilde{A}^{[\alpha\beta]}_i=\frac{1}{r(1-\hat{x}_4)}(\delta^\alpha_i\hat{x}^\beta-\delta^\beta_j\hat{x}^\alpha), \tag{24}$$

which takes its values in so(3).

It follows that the corresponding asymptotic curvature field has the Coulomb decay $1/r^2$, and as a consequence the integral of the YM action density will diverge logarithmically in four dimensions. This simple fact can also be seen by inspecting the spherically symmetric YM action density in (33). Thus, in constructing the density bounded from below by the topological charge density (17), it is not legitimate to employ the usual YM action density.

The remedy is to use instead the YM density constructed from the antisymmetrized product of two curvature two-forms, namely,

$$|F^{abcd}_{\mu\nu\rho\sigma}|^2=|(F^{\alpha[\beta}_{\mu[\nu}F^{\gamma\delta]}_{\rho\sigma]}+F^{[\delta\gamma}_{\mu[\nu}F^{\beta]\alpha}_{\rho\sigma]})|^2.$$

This term arises naturally in reproducing the last term in the charge density (17). To reproduce the second term in the charge density, it is not legitimate to make use of inequality (19) since the latter features the usual YM density. Given that for the instanton (vacuum) interpretation of the solution we need to have the quadratic kinetic term of the scalar field, this necessitates the appearance of the term

$$|F^{\alpha\beta}_{[\mu\nu}D_{\lambda]}\phi^{\gamma}|^2.$$

Finally, to reproduce the first term, ϱ_G, in (17), the most economical option is to adopt the inequality (18). (This avoids the introduction of the additional and unnecessary term $|D_{[\mu}\phi^a D_{\nu]}\phi^b|^2$ in the Lagrangian.)

Following the above arguments, we write down the three topological inequalities corresponding to (18), (19), (20) for the present case with $\omega=\pi/2$. With (18) unchanged, we just give the second two

$$\overline{\kappa}_1^2|D_{[\mu}\phi^a|^2+\overline{\kappa}_3^6|F^{\alpha\beta}_{[\mu\nu}D_{\lambda]}\phi^{\gamma}|^2\geqslant 3\overline{\kappa}_1\overline{\kappa}_3^3\varepsilon_{\mu\nu\rho\sigma}\varepsilon^{\alpha\beta\gamma\delta}\phi^5 D_{\rho}\phi^{\gamma}D_{\sigma}\phi^{\delta}F^{\alpha\beta}_{\mu\nu}, \tag{25}$$

$$\overline{\kappa}_4^8|F^{abcd}_{\mu\nu\rho\sigma}|^2+\tau^2(\phi^5)^6\geqslant\tau\overline{\kappa}_4^{\frac{4}{2}\frac{3}{2}}\varepsilon_{\mu\nu\rho\sigma}\varepsilon^{\alpha\beta\gamma\delta}(\phi^5)^3F^{\alpha\beta}_{\mu\nu}F^{\gamma\delta}_{\rho\sigma}, \tag{26}$$

where the constants $\overline{\kappa}_1$, $\overline{\kappa}_3$, and $\overline{\kappa}_4$ all have the dimension of length, while τ is dimensionless.

Adding (18), (25), and (26) results in an inequality whose right-hand side can be identified (up to a numerical factor) with the topological charge density (17), provided that

$$\overline{\kappa}_1\overline{\kappa}_3^3=3\kappa_1\kappa_3^3, \quad 6\tau\overline{\kappa}_4^4=\kappa_1\kappa_3^3. \tag{27}$$

The resulting topological inequality bounding the action from below, analogous to (22), is

$$\tilde{S}\geqslant\kappa_1\kappa_3^3N, \tag{28}$$

in which the action $\tilde{S}$ is the four-volume integral of

$$\begin{aligned}\tilde{\mathcal{L}}=&\overline{\kappa}_4^8|F^{abcd}_{\mu\nu\rho\sigma}|^2+\overline{\kappa}_3^6|F^{ab}_{[\mu\nu}D_{\lambda]}\phi^c|^2+\kappa_3^6|D_{\mu}\phi^a\times D_{\nu}\phi^b\times D_{\rho}\phi^c|^2\\&+(\kappa_1^2+\overline{\kappa}_1^2)|D_{\mu}\phi^a|^2+\tau^2(\phi^5)^6,\end{aligned} \tag{29}$$

subject to the constraints (27). Note that the potential (3) with $\omega=0$ and $n=6$ appears quite naturally in (29), and in this case its presence is mandatory if the lower bound on the action is to be preserved.

Because (29) does not feature the usual YM term besides the F^4 term, it is not likely to be of any physical interest. Hence we do not analyze it numerically. We note that in the case of the SO(4)×U(1) Higgs model,[6,7] which also features the F^4 YM term to the exclusion of the usual F^2, it could be argued that at high energies that system reduced to a conventional SO(4)×U(1) Higgs system

$$\mathrm{Tr}(\lambda_2F^2_{\mu\nu}+\lambda_1D_{\mu}\Phi^2+\lambda_0(\Phi^2+\eta^2)^2), \tag{30}$$

where the constant η is the VEV of the Higgs field, and all fields are anti-Hermitian. In other words, the SO(4)×U(1) Higgs model was interpreted as the low energy effective action of (30). Unfortunately, we do not have such an interpretation for the system (29).

III. SPHERICAL SYMMETRY

The spherically symmetric Ansatz employed is

$$A_\mu^{[\alpha\beta]}=\frac{a(r)-1}{r}(\delta_\mu^\alpha\hat{x}^\beta-\delta_\mu^\beta\hat{x}^\alpha), \tag{31}$$

$$\phi^\alpha=\sin f(r)\hat{x}^\alpha, \quad \phi^5=\cos f(r). \tag{32}$$

As explained in Sec. II B, we will restrict our numerical analysis to the case of $\omega=0$, and hence give the spherically symmetric reduction only of the terms in the system (1), or (23), pertaining to $\omega=0$.

Substituting (31) and (32) into the component terms of (1) we have, for each term

$$|F_{\mu\nu}^{\alpha\beta}|^2=12\left[\left(\frac{a'}{r}\right)^2+\left(\frac{a^2-1}{r^2}\right)^2\right], \tag{33}$$

$$|D_\mu\phi^a|^2=f'^2+3\left(\frac{a^2\sin^2 f}{r^2}\right), \tag{34}$$

$$|D_\mu\phi^a\times D_\nu\phi^b|^2=12\left(\frac{a^2\sin^2 f}{r^2}\right)\left[f'^2+\left(\frac{a^2\sin^2 f}{r^2}\right)\right], \tag{35}$$

$$|D_\mu\phi^a\times D_\nu\phi^b\times D_\rho\phi^c|^2=36\left(\frac{a^2\sin^2 f}{r^2}\right)^2\left[3f'^2+\left(\frac{a^2\sin^2 f}{r^2}\right)\right]. \tag{36}$$

In the following we will study the classical solutions of the model (1) and characterize them by the classical action S defined by means of

$$S=\frac{1}{8\pi^2}\int d^4x\,\mathcal{L}. \tag{37}$$

The reduced one-dimensional Lagrangian is r^3 times the sum, with the appropriate numerical coefficients in (1), of all the above four terms. We do not display this one-dimensional Lagrangian, nor the ordinary differential equations that follow.

The asymptotic values of the function $f(r)$ corresponding to (5) translate to

$$\lim_{r\to 0} f(r)=\pi, \quad \lim_{r\to\infty} f(r)=\omega, \tag{38}$$

with $\omega=0$, while the asymptotic values of the function $a(r)$ for the cases $q=0$ and $q=1$ translate respectively, to

$$\lim_{r\to 0} a(r)=1, \quad \lim_{r\to\infty} a(r)=1, \tag{39}$$

$$\lim_{r\to 0} a(r)=1, \quad \lim_{r\to\infty} a(r)=-1. \tag{40}$$

Let us first point out that the embedded charge-one-BPST-instanton solutions[4]

$$a_{\mathrm{BPST}}(r)=\frac{k^2-r^2}{k^2+r^2}, \quad f(r)=n\pi \text{ (everywhere)} \tag{41}$$

(k is a real constant, n is an integer) exist irrespectively of the values of $\lambda_{1,2,3}$ and leads to $S_{\mathrm{BPST}}=\frac{4}{3}$, corresponding to the action of the charge-one-instanton solution of the Yang–Mills theory.[4] Here we are interested in classical solutions with nonconstant $f(r)$.

The number of four coupling constants can be reduced to two by using the following scaling argument. Transforming $r\to\sigma r$, we have

$$S(\lambda_1,\lambda_2,\lambda_3,\lambda_0)=S(\lambda_1\sigma^2,\lambda_2,\lambda_3\sigma^{-2},\lambda_0)=\lambda_1\sigma^2 S\left(1,\frac{\lambda_2}{\lambda_1\sigma^2},\frac{\lambda_3}{\lambda_1\sigma^4},\frac{\lambda_0}{\lambda_1\sigma^2}\right). \tag{42}$$

Choosing $\sigma^2=\lambda_0/\lambda_1$ this gives

$$S(\lambda_1,\lambda_2,\lambda_3,\lambda_0)=\lambda_0 S\left(1,\frac{\lambda_2}{\lambda_0},\frac{\lambda_3\lambda_1}{\lambda_0^2},1\right). \tag{43}$$

In the following we will make use of the above scaling property and set $\lambda_1=\lambda_0=1$.

IV. NUMERICAL RESULTS

We have studied numerically the solutions of the classical equations associated with (1) for the $\omega=0$ model, restricting to the one-dimensional spherically symmetric fields given by (33)–(36). Most of the work is carried out with the potential (4) decoupled, i.e., with $\lambda=0$.

In Ref. 1 the above equations have been studied in detail in the case $\lambda_1=\lambda_3=0$. Here we want to study the classical solutions for nonvanishing $\lambda_1,\lambda_2,\lambda_3$. Using the standard Derrick scaling argument, it is easily seen that regular classical solutions will exist only if the coupling constants λ_1,λ_3 are both nonzero. On the other hand, the topological lower bound (22) derived in the preceding section states that in addition to λ_1 and λ_0 (which we have already set to $\lambda_0=\lambda_1=1$ by scaling), both λ_2 and λ_3 must be positive and nonzero. On the basis of the last statement, there is no guarantee that the solution persists when λ_2 vanishes, even though this is consistent with the Derrick scaling requirement.

As a result of our numerical studies, we have learned that with the asymptotics (39), the solution persists when λ_2 vanishes. In this case there remains only one coupling constant to vary, λ_3, which is a simpler case to study and this is presented in Sec. IV A. In Sec. IV B, again with the asymptotics (39), we study the cases where λ_2 is varied for fixed nonzero value of λ_3, and also where λ_3 is varied for fixed nonzero value of λ_2. These families of solutions all have Pontryagin charge equal to zero. In Sec. (IV C), we present the results of our numerical search for solutions with *unit* Pontryagin charge and nontrivial scalar field, with asymptotics (40). The result is negative, and we have supplied an analytic construction in support of the nonexistence of such instantons.

A. Solutions with $a(0)=a(\infty)=1$ and $\lambda_2=0$

With these boundary conditions, the Chern–Pontryagin charge would be zero and the topological lower bound would be stated in terms of the degree of the map only.

Integrating the equations for small values of λ_3 we were able to construct solutions with

$$a(0)=1,\quad a(\infty)=1,\quad f(0)=\pi,\quad f(\infty)=0. \tag{44}$$

The profiles of the functions a,f of this solution are presented in Fig. 1 for $\lambda_3=0.425$ by the solid lines. In the limit $\lambda_3=0$ the classical action tends to zero and the function $a(r)$ tends to a constant : $a(r)=1$. When λ_3 increases, the function $a(r)$ develops a local minimum (at $r=r_m$) which becomes progressively deeper as indicated in Fig. 2. The general dependence of r_m on λ_3 is also reported on Fig. 2. At the same time the classical action of the solution increases with λ_3, and this is illustrated in Fig. 3.

This situation persists up to a critical value of λ_3, say λ_3^c, and numerically we found

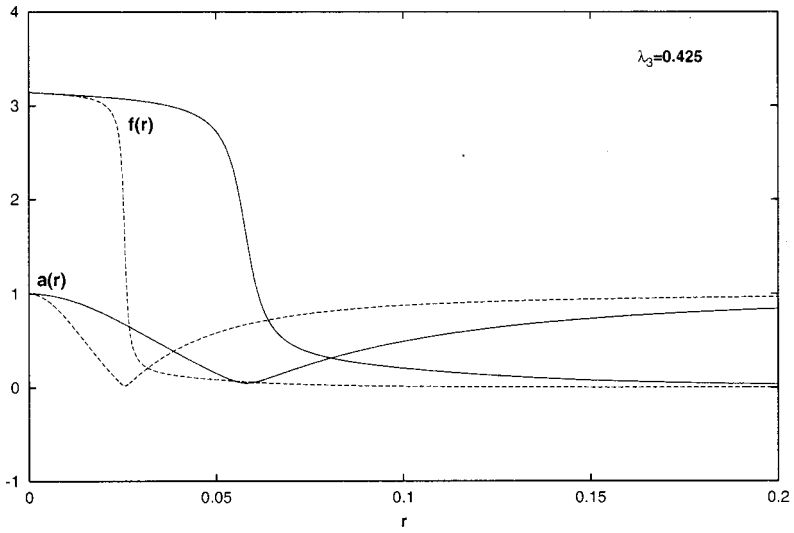

FIG. 1. The profiles of two solutions $a(r)$ and $f(r)$ as functions of r for $\lambda_2=0$ and $\lambda_3=0.425$ for the first branch (solid line) and the second branch (dotted line).

$$\lambda_3^c \approx 0.426\,61. \tag{45}$$

Corresponding to this critical value, we find $r_m \approx 0.041$, $a(r_m) \approx 0.034$, and $S \approx 1.3345$. In particular the value of the action is slightly higher than the value 4/3 corresponding to the action of the instanton solution of the Yang–Mills theory.[4]

In fact, a large part of this action comes from the Yang–Mills part of the Lagrangian and the contribution due to the S^4 valued matter field is rather tiny (less than one percent) because, as indicated by Fig. 1, the function $f(r)$ becomes very steep in the region where the function $a(r)$ has its minimum.

We found no solutions for $\lambda_3 > \lambda_3^c$; however, a careful analysis of the equations strongly suggests that a second branch of solution exists, as illustrated on Fig. 2. As far as the classical

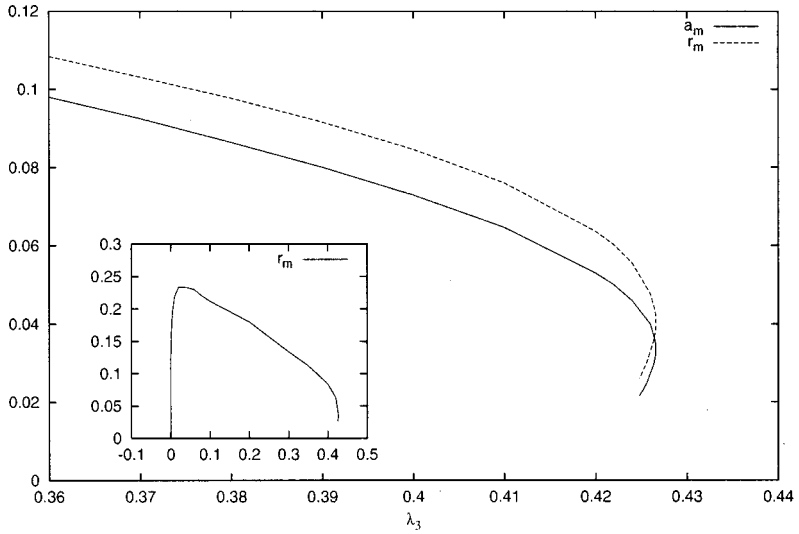

FIG. 2. λ_3 dependence of r_m and $a(r_m)$ for the two branches near the critical value of λ_3 when $\lambda_2=0.1$. The global dependence on r_m is displayed in the window.

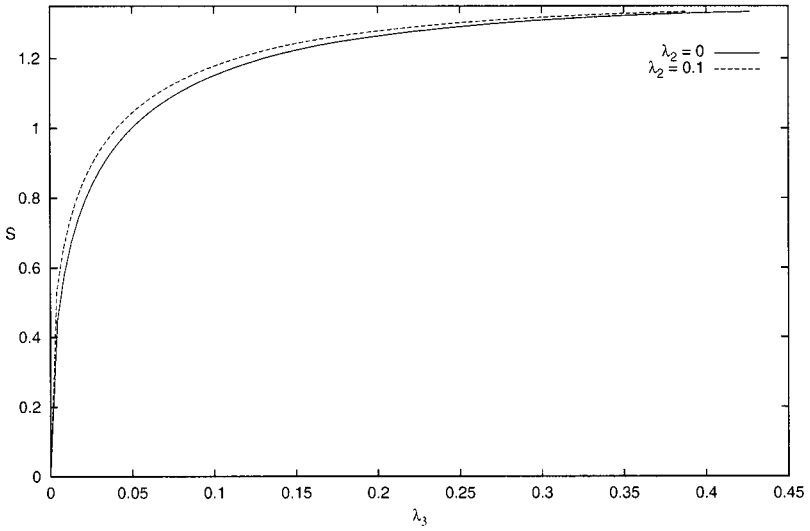

FIG. 3. λ_3 dependence of the action for $\lambda_2=0$ (solid line) and $\lambda_2=0.1$ (dotted line).

action of the two branches is concerned they terminate into a cusp at $\lambda_3=\lambda_3^c$, in a way very similar to Fig. 9 of Ref. 1.

As suggested by Fig. 2, it is very likely that when λ_3 decreases to below λ_3^c on the second branch, the minimum $a(r_m)$ has a tendency to approach zero while the derivative $f'(r_m)$ of the function $f(r)$ becomes infinite. For that reasons, the construction of the classical solution along this branch is numerically difficult and we we had to stop it at $\lambda_3\approx 0.4248$.

Nevertheless, it seems that the profile $a(r)$ of the solution on the second branch is such that

$$\lim_{\lambda_3\to\lambda_3^*} a(r)=|a_{\mathrm{BPST}}(r)|. \tag{46}$$

a_{BPST} being the profile of the charge-1 instanton (41) for an appropriate value of the scaling constant k. The numerical difficulties prevented the evaluation of λ_3^* but, according to Fig. 2, one can expect $\lambda_3^*\approx 0.42$.

The solutions were constructed with the subroutine COLSYS[9] (see Appendix of Ref. 10 for a short description) and with a high degree of accuracy: typically with an error less than 10^{-8}.

To finish this section we mention that the pattern of solutions presented above for $\lambda_2=0$ seems to persist for $\lambda_2>0$. For instance, for $\lambda_2=1$ we find $\lambda_3^c\approx 0.14$, i.e., a much lower value than in the case $\lambda_2=0$. More details are given in the next section.

B. Solutions with $a(1)=a(\infty)=1$ with $\lambda_2>0$, $\lambda_3>0$

In this section we present numerical results for solutions with the same asymptotics as in Sec. IV A, but (a) holding λ_2 fixed at $\lambda_2=0.1$ and varying λ_3, and (b) holding λ_3 fixed at $\lambda_3=0.1$ and varying λ_2.

As in Sec. IV A, the solutions do not appear to persist for arbitrarily large λ_3 (when $\lambda_2=0.1$), and arbitrarily large λ_2 (when $\lambda_3=0.1$). Unlike in Sec. IV A however, we have not endeavoured to find accurate critical values for the λ_2 and λ_3, respectively. The general features of the solutions remain unchanged whether or not λ_2 vanishes.

The action versus λ_3 (with $\lambda_2=0.1$) is plotted in Fig. 3. The action versus λ_2 (with $\lambda_3=0.1$) is plotted in Fig. 4. In both cases we note the remarkable feature that the action rises to just above the BPST instanton action $\frac{4}{3}$. This feature is shared with the restricted model with $\lambda_1=\lambda_3=0$ model studied in Ref. 1.

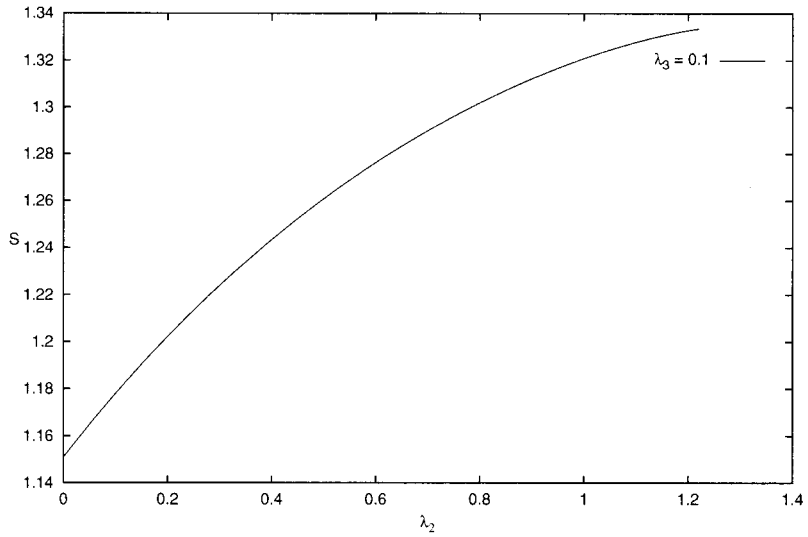

FIG. 4. λ_2 dependence of the action for $\lambda_2 = 0.1$.

Figure 5 is the analogue of Fig. 2, where the progress of $r_{\min}$ and $a_{\min}$, the position of the minimum and the value of the minimum of the function $a(r)$, are plotted against increasing λ_2 (with $\lambda_3 = 0.1$ fixed). Figures 2 (respectively, Fig. 5) describes the manner in which the solutions disappear as the value of the λ_3 (respectively, λ_2) approaches a critical value. (The analysis confirming the existence of two distinct branches is given only in Fig. 2.)

In addition to the above results, we have made a study of the generic system (1) with the potential (4) included. It turns out that decoupling the potential (4) results in no appreciable qualitative changes in the values of the action, for all values of the coupling constants λ_2 and λ_3. This property of the present model is shared by the usual (ungauged) Skyrme model.[2]

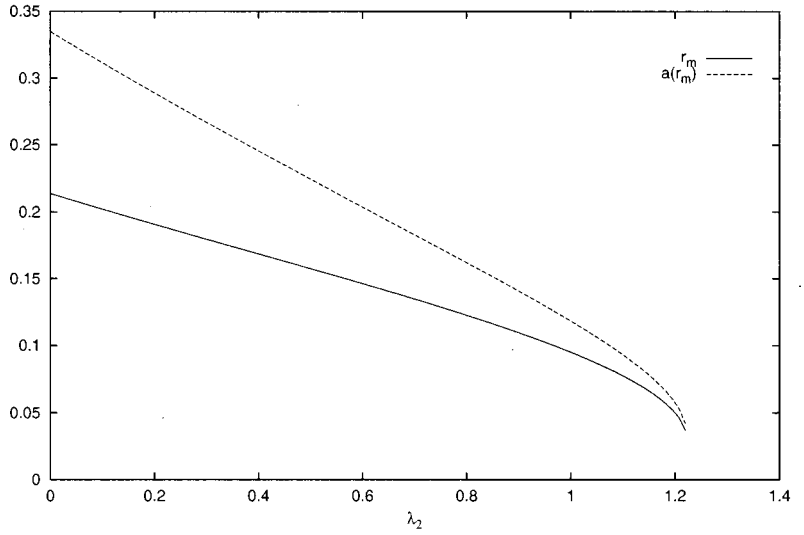

FIG. 5. λ_2 dependence of r_m and a_m for $\lambda_3 = 0.1$.

C. Solutions with $a(0)=-a(\infty)=1$

Should solutions of this type exist, their Chern–Pontryagin charge would be nonzero. As we shall see below, the only such solutions are those with trivial S^4 valued field, i.e., only the pure YM^4 instantons.

The set of boundary conditions

$$a(0)=1, \quad a(\infty)=-1, \quad f(0)=\pi, \quad f(\infty)=0, \tag{47}$$

pertain to *unit* Chern–Pontryagin charge for the spherically symmetric configuration at hand, and provide a natural alternative to the solution discussed above.

Although we could numerically exhibit regular configurations obeying these conditions and with an action slightly higher than 4/3, we have not succeeded in constructing a solution of the equations with these conditions. We used both COLSYS and a relaxation method to find solutions satisfying the boundary conditions (47) and all the numerical results accumulated leads us to the formulation of the following statement: the solutions of the equations of motion obeying (47) are constituted by the functions

$$a(r)=\frac{k^2-r^2}{k^2+r^2}, \quad k\in\mathbb{R}, \quad f(0)=0, \quad f(r)=\pi, \quad r>0 \tag{48}$$

considered in the limit $k\to 0$. The limiting configuration, which is determined in terms of step functions, has action $S=4/3$.

We now give an analytic construction to show that no such smooth solutions exist. To do this we will consider a suitably chosen one parameter family of field configurations and show that in the limit where the parameter vanishes, the field f becomes a step function shrunk near the origin and that the action reduces to the action of the instanton.

First of all let us write the expression for the action after performing the scaling $r=\sigma x$,

$$\begin{aligned} S=\frac{1}{2}\int \Bigg\{ & \lambda_0\left(\left(\frac{a_x}{x}\right)^2+\left(\frac{a^2-1}{x^2}\right)^2\right)+\sigma^2\lambda_1\left(f_x^2+3\left(\frac{a^2\sin^2 f}{x^2}\right)\right) \\ & +\lambda_2\frac{a^2\sin^2 f}{x^2}\left(f_x^2+\frac{a^2\sin^2 f}{x^2}\right)+\frac{\lambda_3}{\sigma^2}\left(\frac{a^2\sin^2 f}{x^2}\right)^2\left(3f_x^2+\frac{a^2\sin^2 f}{x^2}\right)\Bigg\}x^3\,dx. \end{aligned} \tag{49}$$

We then consider the following configuration: for a we take the usual instanton solution and we call x_0 the point where $a(x_0)=0$. For f we take

$$f=\pi \quad \text{if} \quad x\leqslant x_0-\frac{\epsilon}{2}, \tag{50}$$

$$f=\left(x_0+\frac{\epsilon}{2}-x\right)\frac{\pi}{\epsilon} \quad \text{if} \quad x_0-\frac{\epsilon}{2}\leqslant x\leqslant x_0+\frac{\epsilon}{2}, \tag{51}$$

$$f=0 \quad \text{if} \quad x\geqslant x_0+\frac{\epsilon}{2}. \tag{52}$$

We then notice that the support of the action density for the first three terms is the interval $[x_0-\epsilon/2, x_0+\epsilon/2]$. Moreover in that interval we can write

$$a=K(x-x_0)+O((x-x_0)^2), \tag{53}$$

where K is a constant. Defining

$$S_a = \int \frac{\lambda_0}{2}\left(\left(\frac{a_x}{x}\right)^2 + \left(\frac{a^2-1}{x^2}\right)^2\right) r^3\, dr \tag{54}$$

we can write

$$\begin{aligned} S = S_a + \frac{1}{2}\int_{x_0-\epsilon/2}^{x_0+\epsilon/2} \Bigg\{ & \sigma^2 \lambda_1 x^3 \left(\frac{\pi^2}{\epsilon^2} + \frac{3}{x^2}K^2 (x-x_0)^2 \sin^2 f\right) \\ & + \lambda_2 x^3 \left(\frac{K^2}{x^2}(x-x_0)^2 \sin^2 f \left(\frac{\pi^2}{\epsilon^2} + \frac{K^2}{x^2}(x-x_0)^2 \sin^2 f\right)\right) \\ & + \frac{\lambda_3}{\sigma^2} x^3 \left(\frac{K}{x}(x-x_0)\right)^2 \left(\frac{3}{\epsilon^2}\pi^2 + \frac{K^2}{x^2}(x-x_0)^2 \sin^2 f\right) \Bigg\} dx. \end{aligned} \tag{55}$$

We can the replace $\sin f$ by 1 and perform each of the integrals to the lowest order in ϵ which gives

$$\begin{aligned} S \leqslant S_a + \sigma^2 \frac{\lambda_1}{2}\left(\frac{1}{\epsilon} x_0 \pi^2 + K^2 x_0 \epsilon^3\right) + \lambda_1 \sigma^2 O(\epsilon) + \frac{\lambda_2}{2} K^2 \left(\frac{x_0}{3}\pi^2 \epsilon + \frac{K^2 \epsilon^5}{5(x_0+\epsilon/2)}\right) + \lambda_2 O(\epsilon^3) \\ + \frac{\lambda_3}{2\sigma^2} K^4 \left(\frac{3}{(x_0+\epsilon/2)^5}\epsilon^3 + \frac{K^2}{7(x_0+\epsilon/2)^3}\epsilon^7\right) + \frac{\lambda_3}{\sigma^2} O(\epsilon^5) \end{aligned} \tag{56}$$

choosing $\sigma = \epsilon$ we have

$$\lim_{\epsilon \to 0} S = S_a \tag{57}$$

and in that limit the field f becomes singular, showing that there are no regular solutions with this boundary conditions. This is indeed what we observed when we tried to compute such solution numerically.

V. SUMMARY AND DISCUSSION

The coupling of nonlinear sigma models to gauge fields often leads to sets of classical equations whose solutions obey various types of critical phenomena like bifurcations and/or pairs of solutions terminating into a cusp. The classical equations associated with the Lagrangian (1), in the spherically symmetric Ansatz, are of this type. These solutions seem to follow the same pattern, irrespectively of the different Skyrme terms added, i.e., these patterns seem to be independent of the dynamical details.

In this paper, we have studied the classical solutions ensuing from the Lagrangian (1) for three different sets of the two independent coupling constants (λ_2, λ_3). In spite of the fact that our analysis in Sec. II (specifically in Sec. II A) leads to the establishment of a topological lower bound on the action provided that both λ_2 and λ_3 be positive, we have found that in fact solutions persist at $\lambda_2 = 0$. A similar situation arises in the three-dimensional Skyrme model augmented by a sextic Skyrme term. In that case too, when the usual (quartic) Skyrme term is decoupled, thus invalidating the topological lower bound, the solution persists[11] notwithstanding. This most probably means that our (Bogomol'nyi type) analysis in Sec. II is not far reaching enough for the model at hand. For example, in the case of Hopf solitons, there exists no Bogomol'nyi type lower bound on the energy, but instead one finds that a bound nevertheless can be established in terms of Sobolev type inequalities.[12] We have not carried out the appropriate analysis here, but expect that this can be done. Accordingly we have treated the simplified model (1) with $\lambda_2 = 0$ as legitimate and have carried out the detailed analysis of exhibiting the cusp structure alluded to in the previous paragraph, for that model in Sec. IV A, which we summarize in the next paragraphs.

For the $\lambda_2 = 0$ model, clearly the two branches of solutions (the ones with nontrivial S^4 valued matter field) terminate into a cusp at $\lambda_3 = \lambda_3^c$. This is a typical situation met in catastrophe theory.

The spherically symmetric (BPST) instanton of the pure Yang–Mills theory[4] plays a major role and behaves as an attractor (at least when one of the coupling constants approaches a certain value) of the solution which excites both the matter and the gauge fields. It is very likely that the second branch of solutions bifurcates from the BPST branch at the critical value $\lambda_3=\lambda_3^*<\lambda_3^c$. However, due to the absolute value in the limit (46), the bifurcating solution does not occur in a standard, i.e. continuous way.

The qualitative features of the instanton of the $\lambda_2=0$ model just described were confirmed also in the generic model with nonvanishing λ_2 and λ_3, in Sec. IV B, where the cusp resulting from the existence of two distinct branches was not explicitly constructed.

In Sec. IV C, we verified that there existed no instantons with *unit* Pontryagin charge in this model, irrespective of the value of $S^4\to S^4$ winding number. This is important since it tells us that the zero Pontryagin charge instantons of this model are not the analogues of the triangle anomaly, and hence that the nonperturbative quasiclassical effects they describe must be given a new physical interpretation. (We return to this in the last paragraph.)

Before alluding to the possible physical relevance of the model, we note that nonvanishing Pontryagin charge instantons can readily be constructed by changing the model to feature a symmetry breaking potential (3) as opposed to (4). We have presented the simplest such model in Sec. II B, but did not carry out a numerical study in that case because the model involved was rather remote from known physically relevant models.

In short, we have seen that the system consisting of the interacting YM and O(5) sigma models supports instantons with vanishing Pontryagin charge, which do not describe quasiclassical effects analogous to the triangle anomaly, but which have the $S^4\to S^4$ winding number as the topological charge. Besides, the gauge group for this model is not that of the standard model. On the other hand, it is quite straightforward to construct an O(5) model interacting with the SO(3)×SO(2) YM system that supports such instantons, by adapting the analysis of Sec. II to that case. (That remains a future project.) Moreover, the number of independent S^4 valued fields is equal to four, just as the number of the Higgs doublet in the standard model, thus an SO(3)×SO(2) gauged O(5) model added to the standard model, could be regarded as a complicated low energy version of the latter, whose (axially symmetric) instantons can describe new nonperturbative effects. In this sense, the SO(4) gauged O(5) model studied here can be regarded as a prototype of a physically more relevant model.

(Received 16 July 1999; accepted for publication 28 June 2001)

The so(2,1) Lie algebra is applied to three classes of two- and three-dimensional Smorodinsky–Winternitz super-integrable potentials for which the path integral discussion has been recently presented in the literature. We have constructed the Green's functions for two important super-integrable potentials in R^2. Among the super-integrable potentials in R^3, we have considered two examples, one is maximally super-integrable and another one minimally super-integrable. The discussion is made in various coordinate systems. The energy spectrum and the suitably normalized wave functions of bound and continuous states are then deduced. © *2001 American Institute of Physics.* [DOI: 10.1063/1.1396635]

I. INTRODUCTION

Ever since the success of the algebraic approach based on the noncompact groups in calculating the wave functions and the transition amplitudes for the hydrogen atom by Kleinert,[1] a renewed interest for this method has been emerging. Hence a large amount of physical problems for which the Schrödinger equation reduces to the confluent hypergeometric equation have been treated in the framework of this approach. In particular, the radial harmonic oscillator, the radial Coulomb and Morse oscillator potentials and the Natanzon confluent potentials,[2] which generalize the latter, have been discussed in a variety of SO(2,1) realizations.[3–9]

The above so(2,1) algebraic approach has also been applied to noncentral potentials such as the ring-shaped potential[10] introduced by Hartmann[11] to describe the molecular interaction of cyclic polyenes and the so-called double ring-shaped oscillator[12] which is the Quesne ring-shaped oscillator[13] plus an $r^{-2}\sec^2\theta$ term.

The (MS) variant of the algebraic method summarized in Sec. II has been developed by Milshtein and Strakhovenko[14] to construct the Green's function associated with the problem of Dirac electron in a static Coulomb field. The straightforward algebraic calculation of the Green's function for a given potential represents an undeniable advantage which allowed this variant to be given a great deal of attention, in recent years, following the development of path integration techniques. Hence a remarkable set of potentials has been studied in this algebraic approach. Among them, we can quote potentials of practical interest, such as Morse's,[15] the radial harmonic oscillator and the radial Coulomb potentials. The Hartmann ring-shaped potential,[16] the compound Coulomb plus Aharonov–Bohm potential[17] and two highly singular nonisotropic potentials associated to a highly distorted spherical Coulomb field with an additional double ring well and a highly distorted cylindrical Coulomb field have also been studied in parabolic coordinate systems.[18] Within the framework of the R^4 to R^3 non-bijective Kustaanheimo–Stiefel mapping, the Kaluza–Klein monopole system[19] and a noncentral potential[20] which generalizes the Coulomb potential and the Hartmann ring-shaped potential and also, due to its close link with the latter, the compound Coulomb plus Aharonov–Bohm potential have been treated by means of the same algebraic approach as Milshtein and Strakhovenko. Cylindrical parabolic coordinates have also been used in discussion for the so(2,1) algebraic method of another type of noncentral

potentials.[21,22] All these potentials discussed with the help of the (MS) variant appear in the general classification of potentials in two and three dimensions possessing dynamical invariance groups initiated about 30 years ago by Smorodinsky and co-workers,[23] continued by Kibler and Winternitz,[24] and revived, in recent years, by Evans.[25,26] This classification was established according to the number of degrees of freedom, quadratic integrals of motion in the momenta and coordinate systems in which the potential allows the separation of variables. The Hamiltonian systems with these potentials are called super-integrable. Generally, in n dimensions, a system is called ''minimally'' super-integrable if it has $(2n-2)$ constants or integrals of motion (including energy), and it is called ''maximally'' super-integrable if it has $(2n-1)$ integrals of motion.[27] A list of minimally super-integrable and maximally super-integrable potentials with the corresponding constants of motion in the classical form and all separating coordinate systems has been established by Evans.[28] On the basis of this classification, Grosche *et al.*[29] have recently presented a detailed path integral discussion of the so-called Smorodinsky–Winternitz super-integrable potentials in many coordinate systems. It is to be noted that almost all the potentials contained in this classification involve centrifugal or angular barriers which possess point singularities. Consequently, following Kleinert[30] the time sliced path integral for these potentials does not exist in any coordinate system. So, it is necessary to regularize the system in question by an appropriate set of new coordinates in order to find a path integral expression without collapse. This problem does not occur in the framework of the (MS) variant of the so(2,1) algebraic approach owing to its local (differential) character. This constitutes a great advantage in studying the problem of the Smorodinsky–Winternitz potentials in this framework.

The plan of this article is as follows. We briefly review the so(2,1) Lie algebra and its use in calculating Green's functions in Sec. II. We study a set of two potentials in two dimensions, algebraically obtain the Green's function in the various separating coordinate systems and deduce the energy spectrum as well as the corresponding normalized wave functions in Sec. III. Sections IV and V deal with two examples of three-dimensional potentials. The construction of the Green's functions is made in different coordinate systems. The energy spectrum and the normalized wave functions are evaluated. Section VI will be a conclusion.

II. GREEN'S FUNCTION AND so(2,1) LIE ALGEBRA

Let's briefly review the main features of so(2,1) Lie algebra and its use in the calculation of the Green's functions to make this paper self-contained. A set of three operators $\{T_1,T_2,T_3\}$ characterized by the commutation relations[31] define it:

$$[T_1,T_2]=-iT_1,\quad [T_2,T_3]=-iT_3,\quad [T_1,T_3]=-iT_2. \tag{1}$$

Because of the type of potentials we shall deal with in this paper, we have to use the following differential realization of the operators:

$$T_1(x)=-\frac{\hbar^2}{2M}\left(\frac{\partial^2}{\partial x^2}-\frac{\mu(\mu-1)}{x^2}\right),\quad T_2(x)=-\frac{i}{2}\left(x\frac{\partial}{\partial x}+\frac{1}{2}\right),\quad T_3(x)=\frac{M}{4\hbar^2}x^2, \tag{2}$$

with $0<x<\infty$.

By using Schwinger's integral representation,[32] the Green's function associated to a potential $V(x)$ with the SO(2,1) group symmetry is given by

$$G(x,x';E)=\int_0^\infty dS\,\exp\left[\frac{iS}{\hbar}(E+i0)\right]K(x,x';S), \tag{3}$$

where

$$K(x,x';S)=\exp\left\{-\frac{iS}{\hbar}\left[-\frac{\hbar^2}{2M}\nabla_x^2+V(x)\right]\right\}\delta(x-x')$$
$$=\exp\left\{-\frac{iS}{\hbar}[T_1(x)+2\hbar^2\omega^2T_3(x)]\right\}\delta(x-x'). \tag{4}$$

The calculation of this kernel is based upon the use of two Baker–Campbell–Hausdorff formulas[33]

$$\exp\left\{-\frac{iS}{\hbar}[T_1+2\hbar^2\omega^2T_3]\right\}=\exp(-iaT_3)\exp(-ibT_2)\exp(-icT_1), \tag{5}$$

where

$$a=2\hbar\omega\tan(\omega S),\quad b=2Ln[\cos(\omega S)],\quad c=\frac{1}{\hbar\omega}\tan(\omega S), \tag{6}$$

and

$$\exp(-i\alpha T_3)\exp(-i\beta T_2)\exp(-i\gamma T_1)=\exp(-icT_1)\exp(\tau T_3), \tag{7}$$

with

$$\alpha=\frac{i\tau}{1-i\tau c/2},\quad \beta=2Ln\left(1-\frac{i\tau c}{2}\right),\quad \gamma=\frac{c}{1-i\tau c/2}. \tag{8}$$

Here, we also have to use the Laplace transform of the Dirac distribution

$$\delta(x-x')=\frac{M}{2\hbar^2}\frac{x^\mu x'^{1-\mu}}{2i\pi}\int_{-i\infty+\delta}^{i\infty+\delta}d\tau\exp\left[\frac{M}{4\hbar^2}(x^2-x'^2)\tau\right],\quad \delta<0, \tag{9}$$

in order to obtain a manageable result as follows:

$$\exp(-i\gamma T_1)x^\mu=\left[1-i\gamma T_1+\frac{1}{2!}(-i\gamma T_1)^2+\cdots\right]x^\mu=x^\mu. \tag{10}$$

Using relations (9), (5) and (7), the kernel (4) can now be written

$$K(x,x';S)=\frac{M}{2\hbar^2}x'^{1-\mu}\exp(-iaT_3)\exp(-ibT_2)x^\mu\exp\left(\frac{iMx^2}{2\hbar^2c}\right)$$
$$\times\int_{-i\infty+\delta}^{i\infty+\delta}d\tau\frac{\exp\left(-\frac{Mx'^2}{4\hbar^2}\tau\right)\exp\left(\frac{Mx^2}{\hbar^2c^2}\frac{1}{\tau+2i/c}\right)}{\left(1-\frac{i\tau c}{2}\right)^{\mu+1/2}}, \tag{11}$$

where the well-known formula

$$\exp(-i\beta T_2)f(x)=\exp\left(-\frac{\beta}{4}\right)f\left(e^{-\beta/2}x\right) \tag{12}$$

has also been used.

The integral can be calculated thanks to the residue theorem after the $\exp((Mx^2/\hbar^2c^2)[1/(\tau+2i/c)])$ series has been effected. Hence, we obtain

$$K(x,x';S)=\frac{M\omega}{i\hbar\sin(\omega S)}\sqrt{xx'}\exp\left[\frac{iM\omega}{2\hbar}(x^2+x'^2)\cot(\omega S)\right]\times I_\lambda\left(\frac{M\omega xx'}{i\hbar\sin(\omega S)}\right), \tag{13}$$

where $\lambda=\mu-\frac{1}{2}$ and $I_\lambda(x)$ is the modified Bessel function.

We can now use (13) for any coordinate in a multi-dimensional system, provided that the $(H-E)^{-1}$ inverse resolvent operator can be transformed into a linear combination of the above mentioned $T_i\,(i=1,2,3)$ operators.

III. TWO-DIMENSIONAL MAXIMALLY SUPER-INTEGRABLE POTENTIALS

We shall study here a set of two important potentials belonging to a class of two-dimensional Smorodinsky–Winternitz potentials. They are characterized by the existence of three functionally independent integrals of motion, which means that there is a pair of quadratic operators corresponding to these integrals of motion which commute with the system's Hamiltonian. The number of such integrals being superior to that of degrees of liberty, they are thus called maximally super-integrable potentials.

A. Let us study the potential

$$V_1(\vec{\rho})=-\frac{\alpha_0}{\sqrt{x_1^2+x_2^2}}+\frac{\hbar^2}{4M}\frac{1}{\sqrt{x_1^2+x_2^2}}\left(\frac{k_1^2-\frac{1}{4}}{\sqrt{x_1^2+x_2^2}+x_1}+\frac{k_2^2-\frac{1}{4}}{\sqrt{x_1^2+x_2^2}-x_1}\right), \tag{14}$$

with positive α_0, k_1 and k_2 constants. It admits the following three functionally independent integrals of motion:

$$\begin{aligned} H_1&=\frac{P^2}{2M}+V_1(\vec{\rho}),\quad I_1=\frac{L_3^2}{2M}+\frac{\hbar^2\rho^2}{8M}\left(\frac{k_1^2-\frac{1}{4}}{x_1^2}+\frac{k_2^2-\frac{1}{4}}{x_2^2}\right),\\ I_2&=\frac{\{L_3,P_2\}}{4M}+\frac{\alpha(\eta-\xi)}{\xi\eta}-\frac{2(k_1^2-\frac{1}{4})}{\xi^2}+\frac{2(k_2^2-\frac{1}{4})}{\eta^2}. \end{aligned} \tag{15}$$

This potential is exactly solvable in two coordinate systems, namely parabolic and polar. For $k_1=k_2=\frac{1}{2}$, Eq. (14) can be reduced to the Coulomb potential treated with a path integral approach.[34,35] The algebraic solution to this potential via the (MS) variant is easier to establish using the parabolic coordinates or even the Levi-Cevita variables[36] defined by $x_1=u_1^2-u_2^2$, $x_2=2u_1u_2$ $(-\infty<u_1,u_2<+\infty)$. The Green's function $G(\vec{\rho},\vec{\rho'};E)$ associated to the potential (14), in Schwinger's integral representation, is given by

$$\begin{aligned} G(\vec{\rho},\vec{\rho'};E)=&\int_0^\infty\frac{dS}{4\rho}\exp\left\{-\frac{iS}{\hbar}\left[\frac{1}{4\rho}\sum_{j=1}^{2}\left(-\frac{\hbar^2}{2M}\left(\frac{\partial^2}{\partial u_j^2}-\frac{k_j^2-\frac{1}{4}}{u_j^2}\right)\right)-\frac{\alpha_0}{\rho}-E-i0\right]\right\}\\ &\times\prod_{j=1}^{2}\delta(u_j-u_j'). \end{aligned} \tag{16}$$

By applying the time transformation $S\to\tau$ defined by $\tau=S/4\rho$, the Green's function (16) can be written

$$G(\vec{\rho},\vec{\rho'};E)=\int_0^\infty d\tau\exp\left[\frac{i}{\hbar}(4\alpha_0+i0)\tau\right]\prod_{j=1}^{2}K(u_j,u_j';\tau), \tag{17}$$

where

$$K(u_j,u_j';\tau)=\exp\left\{-\frac{i\tau}{\hbar}[T_1(u_j)+2\hbar^2\omega^2T_3(u_j)]\right\}\delta(u_j-u_j'), \tag{18}$$

with $\mu_j=\frac{1}{2}\pm k_j$ and $\omega=\sqrt{-8E/M}$.

Using the Eq. (13), we can write the propagators (18) as follows:

$$K(u_j,u_j';\tau)=\frac{M\omega\sqrt{u_ju_j'}}{i\hbar\sin(\omega\tau)}\exp\left[\frac{iM\omega}{2\hbar}(u_j^2+u_j'^2)\cot(\omega\tau)\right]I_{\pm k_j}\left(\frac{M\omega u_ju_j'}{i\hbar\sin(\omega\tau)}\right). \tag{19}$$

1. Parabolic coordinates

In the parabolic coordinates $\xi=\sqrt{2}u_1$, $\eta=\sqrt{2}u_2$ and after changing $\omega\to 2\omega$ and $\tau\to\tau/2$ and by taking into account (19), the Green's function (17) becomes

$$G(\vec{\rho},\vec{\rho'};E)=\int_0^\infty d\tau\exp\left[\frac{i}{\hbar}(2\alpha_0+i0)\tau\right]K(\xi,\eta,\xi',\eta';\tau), \tag{20}$$

where

$$K(\xi,\eta,\xi',\eta';\tau)=\left(\frac{M\omega}{i\hbar\sin(\omega\tau)}\right)^2\sqrt{\xi\xi'\eta\eta'}\exp\left[\frac{iM\omega}{2\hbar}(\xi^2+\eta^2+\xi'^2+\eta'^2)\cot(\omega\tau)\right]$$
$$\times I_{\pm k_1}\left(\frac{M\omega\xi\xi'}{i\hbar\sin(\omega\tau)}\right)I_{\pm k_2}\left(\frac{M\omega\eta\eta'}{i\hbar\sin(\omega\tau)}\right), \tag{21}$$

with

$$\omega=\sqrt{-\frac{2E}{M}}. \tag{22}$$

To find the energy spectrum and the normalized wave functions of the bound states, we make use of the Hille and Hardy formula[37]

$$\frac{1}{1-z}\exp\left[-z\frac{x+y}{1-z}\right]I_\alpha\left(\frac{2\sqrt{xyz}}{1-z}\right)=(xyz)^{\alpha/2}\sum_{n=0}^\infty\frac{n!}{\Gamma(n+\alpha+1)}L_n^\alpha(x)L_n^\alpha(y)z^n,\quad |z|<1, \tag{23}$$

where the $L_n^\alpha(x)$ are the Laguerre polynomials, and the integration over S yields the quantization condition

$$n_1+n_2\pm\frac{k_1}{2}\pm\frac{k_2}{2}+p=0, \tag{24}$$

where $p=-\alpha_0/\hbar\omega$. Therefore, the Green's function (20) can be written as

$$G(\vec{\rho},\vec{\rho'};E)=i\hbar\sum_{n_1,n_2=0}^\infty\frac{\Psi_{n_1,n_2}(\xi_1,\eta_2)\Psi^*_{n_1,n_2}(\xi_1',\eta_2')}{E+i0-E_{n_1,n_2}}, \tag{25}$$

with the normalized wave functions ($a=\hbar^2/M\alpha_0$ is the Bohr radius)

$$\Psi_{n_1,n_2}(\xi,\eta)=\left[\frac{2}{a^2N^3}\frac{n_1!n_2!}{\Gamma(n_1\pm k_1+1)\Gamma(n_2\pm k_2+1)}\right]^{1/2}\left(\frac{\xi^2}{aN}\right)^{1/4\pm(k_1/2)}\left(\frac{\eta^2}{aN}\right)^{1/4\pm(k_2/2)}$$
$$\times\exp\left[-\frac{\xi^2+\eta^2}{2aN}\right]L_{n_1}^{\pm k_1}\left(\frac{\xi^2}{aN}\right)L_{n_2}^{\pm k_2}\left(\frac{\eta^2}{aN}\right), \tag{26}$$

and the discrete energy spectrum given by

$$E_{n_1,n_2}=-\frac{M\alpha_0^2}{2\hbar^2N^2},\quad N=n_1+n_2\pm\frac{k_1}{2}\pm\frac{k_2}{2}+1. \tag{27}$$

To determine the energy spectrum and the wave functions of the continuous states, let's go back to the expression (21) and use the dispersion formula[38]

$$\frac{2\pi\sqrt{xy}}{\sin\alpha}\exp[-(x+y)\cot\alpha]I_{2\mu}\left(\frac{2\sqrt{xy}}{\sin\alpha}\right)=\int_R dp\,\frac{\Gamma(\frac{1}{2}+\mu+ip)\Gamma(\frac{1}{2}+\mu-ip)}{\Gamma^2(2\mu+1)}M_{ip,\mu}\times(-2ix)M_{-ip,\mu}(2iy). \tag{28}$$

Given $x=(M\omega/2i\hbar)\,\xi'^2$, $y=(M\omega/2i\hbar)\,\xi^2$ and $\alpha=\omega\tau$, we obtain

$$\begin{aligned}K(\xi,\eta,\xi',\eta';\tau)=&\frac{1}{\sqrt{\xi\xi'\eta\eta'}\,\pi^2\Gamma^2(1\pm k_1)\Gamma^2(1\pm k_2)}\int_{-\infty}^{\infty}\int_{-\infty}^{\infty}dp_\xi\,dp_\eta\\&\times\Gamma\left(\frac{1}{2}\pm\frac{k_1}{2}+ip_\xi\right)\Gamma\left(\frac{1}{2}\pm\frac{k_1}{2}-ip_\xi\right)\Gamma\left(\frac{1}{2}\pm\frac{k_2}{2}+ip_\eta\right)\Gamma\left(\frac{1}{2}\pm\frac{k_2}{2}-ip_\eta\right)\\&\times e^{(\pi-2\omega\tau)(p_\xi+p_\eta)}M_{-ip_\xi,\pm(k_1/2)}\left(\frac{M\omega}{\hbar}\xi^2\right)M_{ip_\xi,\pm(k_1/2)}\left(\frac{M\omega}{\hbar}\xi'^2\right)\\&\times M_{-ip_\eta,\pm(k_2/2)}\left(\frac{M\omega}{\hbar}\eta^2\right)M_{ip_\eta,\pm(k_2/2)}\left(\frac{M\omega}{\hbar}\eta'^2\right).\end{aligned} \tag{29}$$

If we now transfer (29) into (20), we shall obtain the poles of the continuous state Green's function by integration on the τ variable. They will be defined by

$$\omega(p_\xi+p_\eta)-\frac{i\alpha_0}{\hbar}=0. \tag{30}$$

If we convert this into energy via (22), the values of the energy will be

$$E_p=\frac{\hbar^2p^2}{2M}\quad\text{with}\quad p=\frac{1}{a(p_\xi+p_\eta)}. \tag{31}$$

Let's now change the variables defined by

$$p_\xi=\frac{1}{2p}\left(\frac{1}{a}+\varsigma\right)\quad\text{and}\quad p_\eta=\frac{1}{2p}\left(\frac{1}{a}-\varsigma\right). \tag{32}$$

In this case, we can write the Green's function as follows:

$$G^c(\xi,\eta,\xi',\eta';E)=i\hbar\int_0^\infty dp\int_{-\infty}^{\infty}d\varsigma\,\frac{\Psi_{p,\varsigma}(\xi,\eta)\Psi^*_{p,\varsigma}(\xi',\eta')}{E+i0-E_p}, \tag{33}$$

with the wave functions given by

$$\begin{aligned}\Psi_{p,\varsigma}(\xi,\eta)=&\frac{\left|\Gamma\left(\frac{1}{2}\pm\frac{k_1}{2}+\frac{i}{2p}\left(\frac{1}{a}+\varsigma\right)\right)\Gamma\left(\frac{1}{2}\pm\frac{k_2}{2}+\frac{i}{2p}\left(\frac{1}{a}-\varsigma\right)\right)\right|}{2\pi\Gamma(1\pm k_1)\Gamma(1\pm k_2)\sqrt{\xi\eta}}\,\frac{e^{\pi/2ap}}{\sqrt{p}}\,M_{-(i/2p)(1/a+\varsigma),\pm(k_1/2)}\\&\times(-ip\xi^2)M_{-(i/2p)(1/a-\varsigma),\pm(k_2/2)}(-ip\eta^2).\end{aligned} \tag{34}$$

2. Polar coordinates

Let's use the (ρ, ϕ) polar coordinates defined by

$$\xi=\sqrt{2}u_1=\sqrt{2\rho}\cos\frac{\phi}{2}, \quad \eta=\sqrt{2}u_2=\sqrt{2\rho}\sin\frac{\phi}{2}, \tag{35}$$

and the addition theorem formula[39]

$$\begin{aligned}\frac{z}{2}I_\nu(z\sin\alpha\sin\beta)I_\mu(z\cos\alpha\cos\beta)&\\ =(\sin\alpha\sin\beta)^\nu(\cos\alpha\cos\beta)^\mu\sum_{n=0}^{\infty}(\nu+\mu+2n+1)&\\ \times\frac{n!}{\Gamma(\nu+n+1)}\frac{\Gamma(\nu+\mu+n+1)}{\Gamma(\mu+n+1)}&\\ \times I_{\mu+\nu+2n+1}(z)P_n^{(\nu,\mu)}(\cos(2\alpha))P_n^{(\nu,\mu)}(\cos(2\beta)).&\end{aligned} \tag{36}$$

This will give us the following form of the Green's function (20):

$$G(\vec{\rho},\vec{\rho'};E)=\sum_{n=0}^{\infty}G_n(\rho,\rho';E)\Phi_n^{(\pm k_2,\pm k_1)}\left(\frac{\phi}{2}\right)\Phi_n^{(\pm k_2,\pm k_1)}\left(\frac{\phi'}{2}\right), \tag{37}$$

where the angular wave functions are those defined in function of the $P_n^{(\pm k_2,\pm k_1)}(\cos\phi)$ Jacobi polynomials by

$$\begin{aligned}\Phi_n^{(\pm k_2,\pm k_1)}(\phi)=&\left[2(2n\pm k_1\pm k_2+1)\frac{n!\Gamma(n\pm k_1\pm k_2+1)}{\Gamma(n\pm k_1+1)\Gamma(n\pm k_2+1)}\right]^{1/2}\\ &\times(\sin\phi)^{1/2\pm k_2}(\cos\phi)^{1/2\pm k_1}P_n^{(\pm k_2,\pm k_1)}(\cos(2\phi)).\end{aligned} \tag{38}$$

The radial Green's function $G_n(\rho,\rho';E)$ included in (37) is defined by

$$\begin{aligned}G_n(\rho,\rho';E)=&\frac{M\omega}{i\hbar}\int_0^\infty\frac{d\tau}{\sin(\omega\tau)}\exp\left[\frac{i}{\hbar}(2\alpha_0+i0)\tau\right]\\ &\times\exp\left[\frac{iM\omega}{2\hbar}(\rho+\rho')\cot(\omega\tau)\right]I_{2\lambda}\left(\frac{2M\omega\sqrt{\rho\rho'}}{i\hbar\sin(\omega\tau)}\right),\end{aligned} \tag{39}$$

with $\lambda=n+\frac{1}{2}(1\pm k_1\pm k_2)$.

Then, thanks to the formula[40]

$$\int_0^\infty dq\,\frac{e^{-2pq}}{\sinh q}\exp\left[-\frac{1}{2}(x+y)\coth q\right]I_{2\gamma}\left(\frac{\sqrt{xy}}{\sinh q}\right)=\frac{\Gamma(p+\gamma+\frac{1}{2})}{\Gamma(2\gamma+1)\sqrt{xy}}M_{-p,\gamma}(x)W_{-p,\gamma}(y), \tag{40}$$

valid for $\mathrm{Re}(p+\gamma+\frac{1}{2})>0$, $\mathrm{Re}(\gamma)>0$, and $y>x$, where $M_{-p,\gamma}(x)$ and $W_{-p,\gamma}(y)$ are the Whittaker functions, we can write (39) as follows:

$$G_n(\rho,\rho';E)=\frac{\Gamma(p+\lambda+\frac{1}{2})}{2i\omega\Gamma(2\lambda+1)\sqrt{\rho\rho'}}M_{-p,\lambda}\left(\frac{2M\omega}{\hbar}\rho'\right)W_{-p,\lambda}\left(\frac{2M\omega}{\hbar}\rho\right), \tag{41}$$

with $p=-\alpha_0/\hbar\omega$, $\omega=\sqrt{-2E/M}$, and $\rho>\rho'$.

From (41) and (37), we can deduce that the complete Green's function is given by

$$G(\vec{\rho},\vec{\rho'};E)=\sum_{n=0}^{\infty}\Phi_n^{(\pm k_2,\pm k_1)}\left(\frac{\phi}{2}\right)\Phi_n^{(\pm k_2,\pm k_1)}\left(\frac{\phi'}{2}\right)\frac{\Gamma(p+\lambda+\frac{1}{2})}{2i\omega\Gamma(2\lambda+1)\sqrt{\rho\rho'}}$$
$$\times M_{-p,\lambda}\left(\frac{2M\omega}{\hbar}\rho'\right)W_{-p,\lambda}\left(\frac{2M\omega}{\hbar}\rho\right). \tag{42}$$

The normalized wave functions and the energy spectrum of the bound states are given by expression (23) applied to $G_n(\rho,\rho';E)$ as defined in (39) provided we make the adequate change of variables and thus obtain:

$$\Psi_{m,n}(\rho,\phi)=\left[\frac{m!}{a^2(m+\lambda+\frac{1}{2})^3\Gamma(m+2\lambda+1)}\right]^{1/2}\left(\frac{2\rho}{a(m+\lambda+\frac{1}{2})}\right)^{\lambda}$$
$$\times\exp\left(-\frac{\rho}{a(m+\lambda+\frac{1}{2})}\right)L_m^{2\lambda}\left(\frac{2\rho}{a(m+\lambda+\frac{1}{2})}\right)\Phi_n^{(\pm k_2,\pm k_1)}\left(\frac{\phi}{2}\right), \tag{43}$$

$$E_{m,n}=-\frac{M\alpha_0^2}{2\hbar^2(m+\lambda+\frac{1}{2})^2}. \tag{44}$$

In order to evaluate the contribution of the continuous spectrum to the Green's function, let's write (41) as follows:

$$G_n(\rho,\rho';E)=\frac{i\hbar}{4\pi\Gamma(2\lambda+1)\sqrt{\rho\rho'}}\oint_C\frac{dz}{E+i0-\frac{\hbar^2z^2}{2M}}\Gamma(p+\lambda+\tfrac{1}{2})$$
$$\times M_{-p,\lambda}\left(\frac{2M\omega}{\hbar}\rho'\right)W_{-p,\lambda}\left(\frac{2M\omega}{\hbar}\rho\right), \tag{45}$$

where C is the closed contour,

$$C:\begin{cases}z=k;\quad k\in[-R,R],\\ z=\mathrm{Re}^{i\phi},\quad \phi\in(\pi,2\pi).\end{cases} \tag{46}$$

At the $R\to\infty$ limit, taking the asymptotic behavior of the Whittaker functions[41] into account, it is easy to demonstrate that the integral over the semicircle vanishes, which leads to

$$G_n(\rho,\rho';E)=\frac{i\hbar}{4\pi\Gamma(2\lambda+1)\sqrt{\rho\rho'}}\int_{-\infty}^{\infty}\frac{dk}{E+i0-\frac{\hbar^2k^2}{2M}}\Gamma(p+\lambda+\tfrac{1}{2})$$
$$\times M_{-p,\lambda}(-2ik\rho')W_{-p,\lambda}(-2ik\rho). \tag{47}$$

By using the following formulas[42]

$$M_{\lambda,\mu}(z)=e^{-i\pi(\mu+\frac{1}{2})}M_{-\lambda,\mu}(-z),\quad \text{with}\quad 2\mu\neq-1,-2,-3,\ldots, \tag{48}$$

and

$$M_{\lambda,\mu}(z)=\Gamma(2\mu+1)e^{i\pi\lambda}\left[\frac{W_{-\lambda,\mu}(-z)}{\Gamma(\mu-\lambda+\frac{1}{2})}+e^{-i\pi(\mu+\frac{1}{2})}\frac{W_{\lambda,\mu}(z)}{\Gamma(\mu+\lambda+\frac{1}{2})}\right], \tag{49}$$

valid for $\arg z\in]-3\pi/2,\pi/2[$, and $2\mu\neq -1,-2,-3,\ldots$, the expression (45) can be written

$$G_n(\rho,\rho';E)=\frac{i\hbar}{4\pi\Gamma^2(2\lambda+1)\sqrt{\rho\rho'}}\int_0^\infty dE_k\frac{\Psi_{k,n}(\rho)\Psi^*_{k,n}(\rho')}{E+i0-E_k} \tag{50}$$

where $E_k=\hbar^2k^2/2M$ and the radial wave functions given by

$$\Psi_{k,n}(\rho)=\left(\frac{M}{4\pi\hbar^2k}\right)^{1/2}\frac{|\Gamma(p+\lambda+\frac{1}{2})|}{\Gamma(2\lambda+1)}\frac{e^{i\pi p/2}}{\sqrt{\rho}}M_{-p,\lambda}(-2ik\rho), \tag{51}$$

with $p=-i/ak$.

B. Let us now study the potential

Let us now study the potential

$$V_2(\vec{\rho})=-\frac{\alpha_0}{\sqrt{x_1^2+x_2^2}}+\frac{\beta_1\sqrt{\sqrt{x_1^2+x_2^2}+x_1}+\beta_2\sqrt{\sqrt{x_1^2+x_2^2}-x_1}}{\sqrt{x_1^2+x_2^2}}, \tag{52}$$

with real β_1 and β_2 constants. This potential has the following three functionally independent integrals of motion:

$$\begin{aligned}H_2&=\frac{P^2}{2M}+V_2(\vec{\rho}),\quad I_1=\frac{\{L_3,P_1\}}{4M}-\frac{\alpha(\xi-\eta)+\beta_1\eta\sqrt{\xi/2}-\beta_2\xi\sqrt{\eta/2}}{\xi+\eta},\\ I_2&=\frac{\{L_3,P_1\}}{4M}-\frac{\alpha(\xi-\eta)+(\beta_1+\beta_2)(\eta\sqrt{\xi/2}-\xi\sqrt{\eta/2})}{\xi+\eta}.\end{aligned} \tag{53}$$

For given parabolic coordinates $x_1=\frac{1}{2}(\xi^2-\eta^2)$, $x_2=\xi\eta$, ($\xi>0$ and $\eta\in R$), in the Schwinger's integral representation, the Green's function associated to this potential can be expressed

$$G(\vec{\rho},\vec{\rho'};E)=\int_0^\infty dS\exp\left[\frac{iS}{\hbar}(E+i0)\right]\exp\left[-\frac{iS}{\hbar}H_2(\xi,\eta)\right]\frac{\delta(\xi-\xi')\delta(\eta-\eta')}{2\rho}, \tag{54}$$

where

$$H_2(\xi,\eta)=-\frac{\hbar^2}{2M}\frac{1}{2\rho}\left(\frac{\partial^2}{\partial\xi^2}+\frac{\partial^2}{\partial\eta^2}\right)-\frac{\alpha_0}{\rho}+\frac{1}{\rho}(\beta_1\xi+\beta_2\eta), \tag{55}$$

with $\rho=\frac{1}{2}(\xi^2+\eta^2)$.

If we now perform the time transformation defined by $\sigma=S/2\rho=S/(\xi^2+\eta^2)$ to separate the ξ and η variables and use the mutually orthogonal parabolic coordinates $(\tilde{\xi},\tilde{\eta})\rightarrow(\xi-(\beta_1/E),\eta-(\beta_2/E))$, we arrive at

$$G(\vec{\rho},\vec{\rho'};E)=\int_0^\infty d\sigma\exp\left[\frac{i\sigma}{\hbar}\left(2\alpha_0-\frac{\beta_1^2+\beta_2^2}{E}+i0\right)\right]K(\tilde{\xi},\tilde{\xi}';\sigma)K(\tilde{\eta},\tilde{\eta}';\sigma), \tag{56}$$

where each of kernels $K(\tilde{\xi},\tilde{\xi}';\sigma)$ and $K(\tilde{\eta},\tilde{\eta}';\sigma)$ can be treated with the so(2,1) Lie algebra and we have

$$K(x,x';\sigma)=\frac{1}{2}\sum_{\mu=0}^{1}\exp\left\{-\frac{i\sigma}{\hbar}[T_1(x)+2\hbar^2\omega^2T_3(x)]\right\}\delta(x-x')$$

$$=\sqrt{\frac{M\omega}{2i\pi\hbar\sin(\omega\sigma)}}\exp\left\{\frac{iM\omega}{2\hbar}\left[(x^2+x'^2)\cot(\omega\sigma)-\frac{2xx'}{\sin(\omega\sigma)}\right]\right\}, \tag{57}$$

with $x\equiv(\tilde{\xi}\text{ or }\tilde{\eta})$ and $\omega=\sqrt{-2E/M}$.

Substituting (57) into (56), we obtain

$$G(\vec{\rho},\vec{\rho'};E)=\frac{M\omega}{2i\pi\hbar}\int_0^\infty\frac{d\sigma}{\sin(\omega\sigma)}\exp\left[\frac{i\sigma}{\hbar}\left(2\alpha_0-\frac{\beta_1^2+\beta_2^2}{E}+i0\right)\right]$$

$$\times\exp\left\{\frac{iM\omega}{2\hbar}\left[(\tilde{\xi}^2+\tilde{\eta}^2+\tilde{\xi}'^2+\eta'^2)\cot(\omega\sigma)-\frac{2(\tilde{\xi}\tilde{\xi}'+\tilde{\eta}\tilde{\eta}')}{\sin(\omega\sigma)}\right]\right\}. \tag{58}$$

In order to determine the energy spectrum and the normalized wave functions of the bound states of the physical system, let's apply the Mehler formula[43]

$$\frac{1}{\sqrt{1-a^2}}\exp\left\{-\frac{1}{2(1-a^2)}[(x^2+x'^2)(1+a^2)-4xx'a]\right\}$$

$$=\exp\left[-\frac{1}{2}(x^2+x'^2)\right]\sum_{n=0}^{\infty}\frac{1}{n!}\left(\frac{a}{2}\right)^nH_n(x)H_n(x'). \tag{59}$$

With the help of an adequate change of variables, the poles of the Green's function (58) will be obtained thanks to an integration over σ; the discrete energy spectrum is found by solving the equation

$$\omega^3-\frac{2\alpha_0}{N\hbar}\omega^2-2\frac{\beta_1^2+\beta_2^2}{NM\hbar}=0,\quad\text{or as well}\quad E_N=-\frac{M\omega_N^2}{2}, \tag{60}$$

with $N=n_1+n_2+1$. α_0 being positive, then this cubic equation has one real root:

$$\omega_N=\frac{2\alpha_0}{3N\hbar}+\lambda_1+\lambda_2, \tag{61}$$

where

$$\lambda_j=\left[\left(\frac{2\alpha_0}{3N\hbar}\right)^3+\frac{\beta_1^2+\beta_2^2}{NM\hbar}+(-1)^j\sqrt{\frac{\beta_1^2+\beta_2^2}{NM\hbar}\left(\frac{\beta_1^2+\beta_2^2}{NM\hbar}+2\left(\frac{2\alpha_0}{3N\hbar}\right)^3\right)}\right]^{1/3}; \tag{62}$$

with $(j=1,2)$.

We may obtain the normalized wave functions of the bound states from the residues of the integrated expression of the Green's function (58),

$$\Psi_{n_1,n_2}(\xi,\eta)=\frac{M}{\hbar}\left(\frac{1}{2^Nn_1!n_2!N\pi}\lim_{\omega\to\omega_N}\frac{\omega^3(\omega^2-\omega_N^2)}{\omega^3-\frac{2\alpha_0}{N\hbar}\omega^2-2\frac{\beta_1^2+\beta_2^2}{NM\hbar}}\right)^{1/2}$$

$$\times\exp\left[-\frac{M\omega_N}{2\hbar}(\tilde{\xi}^2+\tilde{\eta}^2)\right]H_{n_1}\left(\sqrt{\frac{M\omega_N}{\hbar}}\tilde{\xi}\right)H_{n_2}\left(\sqrt{\frac{M\omega_N}{\hbar}}\tilde{\eta}\right). \tag{63}$$

Here, it is obvious that only states with an even total number of oscillator quanta contribute.

To find the wave functions of the continuous states, let's go back to the Green's function (58) and make use of the following relation:

$$\frac{1}{\sqrt{2\pi\sin\alpha}}\exp(-(x+y)\cot\alpha)\exp\left(\frac{2\sqrt{xy}}{\sin\alpha}\right)$$
$$=\frac{1}{(2\pi)^2}\int_{-\infty}^{\infty}dp\,e^{(\pi-2\alpha)p}\Bigg[\left|\Gamma\left(\frac{1}{4}+ip\right)\right|^2 E^{(0)}_{-\frac{1}{2}+2ip}$$
$$\times(e^{-i\pi/4}2\sqrt{x})E^{(0)}_{-\frac{1}{2}-2ip}(e^{i\pi/4}2\sqrt{y})+\left|\Gamma\left(\frac{3}{4}+ip\right)\right|^2 E^{(1)}_{-\frac{1}{2}+2ip}$$
$$\times(e^{-i\pi/4}2\sqrt{x})E^{(1)}_{-\frac{1}{2}-2ip}(e^{i\pi/4}2\sqrt{y})\Bigg], \tag{64}$$

which is established from the dispersion formula (28). The $E^{(0)}_{\nu}(z)$ and $E^{(1)}_{\nu}(z)$ are even and odd parabolic cylinder functions with respect to the variable z, respectively.[44] The poles of the continuous state Green's function will be obtained by integration on the τ variable. They will be given by

$$\omega(p_\xi+p_\eta)-\frac{i}{\hbar}\left(\alpha_0-\frac{\beta_1^2+\beta_2^2}{E}\right)=0. \tag{65}$$

Then, by performing the change of variables $(p_\xi,p_\eta)\rightarrow[(1/2p)((1/\tilde{a})+\varsigma),(1/2p)((1/\tilde{a})-\varsigma)]$ where $\tilde{a}=\hbar^2/M(\alpha_0-M(\beta_1^2+\beta_2^2)/\hbar^2p^2)$, it is possible to write the contribution of the continuous part to the Green's function as

$$G^c(\xi,\eta,\xi',\eta';E)=i\hbar\int_{-\infty}^{\infty}dp\int_{-\infty}^{\infty}d\varsigma\,\frac{\Psi^*_{p,\varsigma}(\xi',\eta')\Psi_{p,\varsigma}(\xi,\eta)}{E+i0-E_p}, \tag{66}$$

where $E_p=-(M\omega^2/2)=(\hbar^2p^2/2M)$, and the continuous functions $\Psi_{p,\varsigma}(\xi,\eta)$ have the form

$$\Psi_{p,\varsigma}(\xi,\eta)=\frac{e^{\pi/2\tilde{a}p}}{4\pi\sqrt{2}}\begin{pmatrix}\Gamma\left(\frac{1}{4}+\frac{i}{2p}\left(\frac{1}{\tilde{a}}+\varsigma\right)\right)E^{(0)}_{-1/2+i/p(1/\tilde{a}+\varsigma)}(e^{-i\pi/4}\sqrt{2p}\tilde{\xi})\\ \Gamma\left(\frac{3}{4}+\frac{i}{2p}\left(\frac{1}{\tilde{a}}+\varsigma\right)\right)E^{(1)}_{-1/2+i/p(1/\tilde{a}+\varsigma)}(e^{-i\pi/4}\sqrt{2p}\tilde{\xi})\end{pmatrix}$$
$$\times\begin{pmatrix}\Gamma\left(\frac{1}{4}+\frac{i}{2p}\left(\frac{1}{\tilde{a}}-\varsigma\right)\right)E^{(0)}_{-1/2+i/p(1/\tilde{a}-\varsigma)}(e^{-i\pi/4}\sqrt{2p}\tilde{\eta})\\ \Gamma\left(\frac{3}{4}+\frac{i}{2p}\left(\frac{1}{\tilde{a}}-\varsigma\right)\right)E^{(1)}_{-1/2+i/p(1/\tilde{a}-\varsigma)}(e^{-i\pi/4}\sqrt{2p}\tilde{\eta})\end{pmatrix}. \tag{67}$$

IV. THREE-DIMENSIONAL MAXIMALLY SUPER-INTEGRABLE POTENTIALS

In three-dimensional Euclidean space, Smorodinsky and co-workers have found a set of five potentials which have five functionally independent integrals of motion. These three-dimensional potentials are called maximally super-integrable potentials. At least, each potential of the so-called class of Smorodinsky–Winternitz potentials can be treated in two coordinate systems through the so(2,1) Lie algebraic approach. Here, we shall restrict ourselves to study the potential

$$V_3(\vec{r}) = -\frac{\alpha_0}{r} + \frac{\hbar^2}{2M}\left(\frac{k_1^2-\frac{1}{4}}{x_1^2} + \frac{k_2^2-\frac{1}{4}}{x_2^2}\right). \tag{68}$$

The integrals of motion are

$$H_3 = \frac{p^2}{2M} + V_3(\vec{r}), \quad I_1 = \frac{L_3^2}{2M} + \frac{\hbar^2}{2M}\left(\frac{k_1^2-\frac{1}{4}}{\cos^2\phi} + \frac{k_2^2-\frac{1}{4}}{\sin^2\phi}\right),$$

$$I_2 = \frac{L_2^2}{2M} + \frac{\hbar^2}{2M}\frac{k_1^2-\frac{1}{4}}{\tan^2\theta\cos^2\phi}, \quad I_3 = \frac{\vec{L}^2}{2M} + \frac{\hbar^2}{2M\sin^2\theta}\left(\frac{k_1^2-\frac{1}{4}}{\cos^2\phi} + \frac{k_2^2-\frac{1}{4}}{\sin^2\phi}\right), \tag{69}$$

$$I_4 = \frac{1}{4M}(I_{x_1x_2} + I_{x_2x_1}) - (\xi-\eta)\left[\frac{\alpha}{\xi+\eta} - \frac{\hbar^2}{2M\xi\eta}\left(\frac{k_1^2-\frac{1}{4}}{\cos^2\phi} + \frac{k_2^2-\frac{1}{4}}{\sin^2\phi}\right)\right],$$

where $I_{ij} = \{L_i, P_j\} = L_iP_j + P_jL_i$ with $(i,j) \equiv (x_1, x_2, x_3)$.

This potential is a generalization of the Coulomb potential analyzed by various authors in the path integral[45–56] and algebraic approach[57,58] contexts. As it features singularities for $x_1 = 0$ and $x_2 = 0$, all we need is to discuss it in the $0 < x_1,\ x_2 < \infty$ and $x_3 \in R$ area. It is possible to evaluate the Green's function

$$G(\vec{r},\vec{r'};E) = \int_0^\infty dS \exp\left[-\frac{iS}{\hbar}(H_3 - E - i0)\right]\delta(\vec{r}-\vec{r'}) \tag{70}$$

in parabolic and spherical coordinates.

A. Parabolic coordinates

For given parabolic coordinates $x_1 = \xi\eta\cos\phi$, $x_2 = \xi\eta\sin\phi$, $x_3 = \frac{1}{2}(\xi^2 - \eta^2)$, $\xi, \eta > 0$ and $0 \leqslant \phi < 2\pi$, the Green's function (70) can be written

$$G(\vec{r},\vec{r'};E) = \int_0^\infty dS \exp\left[-\frac{iS}{\hbar}(\tilde{H}_3 - E - i0)\right]\frac{\delta(\xi-\xi')\delta(\eta-\eta')\delta(\phi-\phi')}{\xi\eta(\xi^2+\eta^2)}, \tag{71}$$

with

$$\tilde{H}_3 = -\frac{\hbar^2}{2M}\left[\frac{1}{\xi^2+\eta^2}\left(\frac{\partial^2}{\partial\xi^2} + \frac{1}{\xi}\frac{\partial}{\partial\xi} + \frac{\partial^2}{\partial\eta^2} + \frac{1}{\eta}\frac{\partial}{\partial\eta}\right) + \frac{1}{\xi^2\eta^2}\frac{\partial^2}{\partial\phi^2}\right] - \frac{2\alpha_0}{\xi^2+\eta^2}$$
$$+ \frac{\hbar^2}{2M}\frac{1}{\xi^2\eta^2}\left(\frac{k_1^2-\frac{1}{4}}{\cos^2\phi} + \frac{k_2^2-\frac{1}{4}}{\sin^2\phi}\right). \tag{72}$$

Separating the angular part of the expression (71) by a time transformation defined by $\tau = S/\xi^2\eta^2$, we can deduce that

$$G(\vec{r},\vec{r'},E) = \int_0^\infty d\tau K(\xi,\eta,\xi',\eta';\tau)K(\phi,\phi';\tau), \tag{73}$$

where

$$K(\xi,\eta,\xi',\eta';\tau) = \exp\left\{-\frac{i\tau}{\hbar}[H_3(\xi,\eta) - E\xi^2\eta^2 - i0]\right\}\frac{\xi\eta}{\xi^2+\eta^2}\delta(\xi-\xi')\delta(\eta-\eta'), \tag{74}$$

and

$$K(\phi,\phi';\tau)=\exp\left\{-\frac{i\tau}{\hbar}\frac{\hbar^2}{2M}\left(-\frac{\partial^2}{\partial\phi^2}+\frac{k_1^2-\frac{1}{4}}{\cos^2\phi}+\frac{k_2^2-\frac{1}{4}}{\sin^2\phi}\right)\right\}\delta(\phi-\phi')$$
$$=\sum_{n=0}^{\infty}\Phi_n^{(\pm k_2,\pm k_1)}(\phi)\Phi_n^{(\pm k_2,\pm k_1)}(\phi')\exp\left(-\frac{i}{\hbar}\frac{\hbar^2\lambda_1^2}{2M}\tau\right), \tag{75}$$

with $\lambda_1=2n\pm k_1\pm k_2+1$.

It is to be noted that the explicit construction of the kernel $K(\phi,\phi';\tau)$ thanks to the (MS) variant of the algebraic technique is being investigated and will be the subject of our forthcoming publication.

Introducing (75) into (73) and applying the $\tau\rightarrow S$ inverse time transformation will allow us to write (73) as follows:

$$G(\vec{r},\vec{r'};E)=\sum_{n=0}^{\infty}\Phi_n^{(\pm k_2,\pm k_1)}(\phi)\Phi_n^{(\pm k_2,\pm k_1)}(\phi')\int_0^{\infty}dS\exp\left[\frac{iS}{\hbar}(E-i0)\right]$$
$$\times\exp\left\{-\frac{iS}{\hbar}[\tilde{H}_3(\xi,\eta)]\right\}\frac{\delta(\xi-\xi')\delta(\eta-\eta')}{\xi\eta(\xi^2+\eta^2)}, \tag{76}$$

where

$$\tilde{H}_3(\xi,\eta)=-\frac{\hbar^2}{2M}\frac{1}{\xi^2+\eta^2}\left(\frac{\partial^2}{\partial\xi^2}+\frac{1}{\xi}\frac{\partial}{\partial\xi}+\frac{\partial^2}{\partial\eta^2}+\frac{1}{\eta}\frac{\partial}{\partial\eta}\right)-\frac{2\alpha_0}{\xi^2+\eta^2}+\frac{\hbar^2\lambda_1^2}{2M\xi^2\eta^2}. \tag{77}$$

If we now eliminate the $(1/\xi)(\partial/\partial\xi)$ and $(1/\eta)(\partial/\partial\eta)$ operators by applying $(\partial^2/\partial\xi^2)+(1/\xi)(\partial/\partial\xi)$ and $(\partial^2/\partial\eta^2)+(1/\eta)(\partial/\partial\eta)$ on $\delta(\xi-\xi')/\sqrt{\xi\xi'}$ and $\delta(\eta-\eta')/\sqrt{\eta\eta'}$, respectively, we can then proceed with a new $S\rightarrow\sigma$ time transformation defined by $\sigma=S/(\xi^2+\eta^2)$, which will allow us to write

$$G(\vec{r},\vec{r'};E)=\sum_{n=0}^{\infty}\Phi_n^{(\pm k_2,\pm k_1)}(\phi)\Phi_n^{(\pm k_2,\pm k_1)}(\phi')\int_0^{\infty}d\sigma\exp\left[\frac{i}{\hbar}(2\alpha_0+i0)\sigma\right]$$
$$\times K_n(\xi,\xi';\sigma)K_n(\eta,\eta';\sigma), \tag{78}$$

with

$$K_n(u,u';\sigma)=\frac{1}{\sqrt{uu'}}\exp\left\{-\frac{i\sigma}{\hbar}\left[-\frac{\hbar^2}{2M}\left(\frac{\partial^2}{\partial u^2}-\frac{\lambda_1^2-\frac{1}{4}}{u^2}\right)-Eu^2\right]\right\}\delta(u-u'), \tag{79}$$

where $u\equiv(\xi$ or $\eta)$.

So, it is possible to give the kernel (79) in function of the so(2,1) Lie algebra operators. Indeed, by following the equations (2) and (13), we obtain

$$K_n(u,u';\sigma)=\frac{1}{\sqrt{uu'}}\exp\left\{-\frac{i\sigma}{\hbar}[T_1(u)+2\hbar^2\omega^2T_3(u)]\right\}\delta(u-u')$$
$$=\frac{M\omega}{i\hbar\sin(\omega\sigma)}\exp\left[\frac{iM\omega}{2\hbar}(u^2+u'^2)\cot(\omega\sigma)\right]I_{\lambda_1}\left(\frac{M\omega uu'}{i\hbar\sin(\omega\sigma)}\right), \tag{80}$$

with $\omega=\sqrt{-2E/M}$. The Green's function (78) can now be written

$$G(\vec{r},\vec{r'};E)=\sum_{n=0}^{\infty}\Phi_n^{(\pm k_2,\pm k_1)}(\phi)\Phi_n^{(\pm k_2,\pm k_1)}(\phi')G_n(\xi,\eta,\xi',\eta';E), \tag{81}$$

with

$$\begin{aligned}G_n(\xi,\eta,\xi',\eta';E)=&\left(\frac{M\omega}{i\hbar}\right)^2\int_0^{\infty}\frac{d\sigma}{\sin^2(\omega\sigma)}\exp\left[\frac{i}{\hbar}(2\alpha_0+i0)\sigma\right]\\&\times\exp\left[\frac{iM\omega}{2\hbar}(\xi^2+\eta^2+\xi'^2+\eta'^2)\cot(\omega\sigma)\right]\\&\times I_{\lambda_1}\left(\frac{M\omega\xi\xi'}{i\hbar\sin(\omega\sigma)}\right)I_{\lambda_1}\left(\frac{M\omega\eta\eta'}{i\hbar\sin(\omega\sigma)}\right).\end{aligned} \tag{82}$$

Thanks to the Hille and Hardy formula (23) for the discrete part and thanks to the scattering relation (28) for the continuous part, the Green's function (81) can be developed into partial waves as follows:

$$\begin{aligned}G(\vec{r},\vec{r'};E)=i\hbar\sum_{n=0}^{\infty}\Bigg\{&\sum_{n_1,n_2=0}^{\infty}\frac{\Psi_{n_1n_2,n}(\xi,\eta,\phi)\Psi^*_{n_1,n_2,n}(\xi',\eta',\phi')}{E+i0-E_N}\\&+\int_0^{\infty}dp\int_{-\infty}^{\infty}d\kappa\,\frac{\Psi_{p,\kappa,n}(\xi,\eta,\phi)\Psi^*_{p,\kappa,n}(\xi',\eta',\phi')}{E+i0-E_p}\Bigg\}.\end{aligned} \tag{83}$$

Hence, for bound states, the normalized wave functions and energy spectrum will be

$$\begin{aligned}\Psi_{n_1,n_2,n}(\xi,\eta,\phi)=&\left[\frac{2}{a^3N^4}\frac{n_1!n_2!}{\Gamma(n_1+\lambda_1+1)\Gamma(n_2+\lambda_2+1)}\right]^{1/2}\left(\frac{\xi\eta}{aN}\right)^{\lambda_1}\\&\times\exp\left(-\frac{\xi^2+\eta^2}{2aN}\right)L_{n_1}^{\lambda_1}\left(\frac{\xi^2}{aN}\right)L_{n_2}^{\lambda_1}\left(\frac{\eta^2}{aN}\right)\Phi_n^{(\pm k_2,\pm k_1)}(\phi),\end{aligned} \tag{84}$$

$$E_N=-\frac{M\alpha_0^2}{2\hbar^2N^2},\quad N=n_1+n_2+\lambda_1+1, \tag{85}$$

and, for the continuous states, the normalized wave functions and the energy spectrum will be

$$\begin{aligned}\Psi_{p,\kappa,n}(\xi,\eta,\phi)=&\frac{\left|\Gamma\left(\frac{1}{2}+\frac{\lambda_1}{2}+\frac{i}{2p}\left(\frac{1}{a}+\kappa\right)\right)\Gamma\left(\frac{1}{2}+\frac{\lambda_1}{2}+\frac{i}{2p}\left(\frac{1}{a}-\kappa\right)\right)\right|}{2\pi\Gamma^2(\lambda_1+1)\xi\eta}\\&\times\frac{e^{\pi/2ap}}{\sqrt{p}}M_{-i/2p[(1/a)+\kappa],(\lambda_1/2)}(-ip\xi^2)M_{-i/2p[(1/a)-\kappa],\lambda_1/2}(-ip\eta^2)\\&\times\Phi_n^{(\pm k_2,\pm k_1)}(\phi),\end{aligned} \tag{86}$$

$$E_p=\frac{\hbar^2p^2}{2M}. \tag{87}$$

B. Spherical coordinates

To study the problem in this coordinate system, we shall use the expression of the partial Green's function (82) and use the following change of variables:

$$(\xi,\eta)\to\left(\sqrt{2r}\cos\frac{\theta}{2},\sqrt{2r}\sin\frac{\theta}{2}\right). \tag{88}$$

The partial Green's function (86) then can be written

$$\begin{aligned}G_n(r,\theta,r',\theta';E)=&\sum_{m=0}^{\infty}(m+\lambda_1+\tfrac{1}{2})\frac{\Gamma(m+2\lambda_1+1)}{m!}P_{m+\lambda_1}^{-\lambda_1}(\cos\theta)\\&\times P_{m+\lambda_1}^{-\lambda_1}(\cos\theta')\int_0^{\infty}\frac{d\sigma}{\sin(\omega\sigma)}\exp\left[\frac{i}{\hbar}(2\alpha+i0)\sigma\right]\\&\times\exp\left[\frac{iM\omega}{\hbar}(r+r')\cot(\omega\sigma)\right]I_{2m+2\lambda_1+1}\left(\frac{2M\omega\sqrt{rr'}}{i\hbar\sin(\omega\sigma)}\right).\end{aligned} \tag{89}$$

We have used here the addition theorem (36), the connection between hypergeometric functions and the Jacobi polynomials[59]

$${}_2F_1\left(l+\alpha+\beta+1,-l;1+\alpha;\frac{1-t}{2}\right)=\frac{l!\Gamma(\alpha+1)}{\Gamma(l+\alpha+1)}P_l^{(\alpha,\beta)}(t), \tag{90}$$

as well as the relation between the hypergeometric functions and the Legendre polynomials,[60] and eventually the link between $P_\nu^{-m}(x)$ and $P_\nu^m(x)$ (Ref. 61).

In order to perform the integration on the σ time variable, we shall use the formula (40). Consequently, the final expression of the Green's function in spherical coordinates will be

$$\begin{aligned}G(\vec{r},\vec{r'};E)=&\sum_{n=0}^{\infty}\sum_{m=0}^{\infty}\left(m+\lambda_1+\frac{1}{2}\right)\frac{\Gamma(m+\lambda_1+1)}{m!}\frac{\Gamma(p+m+\lambda_1+1)}{\Gamma(2m+2\lambda_1+2)}\\&\times\frac{1}{i\omega rr'}M_{-p,m+\lambda_1+\frac{1}{2}}\left(\frac{2M\omega}{\hbar}r'\right)W_{-p,m+\lambda_1+\frac{1}{2}}\left(\frac{2M\omega}{\hbar}r\right)\\&\times P_{m+\lambda_1}^{-\lambda_1}(\cos\theta)P_{m+\lambda_1}^{-\lambda_1}(\cos\theta')\Phi_n^{(\pm k_2,\pm k_1)}(\phi)\Phi_n^{(\pm k_2,\pm k_1)}(\phi'),\end{aligned} \tag{91}$$

where $r>r'$ and $p=-\alpha_0/\hbar\omega$.

The Hille and Hardy formula (23) and an analytic proceeding consisting in using the Sommerfeld-Watson transformation[62] will help us to write the Green's function (91) in the form of a partial wave development consisting of two contributions of a discrete and a continuous part:

$$\begin{aligned}G(\vec{r},\vec{r'};E)=i\hbar\sum_{n,m=0}^{\infty}\Bigg\{&\sum_{l=0}^{\infty}\frac{\Psi_{l,m,n}(r,\theta,\phi)\Psi_{l,m,n}^*(r',\theta',\phi')}{E+i0-E_N}\\&+\int_0^{\infty}dk\frac{\Psi_{k,m,n}(r,\theta,\phi)\Psi_{k,m,n}^*(r',\theta',\phi')}{E+i0-\dfrac{\hbar^2k^2}{2M}}\Bigg\},\end{aligned} \tag{92}$$

with, for bound states, the poles located around the values of E and the normalized wave functions, respectively, given by

$$E_N=-\frac{M\alpha_0^2}{2\hbar^2N^2},\quad N=l+m+\lambda_1+1, \tag{93}$$

$$\Psi_{l,m,n}(r,\theta,\phi)=\left[\frac{(m+\lambda_1+\frac{1}{2})l!\Gamma(m+\lambda_1+1)}{a^3(l+\lambda_2+\frac{1}{2})^4 m!\Gamma(l+2\lambda_2+1)}\right]^{1/2}\left(\frac{2r}{a(l+\lambda_2+\frac{1}{2})}\right)^{\lambda_2-\frac{1}{2}}$$
$$\times\exp\left(-\frac{r}{a(l+\lambda_2+\frac{1}{2})}\right)L_l^{2\lambda_2}\left(\frac{2r}{a(l+\lambda_2+\frac{1}{2})}\right)$$
$$\times P_{m+\lambda_1}^{-\lambda_1}(\cos\theta)\Phi_n^{(\pm k_2,\pm k_1)}(\phi). \tag{94}$$

For continuous states, the normalized wave functions and energy spectrum are, respectively, given by

$$\Psi_{k,m,n}(r,\theta,\phi)=\frac{1}{\sqrt{2\pi}}\left[\left(m+\lambda_1+\frac{1}{2}\right)\frac{\Gamma(m+\lambda_1+1)}{m!}\right]^{1/2}\frac{\left|\Gamma\left(\frac{1}{2}+\lambda_2-\frac{i}{ak}\right)\right|}{\Gamma(2\lambda_2+1)}$$
$$\times\frac{e^{\pi/2ak}}{r}M_{(i/ak),\lambda_2}(-2ikr)P_{m+\lambda_1}^{-\lambda_1}(\cos\theta)\Phi_n^{(\pm k_2,\pm k_1)}(\phi). \tag{95}$$

V. THREE-DIMENSIONAL MINIMALLY SUPER-INTEGRABLE POTENTIALS

There are nine three-dimensional potentials which belong to the class of minimally super-integrable Smorodinsky–Winternitz potentials, that is to say three-dimensional potentials characterized by the existence of four functionally independent integrals of motion. Among them are seven potentials which have SO(2,1) as a dynamical group and thus their exact solution can be given via the (MS) variant of the algebraic approach in different coordinate systems. As an example, we shall discuss the potential

$$V_4(\vec{r})=-\frac{\alpha_0}{r}+\frac{\hbar^2}{2M(x_1^2+x_2^2)}\left(\frac{k_1^2x_3}{r}+F\left(\frac{x_2}{x_1}\right)\right), \tag{96}$$

with k_1 a positive constant. The corresponding observables have the form

$$H_4=\frac{\vec{P}^2}{2M}+V_4(\vec{r}),\quad I_1=\frac{L_z^2}{2M}+F(\tan\phi),\quad I_2=\frac{P_z^2}{2M}+\frac{\hbar^2}{2M}\frac{k_1^2\cos\theta+F(\tan\phi)}{\sin^2\theta},$$
$$I_3=\frac{1}{4M}(I_{x_1x_2}+I_{x_2x_1})-\alpha_0\frac{\xi-\eta}{\xi+\eta}+\frac{\hbar^2}{2M}\left(\frac{1}{\eta}-\frac{1}{\xi}\right)(k_1^2+F(\tan\phi)), \tag{97}$$

where $I_{ij}=\{L_i,P_j\}=L_iP_j+P_jL_i$ with $(i,j)\equiv(x_1,x_2,x_3)$.

The Green's function for this potential can be explicitly evaluated in the parabolic and spherical coordinate systems. For $F(y/x)=\gamma^2$ and γ a real constant, this potential reduces to the ring-shaped potential proposed by Hartmann as a model for the ring-shaped molecules. It has been analyzed by many authors in the framework of path integrals[63–67] and through the algebraic approach.[68–75] We can also notice the close link of the latter with the Coulomb potential plus the barrier created by the solenoid of Aharonov–Bohm[76] treated with the path integrals[77–79] and via the algebraic technique[80]. To give the solution for the potential (96) via the (MS) variant of the so(2,1) algebraic approach, we will use the Kustaanheimo–Stiefel transformation[81] $\{x_1,x_2,x_3\}\rightarrow\{u_j,j\in[1,4]\}$ corresponding to the surjection $R^4\rightarrow R^3$, which can be defined as

$$\begin{pmatrix} x_1 \\ x_2 \\ x_3 \end{pmatrix} = (A) \begin{pmatrix} u_1 \\ u_2 \\ u_3 \\ u_4 \end{pmatrix}, \quad (A) = \begin{pmatrix} u_3 & u_4 & u_1 & u_2 \\ -u_4 & u_3 & u_2 & -u_1 \\ -u_1 & -u_2 & u_3 & u_4 \\ -u_2 & u_1 & -u_4 & u_3 \end{pmatrix} \tag{98}$$

with the constraint

$$dx_4 = 2(-u_2\,du_1 + u_1\,du_2 - u_4\,du_3 + u_3\,du_4) = 0, \tag{99}$$

allowing to define a fourth coordinate

$$x_4 = 2\int^s (-u_2\dot{u}_1 + u_1\dot{u}_2 - u_4\dot{u}_3 + u_3\dot{u}_4)ds. \tag{100}$$

Moreover, we can show that

$$\begin{pmatrix} \dfrac{\partial}{\partial x_1} \\ \dfrac{\partial}{\partial x_2} \\ \dfrac{\partial}{\partial x_3} \\ \dfrac{1}{2r}\dfrac{\partial}{\partial x_4} \end{pmatrix} = \frac{1}{2r}(A) \begin{pmatrix} \dfrac{\partial}{\partial u_1} \\ \dfrac{\partial}{\partial u_2} \\ \dfrac{\partial}{\partial u_3} \\ \dfrac{\partial}{\partial u_4} \end{pmatrix}. \tag{101}$$

The (KS) transformation allows us to write the Laplacian $\vec{\nabla}^2$ in R^3 in terms of the Laplacian $\Box^2$ in R^4 as

$$\vec{\nabla}^2 = \frac{1}{4r}\Box^2 - \frac{1}{4r^2}\frac{\partial^2}{\partial x_4^2}, \quad \Box^2 = \sum_{j=1}^{4} \frac{\partial^2}{\partial u_j^2}, \tag{102}$$

where $r = (x_1^2 + x_2^2 + x_3^2)^{\frac{1}{2}} = u_1^2 + u_2^2 + u_3^2 + u_4^2$.

Using the Schwinger's integral representation, the Green's function relative to the potential $V_4(\vec{r})$ is written

$$G(\vec{r},\vec{r'};E) = \int_0^\infty dS \exp\left\{ -\frac{iS}{\hbar}\left[-\frac{\hbar^2}{2M}\vec{\nabla}^2 + V_4(\vec{r}) - E - i0 \right] \right\} \delta(\vec{r} - \vec{r'}). \tag{103}$$

It is possible to introduce an additional variable x_4 by means of the well-known identity

$$\int_{-\infty}^{\infty} \exp\left[\frac{i}{\hbar}\left(\frac{\hbar^2 S}{8Mr^2}\frac{\partial^2}{\partial x_4^2} \right) \right] \delta(x_4)\,dx_4 = 1, \tag{104}$$

and to show that expression (103) can be written as

$$G(\vec{r},\vec{r'};E) = \int_{-\infty}^{\infty} dx_4\, G(\vec{r},x_4,\vec{r'},0;E), \tag{105}$$

where

$$G(\vec{r},x_4,\vec{r'},0;E)=4r\int_0^\infty dS\,\exp\left\{-\frac{iS}{\hbar}[H_T-E-i0]\right\}\delta(\vec{r}-\vec{r'})\,\delta(x_4), \tag{106}$$

with

$$H_T=-\frac{\hbar^2}{2M}\left(\vec{\nabla}^2+\frac{1}{2r^2}\frac{\partial^2}{\partial x_4^2}\right)+V_4(\vec{r}). \tag{107}$$

Using (102) and (98), the Jacobian of this transformation given by $\partial(x_1,x_2,x_3,x_4)/\partial(u_1,u_2,u_3,u_4)=16r^2$, and the time transformation $\tau=S/4r$, the Green's function (106) can be set in the form

$$G(\vec{r},x_4,\vec{r'},0;E)=\frac{1}{4r}\int_0^\infty d\tau\,\exp\left[\frac{i}{\hbar}(4\alpha_0+i0)\tau\right]\exp\left\{-\frac{i\tau}{\hbar}\left[-\frac{\hbar^2}{2M}\Box^2+V(u)\right]\right\}\prod_{j=1}^{4}\delta(u_j-u_j'), \tag{108}$$

where

$$V(u)=\frac{\hbar^2k_1^2}{2M}\left(\frac{1}{u_1^2+u_2^2}-\frac{1}{u_3^2+u_4^2}\right)+\frac{\hbar^2}{2M}\left(\frac{1}{u_1^2+u_2^2}+\frac{1}{u_3^2+u_4^2}\right)F\left(\frac{u_2u_3-u_1u_4}{u_1u_3+u_2u_4}\right)-4Er. \tag{109}$$

The evaluation of this expression is possible in two coordinate systems.

A. Parabolic coordinates

Going on to the double polar coordinates

$$\begin{aligned}(u_1,u_2)\to(\eta,\phi_1):u_1&=\frac{\eta}{\sqrt{2}}\cos\phi_1,\quad u_2=\frac{\eta}{\sqrt{2}}\sin\phi_1,\\ (u_3,u_4)\to(\xi,\phi_2):u_3&=\frac{\xi}{\sqrt{2}}\cos\phi_2,\quad u_4=\frac{\xi}{\sqrt{2}}\sin\phi_2,\end{aligned} \tag{110}$$

the Green's function (108) becomes

$$\begin{aligned}G(\vec{r},x_4,\vec{r'},0;E)=\frac{1}{2r}\int_0^\infty d\tau\,\exp\left[\frac{i}{\hbar}(2\alpha_0+i0)\tau\right]\exp\left[-\frac{i\tau}{\hbar}H_p\right]\\ \times\frac{\delta(\xi-\xi')\delta(\eta-\eta')}{\sqrt{\xi\xi'\eta\eta'}}\,\delta(\phi_1-\phi_1')\delta(\phi_2-\phi_2'),\end{aligned} \tag{111}$$

where

$$H_p=-\frac{\hbar^2}{2M}\left(\frac{\partial^2}{\partial\xi^2}+\frac{\partial^2}{\partial\eta^2}+\frac{1}{\xi}\frac{\partial}{\partial\xi}+\frac{1}{\eta}\frac{\partial}{\partial\eta}+\frac{1}{\xi^2}\frac{\partial^2}{\partial\phi_1^2}+\frac{1}{\eta^2}\frac{\partial^2}{\partial\phi_2^2}\right)+V_p, \tag{112}$$

with

$$V_p=-\frac{\hbar^2k_1^2}{2M}\left(\frac{1}{\xi^2}-\frac{1}{\eta^2}\right)+\frac{\hbar^2}{2M}\left(\frac{1}{\xi^2}+\frac{1}{\eta^2}\right)F(\tan(\phi_1-\phi_2)-E(\xi^2+\eta^2). \tag{113}$$

Here we have applied the rescaling of 2τ to τ.

At this point, we notice that the separation of variables is not possible. To achieve it, it is necessary to perform the integration on the variable x_4 by using the Euler's angles $\phi_1=(\alpha+\phi)/2$, $\phi_2=(\alpha-\phi)/2$, $(0\leqslant\phi<2\pi, 0\leqslant\alpha<4\pi)$.

Then, it is easy to see that $dx_4=r\,d\alpha$ and that by integration over α we are led to $4\pi\delta_{\nu,0}$. It follows that the Green's function (103) can be written

$$G(\vec{r},\vec{r'};E)=\int_0^\infty d\tau\exp\left[\frac{i}{\hbar}(2\alpha_0+i0)\tau\right]K_{\xi\eta}(\phi,\phi';\tau)K(\xi,\eta,\xi',\eta';\tau), \tag{114}$$

where

$$K_{\xi\eta}(\phi,\phi';\tau)=\exp\left\{-\frac{i\tau}{\hbar}\frac{\hbar^2}{2M}\left(\frac{1}{\xi^2}+\frac{1}{\eta^2}\right)\left[-\frac{\partial^2}{\partial\phi^2}+F(\tan\phi)\right]\right\}\delta(\phi-\phi') \tag{115}$$

and

$$K(\xi,\eta,\xi',\eta';\tau)=\frac{1}{\sqrt{\xi\xi'\eta\eta'}}\exp\left[-\frac{i\tau}{\hbar}H(\xi,\eta)\right]\delta(\xi-\xi')\delta(\eta-\eta'), \tag{116}$$

with

$$H(\xi,\eta)=-\frac{\hbar^2}{2M}\left(\frac{\partial^2}{\partial\xi^2}+\frac{\partial^2}{\partial\eta^2}\right)-\frac{\hbar^2}{2M}\left(k_1^2-\frac{1}{4}\right)\left(\frac{1}{\xi^2}-\frac{1}{\eta^2}\right)-4E(\xi^2+\eta^2). \tag{117}$$

In order to bring to a constant the mass appearing in the Hamiltonian contained the kernel to expression (115) let's perform the time transformation $\tau\rightarrow\sigma$ defined by $\sigma=\tau[(1/\xi^2)+(1/\eta^2)]$. Then, it follows that

$$\begin{aligned}K_{\xi\eta}(\phi,\phi';\tau)&=\exp\left\{-\frac{i\sigma}{\hbar}\frac{\hbar^2}{2M}\left[-\frac{\partial^2}{\partial\phi^2}+F(\tan\phi)\right]\right\}\delta(\phi-\phi')\\&=\int dE_{\lambda_\phi}\exp\left[-\frac{i}{\hbar}\left(\frac{1}{\xi^2}+\frac{1}{\eta^2}\right)E_{\lambda_\phi}\tau\right]\Psi_{\lambda_\phi}(\phi)\Psi^*_{\lambda_\phi}(\phi'),\end{aligned} \tag{118}$$

with $E_{\lambda_\phi}=\hbar^2\lambda_\phi^2/2M$. Here, we have assumed that the propagator associated with the potential $F(\tan\phi)$ is known.

Let's now insert (118) and (116) in the expression (114), we obtain

$$\begin{aligned}G(\vec{r},\vec{r'};E)=&\int dE_{\lambda_\phi}\Psi_{\lambda_\phi}(\phi)\Psi^*_{\lambda_\phi}(\phi')\frac{1}{\sqrt{\xi\eta\xi'\eta'}}\int_0^\infty d\tau\exp\left[\frac{i}{\hbar}(2\alpha_0+i0)\tau\right]\\&\times K(\xi,\xi';\tau)K(\eta,\eta';\tau),\end{aligned} \tag{119}$$

where

$$\begin{aligned}K(u,u';\tau)&=\exp\left\{-\frac{i\tau}{\hbar}\left[-\frac{\hbar^2}{2M}\left(\frac{\partial^2}{\partial u^2}-\frac{\lambda_\phi^2\mp k_1^2-\frac{1}{4}}{u^2}\right)-Eu^2\right]\right\}\delta(u-u')\\&=\exp\left\{-\frac{i\tau}{\hbar}[T_1(u)+2\hbar^2\omega^2T_3(u)]\right\}\delta(u-u');(u\equiv\xi,\eta),\end{aligned} \tag{120}$$

with $\omega=\sqrt{-2E/M}$.

Following formula (13), the kernels (120) are written

$$K(u,u';\tau)=\frac{M\omega}{i\hbar\sin(\omega\tau)}\exp\left[\frac{iM\omega}{2\hbar}(u^2+u'^2)\cot(\omega\tau)\right]I_{\lambda_{\mp}}\left(\frac{M\omega uu'}{i\hbar\sin(\omega\tau)}\right), \tag{121}$$

with $\lambda_{\mp}=\sqrt{\lambda_{\phi}^2\mp k_1^2}$.

Inserting (121) into (114) and by a procedure similar to that which has led to result (83), we obtain

$$G(\vec{r},\vec{r'};E)=i\hbar\int dE_{\lambda_\phi}\left\{\sum_{n_1,n_2=0}^{\infty}\frac{\Psi_{n_1,n_2,\lambda_\phi}(\xi,\eta,\phi)\Psi^*_{n_1,n_2,\lambda_\phi}(\xi',\eta',\phi')}{E+i0-E_N}\right.$$
$$\left.+\int_0^\infty dp\int_{-\infty}^{\infty}d\varsigma\frac{\Psi_{p,\varsigma,\lambda_\phi}(\xi,\eta,\phi)\Psi^*_{p,\varsigma,\lambda_\phi}(\xi',\eta',\phi')}{E+i0-E_p}\right\}, \tag{122}$$

with the normalized wave functions and the energy spectrum for the bound states,

$$\Psi_{n_1,n_2,\lambda_\phi}(\xi,\eta,\phi)=\left[\frac{2}{a^3N^4}\frac{n_1!n_2!}{\Gamma(n_1+\lambda_-+1)\Gamma(n_2+\lambda_++1)}\right]^{1/2}\left(\frac{\xi}{aN}\right)^{\lambda_-/2}\left(\frac{\eta}{aN}\right)^{\lambda_+/2}$$
$$\times\exp\left(-\frac{\xi^2+\eta^2}{2aN}\right)L_{n_1}^{\lambda_-}\left(\frac{\xi^2}{aN}\right)L_{n_2}^{\lambda_+}\left(\frac{\eta^2}{aN}\right)\Psi_{\lambda_\phi}(\phi), \tag{123}$$

$$E_N=-\frac{M\alpha_0^2}{2\hbar^2N^2},\quad N=n_1+n_2+\tfrac{1}{2}(\lambda_-+\lambda_+)+1, \tag{124}$$

for the continuous states,

$$\Psi_{p,\varsigma,\lambda_\phi}(\xi,\eta,\phi)=\frac{\left|\Gamma\left(\frac{1}{2}(1+\lambda_+)+\frac{i}{2p}\left(\frac{1}{a}+\varsigma\right)\right)\Gamma\left(\frac{1}{2}(1+\lambda_-)+\frac{i}{2p}\left(\frac{1}{a}-\varsigma\right)\right)\right|}{2\pi\Gamma(1+\lambda_+)\Gamma(1+\lambda_-)}$$
$$\times\frac{e^{\pi/2ap}}{\sqrt{p}\xi\eta}M_{-(i/2p)[(1/a)+\varsigma],(\lambda_-/2)}(-ip\xi^2)$$
$$\times M_{-(i/2p)[(1/a)-\varsigma],(\lambda_+/2)}(-ip\eta^2)\times\Psi_{\lambda_\phi}(\phi), \tag{125}$$

$$E_p=\frac{\hbar^2p^2}{2M}. \tag{126}$$

B. Spherical coordinates

With the help of the change of variables defined by

$$(\xi,\eta)\rightarrow\left(\sqrt{2r}\cos\frac{\theta}{2},\sqrt{2r}\sin\frac{\theta}{2}\right), \tag{127}$$

and by applying the Bateman's expansion formula (26), expression (119) is rewritten

$$G(\vec{r},\vec{r'};E)=\int dE_{\lambda_\phi}\Psi_{\lambda_\phi}(\phi)\Psi^{*}_{\lambda_\phi}(\phi')\sum_{n=0}^{\infty}\Phi_n^{(\lambda_+,\lambda_-)}\left(\frac{\theta}{2}\right)$$
$$\times\Phi_n^{(\lambda_+,\lambda_-)}\left(\frac{\theta'}{2}\right)\frac{1}{\sqrt{\sin\theta\sin\theta'}}\int_0^{\infty}d\tau\frac{M\omega}{i\hbar\sin(\omega\tau)}\exp\left[\frac{i}{\hbar}(2\alpha_0+i0)\tau\right]$$
$$\times\exp\left[\frac{iM\omega}{\hbar}(r+r')\cot(\omega\tau)\right]I_{2n+\lambda_++\lambda_-+1}\left(\frac{2M\omega\sqrt{rr'}}{i\hbar\sin(\omega\tau)}\right). \tag{128}$$

Performing the integration over the time variable τ with the help of formula (30), we obtain the following final form:

$$G(\vec{r},\vec{r'};E)=\int dE_{\lambda_\phi}\Psi_{\lambda_\phi}(\phi)\Psi^{*}_{\lambda_\phi}(\phi')\sum_{n=0}^{\infty}\frac{1}{\sqrt{\sin\theta\sin\theta'}}\Phi_n^{(\lambda_+,\lambda_-)}\left(\frac{\theta}{2}\right)$$
$$\times\Phi_n^{(\lambda_+,\lambda_-)}\left(\frac{\theta'}{2}\right)\frac{1}{2i\omega rr'}\frac{\Gamma(p+n+\frac{1}{2}(\lambda_++\lambda_-)+1)}{\Gamma(2n+\lambda_++\lambda_-+2)}$$
$$\times M_{-p,n+\frac{1}{2}(\lambda_++\lambda_-+1)}\left(\frac{2M\omega}{\hbar}r'\right)W_{-p,n+\frac{1}{2}(\lambda_++\lambda_-+1)}\left(\frac{2M\omega}{\hbar}r\right), \tag{129}$$

where $r>r'$ and $p=-\alpha_0/\hbar\omega$.

Following the calculation procedure in Sec. IV B, one shows that

$$G(\vec{r},\vec{r'};E)=i\hbar\int dE_{\lambda_\phi}\sum_{n=0}^{\infty}\left\{\sum_{l=0}^{\infty}\frac{\Psi_{l,n,\lambda_\phi}(r,\theta,\phi)\Psi^{*}_{l,n,\lambda_\phi}(r',\theta',\phi')}{E+i0-E_N}\right.$$
$$\left.+\int_0^{\infty}dk\frac{\Psi_{k,n,\lambda_\phi}(r,\theta,\phi)\Psi^{*}_{k,n,\lambda_\phi}(r',\theta',\phi')}{E+i0-\frac{\hbar^2k^2}{2M}}\right\}, \tag{130}$$

where the normalized wave functions and the energy spectrum are given by

$$\Psi_{l,n,\lambda_\phi}(\vec{r})=\frac{1}{a(l+\lambda_1+\frac{1}{2})^2}\left[\frac{2l!}{a\Gamma(l+2\lambda_1+1)}\right]^{1/2}\left(\frac{2r}{a(l+\lambda_1+\frac{1}{2})}\right)^{\lambda_1-1/2}$$
$$\times\exp\left(-\frac{r}{a(l+\lambda_1+\frac{1}{2})}\right)L_l^{2\lambda_1}\left(\frac{2r}{a(l+\lambda_1+\frac{1}{2})}\right)\sqrt{\frac{2}{\sin\theta}}\,\Phi_n^{(\lambda_+,\lambda_-)}\left(\frac{\theta}{2}\right)\Psi_{\lambda_\phi}(\phi), \tag{131}$$

$$E_N=-\frac{M\alpha_0^2}{2\hbar^2N^2},\quad N=l+\lambda_1+\tfrac{1}{2},\quad\text{and}\quad\lambda_1=n+\tfrac{1}{2}(\lambda_++\lambda_-+1), \tag{132}$$

for the bound states and

$$\Psi_{k,n,\lambda_\phi}(\vec{r})=\frac{\left|\Gamma\left(\frac{1}{2}+\lambda_1-\frac{i}{ak}\right)\right|}{\Gamma(2\lambda_1+1)}\frac{e^{\pi/2ak}}{r}M_{-(i/ak),\lambda_1}(-2ikr)\frac{1}{\sqrt{2\sin\theta}}\Phi_n^{(\lambda_+,\lambda_-)}\left(\frac{\theta}{2}\right)\Psi_{\lambda_\phi}(\phi), \tag{133}$$

$$E_k = \frac{\hbar^2 k^2}{2M}, \tag{134}$$

for the continuous states.

VI. CONCLUSION

In this paper, we have analyzed through the Milshtein and Strakhovenko variant of the so(2,1) Lie algebra a set of potentials belonging to three different classes of Smorodinsky–Winternitz potentials. The use of the second order differential operators of this algebra allows to write the Hamiltonian of these physical systems in form of a linear combination of the latter. Using the Schwinger's integral representation and with the help of two Baker–Campbell–Hausdorff formulas allowing the separation of the T_i operators and thus simplifying their action on a Laplace transform of a well chosen Dirac distribution, we have shown that we can construct the Green's functions in compact form in different coordinate systems. This method can be compared to the approach of the Schrödinger equation and to the Feynman's path integral technique. It gives a local view of the problem under consideration like the Schrödinger approach, but its advantage is in the computation of the explicit and compact form of the Green's function from which the energy spectrum and the suitably normalized wave functions are simultaneously extracted for the bound states and for the continuous states if they exist at one and the same time.

The advantage of the path integral approach in comparison with the algebraic method is that it provides a global view of the dynamics of the physical system, but a problem of singularity is often to be found at the origin of coordinates, and it requires a regularization which is rather complicated to perform. From this point of view, we can assert that this algebraic method has the advantage of not presenting this problem owing to the fact that it is local.

The method of Milshtein and Strakhovenko could become a powerful alternative approach to the path integral technique if we manage to extend its use to the treatment of the Pöschl–Teller potential class.

(Received 26 January 2001; accepted for publication 5 July 2001)

We consider an electron constrained to move on a surface with revolution symmetry in the presence of a constant magnetic field B parallel to the surface axis. Depending on B and the surface geometry the transverse part of the spectrum typically exhibits many crossings which change to avoided crossings if a weak symmetry breaking interaction is introduced. We study the effect of such perturbations on the quantum propagation. This problem admits a natural reformulation to which tools from molecular dynamics can be applied. In turn, this leads to the study of a perturbation theory for the time dependent Born–Oppenheimer approximation.
 [DOI: 10.1063/1.1396834]

I. INTRODUCTION

Recent advances in experimental physics have made it possible to produce two-dimensional conducting surfaces of mesoscopic size. In such devices, the mean free path often exceeds the system size so the electron motion is ballistic and quantum coherence effects play a crucial role. This gives a motivation to strive for a complete understanding of the quantum mechanics of corresponding processes. In particular, conducting carbon ''nanotubes'' which are more or less uniform cylinders, belong to the family of surfaces that are nowadays experimentally within reach.[1] Since their discovery, lots of studies have been devoted to the elucidation of the spectral and transport properties of such devices, in a variety of situations and approximations, see, e.g., Refs. 2, 3, 4, and references therein. Nanotubes of different types can be combined, and also coupled to other carbon structures such as fullerene molecules,[5] producing a variety of cylindrical surfaces.

In this paper we study quantum propagation in an ''imperfect nanotube'' subject to a constant magnetic field parallel to the tube axis within a simple model. Our model assumes that a single electron is confined to a surface of revolution with slow variation of the radius along the revolution axis. Moreover, we assume that the rotational symmetry is weakly violated, either by an impurity or by an external field. In other words, the used idealization amounts to neglecting the atomic structure of the tube as well as the interaction between the electrons, but taking into account the gross shape of the device. Our aim is to study the propagation of the electron along such an imperfect nanotube in a homogenous magnetic field by means of the time-dependent Schrödinger equation, starting with an initially localized wave packet, and paying a particular attention to the transitions between angular levels caused by the symmetry breaking perturbation.

To understand the peculiarities of this quantum mechanical problem, it is useful to review briefly its classical counterpart; this is done in Sec. II. The first question in the quantum case is the meaning of the fact that the electron is confined to a surface. The most natural approach, in our opinion, is to consider the surface as a limiting situation of a thin hard-wall layer. This idea goes

[a)]Electronic mail: exner@ujf.cas.cz
[b)]Electronic mail: alain.joye@ujf-grenoble.fr

back to Refs. 6–8 and requires a renormalization in which the transverse contribution to the energy—blowing-up in the limit—is removed. One gets in this way an additional curvature-dependent term, in general attractive, to the potential. For the sake of completeness recall that there has been other recent works treating particle motion on revolution surfaces, see Refs. 9, 10, 11, and references therein. The last two papers aim at solvable models of compact surfaces (neglecting the curvature-dependent term), while Ref. 9 treats the Schrödinger and wave equations on noncompact cylindrical surfaces without a magnetic field from the PDE point of view.

Having thus found the Hamiltonian of our quantum system, we can analyze its spectral properties. When the rotational symmetry is preserved, we can perform (using a suitable gauge) the partial-wave decomposition. We can compute the angular part of the spectrum which depends on the actual cylinder radius varying along the tube axis. This brings to mind analogy with the molecular dynamics in which each angular state corresponds to an ''electronic'' level and the longitudinal coordinate measured along the axis corresponds to the one-dimensional ''nuclear'' configuration coordinate. Furthermore, when the rotational symmetry is broken by a perturbation, the above analogy remains valid and we may invoke the time-dependent Born–Oppenheimer approximation to describe the propagation along coupled angular levels according to Refs. 12–14. Recall that the theory in molecular systems involves a small parameter which is given by the mass ratio between ''electrons'' and ''nuclei.'' In our mesoscopic system, it is replaced by the parameter ϵ defined as the inverse of the length scale over which the variation of the radius of the nanotube takes place. Note, however, that we cannot directly apply the theory of Refs. 12–14 in our perturbative context and a modification is needed as we shall explain in Sec. IV.

The result of the analysis presented below gives a complete and rigorous description to the leading order of the wave function when the dynamics makes the electron go through a region where a perturbation couples angular levels. The basic picture is as follows. As long as the perturbed angular levels along the trajectory remain well isolated, the components of the wave function referring to the corresponding eigenstates are unchanged, to leading order. When the unperturbed angular levels display a crossing or an avoided crossing, transitions between the perturbed angular eigenstates may become non-negligible as in the mentioned molecular analogy, according to the well known mechanism of Landau–Zener transitions, see Ref. 13. At a heuristic level, when the electron meets an avoided crossing, we may replace the quantum mechanical degree of freedom x by a classical trajectory of the type $x \mapsto x_0 + tv$, where v is a velocity which can be considered as constant. This approximation leads to an effective time-dependent two-level system governing the transitions between the considered levels. The choice of a suitable time scale making the classical kinetic energy $mv^2/2$ constant and nonzero as the inverse length scale $\epsilon \to 0$ corresponds to the adiabatic limit $\epsilon \to 0$ in the above mentioned effective two-level Hamiltonian. Therefore, the transition probability $\mathcal{P}$ is then given by the Landau–Zener formula $\mathcal{P} \simeq e^{-c\delta^2/\epsilon}$, where δ is the minimum gap and the constant c is explicit.

We are going to consider precisely the situation where the transition amplitudes are of order one, under perturbations of order $\sqrt{\epsilon}$. In such cases, an initial wave function having a nonzero component in a single angular eigenspace before the (avoided) crossing splits in a nontrivial way between the corresponding angular eigenstates according to the Landau–Zener formula, again to leading order.

Let us note here that since the considered perturbations can arise from deformations and/or external fields, both allowed to vary over a wide range of values, situations where the typical size of the perturbation scales like the square root of the inverse length scale are certainly realistic. We choose to focus on these situations because they cause the most dramatic effects on the propagation. Indeed, we get from the Landau–Zener formula that other scaling laws make the avoided crossing either similar to a true crossing ($\mathcal{P} \simeq 1$) or to a set of well separated levels ($\mathcal{P} \simeq 0$).

We have already mentioned that despite being based on the paper,[13] our description is not a direct application of the molecular time-dependent Born–Oppenheimer approximation. Indeed, in the rigorous derivations of this approximation, the ''electronic'' spectrum and the eigenstates, i.e., the spectrum at fixed coordinate along the rotation axis in our setting, are taken as given data, and the approximate solution to the molecular Schrödinger equation is constructed from this informa-

tion, see Refs. 12–14. In our situation, by hypothesis, we only have access to that spectrum in a perturbative sense, and thus we need to develop a perturbative version of the time-dependent Born–Oppenheimer approximation that only requires knowledge of the leading terms of the Rayleigh–Schrödinger perturbation series. This is done in Sec. V, where the main technical result of the paper is stated in Theorem V.7. We believe that it is of an independent interest.

Precise statements of our results require a certain amount of notation and are therefore given below in Proposition IV.2 and Theorem V.7.

II. CLASSICAL MECHANICS

Let us start by describing the classical dynamics of the system. We consider a particle of mass m and charge e constrained to move on a smooth surface S with revolution symmetry around the axis OX in a homogeneous magnetic field $\mathbf{B}=Be_x$, $B\geqslant 0$, parallel to this axis.

Using cylindrical coordinates, the surface is characterized by the smooth positive real valued function $\mathbb{R}\ni x\mapsto R(x)\in\mathbb{R}_+^*$ such that

$$\begin{aligned} x&=x\\ y&=R(x)\cos(\theta),\\ z&=R(x)\sin(\theta) \end{aligned} \tag{2.1}$$

where $(x,\theta)\in\mathbb{R}\times S^1$. The squared length element on S is $ds^2=(1+R'(x)^2)dx^2+R(x)^2d\theta^2$, so the corresponding metric tensor $g_{ij}(x,\theta)$ is given by

$$g_{ij}(x,\theta)=\begin{pmatrix} 1+R'(x)^2 & 0\\ 0 & R^2(x)\end{pmatrix}. \tag{2.2}$$

Using the circular gauge, we express the vector potential at the surface as

$$\mathbf{A(r)}=\tfrac{1}{2}\mathbf{B}\wedge\mathbf{r}=\frac{R(x)B}{2}\begin{pmatrix}0\\ -\sin(\theta)\\ \cos(\theta)\end{pmatrix}. \tag{2.3}$$

This makes it possible to compute the Lagrangian function of the system,

$$\begin{aligned} L(\mathbf{r},\dot{\mathbf{r}})&=\tfrac{1}{2}m\dot{\mathbf{r}}^2+e\dot{\mathbf{r}}\mathbf{A(r)}\\ &=\frac{1}{2}m(\dot{x}^2(1+R'(x)^2)+R^2(x)\,\dot{\theta}^2)+\frac{eBR^2(x)\,\dot{\theta}}{2}. \end{aligned} \tag{2.4}$$

The system is integrable; we find that the momentum $p_\theta=(\partial L/\partial\dot{\theta})$ and the kinetic energy T are two constants of motion,

$$p_\theta=mR^2(x)\,\dot{\theta}+\frac{eBR^2(x)}{2}, \tag{2.5}$$

$$T=\tfrac{1}{2}m(\dot{x}^2(1+R'(x)^2)+R^2(x)\,\dot{\theta}^2). \tag{2.6}$$

Using (2.5) to express $\dot{\theta}$ as a function of x in (2.6), we deduce

$$T=\frac{1}{2}m\dot{x}^2(1+R'(x)^2)+\frac{1}{2m}\left(\frac{p_\theta^2}{R^2(x)}-p_\theta eB+\frac{e^2B^2}{4}R^2(x)\right)$$
$$=\frac{1}{2}m\dot{x}^2(1+R'(x)^2)+V(R(x)). \tag{27}$$

The effective potential $\mathbb{R}_+^* \ni R \mapsto V(R) \in \mathbb{R}_+$ admits a unique minimum at R_0 such that

$$R_0=\sqrt{\frac{2|p_\theta|}{|e|B}} \quad \text{and} \quad V(R_0)=\begin{cases} 0 & \text{if} \quad ep_\theta \geqslant 0 \\ \dfrac{|ep_\theta|B}{m} & \text{if} \quad ep_\theta<0 \end{cases}. \tag{2.8}$$

Note that if $p_\theta=0$, the potential $V(R)$ is harmonic on $\mathbb{R}_+^*$. From these considerations we deduce easily, in particular, that motions characterized by $\dot{x}(t)=0$ correspond either to $(x(t),\theta(t))=(x_0,\theta_0)$ for any initial conditions (x_0,θ_0), or to $(x(t),\theta(t))=(x_0,\theta_0-(eB/m)t)$, where $|e|B/m=:\omega_c$ is the cyclotronic frequency, for any initial conditions (x_0,θ_0), or finally to $(x(t),\theta(t))=(x_0,\theta_0+\omega t)$, where ω is any constant, for initial conditions (x_0,θ_0) such that $R'(x_0)=0$. In case $R'(x_0)\neq 0$, the first two motions are stable, whereas in the last one the stability depends on the local properties of R around x_0. In a similar way one can treat the general case with $\dot{x}(t)\neq 0$. The motion is governed by the effective potential determined by the shape of S, and the potential minima correspond to the points where the angular motion has the cyclotronic frequency.

Furthermore, notice that the addition of a supplementary exterior potential W, depending on x only, does not effect the functional dependence of p_θ and its value remains independent of time. It is just the second constant of motion which is changed in the sense that the total energy $E=T+W$ is now constant.

Finally, let us also give the corresponding Hamiltonian function of the system for future purposes. With $p_x=\partial L/\partial\dot{x}$ we compute

$$H(x,\theta,p_x,p_\theta)=\left(\frac{p_x^2}{2m(1+R'(x)^2)}+\frac{1}{2mR^2(x)}\left(p_\theta-\frac{eBR^2(x)}{2}\right)^2\right). \tag{2.9}$$

In the sequel we shall consider our charged particle to be an electron, $e=-|e|<0$, and use the rational units in which $|e|=m=1$ as well as $\hbar=c=1$.

III. QUANTUM MECHANICS

Consider now the same system in the framework of quantum mechanics. For the purpose of this section, the function $R:\mathbb{R}\to\mathbb{R}_+$ defining the surface S is supposed to be strictly positive and C^3; later we shall impose stronger requirements.

The Hilbert space of such a system is thus $L^2(S)$. To construct the Hamiltonian, however, it is not sufficient to replace the classical variables in (2.9) by the corresponding canonical operators. The most natural quantization consists in taking a particle confined to a cylindrical layer built over S and squeezing its thickness to zero, c.f. Refs. 6–8. One has of course to renormalize the energy in the limit, by subtracting the blowing-up part corresponding to the transverse motion.

In the absence of magnetic field, one arrives in this way to the Hamiltonian which is equal to the sum of the respective Laplace-Beltrami operator (times 1/2 in our units) and the curvature-induced potential $V(x)=-\frac{1}{8}(\varrho_1(x)^{-1}-\varrho_2(x)^{-1})^2$, where $\varrho_j(x)$, $j=1,2$, are the principal curvature radii at the given point. The second part is of a purely quantum nature and has no classical counterpart. In the present case the locally elliptical intersection of S with the normal plane has the radius $\varrho_1(x)=R(x)$, while for the intersection with the axial plane we find

$$\varrho_2(x)=-\frac{(1+R'(x)^2)^{3/2}}{R''(x)}; \tag{3.1}$$

the signs of ϱ_1, ϱ_2 coincide if both the osculation radii point the same side of the surface. Consequently, the curvature-induced potential equals

$$V(x) = -\frac{1}{8R(x)^2}\left(1+\frac{R(x)R''(x)}{(1+R'(x)^2)^{3/2}}\right)^2. \tag{3.2}$$

To express the kinetic (Laplace–Beltrami) part, $-\frac{1}{2}|g|^{-1/2}\partial_i|g|^{1/2}g^{ij}\partial_j$, we use (2.2) and the corresponding contravariant tensor on S,

$$g^{ij}(x) = \begin{pmatrix} (1+R'(x)^2)^{-1} & 0 \\ 0 & R(x)^{-2} \end{pmatrix}. \tag{3.3}$$

The Hamiltonian in the presence of magnetic field is then obtained by replacing the angular momentum operator $p_\theta = -i\partial_\theta$ by $p_\theta - A(x)R(x)$, where $A(x) := A_\theta(\mathbf{r})$; it acts as

$$\begin{aligned} H = &-\frac{1}{2R(x)\sqrt{1+R'(x)^2}}\partial_x\frac{R(x)}{\sqrt{1+R'(x)^2}}\partial_x + \frac{1}{2R(x)^2}\left(-i\partial_\theta + \frac{BR(x)^2}{2}\right)^2 \\ &-\frac{1}{8R(x)^2}\left(1+\frac{R(x)R''(x)}{(1+R'(x)^2)^{3/2}}\right)^2 \end{aligned} \tag{3.4}$$

on an appropriate domain in $L^2(\mathbb{R}\times S^1, R(x)\sqrt{1+R'(x)^2}\,dx\,d\theta)$. Due to the rotational symmetry it has a simple partial-wave decomposition; its H_m component is obtained replacing $-i\partial_\theta$ by its eigenvalue m. In this way the spectral analysis of H is reduced to a family of one-dimensional Sturm–Liouville problems. The magnetic term also has a natural meaning; we have

$$A(x)R(x) = \frac{BR(x)^2}{2} = \frac{\Phi(x)}{2\pi} = \phi(x), \tag{3.5}$$

where ϕ is the magnetic flux value measured in the standard units $(2\pi)^{-1}$, or the number of flux quanta passing through the cross section of the cylinder.

It may be convenient to get rid of the weight factor replacing the operator H above by an operator $\tilde{H}$ on $L^2(\mathbb{R})\otimes L^2(S^1)$. This is achieved by the unitary transformation $\psi \mapsto R^{1/2}(1+R'^2)^{1/4}\psi$. The only term in (3.4) which changes is the first one: by a straightforward computation we find

$$\tilde{H} = -\partial_x\frac{1}{2(1+R'(x)^2)}\partial_x + \frac{1}{2R(x)^2}\left(-i\partial_\theta + \frac{BR(x)^2}{2}\right)^2 + V_{21}(x) + V_{22}(x) \tag{3.6}$$

with

$$V_{21}(x) = -\frac{1}{8R(x)^2}\left(1+\frac{R(x)R''(x)}{(1+R'(x)^2)^{3/2}}\right)^2 \tag{3.7}$$

and

$$V_{22}(x) = \left(-\frac{R'^2}{8R^2(1+R'^2)} - \frac{7}{8}\frac{R'^2R''^2}{(1+R'^2)^3} + \frac{R''+R(R'R'''+R''^2)}{4R(1+R'^2)^2}\right)(x). \tag{3.8}$$

Spectral properties of the Hamiltonian are influenced by the geometry of S. Suppose, e.g., that the latter has asymptotically constant radius, $\lim_{|x|\to\infty} R(x) = R_0$. In the absence of magnetic field the problem is similar to that of a locally deformed Dirichlet strip[15,16] (it is simpler, however, unless a mode-coupling perturbation is introduced). In the s-wave part the effective potential V_{21}

creates a potential well when S is locally squeezed and a barrier in case of a protrusion. For higher partial waves and nonzero magnetic field, of course, the effective potential consists of several competing contributions.

IV. QUANTUM PROPAGATION

Our main interest in this paper is not so much the spectrum of the Hamiltonian (3.4) than the way in which an electron propagates over the surface of the cylinder. We will be particularly interested in the limiting situation when the radius modulation is gentle. This is conventionally described by means of the scaling transformation $x \mapsto \epsilon x$ which turns $\tilde{H}$ into $H(\epsilon)$ and by considering the asymptotic behavior as $\epsilon \to 0$. This can be considered as a semiclassical limit since as $\epsilon \to 0$ the wave packet size becomes ultimately much smaller than the length scale of the radius variations.

It is clear from the preceding section that the effective potential $V_2 = V_{21} + V_{22}$ is then dominated by the first term. Moreover, the operators (3.4) and (3.6) coincide to leading order, which will be the object of the following investigation. We write the action of $H(\epsilon)$ as

$$H(\epsilon) = -\frac{\epsilon^2}{2}\partial_x \frac{1}{1+\epsilon^2 V_1(x)}\partial_x + V_2(x,\epsilon) + \frac{1}{2R^2(x)}\left(-i\partial_\theta + \frac{BR^2(x)}{2}\right)^2 \tag{4.1}$$

on a suitable domain of $L^2(\mathbb{R}) \otimes L^2(S^1)$, where $R(x)$, $V_1(x) = R'(x)^2$ are smooth on $\mathbb{R}$ and $V_2(x,\epsilon)$ is smooth on $\mathbb{R} \times [-\epsilon_0, \epsilon_0]$, for some $\epsilon_0 > 0$. Introducing an R-dependent operator $h(R)$ for $R \in \mathbb{R}_+^*$ by

$$h(R) = \frac{1}{2R^2}\left(-i\partial_\theta + \frac{BR^2}{2}\right)^2 \tag{4.2}$$

on a suitable domain of $L^2(S^1)$, we can regard $H(\epsilon)$ as an operator on $L^2(\mathbb{R}, L^2(S^1))$ which we write as

$$H(\epsilon) = -\frac{\epsilon^2}{2}\partial_x \frac{1}{1+\epsilon^2 V_1(x)}\partial_x + V_2(x,\epsilon) + h(R(x)). \tag{4.3}$$

The spectral analysis of $h(R)$ is straightforward and yields a family of simple eigenvalues,

$$\sigma(h(R)) = \{\lambda_n(R), n \in \mathbb{Z}\} = \left\{\frac{1}{2R^2}\left(n + \frac{BR^2}{2}\right)^2, n \in \mathbb{Z}\right\}, \tag{4.4}$$

with the corresponding eigenvectors,

$$\varphi_n(\theta) = \exp(in\theta)/\sqrt{2\pi}, \quad n \in \mathbb{Z}. \tag{4.5}$$

Note that the eigenvalues $\lambda_n(R)$ correspond to the classical effective potential $V(R)$ in (2.7) with $n \in \mathbb{Z}$ in place of p_θ. For $n \neq m$ we have

$$\lambda_n(R) - \lambda_m(R) = \frac{(n-m)}{2}\left(\frac{(n+m)}{R^2} + B\right) \tag{4.6}$$

so that

$$\lambda_n(R) = \lambda_m(R) \Leftrightarrow n + m < 0 \quad \text{and} \quad R = R_{n,m} = \sqrt{\frac{-(n+m)}{B}}. \tag{4.7}$$

Moreover,

$$\lambda_n(R_{n,m}) = -\frac{B}{2}\frac{(n-m)^2}{(n+m)} > 0. \tag{4.8}$$

Hence any pair of levels $(\lambda_n(R),\lambda_m(R))$ with $n+m<0$ exhibits one and only one crossing as R varies, whereas other pairs never cross. The crossing points are well separated,

$$\{R_{n,m}:\ (n,m)\in\mathbb{N}^2,\ \ n+m<0\} = \left\{\ \sqrt{\frac{k}{B}} : k\in\mathbb{N}^*\right\}, \tag{4.9}$$

with $\sqrt{k/B} = R_{n,-(k+n)}$, $n\in\mathbb{N}$, and the values of the different pairs of levels crossing at $\sqrt{k/B}$, for k fixed, are also well separated since

$$\lambda_n(R_{n,-(k+n)}) = \frac{B}{2}\frac{(2n+k)}{k}. \tag{4.10}$$

We note also that $\lambda_n(R)-\lambda_{-n}(R) = Bn$.

Thus, depending on our choice of the function $R(x)$, the spectrum of $h(R(x))$ may display real or avoided crossings of an arbitrary width. Our aim is to adapt the techniques developed in Ref. 13 to describe the propagation of Gaussian wave packets (in the variable x) through these (avoided) crossings and, in particular, the splitting of the solution among the different angular levels $\lambda_n(R(x))$ involved. In particular, we can also suppose that the shape of the tube is gently changing in the way described above with the parameter ϵ entering in the definition of R; in any case, it will then turn out that the natural scale for the phenomena we want to describe is $\delta = \sqrt{\epsilon}$. We henceforth adopt δ as our small parameter and consider smooth functions $R(x,\delta)$ defined on $\mathbb{R}\times[-\delta_0,\delta_0]$. This means, in particular, that both the function V_1 and the operator h will depend on both x and δ in a smooth fashion.

However, the model discussed so far cannot exhibit transitions because of the rotational invariance which forbids passages between different levels λ_n. To get a nontrivial result, we perturb our system by introducing a real valued potential $\delta W(x,\theta,\delta)$, which is smooth on $\mathbb{R}\times S^1\times[-\delta_0,\delta_0]$ and violates the symmetry. For example, we can add a constant electric field in the direction $\mathbf{d} = \sin(\alpha)\mathbf{e}_z + \cos(\alpha)\mathbf{e}_x$, where $\alpha\notin\mathbb{Z}\pi$. As a consequence, we lose integrability of the system on the classical level, whereas in the quantum setting transitions between the different perturbed eigenstates become possible. By assumption, when considered as a (bounded) operator on $L^2(S^1)$ for (x,δ) fixed, the operator $\delta W(x,\theta,\delta)$ does not commute with $h(R(x,\delta))$, and therefore it perturbs the spectrum $\sigma(h(R(x,\delta))$. Note that for (x,δ) fixed, the above mentioned electric field gives rise to a bounded operator on $L^2(S^1)$. For the time being, let us keep the general form $\delta W(x,\theta,\delta)$ for the perturbation and describe the differences and similarities of the present case with respect to the paper.[13]

We introduce the operator g on (a suitable domain of) $L^2(\mathbb{R},L^2(S^1))$ by

$$g(x,\delta) = h(R(x,\delta)) + V_2(x,\delta) + \delta W(x,\theta,\delta) \tag{4.11}$$

so that the perturbed full Hamiltonian reads (with a slight abuse of notation)

$$H(\delta) = -\frac{\delta^4}{2}\partial_x\frac{1}{1+\delta^4 V_1(x,\delta)}\partial_x + g(x,\delta). \tag{4.12}$$

Without loss of generality, we can assume that $\int_{S^1} W(x,\theta,\delta)\,d\theta = 0$ by modifying $V_2(x,\delta)$ if necessary. We require the different potentials introduced so far to be smooth so that the following regularity hypothesis is fulfilled.

H0: *The operator g is strongly C^∞ in (x,δ) in $\mathbb{R}\times[-\delta_0,\delta_0]$.*

We want to approximate the solutions to the Schrödinger equation in a suitable time scale,

$$i\delta^2\frac{\partial\psi}{\partial t}=H(\delta)\psi, \tag{4.13}$$

for t in a finite time interval, as $\delta\to 0$, for initial conditions of a ''coherent state'' type, which we shall describe in detail below.

The first difference in comparison with Ref. 13 comes from the fact that the kinetic term gives rise to a perturbed Laplacian,

$$-\frac{\delta^4}{2}\partial_x\frac{1}{1+\delta^4V_1(x,\delta)}\partial_x=-\frac{\delta^4}{2}\partial_x^2+\frac{\delta^8}{2}\partial_x\frac{V_1(x,\delta)}{1+\delta^4V_1(x,\delta)}\partial_x$$

$$\equiv-\frac{\delta^4}{2}\partial_x^2+Y(x,\partial_x,\delta), \tag{4.14}$$

where

$$Y(x,\partial_x,\delta)=-\delta^4\frac{V_1(x,\delta)}{1+\delta^4V_1(x,\delta)}\frac{(-i\delta^2\partial_x)^2}{2}-\frac{\delta^4}{2}\left(-i\delta^2\partial_x\frac{V_1(x,\delta)}{1+\delta^4V_1(x,\delta)}\right)(-i\delta^2\partial_x). \tag{4.15}$$

We assume
H1:

$$\sup_{x\in\mathbb{R},|\delta|\leqslant\delta_0}|V_1^{(k)}(x,\delta)|<\infty,\quad k=0,1. \tag{4.16}$$

The factor δ^8 in front of the operator Y makes it possible to show that the influence of this term is negligible on the propagation of Gaussian states, so that the approximation given in Ref. 13 remains valid. This claim is the main result of this section and will be made precise in Proposition IV.2 below.

The second difference in comparison with Ref. 13 is that unless we have an explicitly solvable situation—and such situations are rare—in general we do not know the exact eigenvalues and eigenstates of the operator $g(x,\delta)$. However, the approximation derived in Ref. 13 is constructed on the basis of this exact knowledge. A way out is to use an incomplete information coming from the perturbation theory. Our second result, Theorem V.7, stated in Sec. V says that it is enough to know the first few terms in the perturbation series in order to construct an approximation that describes the propagation, even in the presence of avoided crossings, and that the result is as good as the one derived in Ref. 13.

The rest of this section is organized as follows. We proceed with the description of the ingredients needed for our approximation, in analogy with Ref. 13, assuming that we know the exact diagonal form of $g(x,\delta)$. Then we prove that the perturbation of the Laplacian by the operator Y does not effect the validity of this approximation. The next section will be devoted to the perturbative aspects mentioned above.

We will denote by $\mu_n(x,\delta)$ the eigenvalue of $g(x,\delta)$ such that $\mu_n(x,\delta)-\lambda_n(R(x,\delta))\to 0$ as $\delta\to 0$, for x such that $R(x,\delta)$ is far from $R_{n,m}$. The corresponding eigenvector will be denoted by $\Phi_n(x,\delta)$. If $R(x,\delta)$ lies in a neighborhood of $R_{n,m}$, we will denote by $\mu_{\mathcal{A}}(x,\delta)\geqslant\mu_{\mathcal{B}}(x,\delta)$ the almost degenerate perturbed eigenvalues with the corresponding eigenvectors $\Phi_{\mathcal{A}}(x,\delta)$ and $\Phi_{\mathcal{B}}(x,\delta)$. The reason for such a convention is that the unperturbed eigenvalues $\lambda_n(R(x,\delta)$ may or may not cross, are therefore the labeling of the μ's in terms of the indices n and m is not straightforward. Let $Q_n(x,\delta)$ be the one-dimensional spectral projection of $g(x,\delta)$ corresponding to $\mu_n(x,\delta)$ in the first case and $P(x,\delta)$ be the two-dimensional spectral projection of $g(x,\delta)$ corresponding to $\mu_{\mathcal{A}}(x,\delta)\geqslant\mu_{\mathcal{B}}(x,\delta)$ in the second case.

The situation we will study is that of avoided crossings of minimum width of order δ. Without loss of generality, we can assume the avoided crossing takes place in a neighborhood of $x=0$.

More precisely we suppose that:
H2: *The eigenvalues* $\mu_{\mathcal{A}}(x,\delta)$ *and* $\mu_{\mathcal{B}}(x,\delta)$ *are such that* $(\mu_{\mathcal{A}}-\mu_{\mathcal{B}})^{(-1)}\{0\}=(0,0)$ *in a neighborhood of* (0,0) *and* $\inf_{x\in I}(\mu_{\mathcal{A}}(x,\delta)-\mu_{\mathcal{B}}(x,\delta))=c|\delta|>0$ *for* $\delta\neq 0$, *where* c *is a constant and* I *is a small interval containing* 0.
We also set

$$g_{\parallel}(x,\delta)=g(x,\delta)P(x,\delta), \tag{4.17}$$

$$g_{\perp}(x,\delta)=g(x,\delta)(\mathbb{I}-P(x,\delta)). \tag{4.18}$$

We know from Ref. 17 that locally around (0,0) there exists an orthonormal basis, denoted by $\{\psi_1(x,\delta),\psi_2(x,\delta)\}$, of $P(x,\delta)L^2(S^1)$, which is regular in (x,δ) around (0,0). It is constructed in the standard Gram–Schmidt way: we choose an orthonormal basis $\{\psi_1,\psi_2\}$ of $P(0,0)L^2(S^1)$ and set

$$\phi_1(x,\delta)=\frac{P(x,\delta)\psi_1}{\|P(x,\delta)\psi_1\|}, \tag{4.19}$$

$$\phi_2(x,\delta)=\frac{(\mathbb{I}-|\phi_1(x,\delta)\rangle\langle\phi_1(x,\delta)|)P(x,\delta)\psi_2}{\|(\mathbb{I}-|\phi_1(x,\delta)\rangle\langle\phi_1(x,\delta)|)P(x,\delta)\psi_2\|}. \tag{4.20}$$

Moreover, there exists a (x,δ) independent unitary transform U such that in the orthonormal basis,

$$\psi_j(x,\delta)=U\phi_j(x,\delta),\quad j=1,2, \tag{4.21}$$

the matrix $g_{\parallel}(x,\delta)$ takes the form

$$\begin{aligned} g_{\parallel}(x,\delta)&=g_1(x,\delta)+\overline{V}(x,\delta)\\ &=\begin{pmatrix}\beta(x,\delta) & \gamma(x,\delta)+i\sigma(x,\delta)\\ \gamma(x,\delta)-i\sigma(x,\delta) & -\beta(x,\delta)\end{pmatrix}+\overline{V}(x,\delta), \end{aligned} \tag{4.22}$$

where $\overline{V}(x,\delta)=\mathrm{trace}(g(x,\delta)P(x,\delta))/2$ is a regular function of (x,δ) around the origin and

$$\begin{aligned} \beta(x,\delta)&=b_1x+b_2\delta+\mathcal{O}(2),\\ \gamma(x,\delta)&=c_2\delta+\mathcal{O}(2),\\ \sigma(x,\delta)&=\mathcal{O}(2),\\ \overline{V}(x,\delta)&=\mathcal{O}(0), \end{aligned} \tag{4.23}$$

where $b_1>0, c_2>0, b_2\in\mathbb{R}$, and the following notation is used for the sake of brevity:

$$\mathcal{O}(m)=\mathcal{O}((x^2+\delta^2)^{m/2}). \tag{4.24}$$

In order to get rid of the δ-dependence in the leading order of $\beta(x,\delta)$ in (4.22), we introduce new variables,

$$x'=b_1x+b_2\delta,\quad \delta'=c_2\delta,\quad t'=b_1^2/c_2^2t. \tag{4.25}$$

In terms of these variables, the Schrödinger Eq. (4.13) for

$$\phi(x',t')=\psi(x(x',\delta'),t(t')) \tag{4.26}$$

becomes

$$i\delta'^2\frac{\partial}{\partial t'}\phi(x',t')=-\frac{\delta'^4}{2}\partial_{x'}\frac{1}{1+\delta'^4V_1'(x',\delta')}\partial_{x'}\phi(x',t')+\frac{c_2^4}{b_1^2}g(x(x',\delta'),\delta(\delta'))\phi(x',t') \tag{4.27}$$

in the limit $\delta'\to 0$, with

$$V_1'(x',\delta')=V_1(x(x',\delta'),\delta(\delta'))/c_2^4, \tag{4.28}$$

$$g_{\|}(x(x',\delta'),\delta(\delta'))=\begin{pmatrix} x_1' & \delta' \\ \delta' & -x_1' \end{pmatrix}+\mathcal{O}(2)+\overline{V}(x(x',\delta'),\delta(\delta')), \tag{4.29}$$

where $\overline{V}(x(x',\delta'),\delta(\delta'))$ and $V_1'(x',\delta')$ are regular in (x',δ') around (0,0) and $\mathcal{O}(2)$ refers to x' and δ'. We introduce the fixed parameter $r=c_2^4/b_1^2>0$ and *henceforth drop the primes on the new variables*. We assume that $g_1(x,\delta)$ has the form (4.22) with the following local behavior around $x=0$ and $\delta=0$:

$$\begin{aligned} \beta(x,\delta)&=rx+\mathcal{O}(2),\\ \gamma(x,\delta)&=r\delta+\mathcal{O}(2),\\ \sigma(x,\delta)&=\mathcal{O}(2),\\ \overline{V}(x,\delta)&=\mathcal{O}(0) \end{aligned} \tag{4.30}$$

with $r>0$.

Let us next describe the building blocks of our Born–Oppenheimer states.

We begin with the definition of the semiclassical ''nuclear'' wave packets denoted as $\varphi_j(A,B,\hbar,a,\eta,x)$. This definition comes from Ref. 18; we have specified it to our setting where $x\in\mathbb{R}$. Since Ref. 18 provides a detailed discussion of these wave packets, we refrain from proving all their properties here.

We assume $a\in\mathbb{R}$, $\eta\in\mathbb{R}$ and $\hbar=\delta^2>0$. Let us stress that while the last symbol is useful when adapting the results of Ref. 18, it has nothing to do with the Planck's constant. We also assume that A and B are nonzero complex numbers that satisfy

$$\mathrm{Re}\,\overline{A}B=1. \tag{4.31}$$

This condition guarantees that $\mathrm{Re}\,BA^{-1}$ is positive, since $(\mathrm{Re}\,BA^{-1})^{-1}=|A|^2$.

Our definition of $\varphi_j(A,B,\hbar,a,\eta,x)$ is based on the following raising operator:

$$\mathcal{A}(A,B,\hbar,a,\eta)^*=\frac{1}{\sqrt{2\hbar}}\left[\overline{B}(x-a)-\overline{A}\left(-i\hbar\frac{\partial}{\partial x}-\eta\right)\right]. \tag{4.32}$$

Definition: For the index $j=0$, we define the normalized complex Gaussian wave packet (modulo the sign of the square root) by

$$\varphi_0(A,B,\hbar,a,\eta,x)=\pi^{-1/4}\hbar^{-1/4}A^{-1/2}\times\exp\{-BA^{-1}(x-a)^2/(2\hbar)+i\eta(x-a)/\hbar\}. \tag{4.33}$$

Then for any positive integer j we define

$$\varphi_j(A,B,\hbar,a,\eta,\cdot)=\frac{1}{\sqrt{j!}}(\mathcal{A}(A,B,\hbar,a,\eta)^*)^j\varphi_0(A,B,\hbar,a,\eta,\cdot). \tag{4.34}$$

Remarks:

(1) For $A=B=1$, $\hbar=1$, and $a=\eta=0$, the $\varphi_j(A, B, \hbar, a, \eta, \cdot)$ are just the standard harmonic-oscillator eigenstates with energies $j+1/2$;
(2) For each A, B, $\hbar$, a, and η, the set $\{\varphi_j(A, B, \hbar, a, \eta, \cdot)\}$ is an orthonormal basis for $L^2(\mathbb{R})$;
(3) The position and momentum uncertainties of the $\varphi_j(A, B, \hbar, a, \eta, \cdot)$ are $\sqrt{(j+1/2)\hbar}\,|A|$ and $\sqrt{(j+1/2)\hbar}|B|$, respectively;
(4) When we solve approximately the Schrödinger equation, the choice of the sign of the square root in the definition of $\varphi_0(A, B, \hbar, a, \eta, \cdot)$ is determined by continuity in t after an arbitrary initial choice;
(5) Defining the scaled Fourier transform to be

$$[\mathcal{F}_\hbar \Psi\,](\xi)=(2\pi\hbar)^{-1/2}\int_{\mathbb{R}}\Psi(x)e^{-i\xi x/\hbar}dx, \tag{4.35}$$

then

$$[\mathcal{F}_\hbar \varphi_l(A,B,\hbar,a,\eta,\cdot)](\xi)=(-i)^l\, e^{-i\eta a/\hbar}\varphi_l(B,A,\hbar,\eta,-a,\xi). \tag{4.36}$$

We also define

$$V^{\mathcal{A}}_{\mathcal{B}}(x,\delta)=\overline{V}(x,\delta)\pm\sqrt{\beta^2(x,\delta)+\gamma^2(x,\delta)+\sigma^2(x,\delta)}, \tag{4.37}$$

where $x\in\mathbb{R}$, $\delta>0$. Let $a^{\mathcal{C}}(t)$ and $\eta^{\mathcal{C}}(t)$ be the solutions of the classical equations of motion,

$$\frac{d}{dt}a^{\mathcal{C}}(t)=\eta^{\mathcal{C}}(t), \tag{4.38}$$

$$\begin{aligned}\frac{d}{dt}\eta^{\mathcal{C}}(t)&=-\nabla V^{\mathcal{C}}(a^{\mathcal{C}}(t),\delta), \quad \mathcal{C}=\mathcal{A},\mathcal{B},\\ \frac{d}{dt}S^{\mathcal{C}}(t)&=\eta^{\mathcal{C}}(t)^2/2-V^{\mathcal{C}}(a^{\mathcal{C}}(t),\delta),\end{aligned} \tag{4.39}$$

with the initial conditions

$$\begin{aligned}a^{\mathcal{C}}(0)&=0,\\ \eta^{\mathcal{C}}(0)&=\eta^0(\delta),\end{aligned} \tag{4.40}$$

where

$$\begin{aligned}\eta^0(\delta)&=\eta^0+\mathcal{O}(\delta), \quad \eta^0>0,\\ S^{\mathcal{C}}(0)&=0.\end{aligned} \tag{4.41}$$

The error term $\mathcal{O}(\delta)$ depends here on whether $\mathcal{C}$ is $\mathcal{A}$ or $\mathcal{B}$. In case of an isolated eigenvalue μ_n, $V^{\mathcal{C}}=V^n=\mu_n$.

We further introduce complex numbers which are defined by means of classical quantities. Let $A^{\mathcal{C}}(t)$ and $B^{\mathcal{C}}(t)$ be the solutions of the linear system,

$$\frac{d}{dt}A^{\mathcal{C}}(t)=iB^{\mathcal{C}}(t),$$
$$\frac{d}{dt}B^{\mathcal{C}}(t)=iV^{\mathcal{C}(2)}(a^{\mathcal{C}}(t),\delta)A^{\mathcal{C}}(t), \tag{4.42}$$

where $a^{\mathcal{C}}(t)$ is the solution of (4.38) and (4.40), with the initial conditions

$$A^{\mathcal{C}}(0)=A_0,$$
$$B^{\mathcal{C}}(0)=B_0, \tag{4.43}$$

and $V^{\mathcal{C}(2)}$ denotes the Hessian matrix of $V^{\mathcal{C}}$. It is easy to see that these quantities actually describe the linearized classical flow around the trajectory $(a^{\mathcal{C}}(t),\eta^{\mathcal{C}}(t))$. The above convention regarding $\mathcal{C}$ applies if μ_n is isolated in the spectrum. The asymptotics of these classical quantities for small t and δ are described in detail in Sec. II of Ref. 13.

The determination of the ''electronic'' part of the Born–Oppenheimer wave packet (B–O state, for short) is as follows. Although the ''electronic'' Hamiltonian is independent of time, it is convenient, since we deal with the time dependent Schrödinger equation, to choose specific time dependent ''electronic'' eigenvectors. Since they may become singular when the corresponding eigenvalues are degenerate, or almost degenerate, we shall define them for t in the outer regime, that is when $a(t)$ is far enough from 0. This outer regime is characterized by times t such that (see Ref. 13),

$$\delta^{1-\xi}\leqslant|t|\leqslant T,\quad \xi<1/3. \tag{4.44}$$

We shall have two sets of eigenvectors, denoted by $\Phi^{\pm}_{\mathcal{C}}(x,t,\delta)$, where the label $\pm$ refers to positive and negative times. Of course, this distinction is irrelevant if we consider an isolated eigenvalue μ.

Let $\eta^{\mathcal{C}}(t)$ be the momentum solution of the classical equations of motion (4.38) and (4.40). The normalized eigenvectors $\Phi^{\pm}_{\mathcal{C}}(x,t,\delta)$ are the solutions of

$$\langle\Phi^{\pm}_{\mathcal{C}}(x,t,\delta)|(\partial/\partial t+\eta^{\mathcal{C}}(t)\partial_x)\Phi^{\pm}_{\mathcal{C}}(x,t,\delta)\rangle\equiv 0 \tag{4.45}$$

for $\mathcal{C}=\mathcal{A},\mathcal{B}$ and $t\gtrless 0$. Since the eigenvalues $\mu_{\mathcal{A}}(x,\delta)$ and $\mu_{\mathcal{B}}(x,\delta)$ are nondegenerate for any time t small enough, such vectors exist, are unique up to an overall time independent phase factors, and are eigenvectors of $g_1(x,\delta)$ associated with $E_{\mathcal{C}}(x,\delta)$ for any time. More precisely, we define the angles $\varphi(x,\delta)$ and $\theta(x,\delta)$ by

$$\beta(x,\delta)=\sqrt{\beta^2(x,\delta)+\gamma^2(x,\delta)+\sigma^2(x,\delta)}\cos(\theta(x,\delta)), \tag{4.46}$$
$$\gamma(x,\delta)=\sqrt{\beta^2(x,\delta)+\gamma^2(x,\delta)+\sigma^2(x,\delta)}\sin(\theta(x,\delta))\cos(\varphi(x,\delta)), \tag{4.47}$$
$$\sigma(x,\delta)=\sqrt{\beta^2(x,\delta)+\gamma^2(x,\delta)+\sigma^2(x,\delta)}\sin(\theta(x,\delta))\sin(\varphi(x,\delta)), \tag{4.48}$$

and construct static eigenvectors. Let

$$\Phi^{-}_{\mathcal{A}}(x,\delta)=e^{i\varphi(x,\delta)}\cos(\theta(x,\delta)/2)\psi_1(x,\delta)+\sin(\theta(x,\delta)/2)\psi_2(x,\delta), \tag{4.49}$$
$$\Phi^{-}_{\mathcal{B}}(x,\delta)=e^{-i\varphi(x,\delta)}\cos(\theta(x,\delta)/2)\psi_2(x,\delta)-\sin(\theta(x,\delta)/2)\psi_1(x,\delta), \tag{4.50}$$

be the eigenvectors of $g_1(x,\delta)$ associated with $\mu_{\mathcal{C}}(x,\delta)$, $\mathcal{C}=\mathcal{A},\mathcal{B}$, for $\pi/2<\theta(x,\delta)\leqslant\pi$, and

$$\Phi^{+}_{\mathcal{A}}(x,\delta)=\cos(\theta(x,\delta)/2)\psi_1(x,\delta)+e^{-i\varphi(x,\delta)}\sin(\theta(x,\delta)/2)\psi_2(x,\delta), \tag{4.51}$$
$$\Phi^{+}_{\mathcal{B}}(x,\delta)=\cos(\theta(x,\delta)/2)\psi_2(x,\delta)-e^{i\varphi(x,\delta)}\sin(\theta(x,\delta)/2)\psi_1(x,\delta) \tag{4.52}$$

be the eigenvectors of $g_1(x,\delta)$ for $0\leqslant\theta(x,\delta)<\pi/2$. The solutions of (4.45) are of the form

$$\Phi_{\mathcal{C}}^{\pm}(x,t,\delta)=\Phi_{\mathcal{C}}^{\pm}(x,\delta)\mathrm{e}^{i\lambda_{\mathcal{C}}^{\pm}(x,t,\delta)},\quad \begin{cases} t>0 \\ t<0 \end{cases}, \tag{4.53}$$

where $\lambda_{\mathcal{C}}^{\pm}(x,t,\delta)$ is a real valued function satisfying the equation,

$$i\frac{\partial}{\partial t}\lambda_{\mathcal{C}}^{\pm}(x,t,\delta)+i\,\eta^{\mathcal{C}}(t)\partial_x\lambda_{\mathcal{C}}^{\pm}(x,t,\delta)+\langle\Phi_{\mathcal{C}}(x,\delta)|\,\eta^{\mathcal{C}}(t)\partial_x\Phi_{\mathcal{C}}(x,\delta)\rangle=0. \tag{4.54}$$

We can get an expression for $\lambda_{\mathcal{C}}^{\pm}$ and its derivatives as follows. We fix values of the indices and drop them in the notation. We introduce the new variable

$$\omega\equiv x-a(t) \tag{4.55}$$

and the notation

$$\lambda_r(\omega,t,\delta)\equiv\lambda(\omega+a(t),t,\delta), \tag{4.56}$$

$$\Phi_r(\omega,t,\delta)\equiv\Phi(\omega+a(t),\delta). \tag{4.57}$$

In terms of these new variables, Eq. (4.54) for λ_r reads

$$i\frac{\partial}{\partial t}\lambda_r(\omega,t,\delta)=-\langle\Phi_r(\omega,t,\delta)|\frac{\partial}{\partial t}|\,\Phi_r(\omega,t,\delta)\rangle \tag{4.58}$$

with

$$\frac{\partial}{\partial t}\Phi_r(\omega,t,\delta)=\eta(t)\partial_x\Phi(\omega+a(t),\delta). \tag{4.59}$$

By integration we get

$$\lambda_r(\omega,t,\delta)=-\int^t\eta(t')\langle\Phi(\omega+a(t'),\delta)|\partial_x\Phi(\omega+a(t'),\delta)\rangle dt'+\lambda_{r0}(\omega,\delta), \tag{4.60}$$

where we are free to set the integration constant $\lambda_{r0}(\omega,\delta)\equiv0$.

The ''nuclear'' wave function is localized around the classical trajectory in the semiclassical regime. In view of the genericity condition $\eta^0>0$, in the outer temporal region, the major part of the ''nuclear'' wave function will be supported away from the neighborhood where the levels almost cross. Hence we can introduce a cutoff function which does not significantly alter the solution and forces the support of the wave function to be away of this neighborhood. Let F be a C^∞ cutoff function,

$$F:\mathbb{R}^+\to\mathbb{R}, \tag{4.61}$$

such that

$$\begin{array}{lll} F(r)=1 & \ldots & 0\leqslant r\leqslant 1 \\ F(r)=0 & \ldots & r\geqslant 2 \end{array}. \tag{4.62}$$

The wave functions we construct below in the outer regime will be multiplied by the regularizing factor,

$$F(\|x-a^{\mathcal{C}}(t)\|/\delta^{1-\delta'}), \tag{4.63}$$

where $0<\delta'<\xi$, for $\mathcal{C}=\mathcal{A},\mathcal{B}$.

Remark: On the support of F the relation,

$$x=\eta^0(\delta)t+\mathcal{O}(\delta^{1-\delta'}+t^2) \tag{4.64}$$

holds true, and since $\eta^0(\delta)=\eta^0+\mathcal{O}(\delta)$, where $\eta^0>0$, we find that

$$|x|>c|t|, \tag{4.65}$$

uniformly in δ.

A Born–Oppenheimer state $\psi_j^{\mathcal{C}\pm}(x,\delta,t)$ is defined by

$$\psi_j^{\mathcal{C}\pm}(x,\delta,t)$$

$$=F(\|x-a^{\mathcal{C}}(t)\|/\delta^{1-\delta'})\varphi_j(A^{\mathcal{C}}(t),B^{\mathcal{C}}(t),\delta^2,a^{\mathcal{C}}(t),\eta^{\mathcal{C}}(t),x)\mathrm{e}^{iS^{\mathcal{C}}(t)/\delta^2}\Phi_{\mathcal{C}}^{\pm}(x,t,\delta). \tag{4.66}$$

It is a good approximation to the solution of the Schrödinger equation (4.13) as $\delta\to 0$ far enough of the crossing region, i.e., in the outer time regime (4.44), and when the operator Y defined in (4.15) is absent, as shown in Ref. 13 Proposition IV.2 below shows this is still true when Y is present.

In the inner time regime, characterized by the inequality (see Ref. 13),

$$-\delta^{1-\xi}\leqslant t\leqslant\delta^{1-\xi},\quad \xi<1/3, \tag{4.67}$$

we look for an approximation constructed by means of the classical quantities associated with the potential $\overline{V}(x,\delta)$, the average of $\mu^{\mathcal{A}}(x,\delta)$ and $\mu^{\mathcal{B}}(x,\delta)$. Let $a(t)$ and $S(t)$ be the corresponding classical quantities satisfying the initial conditions

$$\begin{aligned} a(0)&=0,\\ \eta(0)&=\eta^0,\\ S(0)&=0. \end{aligned} \tag{4.68}$$

It is suitable to use the rescaled variables

$$\begin{aligned} y&=(x-a(t))/\delta\\ s&=t/\delta. \end{aligned} \tag{4.69}$$

It is shown in Ref. 13 that a good approximation ψ_I of solutions to (4.13) in that regime, when Y is absent, is given by

$$\psi_I(y,s,\delta)=F(\|y\|\delta^{\delta'})\exp\left(i\frac{S(\delta s)}{\delta^2}+i\frac{\eta(\delta s)y}{\delta}\right)\chi(y,s,\delta), \tag{4.70}$$

with

$$\chi(y,s,\delta)=f_0(y,s)\psi_1(a(\delta s)+\delta y,\delta)+g_0(y,s)\psi_2(a(\delta s)+\delta y,\delta), \tag{4.71}$$

where f_0,g_0 are complex-valued functions solutions to

$$i\frac{\partial}{\partial s}\begin{pmatrix} f_0(y,s)\\ g_0(y,s)\end{pmatrix}=r\begin{pmatrix} \eta^0 s+y & 1\\ 1 & -(\eta^0 s+y)\end{pmatrix}\begin{pmatrix} f_0(y,s)\\ g_0(y,s)\end{pmatrix}. \tag{4.72}$$

The general solution to this equation is

$$\begin{pmatrix} f_0(y,s) \\ g_0(y,s) \end{pmatrix} = C_1(y) \begin{pmatrix} \dfrac{(1-i)}{2}\sqrt{\dfrac{r}{\eta^0}} D_{ir/2\eta^0-1}\left((-1+i)\sqrt{\dfrac{r}{\eta^0}}(\eta^0 s+y)\right) \\ D_{ir/2\eta^0}\left((-1+i)\sqrt{\dfrac{r}{\eta^0}}(\eta^0 s+y)\right) \end{pmatrix} + C_2(y) \times \begin{pmatrix} D_{-ir/2\eta^0}\left(-(1+i)\sqrt{\dfrac{r}{\eta^0}}(\eta^0 s+y)\right) \\ -\dfrac{(1+i)}{2}\sqrt{\dfrac{r}{\eta^0}} D_{-ir/2\eta^0-1}\left(-(1+i)\sqrt{\dfrac{r}{\eta^0}}(\eta^0 s+y)\right) \end{pmatrix}, \tag{4.73}$$

where the D_ν are parabolic cylinder functions. The coefficients $C_1(y)$ and $C_2(y)$ have to be determined by matching with the incoming solutions of the B–O type at the border of the inner and outer time regimes.

In particular, assuming for definiteness that the incoming B–O state ψ_{OI} is associated with the index l for the "nuclear" component and the $\mathcal{B}$ level with the initial momentum $\eta^{\mathcal{B}}(0)=\eta^0$, i.e., that

$$\psi_{\mathrm{OI}}(x,t,\delta)=\psi_l^{\mathcal{B}-}(x,t,\delta), \quad -T\leqslant t\leqslant -\delta^{1-\xi}, \tag{4.74}$$

we have

$$C_1(y)\equiv 0 \tag{4.75}$$

and

$$C_2(y)=-\delta^{-1/2}\varphi_l(A_0,B_0-irA_0/\eta^0,1,0,0,y)\mathrm{e}^{-(\pi r/8\eta_1^0)}\exp\left(\frac{ir}{2\eta^0}(y^2-2y)\right) \times\exp\left(i\frac{S_0^{\mathcal{B}}(\delta,-)}{\delta^2}+\frac{ir}{4\eta^0}(1+3\ln(2\eta^0)+\ln r-4\ln\delta)\right), \tag{4.76}$$

where $S_0^{\mathcal{B}}(\delta,-)$ is real and can be computed explicitly, see Ref. 13.

The analysis of Ref. 13 shows that in this situation, we get an outgoing solution given by a linear combination of B–O states, with explicit coefficients, associated with the same index l for the "nuclear" component but with both levels. The initial momentum is chosen as $\eta^{\mathcal{A}}(0)=\eta^0-2r\delta/\eta^0$ for the $\mathcal{A}$ level and the outgoing solution ψ_{OO} is of the form,

$$\psi_{\mathrm{OO}}(x,t,\delta)=-\mathrm{e}^{-\pi r/2\eta_1^0}\psi_l^{\mathcal{A}+}(x,\delta,t)+\mathrm{e}^{-\pi r/4\eta^0}\sqrt{\frac{\pi r}{\eta^0}}\frac{\mathrm{e}^{i\lambda(\delta)}}{\Gamma\left(1+\dfrac{ir}{2\eta^0}\right)}\psi_l^{\mathcal{B}+}(x,\delta,t) \tag{4.77}$$

provided $\delta^{1-\xi}\leqslant t\leqslant T$, where

$$\lambda(\delta)=\pi/4+S_0^{\mathcal{A}}(-,\delta)/\delta^2+\frac{r}{2\eta^0}(1+3\ln(2\eta^0)+\ln r-4\ln\delta). \tag{4.78}$$

Here again, $S_0^{\mathcal{A}}(\delta,-)$ is real and can be computed explicitly from Ref. 13.

Moreover, the function obtained by pasting the approximations constructed in the outer and inner temporal regions is an approximate solution to the Schrödinger equation when the perturbation Y of the Laplacian is absent [see (4.14)]. Similar explicit formulas are valid if the ingoing state is associated with the $\mathcal{A}$ level. Hence, the propagation through avoided crossings can be iterated.

We are going to show that the perturbation of the Laplacian in (4.14) does not affect the propagation of B–O states. The general strategy is simple: we write

$$H(\delta) = -\frac{\delta^4}{2}\Delta_x + g(x,\delta) + Y(x,\partial_x,\delta)$$

$$\equiv H_0(\delta) + Y(x,\partial_x,\delta) \tag{4.79}$$

and denote by $\Psi_l(x,t,\delta)$ the approximation given by $\psi_{\mathrm{OI}}, \psi_1, \psi_{\mathrm{OO}}$ in their respective time domains constructed in Ref. 13,

$$\Psi_l(x,t,\delta) = \begin{cases} \psi_{\mathrm{OI}}(x,t,\delta) & \cdots \quad -T \leqslant t \leqslant -\delta^{1-\xi} \\ \psi_1(x,t,\delta) & \cdots \quad -\delta^{1-\xi} \leqslant t \leqslant \delta^{1-\xi} \\ \psi_{\mathrm{OO}}(x,t,\delta) & \cdots \quad \delta^{1-\xi} \leqslant t \leqslant T \end{cases}. \tag{4.80}$$

We define ζ_l by

$$\begin{aligned} \xi_l(x,t,\delta) &= i\delta^2\partial_t\Psi_l(x,t,\delta) - H(\delta)\Psi_l(x,t,\delta) \\ &= i\delta^2\partial_t\Psi_l(x,t,\delta) - H_0(\delta)\Psi_l(x,t,\delta) - Y(x,\partial_x,\delta)\Psi_l(x,t,\delta) \\ &= \zeta_l^0(x,t,\delta) + \zeta_l^1(x,t,\delta), \end{aligned} \tag{4.81}$$

where ζ_l^0 is the error term controlled in Ref. 13 by means of the following abstract lemma.

Lemma IV.1: Suppose $H(\hbar)$ is a family of self-adjoint operators labeled by $\hbar > 0$. Suppose that $\psi(t,\hbar)$ belongs to the domain of $H(\hbar)$, is continuously differentiable in t, and solves approximately the Schrödinger equation in the sense that

$$i\hbar\frac{\partial\psi}{\partial t}(t,\hbar) = H(\hbar)\,\psi(t,\hbar) + \zeta(t,\hbar), \tag{4.82}$$

where $\zeta(t,\hbar)$, satisfies

$$\|\zeta(t,\hbar)\| \leqslant \mu(t,\hbar). \tag{4.83}$$

Then,

$$\|\mathrm{e}^{-itH(\hbar)/\hbar}\,\psi(0,\hbar) - \psi(t,\hbar)\| \leqslant \hbar^{-1}\int_0^t \mu(s,\hbar)\,ds \tag{4.84}$$

holds true for $t > 0$ and the analogous statement is valid for $t < 0$.

Using the same lemma to estimate the norm of ζ_l^1, we get

Proposition IV.2: Under the hypotheses (H0)–(H2), the function $\Psi_l(x,t,\delta)$ defined by (4.80) *is for any $T > 0$ an approximation to the solution $\psi(x,t,\delta)$ of the Schrödinger equation (4.13) such that*

$$\psi(x,t,\delta) = \Psi_l(x,t,\delta) + \mathcal{O}(\delta^p) \tag{4.85}$$

holds in the $L^2(\mathbb{R})$ sense for some $p > 0$ and all $t \in [-T,T]$.

The proof of this technical proposition is given in the Appendix.

V. PROPAGATION OF PERTURBED B–O STATES

Let us now turn to the second indicated step and replace the above B–O approximation by a construction making use of a perturbative knowledge of the exact eigenvectors and eigenvalues of

the operator $g_\parallel$ defined by (4.22). In particular, this needs to be done for the quantities appearing in (4.38), (4.42) determined by means of a classical potential given by an approximation of the spectrum of $g_\parallel$. We will show that it is enough to know the second order perturbation expansion in order to construct an approximation of the solution that is a perturbed version of our initial B–O states and still describes accurately the transitions between the ''electronic'' levels.

In order to make some explicit formulas simpler and to stress the effect of the perturbation, we will assume in this section that both the operators h and W are δ independent, i.e., we shall consider

$$g(x,\delta)=h(R(x))+V_2(x)+\delta W(x,\theta), \tag{5.1}$$

where V_2 commutes with h whereas W does not. This means that $h(x)$ is assumed to have a degeneracy at $x=0$ in the considered part of its spectrum that is lifted by W to leading order in δ. This is the generic situation we set out to investigate when the avoided crossing results from a weak symmetry-breaking violation of a true eigenvalue crossing. Note, however, that we are able to accommodate the general situation considered so far, at the cost of more complicated perturbation formulas.

Let us state a simple lemma which is at the basis of our constructions and which says that an approximation of an approximate solution is an approximate solution.

Lemma V.1: Let $H(\delta)$ be for all $\delta\in(0,\delta_0)$ a self-adjoint operator densely defined in a Hilbert space $\mathcal{H}$, and let $\psi_a(t,\delta)\in\mathcal{H}$, $\varphi_a(t,\delta)\in\mathcal{H}$ be time dependent vectors with the following property; there exists $c,p_1,p_2>0$ such that the relations

$$\|\mathrm{e}^{-iH(\delta)t/\delta^2}\psi_a(0,\delta)-\psi_a(t,\delta)\|\leqslant c\,\delta^{p_1} \tag{5.2}$$

and

$$\|\varphi_a(t,\delta)-\psi_a(t,\delta)\|\leqslant c\,\delta^{p_2} \tag{5.3}$$

hold for all t from an interval $I\subset\mathbb{R}$ and $0<\delta<\delta_0$. Then,

$$\|\mathrm{e}^{-iH(\delta)t/\delta^2}\varphi_a(0,\delta)-\varphi_a(t,\delta)\|\leqslant 3c\,\delta^{\min(p_1,p_2)},$$

$$\|\mathrm{e}^{-iH(\delta)t/\delta^2}\psi_a(0,\delta)-\varphi_a(t,\delta)\|\leqslant 3c\,\delta^{\min(p_1,p_2)}. \tag{5.4}$$

Proof: uses just the unitarity of the evolution group and the Cauchy–Schwarz inequality. □

Our approximate B–O states will require classical quantities defined by means of an approximation $\tilde{V}^{\mathcal{C}}$ of the potential $V^{\mathcal{C}}$ used in (4.38), (4.42). We have to estimate the error induced by this approximation. In order to do that, we make use of Gronwall's lemma (see e.g., Ref. 19) that we recall below.

Lemma V.2: Let E be a Banach space, $U\subset E$ be open, I be an interval of $\mathbb{R}$, and $f\in C^1(I\times U;E)$ be such that there exists $K>O$ with $\sup_{(t,x)\in I\times U}\|D_2f(t,x)\|_{\mathcal{L}(E)}\leqslant K$. Let $g:I\times U\to E$ be continuous and such that there exists $G>0$ with

$$\sup_{(t,x)\in I\times U}\|g(t,x)\|\leqslant G. \tag{5.5}$$

If α and β are C^1 maps from $J\to U$ (where $J\subseteq I$) satisfying for $t\in J$,

$$\alpha'(t)=f(t,\alpha(t)), \tag{5.6}$$

$$\beta'(t)=f(t,\beta(t))+\epsilon g(t,\beta(t)), \tag{5.7}$$

then

$$\|\alpha(t)-\beta(t)\| \leqslant \|\alpha(t_0)-\beta(t_0)\| e^{K|t-t_0|} + \epsilon G(e^{K|t-t_0|}-1)/K. \tag{5.8}$$

For convenience let us recall here our definition (4.66) of a Born–Oppenheimer state $\psi_j^{\mathcal{C}}(x,\delta,t)$ in the exterior regime,

$$\psi_j^{\mathcal{C}}(x,\delta,t) = F(\|x-a^{\mathcal{C}}(t)\|/\delta^{1-\delta'})\varphi_j(A^{\mathcal{C}}(t), B^{\mathcal{C}}(t), \delta^2, a^{\mathcal{C}}(t), \eta^{\mathcal{C}}(t), x) e^{iS^{\mathcal{C}}(t)/\delta^2}\Phi_{\mathcal{C}}^{\pm}(x,t,\delta). \tag{5.9}$$

We want to compare $\psi_j^{\mathcal{C}}(x,\delta,t)$ with an altered but similar definition based on approximate quantum and classical quantities for $\tilde{\psi}_j^{\mathcal{C}}(x,\delta,t)$,

$$\tilde{\psi}_j^{\mathcal{C}}(x,\delta,t) = F(\|x-\tilde{a}^{\mathcal{C}}(t)\|/\delta^{1-\delta'})\varphi_j(\tilde{A}^{\mathcal{C}}(t), \tilde{B}^{\mathcal{C}}(t), \delta^2, \tilde{a}^{\mathcal{C}}(t), \tilde{\eta}^{\mathcal{C}}(t), x) e^{i\tilde{S}^{\mathcal{C}}(t)/\delta^2}\tilde{\Phi}_{\mathcal{C}}^{\pm}(x,t,\delta). \tag{5.10}$$

All "tilded" classical quantities are generated by Eqs. (4.38), (4.42) with an approximate potential $\tilde{V}^{\mathcal{C}}(x,\delta)$ in place of $V^{\mathcal{C}}(x,\delta)$. The vector

$$\tilde{\Phi}_{\mathcal{C}}^{\pm}(x,t,\delta) = \tilde{\Phi}_{\mathcal{C}}^{\pm}(x,\delta) e^{i\tilde{\lambda}_{\mathcal{C}}^{\pm}(x,t,\delta)} \tag{5.11}$$

depends on the approximate classical quantities through the phase $\tilde{\lambda}_{\mathcal{C}}^{\pm}$ and on an approximate normalized quantum eigenstate $\tilde{\Phi}_{\mathcal{C}}^{\pm}(x,\delta)$. Note that we keep the same Gaussian function φ_j to construct the "nuclear" wave packet.

Our next goal is to apply Lemma V.1 to estimate the errors in terms of the difference between $\tilde{V}^{\mathcal{C}}$ and $V^{\mathcal{C}}$.

Lemma V.3: The following inequality holds in the outer time regime for the $L^2(\mathbb{R})$ norm:

$$\begin{aligned}
&\|\psi_j^{\mathcal{C}^{\pm}}(x,\delta,t) - \tilde{\psi}_j{}^{\mathcal{C}^{\pm}}(x,\delta,t)\| \\
&\leqslant c\Bigg(|\tilde{A}(t)-A(t)| + |\tilde{B}(t)-B(t)| + |\tilde{a}(t)-a(t)|/\delta^2 \\
&\quad + |\tilde{\eta}(t)-\eta(t)|/\delta^2 + \frac{|t|}{\delta^2}\sup_{s\in[0,t]}\left(|\tilde{\eta}(s)-\eta(s)| + |\tilde{V}(a(s))-V(a(s))|\right. \\
&\quad + \sup_{x\in[\tilde{a}(s),a(s)]}|\partial_x\tilde{V}(x)||\tilde{a}(s)-a(s)|) + \sup_{(x,t,\delta)}|F(\|x-\tilde{a}(t)\|/\delta^{1-\delta'})\tilde{\Phi}_{\mathcal{C}}^{\pm}(x,t,\delta) \\
&\quad \left. - F(\|x-a(t)\|/\delta^{1-\delta'})\Phi_{\mathcal{C}}^{\pm}(x,t,\delta)|.\right)
\end{aligned} \tag{5.12}$$

with some constant c.

Proof: The index $\mathcal{C}$ being fixed in this context, it will now be omitted. Other irrelevant parameters will also be dropped in the arguments. Note that since the function F is smooth, we can write

$$F(\|x-\tilde{a}(t)\|/\delta^{1-\delta'}) = F(\|x-a(t)\|/\delta^{1-\delta'}) + \mathcal{O}((\tilde{a}(t)-a(t))/\delta^{1-\delta'}) \tag{5.13}$$

and that the $L^2(S^1)$-norm of the vectors $\Phi_{\mathcal{C}}^{\pm}(x,t,\delta)$ equals one. Since

$$\tilde{V}(\tilde{a}) - V(a) = \tilde{V}(\tilde{a}) - \tilde{V}(a) + \tilde{V}(a) - V(a) \tag{5.14}$$

and η and $\tilde{\eta}$ are uniformly bounded, we infer

$$\tilde{S}(t)=\int_0^t(\tilde{\eta}^2(s)/2-\tilde{V}(\tilde{a}(s))ds)$$

$$=S(t)+\mathcal{O}\Big(|t|\sup_{s\in[0,t]}\Big(|\tilde{\eta}(s)-\eta(s)|+|\tilde{V}(a(s))-V(a(s))|$$

$$+\sup_{x\in[\tilde{a}(s),a(s)]}|\partial_x\tilde{V}(x)||\tilde{a}(s)-a(s)|\Big)\Big). \tag{5.15}$$

Then we compute

$$\varphi_l(\tilde{A},\tilde{B},\delta^2,\tilde{a},\tilde{\eta},x)-\varphi_l(A,B,\delta^2,a,\eta,x)$$

$$=e^{i\tilde{\eta}(x-\tilde{a})/\delta^2}(\varphi_l(\tilde{A},\tilde{B},\delta^2,\tilde{a},0,x)-\varphi_l(A,B,\delta^2,a,0,x))$$

$$+\varphi_l(A,B,\delta^2,a,0,x)(e^{i\tilde{\eta}((a-\tilde{a})/\delta^2)}-e^{i(\eta-\tilde{\eta})(x-a)/\delta^2})e^{i\tilde{\eta}(x-a)/\delta^2}. \tag{5.16}$$

From Lemma 3.1 in Ref. 13 we learn that as $\tilde{A}\to A$ and $\tilde{B}\to B$,

$$\varphi_l(\tilde{A},\tilde{B},\delta^2,\tilde{a},0,x)=\varphi_l(A,B,\delta^2,a,0,x)+\mathcal{O}(|\tilde{A}-A|+|\tilde{B}-B|+|\tilde{a}-a|/\delta)$$

holds in the $L^2(\mathbb{R})$ sense, which takes care of the first term. Then we note that the L^2 norm of the remaining term is equal to

$$\|\varphi_l(A,B,\delta^2,a,0,x)e^{i\tilde{\eta}((a-\tilde{a})/\delta^2)}-\varphi_l(A,B,\delta^2,a,\eta-\tilde{\eta},x)\|$$

$$=\|\varphi_l(B,A,\delta^2,0,-a,x)e^{i\tilde{\eta}(a-\tilde{a})/\delta^2}-e^{-i(\eta-\tilde{\eta})a/\delta^2}\varphi_l(B,A,\delta^2,\eta-\tilde{\eta},-a,x)\|$$

$$=\mathcal{O}((\tilde{a}-a)/\delta^2+(\tilde{\eta}-\eta)/\delta^2) \tag{5.17}$$

by using the Plancherel formula, the properties of the φ_j under Fourier transform, $\|\varphi_j\|=1$ and the above lemma again. Then, gathering these estimates and using the facts that $A(t)$ and $B(t)$ are uniformly bounded, we get the result. □

In order to use this lemma, we see that it is necessary to approximate $V^{\mathcal{C}}$ to an error of order $o(\delta^2)$ and to show that this induces errors of the same order in the classical trajectory $(\tilde{a}^{\mathcal{C}},\tilde{\eta}^{\mathcal{C}})$ and errors of order $o(1)$ in the linearized classical flow $(\tilde{A}^{\mathcal{C}},\tilde{B}^{\mathcal{C}})$. Moreover, the corresponding eigenstates $\tilde{\Phi}^{\pm}_{\mathcal{C}}$ should be at most at a distance $o(1)$ from $\Phi^{\pm}_{\mathcal{C}}$.

When we consider times away of the matching regime, i.e., $\tau\leqslant|t|\leqslant T$, where τ is independent of δ, it is easy to show the following result, just by using Gronwall's lemma and regular perturbation theory. We thus omit the proof.

Lemma V.4: Let the time interval (τ,T) be such that the solutions to (4.38), (4.40) satisfy the condition,

$$0\notin\{a^{\mathcal{C}}(t)\,|\,\tau\leqslant t\leqslant T,\quad 0<\delta<\delta_0\}\equiv P, \tag{5.18}$$

where the corresponding potential,

$$V^{\mathcal{C}}(x,\delta)=\mu^{\mathcal{C}}(x,\delta),\quad x\in P, \tag{5.19}$$

is the nondegenerate eigenvalue of $g(x,\delta)$ corresponding to $\Phi_{\mathcal{C}}(x,\delta)$. Let

$$\tilde{V}^{\mathcal{C}}(x,\delta)=\mu_0^{\mathcal{C}}(x)+\delta\mu_1^{\mathcal{C}}(x)+\delta^2\mu_2^{\mathcal{C}}(x),\quad x\in P, \tag{5.20}$$

be the second-order perturbation expansion for $\mu^{\mathcal{C}}(x,\delta)$. *We define* $\tilde{a}^{\mathcal{C}},\tilde{\eta}^{\mathcal{C}},\tilde{A}^{\mathcal{C}},\tilde{B}^{\mathcal{C}},\tilde{S}^{\mathcal{C}}$ *as above with the conditions,*

$$\tilde{a}^{\mathcal{C}}(\tau)=a^{\mathcal{C}}(\tau)+o(\delta^2),\quad \tilde{\eta}^{\mathcal{C}}(\tau)=\eta^{\mathcal{C}}(\tau)+o(\delta^2), \tag{5.21}$$

$$\tilde{A}^{\mathcal{C}}(\tau)=A^{\mathcal{C}}(\tau)+o(1),\quad \tilde{B}^{\mathcal{C}}(\tau)=B^{\mathcal{C}}(\tau)+o(1), \tag{5.22}$$

$$\tilde{S}^{\mathcal{C}}(\tau)=S^{\mathcal{C}}(\tau)+o(\delta^2), \tag{5.23}$$

and

$$\tilde{\Phi}_{\mathcal{C}}(x,t,\delta)=\Phi_{\mathcal{C}}(x,0)\mathrm{e}^{i\tilde{\lambda}_{\mathcal{C}}(x,t,\delta)}, \tag{5.24}$$

where $\tilde{\lambda}_{\mathcal{C}}(x,t,\delta)$ *is given by (4.54) with* $\Phi_{\mathcal{C}}(x,0)$ *in place of* $\Phi_{\mathcal{C}}(x,\delta)$ *and*

$$\tilde{\lambda}_{\mathcal{C}}(x,\tau,\delta)=\lambda_{\mathcal{C}}(x,\tau,\delta)+o(1). \tag{5.25}$$

Then there exists a solution $\psi(x,t,\delta)$ *to Eq. (4.13) such that*

$$\psi(x,t,\delta)=F(\|x-\tilde{a}^{\mathcal{C}}(t)\|/\delta^{1-\delta'})\varphi_j(\tilde{A}^{\mathcal{C}}(t),\tilde{B}^{\mathcal{C}}(t),\delta^2,\tilde{a}^{\mathcal{C}}(t),\tilde{\eta}^{\mathcal{C}}(t),x)\mathrm{e}^{i\tilde{S}^{\mathcal{C}}(t)/\delta^2}\tilde{\Phi}_{\mathcal{C}}(x,t,\delta)+o(1) \tag{5.26}$$

holds true in the L^2*-sense and for all* $\tau\leqslant t\leqslant T$.

Remark: We have the familiar explicit formulas,

$$\mu_0^{\mathcal{C}}(x)=\mu^{\mathcal{C}}(x,0), \tag{5.27}$$

$$\mu_1^{\mathcal{C}}(x)=\langle\Phi_{\mathcal{C}}(x,0)|W(x)\Phi_{\mathcal{C}}(x,0)\rangle, \tag{5.28}$$

$$\mu_2^{\mathcal{C}}(x)=-\langle\Phi_{\mathcal{C}}(x,0)|W(x)(h(x)-\mu^{\mathcal{C}}(x,0))_r^{-1}W(x)\Phi_{\mathcal{C}}(x,0)\rangle, \tag{5.29}$$

where the reduced resolvent is given by

$$(h(x)-\mu^{\mathcal{C}}(x,0))_r^{-1}=\sum_{j\neq\mathcal{C}}\frac{|\Phi_j(x,0)\rangle\langle\Phi_j(x,0)|}{(\mu^j(x,0)-\mu^{\mathcal{C}}(x,0))}. \tag{5.30}$$

The above result has to be modified for times close to the matching regime, since in that case degenerate perturbation theory is required to define the potential. Indeed, the approximate potential chosen in the lemma diverges as $x\to 0$, so that Gronwall's lemma cannot be used as it stands. Let us find the modified potential from perturbation theory.

The two eigenvalues of $g(x,\delta)$ which are of interest to us, $\mu_{\mathcal{A}}(x,\delta)$ and $\mu_{\mathcal{B}}(x,\delta)$, are given by the spectrum of $P(x,\delta)(h(x)+\delta W(x)+V_2(x))$. This operator is represented in the smooth orthonormal eigenbasis (4.21) by the matrix (4.22), which we can expand to second order in δ for any x in a neighborhood of the origin, since the projection $P(x,\delta)$ entering the definition of the basis (4.21) is regular. Hence we can write

$$g_{\|}(x,\delta)=\begin{pmatrix}\beta(x,\delta) & \gamma(x,\delta)+i\sigma(x,\delta)\\ \gamma(x,\delta)-i\sigma(x,\delta) & -\beta(x,\delta)\end{pmatrix}+\overline{V}(x,\delta), \tag{5.31}$$

where

$$\beta(x,\delta)=\beta_0(x)+\delta\beta_1(x)+\delta^2\beta_2(x)+\mathcal{O}(\delta^3)\equiv B_3(x,\delta)+\mathcal{O}(\delta^3), \tag{5.32}$$

$$\gamma(x,\delta)=\gamma_0(x)+\delta\gamma_1(x)+\delta^2\gamma_2(x)+\mathcal{O}(\delta^3)\equiv G_3(x,\delta)+\mathcal{O}(\delta^3), \tag{5.33}$$

$$\sigma(x,\delta)=\sigma_0(x)+\delta\sigma_1(x)+\delta^2\sigma_2(x)+\mathcal{O}(\delta^3)\equiv S_3(x,\delta)+\mathcal{O}(\delta^3), \tag{5.34}$$

$$\overline{V}(x,\delta)=\overline{V}_0(x)+\delta\overline{V}_1(x)+\delta^2\overline{V}_2(x)+\mathcal{O}(\delta^3)\equiv V_3(x,\delta)+\mathcal{O}(\delta^3), \tag{5.35}$$

with the error $\mathcal{O}(\delta^3)$ being C^∞ in x, and [see (4.30)],

$$\beta_0(x)=rx+\mathcal{O}(x^2),\quad \beta_1(x)=\mathcal{O}(x), \tag{5.36}$$

$$\gamma_0(x)=\mathcal{O}(x^2),\quad \gamma_1(x)=r+\mathcal{O}(x), \tag{5.37}$$

$$\sigma_0(x)=\mathcal{O}(x^2),\quad \sigma_1(x)=\mathcal{O}(x). \tag{5.38}$$

Let us set

$$s(x,\delta)=\sqrt{(B_3(x,\delta))^2+(G_3(x,\delta))^2+(S_3(x,\delta))^2} \tag{5.39}$$

and define our (explicit) modified potential by

$$\tilde{V}^{\mathcal{C}}(x,\delta)=\pm s(x,\delta)+V_3(x,\delta), \tag{5.40}$$

where the sign is chosen according to the value of $\mathcal{C}$. It is easy to check that by construction,

$$V^{\mathcal{C}}(x,\delta)-\tilde{V}^{\mathcal{C}}(x,\delta)=\mathcal{O}(\delta^3) \tag{5.41}$$

as $x\to 0$. As above, we employ tilde to mark the values generated by the modified potential. We only consider the dynamics for positive times, the other case being similar.

To define the perturbed classical trajectory, we will start integrating Newton's equations from a positive $t_0(\delta)=\delta^\kappa$, for some $2/3<\kappa<1$, using as initial condition the explicit asymptotic expansion given in Corollary 2.1 of Ref. 13,

Corollary V.5: In the outer regime $\delta\to 0$, $t\to 0$, $|t|/\delta\to\infty$ and $t^3/\delta^2\to 0$, we have

$$\begin{aligned} a^{\mathcal{A}}_{\mathcal{B}}(t)=&-\partial_x\overline{V}_3(0,\delta)\frac{t^2}{2}+\eta^0(\delta)t\pm\frac{r}{\eta^0(\delta)}\delta t\\ &\mp r\left[\frac{t^2}{2}+\frac{\delta^2\ln|t|}{2(\eta^0(\delta))^2}+\frac{\delta^2}{4(\eta^0(\delta))^2}(1+2\ln(2\eta^0(\delta)))-\frac{\delta^2\ln\delta}{2(\eta^0(\delta))^2}\right]\\ &+\mathcal{O}(t^3)+\mathcal{O}(\delta^4/t^2). \end{aligned}$$

The asymptotics for $\eta^{\mathcal{C}}(t)$ in the same regime is obtained by termwise differentiation of the above formulas up to errors $\mathcal{O}(t^2)+\mathcal{O}(\delta^4/t^3)$.

The choice of $t_0(\delta)$ ensures that

$$\tilde{a}(t_0)=a(t_0)+o(\delta^2), \tag{5.42}$$

$$\tilde{\eta}(t_0)=\eta(t_0)+o(\delta). \tag{5.43}$$

Whereas the error is small enough for the position, it is not the case for the momentum. Hence we resort to energy conservation in order to determine the momentum with sufficient accuracy.

Let us first note that due to the uniform boundedness of the force induced by the potentials $V^{\mathcal{C}}$ and $\tilde{V}^{\mathcal{C}}$, there exists $\tau>0$, small but independent of δ, and constants $0<C_1<C_2<\infty$, such that as long as $t\in[-\tau,\tau]$,

$$C_1<\eta^{\mathcal{C}}(t)<C_2, \tag{5.44}$$

and similarly for $\tilde{\eta}^{\mathcal{C}}$.

The unperturbed energy is given by

$$E^{\mathcal{C}}(\delta)=(\eta^{\mathcal{C}}(t))^2/2+V^{\mathcal{C}}(a^{\mathcal{C}}(t),\delta)=(\eta_0^{\mathcal{C}}(\delta))^2/2+V^{\mathcal{C}}(0,\delta)$$

$$\equiv\tilde{E}^{\mathcal{C}}(\delta)+V^{\mathcal{C}}(0,\delta)-\tilde{V}^{\mathcal{C}}(0,\delta), \tag{5.45}$$

where the perturbed energy $\tilde{E}^{\mathcal{C}}(\delta)$ is explicit. Hence

$$\eta^{\mathcal{C}}(t)=\sqrt{2(E^{\mathcal{C}}(\delta)-V^{\mathcal{C}}(a^{\mathcal{C}}(t),\delta))}>0 \tag{5.46}$$

holds for $t\in[-\tau,\tau]$, and we can define $\tilde{\eta}^{\mathcal{C}}(t)$ by energy conservation so that

$$\tilde{\eta}^{\mathcal{C}}(t):=\sqrt{2(\tilde{E}^{\mathcal{C}}(\delta)-\tilde{V}^{\mathcal{C}}(\tilde{a}^{\mathcal{C}}(t),\delta))}$$

$$=\eta^{\mathcal{C}}(t)+\mathcal{O}(\tilde{V}^{\mathcal{C}}(\tilde{a}^{\mathcal{C}}(t),\delta)-V^{\mathcal{C}}(a^{\mathcal{C}}(t),\delta))+\mathcal{O}(\tilde{V}^{\mathcal{C}}(0,\delta)-V^{\mathcal{C}}(0,\delta))$$

$$=\eta^{\mathcal{C}}(t)+\mathcal{O}\left(\sup_{x\to 0}|\tilde{V}^{\mathcal{C}}(x,\delta)-V^{\mathcal{C}}(x,\delta)|+\tilde{a}^{\mathcal{C}}(t)-a^{\mathcal{C}}(t)\right). \tag{5.47}$$

Thus using formula (5.47), we make an error in $\eta^{\mathcal{C}}$ of the same order as the error we make in $a^{\mathcal{C}}$ and $V^{\mathcal{C}}$.

Next we turn to the approximations $\tilde{A}^{\mathcal{C}}(t)$ and $\tilde{B}^{\mathcal{C}}(t)$. They are defined as solutions to the system (4.42) with $\tilde{V}^{\mathcal{C}}$ in place of $V^{\mathcal{C}}$ and initial conditions at $t=\pm t_0$, given by

$$\begin{pmatrix}\tilde{A}^{\mathcal{A}}_{\mathcal{B}}(t)\\ \tilde{B}^{\mathcal{A}}_{\mathcal{B}}(t)\end{pmatrix}=\begin{pmatrix}A(0)\\ B(0)\mp\mathrm{sign}(t)irA(0)/(\eta_0(\delta))\end{pmatrix}. \tag{5.48}$$

It remains finally to consider the perturbed eigenvectors $\tilde{\Phi}_{\mathcal{C}}(x,t,\delta)$ (where we dropped the index referring to the sign of t). The restrictions to the support of F mentioned in lemma V.3 and the estimate (5.44) imply that if we impose the condition

$$1-\delta'-\kappa>0, \tag{5.49}$$

we can write

$$x=a(t)+\mathcal{O}(\delta^{1-\delta'})\geqslant ct(1+\mathcal{O}(\delta^{1-\delta'-\kappa})\geqslant c\,\delta^{\kappa} \tag{5.50}$$

for some positive constant c, and the same estimate is true with a replaced by $\tilde{a}$.

Hence in the considered regime the eigenvalues $\mu^{\mathcal{C}}(x,0)$ of $P(x,0)(h(x)+V_2(x))$ display a gap that is at least of order $x=\mathcal{O}(\delta^{\kappa})$—see the behavior (4.30)—and we call the corresponding eigenvectors $\chi_{\mathcal{C}}(x)$. We define our perturbed static eigenvectors by

$$\tilde{\Phi}_{\mathcal{C}}(x,\delta)=\chi_{\mathcal{C}}(x) \tag{5.51}$$

and similarly, the phase corresponding to time dependent perturbed eigenvectors $\tilde{\Phi}_{\mathcal{C}}(x,t,\delta)$—in view (5.11)—by

$$\tilde{\lambda}_{\mathcal{C}r}(\omega,t,\delta)=i\int_{t_0(\delta)}^{t}ds\,\tilde{\eta}(s)\langle\tilde{\Phi}_{\mathcal{C}}(\omega+\tilde{a}(s),\delta)|\partial_x\tilde{\Phi}_{\mathcal{C}}(\omega+\tilde{a}(s),\delta)\rangle, \tag{5.52}$$

where we used the new variables (4.56) and (4.60).

The next lemma tells us that our definitions of $(\tilde{a}^{\mathcal{C}}(t),\tilde{\eta}^{\mathcal{C}}(t))$, $(\tilde{A}^{\mathcal{C}}(t),\tilde{B}^{\mathcal{C}}(t))$, and $\tilde{\Phi}_{\mathcal{C}}(x,\delta,t)$ are accurate enough for our purpose. The proof can be found in the Appendix.

Lemma V.6: With the definitions above, there exists a positive τ such that for all $t\in[t_0(\delta),\tau]$ we have

$$\tilde{a}^{\mathcal{C}}(t)=a^{\mathcal{C}}(t)+o(\delta^2), \tag{5.53}$$

$$\tilde{\eta}^{\mathcal{C}}(t)=\eta^{\mathcal{C}}(t)+o(\delta^2), \tag{5.54}$$

$$\tilde{A}^{\mathcal{C}}(t)=A^{\mathcal{C}}(t)+o(1), \tag{5.55}$$

$$\tilde{B}^{\mathcal{C}}(t)=B^{\mathcal{C}}(t)+o(1), \tag{5.56}$$

$$\tilde{\Phi}(x,t,\delta)=\Phi(x,t,\delta)+o(1). \tag{5.57}$$

Hence, with the definitions made above, we have a perturbed B–O state given by (5.10) that is explicitly expressed by means of perturbation theory in δ (modulo finding the solution of the classical equations of motion, of course) and which yields an approximation of the solution to the Schrödinger equation (4.13) for finite time intervals as $\delta\to 0$. In particular, putting together our results, we get the following statement:

Theorem V.7: *Adopt the hypotheses (H1) and (H2) and assume the behaviors (4.30). Suppose that* $2/3<\kappa<1$ *and* τ *is as in the above lemma. Let* $\tilde{\psi}_j^{\mathcal{C}\pm}(x,\delta,t)$ *with* $|t|\geqslant\delta^\kappa$ *be a perturbed B–O state according to (5.10) constructed by means of the approximate quantities considered in lemma V.4 if* $|t|\geqslant\tau$ *and in lemma V.6 if* $\delta^\kappa<|t|<\tau$*, subject to the condition that all classical quantities agree at the instants* $t=\pm\tau$*. Let* $\psi(x,\delta,t)$ *be a solution to Eq. (4.13) with* $\psi(x,\delta,-T)=\tilde{\psi}_j^{\mathcal{B}-}(x,\delta,-T)$*. Then,*

$$\psi(x,\delta,t)=\tilde{\psi}_j^{\mathcal{B}-}(x,\delta,t)+o(1), \tag{5.58}$$

holds as $\delta\to 0$ *for all* $-T\leqslant t\leqslant-\delta^\kappa$*, while*

$$\psi(x,\delta,t)=-\mathrm{e}^{-\pi r/2\eta^0}\tilde{\psi}_j^{\mathcal{A}+}(x,\delta,t)+\mathrm{e}^{-\pi r/4\eta^0}\sqrt{\frac{\pi r}{\eta^0}}\frac{\mathrm{e}^{i\lambda(\delta)}}{\Gamma\left(1+\dfrac{ir}{2\eta^0}\right)}\tilde{\psi}_j^{\mathcal{B}+}(x,\delta,t)+o(1) \tag{5.59}$$

holds for all $\delta^\kappa\leqslant t\leqslant T$*, with* $\lambda(\delta)$ *given by (4.78).*

Remarks:

(1) As a direct corollary, we get that to leading order, the transition probability $\mathcal{P}$ from the initial level $\mathcal{B}$ to the level $\mathcal{A}$ is given by the Landau–Zener formula,

$$\mathcal{P}=\mathrm{e}^{-\pi r/\eta^0}+o(1) \tag{5.60}$$

as $\delta\to 0$, where r is defined by the behavior (4.30) of the ''molecular'' Hamiltonian around the avoided crossing and η^0 is the initial classical momentum, see (4.40).

(2) It is possible also to give an explicit approximation of the wave function in the inner time regime, $-\delta^\kappa\leqslant t\leqslant\delta^\kappa$, in terms of quantities coming from perturbation theory. However, this temporal region being so short, it is not crucial for most applications to have a detailed approximation there.

APPENDIX

Proof of Proposition IV.2: It is enough to show that the norm of ζ_l^1 in (4.81) is small and to apply to Lemma IV.1. Expression (4.15) together with (H1) show that we only need to control the effect of $p=-i\delta^2\partial_x$ and $p^2=(-i\delta^2\partial_x)^2$ on $\Psi_l(x,t,\delta)$, since for any ψ we have

$$\|Y(x,\partial_x,\delta)\psi\|\leqslant C(\delta^4\|p^2\psi\|+\delta^6\|p\psi\|). \tag{A1}$$

First consider the outer temporal region and the form (4.66). We know from the computations in Ref. 18 that

$$\|(p-\eta)\varphi_l(A,B,\delta^2,a,\eta,\cdot)\|=|B|\delta\sqrt{l+1/2}, \tag{A2}$$

$$\|(p-\eta)^2\varphi_l(A,B,\delta^2,a,\eta,\cdot)\|=|B|^2\delta^2\sqrt{(6l^2+6l+3)/4}. \tag{A3}$$

Moreover, we estimate

$$|pF(\|x-a^{\mathcal{C}}(t)\|/\delta^{1-\delta'})|\leqslant c_1\delta^{1+\delta'}, \tag{A4}$$

$$|p^2F(\|x-a^{\mathcal{C}}(t)\|/\delta^{1-\delta'})|\leqslant c_2\delta^{2(1+\delta')}, \tag{A5}$$

where the constants c_1,c_2 depend on F only. Away from the crossing region, the "electronic" eigenvectors are well defined and smooth in (x,δ). Hence we only need to consider what is going on in the neighborhood of $x=0$ to get an upper bound on the effect of p and p^2 on the eigenvectors $\Phi_{\mathcal{C}}^{\pm}(x,t,\delta)$ given by (4.53). We drop the indices and consider

$$\Phi(x,t,\delta)=\mathrm{e}^{i\lambda(x,t,\delta)}\Phi(x,\delta), \tag{A6}$$

where $\Phi(x,\delta)$ denote some static eigenvectors and $\lambda(x,\delta,t)$ the corresponding real valued function defined by (4.54). We compute

$$\partial_x\Phi(x,t,\delta)=\mathrm{e}^{i\lambda(x,t,\delta)}[\partial_x\Phi(x,\delta)+(i\partial_x\lambda(x,t,\delta))\Phi(x,\delta)], \tag{A7}$$

$$\begin{aligned}\partial_x^2\Phi(x,t,\delta)=\mathrm{e}^{i\lambda(x,t,\delta)}[&\partial_x^2\Phi(x,\delta)+2(i\partial_x\lambda(x,t,\delta))\partial_x\Phi(x,\delta)\{i\partial_x^2\lambda(x,t,\delta)\\&-(\partial_x\lambda(x,t,\delta))^2\}\Phi(x,\delta)].\end{aligned} \tag{A8}$$

As $\eta,\psi_j,\partial_x\psi_j,\partial_x^2\psi_j,\partial_x^3\psi_j$ are all $\mathcal{O}(0)$ as $(x,t)\to(0,0)$ in the support of F, we have

$$\partial_x\Phi(x,\delta)=\mathcal{O}(\partial_x\theta(x)+\partial_x\varphi(x))+\mathcal{O}(0), \tag{A9}$$

$$\partial_x^2\Phi(x,\delta)=\mathcal{O}((\partial_x\theta(x))^2+(\partial_x\varphi(x))^2+\partial_x^2\theta(x)+\partial_x^2\varphi(x))+\mathcal{O}(0) \tag{A10}$$

in the norm of the "electronic" Hilbert space. In expression (4.60) for λ, we first check by inspection that in all cases,

$$\langle\Phi|\partial_x\Phi\rangle=\mathcal{O}(\partial_x\varphi)+\mathcal{O}(0) \tag{A11}$$

(see, e.g., (3.50) in Ref. 13) since all functions of θ and ϕ are uniformly bounded and, moreover, the factor of $\partial_x\varphi$ is a function of θ only. Hence, by further differentiation we get

$$\partial_x\langle\Phi|\partial_x\Phi\rangle=\mathcal{O}(\partial_x^2\varphi+\partial_x\varphi+\partial_x\varphi\partial_x\theta+\partial_x\theta)+\mathcal{O}(0), \tag{A12}$$

$$\begin{aligned}\partial_x^2\langle\Phi|\partial_x\Phi\rangle=\mathcal{O}(&\partial_x^3\varphi+\partial_x^2\varphi\partial_x\theta+\partial_x\varphi\partial_x^2\theta+(\partial_x\varphi)^2\\&+\partial_x^2\varphi\partial_x\varphi\partial_x\theta+\partial_x^2\theta+(\partial_x\theta)^2+\partial_x\theta+\partial_x\varphi)+\mathcal{O}(0).\end{aligned} \tag{A13}$$

It remains to estimate $\partial_x\varphi$ and $\partial_x\theta$. We have

$$\varphi(x,\delta)=\arctan(\sigma(x,\delta)/\gamma(x,\delta)) \tag{A14}$$

provided $\gamma(x,\delta)$ is different from zero. Hence using (4.30) we get

$$\partial_x\varphi(x,\delta)=\frac{\gamma(x,\delta)\partial_x\sigma(x,\delta)-\sigma(x,\delta)\partial_x\gamma(x,\delta)}{\gamma^2(x,\delta)+\sigma^2(x,\delta)}, \tag{A15}$$

so that with the help of estimates of the type $|\gamma|/\sqrt{\gamma^2+\sigma^2}\leqslant 1$ we arrive at

$$\partial_x\varphi=\mathcal{O}\left(\frac{\partial_x\gamma+\partial_x\sigma}{\sqrt{\gamma^2+\sigma^2}}\right). \tag{A16}$$

By similar operations we eventually obtain

$$\partial_x^2\varphi=\mathcal{O}\left(\frac{\partial_x^2\gamma+\partial_x^2\sigma}{\sqrt{\gamma^2+\sigma^2}}\right)+\mathcal{O}\left(\frac{(\partial_x\gamma)^2+(\partial_x\sigma)^2+\partial_x\gamma\partial_x\sigma}{\gamma^2+\sigma^2}\right) \tag{A17}$$

and

$$\partial_x^3\varphi=\mathcal{O}\left(\frac{\partial_x^3\gamma+\partial_x^3\sigma}{\sqrt{\gamma^2+\sigma^2}}\right)+\mathcal{O}\left(\frac{\partial_x^2\gamma\partial_x\sigma+\partial_x^2\sigma\partial_x\gamma+\partial_x^2\gamma\partial_x\gamma+\partial_x^2\sigma\partial_x\sigma}{\gamma^2+\sigma^2}\right)$$
$$+\mathcal{O}\left(\frac{(\partial_x\gamma)^2\partial_x\sigma+(\partial_x\sigma)^2\partial_x\gamma+(\partial_x\gamma)^3+(\partial_x\sigma)^3}{\sqrt{\gamma^2+\sigma^2}^3}\right). \tag{A18}$$

Assuming further that

$$\|x\|=\mathcal{O}(\delta^\kappa),\quad \xi<2/3<\kappa<1-\xi<1, \tag{A19}$$

we get from the behavior (4.30) in this region

$$\partial_x\varphi=\mathcal{O}\left(\frac{1}{\delta^{1-\kappa}}\right), \tag{A20}$$

$$\partial_x^2\varphi=\mathcal{O}\left(\frac{1}{\delta}\right), \tag{A21}$$

$$\partial_x^3\varphi=\mathcal{O}\left(\frac{1}{\delta^{2-\kappa}}\right). \tag{A22}$$

Then we consider

$$\theta(x,\delta)=\arccos\left(\frac{\beta(x,\delta)}{\sqrt{\beta^2(x,\delta)+\gamma^2(x,\delta)+\sigma^2(x,\delta)}}\right). \tag{A23}$$

By computing derivatives and estimating as above, we easily get

$$\partial_x\theta=\mathcal{O}\left(\frac{\partial_x\beta}{\beta^2+\gamma^2+\sigma^2}\right)+\mathcal{O}\left(\frac{\partial_x\gamma+\partial_x\sigma}{\sqrt{(\beta^2+\gamma^2+\sigma^2)(\gamma^2+\sigma^2)}}\right), \tag{A24}$$

$$\partial_x^2\theta=\mathcal{O}\left(\frac{\partial_x^2\beta}{\beta^2+\gamma^2+\sigma^2}\right)+\mathcal{O}\left(\frac{\partial_x^2\gamma+\partial_x^2\sigma}{\sqrt{(\beta^2+\gamma^2+\sigma^2)(\gamma^2+\sigma^2)}}\right)+\mathcal{O}\left(\frac{\partial_x\beta(\partial_x\gamma+\partial_x\sigma)}{(\beta^2+\gamma^2+\sigma^2)\sqrt{(\gamma^2+\sigma^2)}}\right)$$
$$+\mathcal{O}\left(\frac{(\partial_x\gamma)^2+(\partial_x\sigma)^2+\partial_x\gamma\partial_x\sigma}{\sqrt{(\beta^2+\gamma^2+\sigma^2)}(\gamma^2+\sigma^2)}\right)+\mathcal{O}\left(\frac{(\partial_x\beta)^2}{\sqrt{\beta^2+\gamma^2+\sigma^{23}}}\right). \tag{A25}$$

Using (4.65), $\delta^\kappa C\geqslant|t|\geqslant\delta^{1-\xi}$, and (A19), we thus find

$$\partial_x\theta=\mathcal{O}\left(\frac{1}{\delta^{2(1-\xi)}}\right), \tag{A26}$$

$$\partial_x^2\theta=\mathcal{O}\left(\frac{1}{\delta^{3(1-\xi)}}\right). \tag{A27}$$

Gathering the different pieces, we obtain for the derivatives of λ in the regime just described

$$\lambda(x,t,\delta)=\mathcal{O}(t/\delta^{1-\kappa})=\mathcal{O}(1/\delta^{1-2\kappa}), \tag{A28}$$

$$\partial_x\lambda(x,t,\delta)=\mathcal{O}(1/\delta^{3-2\xi-2\kappa}), \tag{A29}$$

$$\partial_x^2\lambda(x,t,\delta)=\mathcal{O}(1/\delta^{4-4\xi-\kappa}), \tag{A30}$$

so that we obtain the following estimates for the derivatives of the vector $\Phi(x,t,\delta)$:

$$\partial_x\Phi(x,t,\delta)=\mathcal{O}(1/\delta^{2-2\xi}), \tag{A31}$$

$$\partial_x^2\Phi(x,t,\delta)=\mathcal{O}(1/\delta^{4-4\xi}). \tag{A32}$$

We are now in a position to estimate the effect of p and p^2 on the B–O states in the outer time regime,

$$\|p\psi_l^{\mathcal{C}}\|=\|(pF)\varphi_l\Phi^{\mathcal{C}}+F(p\varphi_l)\Phi^{\mathcal{C}}+F\varphi_l(p\Phi^{\mathcal{C}})\|$$
$$\leqslant c(\delta^{1+\delta'}+\|(p-\eta^{\mathcal{C}})\varphi_l\|+|\eta^{\mathcal{C}}|+\delta^2|\partial_x\Phi^{\mathcal{C}}|)$$
$$\leqslant c(l)(\delta^{1+\delta'}+\delta B^{\mathcal{C}}+|\eta^{\mathcal{C}}|+\delta^{2\xi}). \tag{A33}$$

We have already used above the fact that $|\eta^{\mathcal{C}}|$ is uniformly bounded as δ and t go to zero, and the same is true for $B^{\mathcal{C}}$—see Lemma 2.1 and Proposition 2.2 in Ref. 13. Finally we get in the outer temporal regime,

$$\|p\psi_l^{\mathcal{C}}\|\leqslant c(l) \tag{A34}$$

as $\delta\to0$, where $c(l)$ is some constant independent of time. By similar manipulations we also get in the same regime

$$\|p^2\psi_l^{\mathcal{C}}\|\leqslant c(l). \tag{A35}$$

Note that the nonvanishing term comes only from the action of p on the Gaussian state φ_l, which yields essentially $\eta^{\mathcal{C}}$ as expected, whereas the contribution from the derivatives of the ''electronic'' eigenvectors and cutoff function vanish. From the definition of Y we get a supplementary δ^4 which more than compensates for the denominator δ^2 appearing in (4.84),

$$\frac{1}{\delta^2}\int_{\delta^{1-\xi}}^{T}\|Y(x,\partial_x,\delta)\psi_I^{\mathcal{C}}(x,t,\delta)\|dt\leqslant c(l)\,\delta^4. \tag{A36}$$

We now need to perform the same type of analysis on the approximate wave function $\psi_I(y,s,\delta)$ given by (4.70) adopted in the inner temporal region. There we use the variables (4.69) so that the relations

$$\partial_y=\delta\partial_x \quad \text{and} \quad p=-i\,\delta\partial_y \tag{A37}$$

have to be employed to compute the derivatives of the different pieces in the definition of $\psi_I(y,s,\delta)$. In this case we need to show that

$$\begin{aligned}
&\frac{1}{\delta^2}\int_{-\delta^{1-\xi}}^{\delta^{1-\xi}}\|Y(x,\partial_x,\delta)\psi_I(y(x,t),s(t),\delta)\|dt\\
&\quad=\frac{1}{\delta}\int_{-\delta^{-\xi}}^{\delta^{-\xi}}\left\{\int|Y(\delta y+a(s\delta),\delta\partial_y,\delta)\psi_I(y,s,\delta)|^2\,\delta dy\right\}^{1/2}ds\\
&\quad\leqslant\frac{2}{\delta^{1+\xi}}\sup_{-\delta^{-\xi}\leqslant s\leqslant\delta^{-\xi}}\left\{\int|Y(\delta y+a(s\delta),\delta\partial_y,\delta)\psi_I(y,s,\delta)|^2\,\delta dy\right\}^{1/2}
\end{aligned} \tag{A38}$$

is of order δ^p for some positive p as $\delta\to 0$. As above, we denoted at that the norm in the ''electronic'' Hilbert space by a modulus. The estimates (A4), (A5) remain valid and we have

$$|p\,e^{i\eta(s\delta)y/\delta}|=|\eta(s\delta)|\leqslant C, \tag{A39}$$

$$|p^2e^{i\eta(s\delta)y/\delta}|=|\eta^2(s\delta)|\leqslant C, \tag{A40}$$

since $\eta(t)$ is uniformly bounded in the inner temporal regime. Noting that $x=a(\delta s)+\delta y=\mathcal{O}(\delta^{1-\xi})$, we also get from the regularity of the orthonormal basis $\{\psi_1(x,\delta),\psi_2(x,\delta)\}$ around (0,0) that

$$|p\,\psi_j(a(\delta s)+\delta y,\delta)|=\mathcal{O}(\delta^2), \tag{A41}$$

$$|p^2\psi_j(a(\delta s)+\delta y,\delta)|=\mathcal{O}(\delta^4) \tag{A42}$$

for $j=1,2$. Finally, the functions $f_0(y,s)$ and $g_0(y,s)$ determined in (4.73)–(4.76) and their derivatives can be estimated using the following remark. Up to phases, these functions are given as products of a Gaussian, a polynomial in y, a parabolic cylinder function, and a factor $1/\delta^{1/2}$ coming from the normalization of the function φ_l. Asymptotically, these parabolic cylinder functions, their first and second derivatives are of order $\mathcal{O}((s+\|y\|)^0)$, $\mathcal{O}((s+\|y\|))$, and $\mathcal{O}((s+\|y\|)^2)$, respectively, where $s=\mathcal{O}(\delta^{-\xi})$. Hence we can write

$$|f_0(y,s)|\leqslant P_1(y)e^{-y^2/2|A_0|^2}\delta^{-1/2}, \tag{A43}$$

$$|pf_0(y,s)|\leqslant P_2(y)e^{-y^2/2|A_0|^2}\delta^{-1/2+1-\xi}, \tag{A44}$$

$$|p^2f_0(y,s)|\leqslant P_3(y)e^{-y^2/2|A_0|^2}\delta^{-1/2+2-2\xi}, \tag{A45}$$

where A_0 is the initial condition (4.43) and P_j, $j=1,2,3$, are polynomials in y, the coefficients of which are independent of δ. They depend on l, the index of the chosen B–O state. Similar estimates are valid for g_0 in place of f_0. Having

$$p\psi_I = e^{iS(\delta s)/\delta^2} e^{i\eta(s\delta)y/\delta}[(pF + F\eta)(f_0\psi_1 + g_0\psi_2) + F((pf_0)\psi_1 + (pg_0)\psi_2 f_0(p\psi_1) + g_0(p\psi_2))] \tag{A46}$$

and the above estimates, we can write

$$|p\psi_I(y,s,\delta)| \leqslant P_4(y) e^{-y^2/2|A_0|^2} \delta^{-1/2}(\delta^{1+\delta'} + 1 + \delta^2 + \delta^{1-\xi}) \tag{A47}$$

with another polynomial P_4. Hence the right hand-side of (6.38) can be further estimated to give

$$\frac{1}{\delta^{1+\xi}} \sup_{-\delta^{-\xi} \leqslant s \leqslant \delta^{-\xi}} \left\{ \int |p\psi_I(y,s,\delta)|^2 \delta dy \right\}^{1/2} \leqslant c(l)/\delta^{1+\xi}. \tag{A48}$$

By similar manipulations we also get

$$\frac{1}{\delta^{1+\xi}} \sup_{-\delta^{-\xi} \leqslant s \leqslant \delta^{-\xi}} \left\{ \int |p^2\psi_I(y,s,\delta)|^2 \delta dy \right\}^{1/2} \leqslant c(l)/\delta^{1+\xi}. \tag{A49}$$

We note that here the leading order contribution comes from the action of p on the phase $e^{i\eta y/\delta}$ which gives η. The supplementary factor δ^4 in (6.1) yields the final estimate

$$\frac{1}{\delta^2} \int_{-\delta^{1-\xi}}^{\delta^{1-\xi}} \| Y(x, \partial_x, \delta)\psi_I(y(x,t), s(t), \delta) \| dt \leqslant c(l)\delta^{3-\xi}. \tag{A50}$$

Hence the proposition holds with $p = 3 - \xi$. □

Proof of Lemma V.6: As noted above, we cannot directly use Gronwall's lemma as stated in the text. Hence we need to prove that the two evolutions stay close enough to each other between times $t_0(\delta)$ and τ, where τ will be small but independent of δ by a more refined analysis. We consider the index $\mathcal{A}$ and drop it in the notation.

First, it is easy to check the following asymptotic properties as $(x,\delta) \to (0,0)$,

$$s(x,\delta) - \sqrt{\beta^2(x,\delta) + \gamma^2(x,\delta) + \sigma^2(x,\delta)} = \mathcal{O}(\delta^3), \tag{A51}$$

$$\partial_x s(x,\delta) - \partial_x \sqrt{\beta^2(x,\delta) + \gamma^2(x,\delta) + \sigma^2(x,\delta)} = \mathcal{O}\left(\frac{\delta^3}{\sqrt{x^2+\delta^2}} \right), \tag{A52}$$

$$s(x,\delta) = r\sqrt{x^2+\delta^2}\,(1 + \mathcal{O}(x+\delta)), \tag{A53}$$

$$\partial_x s(x,\delta) = \mathcal{O}(1), \tag{A54}$$

$$\partial_x^2 s(x,\delta) = \frac{r\delta^2}{(x^2+\delta^2)^{3/2}} + \mathcal{O}(1). \tag{A55}$$

We collect some preliminary observations on the solution $\tilde{a}(t)$ to the equation,

$$\ddot{\tilde{a}}(t) = -\partial_x \tilde{V}(\tilde{a}(t), \delta) \tag{A56}$$

for $t \in [t_0, \tau]$ with initial condition satisfying (5.42). We can choose $\tau > 0$ independent of δ, such that

$$a(t) - a(t_0(\delta)) \geqslant c_0(t - t_0(\delta)), \tag{A57}$$

for some $c_0 > 0$ and all $t \in [t_0(\delta), \tau]$. This implies easily by means of (5.42) that

$$\tilde{a}(t)-\tilde{a}(t_0(\delta))\geqslant c_1(t-t_0(\delta)) \tag{A58}$$

for all $t\in[t_0(\delta),\tau]$ with a uniform constant. Hence we can write

$$x^2+\delta^2|_{\theta_t}\geqslant c_3(\delta^\kappa+(t-t_0(\delta)))^2, \quad \forall\,\theta_t\in[\tilde{a}(t),a(t)]. \tag{A59}$$

Consider now the identities (dropping the δ dependence in the arguments),

$$\begin{aligned}\ddot{\tilde{a}}(t)-\ddot{a}(t)&=\partial_x V(a(t))-\partial_x\tilde{V}(\tilde{a}(t))\\ &=\partial_x\sqrt{\beta^2+\gamma^2+\sigma^2}(a(t))+\partial_x\overline{V}(a(t))-\partial_x s(\tilde{a}(t))-\partial_x V_3(\tilde{a}(t))\\ &=\partial_x(\sqrt{\beta^2+\gamma^2+\sigma^2}(a(t))-s(a(t)))+\partial_x(\overline{V}(a(t))-V_3(a(t)))\\ &\quad-\partial_x^2 s(\theta_t)(\tilde{a}(t)-a(t))+\partial_x^2 V_3(\theta_t)(\tilde{a}(t)-a(t)),\end{aligned} \tag{A60}$$

where $\theta_t\in(\tilde{a}(t),a(t))$. Now the first order derivatives are of order $\delta^3/(\delta^\kappa+(t-t_0(\delta))$, whereas the second order ones are of order $\delta^3/(\delta^\kappa+(t-t_0))^3$—see (A55) and (A59).

Hence introducing $d(t)=\tilde{a}(t)-a(t)$ we get an ODE of the form

$$\ddot{d}(t)=f(d(t),t)d(t)+g(d(t),t), \tag{A61}$$

where we have the *a priori* bounds,

$$\int_{t_0}^{t}|f(d(s),s)|ds\leqslant c\,\delta^2\int_{t_0}^{t}1/(\delta^\kappa+(s-t_0))^3 ds\leqslant c\,\delta^{2(1-\kappa)}, \tag{A62}$$

and since we can assume without loss that $\delta^k+(t-t_0(\delta))<1$,

$$\begin{aligned}\int_{t_0}^{t}|g(d(s),s)|&\leqslant\int_{t_0}^{t}\frac{c\,\delta^3}{(\delta^\kappa+(s-t_0))^3}ds\leqslant c\,\delta^3(|\ln(\delta^\kappa)|+|\ln(\delta^\kappa+(t-t_0)|)\\ &=\mathcal{O}(\delta^3\ln(\delta)).\end{aligned} \tag{A63}$$

Equation (A61) is equivalent to

$$d(t)=d(t_0)+(t-t_0)\dot{d}(t_0)+\int_{t_0}^{t}ds\int_{t_0}^{s}du(f(d(u),u)d(u)+g(d(u),u)). \tag{A64}$$

Let us denote

$$D(t)=\sup_{s\in[t_0,t]}|d(s)|. \tag{A65}$$

We deduce from the above bounds

$$\begin{aligned}|d(t)|&\leqslant|d(t_0)|+(t-t_0)|\dot{d}(t_0)|+c\int_{t_0}^{t}dsD(s)\,\delta^{2(1-\kappa)}+c\,\delta^3|\ln(\delta)|\\ &\leqslant c\left(|d(t_0)|+|\dot{d}(t_0)|+\delta^3|\ln(\delta)|+\int_{t_0}^{t}dsD(s)\,\delta^{2(1-\kappa)}\right)\end{aligned} \tag{A66}$$

and, as D is not decreasing,

$$D(t)\leqslant c\left(|d(t_0)|+|\dot{d}(t_0)|+\delta^3|\ln(\delta)|+\int_{t_0}^{t}dsD(s)\,\delta^{2(1-\kappa)}\right)$$

$$\leqslant c(|d(t_0)|+|\dot{d}(t_0)|+\delta^3|\ln(\delta)|+D(t)\,\delta^{2(1-\kappa)}). \tag{A67}$$

Since $\delta^{2(1-\kappa)}\to 0$, we find that

$$D(t)\leqslant c(|d(t_0)|+|\dot{d}(t_0)|+\delta^3|\ln(\delta)|). \tag{A68}$$

Plugging this into (A64) finally yields

$$d(t)=d(t_0)+(t-t_0)\dot{d}(t_0)+\mathcal{O}(\delta^{2(1-\kappa)}(|d(t_0)|+|\dot{d}(t_0)|)+\delta^3|\ln(\delta)|). \tag{A69}$$

As an immediate consequence of this result and (5.47) we have for any $t\in[t_0(\delta),\tau]$ with our choice of $t_0(\delta)$ and initial conditions (5.42),

$$\tilde{a}(t)-a(t)=o(\delta^2), \tag{A70}$$

$$\tilde{\eta}(t)-\eta(t)=o(\delta^2). \tag{A71}$$

Turning to $(A(t),B(t))$ and their approximations, we first note that by Ref. 13, p. 102, we have with our choice of $t_0(\delta)$,

$$\begin{pmatrix}\tilde{A}(t_0)\\ \tilde{B}(t_0)\end{pmatrix}-\begin{pmatrix}A(t_0)\\ B(t_0)\end{pmatrix}=o(1). \tag{A72}$$

Then we consider the equation [equivalent to (4.42) and (4.43)],

$$\begin{pmatrix}A(t)\\ B(t)\end{pmatrix}=\begin{pmatrix}A(t_0)\\ B(t_0)\end{pmatrix}+\int_{t_0}^{t}\begin{pmatrix}O & i\\ i\partial_x^2V(a(t)) & 0\end{pmatrix}\begin{pmatrix}A(s)\\ B(s)\end{pmatrix} \tag{A73}$$

and a similar one for the approximations with the tilded symbols everywhere. Introducing

$$\Delta(t)=\begin{pmatrix}\tilde{A}(t)\\ \tilde{B}(t)\end{pmatrix}-\begin{pmatrix}A(t)\\ B(t)\end{pmatrix},$$

we compute

$$\Delta(t)=\Delta(t_0)+\int_{t_0}^{t}\begin{pmatrix}0 & 0\\ i\partial_x^2\tilde{V}(\tilde{a}(s))-\partial_x^2V(a(s)) & 0\end{pmatrix}\begin{pmatrix}\tilde{A}(s)\\ \tilde{B}(s)\end{pmatrix}ds+\int_{t_0}^{t}\begin{pmatrix}0 & i\\ i\partial_x^2V(a(s)) & 0\end{pmatrix}\Delta(s)ds. \tag{A74}$$

But $\|\left(\begin{smallmatrix}\tilde{A}(t)\\ \tilde{B}(t)\end{smallmatrix}\right)\|=\mathcal{O}(1)$ by Ref. 13, $\int_{t_0}^{t}\partial_x^2\tilde{V}(\tilde{a}(s))ds=\mathcal{O}(\delta^{2(1-\kappa)})$ and similarly for the untilded quantities. Hence using the same type of manipulations as above, we deduce

$$\|\Delta(t)\|\leqslant c(\delta^{2(1-\kappa)}+\|\Delta(t_0)\|). \tag{A75}$$

It follows that

$$\begin{pmatrix}\tilde{A}(t)\\ \tilde{B}(t)\end{pmatrix}-\begin{pmatrix}A(t)\\ B(t)\end{pmatrix}=o(1) \tag{A76}$$

holds for any $t\in[t_0(\delta),\tau]$.

In order to deal with the ''electronic'' eigenvectors we consider the perturbation series for the resolvent $(h(x)+V_2(x)+\delta W(x)-z)^{-1}$ when the argument z runs through the circle of radius $|\mu^{\mathcal{A}}(x,0)-\mu^{\mathcal{B}}(x,0)|/4$ centered at any of the eigenvalue $\mu^{C}(x,0)$. Integration on this circle yields the eigenprojector $Q_j(x,\delta)$, $j=\mathcal{A},\mathcal{B}$, and the estimates

$$Q_j(x,\delta)=Q_j(x,0)+\mathcal{O}(\delta W(x)/|\mu^{\mathcal{A}}(x,0)-\mu^{\mathcal{B}}(x,0)|)=Q_j(x,0)+\mathcal{O}(\delta/x), \tag{A77}$$

$$\partial_x Q_j(x,\delta)=\partial_x Q_j(x,0)+\mathcal{O}(\delta/|\mu^{\mathcal{A}}(x,0)-\mu^{\mathcal{B}}(x,0)|^2)=\partial_x P_j(x,0)+\mathcal{O}(\delta/x^2). \tag{A78}$$

This, in turn, yields the following estimates on the eigenvectors $\Phi_j(x,\delta)$ of the perturbed operator $h(x)+\delta W(x)$:

$$\Phi_j(x,\delta)=\chi_j(x)+\mathcal{O}(\delta/x), \tag{A79}$$

$$\partial_x\Phi_j(x,\delta)=\partial_x\chi_j(x)+\mathcal{O}(\delta/x^2). \tag{A80}$$

Now we consider one eigenvector $\chi_j(x)$ and drop the index j. We note here that Eq. (3.58) in Ref. 13 shows that

$$\lambda_r(\omega,t,\delta)=\mathcal{O}(t/\delta^{1-\kappa}), \tag{A81}$$

so that $\lambda_r(\omega,t_0(\delta),\delta)=\mathcal{O}(\delta^{2\kappa-1})\to 0$ with δ. On the other hand, using the fact that $\chi(x)$ is smooth and that $\tilde{\eta}(t)$ is uniformly bounded on $[t_0(\delta),T]$ we find

$$\begin{aligned}
&\int_{t_0(\delta)}^{t} ids\,\eta(s)\langle\Phi(\omega,s,\delta)|\partial_x\Phi(\omega+a(s),\delta)\rangle\\
&\quad=\int_{t_0(\delta)}^{t} ids(\tilde{\eta}(s)+o(\delta^2))\times\langle(\tilde{\Phi}(\omega,s,\delta)\\
&\qquad+\mathcal{O}(\delta/(a(t)+\omega)))|(\partial_x\tilde{\Phi}(\omega+\tilde{a}(s),\delta)+\mathcal{O}(\delta/(a(s)+\omega)^2)))\rangle\\
&\quad=\int_{t_0(\delta)}^{t} ids\,\tilde{\eta}(s)\langle\tilde{\Phi}(\omega,s,\delta)|\partial_x\tilde{\Phi}(\omega+\tilde{a}(s),\delta)\rangle+o(1)\\
&\qquad+0(\delta\ln((t+\omega)/(t_0+\omega)))+\mathcal{O}(\delta(1/(t_0(\delta)+\omega)-1/(t+\omega))).
\end{aligned} \tag{A82}$$

Having $\omega=\mathcal{O}(\delta^{1-\delta'})$ and (5.49), the error terms above can be estimated by

$$o(1)+\mathcal{O}(\delta\ln(\delta)+\delta^{1-\kappa}) \tag{A83}$$

which goes to zero as $\delta\to 0$. It follows then that

$$\tilde{\lambda}(x,t,\delta)-\lambda(x,t,\delta)=o(1) \tag{A84}$$

and in turn we get

$$\tilde{\Phi}(x,t,\delta)-\Phi(x,t,\delta)=o(1), \tag{A85}$$

which concludes the proof. □

Perturbation theory free from secular terms for the equations of motion of anharmonic oscillators

Francisco M. Fernández[a)]

(Received 2 January 2001; accepted for publication 23 July 2001)

We develop a time–independent perturbation theory in operator form for the equations of motion of classical and quantum-mechanical anharmonic oscillators. The method focuses on the frequency of the motion in the former case and in a frequency operator in the latter, producing a power series in a small coupling constant. The resulting expressions are free from secular instabilities that commonly appear in perturbation treatments of nonlinear problems. © *2001 American Institute of Physics.* [DOI: 10.1063/1.1402175]

I. INTRODUCTION

Straightforward application of perturbation theory to classical equations of motion commonly produces secular terms that are unbounded even for periodic motion. For that reason, researchers have developed several alternative approaches that correct or completely overcome this failure of perturbation theory at large time. For example, methods like Lindstedt–Poincaré, renormalization, and multiple scales have been known for a long ago.[1–3] There has recently been great interest in similar approaches for quantum mechanics; the method of multiple scales[4,5] and the construction of minimal normal forms by means of near identity transformations[6] prove suitable for simple models such as anharmonic oscillators.

At first sight those approaches seem to become rather cumbersome even at moderately great orders of perturbation theory. For this reason, here we propose an alternative procedure that in our opinion is more straightforward, and at the same time provides a more systematic treatment of classical and quantum-mechanical perturbation theory. It is based on a recent discussion of the structure of the eigenvalues of nonlinear oscillators.[7] In Sec. II we consider classical anharmonic oscillators in one dimension, and in Sec. III we show that the method also applies to quantum-mechanical models almost without modification.

II. CLASSICAL MECHANICS

In order to simplify the discussion we restrict ourselves to one-dimensional models and use the following notation to indicate dependence of a dynamical variable F on time: $F(t)=F(q(t),p(t))$, $F(0)=F(q(0),p(0))=F(q,p)$, where $q(t)$ and $p(t)$ are the instantaneous values of the coordinate and momentum, respectively, and q and p are their initial values at $t=0$.

We believe that rewriting classical equations of motion in terms of operators facilitates the following discussion. For a given function $F(q,p)$ we construct the differential operator

$$\hat{F}=\frac{\partial F}{\partial q}\frac{\partial}{\partial p}-\frac{\partial F}{\partial p}\frac{\partial}{\partial q} \tag{1}$$

so that $\hat{F}G$ is the well-known Poisson bracket $\{F,G\}$.[3,8] If the Hamiltonian $H(q,p)$ does not depend explicitly on time we solve the time-evolution equation

[a)]Electronic mail: framfer@isis.unlp.edu.ar

$$\frac{\mathrm{d}}{\mathrm{d}t}F(t)=-\hat{H}F(t) \tag{2}$$

formally as[3,8]

$$F(t)=\exp(-t\hat{H})F(0). \tag{3}$$

The present method is based on the assumption that it is possible to obtain a nonzero dynamical variable $A(q,p)$ that satisfies

$$\hat{H}A=i\Omega A, \tag{4}$$

where $\Omega=\Omega(q,p)$ is a constant of the motion:

$$\hat{H}\Omega=0. \tag{5}$$

Notice that for periodic motion Ω is real and therefore A is complex. Taking into account that $\hat{H}A^*=-i\Omega A^*$ one easily proves that $|A|^2$ is a constant of the motion. Moreover, the time evolution of A,

$$A(t)=\exp(-it\Omega)A(0), \tag{6}$$

clearly exhibits the dependence of the period of the motion $\tau=2\pi/\Omega$ on the values of q and p. One easily verifies that if A is a solution of Eq. (4), then $K(H)A$ will also be a solution for any arbitrary function K of H with exactly the same value of Ω. In order to determine A uniquely we add an arbitrary (and convenient) normalization condition. Notice that Ω (as any other property of the system) is independent of normalization.

For example, for the well-known harmonic oscillator

$$H=\frac{p^2}{2m}+\frac{m\omega^2q^2}{2} \tag{7}$$

we have[3]

$$A=\sqrt{\frac{m\omega}{2}}\left(q+\frac{ip}{m\omega}\right), \quad \Omega=\omega, \tag{8}$$

where we see that the period is independent of q and p. In this case we have arbitrarily normalized the function A in such a way that $\{A,A^*\}=-i$.

Except for a few trivial models, one cannot solve Eqs. (4) and (5) exactly, and therefore one resorts to approximate methods like perturbation theory. If we can write

$$H=H_0+\lambda H', \tag{9}$$

where $\lambda H'$ is a small perturbation to the exactly solvable Hamiltonian H_0, then it is reasonable to look for approximate solutions in the form of Taylor series

$$A=\sum_{j=0}^{\infty}A_j\lambda^j, \quad \Omega=\sum_{j=0}^{\infty}\Omega_j\lambda^j. \tag{10}$$

It follows from Eqs. (4) and (5) that the coefficients of the series (10) satisfy

$$\hat{H}_0\Omega_j=-\hat{H}'\Omega_{j-1}, \tag{11}$$

$$(\hat{H}_0 - i\Omega_0)A_j = i\sum_{k=1}^{j} \Omega_k A_{j-k} - \hat{H}' A_{j-1}. \tag{12}$$

As already noted, we assume that we can exactly solve the unperturbed equations

$$\hat{H}_0\Omega_0 = 0, \quad (\hat{H}_0 - i\Omega_0)A_0 = 0. \tag{13}$$

From now on we call zero eigenspace of an operator $\hat{G}$ the set of all functions $Z(q,p)$ that satisfy $\hat{G}Z=0$. If there are no elements of the zero eigenspaces of $\hat{H}_0$ and $\hat{H}_0 - i\Omega_0$ on the right-hand side of Eqs. (11) and (12), respectively, we can solve them formally as

$$\Omega_j = -\hat{H}_0^{-1}\hat{H}'\Omega_{j-1} + g_j, \tag{14}$$

$$A_j = (\hat{H}_0 - i\Omega_0)^{-1}\left(i\sum_{k=1}^{j} \Omega_k A_{j-k} - \hat{H}' A_{j-1} \right) + h_j, \tag{15}$$

where $g_j(q,p)$ and $h_j(q,p)$ are arbitrary elements of the zero eigenspaces of $\hat{H}_0$ and $\hat{H}_0 - i\Omega_0$, respectively. Because $g_j A_0$ belongs to the zero eigenspace of $\hat{H}_0 - i\Omega_0$, we can choose g_j in order to remove all elements of the zero eigenspace of $\hat{H}_0 - i\Omega_0$ from the right-hand side of Eq. (12); and therefore Eq. (15) makes sense. On the other hand, h_j enables us to select an appropriate normalization condition for the dynamical variable $A(q,p)$ (such as, for example, $\{A,A^*\} = -i$).

If $\exp(t\hat{G})q$ and $\exp(t\hat{G})p$ are bounded for all t, then we can invert the operator $\hat{G}$ [e.g., $\hat{G} = \hat{H}_0$ and $\hat{G} = \hat{H}_0 - i\Omega_0$ in Eqs. (11) and (12), respectively] as follows:

$$\begin{aligned} (\hat{G}+\alpha)^{-1} &= \int_{-\infty}^{0} \exp[(\hat{G}+\alpha)t]\,dt, \quad \alpha > 0, \\ \hat{G}^{-1} &= \lim_{\alpha\to 0} (\hat{G}+\alpha)^{-1}. \end{aligned} \tag{16}$$

Taking into account that

$$\lim_{\alpha\to 0} \alpha(\hat{G}+\alpha)^{-1} Z = Z \tag{17}$$

for any element $Z(q,p)$ of the zero eigenspace of $\hat{G}$, we realize that

$$\lim_{\alpha\to 0} \alpha(\hat{G}+\alpha)^{-1} U \tag{18}$$

extracts elements of the zero eigenspace of $\hat{G}$ from $U(q,p)$. We apply this recipe to Eq. (15) in order to determine the appropriate g_j. This approach requires suitable expressions for $\exp(t\hat{H}_0)q$ and $\exp(t\hat{H}_0)p$, which we easily obtain as follows:

$$\begin{aligned} \exp(t\hat{H}_0)q &= q\cos(\omega t) - \frac{p\sin(\omega t)}{m\omega}, \\ \exp(t\hat{H}_0)p &= p\cos(\omega t) + m\omega q \sin(\omega t). \end{aligned} \tag{19}$$

Moreover, for any function $U(q,p)$ we have $\exp(t\hat{H}_0)U(q,p) = U(e^{t\hat{H}_0}q, e^{t\hat{H}_0}p)$. In order to illustrate the application of Eq. (18), we choose the following simple example: $\hat{G} = \hat{H}_0$, and $U = q^2$. It is not difficult to verify that

$$\int_{-\infty}^{0} \exp[t(\hat{H}+\alpha)]q^2\,\mathrm{d}t = \frac{m^2\alpha^2q^2+2m^2\omega^2q^2+2m\alpha qp+2p^2}{m^2(\alpha^2+4\omega^2)\alpha},$$

$$\lim_{\alpha\to 0}\alpha\int_{-\infty}^{0} \exp[t(\hat{H}+\alpha)]q^2\,\mathrm{d}t = \frac{m^2\omega^2q^2+p^2}{2m^2\omega^2}. \tag{20}$$

Notice that the right-hand side of Eq. (20) is the part of q^2 that commutes with H_0 as stated previously, and it is therefore an element of the zero eigenspace of the operator $\hat{H}_0$.

Once we solve Eqs. (14) and (15) for $j=1,2,\ldots$, we easily obtain the period of the motion as a λ-power series

$$\begin{aligned}\tau &= \frac{2\pi}{\Omega_0+\Omega_1\lambda+\Omega_2\lambda^2+\Omega_3\lambda^3+\cdots}\\ &= 2\frac{\pi}{\Omega_0}\left(1-\frac{\Omega_1}{\Omega_0}\lambda-\frac{(\Omega_2\Omega_0-\Omega_1^2)}{\Omega_0^2}\lambda^2-\frac{(\Omega_3\Omega_0^2-2\Omega_1\Omega_2\Omega_0+\Omega_1^3)}{\Omega_0^3}\lambda^3+\cdots\right).\end{aligned} \tag{21}$$

As a simple illustrative example we consider the anharmonic oscillator given by

$$H_0=\frac{p^2}{2m}+\frac{m\omega^2q^2}{2}, \quad H'=q^4. \tag{22}$$

Notice that Eq. (8) gives us A_0 and Ω_0 for this choice of H_0. The calculation is straightforward but tedious; fortunately available software for symbolic computation, like MAPLE,[9] greatly facilitates the process. Notice that Eqs. (14) and (15) are suitable for programming according to Eqs. (16)–(18). (MAPLE worksheets and programs are available upon request.) For the anharmonic oscillator (22) we easily obtain the following expressions for the frequency coefficients in terms of the initial coordinate and momentum:

$$\begin{aligned}\Omega_1 &= \frac{3}{2}\frac{(m^2\omega^2q^2+p^2)}{m^3\omega^3},\\ \Omega_2 &= -\frac{3}{16}\frac{46m^2\omega^2p^2q^2+23p^4+7m^4\omega^4q^4}{m^6\omega^7},\\ \Omega_3 &= \frac{3}{32}\frac{449m^4\omega^4q^4p^2+633p^4m^2\omega^2q^2+27m^6\omega^6q^6+211p^6}{m^9\omega^{11}}.\end{aligned} \tag{23}$$

Notice that we can rewrite Ω_1 as a function of H_0,

$$\Omega_1=3\frac{H_0}{m^2\omega^3}, \tag{24}$$

because $\{H_0,\Omega_1\}=0$, but we cannot do the same with the coefficients Ω_j for $j>1$.

Choosing for simplicity the arbitrary zero-eigenspace elements $h_j(q,p)$ equal to zero we obtain

$$A_1=\frac{\sqrt{2}\sqrt{m\,\omega}[9m\omega qp^2+5m^3\omega^3q^3-3i(p^3+5m^2\omega^2q^2p)]}{16m^4\omega^5}, \tag{25}$$

$$A_2 = -\frac{\sqrt{2}}{32(m^6\omega^8\sqrt{m\omega})}[122m^3\omega^3p^2q^3 + 65m\omega p^4q + 13m^5\omega^5q^5 - i(13p^5 + 86m^2\omega^2q^2p^3 + 101m^4\omega^4pq^4)].$$

In order to verify the above-mentioned results we apply them to Duffing's equation[1,2]

$$\ddot{u}(t) + u(t) + 4\lambda u(t)^3 = 0. \tag{26}$$

Choosing the initial conditions $u(0) = x_0$, $v(0) = \dot{u}(0) = 0$, and expanding the exact period[1] in powers of λ, we obtain

$$\tau = 2\pi - 3\pi x_0^2\lambda + \frac{57\pi x_0^4\lambda^2}{8} - \frac{315\pi x_0^6\lambda^3}{16} + \cdots. \tag{27}$$

On the other hand, if we substitute $m = \omega = 1$, $p = 0$, and $q = x_0$ into Eq. (23), then Eq. (21) gives exactly Eq. (27) as one easily verifies.

III. QUANTUM MECHANICS

The method outlined previously for classical mechanics applies to quantum mechanics almost without modification. In this case the dynamical variables are linear operators $\{\hat{A}, \hat{B}, \hat{C}, \ldots\}$. For every linear operator $\hat{F}$ we define a superoperator $\hat{\hat{F}}$ that acts on the vector space of linear operators as follows: $\hat{\hat{F}}\hat{C} = [\hat{F}, \hat{C}] = \hat{F}\hat{C} - \hat{C}\hat{F}$.[3,10] If the Hamiltonian operator $\hat{H}$ is independent of time we solve the time-evolution equation

$$\frac{d\hat{P}(t)}{dt} = \frac{i}{\hbar}[\hat{H}, \hat{P}(t)] = \frac{i}{\hbar}\hat{\hat{H}}\hat{P}(t), \tag{28}$$

formally as follows:[3,10]

$$\hat{P}(t) = \exp\left(\frac{it\hat{H}}{\hbar}\right)\hat{P}\exp\left(-\frac{it\hat{H}}{\hbar}\right) = \exp\left(\frac{it\hat{\hat{H}}}{\hbar}\right)\hat{P}, \tag{29}$$

where we write $\hat{P}(0) = \hat{P}$.

For simplicity and concreteness we consider the dimensionless Hamiltonian operator $\hat{H}(\hat{a}, \hat{a}^\dagger)$ for a one-dimensional anharmonic oscillator in terms of the annihilation $\hat{a}$ and creation $\hat{a}^\dagger$ operators that satisfy the bosonic commutation relation $[\hat{a}, \hat{a}^\dagger] = \hat{1}$. From now on we set $\hbar = 1$ in order to have dimensionless equations of motion, and omit the identity operator $\hat{1}$. As in the classical counterpart discussed previously, the key of the approach is to construct an operator $\hat{b}(\hat{a}, \hat{a}^\dagger)$ such that

$$\hat{\hat{H}}\hat{b} = -\hat{\Omega}\hat{b}, \tag{30}$$

where $\hat{\Omega}$ is a constant of the motion

$$\hat{\hat{H}}\hat{\Omega} = 0. \tag{31}$$

In the case of bounded motion the frequency operator $\hat{\Omega}$ is Hermitian ($\hat{\Omega}^\dagger = \hat{\Omega}$) and $\hat{b}^\dagger\hat{b}$ results in a constant of the motion. Moreover, the operator $\hat{b}$ changes in time according to

$$\hat{b}(t) = \exp(-it\hat{\Omega})\hat{b}. \tag{32}$$

Exactly as in classical mechanics, Eq. (30) does not determine $\hat{b}$ completely, and we require a normalization condition. The operator $\hat{\Omega}$ is independent of the normalization condition chosen and can therefore be considered to be a property of the system. The quantum-mechanical version of present method is exactly the one developed recently for the discussion of the structure of eigenvalues of nonlinear oscillators;[7] the main difference is that here we concentrate on perturbation theory instead of on the semiclassical limit. Moreover, we compare several normalization conditions for $\hat{b}$.

As in the classical case, it is not possible to solve Eqs. (30) and (31) exactly except for some simple models such as the harmonic oscillator. In nontrivial cases we resort to approximate methods; here we choose perturbation theory and write

$$\hat{H}=\hat{H}_0+\lambda\hat{H}' \tag{33}$$

provided that we can solve

$$\hat{\hat{H}}_0\hat{b}_0=-\hat{\Omega}_0\hat{b}_0,\hat{\hat{H}}_0\hat{\Omega}_0=0 \tag{34}$$

exactly. If we expand the solutions to Eqs. (30) and (31) in Taylor series of the perturbation parameter λ:

$$\hat{b}=\sum_{j=0}^{\infty}\hat{b}_j(\hat{a},\hat{a}^\dagger)\lambda^j,\quad \hat{\Omega}=\sum_{j=0}^{\infty}\hat{\Omega}_j(\hat{a},\hat{a}^\dagger)\lambda^j, \tag{35}$$

we easily obtain

$$(\hat{\hat{H}}_0+\hat{\Omega}_0)\hat{b}_j=-\hat{\hat{H}}'\hat{b}_{j-1}-\sum_{m=1}^{j}\hat{\Omega}_m\hat{b}_{j-m}, \tag{36}$$

$$\hat{\hat{H}}_0\hat{\Omega}_j+\hat{\hat{H}}'\hat{\Omega}_{j-1}=0. \tag{37}$$

We formally solve Eqs. (36) and (37) as follows (we write them in the order they should be solved):

$$\hat{\Omega}_j=\hat{\hat{H}}_0^{-1}[\hat{\Omega}_{j-1},\hat{H}']+\hat{N}_j, \tag{38}$$

$$\hat{b}_j=(\hat{\hat{H}}_0+\hat{\Omega}_0)^{-1}\left([\hat{b}_{j-1},\hat{H}']+\sum_{m=1}^{j}\hat{\Omega}_m\hat{b}_{j-m}\right)+\hat{N}_j', \tag{39}$$

where $\hat{N}_j$ and $\hat{N}_j'$ are zero-eigenspace elements that satisfy $\hat{\hat{H}}_0\hat{N}_j=0$ and $(\hat{\hat{H}}_0+\hat{\Omega}_0)\hat{N}_j'=0$ respectively. At every perturbation order j we choose $\hat{\Omega}_j$ to remove all elements of the zero eigenspace of $\hat{\hat{H}}_0+\hat{\Omega}_0$ from the right-hand side of Eq. (36) before we apply the superoperator $(\hat{\hat{H}}_0+\hat{\Omega}_0)^{-1}$.

For the particular case that

$$\hat{H}_0=\hat{a}^\dagger\hat{a}+\tfrac{1}{2}, \tag{40}$$

we have

$$\hat{b}_0=a,\quad \hat{\Omega}_0=1, \tag{41}$$

and

$$\hat{N}_j=\hat{g}_j(\hat{a}^\dagger\hat{a}),\quad \hat{N}_j'=f_j(\hat{a}^\dagger\hat{a})\hat{a}^\dagger, \tag{42}$$

where $\hat{g}_j(\hat{a}^\dagger\hat{a})$ and $\hat{f}_j(\hat{a}^\dagger\hat{a})$ are arbitrary functions of the number operator $\hat{a}^\dagger\hat{a}$. As indicated previously we choose $\hat{g}_j$ in order to remove all zero-eigenspace elements from the right-hand side of Eq. (36). On the other hand, $\hat{f}_j$ is determined by a normalization condition on the operator $\hat{b}$. We discuss some examples in the following.

The application of Eqs. (38) and (39) is straightforward when $\hat{H}_0$ is given by Eq. (40), and the perturbation is a polynomial function of the boson operators. In principle, we may apply a method similar to the one outlined in Eqs. (16)–(18). However, in what follows we proceed in a different way, and take into account that $F(\hat{\hat{H}}_0)\hat{a}^{\dagger m}\hat{a}^n=F(m-n)\hat{a}^{\dagger m}\hat{a}^n$ for any function $F(x)$ in order to systematically solve Eqs. (38) and (39), where we have $F(x)=x^{-1}$ and $F(x)=(x+1)^{-1}$, respectively. We have performed this calculation by hand, because we found it difficult to implement the necessary operator equations in MAPLE.

It is always instructive to study exactly solvable models; for that reason, in what follows we choose the case in which $\hat{H}_0$ is given by Eq. (40) and the perturbation is quadratic: $\hat{H}'=\frac{1}{2}(\hat{a}^2+\hat{a}^{\dagger 2})$. We easily obtain

$$\begin{aligned}\hat{\Omega}&=\Omega=\sqrt{1-\lambda^2},\\ \hat{b}&=\frac{\lambda}{\sqrt{2\sqrt{1-\lambda^2}(1-\sqrt{1-\lambda^2})}}\left(\hat{a}+\frac{1-\sqrt{1-\lambda^2}}{\lambda}\hat{a}^\dagger\right),\end{aligned} \tag{43}$$

provided that the normalization condition is $[\hat{b},\hat{b}^\dagger]=1$.

It is not difficult to verify that the above-outlined perturbation method exactly gives the Taylor expansions for Ω and $\hat{b}$ that converge for all $|\lambda|<1$. In this case the constant of the motion $\hat{b}^\dagger\hat{b}$ is a linear function of $\hat{H}$:

$$\hat{b}^\dagger\hat{b}=\frac{1}{\sqrt{1-\lambda^2}}\left(\hat{H}-\frac{\sqrt{1-\lambda^2}}{2}\right), \tag{44}$$

and the time evolution of $\hat{b}$ is remarkably simple:

$$\hat{b}(t)=\exp(-i\Omega t)\hat{b}. \tag{45}$$

In principle, we can improve the convergence properties of the perturbation series by an appropriate choice of $\hat{H}_0$.[3] Consider, for example, the operator

$$\hat{H}=\hat{a}^\dagger\hat{a}+\frac{1}{2}+\frac{\lambda}{2}(\hat{a}+\hat{a}^\dagger)^2. \tag{46}$$

The radius of convergence of the λ-power series for

$$\hat{\Omega}=\Omega=\sqrt{1+2\lambda} \tag{47}$$

is determined by a square-root branch point at $\lambda=-\frac{1}{2}$.

If, on the other hand, we split $\hat{H}$ as

$$\hat{H}=(1+\lambda)\left(\hat{a}^\dagger\hat{a}+\frac{1}{2}\right)+\frac{\beta\lambda}{2}(\hat{a}^2+\hat{a}^{\dagger 2}), \tag{48}$$

then the Taylor series about $\beta=0$ converges for all

$$\beta^2 < \frac{(1+\lambda)^2}{\lambda^2}.$$

Choosing $\beta = 1$ in order to recover the original operator (46), we conclude that this alternative approach converges for all $\lambda > -\frac{1}{2}$, which is certainly better than the condition $|\lambda| < \frac{1}{2}$ that follows from the straightforward expansion about $\lambda = 0$ discussed previously. We see that the present approach facilitates the discussion of the convergence properties of the normal forms.

As a nontrivial example we choose one of the anharmonic oscillators discussed by other authors:[6] $\hat{H}_0$ given by Eq. (40) and

$$\hat{H}' = \tfrac{1}{16}(\hat{a}+\hat{a}^\dagger)^4. \tag{49}$$

We believe it worthwhile to compare different normalization conditions for the operator $\hat{b}$. In the first place we choose $[\hat{b},\hat{b}^\dagger]=1$, so that the coefficients $\hat{b}_j$ and $\hat{b}_j^\dagger$ satisfy

$$\sum_{m=0}^{j} [\hat{b}_m, \hat{b}_{j-m}^\dagger] = \delta_{j0}. \tag{50}$$

This condition, which makes the transformation $\{\hat{a},\hat{a}^\dagger\} \to \{\hat{b},\hat{b}^\dagger\}$ canonical, is different from the ones chosen recently by other authors.[6,7]

Solving the perturbation equations of first and second order we easily obtain

$$\begin{aligned} \hat{\Omega}_1 &= \hat{g}_1 = \tfrac{3}{4}(\hat{a}^\dagger\hat{a}+1), \\ \hat{b}_1 &= \tfrac{1}{4}(\tfrac{1}{4}\hat{a}^{\dagger 3} + \tfrac{3}{2}\hat{a}^{\dagger 2}\hat{a} + \tfrac{3}{2}\hat{a}^\dagger - \tfrac{1}{2}\hat{a}^3), \\ \hat{f}_1 &= 0, \end{aligned} \tag{51}$$

and

$$\begin{aligned} \hat{\Omega}_2 &= \tfrac{3}{16}(\tfrac{1}{4}\hat{a}^{\dagger 4} + \hat{a}^{\dagger 3}\hat{a} + \tfrac{3}{2}\hat{a}^{\dagger 2} + \hat{a}^\dagger\hat{a}^3 + \tfrac{1}{4}\hat{a}^4 + \tfrac{3}{2}\hat{a}^2) + \hat{g}_2, \\ \hat{g}_2 &= -\tfrac{3}{64}(17\hat{a}^{\dagger 2}\hat{a}^2 + 51\hat{a}^\dagger\hat{a} + 24), \\ \hat{b}_2 &= \tfrac{3}{64}(\tfrac{1}{6}\hat{a}^{\dagger 5} - \tfrac{3}{4}\hat{a}^{\dagger 4}\hat{a} - \tfrac{21}{2}\hat{a}^{\dagger 3}\hat{a}^2 - \tfrac{3}{2}\hat{a}^{\dagger 3} - \tfrac{63}{2}\hat{a}^{\dagger 2}\hat{a} + 6\hat{a}^\dagger\hat{a}^4 - \tfrac{27}{2}\hat{a}^\dagger + \tfrac{3}{4}\hat{a}^5 + 12\hat{a}^3) + \hat{f}_2\hat{a}, \\ \hat{f}_2 &= \tfrac{27}{512}(\hat{a}^\dagger\hat{a})^2 + \tfrac{27}{256}\hat{a}^\dagger\hat{a} + \tfrac{9}{256}, \end{aligned} \tag{52}$$

respectively. By means of Eq. (51) and the properties of the boson operators we easily derive one of the results of Kahn and Zarni:[6]

$$\hat{b}(t)|0\rangle = \lambda e^{-it}\left[\frac{3}{8}\exp\left(-\frac{3\lambda i t}{2}\right)|1\rangle + \frac{\sqrt{6}}{16}\exp(-3\lambda i t)|3\rangle\right] + \mathcal{O}(\lambda^2), \tag{53}$$

where $|n\rangle, n = 0,1,\ldots$, are the eigenvectors of the number operator $\hat{a}^\dagger\hat{a}$. The difference in the sign of the exponents is due to the fact that Kahn and Zarni chose an uncommon equation of motion for the creation and annihilation operators: $d\hat{a}(t)/dt = i\hat{a} + \cdots$.[6] Notice that if we add corrections of second order to $\hat{b}(t)$, then it is not that easy to obtain a simple expression for $\hat{b}(t)|n\rangle$ because the operators $\hat{\Omega}_1$ and $\hat{\Omega}_2$ that appear in the exponent do not commute. This was presumably the reason why Kahn and Zarmi[6] (as well as other authors[4,5]) did not include such terms in their calculations.

For the second normalization condition we follow Kahn and Zarmi[6] and require that

$$\hat{\Omega} = \alpha \hat{b}^\dagger \hat{b} + \beta, \tag{54}$$

where

$$\alpha = \sum_{j=0}^{\infty} \alpha_j \lambda^j, \quad \beta = \sum_{j=0}^{\infty} \beta_j \lambda^j. \tag{55}$$

On expanding Eq. (54) in a Taylor series about $\lambda = 0$ we obtain

$$\hat{\Omega}_j = \sum_{m=0}^{j} \sum_{k=0}^{m} \alpha_{j-m} \hat{b}_k^\dagger \hat{b}_{m-k} + \beta_j . \tag{56}$$

Taking into account the above-mentioned results for $\hat{\Omega}_0$ and $\hat{\Omega}_1$ we easily obtain $\alpha_0 = 0$, $\beta_0 = 1$, $\alpha_1 = \beta_1 = \frac{3}{4}$. At this point f_1 is still undetermined. From Eq. (56) for $j = 2$ we obtain $\hat{g}_2$ in terms of α_2, β_2, $\hat{f}_1$ and the boson operators. Setting $\hat{f}_1$ in order to remove zero-space elements from the right-hand side of Eq. (36) for $j = 2$ we obtain

$$\begin{gathered} \hat{f}_1 = -\tfrac{17}{32} \hat{a}^\dagger \hat{a}, \\ \alpha_2 = -\tfrac{153}{64}, \quad \beta_2 = -\tfrac{9}{8}, \end{gathered} \tag{57}$$

and exactly the above-given expression for $\hat{g}_2$.

In principle, this variant of the near-identity transformation should be identical to the one of Kahn and Zarmi;[6] however, our expressions

$$\hat{\Omega} = (\tfrac{3}{4}\lambda - \tfrac{153}{64}\lambda^2 + \cdots) \hat{b}^\dagger \hat{b} + 1 + \tfrac{3}{4}\lambda - \tfrac{9}{8}\lambda^2 + \cdots, \tag{58}$$

$$[\hat{b}, \hat{b}^\dagger] = 1 - \frac{17\lambda}{8} \hat{a}^\dagger \hat{a} + \cdots, \tag{59}$$

do not exactly agree with theirs, presumably because of the previously-mentioned sign difference. We believe that our equations are correct as they have passed all the consistency tests; that is to say, they satisfy Eqs. (36), (37), and (56).

In order to stress the flexibility of present approach still further, we try other normalization conditions. For example, it is possible to set the operators $\hat{f}_j$ so that $[\hat{b}, \hat{b}^\dagger] = \hat{\Omega}$; that is to say:

$$\sum_{m=0}^{j} [\hat{b}_m^\dagger, \hat{b}_{j-m}] = \hat{\Omega}_j . \tag{60}$$

In this case we obtain $\hat{g}_1$ and $\hat{g}_2$ as before, and

$$\begin{gathered} \hat{f}_1 = \tfrac{3}{16}(\hat{a}^\dagger \hat{a} + 2), \\ \hat{f}_2 = -\tfrac{1}{256}(25 \hat{a}^{\dagger 2} \hat{a}^2 + 135 \hat{a}^\dagger \hat{a} + 153). \end{gathered} \tag{61}$$

It is not difficult to verify that the normalization condition $[\hat{b}, \hat{b}^\dagger] = \hat{\Omega}$ just discussed is equivalent to the one chosen by Speliotopoulos:[7] $\hat{H} = \hat{b}^\dagger \hat{b} + e$, where e is a real number. Taking into account the operator coefficients $\hat{b}_j$, and $\hat{b}_j^\dagger$, derived previously, one easily obtains the coefficients of

$$e = \sum_{j=0}^{\infty} e_j \lambda^j; \tag{62}$$

the first ones are:

$$e_0=\tfrac{1}{2}, \quad e_1=\tfrac{3}{16}, \quad e_2=-\tfrac{21}{128}. \tag{63}$$

IV. CONCLUSIONS

We have discussed a simple time-independent perturbation theory that leads to perturbation series for time-dependent dynamical variables in classical and quantum mechanics that are free from secular terms. The approach focuses on the frequency of the motion in the former case and on a frequency operator in the latter. We believe that our method is sufficiently clear, straightforward, and systematic, and that it is a useful complement to other procedures proposed earlier for the same purpose.[4–6] The approach is suitable for symbolic programming[9] through Eqs. (16)–(18), and remarkably flexible as it allows one to easily choose the most convenient normalization condition to completely determine the solutions. A noticeable advantage of the present method is that it is based on time-independent equations, which not only facilitate the calculation of perturbation corrections, but also the analysis of convergence of the series. We have also discussed problems that may hinder the application of nonsecular perturbation methods at perturbation orders greater than unity. The present method resembles the multiple-scale approach in that similar equations apply to classical and quantum mechanics,[4,5] but in our opinion the equations in our method are considerably simpler.

JOURNAL OF MATHEMATICAL PHYSICS VOLUME 42, NUMBER 10 OCTOBER 2001

The disorder deviation in the deconfined phase

G. A. Kozlov[a)]
Bogoliubov Laboratory of Theoretical Physics, Joint Institute for Nuclear Research, 141980 Dubna, Moscow Region, Russia

(Received 20 February 2001; accepted for publication 24 April 2001)

A systematic study of the strongly interacting matter under extreme conditions via the form of the thermal ratio of the disorder deviation is presented. The evolution of Fermi and Bose particles (quarks and gluons) is studied in the framework of multiparticle correlation and distribution functions to predict the size of the finite-temperature deconfined phase. © *2001 American Institute of Physics.*
[DOI: 10.1063/1.1387467]

I. INTRODUCTION

The existence of a deconfined phase of gluons and quarks has been predicted by quantum chromodynamics (QCD).[1] Aspects of QCD at finite density are very important as well as instructive in the sense of the observation of quark-gluon plasma (QGP), especially from the heavy vector meson (HVM) suppression, strangeness enhancement, hadron yield distributions versus temperature and dilepton excess. There is large amount of consistency among the different signatures of deconfined phase transition to a new excited state of matter. In the case of HVM suppression (e.g., $c\bar{c}$ bound state suppression), the CERN-SPS experiments clearly show that it is visible in high energy nuclear collisions starting from a definite value of the energy density in the right range. Enhanced strange particle production in high energy nuclear collisions offers another indication for the phase transition: in the deconfined phase strange quarks are more easily produced. The threshold for producing strange quarks is much lower than that for strange hadrons. In addition, the mass of the strange quark goes down in the case of the restoration of the chiral symmetry. Hence, the observation of large ratios for strange particles is considered as a remnant of the unconfined phase. The dilepton abundance, while well explained by ordinary sources in all other cases, for Pb–Pb collisions is instead observed as a neat excess.

There is a very popular point of view in literature that a deconfinement phase transition is predicted to occur at the typical energy scale involved, $T_c \simeq \Lambda_{\mathrm{QCL}} \simeq m_\pi \simeq m_s \simeq 140-200$ MeV, where T_c, Λ_{QCD}, m_π, and m_s are the critical temperature, the scale of QCD, the pion mass and a mass of the strange quark, respectively. Putting all above-mentioned indications together, the case of a high density state of matter onsetting at a critical temperature around 170 MeV is reasonably suitable.

Among the issues related to QGP, we attract attention to the problem of deconfined phase through the calculation of correlation and distribution functions[2] in the thermal theory of quantized fields. We consider the semiphenomenological model for the deconfinement existence within the framework of the Langevine-type equation. To do this, we follow the standard theory of quantized fields, replacing

(1) the asymptotic field operators and
(2) the vacuum expectation values

by

(1) the thermal field operators and
(2) the thermal statistical averages,

a)Electronic mail: kozlov@thsun1.jinr.ru

respectively, in order to formulate correlation and distribution functions of produced particles.

The method of the Langevine equation and its extensions to the quantal case have been suggested and considered in Refs. 3–5 and 6–8, respectively. We propose that real physical processes that happen in the finite-temperature QCD should be replaced by a one-constituent (e.g., gluon or quark) propagation provided by a special kernel operator (in the master evolution equation) to be considered as an input of the model and disturbed by the random force F. We assume F to be the external source proposed as both a c-number function and an operator. The master equation is an operator one, so that there appear new additional issues about the commutation relations and the ordering of operators, which do not exist in the classical case.[8]

Based on the thermal operator-field technique, we introduce a thermal ratio of the disorder deviation (TRDD), reflecting the degree of deviation, from unity, of the ratio of the two-particle thermal momentum-dependent distribution to two one-particle thermal distribution functions of produced particles, gluons and/or quarks (g/q) in a partly deconfined phase state. We study the four-momentum correlations of identical particles which can be both useful and instructive to infer the shape of the particle emitter-source. We estimate the sensitivity of the TRDD functions to the size of the emitter. Within these features, the canonical formalism in a stationary state in the thermal equilibrium (SSTE) is formulated, and a closed structural resemblance between the SSTE and standard quantum field theory is revealed.

To clarify the internal structure of the disordering of particles, we use the consistent approach based on the evolution of dynamical variables as well as the extension to different modes provided by virtual transitions.

II. DISTRIBUTION FUNCTIONS. EVOLUTION EQUATION

Let us consider a hypothetical system of the quark-gluon excited local thermal phase in QCD where a canonical operator a and its Hermitian conjugate a^+ occur. We formulate the distribution functions (DF) of produced particles (gluons and quarks) in terms of point-to-point equal time temperature-dependent thermal correlation functions (CFs) of two operators

$$w(\vec{k},\vec{k}',t;T)=\langle a^+(\vec{k},t)a(\vec{k}',t)\rangle$$

$$=Tr[a^+(\vec{k},t)a(\vec{k}',t)e^{-H\beta}]/Tr(e^{-H\beta}).$$

Here, $\langle \ldots \rangle$ means the procedure of thermal statistical averaging; $\vec{k}$ and t are, respectively, momentum and time variables, $e^{-\mathrm{H}\beta}/Tr(e^{-\mathrm{H}\beta})$ stands for the standard density operator in the equilibrium and the Hamiltonian H is given by the squared form of the annihilation a_p and creation a_p^+ operators for Bose and Fermi particles, $\mathrm{H}=\Sigma_p \epsilon_p a_p^+ a_p$ (the energy ϵ_p and operators a_p, a_p^+ carry some index p,[9] where $p_\alpha=2\pi n_\alpha/L, n_\alpha=0,\pm 1,\pm 2,\ldots; V=L^3$ is the volume of the system considered); β is the inverse temperature of the environment, and $\beta=1/T$. The standard canonical commutation relation

$$[a(\vec{k},t),a^+(\vec{k}',t)]_\pm=\delta^3(\vec{k}-\vec{k}')$$

at every time t is used as usual for Bose $(-)$ and Fermi $(+)$ operators.

The probability to find two particles, gluons or quarks, with momenta $\vec{k}$ and $\vec{k}'$ in the same event at the time t normalized to the single spectrum of these particles is

$$R(\vec{k},\vec{k}',t)=W(\vec{k},\vec{k}',t)/[W(\vec{k},t)\cdot W(\vec{k}',t)].$$

Here, the one-particle thermal DF is defined as

$$W(\vec{k},t)=\langle b^+(\vec{k},t)b(\vec{k},t)\rangle,$$

where

$$b(\vec{k},t)=a(\vec{k},t)+\phi(\vec{k},t)$$

under an assumption of occurrence of the random source-function $\phi(\vec{k},t)$ being an operator, in general. The two-particle DF $W(\vec{k},\vec{k}',t)$ looks like

$$W(\vec{k},\vec{k}',t)=\langle b^+(\vec{k},t)b^+(\vec{k}',t)b(\vec{k},t)b(\vec{k}',t)\rangle.$$

The evolution properties of propagating particles in a randomly distributed environment come from the evolution equations

$$i\partial_t b(\vec{k},t)+A(\vec{k},t)=F(\vec{k},t)+P, \tag{1}$$

$$-i\partial_t b^+(\vec{k},t)+A^*(\vec{k},t)=F^+(\vec{k},t)+P, \tag{2}$$

where both b and b^+ are the special mode operators of the quark and gluon fields,[10] and P and $F(\vec{k},t)$ stand for the stationary external force and the random one, respectively, both acting from the environment. The only operator F has a zeroth value of the statistical average, $\langle F\rangle=0$. The interaction of the particles considered with the surrounding ones as well as providing the propagation is given by the operator $A(\vec{k},t)$, which can be defined as the one closely related to the dissipation force:

$$A(\vec{k},t)=\int_{-\infty}^{+\infty}K(\vec{k},t-\tau)b(\vec{k},\tau)d\tau. \tag{3}$$

An interplay of quarks and gluons with surrounding particles is embedded into the interaction complex kernel $K(\vec{k},t)$, while the real physical transitions are provided by the random source operator $F(\vec{k},t)$ [see Eqs. (1) and (2)]. The random evolution field operator $K(\vec{k},t)$ in (3) stands for the random noise and it is assumed to vary stochastically with a δ-like equal time correlation function[10]

$$\langle K^+(\vec{k},\tau)K(\vec{k}',\tau)\rangle=2(\pi\rho)^{1/2}\kappa\delta(\vec{k}-\vec{k}'),$$

where both the strength of the noise κ and the positive constant $\rho\to\infty$ define the effect of the Gaussian noise on the evolution of quarks and gluons in the thermalized environment.

