The relative values of the frequencies in Eq. (14) play an important part in the superalgebra structures considered later in this work. To this end, it is useful to define the ratio σ of the cyclotron and axial frequencies,

$$\sigma\equiv\omega_c/\omega_z=\left(\frac{qB^2d^2}{mV}\right)^{1/2}. \tag{15}$$

This parameter contains information about the relative values of B and V. For experiments with single trapped electrons, typical values[18] are $d\simeq 0.3$ cm, $B\simeq 6$ T, and $V\simeq 10$ V, giving $\sigma\simeq 3\times 10^3$. In this limit of $\sigma\gg 1$, the motion of the trapped particle is dominated by its interaction with the magnetic field, and Eq. (14) becomes

$$\lim_{\sigma\to\infty}E(N_a,N_b,N_c,N_f;\omega_c,\omega_z,g)=\hbar\omega_c\left[\left(N_a+\frac{1}{2}gN_f\right)-\frac{1}{2}\left(\frac{g-2}{2}\right)\right]. \tag{16}$$

For experiments with single trapped protons, typical values[18] are $d\simeq 0.1$ cm, $B\simeq 5$ T, and $V\simeq 50$ V, giving the lower value $\sigma\simeq 8$. As σ is decreased, the confining effect of the magnetic field is weakened, and trapping becomes impractical when $\sigma=\sqrt{2}$. This corresponds to the excluded case $k=0$. Exceptional measurement precisions are possible: for trapped protons, cyclotron-frequency precisions are at the 90 parts per trillion level,[4] making it feasible to probe minuscule effects such as Lorentz violation.[21]

III. DEGENERACY SUPERALGEBRAS AND FREQUENCY EQUALITIES

The algebraic structures that arise for the single-particle Penning trap are superalgebras because both fermionic and bosonic operators are involved. We focus on *degeneracy* superalgebras formed from operators that commute with the Hamiltonian, thereby linking degenerate eigenstates.

All the symmetries we consider are based on the Hamiltonian (13). Superalgebras arise for special values of the two parameters g and σ, which in turn determine the four characteristic frequencies $\omega_\pm$, ω_z, and ω_g up to an overall factor. As an illustrative example, consider the case of $g=\frac{2}{3}$ and $\sigma=\frac{3}{2}$. The Penning-trap Hamiltonian is

$$H/\hbar\omega_z=(a^\dagger a+c^\dagger c+1)-\tfrac{1}{2}(b^\dagger b-f^\dagger f+1), \tag{17}$$

and there are two distinct frequencies, $\omega_+=\omega_z=2\omega_-=2\omega_g$. The generator $b^\dagger f$ increases N_b by one unit while decreasing N_f by the same amount. It commutes with the Hamiltonian because of the equality of ω_g and ω_-.

In the most general case, $\omega_\pm$, ω_z, and ω_g are distinct. There are four generators constructed from quadratic combinations of creation and annihilation operators that commute with the Hamiltonian: $a^\dagger a$, $b^\dagger b$, $c^\dagger c$, and $f^\dagger f$. They generate an Abelian algebra $\mathrm{u}(1)\times\mathrm{u}(1)\times\mathrm{u}(1)\times\mathrm{u}(1)$ and form a complete set of commuting operators. Their interpretation as constants of the motion is considered in the next section. The generators of this Abelian algebra commute with the Hamil-

tonian and with any other degeneracy operators regardless of the values of g and σ. Therefore, all the degeneracy superalgebras considered below contain this four-dimensional central algebra.

Even with four distinct frequencies, degeneracies in the energies can occur. Consider the case of $\sigma=\frac{9}{4}$ and $g=\frac{2}{3}$. The corresponding Hamiltonian is

$$H/\hbar\omega_z=2(a^\dagger a+\tfrac{1}{2})-\tfrac{1}{4}(b^\dagger b+\tfrac{1}{2})+(c^\dagger c+\tfrac{1}{2})+\tfrac{3}{4}(f^\dagger f-\tfrac{1}{2}). \tag{18}$$

The point is that the associated frequencies are all rational multiples of each other. By taking combinations higher than quadratic in the creation or annihilation operators, generators can be constructed that commute with the Hamiltonian. Take, for example, the operator $a^\dagger c^2$. It increases N_a by one unit and decreases N_c by two units. This ensures commutation with the Hamiltonian because the associated frequencies ω_+ and ω_z are in the ratio 2:1. Other generators that commute with this Hamiltonian are $a(c^\dagger)^2$, $(b^\dagger)^4c^\dagger$, b^4c, ab^8, $a^\dagger(b^\dagger)^8$, and $bcf^\dagger$. A detailed study of the algebraic structures associated with cubic and higher combinations of creation or annihilation operators lies beyond the scope of the present work.

Next, consider the case of three distinct frequencies. For a superalgebra to arise, ω_g must be equated with another frequency. We give a few examples. For $\sigma=\frac{9}{4}$ and $g=\frac{2}{9}$, we find that the ratio $\omega_+:\omega_-:\omega_z:\omega_g$ is 8 : 1 : 4 : 1, so that $\omega_g=\omega_-$. For $\sigma=\frac{11}{6}$ and $g=\frac{18}{11}$, the frequency ratio is 9 : 2 : 6 : 9, so that $\omega_g=\omega_+$. For $\sigma=\frac{9}{4}$ and $g=\frac{8}{9}$, the frequency ratio is 8 : 1 : 4 : 4, so that $\omega_g=\omega_z$. The superalgebras that arise are all isomorphic and are discussed in Sec. V.

Next, consider ways in which the single-particle Penning-trap system can have two distinct characteristic frequencies in a rational ratio. Of these, we focus on the simplest possible ratio, 2:1. It turns out that there are only two cases. One arises for $g=\frac{2}{3}$ and $\sigma=\frac{3}{2}$ and the corresponding Hamiltonian is given in Eq. (17). This case is considered in Sec. VI. The other arises for $\sigma=\frac{3}{2}$ and $g=\frac{4}{3}$. It is the intersection point of the curves ω_+, ω_z, and ω_g as functions of σ, and is illustrated in Fig. 1. For this case, the frequencies are $\omega_+=\omega_z=\omega_g=2\omega_-$ and the associated supersymmetries are considered in detail in Sec. VII.

It is not possible to equate all four frequencies to yield a single characteristic frequency for the system. This can be seen in Fig. 1, which shows that ω_z cannot equal ω_-.

The two cases with two distinct characteristic frequencies are special. They represent the largest possible superalgebras that can be constructed from quadratic generators for the single-particle Penning trap. Both cases have $\sigma=\frac{3}{2}$, but differ in the values of g.

IV. CONSTANTS OF THE MOTION FOR THE SUPERSYMMETRIC CONFIGURATION

For the supersymmetric point $\sigma=\frac{3}{2}$, the Hamiltonian can be written in terms of four constants of the motion H_ρ, H_ϕ, H_z, and H_f to be defined next:

$$H=H_\rho+H_\phi+H_z+H_f. \tag{19}$$

These operators have simple physical interpretations.

The first one is the energy operator of a harmonic oscillator in the xy plane with frequency $\omega_z/4$:

$$\begin{aligned} H_\rho &\equiv -\frac{\hbar^2}{2m}\left(\partial_\rho^2+\frac{1}{\rho}\partial_\rho+\frac{1}{\rho^2}\partial_\phi^2\right)+\frac{1}{2}m\left(\frac{\omega_z}{4}\right)^2\rho^2 \\ &=\frac{\hbar\omega_z}{4}(a^\dagger a+b^\dagger b+1). \end{aligned} \tag{20}$$

The operator H_ϕ is a rotational energy about the z axis:

$$H_\phi\equiv\tfrac{1}{2}\hbar\omega_c i\partial_\phi=-\tfrac{1}{2}\omega_c L_z, \tag{21}$$

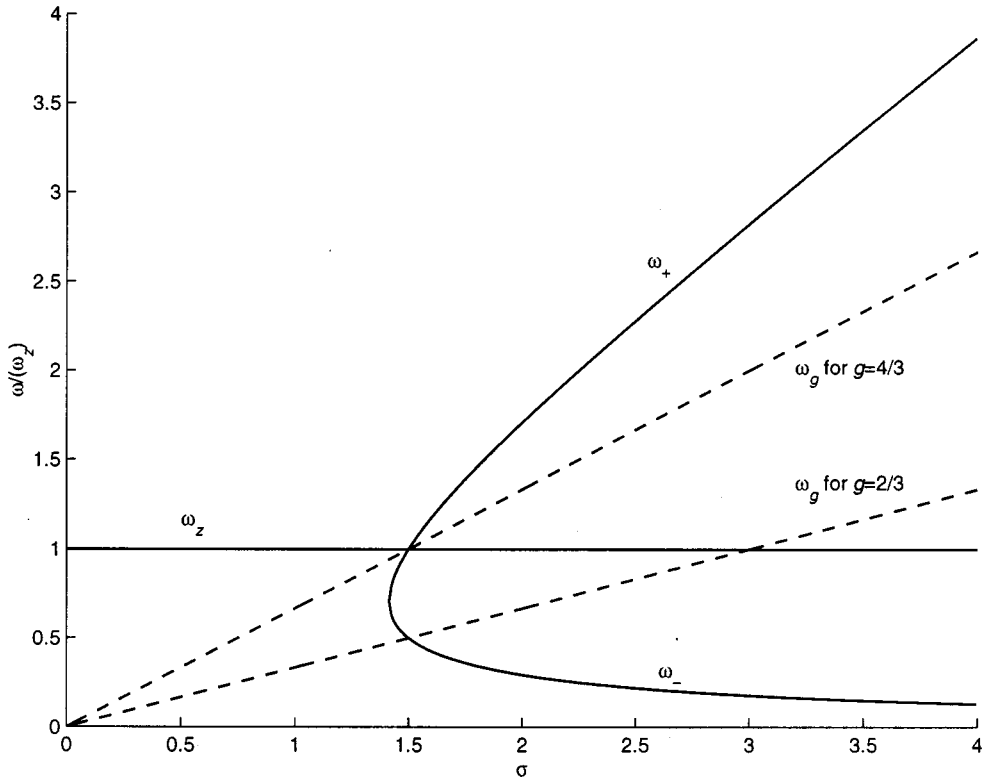

FIG. 1. The four Penning-trap frequencies ω_+, ω_-, ω_g, and ω_z as functions of the parameter $\sigma=\omega_c/\omega_z$. The dashed lines show ω_g for $g=\frac{4}{3}$ and $g=\frac{2}{3}$. For $g=\frac{4}{3}$, there are three equal frequencies $\omega_+=\omega_z=\omega_g=2\omega_-$ at the supersymmetric point $\sigma=\frac{3}{2}$. For $g=\frac{3}{2}$, there are two pairs of distinct equal frequencies at the supersymmetric point. The frequencies ω_+ and ω_- have infinite slopes where they meet at $\sigma=2^{1/2}$.

where $\omega_c=3\omega_z/2$. This term has negative eigenvalues for L_z in the $+z$ direction. This is consistent with the presence of an inverted harmonic oscillator in the Penning trap. The angular momentum about the z axis can be expressed in terms of the creation and annihilation operators[22] as

$$L_z=\hbar(b^\dagger b-a^\dagger a). \tag{22}$$

The operator H_z is the energy operator of a harmonic oscillator with frequency ω_z on the z axis:

$$H_z\equiv-\frac{\hbar^2}{2m}\partial_z^2+\frac{1}{2}m\omega_z^2z^2=\hbar\omega_z\left(c^\dagger c+\frac{1}{2}\right). \tag{23}$$

The operator H_f is the energy operator for the splitting between the two spin projections onto the z axis:

$$H_f\equiv\hbar\omega_g(f^\dagger f-\tfrac{1}{2}). \tag{24}$$

The four operators H_ρ, H_ϕ, H_z, and H_f form an alternative complete set of commuting operators for the single-particle Penning trap. They form a basis of the Abelian center of all the degeneracy superalgebras for this system, and their associated energies are independent of each other.

V. THREE DISTINCT FREQUENCIES

For this case, ω_g must equal one of the other frequencies and the remaining two frequencies must each be distinct from this value and from each other. This can occur in numerous ways. As an example, consider the case with $\sigma=\frac{11}{6}$ and $g=\frac{18}{11}$ mentioned in Sec III. The Hamiltonian is

$$H/\hbar\omega_z=\tfrac{3}{2}(a^\dagger a+f^\dagger f)-\tfrac{1}{3}(b^\dagger b+\tfrac{1}{2})+(c^\dagger c+\tfrac{1}{2}). \tag{25}$$

Define the operators

$$\begin{aligned} J&\equiv a^\dagger a+f^\dagger f,\\ \overline{J}&\equiv a^\dagger a-f^\dagger f+1,\\ F_{+1}&\equiv a^\dagger f,\\ F_{-1}&\equiv a f^\dagger. \end{aligned} \tag{26}$$

Note from Eq. (8) that they depend on the value of k, and that for this case $k=\sqrt{\sigma^2-2}/\sigma=\frac{7}{11}$. They commute with the Hamiltonian and generate a superalgebra. The only nonzero relations are

$$[\overline{J},F_{\pm1}]=\pm 2F_{\pm1},\quad \{F_{+1},F_{-1}\}=J. \tag{27}$$

This algebra has a nontrivial ideal spanned by $J,F_{\pm1}$ and so is not simple. The ideal is the nilpotent superalgebra su$(1|1)$ with Lie part u(1) generated by J. The operator $\overline{J}$ does not commute with the odd operators $F_{\pm1}$, so we denote the superalgebra by u$(1)\oslash$su$(1|1)$ to indicate the absence of a direct product.

The full degeneracy algebra for the Hamiltonian Eq. (25) includes elements which complete the basis of the center. The structure is u$(1)\times$u$(1)\times$u$(1)\oslash$su$(1|1)$, generated by $b^\dagger b$, $c^\dagger c$, $\overline{J}$, and $\{J,F_{\pm1}\}$.

Given a pair $F_{\pm1}$ of mutually Hermitian-conjugate generators, (self-)Hermitian generators are obtained by the combinations $T_1=(F_{+1}+F_{-1})/2$ and $T_2=i(F_{+1}-F_{-1})/2$. We define non-Hermitian ladder generators because they are useful for calculations. The actual Hermitian generators within the superalgebras can always be constructed by this method.

Another way to obtain a supersymmetry with three distinct frequencies in the system is to set $\omega_g=\omega_-$. Consider the example mentioned in Sec. III with $g=\frac{2}{9}$ and $\sigma=\frac{9}{4}$, which corresponds to $k=\frac{7}{9}$. The Hamiltonian is

$$H/\hbar\omega_z=2(a^\dagger a+\tfrac{1}{2})-\tfrac{1}{4}(b^\dagger b-f^\dagger f+1)+(c^\dagger c+\tfrac{1}{2}). \tag{28}$$

We define four operators that commute with the Hamiltonian:

$$\begin{aligned} K&\equiv b^\dagger b+f^\dagger f,\\ \overline{K}&\equiv b^\dagger b-f^\dagger f+1,\\ F_{+2}&\equiv b^\dagger f^\dagger,\\ F_{-2}&\equiv bf. \end{aligned} \tag{29}$$

They generate a superalgebra with nonzero relations

$$[K,F_{\pm2}]=\pm 2F_{\pm2},\quad \{F_{+2},F_{-2}\}=\overline{K}. \tag{30}$$

Comparison of these relations with those in Eq. (27) shows that the two algebras are isomorphic. The full superalgebra for this example is $u(1)\times u(1)\times u(1)\oslash su(1|1)$, generated by $a^\dagger a$, $c^\dagger c$, K, and $\{\overline{K},F_{\pm 2}\}$.

One might expect different superalgebras to arise for the Hamiltonians (25) and (28) because of the opposite signs of $a^\dagger a$ and $b^\dagger b$ relative to $f^\dagger f$. However, this is not the case, and the isomorphism relating the operators in Eqs. (26) and (29) is given explicitly by

$$a\leftrightarrow b, \quad a^\dagger\leftrightarrow b^\dagger, \quad f\leftrightarrow f^\dagger. \tag{31}$$

It follows from this observation that the *only* superalgebra that can arise for three distinct frequencies is $u(1)\oslash su(1|1)$. In all cases of this type, the full symmetry is $u(1)\times u(1)\times u(1)\oslash su(1|1)$.

This supersymmetry is relevant to experiments with electrons or positrons, where $\sigma\gg 1$ and $g\simeq 2$. Taking $g=2$, the Hamiltonian for $\sigma\gg 1$ is

$$H/\hbar\approx\omega_c(a^\dagger a+f^\dagger f)+\omega_z(c^\dagger c+\tfrac{1}{2})-\omega_-(b^\dagger b+\tfrac{1}{2}), \tag{32}$$

with $\omega_c\gg\omega_z\gg\omega_-$. However, the supersymmetry is broken because in the physical situation g is slightly larger than 2, so ω_+ is always slightly less than ω_g no matter how strong the magnetic field. The value of the g factor determines the degree to which this supersymmetry is broken in the strong-B limit. In this regime, the particle experiences a uniform magnetic field and has associated supercoherent states.[23] If g were exactly equal to 2, the anomaly $a_e=(g-2)/2\simeq 10^{-3}$ would be zero, and the spin-up and spin-down ladders would have no relative energy shift.[24]

VI. TWO PAIRS OF EQUAL FREQUENCIES: $\omega_+=\omega_z=2\omega_-=2\omega_g$

For $g=\frac{2}{3}$ and $\sigma=\frac{3}{2}$, the Penning-trap Hamiltonian is given in Eq. (17). Four linearly independent generators constructed from a, $a^\dagger$, c, and $c^\dagger$ that commute with this Hamiltonian are

$$\begin{gathered}\overline{L}\equiv a^\dagger a+c^\dagger c+1,\\ L\equiv\tfrac{1}{2}(a^\dagger a-c^\dagger c), \quad E_{+2}\equiv a^\dagger c, \quad E_{-2}\equiv ac^\dagger.\end{gathered} \tag{33}$$

The generator $\overline{L}$ commutes with the other three, forming a $u(1)$ subalgebra. The generators E_{+2} and E_{-2} are Hermitian conjugates and are themselves non-Hermitian. They are ladder operators, which together with L give the Lie algebra $so(3)$:

$$[L,E_{\pm 2}]=\pm E_{\pm 2}, \quad [E_{+2},E_{-2}]=2L. \tag{34}$$

The remaining generators of the superalgebra are K, $\overline{K}$, and $F_{\pm 2}$ defined in Eq. (29), but with $k=\frac{1}{3}$. They span the superalgebra $u(1)\oslash su(1|1)$ with nonzero relations given in Eq. (30).

Combining the relations of Eqs. (34) and (30), the full degeneracy superalgebra for the Hamiltonian in (17) is $u(1)\times so(3)\times u(1)\oslash su(1|1)$, generated by $\overline{L}$, $\{L,E_{\pm 2}\}$, $\overline{K}$, and $\{K,F_{\pm 2}\}$. It is implicit that for this case $k=\frac{7}{9}$ in the definitions (29).

For $gq<0$, the second term of the Hamiltonian (17) becomes $-(b^\dagger b+f^\dagger f)/2$. A full set of generators that commute with the Hamiltonian is obtained from Eq. (33) and by making the replacements $f\rightarrow f^\dagger$ and $f^\dagger\rightarrow f$ in Eq. (29). This operation is an automorphism, leaving the relations (30) and (34) unchanged.

From a given state $|N_a,N_b,N_c,N_f\rangle$, the elements defined in Eqs. (29) and (33) generate all the states in the degenerate subspace. The Lie algebra $so(3)$ generates states differing in the N_a and N_c eigenvalues. For example,

$$E_{+2}|N_a,N_b,N_c,N_f\rangle\sim|N_a+1,N_b,N_c-1,N_f\rangle. \tag{35}$$

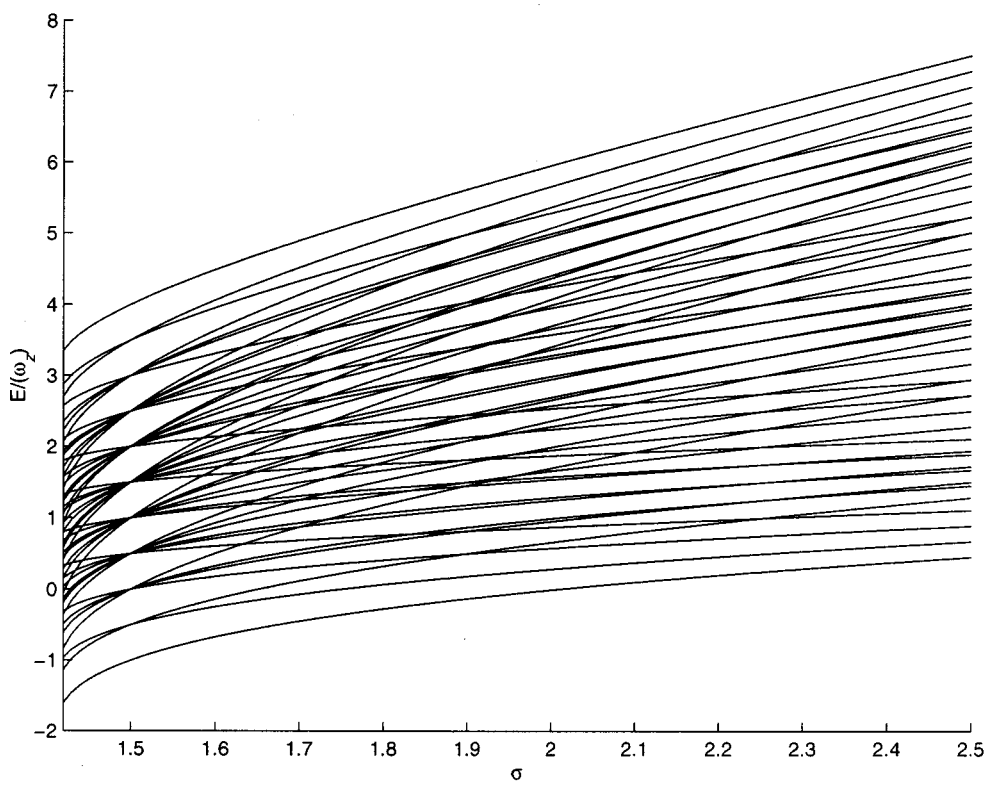

FIG. 2. Penning-trap energies as a function of σ for various states, with $g=\frac{2}{3}$. There are conspicuous degeneracies of the levels at the supersymmetric point $\sigma=\frac{3}{2}$, arising from the superalgebra structure discussed in Sec. VI. Another degeneracy occurs at $\sigma=2.25$. In this plot, $\hbar=1$.

In contrast, the subsuperalgebra su$(1|1)$ acts to give states differing only in N_b and N_f. For example,

$$F_{+2}|N_a,N_b,N_c,N_f\rangle\sim((N_f+1)\text{mod }2)|N_a,N_b+1,N_c,(N_f+1)\text{mod }2\rangle. \tag{36}$$

Insight into the physical implications of the superalgebra can be gained from Fig. 2. It plots the energy levels of the Penning trap versus σ for the states with quantum numbers $N_a=0,1,2$, $N_b=0,...,3$, $N_c=0,1$, and $N_f=0,1$. At $\sigma=\frac{3}{2}$, the Hamiltonian has the form of Eq. (17). The coefficients of the two terms show that the frequencies are in the ratio 2:1. This gives the uniform spacing of the energy levels and creates the sharply defined crossing features at this supersymmetry point on the plot.

Figure 2 also reveals the set of evenly spaced degenerate levels at $\sigma=2.25$, for which the Hamiltonian has the form in Eq. (18).

The operators L, $\overline{L}$, K, and $\overline{K}$ form a complete set of commuting operators for the system. They can be expressed in terms of the more physical operators defined in Sec. IV:

$$\hbar\omega_z\overline{L}=2H_\rho+\tfrac{2}{3}H_\phi+H_z, \tag{37}$$

$$\hbar\omega_z L=H_\rho+\tfrac{1}{3}H_\phi-\tfrac{1}{2}H_z, \tag{38}$$

$$\hbar\omega_z\overline{K}=2H_\rho-\tfrac{2}{3}H_\phi-2H_f, \tag{39}$$

$$\hbar\omega_z K=2H_\rho+\tfrac{2}{3}H_\phi+2H_f. \tag{40}$$

VII. THREE EQUAL FREQUENCIES: $\omega_+=\omega_z=\omega_g=2\omega_-$

Three frequencies can be equated by setting $g=\frac{4}{3}$ and $\sigma=\frac{3}{2}$, giving the Hamiltonian

$$H/\hbar\omega_z=(a^\dagger a+c^\dagger c+f^\dagger f+\tfrac{1}{2})-\tfrac{1}{2}(b^\dagger b+\tfrac{1}{2})\equiv M-\tfrac{1}{2}\overline{M}. \tag{41}$$

The generators M and $\overline{M}$, defined by the expressions in parentheses, commute with each other and with H. They therefore form an independent $\mathrm{u}(1)\times\mathrm{u}(1)$ subalgebra of the full degeneracy superalgebra.

In addition to M and $\overline{M}$, there are four independent even elements given by

$$\tilde{L}\equiv\tfrac{1}{2}(a^\dagger a+c^\dagger c)+f^\dagger f \tag{42}$$

and by $L,E_{\pm2}$ defined in Eq. (33). The generator $\tilde{L}$ commutes with the even elements $L,E_{\pm2}$, which in turn satisfy the commutation relations (34) for the compact Lie algebra su(2).

There are four odd elements that commute with the Hamiltonian: $F_{\pm1}$ as defined in Eq. (26) but with $k=\frac{1}{3}$, and

$$F_{+3}\equiv c^\dagger f,\quad F_{-3}\equiv c f^\dagger. \tag{43}$$

Their nonzero anticommutation relations are

$$\{F_{+1},F_{-1}\}=\tilde{L}+L,\quad \{F_{+3},F_{-3}\}=\tilde{L}-L,\quad \{F_{\pm1},F_{\mp3}\}=E_{\pm2}, \tag{44}$$

and their nonzero commutation relations with the even elements are

$$\begin{aligned}
&[\tilde{L},F_{\pm1}]=\mp\tfrac{1}{2}F_{\pm1},\quad [\tilde{L},F_{\pm3}]=\mp\tfrac{1}{2}F_{\pm3},\\
&[L,F_{\pm1}]=\pm\tfrac{1}{2}F_{\pm1},\quad [L,F_{\pm3}]=\mp\tfrac{1}{2}F_{\pm3},\\
&[E_{\pm2},F_{\pm3}]=\pm F_{\pm1},\quad [E_{\pm2},F_{\mp1}]=\mp F_{\mp3}.
\end{aligned} \tag{45}$$

The superalgebra with generators given in Eqs. (33), (42), and (43) is $\mathrm{su}(2|1)$, with Lie part $\mathrm{u}(1)\times\mathrm{su}(2)$. The first component is generated by $\tilde{L}$ and the second by $\{L,E_{\pm2}\}$. The action of these generators on the eigenstates of the Hamiltonian is similar to that displayed in Eqs. (35) and (36), except that here the values of N_a, N_c, and N_f are affected.

The full degeneracy structure of the Hamiltonian (41) is $\mathrm{u}(1)\times\mathrm{u}(1)\times\mathrm{su}(2|1)$. It has three subalgebras, generated by the sets $\{\overline{M}\}$, $\{M\}$, and $\{L,\tilde{L},E_{\pm2},F_{\pm1},F_{\pm3}\}$.

The Hamiltonian for $gq<0$ is found by replacing $(f^\dagger f-\frac{1}{2})\to-(f^\dagger f-\frac{1}{2})$ in (41). To obtain the generators commuting with this Hamiltonian, the replacements $f\to f^\dagger$ and $f^\dagger\to f$ are made in the definitions for all the operators. This automorphism leaves unchanged the superalgebra relations. Thus, the algebraic structure is again independent of the sign of gq for the trapped particle.

Figure 3 plots the energy levels versus σ for the states with quantum numbers $N_a=0,1,2$, $N_b=0,1,2$, $N_c=0,1$, and $N_f=0,1$. Because the frequencies are in a rational ratio, the supersymmetry point has uniformly spaced crossings at $\sigma=\frac{3}{2}$.

The operators $\overline{M}$, M, $\tilde{L}$, and L form a complete set of commuting operators for the system. They can be expressed in terms of the alternative basis of Sec. IV:

$$\hbar\omega_z\overline{M}=2H_\rho-\tfrac{2}{3}H_\phi, \tag{46}$$

$$\hbar\omega_z M=2H_\rho+\tfrac{2}{3}H_\phi+H_z+H_f, \tag{47}$$

$$\hbar\omega_z\tilde{L}=H_\rho+\tfrac{1}{3}H_\phi+\tfrac{1}{2}H_z+H_f, \tag{48}$$

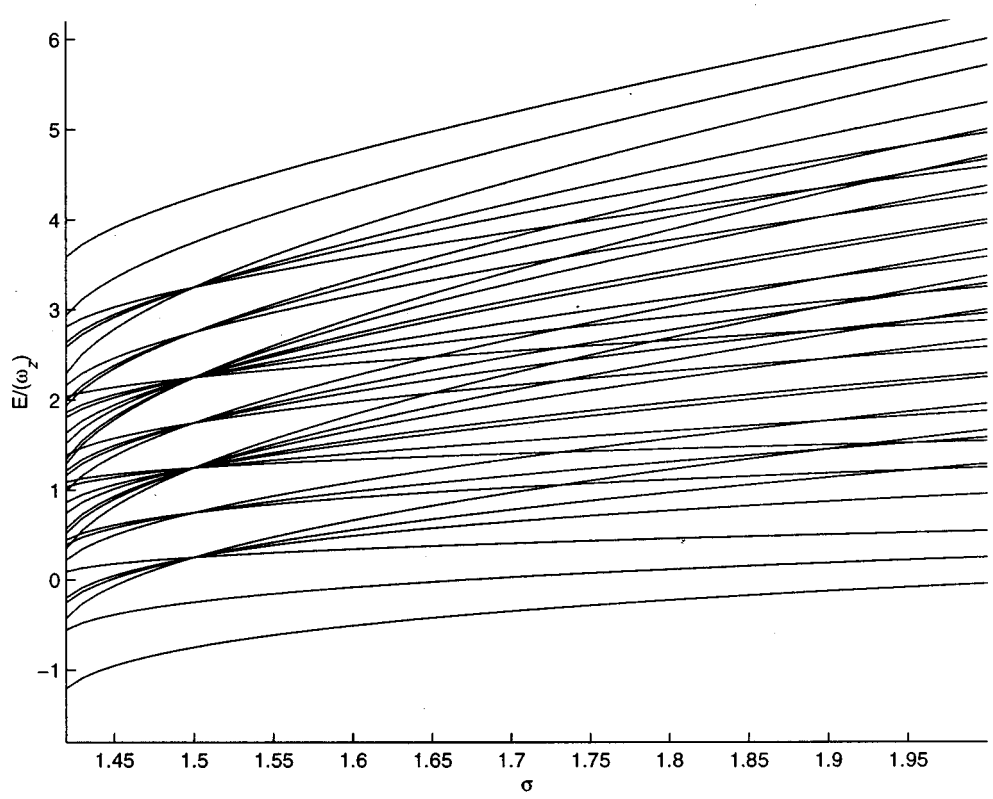

FIG. 3. Penning-trap energies as a function of σ for various states, with $g=\frac{4}{3}$. The evenly spaced crossings at the supersymmetric point $\sigma=\frac{3}{2}$ are discussed in Sec. VII. For this plot, $\hbar=1$.

$$\hbar\omega_z L = H_\rho + \tfrac{1}{3}H_\phi - \tfrac{1}{2}H_z\,. \tag{49}$$

These expressions can be inverted. For example, the spin-splitting operator H_f can be shown to be $H_f=\hbar\omega_z(2\tilde{L}-M)$.

VIII. HYPOTHETICAL CASE OF FOUR EQUAL FREQUENCIES

The largest possible degeneracy superalgebra in a system of the form of (13) would arise if all the frequencies could be set equal. No choices of g and σ allow this in the Penning trap, as can be seen from Fig. 1. Nonetheless, it is of interest to consider the degeneracy superalgebra that would arise from a Hamiltonian of the form

$$H_0 \equiv a^\dagger a - b^\dagger b + c^\dagger c + f^\dagger f, \tag{50}$$

where f and $f^\dagger$ are fermionic and the other operators are bosonic, because this superalgebra contains all the superalgebras discussed in Secs. V–VII as subsuperalgebras. This superalgebra is $\mathrm{u}(1)\times\mathrm{su}(2,1|1)$, as shown later in this work.

The Hamiltonian H_0 forms an independent u(1) subalgebra by definition. There are eight other independent generators commuting with this Hamiltonian that are constructed only from bosonic operators. Expressed in the Cartan–Weyl basis, they are $E_{\pm 2}$ already defined in Eq. (33), and

$$H_1 \equiv b^\dagger b + c^\dagger c + 1, \quad H_2 \equiv a^\dagger a + b^\dagger b + 1,$$

$$E_{+1} \equiv b^\dagger c^\dagger, \quad E_{-1} \equiv bc, \tag{51}$$

$$E_{+3} \equiv a^\dagger b^\dagger, \quad E_{-3} \equiv ab,$$

and they satisfy the nonzero commutation relations

$$\begin{gathered}
[H_1, E_{\pm 1}] = \pm 2E_{\pm 1}, \quad [H_1, E_{\pm 2}] = \mp E_{\pm 2}, \quad [H_1, E_{\pm 3}] = \pm E_{\pm 3}, \\
[H_2, E_{\pm 1}] = \pm E_{\pm 1}, \quad [H_2, E_{\pm 2}] = \pm E_{\pm 2}, \quad [H_2, E_{\pm 3}] = \pm 2E_{\pm 3}, \\
[E_{\pm 2}, E_{\mp 3}] = \mp E_{\mp 1}, \quad [E_{\pm 3}, E_{\mp 1}] = \mp E_{\pm 2}, \quad [E_{\pm 1}, E_{\pm 2}] = \mp E_{\pm 3}, \\
[E_{+1}, E_{-1}] = -H_1, \quad [E_{+2}, E_{-2}] = -H_1 + H_2, \quad [E_{+3}, E_{-3}] = -H_2.
\end{gathered} \tag{52}$$

These generators provide a description of the Lie algebra su(2,1).

Including the two fermionic operators f and $f^\dagger$ allows the introduction of seven more generators that commute with the Hamiltonian (50), of which one,

$$H_3 \equiv a^\dagger a - b^\dagger b + c^\dagger c + 3f^\dagger f - 1, \tag{53}$$

is even and commutes with the eight other even generators. The six others are odd generators defined earlier: $F_{\pm 1}$, $F_{\pm 2}$, and $F_{\pm 3}$. They satisfy anticommutation relations, of which the only nonzero ones are

$$\begin{gathered}
\{F_{\pm 2}, F_{\pm 3}\} = E_{\pm 1}, \qquad \{F_{\pm 1}, F_{\mp 3}\} = E_{\pm 2}, \qquad \{F_{\pm 1}, F_{\pm 2}\} = E_{\pm 3}, \\
\{F_{+1}, F_{-1}\} = -\tfrac{1}{3}H_1 + \tfrac{2}{3}H_2 + \tfrac{1}{3}H_3, \\
\{F_{+2}, F_{-2}\} = \tfrac{1}{3}H_1 + \tfrac{1}{3}H_2 - \tfrac{1}{3}H_3, \\
\{F_{+3}, F_{-3}\} = \tfrac{2}{3}H_1 - \tfrac{1}{3}H_2 + \tfrac{1}{3}H_3.
\end{gathered} \tag{54}$$

Note that these anticommutators yield elements within the even part of the superalgebra, as expected. Commutation relations between even and odd generators produce generators in the odd part of the superalgebra. The nonzero cases are

$$\begin{gathered}
[H_3, F_{\pm 1}] = \mp 2F_{\pm 1}, \quad [H_3, F_{\pm 2}] = \pm 2F_{\pm 2}, \quad [H_3, F_{\pm 3}] = \mp 2F_{\pm 3}, \\
[H_1, F_{\pm 2}] = \pm F_{\pm 2}, \quad [H_1, F_{\pm 3}] = \pm F_{\pm 3}, \\
[H_2, F_{\pm 1}] = \pm F_{\pm 1}, \quad [H_2, F_{\pm 2}] = \pm F_{\pm 2}, \\
[E_{\pm 1}, F_{\mp 2}] = \mp F_{\pm 3}, \quad [E_{\pm 1}, F_{\mp 3}] = \mp F_{\pm 2}, \\
[E_{\pm 3}, F_{\mp 1}] = \mp F_{\pm 2}, \quad [E_{\pm 3}, F_{\mp 2}] = \mp F_{\pm 1},
\end{gathered} \tag{55}$$

and the last two relations of (45). The fifteen-dimensional superalgebra su(2,1|1) considered here has Lie subalgebra u(1)$\times$su(2,1), with the first component generated by H_3. The su(2,1) subalgebra has eight dimensions, with basis given in Eq. (51).

Including the u(1) algebra generated by H_0, the full degeneracy superalgebra for the Hamiltonian (50) is u(1)$\times$su(2,1|1).

IX. PHASE-SPACE SUPERALGEBRA

The degeneracy superalgebras considered above are subsuperalgebras of a still larger superalgebra $\mathcal{A}$, where the generators are formed from *all* possible independent quadratic combinations of creation or annihilation operators. This algebra is not a degeneracy superalgebra, although it contains the degeneracy superalgebras mentioned in the previous sections. In the superalgebra $\mathcal{A}$,

TABLE I. Penning-trap superalgebras for the supersymmetric configuration $\sigma=\frac{3}{2}$. The particle g factor is given in the first column, and the four frequencies in units of ω_z are given in the next four columns. The algebraic structures found and the sections where they are discussed are given in the final two columns. The symbol $\oslash$ is defined in Sec. V. The bottom row represents the hypothetical case with four equal frequencies.

g	ω_+	ω_-	ω_z	ω_g	Structure	Section

$\frac{2}{3}$	1	$\frac{1}{2}$	1	$\frac{1}{2}$	$u(1)\times so(3)\times u(1)\oslash su(1\|1)$	VI
$\frac{4}{3}$	1	$\frac{1}{2}$	1	1	$u(1)\times u(1)\times su(2\|1)$	VII
	1	1	1	1	$u(1)\times su(2,1\|1)$	VIII

there are 12 odd generators formed by pairing each of the six bosonic operators $a,a^\dagger,b,b^\dagger,c,c^\dagger$, with each of the fermionic operators $f,f^\dagger$. There are 21 even generators formed from pairs of bosonic operators including, for example, $a^\dagger a^\dagger,a^\dagger b,bb,bc^\dagger$. These generate an $sp(6)$ subalgebra. A further even generator, $f^\dagger f$, is formed from the fermionic operators. Taken together, the 34 generators define the superalgebra $osp(2|6)$, which has even part $sp(6)\times so(2)$.

The $osp(2|6)$ superalgebra $\mathcal{A}$ is not unique to the Penning-trap system, since it would arise for any combination of signs for the number operators in the Hamiltonian (13). The point is that $\mathcal{A}$ exists even before a potential for the physical problem is defined. The only requirement for $\mathcal{A}$ to be a relevant algebra is that the system describe a single fermion in a phase space with three space and three momentum dimensions. Thus, the superalgebra $osp(2|6)$ describes the properties of the phase space for the problem.

The Hamiltonian for the Penning trap is fixed by specifying the parameters ω_c, ω_z, and g. For each of the cases in Secs. V–VII, the degeneracy superalgebra is a subsuperalgebra of the phase-space superalgebra. We therefore find a hierarchy of nested superalgebras: $\mathcal{A}=osp(2|6)\supset so(2,1|1)\supset\mathcal{D}$, where $\mathcal{D}$ is any of the degeneracy superalgebras of Secs. V–VII.

We have considered only structures arising from *quadratic* combinations of creation or annihilation operators. The issue of the role played by higher-order combinations, such as those commuting with Eq. (18), is related to Clifford-algebra theory[25] but lies outside the scope of this article.

X. SUMMARY AND DISCUSSION

Several superalgebras are associated with the single-particle Penning trap. The various cases depend on the gyromagnetic ratio of the trapped particle and the relative strengths of the magnetic and electric fields. This article considers the degeneracy superalgebras of operators that commute with the Hamiltonian. The relevant superalgebras are summarized in Table I.

In general, superalgebra descriptions might be expected for trap systems having energy separations between spin states equal to the separations between the bosonic oscillator levels. This guarantees the existence of odd generators that commute with the Hamiltonian. Traps in which the spin cannot be reversed, such as the TOP or Ioffe-Pritchard traps,[15] are therefore unlikely to have superalgebra structures of the type described here. Superalgebras of this kind are also unlikely for traps where the spin states are independent of a magnetic field, as is the case for the Paul trap.[15] However, supersymmetries of another type do appear in these systems.[15]

Some other issues beyond the scope of this article are of potential interest. In particular, the spectrum-generating superalgebras would be relevant to a complete study of the properties of the Penning trap. Furthermore, higher-rank combinations of operators, such as those mentioned for the $\sigma=\frac{9}{4}$ point in Fig. 1, can be expected to arise in a study of the relevant Clifford algebras.

(Received 1 March 2001; accepted for publication 31 July 2001)

Classical Calogero–Moser models with rational potential are known to be superintegrable. That is, on top of the r involutive conserved quantities necessary for the integrability of a system with r degrees of freedom, they possess an additional set of $r-1$ algebraically and functionally independent globally defined conserved quantities. At the quantum level, Kuznetsov uncovered the existence of a quadratic algebra structure as an underlying key for superintegrability for the models based on A type root systems. Here we demonstrate in a universal way the quadratic algebra structure for quantum rational Calogero–Moser models based on any root systems. © *2001 American Institute of Physics.* [DOI: 10.1063/1.1404387]

I. INTRODUCTION

Calogero–Moser models[1–3] with the rational potentials, without the harmonic confining force, have the simplest and best understood dynamical structures among models with the other types of potentials. Their superintegrability, that is the existence of $2r-1$ global, functionally independent conserved quantities (constants of motion) for a system of r degrees of freedom, is one of the most striking features. It was found at the classical level by Wojciechowski[4] and at the quantum level by Kuznetsov[5] and Ujino–Wadati–Hikami[6] for models based on the A type root systems. Kuznetsov[5] uncovered an interesting algebraic structure, the so-called *quadratic algebra* as a hidden symmetry of the superintegrability. Ujino–Wadati–Hikami[6] introduced a similar algebraic structure. The concept of superintegrability is closely related with that of *algebraic linearizability* formulated by Caseiro–Françoise[7] and developed further by Caseiro–Françoise–Sasaki[8] for the models based on any root systems. We follow the notation of our previous paper unless otherwise stated.

In this article we show, at the quantum level, that the quadratic algebra is ''universal,'' namely, it is enjoyed by all the rational Calogero–Moser models based on *any* root systems including the noncrystallographic ones. The same assertion at the classical level simply follows as the classical limit of replacing the quantum commutator by the Poisson bracket. The generators of the quadratic algebra are the above mentioned conserved quantities of the superintegrable theory. Among them, the involutive subset of r conserved quantities, which characterize the Liouville integrability of the system with r degrees of freedom, constitute the Cartan subalgebra and an ideal among the conserved quantities. Commutators among the additional conserved quantities turn out to be bi-linear (quadratic) combinations of the two types of conserved quantities. This nonlinear algebra seems to be closely related to the W-algebras,[9] extensions of the Virasoro algebra, or to the algebras related with the R-matrices of integrable theories,[10] but the precise relationship remains to be clarified.

Calogero–Moser models for any root systems were formulated by Olshanetsky and Perelomov,[11] who provided Lax pairs for the models based on the classical root systems, i.e., the A, B, C, D and BC type root systems. A universal *classical* Lax pair applicable to all the Calogero–Moser models based on any root systems including the E_8 and the noncrystallographic

root systems was derived by Bordner–Corrigan–Sasaki[12] which unified various types of Lax pairs known at that time.[13,14] A universal *quantum* Lax pair applicable to all the Calogero–Moser models based on any root systems and for degenerate potentials was derived by Bordner–Manton–Sasaki[15] which provided the basic tools for the present article.

The purpose of the present article is twofold. First, it is to derive and present the *quadratic algebra* for rational Calogero–Moser models based on any root systems in its fullest universality based on the universal Lax pair.[15] Extracting detailed information from the quadratic algebra to elucidate dynamical properties of each specific system would require formulations suitable for the particular systems. This would not be discussed here. Second, we formulate and present the quantum versions of various concepts and formulas related to the algebraic linearizability introduced and developed in Ref. 8. As has been noticed from the earliest days of Calogero–Moser models, the quantum and classical integrability are very closely related. Many formulas related to the algebraic linearizability take the same form at the classical and quantum levels, with some notable exceptions as will be mentioned in the article.

This article is organized as follows. In Sec. II we introduce the model and notations with an emphasis on the difference between the quantum and classical versions. The quantum theorem of the algebraic linearizability for the rational model is derived based on the Lax pair formalism. In Sec. III we evaluate fundamental commutation relations which are necessary for the quadratic algebra. This will be carried out with the help of the Dunkl operators, or the so-called l operators which are equivalent to the quantum L operator. The quantum theorem of the algebraic linearizability for the higher Hamiltonians of the rational model is derived. In Sec. IV the quadratic algebra for rational Calogero–Moser models is derived and presented in its fullest universality. Section V gives the quantum version of the algebraic linearizability of the rational potential model with harmonic confining force. The problem of quantum integrability of rational Calogero–Moser model with quartic interactions is not yet settled. In Sec. VI we present a partial result that the quantum equations of motion can be cast into Lax type matrix equations. The existence of quantum conserved quantities, however, does not follow from these matrix equations. The final section is for comments on the Hermiticity of the algebra generators.

II. QUANTUM CALOGERO–MOSER MODELS WITH RATIONAL POTENTIAL

Let us start with the Hamiltonian of *quantum* Calogero–Moser model with rational potential based on any root system, which could be any one of the crystallographic root systems, A_r, B_r, C_r, D_r, (BC_r), E_6, E_7, E_8, F_4 and G_2 or the noncrystallographic H_3, H_4 and $I_2(m)$, which is the dihedral root system associated with a regular m-gon. The existing works on the quadratic algebras are all for the A_r root system.[5,6,16] Let us denote by Δ a root system of rank r. The dynamical variables are the coordinates $q_i, i=1,\ldots,r$, and their canonically conjugate momenta $p_i, i=1,\ldots,r$, with the canonical commutation relations:

$$[q_j,p_k]=i\delta_{jk}, \quad [q_j,q_k]=[p_j,p_k]=0, \quad j,k=1,\ldots,r. \tag{2.1}$$

As usual the momentum operator, p_j acts as a derivative operator on a (wave) function f of q:

$$f\to p_j f: \quad (p_j f)(q)=-i\frac{\partial f(q)}{\partial q_j}, \quad j=1,\ldots,r.$$

The Hamiltonian for the *quantum* Calogero–Moser model with rational potential is very simple:

$$\mathcal{H}=\frac{1}{2}p^2+\frac{1}{2}\sum_{\rho\in\Delta_+}\frac{g_{|\rho|}(g_{|\rho|}-1)|\rho|^2}{(\rho\cdot q)^2}, \quad \Delta_+ : \text{set of positive roots}, \tag{2.2}$$

in which the real coupling constants $g_{|\rho|}>0$ are defined on orbits of the corresponding finite reflection group, i.e., they are identical for roots in the same orbit. The only difference with the

classical Hamiltonian is the coupling constant dependence, $g_{|\rho|}(g_{|\rho|}-1)$ instead of $g_{|\rho|}^2$ in the classical case. The Hamiltonian is invariant under reflections of the phase space variables about a hyperplane perpendicular to any root

$$\mathcal{H}(s_\alpha(p),s_\alpha(q))=\mathcal{H}(p,q), \quad \forall \alpha\in\Delta, \tag{2.3}$$

with the action of s_α on any vector $\gamma\in\mathbf{R}^r$ defined by

$$s_\alpha(\gamma)=\gamma-(\alpha^\vee\cdot\gamma)\alpha, \quad \alpha^\vee\equiv 2\alpha/|\alpha|^2. \tag{2.4}$$

The integrability is best understood in terms of the quantum Lax pair[15] or the Dunkl operators,[17,18] which are known to be equivalent with the Lax operator.[19] Let us choose a set of $\mathbf{R}^r$ vectors $\mathcal{R}=\{\mu^{(k)}\in\mathbf{R}^r,\ k=1,\ldots,D\}$, which form a single orbit of the Coxeter group with D elements, that is, they are permuted under the action of the Coxeter group. For example, we can choose the set of vector (minimal) weights for A_r or D_r, or the set of short (long) roots for B_r, C_r or F_4, G_2, or the set of all roots for E_6 to E_8. Then the Lax operators are $D\times D$ dimensional matrices

$$\begin{aligned} L(p,q)&=p\cdot\hat{H}+X(q), \quad X(q)=i\sum_{\rho\in\Delta_+} g_{|\rho|}\frac{\rho.\hat{H}}{\rho\cdot q}\hat{s}_\rho,\\ M(q)&=-\frac{i}{2}\sum_{\rho\in\Delta_+} g_{|\rho|}\frac{|\rho|^2}{(\rho.q)^2}(\hat{s}_\rho-I), \end{aligned} \tag{2.5}$$

consisting of operators $\{\hat{H}_j\}$, $(j=1,\ldots,r)$, $\{\hat{s}_\rho\}$ and the identity operator I. Their matrix elements are defined by

$$(\hat{H}_j)_{\mu\nu}=\mu_j\delta_{\mu\nu}, \quad (\hat{s}_\rho)_{\mu\nu}=\delta_{\mu,s_\rho(\nu)}=\delta_{\nu,s_\rho(\mu)}, \quad \mu,\nu\in\mathcal{R}. \tag{2.6}$$

The Lax operators are Coxeter covariant:

$$L(s_\alpha(p),s_\alpha(q))=\hat{s}_\alpha L(p,q)\hat{s}_\alpha, \quad M(s_\alpha(q))=\hat{s}_\alpha M(q)\hat{s}_\alpha, \tag{2.7}$$

and L is Hermitian $L^\dagger=L$ and M is anti-Hermitian $M^\dagger=-M$.

We see that the Heisenberg equations of motion are equivalent to a matrix equation[15,19]

$$\frac{dL}{dt}\equiv\dot{L}=i[\mathcal{H},L]=[L,M], \tag{2.8}$$

in which the matrix elements are quantum operators. This means that in general the *trace* of the product of two matrix operators $A(p,q)$ and $B(p,q)$ is not commutative, $\mathrm{Tr}AB\neq\mathrm{Tr}BA$, or $\mathrm{Tr}[A,B]\neq 0$, implying that $\mathrm{Tr}L^n$ is not *conserved* in quantum theory. However, thanks to the special property of the above M matrix

$$\sum_{\mu\in\mathcal{R}} M_{\mu\nu}=\sum_{\nu\in\mathcal{R}} M_{\mu\nu}=0, \tag{2.9}$$

the *total sum* of the powers of the Lax operator L defined by

$$F_j=\mathrm{Ts}(L^j)\equiv\sum_{\nu,\mu\in\mathcal{R}}(L^j)_{\mu\nu}, \quad j=0,1,\ldots,D-1, \tag{2.10}$$

is conserved:

$$\frac{d}{dt}\mathrm{Ts}(L^j)=\sum_{\mu,\nu\in\mathcal{R}}[(L^jM)_{\mu\nu}-(ML^j)_{\mu\nu}]$$

$$=\sum_{\mu,\nu,\kappa\in\mathcal{R}}[L^j_{\mu\kappa}M_{\kappa\nu}-M_{\mu\kappa}L^j_{\kappa\nu}]$$

$$=\sum_{\mu,\kappa\in\mathcal{R}}L^j_{\mu\kappa}\left(\sum_{\nu\in\mathcal{R}}M_{\kappa\nu}\right)-\sum_{\nu,\kappa\in\mathcal{R}}\left(\sum_{\mu\in\mathcal{R}}M_{\mu\kappa}\right)L^j_{\kappa\nu}=0.$$

It is easy to see from (2.7) that $\{F_j\}$'s are Coxeter invariant. These form the involutive set of conserved quantities of the theory. Not all of them are independent. As is well-known, the independent conserved quantities appear for such j as 1 plus *exponent* of the root system, (see, for example, Refs. 19 and 20). For some choice of the set of vectors $\mathcal{R}$ for some root system Δ, F_j can be vanishing for certain j's. For example, if $\mathcal{R}$ contains a vector μ and $-\mu$ at the same time, then $F_{\mathrm{odd}}\equiv 0$.

The Hamiltonian (2.2) is proportional to F_2,

$$\mathcal{H}=\frac{1}{2C_{\mathcal{R}}}F_2=\frac{1}{2C_{\mathcal{R}}}\mathrm{Ts}(L^2), \tag{2.11}$$

in which the coefficient $C_{\mathcal{R}}$ is defined by

$$\mathrm{Ts}(\hat{H}_j\hat{H}_k)=\sum_{\mu\in\mathcal{R}}\mu_j\mu_k=\delta_{jk}C_{\mathcal{R}}. \tag{2.12}$$

Following the line of argument of Ref. 8 we define

$$Q=q\cdot\hat{H},\quad G_j=\mathrm{Ts}(QL^j),\quad G_j^{(2)}=\mathrm{Ts}(Q^2L^j),\quad j=0,1,\ldots,D-1, \tag{2.13}$$

in which the last quantity Q^2L^j was introduced by Rañada.[21] Under the reflection, Q transforms in the same way as L and M, (2.7):

$$q\to s_\alpha(q),\quad Q(s_\alpha(q))=\hat{s}_\alpha Q(q)\hat{s}_\alpha. \tag{2.14}$$

Thus G_j and $G_j^{(2)}$ are Coxeter invariant, too. The time evolution of Q is exactly the same as in the classical case[8]

$$\dot{Q}=[Q,M]+L, \tag{2.15}$$

leading to the corresponding result:

$$\begin{aligned}\dot{G}_j&=\mathrm{Ts}(\dot{Q}L^j+Q\dot{L}^j)\\&=\mathrm{Ts}(QML^j-MQL^j+L^{j+1}+QL^jM-QML^j)\\&=\mathrm{Ts}(L^{j+1})-\sum_{\nu,\kappa\in\mathcal{R}}\left(\sum_{\mu\in\mathcal{R}}M_{\mu\kappa}\right)(QL^j)_{\kappa\nu}+\sum_{\mu,\kappa\in\mathcal{R}}(QL^j)_{\mu\kappa}\left(\sum_{\nu\in\mathcal{R}}M_{\kappa\nu}\right)\\&=\mathrm{Ts}(L^{j+1})=F_{j+1}.\end{aligned} \tag{2.16}$$

Like $\{F_j\}$'s not all of $\{G_j\}$'s are independent. Independent $\{G_j\}$ appear when $\{j\}$ are the exponents of Δ. This provides the algebraic linearization of the quantum models. Like in the classical theory, we have the following.

Proposition II.1: The quantum Calogero–Moser system (2.2) is superintegrable for any root system.

Proof: On top of the D first integrals F_k which are in involution, we have the $D(D-1)/2$ extra first integrals defined by

$$H_{k,k'}=F_{k+1}G_{k'}-F_{k'+1}G_k, \tag{2.17}$$

$$\dot{H}_{k,k'}=i[\mathcal{H},H_{k,k'}]=0. \tag{2.18}$$

Like in our previous paper for the classical systems,[8] we do not demonstrate that these $D(D-1)/2$ $\{H_{k,k'}\}$'s contain $r-1$ algebraically independent ones. That would require detailed exhaustive arguments for each root system. We refer to Ref. 20 for general arguments of independence of $\{F_j\}$ type conserved quantities.

For the quantum models based on the A type root system, a similar result was derived by Gonera[16] based on a sl(2,**R**) representation. The time evolution of $G_j^{(2)}$ is slightly complicated:

$$\begin{aligned}\dot{G}_j^{(2)}&=\mathrm{Ts}(\dot{Q}QL^j)+\mathrm{Ts}(Q\dot{Q}L^j)+\mathrm{Ts}(Q^2\dot{L}^j)\\&=\mathrm{Ts}(LQL^j)+\mathrm{Ts}(QL^{j+1}).\end{aligned} \tag{2.19}$$

Since L and Q do not commute in quantum theory, the classical relation $\dot{G}_j^{(2)}=2\mathrm{Tr}(QL^{j+1})=2G_{j+1}$ does not hold any longer. In quantum theory we have

$$QL-LQ=i\delta_{kl}\hat{H}_k\hat{H}_l+iK, \quad K\equiv\sum_{\rho\in\Delta_+} g_{|\rho|}(\rho\cdot\hat{H})(\rho^\vee\cdot\hat{H})\hat{s}_\rho. \tag{2.20}$$

The right hand side gives the ''quantum corrections.'' Thus we arrive at

$$\dot{G}_j^{(2)}=2\,\mathrm{Ts}(QL^{j+1})-i\delta_{kl}\mathrm{Ts}(\hat{H}_k\hat{H}_lL^j)-i\,\mathrm{Ts}(KL^j). \tag{2.21}$$

The second term is easy to evaluate, since

$$\delta_{kl}\mathrm{Ts}(\hat{H}_k\hat{H}_lL^j)=\delta_{kl}\sum_{\mu,\nu\in\mathcal{R}}(\mu_k\mu_l(L^j)_{\mu\nu})=\mu^2\mathrm{Ts}(L^j), \tag{2.22}$$

in which μ^2 is the same for all $\mu\in\mathcal{R}$. The third term reads

$$\mathrm{Ts}(KL^j)=\sum_{\rho\in\Delta_+}\sum_{\mu,\nu\in\mathcal{R}} g_{|\rho|}(\rho\cdot\mu)(\rho^\vee\cdot\mu)(L^j)_{\mu\nu},$$

and for any vector $\mu\in\mathbf{R}^r$ we have

$$\sum_{\rho\in\Delta_+} g_{|\rho|}(\rho\cdot\mu)(\rho^\vee\cdot\mu)=\frac{2}{r}\mu^2\sum_{\rho\in\Delta_+} g_{|\rho|}, \tag{2.23}$$

in which

$$\frac{2}{r}\sum_{\rho\in\Delta_+} g_{|\rho|} \tag{2.24}$$

can be considered as a *deformed Coxeter number*. For $g_{|\rho|}\equiv 1$ it reduces to the Coxeter number. Thus we arrive at a quantum formula

$$\dot{G}_j^{(2)} = 2G_{j+1} - i\mu^2\left(1 + \frac{2}{r}\sum_{\rho\in\Delta_+} g_{|\rho|}\right)F_j$$

$$= 2G_{j+1} - i\mu^2\frac{2}{r}\tilde{\mathcal{E}}_0 F_j\,. \tag{2.25}$$

Here, the coefficient of the quantum corrections term $\tilde{\mathcal{E}}_0$ is defined by

$$\tilde{\mathcal{E}}_0 = \frac{r}{2} + \sum_{\rho\in\Delta_+} g_{|\rho|}\,, \tag{2.26}$$

which characterizes the ground state energy of the rational Calogero–Moser model with harmonic confining force [see, for example, (2.21) of Ref. 19]. This fact is closely related with the sl(2,**R**) algebra for rational Calogero–Moser models discussed by many authors (see, for example, Refs. 22–24, 18, and 16). We will not discuss $G_j^{(2)}$ any longer in this article, except for some comments in the final section.

III. BASIC COMMUTATION RELATIONS

Typical generators of the quadratic algebra are $\{F_j\}$'s (2.10) and $\{H_{k,l}\}$'s (2.17). Namely they are either linear in $\{F_j\}$'s or bi-linear combinations of $\{F_j\}$'s and $\{G_k\}$'s. As will be clear in later discussions, see, for example, (4.10), the set of $\{F_j\}$'s must be understood in the broadest sense to include the dependent ones. That is, any polynomials in the independent r involutive conserved quantities are allowed. For example, F_j for $j \neq 1 + exponent$ or $j > h$ (the Coxeter number) enter into the theory naturally. Likewise, the set of $\{G_j\}$'s include the dependent ones, which are independent ones times any polynomial in $\{F_k\}$'s. In order to explore and present the full content of the quadratic algebra, we need to evaluate the commutators such as

$$[F_j, F_k], \quad [F_j, G_k], \quad [G_j, G_k]. \tag{3.1}$$

For this purpose the Dunkl operators[17] or l operators which are the *vector* version of the Lax matrix operator L (Ref. 19) are useful:

$$\mathrm{l}_\mu = \mathrm{l}\cdot\mu = p\cdot\mu + i\sum_{\rho\in\Delta_+} g_{|\rho|}\frac{\rho.\mu}{\rho.q}\check{s}_\rho\,, \quad \mu\in\mathcal{R}, \tag{3.2}$$

in which another reflection operator $\check{s}_\rho$ acts on a (wave) function f of q as

$$f \to \check{s}_\rho f\colon \quad (\check{s}_\rho f)(q) = f(s_\rho(q)). \tag{3.3}$$

The l operator is linear in μ, Coxeter covariant and Hermitian:

$$\check{s}_\rho \mathrm{l}_\mu \check{s}_\rho = \mathrm{l}_{s_\rho(\mu)}\,, \quad \mathrm{l}_\mu = \mathrm{l}_\mu^\dagger\,, \quad \forall\rho\in\Delta. \tag{3.4}$$

It is shown[19] that the Hilbert space of any quantum Calogero–Moser system consists of Coxeter invariant wavefunctions. That is, they satisfy

$$\check{s}_\rho\psi = \psi, \quad \forall\rho\in\Delta. \tag{3.5}$$

It is well-known that the l operators for the rational Calogero–Moser models commute:

$$[\mathrm{l}_\mu, \mathrm{l}_\nu] = 0, \quad \forall\mu,\nu\in\mathcal{R}. \tag{3.6}$$

The relationship between L and l is simple. For any Coxeter invariant function ψ, $F_k\psi$ and $G_k\psi$ are Coxeter invariant, too, and we have[19]

$$F_k\psi \equiv \mathrm{Ts}(L^k)\psi = \sum_{\mu\in\mathcal{R}} \mathrm{l}_\mu^k \psi, \quad \forall k \in \mathbf{Z}_+, \tag{3.7}$$

$$G_k\psi \equiv \mathrm{Ts}(QL^k)\psi = \sum_{\mu\in\mathcal{R}} q\cdot\mu \mathrm{l}_\mu^k \psi, \quad \forall k \in \mathbf{Z}_+. \tag{3.8}$$

The involution of $\{F_j\}$'s is a simple consequence of (3.6) and (3.7):

$$[F_j, F_k] = 0, \quad \forall j,k \in \mathbf{Z}_+, \tag{3.9}$$

which is a well-known result.

For the evaluation of the second and third types of commutators in (3.1) we need to know in general

$$[\mathrm{l}_\mu^n, q\cdot\nu \mathrm{l}_\nu^m]. \tag{3.10}$$

It is straightforward to show by induction

$$[\mathrm{l}_\mu^j, q\cdot\nu] = -i\left[j\mu\cdot\nu \mathrm{l}_\mu^{j-1} + \sum_{\rho\in\Delta_+} g_{|\rho|}(\rho\cdot\mu)(\rho^\vee\cdot\nu)\frac{\mathrm{l}_\mu^j - \mathrm{l}_{s_\rho(\mu)}^j}{\mathrm{l}_\mu - \mathrm{l}_{s_\rho(\mu)}}\check{\mathrm{s}}_\rho\right], \tag{3.11}$$

starting from

$$[\mathrm{l}_\mu, q\cdot\nu] = -i\left[\mu\cdot\nu I + \sum_{\rho\in\Delta_+} g_{|\rho|}(\rho\cdot\mu)(\rho^\vee\cdot\nu)\check{s}_\rho\right], \tag{3.12}$$

and

$$[\mathrm{l}_\mu^2, q\cdot\nu] = -i\left[2(\mu\cdot\nu)\mathrm{l}_\mu + \sum_{\rho\in\Delta_+} g_{|\rho|}(\rho\cdot\mu)(\rho^\vee\cdot\nu)\frac{\mathrm{l}_\mu^2 - \mathrm{l}_{s_\rho(\mu)}^2}{\mathrm{l}_\mu - \mathrm{l}_{s_\rho(\mu)}}\check{\mathrm{s}}_\rho\right]. \tag{3.13}$$

Here the fraction of operators, $\mathrm{l}_\mu^j - \mathrm{l}_{s_\rho(\mu)}^j / \mathrm{l}_\mu - \mathrm{l}_{s_\rho(\mu)}$, is well defined since the l operators commute with each other, (3.6). For example, we have $\mathrm{l}_\mu^2 - \mathrm{l}_{s_\rho(\mu)}^2 / \mathrm{l}_\mu - \mathrm{l}_{s_\rho(\mu)} = \mathrm{l}_\mu + \mathrm{l}_{s_\rho(\mu)}$. Thus we arrive at

$$\begin{aligned}[\mathrm{l}_\mu^j, q\cdot\nu \mathrm{l}_\nu^k] &= [\mathrm{l}_\mu^j, q\cdot\nu]\mathrm{l}_\nu^k \\ &= -i\left[j\mu\cdot\nu \mathrm{l}_\mu^{j-1}\mathrm{l}_\nu^k + \sum_{\rho\in\Delta_+} g_{|\rho|}(\rho\cdot\mu)(\rho^\vee\cdot\nu)\frac{\mathrm{l}_\mu^j - \mathrm{l}_{s_\rho(\mu)}^j}{\mathrm{l}_\mu - \mathrm{l}_{s_\rho(\mu)}}\mathrm{l}_{s_\rho(\nu)}^k\check{\mathrm{s}}_\rho\right].\end{aligned} \tag{3.14}$$

The second term on the right hand side of (3.14) vanishes when summed over μ:

$$V \equiv \sum_{\mu\in\mathcal{R}} g_{|\rho|}(\rho\cdot\mu)(\rho^\vee\cdot\nu)\frac{\mathrm{l}_\mu^j - \mathrm{l}_{s_\rho(\mu)}^j}{\mathrm{l}_\mu - \mathrm{l}_{s_\rho(\mu)}}\mathrm{l}_{s_\rho(\nu)}^k\check{\mathrm{s}}_\rho = 0. \tag{3.15}$$

This can be seen as follows. The set $\mathcal{R}$ is Coxeter invariant, i.e., $s_\rho(\mathcal{R}) = \mathcal{R}$. Consider the change of variables $\mu' = s_\rho(\mu)$. Then $\mu = s_\rho(\mu')$ and

$$V=\sum_{\mu'\in\mathcal{R}} g_{|\rho|}(\rho\cdot s_\rho(\mu'))(\rho^\vee\cdot\nu)\frac{l^j_{s_\rho(\mu')}-l^j_{\mu'}}{l_{s_\rho(\mu')}-l_{\mu'}}l^k_{s_\rho(\nu)}\check{s}_\rho$$

$$=\sum_{\mu'\in\mathcal{R}} g_{|\rho|}(-\rho\cdot\mu')(\rho^\vee\cdot\nu)\frac{l^j_{\mu'}-l^j_{s_\rho(\mu')}}{l_{\mu'}-l_{s_\rho(\mu')}}l^k_{s_\rho(\nu)}\check{s}_\rho=-V.$$

By summing over μ and ν, we obtain from (3.14)

$$\left[\sum_{\mu\in\mathcal{R}} l^j_\mu,\sum_{\nu\in\mathcal{R}} q\cdot\nu l^k_\nu\right]=-ij\sum_{\mu,\nu\in\mathcal{R}}(\mu\cdot\nu)l^{j-1}_\mu l^k_\nu. \tag{3.16}$$

The right hand side is a Coxeter invariant polynomial in l_μ, which corresponds to a polynomial in $\{F_j\}$ to be denoted by $F_{k,j}$:

$$\sum_{\mu,\nu\in\mathcal{R}}(\mu\cdot\nu)l^{j-1}_\mu l^k_\nu\psi\equiv F_{k,j}\psi,\quad \psi:\ \text{Coxeter invariant.} \tag{3.17}$$

Thus we arrive at

$$i[F_j,G_k]=jF_{k,j} \tag{3.18}$$

$$[F_n,F_{k,j}]=0,\quad \forall n\in\mathbf{Z}. \tag{3.19}$$

When the set of vectors $\mathcal{R}$ consists of orthonormal vectors, for example, the vector representation of A_r embedded in an $r+1$ dimensional space, or vector representations of C_r and D_r, or the set of short roots of B_r, the above $F_{k,j}$ has a simpler expression. In such cases, only $\mu=\pm\nu$ terms in (3.17) survive and we have

$$\sum_{\mu,\nu\in\mathcal{R}}(\mu\cdot\nu)l^{j-1}_\mu l^k_\nu=\begin{cases} C_{\mathcal{R}}\sum_{\nu\in\mathcal{R}} l^{j+k-1}_\nu, \\ 0, \end{cases} \tag{3.20}$$

in which $C_{\mathcal{R}}$ is defined by (2.12). That is, (3.18) is replaced by a more explicit formula

$$i[F_j,G_k]=jC_{\mathcal{R}}F_{j+k-1}, \tag{3.21}$$

which was reported in Kuznetsov's paper for A_r case[5] ($C_{\mathcal{R}}=1$). (In the above formula we assume that neither F_j nor G_k vanish.) As for the extra exponent at $r-1$ in D_r theory, the corresponding F and G operators are best expressed by l operators in the orthonormal basis:

$$F_{r'}\leftrightarrow l_1\cdots l_r,\quad G_{r'-1}\leftrightarrow\sum_{j=1}^{r} q_j l_1\cdots\tilde{l}_j\cdots l_r, \tag{3.22}$$

in which $\tilde{l}_j$ means that the factor is missing.

The general commutation relations (3.18) and (3.19) provide the algebraic linearization of the Hamiltonian systems generated by the higher conserved quantities $\{F_j\}$.

Proposition III.1: The Hamiltonian system generated by the higher conserved quantity F_j (2.10) of quantum Calogero–Moser system (2.2) is superintegrable for any root system.

Proof: On top of the D first integrals F_k, we have the $D(D-1)/2$ extra first integrals for the Hamiltonian F_j:

$$H^{(j)}_{k,k'}=F_{k,j}G_{k'}-F_{k',j}G_k, \tag{3.23}$$

$$\frac{dH^{(j)}_{k,k'}}{dt_j}=i[F_j,H^{(j)}_{k,k'}]=0. \tag{3.24}$$

IV. QUADRATIC ALGEBRA

In order to evaluate the commutators among various $\{H^{(j)}_{k,k'}\}$'s we need the knowledge of the third type of commutators in (3.1), that is, $[G_j,G_k]$. From (3.14) we have

$$\begin{aligned}
&[q\cdot\mu \mathrm{l}^j_\mu, q\cdot\nu \mathrm{l}^k_\nu]\\
&\quad=q\cdot\mu[\mathrm{l}^j_\mu, q\cdot\nu \mathrm{l}^k_\nu]+[q\cdot\mu, q\cdot\nu \mathrm{l}^k_\nu]\mathrm{l}^j_\mu\\
&\quad=-i\left\{(\mu\cdot\nu)j(q\cdot\mu)\mathrm{l}^{j-1}_\mu \mathrm{l}^k_\nu+\sum_{\rho\in\Delta_+} g_{|\rho|}(q\cdot\mu)(\rho\cdot\mu)(\rho^\vee\cdot\nu)\frac{\mathrm{l}^j_\mu-\mathrm{l}^j_{s_\rho(\mu)}}{\mathrm{l}_\mu-\mathrm{l}_{s_\rho(\mu)}}\mathrm{l}^k_{s_\rho(\nu)}\check{s}_\rho\right\}\\
&\qquad+i\left\{(\mu\cdot\nu)k(q\cdot\nu)\mathrm{l}^{k-1}_\nu \mathrm{l}^j_\mu+\sum_{\rho\in\Delta_+} g_{|\rho|}(q\cdot\nu)(\rho\cdot\nu)(\rho^\vee\cdot\mu)\frac{\mathrm{l}^k_\nu-\mathrm{l}^k_{s_\rho(\nu)}}{\mathrm{l}_\nu-\mathrm{l}_{s_\rho(\nu)}}\mathrm{l}^j_{s_\rho(\mu)}\check{s}_\rho\right\}.
\end{aligned} \tag{4.1}$$

As in the previous case (3.15), the coupling constant dependent terms, that is the second and fourth terms in (4.1), cancel with each other when summed over μ and ν:

$$\left[\sum_{\mu\in\mathcal{R}}(q\cdot\mu)\mathrm{l}^j_\mu,\sum_{\nu\in\mathcal{R}}(q\cdot\nu)\mathrm{l}^k_\nu\right]=-i\sum_{\mu,\nu\in\mathcal{R}}\{j(\nu\cdot\mu)(q\cdot\mu)\mathrm{l}^{j-1}_\mu \mathrm{l}^k_\nu-k(\mu\cdot\nu)(q\cdot\nu)\mathrm{l}^{k-1}_\nu \mathrm{l}^j_\mu\}. \tag{4.2}$$

Both terms on the right hand side are Coxeter invariant polynomials in q and l which are linear in q and of degree $j+k-1$ in l. Therefore, they are expressible as linear combination of $\{G_l\}$'s or polynomials in $\{F_m\}$'s multiplied on them. This can be checked by direct calculation or by using the Jacobi identity on the left hand side. Thus we express

$$\begin{aligned}
&\sum_{\mu,\nu\in\mathcal{R}}(\mu\cdot\nu)(q\cdot\mu)\mathrm{l}^{j-1}_\mu \mathrm{l}^k_\nu\psi\equiv G_{j,k}\psi,\\
&\qquad\qquad\qquad\qquad\qquad\qquad\psi\text{: Coxeter invariant.}\\
&\sum_{\mu,\nu\in\mathcal{R}}(\mu\cdot\nu)(q\cdot\nu)\mathrm{l}^j_\mu \mathrm{l}^{k-1}_\nu\psi\equiv G_{k,j}\psi,
\end{aligned} \tag{4.3}$$

We arrive at the following general commutation relation

$$i[G_j,G_k]=jG_{j,k}-kG_{k,j}. \tag{4.4}$$

These $\{G_{j,k}\}$'s satisfy the same type of commutation relations as above.

When the set of vectors $\mathcal{R}$ consists of orthonormal vectors, we have

$$\sum_{\mu,\nu\in\mathcal{R}}(\mu\cdot\nu)(q\cdot\mu)\mathrm{l}^{j-1}_\mu \mathrm{l}^k_\nu=\sum_{\mu,\nu\in\mathcal{R}}(\mu\cdot\nu)(q\cdot\nu)\mathrm{l}^j_\mu \mathrm{l}^{k-1}_\nu=\begin{cases}C_{\mathcal{R}}\displaystyle\sum_{\nu\in\mathcal{R}}(q\cdot\nu)\mathrm{l}^{j+k-1}_\nu,\\ 0.\end{cases} \tag{4.5}$$

This leads to a simplified commutation relation

$$i[G_j,G_k]=(j-k)C_{\mathcal{R}}G_{j+k-1}, \tag{4.6}$$

which was reported in Kuznetsov's paper for A_r case[5] ($C_{\mathcal{R}}=1$).

To sum up, we have obtained the following general commutation relations:

$$[F_j,F_k]=0, \tag{4.7}$$

$$i[F_j,G_k]=jF_{k,j}, \tag{4.8}$$

$$i[G_j,G_k]=jG_{j,k}-kG_{k,j}. \tag{4.9}$$

By using these the operators $\{F_j\}$'s and $\{H^{(m)}_{k,l}\}$'s defined by

$$H^{(m)}_{k,l}=F_{k,m}G_l-F_{l,m}G_k, \quad H^{(m)}_{k,l}=-H^{(m)}_{l,k}, \tag{4.10}$$

generate a quadratic algebra

$$[F_j,F_k]=0, \tag{4.11}$$

$$i[F_j,H^{(m)}_{k,l}]=j(F_{k,m}F_{l,j}-F_{l,m}F_{k,j}), \tag{4.12}$$

$$i[H^{(m)}_{k,l},H^{(m')}_{k',l'}]=\text{quadratic in } H^{(n)}_{r,s} \text{ and } F_t. \tag{4.13}$$

This is the quadratic algebra of the quantum rational Calogero–Moser models based on any root systems. For the classical root systems it can be simplified by using the relations (3.21) and (4.6) to the forms given in Kuznetsov's paper.[5] It characterizes the superintegrability structure of quantum models. In applications for specific models, the indices of $\{F\}$'s and $\{G\}$'s and $\{H\}$'s must be chosen properly. This would give more specific forms of the quadratic algebra relations.

V. RATIONAL POTENTIAL MODEL WITH HARMONIC CONFINING FORCE

The arguments for the algebraic linearization for the *quantum* rational potential model with harmonic confining force go almost parallel with the classical ones. So we present only the key formulas. We have to note the coupling dependence is changed from $g^2_{|\rho|}$ (classical) to $g_{|\rho|}(g_{|\rho|}-1)$ (quantum) and instead of *trace* (Tr, classical) we need the *total sum* (Ts, quantum). The Hamiltonian is now

$$\mathcal{H}_\omega=\frac{1}{2}p^2+\frac{1}{2}\omega^2q^2+\frac{1}{2}\sum_{\rho\in\Delta_+}\frac{g_{|\rho|}(g_{|\rho|}-1)|\rho|^2}{(\rho\cdot q)^2}. \tag{5.1}$$

With the same matrix operators L, M and Q as in the rational case the equations of motion can be expressed in matrix forms:

$$\dot{L}=[L,M]-\omega^2Q, \quad \dot{Q}=[Q,M]+L. \tag{5.2}$$

Introduce the matrices

$$L^{\pm}=L\pm i\omega Q \tag{5.3}$$

whose time evolution reads

$$\dot{L}^{\pm}=[L^{\pm},M]\pm i\omega L^{\pm}. \tag{5.4}$$

They can be cast into a Lax form for $\mathcal{L}=L^+L^-$ as

$$\dot{\mathcal{L}}=[\mathcal{L},M]. \tag{5.5}$$

Consider then the functions

$$F_k = \mathrm{Ts}(L^+ \mathcal{L}^k), \quad G_k = \mathrm{Ts}(L^- \mathcal{L}^k). \tag{5.6}$$

The time evolution yields

$$\dot{F}_k = i\omega F_k, \quad \dot{G}_k = -i\omega G_k. \tag{5.7}$$

Thus these functions provide the algebraic linearization of the quantum system.

VI. RATIONAL MODEL WITH A QUARTIC POTENTIAL

As proved by Françoise and Ragnisco[25] for the models based on the A type root systems and by us[8] for the models based on any root systems, the rational Calogero–Moser model can be deformed into an integrable system by adding a quartic potential at the *classical* level. Here we provide a partial result at the quantum level. The equation of motion can be cast into Lax type equations but they fail to produce conserved quantities.

Define again the same matrices L, Q, X and M. Let

$$h(Q) = aQ + bQ^2 \tag{6.1}$$

be a matrix quadratic in Q; (a,b) are just two new independent parameters. The perturbed Hamiltonian is now

$$\mathcal{H}_h \propto \mathrm{Ts}(L^2 + h(Q)^2). \tag{6.2}$$

Like in the classical theory, the equations of motion can be cast into matrix forms by defining

$$L^\pm = L \pm \mathrm{i}h(Q), \quad \mathcal{L}_1 = L^+ L^-, \quad \mathcal{L}_2 = L^- L^+. \tag{6.3}$$

Though care is needed for the quantum noncommutativity, the calculation is essentially the same as in the classical theory and we arrive at the time evolution of $L^\pm$ and $\mathcal{L}_1$, $\mathcal{L}_2$:

$$\dot{L}^\pm = [L^\pm, M] \pm i\,\tfrac{1}{2}(h'(Q)L^\pm + L^\pm h'(Q)), \tag{6.4}$$

$$\dot{\mathcal{L}}_1 = \left[\mathcal{L}_1, M - \frac{i}{2}h'(Q)\right], \quad \dot{\mathcal{L}}_2 = \left[\mathcal{L}_2, M + \frac{i}{2}h'(Q)\right]. \tag{6.5}$$

Because of the term $\pm(i/2)\,h'(Q)$ added to the M matrix, it loses the sum up to zero property (2.9) and thus *neither trace nor total sum* of the powers of $\mathcal{L}_{1,2}$ are conserved at the quantum level.

For the superintegrability of the trigonometric (hyperbolic) potential models, we refer to Refs. 26 and 27.

VII. COMMENTS ON THE HERMITICITY OF ALGEBRA GENERATORS

In quantum mechanics physical quantities or the observables are described by Hermitian operators in Hilbert space.[16] The hermiticity of F_j, (2.10), is obvious from that of L. The original definition of G_j, (2.13), is not Hermitian. With the following redefinition of Hermitian G_j,

$$G_j = \mathrm{Ts}\sum_{k=0}^{j} (L^k Q L^{j-k})/(j+1), \tag{7.1}$$

it satisfies the same formula (2.16). Whereas the definition of $F_{k,j}$ (3.17) remains the same, that of $H^{(j)}_{k,k'}$ (3.23) should be changed to a Hermitian form

$$2H^{(j)}_{k,k'} = F_{k,j}G_{k'} + G_{k'}F_{k,j} - F_{k',j}G_k - G_k F_{k',j}. \tag{7.2}$$

A formulation with explicitly Hermitian G_j could have been achieved by

$$G_{j-1} \propto i[q^2, F_j], \tag{7.3}$$

which is closely related with the extension of the sl(2,**R**) algebra.[22–24,6,18,16] This also explains the assertion that independent $\{G_j\}$'s appear at $j=$exponent.

We chose the current presentation in order to avoid excessively complicated looking formulas and to allow an easy comparison with the original work, Ref. 5, on the quadratic algebra.

(Received 4 April 2001; accepted for publication 12 July 2001)

A symmetry classification of possible interactions in a diatomic molecular chain is provided. For nonlinear interactions the group of Lie point transformations, leaving the lattice invariant and taking solutions into solutions, is at most five-dimensional. An example is considered in which subgroups of the symmetry group are used to reduce the dynamical differential-difference equations to purely difference ones. [DOI: 10.1063/1.1398583]

I. INTRODUCTION

The purpose of this article is to analyze possible interactions in a long one-dimensional molecule consisting of two types of atoms. The model we consider is a very general one, described by the equations

$$E_1 \equiv \ddot{x}_n - F_n(\xi_n, t) - G_n(\eta_{n-1}, t) = 0,$$
$$E_2 \equiv \ddot{y}_n - K_n(\xi_n, t) - P_n(\eta_n, t) = 0, \tag{1.1}$$

where the overdots denote time derivatives and x_n, y_n can be interpreted as the displacement of the nth atom of type X or Y, respectively, from their equilibrium positions. We define

$$\xi_n \equiv y_n - x_n, \quad \eta_n \equiv x_{n+1} - y_n \tag{1.2}$$

and t is time. The functions F_n, G_n, K_n and P_n are as yet unspecified smooth functions. Indeed, our aim is to classify such systems according to the Lie point symmetries that they allow, that is, to classify these functions F_n, G_n, K_n and P_n.

The assumptions built into the model are the following.

(1) The atoms of type X and Y alternate along a fixed uniform one-dimensional chain with positions labeled by the integers n (see Fig. 1).
(2) Only nearest neighbor interactions are considered, i.e., the atom X_n interacts only with Y_{n-1} and Y_n, and Y_n interacts only with X_n and X_{n+1} (see Fig. 1).
(3) The system is invariant under a uniform translation of all atoms in the molecule and also under a Galilei transformations of the chain.

[b)]Electronic mail: tremblay@crm.umontreal.ca
[c)]Electronic mail: wintern@crm.umontreal.ca

FIG. 1. Interactions between atoms of type X and Y along a molecular chain.

(4) The systems are strongly coupled, i.e., we assume

$$\frac{\partial F_n}{\partial \xi_n} \neq 0, \quad \frac{\partial G_n}{\partial \eta_{n-1}} \neq 0, \quad \frac{\partial K_n}{\partial \xi_n} \neq 0, \quad \frac{\partial P_n}{\partial \eta_n} \neq 0. \tag{1.3}$$

(5) In the bulk of the article we assume that the interactions are nonlinear, i.e., at least one of the four functions F_n, G_n, K_n or P_n depends nonlinearly on the argument ξ or η, respectively. The linear case will be treated separately.

(6) A discrete symmetry is built into the model. Indeed, the two equations (1.1) are permuted by the transformation

$$\begin{gathered} x_n \to y_n, \quad y_n \to x_{n+1}, \\ F_n \to P_n, \quad G_n \to K_n, \quad K_{n-1} \to G_n, \quad P_{n-1} \to F_n. \end{gathered} \tag{1.4}$$

Models of this type have many applications in classical mechanics, in molecular physics, or mathematical biology.[1–3] In applications, the form of the functions in Eq. (1.1) are usually *a priori* fixed.

The formalism used in this article is the one called ''intrinsic method'' in earlier articles.[4,5] It has already been applied to monoatomic molecular chains[6] and to a model with two species, or two types of atoms, distributed along a double chain.[7]

In this approach the dependent variables x and y depend on one discrete variable n and one continuous variable t. Symmetry transformations, taking solutions into solutions, act on the variables x, y and t, not, however, on the lattice variable n. The Lie algebra of the symmetry group is realized by vector fields of the form

$$\hat{X} = \tau(x_n, y_n, t)\partial_t + \phi_n(x_n, y_n, t)\partial_{x_n} + \psi_n(x_n, y_n, t)\partial_{y_n}. \tag{1.5}$$

The functions τ, ϕ_n and ψ_n are determined from the requirement that the second prolongation of the vector field $\hat{X}$ should annihilate Eqs. (1.1) on their solution surface. Explicitly we have[4–7]

$$\mathrm{pr}^{(2)}\hat{X} = \tau(t, x_n, y_n)\partial_t + \sum_{k=n-1}^{n+1} \phi_k(t, x_n, y_n)\partial_{x_k} + \sum_{k=n-1}^{n+1} \psi_k(t, x_n, y_n)\partial_{y_k} + \phi_n^{tt}\partial_{\ddot{x}_n} + \psi_n^{tt}\partial_{\ddot{y}_n} \tag{1.6}$$

with

$$\begin{aligned} \phi_n^{tt} &= D_t^2\phi_n - (D_t^2\tau)\,\dot{x}_n - 2(D_t\tau)\,\ddot{x}_n, \\ \psi_n^{tt} &= D_t^2\psi_n - (D_t^2\tau)\,\dot{y}_n - 2(D_t\tau)\,\ddot{y}_n \end{aligned} \tag{1.7}$$

(D_t is the total time derivative). In Eq. (1.6) we have spelled out only those terms which act on Eq. (1.1).

The use of this formalism is not obligatory. Indeed, the group transformations can also act on the lattice[8–11] and generalized symmetries can be very useful.[12] In this article we restrict ourselves to the intrinsic formalism, described earlier in this work.

The present article is organized as follows. In Sec. II we establish the general form of the vector fields (1.5) that realize the symmetry algebra of Eq. (1.1). We also derive the determining

equations for the symmetries and introduce a ''group of allowed transformations.'' Allowed transformations take equations of the type (1.1) into other equations of the same type. They can change the functions F_n, G_n, K_n and P_n into other functions of the same arguments. As in previous articles, we classify equations into symmetry classes under the action of allowed transformations.[6,7,13,14] We also establish that Eqs. (1.1) are invariant under a two-dimensional Abelian group for any functions $F_n,\ldots,P_n$. Section III is devoted to Abelian symmetry algebras. We denote them $A_{j,k,}$, where A means Abelian, j denotes the dimension and $k=1,2,3,\ldots$ enumerates algebras of the same dimension. For each interaction we list only the maximal symmetry algebra. Section IV is devoted to nilpotent symmetry algebras, denoted by $N_{j,k}$ with the same conventions as in Sec. III. In Sec. V we find all solvable symmetry algebras with non-Abelian nilradicals ($SN_{j,k}$). In Sec. VI we find those with Abelian nilradicals ($SA_{j,k}$). All nonsolvable symmetry algebras are listed in Sec. VII ($NS_{j,k}$). In Secs. III–VII we consider only nonlinear interactions. Symmetries of the linear case are discussed in Sec. VIII. Conclusions and some applications of the symmetries are summed up in Sec. IX.

II. DETERMINING EQUATIONS AND ALLOWED TRANSFORMATIONS

The algorithm for finding the symmetry algebra of Eq. (1.1) is

$$\mathrm{pr}\hat{X}\,E_a|_{E_b=0}=0,\quad a=1,2,\quad b=1,2. \tag{2.1}$$

The coefficients of all terms of the type $\dot{x}_n^p\dot{y}_n^q$ must vanish independently and we find that the vector field (1.5) must actually have the form

$$\hat{X}=\tau(t)\partial_t+\left[\left(a+\frac{\dot{\tau}(t)}{2}\right)x_n+\lambda_n(t)\right]\partial_{x_n}+\left[\left(a+\frac{\dot{\tau}(t)}{2}\right)y_n+\mu_n(t)\right]\partial_{y_n}, \tag{2.2}$$

where a is a constant and $\lambda_n(t),\mu_n(t)$ and $\tau(t)$ are functions of the indicated variables. This form (2.2) is valid for any interactions F_n, G_n, K_n and P_n in Eq. (1.1). Moreover, we have

$$\tau=\tau_0+\tau_1 t+\tau_2 t^2, \tag{2.3}$$

where τ_0,τ_1 and τ_2 are constants.

The constants a, τ_i and the functions $\lambda_n(t)$ and $\mu_n(t)$ are subject to two further determining equations that involve the interaction functions explicitly. They are

$$\ddot{\lambda}_n+\left(a-\frac{3}{2}\dot{\tau}\right)(F_n+G_n)+\left[\lambda_n-\mu_n-\left(a+\frac{\dot{\tau}}{2}\right)\xi_n\right]F_{n,\xi_n}+\left[\mu_{n-1}-\lambda_n-\left(a+\frac{\dot{\tau}}{2}\right)\eta_{n-1}\right]G_{n,\eta_{n-1}}$$
$$-\tau(F_{n,t}+G_{n,t})=0, \tag{2.4}$$

$$\ddot{\mu}_n+\left(a-\frac{3}{2}\dot{\tau}\right)(K_n+P_n)+\left[\lambda_n-\mu_n-\left(a+\frac{\dot{\tau}}{2}\right)\xi_n\right]K_{n,\xi_n}+\left[\mu_n-\lambda_{n+1}-\left(a+\frac{\dot{\tau}}{2}\right)\eta_n\right]P_{n,\eta_n}$$
$$-\tau(K_{n,t}+P_{n,t})=0. \tag{2.5}$$

Our task is to perform a complete analysis of Eqs. (2.4) and (2.5). Conceptually, this is very similar to the problem considered in Ref. 7. However, the functions figuring in Eq. (1.1) are less general than those of Ref. 7, hence the computations are simpler.

We shall classify the equations of type (1.1) into equivalence classes under the action of a group of ''allowed transformations.'' These are transformations of the form

$$x_n=\Phi_n(\tilde{x}_n,\tilde{y}_n,\tilde{t}),\quad y_n=\Psi_n(\tilde{x}_n,\tilde{y}_n,\tilde{t}),\quad t=T(\tilde{t}) \tag{2.6}$$

that transform Eqs. (1.1) into equations of the same form, but do not preserve the functions on the right hand side of Eq. (1.1). The requirement that no first derivatives should appear and that the transformed functions $\tilde{F}_n$ and $\tilde{K}_n$ should depend only on $\tilde{\xi}_n$ and $\tilde{t}$, and $\tilde{G}_n$ and $\tilde{P}_n$ only on $\tilde{t}$ and $\tilde{\eta}_{n-1}$ or $\tilde{\eta}_n$, respectively, implies that the transformations actually have the form

$$\begin{pmatrix} x_n(t) \\ y_n(t) \end{pmatrix} = q\,\dot{\tilde{t}}^{-1/2} \begin{pmatrix} \tilde{x}_n(\tilde{t}) \\ \tilde{y}_n(\tilde{t}) \end{pmatrix} + \begin{pmatrix} \alpha_n(t) \\ \beta_n(t) \end{pmatrix}, \tag{2.7}$$

$$\tilde{t} = \frac{c_1 t + c_2}{c_3 t + c_4}, \quad c_1 c_4 - c_2 c_3 = 1, \quad q \neq 0, \tag{2.8}$$

where $q, c_1, \ldots, c_4$ are constants and α_n and β_n are arbitrary functions of n and t.

The transformed system is

$$\begin{aligned} \ddot{\tilde{x}}_n(\tilde{t}) &= \tilde{F}_n(\tilde{\xi}_n, \tilde{t}) + \tilde{G}_n(\tilde{\eta}_{n-1}, \tilde{t}), \\ \ddot{\tilde{y}}_n(\tilde{t}) &= \tilde{K}_n(\tilde{\xi}_n, \tilde{t}) + \tilde{P}_n(\tilde{\eta}_n, \tilde{t}), \end{aligned} \tag{2.9}$$

with

$$\begin{pmatrix} \tilde{F}_n + \tilde{G}_n \\ \tilde{K}_n + \tilde{P}_n \end{pmatrix} = \frac{\dot{\tilde{t}}^{-3/2}}{q} \left[\begin{pmatrix} F_n(\xi_n, t) + G_n(\eta_{n-1}, t) \\ K_n(\xi_n, t) + P_n(\eta_n, t) \end{pmatrix} - \begin{pmatrix} \ddot{\alpha}_n(t) \\ \ddot{\beta}_n(t) \end{pmatrix} \right], \tag{2.10}$$

where

$$\xi_n = y_n - x_n = q\,\dot{\tilde{t}}^{-1/2}(\tilde{x}_n - \tilde{y}_n) + \alpha_n(t) - \beta_n(t), \tag{2.11}$$

$$\eta_n = x_{n+1} - y_n = q\,\dot{\tilde{t}}^{-1/2}(\tilde{x}_{n+1} - \tilde{y}_n) + \alpha_{n+1}(t) - \beta_n(t), \tag{2.12}$$

$$t = \frac{c_4 \tilde{t} - c_2}{-c_3 \tilde{t} + c_1}. \tag{2.13}$$

The vector field $\hat{X}$ of Eq. (2.2) is transformed into a similar field with

$$\tilde{\tau}(\tilde{t}) = \tau(t(\tilde{t}))\,\dot{\tilde{t}}, \quad \tilde{a} = a, \tag{2.14}$$

$$\begin{pmatrix} \tilde{\lambda}_n(\tilde{t}) \\ \tilde{\mu}_n(\tilde{t}) \end{pmatrix} = \frac{\dot{\tilde{t}}^{1/2}}{q} \left[\left(a + \frac{\dot{\tau}}{2} \right) \begin{pmatrix} \alpha_n \\ \beta_n \end{pmatrix} - \tau \begin{pmatrix} \dot{\alpha}_n \\ \dot{\beta}_n \end{pmatrix} + \begin{pmatrix} \lambda_n \\ \mu_n \end{pmatrix} \right]. \tag{2.15}$$

The transformed functions and constants must satisfy the same determining equations (2.4) and (2.5).

As mentioned in the Introduction, translational and Galilei invariance are built into the model. That is easy to check. Indeed $\lambda_n = \mu_n = 1$, $a = 0$, $\tau(t) = 0$ and $\lambda_n = \mu_n = t$, $a = 0$, $\tau(t) = 0$ are solutions of Eqs. (2.4) and (2.5) for F_n, G_n, K_n and P_n arbitrary. No other symmetries exist, unless some constraints on the interactions are imposed.

We shall use the allowed transformations to simplify the vector fields that occur. In particular the coefficient $\tau(t)$ of a given vector field can be transformed into one of the following expressions: 0, 1, t or $t^2 + 1$.

Our strategy will be to first find all Abelian symmetry algebras, then all nilpotent (non-Abelian) ones. Once these are known, we can determine all solvable ones, having the corresponding Abelian or nilpotent ones as nilradicals.[15] Finally, all nonsolvable symmetry algebras will be determined, making use of their Levi decomposition.[15]

Any symmetry algebra will contain the algebra

$$\mathbf{A_{2,1}}: \quad \hat{X}_1=\partial_{x_n}+\partial_{y_n}, \quad \hat{X}_2=t(\partial_{x_n}+\partial_{y_n}), \tag{2.16}$$

as a subalgebra. Allowed transformations leave the algebra (2.16) invariant. Any further element of the symmetry algebra can be transformed into one of the following ones:

$$\hat{Y}_1=\partial_t+a(x_n\,\partial_{x_n}+y_n\,\partial_{y_n}), \quad a=0,1, \tag{2.17}$$

$$\hat{Y}_2=t\,\partial_t+(a+\tfrac{1}{2})(x_n\,\partial_{x_n}+y_n\,\partial_{y_n}), \tag{2.18}$$

$$\hat{Y}_3=(t^2+1)\,\partial_t+(a+t)(x_n\,\partial_{x_n}+y_n\,\partial_{y_n}), \tag{2.19}$$

$$\hat{Y}_4=\lambda_n(t)(\partial_{x_n}+\partial_{y_n}), \quad \ddot{\lambda}_n\neq 0, \quad \lambda_{n+1}\neq\lambda_n, \tag{2.20}$$

$$\hat{Y}_5=\lambda_n(t)\,\partial_{x_n}+\lambda_{n+1}(t)\,\partial_{y_n}, \quad \ddot{\lambda}_n\neq 0, \quad \lambda_{n+1}\neq\lambda_n. \tag{2.21}$$

The interactions that allow these additional terms can easily be determined from Eqs. (2.4) and (2.5). Once this is done, we determine whether the considered interactions allow further symmetries. For each interaction, we shall only list the maximal symmetry algebra allowed, not lower-dimensional subalgebras.

III. ABELIAN SYMMETRY ALGEBRAS

The lowest dimensional maximal symmetry algebra is $A_{2,1}$ of Eq. (2.16), present for any interactions in Eq. (1.1). This algebra can be enlarged into a higher dimensional Abelian algebra by adding elements of the type (2.20) or (2.21). The determining equations for a nonlinear system allow at most four commuting symmetry generators. Moreover, the three-dimensional symmetry algebras are never maximal.

Finally, we obtain two different four-dimensional Abelian symmetry algebras together with the interactions that allow them. They are

$$\mathbf{A_{4,1}}: \quad \hat{X}_1=\lambda_{1,n}(t)(\partial_{x_n}+\partial_{y_n}), \quad \hat{X}_2=\lambda_{2,n}(t)(\partial_{x_n}+\partial_{y_n}),$$

$$\hat{X}_3=\partial_{x_n}+\partial_{y_n}, \quad \hat{X}_4=t(\partial_{x_n}+\partial_{y_n}),$$

$$F_n=F_n(\xi_n,t), \quad G_n=\frac{\ddot{\lambda}_{1,n}}{\lambda_{1,n}-\lambda_{1,n-1}}\,\eta_{n-1},$$

$$K_n=K_n(\xi_n,t), \quad P_n=\frac{\ddot{\lambda}_{1,n}}{\lambda_{1,n+1}-\lambda_{1,n}}\,\eta_n,$$

$$\ddot{\lambda}_{1,n}\neq 0, \quad \ddot{\lambda}_{2,n}\neq 0, \quad \lambda_{1,n+1}\neq\lambda_{1,n},$$

$$\frac{\ddot{\lambda}_{2,n}}{\ddot{\lambda}_{1,n}}=\frac{\lambda_{2,n}-\lambda_{2,n-1}}{\lambda_{1,n}-\lambda_{1,n-1}}=\frac{\lambda_{2,n+1}-\lambda_{2,n}}{\lambda_{1,n+1}-\lambda_{1,n}};$$

$$\mathbf{A_{4,2}}: \quad \hat{X}_1=\lambda_{1,n}(t)\partial_{x_n}+\lambda_{1,n+1}(t)\partial_{y_n}, \quad \hat{X}_2=\lambda_{2,n}(t)\partial_{x_n}+\lambda_{2,n+1}(t)\partial_{y_n},$$

$$\hat{X}_3=\partial_{x_n}+\partial_{y_n},\quad \hat{X}_4=t(\partial_{x_n}+\partial_{y_n}),$$

$$F_n=\frac{\ddot{\lambda}_{1,n}}{\lambda_{1,n+1}-\lambda_{1,n}}\xi_n,\quad G_n=G_n(\eta_{n-1},t),$$

$$K_n=\frac{\ddot{\lambda}_{1,n+1}}{\lambda_{1,n+1}-\lambda_{1,n}}\xi_n,\quad P_n=P_n(\eta_n,t),$$

$$\ddot{\lambda}_{1,n}\neq 0,\quad \ddot{\lambda}_{2,n}\neq 0,\quad \lambda_{1,n+1}\neq\lambda_{1,n},$$

$$\frac{\ddot{\lambda}_{2,n}}{\ddot{\lambda}_{1,n}}=\frac{\lambda_{2,n}-\lambda_{2,n-1}}{\lambda_{1,n}-\lambda_{1,n-1}}=\frac{\lambda_{2,n+1}-\lambda_{2,n}}{\lambda_{1,n+1}-\lambda_{1,n}}.$$

The algebras $A_{4,1}$ and $A_{4,2}$ are actually related by the discrete symmetry (1.4). Algebra $A_{4,1}$ is transformed into $A_{4,2}$ by the substitutions

$$\begin{gathered}F_n(\xi_n)\to P_n(\eta_n),\quad G_n(\eta_{n-1})\to K_n(\xi_n),\\ K_{n-1}(\xi_{n-1})\to G_n(\eta_{n-1}),\quad P_{n-1}(\eta_{n-1})\to F_n(\xi_n),\\ \sigma_n(t)\,\partial_{x_n}\to\sigma_{n+1}(t)\,\partial_{y_n},\quad \sigma_n(t)\,\partial_{y_n}\to\sigma_n(t)\,\partial_{x_n}.\end{gathered}\tag{3.1}$$

The functions $\lambda_{1,n}(t)$ and $\lambda_{2,n}(t)$ in algebras $A_{4,1}$, $A_{4,2}$ satisfy the equations

$$\frac{\ddot{\lambda}_{2,n}}{\ddot{\lambda}_{1,n}}=\frac{\lambda_{2,n}-\lambda_{2,n-1}}{\lambda_{1,n}-\lambda_{1,n-1}}=\frac{\lambda_{2,n+1}-\lambda_{2,n}}{\lambda_{1,n+1}-\lambda_{1,n}}.\tag{3.2}$$

These equations can be solved and we obtain

$$\begin{gathered}\lambda_{1,n}=f(t)\lambda_{2,n}+g(t),\quad \lambda_{2,n}=\frac{\gamma_n}{\dot{f}(t)^{1/2}}-\frac{1}{2\,\dot{f}(t)^{1/2}}\int_{t_0}^{t}\frac{\ddot{g}(s)}{\dot{f}(s)^{1/2}}\,ds,\\ \dot{f}(t)\neq 0,\quad \gamma_{n+1}\neq\gamma_n,\end{gathered}\tag{3.3}$$

where $f(t)$, $g(t)$ are arbitrary smooth functions of t and γ_n is an arbitrary function of n.

Notice that the quantities $\lambda_{1,n}(t)$ and $\lambda_{2,n}(t)$ [or $f(t)$, $g(t)$ and γ_n] figure explicitly in the interaction functions G_n and P_n of $A_{4,1}$, or respectively in F_n and K_n of $A_{4,2}$. The two algebras are thus indeed four-dimensional and completely specified.

IV. NILPOTENT NON-ABELIAN SYMMETRY ALGEBRAS

Nilpotent Lie algebras exist for all dimensions $\dim L\geqslant 3$. For $\dim L=3$ only one type exists, namely the Heisenberg algebra. It has a two-dimensional Abelian ideal. Maximality requires that this ideal be the algebra $A_{2,1}$ of Eq. (2.16). The Heisenberg algebra is obtained by adding the operator $\hat{T}=\partial_t$. We then calculate the interaction allowing this symmetry algebra, and obtain

$$\mathbf{N_{3,1}}:\ \hat{X}_1=\partial_{x_n}+\partial_{y_n},\quad \hat{X}_2=t(\partial_{x_n}+\partial_{y_n}),\quad \hat{T}=\partial_t,$$

$$F_n=f_n(\xi_n),\quad G_n=g_n(\eta_{n-1}),$$

$$K_n = k_n(\xi_n), \quad P_n = p_n(\eta_n).$$

We mention that this algebra is invariant under the substitution (3.1).

Every nilpotent non-Abelian Lie algebra contains the Heisenberg algebra as a subalgebra. We can hence proceed by adding further operators to $N_{3,1}$. Moreover, they can only be added to the Abelian ideal. The determining equations (2.4) and (2.5) allow us to add at most two operators. Maximality requires that we add precisely two. We thus obtain two mutually isomorphic five-dimensional nilpotent Lie algebras with four-dimensional Abelian ideals, namely,

$$\mathbf{N_{5,1}}: \ \hat{X}_1 = \partial_{x_n} + \partial_{y_n}, \quad \hat{X}_2 = t(\partial_{x_n} + \partial_{y_n}), \quad \hat{T} = \partial_t,$$

$$\hat{X}_3 = (\sigma_n + t^2)(\partial_{x_n} + \partial_{y_n}), \quad \hat{X}_4 = \left(\sigma_n t + \frac{t^3}{3}\right)(\partial_{x_n} + \partial_{y_n}),$$

$$F_n = f_n(\xi_n), \quad G_n = \frac{2}{\sigma_n - \sigma_{n-1}}\eta_{n-1},$$

$$K_n = k_n(\xi_n), \quad P_n = \frac{2}{\sigma_{n+1} - \sigma_n}\eta_n, \quad \sigma_{n+1} \neq \sigma_n,$$

where σ_n is an arbitrary function of n.

The second algebra $N_{5,2}$ is obtained from $N_{5,1}$ by the substitution (3.1). We mention that the interactions allowing the symmetry algebra $N_{5,1}$ are special cases of those allowing the Abelian algebra $A_{4,1}$. Similarly for $N_{5,2}$ and $A_{4,2}$.

V. SOLVABLE NON-NILPOTENT SYMMETRY ALGEBRAS WITH NON-ABELIAN NILRADICALS

A solvable Lie algebra L always has a uniquely defined maximal nilpotent ideal, the nilradical $NR(L)$.[15] If a solvable symmetry algebra of the system (1.1) has a non-Abelian nilradical, it must be $N_{3,1}$, $N_{5,1}$ or $N_{5,2}$ of Sec. IV, or a four-dimensional subalgebra of $N_{5,1}$ or $N_{5,2}$.

The determining equations (2.4) and (2.5) do not allow any extension of the four and five-dimensional nilpotent symmetry algebras to solvable ones.

The Heisenberg algebra $N_{3,1}$, on the other hand, leads to three different four-dimensional solvable symmetry algebras. The Lie algebras are given by four basis elements, $\hat{X}_1$, $\hat{X}_2$ and $\hat{T}$ of $N_{3,1}$ and an additional operator $\hat{Y}$. Below we list these elements $\hat{Y}$ together with the invariant interactions that allow the corresponding symmetry groups. In each case we present a matrix A defining the action of $\hat{Y}$ on the nilradical $N_{3,1}$ (i.e., $[\hat{X}, \hat{Y}] = A_{i1}\hat{X} + A_{i2}\hat{T} + A_{i3}\hat{X}_2$).

$$\mathbf{SN_{4,1}}: \ \hat{Y} = t\partial_t + (a + \tfrac{1}{2})(x_n\partial_{x_n} + y_n\partial_{y_n}),$$

$$F_n = (\xi_n)^{(2a-3)/(2a+1)} f_n, \quad G_n = (\eta_{n-1})^{(2a-3)/(2a+1)} g_n,$$

$$K_n = (\xi_n)^{(2a-3)/(2a+1)} k_n, \quad P_n = (\eta_n)^{(2a-3)/(2a+1)} p_n,$$

$$A = \mathrm{diag}\,(a + \tfrac{1}{2}, 1, a - \tfrac{1}{2}), \quad a \neq -\tfrac{1}{2}, \tfrac{3}{2};$$

$$\mathbf{SN_{4,2}}: \ \hat{Y} = t\partial_t + (2x_n + t^2)\partial_{x_n} + (2y_n + t^2)\partial_{y_n},$$

$$F_n = f_n + \tfrac{1}{2}\ln(\xi_n), \quad G_n = \tfrac{1}{2}\ln(\eta_{n-1}),$$

$$K_n = k_n + \tfrac{1}{2}\ln(\xi_n), \quad P_n = \tfrac{1}{2}\ln(\eta_n),$$

$$A = \begin{pmatrix} 2 & 0 & 0 \\ 0 & 1 & 2 \\ 0 & 0 & 1 \end{pmatrix};$$

$$\mathbf{SN_{4,3}}: \quad \hat{Y} = t\partial_t + \sigma_{1,n}\partial_{x_n} + \sigma_{2,n}\partial_{y_n},$$

$$F_n = f_n \exp\left(\frac{2\xi_n}{\sigma_{1,n}-\sigma_{2,n}}\right), \quad G_n = g_n \exp\left(\frac{-2\eta_{n-1}}{\sigma_{1,n}-\sigma_{2,n-1}}\right),$$

$$K_n = k_n \exp\left(\frac{2\xi_n}{\sigma_{1,n}-\sigma_{2,n}}\right), \quad P_n = p_n \exp\left(\frac{-2\eta_n}{\sigma_{1,n+1}-\sigma_{2,n}}\right),$$

$$A = \mathrm{diag}\,(0,1,-1), \quad \sigma_{1,n} \neq \sigma_{2,n}, \quad \sigma_{1,n+1} \neq \sigma_{2,n}.$$

The quantities $f_n, g_n, p_n, k_n, \sigma_{1,n}$ and $\sigma_{2,n}$ depend on n alone.

The transformation (3.1) does not lead to any new algebras or interactions. In the case of the algebra $SN_{4,3}$ we may have $\sigma_{2,n+1} = \sigma_{2,n}$. Then σ_2 can be transformed into $\sigma_{2,n} = \sigma = 0$, and similarly, for $\sigma_{2,n+1} \neq \sigma_{2,n}$, but $\sigma_{1,n+1} = \sigma_{1,n} \equiv \sigma$, we can transform σ_1 into $\sigma_1 = \sigma = 0$.

VI. SOLVABLE NON-NILPOTENT SYMMETRY ALGEBRAS WITH ABELIAN NILRADICALS

A large number of symmetry algebras of the system (1.1) are of this type. To identify and classify them, we use several known results on the structure of solvable Lie algebras.[15]

(1) The nilradical $NR(L)$ is unique and its dimension satisfies

$$\dim NR(L) \geqslant \tfrac{1}{2}\dim L. \tag{6.1}$$

(2) Any solvable Lie algebra L can be written as the algebraic sum of the nilradical $NR(L)$ and a complementary linear space F, i.e., $L = F \dot{+} NR(L)$.

(3) The derived algebra is contained in its nilradical: $[L,L] \subseteq NR(L)$.

(4) For an Abelian nilradical $\{\hat{X}_1, \ldots, \hat{X}_n\}$, the commutation relations can be written as

$$[\hat{X}_i, \hat{Y}_k] = (A_k)_{ij}\hat{X}_j, \quad [A_k, A_l] = 0, \quad [\hat{Y}_i, \hat{Y}_k] = c_{ik}^l \hat{X}_l, \quad [\hat{X}_i, \hat{X}_k] = 0, \tag{6.2}$$

where the elements $\hat{Y}_k$ are the non-nilpotent elements (outside the nilradical). The matrices A_k commute and are linearly nilindependent (i.e., no nontrivial linear combination of them is a nilpotent matrix). If only one element $\hat{Y}$ outside the nilradical exists, the non-nilpotent matrix A can be taken in Jordan canonical form.

In our case we can add that the Abelian nilradical must be one of the algebras found in Sec. III. In principle, the nilradical could be a three-dimensional subalgebra of $A_{4,1}$, or $A_{4,2}$, containing $A_{2,1}$ as a subalgebra. However, it turns out that all choices of this type lead to symmetry algebras that are not maximal for the interactions that they allow.

The following solvable symmetry algebras occur.

A. dim NR(L)=2

The only two-dimensional nilradical that leads to solvable Lie algebras that are maximal for the obtained interaction is $A_{2,1}$. The solvable Lie algebras are always three-dimensional. A basis for them consists of $\hat{X}_1$ and $\hat{X}_2$ of Eq. (2.16) and an additional element $\hat{Y}$. In each case we give the element $\hat{Y}$ and the matrix A representing the action of $\hat{Y}$ on the nilradical:

$$\mathbf{SA_{3,1}}:\ \hat{X}_1=\partial_{x_n}+\partial_{y_n},\quad \hat{X}_2=t(\partial_{x_n}+\partial_{y_n}),\quad \hat{Y}=\partial_t+x_n\partial_{x_n}+y_n\partial_{y_n},$$

$$F_n=\xi_n f_n(\omega_n),\quad G_n=\eta_{n-1}g_n(\zeta_{n-1}),$$

$$K_n=\xi_n k_n(\omega_n),\quad P_n=\eta_n p_n(\zeta_n),$$

$$\omega_n=\xi_n \mathrm{e}^{-t},\quad \zeta_n=\eta_n \mathrm{e}^{-t},\quad A=\begin{pmatrix}1 & -1\\ 0 & 1\end{pmatrix};$$

$$\mathbf{SA_{3,2}}:\ \hat{X}_1=\partial_{x_n}+\partial_{y_n},\quad \hat{X}_2=t(\partial_{x_n}+\partial_{y_n}),\quad \hat{Y}=t\partial_t+(a+\tfrac{1}{2})(x_n\partial_{x_n}+y_n\partial_{y_n}),$$

$$F_n=t^{-2}\xi_n f_n(\omega_n),\quad G_n=t^{-2}\eta_{n-1}g_n(\zeta_{n-1}),$$

$$K_n=t^{-2}\xi_n k_n(\omega_n),\quad P_n=t^{-2}\eta_n p_n(\zeta_n),$$

$$\omega_n=\xi_n t^{-(a+1/2)},\quad \zeta_n=\eta_n t^{-(a+1/2)},\quad A=\mathrm{diag}\,(a-\tfrac{1}{2},a+\tfrac{1}{2});$$

$$\mathbf{SA_{3,3}}:\ \hat{X}_1=\partial_{x_n}+\partial_{y_n},\quad \hat{X}_2=t(\partial_{x_n}+\partial_{y_n}),\quad \hat{Y}=(t^2+1)\partial_t+(a+t)(x_n\partial_{x_n}+y_n\partial_{y_n}),$$

$$F_n=(t^2+1)^{-2}\xi_n f_n(\omega_n),\quad G_n=(t^2+1)^{-2}\eta_{n-1}g_n(\zeta_{n-1}),$$

$$K_n=(t^2+1)^{-2}\xi_n k_n(\omega_n),\quad P_n=(t^2+1)^{-2}\eta_n p_n(\zeta_n),$$

$$\omega_n=\xi_n(t^2+1)^{-1/2}\exp[-a\arctan(t)],\quad \zeta_n=\eta_n(t^2+1)^{-1/2}\exp[-a\arctan(t)],$$

$$A=\begin{pmatrix}a & -1\\ 1 & a\end{pmatrix}.$$

These three algebras are nonisomorphic (since the corresponding matrices A are not mutually conjugate). Each of these three cases is self-conjugate under the substitution (3.1).

B. dim NR(L)=4

The nilradical could be three-dimensional, however the obtained solvable Lie algebra is never maximal. We only need to deal with four-dimensional Abelian ideals of the form $A_{4,1}$ and $A_{4,2}$. An extension to a solvable Lie algebra is only possible for special cases of the functions $\lambda_{1,n}(t)$ and $\lambda_{2,n}(t)$ figuring in the vector fields and interactions. Next we list all inequivalent extensions of $A_{4,1}$. There are precisely nine of them. The corresponding extensions of $A_{4,2}$ are obtained by the substitution (3.1). The action of $\hat{Y}$ on $\{\hat{X}_1,\ldots,\hat{X}_4\}$ is represented by the matrix A:

$$\mathbf{SA_{5,1}}:\ \hat{X}_1=\partial_{x_n}+\partial_{y_n},\quad \hat{X}_2=t(\partial_{x_n}+\partial_{y_n}),$$

$$\hat{X}_3=\sigma_n \mathrm{e}^{t}(\partial_{x_n}+\partial_{y_n}),\quad \hat{X}_4=\sigma_n \mathrm{e}^{-t}(\partial_{x_n}+\partial_{y_n}),$$

$$\hat{Y}=\partial_t+a(x_n\partial_{x_n}+y_n\partial_{y_n}),$$

$$F_n=\xi_n f_n(\omega_n),\quad G_n=\frac{\sigma_n}{\sigma_n-\sigma_{n-1}}\,\eta_{n-1},$$

$$K_n=\xi_n k_n(\omega_n),\quad P_n=\frac{\sigma_n}{\sigma_{n+1}-\sigma_n}\,\eta_n,$$

$$\omega_n=\xi_n e^{-at},\quad \sigma_{n+1}\neq\sigma_n,\quad A=\begin{pmatrix} a-1 & 0 & 0 & 0\\ 0 & a+1 & 0 & 0\\ 0 & 0 & a & 0\\ 0 & 0 & -1 & a\end{pmatrix};$$

$$\mathbf{SA_{5,2}}:\ \hat{X}_1=\partial_{x_n}+\partial_{y_n},\quad \hat{X}_2=t(\partial_{x_n}+\partial_{y_n}),$$

$$\hat{X}_3=\sigma_n\cos(t)(\partial_{x_n}+\partial_{y_n}),\quad \hat{X}_4=\sigma_n\sin(t)(\partial_{x_n}+\partial_{y_n}),$$

$$\hat{Y}=\partial_t+a(x_n\partial_{x_n}+y_n\partial_{y_n}),$$

$$F_n=\xi_n f_n(\omega_n),\quad G_n=\frac{-\sigma_n}{\sigma_n-\sigma_{n-1}}\eta_{n-1},$$

$$K_n=\xi_n k_n(\omega_n),\quad P_n=\frac{-\sigma_n}{\sigma_{n+1}-\sigma_n}\eta_n,$$

$$\omega_n=\xi_n e^{-at},\quad \sigma_{n+1}\neq\sigma_n,\quad A=\begin{pmatrix} a & 1 & 0 & 0\\ -1 & a & 0 & 0\\ 0 & 0 & a & 0\\ 0 & 0 & -1 & a\end{pmatrix};$$

$$\mathbf{SA_{5,3}}:\ \hat{X}_1=\partial_{x_n}+\partial_{y_n},\quad \hat{X}_2=t(\partial_{x_n}+\partial_{y_n}),$$

$$\hat{X}_3=(\sigma_n+t^2)(\partial_{x_n}+\partial_{y_n}),\quad \hat{X}_4=\left(\sigma_n t+\frac{t^3}{3}\right)(\partial_{x_n}+\partial_{y_n}),$$

$$\hat{Y}=\partial_t+a(x_n\partial_{x_n}+y_n\partial_{y_n}),$$

$$F_n=\xi_n f_n(\omega_n),\quad G_n=\frac{2\eta_{n-1}}{\sigma_n-\sigma_{n-1}},$$

$$K_n=\xi_n k_n(\omega_n),\quad P_n=\frac{2\eta_n}{\sigma_{n+1}-\sigma_n},$$

$$\omega_n=\xi_n e^{-at},\quad \sigma_{n+1}\neq\sigma_n,\quad A=\begin{pmatrix} a & 0 & 0 & -2\\ -1 & a & 0 & 0\\ 0 & 0 & a & 0\\ 0 & 0 & -1 & a\end{pmatrix};$$

$$\mathbf{SA_{5,4}}:\ \hat{X}_1=\partial_{x_n}+\partial_{y_n},\quad \hat{X}_2=t(\partial_{x_n}+\partial_{y_n}),$$

$$\hat{X}_3=\sigma_n t^{\alpha}(\partial_{x_n}+\partial_{y_n}),\quad \hat{X}_4=\sigma_n t^{1-\alpha}(\partial_{x_n}+\partial_{y_n}),$$

$$\hat{Y}=t\partial_t+(a+\tfrac{1}{2})(x_n\partial_{x_n}+y_n\partial_{y_n}),$$

$$F_n=t^{-2}\xi_n f_n(\omega_n),\quad G_n=\alpha(\alpha-1)t^{-2}\frac{\sigma_n}{\sigma_n-\sigma_{n-1}}\eta_{n-1},$$

$$K_n=t^{-2}\xi_n k_n(\omega_n),\quad P_n=\alpha(\alpha-1)t^{-2}\frac{\sigma_n}{\sigma_{n+1}-\sigma_n}\eta_n,$$

$$\omega_n=\xi_n t^{-(a+1/2)},\quad \sigma_{n+1}\neq\sigma_n,\quad \alpha\neq 0,1,$$

$$A=\mathrm{diag}\,(a-\alpha+\tfrac{1}{2},a+\alpha-\tfrac{1}{2},a+\tfrac{1}{2},a-\tfrac{1}{2});$$

$$\mathbf{SA_{5,5}}:\ \hat{X}_1=\partial_{x_n}+\partial_{y_n},\quad \hat{X}_2=t(\partial_{x_n}+\partial_{y_n}),$$

$$\hat{X}_3=\sigma_n t^{1/2}\ln(t)(\partial_{x_n}+\partial_{y_n}),\quad \hat{X}_4=\sigma_n t^{1/2}(\partial_{x_n}+\partial_{y_n}),$$

$$\hat{Y}=t\partial_t+(a+\tfrac{1}{2})(x_n\partial_{x_n}+y_n\partial_{y_n}),$$

$$F_n=t^{-2}\xi_n f_n(\omega_n),\quad G_n=-\tfrac{1}{4}t^{-2}\frac{\sigma_n}{\sigma_n-\sigma_{n-1}}\eta_{n-1},$$

$$K_n=t^{-2}\xi_n k_n(\omega_n),\quad P_n=-\tfrac{1}{4}t^{-2}\frac{\sigma_n}{\sigma_{n+1}-\sigma_n}\eta_n,$$

$$\omega_n=\xi_n t^{-(a+1/2)},\quad \sigma_{n+1}\neq\sigma_n,\quad A=\begin{pmatrix} a & -1 & 0 & 0\\ 0 & a & 0 & 0\\ 0 & 0 & a+\frac{1}{2} & 0\\ 0 & 0 & 0 & a-\frac{1}{2}\end{pmatrix};$$

$$\mathbf{SA_{5,6}}:\ \hat{X}_1=\partial_{x_n}+\partial_{y_n},\quad \hat{X}_2=t(\partial_{x_n}+\partial_{y_n}),$$

$$\hat{X}_3=\sigma_n t^{1/2}\cos[\ln(t)](\partial_{x_n}+\partial_{y_n}),\quad \hat{X}_4=\sigma_n t^{1/2}\sin[\ln(t)](\partial_{x_n}+\partial_{y_n}),$$

$$\hat{Y}=t\partial_t+(a+\tfrac{1}{2})(x_n\partial_{x_n}+y_n\partial_{y_n}),$$

$$F_n=t^{-2}\xi_n f_n(\omega_n),\quad G_n=-\frac{5}{4}t^{-2}\frac{\sigma_n}{\sigma_n-\sigma_{n-1}}\eta_{n-1},$$

$$K_n=t^{-2}\xi_n k_n(\omega_n),\quad P_n=-\frac{5}{4}t^{-2}\frac{\sigma_n}{\sigma_{n+1}-\sigma_n}\eta_n,$$

$$\omega_n=\xi_n t^{-(a+1/2)},\quad \sigma_{n+1}\neq\sigma_n,\quad A=\begin{pmatrix} a & 1 & 0 & 0\\ -1 & a & 0 & 0\\ 0 & 0 & a+\frac{1}{2} & 0\\ 0 & 0 & 0 & a-\frac{1}{2}\end{pmatrix};$$

$$\mathbf{SA_{5,7}}:\ \hat{X}_1=\partial_{x_n}+\partial_{y_n},\quad \hat{X}_2=t(\partial_{x_n}+\partial_{y_n}),$$

$$\hat{X}_3=[\sigma_n-\ln(t)](\partial_{x_n}+\partial_{y_n}),\quad \hat{X}_4=t[\sigma_n+\ln(t)](\partial_{x_n}+\partial_{y_n}),$$

$$\hat{Y}=t\partial_t+(a+\tfrac{1}{2})(x_n\partial_{x_n}+y_n\partial_{y_n}),$$

$$F_n=t^{-2}\xi_n f_n(\omega_n),\quad G_n=-t^{-2}\frac{\eta_{n-1}}{\sigma_n-\sigma_{n-1}},$$

$$K_n=t^{-2}\xi_n k_n(\omega_n),\quad P_n=-t^{-2}\frac{\eta_n}{\sigma_{n+1}-\sigma_n},$$

$$\omega_n=\xi_n t^{-(a+1/2)},\quad \sigma_{n+1}\neq\sigma_n,\quad A=\begin{pmatrix} a+\frac{1}{2} & 0 & 1 & 0\\ 0 & a-\frac{1}{2} & 0 & -1\\ 0 & 0 & a+\frac{1}{2} & 0\\ 0 & 0 & 0 & a-\frac{1}{2}\end{pmatrix};$$

$$\mathbf{SA_{5,8}}:\ \hat{X}_1=\partial_{x_n}+\partial_{y_n},\quad \hat{X}_2=t(\partial_{x_n}+\partial_{y_n}),$$

$$\hat{X}_3=\lambda_{1,n}(t)(\partial_{x_n}+\partial_{y_n}),\quad \lambda_{1n}=\sigma_n(t^2+1)^{1/2}\exp[\alpha\arctan(t)],$$

$$\hat{X}_4=\lambda_{2,n}(t)(\partial_{x_n}+\partial_{y_n}),\quad \lambda_{2n}=\sigma_n(t^2+1)^{1/2}\exp[-\alpha\arctan(t)],$$

$$\hat{Y}=(t^2+1)\partial_t+(a+t)(x_n\partial_{x_n}+y_n\partial_{y_n}),$$

$$F_n=(t^2+1)^{-2}\xi_n f_n(\omega_n),\quad G_n=(\alpha^2+1)(t^2+1)^{-2}\frac{\sigma_n}{\sigma_n-\sigma_{n-1}}\eta_{n-1},$$

$$K_n=(t^2+1)^{-2}\xi_n k_n(\omega_n),\quad P_n=(\alpha^2+1)(t^2+1)^{-2}\frac{\sigma_n}{\sigma_{n+1}-\sigma_n}\eta_n,$$

$$\omega_n=\xi_n(t^2+1)^{-1/2}\exp[-a\arctan(t)],\quad \sigma_{n+1}\neq\sigma_n,\quad \alpha\neq 0,$$

$$A=\begin{pmatrix} a-\alpha & 0 & 0 & 0\\ 0 & a+\alpha & 0 & 0\\ 0 & 0 & a & 1\\ 0 & 0 & -1 & a\end{pmatrix};$$

$$\mathbf{SA_{5,9}}:\ \hat{X}_1=\partial_{x_n}+\partial_{y_n},\quad \hat{X}_2=t(\partial_{x_n}+\partial_{y_n}),$$

$$\hat{X}_3=\sigma_n(t^2+1)^{1/2}(\partial_{x_n}+\partial_{y_n}),\quad \hat{X}_4=\sigma_n(t^2+1)^{1/2}\arctan(t)(\partial_{x_n}+\partial_{y_n}),$$

$$\hat{Y}=(t^2+1)\partial_t+(a+t)(x_n\partial_{x_n}+y_n\partial_{y_n}),$$

$$F_n=(t^2+1)^{-2}\xi_n f_n(\omega_n),\quad G_n=(t^2+1)^{-2}\frac{\sigma_n}{\sigma_n-\sigma_{n-1}}\eta_{n-1},$$

$$K_n=(t^2+1)^{-2}\xi_n k_n(\omega_n),\quad P_n=(t^2+1)^{-2}\frac{\sigma_n}{\sigma_{n+1}-\sigma_n}\eta_n,$$

$$\omega_n=\xi_n(t^2+1)^{-1/2}\exp[-a\arctan(t)],\quad \sigma_{n+1}\neq\sigma_n,\quad \alpha\neq 0,$$

$$A=\begin{pmatrix} a & 0 & 0 & 0\\ -1 & a & 0 & 0\\ 0 & 0 & a & 1\\ 0 & 0 & -1 & a\end{pmatrix}.$$

In all cases the interaction terms G_n and P_n are specified, whereas F_n and K_n each involve an arbitrary function of one variable ω_n. The time dependence of the variable ω_n and the functions F_n and K_n depends on the form of the generator $\hat{Y}$.

After the substitution (3.1) we have altogether 18 five-dimensional Lie algebras. No further symmetry generators can be added, at least in the nonlinear case studied so far.

VII. NONSOLVABLE SYMMETRY ALGEBRAS

Any finite dimensional Lie algebra L that is not solvable is either semisimple, or has a nontrivial and unique Levi decomposition

$$L=S\triangleright R, \tag{7.1}$$

where S is semisimple and R is the radical, i.e., the maximal solvable ideal. The only semisimple Lie algebra that can be realized in terms of the vector fields (2.2) is actually simple, namely $\mathrm{sl}(2,\mathbb{R})$. Up to allowed transformations the realization is unique (and given below by the operators $\hat{Y}_1$, $\hat{Y}_2$ and $\hat{Y}_3$). The determining equations (2.4) and (2.5) can be used to obtain the interaction invariant under the corresponding group $\mathrm{SL}(2,\mathbb{R})$. Equations (1.1) will then be invariant under a five-dimensional group that contains the subalgebra $A_{2,1}$. We have

$$\mathbf{NS_{5,1}}:\ \hat{Y}_1=\partial_t,\quad \hat{Y}_2=t\partial_t+\tfrac{1}{2}(x_n\partial_{x_n}+y_n\partial_{y_n}),\quad \hat{Y}_3=t^2\partial_t+t(x_n\partial_{x_n}+y_n\partial_{y_n}),$$

$$\hat{X}_1=\partial_{x_n}+\partial_{y_n},\quad \hat{X}_2=t(\partial_{x_n}+\partial_{y_n}),$$

$$F_n=\xi_n^{-3}f_n,\quad G_n=\eta_{n-1}^{-3}g_n,$$

$$K_n=\xi_n^{-3}k_n,\quad P_n=\eta_n^{-3}p_n.$$

The Lie algebra $NS_{5,1}$ is isomorphic to the special affine algebra $\mathrm{saff}(2,\mathbb{R})$. This is the only maximal nonsolvable symmetry algebra that occurs.

This completes our analysis of possible symmetries of the system (1.1) with nonlinear interactions.

VIII. SYMMETRIES OF LINEAR INTERACTIONS

In Secs. III–VII we have excluded the case of linear interactions. Let us turn to this case now. We specify Eqs. (1.1) to be

$$\begin{aligned}\ddot{x}_n&=A_n(t)\,\xi_n+B_n(t)\,\eta_{n-1}+U_n(t),\\ \ddot{y}_n&=C_n(t)\,\xi_n+D_n(t)\,\eta_n+V_n(t).\end{aligned} \tag{8.1}$$

The system is still strongly coupled, i.e., the functions A_n, B_n, C_n, D_n are all nonzero. The determining equations reduce to

$$\ddot{\lambda}_n-(\mu_n-\lambda_n)A_n-(\lambda_n-\mu_{n-1})B_n+(a-\tfrac{3}{2}\dot{\tau})U_n-\tau\dot{U}_n=0, \tag{8.2}$$

$$\ddot{\mu}_n-(\mu_n-\lambda_n)C_n-(\lambda_{n+1}-\mu_n)D_n+(a-\tfrac{3}{2}\dot{\tau})V_n-\tau\dot{V}_n=0, \tag{8.3}$$

$$2\dot{\tau}A_n+\tau\dot{A}_n=0, \tag{8.4}$$

$$2\dot{\tau}B_n+\tau\dot{B}_n=0, \tag{8.5}$$

$$2\dot{\tau}C_n+\tau\dot{C}_n=0, \tag{8.6}$$

$$2\dot{\tau}D_n+\tau\dot{D}_n=0, \tag{8.7}$$

$$\tau=\tau_0+\tau_1+\tau_2 t^2, \tag{8.8}$$

since the coefficients of ξ_n, η_n, η_{n-1} and 1 vanish separately.

For $A_n(t),\ldots,D_n(t)$ generic, we obtain $\tau=0$ and then only Eqs. (8.2) and (8.3) (with $\tau=0$) survive. These equations can be solved in the generic case and we obtain two types of symmetries, both just a consequence of linearity.

(1) We take $a=0$ and denote $(\lambda_{h,n},\mu_{h,n})$ the general solution of the homogeneous equations, i.e., Eq. (8.1) with $U_n=V_n=0$. The vector field is

$$\hat{X}_h=\lambda_{h,n}(t)\,\partial_{x_n}+\mu_{h,n}(t)\,\partial_{y_n}. \tag{8.9}$$

(2) For $a\neq 0$ we choose $a=-1$ and denote some chosen particular solution of the inhomogeneous system (8.1) $(\lambda_{p,n},\mu_{p,n})$. The vector field is

$$\hat{X}_p=[x_n-\lambda_{p,n}(t)]\partial_{x_n}+[y_n-\mu_{p,n}(t)]\partial_{y_n}. \tag{8.10}$$

In particular, if we have $U_n=V_n=0$, then we take $\lambda_{p,n}=\mu_{p,n}=0$ in Eq. (8.10).

The symmetry (8.9) only means that we can add any solution of the homogeneous equations to a solution of Eq. (8.1). The symmetry (8.10) corresponds to the fact that a solution of the homogeneous system can be multiplied by a constant.

Let us now assume that a further symmetry generator exists. It is of the form (2.2) with $\tau(t)$ as in Eq. (8.8). Allowed transformations can be used to transform τ into one of four cases. Let us consider them separately.

A. $\tau=0$

No symmetries beyond the generic ones are obtained.

B. $\tau=1$

Using allowed transformations we simplify the additional vector field into

$$\hat{T}=\partial_t+a(x_n\,\partial_{x_n}+y_n\,\partial_{y_n}). \tag{8.11}$$

The determining equations restrict the time dependence of the coefficients in Eq. (8.1) and the system reduces to

$$\ddot{x}_n = f_n\,\xi_n + g_n\,\eta_{n-1} + u_n e^{at},$$
$$\ddot{y}_n = k_n\,\xi_n + p_n\,\eta_n + v_n e^{at}. \tag{8.12}$$

C. $\tau = t$

The additional vector field and invariant equations are reduced to

$$\hat{D} = t\,\partial_t + (a + \tfrac{1}{2})(x_n\,\partial_{x_n} + y_n\,\partial_{y_n}), \tag{8.13}$$

$$\ddot{x}_n = \frac{f_n}{t^2}\,\xi_n + \frac{g_n}{t^2}\,\eta_{n-1} + u_n t^{a-3/2},$$
$$\ddot{y}_n = \frac{k_n}{t^2}\,\xi_n + \frac{p_n}{t^2}\,\eta_n + v_n t^{a-3/2}. \tag{8.14}$$

D. $\tau = t^2 + 1$

The additional vector field and invariant equations are

$$\hat{C} = (t^2+1)\partial_t + (a+t)(x_n\partial_{x_n} + y_n\partial_{y_n}), \tag{8.15}$$

$$\ddot{x}_n = \frac{f_n}{(t^2+1)^2}\,\xi_n + \frac{g_n}{(t^2+1)^2}\,\eta_{n-1} + \frac{u_n}{(t^2+1)^{3/2}}\exp[a\arctan(t)],$$
$$\ddot{y}_n = \frac{k_n}{(t^2+1)^2}\,\xi_n + \frac{p_n}{(t^2+1)^2}\,\eta_n + \frac{v_n}{(t^2+1)^{3/2}}\exp[a\arctan(t)]. \tag{8.16}$$

In all cases f_n, g_n, k_n, p_n, u_n and v_n are independent of t. No further symmetries exist for any of the interactions (8.12), (8.14) or (8.16).

IX. CONCLUSIONS

Let us sum up the results obtained earlier.

For nonlinear interactions the symmetry algebra is at most five-dimensional. The following cases occur.

(1) The nonsolvable algebra $NS_{5,1}$ of Sec. VII. The dependence of the right hand side of Eq. (1.1) on ξ_n and η_n is completely specified by an inverse cube relation. The dependence on the discrete variable n remains arbitrary. The interactions are time independent.

(2) The solvable Lie algebras with Abelian nilradicals $SA_{5,1},\ldots,SA_{5,9}$ [and $SA_{5,10},\ldots,SA_{5,18}$ by the substitution (3.1)] of Sec. VI B. The interactions are all "semilinear." By this we mean that the dependence on one variable η_n is specified to be linear, whereas the dependence on ξ_n remains arbitrary (and vice versa for $SA_{5,10},\ldots,SA_{5,18}$). The time dependence of the nonlinear terms in the interaction depends crucially on the form of the non-nilpotent element $\hat{Y}$. Any attempt to enlarge the symmetry algebra by further elements leads to linear interactions.

(3) The nilpotent five-dimensional Lie algebras $N_{5,1}$ and the related algebra $N_{5,2}$ of Sec. IV. For $N_{5,1}$ the interaction is again semilinear with G_n and P_n linear in η_{n-1} and η_n, respectively, and F_n and K_n arbitrary functions of ξ_n (and vice versa for $N_{5,2}$). The interaction is time independent.

(4) Four-dimensional maximal symmetry algebras are either Abelian, or solvable with the Heisenberg algebra as a nilradical. For $A_{4,1}$ and $A_{4,2}$ the interaction is semilinear with an arbitrary

time dependence in the nonlinear terms. For $SN_{4,1}$, $SN_{4,2}$ and $SN_{4,3}$ the dependence on ξ_n and η_n is completely specified as being monomial, logarithmic or exponential, respectively. There is no time dependence.

(5) A three-dimensional maximal symmetry algebra is either nilpotent, or solvable with an Abelian nilradical. For $N_{3,1}$, the Heisenberg algebra, the interaction is time independent, otherwise arbitrary. The model, studied by Campa *et al.*,[1] namely,

$$F_n(\xi_n)=\frac{1}{M_1}(k_1\xi_n+\varepsilon\beta_1\xi_n^2), \quad K_n(\xi_n)=-\frac{M_1}{M_2}F_n(\xi_n),$$

$$G_n(\eta_{n-1})=-\frac{1}{M_1}(k_2\eta_{n-1}+\varepsilon\beta_2\eta_{n-1}^2), \quad P_n(\eta_n)=-\frac{M_1}{M_2}G_{n+1}(\eta_{n+1}),$$

is of this type. For $SA_{3,1}$, $SA_{3,2}$ and $SA_{3,3}$ the interactions involve four arbitrary functions of one variable. The interaction is entirely specified by the element $\hat{Y}$.

(6) As mentioned earlier, the general interaction in Eq. (1.1) is invariant under the group of global translations and Galilei transformations, corresponding to the algebra $A_{2,1}$ of Eq. (2.16).

The symmetries found in this article can be used to perform symmetry reduction on one hand, and to obtain new solutions from known ones on the other.

Let us look at the example of algebra $NS_{5,1}$. The system (1.1) in this case reduces to

$$\ddot{x}_n=\frac{f_n}{\xi_n^3}+\frac{g_n}{\eta_{n-1}^3}, \quad \ddot{y}_n=\frac{k_n}{\xi_n^3}+\frac{p_n}{\eta_n^3}. \tag{9.1}$$

The algebra sl(2,$\mathbb{R}$) has three inequivalent one-dimensional subalgebras, namely $\hat{Y}_1$, $\hat{Y}_2$ and $\hat{Y}_3+\hat{Y}_1$. Each of them can be used to reduce the system (9.1) to a system of two difference equations. Let us look at the three individual cases separately.

A. Subalgebra $\hat{Y}_1$

This algebra leads to stationary solutions. We have

$$x_n=x_{n,0}, \quad y_n=y_{n,0} \tag{9.2}$$

and hence

$$\xi_{n,0}=\left(-\frac{f_n}{g_n}\right)^{1/3}\eta_{n-1,0}=\left(-\frac{k_n}{p_n}\right)^{1/3}\eta_{n,0}. \tag{9.3}$$

B. Subalgebra $\hat{Y}_2$

The reduction formulas in this case are

$$x_n=x_{n,0}\sqrt{t}, \quad y_n=y_{n,0}\sqrt{t} \tag{9.4}$$

and the recursion relations are

$$-\frac{x_{n,0}}{4}=\frac{f_n}{\xi_{n,0}^3}+\frac{g_n}{\eta_{n-1,0}^3}, \quad -\frac{y_{n,0}}{4}=\frac{k_n}{\xi_{n,0}^3}+\frac{p_n}{\eta_{n,0}^3}. \tag{9.5}$$

C. Subalgebra $\hat{Y}_3+\hat{Y}_1$

We put

$$x_n=x_{n,0}\sqrt{t^2+1}, \quad y_n=y_{n,0}\sqrt{t^2+1} \tag{9.6}$$

and obtain the recursion relations

$$x_{n,0}=\frac{f_n}{\xi_{n,0}^3}+\frac{g_n}{\eta_{n-1,0}^3}, \quad y_{n,0}=\frac{k_n}{\xi_{n,0}^3}+\frac{p_n}{\eta_{n,0}^3}. \tag{9.7}$$

In all three cases we can express ξ_n in terms of η_n and obtain a two term recursion relation for η_n. These can be solved, but we will not go into the details here.

There are studied in detail the structure properties of integral submanifold imbedding mapping for a class of algebraically Liouville integrable Hamiltonian systems on cotangent phase spaces and related with it so called Picard–Fuchs type equations. It is shown that these equations can be in general regularly constructed making use of a given *a priori* system of involutive invariants and proved that their solutions in the Hamolton–Jacobi separable variable case give rise exactly to the integral submanifold imbedding mapping being as known a main ingredient for Liouville–Arnold integrability by quadratures of the Hamiltonian system under regard. © *2001 American Institute of Physics.* [DOI: 10.1063/1.1409961]

I. INTRODUCTION

We consider a completely integrable via Liouville–Arnold[1,2] Hamiltonian system on a cotangent canonically symplectic manifold $(T^*(\mathbb{R}^n), \omega^{(2)})$, $n \in \mathbb{Z}_+$, possessing exactly $n \in \mathbb{Z}_+$ functionally independent and Poisson commuting algebraic polynomial invariants $H_j : T^*(\mathbb{R}^n) \to \mathbb{R}$, $j = \overline{1,n}$. Due to the Liouville–Arnold theorem[1,2] this Hamiltonian system can be completely integrated by quadratures in quasiperiodic functions on its integral submanifold when taken compact. It is equivalent to the statement that this compact integral submanifold is diffeomorphic to a torus $\mathbb{T}^n$, which makes it possible to formulate the problem of integrating the system by means of searching the corresponding integral submanifold imbedding mapping $\pi_h : M_h^n \to T^*(\mathbb{R}^n)$, where by definition

$$M_h^n := \{(q,p) \in T^*(\mathbb{R}^n): \quad H_j(q,p) = h_j \in \mathbb{R}, \quad j = \overline{1,n}\}. \tag{1.1}$$

Since $M_h^n \simeq \mathbb{T}^n$, and the integral submanifold (1.1) is invariant subject to all Hamiltonian flows $K_j : T^*(\mathbb{R}^n) \to T(T^*(\mathbb{R}^n))$, $j = \overline{1,n}$, where

$$i_{K_j} \omega^{(2)} = -dH_j, \tag{1.2}$$

there exist[1,2] corresponding "action-angle"-coordinates $(\varphi, \gamma) \in (\mathbb{T}_\gamma^n, \mathbb{R}^n)$ on the torus $\mathbb{T}_\gamma^n \simeq M_h^n$, specifying its imbedding $\pi_\gamma : \mathbb{T}_\gamma^n \to T^*(\mathbb{R}^n)$ by means of a set of smooth functions $\gamma \in \mathcal{D}(\mathbb{R}^n)$, where

[a)]Electronic mail: prikarpa@wms.mat.agh.edu.pl
[b)]Electronic mail: ufuk.taneri@emu.deu.tr

$$\mathbb{T}^n_\gamma := \{(q,p) \in T^*(\mathbb{R}^n): \quad \gamma_j(h) = \gamma_j \in \mathbb{R}, \quad j = \overline{1,n}\}. \tag{1.3}$$

The induced by (1.3) mapping $\gamma: \mathbb{R}^n \ni h \to \mathbb{R}^n$ is of great interest for many applications and was studied still earlier by Picard and Fuchs subject to the corresponding differential equations it satisfies:

$$\partial \gamma_j(h)/\partial h_i = F_{ij}(\gamma; h), \tag{1.4}$$

where $h \in \mathbb{R}^n$ and $F_{ij}: \mathbb{R}^n \times \mathbb{R}^n \to \mathbb{R}$, $i,j = \overline{1,n}$, are some smooth almost everywhere functions. In the case when the right-hand side of (1.4) is a set of algebraic functions on $\mathbb{C}^n \times \mathbb{C}^n \ni (\gamma; h)$, all Hamiltonian flows $K_j: T^*(\mathbb{R}^n) \to T(T^*(\mathbb{R}^n))$, $j = \overline{1,n}$, are said to be algebraically completely integrable[3–6] in quadratures. In general equations like (1.4) were studied in Refs. 7, 3, and 8, a recent interesting example can be found in Refs. 9 and 10. It is necessary to mention here that the problem of describing integral submanifold imbedding mappings within the canonical transformation approach subject to algebraically integrable Hamiltonian systems on $T^*(\mathbb{R}^n)$ had arisen some time before in artful articles,[3,11,4,12,5] where in particular these mappings were called ''quasi-point transformations.'' The main impact into understanding the role of Picard–Fuchs equations as equations on moduli space of the corresponding algebraic curves was done by Francoise.[9,3,13] There was devised an effective differential-geometric approach to treating the corresponding integral submanifold imbedding mappings by means of specially constructed vector fields on the moduli space of algebraic curves naturally related with a given algebraically integrable Hamiltonian system. His construction was further developed and substantially improved by Tsiganov[14–16] in the framework of his general approach to separation of variables.

II. CANONICAL TRANSFORMATIONS PROPERTIES

It is clear enough that Picard–Fuchs equations (1.4) are related to the associated canonical transformation of the symplectic two-form $\omega^{(2)} \in \Lambda^2(T^*(\mathbb{R}^n))$ in a neighborhood $U(M^n_h)$ of the integral submanifold $M^n_h \subset T^*(\mathbb{R}^n)$. To make it more precise, denote $\omega^{(2)}(q,p) = dpr^*\alpha^{(1)}(q;p)$, where for $(q,p) \in T^*(\mathbb{R}^n)$

$$\alpha^{(1)}(q;p) := \sum_{j=1}^{n} p_j \, dq_j = \langle p, dq \rangle \in \Lambda^1(\mathbb{R}^n) \tag{2.1}$$

is the canonical Liouville one-form on $\mathbb{R}^n$, $\langle \cdot, \cdot \rangle$ is the usual scalar product in $\mathbb{R}^n$, $\mathrm{pr}: T^*(\mathbb{R}^n) \to \mathbb{R}^n$ is the bundle projection. One can now define a mapping

$$dS_q: \mathbb{R}^n \to T^*_q(\mathbb{R}^n), \tag{2.2}$$

such that $dS_q(h) \in T^*_q(\mathbb{R}^n)$ is an exact one-form for all $q \in M^n_h$ and $h \in \mathbb{R}^n$, yielding

$$(dS_q)^*(dpr^*\alpha^{(1)}) = (dS_q)^*\omega^{(2)} := d^2 S_q \equiv 0. \tag{2.3}$$

Thereby the mapping (2.2) defines a so-called generating function[1,2] $S_q: \mathbb{R}^n \to \mathbb{R}$, satisfying on M^n_h the relationship

$$\mathrm{pr}^*\alpha^{(1)}(q;p) + \langle t, dh \rangle = dS_q(h), \tag{2.4}$$

where $t \in \mathbb{R}^n$ is the set of evolution parameters. From (2.4) one gets right away that the equality

$$S_q(h) = \int_{q^{(0)}}^{q} \langle p, dq \rangle \Big|_{M^n_h} \tag{2.5}$$

holds for any $q,q^{(0)}\in M_h^n$. On the other hand, one can define a one more generating function $S_\mu:\mathbb{R}^n\to\mathbb{R}$, such that

$$\mathrm{d}S_\mu:\mathbb{R}^n\to T^*_\mu(M_h^n),$$

where $\mu\in M_h^n\simeq\otimes_{j=1}^n\mathbb{S}_j^1$ are global separable coordinates existing on M_h^n owing to the Liouville–Arnold theorem. Thus one can write down the following canonical relationship:

$$\langle w,\mathrm{d}\mu\rangle+\langle t,\mathrm{d}h\rangle=\mathrm{d}S_\mu(h), \tag{2.6}$$

where $w_j:=w_j(\mu_j;h)\in T^*_{\mu_j}(\mathbb{S}_j^1)$ for every $j=\overline{1,n}$. Whence one follows readily that

$$S_\mu(h)=\sum_{j=1}^n\int_{\mu_j^{(0)}}^{\mu_j}w(\lambda;h)\mathrm{d}\lambda, \tag{2.7}$$

satisfying on $M_h^n\subset T^*(\mathbb{R}^n)$ the following relationship:

$$\mathrm{d}S_\mu+\mathrm{d}\mathcal{L}_\mu=\mathrm{d}S_q|_{q=q(\mu;h)} \tag{2.8}$$

for some mapping $\mathcal{L}_\mu:\mathbb{R}^n\to\mathbb{R}$. As a result of (??) and (2.8) one gets that the following important expressions

$$t_i=\partial S_\mu(h)/\partial h_i,\quad \langle p,\partial q/\partial\mu_i\rangle=w_i+\partial\mathcal{L}_\mu/\partial\mu_i \tag{2.9}$$

hold for all $i=\overline{1,n}$. A construction similar to the above-mentioned one can be done subject to the imbedded torus $\mathbb{T}_\gamma^n\subset T^*(\mathbb{R}^n)$:

$$\mathrm{d}\tilde{S}_q(\gamma):=\sum_{j=1}^n p_j\,\mathrm{d}q_j+\sum_{i=1}^n\varphi_i\,\mathrm{d}\gamma_i, \tag{2.10}$$

where owing to (2.2) $\tilde{S}_q(\gamma):=S_q(\xi\cdot\gamma)$, $\xi\cdot\gamma(h)=h$, for all $(q;\gamma)\in U(M_h^n)$. For angle coordinates $\varphi\in\mathbb{T}_\gamma^n$ one obtains from (2.10) that

$$\varphi_i=\partial\tilde{S}_q(\gamma)/\partial\gamma_i \tag{2.11}$$

for all $i=\overline{1,n}$. As $\varphi_i\in\mathbb{R}/2\pi\mathbb{Z}$, $i=\overline{1,n}$, from (2.12) one derives that

$$\frac{1}{2\pi}\oint_{\sigma_j^{(h)}}\mathrm{d}\varphi_i=\delta_{ij}=\frac{1}{2\pi}\frac{\partial}{\partial\gamma_i}\oint_{\sigma_j^{(h)}}\mathrm{d}\tilde{S}_q(\gamma)=\frac{1}{2\pi}\frac{\partial}{\partial\gamma_i}\oint_{\sigma_j^{(h)}}\langle p,\mathrm{d}q\rangle \tag{2.12}$$

for all canonical cycles $\sigma_j^{(h)}\subset M_h^n$, $j=\overline{1,n}$, constituting a basis of the one-dimensional homology group $H^1(M_h^n;\mathbb{Z})$. Thereby, owing to (2.12), it follows that for all $i=\overline{1,n}$ "action" variables can be found as

$$\gamma_i=\frac{1}{2\pi}\oint_{\sigma_i^{(h)}}\langle p,\mathrm{d}q\rangle. \tag{2.13}$$

Recall now that $M_h^n\simeq\mathbb{T}_\gamma^n$ are diffeomorphic also to $\otimes_{j=1}^n\mathbb{S}_j^1$, where $\mathbb{S}_j^1$, $j=\overline{1,n}$, are some one-dimensional real circles. The evolution along any of vector fields $K_j:T^*(\mathbb{R}^n)\to T(T^*(\mathbb{R}^n))$, $j=\overline{1,n}$, on $M_h^n\subset T^*(\mathbb{R}^n)$ is known[17,18] to be a linear winding around the torus $\mathbb{T}_\gamma^n$, that can be interpreted also in the following way: The above-introduced independent of each other global coordinates on circles $\mathbb{S}_j^1$, $j=\overline{1,n}$, are such that the resulting evolution undergoes a quasiperiodic

motion. These coordinates—still being called Hamilton–Jacobi—prove to be very important for accomplishing the complete integrability by quadratures via solving the corresponding Picard—Fuchs type equations.

Let us denote these separable coordinates on the integral submanifold $M_h^n \simeq \otimes_{j=1}^n \mathbb{S}_j^1$ by $\mu_j \in \mathbb{S}_j^1$, $j=\overline{1,n}$, and define the corresponding imbedding mapping $\pi_h: M_h^n \to T^*(\mathbb{R}^n)$ as

$$q=q(\mu;h), \quad p=p(\mu;h). \tag{2.14}$$

Such a general kind of imbedding mappings was also considered before in Refs. 12, 17–20. There exist two important cases subject to the imbedding (2.14).

The first case is related to the integral submanifold $M_h^n \subset T^*(\mathbb{R}^n)$, which can be parametrized as a manifold by means of the base coordinates $q \in \mathbb{R}^n$ of the cotangent bundle $T^*(\mathbb{R}^n)$. This can be explained as follows: The canonical Liouville one-form $\alpha^{(1)} \in \Lambda^1(\mathbb{R}^n)$, in accordance with the diagram

$$\begin{array}{ccccc} T^*(M_h^n) & \simeq & T^*(\otimes_{j=1}^n \mathbb{S}_j^1) & \overset{\overline{\pi}_h^*}{\leftarrow} & T^*(\mathbb{R}^n) \\ \mathrm{pr}\downarrow & & \mathrm{pr}\downarrow & & \mathrm{pr}\downarrow \\ M_h^n & \simeq & \otimes_{j=1}^n \mathbb{S}_j^1 & \overset{\overline{\pi}_h}{\rightarrow} & \mathbb{R}^n \end{array} \tag{2.15}$$

is mapped by the imbedding mapping $\overline{\pi}_h = \mathrm{pr} \cdot \pi_h : M_h^n \to \mathbb{R}^n$ not depending on a set of parameters $h \in \mathbb{R}^n$, into the one-form

$$\alpha_h^{(1)} = \overline{\pi}_h^* \alpha^{(1)} = \sum_{j=1}^n w_j(\mu_j;h)\mathrm{d}\mu_j, \tag{2.16}$$

where $(\mu,w) \in T^*(\otimes_{j=1}^n \mathbb{S}_j^1) \simeq \otimes_{j=1}^n T^*(\mathbb{S}_j^1)$. The imbedding mapping $\overline{\pi}_h: M_h^n \to \mathbb{R}^n$ due to the equality (2.16) makes the function $\mathcal{L}_\mu: \mathbb{R}^n \to \mathbb{R}$ to be zero giving rise to the generating function $S_\mu: \mathbb{R}^n \to \mathbb{R}$, enjoying the condition

$$\mathrm{d}S_\mu = \mathrm{d}S_q\big|_{q=q(\mu)}, \tag{2.17}$$

where as before

$$S_\mu(h) = \sum_{j=1}^n p_j \, \mathrm{d}q_j + \sum_{j=1}^n t_j \, \mathrm{d}h_j \tag{2.18}$$

and $\det\|\partial q(\mu)/\partial\mu\| \neq 0$ almost everywhere on M_h^n for all $h \in \mathbb{R}^n$. Similarly to (2.9), one gets from (2.18) that

$$t_j = \partial S_\mu(h)/\partial h_j \tag{2.19}$$

for $j=\overline{1,n}$. Concerning the second part of the imbedding mapping (2.14) we arrive at the following simple result due to the equality (2.16):

$$p_i = \sum_{j=1}^n w_j(\mu_j;h)\partial\mu_j/\partial q_i, \tag{2.20}$$

where $i=\overline{1,n}$ and $\det\|\partial\mu/\partial q\| \neq 0$ almost everywhere on $\pi(M_h^n)$ due to the local invertibility of the imbedding mapping $\pi: M_h^n \to \mathbb{R}^n$. Thus, we can claim that the problem of complete integrability in the first case is solved if the only imbedding mapping $\pi: M_h^n \to \mathbb{R}^n \subset T^*(\mathbb{R}^n)$ is constructed. This

case was in detail considered in Ref. 21 where the corresponding Picard–Fuchs type equations were built based on a one extension of Galissot–Reeb (see the Theorem of Galissot–Reeb in Ref. 6) and modern Francoise results.[9,3,13] Namely, similar to (1.4), these equations are defined as follows:

$$\partial w_j(\mu_j;h)/\partial h_k = P_{kj}(\mu_j, w_j;h), \tag{2.21}$$

where $P_{kj}: T^*(\otimes_{j=1}^n \mathbb{S}_j^1)\times\mathbb{C}^n \to \mathbb{C}$, $k,j=\overline{1,n}$, are some algebraic functions of their arguments.

Concerning *the second case* when the integral submanifold $M_h^n \subset T^*(\mathbb{R}^n)$ *cannot be* imbedded almost everywhere into the base space $\mathbb{R}^n \subset T^*(\mathbb{R}^n)$, a relationship like (2.18) does not take place, and we are forced to consider the usual canonical transformation from $T^*(\mathbb{R}^n)$ to $T^*(\mathbb{R}^n)$ based on a mapping $d\mathcal{L}_q: \otimes_{j=1}^n \mathbb{S}_j^1 \to T^*(\mathbb{R}^n)$, where $\mathcal{L}_q: \otimes_{j=1}^n \mathbb{S}_j^1 \to \mathbb{R}$ enjoys for all $\mu \in \otimes_{j=1}^n \mathbb{S}_j^1 \simeq M_h^n \ni q$ the following relationship:

$$\mathrm{pr}^*\, \alpha^{(1)}(q;p) = \sum_{j=1}^n w_j\, d\mu_j + d\mathcal{L}_q(\mu). \tag{2.22}$$

In this case we can derive for any $\mu \in \otimes_{j=1}^n \mathbb{S}_j^1$ the introduced before hereditary generating function $\mathcal{L}_\mu: \mathbb{R}^n \to T^*(\otimes_{j=1}^n \mathbb{S}_j^1)$ as

$$d\mathcal{L}_\mu = d\mathcal{L}_q|_{q=q(\mu;h)}, \tag{2.23}$$

satisfying evidently the following canonical transformation condition:

$$dS_q(h) = \sum_{j=1}^n w_j(\mu_j;h)d\mu_j + \sum_{j=1}^n t_j\, dh_j + d\mathcal{L}_\mu(h) \tag{2.24}$$

for almost all $\mu \in \otimes_{j=1}^n \mathbb{S}_j^1$ and $h \in \mathbb{R}^n$. Based on (2.24) one can derive the following relationships:

$$\partial \mathcal{L}_\mu(h)/\partial h_j = \langle p, \partial q/\partial h_j\rangle|_{M_h^n} \tag{2.25}$$

for all $j=\overline{1,2}$, $\mu \in \otimes_{j=1}^n \mathbb{S}_j^1$ and $h \in \mathbb{R}^n$. Whence the following important analytical result

$$\begin{aligned} t_s &= \sum_{j=1}^n \int_{\mu_j^{(0)}}^{\mu_j} (\partial w_j(\lambda;h)/\partial h_s)d\lambda, \\ \sum_{j=1}^n p_j(\mu;h)(\partial q_j/\partial \mu_s) &= w_s + \partial \mathcal{L}_\mu(h)/\partial \mu_s \end{aligned} \tag{2.26}$$

holds for all $s=\overline{1,2}$ and $\mu, \mu^{(0)} \in \otimes_{j=1}^n \mathbb{S}_j^1$ with parameters $h \in \mathbb{R}^n$ being fixed. Thereby we have found a natural generalization of the relationships (2.20) subject to the extended integral submanifold imbedding mapping $\pi_h: M_h^n \to T^*(\mathbb{R}^n)$ in the form (2.14).

Assume now that functions $w_j: \mathbb{C}\times\mathbb{C}^n \to \mathbb{C}$, $j=\overline{1,n}$, satisfy in general Picard–Fuchs equations like (2.21), having due to Refs. 7, 3, 22 the following algebraic solutions:

$$w_j^{n_j} + \sum_{k=0}^{n_j-1} c_{j,k}(\lambda;h) w_j^k = 0, \tag{2.27}$$

where $c_{j,k}: \mathbb{C}\times\mathbb{C}^n \to \mathbb{C}$, $k=\overline{0,n_j-1}$, $j=\overline{1,n}$, are some polynomials in $\lambda \in \mathbb{C}$. Each algebraic curve of (2.27) is known to be in general topologically equivalent due to the Riemann theorem[7,22] to some Riemannian surface $\Gamma_h^{(j)}$ of genus $g_j \in \mathbb{Z}_+$, $j=\overline{1,n}$. Thereby, one can realize the local

diffeomorphism $\rho: M_h^n \to \otimes_{j=1}^n \Gamma_h^{(j)}$, mapping homology group basis cycles $\sigma_j^{(h)} \subset M_h^n$, $j=\overline{1,n}$, into homology subgroup $H_1(\otimes_{j=1}^n \Gamma_h^{(j)};\mathbb{Z})$ basis cycles $\sigma_j(\Gamma_h) \subset \Gamma_h^{(j)}$, $j=\overline{1,n}$, satisfying the following relationships:[23]

$$\rho(\sigma_j^{(h)}) = \sum_{k=1}^{n} n_{jk} \sigma_k(\Gamma_h), \tag{2.28}$$

where $n_{jk} \in \mathbb{Z}$, $k=\overline{1,j}$ and $j=\overline{1,n}$, are some fixed integers. Based on (2.28) and (2.23) one can write down, for instance, expressions (2.13) as follows:

$$\gamma_i = \frac{1}{2\pi} \sum_{j=1}^{n} n_{ij} \oint_{\sigma_j(\Gamma_h)} w_j(\lambda;h)\mathrm{d}\lambda, \tag{2.29}$$

where $i=\overline{1,n}$. Subject to the evolution on $M_h^n \subset T^*(\mathbb{R}^n)$ one can easily obtain from (2.25) that

$$\mathrm{d}t_i = \sum_{j=1}^{n} (\partial w_j(\mu_j;h)/\partial h_i)\mathrm{d}\mu_j \tag{2.30}$$

at $\mathrm{d}h_i = 0$ for all $i=\overline{1,n}$, giving rise evidently to a global τ parametrization of the set of circles $\otimes_{j=1}^n \mathbb{S}_j^1 \subset \otimes_{j=1}^n \Gamma_h^{(j)}$, that is one can define some inverse algebraic functions to Abelian type integrals (2.23) as

$$\mu = \mu(\tau;h), \tag{2.31}$$

where as before, $\tau=(t_1,t_2,\ldots,t_n) \in \mathbb{R}^n$ is a vector of evolution parameters. Recalling now expression (2.14) for integral submanifold mapping $\pi_h: M_h^n \to T^*(\mathbb{R}^n)$, one can at last write down final expressed by ''quadratures'' mappings for evolutions on $M_h^n \subset T^*(\mathbb{R}^n)$ as follows:

$$q = q(\mu(\tau;h)) = \tilde{q}(\tau;h), \quad p = p(\mu(\tau;h)) = \tilde{p}(\tau;h), \tag{2.32}$$

where obviously a vector $(\tilde{q},\tilde{p}) \in T^*(\mathbb{R}^n)$ is quasiperiodic in each variable $t_i \in \tau$, $i=\overline{1,n}$. Thus the following theorem holds.

Theorem 2.1: *Every completely integrable Hamiltonian system admitting an algebraic submanifold $M_h^n \subset T^*(\mathbb{R}^n)$ possesses a separable canonical transformation (2.24) which is described by differential algebraic Picard–Fuchs type equations whose solution is a set of algebraic curves (2.27).*

Therefore, the main ingredient of this scheme of integrability by quadratures is finding the Picard–Fuchs type equations (2.21) corresponding to the integral submanifold imbedding mapping (2.14) depending in general on $\mathbb{R}^n \ni h$-parameters for the case when the integral submanifold $M_h^n \subset T^*(\mathbb{R}^n)$ cannot be imbedded into the base space $\mathbb{R}^n \subset T^*(\mathbb{R}^n)$ of the phase space $T^*(\mathbb{R}^n)$.

Similar to the differential-geometric approach developed in Refs. 9, 21, and 13, one can find one-forms $h_j^{(1)} \in \Lambda^1(T^*(\mathbb{R}^n))$, $j=\overline{1,n}$, enjoying the following identity on $T^*(\mathbb{R}^n)$:

$$\omega^{(2)}(q,p) := \sum_{j=1}^{n} \mathrm{d}p_j \wedge \mathrm{d}q_j = \sum_{j=1}^{n} \mathrm{d}H_j \wedge h_j^{(1)}. \tag{2.33}$$

The one-forms $h_j^{(1)} \in \Lambda^1(T^*(\mathbb{R}^n))$, $j=\overline{1,n}$, possess the following important properties when pulled back to the integral submanifold (1.1):

$$\pi_h^* h_j^{(1)} := \overline{h_j^{(1)}} = \mathrm{d}t_j, \tag{2.34}$$

where $\overline{h_j^{(1)}} \in \Lambda^1(M_h^n)$, and $\pi_{h*}\mathrm{d}/\mathrm{d}t_j = K_j \cdot \pi_h$ for all $j=\overline{1,n}$. Expression (2.34) combined with (2.30) gives rise easily to the following set of relationships:

$$\overline{h}_j^{(1)} = \sum_{j=1}^{n} (\partial w_j(\mu_j;h)/\partial h_i)\mathrm{d}\mu_j \tag{2.35}$$

at $\mathrm{d}h_j = 0$ for all $j = \overline{1,n}$ on $M_h^n \otimes_{j=1}^n \mathbb{S}_j^1 \subset \otimes_{j=1}^n \Gamma_h^{(j)}$ for all $j = \overline{1,n}$. Since we are interested in the integral submanifold imbedding mapping (2.11) being locally diffeomorphic in a neighborhood $U(M_h^n) \subset T^*(\mathbb{R}^n)$, the Jacobian $\det\|\partial q(\mu;h)/\partial\mu\| \neq 0$ almost everywhere in $U(M_h^n)$. On the other hand, as was shown in Refs. 9, 21, and 13, the set of one-forms $\overline{h}_j^{(1)} \in \Lambda^1(M_h^n)$, $j = \overline{1,n}$, can be, in general, represented in $U(M_h^n)$ as

$$\overline{h}_j^{(1)} = \sum_{k=1}^{n} \overline{h}_{jk}^{(1)}(q,p)\mathrm{d}q_k|_{M_h^n}, \tag{2.36}$$

where $\overline{h}_{jk}^{(1)} : T^*(\mathbb{R}^n) \to \mathbb{R}$, $k,j = \overline{1,n}$, are some algebraic expressions of their arguments. Thereby, one easily finds from (2.36) and (2.35) that

$$\partial w_i(\mu_i;h)/\partial h_j = \sum_{k=1}^{n} \overline{h}_{jk}^{(1)}(q(\mu;h),p(\mu;h))(\partial q_k(\mu;h)/\partial\mu_i) \tag{2.37}$$

for all $i,j = \overline{1,n}$. Subject to p-variables in (2.37) we must owing to (2.26) use the expressions

$$\begin{gathered} \sum_{j=1}^{n} p_j(\mu;h)(\partial q_j/\partial\mu_s) = w_s + \partial\mathcal{L}_\mu(h)/\partial\mu_s, \\ \partial\mathcal{L}_\mu(h)/\partial h_j = \langle p, \partial q/\partial h_j\rangle|_{M_h^n}, \end{gathered} \tag{2.38}$$

being true for $s = \overline{1,n}$ and all $\mu \in \otimes_{j=1}^n \mathbb{S}_j$, $h \in \mathbb{R}^n$ in the neighborhood $U(M_h^n) \subset T^*(\mathbb{R}^n)$ chosen before. Thereby, we arrived at the following form of (2.37):

$$\partial w_i(\mu_i;h)/\partial h_j = \overline{P}_{ji}(\mu,w;h), \tag{2.39}$$

where for all $i,j = \overline{1,n}$,

$$\overline{P}_{ji}(\mu,w;h) := \sum_{k=1}^{n} \overline{h}_{jk}^{(1)}(q(\mu;h),p(\mu;h))\partial q_k/\partial\mu_i) \tag{2.40}$$

depend correspondingly only on $\overset{<(i)}{\neq h} \ni (\mu_i,w_i)$-variables for each $i \in \{\overline{1,n}\}$ and all $j = \overline{1,n}$. This condition can be evidently written down as follows:

$$\partial\overline{P}_{ji}(\mu,w;h)/\partial\mu_k = 0 \tag{2.41}$$

for $j,i \neq k \in \{\overline{1,n}\}$ at almost all $\mu \in \otimes_{j=1}^n \mathbb{S}_j^1$ and $h \in \mathbb{R}^n$. The set of conditions (2.37) gives rise in general to a system of algebraic-differential equations subject to the imbedding mapping $\mathrm{pr}\,\pi_h : M_h^n \to \mathbb{R}^n$ defined analytically by (2.14) and the generating function (2.23). As a result of solving these equations we obtain, evidently owing to (2.39) and (2.41), the following system of Picard–Fuchs type equations:

$$\partial w_i(\mu_i;h)/\partial h_j = P_{ji}(\mu_i,w_i;h) \tag{2.42}$$

where, in general, the mappings

$$P_{ji} : \Gamma_h^{(i)} \times \mathbb{R}^n \to \mathbb{C} \tag{2.43}$$

are some algebraic expressions. Since the set of algebraic curves (2.27) must enjoy the Picard–Fuchs type system (2.42), we can retrieve this set just solving them. The latter gives rise due to (2.25) and (2.14) to the integrability of all flows on $M_h^n \subset T^*(\mathbb{R}^n)$ by quadratures as was mentioned in Sec. 1.

Theorem 2.2: *Let there be given a completely integrable Hamiltonian system on the coadjoint manifold $T^*(\mathbb{R}^n)$ whose integral submanifold $M_h^n \subset T^*(R^n)$ is described by Picard–Fuchs type algebraic equations (2.42). The corresponding imbedding mapping $\pi_h : M_h^n \to T^*(R^n)$ (2.14) is a solution of a compatibility condition subject to the differential-algebraic relationships (2.41) on the canonical transformations generating function (2.23).*

In the following we shall show that the scheme described previously really leads to an algorithmic procedure of constructing the Picard–Fuchs type equations (2.42) and the corresponding integral submanifold imbedding mappings $\pi_h : M_h^n \to T^*(\mathbb{R}^n)$ in the form (2.14) applying it to the so called Henon–Heiles and truncated Focker–Plank Hamiltonian systems on the canonically symplectic cotangent space $T^*(\mathbb{R}^2)$.

III. EXAMPLES

A. The Henon–Heiles system

This flow is governed by the Hamiltonian

$$H_1 = \tfrac{1}{2}p_1^2 + \tfrac{1}{2}p_2^2 + q_1 q_2^2 + \tfrac{1}{3}q_1^3 \tag{3.1}$$

on the canonically symplectic phase space $M^4 = T^*(\mathbb{R}^2)$ with the symplectic structure

$$\omega^{(2)} = \sum_{j=1}^{2} \mathrm{d}p_j \wedge \mathrm{d}q_j . \tag{3.2}$$

As is well known, there exists the following additional invariant that commutes with (3.1):

$$H_2 = p_1 p_2 + 1/3 q_2^3 + q_1^2 q_2 , \tag{3.3}$$

that is $\{H_1, H_2\} = 0$ on the entire space M^4. Put $H_j = h_j \in \mathbb{R}$, $j = \overline{1,2}$, thereby defining the integral submanifold

$$M_h^2 := \{(q,p) \in M^4 : h(H_j) = h_j \in \mathbb{R}, j = \overline{1,2}\},$$

if compact and connected, being diffeomorphic to the standard torus $\mathbb{T}^2 \simeq \mathbb{S}^1 \times \mathbb{S}^1$ owing to the Liouville–Arnold theorem. One can therefore find cyclic (separable) coordinates $\mu_j \in \mathbb{S}^1$, $j = \overline{1,2}$, on the torus $\mathbb{T}^2$ such that the symplectic structure (6.2) will take the form:

$$\omega^{(2)} = \sum_{j=1}^{2} \mathrm{d}w_j \wedge \mathrm{d}\mu_j , \tag{3.4}$$

where the conjugate variables $w_j \in T^*(\mathbb{S}^1)$, $j = \overline{1,2}$, on M_h^2 depend only on the corresponding variables $\mu_j \in \mathbb{S}_j^1$, $j = \overline{1,2}$. In this case it is evident that the evolution along M_h^2 will be separable and representable by means of quasiperiodic functions of the evolution parameters. To show this, recall that the fundamental determining equations (2.41) are based on the one-forms $\overline{h}_j^{(1)} \in \Lambda(M_h^2)$, $j = \overline{1,2}$, satisfying the identity

$$\sum_{j=1}^{2} \mathrm{d}H_j \wedge_j \overline{h}_j^{(1)} = \sum_{j=1}^{2} \mathrm{d}p_j \wedge \mathrm{d}q_j . \tag{3.5}$$

Here

$$\overline{h}_j^{(1)}=\sum_{k=1}^{2}\overline{h}_{jk}(q,p)\mathrm{d}q_k, \tag{3.6}$$

where $j=\overline{1,2}$. Substituting (3.7) into (3.6), one obtains

$$\overline{h}_1^{(1)}=\frac{p_1\mathrm{d}q_1}{p_1^2-p_2^2}+\frac{p_2\mathrm{d}q_2}{p_1^2-p_2^2},\quad \overline{h}_2^{(1)}=\frac{p_2\mathrm{d}q_1}{p_{21}^2-p_1^2}+\frac{p_1\mathrm{d}q_2}{p_1^2-p_2^2}. \tag{3.7}$$

On the other hand, the following implication holds on $M_h^2\subset M^4$:

$$\alpha_h^{(1)}=\sum_{j=1}^{2}w_j(\mu_j;h)\mathrm{d}\mu_j\Rightarrow\sum_{j=1}^{2}p_j\,\mathrm{d}q_j:=\alpha^{(1)}, \tag{3.8}$$

where we have assumed that the integral submanifold M_h^2 admits the local coordinates in the base manifold $\mathbb{R}^2$ endowed with the canonical one-form $\alpha_h^{(1)}\in\Lambda(M_h^2)$ as given in (3.9). Thus, making use of the imbedding mapping $\pi_h:M_h^2\to T^*(\mathbb{R}^2)$ in the form

$$q_j=q_j(\mu),\quad p_j=p_j(\mu), \tag{3.9}$$

$j=\overline{1,2}$, one readily finds that the equalities

$$p_j=\sum_{k=1}^{2}w_k(\mu_k;h)\partial\mu_k/\partial q_j \tag{3.10}$$

hold for $j=\overline{1,2}$ on the entire integral submanifold M_h^2.

Substituting (3.11) into (3.8) and using the characteristic relationships (2.41), one obtains after simple but cumbersome calculations the following differential-algebraic expressions:

$$\partial q_1/\partial\mu_1-\partial q_2/\partial\mu_1=0,\quad \partial q_1/\partial\mu_2+\partial q_2/\partial\mu_2=0, \tag{3.11}$$

whose simplest solutions are

$$q_1=(\mu_1+\mu_2)/2,\quad q_2=(\mu_1-\mu_2)/2. \tag{3.12}$$

Using (3.11) one finds that

$$p_1=w_1+w_2,\quad p_2=w_1-w_2, \tag{3.13}$$

where

$$w_1=\sqrt{h_1+h_2-4/3\mu_1^3},\quad w_2=\sqrt{h_1-h_2-4/3\mu_2^3}. \tag{3.14}$$

Consequently, one obtains the separable[11,17,14] Hamiltonian functions (3.1) and (3.3) in some open vicinity of the cotangent space $T^*(M_h^2)$:

$$h_1=\tfrac{1}{2}w_1^2+\tfrac{1}{2}w_2^2+\tfrac{2}{3}(\mu_1^3+\mu_2^3),\quad h_2=\tfrac{1}{2}w_1^2-\tfrac{1}{2}w_2^2+\tfrac{2}{3}(\mu_1^3-\mu_2^3), \tag{3.15}$$

which generate the following separable motions on $M_h^2\subset T^*(\mathbb{R}^2)$:

$$\begin{aligned}\mathrm{d}\mu_1/\mathrm{d}t&:=\partial h_1/\partial w_1=\sqrt{h_1+h_2-4/3\mu_1^3},\\ \mathrm{d}\mu_2/\mathrm{d}t&:=\partial h_1/\partial w_2=\sqrt{h_1-h_2-4/3\mu_2^3}\end{aligned} \tag{3.16}$$

for the Hamiltonian (3.1), and

$$\begin{aligned} \mathrm{d}\mu_1/\mathrm{d}x &:= \partial h_2/\partial w_1 = \sqrt{h_1+h_2-4/3\mu_1^3}, \\ \mathrm{d}\mu_2/\mathrm{d}t &:= \partial h_1/\partial w_2 = -\sqrt{h_1-h_2-4/3\mu_2^3} \end{aligned} \tag{3.17}$$

for the Hamiltonian (3.3), where $x,t\in\mathbb{R}$ are the corresponding evolution parameters.

Analogously, one can show that there exists[12,17,18,20] an integral submanifold imbedding mapping in the form (2.14) for the following integrable modified Henon–Heiles involutive system:

$$\begin{aligned} H_1 &= \tfrac{1}{2}p_1^2+\tfrac{1}{2}p_2^2+q_1q_2^2+\tfrac{16}{3}q_1^3, \\ H_2 &= 9p_2^4+36q_1p_2^2q_2^2-12p_1p_2q_2^3-2q_2^4(q_2^2+6q_1^2), \end{aligned} \tag{3.18}$$

where $\{H_1,H_1\}=0$ on the entire phase space $M^4=T^*(\mathbb{R}^2)$. Based on considerations similar to the above-mentioned ones, one can deduce the following[17,18,20] expressions:

$$\begin{aligned} q_1 &= -\frac{1}{4}(\mu_1+\mu_2)-\frac{3}{8}\left(\frac{w_1+w_2}{\mu_1-\mu_2}\right)^2, \\ q_2^2 &= -2\sqrt{h_2}/(\mu_1-\mu_2), \quad w_1=\sqrt{2/3\mu_1^3-4/3\sqrt{h_2}-8h_1}, \\ p_1 &= \frac{1}{2\sqrt{-6(\mu_1+\mu_2+4q_1)}}\left[\frac{-2\sqrt{h_2}}{\mu_1-\mu_2}-\mu_1\mu_2+4(\mu_1+\mu_2)q_1+32q_1^2\right], \\ p_2 &= \sqrt{h_2}(\mu_{1+}\mu_2+4q_1)/(3(\mu_{1-}\mu_2)), \quad w_2=\sqrt{2/3\mu_2^3+4/3\sqrt{h_2}-8h_1}, \end{aligned} \tag{3.19}$$

thereby solving explicitly the problem of finding the corresponding integral submanifold imbedding $\pi_h: M_h^2\to T^*(\mathbb{R}^2)$ that generates separable flows in the variables $(\mu,w)\in T^*(M_h^2)$.

B. A four-dimensional truncated Focker–Plank Hamiltonian system

Let us consider the flow

$$\left.\begin{aligned} \mathrm{d}q_1/\mathrm{d}t = p_1+\alpha(q_1+p_2)(q_2+p_1), \quad \mathrm{d}q_2/\mathrm{d}t = p_2, \\ \mathrm{d}p_1/\mathrm{d}t = -(q_1+p_2)-\alpha[q_2p_1+1/2(p_1^2+p_2^2+q_2^2)], \\ \mathrm{d}p_2/\mathrm{d}t = -(q_2+p_1), \end{aligned}\right\} = K_1(q,p), \tag{3.20}$$

where $K_1: T^*(\mathbb{R}^2)\to T(T^*(\mathbb{R}^2))$ is the corresponding vector field on $T^*(\mathbb{R}^2)\ni(q,p)$, $t\in\mathbb{R}$ is an evolution parameter, called a truncated four-dimensional Focker–Plank flow. It is easy to verify that functions $H_j: T^*(\mathbb{R}^2)\to\mathbb{R}$, $j=\overline{1,2}$, where

$$H_1 = 1/2(p_1^2+p_2^2+q_1^2)+q_1p_2+\alpha(q_1+p_2)[q_2p_1+1/2(p_1^2+p_2^2+q_2^2)] \tag{3.21}$$

and

$$H_2 = 1/2(p_1^2+p_2^2+q_2^2)+q_2p_1 \tag{3.22}$$

are functionally independent invariants with respect to the flow (3.21). Moreover, the invariant (3.21) is the Hamiltonian function for (3.21), that is the relationship

$$i_{k_1}\omega^{(2)} = -\mathrm{d}H_1 \tag{3.23}$$

holds on $T^*(\mathbb{R}^2)$, where the symplectic structure $\omega^{(2)}\in\Lambda^2(T^*(\mathbb{R}^2))$ is given as follows:

$$\omega^{(2)} := \mathrm{d}pr^*\alpha^{(1)} = \sum_{j=1}^{2} \mathrm{d}p_j \wedge \mathrm{d}q_j, \tag{3.24}$$

with $\alpha^{(1)} \in \Lambda^1(\mathbb{R}^2)$ being the canonical Liouville form on $\mathbb{R}^2$:

$$\alpha^{(1)}(q;p) = \sum_{j=1}^{2} p_j \, \mathrm{d}q_j \tag{3.25}$$

for any $(q,p) \in T^*(\mathbb{R}^2) \simeq \Lambda^1_q(\mathbb{R}^2)$.