The formal solution of (1) in the operator form in $S(\mathfrak{R}_4)$ $[k^\mu=(\omega=k^0,k_j)]$ is

$$\tilde{b}(k_\mu)=\tilde{a}(k_\mu)+\tilde{\phi}(k_\mu),$$

where the operator $\tilde{a}(k_\mu)$ is expressed via the Fourier transformed operator $\tilde{F}(k_\mu)$ and the Fourier transformed kernel function $\tilde{K}(k_\mu)$ [coming from (3)] as

$$\tilde{a}(k_\mu)=\tilde{F}(k_\mu)\cdot[\tilde{K}(k_\mu)-\omega]^{-1},$$

while the function $\tilde{\phi}(k_\mu)\sim P\cdot[\tilde{K}(k_\mu)-\omega]^{-1}$. The random force operator $F(\vec{k},t)$ can be expanded by using the Fourier integral

$$F(\vec{k},t)=\int_{-\infty}^{+\infty}\frac{d\omega}{2\pi}\psi(k_\mu)\hat{c}(k_\mu)e^{-i\omega t}, \tag{4}$$

where the form $\psi(k_\mu)\cdot\hat{c}(k_\mu)$ is just the Fourier operator $\tilde{F}(k_\mu)=\psi(k_\mu)\cdot\hat{c}(k_\mu)$ and the canonical operator $\hat{c}(k_\mu)$ obeys the commutation relation

$$[\hat{c}(k_\mu),\hat{c}^+(k'_\mu)]_\pm=\delta^4(k_\mu-k'_\mu).$$

The function $\psi(k_\mu)$ in (4) is determined by the condition[10]

$$\int_{-\infty}^{+\infty}\frac{d\omega}{2\pi}\left[\frac{\psi(k_\mu)}{\tilde{K}(k_\mu)-\omega}\right]^2=1.$$

III. TRDD AND THE SPACE–TIME SIZE

The enhanced probability for emission of two identical particles is given by the ratio R of DF in $S(\mathfrak{R}_4)$ as follows:

$$R_{b/f}(k_\mu,k'_\mu;T)=\frac{\tilde{W}(k_\mu,k'_\mu;T)}{\tilde{W}(k_\mu)\cdot\tilde{W}(k'_\mu)}, \tag{5}$$

where $\tilde{W}(k_\mu,k'_\mu;T)=\langle\tilde{b}^+(k_\mu)\tilde{b}^+(k'_\mu)\tilde{b}(k_\mu)\tilde{b}(k'_\mu)\rangle$ and $\tilde{W}(k_\mu)=\langle\tilde{b}^+(k_\mu)\tilde{b}(k_\mu)\rangle$. Using the Fourier solution of Eq. (1) in $S(\mathfrak{R}_4)$, one can get R-ratios for DF obeying Bose particles

$$R_b(k_\mu,k'_\mu;T)=1+D_b(k_\mu,k'_\mu;T) \tag{6}$$

and Fermi particles

$$R_f(k_\mu,k'_\mu;T)=R_b(k_\mu,k'_\mu;T)-2\frac{\Xi(k_\mu)\cdot\Xi(k'_\mu)}{\tilde{W}(k_\mu)\cdot\tilde{W}(k'_\mu)}, \tag{7}$$

where

$$D_b(k_\mu,k'_\mu)=\frac{\Xi(k_\mu,k'_\mu)[\Xi(k'_\mu,k_\mu)+\tilde{\phi}^+(k'_\mu)\tilde{\phi}(k_\mu)]+\Xi(k'_\mu,k_\mu)\tilde{\phi}^+(k_\mu)\tilde{\phi}(k'_\mu)}{\tilde{W}(k_\mu)\cdot\tilde{W}(k'_\mu)} \tag{8}$$

and the two-particle CF $\Xi(k_\mu,k'_\mu)$ looks like

$$\Xi(k_\mu,k'_\mu)=\langle\tilde{a}^+(k_\mu)\tilde{a}(k'_\mu)\rangle$$

$$=\frac{\psi^*(k_\mu)\cdot\psi(k'_\mu)}{[\tilde{K}^*(k_\mu)-\omega]\cdot[\tilde{K}(k'_\mu)-\omega']}\cdot\langle\hat{c}^+(k_\mu)\hat{c}(k'_\mu)\rangle. \tag{9}$$

Using the Kubo–Martin–Schwinger condition (μ is the chemical potential)

$$\langle a(\vec{k}',t')a^+(\vec{k},t)\rangle=\langle a^+(\vec{k},t)a(\vec{k}',t-i\beta)\rangle\cdot\exp(-\beta\mu),$$

the thermal statistical averages for the $\hat{c}(k_\mu)$-operator should be presented in the following form:

$$\langle\hat{c}^+(k_\mu)\hat{c}(k'_\mu)\rangle=\delta^4(k_\mu-k'_\mu)\cdot n(\omega,T),$$

$$\langle\hat{c}(k_\mu)\hat{c}^+(k'_\mu)\rangle=\delta^4(k_\mu-k'_\mu)\cdot[1\pm n(\omega,T)]$$

for Bose $(+)$ and Fermi $(-)$ statistics, where $n(\omega,T)=\{\exp[(\omega-\mu)\beta]\pm1\}^{-1}$. Inserting CF (9) into (8) and taking into account that the $\delta^4(k_\mu-k'_\mu)$-function should be changed by the smooth sharp function $\Omega(r)\cdot\exp(-q^2/2)$, one can get the following expression for the D_b-function:

$$D_b(k_\mu,k'_\mu;T)=\lambda(k_\mu,k'_\mu;T)\exp(-q^2/2)$$
$$\times[n(\bar{\omega},T)\Omega(r)\exp(-q^2/2)+\tilde{\phi}^*(k'_\mu)\tilde{\phi}(k_\mu)+\tilde{\phi}^*(k_\mu)\tilde{\phi}(k'_\mu)], \qquad (10)$$

where

$$\lambda(k_\mu,k'_\mu;T)=\frac{\Omega(r)}{\tilde{W}(k_\mu)\cdot\tilde{W}(k'_\mu)}\cdot n(\bar{\omega},T), \quad \bar{\omega}=\frac{1}{2}(\omega+\omega').$$

The function $\Omega(r)\cdot n(\omega;T)\cdot\exp(-q^2/2)$ describes the space–time size of the QGP fireball. Choosing the z-axis along the two-heavy-ion collision axis, one can put

$$q^2=(r_0\cdot Q_0)^2+(r_z\cdot Q_z)^2+(r_t\cdot Q_t)^2,$$

$$Q_\mu=(k-k')_\mu, \quad Q_0=\epsilon_{\vec{k}}-\epsilon_{\vec{k}'}, \quad Q_z=k_z-k'_z, \quad Q_t=[(k_x-k'_x)^2+(k_y-k'_y)^2]^{1/2},$$

$$\Omega(r)\sim r_0\cdot r_z\cdot r_t^2,$$

where r_0, r_z and r_t are timelike, longitudinal and transverse ''size'' components of the QGP fireball. Formally, the function D_b (10) is the positive one ranging from 0 to 1. The quantitative information (longitudinal r_z and transverse r_t components of the QGP spherical volume, the temperature T of the environment) could be extracted by fitting the theoretical formula (10) to the measured TRDD function and estimating the errors of the fit parameters. Formula (10) indicates that a chaotic g/q source emanating from the thermalized g/q fireball exists. Hence, the measurement of the space–time evolution of the g/q source would provide information of the g/q emission process and the general reaction mechanism. In formula (10) for the D_b-function, the temperature of the environment enters through the two-particle CF $\Xi(k_\mu,k'_\mu;T)$. If T is unstable, the $R_{b/f}$-functions (5) will change due to a change of DF $\tilde{W}$ which, in fact, can be considered as an effective density of the g/q source. Formula (6) looks like the following expresion for the experimental R-ratio using a source parametrization:

$$R_T(r)=1+\lambda_T(r)\cdot\exp(-r_t^2\cdot Q_t^2/2-r_z^2\cdot Q_z^2/2),$$

where $r_t(r_z)$ is the transverse (longitudinal) radius parameter of the source with respect to the beam axis and λ_T stands for the effective intercept parameter (chaoticity parameter) which has a general dependence of the mean momentum of the observed particle pair. Here, the dependence on the source lifetime is omitted. Since $0<\lambda_T<1$, one can conclude that the effective function λ_T can be interpreted as a function of the core particles to all particles produced. The chaocity parameter λ_T is the temperature-dependent and the positive one defined by

$$\lambda_T(r)=\frac{|\Omega(r)n(\bar{\omega};T)|^2}{\tilde{W}(k_\mu)\cdot\tilde{W}(k'_\mu)}.$$

Comparing (8) and (10) one can identify

$$\Xi(k_\mu,k'_\mu)=\Omega(r)\cdot n(\bar{\omega};T)\cdot\exp(-q^2/2).$$

There is no satisfactory tool to derive the precise analytical form of the random source function $\tilde{\phi}(k_\mu)$ in (8), but one can put [see (9) and taking into account $\tilde{\phi}(k_\mu)\sim P\cdot[\tilde{K}(k_\mu)-\omega]^{-1}$] (Refs. 11 and 10)

$$\tilde{\phi}(k_\mu)=[\alpha\cdot\Xi(k_\mu)]^{1/2},$$

where α is of the order $O(P^2/n(\omega,T)\cdot|\psi(k_\mu)|^2)$. Thus,

$$D_b(q^2;T)=\frac{\tilde{\lambda}^{1/2}(\bar{\omega};T)}{(1+\alpha)(1+\alpha')}e^{-q^2/2}[\tilde{\lambda}^{1/2}(\bar{\omega};T)e^{-q^2/2}+2(\alpha\alpha')^{1/2}]. \tag{11}$$

It is easy to see that in the vicinity of $q^2\approx 0$ one can get the full correlation if $\alpha=\alpha'=0$ and $\tilde{\lambda}(\bar{\omega};T)=1$. Putting $\alpha=\alpha'$ in (11) we find the formal lower bound on the space–time dimensionless size of the fireball for the Bose system:

$$q_b^2\geqslant\ln\frac{\tilde{\lambda}(\bar{\omega};T)}{[\sqrt{(\alpha+1)^2+\alpha^2}-\alpha]^2}.$$

In the case of Fermi particles, the following restriction on q_f^2 is valid [see (7)]:

$$\ln\frac{\tilde{\lambda}(\bar{\omega};T)}{[\sqrt{2\alpha(\alpha+1)+3}-\alpha]^2}\leqslant q_f^2\leqslant\ln\frac{\tilde{\lambda}(\bar{\omega};T)}{[\sqrt{\alpha^2+2}-\alpha]^2}.$$

In fact, the function $D_b(k_\mu,k'_\mu;T)$ in (10) could not be observed because of some model uncertainties. In the standard consideration, the TRDD function has to contain a background contribution as well as other physical particles (resonances) which have not been included in the calculation of the D_b-function. In order to be close to the experimental data, one has to expand the D_b-function as projected on some well-defined function [in $S(\Re_4)$] of the relative momentum of two particles produced in heavy-ion collisions $D_b(k_\mu,k'_\mu;T)\to D_b(Q_\mu^2;T)$. Thus, it will be very instructive to use the polynomial expansion which is suitable to avoid any uncertainties as well as characterize the degree of deviation from the Gaussian distribution, for example. In $(-\infty,+\infty)$, a complete orthogonal set of functions can be obtained with the help of the Hermite polynomials in the Hilbert space of the square integrable functions with the measure $d\mu(z)=\exp(-z^2/2)dz$. The function D_b corresponds to this class if

$$\int_{-\infty}^{+\infty}dq\,\exp(-q^2/2)|D_b(q)|^n<\infty,\quad n=0,1,2,\ldots.$$

The expansion in terms of the Hermite polynomials $H_n(q)$,

$$D_b(q)=\lambda\sum_n c_n\cdot H_n(q)\cdot\exp(-q^2/2), \tag{12}$$

is well suited for the study of possible deviation from both the experimental shape and the exact theoretical form of the TRDD function D_b in (10). The coefficients c_n in (12) are defined via the integrals over the expanded functions D_b because of the orthogonality condition

$$\int_{-\infty}^{+\infty}H_n(x)H_m(x)\exp(-x^2/2)dx=\delta_{n,m}.$$

Thus, the observation of the two-particle correlation (both for Bose and Fermi symmetrization) enable us to extract the properties of the structure of q^2, i.e., the space–time size of QGP formation.

In order to be close to an experiment one has to replace $R_{b,f}$ functions (6) and (7) with respect to the cylindrical symmetry angles θ and ϕ which are nonobservable ones at fixed Q_t:

$$R_{b,f}(k_\mu,k'_\mu;T)\to\bar{R}_{b,f}(Q_t;T)=N^{-1}\int dq_t dQ_z d\theta d\phi\,\tilde{W}(k_\mu,k'_\mu;T),$$

where

$$N=\int dq_t\, dQ_z d\theta d\phi \tilde{W}(k_\mu)\, \tilde{W}(k'_\mu),$$

$$q_t=\frac{1}{\cos\theta+\sin\theta}\left\{k_x+k_y\mp\frac{1}{2}Q_t[\cos(\theta+\phi)+\sin(\theta+\phi)]\right\}.$$

Then, $\overline{R}_{b,f}(Q_t;T)=1+\overline{D}_{b,f}(Q_t;T)$ with

$$\overline{D}_b(Q_t;T)=\frac{\overline{N}^{-1}(T)}{(1+\alpha)(1+\alpha')}\exp[-(r_tQ_t)^2]\,F_b(Q_t;T),$$

$$\overline{D}_f(Q_t;T)=\frac{1}{(1+\alpha)(1+\alpha')}\{\overline{N}^{-1}(T)\exp[-(r_tQ_t)^2]\,F_b(Q_t;T)-2\},$$

$$F_b(Q_t;T)=\int dq_t\, dQ_z\, d\theta\, d\phi\, n^2(\overline{\omega};T)\, e^{-\beta_{0Z}}[1+2\sqrt{\alpha\alpha'\tilde{\lambda}^{-1}(\overline{\omega};T)}\, e^{q^2/2}],$$

$$\beta_{0Z}\equiv(r_0Q_0)^2+(r_zQ_z)^2,$$

$$\overline{N}(T)=\int dq_t\, dQ_z\, d\theta\, d\phi\, n(\omega;T)\, n(\omega';T).$$

To avoid the trivial result, one should restrict the α-parameter as

$$\alpha\geqslant\tilde{\lambda}^{-1/2}(\overline{\omega};T)e^{q^2/2}-\tfrac{1}{2}\tilde{\lambda}^{1/2}(\overline{\omega};T)\, e^{-q^2/2}.$$

In conclusion of this section, the experimental data are quite desired to make the analysis of the particle fluctuation via TRDD.

IV. CONCLUSION

(1) We investigated the finite temperature DF (of produced identical particles, gluons and quarks) which can be both useful and instructive to infer the shape of the gluon/quark source-emitter. In fact, we have presented the method of extracting the intercept and source parameters from the shape of the TRDD function.
(2) The relations between the CF $\Xi(k_\mu,k'_\mu)$ (9) and the full R-functions for Bose (6) and Fermi (7) particles at the stage of the freeze-out are obtained. We have shown the sensitivity of the correlation functions to the space–time geometry of the source-emitter (10). The TRDD function D_b describes the size and shape of the space–time domain where the secondary observed particles are generated.
(3) One can conclude that, formally, the deconfined phase size scale can be determined by the evolution behavior of the field operators and the critical temperature $T=T_c$ [see formula (10)].
(4) Since, the TRDD function D_b is the positive one and restricted by 1, we expect that the R-ratio at too small values of Q_μ starts from the fixed point $R(Q_\mu\to 0)=2-\epsilon$ $(\epsilon\to+0)$ and then falls down (with the Gaussian shape) up to unity over some momentum scale interval of an order of the inverse source size.

JOURNAL OF MATHEMATICAL PHYSICS VOLUME 42, NUMBER 10 OCTOBER 2001

Creation operators and Bethe vectors of the osp(1|2) Gaudin model

P. P. Kulish[a] and N. Manojlović[b]
Área Departmental de Matemática, F. C. T., Universidade do Algarve Campus de Gambelas, 8000 Faro, Portugal

(Received 31 January 2001; accepted for publication 12 July 2001)

A Gaudin model based on the orthosymplectic Lie superalgebra osp(1|2) is studied. The eigenvectors of the osp(1|2) invariant Gaudin Hamiltonians are constructed by algebraic Bethe ansatz. Corresponding creation operators are defined by a recurrence relation. Furthermore, explicit solution to this recurrence relation is found. The action of the creation operators on the lowest spin vector yields Bethe vectors of the model. The relation between the Bethe vectors and solutions to the Knizhnik–Zamolodchikov equation of the corresponding super-conformal field theory is established. © *2001 American Institute of Physics.*
[DOI: 10.1063/1.1398584]

I. INTRODUCTION

Classifying integrable systems solvable in the framework of the quantum inverse scattering method[1,2] by underlying dynamical symmetry algebras, one could say that the Gaudin models are the simplest ones being related to loop algebras and classical *r*-matrices. More sophisticated solvable models correspond to Yangians, quantum affine algebras, elliptic quantum groups, etc.

Gaudin models[3,4] are related to classical *r*-matrices, and the density of Gaudin Hamiltonians

$$H^{(a)}=\sum_{b\neq a} r_{ab}(z_a-z_b) \tag{1.1}$$

coincides with the *r*-matrix. Condition of their commutativity $[H^{(a)},H^{(b)}]=0$ is nothing else but the classical Yang–Baxter equation (YBE).

The Gaudin models (GM) associated to classical *r*-matrices of simple Lie algebras were studied in many papers (see Refs. 4–11 and references therein). The spectrum and eigenfunctions were found using different methods (coordinate and algebraic Bethe ansatz,[4,5] separated variables,[6] etc.). A relation to the Knizhnik–Zamolodchikov equation of conformal field theory was established.[8–10]

There are additional peculiarities of Gaudin models related to classical *r*-matrices based on Lie superalgebras due to Z_2-grading of representation spaces and operators. The study of the osp(1|2) invariant Gaudin model corresponding to the simplest nontrivial super-case of the osp(1|2) invariant *r*-matrix[12] started in Ref. 13. The spectrum of the osp(1|2) invariant Gaudin Hamiltonians $H^{(a)}$ was given, the antisymmetry property of their eigenstates was claimed, and a two site model was connected with some physically interesting one (a Dicke model).

The creation operators used in the sl(2) Gaudin model coincide with one of the *L*-matrix entry.[4,5] However, in the osp(1|2) case, as we will show, the creation operators are complicated polynomials of the two generators $X^+(\lambda)$ and $v^+(\mu)$ of the loop superalgebra. We introduce *B*-operators belonging to the Borel subalgebra of the loop superalgebra $\mathcal{L}(\mathrm{osp}(1|2))$ by a recurrence relation. Acting on the lowest spin vector (bare vacuum) the *B*-operators generate exact

[a]Electronic mail: kulish@pdmi.ras.ru On leave of absence from Steklov Mathematical Institute, Fontanka 27, 191011, St. Petersburg, Russia.
[b]Electronic mail: nmanoj@ualg.pt

eigenstates of the Gaudin Hamiltonians $H^{(a)}$, provided Bethe equations are imposed on parameters of the states. For this reason the *B*-operators are sometimes refereed to as the creation operators and the eigenstates as the Bethe vectors, or simply *B*-vectors. Furthermore, the recurrence relation is solved explicitly and the commutation relations between the *B*-operators and the generators of the loop superalgebra $\mathcal{L}(\mathrm{osp}(1|2))$ as well as the generators of the global superalgebra $\mathrm{osp}(1|2)\subset\mathcal{L}(\mathrm{osp}(1|2))$ are calculated. We prove that the constructed states are lowest spin vectors of the global finite dimensional superalgebra osp(1|2), as it is the case for many invariant quantum integrable models.[14] Moreover, a striking coincidence between the spectrum of the osp(1|2) invariant Gaudin Hamiltonians of spin s and the spectrum of the Hamiltonians of the sl(2) Gaudin model of the integer spin $2s$ is found.

A connection between the *B*-states, when the Bethe equations are not imposed on their parameters, of the Gaudin models for simple Lie algebras to the solutions to the Knizhnik–Zamolodchikov equation was established in Refs. 8 and 9. An explanation of this connection based on Wakimoto modules at critical level of the underlying affine algebra was given in Ref. 9. An explicit form of the Bethe vectors in the coordinate representation was given in both papers.[8,9] The coordinate Bethe ansatz for the *B*-states of the osp(1|2) Gaudin model is obtained in our article as well. Using commutation relations between the *B*-operators and the transfer matrix $t(\lambda)$, as well as the Hamiltonians $H^{(a)}$, we give an algebraic proof of the fact that explicitly constructed *B*-states yield a solution to the Knizhnik–Zamolodchikov equation corresponding to a super-conformal field theory. This connection permits us to calculate the norm of the eigenstates of the Gaudin Hamiltonians. An analogous connection is expected between the quantum osp(1|2) spin system related to the graded Yang–Baxter equation[12,15,16] and the quantum Knizhnik–Zamolodchikov equation following the lines of Ref. 17. We point out possible modifications of the Gaudin Hamiltonians and corresponding modifications of the Knizhnik–Zamolodchikov equation, similar to the case of the sl(2) Gaudin model which was interpreted in Refs. 18 and 19 as a quantization of the Schlesinger system.

The norm and correlation functions of the sl(2) invariant Gaudin model were evaluated in Ref. 6 using Gauss factorization of a group element and the Riemann–Hilbert problem. The study of this problem for the Gaudin model based on the osp(1|2) Lie superalgebra is in progress. However, we propose a formula for the scalar products of the Bethe states which is analogous to the sl(2) case.

The article is organized as follows. In Sec. II we recall the main data of the quantum osp(1|2) spin system: the osp(1|2) invariant solution to the graded Yang–Baxter equation (*R*-matrix), monodromy matrix $T(\lambda)$, the transfer matrix $t(\lambda)=1/2\,str\,T(\lambda)$, its eigenvalues and the Bethe equations. However, the eigenvectors of this quantum integrable spin system can be constructed only by a complicated recurrence procedure[20] which is not given here. Nevertheless, it is useful to recall the main data of the quantum integrable spin system because some characteristics of the corresponding Gaudin model can be obtained easily as a quasi-classical limit of these data. The osp(1|2) Gaudin model and its creation operators B_M are discussed thoroughly in Sec. III. Some of the most important properties of these operators are formulated and demonstrated: antisymmetry with respect to their arguments, commutation relations with the loop superalgebra generators, commutation relations with the generating function $t(\lambda)$ of the Gaudin Hamiltonians, a differential identity, valid in the case of the Gaudin realization of the loop superalgebra. Using these properties of the *B*-operators we prove in Sec. IV that, acting on the lowest spin vector Ω_-, these operators generate eigenvectors of the generating function of integrals of motion, provided the Bethe equations are imposed on the arguments of the *B*-operators. Possible modifications of the Gaudin Hamiltonians are pointed out also. An algebraic proof is given in Sec. V that constructed Bethe vectors are entering into solutions of the Knizhnik–Zamolodchikov equation of super-conformal field theory. A quasi-classical asymptotic with respect to a parameter of the Knizhnik–Zamolodchikov equation permits us to calculate the norm of the eigenstates of the Gaudin Hamiltonian. Further development on possible evaluation of correlation functions is discussed in the conclusion.

II. OSp(1|2)-INVARIANT *R*-MATRIX

Many properties of the Gaudin models can be obtained as a quasi-classical limit of the corresponding quantum spin systems related to solutions to the Yang–Baxter equation

$$R_{12}(\lambda-\mu)R_{13}(\lambda-\nu)R_{23}(\mu-\nu)=R_{23}(\mu-\nu)R_{13}(\lambda-\nu)R_{12}(\lambda-\mu). \tag{2.1}$$

Here the standard notation of the quantum inverse scattering method[1,2] is used to denote spaces $V_j, j=1,2,3$, on which corresponding R-matrices $R_{ij}, ij=12,13,23$, act nontrivially. In the quasi-classical limit $\eta\to 0$

$$R(\lambda;\eta)=I+\eta r(\lambda)+\mathcal{O}(\eta^2),$$

some relations simplify and therefore can be solved explicitly, providing more detailed results for the Gaudin model.

The graded Yang–Baxter equation[2,12] differs from the usual Yang–Baxter equation (2.1) by some sign factors due to the embedding of R-matrix into the space of matrices acting on the Z_2-graded tensor product $V_1\otimes V_2\otimes V_3$. At this point our aim is to reach a fundamental osp(1|2) invariant solution. The rank of the orthosymplectic Lie algebra osp(1|2) is one and its dimension is five. The three even generators are h, X^+, X^- and the two odd generators are v^+, v^-.[21] The (graded) commutation relations between the generators are

$$\begin{gathered}[h,X^\pm]=\pm 2X^\pm, \quad [h,v^\pm]=\pm v^\pm,\\ [X^+,X^-]=h, \quad [v^+,v^-]_+=-h,\\ [X^\mp,v^\pm]=v^\mp, \quad [v^\pm,v^\pm]_+=\pm 2X^\pm,\end{gathered} \tag{2.2}$$

together with $[X^\pm,v^\pm]=0$. Notice that the generators h and $v^\pm$ considered here in (2.2) differ by a factor of 2 from the ones used in Refs. 21 and 12. Thus the Casimir element is

$$c_2=h^2+2(X^+X^-+X^-X^+)+(v^+v^--v^-v^+)=h^2-h+4X^+X^-+2v^+v^-. \tag{2.3}$$

For further comparison with the sl(2) Gaudin model[4,5] and due to the chosen set of generators (2.2) we parametrize the finite dimensional irreducible representations $V^{(l)}$ of the osp(1|2) Lie superalgebra by an integer l, so that their dimensions $2l+1$ and the values of the Casimir element (2.3) $c_2=l(l+1)$ coincide with the same characteristics of the integer spin l irreducible representations of sl(2).

We proceed to write down the osp(1|2) invariant solution of the graded Yang–Baxter equation and the main data of the corresponding quantum spin system: the L-operator, the transfer matrix $t(\lambda)$, the eigenvalue of the generating function of the integrals of motion $t(\lambda)$ and the Bethe equations.

The fundamental irreducible representation V of osp(1|2) is three dimensional. We choose a gradation (parity) of the basis vectors $e_j;\ j=1,2,3$ to be (0,1,0).

The invariant R-matrix is a linear combination,[12]

$$R=\lambda\left(\lambda+\frac{3\eta}{2}\right)I+\eta\left(\lambda+\frac{3\eta}{2}\right)\mathcal{P}-\eta\lambda K, \tag{2.4}$$

of the three OSp(1|2) group invariant operators

$$[g\otimes g,X]=0, \quad g\in \mathrm{OSp}(1|2), \quad X\in \mathrm{End}(V\otimes V), \tag{2.5}$$

acting on $V\otimes V$: the identity I, the permutation $\mathcal{P}$ and a rank one projector K. In the equation (2.4) λ is the spectral parameter, and η is a quasi-classical parameter.

Using the projectors on the irreducible representation components in the Clebsch–Gordan decomposition $V\otimes V=V^{(2)}\otimes V^{(1)}\otimes V^{(0)}$,

$$P_2=\tfrac{1}{2}(I+\mathcal{P}),\quad P_1=\tfrac{1}{2}(I-\mathcal{P}-2K),\quad P_0=K, \tag{2.6}$$

one can represent the R-matrix (2.4) in the form

$$R(\lambda,\eta)=(\lambda+\eta)\left(\lambda+\frac{3\eta}{2}\right)\left(P_2+\frac{\lambda-\eta}{\lambda+\eta}P_1+\frac{\lambda-3\eta/2}{\lambda+3\eta/2}P_0\right). \tag{2.7}$$

Deforming these projectors to the quantum superalgebra $\mathrm{osp}_q(1|2)$ projectors[22,23] $P_i\to P_i(q)$ and substituting rational functions by trigonometric ones $[(\lambda\pm\eta)\to\sinh(\lambda\pm\eta)]$, one arrives at a trigonometric solution to the graded Yang–Baxter equation, in the braid group form, and corresponding anisotropic models.[23,24]

The L-operator of the quantum spin system on a one-dimensional lattice with N sites coincides with R-matrix acting in a tensor product $V_0\otimes V_a$ of auxiliary space V_0 and the space of states at site $a=1,2,\ldots,N$,

$$L_{0a}(\lambda-z_a)=R_{0a}(\lambda-z_a), \tag{2.8}$$

where z_a is a parameter of inhomogeneity (site dependence).[1,2] Corresponding monodromy matrix T is an ordered product of the L-operators

$$T(\lambda;\{z_a\}_1^N)=L_{0N}(\lambda-z_N)\cdots L_{01}(\lambda-z_1)=\prod_{\substack{a=1\\ \leftarrow}}^{N} L_{0a}(\lambda-z_a). \tag{2.9}$$

The commutation relations of the T-matrix entries follow from the FRT relation[1]

$$R_{12}(\lambda-\mu)T_1(\lambda)T_2(\mu)=T_2(\mu)T_1(\lambda)R_{12}(\lambda-\mu). \tag{2.10}$$

Multiplying (2.10) by R_{12}^{-1} and taking the super-trace over $V_1\otimes V_2$, one gets commutativity of the transfer matrix

$$t(\lambda)=\sum_j (-1)^{j+1}T_{jj}(\lambda;\{z_a\}_1^N)=T_{11}-T_{22}+T_{33} \tag{2.11}$$

for different values of the spectral parameter $t(\lambda)t(\mu)=t(\mu)t(\lambda)$.

The choice of the L-operators (2.8) corresponds to the following space of states of the osp(1|2)-spin system,

$$\mathcal{H}=\bigotimes_{a=1}^{N} V_a.$$

The eigenvalue of the transfer matrix $t(\lambda)$ in this space is[12]

$$\Lambda(\lambda;\{\mu_j\}_1^M)=\alpha_1^{(N)}(\lambda;\{z_a\}_1^N)\prod_{j=1}^{M} S_1(\lambda-\mu_j)-\alpha_2^{(N)}(\lambda;\{z_a\}_1^N)\prod_{j=1}^{M} S_1\left(\lambda-\mu_j+\frac{\eta}{2}\right)$$
$$S_{-1}(\lambda-\mu_j+\eta)+\alpha_3^{(N)}(\lambda;\{z_a\}_1^N)\prod_{j=1}^{M} S_{-1}\left(\lambda-\mu_j+\frac{3\eta}{2}\right), \tag{2.12}$$

where

$$\alpha_j^{(N)}(\lambda;\{z_a\}_1^N)=\prod_{b=1}^{N}\alpha_j(\lambda-z_b),\quad j=1,2,3,$$

$$\alpha_1(\lambda)=(\lambda+\eta)^N(\lambda+3\eta/2)^N,\quad \alpha_2(\lambda)=\lambda^N(\lambda+3\eta/2)^N, \tag{2.13}$$

$$\alpha_3(\lambda)=\lambda^N(\lambda+\eta/2)^N,\quad S_n(\mu)=\frac{\mu-n\eta/2}{\mu+n\eta/2}.$$

Although according to (2.12) the eigenvalue has formally two sets of poles at $\lambda=\mu_j-\eta/2$ and $\lambda=\mu_j-\eta$, the corresponding residues are zero due to the Bethe equations[12]

$$\prod_{a=1}^{N}\left(\frac{\mu_j-z_a+\eta/2}{\mu_j-z_a-\eta/2}\right)=\prod_{k=1}^{M}S_1(\mu_j-\mu_k)S_{-2}(\mu_j-\mu_k). \tag{2.14}$$

If we take different spins l_a at different sites of the lattice and the following space of states

$$\mathcal{H}=\bigotimes_{a=1}^{N}V_a^{(l_a)},$$

then the factors on the left hand side of (2.14) will be spin dependent too:

$$\frac{\mu_j-z_a+\eta l_a/2}{\mu_j-z_a-\eta l_a/2}.$$

The osp(1|2) invariant R-matrix (2.4) has more complicated structure than the sl(2) invariant R-matrix of C. N. Yang, $R=\lambda I+\eta\mathcal{P}$. As a consequence the commutation relations of the entries $T_{ij}(\lambda)$ of the T-matrix (2.9) are more complicated and construction of the eigenstates of the transfer matrix $t(\lambda)$ by the algebraic Bethe ansatz can be done only using a complicated recurrence relation expressed in terms of $T_{ij}(\mu_k)$ [Ref. 20; see also Ref. 15 for the case of osp(1|2)]. It will be shown later that, due to a simplification of this relation in the quasi-classical limit $\eta\to 0$, one can solve it and find the creation operators for the osp(1|2) Gaudin model explicitly. Furthermore, the commutation relations between the creation operators and the generators of the loop superalgebra as well as the generating function $t(\lambda)$ of the Gaudin Hamiltonians will be given explicitly.

III. OSp(1|2) GAUDIN MODEL AND CORRESPONDING CREATION OPERATORS

As in the case of any simple Lie algebra, the classical r-matrix of the orthosymplectic Lie algebra osp(1|2) can be expressed in a pure algebraic form using a (reduced) Casimir element in the tensor product osp(1|2)⊗osp(1|2):[12]

$$\hat{r}(\lambda)=\frac{1}{\lambda}c_2^{\otimes},$$
$$c_2^{\otimes}=h\otimes h+2(X^+\otimes X^-+X^-\otimes X^+)+(v^+\otimes v^--v^-\otimes v^+). \tag{3.1}$$

The matrix form of the Casimir element $\hat{r}$ in the fundamental representation π of osp(1|2) follows from (3.1) by substituting appropriate 3×3 matrices instead of the osp(1|2) generators (2.2)[21] and taking into account the Z_2-graded tensor product of even and odd matrices.[12] Alternatively, the same matrix form of $\hat{r}$ can be obtained as a term linear in η in the quasi-classical expansion of (2.4) and (2.7),

$$r(\lambda)=\frac{1}{\lambda}(\mathcal{P}-K),$$

where $\mathcal{P}$ is a graded permutation matrix and K is a rank one projector. Let us write explicitly the matrix form of $r_0=\mathcal{P}-K$ in the basis $e_1\otimes e_1, e_1\otimes e_2, e_1\otimes e_3, \ldots, e_3\otimes e_3$ of the tensor product of two copies of the fundamental representation $V\otimes V$:

$$r_0=\lambda r(\lambda)=\mathcal{P}-K=\begin{pmatrix} 1 & & & & & & & & \\ & 0 & & 1 & & & & & \\ & & -1 & & -1 & & 2 & & \\ & 1 & & 0 & & & & & \\ & & 1 & & 0 & & -1 & & \\ & & & & & 0 & & 1 & \\ & & 2 & & 1 & & -1 & & \\ & & & & & 1 & & 0 & \\ & & & & & & & & 1 \end{pmatrix} \tag{3.2}$$

with all the other entries of this 9×9 matrix being identically equal to zero.

A quasi-classical limit $\eta\to 0$ of the FRT-relations (2.10) results in a matrix form of the loop superalgebra relation ($T(\lambda;\eta)=I+\eta L(\lambda)+\mathcal{O}(\eta^2)$):

$$[\underset{1}{L}(\lambda),\underset{2}{L}(\mu)]=-[r_{12}(\lambda-\mu),\underset{1}{L}(\lambda)+\underset{2}{L}(\mu)]. \tag{3.3}$$

Both sides of this relation have the usual commutators of even 9×9 matrices $L_1(\lambda)=L(\lambda)\otimes I_3$, $L_2(\mu)=I_3\otimes L(\mu)$ and $r_{12}(\lambda-\mu)$, where I_3 is 3×3 unit matrix and $L(\lambda)$ has loop superalgebra valued entries:

$$L(\lambda)=\begin{pmatrix} h(\lambda) & -v^-(\lambda) & 2X^-(\lambda) \\ v^+(\lambda) & 0 & v^-(\lambda) \\ 2X^+(\lambda) & v^+(\lambda) & -h(\lambda) \end{pmatrix}. \tag{3.4}$$

The relation (3.3) is a compact matrix form of the following commutation relations between the generators $h(\lambda), v^{\pm}(\mu), X^{\pm}(\nu)$ of the loop superalgebra under consideration,

$$[h(\lambda),X^{\pm}(\mu)]=\mp 2\frac{X^{\pm}(\lambda)-X^{\pm}(\mu)}{\lambda-\mu},\quad [h(\lambda),v^{\pm}(\mu)]=\mp\frac{v^{\pm}(\lambda)-v^{\pm}(\mu)}{\lambda-\mu},$$

$$[X^+(\lambda),X^-(\mu)]=-\frac{h(\lambda)-h(\mu)}{\lambda-\mu},\quad [X^{\pm}(\lambda),v^{\mp}(\mu)]=-\frac{v^{\pm}(\lambda)-v^{\pm}(\mu)}{\lambda-\mu}, \tag{3.5}$$

$$[v^+(\lambda),v^-(\mu)]_+=\frac{h(\lambda)-h(\mu)}{\lambda-\mu},\quad [v^{\pm}(\lambda),v^{\pm}(\mu)]_+=\mp 2\frac{X^{\pm}(\lambda)-X^{\pm}(\mu)}{\lambda-\mu},$$

together with $[X^{\pm}(\lambda),v^{\pm}(\mu)]=0$.

Actually these commutation relations (3.5) define the positive part $\mathcal{L}_+(\mathrm{osp}(1|2))$ of the loop superalgebra. The usual generators Y_n of a loop algebra parametrized by a non-negative integer are obtained from the expansion of $Y(\lambda)$,

$$Y(\lambda)=\sum_{n\geqslant 0}\frac{Y_n}{\lambda^{n+1}}.$$

In particular, taking all $Y_n=0$ for $n>0$, one gets an L-operator $L(\lambda)=L_0/\lambda$, where L_0 is an osp(1|2)-valued matrix. This L_0 similar to r_0 satisfies a cubic characteristic equation with the osp(1|2) Casimir element (2.3) as coefficient:

$$L_0^3+2L_0^2-(c_2-1)L_0-c_2I=0. \tag{3.6}$$

A Gaudin realization of the loop algebra (3.5) can be defined through the generators $Y=(h,v^{\pm},X^{\pm})$,

$$Y(\lambda)=\sum_{a=1}^{N}\frac{Y_a}{\lambda-z_a},\quad Y_a\in\mathrm{End}(V_a), \tag{3.7}$$

where Y_a are osp(1|2) generators in an irreducible representation $V_a^{(l_a)}$ of the lowest spin $-l_a$ associated with each site a.[4,5] Then the L-operator (3.4) has the form

$$L(\lambda;\{z_a\}_1^N)=\sum_{a=1}^{N}\frac{L_a}{\lambda-z_a}. \tag{3.8}$$

Here $\{z_a\}_1^N$ are parameters of the model [cf. (2.8) and (2.9)]. It follows from the relation (3.8) that the first term in the asymptotic expansion near $\lambda=\infty$ defines generators of the global $\mathrm{osp}(1|2)\subset\mathcal{L}_+(\mathrm{osp}(1|2))$,

$$L_{gl}=\lim_{\lambda\to\infty}\lambda L(\lambda)=\sum_{a=1}^{N}L_a, \tag{3.9}$$

where

$$L_{gl}=\begin{pmatrix} h_{gl} & -v_{gl}^- & 2X_{gl}^- \\ v_{gl}^+ & 0 & v_{gl}^- \\ 2X_{gl}^+ & v_{gl}^+ & -h_{gl}\end{pmatrix}. \tag{3.10}$$

Moreover, from the equation (3.3) we get

$$\left[\underset{1}{L_{gl}},\underset{2}{L(\mu)}\right]=-\left[\underset{2}{r_0},\underset{2}{L(\mu)}\right], \tag{3.11}$$

here $\underset{1}{L_{gl}}=L_{gl}\otimes I_3$, e.g., $[h_{gl},v^+(\mu)]=v^+(\mu)$.

Let us consider the loop superalgebra $\mathcal{L}_+(\mathrm{osp}(1|2))$ as the dynamical symmetry algebra, i.e., as the algebra of observables. In order to define a dynamical system besides the algebra of observables we need to specify a Hamiltonian. It is a well-known fact that due to the r-matrix relation (3.3), the so-called Sklyanin linear brackets, the elements

$$\begin{aligned} t(\lambda)&=\tfrac{1}{2}\mathrm{str}L^2(\lambda)=h^2(\lambda)+2[X^+(\lambda),X^-(\lambda)]_+ +[v^+(\lambda),v^-(\lambda)]_- \\ &=h^2(\lambda)+h'(\lambda)+4X^+(\lambda)X^-(\lambda)+2v^+(\lambda)v^-(\lambda)\end{aligned} \tag{3.12}$$

commute for different values of the spectral parameter $t(\lambda)t(\mu)=t(\mu)t(\lambda)$. Thus, $t(\lambda)$ can be considered as a generating function of integrals of motion.

It is straightforward to calculate the commutation relations between the operator $t(\lambda)$ and the generators of the loop algebra $X^+(\mu)$ and $v^+(\mu)$:

$$[t(\lambda),X^+(\mu)]=4\frac{X^+(\mu)h(\lambda)-X^+(\lambda)h(\mu)}{\lambda-\mu}-\frac{v^+(\lambda)v^+(\mu)-v^+(\mu)v^+(\lambda)}{\lambda-\mu}, \tag{3.13}$$

$$[t(\lambda),v^+(\mu)]=2\frac{v^+(\mu)h(\lambda)-v^+(\lambda)h(\mu)}{\lambda-\mu}-4\frac{X^+(\mu)v^-(\lambda)-X^+(\lambda)v^-(\mu)}{\lambda-\mu}. \tag{3.14}$$

These relations will be important for the proof of Lemma 3.6 as well as the proof of the main theorem.

A direct consequence of the equation (3.11) is an invariance of the generating function of integrals of motion $t(\lambda)$ under the action of the global osp(1|2):

$$[t(\lambda),L_{gl}]=0. \tag{3.15}$$

Preserving some generality we can consider the representation space $\mathcal{H}_{ph}$ of the dynamical algebra to be a lowest spin $\rho(\lambda)$ representation of the loop superalgebra with the lowest spin vector Ω_-,

$$h(\lambda)\Omega_-=\rho(\lambda)\Omega_-, \quad v^-(\lambda)\Omega_-=0. \tag{3.16}$$

In particular, a representation of the Gaudin realization (3.8) can be obtained by considering irreducible representations $V_a^{(l_a)}$ of the Lie superalgebra osp(1|2) defined by a spin $-l_a$ and a lowest spin vector ω_a such that $v_a^-\omega_a=0$ and $h_a\omega_a=-l_a\omega_a$. Thus,

$$\Omega_-=\bigotimes_{a=1}^{N}\omega_a \quad \text{and} \quad \rho(\lambda)=\sum_{a=1}^{N}\frac{-l_a}{\lambda-z_a}. \tag{3.17}$$

It is a well-known fact in the theory of Gaudin models[4,5] that the Gaudin Hamiltonians

$$H^{(a)}=\sum_{b\neq a}\frac{c_2^{\otimes}(a,b)}{z_a-z_b}=\sum_{b\neq a}\frac{1}{z_a-z_b}(h_ah_b+2(X_a^+X_b^-+X_a^-X_b^+)+(v_a^+v_b^--v_a^-v_b^+)) \tag{3.18}$$

can be obtained as the residue of the operator $t(\lambda)$ at the point $\lambda=z_a$ using the expansion

$$t(\lambda)=\sum_{a=1}^{N}\left(\frac{l_a(l_a+1)}{(\lambda-z_a)^2}+2\frac{H^{(a)}}{\lambda-z_a}\right). \tag{3.19}$$

To construct the set of eigenstates of the generating function of integrals of motion $t(\lambda)$ we have to define appropriate creation operators. The creation operators used in the sl(2) Gaudin model coincide with one of the L-matrix entry.[4,5] However, in the osp(1|2) case the creation operators are complicated functions of the two generators of the loop superalgebra $X^+(\lambda)$ and $v^+(\mu)$.

Definition 3.1: Let $B_M(\mu_1,\ldots,\mu_M)$ *belong to the Borel subalgebra* $\mathcal{B}$ *of the* osp(1|2) *loop algebra* $\mathcal{L}_+(\text{osp}(1|2))$ *such that*

$$B_M(\mu_1,\ldots,\mu_M)=v^+(\mu_1)B_{M-1}(\mu_2,\ldots,\mu_M)+2X^+(\mu_1)\sum_{j=2}^{M}\frac{(-1)^j}{\mu_1-\mu_j}B_{M-2}^{(j)}(\mu_2,\ldots,\mu_M), \tag{3.20}$$

with $B_0=1$, $B_1(\mu)=v^+(\mu)$ *and* $B_M=0$ *for* $M<0$. *The notation adopted here is that upper index of* $B_{M-2}^{(j)}(\mu_2,\ldots,\mu_M)$ *means that the argument* μ_j *is omitted.*

Remark 3.1: It may be useful to write down the explicit expressions for the first few creation operators

$$B_0=1,\quad B_1(\mu)=v^+(\mu),\ B_2(\mu_1,\mu_2)=v^+(\mu_1)v^+(\mu_2)+2\frac{X^+(\mu_1)}{\mu_1-\mu_2},$$

$$B_3(\mu_1,\mu_2,\mu_3)=v^+(\mu_1)B_2(\mu_2,\mu_3)+2X^+(\mu_1)\left(\frac{v^+(\mu_3)}{\mu_1-\mu_2}-\frac{v^+(\mu_2)}{\mu_1-\mu_3}\right), \tag{3.21}$$

$$B_4(\mu_1,\mu_2,\mu_3,\mu_4)=v^+(\mu_1)B_3(\mu_2,\mu_3,\mu_4)+2X^+(\mu_1)\times\left(\frac{B_2(\mu_3,\mu_4)}{\mu_1-\mu_2}-\frac{B_2(\mu_2,\mu_4)}{\mu_1-\mu_3}+\frac{B_2(\mu_2,\mu_3)}{\mu_1-\mu_4}\right).$$

The creation operators $B_M(\mu_1,\ldots,\mu_M)$ together with $h(\nu)$ generate the Borel subalgebra $\mathcal{B}\subset\mathcal{L}_+$. As we will show later, the B-operators are such that the Bethe vectors are generated by their action on the lowest spin vector Ω_- (3.16). To prove this result we will need some important properties of the B-operators which are summarized in the following seven lemmas.

Lemma 3.1: The creation operators $B_M(\mu_1,\ldots,\mu_M)$ are antisymmetric functions of their arguments

$$B_M(\mu_1,\ldots,\mu_k,\mu_{k+1},\ldots,\mu_M)=-B_M(\mu_1,\ldots,\mu_{k+1},\mu_k,\ldots,\mu_M), \tag{3.22}$$

here $1\leqslant k<M$ and $M\geqslant 2$.

Sometimes an alternative formulation of the recurrence relation (3.20) can be useful.

Lemma 3.2: Alternatively, the recurrence relation (3.20) can be written in the following form,

$$B_M(\mu_1,\ldots,\mu_M)=B_{M-1}(\mu_1,\ldots,\mu_{M-1})v^+(\mu_M)+2\sum_{j=1}^{M-1}(-1)^{M-j-1}\times\frac{X^+(\mu_j)}{\mu_j-\mu_M}B^{(j)}_{M-2}(\mu_1,\ldots,\mu_{M-1}), \tag{3.23}$$

with $B_0=1$, $B_1(\mu)=v^+(\mu)$ and $B_N=0$, for $N<0$.

In the subsequent lemmas we will calculate the commutation relations between the generators of the loop superalgebra $\mathcal{L}(\mathrm{osp}(1|2))$ and the B-operators. In order to simplify the formulas we will omit the arguments and denote the creation operator $B_M(\mu_1,\ldots,\mu_M)$ by B_M. We suppose that it will not be difficult to restore the appropriate set of arguments.

Lemma 3.3: The commutation relations between the generator $v^+(\lambda)$ of the loop superalgebra and the creation operator B_M are given by

$$v^+(\lambda)B_M=(-1)^M B_M v^+(\lambda)+2\sum_{j=1}^{M}(-1)^j\frac{X^+(\lambda)-X^+(\mu_j)}{\lambda-\mu_j}B^{(j)}_{M-1}. \tag{3.24}$$

Here as in the previous lemma the upper index of $B^{(j)}_{M-1}$ means that the argument μ_j is omitted.

Lemma 3.4: The generator $h(\nu)$ has the following commutation relation with the B_M elements

$$h(\lambda)B_M=B_M\left(h(\lambda)+\sum_{i=1}^{M}\frac{1}{\lambda-\mu_i}\right)+\sum_{i=1}^{M}\frac{(-1)^i}{\lambda-\mu_i}\left(v^+(\lambda)B^{(i)}_{M-1}+2X^+(\lambda)\sum_{\substack{j=1\\ j\neq 1}}^{M}\frac{(-1)^{j+\Theta(i-j)}}{\mu_i-\mu_j}B^{(i,j)}_{M-2}\right). \tag{3.25}$$

Here $\Theta(j)$ is the Heaviside function,

$$\Theta(j)=\begin{cases}1 & if\ \ j>0,\\ 0 & if\ \ j\leqslant 0,\end{cases}$$

and the meaning of the upper indices of $B^{(i,j)}_{M-2}$ *is that the parameters* μ_i,μ_j *are omitted.*

Lemma 3.5: The generator $v^-(\lambda)$ *of the loop superalgebra has the following commutation relation with the B-operators:*

$$v^-(\lambda)B_M=(-1)^M B_M v^-(\lambda)+\sum_{j=1}^{M}(-1)^{j-1}B^{(j)}_{M-1}\left(\frac{h(\lambda)-h(\mu_j)}{\lambda-\mu_j}+\sum_{\substack{k=1\\k\neq j}}^{M}\frac{1}{(\lambda-\mu_k)(\mu_k-\mu_j)}\right)$$
$$+v^+(\lambda)\sum_{\substack{i,j=1\\i<j}}^{M}(-1)^{i-j-1}\frac{B^{(i,j)}_{M-2}}{\mu_i-\mu_j}\left(\frac{1}{\lambda-\mu_i}+\frac{1}{\lambda-\mu_j}\right). \tag{3.26}$$

Already at this point we can make some useful observations.

Remark 3.2: The commutation relations between the generators of the global osp(1|2) (3.10) *and the* B_M *elements follow from Lemmas 3.3–3.5. To see this we multiply (3.24)–(3.26) by* λ *and then take the limit* $\lambda\to\infty$. *In this way we obtain*

$$v^+_{gl}B_M=(-1)^M B_M v^+_{gl}-2\sum_{j=1}^{M}(-1)^j X^+(\mu_j)B^{(j)}_{M-1}, \tag{3.27}$$

$$h_{gl}B_M=B_M(h_{gl}+M), \tag{3.28}$$

$$v^-_{gl}B_M=(-1)^M B_M v^-_{gl}+\sum_{j=1}^{M}(-1)^j B^{(j)}_{M-1}\left(h(\mu_j)+\sum_{k\neq j}^{M}\frac{1}{\mu_j-\mu_k}\right). \tag{3.29}$$

The subsequent lemma is one of the most important results. The proof of the main theorem is based on the following.

Lemma 3.6: The generating function of integrals of motion $t(\lambda)$ *(3.12) has the following commutation relation with the creation operator* $B_M(\mu_1,\ldots,\mu_M)$*:*

$$t(\lambda)B_M=B_M t(\lambda)+2B_M\left(h(\lambda)\sum_{i=1}^{M}\frac{1}{\lambda-\mu_i}+\sum_{\substack{i,j=1\\i<j}}^{M}\frac{1}{(\lambda-\mu_i)(\lambda-\mu_j)}\right)$$
$$+2\sum_{i=1}^{M}\frac{(-1)^i}{\lambda-\mu_i}\left(v^+(\lambda)B^{(i)}_{M-1}+2X^+(\lambda)\sum_{\substack{j=1\\j\neq i}}^{M}\frac{(-1)^{j+\Theta(i-j)}}{\mu_i-\mu_j}B^{(i,j)}_{M-2}\right)\hat{\beta}_M(\mu_i)$$
$$+4\sum_{i=1}^{M}\frac{(-1)^i}{\lambda-\mu_i}B^{(i)}_{M-1}(X^+(\lambda)v^-(\mu_i)-X^+(\mu_i)v^-(\lambda)). \tag{3.30}$$

Here we use the following notation for the operator:

$$\hat{\beta}_M(\mu_i)=h(\mu_i)+\sum_{\substack{j=1\\j\neq i}}^{M}\frac{1}{\mu_i-\mu_j}.$$

In the Gaudin realization (3.7) the creation operators $B_M(\mu_1,\ldots,\mu_M)$ have some specific analytical properties.

Lemma 3.7: The B-operators in the Gaudin realization (3.7) satisfy an important differential identity,

$$\frac{\partial}{\partial z_a}B_M=\sum_{j=1}^{M}\frac{\partial}{\partial\mu_j}\left(\frac{(-1)^j}{\mu_j-z_a}\left(v_a^+B_{M-1}^{(j)}+2X_a^+\sum_{k\neq j}^{M}\frac{(-1)^{k+\Theta(j-k)}}{\mu_j-\mu_k}B_{M-2}^{(j,k)}\right)\right). \tag{3.31}$$

This identity will be a fundamental step in establishing a connection between the Bethe vectors and the Knizhnik–Zamolodchikov equation.

The proofs of the lemmas are based on the induction method. As illustrations, we prove explicitly lemmas 3.1 and 3.3.

Proof of Lemma 3.1: We prove Lemma 3.1 by induction. Consider $M=2$:

$$B_2(\mu_1,\mu_2)=v^+(\mu_1)v^+(\mu_2)+2\frac{X^+(\mu_1)}{\mu_1-\mu_2}.$$

Using the commutation relations (3.5) it is straightforward to check that $B_2(\mu_1,\mu_2)$ is antisymmetric:

$$B_2(\mu_1,\mu_2)=-B_2(\mu_2,\mu_1).$$

Assume $B_N(\mu_1,\ldots,\mu_N)$ is antisymmetric for $M>N\geqslant 2$. We have to prove that $B_M(\mu_1,\ldots,\mu_M)$ is antisymmetric also.

Consider $j\geqslant 2$. The antisymmetry of $B_M(\mu_1,\ldots,\mu_M)$ with respect to μ_j and μ_{j+1} follows directly from the recurrence relation (3.20) and our assumption. Namely, the terms $B_{M-2}^{(j)}\times(\mu_2,\ldots,\mu_M)/(\mu_1-\mu_j)$ and $B_{M-2}^{(j+1)}(\mu_2,\ldots,\mu_M)/(\mu_1-\mu_{j+1})$ enter with the opposite sign.

Therefore we only have to show the antisymmetry of $B_M(\mu_1,\ldots,\mu_M)$ with respect to the interchange of μ_1 and μ_2. To see this we have to iterate the recurrence relation (3.20) twice and combine the appropriate terms

$$\begin{aligned}B_M(\mu_1,\ldots,\mu_M)=&\left(v^+(\mu_1)v^+(\mu_2)+2\frac{X^+(\mu_1)}{\mu_1-\mu_2}\right)B_{M-2}(\mu_3,\ldots,\mu_M)\\&+2v^+(\mu_1)X^+(\mu_2)\sum_{j=3}^{M}\frac{(-1)^{j+1}}{\mu_2-\mu_j}B_{M-3}^{(j)}(\mu_3,\ldots,\mu_M)\\&+2v^+(\mu_2)X^+(\mu_1)\sum_{j=3}^{M}\frac{(-1)^{j}}{\mu_1-\mu_j}B_{M-3}^{(j)}(\mu_3,\ldots,\mu_M)\\&+4X^+(\mu_1)X^+(\mu_2)\sum_{j=3}^{M}\frac{(-1)^{j}}{\mu_1-\mu_j}\sum_{k=3}^{M}\frac{(-1)^{k+\Theta(j-k)}}{\mu_2-\mu_k}B_{M-4}^{(j,k)}(\mu_3,\ldots,\mu_M),\end{aligned} \tag{3.32}$$

where $B_{M-4}^{(j,k)}(\mu_3,\ldots,\mu_M)$ means that the arguments μ_j and μ_k are omitted. Since $v^+(\mu)$ commutes with $X^+(\nu)$, the antisymmetry of the right hand side of (3.32) with respect to μ_1 and μ_2 follows. Hence we have demonstrated the lemma. □

We proceed now to prove Lemma 3.3.

Proof of Lemma 3.3: In particular, when $M=1$ the expression (3.24) is just the anticommutator between $v^+(\lambda)$ and $v^+(\mu)$. Using the recurrence relations (3.20) it is straightforward to check that the formula (3.24) holds for $M=2$:

$$\begin{aligned}v^+(\lambda)B_2(\mu_1,\mu_2)=&B_2(\mu_1,\mu_2)v^+(\lambda)-2\frac{X^+(\lambda)-X^+(\mu_1)}{\lambda-\mu_1}v^+(\mu_2)\\&+2\frac{X^+(\lambda)-X^+(\mu_2)}{\lambda-\mu_2}v^+(\mu_1).\end{aligned} \tag{3.33}$$

Therefore we can proceed to demonstrate Lemma 3.3 by induction. Assume that the relation (3.24) holds for B_N, $M \geqslant N \geqslant 2$. Then we have to show the formula (3.24) is valid for $M+1$. We use the recurrence relations (3.20) to write

$$\begin{aligned} v^+(\lambda)B_{M+1} &= v^+(\lambda)\left(v^+(\mu_1)B_M + 2X^+(\mu_1)\sum_{j=2}^{M+1}\frac{(-1)^j}{\mu_1-\mu_j}B_{M-1}^{(j)}\right) \\ &= -v^+(\mu_1)v^+(\lambda)B_M - 2\frac{X^+(\lambda)-X^+(\mu_1)}{\lambda-\mu_1}B_M \\ &\quad + 2X^+(\mu_1)\sum_{j=2}^{M+1}\frac{(-1)^j}{\mu_1-\mu_j}v^+(\lambda)B_{M-1}^{(j)}. \end{aligned} \tag{3.34}$$

Now we can substitute the expressions for $v^+(\lambda)B_M$ and $v^+(\lambda)B_{M-1}^{(j)}$. After rearranging the terms in an appropriate way we have

$$v^+(\lambda)B_{M+1} = (-1)^{M+1}B_{M+1}v^+(\lambda) + 2\sum_{j=1}^{M+1}(-1)^j\frac{X^+(\lambda)-X^+(\mu_j)}{\lambda-\mu_j}B_M^{(j)}. \tag{3.35}$$

This completes the proof of the lemma. □

Subsequently we demonstrate Lemma 3.2.

Proof of Lemma 3.2: The first step in this proof is to use the antisymmetry property Lemma 3.1. The second step is to use the defining recurrence relations. Then we use Lemma 3.3 and finally after some cancellations we get the right hand side of the equation (3.23):

$$\begin{aligned} B_M(\mu_1,\ldots,\mu_M) &\overset{(3.22)}{=} (-1)^{M-1}B_M(\mu_M,\mu_1,\ldots,\mu_{M-1}) \\ &\overset{(3.20)}{=} (-1)^{M-1}v^+(\mu_M)B_{M-1}(\mu_1,\ldots,\mu_{M-1}) \\ &\quad + (-1)^{M-1}2X^+(\mu_M)\sum_{j=1}^{M-1}\frac{(-1)^{j-1}}{\mu_M-\mu_j}B_{M-2}^{(j)}(\mu_1,\ldots,\mu_{M-1}) \\ &\overset{(3.24)}{=} B_{M-1}(\mu_1,\ldots,\mu_{M-1})v^+(\mu_M) \\ &\quad + (-1)^{M-1}2\sum_{j=1}^{M-1}(-1)^j\frac{X^+(\mu_M)-X^+(\mu_j)}{\mu_M-\mu_j} \\ &\quad \times B_{M-2}^{(j)}(\mu_1,\ldots,\mu_{M-1}) + (-1)^{M-1}2X^+(\mu_M)\sum_{j=1}^{M-1}\frac{(-1)^{j-1}}{\mu_M-\mu_j} \\ &\quad \times B_{M-2}^{(j)}(\mu_1,\ldots,\mu_{M-1}) \\ &= B_{M-1}(\mu_1,\ldots,\mu_{M-1})v^+(\mu_M) + 2\sum_{j=1}^{M-1}(-1)^{M-j-1}\frac{X^+(\mu_j)}{\mu_j-\mu_M}B_{M-2}^{(j)} \\ &\quad \times(\mu_1,\ldots,\mu_{M-1}). \end{aligned}$$

□

The proofs of the other lemmas are analogous to the proofs of Lemmas 3.1 and 3.3. Since these proofs do not contain illuminating insights and are considerably longer than the two we have seen we will omit them.

The recurrence relation (3.20) can be solved explicitly. To be able to express the solution of the recurrence relation in a compact form it is useful to introduce a contraction operator d.

Definition 3.2: Let d be a contraction operator whose action on an ordered product $\prod_{j=1}^{M}{}_{\rightarrow} v^+(\mu_j)$, $M \geqslant 2$, is given by

$$d(v^+(\mu_1)v^+(\mu_2)\ldots v^+(\mu_M)) = 2\sum_{j=1}^{M-1} X^+(\mu_j) \sum_{k=j+1}^{M} \frac{(-1)^{\sigma(jk)}}{\mu_j-\mu_k} \prod_{m\neq j,k}^{M}{}_{\rightarrow} v^+(\mu_m), \quad (3.36)$$

where $\sigma(jk)$ is the parity of the permutation

$$\sigma:(1,2,...,j,j+1,...,k,\ldots,M)\rightarrow(1,2,...,j,k,j+1,...,M).$$

The d operator can be applied on an ordered product $\prod_{j=1}^{M}{}_{\rightarrow} v^+(\mu_j)$ consecutively several times. As an illustration, we explicitly apply the contraction operator d two times in the case when $M=4$:

$$\begin{aligned}
&d^2(v^+(\mu_1)v^+(\mu_2)v^+(\mu_3)v^+(\mu_4))\\
&\quad = d(d(v^+(\mu_1)v^+(\mu_2)v^+(\mu_3)v^+(\mu_4)))\\
&\quad = 2X^+(\mu_1)\left(\frac{d(v^+(\mu_3)v^+(\mu_4))}{\mu_1-\mu_2} - \frac{d(v^+(\mu_2)v^+(\mu_4))}{\mu_1-\mu_3} + \frac{d(v^+(\mu_2)v^+(\mu_3))}{\mu_1-\mu_4}\right)\\
&\qquad + 2X^+(\mu_2)\left(\frac{d(v^+(\mu_1)v^+(\mu_4))}{\mu_2-\mu_3} - \frac{d(v^+(\mu_1)v^+(\mu_2))}{\mu_2-\mu_4}\right) + 2X^+(\mu_3)\frac{d(v^+(\mu_1)v^+(\mu_2))}{\mu_3-\mu_4}\\
&\quad = 8X^+(\mu_1)\left(\frac{X^+(\mu_3)}{(\mu_1-\mu_2)(\mu_3-\mu_4)} - \frac{X^+(\mu_2)}{(\mu_1-\mu_3)(\mu_2-\mu_4)} + \frac{X^+(\mu_2)}{(\mu_1-\mu_3)(\mu_2-\mu_4)}\right).
\end{aligned}$$

It follows that the contraction operator d can be applied on an ordered product $\prod_{j=1}^{M}{}_{\rightarrow} v^+(\mu_j)$ up to $[M/2]$ times consecutively. The symbol $[M/2]$ denotes the integer part of $M/2$.

Theorem 3.1: Explicit solution to the recurrence relation (3.20) is given by

$$B_M(\mu_1,\ldots,\mu_M) = \prod_{j=1}^{M}{}_{\rightarrow} v^+(\mu_j) + \sum_{m=1}^{[M/2]} \frac{1}{m!} d^m \prod_{j=1}^{M}{}_{\rightarrow} v^+(\mu_j). \quad (3.37)$$

Here d is the contraction operator defined above (3.36).

The properties of the creation operators B_M studied in this section will be fundamental tools in determining some of the most important characteristics of the osp(1|2) Gaudin model. Our primary interest is to obtain the spectrum and the eigenvectors of the generating function of integrals of motion $t(\lambda)$ (3.12).

IV. SPECTRUM OF THE OSp(1|2) GAUDIN MODEL AND ITS MODIFICATIONS

With the help of the creation operators B_M it is possible to obtain the eigenvectors as well as the corresponding eigenvalues of the Gaudin Hamiltonians. This result is a direct consequence of the following theorem.

Theorem 4.1: *The lowest spin vector Ω_-* (3.16) *is an eigenvector of the generating function of integrals of motion* t(λ) *(3.12) with the corresponding eigenvalue $\Lambda_0(\lambda)$:*

$$t(\lambda)\Omega_- = \Lambda_0(\lambda)\Omega_-, \quad \Lambda_0(\lambda) = \rho^2(\lambda) + \rho'(\lambda). \tag{4.1}$$

Furthermore, the action of the B-operators on the lowest spin vector Ω_- yields the eigenvectors

$$\Psi(\mu_1,\ldots,\mu_M) = B_M(\mu_1,\ldots,\mu_M)\Omega_- \tag{4.2}$$

of the $t(\lambda)$ operator

$$t(\lambda)\Psi(\mu_1,\ldots,\mu_M) = \Lambda(\lambda;\{\mu_j\}_{j=1}^M)\Psi(\mu_1,\ldots,\mu_M), \tag{4.3}$$

with the eigenvalues

$$\Lambda(\lambda;\{\mu_j\}_{j=1}^M) = \Lambda_0(\lambda) + 2\rho(\lambda)\sum_{k=1}^M \frac{1}{\lambda-\mu_k} + 2\sum_{k<l}\frac{1}{(\lambda-\mu_k)(\lambda-\mu_l)}, \tag{4.4}$$

provided that the Bethe equations are imposed on the parameters $\{\mu_j\}_{j=1}^M$:

$$\beta_M(\mu_j) = \rho(\mu_j) + \sum_{k\neq j}^M \frac{1}{\mu_j-\mu_k} = 0. \tag{4.5}$$

Proof: The equation (4.1) can be checked by a direct substitution of the definitions of the operator $t(\lambda)$ and the lowest spin vector Ω_-, the equations (3.12) and (3.16), respectively.

To show the second part of the theorem, we use the equation (4.2) to express the Bethe vectors $\Psi(\mu_1,\ldots,\mu_M)$

$$t(\lambda)\Psi(\mu_1,\ldots,\mu_M) = t(\lambda)B_M(\mu_1,\ldots,\mu_M)\Omega_-. \tag{4.6}$$

Our next step is to use Lemma 3.6 and the definition of the lowest spin vector Ω_-, the equation (3.16), in order to calculate the action of the operator $t(\lambda)$ on the Bethe vectors when the Bethe equations (4.5) are imposed:

$$t(\lambda)B_M\Omega_- = B_M t(\lambda)\Omega_- + 2\left(\rho(\lambda)\sum_{i=1}^M\frac{1}{\lambda-\mu_i} + \sum_{i<j}^M\frac{1}{(\lambda-\mu_i)(\lambda-\mu_j)}\right)B_M\Omega_-. \tag{4.7}$$

We can express the first term on the right hand side since we know how the operator $t(\lambda)$ acts on the vector Ω_-, the equation (4.1),

$$t(\lambda)B_M\Omega_- = \left(\Lambda_0(\lambda) + 2\left(\rho(\lambda)\sum_{i=1}^M\frac{1}{\lambda-\mu_i} + \sum_{i<j}^M\frac{1}{(\lambda-\mu_i)(\lambda-\mu_j)}\right)\right)B_M\Omega_-. \tag{4.8}$$

The eigenvalue equation (4.3) as well as the expression for the eigenvalues (4.4) follow from the equation (4.8). □

Corollary 4.1: *In the Gaudin realization of the loop superalgebra given by the equations (3.7) and (3.17) the Bethe vectors $\Psi(\mu_1,\ldots,\mu_M)$ (4.2) are the eigenvectors of the Gaudin Hamiltonians (3.18),*

$$H^{(a)}\Psi(\mu_1,\ldots,\mu_M) = E_M^{(a)}\Psi(\mu_1,\ldots,\mu_M), \tag{4.9}$$

with the eigenvalues

$$E_M^{(a)} = \sum_{\substack{b=1\\ b\neq a}}^N \frac{l_a l_b}{z_a - z_b} + \sum_{j=1}^M \frac{l_a}{\mu_j - z_a}, \tag{4.10}$$

when the Bethe equations are imposed:

$$\beta_M(\mu_j)=\rho(\mu_j)+\sum_{k\neq j}^{M}\frac{1}{\mu_j-\mu_k}=\sum_{a=1}^{N}\frac{-l_a}{\mu_j-z_a}+\sum_{k\neq j}^{M}\frac{1}{\mu_j-\mu_k}=0. \tag{4.11}$$

Proof: The statement of the corollary follows from residue of the equation (4.3) at the point $\lambda=z_a$. The residue can be determined using (3.19), (4.4) and (4.1). □

The eigenvalue (4.4) of the operator $t(\lambda)$ and the Bethe equations (4.5) can be obtained also as the appropriate terms in the quasi-classical limit $\eta\to 0$ of the expressions (2.12) and (2.14).

Comparing the eigenvalues $E_M^{(a)}$ (4.10) of the Gaudin Hamiltonians and the Bethe equations (4.11) with the corresponding quantities of the sl(2) Gaudin model[4,5] we arrive to an interesting observation.

Remark 4.1: The spectrum of the osp(1|2) *Gaudin model with the spins l_a coincides with the spectrum of the* sl(2) *Gaudin system for the integer spins (cf. an analogous observation for partition functions of corresponding anisotropic vertex models in Ref. 23).*

Remark 4.2: The Bethe vectors are eigenstates of the global generator h_{gl},

$$h_{gl}\Psi(\mu_1,\ldots,\mu_M)=\left(-\sum_{a=1}^{N}l_a+M\right)\Psi(\mu_1,\ldots,\mu_M). \tag{4.12}$$

Moreover, these Bethe vectors are the lowest spin vectors of the global osp(1|2) *since they are annihilated by the generator v_{gl}^{-}*

$$v_{gl}^{-}\Psi(\mu_1,\ldots,\mu_M)=0, \tag{4.13}$$

once the Bethe equations are imposed (4.11). These conclusions follow from Remark 3.2*, the equations (3.28) and (3.29) and the definition of the Bethe vectors (4.2).*

Hence, action of the global generator v_{gl}^{+} on the lowest spin vectors $\Psi(\mu_1,\ldots,\mu_M)$ generates a multiplet of eigenvectors of the operator $t(\lambda)$:

$$(v_{gl}^{+})^m\Psi(\mu_1,\ldots,\mu_M),\quad m=1,2,\ldots,2\left(\sum_{a=1}^{N}l_a-M\right). \tag{4.14}$$

One can repeat the arguments of Refs. 14 and 1 to demonstrate combinatorially completeness of the constructed states.

As was pointed out already in Ref. 4 for the sl(2) case, there are several modifications of the Hamiltonians (3.18). One of them is the Richardson's pairing-force Hamiltonian.[25] These modifications can be formulated in the framework of universal L-operator and r-matrix formalism (3.3).[5]

Due to invariance of the r-matrix (3.1),

$$[r(\lambda),Y\otimes I+I\otimes Y]=0,\quad Y\in\mathrm{osp}(1|2), \tag{4.15}$$

one can add to the L-operator any element of osp(1|2),

$$L(\lambda)\to\tilde{L}(\lambda)=gY+L(\lambda), \tag{4.16}$$

preserving commutation relations (3.3). If we choose $Y=h$, then

$$\tilde{t}(\lambda)=\tfrac{1}{2}\,\mathrm{str}\tilde{L}^2(\lambda)=t(\lambda)+2gh(\lambda)+g^2 \tag{4.17}$$

will have the commutativity property, i.e., $\tilde{t}(\lambda)\tilde{t}(\mu)=\tilde{t}(\mu)\tilde{t}(\lambda)$. Hence we can take $\tilde{t}(\lambda)$ to be the generating function of the (modified) integrals of motion:

$$\tilde{t}(\lambda)=\sum_{a=1}^{N}\left(\frac{c_2(a)}{(\lambda-z_a)^2}+2\,\frac{\tilde{H}^{(a)}}{\lambda-z_a}\right)+g^2, \tag{4.18}$$

$$\tilde{H}^{(a)}=gh_a+\sum_{b\neq a}\frac{c_2^{\otimes}(a,b)}{z_a-z_b}. \tag{4.19}$$

Notice that the global osp(1|2) symmetry is now broken down to global $u(1)$:

$$[\tilde{t}(\lambda),h_{gl}]=\left[\tilde{t}(\lambda),\sum_{a=1}^{N}h_a\right]=0. \tag{4.20}$$

In this case the eigenstates Ψ_M are generated by the same B-operators. However, corresponding eigenvalues and Bethe equations are now given by

$$\tilde{\Lambda}(\lambda;\{\mu_j\}_{j=1}^{M})=\Lambda(\lambda;\{\mu_j\}_{j=1}^{M})+2g\rho(\lambda)+2g\sum_{j=1}^{M}\frac{1}{\lambda-\mu_j}+g^2, \tag{4.21}$$

$$\tilde{E}_M^{(a)}=E_M^{(a)}+g(-l_a), \tag{4.22}$$

$$-g+\sum_{a=1}^{N}\frac{l_a}{\mu_j-z_a}=\sum_{k\neq j}^{M}\frac{1}{\mu_j-\mu_k}. \tag{4.23}$$

The crucial step in the proof of these equations is the observation that the commutation relations between the operator $\tilde{t}(\lambda)$ (4.17) and the creation operators B_M are equal to the commutation relations (3.30) but with modified operator $\hat{\beta}_M(\mu_j)\to\hat{\beta}_M(\mu_j)+g$. To see this, notice the similarity between the terms with $v^+(\lambda)B_{M-1}^{(i)}$ operators and with $X^+(\lambda)B_{M-2}^{(i,j)}$ operators in Lemma 3.4, the equation (3.25), and in Lemma 3.6, the equation (3.30).

A Richardson-like Hamiltonian[25] can be obtained as a coefficient in the $\lambda\to\infty$ expansion

$$\tilde{t}(\lambda)=g^2+\frac{2g}{\lambda}\sum_{a=1}^{N}h_a+\frac{1}{\lambda^2}\left(2g\sum_{a=1}^{N}z_ah_a+c_2(gl)\right)+O\left(\frac{1}{\lambda^3}\right). \tag{4.24}$$

The first coefficient in this expansion is h_{gl}, global $u(1)$ symmetry generator (4.20). Let us denote the second coefficient by $2H_g$. Using the global osp(1|2) algebra generators one can write this Hamiltonian in the form

$$H_g=g\sum_{a=1}^{N}z_ah_a+2X_{gl}^{+}X_{gl}^{-}+v_{gl}^{+}v_{gl}^{-}, \tag{4.25}$$

where we have omitted the term $h_{gl}(h_{gl}-1)$. The eigenvalues of the Hamiltonian H_g are given by

$$H_g\Psi_M(\mu_1,\ldots,\mu_M)=E_g\Psi_M(\mu_1,\ldots,\mu_M),\quad E_g=\sum_{j=1}^{M}\mu_j-\sum_{a=1}^{N}l_az_a. \tag{4.26}$$

A realization of the generators in terms of fermionic oscillators in the sl(2) case yields a Richardson Hamiltonian.[25] In the osp(1|2) case, which we consider here, there are extra fermionic degrees of freedom due to the term $v_{gl}^{+}v_{gl}^{-}$ and constraints $(v_{gl}^{\pm})^2=X^{\pm}$.

One can realize Sklyanin bracket (3.3) using an L-operator with bosonic and fermionic oscillator entries,

$$L_{\mathrm{osc}}(\lambda)=\begin{pmatrix}\lambda & -\gamma & 2b\\ \gamma^{+} & 0 & \lambda\\ 2b^{+} & \gamma^{+} & -\lambda\end{pmatrix}, \tag{4.27}$$

where

$$[b,b^+]=1, \quad [\gamma,\gamma^+]_+=1, \quad \gamma^2=(\gamma^+)^2=0. \tag{4.28}$$

It is straightforward to see that the corresponding realization of the loop superalgebra will have only two nonzero commutators. Hence, one can consider a combination of Gaudin and oscillator realizations:

$$\widetilde{L}(\lambda)=L_{\mathrm{osc}}(\lambda)+L(\lambda). \tag{4.29}$$

Intergals of motion can be obtained using

$$\begin{aligned}\widetilde{t}(\lambda)&=\tfrac{1}{2}\,\mathrm{str}(L^2_{\mathrm{osc}}(\lambda)+2L_{\mathrm{osc}}(\lambda)L(\lambda)+L^2(\lambda))\\ &=t(\lambda)+\lambda^2+2(bb^++b^+b)+(\gamma^+\gamma-\gamma\gamma^+)+2(\lambda h(\lambda)+2(bX^+(\lambda)+b^+X^-(\lambda))\\ &\quad+(\gamma^+v^-(\lambda)-\gamma v^+(\lambda))).\end{aligned} \tag{4.30}$$

Corresponding *B*-operators can be constructed using

$$\widetilde{v}^+(\lambda)=\gamma^++v^+(\lambda), \quad \widetilde{X}^+(\lambda)=b^++X^+(\lambda). \tag{4.31}$$

Finally, the eigenvalues $\widetilde{\Lambda}$ and the Bethe equations are given by

$$\widetilde{\Lambda}(\lambda;\{\mu_j\}_{j=1}^M)=\Lambda(\lambda;\{\mu_j\}_{j=1}^M)+2(\lambda\rho(\lambda)+1)+\sum_{j=1}^M\frac{2\lambda}{\lambda-\mu_j}+\lambda^2, \tag{4.32}$$

$$-\mu_j+\sum_{a=1}^N\frac{l_a}{\mu_j-z_a}=\sum_{k\neq j}^M\frac{1}{\mu_j-\mu_k}. \tag{4.33}$$

Further modifications can be obtained considering the quasi-classical limit of the quantum spin system with nonperiodic boundary conditions and corresponding reflection equation.

The expression of the eigenvector of a solvable model in terms of local variables parametrized by sites of the chain or by space coordinates is known as coordinate Bethe ansatz.[4] The coordinate representation of the Bethe vectors gives explicitly analytical dependence on the parameters $\{\mu_i\}_1^M$ and $\{z_a\}_1^N$ useful in a relation to the Knizhnik–Zamolodchikov equation (Sec. V). Using the Gaudin realization (3.7) of the generators

$$v^+(\mu)=\sum_{a=1}^N\frac{v_a^+}{\mu-z_a}, \quad X^+(\mu)=\sum_{a=1}^N\frac{X_a^+}{\mu-z_a},$$

and the definition of the creation operators (3.37), one can get the coordinate representation of the *B*-operators:

$$B_M(\mu_1,\mu_2,\ldots,\mu_M)=\sum_\pi\,(v^+_{a_1}\cdots v^+_{a_M})_\pi\prod_{a=1}^N\,\varphi(\{\mu_m^{(a)}\}_1^{|\mathcal{K}_a|};z_a), \tag{4.34}$$

where the first sum is taken over ordered partitions π of the set $(1,2,\ldots,M)$ into subsets $\mathcal{K}_a$, $a=1,2,\ldots,N$, including empty subsets with the constraints

$$\bigcup_a\mathcal{K}_a=(1,2,\ldots,M), \quad \mathcal{K}_a\cap\mathcal{K}_b=\varnothing \ \text{ for } \ a\neq b.$$

The corresponding subset of quasi-momenta is

$$(\mu_1^{(a)}=\mu_{j_1},\mu_2^{(a)}=\mu_{j_2},\ldots\mu_{|\mathcal{K}_a|}^{(a)}=\mu_{j|\mathcal{K}_a|};j_m\in\mathcal{K}_a),$$

where $|\mathcal{K}_a|$ is the cardinality of the subset $\mathcal{K}_a$, and $j_k<j_{k+1}$, entering into the coordinate wave function

$$\varphi(\{\nu_m\}_1^{|\mathcal{K}|};z)=\sum_{\sigma\in\mathcal{S}_{|\mathcal{K}|}}(-1)^{p(\sigma)}((\nu_{\sigma(1)}-\nu_{\sigma(2)})(\nu_{\sigma(2)}-\nu_{\sigma(3)})\cdots(\nu_{|\mathcal{K}|}-z))^{-1}.$$

Due to the alternative sum over permutations $\sigma\in\mathcal{S}_{|\mathcal{K}|}$, this function is antisymmetric with respect to the quasi-momenta. Finally, the first factor in (4.34),

$$(v_{a_1}^+\cdots v_{a_M}^+)_\pi,$$

means that for $j_m\in\mathcal{K}_a$ corresponding indices of $v_{a_{jm}}^+$ are equal to a so that $v_{a_{jm}}^+=v_a^+$. One can collect these operators into product $\Pi_{a=1}^N(v_a^+)^{|\mathcal{K}_a|}$; consequently we have an extra sign factor $(-1)^{p(\pi)}$.

This coordinate representation is similar to the representations obtained in Refs. 8–10 for the Gaudin models related to the simple Lie algebras (see also Ref. 26). The Z_2-grading results in extra signs, while the complicated structure of the B_M-operators [for the sl(2)-GM they are just products of B_1-operators $B_1(\mu_j)=X^+(\mu_j)$] is connected with the fact that $(v_j^+)^2=X_j^+\neq 0$, while for $j\neq k$ v_j^+ and v_k^+ anticommute.

V. SOLUTIONS TO THE KNIZHNIK–ZAMOLODCHIKOV EQUATION

Correlation functions $\psi(z_1,\ldots,z_n)$ of the two dimensional conformal field theory satisfy the Knizhnik–Zamolodchikov equation[27]

$$\kappa\frac{\partial}{\partial z_a}\psi(z_1,\ldots,z_n)=\left(\sum_{b\neq a}\frac{Y_a^\alpha\otimes Y_b^\alpha}{z_a-z_b}\right)\psi(z_1,\ldots,z_n),\tag{5.1}$$

where Y_a^α are generators of an orthonormal basis of a simple Lie algebra in a finite dimensional irreducible representation V_a and $\psi(z_1,\ldots,z_n)$ is a function of N complex variables taking values in a tensor product $\otimes_{a=1}^N V_a$. The first term on the right hand side of (5.1) is a Gaudin Hamiltonian (1.1).

A relation between the Bethe vectors of the Gaudin model related to simple Lie algebras and the solutions to the Knizhnik–Zamolodchikov equation is well known for sometime.[8,9] The approach used here to obtain solutions to the Knizhnik–Zamolodchikov equation corresponding to superconformal field theory and Lie superalgebra osp(1|2) starting from *B*-vectors (4.2) is based on Ref. 8.

A solution in question is represented as a contour integral over the variables $\mu_1,\ldots,\mu_M$,

$$\psi(z_1,\ldots,z_N)=\oint\cdots\oint\phi(\vec{\mu}|\vec{z})\Psi(\vec{\mu}|\vec{z})d\mu_1\cdots d\mu_M,\tag{5.2}$$

where an integrating factor $\phi(\vec{\mu}|\vec{z})$ is a scalar function

$$\phi(\vec{\mu}|\vec{z})=\prod_{i<j}^M(\mu_i-\mu_j)^{1/\kappa}\prod_{a<b}^N(z_a-z_b)^{l_al_b/\kappa}\left(\prod_{k=1}^M\prod_{c=1}^N(\mu_k-z_c)^{-l_c/\kappa}\right),\tag{5.3}$$

and $\Psi(\vec{\mu}|\vec{z})$ is a Bethe vector (4.2) where the corresponding Bethe equations are not imposed.

As a first step in the proof that $\psi(z_1,\ldots,z_N)$ given by (5.2) is a solution of (5.1) we differentiate the product $\phi\Psi$ with respect to z_a and obtain

$$\partial_{z_a}(\phi\Psi)=\partial_{z_a}(\phi)\Psi+\phi\partial_{z_a}(\Psi). \tag{5.4}$$

Using (5.3) the first term on the right hand side can be calculated explicitly:

$$\kappa\partial_{z_a}\phi=\left(\sum_{\substack{b=1\\b\neq a}}^{N}\frac{l_a l_b}{z_a-z_b}-\sum_{j=1}^{M}\frac{l_a}{z_a-\mu_j}\right)\phi=E_M^{(a)}\phi. \tag{5.5}$$

Furthermore, taking a residue of (3.30) at $\lambda=z_a$ we have

$$H^{(a)}\Psi=E_M^{(a)}\Psi+\sum_{j=1}^{M}\frac{(-1)^j}{z_a-\mu_j}\beta_M(\mu_j)\tilde{\Psi}^{(j,a)}, \tag{5.6}$$

where

$$\tilde{\Psi}^{(j,a)}=\left(v_a^+B_{M-1}^{(j)}+2X_a^+\sum_{k\neq j}^{M}\frac{(-1)^{k+\Theta(j-k)}}{\mu_j-\mu_k}B_{M-2}^{(j,k)}\right)\Omega_-. \tag{5.7}$$

Hence (5.4) can be written as

$$\kappa\partial_{z_a}(\phi\Psi)=H^{(a)}(\phi\Psi)+\phi\sum_{j=1}^{M}\frac{(-1)^j}{\mu_j-z_a}\beta_M(\mu_j)\tilde{\Psi}^{(j,a)}+\kappa\phi\partial_{z_a}(\Psi). \tag{5.8}$$

Moreover, from (5.3) we also have

$$\kappa\partial_{\mu_j}\phi=\left(\sum_{a=1}^{N}\frac{-l_a}{\mu_j-z_a}+\sum_{\substack{j=1\\j\neq k}}^{M}\frac{1}{\mu_j-\mu_k}\right)\phi=\beta_M(\mu_j)\phi, \tag{5.9}$$

and from Lemma 3.7 follows

$$\partial_{z_a}\Psi=\sum_{j=1}^{M}(-1)^j\partial_{\mu_j}\left(\frac{\tilde{\Psi}^{(j,a)}}{\mu_j-z_a}\right). \tag{5.10}$$

Thus, using (5.9) and (5.10),

$$\kappa\partial_{z_a}(\phi\Psi)=H^{(a)}(\phi\Psi)+\kappa\sum_{j=1}^{M}\partial_{\mu_j}\left(\frac{(-1)^j}{\mu_j-z_a}\phi\tilde{\Psi}^{(j,a)}\right). \tag{5.11}$$

A closed contour integration of $\phi\Psi$ with respect to $\mu_1,\ldots,\mu_M$ will cancel the contribution from the terms under the sum in (5.11) and therefore $\psi(z_1,\ldots,z_N)$ given by (5.2) satisfies the Knizhnik–Zamolodchikov equation.

Conjugated Bethe vectors $(B_M\Omega_-)^*$ are entering into the solution $\tilde{\psi}(z_1,\ldots,z_N)$ of the dual Knizhnik–Zamolodchikov equation,

$$-\kappa\frac{\partial}{\partial z_a}\tilde{\psi}(z_1,\ldots,z_N)=\tilde{\psi}(z_1,\ldots,z_N)H^{(a)}. \tag{5.12}$$

The scalar product $(\tilde{\psi}(z_1,\ldots,z_N),\psi(z_1,\ldots,z_N))$ does not depend on $\{z_j\}_1^N$ and its quasi-classical limit $\kappa\to 0$ gives the norm of the Bethe vectors due to the fact that the stationary points of the contour integrals for $\kappa\to 0$ are solutions to the Bethe equations:[10]

$$\frac{\partial S}{\partial \mu_j}=\sum_{a=1}^{N}\frac{-l_a}{\mu_j-z_a}+\sum_{\substack{j=1\\ j\neq k}}^{M}\frac{1}{\mu_j-\mu_k}=0, \tag{5.13}$$

$$S(\vec{\mu}|\vec{z})=\kappa\ln\phi=\sum_{a<b}^{N} l_a l_b\ln(z_a-z_b)+\sum_{i<j}^{M}\ln(\mu_i-\mu_j)-\sum_{a=1}^{N}\sum_{j=1}^{M} l_a\ln(z_a-\mu_j). \tag{5.14}$$

According to the remark at the end of Sec. IV, analytical properties of the Bethe vectors of the osp(1|2) Gaudin model coincide with the analytical properties of the sl(2) Gaudin model. Thus, the expression for the norm of the Bethe vectors Ψ in (4.2) obtained as the first term in the asymptotic expansion $\kappa\to 0$ coincides also

$$(\Psi,\Psi)=\det\left(\frac{\partial^2 S}{\partial\mu_j\partial\mu_k}\right), \tag{5.15}$$

$$\frac{\partial^2 S}{\partial\mu_j^2}=\sum_{a=1}^{N}\frac{l_a}{(\mu_j-z_a)^2}-\sum_{k\neq j}^{M}\frac{1}{(\mu_j-\mu_k)^2},\quad \frac{\partial^2 S}{\partial\mu_j\partial\mu_k}=\frac{1}{(\mu_j-\mu_k)^2},\quad \text{for}\quad j\neq k. \tag{5.16}$$

Finally we notice that the modification of the Gaudin Hamiltonians we discussed at the end of the previous section can be easily transferred to the corresponding modification of the Knizhnik–Zamolodchikov equations. The modification (4.16) for the sl(2) Gaudin model was studied in Ref. 19 as a quantization of the Schlesinger system (see also Ref. 18). Both modifications are related with extra factors in the integrating scalar function (5.3),

$$\phi_j=\exp\left(\frac{S_j}{\kappa}\right),\quad j=0,1,2, \tag{5.17}$$

where $S_0=S$ in (5.14) and

$$S_1=S_0+g\sum_{j=1}^{M}\mu_j-g\sum_{a=1}^{N} l_a z_a, \tag{5.18}$$

$$S_2=S_0+\frac{1}{2}\sum_{j=1}^{M}\mu_j^2-\frac{1}{2}\sum_{a=1}^{N} l_a z_a^2, \tag{5.19}$$

correspond to the first (4.16) and second (4.29) modification, respectively.

VI. CONCLUSION

The Gaudin model corresponding to the simplest nontrivial Lie superalgebra osp(1|2) was studied. A striking similarity between some of the most fundamental characteristics of this system and the sl(2) Gaudin model was found. Although explicitly constructed creation operators B_M in (3.37) of the Bethe vectors are complicated polynomials of the L-operator entries $v^+(\lambda)$ and $X^+(\lambda)$, the coordinate form of the eigenfunctions defers only in signs from the corresponding states in the case of sl(2) model. Moreover, the eigenvalues and the Bethe equations coincide, provided that the sl(2) Gaudin model with integer spins is considered.

Let us point out that by the method proposed in this article one can construct explicitly creation operators of the Gaudin models related to trigonometric Izergin–Korepin r-matrix[20] and trigonometric osp(1|2) r-matrix[24] which have the same matrix structure as (3.2). Similarly to the simple Lie algebra case, solutions to the Knizhnik–Zamolodchikov equation were constructed from the Bethe vectors using algebraic properties of the creation operators B_M and the Gaudin

realization of the loop superalgebra $\mathcal{L}_+(\mathrm{osp}(1|2))$. This interplay between the Gaudin model and the Knizhnik–Zamolodchikov equation enabled us to determine the norm of eigenfunctions of the Gaudin Hamiltonians

$$\|\Psi(\mu_1,\ldots,\mu_M;\{z_a\}_1^N)\|^2=\det\left(\frac{\partial^2 S}{\partial\mu_j\partial\mu_k}\right).$$

The difficult problem of correlation function calculation for general Bethe vectors

$$\mathcal{C}(\{\nu_j\}_1^M;\{\mu_i\}_1^M;\{\lambda_k\}_1^K)=\left(\Omega_-,B_M^*(\nu_1,\ldots,\nu_M)\prod_{k=1}^K h(\lambda_k)B_M(\mu_1,\ldots,\mu_M)\Omega_-\right)$$

was solved nicely for the sl(2) Gaudin model in Ref. 6 using the Gauss factorization of the loop algebra group element and the appropriate Riemann–Hilbert problem. Although the corresponding factorization is known even for the quantum superalgebra $\mathrm{osp}_q(1|2)$,[28] the final expression of the correlation functions is difficult to obtain due to the complicated structure of the creation operators $B_M(\mu_1,\ldots,\mu_M)=\mathrm{Poly}(v^+,X^+)$ in (3.37). The study of this problem is in progress and the following expression for the scalar product of the Bethe states is conjectured (cf. Ref. 6):

$$(\Omega_-,B_M^*(\nu_1,\ldots,\nu_M)B_M(\mu_1,\ldots,\mu_M)\Omega_-)=\sum_{\sigma\in S_M}(-1)^{p(\sigma)}\det\mathcal{M}^\sigma,$$

where the sum is over symmetric group $\mathcal{S}_M$ and $M\times M$ matrix $\mathcal{M}^\sigma$ is given by

$$\mathcal{M}^\sigma_{jj}=\frac{\rho(\mu_j)-\rho(\nu_{\sigma(j)})}{\mu_j-\nu_{\sigma(j)}}-\sum_{k\neq j}^M\frac{1}{(\mu_j-\mu_k)(\nu_{\sigma(j)}-\nu_{\sigma(k)})},$$

$$\mathcal{M}^\sigma_{jk}=\frac{1}{(\mu_j-\mu_k)(\nu_{\sigma(j)}-\nu_{\sigma(k)})},\quad \text{for}\quad j,k=1,2,\ldots,M.$$

Anomalies and Schwinger terms in NCG field theory models

E. Langmann, J. Mickelsson, and S. Rydh[a)]
Theoretical Physics, Royal Institute of Technology, SE-10044, Stockholm, Sweden

(Received 9 March 2001; accepted for publication 2 April 2001)

We study the quantization of chiral fermions coupled to generalized Dirac operators arising in NCG Yang–Mills theory. The cocycles describing chiral symmetry breaking are calculated. In particular, we introduce a generalized locality principle for the cocycles. Local cocycles are by definition expressions which can be written as generalized traces of operator commutators. In the case of pseudodifferential operators, these traces lead in fact to integrals of ordinary local de Rham forms. As an application of the general ideas we discuss the case of noncommutative tori. We also develop a gerbe theoretic approach to the chiral anomaly in the Hamiltonian quantization of NCG field theory. © *2001 American Institute of Physics.*

I. INTRODUCTION

The non-Abelian chiral anomaly appears in two different (but related) ways. First, it modifies the structure of current algebra. Historically, this was the way quantum mechanical symmetry breaking was first observed,[1] but it took some time before a clear mathematical formulation of this phenomenon was obtained.[2] On the other hand, the anomaly appears in the path integral formulation as a lack of gauge invariance of the effective action.[3] In either way, the anomaly can be thought of as an element of an appropriate group (or Lie algebra) cohomology group.

The non-Abelian gauge anomaly arises from a left–right nonsymmetric coupling of vector potentials to a Dirac fermion field. This process can be generalized in a straight-forward way in noncommutative geometry models. Instead of a standard Dirac operator one considers self-adjoint (invertible) unbounded operators D with the property that $1/|D|^p$ is "almost" trace-class for a given real number $p \geqslant 1$. "Almost" means that the spectral integral $\int_0^\Lambda (|\lambda|^p+\epsilon)^{-1} d\mu(\lambda)$ is at most logarithmically divergent at $\Lambda \to \infty$, for any positive number ϵ. After fixing such an operator we study generalized Dirac operators $D_A = D + A$ where A is any Hermitian bounded perturbation.

We stress that our considerations are very general: The family of Dirac operators could for example arise from a coupling of vector potentials through a star product (generalized Moyal brackets). All that is needed is that the L_p estimate mentioned above is valid. This has been proven to hold in a class of star product quantizations[4] defined by a constant antisymmetric θ matrix. We shall study some consequences of this in Sec. VII.

Our starting point for a construction of a NCG field theory model is a triple $(D, \int, \mathcal{B})$, where D is the Dirac operator acting in a Hilbert space H, $\mathcal{B}$ is an associative algebra of operators in H such that $[D, b]$ is bounded for all $b \in \mathcal{B}$. In addition, there is an "integration," or a generalized trace map, from operators ("p-forms") of the type $\omega = b_0[\epsilon, b_1][\epsilon, b_2]\cdots[\epsilon, b_p]$, or alternatively $|D|^{-p} b_0[D, b_1]\cdots[D, b_p]$, to complex numbers;[5] see also the discussion around Definition 10.8 in Ref. 6 for more details. Here $\epsilon = D/|D|$ is the sign of the Dirac operator. In some cases (but not always) one can prove an equality between the integrals of the two alternative expressions.[5] The generalized vector potentials are then linear combinations of 1-forms $A = b_0[D, b_1]$, or sometimes $a = b_0[\epsilon, b_1]$.

We study the BRST double complex based on de Rham forms on the space of vector poten-

a)Electronic mail: samuel@theophys.kth.se

tials A with values in the space of the above operator p-forms ω, with $p=0,1,2,\ldots$. The NCG BSRT complex has been previously studied from different points of view in Ref. 7 and more recently in Ref. 8.

One of the central results in the present paper concerns the question of locality of the BRST cocycles. In abstract NCG models it is not *a priori* clear what this could mean because in the operator approach there is in general no space–time manifold to define local fields. However, in the ordinary space–time geometric setup many of the basic quantities can be written as ''traces'' of commutators of pseudodifferential operators. For example, this holds for non-Abelian Schwinger terms[9] and the gauge anomaly in the path integral formulation.[10] It turns out that these traces are in fact integrals of local differential forms. We adopt this as our starting point: We prove that in the NCG field theory models there is a ''local'' anomaly formula expressing the BRST cocycles as traces of commutators of nontrace-class operators.

The second main result concerns the description of the Hamiltonian anomaly in gerbe theoretic terms in which the basic object is a 3-cohomology class, the Dixmier–Douady class. The results are largely generalizations of the corresponding considerations for the standard coupling of local vector potentials to chiral fermions.[11] However, there is one important technicality which makes a difference between the ''classical'' and the NCG case. In the classical case the Dixmier–Douady class defines a de Rham form on the space of gauge orbits $\mathcal{A}/\mathcal{G}$. This is a smooth manifold when one restricts to the case of so-called based gauge transformations $\mathcal{G}_0$. In the NCG models the concept of based gauge transformations is not well-defined and the space of gauge orbits has singularities.

In order to avoid these singularities we realize the space of NCG gauge potentials for the Schatten index p as loops in gauge potentials for index $p-1$. Correspondingly, the group of gauge transformations for index p is the group of smooth loops in the gauge group for the case of index $p-1$ which allows us to define based gauge transformations in the usual way as loops through the neutral element at a fixed value of the argument. This leads then to a construction of a gerbe and its Dixmier–Douady class as a de Rham form in a standard way.

We want to thank Göran Lindblad for drawing to our attention to Ref. 12.

II. THE GENERAL SETUP FOR NCG DESCENT EQUATIONS AND ANOMALIES

Let D_0 be an unbounded self-adjoint operator in a complex Hilbert space H such that $|D_0|^{-1}\in L_{p+}$, that is, $|D_0|^{-p}\in L_{1+}$ for some $p\geqslant 1$. Here L_{1+} is the Dixmier ideal in the algebra of bounded operators in H. A positive operator T is in L_{1+} if it is compact and

$$\frac{1}{\log N}\sum_{k=1}^{N}\lambda_k$$

has a finite limit, where $\lambda_1\geqslant\lambda_2\geqslant\cdots$ are the eigenvalues of T. We also assume for simplicity that D_0 is invertible. However, the following discussion can be easily generalized to the case when D_0 is a finite rank perturbation of an invertible operator.

We shall work with bounded perturbations of the ''free Dirac operator'' D_0, denote $D_A=D_0+A$ where A is a bounded self-adjoint operator in H such that $[|D_0|,A]$ is bounded. We shall denote F_A a smoothed sign operator associated to D_A. The technical complication is that the map $A\mapsto D_A/|D_A|$ is not continuous when D_A has zero modes. Instead, we can take a smooth function f: $\mathbb{R}\to\mathbb{R}_+$ such that $f(x)-|x|$ approaches zero faster than any power of x as $|x|\mapsto\infty$ and $f(x)\geqslant m$ for some positive constant, and we define $F_A=D_A/f(D_A)$. For example, take $f(x)=+\sqrt{x^2+e^{-x^2}}$. Then $A\mapsto F_A$ is norm continuous. If D_A is the classical Dirac operator associated to a vector potential A on a compact manifold then the difference $D_A/|D_A|-F_A$ is an infinitely smoothing pseudodifferential operator and in particular a trace class operator.

The sign operator $D_A/|D_A|$ defines a Fock space representation of the canonical anticommutation relations algebra CAR. The generators in the CAR algebra are denoted by $a(v)$, $a^*(v)$, where $v\in H$. The algebra is defined by the basic relations

$$a(u)a(v)+a(v)a(u)=0=a^*(u)a^*(v)+a^*(v)a^*(u),$$
$$a^*(u)a(v)+a(v)a^*(u)=\langle v,u\rangle, \tag{2.1}$$

where the Hilbert space inner product $\langle\cdot,\cdot\rangle$ is antilinear in the first argument. The Dirac representation is then fixed by the requirement that there is a *vacuum vector* $|A\rangle\in\mathcal{F}_A$ such that

$$a^*(u)|A\rangle=0=a(v)|A\rangle, \text{ for } u\in H_-(A) \text{ and } v\in H_+(A), \tag{2.2}$$

where $H=H_+(A)\oplus H_-(A)$ is the polarization to the spectral subspaces $D_A\geqslant 0$, $D_A<0$, respectively.

Because of the potential zero modes of the Dirac operator the Dirac vacuum cannot in general be defined as a continuous function of A. Instead, we must be content with a choice of a polarization $H=W(A)\oplus W(A)^\perp$ such that $W(A)\sim H_+(A)$, where the equivalence is defined by the condition that the projection operators to the given subspaces differ only by Hilbert–Schmidt operators. The Hilbert–Schmidt condition comes from the requirement that the CAR representations defined by the two polarizations should be equivalent; for a review on CAR representations see Ref. 13. Let $\epsilon_W=\pi_W-\pi_{W^\perp}$ be the grading operator defined by the orthogonal projection $\pi_W: H\to W$. Then $\epsilon_{W(A)}-\epsilon_{H_+(A)}$ is Hilbert–Schmidt and $\epsilon_{H_+(A)}-F_A$ is trace-class and so F_A is an approximation of $\epsilon_{W(A)}$ modulo Hilbert–Schmidt operators. The advantage of working with F_A is that it is easier to produce explicit formulas (as we saw above), compared with the grading operators $\epsilon_{W(A)}$.

As an operator function $D_A/f(D_A)$ of D_A, the operator F_A satisfies $g^{-1}F_Ag=F_{A^g}$, with $A^g=g^{-1}Ag+g^{-1}[D_0,g]$ for a unitary transformation g such that $[D_0,g]$ is bounded. Denote by $\mathcal{B}$ the algebra of bounded operators b in H such that $[D_0,b]$ and $[|D_0|,b]$ are bounded. Then all the operators $A=b_0[D_0,b_1]$, for $b_i\in\mathcal{B}$, satisfy the condition $[|D_0|,A]$ is bounded. We denote by U_{p+} the group of unitary elements in $\mathcal{B}$. Any element $g\in U_{p+}$ satisfies $[\epsilon,g]\in L_{p+}$ where $\epsilon=D_0/|D_0|$.

Lemma 2.3: $F_A-\epsilon\in L_{p+}$ for any bounded operator A such that $[|D_0|,A]$ is bounded.

Proof: (1) We first prove that $|D_0+A|-|D_0|$ is bounded. We have assumed that D_0 is invertible, so $|D_0|\geqslant\mu$ for some positive constant μ. We use the norm estimate $\||X|-|Y|\|\leqslant\||X^*X-Y^*Y|^{1/2}\|$; see for example [Ref. 12, Sec. X.2]. Set $G=D_0A+AD_0$ and split $G=G_++G_-$ where G_+ commutes with ϵ and G_- anticommutes with ϵ. The linear equation,

$$G=|D_0|Z+Z|D_0|,$$

can be solved as $Z=Z_++Z_-$, with $Z_+=A_+\epsilon$ and

$$Z_-=\int_0^\infty e^{-t|D_0|}[|D_0|,\epsilon A_-]^{-t|D_0|}\,dt,$$

and thus Z is bounded, since $\|e^{-t|D_0|}\|\leqslant e^{-t\mu}$ and since $[|D_0|,\epsilon A_-]=\epsilon[|D_0|,A_-]$ is bounded by assumption. Setting $X=D_0A$ and $Y=|D_0|+Z$ in the above norm estimate we observe that $|D_0+A|-|\,|D_0|+Z|$ is bounded. In the case when $\|Z\|\leqslant\mu$ the operator $|D_0|+Z$ is positive and so $\||D_0|+Z|=|D_0|+Z$ and it follows that $|D_0+A|-|D_0|=(|D_0+A|-|\,|D_0|+Z|)+(|\,|D_0|+Z|-|D_0|)$ is bounded. In the general case, replace $D_0\mapsto D'=D_0+i\alpha$ for a real number α. Clearly $|D+i\alpha|-|D_0|$ and $|D_0+A+i\alpha|-|D_0+A|$ are bounded, so the question of whether $|D_0+A|-|D_0|$ is bounded is equivalent to whether $|D'+A|-|D'|$ is bounded. Now $|D'|\geqslant|\alpha|$ and so we have $\|Z\|\geqslant|D'|$ when we choose α large enough and the proof reduces to the special case above.

(2) We may assume without essential restriction that D_0+A is invertible so we can select $f(x)=|x|$ and

$$\begin{aligned} F_A-\epsilon &= (D_0+A)^{-1}|D_0+A|-D_0^{-1}|D_0| \\ &= (1+D_0^{-1}A)^{-1}D_0^{-1}|D_0+A|-D_0^{-1}|D_0| \\ &= \{(1+D_0^{-1}A)^{-1}-1\}\epsilon+(1+D_0^{-1}A)^{-1}D_0^{-1}T, \end{aligned}$$

for some bounded operator T. The second term on the right is then in L_{p+} since $D_0^{-1}\in L_{p+}$ and the first term is of the form $((1+S)^{-1}-1)\epsilon$ with $S\in L_{p+}$ and thus it belongs also to L_{p+}. □

The following discussion is based on a parametrization of the fermionic Fock space by the operator $a=F_A-\epsilon$. Thus the Dirac vacuum for the vector potential A is given by any grading operator ϵ_a which differs from $\epsilon+a$ by a Hilbert–Schmidt operator. Geometrically, this leads to the construction of a smooth infinite-dimensional vector bundle $\mathcal{F}$ over the parameter space $\mathcal{A}$ of generalized vector potentials. The fiber $\mathcal{F}_a$ is the Fock space defined by the grading operator ϵ_a. The quantized Dirac operator $\hat{D}_A$ acts as an unbounded positive operator in the fiber.

The group U_{p+} acts in the base space of the bundle. The problem arises as to whether the action can be lifted to the total space such that $g^{-1}\hat{D}_A g=\hat{D}_{A^g}$. In case of smooth vector potentials, $A=\gamma^k A_k$, and a massless Dirac operator it is known that the answer is negative. Instead, there is an extension $\hat{\mathcal{G}}$ of the group of gauge transformations $\mathcal{G}$ which acts in the total space. The obstruction to the $\mathcal{G}$ action is the extension term in the commutation relations of the Lie algebra Lie($\mathcal{G}$). This extension (Schwinger term) is a 2-cocycle $c_{n,2}$ of Lie($\mathcal{G}$) in the module of complex functions of the variable A. In the case of one space dimension, $n=1$, the cocycle does not depend on A and one may restrict to the module of constant functions.

There is an equivalent alternative way to view the obstruction. The standard construction in canonical quantization leads naturally to a bundle $P\mathcal{F}$ of *projective Fock spaces* which do not depend on any choices of the grading operator ϵ_a. The existence of a Fock bundle which gives $P\mathcal{F}$ as its projectivization is then related to triviality of a *Dixmier–Douady* class in $H^3(\mathcal{A}/\mathcal{G},\mathbb{Z})$.[11]

The main content of the present article is to explain how the local formulas for gauge anomalies, Schwinger terms, the Dixmier–Douady class, and all the cocycles related to these through the standard BRST descent equations extend to certain cocycles on the space of bounded operators A and the Lie algebra Lie(U_{p+}) such that a restriction to the classical case gives standard local formulas. A central ingredient is to use (noncyclic) extensions of the trace functional to nontrace-class operators.

The "infinitesimal version" of the gauge transformation $A\mapsto A^g$ in terms of the parameter a is

$$\delta_X a=[a,X]+[\epsilon,X], \quad \text{for } X\in\mathbf{u}_p=\mathrm{Lie}(U_{p+}). \tag{2.4}$$

Let us recall the basic definitions in NCG differential calculus for Fredholm modules.[5] The differentials of order n are linear combinations of operators of the type $b_0[\epsilon,b_1]\cdots[\epsilon,b_n]$ where $b_i\in\mathcal{B}$. One denotes $db=[\epsilon,b]$ for $b\in\mathcal{B}$. If $\phi\in\Omega^n$ is a differential of order n then $d\phi=\epsilon\phi+(-1)^{n+1}\phi\epsilon$. This gives a map $d:\Omega^n\to\Omega^{n+1}$ with $d^2=0$. The cohomology of this complex is trivial.

The coboundary operator associated to infinitesimal gauge transformations is denoted by δ. We work with cochains of order k, $\tau\in\Omega_k$, consisting of functions $\tau(a;X_1,\ldots,X_k)$ of $a\in\Omega^1$ and of Lie algebra elements $X_i\in\mathbf{u}_p$, linear in each X_i and totally antisymmetric in the arguments X_i. The standard Lie algebra coboundary operator is defined by

$$\begin{aligned} (\delta\tau_n)(a;X_1,\ldots,X_{n+1}) &= \sum_i (-1)^{i-1}\delta_{X_i}\tau(a;X_1,\ldots,\hat{X}_i,\ldots,X_{n+1}) \\ &\quad +\sum_{i<j}(-1)^{i+j}\tau(a;[X_i,X_j],..,\hat{X}_i,\ldots,\hat{X}_j,\ldots,X_{n+1}), \end{aligned} \tag{2.5}$$

where the hat means that the corresponding argument is deleted and δ_{X_i} is the Lie derivative acting on functions of a, the action on the argument being given by (2.4). We remind that the multilinear forms τ on a Lie algebra can be interpreted as left invariant differential forms on the corresponding Lie group (and *vice versa*) through the standard identification of a Lie algebra as left invariant vector fields.

We shall also work with a (d,δ) double complex consisting of δ forms taking values in the d complex Ω^*, using the standard BRST sign convention. The BRST ghost v can be interpreted as the Maurer–Cartan 1-form on the gauge group, that is, at the identity element it is the the tautological 1-form sending a Lie algebra element onto itself, $v=g^{-1}\,\delta g$. The sign conventions are encoded into the algebraic rules,

$$\begin{gathered} d^2=\delta^2=\delta d+d\,\delta=0, \\ \delta(v)=-v^2=\delta v+v\,\delta, \\ \delta(a)=-[a,v]_+-v^2=\delta a+a\,\delta, \\ d(v)=[\epsilon,v]_+=dv+vd, \\ d(a)=[\epsilon,a]_+=da+ad. \end{gathered} \tag{2.6}$$

We denote $[a,b]_+=ab+ba$.

Here a remark on notation is in order. We want to treat at the same time both the even and odd Fredholm modules (related to odd/even k.) To obtain the correct signs in (2.6), we need to make a reinterpretation of $x=v$, δ, ϵ and a.

Even Fredholm module. In this case we have, by definition, a Hermitian operator Γ in H with $\Gamma^2=1$ which anticommutes with ϵ and α, and the correct signs are accounted for if we interpret the ghost as Γv. To be precise, one should distinguish between v, δ, ϵ and a and

$$\begin{gathered} s(v)=\Gamma v,\ \ s(\delta)=\Gamma\delta, \\ s(\epsilon)=\epsilon,\ \ s(a)=a. \end{gathered} \tag{2.7}$$

Odd Fredholm module. We do not have a Γ at hand but we introduce it by doubling the original Hilbert space, $H\mapsto H\otimes\mathbb{C}^2$, and introducing the usual Pauli sigma matrices σ_3 and σ_1 acting on the second factor. We can then define

$$\begin{gathered} s(v)=v\otimes\sigma_1,\ \ s(\delta)=\delta\otimes\sigma_1, \\ s(\epsilon)=\epsilon\otimes\sigma_3,\ \ s(a)=a\otimes\sigma_3. \end{gathered} \tag{2.8}$$

In particular, the formulas $d(v)=[\epsilon,v]_+$ and $d(a)=[\epsilon,a]_+$ mean

$$d(s(v))=[s(\epsilon),s(v)]_+=[\epsilon,v]\otimes\sigma_3\sigma_1,$$

$$d(s(a))=[s(\epsilon),s(a)]_+=[\epsilon,a]_+\otimes\sigma_3^2=[\epsilon,a]_+\otimes 1,$$

where the sigma matrices account for the correct signs. We stress that the auxiliary space is just a tool to keep track of the signs (the even and odd case could actually be handled in a unified manner, but we choose to utilize Γ in the even case).

In both cases, the symbols $x=v$, δ, ϵ and a in (2.6) should actually be interpreted as $s(x)$ as specified above, and only for simplicity of the notation we write x instead of $s(x)$. We will sometimes also use this simplified notation below, in particular in the Appendix, but we will always clearly point this out.

In the standard discussion of anomalies in quantum field theory one constructs cocycles $c_{n,k}$ in the (Ω_*,δ) complex by integrating de Rham forms $\omega_{n,k}$ in Ω^n_* over a compact manifold of dimension n. In the NCG setting integration of forms is replaced by applying an appropriate trace functional to the operator valued forms. In fact, in the case of an odd Fredholm module the

integral is normally defined as the trace $\mathrm{tr}_C\,\phi$ where the conditional trace is defined as $\mathrm{tr}_C(X)=\frac{1}{2}\mathrm{tr}(X+\epsilon X\epsilon)$. However, in our notation we have to take the trace also in the auxiliary space $\mathbb{C}^2$, and the correct definition is

$$\int \phi=\frac{1}{2}\mathrm{tr}_C\sigma_3\phi. \tag{2.9}$$

In the case of an even Fredholm module the standard definition of the integral is $\mathrm{tr}_C(\Gamma\phi)$ whereas with our conventions the operator expression ϕ is already equipped (for odd k) with the Γ factor and we set

$$\int \phi=\mathrm{tr}_C\,\phi. \tag{2.10}$$

In the case of even k (in an even module) the integral vanishes.

The translation from the classical to NCG setting is straight-forward. The de Rham exterior derivation is replaced by the operation d described above (to the forms after the symbol "$\int$"). All the formal manipulations are done exactly in the same way as in the classical BRST complex. Of course, the nontriviality of the cohomology classes depends on what is meant by the trace [and the definition of the trace is intertwined by the choice of $(H,D_0,\mathcal{B})$].

The construction of a family of cocycles $c_{j,k}$ over a Fredholm module starts from the (NCG) operator valued Chern class F^n, where $F=d(a)+a^2\in\Omega^2$ is the curvature. The Chern–Simons form is defined by

$$c_{2n-1,0}(a)=\int n\int_0^1 dt\, a[td(a)+t^2a^2]^{n-1},$$

where $td(a)+t^2a^2=F(t)$ is the curvature associated with ta (a path connecting a and 0). The other terms in the complex (starting from the Chern class) are given by similar formulas where one has the curvature associated with $d+\delta$ and a path of vector potentials connecting $a+v$ and 0,

$$c_{2n-k-1,k}=\int n\int_0^1 dt(a[td(a)+t^2a^2+(1-t)d(v)]^{n-1})|_{[k]},\quad k=0,\ldots,n-1,$$

where now the curvature in the square brackets is obtained starting from the vector potential $ta+v$, and $(\cdots)|_{[k]}$ means the projection onto those terms which are of degree k in the "ghost" v, and similarly,

$$c_{2n-k-1,k}=\int n\int_0^1 dt(v[td(v)+(t^2-t)v^2]^{n-1})|_{[k]},\quad k=n,\ldots,2n,$$

where now the curvature is associated with tv. We stress that in the previous formulas for $c_{2n-k-1,k}$, we use the simplified notation where $x=v,a$ is short for $s(x)$ as discussed above. (We also recall that one can obtain different but equivalent formulas for $c_{2n-k-1,k}$ depending on the choice of path $a+v\to 0$, and we find it convenient to use the path consisting of two straight lines $a+v\to v$ and $v\to 0$ leading to cocycles with lowest possible powers of a.)[14]

The crucial property are the cocycle relations $\delta c_{j,k}=0$ for all j and k. In the standard case these are a consequence of the fact that the cocycles are integrals of traces of matrix valued de Rham forms, $c_{j,k}=\int_M \mathrm{tr}\omega_{j,k}$, which are linked by the so-called descent equations. These equations start with a relations connecting the Chern class and the Chern–Simons form, $F^n=d\omega_{2n-1,0}+(\cdots)$, and then continue,

$$\delta(\omega_{2n-1-k,k})+d(\omega_{2n-1,k+1})=(\cdots),\quad k=0,\ldots,2n-1,$$

where $(\cdots)$ are terms which have zero trace; they are explicitly commutators of matrix forms. Since all but the first term on the l.h.s. in these latter equations vanish under the combined trace and integral (the second term on the l.h.s. vanishes due to Stokes theorem) and $\delta\int=\int\delta$, one obtains the cocyle relations. In fact, in the standard case one usually applies to these descent equations the matrix trace, and therefore the terms $(\cdots)$ on the r.h.s. become zero. In the NCG generalizations, an analog of the separate matrix trace is usually not available (the matrix trace and the ordinary integration are combined in the abstract integral), and it is therefore natural to also keep the terms $(\cdots)$.[7] In fact, as we will show, the terms $(\cdots)$ contain interesting information: in case of the double complex based in a spectral triple they allow us to connect the forms $\omega_{j,k}$ and $\omega_{j+2,k}$ in different dimensions (d degree) but identical form degree, which, for example, provides an important link of the Schwinger terms in different dimensions (Theorem A4) and, in general, will allow us to obtain local forms of the NCG cocyles (Theorem 3.1).

As an example, the second Chern form is in the classical case the matrix trace of F^2, where $F=d(A)+A^2$ is the curvature form associated to a connection $A=A^\mu\,dx_\mu$. In general, one then can check by straightforward algebraic manipulations,

$$F^2=d(\omega_{3,0})+[a,\tilde{\omega}_{3,0}]_+,$$

where $\omega_{3,0}=\frac{1}{2}[d(a),a]_+ +\frac{2}{3}a^3$ is the three-dimensional Chern–Simons form (before applying the trace functional) and $\tilde{\omega}_{3,0}=\frac{1}{3}[d(a),a]_+ +\frac{1}{2}a^3$ is another 3-form. Note that for standard de Rham forms, the second term vanishes under the matrix trace. If we apply this relation in the Fredholm module setting we use $\int F^2=\mathrm{tr}_C(\Gamma F^2)$, and since $\Gamma[a,\tilde{\omega}]_+=[\Gamma a,\tilde{\omega}]$ the second term becomes a trace of a commutator which vanishes for appropriate p. Of course, in the classical case also the integral of the first term is zero in the case of a manifold without boundary. The other descent equations are, in the simplified notation where $x=a,v,\omega_{3-k,k}$, etc. is short for $s(x)$ as in Eqs. (2.7)–(2.8),

$$\delta(\omega_{3,0})+d(\omega_{2,1})=-\tfrac{1}{3}[a,\omega_{2,1}]_+-[v,\omega_{3,0}]_+,$$

$$\delta(\omega_{2,1})+d(\omega_{1,2})=-\tfrac{2}{3}[a,\omega_{1,2}]_+-[v,\omega_{2,1}]_+,$$

$$\delta(\omega_{1,2})+d(\omega_{0,3})=-[v,\omega_{1,2}]_+,$$

$$\delta(\omega_{0,3})=-\tfrac{1}{2}[v,\omega_{0,3}]_+,$$

where

$$\omega_{2,1}=\tfrac{1}{2}[a,d(v)]_+,\quad \omega_{1,2}=\tfrac{1}{2}[d(v),v]_+,\quad \omega_{0,3}=-\tfrac{1}{3}v^3,$$

all of them can be checked by straight-forward algebraic manipulations. As we have already said, the BRST ghost v can be interpreted as the Maurer–Cartan form on a group manifold, and thus are to be evaluated along tangent vectors X_j at the neutral element (i.e., Lie algebra elements). Moreover, in the end we are interested in integrals of the operator forms and we need to treat the cases of odd or even Fredholm modules separately, as discussed above.

For example, the form $\omega_{1,2}$ when evaluated for Lie algebra elements X, Y and integrated in an odd module of appropriate Schatten index p, gives

$$\int \omega_{1,2}(X,Y)=\tfrac{1}{2}\mathrm{tr}_C([d(X),Y]_+-[d(Y),X]_+),$$

where $d(X)=[\epsilon,X]$, and $\omega_{0,3}$ leads to

$$\int \omega_{0,3}(X,Y,Z)=-\mathrm{tr}_C[[X,Y],Z]_+,$$

and $\omega_{2,1}$ in an even module (appropriate p) leads to

$$\int \omega_{2,1}(X) = -\frac{1}{2}\mathrm{tr}_C[a,\Gamma d(X)]_+ = \frac{1}{2}\mathrm{tr}_C\,\Gamma[a,d(X)].$$

III. "LOCAL" NCG ANOMALIES AND SCHWINGER TERMS

In the case of the classical BRST complex all the cocycles $c_{j,k}$ are given in terms of differential forms which are differential polynomials in variables a,v. The Fredholm module cocycles involve terms like $[\epsilon,v],\epsilon a+a\epsilon$, and therefore are nonlocal in nature; when evaluated using the symbol calculus of pseudodifferential operators they contain terms of arbitrary high order in the partial derivatives.

However, even in the case of the Fredholm module cocycles (for classical vector potentials and gauge transformations) the locality is preserved in a certain sense. Namely, it turns out that the cocycles $c_{j,k}$ are equivalent (in the BRST cohomology) to cocycles $c'_{j,k}$ which can be written as renormalized traces of commutators of PSDO's. In the case of Schwinger terms this was observed in Ref. 9 and the same principle was applied to the calculation of the gauge anomaly for the chiral Dirac determinant in Ref. 10. The trace of a commutator depends only on the term in the asymptotic expansion of a PSDO which has order equal to $-\dim M$, and for this reason one needs to take into account only a finite number of derivatives of the symbols (since each differentiation in a homogeneous term decreases the order by one). In this sense the trace of a commutator is a local expression. In a more general setup, beyond the PSDO calculus, we take this as a *definition* of locality: cocycles which are traces of commutators in the algebra are called local.

We set up the following assumptions. There is a complex linear functional TR on the algebra generated by D_0, $|D_0|$ and $\mathcal{B}$ such that (1) it is equal to the ordinary trace for trace class operators, (2) it has the property that $\mathrm{TR}[A,B]=0$ when $AB,BA\in L_{1+}$ and (3) $\mathrm{TR}[\epsilon,W]=0$ (odd case), $\mathrm{TR}[\Gamma\epsilon,W]=0$ (even case), for bounded operators W, with $\epsilon=D_0/|D_0|$.

Example 1: Set $p=1$ and consider the cocycle $c(X,Y)=\mathrm{tr}_C X[\epsilon,Y]$, for $X,Y\in\mathcal{B}$. Here everything is defined in the original Hilbert space H and not in $H\otimes\mathbb{C}^2$. We can write

$$c_{1,2}(X,Y)=\tfrac{1}{4}\mathrm{tr}\epsilon[\epsilon,X][\epsilon,Y]=\mathrm{tr}_C X[\epsilon,Y]=\tfrac{1}{2}\mathrm{TR}\;\; X[\epsilon,Y]=\tfrac{1}{2}\mathrm{TR}[X\epsilon,Y]-\tfrac{1}{2}\mathrm{TR}\epsilon[X,Y].$$

The last term is the coboundary of the cochain $\theta(X)=\frac{1}{2}\mathrm{TR}\epsilon X$ and therefore the class of $c_{1,2}$ is given by

$$c_{\mathrm{loc}}(X,Y)=\tfrac{1}{2}\mathrm{TR}[X\epsilon,Y].$$

One can also check by a direct computation that c_{loc} is a cocycle:

$$\begin{aligned}2(\delta c_{\mathrm{loc}})(X,Y,Z)&=\mathrm{TR}\{[[X,Y]\epsilon,Z]+\mathrm{cycl.}\}\\&=\mathrm{TR}\{[[X,Y],[\epsilon,Z]]+\mathrm{cycl.}\}\\&=\mathrm{TR}[\epsilon,[[X,Y],Z]]+\mathrm{TR}[Y,[[\epsilon,X],Z]]-\mathrm{TR}[X,[[\epsilon,Y],Z]]+\mathrm{cycl.}\end{aligned}$$

By (3) the first term on the right vanishes and by (2) the second and third terms vanish. In the case when X, Y are multiplication operators, by smooth functions, on the circle S^1 the local cocycle becomes the central term in an affine Lie algebra,

$$c_{\mathrm{loc}}(X,Y)=\frac{1}{2\pi i}\int_{S^1}\mathrm{tr}X\,dY,$$

where the trace under the integral sign is a finite-dimensional matrix trace for the matrix valued functions X, Y.

The cocycle $c_{1,2}$ (or c_{loc}) arises in canonical quantization in the following way. To each pair of basis vectors e_i, e_j in H there corresponds an operator $\hat{e}_{ij}=a^*(e_i)a(e_j)$ in the Fock representation. We may label the basis vectors such that $e_i\in H_+$ for $i=0,1,2,...$, and $e_i\in H_-$ for $i=-1,-2,...$, where $H_\pm=\frac{1}{2}(1\pm\epsilon)H$. Then a matrix (α_{ij}) in this basis has the canonical quantization as the operator $\hat{\alpha}=\Sigma\alpha_{ij}\hat{e}_{ij}$. For infinite matrices this might diverge. Actually, that happens already when α is the unit matrix. To circumvent this one introduces the normal ordering $\hat{e}_{ij}\mapsto\hat{e}_{ij}-\delta_{ij}\theta(-i)$ with $\theta(x)=x$ for $x\geqslant 0$ and $\theta(x)=0$ for $x<0$. With these new operators $\hat{e}_{ij}$ the operator $\hat{\alpha}$ is defined in a dense domain for any bounded operator α such that $[\epsilon,\alpha]$ is Hilbert–Schmidt and the commutation relations are given by

$$[\hat{\alpha},\hat{\beta}]=\widehat{[\alpha,\beta]}+c_{1,2}(\alpha,\beta)$$

(Ref. 15).

Example 2: Here we consider the problem arising from quantization of gauge currents in three space dimensions. Typically, $[\epsilon,X]$ is not Hilbert–Schmidt but it belongs to the ideal $L_{3+}\subset L_4$. For this reason the expression for the 2-cocycle in the previous example does not converge for 3-dimensional gauge currents. Instead, one has to introduce a renormalization of the 2-cocycle,

$$c_{3,2}(a;X,Y)=\tfrac{1}{8}\mathrm{tr}_C a[[\epsilon,X],[\epsilon,Y]],$$

with $a=F_A-\epsilon$. One can check by a direct calculation that this is a cocycle in the sense that

$$c_{3,2}(a;[X,Y],Z)+\delta_X c_{3,2}(a;Y,Z)+\text{cyclic perm. of } X,Y,Z=0.$$

Let next $\eta(a;X)=\frac{1}{8}\mathrm{TR}\epsilon a[\epsilon,X]$. By a direct calculation one can check that $c_{3,2}=\delta\eta+c_{\mathrm{loc}}$ where now

$$8c_{\mathrm{loc}}(a;X,Y)=\mathrm{TR}[Y,\epsilon a[\epsilon,X]]-\mathrm{TR}[X,\epsilon a[\epsilon,Y]]+2\,\mathrm{TR}[X\epsilon,Y]-2\,\mathrm{TR}[Y\epsilon,X]$$

is explicitly a generalized trace of a sum of commutators. Using the "bare" BRST notation (without the auxiliary space $\mathbb{C}^2$) we can write $c_{\mathrm{loc}}=\frac{1}{4}\mathrm{TR}[v\epsilon,v]-\frac{1}{8}\mathrm{TR}[v,\epsilon a[\epsilon,v]]$.

In this example the canonical quantization of gauge currents is ill-defined even after normal ordering, precisely because $[\epsilon,X]$ is not Hilbert–Schmidt. However, there is an operator theoretic interpretation for second quantized $\hat{X},\hat{Y}$. These are now generators for unitary transformations between Fock spaces carrying inequivalent representations of the CAR algebra. Geometrically, there is a bundle of Fock spaces parametrized by the external field a and the gauge transformations act as unitary maps between the fibers.[16]

Example 3: As a final example we discuss the gauge anomaly in two space–time dimensions. Here we are in the even case and we have $\Gamma\epsilon=-\epsilon\Gamma$ and we consider gauge transformations X which commute with Γ. Then $c_{2,1}(a;X)=\mathrm{tr}_C\Gamma a[\epsilon,X]$ is a cocycle,

$$\delta_X c_{2,1}(a;Y)-\delta_Y c_{2,1}(a;X)-c_{2,1}(a;[X,Y])=0,$$

using the fact that $\mathrm{tr}_C[\epsilon,\cdot]=0$. In this case,

$$c_{2,1}(a;X)=\mathrm{TR}[\Gamma a\epsilon,X]+(\delta\eta)(a),$$

where $\eta(a)=\mathrm{TR}\ \Gamma a\epsilon$. In BRST notation, for an even module, $c_{\mathrm{loc}}=\mathrm{TR}[a\epsilon,s(v)]$. We leave it as an exercise for the reader to show that when inserting $\epsilon=D_0/|D_0|$, $D_0=-i\Sigma_{k=1}^2\gamma^k\partial_k$, $D_A=D_0+\Sigma\gamma^k A_k(x)$ and $a=D_A/|D_A|-\epsilon$ one obtains the standard formula for the non-Abelian gauge anomaly in two space–time dimensions,

$$c_{\mathrm{loc}}=\frac{1}{4\pi}\int \mathrm{tr}(A_1\,\partial_2 X-A_2\,\partial_1 X),$$

for a smooth infinitesimal gauge transformation X of compact support.

In the general case we have the following result

Theorem 3.1: *Let $n=1,2,...$, and $k=0,1,2,...$, and let the cocycle $c_{2n-1-k,k}$ be computed from the descent equations in Sec. II. Then for even k the cohomology class $[c_{2n-1-k,k}]$ is represented by a cocycle $c^{loc}_{2n-1-k,k}$ which is a generalized trace of a sum of commutators; each commutator is a polynomial in the operators a, ϵ and X_j (the latter operators correspond to the tangent vectors at which the ghosts were evaluated). In the case of odd k one has to add a term proportional to a generalized trace of $\omega_{0,k}$.*

This theorem is a reformulation of Theorems A4 and A5 in the Appendix, which also gives more explicit formulas.

IV. A MODEL FOR $\mathcal{A}/\mathcal{G}$

When $\mathcal{A}$ is the space of classical smooth vector potentials on a compact manifold M and $\mathcal{G}_0$ is the group of based smooth gauge transformations [based means that $g(p)=1$ at some given point $p\in M$] then the quotient $X=\mathcal{A}/\mathcal{G}_0$ is a smooth infinite-dimensional Banach manifold. If one tries to generalize this to the NCG setting, by replacing $\mathcal{A}$ by all bounded perturbations of the free Dirac operator and taking $\mathcal{G}$ as the group of unitaries in the algebra $\mathcal{B}$, one encounters the problem that there is no natural way to define what is meant by based gauge transformations; this leads to the difficulty that X is not a manifold, it has a lot of singularities since at a generic point in $\mathcal{A}$ the action of $\mathcal{G}$ is not free. Here we shall construct a model for $\mathcal{A}$ and $\mathcal{G}$ such that the quotient will be free of singularities.

Our construction is essentially based on Bott periodicity. Recall that the inductive limit $U(\infty)$ of the group $SU(N)$ as $N\mapsto\infty$ has an odd homotopy type: All its homotopy groups $\pi_{2k+1}U(\infty)$ are isomorphic to $\mathbb{Z}$ whereas the even homotopy groups are trivial. For this reason the group of based gauge transformations $f:M\to U(N)$, in the limit $N\mapsto\infty$, for $M=S^{2n}$ is homotopic to $U(\infty)$. In the odd-dimensional case, $M=S^{2n+1}$, the group of gauge transformations has an even homotopy type: All the even homotopy groups are isomorphic to $\mathbb{Z}$ and the odd homotopy groups are trivial. Denoting the gauge group in the even case by G [which has the homotopy type of $U(\infty)$] then the group of gauge transformations in the odd case is the group of based loops ΩG. This later group has the homotopy type of U'_p for any $p\geqslant 1$ where U'_p is defined in the following way: Let ϵ be a grading operator (it could be the sign of a Dirac operator) in a Hilbert space, with eigenvalues ± 1, both eigenspaces infinite dimensional. Set $U'_p(H)=\{g\in U(H)|[\epsilon,g]\in L_p\}$. Here $U(H)$ is the (contractible) group of all unitaries in the Hilbert space H. Recall that $U_{p+}(H)$ is the group of unitary elements in the algebra $\mathcal{B}$. All elements g in $U_{p+}(H)$ satisfy $[\epsilon,g]\in L_{p+}$.

Let now D_p, p an even integer, be a Hermitian operator in H such that $1/|D_p|\in L_{p+}$ and let Γ be a Hermitian operator in H such that $\Gamma^2=1$ and $\Gamma D_p=-D_p\Gamma$. Let $D_{p+1}=i\Gamma(d/dt)+D_p$. This operator is self-adjoint in an appropriate dense domain in the Hilbert space $\mathcal{H}=L^2(S^1,H)$ and has the property $1/|D_{p+1}|\in L_{(p+1)+}$.

A generalized vector potential is defined as a Hermitian time dependent bounded operator $A(t)$ in H. The ''Dirac operator'' coupled to $A(t)$ is then $D_{p+1}+A(t)$. The vector potential can be split as $A=A_0+A_1$, where A_0 commutes with Γ (the ''time component'' of A) and A_1 anticommutes with Γ (this is the ''space component'' of A). The time dependent gauge transformations are smooth functions $g(t)$ with values in the group $U_{p+}(H,\Gamma)$ of unitary operators $g\in U_{p+}(H)$ such that $[\Gamma,g]=0$. We can split $H=H_1\oplus H_2$ to eigenspaces of Γ corresponding to eigenvalues ± 1. Since $g\in U_{p+}(H,\Gamma)$ commutes with Γ we can write g as a direct sum of linear operators $g_i:H_i\to H_i$, $i=1,2$.

The group $U_{p+}(H,\Gamma)$ is a subgroup of the group $U'_{p+}(H,\Gamma)$ which consists of unitary operators g such that $[\epsilon,g]\in L_{p+}$ and $\Gamma g=g\Gamma$. These conditions mean that $g=g_1\oplus g_2$ with $g_2-\epsilon g_1\epsilon\in L_{p+}$. Thus the group U'_{p+} is parametrized by pairs of unitary operators (g_2,h) with g_2 an arbitrary unitary operator in H_2 and $h=g_2^{-1}\epsilon g_1\epsilon$ an unitary operator in H_2 such that $h-1\in L_{p+}$; we denote the group of these elements by $U^{p+}(H_2)$. Thus by Kuiper's theorem $U'_{p+}(H,\Gamma)$ is homotopy equivalent to $U^{p+}(H_2)$. A similar result holds for the subgroup

$U_{p+} \subset U'_{p+}$. In this case one chooses as parameters g_2 and $\tilde{h} = g_2^{-1} D_+^{-1} g_1 D_+$ and the conditions are as before. Here $D_+ : H_2 \to H_1$ is the restriction of D_p to H_2. [If D_+ has zero modes, replace D_+^{-1} by $D_-/(D_- D_+ + 1)$.]

For each time dependent perturbation there is a unique (nonperiodic) gauge transformation $g(t)$ such that $g(0) = 1$ and $A'(t) = g^{-1} A g + g^{-1}[D_p, g] + i g^{-1} \partial_t g$ is in the generalized temporal gauge, i.e., the even component $A'_0 = 0$. It follows that the quotient $\mathcal{A}/\mathcal{G}_0$, where $\mathcal{G}_0$ is the group of periodic gauge transformations $g(t)$ with $g(0) = 1$, is equal to the product $\mathcal{A}_1 \times U_{p+}(H, \Gamma)$. Here $\mathcal{A}_1$ is the space of bounded operators A in H such that $\Gamma A = -\Gamma A$ and the coordinate $g \in U_{p+}(H, \Gamma)$ comes from the holonomy $g = g(2\pi)$ around the circle.

Since $\mathcal{A}_1$ is an affine space, $\mathcal{A}/\mathcal{G}_0$ is homotopy equivalent to $U_{p+}(H, \Gamma)$.

We end this section by a remark on the homotopy type of the various groups involved. When the condition $[\epsilon, g] \in L_{p+}$ is replaced by $[\epsilon, g] \in L_p$ we obtain the group $U'_p(H, \Gamma) \subset U'_{p+}(H, \Gamma)$. Note that also $U_{p+} \subset U'_{p+\alpha}$ for any $\alpha > 0$. Similarly one can define U^p with $U^p \subset U^{p+} \subset U^{p+\alpha}$. According to Palais,[17] the groups U^p for all $p \geqslant 1$ are homotopy equivalent with $U(\infty)$. Similarly $U'_p(H)$ is homotopy equivalent to the group $U'_0(H)$ of unitary operators g such that $[\epsilon, g]$ is of finite rank. It is plausible that the same holds for the groups U_{p+} and U^{p+}, but the proof in Ref. 17 cannot directly be applied to these cases. The topology of these groups is determined by a norm topology on the operator ideals L_{p+}.

The natural norm on L_{p+} for $p > 1$ is given as

$$\|T\|_{p+} = \sup_{N \geqslant 1} N^{1/p-1} \sigma_N(T),$$

where $\sigma_N(T)$ is the sum of the N largest eigenvalues of $|T|$. In the case $p = 1$ the factor $N^{1/p-1}$ is replaced by $(\log N)^{-1}$.

V. THE GERBE OVER $\mathcal{A}/\mathcal{G}_0$

Each $A \in \mathcal{A}$ and $\lambda \notin \mathrm{Spec}(D_A)$ defines a fermionic Fock space $\mathcal{F}_{A,\lambda}$ with a Dirac vacuum $|A, \lambda\rangle$. To begin with, we have the polarization $\mathcal{H} = \mathcal{H}_+(A, \lambda) \oplus \mathcal{H}_-(A, \lambda)$ to a pair of infinite-dimensional subspaces, defined by the spectral projections $D_A > \lambda$ and $D_A < \lambda$. Then the Fock space $\mathcal{F}_{A,\lambda}$ is generated by the algebra of creation and annihilation operators $a^*(u), a(u)$ with the relations (2.1) and the characterization of the vacuum $|A, \lambda\rangle$ as in (2.2).

The Fock spaces depend on the choice of the vacuum level λ. However, for λ, $\mu \notin \mathrm{Spec}(D_A)$ there is a natural projective isomorphism $\mathcal{F}_{A,\lambda} \equiv \mathcal{F}_{A,\mu}$. This construction is equivariant with respect to the gauge group action, leading to a projective bundle $P\mathcal{F}$ over $\mathcal{A}/\mathcal{G}_0$. The question is whether there exists a true vector bundle $\mathcal{F}$ over $X = \mathcal{A}/\mathcal{G}_0$ such that $P\mathcal{F}$ is the projectivization of $\mathcal{F}$.

In general, there is an obstruction to the existence of $\mathcal{F}$. The obstruction can be described in terms of an element ω in $H^3(\mathcal{A}/\mathcal{G}_0, \mathbb{Z})$. This may or may not correspond to a nontrivial de Rham cohomology class. However, in the present setting there is a nontrivial obstruction as a de Rham form.

A more geometric way to describe the obstruction problem is to construct a family of local complex line bundles $\mathrm{DET}_{\lambda\lambda'}$ over $\mathcal{U}_{\lambda\lambda'} = \mathcal{U}_\lambda \cap \mathcal{U}_{\lambda'}$ with $\mathcal{U}_\lambda = \{A \in \mathcal{A}/\mathcal{G}_0 | \lambda \notin \mathrm{Spec}(D_A)\}$. Here $\mathrm{DET}_{\lambda\lambda'}$ is the top exterior power of the (finite-dimensional) spectral subspace of D_A corresponding to the open interval (λ, λ') (with $\lambda < \lambda'$). These line bundles have a set of natural isomorphisms,

$$\mathrm{DET}_{\lambda\lambda'} \otimes \mathrm{DET}_{\lambda'\lambda''} = \mathrm{DET}_{\lambda\lambda''},$$

which give the relations needed to define *a gerbe* over $\mathcal{A}/\mathcal{G}_0$. The gerbe is trivial if there is a family of local line bundles DET_λ over the open sets $\mathcal{U}_\lambda$ such that $\mathrm{DET}_{\lambda\lambda'} = \mathrm{DET}_\lambda^{-1} \otimes \mathrm{DET}_{\lambda'}$. Physically, these latter bundles are the local fermionic vacuum bundles. The nontriviality of the gerbe is measured by the nontriviality of the *Dixmier–Douady class* ω.[18]

The nontriviality of the obstruction as a de Rham form follows from the considerations in Refs. 11 and 19. The setting in the latter paper was similar to the present case except that a smaller base space, G_1 of unitaries which differ from the identity by a trace class operator, was considered instead of $U_{p+}(H,\Gamma)$.

On the group G_1 the obstruction form is particularly simple. It is given as the left invariant form

$$\omega(X,Y,Z)=\frac{i}{8\pi^2}\,\mathrm{tr}X[Y,Z],$$

where $X,Y,Z\in\mathrm{Lie}(G_1)$. This is normalized such that its integral over a fundamental 3-cycle in $U^3(H)\simeq U_3'(H,\Gamma)$ is equal to one. As it stands, ω does not extend to $U_p'(H,\Gamma)$ for $p>3$. Instead, we have to construct another representative for the cohomology class which extends to $U_p'(H,\Gamma)$, and actually also to the larger group $U_{p+}(H,\Gamma)$. Since $U_{q+}(H,\Gamma)\subset U_p'(H,\Gamma)$ for $q<p$, we get a normalized representative for the cohomology class also in the former group.

We shall treat both the even and odd cases at the same time and U_p' stands for $U_p'(H,\Gamma)$ in the case of an even Fredholm module and $U_p'=U_p'(H)$ in the odd case. In both cases we denote the left invariant Maurer–Cartan 1-form on the group by $g^{-1}\,\delta g$.

Next we consider the (d,δ) BRST bicomplex on the group manifold U_p'. As before, δ is the exterior differentiation on the group manifold with a choice of signs when acting on d forms such that $d\delta+\delta d=0$. We set $\Delta=d+\delta$, so $g^{-1}\,\Delta g=g^{-1}[\epsilon,g]+g^{-1}\,\delta g$ and the second component is the Maurer–Cartan 1-form on the group, i.e., the BRST ghost v.

The form

$$\theta_{k-j,j}=\int\,(g^{-1}\,\Delta g)^k|_{[j]}$$

is closed in the δ cohomology complex for any $k=0,1,2,\ldots$. Here $(\cdots)|_{[j]}$ denotes the component of δ degree (=ghost degree) j. In order that the integral is defined as a (graded) trace we have to assume that $k-j\geqslant p$.

Actually $\theta_{k-j,j}=0$ for all even k's. This follows from the anticommutator relations for d, δ and from the cyclic properties of the integral. The closedness for odd k follows from

$$\delta\theta=\int\,\delta(g^{-1}\,\Delta g)^k=\int\,\Delta(g^{-1}\,\Delta g)^k=-\int\,(g^{-1}\,\Delta g)^{k+1}=0,$$

since $k+1$ is even.

For $j=k$ and with a proper normalization $\theta_{k,j}$ is the generator of $H^k(U_p',\mathbb{Z})$ whereas for $j=0$ the integral gives the Fredholm index of P_+gP_+, where $P_+=\frac{1}{2}(1+\epsilon)$.

The case $j=3$ is of interest to us. In this case $k-j=2n$ is even, so $\theta_{2n,3}$ is an integral of an even d-form. We check that this is a nontrivial cohomology class. For that purpose, choose H as the Hilbert space of square integrable sections in a tensor product of a Dirac spinor bundle over the torus $T^{2n}=(S^1)^{2n}$ and a trivial $\mathbb{C}^N$ bundle with the natural $U(N)$ action in the fibers. The gauge transformations $g:T^{2n}\to U(N)$ act as multiplication operators on the spinor fields. Choosing D_0 as the Dirac operator defined by the metric on the torus and the trivial vector potential $A=0$ in the $\mathbb{C}^N$ bundle, one has,[5,20]

$$\mathrm{tr}_C\Gamma a_0[\epsilon,a_1]\cdots[\epsilon,a_{2n}]=\frac{1}{n!(2\pi i)^n}\int_{T^{2n}}\mathrm{tr}a_0\,da_1\cdots da_{2n},$$

for smooth functions $a_j:T^{2n}\to\mathbf{g}$, where $\mathbf{g}$ is the Lie algebra of $U(N)$ in its fundamental representation and 'd' on the right means the de Rham exterior derivative. It follows that, for any map $g(\cdot):S^3\to\mathrm{Map}(T^{2n},U(N))$, we have

$$\int_{S^3}\theta_{2n,3}=\frac{1}{n!(2\pi i)^n}\int_{S^3\times T^{2n}}\mathrm{tr}(g^{-1}\,dg)^{2n+3},$$

where g is thought of as a $U(N)$ valued function on $S^3\times T^{2n}$. In particular, for large N, this integral is equal to $24\pi^2\times$ a nonzero integer when g represents a nontrivial homotopy class in $\pi_{3+2n}(U(N))\simeq\mathbb{Z}$. Since $\theta_{2n,3}$ is nontrivial on the subgroup of smooth gauge transformations in $U_{2n+}(H,\Gamma)$ it must represent a nonzero cohomology class of the latter group and therefore also in the moduli space $X=\mathcal{A}/\mathcal{G}_0$.

Specializing from the result of Theorem 3.1 (cf. Lemma A3 in the Appendix) to the flat case $a=g^{-1}[\epsilon,g]$ we observe that the forms $\theta_{2n,3}$ can be written as sums of generalized traces of commutators plus a properly normalized 3-form $\mathrm{TR}(g^{-1}\,\delta g)^3$, modulo exact forms.

VI. SCHWINGER TERMS FROM THE DIXMIER–DOUADY CLASS

In this section we shall work with the Fredholm modules based on the ideals L_p instead of L_{p+}, and likewise with the groups of the type U_p'. This is because we want to use available information (based on results in Ref. 17) on the homotopy type of the infinite-dimensional groups.

Let θ_3 be a closed integral 3-form on $X=\mathcal{A}/\mathcal{G}_0$. The pull back $\pi^*\theta_3=\psi_3$ with respect to the canonical projection is a closed 3-form on the contractible space $\mathcal{A}$ and therefore $\psi_3=d\psi_2$ for some 2-form ψ_2. (In this section d means always the de Rham exterior derivative.)

Let $\mathcal{U}_\alpha$ be an open contractible subset of X and write $\theta_3=d\theta_{2,\alpha}$ on $\mathcal{U}_\alpha$. We define

$$\eta_\alpha=\psi_2-\pi^*\theta_{2,\alpha}$$

on $\pi^{-1}(\mathcal{U}_\alpha)$. Now $d\eta_\alpha=\psi_3-d\pi^*\theta_{2,\alpha}=\psi_3-\pi^*\,d\theta_{2\alpha}=\psi_3-\pi^*\theta_3=0$.

If $\mathcal{U}_\beta$ is another open subset of X then on $\mathcal{U}_\alpha\cap\mathcal{U}_\beta$ we have $\eta_\alpha-\eta_\beta=\pi^*(\theta_{2,\alpha}-\theta_{2,\beta})$. From this it follows, by the definition of the pull back map, that η_α and η_β agree *when evaluated along gauge orbits*. Thus there is a vertical 2-form η on $\mathcal{A}$, defined everywhere on $\mathcal{A}$, but which is closed only along gauge directions.

The vertical form η defines an extension of the Lie algebra of $\mathcal{G}$ by the Abelian Lie algebra **a** consisting of functions $f:\mathcal{A}\to\mathbb{C}$. The commutators are defined by

$$[(X,f),(Y,g)]=(\,[X,Y],\delta_X g-\delta_Y f+\eta(X,Y)).$$

On the right the Lie algebra elements X,Y are interpreted as vertical vector fields on $\mathcal{A}$. The Jacobi identity is precisely the condition that η is closed along vertical directions.

We can compute η more explicitly. Let $\mathcal{P}G$ denote the group of smooth paths in a group G originating from the identity in G. The product is defined as a pointwise multiplication along paths. Any $A\in\mathcal{A}$ splits uniquely as $A=A_0+A_1$ to even and odd components with respect to Γ. The even component A_0 is equal to $ig(t)^{-1}\partial_t g(t)$ for a uniquely defined smooth function $g:[0,1]\to U_p'(\Gamma,H)$ with $g(0)=1$. As in Sec. IV, we can write $\mathcal{A}=\mathcal{A}_1\times\mathcal{P}U_p'(\Gamma,H)$ and $\mathcal{A}/\mathcal{G}_0=\mathcal{A}_1\times U_p'(\Gamma,H)$.

Since $\mathcal{A}_1$ is a vector space, any closed form on $\mathcal{A}_1$ is exact and we may assume without loss of generality that θ_3 is a pull back of a form on $U_p'(\Gamma,H)$ with respect to the projection on the second factor.

By a direct calculation one can check that $d\psi_2=\pi^*\theta_3$ when ψ_2 is defined as

$$\psi_2(u,v)=\int_0^1\theta_3(g^{-1}\,\partial_t g,u_0(t),v_0(t))dt,$$

where the components u_0,v_0 of the tangent vectors $u,v\in\mathcal{A}$ are given as paths in the Lie algebra of $U_p'(\Gamma,H)$. Along vertical directions η is equal to ψ_2 and thus

$$\eta(g;X,Y)=\int_0^1 \theta_3(g^{-1}\partial_t g,X(t),Y(t))dt,$$

for periodic functions $X(t),Y(t)$ with values in Lie $(U_p'(\Gamma,H))$.

Since $\pi_2(U_p'(\Gamma,H))=0$, the group $\mathcal{G}_0$ of (based) loops in $U_p'(\Gamma,H)$ is simply connected. On the other hand, $\pi_2(\mathcal{L}_k U_p'(\Gamma,H))=\pi_3(U_p'(\Gamma,H))=\mathbb{Z}$ for any of the connected components $\mathcal{L}_k$ of the group $\mathcal{L}U_p'$ of smooth loops in U_p'. By Hurewicz' theorem, $H^2(\mathcal{L}_k U_p'(\Gamma,H),\mathbb{Z})=\mathbb{Z}$. In fact, the 2-form η restricted to a gauge orbit gives a representative for the basic class in $H^2(\mathcal{L}_k U_p',\mathbb{Z})$.

We shall work only in the connected component of identity $\mathcal{L}_0 U_p'$. The group extension of $\mathcal{L}_0 U_p'(\Gamma,H)$ corresponding to the Lie algebra extension above can be explicitly constructed in the same way as was done in Ref. 21 in the case of groups of classical gauge transformations.

The construction starts from the Cartesian product $\mathcal{P}(\mathcal{L}_0 U_p')\times \mathrm{Map}(\mathcal{A},S^1)$. The product is defined as

$$(f_1,\alpha_1)(f_2,\alpha_2)=\left(f_1 f_2,\alpha_1\alpha_2^{f_1}\exp\left(2\pi i\int_K \eta\right)\right),$$

where $f_1 f_2$ is just the point-wise product in the path group, α^f is the function obtained form α by gauge transforming (using the right action) the argument by $f(1)\in\mathcal{L}_0 U_p'$. The phase is evaluated by integrating the vertical 2-form η over a 2-surface K in the fiber at $A\in\mathcal{A}$. The surface is chosen such that its boundary consists of the paths $A\cdot f_1(t)$, $A\cdot f_1(1)f_2(t)$ and $A\cdot f_1(t)f_2(t)$. The value of the phase factor does not depend on the choice of K since the difference in the exponent is $2\pi i$ times an integral of the integral 3-form ω_3 over a closed 3-surface in U_p' and this is an integer.

The extension $\widehat{\mathcal{L}_0 U_p'}$ is now defined as

$$\mathcal{P}(\mathcal{L}_0 U_p')\times \mathrm{Map}(\mathcal{A},S^1)/\mathcal{Q},$$

where $\mathcal{Q}$ is the group of based loops (at the identity) in $\mathcal{L}_0 U_p'$ and the right action of $\mathcal{Q}$ is defined as the point-wise right action on $\mathcal{P}(\mathcal{L}_0 U_p')$ and as the simultaneous phase shift $\alpha\to\alpha'$,

$$\alpha'(A)=\alpha(A)\exp\left(2\pi i\int_\Sigma \eta\right),$$

where Σ is the 2-surface in the fiber through A, bounded by the loop $A\cdot g(t), g\in\mathcal{Q}$.

VII. THE CASE OF A NONCOMMUTATIVE TORUS

In this section we want to apply the general results for computing cocycles on a noncommutative torus. We start by recalling the basic definitions.[22]

Consider an algebra consisting of finite linear combinations of "noncommutative Fourier modes" u^r, where $r=(r_1,\ldots,r_n)$ is a vector of integers,

$$u^r=e^{\pi i\Sigma_{j<k}\theta_{jk}r_j r_k}u_1^{r_1}\cdots u_n^{r_n}$$

and the relations in the algebra are given as

$$u_i u_j=e^{-2\pi i\theta_{ij}}u_j u_i, \tag{7.1}$$

where θ is a real antisymmetric matrix. These relations lead to the multiplication formula

$$u^r\cdot u^{r'}=\lambda(r,r')u^{r+r'}, \tag{7.2}$$

with $\lambda(r,r')=\exp(-\pi i\Sigma r_j\theta_{jk}r_k')$.

There is an antilinear conjugation defined by $(u^r)^*=u^{-r}$ and a trace τ such that $\tau(u^r)=0$ if $r\neq 0$ and $\tau(u^0)=\tau(1)=1$. We define a Hilbert space H by tensoring the above algebra with the spinor and internal symmetry space $V=\mathbb{C}^{[(n+1)/2]}\otimes\mathbb{C}^N$ and completing with respect to the inner product defined by $\langle u^r,u^{r'}\rangle=\tau((u^r)^*u^{r'})=\delta_{rr'}$. Here $[a]$ is the integer part of a real number a. The trace is extended to the tensor product of the torus algebra and of End V by the matrix trace on End V. The adjoint of a multiplication operator by the element u^r is $(u^r)^*=u^{-r}$.

There is a commutative family of derivations δ_j $(j=1,2,...,n)$ defined by $\delta_j(u^r)=r_ju^r$. These derivations are represented by unbounded operators P_j in the Hilbert space H through $P_ju^r=r_ju^r$ which means that $[P_j,u^r]=r_ju^r$ for the corresponding multiplication operators u^r (we use the same notation for elements in the noncommutative torus algebra and vectors in the Hilbert space).

The (free) Dirac operator is defined by

$$D_0=\sum_k \gamma^k\delta_k,$$

where the gamma matrix algebra is defined using the standard Euclidean metric, $\gamma_i\gamma_j+\gamma_j\gamma_i=2\delta_{i,j}$.

As in the case of pseudodifferential operators on an ordinary torus we can introduce a symbol calculus. Consider first classical PSDO symbols $f=f(p)$ which are functions of the momenta p_j only and which have an asymptotic expansion $f\sim f_N+f_{N-1}+\cdots$ as a series of homogeneous symbols f_j of order j in the momenta, i.e., $f_j(\lambda p)=\lambda^j f(p)$ for $\lambda>1$ and for large momenta. Each such symbol defines an (in general unbounded) operator in H through $fu^r=f(r)u^r$. More generally, we consider operators

$$f=\sum_r u^r f^{(r)},$$

where each $f^{(r)}$ is a classical symbol of the above type tensored with a matrix operating in V. The definition makes sense even for infinite linear combinations assuming that the sequence $|f^{(r)}(p)|$ is rapidly decreasing as $|r|\to\infty$ for all values of p. From the definitions it follows that

$$u^{-r}f(p)u^r=f(p+r), \tag{7.3}$$

and therefore the product of a pair f,g of operators is defined by the "star product"

$$(f*g)^{(r)}(p)=\sum_s f^{(r-s)}(p)g^{(s)}(p+s)\lambda(r-s,s). \tag{7.4}$$

The only difference as compared to the commutative torus is the appearance of complex phases λ on the right hand side. The trace of the operator f (when it is defined) is given by

$$\mathrm{tr}\, f=\sum_{p\in\mathbb{Z}^n}\mathrm{tr}\, f^{(0)}(p),$$

where the trace on the right is the ordinary matrix trace in V. As usual, f is trace-class if and only if $\mathrm{ord}(f)<-n$. The borderline case $\mathrm{ord}(f)=-n$ is of special interest to us.

For complex numbers z with an enough large real part one can define

$$\zeta(z;f)=\mathrm{tr}\,(|P|+1)^{-z}f. \tag{7.5}$$

If f is trace-class then ζ is holomorphic at $z=0$ and $\mathrm{tr}\, f=\zeta(0;f)$. If $\mathrm{ord}(f)\geqslant -n$, the function ζ has in general a pole at $z=0$. The pole depends only on the component f_{-n}. The proof of this

statement follows from the corresponding result for PSDO's on the commutative torus since the spectrum of $f^{(0)}$ is exactly the same as in the commutative case. For the same reason the residue at $z=0$ can be calculated as a momentum space integral,

$$\mathrm{Res}(f)=\mathrm{res}_{z=0}\zeta(z;f)=\int_{|p|=1}\mathrm{tr}\, f^{(0)}_{-n}(p)dp. \tag{7.6}$$

For classical PSDO's on a compact manifold there is a useful formula relating the renormalized (noncyclic) trace of a commutator to an operator residue. This formula was used for the calculation of Schwinger terms in Refs. 9 and 23 and later generalized in Ref. 24 to a wider class of operators. First one defines a renormalized trace for nontraceclass PSDO's by

$$\mathrm{TR}\,A=\lim_{z\to 0}\left(\mathrm{tr}\,A|D|^{-z}-\frac{1}{z}\mathrm{Res}\,A\right). \tag{7.7}$$

The lack of cyclicity of TR is given by

$$\mathrm{TR}[A,B]=\mathrm{Res}\,A[l,B], \tag{7.8}$$

where $l=\log|D_0|=\log|P|$. We check that the same formula holds in the case of a noncommutative torus. By linearity, it is sufficient to prove the formula for each Fourier mode separately. So we take $A=u^r f(p)$ and $B=u^s g(p)$. By the definition of the trace, TR AB is nonzero only when $s=-r$, so we assume this. But now $\mathrm{TR}\,AB=\mathrm{TR}\,\lambda(r,s)\tilde{f}g$, where $\tilde{f}(p)=f(p-r)$. Since $\lambda(r,s)=1$ when $s=-r$, the trace formula for NC torus reduces to the formula on commutative torus and thus (7.8) holds.

Let us look closer at the case $n=3$. We have seen that the Schwinger term in three dimensions is equivalent (modulo coboundaries) to the "local" expression

$$8\omega_{3,2}=\mathrm{TR}\{[X,\epsilon a[\epsilon,Y]]-[Y,\epsilon a[\epsilon,X]]-2[X\epsilon,Y]+2[Y\epsilon,X]\}.$$

We now apply the residue formula in the case of noncommutative multiplication operators X,Y and we obtain

$$8\omega_{3,2}=-\mathrm{Res}\,\epsilon a[\epsilon,Y][l,X]+\mathrm{Res}\,\epsilon a[\epsilon,X][l,Y]. \tag{7.9}$$

Taking $a=F-\epsilon$ and $F=(D_0+A)|D_0+A|^{-1}$, the sign of a Dirac operator defined by a potential $A=\sigma^k A_k$ on the noncommutative torus, a straight-forward computation gives

$$\omega_{3,2}=\frac{i\pi}{6}\tau(A[[D_0,X],[D_0,Y]])=\frac{i\pi}{3}\epsilon^{ijk}\tau(A_i(\delta_j(X)\delta_k(Y)-\delta_j(Y)\delta_k(X))). \tag{7.10}$$

We have used the expansion

$$F=\epsilon+A/|P|-\epsilon A^k P_k/|P|^2+O(1/|P|^2)$$

and the formulas

$$\begin{aligned}[\epsilon,u^{(r)}]&=u^{(r)}(u^{(-r)}\epsilon u^{(r)}-\epsilon)\\&=u^{(r)}\left(\frac{(P_k+r_k)\sigma^k}{|P+r|}-\frac{P_k\sigma^k}{|P|}\right)\\&=u^{(r)}(r_k\sigma^k/|P|-\epsilon P_k r^k/|P|^2+O(1/|P|^2)),\end{aligned}$$

and similarly

$$[l,u^{(r)}]=u^{(r)}P_k r^k/|P|^2+O(1/|P|^2).$$

The derivation of (7.10) is then completed by taking into account

$$\mathrm{tr}\,\sigma_i\sigma_j\sigma_k=2i\epsilon_{ijk}\ \text{ and }\ \mathrm{Res}\frac{p_ip_j}{|p|^5}=\frac{4\pi}{3}\delta_{i,j}.$$

APPENDIX: NONCOMMUTATIVE DESCENT EQUATIONS

We assume linear operators d and δ acting on polynomials generated by a, v, $d(a)$, $d(v)$, $\delta(a)$ and $\delta(v)$, such that $d^2=0=\delta^2=d\delta+\delta d$. These operations are then uniquely fixed by the additional rules in (2.6) together with $\epsilon^2=I$. As mentioned in the text, we will use the simplified notation $x=a$, ϵ, v and δ short for $s(x)$ defined in (2.7), resp. (2.8), for even, resp. odd, Fredholm modules throughout this Appendix except in the Remark at the end.

We now state and give a proof of the noncommutative descent equations. We define

$$F(t)=td(a)+t^2a^2+(1-t)d(v),$$

$$F'(t)=(t^2-t)v^2+td(v)$$

and

$$\omega_{2n-1}=\int_0^1 dt\Psi_{2n-1}(t),\quad \tilde{\omega}_{2n-1}=\int_0^1 dt\ \ t\Psi_{2n-1}(t),$$

and similarly for ω'_{2n-1} and $\tilde{\omega}'_{2n-1}$, where

$$\Psi_{2n-1}(t)=\sum_{\nu=0}^{n-1}F(t)^{n-1-\nu}aF(t)^{\nu},$$

$$\Psi'_{2n-1}(t)=\sum_{\nu=0}^{n-1}F'(t)^{n-1-\nu}vF'(t)^{\nu}.$$

The noncommutative descent equations can be summarized by the following algebraic identities.

Lemma A1:

$$\begin{aligned}\delta(\omega_{2n-1})+d(\omega_{2n-1})&=-[v,\omega_{2n-1}]_+-[a,\tilde{\omega}_{2n-1}]_++F^n-(d(v))^n,\\ \delta(\omega'_{2n-1})+d(\omega'_{2n-1})&=-[v,\tilde{\omega}'_{2n-1}]_++(d(v))^n,\end{aligned}\tag{A2}$$

where $F=d(a)+a^2$.

Comparing equal powers of v we obtain from (A2),

$$\begin{aligned}d(\omega_{2n-1,0})&=-[a,\tilde{\omega}_{2n-1,0}]_++F^n,\\ \delta(\omega_{2n-k,k-1})+d(\omega_{2n-1-k,k})&=-[v,\omega_{2n-k,k-1}]_+-[a,\tilde{\omega}_{2n-k-1,k}]_+,\\ &\qquad k=1,\ldots,n-1,\\ \delta(\omega_{n,n-1})+d(\omega_{n-1,n})&=-[v,\omega_{n,n-1}]_+,\\ \delta(\omega_{2n-k,k-1})+d(\omega_{2n-k-1,k})&=-[v,\tilde{\omega}_{2n-k,k-1}]_+,\\ &\qquad k=n+1,\ldots,2n-1,\end{aligned}\tag{A3}$$

$$\delta(\omega_{0,2n-1}) = -[v, \tilde{\omega}_{0,2n-1}]_+ ,$$

where the k in $\omega_{2n-k-1,k}$ is the ghost degree, i.e., power in v, and

$$\omega_{2n-1} = \omega_{2n-1,0} + \omega_{2n-2,1} + \cdots + \omega_{n,n-1} + \cdots ,$$

$$\omega'_{2n-1} = \omega_{n-1,n} + \omega_{n-2,n+1} + \cdots + \omega_{0,2n-1} + \cdots$$

[note that the equation for $k=n$ is obtained by combining the two equations

$$\delta(\omega_{n,n-1}) = -[v, \omega_{n,n-1}]_+ - (d(v))^n,$$

$$d(\omega_{n-1,n}) = (d(v))^n,$$

obtained from the first and the second relation in Eq. (A2), respectively].

Proof of Lemma A1: (A2): We observe that

$$F(t) = (\epsilon + \delta + ta + v)^2 - I,$$

implying $\partial_t(F(t)) = [\epsilon + \delta + ta + v, a]_+$, and therefore

$$\begin{aligned} F^n - (d(v))^n &= \int_0^1 dt \partial_t (F(t))^n \\ &= \int_0^1 dt \sum_{\nu=0}^{n-1} F(t)^{n-1-\nu} [\epsilon + \delta + ta + v, a]_+ F(t)^\nu \\ &= \int_0^1 dt [\epsilon + \delta + ta + v, \Psi_{2n-1}]_+ \end{aligned}$$

[we used that $\epsilon + \delta + ta + v$ commutes with $F(t)$], implying the first identity in Eq. (A2). In a similar manner,

$$F'(t) = (\epsilon + \delta + tv)^2 - I,$$

implies $\partial_t(F'(t)) = [\epsilon + \delta + tv, v]_+$ and thus

$$\begin{aligned} (d(v))^n &= \int_0^1 dt\, \partial_t (F'(t))^n \\ &= \int_0^1 dt \sum_{\nu=0}^{n-1} F'(t)^{n-1-\nu} [\epsilon + \delta + tv, v]_+ F'(t)^\nu \\ &= \int_0^1 dt [\epsilon + \delta + tv, \Psi'_{2n-1}]_+ , \end{aligned}$$

yielding the second identity in Eq. (A2). □

Some applications: A simple special case of Eqs. (A3) is the following result. We point out that here, $x = a$ and ϵ *need not* to be interpreted as $s(x)$ but can be taken directly as operators in H.

Lemma A2: For flat a, i.e., $a = g^{-1}[\epsilon, g] = [g^{-1}\epsilon, g]$ for some invertible operator g, the following holds true:

$$a^{2n+1} = 4a^{2n-1} + 2[\epsilon, a^{2n-1}\epsilon] - [a, \epsilon a^{2n-1}], \tag{A4}$$

for all positive integers n.

Proof: For flat a we have $F=d(a)+a^2=0$, and thus the first equation in (A3) implies $[\epsilon,\omega_{2n-1,0}]_+=-[a,\tilde{\omega}_{2n-1,0}]_+$ where $\omega_{2n-1,0}$ is obtained from ω_{2n-1} above by substituting $F(t)=(t^2-t)a^2$, i.e., $\omega_{2n-1,0}=\int_0^1 dtn(t^2-t)^{n-1}a^{2n-1}\equiv c_n a^{2n-1}$, and similarly $\tilde{\omega}_{2n-1,0}=\int_0^1 dt\, tn(t^2-t)^{n-1}a^{2n-1}\equiv\tilde{c}_n a^{2n-1}$. Note that

$$2\tilde{c}_n-c_n=\int_0^1 dt\ \ n(2t-1)(t^2-t)^{n-1}=0,$$

implying

$$2[\epsilon,a^{2n-1}]_+=-[a,a^{2n-1}]_+ .$$

Multiplying this identity by ϵ we obtain

$$2\epsilon[\epsilon,a^{2n-1}]_+=4a^{2n-1}+2[\epsilon,a^{2n-1}\epsilon]=-\epsilon[a,a^{2n-1}]_+=-[\epsilon,a]_+a^{2n-1}+[a,\epsilon a^{2n-1}].$$

Inserting $[\epsilon,a]_+=d(a)=-a^2$ we obtain Eq. (A4). □

Note that the lemma gives as a byproduct a simple proof of the known index formula for the Fredholm index $\mathrm{ind}\,P_+gP_+$, where $g\in U_p'(H_+\oplus H_-)$ and P_+ is the projection to H_+. Namely, since according to Ref. 17 the connected components of U_p' are labeled by the Fredholm index of P_+gP_+, the index is a homotopy invariant, and the multiplication operator by the function $f(x)=e^{inx}$ on the unit circle $0\leqslant x\leqslant 2\pi$ has index $\mathrm{ind}\,P_+fP_+=n$ (by a simple exercise in Fourier analysis), it is sufficient to check that

$$n=\tfrac{1}{2}\,\mathrm{tr}\,f^{-1}[\epsilon,f],$$

and the general formula

$$\mathrm{ind}\,P_+gP_+=2^{-p}\,\mathrm{tr}(g^{-1}[\epsilon,g])^p$$

follows for odd positive integers p.

Local cocyles: The basic result implying the existence of the local cocycles is the following.

Lemma A3: The forms defined above obey

$$\begin{aligned}\epsilon[v,\omega_{2n-k,k-1}]_+ + \epsilon[a,\tilde{\omega}_{2n-k-1,k}]_+ &\simeq c_{n,k}\omega_{2n-k+1,k},\quad k=1,...,n-1,\\ \epsilon[v,\omega_{n,n-1}]_+ &\simeq c_{n,n}\omega_{n+1,n},\\ \epsilon[v,\tilde{\omega}_{2n-k,k-1}]_+ &\simeq c_{n,k}\omega_{2n-k+1,k},\quad k=n+1,...,2n,\end{aligned}\tag{A5}$$

where

$$c_{n,k}=\frac{2n+1-k}{n+1},$$

and "≃" means "equal up to commutator terms."

Proof: To prove the first relation in Eq. (A5) we observe

$$\begin{aligned}\epsilon[v,\omega_{2n-k,k-1}]_+ + \epsilon[a,\tilde{\omega}_{2n-k-1,k}]_+ &= [\epsilon,v]_+\omega_{2n-k,k-1}+[\epsilon,a]_+\tilde{\omega}_{2n-k-1,k}+[\epsilon\omega_{2n-k,k-1},v]\\ &\quad +[\epsilon\tilde{\omega}_{2n-k-1,k},a]\simeq d(v)\omega_{2n-k,k-1}+d(a)\tilde{\omega}_{2n-k-1,k},\end{aligned}$$

and thus what we actually need to prove is

$$d(v)\omega_{2n-k,k-1}+d(a)\tilde{\omega}_{2n-k-1,k}\simeq\frac{2n+1-k}{n+1}\omega_{2n-k+1,k}. \tag{A6}$$

For that it is convenient to define an ordering symbol $\{\ \ \}$ so that

$$\sum_{N=0}^{\infty}(a_1+a_2+\cdots a_k)^N:=\sum_{m_1,m_2,\ldots,m_k=0}^{\infty}\{a_1^{m_1},a_2^{m_2},\ldots,a_k^{m_k}\},$$

for all operators a_j (we regard this as generating function defining all possible $\{a_1^{m_1},a_2^{m_2},\ldots,a_k^{m_k}\}$). We observe that this definition implies

$$a_1\{a_1^{m_1},a_2^{m_2},\ldots,a_k^{m_k}\}\simeq\frac{m_1+1}{m_1+m_2+\cdots+m_k+1}\{a_1^{m_1+1},a_2^{m_2},\ldots,a_k^{m_k}\}.$$

We can thus write $\omega_{2n-k-1,k}=\int_0^1 dt\Omega_{2n-k-1,k}$ and $\tilde{\omega}_{2n-k-1,k}=\int_0^1 dt\, t\Omega_{2n-k-1,k}$, where

$$\Omega_{2n-k-1,k}=\{u^k,(p+q)^{n-k-1},a\}=\sum_{l=0}^{n-k-1}\{u^k,p^{n-k-l-1},q^l,a\},$$

with $u\equiv(1-t)d(v)$, $p\equiv td(a)$ and $q\equiv t^2a^2$. To prove Eq. (A6) we thus need to show that

$$\frac{2n+1-k}{n+1}\int_0^1 dt\{u^k,p^{n-k-l},q^l,a\}\simeq\int_0^1 dt\left(\frac{u}{1-t}\{u^{k-1},p^{n-k-l},q^l,a\}+p\{u^k,p^{n-k-l-1},q^l,a\}\right),$$

which follows from

$$\int_0^1 dt\left(\frac{2n+1-k}{n+1}-\frac{k}{(n+1)(1-t)}-\frac{n-k-l}{n+1}\right)t^{n-k-l}t^{2l}(1-t)^k$$
$$=\frac{1}{n+1}\int_0^1 dt\,\partial_t(t^{n+1-k+l}(1-t)^k)=0.$$

The proof of the second and third relations in Eq. (A5) is similar but simpler: Recalling $u=(1-t)d(v)$ we get

$$\epsilon[v,\omega_{n,n-1}]_+\simeq d(v)\omega_{n,n-1}=\int_0^1 dt\frac{1}{1-t}u[u^{n-1},a]_+$$
$$=\int_0^1 dt\frac{1}{1-t}\frac{n}{n+1}[u^n,a]_+$$
$$=\int_0^1 dt[u^n,a]_+=c_{n,n}\omega_{n+1,n},$$

since

$$\frac{n}{n+1}\int_0^1 dt(1-t)^{n-1}=\int_0^1 dt(1-t)^n,$$

and finally, with $r\equiv td(v)$ and $s\equiv(t^2-t)v^2$,

$$\epsilon[v,\tilde{\omega}_{2n-k,k-1}]_+ \simeq d(v)\tilde{\omega}_{2n-k,k-1}$$
$$= \int_0^1 dt \;\; r\{r^{2n-k}, s^{k-1-n}, v\}$$
$$\simeq \int_0^1 dt \, \frac{2n+1-k}{n+1} \{r^{2n+1-k}, s^{k-1-n}, v\} = c_{n,k}\omega_{2n-k+1,k}.$$

□

We obtain a generalization of Lemma A2.

Theorem A4: *Let*

$$\omega'_{2n-1-k,k} = C_{n,k}\omega_{2n-1-k,k}, \quad \text{where} \quad C_{n,k} = (-1)^n \frac{(2n-1-k)!!}{2^n n!}.$$

Then

$$\omega'_{2n+1-k,k} \simeq \omega'_{2n-1-k,k} - \frac{C_{n,k}}{2C_{n,k-1}} \delta(\epsilon\omega'_{2n-k,k-1}). \tag{A7}$$

Proof: Using the lemmas above, we observe that

$$-\delta(\epsilon\omega_{2n-k,k-1}) + 2\omega_{2n-1-k,k} \simeq -c_{n,k}\omega_{2n+1-k,k}, \quad k = 1,2,...,2n-1, \tag{A8}$$

where we have used that $\epsilon d(\omega) = \epsilon[\epsilon,\omega]_+ \simeq 2\omega$. By multiplying this with $(1/2)C_{n,k}$ and using the recursion relation

$$-\tfrac{1}{2}c_{n,k}C_{n,k} = C_{n+1,k},$$

we get Eq. (A7). □

Theorem A5: *For even k the k-cocyle,*

$$\omega^{\mathrm{loc}}_{2n+1-k,k} = \omega_{2n+1-k,k} + \delta B_{2n-k,k-1},$$

is local for some cochain $B_{2n-k,k-1}$, i.e., a sum of commutator terms. In the case when k is odd one has to add a term proportional to $\omega_{0,k}$ to the right hand side of the equation.

Proof: Equation (A8) implies

$$\omega_{2n+1-k,k} \simeq -\frac{2}{c_{n,k}}\omega_{2n-1-k,k} - \frac{1}{c_{n,k}}\delta(\omega_{2n-k,k-1})$$
$$\simeq \sum_{l'=0}^{l} (-1)^{l'+1} \frac{2^{l'}}{c_{n,k}c_{n-1,k}\cdots c_{n-l',k}} \delta(\omega_{2n-2l'-k,k-1})$$
$$+ (-1)^{l+1} \frac{2^l}{c_{n,k}c_{n-1,k}\cdots c_{n-l,k}} \omega_{2n-1-2l-k,k}.$$

In particular,

$$\omega_{2n+1-2k,2k} \simeq \sum_{l'=0}^{n-k} (-1)^{l'+1} \frac{1}{2} \frac{(n+1)!(n-2k-l')!}{(n-l')!(n-2k)!} \delta(\omega_{2n-2l'-2k,2k-1})$$

and

$$\omega_{2n-2k,2k+1} \simeq \sum_{l'=0}^{n-k-1} (-1)^{l'+1} \frac{1}{2} \frac{(n+1)!(n-2k-l'-1)!}{(n-l')!(n-2k-1)!} \delta(\omega_{2n-2l'-2k-1,2k}) + (-1)^{n-k} \frac{1}{2} \binom{n+1}{k} \omega_{0,2k+1},$$

which also gives an explicit formula for $B_{2n-k,k-1}$. □

Remark: Theorem A5 does not yet imply Theorem 3.1: we recall that we worked on an abstract BRST level here and $x=a$, ϵ, v and δ, etc. was short for $s(x)$ as in Eq. (2.7), resp. (2.8). As discussed in the text, to obtain forms $\omega_{2n-1-k,k}(a;X_1,\ldots,X_k)$ one has to evaluate the ghosts v at tangent vectors X_j and, in the case of an odd Fredholm module, take the trace in the auxiliary space with the Pauli matrix σ_3. To complete the proof of Theorem 3.1 one needs to check that the commutators mentioned in Theorem A5—which are on the abstract BRST level—turn into the commutators on the operator level mentioned in Theorem 3.1. We now show that this is indeed the case. For that we need to distinguish $s(x)$ from x. The commutators referred to in Theorem A5 are then of the form $[s(\alpha),s(\beta)]$ where $s(\alpha)$ and $s(\beta)$ are monomials in $s(v)$, $s(a)$ and $s(\epsilon)$.

In the case of an even Fredholm module, there is no extra auxiliary space [cf. (2.7)], and the BRST commutators $[s(\alpha),s(\beta)]$ immediately become operator commutator after the evaluation of the ghosts at the tangent vectors.

We thus can concentrate on odd Fredholm modules. Let n_α be the ghost degree of α [the number of $s(v)$] and d_α the sum of the numbers of $s(\epsilon)$ and $s(a)$ (which is of course only defined modulo 2), and similarly for β. Then $s(\alpha)=\pm\alpha\otimes\sigma_3^{d_\alpha}\sigma_1^{n_\alpha}$ and similarly for β, and thus

$$[s(\alpha),s(\beta)] = \pm((-1)^{n_\alpha d_\beta}\alpha\beta - (-1)^{d_\alpha n_\beta}\beta\alpha)\otimes\sigma_3^{d_\alpha+d_\beta}\sigma_1^{n_\alpha+n_\beta}.$$

In the odd case the ghost degree $k=n_\alpha+n_\beta$ is even and $d_\alpha+d_\beta$ is odd. Evaluating $[s(\alpha),s(\beta)]$ for Lie algebra elements X_j, we obtain (up to an irrelevant overall factor)

$$\sum_{P\in S_k} \mathrm{sign}_P(\alpha(X_{P(1)},\ldots,X_{P(n_\alpha)})\beta(X_{P(n_\alpha+1)},\ldots,X_{P(k)}) - (-1)^{n_\alpha n_\beta}(-1)^{n_\alpha d_\beta + d_\alpha n_\beta}\beta(X_{P(n_\alpha+1)},\ldots,X_{P(k)})\alpha(X_{P(1)},\ldots,X_{P(n_\alpha)})),$$

where S_k is the permutation group of k elements and sign_P gives the parity of a permutation P. One now needs to show that this always corresponds to a sum of commutators. For that we need only to check that the exponent $n_\alpha n_\beta + n_\alpha d_\beta + n_\beta d_\alpha$ is always even. But this follows from the fact that here $n_\alpha+n_\beta$ is even and $d_\alpha+d_\beta$ is odd.

Supersymmetry (SUSY) in quantum mechanics is extended from square-integrable states to those satisfying the outgoing-wave boundary condition, in a Klein–Gordon formulation. This boundary condition allows both the usual normal modes and quasinormal modes with complex eigenvalues ω. The simple generalization leads to three features: The counting of eigenstates under SUSY becomes more systematic; the linear-space structure of outgoing waves (nontrivially different from the usual Hilbert space of square-integrable states) is preserved by SUSY; and multiple states at the same frequency (not allowed for normal modes) are also preserved. The existence or otherwise of SUSY partners is furthermore relevant to the question of inversion: Are open systems uniquely determined by their complex outgoing-wave spectra? © *2001 American Institute of Physics.*
[DOI: 10.1063/1.1388900]

I. INTRODUCTION

A. Outline

Supersymmetry (SUSY) in quantum field theory[1,2] relates bosons to fermions. Its analog in quantum mechanics[3,4] is interesting in its own right, and relates two (typically one-dimensional) Hamiltonians H and $\tilde{H}$ with the same spectrum of normal modes (NMs), or the same spectrum apart from one state. The classical limit[5] relates a one-parameter family of Hamiltonians $H(\xi)$. Although interest in SUSY quantum mechanics has in recent years been prompted by the analogous and important developments in field theory, the method is essentially the theory of Darboux transformations for second-order linear differential equations[6] and is also closely related to the factorization method.[7]

This paper generalizes SUSY in quantum mechanics to open systems and in particular to their quasinormal modes (QNMs), which are eigenfunctions satisfying the outgoing-wave condition (OWC) at infinity. The generalization itself is straightforward, and we focus on the novel features that ensue. After a brief introduction to open systems and QNMs in the rest of this section, this paper presents three main results.

a)Electronic mail: kyoung@cuhk.edu.hk

First, in the conventional discussion for the Schrödinger equation, spectrum preservation can be conveniently expressed in terms of the number of NMs $n(E)$ for H and $\tilde{n}(E)$ for $\tilde{H}$ at the same energy E, namely, that $n(E)=\tilde{n}(E)$ for all real E except a privileged value E_0 (usually chosen to be $E_0=0$). At this value, the difference is given by the Witten index[3]

$$\Delta(E_0)=n(E_0)-\tilde{n}(E_0), \tag{1.1}$$

which can be $+1$, 0, or -1. For open systems with the OWC, time-reversal invariance is broken, and it is appropriate to consider a Klein–Gordon equation (KGE) instead—in effect replacing $\partial_t \mapsto \partial_t^2$ or $E \mapsto \omega^2$ in the time-independent equation, and distinguishing $+\omega$ from $-\omega$ (since reversing the two converts an outgoing to an incoming wave).[8] Section II shows that the equality of spectrum for the KGE extends to the complex ω-plane except at the two privileged frequencies $\pm\Omega=\pm\sqrt{E_0}$, namely,

$$n(\omega)=\tilde{n}(\omega), \quad \omega \neq \pm\Omega. \tag{1.2}$$

At $\pm\Omega$, one needs to consider

$$\Delta(\pm\Omega)=n(\pm\Omega)-\tilde{n}(\pm\Omega). \tag{1.3}$$

These are again $+1$, 0, or -1, but with $\Delta(\Omega)=-\Delta(-\Omega)$ determined by the asymptotic behavior of the SUSY generator, to be defined below. In other words, under $H \mapsto \tilde{H}$, if a state is removed (added) at Ω, then a state is added (removed) at $-\Omega$. This relationship, which also applies to conservative systems and NMs provided we take the KGE point of view, sharpens the information provided by (1.1).

Secondly, SUSY preserves norms and inner products. However, for outgoing waves the usual norms and inner products are not useful. For example, an outgoing wave of frequency ω goes as $\exp[i\omega(|x|-t)]$ at spatial infinity. With $\mathrm{Im}\,\omega<0$ for QNMs (see Sec. I B), the exponential growth in $|x|$ renders the wave function not normalizable in the usual sense. A generalized norm for QNMs was first introduced by Zeldovich[9] many years ago, and shown to be useful for time-independent perturbation theory (of the *complex* eigenvalues).[10] An associated generalized inner product can also be defined.[11] The time-evolution operator turns out to be symmetric under this product (the analog of self-adjoint). Section III shows that SUSY preserves these generalized norms and inner products—a pleasant surprise, since their construction is totally unrelated to SUSY.

Thirdly, for non-conservative systems, there is no guarantee that the Hamiltonian can be completely diagonalized; in general the best that one can do is to decompose it into Jordan blocks (JBs).[12] Each block j, say of size $M_j \times M_j$, is associated with an eigenfrequency ω_j, with $M_j=1$ being the usual case of a QNM. Section IV shows that SUSY preserves the JB structure: except for $\omega_j=\pm\Omega$, a block of size M_j maps to a block also of size M_j at the same frequency ω_j. In fact, if we generalize the definition of $n(\omega_j)$ to be the order M_j of the block, then the relationship between $n(\omega)$ and $\tilde{n}(\omega)$ [cf. (1.2) and (1.3)] remains valid even for $n,\tilde{n}>1$.

Examples are given in Sec. V and a discussion is presented in Sec. VI, including a sketch of some issues for potentials with tails—which can lead to situations with *negative* n and $\tilde{n}$ that are nevertheless accommodated in the same formalism.

B. Quasinormal modes

In open systems, waves are not confined, but can escape: acoustic waves from a musical instrument, electromagnetic waves from a laser, and linearized gravitational waves from a Schwarzschild background (to infinity and into the horizon). These systems are often described (e.g., in the case of gravitational waves[13]) by the KGE

$$[\partial_t^2-\partial_x^2+V(x)]\phi(x,t)=0, \tag{1.4}$$

or (e.g., in the case of optics[14]) by the closely related[11] wave equation

$$[\rho(x)\partial_t^2 - \partial_x^2]\phi(x,t) = 0. \tag{1.5}$$

This paper deals only with the KGE, both because it is readily related to the Schrödinger equation in terms of which SUSY is usually formulated,[3,4] and also because it (unlike the wave equation) admits NMs which are interesting in the present discussion.

Except for Sec. VI D, we shall assume that $V(x)$ [or $\rho(x)-1$ in the case of the wave equation (1.5)] has finite support on the interval $I=[-a,a]$, which is natural for describing a system of limited extent, surrounded by a trivial medium such as vacuum.

We assume that the loss is only due to the boundary conditions. In particular, the potential V is real. Absorption may be described by a complex V, but causality then requires dispersion; the necessary generalization[15] will not be discussed here.

Among the solutions of (1.4), we consider the space Γ of states satisfying the OWC. We leave the time-domain definition to Sec. III; in the frequency domain, a function is in Γ if

$$\phi(x) \sim e^{+i\omega|x|}, \quad |x| \to \infty. \tag{1.6}$$

Because V is trivial outside I, the asymptotic conditions (1.6) can be stated at $x=\pm a$ instead:

$$\frac{\phi'(x)}{\phi(x)} = \pm i\omega, \quad x = \pm a. \tag{1.7}$$

The imposition of two boundary conditions in (1.7) forces the eigenvalues to be discrete, and these fall into two classes. First, there could be bound states or NMs;[16] these must (from the Schrödinger point of view) have $E=\omega^2<0$, and hence ω is purely imaginary. Since bound-state wave functions vanish at infinity, (1.6) dictates that $\mathrm{Im}\,\omega>0$. Second, there could be QNMs with complex eigenvalues ω^2. Because these waves escape, ϕ decreases, so $\mathrm{Im}\,\omega<0$.[17] Provided $\mathrm{Re}\,\omega\neq 0$, they occur in pairs: $\omega_{-j}=-\omega_j^*$, as is readily shown by conjugating the defining equation and boundary conditions. Those with $\mathrm{Re}\,\omega=0$ need not be paired; these *zero modes*[18] will be of particular importance below. Consider the potential shown by the broken line in Fig. 1(a); its NMs and QNMs are shown in Fig. 1(b). In this example, there is one NM (triangle) and a sequence of QNMs (crosses), including a zero mode. In contrast to the Schrödinger formulation, the use of the KGE and the introduction of Γ allows NMs and QNMs to be discussed together—and at least in this example the latter manifestly carry much richer information.

Even though QNM eigenfunctions are not square-integrable and do not form a conventional Hilbert space, they are useful for analyzing outgoing waves. Importantly, the complex QNM frequencies are often directly observable: e.g., the central frequency and width of an optical line observed from a laser cavity, or the rates of repetition and decay of a gravitational-wave signal that may within the next decade be detected by instruments such as LIGO.[19] In fact, the spectrum is often so rich that, under some broad conditions, namely, that $V(x)$ vanishes outside $[-a,a]$ and has singularities at $x=\pm a$, the eigenstates ϕ_j of Γ are *complete* for $x\in I$,[20] so that for $t\geqslant 0$ the observed wave signal can be represented as[21]

$$\phi(x,t) = \sum_{j\in\Gamma} a_j \phi_j(x) e^{-i\omega_j t}. \tag{1.8}$$

In cases where the ϕ_j's are not complete, it may still be possible to characterize the remainder, which could be, for example, a power law in t for long times.[22,23] Moreover, when the eigenstates are complete, one can set up a formalism that closely parallels the conservative case (see Refs. 11 and 24 and Sec. III B). One can even second-quantize using these eigenstates as a basis (e.g., to discuss thermal effects and atom–field interactions in an optical cavity).[25] These developments have been reviewed.[26] We shall see that much of the mathematical structure is preserved under SUSY.

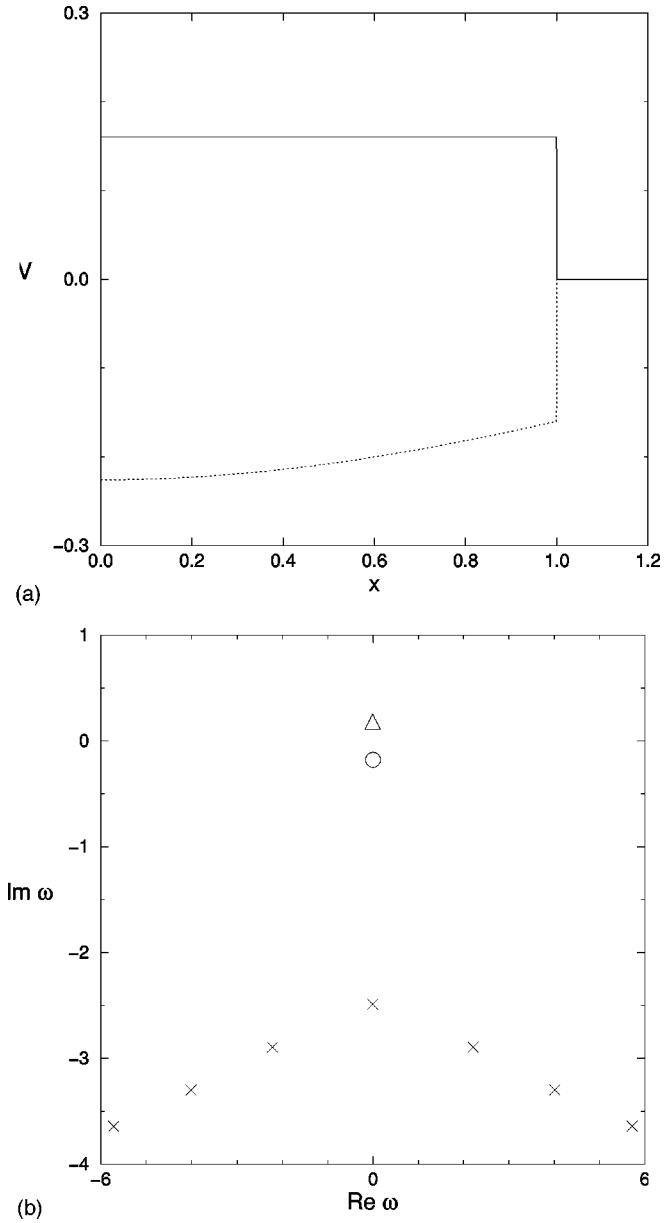

FIG. 1. (a) A square-barrier potential V (solid line) and its SUSY partner potential $\tilde{V}$ (broken line). Both potentials are symmetric and only the $x>0$ part is shown. The SUSY transformation is constructed by using the state at $\Omega=\omega_1=-0.181i$ [circle in (b)] as the generator. (b) The complex ω-plane showing the QNMs common to both potentials (crosses); the mode present only in V (circle), which corresponds to the generator Φ; and the mode present only in $\tilde{V}$ (triangle), which corresponds to $\tilde{\Phi}=\Phi^{-1}$.

II. FORMALISM

A. Supersymmetric quantum mechanics

In this paper we consider SUSY in the one-dimensional KGE (1.4), and especially in the corresponding eigenvalue problem

$$H\phi_j(x)=\omega_j^2\phi_j(x), \tag{2.1}$$

where

$$H = -\partial_x^2 + V(x). \tag{2.2}$$

The boundary conditions will be specified later. Insofar as the interest centers on the time-independent problem (2.1) and the spectrum, the Schrödinger equation, to which reference is usually made,[3,4] is included if we simply relabel $\omega^2 \mapsto E$.

If there exists another system

$$\tilde{H} = -\partial_x^2 + \tilde{V}(x), \tag{2.3}$$

with the same spectrum (or the same spectrum apart from one state), and moreover if the states in the two systems are related by

$$\tilde{\phi}(x) = A\phi(x), \tag{2.4}$$

where

$$\begin{aligned} A &= \partial_x + W(x), \\ -A^\dagger &= \partial_x - W(x), \end{aligned} \tag{2.5}$$

then the two systems are said to be SUSY partners. In particular, if $\phi_j(x)$ is an eigenfunction of H, then $\tilde{\phi}_j(x)$ (provided it does not vanish) is an eigenfunction of $\tilde{H}$ with the same eigenvalue. Normalization is deferred to Sec. III.

In order for (2.4) to preserve the spectrum, one needs

$$AH = \tilde{H}A, \tag{2.6}$$

from which it follows that:

$$\begin{aligned} V(x) &= W(x)^2 - W'(x) + \Omega^2, \\ \tilde{V}(x) &= W(x)^2 + W'(x) + \Omega^2, \end{aligned} \tag{2.7}$$

with $W(x)$ (called the SUSY potential) as in (2.5) and for some constant Ω^2. Since both V and $\tilde{V}$ have to be real, W and Ω^2 are also real. Moreover, the Hamiltonians can be represented as

$$\begin{aligned} H &= A^\dagger A + \Omega^2, \\ \tilde{H} &= AA^\dagger + \Omega^2. \end{aligned} \tag{2.8}$$

The two partner systems can be put into one linear space by introducing Pauli spinors, with the SUSY Hamiltonian $H_S = (-\partial_x^2 + W^2) \otimes \mathbb{1} - W' \otimes \sigma_z = \mathrm{diag}(H - \Omega^2, \tilde{H} - \Omega^2)$ and the supercharges $Q = A\sigma_-$, $Q^\dagger = A^\dagger \sigma_+$ satisfying the commutation and anticommutation relations: $\{Q, Q^\dagger\} = H_S$ and $\{Q, Q\} = \{Q^\dagger, Q^\dagger\} = [Q, H_S] = [Q^\dagger, H_S] = 0$.

Upon reversing the sign of W, (a) $V \leftrightarrow \tilde{V}$ [cf. (2.7)], and (b) $A \leftrightarrow -A^\dagger$ [cf. (2.5)]; thus the mapping from $\tilde{H}$ back to H is (up to a sign) achieved by $A^\dagger$. Note however that the mapping is the "inverse" only in a loose sense: $A^\dagger A$ is not the identity but $H - \Omega^2$ [cf. (2.8)].

We may regard (2.7) as a Riccati equation for W in terms of the given V. For $|x| > a$, both V and $\tilde{V}$ vanish, so $W^2 = -\Omega^2$. The first-order Riccati equation for W can satisfy two boundary conditions (at $x = \pm a$) only at special values of Ω^2; this condition becomes familiar if we define a generator $\Phi(x)$ by

$$W(x) = -\frac{\Phi'(x)}{\Phi(x)}. \tag{2.9}$$

Then (2.7) implies

$$H\Phi(x) = \Omega^2\Phi(x). \tag{2.10}$$

B. Boundary conditions

All the above may be regarded as a review of the familiar SUSY formalism for the Schrödinger equation[3,4] if we put $E=\omega^2$, $E_0=\Omega^2$ and in particular shift $V(x)$ so that $E_0=0$. Conventionally the discussion refers to wave functions which vanish at infinity (or, more precisely, are square-integrable). Here we consider *all* eigenfunctions in Γ, including both NMs and QNMs, with the former in the upper and the latter in the lower half of the frequency plane.

We should check immediately that $\phi\in\Gamma$ implies $\tilde{\phi}\in\Gamma$. For $x>a$, if $\phi(x)=Ce^{i\omega x}$ then $\tilde{\phi}(x)=A\phi(x)=(i\omega+W_+)Ce^{i\omega x}$, where

$$W(x=\pm a)=W_\pm \tag{2.11}$$

are the constant values for $x>a$ and $x<-a$, respectively. Thus ϕ and $\tilde{\phi}$ always satisfy the same type of boundary conditions, and the number of eigenstates in Γ is preserved under SUSY: $n(\omega)=\tilde{n}(\omega)$ [cf. (1.2)]—except when A or $A^\dagger$ destroys a state, to be discussed below.

C. Generator

The various SUSY transformations are related, in a one-to-one manner, to solutions of (2.10) for the generator Φ. First, suppose $\Omega^2>0$, so that Ω is real. Then outside I, Φ is oscillatory: either complex (e.g., $e^{i\Omega x}$), inadmissible since it leads to a complex W; or real (e.g., $\sin\Omega x$), inadmissible since its nodes lead to singularities in W. Thus, $\Omega^2<0$, and we denote $K\equiv|\Omega|$.

At each spatial extreme ($|x|>a$), Φ is in general a sum of increasing and decreasing functions, i.e.,

$$\Phi(x)=ce^{K|x|}+de^{-K|x|}. \tag{2.12}$$

If both $c,d\neq 0$ (to be called the mixed type), then the logarithmic derivative is (e.g., for $x>a$)

$$W(x)=-K+\frac{2dK}{c}e^{-2Kx}+\cdots, \tag{2.13}$$

so that $\tilde{V}=V+2W'$ acquires an exponential tail. (In the special case $\Omega=0$, the tail is not exponential but asymptotically inverse-square.) Thus, if we insist that $\tilde{V}$ also has finite support, the mixed type is not allowed and at each extreme Φ must be either purely decreasing ($\Phi\propto e^{-K|x|}$, denoted as D) or purely increasing ($\Phi\propto e^{K|x|}$, denoted as I). Outside I, the logarithmic derivative is then exactly $\pm K$, so $W'=0$, implying $\tilde{V}=0$. When both extremes are considered together, Φ must be one of three types, conveniently labeled with the parameter

$$\chi=\tfrac{1}{2}[\mathrm{sign}(W_+)-\mathrm{sign}(W_-)], \tag{2.14}$$

where $\chi=+1$, -1, and 0, respectively, for the DD, II, and DI/ID cases (in obvious notation). In the DI/ID case, the generator is purely incoming from one extreme and purely outgoing to the other, hence is a total-transmission mode (TTM). The relaxation to allow exponential tails for V and/or $\tilde{V}$ will be briefly mentioned in Sec. VI D.

The generator is annihilated by SUSY: $A\Phi=0$, trivially from (2.5) and (2.9). Furthermore, since reversing the sign of W interchanges the partners [cf. below (2.8)], in view of (2.9) the

transformation from $\tilde{H}$ back to H is generated by $\tilde{\Phi}=\Phi^{-1}$; this is guaranteed to be an eigenfunction of $\tilde{H}$, also with eigenvalue Ω^2. (Despite the notation, $\tilde{\Phi}$ is not the SUSY partner of Φ: $\tilde{\Phi} \neq A\Phi$.) The boundary conditions for $\tilde{\Phi}=\Phi^{-1}$ interchange D and I, so the reverse transformation is characterized by $\tilde{\chi}=-\chi$.

These observations allow a simple statement of the changes in the number of states when $H \mapsto \tilde{H}$. If $\chi=1$ [cf. below (2.14)], an NM Φ is destroyed at $\Omega=iK$ [$\Delta(iK)=1$] and a QNM $\tilde{\Phi}$ is created at $-\Omega=-iK$ [$\Delta(-iK)=-1$]. If $\chi=-1$, a QNM Φ is destroyed at $\Omega=-iK$ [$\Delta(-iK)=1$] and an NM $\tilde{\Phi}$ is created at $-\Omega=iK$ [$\Delta(iK)=-1$]. If $\chi=0$, no eigenstates of Γ are created or destroyed [$\Delta(iK)=\Delta(-iK)=0$], since Φ and $\tilde{\Phi}$ are TTMs rather than NMs or QNMs. Thus, all three cases satisfy

$$\Delta(iK)=-\Delta(-iK)=\chi, \tag{2.15}$$

where we emphasize the convention $\Omega=\pm iK$ with $K>0$. The cases $\chi=\pm 1$ lead to Hamiltonians whose spectra in Γ differ by one state (said to be essentially isospectral), whereas the case $\chi=0$ leads to Hamiltonians whose spectra in Γ are identical (said to be strictly isospectral).

These remarks provide a more complete picture of the mapping of eigenstates in Γ under SUSY: States do not simply appear or disappear, but are mapped to the mirror point in the complex plane.

Not all NMs, QNMs, or TTMs are eligible as the generator. First, Ω^2 must be real, which restricts QNMs to zero modes. Second, Φ cannot have nodes, or else W would acquire singularities. In the case of NMs, this restricts Φ to the ground state. For QNMs, nodes are not required by general theorems. At least for repulsive potentials, each eigenfunction can have *at most* one node or antinode; thus, for a symmetric repulsive V, even-parity eigenfunctions can have no nodes. There is consequently much more freedom in choosing a QNM (as opposed to an NM) as the generator. Some general statements concerning nodes in QNMs are given in the Appendix.

III. ORTHONORMALITY

A. Orthonormality for NMs

For conservative systems, SUSY preserves orthonormality. There are two issues: Orthogonality is preserved because the transformed NMs are eigenvectors of the self-adjoint operator $\tilde{H}$; and normalization is preserved if the transformation is changed to

$$\phi_j \mapsto \underline{\tilde{\phi}}_j = N_j \tilde{\phi}_j = N_j A \phi_j, \tag{3.1}$$

with

$$N_j^{-2}=\frac{\langle \tilde{\phi}_j | \tilde{\phi}_j \rangle}{\langle \phi_j | \phi_j \rangle}. \tag{3.2}$$

Equation (3.1) applies to each eigenstate j other than the generator Φ itself, namely, the ground state. It is readily shown that $N_j^{-2}=\omega_j^2-\Omega^2$, a result that can also be read off as a special case of the derivation below for states in Γ. Since $\omega_j^2-\Omega^2$ is the eigenvalue of $A^\dagger A$ [see (2.8)], (3.1) can be written in the operator form

$$\phi \mapsto \underline{\tilde{\phi}} = A(A^\dagger A)^{-1/2}\phi, \tag{3.3}$$

valid for any state ϕ, not just frequency eigenfunctions. (This and similar formulas below are restricted to the subspace orthogonal to Φ.) This makes it formally easy to verify the preservation of inner products:

$$\langle \underset{\sim}{\psi} | \underset{\sim}{\phi} \rangle = \langle \psi | (A^\dagger A)^{-1/2} A^\dagger A \, (A^\dagger A)^{-1/2} | \phi \rangle = \langle \psi | \phi \rangle. \tag{3.4}$$

However, when operating on a general wave function ϕ, the factor $(A^\dagger A)^{-1/2}$ can only be evaluated by projecting ϕ onto the eigenfunctions, and scaling each component by N_j. Thus, in practice, the significant result is the evaluation of this factor. We now generalize these concepts to states in Γ, in particular QNMs.

B. Normalization and inner product for QNMs

It is necessary to digress and review the concepts of orthogonality and normalization for QNMs. The central issue is that with the OWC, H is *not* self-adjoint in the usual sense, and different QNMs are *not* orthogonal under the usual inner product. Likewise, the norm $\int |\phi_j|^2 dx$ is divergent, since the wave function grows exponentially at infinity.

An appropriate normalizing factor for QNMs was first introduced by Zeldovich,[9] and later generalized and applied to other situations,[10] including models of linearized waves propagating on a Schwarzschild background:[27]

$$(\phi_j, \phi_j) = 2\omega_j \int_{-a}^{a} \phi_j(x)^2 \, dx + i[\phi_j(-a)^2 + \phi_j(a)^2]. \tag{3.5}$$

This expression goes as ϕ_j^2 rather than $|\phi_j|^2$, and is in general not real. The limits of the integral and the surface terms can be shifted from $\pm a$ to any $b_\pm$, where $\pm b_\pm > a$, without affecting the value of (3.5). This definition also applies to NMs: The surface terms vanish if we take $b_\pm \to \pm\infty$, recovering the conventional norm apart from a factor of $2\omega_j$. In the QNM case, (3.5) is the correct normalizing factor in the sense that, e.g., under a perturbation $V \mapsto V + \Delta V$, the complex QNM eigenvalues change by

$$\Delta(\omega_j^2) = \frac{\int \phi_j(x)^2 \Delta V(x) dx}{(\phi_j, \phi_j)}. \tag{3.6}$$

Since one no longer has positivity, there is the possibility that $(\phi_j, \phi_j) = 0$. This exceptional case can be separately taken care of,[28] and some interesting aspects are dealt with in Sec. IV.

To go beyond the normalizing factor and discuss an analog of orthogonality, one has to first regard each state as a two-component vector $\boldsymbol{\psi} = (\psi^1, \psi^2)^{\mathrm{T}} \equiv (\psi, \partial_t \psi)^{\mathrm{T}}$, which is most easily motivated by noticing that the dynamics requires two sets of initial data. The space Γ is then defined as all $\boldsymbol{\psi}$ satisfying

$$\psi^2(\pm a) = \mp \partial_x \psi^1(\pm a). \tag{3.7}$$

For an eigenstate, $\boldsymbol{\phi}_j = (\phi_j, -i\omega_j \phi_j)^{\mathrm{T}}$, and (1.7) would follow from (3.7).

In terms of the two-component vector, one can define a bilinear map[11,26]

$$(\boldsymbol{\psi}, \boldsymbol{\phi}) = i\left\{ \int_{-a}^{a} [\psi^1(x)\phi^2(x) + \psi^2(x)\phi^1(x)] dx + [\psi^1(-a)\phi^1(-a) + \psi^1(a)\phi^1(a)] \right\}, \tag{3.8}$$

to take the place of the usual inner product. For an eigenfunction, $(\boldsymbol{\phi}_j, \boldsymbol{\phi}_j)$ agrees with (3.5). The dynamics can be written in the first-order form $i\partial_t \boldsymbol{\phi} = \mathcal{H}\boldsymbol{\phi}$, with

$$\mathcal{H} = i \begin{pmatrix} 0 & 1 \\ \partial_x^2 - V & 0 \end{pmatrix}. \tag{3.9}$$

Importantly, $\mathcal{H}$ is symmetric:

$$(\mathcal{H}\boldsymbol{\psi},\boldsymbol{\phi})=(\boldsymbol{\psi},\mathcal{H}\boldsymbol{\phi}), \tag{3.10}$$

in the proof of which the surface terms generated upon integration by parts exactly cancel against those in (3.8). The relation (3.10) is the analog of self-adjointness, and leads to the usual proof that for two eigenvectors,

$$(\boldsymbol{\phi}_k,\boldsymbol{\phi}_j)=0 \tag{3.11}$$

whenever $\omega_k\neq\omega_j$. Provided that $(\boldsymbol{\phi}_j,\boldsymbol{\phi}_j)\neq 0$,[28] one can normalize these eigenfunctions in the usual way, i.e., by requiring (3.11) to be $2\omega_k\delta_{kj}$ in general [cf. (3.5) for this factor]. We henceforth refer to this property as orthonormality [and to (3.11) alone as orthogonality]. It also follows trivially that, provided this orthonormal system is complete (which is the case under fairly broad assumptions; see Sec. I B), time evolution is given by

$$\boldsymbol{\phi}(t)=\sum_j a_j\boldsymbol{\phi}_j e^{-i\omega_j t}, \tag{3.12}$$

generalizing (1.8) to two components, and

$$a_j=\frac{(\boldsymbol{\phi}_j,\boldsymbol{\phi}(t=0))}{(\boldsymbol{\phi}_j,\boldsymbol{\phi}_j)}. \tag{3.13}$$

The preservation of orthonormality under SUSY should therefore be sought in terms of the bilinear map (3.8).

C. Normalized SUSY transformation for QNMs

We first present a derivation of orthonormality that does not explicitly require the two-component formalism. With orthogonality already guaranteed by (3.11), it remains to compute the normalizing factor

$$(\tilde{\phi}_j,\tilde{\phi}_j)=2\omega_j\int_{-a}^{a}[(\partial_x+W)\phi_j]^2dx+i[\tilde{\phi}_j(-a)^2+\tilde{\phi}_j(a)^2]. \tag{3.14}$$

Integrate by parts to convert $(\partial_x\phi)^2$ to $-(\partial_x^2\phi)\phi$ plus a surface term, express the second derivative in terms of $V-\omega_j^2$ by means of the eigenvalue equation, and write the potential as $V=W^2-W'+\Omega^2$. Then, apart from a term $\propto\omega_j^2-\Omega^2$, the integrand becomes a total derivative $\partial_x(W\phi^2)$. Using $W(\pm a)^2=-\Omega^2$ and $\partial_x\phi_j(\pm a)=\pm i\omega_j\phi_j(\pm a)$ then leads to

$$\frac{(\tilde{\phi}_j,\tilde{\phi}_j)}{(\phi_j,\phi_j)}=\omega_j^2-\Omega^2. \tag{3.15}$$

Incidentally, the conservative case (nodal conditions at the ends of the interval[16]) is recovered by simply dropping all surface terms.

Since the ratio (3.15) is the eigenvalue of $A^\dagger A$, we can again write the normalized transformation for each eigenfunction as (3.3).

D. SUSY for two-component form

For eigenstates, the two components are trivially related, but in order to perform SUSY transformations on general wave functions in Γ (e.g., given a time-dependent state, to find its partner at all times), the second component must be considered explicitly.

Since SUSY must commute with time evolution and $\phi^2=\partial_t\phi^1$, both components must transform in the same way. Thus, the (unnormalized) SUSY transformation on two-component vectors is $\mathcal{A}=\mathrm{diag}(A,A)$, which satisfies

$$(\mathcal{A}\boldsymbol{\psi},\boldsymbol{\phi})=(\boldsymbol{\psi},\mathcal{A}^\dagger\boldsymbol{\phi}), \tag{3.16}$$

where $\mathcal{A}^\dagger\equiv\mathrm{diag}(A^\dagger,A^\dagger)$. In deriving (3.16), one has to integrate by parts: ∂_x changes sign so that $\mathcal{A}$ turns into $\mathcal{A}^\dagger$. The surface terms are seen to work out by using, e.g., $\phi^2(a)=\partial_t\phi^1(a)=-\partial_x\phi^1(a)$, and the known values of $W_\pm$. Note that $\mathcal{A}^\dagger\mathcal{A}=(H-\Omega^2)\otimes\mathbb{1}$, $\mathcal{A}\mathcal{A}^\dagger=(\tilde{H}-\Omega^2)\otimes\mathbb{1}$, i.e., the products do not relate to the two-component $\mathcal{H}$.

With (3.16), it is straightforward to show that the normalized SUSY transformation

$$\boldsymbol{\phi}\mapsto\tilde{\boldsymbol{\phi}}=\mathcal{A}(\mathcal{A}^\dagger\mathcal{A})^{-1/2}\boldsymbol{\phi}, \tag{3.17}$$

defined on the subspace orthogonal to $\boldsymbol{\Phi}$, preserves the bilinear map, in a manner that exactly parallels (3.4). In the exceptional case of SUSYs that generate a doubled state (see Sec. IV), the subspace has to exclude the *two* states on which $H-\Omega^2$ vanishes.

The linear-space structure for open systems (e.g., the replacement of inner products by bilinear maps) has an intrinsic geometric meaning for all outgoing states, not just QNMs.[29] It is therefore pleasing that this structure is preserved by SUSY, a superficially unrelated concept.

IV. JORDAN BLOCKS

A key concept in SUSY is the preservation of the spectrum. However, dissipative systems (such as waves satisfying the OWC) admit a spectral property not found for conservative systems. In terms of the Wronskian $J(\omega)$ to be defined below, this is exhibited as an Mth-order zero ($M>1$). Such a multiple zero emerges naturally when M QNM eigenvalues coalesce as system parameters are tuned, so that $M-1$ eigenvectors are "lost"[30] and must be replaced by other degrees of freedom. Thus, the Hamiltonian cannot be written as a diagonal matrix in the (biorthogonal) basis of eigenstates, but can only be decomposed into (Jordan) blocks[12] of size $M\times M$. When this happens, $(\boldsymbol{\phi}_j,\boldsymbol{\phi}_j)$ will vanish for some j, invalidating the formalism in Sec. III [see, e.g., (3.6) and (3.13)]. These issues have been discussed in detail with reference to waves in open systems.[28]

The simplest example of a JB (with $M=2$) is a harmonic oscillator going through critical damping. The eigenvalues $\omega_\pm=\pm\omega_\mathrm{R}-i\gamma$ coalesce when $\omega_\mathrm{R}\to0$. With one eigenvalue lost, the dynamics is not given by a sum of eigenfunctions with time dependence $\exp(-i\omega_\pm t)$, but by only *one* such eigenfunction, plus another term whose time dependence carries a prefactor t.

Our purpose in this Section is to establish that SUSY maps a JB in H into a JB in $\tilde{H}$, preserving the order M except when the eigenvalue coincides with $\pm\Omega$.

A. Wronskian

In this subsection we introduce the Wronskian $J(\omega)$, define JBs in terms of its multiple zeros, and describe the mapping of JBs under SUSY by a relation between $J(\omega)$ and its counterpart $\tilde{J}(\omega)$.

In the original system H, define solutions of the wave equation $f(\omega,x)$ and $g(\omega,x)$ satisfying the boundary conditions $f(\omega,-a)=1$, $f'(\omega,-a)=-i\omega$, $g(\omega,a)=1$, $g'(\omega,a)=i\omega$, where $'=\partial_x$. The function values are arbitrary normalizations, while the derivatives impose the OWC on the left and right, respectively. An eigenstate $\boldsymbol{\phi}_j$ in Γ satisfies the boundary condition on *both* the left (as for f) and the right (as for g): $\boldsymbol{\phi}_j\propto f(\omega_j,x)\propto g(\omega_j,x)$. Thus, the zeros of the (position-independent) Wronskian

$$J(\omega)=f'(\omega,x)g(\omega,x)-f(\omega,x)g'(\omega,x) \tag{4.1}$$

identify the eigenvalues in Γ. It can be shown [see (4.7) below] that $(\boldsymbol{\phi}_j,\boldsymbol{\phi}_j)\propto dJ(\omega_j)/d\omega$, so an Mth-order zero of $J(M>1)$ corresponds to the generalized norm being zero, and is precisely the JB phenomenon that we wish to investigate.

It is natural to generalize the definition of $n(\omega)$ to be the order of the zero, viz.,

$$n(\omega)=\frac{1}{2\pi i}\oint\frac{dJ(\omega')/d\omega'}{J(\omega')}d\omega', \tag{4.2}$$

on a contour of winding number $+1$ enclosing ω. This definition makes it clear that the total number of states (but *not* necessarily of eigenstates) within a contour is preserved under continuous changes of the system parameters. We note for future reference (see Sec. VI D) that poles of J (which can only occur if V does not have finite support) count as negative values of n.

Now consider the analogous construction in the partner system $\tilde{H}$, obtained, for example, by using an NM Φ of H as the generator, i.e., for $\chi=1$. By our convention, Φ is associated with a frequency $\Omega=iK$, and $W_{\pm}=\mp i\Omega$. The SUSY transformation gives[31]

$$\begin{aligned}\tilde{f}(\omega,x)&=(\partial_x+W)f(\omega,x)\\ \tilde{g}(\omega,x)&=(\partial_x+W)g(\omega,x),\end{aligned} \tag{4.3}$$

leading to the Wronskian

$$\tilde{J}^{\mathrm{u}}(\omega)=\tilde{f}'(\omega,x)\tilde{g}(\omega,x)-\tilde{f}(\omega,x)\tilde{g}'(\omega,x). \tag{4.4}$$

When (4.4) is written out using (4.3), some terms cancel by using $J'=0$, the second derivatives can be eliminated by the defining equation, and V is expressed in terms of W and Ω^2. Some arithmetic then leads to

$$\tilde{J}^{\mathrm{u}}(\omega)=(\omega^2-\Omega^2)\,J(\omega). \tag{4.5}$$

This Wronskian is however unnormalized (as indicated by the superscript), since only $C\tilde{f}$ and $D\tilde{g}$ satisfy the normalization conventions at $-a$ and $+a$, respectively, where $C=-D=i(\omega-\Omega)^{-1}$. Thus the normalized Wronskian $\tilde{J}(\omega)=CD\tilde{J}^{\mathrm{u}}(\omega)$ is

$$\tilde{J}(\omega)=\frac{\omega+\Omega}{\omega-\Omega}J(\omega). \tag{4.6}$$

The central result (4.6) neatly summarizes the correspondence between the two spectra for $\chi=1$. [Similar formulas for the other cases can all be consolidated by changing $\Omega\mapsto i\chi K$ in (4.6), and will not be separately discussed.] (a) For $\omega\neq\pm\Omega$, the spectra of H and $\tilde{H}$ are the same: A JB of order M in H maps to a JB also of order M in $\tilde{H}$ at the same frequency. This should be no surprise since up to the point of coalescence (for $M\geqslant 2$), the eigenvalues of the two systems are guaranteed (cf. Sec. II) to be in one-to-one correspondence; in a sense, the result here merely demonstrates that the limit is not singular. (b) Moreover, *at* the special frequencies $\pm\Omega$, M states at Ω (of which only *one* is an eigenstate) are mapped into $M-1$ states at Ω plus one state at $-\Omega$. In other words, we recover (2.15) even for JBs, i.e., even when $n,\tilde{n}>1$. Anticipating the possibility of poles in J (cf. Sec. VI D), we note that (4.6) implies that such poles are also preserved under SUSY, and would be accommodated by (1.2), (1.3), and (2.15) with negative n, $\tilde{n}$.

Incidentally, (3.15) on the change in normalization under SUSY follows simply from (4.5), since the bilinear map is related to the Wronskian by[26,32]

$$(f(\omega_j),g(\omega_j))=-\left[\frac{dJ(\omega)}{d\omega}\right]_{\omega_j}. \tag{4.7}$$

B. Doubling of states by SUSY

We have seen that (say for $\chi=1$) one has $\tilde{n}(-iK)-n(-iK)=1$. Where this increases from 0 to 1, the situation is straightforward—a QNM is created. When the increase is from 1 to 2, the situation is more subtle and merits a detailed examination. [The general case where this increases from M to $M+1$ ($M\geqslant 1$) will not be shown.]

Consider a system H with an NM Φ at $\Omega=iK$ and accidentally also a QNM Ψ_j at $-\Omega'\approx-\Omega$. If $\Omega'\neq\Omega$, there are *two* corresponding QNMs in the $\tilde{H}$-system, namely, $\tilde{\Phi}=\Phi^{-1}$ at $-\Omega$ and $\tilde{\Psi}_j=A\Psi_j$ at $-\Omega'$. Now tune the parameters of H so that $\Omega'\to\Omega$; in the limit we must have $\tilde{\Psi}_j\propto\tilde{\Phi}$,[28,30] as is readily verified. The proportionality constant can be evaluated by

$$\frac{\tilde{\Psi}_j}{\tilde{\Phi}}=\frac{\tilde{\Psi}_j(-a)}{\tilde{\Phi}(-a)}=2i\Omega\Psi_j(-a)\Phi(-a)$$

$$=\frac{\tilde{\Psi}_j(a)}{\tilde{\Phi}(a)}=-2i\Omega\Psi_j(a)\Phi(a). \tag{4.8}$$

The agreement of these two expressions can also be seen without invoking SUSY. One notes that $\mathbf{\Phi}$ and $\mathbf{\Psi}_j$, being eigenfunctions of $\mathcal{H}$ with distinct eigenvalues, are orthogonal. In the bilinear map, the integral term vanishes because the frequencies are opposite, leaving only the surface terms. Thus one finds $0=(\mathbf{\Psi}_j,\mathbf{\Phi})=i[\Psi_j(-a)\Phi(-a)+\Psi_j(a)\Phi(a)]$.

Now the frequency $-\Omega$ in $\tilde{H}$ must be associated with a doubled state. This can be seen in two ways: (a) Until the limit $\Omega'=\Omega$, there are two distinct states; (b) from the key relation (4.6), $\tilde{J}$ has a second-order zero. With the two QNMs collapsed into one, there has to be another basis vector, to which we now turn.

Using the normalization of f, one has $\Psi_j(x)=\Psi_j(-a)f(-\Omega,x)$, implying $\tilde{\Psi}_j(x)=\Psi_j(-a)\tilde{f}(-\Omega,x)$. [Analogous formulas for Φ and $\tilde{\Phi}$ follow from (4.8).] The double zero of $\tilde{J}(\omega)$ at $\omega=-\Omega$ means that $\tilde{f}(\omega,x)$ satisfies the OWC at $x=a$ not only *at* $\omega=-\Omega$, but also to first order away from the zero. This makes it plausible that, in the QNM expansion, $\partial_\omega\tilde{f}(\omega,x)|_{-\Omega}$ takes the place of the ''missing'' eigenfunction when $\tilde{\Phi}$ and $\tilde{\Psi}_j$ coincide, which has been confirmed in detail.[28] One thus defines, for an arbitrary α, a pair of functions $\tilde{\Psi}_{j,n}$, where $n=0,1$ is an intra-block index:

$$\tilde{\Psi}_{j,0}(x)=\tilde{\Psi}_j(x),$$

$$\tilde{\Psi}_{j,1}(x)=\Psi_j(-a)\partial_\omega\tilde{f}(\omega,x)|_{-\Omega}+\alpha\tilde{\Psi}_j(x), \tag{4.9}$$

and the second function satisfies

$$(\tilde{H}-\Omega^2)\tilde{\Psi}_{j,1}=-2\Omega\tilde{\Psi}_{j,0}. \tag{4.10}$$

Using this, one verifies that an outgoing solution is given by $\tilde{\Psi}_{j,1}(t)\equiv(\tilde{\Psi}_{j,1}-it\tilde{\Psi}_{j,0})e^{i\Omega t}$. This time dependence shows that the associated second component should be $\tilde{\Psi}^2_{j,1}=-i(-\Omega\tilde{\Psi}_{j,1}+\tilde{\Psi}_{j,0})$. The prefactor t and its counterpart if any in the H-system will be further explored below.

Next consider the bilinear map and normalization for these functions. For a double zero one always has $(\tilde{\mathbf{\Psi}}_{j,0},\tilde{\mathbf{\Psi}}_{j,0})=0$; cf. (4.7) [a choice of α in (4.9) such that also $(\tilde{\mathbf{\Psi}}_{j,1},\tilde{\mathbf{\Psi}}_{j,1})=0$ would be useful in wave function expansions]. The JB is normalized by one overall factor, the bilinear map between the two basis states[28]

$$\frac{(\tilde{\mathbf{\Psi}}_{j,1},\tilde{\mathbf{\Psi}}_{j,0})}{(\mathbf{\Psi}_j,\mathbf{\Psi}_j)}=\left[\frac{-\frac{1}{2}d^2\tilde{J}^{\mathrm{u}}(\omega)/d\omega^2}{-dJ(\omega)/d\omega}\right]_{-\Omega}=-2\Omega, \tag{4.11}$$

where in the numerator we have used the result analogous to (4.7) for a double zero.

Finally the reverse transform[33] generated by $-A^\dagger$ satisfies the following properties. (a) $A^\dagger\tilde{\Psi}_{j,0}\propto A^\dagger\tilde{\Phi}=0$. (b) Hence in $A^\dagger\tilde{\Psi}_{j,1}(t)$, the term $\propto te^{i\Omega t}$ is annihilated. (c) The remaining term in $A^\dagger\tilde{\Psi}_{j,1}$ is $c\Psi_j$, readily seen by observing that

$$(H-\Omega^2)(A^\dagger\tilde{\Psi}_{j,1})=A^\dagger(\tilde{H}-\Omega^2)\tilde{\Psi}_{j,1}=A^\dagger(-2\Omega\tilde{\Psi}_{j,0})=0, \tag{4.12}$$

so that $A^\dagger\tilde{\Psi}_{j,1}$ is an eigenfunction of H with eigenvalue Ω^2. In particular, the time dependence is $e^{i\Omega t}$ without any prefactor t. A straightforward computation shows that $c=-2\Omega$.

Since $A^\dagger A$ is not the identity, two different states in the H-system can be associated with $\tilde{\Psi}_{j,1}$. The first is $A^\dagger\tilde{\Psi}_{j,1}$ as discussed above. The second is the SUSY pre-image of $\tilde{\Psi}_{j,1}$ under A, which is readily found by noticing that[34]

$$\tilde{\Psi}_{j,1}(x)=\Psi_j(-a)\times\partial_\omega[(\partial_x+W)f(\omega,x)]_{-\Omega}=A\,\Psi_j(-a)\partial_\omega f(\omega,x)|_{-\Omega}. \tag{4.13}$$

However, $\Psi_j(-a)\partial_\omega f(\omega,x)|_{-\Omega}$ is *not* outgoing to $+\infty$, since $J(\omega)$ only has a first-order zero at $-\Omega$, and consequently $f(\omega,x)$ satisfies the OWC at $x=+a$ only *at* $-\Omega$, but not to first order away from it.

These remarks completely resolve the puzzle related to the prefactor t in the time evolution in the $\tilde{H}$-system. Namely, of the two corresponding wave functions of H, one has an exponential time dependence, while the other is not in Γ.

V. EXAMPLES

The formalism developed in this paper is general, in that given $V(x)$ with finite support, SUSY partners can be constructed whenever there are nodeless generator candidates. Nevertheless, some simple examples will suffice for an illustration.

Let V be a square barrier of height V_0 on I; without loss of generality henceforth $a=1$. In the even sector there are two zero modes for small values of V_0; e.g., for $V_0=0.16$ they occur at $\omega_1=-0.181i$, $\omega_2=-2.500i$. The wave functions are $\phi_j(x)=\cosh\alpha_j x$ within I (with $\alpha_1=0.242$, $\alpha_2=2.506$), and a real exponential for $|x|>a$; clearly each ϕ_j has no nodes.

This example already illustrates, as unexceptional, the existence of several nodeless zero modes—any one of which can be used as the generator Φ. We choose the state at $\Omega=\omega_1$; since Φ is purely increasing at both extremes, $\chi=-1$. Figure 1(a) shows V (solid line) and $\tilde{V}$ (dotted line). Figure 1(b) shows the spectra in the complex ω-plane: Most eigenvalues are common (crosses); one QNM exists only in H (circle), while one NM exists only in $\tilde{H}$ (triangle)—the two systems are essentially isospectral. Another essentially isospectral partner can be constructed using the state at ω_2 as the generator. The reverse transformations are characterized by $\tilde{\chi}=1$.

As V_0 increases, the two zero modes move closer together and merge at $V_0=0.291$, forming a JB in H (with $M=2$). This example illustrates the general results of Sec. IV (with H and $\tilde{H}$ interchanged).

As another example, consider a symmetric multi-step square barrier, with $V(x)$ being -10 for $|x|<0.1$, 1 for $0.1<|x|<1$ and zero for $|x|>1$ [solid line in Fig. 2(a)]. In this example, there is a TTM at $\Omega=-0.990i$ [square in Fig. 2(b)]—in fact a parity doublet with one propagating from the left ($\mathrm{TTM_L}$) and one propagating from the right ($\mathrm{TTM_R}$). We choose the former as the generator for a $\chi=0$ transformation. The partner potential $\tilde{V}$ is shown by the broken line in Fig. 2(a). Since

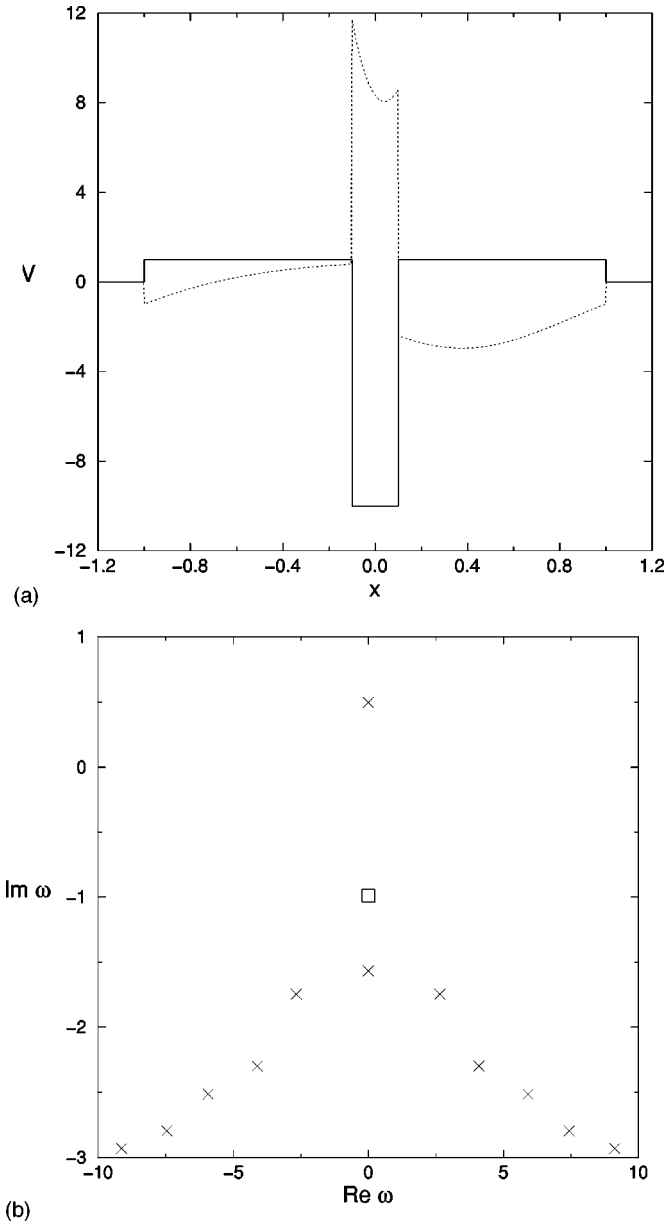

FIG. 2. (a) A multi-step potential V (solid line) and its SUSY partner potential $\tilde{V}$ (broken line). The SUSY transformation is constructed by using the $\mathrm{TTM_L}$ at $\Omega=-0.990i$ [square in (b)] as the generator. (b) The complex ω-plane showing the NM and QNMs common to both potentials (crosses). The square indicates a $\mathrm{TTM_L}$ and a $\mathrm{TTM_R}$ in V, and a doubled $\mathrm{TTM_R}$ in $\tilde{V}$.

the generator is not symmetric, neither is $\tilde{V}$. The states in Γ are exactly preserved [crosses in Fig. 2(b)].

In this example it is interesting to consider not just the states in Γ, but also TTMs (see also Sec. VI C). By arguments similar to those in Sec. II, one $\mathrm{TTM_L}$ Φ is destroyed and one $\mathrm{TTM_R}$ $\tilde{\Phi}=\Phi^{-1}$ is created at the same frequency Ω [square in Fig. 2(b)]. However, in this example, because V is symmetric, there is also a $\mathrm{TTM_R}$ $\Psi(x)=\Phi(-x)$ at Ω, and its partner $\tilde{\Psi}=A\Psi$ is again a $\mathrm{TTM_R}$ in the $\tilde{H}$-system. Thus, in the $\tilde{H}$-system, there is a *doubled* $\mathrm{TTM_R}$ state at Ω. The situation can again be analyzed in terms of the double zero of a Wronskian $\tilde{J}_{\mathrm{R}}(\omega)$, but in this case

J_R and $\tilde{J}_R$ refer to TTM_R's. For example, J_R is now defined in terms of a function f satisfying the outgoing-wave condition at $x=-a$ and a function g satisfying the incoming-wave condition at $x=a$. The obvious adaptation of the discussion in Sec. IV will not be given.

VI. DISCUSSION

A. Summary

In this paper, we have extended the usual discussion of SUSY as a relation between NMs of partner systems to include the QNMs as well. By viewing all these together in the space Γ, a more complete picture emerges. For example, in the usual discussion for NMs only, essentially isospectral transformations are said to lose or gain one state; now we see that (for $\chi=\pm 1$) when an NM appears (disappears), a corresponding QNM disappears (appears).

Furthermore, we have shown that the nontrivial linear-space structure for QNMs and any possible JBs are preserved by SUSY—the latter being a feature not found in conservative systems.

QNMs differ from NMs in two further regards. First, they have complex frequencies; nevertheless, even with twice as many constraints, matching the spectra turns out to be not any more difficult. Second, QNMs need not have an increasing number of nodes, and it is often possible to find several nodeless QNMs which generate distinct SUSY transformations—whereas the analogous operation for NMs would restrict the generator to the nodeless ground state.

These wider perspectives are gained only because attention is paid to the Klein–Gordon rather than the Schrödinger equation, since the concept of outgoing waves has no meaning in an equation that is first order in time.

Two further important properties are also preserved. (a) If V has a singularity say at $x=\pm a$ (e.g., a step), then $\tilde{V}$ will have the same type of singularity, but with the opposite sign, as can be seen from (2.7) by noticing that the most singular part is W'. (b) If V has finite support, then provided Φ is not of the mixed type, $\tilde{V}$ would likewise have no tail. These two properties are precisely the conditions for the eigenstates in Γ to be complete.[26] Thus, SUSY maps a complete basis to a complete basis (if, for the $\chi=\pm 1$ cases, $\Phi \mapsto \tilde{\Phi}$ is included as well).

B. Inversion

This work partially answers the question of QNM *inversion*. It is well known[35] that on a finite interval, *two* sets of real NM frequencies uniquely determine the potential V. Does *one* set of *complex* eigenfrequencies in Γ also uniquely determine V? The answer is negative: There can be strictly isospectral potentials if a TTM with purely imaginary frequency exists and can be used as a $\chi=0$ generator; Fig. 2 provides one such example. However, the following scenario is not yet ruled out. If we consider a half-line problem $0<x<\infty$ (say corresponding to the radial variable in a three-dimensonal system), imposing a nodal condition at $x=0$ and the OWC for $x>a$, can one set of QNM frequencies uniquely determine the potential? SUSY transformations (2.4) do not directly resolve this possibility—for which there is some numerical evidence[36]—since these one-sided systems do not feature an analog of TTMs with which one could construct strictly isospectral partners. Moreover, by (2.7) and (2.9) the nodal condition maps a regular V to $\tilde{V}\sim 2/x^2$ for $x\to 0^+$ (generalizing the well-known result that SUSY increases the angular momentum by one unit in the hydrogen atom). It would, therefore, be interesting to see if an enlarged class of transformations can address this question.

C. Total-transmission modes

The present paper refers in the main to states in Γ, i.e., states that satisfy the OWC at both extremes. One could develop the same formalism for TTMs; see, e.g., the end of Sec. V. Note that we here consider TTMs as states on which SUSY acts, rather than as ($\chi=0$) generators. To be more specific, the SUSY transformation acts on the space Γ_L of TTM_L's

$$\phi(x)\sim e^{i\omega x}, \quad |x|\to\infty, \tag{6.1}$$

or (equivalently, under $\omega \mapsto -\omega$) the space Γ_R of $\mathrm{TTM_R}$'s

$$\phi(x) \sim e^{-i\omega x}, \quad |x| \to \infty. \tag{6.2}$$

One significant difference is that a $\chi = \pm 1$ transformation preserves the eigenvalues in these spaces, whereas a $\chi = 0$ transformation may shift one state.

D. Tails

So far we have only considered potentials with finite support. We end with an outline of some issues that arise for long-range potentials.

The most obvious difference is that if V and/or $\tilde{V}$ are allowed to have tails that decay exponentially or slower in $|x|$, then the mixed-type SUSY transformation is allowed, and there is a *continuous* choice of generators.

However, there are a range of more subtle issues. First, the very definition of an outgoing wave requires care. At the numerical level, special treatment is needed to ensure convergence,[37] but there are matters of principle as well when the OWC $\phi(\omega,x) \sim e^{+i\omega|x|}$ is imposed only as $|x| \to \infty$. In that limit, the condition as stated becomes vacuous for $\mathrm{Im}\,\omega < 0$, since admixture of an (exponentially smaller) incoming solution would not alter this behavior. Rather, it is necessary to define the OWC in the upper half-plane in ω and analytically continue to the lower half-plane. A wave $\phi(\omega,x)$ is incoming if $\phi(-\omega,x)$ is outgoing;[8] this is equivalent to saying that incoming waves are defined first in the lower and continued to the upper half-plane. The necessity for these procedures makes it possible that (at certain singular points ω) a wave function can be *both* incoming and outgoing.

Singularities in the one-sided functions[38] can only occur because of the need to integrate the defining equation over an infinite range. Those values of ω for which these functions (say the left function f) are singular are said to be *anomalous*; if the potential is not oscillating, anomalous points can only occur on the imaginary axis—precisely where possible SUSY generators are to be found. The case of an exponential tail $V(x) \sim V_1 e^{-\lambda|x|}$ is of particular interest because the anomalous points (at $\omega_m = -im\lambda/2$, $m = 1,2,\ldots$) can be studied by the Born approximation, which in this case is equivalent to a power-series expansion in $z = e^{-\lambda|x|}$. More generally, if

$$V(x) = \sum_{k=1}^{\infty} V_k e^{-k\lambda|x|}, \tag{6.3}$$

then for particular choices of the coefficients V_k, one (or more) of the generically anomalous points ω_m may turn out to be regular—a situation we refer to as *miraculous*. The anomalous and miraculous properties for the one-sided functions f and g are inherited by their Wronskian J, which is central to the formalism. These concepts have been discussed in relation to a particular application.[39]

As far as SUSY is concerned, we only make one remark: Such singularities lead to poles in $J(\omega)$, thus are associated with negative values of $n(\omega)$, and are related in SUSY partners by (2.15). The Pöschl–Teller potential[40] $V(x) = \mathcal{V}\,\mathrm{sech}^2(x/b)$ illustrates many interesting features, including the existence of double poles of $J(\omega)$ which can merge with two zeros and lead to "nothing"—a potential that has total transmission at *all* energies.[41]

Anomalous points are exceptional (in the case of exponential tails being a discrete set of measure zero in the ω-plane) and miraculous cancellation of singularities doubly exceptional. One might therefore think that these are not important. Surprisingly however, the problem of linearized gravitational waves propagating on a black-hole background[42] is precisely miraculous in this sense, at the so-called algebraically special frequency Ω.[43] A generator at Ω leads to a SUSY transformation that exactly relates the axial and polar sectors, which are, therefore, isospectral in Γ. Among the more intriguing results is the following:[39] At Ω, there is a mode in the polar sector that is simultaneously a QNM *and* a TTM (i.e., at radial infinity it is purely outgoing but into the event horizon it is both outgoing and incoming), while no modes exist in the axial sector.

The subtle and perhaps counter-intuitive nature of these concepts demands a separate and rigorous examination, to which the foregoing is meant only as a preview—and as further illustration of the utility of SUSY in dealing with waves in open systems.

ACKNOWLEDGMENTS

APPENDIX: NODES IN QNM WAVE FUNCTIONS

Nodeless eigenstates play a special role in SUSY: They are candidates for the generator Φ. It is, therefore, useful to highlight the differences between NMs and QNMs in this regard, especially to contrast with the well-known property that there can be *only one* nodeless NM.

First of all, we show that for QNMs with $\mathrm{Re}\,\omega\neq 0$, there can be at most one node or antinode. This is not surprising: Since the eigenvalue is complex, the wave function has a changing phase, and it would be ''unlikely'' that the real and imaginary parts (or their derivatives) would vanish together. To prove this formally, take the Schrödinger point of view, so that the eigenvalue is $E=\omega^2$ with a nonzero imaginary part. Now consider a time-dependent QNM and suppose that it has nodes or antinodes at two points x_1, x_2. At these two points, the current

$$\mathcal{J}=i[\phi^*(\partial_x\phi)-(\partial_x\phi^*)\phi] \tag{A1}$$

vanishes. Then, flux conservation implies that the total probability in the interval $[x_1,x_2]$ is constant in time. Yet the wave function is either growing or decaying, since $\mathrm{Im}\,E\neq 0$, which is, therefore, a contradiction.

From the perspective of SUSY it is unfortunate that the above proof excludes the crucial imaginary axis. However, on that axis the statement remains valid for repulsive potentials, or more generally for potentials which are so weakly attractive that $V-\omega^2$ is positive definite.[44] Namely, let ϕ be a solution with two (anti)nodes. By taking the real or imaginary part, we may assume ϕ to be real. Now between two nodes ϕ would have an extremum, i.e., $\phi''\phi<0$ which is incompatible with the KGE. Similarly, an antinode can only be a global maximum or minimum, precluding the presence of any other nodes or antinodes.

Thus, except for the imaginary axis in the case of attractive potentials, QNMs can have at most one node or antinode. For symmetric potentials, in the even sector $x=0$ is already an antinode, so there can be no nodes anywhere.

For zero modes, i.e., QNMs with $\mathrm{Re}\,\omega=0$, nodes are more ''likely'': The eigenvalue is real and the wave function has a constant phase (say purely real), so a node requires only *one* condition, rather than two. Nevertheless, in contrast to the conservative case, the proof that there can be only one nodeless eigenstate can be bypassed.

The interlacing nodal structure of NM eigenfunctions follows from well-established Sturm–Liouville theory. For the present purpose, we do not need the full apparatus. Consider, for simplicity, a finite interval $[-a,a]$ and suppose there are two distinct nodeless eigenfunctions ϕ_1,ϕ_2, both real. Then they can both be chosen to be positive, which violates the orthogonality condition for NMs

$$\int_{-a}^{a}\phi_1(x)\,\phi_2(x)\,dx=0. \tag{A2}$$

We can attempt to transplant the argument to QNMs. For zero modes, the wave functions can again be chosen to be real, and if they are nodeless, positive definite. However, the analog of (A2) for two eigenfunctions with eigenvalues $\omega_j=-i\gamma_j$ is

$$-(\gamma_1+\gamma_2)\int_{-a}^{a}\phi_1(x)\phi_2(x)\,dx+[\phi_1(-a)\phi_2(-a)+\phi_1(a)\phi_2(a)]=0. \tag{A3}$$

Note in particular the signs of the two terms. With $\gamma_j>0$, this condition does *not* preclude both eigenfunctions from being positive definite.

Thus, we can make three remarks. (a) For NMs, there can be *only one* nodeless state. (b) For QNMs with $\mathrm{Re}\,\omega=0$, there *could be* more than one state with no node. (c) For QNMs with $\mathrm{Re}\,\omega\neq 0$, or with $\mathrm{Re}\,\omega=0$ but $V-\omega^2$ positive definite, each eigenfunction can have at most one node or antinode, and for symmetric potentials, *every* even eigenfunction is nodeless.

Case (b) in particular opens up the possibility of multiple SUSY transformations.

[16] In other papers, we have also considered NMs obtained as the zero-leakage limit of QNMs, e.g., by considering potentials with a barrier of indefinitely increasing height at $x\approx\pm a$. Such NMs would be defined on finite intervals, and have positive eigenvalues ω^2; thus they are represented on the real ω-axis. In this paper we do *not* consider the zero-leakage limit, so there is no danger of confusing NMs in this sense with the NMs on the positive imaginary axis in the ω-plane.
[17] If $\mathrm{Im}\,\omega>0$, the eigenfunction is square-integrable, so the Hermiticity of H implies that $\omega^2\in\mathbf{R}$.
[18] These are not to be confused with states with zero eigenvalue, which are sometimes called zero modes in the SUSY literature. We shall not use this latter nomenclature.

[30] For a one-dimensional system with $V(|x|>a)=0$, starting at one end (say $x=-a$) and using the known logarithmic derivative ϕ'/ϕ appropriate to the OWC and an arbitrary normalization, one gets a unique wave function. Thus there can be at most one eigenstate in Γ at any ω; there can be no degeneracies.
[31] Note the difference in notation from Ref. 39, where $\tilde{f}$ and $\tilde{g}$ denote *normalized* functions.

[32] This relation also yields a counterpart of (3.15) for the (Q)NM corresponding to the generator Φ itself, $(\tilde{\Phi},\tilde{\Phi}) = J(-\Omega)/[2\Omega\Phi(-a)\Phi(a)]$.

[33] If the double pole is split along the imaginary axis, there are two distinct SUSY transforms generated by $\tilde{\Phi}$ and $\tilde{\Psi}_j$, respectively, which become identical when the poles merge. Thus, in the spirit of the JB approach to the field expansion, one might try to find the "missing" SUSY map generated by $\tilde{\Psi}_{j,1}$. However, no meaningful transformation emerges. This difference with the case of the field expansion can be understood by realizing that, when the poles split perpendicular to the imaginary axis upon changing the sign of the splitting perturbation, the SUSY transforms cease to exist altogether.

[34] The pre-image is unique only up to adding a multiple of $f(\Omega,x)$; but this does not alter the conclusion that none of these pre-images are in Γ.

(Received 21 August 2000; accepted for publication 19 July 2001)

The sufficient conditions under which the S-matrix orthogonal part $U(k)$ is real and even are proved. These conditions are required for generalization of the projection matrices method in the $N\times N$ Riemann–Hilbert boundary value problem, $N=2,3,...,N<+\infty$. The dependence of the analytical properties of the orthogonal matrix $U(k)$ on the S-matrix diagonal part is thoroughly considered. The examples in which the sufficient conditions are not realized and $\mathrm{Re}\,U(k)\neq 0$, $U(-k)=-U(k)$ are demonstrated. © *2001 American Institute of Physics.*
[DOI: 10.1063/1.1401137]

I. INTRODUCTION

The S-matrix belongs to a unitary matrix class and it is widely applied in the scattering theory and the inverse problem Refs. 1–3. As any unitary matrix, the S-matrix can be diagonalized by orthogonal matrix $U(k)$ on the real k axis. However, on the basis of this fact, it is impossible to tell more about analytical properties of $U(k)$.

There is a wide variety of different applications in which it is assumed that the equalities:

$$U^*(k)=U(k), \quad \mathrm{Im}\,k=0, \tag{1}$$

$$U(-k)=U(k), \quad \mathrm{Im}\,k=0, \tag{2}$$

are true; in this case the proof is not considered. As a rule, the reason is that the equalities (1) and (2) can easily be verified by calculations.

However, this approach is not adequate for generalization of fundamental mathematical methods as the mathematical generality of methods can be lost. Moreover, the amount of soluble problems can be decreased too.

Properties (1) and (2) play a really significant part in solving Riemann–Hilbert matrix boundary value problem by projection matrices method Refs. 4–7. This method allows solving the boundary value problem without using the system of the singular integral equations. Conditions (1) and (2) form the basis for the construction procedure of the projection matrices. Nevertheless, the individual proof of these equalities had never been carried out. It was because the equalities automatically resulted from the special assumptions for the S-matrix form and dimension.

For the above mentioned reasons generalization of the projection matrices method is impossible without detailed research of sufficient conditions under which the matrix $U(k)$ is real and even in case of $N\times N$ dimension, $N=2,3,...,N<+\infty$. For the projection matrices method to be promising, these conditions must define rather a wide unitary matrix class. Furthermore, the S-matrix is the fundamental object in the scattering theory and inverse problem. For these reasons the dependence of the analytical properties of the orthogonal matrix $U(k)$ on the S-matrix diagonal part is of great interest and it should be treated as a separate problem.

[a)]Fax: 8462-380965. Electronic mail: muravyev@tfs.ru

The conditions under which the S-matrix orthogonal part is real are considered in Sec. II. The conditions under which the matrix $U(k)$ is even are proved in Sec. III. To illustrate the achieved results, at the end of Secs. II and III we consider the examples in which the sufficient conditions are not realized and $\mathrm{Re}\, U(k)\neq 0$, $U(-k)=-U(k)$.

II. THE SUFFICIENT CONDITION AT WHICH THE MATRIX $U(k)$ IS REAL

Let us consider the unitary matrix $S(k)$ on the real k axis at $k\in(-R,R), R>0$, i.e.

$$(S^*(k))^T=S^{-1}(k),\quad k\in(-R,R). \tag{3}$$

Let us assume that the matrix $S(k)$ has the form

$$S(k)=U(k)S^{(0)}(k)U^T(k),\quad k\in(-R,R), \tag{4}$$

where

$$U^{-1}(k)=U^T(k),\quad k\in(-R,R), \tag{5}$$

$$[S^{(0)}(k)]_{\alpha\beta}=\delta_{\alpha\beta}\exp(i2\,\delta_\alpha(k)),\quad \alpha,\beta=1,2,...,N,\quad k\in(-R,R), \tag{6}$$

$$\mathrm{Im}\,\delta_\alpha(k)=0,\quad \delta_\alpha(-k)=-\delta_\alpha(k),\quad \alpha=1,2,...,N,\quad k\in(-R,R), \tag{7}$$

$$\delta_{\alpha\beta}=\begin{cases}1, & \alpha=\beta,\\ 0, & \alpha\neq\beta,\end{cases}\quad \alpha,\beta=1,2,...,N.$$

Here the symbol $\delta_\alpha(k)$ designates some scalar function and $\delta_{\alpha\beta}$ is Kronecker delta.

Lemma 1. If conditions (3)–(7) are true and

$$\forall\,\alpha\neq\beta,\ \exists k_0,\ \delta_a(k_0)-\delta_\beta(k_0)\neq\pm\pi l,\quad l=0,1,2,...,\ l<+\infty,\quad k_0\in(-R,R), \tag{8}$$

then

$$U^*(k)=U(k),\quad k\in(-R,R). \tag{9}$$

Let us prove property (9). Using conditions (3)–(7) we can write

$$S(k)(S^*(k))^T=S(k)S^*(k)=E,\quad k\in(-R,R), \tag{10}$$

where E is the matrix unit. Let us designate as $C(k)$ the following matrix combination:

$$C(k)=U^T(k)U^*(k),\quad k\in(-R,R). \tag{11}$$

From formula (10) we easily obtain the following equality:

$$S^{(0)}(k)C(k)(S^{(0)}(k))^*=C(k),\quad k\in(-R,R). \tag{12}$$

Using formulas (6) and (7) we can rewrite (12) in the following form:

$$[C(k)]_{\alpha\beta}\exp(i2\,\delta_\alpha(k)-i2\,\delta_\beta(k))=[C(k)]_{\alpha\beta},\quad \alpha,\beta=1,2,...,N,\quad k\in(-R,R). \tag{13}$$

Let us discuss Eq. (13) in detail.

If $\alpha=\beta$ then (13) is true. Let us consider the case when $\alpha\neq\beta$. On the strength of condition (8) we can conclude that Eq. (13) will be true in the only case when

$$[C(k)]_{\alpha\beta}=0,\quad \alpha\neq\beta,\quad \alpha,\beta=1,2,...,N,\quad k\in(-R,R). \tag{14}$$

Let us calculate the value of the matrix element $[C(k)]_{\alpha\alpha}$, $\alpha=1,2,...,N$. Formulas (5) and (11) show us that the matrix $C(k)$ is orthogonal at $k\in(-R,R)$, i.e.,

$$\sum_{\gamma=1}^{N}[C(k)]_{\alpha\gamma}[C^T(k)]_{\gamma\beta}=\sum_{\gamma=1}^{N}[C(k)]_{\alpha\gamma}[C(k)]_{\beta\gamma}=\delta_{\alpha\beta},\quad \alpha,\beta=1,2,...,N,\quad k\in(-R,R). \tag{15}$$

Then from Eqs. (14) and (15) we can conclude that:

$$([C(k)]_{\alpha\alpha})^2=1,\quad \alpha=1,2,...N,\quad k\in(-R,R).$$

Thus

$$[C(k)]_{\alpha\alpha}=\pm 1,\quad \alpha=1,2,...,N,\quad k\in(-R,R). \tag{16}$$

Using formula (11) let us rewrite the left part of Eq. (16) in detail. We obtain the following results:

$$[C(k)]_{\alpha\alpha}=\sum_{\gamma=1}^{N}[U^T(k)]_{\alpha\gamma}[U^*(k)]_{\gamma\alpha}=\sum_{\gamma=1}^{N}[U(k)]_{\gamma\alpha}[U^*(k)]_{\gamma\alpha},\quad k\in(-R,R). \tag{17}$$

Since

$$[U(k)]_{\gamma\alpha}[U^*(k)]_{\gamma\alpha}=|[U(k)]_{\gamma\alpha}|^2\geqslant 0,\quad \alpha,\gamma=1,2,...,N,\quad k\in(-R,R),$$

then from (17) it follows that:

$$[C(k)]_{\alpha\alpha}\geqslant 0,\quad \alpha=1,2,...,N,\quad k\in(-R,R). \tag{18}$$

Taking into account formula (14) and comparing conditions (16) and (18) we can conclude that:

$$[C(k)]_{\alpha\beta}=\delta_{\alpha\beta},\quad \alpha,\beta=1,2,...,N,\quad k\in(-R,R).$$

Then formula (11) has the form

$$E=U^T(k)U^*(k),\quad k\in(-R,R). \tag{19}$$

On the whole property (9) results from (19), i.e., the lemma is proved now. It is evident that property (1) can be obtained from (9) at $R\to+\infty$. Thus, the sufficient conditions at which the S-matrix orthogonal part is real are proved.

Let us consider the simple example when condition (8) is not realized. Let us assume that the S-matrix orthogonal part has the form:

$$S^{(0)}(k)=\begin{pmatrix}\exp(i2\delta_1(k)) & 0 & 0\\ 0 & 1 & 0\\ 0 & 0 & 1\end{pmatrix},\quad k\in(-R,R),$$

i.e., condition (8) is not realized for the matrix elements $[S^{(0)}(k)]_{22}$,$[S^{(0)}(k)]_{33}$. It allows constructing the orthogonal matrix $U(k)$ that is not real

$$U(k)=\frac{1}{\sqrt{k^2-b^2}}\begin{pmatrix}1 & 0 & 0\\ 0 & k & ib\\ 0 & -ib & k\end{pmatrix},\quad k\in(-R,R),\quad b>0.$$

Here we can use any sheet of Riemann surface for $\sqrt{k^2-b^2}$ because it is unimportant in this case. Although, properties (3)–(7) of the S-matrix are true, the matrix $U(k)$ is not real and it can be singular at $k_1=b,\ k_2=-b,\ b<R$ now.

III. THE SUFFICIENT CONDITIONS AT WHICH THE MATRIX $U(k)$ IS EVEN

Let us designate as $A_{(-R,R)}$ the class of continuous matrix at $k\in(-R,R)$ (i.e., the matrix elements are continuous functions).

Lemma 2. If conditions (3)–(8) are true and

$$S(-k)=S^{-1}(k),\quad k\in(-R,R), \tag{20}$$

$$U(k)\in A_{(-R,R)},\quad k\in(-R,R), \tag{21}$$

then

$$U(-k)=U(k),\quad k\in(-R,R). \tag{22}$$

Let us prove property (22). Using the matrix $S(-k)$ instead of the matrix $S^*(k)$ and the matrix:

$$C(k,-k)=U^T(k)U(-k),\quad k\in(-R,R), \tag{23}$$

instead of $C(k)$ in the formulas (10), (12), (13), and (15), we can obtain the following results:

$$[C(k,-k)]_{\alpha\beta}=0,\quad \alpha\neq\beta,\ \alpha,\beta=1,2,...,N,\quad k\in(-R,R), \tag{24}$$

$$[C(k,-k)]_{\alpha\alpha}=\pm 1,\quad \alpha=1,2,...,N,\quad k\in(-R,R). \tag{25}$$

The formulas (24) and (25) are analogous in derivation to (14) and (16), respectively.

Taking into account Eq. (23) let us rewrite the left part of (25) in detail

$$[C(k,-k)]_{\alpha\alpha}=\sum_{\gamma=1}^{N}[U^T(k)]_{\alpha\gamma}[U(-k)]_{\gamma\alpha}=\sum_{\gamma=1}^{N}[U(k)]_{\gamma\alpha}[U(-k)]_{\gamma\alpha},$$
$$\alpha=1,2,...,N,\quad k\in(-R,R). \tag{26}$$

Let us assume that $k=0$ in the Eq. (26). According to lemma conditions, the matrix elements of $U(k)$ are the continuous functions at $k\in(-R,R)$ [see formula (21)]. It means that: $U(+0)=U(-0)$. Thus, Eq. (26) has the form

$$[C(0,0)]_{\alpha\alpha}=\sum_{\gamma=1}^{N}([U(0)]_{\gamma\alpha})^2,\quad \alpha=1,2,...,N, \tag{27}$$

now. Moreover, lemma conditions show us that (9) is true. Consequently, we can write

$$([U(0)]_{\gamma\alpha})^2\geqslant 0,\quad \alpha,\gamma=1,2,...,N. \tag{28}$$

Then from (27) and (28) it follows that:

$$[C(0,0)]_{\alpha\alpha}\geqslant 0,\quad \alpha=1,2,...,N. \tag{29}$$

Let us return to Eq. (25) now. On the strength of Eqs. (21) and (23) we can conclude that matrix elements of $C(k,-k)$ are continuous functions at $k\in(-R,R)$, i.e., $C(k,-k)\in A_{(-R,R)}$. Consequently, from two equalities

$$[C(k,-k)]_{\alpha\alpha}=1,\quad \alpha=1,2,...,N,\quad k\in(-R,R), \tag{30}$$

$$[C(k,-k)]_{\alpha\alpha}=-1, \quad \alpha=1,2,...,N, \quad k\in(-R,R), \tag{31}$$

only one must be true. Taking into account (29) we can conclude that Eq. (30) is true and Eq. (31) is false. Thus, on the basis of Eqs. (24) and (30) we can write

$$[C(k,-k)]_{\alpha\beta}=\delta_{\alpha\beta}, \quad \alpha,\beta=1,2,...,N, \quad k\in(-R,R).$$

Then formula (23) has the following form:

$$E=U^T(k)U(-k), \quad k\in(-R,R). \tag{32}$$

On the whole property (22) results from Eq. (32). It is evident that property (2) can be obtained from (22) at $R\to+\infty$. Thus, the sufficient conditions at which the S-matrix orthogonal part is even are proved.

In order to demonstrate the significance of condition (21) we shall consider the following example. Let us assume that the matrix $U(k)$ has the form:

$$U(k)=\frac{1}{\sqrt{k^2+\sqrt[3]{k^2}}}\begin{pmatrix} k & \sqrt[3]{k} \\ -\sqrt[3]{k} & k \end{pmatrix}, \quad k\in(-R,R), \tag{33}$$

and S-matrix diagonal part satisfies the conditions (6) and (7). Neither (9) nor (21) is true for the matrix $U(k)$ [see formula (33)] in general case. This is because the matrix elements of $U(k)$ are combinations of the 2-sheet and 3-sheet functions. However, using special conditions for the sheets of Riemann surface we can satisfy condition of (9). Since

$$\sqrt[3]{k}=|\sqrt[3]{k}|\exp\left[\frac{i}{3}(\arg k+2\pi l)\right], \quad k\in(-R,R), \quad l=0,1,2,$$

then we can fix the sheets of Riemann surface in the following way:

$$\sqrt[3]{k}=|\sqrt[3]{k}|, \quad k\in(0,R), \quad \arg k=0, \quad l=0, \tag{34}$$

$$\sqrt[3]{k}=-|\sqrt[3]{k}|, \quad k\in(-R,0), \quad \arg k=\pi, \quad l=1. \tag{35}$$

In this case the matrix $U(k)$ satisfies condition (9).

Let us prove that:

$$[U(+0)]_{12}\neq[U(-0)]_{12}. \tag{36}$$

In order to do this we calculate $[U(k)]_{12}$ at $k\in(0,R)$ in detail. On the basis of Eqs. (33) and (34) we can write

$$[U(k)]_{12}=\frac{\sqrt[3]{k}}{\sqrt{k^2+\sqrt[3]{k^2}}}=\frac{|\sqrt[3]{k}|}{\sqrt{|k|^2+|\sqrt[3]{k}|^2}}=\frac{|\sqrt[3]{k}|}{\sqrt{|\sqrt[3]{k}|^2}\sqrt{|k^{2/3}|^2+1}}, \quad k\in(0,R). \tag{37}$$

In this case we can use any sheet of Riemann surface for the function $\sqrt{|\sqrt[3]{k}|^2}$. Let us assume that

$$\sqrt{|\sqrt[3]{k}|^2}=|\sqrt[3]{k}|, \quad k\in(-R,R), \tag{38}$$

then

$$[U(k)]_{12}=\frac{|\sqrt[3]{k}|}{|\sqrt[3]{k}|\sqrt{|k^{2/3}|^2+1}}=\frac{1}{\sqrt{|k^{2/3}|^2+1}}, \quad k\in(0,R). \tag{39}$$

Using (35) and (38) it is easy to demonstrate that

$$[U(k)]_{12}=\frac{-|\sqrt[3]{k}|}{|\sqrt[3]{k}|\sqrt{|k^{2/3}|^2+1}}=\frac{-1}{\sqrt{|k^{2/3}|^2+1}},\quad k\in(-R,0). \tag{40}$$

Let us assume that $k\to+0$ in Eq. (39) and $k\to-0$ in Eq. (40). Thus

$$[U(+0)]_{12}=1,\quad [U(-0)]_{12}=-1,$$

whence follows the proof of Eq. (36).

We can obtain the analogous result for $[U(k)]_{21}$, i.e.,

$$[U(+0)]_{21}=-1,\quad [U(-0)]_{21}=1.$$

Using (34), (35), and (38) we can conclude that

$$[U(+0)]_{11}=[U(-0)]_{11}=0,\quad [U(+0)]_{22}=[U(-0)]_{22}=0.$$

The above introduced considerations show that conditions (3)–(8), and (20) are true. However, the condition (21) is not realized at $k=0$. On the basis of the Eqs. (33)–(35) we can see that

$$U(-k)=-U(k),\quad k\in(-R,R),$$

i.e., the matrix $U(k)$ is odd.

IV. THE CONCLUSION

To prove the conditions under which the matrix $U(k)$ is real we have done the following. One additional condition (8) has been added to the standard properties of the S-matrix (3)–(7) (at $R\to+\infty$). From the physical standpoint it means that processes described by the functions $\delta_\alpha(k)$, $\delta_\beta(k)$ α, $\beta=1,2,...,N$ are not identical.

In addition to formulas (3)–(7), three complementary conditions (8), (20), and (21) have been required to prove property (22). The essence of (8) has been discussed above. Formula (20) describes the standard property of the S-matrix for the elastic scattering at $R\to+\infty$. As for condition (21), it has been introduced for mathematical reasons. However, there are many applications where this condition is realized automatically.

Thus, conditions (3)–(8), (20), and (21) define rather a wide class of the unitary matrix which can be used in applications and in generalization of projection matrices method. Besides, they reflect dependence of analytical properties of the orthogonal matrix $U(k)$ on the S-matrix diagonal part.

n-symplectic algebra of observables in covariant Lagrangian field theory

L. K. Norris
Department of Mathematics, North Carolina State University, Raleigh, North Carolina 27695-8205

(Received 16 February 2001; accepted for publication 5 July 2001)

n-symplectic geometry on the adapted frame bundle $\lambda:L_\pi E\to E$ of an $n=(m+k)$-dimensional fiber bundle $\pi:E\to M$ is used to set up an algebra of observables for covariant Lagrangian field theories. Using the principle bundle $\rho:L_\pi E\to J^1\pi$ we lift a Lagrangian $\mathcal{L}:J^1\pi\to\mathbb{R}$ to a Lagrangian $L:=\rho^*(\mathcal{L}):L_\pi E\to\mathbb{R}$, and then use L to define a "modified n-symplectic potential" $\hat{\theta}_L$ on $L_\pi E$, the Cartan–Hamilton–Poincaré (CHP) $\mathbb{R}^n$-valued 1-form. If the lifted Lagrangian is nonzero, then $(L_\pi E, d\hat{\theta}_L)$ is an n-symplectic manifold. To characterize the observables we define a lifted Legendre transformation ϕ_L from $L_\pi E$ into LE. The image $Q_L:=\phi_L(L_\pi E)$ is a submanifold of LE, and $(Q_L, d(\hat{\theta}|_{Q_L}))$ is shown to be an n-symplectic manifold. We prove the theorem that $\hat{\theta}_L=\phi_L^*(\theta|_{Q_L})$, and pull back the reduced canonical n-symplectic geometry on Q_L to $L_\pi E$ to define the algebras of observables on the n-symplectic manifold $(L_\pi E, d\hat{\theta}_L)$. To find the reduced n-symplectic algebra on Q_L we set up the equations of n-symplectic reduction, and apply the general theory to the model of a k-tuple of massless scalar fields on Minkowski space–time. The formalism set forth in this paper lays the ground work for a geometric quantization theory of fields. © *2001 American Institute of Physics.* [DOI: 10.1063/1.1396835]

I. INTRODUCTION

In order to set up a quantization scheme for Lagrangian field theories modeled on the Kostant–Souriau theory of geometric quantization[1,2] one needs to find an analog of the algebra of observables $C^\infty(M,\mathbb{R})$ under the Poisson bracket and the isomorphic algebra of connection preserving vector fields on a line bundle $L^\times\to M$ over a symplectic manifold (M,ω). In this paper we construct an algebra of observables for covariant Lagrangian field theories using the n-symplectic theory[3–9] as the engine for the construction. In a companion paper[10] the algebra constructed here is used as the basis for setting up a Kostant–Souriau geometric quantization scheme for covariant Lagrangian field theories. For other geometric approaches to quantization of fields see the work of Kanatchikov[11] who bases his work on the polysymplectic geometry of Günther,[12] and also Hrabak,[13] whose work is based on the multisymplectic geometry of Gotay *et al.*[14]

Let $\mathcal{L}:J^1\pi\to\mathbb{R}$ be a field Lagrangian for a section of an $n=m+k$ dimensional fiber bundle $\pi:E\to M$ over the m dimensional manifold M. To use the n-symplectic theory to construct an algebra of observables we lift the Lagrangian on $J^1\pi$ to the bundle of adapted linear frames $L_\pi E$, the subbundle of LE that arises[15,8,9] due to the fiber structure of $E\to M$. (Throughout the paper we use the index range convention $i,j=1,2,\ldots,m$, $A,B=m+1,m+2,\ldots,m+k$, and $\alpha,\beta=1,2,\ldots,m+k$.) A point in $L_\pi E$ is a triple (e,e_i,e_A), where $e\in E$ and (e_i,e_A) is a linear frame for the tangent space to E at e in which the last k vectors (e_A) are vertical on $\pi:E\to M$. The lifting of $\mathcal{L}:J^1\pi\to\mathbb{R}$ to $L_\pi E$ is natural since $L_\pi E$ is known[9] to be an $H=\mathrm{GL}(m)\times\mathrm{GL}(k)$ principal fiber bundle over $J^1\pi$. If $\rho:L_\pi E\to J^1\pi$ then we put $L:=\rho^*(\mathcal{L})$. Using a lifted Legendre transformation we construct the Cartan–Hamilton–Poincaré (CHP) 1-forms $\hat{\theta}_L$ first introduced in

Ref. 9, and prove the theorem that $(L_\pi E, d\hat{\theta}_L)$ is an n-symplectic manifold provided the Lagrangian is nonzero. The observables of the theory are then the $\otimes^p\mathbb{R}^n$-valued functions $\hat{f}$ on $L_\pi E$ that satisfy the n-symplectic structure equation,

$$d\hat{f} = -p!\, X_{\hat{f}} \lrcorner d\hat{\theta}_L \tag{1.1}$$

for some $\otimes^{p-1}\mathbb{R}^n$-valued vector field $\hat{X}_{\hat{f}}$. (Here $\lrcorner$ denotes a tensor product in the range and interior product in the domain.) We will show that the set of allowable observables carries a natural graded Poisson algebra structure, and that the set of all corresponding vector-valued Hamiltonian vector fields $\hat{X}_{\hat{f}}$ has a natural Lie algebra structure as well.

The plan of the paper is the following. In Sec. II we develop the algebraic structure that is defined by an n-symplectic structure on an N-dimensional manifold P. Such a structure is defined by an $\mathbb{R}^n$-valued 2-form $\hat{\omega}$ that is both closed and nondegenerate. We will refer to $(P,\hat{\omega})$ as an n-symplectic manifold. To illustrate the theory we will carry along the canonical example of the bundle of linear frames $P=LE$ (Refs. 3, 4, 5 6) and its canonically defined n-symplectic structure $\hat{\omega}=d\hat{\theta}$, where $\hat{\theta}$ is the $\mathbb{R}^n$-valued soldering 1-form. In the general case we show that $\hat{\omega}$ defines a Poisson algebra SHF of $\otimes^p_{(\mathrm{sym})}\mathbb{R}^n$-valued functions on P, the observables of the theory, together with a Lie algebra of vector-valued Hamiltonian vector fields. When $P=LE$ and $\hat{\omega}=d\hat{\theta}$ the observables are symmetric polynomials in the $\mathbb{R}^n$-valued momenta $\hat{\pi}_\alpha$ with coefficients that are constant on the fibers of $\lambda: LE\to E$. The homogeneous polynomial observables in this case correspond uniquely to symmmetric contravariant tensor fields on E, and the Poisson bracket of two such observables on $L_\pi E$ corresponds[6] to the Schouten–Nijenhuis bracket[16,17] of the corresponding tensor fields on E. There is a corresponding development for $\otimes^p_{(\mathrm{skew})}\mathbb{R}^n$-valued functions on P, which turns out to be a graded Poisson algebra. The direct sum of these two algebras is then a graded Poisson algebra.

In Sec. III we present the relevant details of the canonical n-symplectic geometry on LE, and the reduced subbundle of adapted linear frames $L_\pi E$. In Sec. IV we recall the bundle structure $\rho: L_\pi E\to J^1\pi$ and the definition[9] of the modified soldering 1-forms on $L_\pi E$, which we refer to as the Cartan–Hamilton–Poincaré (CHP) $\mathbb{R}^n$-value 1-form. The CHP 1-form is defined herein as the pull-back, under a lifted Legendre transformation, of the canonical $\mathbb{R}^n$-valued soldering 1-form on LE to $L_\pi E$. We then prove the theorem that $(L_\pi E, d\hat{\theta}_L)$ is an n-symplectic manifold provided that L is nonzero. The algebra of observables defined by a Lagrangian is then the graded Poisson algebra defined by this n-symplectic structure.

In order to find the observables defined by a specific Lagrangian we consider in Sec. V the image $Q_L\subset LE$ of $L_\pi E$ under the lifted Legendre transformation. To characterize the n-symplectic observables on $(Q_L, d\hat{\theta})$ we carry out a reduction of the canonical n-symplectic geometry on LE to Q_L. Our method leads to a system of PDE's that characterize those n-symplectic observables on $(LE, d\hat{\theta})$ that restrict the observables on $(Q_L, d(\hat{\theta}|_{Q_L}))$. In Sec. VI we apply the theory to the massless n-tuple of scalar fields on Minkowski space–time. Section VII contains a brief summary of our results and some ideas for future work.

II. *n*-SYMPLECTIC GEOMETRY

Let P be an N-dimensional manifold, and let $(\hat{r}_\alpha)$ denote the standard basis of $\mathbb{R}^n$, with $1\leqslant n\leqslant N$. We suppose there exists on P an n-**symplectic structure**, namely, an $\mathbb{R}^n$-valued 2-form $\hat{\omega}=\omega^\alpha\otimes\hat{r}_\alpha$ that satisfies the following two conditions:

$$(C-1)\quad d\omega^\alpha=0\quad \forall\,\alpha=1,2,\ldots,n, \tag{2.1}$$

$$(C-2)\quad X\lrcorner\hat{\omega}=0\Leftrightarrow X=0. \tag{2.2}$$

Definition II.1: The pair $(P,\hat{\omega})$ *is an n-symplectic manifold.*

Remark: In Refs. 3–9,15 the term *n*-symplectic structure refers to the two-form that is the exterior derivative of the $\mathbb{R}^n$-valued soldering 1-form on frame bundles or subbundles of frame bundles. Günther[12] was perhaps the first to consider a manifold with a nondegenerate $\mathbb{R}^n$-valued 2-form, and he used the terms *polysymplectic structure* and *polysymplectic manifold* for the nondengenerate 2-form and manifold, respectively. In addition, when one adds a few extra conditions to conditions C-1 and C-2 one arrives at a *k-symplectic manifold*. Specifically, if P is required to support an np-dimensional distribution V such that

$$(C-3) \quad N=p(n+1),$$

$$(C-4) \quad \hat{\omega}|_{V\times V}=0,$$

then P is a *k-symplectic manifold* as defined by both de Léon *et al.*[19] and also by Awane.[18] To make this identification one needs to make the notational changes $n\to k$ and $p\to n$ in the above discussion. Thus all *k*-symplectic manifolds are *n*-symplectic, but not conversely. The canonical frame bundle example $(LE,d\hat{\theta})$ of an *n*-symplectic manifold introduced in the next paragraph is also a *k*-symplectic manifold. On the other hand the important example of the adapted frame bundle $L_\pi E$ that is central to this paper is *n*-symplectic, but not *k*-symplectic. The problem is that the *k*-symplectic dimensional requirement $N=p(n+1)$ cannot be satisifed on $L_\pi E$.

We will continue to use the name *n*-symplectic geometry for the structure in definition II in order to emphasize the geometrical and algebraic developments that our approach provides.

Remark: In this section we will carry along the canonical example $P=LE$, where LE is the (n^2+n)-dimensional bundle of linear frames of the n-dimensional manifold E. The bundle of frames LE supports a canonically defined *n*-symplectic form $\hat{\omega}=d\hat{\theta}$, where $\hat{\theta}$ is the $\mathbb{R}^n$-valued soldering 1-form, and is defined as follows. If X is a tangent vector to LE at $u=(e,e_\alpha)$, then

$$\hat{\theta}_u(X)=e^\alpha(\lambda_*(X))\hat{r}_\alpha, \tag{2.3}$$

where (e^α) denotes the coframe dual to the frame (e_α). The soldering form is evidently the frame bundle counterpart of the canonical 1-form θ on T^*E. It has been shown[4] that much of the canonical symplectic geometry on T^*E can be derived from the *n*-symplectic geometry on LE.

A. Canonical coordinates

Awane[18] has proved a generalized Darboux theorem for *k*-symplectic geometry. Thus in the neighborhood of each point $u\in P$ one can find canonical (or Darboux) coordinates (π_a^α,z^b), $\alpha,\beta=1,2,\ldots,k$ and $a,b=1,2,\ldots,n$. With respect to such canonical coordinates $\hat{\omega}$ takes the form

$$\hat{\omega}=(d\pi_a^\alpha\wedge dz^a)\otimes\hat{r}_\alpha. \tag{2.4}$$

Hence we have the following locally defined equations:

$$d\pi_a^\alpha=-\frac{\partial}{\partial z^a}\lrcorner\omega^\alpha, \quad dz^a=\frac{\partial}{\partial\pi_a^\alpha}\lrcorner\omega^\alpha, \quad (\mathfrak{X}_\alpha). \tag{2.5}$$

Remark: The approach used here to characterize algebras of observables requires the existence of such canonical coordinates. From the results in Ref. 3 we know that not all functions are *allowable n-symplectic* observables, even in the canonical case of frame bundles. Thus, for example, whether or not there exist pairs $(\hat{f}^{\alpha_1\alpha_2\cdots\alpha_p},\hat{X}_f^{\alpha_1\alpha_2\cdots\alpha_{p-1}})$, $p=1,2,\ldots$ that satisfy Eq. (2.8) below for a general *n*-symplectic manifold is an existence question, and must be demonstrated for each *n*-symplectic manifold. The formulas (2.5) will provide local examples of rank 1 solutions of the *n*-symplectic structure equations (2.8) when either the geometry is specialized to $k=n$-symplectic geometry where a Darboux theorem holds, or when canonical coordinates are simply known to exist. Fortunately in the cases we will consider later in this paper, and in particular on the adapted frame bundle $L_\pi E$, canonical coordinates are known to exist.

Example: On the bundle of linear frames $\lambda: LE \to E$ one can introduce canonical coordinates in the following way. Let (z^α) be a local chart on $U \subset E$. Then on $\tilde{U} = \lambda^{-1}(U)$ define coordinate functions $(\pi^\alpha_\beta, \tilde{z}^\mu)$ by

$$\pi^\alpha_\beta(u) := e^\alpha \left(\left. \frac{\partial}{\partial z^\beta} \right|_{\lambda(u)} \right) \forall u = (e, e_\alpha) \in \tilde{U},$$

$$\tilde{z}^\alpha(u) := z^\alpha(\lambda(u)) \forall u \in \tilde{U}. \tag{2.6}$$

Following standard notational conventions we will drop the ''over tilde'' on the lifted coordinates $\tilde{z}^\alpha$ and write simply z^α for both sets of coordinates. With respect to such a coordinate system on LE the soldering 1-form $\hat{\theta}$ has the local coordinate expression,

$$\hat{\theta} = (\pi^\alpha_\beta dz^\beta) \otimes \hat{r}_\alpha. \tag{2.7}$$

The n-symplectic 2-form $d\hat{\theta}$ clearly has the canonical form (2.4) in such a coordinate system.

B. The symmetric Poisson algebra defined by $\hat{\omega}$

Throughout this section we let $(P, \hat{\omega})$ be an n-symplectic manifold as defined above. It is convenient to introduce the multi-index notation,

$$\hat{r}_{\alpha_1 \alpha_2 \cdots \alpha_{n-\mu}} = \hat{r}_{\alpha_1} \otimes_s \hat{r}_{\alpha_2} \otimes_s \cdots \otimes_s \hat{r}_{\alpha_{n-\mu}}, \quad 0 \leqslant \mu \leqslant n-1.$$

In addition round brackets around indices $(\alpha\beta\gamma)$ denotes symmetrization over the enclosed indices.

Definition II.2: For each $p \geqslant 1$, let SHF^p denote the set of all $(\otimes_s)^p \mathbb{R}^n$-valued functions $\hat{f} = (\hat{f}^{\alpha_1 \alpha_2 \cdots \alpha_p}) = (\hat{f}^{(\alpha_1 \alpha_2 \cdots \alpha_p)})$ on P that satisfy the equations

$$d\hat{f}^{\alpha_1 \alpha_2 \cdots \alpha_p} = -p! X^{(\alpha_1 \alpha_2 \cdots \alpha_{p-1}}_{\hat{f}} \lrcorner \omega^{\alpha_p)} \tag{2.8}$$

for some set of vector fields $(X^{\alpha_1 \alpha_2 \cdots \alpha_{p-1}}_{\hat{f}})$. We then set

$$SHF = \oplus_{p \geqslant 1} SHF^p. \tag{2.9}$$

$\hat{f} \in SHF^p$ will be referred to as a symmetric Hamiltonian function of rank p.

Example: The locally defined functions $\hat{f}$ that satisfy (2.8) for the canonical n-symplectic manifold $(LE, d\hat{\theta})$ were given in Ref. 3. In particular, contrary to the situation in symplectic geometry, not all $(\otimes_s)^p \mathbb{R}^n$-valued functions on LE are compatible with Eq. (2.8). The $p = 1,2$ cases will clarify the structure. Let $ST^p(LE)$ denote the vector space of symmetric $(\otimes_s)^p \mathbb{R}^n$-valued GL($n$)-tensorial functions on LE that correspond uniquely to symmetric rank p contravariant tensor fields on E. Similarly let $C^\infty(E, (\otimes_s)^p \mathbb{R}^n)$ denote the set of smooth $(\otimes_s)^p \mathbb{R}^n$-valued functions on LE that are constant on fibers of LE. Then,

$$SHF^1 = T^1(LE) + C^\infty(E, \mathbb{R}^n), \tag{2.10}$$

$$SHF^2 = ST^2(LE) + T^1(LE) \otimes_s C^\infty(E, \mathbb{R}^n) + C^\infty(E, \mathbb{R}^n \otimes_s \mathbb{R}^n). \tag{2.11}$$

For example, if $\hat{f} = (\hat{f}^\alpha) \in SHF^1$ and $\hat{f} = (\hat{f}^{\alpha\beta}) \in SHF^2$, then in canonical coordinates $(\pi^\alpha_\beta, z^\gamma)$ the functions $\hat{f}^\alpha$ and $\hat{f}^{\alpha\beta}$ have the general forms

$$\hat{f}^\alpha = A^a \pi^\alpha_a + B^\alpha, \quad \hat{f}^{\alpha\beta} = A^{\mu\nu} \pi^\alpha_\mu \pi^\beta_\nu + B^{\mu(\alpha} \pi^{\beta)}_\mu + C^{\alpha\beta}, \tag{2.12}$$

where A^a, B^α, $A^{\mu\nu}=A^{(\mu\nu)}$, $B^{\mu\nu}$ and $C^{\mu\nu}=C^{(\mu\nu)}$ are all constant on the fibers of $\lambda:LE\to E$ and hence are pull-ups of functions defined on E.

Remark: The analogous results for the n-symplectic form given in (2.4) above are straightforward to work out in canonical coordinates. For the $p=1$ and $p=2$ symmetric cases, one finds

$$\hat{f}^\alpha=\mathcal{A}^a\pi_a^\alpha+\mathcal{B}^\alpha,\quad \hat{f}^{\alpha\beta}=\mathcal{A}^{ab}\pi_a^\alpha\pi_b^\beta+\mathcal{B}^{a(\alpha}\pi_a^{\beta)}+\mathcal{C}^{\alpha\beta}, \tag{2.13}$$

where now all coefficients are functions of the coordinates z^a.

Remark: Although $\hat{\omega}$ is nondegenerate in the sense given in Eq. (2.2) above, because of the symmetrization on the right-hand side in (2.8) the relationship between $\hat{f}$ and $(X_{\hat{f}}^{\alpha_1\alpha_2\cdots\ \alpha_{p-1}})$ is not unique unless $p=1$. Given a pair $(\hat{f}^{\alpha_1\alpha_2\cdots\ \alpha_p},X_{\hat{f}}^{\alpha_1\alpha_2\cdots\ \alpha_{p-1}})$ that satisfies (2.8) one can always add to $X_{\hat{f}}^{\alpha_1\alpha_2\cdots\ \alpha_{p-1}}$ vector fields $Y^{\alpha_1\alpha_2\cdots\ \alpha_{p-1}}$ that satisfy the kernel equation

$$Y^{(\alpha_1\alpha_2\cdots\ \alpha_{p-1}}\lrcorner\hat{\omega}^{\alpha_p)}=0 \tag{2.14}$$

to obtain a new pair $(\hat{f}^{\alpha_1\alpha_2\cdots\ \alpha_p},\overline{X}_{\hat{f}}^{\alpha_1\alpha_2\cdots\ \alpha_{p-1}})$ that also satisfies (2.8), where

$$\overline{X}_{\hat{f}}^{\alpha_1\alpha_2\cdots\ \alpha_{p-1}}=X_{\hat{f}}^{\alpha_1\alpha_2\cdots\ \alpha_{p-1}}+Y^{\alpha_1\alpha_2\cdots\ \alpha_{p-1}}.$$

Hence we associate with $\hat{f}\in SHF^p$ an equivalence class of $(\otimes_s)^{p-1}\mathbb{R}^k$-valued vector fields, which we denote by $[\![\hat{X}_{\hat{f}}]\!]=[\![X_{\hat{f}}^{\alpha_1\alpha_2\cdots\ \alpha_{p-1}}\hat{r}_{\alpha_1\alpha_2\cdots\ \alpha_{p-1}}]\!]$. We will see below that even though we obtain equivalence classes of Hamiltonian vector fields rather than vector fields, the geometry still carries natural algebraic structures.

Definition II.3: For each $p\geqslant 1$ let SHV^p denote the vector space of all equivalence classes of $(\otimes_s)^{p-1}\mathbb{R}^k$-valued vector fields $[\![\hat{X}_{\hat{f}}]\!]=[\![X_{\hat{f}}^{\alpha_1\alpha_2\cdots\ \alpha_{p-1}}\hat{r}_{\alpha_1\alpha_2\cdots\ \alpha_{p-1}}]\!]$ on P that satisfy Eqs. (2.8) for some $\hat{f}=\hat{f}^{\alpha_1\alpha_2\cdots\ \alpha_p}\hat{r}_{\alpha_1\alpha_2\cdots\ \alpha_p}\in SHF^p$. We then set

$$SHV=\oplus_{p\geqslant 1}SHV^p. \tag{2.15}$$

$[\![\hat{X}_{\hat{f}}]\!]$ will be referred to as the generalized rank p Hamiltonian vector field defined by $\hat{f}$.

Example: The Hamiltonian vector field $\hat{X}_{\hat{f}}$ for the rank 1 element in (2.12) is unique, and has the form

$$\hat{X}_{\hat{f}}=A^\alpha\frac{\partial}{\partial z^\alpha}-\left(\frac{\partial A^\beta}{\partial z^\gamma}\pi_\beta^\alpha+\frac{\partial B^\alpha}{\partial z^\gamma}\right)\frac{\partial}{\partial\pi_\gamma^\alpha}. \tag{2.16}$$

The equivalence class of $\mathbb{R}^n$-valued Hamiltonian vector fields corresponding to the rank 2 element in (2.12) on LE has representatives of the form,

$$\hat{X}_{\hat{f}}^\alpha=(A^{\mu\nu}\pi_\mu^\alpha+B^{\nu\alpha})\frac{\partial}{\partial z^\nu}-\frac{1}{2}\left(\frac{\partial A^{\mu\beta}}{\partial z^\gamma}\pi_\mu^\alpha\pi_\beta^\nu+\frac{\partial B^{\mu(\alpha}}{\partial z^\gamma}\pi_\mu^{\nu)}+\frac{\partial C^{\alpha\nu}}{\partial z^\gamma}\right)\frac{\partial}{\partial\pi_\gamma^\nu}+Y_\gamma^{\alpha\nu}\frac{\partial}{\partial\pi_\gamma^\nu}, \tag{2.17}$$

where $Y_\gamma^{\alpha\beta}$ are functions subject to the constraint

$$Y_\gamma^{(\alpha\beta)}=0,$$

but are otherwise completely arbitrary. The fact that $Y^\alpha=Y_\nu^{\alpha\mu}(\partial/\partial\pi_\nu^\mu)$ is purely vertical on $\lambda:LE\to E$ follows from (2.14).

Remark: For the n-symplectic rank 2 symmetric observable given above in (2.13), one can check easily that the local coordinate form of a representative $X_{\hat{f}}^\alpha$ of the equivalence class of Hamiltonian vector fields $[\![\hat{X}_{\hat{f}}]\!]^\alpha$ that satisfies (2.8) has the form,

$$X^\alpha=(\mathcal{A}^{ab}\pi_a^\alpha+\mathcal{B}^{b\alpha})\frac{\partial}{\partial z^b}-\frac{1}{2}\left(\frac{\partial\mathcal{A}^{ab}}{\partial z^d}\pi_a^\alpha\pi_b^\sigma+\frac{\partial\mathcal{B}^{a(\alpha}}{\partial z^d}\pi_a^{\sigma)}+\frac{\partial\mathcal{C}^{\alpha\sigma}}{\partial z^d}\right)\frac{\partial}{\partial\pi_d^\sigma}+Y^\alpha. \tag{2.18}$$

Poisson brackets:

Definition II.4: For $p,q\geqslant 1$ define a map $\{,\}:SHF^p\times SHF^q\to SHF^{p+q-1}$ as follows. For $\hat f=f^{\alpha_1\alpha_2\cdots\alpha_p}\hat r_{\alpha_1\alpha_2\cdots\alpha_p}\in SHF^p$ and $\hat g=g^{\beta_1\beta_2\cdots\beta_q}\hat r_{\beta_1\beta_2\cdots\beta_q}\in SHF^q$,

$$\{\hat f,\hat g\}^{\alpha_1\alpha_2\cdots\alpha_{p+q-1}}:=p!X_{\hat f}^{(\alpha_1\alpha_2\cdots\alpha_{p-1}}(\hat g^{\alpha_p\alpha_{p+1}\cdots\alpha_{p+q-1})}), \tag{2.19}$$

where $\hat X_{\hat f}^{\alpha_1\alpha_2\cdots\alpha_{p-1}}$ is any set of representatives of the equivalence class $[\![\hat X_{\hat f}]\!]$.

We need to make certain that $\{\hat f,\hat g\}$ is well-defined. Suppose we have two representatives $X_{\hat f}^{\alpha_1\alpha_2\cdots\alpha_{p-1}}$ and $\overline{X}_{\hat f}^{\alpha_1\alpha_2\cdots\alpha_{p-1}}=X_{\hat f}^{\alpha_1\alpha_2\cdots\alpha_{p-1}}+Y^{\alpha_1\alpha_2\cdots\alpha_{p-1}}$ of $[\![\hat X_{\hat f}]\!]$. Then it follows easily from (2.14) that

$$\overline{X}_{\hat f}^{(\alpha_1\alpha_2\cdots\alpha_{p-1}}(\hat g^{\alpha_p\alpha_{p+1}\cdots\alpha_{p+q-1})})=\hat X_{\hat f}^{(\alpha_1\alpha_2\cdots\alpha_{p-1}}(\hat g^{\alpha_p\alpha_{p+1}\cdots\alpha_{p+q-1})}).$$

Hence the bracket is independent of choice of representatives. That $\{\hat f,\hat g\}$ actually is in SHF^{p+q-1} will follow from corollary (2.6) below.

Definition II.5: Let $[\![\hat X_{\hat f}]\!]=[\![X_{\hat f}^{\alpha_1\alpha_2\cdots\alpha_{p-1}}\hat r_{\alpha_1\alpha_2\cdots\alpha_{p-1}}]\!]$ and $[\![\hat X_{\hat g}]\!]=[\![X_{\hat g}^{\alpha_1\alpha_2\cdots\alpha_{p-1}}\hat r_{\alpha_1\alpha_2\cdots\alpha_{p-1}}]\!]$ denote the equivalence classes of vector-valued vector fields determined by $\hat f\in SHF^p$ and $\hat g\in SHF^q$, respectively. Define a bracket $[\![,]\!]:SHV^p\times SHV^q\to SHV^{p+q-1}$ by

$$[\![[\![\hat X_{\hat f}]\!],[\![\hat X_{\hat g}]\!]]\!]=[\![[\hat X_{\hat f}^{(\alpha_1\alpha_2\cdots\alpha_{p-1}},\hat X_{\hat g}^{\alpha_p\alpha_{p+1}\cdots\alpha_{p+q-2})}]\hat r_{\alpha_1\alpha_2\cdots\alpha_{p+q-2}}]\!], \tag{2.20}$$

where the "inside" bracket on the right-hand side is the ordinary Lie bracket of vector fields calculated using arbitrary representatives. (Notice the symmetrization over all the upper indices in this equation.)

We again need to show that this bracket is well-defined. This is shown in the following lemma, in which we will need the formula

$$L_{X^{(J}}\omega^{\alpha)}=0 \tag{2.21}$$

which follows easily from (2.8) and the formula $L_X\omega=X\lrcorner d\omega+d(X\lrcorner\omega)$. In (2.21) J denotes the multiindex $\alpha_1\alpha_2\cdots\alpha_{p-1}$, and X^J denotes a representative of a rank p Hamiltonian vector field satisfying Eq. (2.8). The next lemma shows that the bracket defined in (2.20) is (i) independent of choice of representatives, and (ii) closes on the set of equivalence classes of vector-valued Hamiltonian vector fields.

Lemma II.6: Let $[\![\hat X_{\hat f}]\!]$ and $[\![\hat X_{\hat g}]\!]$ denote the equivalence classes of vector-valued vector fields determined by $\hat f\in SHF^p$ and $\hat g\in SHF^q$, respectively. Then

$$[\![[\![\hat X_{\hat f}]\!],[\![\hat X_{\hat g}]\!]]\!]=\frac{(p+q-1)!}{p!q!}[\![\hat X_{\{\hat f,\hat g\}}]\!] \tag{2.22}$$

Proof: We introduce the multiindex notation $I=\alpha_1\alpha_2\cdots\alpha_{p-1}$ and $J=\beta_1\beta_2\cdots\beta_{q-1}$, so that we may use the shorthand notation $X_{\hat f}^{\alpha_1\alpha_2\cdots\alpha_{p-1}}=X_{\hat f}^I$ and $X_{\hat g}^{\beta_1\beta_2\cdots\beta_{q-1}}=X_{\hat g}^J$. Then using the identity $L_X(Y\lrcorner\omega)=X\lrcorner(L_Y\omega)+[X,Y]\lrcorner\omega$ for any vector fields X,Y and any 2-form ω, we find

$$
\begin{aligned}
[\hat{X}_{\hat{f}}^{(I},\hat{X}_{\hat{g}}^{J}]\lrcorner\omega^{\alpha)} &= L_{\hat{X}_{\hat{f}}^{(I}}(\hat{X}_{\hat{g}}^{J}\lrcorner\omega^{\alpha)}) - \hat{X}_{\hat{f}}^{(I}\lrcorner(L_{\hat{X}_{\hat{g}}^{J}}\omega^{\alpha)}) \\
&= L_{\hat{X}_{\hat{f}}^{(I}}(\hat{X}_{\hat{g}}^{J}\lrcorner\omega^{\alpha)}) \quad [\text{by formula (2.21)}] \\
&= \hat{X}_{\hat{f}}^{(I}\lrcorner d(\hat{X}_{\hat{g}}^{J}\lrcorner\omega^{\alpha)}) + d(\hat{X}_{\hat{f}}^{(I}\lrcorner\hat{X}_{\hat{g}}^{J}\lrcorner\omega^{\alpha)}) \\
&= d(\hat{X}_{\hat{f}}^{(I}\lrcorner\hat{X}_{\hat{g}}^{J}\lrcorner\omega^{\alpha)}) \quad (\text{since } d(\hat{X}_{\hat{g}}^{(J}\lrcorner\omega^{\alpha)}) = d^2\hat{g}^{J\alpha} = 0) \\
&= -\frac{1}{q!}d(\hat{X}_{\hat{f}}^{(I}\lrcorner d\hat{g}^{J\alpha)}) \quad [\text{by (2.8)}] \\
&= -\frac{1}{p!q!}d(\{\hat{f},\hat{g}\}^{IJ\alpha}) \quad [\text{by (2.8)}].
\end{aligned}
$$

Hence we have shown that for arbitrary representatives of $[\![\hat{X}_{\hat{f}}]\!]$ and $[\![\hat{X}_{\hat{g}}]\!]$,

$$
d(\{\hat{f},\hat{g}\}^{IJ\alpha}) = -(p!q!)[\hat{X}_{\hat{f}}^{(I},\hat{X}_{\hat{g}}^{J}]\lrcorner\omega^{\alpha)}. \tag{2.23}
$$

Comparing this result with (2.8) we see that

$$
\frac{p!q!}{(p+q-1)!}[\hat{X}_{\hat{f}}^{(I},\hat{X}_{\hat{g}}^{J)}]\hat{r}_{IJ} \in [\![\hat{X}_{\{\hat{f},\hat{g}\}}]\!] \tag{2.24}
$$

holds for arbitrary representatives. The lemma follows. ■

Corollary II.7:

$$
\{\hat{f},\hat{g}\} \in SHF^{p+q-1}.
$$

Proof: The corollary follows from (2.23). ■

Theorem II.8: $(SHV,[\![,]\!])$ *is a Lie Algebra*.

Proof: The bracket defined in (2.20) is clearly antisymmetric. To check the Jacobi identity we note that we only need check it for arbitrary representatives, and we may use the very definition (2.20) for the calculation. Since the bracket on the right-hand side in (2.20) is the ordinary Lie bracket for vector fields, we see that the bracket defined in (2.20) also must obey the identity of Jacobi. ■

We can now show that SHF is a Poisson algebra under the bracket defined in (2.19).

Theorem II.9: $(SHF,\{,\})$ *is a Poisson algebra over the commutative algebra* $(SHF,\otimes_s)$.

Proof: The bracket defined in (2.19) is evidently antisymmetric. To check the Jacobi identity one proceeds exactly as in Ref. 3, which used a generalization of a proof given in Ref. 20. The proof of the Jacobi identity is given in the Appendix.

Now the symmetrized tensor product $\otimes_s$ makes SHF into a commutative algebra. If we now consider again elements $\hat{f}\in SHF^p$, $\hat{g}\in SHF^q$, and $\hat{h}\in SHF^r$, then by using definition (2.19) one may show that

$$
\{\hat{f},\hat{g}\otimes_s\hat{h}\} = \{\hat{f},\hat{g}\}\otimes_s\hat{h} + \hat{g}\otimes_s\{\hat{f},h\}. \tag{2.25}
$$

Thus the bracket defined in (2.19) acts as a derivation on the commutative algebra. ■

Example: In the canonical case $P=LE$ the brackets just defined have a well-known interpretation. As mentioned above the homogeneous elements in SHF^p make up the space $ST^p(LE)$, the symmetric rank p GL(n)-tensorial functions that correspond to symmetric rank p contravariant

tensor fields on E. Then $ST=\oplus_{p\geq 1}ST^p\subset SHF$, and the bracket $\{,\}:ST^p\times ST^q\to ST^{p+q-1}$ has been shown[6] to be the frame bundle version of the Schouten–Nijenhuis bracket[16,17] of the corresponding symmetric tensor fields on E.

Remark: There is also a Schouten–Nijenhuis bracket for antisymmetric contravariant tensor fields on E, and as one might expect this bracket also extends to LE. This leads to a graded n-symplectic Poisson algebra of tensor-valued functions on LE.[5]

III. THE CANONICAL n-SYMPLECTIC STRUCTURE ON $L_\pi E$

In this section we present a few additional details about canonical n-symplectic geometry on frame bundles that will be needed later. An adapted frame at $e\in E$ is a frame where the last k basis vectors are vertical. Note that coordinate frames that come from adapted coordinates are adapted frames. The adapted frame bundle of π, denoted $L_\pi E$, consists of all adapted frames for E,

$$L_\pi E=\{(e,\{e_i,e_A\}):e\in E,\{e_i,e_A\} \text{ is a basis for } T_eE, \text{ and } d_u\pi(e_A)=0\}.$$

We will use the same notation $\lambda:L_\pi E\to E$ to denote the restriction of the projection from LE to $L_\pi E$.

$L_\pi E$ is a reduced subbundle of LE,[15] the frame bundle of E. As such it is a principal fiber bundle over E. Its structure group is G_v, the nonsingular block lower triangular matrices,

$$G_v=\left\{\begin{pmatrix} A & 0\\ C & B\end{pmatrix}:A\in \mathrm{GL}(m),B\in \mathrm{GL}(k),C\in \mathbb{R}^{km}\right\}.$$

G_v acts on $L_\pi E$ on the right by

$$(e,\{e_i,e_A\})\cdot\begin{pmatrix} A & 0\\ C & B\end{pmatrix}=\{(e,\{e_iA^i_j+e_AC^A_j,e_AB^A_B\}).$$

Coordinates on $L_\pi E$:

If $(z^\alpha)=(x^i,y^A)$ are adapted coordinates on an open set $U\subseteq E$, then one may induce several different coordinates on $\lambda^{-1}(U)$. Coframe or n-symplectic momentum coordinates $(z^\alpha,\pi^i_j,\pi^A_j,\pi^A_B)$ on $\lambda^{-1}(U)$ are defined as follows. Let $u=(e,\{e_i,e_A\})$ denote a general point in $L_\pi E$. Then

$$z^\alpha(u)=z^\alpha(e),\quad \pi^i_j(u)=e^i\left(\frac{\partial}{\partial x^j}\right),\quad \pi^A_B(u)=e^A\left(\frac{\partial}{\partial y^B}\right),\quad \pi^A_j(u)=e^A\left(\frac{\partial}{\partial x^j}\right). \tag{3.1}$$

Here (e^i,e^A) is the coframe dual to (e_i,e_A), and as is customary we have retained the same symbols z^α for the induced horizontal coordinates. Note that the remaining coordinate functions $\pi^i_A(u)=e^i(\partial/\partial y^A)$ are identically zero on $L_\pi E$.

Frame or n-symplectic velocity coordinates $(z^\alpha,v^i_j,v^A_j,v^A_B)$ on $\lambda^{-1}(U)$ are defined by

$$z^\alpha(u)=z^\alpha(e),\ v^i_j(u)=e_j(x^i),\ v^A_B(u)=e_B(y^A),\ v^A_j(u)=e_j(y^A). \tag{3.2}$$

The v coordinates, viewed together as a block triangular matrix, form the inverse of the π coordinates above. The blocks have the following relations:

$$v^i_j\pi^j_k=\delta^i_k,\quad v^A_j\pi^j_k+v^A_B\pi^B_k=0,\quad v^A_B\pi^B_C=\delta^A_C.$$

Finally we define Lagrangian coordinates, which are constructed from the previous two coordinate systems,

$$z^\alpha(u)=z^\alpha(e),\quad u^i_j=\pi^i_j,\quad u^A_B=\pi^A_B,\quad u^A_j=v^A_i\pi^i_j=-v^A_B\pi^B_j. \tag{3.3}$$

The name Lagrangian coordinates refers to the fact, shown in Ref. 9, that the u^A_j coordinates are pull-ups, under the projection ρ defined in the next setion, of the standard jet coordinates on $J^1\pi$.

Later in the paper we will need the following formulas for the fundamental vertical vector fields $E^{*\alpha}_\beta$ on $L_\pi E$ in Lagrangian coordinates,

$$E^{*i}_j = -u^i_k \frac{\partial}{\partial u^j_k}, \quad E^{*A}_B = -u^A_C \frac{\partial}{\partial u^B_C}, \quad E^{*i}_A = u^i_k v^B_A \frac{\partial}{\partial u^B_k}. \tag{3.4}$$

IV. THE MODIFIED *n*-SYMPLECTIC STRUCTURE DEFINED BY A LAGRANGIAN *L*

To bring the Lagrangian into the n-symplectic picture, McLean and Norris[9] showed that $L_\pi E$ is a principal $H=\mathrm{GL}(m)\times\mathrm{GL}(k)$ bundle over the bundle $J^1\pi$ of 1-jets of sections of π. Letting $\rho: L_\pi E \to J^1\pi$ denote the projection, McLean and Norris then defined the CHP 1-forms θ^α_L on $L_\pi E$ as follows. If $\mathcal{L}$ is a Lagrangian on $J^1\pi$, the lifted Lagrangian is $\mathrm{L}=\rho^*(\mathcal{L})$. Define θ^α_L by

$$\theta^i_L := \tau \mathrm{L}\, \theta^i + E^{*i}_A(\mathrm{L})\, \theta^A, \tag{4.1}$$

$$\theta^A_L := \theta^A, \tag{4.2}$$

where $\tau=\tau(m)$ is a positive constant depending only on the dimension m of the base manifold M, and E^{*i}_A denotes the fundamental vertical vector field on $L_\pi E$ [see (3.4) above] corresponding to the element E^i_A in the standard basis (E^α_β) of $\mathrm{gl}(n)$. The quantities $E^{*i}_A(\mathrm{L})$, referred to as the "covariant canonical momenta" in Ref. 9, are globally defined on $L_\pi E$. In local canonical coordinates (z^α, π^μ_ν), these quantities have the local expressions,

$$E^{*i}_A(\mathrm{L}) = \pi^i_j p^j_B v^B_A, \quad p^j_B = \frac{\partial \mathrm{L}}{\partial u^B_j}, \tag{4.3}$$

and clearly are the frame components of the "canonical field momenta" $p^j_B = \partial \mathrm{L}/\partial u^B_j$. For different values of τ one can obtain the de Donder–Weyl theory[21,22] and the Caratheodory theory[23,22] as special cases of the formalism presented in Ref. 9. The significance of these CHP 1-forms as regards other geometrical theories was also considered by MacLean and Norris. In Ref. 9 it was shown that one may construct the CHP m-form on $J^1\pi$ from the CHP 1-forms on $L_\pi E$. In this regard see also Refs. 5, 8, 15.

It is clear from the definitions (4.1) and (4.2) that the CHP 1-forms have the property that

$$X \lrcorner \theta^\alpha_{\mathrm{L}} = 0 \,\forall\, \alpha = 1,2,\ldots,n \Leftrightarrow d\lambda(X) = 0.$$

Because of this property we can think of the CHP 1-forms as "modified soldering 1-forms," although the θ^α_L may not have the same transformation property under right translation as do the θ^α because of the presence of the Lagrangian L. However, by restricting attention to the H bundle $\rho: L_\pi E \to J^1\pi$, we can show that the θ^α_L are tensorial with respect to H transformations.

Lemma IV.1: For all $h \in H$ the CHP 1-forms θ^α_L satisfy the tensorial transformation law,

$$R^*_h(\theta^\alpha_L) = (h^{-1})^\alpha_\beta \theta^\beta_L. \tag{4.4}$$

Proof: The CHP 1-forms given in (4.1) and (4.2) can be expressed, using the Lagrangian coordinates defined in (3.3) above, in the form,

$$\theta^i = u^i_j(-\mathcal{H}^j_k dx^k + p^j_B dy^B), \tag{4.5}$$

$$\theta^A = u^A_B(-u^A_k dx^k + dy^B), \tag{4.6}$$

where we have introduced the definitions,

$$\mathcal{H}^i_j := p^i_A u^A_j - \tau \mathrm{L}\,\delta^i_j, \quad p^i_A := \frac{\partial \mathrm{L}}{\partial u^A_i}. \tag{4.7}$$

Using the additional definitions

$$(h^\alpha_\beta) = \begin{pmatrix} -\mathcal{H}^k_j & p^k_A \\ -u^E_j & \delta^E_A \end{pmatrix}, \quad ((\Delta u)^\alpha_\beta) = \begin{pmatrix} u^k_j & 0 \\ 0 & u^E_A \end{pmatrix}, \tag{4.8}$$

Eqs. (4.5) and (4.6) can be written in the following compact form:

$$\theta^\alpha_L = ((\Delta u)^\alpha_\beta) h^\beta_\gamma dz^\gamma. \tag{4.9}$$

The matrix $((\Delta u)^\alpha_\beta)$ in (4.9) transforms under the group H of the bundle $\rho: L_\pi E \to J^1\pi$ while the second factor (h^α_β) is H-invariant. In particular, $R^*_h((\Delta u)^\alpha_\mu) = (h^{-1})^\alpha_\beta (\Delta u)^\beta_\mu$. The lemma follows. ■

The lemma shows that the CHP 1-forms do behave like modified soldering 1-forms with respect to the bundle $\rho: L_\pi E \to J^1\pi$. The geometrical significance of the lemma is that the CHP-forms define a set of type 1–1 tensor fields on the jet bundle $J^1\pi$. To see this we recall that the canonical soldering 1-forms θ^α define the type 1–1 *identity tensor field* on E. The construction is as follows. Let $u = (e, e_\beta) \in LE$ be an arbitrary point in the bundle of frames of E. The coframe to (e_β) may be written as $(e^\beta = \pi^\beta_\alpha(u) dz^\alpha)$. Then $\hat{\theta} = (\theta^\alpha)$ defines the identity type 1–1 tensor field on E as follows:

$$\hat{\theta}(u) = (\pi^\alpha_\beta dz^\beta)(u) \otimes r_\alpha \to \pi^\alpha_\beta(u) dz^\beta \otimes e_\beta = e^\beta \otimes e_\beta = I_e. \tag{4.10}$$

The tensorial transformation property of $\hat{\theta}$ on LE or any of its subbundles guarantees that the 1–1 tensor field defined in (4.10) is well-defined. We can use a similar construction to define a 1–1 tensor field on $J^1\pi$ based on the CHP 1-forms.

Let $u = (e, e_\beta) \in L_\pi E$ be an arbitrary point in the bundle of adapted linear frames of E, and let $v = \rho(u) \in J^1\pi$ be the projection to $J^1\pi$. Then we define a 1–1 tensor field T on $J^1\pi$ as follows:

$$\begin{aligned} \hat{\theta}_L(u) \to T(v) &= \theta^i_L(u) \otimes e_i + \tau L(u)\, \theta^A_L \otimes e_A \\ &= ((\Delta u)^i_\beta)(u) h^\beta_\gamma(u) dz^\gamma \otimes e_i + \tau L(u) ((\Delta u)^A_\beta)(u) h^\beta_\gamma(u) dz^\gamma \otimes e_A. \end{aligned} \tag{4.11}$$

Notice the inclusion of the H-invariant factor $\tau L(u)$ in the definition.

It is easy to show from the definitions that $((\Delta u)^i_\beta)(u) e_i = \delta^i_\beta((\partial/\partial x^i) + u^A_i(v)\,(\partial/\partial y^A))$ and $((\Delta u)^A_\beta)(u) e_A = \delta^A_\beta(\partial/\partial y^A)$. Using these results together with the definition (4.7) in the last equation we can rewrite it as

$$T(v) = (-\mathcal{H}^i_j) dx^k \otimes \frac{\partial}{\partial x^i} - (u^B_k p^j_B u^A_j) dx^k \otimes \frac{\partial}{\partial y^A} + (p^j_A) dy^A \otimes \frac{\partial}{\partial x^j} + (p^j_B u^A_j + \tau L\, \delta^A_B) dy^B \otimes \frac{\partial}{\partial y^A}. \tag{4.12}$$

T is well-defined since the right-hand side of the definition of $T(v)$ is H-invariant. Hence the CHP 1-forms define a type 1–1 tensor field on $J^1\pi$, whose independent components with respect to any canonical chart on $L_\pi E$ are, after omitting minus signs:

$$\text{(a)} \quad (\mathcal{H}^i_j) dx^k \otimes \frac{\partial}{\partial x^i} \quad \text{the energy-momentum tensor of the field,} \tag{4.13}$$

$$\text{(b)} \quad (p^j_A) dy^A \otimes \frac{\partial}{\partial x^j} \quad \text{the canonical field momentum,} \tag{4.14}$$

$$\text{(c)} \quad (u_k^B p_B^j u_j^A) dx^k \otimes \frac{\partial}{\partial y^A} \quad \text{the canonical field momentum summed with field velocities} \tag{4.15}$$

$$\text{(d)} \quad (p_B^j u_j^A + \tau \mathrm{L} \delta_B^A) dy^B \otimes \frac{\partial}{\partial y^A} \quad \text{a new energy-momentum-type field.}$$

These tensor fields will be of importance in the application presented in Sec. VI.

The Legendre transformation: One can define the CHP 1-forms using a frame bundle version of the Legendre transformation. Given a Lagrangian $L: L_\pi E \to \mathbb{R}$ we obtain a mapping $\phi_L : L_\pi E \to LE$ given by

$$\phi_L(u) = \phi_L(e, e_i, e_A) = \left(e, \frac{1}{\tau L(u)} e_i, e_A - \frac{1}{\tau L(u)} E_A^{*a}(L)(u) e_a \right). \tag{4.16}$$

The condition that this mapping end up in LE is that the Lagrangian be **nonzero**, and *for the rest of this paper we will assume this condition*. We will refer to this mapping as the *n-symplectic Legendre transformation*. Our goal is to prove Theorem (IV.6), namely, that $\hat{\theta}_L = \phi_L^*(\hat{\theta})$, where $\hat{\theta}$ is the canonical soldering 1-form on the image of ϕ_L. This will follow easily once we exhibit the manifold structure of Q_L.

Lemma IV.2: If the lifted Lagrangian is nonzero, then the Legendre transformation (4.16) *is one-one.*

Proof: If $\phi_L(u) = \phi_L(\overline{u})$ then the two adapted frames must project to the same point in E. Equating vectors in the frame we find $[1/\tau \mathrm{L}(\overline{u})]\overline{e_i} = [1/\tau \mathrm{L}(u)] e_i$ and $\overline{e_A} - [1/\tau \mathrm{L}(\overline{u})] E_A^{*a}(\mathrm{L}) \times (\overline{u}) \overline{e_a} = e_A - [1/\tau \mathrm{L}(u)] E_A^{*a}(\mathrm{L})(u) e_a$. Using the first of these relations in the second and rearranging we obtain

$$\overline{e_A} - e_A = (E_A^{*a}(L)(\overline{u}) - E_A^{*a}(L)(u)) \frac{1}{\tau L(u)} e_i .$$

Since both $\overline{e_A}$ and e_A are vertical on E this implies that $(E_A^{*a}(L)(\overline{u}) - E_A^{*a}(L)(u)) = 0$. Hence $\overline{e_A} = e_A$ and $[1/\tau \mathrm{L}(\overline{u})]\overline{e_i} = [1/\tau \mathrm{L}(u)] e_i$. This implies that $\overline{u} = u \cdot h$ for $h \in H \subset G_V$. But since the Lagrangian L is lifted, it is H invariant and so $L(\overline{u}) = L(u)$, which implies that $\overline{u} = u$. ■

To clarify the meaning of the Legendre transformation (4.16) we introduce a new manifold $\tilde{P}$ as follows. Let J denote the subgroup of $\mathrm{GL}(n)$ consisting of matrices of the form,

$$\begin{pmatrix} I & \xi \\ 0 & I \end{pmatrix} \quad \xi \in \mathbb{R}^{m \times k}.$$

Define $\tilde{P}$ by

$$\tilde{P} = L_\pi E \cdot J = \{ (e_i, e_A + \xi_A^j e_j) \,|\, (e_i, e_A) \in L_\pi E, \xi \in \mathbb{R}^{m \times k} \}. \tag{4.17}$$

Lemma IV.3: $\tilde{P}$ is a open dense submanifold of the bundle of frames LE of E.

Proof: Private communication from Mike McLean. ■

Lemma IV.4: There is a canonical diffeomorphism from $\tilde{P}$ to the product manifold $L_\pi E \times \mathbb{R}^{m \times k}$.

Proof: If (e, e_i, e_A) is a point in $L_\pi E$, then we let $\tilde{e}_i = \pi_*(e_i)$. From the structure of $L_\pi E$ it is clear that $(\tilde{e}_i)$ is a linear frame for the tangent space to M at $\pi(e)$. Let $(\tilde{e}^i)$ denote the coframe dual to $(\tilde{e}_i)$. Now suppose $\overline{u} = (\overline{e_i}, \overline{e_A}) = (e_i, e_A + \xi_A^j e_j)$ is an arbitrary point in $\tilde{P}$. Then we have $\pi_*(\overline{e_i}) = \tilde{e}_i$. Using the fact that each e_A is vertical we have $\pi_*(\overline{e_A}) = \xi_A^i \tilde{e}_i$. Hence,

$$\xi_A^i = \tilde{e}^i(\pi_*(\overline{e_A})). \tag{4.18}$$

Define a mapping from $\tilde{P}$ to $L_\pi E \times \mathbb{R}^{m\times k}$ by

$$\overline{u} = (\overline{e_i}, \overline{e_A}) \to ((e_i, e_A), \xi_A^i) = ((\overline{e_i}, \overline{e_A} - \tilde{e}^j(\pi_*(\overline{e_A}))\overline{e_j}), \tilde{e}^i(\pi_*(\overline{e_A}))). \tag{4.19}$$

The mapping (4.19) is easily shown to be 1–1, and it is clearly smooth. The inverse mapping is the multiplication mapping $\mu: L_\pi E \times \mathbb{R}^{m\times k} \to \tilde{P}$ defined by

$$\mu((e_i, e_A), \xi_B^j) = (e_i, e_A + \xi_A^j e_j). \tag{4.20}$$

This inverse is evidently smooth. ■

Remark: The coordinate expression for this mapping is

$$\overline{u} = (\overline{e_i}, \overline{e_A}) \to ((e_i, e_A), \xi_A^i) = ((\overline{e_i}, \overline{e_B} - \overline{\pi}_A^j(\overline{u})\overline{V}_B^A(\overline{u})\overline{e_j}), -\overline{\pi}_A^j(\overline{u})\overline{V}_B^A(\overline{u})), \tag{4.21}$$

where $\overline{V}_B^A(\overline{u}) = v_B^A(u)$ are the components of the matrix inverse of the matrix $(\overline{\pi}_B^A(\overline{u})) = (\pi_B^A(u))$, which must necessarily be nonsingular because of the structure of $L_\pi E$. In the following we let $\overline{\rho}: L_\pi E \times \mathbb{R}^{m\times k} \to L_\pi E$ be the natural projection.

Suppose we are given a Lagrangian L on $L_\pi E$. Then it is easy to see that the Legendre transformation (4.16) can be expressed as the composition $\phi_L = \mu \circ \phi_2 \circ \phi_1$, where μ is the multiplication map defined in (4.20) above, ϕ_1 is the bundle automorphism

$$\phi_1: L_\pi E \to L_\pi E, \quad \phi_1(e_i, e_A) = \left(\frac{1}{\tau \mathrm{L}(u)} e_i, e_A\right), \tag{4.22}$$

and the mapping ϕ_2 is the global section of $\overline{\rho}$ given by

$$\phi_2(u) = \phi_2(e_i, e_B) = \left((e_i, e_B), -\frac{E_A^{*j}(L)(u)}{\tau L(u)}\right). \tag{4.23}$$

The mapping ϕ_1 is 1–1 since the Lagrangian L is invariant under the subgroup H, and $\overline{u} = \phi_1(u) = u \cdot h$ for

$$h = \begin{pmatrix} \tau \mathrm{L}(u) I & 0 \\ 0 & I \end{pmatrix}.$$

Q_L is then the image of $L_\pi E$ in $\tilde{P}$ under the C^∞ Legendre transformation. In particular, Q_L is the smooth image under the multiplication map of the global section $\phi_2(L_\pi E)$ of $\overline{\rho}: L_\pi E \times \mathbb{R}^{m\times k} \to L_\pi E$, and hence is a smooth manifold. The inverse of the Legendre transformation is then the composition $\phi_L^{-1} = \phi_1^{-1} \circ \phi_2^{-1} \circ \mu^{-1}$, where ϕ_2^{-1} is the projection $\overline{\rho}$ restricted to $\mu^{-1}(Q_L,)$ and $\phi_1^{-1}(\overline{u}) = \phi_1^{-1}(\overline{e_i}, \overline{e_A}) = (\mathrm{L}(\overline{u})\overline{e_i}, \overline{e_A})$. The inverse is thus also C^∞, and we have:

Lemma IV.5: If the Lagrangian L is nonzero, then the Legendre transformation $\phi_L: L_\pi E \to Q_L$ is a diffeomorphism.

Theorem IV.6: *Let L be the pull-up of a nonzero Lagrangian $\mathcal{L}$ on $J^1\pi$, and let ϕ_L denote the Legendre transformation defined above in* (4.16). *Then,*

$$\hat{\theta}_L = \phi_L^*(\hat{\theta}). \tag{4.24}$$

Proof: A straightforward calculation.

Remark: This theorem has an obvious analog in symplectic mechanics, where the symplectic form on the velocity phase space TE is, for a regular Lagrangian, the pull back under the Legendre

transformation of the canonical 1-form on T^*M. There is also a similar theorem in multisymplectic geometry where the CHP m- form on $J^1\pi$ is known[14] to be the pull back of the canonical multisymplectic m-form on $J^{1*}\pi$.

Now Q_L, being a submanifold of LE, supports the restriction $\hat{\theta}|_{Q_L}$ of the $\mathbb{R}^n$-valued soldering 1-form $\hat{\theta}$. It is easy to verify that the closed $\mathbb{R}^n$-valued 2-form $d\hat{\theta}|_{Q_L}$ is also nondegenerate, and hence $(Q_L, d(\hat{\theta}|_{Q_L}))$ is an n-symplectic manifold. Using the fact that Q_L and $L_\pi E$ are diffeomorphic under the Legendre transformation, we obtain the following corollary to Theorem IV.6.

Corollary IV.7: $(L_\pi E, d\hat{\theta}_L)$ *is an n-symplectic manifold.*

Remark: It is also not difficult to show by direct calculation that $d\hat{\theta}_L$ is nondegenerate.

We would now like to be able to find the n-symplectic observables defined by the n-symplectic structure $d\hat{\theta}_L$ on $L_\pi E$. However, since the new n-symplectic structure is not in canonical form in standard canonical coordinates (z^α, π^μ_ν), it is rather difficult to find the observables. This fact can be clarified as follows.

The local forms given above in (2.12) of the canonical n-symplectic algebras on LE were given in Ref. 3, and were found by solving the equations

$$L_{X^{(I}_{\hat{f}}} d\theta^{\alpha)} = 0 \tag{4.25}$$

for the locally n-symplectic Hamiltonian vector fields. Lawson[15] used the same technique to characterize the reduced algebra on $L_\pi E$ by solving the equations

$$L_{X^{(I}_{\hat{f}}} d(\theta|_{L_\pi E})^{\alpha)} = 0. \tag{4.26}$$

In both cases the equations were tractable because the n-symplectic forms could be written in canonical coordinates. On the other hand the equations $L_{X^{(I}_{\hat{f}}} d\theta^{\alpha)}_{\mathrm{L}} = 0$ are very complicated and are not easily solved. To get around this problem we will use Corollary (IV.7). If we identify the n-symplectic algebra on the n-symplectic manifold $(Q_L, d(\hat{\theta}|_{Q_L}))$, then we can use the Legendre transformation to transform back to $L_\pi E$. In particular, if $\hat{f}$ and $\hat{X}_{\hat{f}}$ satisfy the equation

$$d\hat{f} = -\hat{X}_{\hat{f}} \lrcorner d(\hat{\theta}) \tag{4.27}$$

on Q_{L}, then $\phi_L^*(\hat{f})$ and $\phi_{L*}^{-1}(\hat{X}_{\hat{f}})$ satisfy the equation

$$d(\phi_L^*(\hat{f})) = -\phi_{L*}^{-1}(\hat{X}_{\hat{f}}) \lrcorner d(\phi_L^*(\hat{\theta})) \tag{4.28}$$

on $L_\pi E$.

V. *n*-SYMPLECTIC REDUCTION

In order to characterize the n-symplectic observables on $(Q_L, d(\hat{\theta}|_{Q_L}))$ we will find a reduction of the n-symplectic geometry of $(\tilde{P}, d\hat{\theta})$ to $(Q_L, d(\hat{\theta}|_{Q_L}))$. Let $i: Q_L \to \tilde{P}$ be the inclusion mapping, and let $\hat{f}: \tilde{P} \to \mathbb{R}^n$ be an $\mathbb{R}^n$-valued observable for the canonical n-symplectic geometry on $(\tilde{P}, d\hat{\theta})$ such that its Hamiltonian vector field $\hat{X}_{\hat{f}}$ is tangent to Q_L at points of Q_L. Then on Q_L we have

$$d(i^*\hat{f}) = -\hat{X}_{\hat{f}} \lrcorner d(i^*\hat{\theta}). \tag{5.1}$$

This follows from the fact that $i_*(i_*^{-1}(\hat{X}_{\hat{f}})) = \hat{X}_{\hat{f}}$ at points of Q_L when $\hat{X}_{\hat{f}}$ is tangent to Q_L. Let $SHF|_{Q_L}$ be the restriction to Q_L of the subset of SHF on $\tilde{P}$ such that the corresponding Hamil-

tonian vector fields are tangent to Q_L at points of Q_L. The set $SHF|_{Q_L}$ will be the reduced symmetric n-symplectic algebra defined by the Lagrangian L. To find the reduced algebra we will derive the equations that $\hat{X}_{\hat{f}}$ must satisfy in order to be tangent to Q_L.

Define new coordinates on Q_L using the Legendre transformation to pull back the Lagrangian coordinates $(z^\alpha, u^i_j, u^A_k, u^A_B)$ define in (3.3) above. We let

$$\tilde{u}^\alpha = z^\alpha \circ \phi_L^{-1}, \quad \tilde{u}^i_j = u^i_j \circ \phi_L^{-1}, \quad \tilde{u}^A_B = u^A_B \circ \phi_L^{-1}, \quad \tilde{u}^A_j = u^A_j \circ \phi_L^{-1}. \tag{5.2}$$

Then the local vector fields

$$\frac{\partial}{\partial \tilde{u}^\alpha}, \quad \frac{\partial}{\partial \tilde{u}^i_j}, \quad \frac{\partial}{\partial \tilde{u}^A_j}, \quad \frac{\partial}{\partial \tilde{u}^A_B} \tag{5.3}$$

form a local basis of the tangent spaces of Q_L. Any vector field that is tangent to Q_L can be expressed locally in terms of this local basis. We first consider a rank 1 Hamiltonian vector field on $\tilde{P}$ given by [see (2.16)]

$$\hat{X}_{\hat{f}} = f^\alpha \frac{\partial}{\partial \overline{z}^\alpha} - \left(\frac{\partial f^\beta}{\partial \overline{z}^\gamma} \overline{\pi}^\alpha_\beta \right) \frac{\partial}{\partial \overline{\pi}^\alpha_\gamma} \tag{5.4}$$

corresponding to the observable $\hat{f}^\alpha = f^\beta(e)\,\overline{\pi}^\alpha_\beta$. We suppose that this vector field can be expanded in the basis 5.3 and write

$$\hat{X}_{\hat{f}} = X^\alpha \frac{\partial}{\partial \tilde{u}^\alpha} + X^i_j \frac{\partial}{\partial \tilde{u}^i_j} + X^A_B \frac{\partial}{\partial \tilde{u}^A_B} + X^A_j \frac{\partial}{\partial \tilde{u}^A_j}. \tag{5.5}$$

Equating these two forms for $\hat{X}_{\hat{f}}$ and using the fact [see (4.9)] that $\overline{\pi}^\alpha_\beta \circ \phi_L = (\Delta u)^\alpha_\sigma h^\sigma_\beta$ we find $X^\alpha = f^\alpha$ and

$$-\frac{\partial f^\sigma}{\partial \overline{z}^\beta} \overline{\pi}^\alpha_\sigma = X^\sigma \widetilde{\frac{\partial h^\kappa_\beta}{\partial z^\sigma}} (\Delta \tilde{u})^\alpha_\kappa + X^i_j \delta^\alpha_i \widetilde{h^j_\beta} + X^A_B \delta^\alpha_A \widetilde{h^B_\beta} + X^A_k (\Delta \tilde{u})^\alpha_\kappa \widetilde{\frac{\partial h^\kappa_\beta}{\partial u^A_k}}, \tag{5.6}$$

where the ''over tildes'' indicate that the term is to be evaluated in the new coordinates (5.2). These equations can be solved for the coefficients X^i_j, X^A_B, and X^A_k in terms of the components of $\partial h^\kappa_\beta / \partial u^A_k$, plus the following constraint equation:

$$-\frac{df^\sigma}{d\overline{z}^B} \tilde{h}^b_\sigma = f^\sigma \widetilde{\frac{\partial p^b_B}{\partial z^\sigma}} - \frac{df^b}{d\overline{z}^I} \tilde{p}^i_B - \frac{1}{\tau L} \left(f^\sigma \widetilde{\frac{\partial L}{\partial z^\sigma}} + \frac{df^\sigma}{\overline{z}^k} \tilde{p}^i_A \tilde{h}^A_\sigma \right) \tilde{p}^b_B + \frac{df^\sigma}{d\overline{z}^k} \tilde{h}^A_\sigma \widetilde{\frac{\partial p^b_B}{\partial u^A_k}}. \tag{5.7}$$

We next consider a rank 1 Hamiltonian vector field on P given by [see (2.16)]

$$\hat{X}_{\hat{f}} = \frac{\partial \xi^\alpha}{\partial \overline{z}^\gamma} \frac{\partial}{\partial \overline{\pi}^\alpha_\gamma} \tag{5.8}$$

corresponding to the observable $\hat{f}^\alpha = \xi^\alpha(e)$. Carrying out the same calculuation that we did for $\hat{f}^\alpha = f^\beta(e)\,\overline{\pi}^\alpha_\beta$ above we find the constraint equation

$$-\tau L \frac{\partial \xi^a}{\partial \overline{z}^b} = \tilde{p}^e_D \left(-\frac{d\xi^a}{d\overline{z}^e} + \tilde{u}^a_b \frac{d\xi^E}{d\overline{z}^k} \tilde{v}^A_E (-\tilde{p}^k_A \delta^b_e + \tilde{p}^b_A \delta^k_e) \right) + \tau \mathrm{L} \frac{d\xi^E}{d\overline{z}^k} \tilde{v}^A_E \tilde{u}^a_b \widetilde{\frac{\partial p^b_D}{\partial u^A_k}}. \tag{5.9}$$

An n-symplectic observable $\hat{f} = (f^\beta \overline{\pi}^\alpha_\beta + \xi^\alpha) r_\alpha$ on $\tilde{P}$ will be in $SHF|_{Q_L}$ if and only if it satisfies the two constraint Eqs. (5.7) and (5.9).

VI. APPLICATION: *k*-TUPLE OF MASSLESS SCALAR FIELDS ON FLAT SPACE–TIME

As an application of the general theory we will study the rank-1 n-symplectic subalgebra of observables that is defined by the simple model of a k-tuple of massless scalar fields on Minkowski space–time. Analysis of the more complicated higher rank portions of the algebra will be left for future work. For the k-tuple of massless scalar fields the bundle $\pi:E\to M$ over Minkowski space–time M is a trivial vector bundle with standard fiber $\mathbb{R}^k$. Such a system has a lifted Lagrangian of the form $L=\frac{1}{2}g^{ab}\delta_{AB}u_a^A u_b^B$, where g^{ab} are the contravariant components of the Minkowski metric tensor in arbitrary coordinates on the space–time manifold and δ_{AB} are the components of the Euclidean metic tensor for the internal space $\mathbb{R}^k$. Since global inertial coordinates exist on Minkowshi space–time, we will for the calculations restrict attention to canonical coordinates on LE that are induced by such inertial coordinates on space–time. Then the components of the metric tensor field will take the constant Minkowski form $(\eta^{ab})=\mathrm{diag}(-1,1,1,1)$, and the Lagrangian will be

$$\mathrm{L}=\tfrac{1}{2}\eta^{ab}\delta_{AB}u_a^A u_b^B. \tag{6.1}$$

Using this Lagrangian for the k-tuple of scalar fields on Minkowski space–time we find the standard result

$$p_A^i=\eta^{ij}\delta_{AB}u_j^B. \tag{6.2}$$

We observe that for this Lagrangian Eqs. (5.7) and (5.9) are satisfied by $f^\alpha=C^\alpha=$constant and $\xi^\alpha=K^\alpha=$constant.

Theorem VI.1: *The rank-1 n-symplectic Hamiltonian vector field (2.16) for the n-symplectic manifold* $(\tilde{P},d\hat{\theta})$ *will satisfy the reduction Eqs. (5.7) and (5.9) for the Lagrangian of the k-tuple of massless scalar fields on Minkowski space–time if*

$$f^\alpha=C^\alpha=\text{constant},\xi^\alpha=K^\alpha=\text{constant}. \tag{6.3}$$

Remark: We recall from Eq. (2.10) that the rank-1 algebra $HF^1=T^1(LE)\oplus C^\infty(E,\mathbb{R}^{m+k})$ is the direct sum of the rank-1 tensorial functions $T^1(LE)$ on LE that correspond uniquely to vector fields on E, with the $\mathbb{R}^{m+k}$-valued functions $C^\infty(LE,\mathbb{R}^{m+k})$ that are constant on fibers of LE, i.e., $C^\infty(E,\mathbb{R}^{m+k})$. The above theorem tells us that the subalgebra corresponding to the tensorial functions is a copy of the translation symmetry group $\mathbb{R}^{m+k}$ of the base manifold $E=\mathbb{R}^{m+k}$. Hence we may interpret the tensorial part of the rank-1 subalgebra corresponding to $f^\alpha=C^\alpha=$constant as the space of translational Killing vectors for the metrics η on M and δ on the fibers of E. The other part of the algebra, characterized by $\xi^\alpha=K^\alpha=$constant, can be identified also with $\mathbb{R}^{m+k}$. The part of the rank-1 algebra $SHF^1|_{Q_L}$ on Q_L determined by the theorem is therefore

$$\mathcal{G}=\mathbb{R}^{m+k}\oplus\mathbb{R}^{m+k}. \tag{6.4}$$

There is an alternative interpretation of the tensorial part of the rank-1 subalgebra in terms of "n-symplectic momentum mapping." In Ref. 5 it was pointed out that the translation group $\mathbb{R}^{m+k}$ lifts from $E=\mathbb{R}^{m+k}$ to LE to define an n-symplectic momentum mapping, and that for each $(\zeta^\alpha)\in\mathbb{R}^n$ the corresponding "momentum" is $\zeta^\alpha\pi_\alpha^\beta\hat{r}_\beta$. Notice that $\zeta^\alpha\pi_\alpha^\beta\hat{r}_\beta$ is precisely $\hat{\zeta}$, i.e., it is the tensorial function corresponding to the vector field $\zeta^\alpha(\partial/\partial z^\alpha)$ on E. Hence the tensorial part of the rank-1 subalgebra can also be thought of as the "set of all momenta" that arise from the n-symplectic momentum map defined by the lift of $\mathbb{R}^{m+k}$ to LE.

The algebra of observables on $L_\pi E$:

To obtain the n-symplectic algebra on $L_\pi E$ we must pull-back the observables $\hat{f}$ and use the inverse Legendre transformation to map the corresponding Hamiltonian vector fields $\hat{X}_{\hat{f}}$ to $L_\pi E$. Letting C^α and K^α denote constants, we have found rank 1 observables on $L_\pi E$ of the form,

$$\hat{F} := \phi_L^*(C^\alpha \overline{\pi}_\alpha^\beta + K^\alpha) r_\alpha = (C^\alpha \phi_L^*(\overline{\pi}_\alpha^\beta) + K^\alpha) r_\alpha .$$

From (4.9) and (4.24) one can infer that $\phi_L^*(\overline{\pi}_\beta^\alpha) = (\Delta u)_\sigma^\alpha h_\beta^\sigma$. Hence the rank 1 observables on $L_\pi E$ have the form,

$$\hat{F} = ((C^\beta (\Delta u)_\sigma^\alpha h_\beta^\sigma) + K^\alpha) r_\alpha . \tag{6.5}$$

Mapping the Hamitonian vector field $\hat{X}_{\hat{f}} = C^\alpha (\partial/\partial \overline{z}^\alpha)$ corresponding to $(C^\alpha \overline{\pi}_\alpha^\beta + K^\alpha) r_\alpha$ to $L_\pi E$ using $(\phi_L^{-1})_*$ one finds in this special case the simple result

$$(\phi_L^{-1})_* \left(C^\alpha \frac{\partial}{\partial \overline{z}^\alpha} \right) = C^\alpha \frac{\partial}{\partial z^\alpha} . \tag{6.6}$$

Hence for fixed values of C^α and K^α we have the n-symplectic rank 1 equation on $(L_\pi E, d\hat{\theta}_L)$,

$$d(C^\beta (\Delta u)_\sigma^\alpha h_\beta^\sigma) + K^\alpha) = -\left(C^\beta \frac{\partial}{\partial z^\beta} \right) \lrcorner d\theta_L^\alpha . \tag{6.7}$$

Because K^α are constants, this equation can be rewritten as

$$C^\beta d((\Delta u)_\sigma^\alpha h_\beta^\sigma)) = -\left(C^\beta \frac{\partial}{\partial z^\beta} \right) \lrcorner d\theta_L^\alpha . \tag{6.8}$$

We recall that in Sec. IV we observed that the CHP 1-forms $\theta_L^\alpha = (\Delta u)_\sigma^\alpha h_\beta^\sigma dz^\beta$ define the physical type 1–1 tensor fields on $J^1\pi$ given in Eq. (4.13)–(4.16). The part $\hat{F} = ((C^\beta (\Delta u)_\sigma^\alpha h_\beta^\sigma))\, r_\alpha$ of the rank 1 observable (6.5) will thus correspond to linear combinations of these type 1–1 tensor fields on $J^1\pi$; that is, linear combinations of field velocities, momentum, and energy-momentum tensors.

Remark: Notice that on Q_L the Hamiltonian vector field for the observable $\hat{f} = (C^\alpha \pi_\alpha^\beta + K^\beta)\hat{r}_\beta$ is $C^\alpha (\partial/\partial \overline{z}^\alpha)$, independent of the constants K^α. In fact the kernel of the mapping $HF^1 \to HV^1$ is the set of observables $K^\alpha \hat{r}_\alpha$, where K^α are all constants. Thus the mapping from the Lie algebra of rank-1 observables to the Lie algebra of rank-1 Hamiltonian vector fields is not an isomorphism. In Ref. 5 it was shown that this kernel for rank 1 observables can be removed by lifting the theory to the bundle of affine frames of E, thereby obtaining the desired isomorphism from observables to the vector fields that will serve as the Hamiltonian operators in a geometric quantization theory.

VII. CONCLUSIONS

The formulation of an n-symplectic algebra of observables for a covariant Lagrangian field theory set forth in this paper lays the foundations for a Kostant–Souriau geometric quantization theory of fields. The paper has three main parts. Part one is Sec. II of this paper, in which we developed the n-symplectic Poisson and graded Poisson algebras of observables defined on an abritrary n-symplectic manifold. These algebras paralleled the algebras presented in Ref. 3 for the special case of the bundle of linear frames of an n-dimensional manifold. In part two of the paper, consisting of Secs. III–IV, we set up the n-symplectic covariant field theory on $L_\pi E$ for a Lagrangian field theory. The theory includes the definition of an n-symplectic Legendre transformation, and the subsequent definition of the CHP 1-forms θ_L^α as the pull-back, under the Legendre transformation, of the canonical soldering 1-forms on LE. We then showed that $(L_\pi E, d\hat{\theta}_L)$ is an n-symplectic manifold, and set up the equations of n-symplectic reduction on $(Q_L, d(\hat{\theta}|_{Q_L})$ in order to identify the observables on $L_\pi E$. The third part of the paper, Sec. VI, presents a simple application of the theory to the model of a k-tuple of massless scalar fields on Minkowski space–time. We found that the rank 1 observables contain the translational Killing vectors of the

Minkowski space–time and the Euclidean fibers. When pulled back to $L_\pi E$ these observables correspond to linear combinations of the field velocities, momentum and energy-momentum tensors on $J^1\pi$.

We have pointed out that in the general theory on $L_\pi E$ the mapping from the Lie algebra of observables to the Lie algebra of Hamiltonian vector fields is not an isomorphism, the kernel of the mapping being the set of all constant $\mathbb{R}^n$-valued functions on $L_\pi E$. This is the analog of what occurs on a symplectic manifold. In a geometric quantization theory one needs an isomorphism in order to geometrize the Dirac quantization rules. In the present case one can establish such an isomorphism by lifting the theory to an appropriate affine frame bundle using the results in Ref. 5, where it was shown how to establish this isomorphism for the rank-1 n-symplectic algebras. This result was extended by Cartin to all n-symplectic observables in Ref. 24. We have therefore arrived at the frontiers of a geometric quantization theory of fields based on n-symplectic geometry.

APPENDIX: PROOF OF THE JACOBI IDENTITY FOR THEOREM 2.9

Let $\hat{X}^I_{\hat{f}}$, $\hat{X}^J_{\hat{g}}$ and $\hat{X}^K_{\hat{h}}$ denote arbitrary sets of representatives of the equivalence classes of Hamiltonian vector fields determined by $\hat{f}\in SHF^p$, $\hat{g}\in SHF^q$, and $\hat{h}\in SHF^r$, respectively, where I,J,K denote the multi-indices $I=\alpha_2\alpha_3\cdots\alpha_p$, $J=\alpha_{p+1}\alpha_{p+2}\cdots\alpha_{p+q-1}$, and $K=\alpha_{p+q}\alpha_{p+q+1}\cdots\alpha_{p+q+r-2}$. Then by using $d\hat{\omega}=0$ and the standard identity for evaluating $d\omega(X,Y,Z)$ for ω a 2-form we obtain

$$\begin{aligned}0&=3d\omega^{(\alpha}(\hat{X}^I_{\hat{f}},\hat{X}^J_{\hat{g}},\hat{X}^{K)}_{\hat{h}})\\&=\hat{X}^{(I}_{\hat{f}}\omega^{\alpha}(\hat{X}^J_{\hat{g}},\hat{X}^{K)}_{\hat{h}})+\hat{X}^{(J}_{\hat{g}}\omega^{\alpha}(\hat{X}^K_{\hat{h}},\hat{X}^{I)}_{\hat{f}})+\hat{X}^{(K}_{\hat{h}}\omega^{\alpha}(\hat{X}^I_{\hat{f}},\hat{X}^{J)}_{\hat{g}})\\&\quad-\omega^{(\alpha}([\hat{X}^I_{\hat{f}},\hat{X}^J_{\hat{g}}],\hat{X}^{K)}_{\hat{h}})-\omega^{(\alpha}([\hat{X}^K_{\hat{h}},\hat{X}^I_{\hat{f}}],\hat{X}^{J)}_{\hat{g}})\\&\quad-\omega^{(\alpha}([\hat{X}^J_{\hat{g}},\hat{X}^K_{\hat{h}}],\hat{X}^{I)}_{\hat{f}}).\end{aligned}\tag{A1}$$

Equations (2.8) and (2.19) can be combined to yield the identity,

$$\omega^{(\alpha}(\hat{X}^I_{\hat{f}},\hat{X}^{J)}_{\hat{g}})=\frac{1}{2p!q!}\{\hat{f},\hat{g}\}^{\alpha IJ}.\tag{A2}$$

Using this formula and formula (2.21) in (A1) we obtain

$$\begin{aligned}0&=\hat{X}^{(I}_{\hat{f}}\left(\frac{1}{2q!r!}\{\hat{g},\hat{h}\}^{JK\alpha)}\right)+\hat{X}^{(J}_{\hat{h}}\left(\frac{1}{2p!q!}\{\hat{f},\hat{g}\}^{IJ\alpha)}\right)+\hat{X}^{(K}_{\hat{g}}\left(\frac{1}{2p!r!}\{\hat{h},\hat{f}\}^{KI\alpha)}\right)\\&\quad-\frac{(p+q-1)!}{p!q!}\omega^{(\alpha}(X^{IJ}_{\{\hat{f},\hat{g}\}},\hat{X}^{K)}_{\hat{h}})-\frac{(p+r-1)!}{p!r!}\omega^{(\alpha}(X^{KI}_{\{\hat{h},\hat{f}\}},\hat{X}^{J)}_{\hat{g}})-\frac{(q+r-1)!}{q!r!}\omega^{(\alpha}(X^{JK}_{\{\hat{g},\hat{h}\}},\hat{X}^{I)}_{\hat{f}}).\end{aligned}$$

Next we use the definition (2.19) in the first three terms and formula (A2) in the last three terms to obtain

$$
\begin{aligned}
0=&\frac{1}{2p!q!r!}\{\hat{f},\{\hat{g},\hat{h}\}\}^L+\frac{1}{2p!q!r!}\{\hat{h},\{\hat{f},\hat{g}\}\}^L+\frac{1}{2p!q!r!}\{\hat{g},\{\hat{h},\hat{f}\}\}^L\\
&-\frac{(p+q-1)!}{p!q!}\left(\frac{1}{2(p+q-1)!r!}\{\{\hat{f},\hat{g}\},\hat{h}\}^L\right)\\
&-\frac{(p+r-1)!}{p!r!}\left(\frac{1}{2(p+r-1)!q!}\{\{\hat{h},\hat{f}\},\hat{g}\}^L\right)\\
&-\frac{(q+r-1)!}{q!r!}\left(\frac{1}{2(q+r-1)!p!}\{\{\hat{g},\hat{h}\},\hat{f}\}^L\right),
\end{aligned}
$$

where the multi-index L denotes (αIJK). Cancelling the common factor $1/p!q!r!$ we obtain

$$
\begin{aligned}
0=&\tfrac{1}{2}\{\hat{f},\{\hat{g},\hat{h}\}\}^L+\tfrac{1}{2}\{\hat{h},\{\hat{f},\hat{g}\}\}^L+\tfrac{1}{2}\{\hat{g},\{\hat{h},\hat{f}\}\}^L-\tfrac{1}{2}\{\{\hat{f},\hat{g}\},\hat{h}\}^L-\tfrac{1}{2}\{\{\hat{h},\hat{f}\},\hat{g}\}^L-\tfrac{1}{2}\{\{\hat{g},\hat{h}\},\hat{f}\}^L\\
=&\{\hat{f},\{\hat{g},\hat{h}\}\}^L+\{\hat{h},\{\hat{f},\hat{g}\}\}^L+\{\hat{g},\{\hat{h},\hat{f}\}\}^L.
\end{aligned}
$$

Hence the n-symplectic bracket defined in (2.19) obeys the identity of Jacobi. ■

On the stochastic mechanics of the free relativistic particle

Michele Pavon[a)]
Dipartimento di Elettronica e Informatica, Università di Padova, and LADSEB-CNR, Padova, Italy

(Received 30 March 2001; accepted for publication 19 July 2001)

Given a positive energy solution of the Klein–Gordon equation, the motion of the free, spinless, relativistic particle is described in a fixed Lorentz frame by a Markov diffusion process with nonconstant diffusion coefficient. Proper time is an increasing stochastic process and we derive a probabilistic generalization of the equation $(d\tau)^2=-(1/c^2)\mathrm{d}X_\nu \mathrm{d}X_\nu$. A random time-change transformation provides the bridge between the t and the τ domain. In the τ domain, we obtain an $\mathbb{M}^4$-valued Markov process with singular and constant diffusion coefficient. The square modulus of the Klein–Gordon solution is an invariant, nonintegrable density for this Markov process. It satisfies a relativistically covariant continuity equation. [DOI: 10.1063/1.1401135]

I. INTRODUCTION

The purpose of this paper is to discuss a possible scenario for the free, spinless, relativistic particle, extending on Nelson's stochastic mechanics. This challenging problem has generated considerable interest in the past twenty years, see Refs. 1–10, and references therein. As is well known, the main difficulty in this generalization stems from the nonexistence of nontrivial Markov diffusion processes possessing the required relativistic covariance.[11,12] A number of attempts have been made to circumvent this problem, for instance by considering different classes of stochastic processes, see, e.g., Refs. 2, 3, 5, 10.

In this paper we propose a new approach. Corresponding to a positive energy solution of the Klein–Gordon equation, motion of the particle is described in a fixed Lorentz frame by an $\mathbb{R}^3$-valued Markov diffusion process with *nonconstant diffusion coefficient* (local covariance matrix). The role of *proper time* is played here by an increasing stochastic process, namely a *quadratic variation* process. We also derive a natural probabilistic generalization of the equation $(\mathrm{d}\tau)^2=-(1/c^2)\mathrm{d}X_\nu \mathrm{d}X_\nu$. A *random time-change transformation* provides the bridge between the t and the τ domain. In the τ domain, we obtain an $\mathbb{M}^4$-valued Markov process with singular and constant diffusion coefficient. The fourth component is proportional to a stopping time. The square modulus of the Klein–Gordon solution is an invariant, nonintegrable density for this Markov process. It satisfies a relativistically covariant continuity equation.

II. BACKGROUND ON DIFFUSION PROCESSES

In this section, we review some essential concepts and results of the kinematics of stochastic mechanics. We refer to Refs. 13–16 for a thorough account. In order to avoid any confusion, stochastic processes will be denoted by capital letters, as is customary in probability. Let $(\Omega,\mathcal{E},\mathbf{P})$ be a probability space. A stochastic process $\{X(t);t_0\leqslant t\leqslant t_1\}$ mapping $[t_0,t_1]$ into $L_n^2(\Omega,\mathcal{E},\mathbf{P})$ is called a *finite-energy diffusion* with constant diffusion coefficient $I_n\sigma^2$ if the path $X(\omega)$ belongs a.s. to $C([t_0,t_1];\mathbb{R}^n)$ (n-dimensional continuous functions) and

a)Electronic mail: pavon@dei.unipd.it

$$X(t)-X(s)=\int_s^t \beta(\tau)\mathrm{d}\tau+\sigma[W_+(t)-W_+(s)],\quad t_0\leqslant s<t\leqslant t_1, \tag{2.1}$$

where the *forward drift* $\beta(t)$ is at each time t a measurable function of the past $\{X(\tau);0\leqslant\tau\leqslant t\}$, and $W_+(\cdot)$ is a standard, n-dimensional *Wiener process* with the property that $W_+(t)-W_+(s)$ is independent of $\{X(\tau);0\leqslant\tau\leqslant s\}$. Moreover, β must satisfy the finite-energy condition

$$E\left\{\int_{t_0}^{t_1}\beta(t)\cdot\beta(t)\mathrm{d}t\right\}<\infty. \tag{2.2}$$

In Ref. 17, Föllmer has shown that a finite-energy diffusion also admits a reverse-time differential. Namely, there exists a measurable function $\gamma(t)$ of the future $\{X(\tau);t\leqslant\tau\leqslant t_1\}$ called *backward drift*, and another Wiener process W_- such that

$$X(t)-X(s)=\int_s^t \gamma(\tau)\mathrm{d}\tau+\sigma[W_-(t)-W_-(s)],\quad t_0\leqslant s<t\leqslant t_1. \tag{2.3}$$

Moreover, γ satisfies

$$E\left\{\int_{t_0}^{t_1}\gamma(t)\cdot\gamma(t)\mathrm{d}t\right\}<\infty, \tag{2.4}$$

and $W_-(t)-W_-(s)$ is independent of $\{X(\tau);t\leqslant\tau\leqslant t_1\}$. Let us agree that $\mathrm{d}t$ always indicates a strictly positive variable. For any function f defined on $[t_0,t_1]$, let

$$d_+f(t):=f(t+\mathrm{d}t)-f(t)$$

be the *forward increment* at time t, and

$$d_-f(t)=f(t)-f(t-\mathrm{d}t)$$

be the *backward increment* at time t. For a finite-energy diffusion, Föllmer has also shown in Ref. 17 that the forward and backward drifts may be obtained as Nelson's conditional derivatives, namely

$$\beta(t)=\lim_{\mathrm{d}t\searrow 0}E\left\{\frac{d_+X(t)}{dt}\middle| X(\tau),t_0\leqslant\tau\leqslant t\right\}, \tag{2.5}$$

and

$$\gamma(t)=\lim_{\mathrm{d}t\searrow 0}E\left\{\frac{d_-X(t)}{dt}\middle| X(\tau),t\leqslant\tau\leqslant t_1\right\}, \tag{2.6}$$

the limits being taken in $L^2_n(\Omega,\mathcal{B},P)$. It was finally shown in Ref. 17 that the one-time probability density $\rho(\cdot,t)$ of $X(t)$ (which exists for every $t>t_0$) is absolutely continuous on $\mathbb{R}^n$ and the following relation holds $\forall t>0$:

$$E\{\beta(t)-\gamma(t)|X(t)\}=\sigma^2\nabla\log\rho(X(t),t). \tag{2.7}$$

Let us introduce the *current drift* $v(t):=(\beta(t)+\gamma(t))/2$ and the *osmotic drift* $u(t):=(\beta(t)-\gamma(t))/2$. Notice that, when σ tends to zero, v tends to $\dot{X}$, and u tends to zero. The finite-energy diffusion $X(\cdot)$ is called *Markovian* if there exist two measurable functions $b_+(\cdot,\cdot)$ and $b_-(\cdot,\cdot)$ such that $\beta(t)=b_+(X(t),t)$ a.s. and $\gamma(t)=b_-(X(t),t)$ a.s., for all t in $[t_0,t_1]$. The duality relation (2.7) now reads

$$b_+(X(t),t)-b_-(X(t),t)=\sigma^2\nabla\log\rho(X(t),t). \tag{2.8}$$

This immediately gives the *osmotic equation*

$$u(x,t)=\frac{\sigma^2}{2}\nabla\log\rho(x,t), \tag{2.9}$$

where $u(x,t):=(b_+(x,t)-b_-(x,t))/2$. The probability density $\rho(\cdot,\cdot)$ of $X(t)$ satisfies (at least weakly) the *Fokker–Planck equation*

$$\frac{\partial\rho}{\partial t}+\nabla\cdot(b_+\rho)=\frac{\sigma^2}{2}\Delta\rho.$$

The latter can also rewritten, in view of (2.8), as the *equation of continuity* of hydrodynamics

$$\frac{\partial\rho}{\partial t}+\nabla\cdot(v\rho)=0, \tag{2.10}$$

where $v(x,t):=(b_+(x,t)+b_-(x,t))/2$.

Nelson's stochastic mechanics[13,16,14,18] is a quantization procedure for classical dynamical systems based on diffusion processes. Given a quantum evolution $\{\psi(x,t);t_0\leqslant t\leqslant t_1\}$, namely a solution of the Schrödinger equation

$$\frac{\partial\psi}{\partial t}=\frac{i\hbar}{2m}\Delta\psi-\frac{i}{\hbar}V(x)\psi, \tag{2.11}$$

satisfying Carlen's *finite action condition*

$$\|\nabla\psi\|_2^2\in L^1_{\mathrm{loc}}[(t_0,+\infty)], \tag{2.12}$$

it is possible to construct a measure on path-space under which the canonical coordinate process X is a finite-energy Markov diffusion process. Writing $\psi(x,t)=\exp R(x,t)+(i/\hbar)S(x,t)$, we have that the process X has current and osmotic drift fields given, respectively, by $v(x,t)=(1/m)\nabla S(x,t)$, and $u(x,t)=(\hbar/m)\nabla R(x,t)$. In particular, the (forward) Ito differential of X is given by

$$dX(t)=\left[\frac{\hbar}{m}\nabla(\Re\log\psi(X(t),t)+\Im\log\psi(X(t),t))\right]\mathrm{d}t+\sqrt{\frac{\hbar}{m}}dW_+(t), \tag{2.13}$$

see Ref. 19 and Ref. 18, Chap. IV, and references therein. Moreover, the probability density $\rho(\cdot,t)$ of $x(t)$ satisfies

$$\rho(x,t)=|\psi(x,t)|^2,\quad \forall t\in[t_0,t_1]. \tag{2.14}$$

We now need to recall the generalization to Markov processes with diffusion coefficient of the form $I_n\sigma(x,t)^2$, with $\sigma(x,t)\in\mathbb{R}$, the above-mentioned kinematics, see, e.g., Refs. 20–23. Let $\{X(t);t_0\leqslant t\leqslant t_1\}$ be an n-dimensional Markov diffusion process whose increments admit the two representations

$$d_+X(t)=b_+(X(t),t)\mathrm{d}t+\sigma_+(X(t),t)d_+W_+(t), \tag{2.15}$$

$$d_-X(t)=b_-(X(t),t)\mathrm{d}t+\sigma_-(X(t),t)d_-W_-(t), \tag{2.16}$$

where the drifts and diffusion coefficients are sufficiently regular. Here, W_+ and W_- are standard, n-dimensional Wiener processes adapted to the past and the future, respectively, of the process X. Then, the following relations hold:

$$\sigma_+(x,t)=\sigma_-(x,t)=\sigma(x,t), \tag{2.17}$$

$$b_+(x,t)-b_-(x,t)=\frac{1}{\rho}\nabla(\sigma(x,t)^2\rho(x,t)). \tag{2.18}$$

Letting, as usual, $v:=(b_++b_-)/2$ denote the current drift, we have, as before, that the Fokker–Planck equation can be rewritten as the continuity equation (2.10). Let $R(x,t):=\frac{1}{2}\log(\sigma(x,t)^2\rho(x,t))$. Then, observing that (2.18) can be rewritten as

$$b_+(x,t)-b_-(x,t)=\sigma(x,t)^2\nabla\log(\sigma(x,t)^2\rho(x,t)),$$

we get the following expression for the osmotic drift u:

$$u(x,t)=\sigma(x,t)^2\nabla R(x,t). \tag{2.19}$$

III. DESCRIPTION IN A FIXED INERTIAL FRAME

For the definitions and results about continuous martingales that occur in this section, we refer the reader to the Appendix and, for a thorough treatment, to Refs. 24 and 25. Let $\varphi:=\exp[R+(i/\hbar)S]$ be a solution of the Klein–Gordon equation

$$\Delta\varphi-\frac{1}{c^2}\frac{\partial^2}{\partial t^2}\varphi=\frac{m^2c^2}{\hbar^2}\varphi \tag{3.1}$$

on $[0,\infty)$, such that S satisfies on the same time interval

$$\frac{\partial S}{\partial t}+c\sqrt{m^2c^2+\nabla S\cdot\nabla S}=0. \tag{3.2}$$

This is precisely the family of solutions that was considered in Ref. 8. Indeed, let

$$\rho(x,t)=\frac{i\hbar}{2mc^2}\left(\overline{\varphi}\frac{\partial\varphi}{\partial t}-\varphi\frac{\partial\overline{\varphi}}{\partial t}\right)(x,t)=|\varphi(x,t)|^2\times\left(-\frac{1}{mc^2}\frac{\partial S}{\partial t}(x,t)\right), \tag{3.3}$$

$$\mathbf{j}(x,t)=\frac{\hbar}{2mi}(\overline{\varphi}\nabla\varphi-\varphi\nabla\overline{\varphi})(x,t)=|\varphi(x,t)|^2\times\left(\frac{1}{m}\nabla S(x,t)\right). \tag{3.4}$$

First of all, observe that because of (3.1), the pair $(\rho,\mathbf{j})$ satisfies a continuity-type equation

$$\frac{\partial\rho}{\partial t}+\nabla\cdot\mathbf{j}=0.$$

Moreover, from (3.2) it also follows that

$$\rho\geqslant 0, \tag{3.5}$$

$$\mathbf{j}\cdot\mathbf{j}-c^2\rho^2=-c^2|\varphi|^4. \tag{3.6}$$

The latter two conditions are equivalent to (5.10) in Ref. 8 (p. 4705). This class of solutions is nonempty. It contains at least all positive-frequency plane-wave solutions, namely solutions of the form

$$\varphi(x,t)=\exp[(i/\hbar)(\mathbf{p}\cdot x-p^0 t)],$$

where

$$p^0=+c\sqrt{\mathbf{p}\cdot\mathbf{p}+m^2c^2}.$$

Let

$$\rho_0(x):=\frac{i\hbar}{2mc^2}\left(\overline{\varphi}\frac{\partial\varphi}{\partial t}-\varphi\frac{\partial\overline{\varphi}}{\partial t}\right)(x,0)=|\varphi(x,0)|^2\times\left(-\frac{1}{mc^2}\frac{\partial S}{\partial t}(x,0)\right).$$

It follows from (3.2) that $\rho_0(x)\geqslant 0$. Let us suppose that ρ_0 integrates to one. Suppose that $\{X(t);t\geqslant 0\}$ is a Markov diffusion process such that $X(0)$ is distributed according to ρ_0, and having forward differential

$$d_+X(t)=\begin{pmatrix}\frac{1}{m}\nabla S+\frac{\hbar}{m}\nabla R\\ -\frac{1}{mc^2}\frac{\partial S}{\partial t}\end{pmatrix}(X(t),t)\,dt+\sqrt{\frac{\hbar}{m}}\frac{1}{\sqrt{-\frac{1}{mc^2}\frac{\partial S}{\partial t}(X(t),t)}}d_+W_+(t),\qquad(3.7)$$

where $W_+(\cdot)$ is a standard, three-dimensional Wiener process. In the previous notation, we have

$$\sigma^2(x,t):=\frac{\hbar}{-\frac{1}{c^2}\frac{\partial S}{\partial t}(x,t)}.$$

A standard calculation[26] shows that $\rho(x,t)$ in (3.3) satisfies the Fokker–Planck equation corresponding to (3.7). Hence, $\rho(x,t)$ is the probability density of $X(t)$. Moreover, the current drift of X is

$$v(X(t),t):=\begin{pmatrix}\frac{1}{m}\nabla S\\ -\frac{1}{mc^2}\frac{\partial S}{\partial t}\end{pmatrix}(X(t),t),\qquad(3.8)$$

and the osmotic drift is given by

$$u(X(t),t)=\begin{pmatrix}\frac{\hbar}{m}\nabla R\\ -\frac{1}{mc^2}\frac{\partial S}{\partial t}\end{pmatrix}(X(t),t).\qquad(3.9)$$

Let us define

$$M^i(t):=\int_0^t\frac{1}{\sqrt{-\frac{1}{mc^2}\frac{\partial S}{\partial s}(X(s),s)}}d_+W_+^i(s),\quad t\geqslant 0,\quad i=1,2,3.\qquad(3.10)$$

The stochastic processes $\{M^i(t);t\geqslant 0\}$ are continuous *local martingales*[24,25] with the same *quadratic variation*

$$\langle M\rangle(t)=\langle M^i\rangle(t):=\int_0^t \frac{1}{-\frac{1}{mc^2}\frac{\partial S}{\partial s}(X(s),s)}\,\mathrm{d}s. \tag{3.11}$$

Moreover, their *cross variations* satisfy

$$\langle M^i,M^j\rangle(t)=0,\quad 1\leqslant i\neq j\leqslant 3,\quad \forall t\geqslant 0. \tag{3.12}$$

Observe that $\langle M\rangle(t)$ is a strictly increasing process with differentiable sample paths. It satisfies, in view of (3.2) and (3.8),

$$\begin{aligned} d\langle M\rangle(t)&=\frac{1}{-\frac{1}{mc^2}\frac{\partial S}{\partial t}(X(t),t)}\,\mathrm{d}t\\ &=\sqrt{\frac{m^2c^2}{m^2c^2+\nabla S(X(t),t)\cdot\nabla S(X(t),t)}}\,\mathrm{d}t\\ &=\sqrt{1-\frac{\nabla S(X(t),t)\cdot\nabla S(X(t),t)}{m^2c^2+\nabla S(X(t),t)\cdot\nabla S(X(t),t)}}\,\mathrm{d}t\\ &=\sqrt{1-\frac{v(X(t),t)\cdot v(X(t),t)}{c^2}}\,\mathrm{d}t. \end{aligned} \tag{3.13}$$

If for some t and ω we have $v(X(t,\omega),t)=0$, then $d\langle M\rangle(t)=\mathrm{d}t$. We can therefore think of $d\langle M\rangle(t)$ as of an increment of the particle *random proper time*. Notice that (3.13) implies

$$\frac{d\langle M\rangle(t)}{\mathrm{d}t}\leqslant 1,\quad a.s.$$

Hence,

$$\langle M\rangle(t)\leqslant t,\ \ a.s.,\ \ \forall t\geqslant 0. \tag{3.14}$$

Furthermore, we have the following property of $d\langle M\rangle(t)$. Let us first recall that, in view of (2.5) and (2.6), we have

$$v(X(t),t)=\lim_{\mathrm{d}t\searrow 0} E\left\{\frac{d_sX(t)}{\mathrm{d}t}\middle| X(t)\right\}, \tag{3.15}$$

where the *symmetric increment* of X at time t is defined by

$$d_sX(t):=\frac{d_+X(t)+d_-X(t)}{2}=\frac{X(t+\mathrm{d}t)-X(t-\mathrm{d}t)}{2}.$$

We can therefore rewrite (3.13) as follows:

$$
\begin{aligned}
c^2[d\langle M\rangle(t)]^2 &= -[(ic)^2 + v(X(t),t)\cdot v(X(t),t)](\mathrm{d}t)^2 \\
&= -\left[\left(\frac{d(ict)}{\mathrm{d}t}\right)^2 + v(X(t),t)\cdot v(X(t),t)\right](\mathrm{d}t)^2 \\
&= -[(d(ict))^2 + E\{d_sX(t)|X(t)\}\cdot E\{d_sX(t)|X(t)\} + o((\mathrm{d}t)^2)].
\end{aligned}
\tag{3.16}
$$

Let us introduce

$$
X_\nu(t) = \begin{pmatrix} X(t) \\ ict \end{pmatrix}.
$$

Then (3.16) can be written as follows:

$$
[d\langle M\rangle(t)]^2 = -\frac{1}{c^2}E\{d_sX_\nu(t)|X_\nu(t)\}\cdot E\{d_sX_\nu(t)|X_\nu(t)\} + o((\mathrm{d}t)^2), \tag{3.17}
$$

generalizing the relation $(\mathrm{d}\tau)^2 = -(1/c^2)\mathrm{d}X_\nu \mathrm{d}X_\nu$ of classical relativistic mechanics.

IV. FROM THE t TO THE τ FORMULATION: A RANDOM TIME CHANGE

An important consequence of Levy's characterization of the Wiener process, see, e.g., Ref. 25, p. 82, is that any continuous local martingale may be viewed as a time-changed Wiener process, cf. Theorem A.2 in the Appendix. For $\tau \geqslant 0$, let us introduce the *stopping time*

$$
T(\tau) := \inf\{\sigma \geqslant 0 : \langle M\rangle(\sigma) \geqslant \tau\}.
$$

[In the case when the probability of the event $\{\omega : \lim_{t\to\infty}\langle M\rangle(t,\omega) = \infty\}$ is strictly less than one, the stopping time $T(\tau)$ has to be suitably modified, see Ref. 24, pp. 174–175.] Notice that

$$
\langle M\rangle(T(\tau)) = \tau, \quad T(\langle M\rangle(t)) = t. \tag{4.1}
$$

Then, the processes

$$
\tilde{W}^i_+(\tau) := M^i_{T(\tau)}, \quad i = 1,2,3,
$$

are standard, one-dimensional Wiener processes. Moreover, in view of property (3.12), we can apply a theorem of Knight (see Theorem A.3 in the Appendix), and conclude that the processes $\tilde{W}^i_+(\tau)$ are pairwise independent, and can, consequently, be viewed as the components of a standard, three-dimensional Wiener process $\tilde{W}_+(\tau)$. Let us introduce the stochastic process

$$
\tilde{X}(\tau) := X(T(\tau)), \quad \tau \geqslant 0.
$$

In view of (3.7), (3.11), and (4.1), the forward differential of $\tilde{X}$ is given by

$$
d_+\tilde{X}(\tau) = \left(\frac{1}{m}\nabla S + \frac{\hbar}{m}\nabla R\right)(\tilde{X}(\tau), T(\tau))\mathrm{d}\tau + \sqrt{\frac{\hbar}{m}}d_+\tilde{W}_+(\tau). \tag{4.2}
$$

Notice that $\tilde{X}(\tau)$ is a non-Markovian $\mathbb{R}^3$-valued diffusion process with constant diffusion coefficient $(\hbar/m)I_3$. The Markov property has therefore been destroyed by the random time change. From the first relation in (4.1), we get

$$\frac{\mathrm{d}T(\tau)}{\mathrm{d}\tau}=\left[\frac{d\langle M\rangle}{\mathrm{d}t}(T(\tau))\right]^{-1}.$$

In view of (3.11), we then get

$$\frac{\mathrm{d}T(\tau)}{\mathrm{d}\tau}=-\frac{1}{mc^2}\frac{\partial S}{\partial t}(\tilde{X}(\tau),T(\tau)). \tag{4.3}$$

Let us now define $\tilde{X}^4(\tau):=icT(\tau)$, $\tilde{S}(x_\nu)=\tilde{S}(x,x^4):=S(x,t)$, and $\tilde{R}(x_\nu)=\tilde{R}(x,x^4):=R(x,t)$. Equations (4.2) and (4.3) can now be rewritten as

$$d_+\tilde{X}(\tau)=\left(\frac{1}{m}\nabla\tilde{S}+\frac{\hbar}{m}\nabla\tilde{R}\right)(\tilde{X}(\tau),\tilde{X}^4(\tau))\mathrm{d}\tau+\sqrt{\frac{\hbar}{m}}d_+\tilde{W}_+(\tau), \tag{4.4}$$

$$d_+\tilde{X}^4(\tau)=\frac{1}{m}\frac{\partial\tilde{S}}{\partial x^4}(\tilde{X}(\tau),\tilde{X}^4(\tau))\mathrm{d}\tau. \tag{4.5}$$

Notice that $\tilde{X}_\nu(\tau)$ defined by

$$\tilde{X}_\nu(\tau)=\begin{pmatrix}\tilde{X}(\tau)\\ \tilde{X}_4(\tau)\end{pmatrix}$$

is an $\mathbb{M}^4$-valued *Markovian* stochastic process with marginal density at $\tau=0$ given by $\rho_0(x)\cdot\delta(x^4)$ since $T(0)=0$ a.s. Let us introduce the diffusion matrix

$$\Sigma^2:=\begin{pmatrix}\frac{\hbar}{m}I_3 & 0\\ 0 & 0\end{pmatrix}.$$

Then (4.4) and (4.5) can be rewritten in the form

$$d_+\tilde{X}_\nu(\tau)=\left(\frac{1}{m}\nabla_\nu\tilde{S}+\Sigma^2\nabla_\nu\tilde{R}\right)(\tilde{X}_\nu(\tau))\mathrm{d}\tau+\Sigma d_+\tilde{W}_\nu(\tau), \tag{4.6}$$

where $\tilde{W}_\nu$ is any standard, four-dimensional Wiener process whose first three components form $\tilde{W}_+$. The Fokker–Plank equation is then

$$\frac{\partial\rho_\nu}{\partial\tau}+\nabla_\nu\cdot\left[\left(\frac{1}{m}\nabla_\nu\tilde{S}+\Sigma^2\nabla_\nu\tilde{R}\right)\rho_\nu\right]=\frac{1}{2}\Sigma^2\Delta_\nu\rho_\nu. \tag{4.7}$$

Because of (3.1), $\varphi(x_\nu):=\exp[\tilde{R}(x_\nu)+(i/\hbar)\tilde{S}(x_\nu)]$ satisfies

$$\nabla_\nu\cdot\nabla_\nu\varphi=\frac{m^2c^2}{\hbar^2}\varphi.$$

The latter is equivalent to the system of p.d.e.s

$$-\frac{1}{2m}\nabla_\nu\tilde{S}\cdot\nabla_\nu\tilde{S}+\frac{\hbar^2}{2m}[\nabla_\nu\tilde{R}\cdot\nabla_\nu\tilde{R}+\nabla_\nu\cdot\nabla_\nu\tilde{R}]=\frac{mc^2}{2}, \tag{4.8}$$

$$\frac{1}{m}\nabla_\nu\tilde{S}\cdot\nabla_\nu\tilde{R}+\frac{1}{2m}\nabla_\nu\cdot\nabla_\nu\tilde{S}=0. \tag{4.9}$$

Let

$$\tilde{\rho}(x_\nu)=|\varphi(x_\nu)|^2.$$

From (4.9), we get that $\tilde{\rho}(x_\nu)$ satisfies (4.7). Thus, $\mu(\mathrm{d}x_\nu):=\tilde{\rho}(x_\nu)\mathrm{d}x_\nu$ is an *invariant* (σ-*finite*) *measure* for (4.4) and (4.5). Notice that $\tilde{\rho}(x_\nu)$ also satisfies the manifestly convariant equation

$$\nabla_\nu\cdot\left(\tilde{\rho}\frac{1}{m}\nabla_\nu\tilde{S}\right)=0.$$

If we give $\mu(\mathrm{d}x_\nu):=\tilde{\rho}(x_\nu)\mathrm{d}x_\nu$ as initial measure to (4.6), the probabilistic picture is lost. Nevertheless, it is possible to make sense of the time-reversed diffusion along the lines of Ref. 18 (pp. 44 and 45). Moreover, consider the *generator* of $\tilde{X}_\nu$ acting on smooth functions with compact support

$$\left(\frac{1}{m}\nabla_\nu\tilde{S}+\Sigma^2\nabla_\nu\tilde{R}\right)\cdot\nabla_\nu+\frac{1}{2}\Sigma^2\Delta_\nu.$$

The adjoint of this operator with respect to the measure $\mu(\mathrm{d}x_\nu)$ (Ref. 13, p. 104) is given by

$$\left(\frac{1}{m}\nabla_\nu\tilde{S}-\Sigma^2\nabla_\nu\tilde{R}\right)\cdot\nabla_\nu-\frac{1}{2}\Sigma^2\Delta_\nu.$$

Hence, in spite of the lack of a probabilistic picture we can still think of $(1/m)\nabla_\nu\tilde{S}$ as a bilateral velocity field associated with the equilibrium measure $\mu(x_\nu)$. Then, recalling that (3.2) implies

$$\nabla_\nu\tilde{S}(x_\nu)\cdot\nabla_\nu\tilde{S}(x_\nu)=-m^2c^2,$$

we get a τ-domain counterpart of relation (3.17).

V. CONCLUSION AND OUTLOOK

Although the process (4.4)–(4.5) is not relativistically covariant, our description does not appear to be in conflict with classical relativistic mechanics nor with Nelson's nonrelativistic theory. Indeed, in the case when we let the noise intensity in (3.7) tend to zero, we recover the equations of classical special relativity. In particular, the quadratic variation $\langle M\rangle$ defined by (3.11) tends to proper time τ and $T(\tau)$ tends to $t(\tau)$. On the other hand, when $v\cdot v\ll c^2$, motion of the particle in a fixed inertial frame is described by a Markov diffusion process with diffusion coefficient nearly equal to $\hbar/m$. The Schrödinger equation is then recovered through some appropriate procedure neglecting terms multiplied by $\hbar^2/c$, cf. Ref. 8, p. 4708.

The author wishes to thank Paolo Dai Pra for some helpful comments on the results of this paper, and Lorenza Viola for several useful conversations on relativistic stochastic mechanics.

APPENDIX: CONTINUOUS MARTINGALES

We collect in this Appendix a few basic facts about continuous martingales. We refer the reader to Refs. 24 and 25 for the proofs and more information. Let $(\Omega,\mathcal{A},\mathbf{P})$ be a probability space, and let $\mathcal{F}:=(\mathcal{F}_t),t\in[t_0,t_1]$, be a nondecreasing family of sub σ-algebras of $\mathcal{A}$. It will be always assumed that $\mathcal{F}_{t_0}$ contains all the zero-probability sets in $\mathcal{A}$, and that the filtration is right-continuous, namely $\{\cap\mathcal{F}_t,t>s\}=\mathcal{F}_s$, for every s. A stochastic process $X:=\{X(t);t\in[t_0,t_1]\}$ is said to be *continuous* if it has continuous trajectories $X(t,\omega),t\in[t_0,t_1]$, with probability one. It is called $\mathcal{F}$-*adapted* if, for every t in $[t_0,t_1]$, $X(t)$ is $\mathcal{F}_t$-measurable. In that case, it

is customary to write $X=(X(t),\mathcal{F}_t)_{t\in[t_0,t_1]}$. The stochastic process $M=(M(t),\mathcal{F}_t)_{t\in[t_0,t_1]}$ is called a *martingale* (with respect to the *filtration* $\mathcal{F}_t, t\in[t_0,t_1]$) if it satisfies the two following conditions:

(1) $E\{|M(t)|\}<\infty, \quad \forall t,$
(2) $E\{M(t)|\mathcal{F}_s\}=M(s), \quad t\geqslant s.$

The continuous martingale $X=(X(t),\mathcal{F}_t)_{t\in[t_0,t_1]}$ is called *square-integrable* if $E\{X(t)^2\}<\infty$, $\forall t$ in $[t_0,t_1]$. Let $X=(X(t),\mathcal{F}_t)_{t\in[t_0,t_1]}$ be a continuous, square-integrable martingale with $X(t_0)=0$ with probability one. Then, the celebrated Doob–Meyer decomposition theorem implies that there exists a unique representation for $X(t)^2$,

$$X(t)^2=\langle X\rangle(t)+M(t), \quad t\in[t_0,t_1],$$

where $\langle X\rangle$ is an adapted, continuous, increasing process with $\langle X\rangle(t_0)=0$, and M is a continuous martingale with $M(t_0)=0$. The process $\langle X\rangle(\cdot)$ is called the *quadratic variation* of $X(\cdot)$. Consider now two continuous, square-integrable martingales $X=(X(t),\mathcal{F}_t)_{t\in[t_0,t_1]}$ and $Y=(Y(t),\mathcal{F}_t)_{t\in[t_0,t_1]}$. Their *cross-variation process* $\langle X,Y\rangle$ is defined for $t\in[t_0,t_1]$ by

$$\langle X,Y\rangle(t):=\tfrac{1}{4}[\langle X+Y\rangle(t)-\langle X-Y\rangle(t)].$$

The cross variation of X and Y is characterized by the fact that $XY-\langle X,Y\rangle$ is a continuous martingale.

A non-negative random variable $T(\omega)$ is called a *Markov time* or a *stopping time* (relative to the *filtration* $\mathcal{F}_t, t\in[t_0,t_1]$) if, for all t in $[t_0,t_1]$,

$$\{\omega: T(\omega)\leqslant t\}\in\mathcal{F}_t.$$

Let T be a stopping time relative to $\mathcal{F}_t, t\in[t_0,t_1]$. Then, the σ-field $\mathcal{F}_T$ *of events determined prior to the stopping time* T consists of those events $A\in\mathcal{A}$ for which $[A\cap\{\omega: T(\omega)\leqslant t\}]\in\mathcal{F}_t$, for every t in $[t_0,t_1]$.

The stochastic process $M=(M(t),\mathcal{F}_t)_{t\geqslant 0}$, is called a *local martingale* if there exists an increasing sequence of stopping times (with respect to $\mathcal{F}$) $\{T_n\}$, $n=1,2,...$ such that

(1) $\mathbf{P}(\lim T_n=\infty)=1;$
(2) for any n, the "stopped process" $(M(t\wedge T_n),t\geqslant 0$, is a martingale.

The decomposition result for the product of two square-integrable martingale extends to local martingales as follows. Let $X=(X(t),\mathcal{F}_t)_{t\in[t_0,t_1]}$ and $Y=(Y(t),\mathcal{F}_t)_{t\in[t_0,t_1]}$ be two continuous, local martingales. Then there is a unique adapted process $\langle X,Y\rangle$ such that $XY-\langle X,Y\rangle$ is a continuous local martingale. We write $\langle X\rangle$ instead of $\langle X,X\rangle$. We can now state Levy's martingale characterization of the Wiener process.

Theorem A.1: *Let $M=(M(t),\mathcal{F}_t)_{t\geqslant 0}$ be a continuous local martingale with $M(0)=0$ a.s. and quadratic variation $\langle M\rangle(t)=t$. Then M is a standard Wiener process.*

As a corollary to this theorem, we have the following result showing that continuous local martingales can be viewed as time-changed Wiener processes.

Theorem A.2: *Let $M=(M(t),\mathcal{F}_t)_{t\geqslant 0}$ be a continuous local martingale with $M(0)=0$ a.s. Suppose that $\lim_{t\to\infty}\langle M\rangle(t)=\infty$ with probability one. Define, for $\tau\geqslant 0$, the stopping time $T(\tau):=\inf\{t\geqslant 0:\langle M\rangle(t)>\tau\}$. Then the time-changed process $W=\{W(\tau):=(M(T(\tau)),\mathcal{G}_\tau:=\mathcal{F}_{T(\tau)})_{\tau\geqslant 0}\}$ is a standard Wiener process and we have, with probability one,*

$$M(t)=W(\langle M\rangle(t)), \quad t\geqslant 0.$$

The multivariate extension of this theorem is due to Knight (Ref. 24, p. 179).

Theorem A.3: *Let* $M=\{M(t)=(M^1(t),\dots,M^n(t)),\mathcal{F}_t)_{t\geq 0}\}$ *be a continuous process with* $M(0)=0$ *a.s. Suppose that the components* M^i *are local martingales satisfying the two following conditions:*

(1) $\lim_{t\to\infty}\langle M^i\rangle(t)=\infty, \quad i=1,...,n$ *a.s.*;
(2) $\langle M^i,M^j\rangle(t)=0, \quad i\neq j, t\geq 0.$

Let $T_i(\tau):=\inf\{t\geq 0:\langle M^i\rangle(t)>\tau\}, t\geq 0, i=1,...,n$. *Then the* $W^i(\tau):=M^i(T_i(\tau)), \tau\geq 0, i=1,...,n$ *are independent, standard Wiener processes.*

The nontrivial content of this theorem is that, although the M^i are not independent, applying first the appropriate time changes, and then forgetting the time changes, we get independent Wiener processes. Forgetting the time changes consists in replacing the filtrations $\{\mathcal{G}_\tau^i\}$ with the poorer filtrations $\{\mathcal{F}_\tau^{W^i}\}$.

(Received 7 August 2000; accepted for publication 11 July 2001)

In this article the quantum version of the source coding theorem is obtained for a completely ergodic source. This result extends Schumacher's quantum noiseless coding theorem for memoryless sources. The control of the memory effects requires some earlier results of Hiai and Petz on high probability subspaces. Our result is equivalently considered as a compression theorem for noiseless stationary channels. © *2001 American Institute of Physics.* [DOI: 10.1063/1.1398335]

I. INTRODUCTION

Although it is difficult to define a discipline, to give some idea we can say that the objective of quantum information theory is the transmission and manipulation of information stored in systems obeying quantum mechanics. A quantum channel has a source that emits systems in quantum states to the channel. For example, the source could be a laser that emits individual monochromatic photons and the channel could be an optical fiber. The noisy signal output of the channel arrives at the receiver. In principle, there are two very different problems about quantum channels. The sender has a quantum system in an unknown state and wants to have the receiver end up with a similar system in the same state. In this case we speak of a pure quantum channel which has a quantum mechanical input and output. On the other hand, one might want to use quantum states to carry classical information, roughly speaking, a sequence of zeros and ones. Now both the input and the output are classical; however, there is a quantum mechanical section in between. The classical information is encoded into a quantum state and this is sent down the channel. The higher the channel noise is, the more redundant the encoding must be in order to restore the original signal at the receiver, where the quantum signal is converted into classical information. In this article we do not deal with the problem of how such a scheme can be realistically implemented; practical quantum encoding and decoding requires a sophisticated ability to manipulate quantum states. However, we are interested in the amount of classical information getting through the channel which is assumed to be noiseless. It was emphasized already by Shannon that a computer memory is a communication channel. (Quantum or classical depends on the type of computer.) In an optimal situation the computer memory is free of any noise and this is the case we are concentrating on in the present work. We want to consider rather general noiseless quantum channels (with possibly memory effects but strong ergodic properties), and our aim is to discuss the quantum source coding theorem. As a general reference on quantum information theory we suggest Ref. 1, but the really necessary definitions are given here.

To each classical input message x_i there corresponds a signal state φ_i of the quantum communication system. The quantum states φ_i are functioning as code words of the messages. The signal states φ_i could be pure and orthogonal in the sense of quantum mechanics, but, for example, in quantum cryptography nonorthogonal states are used intentionally in order to avoid eavesdropping. At the moment we do not impose any condition on the signal states; they could be arbitrary pure or mixed states. In the stochastic model of communication, one assumes that each input message x_i appears with certain probability. Let p_{ji} be the probability that the message x_i is sent and y_j is received. The joint distribution p_{ji} yields marginal probability distributions p_i and q_j on

[a]Electronic mail: petz@math.bme.hu
[b]Electronic mail: mosonyi@chardonnay.math.bme.hu

the set of input and output messages. According to Shannon the mutual information

$$I=\sum_{i,j} p_{ji}\log\frac{p_{ji}}{p_i q_j}$$

measures the amount of information going through the channel from Alice to Bob. Of course, the relation of I to the quantum encoding and decoding should be made clear. This comes next.

The message x_i has *a priori* probability p_i and the mixed quantum state of the channel is

$$\varphi=\sum_i p_i\varphi_i .$$

This might be considered as the statistical operator of the *message ensemble*; for example, when φ_i is a pure state $|i\rangle\langle i|$, then $\varphi=\Sigma_i p_i|i\rangle\langle i|$ acts on the input Hilbert space $\mathcal{H}$. The distribution of the output is determined by a measurement, which is nothing else but a physical word for decoding. To each output message there corresponds an observable A_j on the output Hilbert space $\mathcal{K}$. It is customary to assume that $0\leqslant A_j$, $\Sigma_j A_j=\mathrm{id}$ (id stands for the identity operator) and $p_{ji}=p_i\varphi_i(A_j)$. The so-called *Kholevo bound*[2] provides an upper bound on the amount of information accessible to Bob in terms of von Neumann entropies:

$$I\leqslant S(\varphi)-\sum_i p_i S(\varphi_i).$$

[When $\lambda_1,\lambda_2,\ldots$ are the eigenvalues of the statistical operator of a quantum state ψ, then $S(\psi)=-\Sigma_k\lambda_k\log(\lambda_k)$.] In particular, if all signal states φ_i are pure, then $S(\varphi_i)=0$ and we have $I\leqslant S(\varphi)$. In this way the von Neumann entropy gets an information theoretical interpretation. Kholevo's bound is actually not very strong; it is attained only in trivial situations.[3]

The basic problem of communication theory is to maximize the amount of information received by Bob from Alice. However, up to now this problem is not well posed in our discussion yet. Let us deal with messages of length n; they are n-term-sequences of 0 and 1. (So, the size of this message set is 2^n.) For each message length n we carry out the above procedure of coding and decoding and the amount of information going through the channel is I_n. Since I_n is presumably proportional to n, the good information quantity is I_n/n, that is, the transmitted information per letter. Since Shannon's theory is not only stochastic but asymptotic as well, we are going to let n to ∞. In this way we need to repeat the above information transmission scheme for each n. The message set, the input Hilbert space $\mathcal{H}^{(n)}$, our coding, the channel state $\varphi^{(n)}$, the output Hilbert space $\mathcal{K}^{(n)}$, and the observables applied in the measurement are all depending on the parameter n.

The subject of the present article is faithful signal transmission, which bears the name noiseless channel. In place of faithful transmission, one can think of information storage. In this case the aim is to use the least possible number of Hilbert space dimensions per signal for coding. The new feature of the noiseless channel we are studying is the memory effect. Mathematically this means that the channel state (of the n-fold channel) is not of product type, but we assume stationarity and good ergodic properties. In Sec. II we use the standard formalism of statistical mechanics to describe such a channel. It turns out that the mean von Neumann entropy, familiar also from statistical mechanics, gives the optimal coding rate. The proof of our main result, Theorems 1 and 2, is similar to the proof presented in Ref. 4 for Schumacher's coding theorem. However, instead of typical sequences we use the high-probability subspace of strongly ergodic stationary states, a subject studied by Hiai and Petz in Ref. 5. We note for the interested reader that most of the concepts used in the present article are treated in detail in Ref. 6.

II. AN INFINITE SYSTEM SETTING OF THE SOURCE

If $\mathcal{H}$ is a finite-dimensional Hilbert space, then $(A,B)\mapsto\mathrm{Tr}(A^*B)$ defines an inner product on $\mathcal{B}(\mathcal{H})$, so for every linear functional φ on $\mathcal{B}(\mathcal{H})$ there exists a unique $D_\varphi\in\mathcal{B}(\mathcal{H})$ with the property

$\varphi(A)=\mathrm{Tr}(D_\varphi A)$. When φ is a state, then D_φ is the corresponding density matrix. Let X^n denote the set of all messages of length n. If $x^n\in X^n$ is a message, then a quantum state $\varphi(x^n)$ of the n-fold quantum system corresponds with it. The Hilbert space of the n-fold system is the n-fold tensor product $\mathcal{H}^{\otimes n}$ and $\varphi(x^n)$ has a statistical operator $D(x^n)$. If messages of length n are to be transmitted, then our quantum source should be put in the state $\varphi_n=\Sigma_{x^n}p(x^n)\varphi(x^n)$ with statistical operator $D_n=\Sigma_{x^n}p(x^n)D(x^n)$, where $p(x^n)$ is the probability of the message x^n. Since we want to let $n\to\infty$, it is reasonable to view all the n-fold systems as subsystems of an infinite one. In this way we can conveniently use a formalism standard in statistical physics (see Chap. 15 of Ref. 6).

Let an infinitely extended system be considered over the lattice $\mathbb{Z}$ of integers. The observable confined to a lattice site $k\in\mathbb{Z}$ form the self-adjoint part of a finite-dimensional matrix algebra $\mathcal{A}_k$, that is, the set of all operators acting on the finite-dimensional space $\mathcal{H}$. It is assumed that the local observables in any finite subset $\Lambda\subset\mathbb{Z}$ are those of the finite quantum system

$$\mathcal{A}_\Lambda=\bigotimes_{k\in\Lambda}\mathcal{A}k\,.$$

The quasilocal algebra $\mathcal{A}$ is the norm completion of the normed algebra $\mathcal{A}_\infty=\cup_\Lambda\mathcal{A}_\Lambda$, the union of all local algebras $\mathcal{A}_\Lambda$ associated with finite intervals $\Lambda\subset\mathbb{Z}$.

A state φ of the infinite system is a positive normalized functional $\mathcal{A}\to\mathbb{C}$. It does not make sense to associate a statistical operator to a state of the infinite system in general. However, φ restricted to a finite-dimensional local algebra $\mathcal{A}_\Lambda$ admits a density matrix D_Λ. We regard the algebra $\mathcal{A}_{[1,n]}$ as the set of all operators acting on the n-fold tensor product space $\mathcal{H}^{\otimes n}$. Moreover, we assume that the density D_n from the first part of this section is identical with $D_{[1,n]}$. Under this assumptions we call the state φ the state of the (infinite) channel. Roughly speaking, all the states used in the transmission of messages of length n are marginals of this φ. Coding, transmission, and decoding could be well formulated using the states $\varphi_n\equiv\varphi_{[1,n]}$. However, it is more convenient to formulate our setting in the form of an infinite system, particularly because we do not want to assume that the channel state φ is a product type. This corresponds to the possibility that our quantum source has a memory effect.

The right shift on the set $\mathbb{Z}$ induces a transformation γ on $\mathcal{A}$. A state φ is called *stationary* if $\varphi\circ\gamma=\varphi$. The state φ is called *ergodic* if it is an extremal point in the set of stationary states. Moreover, φ is *completely ergodic* when it is an extreme point for every $m\in\mathbb{N}$ in the convex set of all states ψ such that $\psi\circ\gamma^m=\psi$. By a *completely ergodic stationary quantum source* we simply mean a completely ergodic stationary state φ of the infinite system $\mathcal{A}$. Of course, a stationary product state, corresponding to a memoryless channel, is completely ergodic. The emphasis is put on other states here.

Next we show an example of a completely ergodic stationary quantum source from the context of algebraic states. For the details, see Ref. 7.

Example 1: Let $\mathcal{A}:=M_3(\mathbb{C})$, $\mathcal{B}:=M_2(\mathbb{C})$, *moreover let* $\{E_{ij}\}_{i,j=1}^e$ *be the usual matrix units of* $M_3(\mathbb{C})$. *Set*

$$V_1:=\begin{bmatrix}\frac{1}{\sqrt{2}} & 0\\ 0 & 0\end{bmatrix},\quad V_2:=\begin{bmatrix}0 & 0\\ \frac{1}{\sqrt{2}} & 0\end{bmatrix},\quad V_3:=\begin{bmatrix}0 & 1\\ 0 & 0\end{bmatrix}.$$

Then $\Sigma_{i=1}^3V_i^*V_i=I_\mathcal{B}$.

Let ρ *be a state on* $\mathcal{B}$ *with density matrix*

$$\begin{bmatrix}\frac{2}{3} & 0\\ 0 & \frac{1}{3}\end{bmatrix}.$$

Define $\Sigma:\mathcal{A}\otimes\mathcal{B}\to\mathcal{B}$ *by* $\Sigma(E_{ij}\otimes x):=V_i^*xV_j$. *It is easy to check that* Σ *is a completely positive unital map and* $\rho(\Sigma(I_{\mathcal{A}}\otimes x))=\rho(x), x\in\mathcal{B}$.

Then the algebraic state φ *generated by* $(\mathcal{B}, \Sigma, \rho)$ *is given by*

$$\varphi(E_{i_1j_1}\otimes\cdots\otimes E_{i_nj_n})=\rho(V_{i_1}^*\cdots V_{i_n}^*V_{j_n}\cdots V_{j_1}).$$

It is shown in Ref. 7 that φ *is completely ergodic. Of course, it is not a product state.*

It is well known in quantum statistical mechanics that, due to the subadditivity of the von Neumann entropy (proven first in Ref. 8 by Lieb and Ruskai), the limit

$$\lim_{n\to+\infty}\frac{1}{n}S(\varphi_n)=\inf\frac{1}{n}S(\varphi_n):=h$$

exists for any stationary state and this quantity is called the *mean entropy* of φ. (See Ref. 6 for a textbook treatment of the subject or Ref. 9 for some related properties of the mean entropy.)

III. SOURCE CODING

For a while we fix a message length n and we denote by d the dimension of the Hilbert space $\mathcal{H}$. Assume that our n-fold composite quantum system is operating as a quantum source and emits the quantum states $D^{(1)},D^{(2)},\ldots,D^{(m)}$ with *a priori* probabilities $p_1,p_2,\ldots,p_m$. (Therefore the state of the system is $D_n=\Sigma_i p_iD^{(i)}$.) By source coding we mean an association

$$D^{(i)}\mapsto\tilde{D}^{(i)},$$

where $\tilde{D}^{(i)}$ is some other statistical operator on the Hilbert space $\mathcal{H}^{\otimes n}$. (This definition allows $D^{(i)}=D^{(j)}$ but $\tilde{D}^{(i)}\neq\tilde{D}^{(j)}$. However, in the coding constructed in the proof of Theorem 1 this cannot happen.)

We denote by $\mathcal{K}_n$ the subspace spanned by the eigenvectors corresponding to all nonzero eigenvalues of all statistical operators $\tilde{D}^{(i)}, 1\leqslant i\leqslant m$. The goal of source coding is to keep the dimension of $\mathcal{K}_n$ to be small and to fulfill some fidelity criterium. (A mathematically demanding survey about quantum coding is Ref. 10.) The *source coding rate*

$$\limsup_{n\to\infty}\frac{\log\dim(\mathcal{K}_n)}{n}$$

expresses the resolution of the encoder in qubits per input symbol. (It is actually more precise to speak about ''qunats'' per input symbol, but the difference is only a constant factor.)

The distortion measure is a number which allows us to compare the goodness or badness of communication systems. The *fidelity* of the coding scheme was introduced by Schumacher:[11]

$$F:=\sum_i p_i\mathrm{Tr}D^{(i)}\tilde{D}^{(i)},$$

where p_i is a probability distribution on the input and $\tilde{D}^{(i)}$ is the density used to encode the density $D^{(i)}$. Note that $0\leqslant F\leqslant 1$ and $F=1$ if and only if $D^{(i)}=\tilde{D}^{(i)}$ are pure states.

First we present our positive source coding theorem for a completely ergodic source. The result says that the source coding rate may approach the mean entropy while we can keep the fidelity arbitrarily good.

Theorem 1: *Let* $\mathcal{H}$ *be a finite-dimensional Hilbert space, and* φ *be a completely ergodic state on* $B(\mathcal{H})^{\otimes\infty}$. *Then for every* $\varepsilon,\delta>0$ *there exists* $n_{\varepsilon,\delta}\in\mathbb{N}$ *such that for* $n\geqslant n_{\varepsilon,\delta}$ *there is a subspace* $\mathcal{K}_n(\varepsilon,\delta)$ *of* $\mathcal{H}^{\otimes n}$ *such that*

(i) $\log\dim\mathcal{K}_n(\varepsilon,\delta)<n(h+\delta)$ *and*

(ii) *for every extremal decomposition* $D_n=\Sigma_{i=1}^m p_i D^{(i)}$ *one can find an encoding* $D^{(i)}\mapsto\tilde{D}^{(i)}$ *with density matrices* $\tilde{D}^{(i)}$ *supported in* $\mathcal{K}_n(\varepsilon,\delta)$ *such that the fidelity* $F:=\Sigma_{i=1}^m p_i \mathrm{Tr} D^{(i)}\tilde{D}^{(i)}$ *exceeds* $1-\varepsilon$.

The negative part of the coding theorem tells that the source coding rate cannot exceed the mean entropy when the fidelity is good.

Theorem 2: *Let* $\mathcal{H}$ *be a finite-dimensional Hilbert space, and* φ *be a completely ergodic state on* $B(\mathcal{H})^{\otimes\infty}$. *Then for every* $\delta>0$ *there exist* $0<\eta<1$ *and* $n_\delta\in\mathbb{N}$ *such that for* $n\geqslant n_\delta$

(i) *for all subspaces* $\mathcal{K}_n$ *of* $\mathcal{H}^{\otimes n}$ *with the property* $\log\dim\mathcal{K}_n\leqslant n(h-\delta)$ *and*

(ii) *for every decomposition* $D_n=\Sigma_{i=1}^m p_i D^{(i)}$ *and for every encoding* $D^{(i)}\mapsto\tilde{D}^{(i)}$ *with density matrices* $\tilde{D}^{(i)}$ *supported in* $\mathcal{K}_n$, *the fidelity* $F:=\Sigma_{i=1}^m p_i \mathrm{Tr} D^{(i)}\tilde{D}^{(i)}$ *is smaller than* η.

The detailed proofs are given in the next section. Now we make some comments on the fidelity F. It is possible that $F<1$ although $D^{(i)}=\tilde{D}^{(i)}$. This fact might suggest to use another concept of fidelity. Since $D^{1/2}\geqslant D$ holds for a density matrix, we have

$$\mathrm{Tr}\ D_1^{1/2}D_2^{1/2}=\mathrm{TR}\ D_1^{1/4}D_2^{1/2}D_1^{1/4}\geqslant\mathrm{Tr}\ D_1^{1/4}D_2D_1^{1/4}=\mathrm{Tr}\ D_2^{1/2}D_1^{1/2}D_2^{1/2}$$
$$\geqslant\mathrm{Tr}\ D_2^{1/2}D_1D_2^{1/2}=\mathrm{Tr}\ D_1D_2.$$

This implies that

$$F':=\sum_i p_i \mathrm{Tr}[D^{(i)}]^{1/2}[\tilde{D}^{(i)}]^{1/2}\geqslant F.$$

Both our positive and negative source coding theorems hold if F is replaced by F'. (In the case of Theorem 1, this follows from the inequality $F'\geqslant F$ and, in the proof of Theorem 2, we will show $F'\leqslant\eta$.)

IV. HIGH-PROBABILITY SUBSPACE

The proof of Shannon's original source coding theorem is based on the typical sequences (Ref. 12, Chap. 1). The quantum extension of this result obtained by Schumacher still benefits from the classical result. When the channel state is a product, the densities D_n commute and simultaneous diagonalization is possible. If the memory effects are present, then these densities do not commute and in some sense we are in a really quantum mechanical noncommutative situation. Nevertheless, the high-probability subspace can be used, but new techniques are required.

Let $\mathcal{K}$ be a Hilbert space and D be a density matrix on $\mathcal{K}$. D has a Schatten decomposition $D=\Sigma_i\lambda_i|f_i\rangle\langle f_i|$, where $|f_i\rangle$'s are eigenvectors and the eigenvalues λ_i are numbered decreasingly: $\lambda_1\geqslant\lambda_2\geqslant\cdots$. Choose and fix $0<\varepsilon<1$. Let $n(\varepsilon)$ be the smallest integer such that

$$\sum_{i=1}^{n(\varepsilon)}\lambda_i\geqslant 1-\varepsilon.$$

The subspace $\mathrm{HP}(D,\varepsilon)$ spanned by the eigenvectors $|f_1\rangle,\ldots,|f_{n(\varepsilon)}\rangle$ is called the *high-probability subspace* corresponding to the level ε. Note that $\mathrm{HP}(D,\varepsilon)$ is not completely well defined. If there are multiplicities in the spectrum of D, then the Schatten decomposition is not unique. However, the dimension $n(\varepsilon)$ of $\mathrm{HP}(D,\varepsilon)$ is determined. The term "high-probability subspace" is borrowed from Ref. 13 and its role in macroscopic uniformity was discussed in Ref. 14.

In the following, φ will be a completely ergodic state on $\mathcal{A}^{\otimes\infty}$. For $\varepsilon\in(0,1)$ let

$$\beta_{\varepsilon,n}:=\inf\{\log\mathrm{Tr}_n(q)):q\in\mathbb{P}(\mathcal{A}^{\otimes n}),\varphi_n(q)\geqslant 1-\varepsilon\},$$

where $\mathbb{P}(\mathcal{A}^{\otimes n})$ denotes the set of projections of $\mathcal{A}^{\otimes n}$. ($\exp \beta_{\varepsilon,n}$ is the dimension of the high-probability subspace.) It was shown in Ref. 5 (and formulated in terms of relative entropy) that

$$\limsup_{n\to+\infty} \frac{1}{n}\beta_{\varepsilon,n} \geqslant h, \tag{1}$$

$$\liminf_{n\to+\infty} \frac{1}{n}\beta_{\varepsilon,n} \geqslant \frac{1}{1-\varepsilon}h - \frac{\varepsilon}{1-\varepsilon}\log d. \tag{2}$$

From this one can deduce the following.

Proposition: For every positive δ

(i) and for every positive ε *there exists* $N_{\varepsilon,\delta}\in\mathbb{N}$ *such that for every* $n>N_{\varepsilon,\delta}$ *there exists a projection* $q_n(\varepsilon,\delta)$ *in* $\mathcal{A}^{\otimes n}$ *such that*

$$\log(\mathrm{Tr}_n(q_n(\varepsilon,\delta)))<n(h+\delta) \quad \text{and} \quad \varphi_n(q)\geqslant 1-\varepsilon,$$

(ii) and there exists $1>\eta>0$ *and* $N_\delta\in\mathbb{N}$ *such that for every* $n>N_\delta$ *and for every projection* q *in* $\mathcal{A}^{\otimes n}$

$$\log(\mathrm{Tr}_n(q))\leqslant n(h-\delta)$$

implies $\varphi_n(q)\leqslant\eta$.

Part (i) of the proposition is a plain reformulation of (1). In order to see (ii) we first note that

$$\frac{1}{\eta}h - \frac{1-\eta}{\eta}\log d \to h \quad \text{as} \quad \eta\to 1.$$

Hence given $\delta>0$ we choose $0<\eta<1$ such that

$$\frac{1}{\eta}h - \frac{1-\eta}{\eta}\log d > h-\delta.$$

Next we replace ε by $1-\delta$ in (2):

$$\liminf_{n\to+\infty} \frac{1}{n}\inf\{\log \mathrm{Tr}_n(q)) : q\in\mathbb{P}(\mathcal{A}^{\otimes n}), \varphi_n(q)\geqslant 1-\eta\} \geqslant \frac{1}{\eta}h - \frac{1-\eta}{\eta}\log d > h-\delta. \tag{3}$$

In this way we arrived at (*ii*).

Next we prove the source coding theorem.

Proof of Theorem 1: Use part (*i*) of the proposition and set $q_n := q_n(\varepsilon/2,\delta)$, $\mathcal{K}_n(\varepsilon,\delta) := \mathrm{Ran} q_n$, where $n>n(\varepsilon,\delta):=N_{\varepsilon/2,\delta}$. Given an external decomposition $D_n=\Sigma_{i=1}^k p_i D^{(i)}$, that is, $D^{(i)}=|x_i\rangle\langle x_i|$ for some vectors x_i, we construct the coding densities $\tilde{D}^{(i)}$. Let

$$\tilde{x}_i := \frac{q_n x_i}{\|q_n x_i\|}, \quad \alpha_i := \|q_n x_i\|, \quad \beta_i := \|(I-q_n)x_i\|,$$

and let x be any unit vector such that $q_n x = x$. Then we set

$$\tilde{D}^{(i)} := \alpha_i^2 |\tilde{x}_i\rangle\langle\tilde{x}_i| + \beta_i^2 |x\rangle\langle x|.$$

Since $\tilde{x}_i, x\in\mathcal{K}_n(\varepsilon,\delta)$, we have supp $\tilde{D}^{(i)}\subset\mathcal{K}_n(\varepsilon,\delta)$. Furthermore,

$$\begin{aligned}\mathrm{Tr}\ D^{(i)}\tilde{D}^{(i)} &= \langle x_i, \tilde{D}^{(i)} x_i\rangle = \alpha_i^2 |\langle x_i|\tilde{x}_i\rangle|^2 + \beta_i^2 |\langle x_i, x\rangle|^2 \\ &\geqslant \alpha_i^2 |\langle x_i|\tilde{x}_i\rangle|^2 = \alpha_i^4 \geqslant 2\alpha_i^2 - 1 \\ &= 2\ \mathrm{Tr}\, q_n D^{(i)} - 1.\end{aligned}$$

We need to sum over i:

$$\sum_i\ p_i \mathrm{Tr}\, D^{(i)}\tilde{D}^{(i)} \geqslant \sum_i\ p_i(2\,\mathrm{Tr} q_n D^{(i)} - 1) = 2\,\mathrm{TR} D_n q_n - 1 = 2\varphi_n(q_n) - 1 \geqslant 1 - \varepsilon.$$

Proof of Theorem 2: For the given δ we choose η and $n(\delta)$ according to the proposition. Let q be the projection onto the subspace $\mathcal{K}_n$. We want to use the Schwarz inequality in the form

$$\left|\sum_i\ p_i \mathrm{Tr} x_i y_i\right| \leqslant \left[\sum_i\ p_i \mathrm{TR} x_i^* x_i\right]^{1/2}\left[\sum_i\ p_i \mathrm{TR} y_i^* y_i\right]^{1/2}$$

for $x_i = [D^{(i)}]^{1/2} q$ and $y_i = [\tilde{D}^{(i)}]^{1/2}$. Since $[\tilde{D}^{(i)}]^{1/2} = q[\tilde{D}^{(i)}]^{1/2}$ follows from the hypothesis, we have

$$\begin{aligned}F' = \sum_{i=1}^m\ p_i\, \mathrm{Tr}[D^{(i)}]^{1/2}[\tilde{D}^{(i)}]^{1/2} &= \sum_{i=1}^m\ p_i\, \mathrm{Tr}[D^{(i)}]^{1/2} q [\tilde{D}^{(i)}]^{1/2} \\ &\geqslant \left[\sum_{i=1}^m\ p_i\, \mathrm{Tr} D^{(i)} q\right]^{1/2}\left[\sum_{i=1}^m\ p_i\, \mathrm{Tr} D^{(i)}\right]^{1/2} \\ &= \varphi_n(q)^{1/2} \leqslant \sqrt{\eta}.\end{aligned}$$

This estimate completes the proof.

It was also shown in Ref. 7 that for strongly mixing algebraic states (especially for product states)

$$\lim_{n\to+\infty} \frac{1}{n}\beta_{\varepsilon,n} = h,$$

and, in this case, the negative part of the coding theorem holds in a stronger form: For every ε, $\delta > 0$ there exists $n_{\varepsilon,\delta} \in \mathbb{N}$ such that for $n \geqslant n_{\varepsilon,\delta}$ for all subspaces $\mathcal{K}_n$ of $\mathcal{H}^{\otimes n}$ with the property $\log \dim \mathcal{K}_n < n(h-\delta)$ and for every decomposition $D_n = \Sigma_{i=1}^m p_i D^{(i)}$ and for every encoding $D^{(i)} \leftrightarrow \tilde{D}^{(i)}$ with density matrices $\tilde{D}^{(i)}$ supported in $\mathcal{K}_n(\varepsilon,\delta)$, the fidelity $F := \Sigma_{i=1}^m p_i \mathrm{Tr} D^{(i)}\tilde{D}^{(i)}$ is smaller than ε.

There is a seemingly slight difference between the two theorems. The statistical operator D_n has an external decomposition in the first one and arbitrary decomposition in the second. The difference between the pure and mixed message ensembles is discussed in Ref. 15.

V. DISCUSSION

In this article a theory of quantum source coding subject to a fidelity criterion or quantum data compression is presented. The minimum of the source coding rate is studied under the conditions that Schumacher's fidelity must exceed $1-\varepsilon$ and the quantum mechanical state of the channel has a strong ergodic property. This latter condition allows many states with memory effect. For the mathematical model and in the proof of the main result techniques of quantum statistical mechanics are used. We prove that the minimal source coding rate is the mean entropy of the channel state, and, to some extent, it is independent of the message ensemble.

(Received 13 November 2000; accepted for publication 25 July 2001)

The present paper studies the symmetries of the Hubbard model of electrons with generally n-fold orbital degeneracy. It is shown that $SU_d(2n)$ and $SU_c(2n)$ symmetries hold, respectively, for the model with completely repulsive or attractive on-site interaction and that with partly attractive interactions. An extended Lieb–Mattis transformation is given to map these two symmetries into each other. The subsymmetry $SU_d^{(e)}(n)\otimes SU_d^{(o)}(n)$ is found to be shared by the two models with arbitrary chemical potential μ. By assuming at most two electrons on each site it is found that $SU_d(2n)_{\mathcal{P}}$ and $SU_c(2n)_{\mathcal{P}}$ both exist in each kind of the two models and consequently lead to a larger symmetry $SU_d(2n)_{\mathcal{P}}\times SU_c(2n)_{\mathcal{P}}$. Another underlying symmetry $(SU_c^{(e)}(2)_{\mathcal{P}}\times\cdots\times SU_c^{(e)}(2)_{\mathcal{P}})\otimes(SU_c^{(o)}(2)_{\mathcal{P}}\times\cdots\times SU_c^{(o)}(2)_{\mathcal{P}})$ is also revealed for the unified U model under the excluding. The symmetry is valid for the partially attractive model with chemical potential $\mu=-U$. © *2001 American Institute of Physics.* [DOI: 10.1063/1.1402956]

I. INTRODUCTION

Recently, considerable attention has been directed to studies on correlated electrons in the presence of orbital degrees of freedom, which is relevant to transitional-metal oxides,[1–5] C_{60} materials,[6] and artificial quantum dot arrays.[7] Apart from the numerical[8] and perturbative[9] works, theories based on symmetries were presented for one-dimensional models of these systems. An $SU(4)$ theory describing spin systems with orbital degeneracy was proposed[10,11] for a theoretical understanding of the observed unusual properties. The ground-state phase diagrams for the system with a symmetry breaking of $SU(4)\rightarrow SU(2)\times SU(2)$ were discussed in Refs. 9 and 12. For the two-fold orbital degenerate Hubbard model a recent paper[13] presented the $SU(4)$ theory and showed the underlying $SU_d(4)$ symmetry of spin-orbital double and a charge $SU_c(4)$ symmetry with an extended Lieb–Mattis transformation mapping those two $SU(4)$ generators into each other. On the basis of elementary degenerate perturbative theory, it was also shown that the effective Hamiltonian is equivalent to the $SO(6)$ and $SU(4)$ Heisenberg models, respectively, at half-filling and quarter-filling with strong coupling. In Ref. 14, the one-dimensional $SU(4)$ Hubbard model is extensively studied on the basis of Bethe ansatz solution. As for the symmetry theory of the one-dimensional Hubbard model without orbital degeneracy, it has been well investigated. Yang introduced the pairing operators and so constructed the symmetry $SU(2)\times SU(2)$.[15] Based on the symmetry Eßler *et al.*[16] discussed the completeness of the Bethe ansatz

[a)]Electronic mail: zjying@zimp.zju.edu.cn

solutions, Pernici[17] showed the off-diagonal long-range order, Uglov and Korepin presented the Yangian symmetry $Y(sl(2))\oplus Y(sl(2))$,[18] and Eßler and Frahm considered the density correlations.[19] And it has been argued that the two-dimensional single-band Hubbard model has approximate $SO(5)$ symmetry.[20] But research on the Hubbard model with orbital degeneracy is still being accumulated. In the present paper we study the symmetries of the Hubbard model of electrons with generally n-fold orbital degeneracy. We show and clarify that the $SU_d(2n)$ and $SU_c(2n)$ symmetries hold, respectively, unlike in the simple Hubbard model for which both of the symmetries are valid, for the model with unified on-site interaction and that with partly attractive interactions. But the subsymmetry $SU_d^{(e)}(n)\otimes SU_d^{(o)}(n)$ is found to be valid for the two models and for arbitrary chemical potential μ. An extended Lieb–Mattis transformation as in Ref. 13 is given to map these two symmetries into each other. By assuming at most two electrons on each site, we find that the $SU_d(2n)_{\mathcal{P}}$ and $SU_c(2n)_{\mathcal{P}}$ symmetries both exist in each kind of the two models so we have a larger symmetry $SU_d(2n)_{\mathcal{P}}\times SU_c(2n)_{\mathcal{P}}$. Under the exclusion another underlying symmetry $(SU_c^{(e)}(2)_{\mathcal{P}}\times\cdots\times SU_c^{(e)}(2)_{\mathcal{P}})\otimes(SU_c^{(o)}(2)_{\mathcal{P}}\times\cdots\times SU_c^{(o)}(2)_{\mathcal{P}})$, which is not included in the $SU_d(2n)_{\mathcal{P}}\times SU_c(2n)_{\mathcal{P}}$, is also revealed for the unified U model with $\mu=U$ so that the model totally possesses the symmetry $SU_d(2n)_{\mathcal{P}}\times SU_c(2n)_{\mathcal{P}}\times[(SU_c^{(e)}(2)_{\mathcal{P}}\times\cdots\times SU_c^{(e)}(2)_{\mathcal{P}})\otimes(SU_c^{(o)}(2)_{\mathcal{P}}\times\cdots\times SU_c^{(o)}(2)_{\mathcal{P}})]$. The underlying symmetry is also valid for the partially attractive model with $\mu=-U$.

Consider the n-fold orbital degenerate electrons with states

$$|1\rangle=|1,\uparrow\rangle,\quad |2\rangle=|1,\downarrow\rangle,$$

$$\cdots,$$

$$|2n-1\rangle=|n,\uparrow\rangle,\quad |2n\rangle=|n,\downarrow\rangle, \tag{1}$$

where in a state $|l,\sigma\rangle$ l denotes the lth orbital component and $\sigma=\uparrow,\downarrow$ label the spin components. We start with a general Hamiltonian with n-fold orbital degeneracy expressed by

$$H=-\sum_{x,x'}\sum_{a}(t_{xx'}C_a^{+}(x)C_a(x')+t_{xx'}^{*}C_a^{+}(x')C_a(x))+\sum_{x}\sum_{a\neq a'}U_{aa'}n_a(x)n_{a'}(x)-\mu\sum_{x,a}n_a(x), \tag{2}$$

where $C_a^{+}(x)$ creates a fermion of state $|a\rangle$ at site x and $n_a(x)$ is the corresponding particle number operator. The notation of site is not restricted to one-dimensional case.

II. $SU_D(2n)$ AND $SU_C(2N)$ SYMMETRIES

Besides the $U(1)$ symmetry there exist two kinds of $SU(2n)$ symmetries for the orbital degenerate Hubbard model. We define

$$E_{ss'}=\sum_{x}C_s^{+}(x)C_{s'}(x),$$

$$D_m=N_m-N_{m+1},\quad N_m=\sum_{x}C_m^{+}(x)C_m(x), \tag{3}$$

they fulfill the commutation relations

$$[E_{ss'},E_{tt'}]=\delta_{s',t}E_{st'}-\delta_{s,t'}E_{ts'},$$

$$[D_m,E_{ss'}]=(\delta_{m,s}-\delta_{m,s'}-\delta_{m+1,s}+\delta_{m+1,s'})E_{ss'}. \tag{4}$$

These operators can construct an $SU(2n)$ Lie algebra

$$SU_d(2n):\{D_m,E_{ss'}|m=1,\ldots,2n-1;1\leqslant s\neq s'\leqslant 2n\}, \tag{5}$$

with $n(2n-1)$ of $E_{ss'}$ and there are totally $(2n)^2-1$ of generators. $\{D_m\}$ forms the commuting Cardan subalgebra of rank $2n-1$. The $E_{s(s+1)}$'s are the generators related to the simple roots. For any of $t_{xx'}$ and μ, all generators of $SU_d(2n)$ commute with the Hamiltonian (2) with unified on-site interaction $U_{aa'}=U$, so we have $SU_d(2n)$ symmetry of spin-orbital double in this case.

Let us define another set of operators

$$F_{\alpha_{2k-1}}=\sum_x f(x)C^+_{2k-1}(x)C^+_{2k}(x),$$

$$F_{\alpha_{2k}}=\sum_x f(x)C_{2k}(x)C_{2k+1}(x), \tag{6}$$

$$Q_m=\frac{1}{2}\sum_x [C^+_m(x)C_m(x)+C^+_{m+1}(x)C_{m+1}(x)-1],$$

where $k=1,\ldots,n$, $m=1,\ldots,2n-1$, $f(x)^2=1$, and $f(x+\delta)=-f(x)$ for any site x and nearest-neighbor $x+\delta$. The above-mentioned operators can realize another $SU(2n)$ Lie algebra which we shall denote by $SU_c(2n)$:

$$\{Q_m,F_\alpha,F_{-\alpha}\}. \tag{7}$$

$\{Q_m\}$ is the Cardan subalgebra. The $F_{\alpha_{2k-1}}$ and $F_{\alpha_{2k}}$ are the generators related to the simple roots, other generators relating to positive roots can be obtained by $F_{\alpha_i+\alpha_j}=[F_{\alpha_i},F_{\alpha_j}]$, the generators with negative roots will be $F_{-\alpha}=(F_\alpha)^\dagger$. If we assume that the on-site coupling $U_{aa'}=U$ for the states labeled by a,a' with different spin components while $U_{aa'}=-U$ for states with the same spin components

$$\begin{aligned} U_{aa'}&=U \text{ for odd even pair } a,a',\\ U_{aa'}&=-U \text{ for odd–odd or even–even pair } a,a', \end{aligned} \tag{8}$$

and the amplitudes $t_{xx'}$ of odd-neighbor hopping are real and those of even-neighbor hopping are imaginary

$$\begin{aligned} t^*_{xx'}&=t_{xx'} \text{ when } x\text{-}x' \text{ is odd neighbor},\\ t^*_{xx'}&=-t_{xx'} \text{ when } x\text{-}x' \text{ is even neighbor}, \end{aligned} \tag{9}$$

we will have the following relations:

$$[H,F_{\alpha_{2k}}]=2(\mu-U)F_{\alpha_{2k}},\quad [H,F_{\alpha_{2k-1}}]=-2(\mu-U)F_{\alpha_{2k-1}}. \tag{10}$$

If the chemical potential $\mu=U$, the Hamiltonian will commute with all the generators of $SU_c(2n)$ so the model has the charge $SU_c(2n)$ symmetry. In terms of the partially attractive (8), it can be easily proved that such a Hamiltonian with $\mu=U$ has the half-filled form

$$H=-\sum_{x,x'}\sum_a (t_{xx'}C^+_a(x)C_a(x')+t^*_{xx'}C^+_a(x')C_a(x))+\sum_x\sum_{a\neq a'} U_{aa'}\left(n_a(x)-\frac{1}{2}\right)\left(n_{a'}(x)-\frac{1}{2}\right). \tag{11}$$

The usual Hubbard model with the nearest-neighbor hopping is included in the class of (9). Whether $f(x)$ can be well defined depends on the lattice structures, if in a lattice any sum of the nearest-neighbor pair $\delta+\delta'$ is not a nearest neighbor and there are even sites on every perpendicular direction, $f(x)$ can be well defined as

$$f(x)=\exp(i\pi\cdot\mathbf{x}),\quad \pi=(\pi,\pi,\ldots),\quad \mathbf{x}=(x_1,x_2,\ldots). \tag{12}$$

x_i is the ith components of the site coordinate in the lattice basis. Such lattices (bipartite lattice) can be simple squared, centered squared in two-dimension; simple cubic and body-centered cubic in three-dimension. For the one-dimensional case and even total sites, $f(x)=\exp(i\pi x)$.

According to (10) for $\mu\neq U$, $F_{\alpha_{2k}}$ and $F_{\alpha_{2k-1}}$ are energy-shifting operators

$$\begin{aligned} H(F_{\alpha_{2k}}\psi_E)&=[E+2(\mu-U)](F_{\alpha_{2k}}\psi_E),\\ H(F_{\alpha_{2k-1}}\psi_E)&=[E-2(\mu-U)](F_{\alpha_{2k-1}}\psi_E), \end{aligned} \tag{13}$$

where ψ_E is the eigenstate of the partially attractive Hamiltonian: $H\psi_E=E\psi_E$.

It should be noted that the $SU_d(2n)$ does not commute with the partially attractive Hamiltonian which has only the $SU_c(2n)$ symmetry, neither does $SU_c(2n)$ with the unified U model which possesses the $SU_d(2n)$ symmetry. The two kinds of symmetries can be mapped into each other by an extended Lieb–Mattis transformation

$$\begin{aligned} C_a(x)&\mapsto\exp(i\pi\cdot\mathbf{x})C_a^+(x)\ \text{ for even }\ a,\\ C_a(x)&\mapsto C_a(x)\ \text{ for odd }\ a. \end{aligned} \tag{14}$$

The transformation leaves the hopping term (9) invariant and changes the sign of $U_{aa'}$ with odd–even pair a,a' in (11) so maps the model (11) into the unified $U_{aa'}=-U$ model.

The particle number of each state and the total spin can be expressed by

$$\begin{aligned} N_{2n}&=\left(N_e-\sum_{m=1}^{2n-1}mD_m\right)/2n,\\ N_j&=\sum_{m=j}^{2n-1}D_m+\left(N_e-\sum_{m=1}^{2n-1}mD_m\right)/2n,\quad j<2n, \end{aligned} \tag{15}$$

$$S_{\text{total}}=\sum_{m=1}^{n}D_{2m-1}/2, \tag{16}$$

where N_e is the number of total electrons.

III. $SU_D^{(E)}(N)\otimes SU_D^{(O)}(N)$ SYMMETRY

Unlike in the traditional Hubbard model for which both of the two symmetries are valid for on-site attractive and repulsive interactions, as we can see in Sec. II, for the orbital-degenerate Hubbard model the $SU_d(2n)$ symmetry of spin-orbital double only holds for the unified U Hubbard model with arbitrary chemical potential μ whereas the charge $SU_c(2n)$ symmetry merely exists in the other partly attractive half-filled model of which the chemical potential is $\mu=U$. But considering that $SU_d(2n)$ and $SU_c(2n)$ share some common generators $E_{2\nu,2\nu'}$ and $E_{2\nu-1,2\nu'-1}$, we will find the shared subsymmetry $SU_d^{(e)}(n)\otimes SU_d^{(o)}(n)$ yields for the two models with

$$SU_d^{(e)}(n):\{D_{2\nu,2\nu+2},E_{2\nu',2\nu''}|\,\nu\leqslant n-1,1\leqslant\nu'\neq\nu''\leqslant n\},$$
$$SU_d^{(o)}(n):\{D_{2\nu-1,2\nu+1},E_{2\nu'-1,2\nu''-1},|\,\nu\leqslant n-1,1\leqslant\nu'\neq\nu''\leqslant n\},\tag{17}$$

where $D_{m,m+2}=N_m-N_{m+2}$. In particular, we shall illustrate that the symmetry is valid for the partially attractive model with arbitrary chemical potential μ.

As the hopping term in the Hamiltonian and the chemical potential term $\mu\Sigma_{x,a}\,n_a(x)$ are $SU_d(2n)$ invariant, whether the Hubbard model possesses $SU_d(2n)$ symmetry depends on the commutation relation of the on-site interacting term and the $SU_d(2n)$ generators:

$$\left[E_m^k,\sum_{a\neq a'}U_{aa'}n_a(x)n_{a'}(x)\right]=C_m^+(x)C_{m+k}(x)\left(\sum_{a'\neq m+k}n_{a'}(x)U_{m+k,a'}-\sum_{a'\neq m}n_{a'}(x)U_{m,a'}\right)$$
$$+\left(\sum_{a\neq m+k}n_a(x)U_{a,m+k}-\sum_{a\neq m}n_a(x)U_{a,m}\right)C_m^+(x)C_{m+k}(x),\tag{18}$$

where

$$E_m^k=\sum_x\,C_m^+(x)C_{m+k}(x).$$

Surely for the case of unified $U_{aa'}=U$ we easily find that the above-mentioned commutation vanishes so that we have the $SU_d(2n)$ symmetry in this case, as obtained in the Sec. II. Although for the partially attractive model the above-mentioned commutator does not go null for all $k's$ and consequently we do not have $SU_d(2n)$ symmetry, the case with even k will be an exception. From the partially attractive (8) we find for even k's

$$U_{a,m+k}=U_{a,m}=-U,$$
$$\left(\sum_{a\neq m+k}n_a(x)U_{a,m+k}-\sum_{a\neq m}n_a(x)U_{a,m}\right)=n_m(x)U_{m,m+k}-n_{m+k}(x)U_{m+k,m}$$
$$=(n_m(x)-n_{m+k}(x))(-U).$$

Then Eq. (18) becomes

$$\left[E_m^k,\sum_{a\neq a'}U_{aa'}n_a(x)n_{a'}(x)\right]=C_m^+(x)C_{m+k}(x)(n_m(x)-n_{m+k}(x))(-U)+(n_m(x)$$
$$-n_{m+k}(x))C_m^+(x)C_{m+k}(x)(-U)$$
$$=(-C_m^+(x)C_{m+k}(x)+C_m^+(x)C_{m+k}(x))(-U)=0,$$

where we have used the following relations: $n_mC_m=C_m^+n_m=0$, $n_mC_m^+=C_m^+$, $C_mn_m=C_m$. E_m^k with even k's and odd (or even) m's corresponding to the $SU_d^{(o)}(n)$ (or $SU_d^{(e)}(n)$) generators. As a result, the $SU_d^{(e)}(n)\otimes SU_d^{(o)}(n)$ generators in (17) commute with the Hamiltonian of the partially attractive model for any chemical potential μ. Therefore the $SU_d^{(e)}(n)\otimes SU_d^{(o)}(n)$ symmetry is shared by the two models both for arbitrary μ.

IV. AT MOST TWO ELECTRONS ON EACH SITE

The application of Bethe ansatz method to the one-dimensional degenerate Hubbard model is based on such an assumption that prevents scattering process involving three or more electrons on

one site.[14,21,22] For the traditional Hubbard model the configurations of more than two electrons on one site are excluded automatically by the Pauli principle. In the continuum limit and for small densities or $U \gg t$ in the lattice model, the unwanted configurations in degenerate Hubbard model become negligible, so the Hamiltonian with three-electron configurations excluded will describe the system well. If we exclude more than two electrons on each site, we will find that the Hamiltonian has both $SU_d(2n)_{\mathcal{P}}$ and $SU_c(2n)_{\mathcal{P}}$ symmetries and furthermore a larger symmetry $SU_d(2n)_{\mathcal{P}} \times SU_c(2n)_{\mathcal{P}}$. In addition, we will find an underlying symmetry $(SU_c^{(e)}(2)_{\mathcal{P}} \times \cdots \times SU_c^{(e)}(2)_{\mathcal{P}}) \otimes (SU_c^{(o)}(2)_{\mathcal{P}} \times \cdots \times SU_c^{(o)}(2)_{\mathcal{P}})$.

Consider $U_{aa'} = U$ case, the Hamiltonian reads

$$\mathcal{H} = -t \sum_{\langle x,x' \rangle} \sum_{a} \mathcal{P} C_a^+(x) C_a(x') \mathcal{P} + U \sum_{x} \sum_{a \neq a'} n_a(x) n_{a'}(x) - \mu \sum_{x,a} n_a(x), \tag{19}$$

where $\langle x,x' \rangle$ represents the nearest-neighbor sites and let us define

$$\mathcal{F}_{\alpha_{2k-1}} = \sum_{x} \exp(i\boldsymbol{\pi} \cdot \mathbf{x}) \mathcal{P} C_{2k-1}^+(x) C_{2k}^+(x) \mathcal{P}, \tag{20}$$

$$\mathcal{F}_{\alpha_{2k}} = \sum_{x} \exp(i\boldsymbol{\pi} \cdot \mathbf{x}) \mathcal{P} C_{2k}(x) C_{2k+1}(x) \mathcal{P}, \tag{21}$$

where the operator $\mathcal{P}$ projects onto the subspace of states having at most two electrons on each site.[22] Other generators are also modified from the $SU_c(2n)$ in Sec. II. The $\mathcal{P}$ operator excludes such terms as $n_s C_{s'}^+ C_{s''}^+$, $C_s C_{s'} n_{s''}$ with three different s, s', and s'' so that

$$\left[\mathcal{P} C_s^+(x) C_{s'}^+(x) \mathcal{P}, \sum_{x'} \sum_{a \neq a'} n_a(x') n_{a'}(x') \right] = -2 \mathcal{P} C_s^+(x) C_{s'}^+(x) \mathcal{P}, \tag{22}$$

thus we have the relations similar to (10)

$$[\mathcal{H}, \mathcal{F}_{\alpha_{2k}}] = 2(\mu - U) \mathcal{F}_{\alpha_{2k}}, \quad [\mathcal{H}, \mathcal{F}_{\alpha_{2k-1}}] = -2(\mu - U) \mathcal{F}_{\alpha_{2k-1}}. \tag{23}$$

For $\mu \neq U$, $\mathcal{F}_{\alpha_{2k}}$ and $\mathcal{F}_{\alpha_{2k-1}}$ are energy-shifting operators for $\mathcal{H}$ as in (13). Set $\mu = U$ and the $\mathcal{F}_{\alpha_{2k-1}}$ and $\mathcal{F}_{\alpha_{2k}}$ will commute with the $\mathcal{H}$. $\mathcal{F}_{\alpha_{2k-1}}$, $\mathcal{F}_{\alpha_{2k}}$, and $N_s - N_{s'}$ can generate the $SU_c(2n)_{\mathcal{P}}$ symmetry so that $\mathcal{H}$ has both $SU_d(2n)_{\mathcal{P}}$ and $SU_c(2n)_{\mathcal{P}}$ symmetries,

$$SU_c(2n)_{\mathcal{P}} : \{\mathcal{Q}_m, \mathcal{F}_\alpha\}, \tag{24}$$

$$SU_d(2n)_{\mathcal{P}} : \{\mathcal{D}_m, \mathcal{E}_{ss'}\}, \tag{25}$$

where $\mathcal{Q}_m = \mathcal{P} Q_m \mathcal{P}$ and the $SU_d(2n)$ generators are correspondingly revised to be

$$\mathcal{E}_{ss'} = \mathcal{P} E_{ss'} \mathcal{P}, \quad \mathcal{D}_m = \mathcal{P} D_m \mathcal{P}. \tag{26}$$

The commutation relations are also modified, $\mathcal{E}_{ss'}$ and $\mathcal{E}_{tt'}$ commute except for the case of $s = t'$ and $s' = t$, other commutations remain the same. And it is similar for $\mathcal{F}_\alpha$. The two modified symmetries are not $SU(2n)$, their subsymmetries involving only two states are $SU(2)$.

It also can be similarly shown that both of the symmetries hold for the $\mathcal{P}$-modified model with partially attractive $U_{aa'} = U, -U$. As the two symmetries both hold for each of the models we can construct the larger symmetry $SU_d(2n)_{\mathcal{P}} \times SU_c(2n)_{\mathcal{P}}$ for each of them. If we do not exclude more than two electrons on each site, these two symmetries, respectively, belong to different models.

Besides $SU_d(2n)_{\mathcal{P}} \times SU_c(2n)_{\mathcal{P}}$ there exist some less obvious symmetries. Define

$$\mathcal{F}^{(+)}_{2k,2k'}=\sum_x \exp(i\pi\cdot\mathbf{x})\mathcal{P}C^+_{2k}(x)C^+_{2k'}(x)\mathcal{P},\quad \mathcal{F}^{(-)}_{2k,2k'}=(\mathcal{F}^{(+)}_{2k,2k'})^\dagger, \tag{27}$$

$$\mathcal{F}^{(+)}_{2k-1,2k'-1}=\sum_x \exp(i\pi\cdot\mathbf{x})\mathcal{P}C^+_{2k-1}(x)C^+_{2k'-1}(x)\mathcal{P},\quad \mathcal{F}^{(-)}_{2k-1,2k'-1}=(\mathcal{F}^{(+)}_{2k-1,2k'-1})^\dagger, \tag{28}$$

such generators are not included in (24) which contains pairing operators $\mathcal{F}^{(\pm)}_{ss'}$ only with odd–even pair ss'. It can be easily verified that these operators also commute with the unified U model (19) with $\mu=U$ so we find an underlying symmetry $(SU^{(e)}_c(2)_\mathcal{P}\times\cdots\times SU^{(e)}_c(2)_\mathcal{P})\otimes(SU^{(o)}_c(2)_\mathcal{P}\times\cdots\times SU^{(o)}_c(2)_\mathcal{P})$ with

$$SU^{(e)}_c(2)_\mathcal{P}:\{\mathcal{Q}_{2k,2k'},\quad \mathcal{F}^{(+)}_{2k,2k'},\quad \mathcal{F}^{(-)}_{2k,2k'}\},\quad k\neq k',\quad k,k'=1,\ldots,n, \tag{29}$$

$$SU^{(o)}_c(2)_\mathcal{P}:\{\mathcal{Q}_{2k-1,2k'-1},\quad \mathcal{F}^{(+)}_{2k-1,2k'-1},\quad \mathcal{F}^{(-)}_{2k-1,2k'-1}\},\quad k\neq k',\quad k,k'=1,\ldots,n. \tag{30}$$

There are, respectively, $C^2_n=n(n-1)/2$ of the $SU^{(e)}_c(2)_\mathcal{P}$ and $SU^{(o)}_c(2)_\mathcal{P}$ symmetries, and they are all SU(2). The extended Lieb–Mattis transformation (14) maps the above-mentioned symmetry into itself. A revised Lieb–Mattis transformation mapping into the corresponding $SU^{(e)}_d(2)_\mathcal{P}$ and $SU^{(o)}_d(2)_\mathcal{P}$ will involve a third kind of Hamiltonians with partially attractive $U_{aa'}$, which differs from what we discussed before. So finally we have the symmetry $SU_d(2n)_\mathcal{P}\times SU_c(2n)_\mathcal{P}\times[(SU^{(e)}_c(2)_\mathcal{P}\times\cdots\times SU^{(e)}_c(2)_\mathcal{P})\otimes(SU^{(o)}_c(2)_\mathcal{P}\times\cdots\times SU^{(o)}_c(2)_\mathcal{P})]$ for (19) with $\mu=U$. But for $U_{aa'}=U,-U$ case the underlying symmetry is valid for another chemical potential. The Hamiltonian under that exclusion is

$$\mathcal{H}'=-\sum_{\langle x,x'\rangle}\sum_a t\mathcal{P}C^+_a(x)C_a(x')\mathcal{P}+\sum_x\sum_{a\neq a'}U_{aa'}n_a(x)n_{a'}(x)-\mu\sum_{x,a}n_a(x), \tag{31}$$

where the partially attractive interaction $U_{aa'}$ is also defined by (8). Compared with (10) the commutation relations are different

$$[\mathcal{H}',\mathcal{F}^{(+)}_{2k,2k'}]=-2(\mu+U)\mathcal{F}^{(+)}_{2k,2k'}, \tag{32}$$

$$[\mathcal{H}',\mathcal{F}^{(-)}_{2k,2k'}]=2(\mu+U)\mathcal{F}^{(-)}_{2k,2k'}. \tag{33}$$

The different sign of U comes from $U_{2k,2k'}=-U$ while in Eq. (10) it is $U_{2k,2k\pm1}=U$. Therefore the symmetry $(SU^{(e)}_c(2)_\mathcal{P}\times\cdots\times SU^{(e)}_c(2)_\mathcal{P})\otimes(SU^{(o)}_c(2)_\mathcal{P}\times\cdots\times SU^{(o)}_c(2)_\mathcal{P})$ holds for $\mu=-U$.

It should be noted the underlying symmetry is valid under the exclusion, without the $\mathcal{P}$-exclusion its generators will commute with neither of the two kinds of models. And unlike $SU^{(o)}_d(n)\otimes SU^{(e)}_d(n)\subset SU_d(2n)$ in Sec. III, none of the $SU^{(o)}_c(2)_\mathcal{P}$ or $SU^{(e)}_c(2)_\mathcal{P}$ is any subsymmetry of $SU_c(2n)_\mathcal{P}$. Without the $\mathcal{P}$-exclusion, the $SU^{(e)}_c(2)$ and $SU^{(o)}_c(2)$ are subgroups of $SU_d(2n)\times SU_c(2n)$, since the generators of $SU^{(e)}_c(2)$ and $SU^{(o)}_c(2)$ can be obtained by the commutation product of F_α and $E_{ss'}$. But $SU^{(o)}_c(2)_\mathcal{P}$ or $SU^{(e)}_c(2)_\mathcal{P}$ cannot be generated by the commutations of $\mathcal{F}_\alpha$ and $\mathcal{E}_{ss'}$ which commute with each other under the $\mathcal{P}$-exclusion, so none of the underlying $SU^{(o)}_c(2)_\mathcal{P}$ or $SU^{(e)}_c(2)_\mathcal{P}$ is the subsymmetry of $SU_d(2n)_\mathcal{P}\times SU_c(2n)_\mathcal{P}$. Owing to the noncommuting relations as

$$[\mathcal{Q}_m,\mathcal{E}_{ss'}]=\tfrac{1}{2}\mathcal{E}_{ss'},$$

where $m=s$ but $m+1\neq s'$, the enlarged symmetry still cannot be written in a direct product $SU_d(2n)_\mathcal{P}\otimes SU_c(2n)_\mathcal{P}$ but $SU_d(2n)_\mathcal{P}\times SU_c(2n)_\mathcal{P}$. This is also a difference from the single-band Hubbard model, the symmetry for the single-band case in our notation is a direct product of the two $SU(2)$'s: i.e., $SO(4)\simeq SU_d(2)\otimes SU_c(2)$ on which the discussion on the completeness of the Bethe ansatz solution and the off-diagonal long-range order is based.[16,17]

V. BRIEF SUMMARY

In summary, we studied the symmetries of the Hubbard model of n-fold orbital degenerate electrons. We show and clarify that the $SU_d(2n)$ and $SU_c(2n)$ symmetries hold, respectively, for the model with unified on-site interaction and that with partly attractive interactions. An extended Lieb–Mattis transformation is given to map these two symmetries into each other. But the sub-symmetry $SU_d^{(e)}(n)\otimes SU_d^{(o)}(n)$ is found to be possessed by the two models and both for arbitrary chemical potential μ. By excluding more than two electrons on the same sites we find the $SU_d(2n)_{\mathcal{P}}$ and $SU_c(2n)_{\mathcal{P}}$ symmetries both exist in each kind of the two models, so we have an enlarged symmetry $SU_d(2n)_{\mathcal{P}}\times SU_c(2n)_{\mathcal{P}}$. Under this exclusion, another underlying symmetry $(SU_c^{(e)}(2)_{\mathcal{P}}\times\cdots\times SU_c^{(e)}(2)_{\mathcal{P}})\otimes(SU_c^{(o)}(2)_{\mathcal{P}}\times\cdots\times SU_c^{(o)}(2)_{\mathcal{P}})$ is also found for the unified U model with chemical potential $\mu=U$, and consequently this model has the symmetry $SU_d(2n)_{\mathcal{P}}\times SU_c(2n)_{\mathcal{P}}\times[(SU_c^{(e)}(2)_{\mathcal{P}}\times\cdots\times SU_c^{(e)}(2)_{\mathcal{P}})\otimes(SU_c^{(o)}(2)_{\mathcal{P}}\times\cdots\times SU_c^{(o)}(2)_{\mathcal{P}})]$. The underlying symmetry is valid for the partially attractive model with chemical potential $\mu=-U$.

Proof of a conjecture on the conductivity of checkerboards

Graeme W. Milton
Department of Mathematics, The University of Utah, Salt Lake City, Utah 84112-0090

(Received 7 November 2000; accepted for publication 18 April 2001)

In 1985 Mortola and Steffé conjectured a formula for the effective conductivity tensor of a checkerboard structure where the unit cell of periodicity is square and subdivided into four equal squares each having a different conductivity. In this article their conjecture is proven. The key idea is to superimpose suitably reflected potentials to obtain the solution to the dual problem. This is then related back to the original problem using a well known theorem of Keller, thereby proving the conjecture. The analysis also yields formulas relating the potentials in the four squares. Independently, Craster and Obnosov have obtained a completely different proof of the conjecture. © *2001 American Institute of Physics.* [DOI: 10.1063/1.1385564]

I. INTRODUCTION

There are relatively few microstructures which yield explicit formulas for their effective electrical conductivity. Such formulas are useful as benchmarks for testing numerical codes and as examples for illustrating more general theoretical results. One family of microstructures which has received considerable attention in this regard are checkerboards. Dykhne[1], using a duality argument, found that the effective conductivity σ_* of the standard checkerboard with squares of conductivity σ_1 and σ_2 is simply

$$\sigma_* = \sqrt{\sigma_1 \sigma_2}. \tag{1}$$

This solution was subsequently used[2,3] to show that the effective conductivity of a three-dimensional checkerboard (i.e., a face centered cubic arrangement of touching cubes) is $2\sqrt{\sigma_1\sigma_2}$ in the asymptotic limit when the ratio σ_1/σ_2 of the conductivity of the two phases is large. The result provided a crucial test showing the current limitations of a numerical method[4] based on fast Fourier transforms. Asymptotic and numerical results[3,5–7] for the effective conductivity of rectangular and parallelogram checkerboards were also obtained. The geometry consisting of a square array of squares oriented at 45° to the unit cell, which becomes a checkerboard when the squares touch, has become a test case for checking numerical methods.[8–12]

The explicit solution for the electric potential solving the conductivity equations in the standard two-dimensional checkerboard was obtained by Berdichevskii.[13] Subsequently, Mityushev and Zhorovina[14] and Obnosov[15,16] obtained explicit solutions for rectangular and triangular checkerboards.

Random checkerboards with the phases having a large contrast in their conductivities were studied by Sheng and Kohn,[17] Kozlov,[18] Berlyand and Golden[19] and Golden and Kozlov.[20] Miller,[21,22] Beran and Silnutzer[23] and Silnutzer[24] obtained bounds on the effective conductivity and bulk modulus for a class of materials called cell materials, where space is divided into cells and each cell is assigned randomly as phase 1 or phase 2, weighted according to what volume fraction one desires to achieve. The bounds depend on a certain parameter (denoted as G' in two dimensions and G in three dimensions). This parameter has been evaluated for square cells[25] and cubic cells,[26] thereby providing bounds on the effective conductivity and bulk modulus two- and three-dimensional random checkerboards. Numerical results for the conductivity of random square and hexagonal checkerboards were obtained by Torquato, Kim and Cule[27] and Suquet and Moulinec.[28]

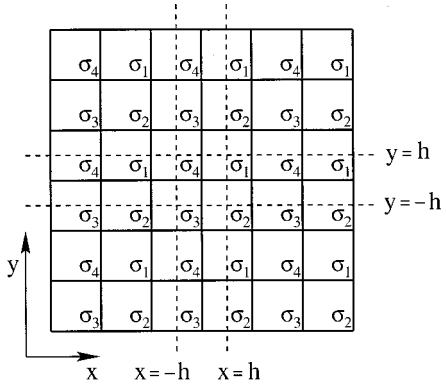

FIG. 1. The two-dimensional checkerboard structure. When the average electric field is applied in the x direction the electric potential is constant along the lines $x=h$ and $x=-h$, while the lines $y=h$ and $y=-h$ are lines of current flow.

Berdichevskii[29] applied a duality result to show that the two effective shear moduli $\mu_*^{(1)}$ and $\mu_*^{(2)}$ (corresponding to shears at 45° to each other) of a periodic checkerboard of two incompressible isotropic phases have the same product as the product of the two shear moduli μ_1 and μ_2 of the two isotropic phases. When both phases share the same two-dimensional bulk modulus κ it follows[30–32] that

$$(1/\mu_*^{(1)}+1/\kappa)(1/\mu_*^{(2)}+1/\kappa)=(1/\mu_1+1/\kappa)(1/\mu_2+1/\kappa). \tag{2}$$

Berlyand and Kozlov[33] obtained asymptotic solutions for the effective elastic moduli of checkerboards in the limit where there is a large contrast in the stiffnesses of the two phases. Interestingly, they found that such checkerboards would have an effective Poisson's ratio close to zero when stretched in a diagonal direction.

Over 15 years ago an interesting conjecture regarding the conductivity of four phase checkerboards was made by Mortola and Steffé.[34] The checkerboard they studied is periodic with a square unit cell of periodicity of side length $4h$. The unit cell is subdivided into four equal subsquares of side length $2h$ each filled with a different phase. These phases are numbered 1, 2, 3 and 4 going clockwise around the unit cell. The resulting checkerboard structure is illustrated in Fig. 1.

The equation of electrical conductivity takes the form

$$\nabla\cdot\sigma(x,y)\nabla\phi(x,y)=0, \tag{3}$$

where $\phi(x,y)$ is the electric potential and $\sigma(x,y)$ is the locally isotropic conductivity field taking the value σ_j in phase $j=1,2,3,4$. Alternatively, one can work with the system of equations

$$\nabla\cdot\mathbf{j}=0,\ \ \mathbf{j}(x,y)=\sigma(x,y)\mathbf{e}(x,y),\quad \mathbf{e}=\left(-\frac{\partial\phi}{\partial x},-\frac{\partial\phi}{\partial y}\right), \tag{4}$$

where $\mathbf{j}(x,j)$ is the current field and $\mathbf{e}(x,y)$ is the electric field. By finding periodic fields $\mathbf{j}$ and $\mathbf{e}$ which solve the equations (4) one can determine the effective conductivity tensor $\boldsymbol{\sigma}_*$ through the relation between the average current and average electric field which is governed by the effective constitutive law,

$$\langle\mathbf{j}\rangle=\boldsymbol{\sigma}_*\langle\mathbf{e}\rangle, \tag{5}$$

where the angular brackets denote averages over the unit cell of periodicity. Now when the average electric field is applied in the x direction, symmetry considerations imply that the lines $x=h$ and $x=-h$ in Fig. 1 are lines of constant electric potential, while the lines $y=h$ and $y=$

$-h$ are lines of current flow. Similarly when the average electric field is applied in the y direction, the lines $x=h$ and $x=-h$ are lines of current flow, while the lines $y=h$ and $y=-h$ are lines of constant electric potential. As observed by Mortola and Steffé[34] these considerations imply that the effective tensor is diagonal

$$\boldsymbol{\sigma}_* = \begin{pmatrix} \sigma_{*x} & 0 \\ 0 & \sigma_{*y} \end{pmatrix}. \tag{6}$$

Mortola and Steffé obtained upper and lower bounds on both σ_{*x} and σ_{*y} and they conjectured that the exact values would be given by the square root of the product of their upper and lower bounds, resulting in the formulas

$$\sigma_{*x} = \sqrt{\frac{\sigma_1\sigma_2\sigma_3\sigma_4(1/\sigma_1+1/\sigma_2+1/\sigma_3+1/\sigma_4)(\sigma_1+\sigma_2)(\sigma_3+\sigma_4)}{(\sigma_1+\sigma_2+\sigma_3+\sigma_4)(\sigma_1+\sigma_4)(\sigma_2+\sigma_3)}}, \tag{7}$$

$$\sigma_{*y} = \sqrt{\frac{\sigma_1\sigma_2\sigma_3\sigma_4(1/\sigma_1+1/\sigma_2+1/\sigma_3+1/\sigma_4)(\sigma_1+\sigma_4)(\sigma_2+\sigma_3)}{(\sigma_1+\sigma_2+\sigma_3+\sigma_4)(\sigma_1+\sigma_2)(\sigma_3+\sigma_4)}}. \tag{8}$$

They showed that these formulas were consistent with many analytical results. For example, when $\sigma_1\sigma_3=\sigma_2\sigma_4$ the formulas agree with an exact result of Marino and Spagnolo[35] for the effective conductivity tensor, and when $\sigma_3=\sigma_1$ and $\sigma_4=\sigma_2$ the formulas reduce to Dykhne's result (1) for the effective conductivity of a two-phase checkerboard. Mortola and Steffé also provided numerical calculations in support of the conjecture in the special case when

$$\sigma_1=\sigma_2=\sigma_3=1, \quad \sigma_4=\delta, \tag{9}$$

corresponding to a two-phase composite comprised of a square array of squares of conductivity δ occupying a volume fraction of $\frac{1}{4}$ in a matrix of conductivity 1. In this case, the effective conductivity tensor is isotropic and their conjecture implies

$$\sigma_{*x}=\sigma_{*y}=\sqrt{(1+3\delta)/(3+\delta)}. \tag{10}$$

This result was proved by Obnosov,[16] who also found explicit formulas for the potentials which solve the conductivity equations, and generalized the result to rectangular arrays of rectangles. When $\delta=100$ the formula (10) gives $\sigma_*=1.709\,482\,406\,194\,2$. Johan Helsing (private communication), using formulas (7) and (8) of Ref. 36, has numerically calculated the result to be $\sigma_*=1.709\,482\,406\,1(8)$ (digit within parenthesis not converged). So the agreement between theory and numerical calculations is outstanding. It should be added that Helsing's computations typically have this accuracy no matter what the geometry of the two-phase two-dimensional composite. Clearly such high accuracy results reduce the need for exact solutions. For the square array of squares at other volume fractions Cole, Li and Bak[37] obtained experimental results, Perrins,[38] Meidell,[39] and Lukkassen[40] obtained numerical results, and Kozlov and Vucans[41] have obtained an implicit formula for σ_* when $\sigma_1=0$.

In this paper I prove that the conjectured formulas (7) and (8) are indeed correct. Craster and Obnosov,[42] whose work I found about after my proof was complete, have also proved the conjecture. Our proofs are quite different. They apply conformal transformations to the solution of a basic problem involving four joined quarter planes, each with a different conductivity. This allows them to also solve the problem of a four-phase rectangular checkerboard. My solution is not so explicit, but on the other hand only involves linear algebra, and the idea of superimposing suitably reflected potentials.

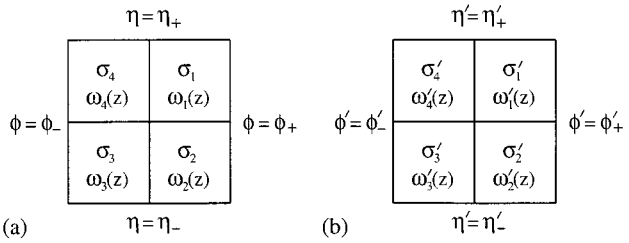

FIG. 2. (a) The region $\mathcal{R}$ bounded by the four lines $x=\pm h$ and $y=\pm h$, showing the complex potentials and conductivities within each phase, and the boundary conditions along each edge of $\mathcal{R}$. (b) By taking new potentials in each quadrant which are linear combinations of the old potential in that quadrant and the old potentials in the three other quadrants, suitably reflected, one obtains another solution to the problem but with new complex potentials and conductivities in the four squares and new boundary conditions along the edges of $\mathcal{R}$.

II. PROOF OF THE CONJECTURE

It suffices to prove the formula (7) for σ_{*x} since the formula (8) for σ_{*y} follows from it, by interchanging the roles of phases 2 and 4. Therefore we will assume that the applied electric field is in the x direction. We let ϕ_+ and ϕ_- denote the constant values that the electric potential takes along the lines $x=h$ and $x=-h$, respectively. The lines $y=h$ and $y=-h$ are lines of current flow. Due to symmetry it suffices to consider the equations in the square region $\mathcal{R}$ bounded by these four lines, as illustrated in Fig. 2(a).

We begin with some standard analysis. Since the field $\mathbf{j}$ is divergence free we can express it in terms of a current potential η:

$$\mathbf{j}=\left(-\frac{\partial \eta}{\partial y},\frac{\partial \eta}{\partial x}\right). \tag{11}$$

The continuity of η ensures continuity of the normal component of the current across each interface. Indeed, if $\mathbf{n}$ is the normal to the interface, then the current flux $\mathbf{j}\cdot\mathbf{n}$ is equal to the gradient of η in the direction tangential to the interface, which will be continuous across the interface. Rather than keeping track of the condition of continuity of the current flux across each interface, it is much simpler to keep track of the condition of continuity of the potential η across each interface. Also the fact that the lines $y=h$ and $y=-h$ are lines of current flow implies that the current potential is constant along these lines, taking values η_+ and η_-, respectively. It is convenient to introduce $z=x+iy$ and the complex potential

$$\omega=\phi+i\psi \quad \text{where} \quad \psi=\eta/\sigma. \tag{12}$$

The constitutive law $\mathbf{j}=\sigma\mathbf{e}$ implies that ϕ and ψ satisfy the Cauchy–Riemann equations, and consequently ω is an analytic function of z within each of the four phases. We let $\omega_j(z)=\phi_i(z)+i\psi_i(z)$ denote its value within phase j.

At the interfaces between the phases the continuity of the potentials ϕ and $\eta=\sigma\psi$ imposes the constraints

$$\begin{aligned}
&\phi_1=\phi_2, \quad \sigma_1\psi_1=\sigma_2\psi_2, \quad \text{when} \quad y=0, \quad 0\leqslant x\leqslant h,\\
&\phi_2=\phi_3, \quad \sigma_2\psi_2=\sigma_3\psi_3, \quad \text{when} \quad x=0, \quad 0\geqslant y\geqslant -h,\\
&\phi_3=\phi_4, \quad \sigma_3\psi_3=\sigma_4\psi_4, \quad \text{when} \quad y=0, \quad 0\geqslant x\geqslant -h,\\
&\phi_4=\phi_1, \quad \sigma_3\psi_3=\sigma_1\psi_1, \quad \text{when} \quad x=0, \quad 0\leqslant y\leqslant h.
\end{aligned} \tag{13}$$

Also the fact that $x=h$ and $x=-h$ are lines of constant electrical potential ϕ implies that

$$\begin{gathered}\phi_1=\phi_+,\ \text{when}\ x=h,\ 0\leqslant y\leqslant h,\\ \phi_2=\phi_+,\ \text{when}\ x=h,\ 0\geqslant y\geqslant -h,\\ \phi_3=\phi_-,\ \text{when}\ x=-h,\ 0\geqslant y\geqslant -h,\\ \phi_4=\phi_-,\ \text{when}\ x=-h,\ 0\leqslant y\leqslant h,\end{gathered}\tag{14}$$

while the fact that $y=h$ and $y=-h$ are lines of constant current potential η implies that

$$\begin{gathered}\sigma_1\psi_1=\eta_+,\ \text{when}\ y=h,\ 0\leqslant x\leqslant h,\\ \sigma_2\psi_2=\eta_-,\ \text{when}\ y=-h,\ 0\leqslant x\leqslant h,\\ \sigma_3\psi_3=\eta_-,\ \text{when}\ y=-h,\ 0\geqslant x\geqslant -h,\\ \sigma_4\psi_4=\eta_+,\ \text{when}\ y=h,\ 0\geqslant x\geqslant -h.\end{gathered}\tag{15}$$

Now the potentials $\phi-(\phi_+-\phi_-)x/(2h)$ and $\eta-(\eta_+-\eta_-)y/(2h)$ are periodic and since the gradient of a periodic potential has average value zero it follows that

$$\langle\mathbf{e}\rangle=(-(\phi_+-\phi_-)/(2h),0),\quad \langle\mathbf{j}\rangle=(-(\eta_+-\eta_-)/(2h),0).\tag{16}$$

Consequently it is the ratio of the two potential drops which determines the effective conductivity in the x direction:

$$\sigma_{*x}=\frac{\eta_+-\eta_-}{\phi_+-\phi_-}.\tag{17}$$

The key idea behind the present proof of the formula (7) for σ_{*x} is to consider new potentials in each quadrant which are linear combinations of the old potential in that quadrant and the old potentials in the three other quadrants, suitably reflected. With appropriate choices of the linear combinations, we will see that these new potentials solve a conductivity problem of the same type but with different conductivities σ_1', σ_2', σ_3', and σ_4' in the four squares, as illustrated in Fig. 2(b). Accordingly, let us introduce new complex potentials,

$$\begin{aligned}\omega_1'(z)&=\phi_1'(z)+i\psi_1'(z)=a_{11}\omega_1(z)+a_{12}\overline{\omega_2(\overline{z})}+a_{13}\omega_3(-z)+a_{14}\overline{\omega_4(-\overline{z})},\\ \omega_2'(z)&=\phi_2'(z)+i\psi_2'(z)=a_{21}\overline{\omega_1(\overline{z})}+a_{22}\omega_2(z)+a_{23}\overline{\omega_3(-\overline{z})}+a_{24}\omega_4(-z),\\ \omega_3'(z)&=\phi_3'(z)+i\psi_3'(z)=a_{31}\omega_1(-z)+a_{32}\overline{\omega_2(-\overline{z})}+a_{33}\omega_3(-z)+a_{34}\overline{\omega_4(\overline{z})},\\ \omega_4'(z)&=\phi_4'(z)+i\psi_4'(z)=a_{41}\overline{\omega_1(-\overline{z})}+a_{42}\omega_2(-z)+a_{43}\overline{\omega_3(\overline{z})}+a_{44}\omega_4(z),\end{aligned}\tag{18}$$

which are analytic functions of z, each defined within that subsquare of $\mathcal{R}$ containing phase 1, 2, 3, or 4, respectively.

We want to ensure that the new electrical potential ϕ' and the new current potential $\eta'=\sigma'\psi'$ are continuous across the interfaces between phases. In particular, the continuity of these potentials across the interface between phases 1 and 2 requires that

$$\begin{aligned}a_{11}\phi_1+a_{12}\phi_2+a_{13}\phi_3+a_{14}\phi_4&=a_{21}\phi_1+a_{22}\phi_2+a_{23}\phi_3+a_{24}\phi_4,\\ \sigma_1'(a_{11}\psi_1-a_{12}\psi_2+a_{13}\psi_3-a_{14}\psi_4)&=\sigma_2'(-a_{21}\psi_1+a_{22}\psi_2-a_{23}\psi_3+a_{24}\psi_4),\end{aligned}\tag{19}$$

when $y=0$ and $0\leqslant x\leqslant h$, where the minus signs in the latter equation arise because of the appearance of complex conjugates in (18). In view of the continuity conditions (13) on the potentials ϕ and $\sigma\psi$ across the interface these constraints reduce to

$$\begin{aligned}&(a_{11}+a_{12}-a_{21}-a_{22})\phi_1+(a_{13}+a_{14}-a_{23}-a_{24})\phi_3=0,\\&(\sigma_1'\sigma_2a_{11}-\sigma_1'\sigma_1a_{12}+\sigma_2'\sigma_2a_{21}-\sigma_2'\sigma_1a_{22})\psi_1/\sigma_2+(\sigma_1'\sigma_4a_{13}-\sigma_1'\sigma_3a_{14}+\sigma_2'\sigma_4a_{23}\\&\quad-\sigma_2'\sigma_3a_{24})\psi_3/\sigma_4=0,\end{aligned}\tag{20}$$

and will be satisfied provided the coefficients in brackets vanish. By similar considerations applied to the remaining interfaces between phases we arrive at the set of equations

$$\begin{aligned}&a_{11}+a_{12}-a_{21}-a_{22}=0,\quad a_{13}+a_{14}-a_{23}-a_{24}=0,\\&a_{31}+a_{32}-a_{41}-a_{42}=0,\quad a_{33}+a_{34}-a_{43}-a_{44}=0,\\&a_{21}+a_{24}-a_{31}-a_{34}=0,\quad a_{22}+a_{23}-a_{32}-a_{33}=0,\\&a_{11}+a_{14}-a_{41}-a_{44}=0,\quad a_{12}+a_{13}-a_{42}-a_{43}=0,\end{aligned}\tag{21}$$

which ensure continuity of the electrical potential ϕ', and at the set of equations

$$\begin{aligned}&\sigma_1'\sigma_2a_{11}-\sigma_1'\sigma_1a_{12}+\sigma_2'\sigma_2a_{21}-\sigma_2'\sigma_1a_{22}=0,\quad \sigma_1'\sigma_4a_{13}-\sigma_1'\sigma_3a_{14}+\sigma_2'\sigma_4a_{23}-\sigma_2'\sigma_3a_{24}=0,\\&\sigma_3'\sigma_2a_{31}-\sigma_3'\sigma_1a_{32}+\sigma_4'\sigma_2a_{41}-\sigma_4'\sigma_1a_{42}=0,\quad \sigma_3'\sigma_4a_{33}-\sigma_3'\sigma_3a_{34}+\sigma_4'\sigma_4a_{43}-\sigma_4'\sigma_3a_{44}=0,\\&-\sigma_2'\sigma_4a_{21}+\sigma_2'\sigma_1a_{24}-\sigma_3'\sigma_4a_{31}+\sigma_3'\sigma_1a_{34}=0,\quad \sigma_2'\sigma_3a_{22}-\sigma_2'\sigma_2a_{23}+\sigma_3'\sigma_3a_{32}-\sigma_3'\sigma_2a_{33}=0,\\&\sigma_1'\sigma_4a_{11}-\sigma_1'\sigma_1a_{14}+\sigma_4'\sigma_4a_{41}-\sigma_4'\sigma_1a_{44}=0,\quad -\sigma_1'\sigma_3a_{12}+\sigma_1'\sigma_2a_{13}-\sigma_4'\sigma_3a_{42}+\sigma_4'\sigma_2a_{43}=0,\end{aligned}\tag{22}$$

which ensure continuity of the current potential $\eta'=\sigma'\psi'$.

It is easy to check that when (21) and (22) are satisfied, then the new electrical potential ϕ' is constant along the lines $x=h$ and $x=-h$, while the new current potential η' is constant along the lines $y=h$ and $y=-h$. Specifically, as illustrated in Fig. 2(b), we have

$$\begin{aligned}&\phi=\phi_+'\ \text{ when }\ x=h,\ \ \phi'=\phi_-'\ \text{ when }\ x=-h,\\&\eta'=\eta_+'\ \text{ when }\ y=h,\ \ \eta'=\eta_-'\ \text{ when }\ y=-h,\end{aligned}\tag{23}$$

where

$$\begin{aligned}\phi_+'&=(a_{11}+a_{12})\phi_++(a_{13}+a_{14})\phi_-,\\\phi_-'&=(a_{31}+a_{32})\phi_++(a_{33}+a_{34})\phi_-,\end{aligned}\tag{24}$$

and

$$\begin{aligned}\eta_+'&=[(a_{11}/\sigma_1-a_{14}/\sigma_4)\eta_++(-a_{12}/\sigma_2+a_{13}/\sigma_3)\eta_-)]\sigma_1',\\\eta_-'&=[(-a_{21}/\sigma_1+a_{24}/\sigma_4)\eta_++(a_{22}/\sigma_2-a_{23}/\sigma_3)\eta_-)]\sigma_2'.\end{aligned}\tag{25}$$

Provided we can find a solution to the 16 equations (21) and (22) with a nonzero value of the potential drop $\phi'_+ - \phi'_-$ the new material with conductivities σ'_1, σ'_2, σ'_3, and σ'_4 must have effective conductivity

$$\sigma'_{*x} = \frac{\eta'_+ - \eta'_-}{\phi'_+ - \phi'_-} \tag{26}$$

in the x direction. If we consider the 16 coefficients a_{ij} and the four conductivities σ'_1, σ'_2, σ'_3, and σ'_4 to be unknowns, then there are more unknowns than equations and so we certainly expect many solutions. This is the basic idea. Finding an appropriate solution is the only difficulty.

Let us set

$$\sigma'_1 = 1/\sigma_2, \quad \sigma'_2 = 1/\sigma_3, \quad \sigma'_3 = 1/\sigma_4, \quad \sigma'_4 = 1/\sigma_1. \tag{27}$$

Then the new material corresponds to taking the original material, replacing all conductivities by their reciprocals, and then rotating the entire structure anticlockwise by 90°. Due to a theorem of Keller[43] (see also Refs. 44, 1, and 45) this new dual material has effective conductivity

$$\sigma'_{*x} = 1/\sigma_{*x} \tag{28}$$

in the x direction. We will see that this equation in conjunction with (26) provides the desired formula for σ_{*x}.

Making the substitutions (27) and using an algebraic manipulator, such as Maple, one solution to the equations is found to be

$$\begin{aligned}
a_{11} &= (\sigma_1+\sigma_3)(\sigma_4+\sigma_1)(\sigma_3+\sigma_4)(\sigma_1+\sigma_2)\sigma_2,\\
a_{12} &= 0,\\
a_{13} &= 0,\\
a_{14} &= (\sigma_4+\sigma_1)(\sigma_3+\sigma_4)(\sigma_4\sigma_1-\sigma_3\sigma_2)\sigma_2,\\
a_{21} &= \sigma_2(\sigma_1-\sigma_3)(\sigma_1+\sigma_3)(\sigma_4+\sigma_1)(\sigma_3+\sigma_4),\\
a_{22} &= (\sigma_1+\sigma_3)(\sigma_4+\sigma_1)(\sigma_3+\sigma_4)(\sigma_2+\sigma_3)\sigma_2,\\
a_{23} &= (\sigma_2+\sigma_3)(\sigma_4+\sigma_1)(\sigma_4\sigma_1-\sigma_3\sigma_2)\sigma_3,\\
a_{24} &= (\sigma_4+\sigma_1)(\sigma_4\sigma_2-\sigma_3^2)(\sigma_4\sigma_1-\sigma_3\sigma_2),\\
a_{31} &= (\sigma_1^2-\sigma_4\sigma_2)(\sigma_3+\sigma_4)(\sigma_1\sigma_2-\sigma_4\sigma_3),\\
a_{32} &= (\sigma_3+\sigma_4)(\sigma_1\sigma_2-\sigma_4\sigma_3)\sigma_2(\sigma_4+\sigma_1),\\
a_{33} &= \sigma_3(\sigma_4+\sigma_1)(\sigma_3\sigma_2\sigma_1+\sigma_3\sigma_1\sigma_4+2\sigma_4\sigma_1\sigma_2+2\sigma_3\sigma_4\sigma_2+\sigma_4\sigma_2^2+\sigma_4^2\sigma_2),\\
a_{34} &= \sigma_4(\sigma_1-\sigma_3)(\sigma_3\sigma_2\sigma_1+\sigma_3\sigma_1\sigma_4+2\sigma_4\sigma_1\sigma_2+2\sigma_3\sigma_4\sigma_2+\sigma_4\sigma_2^2+\sigma_4^2\sigma_2),\\
a_{41} &= \sigma_1(\sigma_1+\sigma_2)(\sigma_3+\sigma_4)(\sigma_1\sigma_2-\sigma_4\sigma_3),\\
a_{42} &= 0,\\
a_{43} &= 0,
\end{aligned} \tag{29}$$

$$a_{44}=(\sigma_3+\sigma_4)\sigma_1(\sigma_3\sigma_2\sigma_1+\sigma_3\sigma_1\sigma_4+2\sigma_4\sigma_1\sigma_2+2\sigma_3\sigma_4\sigma_2+\sigma_4\sigma_2^2+\sigma_4^2\sigma_2).$$

There are other solutions to the equations, but they all lead to the same result provided $\phi'_+ - \phi'_-$ is nonzero. This solution was picked because of its relative simplicity. By inserting the solution (29) in (24) and (25) one finds that the associated potential drops are

$$\begin{gathered}\phi'_+ - \phi'_- = \sigma_1\sigma_2\sigma_3\sigma_4(1/\sigma_1+1/\sigma_2+1/\sigma_3+1/\sigma_4)(\sigma_1+\sigma_2)(\sigma_3+\sigma_4)(\phi_+ - \phi_-),\\ \eta'_+ - \eta'_- = (\sigma_1+\sigma_2+\sigma_3+\sigma_4)(\sigma_1+\sigma_4)(\sigma_2+\sigma_3)(\eta_+ - \eta_-).\end{gathered} \tag{30}$$

Substituting these back in (26) and using (17) yields the desired relation between the effective conductivities σ'_{*x} and σ_{*x},

$$\sigma'_{*x}=\frac{(\sigma_1+\sigma_2+\sigma_3+\sigma_4)(\sigma_1+\sigma_4)(\sigma_2+\sigma_3)}{\sigma_1\sigma_2\sigma_3\sigma_4(1/\sigma_1+1/\sigma_2+1/\sigma_3+1/\sigma_4)(\sigma_1+\sigma_2)(\sigma_3+\sigma_4)}\sigma_{*x}, \tag{31}$$

which in conjunction with (28) proves that σ_{*x} is given by (7).

III. RELATIONS BETWEEN THE POTENTIALS AND EQUIVALENT CHECKERBOARDS

Some conclusions about the potentials in the four phases also follow from this analysis. Let $\mathbf{M}(\sigma_1,\sigma_2,\sigma_3,\sigma_4,\sigma'_1,\sigma'_2,\sigma'_3,\sigma'_4)$ denote the 16 by 16 matrix associated with the homogeneous system of equations (21) and (22). Using Maple one can readily verify that

$$\text{rank}[\mathbf{M}(\sigma_1,\sigma_2,\sigma_3,\sigma_4,\sigma'_1,\sigma'_2,\sigma'_3,\sigma'_4)]\leqslant 14. \tag{32}$$

In other words, the homogeneous system of equations (21) and (22) has a nonzero solution for the set of coefficients a_{ij} for any choice of the new conductivities σ'_1, σ'_2, σ'_3, and σ'_4. However, unless the new conductivities satisfy the condition that

$$\text{rank}[\mathbf{M}(\sigma_1,\sigma_2,\sigma_3,\sigma_4,\sigma'_1,\sigma'_2,\sigma'_3,\sigma'_4)]\leqslant 13, \tag{33}$$

the resulting potential drops $\phi'_+ - \phi'_-$ and $\eta'_+ - \eta'_-$ both turn out to be zero, and the potentials ϕ' and η' must therefore be constant everywhere, that is, one has obtained trivial potentials that solve the conductivity equations in the second checkerboard problem. By adding suitable constants to the original potentials ϕ and η one can ensure that the resulting potentials ϕ' and η' are both zero, implying certain linear relations among the four complex potentials $\omega_1(z)$, $\overline{\omega_2(\overline{z})}$, $\omega_3(-z)$ and $\overline{\omega_4(-\overline{z})}$ that hold for all z. Such relations can be used to reduce the equations (21) and (22) to a system of eight equations with eight unknowns, if desired. When the condition (33) is satisfied we will say that the two materials with conductivities $\sigma(x,y)$ and $\sigma'(x,y)$ are equivalent checkerboards. The equivalence holds in the sense that the potentials solving one checkerboard problem provide through (18) a nontrivial solution for the potentials in the other checkerboard problem.

To see how this works in a particular case, let us consider the special situation solved by Obnosov[16] where $\sigma_1=\sigma_2=\sigma_3=1$ and $\sigma_4=\delta$, as in (9). Then for any choice of the conductivities σ'_1, σ'_2, σ'_3, and σ'_4 the equations (21) and (22) are solved with

$$\begin{gathered}a_{11}=a_{13}=c_1+c_2/\sigma'_1,\quad a_{12}=c_1-c_2/\sigma'_1,\quad a_{14}=c_1\delta-c_2/\sigma'_1,\\ a_{21}=a_{23}=c_1-c_2/\sigma'_2,\quad a_{22}=c_1+c_2/\sigma'_2,\quad a_{24}=c_1\delta+c_2/\sigma'_4,\\ a_{31}=a_{33}=c_1+c_2/\sigma'_3,\quad a_{32}=c_1-c_2/\sigma'_3,\quad a_{34}=c_1\delta-c_2/\sigma'_3,\\ a_{41}=a_{43}=c_1-c_2/\sigma'_4,\quad a_{42}=c_1+c_2/\sigma'_4,\quad a_{42}=c_1\delta+c_2/\sigma'_4.\end{gathered} \tag{34}$$

where c_1 and c_2 are arbitrary constants. By substituting these formulas back in (24) and (25) one finds that

$$\phi'_- = \phi'_+ = c_1[2\phi_+ + (1+\delta)\phi_-], \quad \eta'_- = \eta'_+ = c_2[(1+1/\delta)\eta_+ + 2\eta_-]. \tag{35}$$

So the associated potential drops are zero.

Now, by adding appropriate constants to the electrical potential and conjugate electrical potential we can assume, without loss of generality, that

$$\phi_+ = -(1+\delta)\phi_-/2, \quad \eta_+ = -2\eta_-/(1+1/\delta). \tag{36}$$

Then the resulting potentials ϕ'_-, ϕ'_+, η'_-, and η'_+ given by (35) are zero. Consequently, the potentials $\omega'_1(z)$, $\omega'_2(z)$, $\omega'_3(z)$ and $\omega'_4(z)$ are zero for all z, and by substituting (34) back in (18) we obtain the relations

$$\begin{aligned} \omega_1(z) + \overline{\omega_2(\overline{z})} + \omega_3(-z) + \delta\overline{\omega_4(-\overline{z})} = 0, \\ \omega_1(z) - \overline{\omega_2(\overline{z})} + \omega_3(-z) - \overline{\omega_4(-\overline{z})} = 0. \end{aligned} \tag{37}$$

These identities allow us to express ω_2 and ω_4 in terms of ω_1 and ω_3:

$$\begin{aligned} \omega_2(z) = -(1+\delta)(\overline{\omega_1(\overline{z})} + \overline{\omega_3(-\overline{z})})/(1-\delta), \\ \omega_4(z) = 2(\overline{\omega_1(-\overline{z})} + \overline{\omega_3(\overline{z})})/(1-\delta) = -2\omega_2(-z)/(1+\delta). \end{aligned} \tag{38}$$

Thus there are some very simple relations among the potentials in the four subsquares.

Using Maple one can check that the condition (33) for equivalence will be satisfied if

$$\delta = f(\sigma'_1,\sigma'_2,\sigma'_3,\sigma'_4) \equiv \frac{b+5a+c}{b-3a}, \quad \text{or} \quad \delta = 1/f(\sigma'_1,\sigma'_2,\sigma'_3,\sigma'_4) = \frac{b+5a-c}{b-3a}, \tag{39}$$

where

$$\begin{aligned} a &= \sigma'_1\sigma'_3/(\sigma'_2\sigma'_4) + \sigma'_2\sigma'_4/(\sigma'_1\sigma'_3) - 2, \\ b &= (\sigma'_1+\sigma'_2+\sigma'_3+\sigma'_4)(1/\sigma'_1+1/\sigma'_2+1/\sigma'_3+1/\sigma'_4), \\ c &= 4\left|1/(\sigma'_1\sigma'_3) - 1/(\sigma'_2\sigma'_4)\right| \sqrt{(\sigma'_1+\sigma'_2)(\sigma'_2+\sigma'_3)(\sigma'_3+\sigma'_4)(\sigma'_4+\sigma'_1)}, \end{aligned} \tag{40}$$

The two values of δ given by (39) are reciprocals of each other. Thus any given checkerboard (with arbitrary positive conductivities σ'_1, σ'_2, σ'_3, and σ'_4) is equivalent to a square array of squares at a volume fraction of $\frac{1}{4}$ [with conductivities $\sigma_1=\sigma_2=\sigma_3=1$, and $\sigma_4=\delta$ where δ is given by (39)]. In other words, Obnosov's solution[16] for the square array of squares could be used to generate the solution for the potentials in the given checkerboard, using (18), where the set of coefficients a_{ij} is any solution to the equations (21) and (22) that is independent of the solutions (34). Such a solution can be easily found using Maple, but the expressions are not sufficiently concise to justify their reproduction here, especially in view of the explicit solution obtained by Craster and Obnosov.[42]

More generally, a checkerboard with four arbitrary conductivities σ_1, σ_2, σ_3, and σ_4 is equivalent to a checkerboard with conductivities σ'_1, σ'_2, σ'_3, and σ'_4 [in the sense that (33) is satisfied] if and only if they are each equivalent to a checkerboard with conductivities 1,1,1 and δ for some choice of δ, i.e., if and only if

$$f(\sigma_1,\sigma_2,\sigma_3,\sigma_4) = f(\sigma'_1,\sigma'_2,\sigma'_3,\sigma'_4). \tag{41}$$

The conductivities (27) satisfy this criterion of equivalence, which is what makes this proof of Mortola and Steffé's conjecture possible.

Graphical representation of the partition function of a one-dimensional δ-function Bose gas

Go Kato[a] and Miki Wadati[b]
Department of Physics, Graduate School of Science, University of Tokyo, Hongo 7-3-1, Bunkyo-ku, Tokyo 113-0033, Japan

(Received 12 March 2001; accepted for publication 5 July 2001)

The one-dimensional repulsive δ-function bose system is studied. By only using the Bethe ansatz equation, n-particle partition functions are exactly calculated. From this expression for the n-particle partition function, the n-particle cluster integral is derived. The results completely agree with those of the thermal Bethe ansatz (TBA). This directly proves the validity of the TBA. The theory of partitions and graphs is used to simplify the discussion. © *2001 American Institute of Physics.* [DOI: 10.1063/1.1396836]

I. INTRODUCTION

We study statistical mechanics of a one-dimensional gas of Bose particles interacting through a repulsive delta function potential. The Hamiltonian for the system with n particles reads

$$H_n = -\sum_{i=1}^{n} \frac{\partial^2}{\partial x_i^2} + 2c \sum_{i>j} \delta(x_i - x_j). \tag{1.1}$$

Throughout the paper, we set $\hbar = 1$, $2m = 1$ and assume the potential is repulsive, $c > 0$.

The eigenvalues and the eigenstates are obtained by the Bethe ansatz (BA) method,[1,2] and the quantum inverse scattering method (QISM).[3–8] As a periodic boundary condition, the Bethe ansatz (BA) equation is derived. Using the BA equation, thermodynamic quantities are calculated by the thermal Bethe ansatz (TBA).[9,10] In the TBA, an ''interpretation'' of the particle density and the state density enables us to define the entropy of n-particle system in the thermodynamic limit.

With the quantum Gelfand–Levitan equation,[3,7] the field operator is expressed as a series of the terms each of which is a product of creation and annihilation operators in the scattering data space. The grand partition function is written as a field operator.[5] Creamer, Thacker, and Wilkinson[4] calculated the grand partition function using creation and annihilation operators of this system, but the analysis involves a delicate regularization that $2\pi\delta(0)$ is replaced by the volume L.

To be rigorous, it is desirable to examine these results by a different approach. In this paper, we present a method to calculate the thermodynamical quantities only by use of the BA equation which is derived exactly as a periodic boundary condition from both QISM and BA method. We calculate the n-particle partition function and evaluate the n-particle cluster integral.

The paper is organized as follows: The n-particle partition function and the n-particle cluster integral are derived with a method, which we call a direct method, in Sec. II. This method is shown explicitly for $n = 3$. In Sec. III, we consider the n-particle case, and reformulate the results in graphical expressions. The last section is devoted to concluding remarks and discussions. To avoid complexities, the details of a mathematical proof are summarized in Appendix A.

II. DIRECT METHOD

We assume a finite system size L and the periodic boundary condition. It is known that the total energy E and the wave numbers k_j of the system (1.1) are determined by the following relations:

$$E=\sum_{j=1}^{n} k_j^2, \tag{2.1}$$

$$k_jL=2\pi m_j+\sum_{j'\neq j}\Delta(k_{j'}-k_j), \tag{2.2}$$

where m_j are integers or half-integers, and $\Delta(k)$ is the phase shift of two-particle scattering,

$$m_j\in\begin{cases}\mathbb{Z} & \text{if } N=\text{odd}\\ \mathbb{Z}+\frac{1}{2} & \text{if } N=\text{even},\end{cases} \tag{2.3}$$

$$m_j<m_{j+1}, \tag{2.4}$$

$$\Delta(k)=2\arctan\left(\frac{k}{c}\right), \tag{2.5}$$

$$-\pi<\Delta(k)<\pi.$$

Equation (2.2) is called the Bethe ansatz (BA) equation. Main objects to be calculated are the n-particle partition function Z_n,

$$Z_n=\mathrm{Tr}\,e^{-\beta H_n},\quad \beta=1/k_BT, \tag{2.6}$$

and the n-particle cluster integral b_n,

$$\sum_{n\geqslant 1} b_nz^n=\log\left(\sum_{n\geqslant 0} Z_nz^n\right), \tag{2.7}$$

where $z=e^{\beta\mu}$ with the chemical potential μ. By definition, $Z_0=1$ and we simply have

$$b_1=L^{-1}Z_1=\int\frac{dk}{2\pi}e^{-\beta k^2}. \tag{2.8}$$

We explain a direct method to evaluate the partition function for 3-particle case. To be explicit, the total energy is

$$E=k_1^2+k_2^2+k_3^2, \tag{2.9}$$

and the BA equation is

$$\begin{aligned}k_1L&=2\pi m_1+\Delta(k_2-k_1)+\Delta(k_3-k_1),\\ k_2L&=2\pi m_2+\Delta(k_1-k_2)+\Delta(k_3-k_2),\\ k_3L&=2\pi m_3+\Delta(k_1-k_3)+\Delta(k_2-k_3),\end{aligned} \tag{2.10}$$

$$m_1<m_2<m_3\in\mathbb{Z}. \tag{2.11}$$

By use of these relations (2.9)–(2.11), we can calculate the partition function Z_3 as follows:

$$
\begin{aligned}
Z_3 &= \sum_{m_1<m_2<m_3} e^{-\beta(k_1^2+k_2^2+k_3^2)} = \frac{1}{6}\sum_{m_1,m_2,m_3} e^{-\beta(k_1^2+k_2^2+k_3^2)} - \frac{1}{2}\sum_{m_1,m_2=m_3} e^{-\beta(k_1^2+k_2^2+k_3^2)} \\
&\quad + \frac{1}{3}\sum_{m_1=m_2=m_3} e^{-\beta(k_1^2+k_2^2+k_3^2)} \\
&= \frac{1}{6}\sum_{\tilde{m}_1,\tilde{m}_2,\tilde{m}_3} \int dm_1 dm_2 dm_3 e^{-\beta(k_1^2+k_2^2+k_3^2)+2\pi i(m_1\tilde{m}_1+m_2\tilde{m}_2+m_3\tilde{m}_3)} \\
&\quad - \frac{1}{2}\sum_{\tilde{m}_1',\tilde{m}_2'} \int dm_1', dm_2' e^{-\beta(2k_1'^2+k_2'^2)+2\pi i(m_1'\tilde{m}_1'+m_2'\tilde{m}_2')} + \frac{1}{3}\sum_{\tilde{m}''} \int dm'' e^{-\beta(3k^2)+2\pi i m''\tilde{m}''} \\
&= \frac{1}{6}\sum_{\tilde{m}_1,\tilde{m}_2,\tilde{m}_3} \int dk_1 dk_2 dk_3 \left|\frac{\partial m}{\partial k}\right| e^{-\beta(k_1^2+k_2^2+k_3^2)+iL(k_1\tilde{m}_1+k_2\tilde{m}_2+k_3\tilde{m}_3)} \\
&\quad \times \left(\frac{k_1-k_2+ic}{k_1-k_2-ic}\right)^{\tilde{m}_2-\tilde{m}_1}\left(\frac{k_2-k_3+ic}{k_2-k_3-ic}\right)^{\tilde{m}_3-\tilde{m}_2}\left(\frac{k_3-k_1+ic}{k_3-k_1-ic}\right)^{\tilde{m}_1-\tilde{m}_3} \\
&\quad - \frac{1}{2}\sum_{\tilde{m}_1',\tilde{m}_2'} \int dk_1', dk_2' \left|\frac{\partial m'}{\partial k'}\right| e^{-\beta(2k_1'^2+k_2'^2)+iL(k_1'\tilde{m}_1'+k_2'\tilde{m}_2')}\left(\frac{k_1'-k_2'+ic}{k_1'-k_2'-ic}\right)^{\tilde{m}_2-2\tilde{m}_1} \\
&\quad + \frac{1}{3}\sum_{\tilde{m}''} \int dk'' \frac{\partial m''}{\partial k''} e^{-\beta(3k^2)+iLk''\tilde{m}''},
\end{aligned}
\tag{2.12}
$$

where $|\partial m/\partial k|$, $|\partial m'/\partial k'|$, and $\partial m''/\partial k''$ are the Jacobians to be explained shortly. We have written explicitly all the steps of calculations which are common to those for general n.[11–13] In the second equality, we use a symmetry of the BA equation with respect to the exchange $m_i, k_i \leftrightarrow m_{i'}, k_{i'}$, in the third equality, we apply the Poisson's summation formula, and in the last equality, we change variables of integration from m to k.

The relation between k and m is defined by the BA equation. In (2.12), k', m', k'', and m'' are related as follows:

$$
\begin{aligned}
k_1'L &= 2\pi m_1' + 2\Delta(k_2'-k_1'), \\
k_2'L &= 2\pi m_2' + \Delta(k_1'-k_2'),
\end{aligned}
\tag{2.13}
$$

$$
k''L = 2\pi m''. \tag{2.14}
$$

Thus, the Jacobians, $|\partial m/\partial k|$, $|\partial m'/\partial k'|$, and $\partial m''/\partial k''$, are given by

$$
\begin{aligned}
(2\pi)^3\left|\frac{\partial m}{\partial k}\right| &= L^3 + 2L^2K(k_1-k_2) + 2L^2K(k_2-k_3) + 2L^2K(k_3-k_1) + 3LK(k_2-k_1)K(k_3-k_1) \\
&\quad + 3LK(k_1-k_2)K(k_3-k_2) + 3LK(k_1-k_3)K(k_2-k_3),
\end{aligned}
\tag{2.15}
$$

$$
(2\pi)^2\left|\frac{\partial m'}{\partial k'}\right| = L^2 + 3LK(k_1-k_2), \tag{2.16}
$$

$$
\frac{\partial m''}{\partial k''} = \frac{1}{2\pi}L, \tag{2.17}
$$

where

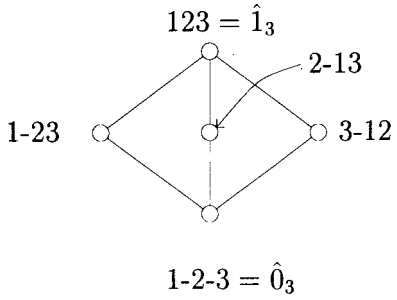

FIG. 1. Vertices of this graph are the elements of Π_3, and if $x<y$ then y is drawn "above" x (i.e., with a higher vertical coordinate). It is called the *Hasse diagram* (Ref. 14) of Π_3.

$$K(k)\equiv\frac{d\Delta(k)}{dk}=\frac{2c}{k^2+c^2}. \tag{2.18}$$

It is readily shown that all terms except $\tilde{m}_i=0$, $\tilde{m}_i'=0$ and $\tilde{m}''=0$ in (2.12) exponentially decay as L gets large. Although the discussion may include these decaying terms, we hereafter consider the expressions in the thermodynamic limit. Then, Z_3 becomes

$$\begin{aligned}Z_3=&\frac{1}{6}\int\frac{dk_1}{2\pi}\frac{dk_2}{2\pi}\frac{dk_3}{2\pi}(L^3+6L^2K(k_1-k_2)+9LK(k_2-k_1)K(k_3-k_1))e^{-\beta(k_1^2+k_2^2+k_3^2)}\\&-\frac{1}{2}\int\frac{dk_1'}{2\pi}\frac{dk_2'}{2\pi}(L^2+3LK(k_1-k_2))e^{-\beta(2k_1'^2+k_3'^2)}+\frac{1}{3}\int\frac{dk''}{2\pi}Le^{-\beta(3k^2)}.\end{aligned} \tag{2.19}$$

It is much easier to show

$$Z_2=\frac{1}{2}\int\frac{dk_1'}{2\pi}\frac{dk_2'}{2\pi}(L^2+2LK(k_1-k_2))e^{-\beta(k_1'^2+k_3'^2)}-\frac{1}{2}\int\frac{dk''}{2\pi}Le^{-\beta(2k''^2)}. \tag{2.20}$$

From (2.8), (2.19), and (2.20), the cluster integral b_3 is given by

$$\begin{aligned}b_3=&\frac{1}{L}\left(Z_3-Z_2Z_1+\frac{1}{3}Z_1^3\right)=\frac{3}{2}\int\frac{dk_1}{2\pi}\frac{dk_2}{2\pi}\frac{dk_3}{2\pi}K(k_2-k_1)K(k_3-k_1)e^{-\beta(k_1^2+k_2^2+k_3^2)}\\&-\frac{3}{2}\int\frac{dk_1'}{2\pi}\frac{dk_2'}{2\pi}K(k_1-k_2)e^{-\beta(2k_1'^2+k_3'^2)}+\frac{1}{3}\int\frac{dk''}{2\pi}e^{-\beta(3k^2)}.\end{aligned} \tag{2.21}$$

Thanks to the effective interaction $K(k)$, b_3 consists of only 3 terms. In the next section, we show that Z_n and b_n can be calculated in the same way.

III. PARTITION FUNCTION AND GRAPHS

A. Partition function

In order to present a general structure of the partition function, we need to explain some terminology in the theory of partition;[14] the partially ordered set (poset, for short).

Let $\Pi(S)$ denote a set of all partitions of a finite set S. In what follows, $[n]$ means a set $\{1,2,\ldots,n\}$, and write Π_n for $\Pi([n])$. We define partially order in $\Pi(S)$ by *refinement*, that is, define $x\leqslant y\in\Pi(S)$ if every block of x is contained in a block of y. For example, if $x\in\Pi_9$ has blocks 137-2-46-58-9 and $y\in\Pi_9$ has blocks 13467-2589, then $x\leqslant y$. Special elements in $\Pi(S)$ are $\hat{0}_S$ and $\hat{1}_S$ such that $x\geqslant\hat{0}_S$ and $x\leqslant\hat{1}_S$ for all $x\in\Pi(S)$. We write $\hat{0}_n$ and $\hat{1}_n$ for $\hat{0}_{[n]}$ and $\hat{1}_{[n]}$. Figure 1 shows the partially ordered elements in Π_3, that is, 1-2-3$<$1-23, 2-13, 3-12$<$123. In

addition, we define Möbius function of $\Pi(S)$ inductively as follows:

$$\mu(x,x)=1 \quad \text{for all } x\in\Pi(S),$$

$$\mu(x,y)=-\sum_{x\leqslant z<y}\mu(x,z) \quad \text{for all } x<y \text{ in } \Pi(S). \tag{3.1}$$

By use of those definitions, we can show some useful relations. For brevity, $\mathbb{N}$ and $\mathbb{C}$ stand, respectively, non-negative integers and complex numbers. (1) Let $\hat{f},\hat{g}:\Pi(S)\to\mathbb{C}$, then,

$$\hat{g}(x)=\sum_{y\geqslant x}\hat{f}(y), \quad \text{for all } x\in\Pi(S),$$

if and only if

$$\hat{f}(x)=\sum_{y\geqslant x}\mu(x,y)\hat{g}(y), \quad \text{for all } x\in\Pi(S). \tag{3.2}$$

This is called the Möbius inversion formula. (2) Let $\hat{g},\hat{J}:\Pi(S)\to\mathbb{C}$ and $f,h:\mathbb{N}\to\mathbb{C}$. If

$$\sum_{n\geqslant 0}h(n)\frac{u^n}{n!}=\exp\left(\sum_{n\geqslant 1}f(n)\frac{u^n}{n!}\right), \tag{3.3}$$

$$h(N_S)=\sum_{x\in\Pi(S)}\mu(\hat{0}_S,x)\hat{g}(x), \tag{3.4}$$

$$\hat{g}(x)=\sum_{\xi\in\Pi(x)}\prod_{y\in\xi}\hat{J}(y), \tag{3.5}$$

then

$$f(n)=\sum_{x\in\Pi_n}\mu(\hat{0}_n,x)\hat{J}(x). \tag{3.6}$$

We prove this relation in the Appendix.

With these two relations, we can derive the partition function Z_n and the cluster integral b_n in a compact way. First we define $f,h:\mathbb{N}\to\mathbb{C}$ and $\hat{h},\hat{g}:\Pi(S)\to\mathbb{C}$,

$$f(n)\equiv n!Lb_n, \tag{3.7}$$

$$h(n)\equiv n!Z_n, \tag{3.8}$$

$$\hat{h}(x)\equiv\sum_{m_1'\neq\cdots\neq m_l'}e^{-\beta(k_1^2+\cdots+k_n^2)}, \tag{3.9}$$

$$\hat{g}(x)\equiv\sum_{m_1',\cdots,m_l'}e^{-\beta(k_1^2+\cdots+k_n^2)}, \tag{3.10}$$

where

$$x\in\Pi(S), \quad \sigma_i\ni s_j\Rightarrow m_i'=m_j, \quad x=\{\sigma_1,\ldots,\sigma_l\}, \quad S=\{s_1,\ldots,s_n\}. \tag{3.11}$$

Recall that m and k are related by the BA equation. We see that Eq. (3.3) holds from the definition of cluster integral b_n, Eq. (2.7). From the definition (3.8)–(3.10), it is easy to show that

$$\hat{g}(x)=\sum_{y\geqslant x}\hat{h}(y), \tag{3.12}$$

$$\hat{h}(\hat{0}_n)=h(n). \tag{3.13}$$

Due to the Möbius inversion formula (3.2), (3.12) is equivalent to

$$\hat{h}(x)=\sum_{y\geqslant x}\mu(x,y)\hat{g}(y). \tag{3.14}$$

Substituting $\hat{0}_n$ for x in this equation, we obtain

$$h(n)=\sum_{y\in\Pi_n}\mu(\hat{0}_n,y)\hat{g}(y). \tag{3.15}$$

This is nothing but condition (3.4).

As we have mentioned in the previous section, we do not include exponentially decaying terms. Then, (3.10) is written as

$$\hat{g}(x)=\int\prod_{\sigma\in x}dm'_\sigma e^{-\beta(k_1^2+k_2^2+\cdots+k_n^2)} \tag{3.16}$$

$$=\int\prod_{\sigma\in x}dk'_\sigma\left|\frac{\partial m'}{\partial k'}\right|e^{-\beta(\Sigma_{\sigma\in x}N_\sigma k'^2_\sigma)}. \tag{3.17}$$

The transformation matrix and the Jacobian are given as follows:

$$\frac{\partial m'_\sigma}{\partial k'_{\sigma'}}=\frac{1}{2\pi}\times\begin{cases}L+\displaystyle\sum_{\sigma''\neq\sigma}N_{\sigma''}K(k'_{\sigma''}-k'_\sigma) & \text{if } \sigma=\sigma'\\ -N_{\sigma'}K(k'_{\sigma'}-k'_\sigma) & \text{if } \sigma\neq\sigma'\end{cases} \tag{3.18}$$

$$\sigma,\sigma',\sigma''\in x$$

$$\left|\frac{\partial m'}{\partial k'}\right|=\sum_{\xi\in\Pi(x)}\prod_{y\in\xi}\frac{L}{(2\pi)^{N_y}}\left(\sum_{\sigma\in y}N_\sigma\right)\sum_{t\in\mathcal{V}(y)}\left(\prod_{\sigma\in y}N_\sigma^{n(\sigma,t)-1}\right)$$

$$\times\left(\prod_{b\in\Xi(t)}K(k'_{\sigma_1(b)}-k'_{\sigma_2(b)})\right). \tag{3.19}$$

We explain the notations in (3.18) and (3.19). The number of elements in a set σ is denoted by N_σ. $\mathcal{V}(S)$ denotes a set of all undirected *trees* with a *vertex* set S. For instance, all the elements in $\mathcal{V}(\{\sigma_1,\sigma_2,\sigma_3\})$ are depicted in Fig. 2. We call a connection of two vertices a *branch.* $\Xi(t)$ denotes a set of all branches contained in a tree t. $n(\sigma,t)$ is the number of branches with which the vertex σ are connected in the tree t. $\sigma_1(b)$ and $\sigma_2(b)$ denote two end-vertices connected by a branch b.

A remaining task is a consistency with (3.5). We define a function $\hat{J}:\Pi(S)\to\mathbb{C}$ by

$$\hat{J}(x)\equiv\int\prod_{\sigma\in x}dk'_\sigma\left|\frac{\partial m'}{\partial k'}\right|_c e^{-\beta(\Sigma_{\sigma\in x}N_\sigma k'^2_\sigma)}, \tag{3.20}$$

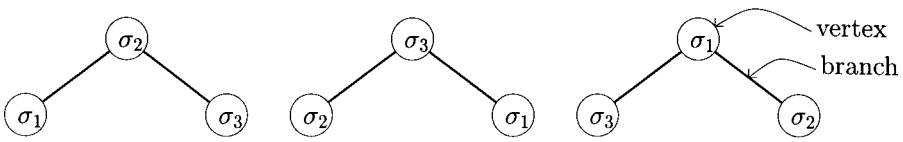

FIG. 2. A set of undirected trees, $\mathcal{V}(\{\sigma_1,\sigma_2,\sigma_3\})$, contains three elements.

where

$$\left|\frac{\partial m'}{\partial k'}\right|_c \equiv \frac{L}{(2\pi)^{N_x}}\left(\sum_{\sigma\in x} N_\sigma\right)\sum_{t\in\mathcal{V}(x)}\left(\prod_{\sigma\in x} N_\sigma^{n(\sigma,t)-1}\right)\left(\prod_{b\in\Xi(t)} K(k'_{\sigma_1(b)}-k'_{\sigma_2(b)})\right). \tag{3.21}$$

We can change the expression of the Jacobian $|\partial m'/\partial k'|$ from (3.19) into a sum of forests, that is, sets of trees. On the other hand, the right-hand side of (3.21) is a sum of connected forests, that is, trees. Therefore, we put a subscript c as $|\partial m'/\partial k'|_c$. With this definition, we see that the condition (3.5) follows from (3.17).

In this way, three conditions (3.3)–(3.5) are shown to be satisfied, which indicates that Eq. (3.6) holds. We write Eq. (3.6) explicitly,

$$b_n=\frac{1}{n!L}\sum_{x\in\Pi_n}\mu(\hat{0}_n,x)\int\prod_{\sigma\in x}dk'_\sigma\left|\frac{\partial m'}{\partial k'}\right|_c e^{-\beta(\Sigma_{\sigma\in x}N_\sigma k'^2_\sigma)}. \tag{3.22}$$

In fact, (3.15) is equivalent to

$$Z_n=\frac{1}{n!}\sum_{x\in\Pi_n}\mu(\hat{0}_n,x)\int\prod_{\sigma\in x}dk'_\sigma\left|\frac{\partial m'}{\partial k'}\right| e^{-\beta(\Sigma_{\sigma\in x}N_\sigma k'^2_\sigma)}. \tag{3.23}$$

The Jacobians in (3.22) and (3.23) are, respectively, (3.21) and (3.19). The explicit form of $\mu(\hat{0}_n,x)$ can be derived from (3.1),

$$\mu(\hat{0}_n,x)=\prod_{\sigma\in x}(-1)^{N_\sigma-1}(N_\sigma-1)! \tag{3.24}$$

It is easily shown[12,13] that the cluster integrals b_n agree with those derived from the thermal Bethe ansatz (TBA). It is also possible to derive the integral equation in TBA from (3.22).[13]

We give two remarks here. First, the Jacobian $|\partial m'/\partial k'|$ is essentially the inner product of the Bethe wave functions.[8] Second, the cluster integrals consist of only a finite number of terms.

B. Graph representation

We further develop a graphical representation of the cluster integral and the partition function. We draw an l times rolled coil for a Boltzmann weight $e^{-\beta l k^2}$ (Fig. 3). We call it l-toron following Montroll and Ward.[15,16] The *tree* consists of a toron or torons connected by branches. The *forest* consists of the trees. We denote by $\mathcal{V}_n$ a set of all the trees which satisfy the following two conditions: (1) all the vertices of the tree are made of torons, and (2) the sum of rolled number of

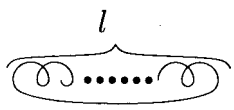

FIG. 3. l-toron.

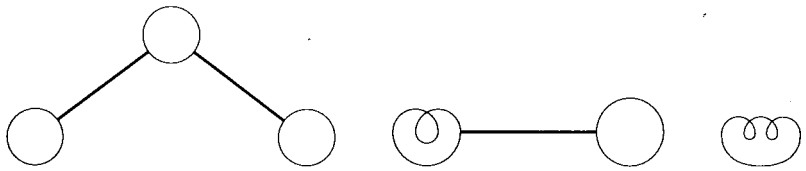

FIG. 4. A set of the trees, $\mathcal{V}_3$, contains three elements.

torons composing the tree is n. Figure 4 shows all the elements in $\mathcal{V}_3$. $\mathcal{W}_n$ is a set of all the forests which satisfy the following two conditions: (1) all the vertices of the forest are made of torons, and (2) the sum of rolled number of torons composing the forest is n. Simply, $\mathcal{V}_n$ is a subset of $\mathcal{W}_n$. Figure 5 exhibits all the elements in $\mathcal{W}_3$.

In terms of these terminologies, we may rewrite (3.23) and (3.22) as

$$Z_n = \sum_{f \in \mathcal{W}_n} \frac{Sym(f)}{n!} \prod_{t \text{ in the forest } f} \mathcal{S}(t), \tag{3.25}$$

$$b_n = \sum_{t \in \mathcal{V}_n} \frac{Sym(t)}{n!L} \mathcal{S}(t). \tag{3.26}$$

Here, $Sym(t)$ and $Sym(f)$ indicate symmetrical factors of graphs. In the case $t \in \mathcal{V}_n$ or $f \in \mathcal{W}_n$, $Sym(t)$ or $Sym(f)$ means the number of different ways in which a set $\{1,\ldots,n\}$ can be distributed to all the vertices of t or f at a time, on the condition that l elements are placed in a vertex made of l-toron. For example,

$$Sym\left(\text{  }\right) = 12, \tag{3.27}$$

$$Sym\left(\text{  }\right) = 3, \tag{3.28}$$

$$Sym\left(\text{  }\right) = 1. \tag{3.29}$$

From (3.22) and (3.23), we can show that $\mathcal{S}(t)$ in (3.25) and (3.26) is given as follows:

$$\mathcal{S}(t) \equiv L \sum_{\omega} N_\omega \left(\prod_{\omega} (-1)^{N_\omega - 1} (N_\omega - 1)! N_\omega^{n(\omega,t)-1} \right) \times \int \prod_{\omega} \frac{dk_\omega}{2\pi} \left(\prod_{b \in \Xi(t)} K(k_{\sigma_1(b)} - k_{\sigma_2(b)}) \right) e^{-\beta(\Sigma_\omega N_\omega k_\omega)}, \tag{3.30}$$

where N_ω denotes the rolled number of toron ω, and Σ_ω (or Π_ω) denotes a sum (or a product) with respect to all the toron ω in the tree t. For example,

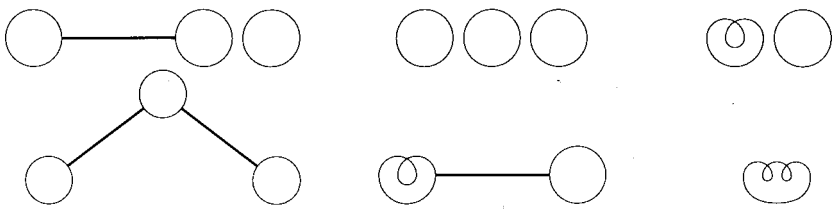

FIG. 5. A set of the forests, $\mathcal{W}_3$. Three graphs in the first line are not trees because the vertices are not connected on partially connected by branch(es).

$$\mathcal{S}\left(\circledcirc\!\!-\!\!\circ\right) = L\times(2+1)\times\left((-1)^1\,1!2^0\times(-1)^0\,0!1^0\right) \times\int\frac{dk_{\omega_1}}{2\pi}\frac{dk_{\omega_2}}{2\pi}\left(K\left(k_{\omega_1}-k_{\omega_2}\right)\right)e^{-\beta\left(2k_{\omega_1}+k_{\omega_2}\right)}. \tag{3.31}$$

Substitution of (3.28) and (3.31) gives the second term in (2.21).

As examples, we list a graphical representation of the cluster integrals $b_1\sim b_4$,

$b_1 =$  (3.32)

$b_2 =$  (3.33)

$b_3 =$  (3.34)

$b_4 =$  (3.35)

IV. CONCLUDING REMARKS AND DISCUSSIONS

In this paper, we have studied a one-dimensional δ-function bose gas, (1.1), and have derived directly the partition function and the cluster integral, (3.23) and (3.22), from the Bethe ansatz equation, (2.2). This should be regarded as a proof of the thermal Bethe ansatz (TBA). The derivation is simplified by use of the partially ordered set in the theory of partition.

This direct method has some advantages. First, the method is rigorous. In the quantum field theoretic method, calculation is done at the infinite volume, therefore an interpretation of $2\pi\delta(0)$ as the volume is unavoidable. In the TBA, it is necessary to define the n-particle entropy. This procedure is based on an interpretation of the particle and state densities. In this sense, both field theoretic method and TBA remained to be proved. On the other hand, the direct method is free from such interpretations, and all calculations are traceable step by step.

Second, the method has a wide applicability. It should be remarked that in the direct method all the dependencies on the systems come only from the BA equation. In other words, the direct method may have the generality at least as well as TBA.

We conclude that the direct method will be useful and important in calculating the thermodynamic quantities in various integrable systems.

APPENDIX: A PROOF OF (3.6)

We use the same notation as in Sec. III A. It can be shown that, on condition that $h,f:\mathbb{N}\to\mathbb{C}$, we have

$$\sum_{n\geqslant 0}h(n)\frac{u^n}{n!}=\exp\left(\sum_{n\geqslant 1}f(n)\frac{u^n}{n!}\right) \tag{A1}$$

if and only if

$$h(n)=\sum_{x\in\Pi_n}\prod_{\sigma\in x}f(N_\sigma), \tag{A2}$$

$$h(0)=1. \tag{A3}$$

This is known as the cumulant expansion formula. Equation (A2) is equivalent to

$$\prod_{\sigma\in x}h(N_\sigma)=\sum_{y\leqslant x}\prod_{\sigma\in y}f(N_\sigma). \tag{A4}$$

For $\hat{H},\hat{F}:\Pi(S)\to\mathbb{C}$, the following relation holds:

$$\hat{H}(x)=\sum_{y\leqslant x}\hat{F}(y)\Leftrightarrow\hat{F}(x)=\sum_{y\leqslant x}\mu(x,y)\hat{H}(y). \tag{A5}$$

This is the Möbius inversion formula, which is a dual form of (3.2). With this formula, Eq. (A4) becomes

$$\prod_{\sigma\in x}f(N_\sigma)=\sum_{y\leqslant x}\mu(y,x)\prod_{\sigma\in y}h(N_\sigma). \tag{A6}$$

Substitution of $\hat{1}_n$ for x in (A6) yields

$$f(n)=\sum_{x\leqslant\hat{1}_n}\mu(y,\hat{1}_n)\prod_{\sigma\in y}h(N_\sigma). \tag{A7}$$

We suppose the existence of $\hat{g}:\Pi(S)\to\mathbb{C}$ which satisfies

$$h(N_S)=\sum_{x\in\Pi(S)}\mu(\hat{0}_S,x)\hat{g}(x). \tag{A8}$$

Using this relation, Eq. (A6) is written as

$$f(n)=\sum_{x\in\Pi_n}\mu(x,\hat{1}_n)\prod_{\sigma\in x}\sum_{y\in\Pi(\sigma)}\mu(\hat{0}_\sigma,y)\hat{g}(y)=\sum_{x\in\Pi_n}\mu(\hat{0}_n,x)\sum_{\xi\in\Pi(x)}\mu(\xi,\hat{1}_x)\prod_{y\in\xi}\hat{g}(y). \tag{A9}$$

In the second equality, we have used the following two relations:

$$\sum_{x\in\Pi_n}F(N_x)\prod_{\sigma\in x}\sum_{y\in\Pi(\sigma)}\hat{G}(y)=\sum_{x\in\Pi_n}\sum_{\xi\in\Pi(x)}F(N_\xi)\prod_{y\in\xi}\hat{G}(y), \tag{A10}$$

for $F:\mathbb{N}\to\mathbb{C}$, $\hat{G}:\Pi(S)\to\mathbb{C}$, and

$$\mu(\hat{0}_n,x)=\prod_{\sigma\in x}\mu(\hat{0}_{N_\sigma},\hat{1}_{N_\sigma}), \tag{A11}$$

for $x\in\Pi_n$. And, we suppose the existence of a map $\hat{J}:\Pi(S)\to\mathbb{C}$ which satisfies

$$\hat{g}(x)=\sum_{\xi\in\Pi(x)}\prod_{y\in\xi}\hat{J}(y). \tag{A12}$$

Then, a main part of the right-hand side of Eq. (A9) becomes

$$\begin{aligned}\sum_{\xi\in\Pi(x)}\mu(\xi,\hat{1}_x)\prod_{y\in\xi}\hat{g}(y)&=\sum_{\xi\in\Pi(x)}\mu(\xi,\hat{1}_x)\prod_{y\in\xi}\sum_{\zeta\in\Pi(y)}\prod_{z\in\zeta}\hat{J}(z)\\&=\sum_{\zeta\in\Pi(x)}\left(\sum_{\lambda\in\Pi(\zeta)}\mu(\lambda,\hat{1}_\zeta)\right)\prod_{z\in\zeta}\hat{J}(z)=\hat{J}(x).\end{aligned} \tag{A13}$$

The third equality is due to the following relation:

$$\sum_{x \in \Pi(S)} \mu(x, \hat{1}_S) = \delta(1, N_S). \tag{A14}$$

By use of relation (A13), (A9) becomes

$$f(n) = \sum_{x \in \Pi_n} \mu(\hat{0}_n, x) \hat{J}(x), \tag{A15}$$

which is (3.6). To summarize, using (A1), (A8), and (A12), we have proved (3.6).

(Received 1 March 2001; accepted for publication 17 May 2001)

We study the elliptic C_n and BC_n Ruijsenaars–Schneider models which are elliptic generalization of systems given in previous paper by the present authors [Chen *et al.*, J. Math. Phys. **41**, 8132 (2000)]. The Lax pairs for these models are constructed by Hamiltonian reduction technology. We show that the spectral curves can be parametrized by the involutive integrals of motion for these models. Taking nonrelativistic limit and scaling limit, we verify that they lead to the systems corresponding to Calogero–Moser and Toda types. © *2001 American Institute of Physics.* [DOI: 10.1063/1.1389091]

I. INTRODUCTION

The Ruijsenaars–Schneider (RS) and Calogero–Moser (CM) models, as integrable many-body models, recently have attracted remarkable attention and have been extensively studied. They describe one-dimensional N-particle systems with pairwise interaction. Their importance lies in various fields ranging from lattice models in statistics physics,[1,2] to the field theory and gauge theory,[3,4] to the Seiberg–Witten theory,[5] etc. In particular, the study of the RS model is of great importance since it is the integrable relativistic generalization of the corresponding CM model.[6,7]

The Lax pairs for the CM models in various root systems have been constructed by Olshanetsky, and Perelomov[8] using reduction on symmetric space, and are further given by Inozemtsev in Ref. 9 without spectral parameter. It was almost 20 years until D'Hoker and Phong[10] constructed the Lax pairs with a spectral parameter for each of the finite dimensional Lie algebras, and the untwisted and twisted Calogero–Moser systems were introduced. Subsequently, Bordner *et al.*[11–13] succeeded in giving two types of Lax pairs associated to all of the Lie algebra: the root type and the minimal type, with and without spectral parameters. Even for all of the Coxeter group, the construction has been obtained in Ref. 14. In Ref. 15, Hurtubise and Markman utilized a so-called ''structure group,'' which combines a semisimple group and Weyl group, to construct CM systems associated with the Hitchin system, which in some degree generalizes the result of Refs. 10–14. Furthermore, the quantum version of the generalization has been developed in Refs. 16 and 17 at least for degenerate potentials of trigonometry after the works of Olshanetsky and Perelomov.[18]

So far as for the RS model, only the Lax pair of the A_{N-1} type RS model was obtained[6,2,19–22] and succeeded in recovering it by applying the Hamiltonian reduction procedure on a two-dimensional current group.[23] Although the commutative operators for the RS model based on various type Lie algebras have been given by Komori and co-workers,[24,25] Diejen,[26,27] and Hasegawa *et al.*,[1,28] the Lax integrability (or Lax pair representation) of the other type of RS model is still an open problem[5] except for a few degenerate cases.[27,30]

In Refs. 29 and 30, we succeeded in constructing the Lax pair for C_n and BC_n RS systems only with the degenerate case (without spectral parameters). The r-matrix structure for them have been derived by Avan *et al.*[31] In this paper, we study the Lax pair for the most general C_n and BC_n RS models—the elliptic C_n and BC_n RS models. We shall give the explicit forms of Lax pairs for these systems by Hamiltonian reduction. We calculate the spectral curves for these systems, which are shown to be parametrized by a set of involutive integrals of motion. In particular, taking their nonrelativistic limit and scaling limit, we shall recover the systems of corresponding CM and Toda types, respectively. The other various degenerate cases are also be discussed and the connection between the Lax pair with a spectral parameter and the one without the spectral parameter is commented on.

The paper is organized as follows. The basic materials of the A_{N-1} RS model are reviewed in Sec. II, where we propose a Lax pair associating with the Hamiltonian which has a reflection symmetry with respect to the particles in the origin. This includes construction of a Lax pair for the A_{N-1} RS system together with its symmetry analysis. The main results are shown in Secs. III and IV. In Sec. III, we present the Lax pairs for the elliptic C_n and BC_n RS models by reducing the A_{N-1} RS model. The explicit forms for the Lax pairs are given in Sec. IV. Section V is devoted to deriving the spectral curves for these systems and their nonrelativistic counterpart, the Calogero–Moser model and scaling limit of the Toda model. Section VI shows the various degenerate limits: the trigonometric, hyperbolic, and rational cases. The last section is a brief summary and discussion.

II. THE A_{N-1}-TYPE RUIJSENAARS–SCHNEIDER MODEL

As a relativistic-invariant generalization of the A_{N-1}-type nonrelativistic Calogero–Moser model, the A_{N-1}-type Ruijsenaars–Schneider systems are completely integrable. The system's integrability was first shownd by Ruijsenaars.[6,7] The Lax pair for this model has been constructed in Refs. 6, 2, 19–22. Recent progress has shown that the compactification of higher dimension SUSY Yang–Mills theory and Seiberg–Witten theory can be described by this model.[5] Instanton correction of the prepotential associated with the sl_2 RS system has been calculated in Ref. 32.

A. Model and equations of motion

Let us briefly give the basics of this model. In terms of the canonical variables p_i, $x_i (i,j=1,\ldots,N)$ enjoying the canonical Poisson bracket

$$\{p_i,p_j\}=\{x_i,x_j\}=0, \quad \{x_i,p_j\}=\delta_{ij}, \tag{II.1}$$

the Hamiltonian of the A_{N-1} RS system reads

$$\mathcal{H}_{A_{N-1}}=\sum_{i=1}^{N}\left(e^{p_i}\prod_{k\neq i} f(x_i-x_k)+e^{-p_i}\prod_{k\neq i} g(x_i-x_k)\right), \tag{II.2}$$

where

$$\begin{aligned} f(x)&:=\frac{\sigma(x-\gamma)}{\sigma(x)},\\ g(x)&:=f(x)\big|_{\gamma\to-\gamma}, \quad x_{ik}:=x_i-x_k, \end{aligned} \tag{II.3}$$

and γ denotes the coupling constant. Here, $\sigma(x)$ is the Weierstrass σ function which is an entire, odd and quasiperiodic function with a fixed pair of the primitive quasiperiods $2\omega_1$ and $2\omega_3$. It can be defined as the infinite product

$$\sigma(x)=x\prod_{w\in\Gamma\setminus\{0\}}\left(1-\frac{x}{w}\right)\exp\left[\frac{x}{w}+\frac{1}{2}\left(\frac{x}{w}\right)^2\right],$$

where $\Gamma=2\omega_1\mathbb{Z}+2\omega_3\mathbb{Z}$ is the corresponding period lattice. Defining a third dependent quasiperiod $2\omega_2=-2\omega_1-2\omega_3$, one has

$$\sigma(x+2\omega_k)=-\sigma(x)e^{2\eta_k(x+\omega_k)},\quad \zeta(x+2\omega_k)=\zeta(x)+2\,\eta_k,\quad k=1,2,3,$$

where

$$\zeta(x)=\frac{\sigma'(x)}{\sigma(x)},\quad \wp(x)=-\zeta'(x),$$

and $\eta_k=\zeta(\omega_k)$ satisfy $\eta_1\omega_3-\eta_3\omega_1=\pi i/2$.

Notice that in Ref. 6 Ruijsenaars used another "gauge" of the momenta such that two are connected by the following canonical transformation:

$$x_i\to x_i,\quad p_i\to p_i+\frac{1}{2}\ln\prod_{j\neq i}^{N}\frac{f(x_{ij})}{g(x_{ij})}. \tag{II.4}$$

The Lax matrix for this model has the form(for the general elliptic case)

$$L(\lambda)=\sum_{i,j=1}^{N}\frac{\Phi(x_i-x_j+\gamma,\lambda)}{\Phi(\gamma,\lambda)}\exp(p_j)b_jE_{ij}, \tag{II.5}$$

where

$$\Phi(x,\lambda):=\frac{\sigma(x+\lambda)}{\sigma(x)\sigma(\lambda)},\quad b_j:=\prod_{k\neq j}f(x_j-x_k),\quad (E_{ij})_{kl}=\delta_{ik}\delta_{jl} \tag{II.6}$$

and λ is the spectral parameter. It is shown in Refs. 21, 33, 34 that the Lax operator satisfies the quadratic fundamental Poisson bracket

$$\{L_1,L_2\}=L_1L_2a_1-a_2L_1L_2+L_2s_1L_1-L_1s_2L_2, \tag{II.7}$$

where $L_1=L_{A_{N-1}}\otimes Id, L_2=Id\otimes L_{A_{N-1}}$ and the four matrices read

$$\begin{aligned} &a_1=a+w,\quad s_1=s-w,\\ &a_2=a+s-s^*-w,\quad s_2=s^*+w. \end{aligned} \tag{II.8}$$

The forms of a,s,w are

$$\begin{aligned} a(\lambda,\mu)&=-\zeta(\lambda-\mu)\sum_{k=1}^{N}E_{kk}\otimes E_{kk}-\sum_{k\neq j}\Phi(x_j-x_k,\lambda-\mu)E_{jk}\otimes E_{kj},\\ s(\lambda)&=\zeta(\lambda)\sum_{k=1}^{N}E_{kk}\otimes E_{kk}+\sum_{k\neq j}\Phi(x_j-x_k,\lambda)E_{jk}\otimes E_{kk},\\ w&=\sum_{k\neq j}\zeta(x_k-x_j)E_{kk}\otimes E_{jj}. \end{aligned} \tag{II.9}$$

The asterisk means

$$r^*=\Pi r\Pi\ \text{ with }\ \Pi=\sum_{k,j=1}^{N}E_{kj}\otimes E_{jk}. \tag{II.10}$$

Noticing that

$$L(\lambda)^{-1}{}_{ij}=\frac{\sigma(\gamma+\lambda)\sigma(\lambda+(N-1)\gamma)}{\sigma(\lambda)\sigma(\lambda+N\gamma)}\times\sum_{i,j=1}^{N}\frac{\Phi(x_i-x_j-\gamma,\lambda+N\gamma)}{\Phi(-\gamma,\lambda+N\gamma)}\exp(-p_i)b_j'E_{ij}, \tag{II.11}$$

$$b_j':=\prod_{k\neq j}g(x_j-x_k) \tag{II.12}$$

(the proof of the above-given identity is sketched in the Appendix) one can get the characteristic polynomials of $L_{A_{N-1}}$ (Refs. 35 and 34),

$$\det(L(\lambda)-v\cdot Id)=\sum_{j=0}^{N}\Phi(\gamma,\lambda)^{-j}(-v)^{N-j}\frac{\mathcal{H}_j^+}{\sigma^j(\gamma)}\times\frac{\sigma(\lambda+j\gamma)}{\sigma(\lambda)}, \tag{II.13}$$

and that of $L^{-1}_{A_{N-1}}$ by using formula given in Eq. (A8),

$$\begin{aligned}&\det\left(\frac{\sigma(\lambda)\sigma(\lambda-N\gamma)}{\sigma(\lambda-\gamma)\sigma(\lambda-(N-1)\gamma)}\times L(\lambda-N\gamma)^{-1}-v\cdot Id\right)\\&\quad=\sum_{j=0}^{N}\Phi(-\gamma,\lambda)^{-j}(-v)^{N-j}\times\frac{(\mathcal{H}_j^-)}{\sigma^j(-\gamma)}\frac{\sigma(\lambda-j\gamma)}{\sigma(\lambda)},\end{aligned} \tag{II.14}$$

where $(\mathcal{H}_0^{\pm})_{A_{N-1}}=(\mathcal{H}_N^{\pm})_{A_{N-1}}=1$, and

$$(\mathcal{H}_i^+)_{A_{N-1}}=\sum_{\substack{J\subset\{1,\ldots,N\}\\|J|=i}}\exp\left(\sum_{j\in J}p_j\right)\prod_{\substack{j\in J\\k\in\{1,\ldots,N\}\setminus J}}f(x_j-x_k), \tag{II.15}$$

$$(\mathcal{H}_i^-)_{A_{N-1}}=\sum_{\substack{J\subset\{1,\ldots,N\}\\|J|=i}}\exp\left(\sum_{j\in J}-p_j\right)\prod_{\substack{j\in J\\k\in\{1,\ldots,N\}\setminus J}}g(x_j-x_k). \tag{II.16}$$

Defining

$$(\mathcal{H}_i)_{A_{N-1}}=(\mathcal{H}_i^+)_{A_{N-1}}+(\mathcal{H}_i^-)_{A_{N-1}}, \tag{II.17}$$

from the fundamental Poisson bracket Eq. (II.7), we can verify that

$$\{(\mathcal{H}_i)_{A_{N-1}},(\mathcal{H}_j)_{A_{N-1}}\}=\{(\mathcal{H}_i^{\varepsilon})_{A_{N-1}},(\mathcal{H}_j^{\varepsilon'})_{A_{N-1}}\}=0,\quad \varepsilon,\varepsilon'=\pm,\quad i,j=1,\ldots,N. \tag{II.18}$$

In particular, the Hamiltonian Eq. (II.2) can be rewritten as

$$\begin{aligned}\mathcal{H}_{A_{N-1}}\equiv\mathcal{H}_1&=(\mathcal{H}_1^+)_{A_{N-1}}+(\mathcal{H}_1^-)_{A_{N-1}}\\&=\sum_{j=1}^{N}(e^{p_j}b_j+e^{-p_j}b_j')\\&=\mathrm{Tr}\left(L(\lambda)+\frac{\sigma(\lambda)\sigma(\lambda+N\gamma)}{\sigma(\gamma+\lambda)\,\sigma(\lambda+(N-1)\gamma)}L(\lambda)^{-1}\right).\end{aligned} \tag{II.19}$$

It should be remarked that the set of integrals of motion Eq. (II.17) has a reflection symmetry which is the key property for the later reduction to C_n and BC_n cases, i.e., if we set

$$p_i \leftrightarrow -p_i, \quad x_i \leftrightarrow -x_i, \tag{II.20}$$

then the Hamiltonians flows $(\mathcal{H}_i)_{A_{N-1}}$ are invariant with respect to this symmetry.

The canonical equations of motion associated with the Hamiltonian flows $\mathcal{H}_1^+$ in its generic (elliptic) form read

$$\ddot{x}_i = \sum_{j \neq i} \dot{x}_i \dot{x}_j (V(x_{ij}) - V(x_{ji})), \quad i = 1, \ldots, N, \tag{II.21}$$

where the potential $V(x)$ is given by

$$V(x) = \zeta(x) - \zeta(x+\lambda), \tag{II.22}$$

in which $\zeta(x) = \sigma'(x)/\sigma(x)$. Here, $x_i = x_i(t)$, $p_i = p_i(t)$, and the superimposed dot denotes t differentiation.

B. The construction of Lax pair for the A_{N-1} RS model

As for the A_{N-1} RS model, a generalized Lax pair has been given in Refs. 6, 2, and 19–22. But there is a common character that the time evolution of the Lax matrix $L_{A_{N-1}}$ is associated with the Hamiltonian $(\mathcal{H}_1^+)_{A_{N-1}}$. We will see in Sec. III that the Lax pair cannot reduce from that kind of forms directly. Instead, we give a new Lax pair in which the evolution of $L_{A_{N-1}}$ is associated with the Hamiltonian $\mathcal{H}_{A_{N-1}}$,

$$\dot{L}_{A_{N-1}} = \{L_{A_{N-1}}, \mathcal{H}_{A_{N-1}}\} = [M_{A_{N-1}}, L_{A_{N-1}}], \tag{II.23}$$

where $M_{A_{N-1}}$ can be constructed with the help of (r,s) matrices as follows:

$$M_{A_{N-1}} = \mathrm{Tr}_2\left((s_1 - a_2)\left(1 \otimes \left(L(\lambda) - \frac{\sigma(\lambda)\sigma(\lambda + N\gamma)}{\sigma(\gamma+\lambda)\,\sigma(\lambda+(N-1)\gamma)} L(\lambda)^{-1} \right) \right) \right). \tag{II.24}$$

The explicit expression of entries for $M_{A_{N-1}}$ is

$$M_{ij} = \Phi(x_{ij}, \lambda) e^{p_j} b_j - \Phi(x_{ij}, \lambda + N\gamma) e^{-p_i} b_j', \quad i \neq j, \tag{II.25}$$

$$M_{ii} = (\zeta(\lambda) + \zeta(\gamma)) e^{p_i} b_i - (\zeta(\lambda+\gamma) - \zeta(\gamma)) e^{-p_i} b_i' \tag{II.26}$$

$$+ \sum_{j \neq i} \left((\zeta(x_{ij} + \gamma) - \zeta(x_{ij})) e^{p_j} b_j \right.$$

$$\left. + \frac{\Phi(x_{ji} + \gamma, \lambda)}{\Phi(\gamma, \lambda)} \Phi(x_{ij}, \lambda + N\gamma) e^{-p_i} b_j' \right). \tag{II.27}$$

III. HAMILTONIAN REDUCTION OF C_n AND BC_n RS MODELS FROM A_{N-1}-TYPE MODELS

Let us first mention some results about the integrability of Hamiltonian (II.2). In Ref. 7 Ruijsenaars demonstrated that the symplectic structure of the C_n- and BC_n-types of RS systems can be proved integrable by embedding their phase space to a submanifold of the A_{2n-1} and A_{2n} type RS ones, respectively, while in Refs. 26, 27, and 25, Diejen and Komori, respectively, gave a series of commuting difference operators which led to their quantum integrability. However, there are not any results about their Lax representations so far except for the special degenerate case.[29,30] In this section, we concentrate our treatment on the exhibition of the explicit forms for general C_n and BC_n RS systems.

For the convenience of analysis of symmetry, let us first give vector representation of A_{N-1} Lie algebra. Introducing an N-dimensional orthonormal basis of $\mathbb{R}^N$,

$$e_j \cdot e_k = \delta_{j,k}, \quad j,k=1,\ldots,N. \tag{III.1}$$

Then the sets of roots and vector weights of A_{N-1} type are,

$$\Delta = \{e_j - e_k : j,k=1,\ldots,N\}, \tag{III.2}$$

$$\Lambda = \{e_j : j=1,\ldots,N\}. \tag{III.3}$$

The dynamical variables are canonical coordinates $\{x_j\}$ and their canonical conjugate momenta $\{p_j\}$ with the Poisson brackets of Eq. (II.1). In a general sense, we denote them by N-dimensional vectors x and p,

$$x=(x_1,\ldots,x_N)\in\mathbb{R}^N, \quad p=(p_1,\ldots,p_N)\in\mathbb{R}^N,$$

so that the scalar products of x and p with the roots $\alpha\cdot x$, $p\cdot\beta$, etc., can be defined. The Hamiltonian of Eq. (II.2) can be rewritten as

$$\mathcal{H}_{A_{N-1}} = \sum_{\mu\in\Lambda}\left(\exp(\mu\cdot p)\prod_{\Delta\ni\beta=\mu-\nu} f(\beta\cdot x)+\exp(-\mu\cdot p)\prod_{\Delta\ni\beta=-\mu+\nu} g(\beta\cdot x)\right). \tag{III.4}$$

Here, the condition $\Delta\ni\beta=\mu-\nu$ means that the summation is over roots β such that for $\exists\,\nu\in\Lambda$,

$$\mu-\nu=\beta\in\Delta. \tag{III.5}$$

So does for $\Delta\ni\beta=-\mu+\nu$.

A. The C_n model

The set of C_n roots consists of two parts, long roots and short roots:

$$\Delta_{C_n}=\Delta_L\cup\Delta_S, \tag{III.6}$$

in which the roots are conveniently expressed in terms of an orthonormal basis of $\mathbb{R}^n$:

$$\begin{aligned}\Delta_L&=\{\pm 2e_j: \quad j=1,\ldots,n\},\\ \Delta_S&=\{\pm e_j\pm e_k,: \quad j,k=1,\ldots,n\}.\end{aligned} \tag{III.7}$$

In the vector representation, vector weights Λ are

$$\Lambda_{C_n}=\{e_j,-e_j: \quad j=1,\ldots,n\}. \tag{III.8}$$

The Hamiltonian of the C_n model is given by

$$\mathcal{H}_{C_n}=\frac{1}{2}\sum_{\mu\in\Lambda_{C_n}}\left(\exp(\mu\cdot p)\prod_{\Delta_{C_n}\ni\beta=\mu-\nu} f(\beta\cdot x)+\exp(-\mu\cdot p)\prod_{\Delta_{C_n}\ni\beta=-\mu+\nu} g(\beta\cdot x)\right). \tag{III.9}$$

From the above-mentioned data, we notice that either for A_{N-1} or C_n Lie algebra, any root $\alpha\in\Delta$ can be constructed in terms with vector weights as $\alpha=\mu-\nu$ where $\mu,\nu\in\Lambda$. By simple comparison of representation between A_{N-1} and C_n, one can find that if replacing e_{j+n} with $-e_j$

in the vector weights of A_{2n-1} algebra, we can obtain the vector weights of C_n algebra. This also holds for the corresponding roots. This gives us a hint that it is possible to get the C_n model by this kind of reduction.

For the A_{2n-1} model let us set restrictions on the vector weights with

$$e_{j+n}+e_j=0, \quad \text{for } j=1,\ldots,n, \tag{III.10}$$

which correspond to the following constraints on the phase space of the A_{2n-1}-type RS model with

$$\begin{aligned} G_i &\equiv (e_{i+n}+e_i)\cdot x = x_i + x_{i+n} = 0, \\ G_{i+n} &\equiv (e_{i+n}+e_i)\cdot p = p_i + p_{i+n} = 0, \quad i=1,\ldots,n. \end{aligned} \tag{III.11}$$

Following Dirac's method,[36] we can show

$$\{G_i, \mathcal{H}_{A_{2n-1}}\} \simeq 0, \quad \text{for } \forall i \in \{1,\ldots,2n\}, \tag{III.12}$$

i.e., $\mathcal{H}_{A_{2n-1}}$ is the first class Hamiltonian corresponding to the constraints in Eq. (III.11). Here the "weak equal" symbol $\simeq$ represents that only after calculating the result of the left-hand side of the identity could we use the conditions of constraints. It should be pointed out that the most necessary condition ensuring Eq. (III.12) is the symmetry property of formula (II.20) for the Hamiltonian Eq. (II.2). So for an arbitrary dynamical variable A, we have

$$\begin{aligned} \dot{A} &= \{A, \mathcal{H}_{A_{2n-1}}\}_D = \{A, \mathcal{H}_{A_{2n-1}}\} - \{A, G_i\}\Delta_{ij}^{-1}\{G_j, \mathcal{H}_{A_{2n-1}}\} \\ &\simeq \{A, \mathcal{H}_{A_{2n-1}}\}, \quad i,j=1,\ldots,2n, \end{aligned} \tag{III.13}$$

where

$$\Delta_{ij} = \{G_i, G_j\} = 2\begin{pmatrix} 0 & Id \\ -Id & 0 \end{pmatrix}, \tag{III.14}$$

and $\{,\}_D$ denotes the Dirac bracket. By straightforward calculation, we have the nonzero Dirac brackets of

$$\begin{aligned} \{x_i, p_j\}_D &= \{x_{i+n}, p_{j+n}\}_D = \tfrac{1}{2}\delta_{i,j}, \\ \{x_i, p_{j+n}\}_D &= \{x_{i+n}, p_j\}_D = -\tfrac{1}{2}\delta_{i,j}. \end{aligned} \tag{III.15}$$

Using the above-mentioned data together with the fact that $\mathcal{H}_{A_{N-1}}$ is the first class Hamiltonian-[see Eq. (III.12)], we can directly obtain a Lax representation of the C_n RS model by imposing constraints G_k on Eq. (II.23),

$$\begin{aligned} \{L_{A_{2n-1}}, \mathcal{H}_{A_{2n-1}}\}_D &= \{L_{A_{2n-1}}, \mathcal{H}_{A_{2n-1}}\}|_{G_k, k=1,\ldots,2n}, \\ &= [M_{A_{2n-1}}, L_{A_{2n-1}}]|_{G_k, k=1,\ldots,2n} = [M_{C_n}, L_{C_n}], \end{aligned} \tag{III.16}$$

$$\{L_{A_{2n-1}}, \mathcal{H}_{A_{2n-1}}\}_D = \{L_{C_n}, \mathcal{H}_{C_n}\}, \tag{III.17}$$

where

$$\mathcal{H}_{C_n} = \tfrac{1}{2}\mathcal{H}_{A_{2n-1}}|_{G_k, k=1,\ldots,2n},$$

$$L_{C_n}=L_{A_{2n-1}}|_{G_k,k=1,\ldots,2n},$$
$$M_{C_n}=M_{A_{2n-1}}|_{G_k,k=1,\ldots,2n}, \tag{III.18}$$

so that

$$\dot{L}_{C_n}=\{L_{C_n},\mathcal{H}_{C_n}\}=[M_{C_n},L_{C_n}]. \tag{III.19}$$

Nevertheless, the $(\mathcal{H}_1^+)_{A_{N-1}}$ is not the first class Hamiltonian, so the Lax pair given by many authors previously cannot reduce to the C_n case directly in this way.

B. The BC_n model

The BC_n root system consists of three parts: long, middle, and short roots:

$$\Delta_{BC_n}=\Delta_L\cup\Delta\cup\Delta_S, \tag{III.20}$$

in which the roots are conveniently expressed in terms of an orthonormal basis of $\mathbb{R}^n$:

$$\begin{aligned}\Delta_L&=\{\pm 2e_j:\quad j=1,\ldots,n\},\\ \Delta&=\{\pm e_j\pm e_k:\quad j,k=1,\ldots,n\},\\ \Delta_S&=\{\pm e_j:\quad j=1,\ldots,n\}.\end{aligned} \tag{III.21}$$

In the vector representation, vector weights Λ can be

$$\Lambda_{BC_n}=\{e_j,-e_j,0:\quad j=1,\ldots,n\}. \tag{III.22}$$

The Hamiltonian of the BC_n model is given by

$$\mathcal{H}_{BC_n}=\frac{1}{2}\sum_{\mu\in\Lambda_{BC_n}}\left(\exp(\mu\cdot p)\prod_{\Delta_{BC_n}\ni\beta=\mu-\nu}f(\beta\cdot x)+\exp(-\mu\cdot p)\prod_{\Delta_{BC_n}\ni\beta=-\mu+\nu}g(\beta\cdot x)\right). \tag{III.23}$$

By similar comparison of representations between A_{N-1} and BC_n, one can find that if replacing e_{j+n} with $-e_j$ and e_{2n+1} with 0 in the vector weights of the A_{2n} Lie algebra, we can obtain the vector weights of the BC_n one. The same holds for the corresponding roots. So by the same procedure as the C_n model, we could get the Lax representation of the BC_n model.

For the A_{2n} model, we set restrictions on the vector weights with

$$\begin{aligned}e_{j+n}+e_j&=0\quad\text{for}\quad j=1,\ldots,n,\\ e_{2n+1}&=0,\end{aligned} \tag{III.24}$$

which correspond to the following constraints on the phase space of the A_{2n}-type RS model with

$$\begin{aligned}G_i'&\equiv(e_{i+n}+e_i)\cdot x=x_i+x_{i+n}=0,\\ G_{i+n}'&\equiv(e_{i+n}+e_i)\cdot p=p_i+p_{i+n}=0,\quad i=1,\ldots,n,\\ G_{2n+1}'&\equiv e_{2n+1}\cdot x=x_{2n+1}=0,\\ G_{2n+2}'&\equiv e_{2n+1}\cdot p=p_{2n+1}=0.\end{aligned} \tag{III.25}$$

Similarly, we can show

$$\{G_i, \mathcal{H}_{A_{2n}}\} \simeq 0, \quad \text{for} \quad \forall i \in \{1,\ldots,2n+1,2n+2\}, \tag{III.26}$$

i.e., $\mathcal{H}_{A_{2n}}$ is the first class Hamiltonian corresponding to the above-mentioned constraints Eq. (III.25). So L_{BC_n} and M_{BC_n} can be constructed as follows:

$$\begin{aligned} L_{BC_n} &= L_{A_{2n}}|_{G'_k, k=1,\ldots,2n+2}, \\ M_{BC_n} &= M_{A_{2n}}|_{G'_k, k=1,\ldots,2n+2}, \end{aligned} \tag{III.27}$$

while $\mathcal{H}_{BC_n}$ is

$$\mathcal{H}_{BC_n} = \tfrac{1}{2}\mathcal{H}_{A_{2n}}|_{G_k, k=1,\ldots,2n+2}, \tag{III.28}$$

due to the similar derivation of Eqs. (III.13)–(III.19).

IV. LAX REPRESENTATIONS OF THE C_n AND BC_n RS MODELS

A. The C_n model

The Hamiltonian of the C_n RS system is Eq. (III.9), so the canonical equations of motion are

$$\dot{x}_i = \{x_i, \mathcal{H}\} = e^{p_i} b_i - e^{-p_i} b'_i, \tag{IV.1}$$

$$\begin{aligned} \dot{p}_i = \{p_i, \mathcal{H}\} = &\sum_{j\neq i}^{n} \left(e^{p_j} b_j (h(x_{ji}) - h(x_j + x_i)) + e^{-p_j} b'_j (\hat{h}(x_{ji}) - \hat{h}(x_j + x_i))\right) \\ &- e^{p_i} b_i \left(2h(2x_i) + \sum_{j\neq i}^{n} (h(x_{ij}) + h(x_i + x_j))\right) \\ &- e^{-p_i} b'_i \left(2\hat{h}(2x_i) + \sum_{j\neq i}^{n} (\hat{h}(x_{ij}) + \hat{h}(x_i + x_j))\right), \end{aligned} \tag{IV.2}$$

where

$$h(x) := \frac{d \ln f(x)}{dx}, \quad \hat{h}(x) := \frac{d \ln g(x)}{dx},$$

$$b_i = f(2x_i) \prod_{k\neq i}^{n} (f(x_i - x_k) f(x_i + x_k)), \tag{IV.3}$$

$$b'_i = g(2x_i) \prod_{k\neq i}^{n} (g(x_i - x_k) g(x_i + x_k)).$$

The Lax matrix for the C_n RS model can be written in the following form:

$$(L_{C_n})_{\mu\nu} = e^{\nu\cdot p} b_\nu \frac{\Phi((\mu - \nu)\cdot x + \gamma, \lambda)}{\Phi(\gamma, \lambda)}, \tag{IV.4}$$

which is a $2n \times 2n$ matrix whose indices are labeled by the vector weights, denoted by $\mu, \nu \in \Lambda_{C_n}$, M_{C_n} can be written as

$$M_{C_n}=D+Y, \tag{IV.5}$$

where D denotes the diagonal part and Y denotes the off-diagonal part

$$Y_{\mu\nu}=e^{\nu\cdot p}b_\nu\Phi(x_{\mu\nu},\lambda)+e^{-\mu\cdot p}b'_\nu\Phi(x_{\mu\nu},\lambda+N\gamma), \tag{IV.6}$$

$$\begin{aligned}D_{\mu\mu}=&(\zeta(\lambda)+\zeta(\gamma))e^{\mu\cdot p}b_\mu-(\zeta(\lambda+\gamma)-\zeta(\gamma))e^{-\mu\cdot p}b'_\mu\\&+\sum_{\nu\neq\mu}\left((\zeta(x_{\mu\nu}+\gamma)-\zeta(x_{\mu\nu}))e^{\nu\cdot p}b_\nu+\frac{\Phi(x_{\nu\mu}+\gamma,\lambda)}{\Phi(\gamma,\lambda)}\Phi(x_{\mu\nu},\lambda+N\gamma)e^{-\mu\cdot p}b'_\nu\right)\end{aligned} \tag{IV.7}$$

and

$$\begin{aligned}b_\mu&=\prod_{\Delta_{C_n}\ni\beta=\mu-\nu}f(\beta\cdot x),\\ b'_\mu&=\prod_{\Delta_{C_n}\ni\beta=\mu-\nu}g(\beta\cdot x),\\ x_{\mu\nu}&:=(\mu-\nu)\cdot x.\end{aligned} \tag{IV.8}$$

The L_{C_n},M_{C_n} satisfies the Lax equation

$$\dot{L}_{C_n}=\{L_{C_n},\mathcal{H}_{C_n}\}=[M_{C_n},L_{C_n}], \tag{IV.9}$$

which is equivalent to the equations of motion (IV.1) and (IV.2). The Hamiltonian $\mathcal{H}_{C_n}$ can be rewritten as the trace of L_{C_n},

$$\mathcal{H}_{C_n}=\operatorname{tr}L_{C_n}=\frac{1}{2}\sum_{\mu\in\Lambda_{C_n}}(e^{\mu\cdot p}b_\mu+e^{-\mu\cdot p}b'_\mu). \tag{IV.10}$$

B. The BC_n model

The Hamiltonian of the BC_n model is expressed in Eq. (III.23), so the canonical equations of motion are

$$\dot{x}_i=\{x_i,\mathcal{H}\}=e^{p_i}b_i-e^{-p_i}b'_i, \tag{IV.11}$$

$$\begin{aligned}\dot{p}_i=\{p_i,\mathcal{H}\}=&\sum_{j\neq i}^{n}(e^{p_j}b_j(h(x_{ji})-h(x_j+x_i))+e^{-p_j}b'_j(\hat{h}(x_{ji})-\hat{h}(x_j+x_i)))\\&-e^{p_i}b_i\left(h(x_i)+2h(2x_i)+\sum_{j\neq i}^{n}(h(x_{ij})+h(x_i+x_j))\right)\\&-e^{-p_i}b'_i\left(\hat{h}(x_i)+2\hat{h}(2x_i)+\sum_{j\neq i}^{n}(\hat{h}(x_{ij})+\hat{h}(x_i+x_j))\right)-b_0(h(x_i)+\hat{h}(x_i)),\end{aligned} \tag{IV.12}$$

where

$$b_i = f(x_i) f(2x_i) \prod_{k \neq i}^{n} (f(x_i - x_k) f(x_i + x_k)),$$

$$b_i' g(x_i) g(2x_i) \prod_{k \neq i}^{n} (g(x_i - x_k) g(x_i + x_k)), \tag{IV.13}$$

$$b_0 = \prod_{i=1}^{n} f(x_i) g(x_i).$$

The Lax pair for the BC_n RS model can be constructed as the form of Eqs. (IV.4)–(IV.8) where one should replace the matrices labels with $\mu, \nu \in \Lambda_{BC_n}$, and roots with $\beta \in \Delta_{BC_n}$.

The Hamiltonian $\mathcal{H}_{BC_n}$ can also be rewritten as the trace of L_{BC_n},

$$\mathcal{H}_{BC_n} = \mathrm{tr}\, L_{BC_n} = \frac{1}{2} \sum_{\mu \in \Lambda_{BC_n}} (e^{\mu \cdot p} b_\mu + e^{-\mu \cdot p} b_\mu'). \tag{IV.14}$$

V. SPECTRAL CURVES OF THE C_n AND BC_n RS SYSTEMS

It has recently been pointed out in Refs. 4, 5, 37 and 38, that the SU(N) RS model is related to five-dimensional gauge theories. In the context of Seiberg–Witten theory, the elliptic RS integrable system can be linked with the relevant low energy effective action when a compactification from five dimension to four dimension is imposed with all of the fields belonging to the adjoint representation of the SU(N) gauge group.[5] More evidence for this correspondence between the SYM and RS models is depicted by calculating instanton correction of prepotential for SU(2) Seiberg-Witten theory in Ref. 32.

As for the spectral curve and its relation to the Seiberg–Witten spectral curve, much progress has been made in the correspondence of ''Calogero-Moser integrable theories and gauge theories.'' See the recent reviews in Refs. 39 and 40, and references therein. In the following we will give the spectral curves for C_n and BC_n systems, which are shown to be parametrized by the integrals of motion of the corresponding system. We will also see that the elliptic Calogero–Moser, Toda (affine and nonaffine) ones are particular limits of these systems.

A. Spectral curve of the C_n RS system

Given the Lax operator with spectral parameter for the Calogero–Moser system and of the RS system associated with Lie algebras $\mathcal{G}$, the spectral curve for the given system is defined as

$$\Gamma: R(v, \lambda) = \det(L(\lambda) - v \cdot Id) \equiv 0. \tag{V.1}$$

It is natural that the function $R(v,z)$ is invariant under time evolution,

$$\frac{\mathrm{d}}{\mathrm{d}t} R(v, \lambda) = \{\mathcal{H}, R(v, \lambda)\} = 0. \tag{V.2}$$

Thus, $R(v,\lambda)$ must be a function of only the n independent integrals of motion, which in super-Yang–Mills theory play the role of *moduli*, parametrizing the supersymmetric vacua of the gauge theory. This has been confirmed in the case of the elliptic Calogero–Moser system for general Lie algebra in Refs. 41 and 42 and in the case of the elliptic SU(N) RS system for the perturbative limit and some nonperturbative special point.[5]

As for the C_n RS system, the spectral curve can be generated by the Lax matrix $L(\lambda)_{C_n}$ as follows:

$$\det(L(\lambda)_{C_n}-v\cdot Id)=\sum_{j=0}^{2n}\frac{(\sigma(\lambda))^{(j-1)}\sigma(\lambda+j\gamma)}{(\sigma(\gamma+\lambda))^{j}}(-v)^{2n-j}(H_j)_{C_n}=0, \tag{V.3}$$

where $(\mathcal{H}_0)_{C_n}=(\mathcal{H}_{2n})_{C_n}=1$ and $(\mathcal{H}_i)_{C_n}=(\mathcal{H}_{2n-i})_{C_n}$ who Poisson commute

$$\{(\mathcal{H}_i)_{C_n},(\mathcal{H}_j)_{C_n}\}=0,\quad i,j=1,\ldots,n. \tag{V.4}$$

This can be deduced by verbose but straightforward calculation to verify that the $(\mathcal{H}_i)_{A_{2n-1}}$, $i=1,\ldots,2n$ is the first class Hamiltonian with respect to the constraints (III.11), using Eqs. (II.18), (III.13) and the first formula of Eq. (III.18).

The explicit form of $(\mathcal{H}_l)_{C_n}$ is

$$(\mathcal{H}_l)_{C_n}=\sum_{\substack{J\subset\{1,\ldots,n\},\ |J|\leqslant l\\ \varepsilon_j=\pm 1, j\in J}}\exp(p_{\varepsilon J})\,F_{\varepsilon J;J^c}\,U_{J^c,l-|J|},\quad l=1,\ldots,n \tag{V.5}$$

with

$$p_{\varepsilon J}=\sum_{j\in J}\varepsilon_j p_j,$$

$$F_{\varepsilon J;\,K}=\prod_{\substack{j,j'\in J\\ j<j'}}f^2(\varepsilon_j x_j+\varepsilon_{j'}x_{j'})\prod_{j\in J k\in K}f(\varepsilon_j x_j+x_k)f(\varepsilon_j x_j-x_k)\prod_{j\in J}f(2\varepsilon_j x_j), \tag{V.6}$$

$$U_{I,p}=\sum_{\substack{I'\subset I\\ |I'|=[p/2]}}\prod_{\substack{j\in I'\\ k\in I\setminus I'}}f(x_{jk})f(x_j+x_k)g(x_{jk})g(x_j+x_k)\begin{cases}0, & (p\ \text{odd})\\ 1, & (p\ \text{even})\end{cases}.$$

Here, $[p/2]$ denotes the integer part of $p/2$. As an example, for the C_2 RS model, the independent Hamiltonian flows $(\mathcal{H}_1)_{C_2}$ and $(\mathcal{H}_2)_{C_2}$ generated by the Lax matrix L_{C_2} are[29]

$$\begin{aligned}(\mathcal{H}_1)_{C_2}=\mathcal{H}_{C_2}=&e^{p_1}f(2x_1)\,f(x_{12})f(x_1+x_2)+e^{-p_1}g(2x_1)\,g(x_{12})g(x_1+x_2)\\ &+e^{p_2}f(2x_2)\,f(x_{21})f(x_2+x_1)+e^{-p_2}g(2x_2)\,g(x_{21})g(x_2+x_1),\end{aligned} \tag{V.7}$$

$$\begin{aligned}(\mathcal{H}_2)_{C_2}=&e^{p_1+p_2}f(2x_1)\,(f(x_1+x_2))^2f(2x_2)+e^{-p_1-p_2}g(2x_1)\,(g(x_1+x_2))^2g(2x_2)\\ &+e^{p_1-p_2}f(2x_1)\,(f(x_{12}))^2f(-2x_2)+e^{p_2-p_1}g(2x_1)\,(g(x_{12}))^2g(-2x_2)\\ &+2f(x_{12})\,g(x_{12})\,f(x_1+x_2)g(x_1+x_2).\end{aligned} \tag{V.8}$$

Similar to the form of ''gauge'' transformation of Eq. (II.4), we can check that the involutive Hamiltonians of Eq. (V.5) are identical to the one given by Diejen in Ref. 26 with the following transformation

$$x_i\to x_i,\quad p_i\to p_i+\frac{1}{2}\ln\left(\frac{f(2x_i)}{g(2x_i)}\prod_{j\neq i}^{n}\frac{f(x_{ij})f(x_i+x_j)}{g(x_{ij})g(x_i+x_j)}\right). \tag{V.9}$$

B. Spectral curve of the BC_n model

Similar to the calculation of the C_n case, the spectral curve of the BC_n RS system can be generated by Lax matrix $L(\lambda)_{BC_n}$ as follows

$$\det(L(\lambda)_{BC_n}-v\cdot Id)=0. \tag{V.10}$$

The explicit form of the spectral curve is

$$\det(L(\lambda)_{BC_n}-v\cdot Id)=\sum_{j=0}^{2n+1}\frac{(\sigma(\lambda))^{(j-1)}\sigma(\lambda+j\gamma)}{(\sigma(\gamma+\lambda))^{j}}(-v)^{2n+1-j}(\mathcal{H}_j)_{BC_n}=0, \tag{V.11}$$

where $(\mathcal{H}_0)_{BC_n}=(\mathcal{H}_{2n})_{BC_n}=1$ and $(\mathcal{H}_i)_{BC_n}=(\mathcal{H}_{2n+1-i})_{BC_n}$ Poisson commute

$$\{(\mathcal{H}_i)_{BC_n},(\mathcal{H}_j)_{BC_n}\}=0,\quad \forall i,j\in\{1,\ldots,n\}. \tag{V.12}$$

This can be deduced similarly to the C_n case to verify that $(\mathcal{H}_i)_{A_{2n}}$, $i=1,\ldots,2n$ is the first class Hamiltonian with respect to the constraints (III.25).

The explicit forms of $(\mathcal{H}_l)_{BC_n}$ are

$$(\mathcal{H}_l)_{BC_n}=\sum_{\substack{J\subset\{1,\ldots,n\},\ |J|\leqslant l\\ \varepsilon_j=\pm 1,\ j\in J}}\exp(p_{\varepsilon J})\,F_{\varepsilon J;J^c}U_{J^c,l-|J|},\quad l=1,\ldots,n \tag{V.13}$$

with

$$p_{\varepsilon J}=\sum_{j\in J}\varepsilon_j p_j,$$

$$F_{\varepsilon J;K}=\prod_{\substack{j,j'\in J\\ j<j'}}f^2(\varepsilon_j x_j+\varepsilon_j,x_{j'})\prod_{\substack{j\in J\\ k\in K}}f(\varepsilon_j x_j+x_k)f(\varepsilon_j x_j-x_k)\prod_{j\in J}f(2\varepsilon_j x_j)\prod_{j\in J}f(\varepsilon_j x_j), \tag{V.14}$$

$$U_{I,p}=\sum_{\substack{I'\subset I\\ |I'|=[p/2]}}\prod_{\substack{j\in I'\\ k\in I\setminus I'}}f(x_{jk})f(x_j+x_k)g(x_{jk})g(x_j+x_k)\begin{cases}\displaystyle\prod_{i\in I\setminus I'}f(x_i)g(x_i), & (p\ \text{odd})\\ \displaystyle\prod_{i\in I}f(x_i)g(x_i), & (p\ \text{even})\end{cases}.$$

It is similar to the C_n case for the relation between $(\mathcal{H}_l)_{BC_n}$ with the one given in Ref. 26:

$$x_i\to x_i,\quad p_i\to p_i+\tfrac{1}{2}\ln\left(\frac{f(x_i)}{g(x_i)}\frac{f(2x_i)}{g(2x_i)}\prod_{j\neq i}^{n}\frac{f(x_{ij})f(x_i+x_j)}{g(x_{ij})g(x_i+x_j)}\right). \tag{V.15}$$

Remarks: So far we have Lax matrices with the spectral parameter of Eq. (IV.4) for the C_n and BC_n RS models, and the corresponding spectral curve equation of Eqs. (V.3) and (V.11). It is expected that they will be useful to study the relation between the $5d$ SUSY gauge theory and these integrable models which have been pointed out in Ref. 5. More exactly, it is expected that these spectral curves would be identical to the complex curve in the context of SUSY gauge theory associated with the corresponding gauge group. On the other hand, these nonsimple laced models may be potential candidates which are connected with orientifold in brane theory, corresponding to the fact that the A_{n-1} RS model is connected with orbifold. This exact correspondence in these directions is missed and certainly desires further investigation.

C. Limit to the Calogero–Moser system and Toda system

The Calogero–Moser system can be achieved by taking the so-called ''nonrelativistic limit.'' The procedure is by rescaling $p_\mu \mapsto \beta p_\mu$, $\gamma \mapsto \beta\gamma$ and letting $\beta \mapsto 0$, followed by making a canonical transformation

$$p_\mu \mapsto p_\mu + \gamma \sum_{\Delta \ni \eta = \mu - \nu} \zeta(\eta \cdot x). \tag{V.16}$$

Here $p_\mu = \mu \cdot p$, such that

$$L \mapsto Id + \beta L_{\mathrm{CM}} + O(\beta^2), \tag{V.17}$$

and

$$\mathcal{H} \mapsto N + 2\beta^2 \mathcal{H}_{\mathrm{CM}} + O(\beta^2), \tag{V.18}$$

where $N = 2n$ for the C_n model and $N = 2n+1$ for BC_n model.

L_{CM} can be expressed as

$$L_{\mathrm{CM}} = p \cdot H + X, \tag{V.19}$$

where

$$H_{\mu\nu} = \mu \delta_{\mu\nu}, \quad X_{\mu\nu} = \gamma \Phi(x_{\mu\nu}, \lambda)(1 - \delta_{\mu\nu}). \tag{V.20}$$

The Hamiltonian $\mathcal{H}_{\mathrm{CM}}$ of the CM model can be given by

$$\mathcal{H}_{\mathrm{CM}} = \frac{1}{2} p^2 - \frac{\gamma^2}{2} \sum_{\alpha \in \Delta} \wp(\alpha \cdot x) = \frac{1}{4} \mathrm{tr}\, L^2 + \mathrm{const}, \tag{V.21}$$

where

$$\mathrm{const} = -\frac{N(N-1)\gamma^2}{4} \wp(\lambda).$$

All of the above-mentioned results are identified with the results of Refs. 8, 10, 12–15 up to a suitable choice of coupling parameters. Now the degenerate RS spectral curve reduces to

$$\Gamma: \; R(v, \lambda) = \det(L(\lambda)_{\mathrm{CM}} - v \cdot Id) \equiv 0, \tag{V.22}$$

which is exactly identified with the spectral curve analyzed in Refs. 39 and 41.

Starting from the CM system to the Toda system is more directly due to the progress that the limit to Toda for the general Lie algebra has been studied extensively in Refs. 43–45. The main idea is making a suitable scaling limit with the following parametrization:

$$\omega_1 = -i\pi, \quad \omega_3 \in \mathbf{R}_+, \quad \tau \equiv \frac{\omega_3}{\omega_1} = i\omega_3/\pi, \tag{V.23}$$

and shifting the dynamical variable x,

$$\begin{aligned} &x \to Q - 2\omega_3 \delta \rho^\vee, \quad p \to P, \\ &\lambda \to \log Z - \omega_3, \quad Z \in \mathbf{R}_+, \end{aligned} \tag{V.24}$$

TABLE I. Root system of A_{n-1}, C_n and BC_n types.

$\mathcal{G}$	All roots	Simple roots Π	$h_{\mathcal{G}}$	Dual Weyl vector $\rho^\vee$	Vector weights
A_{n-1}	$\pm e_i \pm e_j$, $1\leqslant i,\ j\leqslant n$, $i\neq j$	$e_i - e_{i+1}$, $i=1,\ldots,n-1$	n	$\Sigma_{j=1}^{n}(n-j)e_j$	e_i, $i=1,\ldots,n$
C_n	$\pm e_i \pm e_j, \pm 2e_i$, $1\leqslant i,\ j\leqslant n$, $i\neq j$	$e_i - e_{i+1}, 2e_n$, $i=1,\ldots,n-1$	$2n$	$\Sigma_{j=1}^{n}(n+\frac{1}{2}-j)e_j$	$e_i, -e_i$, $i=1,\ldots,n$
BC_n	$\pm e_i \pm e_j, \pm 2e_i, \pm e_i$ $1\leqslant i,\ j\leqslant n$, $i\neq j$	$e_i - e_{i+1}, e_n$, $i=1,\ldots,n-1$	$2n+1$	$\Sigma_{j=1}^{n}(n+1-j)e_j$ (define)	$e_i, -e_i, 0$, $i=1,\ldots,n$

in which $h_{\mathcal{G}}$ is the Coxeter number for the corresponding root system $\mathcal{G}$, $\rho^\vee$ the dual of the Weyl vector defined as $\rho^\vee = \frac{1}{2}\Sigma_{\alpha\in\Delta_+} 2\alpha/\alpha^2$, and δ satisfies $\delta \leqslant 1/h_{\mathcal{G}}$.

For convenience, we give the basics of these root systems as shown in Table I.

As for the C_n model, selecting $\rho^\vee = \rho^\vee_{C_n}$, $\gamma = im\, e^{\omega_3 \delta}$, one has the nonaffine C_n Toda model from the Hamiltonian of the CM model Eq. (V.21),

$$\mathcal{H}^{\text{Toda}}_{C_n} = \frac{1}{2}P^2 + m^2 \sum_{j=1}^{n-1} e^{Q_j - Q_{j+1}} + m^2\, e^{2Q_n}, \tag{V.25}$$

for $\delta < 1/h_{C_n}$ and $C_n^{(1)}$ Toda model

$$\mathcal{H}^{\text{Toda}}_{C_n^{(1)}} = \frac{1}{2}P^2 + m^2 e^{-2Q_1} + m^2 \sum_{j=1}^{n-1} e^{Q_j - Q_{j+1}} + m^2 e^{2Q_n} \tag{V.26}$$

for $\delta = 1/h_{C_n}$.

The same holds for the BC_n model. Selecting $\rho^\vee = \rho^\vee_{BC_n}$, $\gamma = im\, e^{\omega_3 \delta}$, one has the nonaffine B_n Toda model from the Hamiltonian of the CM model Eq. (V.21),

$$\mathcal{H}^{\text{Toda}}_{B_n} = \frac{1}{2}P^2 + m^2 \sum_{j=1}^{n-1} e^{Q_j - Q_{j+1}} + m^2\, e^{Q_n} \tag{V.27}$$

for $\delta < 1/h_{BC_n}$ and BC_n Toda model

$$\mathcal{H}^{\text{Toda}}_{BC_n} = \frac{1}{2}P^2 + m^2 e^{-2Q_1} + m^2 \sum_{j=1}^{n-1} e^{Q_j - Q_{j+1}} + m^2 e^{Q_n} \tag{V.28}$$

for $\delta = 1/h_{BC_n}$.

If we use the following gauge for $\Phi(x,\lambda)$:[46]

$$\Phi(x,\lambda) \to \frac{\sigma(x+\lambda)}{\sigma(\lambda)\sigma(x)} \exp(\zeta(\lambda)x), \tag{V.29}$$

it does not destroy the validity[45] for the Lax pair, We have the following limit for $\gamma\Phi(\alpha\cdot x,\lambda)$:

$$\gamma\Phi(\alpha\cdot x,\lambda)\to -m\exp\left(\frac{\alpha\cdot Q}{2}\right)\quad \text{for}\quad \alpha\in\Pi\quad (\delta\leqslant 1/h_{\mathcal{G}})$$

$$\to mZ\exp\left(-\frac{\alpha\cdot Q}{2}\right)\quad \text{for}\quad \alpha=\alpha_h\quad (\delta=1/h_{\mathcal{G}})$$

$$\to 0\quad \text{otherwise},$$

$$\gamma\Phi(-\alpha\cdot x,\lambda)\to m\exp\left(\frac{\alpha\cdot Q}{2}\right)\quad \text{for}\quad \alpha\in\Pi(\delta\leqslant 1/h_{\mathcal{G}})$$

$$\to -\frac{m}{Z}\exp\left(-\frac{\alpha\cdot Q}{2}\right),\quad \text{for}\quad \alpha=\alpha_h(\delta=1/h_{\mathcal{G}})$$

$$\to 0\quad \text{otherwise}. \tag{V.30}$$

So the Lax operator now reads

$$L_{\text{Toda}}=P\cdot H-im\sum_{\alpha\in\Pi}\exp\left(\frac{\alpha\cdot Q}{2}\right)[E(\alpha)-E(-\alpha)]+im\exp\left(\frac{\alpha_0\cdot Q}{2}\right)[ZE(-\alpha_0)-Z^{-1}E(\alpha_0)], \tag{V.31}$$

where $E(\alpha)_{\mu\nu}=\delta_{\mu-\nu,\alpha}$. This Lax operator holds for all the root systems of $A_{n-1}(A_{n-1}^{(1)})$, $C_n(C_n^{(1)})$, $B_n(BC_n)$ and coincides with the standard form given in Ref. 8. It is not difficult to find that the parameter Z now plays the role of a spectral parameter for the affine Toda model based on $\mathcal{G}^{(1)}$. When we refer to the Toda models based on a finite Lie algebra $\mathcal{G}$, we should only drop the terms containing the affine root α_0.