The invariants (3.22) and (3.23) evidently commute with each other subject to the associated Poisson bracket on $T^*(\mathbb{R}^2)$:

$$\{H_1, H_2\} = 0. \tag{3.26}$$

Thereby, owing to the Abelian Liouville–Arnold theorem[1,2] the dynamical system (3.21) is completely integrable by quadratures on $T^*(\mathbb{R}^2)$, and we can apply the scheme devised in Sec. II to the commuting invariants (3.22) and (3.23) subject to the symplectic structure (3.25). One easily calculates that

$$\omega^{(2)} = \sum_{i=1}^{2} \mathrm{d}H_i \wedge h_i^{(1)}, \tag{3.27}$$

where the corresponding one-forms $\pi_h^* h_i^{(1)} := \overline{h}_i^{(1)} \in \Lambda^1(M_h^2)$, $i = \overline{1,2}$, are given as

$$\begin{aligned} \overline{h}_1^{(1)} &= \frac{p_2 \mathrm{d}q_1 - (p_1+q_2)\mathrm{d}q_2}{p_1p_2 - (p_1+q_2)(q_1+p_2) - \alpha h_2(p_1+q_2)}, \\ \overline{h}_2^{(1)} &= \frac{-[(q_1+p_2)(1+\alpha p_2)+\alpha h_2]\mathrm{d}q_1 + (p_1+\alpha[h_2+(q_2+p_1)(q_1+p_2)])\mathrm{d}q_2}{p_1p_2 - (q_2+p_1)(\alpha h_2 + q_1 + p_2)}, \end{aligned} \tag{3.28}$$

and an invariant submanifold $M_h^2 \subset T^*(\mathbb{R}^2)$ is defined as

$$M_h^2 := \{(q,p) \in T^*(\mathbb{R}^2) : H_i(q,p) = h_i \in \mathbb{R}, i = \overline{1,2}\} \tag{3.29}$$

for some parameters $h \in \mathbb{R}^2$. Based now on expressions (3.29) and (2.37) one can easily construct functions $\overline{P}_{ij}(w;h)$, $i,j = \overline{1,2}$, in (2.39), defined on $T^*(M_h^2) \simeq T^*(\otimes_{j=1}^2 \mathbb{S}_j^1)$ subject to the integral submanifold imbedding mapping $\pi_h : M_h^2 \to T^*(\mathbb{R}^2)$ in coordinates $\mu \in \otimes_{j=1}^2 \mathbb{S}_j^1 \subset \otimes_{j=1}^2 \Gamma_h^{(j)}$, which we do not write down in detail due to their a bit long and cumbersome form. Having applied then the criterion (2.41), we arrive at the following compatibility relationships subject to the mappings $q : (\otimes_{j=1}^2 \mathbb{S}_j^1) \times \mathbb{R}^2 \to \mathbb{R}^2$ and $p : (\otimes_{j=1}^2 \mathbb{S}_j^1) \times \mathbb{R}^2 \to T_q^*(\mathbb{R}^2)$:

$$\begin{aligned} &\partial q_1 / \partial \mu_1 - \partial q_2 / \partial \mu_2 = 0, \\ &\partial w_1 / \partial h_1 (\partial q_1 / \partial h_1) = \partial w_2 / \partial h_1 (\partial q_2 / \partial h_1), \\ &\partial w_1 / \partial h_2 (\partial q_1 / \partial h_2) = \partial w_2 / \partial h_2 (\partial q_2 / \partial h_2), \\ &w_1 \partial w_1 / \partial h_1 - w_2 \partial w_2 / \partial h_2 = 0, \\ &\partial (w_1 \partial w_1 / \partial h_2) / \partial \mu_1 + \alpha \partial q_1 / \partial \mu_1 = 0 \end{aligned} \tag{3.30}$$

and so on, for all $\mu \in \otimes_{j=1}^2 \mathbb{S}_j^1$. Solving equations like (3.11), one can find right away that

$$p_1 = w_1, \quad p_2 = w_2,$$

$$q_1 = c_1 + \mu_1 - w_2(\mu_1;h), \qquad (3.31)$$
$$q_2 = c_2 + \mu_2 - w_1(\mu_2;h),$$

where $c_j(h_1,h_2) \in \mathbb{R}^1$, $j=\overline{1,2}$, are constant, hold on $T^*(M_h^2)$, giving rise to the following Picard–Fuchs type equations in the form (2.42):

$$\begin{gathered}\partial w_1(\mu_1;h)/\partial h_1 = 1/w_1,\\ \partial w_1(\mu_1;h)/\partial h_2 = -\alpha/\mu_1,\\ \partial w_2(\mu_2;h)/\partial h_1 = 0,\\ \partial w_2(\mu_2;h)/\partial h_2 = 1/w_2.\end{gathered} \qquad (3.32)$$

The Picard–Fuchs equations (3.33) can be easily integrated by quadratures as follows:

$$\begin{gathered}w_1^2 + k_1(\mu_1) - 2h_1 = 0,\\ w_2^2 + k_2(\mu_2) - 2h_2 = 0,\end{gathered} \qquad (3.33)$$

where $k_j : \mathbb{S}_j^1 \to \mathbb{C}$, $j=\overline{1,2}$ are still unknown functions. For the to be determined explicitly, it is necessary to substitute (3.12) into expressions (3.22) and (3.23), making use of (3.34) that amounts to the following results:

$$k_1 = \mu_1^2 + \alpha h_2, \quad k_2 = \mu_2^2 \qquad (3.34)$$

under the condition that $c_1=0$, $c_2=0$. Thereby, we have constructed, owing to (3.34), the corresponding (2.27) algebraic curves $\Gamma_h^{(j)}$, $j=\overline{1.2}$, in the explicit form:

$$\begin{gathered}\Gamma_h^{(1)} := \{(\lambda, w_1) : w_1^2 + \lambda^2 + \lambda h_2 - 2h_1) = 0\},\\ \Gamma_h^{(2)} := \{(\lambda, w_2) : w_2^2 + \lambda^2 - 2h^2 = 0\},\end{gathered} \qquad (3.35)$$

where $(\lambda, w_j) \in \mathbb{C}\times\mathbb{C}$, $j=\overline{1,2}$, and $h \in \mathbb{R}^2$ are arbitrary parameters. Making use now of expressions (3.36) and (3.32), one can construct in explicit form the integral submanifold imbedding mapping $\pi_h : M_h^2 \to T^*(\mathbb{R}^2)$ for the flow (3.21):

$$\begin{gathered}q_1 = \mu_1 - \sqrt{2h_2 - \mu_2^2}, \quad p_1 = w_1(\mu_1;h),\\ q_2 = \mu_2 - \sqrt{2h_1 - 2h_2\mu_1 - \mu_1^2}, \quad p_2 = w_2(\mu_2;h),\end{gathered} \qquad (3.36)$$

where $(\mu, w) \in \otimes_{j=1}^2 \Gamma_h^{(j)}$. As was mentioned before in Sec. II, (3.37) together with explicit expressions like (2.26) make it possible right away to find solutions to the truncated Focker–Plank flow (3.21) by quadratures, thereby completing its integrability.

ACKNOWLEDGMENTS

The authors are thankful to Professor D. Blackmore and Professor A. Pelczar for discussions on their seminars and to Professor J. Tavantzis for collaboration during the International ICIAM Congress held in Edinburg. Part of this work was prepared when A.P. was visiting the Faculty of Arts and Sciences at the EMU of Gazimagusa, Cyprus.

Asymptotic expansion of ${}_2F_1(a,b;c;x)$ in terms of confluent hypergeometric functions

Marita C. Chidichimo[a] and Michael D. Thorsley
Department of Applied Mathematics, University of Waterloo, Ontario N2L 3G1, Canada

(Received 21 May 2001; accepted for publication 13 August 2001)

We have developed a new asymptotic formula for ${}_2F_1(a,b;c;x)$ in which a and c are finite, $|b|$ tends to infinity and the argument x tends to zero. We make use of this result to obtain asymptotic expansions of the electric dipole ($E1$) *quantal differential* excitation function for the adiabaticity parameter $\xi=\eta_f-\eta_i$ and the Sommerfeld parameter η_f tending to infinity simultaneously, while the parameter η_i remains finite. © *2001 American Institute of Physics.*

I. INTRODUCTION

The motivation and some of the groundwork for the present article derive from an earlier article,[1] henceforth referred to as I.

We begin our discussion with the quantal expression[2,3] of the differential excitation function,

$$\mathrm{d}f_{E1}(\theta,\eta_i,\xi)=\frac{8\pi^3\eta_i\eta_f}{9\xi^2}\frac{e^{\mp\pi|\xi|}}{\sinh(\pi\eta_i)\sinh(\pi\eta_f)}\frac{d}{dx}\left(-x\frac{d}{dx}|{}_2F_1(-i\eta_i,-i\eta_f;1;x)|^2\right)\mathrm{d}\Omega, \tag{1.1}$$

which determines the angular distribution of inelastically scattered particles in Coulomb excitation.[4,5] We make explicit the distinction between the repulsive and attractive cases by writing ξ as $\mp|\xi|$. We can convert the repulsive case ($\eta_i>0$) to the attractive case ($\eta_i<0$) by simply switching the signs of η_i, η_f and ξ. The total effect of this transformation is to replace the factor of $\exp(-\pi|\xi|)$, for repulsive potentials, by a factor of $\exp(+\pi|\xi|)$ for attractive potentials. The argument x is defined by

$$x=-\frac{4\eta_i\eta_f}{\xi^2}\sin^2\left(\frac{\theta}{2}\right), \tag{1.2}$$

where θ is the deflection angle of the scattered particle. Gauss' hypergeometric function ${}_2F_1(a,b;c;z)$ is defined by

$${}_2F_1(a,b;c;z)=\sum_{n=0}^{\infty}\frac{(a)_n(b)_n}{n!(c)_n}z^n \tag{1.3}$$

within the circle of convergence of this series ($|z|<1$) and by analytic continuation elsewhere. We will henceforth omit the subscripts and write ${}_2F_1(\cdots)$ simply as $F(\cdots)$. The dimensionless Sommerfeld parameter η_i is defined by

$$\eta_i=\frac{Z_1Z_2\mathrm{e}^2}{\hbar v_i}=Z_1Z_2\sqrt{\frac{M}{E_i}}, \tag{1.4}$$

where $Z_1(Z_2)$ is the charge number of the projectile (atomic system), v_i is the relative velocity, M is the reduced mass in electron-mass units, and E_i is the initial kinetic energy of relative motion measured in Rydbergs (13.6 eV). The dimensionless adiabaticity parameter ξ is defined by

[a]Electronic mail. mchidich@math.uwaterloo.ca

$$\xi=\eta_f-\eta_i=\eta_i\left[\left(1-\frac{E_{if}}{E_i}\right)^{-1/2}-1\right]=Z_1Z_2\sqrt{\frac{M}{E_i}}\left[\left(1-\frac{E_{if}}{E_i}\right)^{-1/2}-1\right], \tag{1.5}$$

where the indices i and f refer to the initial and final states, respectively, and $E_{if}=E_i-E_f$. In order to evaluate Eq. (1.1), we first expand the derivatives

$$\begin{aligned}\frac{d}{dx}\left(-x\frac{d}{dx}|F|^2\right)&=\frac{d}{dx}\left[-x\frac{d}{dx}(FF^*)\right]=\frac{d}{dx}\left[-x\left(\frac{dF}{dx}F^*+F\frac{dF^*}{dx}\right)\right]=-\left[\frac{dF}{dx}F^*+F\frac{dF^*}{dx}\right]\\&\quad-x\left[\frac{d^2F}{dx^2}F^*+2\frac{dF}{dx}\frac{dF^*}{dx}+F\frac{d^2F}{dx^2}\right]=-2\mathbf{Re}\left(\frac{dF}{dx}F^*\right)-2x\mathbf{Re}\left(\frac{d^2F}{dx^2}F^*\right)\\&\quad-2x\left|\frac{dF}{dx}\right|^2.\end{aligned} \tag{1.6}$$

We notice that $F^*(a,b;c;z)=F(a^*,b^*;c^*;z^*)$, so that

$$F^*(-i\eta_i,-i\eta_f;1;x)=F(i\eta_i,i\eta_f;1;x). \tag{1.7}$$

With this in place, we can perform the differentiation using equation 15.2.2 of Ref. 6,

$$\frac{d^n}{dz^n}{}_2F_1(a,b;c;z)=\frac{(a)_n(b)_n}{c_n}{}_2F_1(a+n,b+n;c+n;z), \tag{1.8}$$

to obtain

$$\begin{aligned}df_{E1}(\theta,\eta_i,\xi)&=\frac{8\pi^3(\eta_i\eta_f)^2}{9\xi^2}\frac{e^{\mp\pi|\xi|}}{\sinh(\pi\eta_i)\sinh(\pi\eta_f)}\times\{2\mathbf{Re}[F(1-i\eta_i,1\\&\quad-i\eta_f;2;x)F(i\eta_i,i\eta_f;1;x)]+x[\mathbf{Re}\{(1-i\eta_i)(1-i\eta_f)\\&\quad\times F(2-i\eta_i,2-i\eta_f;3;x)F(i\eta_i,i\eta_f;1;x)\}\\&\quad-2\eta_i\eta_f|F(1-i\eta_i,1-i\eta_f;2;x)|^2]\}d\Omega.\end{aligned} \tag{1.9}$$

Using Gauss' relations for contiguous functions and eq. 15.3.3 of Ref. 6 in the previous equation yields

$$\begin{aligned}df_{E1}(\theta,\eta_i,\xi)&=\frac{16\pi^3(\eta_i\eta_f)^2}{9\xi^2}\frac{e^{\mp\pi|\xi|}}{\sinh(\pi\eta_i)\sinh(\pi\eta_f)}\times\left\{\mathbf{Re}\left[\left(1+\frac{4\eta_i\eta_f\sin^2(\theta/2)}{\xi^2}\right)^{1-i(\eta_i+\eta_f)}\right.\right.\\&\quad\times[(1-i\eta_f)\times F(1-i\eta_i,2-i\eta_f;2;x)F(1-i\eta_i,1-i\eta_f;2;x)\\&\quad+i\eta_fF^2(1-i\eta_i,1-i\eta_f;2;x)]-\left(1+\eta_f{}^2+(1-i\eta_i)(1-i\eta_f)\frac{4\eta_i\eta_f\sin^2(\theta/2)}{\xi^2}\right)\\&\quad\times F(1-i\eta_i,2-i\eta_f;2;x)F(1+i\eta_i,1+i\eta_f;2;x)+i\eta_f(1+i\eta_f)\\&\quad\left.\times\left(1+\frac{4\eta_i\eta_f\sin^2(\theta/2)}{\xi^2}\right)\times F(1+i\eta_i,2+i\eta_f;2;x)F(1-i\eta_i,1-i\eta_f;2;x)\right]\\&\quad+(1+\eta_f^2)\left(1+\frac{4\eta_i\eta_f\sin^2(\theta/2)}{\xi^2}\right)|F(1-i\eta_i,2-i\eta_f;2;x)|^2\\&\quad\left.+\eta_f^2|F(1-i\eta_i,1-i\eta_f;2;x)|^2\right\}d\Omega.\end{aligned} \tag{1.10}$$

It is now possible to take the limit as $\theta\to0$ in Eqs. (1.9) and (1.10), respectively, provided we also assume that $\xi\neq0$, i.e., the collision is inelastic. Under these conditions $x=0$, and since all of the hypergeometric functions then have the value of unity, we obtain the following result

$$df_{E1}(\theta=0,\eta_i,\xi)=\frac{16}{9}\frac{\pi^3(\eta_i\eta_f)^2}{\xi^2}\frac{e^{\mp\pi|\xi|}}{\sinh(\pi\eta_i)\sinh(\pi\eta_f)}\,d\Omega. \tag{1.11}$$

In the limiting case $E_f\to 0$ and $\theta\neq 0$, the parameters η_f, ξ both tend to ∞ simultaneously, whereas the parameter η_i remains finite and the argument $x\to 0$. We first obtain an expansion for the ordinary hypergeometric function in terms of confluent hypergeometric functions. One should be aware that some leading and first-order terms cancel out in the subexpressions of Eq. (1.10), and quadratic factors in ξ mean that the second-order terms in ξ^{-1} become important as $\xi\to\infty$.

We used the symbolic computation program MAPLE VI[7] in order to carry out the algebra in this work. Numerical results of Eq. (1.10), for moderate values of ξ, obtained with MAPLE and the FORTRAN code written by Burgess[8] agree to six-decimal figures.

II. EXPANSION FOR HYPERGEOMETRIC FUNCTION

It is well-known (Ref. 9 §2.3.2 and §6.1, Ref. 10 §1.1, and Ref. 11 §3.1) that

$$\lim_{b\to\infty}F\left(a,b;c;\frac{z}{b}\right)={}_1F_1(a,c;z), \tag{2.1}$$

where ${}_1F_1(a,c;z)$ is the confluent hypergeometric function.

We now derive a second-order correction to this result.

By definition

$$F\left(a,b;c;\frac{z}{b}\right)=\sum_{n=0}^{\infty}\frac{(a)_n}{(c)_n n!}z^n\frac{(b)_n}{b^n}, \tag{2.2}$$

but, as was discussed in paper I (§II of Ref. 1)

$$\frac{(b)_n}{b^n}=\prod_{r=1}^{n-1}\left(1+\frac{r}{b}\right)=1+\frac{1}{2}n(n-1)\frac{1}{b}+n(n-1)\left[\frac{1}{3}(n-2)+\frac{1}{8}(n-2)(n-3)\right]\frac{1}{b^2}+\cdots, \tag{2.3}$$

so

$$F\left(a,b;c;\frac{z}{b}\right)=\sum_{n=0}^{\infty}\frac{(a)_n}{(c)_n n!}z^n\left\{1+\frac{1}{2}n(n-1)\frac{1}{b}+n(n-1)\left[\frac{1}{3}(n-2)+\frac{1}{8}(n-2)(n-3)\right]\frac{1}{b^2}\right\}$$
$$+\cdots. \tag{2.4}$$

Interchanging the two summations, we see that the first term sums to $f(z)={}_1F_1(a,c;z)$. To sum the second, third and fourth terms, we note that

$$z^2f''(z)=\sum_{n=0}^{\infty}n(n-1)\frac{(a)_n}{(c)_n n!}z^n,$$

$$z^3f'''(z)=\sum_{n=0}^{\infty}n(n-1)(n-2)\frac{(a)_n}{(c)_n n!}z^n, \tag{2.5}$$

$$z^4f^{(4)}(z)=\sum_{n=0}^{\infty}n(n-1)(n-2)(n-3)\frac{(a)_n}{(c)_n n!}z^n.$$

We can use the differentiation formula (equation 13.4.9 of Ref. 6) to obtain the following expressions for $f''(z)$, $f'''(z)$ and $f^{(4)}(z)$:

$$f''(z)=\frac{d^2}{dz^2}{}_1F_1(a,c;z)=\frac{a(a+1)}{c(c+1)}{}_1F_1(a+2,c+2;z),$$

$$f'''(z)=\frac{d^3}{dz^3}{}_1F_1(a,c;z)=\frac{a(a+1)(a+2)}{c(c+1)(c+2)}{}_1F_1(a+3,c+3;z), \tag{2.6}$$

$$f^{(4)}(z)=\frac{d^4}{dz^4}{}_1F_1(a,c;z)=\frac{a(a+1)(a+2)(a+3)}{c(c+1)(c+2)(c+3)}{}_1F_1(a+4,c+4;z).$$

So, we have the asymptotic expression

$$F\left(a,b;c;\frac{z}{b}\right)\sim{}_1F_1(a,c;z)+\frac{a(a+1)}{c(c+1)}\frac{z^2}{2}{}_1F_1(a+2,c+2;z)\frac{1}{b}+\left[\frac{a(a+1)(a+2)}{c(c+1)(c+2)}\frac{z^3}{3}{}_1F_1(a+3,\right.$$

$$\left.c+3;z)+\frac{a(a+1)(a+2)(a+3)}{c(c+1)(c+2)(c+3)}\frac{z^4}{8}{}_1F_1(a+4,c+4;z)\right]\frac{1}{b^2}, \tag{2.7}$$

for $|b|$ large.

III. SPECIALIZATION TO THE PRESENT CASE

Equations (1.9) and (1.10) have hypergeometric functions with the following form

$$F(\alpha-i\eta_i,\beta-i\eta_f;\gamma;x)=F(\alpha-i\eta,\beta-i(\eta+\xi);\gamma;x), \tag{3.1}$$

or those of the form

$$F(\alpha+i\eta_i,\beta+i\eta_f;\gamma;x)=F(\alpha+i\eta,\beta+i(\eta+\xi);\gamma;x). \tag{3.2}$$

The form (3.1) may be converted to that of (3.2) by making the substitution $\eta\rightarrow-\eta$ and $\xi\rightarrow-\xi$. For this reason, we concern ourselves with expanding only the form (3.1) and make use of this transformation in order to deal with the form (3.2).

Applying (2.7) to (3.1) gives

$$\begin{aligned}F(\alpha-i\eta,\beta-i(\eta+\xi);\gamma;x)\sim{}&{}_1F_1(\alpha-i\eta,\gamma;z)+\frac{(\alpha-i\eta)(\alpha+1-i\eta)}{2\gamma(\gamma+1)}z^2\\&\times{}_1F_1(\alpha+2-i\eta,\gamma+2;z)\frac{1}{\beta-i(\eta+\xi)}\\&+\left\{\frac{(\alpha-i\eta)(\alpha+1-i\eta)(\alpha+2-i\eta)}{3\gamma(\gamma+1)(\gamma+2)}z^3\right.\\&\times{}_1F_1(\alpha+3-i\eta,\gamma+3;z)\\&+\frac{(\alpha-i\eta)(\alpha+1-i\eta)(\alpha+2-i\eta)(\alpha+3-i\eta)}{8\gamma(\gamma+1)(\gamma+2)(\gamma+3)}z^4\\&\left.\times{}_1F_1(\alpha+4-i\eta,\gamma+4;z)\right\}\frac{1}{[\beta-i(\eta+\xi)]^2},\end{aligned} \tag{3.3}$$

where

$$z=[\beta-i(\eta+\xi)]x,$$

and the argument x is defined by Eq. (1.2). The term z is a nonconstant function of ξ. Thus, in addition to the limiting process associated with the expansion of the hypergeometric function, there are additional terms associated with the variation of z as $\xi\to\infty$. We note that

$$z=4i\eta\sin^2\left(\frac{\theta}{2}\right)-4(\beta-2i\eta)\sin^2\left(\frac{\theta}{2}\right)\frac{\eta}{\xi}-4(\beta-i\eta)\sin^2\left(\frac{\theta}{2}\right)\frac{\eta^2}{\xi^2}. \tag{3.4}$$

We also expand, to second-order in powers of ξ^{-1}, quantities related to z and x and obtain

$$\begin{aligned} zx &\sim -16i\frac{\eta^2}{\xi}\sin^4\left(\frac{\theta}{2}\right)+16\frac{\eta^2}{\xi^2}(\beta-3i\eta)\sin^4\left(\frac{\theta}{2}\right),\\ zx^2 &\sim 64i\frac{\eta^3}{\xi^2}\sin^6\left(\frac{\theta}{2}\right),\\ zx^3 &\sim -256\frac{\eta^4}{\xi^2}\sin^8\left(\frac{\theta}{2}\right). \end{aligned} \tag{3.5}$$

Using the differentiation formula (13.4.9) of Ref. 6 and expanding the hypergeometric functions in Eq. (3.3) as a Taylor series about $z_0=4i\eta\sin^2(\theta/2)$, leads to the asymptotic behavior

$$\begin{aligned} F(\alpha-i\eta,\beta-i(\eta+\xi);\gamma;x)\sim{}& {}_1F_1(\alpha-i\eta,\gamma;z_0)-4\frac{\eta}{\xi}\sin^2\left(\frac{\theta}{2}\right)\frac{(\alpha-i\eta)}{\gamma}\Bigg\{(\beta-2i\eta){}_1F_1(\alpha+1\\ &-i\eta,\gamma+1;z_0)+2i\eta\sin^2\left(\frac{\theta}{2}\right)\frac{(\alpha+1-i\eta)}{(\gamma+1)}{}_1F_1(\alpha+2-i\eta,\gamma\\ &+2;z_0)\Bigg\}+4\frac{\eta^2}{\xi^2}\sin^2\left(\frac{\theta}{2}\right)\frac{(\alpha-i\eta)}{\gamma}\Bigg\{-(\beta-i\eta){}_1F_1(\alpha+1-i\eta,\gamma\\ &+1;z_0)+2\sin^2\left(\frac{\theta}{2}\right)(\beta-2i\eta)^2\frac{(\alpha+1-i\eta)}{(\gamma+1)}{}_1F_1(\alpha+2-i\eta,\gamma\\ &+2;z_0)+2\sin^2\left(\frac{\theta}{2}\right)\frac{(\alpha+1-i\eta)}{\gamma+1}\Bigg[(\beta-3i\eta){}_1F_1(\alpha+2-i\eta,\gamma\\ &+2;z_0)+4i\eta\sin^2\left(\frac{\theta}{2}\right)(\beta-2i\eta)\frac{(\alpha+2-i\eta)}{(\gamma+2)}{}_1F_1(\alpha+3-i\eta,\gamma\\ &+3;z_0)\Bigg]+8\eta\sin^4\left(\frac{\theta}{2}\right)\frac{(\alpha+1-i\eta)(\alpha+2-i\eta)}{(\gamma+1)(\gamma+2)}\Bigg[i\frac{2}{3}{}_1F_1(\alpha+3\\ &-i\eta,\gamma+3;z_0)-\eta\sin^2\left(\frac{\theta}{2}\right)\frac{(\alpha+3-i\eta)}{(\gamma+3)}{}_1F_1(\alpha+4-i\eta,\gamma\\ &+4;z_0)\Bigg]\Bigg\}, \end{aligned} \tag{3.6}$$

for $\eta/\xi\ll 1$.

IV. APPLICATION TO DIPOLE EXCITATION FUNCTION

Upon applying the asymptotic expansion of the hypergeometric function [Eq. (3.6)] to Eq. (1.10) we find, for an attractive Coulomb field, the zeroth-order approximation

$$
\begin{aligned}
df_{E1}(\theta,\eta,\xi\to\infty)=\frac{64}{9}\pi^3\eta^2\exp(-2\pi\eta)[1-\exp(-2\pi\eta)]^{-1}\times\Bigg[\mathbf{Re}\Bigg\{\exp\Bigg[-4i\eta\sin^2\left(\frac{\theta}{2}\right)\Bigg]\\
\times\Bigg[({}_1F_1(1-i\eta,2;z_0))^2+2i\eta(1-i\eta)\sin^2\left(\frac{\theta}{2}\right){}_1F_1(2-i\eta,3;z_0){}_1F_1(1\\
-i\eta,2;z_0)\Bigg\}\Bigg]-2\eta\sin^2\left(\frac{\theta}{2}\right)\mathbf{Re}\{i(1+i\eta){}_1F_1(2+i\eta,3;-z_0){}_1F_1(1-i\eta,2;z_0)\}\\
-8\eta^2\sin^4\left(\frac{\theta}{2}\right)\mathbf{Re}\{(1+i\eta){}_1F_1(2+i\eta,3;-z_0){}_1F_1(1-i\eta,2;z_0)\}\\
+4\eta^2\sin^2\left(\frac{\theta}{2}\right)[|{}_1F_1(1-i\eta,2;z_0)|^2+(1+\eta^2)|{}_1F_1(2-i\eta,3;z_0)|^2]\Bigg]d\Omega, \quad (4.1)
\end{aligned}
$$

where $z_0=4i\eta\sin^2(\theta/2)$.

Using the leading order of Eq. (3.6) in Eq. (1.9) gives the equivalent limit of the exact quantal excitation function as $\xi\to\infty$,

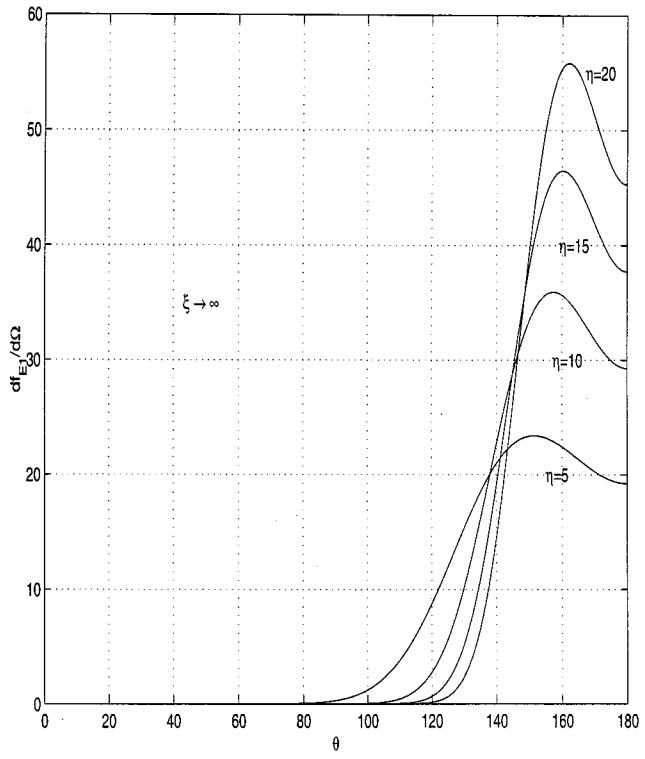

FIG. 1. Asymptotic differential excitation function for an attractive Coulomb field. The functions $df_{E1}(\theta,\eta,\xi\to\infty)/d\Omega$ are plotted as a function of θ for fixed values of η. As $\eta\to\infty$ the function becomes more and more sharply peaked, eventually attaining the singular behavior of the semiclassical approximation.

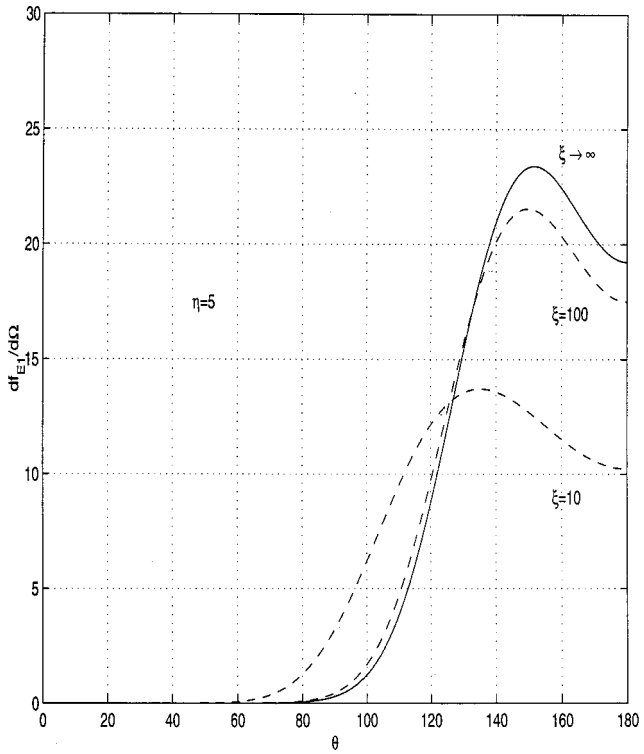

FIG. 2. Differential excitation functions, for an attractive Coulomb field, plotted as a function of θ. $--$, functions $\mathrm{d}f_{E1}(\theta,\eta=5,\xi)/\mathrm{d}\Omega$ for fixed values of ξ; $-$, asymptotic function $\mathrm{d}f_{E1}(\theta,\eta=5,\xi\to\infty)/\mathrm{d}\Omega$.

$$df_{E1}(\theta,\eta,\xi\to\infty)=\frac{64}{9}\,\pi^3\eta^2\exp(-2\pi\eta)[1-\exp(-2\pi\eta)]^{-1}\times\mathbf{Re}\Big\{{}_1F_1(1-i\eta,2;z_0)\,{}_1F_1(i\eta,1;$$
$$-z_0)+2i\eta(1-i\eta)\sin^2\left(\frac{\theta}{2}\right)\,{}_1F_1(2-i\eta,3;z_0)\times{}_1F_1(i\eta,1;-z_0)$$
$$+4\eta^2\sin^2\left(\frac{\theta}{2}\right)|{}_1F_1(1-i\eta,2;z_0)|^2\Big\}\,\mathrm{d}\Omega. \tag{4.2}$$

At this point, we can easily take the limit as $\theta\to 0$ in Eqs. (4.1) and (4.2), and the result is

$$df_{E1}(\theta=0,\eta,\xi\to\infty)=\tfrac{64}{9}\,\pi^3\eta^2\exp(-2\pi\eta)[1-\exp(-2\pi\eta)]^{-1}, \tag{4.3}$$

which is identical to Eq. (1.11), taken in the limit as $\xi\to\infty$. In the repulsive case, the excitation function is everywhere 0, as $\xi\to\infty$. This is expected, since, in that case, the projectile wave function is excluded from being very near the target by the Coulomb barrier. Equations (4.1) and (4.2) are also finite at $\theta=\pi$.

In Fig. 1 we present results for the quantal differential excitation function, using the asymptotic expression [Eq. (4.1)], for different values of the parameter η. As $\eta\to\infty$, the function becomes more and more sharply peaked, eventually attaining the singular behavior of the semiclassical approximation, viz.,

$$\frac{\mathrm{d}f_{E1}}{\mathrm{d}\Omega}(\theta,\eta\to\infty,\xi\to\infty)=\begin{cases}0, & 0\leqslant\theta<\pi,\\ \infty, & \theta=\pi.\end{cases} \tag{4.4}$$

In Fig. 2, we show values of the exact expression [Eq. (1.10)], for $\eta=5$ and different values

of the parameter ξ, and the asymptotic expression [Eq. (4.1)]. In the limit of large values for ξ, the differential excitation function approaches values obtained using the *asymptotic* differential function.

Recently the authors have developed a method [SIAM J. Appl. Math. **61**, 1839–1556 (2001)] capable of solving, in closed form, boundary value problems for four-phase doubly periodic checkerboard composites with continuity between the different phases. The method is based upon a novel conformal mapping that preserves the doubly periodic nature of the physical problem. The aim of the current article is to explore generalizations of that approach where we now replace continuity between some phases by nonconducting or perfectly conducting strips, thereby modeling debonding or electrodes in electrochemical devices. The specific objective is to determine effective resistivities and related parameters for these four-phase objects in a concise and explicit form. © *2001 American Institute of Physics.* [DOI: 10.1063/1.1398336]

I. INTRODUCTION

We shall consider doubly periodic boundary value problems in electrostatics, or other analogous subjects whose underlying governing equation is Laplace's equation. There are many applications in physics: heat transfer, electrostatics, flow in porous media and composite materials; explicit closed-form solutions for model structures are useful benchmarks and can demonstrate theoretical ideas and relations useful either for refining numerical work, or of interest in their own right. We concentrate upon checkerboard structures, and in each repeating checkerboard cell we shall have distinct differing phases and we aim to calculate effective properties, such as effective resistivities and dissipation, when the medium is subjected to some external applied field. Since the problems are harmonic, the most natural approach is to use complex variable techniques; however, there is a fundamental difficulty in that it is very difficult to satisfy all the continuity or boundary conditions between the distinct phases while simultaneously maintaining the periodicity conditions. It is this difficulty that our efforts have been focused upon.

If we have, say, a two-phase material and one phase is perfectly conducting, or of infinite resistivity, then much progress can be made using standard conformal mapping techniques[1] or the method of images.[2] But outside these limits, distinct phases pose a considerable challenge and the only exact solutions to boundary value problems, and corresponding formulas for effective properties, of this doubly periodic class are the classical Rayleigh[3] and Maxwell[4] solutions, and for checkerboard two-phase geometries previous analyses exist for square,[5] or rectangular,[6,7] cells. These checkerboard analyses rest upon solving complicated Markushevich conjugate Riemann–Hilbert problems. Recently the authors[8,9] have bypassed this approach and have been able to consider three- and four-phase rectangular checkerboard geometries. This enabled the present authors to prove the Mortola and Steffé[10] conjecture for the effective resistivities of a four-phase square checkerboard structure as an interesting subcase of rectangular checkerboards. Square checkerboards have the advantage of some additional geometrical symmetry, and for two phases this has led to the well-known geometric mean law and generalizations that emerge from using

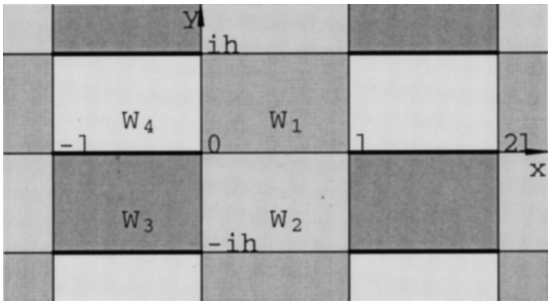

FIG. 1. The geometry for a doubly periodic four-phase checkerboard with a nonconducting strip, the thicker lines lying along $-l<x<0$, $y=\pm nh$, $n=0,1,...$, inserted between phases 3 and 4.

reciprocal relations.[11–13] Very recently Milton[14] extended this approach to also prove the Mortola and Steffé conjecture using a method completely independent of ours.

Our recent approach rests upon a piece of mathematical origami using conformal mapping into a simple object, on a two-sheeted Riemann surface, from the doubly periodic boundary value problem. The purpose of the present article is to explore this further, by considering some phases to be separated by nonconducting or perfectly conducting slits, thereby modeling delamination or electrochemical devices,[15] albeit in a simple model.

It should also be mentioned that an analytical approach using complex analysis is by no means the only avenue open for tackling this type of problem. Estimates of effective parameters are important in several areas of physics and engineering, thus numerical,[16–18] asymptotic,[19] network analogies,[20] variational bounds,[21] and other approaches complementary to ours have been developed, although in most cases two-phase structures have been considered, and the insertion of nonconducting or superconducting strips is a further complication that appears not to have been attempted. In some cases these approaches allow extensions to nonlinear composites.[22] Nonetheless, it is important and, we think, interesting to have some benchmark closed-form solutions available.

II. FORMULATION

We begin from the governing equations for a static electric field $\mathbf{E}$: $\nabla\cdot(\sigma\mathbf{E})=0$, $\nabla\times\mathbf{E}=0$, with the conductivity, σ, constant in each homogeneous region; hereon we exclusively use the language of electrostatics. Then at an interface between dissimilar media we have no jump in the tangential component of the field or the normal component of the current density leading to: $[\![\sigma E_n]\!]=0$, $[\![E_t]\!]=0$, where the $[\![\ ]\!]$ denote jumps in a quantity and the subscripts t, n denote tangential and normal components of the field, $\mathbf{E}=(E_n,E_t)$. As the conductivity, σ, is constant in each cell we can define a potential ϕ such that $\mathbf{E}=-\nabla\phi$ and thus $\nabla^2\phi=0$; ϕ is harmonic and this motivates the complex variable approach.

We choose to use a vector $\mathbf{w}=\sigma\mathbf{E}$, and thus $\nabla\cdot\mathbf{w}=0$, $\nabla\times(\rho\mathbf{w})=0$, with ρ as the resistivity, constant in each cell. The vector $\mathbf{w}$ has interface conditions $[\![\rho w_t]\!]=0$, $[\![w_n]\!]=0$. In each phase, distinguished by the subscript k where we number the phases clockwise and $k=1,...,4$, we find it is most convenient to utilize complex variables, that is, $z=x+iy$ and $w_k(z)=w_{kx}-iw_{ky}$ where $\mathbf{w}_k=(w_{kx},w_{ky})$.

In each problem that we shall consider we apply mean fluxes, a, b in (2.1), across each cell (see for instance the geometry of Fig. 1), $W=[-l,l]\times[-h,h]$, and then calculate the effective resistivities, $\rho_{x,y}$ as defined in (2.2), that in turn can be utilized to find the dissipation and a resistivity tensor. In our evaluations we take integrals for the effective resistivities along the axes themselves, although there is no loss of generality in doing so. That is, ρ_y is the same if calculated as the integral from $y=-h$ to $y=h$ for any $-l<x<l$, and similarly for ρ_x integrated over $x=-l,l$ for $-h<y<h$. This has some bearing upon our later analysis as we shall, for nonconducting boundary conditions along $-l<x<0$, $y=\pm nh$, have three unknowns and apparently only

two imposed mean fluxes; the extra constraint is that the potential, ϕ, is continuous at the ends of the nonconducting strips and thus ρ_x is independent of y. A similar constraint holds for superconducting strips.

For the applied mean fluxes we use $\nabla \cdot \mathbf{w}_k = 0$ in each subcell, with the divergence theorem to show that

$$\int_{W'} \nabla \cdot \mathbf{w}_k \, dV = \int_{S'} \mathbf{w}_k \cdot \mathbf{n} \, dS = 0$$

for any closed surface S' enclosing area W', with outward pointing normal $\mathbf{n}$, within a subcell W_k. Utilizing the continuity conditions across each cell (or $w_y = 0$ on $-l < x < 0$, $y = \pm nh$ for the nonconducting strips) it is clear that

$$\int_{S''} \mathbf{w}_k \cdot \mathbf{n} \, dS = 0$$

with S'' as a closed surface within the cell. After utilizing the double periodicity, it is evident that the mean fluxes a and b defined as

$$a = \frac{1}{2h} \int_{-h}^{h} \mathrm{Re}[w_k(x+iy)] dy, \quad b = \frac{1}{2l} \int_{-l}^{l} \mathrm{Im}[w_k(x+iy)] dx, \tag{2.1}$$

are independent of $x = x_0$ and $y = y_0$, for x_0, y_0 constant, respectively, which is a statement of conservation of charge in each cell.

For the effective resistivities we first define vectors $\mathbf{q}_k = (\rho_k w_{ky}, -\rho_k w_{kx})$ in each phase and, from $\nabla \times (\rho_k \mathbf{w}_k) = 0$, noting that $\nabla \cdot \mathbf{q}_k = 0$, we have

$$\int_{S''} \mathbf{q}_k \cdot \mathbf{n} \, dS = 0$$

around the whole cell. Strictly speaking we should subdivide the region into the subcells, but again continuity means that all those contributions disappear. Utilizing the periodicity and continuity at the edges of the cell, the effective resistivities ρ_x and ρ_y defined as

$$\rho_x = \frac{1}{2la} \int_{-l}^{l} \mathrm{Re}[\rho_k w_k(x+iy)] \, dx, \quad \rho_y = \frac{1}{2hb} \int_{-h}^{h} \mathrm{Im}[\rho_k w_k(x+iy)] \, dy, \tag{2.2}$$

are independent of $y = y_0$ and $x = x_0$ (for x_0, y_0 constant), respectively. If we insert nonconducting strips along $-l < x < 0$, $y = \pm nh$, then

$$\rho_x|_{y_0>0} - \rho_x|_{y_0<0} = [\phi(0,y)]_{y=0-}^{y=0+} - [\phi(-l,y)]_{y=0-}^{y=0+}, \tag{2.3}$$

and from continuity of ϕ this is zero and ρ_x is still independent of y. We use this constraint as an additional condition that our later solution must obey.

Thus, trivially, we have the effective resistivity tensor ρ as

$$\rho = \int_W \rho_k w_k(z) \, dV \Big/ \int_W w_k(z) \, dV \equiv \frac{a\rho_x - ib\rho_y}{a - ib}. \tag{2.4}$$

To calculate the dissipation we define vectors $\mathbf{p}_k$ in each phase as $\mathbf{p}_k = -(\phi w_{kx}, \phi w_{ky})$; notably $\nabla \cdot \mathbf{p}_k = \rho_k (w_{kx}^2 + w_{ky}^2)$ and thus using the divergence theorem, double periodicity, and the conditions across the phases, the dissipation is

$$D=\frac{1}{4lh}\int_W \rho_k |w_k(z)|^2 \,\mathrm{d}V=\frac{1}{4lh}\int_S \mathbf{p}_k\cdot\mathbf{n}\,\mathrm{d}S, \tag{2.5}$$

where S is the boundary of the whole cell enclosing area W. Using periodicity across the cell,

$$4lhD=-\int_{-h}^{h}[\,\phi(x,y)\,]_{x=-l}^{x=l} w_x\,\mathrm{d}y-\int_{-l}^{l}[\,\phi(x,y)\,]_{y=-h}^{y=h} w_y\,\mathrm{d}x, \tag{2.6}$$

and the jumps in the potential across the cell follow from the definition of ρ_x, ρ_y and the dissipation is found to be

$$D=a^2\rho_x+b^2\rho_y. \tag{2.7}$$

These reductions of the resistivity tensor and dissipation to line integrals mean that these are quite general results for doubly periodic systems and the explicit evaluation of various area integrals is unnecessary.

Thus for four-phase rectangular checkerboards, with each phase a different constant resistivity and connected via continuity conditions, for which we have previously calculated[8] ρ_x and ρ_y as

$$\rho_x=\frac{\sigma(\lambda,1-m)}{\sigma(\lambda,m)}\left[\frac{(\rho_2+\rho_3)(\rho_4+\rho_1)}{(\rho_1+\rho_2)(\rho_3+\rho_4)}\right]^{1/2}\left(\frac{\sigma_3}{\sigma_1}\right)^{1/2}, \tag{2.8}$$

$$\rho_y=\frac{\sigma(\lambda,m)}{\sigma(\lambda,1-m)}\left[\frac{(\rho_1+\rho_2)(\rho_3+\rho_4)}{(\rho_2+\rho_3)(\rho_4+\rho_1)}\right]^{1/2}\left(\frac{\sigma_3}{\sigma_1}\right)^{1/2}, \tag{2.9}$$

the dissipation and resistivity now follow instantly; the Mortola and Steffé conjecture is proved by setting $l=h\mapsto m=\frac{1}{2}$ in Eqs. (2.8) and (2.9). These general formulas depend upon the resistivities and the geometry in a nontrivial manner and contain several functions and parameters that require definition: The parameters $\sigma_{1,\ldots,4}$ (σ_2, σ_4 are required later) are given entirely in terms of the resistivities as

$$\begin{gathered}\sigma_1=\rho_1+\rho_2+\rho_3+\rho_4,\quad \sigma_2=\rho_1\rho_3-\rho_2\rho_4,\\ \sigma_3=\rho_1\rho_2\rho_3+\rho_1\rho_2\rho_4+\rho_1\rho_3\rho_4+\rho_2\rho_3\rho_4,\quad \sigma_4=\rho_1^2(\rho_2+\rho_3)+\rho_2^2(\rho_1+\rho_4).\end{gathered} \tag{2.10}$$

An important parameter in the general formulas is $\sigma(\lambda,m)$ defined as

$$\sigma(\lambda,m)=\frac{(2/\pi)K(m)}{P_{\lambda/2-1/2}(1-2m)}, \tag{2.11}$$

wherein we use the Legendre function of the first kind, $P_\nu(1-2m)$, and $K(m)$ is the complete elliptic integral of the first kind with m implicitly defined from $K(m)/K(1-m)=l/h$. The ratio $\sigma(\lambda,m)/\sigma(\lambda,1-m)$ is ubiquitous in the expressions associated with effective parameters and is

$$\frac{\sigma(\lambda,m)}{\sigma(\lambda,1-m)}=\frac{l}{h}\frac{P_{\lambda/2-1/2}(2m-1)}{P_{\lambda/2-1/2}(1-2m)}; \tag{2.12}$$

the geometric dependence in this ratio is encapsulated in the l/h terms and, of course, in m, and the material dependence in each phase is encapsulated in λ defined from

$$\cos\pi\lambda=1-2\Delta^2,\quad \Delta^2=\frac{\sigma_2^2}{\sigma_1\sigma_3+\sigma_2^2}. \tag{2.13}$$

Similar functions and parameters also appear in later calculations.

III. INTERFACIAL GENERALIZATION

Our previous article[8] was a progression from earlier works on checkerboards,[5–7] but we developed the novel concept[9] that much of the previous analysis could be sidestepped by a conformal mapping at the outset of the analytical work. In all of these papers the basic geometry consists of two-, three-, or four-phase rectangles all linked by continuity across their adjoining interfaces. However, real materials in contact may debond due to applied stresses, or thermal stresses during/after fabrication, and the net effect may be to alter these continuity conditions. An extreme example would be to have a nonconducting (or super-conducting) barrier appear between some of the phases. We model this in order to assess the importance of the interface conditions upon the formulas for the effective parameters, and also to assess how easily we can generalize our earlier study.

A. The mapping

We consider the geometry shown in Fig. 1 where four phases exist, but between the phases labeled as 3 and 4 there lies a nonconducting barrier, or for Sec. III C a superconducting strip.

We can map this checkerboard geometry, together with the periodicity conditions, into four joined quarter planes on a two-sheeted Riemann surface. As in our earlier papers[8,9] we search for a doubly periodic function that maps horizontal boundaries to adjoining segments of the real axis in the ζ plane and, in addition, maps the vertical boundaries to the imaginary axis in the ζ plane. If we can achieve this, then we can simply solve a basic four-quarter plane solution and deduce the checkerboard solution. The mapping required is[8,9]

$$\zeta(z)=\left[\frac{1-\mathrm{cn}([2K(m)z/l]|m)}{1+\mathrm{cn}([2k(m)z/l]|m)}\right]^{1/2}, \tag{3.14}$$

where the cn are the Jacobi elliptic cosinus functions. For more details on these functions, see, for instance, Ref. 23. This mapping is built using the initial mapping of the rectangular region consisting of four cells into a four-quarter plane structure using the elliptic sinus

$$\mathrm{sn}\left(\frac{K(m)z}{l}\middle|m\right).$$

But importantly this does not map the continuity conditions on the vertical boundaries correctly, and a further manipulation of this is required that leads to (3.14). The noteworthy feature of this mapping is that we get a two-sheeted Riemann surface, where the boundary conditions on each overlying interface are the same on each sheet. This is important as it allows us to utilize a simpler solution for four joined quarter planes. If this were not the case, we would be severely hampered, and it is not clear if such problems would be solvable. An example would be to consider the same geometry, but to omit alternating nonconducting barriers, that is, remove those at $y=\pm 2nh$ for n integer. Further details of the required mapping can be found in Ref. 8.

B. Basic solution

For four joined quarter planes, with a nonconducting barrier inserted along the negative real axis, and in terms of our complex variable approach, the boundary conditions are that

$$\mathrm{Im}[i(\rho_1 w_1(x)-\rho_2 w_2(x))]=0, \quad \mathrm{Im}[w_1(x)-w_2(x)]=0, \quad \text{on } 0<x<\infty, \tag{3.15}$$

$$\mathrm{Im}[w_3(x)]=\mathrm{Im}[w_4(x)]=0, \quad \text{on} -\infty<x<0, \tag{3.16}$$

$$\mathrm{Im}[i(w_4(\mathrm{i}y)-w_1(\mathrm{i}y))]=0, \quad \mathrm{Im}[\rho_4 w_4(\mathrm{i}y)-\rho_1 w_1(\mathrm{i}y)]=0, \quad \text{on } 0<y<\infty, \tag{3.17}$$

$$\mathrm{Im}[i(w_2(\mathrm{i}y)-w_3(\mathrm{i}y))]=0, \quad \mathrm{Im}[\rho_2 w_2(\mathrm{i}y)-\rho_3 w_3(\mathrm{i}y)]=0, \quad \text{on } -\infty<y<0. \tag{3.18}$$

Following Appendix A of Ref. 8 with minor changes, the solution is found by solving a Riemann–Hilbert problem for four joined quarter planes, and the solution emerges as

$$w_k(\zeta)=C_0 w_{k0}+C_1 A_k(\lambda^{(nc)})\zeta^{\lambda^{(nc)}}+C_2\overline{A_k(\lambda^{(nc)})}\zeta^{-\lambda^{(nc)}},\quad k=1,...,4. \tag{3.19}$$

There is considerable notation embedded within this closed form solution. Since we have three sets of solutions and formulas associated with either continuous interface conditions, or with inserted superconducting, nonconducting strips, we introduce a superscript notation to distinguish them; we use (nc) and (c) for nonconducting and superconducting cases, respectively, and we do not label the formulas for the continuous case.

The general solution (3.19) contains arbitrary real constants C_0, C_1, C_2, to be determined in terms of the applied mean fluxes and continuity of ϕ, and the w_{k0} are explicitly

$$w_{10}=w_{40}=\rho_2,\quad w_{20}=w_{30}=\rho_1.$$

The powers $\lambda^{(nc)}$ follow from

$$e^{\mp i\pi\lambda^{(nc)}}=\frac{\sigma_3-\sigma_4\mp 2i\sqrt{\sigma_3\sigma_4}}{\sigma_3+\sigma_4}, \tag{3.20}$$

where $0<\lambda^{(nc)}\leqslant 1$. The $A_k(\lambda^{(nc)})$ are

$$\begin{aligned} A_1(\lambda^{(nc)})&=\frac{\rho_2\sigma_2-\mathrm{i}\sqrt{\sigma_3\sigma_4}}{\sigma_3+\sigma_4},\quad A_2(\lambda^{(nc)})=\frac{\rho_1\sigma_2-\mathrm{i}\sqrt{\sigma_3\sigma_4}}{\sigma_3+\sigma_4},\\ A_3(\lambda^{(nc)})&=-\mathrm{e}^{\mathrm{i}\pi\lambda^{(nc)}}\frac{\rho_2}{\rho_2+\rho_3},\quad A_4(\lambda^{(nc)})=\mathrm{e}^{-\mathrm{i}\pi\lambda^{(nc)}}\frac{\rho_1}{\rho_1+\rho_4}. \end{aligned} \tag{3.21}$$

Given this general solution we use the doubly periodic mapping (3.14) to perform the mathematical origami folding this four joined quarter plane solution into the doubly periodic cells. Thus (3.19) is the solution to the doubly periodic problem, but with $\zeta(z)$ given by (3.14) and the three unknown constants $C_{0,1,2}$ that we need to determine. We do this by prescribing mean fluxes a and b and using continuity of ϕ which leads to ρ_x being independent of y. We also require various integrals from Obnosov,[6] which we use freely.

The upshot, after some algebra, is that

$$\begin{aligned} C_0&=\frac{2a}{(\rho_1+\rho_2)+\alpha(m)\sigma_2},\quad C_{1,2}=a\,\frac{\alpha(m)(\sigma_3+\sigma_4)}{[(\rho_1+\rho_2)+\alpha(m)\sigma_2]}\,\frac{\sigma(\lambda^{(nc)},1-m)}{(\rho_1+\rho_2)}\\ &\quad\mp b\sqrt{\frac{\sigma_3+\sigma_4}{\sigma_4}}\,\sigma(\lambda^{(nc)},m), \end{aligned} \tag{3.22}$$

where

$$\alpha(m)=\frac{\sigma(\lambda^{(nc)},m)}{\sigma(\lambda^{(nc)},1-m)}\,\frac{\sigma_2}{\sqrt{\sigma_3(\sigma_3+\sigma_4)}}.$$

C. Perfectly conducting strips

A doubly periodic array of perfectly conducting strips inserted between the phases could be used to model arrays of microelectrodes,[15] and is a simple extension of the last section. If we now replace the nonconducting strips by perfect conductors (electrodes), we need only change the boundary conditions on $-\infty<x<0$ to $\mathrm{Im}(iw_3)=0$, $\mathrm{Im}(iw_4)=0$, in the simplified quarter plane problem (3.15)–(3.18). The general solution of the problem has the same form as (3.19), but now

$$w_{10}=w_{20}=\mathrm{i}\rho_3\rho_4, \quad w_{30}=\mathrm{i}\rho_2\rho_4, \quad w_{40}=\mathrm{i}\rho_1\rho_3$$

and

$$A_1(\lambda^{(c)})=\frac{\beta\sqrt{\rho_1\rho_2\sigma_1}-\mathrm{i}\rho_1\sigma_2}{\rho_1(\rho_1+\rho_2)(\rho_2+\rho_3)}, \quad A_2(\lambda^{(c)})=\frac{\beta\sqrt{\rho_1\rho_2\sigma_1}-\mathrm{i}\rho_2\sigma_2}{\rho_2(\rho_1+\rho_2)(\rho_2+\rho_3)},$$

$$A_3(\lambda^{(c)})=-\mathrm{i}\frac{(\rho_1+\rho_4)}{(\rho_2+\rho_3)}\mathrm{e}^{\mathrm{i}\pi\lambda^{(c)}}, \quad A_4(\lambda^{(c)})=\mathrm{i}\mathrm{e}^{-\mathrm{i}\pi\lambda^{(c)}},$$

with

$$\beta=\sqrt{\sigma_3+\sigma_4-\rho_1\rho_2\sigma_1}.$$

The powers in the general solution change to

$$\mathrm{e}^{\mp\mathrm{i}\pi\lambda^{(c)}}=\frac{\rho_1\rho_2\sigma_1-\beta^2\mp 2\mathrm{i}\beta\sqrt{\rho_1\rho_2\sigma_1}}{\sigma_3+\sigma_4}, \tag{3.23}$$

and the superscript (c) used here denotes those solutions, and formulas, associated with perfectly conducting strips. If the full solution is required to, for instance, draw lines of equipotential, one also requires the constants

$$C_0=2b\frac{\rho_1+\rho_2}{\beta^2}, \quad C_{1,2}=\frac{\rho_2+\rho_3}{\beta}\sqrt{\frac{\rho_1\rho_2}{\sigma_1}}\left(a\sigma(1-m)\mp b\sigma(m)\frac{\sigma_2(\rho_1+\rho_2)}{\beta\sqrt{\sigma_3+\sigma_4}}\right). \tag{3.24}$$

D. Effective properties

Given the general solution together with the constants (3.22) and (3.24), we can evaluate the effective resistivities using the definitions (2.2), the first of which gives

$$\rho_x^{(nc)}=\frac{\sigma_4}{[\rho_1+\rho_2+\alpha(m)\sigma_2](\rho_1+\rho_2)}, \quad \rho_x^{(c)}=\frac{\rho_1\rho_2}{(\rho_1+\rho_2)}\frac{\sigma(\lambda^{(c)},1-m)}{\sigma(\lambda^{(c)},m)}\left[\frac{\sigma_3+\sigma_4}{\rho_1\rho_2\sigma_1}\right]^{1/2}. \tag{3.25}$$

The first of these, $\rho_x^{(nc)}$, is quite different from the situation with continuous interface conditions, ρ_x, as the factor $\sigma(\lambda^{(nc)},1-m)/\sigma(\lambda^{(nc)},m)$ is now embedded within the formula $\rho_x^{(nc)}$, rather than as a rescaling prefactor, which implies a more involved dependence upon the cell dimensions h and l. Another notable point is that, for the continuous cases, $\rho_{x,y}$, there exists a solution independent of the aspect ratio, h/l; this emerges if $\rho_1\rho_3=\rho_2\rho_4$ as then $\lambda=0$. For this relation between the resistivities the solution for $\rho_x^{(nc)}$ is also independent of l/h. For $\rho_y^{(nc)}$ the prefactor $\sigma(\lambda^{(nc)},1-m)/\sigma(\lambda^{(nc)},m)$ emerges again and we find that

$$\rho_y^{(nc)}=\frac{\sigma(\lambda^{(nc)},m)}{\sigma(\lambda^{(nc)},1-m)}\left[\frac{(\rho_1+\rho_2)\sigma_3}{(\rho_1+\rho_4)(\rho_3+\rho_4)}\right]^{1/2},$$

$$\rho_y^{(c)}=\frac{(\rho_1+\rho_2)^2}{\beta^2}\left(\rho_3\rho_4+\frac{\sigma_2^2}{(\rho_1+\rho_2)}\frac{\sigma(m)}{\sigma(1-m)}\sqrt{\frac{\rho_1\rho_2}{\sigma_1(\sigma_3+\sigma_4)}}\right) \tag{3.26}$$

with no aspect ratio independence for $\rho_1\rho_3=\rho_2\rho_4$. If ρ_3 (or ρ_4) $\to\infty$, that is, one of the phases sandwiched between the nonconducting strips is itself completely nonconducting, then the expressions $\rho_{x,y}$ and $\rho_{x,y}^{(nc)}$ are equal, as we would also expect. Similarly if we replace either ρ_3 or ρ_4 by

zero, so that phase is perfectly conducting, $\rho_{x,y}\equiv\rho_{x,y}^{(c)}$. The practical computation of these formulas is straightforward; it requires m, found using a standard rootfinding algorithm, and the evaluation of the Legendre functions, using quadrature.

For comparison with numerical simulations, and also from the point of view of physical interpretation, it is useful to consider the extreme limits of very elongated short or long strips, that is, $h\gg l$, $h\ll l$.

For short strips, where $h\gg l$ we can extract asymptotic formulas, from (3.25) and (3.26), for the effective resistivities

$$\rho_x^{(nc),(c)}=\frac{(\rho_1+\rho_4)(\rho_2+\rho_3)}{(\rho_1+\rho_2+\rho_3+\rho_4)},\quad \rho_y^{(nc),(c)}=\left(\frac{\rho_2\rho_3}{\rho_2+\rho_3}+\frac{\rho_1\rho_4}{\rho_1+\rho_4}\right), \tag{3.27}$$

to order $O(l/h)$, if required, and those leading order corrections can be found as in Ref. 9. To leading order these results are exactly those which would be obtained if the strips were absent and replaced by continuity. These $h\gg l$ results can be interpreted in terms of resistors in parallel, series, and combinations thereof.

For long strips, $h\ll l$, and the nonconducting strips now play a major role, and one finds that

$$\rho_x^{(nc)}=\frac{\rho_1\rho_2}{(\rho_1+\rho_2)}+\frac{\rho_3\rho_4}{(\rho_3+\rho_4)},\quad \rho_y^{(nc)}=(\rho_1+\rho_2). \tag{3.28}$$

Notably, to leading order the result for $\rho_y^{(nc)}$ is that which would be obtained if regions 3 and 4 were completely replaced by regions of infinite resistivity. The resistivity in the direction of the x axis is that we would obtain if the nonconducting strips were replaced by continuity conditions, suggesting that ρ_x is not strongly affected by the change in interface conditions, at least for $h\ll l$. For perfectly conducting strips, and $h\ll l$, we obtain

$$\rho_x^{(c)}=\frac{\rho_1\rho_2}{(\rho_1+\rho_2)},\quad \rho_y^{(c)}=\frac{(\rho_4+\rho_3)(\rho_1+\rho_2)}{(\rho_1+\rho_2+\rho_3+\rho_4)}; \tag{3.29}$$

now, conversely to $\rho_{x,y}^{(nc)}$, the former is identical to situation where regions 3 and 4 are completely replaced, now, by regions of zero resistivity, and the latter identical with ρ_y in this limit.

If the checkerboards are square ($h=l$), we no longer have the h,l dependence and $m=\frac{1}{2}$. The results are then that

$$\rho_x^{(nc)}=\frac{\sigma_4\sqrt{\sigma_3(\sigma_3+\sigma_4)}}{(\rho_1+\rho_2)[\sigma_2^2+(\rho_1+\rho_2)\sqrt{\sigma_3(\sigma_3+\sigma_4)}]},\quad \rho_y^{(nc)}=\left[\frac{(\rho_1+\rho_2)\sigma_3}{(\rho_1+\rho_4)(\rho_3+\rho_4)}\right]^{1/2}, \tag{3.30}$$

$$\rho_x^{(c)}=\left[\frac{\rho_1\rho_2(\rho_1+\rho_4)(\rho_2+\rho_3)}{(\rho_1+\rho_2)\sigma_1}\right]^{1/2},$$

$$\rho_y^{(c)}=[\rho_3\rho_4(\rho_1+\rho_2)\sqrt{\sigma_1(\sigma_3+\sigma_4)}+\sigma_2^2\sqrt{\rho_1\rho_2}]\frac{(\rho_1+\rho_2)}{\beta^2\sqrt{\sigma_1(\sigma_3+\sigma_4)}}. \tag{3.31}$$

For continuous interface conditions using (2.8) and (2.9), and limiting to square checkerboards, one can interchange the phases ρ_2 and ρ_4 to translate between ρ_x and ρ_y. Clearly the insertion of perfectly conducting or nonconducting strips removes this simple symmetry. The formulas in (3.30) and (3.31) are the generalizations of the classical Dykhne [12] formulas, or the Mortola and Steffé[10] conjecture, to four-phase media, but additionally with perfectly conducting or nonconducting strips inserted.

Comparing the situation with and without nonconducting strips, the effective resistivity in the x direction is, in general, not too severely affected. However, in the y direction the strips completely block the field between phases 3 and 4, and the effective resistivity rises. A sample

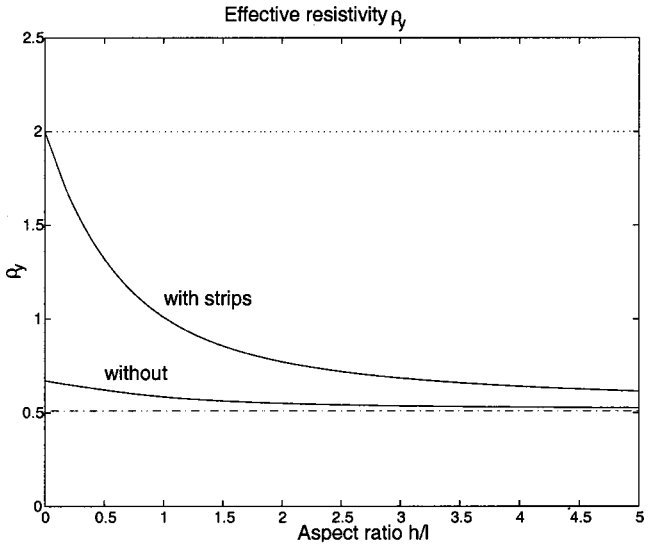

FIG. 2. The effective resistivity ρ_y versus aspect ratio h/l where $\rho_1=\rho_2=\rho_4=1$, $\rho_3=0.01$. The solid lines show ρ_y for continuous phases or inserted nonconducting strips, the dotted and dot–dash lines show the $h \ll l$ and $h \gg l$ limits (3.28) and (3.27).

calculation demonstrating the large changes that can potentially occur is shown in Fig. 2 for the situation when one phase (3) is of low resistivity while the others are all equal to unity. For perfectly conducting strips the converse occurs; the effective resistivity in the y direction is relatively unaffected whereas that in the x direction can vary considerably.

IV. CONCLUDING REMARKS

Conductive and nonconductive strips inserted in doubly periodic structures are simple models for debonding or perfect transmission across interfaces for composite structures. Estimates of the changes in effective properties away from those found with continuous conditions are thus far missing from the literature, as are formulas for four distinct phases; the current article provides those formulas explicitly for four-phase model checkerboard media. Apart from providing general formulas valid for all aspect ratios we also provide simple formulas valid for the useful limiting cases of very elongated geometries and square checkerboards. Many other limiting and special cases emerge from these results, for instance, reductions to three, two, or single phase media are easily possible; in the last case we recover the well-known results for an array of cracks in antiplane elasticity, namely that $\rho_x^{(nc)}=\rho$, that is, it is unaffected by the cracks. The results giving the general solution can also be exploited to show lines of equipotential or any other detail required.

A useful reduction of the power dissipation integral to a line integral is also briefly described; this should be of wide utility in related situations.

(Received 18 April 2001; accepted for publication 24 July 2001)

We study the nonstandard q-deformation $\mathrm{U}_q'(\mathrm{so}_4)$ of the universal enveloping algebra $\mathrm{U}(\mathrm{so}_4)$ obtained by deforming the defining relations for skew-symmetric generators of $\mathrm{U}(\mathrm{so}_4)$. This algebra is used in quantum gravity and algebraic topology. We construct a homomorphism ϕ of $\mathrm{U}_q'(\mathrm{so}_4)$ to the certain nontrivial extension of the Drinfeld–Jimbo quantum algebra $\mathrm{U}_q(\mathrm{sl}_2)^{\otimes 2}$ and show that this homomorphism is an isomorphism. By using this homomorphism we construct irreducible finite-dimensional representations of the classical type and of the nonclassical type for the algebra $\mathrm{U}_q'(\mathrm{so}_4)$. It is proved that for q not a root of unity each irreducible finite-dimensional representation of $\mathrm{U}_q'(\mathrm{so}_4)$ is equivalent to one of these representations. We prove that every finite-dimensional representation of $\mathrm{U}_q'(\mathrm{so}_4)$ for q not a root of unity is completely reducible. It is shown how to construct (by using the homomorphism ϕ) tensor products of irreducible representations of $\mathrm{U}_q'(\mathrm{so}_4)$. [Note that no Hopf algebra structure is known for $\mathrm{U}_q'(\mathrm{so}_4)$.] These tensor products are decomposed into irreducible constituents.
[DOI: 10.1063/1.1402631]

I. INTRODUCTION

In Ref. 1 a q-deformation of the universal enveloping algebra $\mathrm{U}(\mathrm{so}_n)$ was introduced which uses a realization of the Lie algebra so_n by skew-symmetric matrices (rather than by root elements and the diagonal Cartan subalgebra). If $I_{ij}=E_{ij}-E_{ij}$ are the skew-symmetric matrices of so_n, where $(E_{ij})_{sr}:=\delta_{is}\delta_{jr}$, then so_n is generated by the matrices $I_{21},I_{32},\ldots,I_{n,n-1}$ (other basis matrices are obtained by taking commutators of these matrices). The following Serre-type theorem is true (see Ref. 2): *The universal enveloping algebra* $\mathrm{U}(\mathrm{so}_n)$ *is isomorphic to the associative algebra generated by (abstract) elements* $I_{21},I_{32},\ldots,I_{n,n-1}$ *satisfying the relations*

$$I_{i,i-1}^2 I_{i+1,i}-2I_{i,i-1}I_{i+1,i}I_{i,i-1}+I_{i+1,i}I_{i,i-1}^2=-I_{i+1,i},$$

$$I_{i,i-1}I_{i+1,i}^2-2I_{i+1,i}I_{i,i-1}I_{i+1,i}+I_{i+1,i}^2I_{i,i-1}=-I_{i,i-1},$$

$$I_{i,i-1}I_{j,j-1}=I_{j,j-1}I_{i,i-1}\quad \text{for } |i-j|>1.$$

Now we q-deform these relations by $2\to[2]_q\equiv q+q^{-1}$. As a result, we obtain the associative algebra generated by elements $I_{21},I_{32},\ldots,I_{n,n-1}$ satisfying the relations

$$I_{i,i-1}^2 I_{i+1,i}-(q-q^{-1})I_{i,i-1}I_{i+1,i}I_{i,i-1}+I_{i+1,i}I_{i,i-1}^2=-I_{i+1,i},$$

$$I_{i,i-1}I_{i+1,i}^2-(q+q^{-1})I_{i+1,i}I_{i,i-1}I_{i+1,i}+I_{i+1,i}^2I_{i,i-1}=-I_{i,i-1},$$

$$I_{i,i-1}I_{j,j-1}=I_{j,j-1}I_{i,i-1} \quad \text{for} \quad |i-j|>1.$$

We denote this algebra by $U_q'(so_n)$. Associative algebras isomorphic to $U_q'(so_n)$ appear in quantum gravity,[3–5] in discrete Schrödinger equation,[6] in algebraic topology,[7,8] in the theory of q-orthogonal polynomials,[9] and in the theory of q-Laplace operators and q-harmonic polynomials.[10] For this reason, studying the algebra $U_q'(so_n)$ (especially for small numbers n) is of great importance. There are several problems which have to be solved. The most important are the following ones:

(a) relation of $U_q'(so_n)$ to Drinfeld–Jimbo quantum algebras;
(b) structure of the algebra $U_q'(so_n)$ (including explicit form of the center, Casimir elements, automorphism group, etc.); and
(c) construction and classification of irreducible finite-dimensional representations.

Parts of the main problems are solved. For example, it is shown (see Refs. 11 and 12) that $U_q'(so_n)$ can be embedded as a subalgebra into the Drinfeld–Jimbo quantum algebra $U_q(sl_n)$. [Recall that the Drinfeld–Jimbo quantum algebra $U_q(so_n)$ is not contained in $U_q(sl_n)$.] The main classes of irreducible finite-dimensional representations of $U_q'(so_n)$ are constructed for q not a root of unity (see Refs. 13 and 14) and for q a root of unity (see Refs. 12 and 15). But the corresponding classification theorem for the representation theory of $U_q'(so_n)$ is not proved. Casimir elements were constructed for q not a root of unity (see Refs. 16 and 17) and for q a root of unity (see Ref. 18). But it is not known whether they generate the center.

Most problems are solved[19–22] for the algebra $U_q'(so_3)$. In particular, it was shown that $U_q'(so_3)$ can be embedded into a certain extension of the Drinfeld–Jimbo algebra $U_q(sl_2)$ [but $U_q'(so_3)$ is not isomorphic to $U_q(sl_2)$]. The classification theorem for representation theory of $U_q'(so_3)$ were proved.[22] It was shown that the automorphism group of $U_q'(so_3)$ contains a group isomorphic to the modular group $SL(2,Z)$.

The aim of this article is to solve the main problems for the algebra $U_q'(so_4)$ naturally appearing in algebraic topology.[8] [Note that, unlike the classical case, the algebra $U_q'(so_4)$ is not isomorphic to the product of two copies of $U_q'(so_3)$.] The algebra $U_q'(so_4)$ and its irreducible finite-dimensional representations were studied in several paper.[23–25] Nevertheless, the main problems were not solved. The main results of this article are the following:

(I) We construct a homomorphism from $U_q'(so_4)$ to some extension of the Drinfeld–Jimbo quantum algebra $U_q(sl_2)^{\otimes 2}\equiv U_q(sl_2)\otimes U_q(sl_2)$. It is shown that this homomorphism is injective. Thus, $U_q'(so_4)$ is embedded into this extension of $U_q(sl_2)^{\otimes 2}$. This solves for $U_q'(so_4)$ the problem (a).

(II) The theorem classifying irreducible finite-dimensional representations of $U_q'(so_4)$ is proved, when q is not a root of unity. According to this theorem, irreducible representations of the classical type (q-analog of the irreducible representations of the Lie algebra so_4) and irreducible representations of the nonclassical type (these representations do not have any classical analogue) exhaust all irreducible finite-dimensional representations of $U_q'(so_4)$. This solves for $U_q'(so_4)$, when q is not a root of unity, the problem (c).

(III) It is proved that if q is not a root of unity, then any finite-dimensional representation of $U_q'(so_4)$ is completely reducible.

(IV) It is shown how to construct tensor products of irreducible finite-dimensional representations of $U_q'(so_4)$. [Note that no Hopf algebra structure is known on $U_q'(so_4)$.]

In Secs. II–IV q is any complex number different from ± 1. In other sections it is assumed that q is not a root of unity.

II. THE ALGEBRA $U_q'(so_4)$

We first define the q-deformed algebra $U_q'(so_3)$ which is a subalgebra of $U_q'(so_4)$. The algebra $U_q'(so_3)$ is obtained[26] by a q-deformation of the standard commutation relations

$$[I_{21},I_{32}]=I_{31},\quad [I_{32},I_{31}]=I_{21},\quad [I_{31},I_{21}]=I_{32}$$

of the Lie algebra so_3. So, the algebra $U'_q(so_3)$ is the complex associative algebra (with unit element) generated by the elements I_{21}, I_{32}, I_{31} satisfying the defining relations

$$[I_{21},I_{32}]_q:=q^{1/2}I_{21}I_{32}-q^{-1/2}I_{32}I_{21}=I_{31}. \tag{1}$$

$$[I_{32},I_{31}]_q:=q^{1/2}I_{32}I_{31}-q^{-1/2}I_{31}I_{32}=I_{21}, \tag{2}$$

$$[I_{31},I_{21}]_q:=q^{1/2}I_{31}I_{21}-q^{-1/2}I_{21}I_{31}=I_{32}. \tag{3}$$

Note that by (1) the element I_{31} is not independent: it depends on the elements I_{21} and I_{32}. Substituting the expression (1) for I_{31} into (2) and (3) we obtain the relations

$$I_{21}I_{32}^2-(q+q^{-1})I_{32}I_{21}I_{32}+I_{32}^2I_{21}=-I_{21}, \tag{4}$$

$$I_{32}I_{21}^2-(q+q^{-1})I_{21}I_{32}I_{21}+I_{21}^2I_{32}=-I_{32}. \tag{5}$$

The relations (4) and (5) restore the relations (2) and (3) if we introduce the element I_{31} defined by (1). The algebra $U'_q(so_3)$ can be defined as the associative algebra generated by the elements I_{21} and I_{32} satisfying the defining relations (4) and (5).

Starting from the definition of $U'_q(so_3)$ by relations (4) and (5), we give the following definition of the q-deformed algebra $U'_q(so_4)$. It is an associative algebra (with unit element) generated by the elements I_{21}, I_{32}, I_{43} satisfying the defining relations

$$I_{21}I_{32}^2-(q+q^{-1})I_{32}I_{21}I_{32}+I_{32}^2I_{21}=-I_{21}, \tag{6}$$

$$I_{32}I_{21}^2-(q+q^{-1})I_{21}I_{32}I_{21}+I_{21}^2I_{32}=-I_{32}, \tag{7}$$

$$I_{32}I_{43}^2-(q+q^{-1})I_{43}I_{32}I_{43}+I_{43}^2I_{32}=-I_{32}. \tag{8}$$

$$I_{43}I_{32}^2-(q+q^{-1})I_{32}I_{43}I_{32}+I_{32}^2I_{43}=-I_{43}, \tag{9}$$

$$I_{21}I_{43}-I_{43}I_{21}=0. \tag{10}$$

It is clear that $U'_q(so_4)$ contains at least two subalgebras isomorphic to $U'_q(so_3)$. The first one is generated by I_{21} and I_{32}, and the second one by I_{32} and I_{43}.

We can introduce in $U'_q(so_4)$ the elements I_{31}, I_{42}, and I_{41}. They are defined as in (1):

$$I_{31}:=[I_{21},I_{32}]_q,\quad I_{42}:=[I_{32},I_{43}]_q,\quad I_{41}:=[I_{21},I_{42}]_q=[I_{31},I_{43}]_q,$$

where $[A,B]_q:=q^{1/2}AB-q^{-1/2}BA$ is the q-commutator of A and B. Then the elements I_{ij}, $4\geqslant i>j\geqslant 1$, satisfy the relations[13]

$$[I_{21},I_{32}]_q=I_{31},\quad [I_{32},I_{31}]_q=I_{21},\quad [I_{31},I_{21}]_q=I_{32}, \tag{11}$$

$$[I_{32},I_{43}]_q=I_{42},\quad [I_{43},I_{42}]_q=I_{32},\quad [I_{42},I_{32}]_q=I_{43}, \tag{12}$$

$$[I_{31},I_{43}]_q=I_{41},\quad [I_{43},I_{41}]_q=I_{31},\quad [I_{41},I_{31}]_q=I_{43}. \tag{13}$$

$$[I_{21},I_{42}]_q=I_{41},\quad [I_{42},I_{41}]_q=I_{21},\quad [I_{41},I_{21}]_q=I_{42}. \tag{14}$$

$$[I_{21},I_{43}]=0,\quad [I_{32},I_{41}]=0,\quad [I_{42},I_{31}]=(q-q^{-1})(I_{21}I_{43}-I_{32}I_{41}). \tag{15}$$

As in the case of the algebra $U_q'(so_3)$, the relations (11)–(15) are equivalent to the relations (6)–(10). Note that the relations (11)–(15) define the algebra appearing in algebraic topology.[8]

Four sets of relations (11)–(14) gives four subalgebras of $U_q'(so_4)$ isomorphic to $U_q'(so_3)$. They are generated by triples (I_{21},I_{32},I_{31}), (I_{32},I_{43},I_{42}), (I_{31},I_{43},I_{41}), and (I_{21},I_{42},I_{41}), respectively.

The Poincaré–Birkhoff–Witt theorem is true for $U_q'(so_4)$. It can be formulated as: *The elements* $I_{31}^{m_{31}}I_{32}^{m_{32}}I_{41}^{m_{41}}I_{42}^{m_{42}}I_{43}^{m_{43}}I_{21}^{m_{21}}$, $m_{ij}=0,1,2,...$, *form a basis of* $U_q'(so_4)$. This theorem is proved by means of the diamond lemma (see Ref. 27, subsection 4.1.5). As in the case of an ordinary simple Lie algebra, the same theorem holds for any other ordering of the six generators.

We shall need Casimir elements of $U_q'(so_4)$. In order to give them we introduce also the elements $I_{31}^-:=[I_{21},I_{32}]_{q^{-1}}$, $I_{42}^-:=[I_{32},I_{43}]_{q^{-1}}$, and $I_{41}^-:=[I_{31},I_{43}]_{q^{-1}}$, where $[A,B]_{q^{-1}}:=q^{-1/2}AB-q^{1/2}BA$. Then[16]

$$C_4=q^{-1}I_{21}I_{43}-I_{31}I_{42}+qI_{32}I_{41},$$

$$C_4'=q^{-2}I_{21}^2+I_{32}^2+q^2I_{43}^2+q^{-1}I_{31}I_{31}^-+qI_{42}I_{42}^-+I_{41}I_{41}^-$$

are two independent elements of the center of the algebra $U_q'(so_4)$. Using the Poincaré–Birkhoff–Witt theorem the element C_4' can be represented in the form

$$\begin{aligned}C_4'=&q^2I_{21}^2+I_{41}^2+I_{32}^2+q^{-2}(I_{43}^2+I_{21}^2+I_{31}^2)-(q-q^{-1})q^{-3/2}(I_{31}I_{32}I_{21}+I_{31}I_{41}I_{43})\\&-(q-q^{-1})q^{1/2}(I_{32}I_{42}I_{43}+I_{41}I_{42}I_{21})+(q-q^{-1})^2I_{32}I_{41}I_{43}I_{21}.\end{aligned}$$

III. THE ALGEBRA $U_q(sl_2)^{\otimes 2,ext}$

Let e_1, f_1, q^{H_1} and e_2, f_2, q^{H_2} be generating elements of two copies of the quantum algebra $U_q(sl_2)$ satisfying the relations

$$q^{H_i}e_i=qe_iq^{H_i},\quad q^{H_i}f_i=q^{-1}f_iq^{H_i},\quad [e_i,f_i]=\frac{q^{2H_i}-q^{-2H_i}}{q-q^{-1}}.$$

The expressions

$$c_i=e_if_i+\frac{q^{2H_i-1}+q^{-2H_i+1}}{(q-q^{-1})^2},\quad i=1,2,$$

give Casimir elements of these algebras $U_q(sl_2)$. The comultiplication Δ is given in $U_q(sl_2)$ by the formulas

$$\Delta(q^{\pm H_i})=q^{\pm H_i}\otimes q^{\pm H_i},\quad \Delta(e_i)=e_i\otimes q^{H_i}+q^{-H_i}\otimes e_i,\quad \Delta(f_i)=f_i\otimes q^{H_i}+q^{-H_i}\otimes f_i.$$

Let us consider the polynomials

$$p_i(x_i)=q^{-1}x_i^4-c_i(q-q^{-1})^2x_i^2+q,$$

where c_i are the Casimir elements. They are irreducible in $U_q(sl_2)$, that is, there exists no element $a\in U_q(sl_2)$ such that $p_i(a)=0$. Therefore, we can define the quartic algebraic extension $\hat{U}_q(sl_2)$ of the algebra $U_q(sl_2)$ by means of the element x_i commuting with all elements of $U_q(sl_2)$:

$$\hat{U}_q(sl_2)=\{a_3x_i^3+a_2x_i^2+a_1x_i+a_0|a_j\in U_q(sl_2)\},$$

assuming that $p_i(x_i)=0$, that is, $x_i^4=qc_i(q-q^{-1})^2x_i^2-q^2$. This equation is equivalent to the following one

$$c_i=\frac{x_i^2q^{-1}+x_i^{-2}q}{(q-q^{-1})^2}. \tag{16}$$

Note that the element x_i has an inverse in $\hat{U}_q(sl_2)$ since $x_i(-x_i^3q^{-1}+c_i(q-q^{-1})^2x_i)q^{-1}=1$, that is,

$$x_i^{-1}=(-x_i^3q^{-1}+c_i(q-q^{-1})^2x_i)q^{-1}. \tag{17}$$

We consider two algebras $\hat{U}_q(sl_2)$ generated by the elements e_1, f_1, $q^{\pm H_1}$, x_1 and by the elements e_2, f_2, $q^{\pm H_2}$, x_2, respectively. Let $\hat{U}_q(sl_2)^{\otimes 2}$ be the tensor product of these algebras. Then we extend (in the sense of Ref. 28) this algebra $\hat{U}_q(sl_2)^{\otimes 2}$ by adding to it the commuting elements

$$(q^{H_1}q^{H_2}q^j+q^{-H_1}q^{-H_2}q^{-j})^{-1},\quad (q^{H_1}q^{-H_2}q^j+q^{-H_1}q^{H_2}q^{-j})^{-1},\quad j=0,\pm 1,\pm 2,\ldots. \tag{18}$$

This extended algebra will be denoted by $\hat{U}_q(sl_2)^{\otimes 2,\mathrm{ext}}$. It is the associative algebra generated by the elements e_i, f_i, $q^{\pm H_1}$, x_i, $i=1,2$, and by elements (18) such that e_1, f_1, $q^{\pm H_1}$, x_1 and e_2, f_2, $q^{\pm H_2}$, x_2 satisfy the relations determined in the algebra $\hat{U}_q(sl_2)$, each of the elements e_1, f_1, $q^{\pm H_1}$, x_1 commute with each of the elements e_2, f_2, $q^{\pm H_2}$, x_2, each of the elements $q^{\pm H_1}$ and $q^{\pm H_2}$ commutes with each of elements (18), and

$$(q^{H_1+H_2+j}+q^{-H_1-H_2-j})^{-1}e_i=e_i(q^{H_1+H_2+j+1}+q^{-H_1-H_2-j-1})^{-1},$$

$$(q^{H_1+H_2+j}+q^{-H_1-H_2-j})^{-1}f_i=f_i(q^{H_1+H_2+j-1}+q^{-H_1-H_2-j+1})^{-1},$$

$$(q^{H_1-H_2+j}+q^{-H_1+H_2-j})^{-1}e_i=e_i(q^{H_1-H_2+j+\varepsilon}+q^{-H_1+H_2-j-\varepsilon})^{-1},$$

$$(q^{H_1-H_2+j}+q^{-H_1+H_2-j})^{-1}f_i=f_i(q^{H_1-H_2+j-\varepsilon}+q^{-H_1+H_2-j+\varepsilon})^{-1},$$

$$(q^{H_1+H_2+j}+q^{-H_1-H_2-j})^{-1}(q^{H_1+H_2+j}+q^{-H_1-H_2-j})=1,$$

$$(q^{H_1-H_2+j}+q^{-H_1+H_2-j})^{-1}(q^{H_1-H_2+j}+q^{-H_1+H_2-j})=1,$$

where $\varepsilon=1$ if $i=1$ and $\varepsilon=-1$ if $i=2$.

Let us find irreducible finite-dimensional representations of the algebra $U_q(sl_2)^{\otimes 2,\mathrm{ext}}$ for q not a root of unity. For these values of q the algebra $U_q(sl_2)$ has finite-dimensional irreducible representations $T_l\equiv T_l^{(1)}$, $T_l^{(-1)}$, $T_l^{(\mathrm{i})}$, $T_l^{(-\mathrm{i})}$, $l=0,\frac{1}{2},1,\frac{3}{2},\ldots$, acting on the vector space $\mathcal{H}_l$ with basis $|l,m\rangle$, $m=-l,-l+1,\ldots,l$. These representations are given by the formulas

$$T_l^{(1)}(q^H)|l,m\rangle=q^m|l,m\rangle,\quad T_l^{(1)}(e)|l,m\rangle=[l-m]|l,m+1\rangle, \tag{19}$$

$$T_l^{(1)}(f)|l,m\rangle=[l+m]|l,m-1\rangle, \tag{20}$$

where numbers in square brackets mean q-numbers determined by

$$[a]=\frac{q^a-q^{-a}}{q-q^{-1}},$$

and by the formulas

$$T_l^{(-1)}(q^H)|l,m\rangle=-q^m|l,m\rangle,\quad T_l^{(-1)}(X)=T_l^{(1)}(X),\quad X=e,f, \tag{21}$$

$$T_l^{(\mathrm{i})}(q^H)|l,m\rangle=\mathrm{i}q^m|l,m\rangle,\quad T_l^{(\mathrm{i})}(e)=T_l^{(1)}(e),\quad T_l^{(\mathrm{i})}(f)=-T_l^{(1)}(f), \tag{22}$$

$$T_l^{(-\mathrm{i})}(q^H)|l,m\rangle=-\mathrm{i}q^m|l,m\rangle,\quad T_l^{(-\mathrm{i})}(e)=T_l^{(1)}(e),\quad T_f^{(-\mathrm{i})}(f)=-T_l^{(1)}(f) \tag{23}$$

(see, for example, Ref. 27, Chap. 3). The representations $T_l^{(1)},T_l^{(-1)},T_l^{(\mathrm{i})},T_l^{(-\mathrm{i})}$, $l=0,\frac{1}{2},1,\frac{3}{2},\ldots$, are pairwise nonequivalent and any irreducible finite-dimensional representation of $\mathrm{U}_q(\mathrm{sl}_2)$ is equivalent to one of these representations. Values of the Casimir element c on these representations are given by

$$T_l^{(1)}(c)=T_l^{(-1)}(c)=\frac{q^{2l+1}+q^{-2l-1}}{(q-q^{-1})^2},\quad T_l^{(i)}(c)=T_l^{(-i)}(c)=-\frac{q^{2l+1}+q^{-2l-1}}{(q-q^{-1})^2}.$$

Since the Casimir element of $\mathrm{U}_q(\mathrm{sl}_2)$ is multiple to the unit operator on the space $\mathcal{H}_l$, then each of the representations $T_l^{(1)},T_l^{(-1)},T_l^{(\mathrm{i})},T_l^{(-\mathrm{i})}$, $l=0,\frac{1}{2},1,\frac{3}{2},\ldots$, can be extended to a representation of $\hat{\mathrm{U}}_q(\mathrm{sl}_2)$. In order to determine these extensions we have to determine the operators $T_l^{(\varepsilon)}(x)$, $\varepsilon=\pm1,\pm\mathrm{i}$, corresponding to the element x from (16). It follows from (16) that

$$T_l^{(\varepsilon)}(c)=\frac{T_l^{(\varepsilon)}(x)^2q^{-1}+T_l^{(\varepsilon)}(x)^{-2}q}{(q-q^{-1})^2}.$$

If some operator $T_l^{(\varepsilon)}(x)$ is a solution of this equation, then the operators

$$\tilde{T}_l^{(\varepsilon)}(x)=-T_l^{(\varepsilon)}(x),\quad T_l^{(\varepsilon)}(x)^{-1}q,\quad -T_l^{(\varepsilon)}(x)^{-1}q$$

are also its solutions. Each of them can be taken for extension of the representation $T_l^{(\varepsilon)}$ of $\mathrm{U}_q(\mathrm{sl}_2)$. Since the element x commutes with all elements of $\mathrm{U}_q(\mathrm{sl}_2)$, then different extensions of $T_l^{(\varepsilon)}$ (obtained by using different solutions of the previous equation) do not essentially differ from each other. For this reason, we shall use only the solution $T_l^{(\varepsilon)}(x)=q^{-l}I$, where I is the unit operator. We denote the extended representations of $\hat{\mathrm{U}}_q(\mathrm{sl}_2)$, extended by using the solution $T_l^{(\varepsilon)}(x)=q^{-l}I$, by the same symbols $T_l^{(1)},T_l^{(-1)},T_l^{(\mathrm{i})},T_l^{(-\mathrm{i})}$.

It is clear that irreducible finite-dimensional representations of $\hat{\mathrm{U}}_q(\mathrm{sl}_2)^{\otimes2}$ are equivalent to the following ones:

$$T_l^{(\varepsilon)}\otimes T_{l'}^{(\varepsilon')},\quad l,l'=0,\tfrac{1}{2},1,\tfrac{3}{2},\ldots,\quad \varepsilon,\varepsilon'=1,-1,\mathrm{i},-\mathrm{i},$$

where $T_l^{(\varepsilon)}$ and $T_{l'}^{(\varepsilon')}$ are irreducible representations of two copies of the algebra $\hat{\mathrm{U}}_q(\mathrm{sl}_2)$, respectively. Now we wish to extend these representations of $\hat{\mathrm{U}}_q(\mathrm{sl}_2)^{\otimes2}$ to representations of the algebra $\hat{\mathrm{U}}_q(\mathrm{sl}_2)^{\otimes2,\mathrm{ext}}$ by using the relation

$$\begin{aligned}&(T_l^{(\varepsilon)}\otimes T_{l'}^{(\varepsilon')})((q^{H_1+H_2+j}+q^{-H_1-H_2-j})^{-1})\\&\quad=(q^jT_l^{(\varepsilon)}(q^{H_1})\otimes T_{l'}^{(\varepsilon')}(q^{H_2})+q^{-j}T_l^{(\varepsilon)}(q^{H_1})\otimes T_{l'}^{(\varepsilon')}(q^{-H_2}))^{-1},\\&(T_l^{(\varepsilon)}\otimes T_{l'}^{(\varepsilon')})((q^{H_1-H_2+j}+q^{-H_1+H_2-j})^{-1})\\&\quad=(q^jT_l^{(\varepsilon)}(q^{H_1})\otimes T_{l'}^{(\varepsilon')}(q^{-H_2})+q^{-j}T_l^{(\varepsilon)}(q^{-H_1})\otimes T_{l'}^{(\varepsilon')}(q^{H_2}))^{-1}.\end{aligned}$$

Clearly, only those irreducible representations $T_l^{(\varepsilon)}\otimes T_{l'}^{(\varepsilon')}$ of $\hat{\mathrm{U}}_q(\mathrm{sl}_2)^{\otimes2}$ can be extended to representations of $\hat{\mathrm{U}}_q(\mathrm{sl}_2)^{\otimes2,\mathrm{ext}}$ for which all the operators

$$q^jT_l^{(\varepsilon)}(q^{H_1})\otimes T_{l'}^{(\varepsilon')}(q^{H_2})+q^{-j}T_l^{(\varepsilon)}(q^{-H_1})\otimes T_{l'}^{(\varepsilon')}(q^{-H_2}),\quad j=0,\pm1,\ldots,$$

$$q^j T_l^{(\varepsilon)}(q^{H_1}) \otimes T_{l'}^{(\varepsilon')}(q^{-H_2}) + q^{-j} T_l^{(\varepsilon)}(q^{-H_1}) \otimes T_{l'}^{(\varepsilon')}(q^{H_2}), \quad j = 0, \pm 1, \ldots,$$

are invertible. From formulas (19)–(23) it follows that these operators are always invertible for the representations $T_l^{(\varepsilon)} \otimes T_{l'}^{(\varepsilon')}$ such that $\varepsilon, \varepsilon' = 1, -1$ or ε, $\varepsilon' = \mathrm{i}, -\mathrm{i}$, and also for all the representations $T_l^{(\varepsilon)} \otimes T_{l'}^{(\varepsilon')}$ such that $l + l'$ is a half-integral (but not integral) number and $\varepsilon = \pm 1$, $\varepsilon' = \pm \mathrm{i}$ or $\varepsilon = \pm \mathrm{i}$, $\varepsilon' = \pm 1$. For the representations $T_l^{(\varepsilon)} \otimes T_{l'}^{(\varepsilon')}$ with $\varepsilon = \pm 1$, $\varepsilon' = \pm \mathrm{i}$ or $\varepsilon = \pm \mathrm{i}$, $\varepsilon' = \pm 1$ and $l + l' \in Z$ some of these operators are not invertible since they have zero eigenvalue. Denoting the extended representations by the same symbols, we can formulate the following assertion:

Theorem 1: *If q is not a root of unity, then the algebra $\hat{U}_q(sl_2)^{\otimes 2,\mathrm{ext}}$ has irreducible finite-dimensional representations*

$$T_l^{(\varepsilon)} \otimes T_{l'}^{(\varepsilon')}, \quad l, l' = 0, \tfrac{1}{2}, 1, \tfrac{3}{2}, \ldots, \quad \varepsilon, \varepsilon' = \pm 1 \quad \text{or} \quad \varepsilon, \varepsilon' = \pm \mathrm{i},$$

$$T_l^{(\varepsilon)} \otimes T_{l'}^{(\varepsilon')}, \quad l + l' \in \tfrac{1}{2} Z, \quad l + l' \notin Z, \quad \varepsilon = \pm 1, \varepsilon' = \pm \mathrm{i} \quad \text{or} \quad \varepsilon = \pm \mathrm{i}, \ \varepsilon' = \pm 1$$

(all four combinations of signs are possible). Up to values of the operators corresponding to the elements $x_1^k \otimes x_2^s$, $k, s = 1,2,3$, any irreducible finite-dimensional representation of $\hat{U}_q(sl_2)^{\otimes 2,\mathrm{ext}}$ is equivalent to one of these representations.

IV. THE ALGEBRA HOMOMORPHISM $U'_q(so_4) \to \hat{U}_q(sl_2)^{\otimes 2,\mathrm{ext}}$

The aim of this section is to give in an explicit form the algebra homomorphism of $U'_q(so_4)$ to $\hat{U}_q(sl_2)^{\otimes 2,\mathrm{ext}}$. This homomorphism is given by the following theorem:

Theorem 2: *There exists a unique algebra homomorphism ϕ: $U'_q(so_4) \to \hat{U}_q(sl_2)^{\otimes 2,\mathrm{ext}}$ such that*

$$\phi(I_{21}) = \mathrm{i}[H_1 + H_2]_q, \quad \phi(I_{43}) = \mathrm{i}[H_1 - H_2]_q, \tag{24}$$

$$\begin{aligned}
\phi(I_{32}) = &- \frac{x_1^{-1} q^{-H_2+1} + x_1 q^{H_2-1}}{(q^{H_1+H_2-1} + q^{-H_1-H_2+1})(q^{H_1-H_2+1} + q^{-H_1+H_2-1})} E_2 \\
&+ \frac{x_1^{-1} q^{H_2+1} + x_1 q^{-H_2-1}}{(q^{H_1+H_2+1} + q^{-H_1-H_2-1})(q^{H_1-H_2-1} + q^{-H_1+H_2+1})} F_2 \\
&+ \frac{x_2^{-1} q^{-H_1+1} + x_2 q^{H_1-1}}{(q^{H_1+H_2-1} + q^{-H_1-H_2+1})(q^{H_1-H_2-1} + q^{-H_1+H_2+1})} E_1 \\
&- \frac{x_2^{-1} q^{H_1+1} + x_2 q^{-H_1-1}}{(q^{H_1+H_2+1} + q^{-H_1-H_2-1})(q^{H_1-H_2+1} + q^{-H_1+H_2-1})} F_1 .
\end{aligned} \tag{25}$$

Proof: We have to show that three elements $\phi(I_{21})$, $\phi(I_{32})$, and $\phi(I_{43})$ from (24) and (25) satisfy the defining relations (6)–(10). It is made by direct verification. Namely, we substitute the expressions (24) and (25) for $\phi(I_{21}), \phi(I_{43}), \phi(I_{32})$ into (6)–(10) and then permute the generating elements $(q^{H_i})^{\pm 1}, e_i, f_i$ in numerators [using the defining relations of the algebra $U_q(sl_2)$], reducing them to the form $(q^{H_1})^r (q^{H_2})^s e_1^{a_1} e_2^{b_1} f_1^{a_2} f_2^{b_2}, r, s \in Z$. $a_1, b_1, a_2, b_2 \in Z_+$. Then it is directly seen that the relations (7), (8), and (10) are fulfilled. So, we have to prove the relations (6) and (9). We cancel in these relations separately terms ending with e_1^2, e_2^2, f_1^2, and f_2^2. Now in the relation (6) we cancel terms ending with $e_1 e_2, f_1 f_2, f_1 e_2$ and in the relation (9) terms ending with $e_1 f_2, f_1 e_2$. Then we multiply both sides of (6) by

$$(q^{H_1+H_2-1} + q^{-H_1-H_2+1})^{-1} (q^{H_1+H_2+1} + q^{-H_1-H_2-1})^{-1}$$

and both sides of (9) by

$$(q^{H_1-H_2-1}+q^{-H_1+H_2+1})^{-1}(q^{H_1-H_2+1}+q^{-H_1+H_2-1})^{-1}.$$

After that we cancel in (6) terms ending with e_1f_2 and in (9) terms ending with e_1e_2 and f_1f_2. Now we have in (6) and (9) only the terms ending with e_1f_1 and e_2f_2 and terms without any e_jf_k, $j\neq k$. We replace e_1f_1 and e_2f_2 by the expressions following from the expression for the Casimir elements, that is, by $c_i-(q^{2H_i-1}+q^{-2H_i+1})/(q-q^{-1})^2$, respectively, and multiply both sides of both relations by

$$(q^{H_1+H_2-1}+q^{-H_1-H_2+1})(q^{H_1+H_2+1}+q^{-H_1-H_2-1})(q^{H_1+H_2}+q^{-H_1-H_2})(q^{H_1-H_2-1}$$
$$+q^{-H_1+H_2+1})(q^{H_1-H_2+1}+q^{-H_1+H_2-1})(q^{H_1-H_2}+q^{-H_1+H_2}).$$

We obtain the relations, both sides of which are cancelled. The theorem is proved.

V. PROPERTIES OF REPRESENTATIONS OF $U_q'(so_4)$

We assume everywhere below that q is not a root of unity.

Our aim is to obtain irreducible finite-dimensional representations of $U_q'(so_4)$ by using the homomorphism of Theorem 2. But before we need some statements on such representations of $U_q'(so_4)$.

Let $U_q'(so_3)_1$ and $U_q'(so_3)_2$ denote the subalgebras of $U_q'(so_4)$ generated by I_{21}, I_{32} and by I_{32}, I_{43}, respectively. It is known that the restriction of a finite-dimensional representation T of $U_q'(so_4)$ to any of these subalgebras is a completely reducible representation since any finite-dimensional representation of $U_q'(so_3)$ for q not a root of unity is completely reducible (see Ref. 29). Let

$$T\downarrow U_q'(so_3)_1=R_1\oplus R_2\oplus\cdots\oplus R_k, \tag{26}$$

$$T\downarrow U_q'(so_3)_2=R_1'\oplus R_2'\oplus\cdots\oplus R_{k'}'. \tag{27}$$

Next we shall prove some assertions characterizing these decompositions. Using the classification of irreducible finite-dimensional representations of $U_q'(so_3)$ for q not a root of unity (see Ref. 22), we can state that each of the irreducible representations R_i and R_j' in (26) and (27) is a representation of the classical type or a representation of the nonclassical type.

Proposition 1: The decomposition (26), as well as the decomposition (27), contains only irreducible representations of the classical type or only irreducible representations of the nonclassical type.

Proof: Let us prove our proposition for the decomposition (26). It follows from the results of Ref. 30 that the operators $T(I_{41}), T(I_{42}), T(I_{43})$ form a tensor operator transforming under the vector (three-dimensional) representation of $U_q'(so_3)_1$. It is known from Ref. 21 that a tensor product of a classical- (nonclassical) type irreducible representation by the vector representation contains in the decomposition classical- (respectively, nonclassical) type representations. For this reason, if, for example, the representation R_1 in (26) is of the classical type and $|l_1,m_1\rangle$, $m_1=-l_1,-l_1+1,...,l_1$, are basis elements of its representation subspace, then according to the Wigner–Eckart theorem[30] for vector tensor operator $\{T(I_{41}), T(I_{42}), T(I_{43})\}$, the vectors $T(I_{4i})|l_1,m_1\rangle$, $i=1, 2, 3$, are linear combinations of vectors belonging to subspaces of irreducible representations of $U_q'(so_3)_1$ of the classical type. The same assertion is true for vectors belonging to subspaces of representations of the nonclassical type: that is, if R_1 is of the nonclassical type, then the vectors $T(I_{4i})|l_1,m_1\rangle$ are linear combinations of vectors belonging to subspaces of irreducible representations of the nonclassical type. Thus, if in the decomposition (26) there exists an irreducible representation of the classical type, then acting upon vectors of the corresponding subspace by the operators $T(I_{4i})$, $i=1, 2, 3$, we obtain vectors belonging to subspaces on which irreducible representations of the classical type are realized. Since the representation T of $U_q'(so_4)$ is irreducible, then in this case the decomposition (26) contains only irreducible representations of

the classical type. If the decomposition (26) does not contain an irreducible representation of the classical type, then all representations in this decomposition are of the nonclassical type. The proposition is proved.

Proposition 2: Both decompositions (26) and (27) contain irreducible representations of the same type (classical or nonclassical).

Proof: In order to prove this proposition we note (see Ref. 22) that eigenvalues of the operator $R(I_{21})$ of an irreducible representation R of $U'_q(so_3)$ are of the form $i[m], i[m-1], \ldots$ with integral or half-integral $m, m-1, \ldots$ if R is of the classical type, and of the form $\pm[m]_+, \pm[m-1]_+, \ldots$ with only half-integral $\pm m, \pm m-1, \ldots$ if R is of the nonclassical type, where

$$[m]_+ = \frac{q^m + q^{-m}}{q - q^{-1}}. \tag{28}$$

Let the decomposition (26) consist of irreducible representations of the classical type. Then eigenvalues of the operators $R_i(I_{21})$ are of the form $i[m], i[m-1], \ldots$. We state that then the operators $R_i(I_{32})$ can be diagonalized and their eigenvalues are also of this form. Really, the algebra $U'_q(so_3)_1$ has the automorphism τ such that $\tau(I_{21}) = I_{32}$ and $\tau(I_{32}) = I_{21}$. Since $\mathrm{Tr} R_i(I_{21}) = \mathrm{Tr} R_i(I_{32}) = 0$ (this equality characterizes[21] irreducible representations of the classical type), then the representations $R'_i = R_i \circ \tau$ are of the classical type. Moreover, $R'_i \sim R_i$ (since up to equivalence there exists a single irreducible representation of the classical type with a fixed dimension). Then the operators $R'_i(I_{21}) = R_i(I_{32})$ are diagonalizable and the spectrum of $R_i(I_{32})$ coincides with that of $R_i(I_{21})$. Our statement concerning the operator $R_i(I_{32})$ is proved.

Now we consider the decomposition (27). The operator $T(I_{32}) = \Sigma_i \oplus R_i(I_{32})$ coincides with the operator $T(I_{32}) = \Sigma_i \oplus R'_i(I_{32})$. We have found a form of the spectrum of the operator $T(I_{32})$. Now we can conclude that the operators $R'_i(I_{32})$ have eigenvalues of the form $i[m], i[m-1], \ldots$. This means that the irreducible representations R'_i in (27) are of the classical type.

If the decomposition (26) consists of irreducible representations of the nonclassical type, the decomposition (27) consists of representations of the same type. Really, if the decomposition (27) would consist of representations of the classical type, then conducting the above reasoning in the converse order, we would conclude that the decomposition (26) consists of representations of the classical type. The proposition is proved.

Corollary: If T is an irreducible finite-dimensional representation of $U'_q(so_4)$, then both operators $T(I_{21})$ and $T(I_{43})$ can be simultaneously diagonalized and eigenvalues of both these operators are either of the form $i[m], i[m-1], \ldots$ with integral or half-integral $m, m-1, \ldots$ or of the form $[m]_+, [m-1]_+, \ldots$ with half-integral $m, m-1, \ldots$.

Proof: The operators $T(I_{21})$ and $T(I_{43})$ can be simultaneously diagonalized since the operators $R_i(I_{21})$ and $R'_j(I_{43})$ in the decompositions (26) and (27) can be simultaneously diagonalized. [Note that elements I_{21} and I_{43} are commuting in $U'_q(so_4)$.] Since decompositions (26) and (27) consist only of irreducible representations of the classical type or only irreducible representations of the nonclassical type, then the second assertion of the corollary follows. Corollary is proved.

VI. IRREDUCIBLE REPRESENTATIONS OF $U'_q(so_4)$ OF THE CLASSICAL TYPE

If T is a representation of the algebra $\hat{U}_q(sl_2)^{\otimes 2,\mathrm{ext}}$ on a finite-dimensional linear space $\mathcal{H}$, then the mapping

$$R: U'_q(so_4) \to \mathcal{L}(\mathcal{H}) \tag{29}$$

[where $\mathcal{L}(\mathcal{H})$ is the space of linear operators on $\mathcal{H}$] defined by the composition $R = T \circ \phi$ (where ϕ is the homomorphism of Theorem 2) is a representation of $U'_q(so_4)$. Let us consider the representations

$$R_{jj'} \equiv R^{(1,1)}_{jj'} = (T^{(1)}_j \otimes T^{(1)}_{j'}) \circ \phi, \quad j, j' = 0, \tfrac{1}{2}, 1, \tfrac{3}{2}, \ldots, \tag{30}$$

of $\mathrm{U}_q'(\mathrm{so}_4)$, where $T_j^{(1)}\otimes T_{j'}^{(1)}$ are irreducible representations of $\hat{\mathrm{U}}_q(\mathrm{sl}_2)^{\otimes 2,\mathrm{ext}}$ from Theorem 1.

Using formulas for the representations $T_j^{(1)}\otimes T_{j'}^{(1)}$ of $\hat{\mathrm{U}}_q(\mathrm{sl}_2)^{\otimes 2,\mathrm{ext}}$ from Theorem 1 and the expressions (24) and (25) for $\phi(I_{i,i-1})$, $i=2,3,4$, we find that

$$R_{jj'}(I_{21})|k,l\rangle = \mathrm{i}[k+l]|k,l\rangle, \tag{31}$$

$$R_{jj'}(I_{43})|k,l\rangle = \mathrm{i}[k-l]|k,l\rangle, \tag{32}$$

$$\begin{aligned} R_{jj'}(I_{32})|k,l\rangle = {} & \frac{1}{(q^{k+l}+q^{-k-l})(q^{k-l}+q^{-k+l})}\{-(q^{j-l}+q^{-j+l})[j'-l]|k,l+1\rangle \\ & +(q^{j+l}+q^{-j-l})[j'+l]|k,l-1\rangle+(q^{j'-k}+q^{-j'+k})[j-k]|k+1,l\rangle \\ & -(q^{j'+k}+q^{-j'-k})[j+k]|k-1,l\rangle\}, \end{aligned} \tag{33}$$

where numbers in square brackets are corresponding q-numbers and $|k,l\rangle$ denote the basis vector

$$|k,l\rangle \equiv |j,k\rangle\otimes|j',l\rangle$$

of the space $\mathcal{H}_j\otimes\mathcal{H}_{j'}$ of the representation $T_j^{(1)}\otimes T_{j'}^{(1)}$ of $\hat{\mathrm{U}}_q(\mathrm{sl}_2)^{\otimes 2,\mathrm{ext}}$.

Remark: Taking instead of $T_j^{(1)}\otimes T_{j'}^{(1)}$ the irreducible representations with other values of the operators corresponding to the elements $x_1^k\otimes x_2^s$, $k,s=1,2,3$ (see Theorem 1), we would obtain representations of $\mathrm{U}_q'(\mathrm{so}_4)$ equivalent to $R_{jj'}$.

The representation $R_{jj'}$ of $\mathrm{U}_q'(\mathrm{so}_4)$ is equivalent to the representation T_{rs}, $r=j+j'$, $s=j-j'$ from Ref. 24 which in the $\mathrm{U}_q'(\mathrm{so}_3)$ basis $|j'',m\rangle$, $|s|\leqslant j''\leqslant r$, $m=-j'',\ -j''+1,\ldots,j''$, is given by the formulas

$$T_{rs}(I_{21})|j'',m\rangle = i[m]|j'',m\rangle, \tag{34}$$

$$T_{rs}(I_{32})|j'',m\rangle = \frac{1}{q^m+q^{-m}}([j''-m]|j'',m+1\rangle-[j''+m]|j'',m-1\rangle), \tag{35}$$

$$\begin{aligned} T_{rs}(I_{43})|j'',m\rangle = {} & \mathrm{i}\frac{[r+1][s][m]}{[r''][j''+1]}|j'',m\rangle+\frac{[r-j''][j''+s+1]}{[j''+1][2j''+1]}|j''+1,m\rangle \\ & -\frac{[r+j''+1][j''-s][j''-m][j''+m]}{[j''][2j''+1]}|j''-1,m\rangle \end{aligned} \tag{36}$$

[note that our basis elements $|j'',m\rangle$ differ from the basis elements in formula (19) of Ref. 24 by the appropriate multipliers; for this reason, formula (36) differs from formula (19) in Ref. 24]. It was shown[24] that under diagonalization of the operator $T_{rs}(I_{43})$ we obtain a new basis $\{|x,m\rangle\}$ on which the operators $T_{rs}(I_{21}), T_{rs}(I_{43}), T_{rs}(I_{32})$ are given by formulas

$$T_{rs}(I_{21})|x,m\rangle = \mathrm{i}[m]|x,m\rangle, \quad T_{rs}(I_{43})|x,m\rangle = \mathrm{i}[x]|x,m\rangle \tag{37}$$

and by formula (33) in Ref. 24. Under the renotation of the basis elements and multiplying them by the appropriate multipliers we obtain formulas for the representation $R_{jj'}$ obtained earlier in this work. This proves the equivalence stated earlier.

The irreducible representations $R_{jj'}$ are called representations of *the classical type*.[14] If $q\to 1$, then the operators $R_{jj'}(I_{i,i-1})$, $i=2,3,4$, tend to the corresponding operators of the irreducible representations of the Lie algebra so_4.

VII. IRREDUCIBLE REPRESENTATIONS OF $U'_q(so_4)$ OF THE NONCLASSICAL TYPE

Now we apply the method of the previous section to the irreducible representations $T_j^{(-i)} \otimes T_{j'}^{(1)}$ of the algebra $\hat{U}_q(sl_2)^{\otimes 2,ext}$ with j half-integral and j' integral or with j integral and j' half-integral. Then we obtain the representations

$$R_{jj'}^{(-i,1)} = (T_j^{(-i)} \otimes T_{j'}^{(1)}) \circ \phi, \tag{38}$$

of $U'_q(so_4)$ with

$$j = \tfrac{1}{2}, \tfrac{3}{2}, \tfrac{5}{2}, \ldots, \quad j' = 0,1,2,..., \quad \text{or} \quad j = 0,1,2,..., \quad j' = \tfrac{1}{2}, \tfrac{3}{2}, \tfrac{5}{2}, \ldots . \tag{39}$$

Using formulas for the representations $T_j^{(-i)}$ and $T_{j'}^{(1)}$ of $U_q(sl_2)$ and the expression (24) and (25) for $\phi(I_{i,i-1})$, $i=2,3,4$, we find that

$$R_{jj'}^{(-i,1)}(I_{21})|k,l\rangle = [k+l]_+ |k,l\rangle, \tag{40}$$

$$R_{jj'}^{(-i,1)}(I_{43})|k,l\rangle = [k-l]_+ |k,l\rangle, \tag{41}$$

$$R_{jj'}^{(-i,1)}(I_{32})|k,l\rangle = \frac{1}{[k+l][k-l](q-q^{-1})} \{-i[j-l][j'-l]|k,l+1\rangle + i[j+l][j'+l]|k,l-1\rangle$$
$$- i[j'-k][j-k]|k+1,l\rangle + i[j'+k][j+k]|k-1,l\rangle\}, \tag{42}$$

where the numbers in square brackets are the corresponding q-numbers, $[a]_+$ are defined in (28), and $|k, l\rangle$ denotes the basis vectors

$$|k,l\rangle = |j,k\rangle \otimes |j',l\rangle \tag{43}$$

of the space $\mathcal{H}_j \otimes \mathcal{H}_{j'}$ of the representation $T_j^{(-i)} \otimes T_{j'}^{(1)}$ of $\hat{U}_q(sl_2)^{\otimes 2,ext}$. Note that both $j+j'$ and $k+l$ are half-integral.

In this case we have the equalities $[k+l]_+ = [-k-l]_+$, $[k-l]_+ = [-k+l]_+$ and for this reason the operators $R_{jj'}^{(-i,1)}(I_{21})$ and $R_{jj'}^{(-i,1)}(I_{43})$ have multiple eigenvalues. Namely, all pairs of the vectors $|k, l\rangle$ and $|-k,-l\rangle$ have the same eigenvalues:

$$R_{jj'}^{(-i,1)}(I_{21})|k,l\rangle = [k+l]_+ |k,l\rangle, \quad R_{jj'}^{(-i,1)}(I_{43})|k,l\rangle = [k-l]_- |k,l\rangle,$$

$$R_{jj'}^{(-i,1)}(I_{21})|-k,-l\rangle = [k+l]_+ |-k,-l\rangle, \quad R_{jj'}^{(-i,1)}(I_{43})|-k,-l\rangle = [k-l]_+ |-k,-l\rangle.$$

The representation $R_{jj'}^{(-i,1)}$ is reducible. In order to show this we distinguish two case:

(a) j is half-integral and j' integral and
(b) j is integral and j' half-integral.

We consider first the case (a). In order to decompose $R_{jj'}^{(-i,1)}$ into irreducible constituents we choose a new basis in the representation space consisting of the vectors

$$|k,l\rangle^+ = |k,l\rangle + (-1)^l |-k,-l\rangle, \quad k>0,$$

$$|k,l\rangle^- = |k,l\rangle + (-1)^{l+1} |-k,-l\rangle, \quad k>0.$$

Using formulas (40)–(42) we easily find that

$$R_{jj'}^{(-i,1)}(I_{21})|k,l\rangle^\pm = [k+l]_- |k,l\rangle^\pm, \quad R_{jj'}^{(-i,1)}(I_{43})|k,l\rangle^\pm = [k-l]_+ |k,l\rangle^\pm, \tag{44}$$

$$R^{(-\mathrm{i},1)}_{jj'}(I_{32})|k,l\rangle^+=\frac{1}{[k+l][k-l](q-q^{-1})}\{-\mathrm{i}[j-l][j'-l]|k,l+1\rangle^+ +\mathrm{i}[j+l][j'+l]|k,l-1\rangle^+$$
$$-\mathrm{i}[j'-k][j-k]|k+1,l\rangle^+ +\mathrm{i}[j'+k][j+k]|k-1,l\rangle^+\},\quad k\neq\tfrac{1}{2}, \tag{45}$$

$$R^{(-\mathrm{i},1)}_{jj'}(I_{32})\left|\frac{1}{2},l\right\rangle^+=\frac{-1}{[l+\frac{1}{2}][l-\frac{1}{2}](q-q^{-1})}\left\{-\mathrm{i}[j-l][j'-l]\left|\frac{1}{2},l+1\right\rangle^+\right.$$
$$+\mathrm{i}[j+l][j'+l]\left|\frac{1}{2},l-1\right\rangle^+ -\mathrm{i}[j'-\tfrac{1}{2}][j-\tfrac{1}{2}]\left|\frac{3}{2},l\right\rangle^+$$
$$\left.+\mathrm{i}[j'+\tfrac{1}{2}][j+\tfrac{1}{2}](-1)^l\left|\frac{1}{2},-l\right\rangle^+\right\}. \tag{46}$$

The operator $R^{(-\mathrm{i},1)}_{jj'}(I_{32})$ acts on the vectors $|k,l\rangle^-$ by formulas (45) and (46) if to replace all $|k,l\rangle^+$ by the corresponding $|k,l\rangle^-$, and in (46) to replace $(-1)^l$ by $(-1)^{l+1}$.

Let $\mathcal{H}_1$ and $\mathcal{H}_2$ be the subspaces of the representation space of $R^{(-\mathrm{i},1)}_{jj'}$ spanned by the vectors $|k,l\rangle^+$ and by the vectors $|k,l\rangle^-$, respectively. We see from the previous formulas that these subspaces are invariant with respect to the representation $R^{(-\mathrm{i},1)}_{jj'}$. We denote the restrictions of $R^{(-\mathrm{i},1)}_{jj'}$ to $\mathcal{H}_1$ and $\mathcal{H}_2$ by $R^{(+,+,+)}_{jj'}$ and $R^{(+,+,-)}_{jj'}$, respectively. Note that

$$R^{(+,+,+)}_{jj'}(I_{32})\left|\frac{1}{2},0\right\rangle^+=\frac{1}{[\frac{1}{2}]^2(q-q^{-1})}\left\{-\mathrm{i}[j][j']\left|\frac{1}{2},1\right\rangle^+ +i[j][j']\left|\frac{1}{2},-1\right\rangle^+ -\mathrm{i}[j'-\tfrac{1}{2}][j-\tfrac{1}{2}]\right.$$
$$\left.\times\left|\frac{3}{2},0\right\rangle^+ +i[j'+\tfrac{1}{2}][j+\tfrac{1}{2}]\left|\frac{1}{2},0\right\rangle^+\right\}, \tag{47}$$

that is, the operator $R^{(+,+,+)}_{jj'}(I_{32})$ has nonzero diagonal element

$$^+\left\langle\frac{1}{2},0\right|R^{(+,+,+)}_{jj'}(I_{32})\left|\frac{1}{2},0\right\rangle^+=i\frac{[j'+\frac{1}{2}][j+\frac{1}{2}]}{[\frac{1}{2}]^2(q-q^{-1})}.$$

In the same way it is shown that

$$^-\left\langle\frac{1}{2},0\right|R^{(+,+,-)}_{jj'}(I_{32})\left|\frac{1}{2},0\right\rangle^-=-\mathrm{i}\frac{[j'+\frac{1}{2}][j+\frac{1}{2}]}{[\frac{1}{2}]^2(q-q^{-1})}.$$

Now we consider the case (b). The new basis of the representation space is

$$|k,l\rangle^+=|k,l\rangle+(-k)^l|-k,-l\rangle,\quad l>0,$$

$$|k,l\rangle^-=|k,l\rangle+(-1)^{k+1}|-k,-l\rangle,\quad l>0.$$

Then formulas for $R^{(-\mathrm{i},1)}_{jj'}(I_{21})$ and $R^{(-\mathrm{i},1)}_{jj'}(I_{43})$ are the same as in case (a). Formula (45) is the same, but we have consider it for $l\neq 1/2$. Instead of (46) we have the formula

$$R^{(-\mathrm{i},1)}_{jj'}(I_{32})\left|k,\frac{1}{2}\right\rangle^{+}=\frac{1}{[k+\frac{1}{2}][k-\frac{1}{2}](q-q^{-1})}\left\{-\mathrm{i}[j-\tfrac{1}{2}][j'-\tfrac{1}{2}]\left|k,\frac{3}{2}\right\rangle^{+}+\mathrm{i}[j+\tfrac{1}{2}][j'+\tfrac{1}{2}](-1)^{k}\right.$$
$$\left.\left|-k,\frac{1}{2}\right\rangle^{+}-\mathrm{i}[j'-k][j-k]\left|k+1,\frac{1}{2}\right\rangle^{+}+\mathrm{i}[j'+k][j+k]\left|k-1,\frac{1}{2}\right\rangle^{+}\right\}. \tag{48}$$

The operator $R^{(-\mathrm{i},1)}_{jj'}(I_{32})$ acts on the vectors $|k,l\rangle^{-}$ by formulas (45) and (48) if to replace all $|k,l\rangle^{+}$ by $|k,l\rangle^{-}$, respectively, and in (48) to replace $(-1)^k$ by $(-1)^{k+1}$.

We denote the subspaces spanned by the vectors $|k,l\rangle^{+}$ and by the vectors $|k,l\rangle^{-}$ as $\mathcal{H}_1$ and $\mathcal{H}_2$, respectively. As we see from the previous formulas, these subspaces are invariant with respect to the representation $R^{(-\mathrm{i},1)}_{jj'}$. We denote the corresponding subrepresentations by $R^{(+,+,-)}_{jj'}$ and $R^{(+,+,+)}_{jj'}$, respectively. In particular, we have

$$R^{(+,+,-)}_{jj'}(I_{32})\left|0,\frac{1}{2}\right\rangle^{+}=\frac{-1}{[\frac{1}{2}]^2(q-q^{-1})}\left\{-\mathrm{i}[j-\tfrac{1}{2}][j'-\tfrac{1}{2}]\left|0,\frac{3}{2}\right\rangle^{+}+\mathrm{i}[j+\tfrac{1}{2}][j'+\tfrac{1}{2}]\left|0,\frac{1}{2}\right\rangle^{+}\right.$$
$$\left.-\mathrm{i}[j'][j]\left|1,\frac{1}{2}\right\rangle^{+}+\mathrm{i}[j'][j]\left|-1,\frac{1}{2}\right\rangle^{+}\right\}, \tag{49}$$

that is, the operator $R^{(+,+,-)}_{jj'}(I_{32})$ has nonzero diagonal element

$${}^{+}\left\langle 0,\frac{1}{2}\right|R^{(+,+,-)}_{jj'}(I_{32})\left|0,\frac{1}{2}\right\rangle^{+}=-\mathrm{i}\frac{[j'+\frac{1}{2}][j+\frac{1}{2}]}{[\frac{1}{2}]^2(1-q^{-1})}.$$

For the operator $R^{(+,+,+)}_{jj'}(I_{32})$ we have

$${}^{-}\left\langle 0,\frac{1}{2}\right|R^{(+,+,+)}_{jj'}(I_{32})\left|0,\frac{1}{2}\right\rangle^{-}=\mathrm{i}\frac{[j'+\frac{1}{2}][j+\frac{1}{2}]}{[\frac{1}{2}]^2(1-q^{-1})}.$$

Now we consider in the same way the representations

$$R^{(-\mathrm{i},-1)}_{jj'}=(T^{(-\mathrm{i})}_{j}\otimes T^{(-1)}_{j'})\circ\phi$$

of $U'_q(so_4)$. As a result, we obtain for these representations formulas (40)–(42) in which the right-hand sides of (40) and (41) are multiplied by -1 and the right-hand side of (42) is left without any change. These representations are reducible and we have

$$R^{(-\mathrm{i},-1)}_{jj'}=R^{(-,-,+)}_{jj'}\oplus R^{(-,-,-)}_{jj'},$$

where the representations $R^{(-,-,+)}_{jj'}$ and $R^{(-,-,-)}_{jj'}$ act on such subspaces as in the previous case, with these difference that

$$R^{(-,-,\pm)}_{jj'}(I_{21})=-R^{(+,+,\pm)}_{jj'}(I_{21}),\quad R^{(-,-,\pm)}_{jj'}(I_{43})=-R^{(+,+,\pm)}_{jj'}(I_{43}),$$

that is,

$$R^{(-,-,\pm)}_{jj'}(I_{21})|k,l\rangle^{\pm}=-[k+l]_{+}|k,l\rangle^{\pm},\quad R^{(-,-,\pm)}_{jj'}(I_{43})|k,l\rangle^{\pm}=-[k-l]_{+}|k,l\rangle^{\pm}.$$

The operators $R^{(-,-,Z\pm)}_{jj'}(I_{32})$ coincide with the corresponding operators $R^{(+,+,\pm)}_{jj'}(I_{32})$.

Similarly, the representation $R^{(\mathrm{i},1)}_{jj'}=(T^{(\mathrm{i})}_{j}\otimes T^{(1)}_{j'})\circ\phi$ of $U'_q(so_4)$ is reducible and decomposes as

$$R^{(\mathrm{i},1)}_{jj'}=R^{(-,-,+)}_{jj'}\oplus R^{(-,-,-)}_{jj'},$$

where $R^{(-,-,\pm)}_{jj'}$ are such as earlier in this work, and the representation $R^{(\mathrm{i},-1)}_{jj'}=(T^{(\mathrm{i})}_{j}\otimes T^{(-1)}_{j'})\circ\phi$ of $\mathrm{U}'_q(\mathrm{so}_4)$ is reducible and decomposes as

$$R^{(\mathrm{i},-1)}_{jj'}=R^{(+,+,+)}_{jj'}\oplus R^{(+,+,-)}_{jj'},$$

where $R^{(+,+,\pm)}_{jj'}$ are such as earlier in this work.

Let us consider the representation

$$R^{(1,\mathrm{i})}_{j'j}=(T^{(1)}_{j'}\otimes T^{(\mathrm{i})}_{j})\circ\phi$$

of $\mathrm{U}'_q(\mathrm{so}_4)$ (for convenience we take first the index j' and then j). We have

$$R^{(1,\mathrm{i})}_{j'j}(I_{21})|l,k\rangle=-[k+l]_+|l,k\rangle,\quad R^{(1,\mathrm{i})}_{j'j}(I_{43})|l,k\rangle=[k-l]_+|l,k\rangle,$$

$$R^{(1,\mathrm{i})}_{j'j}(I_{32})|l,k\rangle=\frac{1}{[k+l][l-k](q-q^{-1})}\{-\mathrm{i}[j-l][j'-l]|l+1,k\rangle+\mathrm{i}[j+l][j'+l]|l-1,k\rangle-\mathrm{i}[j'-k][j-k]|l,k+1\rangle+\mathrm{i}[j'+k][j+k]|l,k-1\rangle\}.$$

In order to have a similarity with formulas (40)–(42) we denote the vectors $|l,\,k\rangle$ by $|k,\,l\rangle$ and the representation $R^{(1,\mathrm{i})}_{j'j}$ by $\hat{R}^{(\mathrm{i},1)}_{jj'}$.

The operators $\hat{R}^{(\mathrm{i},1)}_{jj'}(I_{21})$ and $\hat{R}^{(\mathrm{i},1)}_{jj'}(I_{43})$ have multiple common eigenvectors $|k,\,l\rangle$ and $|-k,-l\rangle$. The representation $\hat{R}^{(\mathrm{i},1)}_{jj'}$ is analyzed as the representation $R^{(-\mathrm{i},1)}_{jj'}$ given earlier and we have the following result. The representation $\hat{R}^{(\mathrm{i},1)}_{jj'}$ is reducible and decomposes into irreducible subrepresentations as

$$\hat{R}^{(\mathrm{i},1)}_{jj'}=R^{(-,+,+)}_{jj'}\oplus R^{(-,+,-)}_{jj'},$$

where the representations $R^{(-,+,\pm)}_{jj'}$ differ from the representations $R^{(+,+,\pm)}_{jj'}$, respectively, only by the operator $R^{(-,+,\pm)}_{jj'}(I_{21})$ and

$$R^{(-,+,\pm)}_{jj'}(I_{21})=-R^{(+,+,\pm)}_{jj'}(I_{21}).$$

Similarly, the representation

$$R^{(1,-\mathrm{i})}_{j'j}\equiv\hat{R}^{(-\mathrm{i},1)}_{jj'}=(T^{(1)}_{j'}\otimes T^{(-\mathrm{i})}_{j})\circ\phi$$

of $\mathrm{U}'_q(\mathrm{so}_4)$ is reducible and decomposes into irreducible components as

$$\hat{R}^{(-\mathrm{i},1)}_{jj'}=R^{(+,-,+)}_{jj'}\oplus R^{(+,-,-)}_{jj'},$$

where the representations $R^{(+,-,\pm)}_{jj'}$ differ from the representations $R^{(+,+,\pm)}_{jj'}$, respectively, only by the operator $R^{(+,-,\pm)}_{jj'}(I_{43})$ and

$$R^{(+,-,\pm)}_{jj'}(I_{43})=-R^{(+,+,\pm)}_{jj'}(I_{43}).$$

We do not consider other representations $R^{(\pm1,\pm\mathrm{i})}_{j'j}=(T^{(\pm1)}_{j'}\otimes T^{(\pm\mathrm{i})}_{j})$ since they do not give new irreducible representations of $\mathrm{U}'_q(\mathrm{so}_4)$.

Thus, for every value of j and j' such that

$$j=0,1,2,\ldots,\ \ j'=\tfrac{1}{2},\tfrac{3}{2},\tfrac{5}{2},\ldots,\quad\text{or}\quad j=\tfrac{1}{2},\tfrac{3}{2},\tfrac{5}{2},\ldots,\ \ j'=0,1,2,\ldots.$$

we constructed eight representations $R^{(\varepsilon_1,\varepsilon_2,\varepsilon_3)}_{jj'}$, $\varepsilon_i=\pm$. These representations act on the linear space $\mathcal{H}$ with the basis

$$|k,l\rangle, \quad k=j,j-1,...,\tfrac{1}{2}, \quad l=j', \ j'-1,...,-j'$$

if j' is integral, and with the basis

$$|k,l\rangle, \quad k=j,j-1,...,-j, \quad l=j', \ j'-1,...,\tfrac{1}{2}$$

if j is integral. The representations are given by the formulas

$$R^{(\varepsilon_1,\varepsilon_2,\varepsilon_3)}_{jj'}(I_{21})|k,l\rangle=\varepsilon_1[k+l]_+|k,l\rangle, \tag{50}$$

$$R^{(\varepsilon_1,\varepsilon_2,\varepsilon_3)}_{jj'}(I_{43})|k,l\rangle=\varepsilon_2[k-l]_+|k,l\rangle, \tag{51}$$

$$\begin{aligned}R^{(\varepsilon_1,\varepsilon_2,\varepsilon_3)}_{jj'}(I_{32})|k,l\rangle=&\frac{1}{[k+l][k-l](q-q^{-1})}\{-\mathrm{i}[j'-l][j-l]|k,l+1\rangle+\mathrm{i}[j'+l][j+l]|k,l-1\rangle\\&-\mathrm{i}[j'-k][j-k]|k+1,l\rangle+\mathrm{i}[j'+k][j+k]|k-1,l\rangle\},\end{aligned} \tag{52}$$

where $k\neq\frac{1}{2}$ if j is half-integral and $l\neq\frac{1}{2}$ if j' is half-integral, and by

$$\begin{aligned}R^{(\varepsilon_1,\varepsilon_2,\varepsilon_3)}_{jj'}(I_{32})\left|\frac{1}{2},l\right\rangle=&\frac{1}{[l+\frac{1}{2}][l-\frac{1}{2}](q-q^{-1})}\left\{-\mathrm{i}[j-l][j'-l]\left|\frac{1}{2},l+1\right\rangle+\mathrm{i}[j+l][j'+l]\right.\\&\left.\times\left|\frac{1}{2},l-1\right\rangle-\mathrm{i}[j'-\tfrac{1}{2}][j-\tfrac{1}{2}]\left|\frac{3}{2},l\right\rangle+\mathrm{i}[j'+\tfrac{1}{2}][j+\tfrac{1}{2}]\varepsilon_3(-1)^l\left|\frac{1}{2},-l\right\rangle\right\}\end{aligned} \tag{53}$$

if j is half-integral and by

$$\begin{aligned}R^{(\varepsilon_1,\varepsilon_2,\varepsilon_3)}_{jj'}(I_{32})\left|k,\frac{1}{2}\right\rangle=&\frac{1}{[k+\frac{1}{2}][k-\frac{1}{2}](q-q^{-1})}\left\{-\mathrm{i}[j-\tfrac{1}{2}][j'-\tfrac{1}{2}]\left|k,\frac{3}{2}\right\rangle+\mathrm{i}[j+\tfrac{1}{2}][j'+\tfrac{1}{2}]\varepsilon_3\right.\\&\left.(-1)^k\left|-k,\frac{1}{2}\right\rangle-\mathrm{i}[j'-k][j-k]\left|k+1,\frac{1}{2}\right\rangle+\mathrm{i}[j'+k][j+k]\left|k-1,\frac{1}{2}\right\rangle\right\}\end{aligned} \tag{54}$$

if j' is half-integral.

It is seen from formulas for representations that the representations $R^{(\varepsilon_1,\varepsilon_2,\varepsilon_3)}_{jj'}$ and $R^{(\varepsilon_1,-\varepsilon_2,\varepsilon_3)}_{j'j}$ are equivalent. The equivalence operator A is given by the formula $A|k,l\rangle=|l,k\rangle$. For this reason, we consider the representations $R^{(\varepsilon_1,\varepsilon_2,\varepsilon_3)}_{jj'}$ only for $j\geqslant j'$.

Theorem 3: *The representations* $R^{(\varepsilon_1,\varepsilon_2,\varepsilon_3)}_{jj'}$, $j\geqslant j'$, *are irreducible and pairwise nonequivalent.*

Proof: Irreducibility of these representations will be proved in Sec. VIII. In order to prove their pairwise nonequivalence we note that finite-dimensional representations T and T' of $U'_q(so_4)$ cannot be equivalent if for at least one pair $T(I_{i,i-1})$, $T'(I_{i,i-1})$, $i=2,3,4$, we have $\mathrm{Tr}T(I_{i,i-1})\neq\mathrm{Tr}T'(I_{i,i-1})$. For this reason, the representations $R^{(\varepsilon_1,\varepsilon_2,\varepsilon_3)}_{jj'}$ and $R^{(\varepsilon'_1,\varepsilon'_2,\varepsilon'_3)}_{ss'}$ with $(\varepsilon_1,\varepsilon_2,\varepsilon_3)\neq(\varepsilon'_1,\varepsilon'_2,\varepsilon'_3)$ or/and with $(j,j')\neq(s,s')$ are not equivalent.

Irreducible representations $R_{jj'}^{(\varepsilon_1,\varepsilon_2,\varepsilon_3)}$ are called *representations of the nonclassical type*. They have no classical analogue. They are characterized by the property that the operators $R_{jj'}^{(\varepsilon_1,\varepsilon_2,\varepsilon_3)} \times (I_{i,i-1})$, $i=2,3,4$, have a nonzero trace. Note that there exist eight nontrivial one-dimensional representations of the nonclassical type. They coincide with the representations $R_{(1/2)0}^{(\varepsilon_1,\varepsilon_2,\varepsilon_3)}$.

VIII. THE CLASSIFICATION THEOREM

The main aim of this section is to prove that previously constructed irreducible representations of the classical type and of the nonclassical type exhaust all irreducible finite-dimensional representations of the algebra $\mathrm{U}_q'(\mathrm{so}_4)$. We also prove that pairs of the irreducible representations of Theorem 3 are not equivalent. But first we study some auxiliary operators.

Let R be a finite-dimensional representation of $\mathrm{U}_q'(\mathrm{so}_4)$ on a linear vector space $\mathcal{H}$. We suppose that the operators $R(I_{21})$ and $R(I_{43})$ have eigenvalues only of the classical type, that is, of the form $\mathrm{i}[m]$, where $[m]$ means a q-number. Let $|k,\, l\rangle$ be an eigenvector such that

$$R(I_{21})|k,l\rangle = \mathrm{i}[k+l]|k,l\rangle, \quad R(I_{43})|k,l\rangle = \mathrm{i}[k-l]|k,l\rangle.$$

We associate with this eigenvector the operators

$$X_1^{(k,l)} = -R(I_{41}) + q^{-2k}R(I_{32}) - \mathrm{i}q^{-k-l+1/2}R(I_{42}) - \mathrm{i}q^{-k+l-1/2}R(I_{31}), \tag{55}$$

$$X_2^{(k,l)} = -R(I_{41}) + q^{2k}R(I_{32}) + \mathrm{i}q^{k+l+1/2}R(I_{42}) + \mathrm{i}q^{k-l-1/2}R(I_{31}), \tag{56}$$

$$X_3^{(k,l)} = R(I_{41}) + q^{-2l}R(I_{32}) + \mathrm{i}q^{-k-l+1/2}R(I_{42}) - \mathrm{i}q^{k-l-1/2}R(I_{31}), \tag{57}$$

$$X_4^{(k,l)} = R(I_{41}) + q^{2l}R(I_{32}) - \mathrm{i}q^{k+l+1/2}R(I_{42}) + \mathrm{i}q^{-k+l-1/2}R(I_{31}). \tag{58}$$

Note that later we shall use the explicit form of the operators $X_1^{(k,l)}$, $X_2^{(k,l)}$, $X_3^{(k,l)}$, $X_4^{(k,l)}$ under action on the vector $|k,\, l\rangle$. In this case we may consider formulas (55)–(58) as a system of linear equations with unknown vectors $R(I_{32})|k,l\rangle$, $R(I_{31})|k,l\rangle$, $R(I_{42})|k,l\rangle$, and $R(I_{41})|k,l\rangle$. The determinant of this system can be easily calculated:

$$\det\begin{pmatrix} -1 & q^{-2k} & -\mathrm{i}q^{-k-l+1/2} & -\mathrm{i}q^{-k+l-1/2} \\ -1 & q^{2k} & \mathrm{i}q^{k+l+1/2} & \mathrm{i}q^{k-l-1/2} \\ 1 & q^{-2l} & \mathrm{i}q^{-k-l+1/2} & -\mathrm{i}q^{k-l-1/2} \\ 1 & q^{2l} & -\mathrm{i}q^{k+l+1/2} & \mathrm{i}q^{-k+l-1/2} \end{pmatrix} = (q^{k+l}+q^{-k-l})(q^{k-l}+q^{-k+l}).$$

If q is not a root of unity, then this determinant does not vanish for any integral or half-integral k and l. This means that the system of above equations can be solved and we can find how the operators $R(I_{32})$, $R(I_{31})$, $R(I_{42})$, and $R(I_{41})$ act on the vector $|k,\, l\rangle$. This reasoning will be used below.

Lemma 1: The vectors $X_i^{(k,l)}|k,l\rangle$ are eigenvectors of the operators $R(I_{21})$ and $R(I_{43})$:

$$R(I_{21})(X_1^{(k,l)}|k,l\rangle) = \mathrm{i}[k+l+1](X_1^{(k,l)}|k,l\rangle), \quad R(I_{43})(X_1^{(k,l)}|k,l\rangle) = \mathrm{i}[k-l-1](X_1^{(k,l)}|k,l\rangle),$$

$$R(I_{21})(X_2^{(k,l)}|k,l\rangle) = \mathrm{i}[k+l-1](X_2^{(k,l)}|k,l\rangle), \quad R(I_{43})(X_2^{(k,l)}|k,l\rangle) = \mathrm{i}[k-l+1](X_2^{(k,l)}|k,l\rangle),$$

$$R(I_{21})(X_3^{(k,l)}|k,l\rangle) = \mathrm{i}[k+l+1](X_3^{(k,l)}|k,l\rangle), \quad R(I_{43})(X_3^{(k,l)}|k,l\rangle) = \mathrm{i}[k-l+1](X_3^{(k,l)}|k,l\rangle),$$

$$R(I_{21})(X_4^{(k,l)}|k,l\rangle) = \mathrm{i}[k+l-1](X_4^{(k,l)}|k,l\rangle), \quad R(I_{43})(X_4^{(k,l)}|k,l\rangle) = \mathrm{i}[k-l-1](X_4^{(k,l)}|k,l\rangle).$$

Proof: The lemma is proved by direct calculation using the defining relations for the elements $I_{ij} \in U_q'(\mathrm{so}_4)$, $i>j$. For example, by using relations (11)–(14) we have

$$R(I_{21})(X_1^{(k,l)}|k,l\rangle)=R(-qI_{41}+q^{-2k-1}I_{32}-iq^{-k-l-1/2}I_{42}-iq^{k+l+1/2}I_{31})R(I_{21})|k,l\rangle$$
$$+R(iq^{-k-l}I_{41}-iq^{l-k}I_{32}+q^{1/2}I_{42}+q^{-2k-1/2}I_{31})|k,l\rangle$$
$$=i[k+l+1](X_1^{(k,l)}|k,l\rangle).$$

The lemma is proved.

Lemma 1 means that the operators $X_1^{(k,l)}$ and $X_3^{(k,l)}$ increase k and l in the eigenvalues of $R(I_{21})$ and $R(I_{43})$, respectively, and the operators $X_2^{(k,l)}$ and $X_4^{(k,l)}$ decrease these numbers in these eigenvalues. Symbolically we write this in the form

$$X_1:\ l\to l+1,\quad X_2: l\to l-1,$$

$$X_3:\ k\to k+1,\quad X_4: k\to k-1.$$

Lemma 2: The operators (55)–(58) have the properties

$$X_3^{(k,l+1)}X_1^{(k,l)}|k,l\rangle=X_1^{(k+1,l)}X_3^{(k,l)}|k,l\rangle,\quad X_4^{(k,l-1)}X_2^{(k,l)}|k,l\rangle=X_2^{(k-1,l)}X_4^{(k,l)}|k,l\rangle,$$

$$X_4^{(k,l+1)}X_1^{(k,l)}|k,l\rangle=X_1^{(k-1,l)}X_4^{(k,l)}|k,l\rangle,\quad X_3^{(k,l-1)}X_2^{(k,l)}|k,l\rangle=X_2^{(k+1,l)}X_3^{(k,l)}|k,l\rangle.$$

Proof: The first of these relations is proved as follows. Using the expressions (55) and (57) for X_1 and X_3 we express [by using relations (11)–(15)] the elements $X_3^{(k,l+1)}X_1^{(k,l)}$ and $X_1^{(k+1,l)}X_3^{(k,l)}$ as a linear combination of the basis elements from Poincaré–Birkhoff–Witt theorem. As a result, we receive the first relation. Other relations are proved in the same way. The lemma is proved.

Lemma 2 means that the pairs of operators X_1 and X_3, X_2 and X_4, X_1 and X_4, and X_2 and X_3 (with appropriate upper indices) commute under action on the vector $|k,\ l\rangle$.

Lemma 3: The operators (55)–(58) have the properties

$$X_2^{(k,l+1)}X_1^{(k,l)}|k,l\rangle=(C_4'-(q^{2l+1}+q^{-2l-1})C_4+[2l][2(l+1)])|k,l\rangle,$$

$$X_1^{(k,l-1)}X_2^{(k,l)}|k,l\rangle=(C_4'-(q^{2l-1}+q^{-2l+1})C_4+[2l][2(l-1)])|k,l\rangle,$$

$$X_4^{(k+1,l)}X_3^{(k,l)}|k,l\rangle=(C_4'+(q^{2k+1}+q^{-2k-1})C_4+[2k][2(k+1)])|k,l\rangle,$$

$$X_3^{(k-1,l)}X_4^{(k,l)}|k,l\rangle=(C_4'+(q^{2k-1}+q^{-2k+1})C_4+[2k][2(k-1)])|k,l\rangle,$$

where C_4 and C_4' *are the Casimir elements of* $U'_q(so_4)$ *from Sec. II.*

The proof is given in the same way as that of Lemma 2, taking into account expressions for the Casimir elements.

Lemma 3 can be used for evaluation of eigenvalues of Casimir elements C_4 and C_4' on irreducible representations R when the operators $R(I_{21})$ and $R(I_{43})$ have eigenvalues of the classical type. Eigenvectors $|k,\ l\rangle$ of the operators $R(I_{21})$ and $R(I_{43})$ are called *weight vectors* of the representation R. A weight vector $|j,j'\rangle$ is called *a highest weight vector* if

$$X_1^{(j,j')}|j,j'\rangle=0,\quad X_3^{(j,j')}|j,j'\rangle=0.$$

If R is an irreducible representation with classical-type eigenvalues of the operators $R(I_{21})$ and $R(I_{43})$, then we apply both sides of the first and the third relations of Lemma 3 to the vector of highest weight $|j,j'\rangle$. The left-hand sides send this vector to zero, and then the right-hand sides (equating to zero) give the following eigenvalues for C_4 and C_4':

$$C_4=[j+j'+1][j'-j]I,$$

$$C_4'=\{(q^{2j+1}+q^{-2j-1})[j-j'][j+j'+1]-[2j][2j+2]\}I,$$

where I is the unit operator on the representation space. In particular, such eigenvalues have Casimir operators of the classical-type representation $R_{jj'}$.

Later in this work where we prove assertions concerning finite-dimensional representations of $U_q(so_4)$, we shall have in mind the following properties of the operators $X_i^{(k,l)}$ from (55)–(58), which are derived from Lemmas 1–3:

(A) Let $|k,l\rangle$ be such as in Lemma 1. Acting on $|k,l\rangle$ by the operators X_i, $i=1,2,3,4$, with appropriate upper indices, we can obtain a vector $|k,l\rangle'$ with eigenvalues of the operators $R(I_{21})$ and $R(I_{43})$ coinciding with those of the vector $|k,l\rangle$. Then $|k,l\rangle'=a|k,l\rangle$ for some complex number a.

(B) Let $|k,l\rangle$ be such as in Lemma 1. If $X_1^{(k,l)}|k,l\rangle=|k,l+1\rangle=0$ and $|k',l\rangle$ is another weight vector of the operators $R(I_{21})$ and $R(I_{43})$ obtained by action of the operators X_i, $i=1,2,3,4$, with appropriate upper indices, then $X_1^{(k',l)}|k',l\rangle=|k',l+1\rangle=0$. The same assertion is valid for the vectors $X_2^{(k,l)}|k,l\rangle$, $X_3^{(k,l)}|k,l\rangle$, and $X_4^{(k,l)}|k,l\rangle$. This means that by acting on $|k,l\rangle$ by the operators X_i, $i=1,2,3,4$, with appropriate upper indices, we obtain the set of nonzero vectors $|k',l'\rangle$ such that their values (k',l') constitute a parallelogram with vertices (j,j'), $(j,-j')$, $(-j,j')$, and $(-j,-j')$ under some values of j and j'.

Now let R' be a finite-dimensional representation of $U_q'(so_4)$ on a linear space $\mathcal{H}'$. Suppose that the operators $R'(I_{21})$ and $R'(I_{43})$ have eigenvalues only of the nonclassical type, that is, of the form $\pm[m]_+$, where $[m]_+=(q^m+q^{-m})/(q-q^{-1})$ and m are half-integral. If $|k,l\rangle$ is an eigenvector such that

$$R'(I_{21})|k,l\rangle=\varepsilon_1[k+l]_+|k,l\rangle,\quad R'(I_{43})|k,l\rangle=\varepsilon_2[k-l]_-|k,l\rangle,$$

then we associate with it the operators

$$X_1^{(k,l)}=R'(I_{41})+q^{-2k}R'(I_{32})-q^{-k-l+1/2}R'(I_{42})-q^{-k+l-1/2}R'(I_{31}), \tag{59}$$

$$X_2^{(k,l)}=R'(I_{41})+q^{2k}R'(I_{32})-q^{k+l+1/2}R'(I_{42})-q^{k-l-1/2}R'(I_{31}), \tag{60}$$

$$X_3^{(k,l)}=-R'(I_{41})-q^{-2l}R'(I_{32})+q^{-k-l+1/2}R'(I_{42})+q^{-k-l-1/2}R'(I_{31}), \tag{61}$$

$$X_4^{(k,l)}=-R'(I_{41})-q^{2l}R'(I_{32})+q^{k+l+1/2}R'(I_{42})+q^{-k+l-1/2}R'(I_{31}). \tag{62}$$

Next we shall consider relations (59)–(62) as a system of linear equations. The determinant of the matrix of this system is equal to

$$\det\begin{pmatrix} 1 & q^{-2k} & -q^{-k-l+1/2} & -q^{-k+l-1/2} \\ 1 & q^{2k} & -q^{k+l+1/2} & -q^{k-l-1/2} \\ -1 & -q^{-2l} & q^{-k-l+1/2} & q^{k-l-1/2} \\ -1 & -q^{2l} & q^{k+l+1/2} & q^{-k+l-1/2} \end{pmatrix}=(q^{k+l}-q^{-k-l})(q^{k-l}-q^{-k+l}).$$

If q is not a root of unity, then this determinant does not vanish for any half-integral $k\pm l$. Hence, the previous system of equations can be solved and we can find how the operators $R'(I_{32})$, $R'(I_{31})$, $R'(I_{42})$, and $R'(I_{41})$ act on the vector $|k,l\rangle$.

Next we formulate three lemmas for these operators analogous to Lemma 1–3. Proofs of these lemmas are the same as in the case of Lemmas 1–3 and we omit them.

Lemma 4: The vectors $X_i^{(k,l)}|k,l\rangle$ are eigenvectors of the operators $R'(I_{21})$ and $R'(I_{43})$:

$$R'(I_{21})(X_1^{(k,l)}|k,l\rangle)=\varepsilon_1[k+l+1]_+(X_1^{(k,l)}|k,l\rangle),$$

$$R'(I_{43})(X_1^{(k,l)}|k,l\rangle)=\varepsilon_2[k-l-1]_+(X_1^{(k,l)}|k,l\rangle),$$

$$R'(I_{21})(X_2^{(k,l)}|k,l\rangle)=\varepsilon_1[k+l-1]_+(X_2^{(k,l)}|k,l\rangle),$$

$$R'(I_{43})(X_2^{(k,l)}|k,l\rangle)=\varepsilon_2[k-l+1]_+(X_2^{(k,l)}|k,l\rangle),$$

$$R'(I_{21})(X_3^{(k,l)}|k,l\rangle)=\varepsilon_1[k+l+1]_+(X_3^{(k,l)}|k,l\rangle),$$

$$R'(I_{43})(X_3^{(k,l)}|k,l\rangle)=\varepsilon_2[k-l+1]_+(X_3^{(k,l)}|k,l\rangle),$$

$$R'(I_{21})(X_4^{(k,l)}|k,l\rangle)=\varepsilon_1[k+l-1]_+(X_4^{(k,l)}|k,l\rangle),$$

$$R'(I_{43})(X_4^{(k,l)}|k,l\rangle)=\varepsilon_2[k-l-1]_+(X_4^{(k,l)}|k,l\rangle).$$

Lemma 5: The operators (59)–(62) have the properties

$$X_3^{(k,l+1)}X_1^{(k,l)}|k,l\rangle=X_1^{(k+1,l)}X_3^{(k,l)}|k,l\rangle,\quad X_4^{(k,l-1)}X_2^{(k,l)}|k,l\rangle=X_2^{(k-1,l)}X_4^{(k,l)}|k,l\rangle,$$

$$X_4^{(k,l+1)}X_1^{(k,l)}|k,l\rangle=X_1^{(k-1,l)}X_4^{(k,l)}|k,l\rangle,\quad X_3^{(k,l-1)}X_2^{(k,l)}|k,l\rangle=X_2^{(k+1,l)}X_3^{(k,l)}|k,l\rangle.$$

Lemma 6: For the operators (59)–(62) we have

$$X_2^{(k,l+1)}X_1^{(k,l)}|k,l\rangle=(C_4'-(q^{2l+1}+q^{-2l-1})C_4+[2l][2(l+1)])|k,l\rangle,$$

$$X_1^{(k,l-1)}X_2^{(k,l)}|k,l\rangle=(C_4'-(q^{2l-1}+q^{-2l+1})C_4+[2l][2(l-1)])|k,l\rangle,$$

$$X_4^{(k+1,l)}X_3^{(k,l)}|k,l\rangle=(C_4'-(q^{2k+1}+q^{-2k-1})C_4+[2k][2(k+1)])|k,l\rangle,$$

$$X_3^{(k-1,l)}X_4^{(k,l)}|k,l\rangle=(C_4'-(q^{2k-1}+q^{-2k+1})C_4+[2k][2(k-1)])|k,l\rangle,$$

where C_4 and C_4' are the Casimir elements of $U'_q(so_4)$ *from Sec. II.*

Lemma 6 can be used for evaluation of eigenvalues of Casimir elements C_4 and C_4' on irreducible representations R' when the operators $R'(I_{21})$ and $R'(I_{43})$ have eigenvalues of the nonclassical type. Eigenvectors $|k,l\rangle$ of the operators $R'(I_{21})$ and $R'(I_{43})$ are called *weight vectors* of the representation R'. A weight vector $|j,j'\rangle$ is called *a highest weight vector* if

$$X_1^{(j,j')}|j,j'\rangle=0,\quad X_3^{(j,j')}|j,j'\rangle=0.$$

If R' is an irreducible representation with nonclassical type eigenvalues of the operators $R'(I_{21})$ and $R'(I_{43})$, then applying both sides of the first and third relations of Lemma 6 to the vector of highest weight $|j,j'\rangle$ we derive that

$$C_4=[j+j'+1]_+[j-j']_+I,$$

$$C_4'=\{(q^{2j+1}+q^{-2j-1})[j-j']_+[j+j'+1]_+-[2j][2j+2]\}I,$$

where I is the identity operator on the representation space. In particular, such eigenvalues have Casimir operators of the nonclassical type representation $R_{jj'}^{\varepsilon_1,\varepsilon_2,\varepsilon_3}$.

The operators $X_i^{(k,l)}$ from (59)–(62) have the properties similar to the properties (A) and (B).

Proof of the first part of Theorem 3: Let $R_{jj'}^{\varepsilon_1,\varepsilon_2,\varepsilon_3}$ be a representation of the nonclassical type on the vector space $\mathcal{H}$. Then the commuting operators $R_{jj'}^{\varepsilon_1,\varepsilon_2,\varepsilon_3}(I_{21})$ and $R_{jj'}^{\varepsilon_1,\varepsilon_2,\varepsilon_3}(I_{43})$ are simultaneously diagonalized. Since q is not a root of unity, the eigenvalues $(\varepsilon_1[k+l]_+,\varepsilon_2[k-l]_+)$ for the corresponding vector $|k,l\rangle$ are of multiplicity 1. Let $\mathcal{H}'$ be a nontrivial invariant subspace of the representation space $\mathcal{H}$, and let $\Sigma_{k,l}\alpha_{k,l}|k,l\rangle$ be a nonzero vector from $\mathcal{H}'$. Since eigenvalues $(\varepsilon_1[k+l]_+,\varepsilon_2[k-l]_+)$ are of multiplicity 1, then each $|k,l\rangle$ from this linear combination belongs

to $\mathcal{H}'$. Let $|k',l'\rangle$ be one of these vectors. Applying the operators X_1 and X_3 (with appropriate upper indices) to $|k',l'\rangle$ we obtain the vector of highest weight $|j,j'\rangle$ of the representation $R^{\varepsilon_1,\varepsilon_2,\varepsilon_3}_{jj'}$. Applying to $|j,j'\rangle$ the operators X_2 and X_4 (with appropriate indices) we obtain all basis vectors of the space $\mathcal{H}$. Hence, the representation $R^{\varepsilon_1,\varepsilon_2,\varepsilon_3}_{jj'}$ is irreducible. The theorem is proved.

Now we can prove the theorem on classification of irreducible finite-dimensional representations of $\mathrm{U}'_q(\mathrm{so}_4)$.

Theorem 4: *If q is not a root of unity, then each irreducible finite-dimensional representation R of $\mathrm{U}'_q(\mathrm{so}_4)$ is equivalent to one of the irreducible representations of the classical type or to one of the irreducible representations of the nonclassical type.*

Proof: Let us first prove the following assertion: *if eigenvalues of the operators $R(I_{21})$ and $R(I_{43})$ of an irreducible finite-dimensional representation R of $\mathrm{U}'_q(\mathrm{so}_4)$ are of the classical type (that is, of the form $i[m]$, $m\in\frac{1}{2}Z$), then R is equivalent to one of the irreducible representations of the classical type.* We diagonalize both operators $R(I_{21})$ and $R(I_{43})$ and represent their eigenvectors in the form $|k,l\rangle$, where

$$R(I_{21})|k,l\rangle=i[k+l]|k,l\rangle,\quad R(I_{43})|k,l\rangle=i[k-l]|k,l\rangle.$$

(These eigenvectors are called weight vectors.) Due to Lemmas 1 and 2, there exists an eigenvector of highest weight (we denote it by $|j,j'\rangle$), that is such that

$$R(I_{21})|j,j'\rangle=i[j+j']|j,j'\rangle,\quad R(I_{43})|j,j'\rangle=i[j-j']|j,j'\rangle,$$

$$X_1^{(j,j')}|j,j'\rangle=0,\quad X_3^{(j,j')}|j,j'\rangle=0.$$

Applying the first and third relations of Lemma 3 to the vector $|j,j'\rangle$ we find eigenvalues of the Casimir operators $R(C_4)$ and $R(C'_4)$ on the representation R:

$$R(C_4)=[j+j'+1][j'-j], \tag{63}$$

$$R(C'_4)=(q^{2j+1}+q^{-2j-1})[j-j'][j+j'+1]-[2j][2j+2]. \tag{64}$$

Acting on the vector $|j,j'\rangle$ by the operators X_2 (with appropriate upper indices) we construct recursively the vectors

$$|j,j'-s\rangle:=X_2^{(j,j'-s+1)}\cdots X_2^{(j,j'-1)}X_2^{(j,j')}|j,j'\rangle,\quad s=0,1,2,\ldots.$$

Since the representation R is finite dimensional and (by Lemma 1) these vectors have different eigenvalues, there exists smallest positive integer n such that

$$|j,j'-n\rangle:=X_2^{(j,j'-n+1)}|j,j'-n+1\rangle=0. \tag{65}$$

Similarly, between vectors

$$|j-r,j'\rangle:=X_4^{(j-r+1,j')}\cdots X_4^{(j-1,j')}X_4^{(j,j')}|j,j'\rangle,\quad r=0,1,2,\ldots,$$

there exists a nonzero vector with smallest positive integer m such that

$$|j-m,j'\rangle:=X_4^{(j-m+1,j')}|j-m+1,j'\rangle=0. \tag{66}$$

Then using the second and fourth relations of Lemma 3, we find from (63)–(66) that

$$X_1^{(j,j'-n)}X_2^{(j,j'-n+1)}|j,j'-n+1\rangle=[n][n-2j'-1](q^{j'-j-n}+q^{-j'+j+n})(q^{j+j'-n+1}+q^{-j-j'+n-1})|j,j'-n+1\rangle=0,$$

$$X_3^{(j-m,j')}X_4^{(j-m+1,j')}|j-m+1,j'\rangle=[m][m-2j-1](q^{m-j-j'-1}+q^{-m+j+j'+1})(q^{m-j+j'}+q^{-m+j-j'})|j-m+1,j'\rangle=0.$$

Therefore, $[n-2j'-1]=0$ and $[m-2j-1]=0$, that is,

$$m=2j+1, \quad n=2j'+1.$$

Now we act successively on the vectors $|j,j'\rangle,|j,j'-1\rangle,|j,j'-2\rangle,\ldots,|j,-j'\rangle$ by the operators X_4 with the appropriate upper indices. As a result, we construct the vectors

$$|j,j'\rangle, \quad |j-1,j'\rangle, \quad \ldots, \quad -j,j'\rangle,$$

$$|j,j'-1\rangle, \quad |j-1,j'-1\rangle, \quad \ldots, \quad |-j,j'-1\rangle,$$

$$\ldots \quad \ldots \quad \ldots \quad \ldots$$

$$|j,-j'\rangle, \quad |j-1,-j'\rangle, \quad \ldots, \quad |-j,j'\rangle,$$

for which

$$R(I_{21})|k,l\rangle=i[k+l]|k,l\rangle, \quad R(I_{43})|k,l\rangle=i[k-l]|k,l\rangle.$$

We can find how the operators X_i, $i=1,2,3,4$, with appropriate indices act on these vectors:

$$X_2^{(k,l)}|k,l\rangle=|k,l-1\rangle, \quad X_4^{(k,l)}|k,l\rangle=|k-1,l\rangle,$$

$$X_1^{(k,l)}|k,l\rangle=X_1^{(k,l)}X_2^{(k,l+1)}|k,l+1\rangle=(R(C_4')-(q^{2l+1}+q^{-2l-1})R(C_4)+[2l+2][2l])|k,l+1\rangle,$$

$$X_3^{(k,l)}|k,l\rangle=X_3^{(k,l)}X_4^{(k+1,l)}|k+1,l\rangle=(R(C_4')+(q^{(2k+1)}+q^{-2k-1})R(C_4)+[2k+2][2k])|k+1,l\rangle.$$

Putting here the explicit expression for the Casimir operators, substituting these expressions for $X_i^{(k,l)}|k,l\rangle$ to (55)–(58), and considering (55)–(58) as a system of linear equations with unknown $R(I_{32})|k,l\rangle$, $R(I_{31})|k,l\rangle$, $R(I_{42})|k,l\rangle$, and $R(I_{41})|k,l\rangle$, we solve this system and find that

$$R(I_{32})|k,l\rangle=\frac{1}{(q^{k+l}+q^{-k-l})(q^{k-l}+q^{-k+l})}\{|k-1,l\rangle+|k,l-1\rangle-(q^{j-l}+q^{j+l})(q^{j+l+1}+q^{-j-l-1})\times[j'-l][j'+l+1]|k,l+1\rangle-(q^{j'-k}+q^{j+k})(q^{j'+k+1}+q^{-j'-k-1})\times[j-k][j+k+1]|k+1,l\rangle\}.$$

Thus, the vectors $|k,l\rangle$, $-j\leqslant k\leqslant j$, $-j'\leqslant l\leqslant j'$, constitute a basis of the representation space $\mathcal{H}$. Introducing a new basis $\{|k,l\rangle'\}$ such that

$$|k,l\rangle=(-1)^{k+l}\prod_{r=-j}^{k}(q^{j'+r}+q^{-j'-r})^{-1}[j+r]^{-1}\prod_{s=-j'}^{k}(q^{j+s}+q^{-j-s})^{-1}[j'+s]^{-1}|k,l\rangle',$$

we shall obtain for $R(I_{21})$, $R(I_{32})$, and $R(I_{43})$ the operators of the irreducible representation $R_{jj'}$ of the classical type from Sec. IV. Thus, in this case the theorem is proved.

Now we prove the second part of the theorem which can be formulated as follows: *if eigenvalues of the operators $R(I_{21})$ and $R(I_{43})$ of an irreducible finite-dimensional representation R are of the nonclassical type, that is, of the form $\pm[m]_+$, $m\in\frac{1}{2}Z, m\notin Z$, then R is equivalent to one of the irreducible representations of the nonclassical type.*

We first prove that if eigenvalues of the operators $R(I_{21})$ and $R(I_{43})$ are of the form $[m]_+$ (only sign + is taken), then R is equivalent to one of the irreducible representations of the nonclassical type. A proof is similar to that of the previous case and for this reason we do not give details.

Due to Lemmas 4 and 5, there exists an eigenvector of highest weight $|j,j'\rangle$ such that

$$R(I_{21})|j,j'\rangle=[j+j']_+|j,j'\rangle, \quad R(I_{43})|j,j'\rangle=[j-j']_+|j,j'\rangle,$$

$$X_1^{(j,j')}|j,j'\rangle=X_3^{(j,j')}|j,j'\rangle=0.$$

Applying relations of Lemma 6 to $|j,j'\rangle$ we find eigenvalues of the Casimir operators $R(C_4)$ and $R(C_4')$:

$$R(C_4)=[j+j'+1]_+[j-j']_+, \tag{67}$$

$$R(C_4')=(q^{2j+1}+q^{-2j-1})[j-j']_+[j+j'+1]_+-[2j][2j+2]. \tag{68}$$

Now we construct recursively the vectors

$$|j-r,j'-s\rangle:=X_4^{(j-r+1,j'-s)}\cdots X_4^{(j,j'-s)}X_2^{(j,j'-s+1)}\cdots X_2^{(j,j'-1)}X_2^{(j,j')}|j,j'\rangle, \tag{69}$$

$$r,s=0,1,2,\ldots.$$

By Lemma 4, for these vectors we have

$$R(I_{21})|k,l\rangle=[k+l]_+|k,l\rangle, \quad R(I_{43})|k,l\rangle=[k-l]_+|k,l\rangle. \tag{70}$$

These vectors satisfy the relations

$$X_2^{(k,l)}|k,l\rangle=|k,l-1\rangle, \quad X_4^{(k,l)}|k,l\rangle=|k-1,l\rangle, \tag{71}$$

$$\begin{aligned}X_1^{(k,l)}|k,l\rangle&=X_1^{(k,l)}X_2^{(k,l+1)}|k,l+1\rangle\\&=(R(C_4')-(q^{2l+1}+q^{-2l-1})R(C_4)+[2l+2][2l])|k,l+1\rangle,\end{aligned} \tag{72}$$

$$\begin{aligned}X_3^{(k,l)}|k,l\rangle&=X_3^{(k,l)}X_4^{(k+1,l)}|k+1,l\rangle\\&=(R(C_4')-(q^{(2k+1}+q^{-2k-1})R(C_4)+[2k+2][2k])|k+1,l\rangle.\end{aligned} \tag{73}$$

Since the operators $X_1^{(k,l)}$, $X_2^{(k,l)}$, $X_3^{(k,l)}$, and $X_4^{(k,l)}$ acting on the vector $|k,\,l\rangle$ determine the action of the operators $R(I_{32})$, $R(I_{31})$, $R(I_{42})$, and $R(I_{41})$ on this vector, then the vectors

$$|j,j'\rangle, \quad |j-1,j'\rangle, \quad |j-2,j'\rangle, \quad \ldots,$$

$$|j,j'-1\rangle, \quad |j-1,j'-1\rangle \quad |j-2,j'-1\rangle, \quad \ldots,$$

$$|j,j'-2\rangle, \quad |j-1,j'-2\rangle, \quad |j-2,j'-2\rangle, \quad \ldots,$$

$$\ldots \quad \ldots \quad \ldots \quad \ldots$$

span an invariant subspace in the representation space $\mathcal{H}$. Since the representation R is irreducible, they span the whole space $\mathcal{H}$. It follows from (70) that only pairs of vectors $|k,\,l\rangle$ and $|-k,-l\rangle$ have the same eigenvalues for the operators $R(I_{21})$ and $R(I_{43})$.

In order to determine which possibilities exist for the representation R, we proceed as follows. For definiteness we suppose that j is half-integral. Using formula (69) we first create the set of all

possible vectors $|k, l\rangle$, which does not contain pairs $|k, l\rangle$ and $|-k,-l\rangle$. For example, we create all the vectors $|k, l\rangle$ with $k>0$. This set contains the vector $|\frac{1}{2},0\rangle$. There are two possibilities:

(a) The vectors $|\frac{1}{2},0\rangle$ and $|-\frac{1}{2},0\rangle$ are linearly dependent, that is, $X_4^{(1/2,0)}|\frac{1}{2},0\rangle=a|\frac{1}{2},0\rangle$.
(b) The vectors $|\frac{1}{2},0\rangle$ and $|-\frac{1}{2},0\rangle$ are linearly independent.

In the case (a) all pairs $|k, l\rangle$ and $|-k,-l\rangle$ consist of linearly dependent vectors. The reason for this is that

$$X_1^{(k,l)}=X_2^{(-k,-l)}, \quad X_3^{(k,l)}=X_4^{(-k,-l)} \tag{74}$$

[as it follows from expressions (59)–(62) for the operators X_i, $i=1,2,3,4$]. Therefore, for every positive integral r and s the vectors

$$X_3^{(r+1/2,s)}\cdots X_3^{(r+1/2,0)}X_1^{(r-1/2,0)}\cdots X_1^{(1/2,0)}|\tfrac{1}{2},0\rangle,$$

$$X_4^{(-r-1/2,-s)}\cdots X_4^{(-r-1/2,0)}X_2^{(-r+1/2,0)}\cdots X_2^{(-1/2,0)}|\tfrac{1}{2},0\rangle$$

are linearly dependent with the same constant a. The constant a can be explicitly calculated. Namely, since $X_4^{(1/2,0)}|1/2,0\rangle=|-1/2,0\rangle=a|1/2,0\rangle$ and $X_3^{(-1/2,0)}=X_4^{(1/2,0)}$, we have

$$\begin{aligned}X_3^{(-1/2,0)}|-\tfrac{1}{2},0\rangle&=X_3^{(-1/2,0)}X_4^{(-1/2,0)}|\tfrac{1}{2},0\rangle=R(C_4'-2C_4-1)|\tfrac{1}{2},0\rangle\\&=X_3^{(-1/2,0)}\,a|\tfrac{1}{2},0\rangle=aX_4^{(1/2,0)}|\tfrac{1}{2},0\rangle=a^2|\tfrac{1}{2},0\rangle,\end{aligned}$$

that is, $a^2=R(C_4'-2C_4-1)$. This means that a is determined up to a sign. Using expressions for values of the Casimir elements of $U'_q(so_4)$ on irreducible representations with highest weight vector $|j,j'\rangle$, we find that $a=\varepsilon_3(q-q^{-1})[j+\frac{1}{2}][j'+\frac{1}{2}]$, where ε_3 takes one of the values ± 1.

Thus, we received the following set of linear independent vectors of the representation space $\mathcal{H}$:

$$|j,j'\rangle, \quad |j-1,j'\rangle, \quad \cdots, \quad |\tfrac{1}{2},j'\rangle,$$

$$|j,j'-1\rangle, \quad |j-1,j'-1\rangle, \quad \cdots, \quad |\tfrac{1}{2},j'-1\rangle,$$

$$\cdots \quad \cdots \quad \cdots \quad \cdots$$

$$|j,-j'\rangle, \quad |j-1,-j'\rangle, \quad \cdots, \quad |\tfrac{1}{2},-j'\rangle.$$

These vectors constitute a basis of the space $\mathcal{H}$. We introduce a new basis $\{|k,l\rangle'\}$ such that

$$|k,l\rangle=\prod_{r=1/2}^{k}(q^{j'+r}-q^{-j'-r})^{-1}[j+r]^{-1}\prod_{s=-j'}^{k}(q^{j+s}-q^{-j-s})^{-1}[j'+s]^{-1}|k,l\rangle'.$$

Rewriting the relations (71)–(73) for this new basis we obtain a system of linear equations with unknown $R(I_{32})|k,l\rangle'$, $R(I_{42})|k,l\rangle'$, $R(I_{41})|k,l\rangle'$, and $R(I_{31})|k,l\rangle'$. Solving this system we find that the operator $R(I_{32})$ acts on the basis vectors by the formulas for the irreducible nonclassical type representation $R_{jj'}^{(+,+,+)}$ or the irreducible nonclassical type representation $R_{jj'}^{(+,+,-)}$.

Now we consider case (b). Due to the relation (74) we conclude that the vectors

$$|k,l\rangle, \quad k=j,j-1,j-2,\cdots,-j, \quad l=j',j'-1,j'-2,\cdots,-j',$$

are linearly independent and constitute a basis of the representation space $\mathcal{H}$. Solving the system of linear equations (71)–(73) we obtain a representation of $\mathrm{U}_q'(\mathrm{so}_4)$ equivalent to one of the representations $R_{jj'}^{(\pm\mathrm{i},\pm 1)}$ or $R_{jj'}^{(\pm 1,\pm\mathrm{i})}$ from Sec. VI. These representations are reducible. So, case (b) is not possible for our irreducible representation R.

We have considered the case when all eigenvalues of the operators $R(I_{21})$ and $R(I_{43})$ are of the form $[m]_+$ (with sign +). However, due to automorphisms ψ_1 and ψ_2, mapping $I_{21}\to -I_{21}$ and $I_{43}\to -I_{43}$, respectively, and conserving all other generating elements in $\{I_{21},I_{32},I_{43}\}$, to every such irreducible representation R there correspond the representations $R^{(+,-)}=R\circ\psi_2$, $R^{(-,+)}=R\circ\psi_1$, $R^{(-,-)}=R\circ\psi_1\psi_2$ such that

$$R^{(+,-)}(I_{21})|k,l\rangle=[k+l]_+|k,l\rangle,\quad R^{(+,-)}(I_{43})|k,l\rangle=-[k-l]_+|k,l\rangle, \tag{75}$$

$$R^{(-,+)}(I_{21})|k,l\rangle=-[k+l]_+|k,l\rangle,\quad R^{(-,+)}(I_{43})|k,l\rangle=[k-l]_+|k,l\rangle, \tag{76}$$

$$R^{(-,-)}(I_{21})|k,l\rangle=-[k+l]_+|k,l\rangle,\quad R^{(-,-)}(I_{43})|k,l\rangle=-[k-l]_+|k,l\rangle. \tag{77}$$

Conversely, to any of the representations $R^{(+,-)},R^{(-,+)},R^{(-,-)}$ with these properties there corresponds a unique representation R such that

$$R(I_{21})|k,l\rangle=[k+l]_+|k,l\rangle,\quad R(I_{43})|k,l\rangle=[k-l]_+|k,l\rangle \tag{78}$$

for all eigenvactors $|k,l\rangle$. This means that the classification of irreducible representations R with property (78) automatically leads to the classification of irreducible representations with any of the properties (75)–(77) and vice versa. Therefore, any of irreducible representations of $\mathrm{U}_q'(\mathrm{so}_4)$ with one of the properties (75)–(77) is equivalent to one of the irreducible representations of the nonclassical type. The theorem is proved.

In Sec. IV we constructed the homomorphism $\phi:\mathrm{U}_q'(\mathrm{so}_4)\to\hat{\mathrm{U}}_q(\mathrm{sl}_2)^{\otimes 2,\mathrm{ext}}$ (see Theorem 2). Now we are able to prove a stronger assertion:

Corollary: If q is not a root of unity, then the homomorphism $\mathrm{U}_q'(\mathrm{so}_4)\to\hat{\mathrm{U}}_q(\mathrm{sl}_2)^{\otimes 2,\mathrm{ext}}$ of Theorem 2 is injective.

Proof: If the assertion of our corollary is not true, then there exists nonzero element $a\in\mathrm{U}_q'(\mathrm{so}_4)$ such that $\phi(a)=0$. Then for any finite-dimensional representation T of the algebra $\hat{\mathrm{U}}_q(\mathrm{sl}_2)^{\otimes 2,\mathrm{ext}}$ we have $T(\phi(a))=0$. Taking the representations $T_{jj'}^{(\pm 1,\pm 1)}$, $T_{jj'}^{(\pm\mathrm{i},\pm 1)}$ and $T_{jj'}^{(\pm 1,\pm\mathrm{i})}$, where $T_{jj'}^{(\pm\varepsilon_1,\pm\varepsilon_2)}\equiv T_j^{(\pm\varepsilon_1)}\otimes T_{j'}^{(\pm\varepsilon_2)}$ (see Secs. VI and VII), as a representation T, we obtain $T_{jj'}^{(\pm 1,\pm 1)}(\phi(a))=0$, $T_{jj'}^{(\pm\mathrm{i},\pm 1)}(\phi(a))=0$, and $T_{jj'}^{(\pm 1,\pm\mathrm{i})}(\phi(a))=0$ for all admissible values of j and j'. As we have previously seen, any irreducible finite-dimensional representation of $\mathrm{U}_q'(\mathrm{so}_4)$ is equivalent to the representation $T_{jj'}^{(1,1)}\circ\phi$ with appropriate values of j and j' or to one of the irreducible constituents of the representations $T_{jj'}^{(\pm\mathrm{i},\pm 1)}\circ\phi$ and $T_{jj'}^{(\pm 1,\pm\mathrm{i})}\circ\phi$. This means that $R(a)=0$ for any irreducible finite-dimensional representation of $\mathrm{U}_q'(\mathrm{so}_4)$. But it was shown in Ref. 13 (see also Ref. 2) that irreducible finite-dimensional representations of $\mathrm{U}_q'(\mathrm{so}_4)$ separate elements of this algebra. Thus, for our element a there exists an irreducible finite-dimensional representation R such that $R(a)\neq 0$. This contradiction proves the corollary.

IX. COMPLETE REDUCIBILITY OF FINITE-DIMENSIONAL REPRESENTATIONS

It was proved in Ref. 29 that if q is not a root of unity, then every finite-dimensional representation of the algebra $\mathrm{U}_q'(\mathrm{so}_3)$ is completely reducible. The aim of this section is to prove the corresponding theorem for the algebra $\mathrm{U}_q'(\mathrm{so}_4)$.

We denote values of the Casimir operators C_4 and C_4' on irreducible representations of the classical and nonclassical types as follows:

$$C_4(R_{jj'})=C_{jj'},\quad C_4'(R_{jj'})=C_{jj'}',\quad C_4(R_{jj'}^{(\varepsilon_1,\varepsilon_2,\varepsilon_3)})=\tilde{C}_{jj'},\quad C_4'(R_{jj'}^{(\varepsilon_1,\varepsilon_2,\varepsilon_3)})=\tilde{C}_{jj'}'.$$

Then the values $C_{jj'}$ and $C'_{jj'}$ are given by formulas (63) and (64) whereas $\tilde{C}_{jj'}$ and $\tilde{C}'_{jj'}$ are given by (67) and (68). The following assertion will be used for proving the theorem on complete irreducibility.

Proposition 3: If for irreducible representations $R_{jj'}$ and $R_{kk'}$ we have $C_{jj'}=C_{kk'}$ and $C'_{jj'}=C'_{kk'}$, then these representations are equivalent, that is, $(j,j')=(k,k')$. If for irreducible representations $R^{(\varepsilon_1,\varepsilon_2,\varepsilon_3)}_{jj'}$ and $R^{(\varepsilon'_1,\varepsilon'_2,\varepsilon'_3)}_{kk'}$ we have $\tilde{C}_{jj'}=\tilde{C}_{kk'}$ and $\tilde{C}'_{jj'}=\tilde{C}'_{kk'}$, then $(j,j')=(k,k')$. For any irreducible representations $R_{jj'}$ and $R^{(\varepsilon_1,\varepsilon_2,\varepsilon_3)}_{kk'}$ the simultaneous equalities $C_{jj'}=\tilde{C}_{kk'}$ and $C'_{jj'}=\tilde{C}'_{kk'}$ are not possible.

Proof: We prove only the first part of the proposition (other ones are proved similarly). Let $C_{jj'}=C_{kk'}$ and $C'_{jj'}=C'_{kk'}$. We have from (63) and (64) that

$$C'_{kk'}=-(q^{2k+1}+q^{-2k-1})C_{kk'}-[2k][2k+2].$$

Substituting here $C_{kk'}=C_{jj'}$ we obtain from $C'_{jj'}=C'_{kk'}$ that

$$-(q^{2j+1}+q^{-2j-1})C_{jj'}-[2j][2j+2]=-(q^{2k+1}+q^{-2k-1})C_{jj'}-[2k][2k+2].$$

It can be simplified and factorized to the following form:

$$(q^{k+j+1}-q^{-k-j-1})(q^{k-j}-q^{-k+j})(q^{j'+k+1}+q^{-j'-k-1})(q^{j'-k}+q^{-j'+k})=0.$$

Since q is not a root of unity and j,j',k must be non-negative and integral or half-integral, this equality is true only for $k=j$. The relation $C_{jk'}=C_{jj'}$ can also be factorized and we obtain $(q^{k'+j'+1}-q^{-k'-j'-1})(q^{j'-k'}-q^{-j'+k'})=0$. Using similar argumentation, we derive from here that $j'=k'$. The proposition is proved.

Theorem 5: *If q is not a root of unity, then each finite-dimensional representation of $U'_q(so_4)$ is completely reducible.*

Proof: In order to prove this theorem it is enough to show that every finite-dimensional representation R of $U'_q(so_4)$, containing only two irreducible constituents, is completely reducible.

Let R be a finite-dimensional representation of $U'_q(so_4)$ containing only two irreducible constituents R' and R''. It is known that if $C_4(R')\neq C_4(R'')$ or $C'_4(R')\neq C''_4(R'')$, then R is a direct sum of its subrepresentations R' and R''. Thus, we have to consider only the case when $C_4(R')=C_4(R'')$ and $C'_4(R')=C'_4(R'')$. According to Proposition 3, we have to prove the theorem for two cases:

(a) Both constituents R' and R'' are equivalent and belong to the classical type.

(b) Both constituents R' and R'' are of the nonclassical type and are of the form $R^{(\varepsilon_1,\varepsilon_2,\varepsilon_3)}_{jj'}$ and $R^{(\varepsilon'_1,\varepsilon'_2,\varepsilon'_3)}_{jj'}$.

Each case will be proved separately.