So the degenerate spectral curve for the Toda $A_{n-1}^{(1)}$, $C_n^{(1)}$, and $BC_n(A_{2n}^{(2)})$ systems can be defined

$$\Gamma: R(v,\lambda)=\det(L(\lambda)_{\text{Toda}}-v\cdot Id)\equiv 0, \tag{V.32}$$

which is identical to the one given in Refs. 47 and 48.

VI. DEGENERATE CASES

Let us now consider the other various special degenerate cases. As is well known, if one or both of the periods of the Weierstrass sigma function $\sigma(x)$ become infinite, there will occur three degenerate cases associated with trigonometric, hyperbolic, and rational systems. The degenerate limits of the functions $\Phi(x,\lambda)$, $\sigma(x)$, and $\zeta(x)$ will give corresponding Lax pairs which include spectral parameter. Moreover, when the spectral parameter value is on a certain limit, the Lax pairs without spectral parameter will be derived.

A. Trigonometric limit

The limit can be obtained by sending ω_3 to $i\infty$ with $\omega_1=\pi/2$, so that

$$\sigma(x)\to e^{(1/6)x^2}\sin x,$$
$$\zeta(x)\to\cot x+\tfrac{1}{3}x, \tag{VI.1}$$

and the function

$$\Phi(x,\lambda)\equiv\frac{\sigma(x+\lambda)}{\sigma(x)\sigma(\lambda)}$$

reduces to

$$\Phi(x,\lambda)\rightarrow(\cot\lambda-\cot x)e^{(1/3)xu}. \tag{VI.2}$$

By replacing the corresponding functions $\Phi(x,\lambda)$, $\sigma(x)$, and $\zeta(x)$ with the above-given form for the Lax pairs, we will get the corresponding spectral parameter dependent Lax pairs. For simplicity, we notice that the exponential part of the above-mentioned functions can be removed by applying suitable ''gauge'' transformation of the Lax matrix on which condition the functions can be valued as follows:

$$\begin{aligned}\sigma(x)&\rightarrow\sin x,\\ \zeta(x)&\rightarrow\cot x,\\ \Phi(x,\lambda)&\rightarrow(\cot\lambda-\cot x).\end{aligned} \tag{VI.3}$$

As for the spectral parameter independent Lax pair, furthermore, we can take the limit $\lambda\rightarrow i\infty$, so the function

$$\Phi(x,\lambda)\rightarrow\frac{1}{\sin x}, \tag{VI.4}$$

while the corresponding Lax matrix becomes

$$L_{\mu\nu}=e^{\nu\cdot p}b_{\nu}\frac{\sin\gamma}{\sin((\mu-\nu)\cdot x+\gamma)}, \tag{VI.5}$$

which is exactly the same as the spectral parameter independent Lax matrix given in Ref. 30.

B. Hyperbolic limit

In this case, the periods can be chosen by sending ω_1 to $i\infty$ with $\omega_3=\pi/2$, so following all the procedures in achieving the result of the trigonometric case, we can find the hyperbolic Lax pairs by simple replacement of the functions appearing in the trigonometric Lax pair as follows:

$$\begin{aligned}\sin x&\rightarrow\sinh x,\\ \cos x&\rightarrow\cosh x,\\ \cot x&\rightarrow\coth x.\end{aligned} \tag{VI.6}$$

The same as for the trigonometric case, we can get the Lax pairs with and without spectral parameter.

C. Rational limit

As far as the form of the Lax pair for the rational-type system is concerned, we can achieve it by making the following substitutions:

$$\begin{aligned}\sigma(x)&\rightarrow x,\\ \zeta(x)&\rightarrow\frac{1}{x},\\ \Phi(x,\lambda)&\rightarrow\frac{1}{x}+\frac{1}{\lambda}\end{aligned} \tag{VI.7}$$

for the spectral parameter dependent Lax pair, while furthermore, taking the limit $\lambda \to i\infty$, we can obtain the spectral parameter independent Lax pair. The explicit form of Lax matrix without spectral parameter is

$$L_{\mu\nu} = e^{\nu\cdot p} b_\nu \frac{\gamma}{(\mu-\nu)\cdot x+\gamma}. \tag{VI.8}$$

which completely coincides with the spectral parameter independent Lax matrix given in Ref. 30.

Remark: As for the various degenerate cases for the CM and Toda systems, one can follow the same procedure as for the RS model [please refer to Eqs. (VI.1)–(VI.8)].

VII. CONCLUDING REMARKS

In this paper, we have proposed the Lax pairs for elliptic C_n and BC_n RS models. The spectral parameter dependent and independent Lax pairs for the trigonometric, hyperbolic, and rational systems can be derived as the degenerate limits of the elliptic potential case. The spectral curves of these systems are given and shown depicted by the complete sets of involutive constant integrals of motion. They are expected be related to the five-dimensional gauge theory[4,5] and even to brane theory, which desires further study. In the nonrelativistic limit(scaling limit), these systems lead to CM(Toda) systems associated with the root systems of C_n and BC_n. There are still many open problems. For example, it seems to be a challenging subject to carry out a Lax pair with as many independent coupling constants as independent Weyl orbits in the set of roots, as done for the Calogero–Moser systems(see Refs. 8, 11–15). What is also interesting is to generalize the results obtained in this paper to the systems associated with all other Lie Algebras even to those associated with all the finite reflection groups.[14] Moreover, the issue of getting the r-matrix structure for these systems is deserved due to the success of calculating for the trigonometric BC_n RS system by Avan *et al.* in Ref. 31.

APPENDIX

In this appendix we prove the identity equation (II.11) and then derive the relation between the Lax operator $L(\lambda)$ and its inverse of $L(\lambda)^{-1}$.

Using the result given in Ref. 6 of Eq. (B5), we have the following conclusion:

Let

$$C_{ij} = \frac{\sigma(q_i - r_j + \lambda)}{\sigma(q_i - r_j + \mu)}, \quad i,j = 1,\ldots,N, \tag{A1}$$

then one has

$$\det(C) = \sigma(\lambda-\mu)^{N-1}\sigma(\lambda+(N-1)\mu+\Sigma)\times\prod_{i<j}\sigma(q_i-q_j)\sigma(r_j-r_i)\prod_{i,j}\frac{1}{\sigma(q_i-r_j+\mu)}, \tag{A2}$$

where

$$\Sigma = \sum_{i=1}^{N}(q_i - r_j). \tag{A3}$$

So it is straightforward to compute the inverse of matrix C,

$$\begin{aligned}(C^{-1})_{ij} &= \text{the cofactor of } C \text{ with respect to } C_{ji}\\ &= \frac{\sigma(\lambda+(N-2)\mu+q_i-q_j)}{\sigma(\lambda-\mu)\sigma(\lambda+(N-1)\mu)\sigma(q_i-q_j-\mu)}\\ &\quad\times\frac{\Pi_l\sigma(q_j-q_l+\mu)\Pi_l\sigma(q_i-q_l-\mu)}{\Pi_{k\neq i}\sigma(q_i-q_k)\Pi_{k\neq j}\sigma(q_j-q_k)}.\end{aligned} \tag{A4}$$

From Eq. (II.5), we have

$$\begin{aligned}L(\lambda) &= \sum_{i,j=1}^{N}\frac{\Phi(x_{ij}+\gamma,\lambda)}{\Phi(\gamma,\lambda)}\exp(p_j)b_jE_{ij}\\ &= \frac{1}{\Phi(\gamma,\lambda)}\sum_{i,j=1}^{N}\frac{\sigma(x_{ij}+\gamma+\lambda)}{\sigma(x_{ij}+\gamma)\sigma(\lambda)}\exp(p_j)b_j\\ &= \frac{1}{\Phi(\gamma,\lambda)}\sum_{i,j=1}^{N}G_{ij}\exp(p_j)b_j,\end{aligned} \tag{A5}$$

where

$$G_{ij}:=\Phi(x_{ij}+\gamma,\lambda)=\frac{\sigma(x_{ij}+\gamma+\lambda)}{\sigma(x_{ij}+\gamma)\sigma(\lambda)},$$

with the help of Eq. (A4), one has

$$(G^{-1})_{ij}=\frac{\sigma(\lambda+(N-1)\gamma+x_{ij})}{\sigma(\lambda+N\gamma)\sigma(x_{ij}-\gamma)}\times\frac{\Pi_k\sigma(x_{jk}+\gamma)\Pi_k\sigma(x_{ik}-\gamma)}{\Pi_{k\neq i}\sigma(x_{ik})\Pi_{k\neq j}\sigma(x_{jk})}, \tag{A6}$$

so that

$$\begin{aligned}L(\lambda)^{-1}{}_{ij} &= \Phi(\gamma,\lambda)(G^{-1})_{ij}b_j^{-1}\exp(-p_i))E_{ij}\\ &= \frac{-\sigma(\gamma)^2\,\sigma(\lambda+\gamma)\sigma(\lambda+(N-1)\gamma+x_{ij})}{\sigma(\lambda)\sigma(\gamma)\sigma(\lambda+N\gamma)\sigma(x_{ij}-\gamma)}\times\exp(-p_i)\prod_{k\neq j}\frac{\sigma(x_{jk}+\gamma)}{\sigma(x_{jk})}\\ &= \frac{\sigma(\gamma+\lambda)\,\sigma(\lambda+(N-1)\gamma)}{\sigma(\lambda)\sigma(\lambda+N\gamma)}\times\frac{\Phi(x_{ij}-\gamma,\lambda+N\gamma)}{\Phi(-\gamma,\lambda+N\gamma)}\exp(-p_i)b_j'E_{ij}.\end{aligned} \tag{A7}$$

By comparing the forms of $L(\lambda)$ and $L(\lambda)^{-1}{}_{ij}$, we find $L(\lambda)^{-1}{}_{ij}$ can be expressed with $L(\lambda)$ as

$$L(\lambda)^{-1}{}_{ij}=L(\lambda)_{ij}\big|_{\gamma\to-\gamma,\lambda\to\lambda+N\gamma}\times\frac{\sigma(\gamma+\lambda)\,\sigma(\lambda+(N-1)\gamma)}{\sigma(\lambda)\sigma(\lambda+N\gamma)}\exp(-p_i-p_j). \tag{A8}$$

Phase diagram for Abrikosov lattice

Mathieu Dutour[a)]
26 Rue de la Republique 45000 Orleans, France

(Received 7 August 2000; accepted for publication 24 July 2001)

Working in the framework of Abrikosov's theory, we propose a mathematical definition of the phase diagram and prove mathematically the validity of what is usually drawn in the physical literature. © *2001 American Institute of Physics.*

I. INTRODUCTION

In 1953 V. Ginzburg and L. Landau proposed a modelization for describing the states of a superconducting material. They introduced a functional depending on a wave function ϕ and a magnetic potential vector $\mathbf{A}$ whose local minima will describe the properties of the material, $|\phi|^2$ representing the local density of superconducting electrons. Abrikosov[1] has introduced a special modelization which predicts the periodic structure for the zeros of ϕ which was subsequently observed in some experiments. Our aim is to give a mathematical analysis of some aspects of his theory. For simplicity we restrict ourselves to the two-dimensional case and consider a case when the material is submitted to a constant external magnetic field H_{ext} which will be identified to a function. Then if $(\phi,\mathbf{A})$ is in the Sobolev space $H^1_{\text{loc}}(\mathbb{R}^2;\mathbb{C})\times H^1_{\text{loc}}(\mathbb{R}^2;\mathbb{R}^2)$ the density of the Ginzburg–Landau functional is

$$\tfrac{1}{2}\|ik^{-1}\nabla\phi+\mathbf{A}\phi\|^2+\tfrac{1}{4}(1-|\phi|^2)^2+\tfrac{1}{2}(\text{curl}\ \ \mathbf{A}-H_{\text{ext}})^2 \tag{1}$$

and is in $L^1_{\text{loc}}(\mathbb{R}^2)$; the constant k is called the Ginzburg–Landau parameter ($k>0$). Furthermore, this density is invariant under the gauge transform $(\phi',\mathbf{A}')=(\phi e^{ikg},\mathbf{A}+\nabla_g)$ with $g\in H^2_{\text{loc}}(\mathbb{R}^2)$. All other physically significant quantities like the density $|\phi|^2$ and the field curl $\mathbf{A}$ are left invariant by these gauge transforms.

We take $\mathcal{L}_1$ a two-dimensional lattice of $\mathbb{R}^2$ with fundamental domain Ω_1 of area 1. We consider the dilated lattice: $\mathcal{L}_\lambda=\sqrt{\lambda}\mathcal{L}_1$ with fundamental domain $\Omega_\lambda=\sqrt{\lambda}\Omega_1$. Following Abrikosov, we choose λ in $\mathbb{R}_+$ and restrict the variational space to the space $\mathcal{V}_\lambda$ of pairs $(\phi,\mathbf{A})$ which are gauge periodic with respect to $\mathcal{L}_\lambda$.[1] This means that, for all $v\in\mathcal{L}_\lambda$, there exists $g^v\in H^2_{\text{loc}}(\mathbb{R}^2)$ such that

$$\begin{aligned}\phi(z+v)&=e^{ikg^v(z)}\phi(z),\\ \mathbf{A}(z+v)&=\mathbf{A}(z)+\nabla g^v(z).\end{aligned} \tag{2}$$

Consequently, all the considered physical quantities are $\mathcal{L}_\lambda$-periodic. We denote by $|\Omega_\lambda|$ the area of Ω_λ which is actually equal to λ.

It is then a classical consequence of (2) that there exist $d\in\mathbb{Z}$ such that

$$2\pi d=k\int_{\Omega_\lambda}\text{curl}\ \ \mathbf{A}. \tag{3}$$

a)Electronic mail: Mathieu.Dutour@wanadoo.fr

Then we will analyze the problem obtained by fixing some quantization $d \in \mathbb{Z}$ and assuming that (3) is satisfied. This defines a smaller variational space $\mathcal{V}_{\lambda,d}$. The Ginzburg–Landau functional is obtained by integration of the local density over the fundamental domain Ω_λ and division by $|\Omega_\lambda|$. This gives

$$F(\phi,\mathbf{A}) = \frac{1}{|\Omega_\lambda|}\int_{\Omega_\lambda}\left[\frac{1}{2}\|ik^{-1}\nabla\phi+\mathbf{A}\phi\|^2+\frac{1}{4}(1-|\phi|^2)^2+\frac{1}{2}(\text{curl }\mathbf{A}-H_{\text{ext}})^2\right]dx. \tag{4}$$

This should consequently be understood as a mean energy. The analysis for fixed λ of the minima of the functional when $d=0$ is simple and one finds that the infimum of the functional is obtained for the so-called pure state $\phi=1$ and $\mathbf{A}=0$. This energy, which is independent of λ, is called the pure state energy and will be denoted by $E_{\mathcal{P}}$. We have

$$E_{\mathcal{P}} = \frac{H_{\text{ext}}^2}{2}. \tag{5}$$

The case $d=0$ is worthless for explaining the appearance of zeros for some value of (k,H_{ext}) and this leads us to the consideration of the case $d\neq 0$. From now on we assume $H_{\text{ext}}>0$ and $d \in \mathbb{N}^*$ (one can indeed show that the case $d<0$ is not energetically interesting). Let us define

$$\mathcal{E}_{k,H_{\text{ext}}} = \inf_{\lambda>0}\ \inf_{(\phi,\mathbf{A})\in\mathcal{V}_{\lambda,d}} F(\phi,\mathbf{A}). \tag{6}$$

We emphasize that the infimum is also taken with respect to λ, that is that we also minimize on the size of the domain. Let us now compute the energy of the so-called normal state corresponding to $\phi=0$ and curl $\mathbf{A}=H_{\text{ext}}$. An explicit solution is given by

$$\mathbf{A} = \frac{H_{\text{ext}}}{2}\begin{pmatrix}-y\\ x\end{pmatrix}, \tag{7}$$

and we observe that condition (3) imposes that this state belongs to $\mathcal{V}_{\lambda,d}$ with $\lambda = 2\pi d/kH_{\text{ext}}$. The corresponding energy will be called the normal energy and is equal to

$$E_{\mathcal{N}} = \tfrac{1}{4}. \tag{8}$$

This leads immediately to the following inequality:

$$\mathcal{E}_{k,H_{\text{ext}}} \leqslant E_{\mathcal{N}}. \tag{9}$$

We come back to the comparison with the pure energy $E_{\mathcal{P}}$. We will show in Corollary II.2 that, although the pure state is not in the variational space $\mathcal{V}_{\lambda,d}$ when $d\neq 0$, we still have

$$\mathcal{E}_{k,H_{\text{ext}}} \leqslant E_{\mathcal{P}}. \tag{10}$$

For a given $(k,H_{\text{ext}}) \in \mathbb{R}_+^*\times\mathbb{R}_+^*$, the questions are as follows.

(i) What is the infimum $\mathcal{E}_{k,H_{\text{ext}}}$ over $\lambda,\phi,\mathbf{A}$ of the functional?
(ii) Is this infimum attained?
(iii) In this last case, what are the properties of the minimizers?

This leads us to introduce three sets in $\mathbb{R}_+^*\times\mathbb{R}_+^*$:

$$\mathcal{N} = \{(k,H_{\text{ext}}) \in \mathbb{R}_+^*\times\mathbb{R}_+^* \text{ s.t. } \mathcal{E}_{k,H_{\text{ext}}} = E_{\mathcal{N}}\},$$

$$\mathcal{P} = \{(k,H_{\text{ext}}) \in \mathbb{R}_+^*\times\mathbb{R}_+^* \text{ s.t. } \mathcal{E}_{k,H_{\text{ext}}} = E_{\mathcal{P}}\}, \tag{11}$$

$$\mathcal{M}=\{(k,H_{\text{ext}})\in\mathbb{R}_+^*\times\mathbb{R}_+^* \text{ s.t. } \mathcal{E}_{k,H_{\text{ext}}}<\inf(E_{\mathcal{P}},E_{\mathcal{N}})\}.$$

The set $\mathcal{M}$ is the complementary of $\mathcal{P}\cup\mathcal{N}$ in $\mathbb{R}_+^*\times\mathbb{R}_+^*$. In the last case one can show that the infimum is attained for some triplet $(\lambda,\phi,\mathbf{A})$. In this case, $(\phi,\mathbf{A})$ is neither a pure state nor a normal state and is usually called a mixed state. The phase diagram is the picture corresponding to the description of $\mathcal{N}$, $\mathcal{P}$, and $\mathcal{M}$. Our main theorem gives a precise description of the boundaries of $\mathcal{N}$, $\mathcal{P}$, and $\mathcal{M}$.

Theorem I.1: *There exist two continuous functions* $k\mapsto H_{c1}(k)$ *and* $k\mapsto H_{c2}(k)$ on $\mathbb{R}_+$ *satisfying*

(1) $\forall k\leqslant 1/\sqrt{2}$ *we have* $H_{c1}(k)=1/\sqrt{2}$,
(2) $k\mapsto H_{c1}(k)$ *is decreasing and* $\lim_{k\to\infty}H_{c1}(k)=0$,
(3) $H_{c2}(k)=\max(k,1/\sqrt{2})$.

Then

$$\mathcal{N}=\{(k,H_{\text{ext}}),\ s.t.\ H_{\text{ext}}\geqslant H_{c2}(k)\},$$

$$\mathcal{P}=\{(k,H_{\text{ext}}),\ s.t.\ H_{\text{ext}}\leqslant H_{c1}(k)\},\tag{12}$$

$$\mathcal{M}=\{(k,H_{\text{ext}}),\ s.t.\ H_{c1}(k)<H_{\text{ext}}<H_{c2}(k)\}.$$

Let us remark that if $k\leqslant 1/\sqrt{2}$, we have $H_{c1}(k)=H_{c2}(k)=1/\sqrt{2}$, which is called the thermodynamic field. Our article is organized as follows: In the next section we make a change of variable and of unknowns which make the whole problem more easily tractable.

In Sec. III, we write the Bochner–Kodaira–Nakano formula for the rescaled functional which leads to a lower bound of the energy and we analyze the critical points. Then in Sec. IV we prove the monotonicity theorems which play an important role for analyzing the structure of $\mathcal{N}$, $\mathcal{P}$, and $\mathcal{M}$. In Sec. V, we give the qualitative form of the phase diagram.

II. RENORMALIZATION OF THE PROBLEM

We denote by $H_{\text{int}}=(1/\lambda)\int_{\Omega_\lambda}$ curl $\mathbf{A}$ the mean internal magnetic field induced by $\mathbf{A}$. The quantization relation (3) rewrites as

$$2\pi d=k\lambda H_{\text{int}}.\tag{13}$$

It is also a classical result (see Ref. 2 or 3 or Ref. 4, p. 21–29) that we can associate to the pair $(\phi,\mathbf{A})$, another pair $(\phi',\mathbf{A}')$ with the same Ginzburg–Landau energy but satisfying

$$\forall v\in\mathcal{L}_\lambda,\ \begin{cases}\phi'(z+v)=e^{ikg^v(z)}\phi'(z)\\ \mathbf{A}'(z+v)=\mathbf{A}'(z)+\nabla g^v(z)\end{cases}\ \text{with}\ g^v(x,y)=\frac{H_{\text{int}}}{2}(v_x y-v_y x)\tag{14}$$

and $\operatorname{div}\mathbf{A}'=0$. This reduction is rather involved and is performed by a suitable gauge transform and a translation in x. This is actually linked to the classification of complex line bundles over the torus. We will work with the vector bundle $E_{\lambda,d}$ whose C^∞ sections are described by

$$C^\infty(E_{\lambda,d})=\{\phi:\mathbb{R}^2\to\mathbb{C} \text{ s.t. } \forall(x,y)\in\mathbb{R}^2,\forall v=(v_x,v_y)\in\mathcal{L}_\lambda,$$
$$\phi((x,y)+v)=e^{i(\pi d/\lambda)(v_x y-v_y x)}\phi(x,y)\}.\tag{15}$$

In order to respect (13) we introduce

$$\mathcal{B}_d = \begin{cases} (\phi, \mathbf{A}) \in H^1_{\mathrm{loc}}(E_{\lambda,d}) \times H^1_{\mathrm{loc}}(\mathbb{R}^2, \mathbb{R}^2) \ \text{ s.t. } \exists H_{\mathrm{int}} > 0 \\ \text{with } \ 2\pi d = k\lambda H_{\mathrm{int}}, \ \ \mathbf{A} = \dfrac{H_{\mathrm{int}}}{2\pi}\mathbf{A}_0 + \mathbf{P} \\ \text{with } \ \mathbf{P} \ \ \mathcal{L}_\lambda\text{-periodic}, \ \ \mathrm{div}\,\mathbf{P} = 0 \ \ \text{and} \ \ \displaystyle\int_{\Omega_\lambda} \mathbf{P} = 0 \end{cases} \tag{16}$$

with $\mathbf{A}_0 = \pi\binom{-y}{x}$ and analyze the problem restricted to $\mathcal{B}_d$.

Let us start to compute $F(\phi, \mathbf{A})$. With the expression $\mathbf{A} = (H_{\mathrm{int}}/2\pi)\mathbf{A}_0 + \mathbf{P}$, we easily get:

$$\frac{1}{|\Omega_\lambda|}\int_{\Omega_\lambda} \frac{1}{2}(\mathrm{curl}\ \ \mathbf{A} - H_{\mathrm{ext}})^2 = \frac{1}{|\Omega_\lambda|}\int_{\Omega_\lambda} \frac{1}{2}(\mathrm{curl}\ \ \mathbf{P})^2 + \frac{1}{2}(H_{\mathrm{int}} - H_{\mathrm{ext}})^2. \tag{17}$$

This leads to the simple expression

$$F(\phi, \mathbf{A}) = F^{\mathrm{int}}(\phi, \mathbf{P}) + \tfrac{1}{2}(H_{\mathrm{int}} - H_{\mathrm{ext}})^2 \tag{18}$$

with

$$F^{\mathrm{int}}(\phi, \mathbf{P}) = \frac{1}{|\Omega_\lambda|}\int_{\Omega_\lambda} \frac{1}{2}\left\| ik^{-1}\nabla\phi + \left(\frac{H_{\mathrm{int}}}{2\pi}\mathbf{A}_0 + \mathbf{P}\right)\phi \right\|^2 + \frac{1}{4}(1 - |\phi|^2)^2 + \frac{1}{2}(\mathrm{curl}\ \ \mathbf{P})^2. \tag{19}$$

The functional F^{int} is called internal energy and depends only on H_{int}, k, ϕ, and $\mathbf{P}$. The second term on the rhs of (17) is a very simple magnetic energy: $1/2(H_{\mathrm{int}} - H_{\mathrm{ext}})^2$.

We want to analyze the properties of the minimizers in function of two parameters k and H_{ext} as explained in the Introduction and we recall that H_{int} and λ are linked by (13). We first start with a change of variables and of functions:

$$u(x) = \phi\left(x\sqrt{\frac{2\pi}{kH_{\mathrm{int}}}}\right)$$
$$\mathbf{a}(x) = \sqrt{\frac{2\pi k}{H_{\mathrm{int}}}}\left[\mathbf{A} - \frac{H_{\mathrm{int}}}{2\pi}\mathbf{A}_0\right]\left(x\sqrt{\frac{2\pi}{kH_{\mathrm{int}}}}\right) = \sqrt{\frac{2\pi k}{H_{\mathrm{int}}}}\mathbf{A}\left(x\sqrt{\frac{2\pi}{kH_{\mathrm{int}}}}\right) - \mathbf{A}_0(x) \ \ \text{and} \ \ \mu = \frac{H_{\mathrm{int}}}{2\pi k}. \tag{20}$$

In this change, the lattice $\mathcal{L}_\lambda$ becomes $\mathcal{L}_d = \sqrt{d}\mathcal{L}_1$ with fundamental domain $\Omega_d = \sqrt{d}\Omega_1$ of area d. The energy will obviously depend on the geometry of the lattice $\mathcal{L}_1$. It is a physical conjecture supported by many numerical results[5,6] that the minimal energy is attained when varying the geometry by the hexagonal lattice. Note that this remains a mathematical conjecture!

The C^∞ sections u of the new vector bundle E_d satisfy

$$\forall (x,y) \in \mathbb{R}^2, \forall v \in \mathcal{L}_d, \quad u((x,y) + v) = e^{i\pi(v_x y - v_y x)}u(x,y), \tag{21}$$

and the potential vector $\mathbf{a}$ belongs to the space

$$\left\{ \mathbf{a} \in H^1_{\mathrm{loc}}(\mathbb{R}^2; \mathbb{R}^2) \ \text{ such that } \ \mathrm{div}\,\mathbf{a} = 0, \ \ \mathbf{a} \ \text{ is } \ \mathcal{L}_d\text{-periodic and } \ \int_{\Omega_d} \mathbf{a} = 0 \right\}. \tag{22}$$

We denote by $\mathcal{A}_d$ the space of all pairs $(u, \mathbf{a})$ with u being a H^1_{loc} section of E_d (21) and $\mathbf{a}$ belonging to the space (22).

Let us define the functional $E_{H_{\mathrm{int}},k}$ over $\mathcal{A}_d$ by

$$E_{H_{\rm int},k}(u,\mathbf{a})=\frac{1}{d}\int_{\Omega_d}\frac{H_{\rm int}}{4\pi k}\|i\nabla u+(\mathbf{A}_0+\mathbf{a})u\|^2+\frac{1}{4}(1-|u|^2)^2+\frac{H_{\rm int}^2}{2(2\pi)^2}|\text{curl}\ \ \mathbf{a}|^2$$

$$=\frac{1}{d}\int_{\Omega_d}\frac{\mu}{2}\|i\nabla u+(\mathbf{A}_0+\mathbf{a})u\|^2+\frac{1}{4}(1-|u|^2)^2+\frac{\mu^2k^2}{2}|\text{curl}\ \ \mathbf{a}|^2. \tag{23}$$

After the change introduced in (20), the GL functional becomes

$$F(\phi,\mathbf{A})=E_{k,H_{\rm ext}}(H_{\rm int},u,\mathbf{a})=E_{H_{{\rm int},k}}(u,\mathbf{a})+\tfrac{1}{2}(H_{\rm int}-H_{\rm ext})^2. \tag{24}$$

The problem of minimizing the Ginzburg–Landau functional F is then split into two minimizing problems, one for $E_{H_{\rm int},k}$ over $\mathcal{A}_d$ and another one for the functional

$$\mathbb{R}_+\to\mathbb{R},$$

$$H_{\rm int}\mapsto m_E(H_{\rm int},k)+\tfrac{1}{2}(H_{\rm int}-H_{\rm ext})^2, \tag{25}$$

with

$$m_E(H_{\rm int},k)=\inf_{(u,\mathbf{a})\in\mathcal{A}_d}E_{H_{\rm int},k}(u,\mathbf{a}). \tag{26}$$

The quantization relation has disappeared and is now encoded in the functional space $\mathcal{A}_d$ [defined in (21) and (22)].

The function $H_{\rm int}\mapsto m_E(H_{\rm int},k)$ is increasing. We also observe that $\mathcal{E}_{k,H_{\rm ext}}$ introduced in (6) satisfies

$$\mathcal{E}_{k,H_{\rm ext}}=\inf_{H_{\rm int}\in\mathbb{R}_+^*}m_E(H_{\rm int},k)+\tfrac{1}{2}(H_{\rm int}-H_{\rm ext})^2. \tag{27}$$

The infimum of the Ginzburg–Landau functional is also obtained by taking the infimum of the map

$$(H_{\rm int},u,\mathbf{a})\mapsto E_{k,H_{\rm ext}}(H_{\rm int},u,\mathbf{a})=E_{H_{\rm int},k}(u,\mathbf{a})+\tfrac{1}{2}(H_{\rm int}-H_{\rm ext})^2 \tag{28}$$

over $\mathbb{R}_+^*\times\mathcal{A}_d$. Using the fact that $E_{H_{\rm int},k}$ is increasing with $H_{\rm int}$, one can show that

$$\mathcal{E}_{k,H_{\rm ext}}=\inf_{H_{\rm int}\in\,]0,H_{\rm ext}]}m_E(H_{\rm int},k)+\tfrac{1}{2}(H_{\rm int}-H_{\rm ext})^2=\inf_{H_{\rm int}\in\,]0,H_{\rm ext}],(u,\mathbf{a})\in\mathcal{A}_d}E_{k,H_{\rm ext}}(H_{\rm int},u,\mathbf{a}). \tag{29}$$

With the above renormalization we can prove that $E_{\mathcal{P}}$ is effectively obtained. We first show the following.

Proposition II.1: We have $\lim_{H_{\rm int}\to 0}m_E(H_{\rm int},k)=0$.

Proof: We have

$$E_{H_{\rm int},k}(u,0)=\frac{1}{d}\int_{\Omega_d}\frac{H_{\rm int}}{4\pi k}\|i\nabla u+\mathbf{A}_0u\|^2+\frac{1}{4}(1-|u|^2)^2. \tag{30}$$

Let $\epsilon>0$. Starting from $u=1$ in Ω_d, it is easy to find a function u_ϵ with compact support in Ω_d which satisfies

$$\int_{\Omega_d}(1-|u_\epsilon|^2)^2<2d\epsilon. \tag{31}$$

This u_ϵ can be extended to $\mathbb{R}^2$ by using the property (21).

Then we can find $\eta>0$ s.t., $\forall H_{\text{int}} \in]0,\eta]$,

$$\frac{1}{d}\int_{\Omega_d} \frac{H_{\text{int}}}{4\pi k} \| i\nabla u_\epsilon + \mathbf{A}_0 u_\epsilon \|^2 \leqslant \frac{\epsilon}{2}, \tag{32}$$

and we have obtained $E_{H_{\text{int}},k}(u_\epsilon,0)<\epsilon$ for $H_{\text{int}} \in]0,\eta]$. The proposition is then proved. **QED**

Coming back to the original problem and using (28), we obtain the following.

Corollary II.2: There exists a sequence ϕ_{λ_n} of sections of $C^\infty(E_{\lambda_n,d})$ with $\lambda_n \to \infty$ such that $\lim_{n\to\infty} F(\phi_{\lambda_n}, (2\pi d/k\lambda_n^2)\mathbf{A}_0) = H_{\text{ext}}^2/2$.

III. THE FUNCTIONAL $E_{H_{\text{int}},k}$

Let us now analyze the functional introduced in (23). We have the basic property.

Proposition III.1: If $(u,\mathbf{a}) \in \mathcal{A}_d$, then $E_{H_{\text{int}},k}(u,\mathbf{a})<\infty$.

Proof: The basic Sobolev imbeddings give us

$$(u,\mathbf{a}) \in L^p_{\text{loc}}(\mathbb{R}^2;\mathbb{C}) \times L^p_{\text{loc}}(\mathbb{R}^2;\mathbb{R}^2) \quad \text{if} \quad p<\infty. \tag{33}$$

So, the conclusion is obtained using standard Hölder estimates.[7] **QED**

Let us observe that, using the same estimates, one can in fact show that $E_{H_{\text{int}},k}$ is Fréchet differentiable. There is a Bochner–Kodaira–Nakano formula for $E_{H_{\text{int}},k}$ (see Refs. 8–10 for related formulas and results). We set $\mathbf{C}=\mathbf{A}_0+\mathbf{a}$ and we have

$$C_x = -\pi y + a_x, \quad C_y = \pi x + a_y \quad \text{and} \quad \text{curl } \mathbf{C} = 2\pi + \text{curl } \mathbf{a}. \tag{34}$$

Let us define A_+ by

$$A_+(u,\mathbf{a}) = \frac{1}{d}\int_{\Omega_d} \frac{\mu}{2} |D_+ u|^2 + \frac{1}{4} |\mu \text{ curl } \mathbf{C} - (1-|u|^2)|^2, \tag{35}$$

where

$$\mu = \frac{H_{\text{int}}}{2\pi k} \tag{36}$$

and

$$D_+ = \frac{\partial}{\partial x} + i\frac{\partial}{\partial y} + C_y - iC_x. \tag{37}$$

Theorem III.2 (Bochner–Kodaira–Nakano): *If $k=1/\sqrt{2}$ then, for all $(u,\mathbf{a}) \in \mathcal{A}_d$, we have*

$$E_{H_{\text{int},1/\sqrt{2}}}(u,\mathbf{a}) = \mu\pi - (\mu\pi)^2 + A_+(u,\mathbf{a}). \tag{38}$$

Proof: We perform computations with smooth functions and then extend by density:

$$
\begin{aligned}
2d(A_+(u,\mathbf{a})-E_{H_{\mathrm{int},1/\sqrt{2}}}(u,\mathbf{a}))&=\int_{\Omega_d}\mu\left[\left(\frac{\partial u}{\partial x}-iC_xu\right)\overline{\left(i\frac{\partial u}{\partial y}+C_yu\right)}+\overline{\left(\frac{\partial u}{\partial x}-iC_xu\right)}\left(i\frac{\partial u}{\partial y}+C_yu\right)\right.\\
&\quad\left.-(\mathrm{curl}\ \mathbf{C})(1-|u|^2)\right]+\frac{\mu^2}{2}\int_{\Omega_d}\{|\mathrm{curl}\ \mathbf{C}|^2-|\mathrm{curl}\ \mathbf{a}|^2\}\\
&=\mu\int_{\Omega_d}\frac{\partial}{\partial x}\left\{\overline{u}\left(i\frac{\partial u}{\partial y}+C_yu\right)\right\}-\frac{\partial}{\partial y}\left\{\overline{u}\left(i\frac{\partial u}{\partial x}+C_xu\right)\right\}\\
&\quad-\int_{\Omega_d}\mu(\mathrm{curl}\ \mathbf{C})+\frac{\mu^2}{2}\int_{\Omega_d}\{|\mathrm{curl}\ \mathbf{C}|^2-|\mathrm{curl}\ \mathbf{a}|^2\}\\
&=\mu\int_{\Omega_d}\mathrm{div}\,\mathbf{W}+2(\mu\pi)^2-2\mu\pi. \qquad (39)
\end{aligned}
$$

The vector field $\mathbf{W}$ appearing in (39) is defined by

$$
\mathbf{W}=\begin{pmatrix}\overline{u}\left(i\dfrac{\partial u}{\partial y}+C_yu\right)\\ -\overline{u}\left(i\dfrac{\partial u}{\partial x}+C_xu\right)\end{pmatrix} \qquad (40)
$$

and is $\mathcal{L}_d$-periodic on $\mathbb{R}^2$. This implies that $\int_{\Omega_d}\mathrm{div}\,\mathbf{W}=0$ and we immediately obtain (38).

QED

Let us observe as a consequence of (38) that

$$
m_E\left(H_{\mathrm{int}},\frac{1}{\sqrt{2}}\right)\geqslant\mu\pi-(\mu\pi)^2=\frac{H_{\mathrm{int}}}{\sqrt{2}}-\left(\frac{H_{\mathrm{int}}}{\sqrt{2}}\right)^2. \qquad (41)
$$

In fact it is possible to compute $m_E(H_{\mathrm{int}},1/\sqrt{2})$ (see Ref. 4, p. 127).

The spectral theory of $H=[i\nabla+\mathbf{A}_0]^2$ is especially important (see, for example, Ref. 11 or Ref. 4, p. 48). His spectrum $sp(H)$ is discrete and $sp(H)=2\pi+4\pi\mathbb{N}$. The multiplicity of 2π is equal to d.

We are interested in the minima of $E_{H_{\mathrm{int}},k}$ and we would also like to study the local stability of the pair (0, 0).

Proposition III.3: The pair (0, 0) *is a critical point for the functional* $E_{H_{\mathrm{int}},k}$.

The quadratic form $D^2_{(0,0)}E_{H_{\mathrm{int}},k}(\delta u,\delta\mathbf{a})$ *is positive definite if and only if* $k<H_{\mathrm{int}}$.

Proof: The first differential at $(u,\mathbf{a})$ is the linear form

$$
\begin{aligned}
D_{(u,\mathbf{a})}E_{H_{\mathrm{int}},k}(u',\mathbf{a}')&=\frac{1}{d}\int_{\Omega_d}\mathrm{Re}[\overline{u}'\{\mu[i\nabla+(\mathbf{A}_0+\mathbf{a})]^2u-(1-|u|^2)u\}]\\
&\quad+\frac{1}{d}\int_{\Omega_d}\mathbf{a}'\{\mu\,\mathrm{Re}[\overline{u}(i\nabla u+(\mathbf{A}_0+\mathbf{a})u)]+k^2\mu^2\mathrm{curl}^*\mathrm{curl}\ \mathbf{a}\}. \qquad (42)
\end{aligned}
$$

We easily get $D_{(0,0)}E_{H_{\mathrm{int}},k}=0$.

The second differential at $(u,\mathbf{a})$ is the bilinear form defined on $\mathcal{A}_d\times\mathcal{A}_d$ by

$$(u_1,\mathbf{a}_1),(u_2,\mathbf{a}_2)\mapsto \frac{1}{d}\int_{\Omega_d}\mathrm{Re}\{\mu\overline{u_1}[i\boldsymbol{\nabla}+\mathbf{A}]^2u_2\}+2\,\frac{1}{d}\int_{\Omega_d}\mathrm{Re}\left[\mu\int_{\Omega_d}[\mathbf{a}_2\overline{u_1}+\mathbf{a}_1\overline{u_2}]\cdot(i\boldsymbol{\nabla}u+\mathbf{C}u)\right]$$
$$+\frac{1}{d}\int_{\Omega_d}-(1-|u|^2)\mathrm{Re}\,\overline{u_1}u_2+2\,\mathrm{Re}(\overline{u}u_2)\mathrm{Re}(\overline{u}u_1)$$
$$+\frac{1}{d}\int_{\Omega_d}\mu\mathbf{a}_1\cdot\mathbf{a}_2|u|^2+\mu^2k^2\mathrm{curl}\ \ \mathbf{a}_1\cdot\mathrm{curl}\ \ \mathbf{a}_2, \tag{43}$$

with $\mathbf{C}=\mathbf{A}_0+\mathbf{a}$.

We get at (0, 0) the bilinear form

$$D^2_{(0,0)}E_{H_{\mathrm{int}},k}:\mathcal{A}_d\times\mathcal{A}_d\to\mathbb{R}, \tag{44}$$

$$(u_1,\mathbf{a}_1),(u_2,\mathbf{a}_2)\to\frac{1}{d}\int\Omega_d\,\mathrm{Re}\{\overline{u_1}(\mu[i\boldsymbol{\nabla}+\mathbf{A}_0]^2-1)u_2\}+\frac{1}{d}\int_{\Omega_d}\mu^2k^2\,\mathrm{curl}\ \ \mathbf{a}_1\,\mathrm{curl}\ \ \mathbf{a}_2.$$

The associated quadratic form is

$$D^2_{(0,0)}E_{H_{\mathrm{int}},k}(u',\mathbf{a}')=\frac{1}{d}\int_{\Omega_d}\overline{u'}(\mu[i\boldsymbol{\nabla}+\mathbf{A}_0]^2-1)u'+\mu^2k^2|\mathrm{curl}\ \ \mathbf{a}'|^2. \tag{45}$$

The term $\int_{\Omega_d}|\mathrm{curl}\ \ \mathbf{a}'|^2$ is positive definite as one can show using the definition of $\mathcal{A}_d$.
The operator $\mu[i\boldsymbol{\nabla}+\mathbf{A}_0]^2-1$ is positive definite if and only if $2\mu\pi-1>0$, i.e., if and only if $k<H_{\mathrm{int}}$. **QED**

IV. THE MONOTONICITY THEOREMS

Theorem IV.1: *If $(k,H_{\mathrm{ext}})\in\mathcal{P}$, then if $k'\leqslant k$ and $H'_{\mathrm{ext}}\leqslant H_{\mathrm{ext}}$, one has $(k',H'_{\mathrm{ext}})\in\mathcal{P}$.*

Proof: Let $(k,H_{\mathrm{ext}})\in\mathcal{P}$. We have $\mathcal{E}_{k,H_{\mathrm{ext}}}=H^2_{\mathrm{ext}}/2$. By definition (6) and (27) of $\mathcal{E}_{k,H_{\mathrm{ext}}}$, we have

$$\forall H_{\mathrm{int}}>0,\forall(u,\mathbf{a})\in\mathcal{A}_d,\quad E_{H_{\mathrm{int}},k}(u,\mathbf{a})+\frac{1}{2}(H_{\mathrm{int}}-H_{\mathrm{ext}})^2\geqslant\frac{H^2_{\mathrm{ext}}}{2}. \tag{46}$$

The inequality (46) is equivalent to $\forall H_{\mathrm{int}}>0$, $\forall(u,\mathbf{a})\in\mathcal{A}_d$,

$$\left\{\frac{1}{d}\int_{\Omega_d}\frac{H_{\mathrm{int}}}{4\pi k}\|i\boldsymbol{\nabla}u+(\mathbf{A}_0+\mathbf{a})u\|^2+\frac{1}{4}(1-|u|^2)^2+\frac{H^2_{\mathrm{int}}}{2(2\pi)^2}|\mathrm{curl}\ \ \mathbf{a}|^2\right\}+\frac{H^2_{\mathrm{int}}-2H_{\mathrm{int}}H_{\mathrm{ext}}}{2}\geqslant 0. \tag{47}$$

If k is decreasing, then $1/k$ is increasing; the integrals being positive, the left-hand side of (47) is increasing. If H_{ext} is decreasing, then the quantity $-2H_{\mathrm{int}}H_{\mathrm{ext}}$ is increasing and so the left-hand side is increasing again. Consequently, if $k'\leqslant k$ and $H'_{\mathrm{ext}}\leqslant H_{\mathrm{ext}}$, we get the inequality $E_{k',H'_{\mathrm{ext}}}(H_{\mathrm{int}},u,\mathbf{a})\geqslant H'^2_{\mathrm{ext}}/2$, $\forall(u,\mathbf{a})\in\mathcal{A}_d$ and, taking the infimum, $\mathcal{E}_{k',H'_{\mathrm{ext}}}\geqslant H'^2_{\mathrm{ext}}/2$. **QED**

Theorem IV.2: *If $(k,H_{\mathrm{ext}})\in\mathcal{N}$ and $k'\geqslant k$, then $(k',(k'/k)H_{\mathrm{ext}})\in\mathcal{N}$.*

Proof: Let $(k,H_{\mathrm{ext}})\in\mathcal{N}$. We have $\mathcal{E}_{k,H_{\mathrm{ext}}}=1/4$. Let us denote by $H'_{\mathrm{ext}}=(k'/k)H_{\mathrm{ext}}$ the new magnetic field. By definition of the set $\mathcal{N}$ and of $E_{k,H_{\mathrm{ext}}}$ [see (11) and (23)], we obtain

$$\forall H_{\mathrm{int}}>0,\forall(u,\mathbf{a})\in\mathcal{A}_d,$$
$$\left\{\frac{1}{d}\int_{\Omega_d}\frac{H_{\mathrm{int}}}{4\pi k}\|i\boldsymbol{\nabla}u+(\mathbf{A}_0+\mathbf{a})u\|^2+\frac{1}{4}(1-|u|^2)^2+\frac{H^2_{\mathrm{int}}}{8\pi^2}|\mathrm{curl}\ \ \mathbf{a}|^2\right\}+\frac{1}{2}(H_{\mathrm{int}}-H_{\mathrm{ext}})^2\geqslant\frac{1}{4}. \tag{48}$$

The inequality we wish to prove is

$$\forall H'_{\text{int}}>0,\ \forall (u,\mathbf{a})\in\mathcal{A}_d,$$
$$\left\{\frac{1}{d}\int_{\Omega_d}\frac{H'_{\text{int}}}{4\pi k'}\|i\nabla u+(\mathbf{A}_0+\mathbf{a})u\|^2+\frac{1}{4}(1-|u|^2)^2+\frac{H'^2_{\text{int}}}{8\pi^2}|\text{curl}\ \ \mathbf{a}|^2\right\}+\frac{1}{2}(H'_{\text{int}}-H'_{\text{ext}})^2\geqslant\frac{1}{4}. \tag{49}$$

We write in analogy with H'_{ext}, $H'_{\text{int}}=(k'/k)H_{\text{int}}$ and we obtain

$$\frac{H_{\text{int}}}{k}=\frac{H'_{\text{int}}}{k'}. \tag{50}$$

It is enough to show

$$\forall H_{\text{int}}>0,\ \forall (u,\mathbf{a})\in\mathcal{A}_d,$$
$$\left\{\frac{1}{d}\int_{\Omega_d}\frac{H_{\text{int}}}{4\pi k}\|i\nabla u+(\mathbf{A}_0+\mathbf{a})u\|^2+\frac{1}{4}(1-|u|^2)^2+\left(\frac{k'}{k}\right)^2\frac{H^2_{\text{int}}}{8\pi^2}|\text{curl}\ \ \mathbf{a}|^2\right\}+\left(\frac{k'}{k}\right)^2\frac{1}{2}(H_{\text{int}}-H_{\text{ext}})^2$$
$$\geqslant\frac{1}{4}. \tag{51}$$

This inequality is implied by (48) since $k'\geqslant k$. **QED**

Theorem IV.3: *If $(k,H_{\text{ext}})\in\mathcal{N}$, then if $H'_{\text{ext}}\geqslant H_{\text{ext}}$ we have $(k,H'_{\text{ext}})\in\mathcal{N}$.*

Proof: Let $(k,H_{\text{ext}})\in\mathcal{N}$. By definitions (11) and (27) of $\mathcal{E}_{k,H_{\text{ext}}}$, we have

$$\forall H_{\text{int}}>0, m_E(H_{\text{int}},k)+\tfrac{1}{2}(H_{\text{int}}-H_{\text{ext}})^2\geqslant E_{\mathcal{N}}. \tag{52}$$

At $H_{\text{int}}=H_{\text{ext}}$ this inequality implies

$$m_E(H_{\text{ext}},k)\geqslant E_{\mathcal{N}}. \tag{53}$$

We have to show inequality (52) with H_{ext} replaced by H'_{ext}. If $H_{\text{int}}\leqslant H_{\text{ext}}$, we trivially obtain

$$(H_{\text{int}}-H_{\text{ext}})^2\leqslant(H_{\text{int}}-H'_{\text{ext}})^2. \tag{54}$$

Then inequality (52) is shown with $H_{\text{int}}\in\,]0,H_{\text{ext}}]$ and H_{ext} replaced by H'_{ext}.
If $H_{\text{int}}>H_{\text{ext}}$, then we get from (53) and by monotonicity of m_E

$$m_E(H_{\text{int}},k)\geqslant m_E(H_{\text{ext}},k)\geqslant E_{\mathcal{N}}. \tag{55}$$

Consequently, inequality (52) is shown with $H_{\text{int}}\in\,]H_{\text{ext}},\infty[$ and H_{ext} replaced by H'_{ext}. **QED**

Let us consider the special case when $k=H_{\text{ext}}=1/\sqrt{2}$. We have the following lemma:

Lemma IV.4: The value of $\mathcal{E}_{1/\sqrt{2},1/\sqrt{2}}$ is 1/4 and $(1/\sqrt{2},1/\sqrt{2})\in\mathcal{P}\cap\mathcal{N}$.

Proof: We set $k=1/\sqrt{2}$. By the equality (29), it is sufficient to show

$$\forall H_{\text{int}}\in\left]0,\frac{1}{\sqrt{2}}\right],m_E(H_{\text{int}},k)+\frac{1}{2}\left(H_{\text{int}}-\frac{1}{\sqrt{2}}\right)^2\geqslant\frac{1}{4}. \tag{56}$$

Using (41) we remark that inequality (56) is implied by the inequality

$$\forall H_{\text{int}}\leqslant\frac{1}{\sqrt{2}},\ \left[\frac{H_{\text{int}}}{2k}-\left(\frac{H_{\text{int}}}{2k}\right)^2\right]+\frac{1}{2}\left(H_{\text{int}}-\frac{1}{\sqrt{2}}\right)^2\geqslant\frac{1}{4}. \tag{57}$$

But this inequality is in fact an equality and we get the claim.

The energy of normal state is $E_{\mathcal{N}}=1/4$. The energy of the pure state is $E_{\mathcal{P}}=1/2(1/\sqrt{2})^2=1/4$. **QED**

Theorem IV.5 (Type I superconductors): *If* $k\leqslant 1/\sqrt{2}$, *then*

$$\mathcal{E}_{k,H_{\text{ext}}}=\begin{cases} E_{\mathcal{P}} & \text{if } H_{\text{ext}}\leqslant \dfrac{1}{\sqrt{2}}, \\ E_{\mathcal{N}} & \text{if } H_{\text{ext}}\geqslant \dfrac{1}{\sqrt{2}}. \end{cases} \tag{58}$$

Proof: Lemma IV.4 combined with Theorem IV.1 gives the result in the case $H_{\text{ext}}\leqslant 1/\sqrt{2}$. In particular, if $k\leqslant 1/\sqrt{2}$, we have $(k,1/\sqrt{2})\in\mathcal{P}$ and so $\mathcal{E}_{k,1/\sqrt{2}}=E_{\mathcal{P}}=1/2(1/\sqrt{2})^2=1/4$. This is the energy $E_{\mathcal{N}}$. Then Theorem IV.3 gives the conclusion in the case $H_{\text{ext}}\geqslant 1/\sqrt{2}$. **QED**

Theorem IV.6 (Type II superconductors): *If* $H_{\text{ext}}\geqslant k\geqslant 1/\sqrt{2}$, *then*

$$\mathcal{E}_{k,H_{\text{ext}}}=E_{\mathcal{N}}. \tag{59}$$

In this case the infimum of the functional is attained by the normal state. In the case $k\geqslant 1/\sqrt{2}$ *and* $H_{\text{ext}}<k$ *we have* $(k,H_{\text{ext}})\notin\mathcal{N}$.

Proof: Lemma IV.4 combined with Theorems IV.2 and IV.3 gives the first result.

We have the functional equality

$$E_{k,H_{\text{ext}}}(H_{\text{ext}},u,\mathbf{a})=E_{H_{\text{ext}},k}(u,\mathbf{a}) \tag{60}$$

with $k<H_{\text{ext}}=H_{\text{int}}$. So the state $u=0$, $\mathbf{a}=0$ is not a local minimum of the functional by Proposition III.3 and so the normal state is not minimizing. **QED**

V. PHASE DIAGRAM

We define the following pure and normal sets $\mathcal{P}_k$ and $\mathcal{N}_k$ using the definition of pure and normal states (11):

$$\begin{aligned} \mathcal{P}_k&=\{H_{\text{ext}}\in\mathbb{R}_+^* \text{ s.t. } \mathcal{E}_{k,H_{\text{ext}}}=E_{\mathcal{P}}\}, \\ \mathcal{N}_k&=\{H_{\text{ext}}\in\mathbb{R}_+^* \text{ s.t. } \mathcal{E}_{k,H_{\text{ext}}}=E_{\mathcal{N}}\}. \end{aligned} \tag{61}$$

By Theorems IV.5 and IV.6, we know that $\mathcal{N}_k=[\sup(k,1/\sqrt{2}),+\infty[$. So it remains to determine $\mathcal{P}_k$. Here our results are not complete. However, we can show the following properties.

Theorem V.1: *The set* $\mathcal{P}_k$ *is of the form* $]0,H_{c1}(k)]$ *where* $H_{c1}(k)$ *is a continuous decreasing function of k and*

$$\inf\left(\frac{1}{2k},\frac{1}{\sqrt{2}}\right)\leqslant H_{c1}(k)\leqslant\frac{1}{\sqrt{2}}. \tag{62}$$

Proof:

Step 1: By Theorem IV.5 we know that in the case $k\leqslant 1/\sqrt{2}$, we have $]0,1/\sqrt{2}]=\mathcal{P}_k$.

Step 2: We suppose $k\geqslant 1/\sqrt{2}$. By the preceding definitions (61), we have

$$\begin{aligned} H_{\text{ext}}\in\mathcal{P}_k\Leftrightarrow\forall H_{\text{int}},u,\mathbf{a},&E_{H_{\text{int}},k}(u,\mathbf{a})+\frac{1}{2}(H_{\text{int}}-H_{\text{ext}})^2 \\ &\geqslant\frac{H_{\text{ext}}^2}{2} \end{aligned}$$

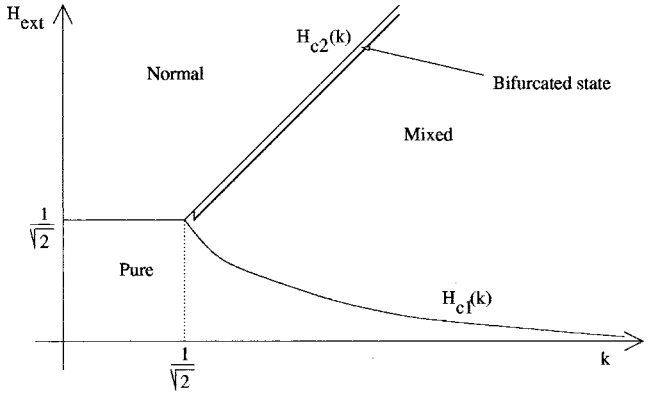

FIG. 1.

$$\Leftrightarrow \forall H_{\text{int}}, u, \mathbf{a}, \frac{1}{H_{\text{int}}} E_{H_{\text{int}},k}(u,\mathbf{a}) + \frac{H_{\text{int}}}{2} \geqslant H_{\text{ext}}$$

$$\Leftrightarrow \begin{cases} \forall H_{\text{int}} > 0, \forall (u,\mathbf{a}) \in \mathcal{A}_d \\ \dfrac{H_{\text{int}}}{2} + \dfrac{1}{4\pi dk} \displaystyle\int_{\Omega_d} \| i\nabla u + (\mathbf{A}_0 + \mathbf{a})u \|^2 \\ + \dfrac{1}{4dH_{\text{int}}} \displaystyle\int_{\Omega_d} (1-|u|^2)^2 + \dfrac{H_{\text{int}}}{2d(2\pi)^2} \int_{\Omega_d} |\text{curl } \mathbf{a}|^2 \geqslant H_{\text{ext}}. \end{cases} \tag{63}$$

But the function defined for $a, b > 0$,

$$\begin{aligned} \mathbb{R}_+^* &\to \mathbb{R}, \\ t &\mapsto at + \frac{b}{t}, \end{aligned} \tag{64}$$

has a minimum of $2\sqrt{ab}$. So we obtain

$$H_{\text{ext}} \in \mathcal{P}_k \Leftrightarrow H_{\text{ext}} \leqslant \inf_{(u,\mathbf{a}) \in \mathcal{A}_d} \left\{ \frac{1}{4\pi dk} \int_{\Omega_d} \| i\nabla u + (\mathbf{A}_0 + \mathbf{a})u \|^2 + \sqrt{\left[\frac{1}{2} + \frac{1}{2d(2\pi)^2} \int_{\Omega_d} |\text{curl } \mathbf{a}|^2 \right] \left[\frac{1}{d} \int_{\Omega_d} (1-|u|^2)^2 \right]} \right\}, \tag{65}$$

and so $\mathcal{P}_k =]0, H_{c1}(k)]$ with

$$H_{c1}(k) = \inf_{(u,\mathbf{a}) \in \mathcal{A}_d} \left\{ \frac{1}{4\pi dk} \int_{\Omega_d} \| i\nabla u + (\mathbf{A}_0 + \mathbf{a})u \|^2 + \sqrt{\left[\frac{1}{2} + \frac{1}{2d(2\pi)^2} \int_{\Omega_d} |\text{curl } \mathbf{a}|^2 \right] \left[\frac{1}{d} \int_{\Omega_d} (1-|u|^2)^2 \right]} \right\}. \tag{66}$$

Step 3: From the expression (66) it follows that $H_{c1}(k)$ is a decreasing function and $kH_{c1}(k)$ is an increasing function. From the first step we know that $H_{c1}(1/\sqrt{2}) = 1/\sqrt{2}$. Then $\forall k \geqslant 1/\sqrt{2}$ we have

$$H_{c1}(k) \leqslant \frac{1}{\sqrt{2}} \text{ and } kH_{c1}(k) \geqslant \frac{1}{2}. \tag{67}$$

The inequalities (62) are then proved.

Step 4: H_{c1} is a decreasing function of k so the limits

$$l_- = \lim_{k \to k_0, k<k_0} H_{c1}(k) \text{ and } l_+ = \lim_{k \to k_0, k>k_0} H_{c1}(k) \tag{68}$$

exist and satisfy $l_+ \leqslant l_-$. The function $kH_{c1}(k)$ is increasing so $k_0 l_- \leqslant k_0 l_+$ and we conclude that H_{c1} is continuous. **QED**

The proof that $H_{c1}(k) \to 0$ as $k \to \infty$ is contained in Ref. 4, p. 143. The exact value of $H_{c1}(k)$ seems impossible to compute; nevertheless, an analysis near $k = 1/2$ of the phase diagram will appear in a subsequent paper.

The phase diagram is a picture in the plane $(k, H_{\text{ext}}) \in \mathbb{R}_+^* \times \mathbb{R}_+^*$ on which all the three preceding states are drawn. We have proved that its qualitative shape is that in Fig. 1, which depends on the number d introduced in (3). This is the diagram encountered in the physical literature.[12–15]

In Ref. 4 there is a more precise analysis of the special case $d = 1$. Among other things there is a bifurcation analysis in the limit H_{ext} near k (Ref. 4, p. 79).[5,16–18] An asymptotic estimate of the energy gap between normal and mixed state extending results from Ref. 19 is available in (Ref. 4 p. 130), using these bifurcated states.

Calogero–Moser systems with periodic and doubly periodic interaction potentials and loop algebras

M. Fleury[a)]
Lycée Camille Guérin, 33 rue de la Gibauderie B.P. 611 86022 Poitiers Cedex France

(Received 15 May 2001; accepted for publication 19 July 2001)

For a finite number of particles on the line pairwise interacting with $1/r^2$ potential, the positions are given by the eigenvalues of some time-dependent matrix. Infinite periodic or doubly periodic replication of the particles yields Calogero–Moser systems with periodic or doubly periodic interaction potential. We are thus led to consider matrices of infinite order, which are identified with Fourier series with matrix coefficients, depending on an additional parameter. These distributional loops of matrices (tori of matrices in the doubly periodic case) are shown to obey simple (partial) differential equations, which allow us to determine them explicitly. Thus we obtain the already known solution of the Calogero–Moser system on the circle, and provide a new insight for the system on the torus. © *2001 American Institute of Physics.* [DOI: 10.1063/1.1401136]

I. INTRODUCTION

Calogero–Moser systems were introduced long ago and were proven to be completely integrable by Lax pairs technics, see Ref. 1. The systems with $1/r^2$ and $1/\sin^2 r$ interaction potentials received in Ref. 2 an enlightening geometric interpretation through Marsden–Weinstein reduction of geodesic flows on Lie algebras or Lie groups. However, the system with a Weierstrass $\mathcal{P}$ function interaction potential remains less understood. The two-particle system has been solved in Ref. 3, and the only known integration scheme in the general case was provided by Krichever in Ref. 4, through the solitonic solutions of the Kadomtsev–Patviashvili (KP) equation.

The present work starts from the solution of the system with $1/r^2$ interaction potential and proceeds by infinite replication. Calogero and Françoise had previously used a duplication scheme to produce new integrable systems and their solutions from the system on the line in Ref. 5. Here we have in mind the Eulerian development of $1/\sin^2$ and proceed by infinite replication by translations of the system on the line. The corresponding matrices are infinite dimensional and are interpreted as distributional elements of some loop algebra. The striking fact is that these distributions are just elementary differential operators. This allows us to give a new proof of the solution of the system with $1/\sin^2 r$ interaction potential.

Then, we apply a doubly infinite replication to investigate the system with Weierstrass $\mathcal{P}$ function interaction potential, which leads us to a partial differential operator on the space of doubly periodic functions with values in $\mathbb{C}^n$. Though this operator is very simple looking and very similar to the preceding one, it is indeed much more involved to determine its spectrum and this is beyond the author's reach. We connect this problem to some finite difference equation in a space of simply periodic analytic functions.

II. INFINITE REPLICATION

It is known that the Calogero–Moser system on the real line with $1/r^2$ pairwise interaction potential can be integrated in the following way.[2]

Let $x_1, x_2, \ldots, x_n$ denote the initial positions of the particles, and $y_1, \ldots, y_n$ their initial velocities,

[a)]Electronic mail: marc.fleury6@freesbee.fr

$$A=\begin{pmatrix} ix_1 & 0 & \dots & 0 \\ 0 & \ddots & \ddots & \vdots \\ \vdots & \ddots & \ddots & 0 \\ 0 & \dots & 0 & ix_n \end{pmatrix},$$

$$B=\begin{pmatrix} iy_1 & \dfrac{1}{x_2-x_1} & \dots & \dfrac{1}{x_n-x_1} \\ \dfrac{1}{x_1-x_2} & \ddots & \ddots & \vdots \\ \vdots & \ddots & \ddots & \dfrac{1}{x_n-x_{n-1}} \\ \dfrac{1}{x_1-x_n} & \dots & \dfrac{1}{x_{n-1}-x_n} & iy_n \end{pmatrix},$$

so that

$$[A,B]=M=\begin{pmatrix} 0 & -i & \dots & -i \\ -i & \ddots & \ddots & \vdots \\ \vdots & \ddots & \ddots & -i \\ -i & \dots & -i & 0 \end{pmatrix}.$$

The position of particles at time t are then the eigenvalues of $A+tB$, divided by i.

We also recall that the positions at time t of the Calogero–Moser system on the circle with pairwise interaction potential $1/\sin^2(r/2)$ (also called the Sutherland system) are the arguments of the eigenvalues of the matrix $\exp(A)\cdot\exp(tC)$, where $C=(c_{k,l})$ with $c_{k,l}=i/e^{i(x_l-x_k)}-1$ for $k\neq l$ and $c_{k,k}=iy_k$,

Our first aim is to show that the solution of the system on the circle can be deduced from a system on the line with infinitely many particles.

Let us recall the Eulerian expansion:

$$\frac{1}{\sin^2 r}=\sum_{k\in\mathbb{Z}}\frac{1}{(r-k\pi)^2}.$$

According to this formula, one can write the Hamiltonian

$$H=\frac{1}{2}\sum_i y_i^2+\frac{1}{2}\sum_{i\neq j}\frac{1}{4\sin^2\dfrac{x_j-x_i}{2}}$$

in the form

$$\begin{aligned} H&=\frac{1}{2}\sum_i y_i^2+\frac{1}{2}\sum_{i\neq j}\sum_{k\in\mathbb{Z}}\frac{1}{(x_j-x_i-2k\pi)^2} \\ &=\frac{1}{2}\sum_i y_i^2+\frac{1}{2}\sum_{i\neq j}\lim_{N\to+\infty}\frac{1}{2N}\sum_{k,l\in[-N,N]}\frac{1}{[(x_j+2k\pi)-(x_i+2l\pi)]^2}. \end{aligned}$$

For all $i\in\mathbb{Z}$, let us write $i=kn+r$ with $1\leqslant r\leqslant n$ and set $x_i=x_r+2k\pi$ and $y_i=y_r$. The Hamiltonian takes thus the form

$$H=\lim_{N\to+\infty}\frac{1}{2N}\left[\frac{1}{2}\sum_{-nN\leqslant i\leqslant nN}y_i^2+\frac{1}{2}\sum_{\substack{-nN\leqslant i,j\leqslant nN\\ i\not\equiv j[n]}}\frac{1}{(x_j-x_i)^2}\right].$$

Therefore, the n-body Sutherland system on the circle is analogous to the infinitely many-body system on the line obtained by associating to each particle on the circle infinitely many particles on the line, 2π-distant of each other and animated with the same velocity.

We thus form the infinite dimensional matrices $\tilde{A}$, $\tilde{M}$, and $\tilde{B}$ indexed by $\mathbb{Z}\times\mathbb{Z}$ where

$$\tilde{A}=\begin{pmatrix}\ddots & & & & \\ & A-2i\pi I & 0 & 0 & \\ & 0 & A & 0 & \\ & 0 & 0 & A+2i\pi I & \\ & & & & \ddots\end{pmatrix},$$

$$\tilde{B}=\begin{pmatrix}\ddots & & & & \\ & P_0 & P_{-1} & P_{-2} & \\ & P_1 & P_0 & P_{-1} & \\ & P_2 & P_1 & P_0 & \\ & & & & \ddots\end{pmatrix},\quad \tilde{M}=\begin{pmatrix}\ddots & & & & \\ & M & M & M & \\ & M & M & M & \\ & M & M & M & \\ & & & & \ddots\end{pmatrix},$$

where

$$P_k=\begin{pmatrix} iy_1\delta_{k,0} & \dfrac{1}{x_2-x_1+2k\pi} & \cdots & \dfrac{1}{x_n-x_1+2k\pi}\\ \dfrac{1}{x_1-x_2+2k\pi} & \ddots & \ddots & \vdots\\ \vdots & \ddots & \ddots & \dfrac{1}{x_n-x_{n-1}+2k\pi}\\ \dfrac{1}{x_1-x_n+2k\pi} & \cdots & \dfrac{1}{x_{n-1}-x_n+2k\pi} & iy_n\delta_{k,0}\end{pmatrix}$$

so that $[\tilde{A},\tilde{B}]=\tilde{M}$.

III. LOOP ALGEBRAIC INTERPRETATION

The matrices $\tilde{A}$ and $\tilde{B}$ will be considered as linear operators on the space of one-periodic $\mathbb{C}^n$-valued functions $f:\theta\mapsto\Sigma_{k\in\mathbb{Z}}f_ke^{2ik\pi\theta}$.

Writing f as

$$f=\begin{pmatrix}\vdots\\ f_{-1}\\ f_0\\ f_1\\ \vdots\end{pmatrix},$$

one gets

$$\tilde{A}f=\begin{pmatrix} \vdots \\ -2i\pi f_{-1}+Af_{-1} \\ Af_0 \\ 2i\pi f_1+Af_1 \\ \vdots \end{pmatrix}=f'+Af,$$

where the prime designates derivation with respect to the variable θ, and

$$\tilde{B}f=\begin{pmatrix} \vdots \\ \cdots+P_0f_{-1}+P_{-1}f_0+P_{-2}f_1+\cdots \\ \cdots+P_1f_{-1}+P_0f_0+P_{-1}f_1+\cdots \\ \cdots+P_2f_{-1}+P_1f_0+P_0f_1+\cdots \\ \vdots \end{pmatrix}=\Lambda f,$$

where $\Lambda(\theta)=\cdots+P_{-1}e^{-2i\pi\theta}+P_0+P_1e^{2i\pi\theta}+\cdots$.

We now proceed to the computation of Λ.

The equation $[\tilde{A},\tilde{B}]=\tilde{M}$ can be rewritten in the following way: $\forall k\in\mathbb{Z}\ AP_k-P_k(A-2ik\pi I)=M$.

Multiplying each member by $e^{2ik\pi\theta}$, we get after summation:

$$A\sum_{k\in\mathbb{Z}}P_ke^{2ik\pi\theta}-\sum_{k\in\mathbb{Z}}P_ke^{2ik\pi\theta}A+\sum_{k\in\mathbb{Z}}2ik\pi P_ke^{2ik\pi\theta}=M\sum_{k\in\mathbb{Z}}e^{2ik\pi\theta}.$$

Thus $[A,\Lambda(\theta)]+\Lambda'(\theta)=M\delta_0$.

In order to solve this equation on the circle, we first solve the associated equation on the line: $[A,\Lambda(\theta)]+\Lambda'(\theta)=M\Sigma_{k\in\mathbb{Z}}\delta_k$ (cf. Poisson summation formula)
and we will retain the one-periodic solutions.

The associated homogeneous equation is

$$\Lambda'(\theta)=-[A,\Lambda(\theta)],$$

the general solution of which is $\Lambda(\theta)=e^{-\theta A}Ke^{\theta A}$ (K constant matrix).

The solution of the complete equation is obtained by varying the constant K, which satisfies the equation $e^{-\theta A}K'e^{\theta A}=M\Sigma_{k\in\mathbb{Z}}\delta_k$.

Therefore, K is constant on each interval $]k,k+1[$ $(k\in\mathbb{Z})$ and has Heaviside singularities at integer points. All that we need is the value of K on $]0,1[$. In order to get this value, we just write

$$B=P_0=\int_0^1\Lambda(\theta)\mathrm{d}\theta=\int_0^1e^{-\theta A}Ke^{\theta A}\,\mathrm{d}\theta.$$

Writing $K=(K_{k,l})_{1\leqslant k,l\leqslant n}$, we get

$$e^{-\theta A}Ke^{\theta A}=(e^{i\theta(x_l-x_k)}K_{kl})_{1\leqslant k,l\leqslant n}$$

and thus $iy_k=B_{k,k}=K_{k,k}$ and for $k\neq l$,

$$\frac{1}{x_l-x_k}=B_{k,l}=\frac{e^{i(x_l-x_k)}-1}{i(x_l-x_k)}K_{k,l},$$

which yields $K_{k,l}=i/e^{i(x_l-x_k)}-1$.

Thus K is the matrix C of the Kazdhan–Kostant–Sternberg theory[2] and $\Lambda(\theta)=e^{-\theta A}Ce^{\theta A}$.

Recall that the positions of the particle at time t are, in the finite case, the eigenvalues of $A+tB$ divided by i. We conjecture that in the case at hand, they are the eigenvalues of $\mathrm{d}/\mathrm{d}\theta+(A+t\Lambda(\theta))id$ (divided by i), acting on the space of one-periodic functions.

Since Λ is continuous except at integer points where it has Heaviside singularities, we look for the one-periodic, differentiable except at integer points, but everywhere continuous solutions of this equation.

On $]0, 1[$, this equation reads

$$f' + (A + e^{-\theta A} C e^{\theta A}) f = \lambda f.$$

Set $f(\theta) = e^{\lambda\theta} e^{-\theta A} g(\theta)$. The preceding differential equation is equivalent to

$$g'(\theta) + tCg(\theta) = 0$$

or

$$f(\theta) = e^{\lambda\theta} e^{-\theta A} e^{-t\theta C} f_0$$

with constant f_0.

This equation is satisfied by a nonzero, one-periodic and continuous function if only if $e^{-\lambda}$ is an eigenvalue of $e^{-A} e^{-tC}$

Thus, the eigenvalues of $\tilde{A} + t\tilde{B}$ are the (pure imaginary) complex numbers the exponentials of which are eigenvalues of $e^{tC} e^{A}$, which are the same as the eigenvalues of $e^{A} e^{tC}$.

This agrees with the solution given in Ref. 2.

IV. DOUBLY PERIODIC POTENTIAL

A. The operator

We apply the same scheme when the pairwise interaction potential is the Weierstrass $\mathcal{P}$ function,

$$\mathcal{P}(z) = \frac{1}{z^2} + \sum_{(k,l)\neq(0,0)} \left(\frac{1}{(z - 2k\pi - 2il\omega\pi)^2} - \frac{1}{(2k\pi + 2il\omega\pi)^2} \right).$$

We will use for this purpose matrices of infinite order indexed by $(\mathbb{Z}\times\mathbb{Z})^2$ instead of $\mathbb{Z}^2$, and the underlying Lie algebra will be the complexification of $u(n)$, that is $gl_n(\mathbb{C})$.

Vectors of $\mathbb{C}^{\mathbb{Z}\times\mathbb{Z}}$ will be identified with $\mathbb{C}^n$-valued doubly periodic functions (with periods 1 and $1/\omega$ with respect to variables θ and ϕ),

$$f(\theta, \phi) = \sum_{k,l} \xi_{k,l} e^{2ik\pi\theta} e^{2il\pi\omega\phi}.$$

The matrix $\tilde{A}$ now has the block decomposition

$$\tilde{A} = (A_{klk'l'})_{k,l,k',l' \in \mathbb{Z}}$$

with $A_{klk'l'} = A + (2ik\pi + 2l\omega\pi) I$ if $k = k'$ and $l = l'$ and $A_{k,l,k',l'} = 0$ otherwise. It is identified with the operator

$$(\tilde{A}f)(\theta, \phi) = Af(\theta, \phi) + \sum_{k,l} \xi_{k,l} (2ik\pi - 2l\omega\pi) e^{2ik\pi\theta} e^{2il\pi\omega\phi}$$

$$= Af(\theta, \phi) + \frac{\partial f}{\partial \theta} - \frac{1}{i} \frac{\partial f}{\partial \phi}$$

$$= Af(z) + 2 \frac{\partial f}{\partial \bar{z}}$$

(by writing $z=\theta+i\phi$).

In the same way, we identify $\tilde{B}$ with the multiplication operator $f\mapsto\Lambda f$ where Λ is a doubly periodic $gl_n(\mathbb{C})$-valued function.

With M having the same meaning as before, Λ satisfies the partial differential equation

$$[A,\Lambda]+2\frac{\partial\Lambda}{\partial\bar{z}}=M\delta_O$$

where O denotes the origin of the torus.

As before, we start by solving the equation on $\mathbb{C}$,

$$[A,\Lambda]+2\frac{\partial\Lambda}{\partial\bar{z}}=M\sum_{k,l}\ \delta_{k+il}/\omega,$$

rather than the equation on the torus, and then we will go back to the initial equation.

The solution of the homogeneous equation are the functions of the form

$$z\mapsto e^{-\bar{z}A/2}Ke^{\bar{z}A/2},$$

where K is any holomorphic matrix valued entire function.

We solve the complete equation by varying the ''constant'' K, which satisfies

$$2e^{-\bar{z}A/2}\frac{\partial K}{\partial\bar{z}}e^{\bar{z}A/2}=M\sum_{k,l}\ \delta_{k+il/\omega},$$

$$\frac{\partial K}{\partial\bar{z}}=\frac{1}{2}\sum_{\Omega\in\mathcal{R}}\ \delta_\Omega e^{\bar{\Omega}A/2}Me^{-\bar{\Omega}A/2},$$

where

$$\mathcal{R}=\mathbb{Z}+\frac{i}{\omega}\mathbb{Z}.$$

The solutions of this equation are the meromorphic functions whose poles are simple and are the points of the network $\mathcal{R}$, the residue at Ω being $(1/2\pi)e^{\bar{\Omega}A/2}Me^{-\bar{\Omega}A/2}$.

But Λ is also doubly periodic, and therefore

$$\forall\Omega\in\mathcal{R}\ \ e^{-(\bar{z}+\bar{\Omega})A/2}K(z+\Omega)e^{(\bar{z}+\bar{\Omega})A/2}=e^{-\bar{z}A/2}K(z)e^{\bar{z}A/2},$$

$$K(z+\Omega)=e^{\bar{\Omega}A/2}K(z)e^{-\bar{\Omega}A/2}.$$

Therefore, the diagonal coefficients of K are pole free (because the diagonal coefficients of M are null) elliptic functions, and thus they are constant. In the same way as mentioned earlier, writing $B=\int\int_{[0,1]^2}\Lambda$, we get $K_{k,k}=iy_k$; and the off-diagonal coefficients $K_{k,l}$ of K are meromorphic functions which satisfy

$$K_{k,l}(z+\Omega)=e^{\bar{\Omega}i(x_k-x_l)/2}K_{k,l}(z)$$

and with simple poles $\Omega\in\mathcal{R}$ and residues $(1/2i\pi)e^{\bar{\Omega}i(x_k-x_l)}$.

As we prefer to deal with (simply) periodic functions, we set

$$P(z)=e^{-zA/2}K(z)e^{zA/2}.$$

One has for all $\Omega\in\mathcal{R}$,

$$P(z+\Omega)=e^{-(z+\Omega)A/2}e^{\bar{\Omega}A/2}K(z)e^{-\bar{\Omega}A/2}e^{(z+\Omega)A/2}$$

$$=e^{-(\Omega-\bar{\Omega})A/2}P(z)e^{(\Omega-\bar{\Omega})A/2}.$$

Thus P is periodic with period 1 and

$$P(z+i/\omega)=e^{-i/\omega A}P(z)e^{i/\omega A}.$$

The diagonal coefficients of P are those of K. They are constants: $P_{k,k}=iy_k$.

The off-diagonal coefficients of P are meromorphic with simple poles on the network and residue at zero: $1/2i\pi$.

They satisfy

$$P_{k,l}(z+1)=P_{k,l}(z) \quad P_{k,l}(z+i/\omega)=e^{(x_k-x_l)/\omega}P_{k,l}(z). \tag{1}$$

Let us recall the definition of Riemann's theta functions (see for instance Ref. 6)

$$\vartheta\begin{bmatrix}a\\b\end{bmatrix}(z)=\sum_{m\in\mathbb{Z}}e^{i\pi[\tau(m-a)^2+2(m-a)(z-b)]},$$

where $\mathrm{Im}(\tau)>0$ and $a,b\in\mathbb{C}$. This defines an entire function which satisfies the fundamental relation

$$\vartheta\begin{bmatrix}a\\b\end{bmatrix}(z+p\tau+q)=e^{i\pi(-2pz-p^2\tau+2pb-2aq)}\vartheta\begin{bmatrix}a\\b\end{bmatrix}(z),$$

$\forall p,q\in\mathbb{Z}$ and the zeros of $\vartheta[{}^a_b]$ are simple and located at the $(a-\frac{1}{2})\tau+b-\frac{1}{2}+\tau b+q, p,q\in\mathbb{Z}$.

Set $\tau=i/\omega$. The function

$$Q=\frac{\vartheta\begin{bmatrix}a\\b\end{bmatrix}}{\vartheta\begin{bmatrix}a'\\b'\end{bmatrix}}$$

satisfies

$$Q\left(z+\frac{i}{\omega}p+q\right)=e^{i\pi(2(p/\omega)(b-b')-2(a-a')q)}Q(z).$$

This matches with (1) if we choose a,b,a',b' such that

$$a-a'=0, \quad b-b'=-i\frac{x_k-x_l}{2\pi\omega}$$

and the location of poles matches if $a'=b'=\frac{1}{2}$.

Then $P_{k,l}/Q$ is an elliptic function with at most one simple pole in the fundamental cell (since theta functions have just one simple zero in the fundamental cell), thus it is constant and equal to its value at zero.

Hence,

$$P_{k,l}(z)=\frac{1}{2i\pi}\times\frac{\vartheta'\begin{bmatrix}1/2\\1/2\end{bmatrix}(0)}{\vartheta\begin{bmatrix}1/2\\\frac{1}{2}-i\frac{x_k-x_l}{2\pi\omega}\end{bmatrix}(0)}\times\frac{\vartheta\begin{bmatrix}1/2\\\frac{1}{2}-i\frac{x_k-x_l}{2\pi\omega}\end{bmatrix}(z)}{\vartheta\begin{bmatrix}1/2\\1/2\end{bmatrix}(z)}$$

$$=\frac{1}{2i\pi}\times\frac{\vartheta_1'(0)}{\vartheta_1\left(i\frac{x_k-x_l}{2\pi\omega}\right)}\times\frac{\vartheta_1\left(z+i\frac{x_k-x_l}{2\pi\omega}\right)}{\vartheta_1(z)},$$

where we have set

$$\vartheta_1=\vartheta\begin{bmatrix}1/2\\1/2\end{bmatrix}$$

(Jacobi's notation).

We have another way for expressing the off-diagonal coefficients of P.

Let $\delta\in]0,2\pi[$. Consider the series

$$f(z)=\sum_{j\in\mathbb{Z}}\frac{e^{-j\delta}}{1-e^{-2j\pi/\omega}e^{2i\pi z}}.$$

This series converges normally on all compact of $\mathbb{C}\backslash\mathcal{R}$ and defines a meromorphic function with period 1 that verifies $f(z+i/\omega)=e^{\delta}f(z)$. Its only poles are simple and are the points of $\mathcal{R}$. Its residue at 0 is $1/-2i\pi$.

In the same way, for $\delta\in]-2\pi,0[$, the series

$$f(z)=\sum_{j\in\mathbb{Z}}\frac{e^{-j\delta}}{1-e^{2j\pi/\omega}e^{-2i\pi z}}$$

defines a meromorphic function with period 1 that verifies $f(z+(i/\omega))=e^{\delta}f(z)$. Its residue at 0 is $1/2i\pi$.

Suppose that $x_1<x_2<\cdots<x_n<x_1+2\pi$. Then one can write

$$\text{if } k<l \quad P_{k,l}(z)=\sum_{j\in\mathbb{Z}}\frac{e^{-j(x_k-x_l)/\omega}}{1-e^{2j\pi/\omega}e^{-2i\pi z}},$$

$$\text{if } k>l \quad P_{k,l}(z)=-\sum_{j\in\mathbb{Z}}\frac{e^{-j(x_k-x_l)/\omega}}{1-e^{-2j\pi/\omega}e^{2i\pi z}}.$$

B. The spectrum

We conjecture that the positions of the particles at time t are the eigenvalues of the operator

$$A+2\frac{\partial}{\partial\bar{z}}+t\Lambda(z)$$

acting on the space of doubly periodic functions (with periods 1 and i/ω).

Let λ be some (pure imaginary) complex number and f some doubly periodic function satisfying

$$Af+2\frac{\partial f}{\partial \bar{z}}+t\Lambda f=\lambda f.$$

Set $f(z)=e^{\lambda \bar{z}/2}e^{-\bar{z}A/2}g(z)$

The preceding equation becomes

$$2e^{\lambda \bar{z}/2}e^{-\bar{z}A/2}\frac{\partial g}{\partial \bar{z}}+te^{-\bar{z}A/2}K(z)e^{\bar{z}A/2}e^{\lambda \bar{z}/2}e^{-\bar{z}A/2}g(z)=0,$$

which amounts to

$$2\frac{\partial g}{\partial \bar{z}}+tK(z)g(z)=0.$$

Recall that K is holomorphic except at the points of the network $\mathcal{R}$. Set $g(z)=e^{-tz\bar{K}(z)/2}h(z)$.

The preceding equation amounts to $\partial h/\partial \bar{z}=0$, except at the points of the network. Therefore, except at these points, f takes the form

$$f(z)=e^{\lambda \bar{z}/2}e^{-\bar{z}A/2}e^{-tz\bar{K}(z)/2}h(z),$$

where h is holomorphic.

The function f is doubly periodic. This means that for all Ω in the network,

$$f(z+\Omega)=f(z).$$

Since

$$\begin{aligned}f(z+\Omega)&=e^{\lambda(\bar{z}+\bar{\Omega})/2}e^{-\bar{z}A/2}e^{-\bar{\Omega}A/2}e^{-t(\bar{z}+\bar{\Omega})K(z+\Omega)/2}h(z+\Omega)\\&=e^{\lambda(\bar{z}+\bar{\Omega})/2}e^{-\bar{z}A/2}e^{-t(\bar{z}+\bar{\Omega})K(z)/2}e^{-\bar{\Omega}A/2}h(z+\Omega),\end{aligned}$$

we get

$$h(z+\Omega)=e^{-\lambda\bar{\Omega}2}e^{\bar{\Omega}A/2}e^{t\bar{\Omega}K(z)/2}h(z).$$

Set then $h(z)=e^{tzK(z)/2}k(z)$ and recall that $K(z+\Omega)=e^{\bar{\Omega}A/2}K(z)e^{-\bar{\Omega}/2}$.

The preceding condition reads

$$e^{\bar{\Omega}A/2}e^{t(z+\Omega)K(z)/2}e^{-\bar{\Omega}A/2}k(z+\Omega)=e^{-\lambda\bar{\Omega}/2}e^{\bar{\Omega}A/2}e^{t\bar{\Omega}L(z)/2}e^{tK(z)/2}k(z),$$

which simplifies to

$$k(z+\Omega)=e^{-\lambda\bar{\Omega}/2}e^{\bar{\Omega}A/2}e^{t(\bar{\Omega}-\Omega)K(z)/2}k(z).$$

Then set $k(z)=e^{-\lambda z/2}e^{zA/2}\phi(z)$. The preceding condition reads thus

$$e^{-\lambda(z+\Omega)/2}e^{(z+\Omega)A/2}\phi(z+\Omega)=e^{-\lambda\bar{\Omega}/2}e^{\bar{\Omega}A/2}e^{t(\bar{\Omega}-\Omega)K(z)/2}e^{-\lambda z/2}e^{zA/2}\phi(z),$$

which simplifies to

$$\phi(z+\Omega)=e^{\lambda(\Omega-\bar{\Omega})/2}e^{-(z+\Omega-\bar{\Omega})A/2}e^{t(\bar{\Omega}-\Omega)K(z)/2}e^{zA/2}\phi(z).$$

Therefore we look for analytic functions on $\mathbb{C}\backslash\mathcal{R}$ satisfying ϕ is periodic with period 1 and

$$\phi(z+i/\omega)=e^{i\lambda/\omega}e^{-(z+2i/\omega)A/2}e^{-it/\omega K(z)}e^{zA/2}\phi(z)=e^{i\lambda/\omega}L(z)\phi(z), \tag{2}$$

where

$$L(z)=e^{-(z+2i/\omega)A/2}e^{-it/\omega K(z)}e^{zA/2}=e^{-i/\omega A}e^{-it/\omega P(z)}.$$

We conjecture that the correct condition is that ϕ, which coincides with f on the real axis, should have no singularity there.

Since ϕ is then holomorphic on the domain $|\mathrm{Im}(z)|<1$, we can write $\phi(z)=\Sigma_{j\in\mathbb{Z}}\phi_j e^{2i\pi jz}$, this expansion being valid in the same domain.

Since $L(x-i/2)$ is a smooth one-periodic function of the real variable x, we can write $L(x-(i/2))=\Sigma_{j\in\mathbb{Z}}L_j e^{2i\pi jx}$.

Condition (2) is satisfied if and only if it is satisfied on the line $\mathbb{R}-i/2$ (because only analytic functions are involved), and this reads:

$$\forall j\in\mathbb{Z}\ e^{-\pi j}\phi_j=e^{i\lambda}\sum_{k\in\mathbb{Z}}L_{j-k}e^{\pi k}\phi_k,$$

that is $e^{-i\lambda}=e^x$ is an eigenvalue of the infinite matrix $T=(T_{j,k})$ (block decomposition) with $T_{j,k}=e^{\pi(j+k)}L_{j-k}$.

Our problem is to express the Fourier expansion of $x\mapsto L(x-i/2)$, which is beyond our reach in the general case. However, some remarks can be made.

ϑ_1 is odd, therefore

$$P_{k,l}(-z)=-P_{l,k}(z)\quad \text{if}\ \ k\neq l.$$

The series expansion of P yields also

$$P_{k,l}(\overline{z})=-\overline{P_{l,k}(z)}.$$

For $x\in\mathbb{R}$, we have for $k\neq l$: $\overline{P_{k,l}(x-i/2)}=-P_{l,k}\overline{(x-i/2)}=-P_{l,k}(x+i/2)=-e^{x_l-x_k}P_{l,k}(x-i/2)$ and this holds also for $k=l$ since $P_{k,k}$ is a pure imaginary number.

Therefore, $e^{-iA/\omega}P(x-i/2)$ is skew-Hermitian, and thus, $-itP/\omega$ is Hermitian with respect to the Hermitian form with matrix e^{-iA}. Thus so is $e^{-itP/\omega}$ and thus $L=e^{-iA/\omega}e^{-itP/\omega}$ is Hermitian (at $x-i/2$ for real x).

Therefore for all integer j,

$$L_j=\int_0^1 e^{-2i\pi jx}L\left(x-\frac{i}{2}\right)\mathrm{d}x=\int_0^1 e^{-2i\pi jx}\left[\overline{L}\left(x-\frac{i}{2}\right)\right]^{\dagger}\mathrm{d}x$$

$$=\left[\overline{\int_0^1 e^{2i\pi jx}L\left(x-\frac{i}{2}\right)\mathrm{d}x}\right]^{\dagger}=[\overline{L}_{-j}]^{\dagger},$$

where the dagger denotes transposition, and thus the infinite matrix T is Hermitian.

Numerical-simulations confirm our conjectures. Quite surprisingly, finite submatrices of small order of the infinite matrix T give very accurate results. Using a submatrix of order 14, in the two-particle case at time 1, we obtained four digit agreement with the positions given by Runge–Kutta integration.

V. CONCLUSION

Our infinite replication scheme has succeeded in reinvestigating the Calogero–Moser system with $1/\sin^2 r$ potential, but made the system with elliptic potential more mysterious than ever by connecting it to a new finite difference equation. Many questions remain open. Does this problem

have a close form solution? How is it connected with the solution given by Krichever[4] through the KP equation? And is there a geometric interpretation of the system analogous to the one given by Kazdhan, Kostant, and Sternberg[5] for $1/\sin^2 r$ potential?

JOURNAL OF MATHEMATICAL PHYSICS VOLUME 42, NUMBER 10 OCTOBER 2001

Relation between the solitons of Yang–Mills–Higgs fields in 2+1 dimensional Minkowski space–time and anti-de Sitter space–time

Zixiang Zhou[a)]
Institute of Mathematics, Fudan University, Shanghai 200433, People's Republic of China

(Received 2 April 2001; accepted for publication 12 July 2001)

The Yang–Mills–Higgs–Bogomolny equations in both $2+1$ dimensional Minkowski space–time and $2+1$ dimensional anti-de Sitter space–time are known to be integrable and their soliton solutions have already been obtained. In this article, we show that there is a natural relation between the Lax pairs and soliton solutions in these two space–times when the curvature changes from 0 to -1. The changes of the asymptotic behaviors of the solitons are also discussed. © *2001 American Institute of Physics.* [DOI: 10.1063/1.1398585]

I. INTRODUCTION

The Yang–Mills–Higgs–Bogomolny equations in both $2+1$ dimensional Minkowski space–time and $2+1$ dimensional anti-de Sitter space–time are known to be integrable.[1–4] There are several ways to solve them explicitly. The Darboux transformation method is one of them, which gives an easy way to obtain explicit soliton solutions.[5,6] Since the Lax pairs in both Minkowski and anti-de Sitter cases are known, the Darboux transformations can be constructed separately in these two cases.

The standard anti-de Sitter space–time has curvature -1. Naturally we can consider the anti-de Sitter space–time with constant curvature $-1/\rho^2(\rho>0)$. When $\rho\to+\infty$, the space–time tends to the Minkowski space–time. In this article, we consider the following problem: When ρ changes from 1 to $+\infty$, do the solitons in the anti-de Sitter space–time change to solitons in the Minkowski space–time?

In Sec. II, the Yang–Mills–Higgs–Bogomolny equations and their Lax pairs for general ρ are considered. When $\rho=1$ and $\rho\to+\infty$, they become the known equations and their Lax pairs for the Minkowski and anti-de Sitter cases. In Sec. III, the Darboux transformation is discussed. Using the Darboux transformation, we construct solitons in the SU(2) case in Sec. IV and give some examples. When ρ changes from 1 to $+\infty$, the shape of the solitons changes a lot. However, when the coordinates of the space–time depend on ρ suitably, the position of the solitons keeps in a finite region and the solitons in part of the anti-de Sitter space–time change to the solitons in the Minkowski space–time.

II. YANG–MILLS–HIGGS–BOGOMOLNY EQUATIONS AND THEIR LAX PAIRS

Let M be a three dimensional Lorentz manifold with metric $g=(g_{\mu\nu})$. $\{A_\mu \mid \mu=1,2,3\}$ is a gauge potential and Φ is a (scalar) Higgs field, both of which are valued in the Lie algebra of an $N\times N$ matrix Lie group G.

The Yang–Mills–Higgs–Bogomolny equation[1,7] is

$$D\Phi=*F, \tag{2.1}$$

or, written in terms of the components,

a)Electronic mail: zxzhou@guomai.sh.cn

$$D_\mu\Phi=\frac{1}{2\sqrt{|g|}}g_{\mu\nu}\epsilon^{\nu\alpha\beta}F_{\alpha\beta}, \tag{2.2}$$

where the action of the covariant derivative $D_\mu=\partial_\mu+A_\mu$ on Φ is $D_\mu\Phi=\partial_\mu\Phi+[A_\mu,\Phi]$, $\partial_\mu=\partial/\partial x^\mu$. $\{F_{\mu\nu}\}$ is the curvature corresponding to $\{A_\mu\}$, hence $F_{\mu\nu}=[D_\mu,D_\nu]$.

The $2+1$ dimensional anti-de Sitter space–time of constant curvature $-1/\rho^2$ $(\rho>0)$ is the hyperboloid $U^2+V^2-X^2-Y^2=\rho^2$ in $\mathbf{R}^{2,2}$ with the metric

$$ds^2=-dU^2-dV^2+dX^2+dY^2. \tag{2.3}$$

By defining

$$r=\frac{\rho}{U+X}-\rho+1,\quad x=\frac{Y}{U+X},\quad t=-\frac{V}{U+X}, \tag{2.4}$$

a part of the $2+1$ dimensional anti-de Sitter space–time with $U+X>0$ is represented by the Poincaré coordinates (r,x,t) with $r>-\rho+1$ and the metric is

$$ds^2=\frac{\rho^2}{(r+\rho-1)^2}(-dt^2+dr^2+dx^2)=\frac{\rho^2}{(r+\rho-1)^2}(dr^2+du\,dv), \tag{2.5}$$

where $u=x+t$ and $v=x-t$. Clearly, when $\rho\to+\infty$, the metric on this part of the $2+1$ dimensional anti-de Sitter space–time tends to the flat Minkowski metric on the whole $\mathbf{R}^{2,1}$. In order to consider the change of the solitons with respect to ρ, we only need to consider the solutions in this part.

With the metric (2.5) and the orientation (v,u,r), (2.2) becomes

$$D_u\Phi=\frac{r+\rho-1}{\rho}F_{ur},\quad D_v\Phi=-\frac{r+\rho-1}{\rho}F_{vr},\quad D_r\Phi=-\frac{2(r+\rho-1)}{\rho}F_{uv}. \tag{2.6}$$

When $\rho=1$, it is reduced to

$$D_u\Phi=rF_{ur},\quad D_v\Phi=-rF_{vr},\quad D_r\Phi=-2rF_{uv}. \tag{2.7}$$

Reference 4 showed that it had a Lax pair

$$(rD_r+\Phi-2(\zeta-u)D_u)\psi=0,\quad \left(2D_v+\frac{\zeta-u}{r}D_r-\frac{\zeta-u}{r^2}\Phi\right)\psi=0, \tag{2.8}$$

where $D_\mu\psi=\partial_\mu\psi+A_\mu\psi$ and ζ is a complex spectral parameter. That is, (2.7) is the integrability condition of the overdetermined system (2.8).

When $\rho>0$, the Yang–Mills–Higgs–Bogomolny equation (2.6) can be derived from (2.7) by substituting $r\to r+\rho-1$ and $\Phi\to\rho\Phi$. Moreover, since ζ is a constant in (2.8), we can replace ζ by $\rho\zeta$. After the substitution

$$r\to r+\rho-1,\quad \Phi\to\rho\Phi,\quad \zeta\to\rho\zeta, \tag{2.9}$$

(2.8) leads to the Lax pair of (2.6):

$$\begin{gathered}((r+\rho-1)D_r+\rho\Phi-2(\rho\zeta-u)D_u)\psi=0,\\ \left(2D_v+\frac{\rho\zeta-u}{r+\rho-1}D_r-\frac{\rho(\rho\zeta-u)}{(r+\rho-1)^2}\Phi\right)\psi=0.\end{gathered} \tag{2.10}$$

It is easy to check directly that the integrability condition of (2.10) is the Yang–Mills–Higgs–Bogomolny equation (2.6).

When $\rho\to+\infty$, the metric (2.5) becomes the standard Minkowski metric

$$ds^2=-dt^2+dr^2+dx^2=dr^2+du\,dv, \tag{2.11}$$

the Yang–Mills–Higgs–Bogomolny equation (2.6) becomes

$$D_u\Phi=F_{ur},\quad D_v\Phi=-F_{vr},\quad D_r\Phi=-2F_{uv}, \tag{2.12}$$

and the Lax pair (2.10) becomes

$$\begin{aligned}&(D_r+\Phi-2\zeta D_u)\psi=0,\\ &(2D_v+\zeta D_r-\zeta\Phi)\psi=0.\end{aligned} \tag{2.13}$$

Remark 1: If we substitute

$$r\to x,\quad \zeta\to\frac{1}{\lambda},\quad u\to y+t,\quad v\to y-t, \tag{2.14}$$

then (2.13) is changed to

$$(\lambda D_x-D_t-D_y+\lambda\Phi)\psi=0,\quad (\lambda D_t-\lambda D_y-D_x+\Phi)\psi=0, \tag{2.15}$$

which is just the Lax pair given by Ref. 2.

III. DARBOUX TRANSFORMATIONS

For $\rho\to+\infty$ and $\rho=1$, Refs. 5 and 6 gave the construction of the Darboux matrix separately based on a general method.[8] Here we show that these are the two special cases for general ρ.

For $\rho=1$, the Darboux transformation is given as follows.[6] Let $Z=\mathrm{diag}(\zeta_1,...,\zeta_N)$ be a diagonal matrix that satisfies

$$\partial_rZ-\frac{2(Z-u)}{r}(\partial_uZ)=0,\quad \partial_vZ+\frac{Z-u}{2r}(\partial_rZ)=0, \tag{3.1}$$

$H=(h_1,\ldots,h_N)$ where h_j is a solution of (2.8) with $\zeta=\zeta_j$. Then $G=\zeta-HZH^{-1}$ is a Darboux matrix for (2.8). That is, for any solution ψ of the Lax pair (2.8), $\tilde{\psi}=G\psi$ satisfies

$$(r\tilde{D}_r+\tilde{\Phi}-2(\zeta-u)\tilde{D}_u)\tilde{\psi}=0,\quad \left(2\tilde{D}_v+\frac{\zeta-u}{r}\tilde{D}_r-\frac{\zeta-u}{r^2}\tilde{\Phi}\right)\tilde{\psi}=0, \tag{3.2}$$

where $\tilde{D}_\mu=\partial_\mu+\tilde{A}_\mu$ and $\tilde{\Phi},\tilde{A}_\mu$ are other functions in the Lie algebra of G.

When $\rho>1$, a similar conclusion is obtained by the substitution (2.9) and $Z\to\rho Z$. Hence the Darboux matrix is given by

$$G(r,u,v,\zeta)=\zeta-\frac{u}{\rho}-S(r,u,v),\quad S(r,u,v)=H\left(Z-\frac{u}{\rho}\right)H^{-1}, \tag{3.3}$$

where $Z=\mathrm{diag}(\zeta_1,...,\zeta_N)$ satisfies

$$\partial_rZ-\frac{2(\rho Z-u)}{r+\rho-1}\partial_uZ=0,\quad \partial_vZ+\frac{\rho Z-u}{2(r+\rho-1)}\partial_rZ=0, \tag{3.4}$$

$H=(h_1,\ldots,h_N)$ and h_j is a solution of (2.10) with $\zeta=\zeta_j$. It can be checked that S satisfies

$$
\begin{aligned}
&(r+\rho-1)(\partial_r S+[A_r,S])-2\rho(\partial_u S+[A_u,S])S+\rho[\Phi,S]-2S=0,\\
&2(\partial_v S+[A_v,S])+\frac{\rho}{r+\rho-1}(\partial_r S+[A_r,S])S-\frac{\rho^2}{(r+\rho-1)^2}[\Phi,S]S=0.
\end{aligned}
\tag{3.5}
$$

By direct computation, we know that for any solution ψ of (2.10), $\tilde{\psi}=G\psi$ satisfies

$$
\begin{aligned}
&((r+\rho-1)\tilde{D}_r+\rho\tilde{\Phi}-2(\rho\zeta-u)\tilde{D}_u)\tilde{\psi}=0,\\
&\left(2\tilde{D}_v+\frac{\rho\zeta-u}{r+\rho-1}\tilde{D}_r-\frac{\rho(\rho\zeta-u)}{(r+\rho-1)^2}\tilde{\Phi}\right)\tilde{\psi}=0
\end{aligned}
\tag{3.6}
$$

with $\tilde{D}_\mu=\partial_\mu+\tilde{A}_\mu$ $(\mu=u,v,r)$,

$$
\begin{aligned}
&\tilde{A}_u=A_u,\\
&\tilde{A}_v=A_v+\frac{\rho}{2(r+\rho-1)}(\partial_r S+[A_r,S])-\frac{\rho^2}{2(r+\rho-1)^2}[\Phi,S],\\
&\tilde{A}_r=A_r-\frac{1+\rho(\partial_u S+[A_u,S])}{r+\rho-1},\\
&\tilde{\Phi}=\Phi-\frac{1+\rho(\partial_u S+[A_u,S])}{\rho}.
\end{aligned}
\tag{3.7}
$$

Hence G is really a Darboux matrix for (2.10).

According to (3.4), each $\zeta_j(j=1,\ldots,N)$ is a constant or a nonconstant solution of

$$
\partial_r\zeta-\frac{2(\rho\zeta-u)}{r+\rho-1}\partial_u\zeta=0,\quad \partial_v\zeta+\frac{\rho\zeta-u}{2(r+\rho-1)}\partial_r\zeta=0. \tag{3.8}
$$

The general nonconstant solution is given implicitly by

$$
v-\frac{(r+\rho-1)^2}{\rho\zeta-u}=C_1(\zeta,\rho), \tag{3.9}
$$

where C_1 is an arbitrary function, which is meromorphic to ζ and smooth to $\rho\in(0,+\infty)$.

In order to consider the limit for $\rho\to+\infty$, we rewrite (3.9) as

$$
v-\frac{(r+\rho-1)^2}{\rho\zeta-u}+\frac{\rho-1}{\zeta}=C(\zeta,\rho). \tag{3.10}
$$

Here $C(\zeta,\rho)$ is also an arbitrary function, which is holomorphic to ζ and smooth to ρ. Moreover, suppose that $\lim_{\rho\to+\infty}C(\zeta,\rho)$ exists.

When $\rho=1$, (3.10) becomes

$$
v-\frac{r^2}{\zeta-u}=C(\zeta,1), \tag{3.11}
$$

which is given by Ref. 6. When $\rho\to+\infty$, (3.10) becomes

$$
v-\frac{u}{\zeta^2}-\frac{2r}{\zeta}=C(\zeta,+\infty)-\frac{1}{\zeta}. \tag{3.12}
$$

When the group $G=U(N)$, there should be more constraints on ζ_j's and h_j's in the construction of the Darboux matrix. They are

$$\begin{gathered}\zeta_j=\zeta_0 \quad \text{or} \quad \overline{\zeta_0} \text{ for certain fixed } \zeta_0,\\ h_j^* h_k=0 \quad \text{if} \quad \zeta_j\neq\zeta_k,\end{gathered} \tag{3.13}$$

as mentioned in Refs. 5 and 6. If so, after the Darboux transformation, $\tilde{\Phi}\in u(N)$, $\tilde{A}_\mu\in u(N)$ provided that $\Phi\in u(N)$, $A_\mu\in u(N)$.

IV. SOLITON SOLUTIONS IN SU(2) CASE

Single soliton solutions are given by Darboux transformations from the trivial seed solution $\Phi=0$, $A_u=A_v=A_r=0$. In the construction of $S=H(Z-u/\rho)H^{-1}$, $Z=\mathrm{diag}(\zeta_1,\ldots,\zeta_N)$, where ζ_j is a constant or a nonconstant solution of (3.8), h_j is a column solution of (2.10) with $\zeta=\zeta_j$.

With the action of the Darboux matrix $G=\zeta-u/\rho-S$, (3.7) gives

$$\tilde{A}_u=0, \quad \tilde{A}_v=\frac{\rho\partial_r S}{2(r+\rho-1)}, \quad \tilde{A}_r=-\frac{1+\rho\partial_u S}{r+\rho-1}, \quad \tilde{\Phi}=-\frac{1+\rho\partial_u S}{\rho}. \tag{4.1}$$

Here we only consider the case where all ζ_j's are constants. When ζ_j's are nonconstant solutions of (3.8), we can obtain solutions in similar ways. However, in the latter case, solutions may only be defined when t is larger than some constant.[6] Now h_j satisfies

$$\partial_r h_j-\frac{2(\rho\zeta_j-u)}{r+\rho-1}\partial_u h_j=0, \quad \partial_v h_j+\frac{\rho\zeta_j-u}{2(r+\rho-1)}\partial_r h_j=0. \tag{4.2}$$

The general solution is

$$h_j=\omega(\zeta_j), \tag{4.3}$$

where

$$\omega(\zeta)=v-\frac{(r+\rho-1)^2}{\rho\zeta-u}+\frac{\rho-1}{\zeta}. \tag{4.4}$$

When $\rho=1$,

$$\omega(\zeta)=v-\frac{r^2}{\zeta-u}, \tag{4.5}$$

which is the same as the result in Ref. 6. When $\rho\to+\infty$,

$$\omega(\zeta)\to v-\frac{u}{\zeta^2}-\frac{2r}{\zeta}+\frac{1}{\zeta}. \tag{4.6}$$

With the substitution (2.14),

$$\omega(\lambda^{-1})\to(1-\lambda^2)y-(1+\lambda^2)t-2\lambda x+\lambda. \tag{4.7}$$

This coincides with Ref. 5.

When $G=\mathrm{SU}(2)$, the conditions (3.13) should be satisfied. Hence we want $\zeta_1=\zeta_0$, $\zeta_2=\overline{\zeta_0}$ for some $\zeta_0\in\mathbf{C}$ and

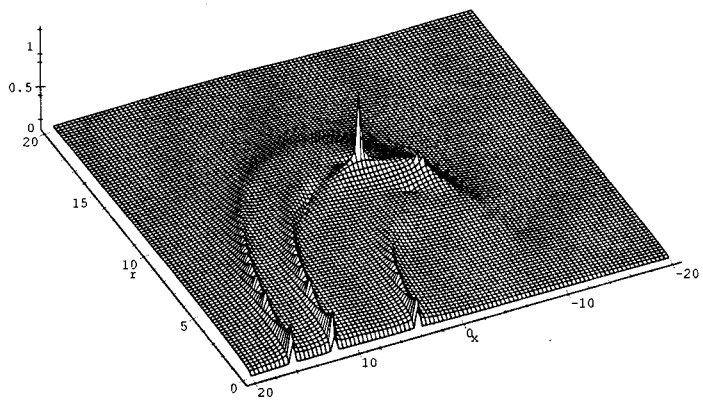

FIG. 1. $\rho=1$.

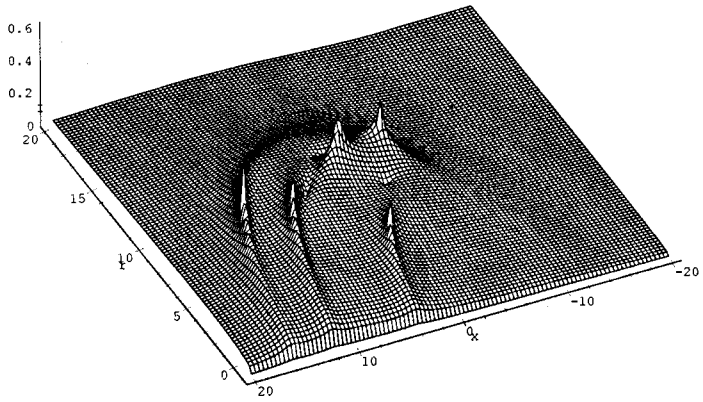

FIG. 2. $\rho=2$.

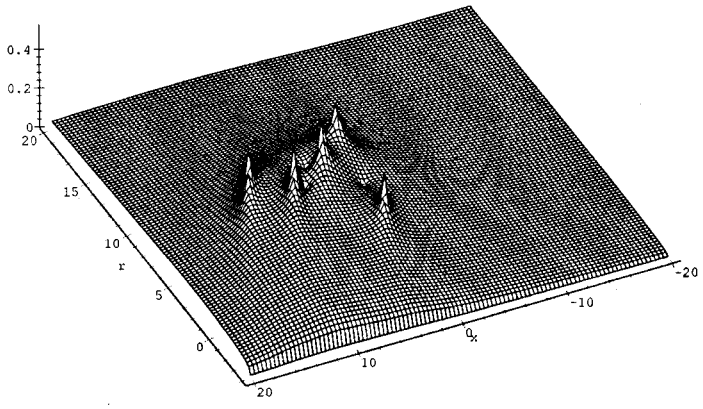

FIG. 3. $\rho=5$.

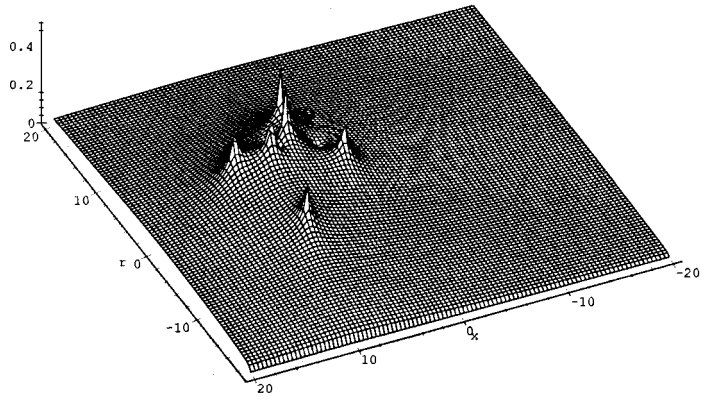

FIG. 4. $\rho=20$.

$$H=\begin{pmatrix} \alpha(\tau) & -\overline{\beta(\tau)} \\ \beta(\tau) & \overline{\alpha(\tau)} \end{pmatrix}, \tag{4.8}$$

where α, β are two holomorphic functions of $\tau=\omega(\zeta_0)$. Let $\sigma(\tau)=\beta(\tau)/\alpha(\tau)$. Then

$$S=\frac{\zeta_0-\overline{\zeta_0}}{1+|\sigma|^2}\begin{pmatrix} 1 & \overline{\sigma} \\ \sigma & |\sigma|^2 \end{pmatrix}+\overline{\zeta_0}-\frac{u}{\rho}, \tag{4.9}$$

$$\tilde{\Phi}=-\partial_u S-\frac{1}{\rho}=\frac{\zeta_0-\overline{\zeta_0}}{(1+|\sigma|^2)^2}\begin{pmatrix} (|\sigma|^2)_u & \overline{\sigma}^2\sigma_u-\overline{\sigma}_u \\ \sigma^2\overline{\sigma}_u-\sigma_u & -(|\sigma|^2)_u \end{pmatrix} \tag{4.10}$$

and

$$-\mathrm{tr}\tilde{\Phi}^2=\frac{8(\mathrm{Im}\,\zeta_0)^2}{(1+|\sigma|^2)^2}|\partial_u\sigma|^2. \tag{4.11}$$

When $\sigma(z)$ is a given meromorphic function of z which is independent of ρ, then by (4.6) and (4.5),

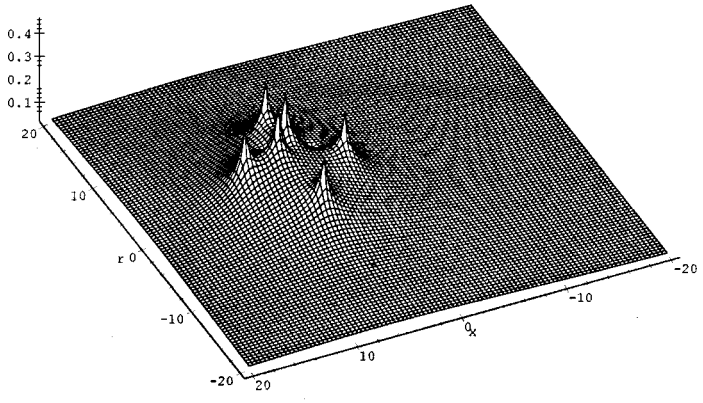

FIG. 5. $\rho=+\infty$.

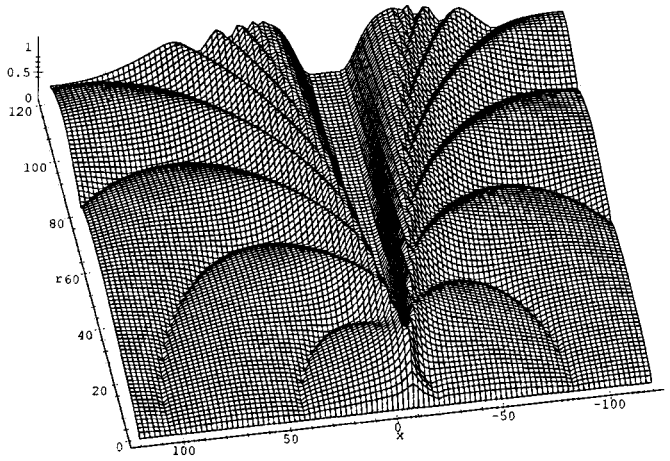

FIG. 6. $\rho=1$.

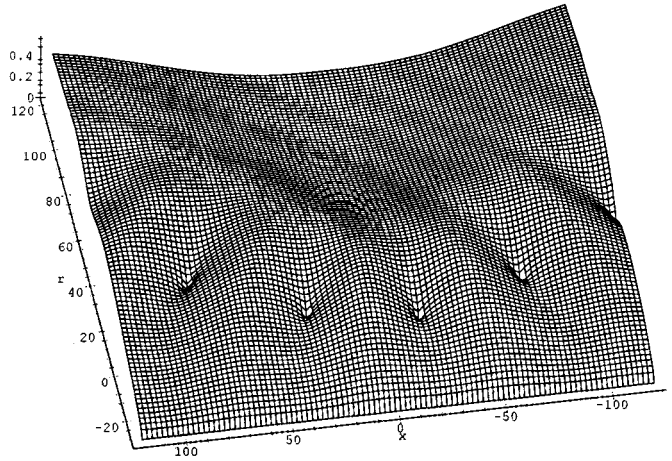

FIG. 7. $\rho=30$.

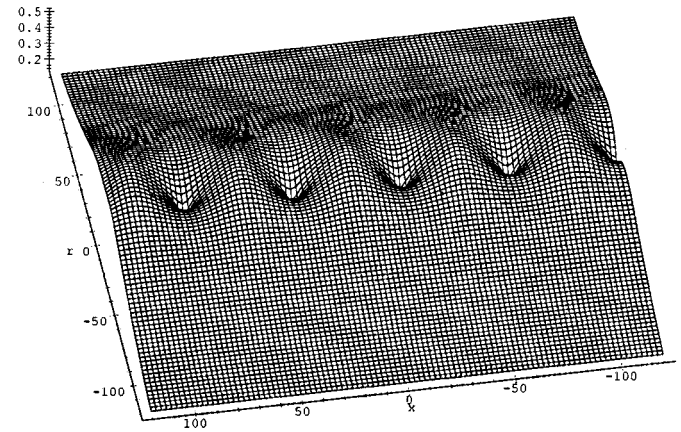

FIG. 8. $\rho=+\infty$.

$$\sigma(\tau)|_{\rho\to+\infty}=\sigma\left(v-\frac{u}{\zeta_0^2}-\frac{2r}{\zeta_0}+\frac{1}{\zeta_0}\right),\quad \sigma(\tau)|_{\rho=1}=\sigma\left(v-\frac{r^2}{\zeta_0-u}\right). \tag{4.12}$$

Hence when $\rho\to+\infty$ and $\rho=1$, the solutions tend to the soliton solutions in the Minkowski and anti-de Sitter space–time, respectively.

These are single soliton solutions. Each solution depends on a complex constant ζ_0 and a meromorphic function σ. Multi-soliton solutions can be constructed by successive Darboux transformations.[5,6] For simplicity, here we only consider the change of single soliton solutions with respect to ρ.

Example 1: $\sigma(\tau)$ is a polynomial of τ without multiple zero. In this case, the solutions are always localized. When $\rho=1$, the behavior of the asymptotic solution as $t\to\infty$ varies according to the roots of $\sigma(\tau)$.[6] Suppose τ_0 is a root of $\sigma(\tau)$. Then (1) if $|\mathrm{Im}\,\tau_0|\ll 1$, it corresponds to a ridge in the graph of $-\mathrm{tr}\tilde{\Phi}^2$; (2) if $\mathrm{Im}\,\tau_0\gg 1$, it corresponds to a peak; (3) if $\mathrm{Im}\,\tau_0\ll -1$, it corresponds to nothing. However, when $\rho\to+\infty$, each root of $\sigma(\tau)$ corresponds to a peak.[5] Figures 1–5 show the change of the solution with respect to ρ for fixed $t=10$, where $\zeta_0=2i$,

$$\sigma(\tau)=(\tau-2)(\tau-6)(\tau+6)(\tau-2i)(\tau-6i)(\tau+6i). \tag{4.13}$$

In these figures the vertical axis is $(-\mathrm{tr}\tilde{\Phi}^2)^{1/16}$.

Example 2: $\sigma(\tau)=\sin(\tau/20)$. For both finite and infinite ρ, the solution is always nonlocalized. For finite ρ, it behaves in a very complicated manner. However, for infinite ρ, (4.12) shows that the solution is invariant if (x,r) is changed to (x',r') with $\mathrm{Re}[(1-\zeta_0^{-2})(x'-x)-2\zeta_0^{-1}(r'-r)]=40\pi k$ (k is an arbitrary integer). Hence the solution is periodic in one direction. Figures 6–8 show this solution for $\rho=1,30,+\infty$ with $t=10$, $\zeta_0=2i$. In these figures the vertical axis is $(-\mathrm{tr}\tilde{\Phi}^2)^{1/8}$.

The classification of plane symmetric spacetimes by isometries

Tooba Feroze, Asghar Qadir,[a] and M. Ziad

(Received 29 June 2000; accepted for publication 11 May 2001)

A complete classification of plane symmetric Lorentzian manifolds according to their additional isometries and metrics (or classes of metrics) is obtained by solving the Killing equations. We obtain all metrics (or classes of metrics), that admit the group of motions G_r (where $r=3,4,5,6,7$ and 10) containing $SO(2)\circledS\mathbb{R}^2$, the minimal symmetry inherited by the plane symmetric manifolds. © *2001 American Institute of Physics.* [DOI: 10.1063/1.1385175]

A plane symmetric spacetime is a Lorentzian manifold possessing a physical stress–energy tensor and admitting $SO(2)\circledS\mathbb{R}^2$, which we shall henceforth denote by G_3, as the minimal isometry group in such a way that the group orbits are spacelike surfaces of constant curvature. The symmetry assumptions reduce the general metric of a Lorentzian manifold to the form[1]

$$ds^2=e^{2\nu(t,x)}\,dt^2-e^{2\lambda(t,x)}\,dx^2-e^{2\mu(t,x)}(dy^2+dz^2). \tag{1}$$

Our aim is to further classify this metric according to the additional isometries it admits. This can be achieved by following the methods developed in Ref. 2 with the modification introduced in Ref. 3. The procedure is to solve the Killing equations (KEs),

$$g_{ab,c}k^c+g_{ac}k^c_{,b}+g_{bc}k^c_{,a}=0 \quad (a,b,c,\ldots=0,1,2,3), \tag{2}$$

where "$_{,a}$" denotes partial derivatives with respect to the variables $x^a=(x^0=t,x^1=x,x^2=y,x^3=z)$. The metric coefficients, g_{ab}, are as given in Eq. (1) and the Killing vector (KV) field, $\mathbf{K}=k^a\partial/\partial x^a$, is arbitrary. This amounts to solving a system of 10 quasi-linear partial differential equations in seven unknown functions: the four functions of four variables, $k^a(a=0,1,2,3)$; and the three functions of two variables $\nu(t,x),\lambda(t,x)$ and $\mu(t,x)$.

For the metric (1), Eqs. (2) can be integrated to give $\mathbf{K}$ in terms of y and z explicitly. The expressions k^a depend upon three arbitrary constants, corresponding to the minimal isometries inherent in (1), and five arbitrary functions of integration depending upon t and x apart from the three functions $\nu(t,x),\lambda(t,x)$ and $\mu(t,x)$. A complete solution of these equations is given, providing all possible metrics admitting higher symmetries than the minimal G_3, along with the generators of KVs, $\mathbf{K}$.

It turns out that all metrics with $\dot{\mu}=0\neq\mu'$ admitting higher than the minimal symmetry group are plane symmetric metrics given (below) by the Eqs. (3), (5), (13), (17), (20), (22). All these metrics, except the metric given by Eq. (17), admit a timelike KV, $\partial/\partial t$.[4,5] The metrics with $\dot{\mu}\neq0=\mu'$ admitting higher (than the minimal) symmetry groups are given by Eqs. (4), (6), (14), (18), (21), (23). These metrics except the metric given by the Eq. (18) admit a spacelike KV, $\partial/\partial x$. The metrics with $\dot{\mu}=0=\mu'$, admitting higher symmetries are all Bertotti–Robinson type metrics given by Eqs. (7), (8), (9), (10), (11), (12).[4,5] The metrics with $\dot{\mu}\neq0\neq\mu'$ admitting higher symmetries are given by Eqs. (15), (16), (19), (24).

A complete list of metrics along with their KVs, corresponding Lie algebras and symmetry groups are provided here for the sake of completeness. All metrics other than those given below,

[a]Electronic mail: ashqadir@kfupm.edu.sa

admit only the symmetry group G_3. For example the plane-fronted gravitational waves solution is one of these infinitely many metrics admitting only the minimal symmetry.

The plane symmetric Lorentzian manifolds admitting G_{10} as the maximal isometry group, other than the Minkowski metric, are: (Ia) the anti-deSitter spacetime,

$$ds^2=e^{2x/a}(dt^2-dy^2-dz^2)-dx^2 \quad (a=\text{const}\neq 0), \tag{3}$$

with generators of the Lie algebra admitted by the metric (3),

$$X_0=\partial/\partial t, \quad X_1=\partial/\partial y, \quad X_2=\partial/\partial z, \quad X_3=z\partial/\partial y-y\partial/\partial z,$$

$$X_4=tz\partial/\partial t-az\partial/\partial x+yz\partial/\partial y+\tfrac{1}{2}(z^2-y^2+t^2-a^2e^{-2x/a})\partial/\partial z,$$

$$X_5=-ty\partial/\partial t+ay\partial/\partial x+\tfrac{1}{2}(z^2-y^2-t^2+a^2e^{-2x/a})\partial/\partial y-yz\partial/\partial z,$$

$$X_6=z\partial/\partial t+t\partial/\partial z, \quad X_7=y\partial/\partial t+t\partial/\partial y,$$

$$X_8=-\frac{1}{2a}(z^2+y^2+t^2+a^2e^{-2x/a})\partial/\partial t+t\partial/\partial x-\frac{ty}{a}\partial/\partial y-\frac{tz}{a}\partial/\partial z,$$

$$X_9=-\frac{t}{a}\partial/\partial t+\partial/\partial x-\frac{y}{a}\partial/\partial y-\frac{z}{a}\partial/\partial z,$$

satisfying the $SO(2,3)$ Lie algebra

$$[X_0,X_4]=X_6, \quad [X_0,X_5]=-X_7, \quad [X_0,X_6]=X_2, \quad [X_0,X_7]=X_1,$$

$$[X_0,X_8]=X_9, \quad [X_0,X_9]=-\frac{1}{a}X_0, \quad [X_1,X_3]=-X_2, \quad [X_1,X_4]=X_3,$$

$$[X_1,X_5]=aX_9, \quad [X_1,X_7]=X_0, \quad [X_1,X_8]=-\frac{1}{a}X_7, \quad [X_1,X_9]=-\frac{1}{a}X_1,$$

$$[X_2,X_3]=X_1, \quad [X_2,X_4]=-aX_9, \quad [X_2,X_5]=X_3, \quad [X_2,X_6]=X_0,$$

$$[X_2,X_8]=-\frac{1}{a}X_6, \quad [X_2,X_9]=-\frac{1}{a}X_2, \quad [X_3,X_4]=X_5, \quad [X_3,X_5]=-X_4,$$

$$[X_3,X_6]=-X_7, \quad [X_3,X_7]=X_6, \quad [X_4,X_6]=aX_8, \quad [X_4,X_9]=\frac{1}{a}X_4,$$

$$[X_5,X_7]=-aX_8, \quad [X_5,X_9]=\frac{1}{a}X_5, \quad [X_6,X_7]=X_3, \quad [X_6,X_8]=-\frac{1}{a}X_4,$$

$$[X_7,X_8]=\frac{1}{a}X_5, \quad [X_8,X_9]=\frac{1}{a}X_8, \quad [X_i,X_k]=0 \quad (\text{otherwise});$$

and (Ib) the deSitter spacetime,

$$ds^2=dt^2-e^{2t/a}(dx^2+dy^2+dz^2) \quad (a\neq 0), \tag{4}$$

with the generators

$$X_0=\partial/\partial x,\quad X_1=\partial/\partial y,\quad X_2=\partial/\partial z,\quad X_3=z\partial/\partial y-y\partial/\partial z,$$

$$X_4=-az\partial/\partial t+xz\partial/\partial x+yz\partial/\partial y+\tfrac{1}{2}(z^2-y^2-x^2+a^2e^{-2t/a})\partial/\partial z,$$

$$X_5=ay\partial/\partial t-xy\partial/\partial x+\tfrac{1}{2}(z^2-y^2+x^2-a^2e^{-2t/a})\partial/\partial y-yz\partial/\partial z,$$

$$X_6=-z\partial/\partial x+x\partial/\partial z,\quad X_7=-y\partial/\partial x+x\partial/\partial y,$$

$$X_8=x\partial/\partial t+\frac{1}{2a}(z^2+y^2-x^2-a^2e^{-2t/a})\partial/\partial x-\frac{xy}{a}\partial/\partial y-\frac{xz}{a}\partial/\partial z,$$

$$X_9=\partial/\partial t-\frac{x}{a}\partial/\partial x-\frac{y}{a}\partial/\partial y-\frac{z}{a}\partial/\partial z,$$

satisfying the $SO(1,4)$ Lie algebra

$$[X_0,X_4]=-X_6,\quad [X_0,X_5]=X_7,\quad [X_0,X_6]=X_2,\quad [X_0,X_7]=X_1,$$

$$[X_0,X_8]=X_9,\quad [X_0,X_9]=-\frac{1}{a}X_0,\quad [X_1,X_3]=-X_2,\quad [X_1,X_4]=X_3,$$

$$[X_1,X_5]=aX_9,\quad [X_1,X_7]=-X_0,\quad [X_1,X_8]=-\frac{1}{a}X_7,\quad [X_1,X_9]=-\frac{1}{a}X_0,$$

$$[X_2,X_3]=X_1,\quad [X_2,X_4]=-aX_9,\quad [X_2,X_5]=X_3,\quad [X_2,X_6]=-X_0,$$

$$[X_2,X_8]=-\frac{1}{a}X_6,\quad [X_2,X_9]=-\frac{1}{a}X_2,\quad [X_3,X_4]=X_5,\quad [X_3,X_5]=-X_4,$$

$$[X_3,X_6]=-X_7,\quad [X_3,X_7]=X_6,\quad [X_4,X_6]=aX_8,\quad [X_4,X_9]=aX_4,$$

$$[X_5,X_7]=-aX_8,\quad [X_5,X_9]=\frac{1}{a}X_5,\quad [X_6,X_7]=-X_3,\quad [X_6,X_8]=\frac{1}{a}X_4,$$

$$[X_7,X_8]=-\frac{1}{a}X_5,\quad [X_8,X_9]=\frac{1}{a}X_8,\quad [X_i,X_k]=0\quad \text{(otherwise)}.$$

Both the metrics given by Eqs. (3) and (4) are Einstein spaces ($R_{ab}\propto g_{ab}$) with constant curvature.[2]

There do not exist Lorentzian metrics admitting G_9 and G_8 as the maximal isometry groups.[6,7]

The metrics admitting G_7 as the maximal group of motions are: (IIa) the anti-Einstein metric,

$$ds^2=dt^2-dx^2-e^{2x/a}(dy^2+dz^2)\quad (a\neq 0), \tag{5}$$

$$X_0=\partial/\partial t,\quad X_1=\partial/\partial y,\quad X_2=\partial/\partial z,\quad X_3=z\partial/\partial y-y\partial/\partial z,$$

$$X_4=ay\partial/\partial x+\tfrac{1}{2}(z^2-y^2+a^2e^{-2x/a})\partial/\partial y-yz\partial/\partial z,$$

$$X_5=-az\partial/\partial x+yz\partial/\partial y+\tfrac{1}{2}(z^2-y^2-a^2e^{-2x/a})\partial/\partial z,$$

$$X_6=a\partial/\partial x-y\partial/\partial y-z\partial/\partial z,$$

$$[X_1,X_3]=-X_2,\quad [X_1,X_4]=X_6,\quad [X_1,X_5]=X_3,\quad [X_1,X_6]=-X_1,$$

$$[X_2,X_3]=X_1,\quad [X_2,X_4]=X_3,\quad [X_2,X_5]=-X_6,\quad [X_2,X_6]=-X_2,$$

$$[X_3,X_4]=-X_5,\quad [X_3,X_5]=X_4,\quad [X_4,X_6]=X_4,\quad [X_5,X_6]=X_5,$$

$$[X_i,X_k]=0\quad \text{(otherwise)},$$

with symmetry structure $SO(1,3)\otimes\mathbb{R}$; (IIb) the metric,

$$ds^2=dt^2-dx^2-e^{2t/a}(dy^2+dz^2)\quad (a\neq 0), \tag{6}$$

$$X_0=\partial/\partial x,\quad X_1=\partial/\partial y,\quad X_2=\partial/\partial z,\quad X_3=z\partial/\partial y-y\partial/\partial z,$$

$$X_4=ay\partial/\partial t+\tfrac{1}{2}(z^2-y^2-a^2e^{-2t/a})\partial/\partial y-yz\partial/\partial z,$$

$$X_5=-az\partial/\partial t+yz\partial/\partial y+\tfrac{1}{2}(z^2-y^2+a^2e^{-2t/a})\partial/\partial z,$$

$$X_6=\partial/\partial t-\frac{y}{a}\partial/\partial y-\frac{z}{a}\partial/\partial z,$$

with the same Lie algebra.

The metrics admitting G_6 as the maximal isometry group are: (IIIa),

$$ds^2=\cosh^2\frac{x}{a}dt^2-dx^2-dy^2-dz^2\quad (a\neq 0), \tag{7}$$

$$X_0=\partial/\partial t,\quad X_1=\partial/\partial y,\quad X_2=\partial/\partial z,\quad X_3=z\partial/\partial y-y\partial/\partial z,$$

$$X_4=-\tanh\frac{x}{a}\sin\frac{t}{a}\partial/\partial t+\cos\frac{t}{a}\partial/\partial x,$$

$$X_5=\tanh\frac{x}{a}\cos\frac{t}{a}\partial/\partial t+\sin\frac{t}{a}\partial/\partial x,$$

$$[X_0,X_4]=-\frac{1}{a}X_5,\quad [X_0,X_5]=\frac{1}{a}X_4,\quad [X_1,X_3]=-X_2,\quad [X_2,X_3]=X_1,$$

$$[X_4,X_5]=\frac{1}{a}X_0,\quad [X_i,X_k]=0\quad \text{(otherwise)},$$

and isometry group $G_3\otimes SO(1,2)$; (IIIb),

$$ds^2=\cos^2\frac{x}{a}dt^2-dx^2-dy^2-dz^2\quad (a\neq 0), \tag{8}$$

$$X_0=\partial/\partial t,\quad X_1=\partial/\partial y,\quad X_2=\partial/\partial z,\quad X_3=z\partial/\partial y-y\partial/\partial z,$$

$$X_4=\tan\frac{x}{a}\sinh\frac{t}{a}\partial/\partial t+\cosh\frac{t}{a}\partial/\partial x,$$

$$X_5=\tan\frac{x}{a}\cosh\frac{t}{a}\,\partial/\partial t+\sinh\frac{t}{a}\,\partial/\partial x,$$

$$[X_0,X_4]=\frac{1}{a}X_5,\quad [X_0,X_5]=\frac{1}{a}X_4,\quad [X_1,X_3]=-X_2,\quad [X_2,X_3]=X_1,$$

$$[X_4,X_5]=\frac{1}{a}X_0,\quad [X_i,X_k]=0\quad \text{(otherwise)},$$

with isometry group $G_3\otimes SO(2,1)$; (IIIc),

$$ds^2=e^{2x/a}\,dt^2-dx^2-dy^2-dz^2\quad (a\neq 0), \tag{9}$$

$$X_0=\partial/\partial t,\quad X_1=\partial/\partial y,\quad X_2=\partial/\partial z,\quad X_3=z\,\partial/\partial y-y\,\partial/\partial z,$$

$$X_4=-\frac{1}{2a}(t^2+a^2e^{-2x/a})\,\partial/\partial t+t\,\partial/\partial x,\quad X_5=-\frac{t}{a}\,\partial/\partial t+\partial/\partial x,$$

$$[X_0,X_4]=X_5,\quad [X_0,X_5]=-\frac{1}{a}X_0,\quad [X_1,X_3]=-X_2,\quad [X_2,X_3]=X_1,$$

$$X_4=-y\partial/\partial t+y\partial/\partial x+\left[\frac{1}{2a}(z^2-y^2)+\frac{a}{2}e^{2(\lambda+t/a)}-\frac{a}{2}e^{2(\nu+t/a)}\right]\partial/\partial y-\frac{yz}{a}\partial/\partial z,$$

$$X_5=z\partial/\partial t-z\partial/\partial x+\frac{yz}{a}\partial/\partial y+\left[\frac{1}{2a}(z^2-y^2)-\frac{a}{2}e^{2(\lambda+t/a)}+\frac{a}{2}e^{2(\nu+t/a)}\right]\partial/\partial z,$$

and a Lie algebra identical to that of the metric (17); (IIIm),

$$ds^2=e^{2\nu(t+x)}dt^2-e^{2\lambda(t+x)}dx^2-e^{-[(t-x)/a]}(dy^2+dz^2)\quad(a\neq 0),\tag{19}$$

subject to the constraint

$$e^{2[\lambda+(t-x)/2a]}=e^{2[\nu+(t-x)/2a]}-\left(\frac{2}{a}\right)\int e^{2[\nu+(t-x)/2a]}dt,$$

$$X_0=\partial/\partial t-\partial/\partial x+\frac{y}{a}\partial/\partial y+\frac{z}{a}\partial/\partial z,\quad X_1=\partial/\partial y,$$

$$X_2=\partial/\partial z,\quad X_3=z\partial/\partial y-y\partial/\partial z,$$

$$X_4=-y\partial/\partial t+y\partial/\partial x+\left[\frac{1}{2a}(z^2-y^2)-\frac{a}{2}e^{2[\nu+(t-x)/2a]}+\frac{a}{2}e^{2[\lambda+(t-x)/2a]}\right]\partial/\partial y-\frac{yz}{a}\partial/\partial z,$$

$$X_5=z\partial/\partial t-z\partial/\partial x+\frac{yz}{a}\partial/\partial y+\left[\frac{1}{2a}(z^2-y^2)+\frac{a}{2}e^{2[\nu+(t-x)/2a]}-\frac{a}{2}e^{2[\lambda+(t-x)/2a]}\right]\partial/\partial z,$$

with a Lie algebra identical to that of the metric (17).

The metrics admitting G_5 as the maximal isometry group are: (IVa),

$$ds^2=e^{2x/a}dt^2-dx^2-e^{2x/b}(dy^2+dz^2)\quad(a\neq 0\neq b\neq a),\tag{20}$$

$$X_0=\partial/\partial t,\quad X_1=\partial/\partial y,\quad X_2=\partial/\partial z,\quad X_3=z\partial/\partial y-y\partial/\partial z,$$

$$X_4=-\frac{t}{a}\partial/\partial t+\partial/\partial x-\frac{y}{b}\partial/\partial y-\frac{z}{b}\partial/\partial z,$$

$$[X_0,X_4]=-\frac{1}{a}X_0,\quad [X_1,X_3]=-X_2,\quad [X_1,X_4]=-\frac{1}{b}X_1,\ [X_2,X_3]=X_1,$$

$$[X_2,X_4]=-\frac{1}{b}X_2,\quad [X_i,X_k]=0\quad(\text{otherwise}),$$

and isometry group $G_3\otimes\mathbb{R}^2$; and (IVb),

$$ds^2=dt^2-e^{2t/a}\,dx^2-e^{2t/b}(dy^2+dz^2)\quad (a\neq 0\neq b\neq a), \tag{21}$$

$$X_0=\partial/\partial x,\quad X_1=\partial/\partial y,\quad X_2=\partial/\partial z,\quad X_3=z\,\partial/\partial y-y\,\partial/\partial z,$$

$$X_4=\partial/\partial t-\frac{x}{a}\,\partial/\partial x-\frac{y}{b}\,\partial/\partial y-\frac{z}{b}\,\partial/\partial z,$$

with a Lie algebra identical to that of the metric (20).

The metrics admitting G_4 as the maximal isometry group are: (Va),

$$ds^2=e^{2\nu(x)}\,dt^2-dx^2-e^{2\mu(x)}(dy^2+dz^2), \tag{22}$$

$$X_0=\partial/\partial t,\quad X_1=\partial/\partial y,\quad X_2=\partial/\partial z,\quad X_3=z\,\partial/\partial y-y\,\partial/\partial z,$$

$$[X_1,X_3]=-X_2,\quad [X_2,X_3]=X_1,\quad [X_i,X_k]=0\quad (\text{otherwise}),$$

admitting $G_3\otimes\mathbb{R}$ with a timelike $\mathbb{R}$; (Vb),

$$ds^2=dt^2-e^{2\lambda(t)}\,dx^2-e^{2\mu(t)}(dy^2+dz^2), \tag{23}$$

$$X_0=\partial/\partial x,\quad X_1=\partial/\partial y,\quad X_2=\partial/\partial z,\quad X_3=z\,\partial/\partial y-y\,\partial/\partial z,$$

with the same Lie algebra and a spacelike $\mathbb{R}$; (Vc),

$$ds^2=dt^2-dx^2-e^{2\mu(t\pm x)}(dy^2+dz^2), \tag{24}$$

$$X_0=\partial/\partial t\pm\partial/\partial x,\quad X_1=\partial/\partial y,\quad X_2=\partial/\partial z,\quad X_3=z\,\partial/\partial y-y\,\partial/\partial z,$$

with the same Lie algebra and a null $\mathbb{R}$.

This completes the classification of plane symmetric Lorentzian manifolds according to their isometries and metrics.

(Received 13 March 2001; accepted for publication 24 July 2001)

Using gyroscopes we generalize results, obtained for the gravitomagnetic clock effect in the particular case when the exterior space–time is produced by a rotating dust cylinder, to the case when the vacuum space–time is described by the general cylindrically symmetric Lewis space–time. Results are contrasted with those obtained for the Kerr space–time. © *2001 American Institute of Physics.*

I. INTRODUCTION

Recently Bonnor and Steadman[1] calculated and analyzed the gravitomagnetic clock effect, which is the difference in periods of a test particle moving in prograde and retrogade circular geodesic orbits around the axis of a rotating body. They applied their results to a cylindrically symmetric system produced by van Stockum metric[2] describing a rotating dust cylinder. The exterior space–time, containing two parameters, is a particular case of the general vacuum stationary cylindrically symmetric Lewis metric[2–4] containing four parameters. We extend some of their results to the general Lewis space–time by using the results obtained by us[5] for the gyroscope precession in cylindrically symmetric space–times. The clock effect and the gyroscope precession amount to similar physical processes. However, as it will be seen, using gyroscopes allows for a wider class of possible ''gedanken'' experiments. Indeed, we have to face two different effects: one is the influence of the rotation of the source on the gravitational field where the gyroscope is placed (the gravitomagnetic effect), which of course is absent in Newtonian theory; the other is related to the fact that the frame of the gyroscope may be rotating, producing a precession in the gyroscope (Thomas-like precession).

II. PRECESSION OF A GYROSCOPE MOVING IN A CIRCLE AROUND THE AXIS OF SYMMETRY

The Lewis metric can be written as

$$ds^2 = -f dt^2 + 2k dt d\phi + e^{\mu}(dr^2 + dz^2) + l d\phi^2, \tag{1}$$

where

$$f = a r^{1-n} - \frac{c^2 r^{1+n}}{n^2 a}, \tag{2}$$

$$k = -Af, \tag{3}$$

[a)]Postal address: Apartado 80793, Caracas 1080A, Venezuela. Electronic mail: laherrera@telcel.net.ve
[b)]Electronic mail: nos@cbpf.br

$$l=\frac{r^2}{f}-A^2 f, \tag{4}$$

$$e^{\mu}=r^{(n^2-1)/2}, \tag{5}$$

with

$$A=\frac{cr^{1+n}}{naf}+b. \tag{6}$$

The parameters n, a, b, and c can be either real or complex, and the corresponding solutions belong to the Weyl or Lewis class, respectively. Here we restrict our study to the Weyl class (not to confound with Weyl metrics representing static and axially symmetric space–times).

The parameters n and a are proportional to the Newtonian energy per unit length and the topological defect, respectively, while b and c describe the stationarity of the source and are proportional to the angular momentum of the source producing a topological defect and the vorticity of the source, respectively.

Now it is important to stress that the transformations[6]

$$d\tau=\sqrt{a}(dt+bd\phi), \tag{7}$$

$$d\overline{\phi}=\frac{1}{n}[-cdt+(n-bc)d\phi] \tag{8}$$

cast the Weyl class of the Lewis metric into the Levi-Civita cylindrical metric (static). However, the transformations in (7) and (8) are not valid globally, and therefore both metrics are equivalent only locally, a fact that can be verified by calculating the corresponding Cartan scalars.[7] In order to globally transform the Weyl class of the Lewis metric into the static Levi-Civita metric, we have to make $b=0$. Indeed, if $b=0$ and c is different from zero, (7) gives an admissible transformation for the time coordinate and (8) represents the transformation to a rotating frame [implying thereby that the frame of (1) is itself rotating]. In other words, if $b=0$, (1) is just the exterior line element of a static cylinder, as seen by a rotating observer. However, since rotating frames (as in special relativity) are not expected to cover the whole space–time, and, furthermore, since the new angle coordinate ranges from $-\infty$ to ∞, it has been argued in the past[7] that both b and c have to vanish for (7) and (8) to be globally valid. This point of view is also reinforced by the fact that, assuming that only b has to vanish in order to globally cast (1) into Levi-Civita, we are lead to the intriguing result that there is no dragging outside rotating cylinders. We shall recall this question later.

The rotation Ω of the compass of inertia, or the gyroscope, with respect to a rotating frame with angular velocity ω moving around the axis of symmetry given by metric (1) can be easily calculated by using the Rindler–Perlick method.[8]

This consists in transforming the angular coordinate ϕ by

$$\phi=\phi'+\omega t, \tag{9}$$

where ω is a constant [observe that (8), with $b=0$, defines a rotation in the sense opposite to that in (9)]. Then the transformed metric is written in a canonical form

$$ds^2=-e^{2\Psi}(dt-\omega_i dx^i)^2+h_{ij}dx^i dx^j, \tag{10}$$

with Latin indexes running from 1 to 3 and Ψ, ω_i, and h_{ij} depend on the spatial coordinate x^i only (we are omitting primes). Then, it may be shown that the four-acceleration A_μ and the rotation three-vector Ω^i of the congruence of world lines $x^i=\text{const}$ are given by

$$A_\mu=(0,\Psi_{,i}), \tag{11}$$

$$\Omega^i=\tfrac{1}{2}e^{\Psi}(\det h_{mn})^{-1/2}\epsilon^{ijk}\omega_{k,j}, \tag{12}$$

where the comma denotes partial derivative. It is clear from the above that if $\Psi_{,i}=0$, then particles at rest in the rotating frame follow circular geodesics. On the other hand, since Ω^i describes the rate of rotation with respect to the proper time at any point at rest in the rotating frame, relative to the local compass of inertia, then $-\Omega^i$ describes the rotation of the compass of inertia (the *gyroscope*) with respect to the rotating frame. Applying (9) to the original frame of (1), with $t=t'$, $r=r'$, and $z=z'$, we cast (1) into the canonical form (10), and obtain [see (43) in Ref. 5]

$$\Omega=MNr^{(1-n^2)/4}\left(M^2ar^{1-n}-\frac{N^2r^{1+n}}{n^2a}\right)^{-1}, \tag{13}$$

where

$$M=1+b\omega, \quad N=n\omega-c(1+b\omega). \tag{14}$$

From (13) we can ask if there are ω's for which the gyroscope precession is null.

We see from (13) that the gyroscope does not precess if $M=0$ or $N=0$, thus producing $\Omega=0$ and implying respectively for the angular velocity of the frame

$$\omega_M=-\frac{1}{b}, \quad \omega_N=\frac{c}{n-bc}. \tag{15}$$

The physical meaning of this result will be discussed later. A similar result has been obtained in Ref. 1, but in the particular context of van Stockum solution, while our result is general and independent of the source.

The tangential velocity W of the gyroscope moving around the axis of symmetry for metric (1) is given by [see (53) in Ref. 9]

$$W=\frac{\omega(fl+k^2)^{1/2}}{f-\omega k}. \tag{16}$$

Substituting (2)–(5) into (16), we obtain

$$W=\frac{n\omega\chi}{(1+b\omega)(1-c^2\chi^2)+nc\omega\chi^2}, \tag{17}$$

where

$$\chi=\frac{r^n}{na}. \tag{18}$$

The angular velocities (15) give, respectively, from (17), the tangential velocities

$$W_M=\frac{1}{c\chi}, \quad W_N=c\chi, \tag{19}$$

and we observe that these velocities do not depend upon b in spite of the corresponding angular velocities depend upon b.

The Newtonian energy per unit length σ is given, in terms of n, by

$$\sigma=\tfrac{1}{4}(1-n), \tag{20}$$

and we consider the range $1>n>-1$ or $0<\sigma<\frac{1}{2}$. This range produces physically reasonable cylindrically symmetric sources.[7] However, no circular timelike geodesics exist for $n<0$, and, furthermore, it is not clear that $n<0$ represent cylinders.[10]

From (19) we see that as $r\to 0$, for $1>n>0$, $W_{M+}\to\infty$ and $W_{N+}\to 0$; while for $0>n>-1$, $W_{M-}\to 0$ and $W_{N-}\to-\infty$. We discard W_{M+} and W_{N-} as being unphysical.

Now, let us suppose that $1>n>0$. Then Ω vanishes for $\omega=\omega_N$. If, furthermore, $b=0$, then it follows at once from (8), that transformation (9) brings the system back to the nonrotating frame (the frame in which the line element is static), thereby explaining the vanishing of the precession. The remarkable fact, however, is that Ω vanishes for ω_N, even if b is different from zero. As for ω_M, we do not have a reasonable interpretation, unless we accept that (1) describes a cylinder only if $1>n>0$.

Now we study the case of infinite precession, $\Omega\to\infty$, for the gyroscope moving around the axis of symmetry. From (13) we have then

$$r^n=\frac{Mna}{N}, \tag{21}$$

and, considering (14), we can rewrite (21) for the angular velocity of the rotating frame,

$$\omega=\frac{1+c\chi}{n\chi-b(1+c\chi)}. \tag{22}$$

The corresponding tangential speed of the gyroscope becomes, using (16), (17), and (22),

$$W=1, \tag{23}$$

which means that the gyroscope attains infinite precession when its tangential velocity around the axis becomes the light velocity.

III. PRECESSION OF A GYROSCOPE AT REST

If the gyroscope is at rest in the original lattice, then we have [see (32) in Ref. 5]

$$\Omega=\frac{cr^{(1-n)(n-3)/4}}{a(1-c^2\chi^2)}. \tag{24}$$

Observe that it is the absolute value of Ω what appears in (31)–(34) in Ref. 5. We see that the precession is infinite if $c\chi=1$. It is remarkable that $c\chi=1$, if the gyroscope is moving around the axis of symmetry, produces a tangential speed of light (19), $W_{N+}=1$, with null precession; on the other hand, in this same case $c\chi=1$, while at rest its precession becomes infinite.

On the other hand, when $b=0$ and $c=0$, i.e., when the Weyl class of Lewis metric becomes the static Levi-Civita cylindrical space–time, the precession of a gyroscope moving around the axis of symmetry results in

$$\Omega=\frac{n\omega r^{(1-n)(n-3)/4}}{a(1-n^2\omega^2\chi^2)}, \tag{25}$$

with a tangential velocity obtained from (17),

$$W=n\omega\chi. \tag{26}$$

We observe that the gyroscope precession is the same in both cases, (24) and (25), if the angular velocity of the gyroscope, in the Levi-Civita space–time, is related to the vorticity of Lewis space–time by

$$\omega=\frac{c}{n}. \tag{27}$$

These two equal precessions, (24) and (25), suggest that (if $b=0$) it is equivalent to measure the precession of a gyroscope at rest with respect to the rotating Lewis source or moving around the corresponding static source. This situation, in turn, is a reminiscense of the non-Machian behavior of Newtonian gravity, where gravitomagnetic effects are absent.

IV. PRECESSION OF A GYROSCOPE IN A LOCALLY NONROTATING FRAME

Using the transformation

$$d\phi=d\bar{\phi}+\omega dt, \tag{28}$$

where ω is

$$\omega=-\frac{k}{l}, \tag{29}$$

the Lewis metric (1) transforms into a diagonal form near $r=r_0$. This frame is called locally nonrotating.[11,12] From (28) for the Lewis metric (1) we have

$$\omega=\frac{n^3a^2c-2n^2a^2bc^2+(bc-n)c^3r_0^{2n}+n^4a^4br_0^{-2n}}{n^4a^2-2n^3a^2bc+2n^2a^2b^2c^2-(n-bc)c^2r_0^{2n}-n^4a^4b^2r_0^{-2n}}, \tag{30}$$

which can be rewritten with (18),

$$\omega=\frac{(n-bc)c\chi_0^2+b}{(n-bc)^2\chi_0^2-b^2}, \tag{31}$$

where $\chi_0=\chi(r_0)$. The tangential velocity (17) with (31) becomes

$$W=\frac{(n-bc)c\chi_0^2+b}{n\chi_0}, \tag{32}$$

and the precession (13) with (31) becomes

$$\Omega=\frac{b(n-bc)r_0^{(1-n)(n-3)/4}}{a[(n-bc)^2\chi_0^2-b^2]}. \tag{33}$$

From (31) we see that there are two cases where ω does not depend upon a particular radius r_0 and produces no precession according to (33). These cases are, for $b=0$,

$$\omega=\frac{c}{n}, \quad W=c\chi_0; \tag{34}$$

and, for $bc=n$,

$$\omega=-\frac{1}{b}, \quad W=\frac{1}{c\chi_0}, \tag{35}$$

where we have included, from (32), the corresponding tangential velocities. We see from (34) that the result corresponds to what we obtained for ω_N in (15) and agrees with the analysis of the gyroscope at rest (24) compared to the precession in Levi-Civita's space–time (25). However, the

case (35), while producing a similar result compared to ω_M in (15), imposes the relation $b=n/c$. When $b\neq 0$ and $b\neq n/c$ the locally nonrotating frame produces non-null precession.

V. THE KERR SPACE–TIME

It is instructive to compare the situation described previously with that in the Kerr space.

In Boyer–Lindquist coordinates with $\theta=\pi/2$, the Kerr metric has the form (the Kerr parameter a, describing angular momentum per unit mass, not to be confounded with the parameter a of the Lewis metric)

$$ds^2=-\left(1-\frac{2m}{r}\right)dt^2-\frac{4am}{r}dtd\phi+\frac{1}{\Pi}dr^2+\left(r^2+a^2+\frac{2a^2m}{r}\right)d\phi^2, \tag{36}$$

where

$$\Pi=1-\frac{2m}{r}+\frac{a^2}{r^2}. \tag{37}$$

Then, applying the Rindler–Perlick method, one obtains after some lengthy calculations

$$e^{2\Psi}=\Lambda, \tag{38}$$

$$\omega_i=(0,0,\omega_\phi), \tag{39}$$

$$\omega_\phi=\frac{1}{\Lambda}\left[\omega(r^2+a^2)-\frac{2am}{r}(1-a\omega)\right], \tag{40}$$

$$h_{rr}=\frac{1}{\Pi}, \tag{41}$$

$$h_{\phi\phi}=\frac{\Pi}{\Lambda}r^2, \tag{42}$$

with

$$\Lambda=1-\omega^2(r^2+a^2)-\frac{2m}{r}(1-a\omega)^2. \tag{43}$$

Substituting (38)–(42) into (12) we obtain

$$\Omega=\frac{2}{\Lambda}\left[\omega-\frac{3m}{r}\omega(1-a\omega)+\frac{am}{r^3}(1-a\omega)^2\right]. \tag{44}$$

The value of the angular velocity ω for which there is no precession ($\Omega=0$) is easily obtained from (44) to be

$$\omega=-\frac{r^2(r-3m)-2ma^2-\sqrt{r^4(r-3m)^2-4ma^2r^3}}{2ma(3r^2+a^2)}; \tag{45}$$

this is the same value for which prograde and retrograde circular geodesics have the same period,[13] and which leads to the condition of no clock effect in Ref. 1, after replacing ω by its expression for a circular geodesic. This result was obtained before[14] and (together with other properties) led some authors to suggest that natural nonrotating observers are those moving with angular velocity (45) (see Ref. 13 and references therein). This identification, however, is not

necessarily correct. In fact, observe that a gyroscope at rest in the frame of (36) ($\omega=0$) will precess unless $a=0$, reflecting the well-known fact that the original frame of (36) is itself rotating with respect to a compass of inertia.[8] Therefore, the vanishing of Ω for observers rotating with angular velocity (45) only shows that the gravitational dragging effect of the source exactly cancels the Thomas-like precession due to the rotation of the frame where the gyroscope is placed: a frame which, as shown in Ref. 1, rotates relative to distant stars. Under these circumstances it becomes difficult to accept that those observers represent ''the most natural standard of non-rotation.''

VI. CONCLUSION

We have seen that a gyroscope at rest in the frame of (1) will precess independently of b, and in a similar way as a gyroscope moving around a static source with angular velocity given by (27). This result, together with the fact that transformations (7) and (8) cast (1) into a static cylindrical Levi-Civita line element if $b=0$, would indicate that the rotation of the source does not affect the gyroscope. However, for the gyroscope moving around the source, there exist two possible angular velocities for which there is no precession. The physical meaning of one of them (ω_M) is not understood by the authors, unless the range of n is restricted to $1>n>0$, in which case it is discarded. The situation with ω_N is clear if $b=0$, in which case (9) is just a transformation to the nonrotating frame if $\omega=\omega_N$. However, if b is not vanishing, then the reasons for the vanishing of Ω are obscure. Finally, if we define a locally nonrotating frame according to (28) and (29), then we see that a gyroscope at rest in such a frame will precess according to (33). The origin of this precession is rather surprising if we note that it appears even if $n=a=1$ (Minkowski) and $c=0$. But under these conditions (1) is not the Minkowskian line element corresponding to a rotating frame. So the question here is, what is the nature of b that makes the gyroscope precess?

In the Kerr case we have seen that the frame in which $\Omega=0$ can hardly be called nonrotating. The difference with the Lewis case (with $b=0$) becomes intelligible, if we note that the frame of (36) with $m=0$ does not represent a rotating Minkowskian observer, a conclusion confirmed by the fact that (44) with $m=\omega=0$ yields $\Omega=0$. However, as mentioned before, the frame of (36) is rotating with respect to a compass of inertia if $m\neq 0$ (yielding $\Omega\neq 0$). This is in contrast with the Lewis case, where Ω is not vanishing for the gyroscope at rest in (1) in the case $n=1$ (Minkowski). This conspicuous difference in the relation between the source of the field and the rotation, in both cases, seems to suggest, loosely speaking, that the behavior of the Kerr metric is more ''Machian'' than that of Lewis.

(Received 12 January 2001; accepted for publication 19 July 2001)

We study a time-dependent five-dimensional (5D) metric which contains a static four-dimensional (4D) sub-metric whose three-dimensional (3D) part is spherically symmetric. An expansion in the metric coefficient allow us to obtain close-to Schwarzschild approximation to a class of spherically symmetric solutions. Using Campbell's embedding theorem and the induced-matter formalism we obtain two 4D solutions. One describes a source with the stiff equation of state believed to be applicable to dense astrophysical objects, and the other describes a spherical source with a radial heat flow. © *2001 American Institute of Physics.*

I. INTRODUCTION

Campbell showed the theorem that any solution of the Einstein equations in N dimensions can be locally embedded in a Ricci-flat manifold of $(N+1)$ dimensions whose field equations in terms of the Ricci tensor are $R_{AB}=0$ $(A,B=0,1,...,N)$.[1] Tavakol and co-workers have recently noted the relevance of this to the embedding of lower-dimensional (possibly quantizeable) gravity in 4D Einstein gravity,[2] and the technique is clearly applicable to the recovery of solutions of 4D general relativity from 10D superstrings, 11D supergravity and M-theory.[3–6] A major application of Campbell's theorem is to induced-matter theory, wherein solutions of the 4D Einstein equations with matter are recovered from the 5D Kaluza–Klein equations in apparent vacuum.[7] This approach has been applied to cosmology,[8] clusters of galaxies[9] and the solar system,[10,11] where there is agreement with observational data. It is valuable in application to general relativity, since solutions of the Kaluza–Klein equations can yield new solutions of the Einstein equations. With regard to the latter, spherically symmetric sources such as stars can be modeled in the simplest way by the interior and exterior Schwarzschild solutions. But to include the radiation outside a star, more complicated solutions are required.[12] These include the Vaidya metric which uses a retarded time coordinate to describe a radiating atmosphere,[13] the metrics of Herrera and co-workers wherein spheres of matter are matched to exterior space–times,[14–16] and the metrics of Glass and Krisch which extend the Vaidya solution to include both a radiation field and a string fluid.[17] However, despite extensive work on starlike solutions of the 4D equations and the existence of Campbell's theorem which shows that such can be embedded in the ND equations, not much work has been done on spherically symmetric solutions of the 5D equations. Notable exceptions are solutions which have an isothermal equation of state in 4D[9] and ones which are flat in 5D but curved in 4D.[18] We will, therefore, present an analysis of a class of 5D metrics, and illustrate their relevance by isolating two 4D solutions. One describes a source with the stiff equation of state believed to be applicable to dense astrophysical objects, and the other describes a spherical source with radiation.

II. 5D METRICS WITH 4D SPHERICAL SOURCES

In this section we let upper-case Latin indices run 0–4 and lower-case Greek indices run 0–3. We absorb the speed of light and the gravitational constant through the choices of units $c=1$, $8\pi G=1$. The coordinates are $x^A=t,\ r,\ \theta,\ \phi,\ y$ with $d\Omega^2\equiv d\theta^2+\sin^2\theta d\phi^2$ with (3D) spherical symmetry.

Consider the 5D line element with interval

$$dS^2=g_{AB}dx^Adx^B=\Phi^2ds^2-\Phi^{-4}dy^2, \tag{1}$$

$$ds^2=g_{\alpha\beta}dx^\alpha dx^\beta, \tag{2}$$

where $g_{\alpha\beta}=g_{\alpha\beta}(x^\mu)$ and $\Phi=\Phi(x^\mu)$. This metric is broad in scope and has been used in other contexts.[19] It also has the advantage that the 5D field equations $R_{AB}=0$ break down neatly into a set involving the 4D Ricci tensor and a conservation-type equation for the scalar field ($g_{44}=-\Phi^{-4}$)

$$R_{\alpha\beta}=6\Phi^{-2}\Phi_\alpha\Phi_\beta, \tag{3}$$

$$\Phi\Phi^\alpha_{;\alpha}-\Phi^\alpha\Phi_\alpha=0. \tag{4}$$

Here $\Phi^\alpha=g^{\alpha\beta}\Phi_\beta$, $\Phi^\alpha_{;\alpha}=g^{\alpha\beta}\Phi_{\alpha;\beta}$ and $R_{\alpha\beta}$ in (3) is made of $g_{\alpha\beta}$. Equations (3) and (4) admit many different types of solution, but here we choose a time-dependent scalar field and a static 4D geometry

$$\Phi=\Phi(t), \tag{5}$$

$$ds^2=B(r)dt^2-A(r)dr^2-r^2d\Omega^2. \tag{6}$$

These require that the left-hand side (lhs) of (3) should be independent of t and the rhs of (3) should be independent of r. Therefore both sides should equal to a constant, say, $6\lambda^2$. So we must have

$$\Phi=e^{\lambda t}. \tag{7}$$

Substituting this into Eq. (4), we find that (4) is satisfied. Using (6) and (7) in (3) gives the nonvanishing components

$$R_{00}=\frac{B''}{2A}-\frac{B'}{4A}\left(\frac{A'}{A}+\frac{B'}{B}\right)+\frac{1}{r}\frac{B'}{A}=6\lambda^2, \tag{8}$$

$$R_{11}=-\frac{B''}{2B}+\frac{B'}{4B}\left(\frac{A'}{A}+\frac{B'}{B}\right)+\frac{1}{r}\frac{A'}{A}=0, \tag{9}$$

$$R_{22}=\sin^{-2}\theta R_{33}=1-\frac{1}{A}+\frac{r}{2A}\left(\frac{A'}{A}-\frac{B'}{B}\right)=0, \tag{10}$$

with $A'\equiv dA/dr$. These are three equations in two unknowns, and determine a class of solutions which is time-dependent in 5D via (7) but static in 4D and spherically symmetric in 3D.

Let us manipulate (8)–(10). The sum of $AB^{-1}R_{00}$ of (8) and R_{11} of (9) gives

$$\frac{A'}{A}+\frac{B'}{B}=6\lambda^2r\frac{A}{B}. \tag{11}$$

And we can rewrite (10) as

$$\frac{A'}{A}-\frac{B'}{B}=-\frac{2}{r}(A-1). \tag{12}$$

Using (11) and (12), we verify that (8) and (9) are satisfied. Therefore, we need to solve (11) and (12) for A and B. Now (12) can be written as $(d/dr)\ln(A/B)=-2(A-1)/r$. Integrating this we get

$$B=A\exp\left[2\int_{r_0}^{r}\frac{A-1}{r}dr\right]. \tag{13}$$

Substituting this into (11), we obtain

$$\frac{A'}{A}+\frac{A-1}{r}=3\lambda^2 r\exp\left[-2\int_{r_0}^{r}\frac{A-1}{r}dr\right]. \tag{14}$$

Without loss of generality, let us introduce a mass function[20,21] via

$$A=\left(1-\frac{2\mu(r)}{r}\right)^{-1}. \tag{15}$$

Then (14) becomes

$$\mu'=\frac{3}{2}\lambda^2 r(r-2\mu)\exp\left[2\int_{r_0}^{r}\left(\frac{1}{r}-\frac{1}{r-2\mu}\right)dr\right]. \tag{16}$$

Here r_0 is a fiducial radius that can be chosen as appropriate to a physical situation. Thus if $r_0\to\infty$ we expect to recover the Schwarzschild case. The latter is indeed recovered for $\lambda=0$, when $\mu=M=$constant and (13) reads

$$B=A\exp\left[2\int_{\infty}^{r}\frac{A-1}{r}dr\right]=1-\frac{2M}{r}. \tag{17}$$

That is, $\lambda=0$ specifies the Schwarzschild limit of a class of solutions determined by (16) and one or the other of (11) and (12).

III. CLOSE-TO-SCHWARZSCHILD APPROXIMATION

We can study close-to-Schwarzschild approximation by expanding the mass function $\mu(r)$ of (15) for $|\lambda|$ small (i.e., $|\lambda|^{-1}\gg M$). Thus we write

$$\mu(r)=\sum_{n=0}^{\infty}\mu_n(r), \tag{18}$$

with $\mu_0=M$. Here μ_0 is the zero-order approximation of μ, $(\mu_0+\mu_1)$ is the first-order approximation, and so on. To obtain μ_1 we substitute μ_0 for μ in the rhs of (16) to obtain μ_1'. Integrating μ_1' gives μ_1. Then we substitute $(\mu_0+\mu_1)$ for μ in the rhs of (16) to obtain μ_2'. In this way we obtain the following recursion formulas for evaluating $\mu_n(r)$

$$\mu_0'=0,$$

$$\mu_1'=-\mu_0'+\frac{3}{2}\lambda^2 r(r-2M)\exp\left[2\int_{r_0}^{r}\left(\frac{1}{r}-\frac{1}{r-2M}\right)dr\right],$$

$$\mu_n'=-\sum_{m=0}^{n-1}\mu_m'+\frac{3}{2}\lambda^2 r\left(r-2\sum_{m=0}^{n-1}\mu_m\right)\exp\left\{2\int_{r_0}^{r}\left[\frac{1}{r}-\left(r-2\sum_{m=0}^{n-1}\mu_m\right)^{-1}\right]dr\right\}. \tag{19}$$

From this we find

$$\mu_1'=\frac{3}{2}\lambda^2\left(1-\frac{2M}{r_0}\right)^2\frac{r^3}{r-2M}, \tag{20}$$

and so

$$\mu_1=\frac{3}{2}\lambda^2\left(1-\frac{2M}{r_0}\right)^2\int_{r_0}^{r}\frac{r^3dr}{r-2M}. \tag{21}$$

In the region $r\gg 2M$ and $r_0\gg 2M$, we find

$$\mu_1\approx\tfrac{1}{2}\lambda^2 r^3, \tag{22}$$

where we have absorbed a constant term in μ_0 without loss of generality, so the first-order approximation of $A(r)$ in (15) is

$$A\approx\left(1-\frac{2M}{r}-\lambda^2 r^2\right)^{-1}. \tag{23}$$

Substituting this equation into (13), keeping only terms up to first order in λ^2 as well as in M, and neglecting a constant factor in B, we find

$$B\approx 1-\frac{2M}{r}+2\lambda^2 r^2. \tag{24}$$

From this coefficient and that of (23) we obtain the first order close-to-Schwarzschild approximation of the 5D solution as

$$dS^2\approx e^{2\lambda t}\left[\left(1-\frac{2M}{r}+2\lambda^2 r^2\right)dt^2-\left(1-\frac{2M}{r}-\lambda^2 r^2\right)^{-1}dr^2-r^2d\Omega^2\right]-e^{-4\lambda t}dy^2. \tag{25}$$

This metric is time-dependent. When $\lambda\to 0$, it tends to the 5D Schwarzschild solution. So we call (25) the close-to-Schwarzschild approximation for small $|\lambda|$, implying that the time-variation of the field should be very slow. We also find that the solution (25) belongs to the Type D class of the general time-dependent 5D metrics.[22] As regards the 4D part inside the square bracket in (25), it is interesting to note that it does *not* define the 4D Schwarzschild–de Sitter solution. In the latter, A and B both contain a term $\Lambda r^2/3$ where Λ is the cosmological constant. By contrast, whereas λ^2 has the same physical dimensions as Λ (namely *time*$^{-2}$ or *length*$^{-2}$), A and B in (23) and (24) contain terms with different signs and different sizes. This situation is analogous to another in Kaluza–Klein theory, where the exact solution of the 5D field equations for a charged point mass

does not exactly reproduce the 4D Reissner–Nordstrom solution.[23] Since the 5D equations are richer than the 4D ones, such situations may be expected; but even so, (25) defines a new solution.

IV. TWO EXACT 4D SOLUTIONS

There are, of course, many other solutions than those which are close to Schwarzschild. In general, we have a class of solutions of $R_{AB}=0$ with a metric

$$dS^2=e^{2\lambda t}[Bdt^2-Adr^2-r^2d\Omega^2]-e^{-4\lambda t}dy^2, \tag{26}$$

whose space–time potentials A, B are determined by (11) and (12). Alternatively, they are determined by (16) and one or the other of (11) and (12). We should recall, however, that while (8), (9), and (10) are 4D relations and can be used as such, the class of metrics (26) is 5D in nature. This means that we can use Campbell's theorem[1] and the induced-matter formalism[7] to generate 4D solutions of Einstein's equations with their appropriate matter. We now proceed to show how the 5D metric (26) produces two exact 4D solutions.

A. Solution with a stiff fluid

The first is obtained by splitting off the part inside square brackets in (26). The 4D metric is then

$$ds^2=g_{\alpha\beta}dx^\alpha dx^\beta=Bdt^2-Adr^2-r^2d\Omega^2, \tag{27}$$

and is static. We, therefore, expect that the source necessary to balance Einstein's equations will also be static. As mentioned above, the Kaluza–Klein equations $R_{AB}=0$ $(A,B=0,123,4)$ contain as a subset the Einstein equations $R_{\alpha\beta}-Rg_{\alpha\beta}/2=T_{\alpha\beta}$ $(\alpha,\beta=0,123)$. Here $T_{\alpha\beta}$ is the 4D energy-momentum tensor, which can always be constructed from the 5D geometry[1,2] and whose form is now well known.[7–9] For the present case, $R_{\alpha\beta}$ is given by (3), so the induced energy-momentum tensor is

$$T_{\alpha\beta}=R_{\alpha\beta}-\tfrac{1}{2}g_{\alpha\beta}R=6\Phi^{-2}(\Phi_\alpha\Phi_\beta-\tfrac{1}{2}g_{\alpha\beta}\Phi^\mu\Phi_\mu). \tag{28}$$

Using (7) and (27), we find that the nonvanishing components of this in mixed form are

$$T^0_0=-T^1_1=-T^2_2=-T^3_3=3\lambda^2B^{-1}. \tag{29}$$

This as expected represents a static source, which we can model as a perfect fluid with

$$T_{\alpha\beta}=(\rho+p)u_\alpha u_\beta-pg_{\alpha\beta}. \tag{30}$$

Here ρ is the density, p is the pressure and the 4-velocity is $u^\alpha=(u^0,0,0,0)$. Combining (29) and (30), we see that the source has

$$\rho=p=3\lambda^2B^{-1}. \tag{31}$$

This is the stiff equation of state in which the speed of sound waves approaches the speed of light, and has been applied in previous studies[14,16,21] to astrophysical situations such as collapsed stars and proto-galactic fluctuations.

B. Two-fluid solution with radiation and heat flow

The second solution we look at is obtained by splitting off the whole of the first part of (26). The 4D metric is then

$$d\tilde{s}^2=\tilde{g}_{\alpha\beta}dx^\alpha dx^\beta=e^{2\lambda t}[Bdt^2-Adr^2-r^2d\Omega^2], \tag{32}$$

and is time dependent. We, therefore, expect that the source necessary to balance Einstein's equations will also be time dependent. It should be noted that this property cannot in general be removed by a coordinate transformation based on Birkhoff's theorem, because the 4D metric (32) will have a source constructed from the 5D geometry that will in general not be vacuum; and because the 4D metric (32) is part of a 5D metric (26) and it is known that Birkhoff's theorem in its standard form breaks down in the transition from 4D to 5D,[24,25] as evidenced by the existence of both static and time-dependent soliton solutions.[24,26] To investigate the time-dependence of (32), let us make the coordinate transformation

$$e^{\lambda t}=1-\lambda\tilde{t}. \tag{33}$$

This brings (32) into the form

$$d\tilde{s}^2=\tilde{g}_{\alpha\beta}d\tilde{x}^{\alpha}d\tilde{x}^{\beta}=Bd\tilde{t}^2-(1-\lambda\tilde{t})^2(Adr^2+r^2d\Omega^2). \tag{34}$$

We can use this with $\phi\equiv\Phi^{-2}=e^{-2\lambda t}=(1-\lambda\tilde{t})^{-2}$ to evaluate the induced matter properties using the standard technique.[7–9] We note that

$$\tilde{R}_{\alpha\beta}=\phi^{-1}\widetilde{\phi_{\alpha;\beta}}, \tag{35}$$

$$\tilde{R}=\phi^{-1}\widetilde{\phi^{\alpha}_{;\alpha}}=0, \tag{36}$$

which can be used to form the induced energy-momentum tensor

$$\tilde{T}_{\alpha\beta}=\tilde{R}_{\alpha\beta}-\tfrac{1}{2}\tilde{g}_{\alpha\beta}\tilde{R}=\phi^{-1}\widetilde{\phi_{\alpha;\beta}}. \tag{37}$$

The nonvanishing components of this in mixed form are

$$\tilde{T}^0_0=6\lambda^2B^{-1}(1-\lambda\tilde{t})^{-2}, \tag{38}$$

$$\tilde{T}^1_1=\tilde{T}^2_2=\tilde{T}^3_3=-2\lambda^2B^{-1}(1-\lambda\tilde{t})^{-2}, \tag{39}$$

$$\tilde{T}^1_0=g_{00}g^{11}\tilde{T}^0_1=\lambda A^{-1}B^{-1}B'(1-\lambda\tilde{t})^{-3}. \tag{40}$$

We see from (38) that the density is inhomogeneous via $B=B(r)$ and is time dependent, as is the pressure by (39) though the latter is isotropic. We also see from (40) that there is an off-diagonal component. The latter can be accommodated by introducing a two-fluid model

$$\tilde{T}_{\alpha\beta}=\tilde{T}^{(1)}_{\alpha\beta}+\tilde{T}^{(2)}_{\alpha\beta}, \tag{41}$$

which as in other work[12,16] we take to be the sum of a perfect fluid and a radial heat flow

$$\tilde{T}^{(1)}_{\alpha\beta}(\tilde{\rho}+\tilde{p})u_{\alpha}u_{\beta}-\tilde{p}\tilde{g}_{\alpha\beta}, \tag{42}$$

$$\tilde{T}^{(2)}_{\alpha\beta}=q_{\alpha}u_{\beta}+u_{\alpha}q_{\beta}. \tag{43}$$

The heat-flux vector and the 4-velocity must obey the orthogonality condition

$$q_{\alpha}u^{\alpha}=0. \tag{44}$$

This we satisfy by taking

$$u^{\alpha}=(u^0,0,0,0), \quad u^0=B^{-1/2}, \tag{45}$$

$$q^{\alpha}=(0,q^{1},0,0), \tag{46}$$

where in (45) we have used the facts that r is a comoving coordinate and that the 4-velocities are normalized via $g_{\alpha\beta}u^{\alpha}u^{\beta}=Bu^{0}u^{0}=1$. Substituting (45) and (46) into (42) and (43) and these into (41) gives the nonvanishing components of the last in mixed form

$$\tilde{T}^{0}_{0}=\tilde{\rho}, \tag{47}$$

$$\tilde{T}^{1}_{1}=\tilde{T}^{2}_{2}=\tilde{T}^{3}_{3}=-\tilde{p}, \tag{48}$$

$$\tilde{T}^{1}_{0}=B^{1/2}q^{1}. \tag{49}$$

Comparing these with (38), (39), and (40) gives us the density, pressure and heat flow in explicit form

$$\tilde{\rho}=3\tilde{p}=6\lambda^{2}B^{-1}(1-\lambda\tilde{t})^{-2}, \tag{50}$$

$$q^{1}=\lambda A^{-1}B^{-3/2}B'(1-\lambda\tilde{t})^{-3}. \tag{51}$$

The equation of state is that of radiation or ultra-relativistic matter, and has been applied in previous studies[16,27] to astrophysical situations such as fermion soliton stars and the early universe.

V. DISCUSSION AND CONCLUSION

We have taken a 5D metric (1) which contains a 4D sub-metric (6) whose 3D part is spherically symmetric. An expansion in the metric coefficient allows us to recover the Schwarzschild case of general relativity in (17) as the zeroth approximation and a close-to-Schwarzschild case in (25) as the first order approximation to a class of spherically symmetric solutions. Any solution of the 5D Kaluza–Klein equations in apparent vacuum can be written as a solution of the 4D Einstein equations with matter. Two solutions have then been shown, with matter properties corresponding to those of a stiff fluid (31), and radiation or ultra relativistic particles with heat flow (50) and (51). These solutions can be applied to astrophysics, but are merely illustrative examples.

In the wider scheme, it is clear that (local) embedding theorems are powerful tools, whether applied to $N<4$ (possibly quantizeable) gravity,[2] 4D Einstein theory,[12] 5D Kaluza–Klein theory,[28] or 10D superstrings, 11D supergravity and M-theory.[3–6] Campbell's theorem ensures that any solution in ND can be embedded in a Ricci-flat solution in $(N+1)D$.[1] The Schwarzschild solution in 4D can of course be embedded in a flat space of $N\geqslant 6$.[29] And any solution in 4D can be embedded in a flat space of $N\geqslant 10$.[30] The implications of embedding theorems are diverse. If the aim is to find new solutions of general relativity, the higher-dimensional field equations are often surprisingly tractable, and the method of reduction to 4D is straightforward.[2] If the aim is to give meaning to higher-dimensional theories, the same method of reduction will inform about physicality in the 4D world. We should recall that field equations like those of Einstein or Kaluza–Klein allow the dimensionality to be freely chosen, which should be done partly with a view to what physics it is desired to describe and partly with a view to what technical constraints are involved. In the latter regard, it is well known that $N<4$ theories run into problems of formulation which are connected with the degenerate nature of lower-dimensional Riemannian spaces. For $N>4$ theories, problems arise with the physics if the spaces are subject to arbitrary technical constraints.[7,31,32] Our opinion, therefore, is that future work should be focused on higher-dimensional, fully covariant theory.

(Received 19 June 2000; accepted for publication 28 June 2001)

In this work we present a new function to represent the approximate solution of a system of three charged particles. This function is based on an extension to two variables of the confluent hypergeometric function ${}_1F_1$ of Kummer and can be obtained using a method similar to that used by Appell and Kampé de Fériet. We analyze the general properties of the function such as integral representations, series expansions, and asymptotic limits. We also show that the proposed functions verify a relation similar to that satisfied by the exponential and trigonometric–hyperbolic ones. A generalization to *n*-dimension is also presented. The mathematical properties of the functions indicate that they are suitable to be included in computation of electronic emission in collision processes. © *2001 American Institute of Physics.* [DOI: 10.1063/1.1396634]

I. INTRODUCTION

Many functions, very common in the solution of wave equations of various kinds, are special cases of the hypergeometric functions (Whittaker and Watson,[1] Sneddon[2]) or its close relative the confluent hypergeometric function. A few examples are the Bessel functions, the Laguerre functions, and the Airy functions. In particular, the solution for one of the most important problems in physics, the two-body Coulomb problem, comes in terms of hypergeometric functions.[3,4] The dynamics of the problem in the different regions of the coordinates space can be analyzed through the different properties of the Kummer functions.[3–5] On the other hand, different approximated solutions for the three-body Coulomb problem are written in terms of hypergeometric functions.[6–9] The approximate solution known as C3 is given by the product of three two-body Coulomb problems and in this way its dynamical properties depend on the Kummer function properties. Recently, the authors and co-workers introduced a new approximate solution for the three-body problem that can be written in terms of the degenerate Appell functions called Φ_2 by Horn.[10,11] The function Φ_2 can be obtained by a confluence process starting from the Appell hypergeometric function F_1 or F_2 (Ref. 12) and in this way is a confluent hypergeometric function in two variables that can be interpreted as the two-variables generalization of the Kummer function.

From the mathematical point of view, Erdélyi performed a detailed study of the Φ_2 hypergeometric function given different integral representations and asymptotic forms.[13] In 1941, Burchnall and Chaundy presented a method to express different hypergeometric functions as expansions in terms of Kummer functions.[14]

Based on the works of Appell and Kampé de Fériet,[10] Erdélyi,[13] and Burchnall and Chaundy,[14] it is possible to perform a carefull study of the dynamical properties of the three-body Coulomb problem modeled by the Φ_2 approach.[9,15] This function fulfills the Redmond asymptotic conditions for Coulomb potentials. The reduction to the two-body Coulomb problem is also verified when each of the charges are switched off. Nevertheless this function does not completely fulfill the Kato cusp's conditions that relate the wave function and its derivatives when one of the coordinates goes to zero.[16] The Φ_2 state is regular at the origin of coordinates, but does not verify these conditions on the derivatives.

In this work we propose a new hyperbolic–hypergeometric function based on physical arguments which retains the mentioned properties and improves the model including the Kato cusp's conditions in both the coordinate and momentum space. The new hyperbolic–hypergeometric function (called Φ_c) gives rise to other three related functions ($\Phi_s, \Phi^{\pm}$). We present a brief statement of the problem in Sec. I. In Sec. II we obtain the Φ_c function and show the relations with the Φ_2 function of two variables. We describe different properties of the new functions, with particular emphasis in the asymptotic behavior of Φ_c. Also we derive different integral representations and series expansions. In Sec. III the functions Φ_s, Φ^+, and Φ^- are obtained from the analysis Φ_c. In Sec. IV the derivatives of the functions Φ_c, Φ_s, Φ^+, and Φ^- and the connection between them and the hyperbolic–trigonometric functions is presented. Finally we outlook further extensions and applications of this set of functions. The appendix outlines the method to generalize these functions to more variables.

II. STATEMENT OF THE PROBLEM

Let us consider a system of three charged particles in the continuum, labeled by $i=1,2,3$. The relative coordinate $\mathbf{r}_i$ represents the distance between the particles j and k. The exact wave function describing the evolution of this system $\Psi(\mathbf{r}_1,\mathbf{r}_2,\mathbf{r}_3)$ is not known in the general case and some physically based approximations are needed. Furthermore, all the approximate states obtained should verify the correct boundary conditions of the Coulomb potential. When all particles are far from each other, the wave function must satisfy the Redmond's conditions.[17] In the case of outgoing waves, we have

$$\Psi(\mathbf{r}_1,\mathbf{r}_2,\mathbf{r}_3)=\prod_{j=1}^{3} \exp(i\alpha_j \ln(k_j r_j-\mathbf{k}_j\cdot\mathbf{r}_j)). \tag{1}$$

On the other hand, the wave function should be regular at the origin of coordinates $\mathbf{r}_j=0$. In 1951, Kato showed that there exists a solution of the Schrödinger equation for a system of charged particles. This equation presents as many singular points as particles involved in the system. These points corresponds to the conditions $|\mathbf{r}_j|=0$, $j=1$, 2 or 3. Besides the solutions $\Psi(\mathbf{r}_1,\mathbf{r}_2,\mathbf{r}_3)$ should be regular in the coordinate space, that is to say,

$$\Psi(r_i=0)=C,$$

where C is a finite number. A second condition related with the momenta of the particles in the singular points can be stated as

$$\left.\frac{\partial\overline{\Psi}(\mathbf{r}_1,\mathbf{r}_2,\mathbf{r}_3)}{\partial r_i}\right]_{r_i=0} = Z_i\Psi(\mathbf{r}_i=0),$$

where $\overline{\Psi}(\mathbf{r}_1,\mathbf{r}_2,\mathbf{r}_3)$ represents the wave function averaged over a small sphere of radius $r\ll 1$ centered at the singular point $|\mathbf{r}_j|=0$:

$$\overline{\Psi}(\mathbf{r}_1,\mathbf{r}_2,\mathbf{r}_3)=\frac{1}{2}\int \Psi(\mathbf{r}_1,\mathbf{r}_2,\mathbf{r}_3)dS\Big]_{r_i\to 0}.$$

There are only a few approximate solutions of the Schrödinger equation for the three-body Coulomb problem. The first proposal relies on a completely separable approximation of the wave equation written in parabolic coordinates. The solution is simply a product of three two-body Coulomb functions for each pair of particles.[4,18]

The Φ_2 approach can be considered as the next step in the approximated solution of the wave equation for a two heavy and one light particles system. In this solution the motion of the heavy partners is described by a two-body function, while the electron–ions interactions are described in a correlated way through the Erdélyi Φ_2 hypergeometric function.[8,13] This function has been successfully included in undistorted and distorted wave treatments of the ion–atom collision process.[4,19] The only drawback of this function is that it does not verify the Kato cusps condition already mentioned. The introduction of the correlation between the motions of the particles implies the generalization of the simple two-body solution given by the Kummer function.

The simplest way to perform this is to include more parameters, giving rise to the ${}_pF_q$ generalized functions. These functions are well documented in the literature.[20] On the other hand, we can generalize the Kummer functions by increasing the number of variables. Starting by the series expansion[21]

$$ {}_1F_1(b,c,x)=\sum_{m=0}^{\infty}\frac{(b)_m}{(c)_m}\frac{x^m}{m!} $$

we can write the product of ${}_1F_1(b,c,x)$ times ${}_1F_1(b',c',y)$ as follows:

$$ {}_1F_1(\beta,\gamma,x){}_1F_1(\beta',\gamma',y)=\sum_{m=0}^{\infty}\sum_{n=0}^{\infty}\frac{(\beta)_m(\beta')_n}{(\gamma)_m(\gamma')_n}\frac{x^m}{m!}\frac{y^n}{n!}, \tag{2} $$

where $(\beta)_m$ is the Pochhammer symbol given by $\beta(\beta+1)\cdots(\beta+m-1)$.

This series does not give us anything new since it is simply the product of two Kummer functions. However, if one or more of the two pairs of products

$$ (\beta)_m(\beta')_n \quad (\gamma)_m(\gamma')_n $$

are replaced by a composed product of the general type

$$ (\gamma)_{m+n} \tag{3} $$

we are lead to some entirely new functions. This procedure has been followed by Appell and Horn to derive the complete set of second order two-variables hypergeometric functions.[11] If we replace (3) in (2) we get the confluent hypergeometric function called Φ_2 by Horn:[11]

$$ \Phi_2(\beta,\beta',\gamma,x,y)=\sum_{m=0}^{\infty}\sum_{n=0}^{\infty}A_{m,n}\frac{x^m}{m!}\frac{y^n}{n!} \tag{4} $$

with

$$ A_{m,n}=\frac{(\beta)_m(\beta')_n}{(\gamma)_{m+n}}. $$

Other confluent hypergeometric function can be obtained using (2) or the product of confluent and Gauss functions and replacing appropriately different pairs of pochhammers.

Burchnall and Chaundy[14] using an operational technic gave a set of 26 expansions of hypergeometric functions, with some of them of confluent type. They showed that the Φ_2 power series (4) can be rewritten as follows in terms of Kummer functions:

$$\Phi_2(\beta,\beta',\gamma,x,y)=\sum_{m=0}^{\infty} A_m(-xy)^m\,{}_1F_1(\beta+m,\gamma+2m,x)\,{}_1F_1(\beta'+m,\gamma+2m,y), \tag{5}$$

where

$$A_m(\beta,\beta',\gamma)=\frac{(\beta)_m(\beta')_m}{m!(\gamma-1+m)_m(\gamma)_{2m}}.$$

This function has been used several times in physical problems. Olsson applied it in nuclear physics.[22] Recently, the author and co-workers made use of the $\Phi_2(\beta,\beta',\gamma,x,y)$ as a partially separable approximated solution for the three-body Coulomb problem (called the Φ_2 model).[8,9] The study of the physical properties of the Φ_2 model has shown that the Kato's cusp conditions are partially satisfied. The condition imposed by Kato over the first order derivative of the wave function means that the coefficient in the power expansion (4) should satisfy the following relation:

$$A_{1n}=\beta' A_{0n}, \quad A_{m1}=\beta A_{m0}$$

which is not satisfied by the Φ_2 function.

To obtain a function with correct Kato conditions, we introduce a new kind of generalization, similar to the one discussed before. Replacing the product of Kummer functions in the series (5) by its generalized form Φ_2 in the following form:

$$(-1)^m\,{}_1F_1[\beta+m,\gamma+2m,x]_1F_1[\beta'+m,\gamma+2m,y]\rightarrow\Phi_2(\beta+m,\beta'+m,\gamma+2m,x,y), \tag{6}$$

where the $(-1)^m$ is included to solve the problem with the Kato condition, we get a new kind of hypergeometric function:

$$\Phi_c(\beta,\beta',\gamma,x,y)=\sum_{m=0}^{\infty} A_m(xy)^m\Phi_2(\beta+m,\beta'+m,\gamma+2m,x,y) \tag{7}$$

which we will call $\Phi_c(\beta,\beta',\gamma,x,y)$. We should note that by the same method we can introduce a complete set of hypergeometric functions starting by the set given by Burchnall and Chaundy.[14]

III. PROPERTIES OF THE Φ_c FUNCTION

Some simple properties of the Φ_c function when the parameters or the variables are zero can be obtained using the reduction properties of the Φ_2 one:

$$\Phi_c(\beta=0)=\Phi_2(0,\beta',\gamma,x,y)={}_1F_1(\beta',\gamma,y),$$

$$\Phi_c(\beta'=0)=\Phi_2(\beta,0,\gamma,x,y)={}_1F_1(\beta,\gamma,y),$$

$$\Phi_c(x=y=0)=\Phi_2(\beta,\beta',\gamma,0,0)=1,$$

$$\Phi_c(x=0)=\Phi_2(\beta,\beta',\gamma,0,y)={}_1F_1(\beta',\gamma,y),$$

$$\Phi_c(y=0)=\Phi_2(\beta,\beta',\gamma,x,0)={}_1F_1(\beta,\gamma,x).$$

Introducing a useful relation satisfied by the Φ_2 function

$$\Phi_2(\beta,\beta',\gamma,x,x)={}_1F_1(\beta+\beta',\gamma,x)$$

we get the following series expansion in the case in which the variables satisfy the condition $x=y$:

$$\Phi_c(x=y)=\sum_{m=0}^{\infty} A_m x^{2m}\,{}_1F_1(\beta+\beta'+2m,\gamma+2m,x).$$

A. Asymptotic expansion

In this section we introduce expressions for the different asymptotic regions. First we analyze the asymptotic form of Φ_c for large values of $|x|$, $|y|$, and $|x-y|$. Then, we present expressions for the situation in which $|y|\to\infty$ and x remains small.

1. Large arguments

To analyze these regions we use the asymptotic form of the function $\Phi_2(\beta,\beta',\gamma,x,y)$ for large arguments, that is to say $|x|$, $|y|$ and $|x-y|\to\infty$. Following Erdélyi,[13] we write the asymptotic form of $\Phi_c(\beta,\beta',\gamma,x,y)$ in terms of Whittaker-type functions $\overline{z_4},\overline{z_5},\overline{z_6}$.

Using the asymptotic expression of the Φ_2 and replacing it in (7) we get

$$\Phi_c(\beta,\beta',\gamma,x,y)=\frac{\Gamma(\gamma)}{\Gamma(\gamma-\beta-\beta')}e^{i\pi(\beta+\beta')}\overline{z_4}+\frac{\Gamma(\gamma)}{\Gamma(\beta)}e^{i\pi(\beta+2\beta'-\gamma)}\overline{z_5}+\frac{\Gamma(\gamma)}{\Gamma(\beta')}e^{i\pi(\beta'-\gamma)}\overline{z_6}, \tag{8}$$

where

$$\overline{z_4}=x^{-\beta}y^{-\beta'}F_4(\beta,\beta',\gamma,x,y),$$

$$\overline{z_5}=(-x)^{\beta+\beta'-\gamma}(y-x)^{-\beta'}e^{x}F_5(\beta,\beta',\gamma,x,y),$$

$$\overline{z_6}=(x-y)^{-\beta}(-y)^{\beta+\beta'-\gamma}e^{y}F_6(\beta,\beta',\gamma,x,y),$$

with

$$F_4(\beta,\beta',\gamma,x,y)=\sum_{m=0}^{\infty}A_m(\gamma)_m\Phi_4\left(\beta+\beta'-\gamma+1,\beta+m,\beta'+M,-\frac{1}{x},-\frac{1}{y}\right),$$

$$F_5(\beta,\beta',\gamma,x,y)=\sum_{m=0}^{\infty}\frac{A_m(\gamma)_m}{(\beta)_m}\left(\frac{xy}{y-x}\right)^m\Phi_4\left(1-\beta-m,\gamma-\beta-\beta',\beta'+m,\frac{1}{x},\frac{1}{x-y}\right),$$

$$F_6(\beta,\beta',\gamma,x,y)=\sum_{m=0}^{\infty}\frac{A_m(\gamma)_m}{(\beta')_m}\left(\frac{xy}{x-y}\right)^m\Phi_4\left(1-\beta'-m,\beta+m,\gamma-\beta-\beta',\frac{1}{y-x},\frac{1}{y}\right),$$

the functions $\overline{z_4},\overline{z_5},\overline{z_6}$ are similar to those ones used by Erdélyi, replacing the functions Φ_i by the generalized F_i with $i=4$, 5 or 6. From the asymptotic limit (8) it can be easily verified that the Φ_c function satisfies the Redmond asymptotic conditions[17] since the leading order for x, $y\to\infty$ is

$$\Phi_c(\beta,\beta',\gamma,x,y)\to x^{-\beta}y^{-\beta'}$$

which is equivalent to (1).

2. Small $x,y\to\infty$

From Eq. (7) and using the asymptotic form of the Φ_2 in the case in which $y\to\infty$ and x^5 remains small

$$\Phi_2(\beta,\beta',\gamma,x,y)=\frac{\Gamma(\gamma)e^{i\pi\beta'}}{\Gamma(\gamma-\beta')}z_7+\frac{\Gamma(\gamma)e^{i\pi(\beta'-\gamma)}}{\Gamma(\beta')}z_6,$$

where

$$z_6=(x-y)^{-\beta}(-y)^{\beta+\beta'-\gamma}e^{y}\Phi_4\left(1-\beta',\beta,\gamma-\beta-\beta',\frac{1}{y-x},\frac{1}{y}\right),$$

$$z_7=y^{-\beta'}\Phi_5\left(\beta,\beta',\gamma-\beta',x,\frac{1}{y}\right).$$

Taking into account Eq. (7) we get

$$\Phi_c(\beta,\beta',\gamma,x,y)=\frac{\Gamma(\gamma)}{\Gamma(\gamma-\beta')}e^{i\pi\beta'}\overline{z_7}+\frac{\Gamma(\gamma)}{\Gamma(\beta')}e^{i\pi(\beta'-\gamma)}\overline{z_6},$$

where

$$\overline{z_7}(\beta,\beta',\gamma,x,y)=y^{-\beta'}G_5(\beta,\beta',\gamma,x,y),$$

with

$$G_5=\sum\frac{(-1)^m(\gamma)_m}{(\gamma-\beta')_m}A_m x^m\Phi_5\left(\beta+m,\beta'+m,\gamma-\beta'+m,x,\frac{1}{y}\right).$$

A similar expression for small $|y|$ and large $|x|$ can be obtained.

B. Integral representation

In this section we analyze two kinds of integral representations based on the two given for the Φ_2 hypergeometric function. This integral representations can be used to obtain analytical transition matrices for a variety of collision processes in atomic physics.

1. Single integral

We start rewriting $\Phi_c(\beta,\beta',\gamma,x,y)$ using the following integral representation for the $\Phi_2(\beta,\beta',\gamma,x,y)$ function:

$$\Phi_2(\beta,\beta',\gamma,x,y)=\frac{\Gamma(\gamma)}{2\pi i}\int e^{s}s^{-\gamma}F_1\left[\gamma,\beta,\beta',\gamma,\frac{x}{s},\frac{y}{s}\right]ds,$$

where

$$F_1\left[\gamma,\beta+m,\beta'+m,\gamma,\frac{x}{s},\frac{y}{s}\right]=\left(1-\frac{x}{s}\right)^{-\beta-m}\left(1-\frac{y}{s}\right)^{-\beta'-m}$$

represent the Appell[10] function for a special case of the parameters. Replacing this expression in (7) we obtain

$$\Phi_c=\frac{\Gamma(\gamma)}{2\pi i}\int ds\,e^{s}s^{-\gamma}\sum_{m=0}^{\infty}(\gamma)_{2m}A_m\left(\frac{x}{s}\right)^m\left(\frac{y}{s}\right)^m F_1\left[\gamma+2m,\beta+m,\beta'+m,\gamma+2m,\frac{x}{s},\frac{y}{s}\right].$$

Defining the new function

$$F_N(\alpha,\beta,\beta',\gamma,x,y)=\sum\ (\alpha)_{2m}A_m x^m y^m F_1(\alpha+2m,\beta+m,\beta'+m,\gamma+2m,x,y)$$

$$=\sum\ (\alpha)_{2m}A_m x^m y^m {}_2F_1(\alpha+2m,\beta+m,\gamma+2m,x)$$

$$\times {}_2F_1(\alpha+2m,\beta'+m,\gamma+2m,y),$$

we can rewrite

$$\Phi_c=\frac{\Gamma(\gamma)}{2\pi i}\int e^s s^{-\gamma} F_N\left(\gamma,\beta,\beta',\gamma,\frac{x}{s},\frac{y}{s}\right)ds.$$

The function ${}_2F_1(a,b,c,x)$ represents the Gauss function,[21] and the function $F_N(\alpha,\beta,\beta',\gamma,x,y)$ can be obtained from

$$F_1(\alpha,\beta,\beta',\gamma,x,y)=\sum\ \frac{(-1)^m(\alpha)_{2m}(\beta)_m(\beta')_m}{m!(\gamma-1+m)_m(\gamma)_{2m}}x^m y^m$$

$$\times F_2(\alpha+2m,\beta+m,\beta'+m,\gamma+2m,\gamma+2m,x,y) \tag{9}$$

by the substitutions

$$F_1(\alpha,\beta,\beta',\gamma,x,y)\to F_N(\alpha,\beta,\beta',\gamma,x,y),$$

$$F_2(\alpha+2m,\beta+m,\beta'+m,\gamma+2m,\gamma+2m,x,y)$$

$$\to(-1)^m F_1(\alpha+2m,\beta+m,\beta'+m,\gamma+2m,\gamma+2m,x,y)$$

on the left-hand and right-hand sides of Eq. (9). The symbol $F_2(\alpha,\beta,\beta',\gamma,\gamma',x,y)$ represents the other four Appell[10] functions.

2. Double integral

Starting from the integral representation of the Φ_2 function

$$\Phi_2=U(\beta,\beta',\gamma)\int_0^1 du\int_0^1 dv\ e^{ux+vy}K(\beta,\beta',\gamma,u,v),$$

where

$$U(\beta,\beta',\gamma)=\frac{\Gamma(\gamma)}{\Gamma(\beta)\Gamma(\beta')\Gamma(\gamma-\beta-\beta')},$$

$$K(\beta,\beta',\gamma,u,v)=u^{\beta-1}v^{\beta'-1}(1-u-v)^{\gamma-\beta-\beta'-1},$$

and replacing it in Φ_c [Eq. (7)], we get

$$\Phi_c=U(\beta,\beta',\gamma)\int_0^1 du\int_0^1 dv\ e^{ux+vy}K(\beta,\beta',\gamma,u,v)\sum\ \frac{1}{m!(\gamma-1+m)_m}(xyuv)^m.$$

The series which appear in the last equation can be added, giving the following result:

$$\sum_{m=0}^{\infty}\frac{(xyuv)^m}{m!(\gamma-1+m)_m}=\begin{cases}\dfrac{1}{\gamma-1}\,{}_1F_2\left(\gamma-1,\dfrac{1}{2}(\gamma-1),\dfrac{\gamma}{2},\dfrac{uvxy}{4}\right), & \gamma\neq 1,2,\\ \cosh(\sqrt{uvxy}), & \gamma=1,2.\end{cases} \tag{10}$$

In case $\gamma=1$ and 2 we can finally write

$$\Phi_c(\beta,\beta',\gamma,x,y)=U(\beta,\beta',\gamma)\int_0^1 du\int_0^1 dv\, e^{ux+vy}\cosh(\sqrt{uvxy})K(\beta,\beta',\gamma,u,v). \tag{11}$$

IV. THE HYPERBOLIC–HYPERGEOMETRIC FUNCTIONS

In this section we study the function (11) obtained in the last section corresponding to $\gamma=1$ and 2. It is possible to verify that the function ${}_1F_2(\gamma-1,\frac{1}{2}(\gamma-1),\gamma/2,uvxy/4)$ can be written in terms of the functions $\cosh(\sqrt{uvxy})$ and $\sinh(\sqrt{uvxy})$. Thus, the function Φ_c given for $\gamma>2$ can be rewritten in terms of the Φ_c function for γ equal to 1 and 2. That is to say, it is possible to obtain continuity relations similar to the ones obtained for the hypergeometric function Φ_2 and use them to write the function Φ_c as a sum of functions corresponding to $\gamma=1$ and 2.

Using the relation between exponential and hyperbolic–trigonometric functions it is possible to rewrite (11) as follows:

$$\Phi_c(\beta,\beta',\gamma,x,y)=\tfrac{1}{2}[\Phi^+(\beta,\beta',\gamma,x,y)+\Phi^-(\beta,\phi',\gamma,x,y)], \tag{12}$$

where

$$\Phi^\pm(\beta,\beta',\gamma,x,y)=U\int_0^1\int_0^1 du\,dv\, e^{ux+vy}e^{\pm\sqrt{uvxy}}K(\beta,\beta',\gamma,u,v). \tag{13}$$

From this equation we can define the function

$$\begin{aligned}\Phi_s(\beta,\beta',\gamma,x,y)&=\tfrac{1}{2}[\Phi^+(\beta,\beta',\gamma,x,y)-\Phi^-(\beta,\beta',\gamma,x,y)]\\&=U\int_0^1\int_0^1 du\,dv\, e^{ux+vy}\sinh(\sqrt{uvxy})K(\beta,\beta',\gamma,u,v)\\&\qquad\text{for}\quad \gamma=1,2\end{aligned} \tag{14}$$

that is similar to the starting point of this work.

The hypergeometric functions $\Phi_s,\Phi_c,\Phi^\pm$ constitute a set similar to the corresponding to the exponential and trigonometric–hyperbolic functions:

$$\Phi^\pm(\beta,\beta',\gamma,x,y)=\Phi_c(\beta,\beta',\gamma,x,y)\pm\Phi_s(\beta,\beta',\gamma,x,y).$$

Using the series expansion for the exponential function in the definitions for Φ^+ and Φ^- we can write

$$\Phi^\pm(\beta,\beta',\gamma,x,y)=U\sum_{m=0}^{\infty}\frac{(\pm1)^m}{m!}(xy)^{m/2}\int_0^1\int_0^1 du\,dv\, e^{ux+vy}(uv)^{m/2}K(\beta,\beta',\gamma,u,v).$$

Using now the relations

$$(uv)^{m/2}K(\beta,\beta',\gamma,u,v)=K\left(\beta+\frac{m}{2},\beta'+\frac{m}{2},\gamma+m,u,v\right)$$

and

$$\int_0^1\int_0^1 du\,dv\;\phi K\left(\beta+\frac{m}{2},\beta'+\frac{m}{2},\gamma+m,u,v\right)$$
$$=U\left(\beta+\frac{m}{2},\beta'+\frac{m}{2},\gamma+m\right)\Phi_2\left(\beta+\frac{m}{2},\beta'+\frac{m}{2},\gamma+m,x,y\right),$$

we get

$$\Phi^{\pm}(\beta,\beta',\gamma,x,y)=\sum_{m=0}^{\infty}(\pm 1)^m\frac{(\beta)_{m/2}(\beta')_{m/2}}{m!(\gamma)_m}(xy)^{m/2}\Phi_2\left(\beta+\frac{m}{2},\beta'+\frac{m}{2},\gamma+m,x,y\right),$$

which are the series expansions for the functions $\Phi^{\pm}(\beta,\beta',\gamma,x,y)$ in terms of the hypergeometric function $\Phi_2(\beta,\beta',\gamma,x,y)$. Furthermore, using the series expansion for the hyperbolic function[21] it is possible to write (14)

$$\Phi_s(\beta,\beta',\gamma,x,y)=\sum_{m=0}^{\infty}\frac{(\beta)_{m+1/2}(\beta')_{m+1/2}}{(2m+1)!(\gamma)_{2m+1}}(xy)^{m+1/2}$$
$$\times\Phi_2\left(\beta+m+\frac{1}{2},\beta'+m+\frac{1}{2},\gamma+2m+1,x,y\right).$$

A. Derivatives of $\Phi^{\pm}$ and $\Phi_{c,s}$ functions

In this section we will write the derivatives of $\Phi^{\pm}$ for the case in which $\gamma=1,2$. Denoting

$$\chi^{\pm}=e^{ux+vy\pm\sqrt{uvxy}},$$

the derivative of the function Φ^{+} is given by

$$\frac{d\Phi^{\pm}}{dx}=U\left[\int_0^1\int_0^1 du\,dv\left(u\pm\frac{uvy}{2\sqrt{uvxy}}\right)\chi^{\pm}K(\beta,\beta',\gamma,u,v)\right]$$

and, using

$$uK(\beta,\beta',\gamma,u,v)=K(\beta+1,\beta',\gamma+1,u,v),$$
$$(uv)^{1/2}K(\beta,\beta',\gamma,u,v)=K(\beta+\tfrac{1}{2},\beta'+\tfrac{1}{2},\gamma+1,u,v),$$

we can write

$$\frac{d\Phi^{\pm}}{dx}=U\int_0^1\int_0^1 du\,dv\;\chi^{\pm}K(\beta+1,\beta',\gamma+1,u,v)$$
$$\pm\frac{1}{2}U\sqrt{\frac{y}{x}}\int_0^1\int_0^1 du\,dv\;\chi^{\pm}K\left(\beta+\frac{1}{2},\beta'+\frac{1}{2},\gamma+1,u,v\right).$$

Then

$$\frac{d\Phi^{\pm}}{dx}=\frac{(\beta)_1}{(\gamma)_1}\Phi^{\pm}(\beta+1,\beta',\gamma+1,x,y)\pm\frac{1}{2}\sqrt{\frac{y}{x}}\frac{(\beta)_{1/2}(\beta')_{1/2}}{(\gamma)_1}\Phi^{\pm}\left(\beta+\frac{1}{2},\beta'+\frac{1}{2},\gamma+1,x,y\right).$$

With these expressions we can write the derivative of $\Phi_c(\beta,\beta',\gamma,x,y)$:

$$\frac{d\Phi_c}{dx}=\frac{1}{2}\frac{(\beta)_1}{(\gamma)_1}\Phi_c(\beta+1,\beta',\gamma+1,x,y)+\frac{1}{4}\sqrt{\frac{y}{x}}\frac{(\beta)_{1/2}(\beta')_{1/2}}{(\gamma)_1}\Phi_s\left(\beta+\frac{1}{2},\beta'+\frac{1}{2},\gamma+1,x,y\right).$$

In a similar way, for the $\Phi_s(\beta,\beta',\gamma,x,y)$ we can get

$$\frac{d\Phi_s}{dx}=\frac{1}{2}\frac{(\beta)_1}{(\gamma)_1}\Phi_s(\beta+1,\beta',\gamma+1,x,y)+\frac{1}{4}\sqrt{\frac{y}{x}}\frac{(\beta)_{1/2}(\beta')_{1/2}}{(\gamma)_1}\Phi_c\left(\beta+\frac{1}{2},\beta'+\frac{1}{2},\gamma+1,x,y\right).$$

We can see through the obtained expressions, that the derivatives of Φ_s and Φ_c satisfy relations which mix the trigonometric and the hypergeometric ones. For example, the derivative of Φ_s is written in terms of the same hypergeometric but with the parameters added in one, and besides depend on the Φ_c. The first term is a typical form for the derivative of a hypergeometric function; the second a typical trigonometric relation.

B. Expansion in terms of Kummer functions

In this section we will introduce a series expansion for the function $\Phi_c(\beta,\beta',\gamma,x,y)$ in terms of the Kummer function. Starting from (7) and using (5) we obtain

$$\Phi_c=\sum_n^\infty\sum_k^\infty(-1)^k A_n(\beta,\beta',\gamma)A_k(\beta+n,\beta'+n,\gamma+2n)$$
$$\times(xy)^{n+k}\,{}_1F_1[\beta+n+k,\gamma+2(n+k),x]\,{}_1F_1[\beta'+n+k,\gamma+2(n+k),y].$$

Now, applying the general relation:[12]

$$\sum_n^\infty\sum_k^\infty C_{k,n}=\sum_n^\infty\sum_k^n C_{k,n-k}$$

to our particular case we get for $\Phi_c(\beta,\beta',\gamma,x,y)$,

$$\Phi_c=\sum_n^\infty B_n(xy)^n\,{}_1F_1[\beta+n,\gamma+2n,x]\,{}_1F_1[\beta'+n,\gamma+2n,y], \tag{15}$$

where

$$B_n=\sum_{k=0}^n(-1)^k A_{n-k}(\beta,\beta',\gamma)A_k(\beta+n-k,\beta'+n-k,\gamma+2(n-k)). \tag{16}$$

The obtained expansion in terms of Kummer functions has some advantages in comparison with the power series one. The convergence is fast and only a few terms are necessary for most of the physical interest. By the other side, the representation (15) allows us to compute transition matrices for ion–atom collision by using the same procedure used in previous works.[15,19] In Fig. 1 we show the calculation of the double differential cross section for the ionization of helium by proton impact. The energy of the incoming proton is 1.5 MeV. We plot the energy of the ionized electrons as a function of its energy and for two different angles of emission. We compare the result obtained by using the continuum correlated wave model based in the Φ_c wave function[19] plotted with full line with the well-known continuum distorted wave–eikonal initial state (CDW)[23] with broken line. We see that some differences around the electron capture to the continuum peak but we are not sure if this effect is due to the inclusion of the Kato cusp conditions or due to the correlation introduced in the wave function. In the autoionization of atoms excited by ion impact

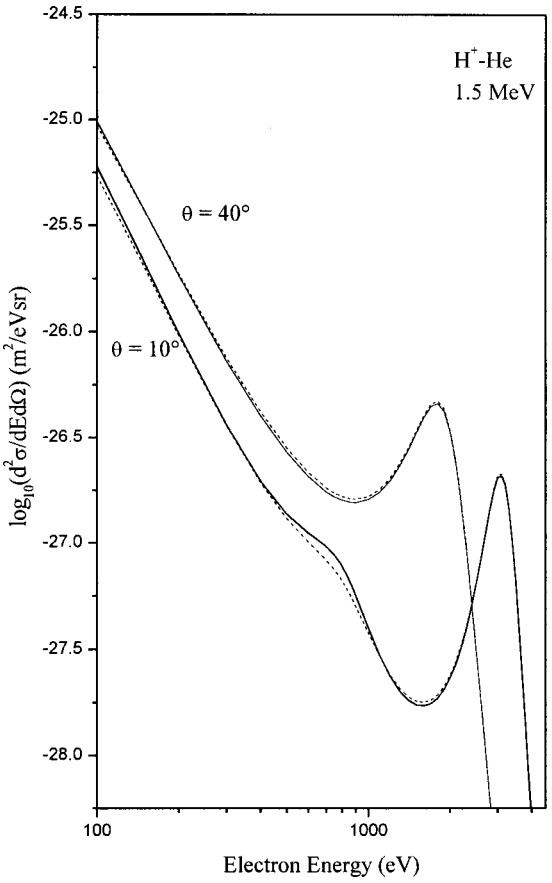

FIG. 1. DDCS for the collision 1.5 MeV $H^+ \rightarrow He$ where angle of the ionized electrons is 10 and 40 degres. Full line, CCWEIS model based in the Φ_c wave function (Ref. 19); broken line, CDWEIS model.

process the Kato cusp conditions are more relevant than in ionization itself, so we are working on that process to perform in future works a comparative analysis between the CDW, the Φ_2 model and the Φ_c one.

V. SUMMARY

In this work we have introduced a new set of functions through a substitution method similar to the used by Appell and Lauricella.[10] The function Φ_c is well founded on physical grounds. The other three Φ_s and $\Phi^{\pm}$, were introduced resulting from the study of the Φ_c one.

We have analyzed different properties like reduction in terms of coefficients and variables. We have introduced different integral representation and series expansion, and the derivatives of all the functions were showed as well as the connection between them.

These functions verify the required physical conditions of a Coulomb many-particle system as can be derived from their mathematical properties. In particular, they fullfil the Kato cusp conditions that were not satisfied by previous generalizations of the Kummer function. Besides of the Redmond asymptotic behavior and the reduction to a two-body Coulomb problem when each of the charges are fixed equal to zero.

We have applied this wave function calculating the double differential cross section for single ionization of He by proton impact. Furthermore, we have contrasted our results with the well-known CDW–EIS theory.

Following a similar method to that given in the present work, it would be possible to generate a complete set of hypergeometric function starting from the list given by Burchnall and Chaundy.[14]

APPENDIX

A possible generalization of the functions Φ_c, Φ_s, Φ^+, and Φ^- to the case of three and more variables can be done using the bounded integral representation. For example, the generalization of the Φ_c to three variables is

$$\phi_c^{(3)} = U^{(3)} \int_0^1 \int_0^1 \int_0^1 du\, dv\, dw\, e^{ux+vy+wz} \cosh(\sqrt{uvwxyz}) K(\beta,\beta',\beta',\gamma,u,v,w),$$

where we define

$$K(\beta_1,\beta_2,\ldots,\beta_n,\gamma,u_1,u_2,\ldots,u_n) = \left(1-\sum_{i=1}^{n} u_i\right)^{\gamma-\Sigma_{i=1}^{n}\beta_i-1} \prod_{i=1}^{n} u_i^{\beta_i-1}$$

and

$$U^{(n)} = \frac{\Gamma(\gamma)}{\Gamma(\gamma-\Sigma_{i=1}^{n}\beta_i)\Pi_{i=1}^{n}\Gamma(\beta_i)}.$$

Using the power series for the cosh (x), we get

$$\Phi_c^{(3)} = U^{(3)} \sum_{m=0}^{\infty} \frac{1}{(2m)!} (xyz)^m \int_0^1 \int_0^1 du\, dv\, e^{ux+vy+wz} K(\beta+m,\beta'+m,\beta'+m,\gamma+3m,u,v,w).$$

Replacing the integral representation of $\Phi_2^{(3)}(\beta,\beta',\beta',\gamma,x,y,z)$:[5]

$$\Phi_2^{(3)}(\beta,\beta',\beta'',\gamma,x,y,z) = U^{(3)} \int_0^1 \int_0^1 du\, dv\, e^{ux+vy+wz} K(\beta,\beta',\beta',\gamma,u,v,w),$$

we obtain the three-dimensional series expansion in terms of $\Phi_2^{(3)}(\beta,\beta',\beta',\gamma,x,y,z)$ for the function $\Phi_c^{(3)}(\beta,\beta',\beta',\gamma,x,y,z)$:

$$\Phi_c^{(3)}(\beta,\beta',\beta'',\gamma,x,y,z) = \sum_{m=0}^{\infty} \frac{(\beta)_m(\beta')_m(\beta')_m}{(2m)!(\gamma)_{3m}} (xyz)^m \times \Phi_2^{(3)}(\beta+m,\beta'+m,\beta'+m,\gamma+3m,x,y,z)$$

or alternatively, using (10) results in

$$\Phi_c^{(3)}(\beta,\beta',\beta'',\gamma,x,y,z) = \sum_{m=0}^{\infty} \frac{(\beta)_m(\beta')_m(\beta'')_m}{m!(\gamma-1+m)_m(\gamma)_{3m}} (xyz)^m \times \Phi_2^{(3)}(\beta+m,\beta'+m,\beta''+m,\gamma+3m,x,y,z)$$

for $\gamma=1,2$. General expressions for arbitrary γ result by the same method using (10).

The three-dimensional integral form Φ_s, Φ^+, and Φ^- are

$$\Phi_s^{(3)}(\beta,\beta',\beta'',\gamma,x,y,z)=U^{(3)}\int_0^1\int_0^1\int_0^1 du\,dv\,dw\,e^{ux+vy+wz}\sinh(\sqrt{uvwxyz})$$
$$\times K(\beta,\beta',\beta'',\gamma,u,v,w),$$

$$\Phi_{(3)}^{\pm}(\beta,\beta',\beta'',\gamma,x,y,z)=U^{(3)}\int_0^1\int_0^1 du\,dv\,e^{ux+vy+wz\pm\sqrt{uvwxyz}}K(\beta,\beta',\beta'',\gamma,u,v,w).$$

On the other hand, the n-dimensional form for $\Phi_c^{(n)}$ is

$$\Phi_c^{(n)}(\beta_1,\beta_2,\ldots,\beta_n,\gamma,x_1,x_2,\ldots,x_n)=U^{(n)}\int_0^1\int_0^1\cdots\int_0^1 du_1\,du_2\cdots du_n\,e^{\sum_{i=1}^n u_i x_i}$$
$$\times\cosh\left(\sqrt{\prod_{i=1}^n u_i x_i}\right)K(\beta_1,\beta_2,\ldots,\beta_n,\gamma,u_1,u_2,\ldots,u_n).$$

Similar expressions can be written for $\Phi_s^{(n)}$, $\Phi_{(n)}^{+}$, and $\Phi_{(n)}^{-}$.

New solutions of the Jacobi equations for three-dimensional Poisson structures

Benito Hernández-Bermejo[a)]
Departamento de Física Matemática y Fluidos, Universidad Nacional de Educación a Distancia. Senda del Rey S/N, 28040 Madrid, Spain

(Received 17 November 2000; accepted for publication 23 July 2001)

A systematic investigation of the skew-symmetric solutions of the three-dimensional Jacobi equations is presented. As a result, three disjoint and complementary new families of solutions are characterized. Such families are very general, thus unifying many different and well-known Poisson structures seemingly unrelated which now appear embraced as particular cases of a more general solution. This unification is not only conceptual but allows the development of algorithms for the explicit determination of important properties such as the symplectic structure, the Casimir invariants and the Darboux canonical form, which are known only for a limited sample of Poisson structures. These common procedures are thus simultaneously valid for all the particular cases which can now be analyzed in a unified and more economic framework, instead of using a case-by-case approach. In addition, the methods developed are valid globally in phase space, thus ameliorating the usual scope of Darboux' reduction which is only of local nature. Finally, the families of solutions found present some new nonlinear superposition principles which are characterized. © *2001 American Institute of Physics.*

I. INTRODUCTION

Poisson structures[1,2] have an important presence in all fields of Mathematical Physics.[1–35] A Poisson description of a given system is often the basis for the obtainment of fruitful insight and information through the use of a plethora of well-known adapted tools.[1,2,7,9,17,34,36–42]

The present work is devoted to finite-dimensional Poisson structures. These, when expressed in terms of a system of local coordinates on an n-dimensional manifold, take the form

$$\dot{x}_i = \sum_{j=1}^{n} J_{ij}\partial_j H, \quad i=1,\ldots,n. \tag{1}$$

Here and in what is to follow ∂_j means $\partial/\partial x_j$. The C^1 and real-valued function $H(x)$ in (1) is a constant of motion of the system, which plays the role of Hamiltonian. The $J_{ij}(x)$, called structure functions, are also C^1 and real-valued and constitute the entries of a $n\times n$ structure matrix $\mathcal{J}$. The $J_{ij}(x)$ have the property of being solutions of the Jacobi equations

$$\sum_{l=1}^{n} (J_{li}\partial_l J_{jk} + J_{lj}\partial_l J_{ki} + J_{lk}\partial_l J_{ij}) = 0. \tag{2}$$

In (2) indices i,j,k run from 1 to n. The structure functions also verify the additional condition of being skew-symmetric

One of the reasons justifying the importance of the Poisson representation is the local equivalence between Poisson systems and classical Hamiltonian systems, as stated by Darboux Theorem.[1]

Theorem 1.1 (Darboux): Consider an n-dimensional Poisson manifold for which the rank of the Poisson structure has constant value $2r$ everywhere. Then at each point of the manifold there exist local coordinates $(p_1,\ldots,p_r,q_1,\ldots,q_r,z_1,\ldots,z_{n-2r})$ in terms of which the equations of motion become

$$\dot{z}_j=0,\quad j=1,\ldots,n-2r.$$

An interesting consequence of Darboux Theorem which will be reconsidered later is that two Poisson structures of the same dimension and rank can be transformed locally into each other by a suitable change of coordinates.[1] Both the Darboux Theorem and the previous remark are important for what follows.

The possibility of describing a given vector field not explicitly written in the form (1) in terms of a Poisson structure is an obvious question of fundamental importance in this context to which important efforts have been devoted in past years in a variety of approaches.[5–17,19,21–28] This explains, together with the intrinsic mathematical interest of the problem, the permanent attention deserved in the literature by the obtainment and classification of skew-symmetric solutions of the Jacobi equations,[3–18,20–24,26,27,29] both in the case of n-dimensional solutions[3,4,13,14,18,20,26,29] as well as in the important and better understood situation of dimension three.[7–12,17,22,23,27] In the three-dimensional case the strategy for finding suitable skew-symmetric solutions of the Jacobi equations makes use of very diverse—often problem-dependent—methods, and the state of affairs is certainly more elaborate than the one existing in general dimension n. Moreover, it is worth recalling that the three-dimensional scenario is particularly relevant for several reasons: First, a large number of three-dimensional systems arising in very diverse fields have a Poisson structure (see Tables I–IV for a sample). Therefore, three-dimensional Poisson structures are the natural framework for their analysis. Second, dimension three corresponds to the first nontrivial case where Poisson structure does not imply symplectic structure, i.e., it is the simplest meaningful kind of Poisson structures which is not symplectic. And third, three is the lowest dimension for which the Jacobi identities are not always identically verified. Since the complexity of equations (2) and (3) is increasing with the dimension n, the three-dimensional case is the simplest nontrivial one as well as a natural first approach to the full problem of analyzing systems (2) and (3).

In this work a systematic investigation of the skew-symmetric solutions of the three-dimensional Jacobi Eqs. (2) and (3) is presented. As we shall see, three disjoint categories of

solutions of the problem appear naturally. For each of them, a new family of solutions is found. Such families are extremely general. This explains that many well-known three-dimensional Poisson structures and dynamical systems now happen to appear embraced as particular cases of a wider family, as we shall see in detail. Therefore, a first outcome is that of the unification of many different Poisson structures seemingly unrelated. Moreover, this unification is not only conceptual. In fact, the new families are amenable to explicit and detailed analysis, in spite of their generality. In particular, it is possible to develop algorithms for the determination of important properties such as the symplectic structure and the Darboux canonical form. The advantage of these common strategies is that they are simultaneously valid for all the particular cases which can now be analyzed in a unified and very economic way, instead of using a case-by-case approach. In addition, the methods developed are valid globally in phase space, thus ameliorating the usual scope of Darboux' theorem which does only guarantee, in principle, a local reduction.[1] The possibility of constructing the Darboux canonical form is also remarkable in view that the practical determination of Darboux' coordinates is a complicated task in general, which has been carried out only for a very limited sample of systems.[2,6,13,14,19] Finally, the families of solutions found have unexpected properties, such as the presence of simple nonlinear superposition principles which will be characterized.

For the sake of conciseness, in what follows we shall use the following notation for the entries of the three-dimensional structure matrix:

$$u(x):=J_{12}(x), \quad v(x):=J_{31}(x), \quad w(x):=J_{23}(x). \tag{4}$$

Now, if in the case $n=3$ we simplify the Jacobi identities (2) with the help of (3) and substitute also definition (4) the joint systems (2) and (3) take the form

$$u\partial_1 v - v\partial_1 u + w\partial_2 u - u\partial_2 w + v\partial_3 w - w\partial_3 v = 0. \tag{5}$$

The three-dimensional version of systems (2) and (3) shall be written in the compact form (5) in the rest of this work.

The structure of the article is as follows. In Secs. II–IV, respectively, three different, disjoint and complementary families of solutions are developed including their derivation and properties as well as examples. To conclude, Sec. V contains some final remarks.

II. FIRST FAMILY OF SOLUTIONS

For the characterization of the first family of solutions, it is convenient to begin with the establishment of an important general property of Eq. (5).

Theorem 2.1: Let $\{u(x),v(x),w(x)\}$ be a set of $C^1(\Omega)$ functions solution of Eq. (5) in an open domain $\Omega\subset\mathbb{R}^3$, and let $\mu(x):\Omega\to\mathbb{R}$ be an arbitrary $C^1(\Omega)$ function. Then $\{u^*(x),v^*(x),w^*(x)\}=\{\mu(x)u(x),\mu(x)v(x),\mu(x)w(x)\}$ is also a solution of Eq. (5).

Proof: It can be verified after direct substitution of $\{\mu(x)u(x),\mu(x)v(x),\mu(x)w(x)\}$ into Eq. (5). Q.E.D.

It is important to stress that this theorem is not valid in general in dimensions higher than three, as it can be easily verified. In order to physically interpret the result contained in Theorem 2.1 it is necessary to first formalize the concept of time reparametrization:[6]

Definition 2.2: Let $\Omega\subset\mathbb{R}^3$ be an open subset. A reparametrization of time is defined as a transformation of the form

$$\mathrm{d}\tau=\frac{1}{\mu(x)}\,\mathrm{d}t, \tag{6}$$

where t is the initial time variable, τ is the new time and $\mu(x):\Omega\to\mathbb{R}$ is a $C^1(\Omega)$ function which does not vanish in Ω.

In addition, let

$$\frac{\mathrm{d}x}{\mathrm{d}t}=\mathcal{J}\cdot\nabla H \tag{7}$$

be an arbitrary three-dimensional Poisson structure defined in an open domain $\Omega\subset\mathbb{R}^3$. Then, every reparametrization of time of the form (6) leads from (7) to the differential system:

$$\frac{\mathrm{d}x}{\mathrm{d}\tau}=\mu\mathcal{J}\cdot\nabla H. \tag{8}$$

Consequently, in the three-dimensional case reparametrizations (6) preserve the existence of a Poisson structure in the system, this time with structure matrix $\mu\mathcal{J}$ in (8). On the contrary, such transformations in general destroy the Poisson structure in higher dimensions because for a given $\mathcal{J}$ which is a structure matrix, $\mu\mathcal{J}$ is not necessarily a solution of (2) and (3).

We proceed now to characterize a first family of solutions of Eq. (5). For this, we shall assume that none of the solution functions $\{u(x),v(x),w(x)\}$ is identically zero (the relaxation of this condition will lead to the other two families of solutions, as we shall see in Sec. III and IV).

Definition 2.3: For every open domain $\Omega\subset\mathbb{R}^3$, we shall denote by $\Gamma_{[u,v,w]}(\Omega)$ the set of solutions of Eq. (5) defined in Ω which are of the form $\{u(x),v(x),w(x)\}$, with $u(x)$, $v(x)$ and $w(x)$ nonvanishing in Ω and $C^1(\Omega)$.

We have the following result:

Theorem 2.4: Consider the family of functions of the form

$$\begin{cases} u(x) &= \eta(x)\psi_1(x_1)\psi_2(x_2)\phi_3(x_3)\\ v(x) &= \eta(x)\psi_1(x_1)\phi_2(x_2)\psi_3(x_3),\\ w(x) &= \eta(x)\phi_1(x_1)\psi_2(x_2)\psi_3(x_3)\end{cases} \tag{9}$$

defined in an open set $\Omega\subset\mathbb{R}^3$, where $\{\eta,\psi_i,\phi_i\}$, $i=1,2,3$, are arbitrary $C^1(\Omega)$ functions of their respective arguments which do not vanish in Ω. Then the family of functions (9) belongs to $\Gamma_{[u,v,w]}(\Omega)$.

Proof: For solutions belonging to $\Gamma_{[u,v,w]}(\Omega)$, we can equivalently write (5) as

$$u^2\partial_1\left(\frac{v}{u}\right)+w^2\partial_2\left(\frac{u}{w}\right)+v^2\partial_3\left(\frac{w}{v}\right)=0. \tag{10}$$

From (10) it is clear that $\{u(x),v(x),w(x)\}$ are solutions if

$$\frac{v}{u}=\alpha(x_2,x_3)\Rightarrow\begin{cases} u &= u_1(x_2,x_3)\psi_1(x)\\ v &= v_1(x_2,x_3)\psi_1(x)\end{cases}, \tag{11}$$

$$\frac{u}{w}=\beta(x_1,x_3)\Rightarrow\begin{cases} u &= u_2(x_1,x_3)\psi_2(x) \\ w &= w_2(x_1,x_3)\psi_2(x) \end{cases}, \tag{12}$$

$$\frac{w}{v}=\gamma(x_1,x_2)\Rightarrow\begin{cases} v &= v_3(x_1,x_2)\psi_3(x) \\ w &= w_3(x_1,x_2)\psi_3(x) \end{cases}. \tag{13}$$

In (11)–(13) the functions $\{\alpha,\beta,\gamma,u_i,v_i,w_i,\psi_j\}$, with $i\in\{1,2,3\}$ and $j=1,2,3$, are $C^1(\Omega)$ and nonvanishing arbitrary functions of their respective arguments. A family of solutions of Eqs. (11)–(13) is found if we assume that $\psi_j(x)\equiv\psi_j(x_j)$ for all $j=1,2,3$. Then, taking also into account Theorem 2.1 and Definition 2.3 we arrive to result (9). Q.E.D.

Corollary 2.5: For every open domain $\Omega\subset\mathbb{R}^3$, solution (9) can be written as

$$J_{ij}(x)=\eta(x)\psi_i(x_i)\psi_j(x_j)\sum_{k=1}^{3}\epsilon_{ijk}\phi_k(x_k), \tag{14}$$

where indexes i,j run from 1 to 3, $\{\eta,\psi_i,\phi_i\}$ are arbitrary $C^1(\Omega)$ functions of their respective arguments which do not vanish in Ω and ϵ is the Levi-Civita symbol.

Definition 2.6: For every open domain $\Omega\subset\mathbb{R}^3$, the subset of $\Gamma_{[u,v,w]}(\Omega)$ composed of those solutions of Eq. (5) characterized by Theorem 2.4 will be denoted $\Delta(\Omega)$.

The family of solutions $\Delta(\Omega)$ is very general, therefore, containing numerous previously known structure matrices of very diverse three-dimensional systems as particular cases, as it can be seen in detail in Table I. Of special relevance are the Lie–Poisson structure matrix associated to the Lie algebra so(3) [for which $\psi_i(x_i)=1$, $\phi_i(x_i)=x_i$ and $\eta=1$] as well as the separable matrices[14] [$\phi_i(x_i)=$constant, $\eta=1$]. It is worth recalling that the time dependence of some of the structure matrices enumerated in Table I is immaterial in this context, since the Jacobi equations are time-independent and therefore time plays the only role of a parameter in the solutions.

As anticipated in Sec. I, the generality of solutions (14) is not an obstacle in what regards the characterization of their main properties. We begin by the symplectic structure and the Casimir invariant.

Proposition 2.7: For every open subset $\Omega\subset\mathbb{R}^3$, the rank of the Poisson structures belonging to $\Delta(\Omega)$ is constant in Ω and equal to 2, and a Casimir function of the family of solutions (14) forming $\Delta(\Omega)$ is

$$C(x)=\sum_{i=1}^{3}\int\frac{\phi_i(x_i)}{\psi_i(x_i)}\mathrm{d}x_i\,. \tag{15}$$

Moreover, the Casimir invariant (15) is globally defined in Ω and $C^2(\Omega)$.

Proof: The rank is constant in Ω and has value 2 as a consequence of the nonvanishing properties of functions $\{\eta,\psi_i,\phi_i\}$. In addition, according to the Pfaffian method,[41] which is the simplest in this case, the Casimir function is found to be the solution of the system

$$\sum_{i=1}^{3}\frac{\phi_i(x_i)}{\psi_i(x_i)}\mathrm{d}x_i=0.$$

The integration is immediate and leads to (15). The remaining properties of the Casimir invariant also arise from those of functions ϕ_i and ψ_i. Q.E.D.

It is interesting to notice that $\eta(x)$ does not affect neither the symplectic structure nor the form of the Casimir invariant. This is to be expected from the fact that it is a common factor of the structure functions.

We proceed now to construct globally the Darboux canonical form.

Theorem 2.8: For every three-dimensional Poisson system

$$\frac{\mathrm{d}x}{\mathrm{d}t}=\mathcal{J}\cdot\nabla H,$$

defined in an open domain $\Omega\subset\mathbb{R}^3$ and such that $\mathcal{J}\in\Delta(\Omega)$, the Darboux canonical form is accomplished globally in Ω in the new coordinate system $\{z_1,z_2,z_3\}$ and the new time τ, where $\{z_1,z_2,z_3\}$ is related to $\{x_1,x_2,x_3\}$ by the diffeomorphism globally defined in Ω

$$z_1(x_1)=\int\frac{\phi_1(x_1)}{\psi_1(x_1)}\mathrm{d}x_1,\quad z_2(x_2)=\int\frac{\phi_2(x_2)}{\psi_2(x_2)}\mathrm{d}x_2,\quad z_3(x)=\sum_{i=1}^{3}\int\frac{\phi_i(x_i)}{\psi_i(x_i)}\mathrm{d}x_i,$$

and the new time τ is given by the time reparametrization of the form (6)

$$\mathrm{d}\tau=\eta(x(z))\phi_1(x_1(z))\phi_2(x_2(z))\phi_3(x_3(z))\mathrm{d}t.$$

Proof: We begin by noticing that the Darboux theorem is applicable to family (14) because its members have constant rank 2 everywhere in Ω, as seen in Proposition 2.7. This is a key necessary condition[2] which is verified in the case of $\Delta(\Omega)$. Recall also that, after a general diffeomorphism $y=y(x)$, a given structure matrix $\mathcal{J}(x)$ is transformed into another one $\mathcal{J}'(y)$ according to the tensor rule

$$J'_{ij}(y)=\sum_{k,l=1}^{n}\frac{\partial y_i}{\partial x_k}J_{kl}(x)\frac{\partial y_j}{\partial x_l}. \tag{16}$$

The reduction can be carried out in three steps:

(i) Step 1: We perform a first change of variables, which is globally diffeomorphic in Ω

$$y_i(x_i)=\int\frac{\phi_i(x_i)}{\psi_i(x_i)}\mathrm{d}x_i,\quad i=1,2,3.$$

According to (16) we arrive to:

$$\mathcal{J}'(y)=\tilde{\eta}(y)\begin{pmatrix}0&1&-1\\-1&0&1\\1&-1&0\end{pmatrix}, \tag{17}$$

where $\tilde{\eta}(y)=\eta(x(y))\phi_1(x_1(y_1))\phi_2(x_2(y_2))\phi_3(x_3(y_3))$;

(ii) Step 2: we can make use of the Casimir $C=y_1+y_2+y_3$ of $\mathcal{J}'$ in (17) and perform a second change of variables globally diffeomorphic in $\mathbb{R}^3\supset\Omega'=y(\Omega)$:

$$z_1=y_1,\quad z_2=y_2,\quad z_3=y_1+y_2+y_3.$$

The new structure matrix can be found by means of (16)

$$\mathcal{J}''(z)=\hat{\eta}(z)\begin{pmatrix}0&1&0\\-1&0&0\\0&0&0\end{pmatrix},$$

where $\hat{\eta}(z)=\tilde{\eta}(y(z))$;

(iii) Step 3: Finally, we can make a reparametrization of time of the form (6), namely $\mathrm{d}\tau=\hat{\eta}(z)\mathrm{d}t$, where τ is the new time and $\hat{\eta}(z)$ is easily seen to be nonvanishing in $\Omega''=z(y(\Omega))$ and $C^1(\Omega'')$. The result is, according to Theorem 2.1 and (7) and (8), a new Poisson system with matrix

$$\mathcal{J}_D(z)=\begin{pmatrix}0&1&0\\-1&0&0\\0&0&0\end{pmatrix}, \tag{18}$$

and time τ. Consequently, the structure matrix $\mathcal{J}_D$ in (18) is already the one corresponding to the Darboux canonical form. The reduction is thus globally completed. Q.E.D.

According to the remarks made in the Introduction in connection with Darboux Theorem, it is worth noting an interesting corollary of Theorem 2.8, namely that all the diverse structures shown in Table I can actually be seen[1] as the global representation of the same basic Poisson structure (namely the Darboux one) in different systems of coordinates. This is obviously a consequence of the tensor transformation rule (16). However, in the case of Theorem 2.8 this equivalence is demonstrated globally in Ω, thus exceeding the usual scope of Darboux theorem. Notice also how this is founded on the fact that the rank of the structure matrix remains constant in Ω, which is ensured by the nonvanishing conditions verified by the solutions. Consideration of a possible variability in the value of the rank would lead to additional geometric issues[1] not regarded in this work for the sake of conciseness.

We conclude the exposition of the properties of the family of solutions (14) with a brief discussion of its associated nonlinear superposition principles. We have the starting result:

Proposition 2.9: For every open domain $\Omega\subset\mathbb{R}^3$, let $\{u,v,w\}$ and $\{u^*,v^*,w^*\}$ be two elements of $\Delta(\Omega)$. Then the set $\Delta(\Omega)$ has the structure of abelian group with respect to the operation of inner sum $\oplus$ given by

$$\oplus: \qquad \Delta(\Omega)\times\Delta(\Omega)\to\Delta(\Omega)$$

$$(\{u,v,w\},\{u^*,v^*,w^*\})\to\{u,v,w\}\oplus\{u^*,v^*,w^*\}=\{uu^*,vv^*,ww^*\}. \tag{19}$$

Proof: It is a consequence of the factorized form of the solutions (14). Q.E.D.

In what follows it will become evident why in this context the natural definition for operation (19) is that of a sum. For this, we need a previous definition:

Definition 2.10: For every open domain $\Omega\subset\mathbb{R}^3$, the subset of $\Delta(\Omega)$ composed of solutions $\{u,v,w\}$ such that $u(x)>0$, $v(x)>0$ and $w(x)>0$ for all $x\in\Omega$ will be denoted $\Delta^+(\Omega)$.

Notice that due to the nonvanishing character of the solutions forming $\Delta(\Omega)$, the definition of $\Delta^+(\Omega)$ is not very restrictive. In fact, most examples of Table I belong to $\Delta^+(\Omega)$ or do have admissible ranges of the system parameters or variables for which the Poisson structure is in $\Delta^+(\Omega)$. It is now possible to establish the following:

Theorem 2.11: For every open domain $\Omega\subset\mathbb{R}^3$, let $\{u,v,w\}$ and $\{u^*,v^*,w^*\}$ be two elements of $\Delta^+(\Omega)$ and let a be a real number. Then the set $\Delta^+(\Omega)$ has the structure of real vector space with respect to the two operations of inner sum $\oplus$ given by

$$\oplus: \qquad \Delta^+(\Omega)\times\Delta^+(\Omega)\to\Delta^+(\Omega)$$

$$(\{u,v,w\},\{u^*,v^*,w^*\})\to\{u,v,w\}\oplus\{u^*,v^*,w^*\}=\{uu^*,vv^*,ww^*\}$$

and product $\otimes$ by scalars

$$\otimes: \qquad \mathbb{R}\times\Delta^+(\Omega)\to\Delta^+(\Omega)$$

$$(a,\{u,v,w\})\to a\otimes\{u,v,w\}=\{u^a,v^a,w^a\}.$$

Proof: It is an extension of the proof of Proposition 2.9. Q.E.D.

Notice the interest of the fact that the results of the operations $\oplus$ and $\otimes$ belong to $\Delta^+(\Omega)$: According to Definition 2.10 this means that the results of those operations are also solutions—of the same kind $\Delta^+(\Omega)$—of Eq. (5). It is also remarkable that the nonlinear superposition principle just described has such a general linear algebraic structure. This is certainly infrequent in the domain of nonlinear PDEs.

The description of the first family of solutions is thus completed. We now proceed to examine a second, complementary case.

III. SECOND FAMILY OF SOLUTIONS

The second family of solutions arises when we consider the case in which one of the solution functions $\{u,v,w\}$ is identically zero, while the remaining two are not.

Definition 3.1: For every open domain $\Omega\subset\mathbb{R}^3$, we shall denote by $\Gamma_{[v,w]}(\Omega)$, $\Gamma_{[u,w]}(\Omega)$ and $\Gamma_{[u,v]}(\Omega)$ the sets of solutions $\{u,v,w\}$ of Eq. (5) defined in Ω which are of the forms $\{0,v(x),w(x)\}$, $\{u(x),0,w(x)\}$ and $\{u(x),v(x),0\}$, respectively, where $u(x)$, $v(x)$, and $w(x)$ are, when present, $C^1(\Omega)$ and nonvanishing in Ω.

Theorem 3.2: For every open subset $\Omega\subset\mathbb{R}^3$, the general solutions of Eq. (5) corresponding to $\Gamma_{[v,w]}(\Omega)$, $\Gamma_{[u,w]}(\Omega)$ and $\Gamma_{[u,v]}(\Omega)$ are, respectively,

$$\Gamma_{[v,w]}(\Omega)\Rightarrow\{u=0,v=\eta(x),w=\eta(x)\xi(x_1,x_2)\}, \tag{20}$$

$$\Gamma_{[u,w]}(\Omega)\Rightarrow\{v=0,w=\eta(x),u=\eta(x)\zeta(x_1,x_3)\}, \tag{21}$$

$$\Gamma_{[u,v]}(\Omega)\Rightarrow\{w=0,u=\eta(x),v=\eta(x)\chi(x_2,x_3)\}, \tag{22}$$

where functions $\{\eta,\xi,\zeta,\chi\}$ appearing in (20)–(22) are arbitrary, $C^1(\Omega)$ with regard to their respective arguments and nonvanishing in Ω.

Proof: It is immediate from Eq. (5). Q.E.D.

Accordingly, for example in the case $u=0$ we have found structure matrices of the form

$$\mathcal{J}=\eta(x)\begin{pmatrix}0 & 0 & -1\\ 0 & 0 & \xi(x_1,x_2)\\ 1 & -\xi(x_1,x_2) & 0\end{pmatrix}, \tag{23}$$

where η and ξ are $C^1(\Omega)$ and nonvanishing in Ω. As it can be seen, the overall factor considered in Theorem 2.1 already appears explicitly in (23) and needs not be added *a posteriori*.

Again, numerous well-known systems from diverse fields have Poisson structures which are particular cases of (20), (21), or (22), as it is displayed in Table II for $\Gamma_{[v,w]}(\Omega)$, in Table III for $\Gamma_{[u,w]}(\Omega)$ and in Table IV for $\Gamma_{[u,v]}(\Omega)$.

Following the same scheme than in the previous section, we now proceed to develop the main properties of the solutions just found. For the sake of conciseness this shall be done only for the case $\Gamma_{[v,w]}(\Omega)$, given that all the corresponding algorithms and results are entirely analogous for $\Gamma_{[u,w]}(\Omega)$ and $\Gamma_{[u,v]}(\Omega)$.

We shall begin with the symplectic structure and Casimir invariants. Again, the Pfaffian method[41] seems to be the simplest one in order to characterize these properties. From (23) the Pfaffian system to be solved is easily seen to be $\xi(x_1,x_2)\mathrm{d}x_1+\mathrm{d}x_2=0$. Clearly, this system cannot be solved without some additional information because it is very generic. In order to circumvent this difficulty, it is worth introducing a definition:

Definition 3.3: Let $\Omega\subset\mathbb{R}^2$ be an open domain and let $\xi:\Omega\rightarrow\mathbb{R}$ be a $C^1(\Omega)$ function which does not vanish in Ω. We shall say that $\xi(x_1,x_2)$ is separable in Ω if it can be written in the form

$$\xi(x_1,x_2)=\frac{\xi_1(x_1)}{\xi_2(x_2)}, \tag{24}$$

for all $(x_1,x_2)\in\Omega$, where $\xi_1(x_1)$ and $\xi_2(x_2)$ are $C^1(\Omega)$ and do not vanish in Ω.

Now note that all specific systems found in practice (see Table II) verify the property that $\xi(x_1,x_2)$ is separable [notice that the only exception is the last item of Table II, but this is not a specific system but a generic situation which does not correspond to any particular vector field, and therefore it does not affect the generality of (24)]. An analogous property is verified for all entries of Tables III and IV. Consequently, it seems well justified to conclude that, typically, ξ will be separable in the form indicated in Definition 3.3.

Proposition 3.4: For every open domain $\Omega\subset\mathbb{R}^3$, if a solution of the form (20) belonging to $\Gamma_{[v,w]}(\Omega)$ has a $\xi(x_1,x_2)$ which is separable in Ω according to (24), then the rank of such Poisson structure is constant in Ω and has value 2, and a Casimir function of the structure is

$$C(x_1,x_2)=\int \xi_1(x_1)\mathrm{d}x_1+\int \xi_2(x_2)\mathrm{d}x_2. \tag{25}$$

In addition, the Casimir invariant (25) is globally defined in Ω and $C^2(\Omega)$.

Proof: The rank is constant and of value 2 in Ω due to the nonvanishing properties of η, ξ_1 and ξ_2. Additionally, taking (24) into account the Pfaffian system to be solved[41] becomes $\xi_1(x_1)\mathrm{d}x_1+\xi_2(x_2)\mathrm{d}x_2=0$. This leads to the Casimir function immediately. The remaining properties of the Casimir invariant are a consequence of those of ξ_1 and ξ_2. Q.E.D.

The Darboux canonical form can also be computed under similar assumptions:

Theorem 3.5: For every three-dimensional Poisson system

$$\frac{\mathrm{d}x}{\mathrm{d}t}=\mathcal{J}\cdot\nabla H,$$

defined in an open subset $\Omega\subset\mathbb{R}^3$ and such that $\mathcal{J}\in\Gamma_{[v,w]}(\Omega)$ is given by (20) and $\xi(x_1,x_2)$ in (20) is separable in Ω according to (24), the Darboux canonical form is accomplished globally in Ω in the new coordinate system $\{y_1,y_2,y_3\}$ and the new time τ, where $\{y_1,y_2,y_3\}$ is related to $\{x_1,x_2,x_3\}$ by the diffeomorphism globally defined in Ω

$$y_1=\int \xi_1(x_1)\mathrm{d}x_1+\int \xi_2(x_2)\mathrm{d}x_2,\quad y_2=x_2,\quad y_3=x_3, \tag{26}$$

and the new time τ is given by the time reparametrization of the form (6)

$$\mathrm{d}\tau=\eta(x(y))\frac{\xi_1(x_1(y))}{\xi_2(y_2)}\mathrm{d}t.$$

Proof: Notice first that the Darboux theorem is applicable in this case[2] because solutions of $\Gamma_{[v,w]}(\Omega)$ of the forms (23) and (24) have constant rank 2 everywhere in Ω, as anticipated in Proposition 3.4. The reduction can be carried out in two steps:

(i) Step 1: The change of variables (26), which is globally diffeomorphic in Ω, is introduced. Notice that (26) is not the only possibility but it would be similar, for instance, to choose $\{y_1=x_1,y_2=C(x_1,x_2),y_3=x_3\}$. From (16), (23), (24), and (26) we are led to:

$$\mathcal{J}'(y)=\tilde{\eta}(y)\begin{pmatrix}0&0&0\\0&0&1\\0&-1&0\end{pmatrix},$$

where $\tilde{\eta}(y)=\eta(x(y))\xi(x(y))=\eta(x(y))\xi_1(x_1(y))/\xi_2(y_2)$.

(ii) Step 2: A reparametrization of time of the kind (6), i.e., $\mathrm{d}\tau=\tilde{\eta}(y)\mathrm{d}t$, where τ is the new time and $\tilde{\eta}(y)$ is clearly nonvanishing in $\Omega'=y(\Omega)$ and $C^1(\Omega')$. The resulting structure matrix is

$$\mathcal{J}_D(y)=\begin{pmatrix}0&0&0\\0&0&1\\0&-1&0\end{pmatrix}. \tag{27}$$

Since $\mathcal{J}_D$ in (27) corresponds to the Darboux canonical form, the reduction has been accomplished globally. Q.E.D.

To complete this section, we now consider the issue of nonlinear superposition principles. We have the following first result:

Proposition 3.6: For every open domain $\Omega\subset\mathbb{R}^3$, let $\{0,v,w\}$ and $\{0,v^*,w^*\}$ be two elements of $\Gamma_{[v,w]}(\Omega)$. Then the set $\Gamma_{[v,w]}(\Omega)$ has the structure of Abelian group with respect to the operation of inner sum $\oplus$ given by

$$\oplus: \quad \Gamma_{[v,w]}(\Omega)\times\Gamma_{[v,w]}(\Omega)\to\Gamma_{[v,w]}(\Omega)$$

$$(\{0,v,w\},\{0,v^*,w^*\})\to\{0,v,w\}\oplus\{0,v^*,w^*\}=\{0,vv^*,ww^*\}.$$

Proof: It is similar to that of Proposition 2.9. Q.E.D.

The corresponding results for $\Gamma_{[u,w]}(\Omega)$ and $\Gamma_{[u,v]}(\Omega)$ are completely analogous. An additional definition is required at this stage:

Definition 3.7: For every open domain $\Omega\subset\mathbb{R}^3$, the subset of $\Gamma_{[v,w]}(\Omega)$ composed of solutions $\{0,v,w\}$ such that $v(x)>0$ and $w(x)>0$ for all $x\in\Omega$ will be denoted $\Gamma^+_{[v,w]}(\Omega)$.

Of course, Definition 3.7 can be extended straightforwardly to characterize the sets $\Gamma^+_{[u,w]}(\Omega)$ and $\Gamma^+_{[u,v]}(\Omega)$. This is omitted for the sake of brevity, as usual. As it was done in the previous section, it is worth noting that the nonvanishing character of the functions constituting $\Gamma_{[v,w]}(\Omega)$, $\Gamma_{[u,w]}(\Omega)$, and $\Gamma_{[u,v]}(\Omega)$ implies that the definitions of $\Gamma^+_{[v,w]}(\Omega)$, $\Gamma^+_{[u,w]}(\Omega)$, and $\Gamma^+_{[u,v]}(\Omega)$ are not very restrictive in practice, as it can be verified in the examples lists provided in Tables II–IV, respectively. It is now possible to establish the main result:

Theorem 3.8: For every open domain $\Omega\subset\mathbb{R}^3$, let $\{0,v,w\}$ and $\{0,v^*,w^*\}$ be two elements of $\Gamma^+_{[v,w]}(\Omega)$ and let a be a real number. Then the set $\Gamma^+_{[v,w]}(\Omega)$ has the structure of real vector space with respect to the two operations of inner sum $\oplus$ given by

$$\oplus: \quad \Gamma^+_{[v,w]}(\Omega)\times\Gamma^+_{[v,w]}(\Omega)\to\Gamma^+_{[v,w]}(\Omega)$$

$$(\{0,v,w\},\{0,v^*,w^*\})\to\{0,v,w\}\oplus\{0,v^*,w^*\}=\{0,vv^*,ww^*\},$$

and product $\otimes$ by scalars

$$\otimes: \quad \mathbb{R}\times\Gamma^+_{[v,w]}(\Omega)\to\Gamma^+_{[v,w]}(\Omega)(a,\{0,v,w\})$$

$$\to a\otimes\{0,v,w\}=\{0,v^a,w^a\}.$$

Proof: It is formally analogous to that of Theorem 2.11. Q.E.D.

Notice that statements similar to Theorem 3.8 can be developed in parallel for $\Gamma^+_{[u,w]}(\Omega)$ and $\Gamma^+_{[u,v]}(\Omega)$. Such results are obviously in correspondence with those established in Theorem 2.11 of Sec. II for the nonlinear superposition principles in $\Delta^+(\Omega)$. Most observations made there are translatable into the present context in a straightforward way and are therefore disregarded.

Our analysis of the solutions of (5) can now be completed. This is the aim of the next section.

IV. THIRD FAMILY OF SOLUTIONS

Following the previous considerations, the last possibility is to look for solutions of (5) such that two of the three functions $\{u,v,w\}$ are identically zero, while the remaining one is not.

Definition 4.1: The sets of solutions $\{u,v,w\}$ of Eq. (5) defined in an open domain $\Omega\subset\mathbb{R}^3$ which are of the forms $\{u(x),0,0\}$, $\{0,v(x),0\}$ and $\{0,0,w(x)\}$, where $u(x)$, $v(x)$ and $w(x)$ are $C^1(\Omega)$ and nonvanishing in Ω, will be denoted $\Gamma_{[u]}(\Omega)$, $\Gamma_{[v]}(\Omega)$, and $\Gamma_{[w]}(\Omega)$, respectively.

Since all the results which are going to be examined are completely analogous for $\Gamma_{[u]}(\Omega)$, $\Gamma_{[v]}(\Omega)$ and $\Gamma_{[w]}(\Omega)$, we shall concentrate without lack of generality on the analysis of $\Gamma_{[w]}(\Omega)$.

Theorem 4.2: For every open domain $\Omega\subset\mathbb{R}^3$, the general solution of Eq. (5) corresponding to $\Gamma_{[w]}(\Omega)$ consists of the sets of functions of the form $\{u=0,v=0,w(x)\}$, where $w(x)$ is an arbitrary function belonging to $C^1(\Omega)$ and nonvanishing in Ω. Analogous results hold for $\Gamma_{[u]}(\Omega)$ and $\Gamma_{[v]}(\Omega)$.

Proof: It is immediate from Eq. (5). Q.E.D.

Accordingly, for example in the case of $\Gamma_{[w]}(\Omega)$ we have arrived to solutions of the form

$$\mathcal{J}(x)=\eta(x)\begin{pmatrix}0 & 0 & 0\\ 0 & 0 & 1\\ 0 & -1 & 0\end{pmatrix}, \tag{28}$$

with $\eta(x)$ a function $C^1(\Omega)$ and nonvanishing in Ω. Notice that the multiplication by a global factor considered in Theorem 2.1 needs not be taken into account here, since it is already explicit in (28). Note also that solutions described by Theorem 4.2 correspond to structure matrices which are just time reparametrizations of the Darboux canonical form. Consequently, this kind of solutions is very simple and is only considered here for the sake of completeness: The analysis of properties such as the Casimir invariants, the Darboux canonical form or the existence of superposition principles becomes a straightforward version of those considered in Secs. II and III, and can, therefore, be omitted. In spite of such simplicity, examples of Poisson structures belonging to $\Gamma_{[u]}(\Omega)$, $\Gamma_{[v]}(\Omega)$, or $\Gamma_{[w]}(\Omega)$ are not uncommon in the literature.[7] In addition, it is worth mentioning that there is an important category of particular cases of (28) which are present in diverse systems, namely the structure matrices associated to the Lie algebra so(3) when expressed in certain noncartesian coordinates. The simplest possibility is probably that of spherical coordinates:[2]

$$\mathcal{J}_{\mathrm{so}(3)}(\rho,\theta,\varphi)=-\frac{1}{\rho\sin\varphi}\begin{pmatrix}0 & 0 & 0\\ 0 & 0 & 1\\ 0 & -1 & 0\end{pmatrix}.$$

Additional instances of (28) arising from the Lie algebra so(3) for other choices of the coordinate system are also of customary use.[19]

V. FINAL REMARKS

Some new families of skew-symmetric solutions of the three-dimensional Jacobi equations have been presented. They have been developed according to a systematic plan consisting in examining solutions of Eq. (5) such that (i) none of the functions $\{u,v,w\}$ is identically zero (Sec. II); (ii) one of them is identically zero (Sec. III); (iii) two of them are identically zero (Sec. IV). This structuration of the solutions naturally embraces all nontrivial possibilities. The three resulting families have some remarkable properties already anticipated:

(i) They generalize many already known Poisson structures from well-known systems, which now become particular cases. Therefore the new solutions unify in a common framework those structures, which seemed to be unrelated. Several lists of such systems are provided in Tables I–IV;

(ii) This unification allows the development of simultaneous methods of analysis valid for every particular system, thus avoiding a case-by-case strategy. Specifically, it has been shown how to construct explicitly the Casimir invariant and the Darboux canonical form. This is interesting, as far as the determination of the Darboux coordinates is a nontrivial task only known for a limited sample of systems. Moreover, in this work such coordinates have been charazerized globally in phase space, therefore beyond the usual scope of Darboux' theorem, which only ensures a local reduction;

(iii) This unifying approach has uncovered the existence of nonlinear superposition principles within the families of solutions of (5). Such principles obey well defined linear algebraic structures, which is a uncommon property in the framework of nonlinear PDEs.

These results seem to indicate that the direct search of solutions of the Jacobi equations is a sensible line of research not only from a purely theoretical or a classification perspective, but also from the point of view of the analysis of Poisson structures, as well as mathematically interesting as an example of nonlinear system of PDEs. Of course, the three-dimensional scenario is probably

the simplest nontrivial representative case in all those senses, but it is worth recalling that a similar strategy has already produced some novel results in the most general n-dimensional situation.[14] Therefore, it seems justified to conclude that this philosophy will be a source of further advances in the understanding of finite-dimensional Poisson structures.

(Received 15 September 2000; accepted for publication 16 April 2001)

Two restricted $C[q,q^{-1}]$-forms of the well known q-boson algebra are introduced and the corresponding restricted q-Fock spaces defined. All of the irreducible highest weight representations, including the infinite dimensional ones, of $U_\epsilon^{\mathrm{res}}(sl_2)$ of type 1 are constructed through the restricted q-Fock spaces. © *2001 American Institute of Physics.* [DOI: 10.1063/1.1389089]

I. INTRODUCTION AND NOTATIONS

In this article we take q and q^{-1} to be two indeterminates. We denote by $C(q)$ the field of rational functions of the indeterminate q and denote by $C[q,q^{-1}]$ the ring of Laurent polynomials in the indeterminates q and q^{-1}. As usual, the integer and non-negative integer sets are denoted by Z and Z^+, respectively, while the positive integer set, or the natural number set, is denoted by N. For $n\in Z, m\in N$ we use the following notations

$$[n]_q=\frac{q^n-q^{-n}}{q-q^{-1}},\quad [m]_q!=[m]_q[m-1]_q\cdots[1]_q,$$

$$\begin{bmatrix} n \\ m \end{bmatrix}_q=\frac{[n]_q[n-1]_q\cdots[n-m+1]_q}{[m]_q!}.$$

For an integer m that is not in N, we adopt the convention

$$\begin{bmatrix} n \\ m \end{bmatrix}_q=0.$$

For $\epsilon\in C$, $\left[\begin{smallmatrix} n \\ m \end{smallmatrix}\right]_\epsilon$ denotes the complex number obtained from $\left[\begin{smallmatrix} n \\ m \end{smallmatrix}\right]_q$ by substituting $q=\epsilon$ into the expression, as the symbol suggests.

Let U_q be an associative algebra over $C(q)$. Naively, it is natural to think of U_q as a family of algebras depending on a "parameter" q. Mathematically, this can be made precise as follows. If $\epsilon\in C$ is transcendental, one can specialize the indeterminate q to ϵ by defining $U_\epsilon=U_q\otimes_{C(q)}C$, via the algebra homomorphism $C(q)\to C$ that takes q to ϵ. When ϵ is algebraic the above homomorphism from $C(q)$ to C is not available and this direct specialization of U_q might not make sense. Nevertheless, one can proceed by first constructing a $C[q,q^{-1}]$-form, or integral form, of U_q, namely, a $C[q,q^{-1}]$-subalgebra $\tilde{U}_q$ of U_q such that $U_q=\tilde{U}_q\otimes_{C[q,q^{-1}]}C(q)$. Then one defines the specialization U_ϵ of U_q as $\tilde{U}_q\otimes_{C[q,q^{-1}]}C$, via the algebra homomorphism $C[q,q^{-1}]\to C$ that takes q to ϵ.

The quantum algebra $U_q(g)$ associated to a Kac–Moody algebra g is an associative algebra over $C(q)$. When ϵ is not a root of unity the representation theory of $U_\epsilon(g)$ has been well

a)Electronic mail: liuxf@pku.edu.cn

established.[1] To deal with the case where ϵ is a root of unity two $C[q,q^{-1}]$-forms of $U_q(g)$, namely, the "nonrestricted" form and the "restricted" form, have been introduced. In the "nonrestricted" form, one takes $\tilde{U}_q(g)$ to be the $C[q,q^{-1}]$-subalgebra of $U_q(g)$ generated by the Chevalley generators e_i, f_i and some other elements of $U_q(g)$. In this case, the finite dimensional representations of $U_\epsilon(g)$ have been studied by De Concini, Kac and Procesi, when g is finite dimensional, and by Beck and Kac, when g is untwisted affine.[2,3] The restricted $C[q,q^{-1}]$-form $U_q^{\mathrm{res}}(g)$ of $U_q(g)$ is introduced by Lusztig.[4] The study of representation theory of $U_\epsilon^{\mathrm{res}}(g)$ is pioneered also by Lusztig and developed by Chari and Pressley.[5–7]

The q-boson realization method has been widely used to construct representations of quantum algebras in both the generic case and the root of unity case.[8–16] Especially, cyclic q-boson algebra has been introduced to obtain the so called cyclic representations of $U_\epsilon(g)$ associated with the nonrestricted $C[q,q^{-1}]$-form of $U_q(g)$.[15,16] In this article, we will introduce two restricted $C[q,q^{-1}]$-forms of the well known q-boson algebra and define the restricted q-Fock spaces correspondingly. Then we will construct all irreducible highest weight representations of $U_\epsilon(sl_2)$ of type 1 on the restricted q-Fock spaces.

II. SOME BASIC FACTS ABOUT $U_\epsilon^{\mathrm{res}}(sl_2)$

Let us recall some definitions and basic facts. For details we refer readers to Ref. 1. Throughout this article we use the notation $\mathcal{A}=C[q,q^{-1}]$.

Definition 2.1: The quantum algebra $U_q(sl_2)$ is the associative algebra over $C(q)$ with generators e, f, K and K^{-1} and the following relations:

$$KK^{-1}=K^{-1}K=1,$$

$$KeK^{-1}=q^2e, \quad KfK^{-1}=q^{-2}f,$$

$$[e,f]=\frac{K-K^{-1}}{q-q^{-1}}.$$

Definition 2.2: The algebra $U_{\mathcal{A}}^{\mathrm{res}}(sl_2)$ is the $\mathcal{A}$-subalgebra of $U_q(sl_2)$ generated by the elements $e^{(r)}$, $f^{(r)}$, $K^{\pm 1}$ $(r\in N)$ for $r\geqslant 1$, where $e^{(r)}=e^r/[r]_q!$ and $f^{(r)}=f^r/[r]_q!$.

From now on we assume that ϵ is a primitive pth root of unity, where p is odd and greater than 1. When necessary, C is considered as $\mathcal{A}$-module via the the algebra homomorphism $\mathcal{A}\to C$ that takes q to ϵ. By definition, the restricted specialization of $U_q(sl_2)$ is

$$U_\epsilon^{\mathrm{res}}(sl_2)=U_{\mathcal{A}}^{\mathrm{res}}(sl_2)\otimes_{\mathcal{A}}C.$$

For simplicity, $e^{(r)}\otimes_{\mathcal{A}}1, f^{(r)}\otimes_{\mathcal{A}}1$ and $K^{\pm 1}\otimes_{\mathcal{A}}1$ will be identified with $e^{(r)}, f^{(r)}$ and $K^{\pm 1}$, respectively.

If V is a representation of $U_\epsilon^{\mathrm{res}}(sl_2)$ on which K is diagonalizable and $K^{\pm p}=1$, it is said to be of type 1.

Definition 2.3: Let m be an integer. The weight space V_m of a $U_\epsilon^{\mathrm{res}}(sl_2)$-module V of type 1 is defined by

$$V_m=\left\{v\in V \middle| Kv=\epsilon^m v, \quad \begin{bmatrix} K;0 \\ p \end{bmatrix}_q v=\begin{bmatrix} m \\ p \end{bmatrix}_\epsilon v\right\},$$

where

$$\begin{bmatrix} K;0 \\ p \end{bmatrix}_q=\prod_{s=1}^{p}\frac{Kq^{1-s}-K^{-1}q^{s-1}}{q^s-q^{-s}}$$

belongs to $U_{\mathcal{A}}^{\mathrm{res}}(sl_2)$ and is identified with $\left[\begin{smallmatrix} K;0 \\ p \end{smallmatrix}\right]_q\otimes_{\mathcal{A}}1$.

For any integer n, write $n=n_0+pn_1$, where n_0 and n_1 are integers and $0\leqslant n_0<p$. It is readily verified that

$$\begin{bmatrix} n \\ p \end{bmatrix}_\epsilon = n_1 .$$

Then by definition, $v\in V_m$ is a weight vector of weight m and we have

$$Kv=\epsilon^{m_0}v, \quad \begin{bmatrix} K;0 \\ p \end{bmatrix}_q v=m_1 v .$$

A $U_\epsilon^{\mathrm{res}}(sl_2)$-module V is called a highest module of type 1 if it is generated by a weight vector $v\in V_\lambda$ with $\lambda\in Z$ such that $ev=e^{(p)}v=0$. It follows by the usual argument that such a V has a unique irreducible quotient module.[1]

Denote by $V_\epsilon^{\mathrm{res}}(\lambda)$ the irreducible highest weight $U_\epsilon^{\mathrm{res}}(sl_2)$-module of type 1 and of highest weight λ. Then by the Verma module construction one can prove the following proposition.[1]

Proposition 2.1: $V_\epsilon^{\mathrm{res}}(\lambda)$ is isomorphic to $V_\epsilon^{\mathrm{res}}(\mu)$ if and only if $\lambda=\mu$.

III. RESTRICTED *q*-FOCK SPACES

The q-boson algebra $B_q(n)$ of rank n is the associative algebra over $C(q)$ generated by the elements a_i, a_i^+, $K_i^{\pm 1}$,1 $(i=1,2,\ldots,n)$ with the following relations:

$$a_i a_i^+ - q^2 a_i^+ a_i = 1, \quad [a_i, a_j^+]=0 \ (i\neq j),$$

$$[a_i, a_j]=[a_i^+, a_j^+]=0,$$

$$K_i a_j^+ K_i^{-1}=q^{\delta_{ij}}a_j^+, \quad K_i a_j K_i^{-1}=q^{-\delta_{ij}}a_j,$$

$$K_i K_i^{-1}=K_i^{-1}K_i=1,$$

where 1 is the unit.

We introduce the notations

$$a_i^{(n)}=\frac{a_i^n}{[n]_q!}, \quad a_i^{+(n)}=\frac{a_i^{+n}}{[n]_q!}$$

and the following definition.

Definition 3.1: The type 1 restricted q-boson algebra $B_q^{\mathrm{res1}}(2)$ of rank 2 is the $\mathcal{A}$-subalgebra of $B_q(2)$ generated by the elements a_i, $a_i^{+(r)}$, $K_i^{\pm 1}$,1 $(i=1,2; r\in N)$. The type 2 restricted q-boson algebra $B_q^{\mathrm{res2}}(2)$ of rank 2 is the $\mathcal{A}$-subalgebra of $B_q(2)$ generated by the elements a_1, $a_1^{+(r)}$, $a_2^{(r)}$, a_2^+, $K_1^{\pm 1}$, $K_2^{\pm 1}$,1 $(r\in N)$.

By induction one can prove the following three lemmas without difficulty.

Lemma 3.1:

$$\begin{bmatrix} r \\ k \end{bmatrix}_q = q^{-k}\begin{bmatrix} r-1 \\ k \end{bmatrix}_q + q^{r-k}\begin{bmatrix} r-1 \\ k-1 \end{bmatrix}_q \text{ for } r\geqslant k\geqslant 0.$$

Lemma 3.2:

$$\begin{bmatrix} r \\ k \end{bmatrix}_q \in C[q,q^{-1}] \text{ for } r\geqslant k\geqslant 0.$$

Lemma 3.3:

$$a_i^n a_i^{+(m)} = \sum_{s=0}^{m} q^{n(s+m)} q^{(s-m)(s+m+1)/2} \begin{bmatrix} n \\ m-s \end{bmatrix}_q a^{+(s)} a^{n-m+s},$$

$$a_i^{(n)} a_i^{+m} = \sum_{s=0}^{m} q^{n(s+m)} q^{(s-m)(s+m+1)/2} \begin{bmatrix} m \\ s \end{bmatrix}_q a^{+s} a^{(n-m+s)}.$$

Proposition 3.1: $\{a_1^{+(r_1)} a_2^{+(r_2)} a_1^{s_1} a_2^{s_2} K_1^{t_1} K_2^{t_2} | r_i, s_i \in Z^+, t_i \in Z; i=1,2\}$ is an $\mathcal{A}$-basis of $B_q^{\mathrm{res}1}(2)$; $\{a_1^{+(r_1)} a_2^{+r_2} a_1^{s_1} a_2^{(s_2)} K_1^{t_1} K_2^{t_2} | r_i, s_i \in Z^+, t_i \in Z; i=1,2\}$ is an $\mathcal{A}$-basis of $B_q^{\mathrm{res}2}(2)$.

Proof: It follows directly from Lemmas 3.2 and 3.3.

Corollary: $B_q^{\mathrm{res}1}(2)$ and $B_q^{\mathrm{res}2}(2)$ are two integral forms of $B_q(2)$.

Consider $B_q^{\mathrm{res}1}(2)$ as a $B_q^{\mathrm{res}1}(2)$-module as well as $C[q,q^{-1}]$-algebra. Let I be the left ideal of $B_q^{\mathrm{res}1}(2)$ generated by the elements

$$K_1 - 1, \quad K_2 - 1, \quad a_1, a_2.$$

Obviously, I is a $B_q^{\mathrm{res}1}(2)$-submodule. Let $\mathcal{F}_{\mathcal{A}}^1(2)$ denote the quotient module $B_q^{\mathrm{res}1}(2)/I$. It follows from Proposition 3.1 that $\mathcal{F}_{\mathcal{A}}^1(2)$ is a free $\mathcal{A}$-module and

$$\mathcal{F}_{\mathcal{A}}^1(2) = \mathrm{span}_{\mathcal{A}}\{a_1^{+(r_1)} a_2^{+(r_2)}|0\rangle | a_1|0\rangle = a_2|0\rangle = 0, \quad K_1|0\rangle = K_2|0\rangle = |0\rangle; r_1, r_2 \in Z^+\},$$

where $\{a_1^{+(r_1)} a_2^{+(r_2)}|0\rangle | r_1, r_2 \in Z^+\}$ is a basis of $\mathcal{F}_{\mathcal{A}}^1(2)$. $\mathcal{F}_{\mathcal{A}}^1(2)$ is called an $\mathcal{A}$-Fock module associated with $B_q^{\mathrm{res}1}(2)$. The $\mathcal{A}$-Fock module $\mathcal{F}_{\mathcal{A}}^2(2)$ associated with $B_q^{\mathrm{res}2}(2)$ can be defined in a similar way:

$$\mathcal{F}_{\mathcal{A}}^2(2) = \mathrm{span}_{\mathcal{A}}\{a_1^{+(r_1)} a_2^{+r_2}|0\rangle | a_1^r|0\rangle = a_2^{(r)}|0\rangle = 0, \quad r \in N; K_1|0\rangle = K_2|0\rangle = |0\rangle; r_1, r_2 \in Z^+\}.$$

It is easy to see that $\mathcal{F}_{\mathcal{A}}^1(2) \otimes_{\mathcal{A}} C(q) = \mathcal{F}_{\mathcal{A}}^2(2) \otimes_{\mathcal{A}} C(q) \triangleq \mathcal{F}_q(2)$ is the ordinary q-Fock space associated with $B_q(2)$. It is a vector space over the field $C(q)$. If we regard $\mathcal{F}_q(2)$ as an $\mathcal{A}$-module, then by identifying $\mathcal{F}_{\mathcal{A}}^1(2)$ with $\mathcal{F}_{\mathcal{A}}^1(2) \otimes_{\mathcal{A}} 1$, $\mathcal{F}_{\mathcal{A}}^1(2)$ becomes a submodule of $\mathcal{F}_q(2)$, and $\mathcal{F}_{\mathcal{A}}^2(2)$ likewise becomes a submodule of $\mathcal{F}_q(2)$. For convenience, in the subsequent discussion we will use the following notations:

$$f(r_1, r_2) = a_1^{+(r_1)} a_2^{+(r_2)}|0\rangle,$$

$$g(r_1, r_2) = a_1^{+(r_1)} a_2^{+r_2}|0\rangle.$$

We define

$$\mathcal{F}_{\epsilon}^1(2) = \mathcal{F}_{\mathcal{A}}^1(2) \otimes_{\mathcal{A}} C,$$

$$\mathcal{F}_{\epsilon}^2(2) = \mathcal{F}_{\mathcal{A}}^2(2) \otimes_{\mathcal{A}} C,$$

and identify $f(r_1, r_2) \otimes_{\mathcal{A}} 1$ and $g(r_1, r_2) \otimes_{\mathcal{A}} 1$ with $f(r_1, r_2)$ and $g(r_1, r_2)$, respectively. $\mathcal{F}_{\epsilon}^1(2)$ and $\mathcal{F}_{\epsilon}^2(2)$ will be referred to as restricted q-Fock spaces. In the following sections, we will construct irreducible representations of $U_{\epsilon}^{\mathrm{res}}(sl_2)$ on the restricted q-Fock spaces.

IV. FINITE DIMENSIONAL REPRESENTATIONS OF $U_{\epsilon}^{\mathrm{res}}(sl_2)$ VIA RESTRICTED q-FOCK SPACE

We recall that $U_q(sl_2)$ has the following realization on $\mathcal{F}_q(2)$:[8]

$$e = K_2^{-1} a_1^+ a_2, \quad f = K_1^{-1} a_1 a_2^+,$$

$$K=K_1K_2^{-1},\quad K^{-1}=K_1^{-1}K_2.$$

Remark: The above realization looks different from that presented in Ref. 8. This is because the generators of the q-boson algebra adopted in this article are slightly different from those in Ref. 8.

By the natural action $\mathcal{F}_q(2)$ becomes a $U_q(sl_2)$-module through this realization. Then naturally it becomes a $U_{\mathcal{A}}^{\mathrm{res}}(sl_2)$-module through the realization

$$e^{(r)}=q^{-r(r-1)/2}K_2^{-r}a_1^{+(r)}a_2^r,\quad f^{(r)}=q^{-r(r-1)/2}K_1^{-r}a_2^{+(r)}a_1^r.$$

It turns out that $\mathcal{F}_{\mathcal{A}}^1(2)$ is a $U_{\mathcal{A}}^{\mathrm{res}}(sl_2)$-submodule. In fact, the action of $U_{\mathcal{A}}^{\mathrm{res}}(sl_2)$ on $\mathcal{F}_{\mathcal{A}}^1(2)$ reads as follows:

$$Kf(r_1,r_2)=q^{r_1-r_2}f(r_1,r_2),\quad K^{-1}f(r_1,r_2)=q^{r_2-r_1}f(r_1,r_2),$$

$$e^{(r)}f(r_1,r_2)=\begin{bmatrix} r+r_1 \\ r \end{bmatrix}_q f(r_1+r,r_2-r),$$

$$f^{(r)}f(r_1,r_2)=\begin{bmatrix} r+r_2 \\ r \end{bmatrix}_q f(r_1-r,r_2+r).$$

Here we have used Lemma 3.3 and the formula

$$a_i^{+(m)}a_i^{+(n)}=\begin{bmatrix} m+n \\ m \end{bmatrix}_q a_i^{+(m+n)}\ \text{ for }\ i=1,2;\quad m,n\in N.$$

Thus it follows that $U_{\mathcal{A}}^{\mathrm{res}}(sl_2)\mathcal{F}_{\mathcal{A}}^1(2)\subset\mathcal{F}_{\mathcal{A}}^1(2)$. This proves the claim.

Clearly, $\mathcal{F}_\epsilon^1(2)$ is a $U_{\mathcal{A}}^{\mathrm{res}}(sl_2)$-module. It then follows that it is also a $U_\epsilon^{\mathrm{res}}(sl_2)$-module. Here the action of $U_\epsilon^{\mathrm{res}}(sl_2)$ on $\mathcal{F}_\epsilon^1(2)$ is induced from that of $U_{\mathcal{A}}^{\mathrm{res}}(sl_2)$ by identifying q with ϵ. Explicitly, we have

$$Kf(r_1,r_2)=\epsilon^{r_1-r_2}f(r_1,r_2),\quad K^{-1}f(r_1,r_2)=\epsilon^{r_2-r_1}f(r_1,r_2),$$

$$e^{(r)}f(r_1,r_2)=\begin{bmatrix} r+r_1 \\ r \end{bmatrix}_\epsilon f(r_1+r,r_2-r),$$

$$f^{(r)}f(r_1,r_2)=\begin{bmatrix} r+r_2 \\ r \end{bmatrix}_\epsilon f(r_1-r,r_2+r).$$

We observe that for $m\in N$ the subspace

$$V_m\triangleq\mathrm{span}_C\{f(r_1,r_2)\,|\,r_1+r_2=m\}$$

of $\mathcal{F}_\epsilon^1(2)$ is a $U_\epsilon^{\mathrm{res}}(sl_2)$-submodule. Define $v_i^{(m)}=f(m-i,i)$ for $i=0,1,\ldots,m$. Then $\{v_0^{(m)},\ldots,v_m^{(m)}\}$ is a basis of V_m.

The action of $U_\epsilon^{\mathrm{res}}(sl_2)$ on V_m is given by

$$Kv_r^{(m)}=\epsilon^{m-2r}v_r^{(m)},\quad K^{-1}v_r^{(m)}=\epsilon^{2r-m}v_r^{(m)},$$

$$ev_r^{(m)}=[m-r+1]_\epsilon v_{r-1}^{(m)},\quad fv_r^{(m)}=[r+1]_\epsilon v_{r+1}^{(m)},$$

$$e^{(p)}v_r^{(m)}=((m-r)_1+1)v_{r-p}^{(m)},\quad f^{(p)}v_r^{(m)}=(r_1+1)v_{r+p}^{(m)}.$$

Here $v_i^{(m)}$ is understood as the zero vector if $i<0$ or $i>m$. We notice that V_m is none other than the so called Weyl module $W_\epsilon^{\mathrm{res}}(m)$ with maximal weight m. Consequently, we have the following result.

Proposition 4.1: V_m is irreducible if and only if either $m<p$ or $m_0=p-1$. If V_m is reducible, it is not completely reducible.

A sketch of the proof of this proposition can be found in Ref. 1. The main point is the observation that

$$V' \triangleq \mathrm{span}_C\{v_r^{(m)} | m_0<r_0<p,\ \ r_1<m_1\}$$

is the unique proper $U_\epsilon^{\mathrm{res}}(sl_2)$-submodule of V_m.