Case (a). We denote our constituents by $R_{jj'}$ and $R'_{jj'}$, respectively. Since restriction of the representation R to the subalgebra $U'_q(so_3)$ is completely reducible, there exists a basis in the space of the representation R consisting of eigenvectors for both operators $R(I_{21})$ and $R(I_{43})$. In this basis there exist exactly two vectors of highest weight. Let $|j,j'\rangle$ and $|j,j'\rangle'$ be these vectors. We create two sets of vectors

$$X_2^r X_4^t|j,j'\rangle, \quad r,t=0,1,2,\ldots, \quad \text{and} \quad X_2^r X_4^t|j,j'\rangle', \quad r,t=0,1,2,\ldots,$$

where each of the operators X_2 and X_4 is taken with the appropriate upper indices. Due to the properties of the operators X_2 and X_4, these two sets span two subspaces V_1 and V_2 which are invariant with respect to the operators $R(I_{21})$, $R(I_{32})$, and $R(I_{43})$. Moreover, we have $V=V_1\oplus V_2$ and the theorem is proved in this case.

Case (b). We distinguish here the following subcases:

(I) two constituents are equivalent;

(II) two constituents are $R_{jj'}^{(\varepsilon_1,\varepsilon_2,\varepsilon_3)}$ and $R_{jj'}^{(\varepsilon_1',\varepsilon_2',\varepsilon_3')}$, where $\varepsilon_1\neq\varepsilon_1'$ or/and $\varepsilon_2\neq\varepsilon_2'$; and

(III) two constituents are $R_{jj'}^{(\varepsilon_1,\varepsilon_2,\varepsilon_3)}$ and $R_{jj'}^{(\varepsilon_1,\varepsilon_2,-\varepsilon_3)}$.

For subcase (I) a proof is such as in case (a). Let us consider subcase (II). Let $\varepsilon_1\neq\varepsilon_1'$. In the representation space V, there exist two linearly independent vectors $|j,j'\rangle$ and $|j,j'\rangle'$ which are of highest weights, that is,

$$X_1^{(i,j')}|j,j'\rangle=X_1^{(j,j')}|j,j'\rangle'=0,\quad X_3^{(jj')}|j,j'\rangle=X_3^{(jj')}|j,j'\rangle'=0,$$

and such that

$$R(I_{21})|j,j'\rangle=\varepsilon_1[j+j']_+|j,j'\rangle,\quad R(I_{21})|j,j'\rangle'=\varepsilon_1'[j+j']_+|j,j'\rangle.$$

We create two sets of vectors

$$X_2^rX_4^t|j,j'\rangle,\quad r,t=0,1,2,\cdots,\quad \text{and}\quad X_2^rX_4^t|j,j'\rangle',\quad r,t=0,1,2,...,$$

where the operators X_2 and X_4 are taken with the appropriate upper indices. No nonzero vector of the first set is a multiple of some vector of the second set (since otherwise these two sets span the same vector subspace of the representation space V). These two sets of vectors span two invariant linear subspaces V_1 and V_2 of V. Since $V=V_1\oplus V_2$, then the representation R is a direct sum of the subrepresentations $R_{jj'}^{(\varepsilon_1,\varepsilon_2,\varepsilon_3)}$ and $R_{jj'}^{(\varepsilon_1',\varepsilon_2',\varepsilon_3')}$.

Let us prove the theorem in subcase (III). We suppose that the representation $R_{jj'}^{(\varepsilon_1,\varepsilon_2,\varepsilon_3)}$ is realized on an invariant subspace V_1 and denote weight vectors for this representation by $|k,l\rangle$. We have $R(I_{32})|\frac{1}{2},0\rangle=\varepsilon_3a|\frac{1}{2},0\rangle+\cdots$, where a is the appropriate constant, and a linear combination of weight vectors with weights, different from that of the vector $|\frac{1}{2},0\rangle$, is denoted by dots. In the space V of the representation R there exists another vector $|\frac{1}{2},0\rangle'$ such that

$$R(I_{32})|\tfrac{1}{2},0\rangle'=-\varepsilon_3a|\tfrac{1}{2},0\rangle'+r|\tfrac{1}{2},0\rangle+\cdots,$$

where dots mean the same as earlier. Then we easily verify that

$$R(I_{32})\left(\left|\frac{1}{2},0\right\rangle'-\frac{r}{2a\varepsilon_3}\left|\frac{1}{2},0\right\rangle\right)=-a\varepsilon_3\left(\left|\frac{1}{2},0\right\rangle'-\frac{r}{2a\varepsilon_3}\left|\frac{1}{2},0\right\rangle\right)+\cdots$$

with the same meaning for dots. Denoting the vector $|\frac{1}{2},0\rangle'-(r/2a\varepsilon_3)|\frac{1}{2},0\rangle$ by $|\frac{1}{2},0\rangle''$ we create the vectors

$$X_1^rX_3^t|\tfrac{1}{2},0\rangle'',\quad r,t=0,1,2,...,$$

then take the vector of highest weight in this set (we denote it by $|j,j'\rangle''$) and create the vectors

$$X_1^rX_3^t|j,j'\rangle'',\quad r,t=0,1,2,...$$

(the operators X_1 and X_3 are taken with the appropriate upper indices). The linear subspace V_2 spanned by the last vectors is invariant and irreducible. Since $V=V_1\oplus V_2$, the theorem is proved also in this subcase.

X. TENSOR PRODUCTS OF REPRESENTATIONS

As in the case of the algebra $U_q'(so_3)$ (see Ref. 21), the homomorphism of Theorem 2 allows us to determine tensor products of irreducible finite-dimensional representations of the algebra $U_q'(so_4)$ and decompose them into irreducible constituents.

Let us explain this on the example of the classical type irreducible representations of $U_q'(so_4)$. Let $T^{(1,1)}_{jj'}=T^{(1)}_j\otimes T^{(1)}_{j'}$ be the irreducible representation of $U_q(sl_2)^{\otimes 2,\mathrm{ext}}$. Then the tensor product $T^{(1,1)}_{jj'}\otimes T^{(1,1)}_{ss'}$ is a well-defined representation of the algebra $U_q(sl_2)^{\otimes 2}$. Thus, we have to determine the operators $(T^{(1,1)}_{jj'}\otimes T^{(1,1)}_{ss'})(x_i)$, $i=1, 2$. For this we use the determined operators $(T^{(1,1)}_{jj'}\otimes T^{(1,1)}_{ss'})(c_i)$, $i=1, 2$, where c_i are Casimir elements from Sec. III. We define the operators $(T^{(1,1)}_{jj'}\otimes T^{(1,1)}_{ss'})(x_i)$ as solutions of quartic equations

$$q^{-1}\{(T^{(1,1)}_{jj'}\otimes T^{(1,1)}_{ss'})(x_i)\}^4-(T^{(1,1)}_{jj'}\otimes T^{(1,1)}_{ss'})(c_i)(q-q^{-1})^2\{(T^{(1,1)}_{jj'}\otimes T^{(1,1)}_{ss'})(x_i)\}^2+q=0 \quad (79)$$

(see the equation for the elements x_i in Sec. III). In order to find these solutions we may diagonalize the operators $(T^{(1,1)}_{jj'}\otimes T^{(1,1)}_{ss'})(c_i)$, which is always possible because the representation $T^{(1,1)}_{jj'}\otimes T^{(1,1)}_{ss'}$ is completely reducible. These operators turn to the block diagonal form with multiples of identity on the diagonal and the solutions of Eqs. (79) can be easily calculated. The solutions $(T^{(1,1)}_{jj'}\otimes T^{(1,1)}_{ss'})(x_i)$ have the same form and therefore clearly commute with all other operators which now have block diagonal form. Composing the representation $T^{(1,1)}_{jj'}\otimes T^{(1,1)}_{ss'}$ of $U_q(sl_2)^{\otimes 2,\mathrm{ext}}$ with the homomorphism ϕ from Theorem 2 we obtain the representation

$$R_{jj'}\otimes R_{ss'}=\{T^{(1,1)}_{jj'}\otimes T^{(1,1)}_{ss'}\}\circ\phi,$$

which is treated as the tensor product of irreducible representations $R_{jj'}$ and $R_{ss'}$ of the algebra $U_q'(so_4)$.

For the representation $T^{(1,1)}_{jj'}\otimes T^{(1,1)}_{ss'}$ of $U_q(sl_2)^{\otimes 2,\mathrm{ext}}$ we have the decomposition

$$T^{(1,1)}_{jj'}\otimes T^{(1,1)}_{ss'}=\bigoplus_{k=|j-s|}^{j+s}\ \bigoplus_{k'=|j'-s'|}^{j'+s'} T^{(1,1)}_{kk'}.$$

Composing the left- and the right-hand sides of this relation with the homomorphism ϕ from Theorem 2,

$$T^{(1,1)}_{jj'}\otimes T^{(1,1)}_{ss'})\circ\phi=\left(\bigoplus_k\ \bigoplus_k T^{(1,1)}_{kk'}\right)\circ\phi,$$

we obtain the decomposition of the tensor product $R_{jj'}\otimes R_{ss'}$:

$$R_{jj'}\otimes R_{ss'}=\bigoplus_{k=|j-s|}^{j+s}\ \bigoplus_{k'=|j'-s'|}^{j'+s'} R_{kk'}.$$

As in the case of the algebra $U_q'(so_3)$ in Ref. 21, we can also determine in a similar way tensor products of irreducible representations of the classical and the nonclassical types and tensor products of irreducible representations of the nonclassical type.

Transformation formulas for double hypergeometric series related to 9-*j* coefficients and their basic analogs

S. Lievens[a] and J. Van der Jeugt[b]
Department of Applied Mathematics and Computer Science, University of Ghent, Krijgslaan 281-S9, B-9000 Gent, Belgium

(Received 4 May 2001; accepted for publication 2 August 2001)

In a recent paper, Ališauskas deduced different triple sum expressions for the 9-*j* coefficient of su(2) and $su_q(2)$. For a singly stretched 9-*j* coefficient, these reduce to different double sum series. Using these distinct series, we deduce a set of new transformation formulas for double hypergeometric series of Kampé de Fériet type and their basic analogs. These transformation formulas are valid for rather general parameters of the series, although a common feature is that all the series appearing here are terminating. It is also shown that the transformation formulas deduced here generate a group of transformation formulas, thus yielding an invariance group or symmetry group of particular double series. © *2001 American Institute of Physics.* [DOI: 10.1063/1.1405126]

I. INTRODUCTION

The Wigner 9-*j* coefficients (or 9-*j* symbols) arise as recoupling coefficients in the coupling (tensor product) of four irreducible representations of su(2), and play an important role in the quantum theory of angular momentum.[1–3] Although the relation between recoupling coefficients, such as the 3-*j* coefficient and the 6-*j* coefficient, and hypergeometric series or (discrete) orthogonal polynomials of hypergeometric type is well understood,[3–6] the 9-*j* coefficient remains somewhat a mystery in this respect. There are many known expressions for the 9-*j* coefficient as a multiple hypergeometric series. The most compact formula is the so-called triple sum series, originally derived by Ališauskas and Jucys,[7] and rederived in Ref. 8. Whether a triple sum expression is really the best one can do for the 9-*j* coefficient is not known; specialists in the field still guess that a double sum series might exist.[9]

The triple sum series of Ališauskas and Jucys was recognized as a special case[5,10] of a triple hypergeometric series defined by Srivastava.[11] It was used to speed up the numerical computation of 9-*j* coefficients,[10] and to derive certain summation and reduction formulas for hypergeometric series by using particular classes of 9-*j* coefficients.[12–14]

Ališauskas and Jucys's triple sum series was recently rederived in two ways. In Ref. 15, Rosengren deduced the triple sum series for 9-*j* coefficients [of su(1,1) rather than of su(2)] based upon the use of coupling kernels; in Ref. 16, he showed that the same formula can be deduced starting from the classical expansion of the 9-*j* coefficient in terms of 6-*j* coefficients and performing Dougall's summation formula[17] for a very well-poised ${}_4F_3(-1)$ series. In a recent paper,[18] Ališauskas realized that this technique can be applied for several distinct expansions of the 9-*j* coefficient in terms of 6-*j* coefficients. Thus he obtained seven different triple sum formulas for the 9-*j* coefficient of su(2). At the same time, he showed that this technique has a basic analogue (or *q*-analog), depending upon a *q*-analog of Dougall's summation formula.[19] So, he also obtained seven triple sum formulas for the 9-*j* coefficient of $su_q(2)$, i.e., for the *q*-9-*j* coefficients.

The study of these different triple sum formulas from the point of view of multiple hypergeo-

[a]Electronic mail: Stijn.Lievens@rug.ac.be
[b]Electronic mail: Joris.VanderJeugt@rug.ac.be

metric series would be interesting, though rather tedious because of the complicated structure of the formulas. However, when considering the class of singly stretched 9-j coefficients (i.e., one of the arguments in the 9-j coefficient is the sum of two others), most of these triple sum formulas reduce to double sum formulas which are less complicated and easier to handle. Ališauskas actually wrote down these double sum formulas (Ref. 18, Sec. IV B), and used them to derive certain rearrangement formulas of double sum series and their basic analogs.

In the present article we shall show that the double sum formulas for the singly stretched 9-j coefficient actually give rise to a fairly complete theory of transformation formulas for terminating double hypergeometric series of Kampé de Fériet type. This is particularly interesting because until now not many transformation formulas for multiple hypergeometric series are known, even though transformation formulas for hypergeometric series of a single variable play an important role.[17,20] The double hypergeometric series appearing in this context are proper Kampé de Fériet functions $F_{q:s;s}^{p:r;r}$ with $q+s=2$ and $p+r=3$. Such functions have been defined in Refs. 21 and 22, and studied by Srivastava and Karlsson,[23] whose notation we follow. This notation is a rather straightforward extension of that for single hypergeometric series, e.g.,

$$F_{0:2;2}^{1:2;2}\left[\begin{matrix} e:a,b;a',b'; \\ :c,d;c',d'; \end{matrix} x,y\right]=\sum_{j,k=0}^{\infty}(e)_{j+k}\frac{(a)_j(b)_j}{(c)_j(d)_j}\frac{(a')_k(b')_k}{(c')_k(d')_k}\frac{x^j}{j!}\frac{y^k}{k!}, \tag{1}$$

and

$$F_{1:1;1}^{1:2;2}\left[\begin{matrix} e:a,b;a',b'; \\ d:\ c\ ;\ c'\ ; \end{matrix} x,y\right]=\sum_{j,k=0}^{\infty}\frac{(e)_{j+k}}{(d)_{j+k}}\frac{(a)_j(b)_j}{(c)_j}\frac{(a')_k(b')_k}{(c')_k}\frac{x^j}{j!}\frac{y^k}{k!}. \tag{2}$$

Herein, $(a)_k$ is the classical Pochhammer symbol,[17,20]

$$(a)_k=a(a+1)\cdots(a+k-1); \tag{3}$$

$a,b,\ldots$ are referred to as the parameters of the series, and x, y as the variables. Observe that factors of the form $(d)_{j+k}$ or $(e)_{j+k}$ are responsible for the fact that such double series cannot simply be written as the product of two single hypergeometric series. The Kampé de Fériet series appearing in the context of double sums related to the 9-j coefficients are those of type $F_{0:2;2}^{1:2;2}$, $F_{1:1;1}^{1:2;2}$ and $F_{1:1;1}^{0:3;3}$.

Convergence properties of such Kampé de Fériet series have been considered in Ref. 24. In this article, however, all the series dealt with are *terminating* series and hence there are no convergence conditions. Note that the termination of Kampé de Fériet series such as (1) or (2) can be assured in two ways:

(i) A common numerator parameter equals a negative integer: e.g., $e=-n$, with n a positive integer, in (1) or (2) yields a terminating series irrespective of the value of the other parameters.

(ii) Two separate numerator parameters are equal to negative integers: e.g., $a=-n$ and $a'=-m$ in (1) or (2), with m and n positive integers.

In both cases the denominator parameters of the Kampé de Fériet series should not be negative integers. If some of the denominator parameters are nevertheless negative integers, then they should be smaller (or equal) than the parameters responsible for the termination of the series.

The transformation formulas deduced here from the double sum expressions for 9-j coefficients turn out to be of a quite general nature. Apart from the parameter(s) responsible for the termination, the remaining parameters of the series are completely general. Furthermore, the transformation formulas, together with trivial permutation symmetries, are shown to generate a *symmetry group* for the double hypergeometric series. In other words, we shall show that for each of the double hypergeometric series considered here, there exists a whole set of transformation formulas related to a group action on the parameters of the double series.

In the paper by Ališauskas,[18] the emphasis is on the q-9-j coefficients, i.e., the 9-j coefficients of $\mathrm{su}_q(2)$. So it would be interesting to see if the transformation theory developed here could be generalized to the basic analog (i.e., the q-analogue). This is indeed the case. We shall give and prove a set of new transformation formulas for basic double series. For the notation related to q-series and single basic hypergeometric series, we refer to the standard book of Gasper and Rahman.[25] The double series appearing in this context, however, are special cases of general basic double series defined by Srivastava and Karlsson (Ref. 23, p. 349).

II. THE STRETCHED 9-j COEFFICIENT AND DOUBLE SERIES

Ališauskas[18] considers the stretched 9-j coefficient denoted by

$$\begin{Bmatrix} j_1 & j_2 & j_{12} \\ j_3 & j_4 & j_{34} \\ j_{13} & j_{24} & j_{12}+j_{34} \end{Bmatrix}, \tag{4}$$

which is a transformation coefficient connecting two different ways in which four angular momenta j_1, j_2, j_3 and j_4 can be coupled. Since they stand for angular momenta, all the arguments in (4) are non-negative integers or half-integers. In fact, in Ref. 18, the q-analogs of such 9-j coefficients are considered, but here we first treat the classical case ($q=1$).

In Ref. 18, Sec. IV B, a list of double sum expressions is determined for (4). It is not difficult to rewrite these in terms of double hypergeometric series of Kampé de Fériet type. For example, from Ref. 18, (4.3d), one deduces

$$\begin{Bmatrix} j_1 & j_2 & j_{12} \\ j_3 & j_4 & j_{34} \\ j_{13} & j_{24} & j_{12}+j_{34} \end{Bmatrix}$$

$$= C F^{1:2;2}_{0:2;2}\left[\begin{matrix} -j_1-j_2+j_{12} : -j_2-j_4+j_{24}, -j_2-j_4-j_{24}-1 ; j_{13}-j_1+j_3+1, -j_1-j_3+j_{13}; \\ : -2j_2, -j_2-j_4+j_{12}+j_{34}-j_{13} ; -2j_1, j_4-j_1-j_{34}+j_{13}+1 ; \end{matrix} 1,1\right], \tag{5}$$

where C is some constant. Similarly, Ref. 18, (4.4b), yields

$$\begin{Bmatrix} j_1 & j_2 & j_{12} \\ j_3 & j_4 & j_{34} \\ j_{13} & j_{24} & j_{12}+j_{34} \end{Bmatrix}$$

$$= C' F^{1:2;2}_{1:1;1}$$

$$\times\left[\begin{matrix} -j_1-j_2+j_{12} & : -j_2-j_4+j_{24}, 1+j_4-j_2+j_{24}; j_{13}-j_1+j_3+1, -j_1-j_3+j_{13}; \\ 1-j_1-j_{34}+j_{13}-j_2+j_{24}: & -2j_2 \quad ; \quad -2j_2 \quad ; \end{matrix} 1,1\right], \tag{6}$$

where C' is another constant. Upon equating the rhs's of (5) and (6), using the actual values of C and C', and relabelling the parameters of the series, one finds

$$F^{1:2;2}_{0:2;2}\left[\begin{matrix} -n : a,b ; a',b' ; \\ : c,d ; c',d' ; \end{matrix} 1,1\right] = \frac{(d-a+n-1)!(d-1)!}{(d-a-1)!(d+n-1)!} F^{1:2;2}_{1:1;1}\left[\begin{matrix} -n \ : a, c-b ; a', b' ; \\ d'+a : \quad c \quad ; \quad c' \quad ; \end{matrix} 1,1\right]. \tag{7}$$

Herein, the parameters satisfy $d+d'=1-n$, so there are in total eight free parameters [as there are in (4)]. Since all the parameters in (4) are non-negative integers or half-integers, the param-

eters in (7) in first instance all correspond to integers. In particular, $-n$ corresponds to a negative integer (due to triangular conditions satisfied by the angular momentum coefficients). However, once the equation is rewritten in the form (7), with

$$\frac{(d-a+n-1)!(d-1)!}{(d-a-1)!(d+n-1)!}=\frac{(d-a)_n}{(d)_n},$$

it is obvious that this is a *rational identity* in the remaining parameters a, b, c, d, a', b', c' and d', once $-n$ is a fixed negative integer. Therefore, (8a) holds for arbitrary parameters a, b, c, d, a', b', c' and d' (but still subject to the constraint $d+d'=1-n$). As such, we have found a rather general transformation formula between two terminating Kampé de Fériet series. This proves the first formula of the following theorem:

Theorem 1: *Let n be a non-negative integer and a, b, c, d, a′, b′, c′ and d′ arbitrary parameters with $d+d'=1-n$. Then the following transformation formulas hold*:

$$F^{1:2;2}_{0:2;2}\left[\begin{matrix}-n:a,b\,;a',b'\,;\\ :c,d\,;c',d'\,;\end{matrix}1,1\right]=\frac{(d-a)_n}{(d)_n}F^{1:2;2}_{1:1;1}\left[\begin{matrix}-n\ :a,c-b\,;a',b'\,;\\ d'+a:\ c\ ;\ c'\ ;\end{matrix}1,1\right] \tag{8a}$$

$$=\frac{(d-b+b')_n}{(d)_n}F^{1:2;2}_{0:2;2}\left[\begin{matrix}-n:c-a,b\ ;c'-a',b'\ ;\\ :c,d'-b'+b\,;c',d-b+b'\,;\end{matrix}1,1\right], \tag{8b}$$

and

$$F^{1:2;2}_{1:1;1}\left[\begin{matrix}-n:a,b\,;a',b'\,;\\ d\ :\ c\ ;\ c'\ ;\end{matrix}1,1\right]=\frac{(d-b-b')_n}{(d)_n}F^{1:2;2}_{1:1;1}\left[\begin{matrix}-n\ :c-a,b\,;c'-a',b'\,;\\ 1-n-d+b+b':\ c\ ;\ c'\ ;\end{matrix}1,1\right]. \tag{9}$$

Proof: The transformation formula (8b) was deduced recently in a different context.[26] This equation can now also be seen in the context of the stretched 9-j coefficient. In fact, it corresponds to a symmetry of this 9-j coefficient [namely a transposition of the first and second column in (4)], reexpressed by means of (5). Finally, applying (8a) to the rhs of (8b) and equating the resulting expression with the rhs of (8a) yields (9) (after appropriate relabelling of the parameters). □

Observe that in this section all Kampé de Fériet series are terminating because a common numerator parameter equals a negative integer. In the following section we shall consider some transformation formulas, also deduced from the stretched 9-j coefficient, for Kampé de Fériet series that are terminating because of the appearance of two negative integers as separate numerator parameters.

III. KAMPÉ DE FÉRIET SERIES WITH TWO NEGATIVE INTEGERS AS PARAMETER

Though the transformation formulas with a single common numerator parameter as a negative integer (i.e., Theorem 1) are new, there do exist some transformation formulas for Kampé de Fériet series with two separate numerator parameters as negative integers. One of these formulas is given by Singh,[27] and reads

$$F^{0:3;3}_{1:1;1}\left[\begin{matrix}:-n,a,b\,;-m,a',b'\,;\\ d:\ c\ ;\ c'\ ;\end{matrix}1,1\right]$$

$$=\frac{(c-a)_n(c'-a')_m}{(c)_n(c')_m}F^{0:3;3}_{1:1;1}\left[\begin{matrix}:\ -n,a,b'\ ;\ -m,a',b\ ;\\ d:1+a-c-n\,;1+a'-c'-m\,;\end{matrix}1,1\right], \tag{10}$$

where n and m are non-negative integers and $b+b'=d$. This, and some other transformation formulas of similar type, can be found in or deduced from Ref. 18, Appendix C.

Let us first consider some transformation formulas that express a Kampé de Fériet series of type $F^{1:2;2}_{0:2;2}$ into a series of a different type:

Theorem 2: *Let m and n be non-negative integers, and a, b, c, d, a′, b′ and c′ be arbitrary parameters with c+c′=1+d. Then*

$$F^{1:2;2}_{0:2;2}\left[\begin{matrix} d:-n,a\,;-m,a'\,; \\ :\ b,c\ ;\ b',c'\ ; \end{matrix}1,1\right]$$
$$=\frac{(b-a)_n(1-c)_m}{(b)_n(c')_m}F^{0:3;3}_{1:1;1}\left[\begin{matrix} :-n,a,-d+c\,;-m,b'-a',d\,; \\ c-m:-n+a-b+1\,; \quad b' \quad ; \end{matrix}1,1\right] \tag{11a}$$

$$=\frac{(1-c)_m}{(c')_m}F^{1:2;2}_{1:1;1}\left[\begin{matrix} d\ :-n,a\,;-m,b'-a'\,; \\ c-m:\ b\ ;\quad b' \quad ; \end{matrix}1,1\right]. \tag{11b}$$

The proof of (11a) follows by comparing Eqs. (4.3c) and (4.3e) of Ref. 18, making appropriate relabellings, and using the same rational expression argument as in the proof of Theorem 1. In a similar way, (11b) follows from (4.3b) and (4.4c) of Ref. 18.

It is worth mentioning that transformation formulas (8a) and (11b) are formally equivalent [after rewriting the Pochhammer symbols in terms of gamma functions and using the constraint $1-c=c'-d$ to eliminate c from the gamma functions in (11b)].

We can now present three results, giving transformation formulas for Kampé de Fériet series of a particular type into series of the same type, for each of the types $F^{1:2;2}_{0:2;2}$, $F^{1:2;2}_{1:1;1}$ and $F^{0:3;3}_{1:1;1}$.

Theorem 3: *Let n and m be non-negative integers and a, b, c, a, b′, c′ and d be arbitrary parameters with c+c=d+1. Then*

$$F^{1:2;2}_{0:2;2}\left[\begin{matrix} d:-n,a\,;-m,a'\,; \\ :\ b,c\ ;\ b',c'\ ; \end{matrix},1,1\right]$$
$$=\frac{(-1)^m(d)_n(b-a)_n(a')_m}{(b)_n(c')_m(b')_m(c)_{n-m}}$$
$$\times F^{1:2;2}_{0:2;2}\left[\begin{matrix} -m-c'+1: & -n,-n-b+1 & ; & -m,-a'+b' & ; \\ & :-n+a-b+1,-n-d+1\,; & & -m-a'+1,-m+n+c\,; \end{matrix}1,1\right] \tag{12a}$$

$$=\frac{(-1)^m(d)_m(b-a)_n(a')_m}{(b)_n(b')_m(c')_m}$$
$$\times F^{1:2;2}_{0:2;2}\left[\begin{matrix} -m-c'+1: & -n,a & ; & -m,1-m-b' & ; \\ & :-n+a-b+1,c\,; & & 1-m-a',1-m-d\,; \end{matrix}1,1\right]. \tag{12b}$$

Proof: The first formula, (12a), follows by comparing expressions (4.3a) and (4.3d) of Ref. 18, and using the rational expression argument. The second formula is derived using (11a) and Singh's formula (10). □

In (12a) the difference $n-m$ might be negative, and then $c_{n-m}=(-1)^{m-n}/(1-c)_{m-n}$, which is the natural extension of the Pochhammer symbol.

Using the above two formulas and (11b) yields the following.

Theorem 4: *Let n and m be non-negative integers and let a, b, a′, b′, c and d be arbitrary parameters. Then*

$$F^{1:2;2}_{1:1;1}\left[\begin{matrix} c: -n,a\,; -m,a'\,; \\ d: b\quad\;\; ; b'\quad\;\; ; \end{matrix} 1,1\right]$$

$$= \frac{(c)_{n+m}(b-a)_n(b'-a')_m}{(d)_{n+m}(b)_n(b')_m}$$

$$\times F^{1:2;2}_{1:1;1}\left[\begin{matrix} d-c & : -n,-n-b+1\,; -m,-m-b'+1\,; \\ -n-m-c+1: & -n+a-b+1\,; -m+a'-b'+1\,; \end{matrix} 1,1\right] \tag{13a}$$

$$= \frac{(b-a)_n(b'-a')_m}{(b)_n(b')_m} F^{1:2;2}_{1:1;1}\left[\begin{matrix} d-c: & -n,a & ; & -m,a' & ; \\ d & : -n+a-b+1\,; & & -m+a'-b'+1\,; & \end{matrix} 1,1\right]. \tag{13b}$$

As a third and final result, we give the transformation formulas for Kampé de Fériet series of type $F^{0:3;3}_{1:1;1}$. The first formula follows from (12a) and (11a); the second is just Singh's formula (10).

Theorem 5: *Let n and m be non-negative integers and let a, b, c, a′, b′, c′ and d be arbitrary parameters such that b+b′=d. Then*

$$F^{0:3;3}_{1:1;1}\left[\begin{matrix} : -n,a,b\,; -m,a',b'\,; \\ d: \quad c \quad ; \quad c' \quad ; \end{matrix} 1,1\right]$$

$$= \frac{(b')_{n+m}(a)_n(c'-a')_m}{(d)_{n+m}(c)_n(c')_m}$$

$$\times F^{0:3;3}_{1:1;1}\left[\begin{matrix} & : -n,c-a,1-n-m-d\,; -m,-c'-m+1,b\,; \\ -n-m+1-b': & -n-a+1 \quad ; & -m+a'-c'+1 \quad ; \end{matrix} 1,1\right] \tag{14a}$$

$$= \frac{(c-a)_n(c'-a')_m}{(c)_n(c')_m} F^{0:3;3}_{1:1;1}\left[\begin{matrix} : & -n,a,b' & ; & -m,a',b & ; \\ d: 1+a-c-n\,; & & & 1+a'-c'-m\,; & \end{matrix} 1,1\right]. \tag{14b}$$

IV. SYMMETRY GROUPS OF TERMINATING KAMPÉ DE FÉRIET SERIES

In the previous sections we have determined transformation formulas between (terminating) Kampé de Fériet series of the same type. It is known that transformation formulas of hypergeometric series of a single variable can give rise to a transformation group.[28] This transformation group, known as the symmetry group or invariance group of the series, arises as a finite group acting on the parameters of the series. The existing transformation formulas are then expressed as the invariance of a certain hypergeometric series under the action of group elements on its parameters. For single hypergeometric series (and basic series), this idea has been expanded in Ref. 28.

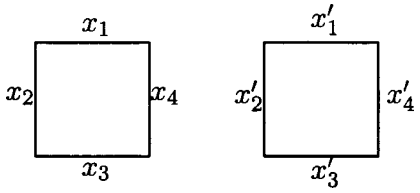
So, it would be interesting to see whether there are any invariance groups behind the transformation formulas for double hypergeometric series, as the ones we are dealing with in this article. One such invariance group for a double series has recently been discussed.[26] This concerns the invariance group related to the transformation formula (8b). Observe that (8b) gives a transformation between two series of the type $F^{1:2;2}_{0:2;2}$. Apart from this transformation, there are also trivial transformations for

$$F^{1:2;2}_{0:2;2}\left[\begin{matrix} -n: a,b\,; a',b'\,; \\ \quad : c,d\,; c',d'\,; \end{matrix} 1,1\right] \quad \text{with} \quad d+d'=1-n, \tag{15}$$

namely the transposition of a and b, or the transposition of a' and b', or the exchange of all primed with the corresponding unprimed parameters. It was shown in Ref. 26 that superposing

such trivial transformations with (8b) gives rise to a set of 64 transformations for the series $F^{1:2;2}_{0:2;2}$ (with one common numerator parameter equal to $-n$). These 64 transformations correspond to a group G of order 64, which we shall briefly describe because it also plays a role in other transformations considered in this article.

First, consider the permutation group S_8 acting on $(x_1,x_2,x_3,x_4,x_1',x_2',x_3',x_4')$, and its subgroup $D_8\times D_8'$. Herein, D_8 stands for the dihedral group[29] (sometimes denoted by D_4) consisting of the eight symmetries of the square (i.e., those permutations of $x_1,\ldots,x_4$ that preserve the square whose sides are labeled by $x_1,\ldots,x_4$). Similarly, D_8' is the same dihedral group but acting on the primed labels $x_1',\ldots,x_4'$. The group $D_8\times D_8'$ consists of 64 elements; superposing on this group the interchange of primed and unprimed elements yields a group of order 128, denoted by $S_2\times(D_8\times D_8')$. This is the invariance group of two squares whose sides are labeled as follows:



The group G now consists of those 64 elements of $S_2\times(D_8\times D_8')$ that preserve the constraint

$$x_1+x_3+x_1'+x_3'-x_2-x_4-x_2'-x_4'=0, \tag{16}$$

i.e., those elements that map $X=x_1+x_3+x_1'+x_3'-x_2-x_4-x_2'-x_4'$ into $\pm X$ by permuting the indices. The following proposition[26] then describes the invariance group generated by the transformation (8b):

Proposition 6: Let x_i, x_i' $(i=1,\ldots,4)$ be arbitrary parameters such that $x_1+x_3+x_1'+x_3'=x_2+x_4+x_2'+x_4'$ and let n be a non-negative integer. Then the expression

$$f_1(x)=\left(\frac{1-n}{2}+x_2-x_2'\right)_n \times F^{1:2;2}_{0:2;2}\left[\begin{matrix} -n: x_2+x_3, x_1+x_2 & ; x_2'+x_3', x_1'+x_2' & ; \\ : \sum_i x_i,\ \frac{1-n}{2}+x_2-x_2' & ; \sum_i x_i',\ \frac{1-n}{2}+x_2'-x_2 & ; \end{matrix}1,1\right]$$

is (up to a sign) invariant under the action of G. The action of an element g of G is by permuting the indices of $x_1,\ldots,x_4'$, and we can write

$$f_1(g\cdot x)=\epsilon^n f_1(x),$$

where $\epsilon=\pm 1$ is determined by $g(X)=\epsilon X$.

When determining the invariance group of the series

$$F^{1:2;2}_{1:1;1}\left[\begin{matrix} -n: a,b; a',b'; \\ d \ : \ c \ ; \ c' \ ; \end{matrix}1,1\right] \tag{17}$$

the following relabeling is appropriate:

$$a=x_2+x_3,\quad b=x_1+x_2,\quad c=\sum_i x_i,$$
$$a'=x_2'+x_3',\quad b'=x_1'+x_2',\quad c'=\sum_i x_i',\quad d=\frac{1-n}{2}+x_2+x_2'. \tag{18}$$

Here again, $-n$ is a negative integer and $x_1,\ldots x_4'$ are arbitrary parameters satisfying (16). Using this relabeling in (17), the transformation (9) corresponds (apart from a factor) to the permutation $g_1=(x_1\,x_2)(x_3\,x_4)(x_1'\,x_2')(x_3'\,x_4')$. The trivial transposition of a and b in (17) corresponds to the permutation $g_2=(x_1\,x_3)$. And the interchange of primed and unprimed parameters in (17) corresponds to the permutation $g_3=(x_1\,x_1')(x_2\,x_2')(x_3\,x_3')(x_4\,x_4')$. It is now easy to see that the elements g_1, g_2 and g_3 generate the group G described earlier. Thus we have the following result:

Proposition 7: Let x_i, x_i' $(i=1,\ldots,4)$ be arbitrary parameters such that $x_1+x_3+x_1'+x_3'=x_2+x_4+x_2'+x_4'$ and let n be a non-negative integer. Then the expression

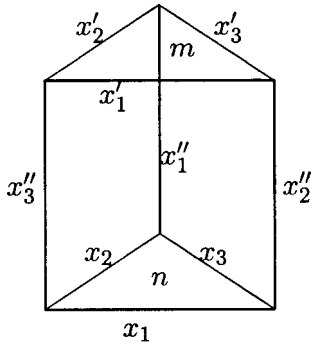
$$f_2(x)=\left(\frac{1-n}{2}+x_2+x_2'\right)_n F^{1:2;2}_{1:1;1}\left[\begin{matrix}-n & : x_2+x_3,x_1+x_2;\ x_2'+x_3',x_1'+x_2';\\ \frac{1-n}{2}+x_2+x_2' : \sum_i x_i & ;\ \sum_i x_i' \end{matrix};1,1\right]$$

is (up to a sign) invariant under the action of G, i.e., $f_2(g\cdot x)=\epsilon^n f_2(x)$, where $\epsilon=\pm 1$ is determined by $g(X)=\epsilon X$.

So the invariance groups of (15) and (17) are the same: both series have 64 symmetries. Moreover, the two nontrivial transformations (8b) and (9) both correspond to the same element, namely g_1, of G.

Now we shall show that also the transformations with two numerator parameters $-n$ and $-m$ being negative integers give rise to an interesting symmetry group. It will be convenient to first describe the group, and then show that under a certain relabeling of the parameters it is indeed the symmetry group of the transformations given in Theorems 3–5.

Consider a prism with an equiangular triangle as basis and edges orthogonal to this basis. The sides of the triangles are labeled by x_1, x_2, x_3 and x_1', x_2', x_3'; the three edges are labeled by x_1'', x_2'', x_3''. For convenience we shall also label the basis triangle by n and the opposite triangle by m:



The symmetry group H of this prism is generated by four planes of symmetry: the three planes of symmetry through an edge $x_i''(i=1,2,3)$ and the plane of symmetry parallel with the basis. Let $r_i(i=1,2,3)$ denote the reflection about a plane of symmetry through an edge x_i'', and let r_0 denote the reflection about the plane of symmetry that is parallel with the basis. These four reflections map the prism into itself, and they generate the symmetry group of the prism. This symmetry group H is a group of order 12, and it is easy to verify that it is isomorphic to the dihedral group D_{12} (i.e., the symmetries of the hexagon). The generating reflections correspond to permutations of $x_1,x_2,\ldots,x_3''$ (and possibly an interchange of n and m):

$$r_1:(x_2\,x_3)(x_2'\,x_3')(x_2''\,x_3''),$$

$$r_2:(x_1\,x_3)(x_1'\,x_3')(x_1''\,x_3''),$$

$$r_3:(x_1\,x_2)(x_1'\,x_2')(x_1''\,x_2''),$$

$$r_0:(x_1\,x_1')(x_2\,x_2')(x_3\,x_3')(n\,m).$$

It turns out that the transformations given in Theorems 3–5 all have the same symmetry group, described by H. Thus we can state the following:

Proposition 8: Let m and n be nonnegative integers, and let x_i, x_i', x_i'' $(i=1,2,3)$ *be arbitrary parameters such that* $\Sigma_{i=1}^3 x_i=0$, $\Sigma_{i=1}^3 x_i'=0$, $\Sigma_{i=1}^3 x_i''=0$. *Then the following expressions,*

$$g_1(x)$$

$$=\left(\frac{2(1-n)}{3}-x_1\right)_n\left(\frac{2-2n+m}{3}-x_2''\right)_n\left(\frac{2(1-m)}{3}-x_1'\right)_m\left(\frac{2-2m+n}{3}-x_3''\right)_m$$

$$\times F^{1:2;2}_{0:2;2}\left[\begin{matrix}\dfrac{1-n-m}{3}+x_1'': -n, \dfrac{1-n}{3}+x_2 & ; -m, \dfrac{1-m}{3}+x_3' & ; \\ : \dfrac{2(1-n)}{3}-x_1, \dfrac{2-2n+m}{3}-x_2''; & \dfrac{2(1-m)}{3}-x_1', \dfrac{2-2m+n}{3}-x_3'' & ;\end{matrix}\ 1,1\right], \tag{19}$$

$$g_2(x)=\left(\frac{2(1-n-m)}{3}+x_2''\right)_{n+m}\left(\frac{2(1-n)}{3}-x_3\right)_n\left(\frac{2(1-m)}{3}-x_3'\right)_m$$

$$\times F^{1:2;2}_{1:1;1}\left[\begin{matrix}\dfrac{1-n-m}{3}-x_3'' & : -n, \dfrac{1-n}{3}+x_2; -m, \dfrac{1-m}{3}+x_2'; \\ \dfrac{2(1-n-m)}{3}+x_2'': \dfrac{2(1-n)}{3}-x_3 & ; \dfrac{2(1-m)}{3}-x_3' \quad ;\end{matrix}\ 1,1\right], \tag{20}$$

$$g_3(x)$$

$$=\left(\frac{2(1-n-m)}{3}-x_1''\right)_{n+m}\left(\frac{2(1-n)}{3}+x_2\right)_n\left(\frac{2(1-m)}{3}+x_3'\right)_m F^{0:3;3}_{1:1;1}$$

$$\times\left[\begin{matrix} & : -n, \dfrac{1-n}{3}-x_1, \dfrac{1-n-m}{3}+x_2''; -m, \dfrac{1-m}{3}-x_1', \dfrac{1-n-m}{3}+x_3''; \\ \dfrac{2(1-n-m)}{3}-x_1'': \dfrac{2(1-n)}{3}+x_2 & ; \dfrac{2(1-m)}{3}+x_3' & ;\end{matrix}\ 1,1\right], \tag{21}$$

are (up to a sign) invariant under the action of H, the symmetries of the prism, i.e., $g_1(h\cdot x)=(-1)^{l_0(n+m)}g_1(x)$, $g_2(h\cdot x)=(-1)^{l(n+m)}g_2(x)$ *and* $g_3(h\cdot x)=(-1)^{l_0(n+m)}g_3(x)$, *where l is the number of reflections* r_1, r_2, r_3 *in the expression of h and* l_0 *is the number of reflections* r_0, r_1, r_2, r_3 *in the expression of h.*

Proof: Consider (19). Equation (12a) of Theorem 3 expresses that $g_1(h_1\cdot x)=g_1(x)$, with $h_1=(x_1\,x_3\,x_2)(x_1'\,x_3'\,x_2')(x_1''\,x_3''\,x_2'')$. Similarly, Eq. (12b) of Theorem 3 expresses that $g_1(h_2\cdot x)$

$=(-1)^{m+n}g_1(x)$, with $h_2=(x_1\,x_3)(x_1'\,x_3')(x_1''\,x_3'')$. Apart from the two transformations given in Theorem 3, there is of course also the trivial transformation interchanging $-n,a,b,c$ with $-m,a',b',c'$; this expresses that $g_1(h_3\cdot x)=g_1(x)$ with $h_3=(x_1\,x_1')(x_2\,x_3')(x_3\,x_2')(x_2''\,x_3'')\times(n\,m)$. It is now easy to verify that h_1, h_2 and h_3 generate H, i.e., the same group as generated by r_i $(i=0,1,2,3)$. Thus the symmetry statement for (19) follows. The remaining cases (20) and (21) follow in a similar way from Theorems 4 and 5. □

V. BASIC ANALOGS OF SOME TRANSFORMATION FORMULAS

In this section we shall be dealing with the basic analogs (or q-analogs) of some of the transformation formulas for double hypergeometric series considered in Secs. II and III. For a general introduction and background to basic hypergeometric series, see Ref. 25, whose notation we follow: thus q is a parameter with $|q|<1$; $(a;q)_n$ is the q-shifted factorial; $(a,b,c;q)_n$ stands for $(a;q)_n(b;q)_n(c;q)_n$; ${}_{p+1}\Phi_p$ is the common notation for a basic hypergeometric series in one variable; etc.

The double basic hypergeometric series appearing in the present context is a special case of general double basic series defined by Srivastava and Karlsson (Ref. 23, p. 349). So, we use their notation to define the series

$$\Phi^{1:2;2}_{0:2;2}\left[\begin{matrix} e:a,b\,;\,a',b'\,;\,q;x,y \\ :c,d\,;\,c',d'\,;\,\lambda,\mu,\nu \end{matrix}\right]$$

$$=\sum_{j,k=0}^{\infty} q^{\lambda\, j(j-1)/2+\mu k(k-1)/2+\nu jk}(e;q)_{j+k}\frac{(a;q)_j(b;q)_j}{(c;q)_j(d;q)_j}\frac{(a';q)_k(b';q)_k}{(c';q)_k(d';q)_k}\frac{x^j}{(q;q)_j}\frac{y^k}{(q;q)_k}; \quad (22)$$

the definition of $\Phi^{1:2;2}_{1:1;1}$ and $\Phi^{0:3;3}_{1:1;1}$ is completely analogous. For double basic series such as (22), ν is usually taken to be 0, in which case this is a straightforward double series analog of the basic series ${}_3\Phi_2$. However, also the cases with $\nu=+1$ or $\nu=-1$ appear in the literature,[27,30] and will play a role in the transformation formulas given here.

The main purpose of this section is to show that the different expressions of q-9-j coefficients of Ref. 18, in the singly stretched case, give rise to new transformation formulas for double basic hypergeometric series of the type $\Phi^{1:2;2}_{0:2;2}$, $\Phi^{1:2;2}_{1:1;1}$ and $\Phi^{0:3;3}_{1:1;1}$. Ališauskas actually realized that his expressions gave rise to ''rearrangement formulas of double sums'' (see Ref. 18, Appendix C), but he did not write them as transformation formulas of series of the type (22). Furthermore, he did not recognize that some of these formulas allow for a set of very general parameters.

In this section we shall discuss some of the q-analogs of theorems given in Secs. II and III. Rather than derive these q-analogs from the different double series expressions of Ališauskas,[18] a direct proof is given. It turns out that the direct proofs of such transformation formulas are fairly easy, and all rely on the same technique.

We know of two genuine transformation formulas for double basic hypergeometric series that have appeared in the literature (by a genuine transformation formula, we mean a formula expressing a basic double series of a particular type into another series of the same type). One of these was given by Singh:[27] if m and n are non-negative integers, and a,b,c,a',b',c' and d arbitrary parameters with $bb'=d$, then

$$\Phi^{0:3;3}_{1:1;1}\left[\begin{matrix} :q^{-n},a,b\,;\,q^{-m},a',b'q\,;\,cdq^n/ab,c'dq^m/a'b' \\ d: \quad c \quad ; \quad c' \quad ; \quad 0,0,1 \end{matrix}\right]$$

$$=\frac{(c/a;q)_n(c'/a';q)_m}{(c;q)_n(c';q)_m}\Phi^{0:3;3}_{1:1;1}\left[\begin{matrix} :q^{-n},a,b'\,;\,q^{1-m},a',b;q\,;\;q,q \\ d:\,q^{1-n}a/c\;;\;q^{1-m}a'/c'\;;0,0,0 \end{matrix}\right]. \quad (23)$$

The other was the topic of a recent paper:[26] if n is a non-negative integer, and a,b,c,d,a',b',c' and d' are arbitrary parameters with $dd'=q^{1-n}$, then

$$\Phi_{0:2;2}^{1:2;2}\left[\begin{matrix} q^{-n}:a,b;a',b';q;cdq^n/ab,c'd'q^n/a'b' \\ :c,d;c',d'; \qquad 0,0,-1 \end{matrix}\right]$$
$$=\frac{(d'b/b';q)_n}{(d';q)_n}b^{-n}\,\Phi_{0:2;2}^{1:2;2}\left[\begin{matrix} q^{-n}: \quad c/a,b \quad ;c'/a',b';q;q,q \\ :c,d'b/b';c',db'/b;\ 0,0,0 \end{matrix}\right]. \tag{24}$$

Observe that (23) is the basic analog of (14b), and (24) is the basic analog of (8b).

We shall now indicate how such formulas, and others, can be derived directly. First, we shall deduce two basic analogs of (8a); namely, if $dd'=q^{1-n}$, then

$$\Phi_{0:2;2}^{1:2;2}\left[\begin{matrix} q^{-n}:a,b;a',b';q;cdq^n/ab,y \\ :c,d;\ c',d' \ ;\ 0,0,-1 \end{matrix}\right]=\frac{(d/a;q)_n}{(d;q)_n}\Phi_{1:1;1}^{1:2;2}\left[\begin{matrix} q^{-n}:a,c/b;a',b';q;q,ay \\ ad':\quad c \quad ;\quad c' \quad ;\ 0,0,0 \end{matrix}\right], \tag{25}$$

and

$$\Phi_{0:2;2}^{1:2;2}\left[\begin{matrix} q^{-n}:a,b;a',b';q;q,y \\ :c,d;c',d';\ 0,0,0 \end{matrix}\right]=\frac{a^n(d/a;q)_n}{(d;q)_n}\Phi_{1:1;1}^{1:2;2}\left[\begin{matrix} q^{-n}:a,c/b;a',b';q;bq/d,y \\ ad':\quad c \quad ;\quad c' \quad ;\ 0,0,0 \end{matrix}\right], \tag{26}$$

Herein, as usual, n is a non-negative integer, a,b,c,d,a',b',c' and d are arbitrary parameters (subject to $dd'=q^{1-n}$), and y is an arbitrary variable.

For a proof, expand the lhs L of (25) into a double series:

$$L=\sum_{j,k}\frac{(q^{-n};q)_{j+k}(a,b;q)_j(a',b';q)_k}{(q,c,d;q)_j(q,c',d';q)_k}\left(\frac{cdq^n}{ab}\right)^j y^k q^{-jk}$$
$$=\sum_k\frac{(q^{-n},a',b';q)_k}{(q,c',d';q)_k}y^k\,{}_3\Phi_2\left[\begin{matrix} q^{-n+k},a,b; \\ c,d \quad ;q,cdq^{n-k}/ab \end{matrix}\right].$$

Now apply Sears' transformation formula [Ref. 25, (III.13)], and expand again:

$$L=\sum_k\frac{(q^{-n},a',b';q)_k}{(q,c',d';q)_k}y^k\frac{(d/a;q)_{n-k}}{(d;q)_{n-k}}\,{}_3\Phi_2\left[\begin{matrix} q^{-n+k},a,c/b; \\ c,aq^{1-n+k}/d; \end{matrix}q,q\right]$$
$$=\sum_{j,k}\frac{(q^{-n};q)_{j+k}(a,c/b;q)_j(a',b';q)_k}{(q,c,aq^{1-n+k}/d;q)_j(q,c',d';q)_k}y^k q^j\frac{(d/a;q)_{n-k}}{(d;q)_{n-k}}. \tag{27}$$

Using $d'=q^{1-n}/d$, and elementary properties of q-shifted factorials, there comes

$$\frac{1}{(aq^{1-n+k}/d;q)_j(d';q)_k}\frac{(d/a;q)_{n-k}}{(d;q)_{n-k}}=\frac{a^k}{(aq^{1-n}/d;q)_{j+k}}\frac{(d/a;q)_n}{(d;q)_n}.$$

Plugging this in (27) yields the rhs of (25). The proof of (26) is completely analogous.

Now we can give the basic analog of (9):

Proposition 9: Let n be a non-negative integer and a,b,c,a′,b′,c′ and d be arbitrary parameters. Then

$$\Phi_{1:1;1}^{1:2;2}\left[\begin{matrix} q^{-n}:a,b;a',b';q;q,dc'q^n/a'b' \\ d\ :\ c\ ;\ c'\ ; \qquad 0,0,0 \end{matrix}\right]$$
$$=\frac{b^n(d/bb';q)_n}{(d;q)_n}\Phi_{1:1;1}^{1:2;2}\left[\begin{matrix} q^{-n} \quad :c/a,b;c'/a',b';q;b'aq/d,q \\ q^{1-n}bb'/d:\quad c \quad ;\quad c' \quad ;\quad 0,0,0 \end{matrix}\right]. \tag{28}$$

Proof: This is now straightforward: apply (25) to the lhs of (24) and (26) to the rhs of (24). Comparing these expressions yields (28). □

With this, we have given basic analogs of all transformation formulas of Sec. II. Also for the transformation formulas with two separate numerator parameters as negative integers, given in Sec. III, the basic analogs can be deduced. The proof of such formulas uses similar steps as illustrated in the proof of (25):

(a) Rewrite the double sum as a single sum over a term containing a ${}_3\Phi_2$ series.
(b) Perform one of Sears' transformation formulas on the ${}_3\Phi_2$ and rewrite the result as a double sum.
(c) Make certain simplifications, using the constraint (if present) between the parameters.
(d) If necessary, repeat (a), (b) and (c) on the double sum obtained so far, and finally rewrite it in the standard notation of a double basic hypergeometric series.

Detailed proofs of the remaining formulas in this section will not be given, since they all follow the above technique. In fact, we will not even give the basic analogs of all of the formulas of Sec. III, but just list those corresponding to the transformation formulas of Theorems 3, 4 and 5.

Here are the basic analogs of (12a) and (12b), given in Theorem 3. The first, (12a), has two basic analogs, namely,

$$\Phi_{0:2;2}^{1:2;2}\left[\begin{matrix} d:q^{-n},a\,;q^{-m},a'\,;q;bcq^n/ad,b'c'q^m/a'd \\ :\ b,c\ ;\ b',c'\ ; \qquad 0,0,-1 \end{matrix}\right]$$
$$=\frac{(-1)^m(d;q)_n(b/a;q)_n(a';q)_m(b'/a'c)^m(c/d)^n q^{\binom{m+1}{2}-mn}}{(b;q)_n(c';q)_m(b';q)_m(c;q)_{n-m}}$$
$$\times\Phi_{0:2;2}^{1:2;2}\left[\begin{matrix} q^{1-m}/c':\ q^{-n},q^{1-n}/b\ ;\ q^{-m},b'/a'\ ;q;aq^{m+1}/c,dq^{n+1}/b' \\ :aq^{1-n}/b,q^{1-n}/d\,;q^{1-m}/a',cq^{n-m}\,; \qquad 0,0,-1 \end{matrix}\right] \tag{29}$$

and

$$\Phi_{0:2;2}^{1:2;2}\left[\begin{matrix} d:q^{-n},a\,;q^{-m},a'\,;q;q,q \\ :\ b,c\ ;\ b',c'\ ;\ 0,0,0 \end{matrix}\right]$$
$$=\frac{(-1)^m(d;q)_n(b/a;q)_n(a';q)_m(d/c)^m a^n q^{\binom{m+1}{2}}}{(b;q)_n(c';q)_m(b';q)_m(c;q)_{n-m}}$$
$$\times\Phi_{0:2;2}^{1:2;2}\left[\begin{matrix} q^{1-m}/c':\ q^{-n},q^{1-n}/b\ ;\ q^{-m},b'/a'\ ;q;q,q \\ :aq^{1-n}/b,q^{1-n}/d\,;q^{1-m}/a',cq^{n-m}\,;\ 0,0,0 \end{matrix}\right], \tag{30}$$

where in both formulas $cc'=qd$. The basic analog of (12b) is

$$\Phi_{0:2;2}^{1:2;2}\left[\begin{matrix} d:q^{-n},a\,;q^{-m},a'\,;q;cbq^n/ad,y \\ :\ b,c\ ;\ b',c'\ ; \quad 0,0,-1 \end{matrix}\right]$$
$$=\frac{(-1)^m(b/a;q)_n(a',d;q)_m q^{-\binom{m+1}{2}}y^m}{(b;q)_n(b',c';q)_m}$$
$$\times\Phi_{0:2;2}^{1:2;2}\left[\begin{matrix} q^{1-m}/c':\ q^{-n},a\ ;\ q^{-m},q^{1-m}/b'\ ;q;q,b'q^{m+2}/a'cy \\ :c,aq^{1-n}/b\,;q^{1-m}/a',q^{1-m}/d\,; \qquad 0,0,0 \end{matrix}\right], \tag{31}$$

where again $cc'=qd$.

The basic analogs of the formulas in Theorem 4 are given by

$$\Phi^{1:2;2}_{1:1;1}\left[\begin{matrix} c : q^{-n},a\,;\, q^{-m},a'\,;\, q;bdq^n/ac,q \\ d: \quad b \quad ;\quad b' \quad ;\quad 0,0,0 \end{matrix}\right]$$
$$= \frac{(b/a;q)_n (b'/a';q)_m (c;q)_{n+m} (a')^m (d/c)^n}{(b;q)_n (b';q)_m (d;q)_{n+m}}$$
$$\times \Phi^{1:2;2}_{1:1;1}\left[\begin{matrix} d/c \quad : q^{-n},q^{1-n}/b\,;\, q^{-m},q^{1-m}/b'\,;\, q;aq^{1-m}/d,q \\ q^{1-n-m}/c: \quad aq^{1-n}/b \quad ;\quad a'q^{1-m}/b' \quad ;\quad 0,0,0 \end{matrix}\right] \tag{32}$$

and

$$\Phi^{1:2;2}_{1:1;1}\left[\begin{matrix} c : q^{-n},a\,;\, q^{-m},a'\,;\, q;dbq^n/ac,q \\ d: \quad b \quad ;\quad b' \quad ;\quad 0,0,0 \end{matrix}\right]$$
$$= \frac{(a')^m (b/a;q)_n (b'/a';q)_m}{(b;q)_n (b';q)_m} \Phi^{1:2;2}_{1:1;1}\left[\begin{matrix} d/c: \quad q^{-n},a \quad ;\quad q^{-m},a' \quad ;q;q,cq/b' \\ d \quad : aq^{1-n}/b'\,;\, a'q^{1-m}/b'\,; \quad 0,0,0 \end{matrix}\right]. \tag{33}$$

Finally, the basic analogs of the transformation formulas (14a) and (14b) of Theorem 5 are given by

$$\Phi^{0:3;3}_{1:1;1}\left[\begin{matrix} \quad : q^{-n},a,b\,;\, q^{-m},a',b'\,;\, q;q,q \\ d: \quad c \quad ;\quad c' \quad ;\, 0,0,0 \end{matrix}\right]$$
$$= \frac{(a')^m b^n (b';q)_{n+m} (a';q)_n (c'/a';q)_m}{(d;q)_{n+m} (c;q)_n (c';q)_m}$$
$$\times \Phi^{0:3;3}_{1:1;1}\left[\begin{matrix} \quad : q^{-n},c/a,q^{1-n-m}/d\,;\, q^{-m},q^{1-m}/c',b\,;\, q;q,q \\ q^{1-n-m}/b': \quad q^{1-n}/a \quad ;\quad q^{1-m}a'/c' \quad ;\, 0,0,0 \end{matrix}\right] \tag{34}$$

and (23), where $bb'=d$ in both formulas.

This completes the list of q-analogs of the transformation formulas of Kampé de Fériet series with two non-negative integers as parameters, as given in Theorems 3–5.

VI. SUMMARY

Using the different double sum expressions of Ališauskas[18] for a singly stretched 9-j coefficient of su(2) or su$_q$(2), we have deduced a set of new transformation formulas for double hypergeometric series of Kampé de Fériet type and their basic analogs. An important observation is that these transformation formulas are valid for quite general parameters, even though the original 9-j coefficients assume only non-negative integer or half-integer values as arguments. The transformation formulas given here for double hypergeometric series of Kampé de Fériet type are all terminating, which means that either a common numerator parameter or else two separate numerator parameters are negative integers.

The transformation formulas seem to inherit some of the symmetries of the 9-j coefficient. In particular, we have shown that the given transformation formulas for a double series of a particular type generate a symmetry group, acting on the parameters of the series. These symmetry groups are explicitly determined and described as subgroups of permutation groups, or as symmetry groups of some geometric object.

In the case of basic double hypergeometric series, corresponding to different expressions of $9\text{-}j$ coefficients of $\mathrm{su}_q(2)$, the relevant series is a double q-series as defined in Ref. 23. Also for these series, the transformation formulas are listed, and we have shown that an independent proof of such transformations is easy.

On the biparametric quantum deformation of GL(2)⊗GL(1)

Deepak Parashar[a)]
Max Planck Institute for Mathematics in the Sciences, Inselstrasse 22-26, D-04103 Leipzig, Germany

(Received 4 June 2001, accepted for publication 10 August 2001)

We study the biparametric quantum deformation of GL(2)⊗GL(1) and exhibit its cross-product structure. We derive explicitly the associated dual algebra, i.e., the quantized universal enveloping algebra employing the *R*-matrix procedure. This facilitates construction of a bicovariant differential calculus which is also shown to have a cross-product structure. Finally, a Jordanian analog of the deformation is presented as a cross-product algebra. © *2001 American Institute of Physics.* [DOI: 10.1063/1.1407280]

I. INTRODUCTION

The biparametric quantum deformation of GL(2)⊗GL(1) was introduced in Ref. 1 as a novel Hopf algebra involving five generators $\{a,b,c,d,f\}$ and two deformation parameters $\{r,s\}$. From among the five generators, four $\{a,b,c,d\}$ correspond to GL(2) and the fifth one f is related to GL(1). These can be arranged in the matrix of generators

$$\mathcal{T}=\begin{pmatrix} f & 0 & 0 \\ 0 & a & b \\ 0 & c & d \end{pmatrix} \tag{1}$$

with the labelling 0, 1, 2. The associated solution of the quantum Yang–Baxter equation is

$$R=\begin{pmatrix} r & 0 & 0 & 0 \\ 0 & \mathsf{S}^{-1} & 0 & 0 \\ 0 & \Lambda & \mathsf{S} & 0 \\ 0 & 0 & 0 & R_r \end{pmatrix} \tag{2}$$

in block form, i.e., in the order (00), (01), (02), (10), (20), (11), (12), (21), (22) (which is chosen in conjunction with the block form of the $\mathcal{T}$-matrix) where

$$R_r=\begin{pmatrix} r & 0 & 0 & 0 \\ 0 & 1 & 0 & 0 \\ 0 & \Lambda & 1 & 0 \\ 0 & 0 & 0 & r \end{pmatrix}; \quad \mathsf{S}=\begin{pmatrix} s & 0 \\ 0 & 1 \end{pmatrix}; \quad \Lambda=\begin{pmatrix} \lambda & 0 \\ 0 & \lambda \end{pmatrix}; \quad \lambda=r-r^{-1}.$$

The $R\mathcal{T}\mathcal{T}$ relations

$$R\mathcal{T}_1\mathcal{T}_2=\mathcal{T}_2\mathcal{T}_1R \tag{3}$$

(where $\mathcal{T}_1=\mathcal{T}\otimes\mathbf{1}$ and $\mathcal{T}_2=\mathbf{1}\otimes\mathcal{T}$) give the commutation relations between the generators *a, b, c, d,* and *f*

[a)]Electronic mail: deepak.parashar@mis.mpg.de

$$ab=r^{-1}ba, \quad bd=r^{-1}db,$$
$$ac=r^{-1}ca, \quad cd=r^{-1}dc, \tag{4}$$
$$bc=cb, \quad [a,d]=(r^{-1}-r)bc,$$

and

$$af=fa, \quad cf=sfc,$$
$$bf=s^{-1}fb, \quad df=fd. \tag{5}$$

Note that the first set of these relations is exactly the q-deformation of GL(2) with deformation parameter r while the second set involves the fifth generator f and the second deformation parameter s. This results in a biparametric q-deformation of GL(2)$\otimes$GL(1), say, $\mathcal{A}_{r,s}$. The coproduct and counit is given as

$$\Delta(\mathcal{T})=\mathcal{T}\otimes\mathcal{T},$$
$$\varepsilon(\mathcal{T})=\mathbf{1}. \tag{6}$$

The Casimir operator $\delta=ad-r^{-1}bc$ is invertible and determines the antipode

$$S(f)=f^{-1}, \quad S(a)=\delta^{-1}d, \quad S(b)=-\delta^{-1}rb, \quad S(c)=-\delta^{-1}r^{-1}c, \quad S(d)=\delta^{-1}a. \tag{7}$$

The quantum determinant $\mathcal{D}=\delta f$ is grouplike but not central. Some of the interesting features of the above quantum deformation are the following:

(i) If we write the set of generators $\{a,b,c,d,f\}$ as $\{f^Na, f^Nb, f^Nc, f^Nd\}$ (N being a fixed nonzero integer), i.e., reducing the five-dimensional set to the four-dimensional set, then we obtain an exact realization of the biparametric (p,q)-deformation of GL(2), i.e., $\mathrm{GL}_{p,q}(2)$ subject to the relations

$$p=r^{-1}s^N \quad \text{and} \quad q=r^{-1}s^{-N}. \tag{8}$$

This realization also reproduces the full Hopf algebraic structure underlying $\mathrm{GL}_{p,q}(2)$.

(ii) Another interesting feature of the $\mathcal{A}_{r,s}$ deformation is that it can be contracted (by means of the contraction procedure[2] based on the concept of singular limit of a similarity transformation) to yield the corresponding biparametric Jordanian deformation of GL(2)$\otimes$GL(1), which in turn provides a complete realization of the biparametric (h,h')-deformation of GL(2), i.e., $\mathrm{GL}_{h,h'}(2)$ in a manner similar to that for the q-deformed case.[3]

(iii) Both the biparametric quantum and Jordanian deformations of GL(2)$\otimes$GL(1) admit colored extensions[3] which also commute with the contraction procedure.

(iv) The physical interest in studying $\mathcal{A}_{r,s}$ lies in the observation that when endowed with a $*$-structure, this specializes to its compact form, i.e., provides a biparametric q-deformation of SU(2)$\otimes$U(1), which is precisely the gauge group for the theory of electroweak interactions.

Another deformation similar to $\mathcal{A}_{r,s}$ has also been recently given in Ref. 4, though in a different context. In the present article, we give an explicit description of the algebra dual to $\mathcal{A}_{r,s}$ as a starting point in further investigation of this quantum group structure. Motivated by the relation of this deformation with gauge theory, we also construct a bicovariant differential calculus since gauge theories have an obvious differential geometric description. This would then provide insights into possible scenarios for constructing q-gauge theories based on this deformation. In pursuing our aim, we follow the convenient R-matrix approach.[5,6] In Sec. II, we give the cross-product structure and go over to the R-matrix duality in Sec. III. The constructive calculus is presented in Sec. IV, while Sec. V is a brief description of the Jordanian analog. The results are discussed in Sec. VI.

II. CROSS-PRODUCT STRUCTURE

The biparametric q-deformation $\mathcal{A}_{r,s}$ can also be considered as the semidirect or cross-product $\mathrm{GL}_r(2)\underset{s}{\rtimes}\mathbb{C}[f,f^{-1}]$ built on the vector space $\mathrm{GL}_r(2)\otimes\mathbb{C}[f,f^{-1}]$ where $\mathrm{GL}_r(2)=\mathbb{C}[a,b,c,d]$ modulo the relations (4) and $\mathbb{C}[f,f^{-1}]$ has the cross relations (5). Then, $\mathcal{A}_{r,s}$ can also be interpreted as a skew Laurent polynomial ring $\mathrm{GL}_r[f,f^{-1};\sigma]$ where σ is the automorphism given by the action of element f on $\mathrm{GL}_r(2)$. Knowing properties of cross-product algebras (general theory given in Refs. 7 and 8), we already know that the algebra dual to $\mathcal{A}_{r,s}$ would be the cross-coproduct coalgebra $\mathcal{U}_{r,s}=\mathrm{U}_r(\mathrm{gl}(2))\underset{s}{\rtimes}\mathbb{C}[[\phi]]$ with ϕ as an element dual to f. If we let $A=\mathrm{GL}_r(2)$ and $H=\mathbb{C}[f,f^{-1}]$, then A is a left H-module algebra and the action of f on $\mathrm{GL}_r(2)$ is given by

$$f\triangleright a=a,\quad f\triangleright b=sb,\quad f\triangleright c=s^{-1}c,\quad f\triangleright d=d. \tag{9}$$

As a vector space, the dual is $\mathcal{U}_{r,s}=\mathrm{U}_r(\mathrm{gl}(2))\otimes\mathrm{U}(\mathrm{u}(1))$. Now, the duality relation between $\langle \mathrm{GL}_r(2),\mathrm{U}_r(\mathrm{gl}(2))\rangle$ is already well known,[9] while that between $\langle\mathbb{C}[f,f^{-1}],\mathrm{U}(\mathrm{u}(1))\rangle$ is given by $\langle f,\phi\rangle=1$, i.e., $\mathrm{U}(\mathrm{u}(1))=\mathbb{C}[[\phi]]$. More precisely, we work algebraically with $\mathbb{C}[s^{\phi},s^{-\phi}]$ where $\langle f,s^{\phi}\rangle=s$ (this is a standard notational convention which we adopt). This induces duality on the vector space tensor products and the left action dualizes to the left coaction. This results in the dual algebra being a cross-coproduct $\mathcal{U}_{r,s}=\mathrm{U}_r(\mathrm{gl}(2))\underset{s}{\rtimes}\mathbb{C}[[\phi]]$. Let us recall[9] that $\mathrm{U}_r(\mathrm{gl}(2))$, the algebra dual to $\mathrm{GL}_r(2)$, is isomorphic to the tensor product $\mathrm{U}_r(\mathrm{sl}(2))\otimes\tilde{U}(\mathrm{u}(1))$ where $\mathrm{U}_r(\mathrm{sl}(2))$ has the usual generators $\{H,X_{\pm}\}$ and $\tilde{U}(u(1))=\mathbb{C}[[\xi]]=\mathbb{C}[r^{\xi},r^{-\xi}]$ with ξ central. Therefore, $\mathcal{U}_{r,s}$ is nothing but $\mathrm{U}_r(\mathrm{sl}(2))$ and two central generators ξ and ϕ, where ξ is the generating element of $\tilde{U}(\mathrm{u}(1))$ and ϕ is the generating element of $\mathrm{U}(\mathrm{u}(1))$. Also note that s^{ϕ} (s being the second deformation parameter) is dually paired with the element f of $\mathcal{A}_{r,s}$. Defining the left coaction $\mathrm{U}_r(\mathrm{gl}(2))\to\mathrm{U}(\mathrm{u}(1))\otimes\mathrm{U}_r(\mathrm{gl}(2))$ we have

$$X_+\to s^{\phi}\otimes X_+,\quad X_-\to s^{-\phi}\otimes X_-,\quad H\to 1\otimes H,\quad \xi\to 1\otimes\xi. \tag{10}$$

It can be checked that this gives the correct duality pairings. For example, we have for X_+

$$\begin{aligned}
&\left\langle \Delta_L(X_+),1\otimes\begin{pmatrix}a&b\\c&d\end{pmatrix}\right\rangle=\left\langle s^{\phi}\otimes X_+,1\otimes\begin{pmatrix}a&b\\c&d\end{pmatrix}\right\rangle=\langle s^{\phi},1\rangle\left\langle X_+,\begin{pmatrix}a&b\\c&d\end{pmatrix}\right\rangle=\begin{pmatrix}0&1\\0&0\end{pmatrix},\\
&\left\langle \Delta_L(X_+),f\otimes\begin{pmatrix}a&b\\c&d\end{pmatrix}\right\rangle=\left\langle s^{\phi}\otimes X_+,f\otimes\begin{pmatrix}a&b\\c&d\end{pmatrix}\right\rangle=\langle s^{\phi},f\rangle\left\langle X_+,\begin{pmatrix}a&b\\c&d\end{pmatrix}\right\rangle=s\begin{pmatrix}0&1\\0&0\end{pmatrix},\\
&\left\langle X_+,f\triangleright\begin{pmatrix}a&b\\c&d\end{pmatrix}\right\rangle=\left\langle X_+,\begin{pmatrix}a&sb\\s^{-1}c&d\end{pmatrix}\right\rangle=s\begin{pmatrix}0&1\\0&0\end{pmatrix}.
\end{aligned} \tag{11}$$

Therefore, the coalgebra structure of $\mathcal{U}_{r,s}$ is given as

$$\Delta(X_+)=X_+\otimes r^{H/2}+r^{-H/2}s^{\phi}\otimes X_+, \tag{12}$$

$$\Delta(X_-)=X_-\otimes r^{-H/2}+r^{H/2}s^{-\phi}\otimes X_+, \tag{13}$$

$$\Delta(H)=H\otimes 1+1\otimes H, \tag{14}$$

$$\Delta(\xi)=\xi\otimes 1+1\otimes\xi, \tag{15}$$

$$\Delta(\phi)=\phi\otimes 1+1\otimes\phi. \tag{16}$$

In this way, we have obtained the Drinfeld–Jimbo form of the dual algebra $\mathcal{U}_{r,s}$ using the cross-product construction. Given other approaches to the problem of duality for quantum groups, we also construct explicitly the dual algebra using the *R*-matrix procedure.

III. *R*-MATRIX DUALITY

The biparametric (r,s)-deformation, $\mathcal{A}_{r,s}$, of GL(2)⊗GL(1) has been defined in the previous section at the group level, i.e., as the q-deformation of algebra of functions on GL(2)⊗GL(1). In this section, we derive explicitly the corresponding quantised universal enveloping algebra, i.e., its dual within the framework of the *R*-matrix formulation. We first construct functionals (matrices) $\mathcal{L}^+$ and $\mathcal{L}^-$ which are dual to the matrix of generators in the fundamental representation. The linear functionals $(\mathcal{L}^\pm)^a_b$ (following the method of Refs. 5 and 7) are defined by their value on the elements of the matrix of generators $\mathcal{T}$

$$\langle (\mathcal{L}^\pm)^a_b, \mathcal{T}^c_d \rangle = (R^\pm)^{ac}_{bd}, \tag{17}$$

where

$$(R^+)^{ac}_{bd} = c^+ (R)^{ca}_{db}, \tag{18}$$

$$(R^-)^{ac}_{bd} = c^- (R^{-1}))^{ac}_{bd}, \tag{19}$$

and c^+, c^- are free parameters. Matrices $(\mathcal{L}^\pm)^a_b$ satisfy

$$\langle (\mathcal{L})^a_b, uv \rangle = \langle (\mathcal{L}^\pm)^a_c \otimes (\mathcal{L}^\pm)^c_d, u \otimes v \rangle = (\mathcal{L}^\pm)^a_c(u)(\mathcal{L}^\pm)^c_d(v), \tag{20}$$

$$\text{i.e.,} \quad \Delta(\mathcal{L}^\pm)^a_b = (\mathcal{L}^\pm)^a_c \otimes (\mathcal{L}^\pm)^c_b .$$

For $\mathcal{A}_{r,s}$, the (R^+) and (R^-) matrices read

$$(R^+) = c^+ \begin{pmatrix} r & 0 & 0 & 0 \\ 0 & \mathsf{S} & \Lambda & 0 \\ 0 & 0 & \mathsf{S}^{-1} & 0 \\ 0 & 0 & 0 & R_r^T \end{pmatrix}; \quad (R^-) = c^- \begin{pmatrix} r^{-1} & 0 & 0 & 0 \\ 0 & \mathsf{S} & 0 & 0 \\ 0 & -\Lambda & \mathsf{S}^{-1} & 0 \\ 0 & 0 & 0 & R_r^{-1} \end{pmatrix}, \tag{21}$$

where R_r, Λ, and S are the same as before and $R_r^{-1} = R_{r^{-1}}$. Before proceeding further, it is pertinent to make the following remark about the $\mathcal{L}^\pm$ functionals. Let $\mathrm{A}(R)$ be a bialgebra or a Hopf algebra underlying a 3×3 quantum matrix and let $\tilde{U}(R)$ be a similar matrix bialgebra with two full matrices $\mathcal{L}^\pm$ of generators. These may be viewed as functionals $\mathrm{A}(R) \to \mathbb{C}$ via (17), but duality pairing at this level may be degenerate. So, we look at appropriate quotients of these such that the pairing is non degenerate. In our case, upon quotienting $\mathrm{A}(R)$ would descend to $\mathcal{A}_{r,s}$, and likewise $\tilde{U}(R)$ to the dual of $\mathcal{A}_{r,s}$. The quotient on $\mathrm{A}(R)$ is obtained by setting certain entries of the T-matrix to zero. The most general 3×3 quantum matrix has nine elements

$$\mathcal{T} = \begin{pmatrix} \mathcal{T}^0_0 & \mathcal{T}^0_1 & \mathcal{T}^0_2 \\ \mathcal{T}^1_0 & \mathcal{T}^1_1 & \mathcal{T}^1_2 \\ \mathcal{T}^2_0 & \mathcal{T}^2_1 & \mathcal{T}^2_2 \end{pmatrix}. \tag{22}$$

Now, let $\mathcal{T}^0_1 = 0 = \mathcal{T}^0_2$ and $\mathcal{T}^1_0 = 0 = \mathcal{T}^2_0$. Checking the coideal property (via coproduct of $\mathcal{T}$), we have

$$\Delta(\mathcal{T}^0_1) = \mathcal{T}^0_0 \otimes \mathcal{T}^0_1 + \mathcal{T}^0_1 \otimes \mathcal{T}^1_1 + \mathcal{T}^0_2 \otimes \mathcal{T}^2_1,$$

$$\begin{aligned}\Delta(\mathcal{T}_2^0)&=\mathcal{T}_0^0\otimes\mathcal{T}_2^0+\mathcal{T}_1^0\otimes\mathcal{T}_2^1+\mathcal{T}_2^0\otimes\mathcal{T}_2^2,\\ \Delta(\mathcal{T}_0^1)&=\mathcal{T}_0^1\otimes\mathcal{T}_0^0+\mathcal{T}_1^1\otimes\mathcal{T}_0^1+\mathcal{T}_2^1\otimes\mathcal{T}_0^2,\\ \Delta(\mathcal{T}_0^2)&=\mathcal{T}_0^2\otimes\mathcal{T}_0^0+\mathcal{T}_1^2\otimes\mathcal{T}_0^1+\mathcal{T}_2^2\otimes\mathcal{T}_0^2.\end{aligned}\tag{23}$$

These generate biideals. Therefore, setting them to zero gives the quotient of $\mathrm{A}(R)$

$$\mathcal{T}=\begin{pmatrix}\mathcal{T}_0^0 & 0 & 0\\ 0 & \mathcal{T}_1^1 & \mathcal{T}_2^1\\ 0 & \mathcal{T}_1^2 & \mathcal{T}_2^2\end{pmatrix}=\begin{pmatrix}f & 0 & 0\\ 0 & a & b\\ 0 & c & d\end{pmatrix}=\mathcal{T}(\mathcal{A}_{r,s}).\tag{24}$$

Similarly, the quotient on $\tilde{U}(R)$ is obtained by setting certain entries of $\mathcal{L}^{\pm}$ matrices to zero. Starting with

$$\mathcal{L}^{+}=\begin{pmatrix}\mathcal{L}_0^{+0} & \mathcal{L}_1^{+0} & \mathcal{L}_2^{+0}\\ \mathcal{L}_0^{+1} & \mathcal{L}_1^{+1} & \mathcal{L}_2^{+1}\\ \mathcal{L}_0^{+2} & \mathcal{L}_1^{+2} & \mathcal{L}_2^{+2}\end{pmatrix},\quad \mathcal{L}^{-}=\begin{pmatrix}\mathcal{L}_0^{-0} & \mathcal{L}_1^{-0} & \mathcal{L}_2^{-0}\\ \mathcal{L}_0^{-1} & \mathcal{L}_1^{-1} & \mathcal{L}_2^{-1}\\ \mathcal{L}_0^{-2} & \mathcal{L}_1^{-2} & \mathcal{L}_2^{-2}\end{pmatrix},\tag{25}$$

we make the ansatz

$$\begin{aligned}\mathcal{L}_1^{+2}&=0=\mathcal{L}_2^{-1},\\ \mathcal{L}_1^{+0}=\mathcal{L}_2^{+0}&=\mathcal{L}_0^{+1}=\mathcal{L}_0^{+2}=0,\\ \mathcal{L}_1^{-0}=\mathcal{L}_2^{-0}&=\mathcal{L}_0^{-1}=\mathcal{L}_0^{-2}=0,\end{aligned}\tag{26}$$

and, similar to the above for $\mathrm{A}(R)$, check the coideal property. We also verify explicitly[7] that this ansatz is compatible with the duality pairing

$$\begin{aligned}\langle\mathcal{L}_1^{+2},\mathcal{T}_j^i\rangle&=R_{1j}^{+2i}=R_{j1}^{i2}=0,\\ \langle\mathcal{L}_2^{-1},\mathcal{T}_j^i\rangle&=R_{2j}^{-1i}=(R^{-1})_{2j}^{1i}=0,\end{aligned}\tag{27}$$

and so on for their pairing with products of the $\mathcal{T}_j^i$. Therefore, setting these elements to zero yields a quotient bialgebra $\mathrm{U}(R)$ of $\tilde{\mathrm{U}}(R)$

$$\mathcal{L}^{+}=\begin{pmatrix}\mathcal{L}_0^{+0} & 0 & 0\\ 0 & \mathcal{L}_1^{+1} & \mathcal{L}_2^{+1}\\ 0 & 0 & \mathcal{L}_2^{+2}\end{pmatrix},\quad \mathcal{L}^{-}=\begin{pmatrix}\mathcal{L}_0^{-0} & 0 & 0\\ 0 & \mathcal{L}_1^{-1} & 0\\ 0 & \mathcal{L}_1^{-2} & \mathcal{L}_2^{-2}\end{pmatrix}.\tag{28}$$

Therefore, the initial pairing $\langle\mathrm{A}(R),\tilde{\mathrm{U}}(R)\rangle$ descends to $\langle\mathcal{A}_{r,s},\mathrm{U}(R)\rangle$. So, for $\mathcal{U}_{r,s}$ [or $\mathrm{U}(R)$] we make the following ansatz for the $\mathcal{L}^{\pm}$ matrices:

$$\mathcal{L}^{+}=c^{+}r\begin{pmatrix}s^{-1/2(\tilde{F}-H_2-1)}r^{1/2(\tilde{F}-H_1-1)} & 0 & 0\\ 0 & s^{-1/2(\tilde{F}-H_1+1)}r^{1/2(-\tilde{F}+H_2-1)} & r^{-1}\lambda\tilde{C}\\ 0 & 0 & s^{-1/2(\tilde{F}+H_1-1)}r^{1/2(-\tilde{F}-H_2-1)}\end{pmatrix},$$

$$\mathcal{L}^{-}=c^{-}r^{-1}\begin{pmatrix}s^{-1/2(\tilde{F}-H_2-1)}r^{-1/2(\tilde{F}-H_1-1)} & 0 & 0\\ 0 & s^{-1/2(\tilde{F}-H_1+1)}r^{-1/2(-\tilde{F}+H_2-1)} & 0\\ 0 & -r\lambda\tilde{B} & s^{-1/2(\tilde{F}+H_1-1)}r^{-1/2(-\tilde{F}-H_2-1)}\end{pmatrix},$$

where $H_1=\tilde{A}+\tilde{D}$, $H_2=\tilde{A}-\tilde{D}$, and $\{\tilde{A},\tilde{B},\tilde{C},\tilde{D},\tilde{F}\}$ is the set of generating elements of the dual algebra. This is consistent with the action on the generators of $\mathcal{A}_{r,s}$ and gives the correct duality pairings. More conveniently,

$$\mathcal{L}^+=\begin{pmatrix} J & 0 & 0 \\ 0 & M & P \\ 0 & 0 & N \end{pmatrix} \quad \text{and} \quad \mathcal{L}^-=\begin{pmatrix} J' & 0 & 0 \\ 0 & M' & 0 \\ 0 & Q & N' \end{pmatrix}, \tag{29}$$

where

$$\begin{aligned} J&=s^{-(1/2)(\tilde{F}-H_2-1)}r^{(1/2)(\tilde{F}-H_1+1)}, \\ M&=s^{-(1/2)(\tilde{F}-H_1+1)}r^{(1/2)(-\tilde{F}+H_2+1)}, \\ N&=s^{-(1/2)(\tilde{F}+H_1-1)}r^{(1/2)(-\tilde{F}-H_2+1)}, \\ J'&=s^{-(1/2)(\tilde{F}-H_2-1)}r^{-(1/2)(\tilde{F}-H_1+1)}, \\ M'&=s^{-(1/2)(\tilde{F}-H_1+1)}r^{-(1/2)(-\tilde{F}+H_2+1)}, \\ N'&=s^{-(1/2)(\tilde{F}+H_1-1)}r^{-(1/2)(-\tilde{F}-H_2+1)}, \end{aligned} \tag{30}$$

and

$$\begin{aligned} P&=\lambda\tilde{C}, \\ Q&=-\lambda\tilde{B}. \end{aligned} \tag{31}$$

These can also be arranged in terms of smaller L^+ and L^- matrices:

$$\begin{aligned} \mathcal{L}^+&=c^+\begin{pmatrix} J & 0 \\ 0 & L^+ \end{pmatrix}, \quad \text{where } L^+=\begin{pmatrix} M & P \\ 0 & N \end{pmatrix}, \\ \mathcal{L}^-&=c^-\begin{pmatrix} J' & 0 \\ 0 & L^- \end{pmatrix}, \quad \text{where } L^-=\begin{pmatrix} M' & 0 \\ Q & N' \end{pmatrix}. \end{aligned} \tag{32}$$

A. Commutation relations of the dual

The dual algebra is generated by $\mathcal{L}^\pm$ functionals which satisfy the q-commutation relations (the so-called $R\mathcal{L}\mathcal{L}$ relations)

$$R_{12}\mathcal{L}_2^\pm\mathcal{L}_1^\pm=\mathcal{L}_1^\pm\mathcal{L}_2^\pm R_{12}, \tag{33}$$

$$R_{12}\mathcal{L}_2^+\mathcal{L}_1^-=\mathcal{L}_1^-\mathcal{L}_2^+R_{12}, \tag{34}$$

where $\mathcal{L}_1^\pm=\mathcal{L}^\pm\otimes\mathbf{1}$ and $\mathcal{L}_2^\pm=\mathbf{1}\otimes\mathcal{L}^\pm$. Since $\mathcal{A}_{r,s}$ is a quotient Hopf algebra, it is necessary to amend the R-matrix to eliminate relations that are inconsistent with the quotient structure. Consequently, the R-matrix for the $R\mathcal{L}\mathcal{L}$ relations is different from the one used in the $R\mathcal{T}\mathcal{T}$ relations. The $R\mathcal{L}\mathcal{L}$ relations are constructed with the R-matrix:

$$R_{12}=c^{-}\langle \mathcal{L}^{-},\mathcal{T}\rangle^{-1}=\begin{pmatrix} r & 0 & 0 & 0 \\ 0 & \mathsf{S}^{-1} & 0 & 0 \\ 0 & 0 & \mathsf{S} & 0 \\ 0 & 0 & 0 & R_r \end{pmatrix}. \tag{35}$$

Evaluating $\mathcal{L}_1^{\pm},\mathcal{L}_2^{\pm}$ matrices and substituting in the above $R\mathcal{L}\mathcal{L}$-relations yields the dual algebra commutation relations. From $R_{12}\mathcal{L}_2^{-}\mathcal{L}_1^{-}=\mathcal{L}_1^{-}\mathcal{L}_2^{-}R_{12}$ and $R_{12}\mathcal{L}_2^{+}\mathcal{L}_1^{+}=\mathcal{L}_1^{+}\mathcal{L}_2^{+}R_{12}$ we obtain

$$R_rL_2^{-}L_1^{-}=L_1^{-}L_2^{-}R_r, \tag{36}$$

$$R_rL_2^{+}L_1^{+}=L_1^{+}L_2^{+}R_r, \tag{37}$$

$$MJ=JM,\quad M'J'=J'M',$$

$$NJ=JN,\quad N'J'=J'N', \tag{38}$$

$$PJ=sJP,\quad J'Q=sQJ',$$

where

$$\begin{gathered} R_rL_2^{-}L_1^{-}=L_1^{-}L_2^{-}R_r\Rightarrow QM'=rM'Q,\quad N'Q=rQN',\quad \text{and}\quad N'M'=M'N' \\ R_rL_2^{+}L_1^{+}=L_1^{+}L_2^{+}R_r\Rightarrow PM=rMP,\quad NP=rPN,\quad \text{and}\quad NM=MN. \end{gathered} \tag{39}$$

In addition, the cross relation $R_{12}\mathcal{L}_2^{+}\mathcal{L}_1^{-}=\mathcal{L}_1^{-}\mathcal{L}_2^{+}R_{12}$ yields

$$\begin{gathered} NJ'=J'N,\quad MJ'=J'M,\quad PJ'=sJ'P, \\ N'J=JN',\quad M'J=JM',\quad JQ=sQJ, \end{gathered} \tag{40}$$

and $R_rL_2^{+}L_1^{-}=L_1^{-}L_2^{+}R_r$ which further implies

$$QP-PQ=-\lambda(N'M-NM'). \tag{41}$$

Simplifying the above, we get the following commutation relations

$$[\tilde{A},\tilde{B}]=\tilde{B},\quad [\tilde{A},\tilde{C}]=-\tilde{C},$$

$$[\tilde{D},\tilde{B}]=-\tilde{B},\quad [\tilde{D},\tilde{C}]=\tilde{C}, \tag{42}$$

$$[\tilde{A},\tilde{D}]=0,\quad [\tilde{F},\bullet]=0,$$

and

$$[\tilde{B},\tilde{C}]=\frac{r^{\tilde{A}-\tilde{D}}s^{-\tilde{F}}-r^{-(\tilde{A}-\tilde{D})}s^{-\tilde{F}}}{r-r^{-1}}=\frac{r^{\gamma^{\tilde{F}}}}{r-r^{-1}}[r^{\tilde{A}-\tilde{D}}-r^{-(\tilde{A}-\tilde{D})}], \tag{43}$$

where $\gamma=(\ln s/\ln r)$. So, we obtain a single-parameter deformation of $\mathrm{U}(\mathrm{gl}(2)\otimes\mathrm{U}(\mathrm{u})(1))$ as an algebra. Including the coproduct, we again obtain a semidirect product $\mathrm{U}_r(\mathrm{gl}(2))\underset{s}{\rtimes}\mathrm{U}(\mathrm{u}(1))$, as expected.

IV. CONSTRUCTIVE CALCULUS

In order to investigate the differential geometric structure of the (r,s)-deformation, $\mathcal{A}_{r,s}$, of $\mathrm{GL}(2)\otimes\mathrm{GL}(1)$, we use Jurčo's constructive procedure[6] based on the R-matrix formulation. This method has so far been applied only to full matrix quantum groups, but we demonstrate here that it works equally well for appropriate quotients of these. For $\mathcal{A}_{r,s}$, we obtain a first-order bicovariant differential calculus employing the ansatz for $\mathcal{L}^{\pm}$ introduced in Sec. III.

A. One-forms

Let $\{\omega\}$ be the basis of all left-invariant quantum one-forms. So, we have

$$\Delta_L(\omega)=\mathbf{1}\otimes\omega. \tag{44}$$

This defines the left action on the bimodule Γ (space of quantum one-forms). The bimodule Γ is further characterized by the commutation relations between ω and $a\in\mathcal{A}(\equiv\mathcal{A}_{r,s})$,

$$\omega a=(f*a)\omega. \tag{45}$$

The left convolution product is

$$f*a=(\mathbf{1}\otimes f)\Delta(a), \tag{46}$$

where $f\in\mathcal{A}'[=\mathrm{Hom}(\mathcal{A},\mathbf{C})]$ belongs to the dual. This means

$$\omega a=(\mathbf{1}\otimes f)\Delta(a)\omega. \tag{47}$$

Now the linear functional f is defined in terms of the $\mathcal{L}^{\pm}$ matrices as

$$f=S(\mathcal{L}^{+})\mathcal{L}^{-}. \tag{48}$$

Thus we have

$$\omega a=[(\mathbf{1}\otimes S(\mathcal{L}^{+})\mathcal{L}^{-})\Delta(a)]\omega. \tag{49}$$

In terms of components,

$$\omega_{ij}a=[(\mathbf{1}\otimes S(l^{+}_{ki})l^{-}_{jl})\Delta(a)]\omega_{kl} \tag{50}$$

using the expressions $\mathcal{L}^{\pm}=l^{\pm}_{ij}$ and $\omega=\omega_{ij}$ where $i,j=1,...,3$. For Γ to be a bicovariant bimodule, the right coaction is given by

$$\Delta_R(\omega)=\omega\otimes M \tag{51}$$

where functionals M are defined in terms of the matrix of generators $\mathcal{T}$.

$$M=\mathcal{T}S(\mathcal{T}). \tag{52}$$

Again, in component form, we can write

$$\Delta_R(\omega_{ij})=\omega_{kl}\otimes t_{ki}S(t_{jl}). \tag{53}$$

Using the above formulas, we obtain the commutation relations of all the left-invariant one-forms with the generating elements $\{a,b,c,d,f\}$ of $\mathcal{A}_{r,s}$:

$$\omega^0 a=a\omega^0,\quad \omega^0 b=b\omega^0,$$

$$\omega^1 a=r^{-2}a\omega^1,\quad \omega^1 b=b\omega^1,$$

$$\omega^+ a = r^{-1} a \omega^+, \quad \omega^+ b = r^{-1} b \omega^+ - \lambda r^{-1} a \omega^1, \tag{54}$$

$$\omega^- a = r^{-1} a \omega^- - \lambda r^{-1} b \omega^1, \quad \omega^- b = r^{-1} b \omega^-,$$

$$\omega^2 a = a \omega^2 - \lambda b \omega^+, \quad \omega^2 b = r^{-2} b \omega^2 - \lambda r^{-1} a \omega^- + \lambda^2 b \omega^1,$$

$$\omega^0 c = c \omega^0, \quad \omega^0 d = d \omega^0,$$

$$\omega^1 c = r^{-2} c \omega^1, \quad \omega^1 d = d \omega^1,$$

$$\omega^+ c = r^{-1} c \omega^+, \quad \omega^+ d = r^{-1} d \omega^+ - \lambda r^{-1} c \omega^1, \tag{55}$$

$$\omega^- c = r^{-1} c \omega^- - \lambda r^{-1} d \omega^1, \quad \omega^- d = r^{-1} d \omega^-,$$

$$\omega^2 c = c \omega^2 - \lambda d \omega^+, \quad \omega^2 d = r^{-2} d \omega^2 - \lambda r^{-1} c \omega^- + \lambda^2 d \omega^1,$$

$$\omega^0 f = r^{-2} f \omega^0,$$

$$\omega^1 f = f \omega^1,$$

$$\omega^+ f = s f \omega^+, \tag{56}$$

$$\omega^- f = s^{-1} f \omega^-,$$

$$\omega^2 f = f \omega^2,$$

where $\omega^0 = \omega_{11}$, $\omega^1 = \omega_{22}$, $\omega^+ = \omega_{23}$, $\omega^- = \omega_{32}$, $\omega^2 = \omega_{33}$ and the components $\omega_{12}, \omega_{13}, \omega_{21}, \omega_{31}$ have null contribution, given the structure of the $\mathcal{T}$ matrix (i.e., $t_{12} = t_{13} = t_{21} = t_{31} = 0$).

B. Vector fields

The linear space Γ (space of all left invariant one-forms) contains a bi-invariant element $\tau = \Sigma_i \omega_{ii}$ which can be used to define a derivative on $\mathcal{A}$. For $a \in \mathcal{A}$, one sets

$$\mathbf{d}a = \tau a - a \tau. \tag{57}$$

Now

$$\omega_{ii} a = [(\mathbf{1} \otimes S(l^+_{ki}) l^-_{il}) \Delta(a)] \omega_{kl}. \tag{58}$$

So,

$$\mathbf{d}a = [(\mathbf{1} \otimes \chi_{kl}) \Delta(a)] \omega_{kl}, \tag{59}$$

where $\chi_{kl} = S(l^+_{ki}) l^-_{il} - \delta_{kl} \varepsilon, \varepsilon$ being the counit. Denote

$$\chi_{ij} = S(l^+_{ik}) l^-_{kj} - \delta_{ij} \varepsilon \tag{60}$$

or more compactly

$$\chi = S(\mathcal{L}^+) \mathcal{L}^- - \mathbf{1} \varepsilon \tag{61}$$

the matrix of left-invariant vector fields χ_{ij} on $\mathcal{A}$. The action of the vector fields on the generating elements is

$$\chi_{ij} a = (S(l^+_{ik}) l^-_{kj} - \delta_{ij} \varepsilon) a, \tag{62}$$

$$\chi_{ij}a=\langle S(l^{+}_{ik})l^{-}_{kj},a\rangle-\delta_{ij}\varepsilon(a). \tag{63}$$

Explicitly, we obtain

$$\chi_0(a)=0,\quad \chi_0(b)=0,$$

$$\chi_1(a)=r^{-2}-1,\quad \chi_1(b)=0,$$

$$\chi_+(a)=0,\quad \chi_+(b)=0, \tag{64}$$

$$\chi_-(a)=0,\quad \chi_-(b)=-(r-r^{-1}),$$

$$\chi_2(a)=0,\quad \chi_2(b)=0,$$

$$\chi_0(c)=,\quad \chi_0(d)=0,$$

$$\chi_1(c)=0,\quad \chi_1(d)=(r-r^{-1})^2,$$

$$\chi_+(c)=-(r-r^{-1}),\quad \chi_+(d)=0, \tag{65}$$

$$\chi_-(c)=0,\quad \chi_-(d)=0,$$

$$\chi_2(c)=0,\quad \chi_2(d)=r^{-2}-1,$$

$$\chi_0(f)=r^{-2}-1,$$

$$\chi_1(f)=0,$$

$$\chi_+(f)=0, \tag{66}$$

$$\chi_-(f)=0,$$

$$\chi_2(f)=0,$$

where $\chi_0=\chi_{11}$, $\chi_1=\chi_{22}$, $\chi_+=\chi_{23}$, $\chi_-=\chi_{32}$, $\chi_2=\chi_{33}$ and again (by previous argument) the components $\chi_{12},\chi_{13},\chi_{21},\chi_{31}$ have null contribution. The left convolution products are given as

$$\chi_0*a=0,\quad \chi_0*b=0,$$

$$\chi_1*a=(r^{-2}-1)a,\quad \chi_1*b=((r-r^{-1})^2)b,$$

$$\chi_+*a=-(r-r^{-1})b,\quad \chi_+*b=0, \tag{67}$$

$$\chi_-*a=0,\quad \chi_-*b=-(r-r^{-1})a,$$

$$\chi_2*a=0,\quad \chi_2*b=(r^{-2}-1)b,$$

$$\chi_0*c=0,\quad \chi_0*d=0,$$

$$\chi_1*c=(r^{-2}-1)c,\quad \chi_1*d=((r-r^{-1})^2)d,$$

$$\chi_+*c=-(r-r^{-1})d,\quad \chi_+*d=0, \tag{68}$$

$$\chi_-*c=0,\quad \chi_-*d=-(r-r^{-1})c,$$

$$\chi_2 * c = 0, \quad \chi_2 * d = (r^{-2}-1)d,$$

$$\chi_0 * f = (r^{-2}-1)f,$$

$$\chi_1 * f = 0,$$

$$\chi_+ * f = 0, \tag{69}$$

$$\chi_- * f = 0,$$

$$\chi_2 * f = 0.$$

C. Exterior derivatives

Using $\mathbf{d}a = \Sigma_i (\chi_i * a)\omega^i$ for $a \in \mathcal{A}$, we obtain the action of the exterior derivatives:

$$\mathbf{d}a = (r^{-2}-1)a\omega^1 - \lambda b\omega^+, \tag{70}$$

$$\mathbf{d}b = \lambda^2 b\omega^1 - \lambda a\omega^- + (r^{-2}-1)b\omega^2, \tag{71}$$

$$\mathbf{d}c = (r^{-2}-1)c\omega^1 - \lambda d\omega^+, \tag{72}$$

$$\mathbf{d}d = \lambda^2 d\omega^1 - \lambda c\omega^- + (r^{-2}-1)d\omega^2, \tag{73}$$

$$\mathbf{d}f = (r^{-2}-1)f\omega^0, \tag{74}$$

where $\lambda = r - r^{-1}$. The exterior derivative $\mathbf{d}: \mathcal{A} \to \Gamma$ satisfies the Leibniz rule and $\mathbf{d}\mathcal{A}$ generates Γ as a left $\mathcal{A}$-module. This then defines a first-order differential calculus $(\Gamma, \mathbf{d})$ on $\mathcal{A}_{r,s}$. Furthermore, the calculus is bicovariant due to the coexistence of the left and the right actions,

$$\Delta_L : \Gamma \to \mathcal{A} \otimes \Gamma, \tag{75}$$

$$\Delta_R : \Gamma \to \Gamma \otimes \mathcal{A}, \tag{76}$$

since $\mathbf{d}$ has the invariance property

$$\Delta_L \mathbf{d} = (\mathbf{1} \otimes \mathbf{d})\Delta, \tag{77}$$

$$\Delta_R \mathbf{d} = (\mathbf{d} \otimes \mathbf{1})\Delta. \tag{78}$$

The bicovariance holds also due to the existence of the bi-invariant element $\tau = \Sigma_i \omega_{ii}$ [Eq. (57)] of the linear space of left-invariant one-forms. If we rewrite the derivatives $\{\mathbf{d}a, \mathbf{d}b, \mathbf{d}c, \mathbf{d}d, \mathbf{d}f\}$ as $\{\mathbf{d}(f^N a), \mathbf{d}(f^N b), \mathbf{d}(f^N c), \mathbf{d}(f^N d)\}$, i.e., reducing from the five-dimensional to the four-dimensional algebra, then the latter set of exterior derivatives provides a realization of the differential calculus on the biparametric (p,q)-deformation of GL(2), i.e., $\mathrm{GL}_{p,q}(2)$, with the defining relations between the two sets of deformation parameters (p,q) and (r,s) as before. Furthermore, the differential calculus also respects the cross-product structure of $\mathcal{A}_{rs}$. It can be checked (using the Leibniz rule) that

$$\mathbf{d}(af - fa) = 0, \quad \mathbf{d}(cf - sfc) = 0, \quad \mathbf{d}(bf - s^{-1}fb) = 0, \quad \mathbf{d}(df - fd) = 0, \tag{79}$$

which is consistent with the cross relations (5).

V. JORDANIAN ANALOG

It was shown in Ref. 3 that the $\mathcal{A}_{r,s}$ deformation could be contracted (by means of singular limit of similarity transformations) to obtain a nonstandard or Jordanian analog, say $\mathcal{A}_{m,k}$, with deformation parameters $\{m,k\}$ and the associated R-matrix is triangular. In analogy with $\mathcal{A}_{r,s}$, $\mathcal{A}_{m,k}$ can also be considered as the semidirect or cross-product $\mathrm{G}\mathcal{L}_m(2)\underset{k}{\rtimes}\mathbb{C}[f,f^{-1}]$ where $\mathrm{GL}_m(2)=\mathbb{C}[a,b,c,d]$ modulo the relations

$$\begin{gathered}[c,d]=-mc^2, \quad [c,b]=-m(ac+cd)=-m(ca+dc),\\ [c,a]=-mc^2, \quad [d,a]=-m(d-a)c=-mc(d-a),\end{gathered} \tag{80}$$

$$\begin{gathered}[d,b]=-m(d^2-\delta),\\ [b,a]=-m(\delta-a^2),\end{gathered} \tag{81}$$

where $\delta=ad-bc+mac=ad-cb-mcd$, and $\mathbb{C}[f,f^{-1}]$ has the cross relations

$$\begin{gathered}[f,a]=kcf, \quad [f,b]=k(df-fa),\\ [f,c]=0, \quad [f,d]=-kcf.\end{gathered} \tag{82}$$

Thus, $\mathcal{A}_{m,k}\simeq\mathrm{GL}_m(2)\underset{k}{\rtimes}\mathbb{C}[f,f^{-1}]$ can also be interpreted as a skew Laurent polynomial ring $\mathrm{GL}_m[f,f^{-1};\sigma]$ where σ is the automorphism given by the action of element f on $\mathrm{GL}_m(2)$. The (left) action is given by

$$f\triangleright a=a+kc, \quad f\triangleright b=b+k(d-a)-k^2c, \quad f\triangleright c=c, \quad f\triangleright d=d-kc. \tag{83}$$

VI. DISCUSSION

In this article, we have investigated the algebro-geometric structure of the biparametric quantum deformation of GL(2)⊗GL(1), namely, $\mathcal{A}_{r,s}$. A particular feature of this deformation is that it has an interpretation as a semidirect or cross-product algebra. We exhibit this cross-product structure and establish a picture of duality in this setting. Using the R-matrix formalism, we have given an explicit derivation of the corresponding dual algebra, i.e., the quantized universal enveloping algebra, and also constructed a bicovariant differential calculus. The dual algebra obtained via R-matrices is isomorphic to the dual algebra obtained by the cross-product construction. We note that the differential calculus satisfies the required axioms, contains the calculus on $\mathrm{GL}_q(2)$, and our results match with those given in Ref. 10. Besides, the calculus is also consistent with the cross-product structure of $\mathcal{A}_{r,s}$. We expect that the calculus could as well be obtained by projection from the calculus on multiparameter q-deformed GL(3). The differential calculus obtained on $\mathcal{A}_{r,s}$ enables us to investigate the associated gauge theory from a noncommutative perspective. It would be useful to repeat the analysis presented in this article for the biparametric Jordanian deformation of GL(2) ⊗GL(1) obtained in Ref. 3 and also to investigate corresponding hybrid (q, h)-deformations.[11,12] Furthermore, it would indeed be interesting to generalize the setting to the case of colored quantum and Jordanian deformations.

Weakly primitive vectors of Kac-modules of the Lie superalgebras $sl(m/n)$

Yucai Su[a)]
Department of Applied Mathematics, Shanghai Jiaotong University, Shanghai 200030, People's Republic of China

(Received 21 March 2000; accepted for publication 17 August 2001)

It was conjectured by Hughes *et al.* [J. Math. Phys. **33**, 470–491 (1992)] that there exists a bijection between the composition factors of a Kac-module and the so-called permissible codes. In a previous paper it was proved that to any unlinked code, there corresponds a composition factor of the Kac-module. Here it is proved that to any linked code, there corresponds a composition factor of the Kac-module.
 [DOI: 10.1063/1.1409347]

I. INTRODUCTION

Lie superalgebras are important generalizations of Lie algebras, of interest to both mathematicians and physicists. In the classification of finite-dimensional modules of the basic classical Lie superalgebras,[1–3] Kac distinguished between typical and atypical modules. He also introduced the Kac-module $\overline{V}(\Lambda)$, which was shown to be simple if and only if Λ is typical. For Λ being atypical, the problem of the structure of $\overline{V}(\Lambda)$, or equivalently, the character of the simple module $V(\Lambda)$, has been the subject of intensive study.[3–7] More generally, the problem of classifying indecomposable modules has received much attention in the literature.[8–10] Kac obtained a character formula for typical modules.[3] The problem for atypical $sl(m/n)$-modules has seemed to be difficult, though several partial solutions have been achieved.[6,11]

Serganova[4] found a solution for the characters of simple $gl(m/n)$-modules, which described the multiplicities $a_{\Lambda\Sigma}$ of composition factors $V(\Sigma)$ of $\overline{V}(\Lambda)$ in terms of Kazhdan–Lusztig polynomials. However, her algorithm of describing $a_{\Lambda\Sigma}$ turns out to be rather complicated. The structure of $\overline{V}(\Lambda)$ is still not so apparent. Hughes *et al.*[11] derived an algorithm to determine all the composition factors of $sl(m/n)$-Kac-modules $\overline{V}(\Lambda)$. They conjectured that there exists a bijection between the composition factors of $\overline{V}(\Lambda)$ and the permissible codes. This conjecture clearly describes the structure of $\overline{V}(\Lambda)$. In Ref. 12, the authors proved that to any unlinked code, there corresponds a composition factor of $\overline{V}(\Lambda)$, by constructing explicitly a primitive vector corresponding to the unlinked code. Here we first determine the bottom composition factor of the Kac-module $\overline{V}(\Lambda)$, then prove that to any linked code, there corresponds a composition factor. Thus, this will give a half proof of the conjecture. Our main results are summarized in Theorems 3.2, 3.5, 3.7, and 4.1.

II. THE LIE SUPERALGEBRA $sl(m+1/n+1)$

We shall only give necessary definitions and notations. For detail, please refer to Ref. 12. Denote $G=sl(m+1/n+1)=\{x=\binom{AB}{CD} | \mathrm{str}(x)=\mathrm{tr}(A)-\mathrm{tr}(D)=0\}$, where A,B,C,D are $(m+1)\times(m+1),(m+1)\times(n+1),(n+1)\times(m+1),(n+1)\times(n+1)$ matrices, respectively. Let $G_{\bar{0}}=\{\binom{A0}{0D}\}$, $G_{\bar{1}}=\{\binom{0B}{C0}\}$. Let H be the Cartan subalgebra of G, H^* the dual of H spanned by

a)Electronic mail: yacai_su@mathstat.concordia.ca

$\epsilon_a\,(a=1,\ldots,m+1),\epsilon'_b\,(b=1,\ldots,n+1)$, where $\epsilon_a:x\to A_{aa}$, $\epsilon'_b:x\to D_{bb}$ for $x=\binom{AB}{CD}$, with $\Sigma_{a=1}^{m+1}\epsilon_a-\Sigma_{b=1}^{n+1}\epsilon'_b=0$; it has an inner product: $\langle\epsilon_a|\epsilon_b\rangle=\delta_{ab},\langle\epsilon_a|\epsilon'_b\rangle=0,\langle\epsilon'_a|\epsilon'_b\rangle=-\delta_{ab}$. Let Δ,Δ_0,Δ_1 be sets of roots, even, odd roots, respectively. Set

$$I_1=\{\bar{m},\ldots,\bar{1}\},\quad I_2=\{1,\ldots,n\},\quad I=I_1\cup\{0\}\cup I_2,\quad \text{where } \bar{i}=-i \text{ for } i\in\mathbb{Z}_+. \tag{2.1}$$

Choose a basis for H: $h_i=E_{m+i+1,m+i+1}-E_{m+i+2,m+i+2}, i\in I_1\cup I_2, h_0=E_{m+1,m+1}+E_{m+2,m+2}$. The simple roots in H^* are: $\alpha_i=\epsilon_{m+i+1}-\epsilon_{m+i+2}, i\in I_1, \alpha_0=\epsilon_{m+1}-\epsilon'_1, \alpha_i=\epsilon'_i-\epsilon'_{i+1}, i\in I_2$. Thus α_0 is the only odd simple root. The symmetric inner product satisfies

$$\begin{gathered}\langle\alpha_i|\alpha_i\rangle=2,\quad i\in I_1,\quad \langle\alpha_0|\alpha_0\rangle=0,\quad \langle\alpha_i|\alpha_i\rangle=-2,\quad i\in I_2,\\ \langle\alpha_{i-1}|\alpha_i\rangle=-1,\quad i\in I_1,\quad \langle\alpha_0|\alpha_{\pm1}\rangle=\pm1,\quad \langle\alpha_i|\alpha_{i+1}\rangle=1,\quad i\in I_2,\end{gathered} \tag{2.2}$$

and $\langle\alpha_i|\alpha_j\rangle=0$, $j\neq i,i\pm1$, and $h_i(\alpha_j)=\alpha_j(h_i)=\langle\alpha_i|\alpha_j\rangle, i\leqslant0$ or $-\langle\alpha_i|\alpha_j\rangle, i>0$. Let $\Delta^{\pm}(\Delta_0^{\pm},\Delta_1^{\pm})$ be sets of positive/negative roots (even, odd roots). Let $\alpha_{ij}=\Sigma_{k=i}^{j}\alpha_k$, then $\Delta_0^{\pm}=\{\pm\alpha_{ij}|i\leqslant j,i,j\in I_1 \text{ or } i,j\in I_2\}$, $\Delta_1^{\pm}=\{\pm\alpha_{ij}|i\in I_1\cup\{0\},j\in\{0\}\cup I_2\}$. The root vectors $e_{ij}=e(\alpha_{ij}),f_{ij}=f(\alpha_{ij})=e(-\alpha_{ij})$ and the elements h_{ij} of H are

$$e_{ij}=E_{m+i+1,m+j+2},\quad f_{ij}=E_{m+j+2,m+i+1},\quad h_{ij}=E_{m+i+1,m+i+1}-(-1)^{\sigma_{ij}}E_{m+j+2,m+j+2}, \tag{2.3}$$

where $\sigma_{ij}=0$ or $1\Leftrightarrow\alpha_{ij}$ is even or odd. Set $e_i=e_{ii},f_i=f_{ii}$. The set $\{e_{ij},f_{ij},h_i|i,j\in I,i\leqslant j\}$ yields a basis for G, with the following nontrivial relations:

$$[e_{ij},e_{j+1,\not}]=e_{i\not},\quad [f_{ij},f_{j+1,\not}]=-f_{i\not},\quad [e_{ij},f_{ij}]=h_{ij},$$

$$[e_{ij},f_{ik}]=\begin{cases}-(-1)^{\sigma_{ij}\sigma_{ik}}f_{j+1,k} & \text{if } j<k\\ -(-1)^{\sigma_{ij}\sigma_{ik}}e_{k+1,j} & \text{if } j>k\end{cases},$$

$$[e_{ik},f_{jk}]=\begin{cases}e_{i,j-1} & \text{if } i<j\\ f_{j,i-1} & \text{if } i>j\end{cases},$$

$$[h_{ij},e_{k\not}]=\mu e_{k\not},\quad [h_{ij},f_{k\not}]=-\mu f_{k\not},\quad \mu=\delta_{i,k}-\delta_{i,\not+1}-(-1)^{\sigma_{ij}}\delta_{j,k-1}+(-1)^{\sigma_{ij}}\delta_{j,\not}. \tag{2.4}$$

Set $G_0^{\pm}=\text{span}\{e(\alpha)|\alpha\in\Delta_0^{\pm}\},G_{\pm1}=\text{span}\{e(\beta)|\beta\in\Delta_1^{\pm}\},G^{\pm}=G_0^{\pm}\oplus G_1^{\pm}$. Note that $G_1^{\pm}=G_{\pm1},G_0^{-}=G_0^{-}\oplus H\oplus G_0^{+},G=G^{-}\oplus H\oplus G^{+}$. For $\lambda\in H^*$, define its *Dynkin labels* to be $a_i=\lambda(h_i),i\in I$. These uniquely determine λ, which can then be represented as $\lambda=[a_{\bar{m}},\ldots,a_{\bar{1}};a_0;a_1,\ldots,a_n]$. λ is called *dominant* if $a_i\geqslant0$ for all $i\neq0$, *integral* if $a_i\in\mathbb{Z}$ for all $i\neq0$.

Let $V^0(\Lambda)$ be the simple G_0^{-}-module with integral dominant highest weight Λ and vector v_Λ. Extend $V^0(\Lambda)$ to be a $G_0^{-}\oplus G_{+1}$ module by setting $G_{+1}V^0(\Lambda)=0$. The *Kac-module*[3] is

$$\overline{V}(\Lambda)=\text{Ind}_{G_0\oplus G_{+1}}^{G}V^0(\Lambda)=\mathbf{U}(G)\otimes_{G_0\oplus G_{+1}}V^0(\Lambda), \tag{2.5}$$

where $\mathbf{U}(G)$ is the universal enveloping algebra of G. Since $\mathbf{U}(G)=\mathbf{U}(G_{-1})\otimes\mathbf{U}(G_0)\otimes\mathbf{U}(G_{+1})$, it implies $\overline{V}(\Lambda)\cong\mathbf{U}(G_{-1})\otimes V^0(\Lambda)$. Set $M=\{v\in\overline{V}(\Lambda)|v_\Lambda\notin\mathbf{U}(G)v\}$, then $V(\Lambda)=\overline{V}(\Lambda)/M$ is a finite-dimensional simple module with highest weight Λ. Define $\rho=\rho_0-\rho_1$, where $\rho_0=\frac{1}{2}\Sigma_{\alpha\in\Delta_0^+}\alpha,\rho_1=\frac{1}{2}\Sigma_{\beta\in\Delta_1^+}\beta$.

Definition 2.1: $\Lambda,\overline{V}(\Lambda),V(\Lambda)$ are called *typical* if $\langle\Lambda+\rho|\beta\rangle\neq0$ for all $\beta\in\Delta_1^+$. If $\beta\in\Delta_1^+$ such that $\langle\Lambda+\rho|\beta\rangle=0$, then $\Lambda,\overline{V}(\Lambda),V(\Lambda)$ are called *atypical* and β is an *atypical root* for Λ. If there exist precisely r distinct atypical roots for Λ, we call $\Lambda,\overline{V}(\Lambda),V(\Lambda)$ *r-fold atypical*.

It is proved[3] that every finite-dimensional simple G-module is isomorphic to a $V(\Lambda)$, characterized by its integral dominant highest weight Λ and that $\overline{V}(\Lambda)$ is simple$\Leftrightarrow\Lambda$ is typical.

A *composition series* of $\overline{V}(\Lambda)$ is a sequence $\overline{V}(\Lambda)=V_0\supset V_1\supset\cdots$ with each V_i/V_{i+1} isomorphic to some simple module $V(\Sigma)$, called a *composition factor* of $\overline{V}(\Lambda)$. A conjecture was made in Ref. 11, giving all the composition factors of $\overline{V}(\Lambda)$. We aim to prove the existence of all these composition factors; for this, important concepts are those defined as follows.

Definition 2.2: A vector $v\neq 0$ in a G-module V is called *weakly G-primitive* if there exists a G-submodule U of V such that $v\notin U$ and $G^+v\subset U$. If $U=0$, v is called *G-primitive*.

We are only concerned with finite-dimensional modules and so we always suppose Λ is an integral dominant weight. Thus, weakly $G_{\bar{0}}$-primitive vectors are in fact $G_{\bar{0}}$-primitive and integral dominant. A *cyclic module* is an indecomposable module generated by a weakly primitive vector. A weakly primitive vector v will determine a cyclic submodule $\mathbf{U}(G)v$ and a composition factor. An important construct in classifying composition factors is the following concept.

Definition 2.3: The *atypicality matrix* $A(\Lambda)$ is the $(m+1)\times(n+1)$ matrix with (b,c)-entry $A(\Lambda)_{bc}=\langle\Lambda+\rho|\beta_{bc}\rangle=\Sigma_{k=\overline{m-b+1}}^{0}a_k-\Sigma_{k=1}^{c-1}\ a_k+m-b-c+2$, where $\beta_{bc}=\alpha_{\overline{m-b+1},c-1}$.

For example, for $G=sl(3/5)$, $\Lambda=[31;0;0020]$ is three-fold atypical and

$$A(\Lambda)=\begin{pmatrix} 6 & 5 & 4 & 1 & 0 \\ 2 & 1 & 0 & \overline{3} & \overline{4} \\ 0 & \overline{1} & \overline{2} & \overline{5} & \overline{6} \end{pmatrix}. \tag{2.6}$$

If Λ is r-fold atypical, we label the atypical roots $\gamma_1<\cdots<\gamma_r$ according to the partial ordering: $\lambda,\mu\in H^*$: $\lambda\geqslant\mu\Leftrightarrow\lambda-\mu=\Sigma_{i\in I}k_i\alpha_i$ with all $k_i\geqslant 0$. For $1\leqslant s<t\leqslant r$, denote by x_{st} the entry in $A(\Lambda)$ at the intersection of the column containing the γ_s zero with the row containing the γ_t zero, and h_{st} the number of steps to go from the γ_s zero via x_{st} to the γ_t zero with the zeros themselves included in the count. Important concepts in the classification of composition factors are the following (we give these concepts in term of mathematical expressions and refer the reader to Refs. 11 and 12 for descriptions and examples if these are not familiar to the reader).

Definition 2.4: Let Λ be r-fold atypical with atypical roots $\{\gamma_1,\ldots,\gamma_r\}$, $1\leqslant s<t\leqslant r$. Define:

(1) γ_s,γ_t are called *n-*, *q-*, or *c-related*$\Leftrightarrow x_{st}>h_{st}-1$, $x_{st}=h_{st}-1$, or $x_{st}<h_{st}-1$.

(2) The *nqc-type* $nqc(\Lambda)$ of Λ is a triangular array of r columns such that for $1\leqslant s\leqslant t\leqslant r$, the $(r-t+1,s)$-entry $nqc(\Lambda)_{st}$ is zero if $s=t$ and $nqc(\Lambda)_{st}=n,q,c\Leftrightarrow\gamma_s,\gamma_t$ are *n-*, *q-*, *c*-related if $s<t$.

(3) A *code* Σ^c for Λ is an array of length r, each element of the array consisting of a nonempty column of increasing labels taken from $\{0,1,\ldots,r\}$ subject to the order relation $1<\cdots<r<0$, such that the (s,t)-entry is either empty (in this case, we set $c_{st}=\varnothing$) or c_{st} with $0\leqslant c_{st}\leqslant r$ satisfying the following rules:

(i) $c_{1s}=0$, s, or a with $s<a\leqslant r$; and $c_{1s}=a\Rightarrow nqc(\Lambda)_{sa}=q$.
(ii) $s<t, nqc(\Lambda)_{st}=\cdots=nqc(\Lambda)_{t-1,t}=c$ and $c_{1t}=a\geqslant t\Rightarrow\exists\ u>1$, $c_{us}=a$ and $c_{1s}\neq 0,a$.
(iii) $u<v$, $c_{uw}=s\neq 0$, and $c_{vw}=t\Rightarrow s<t$, $c_{1t}=t$ and $nqc(\Lambda)_{st}=c$.
(iv) $c_{uv}=c_{wx}\neq\varnothing,0$ and $c_{u+1,v}\neq\varnothing\Rightarrow c_{w+1,x}=c_{u+1,v}$.
(v) $s<t<u, nqc(\Lambda)_{st}=nqc(\Lambda)_{tu}=q$, and $c_{1s}=c_{1u}\neq 0\Rightarrow c_{1t}\neq 0$.
(vi) $s<t<u<v$, $c_{1s}=c_{1u}=a\neq 0$ and $c_{1t}=c_{1v}=b\neq 0\Rightarrow\exists\ w,x$, $c_{ws}=c_{xu}=b$ if $a<b$, or $c_{wt}=c_{xv}=a$ if $a>b$.

(4) A code Σ^c is called a *linked* code if there exist γ_s,γ_t which are linked, i.e., columns s and t have the same nonzero top entry (and in this case we say column s *is linked to* column t in code Σ^c). Otherwise, it is called an *unlinked* code.

(5) A code is called *indecomposable* if all nonzero columns contain a common nonzero entry.

(6) Denote $D=\{(b,c)|1\leqslant b\leqslant m+1, 1\leqslant c\leqslant n+1\}$, $\Gamma_\Lambda=\{(b_s,c_s)|s=1,\ldots,r\}$ the set of, respectively, positions, positions of zeros, of $A(\Lambda)$ (so $\gamma_s=\beta_{b_s,c_s}, s=1,\ldots,r$) and define $\hat{K}$

$=\{\beta_{bc}|(b,c)\in K\}$ for any subset K of D (so $\hat{D}=\Delta_1^+$ and $\hat{\Gamma}_\Lambda=\{\gamma_1,\ldots,\gamma_r\}$). For $1\leqslant s\leqslant r$, set

$$W_\Lambda^e(s)=\left\{(b,c)\in D\,\middle|\,1\leqslant c\leqslant c_s, b=b_s+\sum_{t=c}^{c_s-1}a_t\right\},$$

$$S_\Lambda^e(s)=\left\{(b,c)\in D\,\middle|\,b_s\leqslant b\leqslant m+1, c=c_s-\sum_{t=b_s}^{b-1}a_{\overline{m-t+1}}\right\},$$

$$W_\Lambda(s)=\{(b,c)\in W_\Lambda^e(s)|b<d \text{ or } c<e, \forall\,(d,e)\in S_\Lambda^e(s)\}\cup\{(b_s,c_s)\}, \tag{2.7}$$

$$S_\Lambda(s)=\{(d,e)\in S_\Lambda^e(s)|b<d \text{ or } c<e, \forall\,(b,c)\in W_\Lambda^e(s)\}\cup\{(b_s,c_s)\},$$

$$SW_\Lambda(s)=W_\Lambda(s)\cup S_\Lambda(s).$$

$SW_\Lambda(s)$ is called the *southwest chain* emanating from (b_s,c_s) and $SW_\Lambda=\cup_{s=1}^r SW_\Lambda(s)$ is called the set of all south west chains.

(7) For an unlinked code Σ^c with nonzero columns $C_{s_1},\ldots,C_{s_p}$, define $D_\Sigma=\varnothing$ if $p=0$ or $\cup_{i=1}^p SW_\Lambda(s_i)$ otherwise. The *weight corresponding to* Σ^c is defined by $\Sigma=\Lambda-\Sigma_{\beta\in\hat{D}_\Sigma}\beta$.

(8) For $1\leqslant t\leqslant r$, suppose $W_\Lambda(t),S_\Lambda(t)$ end at $(d_t,e_t),(d_t',e_t')$, respectively, $d_t'\geqslant d_t, e_t'\geqslant e_t$. Define $D(t)$ to be the region of D within or on the boundary consisting of $SW_\Lambda(t)$, the vertical line joining (d_t',e_t) to (d_t,e_t) and the horizontal line joining (d_t',e_t) to (d_t',e_t'). Then it is proved in Ref. 12 that the indecomposable unlinked codes are in 1–1 correspondence with $D(t)$ for $1\leqslant t\leqslant r$.

For the example given in (2.6), $r=3$ with $\gamma_1=\beta_{31},\gamma_2=\beta_{23},\gamma_3=\beta_{15}$, and

$$nqc(\Lambda)=\begin{matrix}q & n & 0\\ c & 0 & \\ 0 & & \end{matrix}.$$

Below we list all seven codes and indicate positions of the chain $SW_\Lambda(s)$ by s:

$$\begin{matrix}000 & 100 & 003 & 103 & 120 & 123 & 303\\ & & & & 2 & 2 & \end{matrix},\quad A(\Lambda)\to\begin{pmatrix}. & . & . & 3 & 3\\ 2 & 2 & 2 & . & .\\ 1 & 2 & . & . & .\end{pmatrix}, \tag{2.8}$$

where the first six codes are unlinked codes corresponding to weights Λ, $\Lambda-\beta_{31}$, $\Lambda-(\beta_{14}+\beta_{15})$, $\Lambda-\beta_{31}-(\beta_{14}+\beta_{15})$, $\Lambda-\beta_{31}-(\beta_{21}+\beta_{22}+\beta_{23}+\beta_{32})$, $\Lambda-\beta_{31}-(\beta_{21}+\beta_{22}+\beta_{23}+\beta_{32})-(\beta_{14}+\beta_{15})$, respectively. It is proved[12] that an unlinked code corresponds to a primitive vector, thus a composition factor of $\overline{V}(\Lambda)$. In this paper, we shall prove that a linked code corresponds to a weakly primitive vector, and is thus a composition factor.

III. THE BOTTOM COMPOSITION FACTOR

Now we are in a position to prove a result about the bottom composition factor of a Kac-module; this will play an important role in the proof of the existence of weakly primitive vectors corresponding to linked codes. Suppose Λ is a r-fold atypical with atypical roots $\gamma_1,\ldots,\gamma_r$. As in Ref. 12, without loss of generality, we can suppose $\gamma_r=\beta_{1,n+1}$ (recall that $\beta_{bc}=\alpha_{\overline{m-b+1,c-1}}$). Let Σ_-^c be the code such that $D_{\Sigma_-}=SW_\Lambda$ [*cf.* Definition 2.4(7)], i.e., Σ_-^c is the unique code containing all numbers $1,\ldots,r$, therefore $\Sigma_-=\Lambda-\Sigma_{\beta\in\widehat{SW}_\Lambda}\beta$. By Definition 2.4, this is clearly an unlinked code, and so, as proved in Ref. 12, it corresponds to a primitive vector v_{Σ_-}.

Define a total ordering on Δ: $\alpha_{ij}<\alpha_{kl}\Leftrightarrow j-i<l-k$ or $j-i=l-k$ but $i>k$. It implies that $\beta_{bc}<\beta_{de}\Leftrightarrow c-b<d-e$ or $c-b=d-e$ but $b>d$. Recalling the notation (2.3), choose a basis B of $\mathbf{U}(G_{-1})$: $B=\{b=\Pi_{\beta\in S} f(\beta)|S\subset\Delta_1^+\}$, where the product $b=f(\beta_1)\cdots f(\beta_s)$ is written in the *proper order:* $\beta_1<\cdots<\beta_s$. Define a total ordering on B by $b>b'=f(\beta_1')\cdots f(\beta_{s'}')\Leftrightarrow s>s'$ or $s=s'$ but $\beta_k>\beta_k'$ and $\beta_i=\beta_i', 1\leqslant i\leqslant k-1$ for some k, where b,b' are in proper order. Recall that an element $v\in\overline{V}(\Lambda)$ can be uniquely written as

$$v=b_1y_1v_\Lambda+b_2y_2v_\Lambda+\cdots b_i\in B, b_1>b_2>\cdots, 0\neq y_i\in\mathbf{U}(G_0^-). \tag{3.1}$$

Clearly, $v\neq 0\Leftrightarrow t=0$. If $v\neq 0$, we call $b_1y_1v_\Lambda$ the *leading term* and we call a term $b_iy_iv_\Lambda$ a *prime term* if y_i is a nonzero scalar. Define a partial ordering on D by: $(b,c)<(d,e)\Leftrightarrow(b,c)$ is located below and to the left of (d,e), i.e., $b>d, c\leqslant e$ or $b=d, c<e$.

Lemma 3.1: Given any $(b,c)\in D$, let K be any subset of $D\backslash SW_\Lambda$ satisfying: (i) $(d,e)\in K\Rightarrow(d,e)<(b,c)$; (ii) $(d,e)\in K\Rightarrow(d',e')\in K\cup SW_\Lambda$ for all $(d',e')<(d,e)$. Then we have

$$e(\beta_{bc})\prod_{\beta\in\hat{K}} f(\beta)v_{\Sigma_-}=0. \tag{3.2}$$

Proof: We shall use induction on $\#K$. If $\#K=0$, i.e., $K=\varnothing$, then it is obvious since v_{Σ_-} is a primitive vector. Suppose now $\#K\geqslant 1$, and suppose that (3.2) holds for all K' such that $\#K'<\#K$. Choose $(d,e)\in K$ first to be topmost and then to be rightmost in K. Let $K'=K\backslash\{(d,e)\}$, then clearly K' still satisfies (i) and (ii); by the inductive hypothesis we have

$$e(\beta_{bc})\prod_{\beta\in\hat{K}} f(\beta)v_{\Sigma_-}=[e(\beta_{bc}),f(\beta_{de})]\prod_{\beta\in\hat{K}'} f(\beta)v_{\Sigma_-}, \tag{3.3}$$

which is equal to zero if both $d\neq b$ and $e\neq c$. Suppose now $d=b$ and hence $e<c$ (the case for $d>b$ and $e=c$ is similar). Then by (2.4),

$$[e(\beta_{bc}),f(\beta_{de})]=e(\alpha_{e+1,c}) \quad \text{is a positive root vector.} \tag{3.4}$$

Write $\Pi_{\beta\in\hat{K}'} f(\beta)v_{\Sigma_-}$ in the form of (3.1),

$$\prod_{\beta\in\hat{K}'} f(\beta)v_{\Sigma_-}=b_1y_1v_\Lambda+b_2y_2v_\Lambda+\cdots, \tag{3.5}$$

where $y_i\in\mathbf{U}(G_0^-), b_1<b_2<\cdots$; then by property (ii) of K' one can see that every b_i can be written as (up to a sign)

$$b_i=\prod_{\beta\in\hat{K}'} f(\beta)\prod_{\beta\in\hat{E}_i} f(\beta)=\prod_{\beta\in\hat{D}_i} f(\beta), \quad \hat{D}_i=\hat{K}'\cup\hat{E}_i \tag{3.6}$$

for some $\hat{E}_i\subset\hat{D}$, where D_i satisfies the following property:

$$(d',e')\in D_i \text{ and } (d',e')<(b,c)\Rightarrow(d'',e'')\in D_i \text{ for all } (d'',e'')<(d',e'). \tag{3.7}$$

Now applying (3.4) to (3.5), noting that applying (3.4) to v_{Σ_-} is zero, we see that the right-hand side of (3.3) is a linear combination of the form

$$[e(\alpha_{e+1,c}),f(\beta)]\prod_{\beta'\in\hat{K}'\backslash\{\beta\}} f(\beta')v_{\Sigma_-}, \quad \beta\in\hat{K}'. \tag{3.8}$$

Using (3.5), (3.6), and (3.7), we see that (3.8) can be written as a linear combination of the form

$$[e(\alpha_{e+1,c}),f(\beta)]\prod_{\beta'\in\hat{D}_i\setminus\{\beta\}} f(\beta')y_i v_\Lambda, \quad \beta\in\hat{K}'. \tag{3.9}$$

Note that by (2.4), for $(d',e')\in K',\beta=\beta_{d',e'}\in\hat{K}'$, $[e(\alpha_{e+1,c}),f(\beta)]$ is either zero or up to a sign equal to $f(\beta_{d'',e''})$ for some $(d'',e'')\prec(d',e')$; by (i) $(d',e')\prec(b,c)$, thus by (3.7) $(d'',e'')\in\hat{D}_i\setminus\{\beta\}$, and so $f(\beta_{d'',e''})$ appears twice, therefore we obtain that (3.9) is zero. This proves (3.2). ■

Theorem 3.2: v_{Σ_-} is contained in every submodule of $\overline{V}(\Lambda)$. Thus it is the primitive vector corresponding to the bottom composition factor.

Proof: Set

$$v'_{\Sigma_-}=\prod_{(b,c)\notin SW_\Lambda} e(\beta_{bc})T_- v_\Lambda, \quad \text{where} \quad T_-=\prod_{(b,c)\in D} f(\beta_{bc}). \tag{3.10}$$

By rewriting v'_{Σ_-}, we have (up to a sign)

$$\begin{aligned} v'_{\Sigma_-}&=\prod_{(b,c)\notin SW_\Lambda} e(\beta_{bc})\prod_{(b,c)\notin SW_\Lambda} f(\beta_{bc})\prod_{(b,c)\in SW_\Lambda} f(\beta_{bc})v_\Lambda \\ &=\prod_{(b,c)\notin SW_\Lambda} e(\beta_{bc})\prod_{(b,c)\notin SW_\Lambda} f(\beta_{bc})v_{\Sigma_-}, \end{aligned} \tag{3.11}$$

where the second equality follows from the fact that when writing v_{Σ_-} in the form of (3.1), other than its leading term, each term contains some factor $f(\beta_{bc})$ with $(b,c)\notin SW_\Lambda$, which therefore appears twice and so vanishes. From (3.11), we have

$$\begin{aligned} v'_{\Sigma_-}&=\prod_{(b,c)\notin SW_\Lambda,b\neq 1} e(\beta_{bc})e(\beta_{11})\cdots e(\beta_{1k})f(\beta_{1k})\cdots f(\beta_{11})\prod_{(b,c)\notin SW_\Lambda,b\neq 1} f(\beta_{bc})v_{\Sigma_-} \\ &=\prod_{(b,c)\notin SW_\Lambda,b\neq 1} e(\beta_{bc})e(\beta_{11})\cdots e(\beta_{1,k-1}) \\ &\quad\times[e(\beta_{1k}),f(\beta_{1k})]f(\beta_{1,k-1})\cdots f(\beta_{11})\prod_{(b,c)\notin SW_\Lambda,b\neq 1} f(\beta_{bc})v_{\Sigma_-}, \end{aligned} \tag{3.12}$$

where we have supposed $\{(1,c)\notin SW_\Lambda\}=\{(1,1),\ldots,(1,k)\}$, and where the last equality follows from Lemma 3.1. Recall that $\beta_{bc}=\alpha_{\overline{m-b+1},c-1}$, by (2.4),

$$h'=[e(\beta_{1k}),f(\beta_{1k})]=h_{\bar{m},k-1}=h_{\bar{m}}+\cdots+h_{\bar{0}}-h_1-\cdots-h_{k-1}. \tag{3.13}$$

Note that in (3.12), $h'=[e(\beta_{1k}),f(\beta_{1k})]$ precedes an element of $\overline{V}(\Lambda)$ which has the weight $\lambda=\Lambda-2\rho_1+\beta_{1k}$. A straightforward computation gives (recall Definition 2.3)

$$\lambda(h')=A(\Lambda)_{1k}-(n-k+1). \tag{3.14}$$

Recall that we assume that $\gamma_r=\beta_{1,n+1}$, we have $A(\Lambda)_{1,n+1}=0$ and by (2.7), $(1,c)\in SW_\Lambda\Leftrightarrow A(\Lambda)_{1,c}=n-c+1$ and $(1,c)\notin SW_\Lambda\Leftrightarrow A(\Lambda)_{1,c}>n-c+1$, thus (3.14) is nonzero. Therefore we can replace $[e(\beta_{1k}),f(\beta_{1k})]$ in (3.12) by a nonzero scalar. Using induction on k, we have

$$v'_{\Sigma_-}=c\prod_{(b,c)\notin SW_\Lambda,b\neq 1} e(\beta_{bc})\prod_{(b,c)\notin SW_\Lambda,b\neq 1} f(\beta_{bc})v_{\Sigma_-}, \tag{3.15}$$

for some nonzero $c\in\mathbb{C}$. By repeating the process, we obtain that $v'_{\Sigma_-}=c'v_{\Sigma_-}$ for some nonzero $c'\in\mathbb{C}$. Since every submodule U of $\overline{V}(\Lambda)$ contains T_-v_Λ, and therefore by (3.10), it contains v'_{Σ_-}, and so contains v_{Σ_-}. This proves the theorem. ■

Using Theorem 3.2, we can prove a theorem, which appears as a conjecture in Ref. 11. First we give the notion of the northeast chains,[11] which will also be important in establishing the relation between linked codes and weakly primitive vectors in Sec. IV.

Definition 3.3: (*cf.* Definition 2.4(6).) For $1\leqslant s\leqslant r$, set

$$E^e_\Lambda(s)=\left\{(b,c)\in D\middle|c_s\leqslant c\leqslant n+1,b=b_s-\sum_{t=c_s}^{c-1}a_t\right\},$$

$$N^e_\Lambda(s)=\left\{(b,c)\in D\middle|1\leqslant b\leqslant b_s,c=c_s+\sum_{t=b}^{b_s-1}a_{\overline{m-t+1}}\right\},$$

$$E_\Lambda(s)=\{(b,c)\in E^e_\Lambda(s)\,|\,b>d \text{ or } c>e,\forall(d,e)\in N^e_\Lambda(s)\}\cup\{(b_s,c_s)\},\tag{3.16}$$

$$N_\Lambda(s)=\{(d,e)\in N^e_\Lambda(s)\,|\,b>d \text{ or } c>e,\forall(b,c)\in E^e_\Lambda(s)\}\cup\{(b_s,c_s)\},$$

$$NE_\Lambda(s)=E_\Lambda(s)\cup N_\Lambda(s).$$

$NE_\Lambda(s)$ is called the set of *northeast chains* emanating from (b_s,c_s). Denote $NE_\Lambda=\cup_{s=1}^r NE_\Lambda(s)$.

For the example given in (2.6), the northeast chains can be expressed by

$$A(\Lambda)\to\begin{pmatrix}.&.&.&.&3\\.&1&2&.&.\\1&1&1&.&.\end{pmatrix}.\tag{3.17}$$

Remark 3.4: Similar to codes, we can define *opposite codes* corresponding to northeast chains and define $D'(t)$ to be the region of D within or on the boundary consisting of $NE_\Lambda(t)$, the vertical line joining (u_t,v_t) to (u'_t,v_t) and the horizontal line joining (u'_t,v'_t) to (u'_t,v_t), where $(u_t,v_t),(u'_t,v'_t)$ are, respectively, the end points of $E_\Lambda(t),N_\Lambda(t),u_t\geqslant u'_t,v_t\geqslant v'_t$. Then indecomposable unlinked opposite codes are in 1–1 correspondence with $D'(t)$ for $1\leqslant t\leqslant r$ [*cf.* Definition 2.4(8)].

Theorem 3.5: The lowest G_0^--highest weight Π of $V(\Lambda)$ is $\Lambda_-+\Sigma_{\beta\in\widehat{NE}_\Lambda}\beta$, where $\Lambda_-=\Lambda-2\rho_1$.

Proof: Set $\Pi_+=\Lambda+\Sigma_{\beta\in\widehat{NE}_\Lambda}\beta$. We have[11] $NE_\Lambda=SW_{\Pi_+}$ and hence by Theorem 3.2, $\Lambda=\Pi_+-\Sigma_{\beta\in\widehat{SW}_{\Pi_+}}\beta$ is the highest weight of the bottom composition factor of $\overline{V}(\Pi_+)$. So $\Pi=\Pi_+-2\rho_1$ (the lowest G_0^--highest weight of $\overline{V}(\Pi_+)$) is the lowest G_0^--highest weight of $V(\Lambda)$. ■

Definition 3.6: Let Σ^c_1,Σ^c be two codes for Λ. We call Σ^c_1 a *subcode* of Σ^c (denoted by $\Sigma^c_1\leqslant\Sigma^c$ and denoted by $\Sigma^c_1<\Sigma^c$ if $\Sigma^c_1\leqslant\Sigma^c$ and $\Sigma^c_1\neq\Sigma^c$), if each nonzero entry in a column of Σ^c_1 is contained as an entry in the same column of Σ^c and if this column of Σ^c corresponding to a nonzero element of Σ^c_1 is linked to another column of Σ^c, then these columns are linked in Σ^c_1.

For example, the first five codes in (2.8) are subcodes of the sixth but no code except the first is a subcode of the seventh. Another example is that $0230<\begin{smallmatrix}4234\\44\end{smallmatrix}$. For any unlinked code Σ^c, we can write it as $\Sigma^c=\Sigma^c_1\cdots\Sigma^c_k$ such that each Σ^c_i is indecomposable. Such Σ^c_i are called *indecomposable components* of Σ^c. For a code Σ^c for Λ, to avoid confusion, sometimes, we need to denote it as $\Sigma^c(\Lambda)$ and denote the corresponding weight as $\Sigma(\Lambda)$. For example, if $\Sigma^c=\Sigma^c_1\Sigma^c_2$ and $\Sigma^c,\Sigma^c_1,\Sigma^c_2$ are unlinked, then we have primitive weights Σ,Σ_1,Σ_2 of Λ, and we have code $\Sigma^c_1(\Sigma_2)$ and primitive weight $\Sigma_1(\Sigma_2)$ of Σ_2.

Theorem 3.7: Let Σ_1^c,Σ^c be unlinked codes for Λ such that $\Sigma_1^c \leqslant \Sigma^c$. Suppose v_{Σ_1},v_Σ are primitive vectors of $\overline{V}(\Lambda)$ corresponding to Σ_1^c,Σ^c, respectively, then $v_\Sigma \in \mathbf{U}(G^-)v_{\Sigma_1}$.

Proof: By Serganova's Theorem,[13] an r-fold atypical indecomposable module over $sl(m+1/n+1)$ is equivalent to an r-fold atypical indecomposable module over $sl(r/r)$; in particular, the structure of an r-fold atypical Kac-module over $sl(m+1/n+1)$ is equivalent to the structure of an r-fold atypical Kac-module over $sl(r/r)$. Thus we can suppose that $G=sl(r/r)$ and that Λ is an r-fold atypical weight with atypical root $\gamma_1<\cdots<\gamma_r$ such that $\gamma_s=\beta_{r+1-s,s}=\alpha_{\overline{s-1,s-1}},s=1,\ldots,r$.

First we would like to make the following remark. In the proof of Theorem 6.6 of Ref. 12, we constructed two weight vectors v_Σ and $\tilde{v}_\Sigma$ and proved that at least one of them is primitive. Now in our case here, since $G=sl(r/r)$, by symmetry, we see that both vectors are primitive. Since both vectors have the same prime term (i.e., the leading term) up to a nonzero scalar, by Lemma 5.1(ii) of Ref. 12, we see that $v_\Sigma=\tilde{v}_\Sigma$ up to a nonzero scalar.

Now we shall use induction on r. If $\Sigma_1^c=\Sigma^c$ or $\Sigma^c=\Sigma_-^c$, then the proof is trivial. Thus suppose $\Sigma_1^c<\Sigma^c<\Sigma_-^c$.

Case 1: Σ^c is indecomposable.

Subcase (i): Column r of Σ^c is zero. Then as in the proof of Theorem 6.6 in Ref. 12, we can regard Σ^c as a code of the weight $\Lambda^{(r-1/r-1)}$ [which is the restriction of Λ to $G^{(r-1/r-1)}=sl(r-1/r-1)$]. The atypicality matrix $A(\Lambda^{(r-1/r-1)})$ is obtained from $A(\Lambda)$ by removing the first row and the last column. So $\Lambda^{(r-1/r-1)}$ is $(r-1)$-fold atypical, and the theorem is obtained by induction on r.

Subcase (ii): Column r of Σ^c is nonzero. Since Σ^c is an indecomposable unlinked code and $\Sigma^c\neq\Sigma_-^c$, every nonzero column of Σ^c must contain r, so column 1 of Σ^c must be zero. Let $I'=I\backslash\{\overline{1},0,1\}$. Let G' be the Lie supersubalgebra of G generated by $\{e_i,f_i,e_0'=e_{\overline{1,1}},f_0'=f_{\overline{1,1}}|i\in I'\}$ (i.e., we regard $\alpha_0'=\alpha_{\overline{1}}+\alpha_0+\alpha_1$ as the odd simple root in G' and simple roots $\alpha_{\overline{1}},\alpha_1$ of G are eliminated in G'). Thus obviously, $G'\cong sl(r-1/r-1)$ and $H'=\mathrm{span}\{h_i,h_0'=h_{\overline{1}}+h_0-h_1|i\in I'\}$ is the Cartan subalgebra of G'. We see that $\Lambda'=\Lambda|_{H'}$ is an $(r-1)$-fold atypical weight of G' whose atypicality matrix $A(\Lambda')$ is obtained from $A(\Lambda)$ by removing the first column and the last row. Thus Σ^c corresponds to a code Σ'^c of G' such that column i of Σ'^c is obtained from column $(i+1)$ of Σ^c with each nonzero label c substituted by $c-1$ for $i=1,\ldots,r-1$. For example, $G=sl(3/3),\Lambda=[02;0;20]$ and $\Sigma^c=\begin{smallmatrix}023\\3\end{smallmatrix}$, then $G'=sl(2/2),\Lambda'=[0;0;0]$ and $\Sigma'^c=\begin{smallmatrix}12\\2\end{smallmatrix}$, and we have the atypicality matrices as follows:

$$A(\Lambda)=\begin{pmatrix}4&1&0\\3&0&\overline{1}\\0&\overline{3}&\overline{4}\end{pmatrix}\rightarrow\begin{pmatrix}.&3&3\\.&2&3\\1&.&.\end{pmatrix},$$

$A(\Lambda')=\left(\begin{smallmatrix}10\\01\end{smallmatrix}\right)\rightarrow\left(\begin{smallmatrix}22\\12\end{smallmatrix}\right)$, where in the final array, we have specified all positions of the southwest chains of Λ and Λ' (keeping this example in mind will help understand the arguments that follow). Similarly, Σ_1^c corresponds to a code Σ'^c_1 of G' and $\Sigma'^c_1<\Sigma'^c$ (for the example we just mentioned, we have $\Sigma_1^c=020$, then $\Sigma'^c_1=10<\Sigma'^c=\begin{smallmatrix}12\\2\end{smallmatrix}$). Observe that the G'-submodule generated by v_Λ in $\overline{V}(\Lambda)$ is the G'-Kac-module $\overline{V}(\Lambda')$. Thus there exists $g_{\Sigma_1'},g_{\Sigma'}\in\mathbf{U}(G'^-)$ such that $v_{\Sigma_1'}=g_{\Sigma_1'}v_\Lambda,v_{\Sigma'}=g_{\Sigma'}v_\Lambda$ are G'-primitive vectors, and by inductive assumption, $v_{\Sigma'}\in\mathbf{U}(G'^-)v_{\Sigma_1'}$, i.e., there exists $g'\in\mathbf{U}(G'^-)$ such that $v_{\Sigma'}=g'v_{\Sigma_1'}=g'g_{\Sigma_1'}v_\Lambda$. Note that by the proof of Theorem 6.6 of Ref. 12, we see that we can label the roots associated with the positions in $D_{\Sigma_1'}$ by $\beta_p=\alpha_{\overline{m_p,n_p}},p=1,\ldots,s$, where $s=\#D_{\Sigma_1'}$, such that $\Lambda_0=\Lambda,\Lambda_p=\Lambda-\Sigma_{q=1}^p\beta_q$, and $v_{\Lambda_p}=\chi_{J_p}^{(m_p+1/n_p+1)}f(\beta_p)v_{\Lambda_{p-1}}$ for $p=1,\ldots,s$, and $\Sigma_1'=\Lambda_s,v_{\Sigma_1'}=v_{\Lambda_s}$. Here $J_p=\{\overline{m_p-y_p+1,\ldots,\overline{2}};2,\ldots,n_p-x_p+1\}\subset I'$, where x_p,y_p are defined as those x,y in (6.2) of Ref. 12 [cf. (6.4) of Ref. 12, note that since in G', $\alpha_0'=\alpha_{\overline{1}}+\alpha_0+\alpha_1$ and we do not have simple roots $\alpha_{\overline{1}},\alpha_1$ in G', thus we do not have elements $\overline{1},1$ in J_p]. Similarly, g' can be written as a

product of the form $\Pi_{p=1}^{s'}\chi_{J'_p,C_p}^{(m'_p+1,n'_p+1)}f(\beta'_p)$ for some $J'_p\subset I'$ and some $C_p\in\mathbb{C}^{\otimes\#J'_p}$ [cf. (6.5a) of Ref. 12], where $s'=\#(D_{\Sigma'}\backslash D_{\Sigma'_1})$ and $\beta'_p=\alpha_{\overline{m}'_p,n'_p}$ are roots associated with the positions in $D_{\Sigma'}\backslash D_{\Sigma'_1}$, for $p=1,\ldots,s'$, such that g' commutes with G'^{+}_0. Now if we set $\tilde{J}_p=J_p\cup\{\overline{1},1\}$ and let $\tilde{v}_{\Lambda_p}=\chi_{\tilde{J}_p}^{(m_p+1/n_p+1)}f(\beta_p)v_{\Lambda_{p-1}}$, then by the proof of Theorem 6.6 of Ref. 12 and the remark in the second paragraph of the proof, we see that $\tilde{v}_{\Sigma'_1}=\tilde{v}_{\Lambda_s}$ is precisely the G-primitive vector corresponding to the code Σ_1 of G. Similarly, if we set $\tilde{J}'_p=J'_p\cup\{\overline{1},1\}$ and let $\tilde{g}'=\Pi_{p=1}^{s'}\chi_{\tilde{J}'_p,\tilde{C}_p}^{(m'_p+1,n'_p+1)}f(\beta'_p)$ for some $\tilde{C}_p\in\mathbb{C}^{\otimes\#\tilde{J}'_p}$ (such that the ith coordinate of $\tilde{C}_p$ is the same as the ith coordinate of C_p for all $i\in J'_p$), then $\tilde{g}'$ commutes with G_0^{+}. Now set $\tilde{v}_{\Sigma'}=\tilde{g}'\tilde{v}_{\Sigma'_1}$, we see that $\tilde{v}_{\Sigma'}$ has the same (up to a nonzero scalar) prime terms as those of $v_{\Sigma'}$, so it is nonzero. By our construction, $\tilde{v}_{\Sigma'}$ must be the G-primitive vector v_Σ corresponding to the code Σ^c of G [since $\tilde{v}_{\Sigma'}$ has the same (up to a nonzero scalar) prime terms as those of v_Σ (in fact, the only prime term is the leading term), and they both are G_0-primitive, thus by Lemma 5.1(ii) of Ref. 12, they must be equal up to a nonzero scalar], and we have the theorem in this case.

Case 2: Suppose that $\Sigma^c=\Sigma'^c\Sigma''^c$ is decomposable and both Σ'^c,Σ''^c are subcodes of Σ^c.

Then we can also write $\Sigma_1^c=\Sigma'^c_1\Sigma''^c_1$ (one of Σ'^c_1,Σ''^c_1 may be zero) such that $\Sigma'^c_1\leqslant\Sigma'^c$ and $\Sigma''^c_1\leqslant\Sigma''^c$. The code $\Sigma'^c_1(\Sigma'')$ for Σ'' is a subcode of $\Sigma'^c(\Sigma'')$. Thus in $\overline{V}(\Sigma'')$, by induction on number of indecomposable components, we have

$$v_{\Sigma'^c(\Sigma')}\in\mathbf{U}(G^-)v_{\Sigma'^c_1(\Sigma'')}. \tag{3.18}$$

As in Ref. 12, define the module homomorphism $\overline{V}(\Sigma'')\to\overline{V}(\Lambda)$ by mapping $v_{\Sigma''}$ in $\overline{V}(\Sigma'')$ to $v_{\Sigma''(\Lambda)}$ in $\overline{V}(\Lambda)$ [Note that[3] every highest weight module with highest weight Σ'' is a quotient module of the Kac-module $\overline{V}(\Sigma'')$ and $\mathbf{U}(G^-)v_{\Sigma''(\Lambda)}$ is a highest weight module with highest weight Σ'', thus there exists a module homomorphism $\overline{V}(\Sigma'')\to\mathbf{U}(G^-)v_{\Sigma''(\Lambda)}\subset\overline{V}(\Lambda)$]. From the proof of Theorem 6.12 of Ref. 12, we see that if we set Σ_0 to be the primitive weight of Λ corresponding to code $\Sigma'^c_1\Sigma''^c$, then the primitive vectors v_Σ,v_{Σ_0} of $\overline{V}(\Lambda)$ are precisely the images of $v_{\Sigma'^c(\Sigma'')},v_{\Sigma'^c_1(\Sigma'')}$. Thus by (3.18),

$$v_\Sigma\in\mathbf{U}(G^-)v_{\Sigma_0}. \tag{3.19}$$

On the other hand, in $\overline{V}(\Lambda)$, the proof of Theorem 6.12 of Ref. 12 shows that there exists $g_{\Sigma''},g_{\Sigma''_1},g_{\Sigma'}\in\mathbf{U}(G^-)$ such that

$$v_{\Sigma''}=g_{\Sigma''}v_\Lambda,\quad v_{\Sigma''_1}=g_{\Sigma''_1}v_\Lambda,\quad v_{\Sigma_0}=g_{\Sigma'_1}v_{\Sigma''},\quad v_{\Sigma_1}=g_{\Sigma'_1}v_{\Sigma''_1}. \tag{3.20}$$

By case 1 and induction on number of indecomposable components, $v_{\Sigma''}\in\mathbf{U}(G^-)v_{\Sigma''_1}$, i.e., we can write $g_{\Sigma''}=g''g_{\Sigma''_1}$ for some $g''\in\mathbf{U}(G^-)$. Then we have

$$\begin{aligned}v_{\Sigma_0}&=g_{\Sigma'_1}v_{\Sigma''}=g_{\Sigma'_1}g_{\Sigma''}v_\Lambda=c_1g_{\Sigma''}g_{\Sigma'_1}v_\Lambda=c_1g''g_{\Sigma''_1}g_{\Sigma'_1}v_\Lambda\\&=c_2g''g_{\Sigma'_1}g_{\Sigma''_1}v_\Lambda=c_2g''v_{\Sigma_1}\in\mathbf{U}(G^-)v_{\Sigma_1},\end{aligned} \tag{3.21}$$

for some $c_1, c_2 \in \mathbb{C}$, where the third, fifth equalities follow from Lemma 5.1 of Ref. 12 since they are primitive vectors of the same weights with the same prime terms (i.e., the leading term) up to scalars. Now the proof is completed by (3.19), (3.21). ■

IV. WEAKLY PRIMITIVE VECTORS

Our main result in this section is the following theorem.

Theorem 4.1: To any linked code Σ^c for Λ, there corresponds a weakly primitive vector v_Σ in $\overline{V}(\Lambda)$. Furthermore, if $\Sigma_1^c \leqslant \Sigma^c$, then $v_\Sigma \in \mathbf{U}(G^-)v_{\Sigma_1}$.

Proof: As in the proof of Theorem 3.7, we suppose $G=sl(r/r)$ and Λ is an r-fold atypical weight with atypical root $\gamma_1<\cdots<\gamma_r$ such that $\gamma_s=\beta_{r+1-s,s}=\alpha_{\overline{s-1,s-1}}, s=1,\ldots,r$.

By introducing the Young diagram for Λ, it was proved in Ref. 11 that all codes (linked or unlinked) for Λ are in 1–1 correspondence with the standard boundary strip removals in the Young diagram for Λ. In Diagram 1, we list the Young diagrams for some Λ and some codes Σ^c, and specify all positions on the boundary removals corresponding to column i of code Σ^c by an entry i for $i=1,2,\ldots,r$. Observe that in Diagram 1(i), column s is wrapped by column t for all s and t with $s<t$ (we say column s *is wrapped by* column t for $s<t$ if the top entry of column t appears somewhere below the top entry in column s); in Diagram 1(ii), column 1 is linked to column 2 and these two columns are wrapped by columns 3 and 4, in this case we say that this link *is wrapped by* column 4; in Diagram 1(iii), columns 1, 2, and 3 appear to be linked to columns 4, 5, and 6,

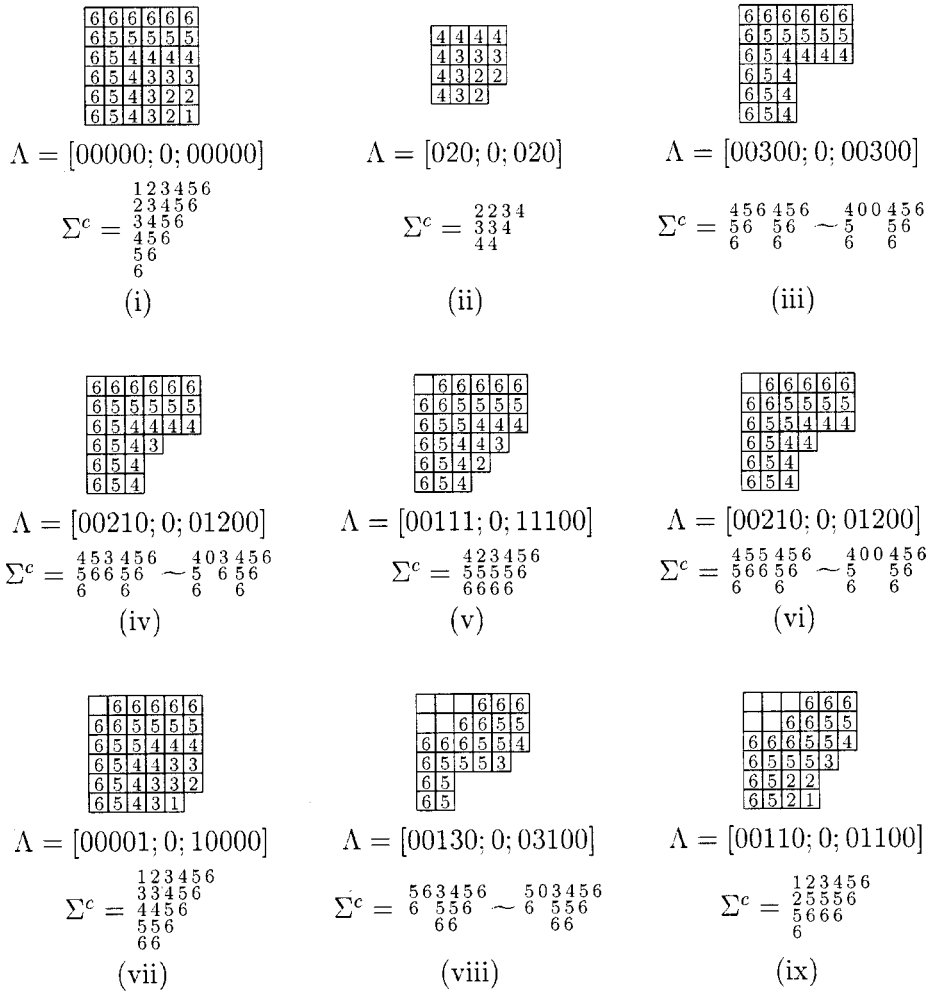

Diagram 1.

respectively, however, the shape of the corresponding boundary removals of the Young diagram just looks like that of Diagram 1(ii): In general if column s is linked to column t for $s<t$ and column u is linked to column v for $s<u<t<v$, then by rule (vi) of code definition, the link of column s to column t is wrapped by column v. This leads us to the following definition:

For any code Σ^c, we denote by $\tilde{\Sigma}^c$ the array obtained from Σ^c obeying the rule: if $s<t<u<v$ and $c_{1s}=c_{1u}=a<b=c_{1t}=c_{1v}$ [cf. Definition 2.4(3.vi)], then column t of $\tilde{\Sigma}^c$ is set to be zero. We call $\tilde{\Sigma}^c$ the *reduced code* of Σ^c and denote $\Sigma^c \sim \tilde{\Sigma}^c$. In particular, $\Sigma^c=\tilde{\Sigma}^c$ if Σ^c is an unlinked code. In general, $\tilde{\Sigma}^c$ is not a code by Definition 2.4(3).

Using this definition, the code in Diagram 1(iii) can be better reinterpreted as: Column 1 is linked to column 4 and this link is wrapped by columns 5 and 6. Thus we have the reduced code in the right-hand side of the symbol $\sim$, which is simply the same code as in Diagram 1(ii) if we delete the columns which are zero (i.e., columns 2 and 3). Similarly, we have other reduced codes in Diagram 1. By the definition of reduced codes, we obtain the following observation.

Observation 1: Suppose $1\leqslant s\leqslant u\leqslant t$ such that column s is linked to column t in a reduced code $\tilde{\Sigma}^c$, then column u cannot be linked to column v for any v such that $v<s$ or $v>t$.

We set

$$B_{\tilde{\Sigma}^c}=\{(s,t)\,|\,1\leqslant s<t\leqslant r,\ \text{columns } s \text{ and } t \text{ of } \tilde{\Sigma}^c \text{ contain a common nonzero top entry}\}. \tag{4.1}$$

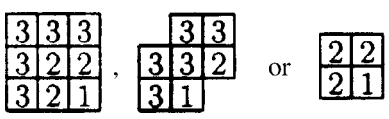
Define the *link number* to be $i_{\tilde{\Sigma}^c}=\#B_{\tilde{\Sigma}^c}$. We shall prove the theorem by induction on $i_{\tilde{\Sigma}^c}$. If $i_{\tilde{\Sigma}^c}=0$, then $\tilde{\Sigma}^c$ is an unlinked reduced code, thus $\Sigma^c=\tilde{\Sigma}^c$, and so Σ^c corresponds to a primitive vector.[12] If $\Sigma_1^c\leqslant\Sigma^c$, then Σ_1^c is also an unlinked code and the second statement of Theorem 4.1 follows from Theorem 3.7.

Now suppose $i_{\tilde{\Sigma}^c}>0$. Define a total ordering on $B_{\tilde{\Sigma}^c}$ by

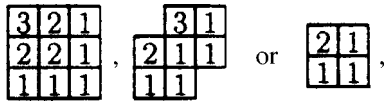
$$(s,t)\leqslant(u,v)\Leftrightarrow t<v \text{ or } t=v \text{ but } s>u. \tag{4.2}$$

Choose $(s,t)\in B_{\tilde{\Sigma}^c}$ to be the smallest pair with respect to the ordering (4.2). Let u be the smallest number such that $s<u<t$ and such that column u of $\tilde{\Sigma}^c$ is nonzero. If such u does not exist, we set $u=t$.

Case 1: $u=t$ or $u<t$ but column u contains the top entry of column t as an entry [thus column v is wrapped by column t for $u\leqslant v<t$ by rule (ii) of code definition]. For any w with $s<w<u$ (if such w exists), by rule (v) of code definition, $nqc(\Lambda)_{wt}\neq q$, and by rule (ii), $nqc(\Lambda)_{wt}\neq c$; thus $nqc(\Lambda)_{wt}=n$ and so $nqc(\Lambda)_{sw}=c$ (since $nqc(\Lambda)_{st}=q$). This shows that $D'(s)=\Sigma_{i=s}^{u-1}NE_\Lambda(i)$ corresponds to an opposite (unlinked) code for Λ, and $\Lambda'=\Lambda+\Sigma_{(b,c)\in D'(s)}\beta_{bc}$ is an integral dominant r-fold atypical root. For example, if the pair (Λ,Σ^c) is shown in Diagram 1(iii), 1(vi), or 1(viii), then Λ' is shown in Diagram 1(i), 1(vii) or 1(ix), respectively (to indicate the boxes in the Young diagram for Λ' corresponding to the northeast chain $D'(s)$, the boxes on the right-bottom corner of the Young diagram labeled as



should be re-labeled as



respectively). Now for the weight Λ', by construction, we have $nqc(\Lambda')_{w,u-1}=c$ for all $s\leqslant w<u-1$. Note that we have

Claim 1. Suppose $1\leqslant s<u'\leqslant r$ such that $D'(s)=\Sigma_{i=s}^{u'}NE_{\Lambda}(i)$ corresponds to an opposite (unlinked) code for Λ, and $\Lambda'=\Lambda+\Sigma_{(b,c)\in D'(s)}\beta_{bc}$ is an integral dominant r-fold atypical root. Then there exists an unlinked code $\Sigma_0^c(\Lambda')$ for Λ', such that $D_{\Sigma_0(\Lambda')}=\Sigma_{i=s}^{u'}SW_{\Lambda'}(i)$ is equal to $D'(s)$.

To obtain this claim, we can restrict our attention to $G^{(u'/u')}=sl(u'/u')$ so that we can suppose $u'=r$. Furthermore, by letting G' be the Lie supersubalgebra of $G^{(u'/u')}$ generated by $\{e_i,f_i,e_0'=e_{\overline{s-1},s-1},f_0'=f_{\overline{s-1},s-1}|i=s,\ldots,u'-1\}$ as in the proof of Theorem 3.7, we can suppose $s=1$. But then, $D'(s)$ is simply the set of northeast chains and the claim is obtained from the proof of Theorem 3.5.

By Claim 1, there exists an unlinked code $\Sigma_0^c(\Lambda')$ for Λ', such that $D_{\Sigma_0(\Lambda')}=\Sigma_{i=s}^{u-1}SW_{\Lambda'}(i)$ is equal to $D'(s)$. For the example we have just given,

$$\Sigma_0^c(\Lambda')=\begin{array}{ccc}1&2&3\\2&3&\\3&&\end{array},\quad\begin{array}{ccc}1&2&3\\3&3&\end{array}\quad\text{or}\quad\begin{array}{cc}1&2\\2&\end{array},$$

respectively. From this and Ref. 12, we obtain the following important fact.

Fact 1: Λ is the primitive weight of Λ' corresponding to the code $\Sigma_0^c(\Lambda')$.

Similarly, we have $nqc(\Lambda')_{vt}=c$ for all $s\leqslant v<t$ and there exists a code $\Sigma^c(\Lambda')$ for Λ' which is obtained from the code $\Sigma_0^c(\Lambda')$ and the code Σ^c by the following rules:

(i) if $w\geqslant t$ or $w<s$, then column w of $\Sigma^c(\Lambda')$ is the same as column w of Σ^c.
(ii) if $s\leqslant v\leqslant t-1$, then column v of $\Sigma^c(\Lambda')$ contains all nonzero entries of column v of $\Sigma_0^c(\Lambda')$ and also contains a as an entry, where a is the top entry of column t of Σ^c (thus contains all entries of column t of Σ^c).

Note that these rules uniquely determine the code $\Sigma^c(\Lambda')$. For the example we have just given, the code $\Sigma^c(\Lambda')$ is given in Diagram 1(i), 1(vii), or 1(ix), respectively. Now the link number for $\Sigma^c(\Lambda')$ is $i_{\tilde{\Sigma}^c(\Lambda')}=i_{\tilde{\Sigma}^c}-1$. By induction, there exists a weakly primitive vector $v_{\Sigma^c(\Lambda')}\in\overline{V}(\Lambda')$. As in the proof of Theorem 3.7, we define a module homomorphism $\overline{V}(\Lambda)\to\overline{V}(\Lambda')$ which maps v_Λ in $\overline{V}(\Lambda)$ to $v_{\Sigma_0(\Lambda')}$ in $\overline{V}(\Lambda')$. Under this homomorphism the preimage of $v_{\Sigma(\Lambda')}$ is a weakly primitive vector of $\overline{V}(\Lambda)$ corresponding to the code Σ [since $\Sigma_0^c(\Lambda')\leqslant\Sigma^c(\Lambda')$ and so $v_{\Sigma(\Lambda')}\in\mathbf{U}(G^-)v_{\Sigma_0(\Lambda')}$). Suppose $\Sigma_1^c\leqslant\Sigma^c$. Then as above we can write a code $\Sigma_1^c(\Lambda')$ for Λ' such that $\Sigma_0^c(\Lambda')\leqslant\Sigma_1^c(\Lambda')\leqslant\Sigma^c(\Lambda')$ and so $v_{\Sigma(\Lambda')}\in\mathbf{U}(G^-)v_{\Sigma_1(\Lambda')}\subset\mathbf{U}(G^-)v_{\Sigma_0(\Lambda')}$. Thus we obtain the second statement of Theorem 4.1.

Case 2: $u<t$ and column u does not contain the top entry of column t as an entry. Let $v<t$ be the largest number such that the top entry of column t does not appear as an entry in column v. Let $\Sigma'^c\leqslant\Sigma^c$ be the subcode of Σ^c such that for $w<u$ or $w>v$, column w is zero and for $u\leqslant w\leqslant v$, column w consists of those entries a of column w of Σ^c such that $u\leqslant a\leqslant v$ (if there is no such a, then column w is set to be zero). Let Λ' be the primitive weight of $\overline{V}(\Lambda)$ corresponding to code Σ'^c. Let $\Sigma^c(\Lambda')$ be a code for Λ' obtained from Σ^c by removing all entries appearing in Σ'^c (if in a column there is no entry after removing, then this column is set to be zero). By code definition, one can verify that $\Sigma^c(\Lambda')$ is indeed a code for Λ' (note that in the code Σ^c since the top entry of column t does not appear in column w for all w with $u\leqslant w\leqslant v$, column w of Σ^c can only contain those entries a with $u\leqslant a\leqslant v$ by code definition; thus column w of $\Sigma^c(\Lambda')$ is in fact zero for all w with $u\leqslant w\leqslant v$). For example, if the pair (Λ,Σ^c) is given in Diagram 1(iv) or 1(v), then $\Sigma'^c=00300$ or 02300 and the pair $(\Lambda',\Sigma^c(\Lambda'))$ is shown in Diagram 1(iii) or 1(vi), respectively. Now $\Sigma^c(\Lambda')$ is a code in Case 1, therefore, there exists a weakly primitive vector $v_{\Sigma(\Lambda')}$

in $\overline{V}(\Lambda')$. Define a module homomorphism: $\overline{V}(\Lambda')\to\overline{V}(\Lambda)$ mapping $v_{\Lambda'}$ in $\overline{V}(\Lambda')$ to $v_{\Sigma'^c}$ (having the same weight Λ') in $\overline{V}(\Lambda)$. We claim that the image of $v_{\Sigma(\Lambda')}$ is nonzero by calculating the coefficient of the leading term as we did in Ref. 12. This image is then the weakly primitive vector corresponding to the code Σ^c for Λ. Similarly, we obtain the second statement of Theorem 4.1. ■

Soliton solutions of XXZ lattice Landau–Lifshitz equation

SADAKANE Tomoyuki[a)]
Department of Fundamental Sciences, Kyoto University, Yoshida, Sakyo-ku, Kyoto 606-8501, Japan

(Received 22 December 2000; accepted for publication 13 August 2001)

Multisoliton solutions of the partially isotropic (classical) lattice Landau–Lifshitz equation are constructed. A trigonometric version of the dressing method is proposed to this aim. The dressing matrix is a matrix valued periodic function of the spectral parameter, and takes almost the same form as the L-matrix except for the number of poles. Both the easy-axis ($J_1=J_2<J_3$) and easy-plane ($J_1<J_2=J_3$) cases can be treated in a parallel way. © *2001 American Institute of Physics.* [DOI: 10.1063/1.1407839]

I. INTRODUCTION

The Landau–Lifshitz (LL) equation is an equation that describes the motion of the classical ferromagnetic spins on a continuous space. It is known that the LL equation is a universal equation in the sense that it reduces to integrable systems in special cases, such as the sine-Gordon (SG) model and the nonlinear Schrödinger (NLS) equation. Sklyanin established that the LL equation itself is a completely integrable Hamiltonian system by constructing the Lax pair.[1]

For an application to the theory of condensed-matter physics, it will be more natural that the spins are configured on a lattice rather than on a continuous space. Although the solitary excitations in one-dimensional magnets have been extensively studied from that point of view,[2] it is known that a ''naive'' discretization does not inherit the complete integrability of the LL equation.[3] A completely integrable lattice version of the LL equation (the LLL equation) has been proposed by an approach from the r-matrix.[4,5] The lattice version, like the continuous case, contains a lattice SG model[6] and a lattice versions of NLS equation[7,8] as its special cases.

In this article, we construct the soliton solutions of the LLL equation by a dressing method. Because the Lax formalism of the LLL equation (as well as the continuous LL equation) contains elliptic functions of the spectral parameters, the usual dressing method[9] has to be modified. Bobenko developed such a variant of the dressing method to construct multisoliton solutions of the continuous LL equation.[10] Volkov applied Bobenko's method to the LLL equation and obtained the one-soliton solution,[11] but did not present an explicit form of multisoliton solutions. This will probably be due to technical difficulties—in Bobenko's approach, multisoliton solutions are obtained by a sequence of dressing transformations, which becomes more complicated as one proceeds. We propose a new dressing method to overcome this difficulty.

Our approach is based on a single dressing matrix rather than a sequence of dressing transformations. This dressing matrix is characterized by several analytic properties, which we shall derive from those of the L-matrix. In order to make the calculations not too complicated, we consider the partially isotropic (XXZ) LLL equation. The dressing matrix for this case is a linear combination of the trigonometric functions, and the coefficients are determined by a procedure similar to the usual dressing method.

This paper is organized as follows. In Sec. II we provide a brief review of the LLL equation and its Lax pair. In Sec. III we illustrate the construction of the multisoliton solution of the easy-axis LLL equation by the dressing method. The easy-plane case is also mentioned in Sec. IV. Section V is for conclusion and discussion.

II. LATTICE LANDAU–LIFSHITZ EQUATION

A. The equation

The Landau–Lifshitz equation

$$\partial_t \vec{S}(x,t) = \vec{S}(x,t)_{xx} \times \vec{S}(x,t) - J\vec{S}(x,t) \times \vec{S}(x,t)$$

is a classical equation for nonlinear spin waves in a ferromagnet. Here, J_l $(l=1,2,3)$ are coupling constants, and $J=\mathrm{diag}(J_1,J_2,J_3)$.

The LLL equation is formulated[4] with an auxiliary real variable $S_{0n}(t)$ besides the three spin variables $S_{1n}(t)$, $S_{2n}(t)$, and $S_{3n}(t)$. The integer n is the index of a lattice site and unrestricted (i.e., the lattice is infinite). The four variables $(S_{0n}(t),S_{1n}(t),S_{2n}(t),S_{3n}(t))$ are required to obey the constraints

$$\kappa_0 = S_{1n}^2 + S_{2n}^3 + S_{3n}^2, \tag{1}$$

$$\kappa_1 = S_{0n}^2 - (J_1 S_{1n}^2 + J_2 S_{2n}^2 + J_3 S_{3n}^2), \tag{2}$$

where κ_0 and κ_1 are positive parameters, and J_1, J_2, and J_3 are coupling constants of two neighboring spins. We assume that

$$J_1 \leqslant J_2 \leqslant J_3, \quad \kappa_1 + J_3\kappa_0 \geqslant 0,$$

so that Eqs. (1) and (2) have a solution in $\mathbf{R}^4$. In the isotropic case $(J_1=J_2=J_3)$, the LLL equation reduces to the so called Heisenberg spin chain model.[12] We investigate two partially isotropic cases, easy-axis $(J_1=J_2<J_3)$ and easy-plane $(J_1<J_2=J_3)$.

We use the three functions of a complex parameter λ,

$$w_1(\lambda) = \rho/\mathrm{sn}(\lambda,k_0),$$

$$w_2(\lambda) = \rho\,\mathrm{dn}(\lambda,k_0)/\mathrm{sn}(\lambda,k_0),$$

$$w_3(\lambda) = \rho\,\mathrm{cn}(\lambda,k_0)/\mathrm{sn}(\lambda,k_0),$$

where sn, cn, and dn are Jacobi's elliptic functions, and k_0 is the modulus of elliptic functions $(0 \leqslant k_0 \leqslant 1)$. The constants ρ and k_0 are defined by the equations

$$\rho = \sqrt{J_3 - J_1}, \tag{3}$$

$$k_0 = \sqrt{\frac{J_2 - J_1}{J_3 - J_1}}. \tag{4}$$

Let λ_0 be a solution of

$$\kappa_1 + \kappa_0((w_\alpha(\lambda_0))^2 + J_\alpha) = 0. \tag{5}$$

We introduce the vector variables at lattice-site n,

$$\vec{S}_n(t) = (S_{1n}(t),S_{2n}(t),S_{3n}(t))^{\mathrm{T}},$$

$$\vec{T}_n(t) = \mathcal{W}(\lambda_0)\vec{S}_n(t),$$

where V^{T} is the transpose of the vector V, and $\mathcal{W}(\lambda) = \mathrm{diag}(w_1(\lambda),w_2(\lambda),w_3(\lambda))$. Here and below, t will be omitted. The LLL equation[4] is then written as follows:

$$\partial_t S_{0n}=2\det \mathcal{W}(\lambda_0)\left(\frac{\vec{T}_{n+1}}{h_{n+1}}+\frac{\vec{T}_{n-1}}{h_n}\right)\cdot\begin{pmatrix}\frac{1}{J_3^2}-\frac{1}{J_2^2} & & \\ & \frac{1}{J_1^2}-\frac{1}{J_3^2} & \\ & & \frac{1}{J_2^2}-\frac{1}{J_1^2}\end{pmatrix}\vec{T}_n, \tag{6}$$

$$\partial_t \vec{T}_n=2\det \mathcal{W}(\lambda_0)\left(\left(\frac{S_{0n+1}}{h_{n+1}}+\frac{S_{0n-1}}{h_n}\right)(\mathcal{W}^{-2}(\lambda_0)\vec{T}_n)\times\vec{T}_n-S_{0n}(\mathcal{W}^{-2}(\lambda_0)\vec{T}_n)\times\left(\frac{\vec{T}_{n+1}}{h_{n+1}}+\frac{\vec{T}_{n-1}}{h_n}\right)\right), \tag{7}$$

where "$\cdot$" and "$\times$" stand for the scalar and vector products, and

$$h_n=S_{0,n-1}S_{0,n}-\sum_{\alpha=1}^{3} w_\alpha^2(\lambda_0)S_{\alpha,n-1}S_{\alpha,n}.$$

In fact,

$$H=-\sum_{n-\infty}^{\infty}\log h_n$$

is the Hamiltonian of this system.[4] We assume that $h_n\neq 0$ because the situation where $h_n=0$ is physically nonsense.

B. Lax formalism

In order to write the LLL equation in the Lax formalism, we define $L_n(\lambda)$ and $M_n(\lambda)$ as follows:[4]

$$L_n(\lambda)=S_{0n}\mathbf{1}+i\sum_{l=1}^{3} w_l(\lambda)S_{ln}\sigma_l, \tag{8}$$

$$M_n(\lambda)=\frac{1}{h_n}\sum_{l=1}^{3}(w_l(\lambda-\lambda_0)\hat{M}_{ln}(\lambda_0)+w_l(\lambda+\lambda_0)\hat{M}_{ln}(-\lambda_0))\sigma_l. \tag{9}$$

Here

$$\hat{M}_{l_3,n}(\lambda)=iw_{l_3}(\lambda)(S_{0,n-1}S_{l_3,n}+S_{l_3,n-1}S_{0,n})-iw_{l_1}(\lambda)w_{l_2}(\lambda)(S_{l_1,n-1}S_{l_2,n}-S_{l_2,n-1}S_{l_1,n})$$

with (l_1,l_2,l_3) being a cyclic permutation of (1,2,3), and λ being a time-independent spectral parameter.

The LLL equation is then equivalent to the Lax equation

$$\partial_t L_n(\lambda)=M_{n+1}(\lambda)L_n(\lambda)-L_n(\lambda)M_n(\lambda) \tag{10}$$

of the linear equations

$$\Psi_{n+1}(\lambda)=L_n(\lambda)\Psi_n(\lambda), \tag{11}$$

$$\partial_t\Psi_n(\lambda)=M_n(\lambda)\Psi_n(\lambda). \tag{12}$$

Equation (10) is the so called compatibility condition of Eqs. (11) and (12). Namely Eqs. (11) and (12) have a nontrivial solution if and only if Eq. (10) is satisfied. Suppose that Eqs. (11) and (12) have a nontrivial solution. Then by calculating $\partial_t \Psi_{n+1}(\lambda)$ in two different ways as

$$\partial_t \Psi_{n+1}(\lambda) = (\partial_t L_n \lambda + L_n(\lambda) M_n(\lambda)) \Psi_n(\lambda)$$

and

$$\partial_t \Psi_{n+1}(\lambda) = M_{n+1}(\lambda) L_n(\lambda) \Psi_n(\lambda),$$

one obtains Eq. (10). The inverse is also true (though we do not need it in the subsequent consideration).

C. Trigonometric case

If k_0 equals zero, i.e., $J_1 = J_2 < J_3$, Jacobi's elliptic functions reduce to trigonometric functions. The L-matrix then takes the form

$$L_n(\lambda) = S_{0n}\mathbf{1} + i\frac{\rho}{\sin\lambda}(S_{1n}\sigma_1 + S_{2n}\sigma_2 + \cos\lambda S_{3n}\sigma_3), \tag{13}$$

and enjoys the symmetry properties

$$\sigma_3 L_n(\lambda)\sigma_3 = L_n(\lambda + \pi), \tag{14a}$$

$$\sigma_2 L_n(\lambda)\sigma_2 = (L_n(\lambda^*))^*, \tag{14b}$$

$$\lim_{y\to+\infty} \sigma_1 L_n(x+iy)\sigma_1 = \lim_{y\to+\infty} L_n(x-iy) \quad (x \in \mathbf{R}). \tag{14c}$$

Equations (14a) and (14c) stem from the double periodicity of the matrix elements of $L_n(\lambda)$ in the totally anisotropic case. Because of Eq. (14a), the diagonal elements of $L_n(\lambda)$ are periodic functions with period π; the off-diagonal elements of $L_n(\lambda)$ are antiperiodic functions with period π ($f(z+\pi) = -f(z)$). Equation (14b) implies that S_{ln} ($l = 0,1,2,3$) are real valued.

III. DRESSING METHOD

In this section, we construct solutions of the easy-axis partially isotropic ($k_0 = 0$) LLL equation. The construction is achieved by three steps. First, an analytic form of the dressing matrix is determined by its quasi-periodicity and its properties of the poles. The residues of the dressing matrix at the poles are free parameters. Second, a set of linear algebraic equations for the residues of the dressing matrix and its inverse matrix is derived and solved. Last, the (n,t) dependence of these residues is specified.

A. The first step

Let us consider the vacuum solution of the LLL equation,

$$\vec{S}_n = (0,0,\sqrt{\kappa_0})^{\mathrm{T}}.$$

The L- and M-matrices take the form

$$L^{(0)}(\lambda) = \sqrt{\kappa_1 + J_3\kappa_0}\mathbf{1} + \frac{i\sqrt{\kappa_0}\rho}{\tan\lambda}\sigma_3, \tag{15}$$

$$M^{(0)}(\lambda) = 2i\sqrt{\frac{\kappa_1 + J_3\kappa_0}{\kappa_0}}\frac{1}{1 + (1/\rho^2)[(\kappa_1 + J_1\kappa_0)/\kappa_0]\sin^2\lambda}\sigma_3. \tag{16}$$

An associated solution of the linear equations (11) and (12) is given by

$$\Phi_n(\lambda)=L^{(0)}(\lambda)^n \exp(M^{(0)}(\lambda)t). \tag{17}$$

The dressing methods seek a nontrivial solution by "dressing" this bare solution. We introduce $\Psi_n(\lambda)$ as

$$\Psi_n(\lambda)=W_n(\lambda)\Phi_n(\lambda). \tag{18}$$

We call $W_n(\lambda)$ the *dressing matrix*. The dressing matrix is determined such that $\Psi_n(\lambda)$ be a solution of the linear equations (11) and (12).

For Eq. (18) to be consistent with Eq. (11), we follow Mikhailov's idea[13] and require that $W_n(\lambda)$ satisfies the following three conditions parallel to Eqs. (14a)–(14c):

$$\sigma_3 W_n(\lambda)\sigma_3=W_n(\lambda+\pi), \tag{19a}$$

$$\sigma_2 W_n(\lambda)\sigma_2=(W_n(\lambda^*))^*, \tag{19b}$$

$$\sigma_1 W_n(i\infty)\sigma_1=W_n(-i\infty). \tag{19c}$$

See the remark at the end of this section. Furthermore, by Eqs. (11) and (12), $\det W_n(\lambda)$ is independent of n and t, thereby a function of only λ. Thus, without loss of generality, we can assume that

$$\lim_{y\to+\infty} \det W_n(iy)=1 \tag{20}$$

(see Appendix B).

To construct a soliton solution, we impose the following additional conditions:

(C-I) Each matrix element of $W_n(\lambda)$ is a meromorphic function of λ. The poles in the strip $D=\{\lambda|0\leqslant \mathrm{Re}\,\lambda<\pi\}$ are located at N mutually distinct nonreal numbers $\alpha_1,\ldots,\alpha_N$ and their complex conjugates $\alpha_1^*,\ldots,\alpha_N^*$. The α_j^*'s are written α_{N+j} in the following.

(C-II) There exists a y_0 (independent of $\mathrm{Re}\,\lambda$) such that each element of $W_n(\lambda)$ is bounded in the domain $|\mathrm{Im}\,\lambda|>y_0$.

(C-III) The residue matrices of $W_n(\lambda)$ at $\lambda=\alpha_j$ $(j=1,\ldots,2N)$ have rank 1.

Some comments are in order. Equation (19a) implies that the diagonal elements of $W_n(\lambda)$ are periodic functions with period π, and the off-diagonal elements are antiperiodic functions with period π. The condition C-II guarantees that the elements of $W_n(\lambda)$ are uniformly bounded in the limit $\mathrm{Im}\,\lambda\to\infty$. Equation (20) is a normalization condition; the condition at $\lambda=-i\infty$ follows from Eqs. (19c) and (20). Owing to the condition C-III, it is guaranteed that all the poles of $\det W_n(\lambda)$ at $\lambda=\alpha_j$ $(j=1,\ldots,2N)$ are simple. If the rank of the residue matrix at α_j is 2, then $\det W_n(\lambda)$ has a double pole at $\lambda=\alpha_j$; if the residue has rank 0, $W_n(\lambda)$ shall not have a pole at $\lambda=\alpha_j$. Under these conditions, the following results are deduced by complex analytic discussion (see Appendices A and B):

(1) $W_n(\lambda)$ can be written

$$W_n(\lambda)=d_{n0}\mathbf{1}+\sum_{j=1}^{2N}\left(\frac{d_{nj}\mathbf{1}+ic_{nj}\sigma_3}{\tan(\lambda-\alpha_j)}+\frac{ia_{nj}\sigma_1+ib_{nj}\sigma_2}{\sin(\lambda-\alpha_j)}\right). \tag{21}$$

Note that Eq. (21) takes the same form as the L-matrix has except for the coefficient of $\mathbf{1}$. The coefficients d_{nj} $(j=1,\ldots,2N)$ have to obey the relation

$$\sum_{j=1}^{2N} d_{nj}=0 \tag{22}$$

as a consequence of Eq. (19c).

(2) $\det W_n(\lambda)$ is a periodic function with period π, and has $2N$ simple poles at $\alpha_1,\ldots,\alpha_{2N}$ in D and the same number of zeros at $\beta_1,\ldots,\beta_{2N}$. Accordingly,

$$\det W_n(\lambda)=\frac{\Pi_{j=1}^{2N}\sin(\lambda-\beta_j)}{\Pi_{j=1}^{2N}\sin(\lambda-\alpha_j)}. \tag{23}$$

Moreover, $\beta_i\neq\alpha_j\,(\mathrm{mod}\,\pi)$. The restriction

$$\sum_{j=1}^{2N}\alpha_j=\sum_{j=1}^{2N}\beta_j\ \ (\mathrm{mod}\,2\pi) \tag{24}$$

follows from Eqs. (19c) and (20), and the inverse is also true.

(3) If the β_j's are mutually distinct, then $W_n^{-1}(\lambda)$ can be written

$$W_n^{-1}(\lambda)=\tilde{d}_{n0}\mathbf{1}+\sum_{j=1}^{2N}\left(\frac{\tilde{d}_{nj}\mathbf{1}+i\tilde{c}_{nj}\sigma_3}{\tan(\lambda-\beta_j)}+\frac{i\tilde{a}_{nj}\sigma_1+i\tilde{b}_{nj}\sigma_2}{\sin(\lambda-\beta_j)}\right), \tag{25}$$

which takes the same form as $W_n(\lambda)$.

B. The second step

Since the residues are rank 1 matrices, there exist column two-vectors $u_{nj},\tilde{u}_{nj}$ and row two-vectors $v_{nj},\tilde{v}_{nj}$ $(j=1,\ldots,2N)$ such that

$$d_{nj}\mathbf{1}+ia_{nj}\sigma_1+ib_{nj}\sigma_2+ic_{nj}\sigma_3=u_{nj}v_{nj},$$

$$\tilde{d}_{nj}\mathbf{1}+i\tilde{a}_{nj}\sigma_1+i\tilde{b}_{nj}\sigma_2+i\tilde{c}_{nj}\sigma_3=\tilde{u}_{nj}\tilde{v}_{nj}.$$

Moreover, since the residues of $W_n(\lambda)W_n^{-1}(\lambda)$ at $\lambda=\alpha_j,\beta_k$ $(1\leqslant j,k\leqslant 2N)$ have to vanish, we have the relations

$$u_{nj}v_{nj}W_n^{-1}(\alpha_j)=0, \tag{26a}$$

$$W_n(\beta_k)\tilde{u}_{nk}\tilde{v}_{nk}=0. \tag{26b}$$

We seek a nontrivial solution of these equations.

Let $u_{nj}^{(l)}$ and $\tilde{u}_{nj}^{(l)}$ ($v_{nj}^{(l)}$ and $\tilde{v}_{nj}^{(l)}$) be the lth components ($l=1,2$) of u_{nj} and $\tilde{u}_{nj}$ (v_{nj} and $\tilde{v}_{nj}$), respectively. $u_n^{(l)}$ and $\tilde{u}_n^{(l)}$ ($v_n^{(l)}$ and $\tilde{v}_n^{(l)}$) denote row (column) vectors whose jth components ($j=1,\ldots,2N$) are $u_{nj}^{(l)}$ and $\tilde{u}_{nj}^{(l)}$ ($v_{nj}^{(l)}$ and $\tilde{v}_{nj}^{(l)}$), respectively. With this notation, the foregoing equations can be rewritten

$$d_{n0}\tilde{u}_n^{(l)}+u_n^{(l)}X_n^{(l)}=0, \tag{27a}$$

$$\tilde{d}_{n0}v_n^{(l)}-X_n^{(l)}\tilde{v}_n^{(l)}=0, \tag{27b}$$

where $X_n^{(l)}(l=1,2)$ are $2N\times 2N$ matrices with the (j,k) elements

$$\{X_n^{(1)}\}_{j,k}=\frac{v_{nj}^{(1)}\tilde{u}_{nk}^{(1)}}{\tan(\beta_k-\alpha_j)}+\frac{v_{nj}^{(2)}\tilde{u}_{nk}^{(2)}}{\sin(\beta_k-\alpha_j)}, \tag{28a}$$

$$\{X_n^{(2)}\}_{j,k}=\frac{v_{nj}^{(1)}\tilde{u}_{nk}^{(1)}}{\sin(\beta_k-\alpha_j)}+\frac{v_{nj}^{(2)}\tilde{u}_{nk}^{(2)}}{\tan(\beta_k-\alpha_j)}. \tag{28b}$$

Here and later, we assume that $X_n^{(l)}$ are nonsingular matrices, so that $u_n^{(l)}$ and $\tilde{v}_n^{(l)}$ are uniquely determined by α_j's, β_j's, $v_{nj}^{(l)}$'s, and $\tilde{u}_{nj}^{(l)}$'s.

By Cramer's rule, we obtain the following expressions for the entries of $W_n(\lambda)$ and $W_n^{-1}(\lambda)$:

$$W_n(\lambda)=d_{n0}\begin{pmatrix}\dfrac{1}{|X_n^{(1)}|} & \\ & \dfrac{1}{|X_n^{(2)}|}\end{pmatrix}\begin{pmatrix}\begin{vmatrix}1 & \tilde{u}_n^{(1)}\\ T_n^{(1)}(\lambda) & X_n^{(1)}\end{vmatrix} & \begin{vmatrix}0 & \tilde{u}_n^{(1)}\\ S_n^{(2)}(\lambda) & X_n^{(1)}\end{vmatrix}\\ \begin{vmatrix}0 & \tilde{u}_n^{(2)}\\ S_n^{(1)}(\lambda) & X_n^{(2)}\end{vmatrix} & \begin{vmatrix}1 & \tilde{u}_n^{(2)}\\ T_n^{(2)}(\lambda) & X_n^{(2)}\end{vmatrix}\end{pmatrix}, \tag{29}$$

$$W_n^{-1}(\lambda)=-\tilde{d}_{n0}\begin{pmatrix}\begin{vmatrix}-1 & \tilde{T}_n^{(1)}(\lambda)\\ v_n^{(1)} & X_n^{(1)}\end{vmatrix} & \begin{vmatrix}0 & \tilde{S}_n^{(1)}(\lambda)\\ v_n^{(2)} & X_n^{(2)}\end{vmatrix}\\ \begin{vmatrix}0 & \tilde{S}_n^{(2)}(\lambda)\\ v_n^{(1)} & X_n^{(1)}\end{vmatrix} & \begin{vmatrix}-1 & \tilde{T}_n^{(2)}(\lambda)\\ v_n^{(2)} & X_n^{(2)}\end{vmatrix}\end{pmatrix}\begin{pmatrix}\dfrac{1}{|X_n^{(1)}|} & \\ & \dfrac{1}{|X_n^{(2)}|}\end{pmatrix}, \tag{30}$$

where $S_n^{(l)}$ and $T_n^{(l)}$ ($\tilde{S}_n^{(l)}$ and $\tilde{T}_n^{(l)}$) are column (row) $2N$-vectors with the jth components

$$\{S_n^{(l)}(\lambda)\}_j=\frac{v_{nj}^{(l)}}{\sin(\lambda-\alpha_j)},\quad \{T_n^{(l)}(\lambda)\}_j=\frac{v_{nj}^{(l)}}{\tan(\lambda-\alpha_j)}, \tag{31}$$

$$\{\tilde{S}_n^{(l)}(\lambda)\}_j=\frac{\tilde{u}_{nj}^{(l)}}{\sin(\lambda-\beta_j)},\quad \{\tilde{T}_n^{(l)}(\lambda)\}_j=\frac{\tilde{u}_{nj}^{(l)}}{\tan(\lambda-\beta_j)}. \tag{32}$$

The leading coefficients d_{n0} and $\tilde{d}_{n0}$ can be determined by the normalization condition (20). Since Eq. (20) implies that

$$\lim_{y\to+\infty}\det W_n(x\pm iy)=d_{n0}^2+\left(\sum_{j=1}^{2N}c_{nj}\right)^2=1,$$

combining this with the identity $W_n(\lambda)W_n^{-1}(\lambda)=\mathbf{1}$, we find that

$$d_{n0}=\pm\tilde{d}_{n0}=\frac{1}{\sqrt{1+(|{}_{v_n^{(l)}}{}^{0}_{X_n^{(l)}}{}^{\tilde{u}_n^{(l)}}|/|X_n^{(l)}|)^2}}, \tag{33}$$

where the denominator is invariant under the choice of the label $l=1,2$.

C. The last step

Let us now determine the (n,t) dependence of v_{nj} and $\tilde{u}_{nj}$.

Equations (11) and (12) yield the equations

$$W_{n+1}(\lambda)L^{(0)}(\lambda)W_n^{-1}(\lambda)=L_n(\lambda), \tag{34a}$$

$$\partial_t W_n(\lambda)W_n^{-1}(\lambda)+W_n(\lambda)M^{(0)}(\lambda)W_n^{-1}(\lambda)=M_n(\lambda) \tag{34b}$$

for $W_n(\lambda)$. Since the residues of the lhs at $\lambda=\alpha_j,\beta_k$ $(0\leqslant j,k\leqslant 2N)$ should vanish, one obtains the equations

$$u_{n+1j}v_{n+1j}L^{(0)}(\alpha_j)W_n^{-1}(\alpha_j)=0, \tag{35a}$$

$$W_{n+1}(\beta_k)L^{(0)}(\beta_k)\tilde{u}_{nk}\tilde{v}_{nk}=0, \tag{35b}$$

$$u_{nj}(\partial_t v_{nj}+v_{nj}M^{(0)}(\alpha_j))W_n^{-1}(\alpha_j)=0, \tag{35c}$$

$$W_n(\beta_k)(\partial_t\tilde{u}_{nk}-M^{(0)}(\beta_k)\tilde{u}_{nk})\tilde{v}_{nk}=0. \tag{35d}$$

A solution of Eqs. (35) is given by

$$v_{nj}(t)=v_{0j}L^{(0)}(-\alpha_j)^n\exp(-\mu(\alpha_j)\sigma_3 t), \tag{36a}$$

$$\tilde{u}_{nk}(t)=L^{(0)}(\beta_k)^n\exp(\mu(\beta_k)\sigma_3 t)\tilde{u}_{0k}, \tag{36b}$$

where v_{0j} and $\tilde{u}_{0k}$ $(j,k=1,\ldots,2N)$ are constant vectors and $\mu(\lambda)$ is the coefficient of σ_3 on the rhs of Eq. (16),

$$\mu(\lambda)=2i\sqrt{\frac{\kappa_1+J_3\kappa_0}{\kappa_0}}\frac{1}{1+(1/\rho^2)[(\kappa_1+J_1\kappa_0)/\kappa_0]\sin^2\lambda}. \tag{37}$$

Equation (19b) implies that

$$\sigma_2(u_{nj}v_{nj})^*\sigma_2=u_{nN+j}v_{nN+j},$$

$$\sigma_2(\tilde{u}_{nj}\tilde{v}_{nj})^*\sigma_2=\tilde{u}_{nN+j}\tilde{v}_{nN+j}.$$

These equations are satisfied if we choose the constant vectors v_{0j} and $\tilde{u}_{0j}$ $(j=N+1,\ldots,2N)$ as

$$v_{0N+j}=v_{0j}^*\sigma_2, \quad \tilde{u}_{0N+j}=\sigma_2\tilde{u}_{0j}^*.$$

We can thus determine the dressing matrix $W_n(\lambda)$ and its inverse matrix $W_n^{-1}(\lambda)$.

D. Spin variables

Evaluating the residues of both sides of Eq. (34a) at $\lambda=0$ gives

$$\sum_{l=1}^{3}S_{ln}\sigma_l=\sqrt{\kappa_0}W_{n+1}(0)\sigma_3W_n^{-1}(0), \tag{38}$$

which determines the spin variables (S_{1n},S_{2n},S_{3n}).

The auxiliary variable S_{0n} can be read off from the boundary values at $\lambda=\pm\infty$:

$$S_{0n}\mathbf{1}\pm S_{3n}\sigma_3=\frac{1}{\rho}W_{n+1}(\pm i\infty)L^{(0)}(\pm i\infty)W_n^{-1}(\pm i\infty).$$

E. Remarks

(1) We summarize the differences between the XXZ case and the isotropic case. The first difference is the number of the linear algebraic equations. We have encountered two different sets of linear algebraic equations—one for $X_n^{(1)}$ and the other for $X_n^{(2)}$. This is a new feature of the present setting. In the isotropic case, we have a single set of linear algebraic equations; this is consistent with the fact that both $X_n^{(1)}$ and $X_n^{(2)}$ tend to a matrix in the isotropic limit of the XXZ case. The second is the restriction of the positions of the poles, Eq. (24). In fact, this restriction is inherited from the corresponding property on zeros and poles of elliptic functions. In the isotropic limit, there is no such restriction because the spectral curve becomes rational.

(2) Equation (38) gives a $2N$-soliton solution in general. This solution is a nonlinear superposition of one-soliton solutions. In fact, one can find the one-soliton solutions associated with α_{j_0}

by setting $\tilde{u}^{(1)}_{nj_0}\tilde{u}^{(2)}_{nj_0}\neq 0$ and $\tilde{u}^{(1)}_{nk}\tilde{u}^{(2)}_{nk}=0$ $(k=1,\ldots,j_0-1,j_0+1,\ldots,N)$; one should set $v^{(1)}_{nj_0}v^{(2)}_{nj_0}\neq 0$ and $v^{(1)}_{nk}v^{(2)}_{nk}=0$ $(k=1,\ldots,j_0-1,j_0+1,\ldots,N)$ to obtain one-soliton solutions associated with β_{j_0}. In general, setting $\tilde{u}^{(1)}_{nj_0}\tilde{u}^{(2)}_{nj_0}=0$ annihilates the soliton associated with α_{j_0}, and setting $v^{(1)}_{nj_0}v^{(2)}_{nj_0}=0$ annihilates the soliton associated with β_{j_0}. Thus, one can obtain an M-soliton solution by setting an appropriate initial condition if $M\leqslant 2N$.

(3) It is easy to find an asymptotic form of the $2N$-soliton solution for N. Two one-soliton solutions associated with γ are obtained depending on either component $(l=1,2)$ of row (column) vector v_{nj_0} $(\tilde{u}_{nj_0})$ is set to be zero. The one for which the first component is set to be zero takes part in the asymptotic form as $t\to\pm\infty$ if $v_g(\gamma)\mathrm{Im}\,\gamma\gtrless 0$. The asymptotic form of the M-soliton solution as $|t|\to\infty$ is indeed a superposition of those one-soliton solutions associated with $\alpha_1,\ldots,\alpha_{2N}$ and $\beta_1,\ldots,\beta_{2N}$.

(4) Equation (19b) could be replaced by

$$W_n(\lambda)^{\dagger}=(W_n(\lambda^*))^{-1}. \tag{39}$$

For this construction to work, however, N has to be greater than one, and the distribution of poles of $W_n(\lambda)$ and $W_n^{-1}(\lambda)$ is required to obey the restrictions

$$\beta_j=\alpha_j^*, \quad \sum_{j=1}^{N}\alpha_j=\sum_{j=1}^{N}\beta_j. \tag{40}$$

IV. EASY-PLANE PARTIALLY ISOTROPIC CASE

In this section, we discuss the easy-plane partially isotropic case, i.e., $k_0=1$ $(J_1<J_2=J_3)$. We use the same notation as in Sec. III.

A. The first step

The L-matrix

$$L_n(\lambda)=S_{0n}\mathbf{1}+i\frac{\rho}{\sinh\lambda}(\cosh\lambda S_{1n}\sigma_1+S_{2n}\sigma_2+S_{3n}\sigma_3) \tag{41}$$

has the following symmetries:

$$\sigma_1 L_n(\lambda)\sigma_1=L_n(\lambda+i\pi), \tag{42a}$$

$$\sigma_2 L_n(\lambda)\sigma_2=(L_n(\lambda^*))^*, \tag{42b}$$

$$\lim_{x\to+\infty}\sigma_3 L_n(x+iy)\sigma_3=\lim_{x\to-\infty}L_n(x+iy). \tag{42c}$$

Under conditions similar to that in Sec. III A, the form of the dressing matrix $W_n(\lambda)$ is determined by the same discussion as in Appendix A:

$$W_n(\lambda)=d_{n0}\mathbf{1}+\sum_{j=1}^{2N}\left(\frac{d_{nj}\mathbf{1}+ia_{nj}\sigma_1}{\tanh(\lambda-\alpha_j)}+\frac{ib_{nj}\sigma_2+ic_{nj}\sigma_3}{\sinh(\lambda-\alpha_j)}\right), \tag{43}$$

$$W_n^{-1}(\lambda)=\tilde{d}_{n0}\mathbf{1}+\sum_{j=1}^{2N}\left(\frac{\tilde{d}_{nj}\mathbf{1}+i\tilde{a}_{nj}\sigma_1}{\tanh(\lambda-\beta_j)}+\frac{i\tilde{b}_{nj}\sigma_2+i\tilde{c}_{nj}\sigma_3}{\sinh(\lambda-\beta_j)}\right). \tag{44}$$

The restriction for the distribution of the poles and zeros is

$$\sum_{j=1}^{2N} \alpha_j = \sum_{j=1}^{2N} \beta_j \pmod{2\pi i}, \tag{45}$$

where $\alpha_{N+j}=\alpha_j^*$, and $\beta_{N+j}=\beta_j^*$ $(j=1,\ldots,N)$. In the following subsections, we construct a one-soliton solution by the same way as in Sec. III.

B. The second step

Because the residue of $W_n(\lambda)$ at $\lambda=\alpha_j$ is written by a column two-vector u_{nj} and a row two-vector v_{nj} as

$$\begin{pmatrix} d_{nj}+ic_{nj} & ia_{nj}+b_{nj} \\ ia_{nj}-b_{nj} & d_{nj}-ic_{nj} \end{pmatrix} = \begin{pmatrix} u_{nj}^{(1)}v_{nj}^{(1)} & u_{nj}^{(1)}v_{nj}^{(2)} \\ u_{nj}^{(2)}v_{nj}^{(1)} & u_{nj}^{(2)}v_{nj}^{(2)} \end{pmatrix},$$

the variables a_{nj}, b_{nj}, c_{nj}, and d_{nj} can be written in terms of the components of u_{nj} and v_{nj}:

$$d_{nj}=\tfrac{1}{2}(u_{nj}^{(1)}v_{nj}^{(1)}+u_{nj}^{(2)}v_{nj}^{(2)}), \tag{46a}$$

$$ia_{nj}=\tfrac{1}{2}(u_{nj}^{(1)}v_{nj}^{(2)}+u_{nj}^{(2)}v_{nj}^{(1)}), \tag{46b}$$

$$b_{nj}=\tfrac{1}{2}(u_{nj}^{(1)}v_{nj}^{(2)}-u_{nj}^{(2)}v_{nj}^{(1)}), \tag{46c}$$

$$ic_{nj}=\tfrac{1}{2}(u_{nj}^{(1)}v_{nj}^{(1)}-u_{nj}^{(2)}v_{nj}^{(2)}). \tag{46d}$$

The variables $\tilde{a}_{nj}$, $\tilde{b}_{nj}$, $\tilde{c}_{nj}$, and $\tilde{d}_{nj}$ have relations with $\tilde{u}_{nj}$ and $\tilde{v}_{nj}$ similar to Eqs. (46).

Since the residues of $W_n(\lambda)W_n^{-1}(\lambda)$ at $\alpha_1,\ldots,\alpha_{2N}$ and $\beta_1,\ldots,\beta_{2N}$ vanish, we have two algebraic relations:

$$v_{nj}W_n^{-1}(\alpha_j)=0,$$

$$W_n(\beta_k)\tilde{u}_{nk}=0.$$

These equations are rewritten as follows:

$$\tilde{d}_{n0}v_n^{(\pm)}-X_n^{(\pm)}\tilde{v}_n^{(\pm)}=0, \tag{47a}$$

$$d_{n0}\tilde{u}_n^{(\pm)}+u_n^{(\pm)}X_n^{(\pm)}=0, \tag{47b}$$

where $X_n^{(\pm)}$ are the $2N\times 2N$ matrices with the (j,k) elements

$$\{X_n^{(+)}\}_{jk}=\frac{v_{nj}^{(+)}\tilde{u}_{nk}^{(+)}}{\tanh(\beta_k-\alpha_j)}+\frac{v_{nj}^{(-)}\tilde{u}_{nk}^{(-)}}{\sinh(\beta_k-\alpha_j)}, \tag{48a}$$

$$\{X_n^{(-)}\}_{jk}=\frac{v_{nj}^{(+)}\tilde{u}_{nk}^{(+)}}{\sinh(\beta_k-\alpha_j)}+\frac{v_{nj}^{(-)}\tilde{u}_{nk}^{(-)}}{\tanh(\beta_k-\alpha_j)}. \tag{48b}$$

Here, we introduced $v_{nj}^{(\pm)}$ and $\tilde{u}_{nk}^{(\pm)}$ as

$$v_{nj}^{(\pm)}=\frac{1}{\sqrt{2}}(v_{nj}^{(1)}\pm v_{nj}^{(2)}), \quad \tilde{u}_{nj}^{(\pm)}=\frac{1}{\sqrt{2}}(\tilde{u}_{nj}^{(1)}\pm\tilde{u}_{nj}^{(2)}).$$

Note that Eqs. (47) have the same form as that of Eqs. (27).

One can solve the linear algebraic equations (47) by Cramer's rule. Therefore, the elements of $W_n(\lambda)$ are expressed in terms of $v_{nj}^{(\pm)}$, $\tilde{u}_{nj}^{(\pm)}$, α_j, and β_j $(j=1,\ldots,2N)$. The result is shown in Appendix C.

C. The last step

We now consider the (n,t) dependence of the vectors $v_{nj}^{(\pm)}$ and $\tilde{u}_{nj}^{(\pm)}$. The L- and M-matrices for the vacuum solution

$$\vec{S}_n=(0,0,\sqrt{\kappa_0})^{\mathrm{T}}$$

are

$$L^{(0)}(\lambda)=\sqrt{\kappa_1+J_3\kappa_0}\mathbf{1}+\frac{i\sqrt{\kappa_0}\rho}{\sinh\lambda}\sigma_3, \tag{49}$$

$$M^{(0)}(\lambda)=2i\sqrt{\frac{\kappa_1+J_3\kappa_0}{\kappa_0}}\frac{\cosh\lambda}{1+(1/\rho^2)[(\kappa_1+J_3\kappa_0)/\kappa_0]\sinh^2\lambda}\sigma_3. \tag{50}$$

The (n,t) dependence of the vectors $v_{nj}^{(\pm)}$ and $\tilde{u}_{nj}^{(\pm)}$ is determined by the linear system (35). A solution of the system is given by

$$v_{nj}=v_{0j}L^{(0)}(-\alpha_j)^n\exp(-\mu(\alpha_j)t\sigma_3), \tag{51}$$

$$\tilde{u}_{nk}=L^{(0)}(\beta_k)^n\exp(\mu(\beta_k)t\sigma_3)\tilde{u}_{0k}, \tag{52}$$

where $\mu(\lambda)$ is the coefficient of σ_3 on the rhs of Eq. (50). If we assume that $v_{0j}^{(1)}v_{0j}^{(2)}\neq 0$ and $\tilde{u}_{0j}^{(1)}\tilde{u}_{0j}^{(2)}\neq 0$, it follows from Eqs. (51) and (52) that

$$\frac{v_{nj}^{(+)}(t)}{v_{nj}^{(-)}(t)}=-\coth\left(\frac{1}{2}\xi(\alpha_j)n+\mu(\alpha_j)t+\delta_j\right), \tag{53}$$

$$\frac{\tilde{u}_{nj}^{(+)}(t)}{u_{nj}^{(-)}(t)}=-\coth\left(\frac{1}{2}\xi(\beta_j)n+\mu(\beta_j)t+\tilde{\delta}_j\right). \tag{54}$$

Here,

$$\delta_j=\frac{1}{2}\log\frac{v_{0j}^{(2)}}{v_{0j}^{(1)}},\quad \tilde{\delta}_j=\frac{1}{2}\log\frac{\tilde{u}_{0j}^{(1)}}{\tilde{u}_{0j}^{(2)}},$$

$$e^{\xi(\gamma)}=\frac{\sqrt{\kappa_1+\kappa_0J_3}+i\rho\sqrt{\kappa_0}/\sinh\gamma}{\sqrt{\kappa_1+\kappa_0J_3}-i\rho\sqrt{\kappa_0}/\sinh\gamma}.$$

One can see that the (n,t) dependence of $W_n(\lambda)$ is determined only by the ratios $v_{nj}^{(+)}/v_{nj}^{(-)}$ and $\tilde{u}_{nj}^{(+)}/\tilde{u}_{nj}^{(-)}$. Therefore, the multisoliton solution depends on n and t via the hyperbolic function $\coth(\frac{1}{2}\xi(\gamma)n+\mu(\gamma)l)$. Thus, the spin components do not oscillate in this case, as opposed to the easy-axis case where S_1 and S_2 oscillate. In other words, the soliton on the easy-plane spins has no carrier wave: The profiles of all spin components travel at the same velocity without changing their shape. On the other hand, the soliton on the easy-axis spins has a carrier wave and an envelope wave.

V. CONCLUSION

We constructed multisoliton solutions of the XXZ-LLL equation by a variant of the dressing method. Our method may be called a ''trigonometric dressing method,'' because the dressing matrix is a matrix valued trigonometric function of the spectral parameter λ. Remarkably, the dressing matrix has almost the same structure as the L-matrix. This is a natural consequence of the construction: The analytic properties of the L-matrix on the λ plane imply similar properties of the dressing matrix, which in turn determine the functional form of the dressing matrix uniquely. One can thus express the dressing matrix as a linear combination of trigonometric functions. The coefficients are then determined, just as in the ordinary dressing method, by a set of linear algebraic equations. We have, however, observed that these linear algebraic equations are slightly different from those of the ordinary dressing method based on a rational dressing matrix.

Let us also mention the issue of space–time discretization of the LL equation. A space–time discretized LL equation is proposed by Date *et al.*[14] They use the theory of τ-functions and free fermions. Nijhoff and Papageorgiou[15] presented another space–time discretization of the LL equation in the Lax formalism (along with a space–time discretized anisotropic principal chiral field model[16]). Since the latter two models have the same L-matrix as the lattice LL equation, our trigonometric dressing method and its ''elliptic'' version can be applied to these models as well. We discuss this issue in Ref. 17.

APPENDIX A: THE FORM OF $W_n(\lambda)$

Let us express $W_n(\lambda)$ as a linear combination of the unit matrix $\mathbf{1}$ and the Pauli matrices σ_l $(l=1,2,3)$:

$$W_n(\lambda)=d_n(\lambda)\mathbf{1}+ia_n(\lambda)\sigma_1+ib_n(\lambda)\sigma_2+ic_n(\lambda)\sigma_3.$$

We first determine the functional form of $a_n(\lambda)$. Equation (19a) implies that $a_n(\lambda)$ is an antiperiodic function with period π. Because of the condition C-I in Sec. III A, $a_n(\lambda)$ has poles at $\lambda=\alpha_j+m\pi i$ $(m\in\mathbf{Z},\ \ j=1,\ldots,2N)$. Thus, $a_n(\lambda)$ acquires the form

$$a_n(\lambda)=\sum_{j=1}^{2N}\frac{a_{nj}}{\sin(\lambda-\alpha_j)}+f(\lambda),$$

where the a_{nj}'s are λ-independent numbers, and $f(\lambda)$ is an entire function of λ. We show that $f(\lambda)=0$. Because $f(\lambda)$ is an entire periodic function of λ, it is bounded on the simply connected domain $|\mathrm{Im}\,\lambda|\leqslant y_0$. On the other hand, owing to the condition C-II, f is uniformly bounded outside this domain. Thus, $f(\lambda)$ is a bounded entire function of λ, i.e., $f(\lambda)$ is a constant. Owing to the antiperiodicity, the constant equals zero. After all,

$$a_n(\lambda)=\sum_{j=1}^{2N}\frac{a_{nj}}{\sin(\lambda-\alpha_j)}.$$

The form of $d_n(\lambda)$ is determined in the same manner. Equation (19a) implies that $d_n(\lambda)$ is a periodic function with period π. Owing to the condition C-I, $d_n(\lambda)$ has poles at $\lambda=\alpha_j+m\pi i$ $(m\in\mathbf{Z},\ \ j=1,\ldots,2N)$. Thus, with an entire function of λ, one can write $d_n(\lambda)$ as follows:

$$d_n(\lambda)=\sum_{j=1}^{2N}\frac{d_{nj}}{\tan(\lambda-\alpha_j)}+(\text{entire function of }\lambda).$$

Because of the condition C-II, the entire function at the second term is bounded in the limit $\lambda \to \pm\infty$. Therefore the entire function equals a constant. Let d_{n0} be this constant. Then, we have obtained Eq. (21). The other two functions, $b_n(\lambda)$, $c_n(\lambda)$ can be determined also in the same way.

Because of Eq. (19c), the relation

$$d_{n0} - i\sum_{j=1}^{2N} d_{nj} = d_{n0} + i\sum_{j=1}^{2N} d_{jn}$$

holds, therefore we obtain Eq. (22).

APPENDIX B: DETERMINANT OF $W_n(\lambda)$

Since it follows from Eqs. (1), (2), (9), and (13) that

$$\det L_n(\lambda) = \det L^{(0)}(\lambda) = \kappa_1 + J_3\kappa_0 + \frac{\rho^2\kappa_0}{\tan^2\lambda}, \tag{B1}$$

$$\mathrm{tr}M_n(\lambda) = \mathrm{tr}M^{(0)}(\lambda) = 0, \tag{B2}$$

$\det W_n(\lambda)$ is a function of only λ.

Now, we calculate $\det W_n(\lambda)$ under the conditions in Sec. III A. Equation (19a) implies that $\det W_n(\lambda)$ is a periodic function with period π. Owing to the condition C-I, $\det W_n(\lambda)$ has simple poles at $\lambda = \alpha_j + m\pi i$ $(m \in \mathbf{Z},\ j = 1,\ldots,2N)$. With nonzero constants A_j $(j = 1,\ldots,2N)$, $\det W_n(\lambda)$ is written as

$$\det W_n(\lambda) = \sum_{j=1}^{2N} \frac{A_j}{\sin(\lambda - \alpha_j)} + (\text{entire function of } \lambda). \tag{B3}$$

Reduce Eq. (B3) to a common denominator and let β_j $(j = 1,\ldots,m)$ be the zeros on D of the numerator. Then

$$\det W_n(\lambda) = f(\lambda)\frac{\Pi_{j=1}^{m}\sin(\lambda - \beta_j)}{\Pi_{j=1}^{2N}\sin(\lambda - \alpha_j)},$$

where $f(\lambda)$ is an entire periodic function of λ without zeros. Then, $\beta_k \neq \alpha_j$ follows from the condition C-III. The integer m equals $2N$ because $\det W_n(iy)$ tends to a nonzero finite number in the limit $y \to +\infty$. As a consequence of Eq. (20), $f(\lambda)$ is identically equal to one, and the restriction Eq. (24) must be satisfied. At last, Eq. (23) is obtained. In the limit $\mathrm{Im}\,\lambda \to \pm\infty$, $\det W_n(\lambda)$ tends to one independently of $\mathrm{Re}\,\lambda$.

If Eq. (21) satisfies the conditions in Sec. III A and Eq. (24), then in the limit $\lambda \to \pm i\infty$,

$$W_n(\lambda) \to \left(d_{n0} \mp \sum_j d_{nj}\right)\mathbf{1} \pm \sum_j c_{nj}\sigma_3. \tag{B4}$$

Equations (B4), (19c), and (20) imply that

$$\left(d_{n0} \mp \sum_j d_{nj}\right)^2 - \left(\sum_j c_{nj}\right)^2 = 1,$$

which leads Eq. (22). With this result, one can conclude that soliton solutions can be constructed from the free parameters α_j's and β_j's if they satisfy Eq. (24).

APPENDIX C: THE ELEMENTS OF $W_n(\lambda)$ FOR THE EASY-PLANE CASE

Let $S_n^{(\pm)}$ and $T_n^{(\pm)}$ ($\tilde{S}_n^{(\pm)}$ and $\tilde{T}_n^{(\pm)}$) be column (row) $2N$-vectors with the jth component

$$\{S_n^{(\pm)}(\lambda)\}_j=\frac{v_{nj}^{(+)}}{\sinh(\lambda-\alpha_j)}\pm\frac{v_{nj}^{(-)}}{\tanh(\lambda-\alpha_j)}, \tag{C1}$$

$$\{T_n^{(\pm)}(\lambda)\}_j=\frac{v_{nj}^{(+)}}{\tanh(\lambda-\alpha_j)}\pm\frac{v_{nj}^{(-)}}{\sinh(\lambda-\alpha_j)}, \tag{C2}$$

$$\{\tilde{S}_n^{(\pm)}(\lambda)\}_j=\frac{\tilde{u}_{nj}^{(+)}}{\sinh(\lambda-\beta_j)}\pm\frac{\tilde{u}_{nj}^{(-)}}{\tanh(\lambda-\beta_j)}, \tag{C3}$$

$$\{\tilde{T}_n^{(\pm)}(\lambda)\}_j=\frac{\tilde{u}_{nj}^{(+)}}{\tanh(\lambda-\beta_j)}\pm\frac{\tilde{u}_{nj}^{(-)}}{\sinh(\lambda-\beta_j)}. \tag{C4}$$

(1) Matrix elements of $W_n(\lambda)$:

$$\{W_n(\lambda)\}_{11}=\frac{d_{n0}}{2|X_n^{(+)}|}\begin{vmatrix}1 & \tilde{u}_n^{(+)}\\ T_n^{(+)}(\lambda) & X_n^{(+)}\end{vmatrix}+\frac{d_{n0}}{2|X_n^{(-)}|}\begin{vmatrix}1 & \tilde{u}_n^{(-)}\\ S_n^{(+)}(\lambda) & X_n^{(-)}\end{vmatrix}, \tag{C5a}$$

$$\{W_n(\lambda)\}_{12}=\frac{d_{n0}}{2|X_n^{(+)}|}\begin{vmatrix}0 & \tilde{u}_n^{(+)}\\ T_n^{(-)}(\lambda) & X_n^{(+)}\end{vmatrix}+\frac{d_{n0}}{2|X_n^{(-)}|}\begin{vmatrix}0 & \tilde{u}_n^{(-)}\\ S_n^{(-)}(\lambda) & X_n^{(-)}\end{vmatrix}, \tag{C5b}$$

$$\{W_n(\lambda)\}_{21}=\frac{d_{n0}}{2|X_n^{(+)}|}\begin{vmatrix}0 & \tilde{u}_n^{(+)}\\ T_n^{(+)}(\lambda) & X_n^{(+)}\end{vmatrix}-\frac{d_{n0}}{2|X_n^{(-)}|}\begin{vmatrix}0 & \tilde{u}_n^{(-)}\\ S_n^{(+)}(\lambda) & X_n^{(-)}\end{vmatrix}, \tag{C5c}$$

$$\{W_n(\lambda)\}_{22}=\frac{d_{n0}}{2|X_n^{(+)}|}\begin{vmatrix}1 & \tilde{u}_n^{(+)}\\ T_n^{(-)}(\lambda) & X_n^{(+)}\end{vmatrix}-\frac{d_{n0}}{2|X_n^{(-)}|}\begin{vmatrix}-1 & \tilde{u}_n^{(-)}\\ S_n^{(-)}(\lambda) & X_n^{(-)}\end{vmatrix}. \tag{C5d}$$

(2) Matrix elements of $W_n^{-1}(\lambda)$:

$$\{W_n^{-1}(\lambda)\}_{11}=\frac{-\tilde{d}_{n0}}{2|X_n^{(+)}|}\begin{vmatrix}-1 & \tilde{T}_n^{(+)}(\lambda)\\ v_n^{(+)} & X_n^{(+)}\end{vmatrix}-\frac{\tilde{d}_{n0}}{2|X_n^{(-)}|}\begin{vmatrix}-1 & \tilde{S}_n^{(+)}(\lambda)\\ v_n^{(-)} & X_n^{(-)}\end{vmatrix}, \tag{C6a}$$

$$\{W_n^{-1}(\lambda)\}_{12}=\frac{-\tilde{d}_{n0}}{2|X_n^{(+)}|}\begin{vmatrix}0 & \tilde{T}_n^{(+)}(\lambda)\\ v_n^{(+)} & X_n^{(+)}\end{vmatrix}+\frac{\tilde{d}_{n0}}{2|X_n^{(-)}|}\begin{vmatrix}0 & \tilde{S}_n^{(+)}(\lambda)\\ v_n^{(-)} & X_n^{(-)}\end{vmatrix}, \tag{C6b}$$

$$\{W_n^{-1}(\lambda)\}_{21}=\frac{-\tilde{d}_{n0}}{2|X_n^{(+)}|}\begin{vmatrix}0 & \tilde{T}_n^{(-)}(\lambda)\\ v_n^{(+)} & X_n^{(+)}\end{vmatrix}-\frac{\tilde{d}_{n0}}{2|X_n^{(-)}|}\begin{vmatrix}0 & \tilde{S}_n^{(-)}(\lambda)\\ v_n^{(-)} & X_n^{(-)}\end{vmatrix}, \tag{C6c}$$

$$\{W_n^{-1}(\lambda)\}_{22}=\frac{-\tilde{d}_{n0}}{2|X_n^{(+)}|}\begin{vmatrix}-1 & \tilde{T}_n^{(-)}(\lambda)\\ v_n^{(+)} & X_n^{(+)}\end{vmatrix}+\frac{\tilde{d}_{n0}}{2|X_n^{(-)}|}\begin{vmatrix}1 & \tilde{S}_n^{(-)}(\lambda)\\ v_n^{(-)} & X_n^{(-)}\end{vmatrix}. \tag{C6d}$$

Families of particular solutions to multidimensional partial differential equations

A. I. Zenchuk[a)]
Department of Mathematics, The University of Arizona, Tucson, Arizona 85721

(Received 22 September 2000; accepted for publication 11 July 2001)

Dressing methods are known as productive tools for construction of the particular solutions to the big class of nonlinear partial differential equations (PDEs) which are integrable by the inverse scattering technique. Recently the modification of the dressing method based on the system of algebraic equations has been suggested which allows us to find the families of particular solutions to certain types of nonintegrable (in classical sense) nonlinear PDEs. This modification represents PDEs as closure reductions of an appropriate differential-difference system. In this article we study the dressing procedure in more detail. Particularly, we consider different families of particular solutions available through the dressing method based on the algebraic system. We give two examples of the differential-difference systems and related PDEs and point to other possible generalizations of the dressing method. © *2001 American Institute of Physics.* [DOI: 10.1063/1.1398337]

I. INTRODUCTION

Dressing method has been developed as a special technique for solving the nonlinear integrable partial differential equations (PDEs).[1–4] Many modifications of the dressing method have been found.[5–8] An important field of application of the dressing methods is the investigation of the $(n+1)$-dimensional $(n>2)$ integrable systems.[8–12]

Recently[13] the algebraic system of $N^{(c)}$ equations

$$L(\psi_m)\equiv\psi_m-\sum_{i=1}^{N^{(c)}}\psi_i\sum_{n=1}^{N^{(r)}}c_{in}R_{nm}=\eta_m,\quad m=1,...,N^{(c)}\ \text{or}$$
$$L(\psi)\equiv\psi-\psi\mathbf{CR}=\eta,\quad \psi=[\psi_1\cdots\psi_{N^{(c)}}],\quad \eta=[\eta_1\cdots\eta_{N^{(c)}}] \tag{1}$$

had been suggested as an auxiliary equation for construction of the particular solutions to the PDE of a certain types. In Eq. (1) we use constant $N^{(c)}\times N^{(r)}$ ($N^{(c)}\neq N^{(r)}$ in general) matrix $\mathbf{C}=\{c_{in}\}$ to provide the possibility to use rectangular (not only square) $N^{(r)}\times N^{(c)}$ matrix $\mathbf{R}=\{R_{nm}\}$. Although the algebraic system can be taken as a starting point for the following discussion, it is important to emphasize its relation with the classical dressing method. For simplicity we refer to the $\overline{\partial}$-problem,[5,6] since the above system of algebraic equations can be considered as the discrete version of this problem. In fact, the $\overline{\partial}$-problem represents the relation between solutions of the nonlinear PDE and solutions of the following linear integral equation:[14]

$$\psi(\lambda)-\int\psi(\nu)c(\nu,\mu)R(\mu,\lambda)d\mu\wedge d\overline{\mu}d\nu\wedge d\overline{\nu}=\eta(\lambda), \tag{2}$$

where R is a kernel of the integral operator and η is a normalization function. Parameters ν, μ, λ are complex. The additional parameters $\mathbf{x}=(x_1,\ldots,x_M)$ are introduced in the kernel R by the formulas

a)Electronic mail: azenchuk@math.arizona.edu

$$\partial_i R(\mu,\lambda)=\sum_{k=1}^{N_i} f_k^{(i)}(\mu)g_k^{(i)}(\lambda), \quad i=1,...,M, \tag{3}$$

which are compatible provided

$$\partial_i \sum_{k=1}^{N_j} f_k^{(j)}(\mu)g_k^{(j)}(\lambda)=\partial_j \sum_{k=1}^{N_i} f_k^{(i)}(\mu)g_k^{(i)}(\lambda), \quad i,j=1,...,M. \tag{4}$$

The link to the particular system of nonlinear PDEs is produced by the special structure of the functions $f_k^{(j)}(\mu)$ and $g_k^{(j)}(\lambda)$. Parameters $\mathbf{x}$ are independent variables of this system.[5,6] Since the conditions (4) should be satisfied for all admitted values of the parameters μ and λ, there is no functional relations between functions $f_k^{(j)}(\mu)$ and $g_k^{(j)}(\lambda)$. This conclusion makes restrictions on the admitted form of the functions $f_k^{(j)}(\mu)$ and $g_k^{(j)}(\lambda)$. For this reason integral equation (2) is related only with completely integrable systems of nonlinear PDEs.

The situation becomes different if one considers the solution of Eq. (2) on the set of discrete points $\nu_i, \mu_n, \lambda_m\ (i,m=1,...,N^{(c)}, n=1,...,N^{(r)})$ on the complex planes of parameters ν, μ, λ and introduces matrices $\mathbf{C}$ and $\mathbf{R}$ with the entries

$$c_{in}\equiv c(\nu_i,\mu_n), \quad R_{nm}\equiv R(\mu_n,\lambda_m).$$

Then one gets the algebraic system (1) with the following discrete version of the equations (3) and (4)

$$\begin{gathered}\partial_i R_{nm}=\sum_{k=1}^{N_i} f_{nk}^{(i)}g_{km}^{(i)}, \quad n=1,...,N^{(r)}, \quad m=1,...,N^{(c)}, \quad i=1,...,M, \text{ or}\\ \partial_i \mathbf{R}=\sum_{k=1}^{N_i} \mathbf{f}^{(ik)}\mathbf{g}^{(ki)}, \quad \mathbf{f}^{(ik)}=[f_{1k}^{(i)}\cdots f_{N^{(r)}k}^{(i)}]^T, \quad \mathbf{g}^{(ki)}=[g_{k1}^{(i)}\cdots g_{kN^{(c)}}^{(i)}],\end{gathered} \tag{5}$$

$$\begin{gathered}\partial_i \sum_{k=1}^{N_j} f_{nk}^{(j)}g_{km}^{(j)}=\partial_j \sum_{k=1}^{N_i} f_{nk}^{(i)}g_{km}^{(i)}, \quad i,j=1,...,M, \text{ or}\\ \partial_i \sum_{k=1}^{N_j} \mathbf{f}^{(jk)}\mathbf{g}^{(kj)}=\partial_j \sum_{k=1}^{N_i} \mathbf{f}^{(ik)}\mathbf{g}^{(ki)}\end{gathered} \tag{6}$$

where

$$f_{nk}^{(j)}=f_k^{(j)}(\mu_n), \quad g_{km}^{(j)}=g_k^{(j)}(\lambda_m).$$

It turned out that the discrete version has a set of properties which makes it very adaptable in applications to different systems of nonlinear PDEs. The basic reason for this is the absence of complex continuous parameters in the equations (6), which become bilinear differential equations on the functions $f_{nk}^{(j)}$ and $g_{km}^{(j)}$ which are functions of parameters $\mathbf{x}$ only. In general the associated systems of nonlinear PDEs are not integrable, but integrable systems are situated among them.

One can recognize that the equations (1) and (2) can be combined into the following one:

$$\psi_m(\lambda)-\int d\mu\wedge d\bar{\mu}d\nu\wedge d\bar{\nu}\sum_{k=1}^{N^{(c)}} \psi_k(\nu)\sum_{n=1}^{N^{(r)}} c_{kn}(\nu,\mu)R_{nm}(\mu,\lambda;\mathbf{x})=\eta_m(\lambda), \quad m=1,...,N^{(c)}, \tag{7}$$

with

$$\partial_i R_{nm}(\mu,\lambda)=\sum_{k=1}^{N_i} f_{nk}^{(i)}(\mu)g_{km}^{(i)}(\lambda). \tag{8}$$

Equation (7) will not be discussed in this article.

For our purpose we require the following properties of the matrix $\mathbf{R}$:[13]

(1) The nonhomogeneous equation (1) has the unique solution, $\psi=[\psi_1\cdots\psi_{N^{(c)}}]$.
(2) The $\mathbf{x}$ dependence [$\mathbf{x}=(x_1,\ldots,x_M)$, M is dimension of $\mathbf{x}$-space] is introduced by the formulas (5).
(3) The equations (5) are compatible, i.e., the set of conditions (6) is held which is the system of PDEs imposed on the functions $f_{nk}^{(i)}$ and $g_{km}^{(i)}$.
(4) The set of self-consistent constraints is imposed on the functions $\mathbf{g}^{(ki)}$ in the form of the system of PDEs

$$\sum_{ik}\hat{L}_{ikm}^{(g)}\mathbf{g}^{(ki)}=0,\quad m=1,\ldots,P \tag{9}$$

(where $\hat{L}_{ikm}^{(g)}$ are scalar linear differential operators and $\mathbf{g}^{(ki)}$ is $1\times N^{(c)}$ row). These constraints should be consistent with the compatibility conditions (6). We will use operators $\hat{L}_{ikm}^{(g)}$ with constant coefficients for simplicity.

The consequence of the first requirement is the fact that homogeneous algebraic system with the same matrix $\mathbf{R}$ has only the trivial solution, i.e.,

$$L(\phi)=0\Leftrightarrow\phi\equiv 0. \tag{10}$$

Equations (1) and (5) produce the following system of algebraic equations (with the same matrix $\mathbf{R}$ and different right-hand sides) for the functions $\partial_j\psi$, $\partial_j^n\psi$ and $\Pi_{s=1}^M\partial_s^{n_s}\psi$:

$$L(\partial_j\psi)=\sum_{k=1}^{N_j} U_{\underbrace{0,\ldots,0}_{M}}^{(jk)}\mathbf{g}^{(jk)}+\partial_j\eta, \tag{11}$$

$$L(\partial_j^n\psi)=h_j,\quad h_j=\partial_j h_{j-1}+\sum_{k=1}^{N_j}\sum_{p=0}^{n}(-1)^p C_n^p\partial_j^{n-p}U_{\underbrace{0,\ldots,}_{j-1}\,p,\ldots,0}^{(jk)}\mathbf{g}^{(jk)}, \tag{12}$$

$$C_n^p=\frac{p!}{n!(n-p)!},$$

$$L\left(\prod_{s=1}^{M}\partial_s^{n_s}\psi\right)=h_{n_1\ldots n_M}, \tag{13}$$

$$h_{n_1\ldots n_M}=\partial_m h_{n_1\ldots(n_m-1)\ldots n_M}+\sum_{k=1}^{N_j}\left(\sum_{p_1=0}^{n_1}\cdots\sum_{p_m=0}^{n_m-1}\cdots\sum_{p_M=0}^{n_M}(-1)^{\Sigma_{i=1}^M p_i}\right.$$

$$\left.\times\left(\prod_{s=1,s\neq m}^{M}C_{n_s}^{p_s}\partial_s^{n_s-p_s}\right)C_{n_m-1}^{p_m}\partial_m^{n_m-p_m-1}U_{p_1,\ldots,p_M}^{(jk)}\mathbf{g}^{(jk)}\right),$$

where

$$U_{n_1\ldots n_M}^{(ik)}=\sum_{n=1}^{N^{(c)}}\psi_n\sum_{m=1}^{N^{(r)}}\left(\prod_{s=1}^{M}\partial_s^{n_s}\right)c_{nm}f_{mk}^{(i)}\equiv\psi\mathbf{C}\left(\prod_{s=1}^{M}\partial_s^{n_s}\right)\mathbf{f}^{(ik)},$$

$$i=1,\ldots,M,\quad k=1,\ldots,N_i. \tag{14}$$

Using these algebraic systems together with the original system (1) and applying the superposition principle for linear nonhomogeneous algebraic systems, one can provide $M^{(L)}$ differential operators $\hat{M}_j$ such that $L(\hat{M}_j\psi)=0$ or in accordance with Eq. (10)

$$\hat{M}_j\psi=0, \quad j=1,...,M^{(L)}, \quad M^{(L)}\geqslant 1. \tag{15}$$

One considers Eqs. (15) as the system of linear PDEs on the function ψ. In addition we require the independence of the operators $\hat{M}_k$, i.e., there is no nonzero set of differential operators $\hat{D}_j$, $j=1,...,M^{(L)}$, such that $\Sigma_{j=1}^{M^{(L)}}\hat{D}_j\hat{M}_j=0$.

The functions $U^{(ik)}_{n_1,...,n_M}$ defined by Eq. (14) are solutions of the appropriate system of differential-difference equations, which can be derived from the linear system (15) (where each equation is $1\times N^{(c)}$ row) by multiplying it by the $N^{(c)}\times 1$ vector

$$\mathbf{v}^{ik}_{n1...n_M}\equiv\mathbf{C}\left(\prod_{s=1}^{M}\partial_s^{n_s}\right)\mathbf{f}^{(ik)}. \tag{16}$$

Let $\mathbf{U}$ be the set of all matrices (14). Then the nonlinear system is the system of scalar equations of the general form

$$\hat{M}_j\psi\mathbf{v}^{ik}_{n1,...,n_M}\equiv\tilde{M}^{ikj}_{n_1,...,n_M}(\mathbf{U})=0, \quad j=1,...,M^{(L)}, \quad i=1,...,M, \quad k=1,...,N_i\,. \tag{17}$$

By construction the total number of discrete parameters equals the number of continuous parameters M in the system (17).

The system (17) represents the general system of differential-difference equations, which is related with the algebraic system (1). The system (17) is the system of pure PDEs if there are numbers $M^{(ikjs)}\geqslant 0$ $(s=1,...,M)$ such that the (sub)set of the equations (17) with subscripts

$$(n_1,\ldots,n_M)\leqslant(M^{(ikj1)},\ldots,M^{(ikjM)}), \quad j=1,...,M^{(L)}, \quad i=1,...,M, \quad k=1,...,N_i$$

(each entry on the left-hand side does not exceed the correspondent entry on the right-hand side) represents the complete system of PDEs.

Otherwise, the system of pure PDEs can be derived from the system (17) by imposing the reductions which introduce the relation among different discrete parameters n_j and reduce their number from M to $\tilde{M}<M$ in such a way that the (sub)system of the system (17) forms the complete system of pure nonlinear PDEs, i.e., the numbers $M^{(ikjs)}\geqslant 0$ $(s=1,...,\tilde{M})$ should exist such that the (sub)set of the equations (17) with subscripts

$$(n_1,\ldots,n_{\tilde{M}})\leqslant(M^{(ikj1)},\ldots,M^{(ikj\tilde{M})})$$

forms the complete system of pure PDEs. To clarify the general form of these reductions, note that each discrete parameter n_j is associated with the derivative $\partial_j\mathbf{f}^{(ik)}$. It means that one needs to impose the relations among the *derivatives* of the functions $\mathbf{f}^{(ik)}$. Then one gets the relations among the functions $U^{(ik)}_{n_1...n_M}$ with fixed superscripts (ik) and different subscripts $(n_1,\ldots,n_M)$ and, consequently, the relations among the discrete parameters. It means that the reductions of our interest have the general form

$$\sum_{in}\tilde{L}^{(f)}_{ikm}\mathbf{f}^{(ik)}=0, \quad m=1,...,P, \tag{18}$$

where $\hat{L}^{(f)}_{ikm}$ are the scalar linear differential operators (with constant coefficients for simplicity). Both systems (9) and (18) should be self-consistent and compatible with the system (6). It is

important to emphasize that the reductions which have the form of *algebraic* relations among different functions $\mathbf{f}^{(ik)}$ do not reduce the number of discrete parameters in the system.

The significant difference between integrable PDEs and ones considered in this article is that the integrable nonlinear systems have operator representation as the compatibility condition of the appropriate overdetermined linear system of equations with variable coefficients (zero curvature representation). The nonlinear PDEs under consideration are related with the systems of linear equations (15) as well, but correspondent operator representation for them has not been found yet.

In the next section (Sec. II) we develop the general approach for construction of the particular solutions for the systems of nonlinear PDEs, associated with the algebraic system (1). In Sec. III we consider the examples of the nonintegrable generalizations of the modified Kadomtsev–Petviashvili equation (mKP) with several families of particular solutions (some of them are given in Ref. 13). In Sec. IV we apply new dressing method to find the possible relations among different integrable hierarchies, for instance, between two different mKP hierarchies. Some generalizations of the dressing method based on the algebraic systems are discussed in Sec. V. We will mention about the algebraic system (1) with non-unit right-hand side, which serves, for example, the generalizations of the Kadomtsev–Petviashvili equation (KP) (see the Appendix). Conclusions are given in Sec. VI.

II. FAMILIES OF PARTICULAR SOLUTIONS

Next we discuss the available families of particular solutions to the nonlinear PDE related with the algebraic system (1). The main problem in construction of particular solutions is to satisfy the compatibility condition (6) together with constrains (9) and (18) for all pairs of variables $(x_i,x_j)\subset\mathbf{x}$. In general, for M-dimensional space one has to satisfy $(M-1)M/2$ conditions each represented by $N^{(r)}\times N^{(c)}$ equations. But under assumption that all products of the functions $f^{(i)}_{nk}g^{(i)}_{km}$ in (5) depend on complete set of variables, $\mathbf{x}$, the number of independent conditions becomes equal to $M-1$, i.e., the system (6) can be replaced, for instance, with the following one:

$$\partial_1\sum_{k=1}^{N_j}\mathbf{f}^{(jk)}\mathbf{g}^{(kj)}=\partial_j\sum_{k=1}^{N_1}\mathbf{f}^{(1k)}\mathbf{g}^{(k1)},\quad j=2,...,M. \tag{19}$$

We consider only such matrices $\mathbf{R}$ which give rise to the solution $\psi=[\psi_1,\dots,\psi_{N^{(c)}}]$ of the algebraic system (1) composed of linearly independent functions $\psi_m, m=1,...,N^{(c)}$:

$$\begin{aligned}&\text{functions } \psi_m\ (m=1,...,N^{(c)}) \text{ in the solution } \psi\\ &\quad=[\psi_1,\dots,\psi_{N^{(c)}}] \text{ of the system (1) are linearly independent.}\end{aligned} \tag{20}$$

The basic factor which defines the variety of the solutions is the allowed dimensions $N^{(r)}$ and $N^{(c)}$ of the matrix $\mathbf{R}$ in the algebraic system (1). Although the form of nonlinear PDEs does not depend on them, the admitted values of these dimensions are related essentially with the particular situation and are defined by both the equations (6) and the relations (9) and (18). In general, different families of particular solutions can be characterized by the four numbers, $N^{(r)}_{\min}$, $N^{(r)}_{\max}$, $N^{(c)}_{\min}$, $N^{(c)}_{\max}$, which represent the minimum and maximum possible values for the parameters $N^{(r)}$ and $N^{(c)}$, respectively, so that $N^{(r)}_{\min}\leqslant N^{(r)}\leqslant N^{(r)}_{\max}$ and $N^{(c)}_{\min}\leqslant N^{(c)}\leqslant N^{(c)}_{\max}$. For our convenience we combine all functions $\mathbf{f}^{(ik)}$ and $\mathbf{g}^{(ki)}$ related with each family in the manifolds $\mathbf{F}^i_{N^{(r)}_{\min}N^{(r)}_{\max}}$ and $\mathbf{G}^i_{N^{(c)}_{\min}N^{(c)}_{\max}}$, respectively. Note that condition (20) requires that parameters $N^{(r)}_{\min}$, $N^{(r)}_{\max}$, $N^{(c)}_{\min}$, $N^{(c)}_{\max}$ do not depend on i, $i=1,...,M-1$. We collect these two sets of manifolds in two general manifolds $\mathbf{F}=\cup_i\mathbf{F}^i_{N^{(r)}_{\min}N^{(r)}_{\max}}$ and $\mathbf{G}=\cup_i\mathbf{G}^i_{N^{(c)}_{\min}N^{(c)}_{\max}}$. Functions from these manifolds we call f- and g-functions, respectively.

We consider three steps of the investigation of the particular solutions, which can be applied to any nonlinear PDE, generated by the algebraic system (1). More detailed investigation can be

specifically performed for each particular system. Subscripts n and m run the values from 1 to $N^{(r)}$ and from 1 to $N^{(c)}$, respectively, in all formulas below, unless otherwise specified.

Step 1. *(Criterion for application of the dressing method.)* First of all, one needs to check if the compatibility conditions (19) can be satisfied at least for $N^{(r)}=N^{(c)}=1$. If this is possible, then the related system of nonlinear PDEs can be treated by the dressing method and one has at least a family of particular solutions for which f- and g-functions are collected in the manifolds $\mathbf{F}^i_{1,1}$ and $\mathbf{G}^i_{1,1}$.

After that we have to study the possibility to satisfy Eqs. (19) with $N^{(r)}>1$ and/or $N^{(c)}>1$. In general the system (19) is nonlinear and it is difficult to solve it. But one can separate the families of particular solutions for this system which can be received by ''splitting'' the equations (19) into the set of linear differential (or algebraic) equations on the f- and g-functions (or their Fourier amplitudes). We assume that all f- and g-functions depend on the whole set of variables $\mathbf{x}$. Due to the reductions (9) and (18) the equations (19) may involve the partial derivatives of f- and g-functions with respect to different sets of variables $\mathbf{x}_1$ and $\mathbf{x}_2$, respectively $(\mathbf{x}_1,\mathbf{x}_2\subseteq\mathbf{x})$. *Step 2* regards the situation when at least one of the sets $\mathbf{x}_1$ or $\mathbf{x}_2$ coincides with $\mathbf{x}$.

Step 2. Let us impose the set of reductions (9) and (18), assume that $\mathbf{x}_1\equiv\mathbf{x}$ (the case $\mathbf{x}_2\equiv\mathbf{x}$ can be considered in the analogous way, see Sec. III). Then the system (19) can be represented as the sum of the products:

$$\sum_{k=1}^{P_i} F^i_{nk}G^i_{km}=0,\quad i=1,...,M-1,$$

$$F^i_{nk}=F^i_k(f^{(j)}_{np},\quad j=1,...,M,\quad p=1,...,N_j), \tag{21}$$

$$G^i_{km}=G^i_k(g^{(j)}_{pm},\quad j=1,...,M,\quad p=1,...,N_j)$$

where we denote F^i_{nk} and G^i_{km} the linear combination of the functions $f^{(j)}_{np}$ and $g^{(j)}_{pm}$ $(j=1,...,M, p=1,...,N_j)$, respectively, and their derivatives in ith equation of the system (19). Let us put $N^{(r)}_{\min}=1$. To find $N^{(c)}_{\min}$ and $N^{(c)}_{\max}$, let us fix $n=1$ in the system (21):

$$\sum_{k=1}^{P_i} F^i_{1k}G^i_{km}=0,\quad i=1,...,M-1,\quad m=1,...,N^{(c)}, \tag{22}$$

and consider the last system as a system of equations on the functions $F^{(i)}_{1k}$.

Let us introduce several definitions. We call the set of functions $\{F^i_{nk},\ i$ is fixed, $k=1,...,G^{(g)}_i\}$ independent if for any permitted value of parameter n there is an appropriate set of functions $\tilde f_n\subset\{f^{(i)}_{nk}, i=1,...,M, k=1,...,N_i\}$ with the same length such that one can establish the uniquely invertible map $\{F^i_{nk}\}\leftrightarrow\tilde f_n$. Analogously, we call the set of functions $\{G^i_{km},\ i$ is fixed, $k=1,...,D^{(f)}_i\}$ linearly independent, if for any admitted value of parameter m there is an appropriate set of functions $\tilde g_m\subset\{g^{(i)}_{km}, i=1,...,M, k=1,...,N_i\}$ with the same length such that one can establish the uniquely invertible map $\{G^i_{km}\}\leftrightarrow\tilde g_m$. Let $D^{(g)}_i$ be the minimum number of independent functions F^i_k for each fixed i and $D^{(g)}=\min(D^{(g)}_i)$. One can always reenumerate functions F^i_k in such a way that functions F^i_k are independent for $k=1,...,D^{(g)}_i$. We impose two requirements:

(1) $D^{(g)}\geqslant M-1$, otherwise the succeeding consideration in the scopes of *Step 2* leads to the nonlinear equations on g-functions.
(2) All functions F^i_k with $k=1,...,D^{(g)}$ and $i=1,...,M-1$ are independent, i.e., one has $(M-1)D^{(g)}$ independent functions altogether.

Then for any number $\tilde D^{(g)}\leqslant D^{(g)}$ the system (22) with $m=1,...,\tilde D^{(g)}$ is the linear system on the functions F^i_k (or on f-functions), which can be resolved provided an appropriate choice of the arbitrary g-functions is made. In this way we have fixed $N^{(c)}_{\min}=N^{(c)}_{\max}=\tilde D^{(g)}$ in the system (21). Let

us denote $\tilde{D}_i^{(f)}$ the number of independent solutions of the equations (22) with $\tilde{D}^{(f)}=\min(\tilde{D}_i^{(f)})$. Then $N_{\min}^{(r)}=1$ and $N_{\max}^{(r)}=\tilde{D}^{(f)}$. So, *f*- and *g*-functions are combined in the manifolds $\mathbf{F}^i_{1\tilde{D}^{(f)}}$ and $\mathbf{G}^i_{\tilde{D}^{(g)}\tilde{D}^{(g)}}$ ($\tilde{D}^{(g)}=1,...,D^{(g)}$ and $\tilde{D}^{(f)}$ depends on $\tilde{D}^{(g)}$). The matrix $\mathbf{R}$ in the algebraic system (1) is represented by its elements $R_{nm}=\partial_i^{-1}\Sigma_{k=1}^{N_i} f_{nk}^{(i)} g_{km}^{(i)}$ with some fixed i and $\mathbf{f}^{(ik)}\in\mathbf{F}^i_{1\tilde{D}^{(f)}}, \mathbf{g}^{(ik)}\in\mathbf{G}^i_{\tilde{D}^{(g)}\tilde{D}^{(g)}}$. We emphasize that all *g*-functions are arbitrary functions of the set of variables $\mathbf{x}$ in the above formulas.

In the previous consideration we separated the part of the system (22) with $m\leqslant\tilde{D}^{(g)}$. Now let us consider the part of the system (22) with $m>\tilde{D}^{(g)}$. If we are able to provide $\tilde{N}$ equations in this system, which are compatible with the first part of the system and appropriate functions $g_{km}^{(i)}$ are linearly independent with functions $g_{km}^{(i)}$, $m\leqslant\tilde{D}^{(g)}$, then the parameter $N_{\max}^{(c)}$ will become equal to $\tilde{D}^{(g)}+\tilde{N}$. In fact, let us consider the subsystem of the system (22) with $m=1,...,\tilde{D}^{(g)}$ as an algebraic system, resolvable for the functions F_k^i ($i=1,...,M-1$, $k=1,...,P_i$). Let n run values from 1 to $\tilde{D}^{*(f)}\leqslant\tilde{D}^{(f)}$. Substitute the solution of this subsystem into the equations of the system (21) with $m>\tilde{D}^{(g)}$ and consider the resultant system as the set of identities for all $n=1,...,\tilde{D}^{*(f)}$. It leads to either the linear or nonlinear equations on *g*-functions. If $\tilde{N}$ is the number of solutions of this system linearly independent with *g*-functions fixed before, then $N_{\max}^{(c)}=\tilde{D}^{(g)}+\tilde{N}$. So, *g*-functions belong to the manifolds $\mathbf{G}^i_{\tilde{D}^{(g)}(\tilde{D}^{(g)}+\tilde{N})}$, with $\tilde{D}^{(g)}=1,...,D^{(g)}$, where $\tilde{N}$ depends on $\tilde{D}^{*(f)}$. *f*-functions belong to the manifolds $\mathbf{F}^i_{1\tilde{D}^{*(f)}}$.

Even if one of the sets $\mathbf{x}_1$ or $\mathbf{x}_2$ coincides with $\mathbf{x}$, it is not necessary that the system (19) be treated by the *Step 2*. It happens, for instance, if $D^{(g)}<M-1$. The solutions provided by the next step are available always if only the *criterion* is satisfied.

Step 3. Since the constrains (9) and (18) are given by the linear differential equations with constant coefficients, one can represent *f*- and *g*-functions in terms of Fourier integrals

$$f_{nk}^{(i)}=\int a_{nk}^{(i)}(\mathbf{k}_n)e^{\mathbf{k}_n\mathbf{x}_1+\tilde{\mathbf{k}}_n\tilde{\mathbf{x}}_1}\,d\mathbf{k}_n, \tag{23}$$

$$g_{km}^{(i)}=\int b_{km}^{(i)}(\omega_m)e^{\omega_m\mathbf{x}_2+\tilde{\omega}_m\tilde{\mathbf{x}}_2}\,d\omega_m, \tag{24}$$

$$\mathbf{k}_n=(k_{n1},\ldots,k_{n\,\dim(\mathbf{x}_1)}),\quad \tilde{\mathbf{k}}_n=(k_{n\,\dim(\mathbf{x}_1)+1},\ldots,k_{nM}), \tag{25}$$

$$\omega_m=(\omega_{m1},\ldots,\omega_{m\,\dim(\mathbf{x}_2)}),\quad \tilde{\omega}_m=(\omega_{m\,\dim(\mathbf{x}_2)+1},\ldots,\omega_{mM}),$$

$$d\omega_m=d\omega_{m1}\ldots d\omega_{m\,\dim(\mathbf{x}_2)},\quad d\mathbf{k}_n=dk_{n1}\ldots dk_{n\,\dim(\mathbf{x}_1)},$$

$$\mathbf{x}_i\cap\tilde{\mathbf{x}}_i=\varnothing,\quad \mathbf{x}_i\cup\tilde{\mathbf{x}}_i=\mathbf{x},$$

where $\tilde{\mathbf{k}}_n(\mathbf{k}_n)$ and $\tilde{\omega}_n(\omega_n)$ represent the dispersion relation for the linear differential equations (9) and (18). In order to satisfy the compatibility conditions (21) in the nonintegrable case, one needs to provide the possibility to establish the relations between spectral parameters $\mathbf{k}_n$ and ω_n. For this purpose one needs to replace at least one of the equations (23) or (24) by the finite Fourier series. Namely, the two following representations for *f*- and *g*-functions can be used (for the sake of simplicity we take the single Fourier harmonic instead of the finite series):

$$f_{nk}^{(i)}=a_{nk}^{(i)}e^{\mathbf{k}_n\mathbf{x}_1+\tilde{\mathbf{k}}_n\tilde{\mathbf{x}}_1},\quad g_{km}^{(i)}=\int b_{km}^{(i)}(\omega_m)e^{\omega_m\mathbf{x}_2+\tilde{\omega}_m\tilde{\mathbf{x}}_2}d\omega_m \tag{26}$$

and

$$f_{nk}^{(i)}=\int a_{nk}^{(i)}(\mathbf{k}_n)e^{\mathbf{k}_n\mathbf{x}_1+\tilde{\mathbf{k}}_n\tilde{\mathbf{x}}_1}\,d\mathbf{k}_n,\quad g_{km}^{(i)}=b_{km}^{(i)}e^{\omega_m\mathbf{x}_2+\tilde{\omega}_m\tilde{\mathbf{x}}_2}. \tag{27}$$

The examination of each of these representations is equivalent, so that we study only the first one.

The compatibility conditions (21) become the system of algebraic equations on the parameters $a_{nk}^{(i)}$, $k_{nj}, b_{km}^{(i)}$, w_{mj}:

$$\sum_{k=1}^{P_i} F_k^i(\mathbf{a}_n,\mathbf{k}_n)G_k^i(\mathbf{b}_m,\omega_m)=0,\quad i=1,...,M-1, \tag{28}$$

$$\mathbf{a}_n=(a_{nk}^{(i)},\quad i=1,...,M,\quad k=1,...,N_i), \tag{29}$$

$$\mathbf{b}_n=(b_{kn}^{(i)},\quad i=1,...,M,\quad k=1,...,N_i), \tag{30}$$

with $\mathbf{k}_n\neq\mathbf{k}_m$ and $\omega_n\neq\omega_m$ if $n\neq m$ in order to satisfy the requirement (20). This system admits following families of solutions:

(1) Let us keep independent continuous parameters ω_{mk} with different k $[k=1,...,\dim(\mathbf{x}_2)]$ and m in the representation (26). Assume $N_{\min}^{(r)}=N_{\min}^{(c)}=1$ and find out the appropriate values for $N_{\max}^{(r)}$ and $N_{\max}^{(c)}$. First of all let us fix $n=1$ in the above system, so that it can be written in the form

$$\sum_{k=1}^{P_i} F_k^i(\mathbf{a}_1,\mathbf{k}_1)G_k^i(\mathbf{b}_m,\omega_m)=0,\quad i=1,...,M-1. \tag{31}$$

Since parameters ω_{mk} are independent, the above equations represent the relations among parameters $b_{km}^{(i)}$. So, one has $M-1$ relations among these parameters for each particular value of the parameter m. This means that if the system (31) is consistent for some fixed m, then it is consistent for any m, i.e., $N_{\max}^{(c)}=\infty$ and the g-functions belong to the manifold $\mathbf{G}_{1\infty}^{(i)}$. Otherwise the system (31) is inconsistent. Assuming the consistence of the system (31), let us define $N_{\max}^{(r)}$. Suppose that $N_{\max}^{(r)}>1$ and consider two equations (28) with $n=1$ and $n=p\leqslant N^{(r)}$. Subtract one equation from another to get

$$\sum_{k=1}^{P_i} (F_k^i(\mathbf{a}_1,\mathbf{k}_1)-F_k^i(\mathbf{a}_p,\mathbf{k}_p))G_k^i(\mathbf{b}_m,\omega_m)=0,\quad i=1,...,M-1. \tag{32}$$

Since this equation should be satisfied for all admitted values of the parameter m, one gets the set of algebraic equations on parameters $\mathbf{a}_p^{(i)}$ and $\mathbf{k}_p$:

$$(F_k^i(\mathbf{a}_1,\mathbf{k}_1)-F_k^i(\mathbf{a}_p,\mathbf{k}_p))=0,\quad k=1,...,P_i,\quad i=1,...,M-1. \tag{33}$$

If set $(\mathbf{a}_p,\mathbf{k}_p), p=1,...,\tilde{n}+1$, represents solutions of this system with different spectral parameters (i.e., $\mathbf{k}_n\neq\mathbf{k}_p$ if $n\neq p$ for $n,p=1,...,\tilde{n}+1$), then $N_{\max}^{(r)}=\tilde{n}+1$ and f-functions belong to the manifolds $\mathbf{F}_{1(\tilde{n}+1)}^{(i)}$.

We assumed that parameters ω_{mk} with different k are independent in the formulas (31)–(33), which is not always possible [see Sec. III A, Eqs. (70)–(72)]. The following family of solutions is not based on this assumption.

(2) For this family of solutions we impose the additional relations among parameters ω_{mk} with different k. These relations can be established in the following way. Let us consider the system (31). For each particular m we select $\tilde{M}\leqslant M-1$ equations of these systems to impose the relations among $\tilde{m}_b$ parameters $b_{km}^{(i)}$ and $\tilde{m}\leqslant\dim(\mathbf{x}_2)$ parameters $\omega_{mk}(\tilde{m}_b+\tilde{m}=\tilde{M})$, i.e., split the complete system (31) into two subsystems,

$$\sum_{k=1}^{P_i} F_k^i(\mathbf{a}_1,\mathbf{k}_1)G_k^i(\mathbf{b}_m,\omega_m)=0, \quad i=1,...,\tilde{M}, \tag{34}$$

$$\sum_{k=1}^{P_i} F_k^i(\mathbf{a}_1,\mathbf{k}_1)G_k^i(\mathbf{b}_m,\omega_m)=0, \quad i=\tilde{M}+1,...,M-1, \tag{35}$$

and consider the first system as an algebraic system of equations for $\tilde{m}_b$ parameters $b_{km}^{(i)}$ and $\tilde{m}$ parameters ω_{mj}. This means that $N_{\min}^{(c)}=1$. If $\tilde{m}<\dim(\mathbf{x}_2)$ and the system (34) is resolvable for some particular m, then it is resolvable for arbitrary m with $(\dim(\mathbf{x}_2)-\tilde{m})$ arbitrary parameters ω_{mk} for each particular m, i.e., $N_{\max}^{(c)}$ is infinity, g-functions belong to the manifolds $\mathbf{G}_{1\infty}^{(i)}$, and the integral in (26) becomes $(\dim(\mathbf{x}_2)-\tilde{m})$-dimensional. If $\tilde{m}=\dim(\mathbf{x}_2)$, then there are no arbitrary parameters ω_{mk}, integration disappears from the Eq. (26), and the maximum dimension $N_{\max}^{(c)}$ is defined by the number m_0 of the solutions of the system (32) with different spectral parameters ω_m: $\omega_m\neq\omega_p$ if $m\neq p$ for all $m,p=1,...,m_0$. Consequently g-functions belong to the manifold $\mathbf{G}_{1m_0}^{(i)}$. Now we have to satisfy the system (35). First of all one needs to substitute the established relations among parameters $\mathbf{b}_m^{(i)}$ and ω_m into the system (35) to end up with the system of the form

$$\sum_{k=1}^{\tilde{P}_i} \tilde{F}_k^i(\mathbf{a}_1,\mathbf{k}_1)\tilde{G}_k^i(\mathbf{b}_m,\omega_m)=0, \quad i=\tilde{M}+1,...,M-1. \tag{36}$$

Considering this system as a set of identities for all admitted m one gets the following system of equations for parameters $\mathbf{a}_1$ and $\mathbf{k}_1$:

$$\tilde{F}_k^i(\mathbf{a}_1,\mathbf{k}_1)=0, \quad k=1,...,\tilde{P}_i, \quad i=\tilde{M}+1,...,M-1.$$

If this system is consistent, then the imposed relations among $b_{km}^{(j)}$ and ω_{mi} are allowed at least for $N_{\min}^{(r)}=1$.

To find $N_{\max}^{(r)}$ one has to assume that $N_{\max}^{(r)}>1$ in (28), substitute all found relations among parameters into the equations of the system (28) with $1<n\leqslant N_{\max}^{(r)}$, and consider them as identities for all m. One gets the system of algebraic equations on the parameters $\mathbf{a}_n$ and $\mathbf{k}_n$. The number of its solutions $\tilde{n}$ with different $\mathbf{k}_n$ ($\mathbf{k}_n\neq\mathbf{k}_p$ if $n\neq p$, $n,p=1,...\tilde{n}+1$) defines the maximum dimension $N_{\max}^{(r)}$: $N_{\max}^{(r)}=\tilde{n}+1$. So, f-functions belong to the manifolds $\mathbf{F}_{1,\tilde{n}+1}^{(i)}$.

(3) To establish the relations among parameters $b_{km}^{(i)}$ and ω_{mk} one can take the subsystem of n_0 equations out of the system (28) with $n=1,...,n_0$. The algorithm is exactly the same. One can establish $\tilde{M}$ relations among $\tilde{m}_b$ parameters $b_{km}^{(i)}$ and $\tilde{m}\leqslant\dim(\mathbf{x}_2)$ parameters ω_{mk} for each particular m ($\tilde{m}_b+\tilde{m}=\tilde{M}$). If the remaining $n_0(M-1)-\tilde{M}$ equations are compatible, one gets the relations among parameters $\mathbf{a}_{nk}^{(i)}$ and $\mathbf{k}_{nk}$ ($n=1,...,n_0$), which mean that $N_{\min}^{(r)}=n_0$. To find $N_{\max}^{(r)}$ one needs to assume that $N_{\max}^{(r)}>n_0$, substitute all found relations into the equation (28) with $n_0<n\leqslant N_{\max}^{(r)}$, consider them as identities for all m, and solve the appropriate system of algebraic equations on the parameters $\mathbf{a}_{nk}^{(i)}$ and $\mathbf{k}_{nk}$. If the set $(\mathbf{a}_p,\mathbf{k}_p)$, $p=1,...,\tilde{n}+n_0$, represents solutions of this system with different spectral parameters $\mathbf{k}_p$ (i.e., $\mathbf{k}_n\neq\mathbf{k}_p$ if $n\neq p$ and $n,p=1,...,\tilde{n}+n_0$), then $N_{\max}^{(r)}=\tilde{n}+n_0$ and f-functions are in the manifolds $\mathbf{F}_{n_0,\tilde{n}+n_0}^{(i)}$. g-functions belong to the manifolds $\mathbf{G}_{1\infty}^{(i)}$ or $\mathbf{G}_{1m_0}^{(i)}$ if $\tilde{m}=\dim(\mathbf{x}_2)$. In the last case m_0 is the number of solutions $(\mathbf{b}_m,\omega_m)$ to the system (28) ($n=1,...,n_0$, $i=1,...,\tilde{M}$) with different ω_m.

III. (3+1)-DIMENSIONAL GENERALIZATION OF mKP

In this section we use the algorithm described above to derive the $(3+1)$-dimensional nonintegrable generalization of mKP. We use $(3+1)$-dimensional equations to show how this algorithm works in multidimension, where the classical integrability theory is applicable only to special types of PDEs. There is no formal restriction on the dimension of PDEs, which can be

treated by the method considered in this article. One can construct $(2+1)$-dimensional nonintegrable generalizations of mKP which will involve different types of nonlinearity. Although the general nonlinear equations [see Eqs. (47) and (48)] are rather cumbersome, they admit a set of reductions which reduce the general system into the simpler equations like Eqs. (61)–(63),[13] which may be regarded as the simplest generalizations of mKP (64).

To start with, let us take $M=4$ (Ref. 13) and normalization $\eta_m=1$, $m=1,...,N^{(c)}$, in the system (1). Introduce $\mathbf{x}$-dependence by the set of equations (5)

$$\partial_1\mathbf{R}=\mathbf{f}^{(11)}\mathbf{g}^{(1)},\quad \partial_2\mathbf{R}=\mathbf{f}^{(21)}\mathbf{g}^{(2)},\quad \partial_3\mathbf{R}=\mathbf{f}^{(31)}\mathbf{g}^{(1)}+\mathbf{f}^{(32)}\partial_1\mathbf{g}^{(1)},$$

$$\partial_4\mathbf{R}=\mathbf{f}^{(41)}\mathbf{g}^{(2)}+\mathbf{f}^{(42)}\partial_2\mathbf{g}^{(2)}+\mathbf{f}^{(43)}\partial_2^2\mathbf{g}^{(2)}, \tag{37}$$

$$\mathbf{g}^{(i)}=[g_1^{(i)}\cdots g_{N^{(c)}}^{(i)}],\quad \mathbf{f}^{(ik)}=[f_{1k}^{(i)}\cdots f_{N^{(r)}k}^{(i)}]^T.$$

To construct the auxiliary linear system, let us write down the set of linear algebraic systems (11)–(13), which is generated by the original system (1) and Eqs. (37):

$$L(\partial_1\psi)=U_{0,0,0,0}^{(11)}\mathbf{g}^{(1)}, \tag{38}$$

$$L(\partial_1^2\psi)=(2\partial_1U_{0,0,0,0}^{(11)}-U_{1,0,0,0}^{(11)})\mathbf{g}^{(1)}+U_{0,0,0,0}^{(11)}\partial_1\mathbf{g}^{(1)}, \tag{39}$$

$$L(\partial_2\psi)=U_{0,0,0,0}^{(21)}\mathbf{g}^{(2)}, \tag{40}$$

$$L(\partial_2^2\psi)=(2\partial_2U_{0,0,0,0}^{(21)}-U_{0,1,0,0}^{(21)})\mathbf{g}^{(2)}+U_{0,0,0,0}^{(21)}\partial_2\mathbf{g}^{(2)}, \tag{41}$$

$$\begin{aligned}L(\partial_2^3\psi)=&(3\partial_2^2U_{0,0,0,0}^{(21)}-3\partial_2U_{0,1,0,0}^{(21)}+U_{0,2,0,0}^{(21)})\mathbf{g}^{(2)}\\&+(3\partial_2U_{0,0,0,0}^{(21)}-U_{0,1,0,0}^{(21)})\partial_2\mathbf{g}^{(2)}+U_{0,0,0,0}^{(21)}\partial_2^2\mathbf{g}^{(2)},\end{aligned} \tag{42}$$

$$L(\partial_3\psi)=U_{0,0,0,0}^{(31)}\mathbf{g}^{(1)}+U_{0,0,0,0}^{(32)}\partial_1\mathbf{g}^{(1)}, \tag{43}$$

$$L(\partial_4\psi)=U_{0,0,0,0}^{(41)}\mathbf{g}^{(2)}+U_{0,0,0,0}^{(42)}\partial_2\mathbf{g}^{(2)}+U_{0,0,0,0}^{(43)}\partial_2^2\mathbf{g}^{(2)}, \tag{44}$$

$$U_{n_1,n_2,n_3,n_4}^{(ik)}=\sum_{m=1}^{N^{(r)}}\psi_m\sum_{n=1}^{N^{(c)}}c_{mn}\partial_1^{n_1}\partial_2^{n_2}\partial_3^{n_3}\partial_4^{n_4}f_{nk}^{(i)}\equiv\psi\mathbf{C}\partial_1^{n_1}\partial_2^{n_2}\partial_3^{n_3}\partial_4^{n_4}\mathbf{f}^{(ik)}, \tag{45}$$

$$\psi=[\psi_1\ldots\psi_{N^{(c)}}].$$

Then the linear system (15) has the form

$$\begin{aligned}M_1\psi\equiv\partial_3\psi+V_1\partial_1^2\psi+V_2\partial_1\psi=0,\\M_2\psi\equiv\partial_4\psi+W_1\partial_2^3\psi+W_2\partial_2^2\psi+W_3\partial_2\psi=0\end{aligned} \tag{46}$$

with

$$V_1=-U_{0,0,0,0}^{(32)}/U_{0,0,0,0}^{(11)},\quad V_2=(-U_{0,0,0,0}^{(31)}-V_1(2\partial_1U_{0,0,0,0}^{(11)}-U_{1,0,0,0}^{(11)}))/U_{0,0,0,0}^{(11)},$$

$$W_1=-U_{0,0,0,0}^{(43)}/U_{0,0,0,0}^{(21)},\quad W_2=(-U_{0,0,0,0}^{(42)}-W_1(3\partial_2U_{0,0,0,0}^{(21)}-U_{0,1,0,0}^{(21)}))/U_{0,0,0,0}^{(21)},$$

$$W_3=(-U_{0,0,0,0}^{(41)}-W_1(3\partial_2^2U_{0,0,0,0}^{(21)}-3\partial_2U_{0,1,0,0}^{(21)}+U_{0,2,0,0}^{(21)})-W_2(2\partial_2U_{0,0,0,0}^{(21)}-U_{0,1,0,0}^{(21)}))/U_{0,0,0,0}^{(21)}.$$

In fact, one can check directly that $L(M_i\psi)=0$, $i=1,2$. Note that each of the equations (46) is a matrix $1\times N^{(c)}$ equation with scalar coefficients V_i and W_i. To get a nonlinear system let us

multiply them by the $N^{(c)}\times 1$ vector functions $\mathbf{C}\partial_1^{n_1}\partial_2^{n_2}\partial_3^{n_3}\partial_4^{n_4}\mathbf{f}^{(ij)}$ and use the definition of potentials $U^{(ik)}_{n1,n2,n3,n4}$ given by (45). One result is the following differential-difference system with four continuous and four discrete parameters:

$$\partial_3 U^{(ij)}_{n_1,n_2,n_3,n_4}-U^{(ij)}_{n_1,n_2,n_3+1,n_4}+V_1(\partial_1^2 U^{(ij)}_{n_1,n_2,n_3,n_4}-2\partial_1 U^{(ij)}_{n_1+1,n_2,n_3,n_4}+U^{(ij)}_{n_1+2,n_2,n_3,n_4})$$
$$+V_2(\partial_1 U^{(ij)}_{n_1,n_2,n_3,n_4}-U^{(ij)}_{n_1+1,n_2,n_3,n_4})=0, \tag{47}$$

$$\partial_4 U^{(ij)}_{n_1,n_2,n_3,n_4}-U^{(ij)}_{n_1,n_2,n_3,n_4+1}+W_1(\partial_2^3 U^{(ij)}_{n_1,n_2,n_3,n_4}-3\partial_2^2 U^{(ij)}_{n_1,n_2+1,n_3,n_4}+3\partial_2 U^{(ij)}_{n_1,n_2+2,n_3,n_4}$$
$$-U^{(ij)}_{n_1,n_2+3,n_3,n_4})+W_2(\partial_2^2 U^{(ij)}_{n_1,n_2,n_3,n_4}-2\partial_2 U^{(ij)}_{n_1,n_2+1,n_3,n_4}+U^{(ij)}_{n_1,n_2+2,n_3,n_4})$$
$$+W_3(\partial_2 U^{(ij)}_{n_1,n_2,n_3,n_4}-U^{(ij)}_{n_1,n_2+1,n_3,n_4})=0, \tag{48}$$

$$(ij)=(11),\ (21),\ (31),\ (32),\ (4p),\quad p=1,2,3.$$

This differential-difference system of equations is a general system generated by the algebraic system (1) with unit right-hand side and **x**-parameters introduced by the formulas (37).

Now let us impose reductions of the form (18) on the functions $f^{(j)}_{nk}$ to decrease the number of discrete parameters and reduce the system (47) and (48) to the complete system of pure PDEs. Below we consider the set of such reductions which eventually leads to mKP (64).

Reduction 1. Introduce the following relations among the functions $\mathbf{f}^{(ij)}$:

$$\partial_2\mathbf{f}^{(ij)}=\partial_1\mathbf{f}^{(ij)},\quad \partial_3\mathbf{f}^{(ij)}=-\partial_1^2\mathbf{f}^{(ij)},\quad \partial_4\mathbf{f}^{(ij)}=\partial_1^3\mathbf{f}^{(ij)}. \tag{49}$$

Appropriate relations among the functions $U^{(ij)}_{n_1,n_2,n_3,n_4}$ read

$$U^{(ij)}_{n_1,n_2,n_3,n_4}=(-1)^{n_3}U^{(ij)}_{n_1+n_2+2n_3+3n_4,0,0,0}\equiv(-1)^{n_3}U^{(ij)}_{n_1+n_2+2n_3+3n_4}. \tag{50}$$

Under this reduction the system (47) and (48) becomes of the form

$$\partial_3 U^{(ij)}_n+U^{(ij)}_{n+2}+V_1(\partial_1^2 U^{(ij)}_n-2\partial_1 U^{(ij)}_{n+1}+U^{(ij)}_{n+2})+V_2(\partial_1 U^{(ij)}_n-U^{(ij)}_{n+1})=0, \tag{51}$$

$$\partial_4 U^{(ij)}_n-U^{(ij)}_{n+3}+W_1(\partial_2^3 U^{(ij)}_n-3\partial_2^2 U^{(ij)}_{n+1}+3\partial_2 U^{(ij)}_{n+2}-U^{(ij)}_{n+3})+W_2(\partial_2^2 U^{(ij)}_n-2\partial_2 U^{(ij)}_{n+1}+U^{(ij)}_{n+2})$$
$$+W_3(\partial_2 U^{(ij)}_n-U^{(ij)}_{n+1})=0, \tag{52}$$

$$(ij)=(11),\ (21),\ (31),\ (32),\ (4p),\quad p=1,2,3,$$

where

$$V_1=-U^{(32)}_0/U^{(11)}_0,\quad V_2=(-U^{(31)}_0-V_1(2\partial_1 U^{(11)}_0-U^{(11)}_1))/U^{(11)}_0,$$

$$W_1=-U^{(43)}_0/U^{(21)}_0,\quad W_2=(-U^{(42)}_0-W_1(3\partial_2 U^{(21)}_0-U^{(21)}_1))/U^{(21)}_0,$$

$$W_3=(-U^{(41)}_0-W_1(3\partial_2^2 U^{(21)}_0-3\partial_2 U^{(21)}_1+U^{(21)}_2)-W_2(2\partial_2 U^{(21)}_0-U^{(21)}_1))/U^{(21)}_0.$$

The complete system of nonlinear PDEs is represented by the system (51) and (52) where index n runs the values 0, 1, 2 in Eq. (51) and 0, 1 in Eq. (52).

Reduction 2. Impose another reduction:

$$\mathbf{f}^{(11)}\equiv\mathbf{f}^{(1)},\quad \mathbf{f}^{(21)}\equiv\mathbf{f}^{(2)},\quad \mathbf{f}^{(31)}=-\partial_1\mathbf{f}^{(32)}\equiv-\partial_1\mathbf{f}^{(3)},$$
$$\mathbf{f}^{(41)}=\partial_1^2\mathbf{f}^{(43)}\equiv\partial_1^2\mathbf{f}^{(4)},\quad \mathbf{f}^{(42)}=-\partial_1\mathbf{f}^{(43)}\equiv-\partial_1\mathbf{f}^{(4)}, \tag{53}$$

or

$$U_n^{(11)} \equiv U_n^{(1)}, \quad U_n^{(21)} \equiv U_n^{(2)}, \quad U_n^{(31)} = -U_{n+1}^{(32)} \equiv -U_{n+1}^{(3)},$$
$$U_n^{(41)} = U_{n+2}^{(43)} \equiv U_{n+2}^{4}, \quad U_n^{(42)} = -U_{n+1}^{(43)} \equiv -U_{n+1}^{(4)}, \tag{54}$$

which reduces the system (51) and (52) into the following one:

$$\partial_3 U_n^{(i)} + U_{n+2}^{(j)} + V_1(\partial_1^2 U_n^{(i)} - 2\partial_1 U_{n+1}^{(i)} + U_{n+2}^{(i)}) + V_2(\partial_1 U_n^{(i)} - U_{n+1}^{(i)}) = 0, \tag{55}$$

$$\partial_4 U_n^{(i)} - U_{n+3}^{(i)} + W_1(\partial_2^3 U_n^{(i)} - 3\partial_2^2 U_{n+1}^{(i)} + 3\partial_2 U_{n+2}^{(i)} - U_{n+3}^{(i)}) + W_2(\partial_2^2 U_n^{(i)} - 2\partial_2 U_{n+1}^{(i)} + U_{n+2}^{(i)})$$
$$+ W_3(\partial_2 U_n^{(i)} - U_{n+1}^{(i)}) = 0, \quad i = 1,2,3,4, \tag{56}$$

where

$$V_1 = -U_0^{(3)}/U_0^{(1)}, \quad V_2 = (U_1^{(3)} - V_1(2\partial_1 U_0^{(1)} - U_1^{(1)}))/U_0^{(1)},$$
$$W_1 = -U_0^{(4)}/U_0^{(2)}, \quad W_2 = (U_1^{(4)} - W_1(3\partial_2 U_0^{(2)} - U_1^{(2)}))/U_0^{(2)},$$
$$W_3 = (-U_2^{(4)} - W_1(3\partial_2^2 U_0^{(2)} - 3\partial_2 U_1^{(2)} + U_2^{(2)}) - W_2(2\partial_2 U_0^{(2)} - U_1^{(2)}))/U_0^{(2)}.$$

The system (55) and (56) represents the complete system of nonlinear PDEs if index n runs the values 0, 1, 2 in Eq. (55) and 0, 1 in Eq. (56).

Reduction 3. Assume now

$$\mathbf{f}^{(3)} = \mathbf{f}^{(1)}, \quad \mathbf{f}^{(4)} = \mathbf{f}^{(2)}, \quad \text{or} \quad U_n^{(3)} = U_n^{(1)}, \quad U_n^{(4)} = U_n^{(2)}. \tag{57}$$

The system (55) and (56) becomes of the form

$$\partial_3 U_n^{(i)} - \partial_1^2 U_n^{(i)} + 2\partial_1 U_{n+1}^{(i)} + V_2(\partial_1 U_n^{(i)} - U_{n+1}^{(i)}) = 0, \tag{58}$$

$$\partial_4 U_n^{(i)} - \partial_2^3 U_n^{(i)} + 3\partial_2^2 U_{n+1}^{(i)} - 3\partial_2 U_{n+2}^{(i)} + W_2(\partial_2^2 U_n^{(i)} - 2\partial_2 U_{n+1}^{(i)} + U_{n+2}^{(i)}) + W_3(\partial_2 U_n^{(i)} - U_{n+1}^{(i)})$$
$$= 0, \quad i = 1,2, \tag{59}$$

where

$$V_2 = 2\partial_1 U_0^{(1)}/U_0^{(1)}, \quad W_2 = 3\partial_1 U_0^{(2)}/U_0^{(2)},$$
$$W_3 = (3\partial_2^2 U_0^{(2)} - 3\partial_2 U_1^{(2)} - W_2(2\partial_2 U_0^{(2)} - U_1^{(2)}))/U_0^{(2)}.$$

This system represents the complete system of PDEs if $n = 0,1$ in Eq. (58) and $n = 0$ in Eq. (59).

Reduction 4. The next possible reduction is

$$\mathbf{f}^{(1)} = \mathbf{f}^{(2)} = \mathbf{f} \quad \text{or} \quad U_n^{(1)} = U_n^{(2)} = U_n. \tag{60}$$

Then the system (58) and (59) becomes of the form

$$\partial_3 U_n - \partial_1^2 U_n + 2\partial_1 U_{n+1} + V_2(\partial_1 U_n - U_{n+1}) = 0, \tag{61}$$

$$\partial_4 U_n - \partial_2^3 U_n + 3\partial_2^2 U_{n+1} - 3\partial_2 U_{n+2} + W_2(\partial_2^2 U_n - 2\partial_2 U_{n+1} + U_{n+2}) + W_3(\partial_2 U_n - U_{n+1}) = 0, \tag{62}$$

where

$$V_2=2\partial_1 U_0/U_0,\quad W_2=3\partial_2 U_0/U_0,\quad W_3=(3\partial_2^2 U_0-3\partial_2 U_1-W_2(2\partial_2 U_0-U_1))/U_0.$$

This system[13] represents the complete system of PDEs if $n=0,1$ in Eq. (61) and $n=0$ in Eq. (62). It can be rewritten as

$$\begin{gathered}u_{x_3}-u_{x_1x_1}+2v_{x_1}+u_{x_1}^2=0,\quad v_{x_3}-v_{x_1x_1}+2w_{x_1}-2vv_{x_1}=0,\\ u_{x_4}-u_{x_2x_2x_2}+3v_{x_2x_2}-3w_{x_2}+3u_{x_2}u_{x_2x_2}-u_{x_2}^3-3u_{x_2}v_{x_2}+3vv_{x_2}=0,\end{gathered}\tag{63}$$

where $U_0=\exp u$, $U_1=vU_0$, and $U_2=wU_0$.

Reduction 5. Finally,[13] the reduction $\partial_2\equiv\partial_1$ reduces the $(3+1)$-dimensional system (63) into mKP:

$$\partial_4 v-1/4\ \partial_1^3 v+3/2\ v^2\partial_1 v+3/2\ \partial_1 v\,\partial_1^{-1}\partial_3 v-3/4\ \partial_1^{-1}\partial_3^2 v=0,\quad v=\partial_1 U_0/U_0.\tag{64}$$

In this way we have demonstrated that the general system (47) and (48) can be regarded as the differential-difference generalization of mKP with four continuous and four discrete parameters.

A. Construction of particular solutions

As we mentioned earlier, the main problem in construction of the particular solutions is the compatibility conditions (6) or (19). We start with the solutions to the general differential-difference system (47) and (48). The condition (19) is represented by the system of three equations:

$$\partial_2 f_m^{(1)}g_m^{(1)}+f_{n1}^{(1)}\partial_2 g_m^{(1)}-\partial_1 f_{n1}^{(2)}g_m^{(2)}-f_{n1}^{(2)}\partial_1 g_m^{(2)}=0,\tag{65}$$

$$(\partial_3 f_{n1}^{(1)}-\partial_1 f_{n1}^{(3)})g_m^{(1)}-(f_{n1}^{(3)}+\partial_1 f_{n2}^{(3)})\partial_1 g_m^{(1)}+f_{n1}^{(1)}\partial_3 g_m^{(1)}-f_{n2}^{(3)}\partial_1^2 g_m^{(1)}=0,\tag{66}$$

$$(\partial_4 f_{n1}^{(2)}-\partial_2 f_{n1}^{(4)})g_m^{(2)}-(f_{n1}^{(4)}+\partial_2 f_{n2}^{(4)})\partial_2 g_m^{(2)}-(f_{n2}^{(4)}+\partial_2 f_{n3}^{(4)})\partial_2^2 g_m^{(2)}+f_{n1}^{(2)}\partial_4 g_m^{(2)}-f_{n3}^{(4)}\partial_2^3 g_m^{(2)}=0,\tag{67}$$

so that one has $\mathbf{x}_1=\mathbf{x}_2=(x_1,x_2,x_3,x_4)$. This system can be considered as the linear system on the functions $f_{nk}^{(j)}$. It is not difficult to understand that this system is resolvable for $N^{(r)}=N^{(c)}=1$ (or $n=m=1$, *step* 1), when it can be treated as the system on the functions $f_{11}^{(j)}$, $j=2,3,4$. All other functions can be taken as arbitrary ones. It means that the whole nonlinear system (47) and (48) can be treated by the dressing method.

Let us fix $N_{\max}^{(c)}=1$ and show that the appropriate $N_{\max}^{(r)}=\infty$. In fact, for each particular n one can solve the system (65)–(67) for the functions $f_{n1}^{(j)}$, $j=2,3,4$. It means that f- and g-functions belong to the manifolds $\mathbf{F}_{1\infty}^{(i)}$ and $\mathbf{G}_{11}^{(i)}$ with arbitrary functions $g_1^{(i)}$ $(i=1,2)$, $f_{n1}^{(1)}$, $f_{n2}^{(j)}$ $(j=3,4)$, $f_{n3}^{(j)}$ $(j=4)$, $n=1,2,\ldots$.

Similarly, the system (65)–(67) is consistent for $N^{(c)}=2$ (*step 2*). In fact, in this case $g_m^{(j)}$ $(m=1,2)$ can be taken as arbitrary functions of $\mathbf{x}$. Then for each particular value of the parameter n the whole system is the linear system of six PDEs for seven functions $f_{nk}^{(j)}$, $(jk)=(1,1),(2,1),(3,1),(3,2),(4,1),(4,2),(4,3)$. One of these functions (say $f_{n1}^{(4)}$) can be arbitrary. So, each of the equations (65)–(67) is a PDE whose solution depends on the arbitrary functions $g_m^{(j)}$ $(m=1,2)$ and $f_{n1}^{(4)}$. This means that $N_{\max}^{(r)}=\infty$. From this we conclude that g-functions form manifolds $\mathbf{G}_{22}^{(i)}$, while f-functions form manifolds $\mathbf{F}_{1\infty}^{(i)}$.

The analysis of the case $N^{(c)}=3$ leads to the *nonlinear* four-dimensional PDE on f- and g-functions.

Let us consider the set of particular solutions in more detail, related with one of the representations (26) or (27) of the f- and g-functions (*step 3*). We take the representation (26), which reads in our case

$$f_{nm}^{(i)}=a_{nm}^{(i)}e^{-k_nx_1-k_nx_2-k_n^2x_3-k_n^3x_4}, \tag{68}$$

$$g_m^{(i)}=\int b_m^{(i)}(\omega_{m1},\omega_{m2},\omega_{m3},\omega_{m4})e^{\omega_{m1}x_1+\omega_{m2}x_2+\omega_{m3}x_3+\omega_{m4}x_4}\,d\omega_{m1}d\omega_{m2}d\omega_{m3}d\omega_{m4}. \tag{69}$$

This representation reduces the system (65)–(67) into the system of algebraic equations. Below we discuss particular solutions to the nonlinear PDEs (47) and (48) with *reductions 1–4*.

Consider the system (51) and (52) associated with *reduction 1*. The equations (65)–(67) become of the form

$$a_{n1}^{(1)}b_m^{(1)}(k_n-\omega_{m2})+a_{n1}^{(2)}b_m^{(2)}(\omega_{m1}-k_n)=0, \tag{70}$$

$$a_{n1}^{(1)}(k_n^2-\omega_{m3})+(a_{n1}^{(3)}+a_{n2}^{(3)}\omega_{m1})(\omega_{m1}-k_n)=0, \tag{71}$$

$$a_{n1}^{(2)}(k_n^3-\omega_{m4})+(a_{n1}^{(4)}+a_{n2}^{(4)}\omega_{m2}+a_{n3}^{(4)}\omega_{m2}^2)(\omega_{m2}-k_n)=0. \tag{72}$$

The following families of particular solutions are available:

(1) (*Criteria*). If $N^{(c)}=N^{(r)}=1$ in (70)–(72), the system is resolvable for $b_1^{(2)}$, ω_{13}, and ω_{14}, so that *f*- and *g*-functions belong to the manifolds $\mathbf{F}_{11}^{(i)}$ and $\mathbf{G}_{11}^{(i)}$, respectively, and (69) becomes of the form

$$g_1^{(i)}=\int b_1^{(i)}(\omega_{11},\omega_{12})e^{\omega_{11}x_1+\omega_{12}x_2+\omega_{13}x_3+\omega_{14}x_4}\,d\omega_{11}d\omega_{12}, \tag{73}$$

where ω_{13} and ω_{14} are functions of ω_{11} and ω_{12}.

(2) Let us take the system (70)–(72) with $n=1$ ($N_{\min}^{(r)}=1$) to fix relations among the parameters $b_m^{(j)}$ ($j=1,2$), ω_{mk} ($k=1,2,3,4$):

$$b_m^{(2)}=\frac{a_{11}^{(1)}b_m^{(1)}(k_1-\omega_{m2})}{a_{11}^{(2)}(k_1-\omega_{m1})}, \tag{74}$$

$$\omega_{m3}=(k_1^2a_{11}^{(1)}-k_1a_{11}^{(3)}+(a_{11}^{(3)}-k_1a_{12}^{(3)})\omega_{m1}+a_{12}^{(3)}\omega_{m1}^2)/a_{11}^{(1)}, \tag{75}$$

$$\omega_{m4}=(k_1^3a_{11}^{(2)}-k_1a_{11}^{(4)}+(a_{11}^{(4)}-k_1a_{12}^{(4)})\omega_{m2}+(a_{12}^{(4)}-k_1a_{13}^{(4)})\omega_{m2}^2+a_{13}^{(4)}\omega_{m2}^3)/a_{11}^{(2)}. \tag{76}$$

Here ω_{m1}, ω_{m2} are integration parameters in Fourier representation (73), which means that $N_{\min}^{(c)}=1$ and $N_{\max}^{(c)}=\infty$. One can check that the system (70)–(72) does not have solutions with different $\mathbf{k}_n\neq\mathbf{k}_1$, i.e., $N_{\max}^{(r)}=1$. So, *f*- and *g*-functions are collected in the manifolds $\mathbf{F}_{11}^{(i)}$ and $\mathbf{G}_{1\infty}^{(i)}$, respectively.

(3) Consider (70)–(72) with $n=1,2$ ($N_{\min}^{(r)}=2$) to express $b_m^{(2)}$, ω_{mj}, $j=1,2,3$, through ω_{m1} and $b_m^{(1)}$. Then along with (74)–(76) one has from the equation (70)

$$\omega_{m2}=\frac{k_1k_2(a_{21}^{(1)}a_{11}^{(2)}-a_{11}^{(1)}a_{21}^{(2)})+(q_1a_{11}^{(1)}a_{21}^{(2)}-q_2a_{21}^{(1)}a_{11}^{(2)})\omega_{m1}}{(q_1-\omega_{m1})a_{21}^{(1)}a_{11}^{(2)}-(q_2-\omega_{m1})a_{11}^{(1)}a_{21}^{(2)}}, \tag{77}$$

from the equation (71)

$$a_{12}^{(3)}=((k_1+k_2)a_{11}^{(1)}-a_{11}^{(3)})/k_2, \tag{78}$$

$$a_{22}^{(3)}=\frac{a_{21}^{(1)}}{a_{11}^{(1)}}a_{12}^{(3)}, \tag{79}$$

$$a_{21}^{(3)}=\frac{a_{21}^{(1)}}{k_2 a_{11}^{(1)}}((k_2^2-k_1^2)a_{11}^{(1)}+k_1 a_{11}^{(3)}), \tag{80}$$

and from the equation (72)

$$a_{13}^{(4)}=\frac{1}{k_2^2}(a_{11}^{(2)}(k_1^2+k_1k_2+k_2^2)-a_{11}^{(4)}-k_2 a_{12}^{(4)}), \tag{81}$$

$$a_{23}^{(4)}=a_{21}^{(2)}a_{13}^{(4)}/a_{11}^{(2)}, \tag{82}$$

$$a_{22}^{(4)}=(a_{21}^{(2)}a_{13}^{(4)}(k_2-k_1)+a_{21}^{(2)}a_{12}^{(4)})/a_{11}^{(2)}, \tag{83}$$

$$a_{21}^{(4)}=a_{21}^{(2)}(a_{11}^{(4)}+(k_2-k_1)a_{12}^{(4)}+a_{13}^{(4)}k_2(k_2-k_1))/a_{11}^{(2)}. \tag{84}$$

One can check that the system (70)–(72) together with formulas (74)–(84) has no solutions with $\mathbf{k}_n\neq\mathbf{k}_1,\mathbf{k}_2$. This means that $N_{\min}^{(r)}=N_{\max}^{(r)}=2$, $N_{\min}^{(c)}=1$, $N_{\max}^{(c)}=\infty$, *f*- and *g*-functions belong to the manifolds $\mathbf{F}_{22}^{(i)}$ and $\mathbf{G}_{1\infty}^{(i)}$, and ω_{m1} is an integration parameter in Fourier representation of *g*-functions:

$$g_m^{(i)}=\int b_m^{(i)}(\omega_{m1})e^{\omega_{m1}x_1+\omega_{m2}x_2+\omega_{m3}x_3+\omega_{m4}x_4}\,d\omega_{m1}. \tag{85}$$

(4) Consider Eqs. (70)–(72) with $n=1,2,3$ to fix the parameters $b_m^{(2)}$, ω_{mj}, $j=1,2,3,4$. One gets

$$\begin{aligned}\omega_{m1}=&(k_1k_2a_{31}^{(1)}(a_{21}^{(1)}a_{11}^{(2)}-a_{11}^{(1)}a_{21}^{(2)})+k_1k_3a_{21}^{(1)}(a_{11}^{(1)}a_{31}^{(2)}-a_{31}^{(1)}a_{11}^{(2)})+k_2k_3a_{11}^{(1)}(a_{31}^{(1)}a_{21}^{(2)}\\&-a_{21}^{(1)}a_{31}^{(2)}))(a_{21}^{(1)}a_{31}^{(1)}a_{11}^{(2)}(q_2-q_3)+a_{11}^{(1)}a_{31}^{(1)}a_{21}^{(2)}(q_3-q_1)+a_{11}^{(1)}a_{21}^{(1)}a_{31}^{(2)}(q_1-q_2))^{-1}\end{aligned} \tag{86}$$

along with (74)–(77). Then the equations (70)–(72) with $n>3$ admit an infinite number of solutions, parametrized, for example, by $a_{n1}^{(1)}$, k_n. The dimensions $N_{\min}^{(c)}=N_{\max}^{(c)}=1$, $N_{\min}^{(r)}=3$, $N_{\max}^{(r)}=\infty$ and integration in (85) disappears:

$$g_m^{(i)}=b_m^{(i)}e^{\omega_{m1}x_1+\omega_{m2}x_2+\omega_{m3}x_3+\omega_{m4}x_4}. \tag{87}$$

Here *f*- and *g*-functions belong to the manifolds $\mathbf{F}_{3\infty}^{(i)}$ and $\mathbf{G}_{11}^{(i)}$. In this case the representation (68) for *f*-functions can be replaced by the Fourier integral [see (27)].

Analogous families of particular solutions are available for the nonlinear systems (55) and (56), and (58) and (59) related to *reductions 2* and *3*, respectively (which mean appropriate reductions on the parameters $a_{nk}^{(i)}$).

Under *reduction 2* one has

$$\begin{gathered}a_{n1}^{(1)}=a_n^{(1)},\quad a_{n1}^{(2)}=a_n^{(2)},\quad a_{n1}^{(3)}=a_n^{(3)}k_n,\quad a_{n2}^{(3)}=a_n^{(3)},\\a_{n1}^{(4)}=a_n^{(4)}k_n^2,\quad a_{n2}^{(4)}=a_n^{(4)}k_n,\quad a_{n3}^{(4)}=a_n^{(4)}.\end{gathered} \tag{88}$$

The system (70)–(72) becomes of the form

$$a_n^{(1)}b_m^{(1)}(k_n-\omega_{m2})+a_n^{(2)}b_m^{(2)}(\omega_{m1}-k_n)=0, \tag{89}$$

$$a_n^{(1)}(k_n^2-\omega_{m3})+a_n^{(3)}(\omega_{m1}^2-k_n^2)=0, \tag{90}$$

$$a_n^{(2)}(k_n^3-\omega_{m4})+a_n^{(4)}(\omega_{m2}^3-k_n^3)=0. \tag{91}$$

Reduction 3 gives

$$a_n^{(3)}=a_n^{(1)}, \quad a_n^{(4)}=a_n^{(2)} \tag{92}$$

and one has

$$a_n^{(1)}b_m^{(1)}(k_n-\omega_{m2})+a_n^{(2)}b_m^{(2)}(\omega_{m1}-k_n)=0, \tag{93}$$

$$\omega_{m1}^2-\omega_{m3}=0, \quad \omega_{m2}^3-\omega_{m4}=0 \tag{94}$$

instead of Eqs. (89)–(91).

Reduction 4 ($a_n^{(1)}=a_n^{(2)}$) keeps Eq. (94) unchanged and reduces Eq. (93) into the following one:

$$b_m^{(1)}(k_n-\omega_{m2})+b_m^{(2)}(\omega_{m1}-k_n)=0, \tag{95}$$

which has been considered in Ref. 13. It admits the family of solutions with $N_{\min}^{(c)}=N_{\max}^{(c)}=1$, $N_{\min}^{(r)}=1$, $N_{\max}^{(r)}=\infty$, where ω_{m1}, ω_{m2} are integration variables in (69). *f*- and *g*-functions are collected in the manifolds $\mathbf{F}_{11}^{(i)}$ and $\mathbf{G}_{1\infty}^{(i)}$.

Finally, *reduction 5* assumes $b_m^{(1)}=b_m^{(2)}$, $\omega_{m1}=\omega_{m2}$ and reduces the system of nonlinear PDEs (63) into the completely integrable equation mKP (64).

IV. RELATION BETWEEN DIFFERENT INTEGRABLE HIERARCHIES

The dressing method based on the algebraic system (1) allows one to establish the relations between solutions of different integrable hierarchies. To demonstrate this let us consider two sets of parameters $\mathbf{x}=(x_1,\ldots)$ and $\mathbf{y}=(y_1,\ldots)$ which are independent variables in two different integrable hierarchies of nonlinear PDEs. These parameters are introduced by the system which is similar to the system (5):

$$\partial_{x_i}\mathbf{R}=\sum_{k=1}^{N_{x_i}}\mathbf{f}^{(x_i,k)}\mathbf{g}^{(k,x_i)}, \quad \partial_{y_i}\mathbf{R}=\sum_{k=1}^{N_{y_i}}\mathbf{f}^{(y_i,k)}\mathbf{g}^{(k,y_i)}, \tag{96}$$

$$\mathbf{f}^{z_i,k}=[f_{1k}^{(z_i)}\cdots f_{N^{(r)}k}^{(z_i)}]^T, \quad \mathbf{g}^{k,z_i}=[g_{k1}^{(z_i)}\cdots g_{kN^{(c)}}^{(z_i)}], \tag{97}$$

where z_i is either x_i or y_i. Since each of the equations (96) serves an integrable system, the compatibility conditions $(\partial_{x_ix_j}-\partial_{x_jx_i})\mathbf{R}=0$ and $(\partial_{y_iy_j}-\partial_{y_jy_i})\mathbf{R}=0$ are satisfied so that the only compatibility condition which should be considered is the following one [see note above the Eq. (19)]:

$$(\partial_{x_1y_1}-\partial_{y_1x_1})\mathbf{R}=0. \tag{98}$$

The equation (98) gives rise to the relations among *f*- and *g*-functions.

Let

$$M_n^{(1)}\psi=0, \quad M_m^{(2)}\psi=0, \quad n=1,..., \quad m=1,..., \quad \psi=[\psi_1\ldots\psi_{N^{(c)}}] \tag{99}$$

be the linear overdetermined systems related with two hierarchies pointed out earlier. The set of functions $\mathbf{U}^{(1)}=\{U_{n_{1\ldots}}^{(1ik)}=\psi\mathbf{C}(\Pi_s\partial_{x_s}^{n_s})\mathbf{f}^{(x_i,k)}\}$ satisfies the first hierarchy of nonlinear equations, while the set of functions $\mathbf{U}^{(2)}=\{U_{n_{1\ldots}}^{(2ik)}=\psi\mathbf{C}(\Pi_s\partial_{y_s}^{n_s})\mathbf{f}^{(y_i,k)}\}$ satisfies the second hierarchy of nonlinear equations. The relation between these two hierarchies is described by the nonlinear system on the ''mixed'' functions $\mathbf{U}=\{U_{n_{1\ldots}}^{(12ik)},U_{n_{1\ldots}}^{(21ik)}\}$, where

$$U^{(12ik)}_{n_1,\dots,m_1,\dots}=\psi\mathbf{C}\left(\prod_s \partial^{n_s}_{x_s}\right)\left(\prod_r \partial^{m_r}_{y_r}\right)\mathbf{f}^{(x_i,k)},\quad U^{(21ik)}_{n_1,\dots,m_1,\dots}=\psi\mathbf{C}\left(\prod_s \partial^{n_s}_{x_s}\right)\left(\prod_r \partial^{m_r}_{y_r}\right)\mathbf{f}^{(y_i,k)}.$$

As an example let us consider two different mKP hierarchies, associated with two different sets of independent variables: $\mathbf{x}=(x_1,\dots)$ and $\mathbf{y}=(y_1,\dots)$. The dependence on these variables is introduced by the following equations:

$$\partial_{x_1}\mathbf{R}=\mathbf{f}^{(1)}\mathbf{g}^{(1)},\quad \partial_{x_2}\mathbf{R}=\mathbf{f}^{(1)}\partial_{x_1}\mathbf{g}^{(1)}-\partial_{x_1}\mathbf{f}^{(1)}\mathbf{g}^{(1)}, \tag{100}$$

$$\partial_{x_3}\mathbf{R}=\mathbf{f}^{(1)}\partial^2_{x_1}\mathbf{g}^{(1)}-\partial_{x_1}\mathbf{f}^{(1)}\partial_{x_1}\mathbf{g}^{(1)}+\partial^2_{x_1}\mathbf{f}^{(1)}\mathbf{g}^{(1)}, \tag{101}$$

$$\partial_{y_1}\mathbf{R}=\mathbf{f}^{(2)}\mathbf{g}^{(2)},\quad \partial_{y_2}\mathbf{R}=\mathbf{f}^{(2)}\partial_{y_1}\mathbf{g}^{(2)}-\partial_{y_1}\mathbf{f}^{(2)}\mathbf{g}^{(2)}, \tag{102}$$

$$\partial_{y_3}\mathbf{R}=\mathbf{f}^{(2)}\partial^2_{y_1}\mathbf{g}^{(2)}-\partial_{y_1}\mathbf{f}^{(2)}\partial_{y_1}\mathbf{g}^{(2)}+\partial^2_{y_1}\mathbf{f}^{(2)}\mathbf{g}^{(2)}, \tag{103}$$

$$\partial_{x_j}\mathbf{g}^{(1)}=\partial^j_{x_1}\mathbf{g}^{(1)},\quad \partial_{x_j}\mathbf{f}^{(1)}=(-1)^j\partial^j_{x_1}\mathbf{f}^{(1)}, \tag{104}$$

$$\partial_{y_j}\mathbf{g}^{(2)}=\partial^j_{y_1}\mathbf{g}^{(2)},\quad \partial_{y_j}\mathbf{f}^{(2)}=(-1)^j\partial^j_{y_1}\mathbf{f}^{(2)}, \tag{105}$$

$$\mathbf{f}^{(i)}=[f^{(i)}_1\cdots f^{(i)}_{N^{(r)}}]^T,\quad \mathbf{g}^{(i)}=[g^{(i)}_1\cdots g^{(i)}_{N^{(c)}}],\quad i=1,2. \tag{106}$$

The compatibility condition (98) has the form

$$\partial_{y_1}(\mathbf{f}^{(1)}\mathbf{g}^{(1)})=\partial_{x_1}(\mathbf{f}^{(2)}\mathbf{g}^{(2)}). \tag{107}$$

The investigation of this condition is analogous to the investigation of the conditions (65)–(67). We do not represent it here. The linear system associated with parameters x_1,x_2,x_3 and y_1,y_2,y_3 follows:

$$\partial_{x_2}\psi-\partial^2_{x_1}\psi+V^{(1)}_1\partial_{x_1}\psi=0, \tag{108}$$

$$\partial_{x_3}\psi-\partial^3_{x_1}\psi+W^{(1)}_1\partial^2_{x_1}\psi+W^{(1)}_2\partial_{x_1}\psi=0, \tag{109}$$

$$\partial_{y_2}\psi-\partial^2_{y_1}\psi+V^{(2)}_1\partial_{y_1}\psi=0, \tag{110}$$

$$\partial_{y_3}\psi-\partial^3_{y_1}\psi+W^{(2)}_1\partial^2_{y_1}\psi+W^{(2)}_2\partial_{y_1}\psi=0, \tag{111}$$

where

$$V^{(1)}_1=2\partial_{x_1}U^{(1)}_{0,0}/U^{(1)}_{0,0},\quad W^{(1)}_1=3\partial_{x_1}U^{(1)}_{0,0}/U^{(1)}_{0,0}, \tag{112}$$

$$W^{(1)}_2=(3\partial^2_{x_1}U^{(1)}_{0,0}-3\partial_{x_1}U^{(1)}_{1,0}-W^{(1)}_1(2\partial_{x_1}U^{(1)}_{0,0,}-U^{(1)}_{1,0}))/U^{(1)}_{0,0} \tag{113}$$

$$V^{(2)}_1=2\partial_{y_1}U^{(2)}_{0,0}/U_{0,0},\quad W^{(2)}_1=3\partial_{y_1}U^{(2)}_{0,0}/U^{(2)}_{0,0}, \tag{114}$$

$$W^{(2)}_2=(3\partial^2_{y_1}U^{(2)}_{0,0}-3\partial_{y_1}U^{(2)}_{0,1}-W^{(2)}_1(2\partial_{y_1}U^{(2)}_{0,0}-U^{(2)}_{0,1}))/U^{(2)}_{0,0}, \tag{115}$$

$$U^{(j)}_{n,m}=\psi\mathbf{C}\partial^n_{x_1}\partial^m_{y_1}\mathbf{f}^{(j)},\quad j=1,2.$$

The system of nonlinear PDEs, which relates two hierarchies, results from the equations (108) and (110) if one multiplies them by the vectors $\mathbf{C}\partial_{x_1}^n\partial_{y_1}^m\mathbf{f}^{(i)}$ ($\mathbf{f}^{(i)}=[f_1^{(i)},\ldots,f_{N^{(r)}}^{(i)}]^T$, $i=1,2$):

$$\partial_{x_2}U_{n,m}^{(i)}-\partial_{x_1}^2U_{n,m}^{(i)}+2\partial_{x_1}U_{n+1,m}^{(i)}+V_1^{(1)}(\partial_{x_1}U_{n,m}^{(i)}-U_{n+1,m}^{(i)})=0,\quad n=0,\quad m=0,1, \tag{116}$$

$$\partial_{y_2}U_{n,m}^{(i)}-\partial_{y_1}^2U_{n,m}^{(i)}+2\partial_{y_1}U_{n,m+1}^{(i)}+V_1^{(2)}(\partial_{y_1}U_{n,m}^{(i)}-U_{n+1,m}^{(i)})=0,\quad n=0,1,\quad m=0. \tag{117}$$

Possible reductions are the following ones,

$$\mathbf{f}^{(1)}=\mathbf{f}^{(2)},\quad \text{or}\quad U_{n,m}^{(1)}=U_{n,m}^{(2)}, \tag{118}$$

and reductions which establish the relation between the discrete parameters n and m. For example, the reduction

$$\partial_{y_1}\mathbf{f}^{(i)}=\partial_{x_1}\mathbf{f}^{(i)} \tag{119}$$

eliminates one of the discrete parameters in the system (116) and (117).

V. POSSIBLE GENERALIZATIONS OF THE DRESSING METHOD

We give some remarks about two generalizations of the algorithm represented in this paper.

(1) Similarly to the $\bar{\partial}$-problem (2), which admits different normalization functions η,[6] the algebraic system (1) also admits different functions η on the right-hand side. For example, the algebraic system (1) can be replaced with the following one: $L(\psi^{(nm)})=\mathbf{g}^{(nm)}$. Generalization of KP is an example of the related system of nonlinear PDEs (see the Appendix).

(2) (Discrete version of the matrix $\bar{\partial}$-problem.[7]) Instead of the scalar system of $N^{(c)}$ equations (1), one can take matrix $K_1\times K_2$ algebraic system of $N^{(c)}$ equations (or tensor equation). In this case each entry of the matrices $\mathbf{C}$ and $\mathbf{R}$ is represented by $K_1\times K$ (K is an arbitrary integer) and $K\times K_2$ matrices, respectively, and the system (5) which introduces the independent variables $\mathbf{x}$ reads: $\partial_i\mathbf{R}_{nm}=\Sigma_{k=1}^{N_i}\mathbf{f}_{nk}^{(i)}\mathbf{g}_{km}^{(i)}$, $(n=1,\ldots,N^{(r)},\ m=1,\ldots,N^{(c)})$, where $\mathbf{f}_{nk}^{(i)}$ are $K\times K_1$ and $\mathbf{g}_{km}^{(i)}$ are $K_1\times K_2$ matrices for all possible values of the indexes i,k,n,m. All scalar equations of the previous sections become the $K_1\times K_2$ matrix equations. This generalization is beyond the scope of this article.

VI. CONCLUSIONS

The introduced modification of the dressing method is aimed at the construction of new classes of either integrable or nonintegrable equations together with families of particular solutions. The families of particular solutions are parametrized either by the arbitrary functions of independent variables or constant parameters. The maximum possible number of these arbitrary functions (or parameters) can be taken as the characteristic of the related nonlinear system. Another characteristic is the maximum possible dimensions $N^{(r)}$ and/or $N^{(c)}$ of the matrix $\mathbf{R}$ in the algebraic system (1). The introduced nonintegrable generalizations of the integrable systems of nonlinear PDEs can be applied in studies of the physical phenomena in systems with small parameters.

Another question which should be studied is the relation of this method with the Hirota method.[15–18] In both cases one relates the original nonlinear PDEs with the bilinear system of equations [Eqs. (6) in our case]. But in our case f- and g-functions are also subjected to the equations (9) and (18), which put additional restrictions on these functions.

ACKNOWLEDGMENTS

The author thanks Academician V. E. Zakharov and Professor S. V. Manakov for helpful discussions, and the referee for useful comments.

APPENDIX: GENERALIZATION OF KP

In this section we consider the example of the $(2+1)$-dimensional system of nonlinear PDEs, related with the first generalization of the dressing method, mentioned in Sec. V. Namely, let us consider the linear algebraic system of the form

$$L(\psi^{(p)})=\mathbf{g}^{(p)},\quad p=1,2,\quad \psi^{(p)}=[\psi_1^{(p)}\cdots\psi_{N^{(c)}}^{(p)}],\quad \mathbf{g}^{(p)}=[g_1^{(p)}\cdots g_{N^{(c)}}^{(p)}], \tag{A1}$$

with $M=3$. Introduce variables x_1,x_2,x_3 by the following formulas:

$$\begin{gathered}\partial_1\mathbf{R}=\mathbf{f}^{(11)}\mathbf{g}^{(1)},\quad \partial_2\mathbf{R}=\mathbf{f}^{(21)}\mathbf{g}^{(2)}+\mathbf{f}^{(22)}\partial_1\mathbf{g}^{(2)},\\ \partial_3\mathbf{R}=\mathbf{f}^{(31)}\mathbf{g}^{(3)}+\mathbf{f}^{(32)}\partial_1\mathbf{g}^{(3)}+\mathbf{f}^{(33)}\partial_1^2\mathbf{g}^{(3)},\quad \mathbf{f}^{(nk)}=[f_{1k}^{(n)}\cdots g_{N^{(r)}k}^{(n)}]^T.\end{gathered} \tag{A2}$$

The algebraic system (A1) and equations (A2) generate the following set of algebraic systems with different nonhomogeneous parts [compare with Eqs. (11)–(13)]:

$$L(\partial_1\psi^{(p)})=U_{0,0,0}^{(p11)}\mathbf{g}^{(1)}+\partial_1\mathbf{g}^{(p)}, \tag{A3}$$

$$L(\partial_1^2\psi^{(p)})=(2\partial_1U_{0,0,0}^{(p11)}-U_{1,0,0}^{(p11)})\mathbf{g}^{(1)}+U_{0,0,0}^{(p11)}\partial_1\mathbf{g}^{(1)}+\partial_1^2\mathbf{g}^{(p)}, \tag{A4}$$

$$\begin{aligned}L(\partial_1^3\psi^{(p)})=&(3\partial_1^2U_{0,0,0}^{(p11)}-3\partial_1U_{1,0,0}^{(p11)}+U_{2,0,0}^{(p11)})\mathbf{g}^{(1)}+(3\partial_1U_{0,0,0}^{(p11)}-U_{1,0,0}^{(p11)})\partial_1\mathbf{g}^{(1)}+U_{0,0,0}^{(p11)}\partial_1^2\mathbf{g}^{(1)}\\&+\partial_1^3\mathbf{g}^{(p)},\end{aligned} \tag{A5}$$

$$L(\partial_2\psi^{(p)})=U_{0,0,0}^{(p21)}\mathbf{g}^{(2)}+U_{0,0,0}^{(p22)}\partial_1\mathbf{g}^{(2)}+\partial_1^2\mathbf{g}^{(p)}, \tag{A6}$$

$$L(\partial_3\psi^{(p)})=U_{0,0,0}^{(p31)}\mathbf{g}^{(3)}+U_{0,0,0}^{(p32)}\partial_1\mathbf{g}^{(3)}+U_{0,0,0}^{(p33)}\partial_1^2\mathbf{g}^{(3)}+\partial_1^3\mathbf{g}^{(p)}, \tag{A7}$$

$$U_{n_1,n_2,n_3}^{pnk}=\psi^{(p)}\mathbf{C}\partial_1^{n_1}\partial_2^{n_2}\partial_3^{n_3}\mathbf{f}^{(nk)}. \tag{A8}$$

By using the set of systems (A1) and (A3)–(A7), one can construct the linear system (15) of PDEs on the functions $\psi^{(p)}$ which has the form

$$\partial_2\psi^{(p)}-\partial_1^2\psi^{(p)}+V_1^{(p)}\partial_1\psi^{(1)}+V_2^{(p)}\partial_1\psi^{(2)}+V_3^{(p)}\psi^{(1)}+V_4^{(p)}\psi^{(2)}=0, \tag{A9}$$

$$\partial_3\psi^{(p)}-\partial_1^3\psi^{(p)}+W_1^{(p)}\partial_1^2\psi^{(1)}+W_2^{(p)}\partial_1^2\psi^{(3)}+W_3^{(p)}\partial_1\psi^{(1)}+W_4^{(p)}\partial_1\psi^{(3)}+W_5^{(p)}\psi^{(1)}+W_6^{(p)}\psi^{(3)}=0, \tag{A10}$$

where V_i and W_i are related with functions $U_{n_1,n_2,n_3}^{(pij)}$ by the following formulas:

$$\begin{gathered}V_1^{(p)}-U_{0,0,0}^{(p11)}=0,\quad V_2^{(p)}+U_{0,0,0}^{(p22)}=0,\\ V_3^{(p)}-(2\partial_1U_{0,0,0}^{(p11)}-U_{1,0,0}^{(p11)})+V_1^{(p)}U_{0,0,0}^{(111)}+V_2^{(p)}U_{0,0,0}^{(211)}=0,\\ V_4^{(p)}+U_{0,0,0}^{(p21)}=0,\quad W_1^{(p)}-U_{0,0,0}^{(p11)}=0,\quad W_2^{(p)}+U_{0,0,0}^{(p33)}=0,\\ W_3^{(p)}-(3\partial_1U_{0,0,0}^{(p11)}-U_{1,0,0}^{(p11)})+W_1^{(p)}U_{0,0,0}^{(111)}+W_2^{(p)}U_{0,0,0}^{(311)}=0,\quad W_4^{(p)}+U_{0,0,0}^{(p32)}=0,\\ W_5^{(p)}-(3\partial_1^2U_{0,0,0}^{(p11)}-3\partial_1U_{0,0,0}^{(p11)}+U_{2,0,0}^{(p11)})+W_1^{(p)}(2\partial_1U_{0,0,0}^{(111)}-U_{1,0,0}^{(111)})+W_2^{(p)}(2\partial_1U_{0,0,0}^{(311)}-U_{1,0,0}^{(311)})\\ +W_3^{(p)}U_{0,0,0}^{(111)}+W_4^{(p)}U_{0,0,0}^{(311)}=0,\quad W_6^{(p)}+U_{0,0,0}^{(p31)}=0.\end{gathered} \tag{A11}$$

The appropriate nonlinear system on the functions $U^{pnk}_{n_1,n_2,n_3}$ (A8) can be received by multiplying each equation of the above linear system (A9) and (A10) (which are $1\times N^{(c)}$ matrix equations) by the $N^{(c)}\times 1$ vector $\mathbf{C}\partial_1^{n_1}\partial_2^{n_2}\partial_3^{n_3}\mathbf{f}^{(nk)}$. One obtains

$$\partial_2 U^{(pkn)}_{n_1,n_2,n_3}-U^{(pkn)}_{n_1,n_2+1,n_3}-\partial_1^2 U^{(pkn)}_{n_1,n_2,n_3}+2\partial_1 U^{(pkn)}_{n_1+1,n_2,n_3}-U^{(pkn)}_{n_1+2,n_2,n_3}+V_1^{(p)}(\partial_1 U^{(1kn)}_{n_1,n_2,n_3}-U^{(1kn)}_{n_1+1,n_2,n_3})+V_2^{(p)}(\partial_1 U^{(2kn)}_{n_1,n_2,n_3}-U^{(2kn)}_{n_1+1,n_2,n_3})+V_3^{(p)}U^{(1kn)}_{n_1,n_2,n_3}+V_4^{(p)}U^{(2kn)}_{n_1,n_2,n_3}=0, \tag{A12}$$

$$\partial_3 U^{(pkn)}_{n_1,n_2,n_3}-U^{(pkn)}_{n_1,n_2,n_3+1}-\partial_1^3 U^{(pkn)}_{n_1,n_2,n_3}+3\partial_1^2 U^{(pkn)}_{n_1+1,n_2,n_3}-3\partial_1 U^{(pkn)}_{n_1+2,n_2,n_3}+U^{(pkn)}_{n_1+3,n_2,n_3}+W_1^{(p)}\times(\partial_1^2 U^{(1kn)}_{n_1,n_2,n_3}-2\partial_1 U^{(1kn)}_{n_1+1,n_2,n_3}+U^{(1kn)}_{n_1+2,n_2,n_3})+W_2^{(p)}(\partial_1^2 U^{(3kn)}_{n_1,n_2,n_3}-2\partial_1 U^{(3kn)}_{n_1+1,n_2,n_3}+U^{(3kn)}_{n_1+2,n_2,n_3})+W_3^{(p)}(\partial_1 U^{(1kn)}_{n_1,n_2,n_3}-U^{(1kn)}_{n_1+1,n_2,n_3})+W_4^{(p)}(\partial_1 U^{(3kn)}_{n_1,n_2,n_3}-U^{(3kn)}_{n_1+1,n_2,n_3})+W_5^{(p)}U^{(1kn)}_{n_1,n_2,n_3}+W_6^{(p)}U^{(3kn)}_{n_1,n_2,n_3}=0, \tag{A13}$$

$$(pkn)=(p11),\ (p31),\ (p32),\ (p4s),\ p=1,2,\ s=1,2,3.$$

This differential-difference system involves three continuous and three discrete parameters. To reduce it to the system of pure nonlinear PDEs one needs to put some additional relations among functions $f^{(j)}_{nk}$. For example, consider the following *Reduction 1*:

$$\partial_2\mathbf{f}^{(jk)}=-\partial_1^2\mathbf{f}^{(jk)},\quad \partial_3\mathbf{f}^{(jk)}=\partial_1^3\mathbf{f}^{(jk)}, \tag{A14}$$

$$\mathbf{f}^{(21)}=-\partial_1\mathbf{f}^{(22)},\quad \mathbf{f}^{(32)}=-\partial_1\mathbf{f}^{(33)},\quad \mathbf{f}^{(31)}=\partial_1^2\mathbf{f}^{(33)}, \tag{A15}$$

or

$$U^{(pkn)}_{n_1,n_2,n_3}=(-1)^{n_2}U^{(pkn)}_{n_1+2n_2+3n_3,0,0}\equiv(-1)^{n_2}U^{(pkn)}_{n_1+2n_2+3n_3}, \tag{A16}$$

$$U_k^{(p11)}\equiv U_k^{(p1)},\quad U_k^{(p21)}=-U_{k+1}^{(p22)}\equiv -U_{k+1}^{(p2)}, \tag{A17}$$

$$U_k^{(p32)}=-U_{k+1}^{(p33)}\equiv -U_{k+1}^{(p3)},\quad U_k^{(p31)}=U_{k+2}^{(p33)}\equiv U_{k+2}^{(p3)}. \tag{A18}$$

Then the system [(A12),(A13)] becomes of the form

$$\partial_2 U_k^{pj}-\partial_1^2 U_k^{pj}+2\partial_1 U_{k+1}^{pj}+U_0^{(p1)}(\partial_1 U_k^{(1j)}-U_{k+1}^{(1j)})-U_0^{(p2)}(\partial_1 U_k^{(2j)}-U_{k+1}^{(2j)}) \tag{A19}$$

$$+(2\partial_1 U_0^{(p1)}-U_1^{(p1)}-U_0^{(p1)}U_0^{(11)}+U_0^{(p2)}U_0^{(21)})U_k^{(1j)}+U_1^{(p2)}U_k^{(2j)}=0,\quad k=0,1,$$

$$\partial_3 U_k^{(pj)}-(\partial_1^3 U_k^{(pj)}-3\partial_1^2 U_{k+1}^{(pj)}+3\partial_1 U_{k+2}^{(pj)})+W_1^{(p)}(\partial_1^2 U_k^{(1j)}-2\partial_1 U_{k+1}^{(1j)}+U_{k+2}^{(1j)})+W_2^{(p)}(\partial_1^2 U_k^{(3j)}-2\partial_1 U_{k+1}^{(3j)}+U_{k+2}^{(3j)}) \tag{A20}$$

$$+W_3^{(p)}(\partial_1 U_k^{(1j)}-U_{k+1}^{(1j)})+W_4^{(p)}(\partial_1 U_k^{(3j)}-U_{k+1}^{(3j)})+W_5^{(p)}U_k^{(1j)}+W_6^{(p)}U_k^{(3j)}=0,$$

$$p=1,2,\quad j=1,2,3,$$

$$W_1^{(p)}=U_0^{(p1)},\quad W_2^{(p)}=-U_0^{(p3)},$$

$$W_3^{(p)}=3\partial_1 U_0^{(p1)}-U_1^{(p1)}-U_0^{(p1)}U_0^{(11)}+U_0^{(p3)}U_0^{(31)},\quad W_4^{(p)}=U_1^{(p3)},$$

$$W_5^{(p)}=3\partial_1^2 U_0^{(p1)}-3\partial_1 U_1^{(p1)}+U_2^{(p1)}-U_0^{(p1)}(2\partial_1 U_0^{(11)}-U_1^{(11)})$$

$$+U_0^{(p3)}(2\partial_1 U_0^{(31)}-U_1^{(31)})-(3\partial_1 U_0^{(p1)}-U_1^{(p1)}-U_0^{(p1)}U_0^{(11)}$$
$$+U_0^{(p3)}U_0^{(31)})U_0^{(11)}-U_1^{(p3)}U_0^{(31)},\quad W_6^{(P)}=-U_2^{(p3)}.$$

Using another *Reduction 2*

$$\mathbf{f}^{(11)}=\mathbf{f}^{(22)}=\mathbf{f}^{(33)}\equiv\mathbf{f},\quad \mathbf{g}^{(11)}=\mathbf{g}^{(21)}=\mathbf{g}^{(31)}\equiv\mathbf{g},\quad \text{or } U_k^{(pj)}\equiv U_k \tag{A21}$$

one reduces the nonlinear system [(A19),(A20)] into KP on the function $u=\partial_1 U_0$:

$$u_{x_3}-\tfrac{1}{4}u_{x_1x_1x_1}+3uu_{x_1}-\tfrac{3}{4}\partial_{x_1}^{-1}u_{x_2x_2}=0. \tag{A22}$$

Different *Reduction 3*

$$\mathbf{f}^{(11)}=\mathbf{f}^{(33)}=-\mathbf{f}^{(22)}\equiv\mathbf{f},\quad \mathbf{g}^{(11)}=\mathbf{g}^{(21)}=\mathbf{g}^{(31)}\equiv\mathbf{g} \tag{A23}$$

reduces the nonlinear system [(A19),(A20)] into the following nonintegrable one

$$\partial_2 U_k-\partial_1^2 U_k+2\partial_1 U_{k+1}+2U_0(\partial_0 U_k-U_{k+1}) \tag{A24}$$

$$+2(\partial_1 U_0-U_1-U_0U_0)U_k=0,\quad k=0,1 \tag{A25}$$

$$\partial_3 U_0-\partial_1^3 U_0+3\partial_1^2 U_1-3\partial_1 U_2+3\partial_1 U_0(\partial_1 U_0-U_1)+3(\partial_1^2 U_0-\partial_1 U_1)U_0-3U_0U_0\partial_1 U_0=0.$$

One can demonstrate that the compatibility condition (6) can be satisfied (at least for $N^{(c)}=N^{(r)=1}$) for all nonlinear equations considered in the Appendix, i.e., the dressing method is applicable to them.

The stationary states of a charged scalar quantum field interacting with a background consisting of both boundaries and a static magnetic field are investigated. Following the development of some general theory, the example of a uniform magnetic field perpendicular to two parallel Dirichlet boundaries is worked through in detail. © *2001 American Institute of Physics.* [DOI: 10.1063/1.1413521]

I. INTRODUCTION

In this paper we investigate the stationary states of a charged scalar quantum field coupled to a static background magnetic field. The study of this problem began many years ago,[1–3] and of course substantial literature has come into existence (see, e.g., Refs. 4–13). Essentially all efforts have been directed toward uniform magnetic fields coupled to charged (spinor and scalar) quantum fields in free, infinite space. There seem to be very few calculations involving quantum fields which are modified by the presence of background objects (i.e., Casimir-type systems) as well as being coupled to background electromagnetic fields. One such study[14] presents a global calculation of the Casimir energy of a charged scalar field confined between parallel boundary planes, and acted on by a uniform magnetic field perpendicular to these planes.

One purpose of the present article is to begin the local investigation of such systems. We present a Schrödinger-picture analysis of a charged scalar field coupled to a general background described by a static potential $V(\mathbf{x})$, as well as to an arbitrary static magnetic field. Then we work through the detailed mathematics of a nontrivial problem with two parallel planar Dirichlet surfaces perpendicular to a uniform magnetic field.

As long as the background magnetic field is not time dependent one is free to assume the background electric field is exactly zero. Then the system has a stable vacuum. Magnetic fields deflect, but do not transfer energy to or from charged particles. No pairs are produced from the vacuum by magnetic fields. Therefore, stationary state methods can be used for an arbitrary arrangement of static boundaries and static background magnetic fields.

The problem of a charged scalar field coupled to a background electric field is far more complex because a sufficiently strong background electric field causes pair production from the vacuum. Consequently the vacuum is unstable and the system is never in equilibrium. Strictly speaking, stationary state methods are not adequate for describing such systems—at least not for following their time evolution. However, the Schrödinger picture provides a nonstationary framework within which one can attempt to deal with the highly nontrivial time evolution of such systems (see e.g., Ref. 15). In a separate paper we intend to pursue this direction of study.

II. CHARGED SCALAR FIELD IN A BACKGROUND MAGNETIC FIELD

A charged scalar field ϕ consists of two real scalar fields $\phi_{1,2}$. We shall write $\phi=(\phi_1+i\,\phi_2)/\sqrt{2}$, where the convenience of the factor $1/\sqrt{2}$ will become apparent later. Most books in

[a)]Electronic mail: aaa2@psu.edu
[b)]Electronic mail: bender@thphys.uni-heidelberg.de

QFT develop the theory of charged scalar fields in terms of the complex field ϕ. The complex field ϕ^* is treated as an independent variable, even though ϕ and ϕ^* satisfy the constraint $(\phi^*)_{cc} = \phi$, cc denoting complex conjugation. While this has certain notational advantages, one encounters notational ambiguities as well. Such ambiguities are eliminated by using the real variables $\phi_{1,2}$ as we shall do in all of our main calculations. However, it will be useful to employ the ϕ, ϕ^* notation as well, particularly when plane wave modes are to be used. Thus we shall change from one notation to the other as convenience dictates.

A. The field representation

The field representation belongs to the Schrödinger picture. One introduces at a specified time (say $t=0$) a complete set of eigenstates $\{|\phi\rangle\}$ of the scalar field operator $\hat{\phi}(\mathbf{x}) \equiv \hat{\phi}(\mathbf{x},0)$,

$$\hat{\phi}(\mathbf{x})|\phi\rangle = \phi(\mathbf{x})|\phi\rangle, \tag{II.1}$$

assuming δ-functional normalization

$$\langle \phi'|\phi\rangle = \delta[\phi' - \phi] = \prod_{\mathbf{x}} \delta(\phi'(\mathbf{x}) - \phi(\mathbf{x})), \tag{II.2}$$

where two-dimensional δ-functions appropriate for complex numbers are understood on the right-hand side.

Then an arbitrary field state $|\Psi(t)\rangle$ can be expressed as a functional integral,

$$|\Psi(t)\rangle = \int [d\phi]\Psi[\phi,t]|\phi\rangle, \tag{II.3}$$

where later more will be said about the functional integration measure. Here the wave functional $\Psi[\phi,t] = \langle\phi|\Psi(t)\rangle$ is the analog of the wave function in quantum mechanics. Specifically, $\Psi[\phi,t]$ is the probability amplitude that, with the field in state $|\Psi(t)\rangle$, a measurement of the field $\hat{\phi}$ everywhere in space at the time t will find the configuration $\phi(\mathbf{x})$.

Already in this statement an awkwardness of the complex variable ϕ has emerged. Not being real, ϕ is not observable; however, $\phi_{1,2}$ are, enabling ϕ to be constructed. Strictly speaking it would be preferable to introduce field configuration states $|\phi_1, \phi_2\rangle$ with

$$\hat{\phi}_{1,2}(\mathbf{x})\,|\phi_1, \phi_2\rangle = \phi_{1,2}(\mathbf{x})|\phi_1, \phi_2\rangle,$$

with δ-functional normalization and the wave functional

$$\Psi[\phi_1, \phi_2, t] = \langle \phi_1, \phi_2|\Psi(t)\rangle.$$

However, these differences are so slight that as a general notation (II.1)–(II.3) seems adequate.

Let us now couple the charged scalar field to a static background gauge potential $A^\mu(\mathbf{x}) = (0,\mathbf{A}(\mathbf{x}))$ representing an arbitrary static background magnetic field $\mathbf{B} = \boldsymbol{\nabla} \times \mathbf{A}$ and vanishing electric field. The Lagrangian density of the system is

$$\mathcal{L} = (D_\mu \phi)^* D^\mu \phi - [m^2 + V(\mathbf{x})]\phi^* \phi, \tag{II.4}$$

where $D^\mu = \partial^\mu - iA^\mu$. Here and throughout this paper A^μ and the magnetic field $\mathbf{B}$ contain the electric charge e. In $\mathcal{L}$ the static potential $V(\mathbf{x}) \geqslant 0$ has been introduced to represent an arbitrary background force of nonelectromagnetic origin acting on the scalar field. The Hamiltonian density corresponding to $\mathcal{L}$ is

$$\mathcal{H} = |\partial_0 \phi|^2 + |\mathbf{D}\phi|^2 + [m^2 + V(\mathbf{x})]|\phi|^2. \tag{II.5}$$

Identifying in the field representation,

$$\Pi(\mathbf{x}) = \partial_0 \phi^*(\mathbf{x}) \to \hat{\Pi}(\mathbf{x}) = -i \frac{\delta}{\delta \phi(\mathbf{x})},$$

$$\Pi^*(\mathbf{x}) = \partial_0 \phi(\mathbf{x}) \to \hat{\Pi}^\dagger = -i \frac{\delta}{\delta \phi^*(\mathbf{x})},$$

and

$$\phi(\mathbf{x}) \to \hat{\phi}(\mathbf{x}) = \phi(\mathbf{x}),$$

the latter statement meaning that $\hat{\phi}(\mathbf{x})$ is simply a multiplicative operator, one obtains the Hamilton operator,

$$\mathbb{H} = \int d\mathbf{x} \left\{ -\frac{\delta^2}{\delta \phi^* \delta \phi} + \phi^* [-\mathbf{D}^2 + m^2 + V]\, \phi \right\}. \tag{II.6}$$

Here $|\mathbf{D}\phi|^2 = -\phi^* \mathbf{D}^2 \phi +$ divergence term is used and the divergence term is discarded. At the level of the Hamiltonian this is allowed, because the divergence term does not influence the equations of motion. However, at the level of densities [e.g., $T_{\mu\nu}(\mathbf{x})$] the same step is not allowed, as will be quite evident in the examples of Sec. III.

Now it is easy to separate $\mathbb{H}$ into a collection of harmonic oscillator (hereafter, HO) Hamiltonians. For this purpose we define a complete, orthonormal set of complex spatial modes $\{\varphi_n(\mathbf{x})\}$ and associated frequencies $\{\omega_n\}$ by the spectral equation,

$$[-\mathbf{D}^2 + V(\mathbf{x})]\varphi_n(\mathbf{x}) = \omega_n^2 \varphi_n(\mathbf{x}). \tag{II.7}$$

Because the operator on the left is Hermitian, the spectrum ω_n^2 on the right is real. Here we are introducing a formal discrete notation. The mode label n represents three sublabels in three spatial dimensions. At least one of these is continuous in infinite space. However, if we make space compact and finite, as we shall do in later calculations, then the notation here is completely appropriate.

Note also that the magnetic vector potential $\mathbf{A}(\mathbf{x})$ and the potential $V(\mathbf{x})$ make their principal contribution to the mathematics in Eq. (II.7). Both $\mathbf{A}(\mathbf{x})$ and $V(\mathbf{x})$ influence the spectral problem (II.7) in their separate ways, and thereby shape the spectral ingredients $\{\varphi_n\}$ and $\{\omega_n\}$ from which observable quantum functions will ultimately be constructed.

Now we expand an arbitrary complex field configuration $\phi(\mathbf{x})$ in terms of the complete set $\{\varphi_n(\mathbf{x})\}$,

$$\phi(\mathbf{x}) = \sum_n \tilde{\phi}_n \varphi_n(\mathbf{x}),$$

$$\tilde{\phi}_n = \int d\mathbf{x} \varphi_n^*(\mathbf{x}) \phi(\mathbf{x}), \tag{II.8}$$

$$\frac{\delta}{\delta \phi(\mathbf{x})} = \sum_n \varphi_n^*(\mathbf{x}) \frac{\partial}{\partial \tilde{\phi}_n},$$

where the variables $\tilde{\phi}_n$ are complex. For immediate use we write

$$\tilde{\phi}_n = (\tilde{\phi}_{1n} + i\tilde{\phi}_{2n})/\sqrt{2},$$

where $\tilde{\phi}_{1n}$, $\tilde{\phi}_{2n}$ are real. Because

$$\int d\mathbf{x}\, \phi^*(\mathbf{x})\phi(\mathbf{x}) = \sum_n \tilde{\phi}_n^* \tilde{\phi}_n = \frac{1}{2}\sum_n (\tilde{\phi}_{1n}^2 + \tilde{\phi}_{2n}^2), \tag{II.9}$$

$$\int d\mathbf{x} \frac{\delta^2}{\delta\phi^*(\mathbf{x})\,\delta\phi(\mathbf{x})} = \sum_n \frac{\partial^2}{\partial\tilde{\phi}_n^* \partial\tilde{\phi}_n} = \frac{1}{2}\sum_n \left(\frac{\partial^2}{\partial\tilde{\phi}_{1n}^2} + \frac{\partial^2}{\partial\tilde{\phi}_{2n}^2} \right), \tag{II.10}$$

the Hamiltonian (II.6) becomes a sum of elementary HO Hamiltonians,

$$\begin{aligned} \mathbb{H} &= \sum_n (\mathbb{H}_{1n} + \mathbb{H}_{2n}), \\ \mathbb{H}_{a\,n} &= \frac{1}{2}\left\{ -\frac{\partial^2}{\partial\tilde{\phi}_{an}^2} + [\omega_n^2 + m^2]\tilde{\phi}_{an}^2 \right\} \quad a = 1,2. \end{aligned} \tag{II.11}$$

Consequently the wave functional $\Psi[\phi,t]$ factorizes

$$\Psi[\phi,t] = \prod_n \psi_{1n}(\tilde{\phi}_{1n},t)\, \psi_{2n}(\tilde{\phi}_{2n},t), \tag{II.12}$$

and the field evolution problem

$$\mathbb{H}\Psi = i\,\partial_t \Psi \tag{II.13}$$

reduces to an infinite set of individual HO problems,

$$\mathbb{H}_{an}\psi_{an}(\tilde{\phi}_{an},t) = i\partial_t \psi_{an}(\tilde{\phi}_{an},t). \tag{II.14}$$

Here $-\infty < \tilde{\phi}_{an} < \infty$ is like a coordinate axis, and $\psi_{an}(\tilde{\phi}_{an},t)$ is a normalized solution of Eq. (II.14). The normalization requirement on ψ_{an} arises from the condition,

$$1 = \langle \Psi(t)|\Psi(t)\rangle = \int [d\phi]\,|\Psi[\phi,t]|^2 = \prod_n \int_{-\infty}^{\infty} \prod_{a=1,2} d\tilde{\phi}_{an} |\psi_{an}(\tilde{\phi}_{an},t)|^2. \tag{II.15}$$

Here we see in more detail what is meant by the functional integration measure. With Eqs. (II.11)–(II.14) we have reached a simple formulation of the time evolution problem $\mathbb{H}|\Psi(t)\rangle = i\partial_t|\Psi(t)\rangle$ of the quantum field in terms of solutions of the HO Eq. (II.14), using real field variables $\tilde{\phi}_{an}$ and complex spatial modes $\varphi_n(\mathbf{x})$ which satisfy Eq. (II.7). In fact, since one knows the solutions of the HO equation (II.14), we have solved the time evolution problem. There still remains the question of selecting, from all possible Hamiltonian eigenstates (II.12), the ones which are eigenstates of the charge operator. To address this problem we now specialize the discussion to stationary field states.

B. Stationary field states

The stationary solutions of the HO Schrödinger equation (II.14) are

$$\psi_{an}(\tilde{\phi}_{an},t) = e^{-i(p_{an}+(1/2))\,\epsilon_n t}\, \chi_{p_{an}}(\sqrt{\epsilon_n}\tilde{\phi}_{an}), \quad \epsilon_n^2 = \omega_n^2 + m^2, \quad p_{an} = 0,1,\ldots, \tag{II.16}$$

where (suppressing subscripts)

$$\chi_p(\sqrt{\epsilon}x)\equiv\left[\frac{1}{2^p p!}\sqrt{\frac{\epsilon}{\pi}}\right]^{1/2} e^{-(1/2)\epsilon x^2} H_p(\sqrt{\epsilon}x), \tag{II.17}$$

and $H_{an}\psi_{an}=(p_{an}+\frac{1}{2})\epsilon_n\psi_{an}$. The $H_p(z)$ are Hermite polynomials satisfying $H_p''-2zH_p'+2pH_p=0$. By inserting the stationary modes (II.16) into the wave functional (II.12) with an arbitrary integer p_{an} for each factor ψ_{an}, one obtains a complete orthonormal basis set of stationary wave functionals for the system, all of these being eigenstates of the Hamiltonian (II.11). Let us give this basis set the shorthand name

$$\Psi(\{p_{an}\})\equiv\text{functional (II.12) with } \psi_{an} \text{ as in Eq. (II.16).} \tag{II.18}$$

Then,

$$\mathbb{H}\Psi(\{p_{an}\})=E(\{p_{an}\})\Psi(\{p_{an}\}), \tag{II.19}$$

with energy eigenvalues

$$E(\{p_{an}\})=\sum_n (p_{1n}+p_{2n}+1)\epsilon_n. \tag{II.20}$$

However, the Hamiltonian eigenstates (II.18) are not eigenstates of the charge operator. To see this we recall that the current operator associated with the Lagrangian (II.4) is

$$j_\mu=\frac{\partial\mathcal{L}}{\partial A^\mu}=i\phi^* D_\mu\phi-i(D_\mu\phi)^*\phi. \tag{II.21}$$

This current density is conserved, $\partial^\mu j_\mu=0$, by virtue of the equation of motion,

$$(D_\mu D^\mu+m^2+V)\phi=0 \tag{II.22}$$

obtained from $\mathcal{L}$. The charge density is therefore

$$j_0=i[\Pi^*\phi^*-\Pi\phi]=\sum_{n,m}\varphi_n(\mathbf{x})\varphi_m^*(\mathbf{x})Q_{nm}, \tag{II.23}$$

where

$$Q_{nm}=\tilde{\phi}_m^*\frac{\partial}{\partial\tilde{\phi}_n^*}-\tilde{\phi}_n\frac{\partial}{\partial\tilde{\phi}_m}=\frac{1}{2}\left[\tilde{\phi}_{1m}\frac{\partial}{\partial\tilde{\phi}_{1n}}-\tilde{\phi}_{1n}\frac{\partial}{\partial\tilde{\phi}_{1m}}+(1\to 2)\right]$$
$$+\frac{i}{2}\left[\tilde{\phi}_{1m}\frac{\partial}{\partial\tilde{\phi}_{2n}}+\tilde{\phi}_{1n}\frac{\partial}{\partial\tilde{\phi}_{2m}}-(1\leftrightarrow 2)\right]. \tag{II.24}$$

The total charge operator is

$$Q=\int d\mathbf{x} j_0(\mathbf{x})=\sum_m Q_{mm}. \tag{II.25}$$

Acting on the wave functional (II.12) it gives

$$Q\,\Psi[\phi,t]=\sum_m Q_{mm}\prod_n \psi_{1n}\psi_{2n}=\sum_m Q_{mm}\psi_{1m}\psi_{2m}\prod_{n\neq m}\psi_{1n}\psi_{2n}, \tag{II.26}$$

where

$$
\begin{aligned}
i\,Q_{mm}\,\psi_{1m}\,\psi_{2m} &= \tilde{\phi}_{2m}\psi'_{1m}\,\psi_{2m} - \tilde{\phi}_{1m}\psi'_{2m}\,\psi_{1m} \\
&= \tilde{\phi}_{2m}\,\partial_{1m}H_{p_{1m}}(\sqrt{\epsilon_m}\tilde{\phi}_{1m})\,H_{p_{2m}}(\sqrt{\epsilon_m}\tilde{\phi}_{2m}) \\
&\quad - \tilde{\phi}_{1m}\,\partial_{2m}H_{p_{2m}}(\sqrt{\epsilon_m}\tilde{\phi}_{2m})\,H_{p_{1m}}(\sqrt{\epsilon_m}\tilde{\phi}_{1m}),
\end{aligned}
\tag{II.27}
$$

with the short-hand notation $\partial_{1m} := \partial/\partial\tilde{\phi}_{1m}$.

Clearly, the only way one can make Eq. (II.26) into an eigenvalue equation is to choose all the $p_{1,2m}=0$, in which case the right-hand side vanishes. This selects the vacuum functional $\Psi_0[\phi,t]$ consisting entirely of factors (II.16) with $p_{an}=0$ as the only wave functional in the basis set (II.18) having definite charge, namely, $Q=0$.

To identify simultaneous eigenstates of the Hamiltonian $\mathbb{H}=\Sigma_n\mathbb{H}_n$ [with $\mathbb{H}_n=\mathbb{H}_{1n}+\mathbb{H}_{2n}$ as in Eq. (II.11)] and the charge operator $Q=\Sigma_n Q_{nn}$ [with Q_{nn} as in Eq. (II.24)] we now focus our attention on the two-dimensional (2D) functional subspace $(\tilde{\phi}_{1n},\tilde{\phi}_{2n})$ associated with a single mode $\varphi_n(\mathbf{x})$. If we arbitrarily introduce a third axis $\tilde{\phi}_{3n}$ perpendicular to the plane $(\tilde{\phi}_{1n},\tilde{\phi}_{2n})$ for the purpose of constructing a fictitious 3D "mode subspace," then obviously

$$
-Q_{nn}=\frac{1}{i}\left(\tilde{\phi}_{1n}\frac{\partial}{\partial\tilde{\phi}_{2n}}-\tilde{\phi}_{2n}\frac{\partial}{\partial\tilde{\phi}_{1n}}\right)=L_{3n}
\tag{II.28}
$$

can be identified with the third component of the angular momentum operator in this subspace. Thus in each mode subspace separately, the task of finding simultaneous eigenstates of $\mathbb{H}$ and Q reduces to the task of identifying simultaneous eigenstates of $\mathbb{H}_n$ and $Q_{nn}=L_{3n}$. The latter is a solved problem in quantum mechanics (see, e.g., Ref. 16, p. 727). We now briefly sketch this solution using the usual coordinate language of quantum mechanics.

In the 2D harmonic oscillator problem, a complete set of normalized stationary eigenstates of $\mathbb{H}=\frac{1}{2}\{-\partial_x^2-\partial_y^2+[\omega^2+m^2](x^2+y^2)\}$ and L_3 is given by[16]

$$
\psi_{pq}=\frac{1}{\sqrt{M!N!}}(a_R^\dagger)^M(a_L^\dagger)^N\psi_{00}\,e^{-i(p+1)\beta^2 t},
\tag{II.29}
$$

where M, N are non-negative integers and $p=M+N$, $q=N-M$,

$$
a_{R,L}^\dagger=\frac{1}{2}\left[\beta(x\pm iy)-\frac{1}{\beta}(\partial_x\pm i\partial_y)\right]=\frac{1}{2}e^{\pm i\theta}\left[\beta r-\frac{1}{\beta}\frac{\partial}{\partial r}\mp\frac{i}{\beta r}\frac{\partial}{\partial\theta}\right],
\tag{II.30}
$$

with $\beta^4=\omega^2+m^2$ and $x=r\cos\theta, y=r\sin\theta$. The ground state is

$$
\psi_{00}=\frac{\beta}{\sqrt{\pi}}e^{-\beta^2r^2/2}\,e^{-i\beta^2 t}
$$

and $a_{R,L}\,\psi_{00}=0$. Because

$$
\mathbb{H}=[a_R^\dagger a_R+a_L^\dagger a_L+1]\,\beta^2
\tag{II.31}
$$

and

$$
L_z=a_R^\dagger a_R-a_L^\dagger a_L
\tag{II.32}
$$

while

$$
[a_R,a_R^\dagger]=[a_L,a_L^\dagger]=1
$$

with other commutators vanishing, one easily verifies

$$\mathbb{H}\psi_{pq}=(p+1)\beta^2\psi_{pq} \tag{II.33}$$

and with $Q:=-L_3$,

$$Q\psi_{pq}=-q\psi_{pq}. \tag{II.34}$$

Note that $-p\leqslant q\leqslant p$ in steps of $\Delta q=2$. Thus for $p=1$ we have states $\psi_{1,\pm 1}$, for $p=2$ the states $\psi_{2,\pm 2}$ and ψ_{20}, for $p=3$ the states $\psi_{3,\pm 3}$ and $\psi_{1,\pm 1}$, and so on. The following general formula can be given (for $N=p$, $M=0$ or $N=0$, $M=p$):

$$\psi_{p,\pm p}=e^{i(p+1)\beta^2 t}\frac{\beta}{\sqrt{\pi p!}}e^{\pm ip\theta}(\beta r)^p e^{-\beta^2 r^2/2}. \tag{II.35}$$

For $|q|<p$ it is more difficult to obtain general formulas. We note that for $N=M=1$,

$$\psi_{2,0}=e^{-i3\beta^2 t}\frac{\beta}{\sqrt{\pi}}[(\beta r)^2-1]e^{-\beta^2 r^2/2}, \tag{II.36}$$

and for $N=2$, $M=1$ or $N=1, M=2$,

$$\psi_{3,\pm 1}=e^{-i4\beta^2 t}e^{\pm i\theta}\frac{\beta^2}{\sqrt{2\pi}}r[(\beta r)^2-2]e^{-\beta^2 r^2/2}. \tag{II.37}$$

Returning to our QFT problem we can now replace the wave functional expression (II.12) by

$$\Psi(\{p_n,q_n\})=\prod_n \psi_{p_n q_n}(\tilde{\phi}_{1n},\tilde{\phi}_{2n},t) \tag{II.38}$$

with the correspondence $x\leftrightarrow\tilde{\phi}_{1n}$, $y\leftrightarrow\tilde{\phi}_{2n}$, $\beta\leftrightarrow\epsilon_n$ and $r_n^2=\tilde{\phi}_{1n}^2+\tilde{\phi}_{2n}^2$, $\theta_n=\arctan(\tilde{\phi}_{2n}/\tilde{\phi}_{1n})$. Clearly the functional (II.38) is a simultaneous eigenfunctional of $\mathbb{H}$ and Q with energy eigenvalue

$$E(\{p_n\})=\sum_n (p_n+1)\epsilon_n \tag{II.39}$$

and charge

$$Q=-\sum_n q_n. \tag{II.40}$$

Thus we are now in possession of a complete set of physical stationary wave functionals for the system, each with definite energy and charge, representing all possible stationary states with an arbitrary number of particles having arbitrary charge compatible with the particle number.

C. Field expectation values

One field expectation value of interest is that of the charge density operator,

$$\begin{aligned}
&\langle \Psi(\{p_n,q_n\})|j_0(\mathbf{x})|\Psi(\{p_n,q_n\})\rangle \\
&\quad=\int \prod_n d\tilde{\phi}_{1n} d\tilde{\phi}_{2n}\, \Psi^*(\{p_n,q_n\}) \sum_{l,m} \varphi_l \varphi_m^* Q_{lm} \Psi(\{p_n,q_n\}) \\
&\quad=\sum_{\substack{l,m \\ l\neq m}} \int d\tilde{\phi}_{1l} d\tilde{\phi}_{2l} d\tilde{\phi}_{1m} d\tilde{\phi}_{2m}\, \varphi_l \varphi_m^*\, \psi^*_{p_l q_l} \psi^*_{p_m q_m} Q_{lm}\, \psi_{p_l q_l} \psi_{p_m q_m} \\
&\qquad+\sum_m \int d\tilde{\phi}_{1m} d\tilde{\phi}_{2m}\, \varphi_m \varphi_m^*\, \psi^*_{p_m q_m} Q_{mm}\, \psi_{p_m q_m} = -\sum_m q_m |\varphi_m(\mathbf{x})|^2. \qquad \text{(II.41)}
\end{aligned}$$

Here in the second equality every term with $l\neq m$ contributes zero by symmetry arguments. For $l\neq m$, Q_{lm} is odd under $\tilde{\phi}_{jl}\to-\tilde{\phi}_{jl}$ $(j=1,2)$ while the remaining factors in the integrand (including the integration measure) are even under this replacement. Thus the area integrals over the upper and lower half of the $\tilde{\phi}_{1l}$–$\tilde{\phi}_{2l}$-plane cancel. However in those terms with $l=m$, the eigenvalue equation $Q_{mm}\,\psi_{p_m q_m}=-q_m\psi_{p_m q_m}$ eliminates Q_{mm}, leaving a trivial integration over normalized wave functions. For normalizable modes $\varphi_n(\mathbf{x})$, Eqs. (II.40) and (II.41) are in agreement. In Eq. (II.41) we see that the charge of a real particle in the mth mode is distributed (in general nonuniformly) throughout all the space occupied by the spatial mode $\varphi_m(\mathbf{x})$.

Formulas such as (II.41) are problematic in infinite space where one has to deal with nonnormalizable modes. For example, if the modes are plane waves $\varphi(\mathbf{x})\to(2\pi)^{-3/2}\exp(i\mathbf{k}\cdot\mathbf{x})$ with δ-function normalization, then in Eq. (II.41) there is a contribution $-q(2\pi)^{-3/2}$ to the density $\langle j_0(\mathbf{x})\rangle$ from each real excitation. Such a term in $\langle j_0(\mathbf{x})\rangle$ leads to infinite charge Q, and the discrete mode notation we are using fails. This difficulty is eliminated if one makes free boundaryless space compact, say by means of toroidal compactification,

$$\varphi(\mathbf{x})\to[L_1L_2L_3]^{-1/2}e^{i2\pi[x_1n_1/L_1+x_2n_2/L_2+x_3n_3/L_3]},$$

where the n_i run over all integers and the toroidal compactification lengths L_i are independent parameters. Then the contributions to the charge density $\langle j_0(\mathbf{x})\rangle$ from individual particle excitations are $-q/L_1L_2L_3$, and the corresponding contribution to Q is $-q$, as in Eq. (II.40).

Another important expectation value is that of the stress-energy-momentum tensor $T_{\mu\nu}$. For the scalar field theory in question the canonical, symmetric $T_{\mu\nu}$ is

$$T_{\mu\nu}=(D_\mu\phi)^*D_\nu\phi+(D_\nu\phi)^*D_\mu\phi-\eta_{\mu\nu}\mathcal{L}, \qquad \text{(II.42)}$$

where $\mathcal{L}$ is the Lagrange density (II.4). Using the equation of motion $[D^2+m^2+V(\mathbf{x})]\phi=0$ and the corresponding complex conjugate equation one finds

$$\partial^\mu T_{\mu\nu}=F_{\mu\nu}j^\mu+(\partial_\nu V)\phi^*\phi, \qquad \text{(II.43)}$$

where j_μ is the current density (II.21) and $F_{\mu\nu}=\partial_\mu A_\nu-\partial_\nu A_\mu$. Appropriately, $T_{\mu0}$ is conserved only if $F_{i0}=0$, i.e., if no background electric field is present. The static potential $V(\mathbf{x})$ does not influence the conservation of $T_{\mu0}$.

To calculate the expectation value $T_{\mu\nu}[\Psi]\equiv\langle\Psi|T_{\mu\nu}|\Psi\rangle$ for any field state $|\Psi\rangle$ of interest one needs certain basic matrix elements. One of these is

$$\langle\{p_n,q_n\}|\hat{\phi}^*(\mathbf{x})\hat{\phi}(\mathbf{y})|\{p_n,q_n\}\rangle=\int\prod_n\,[d\tilde{\phi}_{1n}\,d\tilde{\phi}_{2n}]|\psi_{p_nq_n}|^2\frac{1}{2}\sum_{c,d}\,\varphi_c^*(\mathbf{x})\varphi_d(\mathbf{y})$$
$$\times(\tilde{\phi}_{1c}-i\tilde{\phi}_{2c})(\tilde{\phi}_{1d}+i\tilde{\phi}_{2d})$$
$$=\sum_n\,A(p_nq_n)\,\varphi_n^*(\mathbf{x})\varphi_n(\mathbf{y}),\tag{II.44}$$

where

$$A(p_n,q_n)=\frac{1}{2}\int\,d\tilde{\phi}_{1n}\,d\tilde{\phi}_{2n}\,|\psi_{p_nq_n}|^2\,(\tilde{\phi}_{1n}^2+\tilde{\phi}_{2n}^2)=\frac{(p_n+1)}{2\epsilon_n}.\tag{II.45}$$

Symmetry arguments similar to those leading to the final equation in (II.41) yield the final equality in Eq. (II.42), and the second equality in Eq. (II.45) follows immediately from the virial theorem applied to the harmonic oscillator.

Another basic matrix element is

$$\langle\{p_n,q_n\}|\hat{\Pi}^*(\mathbf{x})\,\hat{\Pi}(\mathbf{y})|\{p_n,q_n\}\rangle=-\int\prod_n\,[d\tilde{\phi}_{1n}\,d\tilde{\phi}_{2n}]\,\Psi^*_{p_nq_n}\frac{1}{2}\sum_{c,d}\,\varphi_c(\mathbf{x})\varphi_d^*(\mathbf{y})$$
$$\times\left[\frac{\partial}{\partial\tilde{\phi}_{1c}}+i\frac{\partial}{\partial\tilde{\phi}_{2c}}\right]\left[\frac{\partial}{\partial\tilde{\phi}_{1d}}-i\frac{\partial}{\partial\tilde{\phi}_{2d}}\right]\Psi_{p_nq_n}$$
$$=\sum_n\,B(p_nq_n)\,\varphi_n(\mathbf{x})\,\varphi_n^*(\mathbf{y}),\tag{II.46}$$

where

$$B(p_n,q_n)=\frac{1}{2}\int\,d\tilde{\phi}_{1n}\,d\tilde{\phi}_{2n}\,\psi^*_{p_nq_n}\left[-\frac{\partial^2}{\partial\tilde{\phi}_{1n}^2}-\frac{\partial^2}{\partial\tilde{\phi}_{2n}^2}\right]\psi_{p_nq_n}=\tfrac{1}{2}(p_n+1)\,\epsilon_n\,.\tag{II.47}$$

Again symmetric area integration is used to reach the second equality in Eq. (II.46). We pause briefly to explain the two integrals (II.45) and (II.47).

According to the virial theorem of quantum mechanics one has, for any stationary state, the expectation value identity,

$$\langle|(\mathbf{r}\cdot\boldsymbol{\nabla})V|\rangle=\langle\mathbf{p}^2\rangle.\tag{II.48}$$

For the 2D harmonic oscillator problem with $V=(\epsilon^2/2)\,(x^2+y^2)$, Eq. (II.48) becomes $\langle V\rangle=\langle T\rangle=\langle\mathbf{p}^2/2\rangle$. Since $\langle T\rangle+\langle V\rangle=E$ it follows that $\langle V\rangle=\langle T\rangle=E/2$. Equations (II.45) and (II.47) express this latter result for the states $\psi_{p_nq_n}$.

Now it is easy to express the elements of $T_{\mu\nu}(\{p_n,q_n\})$ in mode-sum form,

$$T_{00}(\{p_nq_n\})=\langle\{p_n,q_n\}|2\Pi^\dagger\Pi-\mathcal{L}|\{p_n,q_n\}\rangle=\sum_n\,(p_n+1)\,\epsilon_n\,|\varphi_n(\mathbf{x})|^2-\mathcal{L}(\{p_n,q_n\}),\tag{II.49}$$

where

$$\mathcal{L}(\{p_n,q_n\}) = \langle \{p_n q_n\} | \Pi^\dagger \Pi - |\mathbf{D}\phi|^2 - (m^2+V)|\phi|^2 | \{p_n q_n\} \rangle$$
$$= \frac{1}{2}\sum_n \frac{1}{\epsilon_n}(p_n+1)\{[\epsilon_n^2 - m^2 - V]|\varphi_n|^2 - |\mathbf{D}\varphi_n|^2\}$$
$$= \frac{1}{2}\sum_n \frac{1}{\epsilon_n}(p_n+1)\{\varphi_n^*(-\mathbf{D}^2)\varphi_n - |\mathbf{D}\varphi_n|^2\}; \tag{II.50}$$

also

$$T_{ii}(\{p_n,q_n\}) = \langle \{p_n,q_n\} | 2\,(D_i\phi)^*(D_i\phi) + \mathcal{L} | \{p_n,q_n\} \rangle$$
$$= \sum_n \frac{p_n+1}{\epsilon_n}|D_i\varphi_n|^2 + \mathcal{L}(\{p_n,q_n\}), \quad i=1,2,3, \tag{II.51}$$

$$T_{ij}(\{p_n,q_n\}) = \sum_n \frac{p_n+1}{2\epsilon_n}\{(D_i\varphi_n)^* D_j\varphi_n + (D_j\varphi_n)^* D_i\varphi_n\} \quad i\neq j. \tag{II.52}$$

It is important to observe that

$$T_{\mu\nu}(\{p_n,q_n\}) = T_{\mu\nu}[\Psi_0] + \sum_n p_n T_{n\mu\nu}, \tag{II.53}$$

where $T_{n\mu\nu}$ represents the contribution from one real particle in the nth mode to $T_{\mu\nu}$. As long as $\Sigma_n p_n < \infty$ (i.e., the field state contains only a finite number of real particles) only the vacuum contribution $T_{\mu\nu}[\Psi_0]$ can be UV divergent. Thus only $T_{\mu\nu}[\Psi_0]$ needs renormalization.

III. EXAMPLES

The first example is that of a uniform magnetic field **B** in empty space (compactified appropriately so that the field modes are normalizable). This is hardly a new problem except that we are able to give $T_{\mu\nu}$ not only for the vacuum state Ψ_0, but also for all stationary excited field states $\Psi(\{p_n,q_n\})$. Then we observe that factorization enables one to introduce an arbitrary static potential V depending only on x^1, if we choose our coordinate system so that $\mathbf{B}=(B,0,0)$. Indeed, if one can solve the Casimir problem posed by a given background structure along, say, spatial direction x^1, then one can also solve this Casimir problem with added background magnetic field $\mathbf{B}=(B,0,0)$. As an example we present results for two parallel planar Dirichlet boundaries, with these planes perpendicular to the uniform magnetic field **B**.

A. Uniform magnetic field in empty space

To introduce a uniform background magnetic field $\mathbf{B}=(B,0,0)$ we choose the vector potential,

$$\mathbf{A}=(A^1,A^2,A^3)=(0,0,Bx^2). \tag{III.1}$$

Note that the spatial directions $x^{2,3}$ are treated differently by this gauge choice, and that x^2 plays a preferred role in what follows. Because we are going to keep x^2 noncompact, while x^3 will be compactified (see below), the usual gauge freedom displayed by

$$\mathbf{A}=(0,-\alpha x^3 B,\beta x^2 B), \tag{III.2}$$

with $\alpha+\beta=1$ is not available here. There are a number of things to be said about this. For example, the gauge transformation $\lambda=\alpha x^2 x^3 B$ linking the potentials (III.1) and (III.2) cannot be performed for compact x^3, because it introduces nonperiodic dependence on x^3 into the scalar field. Only if we make x^3 noncompact does this conflict disappear, and the gauge potential (III.2) then becomes available.

Alternatively, one can ask if the potential (III.2) is physically acceptable. The answer is—evidently not, as long as x^3 is compact, because (bosonic) physical functions should be periodic around x^3, and the potential (III.2) does not fulfill this criterion unless $\alpha=0$. The reader should also note that we are compactifying x^1 which further reduces the gauge invariance one usually associates with the uniform magnetic field **B**. In Sec. III D, we discuss the question of gauge invariance in somewhat more detail.

In empty space $V(\mathbf{x})$ vanishes. The label n in our general notation is replaced by (k_1,ν,k_3). The modes $\varphi_{k_1\nu k_3}$ are

$$\varphi_{k_1\nu k_3}(\mathbf{x})\to\frac{1}{\sqrt{L_1}}e^{ik_1x^1}\,\psi_{\nu k_3}(x^2)\,\frac{1}{\sqrt{L_3}}e^{ik_3x^3}, \tag{III.3}$$

where $k_{1,3}=2\pi n_{1,3}/L_{1,3}$ with $n_{1,3}$ running over all integers. In order to have normalizable modes we have compactified the x^1 and x^3 spatial directions. Then the mode Eq. (II.7) reduces to the 1D HO equation (as noted by Landau many years ago[17])

$$\left[-\partial_2^2+B^2\left(x^2+\frac{k_3}{B}\right)^2\right]\psi_{\nu k_3}(x^2)=2B\,(\nu+\tfrac{1}{2})\,\psi_{\nu k_3}(x^2), \tag{III.4}$$

whose complete orthonormal stationary solutions are (with $\nu=0,1,2,\ldots$)

$$\psi_{\nu k_3}(x^2)=\chi_\nu\left(\sqrt{B}\left(x^2+\frac{k_3}{B}\right)\right) \tag{III.5}$$

as specified by Eq. (II.17). In the general notation of Eq. (II.7) the eigenvalues ω_n^2 now become $k_1^2+2B(\nu+\frac{1}{2})$.