Remark: It is an established fact that every finite dimensional irreducible $U_\epsilon^{\mathrm{res}}(sl_2)$-module of type 1 is a quotient module of Weyl module. As we have realized the Weyl module $W_\epsilon^{\mathrm{res}}(m)$ for an arbitrary $m \in N$ via the q-Fock space, we have actually presented q-Fock space construction for all finite dimensional irreducible representations of type 1 of $U_\epsilon^{\mathrm{res}}(sl_2)$.

V. INFINITE DIMENSIONAL REPRESENTATIONS OF $U_\epsilon^{\mathrm{res}}(sl_2)$ VIA RESTRICTED q-FOCK SPACE

In this section let us turn to consider q-Fock space construction for some infinite dimensional irreducible representations of $U_\epsilon^{\mathrm{res}}(sl_2)$. To this end, we need to use another q-boson realization of $U_q(sl_2)$. Our starting point is the following well-known q-boson realization of $U_q(sl_2)$ on $\mathcal{F}_q(2)$:[13]

$$K=q^{-1}K_1^{-1}K_2^{-1}, \quad K^{-1}=qK_1K_2,$$

$$e=K_1^{-1}K_2^{-1}a_1a_2, \quad f=-a_1^+a_2^+.$$

By definition $\mathcal{F}_q(2)$ is a $U_q(sl_2)$-module, and thus a $U_{\mathcal{A}}^{\mathrm{res}}(sl_2)$-module, the action on $\mathcal{F}_q(2)$ being the natural one. We have

$$e^{(r)}=q^{-r(r-1)}K_1^{-r}K_2^{-r}a_1^r a_2^{(r)}, \quad f^{(r)}=(-1)^r a_1^{+(r)}a_2^{+r}.$$

Then it follows from Lemma 3.3 that

$$e^{(r)}g(r_1,r_2)=\begin{bmatrix} r_2 \\ r_2-r \end{bmatrix}_q g(r_1-r,r_2-r),$$

$$f^{(r)}g(r_1,r_2)=(-1)^r\begin{bmatrix} r+r_1 \\ r \end{bmatrix}_q g(r_1+r,r_2+r),$$

namely, $U_{\mathcal{A}}^{\mathrm{res}}(sl_2)\mathcal{F}_{\mathcal{A}}^2(2)\subset\mathcal{F}_{\mathcal{A}}^2(2)$. Consequently, $\mathcal{F}_{\mathcal{A}}^2(2)$, and hence $\mathcal{F}_\epsilon^2(2)$, is a $U_{\mathcal{A}}^{\mathrm{res}}(sl_2)$-module. Finally, $\mathcal{F}_\epsilon^2(2)$ becomes a $U_\epsilon^{\mathrm{res}}(sl_2)$-module in the obvious way. Explicitly, the action of $U_\epsilon^{\mathrm{res}}(sl_2)$ on $\mathcal{F}_\epsilon^2(2)$ is as follows:

$$Kg(r_1,r_2)=\epsilon^{-(r_1+r_2+1)}g(r_1,r_2), \quad K^{-1}g(r_1,r_2)=\epsilon^{(r_1+r_2+1)}g(r_1,r_2),$$

$$e^{(r)}g(r_1,r_2)=\begin{bmatrix} r_2 \\ r_2-r \end{bmatrix}_\epsilon g(r_1-r,r_2-r),$$

$$f^{(r)}g(r_1,r_2)=(-1)^r\begin{bmatrix} r+r_1 \\ r \end{bmatrix}_\epsilon g(r_1+r,r_2+r).$$

On $\mathcal{F}_\epsilon^2(2)$, we have

$$\begin{bmatrix} K;0 \\ p \end{bmatrix}_q = \prod_{s=1}^{p} \frac{Kq^{1-s}-K^{-1}q^{s-1}}{q^s-q^{-s}} = \prod_{s=1}^{p} \frac{K_1^{-1}K_2^{-1}q^{-s}-K_1K_2q^s}{q^s-q^{-s}}.$$

Thus

$$\begin{bmatrix} K;0 \\ p \end{bmatrix}_q g(r_1,r_2) = \begin{bmatrix} -r_1-r_2-1 \\ p \end{bmatrix}_\epsilon g(r_1,r_2) = -(r_1+r_2+1)_1 g(r_1,r_2)$$

Hence, $g(r_1,r_2)$ is a weight vector of the weight $-(r_1+r_2+1)$ and $\mathcal{F}_\epsilon^2(2)$ is a $U_\epsilon^{\rm res}(sl_2)$-module of type 1.

For an arbitrary integer s, define

$$V^s = \mathrm{span}_C\{g(r_1,r_1+s)|r_1 \in Z^+\}.$$

We observe that V^s is a $U_\epsilon^{\rm res}(sl_2)$-submodule and there is the following decomposition:

$$\mathcal{F}_\epsilon^2(2) = \sum_{s\in Z} \oplus V^s.$$

For s that satisfies $s_0=0$, namely, $s=\pm rp (r\in Z^+)$, we have the following result.

Proposition 5.1: For $r\in Z^+$, $V^{\pm rp}$ is isomorphic to $V_\epsilon^{\rm res}(-(rp+1))$.

Proof: We only need to consider the case of V^{rp}. The other case is similar. We first show that V^{rp} is an infinite dimensional irreducible $U_\epsilon^{\rm res}(sl_2)$-module. For $m\in Z^+$ define $g(m)=g(m,m+rp)$. Then $\{g(m)|m\in Z^+\}$ is a basis of V^{rp}. We have

$$eg(m) = [m]_\epsilon g(m-1), \quad fg(m) = -[m+1]_q g(m+1)$$

and

$$e^{(p)}g(np) = ng((n-1)p), \quad f^{(p)}g(np-1) = (n-1)g((n+1)p-1)$$

for $n\in N$. Using these relations, one can easily show that as a $U_\epsilon^{\rm res}(sl_2)$-module V^{rp} can be generated by an arbitrary vector in it. The irreducibility is thus proved.

As shown above, $g(0)$ is a weight vector of the weight $-(1+rp)$. It is easy to see that it is actually a highest weight vector. On the other hand, it is clear that V^{rp} is a highest weight module: $V^{rp}= U_\epsilon^{\rm res}(sl_2)g(0)$. The claim then follows from the irreducibility of V^{rp}.

Now let us study V^s with $s_0\neq 0$. When $s>0$, define $v_m=g(m,m+s)$ and the subspace V' of V^s:

$$V' = \mathrm{span}_C\{v_m|p>m_0\geqslant p-s_0\}.$$

When $s<0$, we use W^s to denote V^s for convenience. Then

$$W^s = \mathrm{span}_C\{g(r_1+|s|,r_1)|r_1\in Z^+\}.$$

We define $w_m=g(m+|s|,m)$ and the subspace W' of W^s:

$$W' = \mathrm{span}_C\{w_m|0\leqslant m_0<p-s_0\}.$$

It is not difficult to see that V' and W' are proper submodules of V^s and W^s, respectively.

Proposition 5.2: V' is isomorphic to $V_\epsilon^{\rm res}(\lambda)$ with $\lambda=-(p-s_0+(s_1+1)p+1)$.

Proof: By the explicit action of $U_\epsilon^{\rm res}(sl_2)$ on $\mathcal{F}_\epsilon^2(2)$, it is not difficult to see that V' is irreducible and $V'=U_\epsilon^{\rm res}(sl_2)v_{p-s_0}$. Since v_{p-s_0} is the highest weight vector of V' of the weight $-(p-s_0+(s_1+1)p+1)$, the proposition then follows.

Proposition 5.3: V' is the unique maximal proper $U_\epsilon^{\rm res}(sl_2)$-submodule of V^s with $s>0$ and $s_0\neq 0$.

Proof: Let V'' be an arbitrary proper $U_\epsilon^{\rm res}(sl_2)$-submodule of V^s. To prove the proposition, we only need to show that it is included in V'. We observe that V'' has the vector space decomposition

$$V''=\sum_{\lambda\in\Lambda_s}\oplus(V_\lambda^s\cap V''),$$

where Λ_s stands for the weight set of V^s. Suppose v is a vector in V''. Define

$$\Lambda_s'=\{\lambda\in\Lambda_s|\lambda_0\geqslant p-s_0\},$$

$$\Lambda_s''=\{\lambda\in\Lambda_s|\lambda_0<p-s_0\}.$$

Then we can write $v=v_1+v_2$ where

$$v_1\in\sum_{\lambda\in\Lambda_s''}\oplus V_\lambda^s,\quad v_2\in\sum_{\lambda\in\Lambda_s'}\oplus V_\lambda^s\in V'.$$

Now due to the above vector space decomposition of V'', we have $v_1\in V''$. On the other hand, if v_1 is a nonzero vector, it is not difficult to show that $U_\epsilon^{\rm res}(sl_2)v_1=V^s$. Consequently, $v_1=0$ as V'' is a proper $U_\epsilon^{\rm res}(sl_2)$-submodule by assumption. This means $v=v_2\in V'$, namely, $V''\subset V'$. The proposition is thus proved.

Corollary: For V^s with $s>0$ and $s_0\neq 0$, V^s/V' is isomorphic to $V_\epsilon^{\rm res}(-(s+1))$.

Proof: Since V' is a maximal proper submodule, V^s/V' is irreducible. Moreover, V^s/V' is a highest module with the highest vector $\overline{v_0}\triangleq v_0+V'=g(0,s)+V'$ of the weight $-(s+1)$. The corollary thus follows.

Remark: Obviously, the above studied $U_\epsilon^{\rm res}(sl_2)$-modules V^{np}, V' and V^s/V' are all infinite dimensional. We notice that they are isomorphic to the modules $V_\epsilon^{\rm res}(\lambda)$ with λ negative. This should be the case. Actually, if λ is a positive integer $V_\epsilon^{\rm res}(\lambda)$ must be finite dimensional.

In the same way, we can prove the following result.

Proposition 5.4: W' is isomorphic to $V_\epsilon^{\rm res}(-(|s|+1))$; W^s/W' is isomorphic to $V_\epsilon^{\rm res}(\lambda)$ with $\lambda=-(p-|s|_0+(1+|s|_1)p+1)$.

From Proposition 5.1, the corollary to Proposition 5.3 and the remark at the end of Sec. IV we come to the conclusion that we have constructed all the representations $V_\epsilon^{\rm res}(\lambda)$ of $U_\epsilon^{\rm res}(sl_2)$ with $\lambda\in Z$ via the restricted q-Fock spaces. According to Proposition 2.1 they have exhausted all the irreducible highest representations of $U_\epsilon^{\rm res}(sl_2)$ of type 1. Obviously, the method presented in this article can readily be generalized to be applicable to the case of $U_\epsilon^{\rm res}(sl_n)$.

It might be interesting to probe the unitarity of the representations presented in this article. For this problem we wish to make the following comment. First, in the case of quantum algebras, the problem of unitarity of representations is not so important as in the case of Lie groups. One can clearly see this point from the literature of quantum algebras. Second, whether a representation is a unitary one depends not only on the inner product on the side of the representation space, but also on the so-called*-structure on the side of the quantum algebra. Besides, in our article, most of the irreducible representations that we present are defined on the quotient spaces of the restricted Fock spaces. Hence, it might be too simplistic to think that the question of unitarity can be addressed by simply asking whether $a^\dagger$ is the true adjoint of a.

Chains of extended Jordanian twists are studied for the universal enveloping algebras U(so(M)). The carrier subalgebra of a canonical chain $\mathcal{F}_{\mathcal{B}_{0<p\max}}$ cannot cover the maximal nilpotent subalgebra $N^+(\mathrm{so}(M))$. We demonstrate that there exist other types of Frobenius subalgebras in so(M) that can be large enough to include $N^+(\mathrm{so}(M))$. The problem is that the canonical chains $\mathcal{F}_{\mathcal{B}_{0<p}}$ do not preserve the primitivity on these new carrier spaces. We show that this difficulty can be overcome and the primitivity can be restored if one changes the basis and passes to the deformed carrier spaces. Finally, the twisting elements for the new Frobenius subalgebras are explicitly constructed. This gives rise to a new family of universal R-matrices for orthogonal algebras. For a special case of $g=\mathrm{so}(5)$ and its defining representation we present the corresponding matrix solution of the Yang–Baxter equation. © *2001 American Institute of Physics.* [DOI: 10.1063/1.1402177]

I. INTRODUCTION

Quantizations of triangular Lie bialgebras with antisymmetric classical r-matrices $r=-r_{21}$ satisfying the classical Yang–Baxter equation (CYBE) form an important class of triangular Hopf algebras $\mathcal{A}(m,\Delta,S,\eta,\epsilon;\mathcal{R})$, with R-matrix satisfying the unitarity condition $\mathcal{R}_{21}\mathcal{R}=1$. These quantizations are defined by the twisting elements $\mathcal{F}=\Sigma f_{(1)}\otimes f_{(2)}\in\mathcal{A}\otimes\mathcal{A}$ that satisfy the twist equations:[1]

$$(\mathcal{F})_{12}(\Delta\otimes\mathrm{id})\mathcal{F}=(\mathcal{F})_{23}(\mathrm{id}\otimes\Delta)\mathcal{F},\quad(\epsilon\otimes\mathrm{id})\mathcal{F}=(\mathrm{id}\otimes\epsilon)\mathcal{F}=1. \tag{1}$$

The knowledge of the twisting element is quite important in applications giving (twisted) R-matrix $\mathcal{R}_F=\mathcal{F}_{21}\mathcal{R}\mathcal{F}^{-1}$ and twisted coproduct $\Delta_{\mathcal{F}}=\mathcal{F}\Delta\mathcal{F}^{-1}$.

Although for the general antisymmetric r-matrix the solution of the equation (1) was given in Ref. 1 in terms of Campbell–Hausdorf series quite few twisting elements were known in the explicit form: the Reshetikhin (Abelian) twists[2] and the Jordanian twist.[3,4] The explicit expressions of the more complicated twisting elements $\mathcal{F}$ were found in Ref. 5, for the carrier algebras **L** with special properties of their triangular decompositions. In the minimal case such algebras are four-dimensional. They can be considered as enlarged Heisenberg algebras with the defining relations

$$[H,E]=E,\quad [H,A]=\alpha A,\quad [H,B]=\beta B,$$
$$[A,B]=E,\quad [E,A]=[E,B]=0,\qquad \alpha+\beta=1. \tag{2}$$

If the generators of $\mathbf{L}$ have primitive coproducts, the following group two-cocycle (twist) can be found as a solution of the Drinfeld equation (1):

$$\mathcal{F}_{\mathcal{E}(\alpha,\beta)}=\Phi_{\mathcal{E}(\alpha,\beta)}\Phi_j \tag{3}$$

with the Jordanian twist[3]

$$\Phi_j=\exp\{H\otimes\sigma\},\quad \sigma=\ln(1+E), \tag{4}$$

and the additional twisting factor[5,6]

$$\Phi_{\mathcal{E}(\alpha,\beta)}=\exp\{A\otimes Be^{-\beta\sigma}\}. \tag{5}$$

Such solutions (3) are called the extended Jordanian twists. They define the deformed Hopf algebra $\mathbf{L}_{\mathcal{E}(\alpha,\beta)}$ with the costructure

$$\Delta_{\mathcal{E}(\alpha,\beta)}(H)=H\otimes e^{-\sigma}+1\otimes H-A\otimes Be^{-(\beta+1)\sigma},$$
$$\Delta_{\mathcal{E}(\alpha,\beta)}(A)=A\otimes e^{-\beta\sigma}+1\otimes A,$$
$$\Delta_{\mathcal{E}(\alpha,\beta)}(B)=B\otimes e^{\beta\sigma}+e^{\sigma}\otimes B,$$
$$\Delta_{\mathcal{E}(\alpha,\beta)}(E)=E\otimes e^{\sigma}+1\otimes E=E\otimes 1+1\otimes E+E\otimes E. \tag{6}$$

In the simple Lie algebras of rank greater than 2 one can find not only the subalgebra $\mathbf{L}$ but also its multidimensional analog $\mathbf{L}_K$ $(K=0,1,\dots)$.[5,7] To construct the subalgebra $\mathbf{L}_0\subset g$ it is sufficient to choose an initial root λ_0 and consider the set π of its constituent roots

$$\pi=\{\lambda',\lambda''|\lambda'+\lambda''=\lambda_0,\quad \lambda'+\lambda_0,\lambda''+\lambda_0\notin\Lambda(g)\},$$
$$\pi=\pi'\cup\pi'',\quad \pi'\cap\pi''=0,\quad \pi'=\{\lambda'\},\pi''=\{\lambda''\}. \tag{7}$$

The subalgebra $\mathbf{L}_0$ is generated by the elements $\{E_{\lambda_0},E_\lambda|\lambda\in\pi\}$ and the Cartan generator H_{λ_0} dual to λ_0. The solution $\mathcal{F}_{\mathcal{E}_0\mathcal{J}_0}$ of the twist equations corresponding to the carrier subalgebra $\mathbf{L}_0$ is a multidimensional analog of (3). It also can be decomposed into the product of two factors, the Jordanian twist and the extension:

$$\mathcal{F}_{\mathcal{E}_0\mathcal{J}_0}=\Phi_{\mathcal{E}_0}\cdot\Phi_{\mathcal{J}_0}=\prod_{\lambda'\in\pi'}\exp\left\{E_{\lambda'}\otimes E_{\lambda_0-\lambda'}e^{-(1/2)\sigma_{\lambda_0}}\right\}\cdot\exp\{H_{\lambda_0}\otimes\sigma_{\lambda_0}\}. \tag{8}$$

Here $\sigma_{\lambda_0}=\ln(1+E_{\lambda_0})$ and $[H_{\lambda_0},E_{\lambda_0}]=E_{\lambda_0}$.

Each carrier subalgebra $\mathbf{L}_K$ is a semidirect sum $\mathbf{L}_K=\mathbf{L}\dot{\oplus}\mathbf{L}_{K-1}$. Thus the multidimensional subalgebras $\mathbf{L}_K$ can be constructed successively. To find a multidimensional carrier $\mathbf{L}_1$ in the simple algebra g consider the subset $\Lambda^{\perp}_{\lambda_0^0}$ of roots orthogonal to λ_0^0 and the corresponding subalgebra $g^{\perp}_{\lambda_0^0}\subset g$. In $g^{\perp}_{\lambda_0^0}$ a new initial root λ_0^1 can be chosen and its constituent roots $\pi^1\subset\Lambda(g^{\perp}_{\lambda_0^0})$ can be found according to the rules (7). The corresponding generators $\{H_{\lambda_0^1},E_{\lambda_0^1},E_{\lambda^1}|\lambda^1\in\pi^1\}$ form the subalgebra $\mathbf{L}(g^{\perp}_{\lambda_0^0})$ and $\mathbf{L}_1=\mathbf{L}(g^{\perp}_{\lambda_0^0})\dot{\oplus}\mathbf{L}_0$. The subalgebra $\mathbf{L}(g^{\perp}_{\lambda_0^0})$ commutes with $H_{\lambda_0^0},E_{\lambda_0^0}$ and acts on $\{E_\lambda|\lambda\in\pi^0=\pi\}\subset\mathbf{L}_0$ as on an ideal.

It was shown in Ref. 7 that for the classical Lie algebras g one can always find a subalgebra g_1 in $g^{\perp}_{\lambda_0}$ whose generators become primitive after the twist $\mathcal{F}_{\mathcal{E}_0\mathcal{J}_0}$. The root diagrams $\Lambda(g_1)$ and $\Lambda(g)$ are of the same type. So, it is always possible to the find the root λ^1_0 and the set π^1 in $\Lambda(g_1)$. Repeating this procedure we get the sequence of injections $g_p \subset \cdots \subset g_1 \subset g_0 = g$ and the corresponding sequence of subalgebras $\mathbf{L}_K$. The coproduct primitivization of $g_k \subset g_{k-1}$ (called the Matreshka effect) makes it possible to compose chains of extended twists of the type (8),

&\quad \cdot \prod_{\lambda' \in \pi'_{p-1}} \exp\{E_{\lambda'} \otimes E_{\lambda^{p-1}_0 - \lambda'} e^{-(1/2)\,\sigma_{\lambda^{p-1}_0}}\} \cdot \exp\{H_{\lambda^{p-1}_0} \otimes \sigma_{\lambda^{p-1}_0}\} \\
&\quad \cdot \ldots \\
&\quad \cdot \prod_{\lambda' \in \pi'_0} \exp\{E_{\lambda'} \otimes E_{\lambda^0_0 - \lambda'} e^{-(1/2)\,\sigma_{\lambda^0_0}}\} \cdot \exp\{H_{\lambda^0_0} \otimes \sigma_{\lambda^0_0}\}. \qquad (9)
\end{aligned}
$$

Consider the Bruhat decomposition $g = \mathbf{N}^+ + \mathbf{H} + \mathbf{N}^- = \mathbf{B}^+ + \mathbf{N}^-$. As it was demonstrated earlier, there exists the systematic structure governing the twists with the carriers in the Borel subalgebra $\mathbf{B}^+$ of g. On the other hand, it follows from our studies in Ref. 7 that this structure (a chain of extended twists) is insufficient to compose a solution of Drinfeld equations when the carrier algebra of the classical r-matrix is greater than $\mathbf{B}^+$. In the latter case the twisting element will contain the chain as a factor but as a whole the structure will be considerably different from that of a chain. Thus the twists that can be described by chains have their carriers in $\mathbf{B}^+$. Now let us look at the Cartan subalgebra H of g. In general the number of links of a chain is less than rank(g). For example, for sl(N) the number of links is $[N/2]$. Consider the largest possible twist for sl(N) with the structure of a chain. Its carrier contains $\mathbf{N}^+$. Still, in such chain the $N - [N/2] - 1$ Cartan generators remain uninvolved. This means that to characterize the size of the chain one must compare its carrier with the maximal nilpotent subalgebra $\mathbf{N}^+$ of g. This is why we call the chains *full* if their carriers contain $\mathbf{N}^+$. In the case $g = \mathrm{sl}(N)$ the subalgebras g_k (they remain primitive after the twisting by $\mathcal{F}_{\mathcal{E}_{k-1}\mathcal{J}_{k-1}}$) coincide with $g^{\perp}_{\lambda_{k-1}}$. The result is that the maximal canonical chain $\mathcal{F}_{\mathcal{B}_{0<p\max}}$ for $g = \mathrm{sl}(N)$ is full, and its carrier subalgebra contains all the generators of the nilpotent subalgebra $\mathbf{N}^+(g)$.

For the orthogonal simple algebras the situation is different. In this case $g^{\perp}_{\lambda_{k-1}} = g_k \oplus \mathrm{sl}^{(k)}(2)$ and the coproducts of generators in the space $g^{\perp}_{\lambda_{k-1}} > g_k$ are nontrivially deformed by the twist $\mathcal{F}_{\mathcal{E}_{k-1}\mathcal{J}_{k-1}}$. The next extended twist $\mathcal{F}_{\mathcal{E}_k\mathcal{J}_k}$ does not contain these generators in its carrier space. Such a chain cannot be full.

The canonical twists (9) correspond to solutions of the CYBE related with Frobenius subalgebras in g described by the coboundary bilinear forms $\omega^+_p = \Sigma^p_{k=0} E^*_{\lambda^k_0}([\ ,\ ])$.[8] In this article we show that for the orthogonal algebras these forms can be modified. The Frobenius subalgebras can be enlarged in order to include all nonzero root generators from $g^{\perp}_{\lambda_{k-1}} > g_k$. (Sec. II).

The problem is how to find the corresponding twists, i.e., to solve the equations (1) for the subalgebra $g^{\perp}_{\lambda_{k-1}}$ that contains the generators with deformed coproducts $\Delta_{\mathcal{F}_{\mathcal{E}_k\mathcal{J}_k}}$.

In Ref. 9 it was demonstrated that under certain conditions (while the coproducts in g are nontrivially twisted by $\mathcal{F}$) one can find in $U_{\mathcal{F}}(g)$ the deformed carrier subspace that is primitive and generates a subalgebra of g. Below we show that this effect is in some sense universal. The corresponding deformed spaces for orthogonal algebras can be found for any extended twist $\mathcal{F}_{\mathcal{E}_{k-1}\mathcal{J}_{k-1}}$. As a result the canonical chain of twists $\mathcal{F}_{\mathcal{B}_{0<p}}$ can be extended using some additional

factors (the deformed Jordanian twists). For the maximal value of p the corresponding chain $\mathcal{F}_{\mathcal{G}_{0<p}}$ becomes full and the corresponding carrier space contains all the generators of $\mathbf{N}^+(g)$ (Sec. III).

In Sec. IV we discuss the possible applications of the composed twists. The explicit form of the parametrized R-matrix in the defining representation of so(5) is given in the Appendix.

II. FROBENIUS SUBALGEBRAS

Here we deal with the universal enveloping algebras for simple classical Lie algebras over the field of characteristic zero. In particular we consider the complex orthogonal algebras $g=\mathrm{so}(M)$ of the series B_N (for $M=2N+1$) and D_N (for $M=2N$). The root system $\Lambda(g)$ will be fixed as follows:

$$\Lambda(g)=\begin{cases}\pm e_i,\ \pm e_j\pm e_k & \text{for } g=so(2N+1),\\ \pm e_i\pm e_j & \text{for } g=so(2N),\end{cases}\qquad i,j,k=1,\ldots,N. \tag{10}$$

Let $\mathcal{E}_{i,j}$ be the ordinary matrix units,

$$[\mathcal{E}_{i,j},\mathcal{E}_{k,l}]=\delta_{jk}\mathcal{E}_{i,l}-\delta_{il}\mathcal{E}_{k,j},$$

and $M_{i,j}$ be the antisymmetric ones,

$$[M_{a,b},M_{c,d}]=\delta_{bc}M_{a,d}+\delta_{ad}M_{b,c}-\delta_{ac}M_{b,d}-\delta_{bd}M_{a,c}.$$

The generators of $g=\mathrm{so}(M)$ can be realized as follows. The Cartan subalgebra $\mathcal{H}(g)$ is generated by

$$H_j=\left(-\frac{i}{2}\right)M_{2j-1,2j},\quad j=1,\ldots,N. \tag{11}$$

For Cartan generators we shall also use the notation

$$H_{j\pm(j+1)}=\left(-\frac{i}{2}\right)(M_{2j-1,2j}\pm M_{2j+1,2j+2}). \tag{12}$$

To the roots of $\Lambda(\mathrm{so}(M))$ we attribute the generators

$$\left.\begin{aligned}E_{i+j}&=\tfrac{1}{2}(-M_{2i,2j}+iM_{2i,2j-1}+iM_{2i-1,2j}+M_{2i-1,2j-1});\\ E_{i-j}&=\tfrac{1}{2}(-M_{2i,2j}-iM_{2i,2j-1}+iM_{2i-1,2j}-M_{2i-1,2j-1});\\ E_{-i+j}&=\tfrac{1}{2}(+M_{2i,2j}-iM_{2i,2j-1}+iM_{2i-1,2j}+M_{2i-1,2j-1});\\ E_{-i-j}&=\tfrac{1}{2}(+M_{2i,2j}+iM_{2i,2j-1}+iM_{2i-1,2j}-M_{2i-1,2j-1});\end{aligned}\right\}\quad i<j; \tag{13}$$

and

$$E_{\pm k}=\frac{1}{\sqrt{2}}(\pm M_{2k,2N+1}-iM_{2k-1,2N+1}),\quad k\leqslant N,\quad \text{for so}(2N+1). \tag{14}$$

The Borel subalgebras $B(g)$ are generated by the sets $\{H_i,E_i,E_{i\pm j}\}$ for $g=\mathrm{so}(2N+1)$ and $\{H_i,E_{i\pm j}\}$ for $g=\mathrm{so}(2N)$. To describe the chains of Frobenius subalgebras we shall also need the alternative realization of these generators through the ordinary matrix units. To get it let us renumerate the generators:

$$\left.\begin{aligned} A_{i,j} &\equiv -E_{i-j}, \\ A_{i,2N+2-j} &\equiv -E_{i+j}, \\ A_{i,N+1} &\equiv -E_i, \end{aligned}\right\} \quad \text{for so}(2N+1) \tag{15}$$

and

$$\left.\begin{aligned} A_{i,j} &\equiv -E_{i-j}, \\ A_{i,2N+1-j} &\equiv -E_{i+j}, \end{aligned}\right\} \quad \text{for so}(2N). \tag{16}$$

In these terms the Borel subalgebra $B(\mathrm{so}(M))$ is spanned by the set $\{A_{i,j}|i\leqslant j\}$ and we can also use the following matrix realization:

$$\begin{aligned} H_i &= \tfrac{1}{2}(\mathcal{E}_{i,i}-\mathcal{E}_{M+1-i,M+1-i}), \\ A_{i,j} &= \mathcal{E}_{i,j}-\mathcal{E}_{M+1-j,M+1-i}. \end{aligned} \tag{17}$$

The canonical chains of twists (9) for orthogonal simple Lie algebras are based on the sequence of injections

$$U(\mathrm{so}(M))\supset U(\mathrm{so}(M-4))\supset\cdots\supset U(\mathrm{so}(M-4k))\supset\cdots. \tag{18}$$

Each link of such chains [see (9)] contains the Jordanian twist $\Phi_{\mathcal{J}_k}=\exp\{H_{\lambda_0^k}\otimes\sigma_{\lambda_0^k}\}$ based on one of the long roots:

$$\lambda_0^k=e_1^k+e_2^k \quad (\text{for both } D_N \text{ and } B_N). \tag{19}$$

The hyperplane $V_{\lambda_0^k}^{\perp}$ orthogonal to λ_0^k coincides with the root space of the subalgebra $g_{\lambda_0^k}^{\perp}=\mathrm{so}(M-4(k+1))\oplus so^{(k+1)}(3)$. For each subalgebra $g_{k+1}=\mathrm{so}(M-4(k+1))$ we can again consider independently its root system Λ^{k+1} and choose the next initial root to be

$$\lambda_0^{k+1}=e_1^{k+1}+e_2^{k+1}.$$

On each step we can fix two vector subrepresentations $d^{v(a)}$ in the restriction (to g_{k+1}) of the adjoint representation ad_{g_k}:

$$d_{g_{k+1}}^{v(a)}\subset \mathrm{ad}_{g_k\downarrow g_{k+1}}, \quad a=1,2.$$

It is easy to check that the constituent roots form the weight diagrams for these representations. The representation space for $d_{g_{k+1}}^{v(a)}$ is spanned by the generators

$$\{E_a, E_{a\pm l}\} \text{ with the roots } \{e_a^k,\ e_a^k\pm e_l^k\in\pi_k\}$$

for $M-4k=2N+1$ and

$$\{E_{a\pm k}\} \text{ with the roots } \{e_a^k\pm e_l^k\in\pi_k\}$$

for $M-4k=2N$. In both cases $l=3,\ldots,N$.

For the representations $d_{g_{k+1}}^{v(a)}$ and $d_{g_{k+1}}^{v(a)}\otimes d_{g_{k+1}}^{v(b)}$ the following scalar and tensor invariants, I_{M-4k}^{a} and $I_{M-4k}^{a\otimes b}$ (with $a,b=1,2$), will be used in the construction of twists and twisted coproducts:

$$I^a_{2N+1}=\frac{1}{2}E_a^2+\sum_{l=3}^{N}(E_{a+l}E_{a-l}),$$

$$I^{a\otimes b}_{2N+1}=E_a\otimes E_b+\sum_{l=3}^{N}(E_{a+l}\otimes E_{b-l}+E_{a-l}\otimes E_{b+l}), \tag{20}$$

$$I^{a\wedge b}_{2N+1}=E_a\wedge E_b+\sum_{l=3}^{N}(E_{a+l}\wedge E_{b-l}+E_{a-l}\wedge E_{b+l}),$$

$$I^a_{2N}=\sum_{l=3}^{N}(E_{a+l}E_{a-l}),$$

$$I^{a\otimes b}_{2N}=\sum_{l=3}^{N}(E_{a+l}\otimes E_{b-l}+E_{a-l}\otimes E_{b+l}), \tag{21}$$

$$I^{a\wedge b}_{2N}=\sum_{l=3}^{N}(E_{a+l}\wedge E_{b-l}+E_{a-l}\wedge E_{b+l}).$$

The set of initial roots defines a natural gradation in the root space of the subalgebra $\mathbf{N}^+(\mathrm{so}(M))\subset\mathrm{so}(M)$:

$$\Lambda(\mathbf{N}^+(\mathrm{so}(M)))=\cup_{k=0}^{p_{\max}}(\lambda_0^k\cup\pi_k), \tag{22}$$

where $p_{\max}=[M/4]+[(M+1)/4]$.

The inverse of the map defined by the classical r-matrix is the Frobenius bilinear form. Let us study the Frobenius subalgebras in $B(\mathrm{so}(M))$.

Proposition 1: Let $\mathbf{L}$ *be a semi-direct sum of a subalgebra* $\mathbf{S}$ *and a commutative ideal* $\mathbf{N}$. *Then* $\mathbf{L}$ *is Frobenius if and only if the following conditions hold:*

(i) $\mathbf{L}$ *acts transitively on the space* $\mathbf{N}^*$ *with the generic point* A^*.
(ii) The stationary subalgebra $\mathbf{S}_{A^*}=\{s\in\mathbf{S}:A^*([s,x])=0,\ \text{for any } x\in\mathbf{N}\}$ *is Frobenius with a Frobenius homomorphism* $f_0:\mathbf{S}_{A^*}\to C$.

Moreover, in this case $f=f_0\oplus A^*$ *is a Frobenius homomorphism for* $\mathbf{L}$.

This statement can be obtained as a consequence of Proposition 1 and the Remark after it in Ref. 10. Here is how it can be used in the case of orthogonal simple Lie algebras.

Lemma 1: Let $\mathbf{L}_1\subset B(\mathrm{so}(M))$ *be a subalgebra generated by the set* $\{H_1,H_2,A_{i,j},i=1,2\}$. *Then* $\mathbf{L}_1$ *is Frobenius*.

Proof: In $\mathbf{L}_1$ the following subalgebras can be fixed: $\mathbf{N}_1=\{A_{1,j}\}$ and $\mathbf{S}_1=\{H_1,H_2,A_{2,j}\}$. The generators of the dual space $\mathbf{N}_1^*$ can be identified with the matrices $\{A_{i,1}\}$ defined according to the rule (17) and connected with $A_{1,j}$ through the bilinear form $\langle A,B\rangle=\mathrm{tr}\,(A,B)$ or by a Killing form in the general setting. Since $\dim\mathbf{N}_1=\dim\mathbf{S}_1$ it suffices to find a point $A^*\in\mathbf{N}_1^*$ such that $\mathbf{S}_{A^*}=0$. One can check directly that $A_0^*=\Sigma_{i=2}^{n-1}A_{i1}$ satisfies this condition. ■

This point A_0^* is not unique. If $G(\mathbf{S}_1)$ is the subgroup of $\mathrm{SO}(M)$ corresponding to the algebra $\mathbf{S}_1$, then for any $g\in G(\mathbf{S}_1)$ the point $\mathrm{Ad}^*(g)(A_0^*)=(A_0^*)^g$ satisfies the condition $\mathbf{S}_{(A_0^*)^g}=0$ since $\mathbf{S}_{(A_0^*)^g}=g^{-1}\mathbf{S}_{A_0^*}g=0$. For our purposes it is convenient to choose $A_0^*=A_{2,1}+A_{M-1,1}$ (One can check that this point satisfies the conditions of the Proposition 1.)

Lemma 2: Let $\mathbf{L}_{K,M}$ *be a subalgebra of* $B(\mathrm{so}(M))$ *generated by the set*

$$\{H_i,A_{i,j}|i=1,\ldots,2K;j=1,\ldots M;i<j;2K\leqslant[M/2]\}.$$

Then $\mathbf{L}_{K,M}$ *is Frobenius.*

Proof: The algebra $\mathbf{L}_{K,M}$ has the structure of a semidirect sum:

$$\mathbf{L}_{K,M}=\mathbf{S}_{K,M}\dot{\oplus}\mathbf{N}_{K,M},$$

where

$$\mathbf{N}_{K,M}=\{\{H_i|i=1,\ldots,2K;\}\{A_{i,j}|i=2,\ldots,2K;j=1,\ldots M;i<j\}\}.$$

Evidently $\mathbf{L}_{K,M}$ acts transitively on $\mathbf{N}^*_{K,M}$ with the generic point $A_1^*=A_{2,1}+A_{M-1,1}$. One can easily check that

$$(\mathbf{S}_{K,M})_{(A_0^*)}=\{H_i,A_{i,j}|i=3,\ldots,2K;i<j\}.$$

Thus

$$(\mathbf{S}_{K,M})_{(A_0^*)}\cong\mathbf{L}_{K-1,M-4}\subset B(\mathrm{so}(M-4)).$$

Obvious induction shows that $\mathbf{L}_{K,M}$ is Frobenius due to the Proposition 1. ■

The algebra $\mathbf{L}_{K,M}$ has a nontrivial second cohomology group $H^2(\mathbf{L}_{K,M})$. The latter contains $\Lambda^2(H^*_{K,M})$ where $H^*_{K,M}$ is the space dual to the Cartan subalgebra in $\mathbf{L}_{K,M}$, $H^*_{K,M}=\mathbf{L}_{K,M}\cap\mathcal{H}(\mathrm{so}(M))\subset B(\mathrm{so}(M))$. It is easy to see that all bilinear forms $H_i^*\wedge H_j^*$ are two-cocycles and not coboundaries. Here $H_i^*\in H^*_{K,M}$. Consequently $A^*_{K,M}+\zeta_{ij}H_i^*\wedge H_j^*$ are the nondegenerate two-cocycles on $\mathbf{L}_{K,M}$. The map $A^*_{K,M}$ is a Frobenius homomorphism, $A^*_{K,M}:\mathbf{L}_{K,M}\rightarrow\mathbf{C}$, because $A^*_{K,M}([x,y])$ is a nondegenerate bilinear form on $\mathbf{L}_{K,M}$. The induction procedure shows that $A^*_{K,M}$ can be chosen in the following form:

$$A^*_{K,M}=(A_{21}+A_{43}+A_{65}+\cdots)+(A_{M-1,1}+A_{M-3,3}+A_{M-5,5}+\cdots). \tag{23}$$

In the case of the orthogonal simple Lie algebras, chains of twists (9) introduced in Ref. 7 refer to the Frobenius subalgebras [contained in the corresponding $B(\mathrm{so}(M))$] with the coboundary nondegenerate bilinear forms,[8]

$$\omega_p^+=\sum_{k=0}^{p}\gamma_k(E^{(k)}_{1+2})^*([\,,\,]), \tag{24}$$

where p is the number of links in the chain $\mathcal{F}_{\mathcal{B}_{0<p}}$ and the parameters $\gamma_k=0,1$ indicate that we describe here the set of forms. It is obvious that the forms (24) ignore the subspaces of $\mathrm{so}^{(k)}(3)$ subalgebras that appear on each step of the sequence of injections in (22). According to the formula (23), to describe the maximal Frobenius subalgebras in $B(\mathrm{so}(M))$ the following form must be considered:

$$\omega_p^{\pm}=\sum_{k=0}^{p}(\gamma_k(E^k_{1+2})^*-\delta_k(E^k_{1-2})^*)([\,,\,]). \tag{25}$$

Here both parameters are discrete: $\gamma_k,\delta_k=0,1$. (Notice that this does not lead to the undesirable terms in the corresponding carrier space because in the Borel subalgebra $B(\mathrm{so}(M))$ (fixed by the choice of $\{\lambda_0^k\}$) there are no constituent roots for $e_1^k-e_2^k$. The form $\omega_p^{\pm}$ is considered on $B(\mathrm{so}(M))$. In terms of the integral root system $\Lambda(\mathrm{so}(M))$ (not split in the subsystems $\Lambda^{(k)}$) the generators $E^{(k)}_{1+2}$ and $E^{(k)}_{1-2}$ form the sequence

$$\{E_{1+2},E_{1-2},E_{3+4},E_{3-4},\ldots,E_{(2p+1)+(2p+2)},E_{(2p+1)-(2p+2)}\}$$
$$\approx\{A_{1,M-1},A_{1,2},A_{3,M-3},A_{3,4},\ldots A_{2p+1,M-(2p+1)},A_{2p+1,2p+2},\}.$$

Thus we come to the conclusion that there must be two sets of chains of twists for the orthogonal algebras corresponding to the two sets of the coboundary forms (24) and (25). The first set is the canonical chain of twists (9), whose twisting element can be rewritten in terms of invariants (20) and (21):

$$\begin{aligned}\mathcal{F}_{\mathcal{B}_{0<p}} &= \exp\{I^{1\otimes 2}_{M-4p}(1\otimes e^{-(1/2)\,\sigma^{p}_{1+2}})\}\\ &\quad\cdot\exp\{H^{(p)}_{1+2}\otimes\sigma^{p}_{1+2}\}\cdot\exp\{I^{1\otimes 2}_{M-4(p-1)}(1\otimes e^{-(1/2)\,\sigma^{p-1}_{1+2}})\}\cdot\exp\{H^{(p-1)}_{1+2}\otimes\sigma^{p-1}_{1+2}\}\\ &\quad\cdot\ldots\\ &\quad\cdot\exp\{I^{1\otimes 2}_{M}(1\otimes e^{-(1/2)\,\sigma^{0}_{1+2}})\}\cdot\exp\{H^{(0)}_{1+2}\otimes\sigma^{0}_{1+2}\}\\ &= \prod_{k=p}^{0}\exp\{I^{1\otimes 2}_{M-4k}(1\otimes e^{-(1/2)\,\sigma^{k}_{1+2}})\}\cdot\exp\{H^{(k)}_{1+2}\otimes\sigma^{k}_{1+2}\}\end{aligned}\tag{26}$$

[here $\sigma_{\lambda^k_0}$ are denoted by $\sigma^k_{1+2}=\ln(1+E^{(k)}_{1+2})$ according to (19) and for simplicity we put $\gamma_l=1$].

When dealing with the forms $\omega^{\pm}_p$ the problem is that in the process of twisting by a chain (26) the costructure of the subalgebras $\mathrm{so}^{(k)}$ (3) is considerably changed and the twist equations (1) become extremely difficult to solve.

III. CONSTRUCTION OF THE FULL CHAINS OF TWISTS

According to the general structure of a chain of twists[7] we can study its links separately. Let us assume that we have constructed the $k-1$ links of a chain and found the Matreshka effect. This means that after the chain twisting with $k-1$ links we get the subalgebra $g^{(k)}=\mathrm{so}(M-4k)$ with primitive generators. We shall show that it is possible to construct the next link of the chain so that the twist will correspond to the enlarged form $\omega^{\pm}_p$ [see (25)]. To start the construction of the kth link we have to choose the initial root λ^k_0 [as in (19)] and the subalgebra $\mathbf{L}_{K,M-4k}$ described in Lemma 2 (with $2K=[M/2]$). First we apply the following Jordanian twist to the subalgebra $\mathbf{L}_{K,M-4k}$:

$$\Phi_{\mathcal{J}_k}=\exp(H^k_{1+2}\otimes\sigma^k_{1+2}).\tag{27}$$

This results in the following deformed coproducts:

$$\Delta_{\mathcal{J}_k}(H^k_{1+2})=H^k_{1+2}\otimes e^{-\sigma^k_{1+2}}+1\otimes H^k_{1+2},$$

$$\Delta_{\mathcal{J}_k}(E^k_{1+2})=E^k_{1+2}\otimes e^{\sigma^k_{1+2}}+1\otimes E^k_{1+2},$$

$$\Delta_{\mathcal{J}_k}(E^k_{a\pm l})=E^k_{a\pm l}\otimes e^{1/2\,\sigma^k_{1+2}}+1\otimes E^k_{a\pm l},$$

$$l=3,\ldots,N;\quad a=1,2.$$

For $M=2N+1$ we also get

$$\Delta_{\mathcal{J}_k}(E^k_a)=E^k_a\otimes e^{(1/2)\,\sigma^k_{1+2}}+1\otimes E^k_a.$$

Notice that the generators $\{H^k_{1-2},E^k_{1-2},E^k_{2-1}\}$ remain primitive.

The second twisting factor must be the full canonical extension[5] for the Jordanian twist $\Phi_{\mathcal{J}_k}$ (27):

$$\Phi_{\mathcal{E}_k}=\exp(I^{1\otimes 2}_{M-4k}(1\otimes e^{-(1/2)\,\sigma^k_{1+2}})).\tag{28}$$

The successive application of these two factors performs the extended Jordanian twisting by the element $\Phi_{\mathcal{E}_k}\Phi_{\mathcal{J}_k}$ that leads to the following costructure in $\mathbf{L}_{K,M-4k}$:

$$\Delta_{\mathcal{E}_k\mathcal{J}_k}(H^k_{1+2})=H^k_{1+2}\otimes e^{-\sigma^k_{1+2}}+1\otimes H^k_{1+2}-(1\otimes e^{-(3/2)\,\sigma^k_{1+2}})I^{1\otimes 2}_{M-4k},$$

$$\Delta_{\mathcal{E}_k\mathcal{J}_k}(H^k_{1-2})=H^k_{1-2}\otimes 1+1\otimes H^k_{1-2},$$

$$\Delta_{\mathcal{E}_k\mathcal{J}_k}(E^k_{1+2})=E^k_{1+2}\otimes e^{\sigma^k_{1+2}}+1\otimes E^k_{1+2},$$

$$\Delta_{\mathcal{E}_k\mathcal{J}_k}(E^k_{1\pm k})=E^k_{1\pm k}\otimes e^{-(1/2)\,\sigma^k_{1+2}}+1\otimes E^k_{1\pm k},$$

$$\Delta_{\mathcal{E}_k\mathcal{J}_k}(E^k_{2\pm k})=E^k_{2\pm k}\otimes e^{(1/2)\,\sigma^k_{1+2}}+e^{\sigma^k_{1+2}}\otimes E^k_{2\pm k},$$

$$\Delta_{\mathcal{E}_k\mathcal{J}_k}(E^k_{1-2})=E^k_{1-2}\otimes 1+1\otimes E^k_{1-2}+(1\otimes e^{-(1/2)\,\sigma^k_{1+2}})I^{1\otimes 1}_{M-4k}+I^1_{M-4k}\otimes(e^{-\sigma^k_{1+2}}-1),$$

$$\Delta_{\mathcal{E}_k\mathcal{J}_k}(E^k_{2-1})=E^k_{2-1}\otimes 1+1\otimes E^k_{2-1}+(e^{\sigma^k_{1+2}}-1)\otimes I^2_{M-4k}e^{-\sigma^k_{1+2}}+(1\otimes e^{-(1/2)\,\sigma^k_{1+2}})I^{2\otimes 2}_{M-4k}.$$

And in the case of $M=2N+1$ for the short root generators we get

$$\Delta_{\mathcal{E}_k\mathcal{J}_k}(E^k_1)=E^k_1\otimes e^{-(1/2)\,\sigma^k_{1+2}}+1\otimes E^k_1,$$

$$\Delta_{\mathcal{E}_k\mathcal{J}_k}(E^k_2)=E^k_2\otimes e^{(1/2)\,\sigma^k_{1+2}}+e^{\sigma^k_{1+2}}\otimes E^k_2.$$

It would be necessary to have the coproducts for some of the invariants [see (20) and (21)]:

$$\Delta_{\mathcal{E}_k\mathcal{J}_k}(I^1_{M-4k})=I^1_{M-4k}\otimes e^{-\sigma^k_{1+2}}+1\otimes I^1_{M-4k}+I^{1\otimes 1}_{M-4k}(1\otimes e^{-(1/2)\,\sigma^k_{1+2}}), \tag{29}$$

$$\Delta_{\mathcal{E}_k\mathcal{J}_k}(I^2_{M-4k}e^{-\sigma^k_{1+2}})=I^2_{M-4k}e^{-\sigma^k_{1+2}}\otimes 1+e^{\sigma^k_{1+2}}\otimes I^2_{M-4k}e^{-\sigma^k_{1+2}}+I^{2\otimes 2}_{M-4k}(1\otimes e^{-(1/2)\,\sigma^k_{1+2}}). \tag{30}$$

We have two generators of $\mathbf{L}_{K,M-4k}$ that are not yet incorporated in the carrier subalgebra of the twist: H^k_{1-2} and E^k_{1-2}. The coproduct of the latter is deformed. So the canonical Jordanian factor cannot be used here. In Ref. 9 it was indicated that the reason for the nonprimitivity of the coproduct $\Delta_{\mathcal{E}_k\mathcal{J}_k}(E^k_{1-2})$ is that the generator E^k_{1-2} belongs to the long series of the initial root $\lambda^k_0=e^k_1+e^k_2$. It was shown there that in such a case the deformed carrier subspace must exist with primitive basic elements. In our situation such ''deformed'' generators must have the form

$$\begin{aligned} G^k_{1-2}&=E^k_{1-2}-I^1_{M-4k},\\ G^k_{2-1}&=E^k_{2-1}-I^2_{M-4k}e^{-\sigma^k_{1+2}}. \end{aligned} \tag{31}$$

Using the coproducts (29) and (30), it is easy to check that both G^k_{1-2} and G^k_{2-1} are primitive,

$$\begin{aligned} \Delta_{\mathcal{E}_k\mathcal{J}_k}(G^k_{1-2})&=\Delta_{\mathcal{E}_k\mathcal{J}_k}(E^k_{1-2})-\Delta_{\mathcal{E}_k\mathcal{J}_k}(I^1_{M-4k})\\ &=G^k_{1-2}\otimes 1+1\otimes G^k_{1-2}, \end{aligned}$$

$$\begin{aligned} \Delta_{\mathcal{E}_k\mathcal{J}_k}(G^k_{2-1})&=\Delta_{\mathcal{E}_k\mathcal{J}_k}(E^k_{2-1})-\Delta_{\mathcal{E}_k\mathcal{J}_k}(I^2_{M-4k})(e^{-\sigma^k_{1+2}}\otimes e^{-\sigma^k_{1+2}})\\ &=G^k_{2-1}\otimes 1+1\otimes G^k_{2-1}. \end{aligned}$$

Together with H^k_{1-2} the elements (31) generate a three-dimensional space V^k_G of primitive elements in the algebra $U_{\mathcal{E}_k\mathcal{J}_k}(\mathrm{so}(M-4k))$. Both G^k_{1-2} and G^k_{2-1} commute with $U(\mathrm{so}(M-4(k+1)))$ as well as H^k_{1-2} whose dual vector is orthogonal to the roots of $\mathrm{so}(M-4(k+1))$.

The subspace V^k_G spanned by $\{H^k_{1-2},G^k_{1-2},G^k_{2-1}\}$ is algebraically closed:

$$[H^k_{1-2},G^k_{1-2}]=G^k_{1-2},$$

$$[H^k_{1-2},G^k_{2-1}]=-G^k_{2-1},$$

$$[G^k_{1-2},G^k_{2-1}]=2H^k_{1-2}.$$

Let us denote this algebra by $\mathrm{so}^{(k)}_G(3)$. Clearly it is primitive, commutes with $U(\mathrm{so}(M-4(k+1)))$ and is realized on a deformed subspace. (This space is not orthogonal to H^k_{1+2}. Moreover, G^k_{2-1},G^k_{1-2} are not any longer eigenvectors of $\mathrm{ad}_{H^k_{1+2}}$.)

Another subalgebra which remains primitive after the composition $\Phi_{\mathcal{E}_k}\Phi_{\mathcal{J}_k}$ of twists (27) and (28) is $\mathrm{so}(M-4(k+1))$ (due to the Matreshka effect). We come to the conclusion that the twisted $U_{\mathcal{E}_k\mathcal{J}_k}(\mathrm{so}(M-4k))$ contains the primitive subalgebra $g^{\perp}_{\lambda^k_0}$,

$$U_{\mathcal{E}_k\mathcal{J}_k}(\mathrm{so}(M-4k))\supset g^{\perp}_{\lambda^k_0}=\mathrm{so}(M-4(k+1))\oplus\mathrm{so}^{(k)}_G(3).$$

Its Borel subalgebra is $\mathbf{L}_{K,M-4(k+1)}\oplus B(\mathrm{so}^{(k)}_G(3))$ and it is Frobenius (see Sec. II).

Remember that the subalgebra $g^{\perp}_{\lambda^k_0}$ has a structure of direct sum. Further, twisting by the next factors (such as $\Phi_{\mathcal{E}_{k+s}}\Phi_{\mathcal{J}_{k+s}}$) cannot affect the primitive subalgebra $\mathrm{so}^{(k)}_G(3)$. Each step produces (in the corresponding $g^{\perp}_{\lambda^k_0}$) the additional subalgebra $\mathrm{so}^{(k)}_G(3)$, $k=1,\ldots,p$. The primitive subalgebras that can be found in an orthogonal algebra after the chain twisting (26) with p links contain not only $\mathrm{so}(M-4(p+1))$ but also a direct sum of p copies of $\mathrm{so}_G(3)$:

$$U_{\mathcal{B}_{0<p}}(\mathrm{so}(M))\supset\mathcal{D}=\oplus^p_{k=1}\mathrm{so}^{(k)}_G(3).$$

The main consequence is that in the twisted $U_{\mathcal{B}_{0<p}}(\mathrm{so}(M))$ one can perform further twist deformations with the carrier subalgebra in $\mathcal{D}$. The most interesting among them are the Jordanian twists defined by

$$\Phi^G_{\mathcal{J}_k}=\exp(H^k_{1-2}\otimes\sigma^k_G) \tag{32}$$

that can be attributed to any number of copies $\mathrm{so}_G(3)$. Here $\sigma^k_G=\ln(1+G^k_{1-2})$. Thus in the general expression for the twisting element (26) one can insert in the appropriate k places the additional factors which are the Jordanian twisting elements on the deformed carrier spaces. This means that we can perform a substitution

$$\Phi_{\mathcal{E}_k}\Phi_{\mathcal{J}_k}\Rightarrow\Phi^G_{\mathcal{J}_k}\Phi_{\mathcal{E}_k}\Phi_{\mathcal{J}_k}=\Phi_{\mathcal{G}_k},$$

$$\exp\{I^{1\otimes 2}_{M-4k}(1\otimes e^{-1/2\,\sigma^k_{1+2}})\}\cdot\exp\{H^k_{1+2}\otimes\sigma^k_{1+2}\}$$
$$\Rightarrow\exp(H^k_{1-2}\otimes\sigma^k_G)\cdot\exp\{I^{1\otimes 2}_{M-4k}(1\otimes e^{-1/2\,\sigma^k_{1+2}})\}\cdot\exp(H^k_{1+2}\otimes\sigma^k_{1+2}).$$

Thus *the full chain* has the following form:

$$\mathcal{F}_{\mathcal{G}_{0<p}}=\prod^0_{k=p}\Phi_{\mathcal{G}_k}=\prod^0_{k=p}\exp(H^k_{1-2}\otimes\sigma^k_G)\cdot\exp\{I^{1\otimes 2}_{M-4k}(1\otimes e^{-1/2\,\sigma^k_{1+2}})\}\cdot\exp\{H^k_{1+2}\otimes\sigma^k_{1+2}\}. \tag{33}$$

This result means that we have constructed the explicit quantizations with a triangular universal R-matrix

$$\mathcal{R}_{\mathcal{G}_{0<p}}=(\mathcal{F}_{\mathcal{G}_{0<p}})_{21}(\mathcal{F}_{\mathcal{G}_{0<p}})^{-1}$$

for the following set of classical r-matrices:

$$r_{\mathcal{G}_{0<p}}=\sum_{k=0}^{p}\ \eta_k(H^k_{1+2}\wedge E^k_{1+2}+\xi_k H^k_{1-2}\wedge E^k_{1-2}+I^{1\wedge 2}_{M-4k}).$$

Here all the parameters are independent and continuous. Elementary computations show that these full chains (33) correspond to the coboundary forms (25). To illustrate these quantizations we present in the Appendix the matrix $\mathcal{R}_{\mathcal{G}_{0<p}}$ for the algebra so(5) in the defining representation.

In Sec. II we proved that adding $\zeta_{ij}H^*_i\wedge H^*_j$ to the forms of type (25) we obtain new nondegenerate two-cocycles, which are not coboundaries. We can also construct the corresponding twists for these modified cocycles:

$$\omega^{\pm}_p=\sum_{k=0}^{p}\ (\gamma_k(E^k_{1+2})^*-\delta_k(E^k_{1-2})^*)([,])+\sum_{i,j=0;\ i\neq j}^{p}\ \zeta_{ij}H^*_i\wedge H^*_j\,. \tag{34}$$

Notice that the subalgebras $\mathrm{so}^{(k)}_G(3)$ commute not only with $\mathrm{so}(M-4(k+1))$ but also with any $\{E^{(s)}_{1+2}\,|\,s\leqslant k\}$. This means that after having twisted $U(\mathrm{so}(M))$ by the chain (33) we obtain $p+1$ pairs of commuting primitive elements $\{\sigma^k_{1+2},\sigma^k_G|k=0,\ldots,p\}$. Therefore we can apply the Reshetikhin twist

$$\Phi_{\mathcal{R}}=\exp(\zeta_{ij}\sigma_i\otimes\sigma_j),\quad \sigma_i\in\{\sigma^k_{1+2},\sigma^k_G\,|\,k=0,\ldots,p\} \tag{35}$$

to the algebra $U_{\mathcal{G}_{0<p}}(\mathrm{so}(M))$.

Thus the element

$$\Phi_{\mathcal{R}}\mathcal{F}_{\mathcal{G}_{0<p}}$$

defines also a twist for $U(\mathrm{so}(M))$. It leads to the deformed Hopf algebra $U_{\mathcal{R}G_{0<p}}(\mathrm{so}(M))$ with the universal element

$$\mathcal{R}_{\mathcal{R}G_{0<p}}=(\Phi_{\mathcal{R}}\mathcal{F}_{\mathcal{G}_{0<p}})_{21}(\mathcal{F}_{\mathcal{G}_{0<p}})^{-1}(\Phi_{\mathcal{R}})^{-1}$$

and the classical r-matrix

$$r_{\mathcal{R}G_{0<p}}=\sum_{k=0}^{p}\ \eta_k(H^k_{1+2}\wedge E^k_{1+2}+\xi_k H^k_{1-2}\wedge E^k_{1-2}+I^{1\wedge 2}_{M-4k})+\sum_{i,j=0;\ i\neq j}^{p}\ \zeta_{ij}E^i_s\wedge E^j_t;$$

$$E^k_s,E^k_t\in\{E^k_{1+2},E^k_{1-2}|k=0,\ldots,p\}.$$

The dimensions of the nilpotent subalgebras $\mathbf{N}^+(\mathrm{so}(M))$ in the sequence $g^{\perp}_{\lambda^p_0}\subset g^{\perp}_{\lambda^{p-1}_0}\subset\cdots\subset g^{\perp}_{\lambda^0_0}\subset g$ are subject to the following simple relation:

$$\dim(\mathbf{N}^+(\mathrm{so}(M)))-\dim(\mathbf{N}^+(\mathrm{so}(M-4)))=2(\dim\, d^v_{\mathrm{so}(M-4)}+1). \tag{36}$$

Taking this into account we conclude [from the formula (22)] that the chains (33) are full. Furthermore, this means that for $p=p_{\max}=[M/4]+[(M+1)/4]$ the corresponding carrier spaces contain all the generators of the nilpotent subalgebra $\mathbf{N}^+(\mathrm{so}(M))$. When M is even-odd one can always find in $\mathrm{so}(M)$ one independent Cartan generator which cannot be included in the carrier

subalgebra of a chain. When M is even-even or odd the total number of Jordanian twists in a maximal full chain $\mathcal{F}_{\mathcal{G}_{0<p\ \max}}$ is equal to the rank of so(M). Thus in the latter case the carrier subalgebra is equal to the Borel subalgebra.

IV. CONCLUSIONS

The family of explicit twisting elements was constructed for the universal enveloping algebras $\mathcal{A}=U(\mathrm{so}(M))$ (series B and D) with full nilpotent subalgebras $\mathbf{N}^{+}(\mathrm{so}(M))$ included in the corresponding carrier spaces.

There are a variety of applications for explicitly known twisting elements $\mathcal{F}$. Using a particular (e.g., fundamental) representation for one of the factors of $\mathcal{A}\otimes\mathcal{A}$ we get from the universal R-matrix the L-operator of the FRT-formalism and this results in explicit relations among the generators of the original universal enveloping algebra and the FRT-generators of the twisted one.

Twisting of the coalgebra in $\mathcal{A}$ induces changes in Clebsch–Gordan coefficients of bases in the tensor products of irreducible representations $c_V\otimes d_W$. The evaluation of these coefficients is given by the direct action of the matrix F [F is the value of the twisting element in the corresponding representation: $F=c_V\otimes d_W(\mathcal{F})$] on the original CG coefficients.[11]

Due to the embedding of the simple Lie algebras g into the corresponding Yangians (as Hopf subalgebras) $U(g)\subset\mathcal{Y}(g)$ (Ref. 12), the Yangian R-matrix $R_{\mathcal{Y}}$ can be twisted by the same $\mathcal{F}$ defined for g.[13] As a result, for the case of orthogonal algebra $g=\mathrm{so}(M)$ the R-matrix [in the defining representation $d\subset\mathrm{Mat}(M,\mathbf{C})\otimes\mathrm{Mat}(M,\mathbf{C})$] will be changed:

$$ud(1\otimes 1)+\mathcal{P}-\frac{u}{u-1+M/2}\mathcal{K}\quad\rightarrow\quad ud(\mathcal{F}_{21}\mathcal{F}^{-1})+\mathcal{P}-\frac{u}{u-1+M/2}d(\mathcal{F}_{21})\mathcal{K}d(\mathcal{F}^{-1}).$$

(Here u is a spectral parameter and the operator $\mathcal{K}$ is obtained from the permutation $\mathcal{P}$ by transposing its first tensor factor.) For the canonical chains $\mathcal{F}=\mathcal{F}_{\mathcal{B}_{0<p}}$ the deformed solutions of the YBE were given in the explicit form in Ref. 14. Similarly to the case of canonical chains (9) the twists $\mathcal{F}_{\mathcal{G}_{0<p}}$ produce the sets of deformed Yangians and the new integrable Hamiltonians [cf. the sl(2)-case.[11]].

APPENDIX

The simplest case where the full chain differs nontrivially from the canonical (the deformed carrier space is to be used) is $g=\mathrm{so}(5)$. Three deformation parameters can be intoduced in the corresponding chain of twists. Two of them (ξ and ζ) are continuous and describe the deformation scales in the Jordanian twisting factors. The discrete parameter $\kappa=0,1$ testifies that the extension factor in the chain can be switched off. The twisting element

$$\mathcal{F}_{\mathcal{G}_{0<p}}(\xi,\zeta,\kappa)=\exp(H_{1-2}\otimes\sigma_{G}(\xi,\zeta,\kappa))\cdot\exp\{(\xi\kappa)I_5^{1\otimes 2}(1\otimes e^{-(1/2)\sigma_{1+2}})\}\cdot\exp\{H_{1+2}\otimes\sigma_{1+2}(\xi)\}\tag{A1}$$

contains two Jordanian factors with

$$\sigma_{1+2}(\xi)=\ln(1+\xi E_{1+2})\quad\text{and}\quad\sigma_{G}(\xi,\zeta,\kappa)=\ln(1+\zeta(E_{1-2}-\tfrac{1}{2}\xi\kappa E_1^2)).$$

The corresponding universal $\mathcal{R}$-matrix is

$$\mathcal{R}_{\mathcal{G}_{0<p}}(\xi,\zeta,\kappa)=(\mathcal{F}_{\mathcal{G}_{0<p}}(\xi,\zeta,\kappa))_{21}(\mathcal{F}_{\mathcal{G}_{0<p}}(\xi,\zeta,\kappa))^{-1}.$$

We shall consider it in the defining five-dimensional representation d of so(5). This means that the following matrix realization will be used:

$$\begin{aligned} H_i&=\tfrac{1}{2}(\mathcal{E}_{i,i}-\mathcal{E}_{6-i,6-i}),\\ A_{i,j}&=\mathcal{E}_{i,j}-\mathcal{E}_{6-j,6-i};\\ i,j&=1,\ldots,5. \end{aligned} \tag{A2}$$

As a result we get the solution $d(\mathcal{R}_{\mathcal{G}_{0<p}}(\xi,\zeta,\kappa))$ of the matrix Yang–Baxter equation that can be written in terms of tensor products of 5×5 matrix units $\mathcal{E}_{i,j}$:

$$\begin{aligned} d(\mathcal{R}_{\mathcal{G}_{0<p}}(\xi,\zeta,\kappa))&=d(\mathcal{F}_{\mathcal{G}_{0<p}}(\xi,\zeta,\kappa))_{21}d(\mathcal{F}_{\mathcal{G}_{0<p}}(\xi,\zeta,\kappa))^{-1}\\ &=I\otimes I+(\mathcal{E}_{4,5}-\mathcal{E}_{1,2})\otimes\tfrac{1}{8}\zeta(4(\mathcal{E}_{1,1}-\mathcal{E}_{2,2}+\mathcal{E}_{4,4}-\mathcal{E}_{5,5})+2\zeta(\mathcal{E}_{4,5}-\mathcal{E}_{1,2})+\xi\zeta\kappa\mathcal{E}_{1,5})\\ &\quad+(\mathcal{E}_{4,5}+\mathcal{E}_{1,2})\otimes(-\tfrac{1}{8}\xi\zeta)(\zeta\mathcal{E}_{1,5}+2(\mathcal{E}_{2,5}+\mathcal{E}_{1,4}))+(\mathcal{E}_{3,5}-\mathcal{E}_{1,3})\otimes\xi\kappa(\mathcal{E}_{2,3}-\mathcal{E}_{3,4})\\ &\quad+(\mathcal{E}_{3,4}-\mathcal{E}_{2,3})\otimes\xi\kappa(\mathcal{E}_{3,5}-\mathcal{E}_{1,3})+(\mathcal{E}_{2,5}-\mathcal{E}_{1,4})\otimes\tfrac{1}{4}\xi(2(\mathcal{E}_{1,1}+\mathcal{E}_{2,2}-\mathcal{E}_{4,4}-\mathcal{E}_{5,5})\\ &\quad+\xi(\mathcal{E}_{2,5}-\mathcal{E}_{1,4}))+(\mathcal{E}_{2,5}+\mathcal{E}_{1,4})\otimes\tfrac{1}{8}\xi\zeta(\xi(\kappa-1)\mathcal{E}_{1,5}-2(\mathcal{E}_{4,5}+\mathcal{E}_{1,2}))\\ &\quad+(\mathcal{E}_{1,1}+\mathcal{E}_{2,2}-\mathcal{E}_{4,4}-\mathcal{E}_{5,5})\otimes\tfrac{1}{2}\xi(\mathcal{E}_{1,4}-\mathcal{E}_{2,5})+(\mathcal{E}_{1,1}-\mathcal{E}_{2,2}+\mathcal{E}_{4,4}-\mathcal{E}_{5,5})\\ &\quad\otimes\tfrac{1}{2}\zeta(\mathcal{E}_{1,2}-\mathcal{E}_{4,5})+\mathcal{E}_{1,3}\otimes(-\tfrac{1}{2}\xi\zeta\kappa)\mathcal{E}_{1,3}+\mathcal{E}_{3,5}\otimes(-\tfrac{1}{2}\xi\zeta\kappa)\mathcal{E}_{3,5}+\mathcal{E}_{2,5}\\ &\quad\otimes(-\xi^2\kappa(\mathcal{E}_{1,4})-\tfrac{1}{2}\xi^2\zeta\kappa(\mathcal{E}_{1,5}))(\tfrac{1}{2}\xi^2\kappa\mathcal{E}_{2,4}-\tfrac{1}{4}\xi^2\zeta\kappa\mathcal{E}_{1,4}\\ &\quad-\tfrac{1}{4}\xi\zeta(\kappa+1)(\mathcal{E}_{1,1}-\mathcal{E}_{2,2})+\tfrac{1}{4}\xi\zeta(1-\kappa)(\mathcal{E}_{4,4}-\mathcal{E}_{5,5}))\otimes\mathcal{E}_{1,5}+\mathcal{E}_{1,5}\\ &\quad\otimes(\tfrac{1}{4}\zeta\xi\kappa(\mathcal{E}_{1,1}-\mathcal{E}_{2,2}+\mathcal{E}_{4,4}-\mathcal{E}_{5,5})-\tfrac{1}{4}\xi\zeta(\mathcal{E}_{1,1}-\mathcal{E}_{2,2}-\mathcal{E}_{4,4}+\mathcal{E}_{5,5})+\tfrac{1}{2}\xi^2\kappa\mathcal{E}_{2,4}\\ &\quad+\tfrac{1}{8}\xi^2\zeta(3\kappa+1)\mathcal{E}_{1,4}+\tfrac{1}{8}\xi^2\zeta(\kappa+1)\mathcal{E}_{2,5}+\tfrac{1}{8}\xi\zeta^2(\kappa+1)\mathcal{E}_{4,5}\\ &\quad+\tfrac{1}{8}\xi\zeta^2(1-\kappa)\mathcal{E}_{1,2}+\tfrac{1}{16}\xi^2\zeta^2(3\kappa+1)\mathcal{E}_{1,5}). \end{aligned}$$

This expression presents the two-dimensional set of R-matrices. One can consider the submanifolds corresponding to the special values of the parameters. For $\zeta=0$, without the last (deformed) Jordanian factor, we get the R-matrix for the extended Jordanian twisted algebra $U_{\mathcal{E}J}(\mathrm{so}(5))$. For $\kappa=0$ we obtain the two-Jordanian R-matrix for $U_{\mathcal{J}_1\mathcal{J}_0}(\mathrm{so}(5))$. This is the result of two independent Jordanian twists [corresponding to two orthogonal long roots of so(5)]. For $\zeta=0$ with $\kappa=0$ and for $\xi=0$ we have two pure Jordanian R-matrices equivalent up to the renumeration of the generators.

An algebraic approach to Macdonald–Koornwinder polynomials: Rodrigues-type formula and inner product identity

Akinori Nishino[a] and Yasushi Komori[b]
Department of Physics, Graduate School of Science, University of Tokyo, Hongo 7-3-1, Bunkyo-ku, Tokyo 113-0033, Japan

(Received 17 October 2000; accepted for publication 11 July 2001)

We study Macdonald–Koornwinder polynomials in the context of double affine Hecke algebras. Nonsymmetric Macdonald–Koornwinder polynomials are constructed by use of raising operators provided by a representation theory of the double affine Hecke algebra associated with $A_{2l}^{(2)}$-type affine root system. This enables us to evaluate diagonal terms of scalar products of the nonsymmetric polynomials algebraically. The Macdonald–Koornwinder polynomials are expressed by linear combinations of the nonsymmetric counterparts. We show a new proof of the inner product identity of the Macdonald–Koornwinder polynomials without Opdam–Cherednik's shift operators. © *2001 American Institute of Physics.*
[DOI: 10.1063/1.1398334]

I. INTRODUCTION

Macdonald introduced a new class of orthogonal polynomials,[1–3] which are associated with root systems and are considered as q-deformations of Heckman–Opdam's Jacobi polynomials.[4–6] Since then, the Macdonald polynomials and their descendants have appeared in various areas of mathematics and physics and are studied from several viewpoints.[7–13] Macdonald gave some conjectures for his polynomials, i.e., constant terms, inner products, evaluations, and so on. Cherednik clarified an algebraic structure of the Macdonald polynomials by means of affine Hecke algebras.[14–17] He indeed proved several of the conjectures through a representation theory of the affine Hecke algebra. Among them, the shift operator approach, which was first developed by Opdam in the case of Jacobi polynomials, was generalized in the framework of double affine Hecke algebras to give a proof of Macdonald's inner product identity.

In our previous papers,[18–21] we presented Rodrigues-type formulas which give algebraic expressions for the nonsymmetric polynomials corresponding to the Jacobi and the Macdonald polynomials by use of raising operators. It is remarkable that our raising operators are provided by a representation theory of Cherednik's double affine Hecke algebras in a natural way and enable us to calculate diagonal terms of scalar products for the nonsymmetric polynomials except for those of their constant terms. Moreover we showed that Weyl-symmetrization of the nonsymmetric polynomials gives the Jacobi and the Macdonald polynomials algebraically and we evaluated their inner products without Opdam–Cherednik's shift operators.

Koornwinder introduced multivariable generalizations of the Askey–Wilson polynomials.[22] Koornwinder's polynomials reduce to two types of Macdonald polynomials associated with a *BC*-type nonreduced root system through a specialization of their parameters, which is a reason why they are called the Macdonald–Koornwinder polynomials nowadays. An explicit commutative family of difference operators which characterizes the Macdonald–Koornwinder polynomials and some properties of the polynomials in the self-dual point were investigated by van Diejen.[23,24]

Noumi showed that Cherednik's affine Hecke algebraic approach can also be applied to the Macdonald–Koornwinder polynomials,[25] which was originally proposed by Macdonald[26] and was extensively studied by other people later.[27–30]

Although the Macdonald and Macdonald–Koornwinder polynomials share the similar affine Hecke algebraic approach we have mentioned previously, it seems that a unified approach to both polynomials has not been established. This is because, as for the latter polynomials, the relationship with root systems has not been clarified enough; namely, Noumi employed Lusztig's representation of the $C^{(1)}$-type Hecke algebra to study the Macdonald–Koornwinder polynomials while Koornwinder first introduced them as BC-type Askey–Wilson polynomials. Macdonald's $C^\vee C$-type nonreduced affine root system seems to give a solution on this problem.[26,29,30] However, in studying the Macdonald–Koornwinder polynomials with the $C^\vee C$-type root system, one has to consider the nonextended affine Weyl group and hence the Hecke algebra, since, if one extends the Hecke algebra to the affine one, two degrees of freedom in parameters of the polynomials are lost due to a nontrivial automorphism of the Dynkin diagram. In this paper, we introduce an affine Hecke algebra associated with an affine root system in an analogous way to Refs. 31 and 32. From our point of view, affine Hecke algebras employed by Cherednik in the study of the Macdonald polynomials are associated with affine root systems of nontwisted affine Lie algebras. An affine Hecke algebra associated with the $A_{2l}^{(2)}$-type affine root system enables us to treat the Macdonald–Koornwinder polynomials. We thus obtain a new and unified viewpoint for the Macdonald and Macdonald–Koornwinder polynomials. To give a new proof of an inner product identity for the Macdonald–Koornwinder polynomials is a goal of this paper.

This paper is organized as follows: In Sec. II, we briefly summarize known facts on affine root systems of affine Lie algebras[33] and introduce extended affine Weyl groups in such a way that they preserve the affine root systems.[31,32,34] We define the affine Hecke algebra as a deformation of group algebra of the extended affine Weyl group of type $X_N^{(r)}$ and refer to it as the affine Hecke algebra of type $X_N^{(r)}$. The Macdonald–Koornwinder polynomials are associated with the affine Hecke algebra of type $A_{2l}^{(2)}$ as we have described previously. In giving a representation of the affine Hecke algebra of type $A_{2l}^{(2)}$, we encounter a special situation discussed by Lusztig,[35] which is investigated in detail in the Appendix. After introducing the double affine Hecke algebra of $A_{2l}^{(2)}$-type in analogy with Cherednik's works,[14–17] we give its representation in the endomorphism of the Laurent polynomial ring (Theorem 2.16). In Sec. III, we consider nonsymmetric Macdonald–Koornwinder polynomials which are joint eigenvectors of commutative Cherednik operators. In a way similar to our previous papers, we provide a Rodrigues-type formula of the nonsymmetric polynomials (Theorem 3.14) and evaluate diagonal terms of their scalar products explicitly (Theorem 3.15 and Proposition 3.16). We construct the Macdonald–Koornwinder polynomials through the Weyl-symmetrization of the nonsymmetric polynomials (Proposition 3.21 and Corollary 3.22), and prove their inner product identities (Theorem 3.24). Section IV is devoted to concluding remarks.

II. DOUBLE AFFINE HECKE ALGEBRAS

A. Affine root systems and extended affine Weyl groups

We start to review affine root systems of affine Lie algebras.[33] Let $\mathfrak{g}$ be the affine Lie algebra of type $X_N^{(r)}$ associated with a generalized Cartan matrix $A=(a_{ij})_{i,j\in I}$ where $I:=\{0,1,2,\ldots,l\}$ is a set of indices, and let $S(A)$ be its Dynkin diagram. We denote by $\{a_i|i\in I\}$ the set of numerical labels of $S(A)$ and by $\{a_i^\vee|i\in I\}$ that of $S({}^tA)$. Let $\mathfrak{h}$ be the Cartan subalgebra of $\mathfrak{g}$. Let $R\subset\mathfrak{h}^*$ be the affine root system. We take the set of simple roots $\Pi:=\{\alpha_i|i\in I\}\subset\mathfrak{h}^*$ and the set of simple coroots $\Pi^\vee:=\{\alpha_i^\vee|i\in I\}\subset\mathfrak{h}$ such that $\langle\alpha_i,\alpha_j^\vee\rangle=a_{ij}$. Define the central element K of $\mathfrak{g}$ and a null-root $\delta\in R$ by $K:=\Sigma_{i\in I}\,a_i^\vee\alpha_i^\vee$ and $\delta:=\Sigma_{i\in I}\,a_i\alpha_i$, respectively. We fix elements $\Lambda_0^\vee\in\mathfrak{h}$ and $\Lambda_0\in\mathfrak{h}^*$ satisfying

$$\langle\alpha_i,\Lambda_0^\vee\rangle=\delta_{0i},\quad \langle\Lambda_0,\alpha_i^\vee\rangle=\delta_{0i},\quad \text{for } 0\leqslant i\leqslant l,\quad \langle\Lambda_0,\Lambda_0^\vee\rangle=0. \tag{2.1}$$

We introduce the root lattice Q, the coroot lattice $Q^\vee$, the weight lattice P, and the coweight lattice $P^\vee$, respectively, as

$$\begin{aligned} Q &:= \bigoplus_{i\in I} \mathbb{Z}\alpha_i \subset P := \bigoplus_{i\in I} \mathbb{Z}\Lambda_i \oplus \mathbb{C}\delta \subset \mathfrak{h}^*, \\ Q^\vee &:= \bigoplus_{i\in I} \mathbb{Z}\alpha_i^\vee \subset P^\vee := \bigoplus_{i\in I} \mathbb{Z}\Lambda_i^\vee \oplus \mathbb{C}K \subset \mathfrak{h}, \end{aligned} \tag{2.2}$$

where the fundamental weights Λ_i and coweights $\Lambda_i^\vee$ satisfy $\langle \alpha_i, \Lambda_j^\vee \rangle = \langle \Lambda_i, \alpha_j^\vee \rangle = \delta_{ij}$. We introduce a nondegenerate symmetric bilinear $\mathbb{C}$-value form $(.|.)$ on $\mathfrak{h}$, from which we have an isomorphism $\nu: \mathfrak{h} \to \mathfrak{h}^*$ defined by

$$\langle \nu(h), h' \rangle = (h|h') \quad \text{for } h, h' \in \mathfrak{h},$$

and the induced bilinear form $(.|.)$ on $\mathfrak{h}^*$. We have $a_i^\vee \nu(\alpha_i^\vee) = a_i \alpha_i$, $\nu(K) = \delta$ and $\nu(\Lambda_0^\vee) = a_0 \Lambda_0$.

Let $\mathring{I} := \{1,2,...,l\}$ be another set of indices, and let $\mathring{\Pi} := \{\alpha_i | i \in \mathring{I}\} (\subset \Pi)$ and $\mathring{\Pi}^\vee := \{\alpha_i^\vee | i \in \mathring{I}\}$ $(\subset \Pi^\vee)$. Let $\mathring{\mathfrak{h}}$ (respectively, $\mathring{\mathfrak{h}}_\mathbb{R}$) denote the linear span over $\mathbb{C}$ (respectively, $\mathbb{R}$) of $\mathring{\Pi}^\vee$. The dual notions $\mathring{\mathfrak{h}}^*$ and $\mathring{\mathfrak{h}}_\mathbb{R}^*$ are defined similarly. Set $\mathfrak{h}_\mathbb{R} = \mathring{\mathfrak{h}}_\mathbb{R} + \mathbb{R}K + \mathbb{R}\Lambda_0^\vee$ and $\mathfrak{h}_\mathbb{R}^* = \mathring{\mathfrak{h}}_\mathbb{R}^* + \mathbb{R}\Lambda_0 + \mathbb{R}\delta$. We define the "classical" root system by $\mathring{R} := R \cap \mathring{\mathfrak{h}}^*$, which corresponds to a root system for a finite-dimensional simple Lie algebra, and fix its decomposition by the disjoint union $\mathring{R} = \mathring{R}_+ \cup \mathring{R}_-$, where $\mathring{R}_+ (\subset \mathring{R})$ is the set of positive roots relative to $\mathring{\Pi}$ and $\mathring{R}_- := -\mathring{R}_+$. The sets of short and long roots in $\mathring{R}$ are, respectively, denoted by $\mathring{R}^s$ and $\mathring{R}^l$. We use the notation $\mathring{Q}$, $\mathring{Q}^\vee$, $\mathring{P}$, and $\mathring{P}^\vee$ for the classical root, the classical coroot, the classical weight, and the classical coweight lattices,

$$\begin{aligned} \mathring{Q} &:= \bigoplus_{i\in \mathring{I}} \mathbb{Z}\alpha_i \subset \mathring{P} := \bigoplus_{i\in \mathring{I}} \mathbb{Z}\overline{\Lambda_i} \subset \mathring{\mathfrak{h}}^*, \\ \mathring{Q}^\vee &:= \bigoplus_{i\in \mathring{I}} \mathbb{Z}\alpha_i^\vee \subset \mathring{P}^\vee := \bigoplus_{i\in \mathring{I}} \mathbb{Z}\overline{\Lambda_i^\vee} \subset \mathring{\mathfrak{h}}, \end{aligned} \tag{2.3}$$

where $\overline{\lambda}$ means the orthogonal projection of $\lambda \in \mathfrak{h}^*$ (respectively, $\lambda \in \mathfrak{h}$) on $\mathring{\mathfrak{h}}^*$ (respectively, $\mathring{\mathfrak{h}}$). Let $\mathring{Q}_+$, $\mathring{P}_+$, $\mathring{Q}_+^\vee$ and $\mathring{P}_+^\vee$ denote the corresponding lattices with $\mathbb{Z}_+$ instead of $\mathbb{Z}$.

The set of real roots $R^{\mathrm{re}} \subset R$ are given by

$$R^{\mathrm{re}} := \begin{cases} \{\alpha + n\gamma_\alpha \delta | \alpha \in \mathring{R}, n \in \mathbb{Z}\} & \text{if } A \text{ is not of type } A_{2l}^{(2)} \\ \{\alpha + n\gamma_\alpha \delta | \alpha \in \mathring{R}, n \in \mathbb{Z}\} & \\ \quad \cup \{\tfrac{1}{2}(\alpha + (2n+1)\delta) | \alpha \in \mathring{R}^l, n \in \mathbb{Z}\} & \text{if } A \text{ is of type } A_{2l}^{(2)} \end{cases}, \tag{2.4}$$

where $\gamma_\alpha = r$ if $\alpha \in R^l$ and $\gamma_\alpha = 1$ otherwise. Define the set of positive affine roots by $R_+ := \{\alpha + n\delta \in R^{\mathrm{re}} | \alpha \in \mathring{R}, n > 0\} \cup \mathring{R}_+$. Let $\theta := \delta - a_0 \alpha_0 (\in \mathring{Q})$. One sees that $(\theta|\theta) = 2a_0$, $\theta = a_0 \nu(\theta^\vee)$ and $(\theta^\vee|\theta^\vee) = 2a_0^{-1}$.

Next we consider Weyl groups which act on the root systems. Define a reflection on $\mathfrak{h}^*$ with respect to the hyperplane orthogonal to $\alpha \in R^{\mathrm{re}}$ by

$$s_\alpha(\lambda) := \lambda - \langle \lambda, \alpha^\vee \rangle \alpha \quad \text{for } \lambda \in \mathfrak{h}^*.$$

Simple reflections $\{s_i := s_{\alpha_i} | i \in I\}$ are related to each other by braid relations (Coxeter relations) $(s_i s_j)^{m_{ij}} = 1$,[36] where $m_{ij} = 2,3,4,6$ if α_i and α_j are connected by 0, 1, 2, 3 laces in the Dynkin

diagram $S(A)$, respectively. The reflections $\{s_\alpha|\alpha\in\Pi\}$ generate the affine Weyl group, which we denote by W. The affine Weyl group includes the Weyl group $\mathring{W}$, which is generated by $\{s_\alpha|\alpha\in\mathring{\Pi}\}$, as a subgroup. For $\alpha,\beta:=\delta-h\alpha\in R^{\mathrm{re}}$ with some h, one sees

$$s_\alpha s_\beta(\lambda)=\lambda+\langle\lambda,K\rangle\nu(\beta^\vee)-(\langle\lambda,\beta^\vee\rangle+\tfrac{1}{2}|\beta^\vee|^2\langle\lambda,K\rangle)\delta \quad \text{for } \lambda\in\mathfrak{h}^*.$$

Motivated by this formula, we introduce the following endomorphism $\tau_\mu,(\mu\in\mathring{\mathfrak{h}}^*)$ of $\mathfrak{h}^*$:

$$\tau_\mu(\lambda)=\lambda+\langle\lambda,K\rangle\mu-((\lambda|\mu)+\tfrac{1}{2}|\mu|^2\langle\lambda,K\rangle)\delta \quad \text{for } \lambda\in\mathfrak{h}^*.$$

They satisfy the additivity property $\tau_\lambda\tau_\mu=\tau_{\lambda+\mu}$, $(\lambda,\mu\in\mathring{\mathfrak{h}}^*)$. It is known that the affine Weyl group is isomorphic to the semidirect product $W\simeq\mathring{W}\ltimes\tau_M$ where $M:=\nu(\mathbb{Z}(\mathring{W}(\theta^\vee)))\subset\mathring{\mathfrak{h}}^*$.

Definition 2.1 (Extended affine Weyl groups): Let $\widetilde{M}:=\{\lambda\in\mathring{\mathfrak{h}}^*|\alpha\in R^{\mathrm{re}},(\alpha|\lambda)\in\gamma_\alpha\mathbb{Z}\}$. *The extended affine Weyl group of type* $X_N^{(r)}$ *is the semidirect product* $\widetilde{W}:=\mathring{W}\ltimes\tau_{\widetilde{M}}$.[31,32]

Indeed the lattice $\widetilde{M}$ is given by

$$\widetilde{M}=\begin{cases}\nu(\mathring{P}^\vee) & \text{if } r=1\\ \mathring{P} & \text{otherwise.}\end{cases} \tag{2.5}$$

Then we take a basis $\{\lambda_i|i\in\mathring{I}\}$ of $\widetilde{M}$ as $\lambda_i=\nu(\overline{\Lambda_i^\vee})$ if $r=1$ and $\lambda_i=\overline{\Lambda_i}$ otherwise. One finds that $\widetilde{W}$ is defined so as to preserve the affine root system R.

Proposition 2.2: Let $C^\vee:=\{\lambda\in\mathfrak{h}_{\mathbb{R}}^*|(\lambda|\alpha_i)\geqslant 0 \text{ for } 0\leqslant i\leqslant l\}$ *be the fundamental chamber and let* $\Omega:=\{w\in\widetilde{W}|w(C^\vee)=C^\vee\}$. *The extended affine Weyl group is isomorphic to the semidirect product* $\widetilde{W}\simeq\Omega\ltimes W$.

Let $\mathcal{O}$ be the set of indices of the image of α_0 by the automorphism of the Dynkin diagram $S(A)$. It is known that the elements in Ω are indexed by $r\in\mathcal{O}$[14–16] and each $\omega_r\in\Omega$ is distinguished by $\omega_r(\alpha_0)=\alpha_r$.

Define $\mathfrak{h}_s^*:=\{\lambda\in\mathfrak{h}_{\mathbb{R}}^*|\langle\lambda,K\rangle=s\}$ for $s\in\mathbb{R}$. The action of $\widetilde{W}$ on $\mathfrak{h}_{-1}^*\bmod\mathbb{R}\delta$ is faithful. We identify $\mathfrak{h}_{-1}^*\bmod\mathbb{R}\delta$ with $\mathring{\mathfrak{h}}_{\mathbb{R}}^*$ by projection and obtain an isomorphism af from $\widetilde{W}$ onto a group of affine transformation W_{af} of $\mathring{\mathfrak{h}}_{\mathbb{R}}^*$. Then we have the action of W_{af} on $\overline{\lambda}\in\mathring{\mathfrak{h}}_{\mathbb{R}}^*$,

$$\mathrm{af}(w)(\overline{\lambda})=\overline{w(\lambda)} \quad \text{for } \lambda\in\mathfrak{h}_{-1}^*,$$

from which we observe for $\lambda\in\mathring{\mathfrak{h}}_{\mathbb{R}}^*$ that

$$\mathrm{af}(w)(\lambda)=w(\lambda) \quad \text{for } w\in\mathring{W}, \quad \mathrm{af}(\tau_\mu)(\lambda)=\lambda-\mu \quad \text{for } \mu\in\widetilde{M}.$$

The action of W_{af} induces a function $(\lambda+n\delta)(\mu)=(\lambda|\mu)-n$ on $\mathring{\mathfrak{h}}_{\mathbb{R}}^*$ satisfying

$$(w(\lambda+n\delta))(\mu)=(\lambda+n\delta)(\mathrm{af}(w^{-1})(\mu)) \quad \text{for } \lambda+n\delta\in\mathfrak{h}_0^*, \quad \mu\in\mathring{\mathfrak{h}}_{\mathrm{R}}^*.$$

We define a length of an element $w\in\widetilde{W}$ by

$$\ell(w):=|R_w| \quad \text{where } R_w:=R_+\cap wR_-. \tag{2.6}$$

Here R_w is the set of positive roots which become negative roots by the action of w^{-1}. If we take a reduced expression of $w\in\widetilde{W}$ as $w=s_{i_1}s_{i_2}\ldots s_{i_k}\omega_r,(\ell(w)=k)$, the set R_w is explicitly given by $R_w=\{\alpha^{(1)}=\alpha_{i_1},\alpha^{(2)}=s_{i_1}(\alpha_{i_2}),\ldots,\alpha^{(k)}=s_{i_1}s_{i_2}\ldots s_{i_{k-1}}(\alpha_{i_k})\}$, which is independent of the decomposition of w. For $w=\tau_{-\lambda}$, $(\lambda\in\mathring{\mathfrak{h}}^*)$, we have

$$R_{\tau-\lambda}=\begin{cases}\left\{\alpha+n\gamma_\alpha\delta\,\middle|\,\alpha\in\mathring{R}_+,\frac{1}{\gamma_\alpha}(\lambda|\alpha)>n\geqslant 0,\ \text{or}\ \alpha\in\mathring{R}_-,\frac{1}{\gamma_\alpha}(\lambda|\alpha)\geqslant n>0\right\} & \text{if } A \text{ is not of type } A_{2l}^{(2)},\\ \left\{\alpha+n\gamma_\alpha\delta\,\middle|\,\alpha\in\mathring{R}_+,\frac{1}{\gamma_\alpha}(\lambda|\alpha)>n\geqslant 0,\ \text{or}\ \alpha\in\mathring{R}_-,\frac{1}{\gamma_\alpha}(\lambda|\alpha)\geqslant n>0\right\}\\ \quad\cup\left\{\frac{1}{2}(\alpha+(2n+1)\delta)\,\middle|\,\alpha\in\mathring{R}^l_+,\frac{1}{2}(\lambda|\alpha)>n\geqslant 0,\ \text{or}\ \alpha\in\mathring{R}^l_-,\frac{1}{2}(\lambda|\alpha)>n\geqslant 0\right\}\\ \quad\text{if } A \text{ is of type } A_{2l}^{(2)}\end{cases}. \tag{2.7}$$

We denote the set of distinct weights lying in the $\mathring{W}$-orbit of $\mu\in\tilde{M}$ by $\mathring{W}(\mu)$ and a unique dominant weight in $\mathring{W}(\mu)$ by $\mu^+(\in\tilde{M}_+)$. Define the isotropy group $\mathring{W}_\mu:=\{w\in\mathring{W}|w(\mu)=\mu\}$ for $\mu\in\tilde{M}_+$. In fact $\mathring{W}_\mu$ is genetrated by simple reflections s_i which it contains. Let $\{s_i|i\in\mathring{J}(\subset\mathring{I})\}$ be the set of simple reflections fixing $\mu\in\tilde{M}_+$ and let $\mathring{W}^\mu:=\{w\in\mathring{W}|\ell(ws_i)>\ell(w)\ \text{for all}\ i\in\mathring{J}\}$.

Proposition 2.3 (cf. Ref. 36): Given $w\in\mathring{W}$ and $\mu\in\tilde{M}_+$, there is a unique $u\in\mathring{W}^\mu$ and a unique $v\in\mathring{W}_\mu$ such that $w=uv$.

The above-given proposition shows that, for a general weight $\mu\in\tilde{M}$, there exists a unique element $w\in\mathring{W}^{\mu^+}$ such that $w(\mu^+)=\mu$.

B. Double affine Hecke algebras

We introduce affine Hecke algebras associated with affine root systems in an analogous way to Lusztig's works.[35] Let B be the braid group with generators $T_w,(w\in\tilde{W})$ satisfying braid relations:

$$T_{wv}=T_wT_v\quad\text{if}\ \ell(wv)=\ell(w)+\ell(v)\quad\text{for}\ w,v\in\tilde{W}. \tag{2.8}$$

We write $T_i,(i\in I)$ for T_{s_i}. One sees that, if a reduced expression of $w\in\tilde{W}$ is taken as $w=s_{i_1}s_{i_2}\cdots s_{i_k}\omega_r$, the corresponding element of the braid group B has an expression $T_w=T_{i_1}T_{i_2}\cdots T_{i_k}T_{\omega_r}$. Among the elements $\{T_w\in B|w\in\tilde{W}\}$, we define a set of elements $\{Y^\lambda\in B|\lambda\in\tilde{M}\}$ by

$$\begin{aligned}&(i)\quad Y^\lambda=T_{\tau_{-\lambda}}\ \text{for}\ \lambda\in\tilde{M}_+,\\ &(ii)\quad Y^\lambda=Y^\mu(Y^\nu)^{-1}\ \text{if}\ \lambda=\mu-\nu\in\tilde{M}\ \text{and}\ \mu,\nu\in\tilde{M}_+.\end{aligned} \tag{2.9}$$

The elements $\{Y^\lambda\}$ are well defined for all $\lambda\in\tilde{M}$. By definition (2.8), one has the additivity property $Y^{\lambda+\mu}=Y^\lambda Y^\mu$, $(\lambda,\mu\in\tilde{M})$, which provides the following significant proposition:

Proposition 2.4: The elements $\{Y^\lambda\in B|\lambda\in\tilde{M}\}$ are mutually commutative, and hence the braid group B includes a commutative subgroup generated by $\{Y^\lambda|\lambda\in\tilde{M}\}$.

Proposition 2.5: The elements $\{Y^\lambda,T_i|\lambda\in\tilde{M},i\in\mathring{I}\}$ generate B as a group.

In what follows, we restrict our discussions to the affine root system of type $A_{2l}^{(2)}$ since we are now interested in the Macdonald–Koornwinder polynomials; what it means here will soon be clear. Recall that there is no nontrivial automorphism of the Dynkin diagram $S(A)$ for the $A_{2l}^{(2)}$-type affine root system, that is, $\Omega=\{1\}$, while the corresponding Coxeter diagram has a nontrivial automorphism. The extended affine Weyl group of type $A_{2l}^{(2)}$ is isomorphic to the (nonextended) affine Weyl group of type $C_l^{(1)}$, that is, $\tilde{W}=W$, but structures of weight and coweight lattices they act on are different. We introduce the set of indeterminates $\{t_\alpha|\alpha\in R^{\mathrm{re}}\}$ such that $t_\alpha=t_{w(\alpha)}$ for $w\in\tilde{W}$. Indeed there exist three kinds of indeterminates corresponding to the following sets of real roots with different lengths:

$$(R^{\mathrm{re}})^s=\{\tfrac{1}{2}(\alpha+(2n+1)\delta)|\alpha\in\mathring{R}^l,n\in\mathbb{Z}\},$$

$$(R^{\mathrm{re}})^m=\{\alpha+n\delta|\alpha\in\mathring{R}^s,n\in\mathbb{Z}\},$$

$$(R^{\mathrm{re}})^l=\{\alpha+2n\delta|\alpha\in\mathring{R}^l,n\in\mathbb{Z}\}.$$

We denote the orthogonal projection of R^{re} on $\mathring{\mathfrak{h}}^*$ by $\overline{R^{\mathrm{re}}}$, which is nothing but the BC_l-type nonreduced root system. Note that $\overline{R^{\mathrm{re}}}$ has three kinds of root length, i.e., long, middle, and short roots. Let $\mathbb{C}_t=\mathbb{C}(\{t_\alpha^{1/2}\})$ denote the field of rational functions over $\mathbb{C}$ in square roots of these indeterminates $\{t_\alpha\}$.

Definition 2.6 (affine Hecke algebra): The affine Hecke algebra $H(\tilde{W})$ is the quotient of the group algebra $\mathbb{C}_t[B]$ by the two-sided ideal generated by

$$(T_i-t_i^{1/2})(T_i+t_i^{-1/2})\quad\text{for } 0\leqslant i\leqslant l,$$

where we write t_i for t_{α_i}.

The inverse element of T_i in $H(\tilde{W})$ is given by $T_i^{-1}=T_i-(t_i^{1/2}-t_i^{-1/2})$. One sees that the affine Hecke algebra $H(\tilde{W})$ is indeed generated over the field $\mathbb{C}_t$ by $\{T_i|i\in I\}$ satisfying

$$\begin{aligned}&\text{(i)}\quad (T_i-t_i^{1/2})(T_i+t_i^{-1/2})=0\quad\text{for } 0\leqslant i\leqslant l,\\ &\text{(ii)}\quad T_iT_jT_i\cdots=T_jT_iT_j\cdots,\quad m_{ij}\text{ factors on each side.}\end{aligned}\tag{2.10}$$

Proposition 2.7: Let $\lambda\in\tilde{M}$. In $H(\tilde{W})$, one sees

$$\begin{aligned}&(i)\quad T_iY^\lambda=Y^\lambda T_i\quad \textit{if } \langle\lambda,\alpha_i^\vee\rangle=0\ \textit{ for }\ \alpha_i\in\mathring{\Pi},\\ &(ii)\quad T_iY^{s_i(\lambda)}T_i=Y^\lambda\quad \textit{if } \langle\lambda,\alpha_i^\vee\rangle=1\ \textit{ for }\ \alpha_i\notin 2\tilde{M},\\ &(iii)\quad Y^{s_i(\lambda)}T_i-T_i^{-1}Y^\lambda+(t_{\tilde{\alpha}_i}^{1/2}-t_{\tilde{\alpha}_i}^{-1/2})Y^{\lambda-(1/2)\alpha_i}=0\quad \textit{if } \langle\lambda,\alpha_i^\vee\rangle=1\ \textit{ for }\ \alpha_i\in 2\tilde{M}.\end{aligned}\tag{2.11}$$

Here $\tilde{\alpha}\in R^{\mathrm{re}}$ is the root associated with the reflection $s_{\tilde{\alpha}}=\omega s_\alpha\omega^{-1}$ where ω is the automorphism of the Coxeter diagram corresponding to the Dynkin diagram $S(A)$.

We give a proof of Proposition 2.7 in Appendix.

Proposition 2.8: The affine Hecke algebra $H(\tilde{W})$ is also generated by the elements $\{T_i,Y^\lambda|i\in\mathring{I},\lambda\in\tilde{M}\}$ satisfying (2.10) and (2.11).[35]

By using Proposition 2.7 recursively, we have the following relations:

Proposition 2.9: For $\lambda\in\tilde{M}$, one has

$$T_iY^\lambda-Y^{s_i(\lambda)}T_i=\frac{(\check{t}_{\tilde{\alpha}_i}^{1/2}-\check{t}_{\tilde{\alpha}_i}^{-1/2})Y^{-(1/2)\alpha_i}+t_i^{1/2}-t_i^{-1/2}}{Y^{-\alpha_i}-1}(Y^{s_i(\lambda)}-Y^\lambda)\quad \textit{for }\ 1\leqslant i\leqslant l,\tag{2.12}$$

in $H(\tilde{W})$. Here we have put $\check{t}_\alpha=t_\alpha$ if $\alpha\in(R^{\mathrm{re}})^l$ and $\check{t}_\alpha=1$ otherwise.

Corollary 2.10: The element $Y^\lambda+Y^{s_\alpha(\lambda)},(\lambda\in\tilde{M},\alpha\in\mathring{\Pi})$ commutes with T_{s_α}.

Hence it is clear that elements from the $\mathring{W}$-invariant Laurent polynomial ring $\mathbb{C}_t[Y]^{\mathring{W}}$ are in the center of the affine Hecke algebra $\mathcal{Z}(H(\tilde{W}))$. In fact, the following stronger statement is known:

Theorem 2.11 (G. Lusztig): $\mathcal{Z}(H(\tilde{W}))=\mathbb{C}_t[Y]^{\mathring{W}}$.

We now define the double affine Hecke algebra $\mathcal{H}(\tilde{W})$ associated with the $A_{2l}^{(2)}$-type affine root system. We introduce another set of $\tilde{W}$-invariant indeterminates $\{u_\alpha|\alpha\in R^{\mathrm{re}}\}$ such that $u_\alpha=1$ if $\alpha\in(R^{\mathrm{re}})^m$, and put $u_i:=u_{\alpha_i}$. We take the field $\mathbb{K}:=\mathbb{C}(q^{1/2},\{t_\alpha^{1/2},u_\alpha^{1/2}\})$ of rational functions over $\mathbb{C}$ in square roots of indeterminates $\{q,t_\alpha,u_\alpha\}$.

Definition 2.12 (double affine Hecke algebra): The double affine Hecke algebra $\mathcal{H}(\tilde{W})$ *is generated over the field* $\mathbb{K}$ *by* $\{T_i, X^\mu | i \in I, \mu \in \mathring{P}\}$ *satisfying*

(i) *the relations* (2.10) *for* $\{T_i\}$,

(ii) $X^{\mu+\nu} = X^\mu X^\nu$ *for* $\mu, \nu \in \mathring{P}$,

(iii) $T_i X^\mu = X^\mu T_i$ *if* $\langle \mu, \alpha_i^\vee \rangle = 0$ *for* $\alpha_i \in \mathring{\Pi}$,

$$T_0 X^\mu = X^\mu T_0 \quad \text{if } \langle \mu, -\theta^\vee \rangle = 0,$$

(iv) $X^{s_i(\mu)} T_i^{-1} - T_i X^\mu - (u_{\tilde{\alpha}_i}^{1/2} - u_{\tilde{\alpha}_i}^{-1/2}) X^{\mu - (1/2)\alpha_i} = 0$ *if* $\langle \mu, \alpha_i^\vee \rangle = 1$ *for* $\alpha_i \in \mathring{\Pi}$,

$$X^{s_0(\mu)} T_0^{-1} - T_0 X^\mu - (u_l^{1/2} - u_l^{-1/2}) X^{\mu - \alpha_0} = 0 \quad \text{if } \langle \mu, -\theta^\vee \rangle = 1, \tag{2.13}$$

where

$$X^\mu = q^h \prod_{i \in \mathring{I}} (X^{\overline{\Lambda}_i})^{\mu_i} \quad \text{for } \mu = \sum_{i \in \mathring{I}} \mu_i \overline{\Lambda}_i + h\delta \in \mathring{P} \oplus \frac{1}{2}\mathbb{Z}\delta.$$

Proposition 2.13: For $\mu \in \mathring{P}$, *one has*

$$T_i X^\mu - X^{s_i(\mu)} T_i = \frac{(u_{\tilde{\alpha}_i}^{1/2} - u_{\tilde{\alpha}_i}^{-1/2}) X^{(1/2) n_i \alpha_i} + t_i^{1/2} - t_i^{-1/2}}{X^{n_i \alpha_i} - 1} (X^{s_i(\mu)} - X^\mu) \quad \text{for } 0 \leqslant i \leqslant l, \tag{2.14}$$

where $\{n_\alpha | \alpha \in R^{\mathrm{re}}\}$ *is defined by*

$$n_\alpha := \begin{cases} 2 & \text{if } \alpha \in (R^{\mathrm{re}})^s, \\ 1 & \text{otherwise,} \end{cases} \qquad n_i := n_{\alpha_i} \quad \text{for } 0 \leqslant i \leqslant l.$$

Proposition 2.14: The double affine Hecke algebra $\mathcal{H}(\tilde{W})$ *is also generated by the elements* $\{T_i, X^\mu, Y^\lambda | i \in \mathring{I}, \mu \in \mathring{P}, \lambda \in \tilde{M}\}$.

Proposition 2.15: There exists the following map which can be extended to the anti-involution $*: \mathcal{H}(\tilde{W}) \to \mathcal{H}(\tilde{W})$:

$$*: \ T_i \mapsto T_i^{-1}, \quad X^{\overline{\Lambda}_i} \mapsto X^{-\overline{\Lambda}_i}, \quad Y^{\lambda_i} \mapsto Y^{-\lambda_i} \quad \text{for } 1 \leqslant i \leqslant l,$$

$$q \mapsto q^{-1}, \quad t_\alpha \mapsto t_\alpha^{-1}, \quad u_\alpha \mapsto u_\alpha^{-1}. \tag{2.15}$$

We present a representation of the double affine Hecke algebra $\mathcal{H}(\tilde{W})$ in the endomorphism of the Laurent polynomial ring of variables $\{x^{\overline{\Lambda}_i} | i \in \mathring{I}\}$ over $\mathbb{K}$, which we denote by End $(\mathbb{K}[\mathring{P}])$. To begin with, we put $x^\delta = q$ and define the action of $w \in \tilde{W}$ on $\mathbb{K}[\mathring{P}]$ by

$$w(x^\mu) := x^{w(\mu)} \quad \text{for } x^\mu \in \mathbb{K}[\mathring{P}], \tag{2.16}$$

in particular, $\tau_\lambda(x^\mu) = q^{-(\lambda|\mu)} x^\mu$, $(\lambda \in \tilde{M})$.

Next, we introduce multiplication operators $\{\hat{X}^{\hat{\mu}} \in \mathrm{End}(\mathbb{K}[\mathring{P}]) | \hat{\mu} = \mu + h\delta \in \mathring{P} \oplus \frac{1}{2}\mathbb{Z}\delta\}$,

$$\hat{X}^{\hat{\mu}}(f) = q^h x^\mu f \quad \text{for } f \in \mathbb{K}[\mathring{P}], \tag{2.17}$$

and the Demazure–Lusztig operators $\{\hat{T}_i \in \mathrm{End}(\mathbb{K}[\mathring{P}]) | i \in I\}$:[25,35]

$$\hat{T}_i f := t_i^{1/2} s_i(f) + \frac{(u_{\tilde{\alpha}_i}^{1/2} - u_{\tilde{\alpha}_i}^{-1/2}) x^{(1/2)n_i\alpha_i} + t_i^{1/2} - t_i^{-1/2}}{x^{n_i\alpha_i} - 1}(s_i(f) - f) \quad \text{for } f \in \mathbb{K}[\mathring{P}]. \tag{2.18}$$

Indeed the Demazure–Lusztig operators are induced from Proposition 2.13.

Theorem 2.16: (*cf.* Refs. 25 and 35):

(*i*) *The map* $\pi: \mathcal{H}(\tilde{W}) \to \mathrm{End}(\mathbb{K}[\mathring{P}])$ *defined by*

$$\pi: X^\mu \mapsto \hat{X}^\mu, \quad T_i \mapsto \hat{T}_i \quad \textit{for } 0 \leqslant i \leqslant l,$$

induces a $\mathbb{K}$*-linear homomorphism from* $\mathcal{H}(\tilde{W})$ *to* $\mathrm{End}(\mathbb{K}[\mathring{P}])$.

(*ii*) *The map* π *provides a faithful representation of* $\mathcal{H}(\tilde{W})$.

Definition 2.17: The representation π *gives rise to a commutative family of difference operators* $\{\hat{Y}^\lambda := \pi(Y^\lambda) \in \mathrm{End}(\mathbb{K}[\mathring{P}]) | \lambda \in \tilde{M}\}$ *which we call the Cherednik operators.*

In Refs. 27, 29, and 30, a double affine Hecke algebra and the Cherednik operators are defined with a specific coordinate system for the corresponding root system. Note that we have defined them without using such a specific coordinate system. One sees shortly that the Demazure–Lusztig operators (2.18) include parameters we need for studying the Macdonald–Koornwinder polynomial.[25] We remark that, only in the representation of the double affine Hecke algebra of type $A_{2l}^{(2)}$, we can consider such additional parameters other than $\{t_\alpha\}$.

Definition 2.18: Define the order $\preccurlyeq$ *on* $\mathring{P}$ *by*

$$\nu \preccurlyeq \mu, (\mu, \nu \in \mathring{P}) \Leftrightarrow \begin{cases} \textit{if } \mu^+ \neq \nu^+ & \textit{then } \nu^+ < \mu^+ \\ \textit{if } \mu^+ = \nu^+ & \textit{then } \nu \leqslant \mu, \end{cases} \tag{2.19}$$

where

$$\nu < \mu \Leftrightarrow \mu - \nu \in \overline{Q}_+ = \nu(\mathring{Q}_+^\vee).$$

We show the triangularity of the Cherednik operators $\{\hat{Y}^\lambda | \lambda \in \tilde{M}\}$ in $\mathbb{K}[\mathring{P}]$.[14,17,29,37] Here the triangularity means that, in the expansion of $\hat{Y}^\lambda x^\mu$, only the terms x^ν appear whose weights ν are equal to or smaller than the original weight μ with respect to the order $\preccurlyeq$. Define $\{G_{\alpha_i}^\pm := \hat{T}_i^{\pm 1} s_i \in \mathrm{End}(\mathbb{K}[\mathring{P}]) | i \in I\}$. Since $\{G_\alpha^\pm | \alpha \in \Pi\}$ have a property $w G_\alpha^\pm w^{-1} = G_{w(\alpha)}^\pm$, they can be associated with all the real roots $\{\alpha \in R^{\mathrm{re}}\}$,

$$\begin{aligned} G_\alpha^+ &= t_\alpha^{1/2} + \frac{(u_{\tilde{\alpha}}^{1/2} - u_{\tilde{\alpha}}^{-1/2}) x^{(1/2)n_\alpha\alpha} + t_\alpha^{1/2} - t_\alpha^{-1/2}}{x^{n_\alpha\alpha} - 1}(1 - s_\alpha), \\ G_\alpha^- &= G_\alpha^+ - (t_\alpha^{1/2} - t_\alpha^{-1/2}) s_\alpha. \end{aligned} \tag{2.20}$$

Lemma 2.19: A reduced expression $\tau_{-\lambda} = s_{i_1} s_{i_2} \cdots s_{i_k} \in \tilde{W}$ *gives an expression* $Y^\lambda = T_{i_1}^{\varepsilon_1} T_{i_2}^{\varepsilon_2} \cdots T_{i_k}^{\varepsilon_k} \in H(\tilde{W})$ *where* $\varepsilon_i \in \{\pm 1\}$ *are determined by the set of affine roots* $R_{\tau_{-\lambda}}$, *that is,* $\varepsilon_i = 1$ *if the corresponding affine root is of the form* $\alpha^{(i)} = \alpha + h\delta$, $(\alpha \in \mathring{R}_+)$ *and* $\varepsilon_i = -1$ *otherwise.*

From this lemma, we have an expression of the Cherednik operators,

$$\hat{Y}^\lambda = \hat{T}_{i_1}^{\varepsilon_1} \hat{T}_{i_2}^{\varepsilon_2} \cdots \hat{T}_{i_k}^{\varepsilon_k} = G_{\alpha^{(1)}}^{\varepsilon_1} G_{\alpha^{(2)}}^{\varepsilon_2} \cdots G_{\alpha^{(k)}}^{\varepsilon_k} \tau_{-\lambda},$$

where $\tau_{-\lambda} = s_{i_1} s_{i_2} \cdots s_{i_k} \in \mathrm{End}(\mathbb{K}[\mathring{P}])$. Note that the affine roots $\{\alpha^{(i)} | i \in \{1,2,...,k\}\}$ appearing in the above-given expression run through the set $R_{\tau_{-\lambda}}$. We consider the Cherednik operators with $\lambda \in \tilde{M}_+$; in this case, all $\varepsilon_i = +1$, $(1 \leqslant i \leqslant k)$. Since each operator G_α^+ acts on $\mathbb{K}[\mathring{P}]$ as

$$G_\alpha^+ x^\mu = \begin{cases} t_\alpha^{1/2} x^\mu + \text{lower terms w.r.t. } \prec & \text{if } \langle \mu, \alpha^\vee \rangle \geqslant 0 \\ t_\alpha^{-1/2} x^\mu + \text{lower terms w.r.t. } \prec & \text{if } \langle \mu, \alpha^\vee \rangle < 0, \end{cases} \tag{2.21}$$

one finds that the Cherednik operators $\hat{Y}^\lambda, (\lambda \in \tilde{M}_+)$ have the triangularity in $\mathbb{K}[\mathring{P}]$,

$$\hat{Y}^\lambda x^\mu = c_{\mu\mu} x^\mu + \text{lower terms w.r.t.} \prec . \tag{2.22}$$

The coefficient of the top term x^μ is given by

$$c_{\mu\mu} = q^{(\lambda|\mu^*)},$$

$$\mu^* := \mu + \frac{1}{2} \sum_{\alpha \in R_+}^{\circ} (k_\alpha + \check{k}_{\tilde{\alpha}}) \gamma_\alpha^{-1} \alpha - \sum_{\substack{\alpha \in R_+ \\ \langle \mu, \alpha^\vee \rangle < 0}}^{\circ} (k_\alpha + \check{k}_{\tilde{\alpha}}) \gamma_\alpha^{-1} \alpha = \mu + w_\mu(\rho_k).$$

Here we have put $t_\alpha = q^{k_\alpha}$, $\check{t}_\alpha = q^{\check{k}_\alpha}$, and

$$\rho_k := \frac{1}{2} \sum_{\alpha \in R_+}^{\circ} (k_\alpha + \check{k}_{\tilde{\alpha}}) \gamma_\alpha^{-1} \alpha,$$

and we have denoted by w_μ a unique element in $\mathring{W}^{\mu^+}$ such that $w_\mu^{-1}(\mu) \in \mathring{P}_+$ to define $\rho_k(\mu) := w_\mu(\rho_k)$. We can also show the triangularity of $\hat{Y}^\lambda$ with general elements $\lambda \in \tilde{M}$ by the help of the decomposition $\hat{Y}^\lambda = \hat{Y}^\mu (\hat{Y}^\nu)^{-1}$ such that $\mu, \nu \in \tilde{M}_+$.

Proposition 2.20: The Cherednik operators $\{\hat{Y}^\lambda | \lambda \in \tilde{M}\}$ *have the triangularity in* $\mathbb{K}[\mathring{P}]$:

$$\hat{Y}^\lambda x^\mu = x^\mu q^{(\lambda|\mu + \rho_k(\mu))} + \sum_{\nu < \mu} c_{\mu\nu} x^\nu \quad \textit{for} \quad \mu \in \mathring{P}, \quad c_{\mu\nu} \in \mathbb{K}. \tag{2.23}$$

We remark that $\{G_\alpha^\pm\}$ satisfy the defining relation of Cherednik's root algebra,[38] which is considered as a generalization of the Yang–Baxter relation. A representation of the root algebra obtained by one of us produces the elliptic Ruijsenaars operators associated with affine root systems.[31,32,34,39]

III. MACDONALD–KOORNWINDER POLYNOMIALS

Macdonald gave a classification of his orthogonal polynomials in terms of irreducible admissible pairs.[2] The Macdonald–Koornwinder polynomials, which were not included in Macdonald's classification, were introduced as multivariable generalizations of the Askey–Wilson polynomials and they have five parameters *a, b, c, d, t* apart from *q*.[22] Macdonald proposed in his seminary notes that Cherednik's affine Hecke algebraic approach can be also applied to the Macdonald–Koornwinder polynomials.[26] By using the Demazure–Lusztig operators for the $C^{(1)}$-type Hecke algebra and Theorem 2.11 in Sec. II, Noumi actually constructed a set of commutative operators which characterizes the Macdonald–Koornwinder polynomials as their joint eigenvectors.[25] However his construction is slightly different from Cherednik's theory for the Macdonald polynomials in the sense that he used a (nonextended) affine Weyl group of type *C*, and hence it seems to be hard to give a unified viewpoint for both of them. In Sec. II, we defined the affine Hecke algebra such that the corresponding extended affine Weyl group preserves the affine root system. In our setting, the representation of the affine Hecke algebra associated with $A_{2l}^{(2)}$-type affine root system gave the Demazure–Lusztig operators (2.18) including parameters we need. Thus we obtain a classification of the Macdonald and Macdonald–Koornwinder polynomials in terms of affine root systems as

Affine root systems	Polynomials
$X_l^{(1)}$	X_l-type Macdonald
$A_{2l}^{(2)}$	Macdonald–Koornwinder (BC_l-type Macdonald)

We remark that Macdonald also implied this classification in Ref. 2. Cherednik studied the Macdonald polynomials associated with pairs $(\mathring{R},\mathring{R}^\vee)$ for nonsimply laced classical root systems,[16] which, in this classification, correspond to twisted affine root systems other than of type $A_{2l}^{(2)}$.

A. Nonsymmetric Macdonald–Koornwinder polynomials

First we consider the nonsymmetric Macdonald–Koornwinder polynomials.[18,27,29] Let ι be involution $\iota:\mathbb{K}[\mathring{P}]\to\mathbb{K}[\mathring{P}]$ defined by

$$\iota: q\mapsto q^{-1},\quad t_\alpha\mapsto t_\alpha^{-1},\quad u_\alpha\mapsto u_\alpha^{-1},\quad x^\mu\mapsto x^\mu,$$

and let $^-$ be bar-involution $^-:\mathbb{K}[\mathring{P}]\to\mathbb{K}[\mathring{P}]$ defined by

$$^-: q\mapsto q,\quad t_\alpha\mapsto t_\alpha,\quad u_\alpha\mapsto u_\alpha,\quad x^\mu\mapsto x^{-\mu}.$$

We define the following scalar products in $\mathbb{K}[\mathring{P}]$:

$$\langle f,g\rangle'_{q,t,u}:=[f\overline{g^\iota}\mu_{q,t,u}]_0,\quad (f,g)'_{q,t,u}:=[f\overline{g^\iota}\tilde{\mu}_{q,t,u}]_0, \tag{3.1}$$

where $[f]_0$ stands for the constant term (the coefficient of x^0) of f. The weight function $\mu_{q,t,u}$ is given by

$$\mu_{q,t,u}:=\prod_{\alpha\in R_+^{\mathrm{re}}}\frac{1-x^{n_\alpha\alpha}}{(1-t_\alpha^{1/2}u_{\tilde{\alpha}}^{1/2}x^{(1/2)n_\alpha\alpha})(1+t_\alpha^{1/2}u_{\tilde{\alpha}}^{-1/2}x^{(1/2)n_\alpha\alpha})}, \tag{3.2}$$

and $\tilde{\mu}_{q,t,u}=\mu_{q,t,u}/[\mu_{q,t,u}]_0$.

Proposition 3.1: Coefficients of $\mu_{q,t,u}$ are in the algebra $\mathbb{C}[\{t_\alpha^{1/2},u_\alpha^{1/2}\}][[q^{1/2}]]$ of formal power series in $q^{1/2}$ over polynomials in $\{t_\alpha^{1/2},u_\alpha^{1/2}\}$.

Proof: We give a proof of the proposition above following Ref. 2. Put

$$x_0:=x^{\alpha_0}=q^{1/2}x^{-(1/2)\theta},\quad x_i:=x^{\alpha_i}\quad\text{for } 1\leqslant i\leqslant l-1,\quad x_l:=x^{(1/2)\alpha_l},$$

and consider the polynomial ring $\mathbb{C}[x_0,\ldots,x_l]$. Due to $\theta=\Sigma_{i\in\mathring{I}}a_i\alpha_i=2\Sigma_{i=1}^{l-1}\alpha_i+\alpha_l$, we have $x^\theta=x_0^2x_1^2\cdots x_l^2$. Then $q^{1/2}=x_0x^{(1/2)\theta}=x_0x_1\cdots x_l$. We see that, for $\alpha\in\mathring{R}_+^l$ and $i\in\mathbb{N}$,

$$q^ix^{(1/2)\alpha}=x_0^{2i}x^{i\theta+(1/2)\alpha},\quad q^{i+1/2}x^{(1/2)\alpha}=x_0^{2i+1}x^{(i+1/2)\theta+(1/2)\alpha},$$

$$q^{i+1}x^{-(1/2)\alpha}=x_0^{2(i+1)}x^{(i+1)\theta-(1/2)\alpha},\quad q^{i+1/2}x^{-(1/2)\alpha}=x_0^{2i+1}x^{(i+1/2)\theta-(1/2)\alpha},$$

are monomials in $\mathbb{C}[x_0,\ldots,x_l]$ since $\alpha\leqslant\theta$. For $\alpha\in\mathring{R}^m$ and $i\in\mathbb{N}$,

$$q^ix^\alpha=x_0^{2i}x^{i\theta+\alpha},\quad q^{i+1}x^{-\alpha}=x_0^{2(i+1)}x^{(i+1)\theta-\alpha},$$

are also monomials in $\mathbb{C}[x_0,\ldots,x_l]$. Hence the weight function $\mu_{q,t,u}$ can be rewritten as

$$\mu_{q,t,u}=\sum_{\beta\in\mathbb{N}^{l+1}}b_\beta(t,u)x^\beta,$$

with $x^{\beta}:=x_0^{\beta_0}x_1^{\beta_1}\cdots x_l^{\beta_l}\in\mathbb{C}[x_0,\ldots,x_l]$ and $b_{\beta}(t,u)\in\mathbb{C}[\{t_\alpha^{1/2},u_\alpha^{1/2}\}]$. Moreover, from $x^{\beta}=q^{(1/2)\beta_0}x_1^{\beta_1-\beta_0}\cdots x_l^{\beta_l-\beta_0}(\in\mathbb{K}[\mathring{P}])$, we have

$$\mu_{q,t,u}=\sum_{\mu\in\mathring{P}}a_\mu(q,t,u)x^{\mu},$$

where $a_\mu(q,t,u)=\Sigma_{\beta_0\geqslant 0}q^{(1/2)\beta_0}b_\beta(t,u)\in\mathbb{C}[\{t_\alpha^{1/2},u_\alpha^{1/2}\}][[q^{1/2}]]$ and β is determined from $\mu\in\mathring{P}$ and $\beta_0\in\mathbb{N}$ by the condition $2\mu=2\Sigma_{i=1}^{l-1}(\beta_i-\beta_0)\alpha_i+(\beta_l-\beta_0)\alpha_l$. As a consequence, we see that the coefficients of $\mu_{q,t,u}$ are in $\mathbb{C}[\{t_\alpha^{1/2},u_\alpha^{1/2}\}][[q^{1/2}]]$. □

In terms of the classical root system $\mathring{R}$ corresponding to R, the weight function is rewritten as

$$\mu_{q,t,u}=\prod_{\alpha\in\mathring{R}_+^l}\frac{(x^\alpha,qx^{-\alpha};q)_\infty}{(ax^{(1/2)\alpha},bx^{(1/2)\alpha},cx^{(1/2)\alpha},dx^{(1/2)\alpha},aqx^{-(1/2)\alpha},bqx^{-(1/2)\alpha},cx^{-(1/2)\alpha},dx^{-(1/2)\alpha};q)_\infty}\times\prod_{\alpha\in\mathring{R}_+^s}\frac{(x^\alpha,qx^{-\alpha};q)_\infty}{(t_\alpha x^\alpha,t_\alpha qx^{-\alpha};q)_\infty},\tag{3.3}$$

where we have put $a=t_l^{1/2}u_0^{1/2}$, $b=-t_l^{1/2}u_0^{-1/2}$, $c=t_0^{1/2}u_l^{1/2}q^{1/2}$, $d=-t_0^{1/2}u_l^{-1/2}q^{1/2}$ in a way similar to Ref. 22 and have employed the q-shifted factorials

$$(z;q)_\infty:=\prod_{i=0}^{\infty}(1-zq^i),\quad (z_1,z_2,\ldots,z_k;q)_\infty:=\prod_{i=1}^{k}(z_i;q)_\infty.$$

Lemma 3.2 (cf. Refs. 40, 41). The constant term of $\mu_{q,t,u}$ is given by

$$\langle 1,1\rangle'_{q,t,u}=\prod_{\alpha\in\mathring{R}_+^l}\frac{(abcdq'^2_{0,\alpha};q)_\infty^2}{(qq'_{0,\alpha},abqq'_{0,\alpha},acq'_{0,\alpha},adq'_{0,\alpha},bcq'_{0,\alpha},bdq'_{0,\alpha},cdq'_{0,\alpha},abcdq'_{0,\alpha};q)_\infty}\times\prod_{\alpha\in\mathring{R}_+^s}\frac{(qq'^2_{0,\alpha};q)_\infty^2}{(t_\alpha qq_{0,\alpha}^2,t_\alpha^{-1}qq_{0,\alpha}^2;q)_\infty},\tag{3.4}$$

where $q_{0,\alpha}:=q^{(1/2)(\alpha|\rho_k)}$, $q'_{0,\alpha}:=q^{(1/2)(\alpha|\rho'_k)}$ and $\rho'_k:=(1/2)\Sigma_{\alpha\in\mathring{R}_+^s}k_\alpha\alpha$.

We admit this lemma which is verified from Gustafson's constant term identity,[40,42]

$$\langle 1,1\rangle_{q,t,u}=\prod_{i=1}^{l}\frac{(t,abcdt^{2l-i-1};q)_\infty}{(q,t^{l-i+1},abt^{l-i},act^{l-i},adt^{l-i},bct^{l-i},bdt^{l-i},cdt^{-i};q)_\infty},\tag{3.5}$$

together with Macdonald's identity for the Poincaré polynomials.[41] The definition of the inner product $\langle\cdot,\cdot\rangle_{q,t,u}$ in (3.5) will appear shortly (3.22). In order to see their explicit relation, we need the following identities:

$$\prod_{j<k}\frac{(t^{k-j},qt^{k-j};q)_\infty}{(t^{k-j+1},qt^{k-j-1};q)_\infty}=\prod_{i=1}^{l}\frac{(t,qt^{l-i};q)_\infty}{(q,t^{l-i+1};q)_\infty},$$

$$\prod_{j<k}\frac{(abcdt^{2l-j-k},abcdq^{-1}t^{2l-j-k};q)_\infty}{(abcdt^{2l-j-k+1},abcdq^{-1}t^{2l-j-k+1};q)_\infty}=\prod_{i=1}^{l}\frac{(abcdt^{2l-2i-1},abcdq^{-1}t^{l-i};q)_\infty}{(abcdt^{l-i-1},abcdq^{-1}t^{2(l-i)};q)_\infty},$$

where we put $t=t_i$, $(1\leqslant i\leqslant l-1)$. Another proof of the constant term identity is established by use of the shift operator.[29]

Definition 3.3 (nonsymmetric Macdonald–Koornwinder polynomials): The (monic) nonsymmetric Macdonald–Koornwinder polynomials $E_\mu := E_\mu(x;q,\{t_\alpha,u_\alpha\}) \in \mathbb{K}[\mathring{P}], (\mu \in \mathring{P})$ *are uniquely defined by the following conditions*:

$$\begin{aligned} &(i)\ \ E_\mu = x^\mu + \sum_{\nu \prec \mu} w_{\mu\nu} x^\nu \quad \text{for } w_{\mu\nu} \in \mathbb{K}, \\ &(ii)\ \ (E_\mu, x^\nu)'_{q,t,u} = 0 \quad \text{if } \nu \prec \mu. \end{aligned} \tag{3.6}$$

The weight function $\mu_{q,t,u}$ for the nonsymmetric Macdonald–Koornwinder polynomials were first introduced in Ref. 29. We remark that, by setting $u_\alpha = 1$ and $n_\alpha = 1$ in the weight function (3.2), we can also define nonsymmetric Macdonald polynomials associated with both nontwisted and twisted affine root systems other than of type $A_{2l}^{(2)}$.

Proposition 3.4: The adjoint operators of $\{\hat{T}_i, \hat{Y}^\lambda, \hat{X}^\mu \in \mathrm{End}(\mathbb{K}[\mathring{P}]) | i \in I, \lambda \in \widetilde{M}, \mu \in \mathring{P}\}$ *with respect to the scalar products (3.1) are given by*

$$(\hat{T}_i)^* = \hat{T}_i^{-1}, \quad (\hat{Y}^\lambda)^* = \hat{Y}^{-\lambda}, \quad (\hat{X}^\mu)^* = \hat{X}^{-\mu}.$$

Proof: $(\hat{X}^\mu)^* = \hat{X}^{-\mu}$ is straightforward from the definition of the scalar products (3.1). We show that $(\hat{T}_i)^* = \hat{T}_i^{-1}$. Since $(t_i)^* = t_i^{-1}$, it is sufficient to prove $(T_i - t_i^{1/2})^* = T_i - t_i^{1/2}$. Indeed, we see that

$$s_i^* = \mu_{q,t,u}^{-1} s_i \mu_{q,t,u} = \frac{(1-x^{-n_i\alpha_i})(1-t_i^{1/2}u_{\tilde{\alpha}_i}^{1/2}x^{(1/2)n_i\alpha_i})(1+t_i^{1/2}u_{\tilde{\alpha}_i}^{-1/2}x^{(1/2)n_i\alpha_i})}{(1-x^{n_i\alpha_i})(1-t_i^{1/2}u_{\tilde{\alpha}_i}^{1/2}x^{-(1/2)n_i\alpha_i})(1+t_i^{1/2}u_{\tilde{\alpha}_i}^{-1/2}x^{-(1/2)n_i\alpha_i})} s_i,$$

and hence we obtain

$$\begin{aligned} (\hat{T}_i - t_i^{1/2})^* &= (s_i^* - 1)t_i^{1/2} \frac{(1-t_i^{-1/2}u_{\tilde{\alpha}_i}^{-1/2}x^{-(1/2)n_i\alpha_i})(1+t_i^{-1/2}u_{\tilde{\alpha}_i}^{1/2}x^{-(1/2)n_i\alpha_i})}{1-x^{-n_i\alpha_i}} \\ &= (s_i^* - 1)t_i^{-1/2} \frac{(1-t_i^{1/2}u_{\tilde{\alpha}_i}^{1/2}x^{(1/2)n_i\alpha_i})(1+t_i^{1/2}u_{\tilde{\alpha}_i}^{-1/2}x^{(1/2)n_i\alpha_i})}{1-x^{n_i\alpha_i}} \\ &= \hat{T}_i - t_i^{1/2}. \end{aligned} \tag{3.7}$$

We see that $(\hat{Y}^\lambda)^* = \hat{Y}^{-\lambda}$ from its definition and $(\hat{T}_i)^* = \hat{T}_i^{-1}$. □

Theorem 3.5: *The nonsymmetric Macdonald–Koornwinder polynomials* $E_\mu \in \mathbb{K}[\mathring{P}]$ *are joint eigenvectors of the Cherednik operators* $\{\hat{Y}^\lambda \in \mathrm{End}(\mathbb{K}[\mathring{P}]) | \lambda \in \widetilde{M}\}$,

$$\hat{Y}^\lambda E_\mu = q^{(\lambda|\mu+\rho_k(\mu))} E_\mu. \tag{3.8}$$

Proof: Consider the nonsymmetric Macdonald–Koornwinder polynomial operated by the Cherednik operator $\hat{Y}^\lambda E_\mu, (\lambda \in \widetilde{M}, \mu \in \mathring{P})$. Due to the unitarity of the Cherednik operator $(\hat{Y}^\lambda)^* = \hat{Y}^{-\lambda}$ (Proposition 3.4) and their triangularity in $\mathbb{K}[\mathring{P}]$ (2.23), the polynomial $\hat{Y}^\lambda E_\mu$ satisfies condition (ii) in (3.6) and have the form (i) in (3.6) up to a constant factor $q^{(\lambda|\mu+\rho_k(\mu))}$. The uniqueness of the nonsymmetric Macdonald–Koornwinder polynomials shows that, for all λ $(\in \widetilde{M})$, $\widetilde{Y}^\lambda E_\mu$ coincides with E_μ up to the constant factor, which proves the theorem. □

Note that, since all the eigenvalues $\{q^{(\lambda|\mu+\rho_k(\mu))} | \lambda \in \widetilde{M}\}$ determine the weight $\mu \in \mathring{P}$ uniquely, all the simultaneous eigenspaces of the Cherednik operators $\{\hat{Y}^\lambda | \lambda \in \widetilde{M}\}$ are one dimensional.

Moreover, we see a proposition in the following.

Proposition 3.6 (cf. Refs. 27, 29): (i) We have the orthogonality of the nonsymmetric Macdonald–Koornwinder polynomials:

$$(E_\mu, E_\nu)'_{q,t,u} = 0 \quad \text{if } \mu \neq \nu. \tag{3.9}$$

In fact, the non-symmetric Macdonald–Koornwinder polynomials form an orthogonal basis in $\mathbb{K}[\mathring{P}]$ *with respect to the scalar product* $(\cdot,\cdot)'_{q,t,u}$ *in (3.1).*
(ii) Conditions (i) in (3.6) and (3.9) also determine the nonsymmetric Macdonald–Koornwinder polynomials E_μ *uniquely.*

Proposition 3.7: Applying the Demazure–Lusztig operators $\hat{T}_i, (1 \leqslant i \leqslant l)$ *to* $E_\mu, (\mu \in \mathring{P})$, *we obtain*

$$\hat{T}_i E_\mu = \begin{cases} \dfrac{t_i^{1/2} - t_i^{-1/2} + (\check{t}_{\tilde{\alpha}_i}^{-1/2} - \check{t}_{\tilde{\alpha}_i}^{-1/2}) q_{\mu,i}^{-1}}{1 - q_{\mu,i}^{-2}} E_\mu + t_i^{1/2} E_{s_i(\mu)} & \text{if } \langle \mu, \alpha_i^\vee \rangle < 0 \\ t_i^{1/2} E_\mu \quad \text{if } \langle \mu, \alpha_i^\vee \rangle = 0 \\ \dfrac{t_i^{1/2} - t_i^{-1/2} + (\check{t}_{\tilde{\alpha}_i}^{1/2} - \check{t}_{\tilde{\alpha}_i}^{-1/2}) q_{\mu,i}^{-1}}{1 - q_{\mu,i}^{-2}} E_\mu \\ \quad + \dfrac{t_i^{-1/2}(1 - t_i^{1/2}\check{t}_{\tilde{\alpha}_i}^{1/2} q_{\mu,i}^{-1})(1 + t_i^{1/2}\check{t}_{\tilde{\alpha}_i}^{-1/2} q_{\mu,i}^{-1})(1 - t_i^{-1/2}\check{t}_{\tilde{\alpha}_i}^{-1/2} q_{\mu,i}^{-1})(1 + t_i^{-1/2}\check{t}_{\tilde{\alpha}_i}^{1/2} q_{\mu,i}^{-1})}{(1 - q_{\mu,i}^{-2})^2} E_{s_i(\mu)} \quad \text{if } \langle \mu, \alpha_i^\vee \rangle > 0, \end{cases} \tag{3.10}$$

where $q_{\mu,i} := q^{(1/2)(\alpha_i | \mu + \rho_k(\mu))}$.

Proof: Let $f := (z\hat{T}_i + 1)E_\mu$ for $\langle \mu, \alpha_i^\vee \rangle \neq 0$. z is determined so that f has the same eigenvalues of $\{\hat{Y}^\lambda\}$ as those of $E_{s_i(\mu)}$. Each coefficient is determined by comparing their top terms. The case $\langle \mu, \alpha_i^\vee \rangle = 0$ follows from definition (3.6) and unitarity $(\hat{T}_i)^* = \hat{T}_i^{-1}$. □

Proposition 3.8 (cf. Ref. 27): The map ε *defined by*

$$\begin{gathered} \varepsilon : T_i \mapsto T_i^{-1}, \quad X^{\overline{\Lambda_i}} \mapsto Y^{\overline{\Lambda_i}}, \quad Y^{\overline{\Lambda_i}} \mapsto X^{\overline{\Lambda_i}}, \quad \text{for } 1 \leqslant i \leqslant l, \\ q \mapsto q^{-1}, \quad t_i \mapsto t_i^{-1}, \quad u_i \mapsto u_i^{-1} \quad \text{for } 1 \leqslant i \leqslant l, \\ t_0 \mapsto u_0^{-1}, \quad u_0 \mapsto t_0^{-1}, \end{gathered} \tag{3.11}$$

can be extended to the involution $\varepsilon : \mathcal{H}(\widetilde{W}) \to \mathcal{H}(\widetilde{W})$.

Proof: It is directly verified from the relations between generators of $\mathcal{H}(\widetilde{W})$ (2.13) and their image by the map ε. □

We have omitted details of the proof since the involution ε is essentially the same as that proved by Sahi for his double affine Hecke algebra.[27] The involution ε also provides

$$\varepsilon(T_0) = \varepsilon(T_{s_\theta}^{-1} Y^{(1/2)\theta}) = T_{s_\theta} X^{(1/2)\theta} = Y^{(1/2)\theta} T_0^{-1} X^{(1/2)\theta} =: U_0^{-1}, \tag{3.12}$$

which satisfy the following quadratic relation: $(U_0 - u_0^{1/2})(U_0 + u_0^{-1/2}) = 0$.

Proposition 3.9: Let $\lambda \in \widetilde{M}$. *In* $\mathcal{H}(\widetilde{W})$, *we have*

$$U_0 Y^\lambda - Y^{s_0(\lambda)} U_0 = \frac{(u_l^{1/2} - u_l^{-1/2}) Y^{-\alpha_0} + u_0^{1/2} - u_0^{-1/2}}{Y^{-2\alpha_0} - 1} (Y^{s_0(\lambda)} - Y^\lambda), \tag{3.13}$$

where $Y^\delta = q^{-1}$.

Definition 3.10: We call the following elements $\{S_i \in \mathcal{H}(\widetilde{W}) | i \in I\}$ *intertwiners:*[16,18,27]

$$S_0 := U_0^{-1} Y^{2\alpha_0} - (u_l^{1/2} - u_l^{-1/2}) Y^{\alpha_0} - U_0,$$
$$S_i := T_i^{-1} Y^{\alpha_i} - (\check{t}_{\tilde{\alpha}_i}^{1/2} - \check{t}_{\tilde{\alpha}_i}^{-1/2}) Y^{(1/2)\alpha_i} - T_i \quad \text{for } 1 \leqslant i \leqslant l. \tag{3.14}$$

Lemma 3.11: The elements $\{S_i \in \mathcal{H}(\tilde{W}) | i \in I\}$ *satisfy*

(*i*) $S_i S_j S_i \cdots = S_j S_i S_j \cdots$, m_{ij} *factors on each side,*

(*ii*) $S_i^2 = t_i^{-1}(1 - t_i^{1/2}\check{t}_{\tilde{\alpha}_i}^{1/2} Y^{(1/2)\alpha_i})(1 + t_i^{1/2}\check{t}_{\tilde{\alpha}_i}^{-1/2} Y^{(1/2)\alpha_i})(1 - t_i^{1/2}\check{t}_{\tilde{\alpha}_i}^{1/2} Y^{-(1/2)\alpha_i})$
$\times (1 + t_i^{1/2}\check{t}_{\tilde{\alpha}_i}^{-1/2} Y^{-(1/2)\alpha_i})$ *for* $1 \leqslant i \leqslant l$,

$$S_0^2 = u_0^{-1}(1 - u_0^{1/2}u_l^{1/2}Y^{\alpha_0})(1 + u_0^{1/2}u_l^{-1/2}Y^{\alpha_0})(1 - u_0^{1/2}u_l^{1/2}Y^{-\alpha_0})(1 + u_0^{1/2}u_l^{-1/2}Y^{-\alpha_0}). \tag{3.15}$$

Proof: We verify relations (i) and (ii) by applying the composite $\pi \circ \varepsilon$ to $\{S_i | i \in I\}$,

$$\pi \circ \varepsilon(S_i) = -t_i^{1/2}(1 + t_i^{-1/2}(u_{\tilde{\alpha}_i}^{1/2} - u_{\tilde{\alpha}_i}^{-1/2}) x^{-(1/2)n_i\alpha_i} - t_i^{-1} x^{-n_i\alpha_i}) s_i .$$

□

The concept of intertwiners in Hecke algebras has a long history, and intertwiners in double affine Hecke algebras were first introduced by Cherednik.[15,16] Motivated by Noumi's work,[25] Sahi introduced a set of intertwiners which gives a linear isomorphism between simultaneous eigenspaces of the Cherednik operators (Definition 2.17) to define the nonsymmetric Macdonald–Koornwinder polynomials.[27] In our previous paper,[18] we defined intertwiners by improving Sahi's operators so as to satisfy the braid relation (i) in Lemma 3.11, and we presented a Rodrigues-type formula of the nonsymmetric Macdonald–Koornwinder polynomials with a specific coordinate system for the associated affine root system. Here we have defined the intertwiners (3.14) to give the Rodrigues-type formula without using such a specific coordinate system.

Definition 3.12: For a reduced expression $w = s_{i_1} s_{i_2} \cdots s_{i_k} \in \tilde{W}$, $(k = \ell(w))$, *we define* $S_w := S_{i_1} S_{i_2} \cdots S_{i_k} (\in \mathcal{H}(\tilde{W}))$ *which is well defined for all* $w \in \tilde{W}$ *due to i) in Lemma 3.11. In particular, we write* $A_\mu := S_{\tau_{-\mu}}$ *for* $\mu \in \mathring{P}_+$. *We call* $\{\hat{A}_\mu := \pi(A_\mu) \in \mathrm{End}(\mathbb{K}[\mathring{P}])\}$ *the raising operators.*

Proposition 3.13: For $w \in \tilde{W}$ *and* $\lambda \in \tilde{M}$, *we have* $S_w Y^\lambda = Y^{w(\lambda)} S_w$.

Proof: The relations for $\{S_i | i \in I\}$ are verified from direct calculations, and hence they are extensible to the relations for $\{S_w | w \in \tilde{W}\}$. □

Theorem 3.14 (Rodrigues-type formula): *(i) For* $\mu \in \mathring{P}_+$, *we obtain the nonsymmetric Macdonald–Koornwinder polynomial* E_μ *by applying the raising operators* $\{\hat{A}_\mu | \mu \in \mathring{P}_+\}$ *to the reference state* $E_0 := 1$,

$$E_\mu = d_\mu^{-1} \hat{A}_\mu E_0, \tag{3.16}$$

where the coefficient of the top term is given by

$$d_\mu = q^{-(1/2)(\mu|\rho_k)} \prod_{\alpha \in R_{\tau_\mu}} t_\alpha^{1/2}(q^{n_\alpha \alpha(\rho_k)} - 1),$$

and $(\alpha + n\delta)(\rho_k) = (\alpha|\rho_k) - n$.

(ii) For $\mu \in \mathring{P}$, *we obtain the nonsymmetric Macdonald–Koornwinder polynomial* E_μ *by applying the operator* $\hat{S}_{w_\mu} := \pi(S_{w_\mu})$, $(w_\mu \in \mathring{W}^{\mu^+}, w_\mu^{-1}(\mu) = \mu^+ \in \mathring{P}_+)$ *to* E_{μ^+},

$$E_\mu = d_{w_\mu}^{-1} \hat{S}_{w_\mu} E_{\mu^+}, \tag{3.17}$$

where the coefficient of the top term is

$$d_{w_\mu} := \prod_{\alpha \in R_{w_\mu^{-1}}} \frac{-t_\alpha^{-1/2}(1-t_\alpha^{-1/2}\check{t}_{\tilde{\alpha}}^{-1/2}q_{\mu^+,\alpha})(1+t_\alpha^{-1/2}\check{t}_{\tilde{\alpha}}^{1/2}q_{\mu^+,\alpha})(1-t_\alpha^{1/2}\check{t}_{\tilde{\alpha}}^{-1/2}q_{\mu^+,\alpha})(1+t_\alpha^{1/2}\check{t}_{\tilde{\alpha}}^{1/2}q_{\mu^+,\alpha})}{1-q_{\mu^+,\alpha}^2},$$

and $q_{\mu^+,\alpha}=q^{(1/2)(\alpha|\mu^+ +\rho_k)}$.

Proof: (i) Let $E' := \hat{A}_\mu E_\nu, (\mu,\nu \in \mathring{P}_+)$. Due to Proposition 3.13, we have

$$\hat{Y}^\lambda E' = \hat{Y}^\lambda \hat{A}_\mu E_\nu = \hat{A}_\mu \hat{Y}^{\tau_\mu(\lambda)} E_\nu = q^{(\lambda|\mu)} \hat{A}_\mu \hat{Y}^\lambda E_\nu = q^{(\lambda|\mu+\nu+\rho_k)} E'.$$

Since all the simultaneous eigenspaces of $\hat{Y}^\lambda$ are one dimensional, E' coincides with the nonsymmetric Macdonald–Koornwinder polynomial $E_{\mu+\nu}$ up to a constant factor. Next we calculate coefficients of the top term d_μ. Using a reduced expression $\tau_{-\mu}=s_{i_1}s_{i_2}\cdots s_{i_k}$, $(\ell(\tau_{-\mu})=k)$, we take a set of weights $\{\mu^{(m)}\}=\{\mu^{(m)}=\mathrm{af}(s_{i_{m+1}}s_{i_{m+2}}\cdots s_{i_k})(0) | 1 \leqslant m \leqslant k\}$. For $\alpha_{i_m} \in \Pi$ associated with the simple reflection s_{i_m}, we have

$$\alpha_{i_m}(\mu^{(m)}) = (s_{i_1}\cdots s_{i_m}(\alpha_{i_m}))(\mu) = -(s_{i_1}\cdots s_{i_{m-1}}(\alpha_{i_m}))(\mu) = -\alpha^{(m)}(\mu) < 0,$$

since $\alpha^{(m)} = s_{i_1}\cdots s_{m-1}(\alpha_{i_m}) \in R_{\tau_{-\mu}} \subset R_+^{\mathrm{re}}$. Hence, in applying the operator $\hat{S}_{i_m}$ to the polynomial $E_{\mu^{(m)}}$, only the cases $\langle \mu^{(m)}, \alpha_{i_m}^\vee \rangle < 0$, $(i_m \neq 0)$ and $\langle \mu^{(m)}, -\theta^\vee \rangle < a_0^{-1}, (i_m = 0)$ appear. Then we have

$$\begin{aligned}
\hat{A}_\mu E_0 &= \prod_{\{m | i_m=0\}} q^{-(1/2)(\theta|\rho_k(\mu^{(m)}))} \prod_{m=1}^{k} t_{i_m}^{1/2}(q^{n_{i_m}\alpha_{i_m}(\mu^{(m)}+\rho_k(\mu^{(m)}))}-1)E_\mu \\
&= \prod_{\{m | i_m=0\}} q^{-(1/2)(\theta|\rho_k(\mu^{(m)}))} \prod_{m=1}^{k} t_{i_m}^{1/2}(q^{n_{i_m}(s_{i_k}\cdots s_{i_{m+1}}(\alpha_{i_m}))(\rho_k)}-1)E_\mu \\
&= q^{-(1/2)(\mu|\rho_k)} \prod_{\alpha \in R_{\tau_\mu}} t_\alpha^{1/2}(q^{n_\alpha \alpha(\rho_k)}-1)E_\mu .
\end{aligned}$$

(ii) We see that $E'' := \hat{S}_{w_\mu} E_{\mu^+}$ coincides with the nonsymmetric Macdonald–Koornwinder polynomial E_μ up to a constant factor, since Proposition 3.13 gives

$$\hat{Y}^\lambda E'' = \hat{Y}^\lambda \hat{S}_{w_\mu} E_{\mu^+} = \hat{S}_{w_\mu} \hat{Y}^{w_\mu^{-1}(\lambda)} E_{\mu^+} = q^{(w_\mu^{-1}(\lambda)|\mu^+ +\rho_k)} E'' = q^{(\lambda|w_\mu(\mu^+ +\rho_k))} E''.$$

Coefficients of the top term d_{w_μ} can be also calculated in a way similar to (i). □

It should be remarked that $\hat{S}_i E_\mu = 0$ for $s_i \in \widetilde{W}$ such that $s_i(\mu)=\mu$. We have constructed E_μ in two steps to avoid such situations. Indeed, for an expression $A_\mu = S_{i_1}S_{i_2}\cdots S_{i_k}$, one sees $i_k = 0$ since $\ell(\tau_{-\mu}s_i) = \ell(\tau_{-\mu})+1$, $(\mu \in \mathring{P}_+, i \in \mathring{I})$.

The Rodrigues-type formula we have obtained enables us to evaluate diagonal terms of scalar products for the nonsymmetric Macdonald–Koornwinder polynomials.

Theorem 3.15: *For a dominant weight* $\mu \in \mathring{P}_+$, *we have the scalar product:*

$$\begin{aligned}
\langle E_\mu, E_\mu \rangle'_{q,t,u} = &\prod_{\alpha \in \mathring{R}_+^l} \frac{(abcdq'^2_{\mu,\alpha};q)_\infty^2}{(qq'_{\mu,\alpha}, abqq'_{\mu,\alpha}, acq'_{\mu,\alpha}, adq'_{\mu,\alpha} bcq'_{\mu,\alpha}, bdq'_{\mu,\alpha}, cdq'_{\mu,\alpha}, abcdq'_{\mu,\alpha};q)_\infty} \\
&\times \prod_{\alpha \in \mathring{R}_+^s} \frac{(qq_{\mu,\alpha}^2;q)_\infty^2}{(t_\alpha qq_{\mu,\alpha}^2, t_\alpha^{-1}qq_{\mu,\alpha}^2;q)_\infty},
\end{aligned} \tag{3.18}$$

where $q_{\mu,\alpha}=q^{(1/2)(\alpha|\mu+\rho_k(\mu))}$ *and* $q'_{\mu,\alpha}=q^{(1/2)(\alpha|\mu+\rho'_k(\mu))}$.

Proof: First we calculate $(E_\mu,E_\mu)'_{q,t,u}$ in $\mathbb{K}$. Define $\{N(\alpha)\in\mathcal{H}(\tilde{W})\,|\,\alpha\in R^{\mathrm{re}}\}$ by

$$N(\alpha):=\tilde{t}_\alpha(1-\tilde{t}_\alpha^{-1/2}\tilde{u}_{\tilde{\alpha}}^{-1/2}Y^{(n_\alpha/2)\alpha})(1+\tilde{t}_\alpha^{-1/2}\tilde{u}_{\tilde{\alpha}}^{1/2}Y^{(n_\alpha/2)\alpha})(1-\tilde{t}_\alpha^{-1/2}\tilde{u}_{\tilde{\alpha}}^{-1/2}Y^{-(n_\alpha/2)\alpha})\times(1+\tilde{t}_\alpha^{-1/2}\tilde{u}_{\tilde{\alpha}}^{1/2}Y^{-(n_\alpha/2)\alpha}),\tag{3.19}$$

where we put $\tilde{t}_\alpha:=\varepsilon(t_\alpha)$ and $\tilde{u}_\alpha:=\varepsilon(u_\alpha)$. They satisfy the following properties:

$$N(\alpha_i)=S_i^2,\quad S_wN(\alpha)=N(w(\alpha))S_w\quad\text{for } w\in\tilde{W}.$$

If we take a reduced expression $\tau_{-\mu}=s_{i_1}s_{i_2}\cdots s_{i_k}$ the product $A_\mu^*A_\mu\in\mathcal{H}(\tilde{W})$ is written as

$$A_\mu^*A_\mu=S_{i_k}^*\cdots S_{i_2}^*S_{i_1}^*S_{i_1}S_{i_2}\cdots S_{i_k}=S_{i_k}\cdots S_{i_2}N(\alpha_{i_1})S_{i_2}\cdots S_{i_k}=\prod_{\alpha\in R_{\tau_\mu}}N(\alpha).$$

Thus we see that the operators $\hat{A}_\mu^*\hat{A}_\mu$ can be diagonalized by the nonsymmetric Macdonald–Koornwinder polynomials. The scalar product is calculated as

$$\begin{aligned}
&(E_\mu,E_\mu)'_{q,t,u}\\
&=(d_\mu^{-1}\hat{A}_\mu E_0,d_\mu^{-1}\hat{A}_\mu E_0)'_{q,t,u}=d_\mu^{-1}(d_\mu^{-1})^\iota(E_0,\hat{A}_\mu^*\hat{A}_\mu E_0)'_{q,t,u}\\
&=\prod_{\alpha\in R_{\tau_\mu}}\frac{(1-\tilde{t}_\alpha^{1/2}\tilde{u}_{\tilde{\alpha}}^{1/2}q^{-(n_\alpha/2)\alpha(\rho_k)})(1+\tilde{t}_\alpha^{1/2}\tilde{u}_{\tilde{\alpha}}^{-1/2}q^{-(n_\alpha/2)\alpha(\rho_k)})(1-\tilde{t}_\alpha^{-1/2}\tilde{u}_{\tilde{\alpha}}^{-1/2}q^{-(n_\alpha/2)\alpha(\rho_k)})(1+\tilde{t}_\alpha^{-1/2}\tilde{u}_{\tilde{\alpha}}^{1/2}q^{-(n_\alpha/2)\alpha(\rho_k)})}{(1-q^{-n_\alpha\alpha(\rho_k)})^2}\\
&=\prod_{\alpha\in\mathring{R}_+^l}\prod_{n=1}^{(1/2)(\alpha|\mu)}\frac{(1-t_l^{-1/2}t_0^{-1/2}q^{(1/2)(\alpha|\rho_k)+n})(1+t_l^{-1/2}t_0^{1/2}q^{(1/2)(\alpha|\rho_k)+n})(1-t_l^{1/2}t_0^{1/2}q^{(1/2)(\alpha|\rho_k)+n})(1+t_l^{1/2}t_0^{-1/2}q^{(1/2)(\alpha|\rho_k)+n})}{(1-q^{(\alpha|\rho_k)+2n})^2}\\
&\quad\times\frac{(1-u_0^{-1/2}u_l^{-1/2}q^{(1/2)(\alpha|\rho_k)+n-1/2})(1+u_0^{-1/2}u_l^{1/2}q^{(1/2)(\alpha|\rho_k)+n-1/2})(1-u_0^{1/2}u_l^{1/2}q^{(1/2)(\alpha|\rho_k)+n-1/2})(1+u_0^{1/2}u_l^{-1/2}q^{(1/2)(\alpha|\rho_k)+n-1/2})}{(1-q^{(\alpha|\rho_k)+2n-1})^2}\\
&\quad\times\prod_{\alpha\in\mathring{R}_+^s}\prod_{n=1}^{(\alpha|\mu)}\frac{(1-t_\alpha^{-1}q^{(\alpha|\rho_k)+n})(1-t_\alpha q^{(\alpha|\rho_k)+n})}{(1-q^{(\alpha|\rho_k)+n})^2}.
\end{aligned}$$

By use of the constant term identity (3.4), we have

$$\begin{aligned}
&\langle E_\mu,E_\mu\rangle'_{q,t,u}\\
&=\prod_{\alpha\in\mathring{R}_+^l}\frac{(1-qq_{\mu,\alpha}^2;q)_\infty^2}{(t_l^{-1/2}t_0^{-1/2}qq_{\mu,\alpha},-t_l^{-1/2}t_0^{1/2}qq_{\mu,\alpha},t_l^{1/2}t_0^{1/2}qq_{\mu,\alpha},-t_l^{1/2}t_0^{-1/2}qq_{\mu,\alpha};q)_\infty}\\
&\quad\times\frac{1}{(u_0^{-1/2}u_l^{-1/2}q^{1/2}q_{\mu,\alpha},-u_0^{-1/2}u_l^{1/2}q^{1/2}q_{\mu,\alpha},u_0^{1/2}u_l^{1/2}q^{1/2}q_{\mu,\alpha},-u_0^{1/2}u_l^{-1/2}q^{1/2}q_{\mu,\alpha};q)_\infty}\\
&\quad\times\prod_{\alpha\in\mathring{R}_+^s}\frac{(qq_{\mu,\alpha}^2;q)_\infty^2}{(t_\alpha^{-1}qq_{\mu,\alpha}^2,t_\alpha qq_{\mu,\alpha}^2q)_\infty}.
\end{aligned}\tag{3.20}$$

Hence we obtain (3.18) by rewriting this with a, b, c, and d. Note that we define the right-hand side of (3.20) by expanding them in $\mathbb{C}[\{t_\alpha^{1/2},u_\alpha^{1/2}\}][[q^{1/2}]]$. □

Proposition 3.16: For a weight $\mu\in\mathring{P}$ *lying in the* $\mathring{W}$*-orbit of* $\mu^+\in\mathring{P}_+$, *we have*

$$\frac{\langle E_\mu, E_\mu\rangle'_{q,t,u}}{\langle E_{\mu^+}, E_{\mu^+}\rangle'_{q,t,u}} = \prod_{\alpha\in R_{w_\mu^{-1}}} \frac{(1-q_{\mu^+,\alpha}^2)^2}{(1-t_\alpha^{1/2}\check{t}_{\tilde{\alpha}}^{1/2}q_{\mu+,\alpha})(1+t_\alpha^{1/2}\check{t}_{\tilde{\alpha}}^{-1/2}q_{\mu^+,\alpha})(1-t_\alpha^{-1/2}\check{t}_{\tilde{\alpha}}^{-1/2}q_{\mu^+,\alpha})(1+t_\alpha^{-1/2}\check{t}_{\tilde{\alpha}}^{-1/2}q_{\mu^+,\alpha})}, \tag{3.21}$$

where $q_{\mu^+,\alpha}=q^{(1/2)(\alpha|\mu^+ +\rho_k)}$.

Proof: For a reduced expression $w_\mu=s_{i_1}s_{i_2}\cdots s_{i_k}\in \mathring{W}$, we have

$$S^*_{w_\mu}S_{w_\mu}=S^*_{i_k}\cdots S^*_{i_2}S^*_{i_1}S_{i_1}S_{i_2}\cdots S_{i_k}=S_{i_k}\cdots S_{i_2}N(\alpha_{i_1})S_{i_2}\cdots S_{i_k}=\prod_{\alpha\in R_{w_\mu^{-1}}}N(\alpha).$$

Using the Rodrigues-type formula (3.17), we calculate the scalar product,

$$\begin{aligned}\langle E_\mu, E_\mu\rangle'_{q,t,u}&=\langle d_{w_\mu}^{-1}\hat{S}_{w_\mu}E_{\mu^+}, d_{w_\mu}^{-1}\hat{S}_{w_\mu}E_{\mu^+}\rangle'_{q,t,u}\\ &=d_{w_\mu}^{-1}(d_{w_\mu}^{-1})^\iota\langle E_{\mu^+}, \hat{S}^*_{w_\mu}\hat{S}_{w_\mu}E_{\mu^+}\rangle'_{q,t,u}\\ &=d_{w_\mu}^{-1}(d_{w_\mu}^{-1})^\iota\langle E_{\mu^+}, E_{\mu^+}\rangle'_{q,t,u}\prod_{\alpha\in R_{w_\mu^{-1}}}t_\alpha^{-1}(1-t_\alpha^{1/2}t_{\tilde{\alpha}}^{1/2}q_{\mu^+,\alpha})(1+t_\alpha^{1/2}t_{\tilde{\alpha}}^{-1/2}q_{u^+,\alpha})\\ &\quad\times(1-t_\alpha^{1/2}t_{\tilde{\alpha}}^{1/2}q_{\mu^+,\alpha}^{-1})(1+t_\alpha^{1/2}t_{\tilde{\alpha}}^{-1/2}q_{\mu^+,\alpha}^{-1}),\end{aligned}$$

from which we obtain (3.21). □

B. Macdonald–Koornwinder polynomials

We turn to the main object of our interest, the Macdonald–Koornwinder polynomials. Define the following symmetric inner products in the $\mathring{W}$-invariant Laurent polynomial ring $\mathbb{K}[\mathring{P}]^{\mathring{W}}$:

$$\langle f,g\rangle_{q,t,u}:=\frac{1}{|\mathring{W}|}[f\overline{g}\Delta_{q,t,u}]_0,\quad (f,g)_{q,t,u}:=\frac{1}{|\mathring{W}|}[f\overline{g}\widetilde{\Delta}_{q,t,u}]_0, \tag{3.22}$$

where the weight function $\Delta_{q,t,u}$ is given by

$$\Delta_{q,t,u}:=\Delta^+_{q,t,u}\overline{\Delta^+_{q,t,u}},$$

$$\begin{aligned}\Delta^+_{q,t,u}&:=\prod_{\alpha\in\mathring{R}^l_+}\prod_{n=0}^{\infty}\frac{(1-x^{\alpha+2n\delta})(1-x^{\alpha+(2n+1)\delta})}{(1-t_l^{1/2}u_0^{1/2}x^{(1/2)\alpha+n\delta})(1+t_l^{1/2}u_0^{-1/2}x^{(1/2)\alpha+n\delta})(1-t_0^{1/2}u_l^{1/2}x^{(1/2)\alpha+(n+1/2)\delta})(1+t_0^{1/2}u_l^{-1/2}x^{(1/2)\alpha+(n+1/2)\delta})}\\ &\quad\times\prod_{\alpha\in\mathring{R}^s_+}\prod_{n=0}^{\infty}\frac{1-x^{\alpha+n\delta}}{1-t_\alpha x^{\alpha+n\delta}}\\ &=\prod_{\alpha\in\mathring{R}^l_+}\frac{(x^\alpha;q)_\infty}{(ax^{(1/2)\alpha},bx^{(1/2)\alpha},cx^{(1/2)\alpha},dx^{(1/2)\alpha};q)_\infty}\prod_{\alpha\in\mathring{R}^s_+}\frac{(x^\alpha;q)_\infty}{(t_\alpha x^\alpha;q)_\infty},\end{aligned} \tag{3.23}$$

and $\widetilde{\Delta}_{q,t,u}:=\Delta_{q,t,u}/[\mu_{q,t,u}]_0$.

Definition 3.17 (Macdonald–Koornwinder polynomials): The (monic) Macdonald–Koornwinder polynomials $P_\mu:=P_\mu(x;q,\{t_\alpha,u_\alpha\})\in\mathbb{K}[\mathring{P}]^{\mathring{W}}$, $(\mu\in\mathring{P}_+)$[22] *are uniquely defined by the following conditions*:

$$(i)\ \ P_\mu = m_\mu + \sum_{\nu<\mu} w_{\mu\nu} m_\nu \quad \text{for } w_{\mu\nu} \in \mathbb{K},$$
$$(ii)\ \ (P_\mu, m_\nu)_{q,t,u} = 0 \quad \text{if } \nu < \mu, \tag{3.24}$$

where $m_\mu(x) := \Sigma_{\nu \in \mathring{W}(\mu)} x^\nu \in \mathbb{C}[\mathring{P}]^{\mathring{W}}$ *is orbit sum.*

Proposition 3.18 (T. H. Koornwinder): (i) We have the orthogonality of the Macdonald–Koornwinder polynomials:

$$(P_\mu, P_\nu)_{q,t,u} = 0 \quad \text{if } \mu \neq \nu. \tag{3.25}$$

In fact, the Macdonald–Koornwinder polynomials form an orthogonal basis in $\mathbb{K}[\mathring{P}]^{\mathring{W}}$ *with respect to the inner product* $(\cdot,\cdot)_{q,t,u}$ *in (3.22).*
(ii) Conditions (i) in (3.24) and (3.25) also determine the Macdonald–Koornwinder polynomials P_μ *uniquely.*

To prove the above-mentioned proposition, one needs Koornwinder's difference operator which is Hermitian with respect to the inner products (3.22) and uniquely characterizes the Macdonald–Koornwinder polynomials as its eigenvectors.[22] An explicit commutative family of difference operators including the Koornwinder's operator were obtained in Ref. 23.

Lemma 3.19: For $f, g \in \mathbb{K}[\mathring{P}]^{\mathring{W}}$, *we have*

$$(f,g)'_{q,t,u} = \mathcal{W}(t)(f, g^\iota)_{q,t,u},$$

where

$$\mathcal{W}(t) = \sum_{w \in \mathring{W}} \prod_{\alpha \in R_{w^{-1}}} t_\alpha. \tag{3.26}$$

Proof: We decompose $\mu_{q,t,u}$ as

$$\mu_{q,t,u} = \Delta_{q,t,u} \prod_{\alpha \in \mathring{R}_+} \frac{(1 - t_\alpha^{1/2} u_{\tilde{\alpha}}^{1/2} x^{-(1/2)\alpha})(1 + t_\alpha^{1/2} u_{\tilde{\alpha}}^{-1/2} x^{-(1/2)\alpha})}{1 - x^{-\alpha}}.$$

Then we see that

$$\begin{aligned}
(f,g)'_{q,t,u} &= \frac{1}{|\mathring{W}|} \sum_{w \in \mathring{W}} [w(f\overline{g^\iota})\tilde{\mu}_{q,t,u}]_0 \\
&= \frac{1}{|\mathring{W}|} \sum_{w \in \mathring{W}} [f\overline{g^\iota} w(\tilde{\mu}_{q,t,u})]_0 \\
&= \frac{1}{|\mathring{W}|} \left[f\overline{g^\iota} \tilde{\Delta}_{q,t,u} \sum_{w \in \mathring{W}} w\left(\prod_{\alpha \in \mathring{R}_+} \frac{(1 - t_\alpha^{1/2} u_{\tilde{\alpha}}^{1/2} x^{-(1/2)\alpha})(1 + t_\alpha^{1/2} u_{\tilde{\alpha}}^{-1/2} x^{-(1/2)\alpha})}{1 - x^{-\alpha}} \right) \right]_0 \\
&= \frac{1}{|\mathring{W}|} \left[f\overline{g^\iota} \tilde{\Delta}_{q,t,u} \sum_{w \in \mathring{W}} \prod_{\alpha \in \mathring{R}_+} \frac{(1 - t_\alpha^{1/2} u_{\tilde{\alpha}}^{1/2} x^{-(1/2)w(\alpha)})(1 + t_\alpha^{1/2} u_{\tilde{\alpha}}^{-1/2} x^{-(1/2)w(\alpha)})}{1 - x^{-w(\alpha)}} \right]_0 \\
&= \frac{1}{|\mathring{W}|} [f\overline{g^\iota} \tilde{\Delta}_{q,t,u}]_0 \sum_{w \in \mathring{W}} \prod_{\alpha \in R_{w^{-1}}} t_\alpha.
\end{aligned} \tag{3.27}$$

In the last equality of (3.27), we have used the following identity:

$$\mathcal{W}(t)=\sum_{w\in\mathring{W}}\prod_{\alpha\in\mathring{R}_+}\frac{(1-t_\alpha^{1/2}u_{\tilde{\alpha}}^{1/2}x^{-(1/2)w(\alpha)})(1+t_\alpha^{1/2}u_{\tilde{\alpha}}^{-1/2}x^{-(1/2)w(\alpha)})}{1-x^{-w(\alpha)}}=\sum_{w\in\mathring{W}}\prod_{\alpha\in R_{w^{-1}}}t_\alpha. \tag{3.28}$$

This identity is obtained from expressions of the Poincaré polynomials associated with BC_1-type nonreduced root system $\overline{R^{\mathrm{re}}}$,[41]

$$\mathcal{W}(v)=\sum_{w\in\mathring{W}}\prod_{\alpha\in(R^{\mathrm{re}})_+}\frac{1-v_{2\alpha}^{1/2}v_\alpha x^{-w(\alpha)}}{1-v_{2\alpha}^{1/2}x^{-w(\alpha)}}=\sum_{w\in\mathring{W}}\prod_{\alpha\in R_{w^{-1}}}v_\alpha, \tag{3.29}$$

where $v_{2\alpha}=1$ if $2\alpha\notin\overline{R^{\mathrm{re}}}$. Indeed, by the following change of the indeterminates:

$$v_\alpha\to t_\alpha u_{\tilde{\alpha}}^{-1},\quad v_{(1/2)\alpha}\to u_{\tilde{\alpha}}\quad\text{for }\alpha\in\mathring{R},$$

we can verify (3.28). □

We remark that $\mathcal{W}(t)$ does not depend on u_α and agrees with the Poincaré polynomial associated with the Weyl group of type C_l.

Corollary 3.20: Proposition 3.1 with Lemma 3.19 shows that coefficients of $\Delta_{q,t,u}$ are in the algebra $\mathbb{C}(\{t_\alpha^{1/2},u_\alpha^{1/2}\})[[q^{1/2}]]$ of formal power series in $q^{1/2}$ over the field of rational functions in $\{t_\alpha^{1/2},u_\alpha^{1/2}\}$.

The Macdonald–Koornwinder polynomials $(P_\mu)^\iota$ mapped by involution ι satisfy the defining relations (3.24), since the weight function has the property $(\Delta_{q,t,u})^\iota=f\times\Delta_{q,t,u,}(f\in\mathbb{K})$. Hence $(P_\mu)^\iota=P_\mu$ from their top term. This fact and Lemma 3.19 show that, in defining the Macdonald–Koornwinder polynomials, we can employ the scalar product $(\cdot,\cdot)'_{q,t,u}$ instead of the inner product $(\cdot,\cdot)_{q,t,u}$.

Proposition 3.21: Let $P_\mu,(\mu\in\mathring{P}_+)$ be the following linear combination of the nonsymmetric Macdonald–Koornwinder polynomials $E_\nu,(\nu\in\mathring{P})$:

$$P_\mu=\sum_{\nu\in\mathring{W}(\mu)}a_{\mu\nu}E_\nu, \tag{3.30a}$$

where

$$a_{\mu\nu}:=\prod_{\alpha\in R_{w_\nu^{-1}}}\frac{1+t_\alpha^{-1/2}(\check{t}_{\tilde{\alpha}}^{1/2}-\check{t}_{\tilde{\alpha}}^{-1/2})q_{\mu,\alpha}-t_\alpha^{-1}q_{\mu,\alpha}^2}{1-q_{\mu,\alpha}^2}. \tag{3.30b}$$

The polynomials P_μ are elements in $\mathbb{K}[\mathring{P}]^{\mathring{W}}$. In fact, P_μ satisfy the definition of the Macdonald–Koornwinder polynomials (3.24).

Proof: We use the fact that conditions $\hat{T}_iP_\mu=t_i^{1/2}P_\mu,(1\leqslant i\leqslant l)$ are equivalent to $P_\mu\in\mathbb{K}[\mathring{P}]^{\mathring{W}}$ (see, for example, Ref. 17). If we take the expansion (3.30a), the coefficients $a_{\mu\nu}\in\mathbb{K}$ are uniquely determined under the conditions $\hat{T}_iP_\mu=t_i^{1/2}P_\mu$, $(1\leqslant i\leqslant l)$ and $a_{\mu\mu}=1$. Indeed, if we require

$$\hat{T}_iP_\mu=a_{\mu\nu}\hat{T}_iE_\nu+a_{\mu\nu'}\hat{T}_iE_{\nu'}+\cdots=t_i^{1/2}(a_{\mu\nu}E_\nu+a_{\mu\nu'}E_{\nu'}+\cdots),$$

for $\nu,\nu'=s_i(\nu)(\in\mathring{W}(\mu))$ satisfying $\nu'<\nu\leqslant\mu,(\mu\in\mathring{P}_+)$, we have

$$\frac{a_{\mu\nu'}}{a_{\mu\nu}}=\frac{1+t_i^{-1/2}(\check{t}_{\tilde{\alpha}_i}^{1/2}-\check{t}_{\tilde{\alpha}_i}^{-1/2})q_{\nu,i}-t_i^{-1}q_{\nu,i}^2}{1-q_{\nu,i}^2},$$

from (3.10). To consider $a_{\mu\nu}$ with a general weight $\nu=w_\nu(\mu)$ where $w_\nu\in\mathring{W}^\mu$ such that $w_\nu^{-1}(\nu)\in\mathring{P}_+$, we take a reduced expression $w_\nu=s_{i_1}s_{i_2}\cdots s_{i_k}$ and put $\mu^{(n)}:=s_{i_n}s_{i_{n+1}}\cdots s_{i_k}(\mu)$, $(1\leqslant n\leqslant k+1)$. We find

$$\begin{aligned}
a_{\mu\nu}&=\prod_{n=1}^{k}\frac{a_{\mu\mu^{(n)}}}{a_{\mu\mu^{(n+1)}}}\\
&=\prod_{n=1}^{k}\frac{1+t_{i_n}^{-1/2}(\check{t}_{\tilde{\alpha}_{i_n}}^{1/2}-\check{t}_{\tilde{\alpha}_{i_n}}^{-1/2})q_{\mu^{(n+1)},i_n}-t_{i_n}^{-1}q_{\mu^{(n+1)},i_n}^2}{1-q_{\mu^{(n+1)},i_n}^2}\\
&=\prod_{n=1}^{k}\frac{1+t_{i_n}^{-1/2}(\check{t}_{\tilde{\alpha}_{i_n}}^{1/2}-\check{t}_{\tilde{\alpha}_{i_n}}^{-1/2})q_{\mu,s_{i_k}s_{i_{k-1}}\cdots s_{i_{n+1}}(\alpha_{i_n})}-t_{i_n}^{-1}q_{\mu,s_{i_k}s_{i_{k-1}}\cdots s_{i_{n+1}}(\alpha_{i_n})}^2}{1-q_{\mu,s_{i_k}s_{i_{k-1}}\cdots s_{i_{n+1}}(\alpha_{i_n})}^2}.
\end{aligned}$$

One sees that the roots $\{s_{i_k}s_{i_{k-1}}\cdots s_{i_{n+1}}(\alpha_{i_n})\}$ run through the set $R_{w_\nu^{-1}}$ and hence does not depend on decomposition of w_ν. Then P_μ are of the form (i) in (3.24). They satisfy relation (ii) in (3.24) due to (3.6) and Lemma 3.19. □

Corollary 3.22: As a corollary of Proposition 3.14 and 3.21, we obtain algebraic expressions of the Macdonald–Koornwinder polynomials $P_\mu,(\mu\in\mathring{P}_+)$:

$$P_\mu=\sum_{\nu\in\mathring{W}(\mu)}a_{\mu\nu}d_{w_\nu}^{-1}d_\mu^{-1}\hat{S}_{w_\nu}\hat{A}_\mu E_0. \tag{3.31}$$

Now we consider the inner product identity of the Macdonald–Koornwinder polynomials. In the case of $l=1$, it reduces to that of the Askey–Wilson polynomials.[43] As for the higher rank setting, the identity is first proved at its self-dual point with expansion formulas[24] and a proof beyond the self-dual setting is given by combining van Diejen's work[24] and a duality of the polynomials.[27] Opdam–Cherednik's shift operator approach is also applied to the identity.[29] Although the shift operator approach is so powerful that it contains a proof of the constant term identity, its applications is restricted to the inner product identity with parameters satisfying $t_\alpha=q^{k_\alpha}$, $u_\alpha=q^{h_\alpha}$, $(k_\alpha,h_\alpha\in\mathbb{N})$ because of their properties. Our new proof shown here can be applied to the identity with indeterminates $\{q^{1/2},t_\alpha^{1/2},u_\alpha^{1/2}\}$, that is, we provide a proof of the identity in the algebra $\mathbb{C}(\{t_\alpha^{1/2},u_\alpha^{1/2}\})[[q^{1/2}]]$ of formal power-series in $q^{1/2}$ over the field of rational functions in $\{t_\alpha^{1/2},u_\alpha^{1/2}\}$.

We remark that, for certain renormalized nonsymmetric Macdonald–Koornwinder polynomials, there is an analytic approach to relate diagonal terms of their scalar products to residues of the weight function.[29,30] Using so-called symmetrizers, the results of the nonsymmetric polynomials lead to those of renormalized Macdonald–Koornwinder polynomials. However, in order to see the explicit inner product identity of monic Macdonald–Koornwinder polynomials (i.e., in the form of Theorem 3.24), it is necessary to use evaluation formulas of the polynomials and to put together residues of the weight function and several coefficients appearing in that process. Our approach gives direct and explicit calculation of the inner products for the monic Macdonald–Koornwinder polynomials (3.24) from Theorem 3.15, Proposition 3.16, 3.21 and Lemma 3.19, and hence it does not rely on the evaluation formula. Furthermore we can see that coefficients appearing in our process are nicely combined to produce the final result thanks to the following lemma.

Lemma 3.23: Let $\mu\in\mathring{P}_+$. We have

$$\sum_{\nu\in\mathring{W}(\mu)}\prod_{\alpha\in R_{w_\nu^{-1}}}\frac{t_\alpha(1-t_\alpha^{-1/2}\check{t}_{\tilde{\alpha}}^{-1/2}q_{\mu,\alpha})(1+t_\alpha^{-1/2}\check{t}_{\tilde{\alpha}}^{1/2}q_{\mu,\alpha})}{(1-t_\alpha^{1/2}\check{t}_{\tilde{\alpha}}^{1/2}q_{\mu,\alpha})(1+t_\alpha^{1/2}\check{t}_{\tilde{\alpha}}^{-1/2}q_{\mu,\alpha})}$$

$$=\mathcal{W}(t)\prod_{\alpha\in\mathring{R}_+}\frac{1-q_{\mu,\alpha}^2}{(1-t_\alpha^{1/2}\check{t}_{\tilde{\alpha}}^{1/2}q_{\mu,\alpha})(1+t_\alpha^{1/2}\check{t}_{\tilde{\alpha}}^{-1/2}q_{\mu,\alpha})}. \tag{3.32}$$

Proof: There exists a $\mathbb{K}$-homomorphism $\varphi:\mathbb{C}(q^{1/2},\{t_\alpha^{1/2}\})[\{u_\alpha^{1/2}\},\frac{1}{2}\mathring{Q}]\to\mathbb{C}(q^{1/2},\{t_\alpha^{1/2}\})$ defined by

$$\varphi:x^{-(1/2)\alpha_i}\mapsto q^{(1/2)(\alpha_i|\mu+\rho_k)}=q_{\mu,\alpha_i}\quad\text{for } i\in\mathring{I},\quad u_\alpha\to\check{t}_\alpha.$$

Since $\mathcal{W}(t)\in\mathbb{C}(q^{1/2},\{t_\alpha^{1/2}\})[\{u_\alpha^{1/2}\},\frac{1}{2}\mathring{Q}]$ does not depend on $\{u_\alpha^{1/2},x^{1/2\alpha_i}\}$ as (3.28), we have

$$\begin{aligned}
&\varphi(\mathcal{W}(t))=\mathcal{W}(t)\\
&=\sum_{w\in\mathring{W}}\prod_{\alpha\in\mathring{R}_+}\varphi\left(\frac{(1-t_\alpha^{1/2}u_\alpha^{1/2}x^{-(1/2)w(\alpha)})(1+t_\alpha^{1/2}u_{\tilde{\alpha}}^{-1/2}x^{-(1/2)w(\alpha)})}{1-x^{-w(\alpha)}}\right)\\
&=\sum_{w\in\mathring{W}}\prod_{\alpha\in\mathring{R}_+}\frac{(1-t_\alpha^{1/2}\check{t}_{\tilde{\alpha}}^{1/2}q_{\mu,w(\alpha)})(1+t_\alpha^{1/2}\check{t}_{\tilde{\alpha}}^{-1/2}q_{\mu,w(\alpha)})}{1-q_{\mu,w(\alpha)}^2}\\
&=\sum_{w\in\mathring{W}}\frac{\Pi_{\alpha\in R_w}(1-t_\alpha^{1/2}\check{t}_{\tilde{\alpha}}^{1/2}q_{\mu,\alpha}^{-1})(1+t_\alpha^{1/2}\check{t}_{\tilde{\alpha}}^{-1/2}q_{\mu,\alpha}^{-1})\Pi_{\alpha\in\mathring{R}_+\setminus R_w}(1-t_\alpha^{1/2}\check{t}_{\tilde{\alpha}}^{1/2}q_{\mu,\alpha})(1+t_\alpha^{1/2}\check{t}_{\tilde{\alpha}}^{-1/2}q_{\mu,\alpha})}{\Pi_{\alpha\in R_w}(1-q_{\mu,\alpha}^{-2})\Pi_{\alpha\in\mathring{R}_+\setminus R_w}(1-q_{\mu,\alpha}^2)}\\
&=\frac{\Sigma_{w\in\mathring{W}}\Pi_{\alpha\in R_w}t_\alpha(1-t_\alpha^{-1/2}\check{t}_{\tilde{\alpha}}^{-1/2}q_{\mu,\alpha})(1+t_\alpha^{-1/2}\check{t}_{\tilde{\alpha}}^{1/2}q_{\mu,\alpha})\Pi_{\alpha\in\mathring{R}_+\setminus R_w}(1-t_\alpha^{1/2}\check{t}_{\tilde{\alpha}}^{1/2}q_{\mu,\alpha})(1+t_\alpha^{1/2}\check{t}_{\tilde{\alpha}}^{-1/2}q_{\mu,\alpha})}{\Pi_{\alpha\in\mathring{R}_+}(1-q_{\mu,\alpha}^2)}.
\end{aligned}$$

Thus we obtain the following relation immediately:

$$\sum_{w\in\mathring{W}}\prod_{\alpha\in R_{w^{-1}}}\frac{t_\alpha(1-t_\alpha^{-1/2}\check{t}_{\tilde{\alpha}}^{-1/2}q_{\mu,\alpha})(1+t_\alpha^{-1/2}\check{t}_{\tilde{\alpha}}^{1/2}q_{\mu,\alpha})}{(1-t_\alpha^{1/2}\check{t}_{\tilde{\alpha}}^{1/2}q_{\mu,\alpha})(1+t_\alpha^{1/2}\check{t}_{\tilde{\alpha}}^{-1/2}q_{\mu,\alpha})}$$

$$=\mathcal{W}(t)\prod_{\alpha\in\mathring{R}_+}\frac{1-q_{\mu,\alpha}^2}{(1-t_\alpha^{1/2}\check{t}_{\tilde{\alpha}}^{1/2}q_{\mu,\alpha})(1+t_\alpha^{1/2}\check{t}_{\tilde{\alpha}}^{-1/2}q_{\mu,\alpha})}. \tag{3.33}$$

We show that the sum on the left-hand side of the equation above can be replaced by the sum on $\nu\in\mathring{W}(\mu)$. Consider the isotropy group $\mathring{W}_\mu=\{v\in\mathring{W}|v(\mu)=\mu\}$ for the dominant weight $\mu\in\mathring{P}_+$. Since an element $v\in\mathring{W}_\mu\setminus\{id\}$ can be written by the product of simple reflections fixing μ, $\{s_i|i\in\mathring{J}\subset\mathring{I}\}$ (see Ref. 36), there exists at least one simple root $\alpha_i\in\mathring{\Pi}$ associated with the reflection s_i in the set $R_{v^{-1}}$ if $\mathring{W}_\mu\neq\{id\}$. Hence, for $v\in\mathring{W}_\mu\setminus\{id\}$, we have

$$\begin{aligned}
&\prod_{\alpha\in R_{v^{-1}}}(1-t_\alpha^{-1/2}\check{t}_{\tilde{\alpha}}^{-1/2}q^{(1/2)(\alpha|\mu+\rho_k)})\\
&=(1-t_i^{-1/2}\check{t}_{\tilde{\alpha}_i}^{-1/2}q^{(1/2)(\alpha_i|\mu+\rho_k)})\prod_{\alpha\in R_{v^{-1}}\setminus\{\alpha_i\}}(1-t_\alpha^{-1/2}\check{t}_{\tilde{\alpha}}^{-1/2}q^{(1/2)(\alpha|\mu+\rho_k)})\\
&=(1-t_i^{-1/2}\check{t}_{\tilde{\alpha}_i}^{-1/2}t_i^{1/2}\check{t}_{\tilde{\alpha}_i}^{1/2})\prod_{\alpha\in R_{v^{-1}}\setminus\{\alpha_i\}}(1-t_\alpha^{-1/2}\check{t}_{\tilde{\alpha}}^{-1/2}q^{(1/2)(\alpha|\mu+\rho_k)})=0.
\end{aligned}$$

For $w \in \mathring{W}$, there is a unique $u \in \mathring{W}^{\mu}$ and a unique $v \in \mathring{W}_{\mu}$ such that $w=uv$. The formula $R_{w^{-1}} = R_{v^{-1}} \cup v^{-1} R_{u^{-1}}$ shows that, if $v \neq id$, the product on $\alpha \in R_{w^{-1}}$ in (3.33) vanishes. Thus we obtain the lemma above since the sum on $w \in \mathring{W}$ on the left-hand side of (3.33) can be replaced by that on $u \in \mathring{W}^{\mu}$ which is equivalent to that on $\nu \in \mathring{W}(\mu)$.

Theorem 3.24 (inner product identity): *Let $\mu, \nu \in \mathring{P}_+$. We have*

$$\begin{aligned}\langle P_{\mu}, P_{\nu} \rangle_{q,t,u} &= \delta_{\mu\nu} \prod_{\alpha \in \mathring{R}^l_+} \frac{(abcdq^{-1} q'^2_{\mu,\alpha}, abcdq'^2_{\mu,\alpha}; q)_{\infty}}{(qq'_{\mu,\alpha}, abq'_{\mu,\alpha}, acq'_{\mu,\alpha}, adq'_{\mu,\alpha}, bcq'_{\mu,\alpha}, bdq'_{\mu,\alpha}, cdq'_{\mu,\alpha}, abcdq^{-1} q'_{\mu,\alpha}; q)_{\infty}} \\ &\quad \times \prod_{\alpha \in \mathring{R}^s_+} \frac{(q^2_{\mu,\alpha}, qq^2_{\mu,\alpha}; q)_{\infty}}{(t_{\alpha} q^2_{\mu,\alpha}, t_{\alpha}^{-1} qq^2_{\mu,\alpha}; q)_{\infty}}, \end{aligned} \tag{3.34}$$

where $q_{\mu,\alpha} = q^{(1/2)(\alpha|\mu+\rho_k)}$ and $q'_{\mu,\alpha} = q^{(1/2)(\alpha|\mu+\rho'_k)}$.

Proof: The orthogonality in the case of $\mu \neq \nu$ follows from Lemma 3.19 and Proposition 3.6. Using the relation (3.26), the expansions (3.30a), and the definition of $E_{\nu}, (\nu \in \mathring{P})$ (3.6), we obtain

$$\begin{aligned}\langle P_{\mu}, P_{\mu} \rangle_{q,t,u} &= \mathcal{W}(t)^{-1} \langle P_{\mu}, P_{\mu} \rangle'_{q,t,u} \\ &= \mathcal{W}(t)^{-1} \sum_{\nu \in \mathring{W}(\mu)} a_{\mu\nu}(\alpha_{\mu\nu})^{\iota} \frac{\langle E_{\nu}, E_{\nu} \rangle'_{q,t,u}}{\langle E_{\mu}, E_{\mu} \rangle'_{q,t,u}} \langle E_{\mu}, E_{\mu} \rangle'_{q,t,u} \\ &= \mathcal{W}(t)^{-1} \sum_{\nu \in \mathring{W}(\mu)} \prod_{\alpha \in R_{w_{\nu}^{-1}}} \frac{t_{\alpha}(1 - t_{\alpha}^{-1/2} \check{t}_{\tilde{\alpha}}^{-1/2} q_{\mu,\alpha})(1 + t_{\alpha}^{-1/2} \check{t}_{\tilde{\alpha}}^{1/2} q_{\mu,\alpha})}{(1 - t_{\alpha}^{1/2} \check{t}_{\tilde{\alpha}}^{1/2} q_{\mu,\alpha})(1 + t_{\alpha}^{1/2} \check{t}_{\tilde{\alpha}}^{-1/2} q_{\mu.\alpha})} \langle E_{\mu}, E_{\mu} \rangle'_{q,t,u} \\ &= \prod_{\alpha \in \mathring{R}_+} \frac{1 - q^2_{\mu,\alpha}}{(1 - t_{\alpha}^{1/2} \check{t}_{\tilde{\alpha}}^{1/2} q_{\mu,\alpha})(1 + t_{\alpha}^{1/2} \check{t}_{\tilde{\alpha}}^{-1/2} q_{\mu,\alpha})} \langle E_{\mu}, E_{\mu} \rangle'_{q,t,u}, \end{aligned}$$

where the fourth equality follows from the Lemma 3.23. □

IV. CONCLUDING REMARKS

We have presented an algebraic approach to the Macdonald–Koornwinder polynomials. Let us summarize our results in this paper. First we have introduced the extended affine Weyl group which acts on the affine root system of type $X_N^{(r)}$ to define the affine Hecke algebra of type $X_N^{(r)}$. The affine Hecke algebra of type $X_N^{(r)}$ has provided a new and unified viewpoint for the Macdonald and Macdonald–Koornwinder polynomials. Introducing the double affine Hecke algebra of type $A_{2l}^{(2)}$, we have given its representation in End($\mathbb{K}[\mathring{P}]$), i.e., the Demazure–Lusztig operators. Second we have considered the nonsymmetric Macdonald–Koornwinder polynomials. We have provided the Rodrigues-type formula for the nonsymmetric Macdonald–Koornwinder polynomials by use of the raising operators. The formula enables us to evaluate diagonal terms of scalar products for the nonsymmetric polynomials in an algebraic manner. Third we have algebraically constructed the Macdonald–Koornwinder polynomials through the Weyl-symmetrization of the nonsymmetric polynomials. Their inner product identity has been proved by the Weyl-symmetrization of the scalar products of the nonsymmetric polynomials together with an expression of the Poincaré polynomials.

As we have already described, the Macdonald–Koornwinder polynomials include the Macdonald polynomials associated with admissible pairs (BC_l, B_l) and (BC_l, C_l) for the BC_l-type nonreduced root system.[2,22] Indeed we can see the relations by putting

$$q = x^{\delta}, \quad a = u_0, \quad b = t_l u_0^{-1}, \quad t_0 = u_l = 1 \quad \text{for } (BC_l, B_l)$$

$$q^2=x^{\delta},\quad a=u_0=u_l,\quad b=t_l u_0^{-1}=t_0 u_l^{-1}\quad \text{for } (BC_l,C_l),$$

in the first expression of the weight function (3.23). Then Rodrigues-type formulas, scalar products, Weyl-symmetrization of the nonsymmetric polynomials corresponding to the BC_l-type Macdonald polynomials immediately follow from the replacement above.

It is well-known fact that the Askey–Wilson polynomials play a role of a master family of orthogonal polynomials with one-variable in the Askey scheme.[44] The Macdonald–Koornwinder polynomials also give some known orthogonal polynomials through limit transitions and/or specialization of their parameters.[45–47] It is of interest to investigate multivariable extension of the Askey scheme for both symmetric and nonsymmetric cases from its algebraic structure like double affine Hecke algebras.

APPENDIX: PROOF OF PROPOSITION 2.7

We present a proof of Proposition 2.7 following Lusztig.[35]

In what follows, we consider only the affine root system R of type $A_{2l}^{(2)}$, which contains real roots with three kinds of (square) lengths 1, 2, and 4. We use the following formulas for the length of an element of $\tilde{W}$:

Lemma A.1: For $w\in\tilde{W}$,

(i) $\ell(w^{-1})=\ell(w)$,

(ii) $\ell(ws_i)=\begin{cases}\ell(w)+1 & \text{if } w(\alpha_i)\in R_+\\ \ell(w)-1 & \text{if } w(\alpha_i)\in R_-,\end{cases}$ $\ell(s_iw)=\begin{cases}\ell(w)+1 & \text{if } w^{-1}(\alpha_i)\in R_+\\ \ell(w)-1 & \text{if } w^{-1}(\alpha_i)\in R_-,\end{cases}$

(iii) $\ell(\omega_r w)=\ell(w)$ *for* $r\in\mathcal{O}, w\in\tilde{W}$,

(iv) $\ell(\tau_\lambda)=\sum_{\alpha\in\mathring{R}_+}|(\lambda|\alpha)|$,

(v) $\ell(\tau_{\lambda+\mu})=\ell(\tau_\lambda)+\ell(\tau_\mu)$ *for* $\lambda,\mu\in\tilde{M}_+$.

Lemma A.2: Let $\lambda\in\tilde{M}_+,\alpha\in\mathring{\Pi}$ *be such that* $(\lambda|\alpha)=:p>0$. *Let* $s=s_\alpha$, $w=s\tau_\lambda s\tau_\lambda$. *One sees*

(i) $\ell(\tau_\lambda s)=\ell(\tau_\lambda)-1$,

(ii) $\lambda':=s(\lambda)+\lambda\in\tilde{M}_+$ *and* $\ell(w)=2\ell(\tau_\lambda)-2p$,

(iii) $\ell(\tau_\lambda s\tau_\lambda)=2\ell(\tau_\lambda)-2p+1$,

(iv) $T_sT_{s\tau_{-\lambda}}=T_{\tau_{-\lambda}}$, $T_{w^{-1}}T_s=T_{\tau_{-\lambda}s\tau_{-\lambda}}$,

(v) $T_{\tau_{-\lambda}}T_{s\tau_{-\lambda}}=T_{\tau_{-\lambda}s\tau_{-\lambda}}$ *for* $p=1$.

Proof: (i) We have $\tau_\lambda(\alpha)=\alpha-(\lambda|\alpha)\delta=\alpha-p\delta\in R_-$. Then (i) follows using Lemma A.1.

(ii) We have $w=\tau_{s(\lambda)+\lambda}=\tau_{2\lambda-(2p/|\alpha|^2)\alpha}=\tau_{\lambda'}$ and $\langle\lambda',\beta^\vee\rangle=2\langle\lambda,\beta^\vee\rangle-(2p/|\alpha|^2)\langle\alpha,\beta^\vee\rangle$ for $\beta\in\mathring{\Pi}$. One sees $\langle\lambda,\beta^\vee\rangle\geqslant 0$ since $\lambda\in\tilde{M}_+$. If $\alpha\neq\beta$, then $\langle\alpha,\beta^\vee\rangle<0$ so $\langle\lambda',\beta^\vee\rangle>0$. If $\alpha=\beta$, then $\langle\lambda,\beta^\vee\rangle=2p/|\alpha|^2$ and $\langle\alpha,\beta^\vee\rangle=2$ show $\langle\lambda',\beta^\vee\rangle=0$. Hence we find $\lambda'\in\tilde{M}_+$.

Using Lemma A.1, we have

$$\begin{aligned}\ell(w)&=\sum_{\beta\in\mathring{R}_+}|(s(\lambda)+\lambda|\beta)|\\&=\sum_{\beta\in\mathring{R}_+}(\lambda|s(\beta))+\sum_{\beta\in\mathring{R}_+}(\lambda|\beta)\\&=2\sum_{\beta\in\mathring{R}_+}(\lambda|\beta)-2(\lambda|\alpha)\\&=2\ell(\tau_\lambda)-2p.\end{aligned}$$

(iii) Using Lemma A.1 with $w^{-1}(\alpha)=\tau_{-\lambda'}(\alpha)=\alpha\in R_+$, we have $\ell(\tau_\lambda s\tau_\lambda)=\ell(sw)=\ell(w)+1$.
(iv) From $\ell(s)+\ell(s\tau_{-\lambda})=\ell(\tau_{-\lambda})$ and $\ell(w^{-1})+\ell(s)=\ell(w^{-1}s)=\ell(\tau_{-\lambda}s\tau_{-\lambda})$, we have

$$T_sT_{s\tau_{-\lambda}}=T_{\tau_{-\lambda}},\quad T_{w^{-1}}T_s=T_{\tau_{-\lambda}s\tau_{-\lambda}}.$$

(v) Set $p=1$. From $\ell(\tau_{-\lambda})+\ell(s\tau_{-\lambda})=\ell(\tau_{-\lambda}s\tau_{-\lambda})$, we have $T_{\tau_{-\lambda}}T_{s\tau_{-\lambda}}=T_{\tau_{-\lambda}s\tau_{-\lambda}}$.
□

Recall the definition of the lattice $\tilde{M}$ in (2.5). One sees easily that $\alpha\in 2\tilde{M}$ for $\alpha\in(R^{\mathrm{re}})^l$, which is very special situation discussed by Lusztig. We note that this situation does not occur in the $C_l^{(1)}$-type affine root system.

Lemma A.3: Assume that $\alpha\in 2\tilde{M}$. Tere is a unique element $\lambda\in\tilde{M}$ such that $(\lambda|\alpha)=2$ and $(\lambda|\beta)=0$ for all $\beta\in\mathring{\Pi}\backslash\{\alpha\}$. Moreover, in B, there exists elements $w',w''\in\tilde{W}$ and $\tilde{\alpha}\in R$ such that

$$T_{\tau_{-\lambda}s\tau_{-\lambda}}=T_{w'}T_{w''},\quad T_{\tau_{-2\lambda+(1/2)\alpha}}=T_{w'}T_{s_{\tilde{\alpha}}}T_{w''},\quad T_{\tau_{-\lambda}}T_{s\tau_{-\lambda}}=T_{w'}T_{s_{\tilde{\alpha}}}^2T_{w''}.$$

We give a proof of Lemma A.3 in several steps. For the $A_{2l}^{(2)}$-type affine root system, we have $\tilde{M}=\mathring{P}$. Let $\tilde{W}_1=\mathring{W}\ltimes\nu(\mathring{P}^\vee)$. The length of the elements of $\tilde{W}$ is extended to that of $\tilde{W}_1$ through the original definition (2.6). Let B_1 be the braid group corresponding to $\tilde{W}_1$. Then one sees that $\tilde{W}\subset\tilde{W}_1$ and $B\subset B_1$ in a natural way; moreover, if Ω_1 denotes the set of elements of length 0 in $\tilde{W}_1$, then $\Omega_1=\{1,\omega\}$ is a group of order 2 which is a complement of $\tilde{W}$ in $\tilde{W}_1$ and $\{1,T_\omega\}$ is a complement of B in B_1. In fact conjugation by ω stands for the nontrivial automorphism of the Coxeter diagram corresponding to the Dynkin diagram $S(A)$. Hence one sees $\omega s_\alpha\omega^{-1}=s_{\tilde{\alpha}}\in\tilde{W}$ and $\omega T_{s_\alpha}\omega^{-1}=T_{s_{\tilde{\alpha}}}\in B$ for $\tilde{\alpha}=\omega(\alpha)\in R$.

Lemma A.4: Let $\lambda_1\in\nu(\mathring{P}^\vee)$ such that $(\lambda_1|\alpha)=1$ and $(\lambda|\beta)=0$ for all $\beta\in\mathring{\Pi}\backslash\{\alpha\}$. Let $w'=\tau_{-3\lambda_1+(1/2)\alpha}\omega\in\tilde{W}_1$, $w''=\omega s\tau_{-\lambda_1}\in\tilde{W}_1$ and $\ell_1=\ell(\tau_{\lambda_1})$. Then $w',w''\in\tilde{W}$ and

$$\ell(\tau_{2\lambda-(1/2)\alpha})=4\ell_1-2,\quad \ell(\tau_\lambda s\tau_\lambda)=4\ell_1-3,\quad \ell(w')=3\ell_1-2,\quad \ell(w'')=\ell_1-1.$$

Proof: We have $\lambda_1\notin\mathring{P}$ since, if we have $\lambda_1\in\mathring{P}$, then it follows from $\alpha\in 2\mathring{P}$ that $(\lambda_1|\alpha)\in 2\mathbb{Z}$. Since $\mathring{P}$ has index 2 in $\nu(\mathring{P}^\vee)$, we have $2\lambda_1\in\mathring{P}$. In fact, if we set $\lambda=2\lambda_1$, then $(\lambda|\alpha)=2$ and $(\lambda|\beta)=0$ for all $\beta\in\mathring{\Pi}\backslash\{\alpha\}$. Uniqueness of this element λ is obvious since, if we have two such elements $\lambda,\mu\in\mathring{P}$, $(\lambda\neq\mu)$, then $(\lambda-\mu|\beta)=0$ for all $\beta\in\mathring{\Pi}$, contradicting $\lambda\neq\mu$. From $\lambda_1\in\nu(\mathring{P}^\vee)\backslash\mathring{P}$, we have $\tau_{\lambda_1}\in\omega\tilde{W}$ and $\tau_{3\lambda_1}\in\omega\tilde{W}$. Hence $w',w''\in\tilde{W}$.

Using Lemma A.1 and A.2 with $p=1$, we have $2\lambda_1$, $2\lambda_1-\frac{1}{2}\alpha=s(\lambda_1)+\lambda_1\in\mathring{P}_+$. Then

$$\ell(\tau_{2\lambda-(1/2)\alpha})=\ell(\tau_{2\lambda_1})+\ell(\tau_{2\lambda_1-(1/2)\alpha})=\ell(\tau_{2\lambda_1})+\ell(\tau_{s(\lambda_1)+\lambda_1})=2\ell_1+2\ell_1-2=4\ell_1-2.$$

If we set $p=2$ in (iii) of Lemma A.2, then we have

$$\ell(\tau_\lambda s \tau_\lambda) = 4\ell(\tau_\lambda) - 4 + 1 = 4\ell_1 - 3.$$

Using Lemma A.1 and A.2, we see

$$\ell(w') = \ell(\tau_{-3\lambda_1+(1/2)\alpha}\omega) = \ell(\tau_{-\lambda_1}) + \ell(\tau_{-2\lambda_1+(1/2)\alpha}) = \ell_1 + 2\ell_1 - 2 = 3\ell_1 - 2,$$

$$\ell(w'') = \ell(\omega s \tau_{-\lambda_1}) = \ell(\tau_{-\lambda_1}) - 1 = \ell_1 - 1.$$

□

Proof of Lemma A.3: We have already shown that $w', w'' \in \tilde{W}$ in Lemma A.4. We have

$$w'w'' = \tau_{-3\lambda_1+(1/2)\alpha} s \tau_{-\lambda_1} = \tau_{-2\lambda_1}(\tau_{-\lambda_1+(1/2)\alpha} s)\tau_{-\lambda_1} = \tau_{-2\lambda_1}(s\tau_{-\lambda_1})\tau_{-\lambda_1} = \tau_{-\lambda} s \tau_{-\lambda}.$$

Since Lemma A.2 and A.4 give rise to $\ell(w'w'') = \ell(w') + \ell(w'') = 4\ell_1 - 3$, we can verify $T_{\tau_{-\lambda} s \tau_{-\lambda}} = T_{w'} T_{w''}$.

In a way similar to Lemma. A.4, we find

$$w' s_{\tilde{\alpha}} w'' = \tau_{-3\lambda_1+(1/2)\alpha} \omega s_{\tilde{\alpha}} \omega s \tau_{-\lambda_1} = \tau_{-4\lambda_1+(1/2)\alpha} = \tau_{-2\lambda+(1/2)\alpha},$$

and $\ell(w' s_{\tilde{\alpha}} w'') = \ell(w') + \ell(s_{\tilde{\alpha}}) + \ell(w'') = 4\ell_1 - 2$. Then we have $T_{\tau_{-2\lambda+(1/2)\alpha}} = T_{w'} T_{s_{\tilde{\alpha}}} T_{w''}$.

We verify the last relation as

$$\begin{aligned} T_{\tau_{-\lambda}} T_{s\tau_{-\lambda}} &= T_{\tau_{-\lambda_1}} (T_{\tau_{-\lambda_1}} T_{s\tau_{-\lambda_1}}) T_{\tau_{-\lambda_1}} \\ &= T_{\tau_{-\lambda_1}} T_{\tau_{-\lambda_1} s \tau_{-\lambda_1}} T_{\tau_{-\lambda_1}} \\ &= T_{\tau_{-\lambda_1}} (T_{w^{-1}} T_s)(T_s T_{s\tau_{-\lambda_1}}) \\ &= T_{\tau_{-3\lambda_1+(1/2)\alpha}} T_s^2 T_{s\tau_{-\lambda_1}} \\ &= T_{w'} T_{s_{\tilde{\alpha}}}^2 T_{w''}. \end{aligned}$$

In the first equality, we have used $T_{\tau_{-\lambda}} = T_{\tau_{-\lambda_1}} T_{\tau_{-\lambda_1}}$ and $T_{s\tau_{-\lambda}} = T_{s\tau_{-\lambda_1}} T_{\tau_{-\lambda_1}}$ from (v) in Lemma A.1 and $\ell(\tau_{-\lambda}) = \ell(s\tau_{-\lambda_1}) + \ell(\tau_{-\lambda_1}) = 2\ell_1 - 1$, respectively. In the second and third equality, we have employed (v) and (iv) in Lemma A.2, respectively. The last equality follows immediately from $\omega T_{s_\alpha} \omega^{-1} = T_{s_{\tilde{\alpha}}}$. □

Proposition A.5: Let $\lambda, \mu \in \tilde{M}$ and $\alpha \in \mathring{\Pi}$,

(*i*) $Y^\lambda Y^\mu = Y^{\lambda+\mu}$

(*ii*) $T_s Y^\lambda = Y^\lambda T_s$ *if* $(\lambda|\alpha) = 0$,

(*iii*) $T_s Y^{s(\lambda)} T_s = Y^\lambda$ *if* $(\lambda|\alpha) = 1$ *for* $\alpha \notin 2\tilde{M}$.

(*iv*) *There exist elements* $b', b'' \in B$ *such that*

$$Y^{s(\lambda)} T_s = b' b'', \quad Y^{\lambda-(1/2)\alpha} = b' T_{s_{\tilde{\alpha}}} b'', \quad T_s^{-1} Y^\lambda = b' T_{s_{\tilde{\alpha}}}^2 b'',$$

if $(\lambda|\alpha) = 2$ *for* $\alpha \in 2\tilde{M}$.

Proof: (i) follows from the definition of Y^λ.

(ii) Using the definition of B and $\ell(\tau_{-\lambda} s_\alpha) = \ell(s_\alpha \tau_{-\lambda}) = \ell(\tau_{-\lambda}) + 1$, we have

$$Y^\lambda T_{s_\alpha} = T_{\tau_{-\lambda}} T_{s_\alpha} = T_{\tau_{-\lambda} s_\alpha} = T_{s_\alpha \tau_{-\lambda}} = T_{s_\alpha} T_{\tau_{-\lambda}} = T_{s_\alpha} Y^\lambda.$$

(iii) Using Lemma A.2, we have

$$T_s Y^{s(\lambda)} T_s = T_s (Y^{-\lambda} Y^{\lambda'}) T_s = T_s T_{\tau_{-\lambda}}^{-1} (T_{w^{-1}} T_s) = T_s T_{\tau_{-\lambda}}^{-1} T_{\tau_{-\lambda} s \tau_{-\lambda}} = T_s T_{\tau_{-\lambda}}^{-1} (T_{\tau_{-\lambda}} T_{s\tau_{-\lambda}}) = Y^\lambda.$$

(iv) Set $b'=T_{\tau_{-\lambda}}^{-1}T_{w'}$ and $b''=T_{w''}$. From $\lambda, s(\lambda)+\lambda\in\tilde{M}_+$, we have

$$Y^{s(\lambda)}=(Y^{\lambda})^{-1}Y^{s(\lambda)+\lambda}=T_{\tau_{-\lambda}}^{-1}T_{w^{-1}}=T_{\tau_{-\lambda}}^{-1}T_{\tau_{-\lambda}s\tau_{-\lambda}}T_s^{-1}=T_{\tau_{-\lambda}}^{-1}T_{w'}T_{w''}T_s^{-1}.$$

Then $Y^{s(\lambda)}T_s=T_{\tau_{-\lambda}}^{-1}T_{w'}T_{w''}=b'b''$.

From $\lambda-\frac{1}{2}\alpha\in\tilde{M}_+$ and $\ell(\tau_{-\lambda})+\ell(\tau_{-\lambda+(1/2)\alpha})=\ell(\tau_{-2\lambda+(1/2)\alpha})$, we have

$$Y^{\lambda-(1/2)\alpha}=T_{\tau_{-\lambda+(1/2)\alpha}}=T_{\tau_{-\lambda}}^{-1}T_{\tau_{-2\lambda+(1/2)\alpha}}=T_{\tau_{-\lambda}}^{-1}T_{w'}T_{s_{\tilde{\alpha}}}T_{w''}=b'T_{s_{\tilde{\alpha}}}b''.$$

In a similar way,

$$Y^{\lambda}=T_{\tau_{-\lambda}}=T_sT_{s\tau_{-\lambda}}=T_sT_{\tau_{-\lambda}}^{-1}T_{w'}T_{s_{\tilde{\alpha}}}^2T_{w''}=T_sb'T_{s_{\tilde{\alpha}}}^2b''.$$

Hence $T_s^{-1}Y^{\lambda}=b'T_{s_{\tilde{\alpha}}}^2b''$.

□

Proof of Proposition 2.7: The relations (i) and (ii) follow immediately from Proposition A.5. If we apply Proposition A.5 to case (iii), we have

$$Y^{s_i(\lambda)}T_i-(t_{\tilde{\alpha}_i}^{1/2}-t_{\tilde{\alpha}_i}^{-1/2})Y^{\lambda-(1/2)\alpha_i}-T_i^{-1}Y^{\lambda}=b'(1-(t_{\tilde{\alpha}_i}^{1/2}-t_{\tilde{\alpha}_i}^{-1/2})T_{s_{\tilde{\alpha}_i}}-T_{s_{\tilde{\alpha}_i}}^2)b''.$$

The last expression has image equal to zero in $H(\tilde{W})$. Hence we get (iii). □

(Received 25 July 2000; accepted for publication 16 July 2001)

The present paper concerns the derivation of phase-integral quantization conditions for the two-center Coulomb problem under the assumption that the two Coulomb centers are fixed. With this restriction we treat the general two-center Coulomb problem according to the phase-integral method, in which one uses an *a priori* unspecified *base function*. We consider base functions containing three unspecified parameters $C, \tilde{C}$, and Λ. When the absolute value of the magnetic quantum number m is not too small, it is most appropriate to choose $\Lambda = |m| \neq 0$. When, on the other hand, $|m|$ is sufficiently small, it is most appropriate to choose $\Lambda = 0$. Arbitrary-order phase-integral quantization conditions are obtained for these choices of Λ. The parameters C and $\tilde{C}$ are determined from the requirement that the results of the first and the third order of the phase-integral approximation coincide, which makes the first-order approximation as good as possible. In order to make the paper to some extent self-contained, a short review of the phase-integral method is given in the Appendix. [DOI: 10.1063/1.1399294]

I. INTRODUCTION

The two-center Coulomb problem, that is, the problem of solving the Schrödinger equation for the motion of an electron with the charge $-e$ $(e>0)$ in the field of two fixed Coulomb centers with charges $Z_1 e$ and $Z_2 e$ at the distance r_{12} from each other, plays an important role in several fields of theoretical physics, e.g., in the theory of diatomic molecules, in scattering theory, and in the three-body problem. The two-center Coulomb problem has therefore been the subject of extensive studies both by numerical and by approximate analytical methods, and hence the literature on this problem is very comprehensive. In spite of this fact it is still of interest to continue the treatment of this problem for arbitrary values of Z_1, Z_2, and r_{12}. One reason for this is that the numerically exact solution of the problem meets with difficulties when $|Z_1 - Z_2|$ increases. Also, numerical difficulties appear for large values of r_{12}. For a general review of the problem we refer to Eyring *et al.*,[1] Herzberg,[2] Slater,[3] and Rosen.[4]

Ignoring the finiteness of the mass of the protons, Bates *et al.*[5] obtained important numerical results for the hydrogen molecule ion. Corresponding numerical results were obtained by Wallis and Hulburt[6] for the homonuclear one-electron two-center problem, by Bates and Carson[7] for the ion $HeH^{2+}(Z_1=1, Z_2=2)$, by Wind[8] for the ground state of the hydrogen molecule ion, by Peek[9] for the states $1s\sigma_g$ and $2p\sigma_u$ of the hydrogen molecule ion, and by Ponomarev and Puzynina[10,11]

for several states of the Coulomb two-center system with $Z_1=1$ and $Z_2=2,3,\ldots,8$. Hunter and Pritchard[12] used a numerical procedure to compute nonadiabatic energies for the first few rotation–vibration levels of ${}^2\Sigma_g\, H_2^+$, ${}^2\Sigma\, HD^+$, and ${}^2\Sigma_g\, D_2^+$. For the hydrogen molecule ion Rosenthal and Bright Wilson, Jr.[13] calculated an accurate value of the ground state energy which is in agreement with the values obtained by Wind[8] and Peek.[9] For different internuclear distances Bates and Reid,[14] Murai,[15] and Murai and Takatsu[16] calculated electronic energies for various states of the hydrogen molecule ion under the assumption of infinite proton mass. For a large range of internuclear distances Winter *et al.*[17] made very accurate calculations for the lowest 20 states of the molecule ion HeH^{2+}. Klaus[18] studied the electronic energy of the ground state of the hydrogen molecule ion for small internuclear separation r_{12} and confirmed the remarkable discovery by Byers Brown and Steiner[19] that the electronic energy cannot be expanded in powers of r_{12} alone, but that powers of $\ln r_{12}$ must also be included. Klaus[18] also obtained for the hydrogen molecule ion further terms in the series given by Byers Brown and Steiner[19] for the general two-center Coulomb problem.

There exist also various approximate analytical methods for solving the quantal two-center Coulomb problem. Such approximate methods have great relevance for understanding the various physical aspects of the problem and also for the derivation of suitable accurate analytical expressions for physical quantities. In one of these methods one uses the quasiclassical approximation, that is, the first order of the phase-integral approximation. In using this method, one encountered in the early papers difficulties associated with the divergence of the phase-integral due to an inappropriate choice of the phase integrand (also called the quasimomentum), which is not determined quite uniquely. Different authors have mastered these difficulties in different ways, but no single unifying method has until now been proposed for the two-center Coulomb problem. An essential feature in our method is the use of the phase-integral approximation generated from an unspecified base function; see the Appendix.

The semiclassical quantization of the low-lying electronic states of the hydrogen molecule ion was treated by Strand and Reinhardt.[20] Pajunen[21] calculated the energy levels of the hydrogen molecule ion (under the assumption of infinitely heavy nuclei) in the first and the third order of the phase-integral approximation. Although he refers to one of the papers (his Ref. 10) in which the phase-integral approximation generated from an unspecified base function was introduced, he does not use the freedom to choose optimum expressions for the functions that he denotes by $Q_{\mathrm{mod}}(\mu)$ and $Q_{\mathrm{mod}}(\nu)$, and that in the present paper correspond to the more general base functions $\tilde{Q}(\xi)$ and $Q(\eta)$, respectively. In the present paper we shall make full use of the possibility to choose $\tilde{Q}(\xi)$ and $Q(\eta)$ most conveniently.

The phase-integral method, in which one uses the phase-integral approximation generated from an unspecified base function,[22] offers a method for mastering the previously mentioned difficulties in a unified way for an arbitrary order of the phase-integral approximation. In the present paper we shall apply this method to the quantal two-center Coulomb problem with fixed Coulomb centers. For the convenience of the reader a short review of the phase-integral method and formulas to be used are given in the Appendix.

Bearing in mind the relative ease of obtaining nowadays highly accurate values with the use of computers, one may ask for the purpose of treating the two-center Coulomb problem with the aid of the phase-integral method. When considering this question one should, however, remember that in the numerical methods there occur difficulties for large values of r_{12} as well as for large values $|Z_1-Z_2|$. The phase-integral formulas are, however, in general most accurate for large values of r_{12} and roughly as accurate for small as for large values of $|Z_1-Z_2|$. It may therefore be advantageous to use the phase-integral formulas for large values of r_{12} and $|Z_1-Z_2|$ instead of numerical results. These formulas can be expressed in terms of complete elliptic integrals, which can be evaluated easily with the use of standard computer programs. The latter formulas also have the advantage of making it possible to obtain for the energy and the separation constant accurate analytical expressions that for certain needs may be more useful than purely numerical results. They can, directly or after series expansion, be used to study the dependence of interesting physical quantities on the parameters of the problem. It seems possible that by means of such

analytical expressions one could refine the interesting investigations by Ponomarev[23] on configuration interaction of terms in the two-center Coulomb system and by Komarov and Solov'ev[24] on quasi-intersection of terms in the problem of two Coulomb centers with strongly different charges. The present work may thus be carried further to throw new light on interesting physical properties of the two-center Coulomb system.

A hydrogen atom in an electric field can be considered as the limiting case of an electron in the field of two Coulomb centers that lie far away from each other and have strongly different charges. It is therefore of interest to note the efficiency and accuracy of the phase-integral method in applications to the Stark effect of a hydrogen atom. For a state of a hydrogen atom with the principal quantum number 25 and the magnetic quantum number 1 in an electric field of 2514 V/cm Fröman and Fröman[25] obtained by means of the phase-integral method the energy with six digits already in the third-order approximation. For the same state Silverstone and Koch[26] had obtained the energy with six digits by the use of 24th-order Rayleigh–Schrödinger perturbation theory combined with a [12/12] Padé approximant, but the phase-integral results indicated that the last one of these digits was wrong by one unit. For a state of a hydrogen atom with the principal quantum number 30 and the magnetic quantum number 0 in an electric field of 800 V/cm, Fröman and Fröman[25] obtained by means of the phase-integral method the energy with nine digits already in the third-order approximation. For the same state, Damburg and Kolosov[25] obtained by means of an efficient purely numerical method the same energy with nine digits, but the phase-integral results indicated that the last one of these digits was wrong by one unit. For the same state, Silverstone and Koch[26] had earlier obtained the energy with six digits by the use of 24th-order Rayleigh–Schrödinger perturbation theory combined with a [12/12] Padé approximant, but the last digit was wrong by three units. One can therefore expect that states of the two-center Coulomb system that correspond to states of a hydrogen atom in an electric field with high principal quantum numbers, low magnetic quantum numbers, and large values of $|Z_1-Z_2|$ should be favorable for phase-integral treatment.

For particular single-well potentials one obtains the eigenvalues exactly from the phase-integral quantization condition of any order by determining the base function (which is defined in the Appendix) such that the eigenvalues coincide in the first- and third-order approximations; see Refs. 27–30. This is not possible for the two-center Coulomb problem, but by choosing the two base functions in this problem such that the values of the energy, as well as the values of the separation constant, coincide in the first- and third-order approximations, one obtains optimum results from the first-order quantization conditions. The study of the behavior of physical quantities can thus be performed with the use of the first-order formulas but with the accuracy of the more complicated third-order formulas. It is not possible to achieve this result if one uses the JWKB approximation, since there appears no *a priori* unspecified base function in that approximation. By making the above-mentioned exactness fulfilled in the limit of a parameter value, for which the phase-integral results without this adaptation would not be good, one can also extend the region of validity of the phase-integral treatment; see p. 12 in Ref. 30.

The present paper, referred to as paper I, constitutes the basis for further work by Athavan *et al.*,[31] (paper II), and Athavan *et al.*[32] (paper III), in which the contour integrals, occurring in the quantization conditions, will be expressed in terms of complete elliptic integrals, analogous to the papers by Lakshmanan and Kaliappan[33] and Lakshmanan *et al.*[34,35] In papers II and III calculations are made for the states $1s\sigma$ and $2p\sigma$ of the hydrogen molecule ion $(Z_1=Z_2=1)$, for two states with $Z_1=1$ and $Z_2=2$, for two states with $Z_1=1$ and $Z_2=5$, and for two states with $Z_1=1$ and $Z_2=8$. For the hydrogen molecule ion $(Z_1=Z_2=1)$ and the ion with $Z_1=1$ and $Z_2=2$ the phase-integral method cannot compete in terms of accuracy with the methods that have been used to obtain the extremely accurate numerical results for these ions, but the possibility of using the analytical phase-integral formulas expressed in terms of complete elliptic integrals is an alternative that for certain purposes may be preferable to the use of very accurate numerical results. For other ions the phase-integral method will probably yield results that for large values of r_{12} are more accurate than the results that have been obtained numerically, as can be seen from Tables III–VI in paper III. In fact, the phase-integral method constitutes an important complement to

perturbation theory and numerical methods. It can sometimes be used with significant advantage for problems where highly accurate numerical methods would be difficult to apply or where the analytical phase-integral formulas can give a deeper understanding of physical processes and provide guidance for numerical work. The investigations published in the present series of three papers give new information concerning the phase-integral method and also its potential power for applications to a wider class of physical problems.

II. SEPARATION OF THE SCHRÖDINGER EQUATION IN ELLIPTIC COORDINATES

We start by quoting some well-known results. The time-independent Schrödinger equation for the motion of an electron of mass μ and charge $-e$ $(e>0)$ in the field of two fixed Coulomb centers with charges Z_1e and Z_2e takes the following form:

$$\left(-\frac{\hbar^2}{2\mu}\Delta_{\vec{r}}-\frac{Z_1e^2}{r_1}-\frac{Z_2e^2}{r_2}\right)\Psi(\vec{r})=E\Psi(\vec{r}), \tag{2.1}$$

where r_1 and r_2 are the distances of the electron from the two centers, $\vec{r}$ is the position vector of the electron, and E is the electronic energy. To obtain the total energy one must add the potential energy of the two fixed charges, getting

$$E_{\text{total}}=\frac{Z_1Z_2e^2}{r_{12}}+E, \tag{2.2}$$

where r_{12} is the distance between the two centers. The differential equation (2.1) is separable in elliptic coordinates. If one introduces the variables

$$\xi=\frac{r_1+r_2}{r_{12}}, \quad 1\leqslant\xi<+\infty, \tag{2.3a}$$

$$\eta=\frac{r_1-r_2}{r_{12}}, \quad -1\leqslant\eta\leqslant+1, \tag{2.3b}$$

and puts

$$\Psi(\vec{r})=X(\xi)Y(\eta)e^{im\phi}, \tag{2.4}$$

where m is the magnetic quantum number (positive or negative integer or zero), and ϕ is the corresponding angle, the separation yields, in atomic units $(\hbar=e=\mu=1)$, the following two differential equations:

$$\frac{\mathrm{d}}{\mathrm{d}\xi}\left((\xi^2-1)\frac{\mathrm{d}X}{\mathrm{d}\xi}\right)+\left(-p^2\xi^2+b'\xi+A-\frac{m^2}{\xi^2-1}\right)X=0, \tag{2.5a}$$

$$\frac{\mathrm{d}}{\mathrm{d}\eta}\left((1-\eta^2)\frac{\mathrm{d}Y}{\mathrm{d}\eta}\right)+\left(p^2\eta^2+b\eta-A-\frac{m^2}{1-\eta^2}\right)Y=0, \tag{2.5b}$$

where A is the separation constant and

$$p^2=-\tfrac{1}{2}r_{12}^2E, \tag{2.6a}$$

$$b'=r_{12}(Z_2+Z_1), \tag{2.6b}$$

$$b=r_{12}(Z_2-Z_1). \tag{2.6c}$$

Putting

$$X(\xi)=\frac{f(\xi)}{(\xi^2-1)^{1/2}}, \tag{2.7a}$$

$$Y(\eta)=\frac{g(\eta)}{(1-\eta^2)^{1/2}}, \tag{2.7b}$$

we can transform the differential equations (2.5) into

$$\left(\frac{\mathrm{d}^2}{\mathrm{d}\xi^2}+\tilde{R}(\xi)\right)f(\xi)=0, \tag{2.8a}$$

$$\left(\frac{\mathrm{d}^2}{\mathrm{d}\eta^2}+R(\eta)\right)g(\eta)=0, \tag{2.8b}$$

where

$$\tilde{R}(\xi)=-p^2+\frac{b'\xi+A'}{\xi^2-1}-\frac{m^2-1}{(\xi^2-1)^2}, \tag{2.9a}$$

$$R(\eta)=-p^2+\frac{b\eta-A'}{1-\eta^2}-\frac{m^2-1}{(1-\eta^2)^2}, \tag{2.9b}$$

with

$$A'=A-p^2. \tag{2.10}$$

The differential equations (2.8) are of the Schrödinger type. By solving them simultaneously under the boundary conditions that $f(+1)=f(+\infty)=0$ and $g(-1)=g(+1)=0$, one can obtain the energy and the separation constant as functions of the distance r_{12} and the quantum numbers.

When $Z_1=Z_2$ every bound-state wave function $Y(\eta)$ is either an even or an odd function of η, and when $\vec{r}$ is reflected at the center of symmetry for the two-center Coulomb problem, the wave function (2.4) remains unchanged when $Y(\eta)$ and m are both even or both odd, while the wave function (2.4) changes sign when one of $Y(\eta)$ and m is even and the other is odd.

III. APPLICATION OF THE PHASE-INTEGRAL METHOD

The essential features of the phase-integral method are briefly sketched in the Appendix. The phase-integral solutions of the differential equations (2.8a) and (2.8b), respectively, are linear combinations of the phase-integral functions

$$\tilde{q}^{-1/2}(\xi)\exp\left\{\pm i\int^{\xi}\tilde{q}(\xi)\mathrm{d}\xi\right\} \tag{3.1a}$$

and

$$q^{-1/2}(\eta)\exp\left\{\pm i\int^{\eta}q(\eta)\mathrm{d}\eta\right\}, \tag{3.1b}$$

respectively, where $\tilde{q}(\xi)$ and $q(\eta)$, respectively, are generated according to (A5a), (A5b), (A6a)–(A6c), (A3), and (A2) in the Appendix, with $R(z),Q(z)$ replaced by the appropriate functions $\tilde{R}(\xi),\tilde{Q}(\xi)$ and $R(\eta),Q(\eta)$, respectively, the quantities pertaining to the ξ-equation being characterized by a tilde.

A. Base functions generating phase-integral solutions

As is seen from (2.9a) and (2.9b), the functions $\tilde{R}(\xi)$ and $R(\eta)$ have poles at $\xi=\pm 1$ and $\eta=\pm 1$, respectively; these poles are of the second order if $m\neq\pm 1$, but of the first order if $m=\pm 1$. Furthermore, we note that when $m\neq 0$ the coefficients of the second-order poles differ from $\frac{1}{4}$, while for $m=0$ they are equal to $\frac{1}{4}$.

There are two main alternatives, discussed in the Appendix for the case of the radial Schrödinger equation, for choosing the base functions generating the phase-integral functions (3.1a) and (3.1b). Unifying these two alternatives, we choose the squares of the base functions to be

$$\tilde{Q}^2(\xi)=-p^2+\frac{A'-\tilde{C}+b'\xi}{\xi^2-1}-\frac{\Lambda^2}{(\xi^2-1)^2}, \tag{3.2a}$$

$$Q^2(\eta)=-p^2+\frac{-A'+C+b\eta}{1-\eta^2}-\frac{\Lambda^2}{(1-\eta^2)^2}, \tag{3.2b}$$

where C, $\tilde{C}$, and Λ are parameters, the choice of which we shall discuss in the following. The introduction of these parameters essentially increases the flexibility of the phase-integral formulas to be obtained.

By choosing $C=\tilde{C}=1/4$ one correctly obtains in the limit when $r_{12}\to 0$ the energy E and the reduced separation constant A' from the first-order phase-integral quantization conditions (to be derived in Sec. III B). For arbitrary values of r_{12} it is most appropriate to determine C and $\tilde{C}$ as functions of r_{12} such that one obtains the same value of p^2 (i.e., of the energy) and also of A' in the first and in the third order of the phase-integral approximation. One thereby achieves the optimum accuracy obtainable from the first-order quantization conditions. We emphasize that this can be achieved by the use of the phase-integral approximation generated from an unspecified base function (described in the Appendix), but cannot be achieved by means of the JWKB approximation, in which there is no unspecified base function. The decisive properties of the phase-integral approximation in question versus the JWKB approximation have been explained in some detail by Dammert and Fröman[36] and by Fröman and Fröman.[22]

When $|m|$ is not too small, we choose $\Lambda=|m|\neq 0$, but when $|m|$ is sufficiently small we choose $\Lambda=0$. For $m=0$ one should always choose $\Lambda=0$. The two alternatives $\Lambda=|m|\neq 0$ and $\Lambda=0$ yield solutions with different properties. When $\Lambda=|m|\neq 0$ the phase integral solutions of the differential equations (2.8a) and (2.8b) remain valid as $\xi\to\pm 1$ and $\eta\to\pm 1$, respectively. When $\Lambda=0$ the phase-integral solutions of the differential equations in question break down as $\xi\to\pm 1$ and $\eta\to\pm 1$, respectively, but the regular solutions of the ξ- and η-equations can be obtained at some distances from those points by the use of the connection formula described in Sec. 2 b of the Appendix, when one there replaces l by $(|m|-1)/2$; cf. (2.9a) and (2.9b). The wave functions obtained in that way are expected to be more accurate the stronger the Coulomb singularities of $\tilde{R}(\xi)$ and $R(\eta)$ at $\xi=\pm 1$ and $\eta=\pm 1$ are. However, even if the Coulomb singularities are strong, these wave functions are not expected to be good if $|m|$ is too large, in which case one should choose $\Lambda=|m|\neq 0$, as mentioned in the beginning of this paragraph.

Using the terminology ''classically allowed region'' and ''classically forbidden region'' in a generalized sense, viz. to characterize regions where $\tilde{Q}^2(\xi)$ or $Q^2(\eta)$ is larger than zero and less than zero, respectively, we shall now discuss the wave functions pertaining to the ξ-equation and the η-equation.

1. Wave functions pertaining to the ξ-equation

According to (3.2a) the function $-\tilde{Q}^2(\xi)$, where $1\leqslant\xi<+\infty$, always corresponds to a single-well potential.

For $\Lambda=|m|\neq 0$ there are four zeros of $\tilde{Q}^2(\xi)$, which we denote by ξ_1,ξ_2,ξ_3, and ξ_4; see Fig. 1(a). The zeros ξ_1 and ξ_2 may be real and both less than 1, or they may be complex conjugate. The zeros $\xi_3(>1)$ and $\xi_4(>\xi_3)$ are real. There is thus a classically allowed region between ξ_3 and ξ_4,

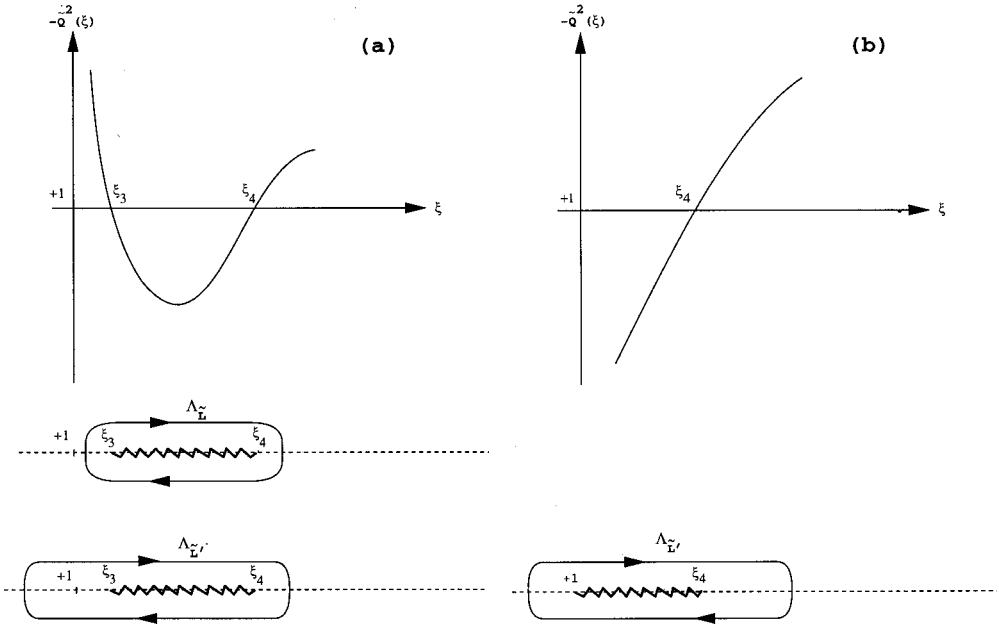

FIG. 1. Schematic pictures of $-\tilde{Q}^2(\xi)$ for $\xi>1$ and of the contours of integration in the complex ξ-plane. The cuts are indicated by wavy lines. On the upper lip of the cut $\tilde{Q}(\xi)$ is positive. Only those zeros of $\tilde{Q}^2(\xi)$ that are relevant for the contours of integration are shown. For $\Lambda=|m|\neq 0$ (a) always applies, and the relation between the integrals associated with the contours $\Lambda_{\tilde{L}}$ and $\Lambda_{\tilde{L}'}$ is $\tilde{L}'=\tilde{L}+|m|/2$; the zeros ξ_1 and ξ_2 of $\tilde{Q}^2(\xi)$, which are not shown, may be real or complex conjugate. For $\Lambda=0$ there are only two zeros, ξ_3 and ξ_4, of $\tilde{Q}^2(\xi)$, and either (a) or (b) may apply.

but classically forbidden regions for $1<\xi<\xi_3$ and $\xi>\xi_4$. The phase-integral wave functions generated from $\tilde{Q}(\xi)$ are good at $\xi=1$, and we can use the arbitrary-order connection formula, given by (A13) and (A14), for tracing the physically acceptable wave function from the classically forbidden region between 1 and ξ_3 to the classically allowed region, that is, the region between ξ_3 and $\xi_4(>\xi_3)$ where $\tilde{Q}^2(\xi)>0$; see Fig. 1(a).

For $\Lambda=0$ there are two zeros of $\tilde{Q}^2(\xi)$, which we denote by $\xi_3(<\xi_4)$ and $\xi_4(>1)$. The classically allowed region lies between ξ_3 and ξ_4 when $\xi_3>1$, but between 1 and ξ_4 when $\xi_3<1$; see Fig. 1. The phase-integral wave function is not good at $\xi=1$, but for the physically acceptable wave function one can obtain a phase-integral expression in the interior of the classically allowed region, when $\xi_3>1$ and the classically forbidden region between 1 and ξ_3 is sufficiently large, by means of the arbitrary-order connection formula given by (A13) and (A14), and when $\xi_3<1$ by means of the connection formula presented in Sec. 2 b of the Appendix.

Both when $\Lambda=|m|\neq 0$ and when $\Lambda=0$ the wave function, obtained in the classically allowed region to the left of ξ_4 as described previously, can be joined to the physically acceptable wave function traced from the classically forbidden region to the right of ξ_4 into the classically allowed region to the left of ξ_4 with the aid of the arbitrary-order connection formula given by (A13) and (A14). In this way, alternative quantization conditions, corresponding to $\Lambda=|m|\neq 0$ and $\Lambda=0$, can be obtained. They can be combined into one quantization condition. Figure 1 illustrates the two possible situations where the classically allowed region is delimited either by ξ_3 and ξ_4 [Fig. 1(a)] or by the pole at $\xi=+1$ and the turning point at $\xi=\xi_4$ [Fig. 1(b)].

2. Wave functions pertaining to the η-equation

The function $-Q^2(\eta)$ may correspond either to a single-well potential or to a double-well potential.

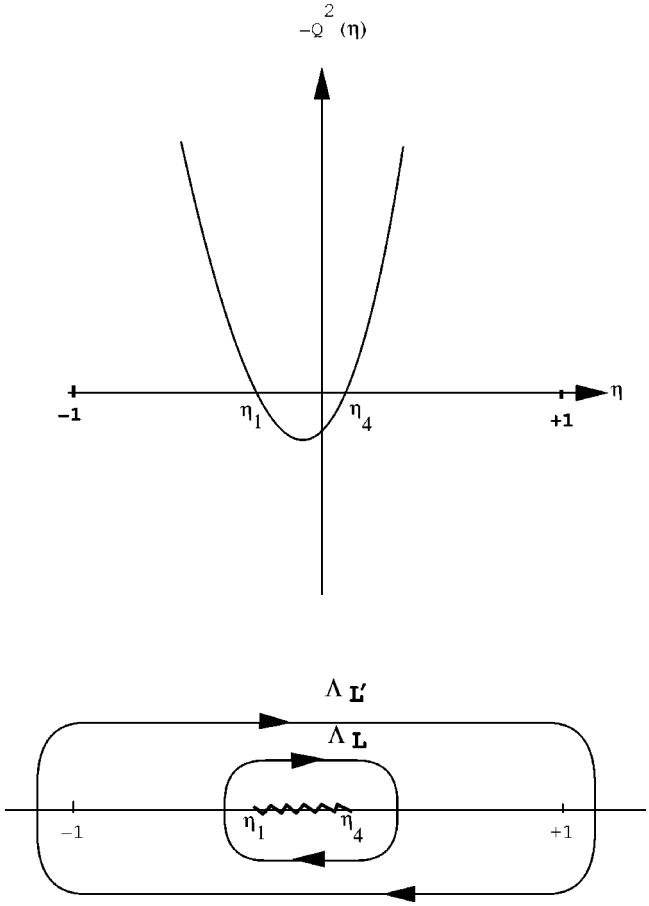

FIG. 2. Schematic pictures of $-Q^2(\eta)$ for $-1<\eta<1$ and of the contours of integration when $-Q^2(\eta)$ in the interval $-1<\eta<1$ is a single-well potential, which may occur for $\Lambda=|m|\neq 0$ as well as for $\Lambda=0$. The cut is indicated by a wavy line, on the upper lip of which $Q(\eta)$ is positive. The contour $\Lambda_{L'}$ can be used only when $\Lambda=|m|\neq 0$, and the relation between the integrals associated with the contours Λ_L and $\Lambda_{L'}$ is then $L'=L+|m|$. The quantization conditions, expressed in terms of complete elliptic integrals, for the situation with $\Lambda=|m|\neq 0$ are the same as the corresponding quantization conditions for the situation in Fig. 4(a). The quantization condition for the case given here with $\Lambda=0$ has so far not appeared in the applications.

For $\Lambda=|m|\neq 0$ the phase-integral solution is valid at the poles $\eta=\pm 1$ (which delimit classically forbidden regions) and can be traced into the classically allowed region closest to the pole in question with the aid of the connection formula given by (A13) and (A14). When there is only one classically allowed region, one obtains the quantization condition by identifying the two expressions for the wave function in that region. This case applies when $-Q^2(\eta)$ is a single-well potential (Fig. 2), or when the energy lies so far above the top of an underdense barrier [Fig. 4(b)] that it is appropriate to disregard the presence of the complex conjugate zeros η_2 and η_3 of $Q^2(\eta)$. When $-Q^2(\eta)$ corresponds to a double-well potential, the wave function can be traced from the region on one side of the barrier to the region on the other side with the aid of the arbitrary-order connection formula for a barrier described in Sec. 3 of the Appendix; see Figs. 3 and 4. Joining the two expressions for the wave function thus obtained to each other, one obtains the quantization condition.

When $\Lambda=0$ [Fig. 2 or Fig. 4(b)] the phase-integral wave function is not good at $\eta=\pm 1$, but at some distance from these points physically acceptable solutions can be obtained in the same classically allowed region by the use of the connection formulas presented in Secs. 2 and 3 of the

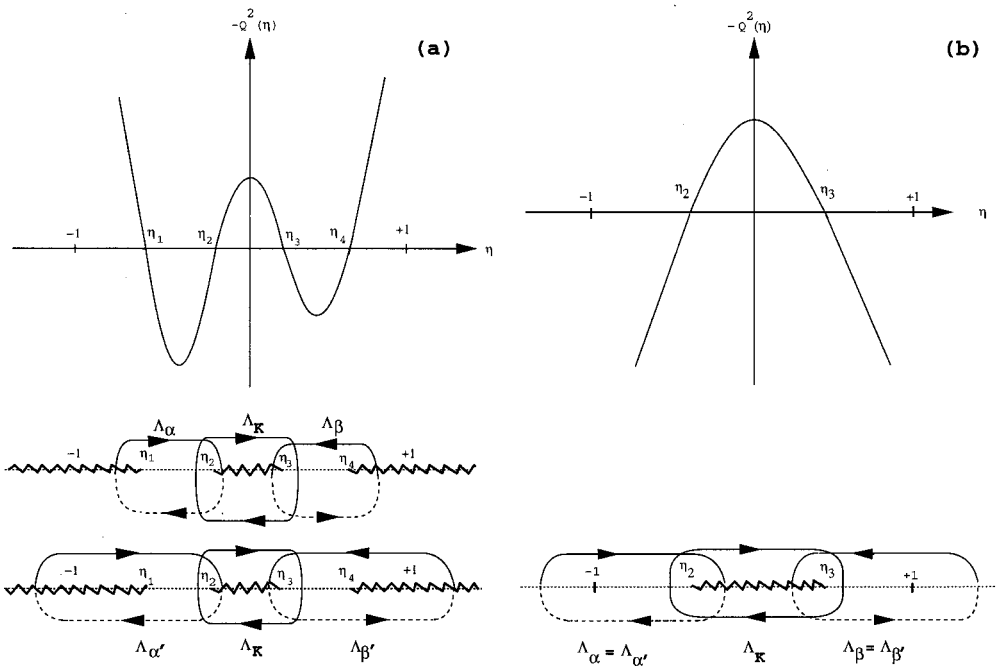

FIG. 3. Schematic pictures of $-Q^2(\eta)$ for $-1<\eta<1$ and of the contours of integration in the complex η-plane, when $-Q^2(\eta)$ corresponds to a double-well potential with a superdense barrier (subbarrier). In (a) $\Lambda=|m|\neq 0$ and in (b) $\Lambda=0$. The cuts are indicated by wavy lines, and the parts of the contours of integration that lie on Riemann sheets adjacent to the complex η-plane under consideration are dashed. In the left-hand classically allowed region $Q(\eta)$ is positive. Only those zeros of $Q^2(\eta)$ that are relevant for the contours of integration are shown. We recall the relations (3.18a) which mean that $\alpha'=\alpha+\Lambda\pi/2$ and $\beta'=\beta+\Lambda\pi/2$.

Appendix. Thus one obtains two expressions for the wave function, and by identifying these expressions one obtains a quantization condition.

B. Quantization conditions

1. Quantization conditions pertaining to the ξ-equation

For the differential equation (2.8a) the physically relevant interval is $1<\xi<\infty$. The phase-integral quantization condition for the situation in Fig. 1(a) involves a contour integral in the complex ξ-plane encircling ξ_3 and ξ_4, while the phase-integral quantization condition for the situation in Fig. 1(b) involves a contour integral encircling the simple pole at $\xi=1$ and the generalized classical turning point ξ_4. The quantization condition (A31) applies to the first situation, and the quantization condition (A32) applies to the second situation. Introducing the notations

$$\tilde{L}=\sum_{n=0}^{N}\tilde{L}^{(2n+1)}, \tag{3.3a}$$

$$\tilde{L}^{(2n+1)}=\frac{1}{2}\int_{\Lambda_{\tilde{L}}}\tilde{q}^{(2n+1)}(\xi)\mathrm{d}\xi, \tag{3.3b}$$

$$\tilde{L}'=\sum_{n=0}^{N}\tilde{L}'^{(2n+1)}, \tag{3.4a}$$

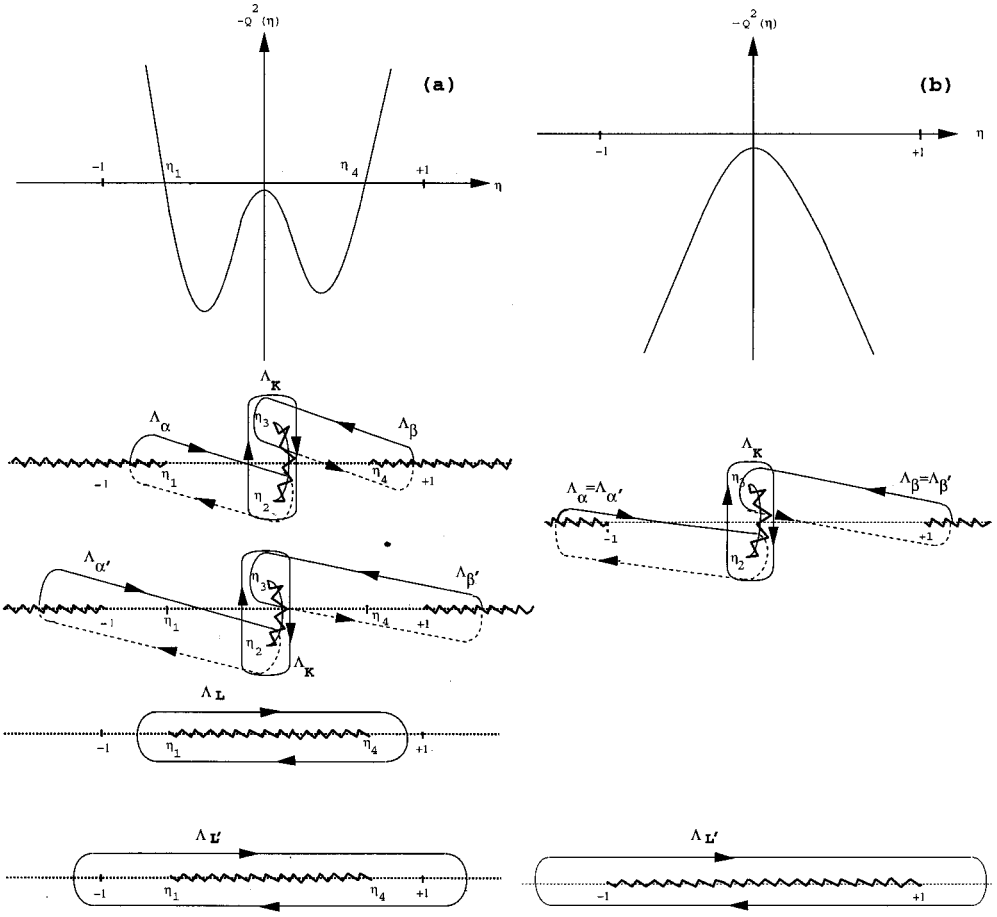

FIG. 4. Schematic pictures of $-Q^2(\eta)$ for $-1<\eta<1$ and of the contours of integration in the complex η plane, when $-Q^2(\eta)$ corresponds to a double-well potential with an under-dense barrier (superbarrier). In (a) $\Lambda=|m|\neq 0$ and in (b) $\Lambda=0$. The cuts are indicated by wavy lines, and the parts of the contours of integration that lie on Riemann sheets adjacent to the complex η-plane under consideration are dashed. In the left-hand classically allowed region $Q(\eta)$ is positive. Only those zeros of $Q^2(\eta)$ that are relevant for the contours of integration are shown. If the energy lies sufficiently far above the top of the barrier, one may treat the double-well potential problem as a single-well potential problem with the classically allowed region between η_1 and η_4 in (a) and between the poles at $\eta=-1$ and $\eta=+1$ in (b). One then introduces new cuts [between η_1 and η_4 in (a) and between -1 and $+1$ in (b)], on the upper lips of which $Q(\eta)$ is positive, and uses the contours Λ_L and $\Lambda_{L'}$. In (a) the relation between the corresponding integrals is $L'=L+|m|$. In both (a) and (b) L is related to α and β by the relation $L=\alpha+\beta$.

$$\tilde{L}'^{(2n+1)}=\frac{1}{2}\int_{\Lambda_{\tilde{L}'}}\tilde{q}^{(2n+1)}(\xi)\mathrm{d}\xi, \tag{3.4b}$$

where $\tilde{q}(\xi)$ is obtained according to (A5a), (A5b), (A6a)–(A6c), (A3), and (A2), and $\Lambda_{\tilde{L}}$ and $\Lambda_{\tilde{L}'}$ are the appropriate contours of integration pertaining to $\xi_3>1$ and $\xi_3<1$, respectively, and shown in Figs. 1(a) and 1(b), respectively, we can write the two quantization conditions corresponding to $\xi_3>1$ and $\xi_3<1$ as follows:

$$\tilde{L}=(\tilde{s}+\tfrac{1}{2})\pi, \quad \xi_3>1, \tag{3.5a}$$

$$\tilde{L}'=\left(\frac{|m|}{2}+\tilde{s}+\frac{1}{2}\right)\pi, \quad \xi_3<1, \tag{3.5b}$$

where $\tilde{s}$ is an integer. If, when $\Lambda=|m|\neq 0$ and hence $\xi_3>1$, we enlarge the contour of integration $\Lambda_{\tilde{L}}$ in Fig. 1(a), so that the new contour $\Lambda_{\tilde{L}'}$ encloses the turning points ξ_3 and ξ_4 as well as the pole at $\xi=1$, and if we compensate in (3.5a) along with (3.3a) and (3.3b) for this change by taking the residue of the integrand at $\xi=1$ into account, we obtain a general quantization condition, valid for both cases $\xi_3>1$ and $\xi_3<1$, i.e., for both situations depicted in Fig. 1, viz.

$$\tilde{L}'=\left(\frac{|m|}{2}+\tilde{s}+\frac{1}{2}\right)\pi, \quad \xi_3>1 \text{ or } \xi_3<1. \tag{3.6}$$

Besides condensing the two alternative quantization conditions (3.5a) and (3.5b) nicely into one formula, the quantization condition (3.6) has the further merit that, if the integration along the contour is made numerically (in cases where expressions in terms of complete elliptic integrals are not available), it may be advantageous to use the contour $\Lambda_{\tilde{L}'}$ instead of $\Lambda_{\tilde{L}}$ when $\xi_3>1$.

The quantization condition (3.6) yields the value of the reduced separation constant A' as a function of p^2 and $\tilde{C}$; see (3.2a).

2. Quantization conditions pertaining to the η-equation

In the physically relevant interval $-1<\eta<1$ the function $-Q^2(\eta)$ may correspond to a single-well potential (Fig. 2) or to a double-well potential with a superdense (Fig. 3) or underdense (Fig. 4) barrier. When, in the case of an underdense barrier, the energy lies sufficiently far above the top of the barrier, it may be preferable to disregard the barrier and to treat the double-well potential problem as a single-well potential problem.

When $\Lambda=|m|\neq 0$ or $\Lambda=0$, and $-Q^2(\eta)$ is or can be considered as a single-well potential, and the classically allowed region is delimited by two simple zeros of $Q^2(\eta)$, as shown in Figs. 2 and 4(a), we obtain from (A31) the single-well quantization condition

$$L=(s+\tfrac{1}{2})\pi, \quad s=\text{non-negative integer}, \tag{3.7}$$

where by definition

$$L=\frac{1}{2}\int_{\Lambda_L} q(\eta)\,\mathrm{d}\eta, \tag{3.8}$$

Λ_L being a closed contour encircling the generalized classical turning points. Note that in the derivation of (3.7) we have considered the classically forbidden regions to be thick also when $\Lambda=0$ (Fig. 2). When $\Lambda=|m|\neq 0$ we can with the aid of residue calculus write (3.7) along with (3.8) as

$$L'=(|m|+s+\tfrac{1}{2})\pi, \tag{3.9}$$

where L' is defined by

$$L'=\frac{1}{2}\int_{\Lambda_{L'}} q(\eta)\,\mathrm{d}\eta, \tag{3.10}$$

$\Lambda_{L'}$ being a closed contour encircling -1 and $+1$; see Figs. 2 and 4(a).

When $\Lambda=0$, and the classically allowed region is delimited by two first-order poles of $Q^2(\eta)$, as shown in Fig. 4(b), and the energy lies far above the top of the barrier, one can consider $-Q^2(\eta)$ as a single-well potential. From (A33) one then obtains the quantization condition (3.9) with L' defined by (3.10), where $\Lambda_{L'}$ is now the contour in Fig. 4(b).

We disregard the possibility that $\Lambda=0$ and the residues of $Q^2(\eta)$ at $\eta=-1$ and $\eta=+1$ have different signs, since this case has so far not appeared in the applications.

When $-Q^2(\eta)$ corresponds to a double-well potential (Figs. 3 and 4), which is usually the case, the quantization condition (A39) gives

$$\cos(\alpha+\beta+\tilde{\phi}-2a)=\frac{\cos(\alpha-\beta)}{[1+\exp(-2\pi\overline{K})]^{1/2}}, \tag{3.11}$$

where

$$a=\frac{\pi}{2} \quad \text{when} \quad \Lambda=|m|\neq 0, \tag{3.12a}$$

$$a=(|m|+1)\frac{\pi}{2} \quad \text{when} \quad \Lambda=0, \tag{3.12b}$$

$$\alpha=\sum_{n=0}^{N}\alpha^{(2n+1)}, \tag{3.13a}$$

$$\alpha^{(2n+1)}=\mathrm{Re}\,\frac{1}{2}\int_{\Lambda_\alpha} q^{(2n+1)}(\eta)\,\mathrm{d}\eta, \tag{3.13b}$$

$$\beta=\sum_{n=0}^{N}\beta^{(2n+1)}, \tag{3.14a}$$

$$\beta^{(2n+1)}=-\mathrm{Re}\,\frac{1}{2}\int_{\Lambda_\beta} q^{(2n+1)}(\eta)\,\mathrm{d}\eta, \tag{3.14b}$$

$$\overline{K}=\sum_{n=0}^{N}\overline{K}_{2n}, \tag{3.15a}$$

$$\overline{K}_{2n}=\frac{i}{2\pi}\int_{\Lambda_K} q^{(2n+1)}(\eta)\,\mathrm{d}\eta. \tag{3.15b}$$

For the superbarrier case (Fig. 4) we can instead of (3.15b) use the alternative formula

$$\overline{K}_{2n}=-2\,\mathrm{Im}\,\frac{1}{2\pi}\int_{\Lambda_\alpha} q^{(2n+1)}(\eta)\,\mathrm{d}\eta$$

$$=-2\,\mathrm{Im}\,\frac{1}{2\pi}\int_{\Lambda_\beta} q^{(2n+1)}(\eta)\,\mathrm{d}\eta, \tag{3.15b$'$}$$

which is useful in connection with the transformation to complete elliptic integrals. With the use of (3.13a), (3.13b), (3.14a), (3.14b), (3.15a), and (3.15b$'$) each one of the quantities α, β, and $\overline{K}$ is then obtained as the real or imaginary part of an integral over the contour Λ_α or Λ_β. The contours of integration $\Lambda_\alpha, \Lambda_\beta$, and Λ_K for subbarrier and superbarrier energies are shown in Figs. 3 and 4. The analytic expression for the quantity $\tilde{\phi}$ is given in terms of $\overline{K}$ and $\overline{K}_{2n}$ by (A28) and (A29a)–(A29c). The quantity $\tilde{\phi}$ is of decisive importance for energies in the neighborhood of the top of the barrier. The quantities α and β are positive. The quantity $\overline{K}_0$ is positive when η_2 and η_3 are real, it is equal to zero when η_2 and η_3 coincide, and it is negative when η_2 and η_3 are complex conjugate. The quantity $\overline{K}_2$ may be positive or negative irrespective of whether η_2 and η_3 are real or complex conjugate.

Analogously as we changed the original contour $\Lambda_{\tilde{L}}$ into $\Lambda_{\tilde{L}'}$, when dealing with the quantization condition (3.5a), we can, when $\Lambda=|m|\neq 0$, change the contours Λ_α and Λ_β depicted in Figs. 3(a) and 4(a), so that, instead of letting them enclose only η_1,η_2 and η_3,η_4, respectively, we make each one of them enclose also a pole, $\eta=-1$ or $\eta=+1$, respectively. Calling the new contours $\Lambda_{\alpha'}$ and $\Lambda_{\beta'}$ [see Figs. 3(a) and 4(a)] and defining

$$\alpha'=\sum_{n=0}^{N}\alpha'^{(2n+1)}, \tag{3.16a}$$

$$\alpha'^{(2n+1)}=\mathrm{Re}\frac{1}{2}\int_{\Lambda_{\alpha'}}q^{(2n+1)}(\eta)\,\mathrm{d}\eta, \tag{3.16b}$$

$$\beta'=\sum_{n=0}^{N}\beta'^{(2n+1)}, \tag{3.17a}$$

$$\beta'^{(2n+1)}=-\mathrm{Re}\frac{1}{2}\int_{\Lambda_{\beta'}}q^{(2n+1)}(\eta)\,\mathrm{d}\eta, \tag{3.17b}$$

and recalling that the functions Y_{2n} are regular analytic at $\eta=\pm 1$ when $\Lambda=|m|\neq 0$, we find with the use of residue calculus that for $\Lambda=|m|\neq 0$

$$\begin{aligned}\alpha'-\alpha&=\beta'-\beta\\&=\Lambda\pi/2,\end{aligned} \tag{3.18a}$$

$$\begin{aligned}\alpha'-\beta'&=\alpha-\beta\\&=-\frac{b\pi}{2p}.\end{aligned} \tag{3.18b}$$

With the aid of (3.18a) and (3.18b) we obtain from (3.11) along with (3.12a) for $\Lambda=|m|\neq 0$ the following quantization condition:

$$\cos[\alpha'+\beta'+\tilde{\phi}-(|m|+1)\pi]=\frac{\cos[b\pi/(2p)]}{[1+\exp(-2\pi\bar{K})]^{1/2}}, \tag{3.19}$$

which has the same merits, relative to the original form of the quantization condition, i.e., (3.11) with (3.12a), as were mentioned in connection with the quantization condition (3.6), pertaining to the ξ-equation. When $\Lambda=0$ we define

$$\alpha'=\sum_{n=0}^{N}\alpha'^{(2n+1)}, \tag{3.20a}$$

$$\alpha'^{(2n+1)}=\alpha^{(2n+1)}, \tag{3.20b}$$

$$\beta'=\sum_{n=0}^{N}\beta'^{(2n+1)}, \tag{3.21a}$$

$$\beta'^{(2n+1)}=\beta^{(2n+1)}, \tag{3.21b}$$

and note that (3.18a) is obviously valid also for $\Lambda=0$. With the use of the theory of complex integration one finds that also (3.18b) is valid for $\Lambda=0$. Then it follows from (3.11), (3.12b),

(3.18a), and (3.18b) that the quantization condition (3.19) is valid also when $\Lambda=0$. The quantization condition (3.19) thus covers in a unified and convenient form both cases $\Lambda=|m|\neq 0$ and $\Lambda=0$.

The quantization condition (3.19) can be rewritten as

$$\alpha'+\beta'+\tilde{\phi}-(|m|+1)\pi=\pm\arccos\frac{\cos[b\pi/(2p)]}{[1+\exp(-2\pi\bar{K})]^{1/2}}+2s'\pi, \tag{3.22}$$

where s' is an integer. As already mentioned, (3.18b) is valid for $\Lambda=|m|\neq 0$ as well as for $\Lambda=0$. When the plus sign in (3.22) applies, we use (3.18b) to express β' in terms of α', and when the minus sign in (3.22) applies, we use (3.18b) to express α' in terms of β'. Replacing s' by s_α or s_β, we thus obtain from (3.22) and (3.18b) the two quantization conditions

$$\alpha'=\left(\frac{|m|}{2}+s_\alpha+\frac{1}{2}\right)\pi-\frac{\tilde{\phi}}{2}-\frac{b\pi}{4p}+\frac{1}{2}\arccos\frac{\cos[b\pi/(2p)]}{[1+\exp(-2\pi\bar{K})]^{1/2}}, \tag{3.23a}$$

$$\beta'=\left(\frac{|m|}{2}+s_\beta+\frac{1}{2}\right)\pi-\frac{\tilde{\phi}}{2}+\frac{b\pi}{4p}-\frac{1}{2}\arccos\frac{\cos[b\pi/(2p)]}{[1+\exp(-2\pi\bar{K})]^{1/2}}, \tag{3.23b}$$

where we choose the branch of arccos such that the last two terms on the right-hand side of (3.23a) and (3.23b) cancel in the limit $\bar{K}\to+\infty$, that is, when the barrier becomes infinitely thick. In this limit, the formulas (3.23a) and (3.23b) simplify to

$$\alpha'=\left(\frac{|m|}{2}+s_\alpha+\frac{1}{2}\right)\pi, \tag{3.24a}$$

$$\beta'=\left(\frac{|m|}{2}+s_\beta+\frac{1}{2}\right)\pi. \tag{3.24b}$$

For the particular case that we have a symmetric two-center Coulomb problem, i.e., that $Z_1=Z_2$, as is the case for the ion H_2^+, the double-well potential pertaining to the η-equation becomes symmetric ($b=0$), and the quantization conditions (3.23a) and (3.23b) can be simplified:

$$\alpha'=\left(\frac{|m|}{2}+s_\alpha+\frac{1}{2}\right)\pi-\frac{\tilde{\phi}}{2}+\frac{1}{2}\arctan\exp(-\pi\bar{K}), \tag{3.25a}$$

$$\beta'=\left(\frac{|m|}{2}+s_\beta+\frac{1}{2}\right)\pi-\frac{\tilde{\phi}}{2}-\frac{1}{2}\arctan\exp(-\pi\bar{K}). \tag{3.25b}$$

The reduced separation constant A', obtained from (3.23a) and (3.23b) in the general case and from (3.25a) and (3.25b) in the symmetric case, is a function of p^2 and C.

3. Comments on the quantization conditions

In the existing semiclassical treatments, the quantization conditions derived on assumptions valid for $m\neq 0$ are in general extrapolated to $m=0$ (corresponding to a particularization of our case $\Lambda=0$) without any motivation. It is, however, not allowed one to obtain a quantization condition corresponding to $m=0$ from a quantization condition corresponding to $m\neq 0$ by letting m take continuous values and tend to zero by a limiting procedure. That the formulas obtained by

such an extrapolation are valid is an *a posteriori* conclusion. The correct justification of the quantization conditions for $\Lambda=0$ rests on the use of the connection formula in Sec. 2 b of the Appendix.

For given values of r_{12}, m and E one can, as already mentioned, obtain the possible values of the reduced separation constant A' in the differential equation (2.8a) with (2.9a) by applying phase-integral quantization conditions for a single-well potential, while to obtain the possible values of the reduced separation constant A' in the differential equation (2.8b) with (2.9b) one has to use quantization conditions either for a single-well potential or for a double-well potential. The appropriate quantization condition for the ξ-equation determines A' as a function of p^2 and $\tilde{C}$. The appropriate quantization condition for the η-equation determines A' as a function of p^2 and C. The eigenvalues of p^2, and hence the energy eigenvalues E, are obtained from the requirement that these two expressions for A' must be equal to each other. One then obtains A' from the quantization condition for the ξ-equation or the η-equation. The value thus obtained for A' depends obviously on the choice of C and $\tilde{C}$. One should choose these parameters as functions of r_{12} in such a way that very accurate values of p^2 and A' are obtained already in the first order of the phase-integral approximation. A practically useful criterion for this can be formulated as follows. For every value of r_{12} one determines C and $\tilde{C}$ such that the first-order approximation gives the same value as the third-order approximation for p^2 (and hence for the energy) as well as for A'. In this way one can make all calculations within the framework of the phase-integral method.

APPENDIX: PHASE-INTEGRAL METHOD

Since the present paper is based on phase-integral formulas that are scattered in different publications, we collect in this Appendix the background material that is necessary for reading the paper.

The phase-integral method for solving differential equations of the type

$$\frac{\mathrm{d}^2\psi}{\mathrm{d}z^2}+R(z)\psi=0 \tag{A1}$$

involves the following items.

(1) Arbitrary-order phase-integral approximation generated from an unspecified base function $Q(z)$, as described in Chap. 1 of Ref. 22; see also Dammert and Fröman.[36]
(2) The method for solving connection problems developed by Fröman and Fröman,[37] generalized to apply to the phase-integral approximation referred to in the above-given item.
(3) Supplementary quantities, expressed analytically in terms of phase-integrals. An example is the quantity $\tilde{\phi}$, which is a new notation for the quantity -2σ in Fröman *et al.*,[38] and which is of decisive importance, when two transition zeros lie close to each other.

We shall first briefly describe the phase-integral approximation referred to in item (1). Then we collect connection formulas pertaining to a single transition point [first-order zero or first-order pole of $Q^2(z)$] and to a real potential barrier, which can be derived by means of the method mentioned in item (2) combined with comparision equation technique for obtaining the supplementary quantity $\tilde{\phi}$ mentioned in item (3) and appearing in the connection formula for a real barrier. Finally we present quantization conditions for single-well and double-well potentials,

which can be derived by means of the connection formulas just mentioned. These quantization conditions are used in our treatment of the two-center Coulomb problem.

1. Phase-integral approximation generated from an unspecified base function

For a detailed description of the phase-integral approximation generated from an unspecified base function we refer to Chap. 1 in Ref. 22. A brief description is given in the following.

In the arbitrary-order phase-integral approximation in question there appears an unspecified function $Q(z)$ called the *base function*. This function is often chosen to be equal to $R^{1/2}(z)$, but in many physical problems it is important to use the possibility of choosing $Q(z)$ differently when there exist certain exceptional points, e.g., the origin in connection with the radial Schrödinger equation, and, correspondingly, the poles of $\tilde{Q}^2(\xi)$ and $Q^2(\eta)$ at $\xi=1$ and $\eta=\pm 1$ in the two-center Coulomb problem. In the present paper we introduce in the base functions a parameter Λ, chosen such that either $\Lambda=|m|\neq 0$ or $\Lambda=0$, and two parameters C and $\tilde{C}$ to be determined such that the first- and third-order results coincide, in order that the first-order approximation be as good as possible.

To be able to write the phase-integral approximation generated from an unspecified base function in condensed form one introduces the new independent variable

$$\zeta=\int^{z} Q(z)\mathrm{d}z \tag{A2}$$

and the function

$$\varepsilon_0=Q^{-3/2}(z)\frac{\mathrm{d}^2}{\mathrm{d}z^2}Q^{-1/2}(z)+\frac{R(z)-Q^2(z)}{Q^2(z)}. \tag{A3}$$

It can be shown that in a local region of the complex z-plane, where the absolute value of ε_0 is small, the differential equation (A1) has the approximate solutions

$$\psi=q^{-1/2}(z)\exp[\pm iw(z)], \tag{A4a}$$

$$w(z)=\int_{z_0}^{z} q(z)\mathrm{d}z, \tag{A4b}$$

where the lower limit of integration z_0 is an unspecified constant, and the function $q(z)$, pertaining to the phase-integral approximation of the order $2N+1$, is given by

$$q(z)=\sum_{n=0}^{N} q^{(2n+1)}(z), \tag{A5a}$$

$$q^{(2n+1)}(z)=Q(z)Y_{2n}, \tag{A5b}$$

with the first few functions Y_{2n} given by

$$Y_0=1, \tag{A6a}$$

$$Y_2=\tfrac{1}{2}\varepsilon_0, \tag{A6b}$$

$$Y_4=-\frac{1}{8}\varepsilon_0^2-\frac{1}{8}\frac{\mathrm{d}^2\varepsilon_0}{\mathrm{d}\zeta^2}. \tag{A6c}$$

The choice of the function $Q(z)$ does not affect the expressions for Y_{2n} in terms of ε_0 and ζ; only the expressions for ε_0 and ζ as functions of z are affected.

It is an essential advantage of the phase-integral approximation described previously versus the Carlini[39] (JWKB) approximation in higher order that the former approximation contains the unspecified base function $Q(z)$, which one can take advantage of in several ways. (As regards the motivation for the terminology Carlini approximation we refer to Ref. 39.) A criterion for the determination of the base function is that the function ε_0 be in some sense small in the region of the complex z-plane that is relevant for the problem under consideration. However, this criterion does not determine the base function $Q(z)$ uniquely; it turns out that, within certain limits, the results are not very sensitive to the choice of $Q(z)$, when the approximation is used in higher orders. With a convenient choice of $Q(z)$ already the first-order approximation can be very good. On the other hand an inconvenient, but possible, choice of $Q(z)$ introduces in the first-order approximation an unnecessarily large error that, however, in general becomes corrected already in the third-order approximation.

The freedom that one has in the choice of the base function $Q(z)$ will be illuminated in a concrete way in the following. For a radial Schrödinger equation the usual choice of $Q^2(z)$ is

$$Q^2(z)=R(z)-\frac{1}{4z^2}. \tag{A7a}$$

However, the replacement of (A7a) by

$$Q^2(z)=R(z)-\frac{1}{4z^2}-\frac{\text{const}}{z}, \tag{A7b}$$

where the coefficient of $1/z$ should be comparatively small, does not destroy the great accuracy of the results usually obtained with the phase-integral approximation in higher orders. There is thus a whole set of base functions that may be used, and there are various ways in which one can take advantage of this nonuniqueness to make the choice of the base function well adapted to the particular problem under consideration. For instance, by adapting the choice of $Q^2(z)$ to the analytical form of $R(z)$ one can sometimes achieve the result that the integrals occurring in the phase-integral approximation can be evaluated analytically. To give an example we assume that $R(z)$ contains only $\exp(z)$ but not z itself. In this case it is convenient to replace the choice (A7b) by the choice

$$Q^2(z)=R(z)-\frac{1}{4(e^z-1)^2}-\frac{\text{const}}{e^z-1}. \tag{A7c}$$

By a convenient choice, for instance of the unspecified coefficient in (A7b) or (A7c), one can sometimes attain the result that, for example, eigenvalues or phase shifts are obtained exactly for some particular parameter value in every order of the phase-integral approximation. As already mentioned in Sec. I, by making this exactness fulfilled in the limit of a parameter value, for which the phase-integral result without this adaptation would not be good, one can actually extend the region of validity of the phase-integral treatment; see p. 12 in Ref. 30. When the differential equation contains one or more parameters, the accurate calculation of the wave function may require different choices of the base function $Q(z)$ for different ranges of the parameter values. To illustrate this fact we consider the radial Schrödinger equation. For sufficiently large values of the angular momentum quantum number l we obtain an accurate phase-integral approximation (valid also close to $z=0$) if we choose $Q^2(z)$ according to (A7a) or (A7b). If the value of l is too small, this phase-integral approximation is not good. It can be considerably improved (except close to $z=0$), when the absolute value of the coefficient of $1/z$ in $R(z)$ is sufficiently large, if one chooses instead

$$Q^2(z)=R(z)+\frac{l(l+1)}{z^2}. \tag{A7d}$$

The corresponding phase-integral approximation is not valid close to $z=0$, but the wave function that is regular and tends to z^{l+1} as $z\to 0$ can be obtained sufficiently far away from $z=0$ by means of the connection formula that will be presented in Sec. 2 b of this Appendix.

The appearance of the unspecified base function $Q(z)$ in the phase-integral approximation is thus very important from several points of view. In our treatment of the two-center Coulomb problem we use two essentially different kinds of base function [corresponding to $\Lambda=|m|\neq 0$ and $\Lambda=0$ in (3.2a) and (3.2b)], which yield approximate solutions with different regions of validity.

When the first-order approximation is used, it is often convenient to choose the constant lower limit of integration z_0 in (A4b) to be a zero or a first-order pole of $Q^2(z)$. This is, however, in general not possible when a higher-order approximation is used, since the integral in (A4b) would then in general be divergent. If z_0 is an odd-order zero or an odd-order pole of $Q^2(z)$, it is therefore convenient to replace the definition (A4b) of $w(z)$ by the definition

$$w(z)=\frac{1}{2}\int_{\Gamma_{z_0}(z)} q(z)\mathrm{d}z, \tag{A8}$$

where $\Gamma_{z_0}(z)$ is a path of integration that starts at the point corresponding to z on a Riemann sheet adjacent to the complex z-plane under consideration, encircles z_0 in the positive or in the negative sense, and ends at z. It is immaterial for the value of the integral in (A8) if the path of integration encircles z_0 in the positive or in the negative sense, but the end point must be z. For the first-order approximation the definitions (A4b) and (A8) are identical.

It is useful to introduce a short-hand notation for the integral in the right-hand member of (A8) by the definition

$$\int_{(z_0)}^{z} q(z)\mathrm{d}z=\frac{1}{2}\int_{\Gamma_{z_0}(z)} q(z)\mathrm{d}z. \tag{A9}$$

For the first order of the phase-integral approximation one can replace (z_0) by z_0 in the left-hand member of (A9) and thus get an ordinary integral from z_0 to z instead of half of the integral along the contour $\Gamma_{z_0}(z)$. In analogy to (A9) one defines a short-hand notation for an integral in which the upper limit of integration is an odd-order zero or an odd-order pole of $Q^2(z)$. When one has two transition points of that kind as limits of integration, one requires that the contours of integration pertaining to the lower and upper limits of integration are encircled in the same direction, and the definition of the short-hand notation with both limits within parentheses implies then that the integral is equal to half of the integral along a closed loop enclosing both transition points. The simplified notation in the left-hand member of (A9) for the integral in the right-hand member of (A9) was introduced by Fröman *et al.*,[40] pp. 160–161. It makes it possible to use, for an arbitrary order of the phase-integral approximation, a similar simple notation and almost the same simple language (although in a generalized sense) as for the first order of the phase-integral approximation. One thus achieves a great formal and practical simplification in the treatment of concrete problems, when an arbitrary order of the phase-integral approximation is used.

We remark that the above-used notations differ from the notations in the original papers published up to the beginning of the 1980s in the respect that $Q^2(z)$ and $Q^2_{\mathrm{mod}}(z)$ in those papers correspond in the present paper to $R(z)$ and $Q^2(z)$, respectively.

2. Connection formulas associated with a single transition point

a. Connection formulas pertaining to a first-order, real transition zero

Before the phase-integral approximation generated from an unspecified base function had been introduced, Fröman[41] derived arbitrary-order connection formulas associated with a turning point for the particular phase-integral approximation of arbitrary order corresponding to $Q^2(z)=R(z)$. After the phase-integral approximation generated from an unspecified base function had

been introduced, it turned out that these connection formulas remain valid also when $Q^2(z) \neq R(z)$. In the following we shall present the general connection formulas.

The functions $R(z)$ and $Q^2(z)$ are assumed to be real on the real z-axis (the x-axis). On this axis there is a generalized classical turning point t, i.e., a simple zero of $Q^2(z)$, and there is, in a generalized sense, a classically allowed region on one side of t, i.e., a region where $Q^2(x)>0$, and a classically forbidden region on the other side of t, i.e., a region where $Q^2(x)<0$. Defining

$$w(x)=\int_{(t)}^{x} q(z)\mathrm{d}z, \tag{A10}$$

we can write the connection formula for tracing a phase-integral solution of (A1) from the classically allowed to the classically forbidden region as

$$A|q^{-1/2}(x)|\exp\left\{i\left[|w(x)|+\frac{\pi}{4}\right]\right\}+B|q^{-1/2}(x)|\exp\left\{-i\left[|w(x)|+\frac{\pi}{4}\right]\right\}$$
$$\rightarrow(A+B)|q^{-1/2}(x)|\exp[|w(x)|], \tag{A11}$$

where A and B are constants, which are arbitrary except for the requirement that $(A+B)/(|A|+|B|)$ must not be too close to zero. As a consequence of (A11) we have the connection formula

$$|q^{-1/2}(x)|\cos\left[|w(x)|+\delta-\frac{\pi}{4}\right]\rightarrow\sin\delta|q^{-1/2}(x)|\exp[|w(x)|], \tag{A12}$$

where δ is a real phase constant that must not be too close to a multiple of π. The connection formula for tracing a phase-integral solution of (A1) from the classically forbidden to the classically allowed region is

$$|q^{-1/2}(x)|\exp[-|w(x)|]+C|q^{-1/2}(x)|\exp[|w(x)|]$$
$$\rightarrow 2|q^{-1/2}(x)|\cos\left[|w(x)|-\frac{\pi}{4}\right], \tag{A13}$$

and it is valid provided that the condition

$$C\exp[|w(x)|]\lesssim\exp[-|w(x)|] \tag{A14}$$

is fulfilled. For a numerical study of the accuracy and the properties of the connection formula (A13) with $C=0$ we refer to Fröman and Mrazek.[42] We emphasize the one-directional character of the connection formulas (A11)–(A13), which means that the tracing of a solution must always be made in the direction of the arrow. This property of the connection formulas has been thoroughly investigated and even illustrated numerically by Fröman[43] for the first order of the Carlini[39] (JWKB) approximation. The whole discussion in Ref. 43 applies in principle to the connection formulas for the higher orders of the phase-integral approximation as well. The above-mentioned connection formulas for the phase-integral approximation of any order may in many cases be used for obtaining very accurate solutions of physical problems, when the classical turning points are well separated, and when there are no other transition points near the real axis in the region of the complex z-plane of interest. Within their range of applicability the connection formulas are very useful because of their simplicity and the great ease with which they can be used.

b. Connection formula pertaining to a first-order transition pole

Now we assume that in a certain region of the complex z-plane around a first-order transition pole t, i.e., a first-order pole of $Q^2(z)$, we have

$$R(z)=-\frac{l(l+1)}{(z-t)^2}+\frac{B}{z-t}+\text{a regular function of } z, \tag{A15}$$

$$Q^2(z)=\frac{\overline{B}}{z-t}+\text{a regular function of } z, \tag{A16}$$

where $2l+1$ is a non-negative integer. We assume that the absolute values of B and $\overline{B}$ are sufficiently large, while the absolute value of $B-\overline{B}$ and the absolute value of the difference between the two regular functions in (A15) and (A16) are sufficiently small. There is one particular curve on which $w(z)$, defined as

$$w(z)=\int_{(t)}^{z} q(z)\mathrm{d}z, \tag{A17}$$

is real. For the first order of the phase-integral approximation this is the anti-Stokes line that emerges from t. Therefore we use, also when a higher order of the phase-integral approximation is used, the terminology an *anti-Stokes line that emerges from t* in a generalized sense to denote the anti-Stokes line on which $w(z)$, defined in (A17), is real. For the first-order approximation (and under certain unnecessarily restrictive assumptions) Fröman and Fröman[37] obtained a phase-integral formula [their Eq. (7.28)], valid sufficiently far away from t on the anti-Stokes line that emerges from t, for the particular solution $\psi(z)$ of (A1) that fulfills the condition

$$\lim_{z\to t}\frac{\psi(z)}{(z-t)^{l+1}}=1. \tag{A18}$$

This formula can be generalized to be valid for an arbitrary order of the phase-integral approximation generated from an unspecified base function and can then be formulated as follows. On the lip of the anti-Stokes line emerging from t, where $\arg w(z)$ is smallest, the solution of (A1) that fulfills the condition (A18) is, sufficiently far away from t, given by the phase-integral formula

$$\psi(z)=\left(\pi c\frac{w(z)}{|w(z)|}\right)^{-1/2} q^{-1/2}(z)\cos\left[|w(z)|-\left(l+\frac{3}{4}\right)\pi\right], \tag{A19}$$

where c is the residue of $[\psi(z)]^{-2}$ at $z=t$ and is thus determined by the expansion of $\psi(z)$ in powers of $z-t$, and the sign of

$$\left[\pi c\frac{w(z)}{|w(z)|}\right]^{-1/2}$$

has to be chosen conveniently. For the special case that $l=0$ one finds that $c=B$. Formula (A19) can easily be particularized to the case that $R(z)$ and $Q^2(z)$ are real on the real z-axis (the x-axis) and t lies on that axis.