Setting all the excitation values $p_n=0$ in Eqs. (II.49)–(II.52) we obtain the vacuum stress tensor $T_{\mu\nu}[\Psi_0]$. Thus using various formulas from Appendix A we find

$$\begin{aligned}T_{00}[\Psi_0]+\mathcal{L}[\Psi_0]&=\frac{1}{L_1L_3}\sum_{n_1,n_3}\sum_{\nu}\,[2B(\nu+\tfrac{1}{2})+k_1^2+m^2]^{1/2}\,|\psi_{\nu k_3}(x^2)|^2\\&=-\int_0^\infty dt\,(4\pi t)^{-2}\,e^{-t\,m^2}\frac{B}{\sinh Bt}\,f_1(t)\,f_3(t|x^2),\end{aligned} \tag{III.6}$$

where

$$f_1(t)=1+2\sum_{n=1}^{\infty}\,e^{-n^2L_1^2/4t}, \tag{III.7}$$

$$f_3(t|x^2)=1+\sum_{n=1}^{\infty}\,e^{-n^2BL_3^2/4\tanh Bt}2\cos(nx^2BL_3); \tag{III.8}$$

and

$$\mathcal{L}[\Psi_0]=\int_0^\infty dte^{-tm^2}(4\pi t)^{-1}\,f_1(t)\frac{1}{L_3}\sum_{n_3}\,\sum_{\nu=0}^{\infty}\,e^{-2B(\nu+\frac{1}{2})t}\{-\psi_{\nu k_3}\psi''_{\nu k_3}-(\psi'_{\nu k_3})^2\} \tag{III.9}$$

$$=-(4\pi)^{-2}\int_0^\infty dt\,e^{-tm^2}t^{-1}f_1(t)\,\frac{B}{2\sinh Bt}\,\partial_2^2f_3, \tag{III.10}$$

where $\partial_2=\partial/\partial x^2$. Note that $\mathcal{L}[\Psi_0]$ is finite. Also

$$T_{11}[\Psi_0]-\mathcal{L}[\Psi_0]=\frac{1}{L_1L_3}\sum_{n_1,n_3}\sum_{\nu}\,[2B(\nu+\tfrac{1}{2})+k_1^2+m^2]^{-(1/2)}\,k_1^2|\psi_{\nu k_3}(x^2)|^2$$

$$=\int_0^\infty dt(4\pi t)^{-2}\,e^{-tm^2}\frac{B}{\sinh Bt}g_1(t)f_3(t|x^2), \tag{III.11}$$

where

$$g_1(t)=1+2\sum_{n=1}^{\infty}\left[1-\frac{n^2L_1^2}{2t}\right]e^{-n^2L_1^2/4t}; \tag{III.12}$$

$$T_{22}[\Psi_0]-\mathcal{L}[\Psi_0]=\frac{1}{L_1L_3}\sum_{n_1,n_3}\sum_{\nu}\,[2B(\nu+\tfrac{1}{2})+k_1^2+m^2]^{-(1/2)}|\psi'_{\nu k_3}(x^2)|^2$$

$$=\frac{1}{(4\pi)^2}\int_0^\infty dt\,e^{-t\,m^2}\,t^{-1}\frac{B^2\cosh Bt}{\sinh^2 Bt}f_1(t)$$

$$\times\left\{f_3(t|x^2)+\frac{\sinh Bt}{2B\cosh Bt}\partial_2^2 f_3(t|x^2)\right\}, \tag{III.13}$$

or more simply,

$$T_{22}[\Psi_0]=\left(\frac{B}{4\pi}\right)^2\int_0^\infty dt\,e^{-tm^2}\,t^{-1}\,f_1(t)\,\frac{\cosh Bt}{\sinh^2 Bt}f_3(t|x_2); \tag{III.14}$$

$$T_{33}[\Psi_0]-\mathcal{L}[\Psi_0]=\frac{1}{L_1L_3}\sum_{n_1,n_3}\sum_{\nu}\,[2B(\nu+\tfrac{1}{2})+k_1^2+m^2]^{-(1/2)}(k_3+Bx^2)^2|\psi_{\nu k_3}(x^2)|^2$$

$$=\frac{1}{(4\pi)^2}\int_0^\infty dt\,e^{-tm^2}t^{-1}\frac{B^2\cosh Bt}{\sinh^2 Bt}f_1(t)\left\{f_3(t|x^2)+\frac{\cosh Bt}{2B\sinh Bt}\partial_2^2 f_3(t|x^2)\right\}. \tag{III.15}$$

One readily verifies that $T_{ij}[\Psi_0]=0$ for $i\neq j$.

$T_{\mu\nu}[\Psi_0]$ of course requires renormalization. Because

$$\frac{B}{\sinh Bt}=\frac{1}{t}-\frac{B^2t}{6}+\frac{7B^4t^3}{360}-\cdots$$

$$\cosh Bt\left(\frac{B}{\sinh Bt}\right)^2=\frac{1}{t^2}+\frac{B^2}{6}-\frac{7B^4t^2}{120}+\cdots \tag{III.16}$$

one can easily regularize $T_{\mu\nu}[\Psi_0]$ by subtracting from $T_{\mu\nu}[\Psi_0]$ the divergent terms

$$T_{00}[\Psi_0]_{\rm div}=-T_{11}[\Psi_0]_{\rm div}=-\int_0^\infty dt(4\pi t)^{-2}\,e^{-tm^2}\left[\frac{1}{t}-\frac{B^2t}{6}\right], \tag{III.17}$$

$$T_{22}[\Psi_0]_{\rm div}=T_{33}[\Psi_0]_{\rm div}=\int_0^\infty dt\,\frac{1}{(4\pi)^2t}e^{-tm^2}\left[\frac{1}{t^2}+\frac{B^2}{6}\right]. \tag{III.18}$$

Thus we define

$$T_{\mu\nu}^{ren}\equiv T_{\mu\nu}[\Psi_0]-T_{\mu\nu}[\Psi_0]_{\rm div}. \tag{III.19}$$

Note that

$$T_{\mu\nu}[\Psi_0]_{\rm div} = T_{\mu\nu}[\Psi_0]_{B=0} + T^B_{\mu\nu} C,$$

where $T^B_{00} = -T^B_{11} = T^B_{22} = T^B_{33} = -B^2/8\pi$ is the classical stress tensor for the background magnetic field $\mathbf{B} = (B,0,0)$ and C is a divergent constant. This allows the absorption of the $O(B^2)$ terms in Eqs. (III.17), (III.18) into $T^B_{\mu\nu}$.

Returning to $T_{\mu\nu}(\{p_n, q_n\})$ for an excited field state, the renormalization procedure just described renormalizes all of these tensors as well, as long as the excitation numbers p_n decrease sufficiently rapidly with increasing n so that $T_{\mu\nu}(\{p_n, q_n\}) - T_{\mu\nu}[\Psi_0]$ is finite. The contribution of one real particle to T_{00} and to the charge density j_0 are $T_{n00} = \epsilon_n |\varphi_n|^2$ and $j_0 = -q_n |\varphi_n|^2$, where

$$|\varphi_n(\mathbf{x})|^2 = \frac{1}{L_1 L_3 2^\nu \nu!} \sqrt{\frac{B}{\pi}} e^{-B(x^2 + k_3/B)^2} [H_n(\sqrt{B}(x^2 + k_3/B))]^2.$$

To those unfamiliar with the Landau modes (III.3) this expression may look peculiar. $|\varphi_n(\mathbf{x})|^2$ represents (in quantum mechanical language) a layer of probability density uniformly distributed in the directions x^1 and x^3, centered at the plane $x^2 = -k_3/B$ and thinning exponentially away from this central plane. This probability layer with thickness $\Delta x^2 \approx 1/\sqrt{B}$ is as close as wave mechanics can come to reproducing the spiral classical trajectory of a charged particle in the uniform magnetic field $\mathbf{B} = (B,0,0)$. Circular motion in the $(x^2 x^3)$ plane is suggested in the modes Eq. (III.3) by the exponential decrease in probabilty amplitude away from $x^2 = -k_3/B$. At the same time, translation invariance along x^3 and along the magnetic field direction x^1 are built into the modes (III.3). The preferred role played by x^2 in Eq. (III.3) is merely a consequence of our gauge choice (III.1). If we were to choose other gauges we would rotate the ''probability layer'' in the $x^2 x^3$ plane about some axis parallel to the magnetic field. The x^1 dependence in Eq. (III.3) would be uneffected. In the example to follow similar comments can be made about the contribution of real particles to $T_{\mu\nu}$. Only the x^1 mode factors need to be modified. Thus we shall not say more about this in Secs. III B and III C.

What effect, exactly, does the background magnetic field **B** have on states of the quantum field? This question is rarely addressed—we know of no discussion in the literature—although surely many have thought about it. Quantum fluctuations of the charged scalar field $\hat{\phi}$ can be visualized in particle terms as electric dipoles. A dipole of vanishing size emerges from the fluctuating vacuum, grows to some maximum size, and shrinks again to nothing. In empty space with $\mathbf{B} = 0$ these dipoles have all possible orientations. In the presence of $\mathbf{B} \neq 0$ the dipoles oriented parallel to **B** are unaffected. However, dipoles oriented perpendicular to **B** are strongly effected. They change from linear dipole-like fluctuations to transient current loops. These transient current loops tend to be oriented such that their magnetic fields oppose **B**. Thus **B** modifies and significantly organizes the quantum fluctuations of the charged scalar field $\hat{\phi}$. The charged-particle vacuum responds like a diamagnetic material.

The factors $f_1(t)$ in $T_{00,22,33}$ and $g_1(t)$ in T_{11} resulting from the compactification of x^1 go smoothly to 1 in the limit $L_1 \to \infty$. More interesting is the factor $f_3(t|x^2)$ common to all nonzero components of $T_{\mu\nu}[\Psi_0]$. Surprisingly, perhaps, this factor is a Fourier cosine series in x^2 with period $\Delta x^2 = 2\pi/BL_3$ (as was mentioned elsewhere[13,18] in a related context). This periodic behavior in the *noncompact* coordinate x^2 is a consequence of both the background magnetic field and the compactification of the perpendicular direction x^3. In either of the limits $L_3 \to \infty$ or $B \to 0$ we see that $f_3(t|x^2) \to 1$. Evidently one is encountering here a physical quantum effect akin to the quantum Hall effect, with vacuum currents flowing around the compact x^3 direction. To verify this we compute the vacuum current density,

$$j_3[\Psi_0]=\langle\Psi_0|i\hat{\phi}^*(D_3\hat{\phi})-i(D_3\hat{\phi})^*\hat{\phi}|\Psi_0\rangle$$
$$=\frac{1}{L_1L_3}\sum_{n_1,n_3}\sum_{\nu}\left[k_1^2+2B(\nu+\tfrac{1}{2})+m^2\right]^{-1/2}(k_3+Bx^2)|\psi_{\nu k_3}|^2$$
$$=\int_0^\infty dt\,e^{-tm^2}(4\pi t)^{-1}f_1(t)\frac{B\cosh Bt}{4\pi\sinh^2 Bt}\partial_2 f_3, \tag{III.20}$$

which is indeed nonzero. However, the other components of the vacuum current vanish: $j_{1,2}[\Psi_0]=0$. In the limit $L_3\to\infty$ when $f_3\to 1$, the current density (III.20) vanishes exponentially. Clearly, vacuum currents around the compact direction x^3 are involved. Quantum fluctuations, visualized as vacuum pairs, can appear on one side of the x^3 circle and annihilate on the other side by traveling in opposite directions. Such vacuum currents are only possible for $L_3<\infty$. The perpendicular B field organizes these vacuum currents into a band structure periodic in x^2.

From the conservation formula (II.43) we see that

$$-\partial_2 T_{22}=F_{32}j^3=B\,j^3. \tag{III.21}$$

The formulas (III.14), (III.20) for T_{22} and j^3 obviously satisfy this relation.

B. Uniform magnetic field with parallel background force

The factorization in Eq. (III.3) (where the x^1 dependent mode factor is independent of $x^{2,3}$ and ν,k_3) enables one to introduce rather arbitrary background structure along x^1, without disturbing the rest of the calculation. Accordingly, in mode equation (II.7), we choose a potential of the form $V(\mathbf{x})=V(x^1)$ and replace the plane wave factors $\exp(ik_1x^1)/\sqrt{L_1}$ in Eq. (III.3) by unknown functions $u_p(x^1)$. Now the mode equation (II.7) reduces to

$$\left[-\frac{d^2}{dx^{1^2}}+V(x^1)\right]u_p(x^1)=\lambda_p^2\,u_p(x^1) \tag{III.22}$$

in addition to Eq. (III.4) which is uneffected by the introduction of $V(x^1)$. In our general notation $\omega_n^2\to\lambda_p^2+2B(n+1/2)$ with λ_p^2 replacing k_1^2. Equation (II.44) for the vacuum field state Ψ_0 becomes

$$\langle\Psi_0|\hat{\phi}^*(\mathbf{x})\hat{\phi}(\mathbf{y})|\Psi_0\rangle=\frac{1}{2\Gamma(s)}\int_0^\infty dt e^{-tm^2}t^{s-1}h(t|x^1,y^1)\sum_n e^{-tB(2n+1)}$$
$$\times\frac{1}{L_3}\sum_{n_3}e^{-ik_3(x^3-y^3)}\psi_{nk_3}(x^2)\psi_{nk_3}(y^2), \tag{III.23}$$

with $s=1/2$, where

$$h(t|x^1,y^1)=\sum_p e^{-t\lambda_p^2}u_p^*(x^1)u_p(y^1) \tag{III.24}$$

is the heat kernel associated with the spectral problem (III.22).

Similarly $\langle\Psi_0|\hat{\Pi}^*(\mathbf{x})\hat{\Pi}(\mathbf{y})|\Psi_0\rangle$ is given by the right-hand side of Eq. (III.23) with $s=-\frac{1}{2}$.

Now it is straighforward to evaluate the basic mode sums needed for $T_{\mu\nu}[\Psi_0]$ in terms of the still general heat kernel h,

$$\sum_n \epsilon_n|\varphi_n|^2=-\frac{2\sqrt{\pi}}{(4\pi)^2}\int_0^\infty dt\,e^{-tm^2}t^{-(3/2)}\frac{B}{\sinh Bt}h(t|x^1,x^1)f_3, \tag{III.25}$$

$$\sum_n \frac{1}{\epsilon_n}|D_1\varphi_n|^2=\frac{4\sqrt{\pi}}{(4\pi)^2}\int_0^\infty dt\, e^{-tm^2}t^{-(1/2)}\frac{B}{\sinh Bt}[\partial_{x^1}\partial_{y^1}h(t|x^1,y^1)]_{x^1=y^1}f_3, \quad \text{(III.26)}$$

$$\sum_n \frac{1}{\epsilon_n}|D_2\varphi_n|^2=\frac{2\sqrt{\pi}}{(4\pi)^2}\int_0^\infty dt\, e^{-tm^2}t^{-(1/2)}\frac{B^2\cosh Bt}{\sinh^2 Bt}h(t|x^1,x^1)\left\{f_3+\frac{\sinh Bt}{2B\cosh Bt}\partial_2^2 f_3\right\}, \quad \text{(III.27)}$$

$$\sum_n \frac{1}{\epsilon_n}|D_3\varphi_n|^2=\frac{2\sqrt{\pi}}{(4\pi)^2}\int_0^\infty dt\, e^{-tm^2}t^{-(1/2)}\frac{B^2\cosh Bt}{\sinh^2 Bt}h(t|x^1,x^1)\left\{f_3+\frac{\cosh Bt}{2B\sinh Bt}\partial_2^2 f_3\right\}, \quad \text{(III.28)}$$

$$\mathcal{L}=-\int_0^\infty dt\, e^{-tm^2}(4\pi t)^{-1/2}\frac{B}{4\pi\sinh Bt}\{(\partial_{y^1}^2+\partial_{x^1}\partial_{y^1})h(t|x^1,y^1)|_{x^1=y^1}f_3+h(t|x^1,x^1)\tfrac{1}{2}\partial_2^2 f_3\}, \quad \text{(III.29)}$$

where $f_3=f_3(t|x^2)$ is the function (III.8). Again we have used equations from the Appendix.

Note that in the limit $L_3\to\infty$ when $f_3\to 1$ the mode sums

$$\frac{1}{\epsilon_n}\sum_n |D_{2,3}\varphi_n|^2$$

become identical, insuring that $T_{22}[\Psi_0]=T_{33}[\Psi_0]$ for any background potential $V(x^1)$. However, $T_{22}[\Psi_0]\neq T_{33}[\Psi_0]$ for finite L_3.

One easily verifies

$$T_{22}=\int_0^\infty dt\, e^{-tm^2}(4\pi t)^{-1/2}\frac{B}{4\pi\sinh Bt}f_3\left\{h\,B\frac{\cosh Bt}{\sinh Bt}-(\partial_{y^1}^2+\partial_{x^1}\partial_{y^1})h|_{x^1=y^1}\right\}, \quad \text{(III.30)}$$

$$\begin{aligned}T_{12}&=\sum_n \frac{1}{2\epsilon_n}[(\partial_1\varphi_n)^*\partial_2\varphi_n+(\partial_2\varphi_n)^*\partial_1\varphi_n]\\&=\int_0^\infty dt e^{-tm^2}(4\pi t)^{-1/2}\frac{B}{8\pi\sinh Bt}(\partial_{x^1}+\partial_{y^1})h|_{x^1=y^1}\partial_2 f_3,\end{aligned} \quad \text{(III.31)}$$

$$\begin{aligned}T_{11}&=\sum_n \frac{1}{\epsilon_n}|\partial_1\varphi_n|^2+\mathcal{L}\\&=\int_0^\infty dt\, e^{-tm^2}(4\pi t)^{-1/2}\frac{B}{4\pi\sinh Bt}\left\{(\partial_{x^1}\partial_{y^1}-\partial_{y^1}^2)h\,f_3-\frac{1}{2}h\,\partial_2^2 f_3\right\}_{x^1=y^1},\end{aligned} \quad \text{(III.32)}$$

while $T_{23}=0$. Similarly $T_{13}=0$ if $\partial_{x^1}h=\partial_{y^1}h$ for $x^1=y^1$, as we do assume. For the vacuum currents we have

$$j^3=\int_0^\infty dt\, e^{-tm^2}(4\pi t)^{-1/2}h|_{x_1=y_1}\frac{B\cosh Bt}{4\pi\sinh^2 Bt}\partial_2 f_3, \quad \text{(III.33)}$$

while $j^2=0$, and $j^1=0$ under the same assumption that makes T_{13} vanish. The nontrivial parts of the conservation rule (II.43) are

$$-\partial_1 T_{11}-\partial_2 T_{21}=\partial_1 V\langle\phi^*\phi\rangle, \quad \text{(III.34)}$$

$$-\partial_1 T_{12}-\partial_2 T_{22}=F_{32}\,j^3. \tag{III.35}$$

One can verify that both relations are satisfied by our preceding quite specific and nontrivial results.

For brevity we do not discuss the renormalization of $T_{\mu\nu}[\Psi_0]$, other than to say that this is done essentially as in the free space example of Sec. III A. The vacuum current (III.33) does not need renormalization.

C. Uniform magnetic field perpendicular to two Dirichlet planes

Now let us consider the Casimir problem of parallel Dirichlet planes at $x^1=0$, L with a uniform background magnetic field perpendicular to them.

For $B=0$ the planes attract; how does $B\neq 0$ influence the Casimir force? Between the planes the mode factors $u_p(x^1)$ are

$$u_p(x^1)=\sqrt{\frac{2}{L}}\sin p\,\frac{\pi x^1}{L},\quad p=1,2,3,\ldots,\quad 0\leqslant x^1\leqslant L, \tag{III.36}$$

with eigenvalue $\lambda_p^2=(\pi p/L)^2$ in Eq. (III.22). Because of our compactification of coordinate x^1 in $0\leqslant x^1\leqslant L_1$ the region ''outside'' the planes has length L_1-L, where obviously we are assuming $L_1>L$. For the purpose of visualization one may as well assume that L_1 is substantially larger than L. Nonetheless our calculations will be exact. Outside the planes the mode factors $u_p(x^1)$ are

$$u_p(x^1)=\sqrt{\frac{2}{L_1-L}}\sin p\,\frac{\pi\,(x^1-L)}{L_1-L},\quad p=1,2,3,\ldots,\quad L\leqslant x^1\leqslant L_1. \tag{III.37}$$

In other words, we have exactly the same calculations to perform in the internal and external regions. Thus in the following we can concentrate on the internal region, and simply quote results from the external region when they are needed.

The heat kernel (III.24) for $u_p(x^1)$ in Eq. (III.36) is

$$h(t|x^1,y^1)=(4\pi t)^{-1/2}\sum_{n=-\infty}^{\infty}\left[e^{-(n\,2L+x^1-y^1)^2/4t}-e^{-(n\,2L+x^1+y^1)^2/4t}\right]. \tag{III.38}$$

Now all we have to do is substitute this h into the various formulas in the preceding subsection to obtain final expressions for $T_{\mu\nu}$ and j_μ. For brevity we concentrate on T_{11} and the Casimir force on the boundary planes.

In the integral (III.32) for T_{11} we have the integrand factor

$$(\partial_{x^1}\partial_{y^1}-\partial_{y^1}^2)\,h\big|_{x^1=y^1}=(4\pi t)^{-1/2}\sum_n\frac{1}{t}\left[1-\frac{2}{t}(nL)^2\right]e^{-n^2L^2/t}. \tag{III.39}$$

As expected, the part of T_{11} which survives the limit $L_3\to\infty$ is independent of x^1, in accordance with Eq. (III.34) above. For the internal region,

$$T_{11}=\int_0^\infty dt\,e^{-tm^2}(4\pi t)^{-1/2}\frac{B}{\sinh Bt}$$
$$\times\left\{\sum_{n=-\infty}^{\infty}\left[1-\frac{2}{t}(nL)^2\right]e^{-n^2L^2/t}f_3(t|x^2)-\frac{t}{2}h(t|x^1,x^1)\partial_2^2 f_3(t|x^2)\right\}. \tag{III.40}$$

The local force/area on the plane at $x^1=0$ is

$$F^1/A = \lim_{\epsilon\to 0}[T_{11}(x^1=-\epsilon)-T_{11}(x^1=\epsilon)]$$

$$= \frac{1}{(4\pi)^2}\int_0^\infty dt\, t^{-2}e^{-tm^2}\frac{B}{\sinh Bt}f_3(t|x^2)$$

$$\times 2\sum_{n=1}^{\infty}\left\{\left[\frac{2}{t}(nL)^2-1\right]e^{-(nL)^2/t}-\left[\frac{2}{t}(n\Delta L)^2-1\right]e^{-n^2\Delta L^2/t}\right\}, \qquad \text{(III.41)}$$

where $\Delta L = L_1 - L$. For $m=0$, $B=0$ and $L_1 \gg L$ this force/area reduces (as it should) to

$$\frac{F_1}{A} = 2\left[\frac{3}{(4\pi)^2 L^4}\zeta(4)\right], \qquad \text{(III.42)}$$

where the quantity in the bracket is the attractive Casimir force/area between parallel Dirichlet planes for a real massless scalar field. Looking at Eq. (III.41) we see that $B\neq 0$ weakens the Casimir force exponentially (relative to the $B=0$ case) by damping the $t\to\infty$ part of the integral. This was previously noticed in Ref. 14.

In Appendix B we compute the Casimir force/area (III.41) using the traditional method of the global Casimir energy. The answer obtained—Eq. (B10)—agrees with Eq. (III.41) except that f_3 is replaced by 1, i.e., the value of f_3 in the limit $L_3\to\infty$, which is also the average value of f_3 for finite L_3. The reason for this seems clear. A global calculation cannot see spatial dependence, such as the periodic x^2 dependence of $f_3(t|x^2)$.

The expected boundary divergences are present in $T_{\mu\nu}$ except for T_{11} where they cancel away. In general one can separate quantum functions like $T_{\mu\nu}(\mathbf{x})$ into "bulk field" (F) and "boundary" (B) terms: $T_{\mu\nu}=T^F_{\mu\nu}+T^B_{\mu\nu}$. The F terms require UV renormalization and are finite at boundaries. The B terms do *not* require UV renormalization and diverge as boundaries are approached. This structure is plainly evident in $T_{\mu\nu}[\Psi_0]$ above.

D. Gauge invariance

Something more should perhaps be said about the gauge invariance of the preceding calculations. We began with the background gauge potential $\mathbf{A}=(0,0,Bx^2)$ which led us to the set of empty-space Landau modes $\varphi_{k_1\nu k_3}(\mathbf{x})$ in Eq. (III.3). Individually, these modes represent a layer of stationary probability density, centered at $x^2=-k_3/B$ and uniform in the x^1 and x^3 directions. In this gauge, when the magnetic field $\mathbf{B}=(B,0,0)$ is turned on, each plane-wave mode of the $\mathbf{B}=0$ system (uniformly filling space, of course) shrinks down to the Landau mode selected by its momentum component k_3.

If x^3 is noncompact the Landau modes form a continuum along x^2 and there is no x^2 periodicity in $T_{\mu\nu}$ or in other local quantum functions. However, when $0\leqslant x^3\leqslant L_3$ is compact so that $k_3=n_3(2\pi/L_3)$ is discrete, the Landau modes become a discrete set of probability density layers centered at $x^2=-n_3(2\pi/BL_3)$. Because all local quantum functions such as $T_{\mu\nu}$ are constructed from these discrete modes, the periodicity along x^2 displayed by our local results seems mathematically understandable—even inevitable.

For $L_3=\infty$ the preferred role played by the coordinate x^2 in all of this is a consequence of our gauge choice. If we had chosen the gauge $\mathbf{A}=(0,-Bx^3,0)$ which leads to the same magnetic field $\mathbf{B}=(B,0,0)$, the spatial modes would be

$$\varphi_{k_1k_2\nu}(\mathbf{x}) = \frac{1}{\sqrt{L_1}}e^{ik_1x^1}\frac{1}{\sqrt{L_2}}e^{ik_2x^2}\,\psi_{\nu k_2}(x^3),$$

where the HO wave function satisfies

$$\left[-\partial_3^2+B^2\left(x^3-\frac{k_2}{B}\right)^2\right]\psi_{\nu k_2}(x_3)=2B\,(\nu+\tfrac{1}{2})\psi_{\nu k_2}(x_3). \tag{III.43}$$

Now the Landau modes are probability density layers arranged along the x^3 axis. Physically there is no difference between the two gauges, as must be the case. The only difference is a 90° coordinate rotation in the x^2x^3 plane, about the magnetic field direction. The orientation of the x^2x^3 plane about the field direction is completely arbitrary, of course.

As soon as coordinate x^3 is made compact, the minor gauge freedom just described disappears entirely. For this reason all the principal ($L_3<\infty$) calculations in this paper are gauge invariant. If x^2 is noncompact and x^3 is compact, rotations mixing these two coordinates are not possible. The gauge (III.1) is the only possible choice for introducing the background magnetic field $\mathbf{B}=(B,0,0)$. The more general potential (III.2) is not periodic in x^3 (for $\alpha>0$) and therefore is not acceptable. Equation (III.43) makes the same point in a different way. This HO Schrödinger equation is meaningless for a compact variable x^3. It only becomes meaningful when x^3 is made noncompact.

For noncompact x^2 and x^3 we can use the gauge potential (III.2). Then the mode equation (II.7) appears to be more complicated than before,

$$[-\partial_1^2-(\partial_2-i\alpha x^3B)^2-(\partial_3-i\beta x^2B)^2]\,\varphi_n=\omega_n^2\,\varphi_n\,. \tag{III.44}$$

However, the *ansatz*,

$$\varphi_n\rightarrow e^{i\alpha x^2x^3B}\,\varphi_{k_1\nu k_3}(\mathbf{x}) \tag{III.45}$$

with $\varphi_{k_1\nu k_3}(\mathbf{x})$ as in Eq. (III.3) reduces Eq. (III.44) to the HO equation (III.4), and the essential mathematics is unchanged. Equation (III.45) is just the appropriate gauge transform of the modes (III.3) of course.

IV. DISCUSSION

General theory has been developed for arbitrary (charged and uncharged) stationary states of a charged quantum scalar field $\hat{\phi}$ coupled to an arbitrary static background magnetic field $\mathbf{B}(\mathbf{x})$. An unusual feature of this general theory is the simultaneous coupling of $\hat{\phi}$ to $\mathbf{B}(\mathbf{x})$ and to a static background potential $V(\mathbf{x})$.

Although we have not discussed this aspect at all, it is a straightforward matter to extend the analysis in Secs. II and III to nonstationary states of the quantum field. For this one uses nonstationary solutions of the HO equation (II.14). We hope to say more about this elsewhere.

For explicit calculations we chose a uniform magnetic field $\mathbf{B}=(B,0,0)$ and considered (otherwise) empty space, and also space with two parallel Dirichlet planes perpendicular to $\mathbf{B}$. For both systems the exact vacuum stress tensor throughout space was calculated. In order to have normalizable modes we compactified a spatial direction (x^3) perpendicular to $\mathbf{B}$. We found that this compactification leads to the presence of a sustained current density j_3 in the vacuum.

In this paper we have only considered static magnetic fields $\mathbf{B}(\mathbf{x})$. Such a background field cannot transfer energy to/from real or virtual charged particles. Of course, neither can a time dependent magnetic field $\mathbf{B}(\mathbf{x},t)$, no matter how extreme the time dependence of $\mathbf{B}(\mathbf{x},t)$ may be. However, a time dependent $\mathbf{B}(\mathbf{x},t)$ cannot exist independently from the induced electric field $\mathbf{E}(\mathbf{x},t)$ prescribed by Maxwell's equations. In this way, the laws of classical electromagnetism dictate that $\mathbf{B}(\mathbf{x},t)$ also produces pairs from the vacuum—via the induced $\mathbf{E}(\mathbf{x},t)$ rather than directly.

Static background electric fields pose a much greater challenge than do static background magnetic fields. The reason, of course, is that background electric fields ongoingly transfer energy to/from charged (real and virtual) particles, and in particular cause pair production from the vacuum. Indeed, there do not exist stable, true stationary states of a charged quantum field in the

presence of any background electric field. An exact description of the states of the charged quantum field must necessarily be a nonstationary one. In subsequent work we intend to present a Schrödinger picture study of such systems.

APPENDIX A: USEFUL FORMULAS

Here we collect and discuss formulas used in the examples in Sec. III. From the general Θ function identity,

$$\sum_{m=-\infty}^{\infty} e^{-x(m+g)^2} e^{2i\pi hm} = e^{-2\pi igh} \sqrt{\frac{\pi}{x}} \sum_{n=-\infty}^{\infty} e^{-\pi^2 (n+h)^2/x} e^{-2i\pi gn} \tag{A1}$$

we find for $k_1 = 2\pi n_1 / L_1$;

$$\frac{1}{L_1} \sum_{n_1=-\infty}^{\infty} e^{-tk_1^2} = (4\pi t)^{-1/2} f_1(t) \tag{A2}$$

with

$$f_1(t) \equiv \sum_{r=-\infty}^{\infty} e^{-r^2 L_1^2/4t} \tag{A3}$$

and

$$\frac{1}{L_1} \sum_{n_1=-\infty}^{\infty} k_1^2 e^{-tk_1^2} = \frac{1}{2t} (4\pi t)^{-1/2} g_1(t) \tag{A4}$$

with

$$g_1(t) \equiv \sum_{r=-\infty}^{\infty} [1 - r^2 L_1^2/2t] e^{-r^2 L_1^2/4t}. \tag{A5}$$

For $k_3 = 2\pi n_3 / L_3$ we have

$$\frac{1}{L_3} \sum_{n_3=-\infty}^{\infty} e^{-B(x^2 + k_3/B)^2 \tanh Bt} = \left[\frac{B}{4\pi \tanh Bt} \right]^{1/2} f_3(t|x^2), \tag{A6}$$

where

$$f_3(t|x^2) \equiv 1 + \sum_{r=1}^{\infty} e^{-r^2 B L_3^2/4 \tanh Bt} 2 \cos(r x^2 B L_3). \tag{A7}$$

Applying $\partial_2 = \partial / \partial x^2$ yields

$$\frac{1}{L_3} \sum_{n_3} (k_3 + Bx^2) e^{-B(x^2 + k_3/B)^2 \tanh Bt} = -\frac{1}{2} \left[\frac{B}{4\pi} \right]^{1/2} (\tanh Bt)^{-3/2} \partial_2 f_3, \tag{A8}$$

which vanishes exponentially as $L_3 \to \infty$, and

$$2B\tanh Bt\,\frac{1}{L_3}\sum_{n_3}\left(x^2+\frac{k_3}{B}\right)^2 e^{-B(x^2+(k_3/B))^2\tanh Bt}=\left[\frac{B}{4\pi\tanh Bt}\right]^{1/2}\left\{f_3+\frac{\cosh Bt}{2B\sinh Bt}\partial_2^2 f_3\right\}. \tag{A9}$$

The stationary HO wave function $\psi_{\nu k_3}(x^2)=\varphi_\nu(\sqrt{B}(x^2+k_3/B))$ is given by Eq. (II.17). It is normalized to one and satisfies

$$\frac{1}{L_3}\sum_{n_3}\sum_{\nu=0}^{\infty} e^{-Bt(2\nu+1)}\,|\psi_{\nu k_3}(x^2)|^2=\frac{B}{4\pi\sinh Bt}\,f_3(t|x^2), \tag{A10}$$

$$\frac{1}{L_3}\sum_{n_3}\sum_{\nu=0}^{\infty} e^{-Bt(2\nu+1)}\,|\psi'_{\nu k_3}(x^2)|^2=\frac{1}{8\pi}B^2\frac{\cosh Bt}{\sinh^2 Bt}\left\{f_3(t|x^2)+\frac{\sinh Bt}{2B\cosh Bt}\partial_2^2 f_3(t|x^2)\right\}, \tag{A11}$$

$$\frac{1}{L_3}\sum_{n_3}\sum_{\nu=0}^{\infty} e^{-Bt(2\nu+1)}\left(x^2+\frac{k_3}{B}\right)^2|\psi_{\nu k_3}(x^2)|^2=\frac{1}{8\pi}\frac{\cosh Bt}{\sinh^2 Bt}\left\{f_3(t|x^2)+\frac{\cosh Bt}{2B\sinh Bt}\partial_2^2 f_3(t|x^2)\right\}, \tag{A12}$$

$$\frac{1}{L_3}\sum_{n_3}\sum_{\nu=0}^{\infty} e^{-Bt(2\nu+1)}\,\psi_{\nu k_3}\psi''_{\nu k_3}=\frac{B^2\cosh Bt}{8\pi\sinh^2 Bt}\left\{-f_3+\frac{\sinh Bt}{2B\cosh Bt}\partial_2^2 f_3\right\}, \tag{A13}$$

$$\frac{1}{L_3}\sum_{n_3}\sum_{\nu=0}^{\infty} e^{-Bt(2\nu+1)}\,\psi_{\nu k_3}\psi'_{\nu k_3}=\frac{B}{8\pi\sinh Bt}\,\partial_2 f_3. \tag{A14}$$

The easiest derivation of Eqs. (A10)–(A14) is via the formula (Ref. 19, p. 194)

$$\sum_{n=0}^{\infty} e^{-tB(2n+1)}\psi_{nk_3}(x^2)\psi_{nk_3}(y^2)=\left[\frac{B}{2\pi\sinh 2Bt}\right]^{1/2} e^{-(1/2)B(x^2-y^2)^2\coth 2Bt}\times e^{-B(x^2+(k_3/B))(y^2+(k_3/B))\tanh Bt}. \tag{A15}$$

APPENDIX B: GLOBAL CASIMIR ENERGY

Here we summarize the global Casimir energy calculations for the examples in Sec. III. In these calculations the basic problem is to compute the mode sum,

$$E[\Psi_0]=E=\sum_n \epsilon_n=V\frac{B}{2\pi}\sum_{p,\nu}\left[\lambda_p^2+2B\left(\nu+\frac{1}{2}\right)+m^2\right]^{1/2} \tag{B1}$$

representing the unrenormalized vacuum energy. Here, as in Sec. III B, the frequencies ω_n are given by $[\lambda_p^2+2B(\nu+\frac{1}{4})]^{1/2}$ with the x^1 axis spectrum λ_p^2 defined by Eq. (III.22).

In the global sum (B1) V represents the (relevant) volume of space, and Σ_p has dimension $(\text{length})^{-1}$ like $\int dk_1$. Then E is an energy and E/V is an average energy density. Familiar manipulations enable one to rewrite Eq. (B1) in the form,

$$E=-V\int_0^\infty dt(4\pi t)^{-3/2}h_1(t)\,e^{-tm^2}\frac{B}{\sinh Bt}, \tag{B2}$$

where $h_1(t)=\Sigma_p\exp(-t\lambda_p^2)$ is the global version of the local 1D heat kernel (III.24).

1. Free infinite space

For noncompact $-\infty<x^1<\infty$ we have $\lambda_p^2\to k_1^2$ with $-\infty<k_1<\infty$ and $\Sigma_p\to(2\pi)^{-1}\int dk_1$, so that $h_1(t)=(4\pi t)^{-1/2}$. Thus

$$E=-V\int_0^\infty dt(4\pi t)^{-2}\,e^{-tm^2}\frac{B}{\sinh Bt} \tag{B3}$$

which reduces for $B\to 0$ to the usual (divergent) vacuum energy expression for infinite free space. This justifies the normalization $(B/2\pi)\,\Sigma_\nu$ of the HO sum in Eq. (B1) and establishes the correspondence,

$$\frac{B}{2\pi}\sum_\nu \leftrightarrow\frac{1}{2\pi}\int dk_2dk_3. \tag{B4}$$

Because

$$\frac{B}{\sinh Bt}=\frac{1}{t}-B^2\frac{t}{6}+B^4\frac{7}{360}t^3+\cdots$$

we see that the vacuum energy shift $E-E(B=0)$ associated with the magnetic field is still logarithmically divergent. The logarithmic divergence is proportional to B^2 and can therefore be absorbed into the energy of the background B field, leaving the finite Casimir energy density,

$$E_{\rm Cas}/V=-\int_0^\infty dt\,(4\pi t)^{-2}\,e^{-tm^2}\left[\frac{B}{\sinh Bt}-\frac{1}{t}+B^2\frac{t}{6}\right]. \tag{B5}$$

2. Free cylindrical space

For compact $0\leqslant x^1\leqslant L_1$, we have the spectrum $\lambda_p^2\to(n_1 2\pi/L_1)^2$ with $n_1=0,\pm1,\ldots$ and $\Sigma_p\to(L_1)^{-1}\Sigma_n$. Thus $h_1(t)=(4\pi t)^{-1}f_1(t)$ with $f_1(t)$ given by Eq. (A3), and

$$E(L_1)_{\rm free}=-A\,L_1\int_0^\infty dt\,(4\pi t)^{-2}\,e^{-tm^2}\frac{B}{\sinh Bt}f_1(t), \tag{B6}$$

where $V=A\,L_1$ and A is the area of the (x^2x^3) cross section of space. The Casimir energy contained within Eq. (B6) is defined exactly as in Eq. (B5).

3. Dirichlet planes at $x^1=0$ and L

Now let us insert parallel Dirichlet planes at $x^1=0$ and $x^1=L$. Between these planes $(0\leqslant x^1\leqslant L)$ we have discrete $k_1=n_1(\pi/L)$ with $n_1=1,2,3,\ldots$ and

$$h_1(t)=\frac{1}{L}\sum_{n_1=1}^\infty e^{-t(n_1\pi/L)^2}=-\frac{1}{2L}+(4\pi t)^{-1/2}\sum_{r=-\infty}^\infty e^{-r^2L^2/t}. \tag{B7}$$

The (unrenormalized) vacuum energy between the planes is, from Eq. (B2),

$$E(L)=-A\int_0^\infty dt\,(4\pi t)^{-3/2}\,e^{-tm^2}\frac{B}{\sinh Bt}\left\{-\frac{1}{2}+(4\pi t)^{-1/2}L\sum_{r=-\infty}^\infty e^{-r^2L^2/t}\right\}. \tag{B8}$$

To find the vacuum energy outside the planes (i.e., in $L\leqslant x_1\leqslant L_1$) we simply have to replace $L\to L_1-L$. Thus an obvious first attempt at defining the Casimir energy of the system is

$$\Delta E(L,L_1)\equiv E(L)+E(L_1-L)-E(L_1)_{\text{free}}$$
$$=-A\int_0^\infty dt(4\pi t)^{-2}e^{-tm^2}\frac{B}{\sinh Bt}\Bigg\{-(4\pi t)^{1/2}+2L\sum_{r=1}^{\infty}e^{-r^2L^2/t}$$
$$+2(L_1-L)\sum_{r=1}^{\infty}e^{-r^2(L_1-L)^2/t}-2L_1\sum_{r=1}^{\infty}e^{-r^2L_1^2/4t}\Bigg\}, \tag{B9}$$

where as expected the most singular terms have cancelled away. The only remaining singular term is the one $\{-(4\pi t)^{1/2}+\cdots\}$ in the curly bracket. Since this term is independent of L and L_1 we simply discard it in Eq. (B9). The finite remaining energy is then, as far as variations of boundary position L are concerned, the global Casimir energy of the system.

The Casimir force/area exerted by the distorted quantum field vacuum on the Dirichlet boundaries,

$$F(L,L_1)/A=\frac{d}{dL}\Delta E(L,L_1)/A$$
$$=-\int_0^\infty dt(4\pi t)^{-2}e^{-tm^2}\frac{B}{\sinh Bt}\sum_{r=1}^{\infty}\Bigg\{2[e^{-r^2L^2/t}-e^{-r^2(L_1-L)^2/t}]$$
$$-\frac{4}{t}r^2[L^2e^{-r^2L^2/t}-(L_1-L)^2e^{-r^2(L_1-L)^2/t}]\Bigg\} \tag{B10}$$

depends on plane separation L and on the x^1 circumference L_1. This force/area vanishes for $L_1=2L$ as it should, because the planes are then the same distance apart in either direction around the x^1 circle (unstable equilibrium). In the limit $L_1\to\infty$ one obtains F/A without finite (spatial) size effects. The two Dirichlet planes experience a mutually attractive Casimir force, weakened by the effects of (i) finite mass m and (ii) the background magnetic field. We recover the familiar Casimir force,

$$F(L,\infty)/A\big|_{m=B=0}=2\left[\frac{3\zeta(4)}{(4\pi)^2L^4}\right] \tag{B11}$$

for $m=B=0$ by performing a simple calculation using the analytic continuation formula

$$\int_0^\infty dt\,t^{s-1}e^{-r^2L^2/t}=(rL)^{2s}\Gamma(-s).$$

This leads to the Casimir energy,

$$\Delta E(L,\infty)\big|_{m=B=0}=2\left[-\frac{A\zeta(4)}{(4\pi)^2L^3}\right], \tag{B12}$$

and differentiation then yields Eq. (B11).

Equations (B11) and (B12) are, correctly, twice the Casimir force and energy of a *real* $m=0$ scalar field confined between parallel Dirichlet planes.

It is important to notice that, because of the lack of explicit dependence on k_3 in the spectrum summed over in Eq. (B1), these global calculations cannot be sensitive to the compactification of x^3. In other words, they are necessarily $L_3=\infty$ calculations. As we see in Sec. III by comparison with local calculations, this expectation is in fact correct.

On the continuum limit of fermionic topological charge in lattice gauge theory

David H. Adams[a)]

(Received 7 February 2001; accepted for publication 6 September 2001)

It is proved that the fermionic topological charge of SU(N) lattice gauge fields on the four-torus, given in terms of a spectral flow of the Hermitian Wilson–Dirac operator or, equivalently, as the index of the overlap Dirac operator, reduces to the continuum topological charge in the classical continuum limit when the parameter m_0 is in the physical region $0<m_0<2$. © *2001 American Institute of Physics.* [DOI: 10.1063/1.1415087]

I. INTRODUCTION

Let T^4 denote the Euclidean four-torus with fixed edge length L and fundamental domain $[0,L]^4 \subset \mathbf{R}^4$. A gauge potential on an SU(N) bundle over T^4 can be viewed as an su(N)-valued gauge field $A_\mu(x)$ on $\mathbf{R}^4$ satisfying

$$A_\mu(x+Le_\nu)=\Omega(x,\nu)A_\mu(x)\Omega(x,\nu)^{-1}+\Omega(x,\nu)\partial_\mu\Omega(x,\nu)^{-1}, \tag{1.1}$$

where e_ν is the unit vector in the positive ν-direction and $\Omega(x,\nu)$, $\nu=1,2,3,4$, are the SU(N)-valued monodromy fields which specify the principal SU(N) bundle over T^4. These also satisfy a cocycle condition which ensures that $A_\mu(x+Le_\nu+Le_\rho)$ is unambiguous and that Eq. (2.4) in this work is consistent. It is always possible to make a gauge transformation so that $\Omega(x,\nu)=1$ for $\nu=1,2,3$ and $\Omega(x,4)$ is periodic in x_1,x_2,x_3. Then for fixed x_4 $\Omega(x,4)$ determines a map $T^3 \to \mathrm{SU(N)}$. The degree of this map [which is independent of x_4 since $\Omega(x,4)$ depends smoothly on x_4] equals the Pontryargin number of the SU(N) bundle over T^4. The Pontryargin number of the bundle is encoded in the gauge field as its topological charge:

$$Q=\frac{-1}{8\pi^2}\int_{T^4}\mathrm{tr}(F\wedge F)=\frac{-1}{32\pi^2}\int d^4x\,\epsilon_{\mu\nu\rho\sigma}\mathrm{tr}(F_{\mu\nu}(x)F_{\rho\sigma}(x)). \tag{1.2}$$

The sections $\psi(x)$ in the standard spinor bundle over T^4 twisted by the SU(N) bundle can be viewed as spinor fields on $\mathbf{R}^4$ satisfying

$$\psi(x+Le_\nu)=\Omega(x,\nu)\psi(x). \tag{1.3}$$

The Dirac operator $\not{D}^A=\gamma^\mu(\partial_\mu+A_\mu)$ acts on these, and the Index Theorem[1] gives

$$Q=\mathrm{index}\not{D}^A. \tag{1.4}$$

The index$\not{D}^A$ is equal to the spectral flow of the Hermitian operator $-\gamma_5(i\not{D}^A-m)$ as m increases from any negative to any positive value [note that eigenvalues can only cross the origin at $m=0$ since $(\gamma_5(i\not{D}-m))^2=\not{D}^2+m^2$.]

The spectral flow description of Q motivates a fermionic definition of topological charge Q_{lat} in lattice gauge theory,[2–4] which has been extensively studied numerically in its various guises;

a)Electronic mail: dadams@staff.maths.adelaide.edu.au

see, e.g., Refs. 2 and 4–11. The purpose of this article is to analytically prove that Q_{lat} reduces to Q in the classical continuum limit. (This result was announced in Ref. 12 although the argument we give here is simpler and more direct than the one sketched there.)

II. STATEMENT OF THE MAIN RESULT

Put a hyper-cubic lattice on $\mathbf{R}^4$ with sites $a\mathbf{Z}^4$. We consider only the lattice spacings a for which L/a is a whole number. Furthermore, we restrict to lattice spacings with the property $a_1\mathbf{Z}^4 \subset a_2\mathbf{Z}^4$ for $a_2 < a_1$. This implies that if $x \in \mathbf{R}^4$ is a lattice site in the lattice with spacing a, then it is also a lattice site in all the other lattices with spacing $a' < a$. In the following, in statements concerning $a \to 0$ limits (in particular Proposition 2 to follow) the variable x always denotes such a point in $\mathbf{R}^4$; it is fixed in $\mathbf{R}^4$ and does not change as we go from one lattice to another.

The lattice transcript of A,

$$U_\mu(x) = T \exp\left(\int_0^1 a A_\mu(x + t a e_\mu) dt \right) \tag{2.1}$$

($T = t-$ ordering), satisfies

$$U_\mu(x + L e_\nu) = \Omega(x,\nu) U_\mu(x) \Omega(x + a e_\mu, \nu)^{-1}. \tag{2.2}$$

Given such a lattice, let $\mathcal{C}$ denote the infinite-dimensional complex vectorspace of lattice spinor fields $\psi(x)$ (i.e., functions on the lattice sites taking values in $\mathbf{C}^4 \otimes \mathbf{C}^N$) and define the inner product

$$\langle \psi_1, \psi_2 \rangle = a^4 \sum_{x \in a\mathbf{Z}^4} \psi_1(x)^* \psi_2(x), \tag{2.3}$$

where a contraction of spinor and color indices is implied. Let $\mathcal{H} \subset \mathcal{C}$ denote the Hilbert space of spinor fields with $\|\psi\| < \infty$ and let $\mathcal{C}_L \subset \mathcal{C}$ denote the finite-dimensional subspace of spinor fields satisfying the lattice version of (1.3):

$$\psi(x + L e_\nu) = \Omega(x,\nu) \psi(x), \quad \forall x \in a\mathbf{Z}^4. \tag{2.4}$$

The fields $\psi \in \mathcal{C}_L$ are determined by their restriction to $\mathcal{F}_L :=$ the set of lattice sites contained in $[0,L)^4 \subset \mathbf{R}^4$. We define an inner product in $\mathcal{C}_L$ by

$$\langle \psi_1, \psi_2 \rangle_L = a^4 \sum_{x \in \mathcal{F}_L} \psi_1(x)^* \psi_2(x). \tag{2.5}$$

The covariant forward (backward) finite difference operators $(1/a)\,\nabla_\mu^+$ ($(1/a)\,\nabla_\mu^-$) are defined on $\mathcal{C}$ by

$$\nabla_\mu^+ \psi(x) = U_\mu(x) \psi(x + a e_\mu) - \psi(x), \tag{2.6}$$

$$\nabla_\mu^- \psi(x) = \psi(x) - U_\mu(x - a e_\mu)^{-1} \psi(x - a e_\mu). \tag{2.7}$$

These are bounded ($\|\nabla_\mu^\pm\| \leqslant 2$) and therefore map $\mathcal{H}$ to $\mathcal{H}$. They also preserve (2.4) and therefore map $\mathcal{C}_L$ to $\mathcal{C}_L$. Note that

$$(\nabla_\mu^\pm)^* = -\nabla_\mu^\mp \tag{2.8}$$

on $\mathcal{H}$ and $\mathcal{C}_L$. The lattice version of $i\not{\partial}^A$ is the Wilson–Dirac operator:

$$D_w = i\frac{1}{a}\nabla\!\!\!/ + \frac{r}{2}a\left(\frac{1}{a^2}\Delta\right), \quad r>0, \tag{2.9}$$

where $(1/a)\,\nabla\!\!\!/ = \Sigma_\mu \gamma^\mu \frac{1}{2}(\nabla_\mu^+ + \nabla_\mu^-)$ is the naive lattice Dirac operator and $(1/a^2)\,\Delta = (1/a^2)\,\Sigma_\mu(\nabla_\mu^- + \nabla_\mu^+) = (1/a^2)\,\Sigma_\mu(\nabla_\mu^+)^*\nabla_\mu^+ = (1/a^2)\,\Sigma_\mu(\nabla_\mu^-)^*\nabla_\mu^-$ is the lattice Laplace operator. We are following the mathmatical convention where the γ^μ's are anti-Hermitian [this explains the factor i in $i(1/a)\,\nabla\!\!\!/$ in (2.9) which is not usually present in the physics literature where the γ^μ's are Hermitian]. Then $\nabla\!\!\!/$ is Hermitian due to (2.8) and Δ is Hermitian and positive. [The Wilson term, i.e., the second term in (2.9), which formally vanishes in the $a\to 0$ limit, is included to avoid the fermion doubling problem: a degeneracy of the nullspace of $\nabla\!\!\!/$ which is a lattice artifact unrelated to the continuum theory.[13,14]] The lattice version of $\gamma_5(i\partial\!\!\!/ - m)$ is the Hermitian operator $(1/a)\,H_m$:

$$\frac{1}{a}H_m = \gamma_5\left(D_w - \frac{rm}{a}\right), \tag{2.10}$$

$$H_m = \gamma_5(i\nabla\!\!\!/ + r(\tfrac{1}{2}\Delta - m)). \tag{2.11}$$

It can be shown that the spectrum of H_m is symmetric and without zero for all $m<0$. Hence the spectral flow of $-H_m$ as m increases from any negative value to some positive value m_0 is equal to half the spectral asymmetry of $-H_{m_0}$.[3,4] This suggests the following fermionic definition of the topological charge of the lattice gauge field $U_\mu(x)$:

$$Q_{\rm lat} = Q_{m_0} := -\frac{1}{2}{\rm Tr}\left(\frac{H_{m_0}}{|H_{m_0}|}\right), \tag{2.12}$$

where H_{m_0} is acting on $\mathcal{C}_L$. The spectral flow of H_m was first studied numerically in Ref. 2. The definition (2.12) arose in the overlap formulation of chiral gauge theory on the lattice.[3,4] Q_{m_0} also arises as an index: $Q_{m_0} = {\rm index}(D_{m_0}) := {\rm Tr}(\gamma_5|_{\ker D_{m_0}})$ where $D = (1/a)\,(1+\gamma_5\,(H/|H|))$ is the overlap Dirac operator.[15]

Unlike in the continuum case, the spectral flow of $-H_m$ depends on the final value $m_0>0$ of m. Numerical studies have shown that for reasonably smooth lattice gauge fields, e.g., when $U_\mu(x)$ is the lattice transcript of a smooth continuum gauge field and the lattice is reasonably fine, the eigenvalue crossings of $-H_m$ are localized around $m=0,2,4,6,8$.[2,8] Furthermore, when the lattice gauge field is the lattice transcript of a continuum field the spectral flow due to crossings close to $m=0$ was found to reproduce the continuum topological charge Q. In this article we complement the previous numerical studies with the following analytical result:

Theorem: In the above setting, where $U_\mu(x)$ is the lattice transcript (2.1) and $m_0 \notin \{0,2,4,6,8\}$, there exists an $a_0>0$ [depending on $A_\mu(x)$ and m_0] such that

$$Q_{m_0} = I(m_0)Q \quad \text{for all lattice spacings } a<a_0, \tag{2.13}$$

where

$$I(m_0) = \begin{array}{|c|c|c|c|c|} \hline 0<m_0<2 & 2<m_0<4 & 4<m_0<6 & 6<m_0<8 & m_0 \notin [0,8] \\ \hline 1 & -3 & 3 & -1 & 0 \\ \hline \end{array} \tag{2.14}$$

Remarks: (i) The dependence on m_0 in (2.13) and (2.14) coincides with that found in the above-mentioned numerical studies with smooth lattice gauge fields. (ii) The definition (2.12) of

Q_{m_0} is only meaningful when H_{m_0} does not have zero-modes. In the present case this is guaranteed when $m_0 \notin \{0,2,4,6,8\}$ and a is sufficiently small. Indeed, it is known that when $\|1-U(p)\|<\epsilon$ for all lattice plaquettes p, where $U(p)$ is the product of the link variables $U_\mu(x)$ around p, then there is a lower bound $H^2_{m_0}>b$, depending only on ϵ and m_0, such that for fixed $m_0 \notin \{0,2,4,6,8\} b>0$ when ϵ is sufficiently small. This bound was established in Ref. 16 (and improved in Ref. 17) for the case where $0<m_0<2$ and can be generalized to arbitrary $m_0 \notin \{0,2,4,6,8\}$.[18] In the present case, where $U_\mu(x)$ is the lattice transcript (2.1), we have

$$1-U(p_{x,\mu\nu})=a^2F_{\mu\nu}(x)+O(a^3)(x) \tag{2.15}$$

leading to

$$\|1-U(p)\|\sim O(a^2). \tag{2.16}$$

Hence the above-mentioned lower bound $H^2_{m_0}>b>0$ holds for all sufficiently small a. Here and in the following $O(a^p)(x)$ denotes a function on the lattice sites $x\in\mathcal{F}_L$ such that the operator norm of $O(a^p)(x)$, considered as a multiplication operator on $\mathcal{C}$, satisfies $\|O(a^p)(x)\|\leqslant a^pK$ for all $x\in\mathcal{F}_L$ where K is a constant independent of a and x. [In (2.15) $O(a^p)(x)$ takes values in the space of linear maps on $\mathbf{C}^N$; sometimes $O(a^p)(x)$ will just be a $\mathbf{C}$-valued function of x, in which case we have $|O(a^p)(x)|\leqslant a^pK$.] We discuss the derivation of (2.15) and (2.16), and other bounds used in the following, in the appendix. In general, to conclude (2.16) from (2.15) we need the $O(a^3)(x)$ term to satisfy $\|O(a^3)(x)\|\leqslant a^3K$ for all $x\in a\mathbf{Z}^4$. For general gauge field $A_\mu(x)$ on $\mathbf{R}^4$ this holds when $\|A_\mu(x)\|$ and $\|\partial_\mu A_\nu(x)\|$ are bounded on $\mathbf{R}^4$ (cf. the Appendix). In the present case the condition (1.1) generally results in divergence of $A_\mu(x)$ at infinity (for topologically nontrivial field). Nevertheless we still have (2.16) in this case: it is a consequence of (2.2) [note that $\|U_\mu(x)\|=1$ since $U_\mu(x)$ is unitary] and the fact that the $O(a^3)(x)$ term satisfies $\|O(a^3)(x)\|\leqslant a^3K$ when x is restricted to be in the fundamental domain $\mathcal{F}_L$.

III. PROOF OF THE THEOREM

The strategy for proving the theorem is to express Q_{m_0} as the sum of a density,

$$Q_{m_0}=a^4\sum_{x\in\mathcal{F}_L} q_L(x), \tag{3.1}$$

and show that

$$q_L(x)=I(m_0)q^A(x)+O(a)(x) \quad (x\in\mathcal{F}_L), \tag{3.2}$$

where

$$q^A(x)=\frac{-1}{32\pi^2}\epsilon_{\mu\nu\rho\sigma}\mathrm{tr}F_{\mu\nu}(x)F_{\rho\sigma}(x). \tag{3.3}$$

Then $\lim_{a\to 0}Q_{m_0}=I(m_0)Q$, and since Q_{m_0} is integer it follows that Q_{m_0} must coincide with $I(m_0)Q$ for small nonzero a as stated in the theorem.

To specify the density $q_L(x)$ in (3.1) we introduce the following definitions. We decompose $\mathcal{C}=\mathcal{C}^{sc}\otimes(\mathbf{C}^4\otimes\mathbf{C}^N)$, $\mathcal{H}=\mathcal{H}^{sc}\otimes(\mathbf{C}^4\otimes\mathbf{C}^N)$ where $\mathcal{C}^{sc}$, $\mathcal{H}^{sc}$ denote the corresponding spaces of scalar lattice fields. $\mathcal{H}^{sc}$ has the orthonormal basis $\{\delta_x/a^2\}_{x\in a\mathbf{Z}^4}$ where $\delta_x(y)=\delta_{xy}$. For linear operator $\mathcal{O}_\mathcal{H}$ on $\mathcal{H}$ we define $\mathcal{O}_\mathcal{H}(x,y)=(1/a^4)\langle(\delta_x/a^2),\mathcal{O}_\mathcal{H}(\delta_y/a^2)\rangle$; this is a linear operator on $\mathbf{C}^4\otimes\mathbf{C}^N$ satisfying

$$\mathcal{O}_\mathcal{H}\psi(x)=a^4\sum_{y\in a\mathbf{Z}^4}\mathcal{O}_\mathcal{H}(x,y)\psi(y) \quad \forall\,\psi\in\mathcal{H}. \tag{3.4}$$

There is also an obvious decomposition $\mathcal{C}_L = \mathcal{C}_L^{sc} \otimes (\mathbf{C}^4 \otimes \mathbf{C}^N)$ with $\mathcal{C}_L^{sc}$ having the basis $\{\phi_x\}_{x \in \mathcal{F}_L}$ where $\phi_x(y) = (1/a^2)\,\delta_{xy}$ for $y \in \mathcal{F}_L$ and is extended to $a\mathbf{Z}^4$ in accordance with (2.4):

$$\phi_x(y+Ln) = \frac{1}{a^2}\Omega^{(n)}(x)\,\delta_{xy}, \quad \Omega^{(n)}(x) = \prod_\nu \Omega(x,\nu)^{n_\nu}, \quad n \in \mathbf{Z}^4. \tag{3.5}$$

For linear operator $\mathcal{O}_L$ on $\mathcal{C}_L$ we define $\mathcal{O}_L(x,y) = (1/a^4)\langle \phi_x, \mathcal{O}_L \phi_y \rangle_L$ for $x,y \in \mathcal{F}_L$; this is a linear operator on $\mathbf{C}^4 \otimes \mathbf{C}^N$ satisfying

$$\mathcal{O}_L\psi(x) = a^4 \sum_{y \in \mathcal{F}_L} \mathcal{O}_L(x,y)\,\psi(y) \quad \forall\ \psi \in \mathcal{C}_L, \quad x \in \mathcal{F}_L. \tag{3.6}$$

The Cauchy–Schwarz inequality gives $\|\mathcal{O}_{\mathcal{H}}(x,y)\| \leqslant (1/a^4)\,\|\mathcal{O}_{\mathcal{H}}\|$ and $\|\mathcal{O}_L(x,y)\| \leqslant (1/a^4)\,\|\mathcal{O}_L\|_L$.

The definition (2.12) of Q_{m_0} can now be rewritten as (3.1) with

$$q_L(x) = -\frac{1}{2}\mathrm{tr}\left(\frac{H}{\sqrt{H^2}}\right)_L (x,x), \tag{3.7}$$

where $H = H_{m_0}$ and the trace is over spinor and color indices (i.e., over $\mathbf{C}^4 \otimes \mathbf{C}^N$). The strategy for deriving (3.2) and (3.3) is now to relate $q_L(x)$ to $q_{\mathcal{H}}(x)$, defined by replacing $(H/\sqrt{H^2})_L$ by $(H/\sqrt{H^2})_{\mathcal{H}}$ in (3.7). (The latter is defined via the spectral theory for bounded operators on Hilbert space.) This approach was suggested to me by Martin Lüscher.[19] The point is that (3.2) and (3.3) are relatively easy to derive for $q_{\mathcal{H}}(x)$; in fact, this has essentially already been done in previous works.[20–23] One potentially problematic aspect with regards to these previous calculations is that in the present case $A_\mu(x)$ can diverge for $|x| \to \infty$. However, we will get around this by exploiting the locality property of $(H/\sqrt{H^2})_{\mathcal{H}}$,[16] which will allow us to replace $A_\mu(x)$ by a gauge field which vanishes outside a bounded region of $\mathbf{R}^4$.

The relation between $q_L(x)$ and $q_{\mathcal{H}}(x)$ is as follows:

Proposition 1:

$$\left(\frac{H}{\sqrt{H^2}}\right)_L (x,y) = \sum_{n \in \mathbf{Z}^4} \left(\frac{H}{\sqrt{H^2}}\right)_{\mathcal{H}} (x,y+Ln)\Omega^{(n)}(y) \quad (x,y \in \mathcal{F}_L), \tag{3.8}$$

where $\Omega^{(n)}(x)$ is defined in (3.5). In particular, setting $y = x$ and substituting in (3.7) we get

$$q_L(x) = q_{\mathcal{H}}(x) - \frac{1}{2}\sum_{n \in \mathbf{Z}^4 - \{0\}} \mathrm{tr}\left(\frac{H}{\sqrt{H^2}}\right)_{\mathcal{H}} (x,x+Ln)\,\Omega^{(n)}(x). \tag{3.9}$$

Proof: We begin by deriving a relation between $\mathcal{O}_L(x,y)$ and $\mathcal{O}_{\mathcal{H}}(x,y)$ for bounded operators $\mathcal{O}$ on $\mathcal{C}$ which leave $\mathcal{C}_L$ invariant. The proposition will then follow by exploiting the fact that $(H/\sqrt{H^2})_L$ and $(H/\sqrt{H^2})_{\mathcal{H}}$ can be simultaneously approximated by such operators. The approximation part is necessary since $H/\sqrt{H^2}$ is not a well-defined operator on the whole of $\mathcal{C}$; the technicalities are related to the fact that $\mathcal{C}_L \not\subset \mathcal{H}$, i.e., elements in $\mathcal{C}_L$ can have infinite norm.

Let $\mathcal{O}$ be a bounded operator on $\mathcal{C}$ which maps $\mathcal{C}_L$ to itself. Then it follows from the above definitions and (3.5) that, for $x,y \in \mathcal{F}_L$,

$$\mathcal{O}_L(x,y)=\frac{1}{a^4}\langle\phi_x,\mathcal{O}\phi_y\rangle_L$$

$$=\sum_{z\in\mathcal{F}_L}\phi_x(z)(\mathcal{O}\phi_y)(z)$$

$$=\frac{1}{a^2}(\mathcal{O}\phi_y)(x)=a^2\sum_{z\in a\mathbf{Z}^4}\mathcal{O}_{\mathcal{H}}(x,z)\,\phi_y(z)$$

$$=\sum_{n\in\mathbf{Z}^4}\mathcal{O}_{\mathcal{H}}(x,y+Ln)\,\Omega^{(n)}(y). \tag{3.10}$$

We now exploit the fact[16] that $1/\sqrt{H^2}$ has a power series expansion $\kappa\Sigma_{k=0}^{\infty}t^kP_k(H^2)$ norm-convergent to $(1/\sqrt{H^2})_L$ and $(1/\sqrt{H^2})_{\mathcal{H}}$ on $\mathcal{C}_L$ and $\mathcal{H}$, respectively. $P_k(\cdot)$ is a Legendre polynomial of order k; $\|P_k(H^2)\|\leqslant 1$; $t=e^{-\theta}$; and the constants $\kappa,\theta>0$ depend only on the (strictly positive) lower and upper bounds on H^2.[16] [We are assuming that a is sufficiently small so that H^2 has a lower bound $b>0$ cf. remark (ii) above]. Set

$$P^{(N)}:=H\left(\kappa\sum_{k=0}^{N}t^kP_k(H^2)\right).$$

For arbitrary finite N this is a bounded operator on $\mathcal{C}$ which maps $\mathcal{C}_L$ to itself. In light of (3.10), to prove the proposition it suffices to show that $(H/\sqrt{H^2})_L(x,y)-P_L^{(N)}(x,y)$ and $\Sigma_{n\in\mathbf{Z}^4}[(H/\sqrt{H^2})_{\mathcal{H}}(x,y+Ln)-P_{\mathcal{H}}^{(N)}(x,y+Ln)]\Omega^{(n)}(y)$ both vanish in the $N\to\infty$ limit. The former is obvious. To show the latter it suffices to show that $\Sigma_{n\in\mathbf{Z}^4}\Sigma_{k=N+1}^{\infty}t^k\|P_k(x,y+Ln)\|$ vanishes in the $N\to 0$ limit. (We have set $P_k(x,z)=[P_k(H^2)](x,z)$.) For simplicity we show this for $y=x$ [the relevant case for (3.9)]; the argument in the general case is a straightforward generalization. Since $P_k(H^2)$ is of order k in H^2, and H couples only nearest neighbor sites, we have $P_k(x,x+Ln)=0$ when $(L/a)\,\Sigma_\mu|n_\mu|>2k$. Since $\|P_k(x,z)\|\leqslant(1/a^4)\,\|P_k(H^2)\|\leqslant a^4$ it follows that

$$\sum_{n\in\mathbf{Z}^4}\sum_{k=N+1}^{\infty}t^k\|P_k(x,x+Ln)\|\leqslant\frac{1}{a^4}t^N\left(\sum_{n\in\mathbf{Z}^4,L/2a\,\Sigma_\mu|n_\mu|\leqslant N}\sum_{k=1}^{\infty}t^k\right)$$

$$+\frac{1}{a^4}\left(\sum_{n\in\mathbf{Z}^4,1/2a\,\Sigma_\mu|n_\mu|>N}t^{((L/2a)\,\Sigma_\mu|n_\mu|)}\sum_{k=1}^{\infty}t^k\right). \tag{3.11}$$

The first sum over n vanishes as N^4t^N for $N\to\infty$, while the second clearly vanishes for $N\to\infty$ since it is convergent for finite N. This completes the proof of the proposition.

We now derive a small a bound on the second term in (3.9). The facts that $P_k(x,x+Ln)=0$ for $(L/a)\,\Sigma_\mu|n_\mu|>2k$ and $\|P_k(H^2)\|\leqslant 1$ imply the following locality property of $(1/\sqrt{H^2})_{\mathcal{H}}$:[16]

$$\left\|\left(\frac{1}{\sqrt{H^2}}\right)_{\mathcal{H}}(x,x+Ln)\right\|\leqslant\left\|\kappa\sum_{k\geqslant(L/2a)\Sigma_\mu|n_\mu|}t^kP_k(x,y)\right\|$$

$$\leqslant\kappa\,t^{((L/2a)\Sigma_\mu|n_\mu|)}\sum_{k=0}^{\infty}t^k\frac{1}{a^4}=\tilde{\kappa}\frac{1}{a^4}\exp\left(-\theta\frac{L}{2a}\sum_\mu|n_\mu|\right), \tag{3.12}$$

where $\tilde{\kappa}:=\kappa/(1-e^{-\theta})$. For sufficiently small a this gives

$$\left\| \sum_{n\in\mathbf{Z}^4-\{0\}} \left(\frac{1}{\sqrt{H^2}}\right)_{\mathcal{H}}(x,x+Ln) \right\| \leqslant \sum_{n\in\mathbf{Z}^4-\{0\}} \frac{\tilde{\kappa}}{a^4}\prod_{\mu} \exp\left(-\theta\frac{L}{2a}|n_\mu|\right)$$

$$\leqslant \frac{\tilde{\kappa}}{a^4}\prod_{\mu}\left[2\int_{1/2}^{\infty}\exp\left(-\theta\frac{L}{2a}t_\mu\right)dt_\mu\right] = \tilde{\kappa}\left(\frac{4}{\theta L}\right)^4 \exp\left(-\frac{\theta L}{a}\right). \tag{3.13}$$

The second inequality follows from the fact that $\int_{1/2}^{\infty}\exp(-(\theta L/2a)\,t)\,dt \geqslant \exp(-(\theta L/2a))$ for sufficiently small a. It now follows from (3.9) that $q_L(x)=q_{\mathcal{H}}(x)+O(e^{-\rho/a})$ for sufficiently small a. (This had already been noted by M. Lüscher in the Abelian case in Ref. 24 although the derivation was not provided there.)

To prove the theorem it now suffices to show (3.2) and (3.3) for $q_{\mathcal{H}}(x)$ instead of $q_L(x)$, i.e., to show

$$q_{\mathcal{H}}(x)=I(m_0)q^A(x)+O(a)(x) \quad \text{for } x\in\mathcal{F}_L\,. \tag{3.14}$$

To simplify the derivation we exploit the fact that $q_{\mathcal{H}}(x)$ is local in the gauge field.[16] Because of this it suffices to show (3.14) in the case where $A_\mu(x)$ is replaced by another SU(N) gauge field $\tilde{A}_\mu(x)$ on $\mathbf{R}^4$ with $\tilde{A}_\mu(x)=A_\mu(x)$ in a neighborhood of $[0,L]^4$ and $\tilde{A}_\mu(x)=0$ outside a bounded region of $\mathbf{R}^4$. Specifically, we can take $\tilde{A}_\mu(x)=\lambda(x)A_\mu(x)$ where $\lambda(x)$ is a smooth function on $\mathbf{R}^4$ equal to 1 on $[-d,L+d]^4$ $(d>0)$ and vanishing outside a bounded region. To see this, let H and $\tilde{H}$ denote the operators defined by (2.11) with lattice gauge fields U and $\tilde{U}$ being the lattice transcripts [defined by (2.1)] of A and $\tilde{A}$, respectively. Then, for small a, just as for H^2 we have $\tilde{H}^2>b>0$ and an expansion $(1/\sqrt{\tilde{H}^2})_{\mathcal{H}}=\kappa\Sigma_{k=0}^{\infty}t^k\tilde{P}_k$ where $\tilde{P}_k=P_k(\tilde{H}^2)$. Since H and $\tilde{H}$ only couple nearest neighbor sites, $P_k(H^2)$ and $P_k(\tilde{H}^2)$ can only couple a lattice site in $[0,L]^4$ to another lattice site in $[0,L]^4$ via a site outside of $[-d,L+d]^4$ if $k\geqslant 2(d/2a)$. Therefore, $P_k(x,y)=\tilde{P}_k(x,y)$ for $x,y\in\mathcal{F}_L$ when $k<d/a$, and we find by an analogous argument to the one leading to (3.12) that, for $x,y\in\mathcal{F}_L$,

$$\left\| \left(\frac{1}{\sqrt{H^2}}\right)_{\mathcal{H}}(x,y) - \left(\frac{1}{\sqrt{\tilde{H}^2}}\right)_{\mathcal{H}}(x,y) \right\| \leqslant \kappa\sum_{k\geqslant d/a}^{\infty} t^k \|P_k(x,y)-\tilde{P}_k(x,y)\| \leqslant \frac{2\tilde{\kappa}}{a^4}e^{-\theta d/a}. \tag{3.15}$$

This together with the ultra-locality of H and $\tilde{H}$ implies

$$q_{\mathcal{H}}(x)=\tilde{q}_{\mathcal{H}}(x)+O\left(\frac{1}{a^4}e^{-\rho/a}\right)(x) \quad \text{for } x\in\mathcal{F}_L \tag{3.16}$$

In light of this, the theorem now follows from (a special case of) the following:

Proposition 2: Let $A_\mu(x)$ be a general smooth SU(N) gauge field on $\mathbf{R}^4$ with the property that $\|A_\mu(x)\|$, $\|\partial_\nu A_\mu(x)\|$, and $\|\partial_\sigma\partial_\nu A_\mu(x)\|$ are all bounded. Let $H=H_{m_0}$ be defined as in (2.11) with the lattice gauge field being the lattice transcript (2.1) of $A_\mu(x)$. Then $q_{\mathcal{H}}(x) = -\frac{1}{2}\mathrm{tr}(H/\sqrt{H^2})_{\mathcal{H}}(x,x)$ satisfies $q_{\mathcal{H}}(x)=I(m_0)q^A(x)+O(a)(x)$ for all $x\in a\mathbf{Z}^4$, where $\|O(a)(x)\|\leqslant aK$ for some constant K independent of x and small a.

Clearly the gauge field $\tilde{A}_\mu(x)$ introduced above satisfies the conditions of the proposition (since it vanishes outside a bounded region). Combining the proposition with (3.16) then gives (3.14), proving the theorem.

To prove Proposition 2 we use an integral representation to expand $1/\sqrt{H^2}$ as a power series following Refs. 12 and 21. (This gives a more explicit power series expansion than the expansion in Legendre polynomials[16] discussed earlier.) Henceforth all operators are assumed to be acting on

$\mathcal{H}$ and we drop the subscript "$\mathcal{H}$" in the notation. Also, from now on $O(a^p)(x)$ denotes a term with $\|O(a^p)(x)\| \leqslant a^p K$ for all $x \in a\mathbf{Z}^4$ (not just for $x \in \mathcal{F}_L$). We first decompose

$$H^2 = L - V, \tag{3.17}$$

where

$$L = -\nabla^2 + r^2(\tfrac{1}{2}\Delta - m_0)^2, \tag{3.18}$$

$$V = = ir\,\tfrac{1}{2}\gamma_\mu V_\mu - \tfrac{1}{4}[\gamma_\mu, \gamma_\nu] V_{\mu\nu}, \tag{3.19}$$

with

$$V_\mu = \frac{1}{2}\left[(\nabla_\mu^+ + \nabla_\mu^-), \sum_\nu (\nabla_\nu^- - \nabla_\nu^+)\right], \tag{3.20}$$

$$V_{\mu\nu} = \tfrac{1}{4}[(\nabla_\mu^+ + \nabla_\mu^-), (\nabla_\nu^+ + \nabla_\nu^-)]. \tag{3.21}$$

As pointed out in Ref. 16, the norms of the commutators of the $\nabla_\mu^\pm$'s are bounded by $\max_p \|1 - U(p)\|$. The bound (2.16) on $\|1 - U(p)\|$ is valid when the conditions of Proposition 2 are satisfied (cf. the Appendix), hence

$$\|V\| \sim O(a^2). \tag{3.22}$$

It follows that for small a we have $\|V\| < b/2$ where b is the lower bound on H^2 mentioned earlier in remark (ii). This in turn implies the lower bound $L > b/2 > 0$ for the positive operator L in (3.18). Thus for sufficiently small a the operator L is invertible, $\|L^{-1}\| \cdot \|V\| < 1$, and we can make the expansion

$$\frac{H}{\sqrt{H^2}} = H\int_{-\infty}^{\infty} \frac{d\sigma}{\pi} \frac{1}{H^2 + \sigma^2} = H\int_{-\infty}^{\infty} \frac{d\sigma}{\pi} \left(\frac{1}{1 - (L + \sigma^2)^{-1} V}\right)\left(\frac{1}{L + \sigma^2}\right) = \int_{-\infty}^{\infty} \frac{d\sigma}{\pi} \sum_{k=0}^{\infty} H(G_\sigma V)^k G_\sigma, \tag{3.23}$$

where $G_\sigma := (L + \sigma^2)^{-1}$. Note that the γ-matrices in (3.17) are all contained in V. Since the trace of γ_5 times a product of less than four γ-matrices vanishes, the $k = 0$ and $k = 1$ terms in (3.23) give vanishing contribution to $q_{\mathcal{H}}(x)$. On the other hand, the terms with $k \geqslant 3$ satisfy the following bound:

$$\begin{aligned}\left\| \int_{-\infty}^{\infty} \frac{d\sigma}{\pi} \sum_{k=3}^{\infty} [H(G_\sigma V)^k G_\sigma](x,x) \right\| &\leqslant \frac{1}{a^4}\|H\| \int_{-\infty}^{\infty} \frac{d\sigma}{\pi} \sum_{k=3}^{\infty} \|G_\sigma\|^{k+1} \|V\|^k \\ &\leqslant a^2 K^3 \|H\| \left[\int_{-\infty}^{\infty} \frac{d\sigma}{\pi} \frac{1}{(b/2 + \sigma^2)^4}\right] \sum_{k=0}^{\infty} \left(\frac{2}{b} a^2 K\right)^k,\end{aligned} \tag{3.24}$$

where we have used (3.22) and the bounds $G_\sigma < (b/2 + \sigma^2)^{-1} \leqslant 2/b$. This is $O(a^2)$ since the integral and sum are finite and remain so in the $a \to 0$ limit. Hence only the $k = 2$ term in (3.23) contributes in the $a \to 0$ limit:

$$q_{\mathcal{H}}(x) = q_{\mathcal{H}}^{(2)}(x) + O(a^2)(x), \tag{3.25}$$

where

$$q^{(2)}_{\mathcal{H}}(x) = -\frac{1}{2}\int_{-\infty}^{\infty}\frac{d\sigma}{\pi}\,\mathrm{tr}[HG_\sigma VG_\sigma VG_\sigma](x,x). \tag{3.26}$$

For lattice operators $\mathcal{O}$ which are polynomials in $\nabla^{\pm}_{\mu}$ we denote by $\mathcal{O}^{(0)}$ the operator obtained by setting $U=1$ in (2.6) and (2.7). Standard arguments give (cf. the Appendix) $\|H-H^{(0)}\| \sim O(a)$ and $\|L-L^{(0)}\|\sim O(a)$. The latter implies $\|G_\sigma - G^{(0)}_\sigma\|\sim O(a)$; this follows from $G_\sigma - G^{(0)}_\sigma = G^{(0)}_\sigma(L^{(0)}-L)G_\sigma$ since G_σ and $G^{(0)}_\sigma$ are bounded from above by $2/b$ when a is sufficiently small. This allows us to replace H and G_σ by $H^{(0)}$ and $G^{(0)}_\sigma$ in (3.26) at the expense of an $O(a)(x)$ term. Furthermore, we have $\|[L^{(0)},V]\|\sim O(a^3)$ (cf. the Appendix). This leads to $\|[G^{(0)}_\sigma,V]\|\sim O(a^3)$ as follows: The bound $\|\nabla^{\pm}_{\mu}\|\leqslant 2$ and triangle inequalities lead to an a-independent upper bound $L<c$ which allows us to expand

$$G_\sigma = \left(\frac{1}{c+\sigma^2}\right)\left(\frac{1}{1-(c-L)/(c+\sigma)}\right) = \frac{1}{c+\sigma^2}\sum_{m=0}^{\infty}\left(\frac{c-L}{c+\sigma^2}\right)^m.$$

Now, since

$$\|[(c-L^{(0)})^m,V]\|\leqslant m\|[L^0,V]\|\cdot\|c-L\|^{m-1}\leqslant m(a^3K)(c-b/2)^{m-1},$$

we get

$$\|[G^{(0)}_\sigma,V]\|\leqslant \frac{a^3K}{c^2}\sum_{m=0}^{\infty}(m+1)\left(\frac{c-b/2}{c}\right)^m,$$

and this is $\sim O(a^3)$ since the sum converges (since $0<b/2<c$). Taking this into account in (3.26), it follows from (3.25) that

$$\begin{aligned} q_{\mathcal{H}}(x) &= -\frac{1}{2}\int_{-\infty}^{\infty}\frac{d\sigma}{\pi}\,\mathrm{tr}[H^{(0)}V^2(G^{(0)}_\sigma)^3](x,x)+O(a)(x)\\ &= -\frac{1}{2}\mathrm{tr}\left[H^{(0)}V^2\int_{-\infty}^{\infty}\frac{d\sigma}{\pi}\,\frac{1}{(L^{(0)}+\sigma^2)^3}\right](x,x)+O(a)(x)\\ &= \frac{-3}{16}\mathrm{tr}[H^{(0)}V^2(L^{(0)})^{-5/2}](x,x)+O(a)(x). \end{aligned} \tag{3.27}$$

Evaluating the trace over spinor indices we find [with $\nabla_\mu = \frac{1}{2}(\nabla^+_\mu+\nabla^-_\mu)$]

$$\begin{aligned} q_{\mathcal{H}}(x) = \frac{-3r}{16}\epsilon_{\mu\nu\rho\sigma}\mathrm{tr}\left[\left(-\nabla^{(0)}_\mu(V_\nu V_{\rho\sigma}+V_{\nu\rho}V_\sigma)+\left(\frac{1}{2}\Delta^{(0)}-m_0\right)V_{\mu\nu}V_{\rho\sigma}\right)(L^{(0)})^{-5/2}\right](x,x)\\ +O(a)(x), \end{aligned} \tag{3.28}$$

where V_μ and $V_{\mu\nu}$ are given by (3.20) and (3.21). Calculations give (cf. the Appendix)

$$[\nabla^{\pm}_\mu,\nabla^{\pm}_\nu]\psi(x) = (a^2F_{\mu\nu}(x)+O(a^3)(x))\psi(x\pm ae_\mu\pm ae_\nu), \tag{3.29}$$

$$[\nabla^{\pm}_\mu,\nabla^{\mp}_\nu]\psi(x) = (a^2F_{\mu\nu}(x)+O(a^3)(x))\psi(x\pm ae_\mu\mp ae_\nu). \tag{3.30}$$

These determine the relevant contributions of V_μ and $V_{\mu\nu}$ in (3.28).

We now exploit the fact that there is a Fourier transformation on $\mathcal{H}^{sc}$ (=the space of scalar lattice fields with $\|\phi\|^2=\Sigma_{x\in a\mathbf{Z}^4}|\phi(x)|^2<\infty$); in particular, δ_x has the Fourier expansion

$$\delta_x = \int_{-\pi}^{\pi} \frac{d^4k}{(2\pi)^4} e^{-ikx/a} \phi_k , \tag{3.31}$$

where $\phi_k(y) := e^{iky/a}$. For a general operator $\mathcal{O}$ this leads to

$$\mathcal{O}_{\mathcal{H}}(x,x) = \frac{1}{a^4} \left\langle \frac{\delta_x}{a^2}, \mathcal{O} \frac{\delta_x}{a^2} \right\rangle = \frac{1}{a^4} \int_{-\pi}^{\pi} \frac{d^4k}{(2\pi)^4} e^{-ikx/a} \frac{1}{a^4} \langle \delta_x, \mathcal{O}\phi_k \rangle$$

$$= \frac{1}{a^4} \int_{-\pi}^{\pi} \frac{d^4k}{(2\pi)^4} e^{-ikx/a} (\mathcal{O}\phi_k)(x). \tag{3.32}$$

In the case where

$$\mathcal{O} = \epsilon_{\mu\nu\rho\sigma} (-\nabla_\mu^{(0)} (V_\nu V_{\rho\sigma} + V_{\nu\rho} V_\sigma) + (\tfrac{1}{2}\Delta^{(0)} - m_0) V_{\mu\nu} V_{\rho\sigma}) (L^{(0)})^{-5/2}, \tag{3.33}$$

a calculation using (3.20) and (3.21) with (3.29) and (3.30) gives

$$(\mathcal{O}\phi_k)(x) = 32\pi^2 a^4 \lambda(k;r,m_0) (q^A(x) + O(a)(x)) \phi_k(x), \tag{3.34}$$

where

$$\lambda(k;r,m_0) = \frac{\Pi_\nu \cos k_\nu (-m_0 + \Sigma_\mu (1 - \cos k_\mu) - \Sigma_\mu (\sin^2 k_\mu / \cos k_\mu))}{[\Sigma_\mu \sin^2 k_\mu + r^2 (-m_0 + \Sigma_\mu (1 - \cos k_\mu))^2]^{5/2}}. \tag{3.35}$$

It follows from (3.28) and (3.32) that

$$q_{\mathcal{H}}(x) = I(r,m_0) q^A(x) + O(a)(x), \tag{3.36}$$

where

$$I(r,m_0) = \frac{-3r}{8\pi^2} \int_{-\pi}^{\pi} d^4k \, \lambda(k;r,m_0). \tag{3.37}$$

This integral was evaluated earlier in Refs. 21 and 23. It was found to be independent of $r > 0$ and a locally constant function of m_0 with values given by (2.14). This completes the proof of Proposition 2.

Remark: It is straightforward to generalize the results of this paper to SU(N) gauge fields on the $2n$-torus for arbitrary $n \geqslant 2$ and to U(1) gauge fields on the two-torus.

Finally, following the suggestion of a referee, we emphasize that a key point in this work is that it is the topological charge (i.e., the integrated Chern character) rather than the topological density that is shown to have the correct continuum limit. In this respect the treatment differs from all earlier treatments which are essentially limited to small (hence topologically trivial) fields.

ACKNOWLEDGMENTS

This work has benefited greatly from the input of Martin Lüscher, for which I thank him. I also thank Ting-Wai Chiu and Herbert Neuberger for discussions/correspondence. The author is supported by an ARC postdoctoral fellowship.

APPENDIX

In this Appendix we recall, for completeness, certain standard facts concerning the lattice transcript of a smooth continuum gauge field on $\mathbf{R}^4$ which lead to the bounds used in this article. The lattice transcript (2.1) can be written as

$$U_\mu(x)=\sum_{n=0}^{\infty} a^n \int_{0\leqslant t_1\leqslant\cdots\leqslant t_n\leqslant 1} dt_n\cdots dt_1\, A_\mu(x,t_n)\cdots A_\mu(x,t_1), \tag{A1}$$

where $A_\mu(x,t)=A_\mu(x+(1-t)ae_\mu)$. When A is bounded, i.e., $\|A_\mu(x)\|\leqslant K$ for all x,μ, we have

$$\Big\|\sum_{n=p}^{\infty} a^n \int_{0\leqslant t_1\leqslant\cdots\leqslant t_n\leqslant 1} dt_n\cdots dt_1\, A_\mu(x,t_n)\cdots A_\mu(x,t_1)\Big\|\leqslant\sum_{n=p}^{\infty} a^n \frac{1}{n!}K^n\leqslant a^pK^pe^{aK}\sim O(a^p). \tag{A2}$$

Therefore, to derive the $O(a^p)$ and $O(a^p)(x)$ bounds used in the text it suffices to consider only a finite number of terms in the expansion (A1) (typically just the first few terms). An immediate consequence of (A2) with $p=1$ is the following: If A is bounded, then for any operator $P=P(\nabla_\mu^{\pm})$ which is a polynomial in the covariant finite difference operators (2.6) and (2.7) we have

$$\|P-P^{(0)}\|\sim O(a).$$

The bounds $\|H-H^{(0)}\|\sim O(a)$ and $\|L-L^{(0)}\|\sim O(a)$ are particular examples of this. If we furthermore assume that the first order partial derivatives of A are bounded, i.e., $\|\partial_\mu A_\nu(x)\|\leqslant K$ for all x,μ,ν, we have

$$\|[\nabla_\mu^{\pm(0)},U_\nu]\|\sim O(a). \tag{A3}$$

To see this, note that

$$\begin{aligned}[\nabla_\mu^{+(0)},U_\nu]\psi(x)&=(U_\nu(x+ae_\mu)-U_\nu(x))\,\psi(x+ae_\mu)\\&=\left(a\int_{0\leqslant t\leqslant 1} dt(A_\nu(x+ae_\mu,t)-A_\nu(x,t))+O(a^2)\right)\psi(x+ae_\mu).\end{aligned} \tag{A4}$$

By the middle-value theorem,

$$A_\nu(x+ae_\mu,t)-A_\nu(x,t)=\partial_\mu A_\nu(x+sae_\mu,t)$$

for some $s\in[0,1]$. Since $\|\partial_\mu A_\nu\|$ is bounded (A3) now follows from (A4). The bound (A3) has the following easy generalization: Let $P=P(\nabla_\mu^{\pm})$ be a polynomial of degree k in the $\nabla_\mu^{\pm}$'s; then, if all the partial derivatives of A of order $\leqslant k$ are bounded, we have

$$\|[P^{(0)},U_\nu]\|\sim O(a). \tag{A5}$$

Moreover, with the same boundedness assumptions on $A_\mu(x)$ and $\partial_\mu A_\nu(x)$, straightforward calculations using the middle-value theorem give

$$1-U(p_{x,\mu,\nu})=a^2F_{\mu\nu}(x)+O(a^3)(x). \tag{A6}$$

Noting that[16]

$$[\nabla_\mu^{+},\nabla_\nu^{+}]\psi(x)=(1-U(p_{x,\mu\nu}))U_\mu(x)U_\nu(x+ae_\mu)\,\psi(x+ae_\mu+ae_\nu) \tag{A7}$$

and similar formulas for the other commutators, a straightforward refinement of the arguments leading to (A5) and (A6) shows

$$\|[P^{(0)},[\nabla_\mu^{\pm},\nabla_\nu^{\pm}]]\|\sim O(a^3),\quad \|[P^{(0)},[\nabla_\mu^{\pm},\nabla_\nu^{\mp}]]\|\sim O(a^3). \tag{A8}$$

The requirement for this is that A and all its partial derivatives up to order r be bounded, where $r=\min\{k,2\}$. Since V is a linear combination of commutators of the $\nabla_\mu^{\pm}$'s we have, in particular,

$\|[L^{(0)},V]\| \sim O(a^3)$ when A and its partial derivatives up to order 2 are bounded. Finally, we remark that (3.29) and (3.30) follow from combining (A7) and the corresponding formulas for the other commutators with (A6).

Some navigation rules for D-brane monodromy

Paul S. Aspinwall
Center for Geometry and Theoretical Physics, Box 90318, Duke University, Durham, North Carolina 27708-0318

(Received 22 June 2001; accepted for publication 20 August 2001)

We explore some aspects of monodromies of D-branes in the Kähler moduli space of Calabi–Yau compactifications. Here a D-brane is viewed as an object of the derived category of coherent sheaves. We compute all the interesting monodromies in some nontrivial examples and link our work to recent results and conjectures concerning helices and mutations. We note some particular properties of the 0-brane. © *2001 American Institute of Physics.* [DOI: 10.1063/1.1409963]

I. INTRODUCTION

There has been something of an evolution in our ideas about how a D-brane should be considered. For the purposes of this article we are interested only in the even-dimensional branes in a type II string (so-called ''B-branes''). The sequence of ideas has progressed roughly as follows

(1) A D-brane is something on which an open string may end.
(2) A D-brane is a U(N) gauge theory living on a subspace with scalar fields spanning the normal bundle.
(3) A D-brane should be viewed as coming from K-theory.[1,2]
(4) A D-brane should be viewed as an object of the derived category of coherent sheaves[3,4] (see also Ref. 5). (In this article the derived category will always be bounded at both ends.)

We could also add that for nontrivial H field a D-brane should be viewed as an object of the derived category of sheaves of modules over an Azumaya algebra.[6] We will assume H is trivial and so view D-branes as an object of the derived category of coherent sheaves. We will consider our target space to be a Calabi–Yau threefold X and we denote the derived category in question as $\mathbf{D}(X)$. For the purposes of this article we ignore any issues concerning the stability of D-branes. Our D-branes, which are objects of $\mathbf{D}(X)$, were called ''topological D-branes'' in Ref. 4 where issues of stability were discussed.

The reason that $\mathbf{D}(X)$ is ''better'' than K-theory is that it contains so much more information. For example *any* 0-brane on X corresponds to the same single element of K-theory whereas the object of $\mathbf{D}(X)$ corresponding to a 0-brane knows *where* this point is. That is, K-theory measures the charge of the D-brane but $\mathbf{D}(X)$ tells us more and possibly all we could wish to know about a particular D-brane.

As well as being knowledgeable about D-branes, $\mathbf{D}(X)$ is also very knowledgeable about X itself. This should not be too surprising as if we know about all the 0-branes on X, then we know about all the points on X and so we should know about X itself. Indeed, for a very large class of algebraic varieties it was shown by Bondal and Orlov[7] that X is completely determined, as an algebraic variety, by $\mathbf{D}(X)$. While this process does not quite work for Calabi–Yau varieties it is easy to speculate that adding such data as the spectrum of central charges while in a ''Calabi–Yau phase'' may provide the missing information. This would allow the target space to be constructed only given worldsheet information. Clearly, therefore, the derived category should be of great *physical* as well as mathematical interest.

An interesting question, also studied in Ref. 7, concerns in how many ways one may associate a derived category to a fixed X. An ''autoequivalence'' of a derived category is a map from the category to itself preserving all the intrinsic algebraic structure associated to the category. Such a

map need not preserve D-branes themselves. For example, an object representing a 2-brane may become something which more resembles a 4-brane under such a transformation. In terms of string theory, these autoequivalences can arise from monodromy in the moduli space of the complexified Kähler form as first observed by Kontsevich.[3] Indeed, the fact that this monodromy action on $\mathbf{D}(X)$ can be understood at all is one the appealing aspects of the derived category. It was suggested in Ref. 8 that the derived category should play a role in the heterotic string for similar reasons.

Since many interesting questions about $\mathbf{D}(X)$ are associated to these monodromies, the purpose of this article is to explore some of the aspects of these monodromies. The analysis of monodromies when the moduli space of complexified Kähler forms has only one complex dimension is pretty easy as we review in Sec. 3. Most of the interesting properties of monodromy do not appear until we explore higher-dimensional moduli spaces. We do this in the later sections.

One should note that many of these problems can be, and have been, performed using the method of solving the Picard–Fuchs equations and using analytic continuation (see Refs. 9–13, etc.). These methods have been used in the context of D-branes in such papers as Refs. 14–17. Instead we will use the language of derived categories where, we believe, the structure is much simpler to understand. In this way, computation of the monodromy is extremely easy (at least on the cohomology classes) and does not require the aid of a computer. Note that we are not being at all original in using the derived category—computations along these lines have been done in Refs. 18–21, for example. Our work differs from the latter only in the way we probe more deeply into the moduli space addressing such questions as monodromy around Landau–Ginzburg points in multi-parameter examples. Monodromy using the derived category approach has also been studied recently in papers such as Ref. 22.

Some interesting papers (Refs. 23–25) have appeared recently which compute the finite monodromy associated to orbifold theories by using the method of ''helices and mutations of exceptional sheaves.'' One of the motivations of this article was to better understand this construction in the language of the derived category. We discuss the connection (and differences) in Sec. IV. We also study the case of reducible exceptional divisors in Sec. VI B, which appears, at least at first sight, to lie somewhat outside the method of helices.

At least in the context of Batyrev-type Calabi–Yau varieties associated to toric geometry,[26] it seems possible to rigorously classify all types of monodromy. Indeed Horja[20] has achieved this in the neighborhood of the large radius limit. Rather than attempt such a classification we will simply go through some examples which appear to demonstrate most of the interesting things which can happen.

Our analysis is closely tied to the ''phase picture'' [27,28] of the moduli space. One has various limit points in the moduli space, each of which lies in the center of some phase. There are naturally embedded $\mathbb{P}^1$'s in the moduli space which connect adjacent limit points. We are concerned with monodromy within, or almost within, such $\mathbb{P}^1$'s. Most of the ''interesting'' questions one could ask about monodromy appear to be contained in this structure.

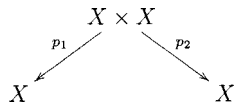
In Sec. V we exhaustively study a two-parameter example obtaining all interesting monodromies associated to this model. In Sec. VI we study some aspects of another couple of examples which exhibit some properties not seen in Sec. V.

Because of the prominent rôle played by the 0-brane in the construction of Bondal and Orlov, we discuss some of its properties under monodromies in Sec. VII.

II. AUTOEQUIVALENCES AND THE FOURIER–MUKAI TRANSFORM

In this section we will quickly review the language we use for the derived category. See Refs. 29 and 30 for more information about the derived category itself and Refs. 19 and 31 for more on some of the notation used later in this work.

Douglas[4] has argued that the even-dimensional D-branes on a Calabi–Yau X should be associated with objects in the derived category of coherent sheaves on X. The morphisms in this category are associated to open strings. Given a particular object $\mathscr{K}$ of $\mathbf{D}(X\times X)$ we associate projections



(1)

and the Fourier–Mukai transform[32,33]

$$T_{\mathscr{K}}(\mathscr{F}) = \mathbf{R}p_{2*}(\mathscr{K} \overset{L}{\otimes} p_1^*\mathscr{F}), \tag{2}$$

for any object $\mathscr{F}$ of $\mathbf{D}(X)$.

If $\mathscr{K}$ is chosen carefully (see Refs. 7 and 34 for details), then the Fourier–Mukai transform will be an "autoequivalence" of $\mathbf{D}(X)$. Namely, it maps $\mathbf{D}(X)$ back to itself while preserving the important algebraic structure associated to the "distinguished triangles." What this means for us is that the physics should remain invariant under such a transformation.

There are two cases of such $\mathscr{K}$'s which are of particular interest which will be denoted $\mathscr{K}^B$ and $\mathscr{K}^K$. First let L be a line bundle (or invertible sheaf) over X and let $j: X \to X \times X$ be the diagonal embedding. Then let $\mathscr{K}_L^B$ (where the superscript B stands for "B-field" for reasons to become clear) be the object of $\mathbf{D}(X \times X)$ given by

$$\cdots \to 0 \to j_* L \to 0 \to \cdots, \tag{3}$$

such that the nontrivial term is at the zeroth position.

Now consider the object of $\mathbf{D}(X)$ given by a sheaf at zeroth position:

$$\cdots \to 0 \to \mathcal{F} \to 0 \to \cdots. \tag{4}$$

If we apply to (4) the Fourier–Mukai transform associated to $\mathscr{K}_L^B$, we obtain

$$\cdots \to 0 \to \mathcal{F} \otimes L \to \cdots. \tag{5}$$

To relate this to string theory, let $\mathcal{F}$ be a sheaf supported over some subspace of X. That is, we have a D-brane wrapping this subspace. All we have done by applying this transform is to change the field strength of the U(1) gauge bundle over the D-brane. Gauge invariance forces the combination $F - B$ to be appear in the action of the D-brane. The above transformation must therefore be equivalent to $B \mapsto B + L$. [Note that we use L to denote the line bundle, the associated divisor class, and the dual two-form $c_1(L)$.]Thus we may assert (as was also done in Ref. 20) that *the transformations associated to $\mathscr{K}_L^B$ are those of a B-field shift $B \mapsto B + L$.*

Another transformation of interest is that of Seidel and Thomas[19] given by

$$\mathscr{K}_{\mathscr{E}}^K = \mathrm{Cone}\{\mathscr{E}^\vee \boxtimes \mathscr{E} \to j_* \mathcal{O}_x\}, \tag{6}$$

where $\mathcal{O}_X$ is the structure sheaf of X. The superscript K stands for "Kontsevich" who was the first to use this kind of transformation in the context of string theory.[18] Here the notation $A \boxtimes B$ is short for $p_1^* A \otimes p_2^* B$. The object $\mathscr{E}$ is any object of $\mathbf{D}(X)$ which satisfies the sphericity conditions given in Ref. 19. We refer to Ref. 30 for a nice description of the cone construction.

Now the associated Fourier–Mukai transform simplifies to the following:[19]

$$T_{\mathscr{K}_g^K}(\mathscr{F}) = \mathrm{Cone}\{\mathrm{Hom}(\mathscr{E}, \mathscr{F}) \otimes \mathscr{E} \overset{f}{\to} \mathscr{F}\}, \tag{7}$$

where f is the obvious evaluation map.

It is worth pointing out a subtle but potentially important point. The cone construction is not a particularly well-defined functor in the context of the derived category. We refer to Sec. 1.4 of Chap. 5 of Ref. 29 for a discussion of the problems. By writing the transformation in the form (7) we potentially expose ourselves to such ambiguities. One should always bear in mind, however,

that the transformation exists as a Fourier–Mukai transform (2) which yields a perfectly well-defined functor from $\mathbf{D}(X)$ to itself. In particular, the cone appearing in (6) is only defining $\mathscr{K}_{\mathscr{E}}^{K}$ as an object and no functorial properties of the cone are required there.

It is difficult to understand the physical meaning of the transformation associated to $\mathscr{K}_{\mathscr{E}}^{K}$ working directly in the derived category. Instead we take Chern characters to see the effect on cohomology. From (7) one deduces that[19]

$$ch(T_{\mathscr{K}_{g}^{K}(\mathscr{E})}(\mathscr{F}))=ch(\mathscr{F})-\langle\mathscr{E},\mathscr{F}\rangle ch(\mathscr{E}), \tag{8}$$

where

$$\langle\mathscr{E},\mathscr{F}\rangle=\sum_{i}(-1)^{i}\dim\ \mathrm{Hom}^{i}(\mathscr{E},\mathscr{F})=\int_{X}^{i}ch(\mathscr{E}^{\vee})ch(\mathscr{F})td(\mathscr{T}_{X}), \tag{9}$$

and $\mathscr{T}_X$ is the tangent sheaf of X.

Now it is generally believed that the (skew-symmetric) inner product $\langle\mathscr{E},\mathscr{F}\rangle$ on X is equal to the (equally skew-symmetric) intersection form for three-cycles on the mirror Y.[14,35,36] According to this analogy, the transformation (8) is nothing more than a Picard–Lefschetz transformation that one would associate to monodromy around a vanishing three-sphere in Y.[19,36] Because of this it seems natural to expect this kind of transformation to be associated to monodromy in the moduli space of complex structures around some parts of the discriminant locus.

III. A ONE-PARAMETER CASE

In this section we will review a computation apparently first done by Kontsevich.[18]

We consider the case where X is the quintic hypersurface in $\mathbb{P}^4$. As is very well known[9] the moduli space of complexified Kähler forms can be taken to be $\mathbb{P}^1$ with three interesting point. These point are as follows:

P_0: The Gepner point. Metrically it lies at an orbifold point $\mathbb{C}/\mathbb{Z}_5$.

P_1: The ''conifold point.'' The mirror of X acquires a conifold singularity. The conformal field theory associated to X is singular.

P_∞: The large radius limit. This point is an infinite distance away from the above two points.

Let H denote the homology class of the four-cycle given by the hyperplane section of the quintic threefold. We will also use H to denote its Poincaré dual which generates $H^2(X,\mathbb{Z})$. We then have

$$td(\mathscr{T}_X)=\frac{(H/1-e^{-H})^5}{(5H/(1-e^{-5H}))},=1+\frac{5}{6}H^2, \tag{10}$$

and

$$\int_X H^3=5. \tag{11}$$

The monodromy around P_0 is expected to be of order 5 because of the $\mathbb{Z}_5$ quantum symmetry of the Gepner model. The monodromy around P_∞ is known to correspond to $B\mapsto B+H$. In other words, we expect it to be given by the transformation $\mathscr{K}^{B}_{\mathcal{O}(H)}$. We will denote this by $\mathscr{K}^{B}_{H}$ for short.

Kontsevich conjectured that the monodromy around P_1 is given by the Fourier–Mukai transform $\mathscr{K}^{K}_{\mathscr{E}}$ of the previous section where $\mathscr{E}$ is given by the structure sheaf $\mathcal{O}_X$. We denote this $\mathscr{K}^{K}_{0}$ for short. We will return to this conjecture in a more precise form in Sec. V.

It follows from the topology of a sphere with three punctures that the product of the monodromy around P_∞ and the monodromy around P_1 should equal the monodromy around P_0 and hence should be of order 5. (Note that we are required to take the loops around P_1 and P_∞ in the

''same direction'' in order for their product to be a loop around P_0. Throughout this article we will have orientation problems such as this. We will not concern ourselves at all with such details. In all the examples we do, we simply find the right combination which gives the expected results.) We may verify that this is consistent with the Chern character of any starting D-brane.

Let us start with $\mathscr{F}$ given by $\mathcal{O}_X$ and apply the desired sequence of monodromy transformations. From (8) we obtain the following:

$$\begin{aligned} ch(\mathscr{F}) &= 1, \\ ch(\mathscr{K}_H^B \mathscr{F}) &= e^H, \\ ch(\mathscr{K}_0^K K_H^B \mathscr{F}) &= e^H - 5, \\ ch(\mathscr{K}_H^B \mathscr{K}_0^K \mathscr{K}_H^B \mathscr{F}) &= e^{2H} - 5e^H, \\ &\vdots \\ ch((\mathscr{K}_0^K \mathscr{K}_H^B)^5 \mathscr{F}) &= 1 + (e^H - 1)^5 = 1, \end{aligned} \tag{12}$$

as $H^4 = 0$ in X. This is therefore consistent.

It would be interesting to check that $(\mathscr{K}_0^K \mathscr{K}_H^B)^5$ gives the identity transform when applied directly to $\mathbf{D}(X)$ rather than just applied to cohomology. We will not attempt this here.

Note that it is easy to apply the same method to other one-parameter examples as listed in Ref. 37, for example.

IV. HELICES AND MUTATIONS

The purpose of this section is to briefly point out similarities and differences between the above computation for the quintic and the notion of helices and exceptional sheaves. The reader who is not directly interested in such things can skip this section.

It is easiest to describe mutations and helices directly in the derived category. See Ref. 38, for example, for more information. Let us consider the space $V = \mathbb{P}^4$ and let H denote the hyperplane class. Now consider the exceptional collection of sheaves $\{\mathcal{O}, \mathcal{O}(H)\}$. We may use a mutation to pull $\mathcal{O}(H)$ to the left through $\mathcal{O}$. Let $\mathscr{E}(H)$ denote the resulting object in $\mathbf{D}(\mathbb{P}^4)$. One can compute $ch(\mathscr{E}(H)) = e^H - 5$.

Similarly we may begin with the set $\{\mathcal{O}, \mathcal{O}(H), \mathcal{O}(2H)\}$ and pull $\mathcal{O}(2H)$ through $\mathcal{O}(H)$ and $\mathcal{O}$ to obtain $\mathscr{E}(2H)$, etc. The result of such mutations appears remarkably similar to the monodromy transformations we considered in the previous section. Indeed one obtains

$$ch(\mathscr{E}(nH)) = ch((\mathscr{K}_0^K \mathscr{K}_H^B)^n \mathscr{F}), \quad \text{for} \quad = 0,...,4. \tag{13}$$

This correspondence fails for $n = 5$, however. In this case we have $ch(\mathscr{E}(5H)) = 0$. This disagreement should come as no surprise. The language of mutations of helices can be recast in the form of the Fourier–Mukai transforms of Sec. II. The key point, however, is that the algebraic variety in question is the ambient $\mathbb{P}^4$ itself rather than the Calabi–Yau hypersurface X. Indeed exceptional sheaves cannot exist on X.

A Fourier–Mukai transformation does *not* yield an autoequivalence of $\mathbf{D}(\mathbb{P}^4)$ as it fails the canonical class constraint of Ref. 34. That is why the fifth application of the supposed monodromy transformation can kill the object in $\mathbf{D}(\mathbb{P}^4)$.

The language of mutations of helices was used in Refs. 23–25 successfully to obtain monodromies because Eq. (13) holds true. Note, however, that the procedure of going from $\mathscr{E}(nH)$ to $\mathscr{E}((n+1)H)$ cannot generally be identified with monodromy around the Gepner point because of the more general failure of this relation.

V. A TWO-PARAMETER CASE

The structure of monodromies becomes considerably more interesting when one starts to look at moduli spaces of more than one dimension. In this case, the ''discriminant locus'' of bad conformal field theories is a subvariety of the moduli space with dimension one or more.

We wish to see if the Fourier–Mukai transforms considered earlier can also be applied in these more complicated situations. Note that this problem has been studied by Horja[20] and by Seidel and Thomas.[19] Horja gave extensive results for monodromy loops which are ''close'' to the large radius limit in some sense. We will be interested in relations obtained by venturing further into the moduli space. The Fourier–Mukai transforms we will consider follow closely the construction by Seidel and Thomas.[19] Reference 39 has appeared very recently which shows that these methods are essentially a special case of Horja's construction.

Our goal in this section will be to obtain a similar result to Sec. III in a two-parameter example. Namely, can we find a sequence of monodromies which give a loop around some point which looks like a Gepner point, and hence has finite order?

Because the moduli space is two-dimensional there is no notion of ''monodromy around a point.'' Given a complex curve in our moduli space we can define a monodromy. We will use two notions extensively later in the text and we wish to emphasize the difference here to avoid confusion. We will often refer to monodromy *around* a curve for a loop in the two-dimensional moduli space which lies external to the curve. We will also refer to the completely different notion of monodromy *within* the curve around a specific point. The words ''around'' and ''within'' will always have the above meaning.

Our example is where X is a blown-up hypersurface of degree 18 in the weighted projected space $\mathbb{P}^4_{9,6,1,1,1}$. This space was studied extensively in Ref. 12 and analyzed in relation to D-branes in Ref. 17. The two generators of $H^2(X,\mathbb{Z})$ (and their Poincaré dual divisors) will be called H and L consistent with Ref. 12. If we put homogeneous coordinates $[z_1,\ldots,z_5]$ on $\mathbb{P}^4_{9,6,1,1,1}$, then the divisor class of $z_1=0$ is given by $3H$, the class of $z_2=0$ is given by $2H$. The class of $z_3=0$ or $z_4=0$ or $z_5=0$ (after the blow-up) is given by L. This weighted projective space has a curve of singularities which intersects the hypersurface at one point. Locally this point looks like the orbifold $\mathbb{C}^3/\mathbb{Z}_3$. We blow this up to produce an exceptional divisor $E\simeq\mathbb{P}^2$. In terms of homology classes, $E=H-3L$.

The remaining topological information required for X is as follows. H^2, HL, L^2 live in $H_2(X)$ or $H^4(X)$ subject to the constraint $H(H-3L)=0$. $H_0(X)$ or $H^6(X)$ has a single generator we denote p, and $H^3=9p$, $H^2L=3p$, $HL^2=p$, $L^3=0$. Obviously any monomial of degree 4 or higher in H or L vanishes. Finally,

$$td(\mathcal{T}_x)=1+\tfrac{1}{2}L^2+\tfrac{1}{4}HL. \tag{14}$$

The mirror, Y, of X has defining equation

$$a_0z_1z_2z_3z_4z_5+a_1z_1^2+a_1z_1^2+a_2z_3^{18}+a_4z_3^{18}+a_4z_4^{18}+a_6z_3^6z_4^6z_5^6. \tag{15}$$

The ''algebraic'' coordinates on the moduli space are then given by

$$x=\frac{a_1^3a_2^2a_6}{a_0^6},\quad y=\frac{a_3a_4a_5}{a_6^3}. \tag{16}$$

We may then define the discriminant as an expression in x and y which vanishes when Y becomes singular. If the data can be presented torically as in this case, then Sec. 3.5 of Ref. 40 gives a nice efficient way of computing this discriminant. In our example, the discriminant factorizes into two parts:

$$\Delta_0 = 6^{12}x^3y + (432x-1)^3,$$
$$\Delta_1 = 27y + 1. \tag{17}$$

We want to picture the moduli space in two different ways. First we use the ''phase'' description of Refs. 27 and 28. See also Sec. 3 of Ref. 41. We project the discriminant into $\mathbb{R}^2$ by plotting $-\log|y|$ against $-\log|x|$. We show the result in Fig. 1. The result is that the two-plane is divided into four ''phases.'' We chose our algebraic coordinates (16) so that the Calabi–Yau phase appears in the positive quadrant. The limit point of this phase is the large radius limit. The positive quadrant may also be viewed as the Kähler cone of X where the class H gives the horizontal direction and L gives the vertical direction.

The other phases are pictured as follows. There is an orbifold phase whose limit point has the orbifold singularity $\mathbb{C}^3/\mathbb{Z}_3$ but the Calabi–Yau has infinite volume. There is a $\mathbb{P}^2$ phase where X collapses onto a $\mathbb{P}^2$. This can happen as X is an elliptic fibration over $\mathbb{P}^2$. In the limit, this elliptic fiber has zero area and the $\mathbb{P}^2$ has infinite volume. Finally, we have a Landau–Ginzburg phase with the Gepner point as the limit point.

The other way of drawing the moduli space is as a complex surface. The phase picture in Fig. 1, i.e., the *secondary fan* of X, is viewed as the fan of a toric variety $\mathscr{M}$ as described in Ref. 28. The coordinates x and y are then naturally coordinates over a patch of the moduli space $\mathscr{M}$. (This is identified by associating the dual of the cone in the positive quadrant with Spec $\mathbb{C}[x,y]$.) In this case $\mathscr{M}$ is a surface with two quotient singularities. The discriminant is a divisor in $\mathscr{M}$.

We sketch $\mathscr{M}$ in Fig. 2 by drawing complex dimensions as real. Our limit points appear as dots in the diagram. We draw the curves $C_1,\ldots,C_4$ as the $\mathbb{P}^1$'s joining adjacent phase limits. Torically these curves are associated to the lines in Fig. 1 which separate the phases. Figure 2 also shows how the discriminant intersects these curves. Note that Δ_0 and Δ_1 are themselves smooth curves in $\mathscr{M}$. The extra circles around the LG and orbifold point denote the fact that both of these points lie at a quotient singularity of the form $\mathbb{C}^2/\mathbb{Z}_3$ in $\mathscr{M}$.

If we followed the analysis of Ref. 12 we would now blow-up $\mathscr{M}$ so that it was smooth and that the intersections of the discriminant with the curves C_i were transverse. This requires several blow-ups. Rather than do this, we find it easier to work directly in $\mathscr{M}$.

We would now like to take each of the curves $C_1,\ldots,C_4$ in turn and do a similar computation to that of Sec. III *within* that curve (or nearly so) to check our monodromy predictions. Note that each curve C_i has three special points on it—the two limit points and a third point where the

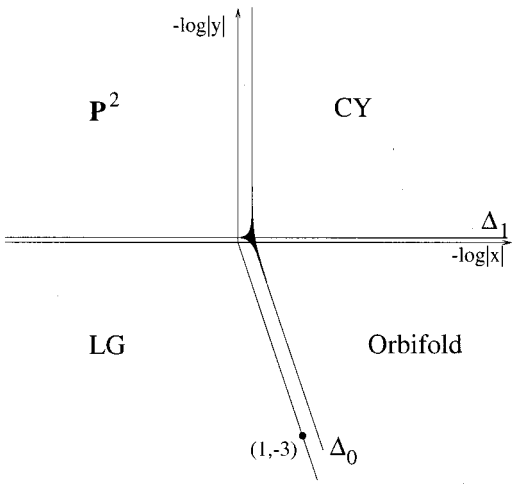


FIG. 1. The four phases of the two-parameter example.

discriminant hits the curve in some way. Thus, just as in Sec. III, we will show that the product of the monodromy around one of the limit points and around the discriminant is equal to the monodromy around the other limit point.

A. C_1

Let us fix a basepoint near the large Calabi–Yau limit point. Because we have identified the cone of this phase with the Kähler cone of X we immediately know the monodromies around C_1 and C_2. Each must be a shift in the B-field. To be precise, a loop around C_1 will correspond to $B \mapsto B+L$ and hence corresponds to $\mathscr{K}_L^B$. Similarly a loop around C_2 is given by $\mathscr{K}_H^B$.

Since C_1 and C_2 intersect transversely, the monodromy around the Calabi–Yau point within C_1 corresponds to going around C_2 and is thus given by $\mathscr{K}_H^B$. In other words $ch(\mathscr{F}) \mapsto e^H ch(\mathscr{F})$.

What about the monodromy within C_1 around the point in the middle where the discriminant hits? A method for computing this was presented in Ref. 20 but we will proceed a little differently. First we need to decide how to go around a generic part of Δ_0. Note that Δ_0 is the irreducible component of the discriminant corresponding to the appearance of singularities in (15) for *nonzero* $z_1,\ldots,z_5$. This was dubbed the "*A*-discriminant" in.[42] (Perhaps rather confusingly, Ref. 42 uses the term "principal *A*-determinant" for the full discriminant $\Delta_0\Delta_1$. Even more confusingly, Δ_0 has sometimes been called the "principal component" of the discriminant.[20]) We will call it the "*primary*" component of the discriminant. One could also define this as the component which is computed by finding solutions to Eqs. (3.45) of Ref. 40. We then state the following conjecture which appears to be due to Horja, Kontsevich, and Morrison in some form or another.[18,20,43]

Conjecture 1: For a suitable choice of basepoint near the Calabi–Yau limit point, a loop around the primary component of the discriminant is given by $\mathscr{K}_0^K = \mathscr{K}_{\mathscr{E}}^K$, *with* $\mathscr{E} = \mathcal{O}_X$.

This is certainly consistent with Sec. III where the primary component was the entire discriminant.

Assuming this conjecture to be true, we still have a complication that makes the computation a little less straightforward. Namely, C_1 does not intersect Δ_0 transversely but rather intersects it tangentially with multiplicity 3. This means that we cannot say that the monodromy within C_1 around the discriminant is given by Conjecture 1.

To proceed with the computation we can put a small three-sphere S^3 around the intersection of Δ_0 and C_1. Since Δ_0 and C_1 are both smooth, it follows that $L_1 = S^3 \cap C_1$ and $L_2 = S^3 \cap \Delta_0$ are both unknotted circles. Because of the tangential intersection, these circles are linked three times. We may remove a point of S^3 and imagine the link in $\mathbb{R}^3$. We show this in Fig. 3.

Next we need to describe $\pi_1(S^3 - (L_1 \cup L_2))$. To do this we use the Wirtinger presentation (see Ref. 44, for example). Imaging fixing a basepoint above the sheet of paper. The arrow a in

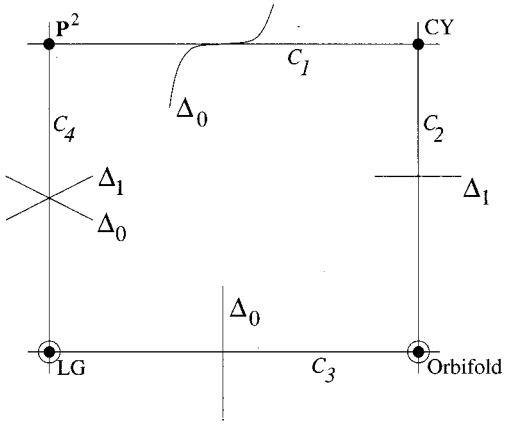

FIG. 2. The moduli space $\mathscr{M}$.

Fig. 3 then represents the element of π_1 looping under the left circle in the direction indicated by the arrow. Similarly, we define b for the right circle. We then have further elements e_i as shown in the figure. Crossing relations then determine

$$\begin{aligned} e_1 &= b^{-1}ab, \\ e_2 &= b^{-1}a^{-1}bab, \\ e_3 &= b^{-1}a^{-1}b^{-1}abab, \\ e_4 &= b^{-1}a^{-1}b^{-1}a^{-1}babab, \\ e_5 &= b^{-1}a^{-1}b^{-1}a^{-1}b^{-1}ababab, \end{aligned} \tag{18}$$

but clearly $e_5 = a$ which yields the relation

$$ababab = bababa. \tag{19}$$

(Our order convention is that ab represents the path b followed by the path a.) Indeed $\pi_1(S^3 - (L_1 \cup L_2))$ is given by the group on two generators (a,b) subject to the single relation (19).

Deform the path within C_1 around the discriminant point a little so that it lies outside C_1. This is the path around which we wish to compute the monodromy. This is the (clockwise) path which follows closely the circle $S^3 \cap C_1$. Such a path is homotopic to $e_1 e_3 e_5 = b^{-2}ababa$. But a is nothing more than a generic loop around Δ_0 and so is given by $\mathscr{K}_0^K$, and similarly b is given by $\mathscr{K}_L^B$. Therefore we claim that monodromy around the discriminant point within C_1 is given by $(\mathscr{K}_L^B)^{-2}\mathscr{K}_0^K\mathscr{K}_L^B\mathscr{K}_0^K\mathscr{K}_L^B\mathscr{K}_0^K$.

Let Q_1 denote the monodromy within $\mathbb{C}_1$ around the $\mathbb{P}^2$ limit point. As this is equal to the combined monodromy around the discriminant point and the Calabi–Yau limit point, we have $Q_1 = \mathscr{K}_H^B(\mathscr{K}_L^B)^{-2}\mathscr{K}_0^K\mathscr{K}_L^B\mathscr{K}_0^K\mathscr{K}_L^B\mathscr{K}_0^K$.

Passing from the Calabi–Yau limit point to the $\mathbb{P}^2$ limit point represents collapsing a large radius elliptic fiber to a Landau–Ginzburg orbifold theory in a manner very similar to the collapse

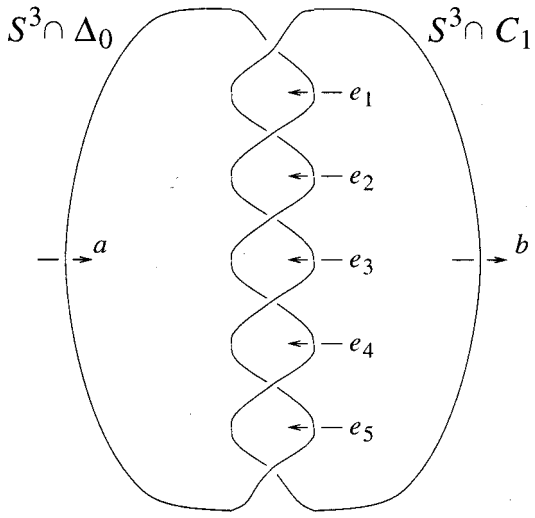

FIG. 3. The triply linked circles.

of the quintic in Sec. III. This Landau–Ginzburg theory is a $\mathbb{Z}_6$-orbifold and thus has a $\mathbb{Z}_6$ quantum symmetry. It should therefore follow that $Q_1^6=1$ in complete analogy with the Landau–Ginzburg point in Sec. III. This is a highly nontrivial check of our picture:

$$\begin{aligned} ch(\mathcal{O}_X)&=1,\\ ch(Q_1\mathcal{O}_X)&=e^H-3e^{H-L}+3e^{H-2L},\\ ch(Q_1^2\mathcal{O}_X)&=e^{2H}-3e^{2H-L}+3e^{2H-2L}-e^H,\\ &\vdots\\ ch(Q_1^6\mathcal{O}_X)&=e^{6H}-3e^{6H-L}+3e^{6H-2L}-e^{5H}-e^{4H}+3e^{4H-L}-3e^{4H-2L}\\ &\quad+3e^{3H-L}-3e^{3H-2L}+e^{2H}+e^H-3e^{H-L}+3e^{H-2L}=1. \end{aligned} \tag{20}$$

B. C_2

So far we have only used $\mathscr{E}=\mathcal{O}_X$ in the Fourier–Mukai transform $\mathscr{K}_{\mathscr{E}}^K$. In this section we use a less trivial choice. The curve C_2 represents the process of blowing-up the $\mathbb{C}^3/\mathbb{Z}_3$ singularity while keeping the rest of the Calabi–Yau at infinite volume. We will attempt to ''localize'' the computations to around the exceptional divisor $E\cong\mathbb{P}^2$.

Let us consider the general case of an irreducible exceptional divisor E in a Calabi–Yau space X of arbitrary dimension. Let the normal bundle be denoted by N. Let us assume that the zero locus of a generic section of $N^\vee$ gives an irreducible variety $W\subset E$ of complex dimension two less than X. W is automatically Calabi–Yau. In our example, W would be a cubic curve in $\mathbb{P}^2$. We therefore have two inclusions

$$i:E\hookrightarrow X,\quad j:W\hookrightarrow E. \tag{21}$$

Now consider two objects $\mathscr{E},\mathscr{F}\in\mathbf{D}(E)$ associated to sheaves on E. In terms of our inner product on X we may apply the Grothendieck–Riemann–Roch theorem to yield the following localization:

$$\begin{aligned} \langle i_*\mathscr{E},i_*\mathscr{F}\rangle_X&=\int_x (ch(i_*\mathscr{E}))^\vee ch(i_*\mathscr{F})td\left(\mathscr{T}_X=\int_E\right)(ch(i_*\mathscr{E}))^\vee ch(\mathscr{F})td(\mathscr{T}_E)\\ &=\int_W (ch(j^*\mathscr{E}))^\vee ch(j^*\mathscr{F})\frac{td(\mathscr{T}_E)}{td(N^\vee)}\\ &=\int_W (ch(j^*\mathscr{E}))^\vee ch(j^*\mathscr{F})td(\mathscr{T}_W)=\langle j^*\mathscr{E},j^*\mathscr{F}\rangle_W. \end{aligned} \tag{22}$$

Therefore, we may compute the inner product between objects of $\mathbf{D}(X)$ which are i_* of something in $\mathbf{D}(E)$ purely in terms of the local geometry of the blow-up.

We may now apply Conjecture 1 to W. In our example W is an elliptic curve and has only one deformation of complexified Kähler form. The discriminant is then a point and therefore primary with respect to W. The associated Fourier–Mukai transform for monodromy is then given by $\mathscr{K}_{\mathscr{E}}^K$ for $\mathscr{E}=\mathcal{O}_W=j^*\mathcal{O}_E$. This naturally motivates the following.

Conjecture 2: The monodromy around a component of the discriminant associated with an irreducible divisor E collapsing to a point is given by $\mathscr{K}_{\mathscr{E}}^K$ for $\mathscr{E}=i_*\mathcal{O}_E$, *where i is the inclusion map*.

Note that $i_*\mathcal{O}_E$ is the structure sheaf of E extended by zero over the rest of X. It can thus be denoted by $\mathcal{O}_E$ itself.

In our example we therefore associate Δ_1 with $\mathscr{K}^K_{\mathscr{E}}$ for $\mathscr{E}=\mathcal{O}_E$ where the class of E is given by $H-3L$. Let us use $\mathscr{K}^K_1$ to denote this transform. Another application of Grothendieck–Riemann–Roch quickly yields

$$ch(\mathcal{O}_E)=1-e^{3L-H}, \tag{23}$$

[and so $ch(\mathcal{O}_E^\vee)=1-e^{H-3L}$].

We are now in a position to compute all the monodromies for C_2. Around the Calabi–Yau limit we have $\mathscr{K}^B_L$. The component Δ_1 hits C_2 transversely and so the monodromy around the discriminant point is given by $\mathscr{K}^K_1$.

Let us use $Q_2=\mathscr{K}^K_1\mathscr{K}^B_L$ to refer to monodromy around the orbifold limit point. A $\mathbb{C}^3/\mathbb{Z}_3$ orbifold has a $\mathbb{Z}_3$ quantum symmetry, so one might naïvely guess that $Q_2^3=1$. Instead we find

$$\begin{aligned} ch(\mathcal{O}_X)&=1,\\ ch(Q_2\mathcal{O}_X)&=e^L,\\ ch(Q_2^2\mathcal{O}_X)&=e^{2L},\\ ch(Q_2^3\mathcal{O}_X)&=e^H. \end{aligned} \tag{24}$$

This suggests the relation $Q_2^3=\mathscr{K}^B_H$. To see why this is so, let us examine more carefully the geometry of the moduli space near the orbifold limit point. As mentioned earlier, this point is actually locally the singularity $\mathbb{C}^2/\mathbb{Z}_3$. We may therefore surround this limit point, not by a sphere, but by a *lens space* $M=S^3/\mathbb{Z}_3$. Now C_2 and C_3 are both smooth curves and therefore they intersect M in unknotted circles.

Consider the free $\mathbb{Z}_3$ quotient map $q:S^3\to M$. The intersection of C_2 and C_3 with M both lift to single circles in S^3 under q^{-1}. These circles are linked once and so π_1 of the complement of these circles in S^3 is the Abelian product $\mathbb{Z}\times\mathbb{Z}$. Let G denote π_1 of the complement of C_2 and C_3 in M. Since q is a normal cover we have

$$1\to\mathbb{Z}\times\mathbb{Z}\to G\to\mathbb{Z}_3\to 1. \tag{25}$$

A more detailed analysis of the geometry shows that $G\cong\mathbb{Z}\times\mathbb{Z}$ where there is a particular element $g_{\text{orb}}\in G$ which cannot be lifted to a loop in S^3 but such that g_{orb}^3 lifts to a loop in S^3 which loops around both C_2 and C_3.

To understand the monodromy we need to deform the loop "inside" C_2 around the orbifold point a little so that it does not intersect C_2 or C_3. There is no unique way to do this. The homotopy class of such a deformation is given by g_{orb} times an arbitrary number of windings *around* C_2. One might argue that the most natural lift is to reduce this extra winding around C_2 and say that the desired loop is simply given by g_{orb}.

Identifying Q_2 with g_{orb} it should then follow that the monodromy Q_2^3 is given by a loop around C_2 followed by a loop around C_3. We see that $Q_2^3=\mathscr{K}^B_H$ is entirely consistent with this so long as *the monodromy around C_3 is trivial*. We also see that our natural deformation of the loop within C_2 is the correct one.

We have therefore understood the monodromy in (24) and argued that the monodromy around C_3 is trivial.

For a true localization to the orbifold point we may put $H=0$. This has the effect of sending that component of the Kähler form of to infinity. Thus the target space looks like a resolution of $\mathbb{C}^3/\mathbb{Z}_3$. In this case the monodromy around the orbifold point really is of order 3. This fact was also determined directly using the Picard–Fuchs system in Ref. 15. Note also that any object of $\mathbf{D}(X)$ which can be written as i_* of something in $\mathbf{D}(E)$ is brought back to itself exactly after looping three times around the orbifold point.

C. C_3

Consider first the loop around the orbifold point within C_3. In order to understand the monodromy we need again to deform this loop a little as in Sec. V B. It turns out that the simplest deformation of this loop is homotopic to the same class g_{orb} as shown earlier. Figure 2 certainly makes this statement counterintuitive! At first sight it looks like a loop within C_2 is like a loop around C_3 and a loop within C_3 looks like a loop around C_2 and these are certainly not equal. It is the quotient singularity which stops this argument from working. Both the loop within C_2 and the loop within C_3 must deform to elements of G which map to the same element of $\mathbb{Z}_3$ in (25). The most natural deformation of these two loops actually makes the loops homotopic.

Therefore, monodromy around the orbifold point within C_3 is given by $Q_2=\mathscr{K}_1^K\mathscr{K}_L^B$. The loop around the discriminant point within C_3 is easy. Since Δ_0 intersects C_3 transversely, the monodromy is given by $\mathscr{K}_0$. The monodromy around the LG point is then given by

$$Q_3=\mathscr{K}_0^K\mathscr{K}_1^K\mathscr{K}_L^B. \tag{26}$$

What properties should we expect for Q_3? The geometry around the LG point is very similar (up to orientation questions) to the geometry around the orbifold point. In particular one may show that the loop corresponding to Q_3 is such that its third power is homotopic to a loop around C_3 and C_4. Now we know that a loop around C_3 induces no monodromy from Sec. V B. The fact that C_4 intersects C_1 transversely at a smooth point in $\mathscr{M}$ tells us that the loop around C_4 is given by Q_1 from Sec. V A. Thus Q_3^3 should have the same properties as Q_1. We saw in Sec. V A that Q_1 was of order 6. *It follows that Q_3 is of order 18.*

We may confirm this explicitly, e.g.,

$$\begin{aligned}
ch(\mathcal{O}_X)&=1,\\
ch(Q_3\mathcal{O}_X)&=e^L-3,\\
ch(Q_3^2\mathcal{O}_X)&=e^{2L}-3e^L+3,\\
ch(Q_3^3\mathcal{O}_X)&=e^H-3e^{2L}+3e^L-1,\\
ch(Q_3^4\mathcal{O}_X)&=e^{H+L}-3e^H+3e^{2L}-e^L,\\
ch(Q_3^5\mathcal{O})&=e^{H+2L}-3e^{H+L}+3e^{H+L}+e^H-e^{2L},\\
ch(Q_3^6\mathcal{O}_X)&=e^{2H}-3e^{H+2L}+3e^{H+L}-e^H-1,\\
ch(Q_3^7\mathcal{O}_X)&=e^{2H+L}-3e^{2H}+3e^{H2L}-e^{H+L}-e^L+3,\\
&\vdots\\
ch(Q_3^{18}\mathcal{O}_X)&=e^{6H}-3e^{5H+2L}+3e^{5H+L}-e^{5H}-e^{4H}+3e^{3H+2L}-3e^{3H+L}\\
&\quad+3e^{2H+2L}-3e^{2H+L}+e^{2H}+e^H-3e^{2L}+3e^L=1.
\end{aligned} \tag{27}$$

Comparing closely (20) and (27) we see that Q_3^3 is not quite the same thing as Q_1, although their effect is very similar. As we have described the loops corresponding to these transformations, they actually differ by a change in basepoint and so Q_1 and Q_3^3 are only equivalent up to conjugation.

The sequence of transformations given in (27) is identical to the sequence predicted by Refs. 23–25 in the language of helices and mutations. There one begins with a sequence of exceptional sheaves on $\mathbb{P}^4_{\{9,6,1,1,1\}}$ of the form $\{\mathcal{O},\mathcal{O}(L),\mathcal{O}(2L),\mathcal{O}(H),\mathcal{O}(H+L),\mathcal{O}(H+2L),\mathcal{O}(2H),\ldots,\mathcal{O}(5H+2L)\}$. One then mutates all the bundles to the left to reverse their order, giving a sequence of objects whose Chern characters are exactly given by (27). It is not hard to see why this is so.

Roughly speaking the transformation $Q_3=\mathscr{K}_0^K\mathscr{K}_1^K\mathscr{K}_L^B$ may be described as follows. $\mathscr{K}_L^B$ takes the sheaf $\mathcal{O}(nL)$ to $\mathcal{O}((n+1)L)$. Next $\mathscr{K}_1^K$ leaves $\mathcal{O}(mH+L)$ or $\mathcal{O}(mH+2L)$ invariant but takes $\mathcal{O}(mH+3L)$ to $\mathcal{O}((m+1)H)$. Finally $\mathscr{K}_0^K$ is a "left mutation" just as it was for the quintic in Sec. IV.

This gives a natural explanation for the funny "jump" seen in the required sequence of exceptional sheaves from $\mathcal{O}(mH+2L)$ to $\mathcal{O}((m+1)H)$. It is effectively caused by the action of $\mathscr{K}_1^K$. Note again the following shortcoming of the method of using sheaves on $\mathbb{P}^4_{\{9,6,1,1,1\}}$. If we extend this process by adding $\mathcal{O}(6H)$ to the above sequence of sheaves, then the 18th transformation of $\mathcal{O}$ would have Chern character equal to 0 rather than 1. Again this is because the corresponding Fourier–Mukai transform on $\mathbb{P}^4_{\{9,6,1,1,1\}}$ is not invertible.

D. C_4

Finally we do the monodromy computation within C_4. This actually yields nothing new. Let Q_4 be the monodromy given by the loop within C_4 around the LG point. Because the LG point is an orbifold point, one can show that this loop (or at least a small deformation of it) is the same as the loop within C_3 around the LG point for reasons essentially identical to the discussion in Sec. V B. This immediately implies $Q_4=Q_3$.

Indeed monodromy around the $\mathbb{P}^2$ point within C_4 is given by $\mathscr{K}_L^B$; and monodromy around the discriminant point requires loops around both Δ_1 and Δ_0 as seen in Fig. 2. Thus we see $Q_4=\mathscr{K}_0^K\mathscr{K}_1^K\mathscr{K}_L^B$ consistent with the above paragraph.

Consider trying to generalize the results of this example. One can show that the specific structure of the monodromy seen in this example depends mainly on the fact that X is a fibration. For example, we could consider a more complicated example with three Kähler moduli such as the resolved hypersurface of degree 24 in $\mathbb{P}^4_{\{1,1,2,8,12\}}$. This is an elliptic fibration over a Hirzebruch surface which itself is a $\mathbb{P}^1$-fibration over $\mathbb{P}^1$. In this example one has a curve in the moduli space which is the analog of C_4 above. It connects the Landau–Ginzburg phase with the $\mathbb{P}^1$ phase. Monodromy around the LG point can then be shown to be of a form $\mathscr{K}_0^K\mathscr{K}_1^K\mathscr{K}_2^K\mathscr{K}_L^B$. This will then reproduce the results of Sec. 9.3 of Ref. 25, for example. Note, however, that the fibration structure is essential here.

VI. OTHER EXAMPLES

The example of Sec. 5 demonstrated many features of monodromy, but there are many other important possibilities which did not appear. In this section we discuss some examples which do exhibit these effects.

A. Surfaces shrinking to curves

All the monodromies around components of the discriminant have been given by a Fourier–Mukai transform of the form (6) studied by Seidel and Thomas. Here we discuss an example that falls outside this class.

Let us consider the resolved hypersurface X of degree 8 in $\mathbb{P}^4_{\{2,2,2,1,1\}}$. We refer to Ref. 11 for extensive details of this model. The space X can be thought of as a K3-fibration over $\mathbb{P}_1$ or as the resolution of a singular space with a curve of singularities of the form $\mathbb{C}^2/\mathbb{Z}_2$. This model has the same moduli space as that of Sec. 5 except for the following aspects:

(i) The $\mathbb{P}^2$ phase is renamed a $\mathbb{P}^1$ phase as this is the base of the fibration.
(ii) The LG and orbifold limit points are now at orbifold points locally of the form $\mathbb{C}^2/\mathbb{Z}_2$.
(iii) The Δ_0 component of the discriminant now intersects C_1 at a point of multiplicity two rather than three.

When we compute the monodromies around the discriminant the real difference appears when we consider Δ_1. Let E be the exceptional divisor in X coming from the resolution of the curve of

singularities. E is a product of a genus 3 curve Z and $\Gamma \cong \mathbb{P}^1$. We associate Δ_1 with the collapse of E down to Z. The discussion in Sec. V B concerned an exceptional divisor contracting to a *point* and so cannot be applied to monodromy around Δ_1.

The computation of the monodromy on Chern characters was computed in Ref. 45. The result may be rephrased as follows. For a divisor E collapsing to a curve Z of genus g, monodromy around Δ_1 is given by

$$ch(\mathscr{F}) \mapsto ch(\mathscr{F}) - \langle \mathcal{O}_E + (1-g)\mathcal{O}_\Gamma, \mathscr{F} \rangle ch(\mathcal{O}_\Gamma) + \langle \mathcal{O}_\Gamma, \mathscr{F} \rangle ch(\mathcal{O}_E), \tag{28}$$

where $\Gamma \cong \mathbb{P}^1$ is the inverse image of a point for the blow-down.

The Fourier–Mukai transform given by (6) is incompatible with (28). A more general form which is consistent is given by Horja in Refs. 20 and 39. [I thank P. Horja for confirming that his construction is consistent with (28).] We refer to these references for more details.

Given the form of the monodromy (28) it is easy to reproduce all the corresponding results of Sec. V for this example.

B. A reducible exceptional divisor

One might have gotten the impression from the localization argument in Sec. V B that we can understand the monodromy associated to an orbifold singularity by studying the little Calabi–Yau W living inside the exceptional divisor E. Indeed this argument shows that the analysis we did in Sec. V for a Calabi-Yau threefold would also apply locally to a Calabi–Yau fivefold which has a $\mathbb{Z}_{18}$ orbifold singularity given by the action

$$(z_1, z_2, z_3, z_4, z_5) \mapsto (\alpha^9 z_1, \alpha^6 z_2, \alpha z_3, \alpha z_4, \alpha z_5), \tag{29}$$

where $\alpha = \exp(2\pi i/18)$. This is because the resolved $\mathbb{P}^4_{\{9,6,1,1,1\}}$ is the exceptional divisor for this five-dimensional orbifold.

While this is useful in some circumstances, it does not mean that any orbifold analysis can be reduced to a Calabi–Yau computation in lower dimensions. The problem is that the exceptional divisor for an orbifold singularity may be *reducible*. Indeed one generically expects an exceptional divisor be to reducible. In this case the notion of the Calabi–Yau ''inside'' the exceptional divisor makes no sense.

At least in the context of toric cases we can make some general statements about the difference between a reducible and irreducible exceptional divisor. The impression one might have been left with from the above examples is that each particular exceptional divisor E is associated with its own component Δ_E of the discriminant divisor. In this case one then associates monodromy around Δ_E with a process involving the collapse of E.

In the Batyrev[26] way of describing Calabi–Yau n-folds, one has a set of points, $\mathcal{A}$, lying in a hyperplane in $\mathbb{R}^{n+2}$. Vectors from the origin to these points generate the one-dimensional edges of a fan. By the usual algorithm in toric geometry this fan gives the canonical line bundle over some $(n+1)$-dimensional variety V. X is then the ''little Calabi–Yau'' living inside V.

Let Q be the convex hull of $\mathcal{A}$. One can show (see Chap. 10 of Ref. 42) that the irreducible components of the discriminant are determined by faces of Q of various dimensions. For a nontrivial component we require at least $k+2$ points in a k-dimensional face.

If each face of Q has at most one point in its interior, then each divisor associated to this interior point gets its own component of the discriminant. This was the case for the examples studied earlier and was the case for all the examples studied in Refs. 23–25. It is precisely when we have a reducible exceptional divisor that this fails.

We will consider an example of this. For a change we will use a K3 surface rather than a Calabi–Yau threefold. The results generalize easily to the threefold case.

Consider the surface X of degree 12 in $\mathbb{P}^3_{\{4,3,3,2\}}$. This has $\mathbb{C}^2/\mathbb{Z}_2$ singularities at three points and $\mathbb{C}^2/\mathbb{Z}_3$ singularities at four points. Each $\mathbb{Z}_2$ singularity is resolved by a single $\mathbb{P}^1$ and each $\mathbb{Z}_3$ singularity is resolved by a sum of two $\mathbb{P}^1$'s intersecting at a point. The fact that the K3 is

TABLE I. The point-set $\mathcal{A}$ for the K3 example.

a_0	0	0	0	1	$-2H$
a_1	0	0	1	1	B
a_2	1	0	0	1	C
a_3	1	2	0	1	C
a_4	-3	-3	-2	1	$-H+A$
a_5	-2	-2	-1	1	$2H-2A+B$
a_6	-1	-1	0	1	$A-2B$
a_7	1	1	0	1	$H-2C$

embedded in the given ambient space ties the blow-ups of the points of similar type together. There are, in fact, only four Kähler degrees of freedom—the overall size of the initial weighted projective space, one blow-up of all the $\mathbb{Z}_2$ fixed points, and two blow-ups for all the $\mathbb{Z}_3$ fixed points.

We list the coordinates of the points $\mathcal{A}$ in Table I. We also show the divisor classes in terms of a basis (H,A,B,C) associated to these vectors. These divisor classes restrict to form a partial basis of $H_2(X)=H^2(X)$. We then demand that the Kähler form of X lies in the span of these generators. This basis has been chosen so that the resulting slice of the Kähler cone is the positive orthant.

We will only concern ourselves with monodromies associated to the $\mathbb{Z}_3$ blow-ups. To do this we only consider variations in the A and B components of the Kähler form. The two divisor classes of interest are those associated to a_5 and a_6 having classes $2H-2A+B$ and $A-2B$, respectively. These each intersect X in four copies of $\mathbb{P}^1$. Each $\mathbb{P}^1$ from one set intersects one member from the other set of $\mathbb{P}^1$'s in one point. Together these form the resolutions of the four $\mathbb{Z}_3$ fixed points. Note that the set $\{a_4,a_5,a_6,a_1\}$ lies on a straight line.

Let us fix algebraic coordinates

$$x=\frac{a_4a_6}{a_5^2},\quad y=\frac{a_1a_5}{a_6^2}. \tag{30}$$

In terms of these, the component of the discriminant associated with the line $\{a_4,a_5,a_6,a_1\}$ is

$$\Delta_1=27x^2y^2-18xy-1+4x+4y. \tag{31}$$

There are two other components of the discriminant—the primary component and one associated to the three $\mathbb{Z}_2$ fixed points. Δ_1 is the part intrinsically associated to the $\mathbb{C}^2/\mathbb{Z}_3$ resolution.

The discriminant (31) divides the $(-\log x,-\log y)$ into four phases as shown in Fig. 4. One has the resolved phase, the $\mathbb{Z}_3$ orbifold phase, and two phases where one of the pair of $\mathbb{P}^1$'s has been blown up to partially resolve the $\mathbb{Z}_3$ fixed point to something that looks locally like a $\mathbb{Z}_2$ fixed point. We will call the latter two phases $\mathbb{Z}_2^{(A)}$ and $\mathbb{Z}_2^{(B)}$ since they are associated to blowing down using the A or B component of the Kähler form, respectively.

Note again that there is only a *single* irreducible component, Δ_1, of the divisor associated to this picture. The same component of the discriminant is responsible for blowing down either of the $\mathbb{P}^1$'s.

Now, of course, the moduli space is really four-dimensional. We want to think of Fig. 4 as representing a slice of the moduli space, where the H and C components of the Kähler form have been taken to infinity. Equivalently, think of Fig. 4 as the toric fan of a two-dimensional subspace of the moduli space associated to this limit.

Let $\mathcal{O}_{a_5}$ be the sum of the four structure sheaves of the $\mathbb{P}^1$'s associated to a_5. Similarly $\mathcal{O}_{a_6}$ is supported only over the four $\mathbb{P}^1$'s associated to a_6. Now consider the $\mathbb{P}^1$ in the moduli space connecting the large radius limit to the $\mathbb{Z}_2^{(A)}$ limit point where the $\mathbb{P}^1$'s associated to a_5 are blown

down. Let us denote this by C_A. We know the monodromy around the large radius limit within C_A multiplies the Chern characters by e^A. Since Δ_1 hits C_A transversely we expect that monodromy around the discriminant point is given by $\mathscr{K}^K_{\mathcal{O}_{a_5}}$ which induces

$$ch(\mathscr{F}) \mapsto ch(\mathscr{F}) - \tfrac{1}{4}\langle \mathcal{O}_{a_5}, \mathscr{F}\rangle \mathcal{O}_{a_5}, \tag{32}$$

where the factor 1/4 appears because $\mathcal{O}_{a_5}$ is associated to *four* irreducible divisors. [It is not hard to convince yourself that such a factor is necessary to get the monodromies to come out correctly. It would be nice to explain this factor more completely. Presumably this is similar to a asking for a better understanding of (28).]

The $\mathbb{Z}_2^{(A)}$ limit point is associated to a $\mathbb{Z}_2$ orbifold point and so we expect going twice around this point gives something simple. One can show that applying $\mathscr{K}^K_{\mathcal{O}_{a_5}} \mathscr{K}^B_A$ twice induces multiplication by exp $(2H+B)$ on the Chern characters. This should be viewed in the same way as in Sec. V B.

What about the curve C_B which connects the large radius limit to the $\mathbb{Z}_2^{(B)}$ limit point? In this case the discriminant point induces monodromy given by $\mathscr{K}^K_{\mathcal{O}_{a_6}}$ which induces

$$ch(\mathscr{F}) \mapsto ch(\mathscr{F}) - \tfrac{1}{4}\langle \mathcal{O}_{a_6}, \mathscr{F}\rangle \mathcal{O}_{a_6}. \tag{33}$$

One can then show that applying $\mathscr{K}^K_{\mathcal{O}_{a_6}} \mathscr{K}^B_B$ twice induces multiplication by exp(A) on the Chern characters.

This is all very well except that $\mathscr{K}^K_{\mathcal{O}_{a_5}}$ and $\mathscr{K}^K_{\mathcal{O}_{a_6}}$ are both monodromies around the *same* component of the discriminant. The reason they are different is that if we fix a base point near the large radius limit, then the loop around Δ_1 inside C_A is not homotopic to the loop around Δ_1 inside C_B. This can happen because Δ_1 itself is not smooth. It has a cusp at the point $(x,y) = (1/3,1/3)$. If we draw an S^3 around this cusp, then we obtain a trefoil knot in the intersection. It is well known that, for a fixed basepoint, loops around different parts of this knot are not homotopic to each other. This allows for the difference between $\mathscr{K}^K_{\mathcal{O}_{a_5}}$ and $\mathscr{K}^K_{\mathcal{O}_{a_6}}$. Note that this is the very same cusp as the one studied by Argyres and Douglas.[46]

Finally, let us see how to compute the effect of monodromy going three times around the $\mathbb{Z}_3$ limit point. Let C_{A2} be the curve connecting the $\mathbb{Z}_2^{(A)}$ limit point to the $\mathbb{Z}_3$ limit point. The monodromy within C_{A2} around the $\mathbb{Z}_2^{(A)}$ limit point is identical to the monodromy within C_A around the $\mathbb{Z}_2^{(A)}$ limit point for the reasons given in Sec. V C. The Δ_1 component of the discrimi-

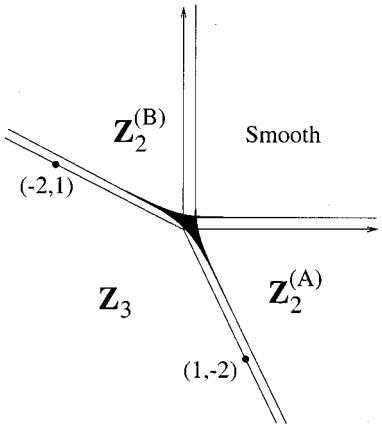

FIG. 4. The $\mathbb{C}^2/\mathbb{Z}_3$ resolution phase space.

nant intersects C_{A2} transversely. Since this is associated with collapsing the divisor associated to a_6, we will assume that monodromy around this discriminant point is given by $\mathscr{K}^K_{\mathcal{O}_{a_6}}$. *We therefore claim that monodromy with C_A around the $\mathbb{Z}_3$ limit point is given by* $\mathscr{K}^K_{\mathcal{O}_{a_6}}\mathscr{K}^K_{\mathcal{O}_{a_5}}\mathscr{K}^B_A$.

We may check that this cubes to something nice. Indeed the effect on the Chern characters implies that

$$\langle \mathscr{K}^K_{\mathcal{O}_{a_6}}, \mathscr{K}^K_{\mathcal{O}_{a_5}}\mathscr{K}^B_A\rangle^3 = (\mathscr{K}^B_H)^4. \tag{34}$$

One can show that this is consistent with the global geometry of the moduli space and so our monodromies all have the expected properties.

VII. DISCUSSION OF THE 0-BRANE

We have given various rules for how to compute the effect of monodromy on the Chern character of a D-brane. In this last section we will discuss the consequences for a 0-brane.

The 0-brane is of particular interest as it is the basic object used in the construction of Bondal and Orlov[7] to build the target space from the derived category. The fact that the 0-brane can transform into something else under monodromy is one reason why the Bondal and Orlov construction is ambiguous for a Calabi–Yau space.

Note again that the following results could have been guessed using the Picard–Fuchs differential equations. In that language the 0-brane often appears as a constant solution to the differential equations.[41] The derived category provides a much simpler picture, however.

For a Calabi–Yau threefold X, let P be an object in $\mathbf{D}(X)$ which corresponds to a 0-brane. This immediately implies that $ch(P)=p$, where $p\in H^6(X)$ is Poincaré dual to a point. Under monodromy about Δ_0 we have

$$p\mapsto p+\int_X p\wedge td(X) = p+1. \tag{35}$$

That is, the 0-brane always picks up a 6-brane charge upon an orbit around Δ_0.

Now consider the other monodromies in this article. They all involve taking the structure sheaf $\mathcal{O}_E$ of some collapsing cycle E and computing $\langle \mathcal{O}_{E,P}\rangle$. If E is of dimension less than 6, then this inner product is always zero. Thus the 0-brane undergoes no monodromy about these kinds of components in the discriminant.

We therefore make the following conjecture.

Conjecture 3: The 0-brane undergoes monodromy if and only if we circle the primary component, Δ_0, of the discriminant.

If we begin in a large-radius smooth Calabi–Yau phase, which other phases may we visit without crossing a wall in the phase diagram which contains Δ_0? In other words, over what area of the phase diagram can we fix a choice of 0-brane without worrying about monodromy? The answer consists of the so-called ''geometric phases'' or ''partially enlarged Kähler moduli space'' of Ref. 28.

The phases correspond to triangulations of Batyrev's reflexive polytope.[26,28] The statement that a phase is geometric corresponds to every simplex in the triangulation having the unique point in the interior of the polytope as a vertex.

Comparing to the example in Sec. V, for example, the geometric phases consist of the Calabi–Yau phase and the orbifold phase where we have a three complex dimensional picture of the target space. Indeed, these phases are separated only by Δ_1 around which the 0-brane has no monodromy.

The geometric phases consist of those reached from the Calabi–Yau phase only by blowing down subspaces. If one reduces the overall dimension of the target space, then one must cross a wall containing Δ_0. There are also exotic ''exoflop'' transitions[28] where part of the target space

remains three-dimensional but a lower-dimensional part grows out of the side of the target space. These exoflops also involve crossing a Δ_0 boundary and are not considered geometric.

Proving the statement about these phases is an application of the combinatorics discussed in Chap. 11 of Ref. 42. There is an object η_T which is a function on the cones of the secondary fan. If η_T changes as you pass to a neighboring cone, then the wall contained Δ_0. It is easy to show that η_T changes as you pass from a geometric phase to a nongeometric phase. This result is essentially contained in corollary 4.5 of Chap. 11 of Ref. 42. It is a more tedious exercise to show that passing between geometric phases of threefolds keeps η_T constant.

This result appears to agree nicely with the Bondal and Orlov construction. We may consistently tie the derived category to a target space interpretation so long as we confine ourselves to geometric phases. Once we leave these phases, then the 0-brane undergoes monodromy and we acquire an ambiguity in the way we construct the target space.

Finally, we should note that there can still be an ambiguity in what exactly is called a 0-brane in the geometric phases. If there are two or more smooth phases related by flops, then each phase has its own 0-branes. The exact way these branes are related to each other was given by Bridgeland.[47]

ACKNOWLEDGMENTS

It is a pleasure to thank M. Douglas, A. Lawrence, D. Morrison, R. Plesser, E. Sharpe, M. Vybornov, and M. Stern for useful conversations. I am particularly grateful to P. Horja for giving me an advanced copy of Ref. 39 while this article was being prepared, and discussing the results with me. The author is supported in part by NSF Grant No. DMS-0074072 and a research fellowship from the Alfred P. Sloan Foundation. Multidimensional phase space and sunset diagrams

A. Bashir,[a] R. Delbourgo,[b] and M. L. Roberts[c]

(Received 30 January 2001; accepted for publication 20 September 2001)

We derive expressions for the phase space of a particle of momentum p decaying into N particles, that are valid for any number of dimensions. These are the imaginary parts of so-called ''sunset'' diagrams, which we also obtain. The results are given as a series of hypergeometric functions, which terminate for odd dimensions and are also well suited for deriving the threshold behavior. © *2001 American Institute of Physics.* [DOI: 10.1063/1.1416887]

I. INTRODUCTION

With so much attention focused on the properties of branes embedded in higher dimensions, it is of interest to examine the way in which the phase space changes as the space–time is enlarged, since this is what primarily determines the statistical properties of multiparticle systems; only when amplitudes are accentuated or suppressed along certain directions in space is there a pronounced effect on the phase space. This paper is devoted to the topic of multidimensional phase space. We assume that extra dimensions are spatial—though one may envisage that timelike coordinates can be handled by Euclidean continuation—and that all particles propagate into the bulk. Not only that, we suppose that the space–time is flat so that we can neglect topological aspects. If conditions arise that constrain the particles to some subspace, then one may obtain the reduced phase space by altering the number $D-1$ of spatial dimensions rather trivially; or else if topological effects become important we may be able to sum over discrete modes along flat directions. Thus in almost every respect we are simply investigating the dimensional continuation of standard four-dimensional expressions for the decay of a system carrying momentum p into *any number* N of particles.

There has been much early work in this area,[1] but it is mostly in the context of four dimensions (or lower) and has often been confined to few particles (like two, three, or four). The most pertinent recent results in this connection are those of Groote *et al.*[2] and of Davydychev and Smirnov[3] because they are the most general. Our own results apply to any value of N and D and are also singularly well suited for deriving threshold expansions as $\sqrt{p^2}\to(m_1+m_2+\cdots+m_N)$. Because phase space ρ is nothing but the imaginary part of the ''sunset diagram'' for $p\to p_1+p_2+\cdots p_N$, our procedure will be to start with this sort of diagram and then obtain ρ_N from its discontinuity in p^2 as we cross the threshold. (Pseudothreshold singularities of these diagrams exist, too, but are not relevant for physical phase space.)

In Sec. II, we give the most convenient Feynman parametric description of the general diagram for any dimension $D=2\ell$ and show how one may readily derive the leading threshold behavior by expanding about the minimum of the combined denominator; although one may in principle derive the next to leading behavior by this method, and so on, we do not pursue this parametric approach any further, as there is a much better way of handling the problem, which is described in the following sections. First, in Sec. III, we derive some special cases of the results (small N) by making use of phase space recurrence methods[1] and next show how they may more easily be found by Fourier transformation of the propagator products in Sec. IV. This is our cue for tackling the most general situation, but because the form of our expressions makes it tricky to take

the massless limit of any individual particle we specifically suppose that M of the particles are massless and $N-M$ are massive. Our results, stated in Sec. V, are given as a series of hypergeometric terms having the form (hereafter F stands for the usual ${}_2F_1$ function)

$$\rho_N \propto \sum_{j=M(3/2-\ell)+2N(\ell-1)-\ell+1/2} \mathrm{d}_j (p^2-\sigma^2)^j F(a,b;c;1-p^2/\sigma^2),$$

where σ is the sum of the masses. An agreeable property of this expansion is that it terminates for odd D and is tailored for deriving the threshold behavior.

II. FEYNMAN PARAMETRIC FORM

In 2ℓ dimensions, sunset diagrams with N internal lines, produce integrals of the type[4]

$$I_N(p;\{\nu\}) = i\left(\prod_{i=1}^{N} \int \frac{i\Gamma(\nu_i)}{(p_i^2-m_i^2)^{\nu_i}} \bar{\mathrm{d}}^{2\ell} p_i\right) \bar{\delta}^{2\ell}\left(p-\sum_i p_i\right). \tag{1}$$

We have included a gamma function in each numerator since the propagator powers usually arise via momentum or mass derivatives of the case $\nu=1$, and it simplifies the subsequent expressions. By attaching a Feynman parameter α to each internal line, one may combine denominators in the standard fashion and integrate over the internal momenta to establish[5] that

$$I_N(p;\{\nu\}) = \frac{(-1)^N}{(-4\pi)^{(N-1)\ell}} \left(\prod_{i=1}^{N} \int_0^1 \frac{\mathrm{d}\alpha_i}{\alpha_i^{\nu_i-\ell+1}}\right) \frac{\Gamma(\Sigma_i \nu_i + \ell - N\ell)\,\delta(1-\Sigma_i \alpha_i)}{[p^2-\Sigma_i (m_i^2/\alpha_i)]^{\Sigma_i \nu_i + \ell - N\ell}}, \tag{2}$$

but it is easier to prove the result by induction in fact. Suppose that (2) is true for N; the case $N+1$ represents a further convolution:

$$I_{N+1}(p;\{\nu\}) = i\int \bar{\mathrm{d}}^{2\ell} k\, I_N(k;\{\nu\})\Gamma(\nu_{N+1})/[(k+p)^2-m_{N+1}^2]^{\nu_{N+1}}$$

so introduce an extra Feynman parameter β. Combining the new denominator with (2) and integrating over intermediate loop momentum k, one remains with

$$I_{N+1}(p) = \frac{(-1)^{N+1}}{(-4\pi)^{N\ell}} \left(\prod_{i=1}^{N} \int_0^1 \frac{\mathrm{d}\alpha_i}{\alpha_i^{\nu_i-\ell+1}}\right) \times \int_0^1 d\beta \frac{\Gamma(\Sigma_{i=1}^{N+1} \nu_i - N\ell)\,\delta(1-\Sigma_i \alpha_i)(1-\beta)^{\nu_{N+1}-1}\beta^{\ell-\nu_{N+1}-1}}{[p^2(1-\beta)-\Sigma_i (m_i^2/\alpha_i)-m_{N+1}^2(1-\beta)/\beta]^{\Sigma_i \nu_i - N\ell + \nu_{N+1}}}.$$

Now all one need do is rescale $\alpha_i = \beta_i/(1-\beta)$ for $i=1$ to N and call $\beta \equiv \beta_{N+1}$. A final relabeling of $\beta \to \alpha$ reproduces (2) for $N \to N+1$. Since we know the result (2) is correct for $N=2$—it is very familiar to graphologists as the simplest self-energy calculation—we have thereby proved the result inductively for any N.

The singularities of $I_N(p)$ in p^2 will arise when p^2 equals the combination $M^2(\alpha) \equiv \Sigma_{i=1}^N (m_i^2/\alpha_i)$, so let us examine the behavior of $M^2(\alpha)$ in the region of integration $0 \leqslant \alpha_i \leqslant 1$, subject to the condition $\Sigma_i \alpha_i = 1$. For definiteness, we shall assume for the rest of this section that all masses are nonzero. By introducing a Lagrangian multiplier for the last constraint, it is easy to see that $M^2(\alpha)$ is minimized in the physical region when the Feynman parameters equal $\alpha_{i0} \equiv m_i/\Sigma_{j=1}^N m_j \equiv m_i/\sigma$, whereupon $M^2(\alpha_0) = (\Sigma_{j=1}^N m_j)^2 = \sigma^2$. Other values of α_i are possible (by reversing one or other of the signs of α_{i0}) but they correspond to pseudothresholds and lie

outside the integration region. It is then clear that the magnitude of $I_N(p)$ will be dominated by α_i values in the vicinity of α_{i0}, so it is sensible to expand about these minima if we want to determine the leading behavior near threshold.

This procedure can be developed systematically (see the Appendix for the example $N=2$ with $\nu_1=\nu_2=1$) but as there is an alternative and preferable way of tackling the problem, which we defer to the following sections, here we shall simply extract the leading threshold behavior, because this can be done rather quickly and painlessly. Begin with (2) and note that

$$M^2(\alpha)=\sigma^2+\sum_i\ (\alpha_i-\alpha_{i0})^2\sigma^3/m_i-\sum_i\ (\alpha_i-\alpha_{i0})^3\sigma^4/m_i^2+\cdots.$$

One sees that for $1-p^2/\sigma^2\equiv\Delta^2$ small the integral is dominated by values of α near the minimum α_0. Therefore write $\alpha_i=\alpha_{i0}+\Delta\xi_i$, so that the denominator of (2) reads

$$-\Delta^2\sigma^2\left[1+\sigma\sum_i\ \xi_i^2/m_i-\Delta\sigma^2\sum_i\ \xi_i^3/m_i^2+O(\Delta^2)\right].$$

Since the integrals in α can be made to run between 0 and ∞, because of the delta-function constraint, the integral over ξ_i runs from $-m_i/\sigma\Delta$ to ∞. So, in the limit as $\Delta\to0$, we can take ξ_i to run from $-\infty$ to ∞ [the correction to the integral is exponentially small as $\exp(-1/\Delta^2)$] and expand the product of the α_i about the minimum. Assuming all masses are nonzero (see later sections for a relaxation of this condition) we are thereby led to the leading behavior,

$$I_N(p,\{\nu\})=c_{N\ell}\Delta^{(N-1)(2\ell+1)-2\Sigma_i\,\nu_i}\left(\prod_i\ m_i^{\ell-\nu_i-1}\right)\Big/\ (4\pi)^{\ell(N-1)}\sigma^{(2-N)\ell-N+\Sigma_i\,\nu_i},\qquad(3)$$

where

$$c_{N\ell}\simeq\left(\prod_i\ \int\ \mathrm{d}\xi_i\right)(-1)^{N-\Sigma_i\,\nu_i}\frac{\delta(\Sigma_i\,\xi_i)\Gamma(\Sigma_i\,\nu_i-(N-1)\ell)}{[1+\sigma\Sigma_i\xi_i^2/m_i]^{\Sigma_i\nu_i-(N-1)\ell}}.$$

If one now represents the delta function and the denominator by integrals, the coefficient $c_{N\ell}$ can be explicitly evaluated as follows:

$$\begin{aligned}c_{N\ell}=&\frac{1}{2\pi}\left(\prod_i\ \int\ \mathrm{d}\xi_i\right)\int_{-\infty}^{\infty}\mathrm{d}k\int_0^{\infty}\mathrm{d}\alpha\ \alpha^{\Sigma_i\,\nu_i-1-(N-1)\ell}\,e^{-\alpha-k^2/4\alpha}\\&\times(-1)^{N-\Sigma_i\,\nu_i}\prod_i\ \exp\left[-\frac{\alpha\sigma}{m_i}\left(\xi_i-\frac{ikm_i}{2\alpha\sigma}\right)^2\right]\\=&(-1)^{N-\Sigma_i\,\nu_i}\varpi^{1/2}\pi^{(N-1)/2}\sigma^{-N/2}\Gamma\left(\sum_i\ \nu_i-(\ell+1/2)(N-1)\right),\varpi\equiv\prod_i\ m_i.\end{aligned}$$

So, all told, the leading threshold behavior is dominated by

$$\begin{aligned}I_N(p,\{\nu\})=&(-1)^{N-\Sigma_i\nu_i}\frac{\pi^{(N-1)/2}}{(4\pi)^{(N-1)\ell}}\,\frac{\Gamma(\Sigma_i\,\nu_i-(N-1)(l+1/2))\Pi_i m_i^{\ell-\nu_i-1/2}}{\sigma^{(2-N)\ell-N/2+\Sigma_i\nu_i}}\\&\times\Delta^{(N-1)(2\ell+1)-2\Sigma_i\nu_i}.\end{aligned}\qquad(4)$$

The case of greatest interest is $\nu_i=1$, all i, when (4) reduces to

$$I_N(p)=\frac{\pi^{(N+1)/2}}{(4\pi)^{(N-1)\ell}}\,\frac{\Gamma((N-1)/2-\ell(N-1))}{\varpi^{3/2-\ell}\sigma^{N/2+\ell(2-N)}}(1-p^2/\sigma^2)^{\ell(N-1)-(N+1)/2}.\qquad(5)$$

We may then continue this expression above threshold ($p^2 \geqslant \sigma^2$), in order to obtain the behavior of the N-body phase space as the discontinuity:

$$\rho_N(p) = 2\Im I_N(p) \simeq \frac{\pi^{(N+1)/2}}{(4\pi)^{(N-1)\ell}} \frac{\varpi^{\ell-3/2}}{\sigma^{N/2+\ell(2-N)}} \frac{(p^2/\sigma^2-1)^{\ell(N-1)-(N+1)/2}}{\Gamma((N-1)(\ell-1/2))}. \tag{6}$$

This result agrees with the answer obtained by Davydychev and Smirnov[3] and reduces to the well-known four-dimensional behavior found by Hagedorn and Almgren,[1] when we set $\ell=2$, namely

$$\rho_N(p) \sim Q^{(3N-5)/2},$$

where $Q=\sqrt{p^2}-\sigma$ is the energy release. However (6) supplies the answer in any dimension with the appropriate coefficient.

III. EXACT RESULTS

We now consider phase space in general and derive some precise results for any ℓ, N as they arise from recurrence relations between phase space expressions for smaller N and not necessarily around threshold. Begin with the definition of the N-body phase space integral,

$$\rho_N(p) \equiv \rho_{p\to 1+2+\cdots N} \equiv \prod_i \left(\int \overline{\mathrm{d}^2}^{\ell} p_i \theta(p_i) \overline{\delta}(p_i^2 - m_i^2) \right) \overline{\delta^2}^{\ell} \left(p - \sum_{i=1}^{N} p_i \right). \tag{7}$$

The measures $\mathrm{d}^{2\ell-1}\vec{p} = |\vec{p}|^{2\ell-2}\mathrm{d}|\vec{p}|.(\sin\theta)^{2\ell-3}\mathrm{d}\theta.2\pi^{\ell-1}/\Gamma(\ell-1) = |\vec{p}|^{2\ell-2}\mathrm{d}|\vec{p}|.2\pi^{\ell-1/2}/\Gamma(\ell-1/2)$, come in useful if one were able to integrate over angles. Thus the two-body result is readily evaluated in this way to be

$$\rho_2(p) = \frac{\pi(4\pi)^{1/2-\ell} q^{2\ell-3}}{\Gamma(\ell-1/2)\sqrt{p^2}},$$

where q is the center of mass spatial momentum, so that $\sqrt{q^2+m_1^2}+\sqrt{q^2+m_2^2}=\sqrt{p^2}$. Tidying up, the result can be expressed covariantly as

$$\rho_{p\to 1+2} = \frac{\pi^{1-\ell}\Gamma(\ell-1)\lambda^{2\ell-3}}{2^{2\ell-1}(p^2)^{\ell-1}\Gamma(2\ell-2)}, \quad \lambda \equiv \sqrt{p^4+m_1^4+m_2^4-2m_1^2m_2^2-2p^2m_1^2-2p^2m_2^2}. \tag{8}$$

The three-body phase space can also be evaluated by brute force methods and reduced to a triangular integral over three Mandelstam variables:

$$\rho_{p\to 1+2+3} = \frac{2\pi(p^2)^{1-\ell}}{(4\pi)^{2\ell}\Gamma(2\ell-2)} \int\int\int \mathrm{d}s\,\mathrm{d}t\,\mathrm{d}u\ \delta(s+t+u-m_1^2-m_2^2-m_3^3-p^2) \times [\Phi(s,t,u)]^{\ell-2}\theta(\Phi),$$

where $\Phi(s,t,u)$ is the Kibble[6] cubic (simply a Gram determinant),

$$\begin{aligned}\Phi(s,t,u) &\equiv stu - s(m_2^2m_3^2+p^2m_1^2) - t(m_3^2m_1^2+p^2m_2^2) - u(m_1^2m_2^2+p^2m_3^2) \\ &\quad + 2(m_1^2m_2^2m_3^2+p^2m_1^2m_2^2+p^2m_2^2m_3^2+p^2m_3^2m_1^2) \\ &= -p^2\lambda^2(|\vec{p}_1|^2,|\vec{p}_2|^2,|\vec{p}_3|^2).\end{aligned}$$

By changing variables to s and $t-u$, one integration may be performed and the problem reduced to the single integral,[7]

$$\rho_{p\to 1+2+3}=\frac{(32\pi)^{2-2\ell}}{(\Gamma(\ell-1/2))^2(p^2)^{\ell-1}}\int_{(m_1+m_2)^2}^{(\sqrt{p^2}-m_3)^2} s^{1-\ell}\mathcal{D}^{\ell-3/2}\,\mathrm{d}s, \tag{9}$$

where $\mathcal{D}=[s-(m_3+\sqrt{p^2})^2][s-(m_3-\sqrt{p^2})^2][s-(m_1+m_2)^2][s-(m_1-m_2)^2]$. When we are in four dimensions ($\ell=2$) the integral is nothing but the area within the Dalitz plot but its evaluation for arbitrary masses is easier said than done, because (9) is an elliptic function in general! However in three dimensions the integration over the region becomes possible because it can be converted into

$$\rho_3(p)\to\frac{1}{32\pi\sqrt{p^2}}\int_{(m_1+m_2)^2}^{(\sqrt{p^2}-m_3)^2}\frac{\mathrm{d}s}{\sqrt{s}}=\frac{1}{16\pi}\left(1-\frac{m_1+m_2+m_3}{\sqrt{p^2}}\right).$$

In fact the three-body phase space integration is tractable for all odd D dimensions, because one remains with a polynomial in half-integral powers of s which is readily handled.[8] Two other cases are amenable to an exact treatment in terms of "elementary" functions for any ℓ and $N=3$, namely (i) two masses are set to zero, or (ii) one mass vanishes and the two other masses are equal. In case (i) put $m_2=m_3=0,\ m_1=m$ so $\mathcal{D}\to(s-p^2)^2(s-m^2)^2$ whereupon the three-body phase space reads

$$\rho_3(p)\to\frac{\pi^{1-2\ell}(p^2/m^2-1)^{4\ell-5}[\Gamma(\ell-1)]^2}{2^{4\ell-1}(m^2)^{3-2\ell}\Gamma(4\ell-4)}F\left(3\ell-3,\ 2\ell-2;4\ell-4;1-\frac{p^2}{m^2}\right)\theta(p^2-m^2),$$

while in case (ii) put $m_3=0,\ m_1=m_2=m$ so that $\mathcal{D}\to s(s-p^2)^2(s-4m^2)$ and

$$\rho_3(p)\to\frac{\pi^{3/2-2\ell}\Gamma(\ell-1)(p^2-4m^2)^{3\ell-7/2}}{2^{6\ell-3}\Gamma(3\ell-5/2)(p^2)^{\ell-1}m}F\left(\frac{1}{2},\ell-\frac{1}{2},\ 3\ell-\frac{5}{2};1-\frac{p^2}{4m^2}\right)\theta(p^2-4m^2).$$

Of course we can also proceed to the limit $m\to 0$ in either case. Any other set of masses produces "elliptic" results[1,7] for even D or integral ℓ.

A more systematic way of arriving at Lorentz invariant answers, without resorting to integrations over spatial momenta in the standard approach and interpreting them covariantly, is to apply Almgren's method. In that method one partitions the set of outgoing particles into subsets (call them A,B, etc.) and obtains ρ via mass integration convolutions; for instance the three-body result (9) can be construed as

$$\rho_{p\to 1+2+3}=\int \rho_{p\to A+3}\rho_{A\to 1+2}\overline{\mathrm{d}}m_A^2,$$

where s is interpreted as the intermediate m_A^2. More generally, one may evaluate the N-body phase space through the double integral

$$\rho_{p\to 1+2+\cdots+j+(j+1)\cdots+N}=\int \rho_{p\to A+B}\rho_{A\to 1+2+\cdots j}\rho_{B\to(j+1)+\cdots+N}\overline{\mathrm{d}}m_A^2\,\overline{\mathrm{d}}m_B^2. \tag{10}$$

Although this is quite a satisfactory numerical way of calculating ρ, it does not shed a great deal of analytical light on the nature of the problem; but it does serve as a nice check of analytical results obtained in a different manner, which we will now exhibit.

IV. COORDINATE SPACE METHOD

The sunset diagram having all $\nu=1$ is nothing but the 2ℓ-dimensional Fourier transform of the product of N causal functions:

$$I_N(p) = -i \int \mathrm{d}^{2\ell} x \exp(ip.x) \prod_{i=1}^{N} [i\Delta_c(x|m_i)], \tag{11}$$

and the phase space integral is simply given by

$$\rho_{p\to 1+2+\cdots+N} = 2\Im I_N(p),$$

which is nonvanishing for $p^2 \geqslant (m_1+m_2+\cdots+m_N)^2$. Of course (11) is easier stated than done except in the simplest cases (like $N=2$ or 3) because the causal function is a Bessel function in general,[9]

$$i\Delta_c(x|m) = \frac{1}{(2\pi)^\ell} \left(\frac{m}{r}\right)^{\ell-1} K_{\ell-1}(mr), \quad r \equiv \sqrt{-x^2+i\epsilon}.$$

In the massless limit, when $m\to 0$, the sunset diagram reduces to a ''superpropagator'' with integer index since

$$i\Delta_c(x|0) \equiv iD_c(x) = \Gamma(\ell-1)/4\pi^\ell r^{2\ell-2}.$$

However, as noted and indeed emphasized by Berends *et al.*[10] and by Groote *et al.*,[2] one can make considerable progress using coordinate space methods in the odd-dimensional massive cases, because the Bessel function reduces to an exponential times a polynomial.

Let us begin systematically by considering the most trivial case *when all intermediate masses vanish.* Carrying out the angular integration in (11), the sunset integral reduces to

$$I_N(p) \to -(2\pi)^\ell q^{1-\ell} \int_0^\infty \mathrm{d}r\, r^\ell J_{\ell-1}(qr) \left[\frac{\Gamma(\ell-1)}{4\pi^\ell r^{2\ell-2}}\right]^N, \quad q^2 \equiv -p^2, \tag{12}$$

which can be evaluated straightforwardly.[11] Thus one finds that

$$\lim_{m_i\to 0} I_N(p) = -(4\pi)^{\ell(1-N)} \frac{[\Gamma(\ell-1)]^N \Gamma(\ell+N-N\ell)}{\Gamma(N\ell-N)} (-p^2-i\epsilon)^{N\ell-\ell-N}, \tag{13}$$

so the massless phase space integral reduces, in 2ℓ dimensions, to[12]

$$\lim_{m_i\to 0} \rho_N(p) = 2\Im I_N(p) = \frac{(4\pi)^{1+\ell-N\ell} [\Gamma(\ell-1)]^N}{2\Gamma(N\ell-N)\Gamma((N-1)(\ell-1))} (p^2)^{N\ell-\ell-N} \theta(p^2). \tag{14}$$

Both (13) and (14) are exact, too. One may readily check that the cases $N=1,2,3$ produce the correct answers, by taking appropriate limits of earliers results. Also it is very instructive to check that the Almgren recurrence formulas, such as (10), are properly obeyed, not only in their momentum dependence, but in their multiplicative coefficients.

Now it turns out that the integral of two Bessel functions with an exponential can also be handled.[11] Therefore one can improve on above and calculate analytically the sunset integral for one particle massive (m) and the remaining N-1 particles massless. In those circumstances one is led to[13]

$$I_N(p)=-\left(\frac{q}{m}\right)^{1-\ell}\int_0^\infty \mathrm{d}r\, r^{2(N-1)(1-\ell)+1}J_{\ell-1}(qr)K_{\ell-1}(mr).\left(\frac{\Gamma(\ell-1)}{4\pi^\ell}\right)^{N-1}$$

$$=-\frac{[\Gamma(\ell-1)]^{N-1}\Gamma(\ell+N-N\ell)\Gamma(N-N\ell+2\ell-1)}{2^{2\ell(N-1)}\pi^{\ell(N-1)}(m^2)^{N+\ell-N\ell}\Gamma(\ell)}$$

$$\times F\left(\ell+N-N\ell,N-N\ell+2\ell-1;\ell;\frac{p^2}{m^2}\right). \tag{15}$$

Noting that in respect of the variable z the hypergeometric function $F(a,b;c;z)$ for real a,b,c has a branch point at $z=1$ and that the discontinuity across the cut (which runs to $+\infty$) is

$$\Im F(a,b;c;z)=-\frac{\pi\Gamma(c)(z-1)^{c-a-b}\theta(z-1)}{\Gamma(a)\Gamma(b)\Gamma(1-a-b+c)}F(c-a,c-b;c-a-b+1;1-z), \tag{16}$$

we deduce the phase space result,

$$\rho_N(p)=\frac{\pi^{1-\ell(N-1)}[\Gamma(\ell-1)]^{N-1}(p^2-m^2)^{2N\ell-2\ell-2N+1}\theta(p^2-m^2)}{2^{2\ell(N-1)-1}(m^2)^{N\ell-N-\ell+1}\Gamma(2(N-1)(\ell-1))}$$

$$\times F\left(N(\ell-1),(N-1)(\ell-1);2(N-1)(\ell-1);1-\frac{p^2}{m^2}\right). \tag{17}$$

The pair of expressions (16) and (17) are precise as well. Contrast (17) with the expression found by Beneke and Smirnov[14] for a one-loop vertex diagram with two massive and one massless particle. By taking the limit $m\to 0$ of (16) and (17) and suitably maneuvering the hypergeometric function[15] one can show that they collapse into (13) and (14). Additionally we may deduce the particular cases $N=2,3$ previously by direct substitution; for instance, in four dimensions ($\ell=2$), one gets

$$\rho_N(p)=\frac{2\pi(p^2-m^2)^{2N-3}}{(16\pi^2)^{N-1}(m^2)^{N-1}\Gamma(2N-2)}F\left(N,N-1;2(N-1);1-\frac{p^2}{m^2}\right)\theta(p^2-m^2),$$

so the three-body phase space with a single massive particle ($p^2\geqslant m^2$) brings in a logarithmic function:

$$\rho_3(p)=\frac{(p^2-m^2)^3}{768\pi^3m^4}F\left(3,2;4;1-\frac{p^2}{m^2}\right)=\frac{m^4}{256\pi^3p^2}\left[\left(\frac{p^4}{m^4}-1\right)-2\frac{p^2}{m^2}\ln\left(\frac{p^2}{m^2}\right)\right].$$

V. HYPERGEOMETRIC EXPANSIONS

As soon as we have at least two massive particles, we come across integrals involving products of three Bessel functions with different arguments and a power of r. This is not given in the standard texts,[16] though it is surely some generalization of a hypergeometric function for we definitely know how to evaluate the $N=2$ case directly in momentum space; but for larger N it would seem that the coordinate space method stalls. Only when $p=0$, which corresponds to a vacuum "watermelon diagram," can the integrations sometimes be carried out.[17] However, we will now present a method which is still suitable for handling the general problem and which works wonderfully well in odd-dimensional spaces. It relies on the observation that the modified Bessel function possesses an asymptotic representation ($\mu\equiv 4\nu^2$),

$$K_\nu(z)\sim\sqrt{\frac{\pi}{2z}}e^{-z}\left[1+\frac{\mu-1}{8z}+\frac{(\mu-1)(\mu-9)}{2!(8z)^2}+\frac{(\mu-1)(\mu-9)(\mu-25)}{3!(8z)^3}+\cdots\right]$$

that *terminates for ν or ℓ half-integral*, corresponding to D odd. Even for integral ℓ or even dimensions, we shall see that it provides a very nice threshold expansion in terms of hypergeometric functions.[18] To show how this works, assume first that all the intermediate particles are massive. Since

$$i\Delta_c(x|m)=\frac{1}{(2\pi)^{\ell}}\left(\frac{m}{r}\right)^{\ell-1}\sqrt{\frac{\pi}{2mr}}e^{-mr}\sum_{j=0}^{\infty}\frac{\Gamma(\ell+j-1/2)}{j!\Gamma(\ell-j-1/2)}(2mr)^{-j}, \tag{18}$$

the product of causal Green functions produces the series

$$\prod_{j=1}^{N} i\Delta_c(x|m_j)=\left(\frac{\pi^{1/2-\ell}}{2^{\ell+1/2}r^{\ell-1/2}}\right)^N\prod_{j=1}^{N} m_j^{\ell-3/2}.e^{-r\Sigma_j m_j}\left[1+\frac{(2\ell-1)(2\ell-3)}{8r}\sum_{j=1}^{N}\frac{1}{m_j}+\cdots\right].$$

The leading (and in 3D the only) term of the right-hand side above yields the leading behavior of the sunset diagram,

$$\begin{aligned}I_N^0(p)&=-\frac{(2\pi)^{\ell-N\ell+N/2}}{q^{\ell-1}\varpi^{3/2-\ell}}\int_0^{\infty}\mathrm{d}r\, r^{\ell-N\ell+N/2}e^{-r\sigma}J_{\ell-1}(qr)\\&=-\frac{2^{1-N\ell-N/2}\pi^{\ell-N\ell+N/2}\Gamma((2-N)\ell+N/2)}{\Gamma(\ell)\sigma^{(2-N)\ell+N/2}\varpi^{3/2-\ell}}\\&\quad\times F\left(\frac{2\ell-N\ell+N/2}{2},\frac{2\ell-N\ell+N/2+1}{2};\ell;\frac{p^2}{\sigma^2}\right),\end{aligned} \tag{19}$$

where $\varpi\equiv\Pi_i m_i$, $\sigma\equiv\Sigma_i m_i$. The imaginary part then produces the leading contribution to the phase space integral,

$$\begin{aligned}\rho_N^0(p)&=\frac{2^{2\ell(1-N)+1}\pi^{\ell(1-N)+(N+1)/2}(p^2-\sigma^2)^{\ell(N-1)-(N+1)/2}}{\varpi^{3/2-\ell}\sigma^{N\ell-1-N/2}\Gamma(\ell(N-1)-(N+1)/2)}\theta(p^2-\sigma^2)\\&\quad\times F\left(\frac{N\ell-N/2}{2},\frac{N\ell-1-N/2}{2};\ell(N-1)-\frac{N-1}{2};1-\frac{p^2}{\sigma^2}\right).\end{aligned} \tag{20}$$

It should be noted that expressions (19) and (20) represent the *complete* results for three dimensions (3D), when they reduce, respectively, to

$$I_N(p)\to-\frac{\pi^{3/2-N}\Gamma(3-N)}{2^{2N-2}\sigma^{3-N}\sqrt{\pi}}F\left(\frac{3-N}{2},\frac{4-N}{2};\frac{3}{2};\frac{p^2}{\sigma^2}\right)$$

and

$$\rho_N(p)\to\frac{\pi^{2-N}(p^2-\sigma^2)^{N-2}}{2^{3N-4}\sigma^{N-1}\Gamma(N-1)}F\left(\frac{N}{2},\frac{N-1}{2};N-1;1-\frac{p^2}{\sigma^2}\right)=\frac{\pi(\sqrt{p^2}-\sigma)^{N-2}\theta(p^2-\sigma^2)}{(4\pi)^{N-1}\Gamma(N-1)\sqrt{p^2}}.$$

The singularity in $I_N(p)$ for integer $N\geqslant 3$ is a reflection of the fact that there exist subdivergences in such multiloop 3D integrals, which must be regulated, e.g., using dimensional continuation, as in (19).

Nonleading behaviors (for values of $\ell\neq 3/2$) of I_N and ρ_N can be found from expansion (18); for instance to the next order we encounter the terms,

$$I_N^1(p)=\frac{(2\ell-1)(2\ell-3)\pi^{\ell((1-N)+N/2)}\Gamma(2\ell-1-N\ell+N/2)}{2^{2+N\ell+N/2}\varpi^{3/2-\ell}\sigma^{\ell(2-N)+N/2-1}\Gamma(\ell)\mu}$$
$$\times F\left(\frac{2\ell-N\ell+N/2-1}{2},\frac{2\ell-N\ell+N/2}{2};\ell;\frac{p^2}{\sigma^2}\right), \tag{21}$$

$$\rho_N^1(p)=\frac{(2\ell-1)(2\ell-3)\pi^{\ell(1-N)+(N+1)/2}(p^2-\sigma^2)^{\ell(N-1)+(1-N)/2}}{2^{2\ell(N-1)+3}\varpi^{3/2-\ell}\sigma^{N(\ell-1/2)}\mu\Gamma(\ell(N-1)+(3-N)/2)}\theta(p^2-\sigma^2)$$
$$\times F\left(\frac{N\ell+1-N/2}{2},\frac{N\ell-N/2}{2};\ell(N-1)+\frac{3-N}{2};1-\frac{p^2}{\sigma^2}\right), \tag{22}$$

where $1/\mu\equiv\Sigma_j 1/m_j$; and so on for higher I_N^k,ρ_N^k. The method is entirely systematic and one may proceed to as high an order k as needed. Observe that the resulting series is a sort of threshold expansion because the powers of $(p^2-\sigma^2)$ which multiply $F(a,b;c;1-p^2/\sigma^2)$ keep on increasing as we raise k while the denominators are associated with sums of the type $\Sigma_j(1/m_j)^k$.

However these expansions are deficient in one respect: it is very tricky to consider the limit as one or several masses vanishes, because the approximation (18) is fairly useless for massless propagators; in that case we should be using directly $iD_c(x)\propto r^{2-2\ell}$, rather than the asymptotic expansion (18). Finally then we will consider the case where M of the N particles are massive while the remaining $N-M$ are massless; this covers essentially all cases of interest. The sunset integral is given *ab initio* by

$$I_N(p)=-\frac{(2\pi)^\ell}{q^{\ell-1}}\int_0^\infty \mathrm{d}r\, r^\ell J_{\ell-1}(qr)\left(\frac{\Gamma(\ell-1)}{4\pi^\ell r^{2\ell-2}}\right)^{N-M}\left(\frac{(\pi r)^{1/2-\ell}}{2^{\ell+1/2}}\right)^M e^{-r\sigma}\varpi^{\ell-3/2}$$
$$\times\left[1+\frac{(2\ell-1)(2\ell-3)}{8r\mu}+\cdots\right], \tag{23}$$

where the symbols now refer simply to the massive intermediate particles; therefore $\varpi\equiv\Pi_{j=1}^M m_j$, $\sigma\equiv\Sigma_{j=1}^M m_j$, $1/\mu\equiv\Sigma_{j=1}^M(1/m_j)$. The integrals in (23) are readily performed and the leading term of the full answer is

$$I_N^0(p)$$
$$=-\frac{2^{2(M-N)+1-M\ell-M/2}\pi^{\ell(1-N)+M/2}[\Gamma(\ell-1)]^{N-M}\Gamma(\ell(2-M)+(M-N)(2\ell-2)+M/2)}{\varpi^{3/2-\ell}\sigma^{\ell(2-M)+(M-N)(2\ell-2)+M/2}\Gamma(\ell)}$$
$$\times F\left(\frac{\ell(2-M)+M/2}{2}+(M-N)(\ell-1),\frac{\ell(2-M)+1+M/2}{2}+(M-N)(\ell-1);\ell;\frac{p^2}{\sigma^2}\right). \tag{24}$$

Taking its discontinuity, the leading phase space behavior is [$c\equiv M(3/2-\ell)+2N(\ell-1)-\ell+1/2$ and $p^2\geqslant\sigma^2$ in the following],

$$\rho_N^0(p)=\frac{2^{2\ell(1-N)+1}\pi^{\ell(1-N)+(M+1)/2}[\Gamma(\ell-1)]^{N-M}(p^2-\sigma^2)^{M(3/2-\ell)+2N(\ell-1)-(\ell+1/2)}}{\varpi^{3/2-\ell}\sigma^{M(7/2-3\ell)+2(M+N)(\ell-1)-1}\Gamma(c)}$$
$$\times F\left((\ell-1)(N-M)+\frac{M(2\ell-1)}{4},(\ell-1)(N-M)+\frac{M(2\ell-1)}{4}-\frac{1}{2};c;1-\frac{p^2}{\sigma^2}\right). \tag{25}$$

All the previous cases fall out of (24) and (25) by making the relevant substitutions for M and ℓ. Of course one may also derive nonleading terms I_N^k, ρ_N^k in exactly the same way as before and they correspond to higher order threshold corrections. Again, these corrections entrain higher powers of $(p^2-\sigma^2)$ and terminate for half-integral ℓ.

VI. CONCLUSIONS

Before we can comprehend the statistical effects of phase space on brane physics, it is vital to understand phase space in flat D-dimensional space–time for any number of particles, with arbitrary masses. This paper has been devoted to that subject and we have arrived at results for $\rho_N(p)$ and $I_N(p)$ that have culminated in formulas (14), (23), (24), and (25). These comprise the high-energy and low-energy characteristics and at any energy in-between. We believe that these analytical expressions are as compact as one can make them and will turn out to be practically useful. Otherwise one will be obliged to resort to numerical methods.

ACKNOWLEDGMENTS

We are grateful to Dr. A.I. Davydychev for supplying us with a comprehensive list of references in this vast topic, for pointing us in the right direction, and for valuable comments on our work. We also thank the Australian Research Council for financial support under Grant No. A00000780.

APPENDIX: AT THE THRESHOLD OF A SUNSET

In this appendix we show explicitly how the threshold expansion can be carried out in momentum space via Feynman parameters. We illustrate the case $N=2$ for any dimension 2ℓ to keep the algebra simple, when the sunset integral is just

$$I_2(p)=\frac{\Gamma(2-\ell)}{(-4\pi)^\ell}\int_0^1 d\alpha_1\int_0^1 d\alpha_2\frac{\delta(\alpha_1+\alpha_2-1)}{[p^2\alpha_1\alpha_2-m_1^2\alpha_2-m_2^2\alpha_1]^{2-\ell}}.$$

Never mind the fact that I_2 can be expressed as a linear combination of two hypergeometric functions ($a=\ell-1,\ b=2-\ell,\ c=\ell$) with arguments $1/2[(m_1^2-m_2^2\pm p^2)/\lambda+1]$ or that it can be accorded an exact geometrical interpretation;[19] our purpose here is to show how one may arrive at a systematic threshold expansion, by expanding about the minimum of the denominator, regarded as a function of α. Thus change variables to

$$\alpha_i=\frac{m_i}{m_1+m_2}+\Delta\rho_i,\quad p^2\equiv(m_1+m_2)^2[1-\Delta^2].$$

The delta-function constraint on α corresponds to $\rho_1=-\rho_2\equiv\rho$, whereupon the sunset integral reduces to

$$I_2(p)=\frac{\Gamma(2-\ell)}{(4\pi)^\ell}\Delta^{2\ell-3}\int_{-m_1/[(m_1+m_2)\Delta]}^{m_2/[(m_1+m_2)\Delta]}\frac{d\rho}{[m_1m_2+\rho^2(m_1+m_2)^2(1-\Delta^2)-\Delta\rho(m_1^2-m_2^2)]^{2-\ell}}.$$

The leading behavior is found by setting $\Delta=0$ in the denominator of the integrand and extending the limits to $\pm\infty$. Since

$$\int_0^\infty\frac{d\rho}{[m_1m_2+\rho^2(m_1+m_2)^2]^{2-\ell}}=\frac{(m_1m_2)^{\ell-3/2}}{2(m_1+m_2)}\int_0^\infty\frac{dv\,v^{-1/2}}{(1+v)^{2-\ell}}=\frac{(m_1m_2)^{\ell-3/2}}{2(m_1+m_2)}\frac{\sqrt{\pi}\Gamma(3/2-\ell)}{\Gamma(2-\ell)},$$

it follows that

$$I_2^0(p)=\frac{(m_1m_2\Delta^2)^{\ell-3/2}\sqrt{\pi}}{(4\pi)^{\ell}(m_1+m_2)}\Gamma(3/2-\ell).$$

However we are keen to obtain all the nonleading terms and this can be accomplished by rewriting the sunset integral as

$$I_2(p)=\frac{\Gamma(2-\ell)(m_1m_2\Delta^2)^{\ell-3/2}}{(4\pi)^{\ell}\sqrt{p^2}}\int_{u_-}^{u_+}\mathrm{d}u[1+u^2-u\,\eta]^{\ell-2},$$

where the new integration variable is $u=\rho\sqrt{p^2/m_1m_2}$, the limits are

$$u_+=\frac{m_2}{(m_1+m_2)\Delta}\sqrt{\frac{p^2}{m_1m_2}}$$

and

$$u_-=-\frac{m_1}{(m_1+m_2)\Delta}\sqrt{\frac{p^2}{m_1m_2}},$$

and the new expansion variable is

$$\eta\equiv\frac{\Delta(m_1^2-m_2^2)}{\sqrt{p^2m_1m_2}}.$$

The series in η reads

$$I_2(p)=\frac{(m_1m_2\Delta^2)^{\ell-3/2}}{(4\pi)^{\ell}\sqrt{p^2}}\sum_{n=0}^{\infty}\frac{\Gamma(2+n-\ell)}{n!}\eta^nU_n,\quad U_n\equiv\int_{u_-}^{u_+}\mathrm{d}u\,(1+u^2)^{\ell-2-n}u^n.$$

In evaluating the coefficients U_n, we make use of the fact that the limits are large and we should distinguish between the cases of n even and n odd. For n even, we split the integral into

$$\begin{aligned}U_n&=\left(2\int_0^{\infty}-\int_{|u_-|}^{\infty}-\int_{|u_+|}^{\infty}\right)\mathrm{d}u\,u^n(1+u^2)^{\ell-2-n}\\&=\frac{\Gamma((n+1)/2)\Gamma((3+n)/2-\ell)}{\Gamma(2+n-\ell)}-\left(\int_{|u_-|}^{\infty}+\int_{|u_+|}^{\infty}\right)\mathrm{d}u\,u^{2\ell-4-n}(1+1/u^2)^{\ell-2-n},\end{aligned}$$

where we may expand the latter two integrals in powers of $1/u^2$—which provides a further subexpansion in powers of Δ. Thus we get

$$\begin{aligned}\Gamma(2+n-\ell)U_n=\Gamma(n+1/2)\Gamma((3+n)/2-\ell)+\sum_{k=0}^{\infty}\frac{(-)^k\Gamma(2+n+k-\ell)}{k!(2\ell-3-n-2k)}\\\times[|u_+|^{2\ell-3-n-2k}+|u_-|^{2\ell-3-n-2k}].\end{aligned}$$

On the other hand, the case of odd n can be treated directly by expanding the integrand below in powers of $1/v$:

$$U_n=\frac{1}{2}\int_{u_-^2}^{u_+^2}\mathrm{d}v\,v^{\ell-(5+n)/2}(1+1/v)^{\ell-2-n}$$

so

$$\Gamma(2+n-\ell)U_n=\sum_{k=0}^{\infty}\frac{(-)^k\Gamma(2+n+k-\ell)}{k!(2\ell-3-n-2k)}[|u_+|^{2\ell-3-n-2k}-|u_-|^{2\ell-3-n-2k}].$$

Again one encounters a subseries in Δ. (The two series make up the "$h-h$" and "$p-p$" contributions of Ref. 3 at one stroke.) In short we see that the sunset integral, and of necessity its imaginary part, can be systematically expanded as a series in Δ which is proportional to the Q value of the reaction by appropriately handling the Feynman parametric representation. It is possible to treat the sunset diagram with N intermediate particles in a similar way, but the method becomes rather unwieldy, which is why we turned to coordinate space methods in Secs. IV and V.[20,21]

Generalized Weyl–Wigner map and Vey quantum mechanics

Nuno Costa Dias[a] and João Nuno Prata[b]
Departamento de Matemática, Departamento de Engenharias, Universidade Lusófona de Humanidades e Tecnologias, Av. Campo Grande, 376, 1749-024 Lisboa, Portugal

(Received 16 April 2001; accepted for publication 6 September 2001)

The Weyl–Wigner map yields the entire structure of Moyal quantum mechanics directly from the standard operator formulation. The covariant generalization of Moyal theory, also known as Vey quantum mechanics, was presented in the literature many years ago. However, a derivation of the formalism directly from standard operator quantum mechanics, clarifying the relation between the two formulations, is still missing. In this article we present a covariant generalization of the Weyl order prescription and of the Weyl–Wigner map and use them to derive Vey quantum mechanics directly from the standard operator formulation. The procedure displays some interesting features: it yields all the key ingredients and provides a more straightforward interpretation of the Vey theory including a direct implementation of unitary operator transformations as phase space coordinate transformations in the Vey idiom. These features are illustrated through a simple example. © *2001 American Institute of Physics.* [DOI: 10.1063/1.1415086]

I. INTRODUCTION

The Weyl–Wigner map[1,2] yields the Moyal formulation of quantum mechanics,[3–8] alternative to the more conventional standard operator[9–12] and path integral formulations. The main features of Moyal quantum mechanics are that it is formulated in terms of phase space functions and the dynamics is based on a deformation of the Poisson bracket, named the Moyal bracket.[3,13–15] This formulation of quantum mechanics has been receiving increased attention namely in the context of the fields of the semiclassical limit of quantum mechanics,[5,14–19] quantum chaos,[20,21] hybrid dynamics[22,23] and also in M-theory.[24–26]

The Weyl–Wigner isomorphism between operators and phase space functions (symbols) provides the entire structure of Moyal quantum mechanics directly from the standard operator formulation. Let us choose a set of fundamental operators $(\hat{q}_i,\hat{p}_i)$ and the corresponding set of canonical variables $(q_i,p_i), i=1,...,N$, for an arbitrary N dimensional dynamical system. The Weyl–Wigner map $W_{(q,p)}:\hat{\mathcal{A}}\rightarrow\mathcal{A}(T^*M)$ attributes to a given operator $\hat{A}$ in the quantum algebra $\hat{\mathcal{A}}$ a unique element of the algebra of functions over the phase space T^*M:

$$W_{(q,p)}(\hat{A})=\int d^N\vec{y}\,e^{-i\vec{p}\cdot\vec{y}}\left\langle \vec{q}-\frac{\hbar}{2}\vec{y}\left|\hat{A}\right|\vec{q}+\frac{\hbar}{2}\vec{y}\right\rangle, \tag{1}$$

where we used the compact notation:

$$\vec{y}\equiv(y_1,\ldots,y_N);\;\; d^N\vec{y}\equiv dy_1\cdots dy_N;\;\; \vec{p}\equiv(p_1,\ldots,p_N)\;\; \vec{q}\equiv(q_1,\ldots,q_N),$$

and the subscript (q,p) means that the corresponding object (the Weyl–Wigner map in this case) is defined in the variables $(\vec{q},\vec{p})$. This specification seems redundant now but is important for the sequel. The Weyl–Wigner map is bijective and unequivocal. Moreover, it is an isomorphism

[a]Electronic mail: nuno.dias@ulusofona.pt
[b]Electronic mail: joao.prata@ulusofona.pt

between the quantum $(\hat{\mathcal{A}},\cdot,[,])$ and the "classical" $(\mathcal{A},*,[,]_M)$ algebras. The quantum algebra $\hat{\mathcal{A}}$ is based on the operator product $\cdot$ and the quantum commutator $[,]$, whereas the classical algebraic structures are the "star" product $*$ and the Moyal bracket $[,]_M$. The Weyl–Wigner map is a morphism in the sense that

$$\begin{aligned} &W_{(q,p)}(\hat{A}\cdot\hat{B})=W_{(q,p)}(\hat{A})*_{(q,p)}W_{(q,p)}(\hat{B}),\\ &W_{(q,p)}\left(\frac{1}{i\hbar}[\hat{A},\hat{B}]\right)=[W_{(q,p)}(\hat{A}),W_{(q,p)}(\hat{B})]_{M_{(q,p)}},\quad \forall\hat{A},\hat{B}\in\hat{\mathcal{A}}, \end{aligned} \tag{2}$$

and it yields the functional structure of the star product and Moyal bracket:

$$A*_{(q,p)}B=Ae^{(i\hbar/2)\hat{\mathcal{J}}_{(q,p)}}B,\quad [A,B]_{M_{(q,p)}}=\frac{2}{\hbar}A\sin\left(\frac{\hbar}{2}\hat{\mathcal{J}}_{(q,p)}\right)B,\quad A,B\in\mathcal{A}, \tag{3}$$

where $\hat{\mathcal{J}}_{(q,p)}$ is the "*Poisson*" operator:

$$\hat{\mathcal{J}}_{(q,p)}\equiv\sum_{i=1}^{N}\left(\frac{\overleftarrow{\partial}}{\partial q_i}\frac{\vec{\partial}}{\partial p_i}-\frac{\overleftarrow{\partial}}{\partial p_i}\frac{\vec{\partial}}{\partial q_i}\right),$$

the derivatives $\overleftarrow{\partial}$ and $\vec{\partial}$ acting on A and B, respectively. Alternatively, $\hat{\mathcal{J}}_{(q,p)}$ can be written as $\hat{\mathcal{J}}_{(q,p)}=\overleftarrow{\partial}_k J^{kl}_{(q,p)}\vec{\partial}_l$, where $J^{kl}_{(q,p)}$ is the klth element of the symplectic matrix in the variables $(\vec{q},\vec{p})$:

$$J_{(q,p)}=\begin{pmatrix}0_{N\times N} & -1_{N\times N}\\ 1_{N\times N} & 0_{N\times N}\end{pmatrix}. \tag{4}$$

We introduced the compact notation, $O^k=p_k, k=1,\ldots,N$; $O^k=q_{k-N}, k=N+1,\ldots,2N$; $\partial/\partial O_k=\partial_k$, and sum over repeated indices is understood.

From Eq. (3) it is trivial to obtain the following expansion in powers of $\hbar$:

$$A*_{(q,p)}B=A\cdot B+\frac{i\hbar}{2}A\overleftarrow{\partial}_k J^{kl}_{(q,p)}\vec{\partial}_l B+\frac{1}{2}\left(\frac{i\hbar}{2}\right)^2 A\overleftarrow{\partial}_k\overleftarrow{\partial}_s J^{kl}_{(q,p)}J^{sn}_{(q,p)}\vec{\partial}_l\vec{\partial}_n B+\cdots. \tag{5}$$

The Weyl–Wigner transform of the density matrix operator is the Wigner distribution function,[2] $f_W(\vec{q},\vec{p};t)=(1/2\Pi\hbar)W_{(q,p)}(|\psi(t)\rangle\langle\psi(t)|)$, which is the fundamental mathematical object of Moyal quantum mechanics. Its time evolution is given by the dynamical equation

$$\dot{f}_W(\vec{q},\vec{p};t)=[H(\vec{q},\vec{p}),f_W(\vec{q},\vec{p};t)]_{M_{(q,p)}},\quad H=W_{(q,p)}(\hat{H}), \tag{6}$$

where $\hat{H}$ is the quantum Hamiltonian. We see that the mathematical structure of Moyal quantum mechanics is very similar to that of classical statistical mechanics. However, these similarities should not be taken too seriously. The procedure by which physical relevant information is obtained is a lot more elaborate. In classical statistical mechanics the fundamental predictions are the probabilities for finding the system in an arbitrary configuration $(\vec{q}_0,\vec{p}_0)$, which are given by the values of a true probability distribution function $\rho(\vec{q}=\vec{q}_0,\vec{p}=\vec{p}_0)$.

On the contrary, in Moyal quantum mechanics the value of $f_W(\vec{q}=\vec{q}_0,\vec{p}=\vec{p}_0)$ cannot be given such straightforward interpretation, given the fact that $f_W(\vec{q},\vec{p})$ might take on negative values. The fundamental physical predictions of Moyal quantum mechanics are obtained through a procedure analogous to that of standard operator quantum mechanics. Given a general observable $A(\vec{q},\vec{p})$ we should solve the star-genvalue equation,[8,27,28]

$$A(\vec{q},\vec{p})*_{(q,p)}g^n_a(\vec{q},\vec{p})=ag^n_a(\vec{q},\vec{p}), \tag{7}$$

where n is a degeneracy index, to obtain the probability for a measurement of A at the time t yielding the value a:

$$P(A(\vec{q},\vec{p};t)=a)=\sum_n \int d^N\vec{q}\int d^N\vec{p}\,g_a^n(\vec{q},\vec{p})f_W(\vec{q},\vec{p};t), \tag{8}$$

where we assumed that the degeneracy index is discrete. If this is not the case, then the sum in n is replaced by a (set of) integral(s) in n. For the fundamental observables q_i and p_i, $i=1,...,N$, Eq. (8) reduces to a more ''classical type'' result:

$$\begin{aligned} P(q_i(t)=q_0)&=\int d^N\vec{q}\int d^N\vec{p}\,f_W(\vec{q},\vec{p};t)\,\delta(q_i-q_0);\\ P(p_i(t)=p_0)&=\int d^N\vec{q}\int d^N\vec{p}\,f_W(\vec{q},\vec{p};t)\,\delta(p_i-p_0), \end{aligned} \tag{9}$$

the same happening to the average value of $A(\vec{q},\vec{p})$:

$$\langle A(\vec{q},\vec{p};t)\rangle=\int d^N\vec{q}\int d^N\vec{p}\,A(\vec{q},\vec{p})f_W(\vec{q},\vec{p};t). \tag{10}$$

An important subject in any dynamical theory is the study of its invariances. Just like standard operator quantum mechanics the Moyal formulation is invariant under the action of general unitary transformations and, contrary to what happens in classical mechanics, is not invariant under the action of a significant set of coordinate transformations. In fact, most unitary operator transformations are not implemented as phase space coordinate transformations in the Moyal idiom.

Many years ago Vey[29] presented a generalization of the star product that renders Moyal quantum mechanics fully invariant under phase space coordinate transformations. The original motivation was not to enlarge the invariance properties of Moyal quantum mechanics, but to derive the general form of the Poisson algebra deformations for curved phase spaces. Vey's original developments have been used in investigations aiming at two major directions: First, to provide a consistent classical interpretation of Moyal dynamics,[14,15] and second, in more mathematically oriented research, to generalize the Moyal–Weyl–Wigner quantization procedure to nonflat phase space manifolds. In Refs. 14 and 15 the problem of constructing an associative star product in a general sympletic manifold was considered. The question of existence of such a product was completely solved in Ref. 30. The same problem for Poisson–Lie groups was consider in Ref. 31. In Refs. 32–34 an alternative construction of star products for a general sympletic manifold was proposed. This construction is given in pure geometrical terms and is thus quite an appealing framework to study the invariance properties of phase space quantum mechanics. In Ref. 33 the action of unitary transformations is implemented, in geometrical terms, as sympletic morphisms of the phase space manifold.

To our knowledge, however, a complete study of the relation between Vey covariant quantum mechanics and standard operator quantum mechanics casting Vey theory at the same level of completeness as Moyal quantum mechanics has not yet been presented. Take, for instance, the Weyl–Wigner map. Although trivial, the covariant generalization of this map is still missing in the literature.

In this article we emphasize the relation between standard operator quantum mechanics and Moyal quantum mechanics and attempt to derive the Vey formulation in a similar fashion. There are two main virtues in this approach: first, it clarifies the relation between the standard operator and Vey quantum mechanics (providing, for instance, a new point of view for the analysis of the invariance properties of covariant phase space quantum mechanics). Second, it yields a (previously missing) covariant generalization of some key ingredients of phase space quantum mechanics, such as the Weyl–Wigner map, the Weyl order prescription, the average and the marginal probability distribution functionals and the star-genvalue equation.

This article is organized as follows: in Sec. II we start by reviewing some well known properties concerning the action of canonical and coordinate transformations in the Moyal formalism. We then present (Sec. III) a covariant generalization of the Weyl–Wigner map. The new map makes it possible to implement a general unitary transformation of standard operator quantum mechanics as a coordinate transformation in the Moyal idiom. In Sec. IV we use the new map to derive the covariant star product and, as a by-product, the dynamical structure of Vey quantum mechanics. In Sec. V we present a summary of the structure of covariant quantum mechanics, including the generalizations of the star-genvalue equation, the average value and the probability functionals. Finally, in Sec. VI some of the features of the formalism are illustrated through a simple example.

Before proceeding let us make an important remark: from the outset we shall restrict our attention to the simpler case of dynamical systems displaying a phase space with the structure of a flat manifold.

II. CANONICAL AND COORDINATE TRANSFORMATIONS

In classical mechanics all canonical transformations are phase space coordinate transformations. Their action is of the form (we shall take the passive point of view)

$$T:T^*M\rightarrow T^*M;(\vec{q},\vec{p})\rightarrow(\vec{q}=\vec{q}(\vec{Q},\vec{P}),\vec{p}=\vec{p}(\vec{Q},\vec{P})), \tag{11}$$

where $(\vec{Q},\vec{P})$ and $(\vec{q},\vec{p})$ are two sets of canonical variables. T yields a transformation of a general observable given by

$$T:A(\vec{q},\vec{p})\rightarrow A'(\vec{Q},\vec{P})=A(\vec{q}(\vec{Q},\vec{P}),\vec{p}(\vec{Q},\vec{P})), \tag{12}$$

and for two general observables $A'(\vec{Q},\vec{P})=T\{A(\vec{q},\vec{p})\}$ and $B'(\vec{Q},\vec{P})=T\{B(\vec{q},\vec{p})\}$ we have

$$\{A(\vec{q}(\vec{Q},\vec{P}),\vec{p}(\vec{Q},\vec{P})),B(\vec{q}(\vec{Q},\vec{P}),\vec{p}(\vec{Q},\vec{P}))\}_{(q,p)}=\{A'(\vec{Q},\vec{P}),B'(\vec{Q},\vec{P})\}_{(Q,P)}, \tag{13}$$

and thus the Hamiltonian equations of motion in the variables $(\vec{q},\vec{p})$ and $(\vec{Q},\vec{P})$ are fully equivalent: they yield identical mathematical solutions and thus identical physical predictions.

This picture does not translate to Moyal quantum mechanics. To see this explicitly let us go back to standard operator quantum mechanics and consider, to make it simpler, the unitary transformation:

$$\hat{\vec{q}}\equiv\hat{\vec{q}}(\hat{\vec{Q}},\hat{\vec{P}})=\hat{U}\hat{\vec{Q}}\hat{U}^{-1},\quad \hat{\vec{p}}\equiv\hat{\vec{p}}(\hat{\vec{Q}},\hat{\vec{P}})=\hat{U}\hat{\vec{P}}\hat{U}^{-1},\quad \hat{A}(\hat{\vec{q}},\hat{\vec{p}})\equiv\hat{U}\hat{A}(\hat{\vec{Q}},\hat{\vec{P}})\hat{U}^{-1}=\hat{A}'(\hat{\vec{Q}},\hat{\vec{P}}). \tag{14}$$

The two sets of fundamental variables provide two Weyl-Wigner maps:

$$\begin{aligned} W_{(Q,P)}(\hat{A})&=\int d^N\vec{Y}e^{-i\vec{P}\cdot\vec{Y}}\left\langle \vec{Q}-\frac{\hbar}{2}\vec{Y}\middle|\hat{A}\middle|\vec{Q}+\frac{\hbar}{2}\vec{Y}\right\rangle,\\ W_{(q,p)}(\hat{A})&=\int d^N\vec{y}e^{-i\vec{p}\cdot\vec{y}}\left\langle \vec{q}-\frac{\hbar}{2}\vec{y}\middle|\hat{A}\middle|\vec{q}+\frac{\hbar}{2}\vec{y}\right\rangle, \end{aligned} \tag{15}$$

from which we can derive the action of unitary transformations in the Moyal formalism. The fundamental variables transform trivially,

$$T:(\vec{q},\vec{p})\rightarrow(\vec{q}=W_{(Q,P)}(\hat{\vec{q}}(\hat{\vec{Q}},\hat{\vec{P}}))=\vec{q}(\vec{Q},\vec{P}),\vec{p}=W_{(Q,P)}(\hat{\vec{p}}(\hat{\vec{Q}},\hat{\vec{P}}))=\vec{p}(\vec{Q},\vec{P})), \tag{16}$$

and a general observable transforms as

$$
\begin{aligned}
T{:}A(\vec{q},\vec{p}) &= W_{(q,p)}(\hat{A}(\hat{\vec{q}},\hat{\vec{p}})) \rightarrow A'(\vec{Q},\vec{P}) \\
&= W_{(Q,P)}(\hat{A}'(\hat{\vec{Q}},\hat{\vec{P}})) \\
&= U(\vec{Q},\vec{P}) *_{(Q,P)} A(\vec{Q},\vec{P}) *_{(Q,P)} U^{-1}(\vec{Q},\vec{P}),
\end{aligned} \tag{17}
$$

which, in general, does not correspond to the action of a coordinate transformation (except if T is linear) since

$$
A'(\vec{Q},\vec{P}) \neq A(\vec{q}(\vec{Q},\vec{P}),\vec{p}(\vec{Q},\vec{P})), \tag{18}
$$

even though the transformation is canonical. For two general observables $A(\vec{q},\vec{p})$ and $B(\vec{q},\vec{p})$ we have

$$
[A'(\vec{Q},\vec{P}),B'(\vec{Q},\vec{P})]_{M_{(Q,P)}} = T([A(\vec{q},\vec{p}),B(\vec{q},\vec{p})]_{M_{(q,p)}}), \tag{19}
$$

and thus the Moyal dynamical equations in the variables $(\vec{Q},\vec{P})$ and $(\vec{q},\vec{p})$,

$$
\dot{A}(\vec{q},\vec{p};t) = [A(\vec{q},\vec{p};t),H(\vec{q},\vec{p})]_{M_{(q,p)}} \quad \text{and} \quad \dot{A}'(\vec{Q},\vec{P};t) = [A'(\vec{Q},\vec{P};t),H'(\vec{Q},\vec{P})]_{M_{(Q,P)}}, \tag{20}
$$

yield two mathematical solutions, related by

$$
A(t) = F(\vec{q},\vec{p},t) \quad \text{and} \quad A'(t) = F'(\vec{Q},\vec{P},t) = U *_{(Q,P)} F(\vec{Q},\vec{P},t) *_{(Q,P)} U^{-1}, \tag{21}
$$

which, in general, are not the same phase space function: $F'(\vec{Q},\vec{P},t) \neq F(\vec{q}(\vec{Q},\vec{P}),\vec{p}(\vec{Q},\vec{P}),t)$, albeit providing the same physical predictions: Eqs. (8)–(10). We see that no physical meaning can be attached to a single value of the observable A since this value is dependent of the particular representation chosen. Take, for instance, the Wigner distribution function that may be positive defined in one representation and become negative under a unitary transformation.

On the other hand, most coordinate transformations act noncanonically in the Moyal formalism (the exceptions, once again, are linear transformations): consider the transformation T in Eq. (16) and the two general phase space functions $G(\vec{q},\vec{p})$ and $F(\vec{q},\vec{p})$. In general we have

$$
\begin{aligned}
&[G(\vec{q}(\vec{Q},\vec{P}),\vec{p}(\vec{Q},\vec{P})),F(\vec{q}(\vec{Q},\vec{P}),\vec{p}(\vec{Q},\vec{P}))]_{M_{(q,p)}} \\
&\quad \neq [G(\vec{q}(\vec{Q},\vec{P}),\vec{p}(\vec{Q},\vec{P})),F(\vec{q}(\vec{Q},\vec{P}),\vec{p}(\vec{Q},\vec{P}))]_{M_{(Q,P)}},
\end{aligned} \tag{22}
$$

which is a consequence of the fact that the star product (sometimes expressed in terms of the symmetric bracket[13]) is also not invariant under a general coordinate transformation:

$$
\begin{aligned}
&G(\vec{q}(\vec{Q},\vec{P}),\vec{p}(\vec{Q},\vec{P})) *_{(q,p)} F(\vec{q}(\vec{Q},\vec{P}),\vec{p}(\vec{Q},\vec{P})) \\
&\quad \neq G(\vec{q}(\vec{Q},\vec{P}),\vec{p}(\vec{Q},\vec{P})) *_{(Q,P)} F(\vec{q}(\vec{Q},\vec{P}),\vec{p}(\vec{Q},\vec{P})).
\end{aligned} \tag{23}
$$

These features of the Weyl-Wigner map and consequently of the star product are well known and have been extensively studied in the past (see, for instance Refs. 14 and 15). Namely, it was proved that the set of observables invariant under general unitary transformations is the set of first order polynomials in the fundamental variables and the coordinate transformations that preserve the Moyal star product are the linear transformations. These properties restrict the validity of the deformation quantization procedure to those phase space manifolds where a global Darboux chart can be naturally defined and thus completely exclude the possibility of extending this quantization procedure to nonflat phase space manifolds. In this context they motivated the original developments by Vey[29] and subsequently by Bayen *et al.*,[14,15] aiming at producing a more robust, coor-

dinate invariant formulation of the deformed structures. This work culminated with the results of Fedosov[33,34] where a pure geometrical implementation of the star product was proposed.

Our analysis of the next sections differs in the approach but not in the final goals. Instead of working directly in the context of Wigner quantum mechanics (like in the previous references) we focus on the relation between standard operator and phase space quantum mechanics. From the analysis leading to Eq. (18) and Eqs. (22) and (23) we see that the behavior of Moyal quantum mechanics under the action of canonical and coordinate transformations can be seen as a consequence of the definition of the Weyl–Wigner map (15). This motivates the purpose of the next section where we will present a generalization of the Weyl–Wigner map and use it to prove that unitary operator transformations can be implemented as coordinate transformations in the Moyal formalism. Furthermore, we will see in Sec. IV that the new map provides a derivation of Vey covariant quantum mechanics directly from standard operator quantum mechanics.

III. GENERALIZED WEYL–WIGNER MAP

We start by introducing a new Weyl–Wigner map in the variables $(\vec{Q},\vec{P})$ (which are not required to be canonical) that copies the Weyl–Wigner map in the variables $(\vec{q},\vec{p})$:

Definition: Generalized Weyl–Wigner map: Let $W_{(q,p)}$ be the standard Weyl–Wigner map [in the variables $(\vec{q},\vec{p})$] from the algebra of linear operators $\hat{\mathcal{A}}(\mathcal{H})$ acting on the physical Hilbert space $\mathcal{H}$ to the algebra of observables in the phase space T^*M. For the variables $(\vec{Q},\vec{P})$, assumed in one-to-one correspondence with the canonical variables $(\vec{q},\vec{p})$, we define a new *generalized* Weyl–Wigner map:

$$W'_{(Q,P)}:\hat{\mathcal{A}}(\mathcal{H})\rightarrow\mathcal{A}(T^*M);\quad W'_{(Q,P)}(\hat{A})=W_{(q,p)}(\hat{A}),\quad \forall\hat{A}\in\hat{\mathcal{A}}(\mathcal{H})\,. \tag{24}$$

For each new choice of the canonical variables $(\vec{q},\vec{p})$ we obtain a new Weyl–Wigner map in the variables $(\vec{Q},\vec{P})$. If the transformation from $(\vec{q},\vec{p})$ to $(\vec{Q},\vec{P})$ is a polynomial of first degree, then $W'_{(Q,P)}=W_{(Q,P)}$. Otherwise the two maps differ.

The aim of this section is to obtain the explicit expression for $W'_{(Q,P)}$. We start by deriving the generalizations of the Weyl order and Weyl symbol prescriptions.

A generic dynamical operator $\hat{A}$ can be cast in a fully symmetrized form according to Weyl's prescription:

$$\hat{A}_{W(q,p)}=\hat{A}(\hat{\vec{q}},\hat{\vec{p}})=\int d^N\vec{x}d^N\vec{y}\,\alpha(\vec{x},\vec{y})e^{i\vec{x}\cdot\hat{\vec{q}}+i\vec{y}\cdot\hat{\vec{p}}}, \tag{25}$$

where the subscript $W(q,p)$ means that $\hat{A}$ is displayed as a fully symmetrized functional of the variables $(\hat{\vec{q}},\hat{\vec{p}})$, and $\vec{x}\cdot\hat{\vec{q}}+\vec{y}\cdot\hat{\vec{p}}\equiv\Sigma_{j=1}^{N}(x_j\hat{q}_j+y_j\hat{p}_j)$. If $\hat{A}$ is Hermitian, then the numerical (usually singular) function $\alpha(\vec{x},\vec{y})$ is subject to the constraint $\alpha^*(\vec{x},\vec{y})=\alpha(-\vec{x},-\vec{y})$. The Weyl symbol, $W_{(q,p)}(\hat{A})$, associated with the operator $\hat{A}$ in Eq. (25) is the c-function of $2N$ phase space variables $(\vec{q},\vec{p})$ given by

$$A(\vec{q},\vec{p})\equiv W_{(q,p)}[\hat{A}(\hat{\vec{q}},\hat{\vec{p}})]=\int d^N\vec{x}d^N\vec{y}\,\alpha(\vec{x},\vec{y})e^{i\vec{x}\cdot\vec{q}+i\vec{y}\cdot\vec{p}}. \tag{26}$$

Let now $(\hat{\vec{Q}},\hat{\vec{P}})$ be another complete set of variables in one-to-one correspondence with $(\hat{\vec{q}},\hat{\vec{p}})$ and let us display the variables $(\hat{\vec{q}},\hat{\vec{p}})$ in a completely symmetrized order in the basis $(\hat{\vec{Q}},\hat{\vec{P}})$, i.e.,

$$\hat{\vec{q}}\equiv\int d^N\vec{z}d^N\vec{w}\,\rho_q(\vec{z},\vec{w})e^{i\vec{z}\cdot\hat{\vec{Q}}+i\vec{w}\cdot\hat{\vec{P}}}, \tag{27}$$

$$\hat{\vec{p}} \equiv \int d^N\vec{x}\, d^N\vec{y}\, \rho_p(\vec{x},\vec{y})\, e^{i\vec{x}\cdot\hat{\vec{Q}}+i\vec{y}\cdot\hat{\vec{P}}}.$$

The new variables are not necessarily canonical: in general, $[\hat{Q}_i,\hat{P}_j]\neq i\hbar\,\delta_{ij}$. The $(\vec{Q},\vec{P})$-Weyl symbols associated with (27) are

$$\begin{aligned}\vec{q} &\equiv W_{(Q,P)}(\hat{\vec{q}}) = \int d^N\vec{z}\, d^N\vec{w}\, \rho_q(\vec{z},\vec{w})\, e^{i\vec{z}\cdot\vec{Q}+i\vec{w}\cdot\vec{P}},\\ \vec{p} &\equiv W_{(Q,P)}(\hat{\vec{p}}) = \int d^N\vec{x}\, d^N\vec{y}\, \rho_p(\vec{x},\vec{y})\, e^{i\vec{x}\cdot\vec{Q}+i\vec{y}\cdot\vec{P}}.\end{aligned} \tag{28}$$

Let us now consider again the operator $\hat{A}$ given by Eq. (25). In the $(\hat{\vec{Q}},\hat{\vec{P}})$ representation $\hat{A}$ is written as $\hat{A}=\hat{A}(\hat{\vec{q}}(\hat{\vec{Q}},\hat{\vec{P}}),\hat{\vec{p}}(\hat{\vec{Q}},\hat{\vec{P}}))=\hat{A}'(\hat{\vec{Q}},\hat{\vec{P}})$ and the explicit functional form of $\hat{A}'$ is given by the *generalized Weyl prescription*:

$$\hat{A}_{W'(Q,P)}=\hat{A}'(\hat{\vec{Q}},\hat{\vec{P}}) = \int d^N\vec{x}\, d^N\vec{y}\, \alpha(\vec{x},\vec{y})\, e^{i\vec{x}\cdot\hat{\vec{q}}(\hat{\vec{Q}},\hat{\vec{P}})+i\vec{y}\cdot\hat{\vec{p}}(\hat{\vec{Q}},\hat{\vec{P}})}, \tag{29}$$

where $\hat{\vec{q}}(\hat{\vec{Q}},\hat{\vec{P}})$ and $\hat{\vec{p}}(\hat{\vec{Q}},\hat{\vec{P}})$ are given (in a fully symmetrized order) by Eq. (27) and the subscript $W'(Q,P)$ means that $\hat{A}$ is displayed as a functional of the variables $(\hat{\vec{Q}},\hat{\vec{P}})$ in a fully symmetrized order in the variables $(\hat{\vec{q}},\hat{\vec{p}})$. Notice that the numerical function $\alpha(\vec{x},\vec{y})$ is the same as in Eq. (25). The standard $(\vec{q},\vec{p})$-Weyl symbol associated with $\hat{A}$ is given by Eq. (26) and thus, using the definition (24), it is straightfoward to conclude that the generalized Weyl symbol associated with $\hat{A}$ is given by

$$A'(\vec{Q},\vec{P}) \equiv W'_{(Q,P)}[\hat{A}'(\hat{\vec{Q}},\hat{\vec{P}})] = \int d^N\vec{x}\, d^N\vec{y}\, \alpha(\vec{x},\vec{y})\, e^{i\vec{x}\cdot\vec{q}(\vec{Q},\vec{P})+i\vec{y}\cdot\vec{p}(\vec{Q},\vec{P})}, \tag{30}$$

and one immediately realizes that $A'(\vec{Q},\vec{P})=A(\vec{q}(\vec{Q},\vec{P}),\vec{p}(\vec{Q},\vec{P}))$ as it should.

Finally, we want to derive the covariant generalization of the Weyl–Wigner map given by Eq. (1). We start by rewriting $W_{(q,p)}$ as follows:

$$A(\vec{q},\vec{p}) = W_{(q,p)}(\hat{A}) = \int d^N\vec{x} \int d^N\vec{y}\, e^{-i\vec{p}\cdot\vec{y}}\, \delta(\vec{x}-\vec{q})\, F(\vec{x},\vec{y}), \tag{31}$$

where $F(\vec{x},\vec{y})=\langle \vec{x}-\frac{\hbar}{2}\vec{y}|\hat{A}|\vec{x}+\frac{\hbar}{2}\vec{y}\rangle$ and $|\vec{x}\pm\frac{\hbar}{2}\vec{y}\rangle$ are eigenstates of $\hat{\vec{q}}$. The function $F(\vec{x},\vec{y})$ is invariant under change of representation:

$$F(\vec{x},\vec{y}) = \left\langle \vec{x}-\frac{\hbar}{2}\vec{y}\right|\hat{A}(\hat{\vec{q}},\hat{\vec{p}})\left|\vec{x}+\frac{\hbar}{2}\vec{y}\right\rangle = \left\langle \vec{x}-\frac{\hbar}{2}\vec{y}\right|_Q \hat{A}(\hat{\vec{q}}(\hat{\vec{Q}},\hat{\vec{P}}),\hat{\vec{p}}(\hat{\vec{Q}},\hat{\vec{P}}))\left|\vec{x}+\frac{\hbar}{2}\vec{y}\right\rangle_Q, \tag{32}$$

where the subscript "Q" makes it explicit that the eigenstates of $\hat{\vec{q}}$ are displayed in the $\hat{\vec{Q}}$ representation. Furthermore, it is trivial to realize that

$$A(\vec{q}(\vec{Q},\vec{P}),\vec{p}(\vec{Q},\vec{P})) = \int d^N\vec{x} \int d^N\vec{y}\, e^{-i\vec{p}(\vec{Q},\vec{P})\cdot\vec{y}}\, \delta(\vec{x}-\vec{q}(\vec{Q},\vec{P}))\, F(\vec{x},\vec{y}), \tag{33}$$

and thus we get the explicit expression for the covariant Weyl–Wigner map:

$$W'_{(Q,P)}(\hat{A})=\int d^N\vec{x}\int d^N\vec{y}e^{-i\vec{p}(\vec{Q},\vec{P})\cdot\vec{y}}\delta(\vec{x}-\vec{q}(\vec{Q},\vec{P}))\left\langle \vec{x}-\frac{\hbar}{2}\vec{y}\right|_Q\hat{A}\left|\vec{x}+\frac{\hbar}{2}\vec{y}\right\rangle_Q \tag{34}$$

satisfying definition (24).

To illustrate the features of the new map let us consider the unitary transformation (14). The generalized map yields a different phase space version of this transformation. The analog of Eq. (17) is given by

$$T{:}A(\vec{q},\vec{p})=W_{(q,p)}(\hat{A}(\hat{\vec{q}},\hat{\vec{p}}))\rightarrow A'(\vec{Q},\vec{P})=W'_{(Q,P)}(\hat{A}'(\hat{\vec{Q}},\hat{\vec{P}})), \tag{35}$$

and we get

$$\begin{aligned}W'_{(Q,P)}(\hat{A}'(\hat{\vec{Q}},\hat{\vec{P}}))&=W'_{(Q,P)}(\hat{U}\hat{A}(\hat{\vec{Q}},\hat{\vec{P}})\hat{U}^{-1})\\&=\int d^N\vec{x}\int d^N\vec{y}e^{-i\vec{p}(\vec{Q},\vec{P})\cdot\vec{y}}\delta(\vec{x}-\vec{q}(\vec{Q},\vec{P}))\\&\quad\times\left\langle \vec{x}-\frac{\hbar}{2}\vec{y}\right|\hat{U}^{-1}(\hat{U}\hat{A}(\hat{\vec{Q}},\hat{\vec{P}})\hat{U}^{-1})\hat{U}\left|\vec{x}+\frac{\hbar}{2}\vec{y}\right\rangle\\&=A(\vec{q}(\vec{Q},\vec{P}),\vec{p}(\vec{Q},\vec{P})),\end{aligned} \tag{36}$$

where $\vec{q}(\vec{Q},\vec{P})$ and $\vec{p}(\vec{Q},\vec{P})$ are given by Eq. (16) and $|\vec{x}\pm\frac{\hbar}{2}\vec{y}\rangle$ are eigenstates of $\hat{\vec{Q}}$ and thus $\hat{U}|\vec{x}\pm\frac{\hbar}{2}\vec{y}\rangle$ are eigenstates of $\hat{\vec{q}}$, displayed in the $\hat{\vec{Q}}$ representation, and with associated eigenvalues $\vec{x}\pm\frac{\hbar}{2}\vec{y}$. As expected, the previous result means that the unitary transformation is mapped by the generalized Weyl–Wigner map to a phase space coordinate transformation.

IV. COVARIANT STAR PRODUCT

The new Weyl–Wigner map yields a new star product through the definition

$$W'_{(Q,P)}(\hat{A}\cdot\hat{B})=W'_{(Q,P)}(\hat{A})*'_{(Q,P)}W'_{(Q,P)}(\hat{B});\quad \forall\hat{A},\hat{B}\in\hat{\mathcal{A}}(\mathcal{H}), \tag{37}$$

and one immediately recognizes that the new product satisfies

$$W'_{(Q,P)}(\hat{A})*'_{(Q,P)}W'_{(Q,P)}(\hat{B})=W'_{(Q,P)}(\hat{A}\hat{B})=W_{(q,p)}(\hat{A}\hat{B})=W_{(q,p)}(\hat{A})*_{(q,p)}W_{(q,p)}(\hat{B}). \tag{38}$$

If $W_{(q,p)}(\hat{A})=A(\vec{q},\vec{p})$, then $W'_{(Q,P)}(\hat{A})=A(\vec{q}(\vec{Q},\vec{P}),\vec{p}(\vec{Q},\vec{P}))=A'(\vec{Q},\vec{P})$ and thus

$$A'(\vec{Q},\vec{P})*'_{(Q,P)}B'(\vec{Q},\vec{P})=A(\vec{q}(\vec{Q},\vec{P}),\vec{p}(\vec{Q},\vec{P}))*_{(q,p)}B(\vec{q}(\vec{Q},\vec{P}),\vec{p}(\vec{Q},\vec{P}))\quad \forall A,B\in\mathcal{A}(T^*M). \tag{39}$$

The former result immediately implies that the new product is also a noncommutative, associative product for the algebra of functions over the classical phase space. Moreover, using the new product we can define a new bracket (named generalized Moyal bracket) alternative to the standard Moyal bracket:

$$[A,B]_{M'_{(Q,P)}}=\frac{1}{i\hbar}(A*'_{(Q,P)}B-B*'_{(Q,P)}A). \tag{40}$$

It follows from Eq. (39) that this is also a Lie bracket.

Neither the new star product nor the new Moyal bracket display the same functional structure as the standard ones $*_{(Q,P)}$ and $[,]_{M_{(Q,P)}}$. The aim of the rest of this section is to derive the explicit form of the new product and in the sequel of the new bracket from the generalized Weyl–Wigner map. Let us start by introducing the notation:

$$\hat{O}^k=\hat{p}_k, \quad k=1,\ldots,N; \quad \hat{O}'^k=\hat{P}_k, \quad k=1,\ldots,N;$$

$$\hat{O}^k=\hat{q}_{k-N}, \quad k=N+1,\ldots,2N; \quad \hat{O}'^k=\hat{Q}_{k-N}, \quad k=N+1,\ldots,2N;$$

and the symbols $O^k\equiv W_{(q,p)}(\hat{O}^k)$, $O'^k\equiv W_{(Q,P)}(\hat{O}'^k)$. Consider the two following operators displayed in the generalized Weyl order (sum over repeated indices is understood):

$$\begin{aligned}\hat{A}_{W'(Q,P)}&=\hat{A}'(\hat{\vec{Q}},\hat{\vec{P}})=\int d^{2N}\vec{a}\,\alpha(\vec{a})e^{ia_k\hat{O}^k(\hat{O}'^s)},\\ \hat{B}_{W'(Q,P)}&=\hat{B}'(\hat{\vec{Q}},\hat{\vec{P}})=\int d^{2N}\vec{b}\,\beta(\vec{b})e^{ib_l\hat{O}^l(\hat{O}'^r)},\end{aligned} \tag{41}$$

where $\vec{a}=(a_1,\ldots,a_{2N})$, $\vec{b}=(b_1,\ldots,b_{2N})$. Let us then calculate $W'_{(Q,P)}(\hat{A}\cdot\hat{B})$ explicitly and express the result in terms of the symbols $A'(\vec{Q},\vec{P})=W'_{(Q,P)}(\hat{A})$ and $B'(\vec{Q},\vec{P})=W'_{(Q,P)}(\hat{B})$:

$$\begin{aligned}W'_{(Q,P)}(\hat{A}\cdot\hat{B})&=\int d^{2N}\vec{a}d^{2N}\vec{b}\,\alpha(\vec{a})\beta(\vec{b})W'_{(Q,P)}\{e^{ia_k\hat{O}^k(\hat{O}'^s)}\cdot e^{ib_l\hat{O}^l(\hat{O}'^r)}\}\\ &=\int d^{2N}\vec{a}d^{2N}\vec{b}\,\alpha(\vec{a})\beta(\vec{b})W_{(q,p)}\{e^{ia_k\hat{O}^k(O'^s)}\cdot e^{ib_l\hat{O}^l(O'^r)}\}\\ &=\int d^{2N}\vec{a}d^{2N}\vec{b}\,\alpha(\vec{a})\beta(\vec{b})[e^{ia_kO^k(O'^s)}]*_{(q,p)}[e^{ib_lO^l(O'^r)}].\end{aligned} \tag{42}$$

Using the explicit expression of the $(\vec{q},\vec{p})$ star product in Eq. (5), we obtain the following expansion in powers of $\hbar$:

$$W'_{(Q,P)}(\hat{A}\cdot\hat{B})=\sum_{k=0}^{\infty}\frac{1}{k!}\left(\frac{i\hbar}{2}\right)^k\int d^{2N}\vec{a}d^{2N}\vec{b}\,\alpha(\vec{a})\beta(\vec{b})[e^{ia_tO^t(O'^s)}]\hat{\mathcal{J}}_k[e^{ib_lO^l(O'^r)}], \tag{43}$$

where

$$\hat{\mathcal{J}}_k=\overleftarrow{\partial}_{i_1}\cdots\overleftarrow{\partial}_{i_k}J^{i_1j_1}_{(q,p)}\cdots J^{i_kj_k}_{(q,p)}\vec{\partial}_{j_1}\cdots\vec{\partial}_{j_k}. \tag{44}$$

At this point we recall that the phase space is assumed to have the structure of a flat manifold and introduce the $2N\times 2N$ "Euclidean" metric,

$$(g_{ij})=\begin{pmatrix}\alpha 1_{N\times N} & 0_{N\times N}\\ 0_{N\times N} & \beta 1_{N\times N}\end{pmatrix}, \tag{45}$$

and the associated covariant derivative ∇_i,

$$\begin{aligned}\nabla_iA&=\partial_iA,\\ \nabla_i\nabla_jA&=\partial_i\partial_jA-\Gamma^k_{ij}\partial_kA, \quad i,j,k=1,\ldots,2N,\end{aligned} \tag{46}$$

where the Christoffel symbols Γ^k_{ij} are fully determined by the metric:

$$\Gamma^{i}_{jk}=\tfrac{1}{2}g^{il}(\partial_k g_{lj}+\partial_j g_{lk}-\partial_l g_{jk}),\quad i,j,k=1,\ldots,2N. \tag{47}$$

Obviously, in the coordinates $(\vec{q},\vec{p})$ we have $\Gamma^{i}_{jk}=0$, $\forall i,j,k=1,\ldots,2N$ and thus $\nabla_i=\partial_i$. (α and β are arbitrary constants introduced to ensure the correct dimensions.)

Under the general coordinate transformation $O^i\to O^i(O'^s)$ $(i=1,\ldots,2N)$ the symplectic matrix and the covariant derivative transform according to

$$J'^{ij}_{(Q,P)}=\frac{\partial O'^{i}}{\partial O^{k}}\frac{\partial O'^{j}}{\partial O^{l}}J^{kl}_{(q,p)}=\{O'^{i},O'^{j}\}_{(q,p)}=O'^{i}\hat{\mathcal{J}}_{(q,p)}O'^{j}, \tag{48}$$

$$\Gamma'^{i}_{jk}=\Gamma^{m}_{bc}\frac{\partial O'^{i}}{\partial O^{m}}\frac{\partial O^{b}}{\partial O'^{j}}\frac{\partial O^{c}}{\partial O'^{k}}+\frac{\partial O'^{i}}{\partial O^{b}}\frac{\partial^2 O^{b}}{\partial O'^{j}\partial O'^{k}}=\frac{\partial O'^{i}}{\partial O^{b}}\frac{\partial^2 O^{b}}{\partial O'^{j}\partial O'^{k}}. \tag{49}$$

Moreover, the terms $[e^{ia_tO^t(O'^s)}]\hat{\mathcal{J}}_k[e^{ib_lO^l(O'^r)}]$ are scalars and thus are left invariant:

$$\begin{aligned}&[e^{ia_tO^t(O'^s)}]\overleftarrow{\partial}_{i_1}\cdots\ \overleftarrow{\partial}_{i_k}J^{i_1j_1}_{(q,p)}\ \cdots\ J^{i_kj_k}_{(q,p)}\vec{\partial}_{j_1}\cdots\ \vec{\partial}_{j_k}[e^{ib_lO^l(O'^r)}]\\&\quad=[e^{ia_tO^t(O'^s)}]\overleftarrow{\nabla}'_{i_1}\cdots\ \overleftarrow{\nabla}'_{i_k}J'^{i_1j_1}_{(Q,P)}\ \cdots\ J'^{i_kj_k}_{(Q,P)}\vec{\nabla}'_{j_1}\ \cdots\ \vec{\nabla}'_{j_k}[e^{ib_lO^l(O'^r)}],\end{aligned} \tag{50}$$

where the new covariant derivative ∇' is given by

$$\begin{aligned}&\nabla'_iA=\partial'_iA,\\&\nabla'_i\nabla'_jA=\partial'_i\partial'_jA-\Gamma'^{k}_{ij}\partial'_kA,\quad \partial'_i=\partial/\partial O'^{i};\quad i,j,k=1,\ldots,2N.\end{aligned} \tag{51}$$

Substituting the result (50) in Eq. (43) and taking into account (41), it is trivial to obtain $W'_{(Q,P)}(\hat{A}\cdot\hat{B})=W'_{(Q,P)}(\hat{A})*'_{(Q,P)}W'_{(Q,P)}(\hat{B})$ where the new star product is given by

$$A'(\vec{Q},\vec{P})*'_{(Q,P)}B'(\vec{Q},\vec{P})=A'(\vec{Q},\vec{P})e^{(i\hbar/2)\,\overleftarrow{\nabla}'_iJ'^{ij}_{(Q,P)}\vec{\nabla}'_j}B'(\vec{Q},\vec{P}), \tag{52}$$

and we recovered the covariant formulation of the star product first introduced by Vey.[29] The covariant formulation ensured the invariant nature of the numerical value for the star-product of two observables in any coordinate system. However, in general, the functional form of the product is altered under an arbitrary coordinate transformation.

We should point out that our construction of the covariant star product being based upon a sympletic and a metric structure over the phase space manifold slightly differs from the construction of Bayen *et al.*, Fedosov and others, where the covariant star product is built upon a sympletic structure w and a Poisson connection ∇, satisfying $\nabla w=0$. This difference, however, is only apparent since our metric uniquely determines the Poisson connection and vice versa.

Finally, we can easily obtain the functional form of the new bracket: $[A',B']_{M'_{(Q,P)}}=(1/i\hbar)\,W'_{(Q,P)}([\hat{A},\hat{B}])$:

$$[A'(\vec{Q},\vec{P}),B'(\vec{Q},\vec{P})]_{M'_{(Q,P)}}=\frac{2}{\hbar}A'(\vec{Q},\vec{P})\sin\left(\frac{\hbar}{2}\overleftarrow{\nabla}'_iJ'^{ij}_{(Q,P)}\vec{\nabla}'_j\right)B'(\vec{Q},\vec{P}), \tag{53}$$

and if $(\vec{Q},\vec{P})$ is a set of canonical variables this is equally a deformation of the Poisson bracket:

$$[A',B']_{M'_{(Q,P)}}\equiv\frac{1}{i\hbar}(A'*'_{(Q,P)}B'-B'*'_{(Q,P)}A')=\{A',B'\}_{(Q,P)}+O(\hbar^2). \tag{54}$$

V. COVARIANT VEY QUANTUM MECHANICS AND DISCUSSION

The covariant formulation of Moyal quantum mechanics lives on the classical phase space T^*M with the structure of the tangent bundle of the configuration space, where a symplectic structure J^{ij} and a metric structure g_{ij} (or alternatively a Poisson connection) can be naturally defined.

The fundamental mathematical objects of the theory are the Wigner distribution function $f'_W(\vec{Q},\vec{P};t)$ and the observables $A'(\vec{Q},\vec{P})$. They all are scalar functions over (T^*M,J^{ij},g_{ij}), and are related with the mathematical objects of standard operator quantum mechanics through the generalized Weyl–Wigner map: $f'_W(\vec{Q},\vec{P};t)=(1/2\pi\hbar)\,W'_{(Q,P)}(|\psi(t)\rangle\langle\psi(t)|)$ and $A'(\vec{Q},\vec{P};t)=W'_{(Q,P)}(\hat{A})$. The time evolution of the Wigner function is given by the dynamical equation:

$$\dot{f}'_W=[H',f'_W]_{M'_{(Q,P)}}, \tag{55}$$

which transforms covariantly under arbitrary phase space difeomorphisms yielding, in any coordinates, identical mathematical solutions and thus identical physical predictions.

Finally, the covariant form of Eqs. (7) and (8) yield the physical relevant predictions. The Moyal star-genvalue equation can be obtained, through the Weyl–Wigner map, from the standard operator eigenvalue equation: $\hat{A}|\psi_a^n\rangle\langle\psi_a^n|=a|\psi_a^n\rangle\langle\psi_a^n|$ (where n is the degeneracy index). We follow the same procedure but use the generalized Weyl–Wigner map and obtain

$$A'(\vec{Q},\vec{P})*'_{(Q,P)}g_a'^n(\vec{Q},\vec{P})=ag_a'^n(\vec{Q},\vec{P}). \tag{56}$$

It is trivial to check that $g_a'^n(\vec{Q},\vec{P})=g_a^n(\vec{q}(\vec{Q},\vec{P}),\vec{p}(\vec{Q},\vec{P}))$ where $g_a^n(\vec{q},\vec{p})$ is the solution of the original star-genvalue equation. Futhermore, the probabilistic functionals are just the coordinate transform of the original ones:

$$P(A'(\vec{Q},\vec{P};t)=a)=\sum_n\int d^N\vec{Q}\int d^N\vec{P}(\det J'^{ij}_{(Q,P)})^{-1/2}g_a'^n(\vec{Q},\vec{P})f'_W(\vec{Q},\vec{P};t), \tag{57}$$

and finally the average value prediction is also trivially covariantized:

$$\langle A'(\vec{Q},\vec{P};t)\rangle=\int d^N\vec{Q}\int d^N\vec{P}(\det J'^{ij}_{(Q,P)})^{-1/2}A'(\vec{Q},\vec{P})f'_W(\vec{Q},\vec{P};t). \tag{58}$$

The covariant formulation of phase space quantum mechanics is a familiar field of mathematical physics. The invariance properties of the theory are well studied even for the case of nonflat sympletic manifolds. The main point of this work was not to derive these results once again but to focus on the relation between standard operator quantum mechanics and phase space quantum mechanics. Such a relation given by the generalized Weyl–Wigner map provided a new point of departure to derive the covariant generalization of phase space quantum mechanics and clarifies the nature of the invariance properties of the theory.

Let us then summarize our results: we presented an original generalized (covariant) formulation of the Weyl-order operator prescription and of the Weyl–Wigner map yielding the entire structure of Vey quantum mechanics directly from standard operator quantum mechanics. All key ingredients of the theory were derived in this fashion, thus casting Vey quantum mechanics at the same level of completeness as Moyal quantum mechanics. Furthermore, we studied the action of standard operator transformations in the Moyal formalism and concluded that through the generalized Weyl–Wigner map these transformations can be implemented as phase space coordinate transformations in the Moyal idiom. It is now easy to realize that the group of ''canonical'' transformations of Vey quantum mechanics (those that preserve the bracket structure) is the subgroup of the symplectic transformations which are also isometries, i.e., the coordinate transformations $O^i\rightarrow O^i(O'^s)$ such that

$$J'^{ij}_{(Q,P)}=\frac{\partial O'^{i}}{\partial O^{k}}\frac{\partial O'^{j}}{\partial O^{l}}J^{kl}_{(q,p)}=J^{ij}_{(q,p)},$$
$$\Gamma'^{i}_{jk}=\frac{\partial O'^{i}}{\partial O^{b}}\frac{\partial^{2}O^{b}}{\partial O'^{j}\partial O'^{k}}=0, \tag{59}$$

and notice that in the limit $\hbar\to 0$ the requirement on the isometry character of the canonical transformations disappears, as it should, and we recover the standard sympletic group of classical mechanics.

Finally, let us make a small remark concerning possible future applications of the generalized Weyl–Wigner map. Recently there has been a considerable interest in developing a fully classical interpretation for Moyal dynamics.[14,15,19] This is a difficult task for several reasons of which the most important are that Moyal dynamics is nonlocal and there is no general criterion to understand what is meant by ''classical.'' Very recently, however, the authors presented a proposal for a classicality criterion and proved that it is fully compatible with the Weyl–Wigner map.[18,19] One of the problems that was left unsolved was how to understand the highly nonclassical behavior of an allegedly Moyal classical dynamics, under the action of canonical transformations. This problem has been previously considered in Refs. 14 and 15 using an approach based on a privileged set of observables.

We may now expect that if the results of Ref. 19 (concerning the compatibility between the classicality criteria and the Weyl–Wigner map) turn out to be extendable to the covariant Weyl–Wigner map, then they will most likely open the path for a consistent classical interpretation of the action of canonical transformations in Moyal dynamics. This will be the subject of a future work.[35]

VI. EXAMPLE

To illustrate some of the features of the formalism let us consider the system of two interacting particles described by the Hamiltonian

$$\hat{H}=\frac{\hat{p}^{2}}{2M}+\frac{\hat{y}^{2}}{2m}+k\hat{q}\hat{y}^{2}, \tag{60}$$

where $(\hat{q},\hat{p})$ are the fundamental variables of the particle of mass M, $(\hat{x},\hat{y})$ are the ones of the particle of mass m and k is a coupling constant.

A. Standard description in the original variables

In the Heisenberg picture the time evolution of the former system is given by

$$\hat{q}(t)=\hat{q}+\frac{\hat{p}}{M}t-\frac{k}{2M}\hat{y}^{2}t^{2},$$
$$\hat{p}(t)=\hat{p}-k\hat{y}^{2}t,$$
$$\hat{x}(t)=\hat{x}+\left\{\frac{\hat{y}}{m}+2k\hat{q}\hat{y}\right\}t+\frac{k}{M}\hat{p}\hat{y}t^{2}-\frac{k^{2}}{3M}\hat{y}^{3}t^{3}, \tag{61}$$
$$\hat{y}(t)=\hat{y}.$$

The standard Weyl–Wigner transform yields the Moyal description of the system. The Hamiltonian is trivially obtained,

$$H=W_{(q,x,p,y)}(\hat{H})=\frac{p^{2}}{2M}+\frac{y^{2}}{2m}+kqy^{2}, \tag{62}$$

and the Moyal time evolution of the system is given by the dynamical equations

$$\dot{A}=[A,H]_{M_{(q,x,p,y)}}, \tag{63}$$

which yield the following solutions (to make it simpler let us concentrate on the dynamics of the particle of mass M):

$$\begin{aligned} q(t)&=q(0)+\frac{p(0)}{M}t-\frac{k}{2M}y(0)^2t^2,\\ p(t)&=p(0)-ky(0)^2t. \end{aligned} \tag{64}$$

Notice that the same predictions can be obtained by applying the Weyl–Wigner map to the solutions (61).

B. Canonical transformation and the standard description in the new variables

Let us now consider the canonical transformation:

$$\begin{aligned} \hat{q}&=\hat{q},\quad \hat{x}=\ln\hat{Q},\\ \hat{p}&=\hat{p},\quad \hat{y}=\tfrac{1}{2}(\hat{Q}\hat{P}+\hat{P}\hat{Q}). \end{aligned} \tag{65}$$

In the new variables $\hat{H}$ takes the form

$$\hat{H}=\frac{\hat{p}^2}{2M}+\frac{(\hat{Q}\hat{P}+\hat{P}\hat{Q})^2}{8m}+\frac{k}{4}\hat{q}(\hat{Q}\hat{P}+\hat{P}\hat{Q})^2, \tag{66}$$

and it yields the Heisenberg picture time evolution (still just for the particle of mass M):

$$\begin{aligned} \hat{q}(t)&=\hat{q}+\frac{\hat{p}}{M}t-\frac{k}{8M}(\hat{Q}\hat{P}+\hat{P}\hat{Q})^2t^2\\ \hat{p}(t)&=\hat{p}-\frac{k}{4}(\hat{Q}\hat{P}+\hat{P}\hat{Q})^2t \end{aligned} \tag{67}$$

To obtain the Moyal formulation of the system in the variables (q,Q,p,P) the first step is to use the standard Weyl–Wigner map to get the phase space representation of the transformation (65):

$$\begin{aligned} q&=W_{(q,Q,p,P)}(\hat{q})=q,\quad x=W_{(q,Q,p,P)}(\hat{x}(\hat{Q},\hat{P}))=\ln Q,\\ p&=W_{(q,Q,p,P)}(\hat{p})=p,\quad y=W_{(q,Q,p,P)}(\hat{y}(\hat{Q},\hat{P}))=QP. \end{aligned} \tag{68}$$

We then express the Hamiltonian using the standard Weyl order prescription:

$$\hat{H}_{W(q,Q,p,P)}=\frac{\hat{p}^2}{2M}+\frac{(\hat{P}^2\hat{Q}^2)_S}{2m}+k\hat{q}(\hat{Q}^2\hat{P}^2)_S+\frac{k}{4}\hbar^2\hat{q}+\frac{\hbar^2}{8m}, \tag{69}$$

where we used the fact that $\frac{1}{4}(\hat{Q}\hat{P}+\hat{P}\hat{Q})^2_{W(q,Q,p,P)}=(\hat{P}^2\hat{Q}^2)_S+\hbar^2/4$ (the subscripted "S" standing for the full symmetrization of the operator), and so $\frac{1}{4}(\hat{Q}\hat{P}+\hat{P}\hat{Q})^2$ can be expressed in the standard Weyl order [Eq. (25)] by making $\alpha(a,b,c,d)=\delta(a)\delta(b)\{\delta''(c)\delta''(d)+\hbar/4\delta(c)\delta(d)\}$, where a, b, c, d are the integration variables associated to the fundamental operatores $\hat{q},\hat{p},\hat{Q},\hat{P}$, respectively. The standard Weyl–Wigner transform of $\hat{H}$ is thus

$$H = W_{(q,Q,p,P)}(\hat{H}) = \frac{p^2}{2M} + \frac{P^2Q^2}{2m} + kqQ^2P^2 + \frac{k}{4}\hbar^2 q + \frac{\hbar^2}{8m}. \tag{70}$$

Finally, the Moyal dynamical equations in the variables (q,Q,p,P) yield

$$q(t) = q(0) + \frac{p(0)}{M}t - \frac{k}{2M}Q(0)^2P(0)^2t^2 - \frac{k\hbar^2}{8M}t^2$$

$$p(t) = p(0) - kQ(0)^2P(0)^2t - \frac{k\hbar^2}{4}t^2. \tag{71}$$

Notice that equivalent results can be obtained by applying the Weyl–Wigner transform to the time evolution operator equations (67). Furthermore, we realize that the transformation (65) does not act as a coordinate transformation in the Moyal formalism. Taking, for instance, the Hamiltonian, we have $H(q,p,x(Q,P),y(Q,P)) \neq W_{(q,Q,p,P)}(\hat{H})$, the left-hand side being given by Eq. (62) and the right-hand side by Eq. (70). Consequently, the two phase space orbits [Eqs. (64) and (71)] are not the coordinate transformation of each other.

C. Covariant formulation

Finally, let us use the generalized Weyl–Wigner map. In the generalized Weyl order prescription Eq. (29), we make $\alpha(a,b,c,d) = -\delta(a)\delta(b)\delta(c)\delta''(d)$, where, this time, a,b,c,d are the integration variables associated to the fundamental operators $\hat{q},\hat{p},\hat{x}(\hat{Q},\hat{P}),\hat{y}(\hat{Q},\hat{P})$, and we obtain

$$\tfrac{1}{4}(\hat{Q}\hat{P}+\hat{P}\hat{Q})^2_{W'(q,Q,p,P)} = \tfrac{1}{4}(\hat{Q}\hat{P}\hat{Q}\hat{P} + \hat{Q}\hat{P}^2\hat{Q} + \hat{P}\hat{Q}^2\hat{P} + \hat{P}\hat{Q}\hat{P}\hat{Q}), \tag{72}$$

and thus

$$H'(q,Q,p,P) = W'_{(q,Q,p,P)}(\hat{H}) = \frac{p^2}{2M} + \frac{Q^2P^2}{2m} + kqQ^2P^2, \tag{73}$$

which, as expected, is the coordinate transformation of the observable H given by Eq. (62). The new star product and the new bracket are given by Eqs. (52) and (53), respectively, where $J'^{ij}_{(Q,P)} = J^{ij}_{(q,p)}$ and the covariant derivatives are associated to the Christoffel symbols:

$$\Gamma'^{1}_{11} = -1/Q; \quad \Gamma'^{2}_{11} = P/Q^2; \quad \Gamma'^{2}_{12} = \Gamma'^{2}_{21} = 1/Q, \tag{74}$$

all the others being zero (we used the notation: $O^1 = x$; $O^2 = y$; $O'^1 = Q$; $O'^2 = P$; $O'^3 = O^3 = q$; $O'^4 = O^4 = p$). Notice that using the new product we can go back and obtain the Hamiltonian H' through a slightly different procedure, by making

$$\begin{aligned} &W'_{(q,Q,p,P)}\{\tfrac{1}{2}(\hat{Q}\hat{P}+\hat{P}\hat{Q})\tfrac{1}{2}(\hat{Q}\hat{P}+\hat{P}\hat{Q})\} \\ &\quad = W'_{(q,Q,p,P)}\{\tfrac{1}{2}(\hat{Q}\hat{P}+\hat{P}\hat{Q})\} *'_{(q,Q,p,P)} W'_{(q,Q,p,P)}\{\tfrac{1}{2}(\hat{Q}\hat{P}+\hat{P}\hat{Q})\} \\ &\quad = QP *'_{(q,Q,p,P)} QP = Q^2P^2, \end{aligned} \tag{75}$$

where in the last step we used the explicit expression for the new star product (52) and (74). It is now easy to check that the generalized Moyal dynamical equations, $\dot{O}'^i = [O'^i, H']_{M'_{(q,Q,p,P)}}$, yield solutions that are just the coordinate transformation of the original ones (64). Equivalent results can obviously be obtained by applying the generalized Weyl–Wigner map to the operator time evolution equations (67).

Spherically symmetric solutions of the sixth order SU(*N*) Skyrme models

I. Floratos[a] and B. M. A. G. Piette[b]
Department of Mathematical Sciences, University of Durham, Durham DH1 3LE, United Kingdom

(Received 20 June 2001; accepted for publication 17 September 2001)

Following the construction described by Ioannidou *et al.* [J. Math. Phys. **40**, 6353 (1999)], we use the rational map ansatz to construct analytically some topologically nontrivial solutions of the generalized SU(3) Skyrme model defined by adding a sixth order term to the usual Lagrangian. These solutions are radially symmetric and some of them can be interpreted as bound states of Skyrmions. The same ansatz is used to construct low-energy configuration of the SU(N) Skyrme model.
 [DOI: 10.1063/1.1415742]

I. INTRODUCTION

The Skyrme model[1] is widely accepted as an effective theory to describe the low-energy properties of nucleons. It was indeed shown[2–4] that in the large N_c limit, the Skyrme model is the low-energy limit of QCD. The classical static solutions of the model describe the bound states of nucleons and every configuration is characterized by a topological charge which, following Skyrme's idea, is interpreted as the baryon charge.

The Skyrme model can be used to predict the properties of the nucleons within 10% to 20%.[3,4] To improve these phenomenological predictions various extensions of the model have been proposed mostly by adding higher order terms[5–8] or extra fields[9] to the Lagrangian.

The study of the classical solutions of the Skyrme model has been done mostly using numerical methods, but recently Houghton *et al.*[10] showed that the classical solutions of the SU(2) model can be well approximated by using an ansatz that involves the harmonic maps from S^2 to S^2. The harmonic map describes the angular distribution of the solution while a profile function describes its radial distribution. This construction was later generalized[11] for the SU(N) model using harmonic maps from S^2 to CP^{N-1}. Moreover, it was shown that using a further generalization of this ansatz one can construct exact spherically symmetric solutions of the SU(N) Skyrme model.

The same method was also used in Ref. 12 to construct solutions of another SU(N) fourth order Skyrme model. In this article, we use the same generalized ansatz to construct solutions of the sixth order SU(3) Skyrme model and low-energy configurations of the SU(N) models defined in Ref. 13.

II. THE SIXTH ORDER SKYRME MODEL

The Skyrme model is described by an SU(N) valued field $U(\vec{x},t)$ which, to ensure finiteness of the energy, is required to satisfy the boundary condition $U\rightarrow I$ as $|\vec{x}|\rightarrow\infty$, where I is the unit matrix. This boundary condition implies that the three dimensional Euclidean space on which the model is defined can be compactified into S^3 and, as a result, the Skyrme field U corresponds to mappings from S^3 into SU(N). As $\pi_3(\mathrm{SU}(N))=Z$ each configuration is characterized by its winding number, or topological charge, which can be obtained explicitly by evaluating the expression

[a]Electronic mail: ioannis.floratos@durham.ac.uk
[b]Electronic mail: b.m.a.g.piette@durham.ac.uk

$$B=\frac{1}{24\pi^2}\int_{R^3} d\vec{x}^3 \varepsilon^{ijk}\, Tr(R_i R_j R_k), \tag{1}$$

where $R_\mu=(\partial_\mu U)U^{-1}$ is the right chiral current. Skyrme's idea was to interpret the winding number associated with these topologically nontrivial mappings as the baryon charge.

The generalized sixth order Skyrme model is defined by the Lagrangian

$$E=-\frac{1}{12\pi^2}\int d\vec{x}^3\left(\frac{1}{2}TrR_i^2+\frac{1-\lambda}{16}Tr[R_i,R_j]^2+\frac{1}{96}\lambda Tr[R_i,R_j][R_j,R_k][R_k,R_i]\right), \tag{2}$$

where this parametrization of the model is chosen such that $\lambda\in[0,1]$ is a mixing parameter between the Skyrme term and the sixth order term: when $\lambda=0$ the model reduces to the usual pure Skyrme model while for $\lambda=1$ the Skyrme term vanishes and the model reduces to what we refer to in what follows as the pure Sk6 model.

The Euler–Lagrange equations derived from (2) for the static solutions are given by

$$\partial_i(R_i-\tfrac{1}{4}(1-\lambda)[R_j,[R_j,R_i]]-\tfrac{1}{16}\lambda[R_j,[R_j,R_k][R_k,R_i]])=0, \tag{3}$$

and the following inequality holds for every configuration:

$$E\geqslant\sqrt{1-\lambda}B. \tag{4}$$

The multi-Skyrmion solutions of the SU(2) Skyrme model have been studied in Ref. 13 where it was shown that they have the same symmetry as the pure Skyrme model. It was also shown that the harmonic map ansatz gives a good approximation to the solutions.

In the next section we describe the harmonic map ansatz. In the third section we prove that due to a constraint coming from the sixth order term, the multi-projector harmonic map ansatz provides exact solutions only for the SU(3) generalized model. We then show that one can nevertheless use the ansatz to construct low-energy configurations of the SU(N) models. In the fourth section we look at these configurations for the SU(4) model, while in the last section we look at some special ansatz for the SU(N) model.

III. HARMONIC MAP ANSATZ

The rational map ansatz, introduced by Houghton *et al.*,[10] is a generalization of the hedgehog ansatz found by Skyrme,[1] to approximate multi-Skyrmion solution of the SU(2) model. The ansatz was later generalized by Ioannidou *et al.*[14] to approximate solutions of the SU(N) Skyrme model using harmonic maps from S^2 into CP^{N-1}. This generalized ansatz is given by

$$U(r,\theta,\varphi)=e^{2if(r)(P(\theta,\varphi)-I/N)}=e^{-2if(r)/N}(I+(e^{2if(r)}-1)P(\theta,\varphi)), \tag{5}$$

where r,θ and φ are the usual polar coordinates. The profile function $f(r)$ must satisfy the boundary conditions $f(0)=\pi$ and $\lim_{r\to\infty}f(r)=0$ and $P(\theta,\varphi)$ is a projector in C^N which must be a harmonic map from S^2 into CP^{N-1} or equivalently a classical solution of the two dimensional CP^{N-1} σ model. These solutions are well known[15,16] and to construct them it is convenient to introduce the complex coordinate $\xi=\tan(\theta/2)e^{i\varphi}$ which corresponds to the stereographic projection of the unit sphere onto the complex plane.

In these coordinates, P must satisfy the equation

$$P\frac{\partial P}{\partial\xi}=0, \tag{6}$$

and the solutions of that equation are given by any projector of the form

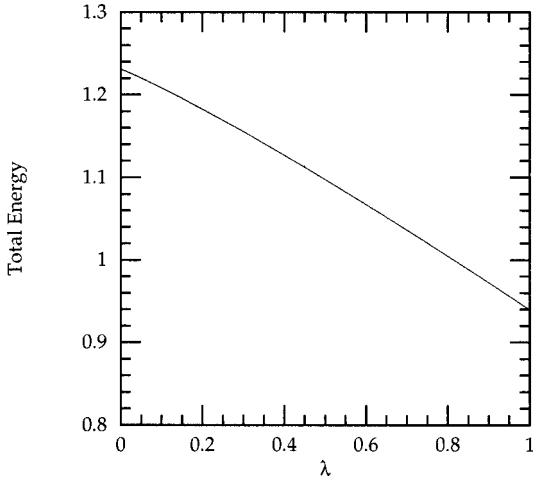

FIG. 1. Total energy of the 1 Skyrmion solution.

$$P(f)=\frac{h\otimes h^{\dagger}}{|h|^2}, \tag{7}$$

where $h\in C^N$ is holomorphic

$$\frac{\partial h}{\partial \bar{\xi}}=0. \tag{8}$$

The topological charge for the ansatz (5), with the prescribed boundary conditions for $f(r)$, is given by the winding number of the $S^2\to CP^{N-1}$. This winding number is itself given by the degree of the harmonic function h[15,16] which must then be a rational function of ξ.

To approximate a solution, one plugs the ansatz (5) into the energy (2) and notices that if P satisfies (6), the integration over the polar angles and the radius decouple. One then has to minimize the integral over the polar angles of an expression which depends only on P. Taking for P the most general harmonic map of the desired degree, one then has to find the parameters of the general map which minimize that integral. Having done this, the profile function f is obtained by solving the Euler Lagrange equation derived from the effective energy.

A special case of this construction is the so-called hedgehog ansatz for the SU(2) model corresponding to one Skyrmion. In this case, we have $h=(1,\xi)^t$ and after inserting (7) into (2) the energy reduces to

$$E=\frac{1}{3\pi}\int dr\left(f_r^2 r^2+2\sin^2 f\,(1+(1-\lambda)f_r^2)+(1-\lambda)\frac{\sin^4 f}{r^2}+\lambda\frac{\sin^4 f}{r^2}f_r^2\right), \tag{9}$$

and the equation for f is given by

$$f_{rr}\left(1+2\,(1-\lambda)\frac{\sin^2 f}{r^2}+\lambda\frac{\sin^4 f}{r^4}\right)+\frac{2}{r}f_r\left(1-\lambda\frac{\sin^4 f}{r^4}\right)$$
$$+\frac{\sin 2g}{r^2}\left((1-\lambda)f_r^2-1+\frac{\sin^2 f}{r^2}(\lambda f_r^2-1+\lambda)\right)=0. \tag{10}$$

This actually corresponds to an exact solution of the model and it is radially symmetric. In Fig. 1 we present the λ dependence of the energy and in Fig. 2 we show the profile function f and the energy density for the pure Skyrme model, $\lambda=0$, and the pure Sk6 model, $\lambda=1$.

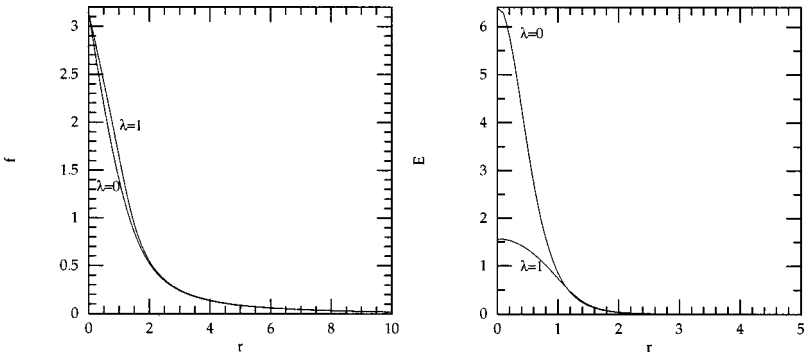

FIG. 2. Function profile f and energy density for the 1 Skyrmion solution of the pure Skyrme model, $\lambda=0$, and the pure Sk6 model, $\lambda=1$.

IV. SPHERICALLY SYMMETRIC SOLUTIONS FOR THE SU(N) MODEL

In this section we will follow the construction described in Ref. 14, to attempt to construct solutions of the extended SU(N) Skyrme model using a generalization of the harmonic map ansatz (5).

To build the new ansatz we need to introduce an operator P_+ which acts on any complex vector $u\in C^N$ and is defined as

$$P_+u=\partial_\xi u-u\,\frac{u^\dagger\,\partial_\xi u}{|u|^2}. \tag{11}$$

Taking a holomorphic vector $h(\xi)$ we then define $P_0^+h=h$ and by induction $V_k=P_+^k h=P_+(P_+^{k-1}h)$. These N vectors are mutually orthogonal[16] and so the corresponding projectors

$$P_k=P(P_+^k h)=\frac{P_+^k h(P_+^k h)^\dagger}{|P_+^k h|^2}\quad k=0,\ldots,N-1, \tag{12}$$

satisfy the orthogonality relations

$$\begin{aligned} P_kP_j&=\delta_{ij}P_k\,,\\ \sum_{k=0}^{N-1}P_k&=1, \end{aligned} \tag{13}$$

as well as other properties discussed in detail in Ref. 14.

The generalized harmonic map ansatz is then defined as

$$\begin{aligned} U&=\exp\left\{ig_0\left(P_0-\frac{I}{N}\right)+ig_1\left(P_1-\frac{I}{N}\right)-\ldots+ig_{N-2}\left(P_{N-2}-\frac{I}{N}\right)\right\}\\ &=e^{-ig_0/N}(I+A_0P_0)\,e^{-ig_1/N}(I+A_1P_1)\cdots e^{-ig_{N-2}/N}(I+A_{N-2}P_{N-2}), \end{aligned} \tag{14}$$

where $g_k(r)$ are $N-1$ profile functions and $A_k=e^{ig_k}-1$. Moreover, for the ansatz to be well defined, the profile functions $g_k(r)$ must be a multiple of 2π at the origin and at infinity.

To proceed with our construction, it is convenient to rewrite the Euler–Lagrange equations of the model (3) using the usual spherical coordinates

$$\partial_r\left\{r^2R_r+\frac{1-\lambda}{4}\left(A_{\theta r\theta}+\frac{1}{\sin^2\theta}A_{\varphi r\varphi}\right)+\frac{1}{16}\lambda\left[\frac{1}{\sin^2\theta}(B_{\theta\theta\varphi r\varphi}+B_{\varphi\varphi\theta r\theta})\right]\right\}$$
$$+\frac{1}{\sin\theta}\partial_\theta\left\{\sin\theta\left[R_\theta+\frac{1-\lambda}{4}\left(A_{r\theta r}+\frac{1}{r^2\sin^2\theta}A_{\varphi\theta\varphi}\right)\right]+\frac{\lambda}{16r^2\sin^2\theta}(B_{rr\varphi\theta\varphi}+B_{\varphi\varphi r\theta r})\right\}$$
$$+\frac{1}{\sin^2\theta}\partial_\varphi\left\{R_\varphi+\frac{1-\lambda}{4}\left(A_{r\varphi r}+\frac{1}{r^2}A_{\theta\varphi\theta}\right)+\frac{\lambda}{16r^2}(B_{rr\theta\varphi\theta}+B_{\theta\theta r\varphi r})\right\}=0, \tag{15}$$

where $A_{jij}\equiv[R_j,[R_i,R_j]]$ and $B_{jjkik}\equiv[R_j,[R_j,R_k][R_i,R_k]]$. It is fairly easy to show that

$$R_r=i\sum_{j=0}^{N-2}\dot g_j\left(P_j-\frac{I}{N}\right), \tag{16}$$

where $\dot g_j$ is the derivative of $g_j(r)$ with respect to r. Using the complex coordinates ξ and $\bar\xi$ introduced before we have

$$R_\xi=\sum_{i=1}^{N-1}[e^{i(g_i-g_{i-1})}-1]\frac{V_iV_{i-1}^\dagger}{|V_{i-1}|^2}, \tag{17}$$

and the derivatives with respect to θ and φ are given by

$$\partial_\theta=\frac{1+|\xi|^2}{2\sqrt{|\xi|^2}}(\xi\partial_\xi+\bar\xi\partial_{\bar\xi}),\quad \partial_\varphi=i(\xi\partial_\xi-\bar\xi\partial_{\bar\xi}). \tag{18}$$

Substituting the above into Eqs. (15) we get

$$\partial_r\left[r^2R_r+(1-\lambda)\frac{(1+|\xi|^2)^2}{8}(A_{\bar\xi r\xi}+A_{\xi r\bar\xi})\right]+\frac{(1+|\xi|^2)^2}{2}((R_{\bar\xi})_\xi+(R_\xi)_{\bar\xi})$$
$$+(1-\lambda)\frac{(1+|\xi|^2)^3}{8r^2}(\xi A_{\xi\xi\bar\xi}-\bar\xi A_{\bar\xi\xi\bar\xi})+(1-\lambda)\frac{(1+|\xi|^2)^4}{16r^2}([A_{\xi\xi\bar\xi}]_{\bar\xi}-[A_{\bar\xi\xi\bar\xi}]_\xi)$$
$$+(1-\lambda)\frac{(1+|\xi|^2)^2}{8}([A_{r\bar\xi r}]_\xi+[A_{r\xi r}]_{\bar\xi})+\frac{\lambda}{16}\left\{\partial_r\left[\frac{(1+|\xi|^2)^4}{4}(B_{\bar\xi\xi\bar\xi r\bar\xi}-B_{\xi\xi\bar\xi r\bar\xi})\right]\right.$$
$$+\frac{(1+|\xi|^2)^2}{4r^2}(\partial_{\bar\xi}[(1+|\xi|^2)^2B_{rr\xi\xi\bar\xi}]-\partial_\xi[(1+|\xi|^2)^2B_{rr\bar\xi\xi\bar\xi}])$$
$$+\frac{(1+|\xi|^2)^2}{2|\xi|^2r^2}\left(\xi\partial_\xi\left[\frac{(1+|\xi|^2)^2}{4|\xi|^2}(-\xi\xi\xi B_{\xi\xi r\xi r})\right]+\bar\xi\partial_{\bar\xi}\left[\frac{(1+|\xi|^2)^2}{4|\xi|^2}(-\overline{\xi\xi\xi}B_{\overline{\xi\xi r}\bar\xi r})\right]\right)$$
$$+\frac{(1+|\xi|^2)^2}{8r^2}(\partial_\xi[(1+|\xi|^2)^2(B_{\xi\bar\xi r\bar\xi r}+B_{\bar\xi\xi r\bar\xi r}-B_{\overline{\xi\xi}r\xi r})]+\partial_{\bar\xi}[(1+|\xi|^2)^2$$
$$\left.\times(-B_{\xi\xi r\bar\xi r}+B_{\xi\bar\xi r\xi r}+B_{\bar\xi\xi r\xi r})]\right)\Bigg\}=0. \tag{19}$$

In Ref. 14 it is shown that if one takes the special holomorphic vector

$$V_0=h=(h_0,h_1,\ldots,h_{N-1})^t, \tag{20}$$

where

$$h_k = \xi^k \sqrt{C_k^{N-1}} \tag{21}$$

and C_k^{N-1} denotes the binomial coefficients, then the terms in (19) coming from the usual Skyrme model, i.e., all the terms except the ones proportional to $\lambda/16$, are all proportional to $P_i - P_{i-1}$ and $P_i - I/N$. Using (13) one can get rid of the projector P_{N-1} and (19) will then be the sum of the $N-1$ terms $P_i - I/N$ for $i=0,\ldots,N-2$, with coefficients that depend only on r. This implies that the equations for the Skyrme model reduce to $N-1$ ordinary differential equations for the profile functions g_i and their solutions, if they exist, will provide us with exact solutions of the SU(N) Skyrme model.

In what follows we will show that the angular dependence of the terms proportional to λ in (19), i.e., the terms coming from the sixth order term, is also coming exclusively from the projectors $P_i - I/N$ or $P_i - P_{i-1}$, but that we have to impose an extra constraint on the profile functions g_i.

We start by noting that

$$[R_\xi, R_{\bar\xi}] = -\sum_{i=1}^{N-1} a_i^2 \frac{|V_i|^2}{|V_{i-1}|^2}\left(\frac{V_i V_i^\dagger}{|V_i|^2} - \frac{V_{i-1}V_{i-1}^\dagger}{|V_{i-1}|^2}\right), \tag{22}$$

$$[R_r, R_\xi] = i\sum_{i=1}^{N-1} (\dot g_i a_i - \dot g_{i-1} a_i)\frac{V_i V_{i-1}^\dagger}{|V_{i-1}|^2} = \sum_{i=1}^{N-1} K_i \frac{V_i V_{i-1}^\dagger}{|V_{i-1}|^2}, \tag{23}$$

$$[R_r, R_{\bar\xi}] = i\sum_{i=1}^{N-1} (\dot g_i a_i - \dot g_{i-1} a_i)\frac{V_{i-1} V_i^\dagger}{|V_{i-1}|^2} = \sum_{i=1}^{N-1} K_i \frac{V_{i-1} V_i^\dagger}{|V_{i-1}|^2}, \tag{24}$$

where $a_i = e^{i(g_i - g_{i-1})} - 1$. It is then straightforward to check that

$$B_{\bar\xi\bar\xi\bar\xi r\xi} - B_{\xi\bar\xi\bar\xi r\bar\xi} = \sum_{i=1}^{N-1}\left(b_i \frac{|V_{i-1}|^2}{|V_{i-2}|^2}\frac{|V_i|^2}{|V_{i-1}|^2} + c_i \frac{|V_i|^4}{|V_{i-1}|^4} + d_i \frac{|V_{i+1}|^2}{|V_i|^2}\frac{|V_i|^2}{|V_{i-1}|^2}\right)(P_i - P_{i-1}), \tag{25}$$

where b_i, c_i and d_i are functions of g_k only. However, as shown in Ref. 14, if V_0 is given by (20) and (21), then $|V_i|^2/|V_{i-1}|^2 \propto (1+|\xi|^2)^{-2}$ and thus

$$\frac{(1+|\xi|^2)^4}{4}(B_{\bar\xi\bar\xi\bar\xi r\xi} - B_{\xi\bar\xi\bar\xi r\bar\xi}) \propto (P_i - P_{i-1}). \tag{26}$$

Furthermore, we have

$$B_{r r \xi\bar\xi\bar\xi} = i\sum_{i=1}^{N-1}\left(e_i \frac{|V_i|^2}{|V_{i-1}|^2} + s_i \frac{|V_{i-1}|^2}{|V_{i-2}|^2}\right)\frac{V_i V_{i-1}^\dagger}{|V_{i-1}|^2} \tag{27}$$

with $e_i = e(g_i)$ and $s_i = s(g_i)$. But in Eq. (19) this term appears as

$$\partial_{\bar\xi}[(1+|\xi|^2)^2 B_{r r \xi\bar\xi\bar\xi}] = 2\bar\xi(1+|\xi|^2) B_{r r \xi\bar\xi\bar\xi} + (1+|\xi|^2)^2 \partial_{\bar\xi}(B_{r r \xi\bar\xi\bar\xi}). \tag{28}$$

Since $\partial_{\bar\xi}|V_i|^2/|V_{i-1}|^2 \propto -2\bar\xi(1+|\xi|^2)^{-3}$ the only parts of (28) that are nonzero are the ones that involve the derivatives of $V_i V_{i-1}^\dagger/|V_{i-1}|^2$ with respect to $\bar\xi$. Since it can be shown that the latter are proportional to $\Sigma_{i-1}^{N-1} C_i (1+|\xi|^2)^{-2}(P_i - P_{i-1})$ where $C_i = C(g_i)$, then one sees that the term that involves $B_{r r \xi\bar\xi\bar\xi}$ in (19) is proportional to $(P_i - P_{i-1})$.

Using similar arguments, it is easy to check that the terms involving $B_{r r \bar\xi\bar\xi\bar\xi}$, $B_{\xi\bar\xi r\bar\xi r}$, $B_{\bar\xi\xi r\bar\xi r}$, $B_{\bar\xi\bar\xi r\xi r}$, $B_{\xi\xi r\bar\xi r}$, $B_{\xi\bar\xi r\xi r}$ and $B_{\bar\xi\xi r\xi r}$ factorize in the same way.

There are a few terms in (19) which we still have to consider. They involve the expressions

$$B_{\xi\,\xi\,r\,\xi\,r}=\sum_{i=3}^{N-1}\,(a_iK_{i-1}K_{i-2}-a_{i-2}K_iK_{i-1})\,\frac{V_iV_{i-3}^{\dagger}}{|V_{i-3}|^2}, \tag{29}$$

$$B_{\overline{\xi}\,\xi\,r\,\overline{\xi}\,r}=\sum_{i=3}^{N-1}\,(a_iK_{i-1}K_{i-2}-a_{i-2}K_iK_{i-1}).\,\frac{V_{i-3}V_i^{\dagger}}{|V_{i-3}|^2}\,, \tag{30}$$

where $K_i=i(\dot{g}_ia_i-\dot{g}_{i-1}a_i)$. It is clear that these terms will always give a $\xi,\overline{\xi}$ dependence besides the projectors P_i and, hence, if we want (19) to reduce to $N-1$ equations that involve only the profile functions g_i, then we have to make sure that (29) and (30) vanish i.e., we must impose the conditions

$$a_iK_{i-1}K_{i-2}-a_{i-2}K_iK_{i-1}=0\;\;\Leftrightarrow\;\;\dot{g}_{i-2}-\dot{g}_{i-3}=\dot{g}_i-\dot{g}_{i-2}\,. \tag{31}$$

This last constraint, which is a result of the addition of the sixth order term, implies that we can only consider two profile functions g_0 and g_1 and that we should thus have only two equations. Unfortunately we have $N-1$ equations which are not compatible with each other. From this we see that the ansatz (5) will provide exact solutions of the generalized Skyrme model for the SU(2) and the SU(3) model only. For larger values of N, the ansatz will nevertheless give some low-energy radially symmetric configurations. The SU(2) case is nothing but the usual hedgehog ansatz and we will focus on the solutions of the SU(3) model in the next section.

In order to derive the equations for the profile functions, it is convenient to write the energy density of the model in terms of $(\xi,\overline{\xi})$:

$$\begin{aligned}E=-\frac{i}{12\pi^2}\int r^2dr\,d\xi d\overline{\xi}\,Tr\left(\frac{1}{(1+|\xi|^2)^2}R_r^2+\frac{1}{r^2}|R_\xi|^2+\frac{1-\lambda}{4r^2}[R_r,R_\xi][R_r,R_{\overline{\xi}}]\right.\\ \left.-(1-\lambda)\,\frac{(1+|\xi|^2)^2}{16r^4}[R_{\overline{\xi}},R_\xi]^2+\lambda\,\frac{(1+|\xi|^2)^2}{64r^4}[[R_r,R_{\overline{\xi}}],[R_r,R_\xi]][R_\xi,R_{\overline{\xi}}]\right).\end{aligned} \tag{32}$$

Defining

$$\begin{aligned}F_i&=g_i-g_{i+1}\quad\text{for}\quad i=0,\ldots,N-3,\\ F_{N-2}&=g_{N-2},\end{aligned} \tag{33}$$

as well as $W_i=(|V_i|^2/|V_{i-1}|^2)\,(1-\cos(F))$ and $W_{N-1}=(|V_{N-1}|^2/|V_{N-2}|^2)\,(1-\cos(g))$, the terms in the above expression can be rewritten as

$$Tr\,R_r^2=\frac{1}{N}\left(\sum_{i=0}^{N-2}\,\dot{g}_i\right)^2-\sum_{i=0}^{N-2}\,\dot{g}_i^2\,, \tag{34}$$

$$Tr|R_\xi|^2=-2\sum_{i=1}^{N-1}\,W_i\,, \tag{35}$$

$$Tr[R_r,R_\xi][R_r,R_{\overline{\xi}}]=-2\sum_{k=1}^{N-1}\,W_k\dot{F}_{k-1}^2\,, \tag{36}$$

$$Tr[R_{\overline{\xi}},R_\xi]^2=4\left(\,W_1^2+\sum_{i=1}^{N-2}\,(W_i-W_{i+1})^2+W_{N-1}^2\right), \tag{37}$$

$$Tr[[R_r,R_{\bar{\xi}}],[R_r,R_\xi][R_\xi,R_{\bar{\xi}}]]=4\left(\dot{F}_0^2W_1^2+\sum_{i=1}^{N-2}(\dot{F}_{i-1}W_i-\dot{F}_iW_{i+1})^2+\dot{F}_{N-2}^2W_{N-1}^2\right). \quad (38)$$

In Ref. 14 it was shown that

$$\frac{|V_k|^2}{|V_{k-1}|^2}=k(N-k)(1+|\xi|^2)^{-2}, \quad (39)$$

and from this we see that all the terms in (32) are proportional to $(1+|\xi|^2)^{-2}$ and that after integrating out the angular dependence the energy reduces to

$$\begin{aligned}E=\frac{1}{6\pi}\int r^2dr\Bigg\{&-\frac{1}{N}\left(\sum_{i=0}^{N-2}\dot{g}_i\right)^2+\sum_{i=0}^{N-2}\dot{g}_i^2+\frac{2}{r^2}\sum_{k=1}^{N-1}Z_k+\frac{(1-\lambda)}{2r^2}\sum_{k=1}^{N-1}(\dot{g}_k-\dot{g}_{k-1})^2Z_k\\&+\frac{(1-\lambda)}{4r^4}\left(Z_1^2+\sum_{k=1}^{N-2}(Z_k-Z_{k+1})^2+Z_{N-1}^2\right)\\&+\frac{\lambda}{16r^4}\left(\dot{F}_0^2Z_1^2+\sum_{k=1}^{N-2}(\dot{F}_{k-1}Z_k-\dot{F}_kZ_{k+1})^2+\dot{F}_{N-2}^2Z_{N-1}^2\right)\Bigg\}, \quad (40)\end{aligned}$$

where $Z_k=k(N-k)(1-\cos(F_{k-1}))$.

In Ref. 14 the fields F_i defined by (33) were used, and very special solutions were obtained by taking $F_0=F_1=\cdots=F_{N-2}$. It was observed that when $F_i(0)=2\pi$ and $F_i(\infty)=0$ this solution of the SU(N) pure Skyrme model has a topological charge $B=(N/6)(N^2-1)$ and has an energy equal exactly to $(N/6)(N^2-1)$ times the energy of the single Skyrmion solutions. It is easy to show that, if one uses the same ansatz for the sixth order Skyrme model, the profile $f=F_0/2$ satisfies the hedgehog profile equation (10) and the energy of the configuration is given by $E(\lambda)=4E_0(\lambda)$ where $E_0(\lambda)$ is the energy of the hedgehog solution for the generalized model. These configurations are not exact solutions, except for the SU(3) model.

To consider the most general ansatz, one can derive from (40) the following equations for the profile functions F_l, $l=0,...,(N-2)$:

$$\begin{aligned}&-\frac{2(l+1)}{N}\sum_{i=0}^{N-2}(i+1)\ddot{F}_i+2\sum_{k=0}^{l}\sum_{i=k}^{N-2}\ddot{F}_i+\frac{(1-\lambda)}{r^2}\ddot{F}_l(l+1)(N-l-1)(1-\cos F_l)\\&+\frac{2}{r}\left(-\frac{2(l+1)}{N}\sum_{i=0}^{N-2}(i+1)\dot{F}_i+2\sum_{k=0}^{l}\left(\sum_{i=k}^{N-2}\dot{F}_i\right)\right)+\frac{(1-\lambda)}{2r^2}\dot{F}_l^2(l+1)(N-l-1)\sin F_l\\&-\frac{2}{r^2}(l+1)(N-l-1)\sin F_l-\frac{(1-\lambda)}{r^4}(l+1)^2(N-l-1)^2(1-\cos F_l)\sin F_l\\&+\frac{(1-\lambda)}{2r^4}(l+1)(N-l-1)\sin F_l[l(N-l)(1-\cos F_{l-1})+(l+2)(N-l-2)(1-\cos F_{l+1})]\\&+\frac{\lambda}{8r^4}\{2\ddot{F}_l(l+1)^2(N-l-1)^2(1-\cos F_l)^2-\ddot{F}_{l-1}l(l+1)(N-l)(N-l-1)(1-\cos F_{l-1})\\&\times(1-\cos F_l)-\ddot{F}_{l+1}(l+1)(l+2)(N-l-1)(N-l-2)(1-\cos F_l)(1-\cos F_{l+1})\}\\&+\frac{-\lambda}{4r^5}\{2\dot{F}_l(l+1)^2(N-l-1)^2(1-\cos F_l)^2-\dot{F}_{l-1}l(l+1)(N-l)(N-l-1)(1-\cos F_{l-1})\\&\times(1-\cos F_l)-\dot{F}_{l+1}(l+1)(l+2)(N-l-1)(N-l-2)(1-\cos F_l)(1-\cos F_{l+1})\}\\&+\frac{\lambda}{8r^4}\{2\dot{F}_l^2(l+1)^2(N-l-1)^2(1-\cos F_l)\sin F_l-\dot{F}_{l-1}^2l(l+1)(N-l)(N-l-1)\sin F_{l-1}\\&\times(1-\cos F_l)-\dot{F}_{l+1}^2(l+1)(l+2)(N-l-1)(N-l-2)(1-\cos F_l)\sin F_{l+1}\}=0. \quad (41)\end{aligned}$$

When $N=3$, the solution of the two equations lead to exact solutions of the model, while for larger values of N, the ansatz (14) corresponds to low-energy configurations.

We would like to point out at this stage that as proved in Ref. 14, the topological charge for the configuration (14) is given by

$$B=\sum_{i=0}^{N-2}\mathcal{D}_k(F_i-\sin F_i)_{r=0}^{r=\infty}, \tag{42}$$

where

$$\mathcal{D}_k=-i\frac{1}{4\pi^2}\int\frac{|P_+^{k+1}h|^2}{|P_+^k h|^2}d\xi d\bar{\xi} \tag{43}$$

takes integer values given by the degree in ξ of the wedge product[16] of h and its derivatives

$$\mathcal{D}_k=\frac{1}{2\pi}\deg(h^{(k)}),\quad h^{(k)}=h\wedge\partial_+ h\wedge\cdots\wedge\partial_+^k h,\quad k=0,\ldots,N-1. \tag{44}$$

Each configuration is thus characterized by the boundary conditions for the profile function F_i and we can without loss of generality impose the condition $\lim_{r\to\infty}F_i(r)=0$. For the configuration to be well-defined at the origin we must also impose a condition of the type

$$F_i(0)=n_i 2\pi, \tag{45}$$

where $n_i\in N$.

V. RADIALLY SYMMETRIC SU(3) SOLUTIONS

To describe the solution of the SU(3) model, we use the profile $F=F_0$ and $g=F_1$ and the energy (40) simplifies to

$$\begin{aligned}E=\frac{1}{6\pi}\int r^2dr\Big\{&\frac{2}{3}(\dot{g}^2+\dot{F}^2+\dot{g}\,\dot{F})+\frac{1}{r^2}((1-\cos F)((1-\lambda)\dot{F}^2+4)+(1-\cos g)\\&\times((1-\lambda)\dot{g}^2+4))+(1-\lambda)\frac{2}{r^4}((1-\cos F)^2-(1-\cos F)(1-\cos g)+(1-\cos g)^2)\\&+\frac{\lambda}{2r^4}(\dot{F}^2(1-\cos F)^2+\dot{g}^2(1-\cos g)^2-(1-\cos F)(1-\cos g)\dot{g}\dot{F})\Big\}.\end{aligned} \tag{46}$$

The equations for the profile function F and g are then given by

$$\begin{aligned}&g_{rr}+\frac{1}{2}F_{rr}+\frac{F_r}{r}+2\frac{g_r}{r}+\frac{3}{2r^2}\left((1-\lambda)(1-\cos g)g_{rr}+\frac{1}{2}\sin g((1-\lambda)g_r^2-4)\right)\\&+\frac{1}{2}\sin g((1-\lambda)g_r^2-4)+(1-\lambda)\frac{3}{2r^4}((1-\cos F)-2(1-\cos g))\sin(g)+\frac{3\lambda}{8r^4}(1-\cos g)\\&\times\left(2\left(\sin g g_r^2+(1-\cos g)\left(g_{rr}-2\frac{g_r}{r}\right)\right)-\sin F F_r^2-(1-\cos F)\left(F_{rr}-2\frac{Fr}{r}\right)\right)=0,\end{aligned} \tag{47}$$

TABLE I. Topological charge and energy of the hedgehog SU(2) solution.

SU(2)		Energy	
n_g	B	$E(0)$	$E(1)$
1	1	1.2315	0.9395

$$F_{rr}+\frac{1}{2}g_{rr}+2\frac{F_r}{r}+\frac{g_r}{r}+\frac{3}{4r^2}(\sin F((1-\lambda)F_r^2-4)+2(1-\lambda)(1-\cos F)F_{rr})$$
$$-(1-\lambda)\frac{3}{2r^4}(2(1-\cos F)-(1-\cos g))\sin F+\frac{3\lambda}{8r^4}(1-\cos F)$$
$$\times\left(12\left(\sin F\,F_r^2+(1-\cos F)\left(F_{rr}-2\frac{F_r}{r}\right)\right)-\sin g\,g_r^2-(1-\cos g)\left(g_{rr}-2\frac{g_r}{r}\right)\right)=0. \tag{48}$$

The topological charge of the solution now reads

$$B=\frac{1}{\pi}((F-\sin F)|_{r=0}^{r=\infty}+(g-\sin(g))|_{r=0}^{r=\infty}) \tag{49}$$

and, if we take the boundary conditions

$$F(0)=n_F 2\pi,$$
$$g(0)=n_g 2\pi, \tag{50}$$

where n_F and n_g are integers, we have $B=2(n_f+n_g)$. When n_F and n_g are of opposite signs, we can interpret the solutions as a mixture of Skyrmions and anti-Skyrmions.

In Table I, we give the energy of the hedgehog solution ($B=1$) for the SU(2) model. This solution is an embedded solution of any SU(N) model and it is the solution with the lowest energy. We thus use it as the reference energy for all the other solutions.

In Table II we present the properties of the different solutions for the SU(3) models. The first two columns specify the boundary condition of the solution, and the third column gives the topological charge of that solution. In columns 4 and 5 we give the energy of the solutions for the pure Skyrme model and the pure Sk6 model while columns 6 and 7 give the corresponding relative energy per Skyrmion, that is, the energy divided by the energy of the single Skyrmion and the total number of Skyrmions. For the solutions corresponding to the superposition of Skyrmions and anti-Skyrmion, we define the total number of Skyrmions as the total number of Skyrmions and anti-Skyrmions. Notice that the cases $n_g=0, n_F=1$ and $n_g=1, n_F=0$ correspond to the same solution modulo an internal rotation.

In Fig. 3, we present the energy of the three different types of solution as a function of λ.

TABLE II. Topological charge and energy of some SU(3) solutions.

SU(3)			Total energy		Relative energy	
n_F	n_g	B	$E(0)$	$E(1)$	$E_B(0)/(\lvert B\rvert E_1(0))$	$E_B(1)/(\lvert B\rvert E_1(1))$

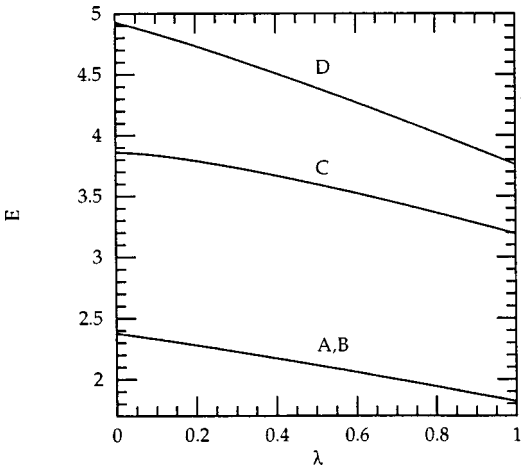

FIG. 3. Energy of the SU(3) solution for the boundary conditions (a) $n_F=0, n_g=1$, (b) $n_F=1, n_g=0$, (c) $n_F=1, n_g=-1$, (d) $n_F=1, n_g=1$.

VI. LOW-ENERGY SU(4) CONFIGURATIONS

As was shown in the last two sections, the ansatz (14) provides an exact solution of the sixth order model only for the SU(3) model, or when $\lambda=0$, that is for the usual Skyrme model. For the SU(N) model with $N\geqslant 4$, the ansatz still produces low-energy configurations. In particular, when λ is small, we can expect the ansatz to be very close to an exact solution. In this section we look at some configurations of the SU(4) model. For this model, we have three profile functions F_0, F_1 and F_2 and the energy for the general ansatz (14) is explicitly given by

$$
\begin{aligned}
E=\frac{1}{6\pi}\int r^2 dr\Bigg\{&\frac{1}{4}(3\dot{F}_0^2+4\dot{F}_1^2+3\dot{F}_2^2+4\dot{F}_0\dot{F}_1+4\dot{F}_1\dot{F}_2+2\dot{F}_0\dot{F}_2)+\frac{2}{r^2}[3(1-\cos F_0)\\
&+4(1-\cos F_1)+3(1-\cos F_2)]+(1-\lambda)\Bigg\{\frac{1}{2r^2}[3\dot{F}_0^2(1-\cos F_0)+4\dot{F}_1^2(1-\cos F_1)\\
&+3\dot{F}_2^2(1-\cos F_2)]+\frac{1}{2r^4}\{9\,(1-\cos F_0)^2+16\,(1-\cos F_1)^2+9\,(1-\cos F_2)^2\\
&-12(1-\cos F_0)(1-\cos F_1)-12(1-\cos F_1)(1-\cos F_2)\}\Bigg\}+\frac{\lambda}{8r^4}\{9\dot{F}_0^2(1-\cos F_0)^2\\
&+16\dot{F}_1^2(1-\cos F_1)^2+9\dot{F}_2^2(1-\cos F_2)^2-12F_0F_1(1-\cos F_0)(1-\cos F_1)\\
&-12F_1F_2(1-\cos F_1)(1-\cos F_2)\}\Bigg\}
\end{aligned}
\tag{51}
$$

from which we can derive the following equations:

$$
\begin{aligned}
&\left(\frac{3\lambda(1-\cos F_0)^2}{2r^4}+\frac{2(1-\lambda)(1-\cos F_0)}{r^2}+1\right)\ddot{F}_0+\left(\frac{2}{3}-\frac{\lambda(1-\cos F_0)(1-\cos F_1)}{r^4}\right)\ddot{F}_1+\frac{1}{3}\ddot{F}_2\\
&-\frac{4\sin F_0}{r^2}+\frac{6\,\dot{F}_0+4\dot{F}_1+2\dot{F}_2}{3r}+\frac{(1-\lambda)\dot{F}_0^2\sin F_0}{r^2}+(1-\lambda)\frac{\sin F_0}{r^4}(4(1-\cos F_1)\\
&-6(1-\cos F_0))+\lambda\frac{(1-\cos F_0)}{r^4}\left(\frac{3}{2}\dot{F}_0^2\sin F_0-\dot{F}_1^2\sin F_1\right)-\lambda\frac{(1-\cos F_0)}{r^5}(3\dot{F}_0(1-\cos F_0)\\
&-2\,\dot{F}_1(1-\cos F_1))=0,
\end{aligned}
\tag{52}
$$

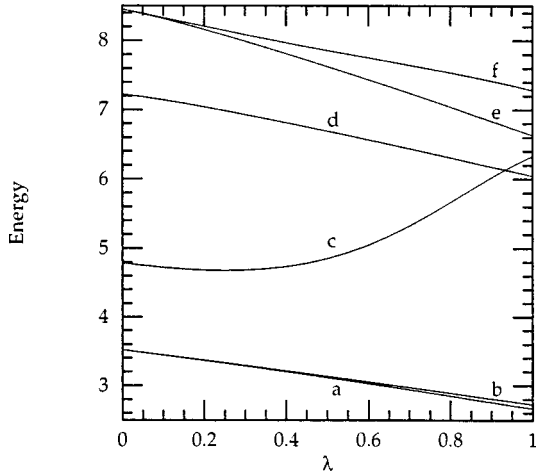

FIG. 4. Energy density of the Su(4) multi-projector ansatz (a) $n_0=0$, $n_1=0$, $n_2=1$; (b) $n_0=1$, $n_1=0$, $n_2=0$; (c) $n_0=0$, $n_1=1$, $n_2=0$; (d) $n_0=1$, $n_1=0$, $n_2=1$; (e) $n_0=1$, $n_1=1$, $n_2=0$; and (f) $n_0=0$, $n_1=1$, $n_2=1$.

$$\left(\frac{1}{2}-\frac{3\lambda(1-\cos F_0)(1-\cos F_1)}{4r^4}\right)\ddot{F}_0+\left(1+\frac{2\lambda(1-\cos F_1)^2}{r^4}+\frac{2(1-\lambda)(1-\cos F_1)}{r^2}\right)\ddot{F}_1$$
$$+\left(\frac{1}{2}-\frac{3\lambda(1-\cos F_1)(1-\cos F_2)}{4r^4}\right)\ddot{F}_2+\frac{(1-\lambda)\dot{F}_1^2\sin F_1}{r^2}+\frac{\dot{F}_0+2\dot{F}_1+\dot{F}_2}{r}-4\frac{\sin F_1}{r^2}$$
$$+(1-\lambda)\frac{\sin F_1}{r^4}(3(1-\cos F_0)+3(1-\cos F_2)-8(1-\cos F_1))-\frac{\lambda}{r^5}(1-\cos F_1)$$
$$\times\left(4\dot{F}_1(1-\cos F_1)-\frac{3}{2}\dot{F}_0(1-\cos F_0)-\frac{3}{2}\dot{F}_2(1-\cos F_2)\right)+\frac{\lambda}{r^4}(1-\cos F_1)$$
$$\times\left(2\dot{F}_1^2\sin F_1-\frac{3}{4}\dot{F}_0^2\sin F_0-\frac{3}{4}\dot{F}_2^2\sin F_2\right)=0, \tag{53}$$

and

$$\left(\frac{2}{3}-\frac{\lambda(1-\cos F_1)(1-\cos F_2)}{r^4}\right)\ddot{F}_1+\left(\frac{3\lambda(1-\cos F_2)^2}{2r^4}+\frac{2(1-\lambda)(1-\cos F_2)}{r^2}+1\right)\ddot{F}_2$$
$$+\frac{1}{3}\ddot{F}_0+\frac{2\dot{F}_0+4\dot{F}_1+6\dot{F}_2}{3r}-4\frac{\sin F_2}{r^2}+\frac{(1-\lambda)\dot{F}_2^2\sin F_2}{r^2}+(1-\lambda)\frac{\sin F_2}{r^4}(4(1-F_1)$$
$$-6(1-F_2))-\lambda\frac{(1-\cos F_2)}{r^5}(3\dot{F}_2(1-\cos F_2)-2\dot{F}_1(1-\cos F_1))$$
$$+\lambda\frac{(1-\cos F_2)}{r^4}\left(\frac{3}{2}\dot{F}_2^2\sin F_2-\dot{F}_1^2\sin F_1\right)=0. \tag{54}$$

Describing the boundary condition for the profile functions as before, $F_i(0)=n_i 2\pi$, the topological charge is given by

$$B=3n_0+4n_1+3n_2. \tag{55}$$

TABLE III. Topological charge and energy of some SU(4) configurations.

SU(4)				Total energy		Relative energy	
n_0	n_1	n_2	B	$E(0)$	$E(1)$	$E_B(0)/(\lvert B\rvert E_1(0))$	$E_B(1)/(\lvert B\rvert E_1(1))$
0	0	1	3	3.517 39	2.666 53	0.952 10	0.945 98

0	1	1	7	8.452 19	7.280 58	0.980 52	1.106 94
1	1	1	10	12.311	9.396 05	1	1

In Table III we present the energy values of various types of configurations when $\lambda=0$ and $\lambda=1$. We notice that when $\lambda=0$, the solutions are symmetric under the exchange $f_0\leftrightarrow f_2$, but that the sixth order term breaks the symmetry. This results in a difference of energy between the configuration with $n_0=0, n_1=0, n_2=1$ and $n_0=1, n_1=0, n_2=0$ as well as between the configurations with $n_0=1, n_1=1, n_2=0$ and $n_0=0, n_1=1, n_2=1$. In Fig. 4, we present the curve for the energy of the configurations as a function of λ.

VII. SU(N) LOW-ENERGY CONFIGURATION

After inserting the ansatz (5) in the full equation for the SU(N) model, we found that we had only two independent profile functions g_0 and g_1 and that the ansatz would only provide solutions for the SU(3) model. One can nevertheless use the SU(N) ansatz to compute low-energy configurations. For example, if we consider the reduced ansatz defined by (5) together with the constraint $\dot{g}_{i-2}-\dot{g}_{i-3}=\dot{g}_i-\dot{g}_{i-2}$ and define the profiles $F=g_0-g_1$ and $g=g_{N-2}$ we can minimize the energy (40) and solve the equations for F and g for various boundary conditions. We found that to get configurations corresponding to a bound state, i.e., a configuration with an energy per Skyrmion smaller than the energy of the hedgehog solution, we must take $n_F=0$ and $n_g=1$. The energies that we found are given in Table IV.

In Figs. 5 and 6 we present the profile and the energy density for different values of N and for $\lambda=0.5$. It shows that the energy density has the shape of a hollow sphere of radius $r=0.7\sqrt{N}$. The profile g has the same shape for all values of N but is shifted to the right as N increases. The profile F, on the other hand, is also shifted as the shell radius increases, but its amplitude decreases like $1/N^2$. Note that in Fig. 6, the profiles for $N=100$ and $N=200$ have been multiplied by 100 to make them visible. For other values of λ the graphics look very much the same except that the shell radius and width are slightly different, but the conclusions remain the same.

Figure 6(b) suggests to simplify the ansatz further for large N by taking $F(r)=0$. This implies that $g_i=g\ \forall i$ and the multi-projector ansatz (5) becomes

$$U=\exp(-ig(P_{N-1}-I/N)), \tag{56}$$

where P_{N-1} can also be written as

TABLE IV. Topological charge and energy for the reduced ansatz with $n_F=0$ and $n_g=1$.

		Total energy		Relative energy	
Model	B	$E(0)$	$E(1)$	$E_B(0)/(\lvert B\rvert E_1(0))$	$E_B(1)/(\lvert B\rvert E_1(1))$
SU(3)	2	2.377	1.819	0.965	0.968
SU(4)	3	3.624	2.759	0.981	0.979
SU(5)	4	4.811	3.632	0.977	0.966
SU(6)	5	6.015	4.518	0.977	0.962

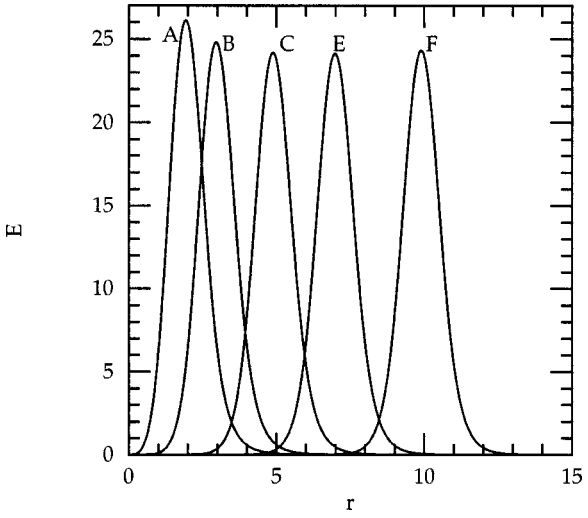

FIG. 5. Energy density of the multi-projector solution with $n_F=0$, $n_g=1$, $\lambda=0.5$. (a) $N=10$, (b) $N=20$, (c) $N=50$, (d) $N=100$, and (e) $n=200$.

$$P_{N-1}=\frac{\tilde{h}\tilde{h}^{\dagger}}{|\tilde{h}|^2}, \tag{57}$$

where $\tilde{h}$ is equal, up to a unitary rotation, to the complex conjugate of the holomorphic vector V_0 defined in (20) and (21): $\tilde{h}=A\overline{V_0}$ for some $A\in \mathrm{SU}(N)$ with $\partial_{\xi}A=\partial_{\bar{\xi}}A=0$. This is shown by using the fact that P_{N-1} is an antiholomorphic projector[16] and that solving (39) recursively we have

$$|V_k|^2=\frac{k!(N-1)!}{(N-1-k)!}|1+|\xi|^2|^{N-1-2k} \tag{58}$$

and so $|V_{N-1}|^2=(N-1)!^2|1+|\xi|^2|^{1-N}$. Knowing that up to an overall coefficient $|V_{N-1}|^2$ is a polynomial in $\bar{\xi}$ of degree $N-1$, we can conclude that up to a unitary iso-rotation, V_{N-1} is equal to the complex conjugate of V_0.

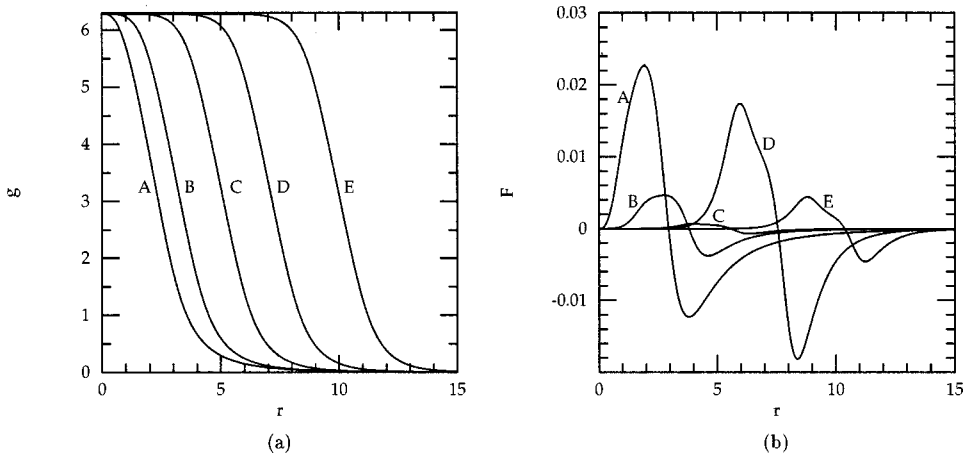

FIG. 6. Profile (a) g and (b) F of the multi-projector solution with $n_F=0$, $n_g=1$, $\lambda=0.5$. (a) F for $N=10$, (b) F for $N=20$, (c) F for $N=50$, (d) $100\times F$ for $N=100$, and (e) $100\times F$ for $N=200$.

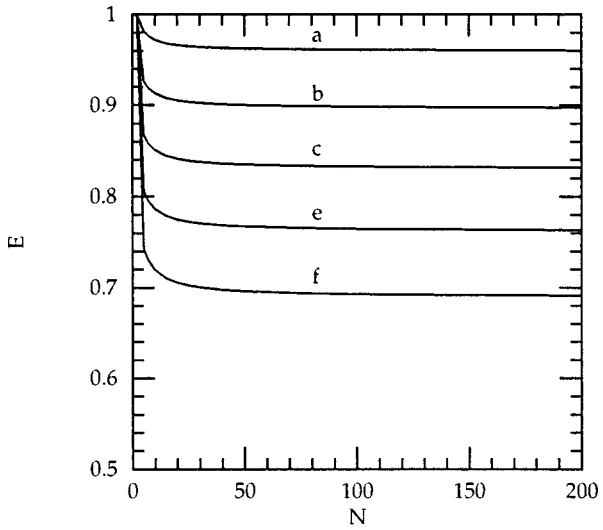

FIG. 7. Energy $E/(E_{B=1}(N-1))$ for the SU(N), configuration (56) for (a) $\lambda=0$, (b) $\lambda=0.25$, (c) $\lambda=0.5$, (d) $\lambda=0.75$, and (e) $\lambda=1$.

The topological charge of the antiholomorphic projector P_{N-1} is equal to $1-N$ and as the profile function is $-g$, the baryon number for this configuration is $N-1$. The ansatz (56) is not a solution, but its energy

$$E=\frac{1}{6\pi}\int r^2 dr\left\{\frac{N-1}{N}\dot{g}^2+\frac{1}{2r^2}+(N-1)(1-\cos g)((1-\lambda)\dot{g}^2+4)\right.$$
$$\left.+\frac{1}{2r^4}(N-1)^2(1-\cos g)^2\left((1-\lambda)+\frac{\lambda}{4r^4}\dot{g}^2\right)\right\}, \tag{59}$$

can easily be computed by solving the equation

$$2g_{rr}+4\frac{g_r}{r}+\frac{N}{r^2}\left((1-\lambda)(1-\cos g)g_{rr}+\frac{1}{2}\sin g((1-\lambda)g_r^2-4)\right)+\frac{\lambda}{4r^4}N(N-1)(1-\cos g)$$
$$\times\left(\sin g g_r^2+(1-\cos g)\left(g_{rr}-2\frac{g_r}{r}\right)\right)=0. \tag{60}$$

In Fig. 7, we present the relative energy, $E(\lambda)/(E_{B=1}(\lambda)(N-1))$, of this configuration as a function of N for different values of λ. We see that this configuration corresponds to a bound state of Skyrmions and that the energy per Skyrmion decreases with N. The energy of this configuration corresponds to an upper bound for the energy of the $B=N-1$ radially symmetric solution of the SU(N) model and these configurations correspond to bound states of Skyrmions for all values of N and all values of λ. As every SU(p) solution can be trivially embedded in an SU(q) solution when $p\leqslant q$ we can claim that for every $B<N$ the SU(N) model has a radially symmetric solution of charge B corresponding to a bound state. With the exception of the hedgehog solutions, these solutions are expected to be unstable when the radial symmetry is broken as their energies are larger than the known SU(2) solutions.[13]

VIII. CONCLUSIONS

In this article we have shown how to construct some radially symmetric solutions of the SU(3) sixth order Skyrme model. The construction is similar to the one used for the pure Skyrme model in Ref. 14 except that, because of an extra constraint, the construction only works for the SU(3)

model. The same ansatz can nevertheless be used to compute low-energy configurations of the SU(N) model. In particular we showed that for every N there is a radially symmetric solution of charge $B<N$ which corresponds to a bound state of Skyrmions.

Gradient corrections for semiclassical theories of atoms in strong magnetic fields

Christian Hainzl[a)]

(Received 12 December 2000; accepted for publication 17 September 2001)

This paper is divided into two parts. In the first one the von Weizsäcker term is introduced to the magnetic Thomas–Fermi theory and the resulting MTFW functional is mathematically analyzed. In particular, it is shown that the von Weizsäcker term produces the Scott correction up to magnetic fields of order $B \ll Z^2$, in accordance with a result of Ivrii on the quantum mechanical ground state energy. The second part is dedicated to gradient corrections for semiclassical theories of atoms restricted to electrons in the lowest Landau band. We consider modifications of the Thomas–Fermi theory for strong magnetic fields (STF), i.e., for $B \ll Z^3$. The main modification consists in replacing the integration over the variables perpendicular to the field by an expansion in angular momentum eigenfunctions in the lowest Landau band. This leads to a functional (DSTF) depending on a sequence of one-dimensional densities. For a one-dimensional Fermi gas the analogue of a Weizsäcker correction has a negative sign and we discuss the corresponding modification of the DSTF functional. © *2001 American Institute of Physics.*

I. INTRODUCTION

In this paper we study gradient correction terms for semiclassical theories describing the ground state energies of heavy atoms in strong homogeneous magnetic fields. Such an atom, with N electrons of charge $-e$ and mass m_e and nuclear charge Ze is described by the nonrelativistic Pauli Hamiltonian

$$H_N = \sum_{1 \leqslant j \leqslant N} \left\{ ((-i\nabla^{(j)} + \mathbf{A}(x_j)) \cdot \sigma^j)^2 - \frac{Z}{|x_j|} \right\} + \sum_{1 \leqslant i < j \leqslant N} \frac{1}{|x_i - x_j|}, \tag{I.1}$$

acting on the Hilbertspace $\wedge_{1 \leqslant j \leqslant N} L^2(\mathbb{R}^3, \mathbb{C}^2)$ of electron wave functions. The units are chosen such that $\hbar = 2m_e = e = 1$. The magnetic field is $\mathbf{B} = (0,0,B)$, with vector potential $\mathbf{A} = \frac{1}{2}B \times (-x_2, x_1, 0)$, where B is the magnitude of the field in units of $B_0 = m_e^2 e^3 c/\hbar^3 = 2.35 \times 10^9$ G, the field strength for which the cyclotron radius $l_B = (\hbar c/(eB))^{1/2}$ is equal to the Bohr radius $a_0 = \hbar^2/(m_e e^2)$. The ground state energy is

$$E^{\mathrm{Q}}(N,Z,B) = \inf\{(\psi, H_N \psi) : \psi \in \text{domain } H_N, (\psi,\psi) = 1\}. \tag{I.2}$$

In Ref. 1 Lieb, Solovej, and Yngvason approximated (1.2) by means of the MTF (magnetic Thomas–Fermi) functional

$$\mathcal{E}^{\mathrm{MTF}}[\rho] = \int \tau_B(\rho) - \int V\rho + D(\rho,\rho), \tag{I.3}$$

where $V(x) = Z/|x|$ and $D(\rho,\rho) = \frac{1}{2}(\rho, |x|^{-1} * \rho)$. The magnetic energy density τ_B is, by definition, the Legendre transform of the pressure P_B, i.e.,

a)Electronic mail: hainzl@thp.univie.ac.at

$$\tau_B(t)=\sup_{w\geqslant 0}[tw-P_B(w)], \tag{I.4}$$

with

$$P_B(w)=\frac{B}{3\pi^2}\left(w^{3/2}-2\sum_{i=1}^{\infty}|2iB-w|_{-}^{3/2}\right). \tag{I.5}$$

The corresponding energy

$$E^{\mathrm{MTF}}(N,Z,B)=\inf\left\{\mathcal{E}^{\mathrm{MTF}}[\rho]\,\middle|\,\rho\geqslant 0,\rho\in D^{\mathrm{MTF}},\int\rho\leqslant N\right\} \tag{I.6}$$

was proved by Lieb, Solovej, and Yngvason to be asymptotically exact, as shown in the following Theorem:

Theorem I.1 (**Ref. 1, Theorem 5.1**)**:** *If $Z\to\infty$ with N/Z fixed and $B/Z^3\to 0$, then*

$$E^{\mathrm{Q}}(N,Z,B)/E^{\mathrm{MTF}}(N,Z,B)\to 1.$$

In the limit $B\to\infty$ the function τ_B is the kinetic energy describing particles confined to the lowest Landau band, i.e.,

$$\tau_\infty(t)=\frac{4\pi^4}{3}t^3/B^2,$$

which results in the STF (strong Thomas–Fermi) functional

$$\mathcal{E}^{\mathrm{STF}}[\rho]=\frac{4\pi^4}{3B^2}\int\rho^3-\int V\rho+D(\rho,\rho). \tag{I.7}$$

The corresponding energy E^{STF} is quantum mechanically exact in the limit $Z\to\infty$ for $Z^{4/3}\ll B\ll Z^3$ (Ref. 1, Proposition 4.16), which emphasizes the fact (Ref. 2, Theorem 1.2) that for $B\gg Z^{4/3}$ the electrons are to leading order confined to the lowest Landau band.

A. Corrections to the leading order of the full Hamiltonian (I.1)

The best result to date concerning corrections to the leading order of (I.2) is presented by Victor Ivrii in Ref. 3, Theorem 0.2:

Theorem I.2 (**Ref. 3, Theorem 0.2**)**:** *Let $B\leqslant Z^3$ and $N\sim Z$, then*

$$|E^{Q}(N,Z,B)-E^{\mathrm{MTF}}(N,Z,B)-\tfrac{1}{4}Z^2|\leqslant R_1+R_2, \tag{I.8}$$

with

$$R_1=CZ^{4/3}(N+B)^{1/3},\quad R_2=CZ^{3/5}B^{4/5}. \tag{I.9}$$

Recall the order of the energy, $E^{Q}\sim Z^{7/3}[1+B/Z^{4/3}]^{2/5}$.

We make a few comments concerning Ivrii's proof. Let

$$H_{\mathbf{A}}=[(-i\nabla+\mathbf{A}(x))\cdot\sigma]^2 \tag{I.10}$$

denote the free Pauli Hamiltonian and

$$\phi^{\mathrm{MTF}}=Z|\mathbf{x}|^{-1}-\rho^{\mathrm{MTF}}*|\mathbf{x}|^{-1} \tag{I.11}$$

the self-consistent magnetic TF potential. The main part of the estimate (I.8) is given by the difference between

$$\mathrm{Tr}[H_{\mathbf{A}}-\phi^{\mathrm{MTF}}+\mu]_-, \tag{I.12}$$

the sum of all negative eigenvalues of the operator $H_{\mathbf{A}}-\phi^{\mathrm{MTF}}+\mu$, and its semiclassical approximation

$$\int P_B(\phi^{\mathrm{MTF}}-\mu). \tag{I.13}$$

For those who are familiar with microlocal analysis we should remark that Ivrii does not really consider ϕ^{MTF} but a smooth mollification, which we also denote with ϕ^{MTF} for simplicity. In order to derive accurate estimates of

$$\left|\mathrm{Tr}[H_{\mathbf{A}}-\phi^{\mathrm{MTF}}+\mu]_- - \int P_B(\phi^{\mathrm{MTF}}-\mu)\right|, \tag{I.14}$$

Ivrii essentially divides the domain into two main zones, for $B\geqslant Z^{4/3}$, namely

$$\chi_1=\{\mathbf{x}|0\leqslant|\mathbf{x}|\leqslant B/Z\} \text{ and } \chi_2=\{\mathbf{x}|B/Z\leqslant|\mathbf{x}|\leqslant r_S=Z^{1/5}B^{-2/5}\}. \tag{I.15}$$

A corresponding partition of unity is given by two functions φ_1 and φ_2, with $\varphi_1+\varphi_2=1$ on $\chi_1\cup\chi_2$ and φ_i essentially supported in χ_i. Using scaling arguments and semiclassical spectral asymptotics Ivrii treats each zone separately. In the inner zone χ_1, where all Landau levels are taken into account and the MTF potential is very similar to the usual TF potential, he gets

$$\chi_1:\left|\mathrm{Tr}(\varphi_1[H_{\mathbf{A}}-\phi^{\mathrm{MTF}}+\mu]_-)-\int \varphi_1 P_B(\phi^{\mathrm{MTF}}-\mu)-\frac{1}{4}Z^2\right|\leqslant R_1. \tag{I.16}$$

We see that in χ_1 the Scott correction is recovered. Moreover, we should note that the machinery of semiclassical spectral asymptotics can only be applied to χ_1 under the condition $Z/B\gg 1/Z$, which means that (I.16) is only valid for $B\leqslant Z^{2-\delta}$, with arbitrary $\delta>0$. For $B\geqslant Z^2$ a semiclassical approximation is no longer possible and the terms (I.12) and (I.13) have to be estimated separately. Since R_2 overcomes Z^2 for $B\geqslant Z^{7/4}$, we should point out that the Scott correction in (I.8) only provides the next to leading order for $B\ll Z^{7/4}$, but in the domain χ_1 it nevertheless makes sense up to $B\ll Z^2$ according to (I.16).

In the outer zone χ_2 only the lowest Landau band is occupied, which implies that in this region the MTF energy is represented by the STF energy corresponding to the functional (I.7). In χ_2 Ivrii derives the estimate

$$\chi_2:\left|\mathrm{Tr}(\varphi_2[H_{\mathbf{A}}-\phi^{\mathrm{MTF}}+\mu]_-)-\int \varphi_2 P_B(\phi^{\mathrm{MTF}}-\mu)\right|\leqslant R_2, \tag{I.17}$$

where the main contribution of (I.17) really stems from the edge of the STF atom $r_S \sim Z^{1/5}B^{-2/5}$.

For low magnetic fields ($B\leqslant Z$) V. Ivrii even improves (I.8) and recovers Dirac and Schwinger corrections as well.

Theorem I.3 (**Ref. 3, Theorem 0.3**)**:** *If $B\leqslant Z$ then*

$$\left|E^{\mathrm{QM}}(N,Z,B)-E^{\mathrm{MTF}}(N,Z,B)-\frac{1}{4}Z^2+c_{\mathrm{DS}}\int(\rho^{\mathrm{TF}})^{4/3}\right|\leqslant CN^{5/3}((1+B)/N)^{\delta} \tag{I.18}$$

holds with some $\delta>0$ and an appropriate parameter c_{DS}.

The von Weizsäcker term introduced to MTF. The von Weizsäcker correction term was successfully introduced to the TF theory in the sense that it reproduces the Scott correction (rigorously proven in Refs. 4 and 5), i.e.,

$$E^{\mathrm{TFW}}=E^{\mathrm{TF}}+O(Z^2)+o(Z^2). \tag{I.19}$$

In addition to the Z^2 correction, the TFW theory remedies some defects of the TF theory: The corresponding TFW density is finite at the nuclei, binding of atoms occurs and negative ions are stable, furthermore the density has exponential fall off at infinity, at least for neutral atoms and molecules.

In the limit $B\to 0$ the function τ_B is the kinetic energy density in zero magnetic field, i.e.,

$$\tau_0(t)=\tfrac{3}{5}(3\pi^2)^{2/3}t^{5/3}.$$

Since for small values of B the introduction of the von Weizsäcker term to the MTF functional is justified, we will further check up to which values of B this definition makes sense. We get the functional

$$\mathcal{E}^{\mathrm{MTFW}}[\rho]=A\int|\nabla\rho^{1/2}|^2+\int\tau_B(\rho)-\int V\rho+D(\rho,\rho), \tag{I.20}$$

with a suitably chosen parameter A. The functional (I.20) can be treated analogously to the usual TFW functional in Ref. 6. So we will just sketch the proofs of the main propositions.

It turns out that for $B\ll Z^2$ the von Weizsäcker term still produces the Scott correction, but makes no longer sense for higher magnetic fields. We will derive the following Theorem:

Theorem I.4: *For all B,Z and N/Z fixed*

$$|E^{\mathrm{MTFW}}-E^{\mathrm{MTF}}-O(Z^2)|\leqslant CB^{4/5}Z^{3/5}+o(Z^2). \tag{I.21}$$

Remark: The estimate (I.21) is clearly useful if $B\leqslant Z^{7/4}$. Theorem I.4 will be proved in Sec. II B.

The Scott correction, just like in TFW theory, comes from distances of order $1/Z$ near the nucleus, whereas the bound $CB^{4/5}Z^{3/5}$ comes from the edge of the MTF atom and dominates the Scott correction for $B\geqslant Z^{7/4}$. Moreover, (I.21) is in accordance with Theorem I.2, which justifies *a posteriori* the introduction of the von Weizsäcker term to the MTF functional.

B. Physics in the lowest Landau band

The quantum mechanical ground state energy of particles confined to the lowest Landau band is given by

$$E^{\mathrm{Q}}_{\mathrm{conf}}(N,Z,B)=\inf_{\|\psi\|_2=1}(\psi,\Pi_0^N H_N\Pi_0^N\psi), \tag{I.22}$$

where Π_0 represents the projector on the lowest Landau band, given by the kernel

$$\Pi_0(x,x')=\frac{B}{2\pi}\exp\left\{\frac{i}{2}(x_\perp\times x'_\perp)\cdot\mathbf{B}-\frac{1}{4}(x_\perp-x'_\perp)^2B\right\}\delta(x_3-x'_3)P_\downarrow, \tag{I.23}$$

where $P_\downarrow$ denotes the projection onto the spin down component, and Π_0^N denotes the Nth tensorial power of Π_0. The leading order of E^Q_{conf}, as $B,Z\to\infty$ with $B\ll Z^3$, is given by E^{STF}, the ground state energy of the functional (I.7). In a companion work we show what is expected by Ivrii's Theorem I.2,

$$|E^Q_{\mathrm{conf}}-E^{\mathrm{STF}}|\leqslant CB^{4/5}Z^{3/5}. \tag{I.24}$$

As we have argued previously the main contribution to the estimate (I.24) comes from the edge of the STF atom, $r_S \sim Z^{1/5}B^{-2/5}$. Recall the order of E^{STF}, $E^{\mathrm{STF}}[N,Z,B] = Z^3(B/Z^3)^{2/5}E^{\mathrm{STF}}[N/Z,1,1]$, so that the estimate is only of interest for $B \ll Z^3$.

As a better approximation to E^Q_{conf}, valid also for $B \geqslant Z^3$, Lieb, Solovej, and Yngvason suggested a density matrix functional defined as

$$\mathcal{E}^{\mathrm{DM}}[\Gamma] = \int_{\mathbb{R}^2} \mathrm{Tr}_{L^2(\mathbb{R})}[-\partial_3^2 \Gamma_{x_\perp}]\mathrm{d}x_\perp - Z\int |x|^{-1}\rho_\Gamma(x) + D(\rho_\Gamma,\rho_\Gamma).$$

Its variable is an operator valued function

$$\Gamma : x_\perp \to \Gamma_{x_\perp},$$

where $\Gamma_{x_\perp}$ is an integral operator on $L^2(\mathbb{R})$, given by a kernel $\Gamma_{x_\perp}(x_3,y_3)$ and satisfying

$$0 \leqslant \Gamma_{x_\perp} \leqslant (B/2\pi)I \tag{I.25}$$

as an operator on $L^2(\mathbb{R})$. The energy

$$E^{\mathrm{DM}}(N,Z,B) = \inf\left\{ \mathcal{E}^{\mathrm{DM}}[\Gamma] \,\middle|\, \Gamma \ \text{satisfies (I.25)} \ \text{and} \ \int \rho_\Gamma \leqslant N \right\}$$

turns out to be asymptotically exact for magnetic fields in the following precise sense:

Theorem I.5 [Ref. 2, Theorems 5.1 and 7.1 and Eqs. (7.3) and (8.5)]: *For some constants, C_λ and C'_λ, we have*

$$R_U \geqslant E^{\mathrm{Q}}_{\mathrm{conf}}(N,Z,B) - E^{\mathrm{DM}}(N,Z,B) \geqslant -R_L, \tag{I.26}$$

with

$$R_L = C_\lambda \min\{Z^{17/15}B^{2/5}, Z^{8/3}[1+(\ln(B/Z^3))^2]\} \tag{I.27}$$

and

$$R_U = C'_\lambda \min\{Z^{5/3}B^{1/3}, Z^{8/3}[1+\ln(Z)+(\ln(B/Z^3))^2]^{5/6}\}.$$

We remark that the STF energy is the natural semiclassical approximation of the DM energy. More precisely, the DM energy can be written as

$$\frac{B}{2\pi}\int \mathrm{d}\mathbf{x}_\perp \, \mathrm{Tr}_{L^2(\mathbb{R})}[-\partial_z^2 - \phi^{\mathrm{DM}}_{x_\perp} - \mu^{\mathrm{DM}}]_- + \mu^{\mathrm{DM}}N - D(\rho^{\mathrm{DM}},\rho^{\mathrm{DM}}), \tag{I.28}$$

whereas the STF energy is given by the corresponding semiclassical expression

$$\frac{B}{2\pi}\int \mathrm{d}\mathbf{x}_\perp \int\int \mathbf{d}p \, \mathbf{d}z [p^2 - \phi^{\mathrm{STF}}_{\mathbf{x}_\perp} - \mu^{\mathrm{STF}}]_- + \mu^{\mathrm{STF}}N - D(\rho^{\mathrm{STF}},\rho^{\mathrm{STF}}). \tag{I.29}$$

With the decomposition $L^2(\mathbb{R}^3,\mathrm{d}\mathbf{x};\mathbb{C}^2) = L^2(\mathbb{R}^2,\mathrm{d}\mathbf{x}_\perp)\otimes L^2(\mathbb{R},\mathrm{d}z)\otimes\mathbb{C}^2$ the projector Π_0 can be written as

$$\Pi_0 = \sum_{m\geqslant 0} |\phi_m\rangle\langle\phi_m| \otimes 1 \otimes P_\downarrow, \tag{I.30}$$

where ϕ_m denotes the function in the lowest Landau band with angular momentum $-m \leqslant 0$, i.e., using polar coordinates (r,φ),

$$\phi_m(\mathbf{x}_\perp) = \sqrt{\frac{B}{2\pi}} \frac{1}{\sqrt{m!}} \left(\frac{Br^2}{2}\right)^{m/2} e^{-im\varphi} e^{-Br^2/4}. \tag{I.31}$$

Using this and $H_{\mathbf{A}}\Phi_m = 0$, we can write

$$\Pi_0 H_{\mathbf{A}} \Pi_0 = \sum_{m \geqslant 0} |\phi_m\rangle\langle\phi_m| \otimes (-\partial_z^2) \otimes P_\downarrow . \tag{I.32}$$

Based on this decomposition the author and R. Seiringer introduced in Ref. 7 a natural modification of the DM functional called *discrete density matrix functional* (DDM)

$$\mathcal{E}^{\mathrm{DDM}}_{B,Z}[\Gamma] = \sum_{m \in \mathbb{N}_0} \left(\mathrm{Tr}[-\partial_z^2 \Gamma_m] - Z \int V_m(z) \rho_m(z) \mathrm{d}z \right) + \widetilde{D}(\rho,\rho), \tag{I.33}$$

where

$$\widetilde{D}(\rho,\rho) = \frac{1}{2} \sum_{m,n} \int V_{m,n}(z-z') \rho_m(z) \rho_n(z') \mathrm{d}z \, \mathrm{d}z', \tag{I.34}$$

and the potentials V_m and $V_{m,n}$ are given by

$$\begin{aligned} V_m(z) &= \int \frac{1}{|\mathbf{x}|} |\phi_m(\mathbf{x}_\perp)|^2 \, \mathrm{d}\mathbf{x}_\perp , \\ V_{m,n}(z-z') &= \int \frac{|\phi_m(\mathbf{x}_\perp)|^2 |\phi_n(\mathbf{x}'_\perp)|^2}{|\mathbf{x}-\mathbf{x}'|} \mathrm{d}\mathbf{x}_\perp \, \mathrm{d}\mathbf{x}'_\perp . \end{aligned} \tag{I.35}$$

Here Γ is a sequence of fermionic density matrices acting on $L^2(\mathbb{R}, \mathrm{d}z)$,

$$\Gamma = (\Gamma_m)_{m \in \mathbb{N}_0}, \tag{I.36}$$

with corresponding densities $\rho = (\rho_m)_m$, $\rho_m(z) = \Gamma_m(z,z)$. Note that $\mathcal{E}^{\mathrm{DDM}}_{B,Z}$ depends on B via the potentials V_m and $V_{m,n}$. The corresponding energy is given by

$$E^{\mathrm{DDM}}(N,Z,B) = \inf \left\{ \mathcal{E}^{\mathrm{DDM}}_{B,Z}[\Gamma] \,\middle|\, \sum_m \mathrm{Tr}[\Gamma_m] \leqslant N \right\}. \tag{I.37}$$

It is shown in Ref. 7 that E^{DDM} correctly reproduces the confined ground state energy E^Q_{conf} apart from errors due to the indirect part of the Coulomb interaction energy:

Theorem I.6 (Ref. 7, Theorem 1.2): *For some constant c_λ depending only on $\lambda = N/Z$,*

$$0 \geqslant E^{\mathrm{Q}}_{\mathrm{conf}}(N,Z,B) - E^{\mathrm{DDM}}(N,Z,B) \geqslant -R_L , \tag{I.38}$$

with

$$R_L = c_\lambda \min\{Z^{17/15} B^{2/5}, Z^{8/3}(1 + [\ln(B/Z^3)]^2)\}. \tag{I.39}$$

Since the functional (I.33) can also be seen as a reduced Hartree–Fock functional, in the sense of Ref. 8, it does not surprise that the upper bound in (I.38) is an improvement to (I.26), the relation between E^{DDM} and E^Q_{conf}. In addition to better estimates, the DDM theory remedies the defect of the DM theory having a sharply cut ground state density supported in the set $\{\mathbf{x} \,|\, |\mathbf{x}| \leqslant \sqrt{2N/B}\}$, for the respective three-dimensional DDM density,

$$\rho^{\mathrm{DDM}}(\mathbf{x})=\sum_m \rho_m^{\mathrm{DDM}}(z)\phi_m^2(x_\perp), \tag{I.40}$$

has exponential fall off at infinity. Furthermore, since the DDM energy describes E^Q_{conf} correctly apart from errors due to the indirect part of the Coulomb interaction energy, the DDM energy could give rise to even recover the exchange term, by means of an improved lower bound on the two-body Coulomb repulsion for particles in the lowest Landau band. For the exchange energy is anticipated to be of order $\ln(B/Z^{4/3})Z^{7/5}B^{1/5}$ for $B\ll Z^3$, which in Ref. 9 by the author (C. H.) and R. Seiringer is conjectured to be given by the term

$$c\sum_i \ln\left(\frac{B^{1/2}\int\rho_i^{\mathrm{DDM}}}{\int(\rho_i^{\mathrm{DDM}})^2}\right)\int(\rho_i^{\mathrm{DDM}})^2. \tag{I.41}$$

This would lead to the relation

$$E^Q_{\mathrm{conf}}=E^{\mathrm{DDM}}-c\sum_i \ln\left(\frac{B^{1/2}\int\rho_i^{\mathrm{DDM}}}{\int(\rho_i^{\mathrm{DDM}})^2}\right)\int(\rho_i^{\mathrm{DDM}})^2+o(\ln(B/Z^{4/3})Z^{7/5}B^{1/5}), \tag{I.42}$$

with c appropriately chosen.

We have stated previously that the STF functional is the natural semiclassical approximation of the DM functional. Hence, we can ask for the natural semiclassical approximation of the DDM functional, of which the answer is given by the so-called DSTF functional

$$\mathcal{E}^{\mathrm{DSTF}}[\rho]=\sum_{m\in\mathbb{N}_0}\left(\kappa\int\rho_m^3(z)-Z\int V_m(z)\rho_m(z)\mathrm{d}z\right)+\tilde{D}(\rho,\rho), \tag{I.43}$$

where ρ is a sequence of one-dimensional densities, $\rho=(\rho_m)_{m\in\mathbb{N}_0}$, $\kappa=\pi^2/3$, and the respective DSTF energy is defined as

$$E^{\mathrm{DSTF}}(N,Z,B)=\inf\left\{\mathcal{E}^{\mathrm{DSTF}}[\rho]\,\middle|\,\sum_m\int\rho_m\leqslant N\right\}. \tag{I.44}$$

In Section III B 2 we will argue that the DSTF functional is even the natural semiclassical approximation of the ground state energy E^Q_{conf} itself.

C. Gradient corrections for semiclassical lowest Landau band theories

1. The Tomishima–Shinjo correction term

For higher magnetic fields, where only the lowest Landau band has to be taken into account, Tomishima and Shinjo[10] obtained the gradient correction term

$$\epsilon^{\mathrm{TS}}[\rho]=\frac{2\pi^4}{B^3}\rho(\nabla_\perp\rho)^2-\frac{1}{3}(\nabla_\parallel\rho^{1/2})^2, \tag{I.45}$$

i.e.,

$$\mathcal{E}^{\mathrm{TS}}[\rho]=\frac{2\pi^4}{B^3}\int\rho(\nabla_\perp\rho)^2-\frac{1}{3}\int(\nabla_\parallel\rho^{1/2})^2+\mathcal{E}^{\mathrm{STF}}[\rho], \tag{I.46}$$

by perturbation expansion of the canonical density matrix. In 1995 the authors of Ref. 11 recovered the TS theory within the framework of current density functional theory. Since (I.46) has a negative gradient correction along the magnetic field the TS functional is no longer bounded from

below. Hence the corresponding energy cannot, as usual, be defined by minimizing over a suitable domain of definition, but only through the solutions of the corresponding Euler–Lagrange equation under the restriction $\int \rho = N$, i.e.,

$$\frac{4\pi^4}{B^2}\rho^2 - \frac{\pi^4}{B^3}[(\nabla_\perp \rho)^2 + 2\rho\Delta_\perp \rho] - \frac{1}{12\rho}\left[\frac{1}{2\rho}(\nabla_\parallel \rho)^2 - \Delta_\parallel \rho\right] = V - \rho * \frac{1}{|x|} - \mu(N). \tag{I.47}$$

A direct attack on this complicated equation does not look promising, but a rough estimate of the corrections to STF can be obtained by inserting the density

$$\rho(r) = \begin{cases} \rho^{\mathrm{STF}}(B^{-1/2}) & \text{for } r \leqslant B^{-1/2}, \\ \rho^{\mathrm{STF}}(r) & \text{for } r \geqslant B^{-1/2}, \end{cases} \tag{I.48}$$

into (I.46). The negative gradient term gives a correction $-O(B^{4/5}Z^{3/5})$ coming from the edge of the STF atom. From (I.24) we know that

$$|E^Q_{\mathrm{conf}} - E^{\mathrm{STF}}| \leqslant CB^{4/5}Z^{3/5}, \tag{I.49}$$

where the main contribution also stems from $r_S \sim Z^{1/5}B^{-2/5}$, the edge of the STF atom.

On the other hand the positive gradient correction orthogonal to the magnetic field in (I.46) produces a correction $O(B^{1/4}Z^{3/2})$ at a distance of order $B^{-1/2}$ from the nucleus. This part of the correction can also be obtained from an *isotropic Tomishima functional*, defined as

$$\mathcal{E}^{\mathrm{IT}}[\rho] = \mathcal{E}^{\mathrm{STF}}[\rho] + \frac{2\pi^4}{B^3}\int \rho(\nabla\rho)^2. \tag{I.50}$$

The functional (I.50) has all the good properties of the usual TF theories, such as convexity and boundedness from below. The study of this functional, which we do in detail in Sec. III A, should help us to get a deeper understanding of the nature of the positive correction term in (I.46). For the ground state energy of (I.50) we will derive the following theorem.

Theorem I.7: *For all B, Z and N/Z fixed*

$$E^{\mathrm{IT}}(N,Z,B) - E^{\mathrm{STF}}(N,Z,B) = O(B^{1/4}Z^{3/2}) + o(B^{1/4}Z^{3/2}). \tag{I.51}$$

Furthermore we will argue in Sec. III A that the $\rho(\nabla\rho)^2$ term remedies the defect of the STF theory that the full Coulomb potential is used although the particles in the lowest Landau band do not see the full singularity, since they are smeared over a region of radius $B^{-1/2}$. In contrast to TFW theory, where the maximal number N_c of electrons that can be bound is strictly larger than Z, it will as a slight surprise turn out that in IT theory $N_c = Z$, just like in the STF theory itself. Also, the radius of atoms in IT theory is finite, as in STF theory. These features confirm that the $\rho(\nabla\rho)^2$ term essentially only effects the density close to the nucleus.

2. Gradient correction for the discrete STF theory

As discussed previously, the gradient term $\sim\rho(\nabla_\perp\rho)^2$ in (I.46) produces essentially a smearing of the Coulomb singularities over a distance of the radius $B^{-1/2}$. The same effect was obtained by replacing STF by DSTF.

Thus, it appears natural to look for a negative gradient term that has an analogous effect in DSTF as the negative gradient term in (I.46) has in STF theory, i.e., provides corrections at the edge of the atom.

The DSTF theory is effectively a theory of coupled one-dimensional problems. Analogous arguments as lead to the von Weizsäcker term for a three-dimensional Fermi gas give for a one-dimensional Fermi gas a gradient correction—$\frac{1}{3}(\nabla\rho^{1/2})^2$, cf. Ref. 12. Hence we suggest the definition of a *discrete von Weizsäcker* functional:

$$\mathcal{E}^{\mathrm{DW}}[\rho]=\sum_{m\in\mathbb{N}_0}\left(-\frac{1}{3}\int|\partial_z\sqrt{\rho_m(z)}|^2+\kappa\int\rho_m^3(z)-Z\int V_m(z)\rho_m(z)\right)+\tilde{D}(\rho,\rho). \quad \text{(I.52)}$$

By denoting $\sqrt{\rho_m}=\psi_m$ we arrive, at under the restriction $\Sigma_m\int\psi_m^2=N$, the corresponding TF equation

$$(1/3)\partial_z^2\psi_n(z)+3\kappa\psi_n^5(z)=[\varphi_n(z)-\mu(N)]\psi_n(z), \quad \forall n\in\mathbb{N}_0, \quad \text{(I.53)}$$

with

$$\varphi_n(z)=ZV_n(z)-\sum_m\int\psi_m^2(z')V_{m,n}(z-z')\mathrm{d}z'.$$

These coupled equations are probably somewhat easier to deal with than (I.47).

If we reduce (I.52) to the angular momentum channel $m=0$ and drop the Coulomb repulsion term, we get the one-dimensional functional

$$\mathcal{E}^{\mathrm{1DW}}[\rho]=-\frac{1}{3}\int|\partial_z\sqrt{\rho(z)}|^2+\kappa\int\rho^3(z)-Z\int V_0(z)\rho(z). \quad \text{(I.54)}$$

This simplified functional will be studied in Sec. III C 2. In particular, we shall show that the negative gradient term reproduces the right QM correction to the energy without the gradient term.

II. THE MAGNETIC TFW THEORY

A. Mathematical analysis of the MTFW functional

In this section we are going to mathematically analyze the MTFW functional

$$\mathcal{E}^{\mathrm{MTFW}}[\rho]=A\int|\nabla\rho^{1/2}|^2+\int\tau_B(\rho)-\int V\rho+D(\rho,\rho). \quad \text{(II.1)}$$

Since the mathematical propositions do not depend on the parameter A, we let A be 1 in this section. The most important features of $\tau_B(t)$ which will be used in our calculations are (compare Ref. 1, Lemma 4.1):

$$\tau_B'(t)\leqslant\kappa_1 t^{2/3}, \quad \tau_B(t)\leqslant\tfrac{3}{5}\kappa_1 t^{5/3}, \quad \text{(II.2)}$$

with $\kappa_1=(4\pi^2)^{2/3}$.

Since the MTFW functional does not differ very much from the functional in Ref. 6, where the authors used a kinetic energy density $\tau(\rho)=(1/p)\rho^p$, our procedure in analyzing (I.20) will be in analogy to their work. We are thus concerned with the minimizing problem

$$\mathrm{Min}\left\{\mathcal{E}^{\mathrm{MTFW}}[\rho]\,|\,\rho\geqslant 0,\rho\in L^1\cap L^{5/3}_{\mathrm{loc}},\nabla\rho^{1/2}\in L^2 \quad \text{and} \quad \int\rho=N\right\}, \quad \text{(II.3)}$$

where N is a positive constant, which physically is the total charge number. Our main result is the following:

Theorem II.1: *There is a critical number* $0<N_c<\infty$, *so that*

(1) if $N\leqslant N_c$ *(II.3) has a unique minimizer,*
(2) if $N>N_c$ *(II.3) has no minimizer,*
(3) $N_c>Z$.

Similar to Ref. 6 we first examine the problem

$$\mathrm{Min}\{\mathcal{E}^{\mathrm{MTFW}}[\rho]|\rho\in D\} \tag{II.4}$$

with

$$D=\{\rho|\rho\geqslant 0,\tau_B(\rho)<\infty,\rho\in L^3,\nabla\rho^{1/2}\in L^2,D(\rho,\rho)<\infty\} \tag{II.5}$$

and prove the existence of a unique minimizer ρ_0. Since D contains the domain of (II.3) we have to show $\rho_0\in L^1(\mathbb{R}^3)$ in order to guarantee $N_c<\infty$. Furthermore we will derive $N_c>Z$, which shows that this theory allows negative ions. The proofs will be based on the Euler–Lagrange equation for $\psi=\sqrt{\rho_0}$.

First we consider some basic properties of (II.1).

Lemma II.2: For D defined in (II.5) we have

$$D\subset\{\rho|\rho\geqslant 0,\rho\in L^3\cap L^{5/3}_{\mathrm{loc}},\nabla\rho^{1/2}\in L^2,D(\rho,\rho)<\infty\}\equiv\overline{D}. \tag{II.6}$$

Proof: According to Ref. 1 (4.19) one gets for all $\Omega\subset\mathbb{R}^3$,

$$\int_\Omega\rho(x)^{5/3}\mathrm{d}x\leqslant\frac{1}{\kappa_3}\int_{\Omega_1}\tau_B(\rho(x))\mathrm{d}x+C\ \mathrm{Vol}(\Omega_2)<\infty$$

with $\Omega=\Omega_1\cup\Omega_2$.

Proposition II.3: The absolute minimum of $\mathcal{E}^{\mathrm{MTFW}}[\rho]$ is achieved for a unique $\rho_0\in D$.

Proof (cf. Ref. 6, Lemmas 2–5): Recall that, by definition (I.4), $\tau_B(t)$ is strictly convex, hence $\mathcal{E}^{\mathrm{MTFW}}[\rho]$ is strictly convex.

Let ρ_n be a minimizing sequence. There exists a constant C such that

$$\|\rho_n\|_3\leqslant C,\int\tau_B(\rho_n)\leqslant C,\|\nabla\rho_n^{1/2}\|_2\leqslant C,D(\rho_n,\rho_n)\leqslant C.$$

By the Banach–Alaoglu theorem we can extract a subsequence, still denoted as ρ_n, with

$$\rho_n\rightharpoonup\rho_0\quad\text{weakly in } L^3, \tag{II.7}$$

$$\nabla\rho_n^{1/2}\rightharpoonup\nabla\rho_0^{1/2}\quad\text{weakly in } L^2. \tag{II.8}$$

Since by use of Hölder's inequality $\|\rho_n^{1/2}\|_{H^1(\Omega)}\leqslant C(\Omega)$ and $H^1(\Omega)$ is relatively compact in $L^2(\Omega)$, if Ω is a bounded smooth domain, $\rho_n^{1/2}$ has a subsequence converging in $L^2(\Omega)$. Using Cantor's diagonal trick on a sequence of increasing Ω's we arrive at

$$\rho_n^{1/2}\to\rho_0^{1/2}\quad\text{a.e.} \tag{II.9}$$

By Fatou's Lemma we get

$$\liminf\int\tau_B(\rho_n)\geqslant\int\tau_B(\rho_0)\ \text{ and }\ \liminf D(\rho_n,\rho_n)\geqslant D(\rho_0,\rho_0).$$

Since L^p norms are weakly lower semicontinuous,

$$\liminf\int|\nabla\rho_n^{1/2}|^2\geqslant\int|\nabla\rho_0^{1/2}|^2.$$

Moreover, one can show, in analogy to Proposition III.3, that

$$\int V\rho_n\to\int V\rho_0,$$

so we altogether arrive at

$$\liminf \mathcal{E}^{\mathrm{MTFW}}[\rho_n] \geqslant \mathcal{E}^{\mathrm{MTFW}}[\rho_0]. \tag{II.10}$$

The uniqueness follows from the strict convexity of $\mathcal{E}^{\mathrm{MTFW}}[\rho]$. □

For the minimizing ρ_0 we now can derive an Euler–Lagrange equation. Denote $\psi = \sqrt{\rho_0}$.

Proposition II.4: The minimizing $\psi^2 = \rho_0$ satisfies

$$-\Delta\psi + \tau_B'(\psi^2)\psi = \varphi\psi, \tag{II.11}$$

in the sense of distributions, with $\varphi = V - \psi^2 * 1/|x|$.

Proof (cf. Ref. 6 Lemma 6): Note that $\psi^2 \in D$ implies $\varphi\psi, \tau_B'(\psi^2)\psi \in L^1_{\mathrm{loc}}$, which gives (II.11) a meaning in the sense of distributions. Consider the set

$$\tilde{D} \equiv \{\zeta | \zeta \in L^6 \cap L^{10/3}_{\mathrm{loc}}, \nabla\zeta \in L^2 \text{ and } D(\zeta^2, \zeta^2) < \infty\}. \tag{II.12}$$

If $\zeta \in \tilde{D}$ then $\rho = \zeta^2 \in D$ and

$$\mathcal{E}^{\mathrm{MTFW}}[\rho] = \int |\nabla\zeta|^2 + \int \tau_B(\zeta^2) - \int V\zeta^2 + D(\zeta^2, \zeta^2) \equiv \phi(\zeta).$$

We find $\phi(\psi) \leqslant \phi(\zeta)$ for all $\zeta \in \tilde{D}$. Let $\eta \in C_0^\infty$. Using the fact that $(\mathrm{d}/\mathrm{d}t)\,\phi(\psi + t\eta)|_{t=0} = 0$, we easily arrive at

$$-\int \psi\Delta\eta + \int \tau_B'(\psi^2)\psi\eta = \int \varphi\psi\eta. \tag{II.13}$$

□

Starting from Eq. (II.11) we can now step by step gain several properties for ψ.

Lemma II.5: ψ is continuous on $\mathbb{R}^3$, more precisely $\psi \in C^{0,\alpha}_{\mathrm{loc}}$ for all $\alpha \leqslant 1$.

Proof (cf. Ref. 6, Lemma 7): Since (II.11) yields $-\Delta\psi \leqslant \varphi\psi$, with $\varphi\psi \in L^{2-\delta}_{\mathrm{loc}}$, one gets $\psi \in L^\infty_{\mathrm{loc}}$ (e.g., by applying a result of Stampaccia in Ref. 13). Again using (II.11) the proposition follows by means of standard elliptic regularity theory (see Ref. 14, Theorem 10.2). □

Proposition II.6: $\psi \in L^2(\mathbb{R}^3)$.

Proof (cf. Ref. 6, Lemma 8): Assume, by contradiction, $\int \psi^2 = \infty$. Then we can choose an r, such that

$$\int_{|x| \leqslant r} \psi^2(x) \geqslant Z + 2\delta,$$

for some $\delta > 0$. Therefore

$$\psi^2 * |x|^{-1} \geqslant \int_{|x| \leqslant r} \psi^2(x)(|x| + |y|)^{-1}\,\mathrm{d}y \geqslant (Z + 2\delta)/(|x| + r),$$

which gives us

$$\varphi(x) = V(x) - \psi^2 * |x|^{-1} \leqslant \frac{Z}{|x| - r} - \frac{Z + 2\delta}{|x| + r},$$

with $|x| > r$. Thus there exists an $r_1 > r$, such that for $|x| > r_1$,

$$\varphi(x) \leqslant -\delta|x|^{-1}. \tag{II.14}$$

From (II.11) we get

$$-\Delta\psi+\delta|x|^{-1}\psi\leqslant 0 \tag{II.15}$$

for $|x|>r_1$. Now we choose a comparison density

$$\tilde{\psi}(x)=Me^{-2(\delta|x|)^{1/2}},$$

which satisfies

$$-\Delta\tilde{\psi}+\delta|x|^{-1}\tilde{\psi}\geqslant 0. \tag{II.16}$$

Hence by (II.15) and (II.16)

$$-\Delta(\psi-\tilde{\psi})+\delta|x|^{-1}(\psi-\tilde{\psi})\leqslant 0$$

for $|x|\geqslant r_1$. We fix M such that

$$\psi(r_1)\leqslant\tilde{\psi}(r_1).$$

If $\psi\to 0$ for $|x|\to\infty$, we immediately get

$$\psi\leqslant\tilde{\psi}\quad\text{for}\quad|x|>r_1 \tag{II.17}$$

from the maximum principle. The fact that $\int\tilde{\psi}^2<\infty$ and $\psi\in L^\infty_{\mathrm{loc}}$ contradicts our assumption. Unfortunately, we only know that $\psi\to\infty$ as $|x|\to\infty$ in a weak sense, namely $\psi\in L^6$, so the authors in Ref. 6 used a variant of Stampaccia's method to verify the statement of the Lemma, which also works in our case. □

Mimicking the proof of Ref. 6, Lemma 10 and using the fact that $\tau_B'(\psi^2)\psi-\varphi\psi$ is continuous but not differentiable we get

Lemma II.7: $\psi>0$ *everywhere and* $\psi\in C^2$, *except at* $x=0$.

Using (II.2) in the proof of Ref. 6, Lemma 11 and afterwards following the proof of Lemma 13 we additionally get

Proposition II.8: $N_c=\int\psi^2>Z$.

Before concluding the proof of Theorem II.1, we need a final lemma, which is the equivalent to Ref. 6, Lemma 14.

Lemma II.9: For every $N>0$ *we have* $\inf\{\mathcal{E}^{\mathrm{MTFW}}[\rho]\,|\,\rho\in\overline{D}\text{ and }\int\rho=N\}=\inf\{\mathcal{E}^{\mathrm{MTFW}}[\rho]\,|\,\rho\in\overline{D}\text{ and }\int\rho\leqslant N\}$.

Proof of Theorem II.1: For every N we set

$$E(N)\equiv\inf\left\{\mathcal{E}^{\mathrm{MTFW}}[\rho]\,\middle|\,\rho\in\overline{D}\text{ and }\int\rho\leqslant N\right\}.$$

Obviously $E(N)$ is nonincreasing and convex. The same proof as in Proposition II.3 shows that there exists a $\rho_N\in\overline{D}$ with $\int\rho_N\leqslant N$ and

$$\mathcal{E}^{\mathrm{MTFW}}[\rho_N]=E(N).$$

With $N_c=\int\psi^2$ it is clear that $E(N)$ is constant for $N>N_c: E(N)=E(N_c)$, while $E(N)$ is strictly decreasing on the interval $[0,N_c]$. For $N\leqslant N_c: \int\rho_N=N$, which implies that (II.3) has a unique solution. On the other hand we deduce from Lemma II.9 that for $N>N_c$ (II.3) has no solution, which concludes the proof of Theorem II.1. □

After having guaranteed the existence of a minimizing density ρ_N for (II.3), we can derive an Euler–Lagrange equation under the variational restriction $\int\rho=N$.

Proposition II.10: Denote $\psi=\rho_N^{1/2}$, *with* ρ_N *the minimizing density for*

$$\inf\left\{ \mathcal{E}^{\mathrm{MTFW}}[\rho] \middle| \rho \in \overline{D}, \int \rho = N \right\}$$

under the restriction $N \leqslant N_c$. *Then we have*

$$-\Delta\psi + \tau_B'(\psi^2)\psi - \varphi\psi = \mu(N)\psi, \tag{II.18}$$

where

$$\mu(N) = \frac{\mathrm{d}}{\mathrm{d}N} E(N). \tag{II.19}$$

Proof: The derivation of (II.18) works analogously to (II.11) apart from the difference that μ is the Lagrange parameter for the restriction $\int \rho = N$. We can infer

$$\frac{\mathrm{d}}{\mathrm{d}t} \mathcal{E}^{\mathrm{MTFW}}[t\rho + (1-t)\rho_N]\Big|_{t=0} = \mu(N) \int (\rho_N - \rho), \tag{II.20}$$

which implies by means of convexity of the functional

$$\mathcal{E}^{\mathrm{MTFW}}[\rho_N] - \mathcal{E}^{\mathrm{MTFW}}[\rho] \geqslant \mu(N) \int (\rho_N - \rho),$$

or equivalently for every N',

$$E(N) - E(N') \geqslant \mu(N)(N - N'). \tag{II.21}$$

On the other hand we derive from (II.20)

$$\mathcal{E}^{\mathrm{MTFW}}[t\rho + (1-t)\rho_N] - \mathcal{E}^{\mathrm{MTFW}}[\rho_N] = t\mu(N) \int (\rho_N - \rho) + o(t),$$

which yields with $\rho = 2\rho_N$ and $\rho = 1/2\rho_N$, respectively,

$$E(N \pm tN) - E(N) \leqslant \pm \mu(N) tN + o(t). \tag{II.22}$$

Hence (II.21) and (II.22) together imply (II.19). □

Next we take a look at the behavior at infinity of the minimizing densities ρ_N. At least for $N < N_c$ one gets exponential decay.

Proposition II.11: (a) Let $\mu < 0$, *which is equivalent to* $N < N_c$, *then for every* $\delta > 0$, *with* $\mu < -\delta$, *there exists a constant* M, *such that, for the corresponding minimizer* $\psi = \rho_N^{1/2}$,

$$\psi \leqslant M e^{-\delta^{1/2}|x|}. \tag{II.23}$$

(b) Let $N = N_c$, *then for every* $\delta < N_c - Z$ *there is a constant* M, *such that*

$$\psi \leqslant M e^{-2(\delta|x|)^{1/2}}. \tag{II.24}$$

Proof: Note that we have not yet shown that $\psi \to 0$ as $|x| \to \infty$ in a strong sense, for we only know $\psi \in L^2$. From Eq. (II.18) we derive $-\Delta\psi \leqslant V\psi$, which implies $(-\Delta + I)\psi \leqslant (V + I)\psi$. Since we know $(V+I)\psi \in L^2$, recall that $(V+I) \in L^2 + L^\infty$ and $\psi \in L^2 \cap L^\infty$, we conclude from

$$\psi \leqslant (-\Delta + I)^{-1}[(V + I)\psi], \tag{II.25}$$

that $\psi \to 0$ at infinity, e.g., from the well-known fact (Ref. 15, Lemma II.25) that the convolution $f * g$ of two functions $f \in L^p, g \in L^g$, with $1/p + 1/q = 1$, goes to 0 at infinity.

(a) (See Ref. 16, Theorem 7.24.) Let $\delta<-\mu$. From (II.18) we get

$$(-\Delta+\delta)\psi=[-\tau_B'(\psi^2)+\varphi+\mu+\delta]\psi \tag{II.26}$$

and

$$\psi=(-\Delta+\delta)^{-1}[-\tau_B'(\psi^2)+\varphi+\mu+\delta]\psi. \tag{II.27}$$

Since $V,\psi\to 0$ as $|x|\to\infty$, there is an r_1, such that $[-\tau_B'(\psi^2)+\varphi+\mu+\delta]<0$ for $|x|>r_1$. This implies

$$\psi(x)\leqslant\int_{|y|\leqslant r_1}(4\pi|x-y|)^{-1}e^{-\delta^{1/2}|x-y|}([-\tau_B'(\psi^2)+\varphi+\mu+\delta]\psi)(y)\mathrm{d}y<\infty, \tag{II.28}$$

and (II.23) with

$$M=\sup_x e^{\delta^{1/2}r_1}\int_{|y|\leqslant r_1}(4\pi|x-y|)^{-1}([-\tau_B'(\psi^2)+\varphi+\mu+\delta]\psi)(y)\mathrm{d}y. \tag{II.29}$$

(b) This follows directly from (II.17) and the fact that $\psi\to 0$ as $|x|\to\infty$. □

We state a final proposition concerning the behavior of the chemical potential at $N=0$ (which is $-\infty$ in the usual TF theory), because of the simple and illuminating proof.