3. Connection formula for a real, smooth, single-hump potential barrier

Our starting point is a paper by Fröman and Fröman.[44] Although it was assumed in the treatment there that $Q^2(z)=R(z)$ with the notations in the present paper, the results obtained are valid also when $Q^2(z)\neq R(z)$. In the present paper it is convenient to introduce partly other notations than in Ref. 44. Thus we now denote by t' and t'' the two relevant zeros of $Q^2(z)$, i.e., the two generalized classical turning points in the subbarrier case ($t'<t''$) and the two complex conjugate transition zeros in the superbarrier case ($\mathrm{Im}\,t'\leqslant 0, \mathrm{Im}\,t''\geqslant 0$). Let x', called x_1 in Ref. 44,

be a point in the classically allowed region of the real z-axis to the left of the barrier, and let x'', called x_2 in Ref. 44, be a point in the classically allowed region of the real z-axis to the right of the barrier. We introduce the notations

$$\theta = |F_{22}| \exp(K), \tag{A20a}$$

$$\vartheta = \arg F_{22}, \tag{A20b}$$

$$\tilde{\phi} = -2\sigma = \frac{\pi}{2} - \arg F_{12}, \tag{A20c}$$

where F_{12} and F_{22} are defined in Ref. 44, and K is defined by Eq. (12) in Ref. 44. In the definitions (A20a)–(A20c) it is assumed that the phase of $q^{1/2}(z)$ is chosen as shown in Fig. 1 in Ref. 44. We shall, however, in the following write the formulas in such a way that they remain unchanged if one changes the phase of $Q^{1/2}(z)$ and hence the phase of $q^{1/2}(z)$; see (A5a) and (A5b). The quantity K in (A20a) is then given by

$$K = \frac{1}{2} i \int_{\Lambda} q(z)\,\mathrm{d}z$$

$$= i \int_{(t')}^{(t'')} q(z)\,\mathrm{d}z, \tag{A21}$$

where Λ [not to be confused with the parameter Λ in the base function $Q(\eta)$] is a closed contour of integration encircling both t' and t'', but no other transition point, and the integration is performed in the direction that in the *first-order approximation* yields $K>0$ for energies below the top of the barrier and $K<0$ for energies above the top of the barrier. If higher-order approximations are used, the quantity K may become negative also for energies below (but not too far from) the top of the barrier; see Table I in Ref. 45. We have replaced σ, defined by Eq. (28) in Ref. 44, by $-\tilde{\phi}/2$ [cf. (A20c)] in order to get better agreement with a notation used by other authors; see for instance Child.[46] Now we define

$$B' = A_1 \exp\left(-i\frac{\pi}{4}\right), \tag{A22a}$$

$$A' = B_1 \exp\left(+i\frac{\pi}{4}\right), \tag{A22b}$$

where the notations in the right-hand members are those used in Ref. 44. Using the short-hand notation defined in (A9), we obtain from Eqs. (25a) and (9a), with x_1 replaced by x', in Ref. 44 and (A22a) and (A22b) in the present paper

$$\psi(x') = A' |q^{-1/2}(x')| \exp\left(+i\left|\mathrm{Re}\int_{(t')}^{x'} q(z)\,\mathrm{d}z\right|\right)$$

$$+ B' |q^{-1/2}(x')| \exp\left(-i\left|\mathrm{Re}\int_{(t')}^{x'} q(z)\,\mathrm{d}z\right|\right), \tag{A23a}$$

and from Eqs. (25b) and (23), with x_2 replaced by x'', in Ref. 44 and (A20a)–(A20c), (A22a), and (A22b) in the present paper

$$\psi(x'')=A''|q^{-1/2}(x'')|\exp\left(+i\left|\mathrm{Re}\int_{(t'')}^{x''}q(z)\mathrm{d}z\right|\right)$$

$$+B''|q^{-1/2}(x'')|\exp\left(-i\left|\mathrm{Re}\int_{(t'')}^{x''}q(z)\mathrm{d}z\right|\right), \tag{A23b}$$

where

$$\begin{pmatrix}A''\\B''\end{pmatrix}=\tilde{M}\begin{pmatrix}A'\\B'\end{pmatrix}, \tag{A24}$$

$$\tilde{M}=\begin{pmatrix}\theta\exp\left[-i\left(\frac{\pi}{2}+\vartheta\right)\right] & (\theta^2+1)^{1/2}\exp(+i\tilde{\phi})\\ (\theta^2+1)^{1/2}\exp(-i\tilde{\phi}) & \theta\exp\left[+i\left(\frac{\pi}{2}+\vartheta\right)\right]\end{pmatrix}, \tag{A25a}$$

$$\det\tilde{M}=-1. \tag{A25b}$$

It is seen from (A23a) and (A23b) that the coefficients A' and A'' are associated with waves traveling away from the barrier, while the coefficients B' and B'' are associated with waves incoming toward the barrier. From (A25a) and (A25b) we obtain

$$\tilde{M}^{-1}=\begin{pmatrix}\theta\exp\left[-i\left(\frac{\pi}{2}-\vartheta\right)\right] & (\theta^2+1)^{1/2}\exp(+i\tilde{\phi})\\ (\theta^2+1)^{1/2}\exp(-i\tilde{\phi}) & \theta\exp\left[+i\left(\frac{\pi}{2}-\vartheta\right)\right]\end{pmatrix}. \tag{A26}$$

One thus obtains $\tilde{M}^{-1}$ from $\tilde{M}$ by replacing ϑ by $-\vartheta$. We emphasize that the above-mentioned formulas are in principle exact, provided that one knows the quantities θ, ϑ, and $\tilde{\phi}$, which depend slightly on x' and x''. Furthermore, the two transition zeros associated with the potential barrier need not lie far away from other possibly existing transition points; see Ref. 44. However, when one introduces for θ, ϑ, and $\tilde{\phi}$ the approximate values that will be given in the following, the barrier is assumed to be well separated (in the sense just described) from all transition points that are not associated with the barrier.

When A' and B' are given constants, associated with a wave function that is given at the point x', the coefficients A'' and B'', which are obtained from (A24) along with (A25a), depend slightly on x' and x'' via the quantities θ, ϑ, and $\tilde{\phi}$. One obtains the derivatives of $\psi(x')$ and $\psi(x'')$ from (A23a) and (A23b) by considering A',B',A'' and B'' *formally* as constants.

When the transition points that are *not* associated with the barrier lie sufficiently far away from t' and t'', it follows from Eq. (43a) in Ref. 44 and (A20a) and (A20b) that

$$\theta\approx\exp(K), \tag{A27a}$$

$$\vartheta\approx 0. \tag{A27b}$$

The quantity $\tilde{\phi}$ is particularly important when the energy is close to the top of the barrier, but it is important also for energies well below the top, if one with the use of higher orders of the phase-integral approximation wants to obtain very accurate results. In practice one cannot obtain useful expressions for $\tilde{\phi}$ from the exact formula (A20c). Under the assumption that $d^2R(z)/dz^2$ is not too close to zero at the top of the barrier, Fröman *et al.*[47] derived by means of comparision equation technique, adapted to yield formulas for supplementary quantities in the phase-integral

method, an approximate, but very accurate, formula in the $(2N+1)$th order of the phase-integral approximation [their eqs. (5.5.30), (5.5.25a)–(5.5.25g), (5.4.23), and (5.4.21)], from which we can obtain the formula

$$\tilde{\phi}=\arg\Gamma\left(\frac{1}{2}+i\overline{K}\right)-\overline{K}\ln|\overline{K}_0|+\sum_{n=0}^{N}\phi^{(2n+1)}, \tag{A28}$$

where

$$\phi^{(1)}=\overline{K}_0, \tag{A29a}$$

$$\phi^{(3)}=-\frac{1}{24\overline{K}_0}, \tag{A29b}$$

$$\phi^{(5)}=-\frac{7}{2880\overline{K}_0^3}+\frac{\overline{K}_2}{24\overline{K}_0^2}-\frac{\overline{K}_2^2}{2\overline{K}_0}, \tag{A29c}$$

with

$$\overline{K}_{2n}=\frac{1}{2\pi i}\int_{\Lambda}Y_{2n}Q(z)\mathrm{d}z, \quad n=0,1,2,\ldots,N, \tag{A30a}$$

$$\overline{K}=\sum_{n=0}^{N}\overline{K}_{2n}=\frac{K}{\pi}, \tag{A30b}$$

Λ being the previously described contour of integration encircling t' and t'' but no other transition point, with the integration performed in the direction that makes $\overline{K}_0$ positive when t' and t'' are real, i.e., when the barrier is superdense, but negative when t' and t'' are complex conjugate, i.e., when the barrier is underdense. [Note that we perform the integrations in (A21) and (A30a) in opposite directions in order to make these formulas agree with Eq. (12) in Ref. 44 and Eq. (5.4.21) in Ref. 47, respectively.] The result given by (A28), (A29a)–(A29c), and (A30a) and (A30b) can also be obtained from Ref. 38, where -2σ is the same as our $\tilde{\phi}$.

We emphasize again that for the validity of (A28) with the expressions (A29a)–(A29c) for $\phi^{(2n+1)}$ the essential restriction is that $|d^2R(z)/dz^2|$ must not be too small at the top of the barrier, which means that close to its top the barrier is approximately parabolic. However, when the energy is close to the top of the barrier, it is the slight deviation from parabolic shape close to the top of the barrier that determines the values of the quantities $\overline{K}_{2n}, n>0$, and one needs accurate values of these quantities for obtaining accurate values of $\tilde{\phi}$ in higher orders of the phase-integral approximation.

The barrier connection formula presented in this section is valid uniformly for all energies, below and above the top of the barrier. We would also like to emphasize that while the connection formulas pertaining to an isolated turning point (Fröman[41]) are one-directional, the barrier connection formula (A23a) and (A23b) with (A24) and (A25a), which is valid when the barrier is well isolated and has an approximately parabolic top, is bidirectional. However, the neighborhood of an energy that corresponds to a resonance requires a careful discussion.

4. Quantization conditions for single-well and double-well potentials

In this section we shall present quantization conditions for general single-well potentials[48–50] and double-well potentials,[38,50–52] valid for any conveniently chosen order of the phase-integral approximation, in forms especially adapted to the two-center Coulomb problem. In the quantiza-

tion conditions pertaining to the double-well potential there appears the supplementary quantity $\tilde{\phi}$, which was discussed in Sec. 3 of this Appendix, and which is of particular importance for energy eigenvalues in the neighborhood of the top of the barrier; cf. numerical results in Ref. 38, where Q^2, Q^2_{mod}, and σ correspond to R, Q^2, and $-\tilde{\phi}/2$, respectively, in the present paper. Comparision with numerical results[38] shows that all energy eigenvalues, also the low-lying ones and those in the neighborhood of the top of the barrier, are obtained very accurately from the phase-integral quantization conditions when the third- or fifth-order approximation is used.

Since arbitrary-order phase-integral quantization conditions for the single-well and for the double-well potential problems have been given in previous works, we restrict ourselves to quoting those results and taking into account the fact that we are dealing with the special potentials pertaining to the two-center Coulomb problem.

a. Quantization conditions for single-well potentials

We assume that $R(z)$ and $Q^2(z)$ are real on the real z-axis (the x-axis) and that there are two transition points t' and t'' $(>t')$ on this axis, each one of which may be either a first-order transition zero, i.e., a first-order zero of $Q^2(z)$, or a first-order transition pole, i.e., a first-order pole of $Q^2(z)$. These transition points are assumed to lie far away from all other transition points. On the real axis between t' and t'' it is assumed that $Q^2(x)$ is positive. With the aid of the connection formulas in Sec. 2 of this Appendix we can derive the quantization conditions that will be presented in the following.

When both t' and t'' are first-order transition zeros, we obtain the quantization condition[48,49]

$$\left| \int_{(t')}^{(t'')} q(z)\mathrm{d}z \right| = \left(s+\frac{1}{2} \right)\pi, \quad s=0,1,2,\ldots. \tag{A31}$$

When one of the transition points t' and t'' is a first-order transition zero, and the other is a first-order transition pole in the neighborhood of which $R(z)$ and $Q^2(z)$ can be expanded according to (A15) and (A16) with $l=(|m|-1)/2$, i.e., $l(l+1)=(m^2-1)/4$, we obtain under the assumptions introduced below those expansions the quantization condition[49]

$$\left| \int_{(t')}^{(t'')} q(z)\mathrm{d}z \right| = \left(\frac{|m|}{2}+s+\frac{1}{2} \right)\pi, \tag{A32}$$

where m is an integer (positive, negative or zero), and s is also an integer.

When both transition points t' and t'' are first-order transition poles, in the neighborhood of which $R(z)$ and $Q^2(z)$ can be expanded according to (A15) and (A16) with $l=(|m|-1)/2$, i.e., $l(l+1)=(m^2-1)/4$ for both transition poles but possibly with different coefficients B and $\overline{B}$ for the two transition poles, we obtain under the assumptions introduced below (A15) and (A16) the quantization condition[30]

$$\left| \int_{(t')}^{(t'')} q(z)\mathrm{d}z \right| = \left(|m|+s+\frac{1}{2} \right)\pi, \tag{A33}$$

where m is an integer (positive, negative, or zero), and s is also an integer.

b. Quantization conditions for double-well potentials

We assume that $R(z)$ and $Q^2(z)$ are real on the real z-axis (the x-axis) and that there are either two generalized classical turning points t' and t'' $(>t')$ [real, simple zeros of $Q^2(z)$] associated with a superdense potential barrier or two complex conjugate simple transition zeros t' and t'' [simple zeros of $Q^2(z)$; $\mathrm{Im}\,t'<0$, $\mathrm{Im}\,t''>0$] associated with an underdense potential barrier. The classically allowed region to the left of the barrier is to the left delimited by a transition point t_- (on the real axis), and the classically allowed region to the right of the barrier is to the right

delimited by a transition point t_+ (on the real axis), where t_- and t_+ are both either generalized classical turning points, i.e., simple zeros of $Q^2(z)$, or first-order transition poles, i.e., first-order poles of $Q^2(z)$. The points t_- and t_+, as well as other possibly existing transition points that are not associated with the barrier, are assumed to lie far away from t' and t''. When t_- and t_+ are simple transition poles we assume that in the neighborhood of $t_\pm$ we have

$$R(z)=\frac{(1-m^2)}{4(z-t_\pm)^2}+\frac{B_\pm}{z-t_\pm}+\text{a regular function of } z, \tag{A34}$$

$$Q^2(z)=\frac{\overline{B}_\pm}{z-t_\pm}+\text{a regular function of } z, \tag{A35}$$

where m is an integer (positive, negative, or zero), $B_\pm$ and $\overline{B}_\pm$ are sufficiently large to their absolute values, while the absolute values of $B_\pm-\overline{B}_\pm$, as well as the difference between the regular functions in (A34) and (A35), is not too large. Under the above-mentioned assumptions we obtain with the aid of connection formulas in Secs. 2 and 3 in this Appendix the quantization condition

$$\tan\left(\left|\operatorname{Re}\int_{(t_-)}^{(t')}q(z)\mathrm{d}z\right|+\frac{\tilde{\phi}}{2}-a\right)\tan\left(\left|\operatorname{Re}\int_{(t_+)}^{(t'')}q(z)\mathrm{d}z\right|+\frac{\tilde{\phi}}{2}-a\right)$$
$$=\frac{[1+\exp(-2K)]^{1/2}-1}{[1+\exp(-2K)]^{1/2}+1}, \tag{A36}$$

where

$$K=\frac{1}{2i}\int_\Lambda q(z)\mathrm{d}z, \tag{A37}$$

Λ being a closed contour, enclosing t' and t'', along which the integration is performed in the direction that makes the first-order contribution to K positive when the barrier is superdense but negative when the barrier is underdense, and

$$a=\begin{cases}\dfrac{\pi}{2} & \text{when } t_- \text{ and } t_+ \text{ are transition zeros}\\[2ex] (|m|+1)\dfrac{\pi}{2} & \text{when } t_- \text{ and } t_+ \text{ are transition poles.}\end{cases} \tag{A38}$$

The quantization condition (A36) can be rewritten into the form

$$\cos\left(\left|\operatorname{Re}\int_{(t_-)}^{(t')}q(z)\mathrm{d}z\right|+\left|\operatorname{Re}\int_{(t_+)}^{(t'')}q(z)\mathrm{d}z\right|+\tilde{\phi}-2a\right)$$
$$=\frac{\cos(|\operatorname{Re}\int_{(t_-)}^{(t')}q(z)\mathrm{d}z|-|\operatorname{Re}\int_{(t_+)}^{(t'')}q(z)\mathrm{d}z|)}{[1+\exp(-2K)]^{1/2}}. \tag{A39}$$

(Received 27 July 2000; accepted for publication 16 July 2001)

The contour integrals, occurring in the arbitrary-order phase-integral quantization conditions given in a previous paper, are in the first- and third-order approximations expressed in terms of complete elliptic integrals in the case that the charges of the Coulomb centers are equal. The evaluation of the integrals is facilitated by the knowledge of quasiclassical dynamics. The resulting quantization conditions involving complete elliptic integrals are solved numerically to obtain the energy eigenvalues and the separation constants of the $1s\sigma$ and $2p\sigma$ states of the hydrogen molecule ion for various values of the internuclear distance. The accuracy of the formulas obtained is illustrated by comparison with available numerically exact results. © *2001 American Institute of Physics.* [DOI: 10.1063/1.1399295]

I. INTRODUCTION

In a previous paper[1] the general two-center Coulomb problem was treated according to the phase-integral method, briefly described in the appendix of that paper, and arbitrary-order quantization conditions were given, valid uniformly for all energies.

The symmetric case, where the charge numbers Z_1 and Z_2 of the two Coulomb centers are equal, represents for $Z_1=Z_2=1$ the hydrogen molecule ion H_2^+. This case has for natural reasons been studied more extensively than the general two-center problem. Thus, the H_2^+ ion was already the subject of treatments with the aid of the old quantum theory[2] and in the early days of quantum mechanics.[3,4] The simplicity of the hydrogen molecule ion grants it an analogous unique position in molecular physics as the hydrogen atom possesses in atomic physics. For instance, H_2^+ plays a role of fundamental significance in the theory of chemical bonding, and it is also of importance in the study of stellar atmospheres.

For the background of the present paper we refer to Ref. 1. In Sec. II of the present paper we present the quasiclassical dynamics of the associated particle system by setting up the equation of motion for a particle moving in the relevant potential and express the solution in terms of Jacobian elliptic functions. In Secs. III and IV we express the quantization conditions given in Ref. 1 in terms of complete elliptic integrals by using the solution in Sec. II. We introduce, analogously to Lakshmanan and Kaliappan,[5] Lakshmanan *et al.*,[6] and Lakshmanan *et al.*,[7] convenient transformations to elliptic functions, in order to be able to express both the real and the complex contour integrals, occurring in the quantization conditions, in terms of complete elliptic integrals. In choosing our transformations we exploit the symmetry of the functions $R(\eta)$ and $Q^2(\eta)$, introduced in Ref. 1, from the beginning of the calculations, since this is much simpler than to

[a]Present address: Department of Physics, Government Arts College, Ariyalur-621 713, India.
[b]Electronic mail: lakshman@bdu.ernet.in

particularize formulas for the general case of arbitrary nuclear charge numbers Z_1 and Z_2 to the case $Z_1=Z_2$. Thus we obtain simple expressions for the quantities appearing in the quantization conditions in Ref. 1. It should be remarked that if one particularizes the η-quantization conditions involving complete elliptic integrals that are valid for arbitrary charge numbers Z_1 and Z_2 (to be derived in the subsequent paper[8]) to the case $Z_1=Z_2$, one must in general make further cumbersome transformations in order to bring the quantization conditions in question into the same form as those obtained by assuming from the begining that $Z_1=Z_2$. The functions $\tilde{R}(\xi)$ and $\tilde{Q}^2(\xi)$, introduced in Ref. 1, do not display an analogous symmetry as $R(\eta)$ and $Q^2(\eta)$ when $Z_1=Z_2$. The treatment of the ξ-equation is thus the same whether $Z_1=Z_2$ or $Z_1\neq Z_2$, and it is analogous to the treatment of the η-equation in the general case when Z_1 may be different from Z_2, which is treated in the third paper[8] in our series of papers concerning the phase-integral treatment of the quantal two-center Coulomb problem. All the contour integrals needed in the calculations are expressed in terms of complete elliptic integrals, corresponding to the use of the first- and third-order phase-integral approximations. Since complete elliptic integrals can easily be evaluated by means of standard computer programs, computational difficulties that may arise in direct numerical calculations (especially of higher-order terms) are thereby eliminated. One achieves also the possibility of being able to utilize well-known properties of complete elliptic integrals, for instance series expansions, for analytic studies on the basis of the quantization conditions. Some of the first-order contour integrals have previously been given in terms of complete elliptic integrals by Strand and Reinhardt,[9] but to the best knowledge of the present authors, even in the first-order approximation only partial results have been given.

The phase-integral formulas derived in this paper are quite flexible due to the presence of two arbitrary parameters C and $\tilde{C}$ introduced in the base functions $Q(\eta)$ and $\tilde{Q}(\xi)$ in Eqs. (3.2b) and (3.2a), respectively, in Ref. 1. In accordance with the discussion in Sec. III A of Ref. 1 we choose C and $\tilde{C}$ such that the first-order results are exactly equal to the third-order results, and we investigate in Sec. V of the present paper the accuracy of our phase-integral quantization conditions for the $1s\sigma$ and $2p\sigma$ states of the hydrogen molecule ion.

II. QUASICLASSICAL DYNAMICS

We have seen in Sec. III of Ref. 1 that the quantization conditions require the evaluation of various contour integrals. In the present section we shall restrict ourselves to the η-equation. The shape of the contours depends on the choice of Λ and on the real or complex nature of the zeros of $Q^2(\eta)$; see Figs. 2–4 in Ref. 1.

Letting, when $-Q^2(\eta)$ is a double-well potential, the zeros of $Q^2(\eta)$ be $\eta_1,\eta_2,\eta_3,\eta_4$ when $\Lambda=|m|\neq 0$ and η_2,η_3 when $\Lambda=0$, we shall evaluate the integrals $\alpha=\beta$ and $\overline{K}$ in the following cases separately.

(1) $\Lambda=|m|\neq 0$:
   (a) Subbarrier case (superdense) ($\eta_1=-\eta_4$ and $\eta_2=-\eta_3$ are real).
   (b) Superbarrier (under-dense) case (η_1,η_4 are real and η_2,η_3 are complex conjugate).

(2) $\Lambda=0$:
   (a) Subbarrier (superdense) case (only two zeros, $\eta_2=-\eta_3$; they are real).
   (b) Superbarrier (under-dense) case (only two zeros, η_2 and η_3; they are complex conjugate).

In each one of these cases the evaluation of the contour integrals in terms of complete elliptic integrals is facilitated by the knowledge of the associated quasiclassical dynamics. In particular the relevant substitution for the integration variable in the various contour integrals can be obtained with the help of, for example, Byrd and Friedman.[10] However, the meaning of these substitutions can be attributed to the associated solution of the equation of motion of the corresponding classical problem as in the case of three-dimensional anharmonic oscillators.[7]

To illustrate what has been said previously, we shall consider the subbarrier case of $\Lambda=|m|$

$\neq 0$. (For the other cases the analysis can be carried out in a similar way.) The base function $Q(\eta)$ for this case is

$$Q(\eta)=p\frac{[(a^2-\eta^2)(\eta^2-b^2)]^{1/2}}{1-\eta^2}, \tag{2.1}$$

where $a=\eta_4=-\eta_1$, $b=\eta_3=-\eta_2$, and $p^2=-(1/2)Er_{12}^2$. Let us define a new integration variable $\bar{u}$ by writing

$$\bar{u}=\int^{\eta}\frac{d\eta}{(1-\eta^2)Q(\eta)}; \tag{2.2}$$

then

$$\frac{d\eta}{d\bar{u}}=(1-\eta^2)Q(\eta)=\hat{Q}(\eta). \tag{2.3}$$

Before solving (2.3), we shall relate this differential equation to the equation of motion for the quasiclassical motion of a particle with a mass μ in a certain potential by differentiating (2.3) with respect to $\bar{u}$, getting

$$\frac{d^2\eta}{d\bar{u}^2}=\frac{1}{2}\frac{d\hat{Q}^2}{d\eta}. \tag{2.4}$$

Defining now the ''time'' variable u as

$$u=\bar{u}\sqrt{\mu}, \tag{2.5}$$

we obtain the equation of quasiclassical motion

$$\mu\frac{d^2\eta}{du^2}=-\frac{dU(\eta)}{d\eta}, \tag{2.6a}$$

$$U(\eta)=-\tfrac{1}{2}\hat{Q}^2(\eta). \tag{2.6b}$$

We can consider (2.6a) as representing the motion of a particle in the potential $U(\eta)$. We shall now solve the differential equation (2.3) in terms of Jacobian elliptic functions when $Q(\eta)$ is given by (2.1). The potential $U(\eta)$ is then given by

$$\begin{aligned}U(\eta)&=-\tfrac{1}{2}\hat{Q}^2(\eta)\\&=-\tfrac{1}{2}(1-\eta^2)^2Q^2(\eta)\\&=-\tfrac{1}{2}p^2(a^2-\eta^2)(\eta^2-b^2),\end{aligned} \tag{2.7}$$

and according to (2.3) and (2.1)

$$\frac{d\eta}{d\bar{u}}=p\sqrt{(a^2-\eta^2)(\eta^2-b^2)}. \tag{2.8}$$

By solving (2.8) with respect to η we obtain

$$\eta(\bar{u})=\frac{b}{\mathrm{dn}\left[\dfrac{p}{a}(\bar{u}-\bar{u}_0)\right]}, \tag{2.9}$$

where $\overline{u_0}$ is an integration constant, and the modulus k of the Jacobian elliptic function is given by

$$k^2=1-\frac{b^2}{a^2}. \tag{2.10}$$

Similarly we can for all other cases interpret the corresponding quasiclassical dynamics by the above-mentioned type of treatment.

III. CASE $\Lambda=|m|\neq 0$

In order to express the contour integrals, occurring in the quantization conditions pertaining to the ξ-equation and the η-equation, in terms of complete elliptic integrals, we transform the integrals in question from the ξ- or η-plane to another complex plane, the u-plane, on which the Jacobian elliptic functions $\mathrm{cn}\,u$, $\mathrm{sn}\,u$, and $\mathrm{dn}\,u$ are defined. We make frequent use of formulas in Ref. 10. As mentioned previously the transformation in question can be attributed to quasiclassical dynamics.

A. Four real zeros of $Q^2(\eta)$ and $\tilde{Q}^2(\xi)$

1. The quantities $\alpha=\beta$ and $\bar{K}$ pertaining to the η-equation: Subbarrier case [Fig. 3(a) in Ref. 1]

Putting $\eta_4=-\eta_1=a$ and $\eta_3=-\eta_2=b$, we have the base function (2.1), that is,

$$Q(\eta)=p\frac{[(a^2-\eta^2)(\eta^2-b^2)]^{1/2}}{1-\eta^2}. \tag{3.1}$$

Using the appropriate transformation on p. 54 in Ref. 10, or equivalently the quasiclassical solution given in Sec. II, we put

$$\eta=\frac{b}{\mathrm{dn}\,u}=\frac{b}{(1-k^2\mathrm{sn}^2\,u)^{1/2}},\quad k^2=1-\frac{b^2}{a^2}. \tag{3.2}$$

Noting that the loop $\eta_2\rightarrow\eta_1\rightarrow\eta_2$, that is $-b\rightarrow-a\rightarrow-b$, in the η-plane, denoted by $\Gamma_{-b,-a}$, represents the contour Λ_α in Fig. 3(a) of Ref. 1 which corresponds in the u plane to $0\rightarrow K\rightarrow 2K$, where K is the complete elliptic integral of the first kind, we obtain for the first-order contribution to α the following transformation of the original integral in the η-plane into an integral in the u-plane:

$$\begin{aligned}\alpha^{(1)}=\frac{1}{2}\int_{\Lambda_\alpha}Q(\eta)\mathrm{d}\eta&=\frac{1}{2}\int_{\Gamma_{-b,-a}}Q(\eta)\mathrm{d}\eta\\&=\frac{p}{g}\frac{1}{2}\int_0^{2K}\left(\frac{\mathrm{d}\eta}{\mathrm{d}u}\right)^2\frac{\mathrm{d}u}{1-\eta^2}\\&=p\frac{k^4b^2}{1-b^2}\frac{1}{2}\int_0^{2K}\frac{\mathrm{sn}^2\,u(1-\mathrm{sn}^2\,u)}{(1-k^2\,\mathrm{sn}^2\,u)(1-\nu^2\,\mathrm{sn}^2\,u)}\mathrm{d}u,\end{aligned} \tag{3.3}$$

which, after decomposition of the integrand into partial fractions and use of recurrence formulas in Ref. 10, yields

$$\alpha^{(1)}=\frac{p}{g}\left[E(k)-\left(1-\frac{k^2}{\nu^2}\right)K(k)+k^2\left(1-\frac{1}{\nu^2}\right)\Pi(\nu^2,k)\right], \tag{3.4a}$$

where

$$\nu^2=\frac{a^2-b^2}{a^2(1-b^2)}=\frac{k^2}{1-b^2},\quad g=\frac{1}{a},\quad k^2=\frac{a^2-b^2}{a^2}. \tag{3.5}$$

Here $K(k)$, $E(k)$, and $\Pi(\nu^2,k)$ are complete elliptic integrals of first, second, and third kind, respectively. Similarly we obtain for the third-order contribution to α [see Eqs. (3.13b), (A5b), (A6b), (A3), (2.9b), and (3.2b) of Ref. 1],

$$\begin{aligned}\alpha^{(3)}&=\frac{1}{2}\int_{\Lambda_\alpha} q^{(3)}(\eta)d\eta\\&=\frac{1}{2}\int_{\Lambda_\alpha}\left[\left(-C+\frac{1}{1-\eta^2}\right)\frac{1}{2Q(1-\eta^2)}-\frac{1}{8}Q^{-3}(\eta)\left(\frac{dQ(\eta)}{d\eta}\right)^2\right]d\eta,\end{aligned} \tag{3.6}$$

where C is the parameter introduced in the base function $Q(\eta)$ in Eq. (3.2b) of Ref. 1. After evaluation of the integrals we obtain

$$\begin{aligned}\alpha^{(3)}=&-\frac{gC}{2p}K(k)+\frac{g}{2p(1-b^2)\nu^2}[k^2K(k)+(\nu^2-k^2)\Pi(\nu^2,k)]\\&-\frac{g(1-b^2)}{8pb^2k^4}[P_1K(k)+P_2E(k)+P_3\Pi(\nu^2,k)],\end{aligned} \tag{3.4b}$$

where

$$P_1=\tfrac{1}{3}[-9k^4+k^2(8+5\nu^2)+4\nu^2-8], \tag{3.7a}$$

$$P_2=\tfrac{1}{3}[k^2(-4-\nu^2)+(8-4\nu^2)] \tag{3.7b}$$

and

$$P_3=4(\nu^2-k^2)^2. \tag{3.7c}$$

Analogous calculations can be performed to evaluate the quantity $\overline{K}$. For this purpose we make use of the appropriate transformation on p. 58 in Ref. 10, that is

$$\eta^2=b^2\,\mathrm{sn}^2\,u. \tag{3.8}$$

The first-order [see Eqs. (3.15b), (A5b), (A6a), and (3.2b) of Ref. 1] and the third-order [see Eqs. (3.15b), (A5b), (A6b), (A3), (2.9b), and (3.2b) of Ref. 1] contributions to $K(=\pi\overline{K})$ are

$$\begin{aligned}\pi\overline{K}_0&=\frac{i}{2}\int_{\Lambda_K}Q(\eta)d\eta\\&=\frac{p\nu^2}{g}\int_0^{2K}\frac{\mathrm{cn}^2\,u\,\mathrm{dn}^2\,u}{1-\nu^2\,\mathrm{sn}^2\,u}du\\&=\frac{p}{g}\left[E(k)+k^2\left(1-\frac{1}{\nu^2}\right)K(k)+(\nu^2-k^2)\left(1-\frac{1}{\nu^2}\right)\Pi(\nu^2,k)\right],\end{aligned} \tag{3.9a}$$

and

$$\pi\overline{K}_2=\frac{i}{2}\int_{\Lambda_K}q^{(3)}(\eta)\mathrm{d}\eta=\frac{i}{2}\int_{\Lambda_K}\left[\left(-C+\frac{1}{1-\eta^2}\right)\frac{1}{2Q(1-\eta^2)}-\frac{1}{8}Q^{-3}(\eta)\left(\frac{\mathrm{d}Q(\eta)}{\mathrm{d}\eta}\right)^2\right]\mathrm{d}\eta$$

$$=\frac{Cg}{p}K(k)-\frac{g}{p}\Pi(\nu^2,k)+\frac{g}{4b^2p}\left[\frac{1}{3k'^6}(-3\nu^2k^6-k^4+8\nu^2k^2-7\nu^2+1)E(k)\right.$$

$$\left.+\frac{3\nu^2-1}{3k'^2}K(k)+4\nu^2\Pi(\nu^2,k)\right], \tag{3.9b}$$

where

$$\nu^2=b^2,\quad g=\frac{1}{a},\quad k^2=\frac{b^2}{a^2},\quad k'^2=1-k^2=\frac{a^2-b^2}{a^2}. \tag{3.10}$$

The integrals α' and β' for the contours $\Lambda_{\alpha'}$ and $\Lambda_{\beta'}$ in Fig. 3(a) in Ref. 1 are obtained from the formulas $\alpha'=\alpha+\Lambda\pi/2$ and $\beta'=\beta+\Lambda\pi/2$, see Eq. (3.18a) in Ref. 1.

2. The quantities $\tilde{L}$ and $\tilde{L}'$ pertaining to the ξ-equation [Fig. 1(a) in Ref. 1]

Denoting the four real zeros $\xi_1<\xi_2<1<\xi_3<\xi_4$ of $\tilde{Q}^2(\xi)$ by the simpler notations $d<c<1<b<a$, respectively, used in Ref. 10, we have

$$\tilde{Q}(\xi)=p\frac{[(a-\xi)(\xi-b)(\xi-c)(\xi-d)]^{1/2}}{\xi^2-1}. \tag{3.11}$$

Using the appropriate transformation on p. 120 in Ref. 10, we obtain (cf. Sec. II)

$$\xi=\frac{b-c\nu_1^2\,\mathrm{sn}^2u}{1-\nu_1^2\,\mathrm{sn}^2u},\quad \nu_1^2=\frac{a-b}{a-c}<1. \tag{3.12}$$

Noting that the loop $\xi_3\to\xi_4\to\xi_3$, that is $b\to a\to b$, in the ξ-plane, denoted by $\Gamma_{b,a}$, represents the contour $\Lambda_{\tilde{L}}$ in Fig. 1(a) of Ref. 1 and corresponds to $0\to K\to 2K$ in the u-plane, and using the transformation (3.12), we obtain the first-order contribution to $\tilde{L}$ through the following transformation of the original integral in the ξ-plane to the u-plane:

$$\tilde{L}^{(1)}=\frac{1}{2}\int_{\Lambda_{\tilde{L}}}\tilde{Q}(\xi)\mathrm{d}\xi$$

$$=\frac{1}{2}\int_{\Gamma_{b,a}}\tilde{Q}(\xi)\mathrm{d}\xi$$

$$=\frac{p}{2g}\int_0^{2K}\left(\frac{\mathrm{d}\xi}{\mathrm{d}u}\right)^2\frac{\mathrm{d}u}{\xi^2-1}$$

$$=\frac{2p(\nu_2^2-\nu_1^2)(\nu_3^2-\nu_1^2)}{g}\int_0^{2K}\frac{\mathrm{sn}^2u(1-\mathrm{sn}^2u)(1-k^2\,\mathrm{sn}^2u)}{(1-\nu_1^2\,\mathrm{sn}^2u)^2(1-\nu_2^2\,\mathrm{sn}^2u)(1-\nu_3^2\,\mathrm{sn}^2u)}\mathrm{d}u, \tag{3.13}$$

where

$$\nu_1^2=\frac{a-b}{a-c},\quad \nu_2^2=\frac{1+c}{1+b}\nu_1^2,\quad \nu_3^2=\frac{1-c}{1-b}\nu_1^2, \tag{3.14}$$

$$g=\frac{2}{[(a-c)(b-d)]^{1/2}},\quad k^2=\frac{(a-b)(c-d)}{(a-c)(b-d)}. \tag{3.15}$$

Note that a, b, c, d, and hence also ν_1, ν_2, ν_3, g, k, depend on the choice of the parameter $\tilde{C}$ in the base function $\tilde{Q}(\xi)$; cf. Eq. (3.2a) in Ref. 1. Decomposing the integrand in (3.13) into partial fractions, and using recurrence formulas in Ref. 10, we obtain the final formula

$$\tilde{L}^{(1)} = -H^{(1)}(\nu_1,\nu_2,\nu_3,g,k,\tilde{C}) \tag{3.16a}$$

$$= \frac{2p}{g}\left[\left(1-2k^2+\frac{3k^2}{\nu_1^2}\right)K(k)-3E(k)\right.$$
$$\left.+\left(2(1+k^2)-\nu_1^2-\frac{3k^2}{\nu_1^2}\right)\Pi(\nu_1^2,k)-\sum_{i=1}^{3} C_i S_i\right], \tag{3.16b}$$

where we have introduced the "universal" function $H^{(1)}$, and

$$C_1 = \frac{2[2\nu_2^2\nu_3^2-\nu_1^2\nu_2^2-\nu_1^2\nu_3^2]}{(\nu_2^2-\nu_1^2)(\nu_1^2-\nu_3^2)}, \tag{3.17a}$$

$$C_2 = \frac{2\nu_2^2(\nu_3^2-\nu_1^2)}{(\nu_2^2-\nu_1^2)(\nu_3^2-\nu_2^2)}, \tag{3.17b}$$

$$C_3 = \frac{2\nu_3^2(\nu_2^2-\nu_1^2)}{(\nu_3^2-\nu_1^2)(\nu_2^2-\nu_3^2)}, \tag{3.17c}$$

$$S_i = \frac{1}{3k^2}\left[(\nu_i^2+2\nu_i^2k^2-3k^2)K(k)-(\nu_i^2+\nu_i^2k^2-3k^2)E(k)\right.$$
$$\left.+\frac{3k^2}{\nu_i^2}(1-\nu_i^2)(k^2-\nu_i^2)[\Pi(\nu_i^2,k)-K(k)]\right], \quad i=1,2,3, \tag{3.18}$$

which can also be written as

$$S_i = \frac{k'^2}{3}\left[\nu_i^2\frac{K(k)-E(k)}{k^2}+\frac{(3-2\nu_i^2)E(k)}{k'^2}-3\Pi\left(\frac{k^2-\nu_i^2}{1-\nu_i^2},k\right)\right], \quad i=1,2,3, \tag{3.18$'$}$$

the last formula being valid if ν_i^2 and k^2 fulfill the conditions stated in Sec. 117.03 in Ref. 10.

Similarly we get for the third-order contribution to $\tilde{L}$:

$$\tilde{L}^{(3)} = \frac{1}{2}\int_{\Lambda_{\tilde{L}}}\left[\left(\tilde{C}+\frac{1}{\xi^2-1}\right)\frac{1}{2\tilde{Q}(\xi)(\xi^2-1)}-\frac{1}{8}\tilde{Q}^{-3}(\xi)\left(\frac{d\tilde{Q}}{d\xi}\right)^2\right]d\xi,$$

that is

$$\tilde{L}^{(3)} = -H^{(3)}(\nu_1,\nu_2,\nu_3,g,k,\tilde{C}) \tag{3.16c}$$

$$= -\frac{g}{64p(\nu_2^2-\nu_1^2)(\nu_3^2-\nu_1^2)}\left[\sum_{i=1}^{4} C_i' K(k) + \sum_{i=1}^{4} D_i E(k)\right]$$
$$-\frac{g}{4p}\left[\tilde{C} + \frac{\nu_1^2(\nu_2^2-\nu_3^2)}{4\nu_2^2(\nu_1^2-\nu_3^2)} + \frac{\nu_1^2(\nu_2^2-\nu_3^2)}{4\nu_3^2(\nu_2^2-\nu_1^2)}\right]K(k), \tag{3.16d}$$

where $H^{(3)}$ is another "universal" function, $\tilde{C}$ is the parameter in the base function $\tilde{Q}(\xi)$ [cf. Eq. (3.2a) in Ref. 1], and

$$C_1' = \frac{4}{3k'^2}[k^4+2k^2-2+(2\nu_1^2+\nu_2^2+\nu_3^2)(1-2k^2)+\{2\nu_1^2(\nu_2^2+\nu_3^2)+\nu_2^2\nu_3^2+\nu_1^4\}(4-3k^2)]$$
$$+\frac{4}{3k'^2}\left[-\{2\nu_1^2\nu_2^2\nu_3^2+\nu_1^4(\nu_2^2+\nu_3^2)\}\frac{11-10k^2}{k^2}+\frac{\nu_1^4\nu_2^2\nu_3^2}{k^4}(14-6k^2-7k^4)\right], \tag{3.19a}$$

$$C_2' = \frac{4}{\nu_2^2\nu_3^2}\left[2\nu_2^4\nu_3^4+\nu_1^4\nu_2^4+\nu_1^4\nu_3^4-2\nu_1^4\nu_2^2\nu_3^2-\frac{2\nu_1^2\nu_2^4\nu_3^4}{k^2}\left(2-\frac{\nu_1^2}{3}\right)+\frac{4\nu_1^4\nu_2^4\nu_3^4}{3k^4}\right], \tag{3.19b}$$

$$C_3' = \frac{8\nu_2^2\nu_3^2}{3k^4}(3k^4-6\nu_1^2k^2+2\nu_1^4+k^2\nu_1^4), \tag{3.19c}$$

$$C_4' = 16\left[-(\nu_1^2\nu_2^2+\nu_2^2\nu_3^2+\nu_3^2\nu_1^2)-\frac{\nu_1^4\nu_2^2\nu_3^2}{k^4}(2+k^2)+\frac{\nu_1^2}{k^2}(\nu_1^2\nu_2^2+\nu_1^2\nu_3^2+4\nu_2^2\nu_3^2)\right], \tag{3.19d}$$

$$D_1 = \frac{4}{3k'^4}[2-3k^2-3k^4+2k^6-(2\nu_1^2+\nu_2^2+\nu_3^2)(1-4k^2+k^4)]$$
$$+\frac{4}{3k'^4}[-\{2\nu_1^2(\nu_2^2+\nu_3^2)+\nu_2^2\nu_3^2+\nu_1^4\}(1+k^2)]$$
$$+\frac{4}{3k'^4}\left[\frac{(11-20k^2+11k^4)\{2\nu_1^2\nu_2^2\nu_3^2+\nu_1^4(\nu_2^2+\nu_3^2)\}}{k^2}\right.$$
$$\left.-\frac{\nu_1^4\nu_2^2\nu_3^2}{k^4}(14-13k^2-13k^4+14k^6)\right], \tag{3.20a}$$

$$D_2 = \frac{16\nu_1^2\nu_2^2\nu_3^2}{3k^4}[3k^2-\nu_1^2(1+k^2)], \tag{3.20b}$$

$$D_3 = D_2, \tag{3.20c}$$

$$D_4 = \frac{16\nu_1^2}{k^2}\left[-(\nu_1^2\nu_2^2+\nu_1^2\nu_3^2+4\nu_2^2\nu_3^2)+\frac{2\nu_1^2\nu_2^2\nu_3^2}{k^2}(1+k^2)\right]. \tag{3.20d}$$

The integral $\tilde{L}'$ for the contour $\Lambda_{\tilde{L}'}$ in Fig. 1(a) in Ref. 1 is obtained from the formula $\tilde{L}' = \tilde{L} + (|m|/2)\pi$. Therefore $\tilde{L}'^{(1)}$ and $\tilde{L}'^{(3)}$ can be obtained from (3.16a)–(3.16d).

B. Two real and two complex conjugate zeros of $Q^2(\eta)$ and $\tilde{Q}^2(\xi)$

1. The quantities $\alpha=\beta$, $\tilde{K}$, L, and L' pertaining to the η-equation: Superbarrier case [Fig. 4(a) or Fig. 2 in Ref. 1]

Putting $\eta_4=-\eta_1=a$, $\eta_2=\eta_3^*=-ia_1$, we have

$$Q(\eta)=p\frac{[(a^2-\eta^2)(a_1^2+\eta^2)]^{1/2}}{1-\eta^2}. \tag{3.21}$$

Using the appropriate transformation on p. 133 of Ref. 10, that is,

$$\eta^2=a^2\,\mathrm{cn}^2\,u, \tag{3.22}$$

we now utilize the fact that the Jacobian elliptic functions are doubly periodic, one of the periods being complex. Thus, the loop $\eta_1\to\eta_2\to\eta_1$, that is $-a\to-ia_1\to-a$, in the η-plane, denoted by $\Gamma_{-a,-ia_1}$, represents the contour Λ_α in Fig. 4(a) of Ref. 1, and it corresponds in the u-plane to $0\to K+iK'\to 2K+2iK'$ where $K'=K(k')$. Denoting by $2\overline{G}^{(2n+1)}$ the integral occurring in the definitions (3.13b) and (3.15b′) in Ref. 1 when $Z_1=Z_2$, we have the following first-order expression:

$$\begin{aligned}\overline{G}^{(1)}&=\frac{1}{2}\int_{\Lambda_\alpha}Q(\eta)\,\mathrm{d}\eta\\&=\frac{1}{2}\int_{\Gamma_{-a,-ia_1}}Q(\eta)\,\mathrm{d}\eta,\end{aligned} \tag{3.23}$$

which when transformed to the variable u becomes

$$\overline{G}^{(1)}=\frac{pa^2}{2g}\int_0^{2K+2iK'}\frac{\mathrm{sn}^2\,u\,\mathrm{dn}^2\,u}{1-a^2\,\mathrm{cn}^2\,u}\,\mathrm{d}u. \tag{3.24}$$

After evaluation of the integral in (3.24) we obtain

$$\begin{aligned}\overline{G}^{(1)}=&\frac{p}{g}\left[E(k)+\frac{k^2}{a^2}(1-a^2)K(k)-\left(\frac{k^2}{a^2}+k'^2\right)\Pi(\nu^2,k)\right]\\&-\frac{p}{g}i\{E(k')+(k^2+a^2k'^2)[\Pi(1-\nu^2,k')-K(k')]\},\end{aligned} \tag{3.25a}$$

where

$$\nu^2=\frac{a^2}{a^2-1},\quad g=\frac{1}{(a^2+a_1^2)^{1/2}},\quad k^2=\frac{a^2}{a^2+a_1^2},\quad k'^2=1-k^2. \tag{3.26}$$

Similarly one obtains

$$\overline{G}^{(3)}=-\frac{Cg}{2p}K(k)+\left\{\frac{g}{2p(1-a^2)}+\frac{(\nu^2-1)g}{4p}\right\}\left[\Pi(\nu^2,k)-\frac{\pi}{2}\sqrt{\frac{a^2(1-a^2)}{k'^2a^2+k^2}}\right]$$
$$-\frac{g}{8\nu^2p}\left[\frac{1}{3}(-4k^2+4\nu^2-1)K(k)+\frac{1}{3k'^2}(-8k^4+8k^2(1-\nu^2)+1+7\nu^2)E(k)\right]$$
$$+i\left\{-\frac{Cg}{2p}K(k')+\left[\frac{g}{2p(1-a^2)}+\frac{(\nu^2-1)g}{4p}\right]\left[(1-a^2)K(k')-\nu^2\Pi(\nu^2-1,k')-\frac{\pi}{2}\right]\right.$$
$$-\frac{g}{8\nu^2p}\left[\frac{1}{3}(-4k^2+4\nu^2-1)K(k')\right.$$
$$\left.\left.+\frac{1}{3k'^2}(-8k^4+8k^2(1-\nu^2)+1+7\nu^2)[K(k')-E(k')]\right]\right\}. \tag{3.25b}$$

Recalling the definition of $\overline{G}^{(2n+1)}$ above (3.23) in the present paper, one sees that according to (3.13b) in Ref. 1 the first- and third-order contributions to α are

$$\alpha^{(1)}=\mathrm{Re}\,\overline{G}^{(1)}, \tag{3.27a}$$

$$\alpha^{(3)}=\mathrm{Re}\,\overline{G}^{(3)}, \tag{3.27b}$$

and that according to (3.15b′) in Ref. 1 the first- and third-order contributions to $K(=\pi\overline{K})$ are

$$\pi\overline{K}_0=-2\,\mathrm{Im}\,\overline{G}^{(1)}, \tag{3.28a}$$

$$\pi\overline{K}_2=-2\,\mathrm{Im}\,\overline{G}^{(3)}. \tag{3.28b}$$

The integrals $\alpha'=\beta'$ associated with the contours $\Lambda_{\alpha'}$ and $\Lambda_{\beta'}$ in Fig. 4 in Ref. 1 are obtained from the integrals $\alpha=\beta$ by means of the relations (3.18a) in Ref. 1, that is $\alpha'=\beta'=\alpha+\Lambda\pi/2=\beta+\Lambda\pi/2$. The integrals L and L' associated with the contours Λ_L and $\Lambda_{L'}$ in Fig. 4(a) in Ref. 1 can be obtained from the integrals $\alpha=\beta$ by means of the formulas $L=\alpha+\beta=2\alpha$ and $L'=L+|m|$.

The only essential difference between $-Q^2(\eta)$ in Fig. 4(a) in Ref. 1 and $-Q^2(\eta)$ in Fig. 2 in Ref. 1 is that in the former figure there is an underdense barrier of $-Q^2(\eta)$, while in the latter figure $-Q^2(\eta)$ has a single minimum. For the case in Fig. 2 one has therefore the formula $L^{(2n+1)}=\alpha^{(2n+1)}+\beta^{(2n+1)}=2\alpha^{(2n+1)}$, with expressions (3.27a) and (3.27b) for $\alpha^{(1)}$ and $\alpha^{(3)}$, and the formula $L'^{(2n+1)}=L^{(2n+1)}+|m|\,\delta_{n,0}$. The case in Fig. 2 has, however, not appeared in our applications.

2. The quantities $\tilde{L}$ and $\tilde{L}'$ pertaining to the ξ-equation [Fig. 1(a) in Ref. 1]

Denoting by $\xi_3=b$ and $\xi_4=a$ the real zeros of $\tilde{Q}^2(\xi)$, and by c and c^* the complex conjugate zeros ξ_1 and ξ_2 of $\tilde{Q}^2(\xi)$, we have

$$\tilde{Q}(\xi)=p\,\frac{[(a-\xi)(\xi-b)(\xi-c)(\xi-c^*)]^{1/2}}{\xi^2-1}. \tag{3.29}$$

Defining

$$c=b_1-ia_1,\quad c^*=b_1+ia_1, \tag{3.30}$$

$$A=[(a-b_1)^2+a_1^2]^{1/2},\quad B=[(b-b_1)^2+a_1^2]^{1/2}, \tag{3.31}$$

and using the appropriate transformation on p. 133 in Ref. 10, we get

$$\xi=\frac{aB+bA+(bA-aB)\operatorname{cn}u}{A+B+(A-B)\operatorname{cn}u}. \tag{3.32}$$

Noting that the loop $b\to a\to b$ in the ξ-plane (denoted by $\Gamma_{b,a}$ for the contour $\Lambda_{\tilde{L}}$) corresponds to the path $0\to 2K\to 4K$ in the u-plane, and using the transformation (3.32), we obtain for the first-order contribution to $\tilde{L}$ the formula [see Fig. 1(a) in Ref. 1],

$$\begin{aligned}\tilde{L}^{(1)}&=\frac{1}{2}\int_{\Lambda_{\tilde{L}}}\tilde{Q}(\xi)\mathrm{d}\xi\\&=\frac{1}{2}\int_{\Gamma_{b,a}}\tilde{Q}(\xi)\mathrm{d}\xi\\&=\frac{p(\nu_1-\nu_2)(\nu_1-\nu_3)}{g}\int_0^{4K}\frac{\operatorname{sn}^2u\,\operatorname{dn}^2u}{(1+\nu_1\operatorname{cn}u)^2+(1+\nu_2\operatorname{cn}u)(1+\nu_3\operatorname{cn}u)}\mathrm{d}u,\end{aligned} \tag{3.33}$$

where

$$\nu_1=\frac{A-B}{A+B},\quad \nu_2=\frac{(1+b)A-(1+a)B}{(1+b)A+(1+a)B},\quad \nu_3=\frac{(1-b)A-(1-a)B}{(1-b)A+(1-a)B}, \tag{3.34}$$

$$g=\frac{1}{\sqrt{AB}},\quad k^2=\frac{(a-b)^2-(A-B)^2}{4AB}. \tag{3.35}$$

By evaluating the last integral in (3.33), and introducing a new "universal" function $\overline{H}^{(1)}$, given by Eqs. (2.19), (2.20a)–(2.20c), and (2.21) in Ref. 8 with $j=0$, we obtain

$$\tilde{L}^{(1)}=-2\,\mathrm{Re}\,\overline{H}^{(1)}(\nu_1,\nu_2,\nu_3,g,k,\tilde{C})[\text{with } j=0] \tag{3.36a}$$

$$\begin{aligned}&=\frac{2p}{g}\left\{\frac{1}{\nu_1^2}\left[\left(2k^2+\frac{\nu_1^2}{1-\nu_1^2}\right)\Pi\left(\frac{\nu_1^2}{\nu_1^2-1},k\right)\right.\right.\\&\left.\left.+(\nu_1^2-2k^2)K(k)-2\nu_1^2E(k)+\nu_1k\pi\right]+\sum_{i=1}^{3}\overline{C}_i\overline{J}_i\right\},\end{aligned} \tag{3.36b}$$

where

$$\overline{C}_1=\frac{\nu_1^2(2\nu_3\nu_2-\nu_1\nu_3-\nu_1\nu_2)}{(\nu_1-\nu_2)(\nu_1-\nu_3)}, \tag{3.37a}$$

$$\overline{C}_2=\frac{(\nu_1-\nu_3)\nu_2^3}{(\nu_1-\nu_2)(\nu_2-\nu_3)}, \tag{3.37b}$$

$$\overline{C}_3=\frac{(\nu_1-\nu_2)\nu_3^3}{(\nu_1-\nu_3)(\nu_3-\nu_2)}, \tag{3.37c}$$

$$\overline{J_i}=\mathrm{Re}\,\overline{S_i}(\text{with } j=0)$$
$$=\frac{1}{\nu_i^4}\left[k^2(1-\nu_i^2)K(k)+\nu_i^2E(k)-(k^2+\nu_i^2k'^2)\Pi\left(\frac{\nu_i^2}{\nu_i^2-1},k\right)\right]$$
$$+\frac{1}{2k\nu_i^3}\left[k^2(\nu_i^2-1)-\frac{\nu_i^2}{2}\right]\pi, i=1,2,3; \tag{3.38}$$

cf. the definition of $\overline{S_i}$ in Eq. (2.21) in Ref. 8. The third-order contribution to $\tilde{L}$ is

$$\tilde{L}^{(3)}=-2\,\mathrm{Re}\,\overline{H}^{(3)}(\nu_1,\nu_2,\nu_3,g,k,\tilde{C})\ \ [\text{with } j=0] \tag{3.39a}$$
$$=-\frac{g}{8p}\left\{\left(4\tilde{C}+\frac{\nu_1^2(\nu_2-\nu_3)^2}{\nu_2\nu_3(\nu_1-\nu_3)(\nu_2-\nu_1)}\right)K(k)\right.$$
$$\left.+\frac{1}{(\nu_1-\nu_3)(\nu_1-\nu_2)}[XK(k)+YE(k)]\right\}, \tag{3.39b}$$

where $\overline{H}^{(3)}$ is another "universal" function, given by Eqs. (2.22) and (2.23a)–(2.23c) in Ref. 8 with $j=0$, and where thus

$$X=-\frac{(1+4k^2)}{3}+\frac{(3+4k'^2)}{3}(\nu_1^2+2\nu_1\nu_2+2\nu_1\nu_3+\nu_2\nu_3)-\frac{k'^2}{3k^2}(17-4k^2)\nu_1^2\nu_2\nu_3$$
$$-2\nu_1(\nu_1+\nu_2+\nu_3)+2\nu_2\nu_3+\nu_1^2\left(\frac{\nu_2}{\nu_3}+\frac{\nu_3}{\nu_2}\right), \tag{3.40a}$$

$$Y=\frac{1}{3k'^2}(1+8k^2-8k^4)+\frac{4}{3}(2k^2-1)(\nu_1^2+2\nu_1\nu_2+2\nu_1\nu_3+\nu_2\nu_3)$$
$$+\frac{\nu_1^2\nu_2\nu_3}{3k^2}(17-8k^2+8k^4). \tag{3.40b}$$

The integral $\tilde{L}'$ associated with the contour $\Lambda_{\tilde{L}'}$ in Fig. 1(a) in Ref. 1 is obtained from the formula $\tilde{L}'=\tilde{L}+(|m|/2)\pi$. One has therefore the formulas $\tilde{L}'^{(1)}=\tilde{L}^{(1)}+(|m|/2)\pi$ and $\tilde{L}'^{(3)}=\tilde{L}^{(3)}$ with $\tilde{L}^{(1)}$ and $\tilde{L}^{(3)}$ given by (3.39a) and (3.39b), respectively.

IV. CASE $\Lambda=0$

A. Two real zeros of $Q^2(\eta)$ and $\tilde{Q}^2(\xi)$

1. The quantities $\alpha=\beta$ and $\bar{K}$ pertaining to the η-equation: Subbarrier case [Fig. 3(b) in Ref. 1]

Putting $\eta_3=-\eta_2=b$ as before, we have

$$Q(\eta)=p\left[\frac{(\eta^2-b^2)}{1-\eta^2}\right]^{1/2}. \tag{4.1}$$

Using (3.2) with $a=1$, the first- and third-order contributions to α become

$$\alpha^{(1)}=p[E(k)-(1-k^2)K(k)], \tag{4.2a}$$

$$\alpha^{(3)}=\frac{1}{2pk^2}\left[(1-Ck^2)K(k)-E(k)-\frac{1}{12}\left((3k^2-8)K(k)-(7k^2-8)\frac{E(k)}{k'^2}\right)\right], \tag{4.2b}$$

where $k^2=1-b^2$.

The first- and third-order contributions to $K(=\pi\overline{K})$ are

$$\pi\overline{K}_0=2p[E(k)-(1-k^2)K(k)], \tag{4.3a}$$

$$\pi\overline{K}_2=\frac{1}{p}\left[CK(k)-\frac{E(k)}{k'^2}+\frac{1}{12k^2}\left(\frac{7k^2+1}{k'^2}E(k)-(3k^2+1)K(k)\right)\right], \tag{4.3b}$$

where $k^2=b^2$.

2. The quantities $\tilde{L}$ and $\tilde{L}'$ pertaining to the ξ-equation [Fig. 1 in Ref. 1]

If the real zeros of $\tilde{Q}^2(\xi)$ are $\xi_3=c(<a)$ and $\xi_4=a$, we have

$$\tilde{Q}(\xi)=p\left[\frac{(\xi-c)(a-\xi)}{(\xi+1)(\xi-1)}\right]^{1/2}. \tag{4.4}$$

We shall treat the three cases $1<c<a$, $-1<c<1<a$, and $c<-1<1<a$ separately.

a. Case $1<c<a$ [Fig. 1(a) in Ref. 1]. For this case we use the transformation on p. 120 of Ref. 10 and the formula in Sec. 256.19 with a suitable choice of parameters to obtain the first- and third-order contributions to $\tilde{L}$ as

$$\begin{aligned}\tilde{L}^{(1)}&=\int_c^a\tilde{Q}(\xi)\mathrm{d}\xi\\&=p\frac{(a-c)(c-1)g}{2\nu^2(\nu^2-k^2)}[(2\nu^2-\nu^4-k^2)\Pi(\nu^2,k)-\nu^2E(k)-(\nu^2-k^2)K(k)],\end{aligned} \tag{4.5a}$$

$$\begin{aligned}\tilde{L}^{(3)}=&\frac{\tilde{C}gK(k)}{2p}+\frac{g}{2(c^2-1)p}\left[\frac{2\nu^2}{k^4}(k^2-\nu^2)K(k)+\frac{1}{k^4k'^2}(k^2(k^2-\nu^4-2\nu^2)+2\nu^4)E(k)\right]\\&-\frac{g}{24\nu^4p(c-1)}[(-2+k^2+2\nu^2-\nu^4)K(k)+2(k^4-(1+\nu^2+\nu^4)k^2-\nu^2+2\nu^4+1)E(k)],\end{aligned} \tag{4.5b}$$

where

$$\nu^2=\frac{a-c}{a-1},\quad g=\frac{2}{[(a-1)(c+1)]^{1/2}},\quad k^2=\frac{2(a-c)}{(a-1)(c+1)}. \tag{4.6}$$

To obtain $\tilde{L}'$ one can use the formula $\tilde{L}'^{(2n+1)}=\tilde{L}^{(2n+1)}+(|m|/2)\delta_{n,0}$ with $\tilde{L}^{(1)}$ and $\tilde{L}^{(3)}$ given by (4.5a) and (4.5b).

b. Case $-1<c<1<a$ [Fig. 1(b) in Ref. 1]. We use in the appropriate transformation on p. 120 of Ref. 10 and the formula in Sec. 256.17 (with $b=1$ and $d=-1$) to obtain the first- and third-order contributions to $\tilde{L}'$ [see Fig. 1(b) in Ref. 1] as

$$\tilde{L}'^{(1)}=\frac{2p}{g}\left[\left(1-\frac{k^2}{\nu^2}\right)K(k)-E(k)+\left(\nu^2-2k^2+\frac{k^2}{\nu^2}\right)\Pi(\nu^2,k)\right], \tag{4.7a}$$

$$\tilde{L}'^{(3)}=\frac{g\tilde{C}K(k)}{2p}+\frac{g}{4p\nu^2(1-c)}\left[\left(1-\frac{\nu^4}{k^2}\right)K(k)+(k^2(2k^2-1-2\nu^2)+\nu^4)\frac{E(k)}{k^2k'^2}\right]$$
$$-\frac{g}{16(1-c)p\nu^2}\left[\frac{4}{3k^2}((2+\nu^4+2\nu^2)k^2-3k^4-2\nu^4)K(k)\right.$$
$$\left.+\frac{8}{3k'^2}\left(-(\nu^4+\nu^2-1)+k^2(\nu^4-\nu^2+2)+\frac{\nu^4}{k^2}\right)E(k)\right], \tag{4.7b}$$

where

$$\nu^2=\frac{a-1}{a-c},\quad g=\left(\frac{2}{a-c}\right)^{1/2},\quad k^2=\frac{(1+c)(a-1)}{2(a-c)}. \tag{4.8}$$

c. Case $c<-1<1<a$ [Fig. 1(b) in Ref. 1]. Using the transformation on p. 120 of Ref. 10 and the formula in Sec. 256.20 with a suitable choice of parameters, we obtain the first- and third-order contributions to $\tilde{L}'$ as

$$\tilde{L}'^{(1)}=\frac{(a-c)(1-c)gp}{2\nu^4}[-\nu^2E(k)+(\nu^2+k^2)K(k)+(\nu^4-k^2)\Pi(\nu^2,k)], \tag{4.9a}$$

$$\tilde{L}'^{(3)}=\frac{\tilde{C}gK(k)}{p}+\frac{g}{4p\nu^2}\left[\left(1-2\nu^2+\frac{\nu^4}{k^2}\right)K(k)-\left(1+\frac{\nu^4}{k^2}\right)E(k)\right]$$
$$-\frac{g}{32p\nu^2}\left\{\frac{4}{3k^2k'^2}[-k^4+k^2(2-\nu^4-2\nu^2)-\nu^4]K(k)\right.$$
$$\left.+\frac{8}{3k^2k'^4}[-k^6+k^4(\nu^2-\nu^4)+k^2(\nu^4+\nu^2-1)-\nu^4]E(k)\right\}, \tag{4.9b}$$

with

$$\nu^2=\frac{a-1}{a+1},\quad g=\frac{2}{[(a+1)(1-c)]^{1/2}},\quad k^2=\frac{(a-1)(-c-1)}{(a+1)(1-c)}. \tag{4.10}$$

B. Two complex conjugate zeros of $Q^2(\eta)$

The case of two complex conjugate zeros of the square of the base function occurs only for the η-equation.

The quantities $\alpha=\beta$ and $\overline{K}$ pertaining to the η-equation: Superbarrier case [Fig. 4(b) in Ref. 1]. With $\eta_2=-ia_1$ and $\eta_3=ia_1$ we have

$$Q(\eta)=p\frac{[(1-\eta^2)(a_1^2+\eta^2)]^{1/2}}{1-\eta^2}=p\left(\frac{a_1^2+\eta^2}{1-\eta^2}\right)^{1/2}. \tag{4.11}$$

Specializing to the case $a=1$ in (3.27a) and (3.27b) and (3.28a) and (3.28b) along with (3.25a) and (3.25b), we obtain the first- and third-order contributions to α as

$$\alpha^{(1)}=\mathrm{Re}\,\overline{G}^{(1)},\quad \alpha^{(3)}=\mathrm{Re}\,\overline{G}^{(3)} \tag{4.12}$$

and the first- and third-order contributions to $K(=\pi\overline{K})$ as

$$\pi\overline{K}_0=-2\,\mathrm{Im}\,\overline{G}^{(1)},\quad \pi\overline{K}_2=-2\,\mathrm{Im}\,\overline{G}^{(3)}, \tag{4.13}$$

where

$$\overline{G}^{(1)}=\frac{p}{g}\{E(k)+i[K(k')-E(k')]\}, \tag{4.14a}$$

$$\overline{G}^{(3)}=\frac{g}{2p}\left[(1-C)K(k)-E(k)-\frac{1}{12}\left(4K(k)+\frac{(8k^2-7)}{k'^2}E(k)\right)\right]$$
$$+i\frac{g}{2p}\left[-CK(k')+E(k')-\frac{1}{12}\left(4K(k')+\frac{(8k^2-7)}{k'^2}\{K(k')-E(k')\}\right)\right] \tag{4.14b}$$

with

$$g=\frac{1}{(1+a_1^2)^{1/2}}, \quad k^2=\frac{1}{1+a_1^2}. \tag{4.15}$$

The integral L' associated with the contour $\Lambda_{L'}$ in Fig. 4(b) in Ref. 1 is obtained from the formula $L'=\alpha+\beta=2\alpha$.

V. ACCURACY OF THE PHASE-INTEGRAL QUANTIZATION CONDITIONS FOR THE $1s\sigma$ AND $2p\sigma$ STATES OF THE HYDROGEN MOLECULE ION

For the $1s\sigma$ and $2p\sigma$ states of the hydrogen molecule ion one has to put $\Lambda=0$. The quantization conditions in Ref. 1 for the $1s\sigma$ state are (3.5a) with $\tilde{s}=0$ [Fig. 1(a) in Ref. 1] and (3.9) with $s=m=0$ [Fig. 4(b) in Ref. 1] when r_{12} is sufficiently small, but (3.5b) with $\tilde{s}=m=0$ [Fig. 1(b) in Ref. 1] and (3.25b) with $s_\alpha=s_\beta=m=0$ [Fig. 3(b) in Ref. 1] when r_{12} is sufficiently large. The quantization conditions in Ref. 1 for the $2p\sigma$ state are (3.5a) with $\tilde{s}=0$ [Fig. 1(a) in Ref. 1] and (3.9) with $s=1$ and $m=0$ [Fig. 4(b) in Ref. 1] when r_{12} is sufficiently small, but (3.5b) with $\tilde{s}=m=0$ [Fig. 1(b) in Ref. 1] and (3.25a) with $s_\alpha=s_\beta=m=0$ [Fig. 3(b) in Ref. 1] when r_{12} is sufficiently large. After having expressed these quantization conditions in the first order and third order of the phase-integral approximation in terms of complete elliptic integrals, as described in the previous sections, we have used these quantization conditions to calculate the energy E and the reduced separation constant A'. We have determined C and $\tilde{C}$ as function of r_{12} such that the first- and third-order quantization conditions give the same values of both E and A'. For the values of C and $\tilde{C}$ thus obtained, the choice of the base functions $Q(\eta)$ and $\tilde{Q}(\xi)$ is optimum in the sense that the most accurate first-order values of E and A' are obtained, since the first- and third-order approximations give the same values of E and A'. In this connection we remark that there are quantal systems for which one can obtain exact values of the energy by choosing the base function such that the first- and third-order results coincide; see p. 1826 in Ref. 11 and p. 16 in Ref. 12.

By determining C and $\tilde{C}$ for each value of r_{12} such that the first- and third-order quantization conditions give the same value of E as well as of A', we have obtained the results in Table I for the $1s\sigma$ state and in Table II for the $2p\sigma$ state of the hydrogen molecule ion; see also Figs. 1 and 2. Especially for large values of r_{12} the phase-integral values of E and A' in Tables I and II are in reasonable agreement with the numerically exact values obtained by Murai and Takatsu,[13,14] as is best seen from Fig. 1 for the state $1s\sigma$ and from Fig. 2 for the state $2p\sigma$. For these states the phase-integral method cannot compete with the numerical method used by Murai and Takatsu, but the possibility of using the analytical phase-integral formulas expressed in terms of complete elliptic integrals is an alternative that may sometimes be preferable to the use of the very accurate numerical results.

It is seen that in Figs. 1 and 2 there are sometimes some irregularities in the values of C, $\tilde{C}$, $|E-E_{\mathrm{MT}}|$ and $|A'-A'_{\mathrm{MT}}|$ for low r_{12} values. It should also be noted that C and $\tilde{C}$ approach the correct limiting value 1/4 as $r_{12}\to 0$.

To obtain the numerical results in Sec. V a general FORTRAN computer program using very rapid library routines was written at the Centre for Nonlinear Dynamics, Department of Physics,

TABLE I. For the state $1s\sigma$ of H_2^+ the values of C and $\tilde{C}$ have been obtained from the requirement that the first- and third-order phase-integral results coincide for E as well as for A'. With the use of these values of C and $\tilde{C}$, the values of E and A' have then been obtained from the quantization conditions that are appropriate depending on whether r_{12} is sufficiently small or sufficiently large. The numerically exact values obtained by Murai and Takatsu (Refs. 13 and 14) are given in the columns E_{MT} and A'_{MT}.

Bharathidasan University, Tiruchirapalli, India. We have carried out the numerical calculations by Silicon Graphics Power Indigo 2 XZ Graphics Workstation (R8000, 64bit processor) using FORTRAN 77 compiler.

Some years ago, a direct numerical integration of the contour integrals in the phase-integral quantization conditions for the hydrogen molecule ion was carried out by Fil. lic. Anders Hökback at the Department of Theoretical Physics, University of Uppsala, Sweden. By means of this numerical material it was possible to make valuable checks of the correctness of the phase-integral quantization conditions expressed in terms of complete elliptic integrals.

ACKNOWLEDGMENTS

The authors are much indebted to Fil. lic. Anders Hökback for placing his unpublished numerical material at their disposal. The authors are extremely grateful to Professor Per Olof Fröman for very critical reading of the manuscript and for making numerous comments which resulted in a much improved presentation. The work of M.L. forms part of a Department of Science and Technology, Government of India, research project. Support from the Swedish Natural Science Research Council for M. Lakshmanan's visits to Uppsala is gratefully acknowledged.

(Received 27 July 2000; accepted for publication 16 July 2001)

In this paper we take up the quantal two-center problem where the Coulomb centers have arbitrary positive charges. In analogy with the symmetric case, treated in the second paper of this series, we use the knowledge on the quasiclassical dynamics to express the contour integrals in the first- and third-order approximations of the phase-integral quantization conditions, given in the first paper of this series of papers, in terms of complete elliptic integrals. For various values of the distance between these charges the accuracy of the formulas obtained is illustrated by comparison with available numerically exact results. © *2001 American Institute of Physics.* [DOI: 10.1063/1.1399296]

I. INTRODUCTION

In this third paper in a series of papers concerning the two-center Coulomb problem we take up the general case in which the charge numbers Z_1 and Z_2 of the two Coulomb centers are arbitrary. The study of such general systems is of considerable importance in the field of molecular physics and elementary particle physics. For example, the calculation of eigenvalues and electronic wave functions for one-electron diatomic molecules with fixed internuclear separation is the starting point for an accurate description of molecular vibrations and rotations and of ion–atom scattering.[1–4] Also the calculation of radiative transition probabilities for a π^- meson moving in the Coulomb field of two fixed nuclei[5] is a good example of the two-center Coulomb problem dealt with in elementary particle physics. Such calculations are of physical interest in connection with experimental[6–8] and theoretical[9] research on the absorption of π^- mesons stopped in substances containing hydrogen.

In the second paper in this series[10] the symmetric case, $Z_1=Z_2$, was considered. Using for the two-center Coulomb problem the general phase-integral quantization conditions derived in the first paper,[11] the relevant contour integrals for the first- and third-order approximations were expressed in terms of complete elliptic integrals so that numerical evaluation of energy eigenvalues and separation constants can easily be carried out. The evaluation of the various contour integrals was facilitated through suitable transformations of the ξ- and η-variables, which can be related to the quasiclassical motion of a particle. In the symmetric case, $Z_1=Z_2$, the squared base function $Q^2(\eta)$ has a symmetry, as discussed in Ref. 10. As a result of this, the evaluation of the quantities $\alpha=\beta$, L, L', and $\bar{K}$ pertaining to the η-quantization conditions was performed with the use of particular transformations in a rather simple way, while for the quantity $\tilde{L}$ in the ξ-quantization

[a]Present address: Department of Physics, Government Arts College, Ariyalur-621 713, India.
[b]Electronic mail: lakshman@bdu.ernet.in

condition rather general transformations are necessary. However, in the general case, where Z_1 may be different from Z_2, no such symmetric structure exists for $Q^2(\eta)$, and $Q^2(\eta)$ and $\tilde{Q}^2(\xi)$, given by Eqs. (3.2a) and (3.2b) in Ref. 11, can have, besides the poles, the following structure of the zeros.

(1) Case $\Lambda=|m|\neq 0$:
   (a) Four real zeros.
   (b) Two real and two complex conjugate zeros.

(2) Case $\Lambda=0$:
   (a) Two real zeros.
   (b) Two complex conjugate zeros of $Q^2(\eta)$.

As a consequence, the evaluation of the contour integrals in the cases of the ξ-equation and the η-equation are analogous, except that certain coefficients change in the different subcases. This allows one to use the "universal" functions $H^{(2n+1)}$ and $\overline{H}^{(2n+1)}$, $n=0$ or 1, valid for the $(2n+1)$ th-order approximation, which were defined in Secs. III A 2 and III B 2 of Ref. 10. These functions depends on five parameters ν_1, ν_2, ν_3, g, and k, which are expressed in terms of the zeros of either $Q^2(\eta)$ or $\tilde{Q}^2(\xi)$, and on the parameter C or $\tilde{C}$ in the base function $Q(\eta)$ or $\tilde{Q}(\xi)$, respectively; see Eqs. (3.2a) and (3.2b) in Ref. 11. Different choices of these parameters allow one to express the relevant quantities α, β (which may now be different from α), L, L', $\overline{K}$, and $\tilde{L}$ in the first- and third-order phase integral approximation (apart possibly from a sign or a constant factor) as the appropriate "universal" function or its real or imaginary part with the appropriate parameters inserted. When the contour integrals are evaluated, one can solve the quantization conditions to obtain the energy levels accurately.

In principle one can specialize the results of the general case when Z_1 may be different from Z_2 to the particular case when $Z_1=Z_2$ in order to obtain the results of Ref. 10, but in practice this is cumbersome due to the different transformation formulas used for the η-part of the quantization conditions in Ref. 10. For the ξ-part such a specialization implies only that Z_1+Z_2 is replaced by $2Z_1$ but no essential simplification.

The plan of the present paper is as follows. In Sec. II A we express α, β, L, L', $\overline{K}$, and $\tilde{L}$ in terms of the "universal" functions appropriate for the subbarrier case with $\Lambda=|m|\neq 0$. In Sec. II B a similar treatment is given for the superbarrier case. In Sec. III an analogous procedure is applied to the case $\Lambda=0$. Finally, in Sec. IV a detailed numerical analysis of the phase-integral quantization conditions is carried out for $Z_1=1$ and different values of Z_2 (=2, 5, and 8), and comparision is made with existing numerically exact results for the energy and the reduced separation constant.

II. CASE $\Lambda=|m|\neq 0$

In this section we utilize for the case of four zeros of $Q^2(\eta)$ or $\tilde{Q}^2(\xi)$ the "universal" functions $H^{(2n+1)}$, $n=0$ or 1, introduced in Ref. 10 and related to the $(2n+1)$ th-order contribution, and the "universal" functions $\overline{H}^{(2n+1)}$, $n=0$ or 1, which will be introduced in Sec. II B 1. In the different cases one finds, as explained in Sec. I, that the forms of the evaluated contour integrals are similar, except for changes of the parameters. One obtains the expressions for the "universal" functions $H^{(1)}$, $H^{(3)}$, $\overline{H}^{(1)}$, and $\overline{H}^{(3)}$ by integrating one specific integral in each case explicitly and then modifying the definition of the parameters in these functions to obtain the other required quantities.

A. Four real zeros of $Q^2(\eta)$ or $\tilde{Q}^2(\xi)$

1. The quantities α, β, and $\overline{K}$ pertaining to the η-equation: Subbarrier case [Fig. 3(a) in Ref. 11]

Denoting the zeros η_1, η_2, η_3, and η_4 by a, b, c, and d, we write the base function for this case as

$$Q(\eta)=p\,\frac{[(\eta-a)(b-\eta)(c-\eta)(d-\eta)]^{1/2}}{1-\eta^2}. \tag{2.1}$$

Using the transformation on p. 103 in Ref. 12, we obtain

$$\eta=\frac{a-d\,\nu_1^2\,\mathrm{sn}^2\,u}{1-\nu_1^2\,\mathrm{sn}^2\,u}, \tag{2.2}$$

the parameter ν_1^2 being defined in (2.4). Noting that the loop $a\to b\to a$, that is $\eta_1\to\eta_2\to\eta_1$ in the η-plane, denoted by $\Gamma_{a,b}$, which represents the contour Λ_α in Fig. 3(a) of Ref. 11, corresponds to $0\to K\to 2K$ in the u-plane, one finds that the first-order contribution to α is

$$\begin{aligned}\alpha^{(1)}&=\frac{1}{2}\int_{\Lambda_\alpha}Q(\eta)\,\mathrm{d}\eta\\&=\frac{1}{2}\int_{\Gamma_{a,b}}Q(\eta)\,\mathrm{d}\eta\\&=\frac{p}{2g}\int_0^{2K}\left(\frac{\mathrm{d}\eta}{\mathrm{d}u}\right)^2\frac{\mathrm{d}u}{1-\eta^2}\\&=\frac{2p(a-d)^2\nu_1^4}{g(1-a^2)}\int_0^{2K}\frac{\mathrm{sn}^2\,u(1-\mathrm{sn}^2\,u)(1-k^2\,\mathrm{sn}^2\,u)\mathrm{d}u}{(1-\nu_1^2\,\mathrm{sn}^2\,u)^2(1-\nu_2^2\,\mathrm{sn}^2\,u)(1-\nu_3^2\,\mathrm{sn}^2\,u)},\end{aligned} \tag{2.3}$$

where

$$\nu_1^2=\frac{a-b}{d-b},\quad \nu_2^2=\frac{1+d}{1+a}\,\nu_1^2,\quad \nu_3^2=\frac{1-d}{1-a}\,\nu_1^2, \tag{2.4}$$

$$g=\frac{2}{[(d-b)(c-a)]^{1/2}},\quad k^2=\frac{(d-c)(b-a)}{(d-b)(c-a)}. \tag{2.5}$$

Decomposing the integrand in (2.3) into partial fractions and evaluating the integrals by means of recurrence formulas in Ref. 12, we obtain

$$\alpha^{(1)}=H^{(1)}(\nu_1,\nu_2,\nu_3,g,k,C), \tag{2.6}$$

where $H^{(1)}$ is the "universal" function defined in Eqs. (3.16a), (3.16b), (3.17a)–(3.17c), and (3.18) of Ref. 10 but with $\tilde{C}$ replaced by C and the parameters ν_i, $i=1,2,3$, given by (2.4), and g and k^2 given by (2.5). The evaluation of the quantity $\alpha^{(1)}$ in the present case is thus similar to the evaluation of the quantity $\tilde{L}^{(1)}$ in Sec. III A 2 of Ref. 10.

Proceeding in a similar way, the third-order contribution to α is found to be

$$\begin{aligned}\alpha^{(3)}&=\frac{1}{2}\int_{\Lambda_\alpha}\left(-C+\frac{1}{1-\eta^2}\right)\frac{\mathrm{d}\eta}{2Q(\eta)(1-\eta^2)}-\frac{1}{16}\int_{\Lambda_\alpha}Q^{-3}(\eta)\left(\frac{\mathrm{d}Q}{\mathrm{d}\eta}\right)^2\mathrm{d}\eta\\&=H^{(3)}(\nu_1,\nu_2,\nu_3,g,k,C),\end{aligned} \tag{2.7}$$

where $H^{(3)}$ is the "universal" function given in Eqs. (3.16c), (3.16d), (3.19a)–(3.19d), and (3.20a)–(3.20d) of Ref. 10 but with $\tilde{C}$ replaced by $-C$ and the parameters ν_i, $i=1,2,3$, given by (2.4), and g and k^2 given by (2.5).

In a similar manner as previously we proceed for the calculation of the first- and third-order contributions to β. The loop $d\to c\to d$, that is $\eta_4\to\eta_3\to\eta_4$ in the η-plane, denoted by $\Gamma_{d,c}$ and represented by the contour Λ_β in Fig. 3(a) of Ref. 11, corresponds to $0\to K\to 2K$ in the u-plane, and hence the first- and third-order contributions to β are

$$\begin{aligned}\beta^{(1)}&=\frac{1}{2}\int_{\Lambda_\beta}Q(\eta)\mathrm{d}\eta\\&=\frac{1}{2}\int_{\Gamma_{d,c}}Q(\eta)\mathrm{d}\eta\\&=H^{(1)}(\nu_1,\nu_2,\nu_3,k,C),\end{aligned}\tag{2.8a}$$

and

$$\beta^{(3)}=H^{(3)}(\nu_1,\nu_2,\nu_3,g,k,C),\tag{2.8b}$$

where now

$$\nu_1^2=\frac{d-c}{d-b},\quad \nu_2^2=\frac{1+b}{1+c}\,\nu_1^2,\quad \nu_3^2=\frac{1-b}{1-c}\,\nu_1^2,\tag{2.9}$$

and g and k^2 are given by (2.5).

Similarly one obtains

$$\pi\overline{K}_0=H^{(1)}(\nu_1,\nu_2,\nu_3,g,k,C),\tag{2.10a}$$

$$\pi\overline{K}_2=H^{(3)}(\nu_1,\nu_2,\nu_3,g,k,C),\tag{2.10b}$$

where now

$$\nu_1^2=\frac{c-b}{d-b},\quad \nu_2^2=\frac{1+d}{1+c}\,\nu_1^2,\quad \nu_3^2=\frac{1-d}{1-c}\,\nu_1^2,\tag{2.11}$$

and g is the same as given in (2.5) and k^2 is now given by

$$k^2=\frac{(c-b)(d-a)}{(d-b)(c-a)}.\tag{2.12}$$

According to Eq. (3.18a) in Ref. 11 the integrals α' and β' for the contours $\Lambda_{\alpha'}$ and $\Lambda_{\beta'}$ in Fig. 3(a) in Ref. 11 are obtained from the formulas $\alpha'=\alpha+\Lambda\pi/2$ and $\beta'=\beta+\Lambda\pi/2$.

2. The quantities $\tilde{L}$ and $\tilde{L}'$ pertaining to the ξ-equation [Fig. 1 in Ref. 11]

The formulas for the first- and third-order contributions to $\tilde{L}$ and $\tilde{L}'$ are derived and presented in Sec. III A 2 of Ref. 10, and they remain unchanged in the present case.

B. Two real and two complex conjugate zeros of $Q^2(\eta)$ or $\tilde{Q}^2(\xi)$

When there are two real and two complex conjugate zeros of $Q^2(\eta)$, the situation of either Fig. 4(a) or Fig. 2 in Ref. 11 may occur. However, the latter situation has so far not appeared in our applications, and therefore we disregard it in our treatment in the following of the η-equation.

1. The quantities α, β, $\bar{K}$, L, and L' pertaining to the η-equation: Superbarrier case [Fig. 4(a) in Ref. 11]

Denoting the real zeros of $Q^2(\eta)$ by $\eta_1=a$ and $\eta_4=d$ and the complex conjugate zeros η_2 and η_3 by c and c^*, we have the base function

$$Q(\eta)=p\frac{[(a-\eta)(\eta-d)(\eta-c)(\eta-c^*)]^{1/2}}{1-\eta^2}. \tag{2.13}$$

Defining

$$c=b_1-ia_1, \quad c^*=b_1+ia_1, \tag{2.14}$$

$$A=[(a-b_1)^2+a_1^2]^{1/2}, \tag{2.15a}$$

$$B=[(d-b_1)^2+a_1^2]^{1/2}, \tag{2.15b}$$

and using the transformation on p. 133 in Ref. 12, we get

$$\eta=\frac{aB+dA+(dA-aB)\operatorname{cn}u}{A+B+(A-B)\operatorname{cn}u}. \tag{2.16}$$

Here we exploit the fact that the Jacobian elliptic functions are doubly periodic, one of the periods being complex. Thus the loop $d\to a_1+ib_1\to d$, that is $\eta_4\to\eta_3\to\eta_4$ in the η-plane, denoted by Γ_{d,c^*}, for the contour Λ_β in Fig. 4(a) of Ref. 11, corresponds in the u-plane to the path $0\to K+iK'\to 2K+2iK'$, where K and K' are complete elliptic integrals of the modulus k, given in (2.18e), and of the complementary modulus $k'=\sqrt{1-k^2}$, respectively. Making use of the transformation (2.16), we obtain for the integral in the first-order expression for β,

$$\begin{aligned}\frac{1}{2}\int_{\Lambda_\beta}Q(\eta)\,\mathrm{d}\eta&=\frac{1}{2}\int_{\Gamma_{d,c^*}}Q(\eta)\,\mathrm{d}\eta\\&=-\frac{p(\nu_1-\nu_2)(\nu_1-\nu_3)}{2g}\int_0^{2K+2iK'}\frac{\operatorname{sn}^2u\,\operatorname{dn}^2u\,\mathrm{d}u}{(1+\nu_1\operatorname{cn}u)^2(1+\nu_2\operatorname{cn}u)(1+\nu_3\operatorname{cn}u)},\end{aligned} \tag{2.17}$$

where

$$\nu_1=\frac{A-B}{A+B}, \tag{2.18a}$$

$$\nu_2=\frac{(1+d)A-(1+a)B}{(1+d)A+(1+a)B}, \tag{2.18b}$$

$$\nu_3=\frac{(1-d)A-(1-a)B}{(1-d)A+(1-a)B}, \tag{2.18c}$$

$$g=\frac{1}{\sqrt{AB}}, \tag{2.18d}$$

$$k^2=\frac{(a-d)^2-(A-B)^2}{4AB}. \tag{2.18e}$$

Similarly one can treat the corresponding integrals in the first-order expressions for α, K, and $\tilde{L}$. When one then evaluates the integrals containing the elliptic functions [cf. (2.17)], one finds that all these integrals can be expressed in terms of a ''universal'' function $\bar{H}^{(1)}$ that is given by

$$\begin{aligned}\bar{H}^{(1)}(\nu_1,\nu_2,\nu_3,g,k,C)=-\frac{p}{g}\Bigg\{&\frac{1}{\nu_1^2}\Bigg[\left(2k^2+\frac{\nu_1^2}{1-\nu_1^2}\right)\Pi\left(\frac{\nu_1^2}{\nu_1^2-1},k\right)+(\nu_1^2-2k^2)K(k)-2\nu_1^2E(k)\\&+\nu_1k(2j+1)\pi-\frac{\nu_1^2(1-2k^2)+2k^2}{[(1-\nu_1^2)(k^2+\nu_1^2k'^2)]^{1/2}}\frac{\nu_1}{2}j\pi\Bigg]\\&+\sum_{i=1}^{3}\bar{C}_i\bar{S}_i+i\Bigg[\left(2k^2+\frac{\nu_1^2}{1-\nu_1^2}\right)\Pi\left(\frac{1}{1-\nu_1^2},k'\right)-2k^2K(k')+2E(k')\Bigg]\Bigg\},\end{aligned} \tag{2.19}$$

where $\bar{C}_1$, $\bar{C}_2$, and $\bar{C}_3$ are given by Eqs. (3.37a)–(3.37c) in Ref. 10, that is,

$$\bar{C}_1=\frac{\nu_1^2(2\nu_3\nu_2-\nu_1\nu_3-\nu_1\nu_2)}{(\nu_1-\nu_2)(\nu_1-\nu_3)}, \tag{2.20a}$$

$$\bar{C}_2=\frac{(\nu_1-\nu_3)\nu_2^3}{(\nu_1-\nu_2)(\nu_2-\nu_3)}, \tag{2.20b}$$

$$\bar{C}_3=\frac{(\nu_1-\nu_2)\nu_3^3}{(\nu_1-\nu_3)(\nu_3-\nu_2)}, \tag{2.20c}$$

and

$$\begin{aligned}\bar{S}_i=&\frac{1}{\nu_i^4}\left[k^2(1-\nu_i^2)K(k)+\nu_i^2E(k)-(k^2+\nu_i^2k'^2)\Pi\left(\frac{\nu_i^2}{\nu_i^2-1},k\right)\right]+\frac{1}{2k\nu_i^3}\\&\times\left[\left(k^2(\nu_i^2-1)-\frac{\nu_i^2}{2}\right)(2j+1)\pi+k[(1-\nu_i^2)(k^2+k'^2\nu_i^2)]^{1/2}j\pi\right]\\&+\frac{i}{\nu_i^2}\left\{-(k^2+\nu_i^2k'^2)\left[\Pi\left(\frac{1}{1-\nu_i^2},k'\right)-K(k')\right]-E(k')\right\},\quad i=1,2,3,\end{aligned} \tag{2.21}$$

j being an integer -1, 0, or $+1$, depending upon whether the quantity $\beta^{(1)}$, $L^{(1)}$, or $\alpha^{(1)}$, respectively, is evaluated, and originating from terms $\tan^{-1}(\mathrm{sd}\,u)$ and $\cos^{-1}(\mathrm{dn}\,u)$ while applying the limits of integration. Note that the quantity $\tilde{L}^{(1)}$, given by Eq. (3.36a) in Ref. 10, is just $-2\,\mathrm{Re}\,\bar{H}^{(1)}$ with $j=0$. For K, which is expressed in terms of the imaginary part of $\bar{H}^{(1)}$, the value of j, which appears only in the real part of $\bar{H}^{(1)}$, does not matter.

Similarly we also introduce the ''universal''function $\bar{H}^{(3)}$ given by

$$\overline{H}^{(3)}(\nu_1,\nu_2,\nu_3,g,k,C)=\frac{g}{16p}\left[\left(-4C+\frac{\nu_1^2(\nu_2-\nu_3)^2}{\nu_2\nu_3(\nu_1-\nu_3)(\nu_2-\nu_1)}\right)K(k)\right.$$
$$\left.+\frac{1}{(\nu_1-\nu_3)(\nu_1-\nu_2)}\left(XK(k)+YE(k)+\frac{2Zj}{k}\pi\right)\right]$$
$$+i\frac{g}{16p}\left[\left(-4C+\frac{\nu_1^2(\nu_2-\nu_3)^2}{\nu_2\nu_3(\nu_1-\nu_3)(\nu_2-\nu_1)}\right)K(k')\right.$$
$$\left.+\frac{1}{(\nu_1-\nu_3)(\nu_1-\nu_2)}\{XK(k')+Y[K(k')-E(k')]\}\right], \quad (2.22)$$

where C is the parameter in the square of the base function $Q(\eta)$ in Eq. (3.2b) of Ref. 11, and

$$X=-\frac{1+4k^2}{3}+\frac{3+4k'^2}{3}(\nu_1^2+2\nu_1\nu_2+2\nu_1\nu_3+\nu_2\nu_3)-\frac{k'^2}{3k^2}(17-4k^2)\nu_1^2\nu_2\nu_3$$
$$-2\nu_1(\nu_1+\nu_2+\nu_3)+2\nu_2\nu_3+\nu_1^2\left(\frac{\nu_2}{\nu_3}+\frac{\nu_3}{\nu_2}\right), \quad (2.23a)$$

$$Y=\frac{1}{3k'^2}(1+8k^2-8k^4)+\frac{4}{3}(2k^2-1)(\nu_1^2+2\nu_1\nu_2+2\nu_1\nu_3+\nu_2\nu_3)$$
$$+\frac{\nu_1^2\nu_2\nu_3}{3k^2}(17-8k^2+8k^4), \quad (2.23b)$$

$$Z=2\nu_1(\nu_1\nu_2+\nu_1\nu_3+4\nu_2\nu_3), \quad (2.23c)$$

where the parameters ν_1, ν_2, ν_3, g, and k^2 are defined in (2.18a)–(2.18e).

Then the first- and third-order contributions to the quantities α, β, and $K(=\pi\overline{K})$ are

$$\alpha^{(1)}=\mathrm{Re}\,\overline{H}^{(1)} \quad \text{with} \quad j=1, \quad (2.24)$$

$$\beta^{(1)}=\mathrm{Re}\,\overline{H}^{(1)} \quad \text{with} \quad j=-1, \quad (2.25)$$

$$\pi\overline{K}_0=-2\,\mathrm{Im}\,\overline{H}^{(1)}, \quad (2.26)$$

$$\alpha^{(3)}=\mathrm{Re}\,\overline{H}^{(3)} \quad \text{with} \quad j=1, \quad (2.27)$$

$$\beta^{(3)}=\mathrm{Re}\,\overline{H}^{(3)} \quad \text{with} \quad j=-1, \quad (2.28)$$

$$\pi\overline{K}_2=-2\,\mathrm{Im}\,\overline{H}^{(3)}, \quad (2.29)$$

where ν_1, ν_2, ν_3, g, and k^2 are still defined by (2.18a)–(2.18e). Since j appears only in the real part of $\overline{H}^{(2n+1)}$, we need not specify a value of j in (2.26) and (2.29).

The integrals α' and β' associated with the contours $\Lambda_{\alpha'}$ and $\Lambda_{\beta'}$ in Fig. 4(a) in Ref. 11 are obtained from α and β by means of the relations (3.18a) in Ref. 11, that is, $\alpha'=\alpha+\Lambda\pi/2$ and $\beta'=\beta+\Lambda\pi/2$. The integrals L and L' associated with the contours Λ_L and $\Lambda_{L'}$ in Fig. 4(a) in Ref. 11 can be obtained from α and β by means of the formulas $L=\alpha+\beta$ and $L'=L+|m|$.

2. The quantities $\tilde{L}$ and $\tilde{L}'$ pertaining to the ξ-equation [Fig. 1(a) in Ref. 11]

The formulas for the first- and third-order contributions to $\tilde{L}$ and $\tilde{L}'$ remain the same as the ones presented in Sec. III B 2 of Ref. 10.

III. CASE $\Lambda=0$

A. Two real zeros of $Q^2(\eta)$ or $\tilde{Q}^2(\xi)$

One should be able to obtain the formulas pertaining to the case $\Lambda=0$ by considering the limits of the "universal" functions $H^{(1)}$ and $H^{(3)}$ when $a\to-1$ and $d\to+1$ in the case of the η-equation. These specialization procedures are, however, much more cumbersome than the direct calculation of the quantities in question, and so we do not carry them out here. Instead we shall evaluate these quantities directly, and therefore no "universal" functions will appear in Sec. III A.

1. The quantities α, β, and $\bar{K}$ pertaining to the η-equation: Subbarrier case [Fig. 3(b) in Ref. 11]

We denote the two real zeros of $Q^2(\eta)$ by $\eta_2=b$ and $\eta_3=c$ and use transformations on pp. 103, 120, and 112 in Ref. 12 for calculating the first- and third-order contributions to α, β, and K, respectively. Here the base function reads

$$Q(\eta)=p\left[\frac{(\eta-b)(c-\eta)}{1-\eta^2}\right]^{1/2}. \tag{3.1}$$

The first- and third-order contributions to α are

$$\alpha^{(1)}=\frac{2p}{g\nu^2}[\nu^2E(k)-(k^2+\nu^2)K(k)+(k^2-\nu^4)\Pi(\nu^2,k)], \tag{3.2a}$$

and

$$\begin{aligned}\alpha^{(3)}=&-\frac{gCK(k)}{p}+\frac{g}{4p\nu^2}\left[\left(1-2\nu^2+\frac{\nu^4}{k^2}\right)K(k)-\left(1+\frac{\nu^4}{k^2}\right)E(k)\right]\\&-\frac{g}{32p\nu^2}\left\{\frac{1}{3k'^2}\left[\frac{1}{k^2}(4\nu^4-6\nu^2)+5\nu^4+4\nu^2+8-k^2(4+3\nu^4)-\frac{6\nu^4}{k^4}\right]K(k)\right.\\&\left.+\frac{1}{3k'^4}\left[-8k^4+(2+8\nu^2+4\nu^4)k^2-8+2\nu^4+\nu^2-\frac{1}{k^2}(2\nu^4+12\nu^2)+\frac{12\nu^4}{k^4}\right]E(k)\right\},\end{aligned} \tag{3.2b}$$

where

$$\nu^2=\frac{c+1}{c-1},\quad k^2=\frac{(1-b)(1+c)}{(1+b)(1-c)},\quad g=\frac{2}{[(1-c)(1+b)]^{1/2}}. \tag{3.3}$$

Similarly the first- and third-order contributions to β are

$$\beta^{(1)}=\frac{2p}{g\nu^2}[\nu^2E(k)+(k^2-\nu^2)K(k)+(\nu^4-k^2)\Pi(\nu^2,k)], \tag{3.4a}$$

and

$$\beta^{(3)}=-\frac{gCK(k)}{2p}+\frac{g}{4p\nu^2(1-c)}\left\{\left(1-\frac{\nu^4}{k^2}\right)K(k)+[k^2(2k^2-1-2\nu^2)+\nu^4]\frac{E(k)}{k^2k'^2}\right\}$$
$$-\frac{g}{16(1-c)p\nu^2}\left\{\frac{4}{3k^2}[(2+\nu^4+2\nu^2)k^2-3k^4-2\nu^4]K(k)\right.$$
$$\left.+\frac{8}{3k'^2}\left(-(\nu^4+\nu^2-1)+k^2(\nu^4-\nu^2+2)+\frac{\nu^4}{k^2}\right)E(k)\right\} \tag{3.4b}$$

with

$$\nu^2=\frac{1-b}{1-c} \tag{3.5}$$

and k^2 and g defined in (3.3).

The first- and third-order contributions to $K(=\pi\overline{K})$ are

$$\pi\overline{K}_0=\frac{2p}{gk^2}[(k^2-\nu^2)K(k)-\nu^2E(k)-(\nu^4-2\nu^2+k^2)\Pi(\nu^2,k)], \tag{3.6a}$$

and

$$\pi\overline{K}_2=-\frac{CgK(k)}{2p}+\frac{g}{2(c^2-1)p}\left[\frac{2\nu^2}{k^4}(k^2-\nu^2)K(k)+\frac{1}{k^4k'^2}\{k^2(k^2-\nu^4-2\nu^2)+2\nu^4\}E(k)\right]$$
$$-\frac{g}{24\nu^4p(c-1)}\{(-2+k^2+\nu^2-\nu^4)K(k)+2[k^4-(1+\nu^2+\nu^4)k^2-\nu^2+2\nu^4+1]E(k)\}, \tag{3.6b}$$

with

$$\nu^2=\frac{b-c}{b+1},\quad k^2=\frac{2(b-c)}{(1+b)(1-c)} \tag{3.7}$$

and g defined in (3.3).

2. The quantities $\tilde{L}$ and $\tilde{L}'$ pertaining to the ξ-equation [Fig. 1 in Ref. 11]

The formulas for the first- and third-order contributions to $\tilde{L}$ and $\tilde{L}'$ are the same as those derived and presented in Sec. IV A 2 of Ref. 10.

B. Two complex conjugate zeros of $Q^2(\eta)$

The situation of two complex conjugate transition zeros can occur only for $Q^2(\eta)$ but not for $\tilde{Q}^2(\xi)$.

The quantities α, β, and $\overline{K}$ pertaining to the η-equation: Superbarrier case [Fig. 4(b) in Ref. 11]. Specializing the general formulas (2.19) and (2.22) by putting $a=-1$, $d=+1$, we obtain

$$\overline{H}^{(1)}=\frac{p}{g}\left\{E(k)-K(k)+\frac{1}{1-\nu^2}\left[\Pi\left(\frac{\nu^2}{\nu^2-1},k\right)-\left(\frac{\nu^2(1-\nu^2)}{k^2+(1-k^2)\nu^2}\right)^{1/2}(2j+1)\pi\right]\right\}$$
$$+i\frac{p}{g}\left[K(k')-E(k')+\frac{\nu^2}{1-\nu^2}\Pi\left(\frac{1}{1-\nu^2},k'\right)\right] \tag{3.8a}$$

and

$$\overline{H}^{(3)}=\frac{g}{16p}\left\{\left(-4C+\frac{4\nu^2}{\nu^2-1}\right)K(k)+\frac{1}{\nu^2-1}\left(\overline{X}K(k)+\overline{Y}E(k)-\frac{16\nu j}{k}\pi\right)\right.$$
$$\left.+i\left[\left(-4C+\frac{4\nu^2}{\nu^2-1}\right)K(k')+\frac{1}{\nu^2-1}(\overline{X}K(k')+\overline{Y}[K(k')-E(k')])\right]\right\} \tag{3.8b}$$

where

$$\nu=\frac{A-B}{A+B},\quad g=\frac{1}{\sqrt{AB}},\quad k^2=\frac{4-(A-B)^2}{4AB} \tag{3.9}$$

with

$$A=[(1-b_1)^2+a_1^2]^{1/2},\quad B=[(1+b_1)^2+a_1^2)]^{1/2} \tag{3.10}$$

and

$$\overline{X}=-\frac{1}{3k^2}[k^2(14+9\nu^2)+17\nu^2], \tag{3.11a}$$

$$\overline{Y}=\frac{1}{3k^2k'^2}[-4k^4(1+\nu^2)+k^2(5+21\nu^2)-17\nu^2]. \tag{3.11b}$$

We now have

$$\alpha^{(1)}=\mathrm{Re}\,\overline{H}^{(1)}\ \text{ with }\ j=1, \tag{3.12a}$$

$$\alpha^{(3)}=\mathrm{Re}\,\overline{H}^{(3)}\ \text{ with }\ j=1, \tag{3.12b}$$

$$\beta^{(1)}=\mathrm{Re}\,\overline{H}^{(1)}\ \text{ with }\ j=-1, \tag{3.13a}$$

$$\beta^{(3)}=\mathrm{Re}\,\overline{H}^{(3)}\ \text{ with }\ j=-1, \tag{3.13b}$$

$$\pi\overline{K}_0=-2\,\mathrm{Im}\,\overline{H}^{(1)}, \tag{3.14a}$$

$$\pi\overline{K}_2=-2\,\mathrm{Im}\,\overline{H}^{(3)}. \tag{3.14b}$$

The integral L' associated with the contour $\Lambda_{L'}$ in Fig. 4(b) in Ref. 11 is obtained from the formula $L'=\alpha+\beta$.

IV. NUMERICAL ILLUSTRATION OF THE ACCURACY OF THE QUANTIZATION CONDITIONS

For the numerical illustration of the asymmetric case we have chosen $Z_1=1$ and considered three different values of Z_2, viz. $Z_2=2$, 5, and 8. The corresponding physical systems are the ions peHe^{2+}, peB^{5+}, and peO^{8+}, respectively, where p is a proton and e is an electron. For each one of these systems we have calculated the eigenvalue p and the reduced separation constant A' for two different σ-states and various values of r_{12}.

For the ion peHe^{2+} we have calculated the eigenvalue p and the reduced separation constant A' for the $1s\sigma$ and $2p\sigma$ states and various values of r_{12}, with appropriate quantization conditions and parameters. The quantization conditions in Ref. 11 for the $1s\sigma$ state are (3.5a) with $\tilde{s}=0$ [Fig. 1(a) in Ref. 11] and (3.9) with $s=m=0$ [Fig. 4(b) in Ref. 11] when r_{12} is sufficiently small, but (3.5b) with $\tilde{s}=m=0$ [Fig. 1(b) in Ref. 11] and (3.23b) with $s_\beta=m=0$ [Fig. 3(b) in Ref. 11] when r_{12} is sufficiently large. The quantization conditions in Ref. 11 for the $2p\sigma$ state are (3.5a) with

TABLE I. For the state $1s\sigma$ of the ion peHe^{2+} ($Z_1=1$, $Z_2=2$) the values of C and $\tilde{C}$ have been obtained from the requirement that the first- and third-order phase-integral results coincide for p as well as for A'. With the use of these values of C and $\tilde{C}$ the values of p and A' have then been obtained from the quantization conditions that are appropriate depending on whether r_{12} is sufficiently small or sufficiently large. The numerically exact values (accurate to all digits quoted) calculated by Winter, Duncan, and Lane (Ref. 4) and obtained as private communication from Professor Winter (see p. 288–289 in Ref. 4), are given in the columns p_{WDL} and A'_{WDL}.

TABLE VI. For the state $4d\sigma$ of the ion peO^{8+} ($Z_1=1$, $Z_2=8$) the values of C and $\tilde{C}$ have been obtained from the requirement that the first- and third-order phase-integral results coincide for p as well as for A'. With the use of these values of C and $\tilde{C}$ the values of p and A' have then been obtained from the quantization conditions that are appropriate depending on whether r_{12} is sufficiently small or sufficiently large. The numerically exact values obtained by Ponomarev and Puzynina (Ref. 13) are given in the columns p_{pp} and A'_{pp}. When r_{12} is so large that the phase integral values of p and A' are approximately as accurate or more accurate than the corresponding values in Ref. 13 we do not give values for $p-p_{\mathrm{pp}}$ and $A'-A'_{\mathrm{pp}}$, but denote them by three asterisks.

r_{12}	C	$\tilde{C}$	p	p_{pp}	$p-p_{\mathrm{pp}}$	A'	A'_{pp}	$A'-A'_{\mathrm{pp}}$

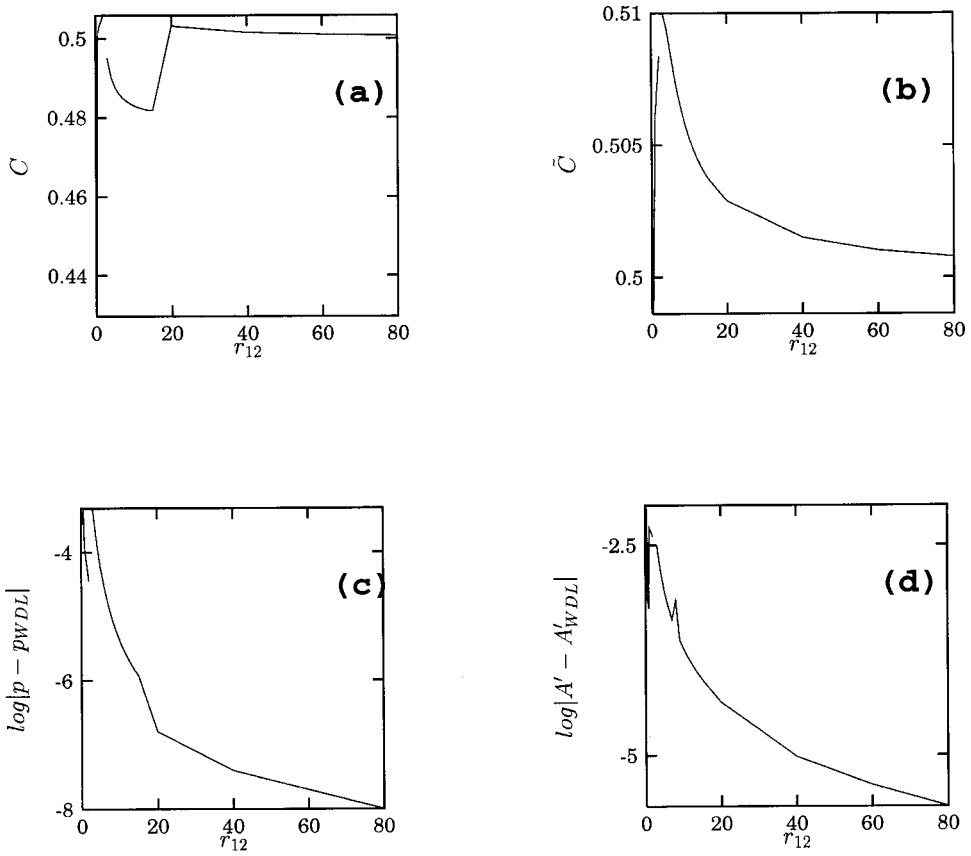

FIG. 1. Plots for the $1s\sigma$ state of the ion peHe^{2+} ($Z_1=1$, $Z_2=2$) of (a) C vs r_{12}, (b) $\tilde{C}$ vs r_{12}, (c) $\log|p-p_{\mathrm{WDL}}|$ vs r_{12}, and (d) $\log|A'-A'_{\mathrm{WDL}}|$ vs r_{12}, when C and $\tilde{C}$ are determined as functions of r_{12} from the requirement that the first-order and the third-order phase-integral results for p as well as for A' coincide. Here p and A' are the phase-integral values obtained in Table I, while p_{WDL} and A'_{WDL} are the corresponding numerically exact values (accurate to all digits quoted) calculated by Winter, Duncan, and Lane (Ref. 4, see pp. 288 and 289) and quoted in Table I. There is a break in each curve between the regions where the quantization conditions for sufficiently small and sufficiently large values of r_{12} have been used.

$\tilde{s}=0$ [Fig. 1(a) in Ref. 11] and (3.9) with $s=1$ and $m=0$ [Fig. 4(b) in Ref. 11] when r_{12} is sufficiently small, but (3.5b) with $\tilde{s}=m=0$ [Fig. 1(b) in Ref. 11] and (3.23a) with $s_\alpha=m=0$ [Fig. 3(b) in Ref. 11] when r_{12} is sufficiently large.

For the ion peB^{5+} we have computed the eigenvalue p and the reduced separation constant A' for the $1s\sigma$ and the $3s\sigma$ states and various values of r_{12}, with appropriate quantization conditions and parameters. The quantization conditions in Ref. 11 for the $1s\sigma$ state are (3.5a) with $\tilde{s}=0$ [Fig. 1(a) in Ref. 11] and (3.9) with $s=m=0$ [Fig. 4(b) in Ref. 11] when r_{12} is sufficiently small, but (3.5b) with $\tilde{s}=m=0$ [Fig. 1(b) in Ref. 11] and (3.23b) with $s_\beta=m=0$ [Fig. 3(b) in Ref. 11] when r_{12} is sufficiently large. The quantization conditions in Ref. 11 for the $3s\sigma$ state are (3.5a) with $\tilde{s}=2$ [Fig. 1(a) in Ref. 11] and (3.9) with $s=m=0$ [Fig. 4(b) in Ref. 11] when r_{12} is sufficiently small, but (3.5b) with $\tilde{s}=m=0$ [Fig. 1(b) in Ref. 11] and (3.23b) with $s_\beta=m=0$ [Fig. 3(b) in Ref. 11] when r_{12} is sufficiently large.

For the ion peO^{8+} we have calculated the eigenvalue p and the reduced separation constant A' for the $1s\sigma$ and the $4d\sigma$ states and various values of r_{12}, with appropriate quantization conditions and parameters. The quantization conditions in Ref. 11 for the $1s\sigma$ state are (3.5a) with $\tilde{s}=0$ [Fig. 1(a) in Ref. 11] and (3.9) with $s=m=0$ [Fig. 4(b) in Ref. 11] when r_{12} is sufficiently small, but (3.5b) with $\tilde{s}=m=0$ [Fig. 1(b) in Ref. 11] and (3.23b) with $s_\beta=m=0$ [Fig. 3(b) in Ref. 11] when r_{12} is sufficiently large. The quantization conditions in Ref. 11 for the $4d\sigma$ state are (3.5a) with

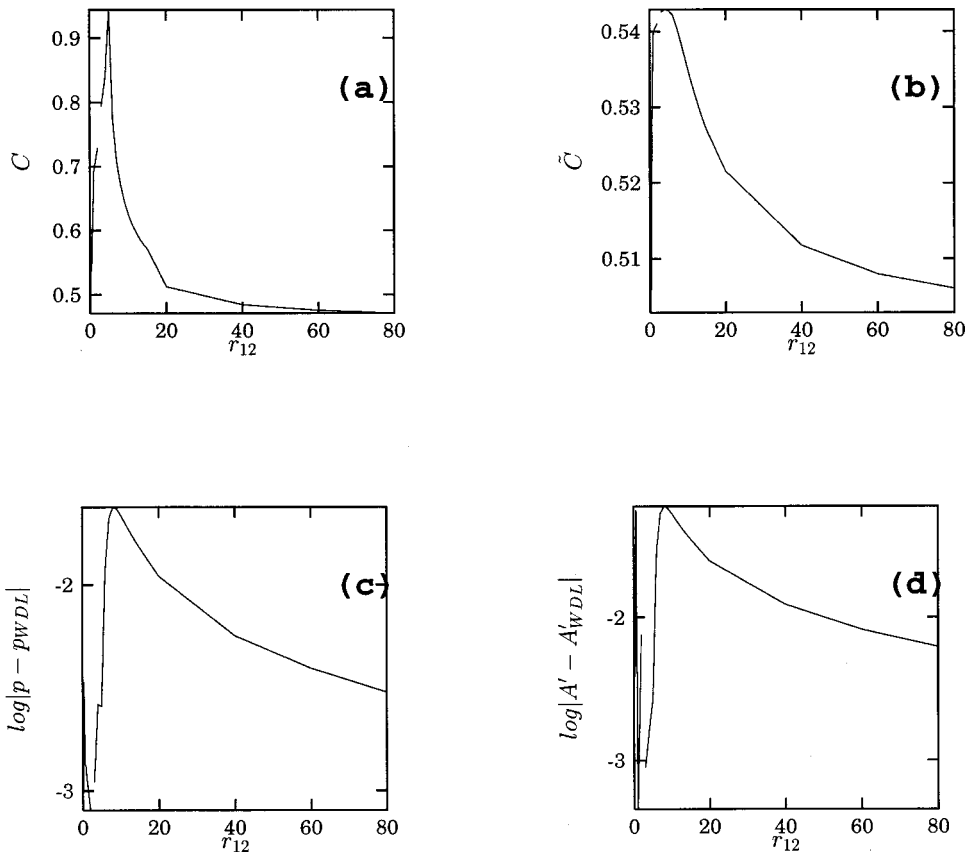

FIG. 2. Plots for the $2p\sigma$ state of the ion peHe^{2+} ($Z_1=1$, $Z_2=2$) of (a) C vs r_{12}, (b) $\tilde{C}$ vs r_{12}, (c) $\log|p-p_{\mathrm{WDL}}|$ vs r_{12}, and (d) $\log|A'-A'_{\mathrm{WDL}}|$ vs r_{12}, when C and $\tilde{C}$ are determined as functions of r_{12} from the requirement that the first-order and the third-order phase-integral results for p as well as for A' coincide. Here p and A' are the phase-integral values obtained in Table II, while p_{WDL} and A'_{WDL} are the corresponding numerically exact values (accurate to all digits quoted) calculated by Winter, Duncan, and Lane (Ref. 4, see pp. 288 and 289) and quoted in Table II. There is a break in each curve between the regions where the quantization conditions for sufficiently small and sufficiently large values of r_{12} have been used.

$\tilde{s}=1$ [Fig. 1(a) in Ref. 11] and (3.9) with $s=2$ and $m=0$ [Fig. 4(b) in Ref. 11] when r_{12} is sufficiently small, but (3.5b) with $\tilde{s}=m=0$ [Fig. 1(b) in Ref. 11] and (3.23b) with $s_\beta=2$ and $m=0$ [Fig. 3(b) in Ref. 11] when r_{12} is sufficiently large.

In the calculations for the above-mentioned three ions we used the quantization conditions expressed in terms of complete elliptic integrals, obtained in the present paper, that correspond to the above-mentioned quantization conditions in Ref. 11.

We have determined the values of C and $\tilde{C}$ for several values of r_{12} such that the first- and third-order quantization conditions give the same value of p as well as of A'. These values are tabulated and compared with the numerically exact results obtained by Winter *et al.*[4] for the ion peHe^{2+} and by Ponomarev and Puzynina[13] for the ions peB^{5+} and peO^{8+}. In Tables I and II we give the results for the system peHe^{2+}. Although the phase-integral values of p and A' are very accurate for the $1s\sigma$ state of the ion peH^{2+} and large values of r_{12}, the phase-integral method cannot compete as regards accuracy with the method used by Winter *et al.*[4] to obtain the numerically exact values quoted in our Tables I and II. However, the possibility of using the analytical phase-integral formulas expressed in terms of complete elliptic integrals is an alternative that sometimes may be preferable to the use of very accurate numerical results. Tables III and IV present the results for the ion peB^{5+}. For the ion peO^{8+} the results are tabulated in Tables V and VI. From these four tables it is seen that for large values of r_{12} the phase-integral results are as

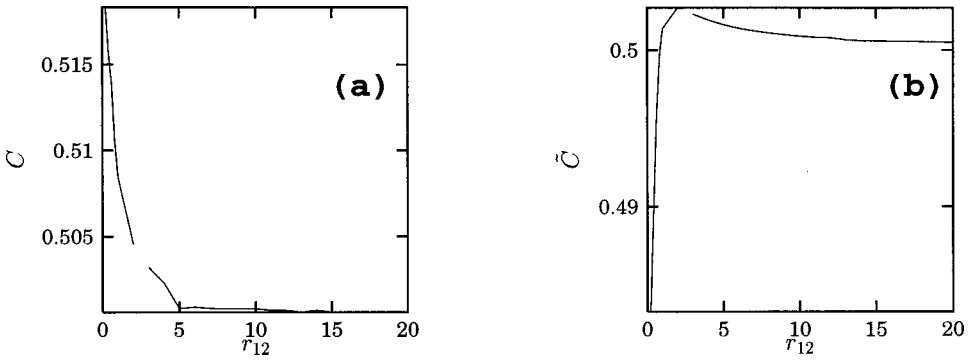

FIG. 3. Plots for the $1s\sigma$ state of the ion peB^{5+} ($Z_1=1$, $Z_2=5$) of (a) C vs r_{12}, (b) $\tilde{C}$ vs r_{12}, when C and $\tilde{C}$ are determined as functions of r_{12} from the requirement that the first-order and the third-order phase-integral results for p as well as for A' coincide (see Table III). There is a break in each curve between the regions where the quantization conditions for sufficiently small and sufficiently large values of r_{12} have been used.

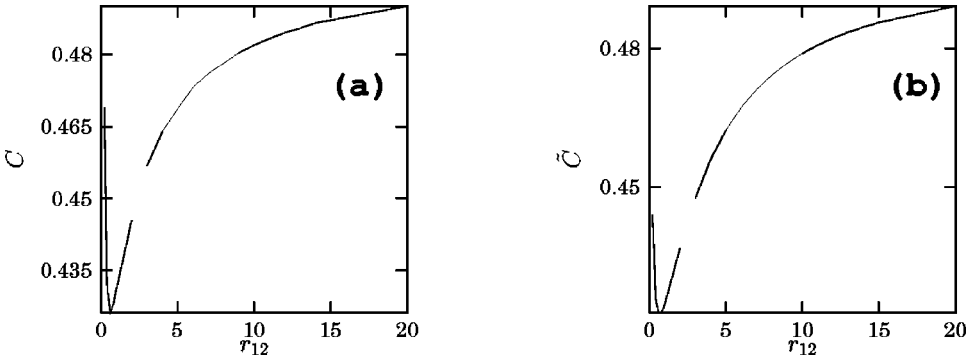

FIG. 4. Plots for the $3s\sigma$ state of the ion peB^{5+} ($Z_1=1$, $Z_2=5$) of (a) C vs r_{12}, (b) $\tilde{C}$ vs r_{12}, when C and $\tilde{C}$ are determined as functions of r_{12} from the requirement that the first-order and the third-order phase-integral results for p as well as for A' coincide (see Table IV). There is a break in each curve between the regions where the quantization conditions for sufficiently small and sufficiently large values of r_{12} have been used.

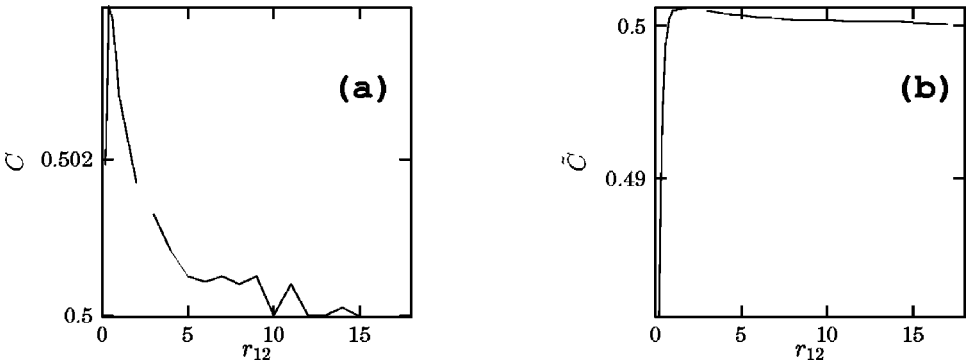

FIG. 5. Plots for the $1s\sigma$ state of the ion peO^{8+} ($Z_1=1$, $Z_2=8$) of (a) C vs r_{12}, (b) $\tilde{C}$ vs r_{12}, when C and $\tilde{C}$ are determined as functions of r_{12} from the requirement that the first-order and the third-order phase-integral results for p as well as for A' coincide (see Table V). There is a break in each curve between the regions where the quantization conditions for sufficiently small and sufficiently large values of r_{12} have been used.

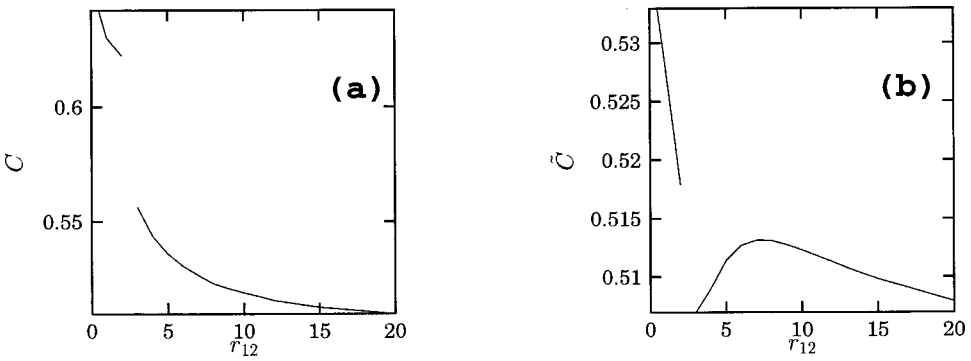

FIG. 6. Plots for the $4d\sigma$ state of the ion peO^{8+} ($Z_1=1$, $Z_2=8$) of (a) C vs r_{12}, (b) $\tilde{C}$ vs r_{12}, when C and $\tilde{C}$ are determined as functions of r_{12} from the requirement that the first-order and the third-order phase-integral results for p as well as for A' coincide (see Table VI). There is a break in each curve between the regions where the quantization conditions for sufficiently small and sufficiently large values of r_{12} have been used.

accurate or more accurate than the results that have been obtained numerically. In fact, the phase-integral values of p are at least as accurate as the numerically exact values of p[13] in Table III for $r_{12}>3$, in Table IV for $r_{12}>10$, in Table V for $r_{12}>2$, and in Table VI for $r_{12}>9$, and the phase-integral values of A' are at least as accurate as the numerically exact values of A'[13] in Table III for $r_{12}>10$, in Table IV for $r_{12}>7$, in Table V for $r_{12}>10$, and in Table VI for $r_{12}>8$. The results in Tables I–VI are presented graphically in Figs. 1–6.

ACKNOWLEDGMENTS

We are much indebted to Professor T. G. Winter for placing the unpublished numerical material mentioned on pp. 288 and 289 in Ref. 4 at our disposal. The authors are also extremely grateful to Professor Per Olof Fröman for very critical reading of the manuscript and making numerous comments which resulted in a much improved presentation. The work of M.L. forms part of a Department of Science and Technology, Government of India, research project. Support from the Swedish Natural Science Research Council for M.L.'s visits to Uppsala is gratefully acknowledged.

JOURNAL OF MATHEMATICAL PHYSICS VOLUME 42, NUMBER 11 NOVEMBER 2001

Multi-resolution analysis and fractional quantum Hall effect: An equivalence result

F. Bagarello[a)]
Dipartimento di Matematica ed Applicazioni, Fac. Ingegneria, Università di Palermo, I-90128 Palermo, Italy

(Received 26 January 2001; accepted for publication 10 August 2001)

In this article we prove that any multi-resolution analysis of $\mathcal{L}^2(\mathbf{R})$ produces, for some values of the filling factor, a single-electron wave function of the lowest Landau level (LLL) which, together with its (magnetic) translation, gives rise to an orthonormal set in the LLL. We also discuss the inverse construction. Moreover, we extend this procedure to the higher Landau levels and we discuss the analogies and the differences between this procedure and the one previously proposed by J.-P. Antoine and the author. © *2001 American Institute of Physics.*

I. INTRODUCTION

The role of wavelets in various applications of mathematics and to some physical problems like signal analysis is now completely established: the existence of a wide literature on this field is sufficient to give an idea of the amount of people involved in this and related topics. For a clear reading on this subject a standard quotation is Ref. 1. Reference 2 is an updated book where other interesting aspects of wavelets are discussed. What cannot be found in many textbooks, since is still to be understood, is the relevance of wavelets in quantum mechanics: at this moment, to our knowledge, very few of the applications proposed in this field (Ref. 3–8 among the others).

One of the most useful features of wavelets concerns their localization properties in both configuration and frequency space. This fact is at the basis of a series of papers[3–6] where different families of orthonormal (o.n.) bases in $\mathcal{L}^2(\mathbf{R})$ are used in the search for the ground state of a two-dimensional electron gas (2DEG) in a uniform positive background and subjected to a uniform electro-magnetic field. This is the physical system which produces the well-known fractional quantum Hall effect (FQHE). The key fact behind this approach is the existence of an unitary map between $\mathcal{L}^2(\mathbf{R})$ and the lowest Landau level (LLL), that is, the subspace of $\mathcal{L}^2(\mathbf{R}^2)$ corresponding to the lowest eigenvalue of the free Hamiltonian of the 2DEG. This implies that any o.n. basis in $\mathcal{L}^2(\mathbf{R})$ (not necessarily a wavelet one!) produces an o.n. basis in the LLL; for this reason the role of wavelets does not seem so crucial. We will comment again on this approach in Sec. V.

In this articles we establish a deeper connection between wavelets and FQHE. In particular we will show that any multi-resolution analysis (MRA) of $\mathcal{L}^2(\mathbf{R})$ produces *automatically* a wave function in $\mathcal{L}^2(\mathbf{R})$ and, as a second step, a wave function in the LLL which turns out to be o.n. to its own (magnetic) translation. This procedure, which works for an even value of the inverse filling factor, is only possible when we start from a MRA, contrary to what happens in Ref. 3, and can also be inverted: to any o.n. basis in the LLL which is generated by a single wave function via the action of magnetic translations can be associated a MRA.

The article is organized as follows:

In the next section we quickly review some of the main properties of a MRA and of the kq-representation,[9] which turns out to be a technical tool useful to implement the orthonormality condition.

[a)]Electronic mail: bagarell@unipa.it

In Sec. III we state the problem of orthonormality of the single electron wave functions in connection with the FQHE.

In Sec. IV we show how, for fillings factors $\nu=1/2L$, $L\in\mathbf{N}$, a MRA produces in a completely natural way a wave function for the 2DEG with the desired orthonormality requirement. We also discuss the inverse procedure.

Section V is devoted to the comparison between this approach and the one proposed in Ref. 3. In particular, the example of the Haar o.n. basis is considered in detail. We also extend our procedure to higher Landau levels.

Section VI contains the conclusions and the plans for the future.

II. MATHEMATICAL TOOLS

In order to keep the article self-contained we now quickly review, for the reader's convenience, the main properties of the mathematical tools we will use in the rest of the article.

A. Multi-resolution analysis

The main result in the theory of MRA is the recipe which allows us to construct an orthonormal basis in $\mathcal{L}^2(\mathbf{R})$ starting from a single function ψ and acting on ψ with dilation and translation operators, generating the set

$$\{\psi_{j,k}(x)\equiv 2^{j/2}\psi(2^j x-k), j,k\in\mathbf{Z}\}. \tag{2.1}$$

Such a basis has the good properties of wavelets, including space *and* frequency localization. This is the key to their usefulness in many physical and mathematical applications. Let us now sketch the construction of these o.n. bases of wavelets. The full story may be found, for instance, in Ref. 1.

A *multi-resolution analysis* of $L^2(\mathbf{R})$ is an increasing sequence of closed subspaces

$$\cdots\subset V_{-2}\subset V_{-1}\subset V_0\subset V_1\subset V_2\subset\cdots, \tag{2.2}$$

with $\cup_{j\in Z}V_j$ dense in $L^2(\mathbf{R})$ and $\cap_{j\in Z}V_j=\{0\}$, and such that

(1) $f(x)\in V_j\Leftrightarrow f(2x)\in V_{j+1}$.
(2) There exists a function $\phi\in V_0$, called a *scaling* function, such that $\{\phi(x-k),k\in\mathbf{Z}\}$ is an o.n. basis of V_0.

Combining (1) and (2), one gets an o.n. basis of V_j, namely $\{\phi_{j,k}(x)\equiv 2^{j/2}\phi(2^j x-k),k\in\mathbf{Z}\}$. The role of V_j as an approximation space and in the direct decomposition of $\mathcal{L}(\mathbf{R})$ is discussed in Ref. 1.

Here we only need to know that the theory asserts the existence of a function ψ, called the *mother* of the wavelets, explicitly computable from ϕ, such that $\{\psi_{j,k}(x)\equiv 2^{j/2}\psi(2^j x-k),j,k\in\mathbf{Z}\}$ constitutes an orthonormal basis of $L^2(\mathbf{R})$: these are the *orthonormal wavelets*.

The construction of ψ proceeds as follows. First, the inclusion $V_0\subset V_1$ yields the relation

$$\phi(x)=\sqrt{2}\sum_{n=-\infty}^{\infty}h_n\phi(2x-n),\quad h_n=\langle\phi_{1,n}|\phi\rangle. \tag{2.3}$$

Taking Fourier transforms, this gives

$$\hat{\phi}(\omega)=m_o(\omega/2)\,\hat{\phi}(\omega/2), \tag{2.4}$$

where

$$m_o(\omega)=\frac{1}{\sqrt{2}}\sum_{-\infty}^{\infty}h_n e^{-in\omega} \tag{2.5}$$

is a 2π-periodic function. Iterating (2.4), one gets the scaling function as the (convergent!) infinite product

$$\hat{\phi}(\omega)=(2\pi)^{-1/2}\prod_{j=1}^{\infty} m_o(2^{-j}\omega). \tag{2.6}$$

Then one defines the function $\psi\in W_0\subset V_1$ by the relation

$$\hat{\psi}(\omega)=e^{i\omega/2}\overline{m_o(\omega/2+\pi)}\,\hat{\phi}(\omega/2), \tag{2.7}$$

or, equivalently,

$$\psi(x)=\sqrt{2}\sum_{n=-\infty}^{\infty}(-1)^{n-1}h_{-n-1}\phi(2x-n), \tag{2.8}$$

and proves that the function ψ indeed generates an o.n. basis with all the required properties.

Actually, this procedure does not produce a unique result. Another possibility, which is the one we will use in the example given later in this work, gives for the mother wavelet the following expansion:

$$\psi(x)=\sqrt{2}\sum_{n=-\infty}^{\infty}(-1)^{n}h_{-n+1}\phi(2x-n). \tag{2.9}$$

Various additional conditions may be imposed on the function ψ (hence on the basis wavelets): arbitrary regularity, several vanishing moments (in any case, ψ has always meant zero), fast decrease at infinity, even compact support. For instance, ψ has compact support if only finitely many h_n differ from zero.

Simple examples of this construction are the Haar basis, which comes from the scaling function $\phi(x)$ equal to 1 for $0\leqslant x<1$ and 0 otherwise, the spline functions,[1] and so on.

What is more interesting for our purposes is the role of the coefficients $\{h_n\}$ defining the two-scale relation (2.3). These are complex quantities which, if $\phi(x)$ is normalized, must satisfy the following relation:

$$\sum_{n\in\mathbf{Z}}|h_n|^2=1. \tag{2.10}$$

Furthermore, it can be proved using the 2π-periodicity of the function $m_o(\omega)$, together with the orthogonality of the set $\{\phi(x-k)\}$ for $k\in\mathbf{Z}$, that

$$|m_o(\omega)|^2+|m_o(\omega+\pi)|^2=1 \tag{2.11}$$

almost everywhere.[1] This equation can be written in two equivalent forms where the coefficients h_n explicitly appear:

$$\sum_{n\in\mathbf{Z}}h_n\overline{h_{n+2k}}=\delta_{k,0},\quad \forall k\in\mathbf{Z}, \tag{2.12}$$

or

$$\sum_{n,k\in\mathbf{Z}}h_n\overline{h_{n+2k}}e^{2,ik\omega}=1,\quad \text{a.e.}, \tag{2.13}$$

or yet, in a more convenient form,

$$\frac{1}{2}\sum_{n,l\in\mathbf{Z}} h_n\overline{h_l}e^{i(l-n)\omega}(1+(-1)^{l+n})=1, \quad \text{a.e.} \tag{2.14}$$

We end this rapid excursus on MRA with the following remark: the set of coefficients $\{h_n\}$ can be considered as the main ingredient of a MRA since it generates $m_o(\omega)$, $\hat{\phi}(\omega)$ and, finally, the mother wavelet $\psi(x)$.

B. kq-representation

The relevance of kq-representation in many-body physics has been established since its first appearance.[9] What was originally a physical tool has become, during the years, also a mathematical interesting object, widely analyzed in the literature, (see Refs. 10 and 11, for instance). We give here only a few definitions and refer to Refs. 9 and 11–13 for further reading and for applications.

The genesis of the kq-representation consists in the well-known possibility of a simultaneous diagonalization of any two commuting operators. In Ref. 12 it is shown that the following distributions,

$$\psi_{kq}(x)=\sqrt{\frac{2\pi}{a}}\sum_{n\in\mathbf{Z}} e^{ikna}\delta(x-q-na), \quad k\in[0,a[, \quad q\in\left[0,\frac{2\pi}{a}\right[, \tag{2.15}$$

are (generalized) eigenstates of both $T(a)=e^{ipa}$ and $\tau(2\pi/a)=e^{ix2\pi/a}$. Here a is a positive real number which plays the role of a lattice spacing.

How it is discussed in Ref. 12, these $\psi_{kq}(x)$ are Bloch-like functions corresponding to infinitely localized Wannier functions. They also satisfy orthogonality and closure properties. This implies that, roughly speaking, they can be used to define a new representation of the wave functions by means of the integral transform $Z:\mathcal{L}^2(\mathbf{R})\to\mathcal{L}^2(\square)$, where $\square=[0,a[\times[0,2\pi/a[$, defined as follows:

$$h(k,q):=(ZH)(k;q):=\int_{\mathbf{R}} d\omega\,\overline{\psi_{kq}(\omega)}H(\omega), \tag{2.16}$$

for all functions $H(\omega)\in\mathcal{L}^2(\mathbf{R})$. The result is a function $h(k,q)\in\mathcal{L}^2(\square)$.

To be more rigorous, Z should be defined first on the functions of $\mathcal{C}_0^\infty(\mathbf{R})$ and then extended to $\mathcal{L}^2(\mathbf{R})$ using its continuity.[10] In this way it is possible to give a rigorous meaning to formula (2.16).

From now on we will work in the following hypothesis:

$$a^2=2\pi, \tag{2.17}$$

which, also in view of the next section, will correspond to fixing the spacing of the lattice underlying the 2DEG.

Replacing $\psi_{kq}(x)$ with its explicit expression, formula (2.16) produces

$$h(k,q)=(ZH)(k,q):=\frac{1}{\sqrt{a}}\sum_{n\in\mathbf{Z}} e^{-ikna}H(q+na), \tag{2.18}$$

which can be inverted and gives the x-representation $H(\omega)\in\mathcal{L}^2(\mathbf{R})$ of a function $h(k,q)\in\mathcal{L}^2(\square)$ as follows:

$$H(\omega)=(Z^{-1}h)(\omega)=\int_{\square} dkdq\,\psi_{kq}(\omega)h(k,q). \tag{2.19}$$

Due to (2.15), this equation gives

$$H(x+na)=\frac{1}{\sqrt{a}}\int_0^a dk e^{ikna}h(k,x), \quad \forall x\in[0,a[, \quad \forall n\in\mathbf{Z}. \tag{2.20}$$

In all the literature concerning kq-representation, the role of the boundary conditions is widely discussed, also in connection with the continuity properties of the functions. For instance, in Ref. 14, a function $h(k,q)\in\mathcal{L}^2(\square)$ is said to be continuous if it is the restriction to the kq-cell of a function continuous in the *extended* kq-plane $(k,q\in\mathbf{R})$, and if it satisfies the following boundary conditions:

$$\begin{aligned} h(k+a,q)&=h(k,q),\\ h(k,q+a)&=e^{ika}h(k,q), \end{aligned} \tag{2.21}$$

which are typical of any function in kq-representation and which will always be assumed here.

III. STATING THE PROBLEM

In this section we will discuss a many-body model of the FQHE looking, in particular, for the single-electron wave function which generates the ground state of the physical system in the way described next. This system is simply a two-dimensional electron gas, 2DEG (that is a gas of electrons constrained in a two-dimensional layer), in a positive uniform background and subjected to a uniform magnetic field along z and an electric field along y.

The Hamiltonian of the system can be written as

$$H^{(N)}=H_0^{(N)}+\lambda(H_c^{(N)}+H_B^{(N)}) \tag{3.1}$$

where $H_0^{(N)}$ is the sum of N contributions:

$$H_0^{(N)}=\sum_{i=1}^{N} H_0(i). \tag{3.2}$$

Here $H_0(i)$ describes the minimal coupling of the electrons with the fields:

$$H_0=\frac{1}{2}(\underline{p}+\underline{A}(r))^2=\frac{1}{2}\left(p_x-\frac{y}{2}\right)^2+\frac{1}{2}\left(p_y+\frac{x}{2}\right)^2. \tag{3.3}$$

Notice that we are adopting here the symmetric gauge $\underline{A}=1/2(-y,x,0)$ and the same unit as in Ref. 15. $H_c^{(N)}$ is the canonical Coulomb interaction between charged particles:

$$H_c^{(N)}=\frac{1}{2}\sum_{i\neq j}^{N}\frac{1}{|\underline{r}_i-\underline{r}_j|} \tag{3.4}$$

and $H_B^{(N)}$ is the interaction of the charges with the background, whose explicit form can be found in Ref. 15.

In the following we will consider, as it is usually done in the literature, $\lambda(H_c^{(N)}+H_B^{(N)})$ as a perturbation of the free Hamiltonian $H_0^{(N)}$, and we will look for eigenstates of $H_0^{(N)}$ in the form of Slater determinant built up single electron wave functions. This approach is known to give good results for low electron (or hole) densities.[15] The easiest way to attack this problem consists in introducing the new variables

$$P'=p_x-y/2, \quad Q'=p_y+x/2. \tag{3.5}$$

In terms of P' and Q' the single electron Hamiltonian, H_0, can be written as

$$H_0 = \tfrac{1}{2}(Q'^2 + P'^2). \tag{3.6}$$

The transformation (3.5) can be seen as a part of a canonical map from (x,y,p_x,p_y) into (Q,P,Q',P') where

$$P = p_y - x/2, \quad Q = p_x + y/2. \tag{3.7}$$

These operators satisfy the following commutation relations:

$$[Q,P] = [Q',P'] = i, \quad [Q,P'] = [Q',P] = [Q,Q'] = [P,P'] = 0. \tag{3.8}$$

It is shown in Refs. 16 and 17 that a wave function in the (x,y)-space is related to its PP'-expression by the formula

$$\Psi(x,y) = \frac{e^{ixy/2}}{2\pi} \int_{-\infty}^{\infty}\int_{-\infty}^{\infty} e^{i(xP' + yP + PP')}\Psi(P,P')\, dP\, dP'. \tag{3.9}$$

The usefulness of the PP'-representation stems from the expression (3.6) of H_0. Indeed, in this representation, the single electron Schrödinger equation admits eigenvectors $\Psi(P,P')$ of H_0 of the form $\Psi(P,P') = f(P')h(P)$. Thus the ground state of (3.6) must have the form $f_0(P')h(P)$, where

$$f_0(P') = \pi^{-1/4} e^{-P'^2/2}, \tag{3.10}$$

and the function $h(P)$ is arbitrary, which manifests the degeneracy of the LLL. With f_0 as above, formula (3.9) becomes

$$\psi(x,y) = \frac{e^{ixy/2}}{\sqrt{2}\,\pi^{3/4}} \int_{-\infty}^{\infty} e^{iyP} e^{-(x+P)^2/2} h(P)\, dP. \tag{3.11}$$

It is worthwhile to stress that at this stage the Coulomb interaction has not yet been considered (and it will not in this article), but the common belief is that the explicit form of $h(P)$ should be fixed by this interaction.

Now the problem arises of how to construct the ground state of the free N-electron Hamiltonian $H_0^{(N)}$. We use a suggestion coming from the classical counterpart of this quantum problem. It is very well known that the ground state for a classical 2DEG is a (triangular) Wigner crystal: the classical electrons are sharply localized on the sites of a lattice whose lattice spacing is fixed by the electron density. What we expect, and what was proven in Ref. 15, is that, at least for certain regions of the filling factor, the quantum ground state should not be very different from this classical picture. Here we only sketch the procedure which is analyzed in more detail Refs. 15 and 3.

We start introducing the so-called magnetic translation operators $T(\vec{a}_i)$ defined by

$$T(\vec{a}_i) \equiv \exp(i\vec{\Pi}_c \cdot \vec{a}_i), \quad i = 1,2, \tag{3.12}$$

where $\vec{\Pi}_c \equiv (Q,P)$ and $\vec{a}_i$ are the lattice basis vectors [$\vec{a}_1 = a(1,0)$, $\vec{a}_2 = (a/2)(1,\sqrt{3})$ for a triangular lattice].

From now on, for simplicity we will work in a square lattice with unit cell of area 2π:

$$\vec{a}_1 = a(1,0), \quad \vec{a}_2 = a(0,1), \quad a^2 = 2\pi. \tag{3.13}$$

This choice is quite useful to keep the notation simple: moreover, its generalization to lattices of arbitrary shape is only a technical step.

The above *rationality* condition on the area has the following useful consequence:

$$[T(\vec{a}_1),T(\vec{a}_2)]=0. \tag{3.14}$$

This is not the only commutativity condition satisfied by the magnetic translations. Due to the commutation relations (3.8), we also find

$$[T(\vec{a}_1),H_0]=[T(\vec{a}_2),H_0]=0. \tag{3.15}$$

With the choice (3.13) of the lattice's basis the magnetic translations take a simple form

$$T_1:=T(\vec{a}_1)=e^{iaQ}, \quad T_2:=T(\vec{a}_2)=e^{iaP}, \tag{3.16}$$

and they act on a generic function $f(x,y)\in\mathcal{L}^2(\mathbf{R}^2)$ as follows

$$f_{m,n}(x,y):=T_1^mT_2^nf(x,y)=(-1)^{mn}e^{i(a/2)(my-nx)}f(x+ma,y+na). \tag{3.17}$$

We see from this formula that, if for instance $f(x,y)$ is localized around the origin, then $f_{m,n}(x,y)$ is localized around the lattice site $a(-m,-n)$.

Now we have all the ingredients to construct the ground state of $H_0^{(N)}$ mimiking the classical procedure. We simply start from the single electron ground state of H_0 given in (3.11), $\psi(x,y)$. Then we construct a set of copies $\psi_{m,n}(x,y)$ of ψ as in (3.17), with $m,n\in\mathbf{Z}$. All these functions still belong to the lowest Landau level for any choice of the function $h(P)$ due to (3.15). N of these wave functions $\psi_{m,n}(x,y)$ are finally used to construct a Slater determinant for the finite system:

$$\psi^{(N)}(\underline{r}_1,\underline{r}_2,\ldots,\underline{r}_N)=\frac{1}{\sqrt{N!}}\begin{vmatrix} \psi_{m_1,n_1}(\underline{r}_1) & \psi_{m_1,n_1}(\underline{r}_2) & \ldots & \psi_{m_1,n_1}(\underline{r}_N) \\ \psi_{m_2,n_2}(\underline{r}_1) & \psi_{m_2,n_2}(\underline{r}_2) & \ldots & \psi_{m_2,n_2}(\underline{r}_N) \\ \cdot & \cdot & \ldots & \cdot \\ \cdot & \cdot & \ldots & \cdot \\ \cdot & \cdot & \ldots & \cdot \\ \psi_{m_N,n_N}(\underline{r}_1) & \psi_{m_N,n_N}(\underline{r}_2) & \ldots & \psi_{m_N,n_N}(\underline{r}_N) \end{vmatrix}. \tag{3.18}$$

It is known[15] that in order to get $\langle\psi^{(N)},\psi^{(N)}\rangle=1$ we need to have

$$\langle\psi_{m_i,n_i}\psi_{m_j,n_j}\rangle=\delta_{m_i,m_j}\delta_{n_in_j}. \tag{3.19}$$

In fact, if these translated functions were not o.n., then we would get $\|\psi^{(N)}\|=1+O(N)$, which is obviously divergent for N diverging. It is clear, therefore, that if we want to perform easily the thermodynamical limit, orthonormality between differently localized single electron wave functions must be required!

In the rest of this section we will discuss how the requirement (3.19) can be handled and, in particular, we will show that the use of kq-representation is quite a useful tool since it produces a very simple constraint. Some of the results we are now going to describe in this section are also due to G. Morchio and F. Strocchi,[18] while the original idea of using kq-representation in connection with an orthonormality constraint is already contained in Ref. 13 in the proof of completeness of lattice states proposed by the authors.

Let $\psi(x,y)$ be as in (3.11) and $\psi_{m,n}(x,y)=T_1^mT_2^n\psi(x,y)=(-1)^{mn}e^{i(a/2)(my-nx)}\psi(x+ma,y+na)$. After few computations and using the rationality condition $a^2=2\pi$ we obtain

$$\psi_{m,n}(x,y)=\frac{e^{i(xy/2)+iamy}}{\sqrt{2}\pi^{3/4}}\int_{-\infty}^{\infty}dP\,e^{i(y+na)P-(x+ma+P)^2/2}h(P). \tag{3.20}$$

We are interested now in finding some conditions on $h(P)$ such that condition (3.19), or its equivalent form

$$S_{m,n} := \langle \psi_{0,0}, \psi_{m,n} \rangle = \delta_{m,0}\delta_{n,0}, \tag{3.21}$$

is satisfied. With the previous definitions we find

$$S_{m,n} = \int_{-\infty}^{\infty} dp e^{inap} \overline{h(p+ma)} h(p), \tag{3.22}$$

which restates the problem of the orthonormality of the wave functions in terms of the PP'-representation. In particular we see that, for $m=n=0$, this equation implies that ψ in normalized in $\mathcal{L}^2(\mathbf{R}^2)$ if and only if $h(P)$ is normalized in $\mathcal{L}^2(\mathbf{R})$. This reflects the unitarity of the transformation (3.9), which, more in general, implies that any o.n. set in $\mathcal{L}^2(\mathbf{R})$ is mapped in an o.n. set in $\mathcal{L}^2(\mathbf{R}^2)$.

In order to use now kq-representation it is convenient to split the integral over $\mathbf{R}$ into an infinite sum of integrals restricted to $[ra,(r+1)a[, r \in \mathbf{Z}$, use the kq-representation, and, then, write everything in terms of a single integral over the unit cell $\square$. We have, using (2.20) and the well-known equality

$$\sum_{l \in \mathbf{Z}} e^{ixl(2\pi/c)} = c \sum_{l \in \mathbf{Z}} \delta(x - cl), \tag{3.23}$$

$$\begin{aligned} S_{m,n} &= \sum_{r \in \mathbf{Z}} \int_{ra}^{(r+1)a} dp e^{inap} \overline{h(p+ma)} h(p) \\ &= \sum_{r \in \mathbf{Z}} e^{inra^2} \int_0^a dp e^{inap} \overline{h(p+(r+m)a)} h(p+ra) \\ &= \sum_{r \in \mathbf{Z}} \frac{1}{a} \int_0^a dq \int_0^a dk \int_0^a dk' e^{ir(k-k')a} e^{inaq - ik'ma} h(k,q) \overline{h(k',q)}, \end{aligned}$$

so that

$$S_{m,n} = \int_{\square} dk dq e^{inaq - ikma} |h(k,q)|^2. \tag{3.24}$$

Due to the completeness of the set $\{e^{inaq-ikma}, n,m \in \mathbf{Z}\}$ in the unit cell $\square$, we conclude that $S_{m,n} = \delta_{m,0}\delta_{n,0}$ if and only if $h(k,q)$ is a phase, so that $|h(k,q)|$ is independent of k and q. This result can be considered as a slight generalization of the procedure discussed in Ref. 13 to the FQHE for filling factor $\nu = 1$.

It is easy to generalize this result to a filling $\nu = 1/2$. The idea is the following:

A filling factor $\nu = 1$ corresponds to all the sites of our square lattice (of spacing $a = \sqrt{2\pi}$) occupied. A $\nu = 1/2$ 2DEG can be seen, on the other hand, as if the same lattice was only partially occupied: one lattice site is free and the other is occupied. If we require the orthonormality of the related set of single electron wave functions, it is enough to ask for $S_{m,2n} = \delta_{m,0}\delta_{n,0}$. This is equivalent also to choose a different lattice, with a unit cell twice that before and basis vectors $a(1,0)$ and $2a(0,1)$. Of course, we would as well have chosen another lattice with basis vectors $a(0,1)$ and $2a(1,0)$, or also any other lattice with unit cell of area 4π. We use the first choice just to fix ideas. Equation (3.24) gives

$$S_{m,2n} = \int_{\square} dk dq e^{i2naq - ikma} |h(k,q)|^2 = \delta_{m,0}\delta_{n,0}, \tag{3.25}$$

which can be rewritten as

$$\frac{1}{2}\int_{\square} dkdq e^{inaq-ikma}\left(\left|h\left(k,\frac{q}{2}\right)\right|^2+\left|h\left(k,\frac{q+a}{2}\right)\right|^2\right). \tag{3.26}$$

This implies, again using the completeness of the functions $e^{inaq-ikma}, n,m\in\mathbf{Z}$, in $\square$, that

$$J_2(k,q):=\left|h\left(k,\frac{q}{2}\right)\right|^2+\left|h\left(k,\frac{q+a}{2}\right)\right|^2=\frac{1}{\pi}, \quad \text{almost everywhere for } k,q\in\square. \tag{3.27}$$

The generalization to $\nu=1/M$ is straightforward: we simply require the orthonormality of the wave functions located at a distance of M sites:

$$S_{m,Mn}=\int_{\square} dkdq e^{iMnaq-ikma}|h(k,q)|^2=\delta_{m,0}\delta_{n,0}$$

and, proceding as above, we deduce that $h(k,q)$ must satisfy the equality

$$J_M(k,q):=\left|h\left(k,\frac{q}{M}\right)\right|^2+\left|h\left(k,\frac{q+a}{M}\right)\right|^2+\cdots+\left|h\left(k,\frac{q+(M-1)a}{M}\right)\right|^2=\frac{M}{2\pi}, \tag{3.28}$$

almost everywhere for $k,q\in\square$.

The extension to a filling $\nu=L/M$, with L and M relatively prime, can be performed by imposing that condition $S_{m,n}=\delta_{m,0}\delta_{n,0}$ holds only for those (m,n) corresponding to a square lattice in which only L among M lattice sites are occupied. We will not consider this extension in this article.

IV. WHAT WE GET FROM MRA

In this section we will describe how two subjects which are so different, at a first sight, as the MRA and the orthonormality condition for a 2DEG discussed previously, are indeed very close.

Let us consider a given MRA of $\mathcal{L}^2(\mathbf{R})$. We have seen in Sec. II that to this MRA is associated a certain set of square-summable complex numbers $\{h_n\}_{n\in Z}$ satisfying, for instance, condition (2.12). This set produces a 2π-periodic function $m_o(\omega)$ and, through this, the scaling function $\hat{\phi}(\omega)$ and the mother wavelet.

Now we use the sequence $\{h_n\}_{n\in\mathbf{Z}}$ to define the following function, which strongly reminds us of $m_o(\omega)$:

$$T_2(\omega)=\begin{cases}\dfrac{1}{\sqrt{a}}\displaystyle\sum_{l\in\mathbf{Z}} h_l e^{-il\omega a}, & \omega\in[0,a[,\\ 0, \quad \text{otherwise.}\end{cases} \tag{4.1}$$

It is clear that $T_2(\omega)$ is square integrable and is not periodic. In particular, due to the normalization condition (2.10), we have $\|T_2\|_2^2=\int_{\mathbf{R}}|T_2(\omega)|^2\,d\omega=1$. Therefore the kq-transform of this function, $t_2(k,q)=(ZT_2)(k,q)$, is well defined in $\mathcal{L}^2(\square)$.

In particular, using (2.18) we find

$$t_2(k,q)=\frac{1}{\sqrt{a}}\sum_{n\in\mathbf{Z}} e^{-ikna}T_2(q+na). \tag{4.2}$$

The boundary conditions (2.21) are obviously satisfied: $t_2(k+a,q)=t_2(k,q)$ and $t_2(k,q+a)=e^{ika}t_2(k,q)$. It is easy to check that $t_2(k,q)$ satisfies also the orthonormality conditions (3.27). In fact, since we are interested to the value of $t_2(k,q)$ only in $\square$, and since $T_2(\omega)$ is different from zero only for $\omega\in[0,a[$, we conclude that, for $(k,q)\in\square$,

$$J_2(k,q)=\frac{1}{a}\left(\left|T\left(\frac{q}{2}\right)\right|^2+\left|T\left(\frac{q+a}{2}\right)\right|^2\right)=\frac{1}{a^2}\sum_{l,s} h_l\overline{h_s}e^{i(s-l)qa/2}(1+(-1)^{l+s}),$$

which is equal to $1/\pi$ a.e. in $k,q\in\square$, due to (2.14). This implies that $t_2(k,q)$ gives rise to a family of functions $\psi_{m,n}(x,y)$ in the LLL mutually orthonormal and corresponding to $\nu=\frac{1}{2}$. We will find the explicit form of these $\psi_{m,n}(x,y)$ in the next section, where we will also compare these results with the ones obtained in Ref. 3.

The above-mentioned procedure can be easily extended to fillings $\nu=1/2L$. The extension to odd denumerator is not so straightforward and will be given elsewhere.

The starting point is again the set $\{h_n\}_{n\in Z}$, producing a MRA of $\mathcal{L}^2(\mathbf{R})$, satisfying condition (2.12). Now we define

$$T_{2L}(\omega)=\begin{cases}\dfrac{1}{\sqrt{a}}\displaystyle\sum_{l\in\mathbf{Z}} h_l e^{-il\omega La}, & \omega\in[0,a[,\\ 0, \quad \text{otherwise.}\end{cases}\tag{4.3}$$

Again, this is a square-integrable function satisfying $\|T_{2L}\|^2=1$. Defining $t_{2L}(k,q)=(ZT_{2L})\times(k,q)$ we have, for $k,q\in\square$, $t_{2L}(k,q)=(1/\sqrt{a})T_{2L}(q)=(1/a)\Sigma_{l\in Z}h_l e^{-ilqLa}$. We also stress that $t_{2L}(k,q)$ satisfies the correct boundary conditions. With these definitions, using the rationality conditions $a^2=2\pi$ and collecting contributions of the form $|t_{2L}(k,q/2L)|^2$, $|t_{2L}(k,(q+2a)/2L)|^2,\ldots$, and the "odd ones," $|t_{2L}(k,(q+a)/2L)|^2,|t_{2L}(k,(q+3a)/2L)|^2,\ldots$, we obtain

$$\begin{aligned}J_{2L}(k,q)&:=\left|t_{2L}\left(k,\frac{q}{2L}\right)\right|^2+\left|t_{2L}\left(k,\frac{q+a}{2L}\right)\right|^2+\cdots+\left|t_{2L}\left(k,\frac{q+(2L-1)a}{2L}\right)\right|^2\\&=L\left(\left|t_{2L}\left(k,\frac{q}{2L}\right)\right|^2+\left|t_{2L}\left(k,\frac{q+a}{2L}\right)\right|^2\right)\\&=\frac{L}{a^2}\sum_{l,s} h_l\overline{h_s}e^{i(s-l)qa/2}(1+(-1)^{l+s}),\end{aligned}\tag{4.4}$$

which is again independent of k and q since it is equal to L/π a.e. in $\square$, due to condition (2.14). Finally, Eq. (3.28) is a consequence of the equality $\nu^{-1}=M=2L$. We conclude that $t_{2L}(k,q)$ produces, in the configuration space, a set of mutually orthonormal wave functions spanning the LLL for $\nu=1/2L$.

This result, which is in a certain sense rather unexpected because it relates two distant fields as MRA and FQHE, is only half of the surprise. In fact, in the rest of this section, we will also show that this relation works in the opposite direction. More in detail, we will show how to construct, starting from a function $h(k,q)$ which produces an o.n. set of translated functions in the LLL, a set of coefficients $\{h_n\}$ satisfying condition (2.14), and, therefore, generating a MRA.

The recipe is rather simple and requires only few lines: let us suppose to have a function $h(k,q)$ belonging to $\mathcal{L}^2(\square)$ satisfying the boundary conditions $h(k+a,q)=h(k,q)$ and $h(k,q+a)=e^{ika}h(k,q)$ and such that

$$|h(k,q/2)|^2+|h(k,(q+a)/2)|^2=\frac{1}{\pi}\quad\text{a.e. in }\square.\tag{4.5}$$

This means that in the configuration space the related set $\{\psi_{m,n}(x,y)\}$ is an o.n. set. Let us now define

$$h_n(k)=\int_0^a dq e^{inaq}h(k,q),\quad k\in[0,a[.\tag{4.6}$$

Even if $h_n(k)$ is, in general, a function of k, it is straightforward to check that if we take $h(k,q)$ coinciding with $t_2(k,q)$ in (4.2), then $h_n(k)=h_n$ for all $n\in\mathbf{Z}$. This means that the dependence on k may disappear in some relevant situation. It is not so surprising, therefore, to check that $\Sigma_{n\in\mathbf{Z}}h_n(k)\overline{h_{n+2l}(k)}$ does not depend on k for *any* choice of $h(k,q)$, if the equality (4.5) is satisfied. In fact, using equality (3.23) and condition (4.5), we find

$$\begin{aligned}\sum_{n\in\mathbf{Z}} h_n(k)\overline{h_{n+2l}(k)} &= a\int_0^a dq|h(k,q)|^2 e^{-2ilaq}\\ &= \frac{a}{2}\int_0^a dq e^{-ilaq}(|h(k,q/2)|^2+|h(k,(q+a)/2)|^2)\\ &= \frac{a}{2\pi}\int_0^a dq e^{-ilaq}=\delta_{l,0}. \end{aligned} \tag{4.7}$$

This result shows that any o.n. basis in the LLL for a filling factor $\nu=1/2$ produces a set of coefficients satisfying the summation rule (2.12) and, therefore, the basic condition giving rise to a MRA of $\mathcal{L}^2(\mathbf{R})$ (which, in general, will depend on an external parameter $k\in[0,a[$). The extension to a filling $\nu=1/2L$, $L\in\mathbf{N}$, is straightforward.

V. EXTENSION TO HIGHER LANDAU LEVELS AND FURTHER REMARKS

In the first part of this section we analyze the relation between the approach we have discussed here with the one originally proposed in Ref. 3 and further developed in Refs. 4 and 5. In those papers we used wavelet analysis in connection with the FQHE as we have done here. In Ref. 5, in particular, we discussed a toy model suggesting the relevance of single electron wave functions arising from wavelet theory in the construction of a Slater-like ground state for a 2DEG. This construction was carried out in detail for the FQHE in Refs. 3 and 4 using the canonical transformation (3.11) and the PP'-representation to generate an o.n. basis of functions in the LLL starting from an o.n. set of wavelets in $\mathcal{L}^2(\mathbf{R})$. This procedure is only apparently close to the one proposed in this article. The first difference is related to the possibility of extending the approach in Ref. 3 to *any* o.n. basis of $\mathcal{L}^2(\mathbf{R})$, a possibility which does not exist here since the procedure proposed in this article only works for an o.n. basis generated by a MRA. The second difference concerns the nature of the operators acting on the *mother* function which generates the o.n. set in the LLL: in Refs. 3 and 4 these operators are dilation and translation operators. Here, on the other hand, we use the magnetic translations defined in (3.12).

Since, however, these two procedures have something in common, we expect that the resulting wave functions should not be very different. And, in fact, this is the outcome of this section, where we will explore the details of the easiest example: the Haar wavelet. For this choice the set $\{h_n\}_{n\in\mathbf{Z}}$ reduces to $h_0=h_1=1/\sqrt{2}$, and all the other coefficients are zero. We have shown in Ref. 3 that this choice produces a function in the LLL localized around the origin which looks like

$$H_{00}(x,y)=\frac{e^{-ixy/2}e^{-y^2/2}}{2\pi^{1/4}}\left\{2\phi\left(\frac{x-iy+1/2}{\sqrt{2}}\right)-\phi\left(\frac{x-iy}{\sqrt{2}}\right)-\phi\left(\frac{x-iy+1}{\sqrt{2}}\right)\right\}, \tag{5.1}$$

where $\phi(z):=(2/\sqrt{\pi})\int_0^z e^{-t^2}dt$ is the error function.[19] The whole set $H_{mn}(x,y)$ is discussed in Ref. 3, where its asymptotic behavior is also discussed in connection with the localization of the electrons. Here we only state the result which will be compared with the one resulting by the approach proposed here. We have

$$H_{00}(x,y)\simeq\frac{e^{ixy/2}e^{-x^2/2}}{2\pi^{1/4}}\sqrt{\frac{2}{\pi}}\left(\frac{1}{x-iy}+\frac{e^{-1/2-x+iy}}{x-iy+1}-2\frac{e^{-1/8-(x-iy)/2}}{x-iy+1/2}\right), \tag{5.2}$$

which displays the Gaussian localization of the wave function in the variable x and shows the rather poor localization in y.

Let us now proceed in a different way. For a filling $\nu=1/2$ and a generic MRA, the function T_2 which produces an o.n. set of translates in the LLL is given in (4.1). Using the transformation rule (3.11) we obtain

$$T_2(x,y)=\frac{e^{ixy/2}}{\sqrt{2}\,\pi^{3/4}}\int_{-\infty}^{\infty}e^{iyQ-(x+Q)^2/2}T_2(Q)=\frac{\sqrt{a}e^{ixy/2}}{2\,\pi^{3/4}}\sum_{l\in\mathbf{Z}}h_l\int_0^a e^{iQ(y-la)-(x+Q)^2/2},$$

which, for the above choice of coefficients corresponding to the Haar wavelet, gives

$$T_2(x,y)=\frac{\sqrt{a}e^{ixy/2}}{2^{3/2}\pi^{5/4}}\int_0^a e^{iQy-(x+Q)^2/2}(1+e^{-iQa})\,dQ. \tag{5.3}$$

Here T_2 can be written in terms of error function $\phi(z)$ as follows:

$$T_2(x,y)=\frac{\sqrt{a}e^{-ixy/2-y^2/2}}{4\,\pi^{3/4}}\left(\phi\left(\frac{x+a-iy}{\sqrt{2}}\right)+\phi\left(\frac{x+a-i(y-a)}{\sqrt{2}}\right)-\phi\left(\frac{x-iy}{\sqrt{2}}\right)\right.$$
$$\left.-\phi\left(\frac{x-i(y-a)}{\sqrt{2}}\right)\right), \tag{5.4}$$

whose asymptotic behavior can be found with the help of Ref. 19:

$$T_2(x,y)\simeq\frac{\sqrt{a}e^{+ixy/2-x^2/2}}{2^{3/2}\pi^{5/4}}\left(\frac{1}{x-iy}+\frac{e^{\pi-ia(x-iy)}}{x-i(y-a)}-\frac{e^{-\pi-a(x-iy)}}{x+(a-iy)}-\frac{e^{-a(x-iy)(1+i)}}{x+a-i(y-a)}\right). \tag{5.5}$$

This formula shows that, even if the two procedures produce different results, the asymptotic behaviors, that is, the localization features of the electrons, coincide for H_{00} and T_2. This result can be considered as a consequence of the Balian–Low theorem applied to the present situation (see Refs. 1 and 6) and of the Battle theorem for our previous proposal (see Refs. 3, 20, and 6). Both these theorems give severe constraints on the localization properties of a wave function when orthonormality requirements of a different kind are imposed. We refer to Ref. 6 for a rather complete review of the localization problem in a generic Landau level.

The function T_2 can be used to construct a Slater determinant for the N-electron system as sketched above: we start considering its (magnetic) translated as in (3.17),

$$(T_2)_{m,n}(x,y)=\frac{\sqrt{a}e^{-ixy/2-ianx-(y+na)^2/2}}{4\,\pi^{3/4}}\left\{\phi\left(\frac{x+(m+1)a-i(y+na)}{\sqrt{2}}\right)-\phi\left(\frac{x+ma-i(y+na)}{\sqrt{2}}\right)\right.$$
$$\left.+\phi\left(\frac{x+(m+1)a-i(y+(n-1)a)}{\sqrt{2}}\right)-\phi\left(\frac{x+ma-i(y+(n-1)a)}{\sqrt{2}}\right)\right\}.$$

These are the functions used to build up the antisymmetric wave function

$$T^{(N)}(\underline{r}_1,\underline{r}_2,\ldots,\underline{r}_N)=\frac{1}{\sqrt{N!}}\begin{vmatrix}(T_2)_{m_1,n_1}(\underline{r}_1) & (T_2)_{m_1,n_1}(\underline{r}_2) & \ldots & (T_2)_{m_1,n_1}(\underline{r}_N)\\ (T_2)_{m_2,n_2}(\underline{r}_1) & (T_2)_{m_2,n_2}(\underline{r}_2) & \ldots & (T_2)_{m_2,n_2}(\underline{r}_N)\\ \cdot & \cdot & \ldots & \cdot\\ \cdot & \cdot & \ldots & \cdot\\ \cdot & \cdot & \ldots & \cdot\\ (T_2)_{m_N,n_N}(\underline{r}_1) & (T_2)_{m_N,n_N}(\underline{r}_2) & \ldots & (T_2)_{m_N,n_N}(\underline{r}_N)\end{vmatrix},$$

where (m_i,n_i) are those indexes compatible with an electron density $\nu=1/2$.

It is evident that our procedure produces many possible N-electron wave functions in the LLL, one for each different MRA of $\mathcal{L}^2(\mathbf{R})$. Among all these possibilities, the one physically relevant is that choice which minimizes the Coulomb energy. Of course, before comparing these results with those obtained using the Laughlin wave function, we first need to generalize our procedure to a triangular lattice. The details of this extension will be considered in a future work.

In the last part of this section we extend the orthonormality constraint (3.21) to levels higher than the lowest.

We begin this analysis with a general remark, which already suggests the final result: orthonormality is required on a set of functions obtained by a single wave function via the action of the magnetic translations T_i. On the other hand, the passage from a Landau level to the other is obtained with the action of the raising and lowering operators $A'^{\dagger}$ and A' defined by

$$A' = \frac{Q' + iP'}{\sqrt{2}}, \tag{5.6}$$

where Q' and P' are given in (3.5). We have already remarked that the translations T_i commute with Q' and P', and with A' and $A'^{\dagger}$ as a consequence, so that it is reasonable to expect that the orthonormality constraint does not change very much moving from the lowest to some higher Landau level. This is exactly what happens, as we will now show explicitly for the first excited level.

All the wave functions of the first Landau level, ILL, are given by formula (3.9) with $\Psi(P,P') = f_1(P')h(P)$. Here $f_1(P') = (\sqrt{2}/\pi^{1/4})P'e^{-P'^2/2}$ is the first excited function of the harmonic oscillator. Performing the integration in P' we obtain

$$\psi(x,y) = \frac{ie^{-ixy/2}}{\pi^{3/4}} \int_{-\infty}^{\infty} e^{iyP} e^{-P^2/2} P h(P-x)\, dP. \tag{5.7}$$

Acting on $\psi(x,y)$ with T_i as in (3.17) and defining $S_{m,n}$ as in (3.21) we obtain

$$\begin{aligned} S_{m,n} &= \frac{1}{\pi^{3/2}} \int d^2r \int_{-\infty}^{\infty} dp \int_{-\infty}^{\infty} dp' e^{-ianx - iyp + i(y+na)p' - (p^2+p'^2)/2} p p' \overline{h(p-x)} h(p'-x-ma) \\ &= \frac{2}{\sqrt{\pi}} \int_{-\infty}^{\infty} dx \int_{-\infty}^{\infty} dq e^{inaq} \overline{h(q)} h(q-ma)(q+x)^2 e^{-(q+x)^2} \\ &= \int_{-\infty}^{\infty} dp e^{inap} \overline{h(p+ma)} h(p), \end{aligned}$$

which coincides with the result obtained for the LLL. This means that, when passing to the kq-representation, the wave function originating the o.n. set in the ILL is exactly the same function originating the o.n. set in the LLL. Needless to say, this does not imply that in the configuration space the two different o.n. sets coincide, because they are generated by different $\psi(P,P')$, belonging to different Landau levels.

Even if the above-mentioned result has been obtained only for the ILL, it gives a strong indication that the orthonormality condition in terms of $h(P)$ takes exactly the same form for all the Landau levels. This also follows form our original remark on the commutativity among T_i and $A'^{\dagger}$.

VI. OUTCOME

In this article we have proven a deep connection between a MRA of $\mathcal{L}^2(\mathbf{R})$ and the FQHE. In particular we have shown how a single electron wave function, which, together with its magnetic translates, produces an o.n. set in the LLL, can be constructed starting from a MRA. This proce-

dure works for $\nu=1/2L, L\in\mathbf{N}$. We have also shown that this procedure can be essentially inverted since to any o.n. basis of translated functions of the LLL (corresponding to $\nu=1/2L$) corresponds a set of coefficients satisfying the main condition of a MRA of $\mathcal{L}^2(\mathbf{R})$. Moreover, we have compared this approach with a similar one, Ref. 3, which is close for the final result but is very different for the philosophy. We have finally extended this procedure to other Landau levels.

What is still to be done is a computation of the energy of the 2DEG for such a basis, in order to see if this procedure can give some hints about the ground state for the FQHE. We also plan to extend this procedure to filling ν of the form $\nu=1/(2L+1)$ and, more generally, $\nu=L/L'$, with L and L' relatively prime natural numbers.

(Received 2 January 2001; accepted for publication 5 July 2001)

We study the total [dynamical plus geometrical (Berry)] phase of cyclic quantum motion for coherent states over homogeneous Kähler manifolds $X=G/H$, which can be considered as the phase spaces of classical systems and which are, in particular cases, coadjoint orbits of some Lie groups G. When the Hamiltonian is linear in the generators of a Lie group, both phases can be calculated exactly in terms of *classical* objects. In particular, the geometric phase is given by the symplectic area enclosed by the (purely classical) motion in the space of coherent states. © *2001 American Institute of Physics.* [DOI: 10.1063/1.1396837]

I. INTRODUCTION

Let us consider a quantum state $\psi(t)$ whose evolution follows a time-dependent Schrödinger equation. If the final state $\psi(T)$ coincides with the initial one $\psi(0)$, then the representative state vectors $|\psi(0)\rangle$ and $|\psi(T)\rangle$ differ one from another just by a phase factor $\exp(i\alpha)$. This phase factor can be split into two parts $\alpha=\beta+\gamma$, called, respectively, dynamical phase and geometrical phase. Both β and γ are important characteristics of the evolution of the system under consideration.

In particular the geometric phase turns out to depend on the Hamiltonian in a rather indirect way, as it is determined *only* by the closed loop traversed by the state in the state space. This geometrical phase associated to any quantum cyclic motion with time-dependent Hamiltonians appears, in addition to the well-known dynamical phase, due to the natural curvature of the line bundle over the projective Hilbert space of states. This was found by Berry[1] for adiabatic motion, interpreted by Simon[2] as above, and extended by Aharonov–Anandan in Ref. 3 (see also Refs. 4 and 5 for arbitrary cyclic motion). However, there are very few cases in which the calculation can be performed explicitly, and it would be nice to exhibit examples where the phases of a cyclic quantum motion can be calculated in closed terms.

We shall consider the important cases in which the Hamiltonian $H(t)$ is *linear* in the generators of a Lie algebra $\mathcal{G}$ acting through some unitary irreducible representation T^{λ} in a Hilbert space $\mathcal{H}^{\lambda}$, where λ labels the representation. The aim of this paper is to show that in these cases, explicit expressions for both β and γ can be given in terms of a related *classical* dynamical system. This is achieved by using the generalized coherent state technique,[6–8] and is done in a frame general enough to cover a wide variety of examples and particular cases, including the well-known situation for evolution of a spin 1/2 in a magnetic field, a standard example which is however an oversimplified one, because its quantum state space is the Riemann sphere $\mathbb{C}P^1$.

Therefore all information on *dynamical and geometrical phases* for these quantum systems

can be obtained by studying the motion of a *purely classical* system in a suitable phase space. As we shall see these are the Kähler (and hence naturally symplectic) homogeneous spaces $X=G/H$, with G the Lie group of the Lie algebra $\mathcal{G}$. Important examples of such spaces are the orbits of the coadjoint representation of compact semisimple Lie groups. For $G=U(n)$ the generic (maximal dimension) coadjoint orbit is $\mathrm{U}(n)/\mathrm{U}(1)^n$; this space is called a flag manifold, and plays an important role in many areas.[9,10]

The setup of this paper is as follows: in Sec. II we present the main ideas leading to closed expressions for dynamical and geometrical phases, in terms of motion in the space X taken as a *classical* space. This is possible when the quantum Hamiltonian is linear in the generators of some representation of a Lie algebra $\mathcal{G}$ and besides X is an homogeneous Kähler manifold of the Lie group G. In Sec. III we describe some homogeneous Kähler manifolds; they include (i) coadjoint orbits of semisimple compact Lie groups, (ii) the so-called bounded symmetric domains which are not compact, and (iii) some other cases, like the Heisenberg ''plane.''

Finally in Appendix A we collect explicit expressions for the kernels which determine the Kähler potential, and we give some differential and topological information on Kähler manifolds, including the Poincaré polynomials. A resumé of relevant details on coherent states, extracted from Ref. 8 is also included as Appendix B.

II. THE GROUP THEORETICAL COMPUTATION OF PHASES

Let us consider the time-dependent Schrödinger equation

$$i\frac{d}{dt}|\psi(t)\rangle=\hat{H}(t)|\psi(t)\rangle, \tag{2.1}$$

with a Hamiltonian of the form

$$\hat{H}(t)=\sum_j a_j(t)X_j^\lambda, \quad X_j^\lambda=\mathcal{T}^\lambda(X_j), \tag{2.2}$$

where $\mathcal{T}^\lambda$ is a unitary irreducible representation of the Lie algebra $\mathcal{G}$, whose generators X_j are represented in $\mathcal{T}^\lambda$ by the (anti-Hermitian) operators iX_j^λ, and $a_j(t)$ is the arbitrary real functions of time. We consider here only those cases when the representation Hilbert space $\mathcal{H}^\lambda$ may be realized as a space $\mathcal{F}^\lambda$ of holomorphic functions on a complex homogeneous space $X=G/H$ which is also a Kähler one. We assume also that the initial state is a generalized coherent state $|x_0\rangle$ labeled by the point $x_0\in X$; for details, see Ref. 8.

In this case, under time evolution the initial coherent state remains a coherent state

$$|x(t)\rangle=U(t,0)|x(0)\rangle \tag{2.3}$$

and then $x(t)$ is a solution of the Hamilton equation for the corresponding *classical* system

$$\dot{x}=\{H(t),x\}^\lambda, \quad \dot{x}=\frac{dx}{dt}, \tag{2.4}$$

where $\{,\}^\lambda$ is the Poisson bracket induced on X by the representation $\mathcal{T}^\lambda$.

The mapping $X\to\mathcal{H}^\lambda$ which associates the point $x_0\in X$ to the coherent state $|x_0\rangle$ allows an isomorphic identification of actual quantum ''trajectories'' starting from $|x_0\rangle$ and obeying the usual Schrödinger equation

$$i\frac{d}{dt}|x(t)\rangle=\hat{H}(t)|x(t)\rangle \tag{2.5}$$

to some *classical* motions in X (taken as a *classical* phase space, not a configuration space), satisfying (2.4). Under this identification, if Γ is a closed loop in X with period T, it is still close

in the projective Hilbert space $\overline{\mathcal{H}}^{\lambda}$, which should be considered as the *true* state space, but not necessarily in the linear Hilbert space $\mathcal{H}^{\lambda}$. In this cyclic motion, the state *vector* picks up a phase

$$|\psi(T)\rangle = \exp(i\alpha)|\psi(0)\rangle, \quad \alpha = \beta + \gamma. \tag{2.6}$$

This can also be seen as follows.[4] Let Γ be a closed path (loop) in the projective Hilbert space $\overline{\mathcal{H}} = \mathbb{C}P^{\infty}$ of states; let $|\psi\rangle = |\psi(t)\rangle$ be a generic point in Γ. There is a tautological line bundle, whereby each point carries its vectors; this line bundle is Hermitian, by the Hermitian product in $\mathcal{H}$. Let $P(t)$ be in the fiber over $|\psi(t)\rangle$. The Hamiltonian $\hat{H}$ works in $\mathcal{H}$, and by projection in $\overline{\mathcal{H}}$ also, so the time evolution carries $P(0) \to P(t)$ and projects to $U(0,t): |\psi(0)\rangle \to |\psi(t)\rangle$. As $P(T)$ is the fibre over $\psi(T)$ which coincides with the fibre over $\psi(0)$, we must have

$$P(T) = \exp(i\alpha)P(0), \tag{2.7}$$

where α is the total phase for the cyclic motion. The lift of the path Γ through the connection of the line bundle L^{λ} would produce an U(1) holonomy γ; this is the *geometric phase*, and the difference, $\beta = \alpha - \gamma$ is the dynamical phase. As explained in detail in Ref. 2, we have the following explicit expressions for both parts of the total phase α:

$$\beta = \int \langle \psi(t)|\hat{H}(t)|\psi(t)\rangle dt, \quad \gamma = \int \langle \psi'(t)|\left(-i\frac{d}{dt}\right)|\psi'(t)\rangle dt, \tag{2.8}$$

where $|\psi'(t)\rangle$ is a trivializing section, i.e., there is no dynamical phase for the whole loop, see Refs. 4 and 11. The connection 1-form of this line bundle θ^{λ} is related locally to the symplectic 2-form as $\omega^{\lambda} = d\theta^{\lambda}$, and this symplectic 2-form is in turn induced by the imaginary part of the Hermitian scalar product in $\mathcal{H}^{\lambda}$.

Under the conditions stated, both phases can be computed directly in terms of the classical motion in X. For the dynamical part we have

$$\beta = \int \langle \psi(t)|\hat{H}(t)|\psi(t)\rangle dt = \int \langle x(t)|\hat{H}(t)|x(t)\rangle dt = \int a_j(t) X_j^{\lambda}(t) dt, \tag{2.9}$$

where $X_j^{\lambda}(t) = \langle x(t)|X_j^{\lambda}|x(t)\rangle$.

The geometric phase γ is given as the integral along Γ of the connection 1-form θ^{λ} which depends on the representation. Due to the Abelian nature of the U(1) group, the Stokes theorem applies and gives

$$\gamma = \gamma_{cl} = \int_{\Gamma} \theta^{\lambda} = \int_{\Sigma} \omega^{\lambda}, \tag{2.10}$$

where $\omega^{\lambda} = d\theta^{\lambda}$ and Σ is any surface having $\Gamma = \partial\Sigma$ as its boundary. Hence, we give the expression for the geometric phase in terms of symplectic area of any surface whose boundary is the given (classical) closed circuit in our Kähler manifold X.

Thus formula (2.10) is valid for arbitrary homogeneous Kähler manifolds. Now if F^{λ} denotes the Kähler potential,[12,13] the expressions for the connection and curvature forms are (see Appendix A)

$$\theta^{\lambda} = \frac{1}{i}\left(\frac{\partial F^{\lambda}}{\partial z_{\mu}} dz_{\mu} - \frac{\partial F^{\lambda}}{\partial \overline{z}_{\mu}} d\overline{z}_{\mu}\right), \quad \omega^{\lambda} = \frac{i}{2}\frac{\partial^2 F^{\lambda}}{\partial z_{\mu} \partial \overline{z}_{\nu}} dz_{\mu} \wedge \partial \overline{z}_{\nu} = d\theta^{\lambda}, \tag{2.11}$$

and the Kähler potential itself is related to the kernel, which generalizes Bergmann's kernel, as

$$F(z,\overline{z}) = \ln(K(z,\overline{w}))|_{w=z}. \tag{2.12}$$

The simplest closed loops are geodesic triangles. For them we can give explicit expressions.

Let us first consider the simplest case $\mathcal{G}=\mathrm{su}(2)$, where $X=\mathbb{C}P^1=\mathrm{SU}(2)/\mathrm{U}(1)$ is the Riemann sphere, and $\mathrm{U}(1)\to\mathrm{SU}(2)=S^3\to S^2$ is the second Hopf sphere bundle. In this case there is a single complex coordinate z, related with the point x on the sphere by the usual stereographic projection, and the Bergmann's kernel is given by

$$K(z,\overline{w})=1+z\overline{w}. \tag{2.13}$$

It is clear that any vertex can be carried to a prescribed point on the sphere, say the North pole, corresponding to $z=0$. Let $|x\rangle,|y\rangle$ denote the two coherent states determining the remaining triangle vertices, corresponding to points x,y on the sphere, and let us denote z,w the complex coordinates corresponding to x,y. The closed expression for the geometric phase associated to this closed loop is

$$\gamma=\frac{1}{2i}\ln\frac{K(\overline{z},w)}{K(z,\overline{w})}=\frac{1}{2i}\ln\frac{1+\overline{z}w}{1+z\overline{w}}=\frac{1}{2i}\ln\frac{\langle x|y\rangle}{\langle y|x\rangle}. \tag{2.14}$$

For $\mathcal{G}=\mathrm{su}(2)$ this result for the phase has been given already in Ref. 6 (see also Ref. 8). In this case the symplectic area is proportional to the Riemannian area for the standard Riemannian structure on S^2; this proportionality is however accidental and may be misleading because this does not hold in higher dimensions; for instance in $\mathbb{C}P^n$ $(n>1)$ the symplectic area of any finite triangle is not proportional to its Riemannian Fubini–Study area.

Let us now consider the general case where the generators X_j^λ close to a unitary irreducible representation of the Lie algebra $\mathcal{G}$. The symplectic area of any closed loop in $\overline{\mathcal{H}}$ is completely determined by the loop; this does not hold for the ''Riemannian'' area determined by a general Kähler metric, which depends essentially on the two-dimensional surface whose boundary is the prescribed loop. In this general case (with group $\mathcal{G}$), it suffices again to give a closed expression for the symplectic area of a triangular loop. If one vertex is carried to a prescribed point on the Kähler homogeneous manifold X (say determined by the complex coordinates $z_\mu=0$), the remaining vertices x,y will correspond to the complex coordinates z_μ,w_ν. The same argument as before leads in this case to the expression

$$\gamma\propto\frac{1}{2i}\ln\frac{K(\overline{z},w)}{K(z,\overline{w})}. \tag{2.15}$$

Appendix A contains explicit expressions for the kernels $K(z,\overline{w})$ for Hermitian symmetric spaces, taken from Ref. 8, where further details on the construction of the kernel $K(z_\mu,\overline{w_\nu})$ for homogeneous Kähler manifolds can be found.

In the case of complex Grassmannians, the usual choice for complex coordinates are called Pontrjagin coordinates and can be arranged as a complex rectangular matrix Z. After substituting for the relevant kernel, the basic expression (2.15) reduces to

$$\gamma\propto\frac{1}{2i}\ln\frac{\det(\mathrm{I}+ZW^\dagger)}{\det(\mathrm{I}+WZ^\dagger)} \tag{2.16}$$

and coincides with the formula for the geometric phase derived through explicit computation by Berceanu, who also points out the validity of a similar formula for any Hermitian symmetric space.[14] However, the arguments given in Ref. 8 appear to hold unrestrictedly for arbitrary homogeneous Kähler manifold X, and not only for Hermitian symmetric spaces.

In the well understood example (see, e.g., Refs. 15 and 16), of a spin 1/2 particle in a magnetic field,

$$i\frac{d}{dt}|\psi(t)\rangle=-\mu\mathbf{B}(t)\cdot\mathbf{S}|\psi(t)\rangle, \tag{2.17}$$

the Hamiltonian is a linear combination of three operators which span a Lie algebra su(2), and quantum evolution can be thus translated into a classical motion of a point on the homogeneous space SU(2)/U(1), the Riemann sphere again. The coadjoint orbits are 2-spheres and $x=\mathbf{x}$ is a unit vector in $\mathbb{R}^3$, so at any fixed time $\hat{H}(t)$ splits into two parts:

$$\hat{H}(t)=\hat{H}_{\parallel}+\hat{H}_{\perp}, \tag{2.18}$$

where

$$\hat{H}_{\perp}|\mathbf{x}(t)\rangle=0, \quad \hat{H}_{\parallel}|\mathbf{x}(t)\rangle=E(t)|\mathbf{x}(t)\rangle. \tag{2.19}$$

The longitudinal part produces only a dynamical phase, as the ray of $|\mathbf{x}\rangle$ and of $E(t)|\mathbf{x}\rangle$ are the same. The geometrical phase comes entirely from the transverse part. In particular, if the field is constant in direction:

$$H(t)=B(t)\sigma_z \tag{2.20}$$

and the initial state is $|\mathbf{x}\rangle=\cos(\theta/2)|+\rangle+\sin(\theta/2)|-\rangle$, the solution is readily obtained

$$|\psi(t)\rangle=a(t)|+\rangle+b(t)|-\rangle, \tag{2.21}$$

where $a(t)=a(0)\exp(-i\int B(t)dt)$, $b(t)=b(0)\exp(i\int B(t)dt)$. For $\theta=0$ or $\theta=\pi$ we have a purely dynamical phase, while for $\theta=\pi/2$ the phase is purely geometrical.

For arbitrary $\mathbf{B}(t)$ there is also a local splitting, and the "parallel" $H_{\parallel}$ and "perpendicular" $H_{\perp}$ parts of the Hamiltonian carry, respectively, the dynamical and geometric phases.

III. HOMOGENEOUS SYMPLECTIC MANIFOLDS AND KÄHLER MANIFOLDS

Relative to the definition of a symplectic manifold, see Ref. 17.

Definition: A symplectic manifold (M,ω) is called homogeneous if there exists on it a transitive action $\Phi_g: M\to M$ of some Lie group $G=\{g\}$ which acts as a group of symplectic transformations, i.e., it leaves invariant the form ω, $\Phi_g^*\omega=\omega$.

Theorem:[18] *Any homogeneous symplectic manifold on which a connected Lie group G acts transitively and by symplectic transformations is locally isomorphic to an orbit of a coadjoint representation of this group G or of a central extension of G by $\mathbb{R}$.*

Thus any coadjoint orbit of the group G is an homogeneous symplectic manifold.

Among the class of all homogeneous symplectic manifolds, the main important subclass is those of coadjoint orbits of *semisimple* Lie groups. These have an additional Kähler homogeneous structure. A Kähler manifold is defined as a complex manifold M endowed with a Kähler metric h, whose imaginary part is a closed 2-form. A Kähler metric is an Hermitian metric h which comes from a function $F(z,\bar{z})$ called the Kähler potential:

$$ds^2=h_{\mu\bar{\nu}}dz^{\mu}\,d\bar{z}^{\nu}, \quad h_{\mu\bar{\nu}}(z,\bar{z})=\partial_{\mu}\partial_{\bar{\nu}}F(z,\bar{z}), \quad \partial_{\mu}=\frac{\partial}{\partial z_{\mu}}, \quad \partial_{\bar{\nu}}=\frac{\partial}{\partial \bar{z}_{\nu}}. \tag{3.1}$$

The imaginary part of this metric is a symplectic 2-form

$$\omega=\frac{i}{2}h_{\mu\bar{\nu}}(z,\bar{z})dz^{\mu}\wedge d\bar{z}^{\nu}, \quad d\omega=0. \tag{3.2}$$

The connection between orbits of the coadjoint representation of compact simple Lie groups and Kähler homogeneous manifolds is stated in the following important result of Borel:

Theorem:[19] *Any orbit of the coadjoint representation of a compact simple Lie group is a compact Kähler homogeneous simply connected manifold, and any compact Kähler homogeneous simply connected manifold is some orbit of the coadjoint representation of the some compact simple Lie group.*

Orbits of the coadjoint representation of a compact Lie group are even rational manifolds.[20] Topologically they are compact and simply connected manifolds. Their topology is described, for example, in the review.[9] In the Appendix A we give some pertinent results.

Many examples of Kähler homogeneous manifolds with a compact group G are known; these spaces are compact, even-dimensional, simply connected and oriented. As the cohomology class $[\omega]\neq 0$, all the even Betti numbers are nonzero. Let us recall some simple examples.

For $G=\mathrm{SU}(2)=\mathrm{Spin}(3)\sim\mathrm{SO}(3)$, the generic coadjoint orbits in $\mathrm{su}(2)\approx\mathbb{R}^3$ are spheres S^2; there is an isolated orbit consisting of a single point, the origin. For each sphere the 2-form is just the area (volume) form, automatically closed by dimensionality. It is a complex (one-dimensional) manifold, the Riemann sphere.

For $G=\mathrm{SU}(3)$, there are three types of coadjoint orbits in $\mathrm{su}(3)\approx\mathbb{R}^8$: the origin, four-dimensional orbits isomorphic to $\mathbb{C}P^2=\mathrm{SU}(3)/\mathrm{SU}(2)\times\mathrm{U}(1)$, and six-dimensional maximal orbits, isomorphic to the flag manifold $\mathbb{F}^3=\mathrm{SU}(3)/\mathrm{U}(1)\times\mathrm{U}(1)$.

For $G=\mathrm{SU}(n)$, the description of the orbits is essentially given by the partitions of n (see Ref. 21).

The general calculation of Kähler metrics on the coadjoint orbits for any compact simple Lie group (the classical and exceptional structures of Cartan) was expelled in Ref. 21.

The main reason why these manifolds are Kähler is that the homogeneous structure is also obtained from the complex extension $G^{\mathbb{C}}$ of G. The role of the subgroup H here is played by some triangular (Borel) subgroup B; both $G^{\mathbb{C}}$ and B are analytic manifolds, and so is $G^{\mathbb{C}}/B$ which turns out to be isomorphic to G/H. The space X is also obviously simply connected, because G can be taken simply connected (for any X) and H is connected. This construction $X=G/H=G^{\mathbb{C}}/B$ is also basic in the Borel–Weil–Bott theory of analytic construction of irreducible representations of G as sections in some holomorphic bundles.

When G is a general simple or semisimple compact Lie group, the orbits of the coadjoint representation exhausts all the compact homogeneous Kähler manifolds.

Other examples of (noncompact) Kähler manifolds are the so-called bounded symmetric domains (see Ref. 22). Recall that a bounded domain $D\subset\mathbb{C}^n$ is called symmetric if each point in D is fixed by an involutive holomorphic diffeomorphism of D. These are characterized by the result.

Theorem: [Helgason,[22] p. 310] *(i) Each bounded symmetric domain D, when equipped with the Bergmann metric, is a Hermitian symmetric space of the noncompact type. In particular, a bounded symmetric domain is neccesarily simply connected.*

(ii) Let M be a Hermitian symmetric space of the noncompact type. Then there exists a bounded symmetric domain D and a holomorphic diffeomorphism of M onto D.

The paradigmatic example is the Lobachevsky plane. This is a Kähler manifold which is noncompact, and of constant negative curvature.

A complete classification of Kähler manifolds is still lacking. Hermitian symmetric spaces, which are completely classified, are examples of Kähler manifolds, while the remaining non-Hermitian symmetric spaces are not Kähler (e.g., the even dimensional spheres $S^{2n}, n>1$ are homogeneous and symmetric, but obviously not Kähler).

Some nonsemisimple groups also provide other Kähler manifolds. A very basic example is that obtained from the Heisenberg–Weyl algebra $\mathrm{hw}(1)$ generated by the usual operators $p,q,1$, by quotient by the subgroup generated by the subalgebra 1. This space is the basic ''quantum'' space q,p, whose noncompact Kähler character becomes obvious after introduction of the complex coordinate $z=p+iq$.

APPENDIX A: KÄHLER HOMOGENEOUS MANIFOLDS

We start by listing some examples of compact Kähler homogeneous manifolds. More details can be found in Refs. 19 and 21.

(1) $G=\mathrm{SO}(3)\sim\mathrm{SU}(2)$ is the rotation group of a three-dimensional vector space $\mathbb{R}^3$. Here the sign $\sim$ means a locally isomorphic group and $\mathcal{G}^*$ is the dual space to the Lie algebra $\mathcal{G}^*=\{\mathbf{x}|\mathbf{x}=(x_1,x_2,x_3)\}\approx\mathbb{R}^3$. There is a zero-dimensional orbit (the origin) while the remaining orbits are generic and are two-dimensional spheres $S_r^2=\{\mathbf{x}|\mathbf{x}^2=x_1^2+x_2^2+x_3^2=r^2\}$.

(2) $G=\mathrm{SU}(3)$. Here we have three types of coadjoint orbits in $\mathrm{su}(3)\approx\mathbb{R}^8$: First, the origin $\mathbf{x}=0$. Second, four-dimensional orbits (isomorphic to $\mathbb{C}P^2$)

$$\mathcal{O}=\frac{\mathrm{SU}(3)}{\mathrm{SU}(2)\times\mathrm{U}(1)}, \tag{A1}$$

and third, six-dimensional orbits isomorphic to the complex flag space $\mathbb{F}^3$

$$\mathcal{O}=\frac{\mathrm{SU}(3)}{\mathrm{U}(1)\times\mathrm{U}(1)}. \tag{A2}$$

(3) $G=\mathrm{SU}(n)$. Here, in addition to the trivial zero-dimensional orbit, we have orbits isomorphic to the complex projective space $\mathbb{C}P^{n-1}$,

$$\mathcal{O}=\frac{\mathrm{SU}(n)}{\mathrm{SU}(n-1)\times\mathrm{U}(1)}\sim\mathbb{C}P^{n-1}. \tag{A3}$$

There are also orbits isomorphic to the complex Grassmannians $\mathbb{C}G_{m,n}$,

$$\mathcal{O}=\frac{\mathrm{SU}(m+n)}{\mathrm{SU}(m)\times\mathrm{SU}(n)\times\mathrm{U}(1)}\sim\mathbb{C}G_{m,n}, \tag{A4}$$

and finally the generic maximal orbits are isomorphic to the complex flag manifold $\mathbb{F}^n$,

$$\mathcal{O}=\frac{\mathrm{SU}(n)}{\mathrm{U}(1)\times\mathrm{U}(1)\times\cdots\times\mathrm{U}(1)}\sim\mathbb{F}^n. \tag{A5}$$

(4) For compact simple Lie algebras, the coadjoint orbits of minimal nonzero dimension were investigated in Ref. 23, and are given in the following table:

G		$\dim\mathcal{O}_{\min}$	H
A_n	$\mathrm{SU}(n+1)$	$2n$	$A_{n-1}\times\mathrm{U}(1)$
B_n	$\mathrm{SO}(2n+1)$	$2(2n-1)$	$B_{n-1}\times\mathrm{SO}(2)$
C_n	$\mathrm{Sp}(n)$	$2(2n-2)$	$C_{n-1}\times\mathrm{U}(1)$
$D_n, n\neq 2$	$\mathrm{SO}(2n)$	$2(2n-2)$	$D_{n-1}\times\mathrm{SO}(2)$
G_2		10	$A_1\times\mathrm{SO}(2)$
F_4		30	$C_3\times\mathrm{SO}(2)$
E_6		32	$D_5\times\mathrm{SO}(2)$
E_7		54	$E_6\times\mathrm{SO}(2)$
E_8		114	$E_7\times\mathrm{SO}(2)$

1. Kernels for some Hermitian symmetric spaces

In this section we give the explicit expressions[24] for kernels of the Hermitian symmetric spaces of classical type, either compact or noncompact (bounded symmetric domains). They belong to four families, which in the Cartan notation are $A_{\mathrm{III}}, C_{\mathrm{I}}, D_{\mathrm{III}}$ and $BD_{\mathrm{I}}(q=2)$.[22] There are two further exceptional Hermitian symmetric spaces, $E_{\mathrm{III}}, E_{\mathrm{VII}}$ related to exceptional Lie algebras.

A_{III}**c**:

For the complex Grasmannians $\mathbb{C}G_{p,q}$ of p-planes in $\mathbb{C}^{p+q}$:

$$X=\mathrm{SU}(p+q)/(\mathrm{SU}(p)\otimes\mathrm{SU}(q)\otimes\mathrm{U}(1)),\quad p\geqslant q, \tag{A6}$$

in terms of the pq complex coordinates arranged in a rectangular $p\times q$ complex matrix Z:

$$K(z,\overline{w})=\det(I^{(p)}+ZW^{\dagger}). \tag{A7}$$

A_{III}**nc**:

The noncompact Cartan duals of the complex Grassmannians are the spaces:

$$X=\mathrm{SU}(p,q)/(\mathrm{SU}(p)\otimes\mathrm{SU}(q)\otimes\mathrm{U}(1)),\quad p\geqslant q, \tag{A8}$$

which can be realized as the bounded domain $I^{(p)}-ZZ^{\dagger}\geqslant 0$ with Z as above; its kernel is

$$K(z,\overline{w})=\det(I^{(p)}-ZW^{\dagger}). \tag{A9}$$

$C_{\mathrm{I}}\mathbf{c}$:

For the manifold of Lagrangian p-spaces in $\mathbb{C}^{2p}$, which is the compact symmetric Hermitian space,

$$X=\mathrm{Sp}(p)/\mathrm{U}(p), \tag{A10}$$

the kernel is given in terms of $p(p+1)/2$ complex coordinates arranged in a $p\times p$ complex symmetric matrix Z as

$$K(z,\overline{w})=\det(I^{(p)}+ZW^{\dagger}). \tag{A11}$$

$C_{\mathrm{I}}\mathbf{nc}$:

The Cartan dual to the previous space:

$$X=\mathrm{Sp}(2p,\mathbb{R})/\mathrm{U}(p) \tag{A12}$$

can be realized as the bounded domain $I^{(p)}-ZZ^{\dagger}\geqslant 0$ in terms of the coordinate matrix Z as above; its kernel is

$$K(z,\overline{w})=\det(I^{(p)}-ZW^{\dagger}). \tag{A13}$$

$D_{\mathrm{III}}\mathbf{c}$:

The kernel for the compact Hermitian symmetric space:

$$X=\mathrm{SO}(2p)/\mathrm{U}(p) \tag{A14}$$

is given in terms of $p(p-1)/2$ complex coordinates arranged in a rectangular $p\times p$ complex skew-symmetric matrix Z as

$$K(z,\overline{w})=\det(I^{(p)}+ZW^{\dagger}). \tag{A15}$$

$D_{\mathrm{III}}\mathbf{nc}$:

For the noncompact Cartan dual space:

$$X=\mathrm{SO}^{*}(2p)/\mathrm{U}(p) \tag{A16}$$

realized as the bounded domain $I^{(p)}-ZZ^{\dagger}\geqslant 0$ in terms of the coordinates Z as above, the kernel is

$$K(z,\overline{w})=\det(I^{(p)}-ZW^{\dagger}). \tag{A17}$$

$BD_{\mathrm{I}}\mathbf{c}$:

The real Grasmannian $\mathbb{R}G_{2,p}$ of 2-planes in $\mathbb{R}^{p+2}$:

$$X=\mathrm{SO}(p+2)/(\mathrm{SO}(p)\otimes\mathrm{SO}(2)). \tag{A18}$$

In terms of p complex coordinates arranged as a $p\times 1$ row complex vector $\mathbf{z}$, with $\mathbf{z}'$ denoting the transpose $1\times p$ column complex vector, then

$$K(z,\overline{w})=1+(\mathbf{z}\cdot\mathbf{z}')(\overline{\mathbf{w}}\cdot\overline{\mathbf{w}}')+2(\mathbf{z}\cdot\overline{\mathbf{w}}'). \tag{A19}$$

BD_{I}**nc**:
The noncompact dual space:

$$X=\mathrm{SO}(p,2)/(\mathrm{SO}(p)\otimes\mathrm{SO}(2)) \tag{A20}$$

can be realized as the bounded domain

$$|\mathbf{z}\cdot\mathbf{z}'|<1, \quad 1+|\mathbf{z}\cdot\mathbf{z}'|^2-2\overline{\mathbf{z}}\cdot\mathbf{z}'>0, \tag{A21}$$

where the p complex coordinates are arranged as a $p\times 1$ row complex vector $\mathbf{z}$, as above; the kernel is

$$K(z,\overline{w})=1+(\mathbf{z}\cdot\mathbf{z}')(\overline{\mathbf{w}}\cdot\overline{\mathbf{w}}')-2(\mathbf{z}\cdot\overline{\mathbf{w}}'). \tag{A22}$$

The two exceptional Hermitian symmetric spaces can be dealt with similarly, by using 3×3 octonionic matrices, as discussed by Hirzebruch.[25]

2. Topology of orbits

Orbits of a coadjoint representation of compact Lie groups are compact simply connected manifolds; this follows from the exact homotopy sequence. They have a nontrivial second homotopy group $\pi_2(X)$ because they are compact symplectic manifolds. Further information on their topology may be found, for example, in the review.[9]

Let $P_X(t)=\Sigma_{j=0}^{N} b_j t^j$ be the Poincaré polynomial of manifold X, b_j being the Betti numbers of the manifold X of dimension N. In our case $X=G/H$, where H is some compact semisimple subgroup of G, and rank $H=$rank $G=r$. In this case, the Hirsch formula (see Ref. 9) is valid

$$P_X(t)=\frac{\Pi_{j=1}^{r}(1-t^{2n_j})}{\Pi_{j=1}^{r}(1-t^{2m_j})}, \tag{A23}$$

where n_j and m_j are the degrees of basic invariants of the Weyl group W of the groups G and H (see Ref. 26). Let us give a few applications of this formula. We have

(i) For the complex projective space:

$$X=\mathbb{C}P^n, \quad P_X(t)=P_n(t)\equiv 1+t^2+t^4+\cdots+t^{2n}. \tag{A24}$$

(ii) For the complex flag manifold $\mathbb{F}^n$:

$$X=\mathbb{F}^n=\frac{\mathrm{SU}(n)}{U(1)\times\cdots\times U(1)}, \quad P_X(t)=P_1(t)P_2(t)\cdots P_{n-1}(t), \tag{A25}$$

where the polynomial $P_n(t)$ was defined above.

(iii) An example of a real Grassmannian $\mathbb{R}G_{3,2}$:

$$X=\frac{\mathrm{SO}(5)}{\mathrm{SO}(3)\times\mathrm{SO}(2)}, \quad P_X(t)=P_3(t). \tag{A26}$$

(iv) An example of a real "flag-like" manifold:

$$X=\frac{\mathrm{SO}(5)}{\mathrm{SO}(2)\times\mathrm{SO}(2)}, \quad P_X=P_1(t)P_3(t). \tag{A27}$$

(v) For the minimal orbits of the coadjoint representation of G_2,

$$X=\frac{G_2}{\mathrm{SU}(2)\times\mathrm{U}(1)}, \quad P_X=P_5(t). \tag{A28}$$

(vi) For the octonionic "flag-like" coadjoint orbit of G_2:

$$X=\frac{G_2}{U(1)\times U(1)},\quad P_X=\frac{(1-t^4)(1-t^{12})}{(1-t^2)(1-t^2)}=P_1(t)P_5(t). \tag{A29}$$

(vii) For the complex Grassmann manifolds $\mathbb{C}G_{m,n}$

$$X=\mathbb{C}G_{m,n}=\frac{\mathrm{SU}(m+n)}{\mathrm{SU}(m)\times\mathrm{SU}(n)\times\mathrm{U}(1)}, \tag{A30}$$

$$P_X=\frac{(1-t^4)\cdots(1-t^{2(m+n)})}{(1-t^2)[(1-t^4)\cdots(1-t^{2m})][(1-t^4)\cdots(1-t^{2n})]}. \tag{A31}$$

For example, for the lowest dimensional complex Grassmann manifold, $\mathbb{C}G_{2,2}$, we have

$$X=\mathbb{C}G_{2,2}=\frac{\mathrm{SU}(4)}{\mathrm{SU}(2)\times\mathrm{SU}(2)\times\mathrm{U}(1)}, \tag{A32}$$

$$P_X=\frac{(1-t^6)(1-t^8)}{(1-t^2)(1-t^4)}=(1+t^4)(1+t^2+t^4)=1+t^2+2t^4+t^6+t^8. \tag{A33}$$

(viii) For the octonionic Cayley plane,

$$X=\frac{F_4}{C_3\times\mathrm{SO}(2)},\quad P_X=\frac{(1-t^{16})(1-t^{24})}{(1-t^2)(1-t^8)}, \tag{A34}$$

$$P_X=(1+t^8)(1+t^2+t^4+\cdots+t^{22})=1+t^2+t^4+\cdots+2t^8+2t^{10}+\cdots+2t^{22}+t^{24}+\cdots+t^{30}.$$

APPENDIX B: COHERENT STATES

As discussed in Sec. II, we consider here classical Hamiltonian systems which correspond to quantum systems of a special type for which the quantum properties are expressed simply in terms of classical ones.

Let (X,ω) be a compact simply connected symplectic manifold on which the semisimple compact Lie group G act transitively.

As it was shown by Borel,[19] this class of manifolds coincides with the class of orbits of a coadjoint or (what is equivalent) adjoint representation of the compact semisimple Lie group G. These manifolds are Kähler homogeneous manifolds, and have even dimension. This means that they admit a Hermitian G-invariant metric, as given in (3.1), whose imaginary part is a closed 2-form given in (3.2). Both are determined by a single function $F(z,\overline{z})$, called the potential of the Kähler metric, which may be found from the Gauss decomposition of the group G.

The G-invariant Hermitian metric (and the G-invariant symplectic structure) on the orbits of coadjoint actions is not uniquely determined. The most general ones are a linear combination of a number r of basic metrics or symplectic forms, the number r being equal to the rank of the manifold.

Let us recall now the construction of unitary irreducible representations of simple compact Lie groups G of rank r. Such representation is characterized by an r-dimensional vector $\lambda=(\lambda_1,\ldots,\lambda_r)$—the so-called highest weight: $T(g)=T^{\lambda}(g)$, where $\lambda=\Sigma\lambda_j w_j$, w_j are the fundamental weights and λ_j are non-negative integers.

Correspondingly, in the representation space $\mathcal{H}^{\lambda}$, there exists a vector (the highest vector) $|\lambda\rangle$ satisfying the conditions

$$\hat{E}_{\alpha}|\lambda\rangle=0,\quad \alpha\in R_+,\quad \hat{H}_j|\lambda\rangle=\lambda_j|\lambda\rangle, \tag{B1}$$

where $\hat{E}_{\alpha}$ and $\hat{H}_j$ are operators in $\mathcal{H}^{\lambda}$ which represent the Chevalley basis for $\mathcal{G}^C$.

In the space $\mathcal{H}^{\lambda}$, there exists a basis $\{|\mu\rangle\}$, where μ is a weight vector, i.e., an eigenvector of all operators H_j:

$$H_j|\mu\rangle=\mu_j|\mu\rangle. \tag{B2}$$

A general representation $T^{\lambda}(g)$ characterized by the highest weight $\lambda=(\lambda_1,\ldots,\lambda_r)$ corresponds to a fiber bundle over $X=G/H=G^{C}/B_{+}=X_{-}$, with the circle as a fiber, with connection and curvature forms:

$$\theta^{\lambda}=\frac{1}{2i}\left(\frac{\partial F^{\lambda}}{\partial z_{\mu}}dz_{\mu}-\frac{\partial F^{\lambda}}{\partial \overline{z}_{\mu}}d\overline{z}_{\mu}\right),\quad \omega^{\lambda}=\frac{1}{2i}\frac{\partial^2 F^{\lambda}}{\partial z_{\mu}\partial \overline{z}_{\nu}}dz_{\mu}\wedge\partial\overline{z}_{\nu}=d\theta^{\lambda}, \tag{B3}$$

where $F=\Sigma_l \lambda_l F^l$, $l=1,2,\ldots,r$. The representation $T^{\lambda}(g)$ with the highest weight λ may be realized in the space of polynomials $\mathcal{F}^{\lambda}$ over X_{-}. Namely,

$$T^{\lambda}(g)f(z)=\alpha_{\lambda}(z,g)f(z_g), \tag{B4}$$

where the quantities $\alpha_{\lambda}(z,g)$ and z_g may be found from the Gaussian decomposition

$$zg=\zeta_1 h_1 z_1, \tag{B5}$$

$$z_g=z_1,\quad \alpha_{\lambda}(z,g)=\delta_1^{\lambda_1}\cdots\delta_r^{\lambda_r}. \tag{B6}$$

The invariant scalar product $\mathcal{F}^{\lambda}$ is introduced by the formulas

$$(f_1,f_2)=d_{\lambda}\int \overline{f_1}(z)f_2(z)d\mu_{\lambda}(z), \tag{B7}$$

where d_{λ} is the dimension of the representation T^{λ}. In this case we have

$$T^{\lambda}(g)f(z)=\exp[iS^{\lambda}(z,g)]f(z_g), \tag{B8}$$

where

$$S^{\lambda}(z,g)=\int_0^z(\theta^{\lambda}-g_{*}\cdot\theta^{\lambda})+S^{\lambda}(0,g), \tag{B9}$$

and the Kähler potential is

$$F^{\lambda}=\sum \lambda_l F_l^{\lambda}(z,\overline{z})=-\ln\langle\lambda|T^{\lambda}(zz^{+})|\lambda\rangle, \tag{B10}$$

which determines after (B3) the connection θ^{λ} and curvature ω^{λ} forms in the fiber bundle with base X, a circle as a fiber, and related to the representation $T^{\lambda}(g)$.

A similar construction works also for degenerate representations for which the highest weight λ is singular, i.e., $(\lambda,\alpha)=0$ for one or several roots α. Then the *isotropy* subgroup $\tilde{B}$ of a vector $|\psi_0\rangle$ is one of the so-called parabolic subgroups. This means that $\tilde{B}$ contains the Borel subgroup B, i.e., the maximal solvable subgroup. The coset space $X=G^{C}/\tilde{B}$ is the degenerate orbit of the coadjoint representation, but this space is still the homogeneous Kähler manifold.[19] Hence the construction considered above is valid completely also in this case.

Following Refs. 6–8, let us now construct the coherent state (hereafter CS) systems for an arbitrary compact Lie group.

To this aim one has to take an initial vector $|0\rangle$ in the space $\mathcal{H}^{\lambda}$. Note first of all that the isotropy subgroup H_{μ} for any state $|\mu\rangle$ corresponding to weight vector μ contains the Cartan subgroup $H=\mathrm{U}(1)\times\cdots\times\mathrm{U}(1)=T^r$, where r is the number of $\mathrm{U}(1)$ factors entering in H, and is called the rank of group G. For generic weight vectors subgroup H_{μ} coincides with H.

In general, the isotropy subgroup for a linear combination of weight vector is a subgroup of the Cartan subgroup. Therefore it is convenient to choose a weight vector $|\mu\rangle$ as an initial element of the CS system. In the general case, the isotropy subgroup H_μ is isomorphic to the Cartan subgroup H, and a CS is characterized by a point of $X=G/H$.

For the degenerate representation, where the highest weight λ is orthogonal to some root $\alpha:(\lambda,\alpha)=0$, the isotropy subgroup H_μ may be larger than T^r for some state vector $|\mu\rangle$. Then any CS $|x\rangle$ is characterized by a point of a degenerate orbit of the adjoint representation. Indeed, in all cases,

$$H_j'|x\rangle=[T(g)H_jT^{-1}(g)]|x\rangle=\mu_j|x\rangle, \quad |x\rangle=T(g)|\mu\rangle. \tag{B11}$$

Therefore if we take a state vector $|\mu\rangle$ as the initial vector $|0\rangle$, then the coherent state $|x\rangle$ is characterized by a point of an orbit of adjoint representation, and the orbit may be degenerate.

Now suppose that $T^\lambda(g)$ is a nondegenerate representation of the compact Lie group G with the highest weight λ, i.e., $(\lambda,\alpha)\neq 0$ for any $\alpha\in R$. We take the vector with the lowest weight $|-\lambda\rangle$ as the initial vector $|0\rangle$ for the CS system. Let us consider the action on this state of operators H_j, E_α, and $E_{-\alpha}(\alpha\in R_+)$ representing the Lie algebra $\mathcal{G}^C$. One can see that subalgebra $\mathcal{B}_-=\{H_j,E_{-\alpha}\},\alpha\in R_+$ is the isotropy subalgebra for the vector $|\lambda\rangle$. The corresponding group B_- is a subgroup of G^C.

Taking the lowest weight vector $|\lambda\rangle$ as $|0\rangle$, applying operators $T^\lambda(g)$ and using the Gaussian decomposition $g=\zeta hz$, with $\zeta\in Z_+$, we obtain the CS system

$$|\zeta\rangle=NT^\lambda(\zeta)|0\rangle=N\exp\left(\sum_{\alpha\in R_+}\zeta_\alpha E_\alpha\right)|0\rangle, \quad N=\langle 0|T^\lambda(g)|0\rangle, \tag{B12}$$

or in another form

$$|\zeta\rangle=D(\xi)|0\rangle, \quad D(\xi)=\exp\left[\sum\ (\xi_\alpha E_\alpha-\overline{\xi}_\alpha E_{-\alpha})\right]. \tag{B13}$$

Note that the unitary operators $D(\xi)$ do not form a group but their multiplication law is

$$D(\xi_1)D(\xi_2)=D(\xi_3)\exp\left(i\sum_j\ \varphi_jH_j\right). \tag{B14}$$

Note also that these CS are eigenstates of operators

$$T(g)H_jT^{-1}(g)=\tilde{H}_j, \quad \tilde{H}_j|x\rangle=-\lambda_j|x\rangle. \tag{B15}$$

The last equations determine the CS up to a phase factor $\exp(i\alpha)$. The constructed CS system has all properties of a general CS system. Some of the most important ones are noted below.

(1) Operators $T^\lambda(g)$ transform one CS into another,

$$T^\lambda(g)|x\rangle=\exp(i\phi_\lambda(x,g))|x_g\rangle, \tag{B16}$$

where $\phi_\lambda(x,g)$ is a phase shift.

(2) CS are not mutually orthogonal. The scalar product is

$$\langle\zeta_1|\zeta_2\rangle=N_1N_2\langle 0|T^+(\zeta_1)T(\zeta_2)|0\rangle=N_1N_2\langle 0|T(\zeta_1^+\zeta_2)|0\rangle=K_\lambda(\zeta_1^+\zeta_2)[K_\lambda(\zeta_1^+\zeta_1)K_\lambda(\zeta_2^+\zeta_2)]^{-1/2}, \tag{B17}$$

where

$$K_\lambda(\zeta_1^+\zeta_2)=\Delta_1^{\lambda_1}(\zeta_1^+\zeta_2)\cdots\Delta_r^{\lambda r}(\zeta_1^+\zeta_2)$$

and quantities Δ_j may be found from the Gaussian decomposition. For the group $G=\mathrm{SU}(n)$, $G^C=\mathrm{SL}(n,\mathbb{C})$, the quantity Δ_j is the lower angular minor of order j of the matrix $\zeta_1^+\zeta_2$.

A physical system showing a classical (deterministic) behavior to an observer can appear to be a quantum system to another observer unable to distinguish between some distinct states. © *2001 American Institute of Physics.*
[DOI: 10.1063/1.1402957]

I. INTRODUCTION

Summary 1: Quantum mechanics is a very precise and powerful physical theory but is accompanied with the negative hypothesis that the measuring process can have only an essentially statistical, nondeterministic character.

It is hard to believe that in the future this assumption will not be overcome or reduced in some way by new experiments or new theories: it does not seem there is any conclusive reason to exclude it.

But is a theory conceivable where the outcomes of the measurements are uniquely defined and the statistical previsions of quantum mechanics exactly respected?

From a mathematical viewpoint it is not difficult to produce an object with these properties. More difficult would be to justify in physical terms the artificial construction we propose; however, we give a general argument showing how the interplay between the classical and quantum mechanics we offer is interpretable as the difference between an imaginary very expert observer and another nonexpert observer compelled to confuse different states or different observables.

The main goal of this article is precisely to give a rigorous meaning to this interplay and a proof that the general quantum system, with all its states and observables, can be obtained from some classical system.

We cannot offer any physical representation for this classical system; we confine here proving that besides the well known theorems concerning the impossibility of hidden variables (Refs. 1 and 2) there is also room for a result in favor of the possibility.

All this is made inside the usual descriptions of the standard quantum physical systems via quantum logic (Refs. 3–5, etc.) and, except for the requirement of hidden variables, does not refer to any nonorthodoxical physical theory.

II. REDUCTION

Definition 2: A (model for a) **classical physical system** is a couple $(S,\mathcal{L})$ of a set S (the **set of pure states**) and a family $\mathcal{L}$ of subets of S (the family of **propositions** of S) distinguishing the elements of S (that is for every couple of different states there is a proposition in $\mathcal{L}$ not containing both of them).

Every L in $\mathcal{L}$ represents the subset where a proposition (an observable taking only the value 0 and 1) is true.

The hypothesis that $\mathcal{L}$ distinguishes the elements of S is made to simplify the situation; we can always suppose this hypothesis verified because otherwise we pass to consider as states the classes of the following equivalence relation: two elements of S are equivalent if every time a proposition contains one of them it contains them both.

a)Electronic mail: cassa@alpha.science.unitn.it

Example 3: Usually $\mathcal{L}$, in the classical case, is the set of all parts of S or the set of all measurable Borel subset of a Borel family.

We are not going to make any restriction on the family $\mathcal{L}$.

Definition 4: An **observable** for a classical system $(S,\mathcal{L})$ is a function $f:S\to\mathbf{R}$ such that for every Borel subset B in the Borel family $\mathcal{B}(\mathbf{R})$ of $\mathbf{R}$ the inverse image $f^{-1}(B)$ is in $\mathcal{L}$.

Example 5: In particular the characteristic functions of the subsets L in $\mathcal{L}$ are observable functions.

Let us denote by $\mathcal{F}$ the set of all the observable functions of the system $(S,\mathcal{L})$.

Remark 6: If f is an observable function of $(S,\mathcal{L})$ and $g:\mathbf{R}\to\mathbf{R}$ is a Borel function, the function $g\circ f:S\to\mathbf{R}$ is an observable. In fact, for every Borel subset B the set $(g\circ f)^{-1}(B)=f^{-1}(g^{-1}(B))$ is in $\mathcal{L}$.

These definitions are given to idealize the situation of an observer (that we will call the precise observer) able to prepare with extreme precision a physical system in a variety of different (pure) states and to perform on the system several measures in such a way that when he prepares the state s and performs the observable f he can get the exact value $f(s)$. Our observer knows all the time and exactly what state is preparating and what observable is performing.

To have a more precise idea of this kind of situation let us suppose that the precise observer has a very huge and efficient laboratory where he can prepare every sort of state of the physical system under consideration and use every sort of measuring apparatus: all he has to do is to give to the laboratory's computer a ''string'' specifying completely and exactly the state to prepare and another ''string'' specifying the observable to measure and the fantastic laboratory does all the work.

The observer checks that given a ''state string'' and an ''observable string'' he always gets the same value and so he can state with certainty that the physical system considered is classical (deterministic).

Let us consider now another observer (that we will call the imprecise observer) studying the same physical system but with a poorer ability; this second observer can produce all the states and observables of the previous one but he does not know exactly what he makes: he gives a ''procedure'' to produce a certain state and another ''procedure'' to produce the measuring apparatus but if he repeats the given procedures he can get different values in a random and, for him, unavoidable way.

Let us suppose, moreover, that the precise observer can describe precisely what the problem is with the imprecise observer: when this second one chooses a ''procedure'' he produces a state among several different ones in a given class of equivalence of S with a certain probability: there is an equivalence relation (the **confusion** relation) $\mathcal{R}$ on the classical system $(S,\mathcal{L})$ and a probability measure μ_p on every equivalence class p in the quotient set $P=S/\mathcal{R}$. When the imprecise observer tries to prepare the system with a given procedure p he does not know which one of the states in the class $p=[s]$ he is really preparing, therefore when he evaluates the observable f he can get any one of the values in the subset $f([s])$. Making several trials he experiments all these values with different frequencies arriving in the end at the conclusion that the measure of the observable f on the ''preparation'' p has a statistical character and that he cannot get anything more that the probability $\pi(f,p,B)$ that the measure of f on p lies in the Borel subset B of $\mathbf{R}$.

For the precise observer it is obvious that

$$\pi(f,p,B)=\mu_p(f^{-1}(B)\cap p).$$

If the imprecise observer is left unaware of his ''confusion'' and convinced that he cannot get any more information on the system, he will decide, coherently, not to distinguish between preparations or measuring apparatuses giving the same probabilities. Therefore, he will define the following concept:

Definition 7: A (model for a) **statistical physical system** is a triple $(P,\mathcal{O},\pi)$ of a set P (the set of statisical **states**), another set $\mathcal{O}$ (the set of statistical **observables**) and a function:

$\pi:\mathcal{O}\times\mathcal{P}\times\mathcal{B}(\mathbf{R})\to[0,1]$ (the **probability** that the measure of an observable on a state lies in a Borel subset of $\mathbf{R}$) such that

(1) $\pi(T',p,B)=\pi(T'',p,B)$ for every p in P and B in $\mathcal{B}(\mathbf{R})$ implies $T'=T''$ and
(2) $\pi(T,p',B)=\pi(T,p'',B)$ for every T in $\mathcal{O}$ and B in $\mathcal{B}(\mathbf{r})$ implies $p'=p''$.

From the viewpoint of the precise observer this means that two states s' and s'' are equivalent in the equivalence relation of confusion if and only if

$$\mu_{[s']}(f^{-1}(B)\cap[s'])=\mu_{[s'']}(f^{-1}(B)\cap[s''])$$

for every f in $\mathcal{F}$ and every B in $\mathcal{B}(\mathbf{R})$.

Moreover, the precise observer makes a discovery: the imprecise observer confuses not only the states but also the observables.

The set of statistical observables $\mathcal{O}$ is the quotient set of $\mathcal{F}$ modulo the equivalence relation stating that two functions f' and f'' of $\mathcal{F}$ are equivalent if

$$\mu_{[s]}(f'^{-1}(B)\cap[s])=\mu_{[s]}(f''^{-1}(B)\cap[s])$$

for every s in S and every B in $\mathcal{B}(\mathbf{R})$.

Therefore, the precise observer can give the following:

Definition 8: A **confusion** relation for a classical system $(S,\mathcal{L})$ is given assigning an equivalence relation $\mathcal{R}$ on S and a probability measure μ_p on every equivalence class in such a way that for every couple of inequivalent elements s' and s'' in S there exists a proposition L in $\mathcal{L}$ with $\mu_{[s']}(L\cap[s'])\neq\mu_{[s'']}(L\cap[s''])$.

It is clear that for every confusion relation $\mathcal{R}$ there is also defined an equivalence relation $\mathcal{M}$ on the set $\mathcal{F}$ of observable functions by taking $f'\mathcal{M}f''$ if

$$\mu_{[s]}(f'^{-1}(B)\cap[s])=\mu_{[s]}(f''^{-1}(B)\cap[s])$$

for every s in S and every B in $\mathcal{B}(\mathbf{R})$.

Therefore a statistical system is well defined by taking

(1) $\hat{S}=S/\mathcal{R}$,
(2) $\hat{\mathcal{F}}=\mathcal{F}/\mathcal{M}$,
(3) $\hat{\mu}:\hat{\mathcal{F}}\times\hat{S}\times\mathcal{B}(\mathbf{R})\to[0,1]$ given by $\hat{\mu}([f],[s],B)=\mu_{[s]}(f^{-1}(B)\cap[s])$.

Definition 9: Given a classical system $(S,\mathcal{L})$ and a confusion relation $(\mathcal{R},\{\mu_p\}_{p\in S/\mathcal{R}})$, the statistical system $(\mathcal{F}/\mathcal{M},\mathcal{S}/\mathcal{R},\hat{\mu})$ is called the **system reduced** by the confusion relation.

Remark 10: We call the procedure given above the reduction just because we pass from a state space to another making a quotient along (essentially) one-dimensional fibers as when we reduce a contact manifold producing a symplectic manifold.

When a statistical system can be obtained as a reduced system of a classical system there is at least a mathematical reason to talk of **hidden variables** (the ''variables'' describing the elements in each equivalence class of the state set of the classical system): under every statistical state $p=[s]$ are ''hidden'' the elements of $[s]$, the ''true states.''

It is possible to make precise this assertion considering the following (Ref. 6, p. 262):

Definition 11: Let $(\mathcal{O},P,\pi)$ be a statistical system. A **model for a system with hidden variables with respect to** $(\mathcal{O},P,\pi)$ is given assigning

(1) a set S (the **space of hidden states**) a surjective map $\rho:S\to P$ (associating to a ''hidden state'' its ''apparent state'');

(2) for each ''apparent'' state $p\in P$ a probability measure μ_p on S (representing the probability to find in a measurable subset of S a ''hidden state'' representing p); and

(3) for each observable $T \in \mathcal{O}$ a function $f_T : S \to \mathbf{R}$ (representing a classical observable giving the values that appear randomly for the statistical observable T) such that for every Borel subset B of $\mathbf{R}$:

$$\pi(T,p,B) = \mu_p(f_T^{-1}(B))$$

(that is the probability that the value of T on p lies in B is given by the probability to find a hidden state of p between the states where the observable f_T takes a value in B).

In fact, in the case of a reduced system, we can take as $\rho : S \to P$ the quotient map and for every p in P as probability measure μ_p, the measure μ_p seen as a measure on all S and not only on $\rho^{-1}(p)$.

We are going to prove that the general quantum system (given by a Hilbert space) is a reduced system of a classical system.

This kind of property is sometimes considered impossible to be proved or in contradiction with the principles of the standard quantum mechanics.

On the contrary, the same property can be considered ''well known'' and quite obvious: if you want a ''hidden variable'' function giving the right statistical outcomes for a self-adjoint operator T of the Hilbert space $\mathbf{H}$ simply take the ''quasi-inverse'' function $f : \mathbf{P}(\mathbf{H}) \times]0,1[\to \mathbf{R}$ (cf. the proof of the following theorem) defined by

$$f([h],t) = sup\{u : \langle E^T_{]-\infty,u]} \rangle_h \geqslant t\}.$$

It seems that all depends on what you mean. In this section we have just tried to suggest a plausible interpretation that can save determinism in observations.

III. THE QUANTUM SYSTEM AS A REDUCED SYSTEM

Definition 12: The (model) for the (irreducible) **quantum system** is given assigning:

(1) the (complex) projective space $\mathbf{P}(\mathbf{H})$ of a Hilbert space $\mathbf{H}$ (of dimension at least two) as state space;

(2) the set $SA(\mathbf{H})$ of self-adjoint operators on $\mathbf{H}$ as observable space; and

(3) the function $\pi : SA(\mathbf{H}) \times \mathbf{P}(\mathbf{H}) \times \mathcal{B}(\mathbf{R}) \to [0,1]$ defined by

$$\boldsymbol{\pi}(T,[h],B) = \langle E^T_B \rangle_h = \frac{\langle h, E^T_B(h) \rangle}{\langle h,h \rangle}$$

(where $E^T_B = \chi_B \circ T$ is the projector operator associated to the Borel subset B of $\mathbf{R}$ in the spectral measure of T) as probability function.

Theorem 13: The quantum system is the reduced system of a classical system.

Proof: For every $[h]$ in $\mathbf{P}(\mathbf{H})$ let us consider a complete separable metric space $S_{[h]}$ with a Borel measure $\mu_{[h]}$ such that $\mu_{[h]}(S_{[h]}) = 1$ and $\mu_{[h]}(\{s\}) = 0$ for every s in $S_{[h]}$. For every such space there is a measurable map $\phi_{[h]} : S_{[h]} \to]0,1[$ such that $\phi_{[h]*}(\mu_{[h]}) = \lambda$, where λ denotes the Lebesgue measure on the interval (cf. Ref. 7, Theorem 9, p. 327).

Let S be the disjoint union of the $\{S_{[h]}\}_{[h] \in \mathbf{P}(\mathbf{H})}$. We will call a subset L of S a proposition if $L \cap S_{[h]}$ is a measurable set for every $[h]$ in $\mathbf{P}(\mathbf{H})$ and if there exists a projector E of $\mathbf{H}$ such that $\mu_{[h]}(L \cap S_{[h]}) = \langle E \rangle_h$ for every $[h]$ in $\mathbf{P}(\mathbf{H})$.

Let $\mathcal{L}$ be the set of all propositions in S.

Every proposition L determines the set of all $[h]$ where $\mu_{[h]}(L \cap S_{[h]}) = 1$ and therefore the projector E. If we denote by $\mathcal{E}$ the set of all projectors of $\mathbf{H}$, it is a map $\varepsilon : \mathcal{L} \to \mathcal{E}$ associating to a proposition its projector is well defined.

The map ε is surjective; fixed E is enough to take in $S_{[h]}$ a measurable subset $L_{[h]}$ such that $\mu_{[h]}(L_{[h]} \cap S_{[h]}) = \langle E \rangle_h$ and then take L as the disjoint union of all the $L_{[h]}$. It is not difficult to prove, in a similar way, that the propositions distinguish the elements in S.

Let us denote by $\mathcal{F}$, as usual, the set of all observable functions for $(S,\mathcal{L})$; we want to prove that to each of these functions f is associated a self-adjoint operator T such that

$$\mu_{[h]}(f^{-1}(B)\cap S_{[h]})=\langle E_B^T\rangle_h$$

for every $[h]$ in $\mathbf{P}(\mathbf{H})$ and B in $\mathcal{B}(\mathbf{R})$.

For every real number t the proposition $L_t=f^{-1}(]-\infty,t])$ determines a projector E_t. The family $\{E_t\}_{t\in\mathbf{R}}$ is a spectral family of projectors of $\mathbf{H}$ [cf. Ref. 8, Definition (7.11), p. 180]; in fact, $\langle E_t\rangle_h= =(f|_{S_{[h]}*}\mu_{[h]})(]-\infty,t])$ for every h and therefore the monotonicity, the left-continuity and the convergence to 0 and 1 properties for the projection operators follow from the analogous properties of cumulative distribution functions for Borel probabilitity measures (cf. Ref. 7, Lemma 10, p. 262).

Hence the spectral family $\{E_t\}_{t\in\mathbf{R}}$ defines a self-adjoint operator T such that for every t in $\mathbf{R}$,

$$\mu_{[h]}(f^{-1}(]-\infty,t])\cap S_{[h]})=\langle E^T_{]-\infty,t]}\rangle_h,$$

and therefore for every Borel subset B of $\mathbf{R}$,

$$\mu_{[h]}(f^{-1}(B)\cap S_{[h]})=\langle E_B^T\rangle_h.$$

The operator T is unambiguously defined by the function f. Let us denote by $\tau:\mathcal{F}\to SA(\mathbf{H})$ the map so defined. Let us prove this map is surjective.

For every $[h]$ let us denote by $F_{[h]}:\mathbf{R}\to]0,1[$ the distribution function $F_{[h]}(u)=\langle E^T_{]-\infty,u]}\rangle_h$; its induced Borel measure $\nu_{F_{[h]}}$ has the property that $\nu_{F_{[h]}}(B)=\langle E_B^T\rangle_h$ for every Borel subset B.

Its quasi-inverse $\widetilde{F_{[h]}}:]0,1[\to\mathbf{R}$ verifies $\widetilde{F_{[h]}}_*(\lambda)=\nu_{F_{[h]}}$ (cf. Ref. 9, Theorem 4, p. 94) and therefore $(\widetilde{F_{[h]}}\circ\phi_{[h]*}(\mu_{[h]})=\nu_{F_{[h]}}$, that is,

$$(\widetilde{F_{[h]}}\circ\phi_{[h]*}(\mu_{[h]})(]a,b=F_{[h]}(b)-F_{[h]}(a)=\langle E^T_{]a,b]}\rangle_h$$

for every $a<b$ in $\mathbf{R}$.

The function $f:S\to\mathbf{R}$ defined by $f(s)=\widetilde{F_{[h]}}(\phi_{[h]}(s))$ (where $[h]$ contains s) has the desired property: $\tau(f)=T$.

Let us prove that the reduced system of $(S,\mathcal{L})$ is the quantum system. Two elements r in $[h]$ and s in $[k]$ are equivalent if and only if $\mu_{[h]}(L\cap S_{[h]})=\mu_{[k]}(L\cap S_{[k]})$ for every proposition L, therefore, if and only if $\langle E\rangle_h=\langle E\rangle_k$ for every projector E of $\mathbf{H}$, that is, if and only if $[h]=[k]$.

Two functions f and g in $\mathcal{L}$ are equivalent if and only if $\langle E_B^{\tau(f)}\rangle_h=\langle E_B^{\tau(g)}\rangle_h$ for every h and B. This means $E_B^{\tau(f)}=E_B^{\tau(g)}$ for every B, that is, $\tau(f)=\tau(g)$. In the end, $\hat{\mu}([f],[h],B)=\mu_{[h]}(f^{-1}(B)\cap S_{[h]})=\langle E_B^{\tau(f)}\rangle_h=\pi(\tau(f),[h],B)$. ■

From now on we will denote by $(S,\mathcal{L})$ a classical system giving the (irreducible) quantum system as reduction, by $\mathcal{F}$ its set of observable functions and by $\rho:S\to\mathbf{P}(\mathbf{H})$, $\tau:\mathcal{F}\to SA(\mathbf{H})$ and $\varepsilon:\mathcal{L}\to\mathcal{E}$ the quotient maps.

Remark 14: If L is in $\mathcal{L}$, then also $(S\backslash L)$ is in $\mathcal{L}$ and $\varepsilon(S\backslash L)=I-\varepsilon(L)$.

Remark 15: If T is a self-adjoint operator with spectral measure $\{B\mapsto E_B\}$ and $g:\mathbf{R}\to\mathbf{R}$ is a Borel function, then a self-adjoint operator $g(T)$ with spectral measure $\{B\mapsto E_{g^{-1}(B)}\}$ is well defined.

Theorem 16: *If f is an observable function of a classical system $(S,\mathcal{L})$ reducing to the quantum system and $g:\mathbf{R}\to\mathbf{R}$ is any Borel function, it holds $\tau(g\circ f)=g(\tau(f))$.*

Proof: The function f gives the operator $\tau(f)=T$ with spectral measure $\{B\mapsto E_B=\varepsilon(f^{-1}(B))\}$. The observable function $g\circ f$ defines the spectral measure $\{B\mapsto\varepsilon(f^{-1}(g^{-1}(B)))\}$ and this is exactly the spectral measure of $g(T)$. ■

Theorem 17: *If f is an observable function of a classical system $(S,\mathcal{L})$ reducing to the quantum system and $g:\mathbf{R}\to\mathbf{R}$ is any Borel function, it holds*

(1) $\langle g(\tau(f))\rangle_h=\int_0^1 g(f([h],t))\cdot d\lambda(t)$,
(2) $\langle \tau(f)\rangle_h=\int_0^1 f([h],t)\cdot d\lambda(t)$.

Proof: The point (2) follows from (1) taking $g=id_{\mathbf{R}}$. Let us prove (1):

$$\langle g(\tau(f))\rangle_h=\int_{\mathbf{R}} g(u)\cdot d\nu_{\langle E^{\tau(f)}_{]-\infty,.]}\rangle_h}=\int_{\mathbf{R}} g(u)\cdot(df_{[h]*}\lambda_{]0,1[})=\int_{]0,1[} g(u)\circ f_{[h]}\cdot d\lambda,$$

cf. Ref. 8, Theorem 7.14(e) and Ref. 9, Corollary 3, p. 93 for the passages. ■

Theorem 18: *Given two projectors E and F, if there exist two propositions L and M in $\mathcal{L}$ such that*

(1) the (finite) Boolean algebra of subsets $\mathcal{A}$ generated by L and M is contained in $\mathcal{L}$ and
(2) the map $\varepsilon:\mathcal{A}\to\mathcal{E}$ sends L in E, M in F transforming the operation $\wedge$ in $\cap$, $\vee$ in $\cup$ and the complementation in the orthogonality,

then the projectors E and F are compatible (that is commute).

Proof: The union $L\cup M=L\cup(\mathsf{C}L\cap M)=M\cup(\mathsf{C}M\cap L)$ belongs to L and

$$\varepsilon(L\cup M)=E\vee F=\varepsilon(L\cup(\mathsf{C}L\cap M))=E\vee(E'\wedge F)=\varepsilon(M\cup(\mathsf{C}M\cap L))=F\vee(F'\wedge E).$$

This proves that E and F are compatible (cf. Ref. 4, Problem 2 of 5–8, p. 87). ■

Remark 19: Therefore, whenever you consider two noncommuting projectors E and F it is impossible to find two propositions L and M with the properties (1) and (2) of the previous theorem.

Definition 20: Let E_1,E_2 and F_1,F_2 be two couples of projectors in $\mathcal{E}$. We will say that the couples **admit proposition intersections** if there are two couples of propositions A_1,A_2 and B_1,B_2 with $\varepsilon(A_i)=E_i$ and $\varepsilon(B_j)=F_j$ for $i,j=1,2$ and such that the 16 intersections $A_i\cap B_j$, $\mathsf{C}A_i\cap B_j$, $A_i\cap\mathsf{C}B_j$, $\mathsf{C}A_i\cap\mathsf{C}B_j$ are all in $\mathcal{L}$ and $\varepsilon(A_i\cap B_j)=E_i\wedge F_j$, $\varepsilon(\mathsf{C}A_i\cap B_j)=(I-E_i)\wedge F_j$, $\varepsilon(A_i\cap\mathsf{C}B_j)=E_i\wedge(I-F_j)$, and $\varepsilon(\mathsf{C}A_i\cap\mathsf{C}B_j)=(I-E_i)\wedge(I-F_j)$.

Notation 21: In this situation we will consider the self-adjoint operators

$$\begin{aligned}T_{ij}(E,F)&=E_i\wedge F_j+(I-E_i)\wedge(I-F_j)-(I-E_i)\wedge F_j-E_i\wedge(I-F_j)\\&=\varepsilon(A_i\cap B_j)+\varepsilon(\mathsf{C}A_i\cap\mathsf{C}B_j)-\varepsilon(\mathsf{C}A_i\cap B_j)-\varepsilon(A_i\cap\mathsf{C}B_j).\end{aligned}$$

Theorem 22: *If E_1,E_2 and F_1,F_2 are two couples of projectors in $\mathcal{E}$ admitting proposition intersections, then for every h in $\mathbf{H}\backslash\{0\}$ it holds the inequality*

$$|\langle T_{11}(E,F)\rangle_h-\langle T_{12}(E,F)\rangle_h|+|\langle T_{21}(E,F)\rangle_h+\langle T_{22}(E,F)\rangle_h|\leqslant 2.$$

Proof: The functions: $f_{ij}=\chi_{A_i\cap B_j}+\chi_{(S\backslash A_i)\cap(S\backslash B_j)}-\chi_{(S\backslash A_i)\cap B_j}-\chi_{A_i\cap(S\backslash B_j)}$ are functions on S with $\int_0^1 f_{ij}([h],t)\cdot d\lambda(t)=\langle T_{ij}(E,F)\rangle_h$. It is not difficult to check in S the following equality: $|f_{11}-f_{12}|+|f_{21}+f_{22}|=2$.

Therefore,

$$\begin{aligned}&|\langle T_{11}(E,F)\rangle_h-\langle T_{12}(E,F)\rangle_h|+|\langle T_{21}(E,F)\rangle_h+\langle T_{22}(E,F)\rangle_h|\\&\quad=\left|\int_0^1 f_{11}([h],t)\cdot d\lambda(t)-\int_0^1 f_{12}([h],t)\cdot d\lambda(t)\right|+\left|\int_0^1 f_{21}([h],t)\cdot d\lambda(t)+\int_0^1 f_{22}([h],t)\cdot d\lambda(t)\right|\\&\quad\leqslant\int_0^1(|f_{11}-f_{12}|+|f_{21}+f_{22}|)([h],t)\cdot d\lambda(t)=2.\end{aligned}$$

■

Remark 23: The proof of the previous theorem mimics the usual one given to prove one of the Bell inequalities and, in fact, if you take in a quantum system two couples of projections not verifying the Bell inequality for some state, you have two couples of projections not admitting proposition intersections.

Problem 24: When we have two couples of projections not admitting proposition intersections we can consider the system as the reduction of a classical system and replace the projectors E_1, E_2, F_1, F_2 with some propositions A_1, A_2, B_1, B_2, but we do not dispose of for example, the proposition $A_1 \cap B_1$ (or this intersection does not correspond to the projector $E_1 \wedge F_1$).

The absence of $A_1 \cap B_1$ is in contrast with the possibility, considered natural in a classical physical theory, to check ''in the same time'' two properties of a system.

This is undoubtly strange and uncomfortable; however, if we take seriously the hypothesis of the precise observer, any objection to this eventuality cannot be considered definitive unless expressed in terms of his physics: in other words, we should be able first to know his description of the physical reality and how he can explain, for example, a possible absence of intersections.

Existence of multivortex solutions in the self-dual Chern–Simons–Higgs theory in a background metric

Kwangseok Choe[a)]
School of Mathematical Sciences, Seoul National University, Seoul 151-747, Korea

(Received 13 September 2000; accepted for publication 23 July 2001)

In this paper we show the existence of the multiple multivortex solutions of the self-duality equations of $(2+1)$ dimensional Chern–Simons–Higgs model in a background metric of the form $g_{\mu\nu}=\mathrm{diag}(1,-b(x),-b(x))$ with $b(x)=O(|x|^{-l})$ as $|x|\to\infty$ for some $l>2$. © *2001 American Institute of Physics.*

I. INTRODUCTION

The first Abelian Chern–Simons–Higgs model in the $(2+1)$ dimensional gauge theory was obtained by Hong, Kim, and Pac,[1] and Jackiw and Weinberg[2] independently. In Ref. 3, Schiff reformulated the Chern–Simons–Higgs model in the background metric of the form $g_{\mu\nu}=\mathrm{diag}(1,-b,-b)$, $b=b(x^1,x^2)$, and obtained self-dual equations by choosing the same Higgs potential as that of Refs. 1 and 2.

The Lagrangian in Schiff's theory is given by (after a rescaling of constants)

$$\mathcal{L}=\frac{\kappa}{4\sqrt{g}}\epsilon^{\mu\nu\rho}F_{\mu\nu}A_\rho+g^{\mu\nu}(D_\mu\phi)(D_\nu\phi)^*-\frac{1}{\kappa^2}|\phi|^2(1-|\phi|^2)^2,$$

where $A=A_\mu\,\mathrm{d}x^\mu$ is a gauge field, $F_{\mu\nu}=\partial_\mu A_\nu-\partial_\nu A_\mu$ is its curvature tensor, $D_\mu=\partial_\mu-iA_\mu$ is the gauge covariant derivative, ϕ is a complex scalar field called the Higgs field, $\epsilon^{\mu\nu\rho}$ is a totally skew-symmetric tensor with $\epsilon^{012}=1$, $\kappa>0$ is a Chern–Simons coupling constant, and $g_{\mu\nu}=\mathrm{diag}(1,-b,-b)$ is a background metric.

The corresponding Euler–Lagrange equations are

$$\begin{aligned}&\frac{\kappa}{2\sqrt{g}}\epsilon^{\mu\nu\rho}F_{\mu\nu}=J^\rho,\quad J^\rho=ig^{\mu\rho}(\phi(D_\mu\phi)^*-\phi^*(D_\mu\phi)),\\&D_\mu(\sqrt{g}g^{\mu\nu}D_\nu\phi)=-\frac{1}{\kappa^2}\sqrt{g}(|\phi|^2-1)(3|\phi|^2-1)\phi.\end{aligned}\tag{1.1}$$

.

We seek the static solution of (1.1), i.e., A_μ and ϕ are functions of (x^1,x^2) only. If $\rho=0$, we obtain a Chern–Simons Gauss law

$$\kappa F_{12}=-2bA_0|\phi|^2.\tag{1.2}$$

Let Φ be the total magnetic flux and Q be the electric charge,

$$\Phi=\int \mathrm{d}^2x F_{12},\quad Q=\int \mathrm{d}^2x\sqrt{g}J^0.$$

Taking (1.2) into account, $Q=\kappa\Phi$. The energy-momentum tensor $T_{\mu\nu}$ is given by

a)Electronic mail: kschoe@math.snu.ac.kr

$$T_{\mu\nu}=(D_\mu\phi)(D_\nu\phi)^*+(D_\mu\phi)^*(D_\nu\phi)-g_{\mu\nu}g^{\alpha\beta}(D_\alpha\phi)(D_\beta\phi)^*+g_{\mu\nu}\frac{1}{\kappa^2}|\phi|^2(1-|\phi|^2)^2.$$

If we assume that $|\phi D_1\phi|+|\phi D_2\phi|=o(|x|^{-1})$ as $|x|\to\infty$, the energy is given by

$$\begin{aligned}E&=\int d^2x\sqrt{g}\,T_{00}=\int d^2x\left(b|D_0\phi|^2+|D_1\phi|^2+|D_2\phi|^2+\frac{1}{\kappa^2}b|\phi|^2(1-|\phi|^2)^2\right)\\&=\int d^2x\left\{\left|\frac{\kappa F_{12}}{2\sqrt{b}|\phi|}\right|\pm\frac{\sqrt{b}}{\kappa}|\phi|(|\phi|^2-1)\right|^2+|D_1\phi\pm iD_2\phi|^2\Bigg\}\pm\int d^2xF_{12}\\&\geqslant\pm\int d^2xF_{12}.\end{aligned}$$

Without loss of generality we may assume that the conserved quantity $\int d^2xF_{12}$ is non-negative, so we choose the upper sign. Then the minimun is saturated if and only if (A,ϕ) satisfy the following self-duality equations:

$$\begin{aligned}D_1\phi+iD_2\phi&=0,\\F_{12}+\frac{2}{\kappa^2}b|\phi|^2(|\phi|^2-1)&=0.\end{aligned}\tag{1.3}$$

When $b\equiv1$, the energy density T_{00} implies that the finite energy solution of (1.2) and (1.3) satisfies either $\phi\to0$ (nontopological solution) or $|\phi|\to1$ (topological solution) as $|x|\to\infty$. For the nontopological solution, Spruck and Yang[4] obtained a radially symmetric N-vortex solution (A,ϕ) with

$$|\phi(x)|^2=O(|x|^{-(2N+4+\beta)})\quad\text{as}\quad|x|\to\infty\tag{1.4}$$

for some constant $\beta>0$. In Ref. 5, Chen *et al.* showed that for every $\beta\in(0,\infty)$, (1.3) admits a radially symmetric N-vortex solution satisfying (1.4). Recently, Chae and Imanuvilov[6] showed that for arbitrary N-vortices, there is a constant $\beta_0>0$ such that for each $\beta\in(0,\beta_0)$, the system (1.2)–(1.3) admits a solution with the decay (1.4).

For the system with $b\equiv1$ and the periodic boundary condition, Caffarelli and Yang[7] showed there is a critical value κ_c such that the system (1.3) admits a maximal solution if $0<\kappa<\kappa_c$. Later, Tarantello[8] showed that if $\kappa=\kappa_c$ (1.3) admits a solution and if $\kappa<\kappa_c$ (1.3) admits a ''mountain pass'' type solution different from the maximal one. Furthermore, she gave the asymptotic behavior of the second solution as $\kappa\to0$ when $N=1$.

When b is non-negative, Hölder continuous, and $b(x)=O(|x|^{-l})$ as $|x|\to\infty$ for some $l>2$, Kurata[9] showed that if $0\leqslant N\leqslant1$ then for each $2(N-2)<\alpha<\min\{0,l-4\}$ there exists a solution of (1.3) such that $|\phi(x)|^2=O(|x|^\alpha)$ as $|x|\to\infty$. He considered a variational formulation in the weighted space introduced in Ref. 10 and used the Moser–Trudinger inequality, which restricted the values of N and α.

In this paper, we show that the values of N and α in Ref. 9 can be extended. We use the supersubsolution method to show that for each $N\geqslant0$ and $\alpha\leqslant0$, (1.3) admits a maximal solution (A,ϕ) such that $|\phi|=O(|x|^\alpha)$ as $|x|\to\infty$. More precisely, we have

Theorem 1.1: *Suppose that b is non-negative, Hölder continuous, $b(0)>0$ and $b(x)=O(|x|^{-l})$ for some $l>2$ as $|x|\to\infty$. For $\alpha\leqslant0$ and $p_1,\ldots,p_N\in\mathbb{R}^2$, there exists a critical value*

$$\kappa_\alpha\in\left(0,\sqrt{\frac{\int b\,dx}{2\pi(2N-\alpha)}}\right)$$

such that for $0<\kappa\leqslant\kappa_\alpha$ *the system (1.2)–(1.3) admits a solution* (A_κ,ϕ_κ) *with the following properties:*

(i) The zeros of ϕ_κ *are* $p_1,\cdots,p_N$.

(ii) (A_κ,ϕ_κ) *satisfies the decay estimates*

$$|\phi_\kappa|^2=O(|x|^\alpha),\quad F_{12}=O(|x|^{-l+\alpha})\quad as\ \ |x|\to\infty.$$

Moreover, if $\alpha<0$ *then* $|D_1\phi_\kappa|^2+|D_2\phi_\kappa|^2=O(|x|^{-2+\alpha})$ *as* $|x|\to\infty$ *and if* $\alpha=0$ *then* $|D_1\phi_\kappa|^2+|D_2\phi_\kappa|^2=O(|x|^{-2-2t})$ *for every* $t<\min\{l-2,1\}$ *as* $|x|\to\infty$.

(iii) The energy, the magnetic flux, and the electric charge are given by

$$E=\Phi=\pi(2N-\alpha),\quad Q=\pi\kappa(2N-\alpha).$$

(iv) (A_κ,ϕ_κ) *is maximal in the sense that* $|\phi_\kappa|$ *takes the largest possible value among the solutions of (1.2)–(1.3) with the same zero set.*

(v) If $b>0$ *then* $|\phi_\kappa|\to1$ *pointwise a.e. and* $\partial_1A_2^{(\kappa)}-\partial_2A_1^{(\kappa)}\to2\pi\Sigma_{j=1}^N\delta_{p_j}$ *in the measure sense as* $\kappa\to0$.

Furthermore, if $N-\alpha>0$ *and* $0<\kappa<\kappa_\alpha$, *there exists a second solution* $(\tilde A_\kappa,\tilde\phi_\kappa)$ *of (1.2)–(1.3) such that* $|\tilde\phi_\kappa|<|\phi_\kappa|$ *in* $\mathbb{R}^2\backslash\{p_1,\cdots,p_N\}$.

Theorem 1.1 is our main result. This theorem will be proved with the help of a reduction of (1.3) to a single elliptic equation. Following Jaffe and Taubes,[11] we find that the set of zeros of ϕ is discrete. Furthermore, for any set $Z(\phi)=\{p_1,\ldots,p_N\}$ of zeros of ϕ, the system (1.3) reduces to a single elliptic equation

$$\Delta u=\frac{4}{\kappa^2}be^u(e^u-1)+4\pi\sum_{i=1}^N\delta_{p_i}\tag{1.5}$$

with unknown $u=\ln|\phi|^2$. Conversely if u is a solution of (1.5), then the solution (A,ϕ) is recovered by

$$\phi(x)=\exp\left(\frac{1}{2}u(x)+i\sum_{j=1}^N\arg(x-p_j)\right),$$

$$A_1=-\operatorname{Re}(2i\partial^*\ln\phi),\quad A_2=-\operatorname{Im}(2i\partial^*\ln\phi),\tag{1.6}$$

$$A_0=\frac{1}{\kappa}(|\phi|^2-1),$$

where $\partial^*=(\partial_1+i\partial_2)/2$.

Let us define some background functions

$$u_0(x)=\sum_{j=1}^N\ln\left(\frac{|x-p_j|^2}{1+|x-p_j|^2}\right),\quad w_0(x)=\sum_{j=1}^N\ln(1+|x-p_j|^2),$$

$$u_\alpha(x)=\ln(1+|x|^2)^{\alpha/2},\quad \alpha\in\mathbb{R}.$$

Set $\lambda=4/\kappa^2$ and $v=u-u_0-u_\alpha$. Then v satisfies

$$\Delta v=\lambda bU_\alpha e^v(U_\alpha e^v-1)+f_\alpha,\tag{1.7}$$

where $U_\alpha=e^{u_0+u_\alpha}$ and $f_\alpha=\Delta(w_0-u_\alpha)$.

Equation (1.7) is the main equation to study in this paper. We shall establish the following:

Proposition 1.1: Suppose that $b\geqslant0$, $b(0)>0$, $b\in C^\nu_{\rm loc}$, *and* $b(x)=O(|x|^{-l})$ *as* $|x|\to\infty$ *for some* $l>2$. *For* $\alpha\leqslant0$ *and* $p_1,\ldots,p_N\in\mathbb{R}^2$, *there is a constant* $\lambda_\alpha\geqslant8\pi(2N-\alpha)/\int b\,dx$ *such that:*

(i) If $\lambda>\lambda_\alpha$ *then (1.7) has a maximal bounded solution and if* $\lambda<\lambda_\alpha$ *then (1.7) has no nontrivial bounded solution. If* $\lambda=\lambda_\alpha$ *then (1.7) has a bounded solution* v_*.

(ii) If $N-\alpha>0$ *and* $\lambda>\lambda_\alpha$ *then (1.7) has at least two bounded solutions* v_2 *and* $\overline{v}_{\lambda,\alpha}$ *such that* $\overline{v}_{\lambda,\alpha}$ *is maximal and* $v_2<\overline{v}_{\lambda,\alpha}$.

Furthermore, for each $t<\min\{1,l-2-\alpha\}$ *and a bounded solution* v *of (1.7), there exists a constant* C *such that*

$$\|(1+|x|^2)^{(t+1)/2}\nabla v\|_{L^\infty(\mathbb{R}^2)}\leqslant C. \tag{1.8}$$

Proposition 1.2: Suppose that b *is positive. The maximal bounded solution* $\overline{v}_{\lambda,\alpha}$ *of (1.7) satisfies*

(i) $\overline{v}_{\lambda,\alpha}\to -u_0-u_\alpha$ *a.e. in* $\mathbb{R}^2$ *as* $\lambda\to\infty$.

(ii) $\lambda b U_\alpha e^{\overline{v}_{\lambda,\alpha}}(1-U_\alpha e^{\overline{v}_{\lambda,\alpha}})\to 4\pi\Sigma_{j=1}^N\delta_{p_j}$ *in the measure sense as* $\lambda\to\infty$.

(iii) $\|u_0+u_\alpha+\overline{v}_{\lambda,\alpha}\|_{C^{2,\nu}(\Omega)}\to 0$ *as* $\lambda\to\infty$ *for any compact domain* $\Omega\subset\mathbb{R}^2\setminus\{p_1,\ldots,p_N\}$. *In fact, there exist positive constants* $c_j=c_j(\Omega)$, $j=1,2$ *such that*

$$\|u_0+u_\alpha+\overline{v}_{\lambda,\alpha}\|_{C^{2,\nu}(\Omega)}\leqslant c_1 e^{-c_2\sqrt{\lambda}}. \tag{1.9}$$

The proof of Proposition 1.1 is mainly based on the supersubsolution method and the variational method used in Ref. 8.

For a bounded solution $v_{\lambda,\alpha}$ of (1.7), the pair (A_μ,ϕ) defined as (1.6) with $u=u_0+u_\alpha+v_{\lambda,\alpha}$ gives rise to a solution of (1.2)–(1.3) such that

$$\begin{aligned}|\phi|^2&=e^u=O(|x|^\alpha),\\ F_{12}&=\frac{\lambda}{2}be^u(1-e^u)=O(|x|^{-l+\alpha})\quad\text{as } |x|\to\infty.\end{aligned} \tag{1.10}$$

Furthermore if $\alpha<0$ then

$$|D_1\phi|^2+|D_2\phi|^2=\tfrac{1}{2}e^u|\nabla u|^2=O(|x|^{-2+\alpha})\quad\text{as } |x|\to\infty \tag{1.11}$$

and if $\alpha=0$ then

$$|D_1\phi|^2+|D_2\phi|^2=O(|x|^{-2-2t})\quad\text{as } |x|\to\infty \tag{1.12}$$

for every $t<\min\{1,l-2\}$. Moreover, in view of (1.3), (1.8) and (1.10)–(1.12), the energy is finite and given by

$$E=\int_{\mathbb{R}^2}\frac{\lambda}{2}be^u(1-e^u)\,dx=\lim_{R\to\infty}\int_{|x|=R}\frac{1}{2}\frac{\partial}{\partial\nu}(w_0-u_\alpha-v_{\lambda,\alpha})d\sigma=\pi(2N-\alpha),$$

where $\partial/\partial\nu$ denotes the outward normal derivative.

Thus we conclude that Theorem 1.1 is an immediate consequence of Propositions 1.1 and 1.2. In Sec. II we will prove Propositions 1.1 and 1.2 in several steps.

II. PROOF OF THEOREM 1.1

We recall some results about weighted space $M^2_{s,\delta}$ which is the closure of $C_0^\infty(\mathbb{R}^2)$ with respect to the norm

$$\|\phi\|_{M^2_{s,\delta}}=\sum_{|\alpha|\leqslant s}\|\sigma^{(\delta+|\alpha|)}\partial_x^\alpha\phi\|_{L^2},$$

where $\sigma(x)=(1+|x|^2)^{1/2}$, s is a non-negative integer, $\delta\in\mathbb{R}$, and $\phi\in C_0^\infty(\mathbb{R}^2)$. $M^2_{s,\delta}$ has the following properties.

Lemma 2.1:

McOwen—Refs. 12 and 10.

(a) $M^2_{s',\delta'}\subset M^2_{s,\delta}$ *if* $s'\geqslant s$ *and* $\delta'\geqslant\delta$. *If* $s'>s$ *and* $\delta'>\delta$, *the inclusion is compact.*

(b) If $-1<\delta<0$ *then the Laplacian* Δ, $\Delta: M^2_{2,\delta}\to M^2_{0,\delta+2}$ *is an injection with closed range* $\{f\in M^2_{0,\delta+2}\,|\int_{\mathbb{R}^2} f=0\}$, *and* $\|u\|_{M^2_{2,\delta}}\leqslant C\|\Delta u\|_{M^2_{0,\delta+2}}$ *with* C *independent of* u.

Cantor—Ref. 13:

(c) For any $\delta,l\in\mathbb{R}$, *the map* $f\mapsto f\sigma^l$ *is a continuous map from* $M^2_{2,\delta}$ *into* $M^2_{2,\delta-l}$.

(d) Let $s>1$ *and* $\delta<1$. *There is a constant* $C>0$ *such that* $\|f\sigma^\delta\|_{L^\infty}\leqslant C\|f\|_{M^2_{s,0}}$ *for all* $f\in C_0^\infty$. *Therefore, if* $\delta>-1$ *and* $f\in M^2_{2,\delta}$ *then* $\|f\sigma^\beta\|_{L^\infty}\leqslant C\|f\|_{M^2_{2,\delta}}$ *for* $\beta<1+\delta$.

With the help of the function space $M^2_{s,\delta}$, we present the asymptotic behavior at infinity of the bounded solution of (1.7).

Lemma 2.2: Suppose $l>2$, $\alpha\leqslant 0$ *and* $v\in C^2_{loc}$ *is a solution of (1.7).*

(i) If $bU_\alpha e^v(U_\alpha e^v-1)$ *belongs to* $M^2_{0,\delta+2}$ *for some* $\delta\in(-1,0)$, *there exist constants* β *and* v_∞ *such that* v *satisfies the asymptotic behavior*

$$v(x)=\beta\ln|x|+v_\infty+o(|x|^\gamma)\quad\text{as}\quad|x|\to\infty \tag{2.1}$$

for every $\gamma>-1-\delta$ *and*

$$\int_{\mathbb{R}^2} bU_\alpha e^v(1-U_\alpha e^v)\,dx=\frac{2\pi}{\lambda}(2N-\alpha-\beta).$$

(ii) Suppose that $u:=u_0+u_\alpha+v$ *is bounded above. If* $\alpha<0$ *then* $u<0$. *If* $\alpha=0$ *and* $N>0$ *then* $u<0$ *and* $\lim_{|x|\to\infty}u(x)<0$.

Remark: It follows from Lemma 2.2 that if (1.7) admits a nontrivial bounded solution then necessarily $\lambda>8\pi(2N-\alpha)/\int b\,dx$.

Proof of Lemma 2.2: Define

$$\beta=\frac{1}{2\pi}\int_{\mathbb{R}^2}\lambda bU_\alpha e^v(U_\alpha e^v-1)\,dx+2N-\alpha.$$

Then Lemma 2.1 implies that there exists $w\in M^2_{2,\delta}\subset C_0(\mathbb{R}^2)$ such that

$$\Delta w=\lambda bU_\alpha e^v(U_\alpha e^v-1)+f_{\alpha+\beta},$$

where $f_{\alpha+\beta}=f_\alpha-\Delta u_\beta$, $u_\beta(x)=\ln(1+|x|^2)^{\beta/2}$.

Then $v=u_\beta+w+h$ for some harmonic function h. Since $bU_\alpha e^v(U_\alpha e^v-1)$ belongs to $M^2_{0,\delta+2}$, h must be constant. The decay estimate of w is an immediate consequence of lemma 2.1. This proves (i).

(ii) can be proved from maximum principle and we will prove only the second part of (ii). For sufficiently large $R>0$, choose a smooth function $\psi>0$ such that $\psi\equiv 1$ for $|x|<R$, $\psi\equiv 0$ for $|x|>2R$, and $\|\nabla\psi\|_{L^\infty}\leqslant 2/R$. Then we obtain

$$0\leqslant\int_{\mathbb{R}^2}u^+\psi\Delta u\,dx=-\int_{\mathbb{R}^2}\psi|\nabla u^+|^2\,dx-\int_{R\leqslant|x|\leqslant 2R}u^+\nabla\psi\cdot\nabla u\,dx,$$

where $u^+=\max\{u,0\}$. Lemma 2.1 (i) implies that there are constants $\beta\leqslant 0$ and v_∞ such that

$$u=u_0+u_\beta+\xi+v_\infty,$$

where $\xi\in M^2_{2,\delta}$ for some $-1<\delta<0$. Without loss of generality, we may assume that $\beta=0$. Then

$$\left|\int_{R\leqslant|x|\leqslant 2R} u^+\nabla\psi\cdot\nabla u\,dx\right| \leqslant C\int_{R\leqslant|x|\leqslant 2R}|x|^{-2-\delta}u^+|\nabla\xi||x|^{1+\delta}\,dx + CR^{-2}$$

$$\leqslant C_\delta R^{-1-\delta}(1+\|u^+\|_{L^\infty}\|\xi\|_{M^2_{2,\delta}}).$$

Letting $R\to\infty$, we obtain $u^+\equiv 0$, which implies that $u<0$.

Suppose that $\lim_{|x|\to\infty}u(x)=0$. Fix a constant $\gamma\in(\max\{-1,-l+2\},0)$ and introduce a comparison function $w=C_0|x|^{\gamma/2}$.

There exists an $R>0$ such that

$$\Delta(u+w)=\lambda b e^u(e^u-1)+\frac{\gamma^2}{4}|x|^{-2}w\geqslant\lambda b(u+w)\quad\text{for } |x|>R.$$

It follows from maximum principle that $u+w\leqslant(u+w)|_{|x|=R}<0$ for $|x|>R$ if C_0 is sufficiently small. But this leads to a contradiction since $u(x)=o(|x|^\gamma)$ as $|x|\to\infty$ from (i). □

We now construct a supersolution of (1.7). Consider the following:

$$\Delta v=\lambda b(U_\alpha e^v-1)+f_\alpha. \tag{2.2}$$

It is easily seen that the bounded solution of (2.2) is a supersolution of (1.7). Moreover it follows from maximum principle that every bounded solution v of (2.2) satisfies that $U_\alpha e^v<1$ in $\mathbb{R}^2$.

Lemma 2.3: For each $\alpha<l-2$, there is a constant $\beta_0\geqslant 0$ such that if $\lambda>\beta_0$ then Eq. (2.2) has a unique bounded solution $v^+_{\lambda,\alpha}\in C^{2,\nu}_{\text{loc}}$ with the following properties:

(i) $v^+_{\lambda,\alpha_1}+u_{\alpha_1}>v^+_{\lambda,\alpha_2}+u_{\alpha_2}$ if $\alpha_2<\alpha_1<l-2$.

(ii) For each λ, $v^+_{\lambda,\beta}\to v^+_{\lambda,\alpha}$ uniformly on any bounded domain as $\beta\to\alpha$. Moreover, if $\alpha\leqslant 0$ then

(iii) $v^+_{\lambda,\alpha}>v^+_{\mu,\alpha}$ if $\lambda>\mu$.

(iv) If $v_{\lambda,\alpha}$ is a bounded solution of (1.7), then $v_{\lambda,\alpha}<v^+_{\lambda,\alpha}$.

The proof of Lemma 2.3 is based on the following theorem and maximum principle.

Theorem 2.2:

McOwen—Ref. 12. If $K\leqslant 0$ in $\mathbb{R}^2$, $K(0)<0$ and $K(x)\geqslant -C|x|^{-l}$ near ∞ for some constant $l>2$, then for every $0<\beta<l-2$, there exists a solution u of

$$\Delta u+Ke^u=0\quad\text{in } \mathbb{R}^2 \tag{2.3}$$

and a constant u_∞ such that

$$u(x)=\beta\ln|x|+u_\infty+O(|x|^\gamma)\quad\text{as } |x|\to\infty \tag{2.4}$$

for every $\gamma>\max\{-1,2-l+\beta\}$.

Cheng and Ni—Ref. 14. For each $0<\beta<l-2$, (2.3) possesses a unique solution u satisfying (2.4).

In view of Theorem 2.2 we can prove Lemma 2.3.

Proof of Lemma 2.3: Define

$$\beta_0=\max\left\{0,\frac{2\pi(2N-\alpha)}{\int_{\mathbb{R}^2}b(y)dy}\right\}$$

and assume that $\lambda>\beta_0$. Define a function h by

$$h(x)=\frac{1}{2\pi}\int_{\mathbb{R}^2}\ln|x-y|\,b(y)\,dy.$$

Let $\gamma=-2N+(\lambda/2\pi)\int_{\mathbb{R}^2}b$. Since h satisfies the asymptotic behavior

$$h(x)=\left(\frac{1}{2\pi}\int_{\mathbb{R}^2} b(y)dy\right)\ln|x|+O(1) \quad \text{as } |x|\to\infty,$$

the function defined by $K_\lambda=\lambda b U_\alpha e^{w_0-u_\alpha-\lambda h}$ satisfies the decay estimate

$$K_\lambda(x)=O(|x|^{-(l+\gamma)}) \quad \text{as } |x|\to\infty.$$

Since $l+\gamma>2$, theorem 2.2 implies that

$$\Delta u-K_\lambda e^u=0 \quad \text{in } \mathbb{R}^2$$

has a unique solution $\tilde{u}$ such that

$$\tilde{u}(x)=(\gamma+\alpha)\ln|x|+u_\infty+o(1) \quad \text{as } |x|\to\infty$$

for some constant u_∞. Then $v^+_{\lambda,\alpha}=\tilde{u}+w_0-u_\alpha-\lambda h$ is the unique bounded solution of (2.2) and elliptic regularity estimate implies that $v^+_{\lambda,\alpha}\in C^{2,\nu}_{\text{loc}}$.

Let $w^+_{\lambda,\alpha}=v^+_{\lambda,\alpha}+u_\alpha$. Then $w^+_{\lambda,\alpha}$ satisfies

$$\Delta w^+_{\lambda,\alpha}=\lambda b(e^{u_0+w^+_{\lambda,\alpha}}-1)+\Delta w_0 \quad \text{in } \mathbb{R}^2. \tag{2.5}$$

It follows from maximum principle that $w^+_{\lambda,\alpha}>w^+_{\lambda,\beta}$ for $\alpha>\beta$, which proves (i).

We can prove (ii) from standard diagonal process and Rellich theorem. Indeed, for any sequence $\{\beta_n\}$ converging to α, Sobolev embedding theorem and Schauder estimates imply that $\|w^+_{\lambda,\beta_n}\|_{C^{2,\nu}(\bar{\Omega})}\leqslant C(\alpha,\Omega)$ for any bounded domain Ω. Then there exists a subsequence $\{w^1_n\}$ of $\{w^+_{\lambda,\beta_n}\}$ and $w^1\in C^2(\overline{B_1(0)})$ such that w^1_n converges to w^1 in $C^2(\overline{B_1(0)})$.

Any sequence $\{w^i_n\}\subset C^2(\overline{B_i(0)})$ converging to $w^i\in C^2(\overline{B_i(0)})$ contains a subsequence $\{w^{i+1}_n\}$ converging to $w^{i+1}\in C^2(\overline{B_{i+1}(0)})$. Rellich theorem implies that $w^i=w^{i+1}$ in $B_i(0)$ for all $i\geqslant 1$.

For $x\in B_N(0)$, define $w_*(x)=w^N(x)$. Then w_* is a well-defined C^2-solution of Eq. (1.7). As shown implicitly in Lemma 2.2, every bounded solution of (2.2) satisfies (2.1) with $\beta=0$ and $\gamma>\max\{-1,-l+2\}$. Then it is easily seen from (i) that w_* satisfies

$$w_*(x)=\alpha\ln|x|+O(1) \quad \text{near } \infty,$$

and w^+_{λ,β_n} converges to w_* uniformly on any bounded domain. Since $\{\beta_n\}$ is arbitrary and the bounded solution of (2.2) is unique, we obtain (ii).

Note that $U_\alpha e^{v^+_{\lambda,\alpha}}<1$ for $\alpha\leqslant 0$. Then it follows from maximum principle that $w^+_{\lambda,\alpha_1}>w^+_{\mu,\alpha_2}$ if $\lambda>\mu$ and $\alpha_2<\alpha_1\leqslant 0$. Then (iii) is an immediate consequence of (ii) and maximum principle.

Suppose that $\alpha\leqslant 0$ and $v_{\lambda,\alpha}$ is any bounded solution of Eq. (1.7). Let $w_{\lambda,\alpha}=v_{\lambda,\alpha}+u_\alpha$ and choose a $\beta\in(\alpha,l-2)$. Since

$$\Delta(w_{\lambda,\alpha}-w^+_{\lambda,\beta})\geqslant\lambda b e^{u_0}(e^{w_{\lambda,\alpha}}-e^{w^+_{\lambda,\beta}}) \quad \text{in } \mathbb{R}^2,$$

$$(w_{\lambda,\alpha}-w^+_{\lambda,\beta})(x)<0 \quad \text{if } |x| \text{ is sufficiently large,}$$

maximum principle implies that $w_{\lambda,\alpha}<w^+_{\lambda,\beta}$ in $\mathbb{R}^2$. Then (ii) and maximum principle imply (iv).□

We now construct a subsolution of (1.7) for each $\alpha\leqslant 0$. Choose a smooth function ρ_α and an open set Ω such that $(\text{supp}\,\rho_\alpha)\subset\Omega\subset(\text{supp}\,b)\setminus\{p_1,\ldots,p_N\}$ and $\int_{\mathbb{R}^2}(f_\alpha-\rho_\alpha)=0$. Let v^- be a bounded solution of

$$\Delta v=f_\alpha-\rho_\alpha \quad \text{in } \mathbb{R}^2. \tag{2.6}$$

Since the bounded solution of (2.6) is unique up to an additive constant, we can choose v^- so that

$$U_\alpha e^{v^-} \leqslant 1/2, \quad v^- < v^+_{\mu,\alpha} \quad \text{for some} \quad \mu > \beta_0 = \frac{2\pi(2N-\alpha)}{\int_{\mathbb{R}^2} b\, dx}.$$

Then

$$bU_\alpha e^{v^-}(U_\alpha e^{v^-} - 1) \leqslant C_0 < 0 \quad \text{in } \Omega$$

for some constant C_0. Thus if $\lambda \geqslant \mu$ is sufficiently large, then $v^- < v^+_{\lambda,\alpha}$ and

$$\Delta v^- = f_\alpha - \rho_\alpha \geqslant \lambda b U_\alpha e^{v^-}(U_\alpha e^{v^-} - 1) + f_\alpha \quad \text{in } \Omega.$$

Moreover,

$$\Delta v^- = f_\alpha \geqslant \lambda b U_\alpha e^{v^-}(U_\alpha e^{v^-} - 1) + f_\alpha \quad \text{in } \mathbb{R}^2 \setminus \Omega$$

for all $\lambda > 0$. Therefore v^- is a subsolution of Eq. (1.7) and $v^- < v^+_{\lambda,\alpha}$ if λ is sufficiently large.

We are now ready to construct a maximal bounded solution of (1.7). Let us consider the following boundary value problem:

$$\begin{cases} \Delta v = \lambda b U_\alpha e^v (U_\alpha e^v - 1) + f_\alpha, & \Omega, \\ v = v^+_{\lambda,\alpha}, & \partial\Omega, \end{cases} \tag{2.7}$$

where Ω is a smooth bounded domain.

Lemma 2.4: There exists a solution v_Ω of (2.7) satisfying $v^- \leqslant v_\Omega \leqslant v^+_{\lambda,\alpha}$ if λ is sufficiently large.

Proof: Let $d = 3\lambda \|b\|_{L^\infty} + 1$ and apply the following iterative scheme

$$(\Delta - d)v_{n+1} = \lambda b U_\alpha e^{v_n}(U_\alpha e^{v_n} - 1) - d v_n + f_\alpha, \quad \Omega \quad (n = 0,1,2,\ldots) \tag{2.8}$$

$$v_{n+1} = v^+_{\lambda,\alpha}, \quad \partial\Omega$$

$$v_0 = v^+_{\lambda,\alpha}.$$

For each $n = 1,2,\ldots$, (2.8) has a solution $v_n \in C^2(\bar{\Omega})$ satisfying $v^- \leqslant v_{n+1} \leqslant v_n$ in Ω. Standard bootstrap argument shows that $v_\Omega = \lim_{n\to\infty} v_n$ is a solution of (2.7). □

We can construct a solution $\bar{v}_{\lambda,\alpha}$ of (1.7) from $\{v_\Omega\}$ by means of standard diagonal process and Rellich theorem. Moreover, $\bar{v}_{\lambda,\alpha}$ is maximal. Indeed, if $v_{\lambda,\alpha}$ is another bounded solution of Eq. (1.7), then $v_{\lambda,\alpha} < v^+_{\lambda,\alpha}$ in $\mathbb{R}^2$ by Lemma 2.3(iv). From the iteration process (2.8), we can show that $v_{\lambda,\alpha} \leqslant v_n$ in each step and conclude that $v_{\lambda,\alpha} \leqslant v_\Omega$ for any bounded domain Ω. Since Ω is arbitrary, $v_{\lambda,\alpha} \leqslant \bar{v}_{\lambda,\alpha}$ in $\mathbb{R}^2$.

Therefore we conclude that if λ is sufficiently large, then (1.7) has a maximal solution $\bar{v}_{\lambda,\alpha}$. Following Caffarelli and Yang,[7] we can also verify that for each $\alpha \leqslant 0$ there exists a critical value $\lambda_\alpha \geqslant 8\pi(2N-\alpha)/\int_{\mathbb{R}^2} b\, dx$ such that if $\lambda > \lambda_\alpha$, Eq. (1.7) has a maximal bounded solution and if $\lambda < \lambda_\alpha$, (1.7) has no nontrivial bounded solution.

Moreover, $\bar{v}_{\lambda,\alpha}$ satisfies the following monotonicity property.

Lemma 2.5: Suppose that $\lambda > \mu > \lambda_\alpha$. If $\alpha < 0$, then there holds

$$\bar{v}_{\lambda,\alpha} > \bar{v}_{\mu,\alpha} \quad \text{and} \quad \lim_{|x|\to\infty} \bar{v}_{\lambda,\alpha}(x) > \lim_{|x|\to\infty} \bar{v}_{\mu,\alpha}(x). \tag{2.9}$$

Equation (2.9) remains true if $\alpha = 0$ and $N > 0$.

Proof: We can use $\bar{v}_{\mu,\alpha}$ (*respectively* $v^+_{\lambda,\alpha}$) as a subsolution (*respectively*, supersolution) of (1.7) to construct $\bar{v}_{\lambda,\alpha}$ such that $\bar{v}_{\mu,\alpha} < \bar{v}_{\lambda,\alpha} < v^+_{\lambda,\alpha}$, which proves the first inequality.

If $\alpha<0$ there exists an R such that $U_\alpha e^{\bar{v}_{\lambda,\alpha}}<1/2$ for $|x|>R$. Choose $\epsilon>0$ such that $w:=\bar{v}_{\mu,\alpha}-\bar{v}_{\lambda,\alpha}+\epsilon<0$ for $|x|=R$. Let ψ be the smooth function such that $\psi\equiv 1$ for $|x|\leqslant R$, $\psi\equiv 0$ for $|x|>2R$, and $\|\nabla\psi\|_{L^\infty}\leqslant 2/R$.

It follows from Lemma 2.2 that there exists a constant c_∞ such that $w=\xi+c_\infty$ for some $\xi\in M^2_{2,\delta}$ with $-1<\delta<\min\{0,l-3-\alpha\}$. Then we obtain

$$0\leqslant\int_{|x|\geqslant R} w^+\psi\Delta w\,dx=-\int_{|x|\geqslant R}\psi|\nabla w^+|^2\,dx-\int_{R\leqslant|x|\leqslant 2R} w^+\nabla\psi\cdot\nabla w\,dx,$$

where $w^+=\max\{w,0\}$. Letting $R\to\infty$, we obtain the result.