Proposition II.12: Let $e_0=-\frac{1}{4}Z^2$ be the smallest eigenvalue of the Schrödinger operator $-\Delta-Z/|x|$. Then

$$\mu(0)=\frac{\mathrm{d}}{\mathrm{d}N}E(N)_{N=0}=e_0. \tag{II.30}$$

Proof (cf. Ref. 6, Lemma 15): Let $\varphi(x)$ be the normalized eigenvector of $-\Delta-Z/|x|$ belonging to the lowest eigenvalue $e_0=-\frac{1}{4}Z^2$ and let $\rho_N=N\varphi(x)^2$. Then

$$\begin{aligned}E(N)\leqslant\mathcal{E}^{\mathrm{MTFW}}[\rho_N]&=\int|\nabla\rho_N^{1/2}|^2-\int V\rho_N+\int\tau_B(\rho_N)+D(\rho_N,\rho_N)\\&=N[(\varphi,-\Delta\varphi)-Z(\varphi,|x|^{-1}\varphi)]\\&\quad+\int\tau_B(\rho_N)+D(\rho_N,\rho_N)\leqslant Ne_0+C_1N^{5/3}+C_2N^2.\end{aligned}$$

On the other hand we have

$$E(N)\geqslant\inf_{\int\rho=N}\left\{\int|\nabla\rho^{1/2}|^2-\int V\rho\right\}=N\inf\ \mathrm{spec}\{-\Delta-Z|x|^{-1}\}=Ne_0,$$

which altogether implies

$$\lim_{N\to+0}\frac{E(N)}{N}=e_0.$$

Taking into account that $E(0)=0$ this is equivalent to (II.30). □

B. The Scott correction

If one takes a look at Lieb's proof[16] that in the usual TF theory without magnetic fields the von Weizsäcker term produces the Scott correction, one realizes that the main correction comes from distances of order Z^{-1} from the nucleus. It is thus reasonable to guess that in the MTF theory the

von Weizsäcker term produces the Scott correction as long as ρ^{MTF}, the density corresponding to the MTF energy (1.6), is well approximated by the usual TF density ρ^{TF} up to distances of order Z^{-1} from the nucleus. This condition is equivalent to the demand that $\tau_B'(\rho)$ is proportional to $\rho^{2/3}$ for $r\sim Z^{-1}$ and this is the case for $B\ll Z^2$. In other words, for $B\ll Z^2$ the von Weizsäcker term produces a Z^2 correction at the distance of order Z^{-1} from the nucleus. At the edge of the MTF atom, the radius is known[1] to be proportional to $Z^{1/5}B^{-2/5}$ and the lowest Landau band is occupied, which leads to $\tau_B'(\rho^{\mathrm{MTF}})=4\pi^4B^{-2}(\rho^{\mathrm{MTF}})^2$ in the outer region. Hence, one computes very easily, by using ρ^{MTF} as comparison density, that the correction coming from the edge of the atom is of order $B^{4/5}Z^{3/5}$.

Proof of Theorem I.4: First of all notice that there is an r_B, such that for $r\geqslant r_B$ the density ρ^{MTF} corresponds to the lowest Landau band, i.e.,

$$\tau_B'(\rho^{\mathrm{MTF}}(r))=\frac{4\pi^4}{B^2}(\rho^{\mathrm{MTF}}(r))^2 \quad \text{for} \quad r\geqslant r_B, \tag{II.31}$$

and for $r\leqslant r_B$ we have

$$\kappa_3(\rho^{\mathrm{MTF}}(r))^{2/3}\leqslant \tau_B'(\rho^{\mathrm{MTF}}(r))\leqslant \kappa_1(\rho^{\mathrm{MTF}}(r))^{2/3}, \tag{II.32}$$

with $\kappa_3=0.83(3\pi^2)^{2/3}$, which we get from Ref. 1, Lemma 4.1. Using (II.31) and (II.32) one realizes that if one fixes any $\varepsilon>0$ with $B\leqslant Z^{2-\varepsilon}$ there is a $\delta>0$ such that $r_B\geqslant Z^{\delta-1}$.

First we treat the case $B\leqslant Z^{7/4}$.

Lower bound: We know from Sec. II A that there exists a ρ_0 satisfying

$$E^{\mathrm{MTFW}}=\mathcal{E}^{\mathrm{MTFW}}[\rho_0]=\int \tau_B(\rho_0)+\int |\nabla\rho_0^{1/2}|^2-\int V\rho_0+D(\rho_0,\rho_0). \tag{II.33}$$

Denote $Z|x|^{-1}=V=\tilde{V}+H$, with

$$H=Z/r-Z^2/b \quad \text{for } r<b/Z \quad \text{and } 0 \quad \text{otherwise},$$

$$\tilde{V}=Z^2/b \quad \text{for } r<b/Z \quad \text{and } Z/r \quad \text{otherwise}.$$

Now let us rewrite the energy functional in the following way:

$$\mathcal{E}^{\mathrm{MTFW}}[\rho_0]=\int \tau_B(\rho_0)-\int \rho_0^{1/2}\Delta\rho_0^{1/2}-\int \rho_0^{1/2}\tilde{V}\rho_0^{1/2}-\int H\rho_0+D(\rho_0,\rho_0).$$

Observe that $-\Delta-H\geqslant \inf_\rho\{(\nabla\rho^{1/2},\nabla\rho^{1/2})-(\rho^{1/2},H\rho^{1/2})\}$, which by using Sobolev's inequality can be bounded from below by

$$-\Delta-H\geqslant \inf_\rho\{\|\rho\|_3^3-\|\rho\|_3\|H\|_{3/2}\}.$$

Since $\|H\|_{3/2}\sim b$ we can guarantee $-\Delta-H\geqslant 0$ with b small enough. Choosing such a b we derive

$$E^{\mathrm{MTFW}}\geqslant \mathcal{E}^{\mathrm{MTF}}[\rho_0,\tilde{V}]\geqslant E^{\mathrm{MTF}}[\tilde{V}]=\int \tau_B(\tilde{\rho})-\int \tilde{\rho}\tilde{V}+D(\tilde{\rho},\tilde{\rho})\geqslant E^{\mathrm{MTF}}[V]+\int H\tilde{\rho}.$$

The density $\tilde{\rho}$ minimizes $\mathcal{E}^{\mathrm{MTF}}[\rho,\tilde{V}]$ and therefore fulfills the TF equation:

$$\tau_B'(\tilde{\rho})=\tilde{V}-\tilde{\rho}*|x|^{-1}.$$

From Ref. 1, Lemma 4.1 we know that (II.32) is valid for all t with $t \geqslant (1/\sqrt{2}\pi^2)\, B^{3/2}$. So it is easy to see that $\tilde{\rho}$ fulfills (II.32) at least for $r \leqslant 1/Z$ and $B \leqslant Z^2$. Therefore we get that $\int H\tilde{\rho} = O(Z^2)$ for $B \leqslant Z^2$, which yields

$$E^{\mathrm{MTFW}} \geqslant E^{\mathrm{MTF}} + O(Z^2). \tag{II.34}$$

Upper bound: In order to get an upper bound we use a variational density ρ in the following way:

$$\rho(r) = \begin{cases} \overline{\rho}^{\mathrm{TF}}(Z^{-1}) & \text{for } r < Z^{-1} \\ \overline{\rho}^{\mathrm{TF}}(r) & \text{for } Z^{-1} \leqslant r \leqslant r_B \\ \rho^{\mathrm{MTF}}(r) & \text{for } r \geqslant r_B, \end{cases} \tag{II.35}$$

where $\overline{\rho}^{\mathrm{TF}}$ indicates that in the surrounding of $r = 1/Z$ we use the usual TF density ρ^{TF}. Only in the region $r_1 \leqslant r \leqslant r_B$, with $r_1 \geqslant 1/Z^{1-\delta}$, we eventually have to modify ρ^{TF}, such that

$$|E^{\mathrm{MTF}} - \mathcal{E}^{\mathrm{MTF}}[\rho]| \leqslant O(Z^2). \tag{II.36}$$

In fact we can construct ρ by following the way of Ref. 3, and taking a (at least C^2) modification W of the effective potential ϕ^{MTF} and defining $4\pi\overline{\rho}^{\mathrm{TF}} = \Delta(W - Z|x|^{-1})$. We set $W = \phi^{\mathrm{TF}}$ for $r \leqslant r_1$. This radius r_1 is given by the maximum value of $\overline{r}$ such that

$$\int_{1/Z \leqslant |x| \leqslant \overline{r}} |\nabla(\phi^{\mathrm{TF}} - \phi^{\mathrm{MTF}})|^2 \leqslant o(Z^2), \tag{II.37}$$

since[3] (0.55) tells us that

$$|E^{\mathrm{MTF}} - \mathcal{E}^{\mathrm{MTF}}[\rho]| = O(Z^2) + C \int_{1/Z \leqslant |x| \leqslant r_B} |\nabla(W - \phi^{\mathrm{MTF}})|^2. \tag{II.38}$$

For $B \ll Z^2$, r_1 can be guaranteed to be $\gg 1/Z$ (see Ref. 3, Proposition 1.6).

By this construction we are sure that the gradient term produces a Z^2-correction at the radius $r \sim 1/Z$. For larger r we just have to choose W such that the oscillations are not too large. For $r \geqslant r_B$ let W be equal to ϕ^{MTF} which is even C^∞ as long as $\phi^{\mathrm{MTF}} > 0$. Between r_1 and r_B we just have to construct W such that

$$\int_{1/Z \leqslant |x| \leqslant r_B} |\nabla(W - \phi^{\mathrm{MTF}})|^2 \leqslant o(Z^2) \tag{II.39}$$

under the condition that W is at least $\in C^2$ (but only $\notin C^3$ on a finite set of surfaces $r = |x|$) and

$$\int_{r_1 \leqslant |x| \leqslant r_B} |\nabla(\Delta W)^{1/2}|^2 \leqslant o(Z^2), \tag{II.40}$$

which is arrived by smoothing ϕ^{MTF}. So ρ is at least continuous and we get

$$\int_{r \leqslant r_B} |\nabla \rho^{1/2}|^2 = O(Z^2), \tag{II.41}$$

$$\int_{r \geqslant r_B} |\nabla \rho^{1/2}|^2 = O(B^{4/5} Z^{3/5}). \tag{II.42}$$

For $B \leqslant Z^{7/4}$ this leads to

$$E^{\mathrm{MTFW}} \leqslant E^{\mathrm{MTF}} + O(Z^2).$$

In the case $B \geqslant Z^{7/4}$ the correction from the edge of the atom overcomes the Scott correction and using a similar variational density as in (II.35) (recall that for $B \sim Z^2$, $r_B \sim 1/Z$) we get the simple estimate

$$0 \leqslant E^{\mathrm{MTFW}} - E^{\mathrm{MTF}} \leqslant O(B^{4/5} Z^{3/5}). \tag{II.43}$$

□

III. GRADIENT CORRECTIONS FOR STF-TYPE THEORIES

A. The functional (I.50)

The starting point in this section is the functional

$$\mathcal{E}^{\mathrm{IT}}[\rho] = \frac{1}{B^2}\int \rho^3 + \frac{1}{B^3}\int (\nabla \rho^{3/2})^2 - \int V\rho + D(\rho,\rho), \tag{III.1}$$

with V and $D(\rho,\rho)$ defined as in (I.3). Compared to (I.50) we rewrite

$$\frac{1}{B^3}\int \rho(\nabla\rho)^2 = \frac{4}{9B^3}\int (\nabla \rho^{3/2})^2,$$

and for simplicity forget about the numerical constant, which does not affect any mathematical statements. The corresponding energy is defined as

$$E(N,Z,B) = \inf\left\{ \mathcal{E}^{\mathrm{IT}}[\rho] \,\middle|\, \rho \in \tilde{D}, \int \rho \leqslant N \right\}, \tag{III.2}$$

where the domain $\tilde{D}$ is given by

$$\tilde{D} = \{\rho \,|\, \rho \geqslant 0, \rho \in L^1 \cap L^3, \nabla \rho^{3/2} \in L^2\}.$$

In analogy to Sec. II we first consider the problem

$$\mathrm{Min}\{\mathcal{E}^{\mathrm{IT}}[\rho] \,|\, \rho \in D\}, \tag{III.3}$$

with

$$D = \{\rho \,|\, \rho \geqslant 0, \rho \in L^3, \nabla \rho^{3/2} \in L^2, D(\rho,\rho) < \infty\} \tag{III.4}$$

and show that the minimum is achieved for a unique ρ_0. By means of the corresponding Euler–Lagrange equation we shall deduce that ρ_0 is in $L^1(\mathbb{R}^3)$, more precisely $\int \rho_0 = Z$.

First of all, we collect some properties of (III.1).

Lemma III.1: There are positive constants α, C, so that

$$\mathcal{E}^{\mathrm{IT}}[\rho] \geqslant \alpha\left(\|\rho\|_3 + \int \tau_B(\rho) + \|\nabla \rho^{3/2}\|_2^2 + D(\rho,\rho) \right) - C, \tag{III.5}$$

Proof: This is a consequence of Lemma 2 in Ref. 6, which tells us that for every $\varepsilon > 0$ there exists a constant C_ε so that

$$\int V\rho \leqslant \varepsilon \|\rho\|_3 + C_\varepsilon D(\rho,\rho)^{1/2}$$

for every $\rho \geqslant 0$. □

Lemma III.2: $\mathcal{E}^{\mathrm{IT}}[\rho]$ is strictly convex in ρ.

Proof: This follows immediately from the strict convexity of $(\nabla\rho^{3/2})^2$ and $\mathcal{E}^{\mathrm{STF}}$. □

By means of these Lemmas we can prove the existence of a unique minimizer in $\tilde{D}$.

Proposition III.3: The minimum of $\mathcal{E}^{\mathrm{IT}}[\rho]$ is achieved by a unique $\rho_0 \in \tilde{D}$.

Proof: The proof is similar to that of Proposition II.3. Let ρ_n be a minimizing sequence. By Lemma III.1 we have

$$\|\rho_n\|_3^3 \leqslant C, \quad \|\nabla\rho_n^{3/2}\|_2^2 \leqslant C, \quad D(\rho_n,\rho_n) \leqslant C. \tag{III.6}$$

With Banach–Alaoglu theorem we therefore extract a subsequence, still denoted by ρ_n, such that

$$\rho_n \rightharpoonup \rho_0 \quad \text{weakly in } L^3, \tag{III.7}$$

$$\nabla\rho_n^{3/2} \rightharpoonup \nabla\rho_0^{3/2} \quad \text{weakly} \quad \text{in } L^2. \tag{III.8}$$

Actually (III.6) implies $\nabla\rho_n^{3/2} \rightharpoonup f$ weakly in L^2, for a function $f \in L^2$. But for $\varphi \in C_c^\infty$ we conclude with (III.7)

$$\int f\varphi = \lim_{n\to\infty} \int \nabla\rho_n^{3/2}\varphi = -\lim_{n\to\infty} \int \rho_n^{3/2}\nabla\varphi = -\int \rho_0^{3/2}\nabla\varphi = \int \nabla\rho_0^{3/2}\varphi. \tag{III.9}$$

Furthermore $\rho_n^{3/2}$ is bounded in H^1, which implies that there exists a further subsequence, again denoted as ρ_n, with

$$\rho_n^{3/2} \to \rho_0^{3/2} \quad \text{a.e.}$$

[This relies on the fact that for a smooth bounded domain Ω, $H^1(\Omega)$ is relatively compact in $L^2(\Omega)$.] Hence, using Fatou's Lemma we get

$$\liminf D(\rho_n,\rho_n) \geqslant D(\rho_0,\rho_0),$$

and by the weak lower semicontinuity of L^p-norms we deduce

$$\liminf \int (\nabla\rho_n^{3/2})^2 \geqslant \int (\nabla\rho_0^{3/2})^2,$$

$$\liminf \int \rho_n^3 \geqslant \int \rho_0^3.$$

In order to prove $\int V\rho_n \to \int V\rho_0$, we decompose $V = V_1 + V_2$ such that both functions are in C^∞. With $V_1 \in L^{3/2}$, (III.7) implies

$$\int V_1\rho_n \to \int V_1\rho_0.$$

On the other hand V_2 fulfills

$$\int V_2\rho_n = \int V_2[-\Delta(\rho_N * |x|^{-1})] = \int (-\Delta V_2)(\rho_n * |x|^{-1}),$$

which converges to

$$\int (-\Delta V_2)(\rho_0 * |x|^{-1}) = \int V_2\rho_0$$

for $-\Delta V_2 \in L^{6/5}$ and $\|\rho_n * |x|^{-1}\|_6$ is bounded. [Note that the boundedness of $\|\rho_n * |x|^{-1}\|_6$ together with (III.7) imply that $\rho_n * |x|^{-1} \rightharpoonup \rho_0 * |x|^{-1}$ weakly in L^6.]

Thus

$$\liminf \mathcal{E}^{\mathrm{IT}}[\rho_n] \geqslant \mathcal{E}^{\mathrm{IT}}[\rho_0].$$

The uniqueness is an immediate consequence of the strict convexity of the functional. □

For this minimizing ρ_0 we can derive an Euler–Lagrange equation.

Proposition III.4: The minimizing $\psi = \rho_0^{3/2}$ satisfies

$$(-\Delta + B)\psi = \frac{B^3}{3}\varphi\psi^{-1/3}, \tag{III.10}$$

with $\varphi = V - \psi^{2/3} * 1/|x|$, in the sense of distributions, on the set where $\psi > 0$.

Proof: The uniqueness of the minimum, the spherical symmetry of the functional (III.1), and the fact that $\psi \in H^1$ imply the continuity of ψ away from the origin. With $\varphi \in L^2_{\mathrm{loc}}$ Eq. (III.10) has a meaning in the sense of distributions on the domain $\{x | \psi(x) > 0\}$. Consider the set

$$\overline{D} = \{\eta | \eta \in H^1, D(\eta^{2/3}, \eta^{2/3}) < \infty\}.$$

If $\eta \in \overline{D}$, then $\rho = (\eta^2)^{1/3} \in D$ and

$$\mathcal{E}^{\mathrm{IT}}[\rho] = \frac{1}{B^2}\int \eta^2 + \frac{1}{B^3}\int (\nabla\eta)^2 - \int V\eta^{2/3} + D(\eta^{2/3}, \eta^{2/3}) \equiv \phi(\eta).$$

For all $\eta \in \overline{D}$ we find $\phi(\psi) \leqslant \phi(\eta)$.

Let $\xi \in C_0^\infty$, then using $(\mathrm{d}/\mathrm{d}t)\,\phi(\psi + t\xi)|_{t=0} = 0$ we infer

$$-\int \psi\Delta\xi + B\int \psi\xi = \frac{B^3}{3}\int \varphi\psi^{-1/3}\xi.$$

□

Proposition III.5: ψ is bounded and ψ is in C^∞ away from the origin and possible points with $\psi(x) = 0$.

Proof: Denote

$$\Omega_\epsilon = \{x | \psi(x) \geqslant \epsilon\}.$$

On this domain we have

$$(-\Delta + B)\psi = f,$$

with $f \in L^2_{\mathrm{loc}}$, since $\varphi \in L^2_{\mathrm{loc}}$. So we conclude from standard elliptic arguments (e.g., [LL] Sec. 10 that ψ is bounded, hence continuous everywhere. From

$$\Delta\varphi = 4\pi(\psi^{2/3}(x) - Z\delta(x))$$

we get the two times differentiability of φ away from the origin and as long as $\psi > 0$. By means of (III.10) and a standard bootstrap argument we conclude $\psi \in C^\infty$. □

Theorem III.6: $\int \psi^{2/3} = Z$.

Proof: Suppose by contradiction $\int \psi^{2/3} = \lambda \neq Z$. We do not assume λ to be finite. Then, as in (II.14), we get that there is some r_1 and an $\epsilon > 0$, such that

$$|\varphi(x)| \geqslant \epsilon/r = \epsilon/|x|, \tag{III.11}$$

for $|x| \geqslant r_1$. [Actually (III.11) follows for $\lambda > Z$. For $\lambda < Z$ we use Newton's theorem.]

We know $\psi \in L^2$ and $\psi(x) = \psi(|x|) = \psi(r)$. Therefore, let us choose $\mathcal{M} = \{r | \psi(r) \leqslant M/r^{3/2}\} \subset \mathbb{R}$ for an arbitrary but fixed $M > 0$. This leads to

$$\infty > \int_{\mathbb{R}^3} |\psi(x)|^2 dx = 4\pi \int_{\mathcal{M}} |\psi(r)|^2 r^2 dr + 4\pi \int_{\mathcal{M}' = \mathbb{R} \setminus \mathcal{M}} |\psi(r)|^2 r^2 dr$$

$$\geqslant 4\pi \int_{\mathcal{M}} |\psi(r)|^2 r^2 dr + 4\pi M^2 \int_{\mathcal{M}'} 1/r dr. \tag{III.12}$$

Consequently $\int_{\mathcal{M}'} 1/r dr < \infty$ and $\int_{\mathcal{M}} 1/r dr = \infty$.

Next we take an auxiliary function $\nu(r) = 1/(1+r^2)$, which is obviously in $H^1(\mathbb{R}^3)$, multiply (III.10) by $\nu(|x|)$ and integrate over $\mathbb{R}^3$. We get

$$\int \nabla \psi \cdot \nabla \nu + B \int \psi \nu = \frac{B^3}{3} \int \varphi \psi^{-1/3} \nu. \tag{III.13}$$

It is a well known fact that φ changes sign at most once. So, either $\varphi(r) > \epsilon/r$ and the right side of (III.13) reads

$$\int_{\mathbb{R}^3} \varphi \psi^{-1/3} \nu \geqslant \epsilon M^{-1/3} \int_{\mathcal{M}} \nu(r) r^{-1/2} r^2 dr = \infty, \tag{III.14}$$

or $\varphi(r) \geqslant -\epsilon/r$ for $r \leqslant r_1$, then

$$\int_{\mathbb{R}^3} \varphi \psi^{-1/3} \nu \leqslant \text{const.} - \epsilon M^{-1/3} \int_{\mathcal{M} \cap |x| \geqslant r_1} \nu(r) r^{-1/2} r^2 dr = -\infty. \tag{III.15}$$

Both cases are a contradition to ψ and $\nu \in H^1$. □

Remark III.7: Theorem III.6 is interesting, since gradient corrections usually give rise to binding of additional electrons. The reason that this is not the case in III.6 relies on the negative exponent of ψ on the right-hand side of (III.10). This fact forces the potential φ to fall off much faster than $O(1/r)$.

Since we only consider atoms with a point nucleus, we get the following remark for the minimizing ρ_0.

Proposition III.8: ρ_0 is a symmetric nonincreasing function of $|\mathbf{x}|$.

Proof: As we have already argued, the symmetry of ρ_0 follows from the symmetry of the functional and the uniqueness of ρ_0.

Denote ρ_0^* the nonincreasing rearrangement of ρ_0. (For a definition see, e.g., Ref. 14, Sec. 3.3.) From the fact that $\int \rho_0 \leqslant Z$ and Ref. 16, Theorem 2.12 we get $\mathcal{E}^{\text{STF}}[\rho_0^*] \leqslant \mathcal{E}^{\text{STF}}[\rho_0]$.[14] Lemma 7.17 implies

$$\int |\nabla (\rho_0^{3/2})^*|^2 \leqslant \int |\nabla (\rho_0^{3/2})|^2 \tag{III.16}$$

and again from Ref. 14, 3.3 (v) we get $(\rho_0^{3/2})^* = (\rho_0^*)^{3/2}$, which proves the statement. □

Proposition III.9: ψ has compact support.

Proof: Inserting $\Delta \varphi = \psi^{2/3}$ into (III.10) yields the following equation for the potential, away from the origin:

$$(\Delta \varphi)^{1/2} [\Delta (\Delta \varphi)^{3/2}] = (\Delta \varphi)^2 - \varphi, \tag{III.17}$$

where we replaced the constants by one. Since φ is spherical symmetric we can use the ansatz $\varphi = (1/r)\chi(r)$ and obtain by (III.17) the following fourth-order equation:

$$2\left[\frac{1}{r^4}\chi''^2-\frac{2}{r^3}\chi''\chi'''+\frac{1}{r^2}\chi'''^2\right]^2+\left[\frac{1}{r}\chi''\right]^2\left[\frac{1}{r}\chi''''\right]^2+\left[\frac{1}{r^4}\chi''^2-\frac{2}{r^3}\chi''\chi'''+\frac{1}{r^2}\chi'''^2\right]\left[\frac{1}{r}\chi''\right]\left[\frac{1}{r}\chi''''\right]$$
$$=\frac{4}{9}\left[\frac{1}{r^2}\chi^2-\frac{2}{r^3}\chi\chi''^2+\left(\frac{1}{r}\chi''\right)^4\right]. \tag{III.18}$$

We can see that in the surrounding of each point $r_0>0$ there exists a local solution

$$\chi=a_6(r-r_0)^6+O((r-r_0)^7),$$

with $a_6=(\text{const})r_0^2$. Since $\chi\equiv 0$ is also a solution of (III.18), every composed function

$$\chi=a_6(r-r_0)^6+O((r-r_0)^7) \quad \text{for } r\leqslant r_0, \quad \chi\equiv 0 \quad \text{for } r>r_0$$

is a local solution around r_0.

Away from 0 the solutions can be uniquely continued up to $r=0$. Hence, there exists a solution χ and a $r_1>0$, such that $\chi(0)=Z$ and $\operatorname{supp}\chi=[0,r_1]$.

Repeating the argument of Ref. 16, Theorem 2.6, one can show that a solution of (III.10), with $\psi\in H^1$ and $\int\psi^{2/3}<\infty$, $(\psi^2)^{1/3}$ uniquely determines the minimum of the functional (III.1). Therefore $\chi(r)$ uniquely determines the self-consistent potential $\phi=\chi/r$, which implies that $\psi=\rho_0^{3/2}=(\Delta\phi)^{3/2}$ has compact support, too. □

Remark III.10: The preceding three propositions are equivalent to those for the STF theory. This confirms that the $\rho(\nabla\rho)^2$ term only amounts to changes close to the nucleus.

By the convexity of the functional (III.1) one easily derives the following properties for the energy $E^{\mathrm{IT}}(N,Z,B)$:

Proposition III.11: $E^{\mathrm{IT}}(N,Z,B)$ is convex as a function of N and strictly monoton decreasing on the interval $[0,Z]$. For $N>Z$ we get $E^{\mathrm{IT}}(N,Z,B)=E^{\mathrm{IT}}(Z,Z,B)$.

Next we prove Theorem I.7.

Proof of Theorem I.7: Upper bound: We use the comparison density $\overline{\rho}$, with

$$\overline{\rho}(r)=\begin{cases}\rho^{\mathrm{STF}}(l_B) & \text{for } r\leqslant l_B=B^{-1/2}\\ \rho^{\mathrm{STF}}(r) & \text{otherwise}\end{cases} \tag{III.19}$$

and immediately get

$$E^{\mathrm{IT}}\leqslant E^{\mathrm{STF}}+O(Z^{3/2}B^{1/4}).$$

Lower bound: Let ρ be the minimizer of the energy (III.2), for given B,Z,N. We can rewrite

$$E^{\mathrm{IT}}=\mathcal{E}^{\mathrm{IT}}[\rho]=\frac{\kappa}{B^2}\int\rho^3+\frac{1}{B^3}\int|\nabla\rho^{3/2}|^2-\int\tilde{H}\rho-\int\tilde{V}\rho+D(\rho,\rho),$$

where $\tilde{H}=Z/r-B^{1/2}Z/b$ for $r\leqslant bl_B$ and 0 otherwise, $\tilde{V}=B^{1/2}Z/b$ for $r\leqslant bl_B$ and Z/r otherwise. Looking at the term

$$\frac{1}{B^3}\int|\nabla\rho^{3/2}|^2-\int\tilde{H}\rho,$$

we infer by means of the Sobolev inequality the estimate

$$\frac{1}{B^3}\int|\nabla\rho^{3/2}|^2-\int\tilde{H}\rho\geqslant\frac{4}{9B^3}\|\rho\|_9^3-\|\tilde{H}\|_{9/8}\|\rho\|_9. \tag{III.20}$$

Since $\|\tilde{H}\|_{9/8}\sim b^{15/9}$ we can choose b such that (III.20)>0. Hence

$$E^{\mathrm{IT}} \geqslant \frac{\kappa}{B^2}\int \rho^3 - \int \tilde{V}\rho + D(\rho,\rho) \geqslant E^{\mathrm{STF}}[\tilde{V}] = \mathcal{E}^{\mathrm{STF}}[\tilde{V},\tilde{\rho}] \geqslant E^{\mathrm{STF}} + \int \tilde{\rho}\tilde{H}.$$

Since $\int \tilde{\rho}\tilde{H} = O(Z^{3/2}B^{1/4})$ we prove the proposition. □

We see that the main contribution of the correction (1.50) comes from the radius $l_B = B^{-1/2}$, in other words the gradient correction repairs the infinity of the STF density at a distance $B^{-1/2}$ from the nucleus. This infinity stems from the fact that in the STF theory the full $|x|^{-1}$ potential is involved, although particles in the lowest Landau band, which are smeared over a radius of at least $B^{-1/2}$, never see the full Coulomb singularity.

Moreover, the Tomishima–Shinjo correction (1.46) orthogonal to the magnetic field remedies the singularity of the Coulomb potential in a similar way as the isotropic gradient term. We will see that the same effect, as caused by (III.1) and (1.46), is also naturally obtained by using the DSTF functional.

B. A discrete von Weizsäcker functional

1. The DSTF functional

First of all we are going to collect some information about the DSTF functional (which is rigorously proved in a companion work). The DSTF functional

$$\mathcal{E}^{\mathrm{DSTF}}[\rho] = \sum_{m\in\mathbb{N}_0}\left(\kappa\int \rho_m^3(z) - \int V_m(z)\rho_m(z)\mathrm{d}z\right) + \tilde{D}(\rho,\rho), \tag{III.21}$$

with V_n and $V_{m,n}$ as in (I.35), is defined on the domain

$$D = \left\{\rho \,\middle|\, \sum_m \int \rho_m^3 < \infty, \sum_m \int \rho_m < \infty, \tilde{D}(\rho,\rho) < \infty\right\} \tag{III.22}$$

with corresponding energy

$$E^{\mathrm{DSTF}}(N,Z,B) = \inf\left\{\mathcal{E}^{\mathrm{DSTF}}[\rho] \,\middle|\, \rho\in D \text{ and } \sum_m \int \rho_m \leqslant N\right\}. \tag{III.23}$$

Following the considerations of Ref. 1 one can easily see that (III.21) is convex and bounded from below on $D^N = \{\rho | \rho \in D, \Sigma_m \int \rho_m \leqslant N\}$ and derive the following Theorem:

Theorem III.12: *With $N \leqslant Z$ fixed there exists a unique minimizer ρ^N for $\mathcal{E}^{\mathrm{DSTF}}$, under the restriction $\Sigma_m \int \rho_m \leqslant N$,* i.e., *$E^{\mathrm{DSTF}}(N,Z,B) = \mathcal{E}^{\mathrm{DSTF}}[\rho^N]$. Moreover, ρ^N satisfies $\Sigma_m \int \rho_m^N = N$.*

Furthermore each minimizer ρ^N obeys the coupled TF equations

$$3\kappa(\rho_m^N(z))^2 = \left[ZV_m(z) - \sum_n \int V_{m,n}(z-z')\rho_n^N(z') + \mu(N)\right]_+ \forall (m\in\mathbb{N}_0), \tag{III.24}$$

where $\mu(N)$ is the Lagrange parameter belonging to the restriction $\Sigma_m \int \rho_m = N$ and $[\ ]_+$, with $[t]_+ = t$ for $t \geqslant 0$ and $[t]_+ = 0$ otherwise, corresponds to the fact that the functional is only varied over positive functions, i.e., $\rho_n \geqslant 0 \forall n \in \mathbb{N}_0$.

By means of the notation

$$ZV_m(z) - \sum_n \int V_{m,n}(z-z')\rho_n^N(z') + \mu(N) = \varphi_{\mathrm{eff}}^{(m)}(z) \tag{III.25}$$

and inserting in the TF equation we can rewrite the energy $E^{\mathrm{DSTF}}(N,Z,B) = \mathcal{E}^{\mathrm{DSTF}}[\rho^N]$ as

$$E^{\mathrm{DSTF}}(N,Z,B)=\sum_m \int\int [p^2-\varphi_{\mathrm{eff}}^{(m)}(z)]_- \frac{\mathrm{d}p\,\mathrm{d}z}{2\pi}+N\mu-\tilde{D}(\rho^N,\rho^N). \tag{III.26}$$

2. Semiclassical approximation of E^Q_{conf}

First of all we want to state a useful theorem concerning the sum of the negative eigenvalues of the one-particle operator $\Pi_0[H_A+\varphi]\Pi_0$, where $H_A=((-i\nabla+\mathbf{A}(x))\cdot\sigma)^2$ and φ is an axially symmetric potential $\varphi(r,z)$ with $r=|\mathbf{x}_\perp|$.

Theorem III.13: *Let $\varphi=\varphi(r,z)$ be axially symmetric. Then one can write the trace of the negative part of the operator $\Pi_0[H_A+\varphi]\Pi_0$ as the sum of one-dimensional traces,* i.e.,

$$\mathrm{Tr}[\Pi_0[H_A+\varphi]\Pi_0]_-=\sum_{m\in\mathbb{N}_0}\mathrm{Tr}_{L^2(\mathbb{R})}[-\partial_z^2+\varphi^{(m)}(z)]_-, \tag{III.27}$$

with

$$\varphi^{(m)}(z)=\int \varphi(x)|\phi_m(\mathbf{x}_\perp)|^2\mathrm{d}\mathbf{x}_\perp. \tag{III.28}$$

Proof: Let L_z denote the angular momentum operator parallel to the magnetic field. Since $\varphi=\varphi(r,z)$, we have

$$[\Pi_0[H_A+\varphi]\Pi_0,L_z]=0, \tag{III.29}$$

which implies that the eigenvectors of the operator $\Pi_0[H_A+\varphi]\Pi_0$ are of the form $|m,i\rangle=\phi_m(\mathbf{x}_\perp)f_m^i(z)$.

Hence we can write the sum of the negative eigenvalues as

$$\begin{aligned}\mathrm{Tr}[\Pi_0[H_A+\varphi]\Pi_0]_-&=\sum_{m,i}\langle m,i|[\Pi_0[H_A+\varphi]\Pi_0]|m,i\rangle\\&=\sum_m\left(\sum_i (f_m^i,[-\partial_z^2+\varphi^{(m)}(z)]f_m^i)\right),\end{aligned} \tag{III.30}$$

showing that the f_m^i's are the eigenvectors of the one-dimensional operator $-\partial_z^2+\varphi^{(m)}(z)$.

Proposition III.14: Let N,Z,B be fixed. Then

$$E^Q_{\mathrm{conf}}(N,Z,B)\leqslant E^{\mathrm{DSTF}}(N,Z,B)+R_1+R_2+R_3, \tag{III.31}$$

$$E^Q_{\mathrm{conf}}(N,Z,B)\geqslant E^{\mathrm{DSTF}}(N,Z,B)-R_1-C\int\rho_\psi^{4/3}, \tag{III.32}$$

with

$$R_1=\left|\sum_{m\in\mathbb{N}_0}\left(\mathrm{Tr}_{L^2(\mathbb{R})}[-\partial_z^2-\varphi_{\mathrm{eff}}^{(m)}(z)]_- -\int\int[p^2-\varphi_{\mathrm{eff}}^{(m)}(z)]_-\frac{\mathrm{d}p\,\mathrm{d}z}{2\pi}\right)\right|, \tag{III.33}$$

$$R_2=D(\rho_\psi-\tilde{\rho},\rho_\psi-\tilde{\rho}), \tag{III.34}$$

$$R_3=\sum_{\lambda_N<\lambda_i<\mu(N)}|(\lambda_i-\mu(N))|, \tag{III.35}$$

where λ_i and $\tilde{\rho}$ are defined in the proof.

Proof: Upper bound: First of all we note that for any Slater determinant ψ and fixed integer N we get

$$E^Q_{\mathrm{conf}} \leqslant (\psi, \Pi_0^N H_N \Pi_0^N \psi) \leqslant \sum_{i=1}^{N} (\psi, \Pi_0^N [H_A(\mathbf{x}_i) - Z|\mathbf{x}_i|^{-1}] \Pi_0^N \psi) + D(\rho_\psi, \rho_\psi), \qquad \text{(III.36)}$$

with

$$\rho_\psi(\mathbf{x}) = N \sum_{s^i} \int |\psi(\mathbf{x}, x_2, .., x_N; s^1, .., s^N)|^2 \mathrm{d}x_2 \ldots \mathrm{d}x_N .$$

If we set $\tilde{\rho}(\mathbf{x}) = \Sigma_m |\phi_m(\mathbf{x}_\perp)|^2 \rho_m^N(z)$, add and subtract $\tilde{\rho} * |\mathbf{x}|^{-1} - \mu(N)$ in the scalar product, and use $\psi = (1/\sqrt{N!})\, \phi_1 \wedge \cdots \wedge \phi_N$, where ϕ_i is the eigenvector corresponding to the ith lowest eigenvalue λ_i of the one-particle operator

$$\Pi_0 (H_A - Z|\mathbf{x}|^{-1} + \tilde{\rho} * |\mathbf{x}|^{-1} - \mu(N)) \Pi_0 , \qquad \text{(III.37)}$$

as comparison wave function, (III.36) reads

$$E^Q_{\mathrm{conf}} \leqslant \mathrm{Tr}[\Pi_0 (H_A - Z|\mathbf{x}|^{-1} + \tilde{\rho} * |\mathbf{x}|^{-1} - \mu(N)) \Pi_0]_- - 2D(\rho_\psi, \tilde{\rho}) + D(\rho_\psi, \rho_\psi) + N\mu(N)$$
$$+ \sum_{\lambda_N < \lambda_i < \mu(N)} |(\lambda_i - \mu(N))|. \qquad \text{(III.38)}$$

Applying Theorem III.13 and (III.26) to the above-mentioned inequality, we finally arrive at the upper bound (III.36).

Lower bound: Let ψ denote the minimizer of (I.22), i.e., $\psi = \psi_{\mathrm{conf}}$. So after again adding and subtracting $\tilde{\rho} * |\mathbf{x}|^{-1} - \mu(N)$ and using the Lieb–Oxford inequality,[17] we can write the lower bound on E^Q_{conf} as follows:

$$\begin{aligned} E^Q_{\mathrm{conf}} = (\psi, \Pi_0^N H_N \Pi_0^N) &\geqslant \sum_{i=1}^{N} (\psi, \Pi_0^N [H_A(\mathbf{x}_i) - Z|\mathbf{x}_i|^{-1} + \tilde{\rho}^* |\mathbf{x}_i|^{-1} - \mu(N)] \Pi_0^N \psi) + D(\rho_\psi, \rho_\psi) \\ &\quad + N\mu(N) - 2D(\rho_\psi, \tilde{\rho}) - C \int \rho_\psi^{4/3} \\ &\geqslant \mathrm{Tr}[\Pi_0 (H_A - Z|\mathbf{x}|^{-1} + \tilde{\rho} * |\mathbf{x}|^{-1} - \mu(N)) \Pi_0]_- + N\mu \\ &\quad - D(\tilde{\rho}, \tilde{\rho}) - C \int \rho_\psi^{4/3} . \end{aligned} \qquad \text{(III.39)}$$

Using (III.26) we arrive at (III.32).

Remark III.15: Due to (III.31) and (III.32) the main contribution to the difference between E^Q_{conf} and E^{DSTF} is given by

$$R_1 = \left| \sum_{m \in \mathbb{N}_0} \left(\mathrm{Tr}_{L^2(\mathbb{R})}[-\partial_z^2 - \varphi_{\mathrm{eff}}^{(m)}(z)]_- - \int \int [p^2 - \varphi_{\mathrm{eff}}^{(m)}(z)]_- \frac{\mathrm{d}p\mathrm{d}z}{2\pi} \right) \right|, \qquad \text{(III.40)}$$

which, by definition, shows that E^{DSTF} is the natural semiclassical approximation of E^Q_{conf}.

As a corollary, e.g., by following the way of Ref. 1 and using coherent states and the above-mentioned estimates, or simply by estimating the difference between E^{DSTF} and E^{STF} one gets

Corollary III.16: If $Z \to \infty$ with N/Z fixed and $B/Z^3 \to 0$, then $E^Q_{\mathrm{conf}}(N,Z,B)/E^{\mathrm{DSTF}}(N,Z,B) \to 1$.

The DSTF theory is equivalent to a three-dimensional functional using *modified* Coulomb potentials,

$$V_\chi(\mathbf{x})=\sum_n \chi^n(\mathbf{x}_\perp)V_n(z) \tag{III.41}$$

replacing the attractive Coulomb potential and

$$\sum_{m,n} V_{n,m}(z-z')\chi_n(\mathbf{x}_\perp)\chi_m(\mathbf{x}'_\perp) \tag{III.42}$$

replacing the Coulomb repulsion, with

$$\chi^n(\mathbf{x}_\perp)=\begin{cases}1 & \text{for } \sqrt{(2n)/B}\leqslant|x_\perp|\leqslant\sqrt{2(n+1)/B}\\ 0 & \text{otherwise.}\end{cases} \tag{III.43}$$

For example, for the respective minimizing density of a resulting MSTF functional, we have $\rho^{\mathrm{MSTF}}(\mathbf{x})=(B/2\pi)\,\Sigma_m\rho_m^{\mathrm{DSTF}}(z)\chi_m(x_\perp)$ as well as $E^{\mathrm{MSTF}}=E^{\mathrm{DSTF}}$ for the energy.

Since $V_\chi(0)\sim B^{1/2}$, $V_\chi(\mathbf{x})$ can be regarded as a cutoff Coulomb potential

$$\overline{V}(\mathbf{x})=\begin{cases}B^{1/2} & \text{for } |\mathbf{x}|\leqslant B^{-1/2},\\ |\mathbf{x}|^{-1} & \text{for } |\mathbf{x}|\geqslant B^{-1/2}.\end{cases} \tag{III.44}$$

Hence, it is obvious that the main contribution to the difference $E^{\mathrm{DSTF}}-E^{\mathrm{STF}}$ stems from the Coulomb potential in the region $r\leqslant B^{-1/2}$, given by the term

$$B\int_{0\leqslant r\leqslant B^{-1/2}}|\phi^{\mathrm{STF}}|^{3/2}=O(B^{1/4}Z^{3/2}), \tag{III.45}$$

which leads to the relation

$$E^{\mathrm{DSTF}}(N,Z,B)-E^{\mathrm{STF}}(N,Z,B)=O(B^{1/4}Z^{3/2}). \tag{III.46}$$

The comparison with Theorem I.7 shows that the DSTF theory has the same effect as the introduction of the gradient correction in (I.50) as well as in (I.46).

C. The discrete von Weizsäcker functional

The variable of the DSTF functional is given by a sum of one-dimensional densities, emphasizing the character of lowest Landau band particles, whose positions orthogonal to the magnetic field are ''frozen'' and they therefore only move parallel to the magnetic field. Now taking into account the result (see, e.g., Shao[12]) that the first-order correction to the semiclassical description of the one-dimensional free Fermi gas is given by $-(1/3)\int(\partial_z\sqrt{\rho(z)})^2$, we are motivated to propose the already mentioned *discrete von Weizsäcker functional*

$$\mathcal{E}^{\mathrm{DW}}[\rho]=\sum_{m\in\mathbb{N}_0}\left(-\frac{1}{3}\int|\partial_z\sqrt{\rho_m(z)}|^2+\kappa\int\rho_m^3(z)-Z\int V_m(z)\rho_m(z)\right)+\widetilde{D}(\rho,\rho). \tag{III.47}$$

Since the von Weizsäcker term appears with negative sign, (III.47) has the same defects as the Tomishima–Shinjo functional (I.46), i.e. it is not bounded from below and not convex. Precisely these two features (boundedness and convexity) of the semiclassical TF functionals, as well the (M)TFW functional, provided not only the existence of a minimizer but the existence of a solution of the corresponding TF equation.

As a way out of this problem we can define the energy corresponding to (III.47) by means of stationary solutions ρ^N, whose variational derivative vanishes under the restriction $\Sigma_m \int \rho_m = N$ and $\rho \geqslant 0$. In order to avoid the assumption of positivity we concentrate on real functions ψ, with $\psi^2 = \rho$ and consider the functional

$$\mathcal{E}[\psi] = \sum_{m \in \mathbb{N}_0} \left(-\frac{1}{3} \int |\partial_z \psi_m(z)|^2 + \kappa \int \psi_m^6(z) - Z \int V_m(z) \psi_m^2(z) \right) + \tilde{D}(\psi^2, \psi^2). \quad \text{(III.48)}$$

Let

$$D = \left\{ \psi \middle| \sum_m \int \psi_m^2 < \infty, \sum \int \psi_m^6 < \infty, \quad \text{and} \quad \sum_m \int (\partial_z \psi_m)^2 < \infty \right\} \quad \text{(III.49)}$$

be the domain of (III.48). The question for stationary points in D, under the restriction $\Sigma_m \int \psi_m^2 = N$, is equivalent to the existence of a Lagrange parameter $\mu(N)$ and a ψ^N, so that

$$\frac{\mathrm{d}}{\mathrm{d}t} \left(\mathcal{E}[\psi^N + t\eta] + \mu(N) \int (\psi^N + t\eta)^2 \right) \Big|_{t=0} = 0, \quad \text{(III.50)}$$

for each $\eta \in D$. (III.50) yields the Euler–Lagrange equation, denoting $\psi^N = \psi$,

$$(1/3) \partial_z^2 \psi_m(z) + 3\kappa \psi_m^5(z) = [\varphi_{\text{eff}}^{(m)}(z) - \mu(N)] \psi_m(z) \quad \forall m \in \mathbb{N}_0. \quad \text{(III.51)}$$

Starting from (III.48), (III.51) *a priori* only exists in the sense of distributions, but if there is a solution for (III.48) then one can conclude that it is even in $C^\infty(\mathbb{R}\backslash\{0\})$. If there is a solution ψ^N for $N \in [0, N_c]$, with $N_c \geqslant Z$, then we can define the corresponding energy by

$$E^{\text{DW}}(N, Z, B) = \mathcal{E}[\psi^N] = \mathcal{E}^{\text{DW}}[(\psi^N)^2]. \quad \text{(III.52)}$$

1. Recovering the exchange term

Now we even go a step further. Following the reflections of Sec. I C 1 concerning the magnitude of the negative von Weizsäcker term we guess that $\mathcal{E}^{\text{DW}}$ is equivalent to the DDM functional (1.33) for $B \ll Z^3$. Hence looking at (I.42) we suggest another functional,

$$\mathcal{E}^{\text{DWHF}}[\rho] = \sum_{m \in \mathbb{N}_0} \left(-(1/3) \int \left| \partial_z \sqrt{\rho_m(z)} \right|^2 + \kappa \int \rho_m^3(z) - Z \int V_m(z) \rho_m(z) \right.$$
$$\left. - c \ln \left(\frac{B^{1/2} \int \rho_m}{\int \rho_m^2} \right) \int \rho_m^2 \right) + \tilde{D}(\rho, \rho), \quad \text{(III.53)}$$

where we recover the exchange energy, which could be compared with the Thomas–Fermi–Dirac–von Weizsäcker functional[16] in the $B = 0$ case.

2. The one-dimensional DW functional

In this section we study a toy model obtained by reducing (I.52) to a one-dimensional functional and dropping the Coulomb repulsion, which leads to the functional

$$\mathcal{E}^{\text{1DW}}[\rho] = -\frac{1}{3} \int |\partial_z \sqrt{\rho(z)}|^2 + \kappa \int \rho^3(z) - Z \int V_0(z) \rho(z). \quad \text{(III.54)}$$

First of all we consider the corresponding TF functional

$$\mathcal{E}_{B,Z}^{\text{1D}}[\rho] = \kappa \int \rho^3(z) - Z \int V_0(z) \rho(z), \quad \text{(III.55)}$$

for which we easily get the following lemma:

Lemma III.17: $\mathcal{E}^{1D}_{B,Z}[\rho]$, *with* $\rho \in L^3(\mathbb{R})$, *is bounded from below, and there exists a unique minimizing density* $\rho_0 \in L^3$, *with* $\mathcal{E}^{1D}_{B,Z}[\rho_0]=E^{1D}(Z,B)$.

Proof: Since $\int V_0\rho \leqslant \|V_0\|_{3/2}\|\rho\|_3$, we get

$$\mathcal{E}^{1D}_{B,Z}[\rho] \geqslant \|\rho\|_3^3 - \|V_0\|_{3/2}\|\rho\|_3. \tag{III.56}$$

Minimizing over $\|\rho\|_3$, we get the first part of the lemma. The proof of second part works analogously to Proposition III.3. □

For the minimizing density ρ_0 we get the simple TF equation

$$3\kappa\rho_0^2(z)=ZV_0(z). \tag{III.57}$$

By the definition (I.35) one easily sees the relation

$$V_0(z)\equiv V_0^B(z)=B^{1/2}V_0^1(B^{1/2}z), \tag{III.58}$$

which implies an interesting scaling relation for the energy $E^{1D}(Z,B)$:

Lemma III.18:

$$E^{1D}(Z,B)=Z^{3/2}B^{1/4}E^{1D}(1,1). \tag{III.59}$$

Proof: Using the scaling relation (III.58) and defining

$$\rho(z)=B^{1/4}Z^{1/2}\overline{\rho}(B^{1/2}z), \tag{III.60}$$

we get

$$\mathcal{E}^{1D}_{B,Z}[\rho]=B^{1/4}Z^{3/2}\mathcal{E}^{1D}_{1,1}[\overline{\rho}]. \tag{III.61}$$

□

In the next Theorem we point out that for $B \ll Z^2$, the energy (III.59) is the semiclassical approximation of $\mathrm{Tr}[-\partial_z^2 - ZV_0(z)]_-$, the sum of all negative eigenvalues of $-\partial_z^2 - ZV_0(z)$.

Theorem III.19: *Let* $B \leqslant Z^2$ *and* $\psi \in C_0^\infty(B(0,B^{-1/2}))$. *Then*

$$\mathrm{Tr}(\psi[-\partial_z^2 - ZV_0(z)]_-)=Z^{3/2}B^{1/4}\int\int \frac{dz\,dp}{2\pi}\psi[p^2-V_0^1(z)]_- - O(B^{3/4}Z^{1/2}), \tag{III.62}$$

and there is a constant C, *such that*

$$\left|\mathrm{Tr}[-\partial_z^2 - ZV_0(z)]_- - Z^{3/2}B^{1/4}E^{1D}(1,1)\right| \leqslant CB^{3/4}Z^{1/2}. \tag{III.63}$$

Proof: Let us rewrite

$$-\partial_z^2 - ZV_0^B(z)=B^{1/2}Z[-(B^{1/2}Z)^{-1}\partial_z^2 - V_0^1(B^{1/2}z)] \tag{III.64}$$

and define the unitary operator

$$(U(l)\psi)(z)=l^{1/2}\psi(lz). \tag{III.65}$$

With $l=B^{-1/2}$ and the fact that unitary transformations do not change traces we derive

$$\mathrm{Tr}[-\partial_z^2 - ZV_0^B(z)]_- = B^{1/2}Z\,\mathrm{Tr}[-h^2\partial_z^2 - V_0^1(z)]_-, \tag{III.66}$$

where

$$h=B^{1/4}Z^{-1/2}. \tag{III.67}$$

So we have the self-adjoint Schrödinger operator

$$H=-h^2\partial_z^2-V_0^1(z), \tag{III.68}$$

and its symbol

$$h(z,p)=p^2-V_0^1(z). \tag{III.69}$$

Using the relation

$$|\partial^\nu V_0^1(z)|\leqslant C^\nu \quad \text{on } B(0,2)=\{z||z|<2\} \tag{III.70}$$

and by means of some cutoff function $\psi\in C_0^\infty$,[18] Theorem 6.1 yields

$$\mathrm{Tr}(\psi(z)[-h^2\partial_z^2-V_0^1(z)]_-)=h^{-1}\int\int\frac{\mathrm{d}p\,\mathrm{d}z}{2\pi}\psi(z)[p^2-V_0^1(z)]_--O(h), \tag{III.71}$$

which together with (III.66) and (III.67) immediately implies (III.62). Recall, that by $[t]_-=t$ for $t\leqslant 0$ and 0 otherwise.

In order to tackle the outer zone $\{z|1\leqslant|z|\leqslant\infty\}$, we note that the potential fulfills

$$|\partial^\nu V_0^1(z)|\leqslant C^\nu|z|^{-\nu} \quad \text{for } |z|\geqslant 1. \tag{III.72}$$

So by definition of the scaling functions $l(z)=|z|$ and $f(z)=1$, we can use[18] Theorem 7.1, which states that with a cutoff function $\psi\in C^\infty(B(1,\infty))$, we get

$$\left|\mathrm{Tr}(\psi[-h^2\partial_z^2-V_0^1(z)]_-)-h^{-1}\int\int\frac{\mathrm{d}p\,\mathrm{d}z}{2\pi}\psi[p^2-V_0^1(z)]_-\right|\leqslant h\int_1^\infty \mathrm{d}z\, l^{-2}\leqslant h. \tag{III.73}$$

Combining (III.71) and (III.73) together with (III.66) and (III.67) completes the proof of Theorem III.19.

Turning back to the functional (III.54), we recall that the corresponding energy has to be defined by means of the solution of the TF equation

$$\partial_z^2\psi(z)+3\kappa\psi^5(z)-ZV_0^B(z)\psi(z)=0. \tag{III.74}$$

Introducing the scaling relations

$$\psi(z)=B^{1/8}Z^{1/4}\varphi(zB^{1/2}), \quad z\to zB^{1/2}, \tag{III.75}$$

(III.74) can be written as

$$\frac{B^{1/2}}{Z}\partial_z^2\varphi(z)+3\kappa\varphi^5(z)-V_0^1(z)=0. \tag{III.76}$$

We set $\varepsilon\equiv B^{1/2}/Z\ll 1$ and make the ansatz $\varphi=\varphi_0+\varepsilon\varphi_1$ to get an approximate solution of (III.76). Rescaling and inserting into (III.54) yields

$$E^{1\mathrm{DW}}=\mathcal{E}^{1\mathrm{DW}}[\psi^2]=Z^{3/2}B^{1/4}E^{1\mathrm{D}}(1,1)-O(B^{3/4}Z^{1/2}), \tag{III.77}$$

which is in accordance with (III.62) and justifies *a posteriori* the introduction of the negative von Weizsäcker term in (I.52) and (III.54).

IV. SOME CONCLUDING REMARKS

Throughout this paper we have studied, among others, two functionals, the MTFW, which represents an approximation to the full quantum mechanical energy E^Q, and the DW functional, which should approximate the ground state energy E^Q_{conf} of particles in the lowest Landau band. Now we can ask for the magnitude of B, for which the use of DW becomes more reasonable than MTFW. This question is connected with the estimation of

$$|E^Q(N,Z,B)-E^Q_{\mathrm{conf}}(N,Z,B)|. \tag{IV.1}$$

For $B\ll Z^3$ this can be compared with the difference of the corresponding semiclassical approximations

$$\left| B\int \phi^{\mathrm{MTF}}(x)|_+^{3/2}\,\mathrm{d}x+2B\sum_{i\geqslant 1}\int |\phi^{\mathrm{MTF}}(x)-2iB|_+^{3/2}\mathrm{d}x-B\int |\phi^{\mathrm{STF}}(x)|_+^{3/2}\mathrm{d}x\right|$$

$$\leqslant C\int |Z|x|^{-1}-2B|_+^{3/2}\mathrm{d}x\leqslant CZ^3/B^{1/2}. \tag{IV.2}$$

From the preceding sections we guess, on the one hand,

$$|E^{\mathrm{DW}}-E^Q_{\mathrm{conf}}|\leqslant o(B^{4/5}Z^{3/5}), \tag{IV.3}$$

and on the other hand we know

$$|E^{\mathrm{MTFW}}-E^Q|\leqslant O(Z^2)+O(B^{4/5}Z^{3/5}). \tag{IV.4}$$

Hence, one might expect the DW theory to give the better description of the quantum mechanical energy, if $Z^3/B^{1/2}\leqslant B^{4/5}Z^{3/5}$, or, in other words, $B\geqslant Z^{24/13}$.

Summing up, we suggest to use MTFW theory for $B\leqslant Z^{24/13}$ and DW for $Z^{24/13}\leqslant B\ll Z^3$.

JOURNAL OF MATHEMATICAL PHYSICS VOLUME 42, NUMBER 12 DECEMBER 2001

Upper bounds on the density of states of single Landau levels broadened by Gaussian random potentials

Thomas Hupfer,[a] Hajo Leschke, and Simone Warzel
Institut für Theoretische Physik, Universität Erlangen-Nürnberg, Staudtstraße 7, D-91058 Erlangen, Germany

(Received 13 November 2000; accepted for publication 19 July 2001)

We study a nonrelativistic charged particle on the Euclidean plane $\mathbb{R}^2$ subject to a perpendicular constant magnetic field and an $\mathbb{R}^2$-homogeneous random potential in the approximation that the corresponding random Landau Hamiltonian on the Hilbert space $L^2(\mathbb{R}^2)$ is restricted to the eigenspace of a single but arbitrary Landau level. For a wide class of $\mathbb{R}^2$-homogeneous Gaussian random potentials we rigorously prove that the associated restricted integrated density of states is absolutely continuous with respect to the Lebesgue measure. We construct explicit upper bounds on the resulting derivative, the restricted density of states. As a consequence, any given energy is seen to be almost surely not an eigenvalue of the restricted random Landau Hamiltonian. © *2001 American Institute of Physics.*

TABLE OF CONTENTS

I. INTRODUCTION

In recent decades considerable attention has been paid to the physics of quasi-two-dimensional electronic structures.[1–5] Some of the occurring phenomena, like the integer quantum Hall effect,[6] are believed to be microscopically explainable in terms of a Fermi gas of noninteracting electrically charged particles in two dimensions subject to a perpendicular constant magnetic field and a static random potential. For these phenomena it should therefore be sufficient to study a single nonrelativistic spinless particle on the Euclidean plane $\mathbb{R}^2$ modeled by the *random Landau Hamiltonian*, which is informally given by

$$H(V^{(\omega)}) := H(0) + V^{(\omega)}. \tag{1}$$

As a random Schrödinger operator it acts on the Hilbert space $L^2(\mathbb{R}^2)$ of Lebesgue square-integrable complex-valued functions on the plane $\mathbb{R}^2$. For any realization $\omega \in \Omega$ of the randomness the potential $V^{(\omega)}$ mimics the disorder present in a real sample. Throughout, we will assume

[a]Electronic mail: thomas.hupfer@theorie1.physik.uni-erlangen.de

that V is homogeneous on the average with respect to Euclidean translations of $\mathbb{R}^2$. The unperturbed part in (1) is the *Landau Hamiltonian*. It represents the kinetic energy of the particle and is informally given (in the symmetric gauge) by the differential expression

$$H(0) := \frac{1}{2}\left[\left(i\frac{\partial}{\partial x_1} - \frac{B}{2}x_2\right)^2 + \left(i\frac{\partial}{\partial x_2} + \frac{B}{2}x_1\right)^2\right] = \frac{B}{2}\sum_{l=0}^{\infty}(2l+1)P_l, \tag{2}$$

in physical units where the mass and the charge of the particle, and Planck's constant divided by 2π are all equal to one. Moreover, $B>0$ denotes the strength of the magnetic field and $i=\sqrt{-1}$ stands for the imaginary unit. The second equality in (2) is the spectral resolution of $H(0)$. It dates back to Fock[7] and Landau.[8] The energy eigenvalue $(l+1/2)B$ is called the lth *Landau level* and the corresponding orthogonal eigenprojection P_l is an integral operator with continuous complex-valued kernel (in other words: position representation)

$$P_l(x,y) := \frac{B}{2\pi}\exp\left[i\frac{B}{2}(x_2y_1 - x_1y_2) - \frac{B}{4}|x-y|^2\right]L_l^{(0)}\left(\frac{B}{2}|x-y|^2\right). \tag{3}$$

Here and in the following, $|x-y|^2 := (x_1-y_1)^2+(x_2-y_2)^2$ denotes the square of the Euclidean distance between the points $x=(x_1,x_2)\in\mathbb{R}^2$ and $y=(y_1,y_2)\in\mathbb{R}^2$. Moreover, $L_l^{(k)}(\xi) := \Sigma_{j=0}^{l}(-1)^j\binom{l+k}{l-j}\xi^j/j!$, with $\xi\geqslant 0$ and $k\in\mathbb{N}_0-l := \{-l,-l+1,-l+2,...\}$, is a generalized Laguerre polynomial, see Sec. 8.97 in Ref. 9. The diagonal $P_l(x,x)=B/2\pi$ is naturally interpreted as the degeneracy per area of the lth Landau level.

A quantity of basic interest in the study of the random Landau Hamiltonian (1) is its *integrated density of states* $\nu(]-\infty,E[)$ as a function of the energy $E\in\mathbb{R}$. The underlying positive Borel measure ν on the real line $\mathbb{R}$ is called the *density-of-states measure* of $H(V)$. If the random potential is not only $\mathbb{R}^2$-homogeneous but also *isotropic*, that is, if all finite-dimensional distributions associated with the probability measure $\mathbb{P}$ on Ω, which governs the randomness, are invariant also under in-plane rotations (with respect to the origin), the density-of-states measure ν can be decomposed according to

$$\nu = \frac{B}{2\pi}\sum_{l=0}^{\infty}\hat{\nu}_l, \quad \hat{\nu}_l(I) := \frac{2\pi}{B}\mathbb{E}[(P_l\chi_I(H(V))P_l)(x,x)], \quad I\in\mathcal{B}(\mathbb{R}), \tag{4}$$

see Refs. 10, 11, and references therein. Here $\mathbb{E}$ denotes the expectation induced by $\mathbb{P}$ and $\chi_I(H(V^{(\omega)}))$ is the spectral projection operator of $H(V^{(\omega)})$ associated with the energy regime $I\in\mathcal{B}(\mathbb{R})$. The contribution $\hat{\nu}_l$ related to the *Landau-level index* l is a probability measure on the Borel sets $\mathcal{B}(\mathbb{R})$ in the real line $\mathbb{R}$. It is actually independent of $x\in\mathbb{R}^2$ due to the homogeneity of V.

In the limit of a strong magnetic field, the spacing B between successive Landau levels approaches infinity and the magnetic length $B^{-1/2}$ tends to zero. Therefore, the effect of so-called level mixing should be negligible if either the strength of the random potential V, typically given by the square root of its single-site variance $\mathbb{E}[V(0)^2]-(\mathbb{E}[V(0)])^2$, is small compared to the level spacing or if the (smallest) correlation length of V is much larger than the magnetic length. In both cases $\hat{\nu}_l(I)$ should be well approximated by $2\pi\mathbb{E}[(P_l\chi_I(P_lH(V)P_l)P_l)(x,x)]/B$. Indeed, this approximation is exact[12] if V is a spatially constant random potential $x\mapsto V^{(\omega)}(0)$. Since the first part of the lth *restricted random Landau Hamiltonian*, $P_lH(V)P_l=(l+1/2)BP_l+P_lVP_l$, causes only a shift in the energy, one may equivalently study the probability measure

$$\nu_l(I) := \frac{2\pi}{B}\mathbb{E}[(P_l\chi_I(P_lVP_l)P_l)(x,x)], \quad I\in\mathcal{B}(\mathbb{R}). \tag{5}$$

We call it the lth *restricted density-of-states measure* and its distribution function $E\mapsto\nu_l(]-\infty,E[)$ the lth *restricted integrated density of states*. Again, they are independent of $x\in\mathbb{R}^2$ due

to the homogeneity of V. From the physical point of view most interesting is the restriction to the *lowest* Landau level, corresponding to $l=0$. If the magnetic field is strong enough, all particles may be accommodated in the lowest level without conflicting with Pauli's exclusion principle, since the degeneracy (per area) $B/2\pi$ increases with B. Up to the energy shift $B/2$, the measure $B\nu_0/2\pi$ should then be a good approximation to ν, since the effects of higher Landau levels are negligible if B is large compared to the strength of the random potential, see Proposition 1 in Ref. 13 in case of a Gaussian random potential.

Neglecting effects of level mixing by only dealing with the sequence of restricted operators $(P_lVP_l)_{l\in\mathbb{N}_0}$ is a simplifying approximation which is often made. The interest in these operators relates to the existence of pure-point components in their spectra[14–17] and, what is simpler, to properties of their restricted density-of-states measures (ν_l). The aim of the present paper is to supply conditions under which ν_l is absolutely continuous with respect to the Lebesgue measure. Actually, in the physics literature this differentiability of the restricted integrated density of states $\nu_l(]-\infty,E[)$ with respect to E is usually taken for granted so that one deals from the outset with its derivative, the lth *restricted density of states*

$$E\mapsto w_l(E):=\frac{\mathrm{d}\nu_l(]-\infty,E[)}{\mathrm{d}E}=\frac{\nu_l(\mathrm{d}E)}{\mathrm{d}E}, \tag{6}$$

see, e.g., Refs. 1–6, 10, 12, 18–25. Due to the involved averaging, the disorder is indeed often believed to broaden each Landau level to a *Landau band* in such a way that the resulting restricted integrated density of states is sufficiently smooth. Example 1 in the following, however, which is taken from Ref. 12, illustrates that this belief is wrong without further assumptions. It even shows that for any given $l\geqslant 1$ it may happen that there is no broadening at all so that the operator P_lVP_l is zero almost surely (although V is nonzero) and hence ν_l is singular. For the formulation of the example we need some preparation. Without losing generality, we will always assume that the homogeneous (but not necessarily isotropic) random potential V has zero mean, $\mathbb{E}[V(0)]=0$. The *variance* σ_l^2 of ν_l is then given by[12]

$$\sigma_l^2:=\int_{\mathbb{R}}\nu_l(\mathrm{d}E)E^2=\frac{2\pi}{B}\,\mathbb{E}[(P_lVP_l)^2(0,0)]=\frac{2\pi}{B}\,(P_lCP_l)(0,0)\leqslant C(0), \tag{7}$$

where $x\mapsto C(x):=\mathbb{E}[V(x)V(0)]$ is the *covariance function* of V. When sandwiched between two projections, C is understood as a (bounded) multiplication operator acting on $L^2(\mathbb{R}^2)$. The standard deviation $\sigma_l:=\sqrt{\sigma_l^2}$ may physically be interpreted as the width of the lth Landau band. We note that the width σ_0 of the lowest Landau band is always strictly positive, provided that the covariance function is continuous and obeys $C(0)>0$. This follows from the formula $\sigma_l^2=\int_{\mathbb{R}^2}\widetilde{C}(\mathrm{d}^2k)\exp(-|k|^2/2B)[L_l^{(0)}(|k|^2/2B)]^2$. Here the so-called *spectral measure* $\widetilde{C}$ which, according to the Bochner–Khintchine theorem (Theorem IX.9 in Ref. 26), is the unique finite positive (and even) Borel measure on $\mathbb{R}^2$ yielding the Fourier representation $C(x)=\int_{\mathbb{R}^2}\widetilde{C}(\mathrm{d}^2k)\exp(ik\cdot x)$ where $k\cdot x:=k_1x_1+k_2x_2$ denotes the standard scalar product on $\mathbb{R}^2$.

Example 1: If V possesses the oscillating covariance function $C(x)=C(0)J_0(\sqrt{2}|x|/\tau)$, where $\tau>0$ and J_0 is the Bessel function of order zero,[9] then

$$\sigma_l^2=C(0)\exp\left(-\frac{1}{B\tau^2}\right)\left[L_l^{(0)}\left(\frac{1}{B\tau^2}\right)\right]^2. \tag{8}$$

Choosing the squared length ratio $1/(B\tau^2)$ equal to a zero of $L_l^{(0)}$, which exists if $l\geqslant 1$, one achieves that $\sigma_l^2=0$. Chebyshev's inequality then implies that ν_l is Dirac's point measure at the origin, informally $w_l(E)=\delta(E)$. Therefore, $P_lV^{(\omega)}P_l=0$ for $\mathbb{P}$-almost all $\omega\in\Omega$.

In the present paper we provide conditions under which exotic situations as in Example 1 cannot occur. More precisely, we prove that (6) indeed defines w_l as a bounded probability density for a wide class of *Gaussian* random potentials, see Theorems 1 and 2 in the following. Moreover,

we construct explicit upper bounds on w_l for these potentials. As an implication, we prove that for any $B>0$ and the class of Gaussian random potentials considered, any given energy $E\in\mathbb{R}$ is almost surely not an eigenvalue of the operator P_lVP_l. In particular, these Gaussian random potentials completely lift the infinite degeneracy of the Landau-level energy (here shifted to zero) for any strength of the magnetic field. This stands in contrast to situations with random point impurities considered in Refs. 19, 16, 27, 28, 17.

The present paper was partially motivated by results of Ref. 29 where the (unrestricted) density-of-states measure ν of the random Landau Hamiltonian is proven to be absolutely continuous with a locally bounded density for a certain class of random potentials (including the Gaussian ones considered in Theorem 1) and where any given energy $E\in\mathbb{R}$ is shown to be almost surely not an eigenvalue of $H(V)$. While absolute continuity of ν immediately implies by (4) that of $\hat{\nu}_l$ for all $l\in\mathbb{N}_0$ (for isotropic V), in itself it does not imply that of ν_l.

II. THE DENSITY OF STATES OF A SINGLE BROADENED LANDAU LEVEL

A. The restricted random Landau Hamiltonian and its integrated density of states

Let $\|F\|:=\sup\{|\langle\varphi,F\varphi\rangle|:\varphi\in L^2(\mathbb{R}^2),\langle\varphi,\varphi\rangle=1\}<\infty$ denote the (uniform) norm of a self-adjoint bounded operator F acting on the Hilbert space $L^2(\mathbb{R}^2)$. The restriction P_lFP_l of F to the eigenspace $P_lL^2(\mathbb{R}^2)\subset L^2(\mathbb{R}^2)$ corresponding to the lth Landau level is an integral operator with kernel $(x,y)\mapsto(P_lFP_l)(x,y):=B\langle\psi_{l,x},F\psi_{l,y}\rangle/2\pi$ which is jointly continuous thanks to the continuity of the usual scalar product $\langle\cdot,\cdot\rangle$ on $L^2(\mathbb{R}^2)$ and the strong continuity of the mapping $\mathbb{R}^2\ni x\mapsto\psi_{l,x}\in P_lL^2(\mathbb{R}^2)$. Here, the two-parameter family of normalized, complex-valued functions ("coherent states") is defined by

$$y\mapsto\psi_{l,x}(y):=\sqrt{\frac{2\pi}{B}}P_l(y,x),\quad x\in\mathbb{R}^2,\quad\langle\psi_{l,x}\psi_{l,x}\rangle=1. \tag{9}$$

Let $(\Omega,\mathcal{A},\mathbb{P})$ be a complete probability space. By a *random potential* we mean a random field $V:\Omega\times\mathbb{R}^2\to\mathbb{R},(\omega,x)\mapsto V^{(\omega)}(x)$ which is jointly measurable with respect to the sigma-algebra $\mathcal{A}$ of event sets in Ω and the sigma-algebra $\mathcal{B}(\mathbb{R}^2)$ of Borel sets in the Euclidean plane $\mathbb{R}^2$.

The next proposition provides conditions under which the (in general unbounded) integral operator P_lVP_l, the (shifted) lth *restricted random Landau Hamiltonian*, is almost surely essentially self-adjoint on the Schwartz space $\mathcal{S}(\mathbb{R}^2)$ of arbitrarily often differentiable complex-valued functions on $\mathbb{R}^2$ with rapid decrease (Definition on p. 133 in Ref. 26).

Proposition 1: Let V be an $\mathbb{R}^2$-homogeneous random potential and assume there exists a constant $M<\infty$ such that $\mathbb{E}[|V(0)|^{2k}]\leqslant(2k)!M^{2k}$ for all $k\in\mathbb{N}$. Then for all $l\in\mathbb{N}_0$ it holds:

(1) *The restricted operator $P_lV^{(\omega)}P_l$ is essentially self-adjoint on $\mathcal{S}(\mathbb{R}^2)$ for all ω in some subset $\Omega_0\in\mathcal{A}$ of Ω with full probability, $\mathbb{P}(\Omega_0)=1$.*

(2) *The mapping $\Omega_0\ni\omega\mapsto P_lV^{(\omega)}P_l$ is measurable in the sense of Definition V.1.3 in Ref. 30.*

(3) *The restricted density-of-states measure ν_l, defined in* (5)*, is a probability measure on the sigma-algebra $\mathcal{B}(\mathbb{R})$ of Borel sets in the real line. Moreover, the following (weak) operator identity holds*

$$\mathbb{E}[P_l\chi_I(P_lVP_l)P_l]=\nu_l(I)P_l,\quad I\in\mathcal{B}(\mathbb{R}). \tag{10}$$

Remark: As far as we know, the operator identity (10) for general $\mathbb{R}^2$-homogeneous V and general $l\in\mathbb{N}_0$ was first shown in Ref. 20, see also Ref. 24.

Proof of Proposition 1: (1) The assumed limitation on the growth of the even moments $\mathbb{E}[|V(0)|^{2k}]$ as a criterion for the almost-sure essential self-adjointness of P_lVP_l is taken from the proof of Theorem 2.1 in Ref. 14, which is based on Nelson's analytic-vector theorem (Theorem X.39 in Ref. 31), see also Ref. 32.

(2) By truncating the large fluctuations of the random potential we construct a sequence of restricted random operators $(P_lV_n^{(\omega)}P_l)_{n\in\mathbb{N}}$, where $V_n^{(\omega)}(x):=V^{(\omega)}(x)\Theta(n-|V^{(\omega)}(x)|)$ is bounded and measurable for all n. Here $\Theta:=\chi_{]0,\infty[}$ denotes Heaviside's unit-step function. For $\mathbb{P}$-almost all

$\omega\in\Omega$ we have the strong convergence $P_l V_n^{(\omega)} P_l\varphi \to P_l V^{(\omega)} P_l\varphi$ as $n\to\infty$ for all $\varphi\in\mathcal{S}(\mathbb{R}^2)$. Consequently, Theorem VIII.25 in Ref. 26 implies that the sequence converges toward $P_l V^{(\omega)} P_l$ in the strong resolvent sense implying that the latter operator is also measurable thanks to Proposition V.1.4 in Ref. 30.

(3) Since $0\leqslant\langle\psi_{l,x},\chi_I(P_l V^{(\omega)}P_l)\psi_{l,x}\rangle\leqslant\langle\psi_{l,x},\chi_{\mathbb{R}}(P_l V^{(\omega)}P_l)\psi_{l,x}\rangle=1$ for all $x\in\mathbb{R}^2$, all $I\in\mathcal{B}(\mathbb{R})$, and $\mathbb{P}$-almost all $\omega\in\Omega$, the right-hand side of (5) indeed defines a probability measure on $\mathcal{B}(\mathbb{R})$. For the proof of (10) we introduce the family of *magnetic translation operators* $\{T_x\}_{x\in\mathbb{R}^2}$ which are unitary on $L^2(\mathbb{R}^2)$ and defined by

$$(T_x\varphi)(y):=\exp\left[i\frac{B}{2}(x_1y_2-x_2y_1)\right]\varphi(y-x),\quad \varphi\in L^2(\mathbb{R}^2). \tag{11}$$

They constitute an irreducible representation of the Heisenberg–Weyl group on $P_l L^2(\mathbb{R}^2)$.[20] Since V is $\mathbb{R}^2$-homogeneous, it follows that

$$T_x^{\dagger}\mathbb{E}[P_l\chi_I(P_l V P_l)P_l]T_x=\mathbb{E}[P_l\chi_I(P_l V P_l)P_l] \tag{12}$$

for all $x\in\mathbb{R}^2$ and all $I\in\mathcal{B}(\mathbb{R})$. A suitable variant of Schur's lemma (Proposition 4 of § 3, Chap. 5 in Ref. 33) then gives the claimed result. □

In Theorems 1 and 2, we will assume that V is a Gaussian random potential in the sense of

Definition 1: A Gaussian random potential is a Gaussian[34,35] random field V which is $\mathbb{R}^2$-homogeneous, has zero mean, $\mathbb{E}[V(0)]=0$, and is characterized by a covariance function $\mathbb{R}^2\ni x\mapsto C(x):=\mathbb{E}[V(x)V(0)]$ which is continuous at the origin where it obeys $0<C(0)<\infty$.

Remarks: (1) Our continuity requirement for the covariance function C of a Gaussian random potential implies that C is uniformly continuous and bounded by $C(0)$. Consequently, there exists a separable version of V which is jointly measurable, see Theorem 3.2.2 in Ref. 36. When speaking about a Gaussian random potential, we will tacitly assume that only this version is dealt with.

(2) A Gaussian random potential fulfills the assumption of Proposition 1 with $M=\sqrt{C(0)}$ by the usual ''Gaussian combinatorics'' to be found, for example, in Lemma 5.3.1 in Ref. 34.

B. Existence and boundedness of the restricted density of states

Wegner estimates[37] have turned out to be an efficient tool for proving the absolute continuity of density-of-states measures for certain random operators and for deriving upper bounds on their respective Lebesgue densities. One method to derive estimates of this genre uses *one-parameter spectral averaging*. It provides upper bounds on the averaged spectral projections of a self-adjoint operator which is perturbed by a bounded positive operator with fluctuating coupling strength. The abstract version of such an averaging, which we will use, is due to Combes and Hislop.[38] It is rephrased as

Lemma 1: Let K, L, and M be three self-adjoint operators acting on a Hilbert space $\mathcal{H}$ with scalar product $\langle\cdot,\cdot\rangle$. Moreover, let K and M be bounded such that $\kappa:=\inf_{K\varphi\neq 0}\langle\varphi,M\varphi\rangle/\langle\varphi,K^2\varphi\rangle>0$ is strictly positive. Finally, let $g\in L^{\infty}(\mathbb{R})$ be a Lebesgue-essentially bounded function on the real line, $\|g\|_{\infty}:=\operatorname{ess\,sup}_{\xi\in\mathbb{R}}|g(\xi)|<\infty$. Then the inequality

$$\int_{\mathbb{R}}\mathrm{d}\xi|g(\xi)|\langle\varphi,K\chi_I(L+\xi M)K\varphi\rangle\leqslant|I|\frac{\|g\|_{\infty}}{\kappa}\langle\varphi,\varphi\rangle \tag{13}$$

holds for all $\varphi\in\mathcal{H}$ and all $I\in\mathcal{B}(\mathbb{R})$.

Proof: See Corollary 4.2 in Ref. 38 and Lemma 3.1 in Ref. 29. □

If one focuses only on the absolute continuity of the measure ν_l without aspiring after sharp upper bounds on the resulting Lebesgue density, a straightforward application of Lemma 1 yields the following:

Theorem 1: *Let V be a Gaussian random potential in the sense of Definition 1. Suppose that there exists a finite signed Borel measure μ on $\mathbb{R}^2$ such that the covariance function C of V obeys*

$$0 \leqslant C_\mu(x) := \int_{\mathbb{R}^2} \mu(\mathrm{d}^2 y) C(x-y) < \infty, \quad \int_{\mathbb{R}^2} \mu(\mathrm{d}^2 y) C_\mu(y) = 1 \tag{14}$$

*for all $x \in \mathbb{R}^2$. Then the l*th *restricted density-of-states measure ν_l is absolutely continuous with respect to the Lebesgue measure and the resulting Lebesgue probability density w_l, the restricted density of states, is uniformly bounded according to*

$$w_l(E) := \frac{\nu_l(\mathrm{d}E)}{\mathrm{d}E} \leqslant \frac{1}{\sqrt{2\pi}\|P_l C_\mu P_l\|} \tag{15}$$

for Lebesgue-almost all energies $E \in \mathbb{R}$. Moreover, any given $E \in \mathbb{R}$ is not an eigenvalue of $P_l V^{(\omega)} P_l$ for $\mathbb{P}$-almost all $\omega \in \Omega$.

Remarks: (1) The second equality in (14) is just a convenient normalization of μ. The measure μ allows one to optimize the upper bound in (15) (see Example 2) as well as to apply Theorem 1 to Gaussian random potentials with certain covariance functions C, also taking on negative values. One such example is $C(x) = C(0)\exp[-|x|^2/(2\tau^2)][1-7|x|^2/(16\tau^2) + |x|^4/(32\tau^4)]$ with arbitrary length scale $\tau > 0$. This may be seen by choosing the Gaussian measure $\mu(\mathrm{d}^2 x) = \mathrm{d}^2 x N \times \exp[-|x|^2/(8\tau^2)]$ with a suitable normalization factor $N > 0$. Of course, for the oscillating covariance function of Example 1 no μ exists yielding the positivity condition (14).

(2) We note that $0 < \langle \psi_{l,0}, C_\mu \psi_{l,0} \rangle \leqslant \|P_l C_\mu P_l\| < \infty$. The first (strict) inequality follows from the assumptions on C in Definition 1, Eq. (14), and the explicit form (9) of $\psi_{l,0}$.

Proof of Theorem 1: The proof consists of two parts. In the first part, we use the fact that the Gaussian random potential V admits a one-parameter decomposition into a standard Gaussian random variable λ and a nonhomogeneous zero-mean Gaussian random field U which are defined by

$$\lambda^{(\omega)} := \int_{\mathbb{R}^2} \mu(\mathrm{d}^d y) V^{(\omega)}(y), \quad U^{(\omega)}(x) := V^{(\omega)}(x) - \lambda^{(\omega)} C_\mu(x). \tag{16}$$

The positive bounded function C_μ is defined in (14). Since $\mathbb{E}[\lambda U(x)] = 0$ for all $x \in \mathbb{R}^2$, λ and U are stochastically independent. We now multiply both sides of (10) from the left and right by $K := (P_l C_\mu P_l)^{1/2}$ and take the quantum-mechanical expectation with respect to an arbitrary nonzero $\varphi \in P_l L^2(\mathbb{R}^2)$ to obtain

$$\begin{aligned} \nu_l(I)\langle \varphi, K^2 \varphi \rangle &= \mathbb{E}[\langle \varphi, K \chi_I(P_l V P_l) K \varphi \rangle] \\ &= \mathbb{E}\left[\int_{\mathbb{R}} \mathrm{d}\xi \frac{e^{-\xi^2/2}}{\sqrt{2\pi}} \langle \varphi, K \chi_I(P_l U P_l + \xi K^2) K \varphi \rangle \right] \\ &\leqslant |I| \frac{\langle \varphi, \varphi \rangle}{\sqrt{2\pi}}. \end{aligned} \tag{17}$$

For the second equality we used the one-parameter decomposition (16) and the stochastic independence of λ and U. The Lebesgue integral in (17), which constitutes a partial averaging, is then bounded with the help of (13) uniformly in ω. The absolute continuity of ν_l with respect to the Lebesgue measure is now a consequence of (17) and the Radón–Nikodým theorem. Minimizing the upper bound on $\nu_l(I)$, coming from (17), with respect to $\varphi \in P_l L^2(\mathbb{R}^2)$ yields the claimed inequality (15).

In the second part, we note that (10) implies the equivalence: ν_l has no pure points, that is, $\nu_l(\{E\}) = 0$ for all $E \in \mathbb{R}$, if and only if $\mathbb{E}[\langle \varphi, \chi_{\{E\}}(P_l V P_l)\varphi \rangle] = 0$ for all $E \in \mathbb{R}$ and all $\varphi \in P_l L^2(\mathbb{R}^2)$. Given an orthonormal basis $\{\varphi_k\}_{k \in \mathbb{N}}$ in $P_l L^2(\mathbb{R}^2)$, there hence exists for every k

$\in\mathbb{N}$ some $\Omega_k\in\mathcal{A}$ with $\mathbb{P}(\Omega_k)=1$ such that $\langle\varphi_k,\chi_{\{E\}}(P_lV^{(\omega)}P_l)\varphi_k\rangle=0$ for all $\omega\in\Omega_k$. As a consequence, $\chi_{\{E\}}(P_lV^{(\omega)}P_l)=0$ for all $\omega\in\cap_{k\in\mathbb{N}}\Omega_k$, hence $\mathbb{P}$-almost all $\omega\in\Omega$. □

Remarks: (1) If the spectral measure $\tilde{C}$ has a (positive) Lebesgue density, C admits the representation $C(x)=\int_{\mathbb{R}^2}\mathrm{d}^2y\,\gamma(x+y)\,\gamma(y)$ with some $\gamma\in L^2(\mathbb{R}^2)$. If furthermore there exists some $f\in L^2(\mathbb{R}^2)$ with $\langle f,f\rangle=1$ such that $0\leqslant u(x):=\int_{\mathbb{R}^2}\mathrm{d}^2y f(x+y)\,\gamma(y)<\infty$ and $u\neq 0$, one may replace C_μ in (15) by u to obtain another upper bound on w_l for the given Gaussian random potential V. Roughly speaking, the idea is to write V as $V^{(\omega)}(x)=\int_{\mathbb{R}^2}\mathrm{d}^2y\,\gamma(x+y)W^{(\omega)}(y)$, where W is the standard delta-correlated (generalized) Gaussian random field on $\mathbb{R}^2$ informally characterized by $\mathbb{E}[W(x)]=0$ and $\mathbb{E}[W(x)W(y)]=\delta(x-y)$. The Gaussian random potential V hence admits a one-parameter decomposition into the standard Gaussian random variable $\lambda^{(\omega)}:=\int_{\mathbb{R}^2}\mathrm{d}^2y f(y)W^{(\omega)}(y)$ and the nonhomogeneous Gaussian random field $U^{(\omega)}(x):=V^{(\omega)}(x)-\lambda^{(\omega)}u(x)$, which is stochastically independent of λ.

(2) The essential ingredients of the above-given proof are the operator identity (10) and the fact that the (not necessarily Gaussian) random potential admits a one-parameter decomposition[39,29] $V^{(\omega)}(x)=U^{(\omega)}(x)+\lambda^{(\omega)}u(x)$ into a positive function u, a random field U, and a random variable λ whose conditional probability measure with respect to the sub-sigma-algebra generated by the family of random variables $\{U(x)\}_{x\in\mathbb{R}^2}$ has a bounded Lebesgue density ρ. Following the lines of reasoning of the above-given proof, the restricted density of states may then be shown to be bounded according to

$$w_l(E)=\frac{\nu_l(\mathrm{d}E)}{\mathrm{d}E}\leqslant\frac{\|\rho\|_\infty}{\|P_luP_l\|} \tag{18}$$

for Lebesgue-almost all $E\in\mathbb{R}$. Moreover, any given $E\in\mathbb{R}$ is not an eigenvalue of $P_lV^{(\omega)}P_l$ for $\mathbb{P}$-almost all $\omega\in\Omega$.

(3) The energy-independent estimate (15) is rather rough, because one expects $w_l(E)$ to fall off to zero for energies E approaching the edges $\pm\infty$ (if $\sigma_l^2>0$) of the almost-sure spectrum of P_lVP_l. More precisely, in the present case of a Gaussian random potential V it follows from arguments in Ref. 12 that the leading asymptotic behavior of the restricted integrated density of states for $|E|\to\infty$ is Gaussian according to

$$\lim_{E\to-\infty}\frac{\ln\nu_l(]-\infty,E[)}{E^2}=\lim_{E\to\infty}\frac{\ln\nu_l(]E,\infty[)}{E^2}=-\frac{1}{2\Gamma_l^2}, \tag{19}$$

where the *decay energy* Γ_l is the solution of the maximization problem

$$\Gamma_l^2:=\sup_{\substack{\varphi\in P_lL^2(\mathbb{R}^2)\\ \langle\varphi,\varphi\rangle=1}}\gamma^2(\varphi),\quad \gamma^2(\varphi):=\mathbb{E}[\langle\varphi,V\varphi\rangle^2]=\int_{\mathbb{R}^2}\mathrm{d}^2x\int_{\mathbb{R}^2}\mathrm{d}^2y|\varphi(x)|^2|\varphi(y)|^2C(x-y). \tag{20}$$

We recall from Ref. 12 the inequalities $\sigma_l^4/C(0)\leqslant\Gamma_l^2\leqslant\sigma_l^2$.

Gaussian random potentials with positive covariance functions nicely illustrate Theorem 1.

Example 2: If $0\leqslant C(x)<\infty$ for all $x\in\mathbb{R}^2$, the optimal μ in (15) belongs to the class of positive measures of the form $\mu(\mathrm{d}^2x)\,\gamma(\varphi)=\mathrm{d}^2x|\varphi(x)|^2$ with $\varphi\in P_lL^2(\mathbb{R}^2)$, $\langle\varphi,\varphi\rangle=1$, and $\gamma(\varphi)$ as defined in (20). Optimizing with respect to φ yields

$$w_l(E)\leqslant\frac{1}{\sqrt{2\pi\Gamma_l^2}}, \tag{21}$$

where Γ_l is the decay energy of the restricted integrated density of states. In particular, for the Gaussian covariance function $C(x)=\alpha^2\exp[-|x|^2/(2\tau^2)]/(2\pi\tau^2)$ with correlation length $\tau>0$ and single-site variance $C(0)=\alpha^2/(2\pi\tau^2)>0$, one has explicitly[12]

$$\Gamma_l^2=\gamma^2(\varphi_{l,-l})=\frac{\alpha^2}{2\pi\tau^2}\left(\frac{B\tau^2}{B\tau^2+2}\right)^{l+1}\mathrm{P}_l\left(\frac{(B\tau^2+1)^2+1}{(B\tau^2+1)^2-1}\right), \tag{22}$$

where the maximizer $\varphi_{l,-l}$ is given in (31) and $\mathrm{P}_l(\xi):=(1/l!2^l)(\mathrm{d}^l/\mathrm{d}\xi^l)(\xi^2-1)^l$ is the lth Legendre polynomial.[9]

Remarks: (1) That the class of measures referred to in Example 2 contains indeed the optimal one, derives from the Fourier representation

$$\langle\varphi,C_\mu\varphi\rangle=\int_{\mathbb{R}^2}\tilde{C}(\mathrm{d}^2k)\left(\int_{\mathbb{R}^2}\mathrm{d}^2x|\varphi(x)|^2e^{ik\cdot x}\right)\left(\int_{\mathbb{R}^2}\mu(\mathrm{d}^2y)e^{-ik\cdot y}\right) \tag{23}$$

valid for all $\varphi\in\mathrm{L}^2(\mathbb{R}^2)$. Since $\tilde{C}$ is positive, the claim follows from (23) with the help of the Cauchy–Schwarz inequality and the positivity of C.

(2) In the physics literature one often considers the limit of a *delta-correlated* Gaussian random potential informally characterized by $C(x)=\alpha^2\delta(x)$ with some $\alpha>0$. It emerges from the Gaussian random potential with the Gaussian covariance function given between (21) and (22) in the limit $\tau\downarrow 0$. In this limit (22) reduces to $\Gamma_l^2=(\alpha^2B/4\pi)(2l)!/(l!2^l)^2$ and the variance of ν_l becomes, by (7), independent of the Landau-level index, $\sigma_l^2=\sigma_0^2=\alpha^2B/(2\pi)$. Remarkably, in this limit explicit expressions for w_0 and w_l, in the additional high Landau-level limit $l\to\infty$, are available. The first result is due to Wegner[18] and reads

$$w_0(E)=\frac{2}{\pi^{3/2}\sigma_0}\frac{\exp(\eta^2)}{1+[2\pi^{-1/2}\int_0^\eta\mathrm{d}\xi\exp(\xi^2)]^2},\quad \eta:=\frac{E}{\sigma_0}, \tag{24}$$

also see Refs. 19, 20, 13. Of course, when specializing the bound in (21), it is consistent with (24) because $2<\pi$. As for the second result, it is known[21,22] that w_l approaches for $l\to\infty$ a semi-elliptic probability density,

$$\lim_{l\to\infty}w_l(E)=\frac{1}{2\pi\sigma_0}\Theta(4-\eta^2)\sqrt{4-\eta^2},\quad \eta=\frac{E}{\sigma_0}. \tag{25}$$

Unfortunately, in the delta-correlated limit the bound in (21) diverges asymptotically like $l^{1/4}/(\pi^{1/4}\sigma_0)$ as $l\to\infty$.

(3) Different from (25), for the above-mentioned Gaussian covariance function with a strictly positive correlation length $\tau>0$, the high Landau-level limit (informally) reads $\lim_{l\to\infty}w_l(E)=\delta(E)$. This follows from Chebyshey's inequality and the fact that the Landau-level broadening vanishes in this limit if $\tau>0$: $\lim_{l\to\infty}\sigma_l^2=0$.[12] In agreement with that, the bound in (21) diverges in this case, as may be seen either from $0\leqslant\Gamma_l^2\leqslant\sigma_l^2$, valid[12] for any covariance function, or directly from (22).

(4) The existence of a bounded w_0 in the delta-correlated limit of a Gaussian random potential stands in contrast to situations with random point impurities, $V^{(\omega)}(x)=\Sigma_j\lambda_j^{(\omega)}\delta(x-p_j^{(\omega)})$. To our knowledge, the following four cases have been considered so far:

(a) the *impurity positions* $p_j\in\mathbb{R}^2$ randomly located according to Poisson's distribution and the *coupling strengths* $\lambda_j\in\mathbb{R}$ nonrandom, strictly positive, and all equal.[19,28]
(b) $p_j\in\mathbb{R}^2$ randomly located according to Poisson's distribution and $\lambda_j\in\mathbb{R}$ independently identically distributed[19] according to a probability measure whose support is a compact interval containing the origin.[27]
(c) $p_j\in\mathbb{Z}^2$ nonrandom and $\lambda_j\in\mathbb{R}$ independently, identically distributed according to a bounded probability density whose support is a compact interval containing the origin.[16]
(d) $p_j=j+d_j$ with $j\in\mathbb{Z}^2$ nonrandom and the *displacements* $d_j\in\mathbb{R}^2$ independently, identically distributed according to a bounded probability density with support contained in the unit square $]-1/2,1/2[^2\subset\mathbb{R}^2$. Moreover, $\lambda_j\in\mathbb{R}$ as in the previous case.[17]

In any of these cases, it has been shown that $P_0V^{(\omega)}P_0$ has an infinitely degenerate eigenvalue at zero energy for $\mathbb{P}$-almost all $\omega\in\Omega$, if the magnetic-field strength B is sufficiently large.

C. Gaussian upper bound on the restricted density of states

As already pointed out, the estimate (15) is rather rough, because it does not depend on the energy. Fortunately, under an additional isotropy assumption and with more effort one may construct an energy-dependent estimate.

Theorem 2: *Suppose the situation of Theorem 1 and that the there-defined convolution C_μ is spherically symmetric (with respect to the origin). Then the l*th *restricted density of states w_l is bounded by a Gaussian in the sense that*

$$w_l(E)\leqslant \frac{1}{\sqrt{2\pi}\langle\psi_{l,0},C_\mu\psi_{l,0}\rangle}\exp\left(-\frac{E^2}{2C(0)}\right) \tag{26}$$

for Lebesgue-almost all energies $E\in\mathbb{R}$. [*Here $\psi_{l,0}$ is defined in (9).*]

Remarks: (1) Equality holds in (26) [and (27) in the following] with $\langle\psi_{l,0},C_\mu\psi_{l,0}\rangle=\sqrt{C(0)}=\sigma_l=\Gamma_l$ for the simple extreme case of a spatially constant Gaussian random potential V, that is, if $C(x)=C(0)$ for all $x\in\mathbb{R}^2$. Of course, V is not ergodic in this case. For a lucid discussion of ergodicity and related notions in the theory of random (Schrödinger) operators, see Ref. 40.

(2) In view of (19), we conjecture the true leading decay of $w_l(E)=\mathrm{d}\nu_l(]-\infty,E[)/\mathrm{d}E$ for $|E|\to\infty$ to be Gaussian with decay energy Γ_l. This energy is strictly smaller than $\sqrt{C(0)}$, if not $C(x)=C(0)$ for all $x\in\mathbb{R}^2$.

(3) Using $\exp(-E^2/2C(0))\leqslant 1$ in (26), one obtains an energy-independent estimate which in general is weaker than (15) because $\langle\psi_{l,0},C_\mu\psi_{l,0}\rangle\leqslant\|P_lC_\mu P_l\|$. In particular this is true in the delta-correlated limit in which the energy dependence of the bound in (26) disappears anyway.

Gaussian random potentials with positive, spherically symmetric covariance functions illustrate Theorem 2.

Example 3: For a positive covariance function $0\leqslant C(x)<\infty$, which is additionally spherically symmetric, the prefactor of the Gaussian in (26) is minimized by taking $\mu(\mathrm{d}^2x)\,\gamma(\psi_{l,0})=\mathrm{d}^2x|\psi_{l,0}(x)|^2$ so that $\langle\psi_{l,0},C_\mu\psi_{l,0}\rangle=\gamma(\psi_{l,0})$. By the Fourier representation (23) and Jensen's inequality, with $\widetilde{C}/C(0)$ as the underlying Borel probability measure on $\mathbb{R}^2$, one finds that $\gamma^2(\psi_{l,0})\geqslant\sigma_l^4/C(0)$. Therefore, the estimate (26) may be weakened to the following more explicit one:

$$w_l(E)\leqslant\frac{C(0)}{\sigma_l^2}\,\frac{1}{\sqrt{2\pi C(0)}}\exp\left(-\frac{E^2}{2C(0)}\right), \tag{27}$$

where σ_l^2 is the variance of ν_l, see (7). Alternatively, (27) may be obtained directly from (26) by choosing $\mu(\mathrm{d}^2x)\sqrt{C(0)}=\mathrm{d}^2x\,\delta(x)$ so that $C_\mu(x)=C(x)/\sqrt{C(0)}$.

Remark: For the Gaussian covariance function $C(x)=C(0)\exp[-|x|^2/(2\tau^2)]$, it is known[23,12] that $\gamma^2(\psi_{0,0})=\Gamma_0^2=C(0)B\tau^2/(B\tau^2+2)$, also see (22). Theorem 2 together with the minimizing result mentioned in Example 3 therefore gives the estimate

$$w_0(E)\leqslant\sqrt{\frac{B\tau^2+2}{B\tau^2}}\,\frac{1}{\sqrt{2\pi C(0)}}\exp\left(-\frac{E^2}{2C(0)}\right) \tag{28}$$

for the restricted density of states of the lowest Landau band. In this setting w_0 has been approximately constructed using a continued-fraction approach.[25] In accordance with the first remark below (26), a comparison with this approximation supports the fact that the estimates (28), (27), and (26) are the sharper, the longer the distance is over which the fluctuations of the Gaussian random potential are significantly correlated, more precisely, the larger the squared length ratio $B\tau^2$ is.

III. PROOF OF THE GAUSSIAN UPPER BOUND

The proof of Theorem 2 requires two major ingredients, an approximation result (Proposition 2) and a Wegner-type of estimate (Proposition 3). We defer the details and proofs of these results to Secs. III B and III C. Taking these results for granted, the arguments for the validity of Theorem 2 are as follows.

Proof of Theorem 2: Since the restricted density-of-states measure is even for a (zero-mean) Gaussian random potential, that is, $\nu_l(I)=\nu_l(-I)$ for all $I\in\mathcal{B}(\mathbb{R})$, and since we already know from Theorem 1 that the density of states w_l exists and is bounded by a constant which does not exceed the prefactor of the Gaussian in (26), it is sufficient to consider ν_l on the strictly negative half-line $]-\infty,0[$.

We now use Proposition 2 to show that a suitably defined sequence of probability measures $(\nu_{l,n})_{n\in\mathbb{N}}$ [see (45)] converges weakly to ν_l as $n\to\infty$. Given $E_1<E_2\leqslant 0$, we introduce the open interval $I:=]E_1,E_2[$. Then we have

$$\nu_l(I)\leqslant\liminf_{n\to\infty}\nu_{l,n}(I), \tag{29}$$

by the portmanteau theorem (Theorem 30.10 in Ref. 41). We now use Proposition 3 to estimate the prelimit expression and obtain

$$\nu_l(I)\leqslant\frac{|I|}{\sqrt{2\pi}\langle\psi_{l,0},C_\mu\psi_{l,0}\rangle}\exp\left(\beta E+\frac{\beta^2}{2}C(0)\right), \tag{30}$$

for all $E\in[E_2,0]$ and all $\beta\geqslant 0$. Choosing $\beta=-E/C(0)\geqslant 0$ gives the claimed upper bound on w_l for $E<0$. □

Before we proceed with the proofs of the approximation result and the Wegner-type of estimate, which were needed in the above-given proof, we collect some preparations in the following.

A. Angular-momentum eigenfunctions

The functions

$$x\mapsto\varphi_{l,k}(x):=\sqrt{\frac{l!}{(l+k)!}}\left[\sqrt{\frac{B}{2}}(x_1+ix_2)\right]^k L_l^{(k)}\left(\frac{B|x|^2}{2}\right)\sqrt{\frac{B}{2\pi}}\exp\left(-\frac{B|x|^2}{4}\right) \tag{31}$$

constitute[7] with $k\in\{-l,-l+1,...\}$ an orthonormal basis in the lth Landau-level eigenspace $P_lL^2(\mathbb{R}^2)$. In fact, $\varphi_{l,k}$ is an *eigenfunction of the (perpendicular component of the canonical) angular-momentum* operator $L_3:=i(x_2\partial/\partial x_1-x_1\partial/\partial x_2)$ corresponding to the eigenvalue k, that is, $L_3\varphi_{l,k}=k\varphi_{l,k}$.

Lemma 2: Let $u:\mathbb{R}^2\to[0,\infty[$ be a measurable, positive, bounded, and spherically symmetric function. Then the operator inequality

$$P_lu_xP_l\geqslant\langle\psi_{l,0},u\psi_{l,0}\rangle\psi_{l,x}\langle\psi_{l,x},\cdot\rangle \tag{32}$$

holds for all $x\in\mathbb{R}^2$. Here the function $u_x(\cdot):=u(\cdot-x)$ is the x-translate of u and $\psi_{l,x}\langle\psi_{l,x},\cdot\rangle$ denotes the orthogonal projection operator onto the one-dimensional subspace spanned by $\psi_{l,x}$, see (9).

Proof: Since the function u is spherically symmetric, the operator P_luP_l is diagonal in the angular-momentum basis such that

$$P_luP_l=\sum_{k=-l}^{\infty}\langle\varphi_{l,k},u\varphi_{l,k}\rangle\varphi_{l,k}\langle\varphi_{l,k},\cdot\rangle\geqslant\langle\varphi_{l,0},u\varphi_{l,0}\rangle\varphi_{l,0}\langle\varphi_{l,0},\cdot\rangle. \tag{33}$$

The shifted operator $P_l u_x P_l = T_x P_l u P_l T_x^\dagger$ results from the left-hand side of (33) by a unitary transformation with the magnetic translation T_x, see (11). The proof is hence completed by observing that $\varphi_{l,0} = \psi_{l,0}$ and $\psi_{l,x} = T_x \psi_{l,0}$. □

Subsequently, we will consider the n-dimensional subspaces $P_{l,n} L^2(\mathbb{R}^2) \subset P_l L^2(\mathbb{R}^2)$ spanned by the first n angular-momentum eigenfunctions. The orthogonal projection $P_{l,n}$ is therefore defined by

$$P_{l,n} := \sum_{k=-l}^{n-l-1} \varphi_{l,k} \langle \varphi_{l,k}, \cdot \rangle, \quad n \in \mathbb{N}. \tag{34}$$

The completeness of $\{\varphi_{l,k}\}$ in $P_l L^2(\mathbb{R}^2)$ implies the strong-limit relation $s\text{-}\lim_{n\to\infty} P_{l,n} = P_l$ on $L^2(\mathbb{R}^2)$. The projections $P_{l,n}$ are integral operators with (continuous) kernels $P_{l,n}(x,y)$, whose diagonals are given by $P_{l,n}(x,x) = B G_{l,n}(B|x|^2/2)/2\pi \leqslant B/2\pi$. Here the function

$$G_{l,n}(\xi) := e^{-\xi} \sum_{k=-l}^{n-l-1} \frac{l!}{(k+l)!} \xi^k (L_l^{(k)}(\xi))^2, \quad \xi \geqslant 0, \quad n \in \mathbb{N}, \tag{35}$$

is approximately one and approximately zero for ξ smaller and larger than $n - 1/2$, respectively. Moreover, the length of the interval on which its values differ significantly from one and zero does not depend on n, also see the remark after the following

Lemma 3: Let $G_{l,n}$ be defined by (35). Then the following scaling-limit relation holds

$$\lim_{n\to\infty} G_{l,n}(n\xi) = \begin{cases} 1 & \text{if} \quad 0 < \xi < 1 \\ 0 & \text{if} \quad 1 < \xi < \infty \end{cases}. \tag{36}$$

Moreover, for every $l \in \mathbb{N}_0$ there exist an $N_l \in \mathbb{N}$ and a real $A_l > 0$, such that $0 \leqslant G_{l,n}(n\xi) \leqslant A_l e^{-\xi}$ for all $\xi \geqslant 0$ and all $n \geqslant N_l$.

Remark: With more effort one may even prove that for every $l \in \mathbb{N}_0$ there exists some polynomial $\zeta \mapsto \mathrm{Pol}(\zeta, l)$ of maximal degree $2l+1$ such that

$$0 \leqslant G_{l,n}((\sqrt{n-1/2} + \zeta)^2) \leqslant e^{-\zeta^2} \mathrm{Pol}(\zeta, l) \tag{37}$$

for all $n \in \mathbb{N}$ and all $\zeta \geqslant 0$. Moreover,

$$1 - e^{-\zeta^2} \mathrm{Pol}(-\zeta, l) \leqslant G_{l,n}((\sqrt{n-1/2} - \zeta)^2) \leqslant 1 \tag{38}$$

for all $n \in \mathbb{N} + l$ and all $0 \leqslant \zeta \leqslant \sqrt{n-1/2}$.

Proof of Lemma 3: The proof is based on the following recurrence relation:

$$G_{l,n}(\xi) - G_{l-1,n}(\xi) = -e^{-\xi} \frac{(l-1)!}{(n-1)!} \xi^{n-l} L_{l-1}^{(n-1)}(\xi) L_l^{(n-l)}(\xi) =: D_{l,n}(\xi) \tag{39}$$

for all $l \geqslant 1$. It follows from the fact that $D_{l,n}$ may be written as a telescope sum according to

$$D_{l,n}(\xi) = e^{-\xi} \sum_{k=-l+1}^{n-l} \frac{(l-1)!}{(k+l-1)!} \xi^k \left[\frac{k+l-1}{\xi} L_{l-1}^{(k-1)}(\xi) L_l^{(k-1)}(\xi) - L_{l-1}^{(k)}(\xi) L_l^{(k)}(\xi) \right]. \tag{40}$$

Equation 8.971(4) in Ref. 9 may be written as $(k+l-1) L_{l-1}^{(k-1)}(\xi) = \xi L_{l-1}^{(k)}(\xi) + l L_l^{(k-1)}(\xi)$. Using this together with Eq. 8.971(5) in Ref. 9, the difference in the square brackets in (40) is seen to be equal to $(L_l^{(k-1)}(\xi))^2 l/\xi - (L_{l-1}^{(k)}(\xi))^2$. Splitting the sum into two parts yields (39). The proof of (36) then follows by mathematical induction on $l \in \mathbb{N}_0$. In case $l = 0$ we write

$$G_{0,n}(\xi)=e^{-\xi}\sum_{k=0}^{n-1}\frac{\xi^k}{k!}=:e^{-\xi}e_n(\xi)-e^{-\xi}\frac{\xi^n}{n!} \tag{41}$$

in terms of the incomplete exponential function e_n (Eq. 6.5.11 in Ref. 42). By Stirling's estimate $n!\geqslant\sqrt{2\pi n}n^n e^{-n}$ for the factorial (Eq. 6.1.38 in Ref. 42) and the elementary inequality $\xi-1-\ln\xi\geqslant 0$, the second term on the right-hand side of (41) vanishes in the scaling limit (36) such that the claim reduces to the content of Eq. 6.5.34 in Ref. 42 for $l=0$. For the induction clause, we use the following exponential, hence rough, growth limitation for Laguerre polynomials:

$$|L_l^{(k)}(\xi)|=\left|\sum_{j=0}^{l}(-1)^j\binom{l+k}{l-j}\frac{\xi^j}{j!}\right|\leqslant\sum_{j=0}^{l}(l+k)^{l-j}\frac{\xi^j}{j!}\leqslant(l+k)^l e^{\xi/(l+k)} \tag{42}$$

which is valid for $k\geqslant 1-l$ and obtained by bounding the binomial coefficients. Using again Stirling's estimate, this yields the inequality

$$|D_{l,n}(n\xi)|\leqslant(l-1)!e^{3\xi}\left(\frac{n}{\xi}\right)^l e^{-(\xi-1-\ln\xi)n} \tag{43}$$

for all $l\geqslant 1$ and all $n\geqslant 2$. Since $\xi-1-\ln\xi>0$ for all $\xi\neq 1$, we have $\lim_{n\to\infty}D_{l,n}(n\xi)=0$ and hence $\lim_{n\to\infty}G_{l,n}(n\xi)=\lim_{n\to\infty}G_{l-1,n}(n\xi)$ for all $\xi\neq 1$, which completes the proof of (36).

For a proof of the exponential bound $0\leqslant G_{l,n}(n\xi)\leqslant A_l e^{-\xi}$ with some $A_l>0$ and n large enough, we first recall that

$$0\leqslant G_{l,n}(\xi)\leqslant G_{l,\infty}(\xi)=1 \tag{44}$$

for all $\xi\geqslant 0$, $l\in\mathbb{N}_0$, and $n\in\mathbb{N}$. Using $n^k\leqslant(n-1)^k e$ for $0\leqslant k\leqslant n-1$ in (41), one obtains $G_{0,n}(n\xi)\leqslant e^{1-\xi}$ for all $\xi\geqslant 0$. The claimed exponential bound for all $l\in\mathbb{N}_0$ then follows from (43) and (39). □

B. Approximating sequence of probability measures on the real line

Employing the $n\times n$ random Hermitian matrices $P_{l,n}V^{(\omega)}P_{l,n}$, we define a sequence $(\nu_{l,n})_{n\in\mathbb{N}}$ of probability measures by

$$\nu_{l,n}(I):=\frac{1}{n}\mathbb{E}\{\mathrm{Tr}[P_{l,n}\chi_I(P_{l,n}VP_{l,n})P_{l,n}]\},\quad I\in\mathcal{B}(\mathbb{R}). \tag{45}$$

Here the trace $\mathrm{Tr}[P_{l,n}\chi_I(P_{l,n}V^{(\omega)}P_{l,n})P_{l,n}]$ is equal to the (random) number of eigenvalues (counting multiplicity) of $P_{l,n}V^{(\omega)}P_{l,n}$ in the Borel set I. For rather general random potentials the sequence $(\nu_{l,n})$ approximates the restricted density-of-states measure ν_l. This is the first ingredient of the proof of Theorem 2.

Proposition 2: Let V be an $\mathbb{R}^2$-homogeneous random potential with $\mathbb{E}\{|V(0)|\}<\infty$. Moreover, assume that $P_lV^{(\omega)}P_l$ and $P_{l,n}V^{(\omega)}P_{l,n}$ for all $n\in\mathbb{N}$ are self-adjoint on $L^2(\mathbb{R}^2)$ for $\mathbb{P}$-almost all $\omega\in\Omega$. Then

$$\nu_l=\lim_{n\to\infty}\nu_{l,n} \tag{46}$$

in the sense of weak convergence of finite measures.

Remark: The assumptions of the proposition are fulfilled for a Gaussian random potential in the sense of Definition 1, because P_lVP_l is almost surely essentially self-adjoint on $\mathcal{S}(\mathbb{R}^2)$ by Proposition 1. Moreover, the random matrix operator $P_{l,n}VP_{l,n}$ is almost surely self-adjoint for all $n\in\mathbb{N}$ because of the almost-sure finiteness $|\langle\varphi_{l,j},V\varphi_{l,k}\rangle|<\infty$ for all $j,k\in\mathbb{N}_0-l$.

Proof of Proposition 2: The claimed weak convergence of (finite) measures is equivalent to pointwise convergence of their Stieltjes transforms, that is,

$$\lim_{n\to\infty}\int_{\mathbb{R}}\frac{\nu_{l,n}(\mathrm{d}E)}{E-z}=\int_{\mathbb{R}}\frac{\nu_l(\mathrm{d}E)}{E-z} \tag{47}$$

for all $z\in\mathbb{C}\backslash\mathbb{R}$, see, for example, Proposition 4.9 in Ref. 43. The spectral theorem and (10) show that the latter convergence follows from

$$\lim_{n\to\infty}\frac{1}{n}\mathbb{E}\{|\mathrm{Tr}[P_{l,n}((P_{l,n}VP_{l,n}-z)^{-1}-(P_lVP_l-z)^{-1})P_{l,n}]|\}=0. \tag{48}$$

As a self-adjoint operator of finite rank, $P_{l,n}V^{(\omega)}P_{l,n}$ is defined on the whole space $L^2(\mathbb{R}^2)$ for $\mathbb{P}$-almost all $\omega\in\Omega$, so that we may use the (second) resolvent equation.[44] Together with the fact that $(P_{l,n}V^{(\omega)}P_{l,n}-z)^{-1}$ and $P_{l,n}$ commute with each other, the absolute value of the trace in (48) is hence seen to be equal to

$$\begin{aligned}&|\mathrm{Tr}[P_{l,n}(P_{l,n}V^{(\omega)}P_{l,n}-z)^{-1}P_{l,n}V^{(\omega)}(P_l-P_{l,n})(P_lV^{(\omega)}P_l-z)^{-1}P_{l,n}]|\\&\quad\leqslant\|(P_{l,n}V^{(\omega)}P_{l,n}-z)^{-1}\|\|(P_lV^{(\omega)}P_l-z)^{-1}\|\|P_{l,n}V^{(\omega)}(P_l-P_{l,n})\|_1\\&\quad\leqslant|\mathrm{Im}\,z|^{-2}\|P_{l,n}V^{(\omega)}(P_l-P_{l,n})\|_1.\end{aligned} \tag{49}$$

Here we employed Hölder's inequality for the trace norm $\|A\|_1:=\mathrm{Tr}(A^\dagger A)^{1/2}$ and $\mathrm{Im}\,z$ denotes the imaginary part of z. The trace norm in (49) is in turn estimated as follows:

$$\begin{aligned}\|P_{l,n}V^{(\omega)}(P_l-P_{l,n})\|_1&=\left\|\frac{B}{2\pi}\int_{\mathbb{R}^2}\mathrm{d}^2x\,V^{(\omega)}(x)\,\psi_{l,x,n}\langle\psi_{l,x}-\psi_{l,x,n},\cdot\rangle\right\|_1\\&\leqslant\frac{B}{2\pi}\int_{\mathbb{R}^2}\mathrm{d}^2x|V^{(\omega)}(x)|\|\psi_{l,x,n}\langle\psi_{l,x}-\psi_{l,x,n},\cdot\rangle\|_1\\&=\int_{\mathbb{R}^2}\mathrm{d}^2x|V^{(\omega)}(x)|\sqrt{P_{l,n}(x,x)[P_l(x,x)-P_{l,n}(x,x)]},\end{aligned} \tag{50}$$

where we introduced the sequence of two-parameter families of complex-valued functions

$$y\mapsto\psi_{l,x,n}(y):=(P_{l,n}\psi_{l,x})(y),\quad x\in\mathbb{R}^2. \tag{51}$$

Note that these functions are not normalized, $\langle\psi_{l,x,n},\psi_{l,x,n}\rangle=2\pi P_{l,n}(x,x)/B=G_{l,n}(B|x|^2/2)\leqslant 1$. Combining (49) and (50), using Fubini's theorem and the homogeneity of the random potential, the left-hand side of (48) is seen to be bounded from above by

$$\begin{aligned}&\lim_{n\to\infty}\frac{\mathbb{E}[|V(0)|]}{n|\mathrm{Im}\,z|^2}\int_{\mathbb{R}^2}\mathrm{d}^2x\sqrt{P_{l,n}(x,x)[P_l(x,x)-P_{l,n}(x,x)]}\\&\quad=\frac{\mathbb{E}[|V(0)|]}{|\mathrm{Im}\,z|^2}\lim_{n\to\infty}\int_0^\infty\mathrm{d}\xi\sqrt{G_{l,n}(n\xi)[1-G_{l,n}(n\xi)]}=0.\end{aligned} \tag{52}$$

Here we employed the definition of $G_{l,n}$ [see the text above (35)], performed the angular integration, changed variables $n\xi:=B|x|^2/2$ in the remaining integral, and used Lemma 3 and the dominated-convergence theorem. □

C. A Wegner-type of estimate

The second ingredient for the proof of Theorem 2 is the following:

Proposition 3: In the situation of Theorem 2 let $E_1<E_2\leqslant E\leqslant 0$ *and put* $I:=]E_1,E_2[$. *Then*

$$\nu_{l,n}(I)\leqslant\left(\frac{|I|}{\sqrt{2\pi}\langle\psi_{l,0},C_\mu\psi_{l,0}\rangle}+s_{l,n}\right)\exp\left(\beta E+\frac{\beta^2}{2}C(0)\right),\tag{53}$$

for all $\beta\geqslant 0$. *Here* $s_{l,n}:=\int_1^\infty \mathrm{d}\xi\, G_{l,n}(n\xi)$ *converges to zero as* $n\to\infty$.

Proof: By the definition of $\nu_{l,n}$ and the spectral theorem one has

$$\nu_{l,n}(I)\leqslant\frac{e^{\beta E}}{n}\,\mathbb{E}\{\mathrm{Tr}[P_{l,n}e^{-\beta P_{l,n}VP_{l,n}}\chi_I(P_{l,n}VP_{l,n})P_{l,n}]\}.\tag{54}$$

We evaluate the trace in an orthonormal eigenbasis of $P_{l,n}V^{(\omega)}P_{l,n}$ and apply the Jensen–Peierls inequality[45] to bound the probabilistic expectation in (54) from above by

$$\begin{aligned}&\mathbb{E}\{\mathrm{Tr}[P_{l,n}e^{-\beta V}P_{l,n}\chi_I(P_{l,n}VP_{l,n})P_{l,n}]\}\\&\quad=\frac{B}{2\pi}\int_{\mathbb{R}^2}\mathrm{d}^2x\,\mathbb{E}\{e^{-\beta V(0)}\langle\psi_{l,x,n},\chi_I(P_{l,n}V(\cdot-x)P_{l,n})\psi_{l,x,n}\rangle\},\end{aligned}\tag{55}$$

where we used Fubini's theorem and the $\mathbb{R}^2$-homogeneity of V. The Lebesgue integral in (55) over the plane may be split into two parts with domains of integration inside and outside a disk centered at the origin and with radius $\sqrt{2n/B}$.

To estimate the inner part, we use the one-parameter decomposition (16) of the Gaussian random potential V. Since U and λ are stochastically independent, we may estimate the conditional expectation of the integrand in (55) relative to the sub-sigma-algebra generated by $\{U(y)\}_{y\in\mathbb{R}^2}$ with the help of Lemma 1. Taking there $g(\xi)=\exp(-\beta\xi C_\mu(0)-\xi^2/2)/\sqrt{2\pi}$, $K=\psi_{l,x,n}\langle\psi_{l,x,n},\cdot\rangle/\langle\psi_{l,x,n},\psi_{l,x,n}\rangle$, and $M=P_{l,n}C_\mu(\cdot-x)P_{l,n}\geqslant\langle\psi_{l,0},C_\mu\psi_{l,0}\rangle\langle\psi_{l,x,n},\psi_{l,x,n}\rangle K^2$, where the last inequality follows from Lemma 2 and the positivity as well as the spherical symmetry of C_μ, we obtain an ω- and x-independent bound according to

$$\begin{aligned}&\int_{\mathbb{R}}\mathrm{d}\xi\,\frac{e^{-\xi^2/2}}{\sqrt{2\pi}}\,e^{-\beta\xi C_\mu(0)}\langle\psi_{l,x,n},\chi_I(P_{l,n}U^{(\omega)}(\cdot-x)P_{l,n}+\xi P_{l,n}C_\mu(\cdot-x)P_{l,n})\psi_{l,x,n}\rangle\\&\quad\leqslant\frac{|I|}{\sqrt{2\pi}\langle\psi_{l,0},C_\mu\psi_{l,0}\rangle}\exp\left(\frac{\beta^2}{2}(C_\mu(0))^2\right).\end{aligned}\tag{56}$$

Using $\mathbb{E}[\exp(-\beta U(0))]=\exp(\beta^2(C(0)-(C_\mu(0))^2)/2)$, the inner part of the integral in (55), may hence be estimated as follows:

$$\begin{aligned}&\int_{|x|^2\leqslant 2n/B}\mathrm{d}^2x\,\mathbb{E}\{e^{-\beta V(0)}\langle\psi_{l,x,n},\chi_I(P_{l,n}V(\cdot-x)P_{l,n})\psi_{l,x,n}\rangle\}\\&\quad\leqslant\frac{2\pi n}{B}\,\frac{|I|}{\sqrt{2\pi}\langle\psi_{l,0},C_\mu\psi_{l,0}\rangle}\exp\left(\frac{\beta^2}{2}C(0)\right).\end{aligned}\tag{57}$$

This gives the first part of the claimed inequality (53).

To complete the proof, we estimate the outer part of the integral in (55) as follows:

$$\int_{|x|^2\geqslant 2n/B} \mathrm{d}^2x\,\mathbb{E}\{e^{-\beta V(0)}\langle \psi_{l,x,n}, \chi_I(P_{l,n}V(\cdot - x)P_{l,n})\psi_{l,x,n}\rangle\}$$

$$\leqslant \mathbb{E}\{e^{-\beta V(0)}\}\int_{|x|^2\geqslant 2n/B} \mathrm{d}^2x\langle \psi_{l,x,n}, \psi_{l,x,n}\rangle = \frac{2\pi n}{B}\,\mathbb{E}\{e^{-\beta V(0)}\}\int_1^\infty \mathrm{d}\xi G_{l,n}(n\xi). \quad (58)$$

Here we employed (51) and changed variables $n\xi := B|x|^2/2$ to obtain the last equality. Thanks to Lemma 3, the last integral in (58), and hence $s_{l,n}$, converges to zero as $n\to\infty$ by the dominated-convergence theorem. □

(Received 15 May 2001; accepted for publication 13 September 2001)

Armstrong's method of relativistic description of atoms in *LS* coupling using the equivalent operator is developed. Its form in terms of standard unit operators acting within a space of one shell is obtained. The interpretation of separate terms of equivalent Breit operator is investigated in a general case of nonequivalent electrons. The relativistic Dirac–Fock equations for the level and term in *LS* coupling are derived. The equivalent operator is applied to obtain the averages of relativistic operators too. © *2001 American Institute of Physics.* [DOI: 10.1063/1.1415429]

I. INTRODUCTION

Relativistic effects become rather important for heavy atoms, however, even within the $5f^N$ open electronic shell in actinidies the coupling remains closer to *LS* than to the *jj* scheme.[1] There are two ways to perform calculations in the relativistic *LS* coupling: to transform relativistic wave functions from *jj* to *LS* coupling[2,3] or to use a relativistic equivalent operator.[4–6] The transformation matrices from *jj* to *LS* coupling have rather complex form, because such transformation requires one not only to change the coupling of moments, but also to separate all equivalent electrons by fractional parentage coefficients of one scheme and then to join them by the corresponding coefficients of the other scheme or to use the recurrence relations.[7] This method was implemented in the computer code.[8] However, the other method proposed in Ref. 4 and elaborated in Refs. 5 and 6 also deserves attention: the introduction of an equivalent operator which can be evaluated with respect to nonrelativistic wave functions to produce the same result as obtained by evaluating the relativistic Hamiltonian with respect to relativistic wave functions. Such operator was obtained in Ref. 5 for the Breit equation using the summation rules for $3nj$ symbols and later by the more effective method of second quantization in Ref. 6. Advantages of this method are a simplicity of the calculation of matrix elements in the appropriate nonrelativistic scheme as well as the possibility to have additional insight into the properties of various parts of the Hamiltonian and in this way to introduce some approximations. The mixing of various relativistic configurations arising from the same nonrelativistic configuration is taken into account automatically by this method.

The aim of this work is to express the equivalent operator in terms of standard operators acting within the space of one shell and to consider the asymptotic of its terms in a general case (Sec. II) as well as to apply this operator to obtain the Dirac–Fock equations in *LS* coupling (Sec. III) and averages of relativistic operators (Sec. IV).

II. EXPRESSIONS FOR THE EQUIVALENT OPERATOR

We will consider the relativistic Dirac–Breit Hamiltonian:

$$H^{\mathrm{rel}} = H_{\alpha_1} + H_{\alpha_2} + H_\beta + H_\gamma + H_\delta, \tag{1}$$

where

[a]Electronic mail: karazija@itpa.lt

$$H_{\alpha_1}=\sum_i\ ((\alpha_i\,\mathbf{p}_i)+(\beta_i-1)\,mc^2),$$

$$H_{\alpha_2}=-\sum_i\ \frac{Ze^2}{r_i},\quad H_\beta=\sum_{i<j}\frac{e^2}{r_{ij}},\tag{2}$$

$$H_\gamma=-\frac{e^2}{2}\sum_{i<j}\frac{(\alpha_i\cdot\alpha_j)}{r_{ij}},\quad H_\delta=-\frac{e^2}{2}\sum_{i<j}\frac{(\alpha_i\cdot\mathbf{r}_{ij})(\alpha_j\cdot\mathbf{r}_{ij})}{r_{ij}^3}.$$

Here the usual notations are employed. The rest mass of electrons is excluded from (1) in order to have the Hamiltonian corresponding to its nonrelativistic analogue.

The way to obtain the equivalent operator O_i corresponding to the relativistic operator H_i as stated in Ref. 5 is as follows. The one-electron (H_1) and two-electron (H_2) relativistic operators are presented in the second quantization form:

$$H_1=\sum_{\substack{n_1l_1j_1m_1\\ n_2l_2j_2m_2}} q_{m_1}^{(j_1)+}(n_1l_1j_1m_1|h_1|n_2l_2j_2m_2)q_{m_2}^{(j_2)},\tag{3}$$

$$H_2=\sum_{\{n_il_ij_im_i\}} q_{m_1}^{(j_1)+}q_{m_2}^{(j_2)+}(n_1l_1j_1m_1n_2l_2j_2m_2|h_2|n_3l_3j_3m_3n_4l_4j_4m_4)q_{m_4}^{(j_4)}q_{m_3}^{(j_3)},\tag{4}$$

where $q_m^{(j)+}$ is a creation operator producing the one-electron state $|nljm)$ and $q_m^{(j)}$ is an annihilation operator destroying such a state; $\{n_il_ij_im_i\}$ means all sets with $i=1-4$. Expressions (3) and (4) also contain one- and two-electron matrix elements with respect to non-antisymmetrized wave functions. The relativistic single-electron state has the form:

$$|nljm)=\begin{pmatrix}|nljm\rangle\\ i|n\overline{l}jm\rangle\end{pmatrix},\tag{5}$$

where $\overline{l}=l\pm1$ as $j=l\pm\frac{1}{2}$. $|nljm\rangle$ can be treated as a nonrelativistic state[6] (relativistic states are indicated by a rounded ket and the nonrelativistic ones by an angular ket). Operators $q_m^{(j)+}$ and $\tilde{q}_m^{(j)}=(-1)^{j-m}q_{-m}^{(j)}$ are transformed like the components of a spherical tensor of rank j.

According to (5) the relativistic operators $q^{(j)+}$ and $\tilde{q}^{(j)}$ of creation or annihilation of electron can be expressed in terms of nonrelativistic operators $a^{(j)+}$ and $\tilde{a}^{(j)}$, and the latter can be transformed into the ls coupling scheme using Clebsch–Gordan coefficients:

$$a_m^{(j)+}=\sum_{m_lm_s}\begin{bmatrix}l & s & j\\ m_l & m_s & m\end{bmatrix}a_{m_lm_s}^{(ls)+},\quad \tilde{a}_m^{(j)}=\sum_{m_lm_s}\begin{bmatrix}l & s & j\\ m_l & m_s & m\end{bmatrix}\tilde{a}_{m_lm_s}^{(ls)}.\tag{6}$$

It is useful to introduce the standard operator $W^{(k_1k_2k)}$ with the orbital rank k_1, spin rank k_2, and total rank k. In the second quantization form of coupled operators a^+ and $\tilde{a}$ the operator $W^{(k_1k_2k)}$ is represented

$$W^{(k_1k_2k)}=-[k_1,k_2]^{-1/2}\sum_{n_1l_1n_2l_2}[a^{(l_1s)+}\times\tilde{a}^{(l_2s)}]^{(k_1k_2k)}\langle n_1l_1s\|w^{(k_1k_2)}(n_1l_1,n_2l_2)\|n_2l_2s\rangle,\tag{7}$$

where $[k_1,k_2]$ means $(2k_1+1)(2k_2+1)$. The reduced matrix element of the one-electron operator (7) is defined

$$\langle n_\alpha l_\alpha s\|w^{(k_1k_2)}(n_1l_1,n_2l_2)\|n_\beta l_\beta s\rangle=[k_1,k_2]^{1/2}\delta(n_1,n_\alpha)\,\delta(l_1,l_\alpha)\,\delta(n_\beta,n_2)\,\delta(l_\beta,l_2).\tag{8}$$

Then

$$W^{(k_1k_2k)}=-\sum_{n_1l_1n_2l_2}[a^{(l_1s)+}\times\tilde{a}^{(l_2s)}]^{(k_1k_2k)}=\sum_{n_1l_1n_2l_2}W^{(k_1k_2k)}(n_1l_1,n_2l_2). \tag{9}$$

At $n_1l_1\equiv n_2l_2$ the operator

$$W^{(k_1k_2k)}(n_1l_1,n_2l_2)\equiv W^{(k_1k_2k)}(n_1l_1) \tag{10}$$

is obtained. It is acting in the space of $n_1l_1^{N_1}$ shell and equals to the sum of one-electron operators $\Sigma_{i=1}^{N_1}w_i(n_1l_1)$.

Application of the Wigner–Eckart theorem to the matrix elements in (3) and (4), coupling of a^+, $\tilde{a}$ operators, and summation of all Clebsch–Gordan coefficients over the projections of moments result in the expressions for the equivalent operators O_1 and O_2.

Contrary to the suggestion given in Ref. 5 the derivation of an equivalent operator does not amount to ignoring the coupling of small components of the wave function. The corresponding terms with the operators $a^{(ls)+}_{m_lm_s}$ and $\tilde{a}^{(ls)}_{m_lm_s}$ vanish when considering the interaction within the particular shells [due to the presence of δ functions in (8)]. Thus these terms can be omitted without making any additional approximations.

The expressions for various one-electron equivalent operators were given in Refs. 4–6, and 9. Its general form for the Hamiltonian with total rank equal to 0 is

$$O_1=\sum_{jkn_1l_1n_2l_2}(-1)^{l_2+1/2+j+k}[j,k]^{1/2}\begin{Bmatrix} l_1 & 1/2 & j \\ 1/2 & l_2 & k \end{Bmatrix}(n_1l_1j\|h_1\|n_2l_2j)W^{(kk0)}(n_1l_1,n_2l_2). \tag{11}$$

This expression is valid not only for a single configuration, but also for configuration interaction approximation.

In the case of two-electron Hamiltonian of the general type

$$H_2=\sum_{i<j}\sum_k(g_i^{(k)}\cdot g_j^{(k)}), \tag{12}$$

where k is a rank with respect to the total momentum, the corresponding equivalent operator obtains the following expression:

$$\begin{aligned} O_2=&\frac{1}{2}\sum_{k\atop\{n_il_ij_i\}}[k]^{-1}(n_1l_1j_1n_2l_2j_2\|g_1^{(k)}g_2^{(k)}\|n_3l_3j_3n_4l_4j_4)\\ &\times\Bigg\{\sum_{k_1K_1k_2K_2}[k_1,K_1,k_2,K_2,j_1,j_2,j_3,j_4]^{1/2}\begin{Bmatrix} l_1 & l_3 & k_1 \\ 1/2 & 1/2 & K_1 \\ j_1 & j_3 & k \end{Bmatrix}\begin{Bmatrix} l_2 & l_4 & k_2 \\ 1/2 & 1/2 & K_2 \\ j_2 & j_4 & k \end{Bmatrix}\\ &\times(W^{(k_1K_1k)}(n_1l_1,n_3l_3)\cdot W^{(k_2K_2k)}(n_2l_2,n_4l_4))-\delta(n_2,n_3)\delta(l_2,l_3)\delta(j_2,j_3)\delta(j_1,j_4)\\ &\times\sum_{k_1}(-1)^{k_1+l_1+j_3+1/2}[k][k_1]^{1/2}\begin{Bmatrix} 1/2 & 1/2 & k_1 \\ l_1 & l_4 & j_1 \end{Bmatrix}W^{(k_1k_10)}(n_1l_1,n_4l_4)\Bigg\}. \end{aligned} \tag{13}$$

The second term appears from the transposition of operators $a^{(l_2s)+}$ and $\tilde{a}^{(l_3s)}$. Equation (13) was derived in Ref. 6, but the function $\delta(j_1,j_4)$ was omitted in its second term.

Expression (13) is applicable in the configuration interaction as well as in the single-configuration approximations. For the latter case it is more convenient to use the single shell reduced matrix elements of operator $W^{(k_1k_2k)}(nl)$ (10) as standard quantities for the calculation of

matrix elements. Consequently, in single-configuration approximation Eq. (13) is useful only for the interaction within a shell of equivalent electrons. The direct and the exchange interactions between $n_1 l_1^{N_1}$ and $n_2 l_2^{N_2}$ shells are described by the following equivalent operators:

$$O_2^d = \sum_{\substack{k k_1 K_1 k_2 K_2 \\ j_1 j_2 j_3 j_4}} [k]^{-1} [k_1, K_1, k_2, K_2, j_1, j_2, j_3, j_4]^{1/2} (n_1 l_1 j_1 n_2 l_2 j_2 \| g_1^{(k)} g_2^{(k)} \| n_1 l_1 j_3 n_2 l_2 j_4) \times \begin{Bmatrix} l_1 & l_1 & k_1 \\ 1/2 & 1/2 & K_1 \\ j_1 & j_3 & k \end{Bmatrix} \begin{Bmatrix} l_2 & l_2 & k_2 \\ 1/2 & 1/2 & K_2 \\ j_2 & j_4 & k \end{Bmatrix} (W^{(k_1 K_1 k)}(n_1 l_1) \cdot W^{(k_2 K_2 k)}(n_2 l_2)), \tag{14}$$

$$O_2^{\mathrm{ex}} = \sum_{\substack{\kappa k k_1 K_1 k_2 K_2 \\ j_1 j_2 j_3 j_4}} (-1)^{k+\kappa} [k_1, K_1, k_2, K_2, j_1, j_2, j_3, j_4]^{1/2} (n_1 l_1 j_1 n_2 l_2 j_2 \| g_1^{(k)} g_2^{(k)} \| n_2 l_2 j_4 n_1 l_1 j_3) \times \begin{Bmatrix} l_1 & l_1 & k_1 \\ 1/2 & 1/2 & K_1 \\ j_1 & j_3 & \kappa \end{Bmatrix} \begin{Bmatrix} l_2 & l_2 & k_2 \\ 1/2 & 1/2 & K_2 \\ j_2 & j_4 & \kappa \end{Bmatrix} \begin{Bmatrix} j_1 & j_3 & \kappa \\ j_2 & j_4 & k \end{Bmatrix} (W^{(k_1 K_1 \kappa)}(n_1 l_1) \cdot W^{(k_2 K_2 \kappa)}(n_2 l_2)). \tag{15}$$

The ranks of operators in the orbital and spin spaces can be joined into the common ranks:

$$(W^{(k_1 K_1 k)} \cdot W^{(k_2 K_2 k)}) = \sum_u [k][u]^{1/2} (-1)^{k_2 + K_1 + u} \begin{Bmatrix} k_1 & K_1 & k \\ K_2 & k_2 & u \end{Bmatrix} [W^{(k_1 K_1)} \times W^{(k_2 K_2)}]^{(uu0)}. \tag{16}$$

The equivalent operators O_β, O_γ, and O_δ are obtained in a simple way from (13) to (15) while substituting the corresponding formulas for the reduced matrix elements given in Refs. 6 and 10 into these equations.

For O_β:

$$(n_1 l_1 j_1 n_2 l_2 j_2 \| g_1^{(k)} g_2^{(k)} \| n_3 l_3 j_3 n_4 l_4 j_4)_\beta = e^2 \int\int (n_1 l_1 j_1 \| h_1^{(k)} \| n_3 l_3 j_3) \times (n_2 l_2 j_2 \| h_2^{(k)} \| n_4 l_4 j_4) \frac{r_<^k}{r_>^{k+1}} \mathrm{d}r_1 \mathrm{d}r_2 \tag{17}$$

with

$$(n_1 l_1 j_1 \| h^{(k)} \| n_3 l_3 j_3) = (-1)^{l_1 + l_3 - j_3 + 1/2} [j_1, j_3]^{1/2} \begin{pmatrix} j_1 & k & j_3 \\ -1/2 & 0 & 1/2 \end{pmatrix} \times [\Delta(l_1 l_3 k) P_1 P_3 + \Delta(\bar{l}_1 \bar{l}_3 k) Q_1 Q_3], \tag{18}$$

where P and Q are, respectively, the large and small components of radial wave function and $\Delta(l_1 l_3 k)$ means the condition that the parameters l_1, l_3, and k form a triangle and their sum is even. $P_i \equiv P_{n_i l_i j_i}(r)$; $Q_i \equiv Q_{n_i \bar{l}_i j_i}(r)$.

For O_γ:

$$(n_1l_1j_1n_2l_2j_2\|g_1^{(k)}g_2^{(k)}\|n_3l_3j_3n_4l_4j_4)_\gamma$$
$$=\frac{e^2}{2}\sum_t\int\int(-1)^{k+t}\frac{r_<^t}{r_>^{t+1}}(n_1l_1j_1\|[C_1^{(t)}\times\alpha_1^{(1)}]^{(k)}\|n_3l_3j_3)$$
$$\times(n_2l_2j_2\|[C_2^{(t)}\times\alpha_2^{(1)}]^{(k)}\|n_4l_4j_4)\mathrm{d}r_1\mathrm{d}r_2 \tag{19}$$

with

$$(n_1l_1j_1\|[C^{(t)}\times\alpha^{(1)}]^{(k)}\|n_3l_3j_3)$$
$$=i[k,j_1,j_3]^{1/2}(-1)^{l_1+l_3+j_1+j_3+k}\Bigg\{(-1)^{l_1+1}\sqrt{2}\begin{pmatrix}1&t&k\\-1&0&1\end{pmatrix}\begin{pmatrix}j_1&j_3&k\\-1/2&-1/2&1\end{pmatrix}$$
$$\times[\Delta(l_1\bar{l}_3t)P_1Q_3+\Delta(\bar{l}_1l_3t)Q_1P_3]+(-1)^{j_3+1/2+t}\begin{pmatrix}1&t&k\\0&0&0\end{pmatrix}\begin{pmatrix}j_1&j_3&k\\-1/2&1/2&0\end{pmatrix}$$
$$\times[\Delta(l_1\bar{l}_3t)P_1Q_3-\Delta(\bar{l}_1l_3t)Q_1P_3]\Bigg\}. \tag{20}$$

For O_δ:

$$(n_1l_1j_1n_2l_2j_2\|g_1^{(k)}g_2^{(k)}\|n_3l_3j_3n_4l_4j_4)_\delta$$
$$=\frac{e^2}{6}\sum_t\int\int(n_1l_1j_1\|[C_1^{(t)}\times\alpha_1^{(1)}]^{(k)}\|n_3l_3j_3)(n_2l_2j_2\|[C_2^{(t)}\times\alpha_2^{(1)}]^{(k)}\|n_4l_4j_4)$$
$$\times(-1)^{k+t}\frac{r_<^t}{r_>^{t+1}}\mathrm{d}r_1\mathrm{d}r_2+\frac{5e^2}{2}\sum_{tpq}F(tqp)\begin{Bmatrix}1&1&2\\q&p&k\end{Bmatrix}$$
$$\times\int_0^\infty\mathrm{d}r_2\Bigg[\int_0^{r_2}\mathrm{d}r_1\frac{r_1^t}{r_2^{t+1}}(n_1l_1j_1\|[C_1^{(q)}\times\alpha_1^{(1)}]^{(k)}\|n_3l_3j_3)(n_2l_2j_2\|[C_2^{(p)}\times\alpha_2^{(1)}]^{(k)}\|n_4l_4j_4)$$
$$+\int_{r_2}^\infty\mathrm{d}r_1\frac{r_2^t}{r_1^{t+1}}(n_1l_1j_1\|[C_1^{(p)}\times\alpha_1^{(1)}]^{(k)}\|n_3l_3j_3)(n_2l_2j_2\|[C_2^{(q)}\times\alpha_2^{(1)}]^{(k)}\|n_4l_4j_4)\Bigg] \tag{21}$$

with

$$F(tqp)=\begin{cases}\left[\dfrac{8t(t+1)(2t+1)}{15(2t-1)(2t+3)}\right]^{1/2}, & \text{if } q=p=t,\\ -\left[\dfrac{t(t-1)(2t-3)(2t+1)}{5(2t-1)}\right]^{1/2}, & \text{if } q=t-2,\ p=t,\\ \left[\dfrac{(t+1)(t+2)(2t+1)(2t+5)}{5(2t+3)}\right]^{1/2}, & \text{if } q=t,\ p=t+2.\end{cases} \tag{22}$$

In Ref. 6 the multiplier t was written instead of $t+1$ for $F(t\,t\,t+2)$.

It was shown in Ref. 5, that various terms of operators O_α, O_β, O_γ, and O_δ asymptotically turn into the operators of relativistic corrections in the Breit–Pauli approximation. For such identification the small component of relativistic wave function is expressed by the large component. After some transformations of radial integrals only the terms of the lowest order (up to α^2) are retained. In Ref. 5 such identification was accomplished for the equivalent electrons.

TABLE I. Correspondence of the terms of equivalent operators to the nonrelativistic and Breit–Pauli interaction operators.

Equivalent operator	Ranks k	Ranks k	Breit–Pauli interaction operator
O_{α_1}	0	0	Kinetic energy and mass correction
	1	1	Does not give contribution of order α^0, α^2
O_{α_2}	0	0	$-Ze^2/r$, Darwin and mass correction
	1	1	Spin–orbit

Equivalent operator	Ranks k_1	Ranks K_1	Ranks k_2	Ranks K_2	Breit–Pauli interaction operator
O_β	k	0	k	0	e^2/r_{12}, Darwin and mass correction
	k	0	k	1	Spin–other–orbit
	k	1	k	0	Spin–other–orbit
	k	0	$k-1$	1	Spin–other–orbit
	k	0	$k+1$	1	Spin–other–orbit
	$k-1$	1	k	0	Spin–other–orbit
	$k+1$	1	k	0	Spin–other–orbit
	k	1	k	1	Does not give contribution of order α^2
	$k-1$	1	$k-1$	1	Does not give contribution of order α^2
	$k-1$	1	$k+1$	1	Does not give contribution of order α^2
	$k+1$	1	$k-1$	1	Does not give contribution of order α^2
	$k+1$	1	$k+1$	1	Does not give contribution of order α^2
O_γ, O_δ	$k-1$	1	$k+1$	1	Spin–spin
	$k+1$	1	$k-1$	1	Spin–spin
	k	0	k	0	orbit–orbit
	k	0	k	1	Spin–other–orbit
	k	1	k	0	Spin–other–orbit
	k	0	$k-1$	1	Spin–other–orbit
	k	0	$k+1$	1	Spin–other–orbit
	$k-1$	1	k	0	Spin–other–orbit
	$k+1$	1	k	0	Spin–other–orbit
	$k-1$	1	$k-1$	1	Spin–spin–contact (at $u=0$) or
	k	1	k	1	does not give contribution
	$k+1$	1	$k+1$	1	of order α^2 (at $u \geqslant 1$)

It follows from the second quantization form for operator H_2 (4) that for such investigation in a general case it is sufficient to obtain the asymptotic relations for the two-electron matrix elements. Their expressions for various Breit–Pauli operators in the case of nonequivalent electrons were presented in Refs. 11–13. The final results are presented in Table I. They mainly correspond to the identification given in Ref. 5 but some restrictions for the ranks of operators are removed in a general case. The additional terms for the nonequivalent operators appear: the terms of O_β, O_γ, and O_δ with the ranks $k_1=k_2=k$, $K_1=1$, $K_2=0$ corresponding to the spin-other-orbit interaction as well as the terms of O_β with $k_1=k_2=k$, $K_1=K_2=1$, which do not give contribution of order α^2. The terms of O_γ and O_δ corresponding to spin–spin and spin–spin–contact interactions also give the additional operator, whose matrix elements vanish in the general case (direct and exchange parts of the matrix element cancel each other).

Some terms of the equivalent operators give the contributions to various Breit–Pauli operators: the terms of O_{α_2} with $k=0$ and of O_β with $k_1=k_2=k$, $K_1=K_2=0$ containing large components of orbitals turn into the operators of Coulomb interaction $-Ze^2/r$ and e^2/r_{12}. On the other hand, the same terms of these operators with small components of orbitals turn into the Darwin and mass corrections. The term of O_{α_1} with the rank $k=0$ in order α^0 gives the operator of kinetic energy and in order α^2 gives contribution to the mass correction; the part of this operator with the rank $k=1$ vanishes in the Breit–Pauli approximation. The part of the equivalent

operators O_γ and O_δ with orbital ranks $k_1=k_2$ equal to k, $k\pm1$ and spin ranks $K_1=K_2=1$ turns at $u=0$ into the operator of spin–spin–contact interaction but at $u=1,2$ does not give contribution of order α^2.

The terms of O_γ and O_δ corresponding to spin–spin and spin–spin–contact interactions also give some additional operators, whose matrix elements vanish in a general case.

The expressions for matrix elements of equivalent operators are obtained by applying the formulas presented in Refs. 14 and 15.

III. RELATIVISTIC DIRAC–FOCK EQUATIONS FOR A LEVEL AND TERM IN *LS* COUPLING

For some excited configurations, especially those with the collapsing electron, a dependence of the radial orbitals on the many-electron state can become rather strong. Then it is necessary to solve the term-dependent equations instead of the usual ones for the average energy.

If a coupling scheme within the electronic shell for rather heavy atoms remains closer to LS than to jj coupling, the relativistic equations for the LS state have to be solved.

The relativistic equations for the LS state can be obtained using the expression for the matrix element of the equivalent operator as a functional. We will take into account only the main terms of the equivalent relativistic Hamiltonian O_{α_1}, O_{α_2}, and O_β. Let us present the matrix elements of operators $O_{\alpha_1}+O_{\alpha_2}$, and O_β in the following form:

$$\langle K\gamma|O_{\alpha_1}+O_{\alpha_2}|K\gamma\rangle=\sum_{lj}\ \alpha_j(l^N\gamma)I(lj), \tag{23}$$

$$\begin{aligned}\langle K\gamma|O_\beta|K\gamma\rangle=&\sum_{ljj'}\ \sum_k\ \varphi_{kjj'}(l^N\gamma)F^k(lj,lj')+\sum_{ljj'(j\neq j')}\ \sum_k\ \gamma_{kjj'}(l^N\gamma)G^k(lj,lj')\\&+\frac{1}{2}\sum_{ll'(l\neq l')jj'}\ \sum_k\ [\varphi_{kjj'}(l^Nl'^{N'}\gamma)F^k(lj,l'j')+\gamma_{kjj'}(l^Nl'^{N'}\gamma)G^k(lj,l'j')],\end{aligned} \tag{24}$$

where I, F^k, and G^k are the relativistic radial integrals[8] and α_k, φ_k, and γ_k are the coefficients at these integrals.

The Dirac–Fock equations in LS coupling are then presented:

$$\begin{aligned}\left(\frac{\mathrm{d}}{\mathrm{d}r}+\frac{\kappa}{r}\right)P_{nlj}(r)=&\frac{1}{c}[2c^2-\varepsilon_{nlj}-Y_{nlj}(r)]\,Q_{n\bar{l}j}(r)-X^P_{nlj}(r)\\&-\frac{1}{c}\sum_{n'l'j'(\neq nlj)}\ \delta(\kappa,\kappa')\,\varepsilon_{nlj,n'l'j'}\,Q_{n'\bar{l}'j'}(r),\\\left(\frac{\mathrm{d}}{\mathrm{d}r}-\frac{\kappa}{r}\right)Q_{n\bar{l}j}(r)=&\frac{1}{c}[\varepsilon_{nlj}+Y_{nlj}(r)]\,P_{nlj}(r)+X^Q_{n\bar{l}j}(r)\\&+\frac{1}{c}\sum_{n'l'j'(\neq nlj)}\ \delta(\kappa,\kappa')\varepsilon_{nlj,n'l'j'}\,P_{n'l'j'}(r),\end{aligned} \tag{25}$$

where the direct and exchange potentials are given by

$$Y_{nlj}(r)=\frac{1}{r}\Bigg\{-Z+\alpha_j(l^N\gamma)^{-1}\sum_{j'k}\ \varphi_{kjj'}(l^N\gamma)\,[1+\delta(j,j')]\,[Y^k_{nlj',nlj'}(r)+Y^k_{n\bar{l}j',n\bar{l}j'}(r)]$$

$$+\alpha_j(l^N\gamma)^{-1}\sum_{n'l'(\neq nl)}\ \sum_{j'k}\ \varphi_{kjj'}(l^N l'^{N'}\gamma)[Y^k_{n'l'j',n'l'j'}(r)+Y^k_{n'\bar{l}'j',n'\bar{l}'j'}(r)]\Bigg\}, \tag{26}$$

$$X^P_{nlj}(r)=\frac{1}{cr}\,\alpha_j(l^N\gamma)^{-1}\Bigg\{\sum_{j'(\neq j)}\ \sum_k\ \gamma_{kjj'}(l^N\gamma)\,[Y^k_{nlj,nlj'}(r)+Y^k_{n\bar{l}j,n\bar{l}j'}(r)]\,Q_{n\bar{l}j'}(r)$$

$$+\sum_{l'\neq l}\ \sum_{kj'}\ \gamma_{kjj'}(l^N l'^{N'}\gamma)\,[Y^k_{nlj,n'l'j'}(r)+Y^k_{n\bar{l}j,n'\bar{l}'j'}(r)]\,Q_{n'\bar{l}'j'}(r)\Bigg\}, \tag{27}$$

$$X^Q_{nlj}(r)=\frac{1}{cr}\,\alpha_j(l^N\gamma)^{-1}\Bigg\{\sum_{j'(\neq j)}\ \sum_k\ \gamma_{kjj'}(l^N\gamma)\,Y^k_{n\bar{l}j,n\bar{l}j'}(r)\,P_{nlj'}(r)$$

$$+\sum_{n'l'(\neq nl)}\ \sum_{kj'}\ \gamma_{kjj'}(l^N l'^{N'}\gamma)\,Y^k_{nlj,n'\bar{l}'j'}(r)\,P_{n'l'j'}(r)\Bigg\}. \tag{28}$$

In (26)–(28) the integral function Y^k is defined:

$$Y^k_{nlj,n'l'j'}(r)=r^{-k}\int_0^r r_1^k\,P_{nlj}(r_1)\,P_{n'l'j'}(r_1)\,\mathrm{d}r_1+r^{k+1}\int_r^\infty r_1^{-k-1}\,P_{nlj}(r_1)\,P_{n'l'j'}(r_1)\,\mathrm{d}r_1. \tag{29}$$

When in its notation the quantum number l is replaced by $\bar{l}$, the radial function $Q_{n\bar{l}j}(r)$ is used instead of $P_{nlj}(r)$. The quantum number κ is defined:

$$\kappa=\begin{cases} l & \text{for } j=l-1/2\\ -l-1 & \text{for } j=l+1/2.\end{cases} \tag{30}$$

The potentials (26)–(28) correspond to the equations for the LSJ level. If we like to obtain the equations for the LS term, it is necessary to take into account only the term with the rank $k=0$ in α_{kj} and to leave only the terms with $K_1=K_2=0$ in $\varphi_{kjj'}$, $\gamma_{kjj'}$.

IV. THE AVERAGES OF THE RELATIVISTIC OPERATORS

The expressions for the equivalent operator in terms of standard operators enable us to obtain the average values of various parts of Hamiltonian in a simple way.

The average values of the operators $(W^{(k_1K_1k)}\cdot W^{(k_2K_2k)})$ and $W^{(kk0)}$ have the expressions:

$$\frac{1}{g(l^N)}\sum_{\gamma LSJ}[J]\langle nl^N\gamma LSJ|(W^{(k_1K_1k)}(nl)\cdot W^{(k_2K_2k)}(nl))|nl^N\gamma LSJ\rangle$$

$$=\frac{N(N-1)}{(4l+1)(2l+1)}\,\delta(k_1,k_2)\,\delta(K_1,K_2)[[l]\,\delta(k_1,0)\,\delta(K_1,0)+2l\,(-1)^{k_1+K_1+k}[k]], \tag{31}$$

$$\frac{1}{g(l^N)}\sum_{\gamma LSJ}[J]\langle nl^N\gamma LSJ|W^{(kk0)}(nl)|nl^N\gamma LSJ\rangle=\frac{N(N-1)}{2}\sqrt{\frac{2}{2l+1}}\,\delta(k,0), \tag{32}$$

$$\frac{1}{g(l_1^{N_1}l_2^{N_2})}\sum_{\gamma LSJ}[J]\langle n_1 l_1^{N_1} n_2 l_2^{N_2}\gamma LSJ|(W^{(k_1K_1k)}(n_1l_1)\cdot W^{(k_2K_2k)}(n_2l_2))|n_1 l_1^{N_1} n_2 l_2^{N_2}\gamma LSJ\rangle$$

$$=\frac{N_1N_2}{2[l_1,l_2]^{1/2}}\delta(k,0)\,\delta(k_1,0)\,\delta(k_2,0)\,\delta(K_1,0)\,\delta(K_2,0), \tag{33}$$

where $g(l^N)$ and $g(l_1^{N_1}l_2^{N_2})$ are the statistical weights of configurations.

The substitution of (31)–(33) into the averages of the equivalent operator O_2 and summation over the ranks give the following results:

$$\frac{1}{g(l^N)}\sum_{\gamma LSJ}[J]\langle nl^N\gamma LSJ|O_2|nl^N\gamma LSJ\rangle$$

$$=\frac{N(N-1)}{2(4l+1)(4l+2)}\Bigg[\sum_{k(>0)j_1j_2}(-1)^{j_1+j_2}(nlj_1nlj_2\|g_1^{(k)}g_2^{(k)}\|nlj_2nlj_1)$$

$$+\sum_{j_1j_2}[j_1,j_2]^{1/2}(nlj_1nlj_2\|g_1^{(0)}g_2^{(0)}\|nlj_1nlj_2)\Bigg], \tag{34}$$

$$\frac{1}{g(l_1^{N_1}l_2^{N_2})}\sum_{\gamma LSJ}[J]\langle n_1 l_1^{N_1} n_2 l_2^{N_2}\gamma LSJ|O_2^d|n_1 l_1^{N_1} n_2 l_2^{N_2}\gamma LSJ\rangle$$

$$=\frac{N_1N_2}{(4l_1+2)(4l_2+2)}\sum_{j_1j_2}[j_1,j_2]^{1/2}(n_1l_1j_1n_2l_2j_2\|g_1^{(0)}g_2^{(0)}\|n_1l_1j_1n_2l_2j_2), \tag{35}$$

$$\frac{1}{g(l_1^{N_1}l_2^{N_2})}\sum_{\gamma LSJ}[J]\langle n_1 l_1^{N_1} n_2 l_2^{N_2}\gamma LSJ|O_2^{\mathrm{ex}}|n_1 l_1^{N_1} n_2 l_2^{N_2}\gamma LSJ\rangle$$

$$=\frac{N_1N_2}{(4l_1+2)(4l_2+2)}\sum_{kj_1j_2}(-1)^{j_1+j_2}(n_1l_1j_1n_2l_2j_2\|g_1^{(k)}g_2^{(k)}\|n_2l_2j_2n_1l_1j_1). \tag{36}$$

The average energy of interactions described by the operators H_β, H_γ, and H_δ is obtained substituting in (34)–(36) the corresponding formulas for the reduced matrix elements.

Only the spherical terms with $k=0$ give the contribution to the average of the direct part of the interaction between electronic shells. However, such term vanishes for O_γ and O_δ operators due to the properties of the reduced matrix element (20). Thus the average of the corresponding interaction energy has only the exchange part.

The obtained averages are equivalent to the averages for a complex of relativistic configurations arising from the same nonrelativistic configuration.

V. CONCLUSIONS

The equivalent relativistic operator produces the same result in the nonrelativistic LS scheme as obtained by evaluating the relativistic Hamiltonian with respect to relativistic wave functions, any additional simplifications are not needed. The mixing of relativistic configurations arising from the same nonrelativistic configuration is taken into account. This method has several advantages in comparison with a rather complicated transformation from jj to LS coupling: (i) all parts of the equivalent Hamiltonian are expressed in terms of the same scalar product of standard operators and their matrix elements can be evaluated in the more simple nonrelativistic scheme; (ii) the insight into the structure of equivalent operator gives the possibility to make some approximations (for example, to omit small terms having no analogue in the Breit–Pauli Hamiltonian or corresponding to a weak spin–spin interaction).

The form of the equivalent operator useful for practical calculations is obtained. It is implemented in a general computer code. The Dirac–Fock equations for a level and term in LS coupling are derived, they can be useful for the description of excited configurations, especially with a collapsing electron as well as for the calculation of the binding energies and system differences.

The correspondence between the equivalent relativistic and Breit–Pauli operators gives the possibility to obtain the general relations between the nonrelativistic and relativistic radial integrals.

(Received 30 April 2001; accepted for publication 19 September 2001)

Applying certain known theorems about one-dimensional periodic potentials, we show that the energy spectrum of the associated Lamé potentials, $a(a+1)m\,\mathrm{sn}^2(x,m)+b(b+1)m\,\mathrm{cn}^2(x,m)/\mathrm{dn}^2(x,m)$, consists of a finite number of bound bands followed by a continuum band when both a and b take integer values. Further, if a and b are unequal integers, we show that there must exist some zero band-gap states, i.e., doubly degenerate states with the same number of nodes. More generally, in case a and b are not integers, but either $a+b$ or $a-b$ is an integer $(a\neq b)$, we again show that several of the band-gaps vanish due to degeneracy of states with the same number of nodes. Finally, when either a or b is an integer and the other takes a half-integral value, we obtain exact analytic solutions for several mid-band states. © *2001 American Institute of Physics.*

I. INTRODUCTION

The energy spectrum of electrons on a lattice is of central importance in condensed matter physics. In particular, the knowledge of the existence and locations of band edges and band-gaps determines many physical properties. Unfortunately, even in one dimension, there are very few analytically solvable periodic potential problems in quantum mechanics. The Lamé potential,

$$V(x)=a(a+1)m\,\mathrm{sn}^2(x,m),\quad a=1,2,3,\ldots, \tag{1}$$

is well-known to be exactly solvable. Here $\mathrm{sn}(x,m)$ is a Jacobi elliptic function of real elliptic modulus parameter m $(0\leqslant m\leqslant 1)$ with period $4K(m)$. For simplicity, from now onward, we will not explicitly display the modulus parameter m as an argument of Jacobi elliptic functions.[1]

Recently, we have vastly extended[2] the list of known solvable potentials by exploiting two different directions. First, we have shown that the supersymmetric partners of the Lamé potential constitute a wide class of new exactly solvable periodic potentials, which are distinctly different from the Lamé potential of Eq. (1) (for $a>1$), even though they have the same energy band structure. Second, we have shown[2] that the associated Lamé potentials,[3]

$$V(x)=pm\,\mathrm{sn}^2 x+qm\,\frac{\mathrm{cn}^2 x}{\mathrm{dn}^2 x},\quad p\equiv a(a+1),\quad q\equiv b(b+1) \tag{2}$$

(which constitute a much richer class of periodic potentials) and their supersymmetric partners yield many additional solvable and quasi-exactly solvable (QES) periodic problems provided $a+b$ and/or $a-b$ is an integer. Here, like $\mathrm{sn}\,x$, the Jacobi elliptic functions $\mathrm{cn}\,x$ and $\mathrm{dn}\,x$ also have the same modulus parameter m which, for notational convenience, is not explicitly displayed.

a)Electronic mail: khare@iopb.res.in
b)Electronic mail: sukhatme@uic.edu

Without any loss of generality, we shall always consider associated Lamé potentials with $p \geqslant q$.[2] All associated Lamé potentials have a period $2K(m)$, but the special case $p=q$ has a period $K(m)$.

There are several issues which were not addressed in our previous paper,[2] hereafter simply referred to as I. For example, in the case of the Lamé potential (1), it is well known that there are a ($|a+1|$) bound bands followed by a continuum band when a is a positive (negative) integer.[4] What about the associated Lamé case, especially when both a and b are integers? In particular, for these cases, are there only a finite number of bound bands followed by a continuum band? What happens if a and b are not integers but either $a+b$ or $a-b$ are integers? Furthermore, for the Lamé potential, when a takes half-integral values (say $a=n+1/2, \quad n=0,1,2,\ldots$), then $(n+1)$ doubly-degenerate solutions are known[3,4] for the mid-band states (i.e., states with period $8K$). Can one also analytically obtain the mid-band states for the associated Lamé potentials?

Our purpose in this paper is to address the issues raised above. In particular, using certain known theorems about periodic problems in one dimension, we show that even in the associated Lamé case, there are only a finite number of bound bands followed by a continuum band in case both a and b are integers. Further, as long as a and b (and hence p,q) are unequal integers, then we also show that some of the band-gaps (either of period $2K$ or $4K$) disappear. On the other hand, if a,b are not integers but either $a+b$ or $a-b$ is an integer ($a \neq b$), then in general there are an infinite number of bands out of which, but for the lowest few, all other band gaps of either period $2K$ or $4K$ vanish. Finally, when a is a half integer and b is an integer, we obtain several exact mid-band states (i.e., states of period $8K$).

The plan of this paper is as follows. In Sec. II we describe some known theorems about the number of band-gaps in a periodic potential in one dimension. Using these theorems, we show that if a and b are integers such that $p>q>0$, then the associated Lamé potential has also only a bound bands followed by a continuum band. Further, if $a-b$ is an even (odd) integer, then there are b doubly-degenerate band edges of period $4K$ $(2K)$ (i.e., in these cases the corresponding band-gaps are zero). Unfortunately, we are unable to obtain energy eigenstates for any of these $2b$ states. However, we do obtain exact expressions for the remaining $2a+1$ band edges. In particular, if $a-b$ is an even (odd) integer, then one can obtain the energy eigenvalues and eigenfunctions for the $a+b+1$ $(a-b)$ states of period $2K$ and $a-b$ $(a+b+1)$ states of period $4K$. In Sec. III we discuss the case when both a,b are half-integral and such that $p>q>0$. In this case we show that if $a-b$ is an even (odd) integer, one can obtain exact eigenvalues and eigenfunctions for the $b+1/2$ doubly-degenerate states of period $4K$ $(2K)$ (i.e., in these cases, the corresponding band gaps are zero) as well as $a-b$ nondegenerate states of the same period. Unfortunately, in this case one is not able to obtain any eigenstates of period $2K$ $(4K)$. In Sec. IV we consider the case when a is half-integral ($a=k+1/2$) and b is an integer ($b=s, \quad s=0,1,2,\ldots,N, \quad k=N-s$) and show that for every possible value of s, one can obtain exact, doubly-degenerate, $k+1$ mid-band states of period $8K$. Finally, in the last section we summarize the results obtained in this paper and point out some open problems.

II. a,b INTEGRAL AND FINITE NUMBER OF BOUND BANDS

Consider the Schrödinger equation for the associated Lamé potential specified in Eq. (2) for the usual case of a particle of mass 1/2 using units with $\hbar=1$:

$$-\frac{d^2\psi(x)}{dx^2}+\left[a(a+1)m\,\mathrm{sn}^2(x)+b(b+1)m\,\frac{\mathrm{cn}^2 x}{\mathrm{dn}^2 x}\right]\psi(x)=E\psi(x). \tag{3}$$

Following the procedure described in I, we substitute

$$\psi(x)=[\mathrm{dn}\,x]^{-b}y(x), \tag{4}$$

yielding

$$y''(x)+2bm\frac{\mathrm{sn}\,x\,\mathrm{cn}\,x}{\mathrm{dn}\,x}y'(x)+[\lambda-(a+b)(a+1-b)m\,\mathrm{sn}^2\,x]y(x)=0. \tag{5}$$

On further substituting $\mathrm{sn}\,x\equiv\sin t, y(x)\equiv z(t)$, it is easily shown that $z(t)$ satisfies Ince's equation,

$$(1+A\cos 2t)z''(t)+B\sin 2tz'(t)+(C+D\cos 2t)z(t)=0, \tag{6}$$

where

$$A=\frac{m}{2-m},\quad B=\frac{(2b-1)m}{2-m},\quad C=\frac{\lambda-(a+b)(a+1-b)m}{2-m},$$

$$D=\frac{(a+1-b)(a+b)m}{2-m},\quad \lambda=E-mb^2. \tag{7}$$

Now several exact results for Ince's equation are known in the literature. In particular, it is known that the system satisfying Ince's equation (6) has *at most* $j+1$ band-gaps of period $\pi[2\pi]$ in case the polynomial $Q(\mu)[Q^*(\mu)]$ has non-negative integral roots, the highest of which is j.[5] Here the quadratic polynomials $Q(\mu)$ and $Q^*(\mu)$ are given by

$$Q(\mu)=2A\mu^2-B\mu-\frac{D}{2},\quad Q^*(\mu)=2A\left(\mu-\frac{1}{2}\right)^2-B\left(\mu-\frac{1}{2}\right)-\frac{D}{2}. \tag{8}$$

On the other hand, if $Q(\mu)[Q^*(\mu)]$ has negative integral roots, the smallest of which is $-j_0-1$, then the system satisfying Ince's equation (6) has *at most* j_0+1 band-gaps of period $\pi[2\pi]$. It must be noted here that in the notation of Ref. 5, the lowest band-gap of period π *always* exists and is from $E=-\infty$ to $E=E_0$, when E_0 denotes the energy of the lower edge of the lowest energy band.

Using these theorems it is easily shown[3] that the Lamé potential (1) has a ($|a+1|$) bound bands followed by a continuum band in case a is a positive (negative) integer.

Let us now apply these results to the associated Lamé potential (2). We might add here that the period $\pi[2\pi]$ for Ince's equation corresponds to period $2K(m)[4K(m)]$ in the associated Lamé case (note $\mathrm{sn}\,x\equiv\sin t$). On using the expressions for A,B,C,D as given in Eq. (7) it is easily shown that the roots of $Q(\mu)$ are at

$$\mu_1=\frac{a+b}{2},\quad \mu_2=\frac{b-a-1}{2}, \tag{9}$$

while the roots of $Q^*(\mu)$ are at

$$\mu_1^*=\frac{a+b+1}{2},\quad \mu_2^*=\frac{b-a}{2}. \tag{10}$$

These roots are integral if and only if $a+b$ and/or $a-b$ take integer values. In this section we consider the case when both a and b are integral while in the next section we consider the other possibilities.

When both a and b take integer values then it follows from Eqs. (9) and (10) that either the roots μ_1 and μ_2^* or the roots μ_2 and μ_1^* are integral. In particular, it both a and b or odd or even then the roots μ_1 and μ_2^* are integral while if one of them is odd and the other even then μ_2 and μ_1^* are integral. Thus in both cases, there are only a finite number of band-gaps of period π and 2π [and hence of periods $2K$ and $4K$ for the associated Lamé potential (2)]. Hence it follows that when both a and b take integer values, then there are only a finite number of bound bands followed by a continuous band.

In fact, as we show now, these theorems when supplemented with the exact results obtained in I (see Table III of I) tell us quite a lot about the nature of band structure in these cases. We consider the two cases of $a-b$ being odd or even integer separately.

(i) $a-b=$ odd integer

From Eq. (9) it then follows that there are at most an $(a-b+1)/2$ number of band-gaps of period $2K$. An examination of the few explicit cases confirms the fact that there are indeed so many band-gaps (and not less) of period $2K$. This implies that in this case there are only $a-b$ number of nondegenerate states of period $2K$. Quite remarkably, all these $a-b$ states are QES states. In particular, the solution for these states can be obtained from Table III of I in case $p=a(a+1)$ while $q=[a-(a-b-1)][a-(a-b)]$.

On the other hand, from Eq. (10), it follows that in case $a-b$ is an odd integer, then there are at most an $(a+b+3)/2$ number of band-gaps of period $4K$. However, specific examples show that there are in fact only an $(a+b+1)/2$ number of band-gaps. This also follows from Eq. (10) in case we take $a>0$ but instead of b take $-b-1$ (note that q is invariant under $b\rightarrow -b-1$). We see that μ_2^* has an integral root at $-(a+b+1)/2$ and hence there are at most an $(a+b+1)/2$ number of band-gaps, i.e., $a+b+1$ number of nondegenerate states of period $4K$. Again all these are QES states, the solution for which is obtained from Table III of I in case $p=a(a+1)$, $q=[a-(a+b)][a-(a+b+1)]$.

Thus we see that when $a-b$ is an odd integer then there are $(a+b+1)/2$ band-gaps of period $4K$ but only $(a-b+1)/2$ band-gaps of period $2K$ and the corresponding band edges are known in principle from Table III of I. However, since the band edge wavefunctions arranged in order of increasing energy are of period $2K,4K,4K,2K,2K,\ldots$, hence it follows that in this case there must also be b band-gaps of period $2K$ which must be of zero width, i.e., there must be b doubly degenerate states of period $2K$. Unfortunately, so far, we have not been able to obtain either the eigenvalues or the eigenfunctions of even one of these states. Thus in this case there are in all a bound bands followed by a continuum band out of which the top b bound bands are a bit unusual in that both of their band edges have period $4K$ and two degenerate states of period $2K$ lie inside each of these bound bands.

As an illustration, consider the case of $p=12$, $q=6$, i.e., $a=3$, $b=2$. From the above discussion it follows that there must be 1 QES band edge of period $2K$ which is the ground state. Using Table III of I, it is easily seen that the eigenvalue and the eigenfunction of this state is

$$\psi_0=\mathrm{dn}^3 x, \quad E_0=9m. \tag{11}$$

In addition, there must be 6 nondegenerate QES band edges of period $4K$ and the eigenvalues and eigenfunctions for these six states are easily obtained. In particular, it is easily shown that three of the eigenstates have the form

$$\psi_{1,6,9}=\frac{\mathrm{cn}\, x}{\mathrm{dn}^2 x}[A+B\,\mathrm{sn}^2 x+D\,\mathrm{sn}^4 x], \tag{12}$$

and the corresponding three eigenvalues $E_{1,6,9}$ satisfy the cubic equation

$$\lambda^3-4(8-m)\lambda^2+48(4+m)\lambda-576m=0, \quad E=\lambda+1+4m. \tag{13}$$

The other three eigenstates have the form

$$\psi_{2,5,10}=\frac{\mathrm{sn}\, x}{\mathrm{dn}^2 x}[A+B\,\mathrm{sn}^2 x+D\,\mathrm{sn}^4 x], \tag{14}$$

and the corresponding three eigenvalues $E_{2,5,10}$ satisfy the cubic equation

$$\lambda^3-8(4+m)\lambda^2+48(4+7m)\lambda-576m(3+m)=0, \quad E=\lambda+1+m. \tag{15}$$

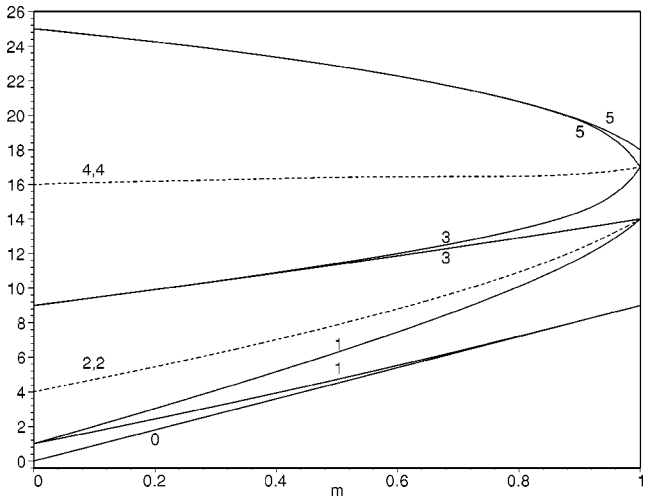

FIG. 1. Band edge energies for the associated Lamé potential (12,6) as a function of the elliptic modulus parameter m. The band edges are labeled by the number of wave function nodes in the interval $2K(m)$. Note that the band gap between the two states with 2 nodes as well as with four nodes is zero, that is $E_3=E_4$ and $E_7=E_8$. The energy eigenvalues of these degenerate states have been calculated numerically and are shown by dotted lines.

In view of the oscillation theorem, it is then clear that there must be a pair of doubly-degenerate states $(\psi_{3,4})$ and $(\psi_{7,8})$ of period $2K$ whose energy must go to 4(14) and 16(17), respectively, as $m\to 0(1)$. Thus whereas four states $\psi_{2,3,4,5}$ must merge at $E=14$ as $m\to 1$ the other four states $\psi_{6,7,8,9}$ must merge at $E=17$ as $m\to 1$. Thus, as shown in Fig. 1, in this case there are three bound bands followed by a continuum band. The two upper-most bound bands have both of their band edges of period $4K$ and in between are the pair of doubly-degenerate states $\psi_{3,4}$ and $\psi_{7,8}$ of period $2K$ whose energy eigenvalues and eigenfunctions are not known analytically. We have therefore computed these energy eigenvalues numerically and these are shown by the dotted lines in the figure.

As another illustration, consider the case of $p=6,q=2$, i.e., $a=2,b=1$. From the above discussion it follows that in this case there must be 1 QES band edge of period $2K$ and 4 QES band edges of period $4K$ and interestingly enough the eigenvalues and eigenfunctions for these five states were already given in the Table IV of I. Further, as stated in I, two states of period $2K$ must also be present but so far we are unable to obtain these states analytically. However, what was not clear at that time was that the two states of period $2K$ must be degenerate and whose energy goes to 4 (7) as $m\to 0(1)$ so that as $m\to 1$, four of the states $\psi_{2,3,4,5}$ must merge at $E=7$. Besides, it was also not clear then that in this case there are only two bound bands followed by a continuum band and that the upper band is a bit unusual in that both of its band edges are of period $4K$ and inside the band there are two degenerate states of period $2K$.

(ii) $a-b=$ even integer

From Eq. (9), it follows that in this case there are at most $(a+b+2)/2$ band-gaps of period $2K$. Explicit examples confirm that this is indeed so. Hence, in this case one has an $a+b+1$ number of nondegenerate states. Quite remarkably, all these are QES states for which a solution can be obtained from Table III of I when $p=a(a+1)$, $q=[a-(a+b)][a-(a+b+1)]$.

On the other hand, from Eq. (10), it follows that there are at most $(a-b)/2$ band-gaps of period $4K$ and hence $a-b$ number of nondegenerate states of period $4K$. Specific examples confirm the expectation. These are all QES states which can be obtained from Table III of I in case $p=a(a+1)$, $q=[a-(a-b)][a-(a-b-1)]$.

Thus when $a-b$ is an even integer (with both an a,b integer), then there are $(a+b+2)/2$ band gaps of period $2K$ but only $(a-b)/2$ band gaps of period $4K$ and in principle the corresponding band edges are all analytically known from Table III of I. In view of the fact that the band edge wave functions in increasing order of energy are of period $2K,4K,4K,2K,2K,\ldots,$ it

then follows that in this case, too, there must be b zero band-gaps of period $4K$, i.e., there must be b doubly-degenerate states of period $4K$. Unfortunately, so far, we have not been able to obtain an analytic solution for even one of these $(2b)$ states. Thus in this case also there are in all a bound bands followed by a continuum band out of which the top b bound bands are again a bit unusual in that both of their band edges are of period $2K$ and two degenerate states of period $4K$ lie inside each of these bound bands.

As an illustration, consider the case of $p=12$, $q=2$, i.e., $a=3$, $b=1$. As described in I, this potential is oscillatory for $m<\frac{5}{6}$, but has interesting structure coming from secondary extrema for $m>\frac{5}{6}$. From the above discussion it follows that the (12,2) potential must have 2 nondegenerate QES states of period $4K$. Using Table III of I, it is easily seen that the eigenvalues and the eigenfunctions of these states is given by

$$\psi_1=\mathrm{cn}\,x\,\mathrm{dn}^2\,x,\quad E_1=1+4m, \tag{16}$$

$$\psi_2=\mathrm{sn}\,x\,\mathrm{dn}^2\,x,\quad E_2=1+9m. \tag{17}$$

In addition there must be 5 nondegenerate states of period $2K$ whose eigenvalues and eigenfunctions are easily obtained from Table III of I. In particular, the eigenvalues and the eigenfunctions of two of the states are

$$\psi_{8,3}=\frac{\mathrm{sn}\,x\,\mathrm{cn}\,x}{\mathrm{dn}\,x}[5m\,\mathrm{sn}^2\,x-3-m\pm\delta_7],\quad E_{8,3}=10+2m\pm2\,\delta_7, \tag{18}$$

where $\delta_7=\sqrt{9-9m+m^2}$. On the other hand, the remaining three eigenstates have the form

$$\psi_{0,4,7}=\frac{1}{\mathrm{dn}\,x}[A+B\,\mathrm{sn}^2\,x+D\,\mathrm{sn}^4\,x], \tag{19}$$

and the three corresponding eigenvalues $E_{0,4,7}$ satisfy the cubic equation [see Eqs. (39) and (40) of I]

$$\lambda^3-4(2m+5)\lambda^2+16(4+11m)\lambda-192m(2+m)=0,\quad E=\lambda+m. \tag{20}$$

In view of the oscillation theorem, it is then clear that there must also be two degenerate states $(\psi_{5,6})$ of period $4K$ whose energy tends to 9(13) as $m\to0(1)$ so that the four states $\psi_{4,5,6,7}$ must merge at $E=13$ as $m\to1$. Thus, as shown in Fig. 2, in this case, there are three bound bands followed by a continuum band. Further, the upper-most bound band has both of its band edges of period $2K$ and in between are the two degenerate states of period $4K$ whose energy eigenvalue and eigenfunctions are not known analytically. We have computed the degenerate energy eigenvalue numerically and it is shown by a dotted line in Fig. 2.

What happens if $a=b$ with both being an integer? In this case the associated Lamé potential has period $K(m)$ rather than $2K(m)$ and hence the results from Ince's equation are not directly applicable. However, as has been shown in I for $a=b=1,2$ (and also explicitly verified for $a=b=3,4$), in this case there are a bound bands followed by a continuum band and $2a+1$ band edges all of which are in principle explicitly known from Table III of I. Further, in this case, there are no band gaps of zero width.

III. a,b HALF-INTEGRAL AND INFINITE NUMBER OF BAND-GAPS OF ZERO WIDTH

Let us now specialize to the case when both a and b are half-integral such that $p>q>0$. From Eqs. (9) and (10) it is clear that in this case either the roots μ_1 and μ_2 or μ_1^* and μ_2^* are integral but not both. In particular, if $a-b$ is an odd integer, then both the roots μ_1 and μ_2 are integral while μ_1^* and μ_2^* are not integral while if $a-b$ is an even integer, then the roots μ_1^* and μ_2^* are integral while μ_1 and μ_2 are not integral. Thus it follows that unlike the integral a,b case, here

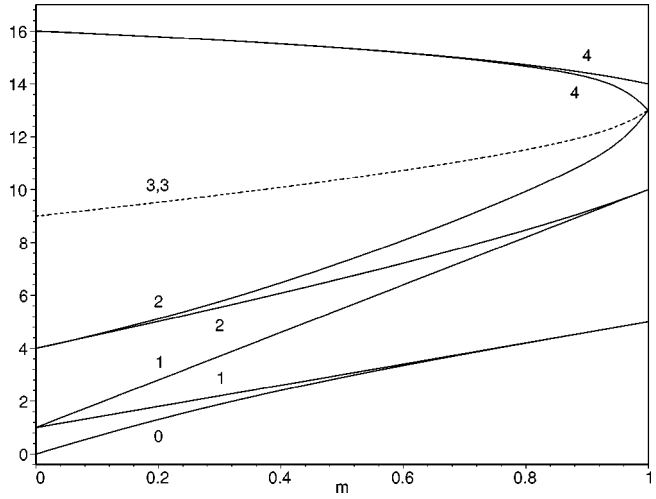

FIG. 2. Band edge energies for the associated Lamé potential (12,2) as a function of the elliptic modulus parameter m. The band edges are labeled by the number of wave function nodes in the interval $2K(m)$. Note that the band gap between the two states with 3 nodes is zero. The energy eigenvalue $E_5=E_6$ of these degenerate states has been calculated numerically and is shown by a dotted line.

one will in general have an infinite number of bands but only a finite number of band-gaps of either period $2K$ or $4K$ depending on whether $a-b$ is an odd or an even integer. As before, let us discuss the two cases separately.

(i) $a-b=$ odd integer

From Eqs. (9) and (10) it follows that in this case both μ_1 and μ_2 are integral while μ_1^* and μ_2^* are half-integral. Thus in this case there will be infinite number of band-gaps of period $4K$ but *at most* $(a+b+2)/2$ band gaps of period $2K$. However, a study of several explicit examples show that there are in fact only an $(a-b+1)/2$ number of band-gaps of period $2K$ and hence there are only an $a-b$ number of nondegenerate states of period $2K$ and all these are QES states. However, using Table III of I it is easily shown that in this case there are in fact $a+b+1$ QES states of period $2K$. This then implies that the remaining $2b+1$ QES states must correspond to doubly-degenerate eigenstates of period $2K$, i.e., in this case there are $b+1/2$ doubly degenerate QES states of period $2K$, each of which is lying inside a band. It is interesting to note that whereas when both a and b are integers, then one does not have an analytic expression for even one doubly degenerate state, when both a,b are half-integral, energy eigenvalues and eigenfunctions are known in principle from Table III of I for $b+1/2$ doubly-degenerate QES states.