If $\alpha=0$ and $N>0$ choose R such that $R>\sup_i|p_i|$. Let

$$K=\frac{(U_0e^{\bar{v}_{\mu,0}}(U_0e^{\bar{v}_{\mu,0}}-1)-U_0e^{\bar{v}_{\lambda,0}}(U_0e^{\bar{v}_{\lambda,0}}-1))}{\bar{v}_{\mu,0}-\bar{v}_{\lambda,0}}.$$

Note that $|K|\leqslant 1$ and $U_0e^{\bar{v}_{\lambda,0}}(U_0e^{\bar{v}_{\lambda,0}}-1)\leqslant -C_0<0$ for $|x|>R$. Choose $\epsilon>0$ such that $w:=\bar{v}_{\mu,0}-\bar{v}_{\lambda,0}+\epsilon<0$ for $|x|=R$ and $-2\mu\epsilon+(\lambda-\mu)C_0>0$. Then we obtain

$$\Delta w-\mu b(K+1)w=b[-\epsilon\mu(K+1)-\mu(\bar{v}_{\mu,0}-\bar{v}_{\lambda,0})+(\mu-\lambda)U_0e^{\bar{v}_{\lambda,0}}(U_0e^{\bar{v}_{\lambda,0}}-1)]$$

$$\geqslant 0\quad\text{for } |x|>R. \tag{2.10}$$

Multiplying both sides of (2.10) by ψw^+ and integrating by parts, we obtain the desired result.□

Lemma 2.5 enables us to obtain a function given by

$$v_*(x)=\inf_{\lambda>\lambda_\alpha}\bar{v}_{\lambda,\alpha}(x).$$

Lemma 2.6: v_* belongs to $C^{2,\nu}_{\mathrm{loc}}$ and it is a bounded solution of (1.7) for $\lambda=\lambda_\alpha$.

Proof: By a result of Brezis and Merle[15] it is possible to show that $\{\bar{v}_{\lambda,\alpha}\}_{\lambda_\alpha<\lambda<2\lambda_\alpha}$ is uniformly bounded on a compact domain of $\mathbb{R}^2$. Indeed, if we define $z_{\lambda,\alpha}=\bar{v}_{\lambda,\alpha}+u_\alpha-w_0$, then $z_{\lambda,\alpha}$ satisfies

$$-\Delta z_{\lambda,\alpha}=\lambda be^{u_0+w_0+z_{\lambda,\alpha}}(1-e^{u_0+w_0+z_{\lambda,\alpha}}).$$

Moreover, $\lambda be^{u_0+w_0}(1-e^{u_0+w_0+z_{\lambda,\alpha}})$ is uniformly bounded in B_r and $\int_{B_r}e^{z_{\lambda,\alpha}}\leqslant C_r$ for each $r>0$. Then $\{z_{\lambda,\alpha}\}$ has a subsequence $z_n=z_{\lambda_n,\alpha}$ ($\lambda_n\to\lambda_\alpha$ as $n\to\infty$) satisfying the following alternative:

(a) z_n is bounded on B_r.

(b) $z_n\to-\infty$ uniformly on B_r.

(c) There exists a set $S=\{a_1,\ldots,a_m\}\subset B_r$ and sequences $x_n^i\to a_i$ ($i=1,\ldots,m$) such that $z_n(x_n^i)\to\infty$ and $z_n\to-\infty$ uniformly on compact subsets of $\mathbb{R}^2\setminus S$.

Note that

$$bU_\alpha e^{\bar{v}_{\lambda,\alpha}}(1-U_\alpha e^{\bar{v}_{\lambda,\alpha}})\leqslant b\quad\text{in } \mathbb{R}^2. \tag{2.11}$$

In view of (2.11), Lemma 2.2(i), and the monotonicity property (2.9), (b) and (c) are excluded and we conclude that $\{z_{\lambda,\alpha}\}$ is uniformly bounded on B_r for each $r>0$. Then the diagonal process and standard elliptic theory imply that v_* belongs to $C^{2,\nu}_{\mathrm{loc}}$ and it is a solution of (1.7) when $\lambda=\lambda_\alpha$.

Moreover, Lemma 2.2 implies that v_* satisfies

$$v_*(x)=\delta\ln|x|+v_\infty+o(1)\quad\text{as}|x|\to\infty$$

and

$$\int_{\mathbb{R}^2} bU_\alpha e^{v_*}(1-U_\alpha e^{v_*}) = \frac{2\pi}{\lambda_\alpha}(2N-\alpha-\delta)$$

for some constants δ and v_∞. It follows from dominated convergence theorem that $\delta=0$, which in turn implies that v_* is bounded. □

We now show that if $\alpha\leqslant 0$, $N-\alpha>0$, and $\lambda>\lambda_\alpha$ then there exists a second solution v_2 of (1.7) such that $v_2<\overline{v}_{\lambda,\alpha}$.

Given $l>2$, fix $\epsilon\in(2,\min\{l,4\})$ and define $h(x)=(1+|x|^2)^{-\epsilon/2}$. We recall some results about the weighted space $\mathcal{H}$[10] which is the Hilbert space of L^2_{loc}-functions for which

$$\|v\|_{\mathcal{H}}=(\|\nabla v\|^2_{L^2(\mathrm{d}x)}+\|v\|^2_{L^2(\mathrm{d}\mu)})^{1/2}<\infty, \tag{2.12}$$

where $\mathrm{d}\mu=h\,\mathrm{d}x$. Note that $\mathcal{H}\subset M^2_{1,-\epsilon/2}$.

Let $\mathcal{H}'=\{v\in\mathcal{H}|\int_{\mathbb{R}^2}v\,\mathrm{d}\mu=0\}$.

Lemma 2.7:

McOwen—Ref. 10.

(i) Let $\eta>0$. Then there exists a constant C_η such that

$$\|v\|_{M^2_{0,-1-\eta}}\leqslant C_\eta\|\nabla v\|_{L^2}$$

for every $v\in\mathcal{H}'$.

(ii) For $\beta\in(0,\min\{4\pi,2\pi(\epsilon-2)\})$, there exists a constant C_β such that

$$\int_{\mathbb{R}^2} e^{|v|}\,\mathrm{d}\mu\leqslant C_\beta\exp\left(\frac{1}{4\beta}\|\nabla v\|^2_{L^2}\right)$$

for every $v\in\mathcal{H}'$.

Note that Eq. (1.7) has a variational structure. In a similar way as in Tarantello,[8] we consider the functional

$$I_\lambda(v)=\frac{1}{2}\|\nabla v\|^2_{L^2}+\frac{\lambda}{2}\int_{\mathbb{R}^2}K(U_\alpha e^v-1)^2\,\mathrm{d}\mu+\int_{\mathbb{R}^2}Fv\,\mathrm{d}\mu$$

defined on the set

$$\Lambda=\{\,v\in\mathcal{H}|v\geqslant v_*\quad a.e.\,\},$$

where $K=bh^{-1}$, $F=f_\alpha h^{-1}$, and $v_*=\inf_{\lambda>\lambda_\alpha}\overline{v}_{\lambda,\alpha}$. It is easily verified that I_λ is bounded below, coercive and lower semicontinuous on Λ. Then there exists $v_0\in\Lambda$ such that $I_\lambda(v_0)=\inf_{v\in\Lambda}I_\lambda(v)$. It can be shown[8] that v_0 is a C^2-solution of (1.7) and $v_0>v_*$.

Fix $t\in(0,-1+\epsilon/2)$. Let us denote $\mathcal{V}$ the Banach space of C^1-functions for which

$$\|v\|_{\mathcal{V}}=(\|\sigma^{1+t}\nabla v\|_{L^\infty}+\|v\|_{L^\infty})<\infty,\quad \sigma(x)=(1+|x|^2)^{1/2}.$$

Note that I_λ is well defined on $\mathcal{V}$ as well as $\mathcal{H}$.

Lemma 2.8: The function v_0 is a local minimum of I_λ in $\mathcal{H}$.

Proof: We follow Ref. 8 and argue by contradiction. Suppose that for each $n=1,2,\ldots$, there exists $v_n\in\mathcal{H}$ such that

$$I_\lambda(v_0)>I_\lambda(v_n)=\inf_{\|v_n-v_0\|_{\mathcal{H}}\leqslant 1/n}I_\lambda(v).$$

Then v_n satisfies

$$-\Delta v_n+\lambda bU_\alpha e^{v_n}(U_\alpha e^{v_n}-1)+f_\alpha=\eta_n(-\Delta(v_n-v_0)+h(v_n-v_0)). \tag{2.13}$$

Clearly $\eta_n \leqslant 0$. We rewrite (2.13) as

$$\Delta(v_n - v_0) = \frac{\lambda}{1+|\eta_n|} b U_\alpha^2 (e^{2v_n} - e^{2v_0}) - \frac{\lambda}{1+|\eta_n|} b U_\alpha (e^{v_n} - e^{v_0}) + \frac{|\eta_n|}{1+|\eta_n|} h(v_n - v_0)$$
$$:= \xi_n \quad \text{in } \mathbb{R}^2.$$

Since ξ_n belongs to $M^2_{0,\epsilon/2}$, there exist $\phi_n \in C^1 \cap M^2_{2,-2+\epsilon/2} \subset C_0(\mathbb{R}^2)$ and a constant c_n such that

$$v_n - v_0 = \frac{\beta_n}{2} \ln(|x|^2+1) + \phi_n + c_n$$

with

$$\beta_n = \frac{1}{2\pi} \int_{\mathbb{R}^2} \xi_n \, dx.$$

Since $v_n - v_0 \in \mathcal{H}$, $\beta_n = 0$. Note that by the inequality $|e^s - 1| \leqslant |s| e^{|s|}$, $s \in \mathbb{R}$, ξ_n satisfies

$$|\xi_n| \leqslant Ch |v_n - v_0| (e^{2|v_n - v_0|} + 1).$$

Decompose $v_n - v_0 = w_n + a_n$, $w_n \in \mathcal{H}'$, and $a_n \in \mathbb{R}$. Then we have $\|\nabla w_n\|_{L^2} + |a_n| \leqslant C/n$ from our assumption.

It follows from Lemma 2.1 that

$$\|\sigma^t \phi_n\|^2_{L^\infty} \leqslant C \|\phi_n\|^2_{M^2_{2,-2+\epsilon/2}} \leqslant C \|\xi_n\|^2_{M^2_{0,\epsilon/2}} \leqslant C \int_{\mathbb{R}^2} (|w_n|^2 + |a_n|^2) e^{4(|w_n| + |a_n|)} d\mu$$
$$\leqslant C(\|w_n\|_{L^2(d\mu)} + |a_n|^2) \left(\int_{\mathbb{R}^2} e^{10(|w_n| + |a_n|)} d\mu \right)^{1/2}$$
$$\leqslant C(\|\nabla w_n\|_{L^2} + |a_n|^2) \exp(C \|\nabla w_n\|^2_{L^2}) \leqslant C/n.$$

Moreover we obtain

$$\int_{\mathbb{R}^2} |v_n - v_0|^2 \, d\mu = \int_{\mathbb{R}^2} |c_n + \phi_n|^2 \, d\mu \geqslant \int_{\mathbb{R}^2} \left(\frac{c_n^2}{2} - \|\phi_n\|^2_{L^\infty} \right) d\mu,$$

which implies that $|c_n| \leqslant C/\sqrt{n}$.

Given $x_0 \in \mathbb{R}^2$, let $\Omega = \{y \in \mathbb{R}^2 | \frac{1}{2}|x_0| < |y| < \frac{3}{2}|x_0|\}$ if $|x_0| > 1$ and let $\Omega = \{y \in \mathbb{R}^2 | |y| < 2\}$ if $|x_0| \leqslant 1$. Then we obtain

$$\sigma(x_0) |\nabla \phi_n(x_0)| \leqslant C(\sup_\Omega |\phi_n| + \sigma^2(x_0) \sup_\Omega |\Delta \phi_n|)$$
$$\leqslant C(|\phi_n(y)| + \sigma^2(x_0) h(z) |c_n + \phi_n(z)|) \quad \text{for some } y, z \in \overline{\Omega}$$
$$\leqslant \frac{C}{\sqrt{n}} (\sigma^{-t}(y) + \sigma^2(x_0) \sigma^{-\epsilon}(z))$$
$$\leqslant \frac{C}{\sqrt{n}} \sigma^{-t}(x_0)$$

with C independent of x_0 and n. Since $x_0 \in \mathbb{R}^2$ is arbitrary, we obtain $\|\sigma^{1+t} \nabla \phi_n\|_{L^\infty} \leqslant C/\sqrt{n}$.

Therefore $v_n - v_0$ belongs to $\mathcal{V}$ and $\|v_n - v_0\|_{\mathcal{V}} \to 0$ as $n \to \infty$, which leads to a contradiction since v_0 is a local minimum of I_λ in $\mathcal{V}$. Indeed, note that $bU_\alpha e^{v_0}(U_\alpha e^{v_0} - 1) + f_\alpha$ belongs to $M^2_{0,\epsilon/2}$. Then we can prove that $v_0 \in \mathcal{V}$ by using the argument similar to the one above. Moreover a slight modification of the proof of Lemma 2.5 shows that $\lim_{|x|\to\infty} v_0(x) > \lim_{|x|\to\infty} v_*(x)$. □

We may assume that the maximal solution $\overline{v}_{\lambda,\alpha}$ is a local minimum of I_λ in $\mathcal{H}$ and $I_\lambda(\overline{v}_{\lambda,\alpha}) < \inf_{\|v - v_0\|_{\mathcal{H}} = r} I_\lambda(v)$ for some $r > 0$.

Note that the functional I_λ has a mountain pass structure, i.e., $I_\lambda(\overline{v}_{\lambda,\alpha} + c) \to -\infty$ as $c \to -\infty$. Moreover, it can be shown similar to Ref. 8 that I_λ satisfies the Palais–Smale condition in $\mathcal{H}$. Therefore we obtain a second solution $v_2 \in \mathcal{H}$ of (1.7) such that

$$I_\lambda(v_2) = \inf_{s \in \mathcal{P}} \max_{t \in [0,1]} I_\lambda(s(t))$$

where $\mathcal{P} = \{s : [0,1] \to \mathcal{H} \mid s \text{ is continuous, } s(0) = \overline{v}_{\lambda,\alpha}, \text{ and } s(1) = \overline{v}_{\lambda,\alpha} + c_\lambda\}$ and c_λ is a fixed constant so that $I_\lambda(\overline{v}_{\lambda,\alpha} + c_\lambda) < I_\lambda(\overline{v}_{\lambda,\alpha})$. Maximum principle implies that $v_2 < \overline{v}_{\lambda,\alpha}$.

We are ready to prove Proposition 1.1.

Proof of Proposition 1.1: We have only to prove the inequality (1.8). If v is a bounded solution of (1.7), then $\lambda b U_\alpha e^v (U_\alpha e^v - 1) + f_\alpha$ belongs to $M^2_{0,\delta+2}$ for every $-1 < \delta < \min\{0, l - \alpha - 3\}$. Then a slight modification of the proof of Lemma 2.8 proves the inequality (1.8). □

Proof of Proposition 1.2: Since (i) and (ii) are similarly proved as in Ref. 8, we prove (iii) only. Let $\overline{u}_{\lambda,\alpha} = u_0 + u_\alpha + \overline{v}_{\lambda,\alpha}$. Let $d = \frac{1}{3}\mathrm{dist}(\{p_j\}, \Omega) > 0$ and $\Omega_r = \{x \in \mathbb{R}^2 \mid \mathrm{dist}(x, \Omega) < r\}$ for $r > 0$. Define two constants

$$m_1 = \inf_{x \in \Omega_{2d}} \overline{u}_{\lambda_\alpha,\alpha}, \quad m_2 = \inf_{x \in \Omega_{2d}} b(x).$$

Hence if $\lambda > \lambda_\alpha$ then

$$b e^{\overline{u}_{\lambda,\alpha}}(e^{\overline{u}_{\lambda,\alpha}} - 1) < m_2 e^{2m_1} \overline{u}_{\lambda,\alpha} \quad \text{in } \Omega_{2d}.$$

Letting $m = m_2 e^{2m_1}$, we obtain $\Delta \overline{u}_{\lambda,\alpha} - \lambda m \overline{u}_{\lambda,\alpha} < 0$ in Ω_{2d}.

Given $x_0 \in \Omega_d$, define

$$w(x) = (1 - m_1)\exp\left(\frac{\sqrt{\lambda m}}{4\mathrm{d}}(|x - x_0|^2 - d^2)\right), \quad |x - x_0| \leqslant d.$$

If $\lambda > 2/m\mathrm{d}^2$, w satisfies

$$\Delta w - \lambda m w = \left(\frac{\lambda m}{4\mathrm{d}^2}\left|x - x_0\right|^2 + \frac{\sqrt{\lambda m}}{d} - \lambda m\right) w < 0 \quad \text{in } B_d(x_0).$$

Then we obtain

$$\Delta(\overline{u}_{\lambda,\alpha} + w) - \lambda m(\overline{u}_{\lambda,\alpha} + w) < 0, \quad B_d(x_0)$$

$$\overline{u}_{\lambda,\alpha} + w > 0, \quad \partial B_d(x_0).$$

Maximum principle implies that $\overline{u}_{\lambda,\alpha} > -w$ in $B_d(x_0)$. In particular, this inequality holds for $x = x_0$ and hence we obtain

$$\overline{u}_{\lambda,\alpha} > -(1 - m_1)\exp\left(-\frac{\sqrt{\lambda m}}{4} d\right) \text{in } \Omega_d,$$

since $x_0 \in \Omega_d$ is arbitrary. Since $\|\Delta \overline{u}_{\lambda,\alpha}\|_{L^2(\Omega_d)} \leqslant c_1 e^{-c_2\sqrt{\lambda}}$ for some constants $c_j = c_j(\Omega) > 0$ $(j = 1,2)$, then Sobolev embedding theorem and interior Schauder estimate imply (1.9). □

The proof of Theorem 1.1 is complete.

To what extent do the classical equations of motion determine the quantization scheme?

J. Cislo and J. Lopuszański
Institute of Theoretical Physics, University of Wroclaw, pl. M. Borna 9, 50-205 Wroclaw, Poland

(Received 3 January 2001; accepted for publication 2 August 2001)

A simple example of one particle moving in a $(1+1)$ space–time is considered. As an example we take the harmonic oscillator. We confirm the statement that the classical equations of motion do not determine at all the quantization scheme. To this aim we use two inequivalent Lagrange functions, yielding Euler–Lagrange equations, having the same set of solutions. We present in detail the calculations of both cases to emphasize the differences occuring between them. © *2001 American Institute of Physics.* [DOI: 10.1063/1.1405125]

I. INTRODUCTION

In classical physics the content of dynamical process is mainly characterized by the equations of motion of the physical system. It may happen that these equations can be derived from a certain Lagrange function as the Euler–Lagrange equations. If this is the case we may expect that there can be many (even infinitely many!) nonequivalent Lagrange functions linked to these equations of motion, yielding the same set of solutions—so called s-equivalent equations. This fact is well known.[1,2]

Two nonequivalent but s-equivalent Lagrange functions lead to two distinct Hamilton functions and distinct canonical momentum variables. If we take as the starting point for our consideration these two Hamilton functions as well as these two sets of canonical momenta and try to quantize them in a standard way we get, in general, two distinct quantization schemes, differing essentially from each other, althought both having common roots coming from the same equations of motion. This fact is not new and well known to some physicists,[1,2] but—strange enough—not much attention was paid by them to this problem.

From what was said so far we may infer that the answer to the question posed in the title is that the equations of motion do not determine the quantization scheme.

Below we shall present an elucidating example in favor of the statement made above.

One remark is in order here. If we choose two inequivalent but s-equivalent Lagrange functions, say, L, and L', we get two sets of canonical variables

$$\left(x,p\equiv\frac{\partial L}{\partial\dot{x}}\right) \quad \text{and} \quad \left(x,p'\equiv\frac{\partial L'}{\partial\dot{x}}\right). \tag{1.1}$$

Notice that those canonical variables are not connected to each other by a canonical transformation, viz.

$$(x,p)\rightarrow(X(x,p),P(x,p)). \tag{1.2}$$

Should they be linked to each other by a point transformation

$$(x,p)\rightarrow(x,p'(x,p)) \tag{1.3}$$

it would follow from the canonical Poisson brackets that

$$p' = p + f(x), \quad f(x) - \text{arbitrary function}, \tag{1.4}$$

which is not the case considered by us in this note.

II. THE CASE OF ONE CLASSICAL PARTICLE IN A (1+1) SPACE–TIME. THE MASTER EQUATION FOR $H'(x,p')$

To buttress the above observations and make plain the goal of this note, we shall investigate a very simple problem of classical mechanics. So let us restrict ourselves to the case of one classical particle, moving in a $(1+1)$ space–time. Let us take sufficiently smooth equation of motion

$$\ddot{x} = f(x,\dot{x},t), \tag{2.1}$$

where $x(t)$ denotes the location of the particle and $\dot{x} \equiv dx/dt$ and $\ddot{x} \equiv d^2x/dt^2$ denote its velocity and acceleration, respectively, t being the independent time variable. To every such equation belongs a Lagrange function,[2,3] $L(x,\dot{x},t)$. Let us further restrict ourselves for simplicity reasons to automonous Lagrange functions. It is known[2,4] that the most general expression for Lagrange function $L'(x,\dot{x})$, s-equivalent to $L(x,\dot{x})$, is

$$L' = \dot{x} \int_c^{\dot{x}} \frac{d\Sigma(H)}{dH} \frac{\partial^2 L}{\partial \dot{x}^2}\bigg|_{\dot{x}=u} du - \Sigma(H), \tag{2.2}$$

where $\Sigma(H)$ is an arbitrary differentiable function of H, different from zero a.e., and

$$H \equiv \dot{x}\frac{\partial L}{\partial \dot{x}} - L, \tag{2.3}$$

the Hamilton function. The constant c is so chosen that the integral on the rhs of (2.2) does not diverge. It is easy to see that we have

$$\frac{\partial L'}{\partial x} - \dot{x}\frac{\partial^2 L'}{\partial \dot{x}\partial x} - \ddot{x}\frac{\partial^2 L'}{\partial \dot{x}^2} = \frac{d\Sigma(H)}{dH}\left(\frac{\partial L}{\partial x} - \dot{x}\frac{\partial^2 L}{\partial \dot{x}\partial x} - \ddot{x}\frac{\partial^2 L}{\partial \dot{x}^2}\right). \tag{2.4}$$

[The presence of $d\Sigma(H)/dH$ in (2.4) causes the set of solutions of equation on the lhs of (2.4) and the one on the rhs to differ by a set of measure zero.] Thus L' is, indeed, s-equivalent to L. We have

$$H' \equiv \dot{x}\frac{\partial L'}{\partial \dot{x}} - L' = \Sigma(H). \tag{2.5}$$

We get also

$$p' \equiv \frac{\partial L'}{\partial \dot{x}}. \tag{2.6}$$

It is trivial to find H' and p' for given Σ and L as functions of x and $\dot{x}$. It is, however, not so simple to get H' as a function of x and p'. To get that let us observe that from (2.6) and (2.2) follows

$$1 = \frac{d\Sigma}{dH}\frac{\partial^2 L}{\partial \dot{x}^2}\frac{\partial \dot{x}(x,p')}{\partial p'}. \tag{2.7}$$

Taking into account the relation

$$\frac{\partial H'(x,p')}{\partial p'} = \dot{x}(x,p') \tag{2.8}$$

we get from (2.7) and (2.8)

$$\frac{\partial^2 H'(x,p')}{\partial p'^2} = \frac{\partial \dot{x}(x,p')}{\partial p'} = \left(\frac{dH'}{dH} \frac{\partial^2 L}{\partial \dot{x}^2}\bigg|_{\dot{x}=\partial H'/\partial p'} \right)^{-1}. \tag{2.9}$$

This is the master equation for H' as a function of p' and x; it is, in general, nonlinear.

The solutions of this master equation have to satisfy a physically justified requirement that p' has to tend to zero as $\dot{x}$ tends to zero and vice versa, or, in other words,

$$\frac{\partial H'}{\partial p'}\bigg|_{p'=0} = 0. \tag{2.10}$$

III. APPLICATION OF THE MASTER EQUATION

To make use of this master equation one has, of course, to specify what L and Σ are. This will be done now. We choose

$$L = \tfrac{1}{2}\dot{x}^2 - V(x), \tag{3.1}$$

where $V(x)$ is a non-negative function of x and

$$\Sigma(H) = H' = \sqrt{2H}. \tag{3.2}$$

[In case $V(x)$ is just bounded from below we may make it non-negative for each x by adding to it a suitably choosen positive constant.]

Square root means non-negative root. [The equality (3.2) should be understood as follows:

$$H' = \alpha\sqrt{2H}, \quad \alpha - \text{const.}$$

As H' as well H should have the same dimensions it follows that the constant α has to have the dimension

$$[\alpha] = g^{1/2} \text{ cm/s}.$$

The equation (3.3) reads

$$\frac{\partial^2 H'}{\partial p^2} = \frac{1}{\alpha^2 m} H'$$

as L in (3.1) becomes

$$L = \tfrac{1}{2} m\dot{x}^2 - V(x),$$

where m denotes the mass of the particle. In this note we put

$$a = m = 1.]$$

For this choice of L and Σ Eq. (2.9) reduces to

$$\frac{\partial^2 H'}{\partial p'^2} = H'. \tag{3.3}$$

The solution of (3.3) reads

$$H' = \alpha(x)\sinh p' + \beta(x)\cosh p'. \tag{3.4}$$

This solution has to satisfy the requirement (2.10) and therefore

$$\alpha(x) = 0. \tag{3.5}$$

From (3.1) and the Hamilton equation, we obtain

$$\frac{d}{dt}\frac{\partial H'}{\partial p'} = \ddot{x} = -\frac{\partial V}{\partial x}. \tag{3.6}$$

If we insert in (3.6)

$$\dot{x} = \beta(x)\sinh p', \tag{3.7}$$

$$\dot{p}' = -\frac{\partial H'}{\partial x} = -\frac{\partial \beta}{\partial x}\cosh p', \tag{3.8}$$

following from the Hamilton equations, we obtain

$$\frac{1}{2}\frac{\partial}{\partial x}\beta^2 = \frac{\partial V}{\partial x}$$

or

$$\beta = \pm\sqrt{2(V+C)}, \tag{3.9}$$

C being a constant. Hence

$$H' = \pm\sqrt{2(V(x)+C)}\cosh p'. \tag{3.10}$$

According to our choice (3.2) taking into account (3.9), we should have

$$\pm\sqrt{2(V+C)}\cosh p' = \sqrt{2(\dot{x}^2/2+V)}. \tag{3.11}$$

To keep both sides of the relation (3.11) compatible with each other we have to choose the $(+)$ sign on the lhs of (3.11). Since for p' tending to zero $\dot{x}$ should also tend to zero we conclude that $C=0$. Thus eventually we have

$$H' = \sqrt{2V(x)}\cosh p'. \tag{3.12}$$

Notice that we could as well choose in the definition on the rhs of (3.2) the $(-)$ sign in front of the root or use both signs suitable for certain nonoverlapping intervals of the variable x. This would cause a change of our model. In each case, mentioned earlier, the Hamilton equations are s-equivalent to original equations of motions and the Hamilton functions are constants of motion.

The original Hamilton function reads

$$H = \tfrac{1}{2}p^2 + V(x). \tag{3.13}$$

IV. EXAMPLE OF THE HARMONIC OSCILLATOR

For the case of the harmonic oscillator

$$V(x) = \tfrac{1}{2}x^2, \tag{4.1}$$

and we choose the model

$$H' = \sqrt{x^2}\cosh p'. \tag{4.2}$$

[Relation (4.2) has to be understood as follows

$$H' = \sqrt{m}\omega\alpha x \cosh\left(\frac{p'}{\sqrt{m}\alpha}\right)$$

as we have $L = \frac{1}{2}m\dot{x}^2 - \frac{1}{2}m\omega^2x^2$, $[\omega] = 1/\mathrm{s}$. We put $m = \alpha = \omega = 1$.] H' is bounded from below. As H' is a conserved quantity the singularity of the trajectory appears at $x = 0$. It can be easily removed by taking as the potential

$$V(x) = \tfrac{1}{2}x^2 + a, \tag{4.3}$$

a an arbitrary positive constant. We are not going to use this procedure as it would essentially complicate our further calculations. For the case (4.2) the classical trajectories would be given by

$$\sqrt{x^2}\cosh p' = b, \quad b - a \text{ const.} \tag{4.4}$$

For $b > 0$ the phase trajectory lies in the strip $0 < x \leqslant b$ and $-b \leqslant x < 0$, while $-\infty < p' < +\infty$. If $|x| \to b$, then $dp'/dx \to \infty$. In the following we shall use one branch,

$$x\cosh p' = b, \tag{4.5}$$

for simplicity reasons.

It is easy to see that (4.2) gives rise to the equation

$$\ddot{x} + x = 0. \tag{4.6}$$

Indeed, we have

$$\frac{\partial H'}{\partial x} = \cosh p' = -\dot{p}', \quad \frac{\partial H'}{\partial p'} = x\sinh p' = \dot{x}. \tag{4.7}$$

Then

$$\ddot{x} = \dot{x}\sinh p' + \dot{p}'x\cosh p' = x(\sinh p')^2 - x(\cosh p')^2 = -x. \tag{4.8}$$

V. QUANTIZATION

Let us now try to quantize H and H'. We assume that the operators $(x, \hat{p})$ and $(x, \hat{p}')$ satisfy the standard canonical commutation relations. Then $\hat{p}$ as well as $\hat{p}'$ can be replaced by

$$-i\partial_x \tag{5.1}$$

in formulas (3.13) and (3.12), respectively. We get the following differential expressions, viz.

$$H_Q = -\tfrac{1}{2}(\partial_x)^2 + V(x) \tag{5.2}$$

$$H'_Q = \sqrt{\tfrac{1}{2}V(x)}\cos(\partial_x) + \cos(\partial_x)\sqrt{\tfrac{1}{2}V(x)}. \tag{5.3}$$

These expressions applied to $C_0^\infty(\mathbf{R})$ define symmetric operators in $L^2(\mathbf{R})$. (As it is well known, H_Q can be extended to a self-adjoint operator.) Notice that the operator (5.3) is not local, viz.

$$\cos(\partial_x)\Psi(x)=\tfrac{1}{2}(\Psi(x+i)+\Psi(x-i)) \tag{5.4}$$

and therefore (we denote the operator also by H'_Q)

$$H'_Q\Psi(x)=\frac{1}{\sqrt{2}}(\sqrt{V(x)}+\sqrt{V(x+i)})\Psi(x+i)+\frac{1}{\sqrt{2}}(\sqrt{V(x)}+\sqrt{V(x-i)})\Psi(x-i). \tag{5.5}$$

VI. HARMONIC OSCILLATOR

The potential is given by (4.1). As it is well known the eigenvalues for H_Q are

$$n+\tfrac{1}{2}, \quad n-\text{natural number or } 0, \tag{6.1}$$

and the eigenfunctions are the Hermitian functions

$$\Psi_n=\exp(-x^2/2)H_n(x), \tag{6.2}$$

where H_n are the Hermitian polynomials.[5]

For the case H'_Q we have [see (5.3)]

$$H'_Q=\tfrac{1}{2}(x\cos(\partial_x)+\cos(\partial_x)x). \tag{6.3}$$

The case of nonlocal H'_Q will be investigated in Sec. VII.

It seems more convenient to start the discussion by using different canonically conjugate variables, namely (hereafter we shall use the letter p instead of p')

$$-i\partial_x\to p \quad \text{and} \quad x\to i\partial_p. \tag{6.4}$$

Notice that the two systems of variables are linked by a Fourier transformation.

Let us denote the new Hamilton operator by K. Then we get from (6.3)

$$K=\frac{i}{2}(\partial_p\cosh(p)+\cosh(p)\partial_p). \tag{6.5}$$

The differential expression (6.5) when applied to $C_0^\infty(\mathbf{R})$ defines a symmetric operator in $L^2(\mathbf{R})$, which we shall also denote by K. This statement as well as the following results are dicussed *in extenso* in the Appendix. It is shown that for real γ,

$$0\leqslant\gamma<2, \tag{6.6}$$

the system of functions

$$\{\Psi_{2n+\gamma}(p)\}_{n\in\mathbf{Z}}, \tag{6.7}$$

where

$$\Psi_{2n+\gamma}(p)=\frac{1}{\sqrt{\pi\cosh p}}\exp(-i(2n+\gamma)\operatorname{arctan}\sinh p) \tag{6.8}$$

are the solution of the equations

$$K\Psi_{2n+\gamma}(p)=(2n+\gamma)\Psi_{2n+\gamma}(p), \tag{6.9}$$

is an orthonormal basis for $L^2(\mathbf{R})$. Thus for each fixed γ of the interval (6.6) K has a self-adjoint extension K_α, $\alpha\equiv\exp(-i\gamma\pi)$.

VII. FOURIER TRANSFORM OF THE EIGENFUNCTIONS

In this section we investigate Fourier transforms of eigenfunctions of the Hamilton operator (6.5). We find an expression for the Fourier transform in the case when eigenvalues are equal to $n+1/2$, where n is an integer. However, we do not see how to solve the problem for other eigenvalues. We show that in the considered case the Fourier transforms are eigenfunctions of nonlocal Hamilton operator (6.3). These eigenfunctions form two bases in the Hilbert space. They are expressed by the polynomial of Meixner and Pollaczek.

Let us rewrite the result (6.8). The normalized eigenfunction belonging to the eigenvalue λ reads

$$\Psi_\lambda(p)=\frac{1}{\sqrt{\pi\cosh p}}\ \exp(-i\lambda\ \text{arctan}\ \sinh p). \tag{7.1}$$

We start with two identities:

$$\frac{1}{\sqrt{\cosh p}}\ \exp\left(-\frac{i}{2}\text{arctan}\ \sinh p\right)=\frac{1+i}{1+ie^p}e^{p/2}, \tag{7.2}$$

$$\exp(-i\ \text{arctan}\ \sinh p)=i\frac{1-ie^p}{1+ie^p}. \tag{7.3}$$

To check these identities it is most simple to compare the moduli and arguments of the complex number on both sides of the equalities.

Mulitiplying the first identity by the nth power of the second identity we obtain

$$\Psi_{n+1/2}(p)=\frac{1}{\sqrt{\pi}}\left(i\frac{1-ie^p}{1+ie^p}\right)^n\frac{1+i}{1+ie^p}e^{p/2}. \tag{7.4}$$

To get the Fourier transform of (7.4),

$$\Phi_\lambda(x)\equiv\frac{1}{\sqrt{2\pi}}\int_{-\infty}^{+\infty}\Psi_\lambda(p)e^{ipx}dp, \tag{7.5}$$

we employ the method of generating function. We define

$$\Psi(p,t)\equiv\sum_{n=0}^{\infty}\Psi_{n+1/2}(p)t^n=\frac{1}{\sqrt{\pi}}\frac{1+i}{(1-it)+i(1+it)e^p}e^{p/2}. \tag{7.6}$$

The computation of (7.6) amounts to summing up the geometrical series covergent for $|t|<1$. The Fourier transform of the generating function (7.6) yields the generating function for the Fourier transforms of the eigenfunctions:

$$\Phi(x,t)\equiv\frac{1}{\sqrt{2\pi}}\int_{-\infty}^{+\infty}\Psi(p,t)e^{ipx}dp=\sum_{n=0}^{\infty}\Phi_{n+1/2}(x)t^n. \tag{7.7}$$

To evaluate the integral (7.7) we shall use the method of complex analysis. Let us consider the function

$$\frac{1}{\sqrt{2\pi}}\Psi(p,t)e^{ipx} \tag{7.8}$$

as the function of a complex variable p and let us compute the integral of function (7.8) along the contour of the rectangle with the vertices located at the points $(-a,0)$, $(a,0)$, $(a,2\pi i)$, $(-a,2\pi i)$, $a>0$, running in the counter-clockwise direction. In the limit when a tends to infinity, the integral along the lower side yields $\Phi(x,t)$. To get the integral along the upper side of the rectangle we exploit the relation

$$\frac{1}{\sqrt{2\pi}}\int_{-\infty}^{+\infty}\Psi(p+2\pi i,t)e^{i(p+2\pi i)x}dp=-\Phi(x,t)e^{-2\pi x}, \tag{7.9}$$

which follows from the property

$$\Psi(p+2\pi i,t)=-\Psi(p,t). \tag{7.10}$$

In the limit the contributions from both remaining sides of the rectangle vanish. Then the integral along the rectangle in the limit is equal to

$$\Phi(x,t)+\Phi(x,t)e^{-2\pi x}. \tag{7.11}$$

Function (7.6) is a meromorphic function and has inside of the rectangle a simple pole at the point

$$\tilde{p}=\frac{i\pi}{2}-2i\arctan t. \tag{7.12}$$

We can express the integral of the function (7.6) along the rectangle by residuum of the function at the point $\tilde{p}$ which is equal to

$$-\frac{i}{\pi}e^{-\pi x/2}\frac{1}{\sqrt{1+t^2}}\exp(2x\arctan t). \tag{7.13}$$

The integral (7.11) is the product of $2\pi i$ and the residuum (7.13). Finally, we get

$$\Phi(x,t)=\frac{2e^{-\pi x/2}}{1+e^{-2\pi x}}\frac{1}{\sqrt{1+t^2}}\exp(2x\arctan t). \tag{7.14}$$

Let us set

$$W(x,t)\equiv\frac{1}{\sqrt{1+t^2}}\exp(2x\arctan t)=\sum_{n=0}^{\infty}W_n(x)\frac{t^n}{n!}. \tag{7.15}$$

The formula (7.15) defines the sequence of polynomials $W_n(x)$. Degree of the polynomial $W_n(x)$ equals n. The polynomials $W_n(x)$ are even functions for even n and odd functions for odd n.

Comparing definitions (7.7) and (7.15) and the formula (7.14) we can write

$$\Phi_{n+1/2}(x)=\frac{2e^{-\pi x/2}}{1+e^{-2\pi x}}\frac{W_n(x)}{n!}=\Phi_{1/2}(x)\frac{W_n(x)}{n!}. \tag{7.16}$$

This formula holds for non-negative integer n. From the definition of the Fourier transformation (7.5) and from the relation

$$\Psi_{-\lambda}(p)=\overline{\Psi_{\lambda}(p)} \tag{7.17}$$

follows

$$\Phi_{-\lambda}(x)=\Phi_{\lambda}(-x). \tag{7.18}$$

Thus for non-negative integer n we have

$$\Phi_{-n-1/2}(x)=(-1)^n\frac{2e^{\pi x/2}}{1+e^{2\pi x}}\frac{W_n(x)}{n!}=(-1)^n\Phi_{-1/2}(x)\frac{W_n(x)}{n!}, \tag{7.19}$$

which supplements relation (7.16).

Let us investigate the polynomials $W_n(x)$. For this aim we differentiate $W(x,t)$, given by (7.15), with respect to t. We get

$$\frac{\partial W(x,t)}{\partial t}=\frac{2x-t}{1+t^2}W(x,t). \tag{7.20}$$

If we multiple both sides of (7.20) by $(1+t^2)$ and compare the coefficients of the same power of t on both sides of (7.20), we obtain

$$\begin{aligned} W_0(x)&=1,\\ W_1(x)&=2x,\\ W_2(x)&=4x^2-1,\\ W_3(x)&=8x^3-10x,\\ W_4(x)&=16x^4-56x^2+9, \quad \text{etc.}, \end{aligned} \tag{7.21}$$

as well as recurrence formula

$$W_{n+1}(x)+n^2W_{n-1}(x)=2xW_n(x), \quad n>0. \tag{7.22}$$

Now we are going to show that the Fourier transformed functions $\Phi_{n+1/2}$ are eigenfunctions of the nonlocal Hamilton operator (6.3):

$$H'_Q\Phi_{n+1/2}(x)\equiv\frac{i}{2}\left(\frac{1}{2}-ix\right)\Phi_{n+1/2}(x+i)-\frac{i}{2}\left(\frac{1}{2}+ix\right)\Phi_{n+1/2}(x-i)=(n+1/2)\Phi_{n+1/2}(x). \tag{7.23}$$

We shall prove (7.23) for non-negative integer n; for negative ones the proof is very similar to that for non-negative.

Taking into account the relation

$$\Phi_{1/2}(x\pm i)=\mp i\Phi_{1/2}(x) \tag{7.24}$$

and the formula (7.16) we conclude that (7.23) holds iff

$$hW_n(x)\equiv\tfrac{1}{2}(\tfrac{1}{2}-ix)W_n(x+i)+\tfrac{1}{2}(\tfrac{1}{2}+ix)W_n(x-i)=(n+1/2)W_n(x). \tag{7.25}$$

To prove relation (7.25) let us apply the expression h upon $W(x,t)$, namely,

$$\begin{aligned} hW(x,t)&=\frac{1}{2}\left(\frac{1}{2}-ix\right)W(x+i,t)+\frac{1}{2}\left(\frac{1}{2}+ix\right)W(x-i,t)\\ &=\left(\frac{1}{2}+t\frac{2x-t}{1+t^2}\right)W(x,t)=\frac{1}{2}W(x,t)+t\frac{\partial W(x,t)}{\partial t}. \end{aligned} \tag{7.26}$$

The last equality follows from the formula (7.20). If we compare the coefficients of the same power of t on both sides of (7.26), we get (7.25). This completes the proof.

Let us return to the consideration of the previous section. There we learned that for any fixed λ the functions $\Psi_{2n+\gamma}$, $n=0,\pm1,\pm2,\pm3,\ldots$, form an orthonormal basis in $L^2(\mathbf{R})$. It is known that the Fourier transformation maps an orthonormal basis into a new orthonormal basis.

We have found the Fourier transforms of the eigenfunctions only for $\gamma=1/2$ and $\gamma=3/2$. Further, we choose $\gamma=1/2$ and consider an orthonormal basis:

$$\Phi_{2n+1/2}, \quad n=0,\pm1,\pm2,\pm3,\ldots. \tag{7.27}$$

Taking into account the definition (7.16) and (7.18) and property of polynomials $W_m(-x)=(-1)^m W_m(x)$ we get for non-negative integer n and k

$$\int_{-\infty}^{+\infty}\Phi_{2n+1/2}(x)\Phi_{2k+1/2}(x)dx=\int_{-\infty}^{+\infty}\frac{1}{2}(\Phi_{2n+1/2}(x)\Phi_{2k+1/2}(x)+\Phi_{2n+1/2}(-x)\Phi_{2k+1/2}(-x))dx$$

$$=\int_{-\infty}^{+\infty}\frac{W_{2n}(x)}{(2n)!}\frac{W_{2k}(x)}{(2k)!}\frac{dx}{\cosh\pi x}. \tag{7.28}$$

Similar computation for positive integers n and k gives

$$\int_{-\infty}^{+\infty}\Phi_{-2n+1/2}(x)\Phi_{-2k+1/2}(x)dx=\int_{-\infty}^{+\infty}\frac{W_{2n-1}(x)}{(2n-1)!}\frac{W_{2k-1}(x)}{(2k-1)!}\frac{dx}{\cosh\pi x}. \tag{7.29}$$

Functions on the left sides of (7.28) and (7.29) are orthonormal. Therefore for non-negative integer n and k, both odd or even, we have

$$\int_{-\infty}^{+\infty}\frac{W_n(x)W_k(x)}{\cosh\pi x}dx=(n!)^2\delta_{n,k}. \tag{7.30}$$

If n is odd and k is even, then the integrated function is odd and the integral vanish.

We may regard the set of polynomials $W_n(x)$ as the system of orthogonal polynomials with respect to the scalar product

$$\langle f,g\rangle\equiv\int_{-\infty}^{+\infty}\frac{\overline{f(x)}g(x)}{\cosh\pi x}dx. \tag{7.31}$$

We may prove orthogonality relation (7.30) directly, not refering to Fourier transformation. We are going to use the generating function $W(x,t)$.

Let us calculate in two different ways an integral

$$\int_{-\infty}^{+\infty}\frac{W(x,s)W(x,t)}{\cosh\pi x}dx. \tag{7.32}$$

On the one hand, we have

$$\sum_{n=0}^{\infty}\sum_{k=0}^{\infty}s^n t^k\int_{-\infty}^{+\infty}\frac{W_n(x)W_k(x)}{\cosh\pi x}dx. \tag{7.33}$$

On the other hand, we have

$$\int_{-\infty}^{+\infty}\frac{\exp(2x(\arctan s+\arctan t))}{\sqrt{1+s^2}\sqrt{1+t^2}\cosh\pi x}dx=\frac{1}{1-st}=\sum_{n=0}^{\infty}s^n t^n. \tag{7.34}$$

Comparing the coefficent of the same power s and t in the formulas (7.33) and (7.34) we get (7.30). To compute the integral (7.34) we exploit the relations

$$\int_{-\infty}^{+\infty} \frac{e^{2x\theta}}{\cosh \pi x} dx = \frac{1}{\cos \theta}, \quad -\frac{\pi}{2} < \theta < \frac{\pi}{2}, \tag{7.35}$$

and

$$\cos(\arctan s + \arctan t) = \frac{1 - st}{\sqrt{1+s^2}\sqrt{1+t^2}}. \tag{7.36}$$

The integral (7.35) we can calculate using the complex analysis method in a very similar way to the way we calculated the Fourier transform of the generating function (7.7). We exploit the following property of integrated function $f(x) \equiv \exp(2x\theta)/\cosh \pi x$:

$$f(x+i) = -f(x)e^{2i\theta}. \tag{7.37}$$

VIII. FINAL REMARKS

(1) Let us define the expression:

$$Rf(x) \equiv \frac{i}{2}\left(\frac{1}{2} - ix\right) f(x+i) - \frac{i}{2}\left(\frac{1}{2} + ix\right) f(x-i) + xf(x). \tag{8.1}$$

Then R behaves as a ''creation operator''

$$[h, R] = R, \tag{8.2}$$

where h is defined by formula (7.25). Therefore,

$$hf = \lambda f \quad \text{implies} \quad hRf = (\lambda + 1)Rf. \tag{8.3}$$

That confirms the designation ''creation operator'' for R. More exactly, we have

$$RW_n = W_{n+1}. \tag{8.4}$$

(2) The equation

$$\frac{i}{2}\left(\frac{1}{2} - ix\right)\Phi(x+i) - \frac{i}{2}\left(\frac{1}{2} + ix\right)\Phi(x-i) = \frac{1}{2}\Phi(x) \tag{8.5}$$

is not only solved by the function

$$\Phi_{1/2}(x) = \frac{2e^{-\pi x/2}}{1 + e^{-2\pi x}}, \tag{8.6}$$

but also by the function

$$\Phi(x) \equiv \Phi_{1/2}(x + a). \tag{8.7}$$

The Fourier transform of Φ reads

$$\Psi(p) = \frac{1}{\sqrt{2\pi}} \int_{-\infty}^{+\infty} \Phi(x) e^{-ipx} dx = \Psi_{1/2}(p) e^{-ipa}, \tag{8.8}$$

where

$$\Psi_{1/2}(p)=\frac{1+i}{1+ie^{p}}e^{p/2}. \tag{8.9}$$

We have

$$K\Psi(p)=(\tfrac{1}{2}+a\cosh p)\Psi(p), \tag{8.10}$$

and for $a\neq 0$ the function $\Psi(p)$ is not an eigenfunction of K.

ACKNOWLEDGEMENTS

We are deeply indebted to Dr. Witold Karwowski for his assistance in formulating properly the mathematical problems in the Appendix. We are also grateful to Dr. Andrzej Hulanicki, Dr. Jerzy Lukierski, Dr. Helmut Reeh and Dr. Ludwik Turko for inspiring discusions.

APPENDIX

Let us start with (6.5), viz.

$$K=\frac{i}{2}(\partial_p\cosh(p)+\cosh(p)\partial_p). \tag{A1}$$

This differential expression when applied to $C_0^{\infty}(\mathbf{R})$ defines a symmetric operator in $L^2(\mathbf{R})$ as stated in Sec. VI. We shall denote this operator also by K. Indeed, if Ψ and Φ belong to $C_0^{\infty}(\mathbf{R})$, then

$$\int_{-\infty}^{+\infty}\overline{\Psi(p)}K\Phi(p)dp-\int_{-\infty}^{+\infty}\overline{K\Psi(p)}\Phi(p)dp=i\int_{-\infty}^{+\infty}\frac{d}{dp}(\cosh(p)\overline{\Psi(p)}\Phi(p))dp$$
$$=i\cosh(p)\overline{\Psi(p)}\Phi(p)\Big|_{-\infty}^{+\infty}=0. \tag{A2}$$

Let λ belong to $\mathbf{C}$. Then the equation

$$K\Psi_{\lambda}(p)=\lambda\Psi_{\lambda}(p) \tag{A3}$$

has the solution

$$\Psi_{\lambda}(p)=C_{\lambda}\frac{1}{\sqrt{\cosh p}}\exp(-i\lambda\ \text{arctan sinh}\,p), \tag{A4}$$

which is unique up to the multiplicative constant C_{λ}. We may use this constant to normalize Ψ_{λ}. Clearly Ψ_{λ} belongs to $L^2(\mathbf{R})$ as (for λ, $\mu\in\mathbf{R}$ and $\lambda\neq\mu$ we have $\int_{-\infty}^{+\infty}\overline{\Psi_{\lambda}(p)}\Psi_{\mu}(p)dp=\overline{C_{\lambda}}C_{\mu}[\sin(\lambda-\mu)\pi/2]/[(\lambda-\mu)\pi/2]$)

$$\int_{-\infty}^{+\infty}\overline{\Psi(p)}\Psi(p)dp=|C_{\lambda}|^2\int_{-\infty}^{+\infty}\frac{dp}{\cosh p}=|C_{\lambda}|^2\pi. \tag{A5}$$

Thus the defect subspaces for the adjoint operator, K^{+}, are one dimensional and the defect indices are $\{-1,1\}$. Hence K has the one-parameter family of self-adjoint extensions, which can be defined as follows. Let

$$\alpha\in\mathbf{C},\quad |\alpha|=1, \tag{A6}$$

and define

$$M_\alpha=\left\{\Phi\in C^\infty(\mathbf{R}):\ \lim_{p\to-\infty}(\sqrt{\cosh p}\Phi(p))=\alpha\lim_{p\to+\infty}(\sqrt{\cosh p}\Phi(p))\right\}. \tag{A7}$$

Let us further define the operator K_α as

$$K_\alpha\Phi(p)=\frac{i}{2}\left(\sinh(p)+2\cosh(p)\frac{d}{dp}\right)\Phi(p),\quad \Phi\in M_\alpha. \tag{A8}$$

The operator K_α is essentially self-adjoint. To see this we observe that

$$\mathrm{Ran}(K_\alpha\pm i\mathbb{1})$$

is dense in $L^2(\mathbf{R})$. Indeed, taking

$$\Psi=\Psi_{\pm i},$$

we see that (A2) does not hold for all $\Phi\in M_\alpha$. Thus Ψ do not belong to the domain $D(K_\alpha^+)$ of K_α^+. Consequently, if $\Psi\in D(K_\alpha^+)$, then

$$K\Psi=K_\alpha^+\Psi=\pm i\Psi\quad\text{implies}\quad\Psi=0. \tag{A9}$$

This implies that if

$$(\Psi,(K_\alpha\mp i\mathbb{1})\Phi)=((K_\alpha^+\pm i\mathbb{1})\Psi,\Phi)=0 \tag{A10}$$

for all $\Phi\in M_\alpha$, then $\Psi=0$ and hence

$$\mathrm{Ran}(K_\alpha\pm i\mathbb{1}) \tag{A11}$$

is dense and K_α is essentially self-adjoint. We shall denote the closure of K_α by $\overline{K_\alpha}$.

Let us now consider the function (A4). For real λ we have

$$\lim_{p\to-\infty}(\sqrt{\cosh p}\ \Psi_{2n+\gamma}(p))=\alpha\lim_{q\to+\infty}(\sqrt{\cosh p}\ \Psi_{2n+\gamma}(p)), \tag{A12}$$

where

$$\alpha=e^{i\pi\gamma}.$$

We conclude that for any $0\leqslant\gamma<2$ the functions

$$\{\Psi_{2n+\gamma}\}_{n\in\mathbf{Z}} \tag{A13}$$

form a system of eigenvectors for the self-adjoint operator

$$\overline{K_\alpha},\quad \alpha=e^{-i\gamma\pi}. \tag{A14}$$

The corresponding eigenvalues are

$$\{2n+\gamma\}_{n\in\mathbf{Z}}. \tag{A15}$$

It follows from (A5) that if $C_{2n+\gamma}=1/\sqrt{\pi}$, then $\Psi_{2n+\gamma}$ are normalized. We show that for any

$$0\leqslant\gamma<2$$

the system

$$\{\Psi_{2n+\gamma}\}_{n\in\mathbf{Z}}$$

is an orthonormal basis for $L^2(\mathbf{R})$. It is sufficient to show that for any

$$f \in L^2(\mathbf{R})$$

there is

$$\sum_{n \in \mathbf{Z}} |(f, \Psi_{2n+\gamma})|^2 = \|f\|^2, \tag{A16}$$

where $(.,.)$ and $\|.\|$ denote the inner product and the norm in L^2, respectively. To prove (A16) let us observe that

$$(f, \Psi_{2n+\gamma}) = \frac{1}{\sqrt{\pi}} \int_{-\infty}^{+\infty} \overline{f(p)} (\cosh\, p)^{-1/2} \exp(-i(2n+\gamma) \operatorname{arctan} \sinh p) dp. \tag{A17}$$

Let us change the variables as follows

$$\begin{aligned} &\sinh p = \tan \frac{\theta}{2}, \quad -\pi \leqslant \theta \leqslant \pi, \\ &\cosh p = \frac{1}{\cos\, \theta/2}, \quad dp = \frac{d\theta}{\cos\, \theta/2}. \end{aligned} \tag{A18}$$

Then (A17) takes the form

$$(f, \Psi_{2n+\gamma}) = \frac{1}{2\sqrt{\pi}} \int_{-\pi}^{+\pi} \overline{f\left(\operatorname{arcsinh} \tan \frac{\theta}{2} \right)} \left(\cos \frac{\theta}{2} \right)^{-1/2} \exp\left(\frac{-i\gamma\theta}{2} \right) \exp(-in\theta) d\theta. \tag{A19}$$

We get further

$$\sum_{n \in \mathbf{Z}} |(f, \Psi_{2n+\gamma})|^2 = \frac{1}{4\pi} \sum_{n \in \mathbf{Z}} \left| \int_{-\pi}^{\pi} \overline{\tilde{f}(\theta)} e^{-in\theta} d\theta \right|^2 = \frac{1}{2} \int_{-\pi}^{\pi} |\tilde{f}(\theta)|^2 d\theta = \int_{-\infty}^{+\infty} |f(q)|^2 dq = \|f\|^2, \tag{A20}$$

where

$$\tilde{f}(\theta) \equiv f\left(\operatorname{arcsinh} \tan \frac{\theta}{2} \right) \left(\cos \frac{\theta}{2} \right)^{-1/2} e^{i\gamma\theta/2}. \tag{A21}$$

Formula (A20) is the Parseval equality.

Note: Notice that the model linked to formula (4.5) is not s-equivalent to the initial model.

Trions in a periodic potential

Wojciech Florek[a)]
A. Mickiewicz University, Institute of Physics, ul. Umultowska 85, 61–614 Poznań, Poland

(Received 1 September 2000; accepted for publication 17 August 2001)

The group-theoretical classification of trion states (charged excitons $X^{\pm}$) is presented. It is based on considerations of products of irreducible projective representations of the two-dimensional translation group. For a given BvK period N degeneracy of obtained states is N^2. Trions $X^{\pm}$ consist of two identical particles (holes or electrons), so the symmetrization of states with respect to particles transposition is considered. There are $N(N+1)/2$ symmetric and $N(N-1)/2$ antisymmetric states. Completely antisymmetric states can be constructed by introducing antisymmetric and symmetric spin functions, respectively. Two symmetry-adapted bases are considered: The first is obtained from a direct conjugation of three representations, whereas in the second approach the states of an electrically neutral pair hole–electron are determined in the first step. The third possibility, a conjugation of representations corresponding to identical particles in the first step, is presented elsewhere. © *2001 American Institute of Physics.* [DOI: 10.1063/1.1409350]

I. INTRODUCTION

The quantum Hall effect and high temperature superconductivity have given rise to interest in properties of the two-dimensional electron gas subjected to electric and magnetic fields. The observation of (negatively) charged excitons[1] has recalled a 40-year-old concept of excitons ''trions'' or ''charged excitons'' introduced by Lampert in 1958.[2] Recently, such excitons, consisting of two holes and an electron or two electrons and hole (denoted $X^{\pm}$, respectively), have been investigated both experimentally and theoretically.[3–5]

In this paper classification based on translational symmetry in the presence of a periodic potential and an external magnetic field is presented. To perform this task the so-called magnetic translation operators, introduced by Brown[6] and Zak,[7] are used. These operators commute with the standard Hamiltonian of an electron in the magnetic field $\mathbf{H}=\nabla\times\mathbf{A}$ and a periodic potential $V(\mathbf{r})$,

$$\mathcal{H}=\frac{1}{2m}\left(\mathbf{p}+\frac{e}{c}\mathbf{A}\right)^2+V(\mathbf{r}). \tag{1}$$

Brown and Zak's concepts can be generalized to a local gauge of the vector potential $\mathbf{A}$,[8,9] N-dimensional lattices,[10,11] and the spatially inhomogeneous magnetic field.[12] This paper exploits the fact that after imposing the Born–von Kármán (BvK) periodic conditions the magnetic translations form a finite-dimensional projective representation of the two-dimensional (2D) translation group. Kronecker products of irreducible projective representations can be applied to description of multiparticle states.[13,14]

Considering problems which involve the magnetic field $\mathbf{H}$ determined by the vector potential $\mathbf{A}$, one has to keep in mind that some results may depend on a chosen gauge, though physical properties should be gauge independent. Two gauges are most frequently used in the description of 2D electron systems: the Landau gauge with $\mathbf{A}=[0,xH,0]$ and the antisymmetric one with $\mathbf{A}=(\mathbf{H}\times\mathbf{r})/2$. The relations between these gauges were discussed in the earlier article,[9] so this problem is left out in the present considerations. However, it should be underlined that form

a)Electronic mail: florek@amu.edu.pl

representation matrices depend on the chosen gauge and, moreover, obtained representations are inequivalent, which means, among other things, that their bases are not related by a unitary transformation. This question is briefly discussed in Sec. IV.

II. IRREDUCIBLE PROJECTIVE REPRESENTATIONS OF THE 2D TRANSLATION GROUP

All finite-dimensional irreducible projective representations of the 2D translation for a given BvK period N are labeled n,l,k_1,k_2, where n is a divisor of N, $0<l<n$ is mutually prime with n, and $\mathbf{k}=(k_1,k_2)$ labels irreducible representations of 2D translation group with the BvK period N/n, so $k_1,k_2=0,1,\ldots,(N/n)-1$. In the special case $n=N$ matrix elements are given by the following formula:[14]

$$D^l_{jk}[n_1,n_2]=\delta_{j,k-n_2}\omega_N^{ln_1j}, \tag{2}$$

where l is mutually prime with N, $\omega_N=\exp(2\pi i/N)$, $j,k,n_1,n_2=0,1,\ldots,N-1$ (so all expressions are calculated modulo N), and $[n_1,n_2]$ denotes a vector of the 2D translation group (strictly speaking, their coordinates in the lattice basis $\{\mathbf{a}_1,\mathbf{a}_2\}$). For the sake of simplicity the considerations are limited to this case and the results presented correspond to the limit of high magnetic fields, i.e., there is no mixing of the Landau levels. The other special case $n=1$ leads to the standard (vector) representations of the translation group, i.e.,

$$D^{\mathbf{k}}[n_1,n_2]=\omega_N^{k_1n_1+k_2n_2}. \tag{3}$$

It has been shown in the earlier paper[14] that for a given magnetic field $\mathbf{H}$ the indices l and n are related to the charge of a moving particle. In the considered case it is assumed that the representation D^l corresponds to a hole, whereas D^{-l} corresponds to an electron. The vector representation $D^{\mathbf{k}}$ corresponds to a neutral particle or to an electron–hole pair, which is a case considered here. Hence, trions $X^{\pm}$ correspond to the Kronecker product of three representations: $D^{\pm l}\otimes D^{\pm l}\otimes D^{\mp l}$.

III. TRION STATES AND THEIR SYMMETRIZATION

A. Direct conjugation

The trions $X^{\pm}$ are charged excitons with the charge $\pm e$ equal to that of a single hole or electron, so, from the group-theoretical point of view, their states have to transform as vectors of the irreducible projective representation $D^{\pm l}$. Since representations $D^{\pm l}$ are N-dimensional then the following decomposition is true (see also Ref. 14):

$$D^{\pm l}\otimes D^{\pm l}\otimes D^{\mp l}=N^2D^{\pm l}. \tag{4}$$

This relation expressed in terms of the basis vectors has a form

$$|w\rangle_{\pm}^{pq}=\sum_{stu} a^{pq}_{stu,w}|stu\rangle_{\pm\pm\mp}, \tag{5}$$

where $s,t,u,w,p,q=0,1,\ldots,N-1$, $|w\rangle_{\pm}$ is a state of the trion $X^{\pm}$, $|stu\rangle_{\pm\pm\mp}$ is a three-particle state with s,t labeling states of two holes (electrons), u being a label of a single electron (hole), and the pair p,q plays a role of a repetition index. The state $|w\rangle_{\pm}$ should behave as a basis vector of the representation $D^{\pm l}$, so

$$D^{\pm l}[n_1,n_2]|w\rangle_{\pm}=\omega_N^{\pm ln_1(w-n_2)}|w-n_2\rangle_{\pm}; \tag{6}$$

it is satisfied if $a^{pq}_{stu,w}=\delta_{s,w+p}\delta_{t,w+q}\delta_{u,w+p+q}$, or

$$|w\rangle_{\pm}^{pq}=|(w+p)\,(w+q)\,(w+p+q)\rangle_{\pm\pm\mp}. \tag{7}$$

Namely, for each pair p,q the product (4) acts on a ket $|w\rangle_{\pm}^{pq}$ as follows:

$$\begin{aligned} D^{\pm l}\otimes D^{\pm l}\otimes D^{\mp l}[n_1,n_2]|w\rangle_{\pm}^{pq} &= D^{\pm l}[n_1,n_2]|w+p\rangle D^{\pm l}[n_1,n_2]|w+q\rangle D^{\mp l}[n_1,n_2]|w+p+q\rangle \\ &= \omega_N^{\pm ln_1(w-n_2)}|(w+p-n_2)(w+q-n_2)(w+p+q-n_2)\rangle_{\pm\pm\mp} \\ &= \omega_N^{\pm ln_1(w-n_2)}|w-n_2\rangle_{\pm}^{pq}. \end{aligned}$$

For $p=q$ the states obtained are symmetric with respect to the transposition of identical particles (holes or electrons). In the other cases ($p\neq q$) it is easy to form symmetric and antisymmetric combinations:

$$|w\rangle_{\pm}^{pq\pm}=2^{-1/2}(|w\rangle_{\pm}^{pq}\pm|w\rangle_{\pm}^{qp}), \tag{8}$$

where now $q>p=0,1,\ldots,N-1$. In this way one obtains $N(N-1)/2$ antisymmetric states and (together with those for $p=q$) $N(N+1)/2$ symmetric ones. Completely antisymmetric states can be constructed by introducing symmetric and antisymmetric spin functions, respectively. Noninteracting trions, therefore, will be described by a similar Hamiltonian as for free holes (electrons) [cf. Eq. (1)] with a modified effective mass and, if necessary, an appropriate potential $V(\mathbf{r})$. However, the degeneracy of energy levels is N^2 times larger.

Another form of the irreducible basis can be obtained when one considers at first conjugation of two representations and next conjugation of the resultant representation with the third one. The first step can be done in two ways: (i) two identical representations are conjugated, i.e., one considers a product $D^l\otimes D^l$ or $D^{-l}\otimes D^{-l}$ and (ii) states of a pair hole–electron are determined. The first method is more interesting since it can be used in problems where pairs of identical particles come into play (e.g., superconducting states). However, the considerations are a bit more complicated since the parity of N has to be taken into account.[15] Hence, in this paper the second possibility will be investigated, whereas the first is presented elsewhere.[16]

B. States of a hole–electron pair

We start the considerations from constructing states of a hole–electron pair (in a general case: a particle–antiparticle pair). Since such a pair has the charge zero, then its behavior in the external magnetic field should be similar (up to effective mass, etc.) to this of a noncharged particle. It means that in the algebraic picture ordinary (vector) representations of the translation group have to appear. This is confirmed by the brief outlook presented previously: Projective representations used to labeling of electron and hole states differ in the sign of l only. When both particles move in the same magnetic field then corresponding representations are D^{+l} and D^{-l} (of course, the BvK period N is identical in both cases). In this case matrix elements of these representations are given by (2) and those of their product are

$$(D^{+l}\otimes D^{-l})_{jj',kk'}[n_1,n_2]=D_{jk}^{+l}[n_1,n_2]D_{j'k'}^{-l}[n_1,n_2]=\delta_{j,k-n_2}\delta_{j+k',k+j'}\omega_N^{ln_1(j-j')}. \tag{9}$$

The product of representations $D^{+l}\otimes D^{-l}$ is a reducible representation, which can be decomposed into the irreducible one-dimensional vector representations (3),

$$D^{+l}\otimes D^{-l}=\bigoplus_{\mathbf{k}} D^{\mathbf{k}}. \tag{10}$$

There is no need to use the repetition index, because each representation appears only once. We are looking for such N^2 linear combinations

$$|0\rangle_{\mathbf{k}}=\sum_{s,t} a_{st}^{\mathbf{k}}|s\rangle_{+}|t\rangle_{-},$$

each of which behaves as a basis vector of a given irreducible representation $D^{\mathbf{k}}$. It can be shown that $a_{st}^{\mathbf{k}}=\delta_{t,s-xk_1}\omega_N^{sk_2}$, where x is the inverse of l modulo N (since l is mutually prime with N, then x is well determined), i.e., $xl=1 \bmod N$. Namely one obtains

$$\begin{aligned}(D^{+l}\otimes D^{-l})[n_1,n_2]|0\rangle_{\mathbf{k}} &= \sum_s \omega_N^{sk_2} D^{+l}[n_1,n_2]|s\rangle_{+} D^{-l}[n_1,n_2]|s-xk_1\rangle_{-} \\ &= \sum_s \omega_N^{sk_2}\omega_N^{ln_1(s-n_2)}|s-n_2\rangle_{+}\omega_N^{ln_1(n_2+xk_1-s)}|s-xk_1-n_2\rangle_{-} \\ &= \omega_N^{k_1n_1+k_2n_2}\sum_{s'} \omega_N^{s'k_2}|s'\rangle_{+}|s'-xk_1\rangle_{-} \\ &= D^{\mathbf{k}}[n_1,n_2]|0\rangle_{\mathbf{k}}.\end{aligned}$$

C. Trion states

The results presented in the previous section yield

$$|0\rangle_{\mathbf{k}}=\sum_s \omega_N^{sk_2}|s\,(s-xk_1)\rangle_{+-}, \quad xl=1 \bmod N. \tag{11}$$

Therefore,

$$D^{+l}\otimes D^{-l}\otimes D^{\pm l}=\bigoplus_{\mathbf{k}} D^{\mathbf{k}}\otimes D^{\pm l}$$

and trion states $|w\rangle_{\pm}^{\mathbf{k}}$, $w=0,1,\ldots,N-1$, can be written as

$$|w\rangle_{\pm}^{\mathbf{k}}=\sum_{s,t,u} b_{stu}^{w;\mathbf{k}}|stu\rangle_{+-\pm},$$

where s,t label states of a pair and u those of the second hole (electron) for a trion $X^{\pm}$. The repetition index $\mathbf{k}$ follows from the way in which the final states are constructed: at first states $|s\rangle_{+}$ and $|t\rangle_{-}$ are conjugated to the states $|0\rangle_{\mathbf{k}}$ according to Eq. (11) and next linear combinations of pairs $|0\rangle_{\mathbf{k}}|u\rangle_{\pm}$ are considered. Therefore, one can write

$$|w\rangle_{\pm}^{\mathbf{k}}=\sum_u c_u^{w;\mathbf{k}}|0\rangle_{\mathbf{k}}|u\rangle_{\pm}.$$

Since for each $\mathbf{k}=(k_1,k_2)$, $k_1,k_2=0,1,\ldots,N-1$ one has[13,14]

$$D^{\mathbf{k}}\otimes D^{\pm l}=D^{\pm l},$$

then each such product yields states $|w\rangle_{\pm}$, but the coefficients c_u^w depend on $\mathbf{k}$ and are given as

$$c_u^{w;\mathbf{k}}=\omega_N^{-wk_2}\delta_{u,w\mp xk_1},$$

where, again, $xl=1 \bmod N$, so

$$|w\rangle_{\pm}^{\mathbf{k}}=\omega_N^{-wk_2}|0\rangle_{\mathbf{k}}|w\mp xk_1\rangle_{\pm}\,. \tag{12}$$

Taking into account Eqs. (3) and (6) one obtains

$$\begin{aligned}(D^{\mathbf{k}}\otimes D^{\pm l})[n_1,n_2]|w\rangle_{\pm}^{\mathbf{k}}&=\omega_N^{-wk_2}D^{\mathbf{k}}[n_1,n_2]|0\rangle_{\mathbf{k}}D^{\pm l}[n_1,n_2]|w\mp xk_1\rangle_{\pm}\\&=\omega_N^{-(w-n_2)k_2}\omega_N^{\pm ln_1(w-n_2)}|0\rangle_{\mathbf{k}}|w\mp xk_1-n_2\rangle_{\pm}\\&=\omega_N^{\pm ln_1(w-n_2)}|w-n_2\rangle_{\pm}=D^{\pm l}[n_1,n_2]|w\rangle_{\pm}\,.\end{aligned}$$

Equations (11) and (12) lead to the final expression ($xl=1 \bmod N$, $N^{-1/2}$ is a normalization factor)

$$|w\rangle_{\pm}^{\mathbf{k}}=N^{-1/2}\omega_N^{-wk_2}\sum_s\ \omega_N^{sk_2}|s\ (s-xk_1)\ (w\mp xk_1))\rangle_{+-\pm}\,. \tag{13}$$

In such a state there is a kind of symmetry between an electron and a hole forming the neutral pair electron–hole, but there is no symmetry between two holes (electrons) in the trion $X^{\pm}$. Since there are N^2 trion states labeled by w then it is possible to construct states symmetric and antisymmetric with respect to transposition of particles. One of the possible ways is presented in Sec. III A and it is easy to determine a transformation between the basis obtained earlier and that presented previously.

Let us consider states of a trion X^+. The results of Sec. III A read

$$|w\rangle_+^{pq}=|(w+p)\ (w+q)\ (w+p+q))\rangle_{++-}\,, \tag{14}$$

where the first two indices correspond to the states of a hole and a third one to the state of an electron. In the above-presented formula (13) holes are labeled by the first and the third indices, whereas the middle one corresponds to an electron. Therefore, to calculate scalar products the order of indices has to be changed in one of these formulas. Having this done one obtains

$$\begin{aligned}{}_+^{\mathbf{k}}\langle w|w\rangle_+^{pq}&=N^{-1/2}\omega_N^{wk_2}\sum_s\ \omega_N^{-sk_2}{}_{+-+}\langle s\ (s-xk_1)\ (w-xk_1)|(w+p)\ (w+p+q)\ (w+q)\rangle_{+-+}\\&=N^{-1/2}\omega_N^{-pk_2}\delta_{q+xk_1,0}\,.\end{aligned} \tag{15}$$

In the simplest case $N=2$ this formula yields [the unique representation is obtained for $l=x=1$; $\mathbf{k}=(k_1,k_2)$]

$$|w\rangle_+^{00}=2^{-1/2}(|w\rangle_+^{(0,0)}+|w\rangle_+^{(1,0)}),$$

$$|w\rangle_+^{01}=2^{-1/2}(|w\rangle_+^{(0,0)}-|w\rangle_+^{(1,0)}),$$

$$|w\rangle_+^{10}=2^{-1/2}(|w\rangle_+^{(0,1)}+|w\rangle_+^{(1,1)}),$$

$$|w\rangle_+^{11}=2^{-1/2}(|w\rangle_+^{(0,1)}-|w\rangle_+^{(1,1)}).$$

The second and the third formulas can be symmetrized, which yields

$$|w\rangle_+^{01+}=2^{-1}(|w\rangle_+^{(0,0)}-|w\rangle_+^{(1,0)}+|w\rangle_+^{(0,1)}+|w\rangle_+^{(1,1)}),$$

$$|w\rangle_+^{01-}=2^{-1}(|w\rangle_+^{(0,0)}-|w\rangle_+^{(1,0)}-|w\rangle_+^{(0,1)}-|w\rangle_+^{(1,1)}).$$

IV. OTHER GAUGES

A trivial factor system θ (of an extension of groups or a projective representation) is determined by any mapping $\phi: G \to \mathrm{U}(1)$ by[9,17]

$$\theta(\mathbf{R},\mathbf{R}') = \phi(\mathbf{R})\,\phi(\mathbf{R})/\phi(\mathbf{R}+\mathbf{R}');$$

the factor system θ is standard if $\phi(\mathbf{0})=1$. If $\mu'(\mathbf{R},\mathbf{R}') = \mu(\mathbf{R},\mathbf{R}')\,\theta(\mathbf{R},\mathbf{R}')$ then factor systems μ and μ' are called equivalent. It can be easily shown[9] that these factor systems lead to the same value of the magnetic flux encircled by a loop formed by the vectors $\mathbf{R}$, $\mathbf{R}'$, $-\mathbf{R}$, and $-\mathbf{R}'$ and, therefore, is related to the magnitude of the magnetic field and is gauge independent (i.e., does not depend on the vector potential $\mathbf{A}$). Let θ be a standard trivial factor system determined by a mapping ϕ and let D be a projective representation with a factor system μ, i.e.,

$$D(\mathbf{R})D(\mathbf{R}') = \mu(\mathbf{R},\mathbf{R}')D(\mathbf{R}+\mathbf{R}').$$

A new representation D' determined as $D'(\mathbf{R}) = \phi(\mathbf{R})D(\mathbf{R})$ has an equivalent factor system $\mu' = \theta\mu$. On the other hand, for any unitary operator S and $D''(\mathbf{R}) = SD(\mathbf{R})S^{-1}$ one obtains

$$D''(\mathbf{R})D''(\mathbf{R}') = \mu(\mathbf{R},\mathbf{R}')D''(\mathbf{R}+\mathbf{R}'),$$

so *equivalent* representations have *identical* factor systems. It means that bases introduced for representations with equivalent (but different) factor systems are *not* related to each other by means of a *global* unitary transformation.[17] The relation between representations D and D' is *local*, since it depends on a vector $\mathbf{R}$ of the translation group.

These considerations give rise to the problem in which way bases obtained for different choices of the vector potential (different gauges) are related to each other. The most popular gauges, i.e., the Landau and the symmetric ones, are the special cases of the so-called linear gauge,[11] which in the 2D case has the form

$$\mathbf{A}(\mathbf{r}) = H[-\beta y, (1-\beta)x],$$

where H is a magnitude of the magnetic field $\mathbf{H}=[0,0,H]$. The relation between the vector potential $\mathbf{A}$ and the factor system of a projective representation shown in Ref. 8 yields that $\beta = 0$ corresponds to the representation (2), whereas $\beta=1$ and $\beta=1/2$, determining the other form of the Landau gauge and the (anti)symmetric one $\mathbf{A}=(\mathbf{H}\times\mathbf{r})/2$, lead to matrices

$${}^{1}D^{l}_{jk}[n_1,n_2] = \delta_{j,k-n_2}\omega_N^{ln_1k}, \quad {}^{1/2}D^{l}_{jk}[n_1,n_2] = \delta_{j,k-n_2}\omega_N^{ln_1(j+k)/2}.$$

In a general case one obtains

$${}^{\beta}D^{l}_{jk}[n_1,n_2] = \delta_{k-j,n_2}\omega_N^{ln_1[(1-\beta)j+\beta k]} = \delta_{k-j,n_2}\omega_N^{ln_1(j+\beta n_2)} = \omega_N^{ln_1n_2\beta}\,{}^{0}D^{l}_{jk}[n_1,n_2]. \tag{16}$$

The action of operators ${}^{\beta}D^{l}$ for vectors $[n_1,0]$ and $[0,n_2]$ on the basis vectors yields

$${}^{\beta}D^{l}[n_1,0]|j\rangle = \omega_N^{ln_1j}|j\rangle, \quad {}^{\beta}D^{l}[0,n_2]|j\rangle = |j-n_2\rangle.$$

Therefore, they behave in the same way for all real numbers β. The differences can only be noticed for general translations $[n_1,n_2]$ and, moreover, the nonzero matrix elements obtained for different β appear in the same places (it is controlled by the δ_{k-j,n_2}), but are multiplied by different powers of ω_N^l. Let us recall the former name of projective representations, used especially by physicists (see, e.g., Ref. 6). They were called *ray* representations, which was strongly related to the notion of *rays* in quantum mechanics.[18] Since only a module of a bracket $\langle j|k\rangle$ has

a physical meaning, then vectors (complex functions) $|j\rangle$, $|k\rangle$ are determined up to factors $\lambda \in U(1)$. Therefore, a chosen state $|j\rangle$ represents in fact a ray, i.e., the set $||j\rangle\rangle=\{\lambda|j\rangle|\lambda \in U(1)\}$. In a general case

$$ {}^{\beta}D^{l}_{jk}[n_1,n_2]=\langle j|{}^{\beta}D^{l}[n_1,n_2]|k\rangle=\delta_{k-j,n_2}\omega_N^{-ln_1j\beta}\omega_N^{ln_1j}\omega_N^{ln_1k\beta}. $$

Therefore, replacing each vector $|j\rangle$ by an element of the same ray $|j'\rangle=\omega_N^{-ln_1j\beta}$ one obtains

$$ \langle j'|{}^{\beta}D^{l}[n_1,n_2]|k'\rangle=\omega_N^{ln_1(j-k)\beta}\langle j|{}^{\beta}D^{l}[n_1,n_2]|k\rangle=\delta_{k-j,n_2}\omega_N^{ln_1j}={}^{0}D^{l}_{jk}[n_1,n_2]. $$

However, this transformation is *local*, because it depends on n_1 and, in fact, n_2, since $k-j=n_2$ for nonzero matrix elements. If can be verified that Eq. (7) is invariant under this transformation, so all relations derived here for the Landau gauge are valid for other linear gauges.

V. FINAL REMARKS

The presented considerations have shown that free trions should behave in a similar way to free electrons or holes. However, due to their internal structure the degeneracy is higher and there are many possibilities to construct states $|w\rangle_{\pm}$, two of which have been discussed previously. In these simplified considerations there are no interactions between trions or mixing of Landau levels and the spin or angular momentum numbers have not been considered. Taking into account spins will allow one to construct states completely antisymmetric with respect to the permutational symmetry. Such problem has been discussed lately by Dzyubenko *et al.*[5] for the case of free trions (i.e., without a periodic potential, so there is no discrete translational symmetry). A sum of indices on the right-hand side of (14), taking into account signs of charges, is $(2w+p+q)-(w+p+q)=w$, which is equal to the index on the left-hand side of this equation. This is the same result as presented in Ref. 5, where the total angular momentum projection of a trion equals $(n_1-m_1)+(n_2-m_2)-(n_3-m_3)$, where (n_j-m_j) is the total angular momentum projection for holes ($j=1,2$) and an electron ($j=3$), with n and m being the Landau level and the oscillator quantum numbers, respectively. It is interesting that Dzyubenko *et al.* obtained their results in the antisymmetric gauge $\mathbf{A}=(\mathbf{H}\times\mathbf{r})/2$, whereas in the presented considerations the Landau gauge has been used. It confirms that the physical properties are gauge independent. On the other hand, the actual form of wave functions is not discussed here, but the relations between representations and their product are taken into account only. These relations are independent of the matrix representations and, similarly, the form of resultant basis is independent of the function form: for a given BvK period N and any linear gauge irreducible projective representations are N-dimensional and their action on basis vectors are similar (up to a factor system).[6,7,9,19]

(Received 26 October 2000; accepted for publication 10 July 2001)

We consider the $(\lambda/4!)(\varphi_1^4+\varphi_2^4)$ model on a d-dimensional Euclidean space, where all but one of the coordinates are unbounded. Translation invariance along the bounded coordinate, z, which lies in the interval $[0,L]$, is broken because of the boundary conditions (BCs) chosen for the hyperplanes $z=0$ and $z=L$: DD and NN, where D denotes Dirichlet and N Neumann, respectively. The renormalization procedure up to one-loop order in the two-point function is applied, obtaining two main results. The first is the fact that the renormalization program requires the introduction of counterterms which are surface interactions. The second one is that the tadpole graphs for DD and NN have the same z dependent part in modulus but with opposite signs. We investigate the relevance of this fact to the elimination of surface divergences. © *2001 American Institute of Physics.*

I. INTRODUCTION

In this article we consider an interacting quantum field theory model in the presence of boundaries. We shall assume that the system is finite along one dimension $z\in[0,L]$, and infinitely extended along the remaining $(d-1)$ directions.

The presence of geometric restrictions on the domain of one of the coordinates of the system demands the introduction of classical boundary conditions, to be satisfied by the fields on the two hypersurfaces at $z=0$ and $z=L$. If we restrict ourselves to a real scalar field, Hermiticity of the Hamiltonian leads us to five different (inequivalent) choices for the BCs, namely, DD, NN, DN, periodic and antiperiodic. The last two choices are usual in the finite-temperature literature and shall not be dealt with here since they do not break translation invariance, which is the phenomenon we are concerned with.

Physical systems will be, in general, finite along several directions. For the sake of simplicity we will consider a d-dimensional layered geometry. Although the highly idealized case of planar boundaries misses a whole series of features that are present in the general, curved boundary case, for more general shapes the multiple reflection method can be used to find the correlation functions of the model.[1]

Most of the papers in the literature deal with periodic or antiperiodic boundary conditions, where translation symmetry is maintained and surface effects avoided. Moreover, in quantum systems where translation symmetry is broken, the renormalization procedure is more involved than for translation invariant systems, either bounded or unbounded. The diagrammatic expansion and the renormalization program for an unbounded system are conveniently performed in momentum space. On the other hand, when DD or NN BCs are implemented, one may still work with Green's functions at fixed $(d-1)$-dimensional momenta, since there is translation symmetry along those dimensions. In this case a convenient representation for the Green functions is a mixed $(\vec{p},z)$ space.

It is well known that the electromagnetic field confined between two parallel plates has a finite

renormalized stress-tensor near the boundaries without surface divergences. In the Casimir subtraction, one finds that when $\langle 0|\vec{E}^2|0\rangle$ and $\langle 0|\vec{B}^2|0\rangle$ are added their boundary singularities cancel. In this article we reexaminate this result and we will use two different facts to rederive it:

(i) First it was shown that for an electromagnetic field confined in a perfectly conducting cavity it is possible to treat the electric and magnetic modes separately where each one satisfies Dirichlet and Neumann boundary conditions, respectively.[2]
(ii) Second is the fact that the size-dependent parts of the tadpole for *DD* and *NN* BC have the same functional form and opposite signs.

Consequently, the study of two mutually noninteracting scalar fields subject to different boundary conditions reproduces exactly the electromagnetic case. It is a different way to rederive the case of finiteness of the renormalized electromagnetic stress-tensor near a perfectly conducting plate.

In this article we will consider a massive scalar theory subject to two different classical BCs: *DD* and *NN* (the mass acts just as an infrared regulator). Besides the lack of translational invariance, we shall face the problem of surface divergences. One way to avoid them is to smooth out the plates surface. But in this case an ambiguity appears, since loop-graphs will depend on an *ad hoc* model assumption, namely, the particular features of the smooth walls. Consequently, we prefer to maintain the hard walls assumption. In the context of the Casimir energy of minimally coupled scalar fields, many authors used soft, hard and semi-hard BCs.[3] Different questions sometimes require more complicated BCs, like the quantum mechanical treatment of the boundary conditions presented by Ford and Svaiter,[4] a device implemented to solve a long standing paradox concerning the renormalized energy of minimally and conformally coupled scalar fields.

For translation invariant systems, because of Poincaré invariance, one should expect that overlapping divergences will not obstruct the implementation of the renormalization program.[5] In systems where Poincaré invariance does not hold, these proofs do not apply, and one must show that it is still possible to implement such program. A technical difficulty is also met here, since the presence of geometric restrictions makes Feynman diagrams harder to compute than is ordinary quantum field theory in unbounded systems. A crucial work on this subject has been presented by Symanzik.[6] Of particular importance are also the papers by Nemirovsky and Freed, and Krech and Dietrich.[7]

The organization of the article is as follows: In Sec. II we discuss the slab configurations, dealing with the two-point and four-point functions, both for *DD* and *NN* BCs. In Sec. III we analyze the divergences of the translational invariant part of the tadpoles. Section IV deals with the analysis of the ultraviolet and infrared divergences of the z-dependent part of the tadpoles. Finally, Sec. V contains our conclusions. Throughout this article we use $\hbar = c = 1$.

II. FINITE SIZE EFFECTS AND CLASSICAL BOUNDARY CONDITIONS

Let us consider a d-dimensional Euclidean space with the anisotropic Landau–Ginzburg model for an $N=2$ component order parameter with a Lagrange density $\mathcal{L}=\mathcal{L}_0+\mathcal{L}_{\rm int}$, where

$$\mathcal{L}_0(\varphi_1,\varphi_2)=\tfrac{1}{2}(\partial\varphi_1)^2+\tfrac{1}{2}(\partial\varphi_2)^2+\tfrac{1}{2}m^2\varphi_1^2+\tfrac{1}{2}m^2\varphi_2^2 \tag{1}$$

and

$$\mathcal{L}_{\rm int}=\frac{\lambda}{4!}(\varphi_1^4+\varphi_2^4). \tag{2}$$

As discussed before, we will assume that the system is confined between two parallel plates localized at $z=0$ and $z=L$, and use the Cartesian coordinates $x^\mu=(\vec{r},z)$ where $\vec{r}$ is a

$(d-1)$-dimensional vector perpendicular to the z direction. For the cubic anisotropic model, we define the boundary conditions over the plates for the fields $\varphi_1(x)$ and $\varphi_2(x)$. For the $\varphi_1(x)$ field we assume Dirichlet–Dirichlet boundary conditions, i.e.,

$$\varphi_1(\vec{r},z)|_{z=0}=\varphi_1(\vec{r},z)|_{z=L}=0, \tag{3}$$

and for the $\varphi_2(x)$ we will assume Neumann–Neumann boundary conditions, i.e.,

$$\frac{\partial}{\partial z}\varphi_2(\vec{r},z)\bigg|_{z=0}=\frac{\partial}{\partial z}\varphi_2(\vec{r},z)\bigg|_{z=L}=0. \tag{4}$$

It is well known that ^{4}He films close to the λ transition satisfy DD BCs. Another well known example of such kind of boundary conditions is the electromagnetic field. It was shown that for an electromagnetic field confined in a perfectly conducting cavity, it is possible to treat the electric and magnetic modes separately, where each one satisfies Dirichlet and Newmann BCs, respectively.[2] Going back to our discussion, since the translational invariance is not preserved, let us use a Fourier expansion of the fields in the following form:

$$\varphi(\vec{r},z)=\frac{1}{(2\pi)^{(d-1)/2}}\int d^{d-1}p\sum_n \phi_n(\vec{p})e^{i\vec{p}\cdot\vec{r}}u_n(z), \tag{5}$$

where the $u_n(z)$ are the normalized eigenfunctions of the operator $-d^2/dz^2$ satisfying the completeness and orthonormality relations, i.e.,

$$\sum_n u_n(z)u_n^*(z')=\delta(z-z'), \tag{6}$$

$$\int_0^L dz u_n(z)u_{n'}^*(z)=\delta_{n,n'}, \tag{7}$$

and finally

$$-\frac{d}{dz^2}u_n(z)=k_n^2u_n(z), \tag{8}$$

where $k_n=n\pi/L$, $n=1,2,...$, for DD BCs and $n=0,1,2,...$,for NN BCs.

Coming back to the case of DD and NN boundary conditions, the eigenfunctions are, respectively,

$$u_n(z)=\sqrt{\frac{2}{L}}\sin\left(\frac{n\pi z}{L}\right), \quad n=1,2,..., \tag{9}$$

and

$$u_n(z)=\sqrt{\frac{2}{L}}\cos\left(\frac{n\pi z}{L}\right), \quad n=1,2,\dots . \tag{10}$$

For NN BCs, we also have the zeroth mode $u_0(z)=1/\sqrt{L}$. The free propagator can be expressed in the following form:

$$G_0^{(2)}(\vec{r},z,z')=\frac{1}{(2\pi)^{d-1}}\int d^{d-1}p\sum_n e^{i\vec{p}\cdot\vec{r}}u_n(z)u_n^*(z')G_{0,n}(\vec{p}), \tag{11}$$

where it is not difficult to show that $G_{0,n}(\vec{p})$ is given by

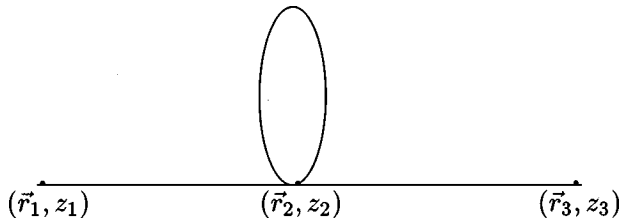

FIG. 1. The two-point function for $\varphi_1(x)$.

$$G_{0,n}(\vec{p}) = (\vec{p}^2 + k_n^2 + m^2)^{-1}. \tag{12}$$

As we discussed before, for translational invariant systems we have $G_0^{(2)}(x,x') = G_0^{(2)}(x - x')$ and from coordinate space Feynman rules we can go to momentum space representation, which is the more convenient framework to analyze the divergences of the theory. Translation invariance is reflected in momentum conservation conditions. Since our system possesses translation invariance along the direction parallel to the plates, the parallel momentum, $\vec{p}$, is conserved. In this case a convenient representation is a mixed $(\vec{p},z)$ space. The Feynman rules for different boundary conditions were derived in many references and we will not repeat the rules here. For a careful study of Feynman rules in such systems, see, for example, Ref. 8. Let us study the one-loop correction to the bare two-point function $G_0^{(2)}(x,x')$, both for the *DD* and *NN* cases. Using the Feynman rules (see Fig. 1) we have

$$G_0^{(2)}(\lambda,\vec{r}_1,z_1,\vec{r}_3,z_3) = \frac{\lambda}{2}\int d^{d-1}r_2 \int_0^L dz_2 G_0^{(2)}(\vec{r}_1,z_1;\vec{r}_2,z_2) \times G_0^{(2)}(\vec{r}_2,z_2;\vec{r}_2,z_2) G_0^{(2)}(\vec{r}_2,z_2;\vec{r}_3,z_3). \tag{13}$$

Each of these expressions can, for the case of *DD* BCs, be expanded as

$$G_0^{(2)}(\vec{r}_1 - \vec{r}_2, z_1, z_2) = \frac{2}{L}\frac{1}{(2\pi)^{d-1}} \sum_{n=1}^{\infty} \sin\left(\frac{n\pi z_1}{L}\right) \sin\left(\frac{n\pi z_2}{L}\right) \int d^{d-1}p \, \frac{e^{i\vec{p}.(\vec{r}_1 - \vec{r}_2)}}{(\vec{p}^2 + (n\pi/L)^2 + m^2)}. \tag{14}$$

$$G_0^{(2)}(\vec{r}_2 - \vec{r}_3, z_2, z_3) = \frac{2}{L}\frac{1}{(2\pi)^{d-1}} \sum_{n'=1}^{\infty} \sin\left(\frac{n\pi z_2}{L}\right) \sin\left(\frac{n\pi z_3}{L}\right) \int d^{d-1}p \, \frac{e^{i\vec{p}.(\vec{r}_2 - \vec{r}_3)}}{(\vec{p}^2 + (n'\pi/L)^2 + m^2)}, \tag{15}$$

and finally using the notation $G_0^{(2)}(\vec{r}_2,z_2;\vec{r}_2,z_2) = G_0^{(2)}(\vec{0},z_2)$ we have

$$G_0^{(2)}(\vec{0},z_2) = \frac{2}{L}\frac{1}{(2\pi)^{d-1}} \sum_{n''=1}^{\infty} \sin^2\frac{n''\pi z_2}{L} \int d^{d-1}p \, \frac{1}{(\vec{p}^2 + (n''\pi/L)^2 + m^2)}. \tag{16}$$

Although the functions $G_0^{(2)}(\vec{r}_1 - \vec{r}_2, z_1, z_2)$ and $G_0^{(2)}(\vec{r}_2 - \vec{r}_3, z_2, z_3)$ are singular at $\vec{r}_1 = \vec{r}_2$, $z_1 = z_2$ and $\vec{r}_2 = \vec{r}_3$, $z_2 = z_3$, the singularities are integrable (for points outside the plates), consequently only the tadpole is divergent and needs a regularization and renormalization procedure. A straightforward calculation yields the order λ correction to the bare two-point function in the one-loop approximation:

$$G_0^{(2)}(\lambda,\vec{r}_1-\vec{r}_3,z_1,z_3)=\frac{2}{L^2}\frac{1}{(2\pi)^{d-1}}\int_0^L dz_2\sum_{n,n'=1}^{\infty}\sin\left(\frac{n\pi z_1}{L}\right)\times\sin\left(\frac{n\pi z_2}{L}\right)\sin\left(\frac{n'\pi z_2}{L}\right)\sin\left(\frac{n'\pi z_3}{L}\right)\times\int d^{d-1}p\,\frac{e^{i\vec{p}(\vec{r}_1-\vec{r}_3)}}{(\vec{p}^2+(n\pi/L)^2+m^2)(\vec{p}^2+(n'\pi/L)^2+m^2)}T_{DD}(L,m,d,z_2),\tag{17}$$

where, since we will use dimensional regularization, we introduce a dimensional parameter μ, and define $g=\lambda\mu^{4-d}$. The expression for the tadpole $T_{DD}(L,m,d,z)$ is then

$$T_{DD}(L,m,d,z)=\frac{2g}{L}\frac{1}{(2\pi)^{d-1}}\sum_{n=1}^{\infty}\sin^2\left(\frac{n\pi z}{L}\right)\int d^{d-1}p\,\frac{1}{(\vec{p}^2+(n\pi/L)^2+m^2)}.\tag{18}$$

The tadpole graph in the case of NN BCs can also be easily found, and it is given by

$$T_{NN}(L,m,d,z)=\frac{g}{L}\frac{1}{(2\pi)^{d-1}}\int d^{d-1}k\,\frac{1}{(\vec{k}^2+m^2)}+\frac{2g}{L}\frac{1}{(2\pi)^{d-1}}\sum_{n=1}^{\infty}\cos^2\left(\frac{n\pi z}{L}\right)\int d^{d-1}p\,\frac{1}{(\vec{p}^2+(n\pi/L)^2+m^2)}.\tag{19}$$

Note that both $T_{DD}(L,m,d,z)$ and $T_{NN}(L,m,d,z)$ diverge in their continuum momenta integrals and also in the n summation. In the next section we will analyze the ultraviolet behavior of the bare two-point functions, i.e., $T_{DD}(L,m,d,z)$ and $T_{NN}(L,m,d,z)$.

III. ANALYSIS OF THE ULTRAVIOLET DIVERGENCES OF $T_{DD}(L,m,d,z)$ AND $T_{NN}(L,m,d,z)$

The aim of this section is to analyze the structure of the divergences of the bare two-point functions for cases of both DD and NN boundary conditions. Let us start from the expression of the vacuum activity for the case of DD boundary conditions, i.e.,

$$T_{DD}(L,m,d,z)=\frac{2g}{L}\frac{1}{(2\pi)^{d-1}}\sum_{n=1}^{\infty}\sin^2\left(\frac{n\pi z}{L}\right)\int d^{d-1}p\,\frac{1}{(\vec{p}^2+(n\pi/L)^2+m^2)}.\tag{20}$$

Using trigonometric identities and also the relation[9]

$$\sum_{n=1}^{\infty}\frac{\cos nx}{n^2+a^2}=-\frac{1}{2a^2}+\frac{\pi}{2a}\frac{\cosh a(\pi-x)}{\sinh\pi a},\tag{21}$$

which is valid for $0\leqslant x\leqslant 2\pi$, it is easy to show that the vacuum activity in the case of DD BCs is given by

$$T_{DD}(L,m,d,z)=\frac{g}{2L}\frac{1}{(2\pi)^{d-1}}\sum_{n=-\infty}^{\infty}\int d^{d-1}p\,\frac{1}{(\vec{p}^2+(n\pi/L)^2+m^2)}-gf_2(d,L,m,z),\tag{22}$$

where

$$f_2(L,m,d,z)=\frac{1}{2}\frac{1}{(2\pi)^{d-1}}\int d^{d-1}p\,\frac{1}{(\vec{p}^2+m^2)^{1/2}}\frac{\cosh\left((L-2z)(\vec{p}^2+m^2)^{1/2}\right)}{\sinh\left(L(\vec{p}^2+m^2)^{1/2}\right)}. \tag{23}$$

In an analogous way, it is also possible to calculate the vacuum activity for the NN BCs, i.e., $T_{NN}(L,m,d,z)$ and we obtain

$$T_{NN}(L,m,d,z)=\frac{g}{2L}\frac{1}{(2\pi)^{d-1}}\sum_{n=-\infty}^{\infty}\int d^{d-1}p\,\frac{1}{(\vec{p}^2+(n\pi/L)^2+m^2)}+g f_2(L,m,d,z). \tag{24}$$

Since $T_{DD}(L,m,d,z)$ and $T_{NN}(L,m,d,z)$ have the same functional form, both have the same kind of ultraviolet divergences. Let us define $f_1(L,m,d)$ by

$$f_1(L,m,d)=\frac{1}{2L}\frac{1}{(2\pi)^{d-1}}\sum_{n=-\infty}^{\infty}\int d^{d-1}p\,\frac{1}{(\vec{p}^2+(n\pi/L)^2+m^2)}. \tag{25}$$

The equation above has ultraviolet divergences, but it is (formally) proportional to the tadpole in finite temperature field theory, after the identification: $\beta\equiv 2L$. To deal with the divergences of the one-loop two-point function at finite temperature we have to do frequency sums and $(d-1)$-dimensional integrals for the continuum momenta. The most popular method to deal with Matsubara sums is analytic extension away from the discrete complex energies down to real axis with the replacement of the energy sums by contour integrals.[10] We prefer to use dimensional regularization in the continuum,[11] and afterwards to analytically extend the modified Epstein zeta function which appears after the dimensional regularization.[12] Since the formalism has already been developed by Malbouisson and Svaiter in Ref. 13, we will only sketch the procedure here. First we have to use a well known result of dimensional regularization, i.e.,

$$\int\frac{d^dk}{(k^2+a^2)^s}=\frac{\pi^{d/2}}{\Gamma(s)}\Gamma\left(s-\frac{d}{2}\right)\frac{1}{a^{2s-d}}, \tag{26}$$

and let us define the modified Epstein zeta function $\zeta(z,a)$ by

$$\zeta(z,a)=\sum_{n=-\infty}^{\infty}\frac{1}{(n^2+a^2)^z},\quad a^2>0, \tag{27}$$

which is analytic for $\mathrm{Re}(z)>\frac{1}{2}$. It is possible to analytically extend the modified Epstein zeta function where the integral representation is valid for $\mathrm{Re}(z)<1$[14]

$$\sum_{n=-\infty}^{\infty}(n^2+a^2)^{-z}=a^{1-2z}\left[\sqrt{\pi}\frac{\Gamma\left(z-\frac{1}{2}\right)}{\Gamma(z)}+4\sin\pi z\int_1^{\infty}\frac{(t^2-1)^{-z}dt}{e^{2\pi at}-1}\right]. \tag{28}$$

Using Eqs. (26) and (28) in Eq. (25), we get a polar part (size independent) plus a size dependent analytic correction. It is clear that the mass counterterm generated by $f_1(L,m,d)$ is size independent, as the finite temperature field theory has no temperature dependent counterterm. The first interesting result of the article is given by Eqs. (22) and (24). The tadpole graphs expressed by $T_{DD}(L,m,d,z)$ and $T_{NN}(L,m,d,z)$ have the same z dependent part in modulus but with opposite signs. From the previous discussion it is possible to understand the finiteness of the renormalized stress-tensor of an electromagnetic field near a flat prefectly conducting plate. Although the expectation values of the squared electric and magnetic field are divergent, a delicate cancellation makes the renormalized stress-tensor finite. As the size dependent parts of $T_{DD}(L,m,d,z)$ and $T_{NN}(L,m,d,z)$ have the same functional form and opposite signs, and recalling that it is possible to treat the electric and magnetic modes separately (where one obeys DD and the other NN BCs),

we automatically obtain a finite result for the vacuum expectation value of the stress-tensor of the electromagnetic field. It is important to stress that when the conducting boundary is curved, the energy density diverges on the boundary.[15]

We shall deal with the renormalization program in the one-loop approximation in the next section, also discussing, for the sake of completeness, the issue of infrared (IR) divergencies in different numbers of dimensions.

IV. ANALYSIS OF THE ULTRAVIOLET AND INFRARED DIVERGENCES OF THE *z*-DEPENDENT PART OF THE TADPOLES

Let us use the fact that $d^{d-1}p=p^{d-2}dpd\Omega_{d-1}$ and $\int d\Omega_{d-1}=2\pi^{(d-1)/2}/\Gamma((d-1)/2)$. It should be noted that, had we chosen $m^2=0$, the ultraviolet divergences would have kept the same polar structure. Consequently, for simplicity let us choose again $m=0$, and, for reasons that will become evident later, we first assume $d>3$. The special case $d=3$ is discussed at the end of this section. Defining $h_2(d)$ by

$$h_2(d)=\frac{1}{2^{d-2}}\,\frac{1}{\pi^{(d-1)/2}}\,\frac{1}{\Gamma((d-1)/2)}, \tag{29}$$

it is possible to write $f_2(L,m,d,z)|_{m=0}$ as

$$f_2(L,m,d,z)|_{m=0}=\frac{1}{2}h_2(d)\int_0^\infty dk k^{d-3}\coth kL\cosh 2kz-h_2(d)\int_0^\infty dk k^{d-3}\cosh kz\sinh kz. \tag{30}$$

In a general way, the regularization process is achieved by introducing exponential cut-off regulators and after that the identification of the poles of the regularized quantity by means of the Laurent series expansion around some point, i.e., the negative power portion of such series. Note that instead of imposing renormalization conditions over the 1PI correlation functions, we can simply subtract the singular part of the Laurent series around some point, by the introduction of the counterterms. Let us assume $z\neq 0$ and $z\neq L$. A straightforward calculation gives

$$f_2(L,m,d,z)|_{m=0}=\frac{1}{2}h_2(d)\left[\int_0^\infty dk k^{d-3}(\coth kL-1)\cosh 2kz + \int_0^\infty dk k^{d-3}(\cosh 2kz-\sinh 2kz)\right]. \tag{31}$$

In the first integral for large k, $(\coth kL-1)$ has the behavior $(\coth kL-1)\sim e^{-2kL}$. Moreover, the second integral in Eq. (31) is ultraviolet finite for $z\neq 0$. Let us define $x=kL$ and $q=kz$ in the first and second integrals above, respectively. Then Eq. (31) becomes

$$f_2(L,m,d,z)|_{m=0}=\frac{1}{2}h_2(d)\frac{1}{L^{d-2}}\int_0^\infty dx x^{d-3}(\coth x-1)\cosh\left(\frac{2z}{L}x\right) + \frac{1}{2}h_2(d)\frac{1}{z^{d-2}}\int_0^\infty dq q^{d-3}(\cosh 2q-\sinh 2q). \tag{32}$$

The second term in the above equation gives us the well known result that for a massless minimal coupled scalar field $\langle\varphi^2(x)\rangle$ diverges as $1/z^2$ if we approach the plate.[16] In order to analyze the polar part of $f_2(L,0,d,z)$, we use the definition of the gamma function. Let us define $I_1(\nu,\mu)$ and $I_2(\mu,\beta)$ by

$$I_1(\mu,\nu)=\int_0^\infty dx x^{\mu-1}e^{-\nu x}=\frac{1}{\nu^\mu}\Gamma(\mu),\quad \mathrm{Re}(\mu)>0,\quad \mathrm{Re}(\nu)>0, \tag{33}$$

and

$$I_2(\mu,\beta)=\int_0^\infty dx x^{\mu-1}e^{-\beta x}(\coth x-1)=2^{1-\mu}\Gamma(\mu)\zeta\left(\mu,\frac{\beta}{2}+1\right),\quad \mathrm{Re}(\beta)>0,\quad \mathrm{Re}(\mu)>1, \tag{34}$$

where $\zeta(z,a)$ is the Riemann zeta function defined by[9]

$$\zeta(z,a)=\sum_{n=0}^{\infty}\frac{1}{(n+a)^z},\quad \mathrm{Re}(z)>1,\quad a\neq 0,-1,-2,\ldots . \tag{35}$$

Then, using Eqs. (33)–(35) in Eq. (32) we have that

$$f_2(L,m,d,z)|_{m=0}=\frac{1}{2}h_2(d)\frac{1}{L^{d-2}}\left[2^{2-d}\Gamma(d-2)\left(\zeta\left(d-2,\frac{z}{L}+1\right)+\zeta\left(d-2,-\frac{z}{L}+1\right)\right)\right]+\frac{1}{(2z)^{d-2}}h_2(d)\Gamma(d-2). \tag{36}$$

Using the definition of the zeta function, it is evident that

$$\frac{1}{L^{d-2}}\left(\zeta\left(d-2,\frac{z}{L}+1\right)+\zeta\left(d-2,-\frac{z}{L}+1\right)\right)=\frac{1}{L^{d-2}}\sum_{n=0}^{\infty}\frac{1}{(n+(1+z/L))^{d-2}}+\frac{1}{(L-z)^{d-2}}+\frac{1}{L^{d-2}}\sum_{n=1}^{\infty}\frac{1}{(n+(1-z/L))^{d-2}}. \tag{37}$$

We see that the regularized $f_2(L,0,d,z)$ has two poles of order $(d-2)$ in $z=0$ and in $z=L$. Note that the residues of the poles in $z=0$ and in $z=L$ are L independent. Since the domain of analyticity of the zeta function is $d>3$, the case $d=3$ must be studied separately. Different treatments for $d=3$ and $d=4$ simply express the fact that infrared divergences are more severe in lower dimensions.

We will go back to Eq. (23), studying the case $m^2\neq 0$, to see how the IR divergences pop up in the $m^2\to 0$ limit. It is important to stress that, only in the *NN* BC case, we have IR divergences for massless fields, coming from the term $n=0$, i.e., Eq. (22) is IR finite for $m=0$. A straightforward calculation yields

$$f_2(L,m,d,z)=\frac{1}{2}h_2(d)\int_0^\infty d\rho\,\frac{\rho^{d-2}}{(\rho^2+m^2)^{1/2}}\,\frac{\cosh\left((L-2z)(\rho^2+m^2)^{1/2}\right)}{\sinh(L(\rho^2+m^2)^{1/2})}. \tag{38}$$

Defining $\sigma=(\rho^2+m^2)^{1/2}$ and using the fact that $d=3$, we have

$$f_2(L,m,d,z)|_{d=3}=\frac{1}{2}h_2(3)\left[\int_m^\infty d\sigma(\coth\sigma L-1)\cosh 2\sigma z+\int_m^\infty d\sigma(\cosh 2\sigma z-\sinh 2\sigma z)\right]. \tag{39}$$

The second integral in the above expression is convergent for $z\neq 0$, and, defining $v=2\sigma z$, it becomes

$$\frac{1}{4z}h_2(3)\int_{2mz}^{\infty}dv\,e^{-v}=\frac{1}{4z}h_2(3)\Gamma(1,2mz), \tag{40}$$

where $\Gamma(a,x)$ is the incomplete gamma function. Consequently, we have a simple pole for $z=0$. Again, the residue of this pole is L independent. To complete the regularization procedure we now have to analyze the first integral of Eq. (39):

$$\frac{1}{2}h_2(3)\int_m^{\infty}d\sigma(\coth\sigma L-1)\cosh 2\sigma z=\frac{1}{8L}h_2(3)\int_{2mL}^{\infty}du\,\frac{e^{(z/L)\,u}}{e^u-1}+\frac{1}{8L}h_2(3)\int_{2mL}^{\infty}du\,\frac{e^{-(z/L)\,u}}{e^u-1}. \tag{41}$$

The second integral on the right side of Eq. (41) is convergent and the first one has a simple pole at $z=L$, again with an L independent residue.

As we have already taken care of the ultraviolet divergences, let us study the infrared divergent piece (for $m=0$) of $f_2(L,m,d,z)|_{d=3}$. Let us call this piece $f_2^*(L,m,d,z)|_{d=3}$. Note that we introduce an ultraviolet cut-off in order to use the Bernoulli representation of the integrand:

$$f_2^*(L,m,d,z)|_{d=3}=\frac{1}{4L}h_2(3)\left(\int_{mL}^{2\pi}du\,\frac{e^{(z/L)\,u}}{e^u-1}+\int_{mL}^{2\pi}du\,\frac{e^{-(z/L)\,u}}{e^u-1}\right). \tag{42}$$

Writing the integrand using the Bernoulli polynomials it is not difficult to show that

$$f_2^*(L,m,3,z)=\frac{1}{2L}h_2(3)B_0\left(\frac{z}{L}\right)\ln\left(\frac{2\pi}{mL}\right)+\text{regular part}\ \ (f_2^*(L,m,z)). \tag{43}$$

From the previous discussion, we can conclude that, in order to eliminate the ultraviolet divergences of the theory we have to introduce counterterms as surface interactions, and consequently the full action will have the following form for both fields φ_1 and φ_2:

$$S(\varphi)=\int_0^L dz\int d^{d-1}r\left(\frac{1}{2}(\partial\varphi)^2+\frac{1}{2}m^2\varphi^2+\frac{1}{4!}\lambda\varphi^4\right)+\int d^{d-1}r(c_1\varphi^2(\vec{r},0)+c_2\varphi^2(\vec{r},L)). \tag{44}$$

We have seen that, to renormalize the theory, counterterms corresponding to surface interactions are required. We conjecture that one can avoid this difficulty by equipping the model with a $\varphi_1^2\varphi_2^2$ interaction. Then, the z dependent pieces of each tadpole may cancel each other out, and the two fields develop a size dependent mass Δm^2 proportional to gL^{-2}, as for the single φ^4 model at finite temperature. The study of the $O(2)$ symmetric model is under investigation by the authors.

V. CONCLUSIONS

In this article we studied finite size effects in an interacting field theory, with broken translation invariance. We calculated the vacuum activity for an anisotropic model, between two parallel plates in a d dimensional Euclidean space. It has been possible to obtain closed expressions for $\langle\varphi_1^2(x)\rangle$ and $\langle\varphi_2^2(x)\rangle$, for fields satisfying DD and NN BCs, respectively. We presented a model having the interesting property that the z-dependent part of the tadpole graphs for DD and NN BCs have the same modulus and opposite signs. This fact could explain the boundedness of the renormalized vacuum expectation value of the energy-stress tensor of the electromagnetic field in the Casimir-like configuration.

There are several directions in which the finite size effects for systems with breaking of translational invariance which may deserve further research. They are, to mention a few of them: the study ofinteracting fermions, the nonlinear σ model in domains with one finite direction and $(d-1)$ infinite directions,[17] and, finally, as a straightforward extension of this work, the study of

the $O(2)$ symmetric model at the two-loop approximation. As discussed in the Introduction, one should prove that the the renormalization program can be implemented beyond the one-loop approximation, where overlapping divergences emerge.

ACKNOWLEGMENTS

We would like to thank B. Schroer and R. De Paola for several helpful discussions. We are also grateful to B. F. Svaiter for very useful discussions and comments. N.F.S. would like to acknowledge the hospitality of the Centro Atómico Bariloche where part of this work was carried out. This article was supported by Conselho Nacional de Desenvolvimento Cientifico e Tecnológico do Brazil (CNPq) and Centro Latino Americano de Fisica (CLAF).

JOURNAL OF MATHEMATICAL PHYSICS VOLUME 42, NUMBER 11 NOVEMBER 2001

Cosmological implications of a nonseparable 5D solution of the vacuum Einstein field equations

Takao Fukui,[a] Sanjeev S. Seahra,[b] and Paul S. Wesson[c]
Department of Physics, University of Waterloo, Waterloo, Ontario N2L 3G1, Canada

(Received 29 March 2001; accepted for publication 13 August 2001)

An exact class of solutions of the 5D vacuum Einstein field equations (EFEs) is obtained. The metric coefficients are found to be nonseparable functions of time and the extra coordinate l and the induced metric on $l=$const hypersurfaces has the form of a Friedmann–Robertson–Walker cosmology. The 5D manifold and 3D and 4D submanifolds are in general curved, which distinguishes this solution from previous ones in the literature. The singularity structure of the manifold is explored: some models in the class do not exhibit a big bang, while others exhibit a big bang and a big crunch. For the models with an initial singularity, the equation of state of the induced matter evolves from radiation-like at early epochs to Milne-like at late times and the big bang manifests itself as a singular hypersurface in 5D. The projection of comoving 5D null geodesics onto the 4D submanifold is shown to be compatible with standard 4D comoving trajectories, while the expansion of 5D null congruences is shown to be in line with conventional notions of the Hubble expansion. [DOI: 10.1063/1.1407836]

I. INTRODUCTION

The vacuum EFEs for space–time plus an extra dimension are given in terms of the Ricci tensor by $R_{AB}=0$ $(A,B=0-3,4)$. These contain the field equations of general relativity, which in terms of the Einstein tensor and an induced energy-momentum tensor are $G_{\alpha\beta}=8\pi T_{\alpha\beta}$ $(\alpha,\beta=0-3)$. The latter is obtained by a well-known technique.[1] Mathematically it can depend on $g_{4\alpha}$, g_{44} and derivatives of $g_{\alpha\beta}$ with respect to $x^4=l$, while physically it can describe a perfect fluid with density ρ and pressure p. If there is no dependency on l, the equation of state is that of radiation or ultrarelativistic particles, $p=\rho/3$.[2] If there is dependency on l, a wide range is available for the equation of state.[3] What are often referred to as the standard 5D cosmological models were found as a class of solutions of $R_{AB}=0$ by Ponce de Leon.[4] These solutions are separable in the time (t), space (r,θ,ϕ) and the extra coordinate (l). On the hypersurfaces $l=$const, which we label Σ_l; they reduce to the standard Friedmann–Robertson–Walker (FRW) models of 4D cosmology with flat space sections $(k=0)$. The class depends on one dimensionless parameter which fixes the scale-factor a for the dynamics and the equation of state for the matter. It includes the $a=t^{2/3}$, $p=0$ Einstein–de Sitter solution for the late universe, and the $a=t^{1/2}$, $p=\rho/3$ radiation solution for the early universe. However, the Ponce de Leon solutions are not unique as the 5D analysis of the standard 4D FRW solutions.

In Sec. II, we obtain a nonseparable solution of the scale factor. Sections III and IV are devoted to cosmological implications, i.e., singularities and geodesics, respectively. Section V is for comments.

II. NONSEPARABLE SOLUTION

A class of solutions which is mathematically different and physically reasonable has a 5D line element given by

[a]Electronic mail: fukui@sciborg.uwaterloo.ca Permanent address: Dokkyo University, Soka, Saitama 340-0042, Japan.
[b]Electronic mail: ssseahra@sciborg.uwaterloo.ca
[c]Electronic mail: wesson@astro.uwaterloo.ca

$$dS^2=\sigma\left\{dt^2-a^2\left[\frac{dr^2}{(1-kr^2)}+r^2d\Omega^2\right]\right\}+\epsilon b^2dl^2. \tag{1}$$

Here $k=\pm1,0$ describes the 3D curvature, $d\Omega^2\equiv d\theta^2+\sin^2\theta d\phi^2$ describes the 2D spherical geometry, and $\epsilon=\pm1$ describes the nature of the extra dimension. The functions $\sigma=\sigma(l)$, $a=a(t,l)$, $b=b(t,l)$ are to be fixed by the 5D field equations. We have studied the latter, particularly with regard to the 4D properties of matter. Hereafter we employ $c=G=1$ unit system, that is, $L=M=T$.

A simple class of solutions of $G_{AB}=0$ is obtained if we write $\sigma=\text{const}\equiv\sigma_0$, $\hat{a}\equiv\partial a/\partial l=f(l)b$ (here and henceforth, we use hats to denote $\partial/\partial l$). Then the scale factors for ordinary space–time and the extra dimension are

$$a=\sqrt{-Ft^2+gt+h}, \tag{2}$$

$$b=\frac{-2\epsilon\sigma_0f\hat{f}t^2+\hat{g}t+\hat{h}}{2fa}. \tag{3}$$

Here $F\equiv\epsilon\sigma_0f^2+k$, $g=g(l)$ and $h=h(l)$ are functions, so including $f=f(l)$ we have three such. There exists a relation between these, set by the field equations. It is

$$h=-\frac{g^2+\kappa}{4F}, \tag{4}$$

where κ is a constant with the physical dimensions of (length)^2. In terms of this, the 3D scale factor (2) is given by

$$a^2=-\frac{[(2Ft-g)^2+\kappa]}{4F}. \tag{5}$$

The extra-dimensional scale-factor (3) is given by

$$b=-\frac{[4\epsilon\sigma_0f\hat{f}Ft^2-2\hat{g}F^2t+g\hat{g}F-\epsilon\sigma_0f\hat{f}(g^2+\kappa)]}{4afF^2}. \tag{6}$$

The new solutions have some properties in common with the Ponce de Leon cosmologies[4] and some which are different. The Ponce de Leon solutions only exist for $\epsilon=-1$, but the new ones have $\epsilon=\pm1$ so the extra dimension can be spacelike or timelike. Other (wavelike) solutions are known for $\epsilon=+1$,[5] but the new solutions open the way to testing the signature of the 5D manifold by observations of the 4D properties of matter as given by (8) and (9). The solution (6) is in general somewhat complicated, but we will not be much concerned with it because it is (5) which, via the Friedmann equations, determines the properties of matter. These for perfect fluid mean that Einstein's equations read as usual

$$G_{\alpha\beta}=8\pi T_{\alpha\beta}=8\pi[(\rho+p)u_\alpha u_\beta-pg_{\alpha\beta}]. \tag{7}$$

Here the four-velocities $u^\alpha\equiv dx^\alpha/ds$ are defined in terms of the 4D interval s, which is included in S of (1), and we have $u^\alpha=(1,0,0,0)$. Then the density and pressure are given by

$$\frac{8\pi\rho}{3}=-\frac{\epsilon f^2}{a^2}-\frac{\kappa}{4\sigma_0a^4}, \tag{8}$$

$$8\pi p=\frac{\epsilon f^2}{a^2}-\frac{\kappa}{4\sigma_0a^4}. \tag{9}$$

We recover FRW-like models on Σ_l that contain an exotic type of induced matter, with an equation of state which follows from (8) and (9),

$$p=\frac{\rho}{3}\left[1-\frac{8\epsilon\sigma_0 a^2 f^2}{(4\epsilon\sigma_0 a^2 f^2+\kappa)}\right]. \tag{10}$$

This equation of state is manifestly dependent on time and completes the formal part of our analysis, which a fast computer package[6] has confirmed. The form of these relations suggests a two-fluid model as used in solutions of straight general relativity. The first terms in (8) and (9) by themselves imply $(\rho+3p)=0$, which is the 4D signature of matter with zero gravitational density.[1,7] This kind of matter has been suggested as relevant to cosmic strings, i.e., open strings with subrelativity transverse motions,[8] and K-matter which existence mentions the possibility of a universe dominated by cosmic strings,[9] to zero-point fields required by quantum theory[10,11] and to extreme sources for the Reissner–Nordström metric which require that the material contents of the sphere has no effect on gravitational interactions at its center.[12] The second terms in (8) and (9) by themselves imply $p=\rho/3$, which of course means photon-like matter. These identifications are supported by the behavior of the scale-factor (2) or (5), where the latter may vary as $t^{1/2}$ in the radiation model or as t in the empty (Milne) model. They become exact when in (8) and (9) $f\to 0$, and $\kappa\to 0$, respectively. Or on a given Σ_l hypersurface, we find in (2) that as $t\to\infty$, $a(t,l)\to\infty$—provided that $F<0$—which implies in (10) that $p\to-\rho/3$. This is the equation of state of the Milne, or empty universe where the gravitational density of matter is zero. Hence, it might be understood that the 4D cosmologies on the Σ_l hypersurface are asymptotically empty as $t\to\infty$. However, it should be noted that ρ, p of (8) and (9) refer to the total density and pressure, and that any split is in general arbitrary in the absence of information about the particles which make up the matter. Some of the latter may, in principle, be of nonstandard type, since $g_{44}=\epsilon b^2(t,l)$ describes a 3D homogeneous scalar-field.[1] This can manifest itself in 4D as a time-dependent cosmological "constant," as required to harmonize astrophysical data on the age of the universe.[13,14] A time-dependent scalar field generalizes the constant vacuum of Einstein's theory, whose density and pressure are given in terms of the cosmological constant by $\rho=-p=\Lambda/8\pi$. The positive Λ is concluded by revisiting the Tinsley diagram with the recent determinations of the Hubble constants.[15]

III. SINGULARITIES

The age of the universe is defined in 4D models as the time elapsed since the big bang, but the latter concept has to be treated carefully in 5D models. In solutions of the 5D field equations which are flat in 5D but contain a curved space which is singular in 4D, the big bang has to be identified as a defect of the geometry.[1,4]

To analyze the early behavior of the 4D cosmologies embedded in (1), we need to establish whether or not these models contain big bang singularities. Related to this issue is the nature of the singularity structure of 5D manifold as related to the singularity structure of the 4D submanifolds. It is well known that the 5D Ponce de Leon cosmological metrics contain 4D Σ_l hypersurfaces that precisely mimic standard FRW cosmologies complete with a big bang singularity. However, the 5D manifold is flat $R^A_{BCD}=0$, which suggests that the 4D big bang is merely a consequence of the way in which the Σ_l hypersurfaces are embedded in 5D Minkowski space, or, equivalently, the choice of 5D coordinates. The Ponce de Leon solutions are flat in 3D, curved in 4D and (perhaps surprisingly) flat in 5D.[1,16] That is, the Riemann–Christoffel tensors for 5D and 4D are $R^A_{BCD}=0$ and $R^\alpha_{\beta\gamma\delta}\neq 0$, so a flat manifold smoothly embeds a curved one (locally), like 3D Euclidean space embeds the 2D surface of the Earth. We wish to address the issue of whether or not the present manifold (1) is curved or flat, and whether or not it contains a genuine singularity.

A direct attack on the problem could entail the calculation of the 5D Kretschmann curvature invariant $K\equiv R^{ABCD}R_{ABCD}$ for (1). The divergence of this quantity is usually interpreted as being indicative of a curvature singularity in the manifold.[1,17] However, the calculation of K for (1) is difficult, even by computer. We can make some headway by considering a special case defined by

$$\epsilon=-1,\ \ k=0,\ \ f(l)=1/\sqrt{2\sigma_0},\ \ g(l)=l. \tag{11}$$

In this model we have

$$a(t,l)=\sqrt{\frac{(t+l)^2+\kappa}{2}}. \tag{12}$$

The associated curvature invariant is

$$K=\frac{72\kappa^2}{\sigma_0^2[(t+l)^2+\kappa]^4}. \tag{13}$$

The scale factor $a(t,l)$ goes to zero and the Kretschmann scalar K becomes infinity along the hypersurfaces

$$0=t+l\pm\sqrt{-\kappa}. \tag{14}$$

Clearly, there will be no curvature singularity for $\kappa>0$. Therefore, for at least one specific case, we find that the manifold (1) is curved in 5D and singular where the scale factor $a(t,l)$ vanishes, in sharp contrast with the Ponce de Leon solutions. For the present model, the density and pressure of (8) and (9) will diverge in general as $a\to 0$ along the hypersurfaces of (14).

It is interesting to note that $K=0$ for $\kappa=0$ in the model presented above. Indeed, an analysis of the general metric (1) via computer shows that $R^A_{BCD}=0$ for $\kappa=0$. In this eventuality, the scale factor (2) with (4) becomes

$$a(t,l)=\frac{g(l)t+2h(l)}{2h^{1/2}(l)}, \tag{15}$$

which is linear in time, just like the scale factor for the Milne universe (indeed, the equation of state of the induced matter is $p=-\rho/3$). So the $\kappa=0$ case entails induced matter with zero gravitational density, is curved in 4D and is flat in 5D. However, it bears repeating that when $\kappa\neq 0$, it is possible to have curved 5D solutions.

Now, by analogy with the standard FRW model, it is obvious that the 4D submanifolds on Σ_l will be singular for times $t_*(l)$ such that $a(t_*,l)=0$, an epoch commonly referred as the big bang. Solving $a(t_*,l)=0$ in (5) for t_* gives two solutions:

$$t_*^{\pm}(l)=\frac{g(l)\pm\sqrt{-\kappa}}{2F}. \tag{16}$$

Two things are apparent from this result. First, there can be no 4D big bang if $\kappa>0$. This is in agreement with the special case presented above, where the scale factor can only vanish if $\kappa\leqslant 0$. Second, we see that if $\kappa<0$, there are two separate singularities, or, in other words, two big bangs in $F<0$. These 4D events are located on the two 4D hypersurfaces defined by (16). In the neighborhood of the big bang, $a^2(t_*^{\pm}+\delta t,l)\sim a_*(l)\,\delta t$ where $a_*(l)$ is some function of l at $t=t_*^{\pm}$. The equation of state of the cosmological matter is then

$$p=\frac{\rho}{3}\left[\frac{\kappa-\tilde{a}_*(l)\,\delta t}{\kappa+\tilde{a}_*(l)\,\delta t}\right]=\frac{\rho}{3}-O(\delta t), \tag{17}$$

where $\tilde{a}_*(l)$ is some other function of l. As $\delta t\to 0$, we recover $p=\rho/3$. So, near the big bang(s), the induced matter behaves like radiation while at late times it behaves like the matter in the Milne model.

Finally, we consider the case $F>0$, which is guaranteed for $\epsilon=1$ and $k=0,1$ since we must have $\sigma_0>0$. If we also have $\kappa<0$, it is clear that on Σ_l, $a(t,l)$ is real only between t_*^- and t_*^+. This is a cosmological model with both a big bang and a big crunch, similar to the standard $k=+1$ FRW metrics. There therefore exists a hiearchy of 4D cosmologies on the Σ_l hypersurfaces.

TABLE I. Characteristics of the 5D manifold and the 4D cosmologies embedded on the Σ_l hypersurfaces.

	$F<0$	$F>0$
$\kappa>0$ and $R^A_{BCD}\neq 0$ in general	no big bang	$a(t,l)$ is complex
$\kappa=0$, $R^A_{BCD}=0$	one big bang	$a(t,l)$ is complex
$\kappa<0$ and $R^A_{BCD}\neq 0$ in general	two big bangs	big bang and big crunch

If $\kappa<0$, then the issue of whether each of the cosmologies is forever expanding or destined to end in a big crunch is entirely determined by the value of $f(l)$ on that hypersurface. If $\kappa\geqslant 0$, the quantity inside the radical in the definition of $a(t,l)$ in (5) will be less than or equal to zero for all times, which makes $a(t,l)$ complex and has the effect of switching the signature of the (x^1,x^2,x^3) coordinates from spacelike to timelike (this also happens for $t\notin[t_*^-,t_*^+]$ if $\kappa<0$). Table I summarizes all the cases discussed in this section for both the global 5D geometry and the type of cosmology embedded on the Σ_l hypersurfaces.

IV. GEODESICS

The possibility the test particles move on higher dimensional geodesics has been studied by many authors.[1,18–20] In particular, it has recently been demonstrated that particles that are massless in 5D appear to be massive in 4D.[21] In this section, we examine the 5D null and comoving geodesics of the metric (1) for the $\epsilon=-1$ case and identify the 4D GR limit.

We take $\epsilon=-1$ and define $\Sigma^2\equiv\sigma_0$. Then, the metric (1) may be written as

$$dS^2=[\Sigma dt+b(t,l)dl][\Sigma dt-b(t,l)dl]-\Sigma^2a^2(t,l)ds_3^2, \tag{18}$$

where $\Sigma^2a^2(t,l)ds_3^2$ represents the spatial three-metric, with

$$ds_3^2=\frac{dr^2}{1-kr^2}+r^2d\Omega^2. \tag{19}$$

Now, since the terms in square brackets represent a two-dimensional manifold, which must be conformally flat, it is in principle possible to find a coordinate transformation

$$\eta=\eta(t,l),\quad \xi=\xi(t,l) \tag{20}$$

that will cast the metric in the form

$$dS^2=C(\eta,\xi)d\eta d\xi-\Sigma^2a^2(\eta,\xi)ds_3^2. \tag{21}$$

Then, the null geodesics of the manifold that are spatially comoving ($ds_3^2=0$) are just the $d\eta=0$ or $d\xi=0$ trajectories. However, the transformation (20) is not immediately obvious. Therefore, we must be content with an indirect analysis of the properties of the 5D null-comoving paths.

Consider the vectors

$$k^A\partial_A=\frac{1}{\sqrt{2}\Sigma}\partial_t+\frac{1}{\sqrt{2}b(t,l)}\partial_l, \tag{22}$$

$$N^A\partial_A=\frac{1}{\sqrt{2}\Sigma}\partial_t-\frac{1}{\sqrt{2}b(t,l)}\partial_l. \tag{23}$$

They satisfy

$$k^Ak_A=0,\quad N^AN_A=0,\quad k^AN_A=1. \tag{24}$$

Both k^A and N^A are tangent to null geodesics and can be thought of as the principal and auxiliary vectors of a null congruence. They both share the same parametrization, defined by

$$\frac{dt}{d\lambda} = \frac{1}{\sqrt{2}\Sigma},$$

$$\frac{dl}{d\lambda} = +\frac{1}{\sqrt{2}b(t,l)} \quad (\text{for } k^A),$$

$$= -\frac{1}{\sqrt{2}b(t,l)} \quad (\text{for } N^A). \tag{25}$$

In order to determine if λ is a 5D affine parameter, we calculate

$$k^A \nabla_A k^B = \left[\frac{1}{\sqrt{2}\Sigma}\frac{\partial}{\partial t}\ln b(t,l)\right] k^B, \tag{26}$$

with a similar expression for N^A. ∇_A is the 5D covariant derivative operator. This shows that λ is not a 5D affine parameter. However, it is easy to see that the 4D projections of k^A and N^A onto Σ_l satisfy the 4D geodesic equation for timelike geodesics. Therefore, λ is the 4D proper time $\tau = \Sigma t$ comoving geodesics (up to a constant prefactor). This is an excellent example of how a null path in 5D can appear to be the trajectory of a massive particle in 4D.

We now explore the possibility that galaxies travel along 5D trajectories described by (22) or (23). The tangent space to the null vectors k^A and N^A is necessarily three dimensional and has the metric

$$q_{AB} = g_{AB} - k_A N_B - k_B N_A, \tag{27}$$

which gives

$$q_{AB} dx^A dx^B = -\Sigma^2 a^2(t,l) ds_3^2. \tag{28}$$

It is clear that the tangent space of k^A and N^A is equivalent to the $t = \text{const}$, $l = \text{const}$ three-surface of the 5D manifold. Hence, observers traveling along 5D null-comoving geodesics 4D comoving geodesics (confined to Σ_l) share the same tangent space, which suggests that they will observe the world around them in the same manner. In particular, we can calculate the expansion Θ of a congruence of 5D geodesics with tangent vector k^A. For nonaffinity parametrized geodesics, Θ is given by

$$\Theta = \nabla^A k_A - N_B k^A \nabla_A k^B. \tag{29}$$

Plugging in expression for k^A and N^A, we get

$$\Theta = \frac{3}{a}\left(\frac{1}{\sqrt{2}\Sigma}\frac{\partial a}{\partial t} + \frac{1}{\sqrt{2}b(t,l)}\frac{\partial a}{\partial l}\right) = \frac{3}{a}\frac{da}{d\lambda}. \tag{30}$$

Since the expansion scalar represents the fractional rate of change in the three-volume δV of the congruence, i.e., $\Theta = (\delta V)^{-1} d(\delta V)/d\lambda$, we see that $\delta V \sim a^3(\lambda)$ as expected. That is, an observer in a galaxy traveling along a 5D null-comoving geodesic will see the other galaxies receding away in a Hubble-like expansion with scale factor $a(\lambda)$ (recall that $\lambda = \sqrt{2}\tau$).

We are now in a position to identify the 4D limit of the theory. The geodesic paths described by k^A and N^A would be identical to 4D geodesics if $dl = 0$, that is, they are confined to Σ_l hypersurfaces. This will be true if $|dl/d\tau| = b^{-1}(t,l) \ll 1$, which can be physically interpreted as

demanding that large changes in the 4D proper time τ be accompanied by small changes in the extra coordinate l. This can be accomplished in the $\epsilon=-1$ case by choosing $f(l)$ and σ_0 such that $|f(l)|\ll 1$ and $[f^2(l)\sigma_0-k]>0$, which ensures that $a(t,l)$ is real as $t\to\infty$. In terms of the toy model (11), we recover the 4D limit for $\Sigma\to\infty$.

V. COMMENTS

The new nonseparable solution (2) gives a physical meaning of the coefficients K_1 and K_2 which appear in the solution of the scale factor.[22] That is, these constants and the coefficient of t^2 as well are originated in $f(l),g(l)$ and $h(l)$ on the hypersurface Σ_l. This helps us to consider the special case (11).

The physical big bang in 4D is a hypersurface in 5D. This kind of behavior has been observed in other 5D solutions, e.g., in a ''wavelike'' class of exact cosmological solutions which look like waves propagating in the fifth dimension.[23] For the example just considered, the 4D big bang is akin to a 5D shock wave.[24] It is different to what happens in the Ponce de Leon cosmologies,[4] because of the nonseparable nature of the solutions. In general, 5D cosmologies where the 4D big bang is a geometrical effect have major implications for the early universe, notably in regard to particle masses during the inflationary epoch[25] and the thermalization of photons by the particle mass varying quadratically with the time during the subsequent radiation epoch.[26] The 5D cosmologies imply the variability of the masses of all particles.[1] The precise nature of the transformation (20) for general choices of $f(l),g(l)$ and $h(l)$ will naturally give us closed form solutions for the comoving null geodesic equation and enable us to study those cosmological phenomena in the early universe. These studies and a study of timelike 5D geodesics ($\epsilon=1$) are left for future work.

Batalin–Tyutin quantization of the spinning particle model

Subir Ghosh[a)]
Physics and Applied Mathematics Unit, Indian Statistical Institute, 203 B. T. Road, Calcutta 700035, India

(Received 17 April 2001; accepted for publication 6 August 2001)

The spinning particle model for anyon is analyzed in the Batalin–Tyutin scheme of quantization in extended phase space. Here additional degrees of freedom are introduced in the phase space such that all the constraints in the theory are rendered first class, that is, commuting in the sense of Poisson brackets. Thus the theory can be studied without introducing the Dirac brackets which appear in the presence of noncommuting or second class constraints. In the present case the Dirac brackets make the configuration space of the anyon noncanonical and also, being dynamical variable dependent, poses problems for the quantization program. We show that previously obtained results (e.g., gyromagnetic ratio of anyon being 2) are recovered in the Batalin–Tyutin variable independent sector in the extended space. The Batalin–Tyutin variable contributions are significant and are computable in a straightforward manner. The latter can be understood as manifestations of the noncommutative space–time in the enlarged phase space. © *2001 American Institute of Physics.* [DOI: 10.1063/1.1405847]

I. INTRODUCTION

Theoretical models for anyons,[1] excitations of arbitrary spin and statistics in $2+1$-dimensions, have been proposed from different perspectives, the most popular ones being the point-charge Chern–Simons gauge field interacting theory[2] and the later symplectic models (SMs)[3,4] and the spinning particle models (SPMs).[5,6] The SM and SPM can be related to the anyon field equation proposed in Ref. 7. It has been questioned[8] whether the former interacting theory is a minimal description of the anyon. The latter models are free from complications of this type and both of them agree regarding results [such as rigidity of the angular momentum and the gyromagnetic ratio (g) being equal to 2] for free anyons as well as anyons interacting with Abelian external gauge field, respectively.

However, the SMs or SPMs are also interesting from another point of view. They have a close connection with the noncommutative space–time theories, which have created a lot of interest lately.[9]

In SMs,[4] the symplectic structure has been posited, which gives rise to the noncommutativity in the particle configuration space. On the other hand, in SPMs,[5,6] the above mentioned feature is a result of the constraint structure of the model. The set of second class constraints (SCCs), with noncommuting Poisson brackets (PBs) (in the sense of Dirac classification scheme[10]), induces nontrivial Dirac brackets (DBs) among the coordinate variables. Since we will concentrate on SPMs[6] in the present work, these comments will be elaborated.

Let us now impose a bit of caution on the methodology of evaluation of the g value of anyon in SMs and SPMs. One compares the Hamiltonian (in the former[4]) and equations of motion (in the latter[6]) with the corresponding expressions obtained for a charged particle with spin in background electromagnetic field *in conventional (commuting) configuration space*. The validity of this matching procedure can be questioned on the grounds that the nature of the configuration spaces in the two systems that are being compared are qualitatively different. But more importantly, the quantization procedure runs into trouble due to operator ordering ambiguities in the DBs in SPs and

a)Electronic mail: sghosh@isical.ac.in

SPMs. This complication arises since in theories with nonlinear constraints, the DBs can involve dynamical variables, which is true for the present case. When these DBs are elevated to commutation relations in the process of quantization, the above mentioned feature creates problems.

Finally (as has been pointed out before[5,6]), the induced nonvanishing DB algebra $[A_a(\mathbf{x},t), A_b(\mathbf{y},t)]$ between supposedly ''external'' electromagnetic field variables makes us wonder as to how far the treatment of the gauge fields being nondynamical is justified. The problems related to the noncanonical nature of the coordinate system have also been discussed in Ref. 11.

Now we come to the motivation of the present work. All of the above problems can be naturally addressed in the Batalin–Tyutin (BT) quantization scheme[12] (which is a particular type of the more general quantization method[13]), where additional phase space degrees of freedom (BT variables) are introduced in such a way that existing SCCs are converted into (Abelian) first class constraints (FCCs, see Ref. 10), thereby enhancing the gauge symmetry of the extended system. Thus the problematic DBs can be avoided. One can resort to Dirac quantization of FCC systems by requiring that the physical states obey the FCCs (i.e., $FCC|physical\ state\rangle=0$). Or else one can work in a convenient gauge where the problematic DBs do not appear. Later on we will use the first alternative.

Apart from the above reasons, we will find that by its own right, the problem of BT extension of SPMs has several interesting features, some of them not addressed in the literature. First, the SCC system in SPMs can be expressed[5,6] in a covariant (and neat) form which, however, is reducible, that is, the SCCs, are not independent. The BT formulation has been developed for irreducible or independent set of SCCs only. This forces us to choose an independent set of SCCs, thereby losing manifest covariance. As an unsolved problem, it will be interesting to study the BT extension of a generic reducible SCC system.

Let us put the present work in its proper perspective. We have developed a framework for treating the spinning particle model as an FCC system in a BT-extended phase space where the background space–time is normal (that is, commuting), so that comparison between results obtained for anyons and analogous models in conventional space–time do not pose any ambiguity. (In particular, we will recover the result that for anyons $g=2$, but will indicate the presence of correction terms as well.) Also the canonical quantization program is rigorous since DBs do not appear and so operator ordering problems are absent in the canonical commutation relations.

Lastly we note that the present BT extension is classical in the sense that operator ordering problems in the extended system have not been addressed.[14]

The article is organized as follows: in Sec. II we briefly reproduce the skeleton of BT formalism. This will also help us to fix the notations. We quickly introduce the SPM in Sec. III for completeness. Section IV is devoted to developing the BT extension of SPMs. This constitutes the main body of our work. Section V deals with the quantization procedure and recovering of previous results. In Sec. VI we conclude with a discussion and some future lines of work.

II. BATALIN–TYUTIN FORMULATION

In this section we state the main results of BT prescription[12] to be used. The basic idea behind the scheme is to introduce additional phase space variables (BT variables) ϕ_a^α, besides the existing physical degrees of freedom (q,p), such that *all* the constraints in the extended system are reduced to FCCs. This means that one has to modify the original constraints and Hamiltonian accordingly by putting BT-extension terms in them. The way to achieve this at the classical level has been proved in Ref. 12. Let us consider a set of constraints $(\Theta_\alpha^a, \Psi_l)$ and a Hamiltonian operator H with the following Poisson Bracket (PB) relations,

$$\{\Theta_\alpha^a(q,p),\Theta_\beta^b(q,p)\}\approx\Delta_{\alpha\beta}^{ab}(q,p)\neq 0,\ \{\Theta_\alpha^a(q,p),\Psi_\beta^l(q,p)\}\approx 0,$$
$$\{\Psi_l(q,p),\Psi_n(q,p)\}\approx 0,\ \{\Psi_l(q,p),H(q,p)\}\approx 0. \tag{1}$$

In the above (q,p) are referred to as physical variables and "$\approx$" means that the equality holds on the constraint surface and $\{p_a,x_b\}=g_{ab}$; $g_{ab}=\mathrm{diag}(1,-1,-1)$. Clearly Θ^a_α and Ψ_l are SCC and FCC,[10] respectively. The latter are responsible for gauge invariance and the former can be used as operator identities provided one uses the DBs[10] as defined:

$$\{A(q,p),B(q,p)\}_{\mathrm{DB}}=\{A,B\}-\{A,\Theta^a_\alpha\}\Delta^{\alpha\beta}_{ab}\{\Theta^b_\beta,B\},\quad \Delta^{ab}_{\alpha\beta}\Delta^{\beta\gamma}_{bc}=\delta^a_c\delta^\alpha_\gamma. \tag{2}$$

However, in systems with nonlinear SCCs, in general the DBs can become dynamical variable dependent[5,6,15] due to the $\{A,\Theta^a_\alpha\}$ and $\Delta^{\alpha\beta}_{ab}$ terms, leading to problems for the quantization program. To cure this type of pathology, BT formalism is a systematic framework where one introduces the BT variables ϕ^α_a, obeying

$$\{\phi^\alpha_a,\phi^\beta_b\}=\omega^{\alpha\beta}_{ab}=-\omega^{\beta\alpha}_{ba}, \tag{3}$$

where $\omega^{\alpha\beta}_{ab}$ is a constant (or at most a c-number funtion) matrix, with the aim of modifying the SCC $\Theta^a_\alpha(q,p)$ to $\tilde{\Theta}^a_\alpha(q,p,\phi^\alpha_a)$ such that

$$\{\tilde{\Theta}^a_\alpha(q,p,\phi),\tilde{\Theta}^b_\beta(q,p,\phi)\}=0,\ \ \tilde{\Theta}^a_\alpha(q,p,\phi)=\Theta^a_\alpha(q,p)+\Sigma^\infty_{n=1}\tilde{\Theta}^{a(n)}_\alpha(q,p,\phi),\ \ \tilde{\Theta}^{a(n)}\approx O(\phi^n). \tag{4}$$

The explicit terms in the above expansion are[12]

$$\tilde{\Theta}^{a(1)}_\alpha=X^{ab}_{\alpha\beta}\phi^\beta_b,\quad \Delta^{ab}_{\alpha\beta}+X^{ac}_{\alpha\gamma}\omega^{\gamma\delta}_{cd}X^{bd}_{\beta\delta}=0, \tag{5}$$

$$\tilde{\Theta}^{a(n+1)}_\alpha=-\frac{1}{n+2}\phi^\delta_d\omega^{dc}_{\delta\gamma}X^{\gamma\beta}_{cb}B^{ba(n)}_{\beta\alpha},\quad n\geqslant 1, \tag{6}$$

$$B^{ba(1)}_{\beta\alpha}=\{\tilde{\theta}^{b(0)}_\beta,\tilde{\theta}^{a(1)}_\alpha\}_{(q,p)}-\{\tilde{\theta}^{a(0)}_\alpha,\tilde{\theta}^{b(1)}_\beta\}_{(q,p)}, \tag{7}$$

$$B^{ba(n)}_{\beta\alpha}=\Sigma^n_{m=0}\{\tilde{\theta}^{b(n-m)}_\beta,\tilde{\theta}^{a(m)}_\alpha\}_{(q,p)}+\Sigma^n_{m=0}\{\tilde{\theta}^{b(n-m)}_\beta,\tilde{\theta}^{a(m+2)}_\alpha\}_{(\phi)},\quad n\geqslant 2. \tag{8}$$

In the above, we have defined

$$X^{ab}_{\alpha\beta}X^{\beta\gamma}_{bc}=\omega^{ab}_{\alpha\beta}\omega^{\beta\gamma}_{bc}=\delta^\gamma_\alpha\delta^a_c. \tag{9}$$

A very useful idea is to introduce the improved variable $\tilde{f}(q,p)$ (Ref. 12) corresponding to each $f(q,p)$,

$$\tilde{f}(q,p,\phi)\equiv f(\tilde{q},\tilde{p})=f(q,p)+\Sigma^\infty_{n=1}\tilde{f}(q,p,\phi)^{(n)},\ \ \tilde{f}^{(1)}=-\phi^\beta_c\omega^{cb}_{\beta\gamma}X^{\gamma\delta}_{bd}\{\theta^a_\delta,f\}_{(q,p)}, \tag{10}$$

$$\tilde{f}^{(n+1)}=-\frac{1}{n+1}\phi^\beta_c\omega^{cb}_{\beta\gamma}X^{\gamma\delta}_{bd}G(f)^{d(n)}_\delta,\quad n\geqslant 1, \tag{11}$$

$$G(f)^{b(n)}_\beta=\Sigma^n_{m=0}\{\tilde{\theta}^{b(n-m)}_\beta,\tilde{f}^{(m)}\}_{(q,p)}+\Sigma^{(n-2)}_{m=0}\{\tilde{\theta}^{b(n-m)}_\beta,\tilde{f}^{(m+2)}\}_{(\phi)}+\{\tilde{\theta}^{b(n+1)}_\beta,\tilde{f}^{(1)}\}_{(\phi)}, \tag{12}$$

which have the property $\{\tilde{\Theta}^a_\alpha(q,p,\phi),\tilde{f}(q,p,\phi)\}=0$. It can be proved that extensions of the original FCC Ψ_l and Hamiltonian H are simply

$$\tilde{\Psi}_l=\Psi(\tilde{q},\tilde{p}),\ \ \tilde{H}=H(\tilde{q},\tilde{p}). \tag{13}$$

One can also reexpress the converted SCCs as $\tilde{\Theta}^a_\alpha\equiv\Theta^a_\alpha(\tilde{q},\tilde{p})$. The following identification theorem,

$$\{\tilde{A},\tilde{B}\}=\{\widetilde{A,B}\}_{\mathrm{DB}},\ \ \{\tilde{A},\tilde{B}\}|_{\phi=0}=\{A,B\}_{\mathrm{DB}},\ \ \tilde{0}=0, \tag{14}$$

will play a crucial role in our later application. Hence the outcome of the BT extension is the closed system of FCCs with the FC Hamiltonian given by

$$\{\tilde{\Theta}^a_\alpha,\tilde{\Theta}^b_\beta\}=\{\tilde{\Theta}^a_\alpha,\tilde{\Psi}_l\}=\{\tilde{\Theta}^a_\alpha,H\}=0,\ \ \{\tilde{\Psi}_l,\tilde{\Psi}_n\}\approx 0,\ \ \{\tilde{\Psi}_l,H\}\approx 0. \tag{15}$$

We will see that due to the nonlinearity in the SCCs, the extensions in the improved variables (and subsequently in the FCCs and FC Hamiltonian) turn out to be infinite series. This type of situation has been encountered before.[15]

III. SPINNING PARTICLE MODEL REVISITED

The SPM proposed by us[6] where an anyon interacts with a $U(1)$ gauge field in $2+1$-dimensions is given by the Lagrangian

$$L=\left(m^2U^aU_a+\frac{j^2}{2}\sigma^{ab}\sigma_{ab}+mj\epsilon^{abc}U_a\sigma_{bc}\right)^{1/2}+eU_aA^a, \tag{16}$$

where

$$U^a=\frac{dx^a}{d\tau},\ \ \sigma^{ab}=\frac{1}{2}\epsilon^{abc}\sigma_c=\Lambda^a_c\frac{d\Lambda^{cb}}{d\tau},\ \ \Lambda^a_c\Lambda^{cb}=\Lambda^a_c\Lambda^{bc}=g^{ab}.$$

Here (x^a,Λ^{ab}) is a Poincaré group element and also a set of dynamical variables of the theory. The canonical momenta are defined in the following way:[5,6]

$$p^a=-\frac{\partial L}{\partial U_a}\equiv\pi^a-eA^a,\ \ S^{ab}=-\frac{\partial L}{\partial\sigma_{ab}}\equiv\frac{1}{2}\epsilon^{abc}S_c. \tag{17}$$

The phase space algebra is

$$\{x_a,x_b\}=0,\ \ \{p_a,x_b\}=g_{ab},\ \ \{\pi_a,\pi_b\}=eF_{ab}=e(\partial_aA_b-\partial_bA_a), \tag{18}$$

$$\{S^a,S^b\}=\epsilon^{abc}S_c,\ \ \{S^a,\Lambda^{0b}\}=\epsilon^{abc}\Lambda^0{}_c,\ \ \{\Lambda^{0a},\Lambda^{0b}\}=0. \tag{19}$$

In the free theory, one encounters the following set of FCC and SCC, respectively:

$$\Psi_1\equiv\pi_a\pi^a-m^2\approx 0,\ \ \Psi_2\equiv\pi.S-\frac{mj}{2}\approx 0,$$

$$\Theta^a_1\equiv\Lambda^{0a}-\frac{p^a}{m}\approx 0,\ \ \theta^a_2\equiv S^{ab}p_b=\epsilon^{abc}p_bS_c\approx 0.$$

In the free theory, Ψ_1 and Ψ_2 are respectively the mass-shell condition and the Pauli–Lubanski relation.

In the interacting theory, one obtains to $O(e)$ the following set of FCCs and SCCs:

$$\Psi_1\equiv\pi_a\pi^a-m^2+\frac{2eF_{ab}\pi^a}{\pi^2}\Theta^b_2\approx 0,\ \ \Psi_2\equiv\pi.S-\frac{mj}{2}+\frac{ejF_{ab}\pi^a}{2m\pi^2}\Theta^b_2\approx 0, \tag{20}$$

$$\Theta^a_1\equiv\Lambda^{0a}-\frac{\pi^a}{m}\approx 0,\ \ \theta^a_2\equiv S^{ab}\pi_b=\epsilon^{abc}\pi_bS_c\approx 0. \tag{21}$$

Actually one can check that $S^aS_a=j^2/4$, but this is not independent of Ψ_l given above (20). To verify the constraint algebra after computing the PBs, one has to invoke the relation $S^a=(j/2m)\,\pi^a$, which is consistent with the SCC Θ_2^a and the normalization agrees with the free theory. The above relation is valid also at the level of DBs.[6]

Note that in the above set of SCCs, Θ_1^a has been imposed from outside such that the angular coordinates are properly restricted. It is easy to ascertain that the SCCs Θ_α^a form a reducible set, since

$$\pi^a\Theta_{1a}=-\tfrac{1}{2}m\Theta^{1a}\Theta_{1a},\quad \pi^a\Theta_{2a}=0.$$

(With $e=0$, these features are true for the free theory stated earlier.) However, one works with this reducible set because the manifestly covariant structure simplifies calculations and one can invert[5,6] the SCC algebra matrix perturbativly to get the DBs. To $O(e)$ we obtain the DB between two generic field as[6]

$$\{A,B\}_{\mathrm{DB}}=\{A,B\}+\frac{eF_{ab}}{m^2}\{A,\Theta_2^a\}\{\Theta_2^b,B\}-\frac{1}{2}\epsilon^{abc}S_c\{A,\Theta_{1a}\}\{\Theta_{1b},B\}$$

$$+\frac{1}{2m}\{A,\Theta_2^a\}\{\Theta_{1a},B\}-\frac{1}{2m}\{A,\Theta_1^a\}\{\Theta_{2a},B\}. \tag{22}$$

In particular, the following DB,

$$\{x^a,x^b\}_{\mathrm{DB}}=-\frac{1}{2m^2}\epsilon^{abc}S_c+O(e), \tag{23}$$

gives rise to the noncommutative space–time, which in turn generates the arbitrary spin contribution in the angular momentum. Note that the algebra (23) is nontrivial in the free theory as well. Fixing the gauge condition $x_0=\tau$ as the proper time and using Ψ_1 one ends up with the Hamiltonian,

$$H=(m^2-\pi^i\pi_i)^{1/2}-eA_0, \tag{24}$$

where the Θ_2^a dependent term has been dropped since we used DBs.[6,5] To $O(e)$ the $2+1$-dimensional analog of the $3+1$-dimensional Bargmann–Michel–Telegdi equation[16] is

$$\dot{S}^a=\{H,S^a\}_{\mathrm{DB}}=\frac{e}{m}F^{ab}S_b. \tag{25}$$

Comparison with the original equation[16] reveals that $g=2$ for the particle.

As we have mentioned before, the comparison has been carried out between the present system in noncommutative configuration space and the original Bargmann–Michel–Telegdi equation in normal coordinate system.

The connection between our result and that of the SM[4] is very direct but subtle. Remember that in SMs,[4] a modified expression [with an $O(eF)$ term] for the ''mass-shell'' condition is used. [In our analysis, an analogous Θ_2^a-dependent term in (24) was ''strongly'' put to zero since it was proportional to the SCCs and we use DBs.] The analysis in the SM is for the FCC system, according to Dirac, where one demands that the FCCs annihilate the physical states. (In our BT extended theory, we will also follow this route.) Now in Ref. 4, one solves perturbatively, for small e, the noncanonical symplectic algebra (which is equivalent to our DBs), in terms of a set of canonical phase space variables, and rewrites the Hamiltonian in terms of these *new* variables and finally compares this expression with the Hamiltonian of a charged particle in ordinary

space–time. Again the $g=2$ result[4] is reproduced. Obviously this derivation[4] also suffers from the same conceptual drawback as the previous one.[6] With this background, we now move on to the BT extension of the SPM.

IV. BATALIN–TYUTIN EXTENSION OF THE SPINNING PARTICLE MODEL

This section comprises of the main body of our work where we introduce the BT machinery[12] in order to take into account the SCCs of the theory but at the same time avoid using a noncanonical coordinate. As mentioned before, we now use a smaller set of SCCs which are irreducible. Also note that in the extended space the constraints will be modified and we can no longer use the original constraints to simplfy the SCC algebra. Choosing Θ^i_α as the irreducible set of SCCs, the PB algebra is

$$\{\Theta^i_\alpha,\Theta^j_\beta\}=\Delta^{ij}_{\alpha\beta}, \tag{26}$$

$$\Delta^{ij}_{11}=\frac{eF^{ij}}{m^2}, \tag{27}$$

$$\Delta^{ij}_{12}=-\left[(\pi.\Lambda)g^{ij}-\pi^i\Lambda^{0j}+\frac{e}{m}\epsilon^{jbc}F^i{}_bS_c\right]=-\Delta^{ji}_{21},\quad \pi.\Lambda=\pi_a\Lambda^{0a}, \tag{28}$$

$$\Delta^{ij}_{22}=[\pi_0(\pi.S)\epsilon^{ij}+e(F^{ij}S^2+S_bF^{bi}S^j+S^iF^{jb}S_b],\quad S^2=S_aS^a. \tag{29}$$

Next, following (5), we need to compute $X^{ij}_{\alpha\beta}$ as the whole calculational scheme rests on this quantity and its inverse. This we do perturbatively by first considering the free theory (i.e., $e=0$), where

$$\Theta^i_1\equiv\Lambda^{0i}-\frac{p^i}{m},\quad \Theta^i_2\equiv\epsilon^{ibc}p_bS_c, \tag{30}$$

$$\{\Theta^i_\alpha,\Theta^j_\beta\}=\Delta^{ij}_{\alpha\beta}=\begin{pmatrix}0 & -((p.\Lambda)g^{ij}-p^i\Lambda^{0j})\\ ((p.\Lambda)g^{ij}-p^j\Lambda^{0i}) & p_0(p.S)\epsilon^{ij}\end{pmatrix}. \tag{31}$$

For the free theory we propose

$$X^{ij}_{\alpha\beta}|_{e=0}\equiv x^{ij}_{\alpha\beta}=\begin{pmatrix}0 & -((p.\Lambda)g^{ij}-p^i\Lambda^{0j})\\ g^{ij} & \frac{1}{2}p_0(p.S)\epsilon^{ij}\end{pmatrix}. \tag{32}$$

One can check that $x^{ij}_{\alpha\beta}$ satisfies (5) for the free theory, provided we choose $\omega^{\alpha\beta}_{ab}=\epsilon^{\alpha\beta}g_{ab}$, $\epsilon^{12}=1$. Since there is some arbitrariness involved in $x^{ij}_{\alpha\beta}$ and $\omega^{\alpha\beta}_{ab}$, their choices are dictated by convenience. The inverse is defined

$$\begin{gathered}x^{\alpha\beta}_{ij}x^{jk}_{\beta\gamma}=\delta^\alpha_\gamma g^i_k,\\ x^{\gamma\delta}_{jk}=\begin{pmatrix}\frac{p_0(p.S)}{2(p.\Lambda)}\left(\epsilon_{jk}-\frac{\epsilon_{jl}p_l\Lambda_{0k}}{p_0\Lambda_{00}}\right) & g_{jk}\\ -\frac{1}{(p.\Lambda)}\left(g_{jk}+\frac{p_j\Lambda_{0k}}{p_0\Lambda_{00}}\right) & 0\end{pmatrix}.\end{gathered} \tag{33}$$

This is an exact result. Now, for the interacting theory, we find to $O(e)$,

$$X^{ij}_{\alpha\beta}=x^{ij}_{\alpha\beta}(p_a\to\pi_a)+ey^{ij}_{\alpha\beta}, \tag{34}$$

$$y_{11}^{ij}=\frac{F^{il}\Lambda_{0l}p^j}{m^2p_0\Lambda_{00}(p^k\Lambda_{0k})};\quad y_{22}^{ij}=\frac{1}{2}\,(S_0)^2F^{ij}, \tag{35}$$

$$y_{21}^{ij}=\frac{S_0\epsilon^{rl}F^{0r}S^l}{p_0(p.S)}g^{ij}, \tag{36}$$

$$y_{12}^{ij}=-\frac{1}{m}\,F^i{}_b\epsilon^{jbc}S_c+\frac{F^{il}\Lambda_{0l}p_k\epsilon^{jk}p_0(p.S)}{2m^2p_0\Lambda_{00}(p^k\Lambda_{0k}}+\frac{S_0\epsilon^{rl}F^{0r}S^l}{p_0(p.S)}\,((p.\Lambda)g^{ij}-p^i\Lambda^{0j}). \tag{37}$$

The inverse, to $O(e)$, is of the form

$$X_{ij}^{\alpha\beta}=x_{ij}^{\alpha\beta}(p_a\to\pi_a)-ex_{ik}^{\alpha\mu}(p)y_{\mu\nu}^{kl}(p)x_{lj}^{\nu\beta}(p). \tag{38}$$

In the present work the explicit form of $X_{ij}^{\alpha\beta}$ will not be utilized. From the relation

$$\tilde{\Theta}_\alpha^{i(1)}=X_{\alpha\beta}^{ij}\phi_j^\beta, \tag{39}$$

the explicit expressions for $\tilde{\Theta}_\alpha^{i(1)}$ (i.e., one BT variable extension term) are

$$\tilde{\Theta}_1^{i(1)}=-(g^{ik}(\pi.\Lambda)-\pi^i\Lambda^{0k})\phi_k^2+e(y_{12}^{ik}\phi_k^2+y_{11}^{ik}\phi_k^1), \tag{40}$$

$$\tilde{\Theta}_2^{i(1)}=\tfrac{1}{2}\,\pi_0(\pi.S)\epsilon^{ik}\phi_k^2+\phi^{1i}+e(y_{21}^{ik}\phi_k^1+y_{22}^{ik}\phi_k^2). \tag{41}$$

We emphasize that the series for $\tilde{\Theta}_1^i$ and $\tilde{\theta}_2^i$ do not terminate and the higher order terms in ϕ_i^α can be derived by a straightforward but extremely tedious calculation. However, to check whether our target of converting SCCs to FCCs has really been achieved (to $O(e)$), one can convince oneself that

$$\{(\Theta_\alpha^i+\tilde{\Theta}_\alpha^{i(1)}),(\Theta_\beta^j+\tilde{\Theta}_\beta^{j(1)})\}=0+O(\phi).$$

To check the cancellation of $O(\phi)$ terms, $\Theta_\alpha^{i(2)}$ terms are required.

Now we move on to the *one BT extension* of the physical degrees of freedom, i.e., the improved variables. The BT extensions of the BT variables themselves will vanish. Let us start by constructing the extensions for π^a. From the generic expression given in (10), we have

$$\begin{aligned}\tilde{\pi}^{a(1)}&=-\phi_c^\beta\omega_{\beta\gamma}^{cb}X_{bd}^{\gamma\delta}\{\Theta_\delta^d,\pi^a\}_{(q,p)}\\&=\frac{e}{m}\,(\phi^{2j}x_{ji}^{11}-\phi^{1j}x_{ji}^{21})F^{ia}-e\phi_i^2\epsilon^{ide}S_eF_d{}^a\\&=\frac{e}{m}\,F^{ia}\left[\left(\phi^{2j}\,\frac{p_0(p.S)}{2(p.\Lambda)}\left(\epsilon_{ji}-\frac{\epsilon_{jl}p_l\Lambda^0{}_i}{p_0\Lambda_{00}}\right)+\phi^{ij}\,\frac{1}{(p.\Lambda)}\left(g_{ij}+\frac{p_j\Lambda_{0i}}{p_0\Lambda_{00}}\right)\right)\right]-e\phi_i^2\epsilon^{ide}S_eF_d{}^a\,.\end{aligned} \tag{42}$$

In a straightforward manner, one can compute the rest of the improved variables, from the structures given here:

$$\tilde{x}^{a(1)}=-\phi_c^\beta\omega_{\beta\gamma}^{cb}X_{bd}^{\gamma\delta}\{\Theta_\delta^d,x^a\}_{(q,p)}=\frac{g^{ai}}{m}\,(\phi^{2j}x_{ji}^{11}-\phi^{1j}x_{ji}^{21})+\epsilon^{aic}S_c(\phi^{2j}X_{ji}^{12}-\phi^{1j}X_{ji}^{22}), \tag{43}$$

$$\begin{aligned}\tilde{S}^{a(1)}&=-\phi_c^\beta\omega_{\beta\gamma}^{cb}X_{bd}^{\gamma\delta}\{\Theta_\delta^d,S^a\}_{(q,p)}\\&=\epsilon^{aic}\Lambda_{0c}(-\phi^{1j}X_{ji}^{21}+\phi^{2j}X_{ji}^{11})-(g^{ai}(\pi.S)-S^i\pi^a)(\phi^{2j}X_{ji}^{12}-\phi^{1j}X_{ji}^{22}),\end{aligned} \tag{44}$$

$$\tilde{\Lambda}^{0a(1)} = -\phi_c^\beta \omega_{\beta\gamma}^{cb} X_{bd}^{\gamma\delta} \{\Theta_\delta^d, \Lambda^{0a}\}_{(q,p)} = (g^{ai}(\pi.\Lambda) - \Lambda^{0i}\pi^a)(\phi^{1j} X_{ji}^{22} - \phi^{2j} X_{ji}^{12}). \tag{45}$$

These improved variables also comprise of infinite sequences of higher order ϕ_i^α terms. As a nontrivial consistency check, we have tested the validity of the assertion that, to $O(\phi)$, $\tilde{\Theta}_\alpha^a \equiv \Theta_\alpha^a(\tilde{q},\tilde{p})$ holds. To examine the *two*-ϕ-term, $O(\phi^2)$-terms in $\tilde{\Theta}_\alpha^i$ and $\tilde{f}(q,p)$ are required. In the next section we will make use of these results to redetermine the g-value for the anyon in the extended phase space. However, as we have stressed before, the main achievement is that a consistent framework has been provided wherein quantization of the SPM is unambiguous and derivation of the previous results are more transparent.

V. APPLICATION—*g* IN EXTENDED SPACE

Let us start by recovering the ''mass shell'' condition $\tilde{\Psi}_1$ in BT extended space, which is simply given by

$$\tilde{\Psi}_1 \equiv \tilde{\pi}_a \tilde{\pi}^a - m^2 + \frac{2e\tilde{F}_{ab}\tilde{\pi}^a}{\tilde{\pi}^2}\tilde{\Theta}_2^b \approx 0. \tag{46}$$

Remembering that *all* the improved variables are of the form

$$\tilde{\mathcal{A}}(q,p,\phi) = \mathcal{A}(q,p) + O(\phi) + \ldots, \quad \tilde{F} = F(\tilde{x}) = F(x) + (\partial F)\phi + \ldots,$$

and neglecting ∂F terms, it is clear that ϕ-independent *polynomial* expressions of relevant operators will remain intact and, so, up to non-ϕ terms, the previous relations survive. Hence proceeding in the same way as before, in the extended space, one can compare the Schrödinger equation to derive $g = 2 + O(\phi)$ for anyons. However, more work is to be done to ascertain whether the ϕ-terms can contribute to g even in the nonrelativistic limit $p_0 \approx m \gg |\mathbf{p}|$ used in Ref. 4. Notice that the Pauli–Lubanski relation is modified to

$$\tilde{\Psi}_2 \equiv \tilde{\pi}.\tilde{S} - \frac{mj}{2} + \frac{ej\tilde{F}_{ab}\tilde{\pi}^a}{2m\tilde{\pi}^2}\tilde{\Theta}_2^b \approx 0.$$

This discussion corresponds to the SM model.[4]

Returning to our SPM model,[6] we follow the discussion in Sec. III and introduce the gauge fixing condition for $\tilde{\Psi}_1$ to be $\tilde{x}_0 - \tau = 0$ and obtain the Hamiltonian as

$$\tilde{H} = (m^2 - \tilde{\pi}^i\tilde{\pi}_i + \tilde{\Theta}_2^a - \text{term})^{1/2} - e\tilde{A}_0. \tag{47}$$

We immediately notice that the Hamiltonian in extended space is not a rational function of the phase space variables and also that the Θ_2^a term cannot be dropped. But the theorem in (14) comes to the rescue. The Θ_2^a can contribute to the equations of motion of the generic form $\dot{\tilde{\mathcal{A}}} = \{\tilde{H}, \tilde{\mathcal{A}}\}$ by terms proportional to $\tilde{\Theta}_2^a$ only since PBs in extended space with $\tilde{\Theta}_\alpha^i$ vanish. So long as we are concerned with computing PBs, the theorem (14) can be applied without going to the details of the explicit structure of the respective operators in the PB. Hence utilizing (14), we can simply transform the BMT equation of motion for the spin variable,[6] in terms of the improved variables, and get

$$\dot{\tilde{S}}^a = \frac{e}{m}\tilde{F}^{ab}\tilde{S}_b \approx \frac{e}{m}F^{ab}\tilde{S}_b. \tag{48}$$

This is our cherished Bargmann–Michel–Telegdi equation for anyon in BT-extended space. Obviously in the the BT-extended space, the expression for g is modified to $g = 2 + O(\phi)$ for anyons, with the additional terms coming from the BT-variable dependent terms.

To facilitate a comparison with the results obtained in the physical variable sector (without introducing BT variables), we can rewrite the improved variables by their physical counterpart and the BT extension terms. Since the phase space PB algebra (18), (19), and (3) is trivially known, we can compute $\dot{S}^a$ from (51) in a straightforward way. Obviously it will be of the form

$$\dot{\tilde{S}}^a \approx \frac{e}{m} F^{ab} \tilde{S}_b + O(\phi). \tag{49}$$

In a restricted way, we can eliminate the BT variables in terms of the physical variables if we adopt the Dirac quantization prescription for systems with FCCs only, where the physical sector of Hilbert space is required to satisfy $FCC\ |physical\ state\rangle = 0$.[17] In the present case, this reduces to

$$\tilde{\Theta}^i_\alpha |ph.\ \ st.\rangle = \tilde{\Psi}_l |ph.\ \ st.\rangle = 0. \tag{50}$$

Since we are interested in substituting the BT variables in the expression of the Hamiltonian in (47), we can solve the constraints for $e=0$ as the terms involving BT variables are already of $O(e)$. This leads to the set of equations

$$\begin{aligned} \tilde{\Theta}^i_1|_{e=0} &= \Theta^i_1|_{e=0} - (g^{ij}(p.\Lambda) - p^i \Lambda^{oj})\phi^2_j = 0, \\ \tilde{\Theta}^i_2|_{e=0} &= \Theta^i_2|_{e=0} + \phi^{1i} + \tfrac{1}{2} m^2 S_0 \epsilon^{ik} \phi^2_k = 0. \end{aligned} \tag{51}$$

From the solutions of the above equations, we find

$$\begin{aligned} \phi^{1i} &= -\Theta^i_2 - \tfrac{1}{2} m^2 S_0 \epsilon^{ij} \phi^2_j, \\ \phi^{2i} &= \frac{\Theta_{1j}}{(p.\Lambda)} \left(g^{ij} + \frac{p^i \Lambda^{0j}}{p_0 \Lambda_{00}} \right). \end{aligned} \tag{52}$$

Notice that the BT variables in this restricted derivation, being proportional to Θ^i_α, are nonvanishing even in the free theory since in the extended sector Θ^i_α are no longer the constraints. It should be emphasized that this is not the whole story since $\tilde{\Theta}^i_\alpha$ consists of an infinite number of terms. Also there are indications that higher order terms will survive even if, on top of our small e restriction, we incorporate the nonrelativistic limit (that is, $p_0 \approx m \gg |\mathbf{p}|$, as has been done in Ref. 4). On the other hand, putting these expressions in the BMT equation shows the leading term in $g=2$ survives but there can be nontrivial velocity dependent corrections. Putting the BT variables back in (49) we get the BMT equation completely in the physical sector.

VI. CONCLUSION

To conclude, in the present work we have formulated an extension of the spinning particle model for anyon[6] along the lines of Batalin–Tyutin quantization scheme.[12] The reason behind working in the extended phase space lies in the presence of nonlinear second class constraints in the model, which induce a noncanonical structure in the particle coordinate. Specifically, the position coordinates become noncommuting, which creates a problem for the quantization programs. Also this makes the comparison between results obtained here and in conventional space–time models difficult. The gyromagnetic ratio of anyon was obtained to be 2[4,6] by invoking precisely this type of matching.

To avoid this type of nontrivial structure in the space–time, the Batalin–Tyutin formalism[12] is adopted where extra BT variables are introduced in the phase space in such a way that all the constraints become first class in the extended space and the problematic Dirac brackets can be avoided. Hence the commuting space–time structure is kept intact. However, the price to pay is that the extensions of the constraints and relevant variables turn out to be infinite series (even to

lowest order in e, the electromagnetic coupling), with higher powers of BT variables. One has to be very careful in taking the nonrelativistic limit[4] and *a prior* it is difficult to determine whether the series will terminate or not.

In the present work we have computed explicitly the one-ϕ extensions of *all* the constraints and degrees of freedom. From the nature of the extensions, it is clear the BT-variable independent relations remain the same as the original ones. Hence one might say that the BT terms are effects of the noncommuting space–time algebra. However, we note that these results are partial in the sense that higher BT-variable terms may also contribute to this order of accuracy. One of our immediate goals in this area is to compute explicitly effect of the BT-variable terms in observable quantities, e.g., g.

From another point of view, this work is significant since it may provide a mapping between theories in *noncommuting* space–time on one hand, and theories in conventional configuration space with extra *spin* degrees of freedom. Subsequently, Batalin–Tyutin extension can be introduced and one can check if results of simple noncommutative models[9] are reproduced.

Another interesting problem of the formal kind is to develop the Batalin–Tyutin scheme for reducible second class constraint systems, such as the spinning particle model in manifestly covariant form. One has to be careful in introducing the BT variables since reducibility in the system will be reflected in the number of these degrees of freedom.

A quantum effect is an operator A on a complex Hilbert space H that satisfies $0 \leqslant A \leqslant I$. We denote the set of quantum effects by $\mathcal{E}(H)$. The set of self-adjoint projection operators on H corresponds to sharp effects and is denoted by $\mathcal{P}(H)$. We define the sequential product of $A,B \in \mathcal{E}(H)$ by $A \circ B = A^{1/2}BA^{1/2}$. The main purpose of this article is to study some of the algebraic properties of the sequential product. Many of our results show that algebraic conditions on $A \circ B$ imply that A and B commute for the usual operator product. For example, if $A \circ B$ satisfies certain distributive or associative laws, then $AB = BA$. Moreover, if $A \circ B \in \mathcal{P}(H)$, then $AB = BA$ and $A \circ B = B$ or $B \circ A = B$ if and only if $AB = BA = B$. A natural definition of stochastic independence is introduced and briefly studied. © *2001 American Institute of Physics.* [DOI: 10.1063/1.1407837]

I. INTRODUCTION

Two measurements A and B cannot be performed simultaneously in general, so they are frequently executed sequentially. We denote by $A \circ B$ a sequential measurement in which A is performed first and B second. We restrict our attention to yes–no measurements that have only two possible results usually taken to be 0 and 1. A paradigm situation is an optical bench in which a beam of particles prepared in a certain state is injected at the left and then subjected to a sequence of filters $F_1,\ldots,F_n$. An individual particle either passes through a filter F_i or does not so the filters can be thought of as yes–no measurements. Particles that pass through all the filters enter a detection device at the right of F_n and are counted. Because of quantum interference, the order of placement of the filters usually makes a difference. The resulting sequential measurement is $F_1 \circ F_2 \circ \cdots \circ F_n$ and the probability that a particle is detected is denoted by $P(F_1 \circ F_2 \circ \cdots \circ F_n)$. In practice, this probability is usually approximated by a relative long-run frequency. Thus, if a large number N_{in} of particles is injected and N_{out} particles are detected, then

$$P(F_1 \circ F_2 \circ \cdots \circ F_n) \approx \frac{N_{\text{in}}}{N_{\text{out}}}.$$

Following the standard terminology, we call yes–no measurements **effects**.[1–3] For effects A and B, it is reasonable to assume that

$$P(A \circ B) = P(A)P(B|A). \tag{1.1}$$

For a classical system, A and B are represented by sets and P is represented by a probability measure. In this case we have

$$P(A \circ B) = \frac{P(A)P(A \cap B)}{P(A)} = P(A \cap B)$$

[a)]Electronic mail: sgudder@cs.du.edu
[b)]Electronic mail: nagy@math.ksu.edu

when $P(A)\neq 0$. Hence, $A\circ B$ is represented by $A\cap B$ and we write $A\circ B=A\cap B$. But then

$$A\circ B=A\cap B=B\cap B=B\circ A$$

and this does not describe quantum interference. For this reason, we must abandon classical probability theory and we are forced to employ quantum probability theory. For example, let A and B be polarizing filters in planes perpendicular to the particle beam, where A polarizes vertically and B at a 45° angle. If the incoming beam is prepared in a state of horizontal polarization, then $A\circ B$ will transmit no particles, while $B\circ A$ will transmit particles. In this case, $A\circ B\neq B\circ A$.

In quantum mechanics, sharp effects are represented by self-adjoint projection operators on a complex Hilbert space H and general effects that may be unsharp (imprecise) are represented by operators on H satisfying $0\leqslant A\leqslant I$.[1–3] This latter condition means that

$$0\leqslant\langle Ax,x\rangle\leqslant\langle x,x\rangle$$

for all $x\in H$ and it easily follows that A is self-adjoint. We denote the set of sharp effects by $\mathcal{P}(H)$ and the set of general effects by $\mathcal{E}(H)$. If $W\in\mathcal{E}(H)$ is of trace class and satisfies $\mathrm{tr}(W)=1$, then W is called a **density operator**. We denote the set of density operators by $\mathcal{D}(H)$. Each $W\in\mathcal{D}(H)$ represents a quantum state and $P_W(A)=\mathrm{tr}(AW)$ is the probability that the effect A occurs (has value 1) when the system is prepared in the state W.

For $A,B\in\mathcal{E}(H),W\in\mathcal{D}(H)$, we define the **conditional probability of** B **given** A by

$$P_W(B|A)=\frac{\mathrm{tr}(BA^{1/2}WA^{1/2})}{\mathrm{tr}(AW)}=\frac{\mathrm{tr}(A^{1/2}BA^{1/2}W)}{\mathrm{tr}(AW)} \tag{1.2}$$

when $\mathrm{tr}(AW)\neq 0$.[1,4,5] As usual, $A^{1/2}$ is the unique positive square root of A. Equation (1.2) generalizes the well-known von Neumann–Lüders formula[6]

$$P_W(B|A)=\frac{\mathrm{tr}(BAWA)}{\mathrm{tr}(AW)}$$

for $A,B\in\mathcal{P}(H)$. Applying Eqs. (1.1) and (1.2) we have

$$P_W(A\circ B)=P_W(A)P_W(B|A)=\mathrm{tr}(A^{1/2}BA^{1/2}W)=P_W(A^{1/2}BA^{1/2}). \tag{1.3}$$

Notice that $A^{1/2}BA^{1/2}\in\mathcal{E}(H)$ because

$$0\leqslant\langle A^{1/2}BA^{1/2}x,x\rangle=\langle BA^{1/2}x,A^{1/2}x\rangle\leqslant\langle A^{1/2}x,A^{1/2}x\rangle=\langle Ax,x\rangle\leqslant\langle x,x\rangle.$$

Since (1.3) holds for every $W\in\mathcal{D}(H)$, we define $A\circ B=A^{1/2}BA^{1/2}$ and we have just shown that $A\circ B\leqslant A$. We call $A\circ B$ the **sequential product** of A and B.

We say that $A,B\in\mathcal{E}(H)$ are **compatible** if $AB=BA$. The sequential product illustrates why it is important to consider unsharp effects. Even if $A,B\in\mathcal{P}(H)$ are sharp, $A\circ B=ABA\notin\mathcal{P}(H)$ unless A and B are compatible. In this article, we shall study various properties of the sequential product. Many of our results show that if one tries to impose classical conditions on $A\circ B$, then it forces A and B to be compatible.

II. SEQUENTIAL INDEPENDENCE

It is clear that the sequential product satisfies $0\circ A=0$, $I\circ A=A$, $A\circ(B+C)=A\circ B+A\circ C$ whenever $B+C\leqslant I$, and $(\lambda A)\circ B=A\circ(\lambda B)=\lambda(A\circ B)$ for every $0\leqslant\lambda\leqslant 1$. We shall show that $A\circ B$ has practically no other algebraic properties unless compatibility conditions are imposed. To illustrate the fact that $A\circ B$ does not have properties that one might expect, we now show that $A\circ B=A\circ C$ does not imply $B\circ A=C\circ A$ even for $A,B,C\in\mathcal{P}(H)$. In $H=\mathbb{C}^2$, consider $A,B,C\in\mathcal{P}(H)$ given by the following matrices:

$$A=\frac{1}{2}\begin{bmatrix}1 & 1\\ 1 & 1\end{bmatrix},\quad B=\begin{bmatrix}1 & 0\\ 0 & 0\end{bmatrix},\quad C=\begin{bmatrix}0 & 0\\ 0 & 1\end{bmatrix}.$$

We then have

$$A\circ B=ABA=\tfrac{1}{2}A=ACA=A\circ C.$$

However,

$$B\circ A=BAB=\tfrac{1}{2}B\neq\tfrac{1}{2}C=CAC=C\circ A.$$

This example also shows that $A\circ B\not\leqslant B$ in general, even though we always have $A\circ B\leqslant A$.

We say that $A,B\in\mathcal{E}(H)$ are **sequentially independent** if $A\circ B=B\circ A$. It is clear that if A and B are compatible, then they are sequentially independent. To prove the converse, we shall need the following result due to Fuglede–Putnam–Rosenblum.[7]

Theorem 2.1: *If M, N, T are bounded linear operators on H with M and N normal, then $MT=TN$ implies $M^*T=TN^*$.*

Although the next result was given in Ref. 5 we include the proof because it is very short.

Corollary 2.2: For $A,B\in\mathcal{E}(H)$, $A\circ B=B\circ A$ implies $AB=BA$.

Proof: Since $A\circ B=B\circ A$, we have

$$A^{1/2}B^{1/2}B^{1/2}A^{1/2}=B^{1/2}A^{1/2}A^{1/2}B^{1/2}.$$

Hence, $M=A^{1/2}B^{1/2}$ and $N=B^{1/2}A^{1/2}$ are normal. Letting $T=A^{1/2}$, we have $MT=TN$. Applying Theorem 2.1 we conclude that $B^{1/2}A=AB^{1/2}$. It immediately follows that $BA=AB$. □

Sequential independence for three or more effects was considered in Ref. 5 and a more general result was proved. Our next result shows that if $A\circ B$ is sharp, then A and B are compatible (and hence, sequentially independent).

Theorem 2.3: *For $A,B\in\mathcal{E}(H)$, if $A\circ B\in\mathcal{P}(H)$, then $AB=BA$.*

Proof: Assume that $A^{1/2}BA^{1/2}=A\circ B\in\mathcal{P}(H)$. Suppose that $A\circ Bx=x$ where $\|x\|=1$. We then have $\langle BA^{1/2}x,A^{1/2}x\rangle=1$. By Schwarz's inequality we have $BA^{1/2}x=A^{1/2}x$ and, hence, $Ax=A\circ Bx=x$. Since x is an eigenvector of A with eigenvalue 1, the same holds for $A^{1/2}$. Thus, $A^{1/2}x=x$ so that $BA^{1/2}x=A\circ Bx$. We conclude that $BA^{1/2}x=A\circ Bx$ for every x in the range $R(A\circ B)$. Now suppose that $A\circ Bx=0$. We then have

$$\|B^{1/2}A^{1/2}x\|^2=\langle B^{1/2}A^{1/2}x,B^{1/2}A^{1/2}x\rangle=\langle A\circ Bx,x\rangle=0$$

so that $B^{1/2}A^{1/2}x=0$. Hence, $BA^{1/2}x=0$ and it follows that $BA^{1/2}x=A\circ Bx$ for every x in the null space $N(A\circ B)$. We conclude that $BA^{1/2}=A\circ B$. Hence,

$$BA^{1/2}=A\circ B=(A\circ B)^*=A^{1/2}B$$

so that $AB=BA$. □

Simple examples show that the converse of Theorem 2.3 does not hold. However, the converse does hold for sharp effects.

Corollary 2.4: For $A,B\in\mathcal{P}(H)$, $A\circ B\in\mathcal{P}(H)$ if and only if $AB=BA$.

This last result shows that $\mathcal{P}(H)$ is not closed under sequential products. Theorem 2.3 can be stated in the following equivalent form. For $A,B\in\mathcal{E}(H)$, if $ABA\in\mathcal{P}(H)$, then $AB=BA$. It is interesting to note that this form does not hold for arbitrary bounded self-adjoint operators.

Example: In $\mathbb{C}^3$ consider the self-adjoint operators $B=\mathrm{diag}(0,1,1)$ and

$$A=\begin{bmatrix}0 & 1 & 0\\ 1 & 0 & 0\\ 0 & 0 & 0\end{bmatrix}.$$

Then $AB \neq BA$ but $ABA = \mathrm{diag}(1,0,0) \in \mathcal{P}(H)$. □

It follows from Corollary 2.4 that for $A,B \in \mathcal{P}(H)$ we have $A \circ B = B$ if and only if $AB = BA = B$. We now generalize this result to arbitrary effects.

Theorem 2.5: *For $A,B \in \mathcal{E}(H)$ the following statements are equivalent.* (a) $A \circ B = B$. (b) $B \circ A = B$. (c) $AB = BA = B$.

Proof: It is clear that (c) implies both (a) and (b). It then suffices to show that (a) and (b) each imply (c). If $A \circ B = B$ we have

$$A^{1/2}B^2A^{1/2} = A^{1/2}BA^{1/2}BA = B^2A.$$

Taking adjoints gives $B^2A = AB^2$. It follows that $AB = BA = B$. If $B \circ A = B$, then for any $x \in H$ we have

$$\langle AB^{1/2}x, B^{1/2}x\rangle = \langle B \circ Ax, x\rangle = \langle Bx, x\rangle = \|B^{1/2}x\|^2.$$

If $B^{1/2}x \neq 0$, then

$$\left\langle A\frac{B^{1/2}x}{\|B^{1/2}x\|}, \frac{B^{1/2}x}{\|B^{1/2}x\|}\right\rangle = 1.$$

It follows from Schwarz's inequality that $AB^{1/2}x = B^{1/2}x$. Hence, $AB^{1/2} = B^{1/2}$ so that $AB^{1/2} = B^{1/2}A = B^{1/2}$. We conclude that $AB = BA = B$. □

Theorem 2.5(a) cannot be strengthened to the case $A \circ B \leqslant B$. That is, $A \circ B \leqslant B$ does not imply $AB = BA$.

Example: In $\mathbb{C}^2$ let

$$A = \frac{1}{4}\begin{bmatrix} 1 & 1 \\ 1 & 1 \end{bmatrix}, \quad B = \begin{bmatrix} \frac{3}{4} & 0 \\ 0 & \frac{1}{4} \end{bmatrix}.$$

Then $A \circ B \leqslant B$ but $AB \neq BA$. □

The next result strengthens Theorem 2.5 for certain special cases.

Theorem 2.6: (a) *For $A,B \in \mathcal{P}(H)$ we have $A \circ B \leqslant B$ if and only if $AB = BA$.* (b) *For $A,B \in \mathcal{P}(H)$ we have $A \circ B \geqslant B$ if and only if $AB = BA = B$.* (c) *If $A,B \in \mathcal{E}(H)$ with $\dim H < \infty$ and $A \circ B \geqslant B$, then $AB = BA = B$.*

Proof: (a) Clearly, $AB = BA$ implies $A \circ B \leqslant B$. Conversely, if

$$ABA = A \circ B \leqslant B,$$

then it follows that

$$BABA = ABAB = ABA.$$

Now $ABA \in \mathcal{P}(H)$ because

$$ABAABA = ABABA = BABA = ABA.$$

Applying Theorem 2.3 we have $AB = BA$.

(b) Again it is clear that $AB = BA = B$ implies $A \circ B \geqslant B$. Conversely, if

$$ABA = A \circ B \geqslant B,$$

then we have

$$BABA = ABAB = B.$$

As before, $(A\circ B)^2=BABA=B$ so that $A\circ B=B$. Hence, $AB=BA=B$. (c) Let $x_1,\ldots,x_n$ be an orthonormal basis of eigenvectors of $A^{1/2}$ with corresponding eigenvalues $\lambda_1,\ldots,\lambda_n$. Since

$$\langle Bx_i,x_i\rangle\leqslant\langle BA^{1/2}x_i,A^{1/2}x_i\rangle=\lambda_i^2\langle Bx_i,x_i\rangle$$

we have $Bx_i=0$ if $\lambda_i<1$. Moreover, if $\lambda_i=1$, we have

$$\langle(A^{1/2}BA^{1/2}-B)x_i,x_i\rangle=0. \tag{2.1}$$

Hence, (2.1) holds for $i=1,2,\ldots,n$. Since $A^{1/2}BA^{1/2}-B\geqslant 0$, we conclude that $(A\circ B-B)x_i=0$ for $i=1,2,\ldots,n$. Hence, $A\circ B=B$ and the result follows from Theorem 2.5(a). □

Theorem 2.6(c) says that when $\dim H<\infty$ we cannot amplify an effect by preceding it by another effect. It is an open problem whether this result holds when $\dim H=\infty$.

III. ASSOCIATIVITY

For a unit vector $x\in H$, we denote the self-adjoint projection onto the one-dimensional subspace spanned by x by P_x. We first prove a lemma that is needed for the following theorem on associativity.

Lemma 3.1: (a) *If* $|\langle y,x\rangle|=|\langle z,x\rangle|$ *for every* $x\in H$, *then* $y=cz$ *where* $|c|=1$. (b) *If* $f:H\to\mathbb{C}$, T *is a nonzero bounded linear operator on* H, *and* $Mx=f(x)Tx$ *is linear, then* $f(x)=f(y)$ *for every* $x,y\neq 0$.

Proof: (a) The result clearly holds if $y=0$ so suppose that $y\neq 0$. We then have

$$\|y\|^2=\langle y,y\rangle=|\langle z,y\rangle|=|\langle y,z\rangle|=\langle z,z\rangle=\|z\|^2.$$

Hence, $\|y\|=\|z\|$ and we have $|\langle y,z\rangle|=\|z\|\|y\|$. We conclude that $y=cz$ with $|c|=1$.

(b) For $\alpha\in\mathbb{C}$ we have

$$\alpha f(\alpha x)Tx=f(\alpha x)T(\alpha x)=M(\alpha x)=\alpha Mx=\alpha f(x)Tx.$$

Hence, $f(\alpha x)=f(x)$ for every $\alpha\in\mathbb{C}$ with $\alpha\neq 0$. Moreover,

$$f(x+y)Tx+f(x+y)Ty=M(x+y)=Mx+My=f(x)Tx+f(y)Ty.$$

If Tx and Ty are linearly independent, we conclude that $f(x)=f(y)$. Suppose that $Tx\neq 0$ and $Ty\neq 0$ are linearly dependent. If T has one-dimensional range, then T is essentially a linear functional and the result follows. Otherwise, there exists a $z\in H$ such that Tz and Tx are linearly independent and hence Tz and Ty are linearly independent. But then $f(y)=f(z)=f(x)$. □

Theorem 3.2: *For* $A,B\in\mathcal{E}(H)$ *we have* $A\circ(B\circ C)=(A\circ B)\circ C$ *for every* $C\in\mathcal{E}(H)$ *if and only if* $AB=BA$.

Proof: If $AB=BA$, then clearly $A\circ(B\circ C)=(A\circ B)\circ C$ for every $C\in\mathcal{E}(H)$. Conversely, suppose that $A\circ(B\circ C)=(A\circ B)\circ C$ for every $C\in\mathcal{E}(H)$. Then $A\circ(B\circ P_x)=(A\circ B)\circ P_x$ for every unit vector $x\in H$. For any $x,y\in H$ with $\|x\|=1$ we have

$$\begin{aligned}|\langle B^{1/2}A^{1/2}y,x\rangle|^2&=\langle B^{1/2}A^{1/2}y,x\rangle\langle x,B^{1/2}A^{1/2}y\rangle=\langle P_xB^{1/2}A^{1/2}y,B^{1/2}A^{1/2}y\rangle=\langle A\circ(B\circ P_x)y,y\rangle\\&=\langle(A\circ B)\circ P_xy,y\rangle=\langle(A^{1/2}BA^{1/2})^{1/2}P_x(A^{1/2}BA^{1/2})^{1/2}y,y\rangle\\&=\langle P_x(A^{1/2}BA^{1/2})^{1/2}y,(A^{1/2}BA^{1/2})^{1/2}y\rangle=|\langle(A^{1/2}BA^{1/2})^{1/2}y,x\rangle|^2.\end{aligned}$$

Applying Lemma 3.1(a), we conclude that

$$(A^{1/2}BA^{1/2})^{1/2}x=f(x)B^{1/2}A^{1/2}x$$

for every $x\in H$ where $f:H\to\mathbb{C}$ satisfies $|f(x)|=1$. It follows from Lemma 3.1(b) that

$$(A^{1/2}BA^{1/2})^{1/2}=cB^{1/2}A^{1/2}$$

for some $c\in\mathbb{C}$ with $|c|=1$. Taking adjoints gives $cB^{1/2}A^{1/2}=c^*A^{1/2}B^{1/2}$. Hence, $A^{1/2}B^{1/2}=B^{1/2}(dA^{1/2})$ where $|d|=1$. Applying Theorem 2.1, we have $A^{1/2}B^{1/2}=B^{1/2}(d^*A^{1/2})$ so that $dB^{1/2}A^{1/2}=d^*B^{1/2}A^{1/2}$. Hence, either $B^{1/2}A^{1/2}=0$ or $d=d^*$. In the first case,

$$B^{1/2}A^{1/2}=A^{1/2}B^{1/2}=0$$

so that $AB=BA$. In the second case, d is real so that $d=\pm 1$. If $d=1$, we again have $AB=BA$. If $d=-1$, we have $A^{1/2}B^{1/2}=-B^{1/2}A^{1/2}$. But then $A^{1/2}B^{1/2}A^{1/2}=-B^{1/2}A$ which implies $AB^{1/2}=B^{1/2}A$. Hence, $AB=BA$. □

The fact that $A\circ(B\circ C)\neq(A\circ B)\circ C$, in general, presents a puzzling quantum paradox. In applications, one always uses

$$A\circ(B\circ C)=A^{1/2}B^{1/2}CB^{1/2}A^{1/2}$$

to describe a sequential measurement (A,B,C). This prescription for (A,B,C) states that A is measured first and then the sequential measurement $B\circ C$ is performed. The expression

$$(A\circ B)\circ C=(A^{1/2}BA^{1/2})^{1/2}C(A^{1/2}BA^{1/2})^{1/2}$$

is never used to describe (A,B,C). This latter prescription states that the sequential measurement $A\circ B$ is performed first and then C is measured. Physically, one would expect that these two procedures should give the same result. The fact that the results may be different mathematically indicates that both of these procedures should be described by $A\circ(B\circ C)$ and that $(A\circ B)\circ C$ is simply a nonphysical mathematical construct. However, if it turns out that $(A\circ B)\circ C$ does have a physical meaning, then the fact that these two procedures are different would be quite interesting.

We have seen that the associative law $A\circ(B\circ C)=(A\circ B)\circ C$ holds for every $C\in\mathcal{E}(H)$ if and only if A and B are compatible. It is interesting that we obtain a stronger result if $A\circ(C\circ B)=(A\circ C)\circ B$ for every $C\in\mathcal{E}(H)$. In order to prove this result we shall need a preliminary theorem.

Lemma 3.3: If $\alpha_i,\beta_i,\gamma_i\in\mathbb{R}$, $i=1,2,...,n$, *satisfy*

$$\left(\sum_{j=1}^{n} d_jt_j\right)\left(\sum_{k=1}^{n}\beta_kt_k\right)=\left(\sum_{j=1}^{n}\gamma_jt_j\right)\left(\sum_{k=1}^{n}t_k\right) \tag{3.1}$$

for all $t_i\in\mathbb{R}$, $i=1,2,...,n$, *then either* $\alpha_1=\alpha_2=\cdots=\alpha_n$ *or* $\beta_1=\beta_2=\cdots=\beta_n$.

Proof: Identifying coefficients (or taking second partial order derivatives), (3.1) gives

$$\alpha_j\beta_k+\alpha_k\beta_j=\gamma_j+\gamma_k$$

for all $j,k\in\{1,...,n\}$. In particular, we have $\gamma_j=\alpha_j\beta_j$ for all $j\in\{1,...,n\}$. Hence, if $j\neq k$ we obtain

$$(\alpha_j-\alpha_k)(\beta_j-\beta_k)=(\alpha_j\beta_j+\alpha_k\beta_k)-(\alpha_j\beta_k+\alpha_k\beta_j)=0.$$

Thus, either $\alpha_j=\alpha_k$ or $\beta_j=\beta_k$ for all $j,k\in\{1,...,n\}$. Now let $M\subseteq\{1,...,n\}$ be a maximal set of indices such that either $\alpha_j=\alpha_k$ for all $j,k\in M$ or $\beta_j=\beta_k$ for all $j,k\in M$. Suppose that $M\neq\{1,...,n\}$ and let $m\in\{1,...,n\}\backslash M$. Assume without loss of generality that $\alpha_j=\alpha_k$ for all $j,k\in M$. By the maximality of M, we have that $\alpha_m\neq\alpha_j$ for all $j\in M$ but this forces $\beta_j=\beta_m$ for all $j\in M$. Since $\beta_j=\beta_k$ for all $j,k\in M\cup\{m\}$, this contradicts the maximality of M. Hence, $M=\{1,...,n\}$. □

Theorem 3.4: *Let A,B,C be bounded self-adjoint operators on a complex Hilbert space H with the property*

$$\langle Ax,x\rangle\langle Bx,x\rangle=\langle Cx,x\rangle \tag{3.2}$$

for all $x \in H$ with $\|x\| = 1$. Then $A = cI$ or $B = cI$ for some $c \in \mathbb{R}$.

Proof: Notice that (3.2) has the following equivalent version,

$$\langle Ax,x\rangle\langle Bx,x\rangle = \langle Cx,x\rangle\langle x,x\rangle, \tag{3.3}$$

for all $x \in H$. We first assume that H is finite dimensional. In this case, we can diagonalize C and represent A,B,C by self-adjoint matrices $A = [\alpha_{jk}]$, $B = [\beta_{jk}]$, $C = \operatorname{diag}(\gamma_1,...,\gamma_n)$ on $\mathbb{C}^n$ where $\gamma_1,\ldots,\gamma_n \in \mathbb{R}$. Then (3.3) becomes

$$\left(\sum_{j,k=1}^{n} \alpha_{jk}\overline{\lambda}_j\lambda_k\right)\left(\sum_{j,k=1}^{n} \beta_{jk}\overline{\lambda}_j\lambda_k\right) = \left(\sum_{j=1}^{n} \gamma_j|\lambda_j|^2\right)\left(\sum_{j=1}^{n} |\lambda_j|^2\right) \tag{3.4}$$

for every $(\lambda_1,\ldots,\lambda_n) \in \mathbb{C}^n$. Suppose that $j \neq k$ and let $\lambda_m = 0$ for all $m \in \{1,...,n\}\backslash\{j,k\}$. Then (3.4) gives

$$\begin{aligned}&(\alpha_{jj}|v|^2 + \alpha_{kk}|w|^2 + \alpha_{jk}\overline{v}w + \overline{\alpha}_{jk}v\overline{w})(\beta_{jj}|v|^2 + \beta_{kk}|w|^2 + \beta_{jk}\overline{v}w + \overline{\beta}_{jk}v\overline{w})\\ &\quad = (\gamma_j|v|^2 + \gamma_k|w|^2)(|v|^2 + |w|^2)\end{aligned}$$

for all $v,w \in \mathbb{C}$. If we take $w = 1$ and $|v| = 1$, the previous equation becomes

$$(u_0 + u_1\overline{v} + \overline{u_1}v)(z_0 + z_1\overline{v} + \overline{z_1}v) = 2(\gamma_j + \gamma_k) \tag{3.5}$$

for all $v \in \mathbb{C}$ with $|v| = 1$, where $u_0 = \alpha_{jj} + \alpha_{kk}$, $z_0 = \beta_{jj} + \beta_{kk}$, $u_1 = \alpha_{jk}$, $z_1 = \beta_{jk}$. But (3.5) implies that $u_1 = z_1 = 0$ and we conclude that

$$\alpha_{jk} = \beta_{jk} = 0, \quad j \neq k. \tag{3.6}$$

Applying (3.6), (3.4) becomes

$$\left(\sum_{j=1}^{n} \alpha_{jj}|\lambda_j|^2\right)\left(\sum_{j=1}^{n} \beta_{jj}|\lambda_j|^2\right) = \left(\sum_{j=1}^{n} \gamma_j|\lambda_j|^2\right)\left(\sum_{j=1}^{n} |\lambda_j|^2\right).$$

Applying Lemma 3.3, it follows that either $\alpha_{11} = \cdots = \alpha_{nn}$ or $\beta_{11} = \cdots = \beta_{nn}$. Hence, the result holds if H is finite dimensional.

We now assume that H is infinite dimensional. Denote by $\mathcal{F}(H)$ the set of all finite dimensional subspaces in H. For every $F \in \mathcal{F}(H)$ we define P_F to be the orthogonal projection onto F and we define the self-adjoint operators $A_F = P_FAP_F$, $B_F = P_FBP_F$ and $C_F = P_FCP_F$. For every $F \in \mathcal{F}(H)$ and every $x \in F$ with $\|x\| = 1$, (3.2) gives

$$\langle A_Fx,x\rangle\langle B_Fx,x\rangle = \langle Ax,x\rangle\langle Bx,x\rangle = \langle Cx,x\rangle = \langle C_Fx,x\rangle.$$

It follows from our work in the previous paragraph that either there exists an $\alpha_F \in \mathbb{R}$ such that $A_Fx = \alpha_Fx$ for every $x \in F$ or there exists a $\beta_F \in \mathbb{R}$ such that $B_Fx = \beta_Fx$ for every $x \in F$. Thus, either $A_F = \alpha_FP_F$ or $B_F = \beta_FP_F$. For every $F \in \mathcal{F}(H)$, define

$$\lambda_F = \begin{cases} \alpha_F & \text{if } A_F = \alpha_FP_F, \\ \|A\| + 1 & \text{otherwise,} \end{cases} \quad \mu_F = \begin{cases} \beta_F & \text{if } B_F = \beta_FP_F, \\ \|B\| & \text{otherwise.} \end{cases}$$

It is clear that $\lambda_F \leqslant \|A\| + 1$ and $\mu_F \leqslant \|B\| + 1$. If we order $\mathcal{F}(H)$ by inclusion, we have a bounded net (λ_F,μ_F) in $\mathbb{R}^2$. By compactness, this net has a convergent subnet. Hence, there exists a directed set $(\Sigma, \leqslant)$ and a map $\phi:\Sigma \to \mathcal{F}(H)$ such that for every $F \in \mathcal{F}(H)$ there exists a $\sigma_F \in \Sigma$ such that $F \leqslant \phi(\sigma)$ for every $\sigma_F \leqslant \sigma$ and

$$\lim_{\sigma\in\Sigma} (\lambda_{\phi(\sigma)},\mu_{\phi(\sigma)}) = (\alpha,\beta)$$

for some $(\alpha,\beta)\in\mathbb{R}^2$. If $\alpha\neq\|A\|+1$, then for σ sufficiently large we have $\lambda_{\phi(\sigma)}=\alpha_{\phi(\sigma)}\leqslant\|A\|$. In this case $A_{\phi(\sigma)}=\alpha_{\phi(\sigma)}P_{\phi(\sigma)}$. Since the net $P_{\phi(\sigma)}$ converges in the strong operator topology to I, it follows that the net $A_{\phi(\sigma)}$ converges in the strong operator topology to A. It follows that $A=\alpha I$. If $\alpha=\|A\|+1$, then for σ sufficiently large we must have $\lambda_{\phi(\sigma)}=\|A\|+1$. Hence, $\mu_{\phi(\sigma)}\neq\|B\|+1$ so $\mu_{\phi(\sigma)}=\beta_{\phi(\sigma)}$. Arguing as before, we conclude that $B=\beta I$. □

We now apply this theorem to prove the following result about associativity.

Theorem 3.5: *For $A,B\in\mathcal{E}(H)$, the following statements are equivalent.* (a) $A\circ(C\circ B)=(A\circ C)\circ B$ *for every* $C\in\mathcal{E}(H)$. (b) $C\circ(A\circ B)=(C\circ A)\circ B$ *for every* $C\in\mathcal{E}(H)$. (c) $\langle A\circ Bx,x\rangle=\langle Ax,x\rangle\times\langle Bx,x\rangle$ *for every* $x\in H$ *with* $\|x\|=1$. (d) $A=cI$ *or* $B=cI$ *for some* $0\leqslant c\leqslant 1$.

Proof: If (a) holds, then $A\circ(P_x\circ B)=(A\circ P_x)\circ B$ holds for every unit vector $x\in H$. If $A^{1/2}x\neq 0$, let $y=A^{1/2}x/\|A^{1/2}x\|$. We then have for every $z\in H$ that

$$A\circ(P_x\circ B)z=A^{1/2}P_xBP_xA^{1/2}z=\langle A^{1/2}z,x\rangle A^{1/2}P_xBx=\langle A^{1/2}z,x\rangle\langle Bx,x\rangle A^{1/2}x=\langle Bx,x\rangle\|A^{1/2}x\|^2P_yz.$$

Hence, $A\circ(P_x\circ B)=\langle Bx,x\rangle\|A^{1/2}x\|^2P_y$. Moreover,

$$A\circ P_xz=A^{1/2}P_xA^{1/2}z=\langle A^{1/2}z,x\rangle A^{1/.2}x=\|A^{1/2}x\|^2P_yz$$

so that $A\circ P_x=\|A^{1/2}x\|^2P_y$. Hence,

$$(A\circ P_x)\circ B=(A\circ P_x)^{1/2}B(A\circ P_x)^{1/2}=\|A^{1/2}x\|^2P_yBP_y.$$

We conclude that $P_yBP_y=\langle Bx,x\rangle P_y$. It follows that

$$\langle Bx,x\rangle y=P_yBy=\langle By,y\rangle y$$

so that $\langle Bx,x\rangle=\langle By,y\rangle$. Since $y=A^{1/2}x/\|A^{1/2}x\|$, this last expression becomes

$$\langle A\circ Bx,x\rangle=\langle Ax,x\rangle\langle Bx,x\rangle,$$

so (a) implies (c).

If (b) holds, then for any unit vector $x\in H$ we have

$$\begin{aligned}(A\circ Bx,x)P_x&=P_x(A\circ B)P_x=P_x\circ(A\circ B)=(P_x\circ A)\circ B=(P_xAP_x)^{1/2}B(P_xAP_x)^{1/2}\\&=\langle Ax,x\rangle P_xBP_x=\langle Ax,x\rangle\langle Bx,x\rangle P_x.\end{aligned}$$

Hence, (b) implies (c). It follows from Theorem 3.4 that (c) implies (d). Finally, it is clear that (d) implies both (a) and (b). □

IV. STOCHASTIC INDEPENDENCE AND TOTAL PROBABILITY

We say that $A,B\in\mathcal{E}(H)$ are **stochastically independent relative to the state** $W\in\mathcal{D}(H)$ if $P_W(A\circ B)=P_W(A)P_W(B)$. We can also write this condition in the form

$$\mathrm{tr}[(A\circ B)W]=\mathrm{tr}(AW)\mathrm{tr}(BW). \tag{4.1}$$

In the case of a pure state $W=P_x$, (4.1) becomes

$$\langle A\circ Bx,x\rangle=\langle Ax,x\rangle\langle Bx,x\rangle. \tag{4.2}$$

Notice that (4.2) appears in condition (c) of Theorem 3.5

Corollary 4.1: For $A,B\in\mathcal{E}(H)$ the following statements are equivalent. (a) *A and B are stochastically independent relative to every state $W\in\mathcal{D}(H)$.* (b) *A and B are stochastically independent relative to every pure state P_x.* (c) $A=cI$ *or* $B=cI$ *for some* $0\leqslant c\leqslant 1$.

Proof: This follows directly from Theorem 3.5. □

It is interesting to note that the classical counterpart to Corollary 4.1 holds. Recall that two bounded random variables f,g are **uncorrelated relative to a probability measure** μ if $\int fg\,d\mu = \int f\,d\mu \int g\,d\mu$.

Theorem 4.2: *Two bounded random variables f,g are uncorrelated relative to every probability measure on their sample space if and only if f or g is constant.*

Proof: It is clear that if f or g is constant, then they are uncorrelated. Conversely, assume that f,g are uncorrelated relative to every probability measure and that g is not constant. Then there exist an x and y in their sample space Ω such that $g(x)\neq g(y)$. Let μ be the probability measure $\mu = 1/2\,\delta_x + 1/2\,\delta_y$ where δ_x denotes the Dirac measure concentrated at x. We then have

$$\frac{1}{2}f(x)g(x)+\frac{1}{2}f(y)g(y)=\int fg\,d\mu=\int f\,d\mu\int g\,d\mu=\frac{1}{4}[f(x)+f(y)][g(x)+g(y)].$$

It follows that

$$f(x)g(x)+f(y)g(y)=f(y)g(x)+f(x)g(y).$$

Hence,

$$f(x)[g(x)-g(y)]=f(y)[g(x)-g(y)]$$

so that $f(x)=f(y)$. Let $z\in\Omega$ with $z\neq x, z\neq y$. Then either $g(z)\neq g(x)$ or $g(z)\neq g(y)$. In either case, by the previous reasoning we have $f(z)=f(x)$. Hence, f is constant. □

Stochastic independence appears to be quite rare. One case in which it does occur is in a tensor product space $\mathcal{E}(H\otimes H)$. In this case any two effects of the form $A\otimes I, I\otimes B$ are stochastically independent relative to a pure tensor state $x\otimes y$. Indeed,

$$\begin{aligned}\langle (A\otimes I)\circ(I\otimes B)x\otimes y, x\otimes y\rangle &= \langle Ax\otimes By, x\otimes y\rangle\\ &= \langle Ax,x\rangle\langle By,y\rangle\\ &= \langle A\otimes Ix\otimes y, x\otimes y\rangle\langle I\otimes Bx\otimes y, x\otimes y\rangle.\end{aligned}$$

Another case is when x is a unit eigenvector of A. In this case A,B are stochastically independent relative to P_x for every $B\in\mathcal{E}(H)$. The next result generalizes this situation.

Theorem 4.3: (*i*) *The following statements are equivalent.* (a) $P_W(A)=1$. (b) $WA=AW=W$. (c) $P_W(A\circ B)=P_W(B)$ *for every* $B\in\mathcal{E}(H)$. (*ii*) $P_W(A)=P_W(B)=1$ *if and only if* $P_W(A\circ B)=1$.

Proof: (*i*) Suppose that (a) holds. If λ_i, $i=1,2,...$, are the nonzero eigenvalues of W (including multiplicity) and x_i are the corresponding unit eigenvectors, then $\Sigma\lambda_i=1$ and

$$\sum \lambda_i\langle Ax_i, x_i\rangle = \mathrm{tr}(AW)=1.$$

It follows that $\langle Ax_i, x_i\rangle = 1$ and hence $Ax_i = x_i$, $i=1,2,...$. Thus, $AWx_i = Wx_i$. It follows that $AW=WA=W$ so (a) implies (b). If (b) holds, we have for every $B\in\mathcal{E}(H)$ that

$$P_W(A\circ B)=\mathrm{tr}(BA^{1/2}WA^{1/2})=\mathrm{tr}(BWA)=\mathrm{tr}(BW)=P_W(B).$$

Hence, (b) implies (c). Finally (c) implies (a) because we can let $B=I$.

(*ii*) If $P_W(A)=P_W(B)=1$, then by (c) we have $P_W(A\circ B)=P_W(B)=1$. Conversely if $P_W(A\circ B)=1$, then since $A\circ B\leqslant A$ we have $P_W(A)=1$. By (c) we have $P_W(B)=P_W(A\circ B)=1$. □

Notice that Theorem 4.3(c) says that if $P_W(A)=1$, then A and B are stochastically independent relative to W for every $B\in\mathcal{E}(H)$. The next example shows that if $P_W(A)=1$, then we need not have that $P_W(B\circ A)=P_W(B)$. Moreover, $P_W(B\circ A)\neq P_W(B)P_W(A)$ so B and A are not stochastically independent relative to W. This shows that stochastic independence is not a symmetric relation.

Example: Let $\dim H \geqslant 2$ and let x and y be linearly independent, nonorthogonal, unit vectors. Letting $W = P_x$ we have

$$P_W(P_x) = \mathrm{tr}(P_x) = 1.$$

We then obtain

$$P_W(P_x \circ P_y) = P_W(P_y) = |\langle x,y\rangle|^2 \neq 0,1.$$

However,

$$P_W(P_y \circ P_x) = \langle P_y P_x P_y x, x\rangle = |\langle x,y\rangle|^4 \neq |\langle x,y\rangle|^2 = P_W(P_y).$$

□

The simplest version of the law of total probability would say that

$$P_W(B) = P_W(A)P_W(B|A) + P_W(I-A)P_W(B|I-A).$$

In terms of the sequential product this can be stated as

$$P_W(B) = P_W(A \circ B) + P_W((I-A)\circ B) = P_W(A \circ B + (I-A)\circ B).$$

Does this equation hold for every $W \in \mathcal{D}(H)$? Equivalently, does the following equation hold?

$$B = A \circ B + (I-A)\circ B. \tag{4.3}$$

The next result is proved in Ref. 8. However, our proof is slightly different and perhaps simpler.

Theorem 4.4: *For $A,B \in \mathcal{E}(H)$, (4.3) holds if and only if $AB = BA$.*

Proof: It is clear that (4.3) holds if $AB = BA$. Conversely, assume that (4.3) holds and write it as

$$B = A^{1/2}BA^{1/2} + (I-A)^{1/2}B(I-A)^{1/2}.$$

Multiplying by $A^{1/2}$ on the left and right, we obtain

$$\begin{aligned} A^{1/2}BA^{1/2} &= ABA + A^{1/2}(I-A)^{1/2}B(I-A)^{1/2}A^{1/2} \\ &= ABA + (I-A)^{1/2}A^{1/2}BA^{1/2}(I-A)^{1/2} \\ &= ABA + (I-A)^{1/2}[B - (I-A)^{1/2}B(I-A)^{1/2}](I-A)^{1/2} \\ &= ABA - (I-A)B(I-A) + (I-A)^{1/2}B(I-A)^{1/2} \\ &= ABA - (I-A)B(I-A) + B - A^{1/2}BA^{1/2}. \end{aligned}$$

Hence,

$$2A^{1/2}BA^{1/2} = ABA - (I-A)B(I-A) + B = AB + BA. \tag{4.4}$$

Using the commutator notation $[X,Y] = XY - YX$ (4.4) gives

$$[A^{1/2},[A^{1/2},B]] = A^{1/2}(A^{1/2}B - BA^{1/2}) - (A^{1/2}B - BA^{1/2})A^{1/2} = AB - 2A^{1/2}BA^{1/2} + BA = 0.$$

If follows that for every spectral projection E of A we have

$$[E,[A^{1/2},B]] = 0.$$

By the Jacobi identity

$$[E,[A^{1/2},B]]+[B,[E,A^{1/2}]]+[A^{1/2},[B,E]]=0$$

we have that $[A^{1/2},[E,B]]=0$. As before we obtain $[E,[E,B]]=0$. Hence,

$$0=E(EB-BE)-(EB-BE)E=EB+BE-2EBE,$$

which we can write as

$$EB=2EBE-BE.$$

Multiplying on the left by E gives $EB=EBE$. Hence,

$$EB=(EBE)^*=BE.$$

It follows that $AB=BA$. □

Although the sequential product is always distributive on the right, Theorem 4.4 shows that it is not always distributive on the left. That is, $(A+B)\circ C\neq A\circ C+B\circ C$ in general, when $A+B\leqslant I$. Indeed, if $AC\neq CA$, then by Theorem 4.4 we have

$$A\circ C+(I-A)\circ C\neq C=(A+(I-A))\circ C.$$

Example: One might conjecture that the following generalization of Theorem 4.4 holds. If $A+B\leqslant I$ and $(A+B)\circ C=A\circ C+B\circ C$, then $CA=AC$ or $CB=BC$. However, this conjecture is false. Suppose that $CB\neq BC$. Nevertheless, we have

$$(\tfrac{1}{2}B+\tfrac{1}{2}B)\circ C=B\circ C=\tfrac{1}{2}B\circ C+\tfrac{1}{2}B\circ C=(\tfrac{1}{2}B)\circ C+(\tfrac{1}{2}B)\circ C.$$

□

We close with an open problem that generalizes Theorem 4.4. Suppose that $A_i\in\mathcal{E}(H)$, $i=1,...,n$, with $\Sigma A_i=I$ and that $B=\Sigma A_i\circ B$. Does this imply that $BA_i=A_iB$, $i=1,...,n$? Notice that the answer is affirmative if $A_i\in\mathcal{P}(H)$, $i=1,...,n$. In fact, we only need $A_i\in\mathcal{P}(H)$, $i=1,...,n$, and $\Sigma A_i\leqslant I$. In this case, we have $A_iA_j=A_jA_i=0$ for $i\neq j$. Hence, if $B=\Sigma A_i\circ B$, then $A_iB=BA_i=A_i\circ B$, $i=1,...,n$. It is shown in Ref. 8 that the answer is affirmative when B has discrete spectrum with a strictly decreasing sequence of eigenvalues.

I. INTRODUCTION

In 1986, Zhou and Guo[1] proved the global existence of weak solution for generalized Landau–Lifhsitz equations without Gilbert term in multidimensions. They considered the homogeneous boundary problem

$$\vec{u}(x,t)=0, \quad \text{for } x\in\partial\Omega, \quad 0\leqslant 1\leqslant T \tag{1}$$

with the initial value condition

$$\vec{u}(x,0)=\phi(x), \quad \text{for } x\in\Omega \tag{2}$$

for the system of ferromagnetic chain with several variables

$$\vec{u}_t=\vec{u}\times\Delta\vec{u}+\vec{f}(x,t,\vec{u}), \tag{3}$$

where $\vec{f}(x,t,\vec{u})$ is a given three-dimensional vector function in $x\in R^n$, $t\in R^+$, $\vec{u}\in R^3$. $\phi(x)$ is a given three-dimensional initial value function on $\overline{\Omega}$, Ω is a bounded domain in n-dimensional Euclidean space R^n. Under some conditions on $\vec{f}(x,t,\vec{u})$ and $\phi(x)$, they proved that the initial homogeneous boundary problem (1), (2) with the system of ferromagnetic chain (3) has at least one global weak solution

$$\vec{u}(x,t)\in L^{\infty}(0,T;H_0^1(\Omega))\cap C^{(0,1/(3+[n/2]))}(0,T;L^2(\Omega)).$$

Whether the global existence of the smooth solution for a Landau–Lifshitz equation in multidimensions ($n\geqslant 2$) is still an important open problem.

In 1999, Chang, Shatah, and Uhlenbeck[2] considered the following initial value problem for the two-dimensional cylindrical symmetric Landau–Lifshitz equations:

$$\vec{Z}_t=\vec{Z}\times\vec{Z}_{rr}+\frac{1}{r}\vec{Z}\times\vec{Z}_r. \tag{4}$$

a)Electronic mail: guobl@mail.iapcm.ac.cn

Under the small energy initial condition, they proved that there exists one global smooth solution for Eq. (4). We constructed one exact blow-up solution for two-dimensional Landau–Lifshitz equations (4) in Ref. 4. In Ref. 3, we constructed some exact blow-up solutions for n-dimensional Landau-Lifshitz equations:

$$\vec{Z}_t=\vec{Z}\times\vec{Z}_{rr}+\frac{n-1}{r}\vec{Z}\times\vec{Z}_r, \quad n\geqslant 2 \tag{5}$$

and

$$\vec{Z}_t=\vec{Z}\times\Delta Z \tag{6}$$

where

$$\Delta=\sum_{i=1}^{n}\frac{\partial^2}{\partial x_i^2}, \quad n\geqslant 2.$$

In this paper, we will construct some exact nontrivial global solutions with values in unit sphere for Eq. (4), and get a continuum from those global smooth solutions of a tuft of Landau–Lifshitz Equations on unit sphere.

II. SOME EXACT GLOBAL SOLUTIONS OF (4)

Theorem 1: *Let* $\Omega_a=(0,a)(0<a<\infty)$, $S=\{(u_1,u_2,u_3)|u_1^2+u_2^2+u_3^2=1,u_1,u_2,u_3\in R\}$, *if* $n=2$, *for every nonzero constant* C,

$$\vec{Z}(r,t)=\left(\frac{\cos\dfrac{Cr^2}{4\sqrt{1+C^2t^2}}}{\sqrt{1+C^2t^2}},\frac{\sin\dfrac{Cr^2}{4\sqrt{1+C^2t^2}}}{\sqrt{1+C^2t^2}},\frac{Ct}{\sqrt{1+C^2t^2}}\right), \tag{7}$$

is an exact global solution of (4) with the initial-boundary conditions:

(i) Initial condition,

$$\vec{Z}(r,0)=\left(\cos\frac{Cr^2}{4},\sin\frac{Cr^2}{4},0\right)\in S, \quad (r,0)\in\Omega_a\times\{0\},$$

(ii) boundary conditions,

$$\vec{Z}(0,t)=\left(\frac{1}{\sqrt{1+C^2t^2}},0,\frac{Ct}{\sqrt{1+C^2t^2}}\right), \quad (0,t)\in\{0\}\times[0,\infty),$$

$$\vec{Z}(a,t)=\left(\frac{\cos\dfrac{Ca^2}{4\sqrt{1+C^2t^2}}}{\sqrt{1+C^2t^2}},\frac{\sin\dfrac{Ca^2}{4\sqrt{1+C^2t^2}}}{\sqrt{1+C^2t^2}},\frac{Ct}{\sqrt{1+C^2t^2}}\right), \quad (a,t)\in\{a\}\times[0,\infty),$$

and $\vec{Z}(r,t)$ *satisfy*

(iii)

$$\vec{Z}(r,t)\in C^\infty(\Omega_a\times(0,\infty)), \quad (\forall 0<a<\infty).$$

(iv) Let

$$E(t)=\int_0^\infty |Z_r|^2 r\,\mathrm{d}r.$$

Then

$$E(t)=\frac{C^2a^4}{4(1+C^2t^2)^2}$$

and

$$\sup_{t\in[0,\infty)} E(t)=E(0)=\tfrac{1}{4}C^2a^4,$$

(v)

$$\lim_{t\to\infty}\vec{Z}(r,t)=(0,0,1)\in S,\quad (\forall C\neq 0)$$

and (0, 0, 1) *is a trivial solution of (4).*

(vi)

$$\vec{Z}(r,t)\in S,\quad (r,t)\in[0,a]\times[0,\infty].$$

Proof: We only verify that $\vec{Z}(r.t)$ are all solutions of (4), for all nonzero constants C,

$$\vec{Z}_t=\left(-\frac{C^2t\cos\frac{Cr^2}{4\sqrt{1+C^2t^2}}}{\sqrt{(1+C^2t^2)^3}}+\frac{C^3r^2t\sin\frac{Cr^2}{4\sqrt{1+C^2t^2}}}{4(1+C^2t^2)^2},-\frac{C^2t\sin\frac{Cr^2}{4\sqrt{1+C^2t^2}}}{\sqrt{(1+C^2t^2)^3}}-\frac{C^3r^2t\cos\frac{Cr^2}{4\sqrt{1+C^2t^2}}}{4(1+C^2t^2)^2},\frac{C}{\sqrt{(1+C^2t^2)^3}}\right),$$

$$\vec{Z}_r=\left(-\frac{Cr\sin\frac{Cr^2}{4\sqrt{1+C^2t^2}}}{2(1+C^2t^2)},\frac{Cr\cos\frac{Cr^2}{4\sqrt{1+C^2t^2}}}{2(1+C^2t^2)},0\right),$$

$$\vec{Z}_{rr}=\left(-\frac{C\sin\frac{Cr^2}{4\sqrt{1+C^2t^2}}}{2(1+C^2t^2)}-\frac{C^2r^2\cos\frac{Cr^2}{4\sqrt{1+C^2t^2}}}{4\sqrt{(1+C^2t^2)^3}},\frac{C\cos\frac{Cr^2}{4\sqrt{1+C^2t^2}}}{2(1+C^2t^2)}-\frac{C^2r^2\sin\frac{Cr^2}{4\sqrt{1+C^2t^2}}}{4\sqrt{(1+C^2t^2)^3}},0\right).$$

Therefore,

$$\vec{Z}\times\vec{Z}_{rr}+\frac{1}{r}\vec{Z}\times\vec{Z}_r$$

$$=\left(-\frac{C^2t\cos\frac{Cr^2}{4\sqrt{1+C^2t^2}}}{\sqrt{(1+C^2t^2)^3}}+\frac{C^3r^2t\sin\frac{Cr^2}{4\sqrt{1+C^2t^2}}}{4(1+C^2t^2)^2},-\frac{C^2t\sin\frac{Cr^2}{4\sqrt{1+C^2t^2}}}{\sqrt{(1+C^2t^2)^3}}\right.$$

$$\left.-\frac{C^3r^2t\cos\frac{Cr^2}{4\sqrt{1+C^2t^2}}}{4(1+C^2t^2)^2},\frac{C}{\sqrt{(1+C^2t^2)^3}}\right)=\vec{Z}_t.$$

Consequently (8) satisfy (4). □

One can verify following general theorem

Theorem 2: *Let*

$$A=\begin{pmatrix}a_{11}&a_{12}&a_{13}\\a_{21}&a_{22}&a_{23}\\a_{31}&a_{32}&a_{33}\end{pmatrix}$$

be any fixed third-order constant orthogonal matrix, then for every nonzero constant C,

$$\vec{Z}(r,t)=\left(\frac{\cos\frac{Cr^2}{4\sqrt{1+C^2t^2}}}{\sqrt{1+C^2t^2}},\frac{\sin\frac{Cr^2}{4\sqrt{1+C^2t^2}}}{\sqrt{1+C^2t^2}},\frac{Ct}{\sqrt{1+C^2t^2}}\right)A \tag{8}$$

is an exact global solution of (4) with the initial-boundary conditions:

(i) Initial condition,

$$\vec{Z}(r,0)=\left(\cos\frac{Cr^2}{4},\sin\frac{Cr^2}{4},0\right)A\in S,\quad r\in\Omega_a,$$

(ii) boundary conditions,

$$\vec{Z}(0,t)=\left(\frac{1}{\sqrt{1+C^2t^2}},0,\frac{Ct}{\sqrt{1+C^2t^2}}\right)A,\quad t\in[0,\infty),$$

$$\vec{Z}(a,t)=\left(\frac{\cos\frac{Ca^2}{4\sqrt{1+C^2t^2}}}{\sqrt{1+C^2t^2}},\frac{\sin\frac{Ca^2}{4\sqrt{1+C^2t^2}}}{\sqrt{1+C^2t^2}},\frac{Ct}{\sqrt{1+C^2t^2}}\right)A,\quad t\in[0,\infty),$$

and $\vec{Z}(r,t)$ *satisfy*

(iii)

$$\vec{Z}(r,t)\in C^\infty(\Omega_a\times(0,\infty)),\quad(\forall 0<a<\infty).$$

(iv) Let

$$E(t)=\int_0^\infty|Z_r|^2r\,dr.$$

Then

$$E(t)=\frac{C^2a^4}{4(1+C^2t^2)^2}$$

and

$$\sup_{t\in[0,\infty)} E(t)=E(0)=\tfrac{1}{4}C^2a^4.$$

(v)

$$\lim_{t\to\infty}\vec{Z}(r,t)=(a_{31},a_{32},a_{33})\in S,\quad(\forall C\neq 0)$$

and (a_{31},a_{32},a_{33}) *is a trivial solution of (4).*

(vi)

$$\vec{Z}(r,t)\in S,\quad (r,t)\in[0,a]\times[0,\infty).$$

Remark 1: Theorems 1 and 2 reply partly to the open problem about the existence of global smooth solution for multidimensional Landau–Lifshitz equations under the initial-boundary conditions.

Remark 2: In Landau–Lifshitz equations $\vec{Z}$ *is the spin field, it describes the evolution of spin field in continuum ferromagnets,* $\vec{Z}_{rr}+(1/r)\vec{Z}_r$ *is an effective field. Theorem 1 shows that there exists at least a global smooth solution, though the initial energy is not small. Theorem 2 implies that there exists a continuum which can be made from those global smooth solutions of a tuft of Landau–Lifshitz equations on unit sphere.*

We study the spectrum of the Salpeter Hamiltonian $H=\beta\sqrt{m^2+\mathbf{p}^2}+V(r)$, where $V(r)$ is an attractive central potential in three dimensions. If $V(r)$ is a convex transformation of the Coulomb potential $-1/r$ and a concave transformation of the harmonic-oscillator potential r^2, then both upper and lower bounds on the discrete eigenvalues of H can be constructed, which may all be expressed in the form $E=\min_{r>0}[\beta\sqrt{m^2+P^2/r^2}+V(r)]$ for suitable values of P here provided. At the critical point $r=\hat{r}$ the relative growth to the Coulomb potential $h(r)=-1/r$ must be bounded by $\mathrm{d}V/\mathrm{d}h<2\beta/\pi$. © *2001 American Institute of Physics.*

I. INTRODUCTION

We study the (semirelativistic) ''spinless-Salpeter'' Hamiltonian

$$H=\beta\sqrt{m^2+\mathbf{p}^2}+V(r), \quad \beta>0, \tag{1}$$

in which $V(r)$ is a central potential in three spatial dimensions. The eigenvalue equation of this operator is called the ''spinless Salpeter equation.'' This equation of motion arises as a well-defined standard approximation to the Bethe–Salpeter formalism[1] for the description of bound states within a (relativistic) quantum field theory and is arrived at by the following simplifying steps:

(1) Eliminate all timelike variables by assuming the Bethe–Salpeter kernel that describes the interactions between the bound-state constituents to be static, i.e., instantaneous; the result of this reduction step is called the ''instantaneous Bethe–Salpeter equation'' or the ''Salpeter equation.'' [2]
(2) Neglect the spin of the bound-state constituents, assume the Bethe–Salpeter kernel to be of convolution type (as is frequently the case), and consider merely positive-energy solutions ψ, in order to arrive at the so-called ''spinless Salpeter equation'' $H\psi=E\psi$, with a Hamiltonian H of the form (1). (For two particles, this form of the Hamiltonian H holds only for equal masses m of the bound-state constituents.)

(For a more detailed account of the reduction of the Bethe–Salpeter equation to the spinless

Salpeter equation, consult, e.g., the introductory sections of Refs. 3 and 4.) This wave equation describes the bound states of spin-zero particles (scalar bosons) as well as the spin-averaged spectra of the bound states of fermions.

In this article we consider potentials which are at the same time convex transformations $V(r)=g(h(r))$ of the Coulomb potential $h(r)=-1/r$ and concave transformations of the harmonic-oscillator potential $h(r)=r^2$. The reason for this is that spectral information is known for these two ''basis'' potentials $h(r)$. Thus the class of potentials is those $V(r)$ that have a dual representation

$$V(r)=g^{(1)}\left(-\frac{1}{r}\right)=g^{(2)}(r^2),$$

in which $g^{(1)}$ is convex ($g^{(1)\prime\prime}>0$) and $g^{(2)}$ is concave ($g^{(2)\prime\prime}<0$). An example of a potential in this class is

$$V(r)=-\frac{c_1}{r}+c_2\ln r+c_3 r+c_4 r^2, \tag{2}$$

where the coefficients $\{c_i\}$ are not negative and are not all zero. Thus tangent lines to the transformation function $g(h)$ are of the form $ah+b$ and are either Coulomb potentials lying below V, or harmonic-oscillator potentials lying above V. This geometrical idea is the basis for our approach to the spectral problem posed by H. We recall the application of this idea to the (nonrelativistic) Schrödinger problem in Sec. III. The general envelope formalism for the derivation of upper and lower bounds on the eigenvalues of the semirelativistic Salpeter Hamiltonian H of Eq. (1) is established in Sec. IV.

It is fundamental to our method that we first know something about the spectrum of H in those cases where $V(r)$ is one of the basis potentials, i.e., the Coulomb and the harmonic oscillator. These two spectra are discussed in Sec. II. In Sec. V we look at the example of the Coulomb-plus-linear potential.

II. THE COULOMB AND HARMONIC-OSCILLATOR POTENTIALS

A. Scaling behavior

Since the two basis potentials are both pure powers, it is helpful first to determine what can be learned about the corresponding eigenvalues by the use of standard scaling arguments. By employing a wave function $\phi(cr)$ depending on a scale variable $c>0$, we find the following scaling rule for the eigenvalues corresponding to attractive pure power potentials $v\ \mathrm{sgn}(q)r^q$. The Hamiltonian

$$H=\beta\sqrt{m^2+\mathbf{p}^2}+v\ \mathrm{sgn}(q)r^q$$

has the (energy) eigenvalues $E(v,\beta,m)$, where

$$E(v,\beta,m)=\beta m E\left(\frac{v}{\beta m^{1+q}},1,1\right),\quad q\geqslant -1.$$

The scaling behavior described by the above formula allows us to consider the one-particle, unit-mass special case $m=\beta=1$ initially, that is to say, to work w.l.o.g. with the operator

$$H=\sqrt{1+\mathbf{p}^2}+v\ \mathrm{sgn}(q)r^q.$$

B. Coulomb potential

In the case of the Coulomb potential $V(r)=-v/r$ it is well known[5] that the Hamiltonian H has a Friedrichs extension provided the coupling constant v is not too large. Specifically, it is necessary in this case that v is smaller than a critical value v_c of the coupling constant:

$$v<v_c=\frac{2}{\pi}.$$

With this restriction, a lower bound to the bottom of the spectrum is provided by Herbst's formula

$$E_0\geqslant\sqrt{1-(\sigma v)^2},\quad \sigma\equiv\frac{\pi}{2}. \tag{3}$$

By comparing the spinless Salpeter problem to the corresponding Klein–Gordon equation, Martin and Roy[6] have shown that if the coupling constant is further restricted by $v<\frac{1}{2}$, then an improved lower bound is provided by the expression

$$E_0\geqslant\sqrt{\frac{1+\sqrt{1-4v^2}}{2}},\quad v<\frac{1}{2}. \tag{4}$$

It turns out that our lower-bound theory has a simpler form when the Coulomb eigenvalue formula has the form of Eq. (3) rather than that of Eq. (4). For this reason, we have derived from Eq. (4) a family of Coulomb bounds which, by rather elementary methods, is found to read

$$E_0\geqslant\sqrt{1-(\sigma v)^2},\quad v\leqslant\frac{\sqrt{\sigma^2-1}}{\sigma^2}<\frac{1}{2}. \tag{5}$$

All these (lower) bounds are slightly weaker than the Martin–Roy bound (4) but above the Herbst bound (3). We note that these functions of the coupling constant v are all monotone and *concave*.

C. Harmonic-oscillator potential

In the case of the harmonic-oscillator potential, i.e., $V(r)=vr^2$, much more is known.[7,8] In momentum-space representation the operator $\mathbf{p}$ becomes a c-variable and, thus, from the spectral point of view, the Hamiltonian $H=\sqrt{1+\mathbf{p}^2}+vr^2$ is equivalent to the Schrödinger operator

$$H=-v\Delta+\sqrt{1+r^2}. \tag{6}$$

Since the potential $V(r)$ increases without bound, the spectrum of H is entirely discrete.[9] We denote its eigenvalues by $\mathcal{E}_{n\mathrm{l}}(v)$, where $n=1,2,3,\ldots$ "counts" the radial states in each angular-momentum subspace labeled by $\mathrm{l}=0,1,2,\ldots$. Later we shall either approximate the eigenvalues $\mathcal{E}(v)$ analytically or assume them to be known numerically. The eigenvalues $\mathcal{E}(v)$ of such Schrödinger operators are *concave* functions of the coupling constant v.[10,11]

D. The spectral comparison theorem

For the class of interaction potentials given by (2) with the coefficient of the Coulombic term not too large, that is, for all potentials which satisfy the constraint $\lim_{r\to 0}r^2V'(r)<2\beta/\pi$, the semirelativistic Salpeter Hamiltonian H is bounded below and is essentially self-adjoint.[5] Consequently, the discrete spectrum of H is characterized variationally[9] and it follows immediately from this that, if we compare two such Hamiltonians H having the potentials $V^{(1)}(r)$ and $V^{(2)}(r)$, respectively, and we know that $V^{(1)}(r)<V^{(2)}(r)$, then we may conclude that the corresponding discrete eigenvalues $E_{n\mathrm{l}}$ satisfy the inequalities $E_{n\mathrm{l}}^{(1)}<E_{n\mathrm{l}}^{(2)}$. We shall refer to this fundamental result as the "spectral comparison theorem." In the more common case of nonrelativistic dynam-

ics, i.e., for a (nonrelativistic) kinetic term of the form $\beta \mathbf{p}^2/2m$ in the Hamiltonian H, a constraint similar to the above would hold for the coefficient of a possible additional (attractive) $-1/r^2$ term in the potential $V(r)$.

III. GENERAL ENVELOPE THEORY OF SCHRÖDINGER OPERATORS

In nonrelativistic envelope theory,[11–13] if the potential V is a smooth transformation $V(r) = g(\mathrm{sgn}(q) r^q)$ of the power-law potential $\mathrm{sgn}(q) r^q$, the eigenvalues of $H = -\Delta + V(r)$ are approximated by

$$E_{nl} \approx \min_{r>0} \left[\frac{P_{nl}^2(q)}{r^2} + V(r) \right]. \tag{7}$$

The numbers $P_{nl}(q)$ can be derived from the eigenvalues of $-\Delta + \mathrm{sgn}(q) r^q$.[13] If g is convex ($g'' > 0$), Eq. (7) yields lower bounds; if g is concave ($g'' < 0$), the results are upper bounds.

As an immediate application we consider the (nonrelativistic) Schrödinger Hamiltonian (6) for the (relativistic) Salpeter harmonic-oscillator problem (1). Here we have $H = -v\Delta + V(r)$, with $V(r) = \beta\sqrt{m^2 + r^2}$; hence, the potential is a convex transformation of a linear potential and a concave transformation of a harmonic-oscillator potential. We conclude therefore from (7)

$$\min_{r>0} \left[v \frac{P_{nl}^2(1)}{r^2} + \beta\sqrt{m^2 + r^2} \right] \leqslant \mathcal{E}_{nl}(v) \leqslant \min_{r>0} \left[v \frac{P_{nl}^2(2)}{r^2} + \beta\sqrt{m^2 + r^2} \right]; \tag{8}$$

the numbers $P_{nl}(1)$ are given in Table 1 of Ref. 14, and $P_{nl}(2) = 2n + l - \frac{1}{2}$. Interestingly the upper and lower bounds (8) are equivalent to the corresponding bounds obtained in Ref. 8; however, these earlier specific bounds were not derived as part of a general theory.

IV. GENERAL ENVELOPE THEORY OF SALPETER HAMILTONIANS

Let us now turn to our main topic and consider the spinless-Salpeter Hamiltonian of Eq. (1),

$$H = \beta\sqrt{m^2 + \mathbf{p}^2} + V(r),$$

and its eigenvalues E. We shall assume that the potential $V(r)$ is a smooth transformation $V(r) = g(h(r))$ of another potential $h(r)$ and that g has definite convexity so that we obtain bounds to the energy eigenvalues E. We suppose that the "basis" potential $h(r)$ generates a "tangential" Salpeter problem

$$\mathcal{H} = \beta\sqrt{m^2 + \mathbf{p}^2} + v\,h(r),$$

for which the eigenvalues $e(v)$, or bounds to them, are known. We shall follow here as closely as possible the development in Refs. 11–13 for the corresponding Schrödinger problem. We express our results in the form of two theorems.

(1) The approximations we shall use from Sec. II, regarded as functions of the coupling v, and also the (unknown) energy functions $e(v)$ of the "tangential" Salpeter problem are all *concave*: $e''(v) < 0$. The latter result represents the principal claim of Theorem 1.
(2) In Theorem 2 we begin by using an envelope representation for the potential $V(r)$ and then demonstrate that all the spectral formulas that follow possess a certain structure.

Finally, as an application, we specialize to the case of pure power-law "basis" potentials $h(r)$ and, more particularly, to the Coulomb potential and the harmonic-oscillator potential for which, at this time, we have spectral information (cf. the discussions in Secs. II B and II C).

A. Convexity of the energy function

We begin by proving the following.

Theorem 1: *The function $e(v)$ is concave, that is, $e''(v)<0$.*

Proof: Suppose the exact eigenvalue and (normalized) eigenvector for the problem posed by $\mathcal{H}=\beta\sqrt{m^2+\mathbf{p}^2}+vh(r)$ are $e(v)$ and $\psi(v,r)$. By differentiating $(\psi,\mathcal{H}\psi)$ with respect to v we find $e'(v)=(\psi,h\psi)$. If we now apply $\psi(v,r)$ as a trial vector to estimate the energy of the operator $\beta\sqrt{m^2+\mathbf{p}^2}+uh(r)$, in which v has been replaced by u, we obtain an upper bound to $e(u)$ which may be written in the form $e(u)\leqslant e(v)+(u-v)e'(v)$. This inequality tells us that the function $e(u)$ lies beneath its tangents; that is to say, $e(u)$ is *concave*. □

B. The principal envelope formula

With the help of Theorem 1 we are able to prove the following theorem.

Theorem 2 (principal envelope formula): *Suppose that the operator $\beta\sqrt{m^2+\mathbf{p}^2}+vh(r)$ has the exact lowest eigenvalue $e(v)$, and suppose that the operator $\beta\sqrt{m^2+\mathbf{p}^2}+g(h(r))$ has the exact lowest eigenvalue E. Then*

$$E\approx\mathcal{E}\equiv\min_{v>0}[e(v)-ve'(v)+g(e'(v))]. \tag{9}$$

If g is concave (that is, $g''<0$), then $E\leqslant\mathcal{E}$; if g is convex (that is, $g''>0$), then $E\geqslant\mathcal{E}$.

Proof: All tangential potentials we shall employ have the form $V^{(t)}(r)=a(t)h(r)+b(t)$, where the coefficients $a(t)$ and $b(t)$ are given by

$$a(t)=\frac{V'(t)}{h'(t)}=g'(h(t)),\quad b(t)=V(t)-a(t)h(t)=g(h(t))-g'(h(t))h(t),$$

and $r=t$ is the point of contact of the potential $V(r)$ and its tangent $V^{(t)}(r)$. If, for definiteness, we assume that $V=g(h)$ with g concave (i.e., $g''<0$), we obtain a family of upper bounds given by

$$E\leqslant\varepsilon(t)=e(a(t))+b(t).$$

The best of these is given by optimizing over t:

$$E\leqslant\varepsilon(\hat{t})=e(a(\hat{t}))+b(\hat{t}),$$

where $\hat{t}$, the value of t which optimizes these bounds, is to be determined as the solution of

$$e'(g'(h(\hat{t})))=h(\hat{t}).$$

In the spirit of the Legendre transformation[15] we now consider another problem which has the same solution; this second problem is the one that provides us with our basic eigenvalue formula. We consider

$$\mathcal{E}=\min_{v>0}[e(v)-ve'(v)+g(e'(v))],$$

which is well defined since $e(v)$ is concave. The solution has the critical point $\hat{v}=g'(e'(\hat{v}))$. If we now apply the correspondence $h(\hat{t})=e'(\hat{v})$, the critical point $\hat{v}$ becomes $\hat{v}=g'(h(\hat{t}))$ and the tangential-potential coefficients a and b become

$$a(\hat{t})=g'(e'(v))=v,\quad b(\hat{t})=g(e'(v))-ve'(v),\quad v=\hat{v}. \tag{10}$$

Meanwhile, the original critical (energy) value is given by

$$\varepsilon(\hat{t}) = e(a(\hat{t})) + b(\hat{t}) = e(v) - ve'(v) + g(e'(v)), \quad v = \hat{v}.$$

□

From the proof of Theorem 2 it follows immediately that, if the *exact* energy function $e(v)$ corresponding to the basis potential h is not available, then, for $g(h)$ concave, concave *upper* approximations $e_u(v) > e(v)$ or, for $g(h)$ convex, concave *lower* approximations $e_l(v) < e(v)$ may be used instead of the exact energy function $e(v)$ in the principal envelope formula (9). Then all the lower tangents will lie even lower and all the upper tangents will lie even higher. If g is convex, we obtain a lower bound; if g is concave, we obtain an upper bound; because of the concavity of $e(v)$, *this* extremum is a minimum in *both* cases. If we wish to use numerical solutions to the "basis" problem [generated by $h(r)$], or if a completely new energy-bound expression becomes available, the principal envelope formula (9) is what would be used first.

Interestingly, in the formula (9) the tangential-potential apparatus is no longer evident; only the correct convexity is required. As in the Schrödinger case,[11] once we have the basic result, the reformulation in terms of "kinetic potentials" is often useful: the kinetic potential $\overline{h}(s)$ corresponding to some basis potential $h(r)$ is given by the Legendre transformation[15]

$$\overline{h}(s) = e'(v), \quad s = e(v) - ve'(v).$$

Meanwhile the envelope approximation has the kinetic-potential expression $\overline{V}(s) \approx g(\overline{h}(s))$.

For both the Coulomb lower bounds (3) or (5) and the harmonic-oscillator upper bounds (8) which we have at present, we may express our general results in a special common form which will now be derived.

C. The Coulomb lower bound

We consider first the Coulomb lower bound in which we assume that the potential $V(r)$ is a convex transformation $V(r) = g(h(r))$ of the Coulomb potential $h(r) = -1/r$. According to Sec. II B, in this case all the "lower" $e_l(v)$ have been arranged—with the parameters β and m returned—in the form

$$e_l(v) = \beta m \sqrt{1 - \left(\frac{\sigma v}{\beta}\right)^2}.$$

From this it follows by elementary algebra that if we define a new optimization variable r by $e_l'(v) = h(r) = -1/r$, we have

$$e_l(v) - ve_l'(v) = \beta \sqrt{m^2 + \frac{P^2}{r^2}}, \quad P \equiv \frac{1}{\sigma}.$$

Consequently, the lower bound on the energy eigenvalues E of the spinless Salpeter equation becomes

$$E \geqslant \min_{r>0} \left[\beta \sqrt{m^2 + \frac{P^2}{r^2}} + V(r) \right], \quad v < \beta v_P. \tag{11}$$

Here the boundary value v_P of the Coulomb coupling v is given, when simply determined by the requirement of boundedness from below of the operator (1), by the critical coupling v_c,

$$v_P = v_c = \frac{2}{\pi},$$

and, when arising from the region of validity of our Coulomb-like family of lower bounds (5), via $P = 1/\sigma$, by

$$v_P = P\sqrt{1-P^2} < \tfrac{1}{2}. \tag{12}$$

$\{P, v_P\}$ pairs may be easily generated from the upper bound on the coupling v in Eq. (12). The meaning of the Coulomb-coupling constraint is $a(\hat{t}) < \beta v_P$, where a is the coefficient in the tangential Coulomb potential given by (10).

D. The harmonic-oscillator upper bounds

Next, let us turn to the harmonic-oscillator upper bounds. Our main assumption here is that $V(r) = g(r^2)$, with $g'' < 0$. In this case the only difficulty is that the basis problem $h(r) = r^2$ is equivalent to a Schrödinger problem whose solution $\mathcal{E}_{nl}(v)$ is not known exactly. Following the discussion after the proof of Theorem 2, let us call the upper bound provided by Eq. (8) $e_u(v)$ and let us introduce the shorthand notation $P_{nl}(2) = 2n + l - \frac{1}{2} = P$. Then we have the following parametric equations for $e_u(v)$:

$$e_u(v) = v\,\frac{P^2}{r^2} + \beta\sqrt{m^2 + r^2}, \quad v = \frac{\beta r^4}{2P^2\sqrt{m^2+r^2}}, \quad e_u'(v) = \frac{P^2}{r^2}.$$

By substituting these expressions into the fundamental envelope formula (9) we obtain the following upper bound on all the eigenvalues E_{nl} of the spinless-Salpeter problem with potential $V(r) = g(r^2)$ and $g'' < 0$:

$$E_{nl} \leqslant \min_{r>0}\left[\beta\sqrt{m^2 + \frac{P^2}{r^2}} + V(r)\right], \quad P = P_{nl}(2) = 2n + l - \frac{1}{2}. \tag{13}$$

V. THE COULOMB-PLUS-LINEAR (OR "FUNNEL") POTENTIAL

In order to illustrate the above results by a physically motivated example, let us apply these considerations to the Coulomb-plus-linear or (in view of its shape) "funnel" potential

$$V(r) = -\frac{c_1}{r} + c_2 r, \quad c_1 \geqslant 0, \quad c_2 \geqslant 0.$$

(This potential provides a reasonable overall description of the strong interactions of quarks in hadrons. For the phenomenological description of hadrons in terms of both nonrelativistic and semirelativistic potential models, see, e.g., Refs. 16 and 17.) By choosing as basis potential $h(r) = -1/r$, we may write $V(r) = g(h(r))$ with

$$g(h) = c_1 h - \frac{c_2}{h},$$

which is clearly a convex function of $h < 0$: $g'' > 0$. Thus the convexity condition is satisfied. However, we are not free to choose the coupling constants c_1 and c_2 as large as we please. It is immediately obvious that, for a particular $\{P, v_P\}$ pair, we must in any case have $c_1 < \beta v_P$. For the full problem the coefficient c_2 of the linear term will also be involved. The coupling v we are concerned about is given by (10). We have

$$v = g'(e'(v)) = \frac{\beta P^2}{r\sqrt{m^2 + (P/r)^2}} = c_1 + \frac{c_2}{h^2} = c_1 + c_2 r^2.$$

From this we obtain, for given values of the parameters m and β and for a given $\{P, v_P\}$ pair, as a sufficient condition for $v < \beta v_P$ the "Coulomb coupling constant constraint" on the two coupling strengths c_1 and c_2 in the funnel potential:

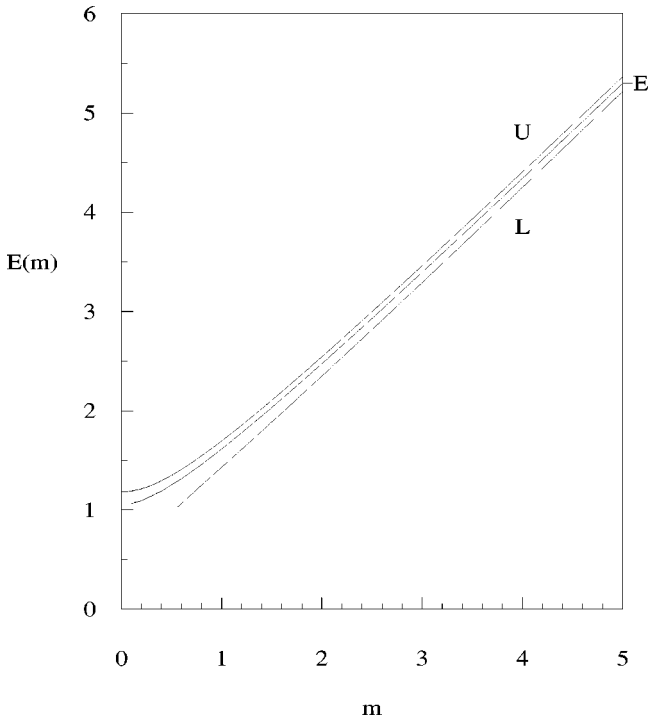

FIG. 1. Lower bounds (L), according to (11), and upper bounds (U), according to (13), on the energy eigenvalue E of the ground state $[(n,l)=(1,0)]$ of the spinless Salpeter equation with a Coulomb-plus-linear potential $V(r)=-c_1/r+c_2 r$, for $\beta=1$, $c_1=0.1$, and $c_2=0.25$. The lower bound is given by the general result (11) with the "best" $P(m)$ provided by (15). In order to satisfy the Coulomb coupling constraint (15), the mass m must fulfil $m>\sqrt{5}/4$. For comparison, a (very accurate) Rayleigh–Ritz variational upper bound E is depicted, too.

$$c_1+\frac{P^2}{m^2}\left(\frac{P^2}{v_P^2}-1\right)c_2<\beta v_P\,. \tag{14}$$

In the case $\{P=1/\sqrt{2}, v_P=\frac{1}{2}\}$ and $\beta=m=1$ this condition reduces to $c_1+\frac{1}{2}c_2<\frac{1}{2}$. For Herbst's lower bound (3), i.e., $P=v_P=v_c=2/\pi$, this constraint clearly yields $c_1<\beta v_P$. There is no escaping this feature of all energy bounds involving the Coulomb potential: the constraint derives from the fundamental observation that the Coulomb coupling v must not be too large, so that the (relativistic) kinetic energy is able to counterbalance the Coulomb potential in order to maintain the Hamiltonian (1) with $V(r)=-v/r$ bounded from below.

For example, if we seek the largest allowed value of the parameter P by solving Eqs. (12) and (14) together, we find that this largest P is given by

$$\frac{c_2\sin^4 t}{\cos^2 t(\beta\sin t\cos t-c_1)}=m^2,\quad P\equiv\sin t. \tag{15}$$

For the Coulomb-plus-linear potential $V(r)=-c_1/r+c_2 r$ under consideration, Fig. 1 shows the lower and upper bounds on the lowest energy eigenvalue E of the spinless Salpeter equation, given by the envelopes of the lower and upper families of tangential energy curves (11) and (13). In the case of the lower bound (11), we have used for each m the best possible $P(m)$ provided by (15). As $m\to 0$, the "basis" Coulomb problem $H=\beta\sqrt{m^2+\mathbf{p}^2}-v/r$ has energy $e(m)\to 0$; thus the Coulomb lower bound for a non-Coulomb problem becomes very weak for small values of m. Of course, Eq. (13) provides us with rigorous upper bounds for *every* energy level.

In order to get an idea of the location of the exact energy eigenvalues E, Fig. 1 also shows the ground-state energy curve $E(m)$ obtained by the Rayleigh–Ritz variational technique[9] with the

Laguerre basis states for the trial space defined in Ref. 18. Strictly speaking, this energy curve represents only an upper bound to the precise eigenvalue E. However, from the findings of Ref. 18 the deviations of these Laguerre bounds from the exact eigenvalues may be estimated, for the superposition of 25 basis functions used here, to be of the order of 1%.

VI. SUMMARY AND CONCLUSION

In this analysis we have studied the discrete spectrum of semirelativistic ''spinless-Salpeter'' Hamiltonians H, defined in Eq. (1), by an approach which is based principally on convexity. We have at our disposal very definite information concerning, on the one hand, the bottom of the spectrum of H for the Coulomb potential, $h(r)=-1/r$, and, on the other hand, the entire spectrum of H for the harmonic-oscillator potential, $h(r)=r^2$. The class of potentials that are at the same time a convex transformation of $-1/r$ and a concave transformation of r^2 includes, for example, arbitrary linear combinations of Coulomb, logarithmic, linear, and harmonic-oscillator terms. The envelope technique applied here takes advantage of the fact that all ''tangent lines'' to the interaction potential $V(r)=g(h(r))$ in H are potentials of the form $ah(r)+b$, and that, by convexity and the comparison theorem recalled in Sec. II D, the energy eigenvalues corresponding to these ''tangent'' potentials provide rigorous bounds to the unknown exact eigenvalues E of H. If $e(v)$ denotes the energy function—or a suitable bound to it—corresponding to the problem posed by a ''basis'' potential $vh(r)$, where v is a positive coupling parameter, the envelopes of upper and lower families of energy curves may be found with the help of the ''principal envelope formula''

$$E \approx \min_{v>0}[e(v)-ve'(v)+g(e'(v))].$$

Here, a sign of approximate equality is used to indicate that, for a definite convexity of $g(h)$, the envelope theory yields lower bounds for convex $g(h)$ and upper bounds for concave $g(h)$. With the above principal envelope formula at hand, all new spectral pairs $\{h(r),e(v)\}$ which may become available at some future time can immediately be used to enrich our collection of energy bounds. If the basis potential $h(r)$ is a pure power, these bounds can be written as

$$E_{nl} \approx \min_{r>0}\left[\beta\sqrt{m^2+\frac{P_{nl}^2}{r^2}}+V(r)\right],$$

where the numbers P_{nl} are obtained from the corresponding underlying basis problems. The power of this technique is illustrated, in Sec. V, by our application to the so-called funnel potential, $V(r)=-c_1/r+c_2 r$. For this problem, we have employed both the semirelativistic Coulomb and harmonic-oscillator problems to calculate, respectively, lower and upper bounds on the energy eigenvalues of the spinless Salpeter equation.

We expect that such results would provide bounds on the energy eigenvalues for general theoretical discussions, or be used as guides for more tightly focused analytic or numerical studies of the spectra of semirelativistic ''spinless-Salpeter'' Hamiltonians.

Generalized Yang–Mills actions from Dirac operator determinants

Edwin Langmann[a)]
Mathematical Physics, Department of Physics, KTH, SCFAB, SE-106 91 Stockholm, Sweden

(Received 8 April 2001; accepted for publication 17 July 2001)

We consider the quantum effective action of Dirac fermions on four-dimensional flat Euclidean space coupled to external vector- and axial Yang–Mills fields, i.e., the logarithm of the (regularized) determinant of a Dirac operator on flat $\mathbb{R}^4$ twisted by generalized Yang–Mills fields. According to physics folklore, the logarithmic divergent part of this effective action in the pure vector case is proportional to the Yang–Mills action. We present a simple explicit computation proving this fact and extending it to the chiral case. We use an efficient computation method for quantum effective actions which is based on calculation rules for pseudo-differential operators and which yields an expansion of the logarithm of Dirac operators in local and quasi-gauge invariant polynomials of decreasing scaling dimension. © *2001 American Institute of Physics.* [DOI: 10.1063/1.1399297]

I. INTRODUCTION

Determinants of differential operators arise as (exponentials of) effective actions in quantum field theory. The precise definition and investigation of such objects is an interesting and challenging mathematical problem which has led to an active and fruitful interplay between mathematics and physics.

In this paper we compute the logarithmic divergent part, $S_{\log}(A)$, of the logarithm of the regularized determinant for Dirac operators D_A describing Dirac fermions coupled to a generalized Yang–Mills field A on four-dimensional spacetime. For simplicity we assume spacetime to be flat $\mathbb{R}^4$ with Euclidean signature and the natural spin structure. The Yang–Mills fields we consider contain, besides the vector part V, also a chiral (axial) part C [for precise definitions see Eq. (7) *ff.* below]; we write $A=(V,C)$. Our definition of $S_{\log}$ is motivated by physical considerations and will be explained further below. To indicate the mathematical significance of our calculation, we note that $S_{\log}(A)$ is (essentially) the noncommutative residue [Wodzicki (1985)] of the logarithm of D_A [see Eq. (3) for the precise statement]. A main motivation for this work is to present a computation method for effective fermion actions which at the same time is mathematically rigorous, close to standard Feynman diagram computations in quantum field theory [see, e.g., Itzykson and Zuber (1985) and Weinberg (1996)], and simple to use. We believe that this method is a useful alternative to other methods like the ζ-function regularizations or the heat kernel expansions [see, e.g., Gilkey (1995) and Berline *et al.* (1992)]. We, therefore, made some effort to present this method in a self-contained way, in the hope that this is useful also for readers who are mainly interested in learning how to compute effective actions.

We now discuss our computation method [parts of this method were used previously by us in Langmann (1995) and Langmann and Mickelsson (1996)]. We regard the Dirac operator D_A as a PSDO (pseudo-differential operator) on a Hilbert space of square-integrable functions on $\mathbb{R}^4$. Our starting point is the following definition for the regularized effective fermion action:

$$S_\Lambda(A) := \mathrm{Tr}_\Lambda\left(\log\left(\frac{\mathsf{D}_A+\mathrm{i}m}{\Lambda_0}\right)-\log\left(\frac{\mathsf{D}_0+\mathrm{i}m}{\Lambda_0}\right)\right), \tag{1}$$

a)Electronic mail: langmann@theophys.kth.se

where m is a real parameter which has the physical interpretation of a fermion mass, and Λ is a positive regularization parameter which we call UV (ultraviolet) *cutoff*. The role of the nonzero and complex parameter Λ_0 is twofold. Firstly, it makes the argument of the logarithm dimensionless, and secondly, setting $\Lambda_0 = |\Lambda_0|/(1+i0^+)$ avoids possible ambiguities due to the branch cuts of the logarithm which otherwise can arise. (Of course, all results must be independent of $|\Lambda_0|$, and this is a useful check.) This definition above has three ingredients. Firstly, a definition of the log of an operator a as an integral of the resolvent of a. Secondly, some basic facts about PSDO which imply a simple and powerful formula for the symbol of the resolvent of the Dirac operator D_A. And thirdly, a definition of a regularized Hilbert space trace Tr_Λ (where removing the regularization corresponds to the limit $\Lambda \to \infty$). Combining these ingredients we obtain an expansion of $S_\Lambda(A)$ in local and quasi-gauge invariant polynomials of decreasing scaling dimension. We find

$$S_\Lambda(A) = \Lambda^2 S^{(2)}(A) + \log\left(\frac{\Lambda}{|m|}\right) S_{\log}(A) + S^{(0)}(A) + \mathcal{O}(\Lambda^{-1}), \tag{2}$$

and this provides our definition of $S_{\log}(A)$. Our results for $S_{\log}(A)$ and $S^{(2)}(A)$ will be presented in the next Section. We shall also demonstrate on our way that $S_{\log}(A)$ is proportional to the noncommutative residue Wodzicki (1985) of the logarithm of the Dirac operator D_A:

$$S_{\log}(A) = 4\,\mathrm{Res}\left(\log\left(\frac{\mathsf{D}_A + \mathrm{i}m}{\Lambda_0}\right) - \log\left(\frac{\mathsf{D}_0 + \mathrm{i}m}{\Lambda_0}\right)\right). \tag{3}$$

The logarithm of the regularized trace of the determinant of the Dirac operator can then be defined as

$$S^{(0)}(A) = \mathrm{TR}\left(\log\left(\frac{\mathsf{D}_A + \mathrm{i}m}{\Lambda_0}\right) - \log\left(\frac{\mathsf{D}_0 + \mathrm{i}m}{\Lambda_0}\right)\right), \tag{4}$$

where TR is the renormalized trace which we will define, and we will provide all mathematical tools necessary for computing $S^{(0)}(A)$ explicitly.

We note that our computation method is closely related to methods which have been used in the physics literature for a long time [see, e.g., DeWitt (1965), Itzykson and Zuber (1985), and Weinberg (1996)]. The regularization we use is simple and close to how regularizations are often done in Feynman diagram computations, i.e., by introducing a sharp UV cutoff [see Eq. (32)]. We believe, however, that we can offer some improvements in detail which make computations easier, more transparent in structure, but nevertheless such that each step can be easily justified with mathematical rigor.

We now discuss some motivation for our computation from a quantum field theory point of view. As was known already to Schwinger for the Abelian case, the effective action of fermions coupled to a Yang–Mills field $A = V$ (i.e., $C = 0$) contains a logarithmic divergence, $\log(\Lambda/m)\, S_{\log}(A)$, and $S_{\log}(A)$ (for $C = 0$) is proportional to the usual Yang–Mills (YM) action

$$S_{\mathrm{YM}}(A) = \frac{1}{2g^2} \int_{\mathbb{R}^4} \mathrm{d}^4x\, \mathrm{tr}\, \mathcal{F}_{\mu\nu}\mathcal{F}^{\mu\nu},$$

[see, e.g., Itzykson and Zuber (1985) Eq. (12.123) where $1/\epsilon$ corresponds to $\log(\Lambda/m)$]. This is important since it implies that a change in the cutoff in the gauge theory, $\Lambda \to \Lambda'$, leads to a finite change of the effective fermion action which can be absorbed by changing the Yang–Mills coupled constant, $g^{-2} \to (g')^{-2} = g^{-2} + const.\log(\Lambda'/\Lambda)$. The logarithmic dependence of the Yang–Mills coupling constant on the UV cutoff is remarkable and distinguishes four space–time dimensions from all others.

Our computation is closely related to more recent ideas which have led to a deeper geometric understanding of the standard model of elementary particle physics (including Higgs sector). This approach is based on Connes' NCG [noncommutative geometry; textbooks on this subject are

Connes (1994) and Gracia-Bondia *et al.* (2001)]. One important ingredient of this approach is to define a generalized Dirac operator D_A, and this Dirac operator not only specifies the fermion part of the action of the model but also the Yang–Mills part $S_{\rm YM}(A)$: There is a definition of $S_{\rm YM}(A)$ in terms of D_A [see Chamseddine and Connes (1997) and references therein]. Our discussion above suggests a simple physical interpretation of this *spectral action principle* [Chamseddine and Connes (1997)]: The logarithmic divergence of the fermion effective action is potentially ''dangerous'' since it can make the model ambiguous: There is no preferred choice for the cut-off, and changing it generates a term proportional to $S_{\log}(A)$. However, the fact that $S_{\log}(A)$ is proportional to the Yang–Mills action resolves this problem for the standard (purely vector) Yang–Mills theory on $\mathbb{R}^4$, as discussed above. It, therefore, is natural to *require that the Yang–Mills action is proportional to the logarithmic divergent part of the fermion effective action in any gauge theory models*. In particular this suggests the following definition of the generalized (vector and chiral) Yang–Mills action in terms of the generalized Dirac operators D_A

$$S_{\rm YM}(A) := const.\,\frac{1}{2g^2}\,S_{\log}(A), \tag{5}$$

(for one fermion flavor $const. = 24\pi^2$). Equation (3) shows that for flat Euclidean space $\mathbb{R}^4$, this definition is equivalent to the one given in Chamseddine and Connes (1997). We conjecture that this is true for other four dimensional spin manifolds as well.

The plan of this paper is as follows. We summarize our notation and results in Sec. II. Section III contains a summary of the mathematical prerequisites, i.e., the three ingredients of our method mentioned above. The computations of $S_{\log}(A)$ is presented in Section IV with some computation details deferred to Appendix B. We conclude with some remarks in Sec. V. Appendix A contains some discussion on regularized traces and the noncommutative residue.

Notation: We write gl_N for the complex $N\times N$ matrices and GL_N for the invertible matrices in gl_N. We sometimes write I_V or I for the identity operator on a vector space V but often abuse notation and do not distinguish between cI and c for complex numbers. For V, W vector spaces and a an operator on V, we often use the same symbols a to also denote the corresponding operator $a\otimes I_W$ and $I_W\otimes a$ on $V\otimes W$ and $W\otimes V$, respectively. The real part of a complex number c is denoted as $\Re c$.

II. DEFINITIONS AND RESULTS

For simplicity we assume spacetime $M^4=\mathbb{R}^4$ with Euclidean signature (the extension of our calculation to other four–dimensional spin manifolds should be possible using symbol calculus of pseudo–differential operators [Hörmander (1995)]).

We consider the Hilbert

$$\mathcal{H} = L^2(\mathbb{R}^4)\otimes\mathbb{C}^4_{\rm spin}\otimes\mathbb{C}^N_{\rm color}, \tag{6}$$

which has the physical interpretation as space of the one–particle states of the fermions. We also introduce the space $\mathcal{D}$ of functions in $\mathcal{H}$ which are smooth (i.e., C^∞) and L^1; $\mathcal{D}$ is a convenient dense domain in $\mathcal{H}$.

The Dirac operators of interest to us are of the form

$$\hat{D}_A = \gamma^\nu(-\mathrm{i}\partial_\nu + V_\nu(x) + \mathrm{i}\gamma_5 C_\nu(x)), \tag{7}$$

where $A=(V,C)$ (repeated indices $\nu,\mu\ldots=1,2,3,4$ are summed over; $x=(x^1,x^2,x^3,x^4)\in\mathbb{R}^4$), with $\partial_\nu=\partial/\partial x^\nu$ and γ^ν the Dirac spin matrices acting on $\mathbb{C}^4_{\rm spin}$ and obeying

$$\gamma^\mu\gamma^\nu+\gamma^\nu\gamma^\mu = 2\,\eta^{\mu\nu}, \tag{8}$$

for $\mu,\nu=1,2,3,4$, where $\eta^{\mu\nu}=\eta_{\mu\nu}=diag(1,1,1,1)$ is the metric tensor, and

$$\gamma_5 := \gamma^1\gamma^2\gamma^3\gamma^4, \tag{9}$$

as usual (for the convenience of the reader, explicit formulas for these matrices are given in Appendix A 1).

For simplicity we assume that the functions V_ν and C_ν, $\mathbb{R}^4 \to \mathrm{gl}_N$, are *regular*, i.e., they are C^∞ and vanish like $\mathcal{O}(|x|^{-4-\varepsilon})$, for some $\varepsilon > 0$, as $|x| \to \infty$ (the latter condition is to ensure that integrals of regular functions over $\mathbb{R}^4$ absolutely converge).

In particular, the free Dirac operator is defined by the differential operator

$$\hat{D}_0 = -\mathrm{i}\gamma^\nu \partial_\nu . \tag{10}$$

We define the *gauge group* $\mathcal{G}$ as follows. Let GL_N be the group of all invertible matrices in gl_N. Then $\mathcal{G}$ is the group of all GL_N-valued functions U on $\mathbb{R}^4$ such that $U(x) - 1$ is a regular function. Note that one can write

$$\hat{D}_A = \tfrac{1}{2}(1-\gamma_5)\gamma^\nu(-\mathrm{i}\partial_\mu + V_\mu + \mathrm{i}C_\mu) + \tfrac{1}{2}(1+\gamma_5)\gamma^\nu(-\mathrm{i}\partial_\mu + V_\mu - \mathrm{i}C_\mu),$$

where $V_\mu \pm \mathrm{i}C_\mu$ are the *chiral* components of the gauge field. This representation shows that it is natural to consider two kinds of gauge transformations,

$$V_\mu \pm \mathrm{i}C_\mu \to (U_\pm)^{-1}(V_\mu \pm \mathrm{i}C_\mu)U_\pm - \mathrm{i}(U_\pm)^{-1}\partial_\mu U_\pm , \quad U_\pm \in \mathcal{G}. \tag{11}$$

For $U_+ = U_- = U$ we denote these as *vector gauge transformation*, otherwise as *chiral gauge transformation*.

Note that $\hat{D}_A$ in Eq. (7) is well-defined on the domain $\mathcal{D} \subset \mathcal{H}$, and we find it useful to distinguish this formally self-adjoint differential operator in notation from the corresponding self-adjoint extension on $\mathcal{H}$ which we denote as D_A, i.e., $(\mathsf{D}_A f)(x) = \hat{D}_A f(x)$ for all $f(x) \in \mathcal{D}$. We also write

$$\mathsf{D}_A = \mathsf{D}_0 + \mathsf{A}, \tag{12}$$

where D_0 is the free Dirac operator (i.e., self-adjoint extension of $\hat{D}_0$) and A the operator defined by multiplication with the generalized Yang–Mills field

$$\hat{A}(x) = \gamma^\nu(V_\nu(x) + \mathrm{i}\gamma_5 C_\nu(x)). \tag{13}$$

We will compute the fermion effective action $S_\Lambda(A)$ defined in Eq. (1), and we will show that it can be expanded as in Eq. (2). As discussed, Tr_Λ is a Hilbert space trace with an UV cutoff $\Lambda > 0$, and Λ_0 is an arbitrary, in general complex, parameter making the argument of the logarithm dimensionless. Moreover, the real (positive or negative) parameter m corresponds to a fermion mass and serves as an infrared (IR) regulator in our computation. Our main result is an explicit formula for $S_{\log}(A)$.

Proposition: *The logarithmic divergent piece* $S_{\log}(\mathrm{A})$ *of the logarithm of the (regularized) determinant of the Dirac operator* D_A *equals*

$$S_{\log}(A) = \frac{1}{24\pi^2}\int_{M^4} d^4x\, \mathrm{tr}_N\left(\tfrac{1}{2}\mathcal{F}^+_{\mu\nu}(\mathcal{F}^+)^{\mu\nu} + \tfrac{1}{2}\mathcal{F}^-_{\mu\nu}(\mathcal{F}^-)^{\mu\nu} - 6m^2 C^\mu C_\mu\right), \tag{14}$$

where tr_N *is the usual matrix trace in* gl_N *and* ($[a,b] := ab - ba$)

$$\mathcal{F}^\pm_{\mu\nu} := \partial_\mu A^\pm_\nu - \partial_\nu A^\pm_\mu + \mathrm{i}[A^\pm_\mu, A^\pm_\nu], \quad A^\pm_\mu := V_\mu \pm C_\mu , \tag{15}$$

is the curvature associated with the chiral component $A^\pm$ *of the Yang–Mills field.*

(*Proof in Sec.* IV *with some details deferred to Appendix B.*)

For $C=0$ (no chiral field) we obtain

$$S_{\log}(A)=\frac{1}{24\pi^2}\int_{M^4}d^4x\,\mathrm{tr}_N\mathcal{F}_{\mu\nu}\mathcal{F}^{\mu\nu},$$

with

$$\mathcal{F}_{\mu\nu}=\partial_\mu V_\nu-\partial_\nu V_\mu+\mathrm{i}[V_\mu,V_\nu], \tag{16}$$

which is the standard Yang–Mills action. Note that $\mathcal{F}_{\mu\nu}=\mathrm{i}[D_\mu,D_\nu]$ with

$$D_\nu:=-\mathrm{i}\partial_\nu+V_\nu(x), \tag{17}$$

the covariant derivative, and similarly

$$\mathcal{F}^{\pm}_{\mu\nu}=\mathrm{i}[D_\mu\pm\mathrm{i}C_\mu,D_\nu\pm\mathrm{i}C_\nu]. \tag{18}$$

It is important to note that for $m=0$, $S_{\log}(A)$ in Eq. (14) this is manifestly invariant under all gauge transformations Eq. (11). For $m\neq 0$, there is also a mass term $\propto C^\mu C_\mu$ for the chiral gauge field which is only invariant under vector gauge transformations, i.e., only the transformations Eq. (11) with $U_+=U_-=U$. The parameter in front of this term is fixed by the fermion mass. There is no similar term for the vector gauge field (note that such a term would spoil vector gauge invariance).

It is interesting to note that the result of our computation in Sec. IV suggests that for manifolds M^4 with boundary ∂M^4, $S_{\log}(A)$ has an additional contribution

$$\Delta S_{\log}(A)=\frac{1}{24\pi^2}\int_{M^4}d^4x\,\partial^\mu\mathrm{tr}_N J_\mu, \tag{19}$$

with

$$J_\mu:=2C_\mu\mathrm{i}[D_\nu,C^\nu]-2C^\nu\mathrm{i}[D_\nu,C_\mu]+2\mathrm{i}[D_\mu,C^\nu C_\nu]. \tag{20}$$

This is a boundary term (by Stokes's theorem). Note that this term is also invariant under vector gauge transformations, and it vanishes if the axial Yang–Mills field C_μ is zero.

It is also worth noting that, as a by-product, we also obtain the explicit expression for the quadratic divergent part of the effective action:

$$S^{(2)}(A)=\frac{1}{16\pi^2}\int_{M^4}d^4x\,\mathrm{tr}_N(-V^\mu V_\mu+C^\mu C_\mu). \tag{21}$$

In contrast to $S_{\log}(A)$ this term is not gauge invariant (as already mentioned, the term $\propto V^\mu V_\mu$ spoils vector gauge invariance)! This highlights the fact that the regularization procedure we use is not manifestly gauge invariant but only quasi-gauge invariant. It shows that the vector gauge invariance of our result for $S_{\log}$ is somewhat remarkable. It is also interesting to note that for $V_\mu=\pm C_\mu$, $S^{(2)}(A)=0$.

III. CALCULATION TOOLS

In this Section we collect the mathematical prerequisites for our computation. We will explain the three ingredients for our method: Firstly, a definition of the logarithm of operators a in terms of an integral of the resolvent of a. Secondly, a few basic definitions for PSDO which imply a simple and elegant formula for the symbol of the resolvent of Dirac operators D_A. And finally, a

definition of a regularized Hilbert space trace Tr_Λ (corresponding to introducing an UV cutoff Λ). In the next Section we will put these ingredients together and obtain an expansion of the effective action as described in the Introduction.

A. The logarithm of operators

Let a be a bounded operator on a Hilbert space $\mathcal{H}$ with norm less than one. Then ($I=I_{\mathcal{H}}$ is the identity operator)

$$\log(I+a)=\int_0^1 \frac{\mathrm{d}s}{s}(I-(I+sa)^{-1}), \tag{22}$$

as can be seen by a Taylor expansion,

$$\log(I+a)=\sum_{n=1}^{\infty}\frac{(-1)^{n-1}}{n}a^n=-\sum_{n=1}^{\infty}\int_0^1\frac{\mathrm{d}s}{s}(-sa)^n,$$

interchanging summation and integration, and using the geometric series.

We take this as a motivation to *define*

$$\log\left(\frac{\mathsf{D}_A+\mathrm{i}m}{\Lambda_0}\right):=\int_0^1\frac{\mathrm{d}s}{s}\left(I-\left(I+s\left[\frac{\mathsf{D}_A+\mathrm{i}m}{\Lambda_0}-I\right]\right)^{-1}\right), \tag{23}$$

where Λ_0 is a some complex number. This representation of the logarithm as integral of a resolvent will be convenient for us since there is a simple formula for the resolvent of (generalized) Dirac operators, as discussed below.

B. Pseudo–differential operators

1. Generalities

We summarize some basic facts about pseudo-differential operators (PSDO) on $\mathbb{R}^4$ [a discussion for general manifolds can be found, e.g., in Hörmander (1985)]. We consider PSDO a on $\mathcal{H}$ which can be represented by their *symbol* $\sigma[a](p,x)$, i.e., a $\mathrm{gl}_4\otimes\mathrm{gl}_N$–valued functions on phase space $\mathbb{R}^4\times\mathbb{R}^4$ defined such that [Hörmander (1985)]

$$(af)(x)=\int_{\mathbb{R}^4}\frac{\mathrm{d}^4p}{(2\pi)^4}\int_{\mathbb{R}^4}d^4y\,e^{ip\cdot(x-y)}\sigma[a](p,x)f(y), \tag{24}$$

for all $f(y)\in\mathcal{D}$ (matrix multiplication is understood; $p\cdot x=x^\nu p_\nu$). In particular, D_0 and A are PSDO with symbols

$$\sigma[\mathsf{D}_0](p,x)=\not{p}:=\gamma^\nu p_\nu,\quad \sigma[\mathsf{A}](p,x)=\hat{A}(x). \tag{25}$$

Eq. (24) implies the following equation which encodes the product of operators in terms of their symbols:

$$\sigma[ab](p,x)=\int_{\mathbb{R}^4}\frac{\mathrm{d}^4q}{(2\pi)^4}\int_{\mathbb{R}^4}d^4y\,\mathrm{e}^{\mathrm{i}(x-y)\cdot(p-q)}\sigma[a](q,x)\sigma[b](p,y). \tag{26}$$

We will encounter PSDO a which allow an asymptotic expansion

$$\sigma[a]\sim\sum_{j=0}^{\infty}\sigma_{K-j}[a], \tag{27}$$

where $\sigma_{K-j}[a](p,x)$ is homogeneous of degree $K-j$ in p, [i.e., $\sigma_{K-j}[a](sp,x) = s^{K-j}\sigma_{K-j}[a](p,x)$ for all $s>0$ and $|p|>0$] and behaves as $|p|^{K-j}$ for $|p|\to\infty$ ($|p| := \sqrt{p\cdot p}$). We write

$$\sigma[a](p,x) = \sum_{j=0}^{n} \sigma_{K-j}[a](p,x) + \mathcal{O}(|p|^{K-n-1}), \tag{28}$$

for all integers n. Eq. (26) implies

$$\sigma[ab](p,x) \sim \sum_{n=0}^{\infty} \frac{(-\mathrm{i})^n}{n!} \frac{\partial^n \sigma[a](p,x)}{\partial p_{i_1}\cdots\partial p_{i_n}} \frac{\partial^n \sigma[b](p,x)}{\partial x_{i_1}\cdots\partial x_{i_n}}. \tag{29}$$

This equation allows to determine the asymptotic expansions of $\sigma[ab]$ and $\sigma[a^{-1}]$ from the ones of $\sigma[a]$ and $\sigma[b]$.

2. The symbol of the resolvent

Equation (23) expresses $\log(\mathsf{D}_A + \mathrm{i}m)$ as an integral of resolvents of the Dirac operator D_A, i.e., of operators $(c_1 I + c_2 \mathsf{D}_A)^{-1}$ with $c_{1,2}$ complex numbers. We will therefore need the symbol of such a resolvent. To determine this we note that

$$\sigma[c_1 I + c_2 \mathsf{D}_A](p,x) = c_1 + c_2[\not{p} + \hat{A}(x)]. \tag{30}$$

We then could use Eq. (29) to find the expansion for $\sigma[(c_1 I + c_2 \mathsf{D}_A)^{-1}](p,x)$. We now present a useful result summarizing this expansion in a simple formula.

Lemma: The following holds for all $c_1, c_2 \in \mathbb{C}$

$$\sigma[(c_1 I + c_2 \mathsf{D}_A)^{-1} a](p,x) = (c_1 + c_2[\not{p} + \hat{D}_A])^{-1} \sigma[a](x,p). \tag{31}$$

Remark: The proper interpretation of this equation is as follows:

$$\sigma[(c_1 I + c_2 \mathsf{D}_A)^{-1} a](p,x) \sim \sum_{n=0}^{\infty} (-1)^n (c_1 + c_2 \not{p})^{-1} [\hat{D}_A (c_1 + c_2 \not{p})^{-1}]^n \sigma[a](x,p),$$

where the differential operators ∂_ν in $\hat{D}_A = -\mathrm{i}\gamma^\mu \partial_\nu + \hat{A}(x)$ act to the right on the functions $\hat{A}(x)$ according to the Leibniz rule. We note that we will need this equation only for $a = I$.

Proof of the Lemma: One can check Eq. (31) by using Eqs. (27) and (29), taking $c_1 I + c_2 \mathsf{D}_A$ for a and $[c_1 I + c_2 \mathsf{D}_A]^{-1} a$ for b, and inserting Eq. (30). A simpler argument avoiding tedious expansions is as follows: Note that by definition, $(\mathsf{D}_A f)(x) = [\hat{D}_0 + \hat{A}(x)] f(x)$ for all $f \in \mathcal{D}$, thus

$$((c_1 I + c_2 \mathsf{D}_A) a f)(x) = (c_1 + c_2[\hat{D}_0 + \hat{A}(x)])(af)(x) = \int_{\mathbb{R}^4} \frac{\mathrm{d}^4 p}{(2\pi)^4} \int_{\mathbb{R}^4} d^4 y\, e^{ip\cdot(x-y)} (c_1 + c_2[\not{p} + \hat{D}_0 + \hat{A}(x)]) \sigma[a](p,x) f(y),$$

where we used Eq. (24) and the Leibniz rule. Replacing a in this equation by $(c_1 I + c_2 \mathsf{D}_A)^{-1} a$, we see that this is equivalent to Eq. (31). [Note that this argument implies the interpretation of Eq. (31) as given above!] □

Remark: We believe that our expansion in powers of the differential operator $\hat{D}_A$ is very natural for at least two reasons. Firstly, since under a vector gauge transformation, $\hat{D}_A \to U^{-1} \hat{D}_A U$, such an expansion is close to being manifestly gauge invariant (we will discuss this point in more detail below). Secondly, it is natural from the point of view of power counting: In

contrast to an expansion in $\hat{A}$, the nth order term in our expansion includes precisely those local polynomials in V_μ and C_ν (and derivatives thereof) which all have the same scaling dimension $4-n$.

Remark: Loosely speaking, PSDO are useful since they allow to interpolate between Fourier- and position space: Generically in quantum theory one deals with operators H on some Hilbert space of L^2-functions on $\mathbb{R}^n$ which are a sum of a free part H_0 diagonal in Fourier space, [$\hat{f}(p) = \int_{\mathbb{R}^n} \mathrm{d}^n x\, e^{ip\cdot x} f(x)$ denotes the Fourier transform], $\widehat{(H_0 f)}(p) = E_0(p)\hat{f}(p)$, and a potential term V diagonal in position space, $(Vf)(x) = V(x)f(x)$. The symbol of H is then simply the sum of $E_0(p)$ and $V(x)$, which is an attractive feature. The price one has to pay is that the symbol of ("nice") functions F of H are somewhat complicated: In a first approximation, $\sigma[F(H)](p,x) \sim F(E_0(p)+V(x))+\cdots$, but there are correction terms $\cdots$ depending on derivatives. The Lemma above is a special case of the following formula,

$$\sigma[F(H)](p,x) \sim F(E_0(p-\mathrm{i}\partial)+V(x))1,$$

nicely summarizing the systematic derivative expansion of functions of H.

C. Regularized traces and the noncommutative residue

We now define the regularized trace which we will use. We first note that due to our technical assumptions on the gauge fields all operators a which we will encounter are PSDO which have symbols $\sigma[a](p,x)$ which go at least like $\mathcal{O}(|x|^{-4-\varepsilon})$, some $\varepsilon>0$, for fixed p and $|x|\to\infty$, and are finite for finite p. Thus

$$\mathrm{Tr}_\Lambda(a) := \int_{|p|\leqslant\Lambda} \frac{\mathrm{d}^4 p}{(2\pi)^4} \int_{\mathbb{R}^4} d^4x\, \mathrm{tr}\, \sigma[a](x,p), \tag{32}$$

where tr is the full matrix trace (including the trace tr_ν in gl_4 and the trace tr_N in gl_N), is well-defined for $\Lambda<\infty$, and this defines a regularized Hilbert space trace: If a is a trace–class operator then $\mathrm{Tr}_\Lambda(a)$ has a well-defined limit $\Lambda\to\infty$ which is equal to the Hilbert space trace of a [Hörmander (1985)]. More generally one can consider PSDO a for which $\mathrm{Tr}_\Lambda(a)$ can be expanded as

$$\mathrm{Tr}_\Lambda(a) = c^{(K)}(a)\Lambda^K + c^{(K-1)}(a)\Lambda^{K-1} + \cdots + c^{(1)}(a)\Lambda + c_{\log}(a)\log\left(\frac{\Lambda}{|m|}\right) + c^{(0)}(a) + \mathcal{O}(\Lambda^{-1}), \tag{33}$$

with K some non-negative integer.

We recall that the noncommutative residue [Wodzicki (1985)] of a PSDO a with an asymptotic expansion as in Eq. (27) can be defined as [see, e.g., Eq. (2.7) in Varilly and Gracia-Bondia (1993)]

$$\mathrm{Res}(a) := \frac{1}{4}\int_{\mathbb{R}^4} \frac{\mathrm{d}^4 p}{(2\pi)^4}\, \delta(|p|-1) \int_{\mathbb{R}^4} d^4x\, \mathrm{tr}\sigma_{-4}[a](x,p), \tag{34}$$

and for PSDO a as above:

$$\mathrm{Res}(a) = \tfrac{1}{4} c_{\log}(a), \tag{35}$$

i.e., the residue is equal, up to a constant, to the logarithmic divergent part of the regularized trace of a. (An elementary proof of this latter fact is outlined in Appendix A.)

Remark: In our definition of Tr_Λ we use a sharp cutoff, i.e.,

$$\mathrm{Tr}_\Lambda(a)=\int_{\mathbb{R}^4}\frac{\mathrm{d}^4p}{(2\pi)^4}f\left(\frac{|p|}{\Lambda}\right)\int_{|p|\leqslant\Lambda}d^4x\,\mathrm{tr}\sigma[a](x,p), \tag{36}$$

where $f(t)$ equals the Heaviside step function $\theta(1-t)$. In principle one could define a regularized trace using Eq. (36) and choosing any non-negative, piece-wise smooth, function $f(t)$ which vanishes exponentially fast for $|t|\to\infty$ and is such that $f(0)=1$. For example, the choice $f(t)=\exp(-t^2)$ would correspond to the standard heat kernel regularization.

We will show in Appendix A that $c_{\log}(a)$ is in fact independent of f.

Using any such regularization one can define the *renormalized trace* as the finite part of the regularized trace:

$$\mathrm{TR}(a):=c_0(a), \tag{37}$$

but this is not quite independent of the regularization: As also discussed in Appendix A, changing the regularization function $f\to\tilde{f}$ amounts to changing

$$\mathrm{TR}(a)\to\mathrm{TR}(a)+\log(s)\,c_{\log}(a), \tag{38}$$

with some constant $s>0$ depending on f and $\tilde{f}$: The logarithmic divergent piece accounts for the regularization dependence of the renormalized trace, and this is the reason for our interest in it, as discussed in the Introduction.

Remark: We note Eq. (36) is equivalent to

$$\mathrm{Tr}_\Lambda(a)=\mathrm{Tr}(P_\Lambda a),\quad P_\Lambda:=f(|\mathsf{D}_0|/\Lambda), \tag{39}$$

(using the spectral theorem for self-adjoint operators). This naturally extends the definition of Tr_Λ from PSDO to a large class of operators on $\mathcal{H}$. More generally, one could change the regularization by changing $\mathsf{D}_0\to\mathsf{D}_B$ in the definition of P_Λ, for some fixed Yang–Mills field B. One can show that this would change $\mathrm{TR}(a)$ by a term proportional to $\mathrm{Res}([\log(\mathsf{D}_B)-\log(\mathsf{D}_0)]a)$ [see, e.g., Eq. (1.6) in Cardona *et al.* (2000)]. It would be interesting to explore this possibility in more detail.

IV. COMPUTATION OF EFFECTIVE FERMION ACTION

In this Section we present the explicit computation of the effective fermion action and thus prove the proposition in Sec. II. Our computation amounts to a quasi-gauge invariant gradient expansion, which is essentially an expansion in powers of the UV cutoff Λ. This allows us to extract, in a simple manner, the quadratic and logarithmic divergent pieces which is what we are interested in.

A. Quasi-gauge covariant expansion

We write

$$S_\Lambda(A)=\int_{|p|\leqslant\Lambda}\frac{\mathrm{d}^4p}{(2\pi)^4}\int_{\mathbb{R}^4}d^4x\,\mathrm{tr}\,\mathcal{S}(x,p)\,1, \tag{40}$$

where $\mathcal{S}(x,p)$ is obtained by computing the symbol of the operator $\log(\mathsf{D}_A+\mathrm{i}m)/\Lambda_0-\log(\mathsf{D}_0+\mathrm{i}m)/\Lambda_0$ as explained in the last Section, i.e.,

$$\begin{aligned}\mathcal{S}(x,p)&=\int_0^1\frac{\mathrm{d}s}{s}([1-s+s\not{p}+s\not{a}]^{-1}-[1-s+s\not{p}]^{-1})\\&=\int_0^\infty\frac{\mathrm{d}u}{u}([1+u\not{p}+u\not{a}]^{-1}-[1+u\not{p}]^{-1}),\end{aligned} \tag{41}$$

where we used Eqs. (22) and (31), introduced the convenient short-hand notion

$$\tilde{\not{p}} := \frac{\not{p} + \mathrm{i}m}{\Lambda_0}, \quad \tilde{\not{a}} := \frac{-\mathrm{i}\not{\partial} + \hat{\not{A}}}{\Lambda_0}, \tag{42}$$

and changed integration variables, $s = u/(1+u)$. The 1 on the right-hand side (r.h.s.) of Eq. (40) is the symbol of the identity operator. As explained in more detail below, $\mathcal{S}$ here is to be regarded as a differential operator acting on 1. It is straightforward to expand the integrand in this equation in powers of $\tilde{\not{a}}$:

$$\mathcal{S} = \sum_{n=1}^{L} (-1)^{n-1} \mathcal{S}_n + \mathcal{R}_{L+1}, \tag{43}$$

where

$$\mathcal{S}_n = (-1)^{n-1} \int_0^\infty \frac{\mathrm{d}u}{u} \frac{1}{1+u\tilde{\not{p}}} \left(u\tilde{\not{a}} \frac{1}{1+u\tilde{\not{p}}} \right)^n \tag{44}$$

and

$$\mathcal{R}_{L+1} = \int_0^\infty \frac{\mathrm{d}u}{u} \frac{1}{1+u\tilde{\not{p}}} \left(u\tilde{\not{a}} \frac{1}{1+u\tilde{\not{p}}} \right)^L u\tilde{\not{a}} [1 + u(\tilde{\not{p}} + \tilde{\not{a}})]^{-1}, \tag{45}$$

is a remainder term.

In the following we find it convenient to use the short-hand notation and write:

$$\hat{D}_A = \sum_{s=0,5} \gamma_s^\nu D_\nu^s \tag{46}$$

where

$$D_\nu^0 := D_\nu \quad D_\nu^5 := C_\nu \tag{47}$$

and

$$\gamma_0^\nu := \gamma^\nu, \quad \gamma_5^\nu := \mathrm{i}\gamma^\nu \gamma_5. \tag{48}$$

We then define

$$\mathcal{M}_{n;s_1\cdots s_n}^{\nu_1\cdots\nu_n} := (\Lambda_0)^{-n} \int_{|p|\leqslant\Lambda} \frac{\mathrm{d}^4 p}{(2\pi)^4} \mathrm{tr}_\nu \int_0^\infty \mathrm{d}u u^{n-1} \frac{1}{1+u\tilde{\not{p}}} \gamma_{s_1}^{\nu_1} \frac{1}{1+u\tilde{\not{p}}} \cdots \gamma_{s_n}^{\nu_n} \frac{1}{1+u\tilde{\not{p}}}, \tag{49}$$

where $s_j = 0,5$ and $\nu_j = 1,2,3,4$. This allows us to write

$$\mathcal{S}_n := \int_{|p|\leqslant\Lambda} \frac{\mathrm{d}^4 p}{(2\pi)^4} \int_{\mathbb{R}^4} d^4x \mathrm{tr}\, \mathcal{S}_n(x,p) = \sum_{\underline{s}} \mathcal{M}_{n;\underline{s}}^{\nu_1\cdots\nu_n} \int_{\mathbb{R}^4} d^4x \mathrm{tr}_N D_{\nu_1}^{s_1} \cdots D_{\nu_n}^{s_n}: \tag{50}$$

here and in the following, $\underline{s}$ is short for $(s_1,..,s_n)$.

The following Lemma simplifies the computation significantly: It implies that the $\mathcal{S}_n$ for *odd* integers n all vanish, and that a series expansion in the mass m only has nonzero *even* powers.

Lemma: The coefficients $\mathcal{M}_{n;\underline{s}}^{\nu}$ in Eq. (49) are nonzero only for even integers n, and they are invariant under $m \to -m$, i.e., they are independent of the sign of the mass.
(Proof in Appendix B.)

Remark: We now can explain why we denote our expansion quasi–gauge invariant. This is because the operators D_ν^s transform gauge covariantly under a vector gauge transformation U,

$D^s_\nu \to U^{-1} D^s_\nu U$. This implies that the differential operators defined in Eq. (50) all are gauge invariant. However, the action is a polynomial which is obtained by applying these differentiation operators to 1 [cf. Eqs. (40)] using Leibniz rule and $\partial_\nu 1 = 0$, e.g.,

$$\begin{aligned} D_\nu 1 &= V_\nu(x), \\ D_{\nu_1} C_{\nu_2} 1 &= -\mathrm{i}[\partial_{\nu_1} C_{\nu_2}(x)] + V_{\nu_1}(x) C_{\nu_2}(x), \\ D_{\nu_1} D_{\nu_2} 1 &= -\mathrm{i}[\partial_{\nu_1} V_{\nu_2}(x)] + V_{\nu_1}(x) V_{\nu_2}(x), \end{aligned} \tag{51}$$

etc. The result will be gauge invariant only if the differential operator in Eq. (50) is already a polynomial. This happens, e.g., if the differential operators D_ν only appear in combinations $[D_\nu, D_\mu]$ and $[D_\nu, C_\mu]$. This is not obvious. However, we will see below that this happens for the terms leading to logarithmic divergent part.

B. Expansion in powers of the UV cutoff

We now show that our expansion above is essentially an expansion in powers of the UV cutoff Λ. Our computation can be simplified by the following argument (this argument is refined and justified in detail in Appendix B). As mentioned, m serves as a particular IR cutoff for momentum integrals. We expect that our result is independent of the precise form of the IR regularization. Thus we use instead the following, simpler one: we set $m = 0$ in $\not{p}$ but restrict integrations over p to $m \leqslant |p| \leqslant \Lambda$. *We stress that we use this simplification in the main text only to ease our presentation, and that it is appropriate only for computing the diverging contributions to the regularized determinant: The computation of the finite part should be done with the method explained in Appendix B.* Below we shall see that this simplified procedure gives an IR regularization provided we also set $\Lambda_0 = |\Lambda_0|/(1 + \mathrm{i}0^+)$ (a justification of this can be also found in the Appendix B). Using then

$$\frac{1}{1 + u\not{p}} = \frac{1}{1 - u^2 |p|^2 (\Lambda_0)^{-2}} [1 - u\not{p}(\Lambda_0)^{-1}],$$

and rescaling $u|p|(\Lambda_0)^{-1} \to u(1 + \mathrm{i}0^+)$ we see that $\mathcal{M}_n$ in Eq. (49) becomes (we use the different symbol $\tilde{\mathcal{M}}_n$ to indicate that these numbers are obtained with a simplified IR regularization.)

$$\tilde{\mathcal{M}}^\nu_{n;\underline{s}} = \frac{1}{8\pi^2} \int_{|m|}^{\Lambda} \mathrm{d}|p| |p|^{3-n} \mathcal{J}^\nu_{n;\underline{s}}(p), \tag{52}$$

where

$$\mathcal{J}^{\nu_1 \cdots \nu_n}_{n;\underline{s}} := \int_0^\infty \mathrm{d}u\, u^{n-1} \left(\frac{1}{1 - [u(1 + \mathrm{i}0^+)]^2} \right)^{n+1} \langle \mathrm{tr}_\nu (1 - u\not{\xi}) \gamma^{\nu_1}_{s_1} (1 - u\not{\xi}) \cdots \gamma^{\nu_n}_{s_n} (1 - u\not{\xi}\not{\xi}) \rangle, \tag{53}$$

and we used $(2\pi)^{-4} \int_{m \leqslant |p| \leqslant \Lambda} \mathrm{d}^4 p\, g(p) = (8\pi^2)^{-1} \int_{|m|}^{\Lambda} \mathrm{d}|p| |p|^3 \langle g(|p|\xi) \rangle$ with

$$\langle g(\xi) \rangle := \frac{1}{2\pi^2} \int_{\mathbb{R}^4} \frac{\mathrm{d}^4 \xi}{(2\pi)^4}\, \delta(|\xi| - 1)\, g(\xi), \tag{54}$$

the angular average (i.e., integration over the unit sphere in $\mathbb{R}^4$). We now see that $\Lambda_0 = |\Lambda_0|/(1 + \mathrm{i}0^+)$ is needed to specify how to treat the singularity in the u-integral. These u-integrals are then finite [see Eqs. (56) and (57) below]. The result we get is independent of $|\Lambda_0|$, as expected. It shows explicitly that our expansion leads to an expansion of the action in powers of Λ. We are

interested in $\Lambda\to\infty$. In this limit, $\tilde{\mathcal{M}}_n \propto |\Lambda|^{n-4}$ for $n<4$ and $\propto |m|^{4-n}$ for $n>4$: The former terms are divergent in the UV (i.e., for $\Lambda\to\infty$), the latter in the IR (i.e., for $m\to 0$). It is precisely the "boundary case" $n=4$ which gives rise to the logarithmic divergence.

This result obtained with the simplified IR treatment is correct only in leading order in Λ. In Appendix B we show how to do the computation without this simplification, and that

$$\mathcal{M}_n = \tilde{\mathcal{M}}_n + \mathcal{O}(m^2 \Lambda^{2-n}), \quad n>2, \tag{55}$$

showing that the simplified IR treatment gives the correct result for the diverging terms for all n but $n=2$. For $n=2$ there are corrections $\propto m^2 \log(\Lambda/m)$ which contribute to $S_{\log}$ and which we, therefore, have to compute exactly.

C. Computation of diverging parts of the effective action

We now proceed to compute the coefficients $\mathcal{J}_n$ Eq. (53) for those terms we are interested in, i.e., for $n=1,2,3,4$. Using Eq. (52) this is straightforward: One only needs to evaluate the integrals

$$\mathcal{N}_{n,k} = \int_0^\infty du\, u^{n+k-1} (1-[u(1+i0^+)]^2)^{-n-1}, \tag{56}$$

the angular averages $\langle \xi_{\nu_1} \cdots \xi_{\nu_k} \rangle$, and traces of products of Dirac matrices. The integrals in Eq. (56) are [cf., e.g., Eq. 3.251(11.) in Gradshteyn and Ryzhik (1980)]

$$\mathcal{N}_{n,k} = -(-1)^{(n-k)/2} B\left(\frac{n+k}{2}, \frac{n-k}{2}+1\right), \tag{57}$$

where $B(x,y)=\Gamma(x)\Gamma(y)/\Gamma(x+y)$. We only need

$$\mathcal{N}_{2,0} = \tfrac{1}{4}, \quad \mathcal{N}_{2,2} = -\tfrac{1}{4},$$

$$\mathcal{N}_{4,0} = \tfrac{1}{24}, , \quad \mathcal{N}_{4,2} = -\tfrac{1}{24}, \quad \mathcal{N}_{4,4} = \tfrac{1}{8}.$$

The computation of the traces of Dirac matrices is simplified using the following relations:

$$(1-u\xi)\gamma^\nu = \gamma^\nu (1+u\xi) - 2u\xi^\nu, \quad \nu = 1,2,3,4,$$

$$\gamma_5 \xi \gamma_5 = -\xi, \quad \xi^2 = |\xi|^2, \tag{58}$$

which follow from Eq. (8). We also need

$$\langle 1 \rangle = 1, \quad \langle \xi_{\mu_1} \xi_{\mu_2} \rangle = \tfrac{1}{4} \eta_{\mu_1\mu_2}$$

$$\langle \xi_{\mu_1} \xi_{\mu_2} \xi_{\mu_3} \xi_{\mu_4} \rangle = \tfrac{1}{24} (\eta_{\mu_1\mu_2}\eta_{\mu_3\mu_4} + \eta_{\mu_1\mu_3}\eta_{\mu_2\mu_4} + \eta_{\mu_1\mu_4}\eta_{\mu_2\mu_3}), \tag{59}$$

and that the angular average for a product of an odd number of components ξ_{μ_j} is zero. Moreover,

$$\mathrm{tr}_\nu(\gamma^{\mu_1}\gamma^{\mu_2}) = 4\eta^{\mu_1\mu_2},$$

$$\mathrm{tr}_\nu(\gamma^{\mu_1}\gamma^{\mu_2}\gamma^{\mu_3}\gamma^{\mu_4}) = 4(\eta^{\mu_1\mu_2}\eta^{\mu_3\mu_4} - \eta^{\mu_1\mu_3}\eta^{\mu_2\mu_4} + \eta^{\mu_1\mu_4}\eta^{\mu_2\mu_3}), \tag{60}$$

$$\mathrm{tr}_\nu(\gamma_5\gamma^{\mu_1}\gamma^{\mu_2}\gamma^{\mu_3}\gamma^{\mu_4}) = 4\epsilon^{\mu_1\mu_2\mu_3\mu_4},$$

where $\epsilon^{\mu_1\mu_2\mu_3\mu_4}$ is the completely antisymmetric symbol with $\epsilon^{1234}=1$. Note that $\mathrm{tr}_\nu(\gamma_\mu^s) = \mathrm{tr}_\nu(\gamma_{\mu_1}^{s_1}\gamma_{\mu_2}^{s_2}\gamma_{\mu_3}^{s_3}) = 0$ always.

TABLE I. Parameters in Eq. (65) where $\underline{s}=(s_1,s_2,s_3,s_4)$.

s_1	1	1	1	1	5	5	5	5	1	1	1	1	5	5	5	5
s_2	1	1	5	5	1	1	5	5	1	1	5	5	1	1	5	5
s_3	1	5	1	5	1	5	1	5	1	5	1	5	1	5	1	5
s_4	1	5	5	1	5	1	1	5	5	1	1	5	1	5	5	1
$A_{\underline{s}}$	0	−2	−2	2	−2	−2	−2	0	0	0	0	0	0	0	0	0
$B_{\underline{s}}$	−2	2	2	0	4	2	2	−2	0	0	0	0	0	0	0	0
$C_{\underline{s}}$	2	−2	0	2	−2	0	−2	2	0	0	0	0	0	0	0	0
$D_{\underline{s}}$	0	0	0	0	0	0	0	0	−i	−i	i	i	i	i	−i	−i

It is now easy to see that $\mathcal{J}^{\mu}_{1,s}=\mathcal{J}^{\mu_1\mu_2\mu_3}_{3;s_1s_2s_3}=0$, thus

$$\mathcal{S}_1=\mathcal{S}_3=0. \tag{61}$$

The simplest nonzero terms are for $n=2$. Combining the formulas given above it is easy to see that

$$\mathcal{J}^{\mu_1\mu_2}_{2;s_1s_2}=\frac{1}{8\pi^2}A_{s_1s_2}\eta^{\mu_1\mu_2},$$

$$A_{55}=-A_{00}=1,\quad A_{50}=A_{05}=0. \tag{62}$$

Thus

$$\tilde{\mathcal{S}}_2=\Lambda^2\frac{1}{16\pi^2}\int d^4x\,\mathrm{tr}_N(-D^{\mu}D_{\mu}+C^{\mu}C_{\mu}). \tag{63}$$

This is a gauge invariant differential operator. When acting on 1 [cf. Eq. (51)] we obtain the quadratic divergent part of the effective action Eq. (21) which is not gauge invariant.

As mentioned, $\tilde{\mathcal{S}}^{(2)}$ is only the leading order contribution to $\mathcal{S}^{(2)}$. A more careful computation without the simplified IR regularization gives (see Appendix B)

$$\mathcal{S}_2=\tilde{\mathcal{S}}_2-m^2\log\left(\frac{\Lambda}{|m|}\right)\frac{1}{8\pi^2}\int d^4x\,\mathrm{tr}_N(C^{\mu}C_{\mu})+\cdots, \tag{64}$$

where "$\cdots$" are terms which remain finite for $\Lambda\to\infty$. We see that the subleading term which was missed by the naive IR regularization contributes to $S_{\log}$. As discussed in Sec. II, this term is gauge invariant.

We now turn to the case $n=4$ which leads to the logarithmic divergence. All relations needed to compute the $\mathcal{J}^{\nu_1\nu_2\nu_3\nu_4}_{\underline{s}}$ were listed above. The result can be written as follows:

$$\mathcal{J}^{\nu_1\nu_2\nu_3\nu_4}_{\underline{s}}=\tfrac{1}{3}(A_{\underline{s}}\eta^{\nu_1\nu_2}\eta^{\nu_3\nu_4}+B_{\underline{s}}\eta^{\nu_1\nu_3}\eta^{\nu_2\nu_4}+C_{\underline{s}}\eta^{\nu_1\nu_4}\eta^{\nu_2\nu_3}+D_{\underline{s}}\epsilon^{\nu_1\nu_2\nu_3\nu_4}), \tag{65}$$

where $\underline{s}=(s_1,s_2,s_3,s_4)$. The numbers $A_{\underline{s}},B_{\underline{s}},C_{\underline{s}},D_{\underline{s}}$ are all given in Table I. (We have checked this result extensively using the symbolic programming language MAPLE.) We note that the numbers $A_{\underline{s}},B_{\underline{s}},C_{\underline{s}}$ ($D_{\underline{s}}$) all are real (purely imaginary) and nonzero only if an even (odd) number of the s_j equal 5.

Combining these results we find

$$\tilde{S}_4=\log\left(\frac{\Lambda}{|m|}\right)\frac{1}{24\pi^2}\int_{\mathbb{R}^4}d^4x\,\mathrm{tr}_N[\mathcal{P}_R+\mathcal{P}_I], \tag{66}$$

where

$$\mathcal{P}_R=\sum_{\underline{s}}\ (A_{\underline{s}}\eta^{\nu_1\nu_2}\eta^{\nu_3\nu_4}+B_{\underline{s}}\eta^{\nu_1\nu_3}\eta^{\nu_2\nu_4}+C_{\underline{s}}\eta^{\nu_1\nu_4}\eta^{\nu_2\nu_3})D^{s_1}_{\nu_1}D^{s_2}_{\nu_2}D^{s_3}_{\nu_3}D^{s_4}_{\nu_4}$$

$$\mathcal{P}_I=\sum_{\underline{s}}\ D_{\underline{s}}\epsilon^{\nu_1\nu_2\nu_3\nu_4}D^{s_1}_{\nu_1}D^{s_2}_{\nu_2}D^{s_3}_{\nu_3}D^{s_4}_{\nu_4}, \tag{67}$$

with the coefficients given in Table I. $\mathcal{P}_R$ is a sum of 19 nonzero terms. We now claim that it is possible to write $\mathcal{P}_R=\mathcal{P}_{R,1}+\mathcal{P}_{R,2}$ where

$$\begin{aligned}\mathcal{P}_{R,1}=&-[D^\mu,D^\nu][D_\mu,D_\nu]-[C^\mu,C^\nu][C_\mu,C_\nu]+[D^\mu,D^\nu][C_\mu,C_\nu]+[C^\mu,C^\nu][D_\mu,D_\nu]\\&+2[D^\mu,C^\nu][D_\mu,C_\nu]+2[D^\mu,C^\nu][C_\mu,D_\nu]\end{aligned} \tag{68}$$

and

$$\mathcal{P}_{R,2}=\mathrm{i}[D^\mu,J_\mu]+[[D^\mu,D^\nu],[C_\mu,C_\nu]]-2[C^\mu,[D_\mu,D_\nu]C^\nu] \tag{69}$$

with J_μ given in Eq. (20). Similarly

$$\mathcal{P}_I=\frac{\mathrm{i}}{2}\epsilon^{\nu_1\nu_2\nu_3\nu_4}[[D_{\nu_1},D_{\nu_2}]+[C_{\nu_1},C_{\nu_2}],[D_{\nu_3},C_{\nu_4}]]. \tag{70}$$

[The proof of Eqs. (68)–(70) are straightforward calculation which we skip.]

We see that, $\mathcal{P}_{R,1}$ equals $\frac{1}{2}(\mathcal{F}^+_{\mu\nu}(\mathcal{F}^+)^{\mu\nu}+\mathcal{F}^-_{\mu\nu}(\mathcal{F}^-)^{\mu\nu})$ with $\mathcal{F}^\pm_{\mu\nu}$ defined in Eq. (15). The remaining terms are linear combinations of commutators! Using the cyclicity of the matrix trace we thus obtain

$$\mathrm{tr}_N\mathcal{P}_{R,2}=\partial^\mu\mathrm{tr}_N J_\mu,\quad \mathrm{tr}_N\mathcal{P}_I=0. \tag{71}$$

This implies Eqs. (14)–(20) and completes our computation. □

Remark: Note that $\mathcal{P}_R$ and $\mathcal{P}_I$ are not differential operators but polynomials [i.e., there are no terms $(\cdots)D_\mu$]. This implies that both these terms are gauge covariant which, as we believe, is remarkable.

V. CONCLUSIONS

The regularization which we used was simple but not manifestly gauge invariant. For the result computed in this paper the latter property is irrelevant: since the logarithmic divergence is regularization dependent one can compute it using any regularization. However, we believe that our method is useful even for computing the finite part of the effective action, i.e., $S^{(0)}(A)$ in Eq. (4). We stress again that the simplified IR regularization used in the main text is not appropriate in this computation but the formulas given in Appendix B should be used. We conjecture that $S^{(0)}(A)$ computed in this way is gauge invariant.

As mentioned in the Remark at the end of Sec. 3, we defined a renormalized trace $\mathrm{TR}_{|\mathsf{D}_0|}$ using the free Dirac operator D_0. More general we could use the Dirac operator D_B with some fixed nontrivial Yang–Mills field B. In particular, we expect that the standard ζ-function regularization of the logarithm of the determinant of D_A should be identical with

$$\mathrm{TR}_{|\mathsf{D}_A|}\log\left(\frac{\mathsf{D}_A+\mathrm{i}m}{\Lambda_0}\right),$$

where the regularization function is $f(t)=\exp(-t^2)$. The latter definition has the advantage that it is manifestly gauge invariant, but it seems less easy to use for explicit computations as ours. It is natural to expect that the difference between the latter definition and $S^{(0)}(A)$ in Eq. (4) is also proportional to $S_{\log}(A)$.

Effective action computations are used in many applications of quantum field theory. We believe that the methods which we presented should be useful in other such contexts as well.

APPENDIX A: MORE ON REGULARIZED TRACES

In this Appendix we outline elementary proofs of some facts about regularized traces stated in the main text.

1. The logarithmic divergence

We compute the regularized trace in Eq. (36) for an operator a with a symbol allowing for an asymptotic expansion as in Eq. (27). It is easy to see that the contribution of $\sigma_k[a](p,x)$ to $\mathrm{Tr}_\Lambda(a)$ is

$$\int_0^\infty d|p||p|^{k+3} f\left(\frac{|p|}{\Lambda}\right) \int_{\mathbb{R}^4} \frac{\mathrm{d}^4\xi}{(2\pi)^4}\, \delta(|\xi|-1) \int_{\mathbb{R}^4} d^4x\, \mathrm{tr}\sigma_k[a](\xi,x),$$

where we used the homogeneity of $\sigma_k[a]$. Changing variables, $|p|\to u=|p|/\Lambda$, and comparing with Eq. (33) we see that for all $k\geqslant -3$

$$c_{k+4}(a)=N_k \int_{\mathbb{R}^4} \frac{\mathrm{d}^4\xi}{(2\pi)^4}\, \delta(|\xi|-1)\, \mathrm{tr}\sigma_k[a](\xi,x), \tag{A1}$$

with $N_k=\int_0^\infty \mathrm{d}u u^{k+3} f(u)$ constants depending on f. For $k=-4$ the computation above does not make sense (the constant N_{-4} diverges), but we can compute $c_{\log}(a)$ as follows. We first subtract from the symbol of a the diverging part which we already accounted for and define

$$\sigma^\perp_{-3}[a](p,x) := \sigma[a](p,x) - \sum_{j=0}^{K+3} \sigma_{K-j}[a](p,x) = \sigma_{-4}[a](p,x) + \mathcal{O}(|p|^{-5}). \tag{A2}$$

Equation (33) then suggests that

$$c_{\log}(a) = \lim_{\Lambda\to\infty} \frac{1}{\log(\Lambda)} \int_{\mathbb{R}^4} \frac{\mathrm{d}^4p}{(2\pi)^4} f\left(\frac{|p|}{\Lambda}\right) \int_{\mathbb{R}^4} d^4x\, \mathrm{tr}\, \sigma[a]^\perp_{-3}(p,x).$$

Computing this using L'Hospital's rule we obtain

$$\begin{aligned} c_{\log}(a) &= \lim_{\Lambda\to\infty} \Lambda \int_{\mathbb{R}^4} \frac{\mathrm{d}^4p}{(2\pi)^4} f'\left(\frac{|p|}{\Lambda}\right)\left(-\frac{|p|}{\Lambda^2}\right) \int_{\mathbb{R}^4} d^4x\, \mathrm{tr}\, \sigma[a]^\perp_{-3}(p,x) \\ &= \lim_{\Lambda\to\infty} \left(\int_{\mathbb{R}^4} \frac{\mathrm{d}^4p}{(2\pi)^4} \left(-f'\left(\frac{|p|}{\Lambda}\right)\frac{|p|}{\Lambda}\right) \int_{\mathbb{R}^4} d^4x\, \mathrm{tr}\, \sigma[a]_{-4}(p,x) + \mathcal{O}(\Lambda^{-1}) \right). \end{aligned}$$

Changing variables etc. as above and using $\int_0^\infty du(-f'(u))=f(0)=1$ (independent of f!) we obtain

$$c_{\log}(a) = \int_{\mathbb{R}^4} \frac{\mathrm{d}^4\xi}{(2\pi)^4}\, \delta(|\xi|-1) \int_{\mathbb{R}^4} d^4x\, \mathrm{tr}\sigma_{-4}(a)(\xi,x). \tag{A3}$$

Recalling Eq. (34) we obtain Eq. (35). □

2. Renormalized traces

It is obvious that changing the regularization functions $f(t)\to\tilde{f}(t)=f(t/s)$ for some fixed $s>0$, amounts to changing $\Lambda\to s\Lambda$, and thus changes $c^{(0)}\to c^{(0)}+\log(s)\,c_{\log}$. Thus (33) is obvious for this special case. For more general changes $f(t)\to\tilde{f}(t)$ of the regularization function, Eq. (33) can be shown using

$$\int_{\mathbb{R}^4}\frac{\mathrm{d}^4p}{(2\pi)^4}f\left(\frac{|p|}{\Lambda}\right)\int_{\mathbb{R}^4}d^4x\,\mathrm{tr}\,\sigma[a]^{\perp}_{-3}(p,x)=c_{\log}(a)\log\left(\frac{\Lambda}{|m|}\right)+c^{(0)}(a)+\mathcal{O}(\Lambda^{-1}),$$

which follows from our discussion above.

APPENDIX B: COMPUTATION DETAILS

In this Appendix we present some details concerning our computations discussed in the main text. In particular, we give explicit formulas for the Dirac matrices, and we also show show how to compute the structure constants $\mathcal{M}_n$ in Eq. (49) exactly, i.e., without the simplified IR regularization. We also prove the Lemma in Sec. IV A and Eq. (55), and we give some details about the computation yielding Eq. (64).

1. Dirac matrices

A convenient representation for the Dirac matrices is as follows:

$$\gamma^j=\begin{pmatrix}\mathbf{0}&\sigma_j\\ \sigma_j&\mathbf{0}\end{pmatrix},\quad j=1,2,3,\quad \gamma^4=\begin{pmatrix}\mathbf{0}&\mathrm{i}\mathbf{1}\\ -\mathrm{i}\mathbf{1}&\mathbf{0}\end{pmatrix},\quad \gamma_5=\begin{pmatrix}\mathbf{1}&\mathbf{0}\\ \mathbf{0}&-\mathbf{1}\end{pmatrix},\tag{B1}$$

where $\mathbf{1}$ and $\mathbf{0}$ are the 2×2 unit- and zero matrices and

$$\sigma_1=\begin{pmatrix}0&1\\1&0\end{pmatrix},\quad \sigma_2=\begin{pmatrix}0&-\mathrm{i}\\ \mathrm{i}&0\end{pmatrix},\quad \sigma_3=\begin{pmatrix}1&0\\0&-1\end{pmatrix},$$

the Pauli sigma matrices as usual.

2. Details about the gradient expansion

We start by rewriting the $\mathcal{M}_n$ in a convenient form. We define

$$P_\varepsilon:=\frac{1}{2}\left(1+\varepsilon\frac{\not{p}}{|p|}\right),\quad \varepsilon=\pm,\tag{B2}$$

which are orthogonal projections, $P_\varepsilon P_{-\varepsilon}=0$ and $P_\varepsilon^2=P_\varepsilon$, satisfying $P_++P_-=1$. We then can write

$$(1-u\not{p})^{-1}=\sum_{\varepsilon=\pm}P_\varepsilon\frac{1}{1+u\dfrac{\varepsilon|p|+\mathrm{i}m}{\Lambda_0}},$$

which we insert $n+1$ times in Eq. (49)

$$\mathcal{M}^{\nu_1\cdots\nu_n}_{n;s_1\cdots s_n}=(\Lambda_0)^{-n}\int_{|p|\leqslant\Lambda}\frac{\mathrm{d}^4p}{(2\pi)^4}\int_0^\infty \mathrm{d}u\,u^{n-1}$$
$$\times\sum_{\varepsilon_1,\ldots,\varepsilon_{n+1}=\pm}\left(\prod_{j=1}^{n+1}\frac{1}{1+u\dfrac{\varepsilon_j|p|+\mathrm{i}m}{\Lambda_0}}\right)\mathrm{tr}_\nu(P_{\varepsilon_1}\gamma_{s_1}^{\nu_1}P_{\varepsilon_2}\cdots\gamma_{s_n}^{\nu_n}P_{\varepsilon_{n+1}}).$$

We thus obtain

$$\mathcal{M}^{\nu_1\cdots\nu_n}_{n;s_1\cdots s_n}=\sum_{\varepsilon_1,\ldots,\varepsilon_{n+1}=\pm}\mathcal{I}_{n;\varepsilon_1,\ldots,\varepsilon_{n+1}}\mathrm{tr}_\nu\langle P_{\varepsilon_1}\gamma_{s_1}^{\nu_1}P_{\varepsilon_2}\cdots\gamma_{s_n}^{\nu_n}P_{\varepsilon_{n+1}}\rangle, \tag{B3}$$

with

$$\mathcal{I}_{n;\varepsilon_1,\ldots,\varepsilon_{n+1}}=\mathcal{I}_{n;k},\quad k\ \text{ such that }\ \sum_{j=1}^{n+1}\varepsilon_j=n+1-2k \tag{B4}$$

and

$$\mathcal{I}_{n;k}=(\Lambda_0)^{-n}\frac{1}{8\pi^2}\int_0^\Lambda \mathrm{d}|p||p|^3\int_0^\infty \mathrm{d}u\,u^{n-1}\left(\frac{1}{1+u\dfrac{|p|+\mathrm{i}m}{\Lambda_0}}\right)^{n+1-k}\left(\frac{1}{1+u\dfrac{-|p|+\mathrm{i}m}{\Lambda_0}}\right)^{k}.$$

Rescaling $u\Lambda/\Lambda_0\to u$ and introducing $\xi=|p|/\Lambda$ yields

$$\mathcal{I}_{n;k}=(\Lambda)^{4-n}\frac{1}{8\pi^2}\int_0^1 \mathrm{d}\xi\xi^3\int_0^\infty \mathrm{d}u\,u^{n-1}\left(\frac{1}{1+u\left[\xi+\mathrm{i}\dfrac{m}{\Lambda}\right]}\right)^{n+1-k}\left(\frac{1}{1+u\left[-\xi+\mathrm{i}\dfrac{m}{\Lambda}\right]}\right)^{k}. \tag{B5}$$

Proof of the Lemma in Sec. IV A: We note that

$$\mathrm{tr}_\nu\langle P_{\varepsilon_1}\gamma_{s_1}^{\nu_1}P_{\varepsilon_2}\cdots\gamma_{s_n}^{\nu_n}P_{\varepsilon_{n+1}}\rangle=:T^\nu_{\underline{\varepsilon},\underline{s}},$$

is invariant under $\varepsilon_j\to-\varepsilon_j$ [since the latter transformation amounts to the variable change $\xi\to-\xi$ in the integral Eq. (54) defining the angular average]. Moreover, the cyclicity of trace and $\gamma_5^2=1$ implies that $T^\nu_{\underline{\varepsilon},\underline{s}}$ does not change if we replace all P_{ε_j} and $\gamma_{s_j}^{\nu_j}$ by $\gamma_5P_{\varepsilon_j}\gamma_5$ and $\gamma_5\gamma_{s_j}^{\nu_j}\gamma_5$, respectively. Using $\gamma_5P_\varepsilon\gamma_5=P_{-\varepsilon}$ and $\gamma_5\gamma_s^\nu\gamma_5=-\gamma_s^\nu$ we obtain $T^\nu_{\underline{\varepsilon},\underline{s}}=(-1)^nT^\nu_{-\underline{\varepsilon},\underline{s}}$, and using $T^\nu_{-\underline{\varepsilon},\underline{s}}=T^\nu_{\underline{\varepsilon},\underline{s}}$ this proves that $T^\nu_{\underline{\varepsilon},\underline{s}}$— and thus $\mathcal{M}_n$ in Eq. (49)—is nonzero only for even n.

From Eq. (B4) it is obvious that $\varepsilon_j\to-\varepsilon_j$ corresponds to $k\to n+1-k$, and thus $T^\nu_{\underline{\varepsilon},\underline{s}}=T^\nu_{-\underline{\varepsilon},\underline{s}}$ implies that we can replace $\mathcal{I}_{n;k}$ by $[\mathcal{I}_{n;k}+\mathcal{I}_{n;n+1-k}]/2$ in Eq. (B3). We can write the latter as a sum of the terms which are even and odd under the change of the sign of the mass $m\to-m$. A simple change of variables shows that u-integrals in the odd term

$$\tfrac{1}{4}[\mathcal{I}_{n;k}(m)+\mathcal{I}_{n;n+1-k}(m)-\mathcal{I}_{n;k}(-m)-\mathcal{I}_{n;n+1-k}(-m)],$$

can be written as follows (n even):

$$\frac{1}{4}\int_{-\infty}^\infty \mathrm{d}u\,u^{n-1}\left(\frac{1}{1+u\left[\xi+\mathrm{i}\dfrac{m}{\Lambda}\right]}\right)^{n+1-k}\left(\frac{1}{1+u\left[-\xi+\mathrm{i}\dfrac{m}{\Lambda}\right]}\right)^{k},$$

plus the same integral but with k and $n+1-k$ interchanged. The latter integrals can be computed using Cauchy's theorem: The poles of the integrand are in $u=-1/(\xi+\mathrm{i}m/\Lambda)$ and $u=1/(\xi-\mathrm{i}m/\Lambda)$ and thus both always in the same half of the complex u-plane (upper or lower, depending on the sign of m). Computing the integral by closing the integration path in the half plane where the integrand is analytic (which is possible since the integrand vanishes like $\mathcal{O}(|u|^{-2})$ for $|u|\to\infty$) one sees that the integral is zero. This implies $\mathcal{M}_n(-m)=\mathcal{M}_n(m)$. □

Proof of Eq. (55): Our discussion above implies that we can replace $\mathcal{I}_{n;k}$ in Eq. (B3) by $\Re\mathcal{I}_{n;k}=[\mathcal{I}_{n;k}(m)+\mathcal{I}_{n;k}(-m)]/2$.

We are interested in the terms which diverge for $\Lambda\to\infty$. To isolate them it is convenient to determine $\partial\mathcal{M}_n/\partial\Lambda$. We thus compute

$$\frac{\partial}{\partial\Lambda}\Re\mathcal{I}_{n;k}=\Lambda^{3-n}\frac{1}{8\pi^2}I_{n,k}\left(\frac{m}{\Lambda}\right), \tag{B6}$$

where we introduced the functions

$$I_{n,k}(\eta)=\Re\int_0^\infty \mathrm{d}u\,u^{n-1}\left(\frac{1}{1+u[1+\mathrm{i}\eta]}\right)^{n+1-k}\left(\frac{1}{1+u[-1+\mathrm{i}\eta]}\right)^{k}. \tag{B7}$$

Note that the functions $I_{n,k}(\eta)$ are well-defined for all real $\eta\neq 0$, have a finite limit $I_{n,k}(0^+)$ as $\eta\to 0$, and they have series expansions in η^2. [To see this note that $I_{n,k}(\eta)=\Re\int_0^\infty \mathrm{d}s(1/(s+1+\mathrm{i}\eta))^{n+1-k}(1/(s-1+\mathrm{i}\eta))^k$.]

It is easy to see that with the simplified regularization used in the main text we can obtain a formula for $\tilde{\mathcal{M}}^{\nu_1\cdots\nu_n}_{n;s_1\cdots s_n}$ as in Eqs. (B3) and (B4) but with $\mathcal{I}_{n;k}$ replaced by

$$\tilde{\mathcal{I}}_{n;k}=\frac{1}{8\pi^2}\int_0^\Lambda \mathrm{d}|p||p|^{3-n}I_{n;k}(0^+). \tag{B8}$$

We thus get

$$\frac{\partial}{\partial\Lambda}(\mathcal{I}_{n;k}-\tilde{\mathcal{I}}_{n;k})=\frac{1}{8\pi^2}\Lambda^{3-n}\left(I_{n;k}\left(\frac{m}{\Lambda}\right)-I_{n;k}(0^+)\right)=\mathcal{O}(m^2\Lambda^{1-n}), \tag{B9}$$

which proves Eq. (55). □

Remark: We now can explain the reason for our choice $\Lambda_0=|\Lambda_0|/(1+\mathrm{i}0^+)$ in the main text: This yields a regularization specifying the otherwise undefined integrals $I_{n;k}(0)$, and from Eq. (B9) it is clear that this is the regularization yielding a result identical with the one obtained with the proper regularization, up to lower order terms.

Computation of $\boldsymbol{\mathcal{S}}_2$: For $n=2$ we need to compute $\mathcal{M}_2$ in Eq. (49) exactly, using the formulas given above.

Similarly as explained in the main text we compute [cf. Eq. (B3)]

$$\mathrm{tr}_\nu\langle P_{\varepsilon_1}\gamma_{s_1}^{\nu_1}P_{\varepsilon_2}\cdots\gamma_{s_2}^{\nu_2}P_{\varepsilon_3}\rangle=\delta_{\varepsilon_1,\varepsilon_3}\eta^{\nu_1\nu_2}(1-\varepsilon_1\varepsilon_2(-1)^{s_1}).$$

Moreover, the integrals defined in Eq. (B7) for $n=2$ and $k=0,1$ are

$$I_{2,0}(\eta)=\Re\frac{1}{2(1+\mathrm{i}\eta)^2}=\frac{1}{2}-\frac{3}{2}\eta^2+\mathcal{O}(\eta^4),$$

$$I_{2,1}(\eta)=\Re\frac{1}{4(1+\mathrm{i}\eta)}\left((1+\mathrm{i}\eta)\log\left(\frac{1+\mathrm{i}\eta}{1-\mathrm{i}\eta}\right)-2\right)=\frac{1}{2}+\frac{1}{2}\eta^2+\mathcal{O}(\eta^4),$$

and with Eqs. (B6), (B3), and (B4) we can compute $\partial\mathcal{M}_2/\partial\Lambda$. Straightforward computations yield

$$\mathcal{M}^{\nu_1\nu_2}_{2;s_1s_2} = \delta_{s_1s_2}\eta^{\nu_1\nu_2}\frac{1}{16\pi^2}\left(\Lambda^2 A_{s_1s_2} + m^2\log\left(\frac{\Lambda}{|m|}\right)A^{(0)}_{s_1s_2} + \mathcal{O}(\Lambda^0)\right),$$

$$A_{55} = -A_{00} = 1, \quad A^{(0)}_{55} = -2, \quad A^{(0)}_{00} = 0, \tag{B10}$$

and with Eq. (50) we obtain Eqs. (63)–(64).

(Received 14 March 2001; accepted for publication 17 August 2001)

In this paper some properties of the irreducible multiplets of representation for the $N=(p,q)$-extended supersymmetry in one dimension are discussed. Essentially two results are presented. At first a peculiar property of the one dimension is exhibited, namely that any multiplet containing $2d$ (d bosonic and d fermionic) particles in M different spin states is equivalent to a $\{\mathbf{d},\mathbf{d}\}$ multiplet of just two spin states (all bosons and all fermions being grouped in the same spin). Later, it is shown that the classification of all multiplets of this kind carrying an irreducible representation of the N-extended supersymmetry is in one-to-one correspondence with the classification of real-valued Clifford Γ-matrices of Weyl type. In particular, $p+q$ is mapped into D, the space–time dimensionality, while $2d$ is determined to be the dimensionality of the corresponding Γ-matrices. The implications of these results to the theory of spinning particles are analyzed. © *2001 American Institute of Physics.* [DOI: 10.1063/1.1409349]

I. INTRODUCTION

Recently we have assisted in renewing interest in the theory of supersymmetric and superconformal quantum mechanics due to different physical motivations and viewpoints. Supersymmetric and superconformal[1] (see also Ref. 2) quantum mechanical models succeed in describing the low-energy effective dynamics, as well as the moduli space, of a certain class of black holes. Particle models with extended world-line supersymmetries naturally describe the related geometries, see Ref. 3. Another scenario involving supersymmetric quantum mechanics (SQM) concerns the light–cone quantization of supersymmetric theories.[4] Besides that, SQM models offer a natural setup for testing, under a rigorous mathematical framework, some conjectures (like the AdS/CFT correspondence for AdS_2) or properties and consequences of dimensionally reduced supersymmetric field theories[5] and such phenomena as their spontaneous supersymmetry breaking,[6,7] including the partial breaking.[8,9] Having this in mind, the importance of the investigation of large N-extended (SQM) models cannot be overestimated. Indeed, since the reduced version to a one (temporal) dimension of a supersymmetric $4d$ theory gets four times the number of supersymmetries of the original model, $N=2,4$ super-Yang–Mills are reduced to, respectively, $N=8$ and $N=16$ SQM models, while the $N=8$ supergravity is associated with the $N=32$ SQM theory.

However, not much attention has been paid to such large-N SUSY quantum models and only partial results are known.[10,5] The reason however is clear—$N=4$ is the largest number of extended supersymmetry for which a superfield formalism is known. Investigating the $N>4$ case requires the use of component fields and computations soon become cumbersome.

In this paper we attack the problem of investigating large N SQM models from a different

[a)]Electronic mail: pashnev@thsun1.jinr.ru
[b)]Electronic mail: toppan@cbpf.br

viewpoint. We are able to classify the irreducible multiplets of representations of the N extended supersymmetry. We prove at first that all such multiplets are associated with fundamental short multiplets in which all bosons and all fermions are accommodated into just two spin states. As a consequence of that, differently presented dynamical systems turn out to be expressions of the same algebraic structure. Later, we give the full classification of the short multiplets. We further mention how the above-mentioned results find application to the theory of the particles with spin.

The closest references to the results presented here are given in Refs. 11 and 12 in which the classification of (in our language) the short multiplets for the Euclidean supersymmetry was derived, i.e., representations of the (1.2) algebra with positive eigenvalues only. See also Ref. 13 for explicit constructions of multiplets of extended supersymmetries.

In our work we further prove that all multiplets fit into equivalence classes characterized by the short multiplets. Besides that, we extend the classification of Refs. 11 and 12 to the pseudo-Euclidean supersymmetry [arbitrary signatures of the eigenvalues of the ω_{ij} matrix in formula (1.2)]. Indeed, as we will prove in the following, it is in this larger class that symmetries of the particles with spin moving in a Minkowskian or AdS-like background should be looked for. The analysis which follows is based on the results for the classification of real-valued Clifford algebras as presented in Ref. 14.

It is well known that the SQM, being the simplest example of a theory which includes simultaneously commuting and anticommuting variables, realizes as its symmetry group the one-dimensional supersymmetry. In general this supersymmetry is generated by N supercharges $Q_i, i=1,2,\ldots,N$ and the Hamiltonian

$$H=-i\frac{\partial}{\partial t} \tag{1.1}$$

with the following algebra:

$$\{Q_i,Q_j\}=\omega_{ij}H, \tag{1.2}$$

where the constant tensor ω_{ij} has p positive and q negative eigenvalues. Usually all eigenvalues are positive and the above-mentioned algebra is named the N-extended one-dimensional supersymmetry. Nevertheless, in general, reasons can exist leading to an indefinite tensor ω_{ij}.[15] In the following, without loss of generality, the algebra of supercharge Q_i's will be conveniently diagonalized and normalized in such a way that the tensor ω_{ij} can be expressed as

$$\omega_{ij}=\eta_{ij}, \tag{1.3}$$

where η_{ij} is a pseudo-Euclidean metric with the signature (p,q).

The representation of the algebra (1.2) is formed by commuting (Bosonic) and anticommuting (Fermionic before the quantization and Clifford after it) variables. Some of them are true physical variables, others play an auxiliary role. Usually all these variables are taken to be the components of irreducible superfields.

The simplest way to construct a classical Lagrangian for the SQM in D dimensions is to consider the superfields $(A=1,2,\ldots,D)$,

$$\Phi_A(\tau,\eta^\alpha)=\Phi^0_A(\tau)+\eta^\alpha\Phi^1_{A\alpha}(\tau)+\eta^{\alpha_1}\eta^{\alpha_2}\Phi^2_{A\alpha_1\alpha_2}(\tau)+\cdots+\eta^{\alpha_1}\eta^{\alpha_2}\cdots\eta^{\alpha_N}\Phi^N_{A\alpha_1\alpha_2\cdots\alpha_N}(\tau), \tag{1.4}$$

in the superspace (τ,η^α) with one bosonic coordinate τ and N Grassmann coordinates η^α. Such superfields for general N are highly reducible and only lower values of N were investigated in detail. The first components of the superfields are the usual bosonic coordinates $\Phi^0_A(\tau)$, the next ones $\Phi^1_{A\alpha}(\tau)$ are the Grassmann coordinates. All the other components of the superfields are auxiliary. So, the classical Lagrangian of the SQM describes the evolution of bosonic and addi-

tional Grassmann degrees of freedom, which after quantization become generators of the Clifford algebra. This fact naturally leads to the matrix realization of the Hamiltonian and supercharges of SQM.[6,16,17]

The dimensionality of such realization depends on the total number of Grassmann variables. In the case of scalar superfields (1.4) the dimensionality is $2^{[DN/2]}$. So, it rapidly grows for extended supersymmetry. The way out of this difficulty is to use more complicated representations of the extended supersymmetry.[18–23] The simplest of them is given by the chiral superfield, which contains one complex bosonic and $N/2$ complex Grassmann fields. The Lagrangian for such superfield naturally describes the two-dimensional SQM. The ratio of numbers (Fermi/boson) in this case is $N/2$ instead of N as for scalar superfields. For more complicated representations this ratio grows even more slowly.[19–23] This fact has an essential influence on the dimensionality of the matrix realizations of the Hamiltonian and supercharges—they are smaller for the same number of bosonic coordinates Φ^0_A. The distinguishing feature of such representations is the fact that the lowest components $\Phi^0_A(\tau)$ $(A=1,2,\ldots,D)$ of the superfields (1.4) *all together* form an irreducible representation of some subgroup of the automorphism group of the algebra (1.2). The corresponding actions are also invariant under the transformations of this subgroup, which thus plays the role of space (or space–time) rotations. In particular the inclusion of the time coordinate $t(\tau)$ along with the space ones $x^a(\tau)$ in an irreducible representation $\Phi^0_A(\tau)$ of such subgroup means that such a subgroup, as well as the whole automorphism group of the algebra (1.2), is pseudo-Euclidean.[15] In consequence of that the metric tensor η_{ij} in (1.3) is pseudo-Euclidean too.

So, the number of bosonic and fermionic physical components and, correspondingly, the dimensionality of quantum Hamiltonian and supercharges realized as matrices, crucially depend on the choice of the irreducible superfield or, equivalently, irreducible representation of the algebra (1.2). In this sense the classification of all such representations is very useful.

II. THE EQUIVALENCE RELATIONS

In this section we analyze the structure of the supermultiplets of the N-extended supersymmetry in one-dimensional space. We will show in which sense all irreducible representations are equivalent to the representations with a definite structure of the multiplets. To fix the notation, let N denote the number of extended supersymmetries and $2d$ (d bosons and d fermions) the dimensionality of the corresponding multiplet, (may be reducible), carrying the N-extended SUSY representation. In general such multiplet can be represented in the form of a chain

$$\Phi^0_{a_0}, \quad \Phi^1_{a_1},\ldots,\Phi^{M-1}_{a_{M-1}}, \quad \Phi^M_{a_M} \tag{2.1}$$

whose components $\Phi^I_{a_I}$, $(a_I=1,2,\ldots,d_I)$ are real. All the components with even I have the same Grassmann parity as that of $\Phi^0_{a_0}$, while the components with odd values of I have the opposite one. Such structure of the multiplet is closely related to the superfield representations; the upper index I, numbering the elements of the chain, corresponds to their place in the superfield expansion (1.4) or to their dimensionality which decreases by 1/2 at each step along the chain if one chooses

$$\dim(\tau)=1, \quad \dim(\eta)=\tfrac{1}{2}. \tag{2.2}$$

The number $M+1$ is the length of the supermultiplet, M being subjected to the constraint $M \leqslant N$ since, for example in the case of irreducible representations, not all the components of the superfield (1.4) are independent—some of the higher components are expressed in terms of time derivatives of the lower ones.

For the supermultiplet (2.1) we will also use the short notation $\{\mathbf{d_0},\mathbf{d_1},\ldots,\mathbf{d_M}\}$. As an example, in the case of $N=2$ one can consider the irreducible representations $\{\mathbf{1},\mathbf{2},\mathbf{1}\}$ (real superfield)

$$\Phi=\Phi(\tau,\eta_1,\eta_2)=\Phi^0(\tau)+i\,\eta^\alpha\Phi^1_\alpha(\tau)+i\,\eta^1\eta^2\Phi^2(\tau), \tag{2.3}$$

and $\{\mathbf{2},\mathbf{2}\}$ (chiral superfield)

$$\tilde{\Phi}(\tau,\eta,\overline{\eta})=\tilde{\Phi}^0(\tau)+\eta\tilde{\Phi}^1(\tau)+\frac{i}{2}\overline{\eta}\eta\dot{\tilde{\Phi}}^0(\tau), \tag{2.4}$$

where $\eta=\eta_1+i\,\eta_2$, $\overline{\eta}=\eta_1-i\,\eta_2$ are complex Grassmann coordinates. The last component in expression (2.4) is proportional to the time derivative of the first one. Both $\tilde{\Phi}^0(\tau)$ and $\tilde{\Phi}^1(\tau)$ in (2.4) are complex. Obviously, in both cases (2.3) and (2.4), $\Sigma_I\,d_I=2$ separately for real bosonic and fermionic components.

Due to dimensionality arguments the supersymmetry transformation law for the components $\Phi^I_{a_I}$ is of the following form (ε^i are infinitesimal Grassmann parameters):

$$\delta_\varepsilon\Phi^I_{a_I}=\varepsilon^i(C^I_i)_{a_I}{}^{a_{I+1}}\Phi^{I+1}_{a_{I+1}}+\varepsilon^i(\tilde{C}^I_i)_{a_I}{}^{a_{I-1}}\frac{d}{d\tau}\Phi^{I-1}_{a_{I-1}}. \tag{2.5}$$

Evidently, due to the absence in (2.1) of the components with $I=-1$, $I=M+1$, the transformation laws for the end components of the chain are simpler:

$$\delta_\varepsilon\Phi^0_{a_0}=\varepsilon^i(C^0_i)_{a_0}{}^{a_1}\Phi^1_{a_1},\quad \delta_\varepsilon\Phi^M_{a_M}=\varepsilon^i(\tilde{C}^M_i)_{a_M}{}^{a_{M-1}}\frac{d}{d\tau}\Phi^{M-1}_{a_{M-1}}. \tag{2.6}$$

The transformation law for the last component of the multiplet reads that it transforms as a total derivative. It is a very essential property, because the integral of this component is invariant under the supersymmetry transformations and can be used to construct invariant actions.

Another very important consequence of the transformation law of the last components is present only in one dimension. Just in this case one can redefine this component

$$\Phi^M_{a_M}=\frac{\mathrm{d}}{\mathrm{d}\tau}\Psi^{M-2}_{a_M} \tag{2.7}$$

in terms of some functions $\Psi^{M-2}_{a_M}$. This correspondence is exact up to some constants $C^M_{a_M}$ which describe the trivial representations of the supersymmetry algebra. The dimensionality of the new components $\Psi^{M-2}_{a_M}$ coincides with the dimensionality of the components $\Phi^{M-2}_{a_{M-2}}$. Moreover, their transformation law is of the same type—they transform through the components $\Phi^{M-1}_{a_{M-1}}$ and $\Phi^{M-3}_{a_{M-3}}$ (with vanishing coefficients before the time derivative of the latter),

$$\delta_\varepsilon\Psi^{M-2}_{a_M}=\varepsilon^i(\tilde{C}^M_i)_{a_M}{}^{a_{M-1}}\Phi^{M-1}_{a_{M-1}}. \tag{2.8}$$

So, we have shown that up to trivial representations of the supersymmetry algebra the supermultiplet $\{\mathbf{d_0},\mathbf{d_1},\ldots,\mathbf{d_{M-2}},\mathbf{d_{M-1}},\mathbf{d_M}\}$ is equivalent to the supermultiplet $\{\mathbf{d_0},\mathbf{d_1},\ldots,\mathbf{d_{M-2}}+\mathbf{d_M},\mathbf{d_{M-1}},\mathbf{0}\}$. It means that the initial supermultiplet of length $M+1$ is equivalent to a shorter multiplet of length M. Evidently, the total number of bosonic and fermionic components in both supermultiplets is the same. This procedure can obviously be repeated $M-1$ times, so that at the end one reaches the shortest multiplet of length 2—the multiplet $\{\mathbf{d},\mathbf{d}\}$.

The simplest example of such shortening of the length is given in the case of $N=2$. The component $\Phi^2(\tau)$ in the real superfield (2.3) transforms as a total derivative of some new field $\Psi^0(\tau)$ which, together with $\Phi^0(\tau)$, forms the complex $\tilde{\Phi}^0(\tau)$ of (2.4). A more complicated example is furnished by the $N=4$ representation multiplets $\{\mathbf{1},\mathbf{4},\mathbf{3}\}$, $\{\mathbf{2},\mathbf{4},\mathbf{2}\}$, and $\{\mathbf{3},\mathbf{4},\mathbf{1}\}$ which were used in Refs. 19, 20, and 8 for one-dimensional,[23] two-dimensional,[21,22] and three-dimensional

SQM, respectively. The corresponding components of these representations are interconnected by the transformation (2.7). To our knowledge, the multiplet (4,4) which should be useful in the four-dimensional case was not considered in the literature.

In principle, one can consider the inverse procedure—the lengthening of the multiplet starting from the one for $\{\mathbf{d},\mathbf{d}\}$. Only the first step is trivial—the transition from the $\{\mathbf{d},\mathbf{d}\}$ multiplet to the $\{\mathbf{d}-\mathbf{d_1},\mathbf{d},\mathbf{d_1}\}$ multiplet can always be done with the help of the transformation inverse to (2.7) applied to an arbitrary number $d_1 \leqslant d$ of the first components of the initial multiplet. The possibility of further lengthening must be analyzed separately in each particular case and will be shortly discussed at the end of the paper.

It should be noticed that $d_1 = d$ is allowed. The corresponding transformation links two length-2 multiplets, the one in which bosons have higher spin, to the one in which fermions have higher spins. Explicitly we have

$$\delta_\varepsilon \Phi_a = \varepsilon^i (C_i)_a^{\ b} \Psi_b, \quad \delta_\varepsilon \Psi_a = \varepsilon^i (\tilde{C}_i)_a^{\ b} \frac{\mathrm{d}}{\mathrm{d}\tau} \Phi_b, \tag{2.9}$$

while for $\Xi_a = (\mathrm{d}/\mathrm{d}\tau)\,\Psi_a$ we get

$$\delta_\varepsilon \Xi_a = \varepsilon^i (C_i)_a^{\ b} \Phi_b, \quad \delta_\varepsilon \Phi_a = \varepsilon^i (\tilde{C}_i)_a^{\ b} \frac{\mathrm{d}}{\mathrm{d}\tau} \Xi_b. \tag{2.10}$$

We finally comment that, due to the previous considerations, the classification of all supermultiplets of length 2 automatically provides the classification of all supermultiplets of length 3. In many physical applications of interest, this is quite sufficient.

III. EXTENDED SUPERSYMMETRIES AND REAL-VALUED CLIFFORD ALGEBRAS

The main result of Sec. II is that the problem of classifying all N-extended supersymmetric quantum mechanical systems is reduced to the problem of classifying the irreducible representations (2.1) of length 2. Having this in mind we simplify the notations. Let the indices $a, \alpha = 1,\ldots,d$ number the bosonic (and, respectively, fermionic) elements in the SUSY multiplet. All of them are assumed to depend on the time coordinate τ ($X_a \equiv X_a(\tau)$, $\theta_\alpha \equiv \theta_\alpha(\tau)$).

In order to be definite and without loss of generality let us take the bosonic elements to be the first ones in the chain $\{\mathbf{d},\mathbf{d}\}$, which can be conveniently represented also as a column

$$\Psi = \begin{pmatrix} X_a \\ \theta_\alpha \end{pmatrix}. \tag{3.1}$$

Equation (2.5) is reduced to the following set of equations:

$$\begin{aligned} \delta_\varepsilon X_a &= \varepsilon^i (C_i)_a^{\ \alpha} \theta_\alpha \equiv i(\varepsilon^i Q_i \Psi)_a, \\ \delta_\varepsilon \theta_\alpha &= \varepsilon^i (\tilde{C}_i)_\alpha^{\ b} \frac{\mathrm{d}}{\mathrm{d}\tau} X_b \equiv i(\varepsilon^i Q_i \Psi)_\alpha, \end{aligned} \tag{3.2}$$

where, as a consequence of (1.2),

$$C_i \tilde{C}_j + C_j \tilde{C}_i = i\,\eta_{ij} \tag{3.3}$$

and

$$\tilde{C}_i C_j + \tilde{C}_j C_i = i\,\eta_{ij}. \tag{3.4}$$

Since $\varepsilon_i, X_a, \theta_\alpha$ are real, the matrices C_i, $\tilde{C}_i$ have to be imaginary and real, respectively. If we set (just for normalization)

$$C_i=\frac{i}{\sqrt{2}}\sigma_i,$$
$$\tilde{C}_i=\frac{1}{\sqrt{2}}\tilde{\sigma}_i \tag{3.5}$$

and accommodate $\sigma_i,\tilde{\sigma}_i$ into a single matrix

$$\Gamma_i=\begin{pmatrix}0 & \sigma_i\\ \tilde{\sigma}_i & 0\end{pmatrix}, \tag{3.6}$$

they form a set of real-valued Clifford Γ-matrices of Weyl type (i.e., block antidiagonal), obeying the (pseudo-) Euclidean anticommutation relations

$$\{\Gamma_i,\Gamma_j\}=2\eta_{ij}. \tag{3.7}$$

Conversely, given a set of (pseudo-) Euclidean real-valued Clifford Γ-matrices of Weyl type, one can invert the above-mentioned procedure and reconstruct the supercharges Q_i,

$$Q_i=\frac{1}{\sqrt{2}}\begin{pmatrix}0 & \sigma_i\\ \tilde{\sigma}_i\cdot H & 0\end{pmatrix}, \tag{3.8}$$

in the basis (3.1).

In addition to the matrices Γ^i (3.6) in the space of vectors (3.1) the further matrix Γ^{N+1}, which anticommutes with the supercharges and corresponds to the fermionic number, exists

$$\Gamma_{N+1}=\begin{pmatrix}1 & 0\\ 0 & -1\end{pmatrix}. \tag{3.9}$$

Altogether the matrices (3.6) and (3.9) form the real-valued representation Γ_I of the (pseudo-) Euclidean Clifford algebra with the signature $(p+1,q)$.

Instead of (3.5) one can take

$$C_i=\frac{i}{\sqrt{2}}\sigma_i,$$
$$\tilde{C}_i=-\frac{1}{\sqrt{2}}\tilde{\sigma}_i, \tag{3.10}$$

and accommodate $\sigma_i,\tilde{\sigma}_i$ into the matrices (3.6), which now obey the (pseudo-) Euclidean anticommutation relations

$$\{\tilde{\Gamma}_i,\tilde{\Gamma}_j\}=-2\eta_{ij} \tag{3.11}$$

with opposite to (3.7) sign of the right-hand side. Together with fermion number matrix (3.9) the new matrix $\tilde{\Gamma}_i$ forms the real-valued representation of the (pseudo-) Euclidean Clifford algebra with the signature $(q+1,p)$. This fact means that the representations of $C_{p+1,q}$ and $C_{q+1.p}$ should be connected one with the other. Indeed, this connection is established by the correspondence

$$\tilde{\Gamma}_i = \Gamma_{N+1}\Gamma_i . \tag{3.12}$$

Thus, the representations of the (p,q)- extended supersymmetry algebra (1.2) are in one-to-one correspondence with the real-valued representations of the Clifford algebra $C_{p+1,q} \sim C_{q+1,p}$.

In general the real Clifford algebras were classified in Ref. 24 (for the compact case $q=0$) and in Ref. 25 (for the noncompact case). The construction along the lines (3.2)–(3.9) for representations of the type $\{\mathbf{d},\mathbf{d}\}$ in the case of positively definite signature $(p,q)=(N,0)$ was performed in Ref. 11 (see also Ref. 12) where the dimensionalities as well as realizations of the Γ-matrices (3.6) were described. In the case of pseudo-Euclidean metric with signature (p,q) such construction extensively uses the considerations of Ref. 14. The results will be presented in Sec. IV.

IV. CLASSIFICATION OF THE IRREDUCIBLE REPRESENTATIONS

According to the results of Sec. III the classification of irreducible multiplets of representation of a (p,q) extended supersymmetry is in one-to-one correspondence with the classification of the real Clifford algebras $C_{p,q}$ with the further property that the Γ matrices can be realized in Weyl (i.e., block antidiagonal) form.

For what concerns real matrix representations of the Clifford algebras we borrow the results of Ref. 14. Three cases have to be distinguished for real representations, specified by the type of most general solution allowed for a real matrix S commuting with all the Clifford Γ_i matrices, i.e.,

(i) the normal case, realized when S is a multiple of the identity,
(ii) the almost complex case, for S being given by a linear combination of the identity and of a real $J^2=-\mathbf{1}$ matrix,
(iii) finally the quaternionic case, for S being a linear combination of real matrices satisfying the quaternionic algebra.

Real irreducible representations of normal type exist whenever the condition $p-q=0,1,2 \bmod 8$ is satisfied (their dimensionality being given by $2^{[N/2]}$, where $N=p+q$), while the almost complex and the quaternionic type representations are realized in the $p-q=3,7 \bmod 8$ and in the $p-q=4,5,6 \bmod 8$ cases, respectively. The dimensionality of these representations is given in both cases by $2^{[N/2]+1}$.

We further require the extra condition that the real representations should admit a block antidiagonal realization for the Clifford Γ matrices. This condition is met for $p-q=0 \bmod 8$ in the normal case (it corresponds to the standard Majorana–Weyl requirement), $p-q=7 \bmod 8$ in the almost complex case and $p-q=4,6 \bmod 8$ in the quaternionic case. In all these cases the real irreducible representation is unique.

The above-mentioned results can be summarized as follows, expressing the dimensionality of the irreducible representations of the algebra (1.2) [independently of the length $M+1$ of the chain (2.1)] as function of the signature (p,q). Let $q=8k+m$, $0\leqslant m\leqslant 7$, and $p=8l+m+n$, $1\leqslant n\leqslant 8$ ($l=-1$ when $k=0$ and $p\leqslant q$). Then, the dimensionalities of the bosonic (fermionic) spaces are given by

$$d=2^{4k+4l+m}\cdot G(n), \tag{4.1}$$

where the so-called Radon–Hurwitz function $G(n)$ is defined with the help of the table which can be encountered in Ref. 12

$$\begin{array}{cccccccccc} n & 1 & 2 & 3 & 4 & 5 & 6 & 7 & 8 \\ G(n) & 1 & 2 & 4 & 4 & 8 & 8 & 8 & 8 \end{array}. \tag{4.2}$$

In words, $G(n)=2^r$, where r is the nearest integer which is greater or equal to $\log_2 n$.

Conversely, a second useful table expresses which kind of signatures (p,q) are possible for a given dimensionality of the bosonic and fermionic spaces. In order to do so it is convenient to introduce the notion of maximally extended supersymmetry. The $C_{p,q}$ $(p-q=6 \bmod 8)$ real representation for the quaternionic case can be recovered from the 7 mod 8 almost complex $C_{p+1,q}$ representation by deleting one of the Γ matrices; in turn the latter representation is recovered from the $C_{p+2,q}$ normal Majorana–Weyl representation by deleting another Γ matrix. The dimensionality of the three representations mentioned previously being the same, the normal Majorana–Weyl representation realizes the maximal possible extension of supersymmetry compatible with the dimensionality of the representation. In search for the maximal extension of supersymmetry we can therefore limit ourselves to consider the normal Majorana–Weyl representations, as well as the quaternionic ones satisfying the $p-q=4 \bmod 8$ condition.

Therefore let $p=8l+m+8+4\epsilon$ and $q=8k+m$, where the range of values for k,l,m is the same as before, while ϵ assumes two values, distinguishing the Majorana–Weyl $(\epsilon=0)$ and the quaternionic case $(\epsilon=1)$. A space of $d=2^t$ bosonic and $d=2^t$ fermionic states can carry the following set of maximally extended supersymmetries:

$$(p=t-4z+5-3\epsilon, q=t+4z+\epsilon-3), \tag{4.3}$$

where the integer $z=k-l$ must take values in the interval

$$\tfrac{1}{4}(3-t-\epsilon)\leqslant z\leqslant \tfrac{1}{4}(t+5-3\epsilon) \tag{4.4}$$

in order to guarantee the $p\geqslant 0$ and $q\geqslant 0$ requirements. It is also convenient to represent the answer by the following table:

d	(p,q)
2^{4l}	$(8l-4k+1,4k+1),(8l-4k-2,4k+2)$
2^{4l+1}	$(8l-4k+2,4k+2),(8l-4k-1,4k+3)$
2^{4l+2}	$(8l-4k+4,4k),(8l-4k+3,4k+3)$
2^{4l+3}	$(8l-4k+8,4k),(8l-4k+5,4k+1),$

(4.5)

where k is an integer satisfying the conditions $p\geqslant 0$, $q\geqslant 0$.

For the lowest values of dimensionality d the solutions are given by the table:

d	(p,q)
1	(1,1)
2	(2,2)
4	(4,0),(3,3),(0,4) (4,6)
8	(8,0),(5,1),(4,4),(1,5),(0,8)
16	(9,1),(6,2),(5,5),(2,6),(1,9)
32	(10,2),(7,3),(6,6),(3,7),(2,10).

(4.6)

As already recalled, obviously the representations (p',q') with $p'\leqslant p, q'\leqslant q$ also exist for the same dimensionality d. These representations are also irreducible unless either p' or q' becomes too small. For example, the $d=16$-dimensional representations are irreducible not only for the signature $(p,q)=(5,5)$, but also for the pairs (5,4),(5,3),(5,2),(4,5),(3,5),(2,5), while the irreducible representations for the signatures (5,1),(4,4),(1,5) are encountered in $d=8$ dimensions.

V. EXAMPLES OF REPRESENTATIONS FOR SUPERCHARGES

For the case $(p,q)=(4,0)$ the following matrices realize four supercharges:

$$Q_1=\frac{1}{\sqrt{2}}\begin{vmatrix} 0 & 0 & 0 & 0 & 0 & 0 & 0 & 1 \\ 0 & 0 & 0 & 0 & 0 & 0 & 1 & 0 \\ 0 & 0 & 0 & 0 & 0 & 1 & 0 & 0 \\ 0 & 0 & 0 & 0 & 1 & 0 & 0 & 0 \\ 0 & 0 & 0 & H & 0 & 0 & 0 & 0 \\ 0 & 0 & H & 0 & 0 & 0 & 0 & 0 \\ 0 & H & 0 & 0 & 0 & 0 & 0 & 0 \\ H & 0 & 0 & 0 & 0 & 0 & 0 & 0 \end{vmatrix},$$

$$Q_2=\frac{1}{\sqrt{2}}\begin{vmatrix} 0 & 0 & 0 & 0 & 0 & 0 & 1 & 0 \\ 0 & 0 & 0 & 0 & 0 & 0 & 0 & -1 \\ 0 & 0 & 0 & 0 & 1 & 0 & 0 & 0 \\ 0 & 0 & 0 & 0 & 0 & -1 & 0 & 0 \\ 0 & 0 & H & 0 & 0 & 0 & 0 & 0 \\ 0 & 0 & 0 & -H & 0 & 0 & 0 & 0 \\ H & 0 & 0 & 0 & 0 & 0 & 0 & 0 \\ 0 & -H & 0 & 0 & 0 & 0 & 0 & 0 \end{vmatrix}, \tag{5.1}$$

$$Q_3=\frac{1}{\sqrt{2}}\begin{vmatrix} 0 & 0 & 0 & 0 & 1 & 0 & 0 & 0 \\ 0 & 0 & 0 & 0 & 0 & 1 & 0 & 0 \\ 0 & 0 & 0 & 0 & 0 & 0 & -1 & 0 \\ 0 & 0 & 0 & 0 & 0 & 0 & 0 & -1 \\ H & 0 & 0 & 0 & 0 & 0 & 0 & 0 \\ 0 & H & 0 & 0 & 0 & 0 & 0 & 0 \\ 0 & 0 & -H & 0 & 0 & 0 & 0 & 0 \\ 0 & 0 & 0 & -H & 0 & 0 & 0 & 0 \end{vmatrix},$$

$$Q_4=\frac{1}{\sqrt{2}}\begin{vmatrix} 0 & 0 & 0 & 0 & 0 & 1 & 0 & 0 \\ 0 & 0 & 0 & 0 & -1 & 0 & 0 & 0 \\ 0 & 0 & 0 & 0 & 0 & 0 & 0 & -1 \\ 0 & 0 & 0 & 0 & 0 & 0 & 1 & 0 \\ 0 & -H & 0 & 0 & 0 & 0 & 0 & 0 \\ H & 0 & 0 & 0 & 0 & 0 & 0 & 0 \\ 0 & 0 & 0 & H & 0 & 0 & 0 & 0 \\ 0 & 0 & -H & 0 & 0 & 0 & 0 & 0 \end{vmatrix}.$$

These supercharges act in the space with four bosonic and four fermionic coordinates forming the representation {**4**,**4**}. The automorphism group SO(p,q) of the algebra (1.2) is now SO(4).

Besides the transformations of the automorphism group $Q_i' = \Lambda_i^j Q_j$ the algebra of supercharges is invariant under the more general transformations of the type

$$Q_i' = U Q_i U^{-1} \tag{5.2}$$

with block-diagonal 8×8 matrices U. When the matrix U is nonsingular and real the transformation (5.2) simply means a change of basis in bosonic and fermionic sectors. On the other hand this transformation drastically changes the representation when U depends on the operator $H = -i\mathrm{d}/\mathrm{d}\tau$. In this case the transformation (5.2) is in general nonlocal. Nevertheless, transformations exist which do not lead to any nonlocality. In particular, in the framework of the example (5.1) one can take

$$U_1 = \mathrm{diag}\{1,1,1,H,1,1,1,1\} \tag{5.3}$$

and obtain the new realization for the operators Q_i,

$$Q_1 = \frac{1}{\sqrt{2}} \begin{vmatrix} 0 & 0 & 0 & 0 & 0 & 0 & 0 & 1 \\ 0 & 0 & 0 & 0 & 0 & 0 & 1 & 0 \\ 0 & 0 & 0 & 0 & 0 & 1 & 0 & 0 \\ 0 & 0 & 0 & 0 & H & 0 & 0 & 0 \\ 0 & 0 & 0 & 1 & 0 & 0 & 0 & 0 \\ 0 & 0 & H & 0 & 0 & 0 & 0 & 0 \\ 0 & H & 0 & 0 & 0 & 0 & 0 & 0 \\ H & 0 & 0 & 0 & 0 & 0 & 0 & 0 \end{vmatrix},$$

$$Q_2 = \frac{1}{\sqrt{2}} \begin{vmatrix} 0 & 0 & 0 & 0 & 0 & 0 & 1 & 0 \\ 0 & 0 & 0 & 0 & 0 & 0 & 0 & -1 \\ 0 & 0 & 0 & 0 & 1 & 0 & 0 & 0 \\ 0 & 0 & 0 & 0 & 0 & -H & 0 & 0 \\ 0 & 0 & H & 0 & 0 & 0 & 0 & 0 \\ 0 & 0 & 0 & -1 & 0 & 0 & 0 & 0 \\ H & 0 & 0 & 0 & 0 & 0 & 0 & 0 \\ 0 & -H & 0 & 0 & 0 & 0 & 0 & 0 \end{vmatrix}, \tag{5.4}$$

$$Q_3 = \frac{1}{\sqrt{2}} \begin{vmatrix} 0 & 0 & 0 & 0 & 1 & 0 & 0 & 0 \\ 0 & 0 & 0 & 0 & 0 & 1 & 0 & 0 \\ 0 & 0 & 0 & 0 & 0 & 0 & -1 & 0 \\ 0 & 0 & 0 & 0 & 0 & 0 & 0 & -H \\ H & 0 & 0 & 0 & 0 & 0 & 0 & 0 \\ 0 & H & 0 & 0 & 0 & 0 & 0 & 0 \\ 0 & 0 & -H & 0 & 0 & 0 & 0 & 0 \\ 0 & 0 & 0 & -1 & 0 & 0 & 0 & 0 \end{vmatrix},$$

$$Q_4=\frac{1}{\sqrt{2}}\begin{vmatrix} 0 & 0 & 0 & 0 & 0 & 1 & 0 & 0 \\ 0 & 0 & 0 & 0 & -1 & 0 & 0 & 0 \\ 0 & 0 & 0 & 0 & 0 & 0 & 0 & -1 \\ 0 & 0 & 0 & 0 & 0 & 0 & H & 0 \\ 0 & -H & 0 & 0 & 0 & 0 & 0 & 0 \\ H & 0 & 0 & 0 & 0 & 0 & 0 & 0 \\ 0 & 0 & 0 & 1 & 0 & 0 & 0 & 0 \\ 0 & 0 & -H & 0 & 0 & 0 & 0 & 0 \end{vmatrix}$$

in which all the elements of the last column in the left off-diagonal block have lost the multiplier H. Instead, all the elements of the last arrow in the right off-diagonal block acquired H as a multiplier. This representation of the supercharges corresponds to the irreducible supermultiplet $\{\mathbf{3},\mathbf{4},\mathbf{1}\}$ which was used in Refs. 21 and 22 for constructing the three-dimensional $N=4$ extended SQM. The supermultiplets $\{\mathbf{2},\mathbf{4},\mathbf{2}\}$ and $\{\mathbf{1},\mathbf{4},\mathbf{3}\}$ are derived with the help of the following matrices U:

$$U_2=\mathrm{diag}\{1,1,H,H,1,1,1,1\}, \quad U_3=\mathrm{diag}\{1,H,H,H,1,1,1,1\}. \tag{5.5}$$

The next one in this sequence

$$U_4=\mathrm{diag}\{H,H,H,H,1,1,1,1\} \tag{5.6}$$

again gives the supermultiplet $\{\mathbf{4},\mathbf{4}\}$ but with the opposite grading—the first in the chain is the fermionic subspace. This completes the classification of the irreducible supermultiplets of the $N=4$ extended SQM. One can show that all the irreducible supermultiplets of the (p,q) extended SQM are of length which does not exceed 3 when the constraint

$$d\leqslant p+q \tag{5.7}$$

is fulfilled. The determination of the possible values of the lengths of irreducible supermultiplets, as well as their detailed structure, in the case when (5.7) is not fulfilled needs a separate investigation.

A simple example of an irreducible supermultiplet of length 4 is given by the $(p,q)=(3,0)$ case, in which the irreducible representation has also $d=4$ and supercharges in the $\{\mathbf{4},\mathbf{4}\}$ representation are given by Q_1,Q_2,Q_3 in (5.1). Taking

$$U_5=\mathrm{diag}\{1,H,H,H,1,H,1,1\} \tag{5.8}$$

one derives the expressions for all four supercharges

$$Q_1=\frac{1}{\sqrt{2}}\begin{vmatrix} 0 & 0 & 0 & 0 & 0 & 0 & 0 & 1 \\ 0 & 0 & 0 & 0 & 0 & 0 & H & 0 \\ 0 & 0 & 0 & 0 & 0 & 1 & 0 & 0 \\ 0 & 0 & 0 & 0 & H & 0 & 0 & 0 \\ 0 & 0 & 0 & 1 & 0 & 0 & 0 & 0 \\ 0 & 0 & H & 0 & 0 & 0 & 0 & 0 \\ 0 & 1 & 0 & 0 & 0 & 0 & 0 & 0 \\ H & 0 & 0 & 0 & 0 & 0 & 0 & 0 \end{vmatrix},$$

$$
Q_2=\frac{1}{\sqrt{2}}\begin{vmatrix}
0 & 0 & 0 & 0 & 0 & 0 & 1 & 0\\
0 & 0 & 0 & 0 & 0 & 0 & 0 & -H\\
0 & 0 & 0 & 0 & H & 0 & 0 & 0\\
0 & 0 & 0 & 0 & 0 & -1 & 0 & 0\\
0 & 0 & 1 & 0 & 0 & 0 & 0 & 0\\
0 & 0 & 0 & -H & 0 & 0 & 0 & 0\\
H & 0 & 0 & 0 & 0 & 0 & 0 & 0\\
0 & -1 & 0 & 0 & 0 & 0 & 0 & 0
\end{vmatrix},
$$

$$
Q_3=\frac{1}{\sqrt{2}}\begin{vmatrix}
0 & 0 & 0 & 0 & 1 & 0 & 0 & 0\\

0 & 0 & -1 & 0 & 0 & 0 & 0 & 0
\end{vmatrix}
$$

from which one can easily see that the fourth supercharge Q_4 becomes singular after the transformation. Indeed, just the first three supercharges in (5.9) are realized in the irreducible representation $\{\mathbf{1},\mathbf{3},\mathbf{3},\mathbf{1}\}$ of length 4.

The Weyl-type $C_{0,4}$ representation has been explicitly presented in Ref. 14. Due to the mod 8 property of Γ matrices, it allows, together with $C_{4,0}$, one to construct all quaternionic representations of Weyl type for the allowed values of (p,q). For what concerns the Majorana–Weyl representations, an algorithm to explicitly construct them can be found, e.g., in Ref. 26. Moreover, the following symmetry property

$$
\Gamma_i^T=\begin{cases}\Gamma_i, & i\leqslant p\\ -\Gamma_i, & (p+1)\leqslant i\leqslant(p+q)\end{cases}
\tag{5.10}
$$

can always be assumed to be valid.

VI. AN APPLICATION: SUPERSYMMETRIES OF THE FREE KINETIC LAGRANGIANS OF THE "SPINNING" PARTICLE

We present for completeness the analysis of the extended supersymmetric invariances for the simplest action of the ''spinning'' particle model, given by the free kinetic term. We use the quotation marks in the word ''spinning'' because actually the considered actions describe particles

with spin and are different from the spinning particle models in which both fermions and bosons are space–time vectors and bosons, in addition, are scalars with respect to the supersymmetry transformations.

In general the most significant dynamical systems are σ-models presenting a nonlinear kinetic term; for such systems the extended supersymmetries put constraints on the metric of the target. We avoid entering this problem here and just limit ourselves to illustrate how invariances under pseudo-Euclidean supersymmetries can arise. We show in fact that a ''spinning'' particle evolving in a non-Euclidean background in general admits invariances under pseudo-Euclidean supersymmetries.

We consider the models involving d bosonic fields X_a and d spinors Θ_α collected in the vector Ψ (3.1) (no auxiliary fields are present).

The free kinetic action is given by

$$S_K=\int \mathrm{d}t\, \mathcal{L}=\frac{1}{2}\int \mathrm{d}t \Psi^T \Lambda \Psi=\frac{1}{2}\int \mathrm{d}t (X,\Theta)\begin{pmatrix} \lambda_1 H^2 & 0 \\ 0 & \lambda_2 H \end{pmatrix}\begin{pmatrix} X \\ \Theta \end{pmatrix} \tag{6.1}$$

$$=\frac{1}{2}\int \mathrm{d}t(\dot{X}_a \lambda_1^{ab}\dot{X}_b - i\Theta_\alpha \lambda_2^{\alpha\beta}\dot{\Theta}_\beta), \tag{6.2}$$

where the structure of the matrix Λ is dictated by the conservation of the fermion number and by dimensional arguments. Both λ_1,λ_2 should be symmetrical in addition: $\lambda_M^T=\lambda_M$.

The invariance of the action under the supersymmetry transformations (3.2),

$$\delta S_K=\frac{i}{\sqrt{2}}\varepsilon^i X_a(\lambda_1\sigma_i-\tilde{\sigma}_i^T\lambda_2)^{a\alpha}H^2\Theta_\alpha=0, \tag{6.3}$$

means that the following property of λ's,

$$\lambda_1\sigma_i-\tilde{\sigma}_i^T\lambda_2=0, \tag{6.4}$$

should be valid, in accordance with (5.10)

$$\tilde{\sigma}_i^T=\eta^{ii}\sigma_i. \tag{6.5}$$

It means that in the case of Euclidean supersymmetry ($q=0$) we get

$$\lambda_1=\lambda_2=I, \tag{6.6}$$

where I is a d dimensional identity matrix (see also Ref. 12). In the general case ($q\geqslant 1$) the following representation for the Γ_i matrices[14] is useful

$$\Gamma_\mu=\begin{pmatrix} 0 & \gamma_\mu \\ \gamma_\mu & 0 \end{pmatrix},\quad \mu=1,2,\ldots,p+q-1,\quad \Gamma_{p+q}=\begin{pmatrix} 0 & I \\ -I & 0 \end{pmatrix}, \tag{6.7}$$

where γ_μ form a real valued representation of the Clifford algebra $C_{p,q-1}$ with the symmetry property (5.10). So, the conditions (6.4) give, in particular, $\lambda_1=-\lambda_2\equiv C$ and

$$C\gamma_\mu+\gamma_\mu^T C=0, \tag{6.8}$$

which means that the matrix C is the charge conjugation matrix for the Clifford algebra $C_{p,q-1}$. The additional property of symmetry for this matrix $C^T=C$ limits the possible signatures (p,q) for which the free action (6.1) is invariant under all $p+q$ supersymmetries. These possible signatures (p,q) can be represented by the following table:

$p\backslash q$	0	1	2	3	4	5	6	7	8
0	+	+	+	+	+	+	+	+	+
1	+		+		+		+	+	+
2	+			+	+	+	+	+	+
3	+				+	+	+		+
4	+	+	+	+	+	+	+	+	+
5	+		+	+	+		+		+
6	+	+	+	+	+			+	+
7	+	+	+		+				+
8	+	+	+	+	+	+	+	+	+

(6.9)

which together with the modulo-8 periodicity gives the total answer. Therefore, for the cases of empty entries of the table it should be checked separately for each specific choice of the matrices λ_1, λ_2 which supersymmetries survive as invariances of the action.

The first nontrivial example concerns a two-dimensional "spinning" particle ($d=2$). Its two bosonic and two fermionic degrees of freedom carry the $\{\mathbf{2},\mathbf{2}\}$ representation of (2,2) extended supersymmetry. However, due to the condition (6.4) only half of these supersymmetries can be invariances of the action. We obtain in fact invariance under either the (2,0) or the (1,1) extended supersymmetries, whether the target space is, respectively, Euclidean or Minkowskian. Therefore already for the two-dimensional Minkowskian "spinning" particle we observe the arising of the pseudo-Euclidean supersymmetry invariance.

More generally, in all the cases except the Euclidean one ($q=0$ *or* $p=0$), exactly half of the eigenvalues of the charge conjugation matrix C are negative. It means that the action (6.1) describes the free motion in the space–time with signature $(d/2,d/2)$ with equal numbers of spacelike and timelike coordinates. Both of them transform as irreducible spinors of the isomorphisms group $\mathrm{SO}(p,q)$ generated by

$$J_{ik}=\tfrac{1}{4}[\Gamma_i,\Gamma_k]. \tag{6.10}$$

If one wants to have another space–time signature, some of the bosonic coordinates can be converted into the auxiliary ones with the help of the procedure described at the end of Sec. V. Formally it means that in the action (6.1) the time derivatives of some bosonic coordinates $\dot{X}_a$ are replaced by new auxiliary variables F_a.

The resulting representation $\{\mathbf{D},\mathbf{d},\mathbf{d}-\mathbf{D}\}$ can, for example, contain only 1 timelike and $D-1$ spacelike bosonic dynamical coordinates. Its corresponding action describes the "spinning" particle with all its space–time coordinates belonging to *one* irreducible representation of the extended supersymmetry. All the additional $d-D$ bosonic coordinates are auxiliary. The example of such description of the four-dimensional spinning particle with (4,4) extended supersymmetry was given in Ref. 15.

VII. CONCLUSIONS

In this paper we presented some results concerning the representation theory for irreducible multiplets of the one-dimensional $N=(p,q)$-extended supersymmetry. As pointed out in the text, a peculiar feature of the one-dimensional supersymmetric algebras consists in the fact that the supermultiplets formed by d bosonic and d fermionic degrees of freedom accommodated in a chain with $M+1$ $(M\geqslant 2)$ different spin states such as (2.1) uniquely determines a two-chain multiplet of the form $\{\mathbf{d},\mathbf{d}\}$ which carries a representation of the N extended supersymmetry. Furthermore, it is shown that all such two-chain irreducible multiplets of the (p,q) extended supersymmetry are fully classified; when, e.g., the condition $p-q=0 \bmod 8$ is satisfied, their classification is equivalent to those of Majorana–Weyl spinors in any given space–time, the number $p+q$ of extended supersymmetries being associated with the dimensionality D of the space–time, while the $2d$ supermultiplet dimensionality is the dimensionality of the corresponding Γ matrices. The more general case for arbitrary values of p and q has also been fully discussed.

These mathematical properties can find a lot of interesting applications in connection with the construction of supersymmetric and superconformal quantum mechanical models. These theories are vastly studied due to their relevance in many different physical domains. To name just a few we mention the low-energy effective dynamics of black-hole models, the dimensional reduction of higher-dimensional superfield theories, which are a laboratory for the investigation of the spontaneous breaking of the supersymmetry (for such investigations the extended supersymmetry is an essential ingredient), as well as many others. As recalled in Sec. I, it is very crucial to build extended supersymmetric models realized with the lowest-dimensional representations.

Another area in which we have started applying the tools here elaborated is that one of supersymmetric integrable hierarchies in $1+1$ dimensions. They are globally supersymmetric nonlinear nonrelativistic theories, the one-dimensional susy's being realized through charges obtained by integrating the supercurrents along the spatial line.

JOURNAL OF MATHEMATICAL PHYSICS VOLUME 42, NUMBER 11 NOVEMBER 2001

Four-dimensional lattice gauge theory with ribbon categories and the Crane–Yetter state sum

Hendryk Pfeiffer[a)]
Department of Applied Mathematics and Theoretical Physics, Centre for Mathematical Sciences, Wilberforce Road, Cambridge CB3 0WA, United Kingdom

(Received 4 June 2001; accepted for publication 10 July 2001)

Lattice Gauge Theory in four-dimensional Euclidean space–time is generalized to ribbon categories which replace the category of representations of the gauge group. This provides a framework in which the gauge group becomes a quantum group while space–time is still given by the ''classical'' lattice. At the technical level, this construction generalizes the spin foam model dual to lattice gauge theory and defines the partition function for a given triangulation of a closed and oriented piecewise-linear four-manifold. This definition encompasses both the standard formulation of $d=4$ pure Yang–Mills theory on a lattice and the Crane–Yetter invariant of four-manifolds. The construction also implies that certain classes of spin foam models formulated using ribbon categories are well-defined even if they do not correspond to a topological quantum field theory. © *2001 American Institute of Physics.* [DOI: 10.1063/1.1398063]

I. INTRODUCTION

The formulation of gauge theory on a lattice[1] combines manifest gauge symmetry with the path integral approach although space–time cannot be retained as a smooth manifold and is replaced instead by a discrete structure. In the present article lattice gauge theory (LGT) always refers to pure gauge theory in Euclidean space–time.

LGT offers a number of generalizations that do not have a naïve continuum analogy such as gauge theory with finite gauge groups. Furthermore, in three dimensions it is possible to define LGT for quantum groups.[2,3] Combining the various actions and Boltzmann weights with suitable ''gauge groups'' (finite groups, Lie groups or quantum groups), this model has several special cases that belong to different branches of physics and mathematics. It is at the center of the relation between LGT with Yang–Mills[1] or with Chern–Simons action,[4,5] the Turaev–Viro invariant of three-manifolds,[6,7] a purely algebraic construction of Topological Quantum Field Theory[4,6] and three-dimensional Euclidean quantum gravity without or with cosmological constant.[8]

At least some of the above constructions are known to have analogies in four dimensions. Even though the question of which is a suitable unified model remains unsolved in full generality, some of the relations known from three dimensions persist also in four dimensions. In the present article we concentrate on the standard formulation of LGT and on the Crane–Yetter state sum.[9,10] We present a definition which encompasses both and generalizes four-dimensional LGT to quantum groups. Technically this is realized for ribbon categories which arise as the categories of representations of certain quantum groups and which replace the category of representations of the gauge group of LGT.

The main result of the present article is the existence of such a generalized LGT in four-dimensional Euclidean space–time using ribbon categories. This model contains the Crane–Yetter state sum as a special case for a particular Boltzmann weight and agrees on the other hand with the spin foam model which is strong-weak dual to LGT if the ribbon category is the category of

a)Electronic mail: h.pfeiffer@damtp.cam.ac.uk

finite-dimensional representations of a compact Lie group. Beyond this, it provides a definition of spin foam models in $d=4$ using ribbon categories which includes in particular the proof that this construction is well-defined even in cases in which the model does not correspond to a Topological Quantum Field Theory.

At the technical level, the construction of these spin foam models using ribbon categories can be motivated from the following observations. From the study of nonperturbative quantum gravity it has emerged that LGT admits a reformulation as a spin foam model—see, for example, Refs. 8, 11, and 12. Many models of interest in quantum gravity are either Topological Quantum Field Theories and use ''delta-functions'' as Boltzmann weights (for example, Ref. 13), or they are topological up to constraints which do not change the weights, but restrict the set of admissible representations. This is the case for some versions of the Barrett–Crane model.[14]

LGT, however, admits more general Boltzmann weights,

$$w: G \to \mathbb{R}, \quad g \mapsto \exp(-s(g)). \tag{1.1}$$

Here the compact Lie group G is the gauge group, the (local) action $s: G \to \mathbb{R}$ is a real, bounded and L^2-integrable class function, and the Boltzmann weight $w(g)$ is evaluated for each plaquette of the lattice. This model encompasses lattice Yang–Mills theory, for example using Wilson's action, but it is not restricted to this case. For general background on LGT the reader is referred to standard textbooks, for example, Refs. 15 and 16.

The spin foam model corresponding to the standard formulation of LGT on a hypercubic lattice was constructed in detail in Ref. 17, where it was found that it generalizes the strong-weak dual of LGT which had been known only in the Abelian case[18,19] and for SU(2) in $d=3$ (Ref. 20) before. The Boltzmann weight (1.1) enters the spin foam model via the coefficients $\hat{w}_\rho$ of its character expansion,

$$w(g) = \sum_{\rho \in \mathcal{R}} \hat{w}_\rho \chi^{(\rho)}(g), \quad \hat{w}_\rho = \dim V_\rho \int_G \overline{\chi^{(\rho)}(g)} w(g)\, dg. \tag{1.2}$$

Here $\chi^{(\rho)}: G \to \mathbb{C}$ denotes the character of the finite-dimensional irreducible representation V_ρ, the sum is over equivalence classes of finite-dimensional irreducible representations of G, and $\int_G$ is the normalized Haar measure on G.

The way the coefficients $\hat{w}_\rho$ appear in the spin foam model dual to LGT[17] compared with the Ooguri state sum[13] indicates that there exists a unified construction encompassing both. In addition, the fact that the Crane–Yetter state sum[9,10] can be understood as a generalization of the Ooguri model to quantum groups suggests the construction given in the present article.

The strategy for the definition of $d=4$ LGT using ribbon categories is as follows. The construction is based on a triangulation of a closed and oriented piecewise-linear four-manifold M which is specified by an abstract combinatorial complex. In the special case of a Lie group symmetry, the definition shall coincide with the spin foam model dual to LGT if that LGT is formulated on the two-complex dual to the triangulation (note that we formulate the spin foam model on the triangulation itself, following Ref. 10). In the Lie group case, both pictures are available: the spin foam model on the triangulation and LGT on the dual two-complex. They are dual to each other in the sense of Ref. 17. Physically this means strong-weak duality between LGT and the spin foam model while on the mathematical side the two models are related by a Tannaka–Krein-like reconstruction theorem relating LGT (formulated in terms of the gauge group G) with the spin foam model (formulated in terms of the category of representations Rep G). For details on quantum groups, ribbon categories and the reconstruction theorems, the reader is referred to standard textbooks such as Refs. 21 and 22.

The generalization takes place in the spin foam picture where the category Rep G is replaced by a suitable ribbon category $\mathcal{C}$. Loosely speaking, using the reconstruction theorems, this provides a definition of LGT in which the gauge group is replaced by a quantum group. Technically, the

notion of gauge group is lost, but one can think of replacing the algebra of representation functions $C_{\mathrm{alg}}(G)$ by a noncommutative algebra (a suitable ribbon Hopf algebra) while space–time is still given by the 'classical' lattice.

The generalization from Rep G to a generic ribbon category $\mathcal{C}$ involves choices of the ordering of tensor factors and choices of the braiding whenever tensor factors are exchanged. These choices are not at all obvious from the Lie group case which involves only the symmetric category Rep G.

The method to achieve a consistent definition in the spin foam picture is to choose a linear order of vertices for the combinatorial complex and to define the partition function in a way that employs special choices and that refers explicitly to that order. It is then possible to show in a second step that the partition function is actually independent of the order (combinatorially invariant) and is thus well-defined for a given triangulation. This approach can be seen as a generalization to four dimensions of the strategy which Barrett and Westbury[7] employ in their approach to the Turaev–Viro invariant.[6]

Another point of view on the definition given in the present article is related to the construction of the Crane–Yetter state sum in Ref. 10. The authors of Ref. 10 first show that the state sum is independent of the triangulation, which in our terminology relies on the choice of a particular Boltzmann weight. Triangulation independence then implies combinatorial invariance and thus establishes that the state sum is well-defined. As an alternative proof, it is conceivable to show combinatorial invariance in the first step. This holds for any choice of Boltzmann weights. One could then prove in a second step that the choice of special Boltzmann weights implies triangulation independence by standard arguments as in Refs. 9, 10, and 13. The construction presented in the present article can be viewed as the first of these two steps.

Finally, we would like to mention D. V. Boulatov's approach to LGT for quantum groups in three dimensions.[2] His construction makes use of the general result of Reshetikhin and Turaev[23] establishing a functor from the category of ribbon graphs in $\mathbb{R}^3$ to the ribbon category $\mathcal{C}$. The strategy in Ref. 2 is to construct a suitable ribbon graph in the triangulated manifold which then yields a well-defined partition function as the quantum trace of a ribbon morphism.

A related definition of $d=3$ LGT for quantum groups was developed by R. Oeckl[3] in which the duality between LGT and its dual spin foam model is understood entirely in terms of manipulations of ribbon graphs. The approach of Ref. 3 also develops the correspondence of ribbon categories with suitable quantum groups, namely coribbon Hopf algebras, in a way that transparently generalizes the duality transformation of the Lie group case.

However, since the Reshetikhin–Turaev functor is available only for ribbon graphs in $\mathbb{R}^3$, these approaches do not have a direct generalization to higher dimension. In the present article, we use the functor mainly to justify diagrammatic calculations.

The present article is organized as follows. In Sec. II, we review some mathematical background on the Peter–Weyl theory for compact Lie groups and on ribbon categories, and we introduce our notation for combinatorial and simplicial complexes. The duality transformation for LGT with Lie gauge groups which was derived in Ref. 17 on a cubic lattice is reviewed in Sec. III and formulated there on a two-complex. In Sec. IV, we define the spin foam model generalizing the dual of LGT to suitable ribbon categories. This section contains the definition of the partition function, the proof that it is well-defined and comments on the construction of observables and on the role played by the gauge transformations in the spin foam model. In Sec. V, we indicate how these definitions specialize to the standard formulation of LGT with a compact Lie group (or a finite group) as the gauge group and to the Crane–Yetter invariant. We also comment on possible generalizations and relations with other spin foam models. Section VI contains a conclusion and comments on open questions.

II. PRELIMINARIES

A. Peter–Weyl theory

In this section, we briefly summarize definitions and basic statements related to the algebra of representation functions $C_{\mathrm{alg}}(G)$ of G where G is a compact Lie group (or a finite group). These

results are needed in Sec. III in order to present the duality transformation relating LGT and the spin foam model. For more details, the reader is referred to the Introduction of Ref. 17 or to textbooks such as Refs. 24 and 25.

1. Representation functions

Finite-dimensional complex vector spaces on which G is represented are denoted by V_ρ and by $\rho: G \to \mathrm{Aut}V_\rho$ the corresponding group homomorphism. Let $\tilde{\mathcal{R}}$ denote a set containing one unitary representative of each class of finite-dimensional representations and $\mathcal{R}$ the subset of irreducible representations. For a representation $\rho \in \tilde{\mathcal{R}}$, the dual representation is denoted by ρ^*, and the dual vector space of V_ρ by V_ρ^*. The dual representation is given by $\rho^*: G \mapsto \mathrm{Aut}V_\rho^*$, where $\rho^*(g): V_\rho^* \to V_\rho^*$, $\eta \mapsto \eta \circ \rho(g^{-1})$, i.e., $(\rho^*(g)\eta)(v) = \eta(\rho(g^{-1})v)$ for all $v \in V_\rho$. There exists a one-dimensional "trivial" representation of G which is denoted by $V_{[1]} \cong \mathbb{C}$.

For the unitary representations V_ρ, $\rho \in \tilde{\mathcal{R}}$, there exist standard sesquilinear scalar products $\langle \cdot ; \cdot \rangle$ and orthonormal bases (v_j) in such a way that the basis (v_j) of V_ρ is dual to the basis (η^j) of V_ρ^*, i.e., $\eta^j(v_k) = \delta_k^j$. Duality is here given by the scalar product, i.e., $\langle v_j ; v_k \rangle = \eta^j(v_k)$ and $\langle \eta^j ; \eta^k \rangle = \eta^k(v_j)$, $1 \leqslant j,k \leqslant \dim V_\rho$.

The complex-valued functions

$$t^{(\rho)}_{\eta,v} : G \to \mathbb{C}, \quad g \mapsto \eta(\rho(g)v), \tag{2.1}$$

where $\rho \in \tilde{\mathcal{R}}$, $v \in V_\rho$ and $\eta \in V_\rho^*$, are called *representation functions* of G. They form a commutative and associative unital algebra over $\mathbb{C}$,

$$C_{\mathrm{alg}}(G) := \{\, t^{(\rho)}_{\eta,v} : \quad \rho \in \tilde{\mathcal{R}}, v \in V_\rho, \eta \in V_\rho^* \,\}, \tag{2.2}$$

whose operations are given by

$$(t^{(\rho)}_{\eta,v} + t^{(\sigma)}_{\vartheta,w})(g) := t^{(\rho \oplus \sigma)}_{\eta + \vartheta, v+w}(g), \tag{2.3a}$$

$$(t^{(\rho)}_{\eta,v} \cdot t^{(\sigma)}_{\vartheta,w})(g) := t^{(\rho \otimes \sigma)}_{\eta \otimes \vartheta, v \otimes w}(g), \tag{2.3b}$$

for $\rho, \sigma \in \tilde{\mathcal{R}}$ and $v \in V_\rho$, $w \in V_\sigma$, $\eta \in V_\rho^*$, $\vartheta \in V_\sigma^*$ and $g \in G$. The zero element of $C_{\mathrm{alg}}(G)$ is $t^{[1]}_{0,0}(g) = 0$ and its unit element $t^{[1]}_{\eta,v}(g) = 1$ where the normalization is such that $\eta(v) = 1$.

The algebra $C_{\mathrm{alg}}(G)$ is furthermore equipped with a Hopf algebra structure employing the coproduct $\Delta: C_{\mathrm{alg}}(G) \to C_{\mathrm{alg}}(G) \otimes C_{\mathrm{alg}}(G) \cong C_{\mathrm{alg}}(G \times G)$, the co-unit $\varepsilon: C_{\mathrm{alg}}(G) \to \mathbb{C}$ and the antipode $S: C_{\mathrm{alg}}(G) \to C_{\mathrm{alg}}(G)$, which are defined by

$$\Delta t^{(\rho)}_{\eta,v}(g,h) := t^{(\rho)}_{\eta,v} g(\cdot h), \tag{2.4a}$$

$$\varepsilon t^{(\rho)}_{\eta,v} := t^{(\rho)}_{\eta,v}(1), \tag{2.4b}$$

$$S t^{(\rho)}_{\eta,v}(g) := t^{(\rho)}_{\eta,v}(g^{-1}), \tag{2.4c}$$

for $\rho \in \tilde{\mathcal{R}}$ and $v \in V_\rho$, $\eta \in V_\rho^*$ and $g,h \in G$. For unitary representations, the antipode relates a representation with its dual which is just the conjugate representation,

$$S t^{(\rho)}_{mn}(g) = t^{(\rho^*)}_{nm}(g) = \overline{t^{(\rho)}_{nm}(g)}. \tag{2.5}$$

The bar denotes complex conjugation.

2. Peter–Weyl decomposition and theorem

The structure of the algebra $C_{\mathrm{alg}}(G)$ can be understood if $C_{\mathrm{alg}}(G)$ is considered as a representation of $G \times G$ by combined left and right translation of the function argument.

Theorem 2.1 (Peter–Weyl decomposition): Let G be a compact Lie group (or a finite group).

(1) There is an isomorphism

$$C_{\mathrm{alg}}(G) \cong_{G\times G} \bigoplus_{\rho\in\mathcal{R}} (V_\rho^* \otimes V_\rho) \tag{2.6}$$

of representations of $G\times G$. Here the direct sum is over one unitary representative of each equivalence class of finite-dimensional irreducible representations of G. The direct summands $V_\rho^*\otimes V_\rho$ are irreducible as representations of $G\times G$.

(2) The direct sum in (2.6) is orthogonal with respect to the L^2-scalar product on $C_{\mathrm{alg}}(G)$, which is formed using the Haar measure on G on the left hand side, and using the standard scalar products on the right hand side, namely

$$\langle t^{(\rho)}_{\eta,v}; t^{(\sigma)}_{\vartheta,w}\rangle_{L^2} = \int_G \overline{t^{(\rho)}_{\eta,v}(g)}\cdot t^{(\sigma)}_{\vartheta,w}(g)\, dg = \frac{1}{\dim V_\rho}\,\delta_{\rho\sigma}\overline{\langle \eta;\vartheta\rangle}\langle v;w\rangle, \tag{2.7}$$

where $\rho,\sigma\in\mathcal{R}$ are irreducible. The Haar measure is denoted by $\int_G$ and normalized such that $\int_G dg = 1$.

Each representation function $f\in C_{\mathrm{alg}}(G)$ can thus be decomposed according to (2.6) such that its L^2-norm is given by

$$\|f\|_{L^2}^2 = \sum_{\rho\in\mathcal{R}} \frac{1}{\dim V_\rho}\|f_\rho\|^2, \tag{2.8}$$

where $f_\rho\in V_\rho^*\otimes V_\rho \cong \mathrm{Hom}(V_\rho,V_\rho)$, $\rho\in\mathcal{R}$, and all except finitely many f_ρ are zero.

Theorem 2.2 (Peter–Weyl theorem): Let G be a compact Lie group. Then $C_{\mathrm{alg}}(G)$ forms a dense subset of $L^2(G)$.

The characters $\chi^{(\rho)}: G\to\mathbb{C}$ associated with the finite-dimensional unitary representations $\rho\in\widetilde{\mathcal{R}}$ of G are given by the traces,

$$\chi^{(\rho)} := \sum_{j=1}^{\dim V_\rho} t^{(\rho)}_{jj}. \tag{2.9}$$

Each class function $f\in C_{\mathrm{alg}}(g)$ can be character-decomposed

$$f(g) = \sum_{\rho\in\mathcal{R}} \chi^{(\rho)}(g)\,\hat{f}_\rho, \quad \text{where} \quad \hat{f}_\rho = \dim V_\rho \int_G \overline{\chi^{(\rho)}(g)} f(g)\, dg, \tag{2.10}$$

such that the completion of $C_{\mathrm{alg}}(G)$ to $L^2(G)$ is compatible with this decomposition.

3. The Haar measure

The Haar measure on G can be understood in terms of the Peter–Weyl decomposition (2.6) as follows.

Proposition 2.3: Let G be a compact Lie group (or a finite group) and $\rho\in\widetilde{\mathcal{R}}$ be a finite-dimensional unitary representation of G with the orthogonal decomposition

$$V_\rho \cong \bigoplus_{j=1}^{k} V_{\tau_j}, \quad \tau_j\in\mathcal{R}, k\in\mathbb{N}, \tag{2.11}$$

into irreducible components τ_j. Let $P^{(j)}: V_\rho \to V_{\tau_j} \subseteq V_\rho$ be the G-invariant orthogonal projectors associated with the above decomposition. Assume that precisely the first l components $\tau_1, \ldots, \tau_l$, $0 \leqslant l \leqslant k$, are equivalent to the trivial representation. Then the Haar measure of a representation function $t^{(\rho)}_{mn}$, $1 \leqslant m,n \leqslant \dim V_\rho$, is given by

$$\int_G t^{(\rho)}_{mn}(g)\, dg = \sum_{j=1}^{l} P^{(j)m} P^{(j)}_n, \quad P^{(j)m} = \eta^m(w^{(j)}), \quad P^{(j)}_n = \vartheta^{(j)}(v_n). \tag{2.12}$$

Here (v_n) and (η^m) are dual bases of V_ρ and V^*_ρ, the $w^{(j)}$ are normalized vectors in $V_{\tau_j} \subseteq V_\rho$, and $\vartheta^{(j)}$ denotes the linear form dual to $w^{(j)}$.

B. Ribbon categories

Ribbon categories are used in the present article as a generalization of the category of representations of the gauge group. A ribbon category is a braided monoidal category with some additional structure. In this section, we summarize the basic definitions with emphasis on a convenient diagrammatic notation. We refer the reader to the literature for more details, for example, to Refs. 21 and 22. Our presentation is similar to that of Ref. 3; we essentially follow Ref. 22, but use the diagrams of Ref. 21. Also relevant in the context of the present article are the results of Reshetikhin and Turaev.[23,26]

1. Basic definitions

Definition 2.4: A *strict monoidal category* is a category $\mathcal{C}$ together with a covariant functor $\otimes: \mathcal{C} \times \mathcal{C} \to \mathcal{C}$ and a *unit object* $\mathbf{1}$ such that

$$U \otimes (V \otimes W) = (U \otimes V) \otimes W, \tag{2.13a}$$

$$V \otimes \mathbf{1} = V = \mathbf{1} \otimes V, \tag{2.13b}$$

for all objects U, V, W.

Definition 2.5: A *strict braided monoidal category* is a strict monoidal category with natural isomorphisms (the *braiding*),

$$\psi_{V,W}: V \otimes W \to W \otimes V, \tag{2.14}$$

such that

$$\psi_{U \otimes V, W} = (\psi_{U,W} \otimes \mathrm{id}_V) \circ (\mathrm{id}_U \otimes \psi_{V,W}), \tag{2.15a}$$

$$\psi_{U, V \otimes W} = (\mathrm{id}_V \otimes \psi_{U,W}) \circ (\psi_{U,V} \otimes \mathrm{id}_W), \tag{2.15b}$$

$$\psi_{V,\mathbf{1}} = \mathrm{id}_V = \psi_{\mathbf{1},V}, \tag{2.15c}$$

for all objects U, V, W. The category is called *symmetric* if in addition

$$\psi_{W,V} \circ \psi_{V,W} = \mathrm{id}_{V \otimes W}. \tag{2.16}$$

Definition 2.6: A strict monoidal category $\mathcal{C}$ is called *rigid* if for each object V there exists an object V^* (the *left dual*) and if there are natural isomorphisms

$$\mathrm{ev}_V: V^* \otimes V \to \mathbf{1}, \quad \text{(evaluation)}, \tag{2.17a}$$

$$\mathrm{coev}_V: \mathbf{1} \to V \otimes V^* \quad \text{(co-evaluation)}, \tag{2.17b}$$

which satisfy for all objects V,

$$\mathrm{id}_V = (\mathrm{id}_V \otimes \mathrm{ev}_V) \circ (\mathrm{coev}_V \otimes \mathrm{id}_V), \tag{2.18a}$$

$$\mathrm{id}_{V^*} = (\mathrm{ev}_V \otimes \mathrm{id}_{V^*}) \circ (\mathrm{id}_{V^*} \otimes \mathrm{coev}_V). \tag{2.18b}$$

For a given morphism $f: V \to W$, the dual morphism $f^*: W^* \to V^*$ is defined by

$$f^* := (\mathrm{ev}_W \otimes \mathrm{id}_{V^*}) \circ (\mathrm{id}_{W^*} \otimes f \otimes \mathrm{id}_{V^*}) \circ (\mathrm{id}_{W^*} \otimes \mathrm{coev}_V). \tag{2.19}$$

Left duality thus defines a contravariant functor $*: \mathcal{C} \to \mathcal{C}$.

Definition 2.7: A *strict ribbon category* $\mathcal{C}$ is a strict rigid braided monoidal category with natural isomorphisms (the *twist*),

$$\nu_V : V \to V, \tag{2.20}$$

such that for all objects V, W,

$$\nu_{V \otimes W} = (\nu_V \otimes \nu_W) \circ \psi_{W,V} \circ \psi_{V,W}, \tag{2.21a}$$

$$(\nu_V)^* = \nu_{V^*}, \tag{2.21b}$$

$$\nu_{\mathbf{1}} = \mathrm{id}_{\mathbf{1}}. \tag{2.21c}$$

It is now possible to construct right duals ${}^*V$ from the braiding, the twist and the left duals. The right dual objects agree in this case with the left duals, ${}^*V = V^*$, and right evaluation and right co-evaluation are given by

$$\widetilde{\mathrm{ev}}_V : V \otimes V^* \to \mathbf{1}, \quad \widetilde{\mathrm{ev}}_V := \mathrm{ev}_V \circ \psi_{V,V^*} \circ (\nu_V \otimes \mathrm{id}_{V^*}), \tag{2.22a}$$

$$\widetilde{\mathrm{coev}}_V : \mathbf{1} \to V^* \otimes V, \quad \widetilde{\mathrm{coev}}_V := (\nu_{V^*} \otimes \mathrm{id}_V) \circ \psi_{V,V^*} \circ \mathrm{coev}_V. \tag{2.22b}$$

Finally, right and left duals can be employed in order to define the analog of trace and dimension.

Definition 2.8: Let $\mathcal{C}$ be a strict ribbon category, V an object of $\mathcal{C}$ and $f: V \to V$.

(1) The *quantum trace* of f is defined by

$$\mathrm{qtr}(f) := \widetilde{\mathrm{ev}}_V \circ (f \otimes \mathrm{id}_{V^*}) \circ \mathrm{coev}_V. \tag{2.23}$$

(2) The *quantum dimension* of V is defined by

$$\mathrm{qdim} V := \mathrm{qtr}(\mathrm{id}_V) = \widetilde{\mathrm{ev}}_V \circ \mathrm{coev}_V. \tag{2.24}$$

Note that the quantum trace satisfies $\mathrm{qtr}(g \circ f) = \mathrm{qtr}(f \circ g)$ for $f: V \to W$ and $g: W \to V$. Furthermore, for $h: V \to V$ and $k: W \to W$, $\mathrm{qtr}(h \otimes k) = \mathrm{qtr}(h) \circ \mathrm{qtr}(k)$ and $\mathrm{qdim}(V \otimes W) = \mathrm{qdim} V \circ \mathrm{qdim} W$, where the compositions are in $\mathrm{Hom}(\mathbf{1}, \mathbf{1})$.

All monoidal categories defined above, starting from Definition 2.4, are strict. If a non-strict category is given, there exists an equivalent strict version[23] which can be used instead. As a consequence of the coherence conditions on associativity and unit constraints in the definition of a (nonstrict) monoidal category, it would also be possible to make a choice of parentheses in all definitions and to insert the constraints in a consistent way in all equations. The same would apply to the calculations and results presented in the following sections of this paper.

Furthermore, all categories of interest in this article, are $\mathbb{C}$-linear (for details see, for example, Refs. 21 and 27). This means that there is the notion of a (finite) direct sum of objects, that, furthermore, for given objects V, W the sets $\mathrm{Hom}(V, W)$ form $\mathbb{C}$-vector spaces and that composition of morphisms is $\mathbb{C}$-bilinear. Additionally, there are notions of monomorphism and epimorphism which have the usual properties known from linear algebra. The reader might think of the

case where all objects are $\mathbb{C}$-vector spaces. Finally, the additional structures such as tensor product, braiding, duality and twist are required to be compatible with the $\mathbb{C}$-linear structure, in particular $\mathrm{Hom}(\mathbf{1},\mathbf{1})\cong\mathbb{C}$ such that composition corresponds to multiplication.

As a consequence, $\mathrm{Hom}(U\otimes V,W)\cong\mathrm{Hom}(V,W\otimes U^*)$ are isomorphic as $\mathbb{C}$-vector spaces. We also need the dual space of $\mathrm{Hom}(V,W)$. One can make use of a nondegenerate $\mathbb{C}$-bilinear pairing

$$\mathrm{Hom}(V^*,W^*)\otimes_{\mathbb{C}}\mathrm{Hom}(V,W)\to\mathbb{C},\ f\otimes g\mapsto \mathrm{ev}_W\circ(g\otimes f)\circ\widetilde{\mathrm{coev}}_V, \tag{2.25}$$

in order to define the dual space $\mathrm{Hom}(V,W)^*$ up to isomorphism. Here we use $\mathrm{Hom}(V^*,W^*)$ rather than $\mathrm{Hom}(W,V)$ because some diagrams in the following sections are then related by a mirror symmetry.

All conditions that are required for the construction of the spin foam model are summarized in the following definition.

Definition 2.9: An *admissible* ribbon category is a $\mathbb{C}$-linear strict ribbon category which satisfies the following conditions.

(1) For all objects V, W of $\mathcal{C}$ the space $\mathrm{Hom}(V,W)$ is finite-dimensional as a $\mathbb{C}$-vector space.
(2) The pairing (2.25) is nondegenerate for all objects V, W of $\mathcal{C}$.

A *set of colors* $\mathcal{C}_0$ is a countable set of objects of $\mathcal{C}$ such that

(1) no two elements of $\mathcal{C}_0$ are isomorphic, and
(2) for each object $V\in\mathcal{C}_0$, the set $\mathcal{C}_0$ also contains an object which is isomorphic to V^*.

There are two cases in which one wants to require stronger conditions. First, in order to have a correspondence of the spin foam model with LGT, one seeks a categorical version of the Peter–Weyl theorem and of the Haar measure.

The role of the irreducible representations in the Peter–Weyl theory is now played by the simple objects:

Definition 2.10: Let $\mathcal{C}$ be a $\mathbb{C}$-linear strict ribbon category.

(1) An object V of $\mathcal{C}$ is called *simple* if each nonzero monomorphism $f:U\to V$ is an isomorphism and each nonzero epimorphism $f:V\to W$ is an isomorphism.
(2) $\mathcal{C}$ is called *semi-simple* if each object V of $\mathcal{C}$ is isomorphic to a (finite) direct sum of simple objects.
(3) $\mathcal{C}$ is called *finitely* (*countably*) *semi-simple* if $\mathcal{C}$ is semi-simple and if there are only finitely (countably) many simple objects up to isomorphism.

Corollary 2.11: Let $\mathcal{C}$ be a countably semi-simple and admissible ribbon category such that the unit object $\mathbf{1}$ is simple and such that for each simple object J we have $\mathrm{Hom}(J,J)\cong\mathbb{C}$. Let $\mathcal{C}_0$ denote a set containing one representative per equivalence class of simple objects of $\mathcal{C}$ and let V, W be objects of $\mathcal{C}$. Then the natural map given by composition of morphisms,

$$\bigoplus_{J\in\mathcal{C}_0}\mathrm{Hom}(V,J)\otimes_{\mathbb{C}}\mathrm{Hom}(J,W)\to\mathrm{Hom}(V,W), \tag{2.26}$$

is an isomorphism of $\mathbb{C}$-vector spaces.

The direct sum in (2.26) plays the role of the Peter–Weyl decomposition (2.6) in the categorical framework.

Remark 2.12: Under the conditions of Corollary 2.11, there exists furthermore for each natural transformation $f_V:V\to V$ another natural transformation $(Tf)_V:V\to V$ which is defined by the projection onto the direct summand labeled by $J=\mathbf{1}$ in (2.26),

$$T:\mathrm{Hom}(V,V)\to\mathrm{Hom}(V,\mathbf{1})\otimes\mathrm{Hom}(\mathbf{1},V)\subseteq\mathrm{Hom}(V,V). \tag{2.27}$$

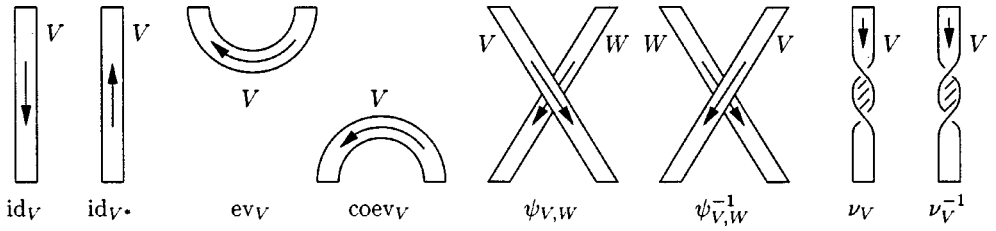

FIG. 1. Some basic ribbon diagrams: The identity morphisms id_V and id_{V^*}, evaluation ev_V and coevaluation coev_V, the braiding $\psi_{V,W}$, the twist ν_V and their inverses, cf. Definitions 2.4–2.7.

These $(Tf)_V$ satisfy, for example, $(Tf)_J=0$ for all simple objects J which are not isomorphic to the unit object **1**.

The projection T can be viewed as the translation of the Haar measure $\int: C_{\mathrm{alg}}(G)\to\mathbb{C}$ into the categorical language, cf. (2.12).

A detailed explanation of how Corollary 2.11 and Remark 2.12 are related with Peter–Weyl decomposition and Haar measure in the Lie group case can be found in Ref. 3. In the picture of Ref. 3, the algebra of representation functions $C_{\mathrm{alg}}(G)$ of the Lie group G co-acts on the vector spaces dual to the representations V_ρ of G.

A second situation in which one sometimes requires semi-simplicity is the case when the spin foam model defines a topological invariant; see, for example, Ref. 10. Recall, however, that the categories of finite-dimensional representations of the quantum groups $U_q(\mathfrak{g})$, q a root of unity, which form important examples, are not semi-simple.[21] I thank R. Oeckl for pointing out that the weaker notions of quasi-dominance and dominance (Chapt. XI of Ref. 26) can be used to establish a uniform treatment of all interesting cases.

The problem of the definition of the spin foam model with ribbon categories which is the subject of the present article is, however, not affected by these subtleties since it relies only on Definition 2.9.

2. Ribbon diagrams

There exists a very convenient notation for morphisms of a ribbon category $\mathcal{C}$ in terms of *ribbon diagrams* (Fig. 1). The diagrams consist of ribbons which have a white side (normally facing up) and a black side (facing down). They are directed which is denoted by arrows, and they are labeled with objects of $\mathcal{C}$.

The identity morphism id_V is represented by a ribbon labeled V with the arrow pointing down. The identity morphism id_{V^*} of the dual object has the same label V, but an arrow pointing up. The diagrams are generally read from top to bottom. Putting diagrams below each other denotes composition of morphisms while putting them next to each other denotes the tensor product of

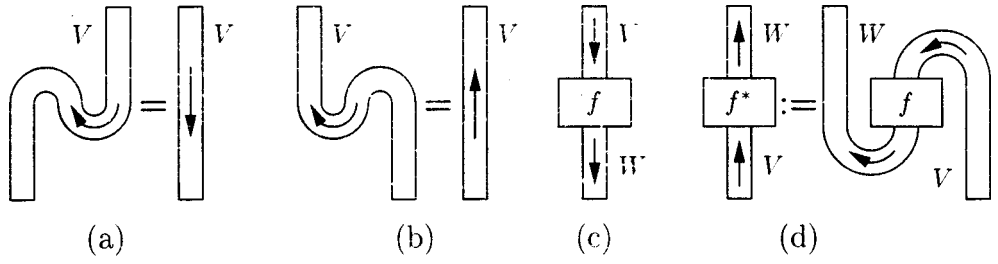

FIG. 2. The conditions (2.18a) and (2.18b) on evaluation and coevaluation are depicted in diagrams (a) and (b). A morphism $f: V\to W$ is represented by a coupon as in (c). Diagram (d) shows the definition of the dual morphism f^* as given by (2.19).

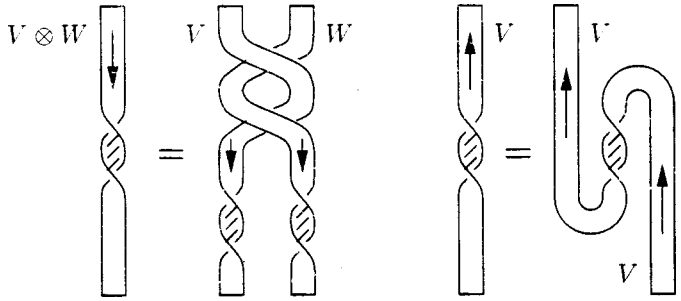

FIG. 3. The conditions (2.21a) and (2.21b) on the twist ν_V in diagrammatic notation.

morphisms. Figure 1 also shows the natural isomorphisms ev_V, coev_V of (2.17), the braiding $\psi_{V,W}$ of (2.14), the twist ν_V of (2.20) and their inverses, respectively. The unit object **1** is invisible in the diagrams which is justified by (2.13b), (2.15c) and (2.21c).

Figure 2 shows the conditions (2.18a) and (2.18b) on evaluation and coevaluation in (a) and (b). Morphisms $f: V \to W$ are represented by a *coupon* labeled f with an incoming and an outgoing ribbon as in (c). Figure 2 also shows the definition of the dual morphism (2.19) in diagram (d).

The conditions (2.21a) and (2.21b) on the twist ν_V in a ribbon category are depicted in Fig. 3. Figure 4 shows the definition of right duals via $\widetilde{\mathrm{ev}}_V$ and $\widetilde{\mathrm{coev}}_V$ of (2.22), the quantum trace (2.23) and the quantum dimension (2.24).

The main purpose of the ribbon diagrams presented in this section is that they have an immediate translation into algebraic language in terms of morphisms of the ribbon category $\mathcal{C}$ and at the same time provide an intuitive way of dealing with the algebraic manipulations. One can imagine that the ribbons shown in the diagrams are embedded in $\mathbb{R}^3$. The obvious isotopies then correspond to relations in $\mathcal{C}$. This is a direct consequence of the functor constructed by Reshetikhin and Turaev in Ref. 23 where more details can be found. In the following, we present many calculations in the diagrammatic language. If required, they can be translated at any stage into the corresponding algebraic expressions.

In the remaining parts of the article, we employ a simplified notation in which the ribbons are represented by single directed lines, and it is understood that their white side always faces up. This is known as *blackboard framing*. It is particularly convenient here because it turns out that the relevant diagrams in the following sections can be drawn without twists.

3. Quantum groups and ribbon categories

The ribbon categories arising in Ref. 23 are constructed as the categories of finite-dimensional representations of suitable ribbon Hopf algebras (see also Refs. 21, 22, and 26).

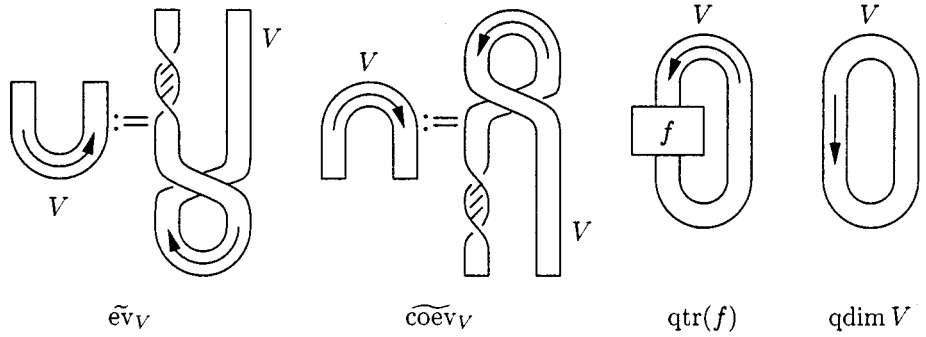

FIG. 4. Definition of right duality, $\widetilde{\mathrm{ev}}_V$ and $\widetilde{\mathrm{coev}}_V$ of (2.22), the quantum trace (2.23) and the quantum dimension (2.24).

An alternative picture is developed in Ref. 3. It is dual to the former in the sense that it uses the dual Hopf algebra co-acting on the dual spaces of the representations. It is thus based on coribbon Hopf algebras and their ribbon category of corepresentations. This point of view is much closer to the duality transformation for LGT with Lie groups (see Sec. III or Ref. 17) since the algebra of representation functions $C_{\mathrm{alg}}(G)$ of the gauge group naturally coacts on the dual spaces of the representations of G and can be replaced by a suitable coribbon Hopf algebra.[3]

C. Combinatorial and simplicial complexes

1. Triangulations

For the construction of the spin foam model using ribbon categories, we need combinatorial complexes and simplicial complexes. Combinatorial complexes contain the information of which simplices are contained in the boundary of a given simplex while simplicial complexes also provide a linear order of the vertices and keep track of all relative orientations. This terminology follows Ref. 7. In order to construct a spin foam model for ribbon categories, we aim for a definition of the partition function which takes the relative orientations into account, but which does not depend on the linear order of vertices.

For the purpose of the present article, it is furthermore sufficient to deal with abstract complexes. The details of how their simplices are mapped to the given manifold are not discussed here except for a few restrictions that apply if the complex corresponds to a closed and oriented manifold.

Definition 2.13: For a given set Λ of *vertices*, a *combinatorial complex* $\Lambda^{(*)}$ is a nonempty set of subsets of Λ,

$$\varnothing \neq \Lambda^{(*)} \subseteq \mathcal{P}\Lambda, \tag{2.28}$$

such that for each $v \in \Lambda$, $\{v\} \in \Lambda^{(*)}$ and for each set $X \in \Lambda^{(*)}$, all its nonempty subsets are also contained in $\Lambda^{(*)}$, i.e.,

$$X \in \Lambda^{(*)} \quad \text{and} \quad \varnothing \neq Y \subseteq X \Rightarrow Y \in \Lambda^{(*)}. \tag{2.29}$$

The sets $X \in \Lambda^{(*)}$ are called *simplices*. The subsets $\varnothing \neq Y \subseteq X$ are the *faces of* X. The elements of the set

$$\Lambda^{(k)} := \{X \in \Lambda^{(*)}: \quad |X| = k+1\}, \quad k \in \mathbb{N}, \tag{2.30}$$

are called k-simplices. Here $|\cdot|$ denotes the cardinality of a set. A *combinatorial k-complex* is a combinatorial complex for which $\Lambda^{(j)} = \varnothing$ for all $j > k$. For each k-simplex $X \in \Lambda^{(k)}$, its *boundary* is defined as the collection of $(k-1)$-simplices,

$$\partial X := \{Y \subseteq X: \ |Y| = k\}. \tag{2.31}$$

A combinatorial complex is called *finite* if $\Lambda^{(*)}$ is a finite set.

Definition 2.14: A *simplicial complex* $(\Lambda^{(*)}, <)$ is a combinatorial complex $\Lambda^{(*)}$ with a linear order $(<)$ of the vertices Λ. The k-simplices $X \in \Lambda^{(k)}$ can then be represented by $(k+1)$-tuples $(v_0, v_1, \ldots, v_k)$ of vertices $v_j \in \Lambda$ in standard order $v_0 < v_1 < \ldots < v_k$. In the free $\mathbb{Z}$-module generated by $\Lambda^{(*)}$, the boundary of a k-simplex is given as a sum over the $(k-1)$-simplices in ∂X,

$$\partial(v_0, v_1, \ldots, v_k) := \sum_{j=0}^{k} (-1)^j (v_0, v_1, \ldots, \hat{v}_j, \ldots, v_k), \tag{2.32}$$

where the hat $(\hat{\ })$ indicates that a symbol is omitted. An abbreviated notation is

$$(01\cdots k) := (v_0, v_1, \ldots, v_k). \tag{2.33}$$

In the following we also use the notation $(v_0,v_1,\ldots,v_k)$ with arbitrary vertex order. In the simplicial complex this denotes an oriented k-simplex $\mathrm{sgn}\tau\cdot(v_{\tau(0)},\ldots,v_{\tau(k)})$ where the sign depends on the sign of the permutation $\tau\in\mathcal{S}_{k+1}$ which is required to sort the vertices such that $v_{\tau(0)}<\ldots<v_{\tau(k)}$.

The triangulations of a compact piecewise-linear k-manifold M can be chosen to have only finitely many simplices. In this case their combinatorics are described by a finite combinatorial k-complex for which there always exists a linear order of vertices.

For a simplicial k-complex which corresponds to the triangulation of a closed and oriented k-manifold M, the relative orientation of each simplex σ with respect to M is given, i.e., whether $+\sigma$ or $-\sigma$ is isomorphic to a simplex in M. Observe further that in this case each $(k-1)$-simplex is contained in the boundary of exactly two k-simplices: once with positive and once with negative relative orientation.

2. The dual two-complex

In the present article the spin foam model is defined on a combinatorial complex $\Lambda^{(*)}$. This point of view agrees with, Refs. 7 and 10, but is dual to the definition given in Ref. 12.

In order to compare the spin foam model on $\Lambda^{(*)}$ with LGT, this LGT has to be formulated on the two-complex dual to $\Lambda^{(*)}$. In this section, we define a generalized notion of two-complexes which includes polygons rather than just triangles and which makes the cyclic ordering of edges around the polygons explicit. This ordering is necessary to arrange the factors of the group products which are used in the definition of LGT.

Definition 2.15: A *finite generalized two-complex with cyclic structure* (V,E,F) consists of finite sets V (*vertices*), E (*edges*) and F (*polygons*) together with maps

$$\partial_+ : E\to V \quad \text{(end point of an edge)}, \tag{2.34a}$$

$$\partial_- : E\to V \quad \text{(starting point of an edge)}, \tag{2.34b}$$

$$N: F\to\mathbb{N} \quad \text{(number of edges in the boundary of a polygon)}, \tag{2.34c}$$

$$\partial_j : F\to E \quad \text{(the } j\text{th edge in the boundary)}, \tag{2.34d}$$

$$\varepsilon_j : F\to\{-1,+1\} \quad \text{(its orientation)} \tag{2.34e}$$

such that

$$\partial_{-\varepsilon_j f}\partial_j f=\partial_{\varepsilon_{j+1}f}\partial_{j+1}f, \quad 1\leqslant j\leqslant N(f)-1, \tag{2.35a}$$

$$\partial_{-\varepsilon_{N(f)}f}\partial_{N(f)}f=\partial_{\varepsilon_1 f}\partial_1 f, \tag{2.35b}$$

for all $f\in F$.

The conditions (2.35) state that the edges in the boundary of a polygon $f\in F$ are in cyclic ordering from $\partial_1 f$ to $\partial_{N(f)}f$ where one encounters the edges with a relative orientation given by $-\varepsilon_j f$, (see Fig. 5). Observe that (2.35) can be used to generalize the condition $\partial\circ\partial=0$ to the situation where the edges are labeled with noncommutative variables.

Given a finite simplicial k-complex $\Lambda^{(*)}$, one can construct the dual two-complex (V,E,F) in the standard way: The dual vertices are just the k-simplices, $V:=\Lambda^{(k)}$. The dual edges are the $(k-1)$-simplices, $E:=\Lambda^{(k-1)}$, and the dual polygons are given by the $(k-2)$-simplices, $F:=\Lambda^{(k-2)}$. Observe that the $(k-2)$-simplices $\Lambda^{(k-2)}$ are in general contained in the boundaries of more than three $(k-1)$-simplices which implies that the polygons F have in general more than three edges. The maps ∂_j, ε_j, etc. of (2.34) can be constructed inductively from the boundary relation of the simplicial complex.

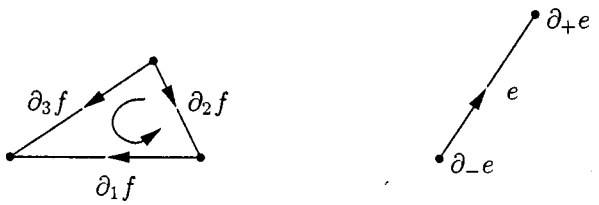

FIG. 5. The maps ∂_j and ε_j and the conditions (2.35). Here $N(f)=3$, $\varepsilon_1 f=+1$, $\varepsilon_2 f=+1$ and $\varepsilon_3 f=(-1)$.

In the calculations of the next section, the following abbreviations are convenient: For a given edge $e \in E$, the sets

$$e_+ := \{f \in F:\ e=\partial_j f,\quad \varepsilon_j f=(+1)\quad \text{for some } j,\quad 1 \leqslant j \leqslant N(f)\}, \tag{2.36a}$$

$$e_- := \{f \in F:\ e=\partial_j f,\quad \varepsilon_j f=(-1)\quad \text{for some } j,\quad 1 \leqslant j \leqslant N(f)\}, \tag{2.36b}$$

contain all polygons that have the edge e in their boundary with positive $(+)$ or negative $(-)$ orientation. For a given polygon $f \in F$, the set

$$f_0 := \{v \in V:\ v=\delta_- \delta_j f \quad \text{for some } j,\quad 1 \leqslant j \leqslant N(f)\} \tag{2.37}$$

denotes all vertices that are contained in the boundary of the polygon f. Finally, the sets

$$f_+ := \{e \in E:\ e=\partial_j f,\quad \varepsilon_j f=(+1)\quad \text{for some } j,\quad 1 \leqslant j \leqslant N(f)\}, \tag{2.38a}$$

$$f_- := \{e \in E:\ e=\partial_j f,\quad \varepsilon_j f=(-1)\quad \text{for some} j,\quad 1 \leqslant j \leqslant N(f)\}, \tag{2.38b}$$

denote all edges in the boundary of the polygon f with positive $(+)$ or negative $(-)$ orientation.

III. THE DUALITY TRANSFORMATION

In this section, we recall the duality transformation relating LGT for Lie groups on the dual generalized two-complex (V,E,F) with a spin foam model. This transformation was carried out in Ref. 17 on a hypercubic lattice and is formulated here for generic two-complexes.

The calculation is presented entirely in terms of the two-complex (V,E,F) and does not refer to the simplicial complex $\Lambda^{(*)}$. Its relation with $\Lambda^{(*)}$ will be discussed in the following section. The calculation is furthermore valid in arbitrary dimension $d \geqslant 2$.

Definition 3.1: Let G be a compact Lie group (or a finite group). The partition function of LGT on the finite generalized two-complex (V,E,F) with cyclic structure is defined by

$$Z = \left(\prod_{e \in E} \int_G dg_e \right) \prod_{f \in F} w(g_f), \quad g_f := g_{\partial_1 f}^{\varepsilon_1 f} \cdots g_{\partial_{N(f)} f}^{\varepsilon_{N(f)} f}. \tag{3.1}$$

Here $\int_G$ denotes the normalized Haar measure on G, $w: G \to \mathbb{R}$ is the Boltzmann weight (1.1), and g_f is the cyclicly ordered product of the group elements attached to the edges in the boundary of the polygon $f \in F$.

Remark 3.2: (1) Observe that even though this definition explicitly refers to the cyclic structure, the value of Z is actually independent of it. The starting point for the cyclic numbering of edges in the boundary of a polygon does not matter because the Boltzmann weight is given by a class function and thus invariant under cyclic permutation of the factors of g_f. Reversal of the orientation is also a symmetry because it replaces g_f by g_f^{-1} which yields the complex conjugate of the class function, but this function is real.

(2) Let $h: V \to G, v \mapsto h_v$ associate a group element to each vertex. The weight $w(g_f)$ in (3.1) is invariant under the *local gauge transformations*,

$$g_e \mapsto h_{\partial_+ e} \cdot g_e \cdot h_{\partial_- e}^{-1}. \tag{3.2}$$

In order to prove this invariance, one has to make use of the conditions (2.35).

The first step of the duality transformation is to insert the character expansion (1.2) of the Boltzmann weight into (3.1),

$$Z = \left(\prod_{e \in E} \int_G dg_e \right) \prod_{f \in F} \sum_{\rho_f \in \mathcal{R}} \hat{w}_{\rho_f} \sum_{n_f=1}^{\dim V_{\rho_f}} t^{(\rho_f)}_{n_f n_f}(g_f). \tag{3.3}$$

The trace of the character is responsible for summations over one index n_f per polygon $f \in F$. The application of coproduct and antipode [Eqs. (2.4a) and (2.4c)] to the product g_f [Eq. (3.1)] yields further vector index summations. In total there is one summation per polygon and per vertex of that polygon. These summation variables are denoted by $n(f,v)$ where $f \in F$ and $v \in f_0$,

$$\begin{aligned} Z = \left(\prod_{e \in E} \int_G dg_e \right) \prod_{f \in F} \sum_{\rho_f \in \mathcal{R}} \hat{w}_{\rho_f} \sum_{n(f,\partial_- \partial_1 f)=1}^{\dim V_{\rho_f}} \cdots \sum_{n(f,\partial_- \partial_{N(f)} f)=1}^{\dim V_{\rho_f}} \\ t^{(\rho_f)}_{n(f,\partial_+ \partial_1 f), n(f,\partial_- \partial_1 f)}(g_{\partial_1 f}^{\varepsilon_1 f}) \cdots t^{(\rho_f)}_{n(f,\partial_+ \partial_{N(f)} f), n(f,\partial_- \partial_{N(f)} f)}(g_{\partial_{N(f)} f}^{\varepsilon_{N(f)} f}). \end{aligned} \tag{3.4}$$

Recall that the conditions (2.35) of the two-complex apply here. The above expression can now be reorganized, moving all summations to the left,

$$\begin{aligned} Z = \left(\prod_{e \in E} \int_G dg_e \right) \left(\prod_{f \in F} \sum_{\rho_f \in \mathcal{R}} \right) \left(\prod_{f \in F} \hat{w}_{\rho_f} \right) \left(\prod_{f \in F} \prod_{v \in f_0} \sum_{n(f,v)=1}^{\dim V_{\rho_f}} \right) \\ \prod_{f \in F} \left(\prod_{e \in f_+} t^{(\rho_f)}_{n(f,\partial_+ e), n(f,\partial_- e)}(g_e) \right) \left(\prod_{e \in f_-} t^{(\rho_f^*)}_{n(f,\partial_- e), n(f,\partial_+ e)}(g_e) \right). \end{aligned} \tag{3.5}$$

Here the notation

$$\left(\prod_{f \in F} \sum_{\rho_f \in \mathcal{R}} \right) := \sum_{\rho_f \in \mathcal{R}} \cdots \sum_{\rho_f \in \mathcal{R}} \tag{3.6}$$

denotes one summation per polygon $f \in F$. Sorting the product of representation functions by edge rather than by polygon amounts to just a slight change in the enumeration of polygons and edges,

$$\begin{aligned} Z = \left(\prod_{f \in F} \sum_{\rho_f \in \mathcal{R}} \right) \left(\prod_{f \in F} \hat{w}_{\rho_f} \right) \left(\prod_{f \in F} \prod_{v \in f_0} \sum_{n(f,v)=1}^{\dim V_{\rho_f}} \right) \\ \prod_{e \in E} \int_G dg_e \left[\prod_{e \in E} \left(\prod_{f \in e_+} t^{(\rho_f)}_{n(f,\partial_+ e), n(f,\partial_- e)}(g_e) \right) \left(\prod_{f \in e_-} t^{(\rho_f^*)}_{n(f,\partial_- e), n(f,\partial_+ e)}(g_e) \right) \right]. \end{aligned} \tag{3.7}$$

The integrals can now be evaluated using the formula (2.12),

$$\int_G dg_e [\cdots] = \sum_{P^{(e)} \in \mathcal{P}_e} P^{(e) \overbrace{n(f,\partial_+ e),\ldots}^{f \in e_+} \overbrace{n(f,\partial_- e),\ldots}^{f \in e_-}} P^{(e)}_{\underbrace{n(f,\partial_- e),\ldots}_{f \in e_+} \underbrace{n(f,\partial_+ e),\ldots}_{f \in e_-}}, \tag{3.8}$$

where $\mathcal{P}_e$ denotes a basis of orthogonal G-invariant projectors onto the trivial components in the complete decomposition of

$$\left(\bigotimes_{f\in e_+}\rho_f\right)\otimes\left(\bigotimes_{f\in e_-}\rho_f^*\right). \tag{3.9}$$

The curly brackets in (3.8) indicate that there is one index $n(f,\partial_+ e)$ for each $f\in e_+$ etc. Finally, the sums over projectors are moved to the left of the expression,

$$Z=\left(\prod_{f\in F}\sum_{\rho_f\in\mathcal{R}}\right)\left(\prod_{e\in E}\sum_{P^{(e)}\in\mathcal{P}_e}\right)\left(\prod_{f\in F}\hat{w}_{\rho_f}\right)\left(\prod_{f\in F}\prod_{v\in f_0}\sum_{n(f,v)=1}^{\dim V_{\rho_f}}\right)$$
$$\prod_{e\in E}P^{(e)\overbrace{n(f,\partial_+e),\ldots}^{f\in e_+}\overbrace{n(f,\partial_-e),\ldots}^{f\in e_-}}P^{(e)}_{\underbrace{n(f,\partial_-e),\ldots}_{f\in e_+}\underbrace{n(f,\partial_+e),\ldots}_{f\in e_-}}. \tag{3.10}$$

This formula can now be reorganized and yields the final result:

Theorem 3.3: The partition function (3.1) of LGT on the finite generalized two-complex (V,E,F) with cyclic structure is equal to the expression

$$Z=\left(\prod_{f\in F}\sum_{\rho_f\in\mathcal{R}}\right)\left(\prod_{e\in E}\sum_{P^{(e)}\in\mathcal{P}_e}\right)\left(\prod_{f\in F}\hat{w}_{\rho_f}\right)\left(\prod_{v\in V}C(v)\right). \tag{3.11}$$

Here $\mathcal{P}_e$ denotes a basis of orthogonal G-invariant projectors onto the trivial components in the complete decomposition of (3.9). The weights per polygon $\hat{w}_{\rho_f}$ are the coefficients of the character expansion (1.2) of the original Boltzmann weight. The weights per vertex $C(v)$ are given by a trace involving representations and projectors in the neighborhood of the vertex $v\in V$,

$$C(v)=\left(\prod_{\substack{f\in F:\\ v\in f_0}}\sum_{n_f=1}^{\dim V_{\rho_f}}\right)\left(\prod_{\substack{e\in E:\\ v=\partial_+e}}P^{(e)\overbrace{n_fn_f\ldots}^{f\in e_+}\overbrace{n_fn_f\ldots}^{f\in e_-}}\right)\left(\prod_{\substack{e\in E:\\ v=\partial_-e}}P^{(e)}_{\underbrace{n_fn_f\ldots}_{f\in e_+}\underbrace{n_fn_f\ldots}_{f\in e_-}}\right). \tag{3.12}$$

Remark 3.4: (1) The projectors onto the trivial representations,

$$P^{(e)}:\left(\bigotimes_{f\in e_+}\rho_f\right)\otimes\left(\bigotimes_{f\in e_-}\rho_f^*\right)\to\mathbb{C}, \tag{3.13}$$

can be replaced via the isomorphisms $\mathrm{Hom}(V\otimes W^*,\mathbb{C})\cong\mathrm{Hom}(V,W)$ by representation morphisms

$$\varphi^{(e)}:\bigotimes_{f\in e_+}\rho_f\to\bigotimes_{f\in e_-}\rho_f. \tag{3.14}$$

The partition function then contains a sum over a basis of the space of representation morphisms for each edge $e\in E$,

$$\mathrm{Hom}\left(\bigotimes_{f\in e_+}\rho_f\,,\ \bigotimes_{f\in e_-}\rho_f\right). \tag{3.15}$$

(2) The expression $C(v)$ is a trace in the category of finite dimensional representations Rep G, cf. Fig. 6(a). Observe that all vector indices n_f are contracted. The complexity of the $C(v)$ depends on the number of edges which contain $v\in V$ in their boundary. In order to generalize this spin foam model to ribbon categories, $C(v)$ has to be replaced by a quantum trace. The main motivation for formulating LGT on the two-complex dual to a triangulation is that it is now guaranteed that in dimension 4 there are always precisely five edges which contain v. Without this restriction, the generalization of $C(v)$ to the ribbon case would be much harder.

(3) Observe that for $G=\mathrm{SU}(2)$ in three dimensions, the $C(v)$ are essentially the $6j$-symbols of SU(2).

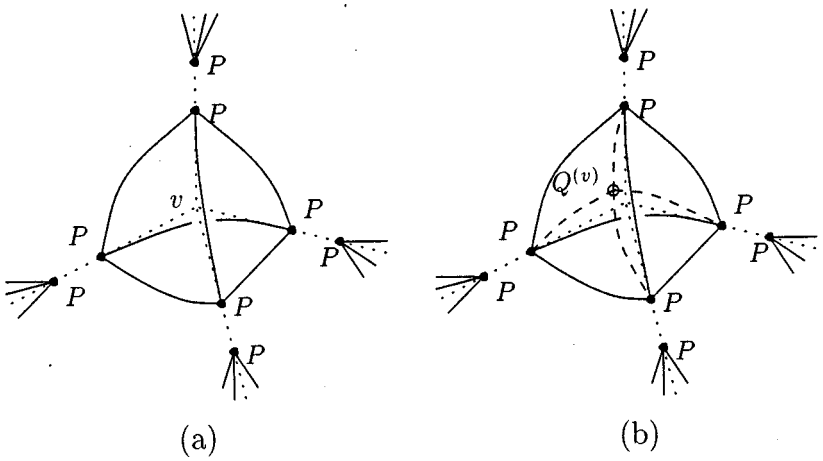

FIG. 6. The neighborhood of a vertex $v \in V$ on the dual two-complex in the three-dimensional case. The dotted lines denote the four edges attached to the vertex. Diagram (a) shows the weight $C(v)$ per vertex $v \in V$ occurring in the spin foam model where the full dots denote projectors $P^{(e)}$, and the solid lines the representations V_ρ. Diagram (b) visualizes the weight $\tilde{C}(v)$ in the spin network expectation value. Here $Q^{(v)}$ is the morphism attached to v, and the dashed lines denote the representations τ_e.

The generic observables of LGT that have nonvanishing expectation values under the path integral are *spin networks*, the generalization of Wilson loops to the non-Abelian case.

Definition 3.5: Let G be a compact Lie group (or a finite group), (V,E,F) be a finite generalized two-complex with cyclic structure and Z denote the partition function of LGT of Definition 3.1. Let $\tau: E \to \mathcal{R}$ assign a unitary finite-dimensional irreducible representation τ_e to each edge $e \in E$ and for each vertex $v \in V$, let

$$Q^{(v)}: \bigotimes_{\substack{e \in E: \\ v = \partial_+ e}} \tau_e \to \bigotimes_{\substack{e \in E: \\ v = \partial_- e}} \tau_e \tag{3.16}$$

denote a representation morphism. The *spin network* labeled by τ_e and $Q^{(v)}$ associates to each configuration $E \to G, e \mapsto g_e$ the value

$$W(\tau,Q) := \frac{1}{Z}\left(\prod_{e \in E} \sum_{k_e,l_e=1}^{\dim V_{\tau_e}}\right)\left(\prod_{e \in E} t^{(\tau_e)}_{k_e l_e}(g_e)\right)\left(\prod_{v \in V} Q^{(v)}_{\underbrace{k_e \cdots}_{\substack{e \in E: \\ v = \partial_+ e}} \ \underbrace{l_e \cdots}_{\substack{e \in E: \\ v = \partial_- e}}}\right). \tag{3.17}$$

For more details on this definition and for the proof of the following result, we refer the reader to Ref. 17.

Theorem 3.6: Let G be a compact Lie group (or a finite group) and (V,E,F) be a finite generalized two-complex with cyclic structure. Let τ_e and $Q^{(v)}$ define a spin network as in Definition 3.5. The expectation value of the spin network,

$$\langle W(\tau,Q)\rangle = \left(\prod_{e \in E} \int_G dg_e\right)\left[W(\tau,Q)\prod_{f \in F} w(g_f)\right], \tag{3.18}$$

TABLE I. The partition function of the spin foam model dual to LGT (3.11) is a sum over all colorings where the summands contain certain weights. Here colorings and weights are given for LGT living on the two-complex dual to the triangulation.

Triangulation	Dual two-complex	Coloring	Weights
four-simplex	vertex	-	$C(v)$
tetrahedron	edge	morphism	-
triangle	polygon	simple object	$\hat{w}_\rho$
edge	-	-	-
vertex	-	-	-

is equal to

$$\langle W(\tau,Q)\rangle = \frac{1}{Z}\left(\prod_{f\in F}\sum_{\rho_f\in\mathcal{R}}\right)\left(\prod_{e\in E}\sum_{P^{(e)}\in\tilde{\mathcal{P}}_e}\right)\left(\prod_{f\in F}\hat{w}_{\rho_f}\right)$$
$$\prod_{v\in V}\left[\left(\prod_{\substack{e\in E\\ v=\partial_+ e}}\sum_{k_e=1}^{\dim V_{\tau_e}}\right)\left(\prod_{\substack{e\in E\\ v=\partial_- e}}\sum_{l_e=1}^{\dim V_{\tau_e}}\right)\tilde{C}(v)\cdot Q^{(v)}_{\underbrace{k_e\ldots}_{\substack{e\in E:\\ v=\partial_+ e}}\ \underbrace{l_e\ldots}_{\substack{e\in E:\\ v=\partial_- e}}}\right]. \tag{3.19}$$

Here $\tilde{\mathcal{P}}_e$ is a basis of orthogonal G-invariant projectors onto the trivial components in the complete decomposition of

$$\left(\bigotimes_{f\in e_+}\rho_f\right)\otimes\left(\bigotimes_{f\in e_-}\rho_f^*\right)\otimes\tau_e\,. \tag{3.20}$$

The weights per polygon $\hat{w}_{\rho_f}$ are the coefficients of the character expansion (1.2) of the original Boltzmann weight. The weights per vertex $\tilde{C}(v)$ are given by the trace

$$\tilde{C}(v)=\left(\prod_{\substack{f\in F:\\ v\in f_0}}\sum_{n_f=1}^{\dim V_{\rho_f}}\right)\left(\prod_{\substack{e\in E:\\ v=\partial_+ e}}P^{(e)\overbrace{n_f n_f\ldots}^{f\in e_+}\overbrace{n_f n_f\ldots}^{f\in e_-}k_e}\right)\left(\prod_{\substack{e\in E:\\ v=\partial_- e}}P^{(e)}_{\underbrace{n_f n_f\ldots}_{f\in e_+}\underbrace{n_f n_f\ldots}_{f\in e_-}l_e}\right). \tag{3.21}$$

Remark 3.7: (1) The Theorem 3.6 is an example for an explicit calculation how the spin foams that are the configurations in the partition function couple to the spin network $W(\tau,Q)$. Figure 6(b) visualizes the trace which gives the weights per vertex $\tilde{C}(v)$.

(2) If the set of edges for which the representations τ_e are nontrivial forms a closed loop, then $W(\tau,Q)$ is nonzero only if the non-trivial τ_e are all isomorphic. The morphisms $Q^{(v)}$ are then unique up to normalization. In this case $W(\tau,Q)$ describes a Wilson loop.

IV. THE SPIN FOAM MODEL FOR RIBBON CATEGORIES

In Sec. III, the spin foam model dual to LGT was derived for the case in which the gauge group G is a Lie group. If LGT is defined on the two-complex dual to the triangulation, the partition function of the spin foam model consists of a sum over all labelings of triangles with irreducible representations (simple objects) and of all tetrahedra with invariant projectors (representation morphisms) (see Table I).

This spin foam model shall be generalized to a ribbon category $\mathcal{C}$ which replaces the category of representations Rep G of the gauge group G. The partition function will contain the sum over all colorings of triangles with simple objects explicitly while the sum over all colorings of tetrahedra with morphisms will be implemented as a trace over suitable state spaces.

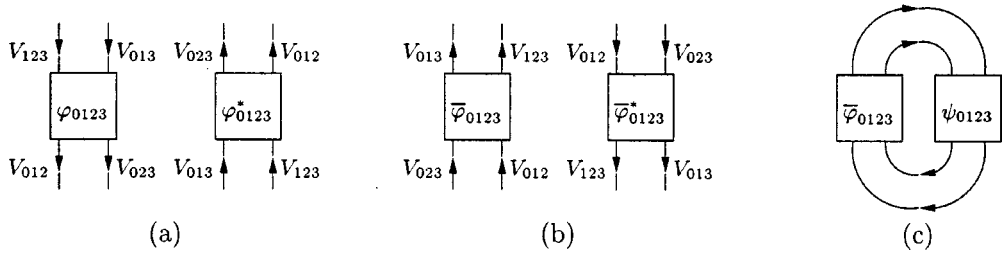

FIG. 7. (a) The coupons denoting morphisms $\varphi_{0123}\in H_{0123}$ and their duals φ^*_{0123} (4.4a) as well as (b) morphisms of the dual state spaces, $\overline{\varphi}_{0123}\in H^*_{0123}$ and their duals $\overline{\varphi}^*_{0123}$ (4.3b). Diagram (c) shows the pairing (4.5). All ribbons are drawn in blackboard framing.

The definition of the spin foam model is formulated in a first step for a given simplicial four-complex. The definition thus refers explicitly to the linear order of vertices. In a second step we will prove that it does not depend on that order and that it is thus well-defined for any combinatorial complex that corresponds to the triangulation of a closed and oriented piecewise-linear four-manifold.

A. Definition of the partition function

First we define the colorings which will be explicitly summed over in the partition function.

Definition 4.1: Let $\Lambda^{(*)}$ denote a simplicial complex, $\mathcal{C}$ be an admissible ribbon category (Definition 2.9) and $\mathcal{C}_0$ be a set of colors.

(1) A *coloring* $V:\Lambda^{(2)}\to\mathcal{C}_0$ associates an object $V(v_0,v_1,v_2)\in\mathcal{C}_0$ to each triangle $(v_0,v_1,v_2)\in\Lambda^{(2)}$ with standard vertex order $v_0<v_1<v_2$.

(2) For any permutation $\sigma\in\mathcal{S}_3$ (acting on $\{0,1,2\}$) define

$$V(v_{\sigma(0)},v_{\sigma(1)},v_{\sigma(2)}):=\begin{cases} V(v_0,v_1,v_2), & \text{if} \quad \operatorname{sgn}\sigma=1,\\ V(v_0,v_1,v_2)^*, & \text{if} \quad \operatorname{sgn}\sigma=-1. \end{cases} \tag{4.1}$$

For given vertices $v_0,v_1,v_2\in\Lambda$, we use the abbreviated notation

$$V_{012}:=V(v_0,v_1,v_2), \quad V_{021}:=V(v_0,v_2,v_1), \tag{4.2}$$

and so on, for example, $V_{021}=V^*_{012}$.

Recall that $(V^*)^*\cong V$ is isomorphic in $\mathcal{C}$, but in general not equal. The Definition 4.1 therefore describes an action of the symmetric group $\mathcal{S}_3$ only up to isomorphism.

The state spaces are defined in the next step. A trace over these spaces will yield the summation over colorings of the tetrahedra with morphisms.

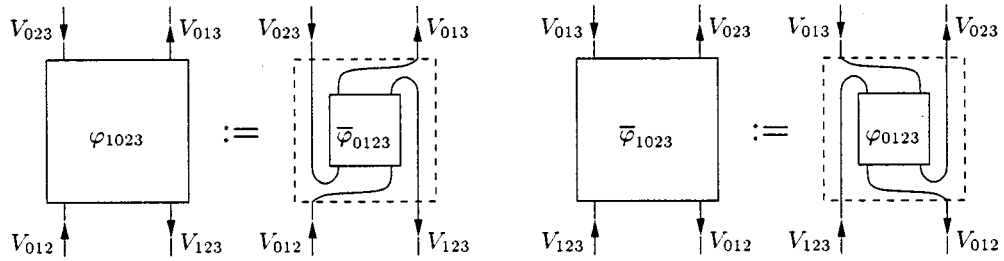

FIG. 8. The definition of the morphisms $\varphi_{1023}:=\tau_0^{*-1}(\overline{\varphi}_{0123})\in H_{1023}$ and $\overline{\varphi}_{1023}:=\tau_0(\varphi_{0123})\in H^*_{1023}$ for given $\overline{\varphi}_{0123}\in H^*_{0123}$ and $\varphi_{0123}\in H_{0123}$ [see (4.6a)].

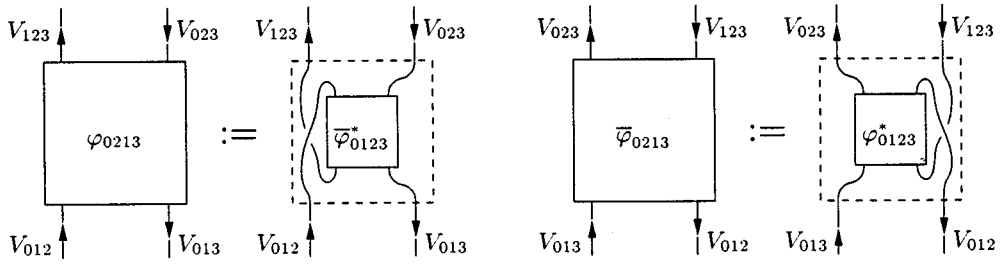

FIG. 9. The definition of the morphisms $\varphi_{0213} := \tau_1^{*-1}(\overline{\varphi}_{0123}) \in H_{0213}$ and $\overline{\varphi}_{0213} := \tau_1(\varphi_{0123}) \in H^*_{0213}$ for given $\overline{\varphi}_{0123} \in H^*_{0123}$ and $\varphi_{0123} \in H_{0123}$ [see (4.6b)].

Definition 4.2: Let $V: \Lambda^{(2)} \to \mathcal{C}_0$ denote a coloring. The *state space* associated with a tetrahedron (v_0, v_1, v_2, v_3) with arbitrary vertex order is defined by

$$H^{(V)}(v_0, v_1, v_2, v_3) := \mathrm{Hom}(V(v_1, v_2, v_3) \otimes V(v_0, v_1, v_3), V(v_0, v_1, v_2) \otimes V(v_0, v_2, v_3)). \tag{4.3a}$$

The dual state space is then given up to isomorphism by the pairing (2.25),

$$H^{(V)}(v_0, v_1, v_2, v_3)^* := \mathrm{Hom}(V(v_0, v_1, v_3)^* \otimes V(v_1, v_2, v_3)^*, V(v_0, v_2, v_3)^* \otimes V(v_0, v_1, v_2)^*). \tag{4.3b}$$

The following abbreviated notation is used,

$$H_{0123} = \mathrm{Hom}(V_{123} \otimes V_{013}, V_{012} \otimes V_{023}), \tag{4.4a}$$

$$H^*_{0123} = \mathrm{Hom}(V^*_{013} \otimes V^*_{123}, V^*_{023} \otimes V^*_{012}), \tag{4.4b}$$

so that the pairing (2.25) reads in this case

$$\langle \cdot, \cdot \rangle_{0123} : H^*_{0123} \otimes H_{0123} \to \mathbb{C}, (\overline{\varphi}_{0123}, \psi_{0123}) \mapsto \langle \overline{\varphi}_{0123}, \psi_{0123} \rangle_{0123}. \tag{4.5}$$

The ribbon diagrams corresponding to a morphism $\varphi_{0123} \in H_{0123}$ and its dual φ^*_{0123} are depicted in Fig. 7(a). The morphism of the dual state space $\overline{\varphi}_{0123} \in H^*_{0123}$ and its dual $\overline{\varphi}^*_{0123}$ are represented diagrammatically as in Fig. 7(b). Dual morphisms are denoted by a star (*) whereas we indicate by a bar ($\overline{\ }$) that a morphism belongs to a dual state space. Figure 7(c) shows the pairing (4.5) for morphisms $\overline{\varphi}_{0123} \in H^*_{0123}$ and $\psi_{0123} \in H_{0123}$. In Fig. 7 and in the following we use blackboard framing (see Sec. II B 2).

Remark 4.3: (1) Definition 4.2 applies to any order of vertices. In particular, the definition of H_{0123} involves $V(v_0, v_1, v_2)$ etc., as given by (4.1).

(2) The definition (4.3b) implements a special choice of isomorphism between H_{0123} and H^*_{0123} via the pairing (4.5). This choice is used consistently in the following.

The state spaces of Definition 4.2 for different vertex order are related by linear isomorphisms which are defined in the next step.

Definition 4.4: Let H_{0123} and H^*_{0123} denote the state space and its dual for a tetrahedron (v_0, v_1, v_2, v_3). The linear maps

$$\tau_0 : H_{0123} \to H^*_{1023}, \quad \tau_0^{*-1} : H^*_{0123} \to H_{1023}, \tag{4.6a}$$

$$\tau_1 : H_{0123} \to H^*_{0213}, \quad \tau_1^{*-1} : H^*_{0123} \to H_{0213}, \tag{4.6b}$$

$$\tau_2 : H_{0123} \to H^*_{0132}, \quad \tau_2^{*-1} : H^*_{0123} \to H_{0132}, \tag{4.6c}$$

are defined by the diagrams in Figs. 8–10.

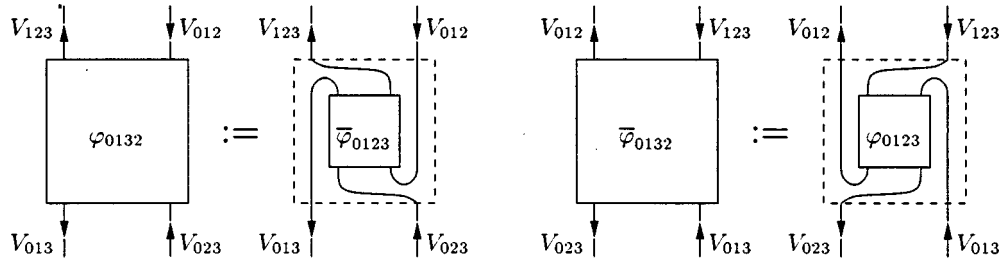

FIG. 10. The definition of the morphisms $\varphi_{0132} := \tau_2^{*-1}(\overline{\varphi}_{0123}) \in H_{0132}$ and $\overline{\varphi}_{0132} := \tau_2(\varphi_{0123}) \in H_{0132}^*$ for given $\overline{\varphi}_{0123} \in H_{0123}^*$ and $\varphi_{0123} \in H_{0123}$ [see (4.6c)].

Note that τ_j exchanges the jth and the $(j+1)$-th vertices of the four arguments of $H(v_0, v_1, v_2, v_3)$, counting from zero. These need not be the vertices with number j and $j+1$, for example,

$$\tau_0 : H_{1234} \to H_{2134}^*, \quad \tau_1 : H_{0214} \to H_{0124}^*. \tag{4.7}$$

Lemma 4.5: Let τ_j, $0 \leqslant j \leqslant 2$, denote the linear maps of Definition 4.4.

(1) The τ_j satisfy $\tau_j^{*-1} \circ \tau_j = \mathrm{id}$ and $\tau_j \circ \tau_j^{*-1} = \mathrm{id}$. In particular, the τ_j and τ_j^{*-1} form linear isomorphisms.

(2) The τ_j satisfy $\langle \tau_j^{*-1}(\psi_{0123}), \tau_j(\overline{\varphi}_{0123}) \rangle_{1023} = \langle \overline{\varphi}_{0123}, \psi_{0123} \rangle_{0123}$ for all $\overline{\varphi}_{0123} \in H_{0123}^*$ and $\psi_{0123} \in H_{0123}$ which motivates the notation τ_j^{*-1}.

Proof: (1) The relations $\tau_j^{*-1} \circ \tau_j = \mathrm{id}$ can be verified diagrammatically using the identities that hold in ribbon categories. Figure 11 shows the calculation for $\tau_1^{*-1} \circ \tau_1 = \mathrm{id}_{H_{0123}}$. The other cases are analogous.

(2) This claim can also be verified diagrammatically. It is essentially a consequence of the fact that the maps τ_j on the dual state spaces in Figs. 8–10 are given by the mirror images of the maps on the original state spaces. □

Remark 4.6: In analogy with the three-dimensional case, one could conjecture that the τ_j generate an action of the symmetric group $\mathcal{S}_4$ on some collection of state spaces. This is not the case. Only in the final step we will have an action of the symmetric group when it is proved that the partition function is well-defined.

At this point, the colorings V_{jkl} and the spaces H_{jklm} are defined for a generic vertex order. The summation over all coulorings of tetrahedra with morphisms, which is part of the partition function, will be implemented as a trace. This trace is over the tensor product of maps $Z_{01234}^{(V)}$ for all four-simplices $(v_0, \ldots, v_4) \in \Lambda^{(4)}$. These building blocks $Z_{01234}^{(V)}$ are defined first.

Definition 4.7: Let $V : \Lambda^{(2)} \to \mathcal{C}_0$ be a coloring and the state spaces for the tetrahedra be given by Definition 4.2.

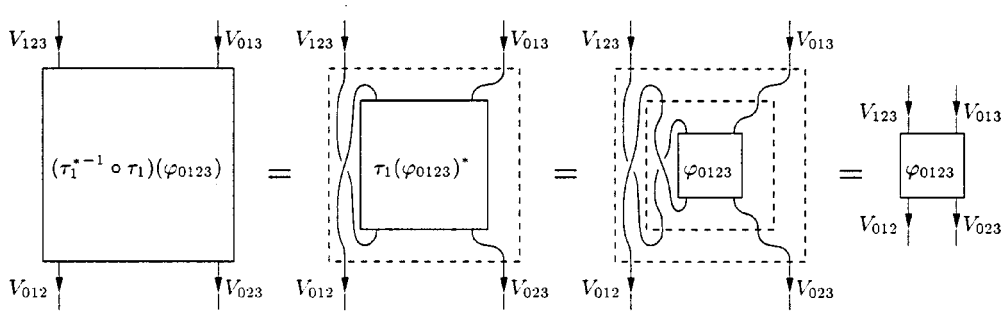

FIG. 11. Diagrammatic proof of the identity $\tau_1^{*-1} \circ \tau_1 = \mathrm{id}_{H_{0123}}$ in Lemma 4.5. Here $\varphi_{0123} \in H_{0123}$.

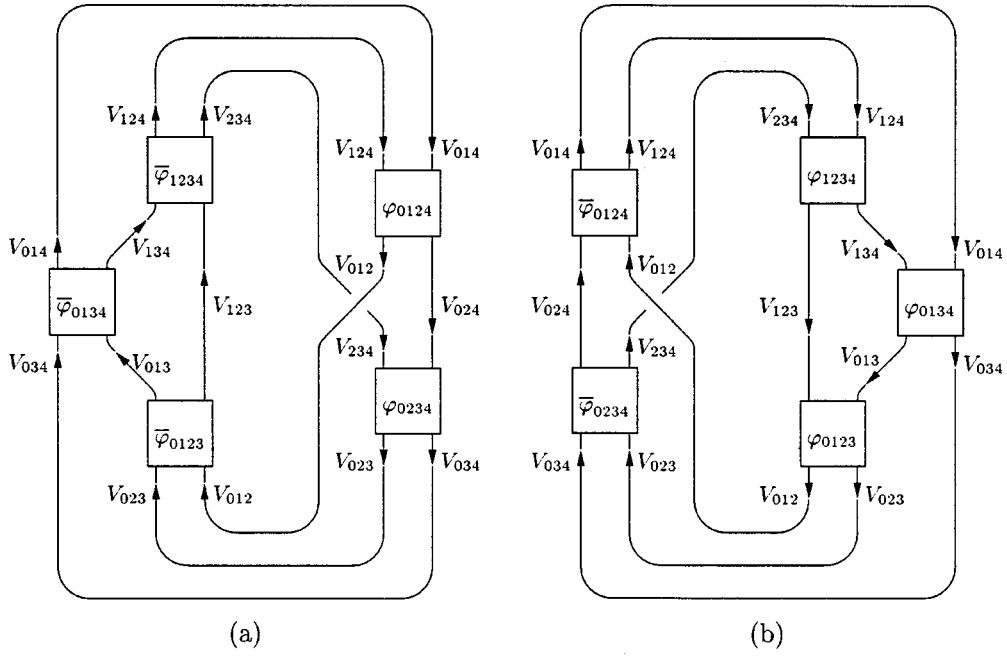

FIG. 12. (a) The quantum trace (4.8b) defining the four-simplex map for a four-simplex with positive relative orientation in M. (b) The quantum trace (4.9b) for negative relative orientation. The morphisms are denoted by $\varphi_{jklm} \in H_{jklm}$ and $\overline{\varphi}_{jklm} \in H^*_{jklm}$ and represented by the coupons of Fig. 7.

(1) For any four-simplex $(v_0,\ldots,v_4)$ whose relative orientation in the manifold M is positive, define the four-*simplex map*

$$Z^{(V),(+)}_{01234} : H_{0234} \otimes H_{0124} \to H_{1234} \otimes H_{0134} \otimes H_{0123} \tag{4.8a}$$

to be the linear map that is related by the pairing (2.25) to the quantum trace

$$Z'^{(V),(+)}_{01234} : H^*_{1234} \otimes H_{0234} \otimes H^*_{0134} \otimes H_{0124} \otimes H^*_{0123} \to \mathbb{C}, \tag{4.8b}$$

which is depicted in Fig. 12(a).

(2) For any four-simplex with negative relative orientation in M, the four-*simplex map*

$$Z^{(V),(-)}_{01234} : H_{1234} \otimes H_{0134} \otimes H_{0123} \to H_{0234} \otimes H_{0124} \tag{4.9a}$$

is defined by the quantum trace

$$Z'^{(V),(-)}_{01234} : H_{1234} \otimes H^*_{0234} \otimes H_{0134} \otimes H^*_{0124} \otimes H_{0123} \to \mathbb{C}, \tag{4.9b}$$

which is depicted in Fig. 12(b).

Remark 4.8: (1) The assignment of the H_{jklm} to domain or codomain and the assignment of duality stars (*) in the above definitions is according to the orientation of the tetrahedra in the boundary of the four-simplex,

$$\partial(01234) = (1234) - (0234) + (0134) - (0124) + (0123). \tag{4.10}$$

(2) Observe that Fig. 12(b) is the mirror image of (a) with all arrows reversed. This is different from the quantum trace of the dual morphism which would also replace the over-crossing by an under-crossing.

In order to obtain a summation over a basis of each state space H_{jklm}, the partition function is defined as a trace over the tensor product of all four-simplex maps.

Definition 4.9: Let $\Lambda^{(*)}$ be a finite combinatorial four-complex corresponding to a triangulation of a closed oriented piecewise-linear four-manifold M. Choose a fixed linear order of the vertices of Λ. Let $V:\Lambda^{(2)}\to\mathcal{C}_0$ be a coloring and let the four-simplex maps $Z^{(V),(\pm)}_{jklmn}$ be given by Definition 4.7.

The *partition function per coloring* is defined as

$$Z^{(V)}:=\mathrm{tr}_{\mathcal{H}}\left[P\circ\left(\bigotimes_{(v_0,\ldots,v_4)\in\Lambda^{(4)}} Z^{(V),(\varepsilon_{01234})}_{01234}\right)\right]. \tag{4.11}$$

Here $\varepsilon_{01234}\in\{+1,-1\}$ denotes the relative orientation of the four-simplex $(v_0,\ldots,v_4)\in\Lambda^{(4)}$ in M. Since every tetrahedron occurs precisely twice in the boundary of a four-simplex, once with positive and once with negative relative orientation, both domain and codomain of the tensor product over the $Z^{(V),(\pm)}_{01234}$ are permutations of the tensor factors of

$$\mathcal{H}:=\bigotimes_{(v_0,v_1,v_2,v_3)\in\Lambda^{(3)}} H^{(V)}(v_0,v_1,v_2,v_3). \tag{4.12}$$

The permutation operator P in (4.11) is the unique permutation which sorts the tensor factors of the codomain such that their ordering agrees with the ordering of factors in the domain.

Remark 4.10: The trace over the tensor product $\mathcal{H}$ in the above definition essentially contains the quantum traces (4.8b) or (4.9b) for all four-simplices plus an additional summation over bases of all state spaces. In the partition function the traces generalize the weights $C(v)$, cf. Table I and (3.12). Figure 12 is the four-dimensional analogue of Fig. 6(a) with a particular choice of over- and under-crossings.

Definition 4.11: Let $\Lambda^{(*)}$ be a finite combinatorial four-complex corresponding to a triangulation of a closed oriented piecewise-linear four-manifold M. Choose a fixed linear order of the vertices of Λ. For each coloring $V:\Lambda^{(2)}\to\mathcal{C}_0$, let the partition function per coloring, $Z^{(V)}$, be given by Definition 4.9. The *partition function* is defined as

$$Z:=\sum_{V:\Lambda^{(2)}\to\mathcal{C}_0}\left(\prod_{(v_0,v_1,v_2)\in\Lambda^{(2)}}\hat{w}(v_0,v_1,v_2)(V_{012})\right)Z^{(V)}. \tag{4.13}$$

The weights $\hat{w}(v_0,v_1,v_2):\mathcal{C}_0\to\mathbb{R}$ assign a real number to the object associated with the triangle $(v_0,v_1,v_2)\in\Lambda^{(2)}$ and are required to satisfy the *reality condition*,

$$\hat{w}(v_0,v_1,v_2)(V^*)=\hat{w}(v_0,v_1,v_2)(V), \tag{4.14}$$

and to be functions on equivalence classes of isomorphic objects, i.e.,

$$\hat{w}(v_0,v_1,v_2)(V)=\hat{w}(v_0,v_1,v_2)(\tilde{V}) \quad \text{if} \quad V\cong\tilde{V}. \tag{4.15}$$

Section IV B is devoted to proving that this definition is actually independent of the linear order of vertices and of the choice of colors $\mathcal{C}_0$ up to isomorphism. The partition function is therefore well-defined for a combinatorial complex that corresponds to the triangulation of a closed and oriented manifold. In Sec. V, we discuss some relevant special cases in more detail that are covered by (4.13), in particular the relation with the standard formulation of LGT for Lie groups and the Crane–Yetter state sum. There, we also comment on the convergence of (4.13) if $\mathcal{C}_0$ is not a finite set.

B. Properties of the partition function

First we show that the partition function (4.13) does not depend on the choice of colors $\mathcal{C}_0$ up to isomorphism.

Theorem 4.12: Let $V:\Lambda^{(2)}\to\mathcal{C}_0$ denote a coloring, and for each triangle $(v_0,v_1,v_2)\in\Lambda^{(2)}$, $v_0<v_1<v_2$, let

$$\Phi(v_0,v_1,v_2):V(v_0,v_1,v_2)\to\tilde{V}(v_0,v_1,v_2) \tag{4.16}$$

be an isomorphism in $\mathcal{C}$ for some object $\tilde{V}(v_0,v_1,v_2)$. Then the partition functions per coloring (4.11) for V and $\tilde{V}$ agree,

$$Z^{(V)}=Z^{(\tilde{V})}. \tag{4.17}$$

Proof: Using the standard abbreviations, the given isomorphisms are of the form $\Phi_{012}:V_{012}\to\tilde{V}_{012}$ for all triangles (v_0,v_1,v_2) with standard vertex order $v_0<v_1<v_2$. For any permutation $\sigma\in\mathcal{S}_3$ we define isomorphisms $\Phi_{\sigma(0)\sigma(1)\sigma(2)}:V_{\sigma(0)\sigma(1)\sigma(2)}\to\tilde{V}_{\sigma(0)\sigma(1)\sigma(2)}$ by

$$\Phi_{\sigma(0)\sigma(1)\sigma(2)}:=\begin{cases}\Phi_{012}:V_{012}\to\tilde{V}_{012}, & \text{if } \operatorname{sgn}\sigma=1,\\ \Phi^{*-1}_{012}:V^*_{012}\to\tilde{V}^*_{012}, & \text{if } \operatorname{sgn}\sigma=-1.\end{cases} \tag{4.18}$$

Observe that this assignment is compatible with Definition 4.1. These definitions provide us with isomorphisms $\Phi_{012}:V_{012}\to\tilde{V}_{012}$ and with their dual maps $\Phi^*_{012}:\tilde{V}^*_{012}\to V^*_{012}$ for all triangles (v_0,v_1,v_2) with arbitrary vertex order.

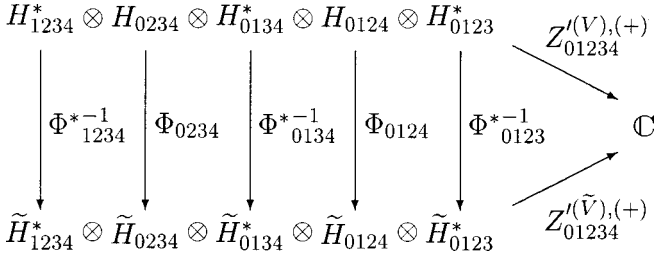
Furthermore, there are induced linear isomorphisms of the state spaces,

$$\begin{gathered}\Phi_{0123}:\operatorname{Hom}(V_{123}\otimes V_{013},V_{012}\otimes V_{023})\to\operatorname{Hom}(\tilde{V}_{123}\otimes\tilde{V}_{013},\tilde{V}_{012}\otimes\tilde{V}_{023}),\\ \varphi_{0123}\mapsto(\Phi_{012}\otimes\Phi_{023})\circ\varphi_{0123}\circ(\Phi^{-1}_{123}\otimes\Phi^{-1}_{013}),\end{gathered} \tag{4.19a}$$

and

$$\begin{gathered}\Phi^*_{0123}:\operatorname{Hom}(\tilde{V}^*_{013}\otimes\tilde{V}^*_{123},\tilde{V}^*_{023}\otimes\tilde{V}^*_{012})\to\operatorname{Hom}(V^*_{013}\otimes V^*_{123},V^*_{023}\otimes V^*_{012}),\\ \overline{\varphi}_{0123}\mapsto(\Phi^*_{023}\otimes\Phi^*_{012})\circ\overline{\varphi}_{0123}\circ(\Phi^{*-1}_{013}\otimes\Phi^{*-1}_{123}).\end{gathered} \tag{4.19b}$$

A convenient abbreviated notation for these maps is $\Phi_{0123}:H_{0123}\to\tilde{H}_{0123}$, $\Phi^*_{0123}:\tilde{H}^*_{0123}\to H^*_{0123}$ writing $\tilde{H}_{0123}:=\operatorname{Hom}(\tilde{V}_{123}\otimes\tilde{V}_{013},\tilde{V}_{012}\otimes\tilde{V}_{023})$ etc. Now the following diagram for the traces $Z'^{(V),(+)}_{01234}$ commutes:



To see this, imagine Fig. 12(a) drawn for maps $\tilde{\varphi}_{jklm}\in\tilde{H}_{jklm}$ etc. and insert the definitions of the linear isomorphisms Φ_{jklm} of (4.19). Then the isomorphisms in $\mathcal{C}$, $\Phi_{jkl}:V_{jkl}\to\tilde{V}_{jkl}$, appear twice in each ribbon in a way such that they cancel.

Let $\langle\cdot,\cdot\rangle^{\sim}:\tilde{H}^*_{0123}\otimes\tilde{H}_{0123}\to\mathbb{C}$ denote the pairing (4.5) applied to the state spaces which use the coloring $\tilde{V}$. We find

$$\langle \Phi^{*-1}_{0123}(\overline{\varphi}_{0123}), \Phi_{0123}(\psi_{0123})\rangle^{\sim} = \langle \overline{\varphi}_{0123}, \psi_{0123}\rangle, \tag{4.20}$$

for all $\overline{\varphi}_{0123} \in H^*_{0123}$ and $\psi_{0123} \in H_{0123}$. As a consequence the following diagram involving the four-simplex maps themselves also commutes:

$$\begin{array}{ccc}
H_{0234} \otimes H_{0124} & \xrightarrow{Z^{(V),(+)}_{01234}} & H_{1234} \otimes H_{0134} \otimes H_{0123} \\
\downarrow \Phi_{0234} \quad \downarrow \Phi_{0124} & & \downarrow \Phi_{1234} \quad \downarrow \Phi_{0134} \quad \downarrow \Phi_{0123} \\
\widetilde{H}_{0234} \otimes \widetilde{H}_{0124} & \xrightarrow{Z^{(\tilde{V}),(+)}_{01234}} & \widetilde{H}_{1234} \otimes \widetilde{H}_{0134} \otimes \widetilde{H}_{0123}
\end{array}$$

Analogous diagrams are available for $Z^{(V),(-)}_{01234}$ and Fig. 12(b) in the case of opposite orientation.

Finally, each tetrahedron occurs precisely twice in the boundaries of four-simplices, once with positive and once with negative relative orientation. Therefore the tensor product of all four-simplex maps in (4.11) is conjugated by a linear isomorphism Φ which can be obtained from a tensor product of the Φ_{jklm},

$$P \circ \left(\bigotimes_{\sigma \in \Lambda^{(4)}} Z^{(V),(\varepsilon_\sigma)}_{\sigma} \right) = \Phi \left[P \circ \left(\bigotimes_{\sigma \in \Lambda^{(4)}} Z^{(\tilde{V}),(\varepsilon_\sigma)}_{\sigma} \right) \right] \Phi^{-1}. \tag{4.21}$$

Since $Z^{(V)}$ is the trace of (4.21), it agrees with $Z^{(\tilde{V})}$. □

Corollary 4.13: The partition function (4.13) does not depend on the choice of colors $\mathcal{C}_0$ up to isomorphism.

Proof: Consider another set of colors $\widetilde{\mathcal{C}}_0$ such that each coloring $V:\Lambda^{(2)} \to \mathcal{C}_0$ induces a coloring $\tilde{V}:\Lambda^{(2)} \to \widetilde{\mathcal{C}}_0$ for which $V_{012} \cong \tilde{V}_{012}$ are isomorphic in $\mathcal{C}$ for all triangles $(v_0, v_1, v_2) \in \Lambda^{(2)}$. The partition function (4.13) defined using $\mathcal{C}_0$ agrees with that one defined using $\widetilde{\mathcal{C}}_0$ because the weights satisfy $\hat{w}(v_0, v_1, v_2)(V_{012}) = \hat{w}(v_0, v_1, v_2)(\tilde{V}_{012})$ and because $Z^{(V)} = Z^{(\tilde{V})}$ according to Theorem 4.12. □

In order to prove the independence of the partition function (4.13) of the linear order of vertices, a generic four-simplex (01234) is considered. It is proved that any permutation of its vertices that results in different four-simplex maps H_{jklm} according to Definitions 4.2 and 4.7 does not change the partition function (4.13).

This statement is verified for the four elementary transpositions of $\mathcal{S}_5$ (acting on the vertices {0,1,2,3,4}). The following lemmas prepare the proof. They establish diagrammatical isotopies which permute the coupons in Fig. 12(a) in order to reach a configuration similar to Fig. 12(b). Recall that the orientation of the four-simplex changes if an odd permutation is applied to its vertices.

Lemma 4.14: For any coloring $V:\Lambda^{(2)} \to \mathcal{C}_0$ and morphisms $\varphi_{jklm} \in H_{jklm}$ and $\overline{\varphi}_{jklm} \in H^*_{jklm}$, the quantum trace in Fig. 12(a) is equal to the quantum trace in Fig. 13.

Proof: The calculation is described in diagrammatic language and can be translated into equalities for morphisms of the ribbon category $\mathcal{C}$ as described in Sec. II B. First, a number of coupons are moved around in the plane without twisting or braiding any ribbons: Move the coupon φ_{0124} to the left and place it above $\overline{\varphi}_{1234}$, then move $\overline{\varphi}_{0134}$ down and to the right and place it below and right of φ_{0234}. Move $\overline{\varphi}_{0123}$ to the right and place it below $\overline{\varphi}_{0123}$ and below and left of $\overline{\varphi}_{0134}$. Rotate the coupon $\overline{\varphi}_{0123}$ by 360 degrees in order to place its ribbons as depicted in Fig. 13. Finally, lift the ribbon labeled V_{014} out of the plane, move it across the entire diagram, and place it as shown in Fig. 13. □

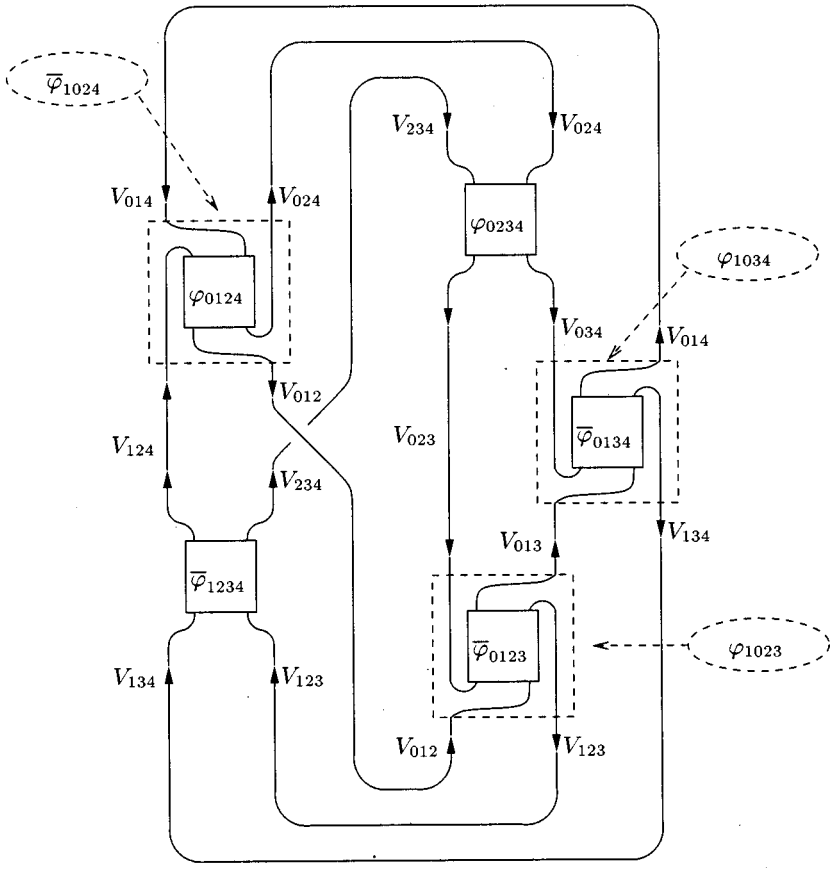


FIG. 13. This diagram is isotopic to the quantum trace $Z'^{(V),(+)}_{01234}$ in Figure 12(a), cf. Lemma 4.14 and Lemma 4.16. The morphisms in the dashed boxes are by definition of τ_0 (Definition 4.4) just morphisms $\overline{\varphi}_{1024} \in H^*_{1024}$, $\varphi_{1034} \in H_{1034}$ and $\varphi_{1023} \in H_{1023}$. With these replacements this quantum trace is similar to Figure 12(b) defining $Z^{(V),(-)}_{10234}$ for opposite relative orientation with a non-standard order (10234) of vertices. Note that the permutation $(01) \in \mathcal{S}_5$ also replaces V_{012}, V_{013} and V_{014} by their duals according to Definition 4.1.

Lemma 4.15: For any coloring $V:\Lambda^{(2)} \to \mathcal{C}_0$ and morphisms $\varphi_{jklm} \in H_{jklm}$ and $\overline{\varphi}_{jklm} \in H^*_{jklm}$, the quantum trace in Fig. 12(a) is equal to the quantum trace in Fig. 14.

Proof: The proof is again explained diagrammatically: Start with Fig. 12(a). Lift the ribbon V_{012} out of the plane and move it across the coupon φ_{1234} so that V_{012} now over-crosses V_{123}, V_{134} and V_{124} rather than V_{234}. Then the coupons can be moved around in the plane without introducing twists or braidings such that the configuration in Fig. 14 is obtained. □

There exist two more lemmas that deal with the elementary transpositions (23) and (34) as well as four lemmas dealing with the case of opposite relative orientation. They are not stated explicitly here since they are very similar and completely analogous to prove.

The results of the preceding lemmas, Figs. 13 and 14, are furthermore related to the quantum trace of Fig. 12(b) for a four-simplex with a different order of vertices. This is stated in the following lemmas.

Lemma 4.16: Let $\tau = (01)$ and consider the four-simplex (01234). Let $V:\Lambda^{(2)} \to \mathcal{C}_0$ denote a coloring. Then there exists another coloring $\tilde{V}$ with isomorphic objects for each triangle, $\tilde{V}_{012} \cong V_{012}$, such that the following diagram commutes:

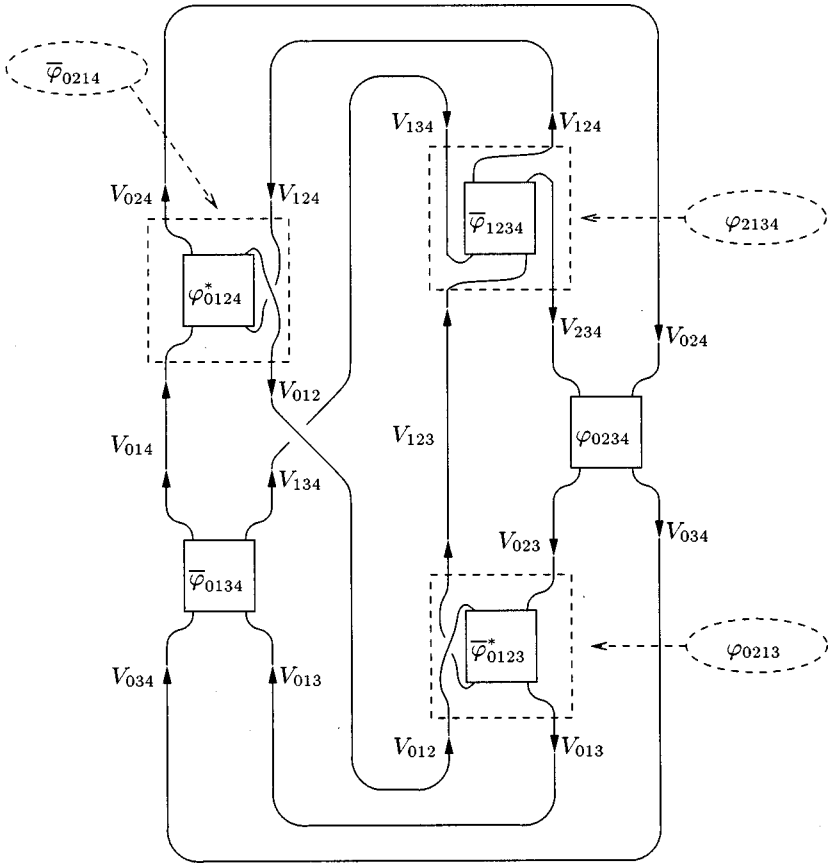

FIG. 14. This diagram is isotopic to the quantum trace defining $Z^{(V),(+)}_{01234}$ in Figure 12(a), cf. Lemma 4.15 and Lemma 4.17.

$$\begin{array}{ccc} H_{0234}\otimes H_{0124} & \xrightarrow{Z^{(V),(+)}_{01234}} & H_{1234}\otimes H_{0134}\otimes H_{0123} \\ \downarrow \mathrm{id} \quad \downarrow \tau_0 & & \downarrow \mathrm{id} \quad \downarrow \tau_0 \quad \downarrow \tau_0 \\ H_{0234}\otimes H^*_{1024} & \longrightarrow & H_{1234}\otimes H^*_{1034}\otimes H^*_{1023} \end{array}$$

Here $Z^{(V),(+)}_{01234}$ is the four-simplex map of Definition 4.7, the maps τ_0 are given in Definition 4.4, and the bottom horizontal map is determined, using the pairing (4.5), by the four-simplex map

$$Z^{(\tilde{V})(-)}_{10234}: H_{0234}\otimes H_{1034}\otimes H_{1023}\to H_{1234}\otimes H_{1024}. \tag{4.22}$$

Proof: Consider Fig. 13 whose quantum trace agrees with $Z'^{(V),(+)}_{01234}$ of Fig. 12(a) according to Lemma 4.14. The linear isomorphisms τ_0 of Definition 4.4 can now be used to replace the dashed boxes of Fig. 13 by morphisms of the state spaces H_{jklm} with a different vertex order. The result is very similar to the trace $Z'^{(V)(-)}_{10234}$ of Fig. 12(b) for the four-simplex (10234).

Observe, however, that in Fig. 12(b) the arrows of the ribbons corresponding to the triangles (012), (013) and (014) are reversed compared with Fig. 13. We can reverse these arrows in Fig. 13 if we label them instead by V^*_{012}, V^*_{013} and V^*_{014}, respectively.

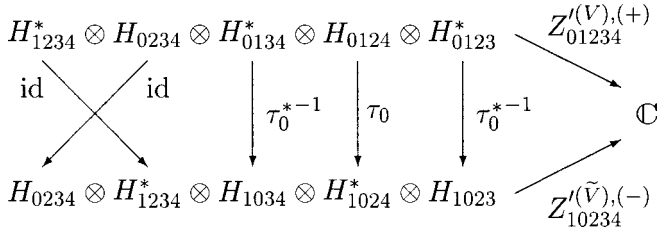
Consider the triangle (012). If (v_0,v_1,v_2) is an even permutation of the standard vertex order, then Fig. 13 contains $V_{012}=V$ for some object $V\in\mathcal{C}_0$, i.e., upon reversal of the arrows this label changes to $V^*_{012}=V_{102}$. This is the same label as the label arising in $Z'^{(V)(-)}_{10234}$.

If, however, (v_0,v_1,v_2) is an odd permutation of the standard vertex order, then Fig. 13 contains $V_{012}=V^*$ for some object $V\in\mathcal{C}_0$, i.e., upon arrow reversal this becomes $V^*_{012}=(V^*)^*$. This is in general not identical, but still isomorphic to V which arises in $Z'^{(V)(-)}_{10234}$ in this case. This is the reason why the present lemma holds only for a coloring $\tilde{V}$ with isomorphic objects at all triangles.

Let (w_0,w_1,w_2) denote any triangle in standard vertex order, $w_0<w_1<w_2$. Define the coloring $\tilde{V}$ by

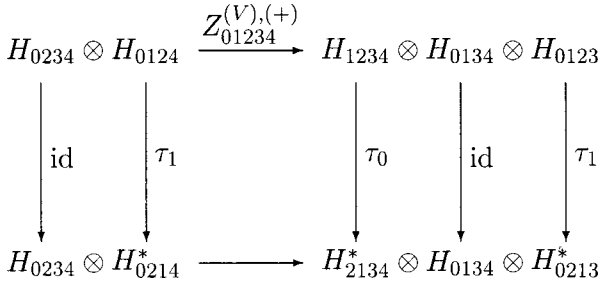
$$\tilde{V}_{\sigma(0)\sigma(1)\sigma(2)}:=\begin{cases}(V^*_{012})^*, & \text{if} \quad \mathrm{sgn}\sigma=1,\\ V^*_{012}, & \text{if} \quad \mathrm{sgn}\sigma=-1,\end{cases} \tag{4.23}$$

if $\{w_0,w_1,w_2\}\in\{\{v_0,v_1,v_2\},\{v_0,v_1,v_3\},\{v_0,v_1,v_4\}\}$ and by $\tilde{V}_{\sigma(0)\sigma(1)\sigma(2)}:=V_{\sigma(0)\sigma(1)\sigma(2)}$ for the other triangles. Then the quantum trace of Fig. 13 with arrows (012), (013) and (014) reversed agrees with the trace of Fig. 12(b) for the coloring $\tilde{V}$. The following diagram therefore commutes:



Using Lemma 4.5, this implies the commutativity of the diagram claimed in the present lemma.□

Lemma 4.17: Let $\tau=(12)$ and $V:\Lambda^{(2)}\to\mathcal{C}_0$ be a coloring. Then there exists another coloring $\tilde{V}$ with isomorphic objects for each triangle such that the following diagram commutes:

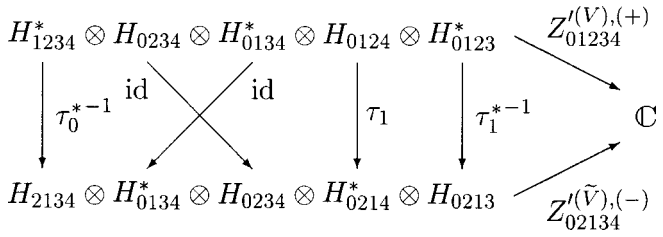


Here the τ_j are the isomorphisms given in Definition 4.4, and the bottom horizontal map is determined, using the pairing (4.5), by the four-simplex map

$$Z^{(\tilde{V}),(-)}_{02134}:H_{2134}\otimes H_{0234}\otimes H_{0213}\to H_{0134}\otimes H_{0214}. \tag{4.24}$$

Proof: Consider Fig. 14 whose quantum trace agrees with $Z'^{(V),(+)}_{01234}$ of Fig. 12(a) according to Lemma 4.15. The linear isomorphisms τ_0 and τ_1 of Definition 4.4 can now be used to replace the dashed boxes of Fig. 14 by morphisms of the state spaces H_{jklm} with a different vertex order. The result is the trace $Z'^{(\tilde{V}),(-)}_{02134}$ of Fig. 12(b) for the four-simplex (02134) up to the choice of isomorphic objects for the triangles (012), (123) and (124). These isomorphisms arise from double dualization as in Lemma 4.16.

The following diagram therefore commutes:



Employing Lemma 4.5, this proves the claim. □

There exist similar lemmas for the other elementary transpositions (23) and (34) as well as for the corresponding statements with opposite relative orientations, i.e., where $Z^{(V),(+)}$ and $Z^{(V),(-)}$ are exchanged. Their proofs are entirely analogous.

Theorem 4.18: The partition function (4.13) does not depend on the choice of the linear order of vertices.

Proof: Equip the set of vertices with a different linear order which is induced from the given one by a permutation τ of the vertices. The partition function using this new order can be expressed in terms of the original order if τ is applied both to the vertices and to the coloring,

$$Z_\tau = \sum_{V:\Lambda^{(2)}\to\mathcal{C}_0} \left(\prod_{(v_0,v_1,v_2)\in\Lambda^{(2)}} \hat{w}(v_{\tau^{-1}(0)}, v_{\tau^{-1}(1)}, v_{\tau^{-1}(2)})((\tau V)_{012}) \right) Z_\tau^{(\tau V)}. \tag{4.25}$$

Here

$$Z_\tau^{(\tau V)} = \mathrm{tr}_{\mathcal{H}}\left[P \circ \left(\bigotimes_{s\in\Lambda^{(4)}} Z_{\tau(s)}^{(\tau V),(\varepsilon_{\tau(s)})} \right) \right] \tag{4.26}$$

replaces the partition function per coloring in the case of the new vertex order, $\tau(s)$ denotes $(\tau^{-1}(0)\cdots\tau^{-1}(4))$ for a given four-simplex $s=(01234)$, and τV is the coloring induced by τ, i.e., $(\tau V)_{012} = V_{\tau^{-1}(0)\tau^{-1}(1)\tau^{-1}(2)}$ for all triangles $(v_0,v_1,v_2)\in\Lambda^{(2)}$.

The permutation τ replaces triangles (012) by $(\tau^{-1}(0)\tau^{-1}(1)\tau^{-1}(2))$ and therefore just permutes the factors of the product in (4.25). This product can be reorganized so that we obtain

$$Z_\tau = \sum_{V:\Lambda^{(2)}\to\mathcal{C}_0} \left(\prod_{(v_0,v_1,v_2)\in\Lambda^{(2)}} \hat{w}(v_0,v_1,v_2)(V_{012}) \right) Z_\tau^{(\tau V)}, \tag{4.27}$$

where the vertex order of the triangles does not matter because of the reality condition (4.14).

Any permutation τ which just permutes the four-simplices but does not change the vertex order of these four-simplices, permutes the tensor factors in (4.26) and therefore leaves the trace invariant. It is thus sufficient to prove invariance under permutations τ that change the vertex order for fixed four-simplices.

Consider a four-simplex $s=(01234)$ and and let τ be an elementary transposition, $\tau \in \{(01),(12),(23),(34)\}$. The colouring τV associates with each triangle $(w_0,w_1,w_2)\in\Lambda^{(2)}$ either the object $V(w_3,w_4,w_5)$ assigned to some triangle $(w_3,w_4,w_5)\in\Lambda^{(2)}$ or the dual of that object.

Since the set of colors $\mathcal{C}_0$ contains for each given object V exactly one object that is isomorphic to V^*, there exists a unique coloring $\overline{V}:\Lambda^{(2)}\to\mathcal{C}_0$ such that $\overline{V}_{012}\cong(\tau V)_{012}$ for all triangles. Moreover, since τ is a transposition, $(\tau\overline{V})_{012}\cong V_{012}$ so that τ induces an involution on the set of colorings $\Lambda^{(2)}\to\mathcal{C}_0$. We can now sum over $\overline{V}$ rather than V in (4.27) and obtain

$$Z_\tau = \sum_{V:\Lambda^{(2)}\to\mathcal{C}_0} \left(\prod_{(v_0,v_1,v_2)\in\Lambda^{(2)}} \hat{w}(v_0,v_1,v_2)(V_{012}) \right) Z_\tau^{(V)}, \tag{4.28}$$

$$Z_\tau^{(V)} = \mathrm{tr}_{\mathcal{H}}\left[P\circ\left(\bigotimes_{s\in\Lambda^{(4)}} Z_{\tau(s)}^{(V),(\varepsilon_{\tau(s)})} \right) \right], \tag{4.29}$$

where we have used (4.14) and where we have written V instead of $\overline{V}$ for simplicity.

In the preceding lemmas we have constructed linear isomorphisms which form the vertical maps in commutative diagrams of the following form:

$$\begin{array}{ccc} H_{0234}\otimes H_{0124} & \xrightarrow{Z_{01234}^{(V),(+)}} & H_{1234}\otimes H_{0134}\otimes H_{0123} \\ \downarrow \Phi_1 \quad \downarrow \Phi_2 & & \downarrow \Phi_3 \quad \downarrow \Phi_4 \quad \downarrow \Phi_5 \\ H^{(1)}\otimes H^{(2)} & \longrightarrow & H^{(3)}\otimes H^{(4)}\otimes H^{(5)} \end{array}$$

Here the $H^{(j)}$ are suitable state spaces such that the bottom horizontal map is related to the four-simplex map $Z_{\tau(s)}^{(\tilde{V})(-)}$ by the pairing (4.5). The coloring $\tilde{V}$ is such that $\tilde{V}_{012}\cong V_{012}$ for all triangles (012).

Since each tetrahedron occurs twice in the boundary of some four-simplices, once with positive and once with negative relative orientation, each state space $H_{\tau(jklm)}$ occurs twice among the $H^{(j)}$, once as $H_{\tau(jklm)}$ and once as the dual state space $H^*_{\tau(jklm)}$. In both cases, the corresponding map Φ_j is the same, either one of the τ_i or the identity. Therefore the tensor product of all four-simplex maps is conjugated by a linear isomorphism Φ which can be obtained from a tensor product of these Φ_j,

$$P\circ\left(\bigotimes_{s\in\Lambda^{(4)}} Z_s^{(V),(\varepsilon_s)} \right) = \Phi\left[P\circ\left(\bigotimes_{s\in\Lambda^{(4)}} Z_{\tau(s)}^{(V),(\varepsilon_{\tau(s)})} \right) \right] \Phi^{-1}. \tag{4.30}$$

Observe that here $\varepsilon_{\tau(s)} = -\varepsilon_s$ and that the coloring $\tilde{V}$ can be replaced by V as a consequence of Theorem 4.12.

Since $Z_\tau^{(V)}$ is the trace over (4.30), we find $Z_\tau^{(V)} = Z^{(V)}$ and therefore $Z_\tau = Z$. □

C. Gauge symmetry

In order to understand the gauge symmetry of LGT in the picture of the spin foam model, consider first the case in which $\mathcal{C}$ is the category of finite-dimensional representations of the gauge group G. The group then acts on its representations via natural equivalences $(t_g^{(V)})_V$, $g\in G$, i.e., natural isomorphisms $t_g^{(V)}: V\to V$ for all objects V.

In LGT on the two-complex (V,E,F) dual to the simplicial complex $\Lambda^{(*)}$, consider a gauge transformation involving only one vertex $v\in V$. This means that the group elements g_e attached to the edges $e\in E$ are transformed as

$$g_e \mapsto g_e\cdot h_v^{-1}, \quad \text{if} \quad v=\partial_- e, \tag{4.31a}$$

$$g_e \mapsto h_v\cdot g_e, \quad \text{if} \quad v=\partial_+ e, \tag{4.31b}$$

for $h_v\in G$ while all other variables g_e remain unchanged. For each polygon containing the vertex v in its boundary, precisely two edges are affected in such a way that the effect of the transformation cancels for the polygon.

In the spin foam picture, only the four-simplex dual to the vertex $v \in V$ is affected. Let (v_0, v_1, v_2) denote the triangle to which a polygon is dual. The gauge transformation then inserts natural isomorphisms $t_g^{(V_{012})}$ and $(t_g^{(V_{012})})^{-1}$ into the ribbon corresponding to that triangle, i.e., to the ribbon labeled by the object V_{012}. These isomorphisms cancel.

In the categorical picture, however, this symmetry can be understood in other terms. Let now $\mathcal{C}$ denote any admissible ribbon category and choose a coloring $V: \Lambda^{(2)} \to \mathcal{C}_0$. Consider a morphism $\varphi_{0123} \in H_{0123}$, i.e., $\varphi_{0123}: V_{123} \otimes V_{013} \to V_{012} \otimes V_{023}$. Then for any natural equivalence $(t^{(V)})_V$, naturality means

$$\varphi_{0123} = (t^{(V_{013})} \otimes t^{(V_{012})}) \circ \varphi_{0123} \circ (t^{(V_{123})^{-1}} \otimes t^{(V_{013})^{-1}}). \tag{4.32}$$

If this transformation for the natural equivalence $(t^{(V)})_V$ is applied simultaneously to all morphisms φ_{jklm} in Fig. 12(a) or 12(b), the isomorphisms $t^{(V_{jkl})}$ cancel pairwise in each ribbon, and the quantum trace remains unchanged.

In the categorical description of the spin foam model, the gauge symmetry is therefore automatically implemented. It is just the naturality property of natural equivalences together with the fact that all ribbon diagrams used in the definition of the partition function are quantum traces.

D. Wilson loop and spin networks

Having generalized the partition function of LGT to ribbon categories, it is desirable to understand the corresponding generalization for the observables of LGT, namely for Wilson loops and spin networks (Definition 3.5).

In order to define the expectation value of a spin network, recall that the quantum traces in Fig. 12 generalize the four-dimensional version of Fig. 6(a). One should therefore extend Fig. 12 and include five additional ribbons and one coupon for the spin network as Fig. 6(b) suggests. However, it seems to be impossible to find a ribbon diagram which has the symmetries required in Sec. IV B.

A possible explanation is the following argument. In the Lie group case, the spin network (3.17) attaches representations to the edges and morphisms to the vertices of the two-complex (V, E, F). Its generalization to the ribbon case should therefore be given by a ribbon graph in four dimensions. In four dimensions, however, there is no canonical way of associating to each ribbon graph a morphism in the ribbon category $\mathcal{C}$ because there is no four-dimensional analogs of the Reshetikhin–Turaev functor. It is conceivable that the notion of a spin network in four dimensions using ribbon categories is not a good definition.

For the constructions of observables that generalize Definition 3.5 to the case of ribbon categories, one therefore has to choose a linear order of vertices on which the result will then depend in a crucial way. Spin network observables are thus defined for simplicial complexes, but not in general for combinatorial complexes.

These restrictions are important if one wants to construct particular physical models which are based on a spin foam model using ribbon categories. It remains to be studied under which conditions one can define at least a certain class of observables and how the dependence on the vertex order can be interpreted. The reader is also referred to the diagrammatic approach to observables in three dimensions in Ref. 3.

V. SPECIAL CASES AND GENERALIZATIONS

The partition function (4.13) of the spin foam model using ribbon categories covers a number of special cases which were already known in other contexts. In this section, we comment on the relations between these models.

A. Lattice gauge theory

The category $\mathcal{C}=\mathrm{Rep}\ G$ of finite-dimensional representations of a compact Lie group G forms a semi-simple admissible ribbon category. The relation of the spin foam model with LGT holds if the set of colors $\mathcal{C}_0$ is a set containing one representative of each equivalence class of simple objects.

In this case one can use the generic Boltzmann weight (1.1) for any action which is local, i.e., evaluated once for each polygon, and which is a real and bounded L^2-integrable class function of G. In particular, the standard *Wilson action* and the *heat kernel* or *generalized Villain action* are of this form. For details about these actions and about their character expansion, we refer the reader to standard textbooks such as Refs. 15 and 16.

In general the set of representatives $\mathcal{C}_0$ of the simple objects is countably infinite. However, the partition function (4.13) is a convergent series because the Boltzmann weight is an L^2-function, and its character expansion therefore forms a square summable series due to the Peter–Weyl theorem. For more details, see Refs. 17 and 25.

In this case both pictures, LGT and the spin foam model, are well-defined and are dual to each other in the sense of Ref. 17. A comparison of the spin foam model dual to LGT (3.11) and the generalization (4.13) shows the following correspondences, cf. Table I. The sum over colorings of triangles/polygons and the weights $\hat{w}$ are explicitly contained in the partition function. The sum over colorings of tetrahedra/edges with morphisms is explicit in (3.11) and it is the result of the trace over the tensor product $\mathcal{H}$ in (4.11). The weights $C(v)$ per four-simplex/vertex are given by the formula (3.12) and agree with the quantum traces of Fig. 12 which appear as a result of the trace over the four-simplex maps in (4.11).

For standard actions of LGT such as Wilson's action or the heat kernel action, the character expansion coefficients behave qualitatively like $\exp((1/\beta)\, s^*(V_\rho))$ if the Boltzmann weight is of the form $\exp(\beta s(g))$. Here β is the *inverse temperature*, $s(g)$ denotes the action and $s^*(V_\rho)$ the *dual action*, a function assigning a real number to each finite-dimensional irreducible representation of G. The transformation between LGT and the spin foam model thus realizes a low temperature–high temperature duality or a strong-weak duality in the bare coupling g_0 if $\beta = 1/g_0^2$.

For the heat kernel action, the dual action $s^*(V_\rho) \sim C_\rho^{(2)}$ is essentially given by the second order Casimir operator $C_\rho^{(2)}$ of the representation. One can thus sort the configurations of the spin foam model by the sum of the Casimir eigenvalues over all triangles, and recovers the full strong coupling expansion of non-Abelian LGT.

Observe finally that LGT was formulated here on the two-complex dual to a generic triangulation. In order to obtain the usual continuum limit, the Boltzmann weight $\hat{w}(v_0,v_1,v_2)$ should now depend on the geometry of the triangle (v_0,v_1,v_2) in a suitable way.

B. Gauge theory with finite groups

If $\mathcal{C}=\mathrm{Rep}\, G$ is the category of representations of a finite group G, all comments of Sec. V A still apply. In this case, there are only finitely many simple objects up to isomorphism and the partition functions in both pictures, in LGT and in the spin foam model, are well-defined.

It is now also possible to study the "topological" Boltzmann weight

$$w(g)=\delta(g):=\begin{cases} |G|, & \text{if} \quad g=1, \\ & \\ 0 & \text{else,} \end{cases} \qquad \text{i.e.,} \quad \hat{w}_\rho=\dim V_\rho\,. \tag{5.1}$$

With suitable prefactors, the partition function is then independent of the triangulation and thus forms a topological invariant which is well known and depends only on the gauge group and on the first fundamental group of the manifold. See, for example, the comments in Sec. 2.2 of Ref. 28.

C. The Crane–Yetter state sum

Let $\mathcal{C}$ be a finitely semi-simple and admissible ribbon category satisfying the conditions of Corollary 2.11 and $\mathcal{C}_0$ be a set containing one representative for each equivalence class of simple objects. This case is beyond the standard formulation of LGT, and only the spin foam model (4.13) makes sense. The partition function is a finite sum. It is again possible to choose ''topological'' Boltzmann weights which here means the quantum dimension of the simple objects,

$$\hat{w}(V) = \mathrm{qdim} V. \tag{5.2}$$

With suitable prefactors the partition function (4.13) agrees with the Crane–Yetter invariant.[10] For a comparison of Fig. 12(a) with the main diagram in Ref. 10, observe that the state spaces H_{0123} used in the present article can be further decomposed employing semi-simplicity (2.26), for example,

$$H_{0123} = \mathrm{Hom}(V_{123} \otimes V_{013}, V_{012} \otimes V_{023}) \cong \oplus_{J \in \mathcal{C}_0} \mathrm{Hom}(V_{123} \otimes V_{013}, J) \otimes \mathrm{Hom}(J, V_{012} \otimes V_{023}). \tag{5.3}$$

If this decomposition is applied to the state spaces associated with all tetrahedra, one has to color in addition the tetrahedra with simple objects [the J in (5.3)] and the tetrahedra (0123) with two types of morphisms, $\mathrm{Hom}(V_{123} \otimes V_{013}, J)$ and $\mathrm{Hom}(J, V_{012} \otimes V_{023})$. These colorings are used in the standard formulation of the Crane–Yetter state sum in Ref. 10. Note that the additional weight $1/J$ per tetrahedron in Ref. 10 is a consequence of the choice of bases of $\mathrm{Hom}(V_{123} \otimes V_{013}, J)$ and $\mathrm{Hom}(J, V_{012} \otimes V_{023})$.

D. The generic case

The construction presented generalizes LGT and the Crane–Yetter state sum, but also contains the generic case. Here $\mathcal{C}$ is any admissible ribbon category, in particular not required to be semi-simple, and the weights $\hat{w}(V)$ for given simple objects V can be quite freely chosen. If the set of colors $\mathcal{C}_0$ is finite, the partition function is a finite sum and thus well-defined for any choice of weights. If $\mathcal{C}_0$ is a countable set, similar convergence issues arise as for Lie groups.[17] Note that here it is also necessary to examine the quantum traces of Fig. 12 in order to prove convergence of the partition function.

E. Generalizations and the Barrett–Crane model

If $\mathcal{C} = \mathrm{Rep}\, G$ for a compact Lie group, for example, $G = \mathrm{SU}(2)$, and if the Boltzmann weight is chosen to be ''topological,''

$$w(g) = \delta(g), \quad \hat{w}(V_\rho) = \dim V_\rho, \tag{5.4}$$

the partition function is just a (divergent) formal expression. This is the case for the Ooguri model[13] which can be formulated in the LGT or in the spin foam picture.

The simplest version of a spin foam model of Barrett–Crane type[14] is obtained from the Ooguri model for SO(4) in the spin foam picture by restricting the representations in all sums to the *simple* representations of SO(4). Simple here means that the representation is of the form $V \otimes V$ as a representation of $\mathrm{SU}(2) \times \mathrm{SU}(2)$ for some irreducible representation V of SU(2).

In order to implement this restriction one can choose the set of colors $\mathcal{C}_0$ to contain one representative per isomorphism class of simple representations of SO(4). However, in addition one has to restrict the sum over J in (5.3) to simple representations. As a consequence the state spaces H_{0123} are certain subspaces of $\mathrm{Hom}(V_{123} \otimes V_{013}, V_{012} \otimes V_{023})$.

The results of the present article can be generalized to state spaces that are subspaces of $\mathrm{Hom}(V_{123} \otimes V_{013}, V_{012} \otimes V_{023})$ as long as the pairing (4.5) and the maps τ_j of Definition 4.4 can be consistently restricted to these subspaces. The correspondence with LGT with a partition function (3.1) is, however, lost as a consequence of this generalization.

VI. CONCLUSION AND OUTLOOK

The spin foam model for ribbon categories defined in the present article generalizes the spin foam model dual to lattice gauge theory (LGT) and can be used as a definition of LGT for gauge groups which are quantum groups rather than Lie groups. Furthermore, the definition presented here encompasses state sum models that are of interest both in topology and in quantum gravity. The definition presented provides a bridge between the standard (Lie group) formulation of LGT and the Crane–Yetter invariant which uses ribbon categories. It can also be used to construct other spin foam models that do not correspond to topological quantum field theories and provides proofs that they are well-defined. This work might finally help to make the relation of LGT and the spin foam models used in other areas more transparent and the common concepts and open questions more accessible.

If one seeks to construct even more general spin foam models than defined here, it is worth pointing out that consistency of the definition restricts the quantum traces of Fig. 12 very tightly. The introduction of further weights, however, seems to be much easier to achieve.

The definition of LGT with ribbon categories presented here is restricted to four dimensions. Technically, this is due to the fact that the key diagrams in Fig. 12 are handmade for this construction. Due to the generality of ribbon categories it involves choices of over- or undercrossings, and only with a good choice is the partition function well-defined. While the corresponding approaches in $d=3$[2,3] are canonical in the sense that their construction is well-defined due to general principles, the $d=4$ construction presented here involves choices and one has to verify *a posteriori* that it is consistent. It is not obvious whether the result of Ref. 29 in arbitrary dimension in the Lie group case can be generalized to ribbon categories. It is, in any case, a striking observation that there exist constructions in $d=3$ (Ref. 3) and in $d=4$ (presented here) which both generalize the spin foam model dual to LGT. Notice, however, that the $d=3$ case can be handled with spherical categories[7] which are more general than ribbon categories. For the construction in $d=4$, we make explicit use of ribbon categories because the basic diagrams in Fig. 12 always contain a crossing. If ribbon categories are used in the construction in $d=3$, all spin network observables can be defined[3] whereas in $d=4$ there are no canonical expressions for the spin network observables anymore. It therefore seems that one has to use more and more restrictive structures if one wishes to increase the dimension.

A new class of entanglement measures

Oliver Rudolph
Kielmannseggstraße 132, 22043 Hamburg, Germany

(Received 31 January 2001; accepted for publication 10 July 2001)

We introduce new entanglement measures on the set of density operators on tensor product Hilbert spaces. These measures are based on the greatest cross norm on the tensor product of the sets of trace class operators on Hilbert space. We show that they satisfy the basic requirements on entanglement measures discussed in the literature, including convexity, invariance under local unitary operations and nonincrease under local quantum operations and classical communication. © *2001 American Institute of Physics.* [DOI: 10.1063/1.1398062]

I. INTRODUCTION

This paper is devoted to the study of entanglement of quantum states, which is one of the most decisively nonclassical features in quantum theory. The question of quantifying entanglement in the case of mixed quantum states represented by density operators on finite dimensional Hilbert spaces has recently been studied extensively in the context of quantum information theory, see, e.g., Refs. 1–10, and references therein.

An *entanglement measure* is a real-valued function defined on the set of density operators on some tensor product Hilbert space subject to further physically motivated conditions, see, e.g., Refs. 3–7 and below. A number of entanglement measures have been discussed in the literature, such as the von Neumann reduced entropy, the relative entropy of entanglement,[4] the entanglement of distillation and the entanglement of formation.[2] Several authors proposed physically motivated postulates to characterize entanglement measures, see below. These postulates (although they vary from author to author in the details) have in common that they are based on the concepts of the operational formulation of quantum mechanics.[11] We shall discuss one version of these *operational characterizations* of entanglement measures in Sec. IV.

In this paper we introduce new entanglement measures based on the greatest cross norm on the tensor product of the sets of trace class operators on Hilbert space (see Secs. V and VI). We shall show that the measures introduced in this work satisfy all the basic requirements for entanglement measures. These include convexity, invariance under local unitary transformations, and nonincrease under procedures composed of local quantum operations and classical communication.

Throughout this paper the set of trace class operators on some Hilbert space $\mathcal{H}$ is denoted by $\mathcal{T}(\mathcal{H})$ and the set of bounded operators on $\mathcal{H}$ by $\mathcal{B}(\mathcal{H})$. A density operator is a positive trace class operator with trace one.

II. PRELIMINARIES

In this section we collect some basic definitions and results which are used in the course of this paper.

In the present paper we restrict ourselves mainly to the situation of a composite quantum system consisting of two subsystems with Hilbert space $\mathcal{H}_1 \otimes \mathcal{H}_2$ where $\mathcal{H}_1$ and $\mathcal{H}_2$ denote the Hilbert spaces of the subsystems (except in Sec. VI). The states of the system are identified with the density operators on $\mathcal{H}_1 \otimes \mathcal{H}_2$.

Definition 1: Let $\mathcal{H}_1$ and $\mathcal{H}_2$ be two Hilbert spaces of arbitrary dimension. A density operator ρ on the tensor product $\mathcal{H}_1 \otimes \mathcal{H}_2$ is called separable *or* disentangled *if there exist a family $\{\omega_i\}$ of*

positive real numbers, a family $\{\rho_i^{(1)}\}$ *of density operators on* $\mathcal{H}_1$ *and a family* $\{\rho_i^{(2)}\}$ *of density operators on* $\mathcal{H}_2$ *such that*

$$\rho = \sum_i \omega_i \rho_i^{(1)} \otimes \rho_i^{(2)}, \tag{1}$$

where the sum converges in trace class norm.

The set of states is a convex set and its extreme points, which are also called *pure states*, are the projection operators. Every pure state obviously corresponds to a unit vector ψ in $\mathcal{H}_1 \otimes \mathcal{H}_2$. We denote the projection operator onto the subspace spanned by the unit vector ψ by P_ψ.

The Schmidt decomposition is of central importance in the characterization and quantification of entanglement associated with pure states.

Lemma 2: Let $\mathcal{H}_1$ *and* $\mathcal{H}_2$ *be Hilbert spaces of arbitrary dimension and let* $\psi \in \mathcal{H}_1 \otimes \mathcal{H}_2$. *Then there exist a family of non-negative real numbers* $\{p_i\}_i$ *and orthonormal bases* $\{a_i\}_i$ *and* $\{b_i\}_i$ *of* $\mathcal{H}_1$ *and* $\mathcal{H}_2$, *respectively, such that*

$$\psi = \sum_i \sqrt{p_i} a_i \otimes b_i .$$

The family of positive numbers $\{p_i\}_i$ is called the family of *Schmidt coefficients* of ψ. For pure states the family of Schmidt coefficients of a state completely characterizes the amount of entanglement of that state. A pure state ψ is separable if and only if $\psi = a \otimes b$ for some $a \in \mathcal{H}_1$ and $b \in \mathcal{H}_2$.

The *von Neumann* (vN) *reduced entropy* for density operators σ on a tensor product Hilbert space $\mathcal{H}_1 \otimes \mathcal{H}_2$ is defined as

$$S_{\mathrm{vN}}(\sigma) := -\mathrm{Tr}_{\mathcal{H}_1}(\mathrm{Tr}_{\mathcal{H}_2}\sigma \ln(\mathrm{Tr}_{\mathcal{H}_2}\sigma)), \tag{2}$$

where $\mathrm{Tr}_{\mathcal{H}_1}$ and $\mathrm{Tr}_{\mathcal{H}_2}$ denote the partial traces over $\mathcal{H}_1$ and $\mathcal{H}_2$, respectively. In the case of pure states $\sigma = P_\psi$, it can be shown that $-\mathrm{Tr}_{\mathcal{H}_1}(\mathrm{Tr}_{\mathcal{H}_2} P_\psi \ln(\mathrm{Tr}_{\mathcal{H}_2} P_\psi)) = -\mathrm{Tr}_{\mathcal{H}_2}(\mathrm{Tr}_{\mathcal{H}_1} P_\psi \ln(\mathrm{Tr}_{\mathcal{H}_1} P_\psi)) = -\Sigma_i p_i \ln p_i$ where $\{p_i\}_i$ denotes the family of Schmidt coefficients of ψ. However, for a general mixed state σ we have $\mathrm{Tr}_{\mathcal{H}_1}(\mathrm{Tr}_{\mathcal{H}_2}\sigma \ln(\mathrm{Tr}_{\mathcal{H}_2}\sigma)) \neq \mathrm{Tr}_{\mathcal{H}_2}(\mathrm{Tr}_{\mathcal{H}_1}\sigma \ln(\mathrm{Tr}_{\mathcal{H}_1}\sigma))$.

III. EFFECTS AND OPERATIONS

In this section we recall some of the fundamental concepts and definitions in the operational approach to quantum theory and in quantum measurement theory.[11–15] The quantum mechanical *state* of a quantum system is described by a density operator ρ on the system's Hilbert space $\mathcal{H}$, i.e., by a positive trace class operator with trace one. Let $\mathcal{K}$ be another Hilbert space. An *operation* is a positive linear map $T: \mathcal{T}(\mathcal{H}) \to \mathcal{T}(\mathcal{K})$ such that T is trace nonincreasing for positive trace class operators, i.e., $0 \leq \mathrm{Tr}(T(\sigma)) \leq \mathrm{Tr}(\sigma)$ for all positive $\sigma \in \mathcal{T}(\mathcal{H})$. Following Refs. 2 and 7 we adopt the point of view that allowed operations in a laboratory are (O1) adding an ancilla, (O2) tracing out part of the system, (O3) performing unitary operations, and (O4) performing possibly selective yes–no experiments. It can be shown (for a detailed proof see, e.g., Ref. 16) that the class of operations $T: \mathcal{T}(\mathcal{H}) \to \mathcal{T}(\mathcal{K})$ composed out of operations of the form (O1)–(O4) coincides with the class of trace nonincreasing *completely positive* operations, i.e., has the property that for all $n \geq 0$ the map T_n on $\mathcal{T}(\mathcal{H} \otimes \mathbb{C}^n)$ defined by $T_n := T \otimes 1_n$, where $1_n \in \mathcal{B}(\mathbb{C}^n)$ denotes the unit matrix, is positive. For a further physical motivation of the requirement of complete positivity see, e.g., Ref. 11. In the sequel it is always understood that all operations are completely positive. If $\mathcal{H}$ and $\mathcal{K}$ are both finite dimensional Hilbert spaces, then it follows from the Choi–Kraus representation theorem for operations[11,13,17] that for every operation $T: \mathcal{T}(\mathcal{H}) \to \mathcal{T}(\mathcal{K})$ there exists a family of bounded operators $\{A_k : \mathcal{H} \to \mathcal{K}\}_k$ with $\Sigma_k A_k A_k^\dagger \leq 1_\mathcal{K}$ such that T can be expressed as

$$T(\sigma)=\sum_k A_k^\dagger \sigma A_k, \tag{3}$$

for all $\sigma\in\mathcal{T}(\mathcal{H})$. If $\mathcal{H}=\mathcal{K}$, the Choi–Kraus representation is also valid for infinite dimensional Hilbert spaces (all sums converge in trace class norm). The family $\{A_k\}_k$ is not unique. However, the operator $E:=\Sigma_k A_k A_k^\dagger = T^*(1)$ is independent of the family $\{A_k\}_k$ chosen and is called the *effect* corresponding to the operation T and its associated yes-no measurement (T^* denotes the adjoint of T[11]). Generally, an operator E is called an *effect operator* if E is bounded and Hermitean and if $0\leqslant E\leqslant 1$. *Effect operator valued measures* are then the most general *observables* in the theory.[14] They are also called *positive operator valued (POV) measures*. A *Lüders–von Neumann operation* is an operation of the form $T_L(\sigma)=\Sigma_k P_k\sigma P_k$ where $\{P_k\}_k$ is a set of mutually orthogonal projection operators on $\mathcal{H}$. Lüders–von Neumann operations are repeatable. In the case of a general operation, it is possible to view the terms in its Choi–Kraus representation as representing different possible measurement outcomes. In the terminology of operational quantum theory the individual terms in the Choi–Kraus representation (3) form a set of operations corresponding to coexistent effects, see Refs. 11 and 14: Two effect operators E_1 and E_2 are called *coexistent* if there exist effect operators F,G,H with $F+G+H\leqslant 1$ such that $E_1=F+G$ and $E_2=F+H$ (in general $F,G,$ and H will not be unique, however). Therefore, in general two coexistent effect operators E_1 and E_2 do not correspond to mutually complementary measurement outcomes but instead may have some ''overlap'' represented by the operator F even if $E_1+E_2\leqslant 1$. Coexistent effect operators need not commute.

IV. ENTANGLEMENT MEASURES

An entanglement measure is a functional E defined on the set of density operators on the Hilbert space of a composite quantum system measuring the degree of entanglement of every given density operator. Every measure of entanglement E should satisfy the following requirements:[2–4,6,7]

(E0) An entanglement measure is a positive real-valued functional E which for any given two systems is well-defined on the set $\mathcal{D}(\mathcal{H}_1\otimes\mathcal{H}_2)$ of density operators on the tensor product $\mathcal{H}_1\otimes\mathcal{H}_2$ of the Hilbert spaces of the two systems. Moreover, E is *expansible*, i.e., whenever $\rho\in\mathcal{D}(\mathcal{H}_1\otimes\mathcal{H}_2)\subset\mathcal{D}(\mathsf{H}_1\otimes\mathsf{H}_2)$ with embeddings $\mathcal{H}_1\hookrightarrow\mathsf{H}_1$ and $\mathcal{H}_2\hookrightarrow\mathsf{H}_2$ of Hilbert spaces $\mathcal{H}_1$ and $\mathcal{H}_2$ into larger Hilbert spaces H_1 and H_2 respectively, then $E|_{\mathcal{H}_1\otimes\mathcal{H}_2}(\rho)=E|_{\mathsf{H}_1\otimes\mathsf{H}_2}(\rho)$;

(E1) if σ is separable, then $E(\sigma)=0$;

(E2) local unitary transformations leave E invariant, i.e.,
$$E(\sigma)=E((U_1\otimes U_2)\sigma(U_1^\dagger\otimes U_2^\dagger))$$
for all unitary operators U_1 and U_2 acting on $\mathcal{H}_1$ or $\mathcal{H}_2$ respectively,

(E3) entanglement cannot increase under procedures consisting of local operations on the two quantum systems and classical communication. If T is an operation which is trace-preserving on positive operators and can be realized by means of local operations and classical communication, i.e., is composed out of local operations of the form (O1)–(O4) and classical communication, then
$$E(T(\sigma))\leqslant E(\sigma), \tag{4a}$$
for all $\sigma\in\mathcal{D}(\mathcal{H}_1\otimes\mathcal{H}_2)$. It is clear that every procedure acting on an individual single quantum system $\mathcal{H}_1\otimes\mathcal{H}_2$ composed only of local operations and classical communication can formally be represented as a finite sequence of operations of the form $T_1\otimes T_2$, where T_1 and T_2 are local operations on $\mathcal{H}_1$ and $\mathcal{H}_2$, respectively. The requirement that entanglement cannot increase under local operations and classical communication is thus equivalent to
$$E((T_1\otimes T_2)(\sigma))\leqslant E(\sigma), \tag{4b}$$
for all $\sigma\in\mathcal{D}(\mathcal{H}_1\otimes\mathcal{H}_2)$.

Remark 3: Equation 4(b) stipulates that local operations cannot increase entanglement. In the quantum information literature most authors replace Eqs. (4a) and (4b) by the stronger requirement

$$\sum_i p_i E(\sigma_i) \leqslant E(\sigma). \tag{5}$$

Equation (5) stipulates that after the measurement the entanglement (as measured by E) averaged over the possible output states σ_i is less than or equal to the original entanglement. Here p_i denotes the probability that the final state σ_i occurs. In the literature Eq. (5) is normally taken as the formal expression for the paradigm that it is impossible to create or increase entanglement by performing procedures composed of local quantum operations and classical communication alone. A disadvantage of Eq. (5) is that it makes sense only in measurement situations and that the "possible output states" corresponding to a given operation T are not uniquely defined. Mathematically this corresponds to the fact that the Choi–Kraus representation of an operation T is in general not unique. The difference between Eqs. (4a) and (5) is that Eq. (5) stipulates that entanglement cannot increase on average under local operations and classical communications (for a detailed discussion of this point see Ref. 7). In contrast Eq. (4a) says that entanglement cannot increase for any operation which acts on individual systems and is composed of local operations and classical communication. If one takes up the former (ensemble) point of view of Eq. (5), then Eq. (4b) does no longer represent the most general condition because from the ensemble point of view the most general operations composed out of local operations and classical communications can contain correlations between terms of the Choi–Kraus representations of subsequent local operations. A precise definition can be found, e.g., in Ref. 16. Some authors consider also other classes of local operations, most prominently the class of separable *operations considered in Ref. 3;*

(E4) mixing of states does not increase entanglement, i.e., E is convex

$$E(\lambda\sigma+(1-\lambda)\tau) \leqslant \lambda E(\sigma)+(1-\lambda)E(\tau)$$

for all $0 \leqslant \lambda \leqslant 1$ and all $\sigma, \tau \in \mathcal{D}(\mathcal{H}_1 \otimes \mathcal{H}_2)$.

Apart from the requirements (E0)–(E4) on entanglement measures many authors add further requirements to the definition of entanglement measures but we are not going to discuss them in this paper. For details, see Ref. 16. In the sequel we exclude the trivial functional $E \equiv 0$ which also satisfies (E0)–(E4).

Remark 4: Postulate (E2) is an immediate consequence of (E3).

Remark 5: It has been argued in Ref. 8 that the entanglement of distillation E_D introduced in Ref. 2 does vanish for certain nonseparable states (so-called bound entangled states). Therefore, it has been pointed out in Ref. 6 that replacing (E1) by the stronger requirement that for every entanglement measure $E(\sigma)=0$ if and only if σ is separable might exclude interesting entanglement measures. For more information the reader is referred to the references.

Example 6: Post selection of a subensemble means selecting a (non-normalized) output state of a quantum operation and normalizing its trace to 1. This procedure can lead to an increase in entanglement. This can be seen by considering a very simple example. Consider a composite quantum system composed of two three-level quantum systems and the state

$$\rho_\varepsilon = (1-\varepsilon)|00\rangle\langle 00| + \frac{\varepsilon}{2}(|12\rangle - |21\rangle)(\langle 12| - \langle 21|).$$

For ε small it is intuitively obvious that this state does not contain "much" entanglement and every entanglement measure should reflect this. Indeed consider, for example, the relative entropy of entanglement introduced in Ref. 3 defined by:

$$E_S(\sigma) := \inf_{\rho}(\mathrm{Tr}(\sigma \ln \sigma - \sigma \ln \rho)), \tag{6}$$

where the infimum runs over all separable states ρ for which $\mathrm{Tr}(\sigma \ln \rho)$ is well-defined and finite. Elementary estimates using the results of Ref. 3 show that

$$E_S(\rho_\varepsilon) \leqslant \varepsilon \ln 2.$$

If we subject the system to an operation testing whether or not the system is in the state $|00\rangle$ and select after the measurement the subensemble corresponding to the negative outcome (system is not in the state $|00\rangle$), then clearly the final state after the operation and post selection is given by $\frac{1}{2}(|12\rangle - |21\rangle)(\langle 12| - \langle 21|)$. Notice that this operation can be achieved by local operations and classical communication. We find

$$E_S(\tfrac{1}{2}(|12\rangle - |21\rangle)(\langle 12| - \langle 21|)) = \ln 2 > E_S(\rho_\varepsilon).$$

Similarly it can be shown that the entanglement measure $\|\cdot\|_\gamma$ to be introduced below may increase under post selection of subensembles. Therefore, we see that we must not replace the operation in Eq. (4a) by some normalized nonlinear operation $\rho \mapsto T(\rho)/\mathrm{Tr}(T(\rho))$ corresponding to post selection of a subensemble.

V. A NEW CLASS OF ENTANGLEMENT MEASURES

Consider the situation that the two Hilbert spaces $\mathcal{H}_1$ and $\mathcal{H}_2$ are both finite dimensional and consider the spaces $\mathcal{T}(\mathcal{H}_1)$ and $\mathcal{T}(\mathcal{H}_2)$ of trace class operators on $\mathcal{H}_1$ and $\mathcal{H}_2$, respectively. Both spaces are Banach spaces when equipped with the trace class norm $\|\cdot\|_1^{(1)}$ or $\|\cdot\|_1^{(2)}$, respectively, see, e.g., Schatten.[18] In the sequel we shall drop the superscript and write $\|\cdot\|_1$ for both norms, slightly abusing the notation; it will always be clear from the context which norm is meant. The algebraic tensor product $\mathcal{T}(\mathcal{H}_1) \otimes_{\mathrm{alg}} \mathcal{T}(\mathcal{H}_2)$ of $\mathcal{T}(\mathcal{H}_1)$ and $\mathcal{T}(\mathcal{H}_2)$ is defined as the set of all finite linear combinations of elementary tensors $u \otimes v$, i.e., the set of all finite sums $\Sigma_{i=1}^n u_i \otimes v_i$ where $u_i \in \mathcal{T}(\mathcal{H}_1)$ and $v_i \in \mathcal{T}(\mathcal{H}_2)$ for all i.

It is well known that we can define a cross norm on $\mathcal{T}(\mathcal{H}_1) \otimes_{\mathrm{alg}} \mathcal{T}(\mathcal{H}_2)$ by[19]

$$\|t\|_\gamma := \inf\left\{ \sum_{i=1}^n \|u_i\|_1 \|v_i\|_1 \,\middle|\, t = \sum_{i=1}^n u_i \otimes v_i \right\}, \tag{7}$$

where $t \in \mathcal{T}(\mathcal{H}_1) \otimes_{\mathrm{alg}} \mathcal{T}(\mathcal{H}_2)$ and where the infimum runs over all finite decompositions of t into elementary tensors. It is also well known that $\|\cdot\|_\gamma$ majorizes any subcross seminorm on $\mathcal{T}(\mathcal{H}_1) \otimes_{\mathrm{alg}} \mathcal{T}(\mathcal{H}_2)$. We denote the completion of $\mathcal{T}(\mathcal{H}_1) \otimes_{\mathrm{alg}} \mathcal{T}(\mathcal{H}_2)$ with respect to $\|\cdot\|_\gamma$ by $\mathcal{T}(\mathcal{H}_1) \otimes_\gamma \mathcal{T}(\mathcal{H}_2)$. $\mathcal{T}(\mathcal{H}_1) \otimes_\gamma \mathcal{T}(\mathcal{H}_2)$ is a Banach algebra.[19]

As both $\mathcal{H}_1$ and $\mathcal{H}_2$ are finite dimensional, $\mathcal{T}(\mathcal{H}_1) = \mathcal{B}(\mathcal{H}_1)$ and $\mathcal{T}(\mathcal{H}_2) = \mathcal{B}(\mathcal{H}_2)$ and $\mathcal{B}(\mathcal{H}_1) \otimes_{\mathrm{alg}} \mathcal{B}(\mathcal{H}_2) = \mathcal{B}(\mathcal{H}_1 \otimes \mathcal{H}_2)$, see, e.g., Ref. 20, Example 11.1.6. In finite dimensions all Banach space norms on $\mathcal{B}(\mathcal{H}_1 \otimes \mathcal{H}_2)$, in particular the operator norm $\|\cdot\|$, the trace class norm $\|\cdot\|_1$, and the norm $\|\cdot\|_\gamma$, are equivalent, i.e., generate the same topology on $\mathcal{B}(\mathcal{H}_1 \otimes \mathcal{H}_2)$.

For later reference we compute the value of $\|P_\psi\|_\gamma$ for one-dimensional projection operators $P_\psi = |\psi\rangle\langle\psi|$ on $\mathcal{H}_1 \otimes \mathcal{H}_2$ in terms of the coefficients in the Schmidt representation of $|\psi\rangle$. In this section we make extensive use of the Dirac bra-ket notation.

Proposition 7: Let $|\psi\rangle \in \mathcal{H}_1 \otimes \mathcal{H}_2$ be a unit vector and $|\psi\rangle = \Sigma_i \sqrt{p_i} |\phi_i\rangle \otimes |\chi_i\rangle$ its Schmidt representation, where $\{|\phi_i\rangle\}_i$ and $\{|\chi_i\rangle\}_i$ are orthonormal bases of $\mathcal{H}_1$ and $\mathcal{H}_2$, respectively and where $p_i \geqslant 0$ and $\Sigma_i p_i = 1$. Let P_ψ denote the one-dimensional projection operator onto the subspace spanned by $|\psi\rangle$. Then

$$\|P_\psi\|_\gamma = \sum_{ij} \sqrt{p_i p_j} = \left(\sum_i \sqrt{p_i} \right)^2.$$

Proof: Without loss of generality we assume that $\mathcal{H}_1=\mathcal{H}_2$ which can always be achieved by possibly suitably enlarging one of the two Hilbert spaces. Further, we identify $\mathcal{H}_1=\mathcal{H}_2$ with $\mathbb{C}^n$, where $n=\dim\mathcal{H}_1$, i.e., we fix an orthonormal basis in $\mathcal{H}_1$ which we identify with the canonical real basis in $\mathbb{C}^n$. With respect to this canonical real basis in $\mathbb{C}^n$ we can define complex conjugates of elements of $\mathcal{H}_1$ and the complex conjugate as well as the transpose of a linear operator acting on $\mathcal{H}_1$. From the Schmidt decomposition it follows that:

$$P_\psi=|\psi\rangle\langle\psi|=\sum_{ij}\sqrt{p_ip_j}|\phi_i\rangle\langle\phi_j|\otimes|\chi_i\rangle\langle\chi_j|. \tag{8}$$

From the definition of $\|\cdot\|_\gamma$ it is thus obvious that $\|P_\psi\|_\gamma\leqslant\Sigma_{ij}\sqrt{p_ip_j}$. Now consider the Hilbert space $\mathfrak{H}$ of Hilbert–Schmidt operators on $\mathcal{H}_1\otimes\mathcal{H}_2$ equipped with the Hilbert–Schmidt inner product $\langle f|g\rangle=\mathrm{Tr}(f^\dagger g)$. Equation (8) induces an operator $\mathfrak{A}_\psi$ on $\mathfrak{H}$ as follows. Every element ζ in $\mathfrak{H}$ can be written $\zeta=\Sigma_k x_k\otimes y_k$ where x_k and y_k are trace class operators on $\mathcal{H}_1$ and $\mathcal{H}_2$, respectively. Then $\mathfrak{A}_\psi$ is defined on ζ as $\mathfrak{A}_\psi(\zeta):=\Sigma_{ijk}\sqrt{p_ip_j}\langle\chi_i^*|x_k|\chi_j^*\rangle|\phi_i\rangle\langle\phi_j|\otimes y_k$ where $|\chi_i^*\rangle$ denotes the complex conjugate of the vector $|\chi_i\rangle$ with respect to the canonical real basis in $\mathbb{C}^n$. Proposition 11.1.8 in Ref. 20 implies that $\mathfrak{A}_\psi(\zeta)$ is independent of the representation of ζ. Consider a representation $P_\psi=\Sigma_{i=1}^r u_i\otimes v_i$ of P_ψ as sum over simple tensors. Denote the transpose of v_i by v_i^T. Then the operator defined by

$$\mathcal{A}_\psi(\zeta):=\sum_{i,k=1}^{r}\mathrm{Tr}(v_i^Tx_k)u_i\otimes y_k, \tag{9}$$

is equal to $\mathfrak{A}_\psi$ (by virtue of Proposition 11.1.8 in Ref. 20). We denote the trace norm on $\mathcal{T}(\mathfrak{H})$ by $\tau(\cdot)$. The operator $\mathfrak{A}_\psi$ is of trace class and the right-hand side of Eq. (8) is the so-called polar representation of $\mathfrak{A}_\psi$ which implies $\tau(\mathfrak{A}_\psi)=\Sigma_{ij}\sqrt{p_ip_j}$, see Ref. 18. $\mathfrak{A}_\psi$ admits also many other representations $\mathfrak{A}_\psi=\Sigma_i f_i\otimes g_i$ with families of operators $\{f_i\}$ and $\{g_i\}$ acting on $\mathcal{H}_1$ and $\mathcal{H}_2$, respectively. It is well known that

$$\tau(\mathfrak{A}_\psi)=\inf\left\{\sum_i\|f_i\|_2\|g_i\|_2\,\middle|\,\mathfrak{A}_\psi=\sum_i f_i\otimes g_i\right\}\leqslant\|P_\psi\|_\gamma,$$

where $\|\cdot\|_2$ denotes the Hilbert–Schmidt norm and where the latter inequality follows from $\|z\|_2\leqslant\|z\|_1$ and from the fact that each decomposition of $\mathfrak{A}_\psi$ corresponds in an obvious one-to-one fashion to a decomposition of P_ψ. This proves the proposition. □

Corollary 8: Let ρ be a density operator on $\mathcal{H}_1\otimes\mathcal{H}_2$, where $\mathcal{H}_1$ and $\mathcal{H}_2$ are finite dimensional Hilbert spaces. If $\rho=\Sigma_{ij}a_{ij}|\phi_i\rangle\langle\phi_j|\otimes|\chi_i\rangle\langle\chi_j|$, then $\|\rho\|_\gamma=\Sigma_{ij}|a_{ij}|$.

An immediate corollary of Proposition 7 is that a pure state $|\psi\rangle\in\mathcal{H}_1\otimes\mathcal{H}_2$ is separable if and only if $\|P_\psi\|_\gamma=1$. In Ref. 1 it has been proven that more generally all separable density matrices can be characterized by $\|\cdot\|_\gamma$.

Theorem 9: *Let $\mathcal{H}_1$ and $\mathcal{H}_2$ be finite dimensional Hilbert spaces and ρ be a density operator on $\mathcal{H}_1\otimes\mathcal{H}_2$. Then ρ is separable if and only if $\|\rho\|_\gamma=1$.*

In Ref. 1 it has been tentatively suggested that $\|\cdot\|_\gamma$ can be considered as a quantitative measure of entanglement. In the present work we substantiate this claim by proving

Proposition 10: The function

$$E_\gamma(\sigma):=\|\sigma\|_\gamma\log\|\sigma\|_\gamma,$$

satisfies the criteria $(E0)$–$(E4)$ for entanglement measures.

Proof: (E1) is an immediate consequence of Theorem 9 and (E0) and (E2) are clear. (E3): Let T be an operation composed of local operations, and classical communication. As we have argued above every such T can be realized as a sequence of operations of the form $T_1\otimes T_2$ where T_1 and T_2 are local operations on system 1 and 2, respectively. We show that $\|(T_1\otimes T_2)(\sigma)\|_\gamma\leqslant\|\sigma\|_\gamma$. By

linearity of $T_1\otimes T_2$ every decomposition of σ into finite sums of simple tensors $\sigma=\Sigma_{i=1}^r x_i\otimes y_i$, where x_i and y_i are trace class operators on $\mathcal{H}_1$ and $\mathcal{H}_2$, respectively, induces a decomposition of $(T_1\otimes T_2)(\sigma)$ into a sum of simple tensors $(T_1\otimes T_2)(\sigma)=\Sigma_{i=1}^r T_1(x_i)\otimes T_2(y_i)$. Thus

$$\begin{aligned}\|(T_1\otimes T_2)(\sigma)\|_\gamma &= \inf\left\{\sum_{i=1}^r \|X_i\|_1\|Y_i\|_1 \,\middle|\, (T_1\otimes T_2)(\sigma)=\sum_{i=1}^r X_i\otimes Y_i\right\}\\ &\leqslant \inf\left\{\sum_{i=1}^r \|T_1(x_i)\|_1\|T_2(y_i)\|_1 \,\middle|\, \sigma=\sum_{i=1}^r x_i\otimes y_i\right\}\\ &\leqslant \|T_1\|\|T_2\|\inf\left\{\sum_{i=1}^r \|x_i\|_1\|y_i\|_1 \,\middle|\, \sigma=\sum_{i=1}^r x_i\otimes y_i\right\}\\ &\leqslant \inf\left\{\sum_{i=1}^r \|x_i\|_1\|y_i\|_1 \,\middle|\, \sigma=\sum_{i=1}^r x_i\otimes y_i\right\}\\ &= \|\sigma\|_\gamma,\end{aligned}$$

where we have used that both T_1 and T_2 are bounded maps on the space of trace class operators on $\mathcal{H}_1$ and $\mathcal{H}_2$, respectively and that

$$\|T_i\|=\sup\{\mathrm{Tr}(T_i(\rho))\,|\,\rho\in\mathcal{T}(\mathcal{H}_i),\rho\geqslant 0 \ \text{ and } \ \mathrm{Tr}(\rho)=1\}\leqslant 1,$$

see, e.g., Lemma 2.2.1 in Ref. 12. (E3) follows from the fact that $[1,\infty[\ni s\mapsto s\log s$ is monotone. Finally, (E4) follows from the facts that $\|\cdot\|_\gamma$ is subadditive and that $[1,\infty[\ni s\mapsto s\log s$ is monotone and convex. □

Remark 11: It follows from the proof of Proposition 10 that if f is a convex, monotonously increasing function on $[1,\infty[$ with $f(1)=0$, then

$$E_f(\sigma):=f(\|\sigma\|_\gamma),$$

is an entanglement measure satisfying the requirements $(E0)$–$(E4)$. A possible choice is $f_1(x)=x-1$ leading to the entanglement measure $E_{f_1}(\sigma)=\|\sigma\|_\gamma-1$. This shows that indeed (as claimed in Ref. 1) the function $\|\sigma\|_\gamma-1$ is an entanglement measure on the space of density operators. Other possible choices for f are $f_2(x)=x\ln x-x+1$, $f_3(x)=e^{a(x-1)}, a>0$ and so forth.

Corollary 12: The entanglement measures constructed in Remark 11 (including the measure E_γ from Proposition 10) satisfy that $E_f(\sigma)=0$ if and only if σ is separable.

Proof: This is an immediate consequence of Theorem 9. □

Proposition 13: Let T_1 and T_2 be two trace-preserving Lüders–von Neumann operations on finite dimensional Hilbert spaces $\mathcal{H}_1$ and $\mathcal{H}_2$, respectively, and let *$T_L=T_1\otimes T_2$ denote the corresponding Lüders–von Neumann operation acting locally on $\mathcal{H}_1\otimes\mathcal{H}_2$. Let $T_1(\sigma_1)=\Sigma_i P_i\sigma_1 P_i$ and $T_2(\sigma_2)=\Sigma_j Q_j\sigma_2 Q_j$ be Choi–Kraus representations of T_1 and T_2, respectively, in terms of families $\{P_i\}$ and $\{Q_j\}$ of, respectively, mutually orthogonal projection operators. Then the entanglement measure $E_{f_1}=\|\cdot\|_\gamma-1$ as in Remark 11 satisfies*

$$\sum_{ij} p_{ij}(\|\sigma_{ij}\|_\gamma-1)\leqslant\|\sigma\|_\gamma-1,$$

where $p_{ij}:=\mathrm{Tr}((P_i\otimes Q_j)\sigma(P_i\otimes Q_j))$ and $\sigma_{ij}=(P_i\otimes Q_j)\sigma(P_i\otimes Q_j)/p_{ij}$ and where σ is a density operator on $\mathcal{H}_1\otimes\mathcal{H}_2$.

Proof: Let P and P' be orthogonal projection operators. Then $\|PxP+P'yP'\|_1=\|PxP\|_1+\|P'yP'\|_1$ for all operators x,y. This follows from considering the spectral resolutions of PxP and $P'yP'$. Hence $\Sigma_i\|P_ix_kP_i\|_1=\|\Sigma_iP_ix_kP_i\|_1\leq\|x_k\|_1$. A similar argument shows that $\Sigma_j\|Q_j\tilde{z}Q_j\|_1\leq\|\tilde{z}\|_1$ for all $\tilde{z}\in\mathcal{B}(\mathcal{H}_2)$. Hence

$$\begin{aligned}\sum_{ij}p_{ij}(\|\sigma_{ij}\|_\gamma-1)&\leq\inf\left\{\sum_{ijk}\|P_ix_kP_i\|_1\|Q_jy_kQ_j\|_1\,\middle|\,\sigma=\sum_k x_k\otimes y_k\right\}-1\\&\leq\inf\left\{\sum_k\|x_k\|_1\|y_k\|_1\,\middle|\,\sigma=\sum_k x_k\otimes y_k\right\}-1\\&=\|\sigma\|_\gamma-1.\end{aligned}$$

□

It is known that some physically interesting entanglement measures coincide with the von Neumann reduced entropy on pure states, for instance the relative entropy of entanglement.[4] However, it follows immediately from Proposition 7 that E_γ does not coincide with the von Neumann reduced entropy on pure states: It follows from Ref. 4 that the entropy of entanglement for a pure state of the form $|\phi\rangle=\alpha|00\rangle+\beta|11\rangle$ is equal to $-|\alpha|^2\ln|\alpha|^2-|\beta|^2\ln|\beta|^2$, whereas it follows from Proposition 7 that $E_\gamma(|\phi\rangle\langle\phi|)=2(|\alpha|+|\beta|)^2\ln(|\alpha|+|\beta|)$. Therefore, we have explicitly constructed an entanglement measure satisfying a physically reasonable set of requirements which is not equal to the von Neumann reduced entropy on pure states. We have proven

Proposition 14: E_γ and S_{vN} do not coincide on pure states.

In Ref. 16 necessary and sufficient conditions for an entanglement measure to coincide with S_{vN} on pure states were derived. It is easy to see that, e.g., E_γ does not satisfy the additivity condition (P4) considered in Ref. 16.

VI. HIGHER TENSOR PRODUCT HILBERT SPACES

So far we restricted ourselves to tensor product Hilbert spaces of two finite dimensional Hilbert spaces. It is straightforward, however, to generalize our results to the situation of tensor products of more than two, but at most finitely many, finite dimensional Hilbert spaces. To this end consider the tensor product $\mathcal{H}=\mathcal{H}_1\otimes\cdots\otimes\mathcal{H}_n$ of n finite dimensional Hilbert spaces $\mathcal{H}_1,\ldots,\mathcal{H}_n$. The obvious generalization of the definition of $\|\cdot\|_\gamma$ is

$$\|t\|_\gamma^{(n)}:=\inf\left\{\sum_{i=1}^r\|u_i^{(1)}\|_1\cdots\|u_i^{(n)}\|_1\,\middle|\,t=\sum_{i=1}^r u_i^{(1)}\otimes\cdots\otimes u_i^{(n)}\right\},\tag{10}$$

where t is a trace class operator on $\mathcal{H}$.

It is straightforward to generalize the main result of Ref. 1 to n-fold tensor product Hilbert spaces $\mathcal{H}=\mathcal{H}_1\otimes\cdots\otimes\mathcal{H}_n$.

Definition 15: Let $\mathcal{H}_1,\ldots,\mathcal{H}_n$ be Hilbert spaces of arbitrary dimension. A density operator ρ on the tensor product $\mathcal{H}_1\otimes\cdots\otimes\mathcal{H}_n$ is called disentangled *or* separable *(with respect to $\mathcal{H}_1,\ldots,\mathcal{H}_n$) if there exist a family $\{\omega_i\}$ of positive real numbers, and families $\{\rho_i^{(k)}\}$ of density operators on $\mathcal{H}_k$ respectively, where $1\leq k\leq n$, such that*

$$\rho=\sum_i\omega_i\rho_i^{(1)}\otimes\cdots\otimes\rho_i^{(n)},\tag{11}$$

where the sum converges in trace class norm.

Theorem 16: *Let $\mathcal{H}_1,\ldots,\mathcal{H}_n$ be finite dimensional Hilbert spaces and ρ be a density operator on $\mathcal{H}=\mathcal{H}_1\otimes\cdots\otimes\mathcal{H}_n$. Then ρ is separable if and only if $\|\rho\|_\gamma^{(n)}=1$.*

We now consider the situation that $\mathcal{H}$ is the m-fold tensor product of $\mathfrak{H}_1 \otimes \mathfrak{H}_2$ with two finite dimensional Hilbert spaces $\mathfrak{H}_1$ and $\mathfrak{H}_2$. The functional E_γ from Proposition 10 admits an obvious extension

$$E_\gamma(\sigma) := \|\sigma\|_\gamma^{(n)} \ln \|\sigma\|_\gamma^{(n)}, \tag{12}$$

for all trace class operators σ on $\mathcal{H}$.

Proposition 17: The functional defined by Eq. (12) satisfies the criteria $(E0)$–$(E4)$ *for entanglement measures.*

VII. CONCLUSION

To conclude, in this paper we have introduced a new class of entanglement measures on the space of density operators on tensor product Hilbert spaces. Our entanglement measures are based on the greatest cross norm $\|\cdot\|_\gamma$ on the set of trace class operators on the tensor product Hilbert space. We showed that our entanglement measures satisfy a number of physically desirable requirements, in particular that they do not increase under local quantum operations.

JOURNAL OF MATHEMATICAL PHYSICS VOLUME 42, NUMBER 11 NOVEMBER 2001

Superalgebras for the Penning trap

Neil Russell
Physics Department, Northern Michigan University, Marquette, Michigan 49855

(Received 29 March 2001; accepted for publication 31 July 2001)

The Hamiltonian describing a single fermion in a Penning trap is shown to be supersymmetric in certain cases. The supersymmetries of interest occur when the ratio of the cyclotron frequency to the axial frequency is $\frac{3}{2}$ and the particle has anomalous magnetic moment $\frac{4}{3}$ or $\frac{2}{3}$. At these supersymmetric points, the spectrum shows uniformly spaced crossed levels. The associated superalgebras are su$(2|1)$ and su$(1|1)$. The phase space for this problem has an osp$(2|6)$ structure and contains all the degeneracy superalgebras. © *2001 American Institute of Physics.* [DOI: 10.1063/1.1404386]

I. INTRODUCTION

The Penning trap[1,2] is an impressive tool for precision spectroscopy of charged particles. High-precision measurements conducted on particles in a Penning trap include a comparison of the anomalous magnetic moments for the electron and positron to a precision of 10^{-12},[3] a measurement of the charge-to-mass ratio for protons and antiprotons to 10^{-10},[4] and a search for time dependence in the anomaly frequency of a trapped electron.[5] Comparable precisions have been attained in measurements of the mass ratio of the proton to the electron,[6] the masses of molecular ions,[7] and bounds on the anisotropy of space.[8] Recent theoretical investigations indicate that Penning-trap experiments can constrain Lorentz and CPT violation at the level of 10^{-20} in the context of a general standard-model extension.[9] Numerous other applications of Penning traps exist.[10]

In the present article, we investigate the symmetries of the Hamiltonian describing a single charged fermionic particle confined in a Penning trap with hyperbolic electrodes. The symmetry depends on the relative values of the magnetic and electric fields and on the gyromagnetic ratio of the trapped particle. For certain values of these parameters, superalgebras[11] arise.

There are relatively few physical manifestations of superalgebras. One arises in nuclear physics.[12] Another exists in atomic systems,[13,14] where a broken quantum-mechanical supersymmetry has been shown to underlie the properties of the chemical elements. It has recently been suggested that a supersymmetry also exists in the context of traps.[15] In this case, a radial supersymmetry for the trap wave functions provides a description of a small cloud of particles in a trap via an effective single-particle formalism. The associated parallels between traps and atoms in the context of quantum-mechanical supersymmetry have been studied in some detail.[16] Some other results in quantum-mechanical supersymmetry are reviewed in Ref. 17.

The supersymmetries discussed in this article for the Penning trap are of a different type. The idea is to consider the full Hamiltonian written in terms of creation and annihilation operators. The (anti)commutation relations satisfied by quadratic combinations of these operators define the superalgebras relevant to the problem.

In Sec. II, the relevant features of the Penning trap are reviewed and some definitions are given. The relative strengths of the trapping fields required for degeneracies to occur are discussed in Sec. III. The central algebra common to all cases is given in Sec. IV, and each of the five relevant superalgebras are presented in turn in Secs. V–IX. In Sec. X we summarize and discuss the results.

II. THE PENNING TRAP

In most situations, the dynamics of a particle in a Penning trap is dominated by its interaction with a uniform magnetic field **B**. For convenience, we work in cylindrical coordinates (ρ,ϕ,z) with $\mathbf{B}=B\hat{\mathbf{z}}$. A suitable choice of vector potential is $\mathbf{A}=(B\rho/2)\hat{\phi}$.

The quadrupole electric field of the trap is produced by electrodes in one of several possible forms.[18,19] We restrict attention to the case with electrode surfaces given in cylindrical coordinates by the expressions

$$z^2=\rho^2/2\pm d^2, \tag{1}$$

where d is a constant. The upper equation is a hyperboloid of two sheets and describes the endcap surfaces, which intersect the z axis at $z=\pm d$ and have potential $V/2$. The remaining electrode surface has potential $-V/2$ and has shape determined by the lower sign in Eq. (1). It is a hyperboloid of one sheet encircling the z axis with waist radius $\sqrt{2}d$ in the $z=0$ plane. The electrostatic potential is

$$\phi(\rho,\phi,z)=\frac{V}{2d^2}(z^2-\rho^2/2) \tag{2}$$

in the trapping region.

Let the trapped particle have charge q and mass m. We assume that q and V have the same sign, thereby ensuring axial trapping. Defining the axial frequency $\omega_z=(qV/md^2)^{1/2}$ and the cyclotron frequency $\omega_c=|qB|/m$, the Hamiltonian for $q>0$ is

$$\tilde{H}=-\frac{\hbar^2}{2m}\boldsymbol{\nabla}^2+\frac{1}{8}m\Omega^2\rho^2+\frac{1}{2}m\omega_z^2z^2+\frac{1}{2}\hbar\omega_c i\frac{\partial}{\partial\phi}, \tag{3}$$

where $\Omega=(\omega_c^2-2\omega_z^2)^{1/2}$. For $q<0$, the last term would be negative. The algebraic structure of the problem turns out to be independent of the sign of q, and to avoid carrying two signs in the expressions that follow, we restrict attention to the case $q>0$.

Equation (3) separates by defining $\Psi(\rho,\phi,z)\equiv(r_0/\rho)^{1/2}W(\rho)\Theta(\theta,z)$, where $r_0=(\hbar/m\omega_c)^{1/2}$. The equation in ρ is

$$\left\{-\frac{\hbar^2}{2m}\frac{d^2}{d\rho^2}+\frac{\hbar^2}{2m}\frac{(\hat{M}^2-\frac{1}{4})}{\rho^2}+\frac{1}{8}m\Omega^2\rho^2-\left[E-\left(\hat{K}+\frac{1}{2}\right)\hbar\omega_z+\frac{1}{2}\hat{M}\hbar\omega_c\right]\right\}W(\rho)=0, \tag{4}$$

where $\hat{M}$ and $\hat{K}$ are separation constants taking values $\hat{M}=0,\pm1,\pm2,\ldots$ and $\hat{K}=0,1,2,\ldots$. The energy eigenvalues E for this problem are

$$E_{N,\hat{K},\hat{M}}=\frac{\hbar}{2}[\Omega N+2\omega_z\hat{K}-\omega_c\hat{M}+(\Omega+\omega_z)], \tag{5}$$

where N takes values $N=|\hat{M}|,|\hat{M}|+2,|\hat{M}|+4,\ldots$. The full solution to the stationary problem $\tilde{H}\Psi=E\Psi$ involves generalized Laguerre and Hermite polynomials,

$$\Psi_{N,\hat{K},\hat{M}}(\rho,\phi,z)=C_{N,\hat{K},|\hat{M}|}\left(\frac{\rho}{r_0}\right)^{|\hat{M}|}\exp\left[-\frac{k}{4}\left(\frac{\rho}{r_0}\right)^2-\frac{1}{2}\left(\frac{z}{s_0}\right)^2+i\hat{M}\phi\right]$$
$$\times L_{N/2-|\hat{M}|/2}^{(|\hat{M}|)}\left(\frac{k}{2}\left(\frac{\rho}{r_0}\right)^2\right)H_{\hat{K}}\left(\frac{z}{s_0}\right), \tag{6}$$

where $k=\Omega/\omega_c$, $s_0=(\hbar/m\omega_z)^{1/2}$, and the normalization coefficient is

$$C_{N,\hat{K},|\hat{M}|}=\left[\frac{\sqrt{k}}{r_0^2 s_0 2^{\hat{K}}\pi^{3/2}}\left(\frac{k}{2}\right)^{|\hat{M}|+1/2}\frac{\Gamma(N/2-|\hat{M}|/2+1)}{\Gamma(N/2+|\hat{M}|/2+1)\Gamma(\hat{K}+1)}\right]^{1/2}. \tag{7}$$

For the special case $k=0$, the coefficient of the ρ^2 term in Eq. (4) would vanish and the above solutions would change. We exclude this case because it does not allow long-term confinement. In the initial stages of trapping before significant cooling has occurred, the motion of the particle can be understood classically. The possible trajectories are either circles about the central axis or curves that exit the trap. The former are unstable to radial perturbations. We therefore restrict attention to the range of values $0<k\leqslant 1$, or, equivalently, $0<\Omega\leqslant\omega_c$.

The Hamiltonian $\tilde{H}$ can be expressed in terms of creation and annihilation operators. A transformation of the phase space yields six dimensionless operators

$$\begin{aligned}
a,a^\dagger &= \frac{r_0}{\sqrt{2k}}(\pm\partial_x+i\partial_y)+\sqrt{\frac{k}{8}}\frac{1}{r_0}(x\pm iy),\\
b,b^\dagger &= \frac{r_0}{\sqrt{2k}}(\mp\partial_x+i\partial_y)-\sqrt{\frac{k}{8}}\frac{1}{r_0}(x\mp iy),\\
c,c^\dagger &= \pm\frac{s_0}{\sqrt{2}}\partial_z+\frac{1}{\sqrt{2}\,s_0}z.
\end{aligned} \tag{8}$$

They commute with each other except for the cases

$$[a,a^\dagger]=1,\quad [b,b^\dagger]=1,\quad [c,c^\dagger]=1. \tag{9}$$

The transformation (8) preserves the canonical properties of the phase space, including the commutation relations for the momentum and position operators. Therefore, it is symplectic.[20]

The symplectic transformation casts the Hamiltonian into the form

$$\tilde{H}=\hbar\omega_+(a^\dagger a+\tfrac{1}{2})-\hbar\omega_-(b^\dagger b+\tfrac{1}{2})+\hbar\omega_z(c^\dagger c+\tfrac{1}{2}), \tag{10}$$

where $\omega_+=(\omega_c+\Omega)/2$ and $\omega_-=(\omega_c-\Omega)/2$ are called the modified cyclotron frequency and the magnetron frequency, respectively. The negative sign in Eq. (10) reveals an inverted oscillator in the system, which in principle could lead to an instability in the presence of radiation. However, in practical situations this energy loss is controlled by ensuring $\omega_+\gg\omega_-$, so particles may be trapped "indefinitely."[18]

For particles with spin $\frac{1}{2}$, a term H' must be added to the Hamiltonian (3),

$$H'\equiv-\vec{\mu}\cdot\mathbf{B}=-\frac{g}{4}\hbar\omega_c\sigma_3, \tag{11}$$

where g is the Landé factor relating the spin to the magnetic dipole moment and σ_3 is the third Pauli matrix. The operators $f\equiv(\sigma_1+i\sigma_2)/2$ and $f^\dagger\equiv(\sigma_1-i\sigma_2)/2$ have one nonzero anticommutation relation,

$$\{f,f^\dagger\}\equiv ff^\dagger+f^\dagger f=1, \tag{12}$$

and they provide a formalism for describing the spin degree of freedom. The additional term in the Hamiltonian is $H'=\hbar\omega_g(f^\dagger f-\frac{1}{2})$, where $\omega_g=|g|\omega_c/2$. The sign of this term assumes $gq>0$.

Combining the bosonic and fermionic degrees of freedom we obtain the full Hamiltonian $H\equiv\tilde{H}+H'$ in operator form:

$$H=\hbar\omega_+(a^\dagger a+\tfrac{1}{2})-\hbar\omega_-(b^\dagger b+\tfrac{1}{2})+\hbar\omega_z(c^\dagger c+\tfrac{1}{2})+\hbar\omega_g(f^\dagger f-\tfrac{1}{2}). \tag{13}$$

The basis states for this problem can be denoted by $|N_a,N_b,N_c,N_f\rangle$, where $N_a,N_b,N_c \in\{0,1,2,\ldots\}$ are the eigenvalues of the number operators $a^\dagger a$, $b^\dagger b$, and $c^\dagger c$, and where $N_f \in\{0,1\}$ is the eigenvalue of $f^\dagger f$.

The energy eigenvalues of the system follow from Eq. (13):

$$E(N_a,N_b,N_c,N_f;\omega_c,\omega_z,g)/\hbar\equiv\omega_+(N_a+\tfrac{1}{2})-\omega_-(N_b+\tfrac{1}{2})+\omega_z(N_c+\tfrac{1}{2})+\omega_g(N_f-\tfrac{1}{2}). \tag{14}$$

The quantum numbers used here are related to the ones in Eq. (5) by $N_a=(N-\hat{M})/2$, $N_b=(N+\hat{M})/2$, and $N_c=\hat{K}$.