Summarizing, when $a-b$ is an odd integer, then there are infinite number of bands out of which except for the lowest $a-b$ bands, the rest are rather unusual in that both of their band edges have period $4K$ and two degenerate states of period $2K$ reside inside each of these bands.

As an illustration, consider the case of $p=15/4, q=3/4$, i.e., $a=3/2$, $b=1/2$. From the above discussion, it follows that in this case one must have one nondegenerate and one doubly-degenerate QES state of period $2K$. Using Table III of I it is easily seen that the eigenvalue and the eigenfunction for the nondegenerate state is given by

$$\psi_0=\mathrm{dn}^{3/2}x, \quad E_0=\frac{9m}{4}, \tag{21}$$

while the energy eigenvalue and the corresponding two degenerate eigenfunctions are given by

$$\psi_3=\frac{\mathrm{sn}\,x\,\mathrm{cn}\,x}{\mathrm{dn}^{1/2}x}, \quad \psi_4=\frac{[2\,\mathrm{sn}^2x-1]}{\mathrm{dn}^{1/2}x}, \quad E_{3,4}=4+\frac{m}{4}. \tag{22}$$

Note that in this case, out of the infinite number of bands, except for the lowest band, all other bands have both of their band edges of period $4K$.

Another case, already discussed in I (see Table VII) is when $p=63/4, q=3/4$, i.e., $a=7/2$, $b=1/2$. As shown there, in this case one has three nondegenerate QES states of period $2K$ and one doubly-degenerate level of the same period. Further, in this case, but for the lowest three bands, all other bands have both of their band edges of period $4K$.

(ii) $a-b=$ even integer

From Eqs. (9) and (10) it follows that in this case both μ_1^* and μ_2^* are integral while μ_1 and μ_2 are half-integral. Hence, in this case there will be infinite number of band-gaps of period $2K$ but *at most* an $(a+b+1)/2$ number of band-gaps of period $4K$. However, a study of several explicit examples reveals that in this case there are only an $(a-b)/2$ number of band gaps and hence an $a-b$ number of nondegenerate QES states of period $4K$. However, using Table III of I it is easily shown that in this case there are in fact an $a+b+1$ number of QES states of period $4K$. This implies that in addition to the $a-b$ nondegenerate QES states, there must also be $2b+1$ QES degenerate states of period $4K$, i.e., in this case also there are $b+1/2$ doubly-degenerate QES states of period $4K$, each of which is lying inside a band.

Thus, in this case too, there are an infinite number of bands out of which except for the lowest $a-b$ bands, the rest are rather unusual in that both of their band edges are of period $2K$ and two degenerate states of period $4K$ reside inside each of these bands.

As an illustration, consider the case of $p=35/4, q=3/4$, i.e., $a=5/2, b=1/2$. In view of the above discussion, we expect two nondegenerate and one doubly-degenerate QES states of period $4K$. Using Table III of I it is easily shown that the energy eigenstates for the two nondegenerate states are

$$\psi_1=\mathrm{cn}\,x\,\mathrm{dn}^{3/2}x, \quad E_1=1+\frac{9m}{4}, \tag{23}$$

$$\psi_2=\mathrm{sn}\,x\,\mathrm{dn}^{3/2}x, \quad E_2=1+\frac{25m}{4}, \tag{24}$$

while for the two degenerate states one has

$$\psi_5=\frac{\mathrm{cn}\,x(4\,\mathrm{sn}^2x-1)}{\mathrm{dn}^{1/2}x}, \quad \psi_6=\frac{\mathrm{sn}\,x\,(4\,\mathrm{sn}^2x-3)}{\mathrm{dn}^{1/2}x}, \quad E_{5,6}=9+\frac{m}{4}. \tag{25}$$

Thus, in this case (out of the infinite number of bands) except for the two lowest bands, all other bands are a bit unusual in that both of their band edge eigenfunctions are of period $2K$.

We thus have seen that for half-integral a,b with $a>b$, one has $a-b$ nondegenerate and $b+1/2$ doubly-degenerate QES states of period $2K$ or $4K$ depending on whether $a-b$ is an odd or an even integer. Thus for $b=1/2,3/2,\ldots(a>b)$, we expect $1,2,\ldots$, doubly-degenerate QES states. We now show that the energy eigenvalues of these doubly-degenerate states can be easily obtained analytically in case $b=1/2$ or $3/2$ and a being an arbitrary half-integer (with $a>b$). In particular, if we start with the ansatz

$$y_1(x)=\sum_{k=0}^{N+1} A_k\,\mathrm{sn}^{2k}x, \tag{26}$$

then on substituting it in the associated Lamé equation (5) and equating coefficient of terms with $\mathrm{sn}^{2N+4}x$ and $\mathrm{sn}^{2N+2}x$ we find that in case $a=2N+3/2, b=1/2$ then the corresponding energy eigenvalue is

$$E=(2N+2)^2+m/4, \quad N=0,1,2,\ldots. \tag{27}$$

In fact E as given by Eq. (27) is also the energy eigenvalue in case we start with the ansatz

$$y_2(x)=\sum_{k=0}^{N} A_k \,\mathrm{sn}^{2k+1} x \,\mathrm{cn}\, x, \tag{28}$$

and substitute it in Eq. (5). As expected, the results given in Eq. (22) agree with these given above in case $N=0$ while for $N=1$ our results agree with those given in Table VII of I.

Similarly, it is easily shown that in case $a=2N+5/2,\ b=1/2$ then the degenerate eigenvalue and the corresponding eigenfunctions are

$$E=(2N+3)^2+m/4, N=0,1,2,\ldots, \tag{29}$$

$$y_1(x)=\sum_{k=0}^{N+1} A_k \,\mathrm{sn}^{2k+1} x, \quad y_2(x)=\sum_{k=0}^{N+1} B_k \,\mathrm{cn}\, x \,\mathrm{sn}^{2k} x. \tag{30}$$

For the special case of $N=0$, our results agree with those given in Eq. (25).

On the other hand, for $b=3/2$ and $a=2N+5/2$, the two degenerate energy eigenvalues are

$$E=4N^2+12N+10+\frac{5m}{4}\pm\sqrt{(4N+6)^2-(4N+6)^2m+m^2}, \quad N=0,1,2,\ldots, \tag{31}$$

while the corresponding eigenfunctions are of the form

$$y_1(x)=\sum_{k=0}^{N+2} A_k \,\mathrm{sn}^{2k} x, \quad y_2(x)=\sum_{k=0}^{N+1} B_k \,\mathrm{cn}\, x \,\mathrm{sn}^{2k+1} x. \tag{32}$$

However, for $b=3/2$ and $a=2N+7/2$, the two degenerate energy eigenvalues are

$$E=4N^2+16N+17+\frac{5m}{4}\pm\sqrt{16(N+2)^2-16(N+2)^2m+m^2}, \quad N=0,1,2,\ldots, \tag{33}$$

while the corresponding degenerate eigenfunctions are of the form

$$y_1(x)=\sum_{k=0}^{N+2} A_k \,\mathrm{sn}\, x^{2k+1}, \quad y_2(x)=\sum_{k=0}^{N+2} B_k \,\mathrm{cn}\, x \,\mathrm{sn}^{2k} x. \tag{34}$$

It is worth adding that in case $b=-1/2(a>b)$, one obtains $a+1/2$ nondegenerate QES states of period $2K(4K)$ depending on if $a+1/2$ is an odd or an even integer. Note that when $b=-1/2$ then $q=-1/4$ while $p>0$. As an illustration, consider $a=5/2,\ b=-1/2$, i.e., $p=35/4,\ q=-1/4$. In this case we have 3 QES states of period $2K$ whose energy eigenvalues and eigenfunctions are easily obtained from Table III of I when $q=(a-2)(a-3)$ and of course $p=a(a+1)$.

Finally, let us discuss the case when a,b are neither integral nor half-integral but are such that either $a+b$ or $a-b$ is an integer. It is easily seen from Eqs. (9) and (10) that if either $a+b=2N$ or $a-b=2N+1$ then there are at most $N+1$ band-gaps of period $2K$ while if $a-b=2N$ or $a+b=2N-1$ then there are at most N band-gaps of period $4K$. Further, from Table III of I we find that when either $a+b=2N$ or $a-b=2N+1$ then there are precisely $2N+1$ QES states of period $2K$ while if $a+b=2N-1$ or $a-b=2N$ then there are precisely $2N$ QES states of period $4K$ and all these are nondegenerate states.

IV. MID-BAND STATES

For the Lamé potential, the majority of results are for integral a (and hence p). However, for half-integral values of a, analytic expressions for $a+1/2$ mid-band states (of period $8K$) have been obtained.[4] In particular, it is known that if $a=2N+1/2$, there are $2N+1$ mid-band states of the form ($N=0,1,2,\ldots$)

$$\psi(x)=\sqrt{\mathrm{dn}\,x+\mathrm{cn}\,x}\,u(x), \tag{35}$$

where

$$u(x)=\sum_{k=0}^{N} A_k\,\mathrm{sn}^{2k}x+\sum_{k=0}^{N-1} B_k\,\mathrm{cn}\,x\,\mathrm{dn}\,x\,\mathrm{sn}^{2k}x, \tag{36}$$

while if $a=2N+3/2$, then there are $2N+2$ states of the form (35) but where ($N=0,1,2,\ldots$)

$$u(x)=\mathrm{dn}\,x\sum_{k=0}^{N} A_k\,\mathrm{sn}^{2k}x+\mathrm{cn}\,x\sum_{k=0}^{N} B_k\,\mathrm{sn}^{2k}x. \tag{37}$$

Further, since the Lamé equation is invariant under $x\to x+2K(m)$, it follows that in each case one obtains another solution with the *same* energy by changing $\mathrm{cn}\,x$ to $-\mathrm{cn}\,x$.

In this section we show that the associated Lamé potential (2) also has a similar form of mid-band solutions (of period $8K$) in case a is half-integral while b takes integral values. In particular, if $a=k+1/2, b=s$ while $k=2N$ with N,k,s being non-negative integers, then for a given k, one obtains $k+1$ doubly-degenerate solutions for every possible (non-negative integral) value of s. Further, in this case too, all solutions are also doubly degenerate since the associated Lamé equation is invariant under $\mathrm{cn}\,x\to-\mathrm{cn}\,x$.

We begin by substituting the ansatz

$$y(x)=\sqrt{\mathrm{dn}\,x+\mathrm{cn}\,x}\,z(x), \tag{38}$$

into Eq. (5). We find that $z(x)$ satisfies the equation

$$\begin{aligned}\mathrm{sn}\,x\,\mathrm{dn}\,x\,z''(x)+[2bm\,\mathrm{sn}^2x\,\mathrm{cn}\,x-\mathrm{dn}\,x+\mathrm{cn}\,x\,\mathrm{dn}^2x]z'(x)+[\lambda_1\,\mathrm{sn}\,x\,\mathrm{dn}\,x-rm\,\mathrm{sn}^3x\,\mathrm{dn}\,x\\ -bm\,\mathrm{cn}\,x\,\mathrm{sn}\,x+bm\,\mathrm{cn}^2x\,\mathrm{sn}\,x\,\mathrm{dn}\,x]z(x)=0,\end{aligned} \tag{39}$$

where

$$\lambda_1=\lambda-\frac{1+m}{4},\quad r=(a+1-b)(a+b)-3/4. \tag{40}$$

Not surprisingly, $z(x)=\mathrm{const}$ is a solution with energy $E=(1+m)/4$ (note $E=\lambda+mb^2$) provided $b=0$ and $a=1/2$, i.e., $p=3/4$, $q=0$. Following the discussion given above, we try the ansatz (37) with $N=0$, i.e.,

$$z(x)=A\,\mathrm{dn}\,x+B\,\mathrm{cn}\,x, \tag{41}$$

in Eq. (39). It is easily shown that there are two possible solutions in this case.

(i) $b=0$, $a=3/2$:

$$\psi(x)=[\mathrm{dn}\,x-(1-m\pm\sqrt{1-m+m^2})\,\mathrm{cn}\,x]\,\sqrt{\mathrm{dn}\,x+\mathrm{cn}\,x},\quad E=\tfrac{5}{4}(1+m)\pm\sqrt{1-m+m^2}. \tag{42}$$

(ii) $b=1$, $a=1/2$:

$$\psi(x)=\left[1-\frac{2\,\mathrm{cn}\,x}{\mathrm{dn}\,x}\right]\sqrt{\mathrm{dn}\,x+\mathrm{cn}\,x}, \quad E=\frac{9+m}{4}. \tag{43}$$

Several comments are in order at this stage.

(1) On making use of the fact that as $m\to 0$, $\mathrm{dn}\,x\to 1$ while $\mathrm{cn}\,x\to\cos x$ it is easily shown that in case $b=0$, $a=3/2$, the two solutions go over to $\cos(x/2)$ and $\cos(3x/2)$ with energies 1/4 and 9/4, respectively. On the other hand, as $m\to 1$, the two states go over to the ground and excited states of the potential $V=15/4\tanh^2 x$ with eigenvalues 3/2 and 7/2, respectively.
(2) On the other hand, as $m\to 0$ the solution with $b=1$ and $a=1/2$ goes over to $\cos(3x/2)$ with energy 9/4 while as $m\to 1$, it goes over to the ground state of the potential $V=3/4\tanh^2 x+2$ with energy eigenvalue 5/2.
(3) Degenerate solutions are obtained in all these cases by changing $\mathrm{cn}\,x$ to $-\mathrm{cn}\,x$, and as $m\to 0$ these go over to $\sin(x/2)$ or $\sin(3x/2)$ as the case may be.

One can now immediately generalize to the general ansatz (37) and show that for a given N, if $a=k+1/2$ and $b=s$ with $k=2N+1-s$ ($N=0,1,2,\ldots$) then $k+1$ doubly-degenerate eigenvalues and eigenfunctions can be obtained for every possible non-negative s. For example, let us consider the ansatz (37) with $N=1$, i.e.,

$$z(x)=\mathrm{dn}\,x\,[A_0+A_1\,\mathrm{sn}^2 x]+\mathrm{cn}\,x\,[B_0+B_1\,\mathrm{sn}^2 x]. \tag{44}$$

After substituting this ansatz in Eq. (39) and performing lengthy algebraic manipulations, it is easily shown that there are four possible solutions in this case.

(i) $b=0$, $a=7/2$

As is well known,[4] in this case $\lambda_1=E-(1+m)/4$ satisfies a quartic equation,

$$\lambda_1^4-20(1+m)\lambda_1^3+18(6+19m+6m^2)\lambda_1^2-36(4+39m+39m^2+4m^3)\lambda_1+135m(8+23m+8m^2)=0, \tag{45}$$

all of whose roots are real and that as $m\to 0$ the solutions go over to $\cos(x/2)$, $\cos(3x/2)$, $\cos(5x/2)$, $\cos(7x/2)$ with energies 1/4, 9/4, 25/4 and 49/4, respectively.

(ii) $b=1$, $a=5/2$

In this case λ_1 can be shown to satisfy the cubic equation [note $E=\lambda_1+(1+m)/4+mb^2$]

$$\lambda_1^3-(5m+14)\lambda_1^2+(24+88m-m^2)\lambda_1+5m^3-98m^2-96m=0, \tag{46}$$

whose all three roots are real for any $m(0\leqslant m\leqslant 1)$. As $m\to 0$, we find that the solutions go over to $\cos(x/2)$, $\cos(3x/2)$, $\cos(7x/2)$ with energies 1/4, 9/4, 49/4, respectively.

(iii) $b=2$, $a=3/2$

In this case there are two solutions with the corresponding energies being

$$E=\frac{29+5m}{4}\pm\sqrt{25-25m+m^2}. \tag{47}$$

Note that as $m\to 0$ the two energies go over to 9/4 and 49/4 and the corresponding solutions go over to $\cos(3x/2)$ and $\cos(7x/2)$, respectively.

(iv) $b=3$, $a=1/2$

In this case there is only one solution given by

$$\psi=\left(\mathrm{dn}\,x\left[1-\frac{(4-m)}{3}\,\mathrm{sn}^2 x\right]-\frac{4}{3}\,\mathrm{cn}\,x\,[1-(2-m)\,\mathrm{sn}^2 x]\right)\sqrt{\mathrm{dn}\,x+\mathrm{cn}\,x}, \quad E=\frac{49+m}{4}. \tag{48}$$

It is easily checked that as $m \to 0$ the solution goes over to $\cos(7x/2)$ and the corresponding energy is 49/4.

On the other hand if $a = k + 1/2, b = s$ and $k = 2N - s$ ($N = 0,1,2,\ldots$) then we start with the ansatz (36) and obtain $k+1$ (doubly-degenerate) eigenvalues and eigenfunctions for every possible non-negative s. For $N = 0$, the only possibility is of course $a = 1/2$, $b = 0$ and in this case the solution is already well known.[4] For $N = 1$ we start with the ansatz,

$$z(x) = A_0 + A_1 \,\mathrm{sn}^2 x + B_0 \,\mathrm{cn}\, x \,\mathrm{dn}\, x. \tag{49}$$

On substituting this ansatz in Eq. (39), after lengthy but straightforward algebraic manipulations, we find the following three solutions.

(i) $b = 0$, $a = 5/2$

As is well known,[4] in this case $\lambda_1 = E - (1+m)/4$ satisfies a cubic equation,

$$\lambda_1^3 - 8(1+m)\lambda_1^2 + 4(3+13m+3m^2)\lambda_1 - 48m(1+m) = 0, \tag{50}$$

all of whose roots are real and as $m \to 0$, the solutions go over to $\cos(x/2), \cos(3x/2), \cos(5x/2)$ with energies $1/4, 9/4$ and $25/4$, respectively.

(ii) $b = 1$, $a = 3/2$

In this case there are two solutions with the corresponding energies being

$$E = \frac{13+5m}{4} \pm \sqrt{9 - 9m + m^2}. \tag{51}$$

Note that as $m \to 0$ the energies go over to $1/4$ and $25/4$ while the corresponding solutions go over to $cos(x/2)$ and $\cos(5x/2)$, respectively.

(iii) $b = 2$, $a = 1/2$

In this case there is only one solution:

$$\psi = \sqrt{\mathrm{dn}\, x + \mathrm{cn}\, x}\left[1 - \frac{(4-m)}{3}\,\mathrm{sn}^2 x - \frac{2}{3}\,\mathrm{cn}\, x \,\mathrm{dn}\, x\right], \quad E = \frac{25+m}{4}. \tag{52}$$

As $m \to 0$ the solution goes over to $\cos(5x/2)$ with energy $25/4$.

Before closing this section it is worth pointing out that the mid-band states have already been obtained in I in case $a = b = N + 1/2 (N = 0,1,2,\ldots)$. In particular, it may be noted that when $a = b$, then the associated Lamé potential has period K rather than $2K$ and hence the band edges will be of period K and $2K$ while the mid-band states will be of period $4K$. Now if one looks at the Table III of I then one notices that if $a = b = N + 1/2$, then there are $N+1$ doubly-degenerate QES states of period $4K$ which are obtained in principle from Table III of I in case $a = N + 1/2$ and $q = [a - (N+1)][a - (N+2)]$. For example, for $N = 0$, i.e., for $p = q = 3/4$, the doubly-degenerate mid-band states are

$$\psi_1 = \frac{\mathrm{cn}\, x}{\sqrt{\mathrm{dn}\, x}}, \; \psi_2 = \frac{\mathrm{sn}\, x}{\sqrt{\mathrm{dn}\, x}}, \quad E = 1 + \frac{m}{4}. \tag{53}$$

On the other hand, for $N = 1$ the pair of doubly-degenerate mid-band states are

$$\psi_1 = \frac{\mathrm{cn}\, x(4 - m - 2\mathrm{sn}^2 x)}{\mathrm{dn}^{3/2} x}, \; \psi_2 = \frac{\mathrm{sn}\, x(4 - 2\mathrm{sn}^2 x)}{\mathrm{dn}^{3/2} x}, \quad E = 1 + \frac{9m}{4}, \tag{54}$$

$$\psi_1 = \frac{\mathrm{cn}\, x \,\mathrm{sn}^2 x}{\mathrm{dn}^{3/2} x}, \; \psi_2 = \frac{\mathrm{sn}\, x(2\mathrm{sn}^2 x - 1)}{\mathrm{dn}^{3/2} x}, \quad E = 9 + \frac{m}{4}. \tag{55}$$

V. CONCLUSION AND OPEN PROBLEMS

In this paper we have clarified several issues regarding the associated Lamé potential. In particular, we have shown that when both a,b are integers then just like Lamé, the associated Lamé potential is also a finite band problem. The only difference from the Lamé case arises when $a \neq b$—in that case one has some bands with both band edges of the same period. We have also seen that when both a,b take half-integral but unequal values then one has a genuine QES problem and band edges of either period $2K$ or $4K$ are known, but not both. We have also shown that in this case, but for the few low lying bands, all other bands have both of their band edges of the same period ($2K$ or $4K$). Finally, when a is a half-integer and b is an integer, we can obtain several mid-band states.

It would be nice if one could (i) say something concrete about the band structure when a,b are neither integral or half-integral; (ii) derive dispersion relations for at least some of the finite band associated Lamé problems; (iii) obtain the band edges of the associated Lamé problem algebraically, analogous to the Lamé potential. We hope to address some of these issues in the near future.

Hofstadter butterfly as quantum phase diagram

D. Osadchy and J. E. Avron[a)]
Department of Physics, Technion, 32000 Haifa, Israel

(Received 20 June 2001; accepted for publication 29 August 2001)

The Hofstadter butterfly is viewed as a quantum phase diagram with infinitely many phases, labeled by their (integer) Hall conductance, and a fractal structure. We describe various properties of this phase diagram: We establish Gibbs phase rules; count the number of components of each phase, and characterize the set of multiple phase coexistence. © *2001 American Institute of Physics.*
[DOI: 10.1063/1.1412464]

I. INTRODUCTION

Azbel[1] recognized that the spectral properties of two-dimensional, periodic, quantum systems have sensitive dependence on the magnetic flux through a unit cell. A simple model conceived by Peierls and put to the eponymous Harper as a thesis problem, gained popularity with D. Hofstadter's Ph.D. thesis,[2] where a wonderful diagram, reminiscent of a fractal butterfly, provided a source of inspiration and a tool for spectral analysis.[3–9]

The Hofstadter butterfly can also be viewed as the quantum (zero temperature) phase diagram for the integer quantum Hall effect. It is a fractal phase diagram with infinitely many phases.[10,11] The diagram leads to certain natural questions: Count the number of components of a given phase; classify which phases coexist and where. It also leads to the general question: What form does the Gibbs phase rule[12,13] take for quantum phase transitions.

Fractal phase diagrams and/or infinitely many phases appear in dynamical systems.[14,15] In classical lattice systems fractal phase diagrams[12,16,17,13] are commonly viewed as a pathology due to either long range interactions, or, as is the case for spin glasses, loss of translation invariance. The Hofstadter model, when viewed as a statistical mechanical model, is both short range and translation invariant in a natural way. But, it is quantum and the translation group is noncommutative. It suggests that the fractal phase diagram may be more common in quantum phase transitions than in classical phase transitions.

II. THE HOFSTADTER MODEL

The model conceived by Peierls has two versions. For the sake of concreteness we shall focus here on the tight binding version. On the lattice $\mathbb{Z}^2$, define magnetic shifts

$$(U\psi)(n,m)=\psi(n-1,m), \quad (V(\Phi)\psi)(n,m)=e^{2\pi i n\Phi}\psi(n,m-1) \quad n,m\in\mathbb{Z}. \tag{1}$$

$2\pi\Phi$ is the magnetic flux through a unit cell. The Hofstadter model is

$$H(\Phi,a,b)=a(U+U^*)+b(V(\Phi)+V^*(\Phi)), \tag{2}$$

where $a,b>0$ are ''hopping'' amplitudes. $a=b$ is called the self-dual case[18] and we shall focus on that case in the following. We set $H(\Phi)=H(\Phi,1,1)$.

U and V, and therefore also $H(\Phi)$, commute with the (dual) magnetic translations $\mathcal{U}$ and $\mathcal{V}$,

$$(\mathcal{U}\psi)(n,m)=\psi(n,m-1) \quad (\mathcal{V}\psi)(n,m)=e^{2\pi i\Phi m}\psi(n-1,m). \tag{3}$$

a)Electronic mail: avron@physics.technion.ac.il

This makes $H(\Phi)$ translation invariant in a natural way. The group of magnetic translations[19] is noncommutative:

$$U^*V^*UV=\mathcal{U}\mathcal{V}\mathcal{U}^*\mathcal{V}^*=e^{-2\pi i\Phi}. \tag{4}$$

The one-particle representation of the Hofstadter model, Eq. (2), is natural for spectral studies. In the context of statistical mechanics the second quantized representation of the model is also instructive because it makes it clear that the model has short range, in fact, only on site and nearest neighbors, interactions. The fractal features of the phase diagram are, therefore, not a consequence of long range forces, as in some classical statistical mechanics models. The second quantized form is

$$\mathcal{H}(\Phi,\mu)=\sum\ e^{i\gamma(nm;n'm')}a^\dagger_{nm}a_{n'm'}+\mu\sum\ a^\dagger_{nm}a_{nm}, \tag{5}$$

where

$$e^{i\gamma(mn;m'n')}=\begin{cases}1, & n-n'=\pm 1,\ m=m'\\ e^{\pm 2\pi i n\Phi}, & m-m'=\pm 1,\ n=n'\\ 0 & \text{otherwise.}\end{cases} \tag{6}$$

μ is the chemical potential and $a^\dagger,a$ are the usual Fermionic operators.

Let us recall a few elementary features of the spectrum:

$$S(H(\Phi))=-S(H(\Phi))=-S(H(1-\Phi)). \tag{7}$$

The first is a consequence of $\mathbb{Z}^2$ being bipartite, and the second is a consequence of time reversal. Together, they imply a fourfold symmetry, manifest in the Hofstadter butterfly.

The electronic density, $\rho(\Phi,\mu)$ (=integrated density of state), is

$$\rho(\Phi,\mu)=\langle 0|\,\theta(\mu-H(\Phi))|0\rangle, \tag{8}$$

where $|0\rangle$ is Kroneker delta at the origin. $0\leqslant\rho(\Phi,\mu)\leqslant 1$ is an increasing function of μ. θ is the usual step function.

The gaps in the spectrum are labeled by an integer, k, which is a solution of[20,3]

$$\Phi\, k=\rho \bmod 1. \tag{9}$$

k is the Hall conductance. We picked the letter k because it is naturally associated with an integer, and it is also the first letter in von Klitzing's name. By Eqs. (9) and (7),

$$k(\mu,\Phi)=-k(\mu,1-\Phi)=-k(-\mu,\Phi), \tag{10}$$

which implies a fourfold (anti) symmetry of the butterfly.

We shall assume that the Ten Martini conjecture[21] holds. Namely, that for all irrational Φ's, all the gaps are open, so Eq. (9) has ρ in an open gap for all $k\in\mathbb{Z}$.

Figure 1 shows the Hofstadter butterfly, color coded according to the Hall conductance. Zero Hall conductance is left blank. The gross features of the diagram are associated with small integers where the color coding is faithful.

The colored picture emphasizes the gaps while the standard Hofstadter butterfly emphasizes the spectrum. The colored figure is prettier and displays the regular aspects of the diagram: Gaps are better behaved than spectra. The colored diagram is also more faithful to certain spectral characteristics. For example, the spectrum is a small set (in fact, one of zero Lebesgue measure), something that is manifest in the colored diagram, but is less obvious from the usual Hofstadter butterfly which plots the spectrum.

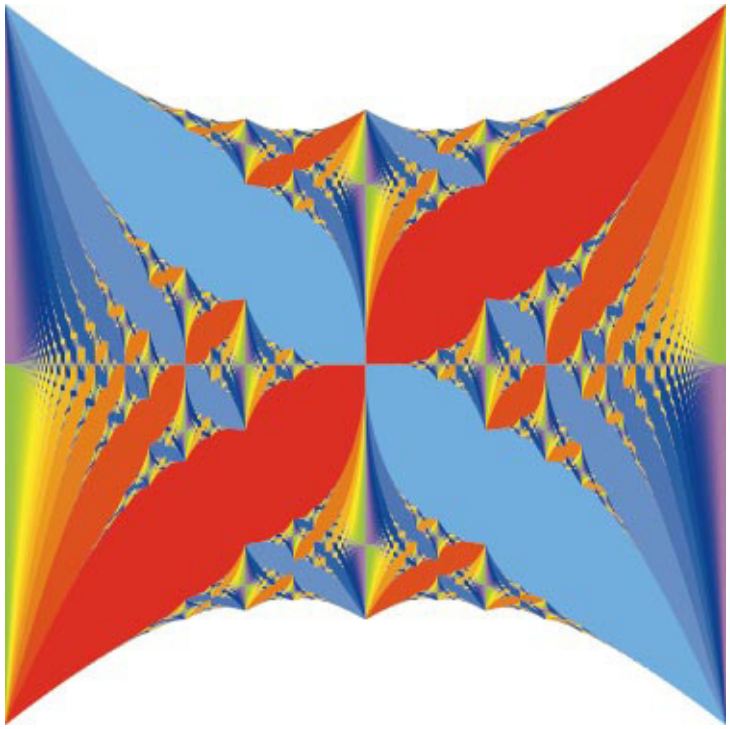

FIG. 1. (Color.) Hofstadter colored butterfly.

We also broke with tradition in that the colored Hofstadter butterfly is rotated by 90°: In Fig. 1 the horizontal axis is Φ and the vertical axis is the energy, or $S(H(\Phi))$. The reason we chose to do so is that this way emphasizes the fact that phase boundaries are functions (of Φ).

We denote by $P(k)$ the kth phase. Formally,

$$P(k)=\{\Phi,\mu|\Phi k=\rho(\Phi,\mu)\bmod 1,\mu\notin S(H(\Phi))\}. \tag{11}$$

$P(k)$ is an open set in the (Φ,μ) plane, with a finite number of components. For example, $P(1)$ is two of the four big wings of the butterfly. We call $P(k)$ a *pure phase* and denote its number of components $|P(k)|$. The closure of the pure phase is denoted $\overline{P(k)}$ and the phase boundary is $\partial P(k)$. We call $\cup_k \partial P(k)$ the total boundary.

III. COUNTING COMPONENTS

The kth pure phase is made of several components. The $k=0$ phase (blank) has two components. For $k\neq 0$ the number of components is

$$|P(k)|=\sum_{j=1}^{2|k|}\phi(j)=12\frac{k^2}{\pi^2}+O(k\log k), \tag{12}$$

where $\phi(j)$ is Euler (totient) function. Recall that $\phi(j)$ counts the number of integers, up to j (and including 1), that are prime to j: $\phi(1)=1$, $\phi(2)=1$, $\phi(3)=2$ etc.

To prove Eq. (12) note first that from Eq. (9)

$$k(\rho,\Phi)=k(\rho',\Phi)\Rightarrow\rho=\rho'. \tag{13}$$

Hence, a given color would appear *at most* once on any vertical line of fixed Φ.

When $\Phi = p/q$ with $\gcd(p,q)=1$ [$\gcd(p,q)$ is the greatest common divisor of p and q], the spectrum of the Hofstadter model has q finite bands and $q-1$ gaps which are all open intervals (except when q is even the central gap is closed). We then number the gaps by their natural order $1,\ldots,q-1$. The semi-infinite interval below the spectrum is, formally, the 0th gap, and the semi-infinite interval above the spectrum as the qth gap. Equation (9), for the jth gap, can be written as

$$p\,k = j \bmod q. \tag{14}$$

Given p,q, and j the equation has a unique solution for each open gap such that $|k|<q/2$. In particular, once q has been fixed, the Hall conductance takes all (nonzero) integer values, from $-\lfloor q/2 \rfloor$ to $\lfloor q/2 \rfloor$, and each value appears once. For even q, the central gap is closed and formally can be assigned a value of $\pm q/2$.

The number of components of the kth phase is the same as the number of flux values, $\Phi_{\diagup}$, which accommodate the wing tips, minus one. The kth wing tips are located at those values of Φ where the kth color is absent (the kth color *is* present in any small neighborhood of those values of Φ, because this neighborhood contains fractions with arbitrary large q's). Given $k\neq 0$, it must appear once on a horizontal interval with $\Phi = p/q$ provided $q/2>|k|$. The tips of a wing with a given color must, therefore, be located at those values of Φ which do not admit k as solution of Eq. (14) for any ρ. In other words, the wing tips lie at those values of Φ where q is too small to accommodate $|k|$. This is the finite set, a Farey sequence,

$$F_{2|k|}=\left\{\frac{p}{q}\middle| 0\leqslant p\leqslant q, \gcd(p,q)=1, q\leqslant 2|k|\right\}=\bigcup_{q=1}^{2|k|}\left\{\frac{p}{q}\middle| 0<p\leqslant q, \gcd(p,q)=1\right\}\bigcup\{0\}. \tag{15}$$

Let $|F|$ be the number of elements in F. Then from (15),

$$|P(k)|=|F_{2|k|}|-1=\sum_{q=1}^{2|k|}\phi(q) \tag{16}$$

essentially from the definition of the Euler function.

The asymptotic expansion for the sum in Eq. (12) is taken from Ref. 22.

IV. PURE PHASES AND PHASE BOUNDARIES

In thermodynamics and statistical mechanics, Gibbs phase rule is a statement about the structure of pure phases and their boundaries. A weak form of the Gibbs phase rule says that pure phases are a set of full measure; two phases coexist, generically, on a set of Hausdorff co-dimension one, etc.[12] This is the form that one gets if one considers general convex functions for thermodynamic potentials. The number of coexisting phases is related to the dimension of tangent planes, and the Gibbs phase rule is a consequence of theorems about convex functions. There is a stronger form of the rule[13] which posits, in addition, that the sets are (locally) manifolds. This form is a consequence of additional regularity of the thermodynamic potentials.

Gibbs phase rule is a consequence of the convexity of thermodynamic potentials and so is ultimately based on the second law of thermodynamics. It has nothing to say about the zero temperature phase diagram of quantum phase transitions in general,[23] and the Hofstadter model in particular (because the entropy vanishes identically). A question that arises is then what form might Gibbs phase rule take for quantum phase transition. The Hofstadter model restricts what could and what could not be true in general. As we shall see, the phase diagram of the Hofstadter model turns out to satisfy only a weak form of the Gibbs phase rules.

Figure 1 suggests that the set of unique phase is a set of full measure and that the phase boundaries, though fractal, are not too wild. More precisely, we have the following.

Gibbs-like phase rule: The phase diagram of the self-dual Hofstadter model is such that pure phases, labeled by their Hall conductances, are full measure; phase boundaries are not manifolds—they are nowhere differentiable—but they are almost so in the sense that their Hausdorff co-dimension is integral, in fact:

$$\dim_H(\partial P(k))=1. \tag{17}$$

Since the number of phases is countable the total phase boundary $\cup_m(\partial P(m))$ *is a set of Hausdorff dimension one as well. Finally, infinitely many phases coexist on a countable set, and therefore a set of Hausdorff dimension zero.*

The first part of the Gibbs-like phase rule is an easy consequence of a result of Last,[6] which states that $|S(H(\Phi))|=0$ for a set of Φ of full measure. That phase boundaries are nowhere differentiable follows from results of Wilkinson,[9] Rammal, and Helffer and Sjöstrand,[5] who showed that the phase boundaries $\partial P(k)$ possess distinct left and right tangent at every rational Φ. That the Hausdorff dimension of the boundary is one follows from results of Bellissard,[24] who showed that away from the wings tips, $\partial P(k)$ can be represented by functions of Φ that are *uniformly* Lipshitz. By standard results,[25] it then follows that the Hausdorff dimension is one. The set of infinite phase coexistence is analyzed in the following.

V. COEXISTENCE

In Ref. 15 the term lakes of Wada was used to describe dynamical systems with the property that any point on the boundary of the one basin of attraction is also on the boundary of all other basins. We shall say that a system is almost Wada of order m if every circle that contains two pure phases contains m pure phases.

The Hofstadter butterfly is almost Wada of infinite order. This is seen from the figure, and can also be shown to follow from Eq. (9).

We say that the two pure phases, $P(m)$, $P(n)$, coexist on

$$C(m,n)=\partial P(m)\cap\partial P(n). \tag{18}$$

No two phase coexists for any irrational flux. This is easily seen from Eq. (9): For irrational Φ the electron density ρ takes a dense set of values in the gaps. Therefore, any two phases, $P(m)$ and $P(n)$, are separated by infinitely many other phases. It follows that the set of phase coexistence is a countable set, and so of zero Hausdorff dimension.

The following result gives a complete characterization of phase coexistence:

Proposition: Consider a point $x\in\partial P(k)$ *with* $\Phi(x)=p/q$ *with* $\gcd(p,q)=1$. *Then* $x\in\partial P(k+\ell q)$ *for all* $\ell\in\mathbb{Z}$. *Moreover* $x\notin\partial P(k')$ *if* $k'\neq k+\ell q$ *for each* $\ell\in\mathbb{Z}$

Proof: Since $\gcd(p,q)=1$ the equation

$$pa-qb=1 \tag{19}$$

has a solution with integer a and b (where a is nonunique mod q). Let $p_n/q_n=(np-b)/(nq-a)$ with $n\in\mathbb{Z}$. Then

$$p_nq-q_np=1. \tag{20}$$

From Eq. (14) it follows that each band at p_n/q_n carries Hall conductance $q\ (\mathrm{mod}\, q_n)$.

Now consider a point x on the right boundary of $P(k)$. We shall first show that x is also on the left boundary of $P(k+q)$. Since $P(k+q)$ has a finite set of wing tips, Eq. (15), when n is large enough, the gap with label (=Hall conductance) $k+q$ at flux p_n/q_n must be open, and must remain open for all large n. By a bound of Last and Wilkinson[26] for the total width of the spectrum at p_n/q_n, each band is small and hence

$$\mathrm{dist}(P(k),P(k+q))<\frac{24}{q_n}. \tag{21}$$

Taking $n\to\infty$ we see that $x\in\partial P(k+q)$ as claimed.

By considering the next band we shall now show that x also lies on the boundary of $P(k+2q)$. Now, $P(k+2q)$ at p_n/q_n is separated from $P(k)$ by two bands and a gap. The bands are small by the Last–Wilkinson bound. The gap is also small by the Hölder continuity of the spectrum:

$$|\mathrm{gap}|<18\sqrt{\frac{p_n}{q_n}-\frac{p}{q}}=\frac{18}{\sqrt{qq_n}} \tag{22}$$

and from this

$$\mathrm{dist}(P(k),P(k+2q))<\frac{24}{q_n}+\frac{18}{\sqrt{qq_n}}. \tag{23}$$

Taking the limit $n\to\infty$ yields the result. The argument can be repeated for any $P(k+\ell q)$ with ℓ finite and positive. Negative values $P(k-\ell q)$ are obtained by letting $n\to-\infty$ in the above-mentioned argument.

For the left boundary point of $P(k)$, $n\to\infty$ will give $P(k-\ell q)$ and $n\to-\infty$ will give $P(k+\ell q)$. This formula applies also to the phase $k=0$, with its right boundary being the leftmost point of the spectrum and vice-versa. The Hall conductance for the middle gap with even q (which is closed) is formally $\pm q/2$, so it is common to phases $P(\pm q/2+\ell' q)$ which is the same as $P(q/2+\ell q)$ for $\ell,\ell'\in\mathbb{Z}$.

The second part of the proposition follows from the equality

$$\bigcup_{k\leqslant|\frac{q}{2}|}\bigcup_{\ell\in\mathbb{Z}}P(k+\ell q)=\bigcup_{k\in\mathbb{Z}}P(k)$$

and the fact that for fixed Φ, each Hall conductance k can appear only once.

We construct a coherent state path integral formalism for the one-dimensional Bloch particle within the single band model. The transition amplitude between two coherent states is a sum of transition amplitudes with different winding numbers on the two-dimensional phase space which has the same topology as that of the cylinder. Appearance of the winding number is due to the periodicity of the quasimomentum of the Bloch particle. Our formalism is successfully applied to a semiclassical motion of the Bloch particle under a uniform electric field. The wave packet exhibits not only the Bloch oscillation but also a similar breathing to the one for the squeezed state of a harmonic oscillator. © *2001 American Institute of Physics.* [DOI: 10.1063/1.1416489]

I. INTRODUCTION

The path integral formalism[1] of quantum mechanics uses classical paths to evaluate a quantum-mechanical transition amplitude. This is an advantage of the formalism over other formulations of quantum mechanics because intuitive arguments are available on solving separate problems in quantum mechanics. The path integral formalism is particularly useful when a physics in a semiclassical regime is considered. In quantum mechanics, dynamical variables are usually quantized and can be mutually incommutable. On the other hand, in the classical mechanics, they are continuous and are mutually commutable. The path integral formalism fully exploits these properties of the classical mechanics. A typical example is the coherent state path integral formalism[2,3] for the quantum spin system.[4]

Meanwhile, the motion of a single electron in a crystal lattice is successfully treated by the single band model,[5] in which the relevant Hilbert space is restricted to the subspace associated with a particular band. We may call such an electron a Bloch particle (electron).[6] We shall consider, for simplicity, the one-dimensional (1D) Bloch particle. On account of the restricted Hilbert space, the position and the momentum of the Bloch particle have important differences from those of the conventional particle: (i) the position is quantized in unit of the lattice spacing a and (ii) the momentum is not a true momentum but a quasimomentum which has a periodicity with the period $2\pi\hbar/a$. The two points, (i) and (ii), are closely related to each other because the position and the quasimomentum are canonically conjugate to each other. They prevent us from directly applying the path integral formalism for the conventional particle to quantum mechanics of the Bloch particle. If there ever exists a consistent path integral formalism for the Bloch particle, the position of the Bloch particle must be treated as a continuous variable in the formulation.

The purpose of this paper is to present a coherent state path integral formalism for the Bloch particle. The theory will be applied to the transition amplitude of the coherent state of the Bloch particle under a uniform electric field, and famous Bloch oscillations[6,7] will be reproduced.

The paper is organized as follows. In Sec. II we construct the coherent state for the Bloch particle. This is given in the Wannier representation. In Sec. III we compute matrix elements of the

a)Electronic mail: shibata@acty.phys.sci.osaka-u.ac.jp

kinetic energy and the potential energy for the coherent states by use of the Poisson summation formula. In Sec. IV we construct the coherent state path integral formalism for the Bloch particle. In Sec. V, we evaluate the transition amplitude for the Bloch particle under a uniform electric field on the basis of the stationary-action approximation. In Sec. VI we conclude this paper with a summary and a discussion.

II. COHERENT STATE OF BLOCH PARTICLE

The Wannier states, $|n\rangle, n \in \mathbf{Z}$, form an orthonormal complete set of the Hilbert space of the Bloch particle:

$$\sum_{n=-\infty}^{\infty} |n\rangle\langle n| = 1. \tag{1}$$

The position operator, $\hat{x}$, is diagonal in the Wannier representation:

$$\hat{x} = \sum_{n=-\infty}^{\infty} |n\rangle x_n \langle n|, \quad x_n := na, \tag{2}$$

while the translation operator is off-diagonal:

$$\hat{T} = \sum_{n=-\infty}^{\infty} |n+1\rangle\langle n|, \tag{3}$$

or, equivalently, $\hat{T}|n\rangle = |n+1\rangle$. Then, $\hat{x}$ and $\hat{T}$ satisfy the commutation:

$$[\hat{x}, \hat{T}] = a\hat{T}, \tag{4}$$

in which the quantization of $\hat{x}$ is built in. The quasimomentum operator $\hat{p}$ is ill-defined but is related to the well-defined operator $\hat{T}$ by

$$\hat{T} = \exp\left(-\frac{i}{\hbar} a\hat{p}\right). \tag{5}$$

The translation operator $\hat{T}$, which is unitary, is diagonal in the Bloch representation which is based on the Bloch state (the momentum state), $|p\rangle$. That is,

$$\hat{T}|p\rangle = \exp\left(-\frac{i}{\hbar} ap\right)|p\rangle. \tag{6}$$

The Bloch state is specified by its wave function, $\langle n|p\rangle = \sqrt{a/(2\pi\hbar)}\exp(inap/\hbar)$. It is periodic: $|p + 2\pi\hbar/a\rangle = |p\rangle$, so that p is a variable on a circle (or, equivalently, the Brillouin zone) whose radius is equal to $\hbar/a$. It is unnormalizable but two different Bloch states are mutually orthogonal. The completeness of Bloch states is represented as

$$\int_{\mathrm{Bz}} \mathrm{d}p\, |p\rangle\langle p| = 1, \tag{7}$$

where the symbol Bz stands for the Brillouin zone.

It is convenient to introduce the angular variable, $\phi := ap/\hbar$, which is the dimensionless quasimomentum. It is a variable on the unit circle, S^1. Its operator version, $\hat{\phi}$, is related to $\hat{T}$ by

$$\hat{T} = \exp(-i\hat{\phi}). \tag{8}$$

Since ϕ has a different scale from that of p, we shall change the normalization for $|p\rangle$ to obtain $|\phi\rangle := \sqrt{\hbar/a}\,|p\rangle$ or, equivalently, $\langle n|\phi\rangle = \exp(in\phi)/\sqrt{2\pi}$. Hence, we may write

$$|\phi\rangle = \frac{1}{\sqrt{2\pi}} \sum_{n=-\infty}^{\infty} e^{in\phi}|n\rangle, \tag{9}$$

$$\oint \mathrm{d}\phi\, |\phi\rangle\langle\phi| = 1. \tag{10}$$

Our path integral formalism for the Bloch particle will be established through an extension of the coherent state path integral formalism for the conventional particle.[3] In the latter formalism, we use coherent states, in each of which the position and the momentum are specified within the restriction imposed by the Heisenberg uncertainty principle. Therefore, the coherent state is a minimal packet and is an eigenstate of the non-Hermitian operator: $\hat{z} := \kappa\hat{x} + i\lambda\hat{p}$, where κ and λ are positive parameters characterizing the coherent state. Since $[\hat{z},\hat{z}^\dagger] = \kappa\lambda/2$, $\hat{z}$ is an unnormalized annihilation operator of a harmonic oscillator, and we assume that κ and λ are chosen so that $\hat{z}$ is dimensionless. Different coherent states are different eigenstates: $\hat{z}|z\rangle = z|z\rangle$, where $z := \kappa x + i\lambda p$ is a complex parameter specifying the coherent state. The position and the momentum of the coherent state are not sharply defined but their mean values are given by x and p, respectively, while their spreads by

$$\delta x = \sqrt{\frac{\hbar\lambda}{2\kappa}}, \quad \delta p = \sqrt{\frac{\hbar\kappa}{2\lambda}}, \tag{11}$$

which satisfy $\delta x\,\delta p = \hbar/2$. Note that the ratio κ/λ is more important than the two separate parameters themselves. The complex z plane is isomorphic to the two-dimensional phase space (x,p), and z can be treated as a complex dynamical variable in the coherent state path integral formalism.

We shall return to the case of the Bloch particle. A drawback for the case is that $\hat{p}$ is ill defined. To circumvent it, we set $\lambda = a/\hbar$ and introduce a new non-Hermitian operator by the formal equation, $\hat{A} := \exp(-\hat{z})$, which is well defined because

$$\hat{z} = \kappa\hat{x} + i\hat{\phi}. \tag{12}$$

The formal expression for $\hat{A}$ can be transformed with a standard procedure of the operator algebra into the exact one:

$$\hat{A} = \exp\left[-\kappa\left(\hat{x} - \frac{a}{2}\right)\right]\hat{T}. \tag{13}$$

The coherent state, $|z\rangle$, of the Bloch particle is an eigenstate of $\hat{A}$:

$$\hat{A}|z\rangle = e^{-z}|z\rangle, \quad z := \kappa x + i\phi. \tag{14}$$

It is of a vital importance in a later argument that the phase space for the complex dynamical variable z is the cylinder $\Gamma := \mathbf{R}\otimes S^1$ or, equivalently, the fundamental strip, $\Sigma := -\pi < \Im z \leqslant \pi$, on the complex z plane. Remember that Γ as well as S^1 is not simply connected.

If the coherent state is normalized appropriately, it is given in the Wannier representation as

$$|z\rangle = \sum_{n=-\infty}^{\infty} C_n(z)|n\rangle, \tag{15}$$

$$C_n(z) := \langle n|z\rangle = N\exp\left[-\frac{\kappa}{2a}(x_n - x)^2 + in\phi\right], \quad N = \left(\frac{\kappa a}{\pi}\right)^{1/4}. \tag{16}$$

Thus, the coherent state is of a wave packet, whose spread is equal to $\delta x := \sqrt{a/(2\kappa)}$.

The Bloch representation for the coherent state is readily obtained from this equation together with (9):

$$\langle \phi' | z \rangle = \sum_{n=-\infty}^{\infty} \frac{N}{\sqrt{2\pi}} \exp\left[-\frac{\kappa}{2a}(x_n - x)^2 + in(\phi - \phi') \right], \tag{17}$$

which can be rewritten with the Poisson summation formula into

$$\langle \phi' | z \rangle = \sum_{m=-\infty}^{\infty} N' \exp\left[-\frac{1}{2\kappa a}(\phi' - \phi_m)^2 - i\frac{x}{a}(\phi' - \phi_m) \right], \quad N' := (\pi\kappa a)^{-1/4} \tag{18}$$

with $\phi_m := \phi + 2\pi m$, where m is an integral variable to be called the *winding number*. The coherent state has a form of a wave packet in the momentum space as well, and its spread is equal to $\delta\phi := \sqrt{\kappa a/2}$, which is consistently related to δx by the Heisenberg uncertainty equality.

Although the left-hand side of (18) is periodic on the variable ϕ', each summand on the rhs (right-hand side) is not. Hence, the variable ϕ' should be regarded in the rhs as a variable on $\mathbf{R}$, which is simply connected and is the universally covering space for S^1. A similar situation will be realized in other infinite series of periodic functions to appear.

The inner product between different coherent states can be calculated in the Wannier representation as

$$\langle z | z' \rangle = N^2 \sum_{n=-\infty}^{\infty} \exp\left[-\kappa a n^2 + n(z^* + z') - \frac{\kappa}{2a}(x^2 + x'^2) \right], \tag{19}$$

which is transformed with the Poisson summation formula into

$$\langle z | z' \rangle = \sum_{m=-\infty}^{\infty} \exp\left[\frac{i}{\hbar}\mathcal{S}_c(z, z'_m) \right], \quad z'_m := z' + 2\pi m, \tag{20}$$

where

$$\frac{i}{\hbar}\mathcal{S}_c(\zeta, \zeta') = \frac{1}{8\kappa a}[2(\zeta^* + \zeta')^2 - (\zeta^* + \zeta)^2 - (\zeta'^* + \zeta')^2]. \tag{21}$$

Note that $\mathcal{S}_c(z, z'_m)$ depends on m because $\mathcal{S}_c(z, \zeta)$ is periodic on neither of the two variables. In particular, we obtain

$$\langle z | z \rangle = \sum_{m=-\infty}^{\infty} \exp\left[-\frac{\pi^2}{\kappa a} m^2 + i\frac{\pi x}{a} m \right] \tag{22}$$

$$= \vartheta_3\left(\frac{\pi x}{2a} \middle| \frac{i\pi}{\kappa a} \right), \tag{23}$$

where $\vartheta_3(z|\tau)$ is the θ-function[8] defined by

$$\vartheta_3(z|\tau) := \sum_{n=-\infty}^{\infty} e^{in^2\pi\tau + i2\pi nz}, \quad \Im\tau > 0. \tag{24}$$

Hence, the coherent state $|z\rangle$ is not normalized to unity. In fact, the right-hand sides of (17)–(20) are all represented with the third θ-function, ϑ_3, but with different arguments. The transformation combining the two expressions for $\langle\phi'|z\rangle$ or $\langle z|z'\rangle$ is the famous Jacobi's imaginary-number transformation for the θ-function.

We can consider $C_n^*(z)=\langle z|n\rangle$ to be the wave function of the Wannier state $|n\rangle$ in the coherent-state representation. The wave functions of Wannier states are orthonormal in the sense represented as

$$\int C_n(z)C_{n'}^*(z)\mathrm{d}\mu(z)=\delta_{n,n'}, \quad \mathrm{d}\mu(z):=\frac{\mathrm{d}x\,\mathrm{d}\phi}{2\pi a}, \tag{25}$$

where the integral must be performed over the entire phase space. The coherent states form an overcomplete set but we can derive from this result the following resolution of unit:

$$\int \mathrm{d}\mu(z)\,|z\rangle\langle z|=1. \tag{26}$$

This is a basic result for the construction of the coherent state path integral formalism.

The above-presented discussions show that the coherent state of the Bloch particle has similar properties to those of the coherent state of the conventional particle. The former coherent state tends asymptotically to the latter in the quasicontinuous limit, $a\kappa\ll 1$, where the spread of the packet in the real space is much larger than a, the lattice spacing.

It is important in a later discussion that, for a given ϕ', the summation on the rhs of (18) is dominated by a single term if $a\kappa\ll 1$, so that the interference among terms with different winding numbers vanishes then. Before closing this section, we should add a few articles on other representations for the state of the Bloch particle. The one is the "kq-representation" by Zak.[9] The other one is the "Gaussian representation" by Zeiner *et al.*[10]

III. MATRIX ELEMENTS

In order to construct the coherent state path integral formalism, we need to compute the matrix elements of the Hamiltonian, $\hat{H}$, for the coherent states. We assume that $\hat{H}$ is written as

$$\hat{H}=\hat{\mathcal{V}}+\hat{\mathcal{G}}, \tag{27}$$

where $\hat{\mathcal{V}}$ and $\hat{\mathcal{G}}$ are the kinetic energy and the potential energy, respectively, and are commutable with $\hat{T}$ and $\hat{x}$, respectively.

We begin our calculation with $\hat{\mathcal{G}}$. We assume it to be represented with an analytic function $g(\zeta)$ as $\hat{\mathcal{G}}=g(\hat{x})$. Its matrix element for coherent states is calculated in the Wannier representation as

$$\langle z|\hat{\mathcal{G}}|z'\rangle=N^2\sum_{n=-\infty}^{\infty} g(na)\exp\left[-\kappa a n^2+n(z^*+z')-\frac{\kappa}{2a}(x^2+x'^2)\right], \tag{28}$$

which is transformed by use of the Poisson summation formula into

$$\langle z|\hat{\mathcal{G}}|z'\rangle=\sum_{m=-\infty}^{\infty} \exp\left[\frac{i}{\hbar}\mathcal{S}_c(z,z'_m)\right]G(z^*,z'_m), \tag{29}$$

where

$$G(\zeta,\zeta')=\left(\frac{\kappa a}{\pi}\right)^{1/2}\int_{-\infty}^{\infty}\mathrm{d}t\,e^{-\kappa t^2/a}g\left(t+\frac{\zeta+\zeta'}{2\kappa}\right). \tag{30}$$

Meanwhile, the Bloch state $|\phi\rangle$ is an eigenstate of $\hat{\mathcal{V}}$, which is commutable with $\hat{T}$. The eigenvalue $W(\phi)$ is a periodic function: $W(\phi+2\pi)=W(\phi)$. Let us write the Fourier expansion of $W(\phi)$ as

$$W(\phi)=\sum_{l=-\infty}^{\infty} V_l e^{-il\phi}, \quad V_{-l}=V_l^* . \tag{31}$$

If the potential term is absent, the eigen-energy is specified by ϕ as $E=W(\phi)$, which is nothing but the dispersion relation for the Bloch particle. A simplest expression for $W(\phi)$ is

$$W(\phi)=-V\cos\phi. \tag{32}$$

The relevant bandwidth is $2V$ provided that $V>0$.

For (31), we obtain

$$\hat{\mathcal{V}}=\sum_{l=-\infty}^{\infty} V_l \hat{T}^l. \tag{33}$$

The matrix elements of $\hat{T}^l$ for coherent states can be calculated by a similar procedure to the one for $\hat{\mathcal{G}}$:

$$\begin{aligned}\langle z|\hat{T}^l|z'\rangle &= N^2 \sum_{n=-\infty}^{\infty} \exp\left[-\kappa a n^2+n(z^*+z'+l\kappa a)-lz'-\frac{\kappa}{2a}(x^2+x'^2)-\frac{\kappa a}{2}l^2\right] \\ &= \sum_{m=-\infty}^{\infty} \exp\left[\frac{i}{\hbar}\mathcal{S}_c(z,z'_m)+\frac{l}{2}(z^*-z'_m)-\frac{\kappa a}{4}l^2\right].\end{aligned} \tag{34}$$

Thus,

$$\langle z|\hat{\mathcal{V}}|z'\rangle=\sum_{m=-\infty}^{\infty} \exp\left[\frac{i}{\hbar}\mathcal{S}_c(z,z'_m)\right]W(z^*,z'_m), \tag{35}$$

where

$$W(\zeta,\zeta')=\sum_{m=-\infty}^{\infty} e^{-\kappa a l^2/4}V_l e^{l(\zeta-\zeta')/2}. \tag{36}$$

From (27), (29), and (35), we obtain

$$\langle z|\hat{\mathcal{H}}|z'\rangle=\sum_{l=-\infty}^{\infty} \exp\left[\frac{i}{\hbar}\mathcal{S}_c(z,z'_m)\right]H(z^*,z'_m) \tag{37}$$

with

$$H(\zeta,\zeta'):=W(\zeta,\zeta')+G(\zeta,\zeta'). \tag{38}$$

IV. COHERENT STATE PATH INTEGRAL FORMALISM

Now, we can construct a coherent state path integral formalism for the Bloch particle. We write the transition amplitude between the initial state $|z_I\rangle$ and the final state $|z_F\rangle$ as

$$\mathcal{K}(z_F,z_I;T):=\langle z_F|\exp(-iT\hat{H}/\hbar)|z_I\rangle. \tag{39}$$

We slice the time interval into N identical pieces of length $\epsilon := T/N$, and write $\exp(-iT\hat{H}/\hbar) = [\exp(-i\hat{H}\epsilon/\hbar)]^N$. Inserting the resolution of unit, (26), into the relevant site associated with each discrete time yields

$$\mathcal{K}(z_F, z_I; T) = \lim_{N\to\infty} \int \prod_{j=1}^{N-1} \mathrm{d}\mu(z_j) \prod_{j=1}^{N} \langle z_j | e^{-i\epsilon\hat{H}/\hbar} | z_{j-1} \rangle \tag{40}$$

with $z_0 := z_I$ and $z_N := z_F$. The transition amplitude $\langle z|\exp(-i\epsilon\hat{H}/\hbar)|z'\rangle$ can be rewritten to the order ϵ as

$$\begin{aligned} \langle z | e^{-i\epsilon\hat{H}/\hbar} | z' \rangle &\simeq \langle z | (1 - i\epsilon\hat{H}/\hbar) | z' \rangle \\ &= \langle z | z' \rangle - \frac{i\epsilon}{\hbar} \langle z | \hat{H} | z' \rangle. \end{aligned} \tag{41}$$

Using (20) and (37), we can rewrite this equality to the order ϵ as

$$\langle z | e^{-i\epsilon\hat{H}/\hbar} | z' \rangle \simeq \sum_{m=-\infty}^{\infty} \exp\left[\frac{i}{\hbar} \mathcal{S}(z, z'_m) \right], \tag{42}$$

with

$$\mathcal{S}(\zeta, \zeta') := \mathcal{S}_c(\zeta, \zeta') - \epsilon H(\zeta, \zeta'). \tag{43}$$

Using (42), we can change (40) to obtain

$$\mathcal{K}(z_F, z_I; T) = \lim_{N\to\infty} \int \prod_{j=1}^{N-1} \mathrm{d}\mu(z_j) \prod_{j=1}^{N} \sum_{m_j=-\infty}^{\infty} \exp\left[\frac{i}{\hbar} \mathcal{S}(z_j, z_{j-1} + 2\pi i m_j) \right]. \tag{44}$$

Since $H(\zeta, \zeta')$ is composed of two terms, $W(\zeta, \zeta')$ and $G(\zeta, \zeta')$, $\mathcal{S}(\zeta, \zeta')$ has three terms. From (21), (30), and (36), we see that $\mathcal{S}(z_j, z_{j-1} + 2\pi i m_j)$ depends on m_j through the two forms:

$$z_j^* + z_{j-1} + 2\pi i m_j, \quad z_j^* - z_{j-1} - 2\pi i m_j. \tag{45}$$

We can rewrite (44) into a more convenient form if we employ a procedure in a textbook,[4] in which the authors discuss the Feynman kernel in a periodic system. We begin with changing the integer variables, m_j's, into others, m'_j's, by

$$m_j = m'_j - m'_{j-1}, \quad m'_0 = 0, \quad j = 1,2,\ldots,N. \tag{46}$$

Then, the sum on m_j's is transformed to that on m'_j's. We next change ϕ_j into

$$\phi_j = \phi'_j + 2\pi m'_j, \quad j = 1,2,\ldots,N-1. \tag{47}$$

Then, two quantities in (45) are transformed to

$$z_j'^* + z'_{j-1}, \quad z_j'^* - z'_{j-1} - 4\pi i m'_j, \tag{48}$$

respectively, where $z'_j := \kappa x_j + i\phi'_j$. Since z_j is a variable on the fundamental strip Σ, z'_j is a variable on the shifted strip, $\Sigma - 2\pi i m'_j$. From the considerations made up to this point, we can conclude that the integration on ϕ_j's in (44) is transformed as

$$\prod_{j=1}^{N}\sum_{m_j=-\infty}^{\infty}\prod_{j=1}^{N-1}\int_{-\pi}^{\pi}\mathrm{d}\phi_j=\sum_{m'_N=-\infty}^{\infty}\prod_{j=1}^{N-1}\int_{-\infty}^{\infty}\mathrm{d}\phi'_j\,, \tag{49}$$

where the quantity $\mathcal{S}(z_j,z_{j-1}+2\pi i m_j)$ included in the summand of (44) must be replaced simultaneously by $\mathcal{S}(z'_j,z'_{j-1})$. Note that the term $-4\pi i m'_j$ in the second quantity of (48) does not effect the summand because of the form of (36). Thus, we arrive at the final expression for the transition amplitude:

$$\mathcal{K}(z_F,z_I;T):=\sum_{m=-\infty}^{\infty}\mathcal{L}(z_F^m,z_I;T),\quad z_F^m:=z_F+i2\pi m \tag{50}$$

with

$$\mathcal{L}(z_F^m,z_I;T)=\lim_{N\to\infty}\prod_{j=1}^{N-1}\int_{-\infty}^{\infty}\int_{-\infty}^{\infty}\frac{\mathrm{d}x_j}{a}\frac{\mathrm{d}\phi_j}{2\pi}\exp\left(\frac{i}{\hbar}\mathcal{S}[\mathbf{z}^*,\mathbf{z}]\right), \tag{51}$$

where the action $\mathcal{S}[\mathbf{z}^*,\mathbf{z}]$ is a ''functional'' of the path $\mathbf{z}:=(z_0,z_1,\ldots,z_N)$ with $z_N:=z_F^m$, and is given by

$$\mathcal{S}[\mathbf{z}^*,\mathbf{z}]=\sum_{j=1}^{N}\mathcal{S}(z_j,z_{j-1}). \tag{52}$$

It is important to notice here that the phase space for the path $\mathbf{z}$ is the complex plane $\mathbf{C}$, which is the universally covering space for the cylinder Γ. The transition amplitude has been represented as a sum of transition amplitudes each of which is associated with the final state $z_F^m=z_F+i2\pi m$ with a specified m. Note that $z_F^m=\kappa x_F+i\phi_F^m$ with $\phi_F^m:=\phi_F+2\pi m$. Although $|z_F^m\rangle$ and $|z_F\rangle$ are an identical state of the Bloch particle, one needs to distinguish them and sum over the relevant paths in the path integral formula. This is derived from the fact that Γ is not simply connected.[11]

We shall rewrite the expression for $\mathcal{S}[\mathbf{z}^*,\mathbf{z}]$ into a more tractable form. It is composed of the canonical term and the dynamical term:

$$\mathcal{S}[\mathbf{z}^*,\mathbf{z}]=\mathcal{S}_c[\mathbf{z}^*,\mathbf{z}]+\mathcal{S}_d[\mathbf{z}^*,\mathbf{z}], \tag{53}$$

$$\mathcal{S}_c[\mathbf{z}^*,\mathbf{z}]:=\sum_{j=1}^{N}\mathcal{S}_c(z_j,z_{j-1}), \tag{54}$$

$$\mathcal{S}_d[\mathbf{z}^*,\mathbf{z}]:=-\sum_{j=1}^{N}\epsilon H(z_j,z_{j-1}). \tag{55}$$

We introduce here a new quantity by

$$\frac{i}{\hbar}\mathcal{S}_c(z_j,z_{j-1})=P(z_j)-P(z_{j-1})+\frac{i}{\hbar}\tilde{\mathcal{S}}_c(z_j,z_{j-1}) \tag{56}$$

with

$$P(z):=\frac{1}{8\kappa a}\{(z^*)^2-z^2\}. \tag{57}$$

Then, we may write

$$\frac{i}{\hbar}\mathcal{S}_c[\mathbf{z}^*,\mathbf{z}]=P(z_F^m)-P(z_I)+\frac{i}{\hbar}\tilde{\mathcal{S}}_c[\mathbf{z}^*,\mathbf{z}], \tag{58}$$

$$\frac{i}{\hbar}\tilde{\mathcal{S}}_c[\mathbf{z}^*,\mathbf{z}]:=\sum_{j=1}^{N}\left(-\frac{1}{4\kappa a}\right)\{z_j^*(z_j-z_{j-1})-(z_j^*-z_{j-1}^*)z_{j-1}\}, \tag{59}$$

where the summand is just an explicit form for $(i/\hbar)\tilde{\mathcal{S}}_c(z_j,z_{j-1})$. The first two terms on the rhs of (58) are purely imaginary, so that they may be called gauge terms because they give rise to a phase factor of (51). The phase factors affect the interference among different terms in (50).

Equation (59) reduces in the continuum-time limit to the functional:

$$\frac{i}{\hbar}\tilde{\mathcal{S}}_c[z^*,z]=-\frac{1}{4\kappa a}\int_0^T \mathrm{d}t\left\{z^*(t)\frac{\mathrm{d}z(t)}{\mathrm{d}t}-\frac{\mathrm{d}z^*(t)}{\mathrm{d}t}z(t)\right\}. \tag{60}$$

However, we should emphasize the necessity of the discrete-time formalism of the coherent state path integral in order to obtain a correct result for the transition amplitude.[12] Thus, Eq. (60) is usable only for the evaluation of the stationary action. We should mention, finally, that the discrete-time formalism of the coherent state path integral can be consistently formulated because $\tilde{\mathcal{S}}_c[\mathbf{z}^*,\mathbf{z}]$ and $\mathcal{S}_d[\mathbf{z}^*,\mathbf{z}]$ are holonomic functions of two sets of complex variables $\mathbf{z}$ and $\mathbf{z}^*$, where the two sets are regarded to be independent variables.[12]

V. APPLICATION TO THE BLOCH OSCILLATION

As an application of the present formalism, we consider the time evolution of the coherent state of the Bloch particle under a uniform electric field F. As a consequence of the boundedness of the energy band, the Bloch particle exhibits the so-called Bloch oscillation.[6,7] If the simplest dispersion (32) is adopted, the Hamiltonian assumes

$$\hat{H}=-V\cos\hat{\phi}-F\hat{x}, \tag{61}$$

whose matrix element is

$$H(z_j^*,z_{j-1})=-Ve^{-\kappa a/4}\cosh\left(\frac{z_j^*-z_{j-1}}{2}\right)-\frac{F}{2\kappa}(z_j^*+z_{j-1}). \tag{62}$$

To evaluate the transition amplitude, we employ the stationary-action approximation, which is justified for a semiclassical motion.

We consider here the classical motion of the Bloch particle. The equation of motion is

$$\frac{\mathrm{d}x}{\mathrm{d}t}=\frac{aV}{\hbar}\sin\phi, \tag{63}$$

$$\frac{\mathrm{d}\phi}{\mathrm{d}t}=\omega \tag{64}$$

with

$$\omega:=\frac{Fa}{\hbar}. \tag{65}$$

The solution for the initial condition, $x(0)=x_I$ and $\phi(0)=\phi_I$, is given by

$$x=x_{\mathrm{cl}}(t):=x_I+L_{\mathrm{cl}}[\cos\phi_I-\cos(\omega t+\phi_I)], \tag{66}$$

$$\phi = \phi_{\rm cl}(t) := \phi_I + \omega t, \tag{67}$$

where $L_{\rm cl} := V/F$ is the so-called localization length. This solution shows the Bloch oscillation with the angular frequency ω.

Thus, the condition for the motion to be semiclassical is given by $L_{\rm cl} \gg \delta x \simeq \sqrt{a/\kappa} \gg a$.

A. Stationary action

The primary task is to find the stationary point, namely, stationary action path of the action $\mathcal{S}[\mathbf{z}^*,\mathbf{z}]$ or, equivalently, $\tilde{\mathcal{S}}[\mathbf{z}^*,\mathbf{z}]$. We will execute it by a similar procedure to the one presented in Ref. 10. The equation of motion for the stationary action path is obtained by differentiating the action:

$$\left.\frac{\partial \tilde{\mathcal{S}}[\mathbf{z}^*,\mathbf{z}]}{\partial z_j^*}\right|_s = \left.\frac{\partial \tilde{\mathcal{S}}[\mathbf{z}^*,\mathbf{z}]}{\partial z_j}\right|_s = 0, \quad j = 1,2,\ldots,N-1. \tag{68}$$

For the stationary action path $\{\mathbf{z}^s,\overline{\mathbf{z}^s}\}$, we are allowed to take the continuous-time limit,[12] so that

$$\frac{{\rm d}z^s(t)}{{\rm d}t} = i\omega + i\Omega \sinh\left(\frac{\overline{z}^s(t) - z^s(t)}{2}\right), \tag{69}$$

$$\frac{{\rm d}\overline{z}^s(t)}{{\rm d}t} = -i\omega + i\Omega \sinh\left(\frac{\overline{z}^s(t) - z^s(t)}{2}\right) \tag{70}$$

with

$$\omega := \frac{Fa}{\hbar}, \quad \Omega := \frac{\kappa a}{\hbar} V e^{-\kappa a/4}. \tag{71}$$

These equations must be solved under the following boundary conditions:[12]

$$z^s(0) = z_I, \quad \overline{z}^s(T) = z_F^m{}^*. \tag{72}$$

It should be noted that $z^s(t)$ and $\overline{z}^s(t)$ are not necessary complex conjugate to each other.[12]

From (70) we obtain

$$\tfrac{1}{2}(z^s(t) - \overline{z}^s(t)) = i(\omega t + \phi_0), \tag{73}$$

where ϕ_0 is a complex constant. Inserting this into the rhs of (70), we can solve for $z^s(t)$ and $\overline{z}^s(t)$ to obtain

$$z^s(t) = z^s(t,\phi_0) := z_I + i\omega t - \frac{\Omega}{\omega}[\cos(\omega t + \phi_0) - \cos\phi_0], \tag{74}$$

$$\overline{z}^s(t) = \overline{z}^s(t,\phi_0) := z_F^m{}^* - i\omega(t-T) - \frac{\Omega}{\omega}[\cos(\omega t + \phi_0) - \cos(\omega T + \phi_0)], \tag{75}$$

where the integration constants are fixed by the boundary conditions (72). This solution is consistent to (73) only if ϕ_0 satisfies

$$D(\phi_0) := z_F^m{}^* - z^s(T,\phi_0) + 2i(\omega T + \phi_0) = 0, \tag{76}$$

where use has been made of $\overline{z}^s(T,\phi_0) = z_F^m{}^*$.

The following two quantities are introduced here for a convenience of later arguments:

$$\tilde{\Omega}(t) := \frac{\Omega}{2}\cos(\omega t + \phi_0), \tag{77}$$

$$Z(t,\phi_0) := \int_0^t dt' \tilde{\Omega}(t') = \frac{\Omega}{2\omega}[\sin(\omega t + \phi_0) - \sin\phi_0]. \tag{78}$$

Alternatively, we may write

$$Z(t,\phi_0) = \frac{1}{2}\frac{\partial z^s(t,\phi_0)}{\partial \phi_0}. \tag{79}$$

The stationary action, $\mathcal{S}_m^s := \mathcal{S}[\overline{\mathbf{z}}^s, \mathbf{z}^s]$, can be obtained by substituting (74) and (75) into the action (53) with (55), (58), and (60):

$$\frac{i}{\hbar}\mathcal{S}_m^s = -\frac{i}{2a}\{x_F\phi_F^m - x_I\phi_I\} - \frac{1}{4\kappa a}\Bigg[|z_F^m|^2 + |z_I|^2 - 2z_F^{m*}z_I - (z_F^{m*} - z_I + i\omega T + 2i\phi_0)^2$$
$$- 2i\omega T\left(z_F^{m*} + z_I + i\frac{\omega T}{2}\right) - 8iZ(T,\phi_0)\Bigg]. \tag{80}$$

B. Semiclassical stationary action

Let $z_{sc}(t) := z^s(t,\phi_I)$. Then $z(t) := z_{sc}(t)$ and $\overline{z}(t) := z_{sc}^*(t)$ satisfy the equation of motion (70) with the initial condition, $z(0) = z_I$ and $\overline{z}(0) = z_I^*$. More explicitly,

$$z_{sc}(t) = \kappa x_{sc}(t) + i\phi_{sc}(t), \tag{81}$$

$$x_{sc}(t) = x_I + L[\cos\phi_I - \cos(\omega t + \phi_I)], \tag{82}$$

$$\phi_{sc}(t) = \phi_I + \omega t \tag{83}$$

with

$$L := \frac{\Omega}{\omega\kappa} = \frac{V}{F}e^{-\kappa a/4}. \tag{84}$$

The solution (81) is the semiclassical solution, which tends to the classical solution (67) in the limit $\kappa a \to 0$ because $L = L_{cl}\exp(-\kappa a/4)$.

Let $\Delta z := z_F^m - z_{sc}(T)$. Then

$$\Delta z = \kappa\Delta x + i\Delta\phi, \tag{85}$$

$$\Delta x = x_F - x_{sc}(T), \tag{86}$$

$$\Delta\phi = \phi_F^m - \phi_{sc}(T). \tag{87}$$

The condition for the semiclassical solution to satisfy the boundary conditions (72) is given by $\Delta z = 0$ for an integer m. If this condition is satisfied, the solution of Eq. (76) is given by $\phi_0 = \phi_I$.

It will be shown later on that under the semiclassical condition, we can assume $|\Delta z|^2 = (\kappa\Delta x)^2 + (\Delta\phi)^2 \ll 1$. Then, we are allowed to solve Eq. (76) for ϕ_0 to the first order on Δz. We set $\phi_0 := \phi_I + \delta\phi$, and expand $D(\phi_0)$ to the first order on $\delta\phi$ to obtain

$$D(\phi_0) \simeq \Delta z^* + 2(i - Z(T,\phi_I))\,\delta\phi, \tag{88}$$

where use has been made of $D(\phi_I)=\Delta z^*$ and (79). Therefore, we obtain

$$\phi_0 \simeq \phi_I + \frac{i\Delta z^*}{2\{1+iZ(T,\phi_I)\}}. \tag{89}$$

In the similar way, let $\tilde{z}_{sc}(t) := z^s(t-T,\phi_F^m)$ and $\Delta\tilde{z} := \Delta\tilde{z}_{sc}(0)-z_I$. Then, under the semiclassical condition, $|\Delta\tilde{z}|^2 \ll 1$, we can obtain the correspondence with $\delta\phi$ as

$$\delta\tilde{\phi} := \frac{i\Delta\tilde{z}}{2\{1+iZ(T,\phi_F^m-\omega T)\}}. \tag{90}$$

We should remark here that the following equality holds to the zeroth order on $\Delta\phi$:

$$Z(T,\phi_I) \simeq Z(T,\phi_F^m-\omega T) \simeq \frac{\Omega}{\omega}\cos\left(\frac{\phi_F^m+\phi_I}{2}\right)\sin\frac{\omega T}{2} =: C(T), \tag{91}$$

which is symmetrical with respect to ϕ_I and ϕ_F^m. Hence, we set

$$\phi_0 = \frac{\phi_F^m+\phi_I-\omega T}{2} + \frac{i\kappa\Delta\overline{x}}{2\{1+iC(T)\}}, \tag{92}$$

$$\Delta\overline{x} := x_F - x_I + L\left[\cos\left(\frac{\phi_F^m+\phi_I+\omega T}{2}\right) - \cos\left(\frac{\phi_F^m+\phi_I-\omega T}{2}\right)\right], \tag{93}$$

and substituting (92) into (80) and (105), we find the following semiclassical stationary action:

$$\frac{i}{\hbar}\mathcal{S}_m^s = -\frac{\kappa}{4a}\frac{(\Delta\overline{x})^2}{1+iC(T)} - \frac{1}{4\kappa a}(\Delta\phi)^2 - \frac{i}{2a}(x_F+x_I)\Delta\phi + \frac{2i}{\kappa a}C(T). \tag{94}$$

C. Fluctuation

We introduce the fluctuation variables through

$$z_j = z_j^s + \zeta_j, \quad z_j^* = \overline{z_j^s} + \zeta_j^*, \quad j=1,2,\ldots,N-1. \tag{95}$$

Substituting (95) into the action $\mathcal{S}[\overline{\mathbf{z}},\mathbf{z}]$, and expanding the result up to the second order in the fluctuation, we obtain

$$\mathcal{S}[\overline{\mathbf{z}^s}+\zeta^*,\mathbf{z}^s+\zeta] \simeq \mathcal{S}_m^s + \mathcal{S}_m^2[\zeta^*,\zeta], \tag{96}$$

where $\mathcal{S}_m^2[\zeta^*,\zeta]$ is a quadratic form on the fluctuation variables. Therefore, the contribution of the fluctuation to the action is represented as a factor of

$$\mathcal{F}_m(T) := \lim_{N\to\infty}\int_{-\infty}^{\infty}\prod_{j=1}^{N-1}\frac{\mathrm{d}(\Re\zeta_j)\mathrm{d}(\Im\zeta_j)}{2\kappa a}\exp\left(\frac{i}{\hbar}\mathcal{S}_m^2[\zeta^*,\zeta]\right), \tag{97}$$

which is a multidimensional Gaussian integral. The leading contribution to $(i/\hbar)\mathcal{S}_m^2[\zeta^*,\zeta]$ is written as $-\Sigma_j\zeta_j^*\zeta_j/(2\kappa a)$, and the fluctuation of ζ is of the order $\sqrt{\kappa a}$, which is small when $\kappa a \ll 1$.

There exists a standard procedure to evaluate $\mathcal{F}_m(T)$.[13,14] To evaluate the Gaussian integral is reduced to a calculation of the determinant of a symmetric matrix associated with the quadratic form. Since the matrix is tridiagonal its determinant is given as the last term of coupled three-term recursion relations. In the limit of $\epsilon\to 0$, they reduce to a set of coupled first-order differential equations:

$$\frac{\mathrm{d}M(t)}{\mathrm{d}t} = -\tilde{\Omega}(t)M'(t), \tag{98}$$

$$\frac{\mathrm{d}M'(t)}{\mathrm{d}t} = -\tilde{\Omega}(t)\{M(t)+2iM'(t)\} \tag{99}$$

with the initial condition

$$M(0)=1, \tag{100}$$

$$M'(0)=0. \tag{101}$$

The differential equations are readily solved to obtain

$$M(t)=e^{-iZ(t)}[1+iZ(t)], \tag{102}$$

$$M'(t)=-Z(t)\,e^{-iZ(t)} \tag{103}$$

with $Z(t):=Z(t,\phi_0)$. Hence,

$$\mathcal{F}_m(T)=[M(T)]^{-1/2} \tag{104}$$

$$=\frac{e^{iC(T)/2}}{\sqrt{1+iC(T)}}, \tag{105}$$

where we have used the semiclassical expression, $C(T)\simeq Z(T,\phi_I)$.

D. Transition amplitude

The transition amplitude in the semiclassical approximation is given by

$$\mathcal{K}(z_F,z_I;T)\simeq\sum_{m=-\infty}^{\infty}\mathcal{L}^s(z_F^m,z_I;T), \tag{106}$$

$$\mathcal{L}^s(z_F^m,z_I;T):=\mathcal{F}_m(T)\,e^{iS^s_m/\hbar}, \tag{107}$$

$$\mathcal{F}_m(T)=\frac{1}{\sqrt{1+iC(T)}}. \tag{108}$$

It follows that

$$|\mathcal{L}^s(z_F^m,z_I;T)|^2=\frac{1}{\sqrt{1+(C(T))^2}}\exp\left[-\frac{\kappa}{2a}\frac{(\Delta\overline{x})^2}{1+(C(T))^2}-\frac{1}{2\kappa a}(\Delta\phi)^2\right] \tag{109}$$

or, equivalently,

$$|\mathcal{L}^s(z_F^m,z_I;T)|^2=\frac{1}{\sqrt{1+(C(T))^2}}\exp\left[-\frac{\kappa}{2a}\frac{(x_F-\overline{x}_{\mathrm{sc}}(T))^2}{1+(C(T))^2}-\frac{1}{2\kappa a}(\phi_F^m-\phi_{\mathrm{sc}}(T))^2\right], \tag{110}$$

$$\overline{x}_{\mathrm{sc}}(T):=x_I+2L\sin\left(\frac{\phi_F^m+\phi_I}{2}\right)\sin\frac{\omega T}{2}. \tag{111}$$

For given x_F and ϕ_F, the summation on the rhs of (106) is dominated by a single term because we have assumed that $a\kappa \ll 1$. Therefore, the interference among terms with different winding numbers vanishes then. Since $\phi_{sc}(T)$ changes linearly with T, the leading term in (106) changes discontinuously with T. It follows from (110) that, for a given initial condition (x_I, ϕ_I), the wave packet centroid in the extended phase space, $x_F - \phi_F$, exhibits the Bloch oscillations along the position axis. While, the time dependence of the spreads of the wave packet in the phase space is given by

$$\delta x(T) = \sqrt{\frac{2a}{\kappa}\{1 + (C(T))^2\}}, \quad \delta\phi = \sqrt{2\kappa a} \tag{112}$$

along the momentum and the position axes, respectively. The maximum value of $\delta x(T)$ is equal to $\sqrt{(2a/\kappa)\{1+(C(T))^2\}}$, so that our assumption $|\Delta z|^2 \ll 1$ has been justified under the semiclassical condition.

The expressions for $\delta x(0)$ and $\delta\phi$ are larger by the factor $\sqrt{2}$ than those for the relevant coherent states. This is because $\langle z_F^m | z_I \rangle$ is a sort of the convolution of the two coherent states. The time dependence of the spread of the wave packet along the position axis is periodic by (112) with (91). This breathing behavior is similar to the behavior of the squeezed state of the harmonic oscillator.[15]

Our solution remains correct in the zero-field limit, $F = 0$, where the Bloch particle exhibits a ballistic motion: $x_{sc}(T) = x_I + v_I T$, $\phi_{sc}(T) = \phi_I$, and $C(T) = (\Omega T/2)\cos\phi_I$ with $v_I := (aV/\hbar)\sin\phi_I$ being the group velocity. The spread of the wave packet, $\delta x(T)$, increases monotonously with T because of the dispersion of the phase velocity.

VI. SUMMARY AND DISCUSSION

We have succeeded in properly defining the coherent states for the Bloch particle. Using them, we have constructed a coherent state path integral formalism for the Bloch particle. The transition amplitude involves contribution from paths with different winding numbers associated with the quasimomentum. The theory has been successfully applied to the semiclassical motion of the Bloch particle under a uniform electric field, and the famous Bloch oscillation has been reproduced.

If one of two dynamical variables which are canonically conjugate to each other is continuous but periodic, the other is discrete and unbounded on both the positive and the negative sides of its value. The converse of this statement is also true. The second example in addition to the Bloch particle is the rigid rotator, where the rotation angle, ϕ, is continuous but the angular-momentum, L_z, is discrete. That is, the roles of the position and the momentum are reversed from the case of the Bloch particle. Therefore, the roles of the kinetic energy and the potential energy are reversed as well. The periodic potential energy $W(\phi)$ stands for the hindering potential, and can assume various forms depending on the physical condition for the rigid rotator. On the contrary, the kinetic energy is restricted to the form $(L_z)^2/(2I)$ with I being the moment of inertia. The third example is the order parameter of a mesoscopic superconductor or the BEC of an ultracold gas, where the phase of the order parameter, ϕ, is continuous but the number of the condensate, N, is discrete. Anyway, the coherent state path integral formalism established in the present paper can be applied to other systems than the Bloch particle.

It is our hope that the path integral formalism will help to achieve solving more complicated problems for the Bloch particle or other systems. In fact, the authors have found recently equivalence of the quantum dynamics of a domain wall in a quasi-one-dimensional mesoscopic ferromagnet to that of the Bloch particle. This subject is discussed in a separate paper.[16]

(Received 9 August 2001; accepted for publication 14 September 2001)

The Schrödinger operator with point interaction in one dimension has a U(2) family of self-adjoint extensions. We study the spectrum of the operator and show that (i) the spectrum is uniquely determined by the eigenvalues of the matrix $U \in \mathrm{U}(2)$ that characterizes the extension, and that (ii) the space of distinct spectra is given by the orbifold $T^2/\mathbb{Z}_2$ which is a Möbius strip with boundary. We employ a parametrization of U(2) that admits a direct physical interpretation and furnishes a coherent framework to realize the spectral duality and anholonomy recently found. This allows us to find that (iii) physically distinct point interactions form a three-parameter quotient space of the U(2) family. © *2001 American Institute of Physics.* [DOI: 10.1063/1.1415432]

I. INTRODUCTION

Quantum mechanical motion of a particle subject to a point interaction on a line $\mathbb{R}$ is described by the free Schrödinger (the Laplacian) operator,

$$H = -\frac{\hbar^2}{2m}\frac{\mathrm{d}^2}{\mathrm{d}x^2}, \tag{1}$$

with one point perturbation. This is implemented by deleting a point, say $x=0$ on the line, and thereby considering the family Ω of self-adjoint operators H defined on proper domains in the Hilbert space $\mathcal{H}=L^2(\mathbb{R}\backslash\{0\})$. The theory of self-adjoint extensions then dictates that the family Ω is given by the group U(2), which covers all allowable distinct point interactions.[1] Studies show that the spectrum of the operator H consists of the essential spectrum $[0,\infty)$ together with a discrete spectrum having at most two levels of bound states[2] (see also Refs. 3 and 4, and references therein). Symmetries such as parity or time reversal are used to classify the family $\Omega \simeq \mathrm{U}(2)$ in terms of their invariant subfamilies.[5]

Recently, we have examined the spectral properties of this simple system and found a number of interesting features which are usually ascribed to more complex systems. These features include duality in the spectra under strong versus weak coupling exchange,[6,7] anholonomy both in the phase of states (the Berry phase) and in levels under a cycle in Ω,[8,9] and the double degeneracy

which leads to supersymmetry.[10] Meanwhile, a similar study has been made on a circle S^1 with point interaction,[11] where it is shown that the spectrum of H does not depend on the entire U(2) parameters as one naïvely expects.

The aim of the present paper is to furnish a comprehensive picture of the spectral structure of the entire family of the Schrödinger operators H on a line $\mathbb{R}$ as well as on an interval $[l,-l]$ (under some innocuous boundary conditions) with the point $x=0$ removed. Our main results are given in three theorems. Theorem 1 states that the spectrum is uniquely determined by the eigenvalues of the U(2) matrix which characterizes the point interaction, and Theorem 2 shows that, for the case of the interval, the space Σ consisting of all distinct spectra is given by a Möbius strip with boundary, while for the case of the line Σ is a subspace of it. The key observation to reach these statements is that the set of su(2) parity transformations on the operator H which preserve the spectrum[7,10] can be generalized in order to narrow the dependence from U(2) down to its subspace. We also provide a generalization in symmetry transformations in order to associate a pertinent invariant subfamily to any point interaction in Ω. In our treatment emerges a natural parametrization of Ω which admits a direct physical interpretation and furnishes a framework to describe the above-mentioned features in a coherent manner. As part of the physical interpretation given as Theorem 3, we find a one-parameter gauge equivalence within Ω and conclude that physically distinct point interactions form a three-parameter quotient space of Ω.

II. SPECTRAL STRUCTURE

Let us first recall the description of the U(2) family of self-adjoint operators H[7] (see also Ref. 12). The domain of such a self-adjoint operator H is a subspace of $\mathcal{H}$ specified by a boundary condition at the missing point $x=0$ on the line. Let φ be a state in the domain, and consider the two-component boundary vectors

$$\Phi := \begin{pmatrix} \varphi(0_+) \\ \varphi(0_-) \end{pmatrix}, \quad \Phi' := \begin{pmatrix} \varphi'(0_+) \\ -\varphi'(0_-) \end{pmatrix}, \tag{2}$$

where 0_+ and 0_- denote the limits at $x=0$ from the right and the left, respectively. We require φ and its derivative φ' to be absolutely continuous on $\mathbb{R}\backslash\{0\}$ (see Ref. 12). In terms of a matrix $U\in \mathrm{U}(2)$ the boundary condition is then given as

$$(U-I)\Phi + iL_0(U+I)\Phi' = 0, \tag{3}$$

with some constant $L_0\neq 0$ of length dimension, where I denotes the unit matrix in U(2). We note that the self-adjointness of H is equivalent to the requirement of (global) probability conservation, and that the constant L_0 adds no extra freedom to that given by U.[10] To indicate the U(2)-dependence of the operator H, we use the notation H_U.

We now begin our discussion of the spectral structure of the family Ω of the operators H_U by providing the following

Definition 1: A unitary transformation $\mathcal{X}:\mathcal{H}\to\mathcal{H}$ is called *a generalized symmetry* of the family Ω if, for any $U\in \mathrm{U}(2)$,

$$\mathcal{X}^{-1}H_U\mathcal{X} = H_{U_{\mathcal{X}}}, \tag{4}$$

for some $U_{\mathcal{X}}\in \mathrm{U}(2)$.

We note that condition (4) embodies two requirements: first, the domain of H_U is mapped into the domain of $H_{U_{\mathcal{X}}}$, and second, $\mathcal{X}^{-1}H_U\mathcal{X}$ acts on this new domain as the differential operator (1). Note also that the two operators H_U and $H_{U_{\mathcal{X}}}$ share the same spectrum.

The following lemmas will be useful in proving Theorem 1.

Lemma 1: The operators $\mathcal{P}_j$ $(j=1,2,3)$ *defined as*

$$(\mathcal{P}_1\varphi)(x) := \varphi(-x),$$

$$(\mathcal{P}_2\varphi)(x) := i[\Theta(-x)-\Theta(x)]\varphi(-x), \tag{5}$$

$$(\mathcal{P}_3\varphi)(x) := [\Theta(x)-\Theta(-x)]\varphi(x)$$

(where Θ denotes the Heaviside step function) are generalized symmetries. Further, they are parity-type operators (i.e., $\mathcal{P}_j^2=\mathrm{id}_{\mathcal{H}}$, $P_j\neq\pm\mathrm{id}_{\mathcal{H}}$) and satisfy the su(2) *commutation relations $[\mathcal{P}_j,\mathcal{P}_k]=2i\Sigma_{l=1}^{3}\epsilon_{jkl}\mathcal{P}_l$ and the anticommutation relations $\{\mathcal{P}_j,\mathcal{P}_k\}=2\delta_{jk}\,\mathrm{id}_{\mathcal{H}}$.*

Proof: It is straightforward to check that these operators are unitary and parity type, fulfilling the stated commutation and anticommutation relations. To show that they are generalized symmetries, let us observe that, under a $\mathcal{P}_j$, the boundary vectors (2) change as $\Phi\mapsto\sigma_j\Phi$ and $\Phi'\mapsto\sigma_j\Phi'$, where σ_j's denote the Pauli matrices. In the boundary condition (3), this change can be absorbed by the change in the matrix U as

$$U\mapsto U_{\mathcal{P}_j} := \sigma_j\, U\, \sigma_j\,. \tag{6}$$

This implies that a $\mathcal{P}_j$ maps the domain of an H_U to the domain of $H_{U_{\mathcal{P}_j}}$ with $U_{\mathcal{P}_j}$ given in (6) (clearly, $\mathcal{P}_j$'s preserve the smoothness properties mentioned in Ref. 1, too). It is also easy to see that $\mathcal{P}_jH_U\mathcal{P}_j$ remains the differential operator (1) on this new domain, since, under any of the transformations (5), φ acquires merely an overall complex phase factor that is constant on both $\mathbb{R}_+$ and $\mathbb{R}_-$. Q.E.D.

The three transformations defined previously are not the only parity-type generalized symmetries. Indeed, operators given by the linear combinations of the three,

$$\mathcal{P} := \sum_{j=1}^{3} c_j\,\mathcal{P}_j \quad \text{with} \quad c_j\in\mathbb{R}, \quad \sum_{j=1}^{3} c_j^2=1, \tag{7}$$

are all generalized symmetries and fulfill the parity property $\mathcal{P}^2=\mathrm{id}_{\mathcal{H}}$, where now the induced transformation on U reads

$$U\mapsto U_{\mathcal{P}}=\sigma U\sigma, \quad \sigma := \sum_{j=1}^{3} c_j\,\sigma_j\,. \tag{8}$$

We therefore arrive at

Lemma 2: For any su(2) *element σ normalized as $\sigma^2=I$, and for any $U\in\mathrm{U}(2)$, H_U and $H_{\sigma U\sigma}$ share an identical spectrum.*

Using Lemma 2, we now show

Theorem 1: *The spectrum of the Schrödinger operator H_U is uniquely determined by the eigenvalues of the matrix U.*

Proof: Let $e^{i\theta_+}$ and $e^{i\theta_-}$ with $\theta_\pm\in[0,2\pi)$ be the two eigenvalues of the unitary matrix U. These eigenvalues arise in the matrix,

$$D=\begin{pmatrix} e^{i\theta_+} & 0 \\ 0 & e^{i\theta_-} \end{pmatrix}, \tag{9}$$

which appears when one diagonalizes

$$U=V^{-1}DV, \tag{10}$$

with an appropriate $V\in\mathrm{SU}(2)$. To proceed, let us set

$$D=e^{i\xi}e^{i\rho\sigma_3}, \quad \xi=\frac{\theta_++\theta_-}{2}, \quad \rho=\frac{\theta_+-\theta_-}{2}, \tag{11}$$

to rewrite (10) as

$$U = e^{i\xi} e^{i\rho\, V^{-1}\sigma_3 V}. \tag{12}$$

Note that $V^{-1}\sigma_3 V$ in the exponent is just an element of su(2) obtained by the rotation of σ_3 with respect to an axis determined by V. Note also that, since $\sigma = (1/i)\, e^{(\pi/2)\, i\sigma} = \sigma^{-1}$, the product $\sigma\sigma_3\sigma$ is an element of su(2) obtained by the rotation of σ_3 with respect to σ by the angle π. This implies that, to a given V, one can always find some σ such that $V^{-1}\sigma_3 V = \sigma\sigma_3\sigma$ holds. With such σ we now have

$$U = e^{i\xi} e^{i\rho\, \sigma\sigma_3\sigma} = \sigma\, D\, \sigma. \tag{13}$$

Lemma 2 then ensures that the spectrum of H_U coincides with the spectrum of H_D. Q.E.D.

From this theorem we obtain

Corollary 1: A point interaction characterized by U possesses the isospectral subfamily

$$\Omega(D) := \{H_{V^{-1}DV} | V \in \mathrm{SU}(2)\}, \tag{14}$$

where D is the diagonal eigenvalue matrix in the decomposition (10) of U. The isospectral subspace $\Omega(D)$ *is homeomorphic to the coadjoint orbit of* SU(2) *passing through the element* $e^{i\rho\sigma_3}$, *and hence* $\Omega(D) \simeq S^2$ *except for the case* $D = e^{i\theta}\cdot I$ $(\theta \in [0, 2\pi))$ *for which* $\Omega(D)$ *consists of D alone*.

We mention that the exceptional cases $(\theta = \theta_+ = \theta_-)$ occur at

$$U = e^{i\theta}\cdot I, \quad \theta \in [0, 2\pi), \tag{15}$$

which form what we call the *self-dual subfamily* $\Omega_{\mathrm{SD}} \simeq \mathrm{U}(1)$ in the entire set of point interactions $\Omega \simeq \mathrm{U}(2)$ (see also Proposition 3 and the remark which follows).

Clearly, the two eigenvalues of U appearing in D are interchangeable, and this is realized for $\Omega(D)$ by setting, e.g., $V \mapsto i\sigma_2 V$. Thus, if we write $D = D(\theta_+, \theta_-)$ for the diagonal matrix D in (9), we have

Corollary 2: The two isospectral subfamilies associated with $D(\theta_+, \theta_-)$ *and* $D(\theta_-, \theta_+)$ *are identical,*

$$\Omega(D(\theta_+, \theta_-)) = \Omega(D(\theta_-, \theta_+)), \tag{16}$$

and hence the spectrum occurring at $D(\theta_+, \theta_-)$ *and that occurring at* $D(\theta_-, \theta_+)$ *are the same.*

The above-discussed spectral feature is seen in the discrete spectrum, but it is largely obscured because the spectrum consists mostly of the continuous spectrum $[0, \infty)$. However, the structure becomes manifest if one considers, instead of a line, a box (interval) on which the entire spectrum becomes discrete. This can be done by imposing a boundary condition at both ends of the box in such a way that it does not affect the consequences of the operations of $\mathcal{P}$ in (7). Specifically, if we let the interval $[-l, l]$ be the box where the point interaction is placed at $x = 0$, then we seek boundary conditions at $x = \pm l$ which remain invariant under any of the transformations induced by $\mathcal{P}$. These are given by

Proposition 1: The boundary conditions at $x = \pm l$ *which are left unchanged under any of the transformations induced by* $\mathcal{P}$ *(and hence provide a domain for H so that the entire discrete spectrum exhibits the spectral structure manifestly) are*

$$\varphi(l) + L\varphi'(l) = 0, \quad \varphi(-l) - L\varphi'(-l) = 0, \tag{17}$$

where $L \in (-\infty, \infty) \cup \{\infty\}$ *is an arbitrary parameter.*

Proof: The operator H remains self-adjoint if the boundary condition at $x = \pm l$ ensures the probability conservation, and this is exactly the demand we used to obtain the boundary condition

(3) at $x=0$. (More precisely, one needs to require further that the probability current vanish at the both ends, but this will be seen to be satisfied at the end.) This suggests that, if we use the boundary vectors similar to (2),

$$\Psi := \begin{pmatrix} \varphi(l) \\ \varphi(-l) \end{pmatrix}, \quad \Psi' := \begin{pmatrix} \varphi'(l) \\ -\varphi'(-l) \end{pmatrix}, \tag{18}$$

the boundary conditions at the ends can be given analogously as

$$(\tilde{U}-I)\Psi + iL_0(\tilde{U}+I)\Psi' = 0, \tag{19}$$

in terms of a matrix $\tilde{U}\in \mathrm{U}(2)$ characterizing the two ends. The transformation of the operator $\mathcal{P}$ on the boundary vectors (18) is the same as before, and hence it induces the same action $\tilde{U}\mapsto \tilde{U}_{\mathcal{P}}=\sigma\,\tilde{U}\,\sigma$ on the matrix $\tilde{U}$. Thus, the required boundary condition must satisfy $\sigma\,\tilde{U}\,\sigma = \tilde{U}$, that is, we find $\tilde{U}=e^{i\theta\cdot I}$ for $\theta\in[0,2\pi)$. Putting $L=L_0\cot(\theta/2)$ we obtain the statement. Q.E.D.

We remark that both the Dirichlet condition $\varphi(l)=\varphi(-l)=0$ and the Neumann condition $\varphi'(l)=\varphi'(-l)=0$ are of the type (17).

If we now introduce the space of distinct spectra, $\Sigma := \{\mathrm{Spec}(H_U) \,|\, U\in \mathrm{U}(2)\}$, then from the foregoing argument we find that Σ is a subspace of the torus $T^2=S^1\times S^1=\{(\theta_+,\theta_-)\}$ subject to the identification $(\theta_+,\theta_-)\equiv(\theta_-,\theta_+)$. The quotient space obtained by the identification is the orbifold $T^2/\mathbb{Z}_2$, which is the domain of the triangle shown in Fig. 1. The elementary observation in Fig. 1 leads to

Theorem 2: *The spectral space Σ of point interactions is a subspace of the orbifold $T^2/\mathbb{Z}_2$ which is homeomorphic to a Möbius strip with boundary. In particular, for the box $[l,-l]$ the spectral space Σ is the entire $T^2/\mathbb{Z}_2$.*

Proof: The first half is already shown (see Fig. 1). To show the second half, we observe that for an isospectral subfamily $\Omega(D)$ the spectrum is determined by the boundary condition (3) for $U=D$, which splits into

$$\varphi(0_+)+L_+\varphi'(0_+)=0, \quad \varphi(0_-)-L_-\,\varphi'(0_-)=0, \tag{20}$$

where we have used

$$L_\pm := L_0 \cot\frac{\theta_\pm}{2}. \tag{21}$$

Then for the box $[l,-l]$ the problem boils down to determining the spectrum of the operator in two separate boxes, $[-l,0_-)$ and $(0_+,l]$, under the combined boundary conditions, (17) and (20). For the interval $(0_+,l]$, for instance, the positive spectrum $E=\hbar^2k^2/(2m)$ is determined by the condition, $\tan kl = k(L-L_+)/(1+k^2LL_+)$, which admits a distinct set of solutions for different L_+ under fixed L. It thus follows that to each pair (L_+,L_-) or (θ_+,θ_-) modulo the exchange $\theta_+\leftrightarrow\theta_-$ there arises a distinct spectrum. Q.E.D.

We have seen that the product form (10) for the matrix U furnishes a useful parametrization for the point interaction in one dimension, where the spectral property resides solely in the diagonal part D. The adjoint part V, on the other hand, may be used to provide a parity transformation pertinent to the point interaction as follows.

Proposition 2: To a point interaction specified by U there is a parity operator $\mathcal{P}$ of the form (7) whose action leaves U invariant. The operator $\mathcal{P}$ is unique (up to the sign) except when $U\in\Omega_{\mathrm{SD}}$ for which $\mathcal{P}$ is arbitrary.

Proof: Consider the su(2) element σ in (8) given by

$$\sigma=\sigma(V):=V^{-1}\sigma_3 V, \tag{22}$$

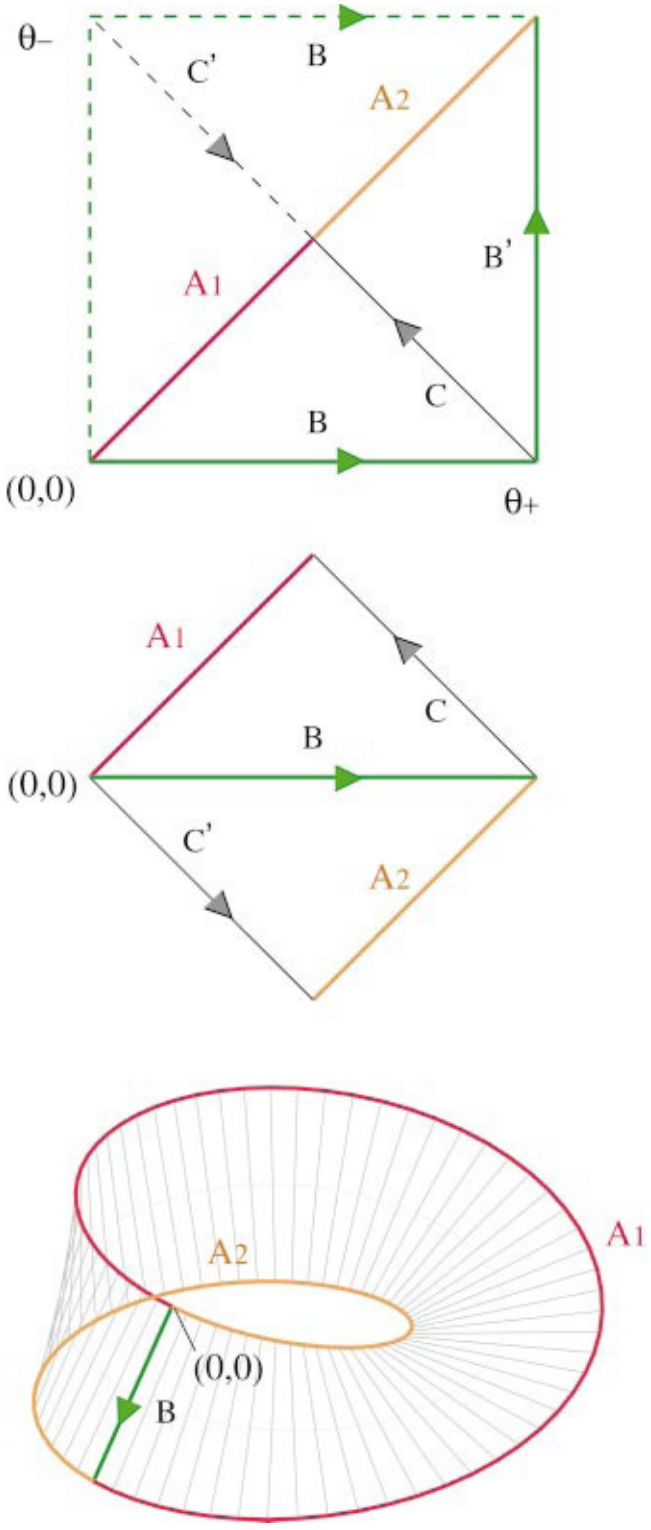

FIG. 1. (Color.) At the top, the spectral space Σ is the triangle surrounded by edges A_1+A_2, B and B'. We divide this triangle into two subtriangles $B-C-A_1$ and $B'-C-A_2$. Since the latter subtriangle is spectrally identical to its dual image $B-C'-A_2$, Σ can be represented by the square $A_1-C'-A_2-C$ in the middle figure. When the two spectrally identical edges C and C' are stitched together with the right orientation, we obtain the Möbius strip with boundary A_1-A_2 representing the self-dual subfamily Ω_{SD} (the bottom figure).

where V is the SU(2) matrix appearing in (10) for the the diagonalization of the matrix $U \notin \Omega_{\mathrm{SD}}$. Note that in (10) the matrix V is determined only up to the left action $e^{i\chi\sigma_3}V$, but this ambiguity does not affect in specifying σ in (22). We now expand $\sigma(V)$ in the su(2) basis as $\sigma(V) = \Sigma_{j=1}^{3} c_j(V)\,\sigma_j$ and define the corresponding parity operator,

$$\mathcal{P}(V) := \sum_{j=1}^{3} c_j(V)\,\mathcal{P}_j\,. \tag{23}$$

We then see at once that, under the transformation induced by $\mathcal{P}(V)$, the matrix U is left invariant, $\sigma(V)\,U\,\sigma(V) = U$. The parity $-\mathcal{P}(V)$ corresponding to $-\sigma(V)$ also leaves U invariant. For $U \in \Omega_{\mathrm{SD}}$, it is obvious that any σ, and hence any $\mathcal{P}$ in (7) leaves U invariant. Q.E.D.

The content of Proposition 2 may equally be stated as

Proposition 2′: The Schrödinger operator H_U commutes with a parity operator $\mathcal{P}$ given by (7), $[H_U, \mathcal{P}] = 0$, where for $U \notin \Omega_{\mathrm{SD}}$ the operator $\mathcal{P}$ is uniquely determined as $\mathcal{P} = \mathcal{P}(V)$ (up to sign) in (23), while for $U \in \Omega_{\mathrm{SD}}$ it is arbitrary.

We note that, for an H_U and the parity operator $\mathcal{P}$ commuting with it, the Hilbert space $\mathcal{H}$ can be decomposed into two orthogonal closed linear subspaces, $\mathcal{H} = \mathcal{H}_+ \oplus \mathcal{H}_-$, where $\mathcal{H}_+$ and $\mathcal{H}_-$ are the eigenspaces of $\mathcal{P}$ corresponding to the eigenvalues 1 and -1, respectively. The nondegenerate eigenfunctions of H_U belong to either $\mathcal{H}_+$ or $\mathcal{H}_-$. For doubly degenerate eigenvalues, the eigenfunctions can be chosen such that one belongs to $\mathcal{H}_+$ and the other to $\mathcal{H}_-$. Note that, since the eigenvalue equation is a second-order differential equation on both half lines, the eigenvalues of H_U are at most doubly degenerate. Namely, these degenerate solutions contain two free constants each, and the boundary condition (3) reduces this four-parameter freedom to a two-parameter one. These statements are valid for the non-normalizable eigenfunctions (scattering states) of H_U, too, in the rigged Hilbert space sense [note that the definition (5), and correspondingly the definition of $\mathcal{P}(V)$, can be extended to any $\mathbb{R}\backslash\{0\} \to \mathbb{C}$ function in a natural way, which involves the natural extension of $\mathcal{H}_+$ and $\mathcal{H}_-$].

A distinguished family of generalized symmetries which interchange the subspaces $\mathcal{H}_+$ and $\mathcal{H}_-$ exist, that is,

Proposition 3: For an H_U and the associated parity operator $\mathcal{P}$ commuting with it, there exists a U(1) *family of generalized symmetries $\mathcal{D}$ such that each $\mathcal{D}$ maps $\mathcal{H}_+$ to $\mathcal{H}_-$ and vice versa, and satisfies $(U_{\mathcal{D}})_{\mathcal{D}} = U$.*

Proof: Consider the generalized symmetries $\mathcal{D}$ corresponding to the U(1) family of su(2) elements,

$$\sigma_{\mathcal{D}} := V^{-1}\,\tilde{\sigma}(\phi)\,V, \tag{24}$$

where we have defined $\tilde{\sigma}(\phi) = \cos\phi\,\sigma_1 + \sin\phi\,\sigma_2$ for $\phi \in [0, 2\pi)$, and introduced $\mathcal{D} := \Sigma_{j=1}^{3} c_j' \mathcal{P}_j$ using the expansion $\sigma_{\mathcal{D}} = \Sigma_{j=1}^{3} c_j' \sigma_j$ of $\sigma_{\mathcal{D}}$. On $U = V^{-1} D(\theta_+, \theta_-)\,V$ these $\mathcal{D}$ induce

$$U \mapsto U_{\mathcal{D}} = \sigma_{\mathcal{D}}\,U\,\sigma_{\mathcal{D}} = V^{-1}\,\tilde{\sigma}(\phi)\,D(\theta_+, \theta_-)\,\tilde{\sigma}(\phi)V = V^{-1} D(\theta_-, \theta_+)V, \tag{25}$$

and hence implement the interchange $\theta_+ \leftrightarrow \theta_-$. From this $(U_{\mathcal{D}})_{\mathcal{D}} = U$ is clear. To prove that a $\mathcal{D}$ maps any eigenfunction of $\mathcal{P}$ to another one with opposite eigenvalue, we show that $\{\mathcal{P}, \mathcal{D}\} = 0$. Indeed, from $\{\mathcal{P}_j, \mathcal{P}_k\} = \mathrm{Tr}(\sigma_j \sigma_k)\mathrm{id}_{\mathcal{H}}$ and (23) it follows that

$$\{\mathcal{P}, \mathcal{D}\} = \mathrm{Tr}\left(\sum_{j=1}^{3} c_j \sigma_j \sum_{k=1}^{3} c_k' \sigma_k \right) \mathrm{id}_{\mathcal{H}} = \mathrm{Tr}(\sigma \sigma_{\mathcal{D}})\mathrm{id}_{\mathcal{H}} = \mathrm{Tr}(\sigma_3 \tilde{\sigma}(\phi))\mathrm{id}_{\mathcal{H}} = 0. \tag{26}$$

Q.E.D.

Hence, in the light of these properties, $\mathcal{D}$ may be called *duality transformation*. The duality found in Refs. 7 and 10 is a special case of $\mathcal{D}$.

The role of the point interaction and the parity operator in Proposition 2 can be reversed to obtain

Proposition 4: To a parity operator $\mathcal{P}$ given in (7) there is a subfamily of point interactions which are left invariant under $\mathcal{P}$. For any $\mathcal{P}$ the subfamily $\Omega_{\mathcal{P}}$ is homeomorphic to a torus T^2.

Proof: The subfamily $\Omega_{\mathcal{P}}$ is given by

$$\Omega_{\mathcal{P}} := \{\, U \in \mathrm{U}(2) \,|\, \sigma U \sigma = U \,\}, \tag{27}$$

where σ is determined from $\mathcal{P}$ by (8). The matrices U belonging to $\Omega_{\mathcal{P}}$ are then found to be of the form,

$$U = e^{i\xi} e^{i\rho\sigma}, \quad \xi \in [0,\pi), \quad \rho \in [0,2\pi), \tag{28}$$

which is homeomorphic to a torus T^2 for any $\mathcal{P}$. Q.E.D.

For instance, if we choose $\mathcal{P}=\mathcal{P}_1$, the subfamily $\Omega_{\mathcal{P}_1}$ is just the set of parity invariant (left–right symmetric) point interactions in the usual sense of the word. If, on the other hand, we choose $\mathcal{P}=\mathcal{P}_3$, then the resultant subfamily $\Omega_{\mathcal{P}_3}$ becomes the so-called separated subfamily where no probability flow through the gap $x=0$ is allowed. One may also choose for $\mathcal{P}$ the one $\mathcal{P}(V)$ that corresponds to a specific U. The invariant subfamily $\Omega_{\mathcal{P}(V)}$ then contains U by construction, and becomes a subfamily pertinent to the point interaction characterized by U. One then finds from Propositions 3 and 4 that $\Omega_{\mathcal{P}(V)} \simeq T^2$ except when $U \in \Omega_{\mathrm{SD}}$ for which $\Omega_{\mathcal{P}(V)}$ coincides with the entire family $\Omega \simeq \mathrm{U}(2)$.[13]

The self-dual subfamily Ω_{SD} has also the following distinguished characteristics:

Proposition 5: For any point interaction belonging to Ω_{SD} (i.e., $U \in \Omega_{\mathrm{SD}}$), *all eigenvalues of H_U (including the generalized ones) are doubly degenerate.*

Proof: For any $U \in \Omega_{\mathrm{SD}}$, we have from Proposition 2′ that $[H_U, \mathcal{P}_j]=0$ for $j=1, 2, 3$. This implies that, on any eigenspace of H_U, a representation of su(2) formed by $\{\mathcal{P}_j\}_{j=1,2,3}$ is given. Since an eigenfunction of, say, $\mathcal{P}_1$ cannot be an eigenfunction of $\mathcal{P}_2$, the eigenspaces of H_U must be doubly degenerate. This argument is valid for the generalized eigenvalues (scattering state energies) and the corresponding eigenspaces as well. Q.E.D.

The double degeneracy implies that the system with point interaction belonging to Ω_{SD} may be regarded as supersymmetric. As shown in Ref. 10, this is in fact the case for $U=-I$, where the energy of the two bound states vanishes yielding an $N=2$ Witten model with a "good SUSY."[14] Generically, however, the ground state energy of the system is nonvanishing and the system is not supersymmetric even though it admits a formally supersymmetric reformulation for any U of Ω_{SD}. The obstacle for being supersymmetric is the fact that the presumed supercharges are not self-adjoint unless $U=-I$.

We have learned that the spectrum of the operator H_U is determined by the two parameters in D in the decomposition $U=V^{-1}DV$, and that, in particular, for the box the space Σ of the spectra is given by a Möbius strip. One can proceed further and assign more general physical meaning to the parameters in the matrix U. To see this we first rewrite the boundary condition (3) using the decomposition as

$$V\Phi + \begin{pmatrix} L_+ & 0 \\ 0 & L_- \end{pmatrix} V\Phi' = 0, \tag{29}$$

with $L_\pm$ given in (21). We further parametrize V by the Euler angles (with the first factor $e^{i\chi\sigma_3}$ which does not affect U being dropped),

$$V = e^{i(\mu/2)\sigma_2} e^{i(\nu/2)\sigma_3}, \quad \mu \in [0,\pi], \quad \nu \in [0,2\pi), \tag{30}$$

and thereby present

$$\{(L_+, L_-, \mu, \nu) \,|\, L_\pm \in (-\infty,\infty) \cup \{\infty\},\ \mu \in [0,\pi],\ \nu \in [0,2\pi)\}, \tag{31}$$

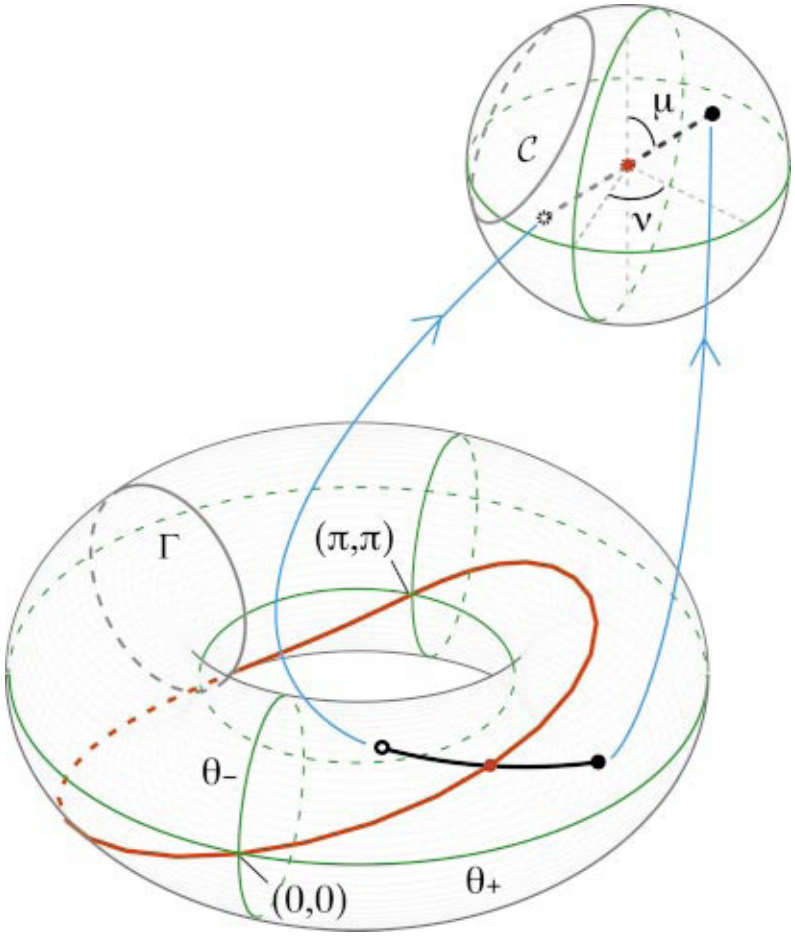

FIG. 2. (Color.) The parameter space $\{(\theta_+,\theta_-,\mu,\nu)\}$ is a product of the spectral torus T^2 specified by the angles (θ_+,θ_-) and the isospectral sphere S^2 specified by the angles (μ,ν) with radius $\rho=(\theta_+-\theta_-)/2$ (cf. Corollary 1) which collapses to a point for the self-dual case $\theta_+=\theta_-$. A cyclic path $\mathcal{C}$ on the sphere yields a phase anholonomy (the Berry phase) proportional to the area enclosed by $\mathcal{C}$ due to the degeneracy present at the center of the sphere. A cyclic path Γ on the torus, on the other hand, yields a level anholonomy (level shifts) if Γ is homotopically nontrivial. A generic cycle is a combination of the two, and hence yields an anholonomy in both phase and level. The parametrization shown here provides a double covering of the entire family $\Omega\simeq\mathrm{U}(2)$, where the two antipodal points on the spheres equidistant from the self-dual line $\theta_+=\theta_-$ are identified. This identification determines the spectral space Σ to be given by $T^2/\mathbb{Z}_2$ which is a Möbius strip with boundary.

as a basic set for the parametrization of the point interactions on a line. On account of the double specification of the eigenvalues of U, the set (31) is in a two-to-one correspondence to U, providing a double covering[15] of the whole family $\Omega\simeq\mathrm{U}(2)$ (see Fig. 2). We then have

Theorem 3: *The parameters in the set* (31) *possess the following physical properties:*

(i) The two parameters $L_\pm$ furnish two independent length scales to the point interaction.

(ii) The angle ν is physically irrelevant (unobservable).

(iii) The angle μ measures the extent of mixture of states between the positive and negative half lines.

Proof: (i) is evident because in the boundary condition (29) $L_\pm$ are the only parameters with length dimension. To show (ii), we observe from (30) and (29) that the angle ν can be absorbed by introducing the new vectors $e^{i\nu\sigma_3/2}\Phi$ and $e^{i\nu\sigma_3/2}\Phi'$ which arise if we replace $\varphi(0_\pm)\mapsto e^{\pm i\nu/2}\varphi(0_\pm)$ and $\varphi'(0_\pm)\mapsto e^{\pm i\nu/2}\varphi'(0_\pm)$. This is implemented by the U(1) phase transformation (gauge transformation) on the state,

$$\varphi(x)\mapsto e^{(i/\hbar)\,\vartheta(x)}\varphi(x),\quad \vartheta(x):=\frac{\nu}{2}[\Theta(x)-\Theta(-x)]\hbar. \tag{32}$$

Since the phase shift $\vartheta(x)$ is constant over $\mathbb{R}\backslash\{0\}$, and since the phase gap (which occurs at the missing point $x=0$) cannot be observed on a line,[16] the transformed state is equivalent to the original state in quantum theory, that is, the angle ν is irrelevant physically. Finally, (iii) is also evident in the boundary condition (29) because the factor $e^{i(\mu/2)\,\sigma_2}$ mixes the two rows of the boundary vectors by rotation according to the angle μ. Q.E.D.

An important point to be noted here is that the existence of the one-parameter gauge equivalence within Ω implies that point interactions which are distinct physically—not just on the spectral basis—form a three-parameter quotient space of Ω.

The properties stated in Theorem 3 can be seen explicitly in the solutions of the Schrödinger equation under the operator H_U being the Hamiltonian. For instance, the bound states allowed under H_U on the line are given by

$$\varphi_\kappa(x)=\begin{cases} A_\kappa^- e^{\kappa x}, & x<0 \\ B_\kappa^+ e^{-\kappa x}, & x>0 \end{cases}, \tag{33}$$

where κ determines the bound state energy $E_{\text{bound}}=-\hbar^2\kappa^2/(2m)$, and the constants A_κ^- and B_κ^+ are subject to the normalization condition $|A_\kappa^-|^2+|B_\kappa^+|^2=2\kappa$. A nonvanishing solution is then ensured if

$$\kappa=\frac{1}{L_+}\quad\text{or}\quad\kappa=\frac{1}{L_-}, \tag{34}$$

which shows that there exist two bound states if $L_+>0$ and $L_->0$, and one if $L_+L_-<0$, and none if $L_+<0$ and $L_-<0$. The parameters $L_\pm$ thus give (in case they are positive) the scales of the trapped particle. In terms of (30) the coefficients are found to be

$$\begin{pmatrix} B_\kappa^+ \\ A_\kappa^- \end{pmatrix}=\sqrt{\frac{2}{L_+}}\begin{pmatrix} e^{-2i\nu}\cos\dfrac{\mu}{2} \\ \sin\dfrac{\mu}{2} \end{pmatrix},\quad \begin{pmatrix} B_\kappa^+ \\ A_\kappa^- \end{pmatrix}=\sqrt{\frac{2}{L_-}}\begin{pmatrix} -e^{-2i\nu}\sin\dfrac{\mu}{2} \\ \cos\dfrac{\mu}{2} \end{pmatrix}, \tag{35}$$

for $\kappa=1/L_+$ and $1/L_-$, respectively. Note that the relative phase factor $e^{-2i\nu}$ attached to the coefficients of the states on the positive half line can be removed by (32). Similarly, the scattering states for the particle (with velocity $v=\hbar k/m$) incident, say, from the positive side,

$$\varphi_k^{(+)}(x)=\frac{1}{\sqrt{2\pi}}\begin{cases} t_k^{(+)}e^{-ikx}, & x<0 \\ e^{-ikx}+r_k^{(+)}e^{ikx}, & x>0 \end{cases}, \tag{36}$$

have the reflection and transmission coefficients

$$\begin{pmatrix} r_k^{(+)} \\ t_k^{(+)} \end{pmatrix}=-\frac{1}{(1+ikL_+)(1+ikL_-)}\begin{pmatrix} 1+k^2L_+L_--ik(L_+-L_-)\cos\mu \\ -ik(L_+-L_-)\sin\mu\, e^{i\nu} \end{pmatrix}. \tag{37}$$

We observe that, in accordance with the interpretation, the factor $e^{i\nu}$ is simply the phase which is acquired by the transmitted wave when the incoming wave passes the point $x=0$. We can also see that, unlike ν, each of the other three parameters plays an independent and physical role in the eigenstates of H_U.

Finally, let us illustrate the basic structure of the U(2) family by considering a generic point interaction specified by U in the U(2) parameter space which is shown in Fig. 2 as a product of a torus representing (θ_+,θ_-) and a sphere with radius ρ [see (13) and Corollary 1] representing

(μ,ν). On this torus, two point interactions connected by the duality transformation (25) are represented by two equidistant points from the self-dual loop, $\theta_+=\theta_-$. The double covering of the parametrization implies that the two spheres attached to these dual points are actually the same, with antipodal points on the two spheres identified. Under a cyclic process on the sphere one can expect a phase anholonomy (the Berry phase) to arise, since the spectrum becomes degenerated at the center $\theta_+=\theta_-$ which belongs to Ω_{SD} (see Proposition 5). One can also expect a level shift if the cycle is homotopically nontrivial on the torus (see, e.g., Ref. 17). The anholonomy both in phase and level has indeed been observed[10] for cycles passing through $U=\sigma_3$, that is, $(\theta_+,\theta_-)=(\pi,0)$ and $(\mu,\nu)=(0,0)$. We note that this point $U=\sigma_3$ is rather special because it has the invariant parity $\mathcal{P}(V=I)=\mathcal{P}_3$ and hence its invariant subfamily is just the separated subfamily $\Omega_{\mathcal{P}_3}$. Further, its isospectral subfamily $\Omega(D=\sigma_3)$ is (the continuous part of) the scale invariant subfamily Ω_W (Ref. 5) in view of the fact[10] that such U satisfies the condition for scale invariance, $\det(U\pm I)=\det(\sigma_3\pm I)=0$. We stress, however, that the anholonomy in phase and/or level is a generic phenomenon observed for any cyclic process in the parameter space $\Omega\simeq\mathrm{U}(2)$.

JOURNAL OF MATHEMATICAL PHYSICS VOLUME 42, NUMBER 12 DECEMBER 2001

Asymptotics for the condensate multivortex solutions in the self-dual Chern–Simons CP(1) model

Hee-Seok Nam[a)]
Department of Mathematics, Yonsei University, Seoul 120-749, Korea

(Received 15 November 2000; accepted for publication 20 August 2001)

In this paper we study the asymptotics for the condensate multivortex solutions in the self-dual Chern–Simons CP(1) model. When the breaking parameter s belongs to $(-\frac{1}{2},\frac{1}{2})$, we show that for any sequence of multivortex solutions which lies between suitable super- and subsolutions with respect to the Chern–Simons coupling constant κ, we can find a subsequence which converges to a constant depending only on s as κ goes to zero. Also we investigate the locally uniform convergence speed. © *2001 American Institute of Physics.* [DOI: 10.1063/1.1409962]

I. INTRODUCTION

The CP(1) model which is equivalent to the $O(3)$ sigma model is a basic model in field theory. Though this model is useful as a toy model for the instantons in non-Abelian Yang–Mills theories, it is scale invariant and yields instantons of arbitrary size. This makes the model unsuitable as a model for real particles and there have been many attempts to break the scale invariance. Among them, one of the most elegant ways is to introduce a gauge field which incorporates the kinetic term. Gauging a theory is useful to obtain the finite energy solitons. Schroers[1] proposed a gauged model by introducing a U(1) gauge field whose dynamics is governed by a Maxwell term. On the other hand, Ghosh and Ghosh[2] proposed a gauged $O(3)$ sigma model with the gauge field dynamics governed solely by a Chern–Simons term. In Ref. 3 the authors generalized the gauged CP(1) case to the gauged CP(N) models with the kinetic term governed by a Chern–Simons term. These models yield to a Bogomol'nyi limit or self-dual equations which are easy to analyze mathematically compared to full second-order Euler–Lagrange equation. We note that the Bogomol'nyi limit in superconductivity plays an important role as it permits one to distinguish between the type of superconductors.[4]

In this paper, we consider the Chern–Simons CP(1) model where the gauge field dynamics is solely governed by the Chern–Simons term. Multiple existence of solutions is already studied in our previous paper[5] and we will concentrate on the asymptotics for the solutions.

The organization of this paper is as follows. In Sec. II, we briefly introduce the Chern–Simons CP(1) model, formulate its mathematical settings, and recall previous results. In Sec. III, we study the asymptotics for multivortex solutions with the breaking parameter s belonging to $(-\frac{1}{2},\frac{1}{2})$. We show that for any sequence of multivortex solutions which lies between suitable super- and subsolutions with respect to the Chern–Simons coupling constant κ constructed in Ref. 5, we can find a subsequence which converges to a constant depending only on s as κ goes to zero. Also we study the locally uniform convergence speed.

We remark that Tarantello[6] studied the asymptotic behavior of solutions of the Chern–Simons–Higgs model in a doubly periodic domain. Han[7] applied the arguments in Ref. 8 to the above-mentioned model and obtained some interior estimates. Their studies were the main motivation for our work here.

II. THE CHERN–SIMONS CP(1) MODEL

In this section we briefly introduce the Chern–Simons CP(1) model. After reducing the self-dual equations to semilinear elliptic partial differential equations, we recall the corresponding existence theorem (see Ref. 5).

The CP(1) model consists of two complex scalar fields z_1, z_2 in $\mathbb{R}^2$. Denoting $\mathbf{z}=(z_1,z_2)$, the model requires that $|\mathbf{z}|^2=z_1\overline{z_1}+z_2\overline{z_2}=1$ and $\mathbf{z}$ is equivalent to the overall phase rotations.

The Lagrangian for the self-dual Chern–Simons CP(1) model is

$$\mathcal{L}=\frac{\kappa}{2}\epsilon^{\mu\nu\rho}A_\mu\partial_\nu A_\rho+|\nabla_\mu\mathbf{z}|^2-V(\mathbf{z}),$$

where $\epsilon^{\mu\nu\rho}$ is the totally skew-symmetric tensor with $\epsilon^{012}=1$, $R=\mathrm{diag}(\frac{1}{2},-\frac{1}{2})$, $A_\mu R$ is the matrix valued gauge field, $V(\mathbf{z})$ is a potential term which will be fixed later, and the "covariant derivatives" ∇_μ and D_μ are defined as follows:

$$\nabla_\mu\mathbf{z}=D_\mu\mathbf{z}-(\overline{\mathbf{z}}D_\mu\mathbf{z})\mathbf{z},\quad D_\mu\mathbf{z}=\partial_\mu\mathbf{z}-iA_\mu R\mathbf{z}.$$

The Gauss law constraint obtained from the variation of A_0 is given by

$$\kappa F_{12}=i\{\nabla_0\overline{\mathbf{z}}[R\mathbf{z}-\mathbf{z}(\overline{\mathbf{z}}R\mathbf{z})]-\overline{\nabla_0\overline{\mathbf{z}}[R\mathbf{z}-\mathbf{z}(\overline{\mathbf{z}}R\mathbf{z})]}\},\tag{1}$$

where $F_{12}=\partial_1A_2-\partial_2A_1$. The theory possesses the following conserved topological current:

$$K^\mu=-i\epsilon^{\mu\nu\rho}\partial_\nu(\overline{\mathbf{z}}D_\rho\mathbf{z})$$

and a conserved global $U(1)$ current for the generator R,

$$J^\mu=i\{\nabla^\mu\overline{\mathbf{z}}[R\mathbf{z}-\mathbf{z}(\overline{\mathbf{z}}R\mathbf{z})]-\overline{\nabla^\mu\overline{\mathbf{z}}[R\mathbf{z}-\mathbf{z}(\overline{\mathbf{z}}R\mathbf{z})]}\}.$$

If we choose the potential as given by

$$V(\mathbf{z})=\frac{1}{\kappa^2}|[R\mathbf{z}-\mathbf{z}(\overline{\mathbf{z}}R\mathbf{z})](\overline{\mathbf{z}}R\mathbf{z})-s[R\mathbf{z}-\mathbf{z}(\overline{\mathbf{z}}R\mathbf{z})]|^2,$$

where s is a free real parameter, then we can find that the field configurations saturating the energy bound satisfy the Gauss law constraint (1) and the self-dual equations,

$$(\nabla_1\pm i\nabla_2)\mathbf{z}=0,$$

$$\nabla_0\mathbf{z}\pm\frac{i}{\kappa}\{[R\mathbf{z}-\mathbf{z}(\overline{\mathbf{z}}R\mathbf{z})](\overline{\mathbf{z}}R\mathbf{z})-s[R\mathbf{z}-\mathbf{z}(\overline{\mathbf{z}}R\mathbf{z})]\}=0.$$

Indeed, the energy functional E can be expressed as follows:

$$\begin{aligned}E&=\int \mathrm{d}^2x\{|\nabla_0\mathbf{z}|^2+|\nabla_1\mathbf{z}|^2+|\nabla_2\mathbf{z}|^2+V(\mathbf{z})\}\\&=\int \mathrm{d}^2x\{|(\nabla_1\pm i\nabla_2)\mathbf{z}|^2+|\nabla_0\mathbf{z}\pm\frac{i}{\kappa}\{[R\mathbf{z}-\mathbf{z}(\overline{\mathbf{z}}R\mathbf{z})]\\&\quad\times(\overline{\mathbf{z}}R\mathbf{z})-s[R\mathbf{z}-\mathbf{z}(\overline{\mathbf{z}}R\mathbf{z})]\}|^2\}\pm\int \mathrm{d}^2x\left(K_0+\frac{s}{\kappa}J_0\right)\\&\geqslant\pm\int \mathrm{d}^2x\left(K_0+\frac{s}{\kappa}J_0\right)\equiv T,\end{aligned}$$

and we will compute the generalized topological charge T later.

By elementary computations, from the above-mentioned self-dual equations, we obtain that, away from the zeroes of z_1 and z_2, there hold

$$\begin{cases} z_2\overline{\partial}z_1 - z_1\overline{\partial}z_2 = iz_1z_2(A_1+iA_2), \\ F_{12} = \mp\dfrac{\lambda}{2}|z_1|^2|z_2|^2(|z_1|^2-|z_2|^2-2s), \end{cases} \tag{2}$$

where $\overline{\partial}=(\partial_1+i\partial_2)/2$ and $\lambda=2/\kappa^2$.

We choose the upper signs and consider a doubly periodic boundary conditions due to 't Hooft.[9] First we note that the Lagrangian $\mathcal{L}$ is invariant under the following gauge transformations:

$$\mathbf{z}(x)\mapsto e^{i\theta(x)}\mathbf{z}(x), \quad A_0(x)\mapsto A_0(x), \quad A_j(x)\mapsto A_j(x)+\partial_j\theta(x),$$

where θ is a real-valued function and $j=1,2$. We set the doubly periodic region Ω by

$$\Omega=\{x=(x_1,x_2)\in\mathbb{R}^2 | x=t_1a^1+t_2a^2, 0<t_1,t_2<1\},$$

where a^1 and a^2 are linearly independent vectors in $\mathbb{R}^2$, and define $\Gamma^k=\{x\in\mathbb{R}^2|x=t_ka^k, 0<t_k<1\}$ for $k=1,2$. Then the boundary $\partial\Omega$ can be written as

$$\partial\Omega=\Gamma^1\cup\Gamma^2\cup\{a^1+\Gamma^2\}\cup\{a^2+\Gamma^1\}\cup\{O,a^1,a^2,a^1+a^2\}.$$

Here we impose the following doubly periodic boundary condition:

$$\exp(i\theta_k(x+a^k))\mathbf{z}(x+a^k)=\exp(i\theta_k(x))\mathbf{z}(x),$$

$$A_0(x+a^k)=A_0(x),$$

$$(A_j+\partial_j\theta_k)(x+a^k)=(A_j+\partial_j\theta_k)(x),$$

where $x\in\Gamma^1\cup\Gamma^2-\Gamma^k$ for $k=1,2$ and θ_1,θ_2 are real-valued smooth functions defined in a neighborhood of $\Gamma^2\cup\{a^1+\Gamma^2\}$, $\Gamma^1\cup\{a^2+\Gamma^1\}$, respectively.

If we denote by q_k's the zeroes of z_1 for $k=1,\ldots,m$ and p_l's the zeroes of z_2 for $l=1,\ldots,n$ counted with multiplicity, then we can calculate the magnetic flux Φ and the energy E as follows:

$$\Phi=\int_\Omega F_{12}\,dx=\int_{\partial\Omega}A_j\,dx^j=-\int_{\partial\Omega}\partial_j\theta_k\,dx^j=2\pi(m-n),$$

$$E=T=\int_\Omega K_0+\frac{s}{\kappa}J_0=\int_\Omega\partial_2(A_1R\mathbf{z})-\partial_1(A_2R\mathbf{z})+sF_{12}=2\pi((m+n)+s(m-n)).$$

On the other hand, setting $u=\ln|z_1/z_2|^2$ and following the argument of Taubes,[10] we reduce the self-dual equations (2) to

$$\Delta u=(1-2s)\lambda\frac{e^u}{(1+e^u)^3}\left(e^u-\frac{1+2s}{1-2s}\right)+4\pi\sum_{k=1}^{m}\delta_{q_k}-4\pi\sum_{l=1}^{n}\delta_{p_l} \quad \text{in } \Omega. \tag{3}$$

Conversely, if u is given, then we can recover $(\mathbf{z},A)$ using the relations

$$\frac{z_1}{z_2}=e^{u/2+i\Theta}, \quad \frac{A_1+iA_2}{2}=-i\partial\ln\frac{z_1}{z_2},$$

where $\Theta=\Sigma_{k=1}^m\arg(z-q_k)-\Sigma_{l=1}^n\arg(z-p_l)$.

It is convenient to introduce a reference function w as the unique solution of

$$\Delta w = -\frac{4\pi(m-n)}{|\Omega|} + 4\pi\sum_{k=1}^{m}\delta_{q_k} - 4\pi\sum_{l=1}^{n}\delta_{p_l}, \quad \int_\Omega w = 0. \tag{4}$$

Setting $u_\lambda = w + v_\lambda$, from (3) we have

$$\Delta v_\lambda = (1-2s)\lambda\frac{e^{w+v_\lambda}}{(1+e^{w+v_\lambda})^3}\left(e^{w+v_\lambda} - \frac{1+2s}{1-2s}\right) + \frac{4\pi(m-n)}{|\Omega|} \tag{5}$$

and the constraint obtained by integrating over Ω,

$$(1-2s)\lambda\int_\Omega \frac{e^{w+v_\lambda}}{(1+e^{w+v_\lambda})^3}\left(e^{w+v_\lambda} - \frac{1+2s}{1-2s}\right) = -4\pi(m-n).$$

Furthermore we can derive the associated functional I_λ as

$$I_\lambda(v) = \frac{1}{2}\|\nabla v\|_{L^2}^2 + \lambda\int_\Omega \frac{s-(2-s)e^{w+v}}{(1+e^{w+v})^2} + \frac{4\pi(m-n)}{|\Omega|}\int_\Omega v. \tag{6}$$

Let ϵ be a sufficiently small positive number so that the $(m+n)$ balls with center p_l's or q_k's of radius 2ϵ are mutually disjoint and $8\pi(m+n)\epsilon^2 < |\Omega|$. We define a smooth function g^+ with $-1 \leqslant g^+ \leqslant 0$ by

$$g^+(x) = \begin{cases} -1, & x \in \cup_{l=1}^n B(p_l, \epsilon) \\ 0, & x \in \Omega \setminus \cup_{l=1}^n B(p_l, 2\epsilon), \end{cases}$$

and let v^+ be a solution of

$$\Delta v^+ = \frac{4\pi m}{|\Omega|} + \frac{1}{\epsilon^2}g^+ - \frac{1}{\epsilon^2|\Omega|}\int_\Omega g^+ - 4\pi\sum_{k=1}^{m}\delta_{q_k}.$$

Since v^+ can be determined up to constant, we may assume that

$$w + v^+ \geqslant \ln\frac{2+\sqrt{4s^2+3}}{1-2s} \quad \text{in } \Omega.$$

Replacing -1, p_l, m with 1, q_k and n, respectively, in the definitions of g^+ and v^+, we obtain g^- and v^- analogously. Also we may assume that

$$w + v^- \leqslant \ln\frac{1+2s}{2+\sqrt{4s^2+3}} \quad \text{in } \Omega.$$

We note that v^+ and v^- are super- and subsolutions of (5), respectively. Finally we state the existence theorem.[5]

Theorem 1: *Let $-\frac{1}{2} < s < \frac{1}{2}$ and v^+ and v^- be defined as above. Then there exists λ_0 such that for all $\lambda \geqslant \lambda_0$, there exists a multivortex solution v_λ which is a local minimizer of I_λ and satisfies $v^- < v_\lambda < v^+$. Moreover, if $m \neq n$, then there exists another multivortex solution $\tilde{v}_\lambda$ which is a critical point of I_λ.*

III. ASYMPTOTICS

In this section, we will prove the following theorem:

Theorem 2: *Let $-\frac{1}{2} < s < \frac{1}{2}$ and v_λ be a solution which lies between v^- and v^+. Then for any $r_0 > 0$, there exists a constant $C = C(r_0)$ such that*

$$|v_\lambda(q_k)| \leqslant C\lambda^{r_0}, \quad |v_\lambda(p_l)| \leqslant C\lambda^{r_0}.$$

Moreover, there exists a subsequence $\{v_{\lambda_j}\}$ *such that* $u_{\lambda_j} = w + v_{\lambda_j}$ *satisfies*
(i) $(1-2s)\lambda_j e^{u_{\lambda_j}}(e^{u_{\lambda_j}} - (1+2s)/(1-2s))/(1+e^{u_{\lambda_j}})^3 \to -4\pi\Sigma_{k=1}^{m}\delta_{q_k} + 4\pi\Sigma_{l=1}^{n}\delta_{p_l}$ *in the sense of measure as* $\lambda_j \to \infty$,
(ii) $\|u_{\lambda_j} - \ln(1+2s)/(1-2s)\|_{W^{1,r}(\Omega)} \to 0$ *for* $1 < r < 2$ *as* $\lambda_j \to \infty$,
(iii) $\|u_{\lambda_j} - \ln(1+2s)/(1-2s)\|_{L^\infty(K)} \leqslant C(K)/\lambda_j$ *for* $K \subset\subset \Omega \setminus \cup_{l=1}^{n}\{p_l\} \cup_{k=1}^{m}\{q_k\}$.

The proof of the theorem consists of several lemmas and we begin by constructing upper and lower bounds. This lemma plays a key role.

Lemma 1: Let v_λ *be a solution of* (5) *which lies between* v^- *and* v^+. *For* $u_\lambda = w + v_\lambda$, *there exist* $\mathfrak{U}^-$, $\mathfrak{U}_\lambda^-$, $\mathfrak{U}^+$, $\mathfrak{U}_\lambda^+$ *such that* $\mathfrak{U}^-$ *and* $\mathfrak{U}^+$ *are independent of* λ *and the following inequalities hold for sufficiently large* λ:

$$\mathfrak{U}^- < \mathfrak{U}_\lambda^- < \ln\frac{1+2s}{1-2s} < \mathfrak{U}_\lambda^+ < \mathfrak{U}^+, \quad \mathfrak{U}_\lambda^- < u_\lambda < \mathfrak{U}_\lambda^+. \tag{7}$$

Moreover, $\mathfrak{U}_\lambda^-$ *and* $\mathfrak{U}_\lambda^+$ *satisfies*

$$\Delta\mathfrak{U}_\lambda^- = (1-2s)\lambda\frac{e^{u_\lambda}}{(1+e^{u_\lambda})^3}\left(e^{\mathfrak{U}_\lambda^-} - \frac{1+2s}{1-2s}\right) + 4\pi\sum_{k=1}^{m}\delta_{q_k} \quad \text{in } \Omega, \tag{8}$$

$$\Delta\mathfrak{U}_\lambda^+ = (1-2s)\lambda\frac{e^{u_\lambda}}{(1+e^{u_\lambda})^3}\left(e^{\mathfrak{U}_\lambda^+} - \frac{1+2s}{1-2s}\right) - 4\pi\sum_{l=1}^{n}\delta_{p_l} \quad \text{in } \Omega. \tag{9}$$

Proof: Let g be a smooth function with $0 \leqslant g \leqslant 1$ satisfying

$$g(x) = \begin{cases} 1, & x \in \cup_{l=1}^{n} B(p_l, \epsilon) \cup_{k=1}^{m} B(q_k, \epsilon) \\ 0, & x \in \Omega \setminus \cup_{l=1}^{n} B(p_l, 2\epsilon) \cup_{k=1}^{m} B(q_k, 2\epsilon). \end{cases}$$

We define $\mathfrak{U}^-$ as a solution of

$$\Delta\mathfrak{U}^- = -\frac{4\pi m}{|\Omega|} + 4\pi\sum_{k=1}^{m}\delta_{q_\lambda} + \frac{1}{\epsilon^2}g - \frac{1}{\epsilon^2|\Omega|}\int_\Omega g.$$

Since $\mathfrak{U}^-$ can be determined up to constant, we may assume that

$$\mathfrak{U}^- \leqslant \ln\frac{1+2s}{1-2s} - 1.$$

Similarly, we define $\mathfrak{U}^+ \geqslant \ln(1+2s)/(1-2s) + 1$ as a solution of

$$\Delta\mathfrak{U}^+ = \frac{4\pi n}{|\Omega|} - 4\pi\sum_{l=1}^{n}\delta_{p_l} - \frac{1}{\epsilon^2}g + \frac{1}{\epsilon^2|\Omega|}\int_\Omega g.$$

If $x \in \cup_{l=1}^{n} B(p_l, \epsilon) \cup_{k=1}^{m} B(q_k, \epsilon)$, then

$$\Delta\mathfrak{U}^- \geqslant -\frac{4\pi m}{|\Omega|}+4\pi\sum_{k=1}^{m}\delta_{q_k}+\frac{1}{\epsilon^2}-\frac{4\pi(m+n)}{|\Omega|}$$

$$\geqslant \frac{1}{\epsilon^2}-\frac{8\pi(m+n)}{|\Omega|}+4\pi\sum_{k=1}^{m}\delta_{q_k}$$

$$\geqslant (1-2s)\lambda\frac{e^{u_\lambda}}{(1+e^{u_\lambda})^3}\left(e^{\mathfrak{U}^-}-\frac{1+2s}{1-2s}\right)+4\pi\sum_{k=1}^{m}\delta_{q_k}.$$

We define two constants u_*^+, u_*^- which are independent of λ as

$$u_*^+\equiv\sup\{w+v^+|x\in\Omega\backslash\bigcup_{l=1}^{n}B(p_l,\epsilon)\}<\infty,$$

$$u_*^-\equiv\inf\{w+v^-|x\in\Omega\backslash\bigcup_{k=1}^{m}B(q_k,\epsilon)\}>-\infty.$$

If $x\in\Omega\backslash\cup_{l=1}^{n}B(p_l,\epsilon)\cup_{k=1}^{m}B(q_k,\epsilon)$, then

$$\frac{e^{u_\lambda}}{(1+e^{u_\lambda})^3}\geqslant c_*=\min\left\{\frac{e^{u_*^+}}{(1+e^{u_*^+})^3},\frac{e^{u_*^-}}{(1+e^{u_*^-})^3}\right\}>0$$

and

$$\lambda\frac{e^{u_\lambda}}{(1+e^{u_\lambda})^3}\geqslant\lambda c_*\to\infty \quad \text{as} \quad \lambda\to\infty.$$

Thus

$$\Delta\mathfrak{U}^- \geqslant -\frac{4\pi m}{|\Omega|}+4\pi\sum_{k=1}^{m}\delta_{q_k}-\frac{4\pi(m+n)}{|\Omega|}$$

$$\geqslant 4\pi\sum_{k=1}^{m}\delta_{q_k}-\frac{8\pi(m+n)}{|\Omega|}$$

$$\geqslant 4\pi\sum_{k=1}^{m}\delta_{q_k}-\frac{1}{\epsilon^2}$$

$$\geqslant (1-2s)\lambda\frac{e^{u_\lambda}}{(1+e^{u_\lambda})^3}\left(e^{\mathfrak{U}^-}-\frac{1+2s}{1-2s}\right)+4\pi\sum_{k=1}^{m}\delta_{q_k}$$

for $\lambda>e/(e-1)(1+2s)c_*\epsilon^2$. This shows that $\mathfrak{U}^-$ is a subsolution of (8) which is less than $\ln(1+2s)/(1-2s)$. Since $\ln(1+2s)/(1-2s)$ is a supersolution, the standard iteration method implies the existence of a solution $\mathfrak{U}_\lambda^-$ of (8).

Similarly, we can check that $\mathfrak{U}^+$ and $\ln(1+2s)/(1-2s)$ are super- and subsolutions of (9), respectively. Since $\ln(1+2s)/(1-2s)\leqslant\mathfrak{U}^+$, we obtain the existence of a solution $\mathfrak{U}_\lambda^+$ of (9). Finally, the maximum principle implies the desired inequality (7) and this completes the proof. Q.E.D.

Remark 1: Integrating (8) *over* Ω, *we obtain*

$$(1-2s)\int_\Omega\frac{e^{u_\lambda}}{(1+e^{u_\lambda})^3}\left(e^{\mathfrak{U}_\lambda^-}-\frac{1+2s}{1-2s}\right)=-\frac{4\pi m}{\lambda}\to 0 \quad \text{as} \quad \lambda\to\infty.$$

Since $\mathfrak{U}^- < \mathfrak{U}_\lambda^- \leqslant \ln(1+2s)/(1-2s)$, *we can find a subsequence* $\{\lambda_j\}$ *such that*

$$\mathfrak{U}_{\lambda_j}^- \to \ln\frac{1+2s}{1-2s} \quad \text{a.e. as } \lambda_j \to \infty.$$

Similarly, we may assume that $\mathfrak{U}_{\lambda_j}^+ \to \ln(1+2s)/(1-2s)$ *almost everywhere as* $\lambda_j \to \infty$. *Then by lemma 1, we have*

$$u_{\lambda_j} \to \ln\frac{1+2s}{1-2s} \quad \text{a.e. as } \lambda_j \to \infty.$$

Lemma 2: Let v_λ *be as in Lemma 1. Then for any* $r_0 > 0$, *there exists a constant* $C = C(r_0)$ *such that*

$$\|v_\lambda\|_{L^\infty(\Omega)} \leqslant C\lambda^{r_0}.$$

In particular,

$$|v_\lambda(q_k)| \leqslant C\lambda^{r_0}, \quad |v_\lambda(p_l)| \leqslant C\lambda^{r_0}.$$

Proof: We may assume that $0 < r_0 < \frac{1}{2}$. Observing that the absolute value of the first term on the right-hand side of (5) is less than λ, if $r > 1$ then we have

$$\begin{aligned}
\|\Delta v_\lambda\|_{L^r(\Omega)}^r &= \int_\Omega \left| (1-2s)\lambda \frac{e^{w+v_\lambda}}{(1+e^{w+v_\lambda})^3}\left(e^{w+v_\lambda} - \frac{1+2s}{1-2s}\right) + \frac{4\pi(m-n)}{|\Omega|}\right|^r \\
&\leqslant 2^{r-1}\left[\lambda^{r-1}\int_\Omega (1-2s)\lambda \frac{e^{w+v_\lambda}}{(1+e^{w+v_\lambda})^3}\left| e^{w+v_\lambda} - \frac{1+2s}{1-2s}\right| + \left(\frac{4\pi|m-n|}{|\Omega|}\right)^r\right] \\
&\leqslant C\left[1 + \lambda^{r-1}\int_\Omega (1-2s)\lambda \frac{e^{w+v_\lambda}}{(1+e^{w+v_\lambda})^3}\left((e^{u_\lambda} - e^{\mathfrak{U}_\lambda^-}) + \left(\frac{1+2s}{1-2s} - e^{\mathfrak{U}_\lambda^-}\right)\right)\right] \\
&\leqslant C[1 + 4\pi(m+n)\lambda^{r-1}] \leqslant C\lambda^{r-1}.
\end{aligned}$$

We use the interpolation type inequality and Lemma 1 to obtain

$$\|v_\lambda\|_{L^\infty(\Omega)} \leqslant C\|v_\lambda\|_{L^1(\Omega)}^{(r-1)/(2r-1)}\|D^2 v_\lambda\|_{L^r(\Omega)}^{r/(2r-1)} \leqslant C\|\Delta v_\lambda\|_{L^r(\Omega)}^{r/(2r-1)} \leqslant C\lambda^{(r-1)/(2r-1)}.$$

Then for $r = (r_0-1)/(2r_0-1)$, we get the desired result. Q.E.D.

Modifying Tarantello's argument,[6] we have the following weak convergence results.

Lemma 3: Let $\{u_\lambda\}$ *be any sequence of solutions as in Lemma 1. Then there exists a subsequence* $\{\lambda_j\}$ *such that, as* $\lambda_j \to \infty$,
(i) $(1-2s)\lambda_j e^{u_{\lambda_j}}(e^{u_{\lambda_j}} - (1+2s)/(1-2s))/(1+e^{u_{\lambda_j}})^3 \to -4\pi\Sigma_{k=1}^m \delta_{q_k} + 4\pi\Sigma_{l=1}^n \delta_{p_l}$ *in the sense of measure,*
(ii) $u_{\lambda_j} \to \ln(1+2s)/(1-2s)$ *in* $W^{1,r}(\Omega)$, $1 < r < 2$.

Proof: We rewrite $u_\lambda - \ln(1+2s)/(1-2s)$ as a difference of two non-negative terms,

$$u_\lambda - \ln\frac{1+2s}{1-2s} = (u_\lambda - \mathfrak{U}_\lambda^-) - \left(\ln\frac{1+2s}{1-2s} - \mathfrak{U}_\lambda^-\right).$$

Subtracting (8) from (3), we have

$$\Delta(u_\lambda - \mathfrak{U}_\lambda^-) = (1-2s)\lambda\frac{e^{u_\lambda}}{(1+e^{u_\lambda})^3}(e^{u_\lambda} - e^{\mathfrak{U}_\lambda^-}) - 4\pi\sum_{l=1}^n \delta_{p_l} \equiv J_\lambda - 4\pi\sum_{l=1}^n \delta_{p_l}.$$

Since $J_\lambda \geqslant 0$ and $\|J_\lambda\|_{L^1(\Omega)} = 4\pi n$, there exist a subsequence $\{\lambda_j\}$ and a measure η such that $J_{\lambda_j} \to \eta$ in the sense of measure. By Lemma 1 we may assume that $\mathfrak{U}^{\pm}_{\lambda_j} \to \ln(1+2s)/(1-2s)$ as λ_j goes to infinity. Multiplying a smooth function φ, integrating over Ω, and taking the limit, we have

$$\int_\Omega \varphi J_{\lambda_j} \to 4\pi \sum_{l=1}^{n} \varphi(p_l) \quad \text{as} \quad \lambda_j \to \infty,$$

and thus $\eta = 4\pi \Sigma_{l=1}^{n} \delta_{p_l}$. Similarly,

$$(1-2s)\lambda_j \frac{e^{u_{\lambda_j}}}{(1+e^{u_{\lambda_j}})^3} \left(\frac{1+2s}{1-2s} - e^{\mathfrak{U}^-_{\lambda_j}} \right) \to 4\pi \sum_{k=1}^{m} \delta_{q_k}$$

in the sense of measure and (i) is proved.

Let w_1 be the unique solution of

$$\Delta w_1 = \frac{4\pi n}{|\Omega|} - 4\pi \sum_{l=1}^{n} \delta_{p_l}, \quad \int_\Omega w_1 = 0$$

and $u_{\lambda_j} - \mathfrak{U}^-_{\lambda_j} = w_1 + \mathcal{U}_{\lambda_j}$. Then $\mathcal{U}_{\lambda_j}$ satisfies

$$\Delta \mathcal{U}_{\lambda_j} = (1-2s)\lambda_j \frac{e^{u_{\lambda_j}}}{(1+e^{u_{\lambda_j}})^3} (e^{u_{\lambda_j}} - e^{\mathfrak{U}^-_{\lambda_j}}) - \frac{4\pi n}{|\Omega|}.$$

For any fixed $1 < r < 2$ and $r' = r/(r-1) > 2$,

$$\|\nabla(u_{\lambda_j} - \mathfrak{U}^-_{\lambda_j})\|^r_{L^r(\Omega)} = \int_\Omega |\nabla(w_1 + \mathcal{U}_{\lambda_j})|^r = \int_\Omega \nabla(w_1 + \mathcal{U}_{\lambda_j}) \nabla \varphi,$$

where φ is a unique solution of

$$\begin{cases} \Delta \varphi = \operatorname{div}[|\nabla(w_1 + \mathcal{U}_{\lambda_j})|^{r-2} \nabla(w_1 + \mathcal{U}_{\lambda_j})] & \text{in } \Omega \\ \int_\Omega \varphi = 0. \end{cases}$$

Using Calderon–Zygmund inequality, we have

$$\|\nabla \varphi\|_{L^{r'}(\Omega)} \leqslant C(r) \|\nabla(w_1 + \mathcal{U}_{\lambda_j})\|^{r-1}_{L^r(\Omega)}$$

and then

$$\begin{aligned} \|\nabla(w_1 + \mathcal{U}_{\lambda_j})\|_{L^r(\Omega)} = \frac{\int_\Omega \nabla(w_1 + \mathcal{U}_{\lambda_\varphi}) \nabla \varphi}{\|\nabla(w_1 + \mathcal{U}_{\lambda_j})\|^{r-1}_{L^r(\Omega)}} &\leqslant C(r) \int_\Omega \nabla(w_1 + \mathcal{U}_{\lambda_j}) \nabla \left(\frac{\varphi}{\|\nabla \varphi\|_{L^{r'}(\Omega)}} \right) \\ &\leqslant C(r) \int_\Omega \nabla(w_1 + \mathcal{U}_{\lambda_j}) \nabla \varphi_{\lambda_j}. \end{aligned} \tag{10}$$

Here φ_{λ_j} is defined by

$$\int_\Omega \nabla(w_1 + \mathcal{U}_{\lambda_j}) \nabla \varphi_{\lambda_j} = \sup \left\{ \int_\Omega \nabla(w_1 + \mathcal{U}_{\lambda_j}) \nabla \varphi \,\middle|\, \|\varphi\|_{W^{1,r'}(\Omega)} = 1, \int_\Omega \varphi = 0 \right\}.$$

Noting that $\|\varphi_{\lambda_j}\|_{W^{1,r'}(\Omega)}=1$ and $\int_\Omega \varphi_{\lambda_j}=0$, we can find $\varphi_0 \in W^{1,r'}(\Omega)$ and weakly convergent subsequence $\{\varphi_{\lambda_j}\}$, still we use the same notation, such that $\varphi_{\lambda_j}\to\varphi_0$ in $L^\infty(\Omega)$. From (10) we have

$$\begin{aligned}\frac{1}{C(r)}\|\nabla(w_1+\mathcal{U}_{\lambda_j})\|_{L^r(\Omega)} &\leqslant \int_\Omega \nabla(w_1+\mathcal{U}_{\lambda_j})\nabla\varphi_{\lambda_j}\\ &= \int_\Omega \nabla w_1\nabla\varphi_{\lambda_j}+\int_\Omega \nabla\mathcal{U}_{\lambda_j}\nabla(\varphi_{\lambda_j}-\varphi_0)+\int_\Omega \nabla\mathcal{U}_{\lambda_j}\nabla\varphi_0\\ &= -\int_\Omega \Delta w_1\varphi_{\lambda_j}-\int_\Omega \Delta\mathcal{U}_{\lambda_j}(\varphi_{\lambda_j}-\varphi_0)+\int_\Omega \nabla\mathcal{U}_{\lambda_j}\nabla\varphi_0\\ &\leqslant 4\pi\sum_{l=1}^n \varphi_{\lambda_j}(p_l)+4\pi n\|\varphi_{\lambda_j}-\varphi_0\|_{L^\infty(\Omega)}-4\pi\sum_{l=1}^n \varphi_0(p_l)+o(1).\end{aligned}$$

Here we used (i) in the last inequality. Since $\varphi_{\lambda_j}\to\varphi_0$ in $L^\infty(\Omega)$, we have that $\|\nabla(w_1+\mathcal{U}_{\lambda_j})\|_{L^r(\Omega)}\to 0$ as $\lambda_j\to\infty$. Finally, using dominated convergence theorem, $w_1+\mathcal{U}_{\lambda_j}\to 0$ in $L^r(\Omega)$ and $u_{\lambda_j}-\mathfrak{U}^-_{\lambda_j}\to 0$ in $W^{1,r}(\Omega)$.

Similarly, $\mathfrak{U}^-_{\lambda_j}-\ln(1+2s)/(1-2s)\to 0$ in $W^{1,r}(\Omega)$ and thus (ii) holds. Q.E.D.

Remark 2: From (i), for any compact subset K of $\Omega\backslash\cup_{l=1}^n\{p_l\}\cup_{k=1}^m\{q_k\}$,

$$\int_K (1-2s)\lambda_j\frac{e^{u_{\lambda_j}}}{(1+e^{u_{\lambda_j}})^3}\left(e^{u_{\lambda_j}}-\frac{1+2s}{1-2s}\right)\to 0 \quad \text{as } \lambda_j\to\infty.$$

Next, we investigate the locally uniform convergence. The arguments of the proof are due to Refs. 8 and 7.

Lemma 4: Let $\{u_\lambda\}$ *be as in Lemma 1. For any compact subset* $K\subset\Omega\backslash\cup_{l=1}^n\{p_l\}\cup_{k=1}^m\{q_k\}$, *there exists a subsequence* $\{u_{\lambda_j}\}$ *such that* $u_{\lambda_j}\to\ln(1+2s)/(1-2s)$ *uniformly on K as* $\lambda_j\to\infty$.

Proof: Let K and K' be compact subsets of Ω with $K\subset\subset K'\subset\subset\Omega\backslash\cup_{l=1}^n\{p_l\}\cup_{k=1}^m\{q_k\}$. Since $\mathfrak{U}^-_\lambda<u_\lambda<\mathfrak{U}^+_\lambda$ by Lemma 1, it suffices to show that $\mathfrak{U}^\pm_\lambda\to\ln(1+2s)/(1-2s)$ uniformly on K.

First consider the case $\mathfrak{U}^-_\lambda$. Let w_2 be the unique solution of

$$\Delta w_2=-\frac{4\pi m}{|\Omega|}+4\pi\sum_{k=1}^m \delta_{q_k},\quad \int_\Omega w_2=0. \tag{11}$$

If we set $\mathfrak{U}^-_\lambda=w_2+\mathcal{V}^-_\lambda$, then $\mathcal{V}^-_\lambda$ satisfies

$$\Delta\mathcal{V}^-_\lambda=(1-2s)\lambda\frac{e^{u_\lambda}}{(1+e^{u_\lambda})^3}\left(e^{w_2+\mathcal{V}^-_\lambda}-\frac{1+2s}{1-2s}\right)+\frac{4\pi m}{|\Omega|}. \tag{12}$$

Using Lemma 1 and interpolation type inequality (see, e.g., Ref. 8), we have

$$\|\nabla\mathcal{V}^-_\lambda\|^2_{L^\infty(K)}\leqslant C\left(\|\Delta\mathcal{V}^-_\lambda\|_{L^\infty(K')}\|\mathcal{V}^-_\lambda\|_{L^\infty(K')}+\frac{1}{\operatorname{dist}(K,\partial K')}\|\mathcal{V}^-_\lambda\|^2_{L^\infty(K')}\right)\leqslant C(K')\lambda.$$

Now suppose that $\|\mathfrak{U}^-_\lambda-\ln(1+2s)/(1-2s)\|_{L^\infty(K)}\nrightarrow 0$. Then there exists $\tilde\epsilon>0$ such that $\|\mathfrak{U}^-_{\lambda_j}-\ln(1+2s)/(1-2s)\|_{L^\infty(K)}>\tilde\epsilon$ for some subsequence $\{\lambda_j\}$. For $|x_j-x|<\operatorname{dist}(K,\partial K')$, we observe that

$$\left|\left(\mathfrak{U}_{\lambda_j}^- - \ln\frac{1+2s}{1-2s}\right)(x_j) - \left(\mathfrak{U}_{\lambda_j}^- - \ln\frac{1+2s}{1-2s}\right)(x)\right| \leqslant |w_2(x_j)-w_2(x)| + |\mathcal{V}_{\lambda_j}^-(x_j)-\mathcal{V}_{\lambda_j}^-(x)|$$
$$\leqslant \|\nabla w_2\|_{L^\infty(K')}|x_j-x| + \|\nabla \mathcal{V}_{\lambda_j}^-\|_{L^\infty(K')}|x_j-x|$$
$$\leqslant \sqrt{C(K')\lambda_j}|x_j-x|.$$

If we choose $x_j \in K$ so that $(\mathfrak{U}_{\lambda_j}^- - \ln(1+2s)/(1-2s))(x_j) < -\tilde{\epsilon}$, then

$$\left(\mathfrak{U}_{\lambda_j}^- - \ln\frac{1+2s}{1-2s}\right)(x) < -\frac{\tilde{\epsilon}}{2}$$

for $x \in B(x_j, r_j) \subset K'$ where $r_j \equiv \min\{\mathrm{dist}(K, \partial K'), \tilde{\epsilon}/2\sqrt{C(K')\lambda_j}\}$. Then for sufficiently large λ_j, we have $r_j = \tilde{\epsilon}/2\sqrt{C(K')\lambda_j}$ and

$$\int_{K'} (1-2s)\lambda_j \frac{e^{u_{\lambda_j}}}{(1+e^{u_{\lambda_j}})^3}\left(e^{\mathfrak{U}_{\lambda_j}^-} - \frac{1+2s}{1-2s}\right)$$
$$\leqslant (1-2s)\inf_{K'}\frac{e^{\mathfrak{U}^-}}{(1+e^{\mathfrak{U}^-})^3}\int_{K'}\lambda_j\left(e^{\mathfrak{U}_{\lambda_j}^-} - \frac{1+2s}{1-2s}\right)$$
$$\leqslant (1-2s)\inf_{K'}\frac{e^{\mathfrak{U}^-}}{(1+e^{\mathfrak{U}^-})^3}\inf_{K'} e^{\mathfrak{U}^-}\int_{B(x_j,r_j)}\lambda_j\left(\mathfrak{U}_{\lambda_j}^- - \ln\frac{1+2s}{1-2s}\right)$$
$$\leqslant -\frac{\tilde{\epsilon}}{2}(1-2s)\inf_{K'}\frac{e^{\mathfrak{U}^-}}{(1+e^{\mathfrak{U}^-})^3}\inf_{K'} e^{\mathfrak{U}^-}\lambda_j\pi\left(\frac{\tilde{\epsilon}}{2\sqrt{C(K')\lambda_j}}\right)^2$$
$$\leqslant -\frac{(1-2s)\pi\tilde{\epsilon}^3}{8C(K')}\inf_{K'}\frac{e^{\mathfrak{U}^-}}{(1+e^{\mathfrak{U}^-})^3}\inf_{K'} e^{\mathfrak{U}^-}.$$

On the other hand, as in the proof of Lemma 3(i), we have

$$\int_{K'}(1-2s)\lambda_j\frac{e^{u_{\lambda_j}}}{(1+e^{u_{\lambda_j}})^3}\left(e^{\mathfrak{U}_{\lambda_j}^-} - \frac{1+2s}{1-2s}\right) \to 0 \quad \text{as } \lambda_j \to \infty.$$

This is a contradiction and we obtain the uniform convergence.

The case for $\mathfrak{U}_\lambda^+$ is similar and we omit the details. Q.E.D.

To study the convergence speed, we need the following lemmas.

Lemma 5: Let $\{u_\lambda\}$ be as in Lemma 1. For any compact subset $K \subset\subset \Omega\backslash\cup_{l=1}^n\{p_l\}\cup_{k=1}^m\{q_k\}$, there exists a subsequence $\{u_{\lambda_j}\}$ such that

$$\int_K |\nabla u_{\lambda_j}|^2 \leqslant 2\int_K\left|\nabla\left(\mathfrak{U}_{\lambda_j}^- - \ln\frac{1+2s}{1-2s}\right)\right|^2 + |\nabla(u_{\lambda_j} - \mathfrak{U}_{\lambda_j}^-)|^2 \to 0 \quad \text{as } \lambda_j \to \infty.$$

Proof: Fix $K\subset\subset K'\subset\subset\Omega\backslash\cup_{l=1}^{n}\{p_l\}\cup_{k=1}^{m}\{q_k\}$ and let ζ be a smooth function with $0\leqslant\zeta\leqslant 1$, $\zeta\equiv 1$ on K and supp $\zeta\subset K'$. Multiplying $(\mathfrak{U}_\lambda^- - \ln(1+2s)/(1-2s))\zeta$ to (8) and integrating over Ω, we have

$$\begin{aligned}0&\leqslant\int_{K'}\frac{e^{u_\lambda}}{(1+e^{u_\lambda})^3}\left(e^{\mathfrak{U}_\lambda^-}-\frac{1+2s}{1-2s}\right)\left(\mathfrak{U}_\lambda^- - \ln\frac{1+2s}{1-2s}\right)\zeta\\&=\int_{K'}\left(\mathfrak{U}_\lambda^- - \ln\frac{1+2s}{1-2s}\right)\zeta\Delta\left(\mathfrak{U}_\lambda^- - \ln\frac{1+2s}{1-2s}\right)\\&=-\int_{K'}\nabla\left[\left(\mathfrak{U}_\lambda^- - \ln\frac{1+2s}{1-2s}\right)\zeta\right]\nabla\left(\mathfrak{U}_\lambda^- - \ln\frac{1+2s}{1-2s}\right).\end{aligned}$$

By Lemma 3(ii), if $1<r<2$ then there exists a subsequence $\{\lambda_j\}$ such that

$$\begin{aligned}\int_K\left|\nabla\left(\mathfrak{U}_{\lambda_j}^- - \ln\frac{1+2s}{1-2s}\right)\right|^2&\leqslant\int_{K'}\left|\nabla\left(\mathfrak{U}_{\lambda_j}^- - \ln\frac{1+2s}{1-2s}\right)\right|^2\zeta\\&\leqslant-\int_{K'}\left(\mathfrak{U}_{\lambda_j}^- - \ln\frac{1+2s}{1-2s}\right)\nabla\left(\mathfrak{U}_{\lambda_j}^- - \ln\frac{1+2s}{1-2s}\right)\nabla\zeta\\&\leqslant\left\|\mathfrak{U}_{\lambda_j}^- - \ln\frac{1+2s}{1-2s}\right\|_{L^\infty(K')}\left\|\nabla\left(\mathfrak{U}_{\lambda_j}^- - \ln\frac{1+2s}{1-2s}\right)\right\|_{L^r(K')}\|\nabla\zeta\|_{L^{r'}(K')}\to 0.\end{aligned}$$

Similarly, we obtain that $\int_K|\nabla(u_{\lambda_j}-\mathfrak{U}_{\lambda_j}^-)|^2\to 0$ as $\lambda_j\to\infty$. Q.E.D.

Lemma 6: *Let* $\{\mathfrak{U}_\lambda^\pm\}$ *be as in Lemma 1. For any compact subset* $K\subset\subset\Omega\backslash\cup_{l=1}^{n}\{p_l\}\cup_{k=1}^{m}\{q_k\}$, *there exist a subsequence* $\{\mathfrak{U}_{\lambda_j}^\pm\}$ *and a constant* $C=C(K)$ *such that*

$$\|\mathfrak{U}_{\lambda_j}^\pm\|_{W^{2,2}(K)}\leqslant C.$$

Proof: Fix $K\subset\subset K'\subset\subset\Omega\backslash\cup_{l=1}^{n}\{p_l\}\cup_{k=1}^{m}\{q_k\}$. For any $\tilde{\epsilon}>0$, we can choose $r_1<\mathrm{dist}(K,\partial K')$ sufficiently small so that $\int_{B(x,r_1)}|\nabla w_2|^2\leqslant\tilde{\epsilon}/4$ where w_2 is defined in (11) and $x\in K$. If we fix $x_0\in K$, then by Lemma 5, there exists a subsequence $\{\lambda_j\}$, still we denote $\{\lambda\}$ for simplicity, such that

$$\int_{B(x_0,r_1)}|\nabla\mathcal{V}_\lambda^-|^2\leqslant 2\int_{B(x_0,r_1)}|\nabla w_2|^2+|\nabla\mathfrak{U}_\lambda^-|^2\leqslant\tilde{\epsilon}$$

for sufficiently large λ. For $r_2<r_1/2$, we define a smooth function ζ with $0\leqslant\zeta\leqslant 1$, $\zeta\equiv 1$ on $B(x_0,r_2)$ and supp $\zeta\subset B(x_0,2r_2)$.

We now recall the identity

$$\Delta|\nabla\mathcal{V}_\lambda^-|^2=2|D^2\mathcal{V}_\lambda^-|^2+2\nabla\mathcal{V}_\lambda^-\nabla(\Delta\mathcal{V}_\lambda^-).$$

From this identity and (12) we have that, for $x\in K'$,

$$
\begin{aligned}
|D^2\mathcal{V}_\lambda^-|^2 &= \frac{1}{2}\Delta|\nabla\mathcal{V}_\lambda^-|^2 - \nabla\mathcal{V}_\lambda^-\nabla(\Delta\mathcal{V}_\lambda^-) \\
&= \frac{1}{2}\Delta|\nabla\mathcal{V}_\lambda^-|^2 - (1-2s)\lambda\frac{e^{u_\lambda}}{(1+e^{u_\lambda})^3}\left(e^{w_2+\mathcal{V}_\lambda^-} - \frac{1+2s}{1-2s}\right)\nabla\mathcal{V}_\lambda^-\nabla u_\lambda \\
&\quad -(1-2s)\lambda\frac{e^{u_\lambda}}{(1+e^{u_\lambda})^3}e^{w_2+\mathcal{V}_\lambda^-}\nabla\mathcal{V}_\lambda^-\nabla(w_2+\mathcal{V}_\lambda^-) \\
&\quad +3(1-2s)\lambda\frac{e^{u_\lambda}}{(1+e^{u_\lambda})^3}\left(e^{w_2+\mathcal{V}_\lambda^-} - \frac{1+2s}{1-2s}\right)\frac{e^{u_\lambda}}{1+e^{u_\lambda}}\nabla\mathcal{V}_\lambda^-\nabla u_\lambda \\
&\leqslant \frac{1}{2}\Delta|\nabla\mathcal{V}_\lambda^-|^2 - \nabla\mathcal{V}_\lambda^-\nabla u_\lambda\left(\Delta\mathcal{V}_\lambda^- - \frac{4\pi m}{|\Omega|}\right) \\
&\quad +(1-2s)\lambda\frac{e^{u_\lambda}}{(1+e^{u_\lambda})^3}e^{w_2+\mathcal{V}_\lambda^-}\nabla w_2\nabla(w_2+\mathcal{V}_\lambda^-) \\
&\quad +3\left(\Delta\mathcal{V}_\lambda^- - \frac{4\pi m}{|\Omega|}\right)\frac{e^{u_\lambda}}{1+e^{u_\lambda}}\nabla\mathcal{V}_\lambda^-\nabla u_\lambda \\
&\leqslant \frac{1}{2}\Delta|\nabla\mathcal{V}_\lambda^-|^2 + C(|\nabla\mathcal{V}_\lambda^-|^4 + |\nabla v_\lambda|^4 + 1) \\
&\quad +\frac{1}{2}|\Delta\mathcal{V}_\lambda^-|^2 + (1-2s)\lambda\frac{e^{u_\lambda}}{(1+e^{u_\lambda})^3}e^{w_2+\mathcal{V}_\lambda^-}\nabla w_2\nabla(w_2+\mathcal{V}_\lambda^-),
\end{aligned}
$$

where we used Young's inequality in the last inequality. Thus

$$
|D^2\mathcal{V}_\lambda^-|^2 \leqslant \Delta|\nabla\mathcal{V}_\lambda^-|^2 + C(1+|\nabla v_\lambda|^4 + |\nabla\mathcal{V}_\lambda^-|^4) + (1-2s)\lambda\frac{e^{u_\lambda}}{(1+e^{u_\lambda})^3}\nabla\left(e^{w_2+\mathcal{V}_\lambda^-} - \frac{1+2s}{1-2s}\right)\nabla w_2.
$$

Multiplying ζ^2 and integrating over Ω, we obtain

$$
\begin{aligned}
\int_\Omega |D^2\mathcal{V}_\lambda^-|^2\zeta^2 &\leqslant C\left(1 + \int_\Omega |\nabla\mathcal{V}_\lambda^-|^2\Delta\zeta^2 + \int_\Omega |\nabla v_\lambda|^4\zeta^2 + \int_\Omega |\nabla\mathcal{V}_\lambda^-|^4\zeta^2\right) \\
&\quad + \int_\Omega (1-2s)\lambda\frac{e^{u_\lambda}}{(1+e^{u_\lambda})^3}\nabla\left(e^{w_2+\mathcal{V}_\lambda^-} - \frac{1+2s}{1-2s}\right)\nabla w_2\zeta^2 \\
&\leqslant C\left(1 + \int_\Omega |\nabla\mathcal{V}_\lambda^-|^2\Delta\zeta^2 + \int_\Omega |\nabla v_\lambda|^4\zeta^2 + \int_\Omega |\nabla\mathcal{V}_\lambda^-|^4\zeta^2\right),
\end{aligned}
$$

where we used Lemma 5 and the following estimate in the last inequality:

$$
\begin{aligned}
&(1-2s)\lambda\int_\Omega \frac{e^{u_\lambda}}{(1+e^{u_\lambda})^3}\nabla\left(e^{w_2+\mathcal{V}_\lambda^-}-\frac{1+2s}{1-2s}\right)\nabla w_2\zeta^2\\
&\quad=-(1-2s)\lambda\int_\Omega \frac{e^{u_\lambda}}{(1+e^{u_\lambda})^3}\left(e^{w_2+\mathcal{V}_\lambda^-}-\frac{1+2s}{1-2s}\right)\nabla(\nabla w_2\zeta^2)\\
&\qquad-(1-2s)\lambda\int_\Omega \frac{e^{u_\lambda}}{(1+e^{u_\lambda})^3}\left(e^{w_2+\mathcal{V}_\lambda^-}-\frac{1+2s}{1-2s}\right)\frac{1-2e^{u_\lambda}}{1+e^{u_\lambda}}\nabla u_\lambda\nabla w_2\zeta^2\leqslant o(1)\\
&\qquad+\int_\Omega\left(\Delta\mathcal{V}_\lambda^- -\frac{4\pi m}{|\Omega|}\right)\zeta\frac{1-2e^{u_\lambda}}{1+e^{u_\lambda}}\nabla u_\lambda\nabla w_2\zeta\\
&\quad\leqslant o(1)+\int_\Omega|\Delta\mathcal{V}_\lambda^-\zeta||\nabla u_\lambda\nabla w_2\zeta|+\int_\Omega\frac{4\pi m}{|\Omega|}|\nabla u_\lambda\nabla w_2\zeta^2|\\
&\quad\leqslant\frac{1}{2}\int_\Omega|\Delta\mathcal{V}_\lambda^-|^2\zeta^2+C\int_{K'}|\nabla u_\lambda|^2+o(1)\leqslant\frac{1}{2}\int_\Omega|D^2\mathcal{V}_\lambda^-|^2\zeta^2+C.
\end{aligned}
$$

Similarly,

$$
\int_\Omega|D^2v_\lambda|^2\zeta^2\leqslant C\left(1+\int_\Omega|\nabla v_\lambda|^2\Delta\zeta^2+\int_\Omega|\nabla v_\lambda|^4\zeta^2\right).
$$

Again by Lemma 5 and the imbedding $W^{1,1}(\Omega)\hookrightarrow L^2(\Omega)$ applied to $|\nabla v_\lambda|^2\zeta$, we obtain

$$
\begin{aligned}
\int_\Omega|D^2v_\lambda|^2\zeta^2+|D^2\mathcal{V}_\lambda^-|^2\zeta^2&\leqslant C\left(1+\int_\Omega|\nabla v_\lambda|^4\zeta^2+|\nabla\mathcal{V}_\lambda^-|^4\zeta^2\right)\\
&\leqslant C\left(1+\int_\Omega\zeta|\nabla v_\lambda||D^2v_\lambda|+\int_\Omega\zeta|\nabla\mathcal{V}_\lambda^-||D^2\mathcal{V}_\lambda^-|\right)^2\\
&\leqslant C+\frac{1}{2}\left(\int_\Omega|D^2v_\lambda|^2\zeta^2+|D^2\mathcal{V}_\lambda^-|^2\zeta^2\right).
\end{aligned}
$$

Hence

$$
\int_{B(x_0,r_1)}|D^2v_\lambda|^2+|D^2\mathcal{V}_\lambda^-|^2\leqslant C.
$$

Since $x_0\in K$ is arbitrary and K is compact, we have $\|\mathfrak{U}_\lambda^-\|_{W^{2,2}(K)}\leqslant C$.

The other part is similar and we omit the details. Q.E.D.

Finally, we study the locally uniform convergence speed and this, combined with previous lemmas, completes the proof of Theorem 2.

Lemma 7: Let $\{u_\lambda\}$ *be as in Lemma 1. For* $K\subset\subset\Omega\backslash\cup_{l=1}^n\{p_l\}\cup_{k=1}^m\{q_k\}$, *there exist a subsequence* $\{\lambda_j\}$ *and a constant* $C=C(K)$ *such that*

$$
\left|u_{\lambda_j}-\ln\frac{1+2s}{1-2s}\right|\leqslant\frac{C}{\lambda_j}\quad in\,K.
$$

Proof: Since $\mathfrak{U}_\lambda^-<u_\lambda<\mathfrak{U}_\lambda^+$ by Lemma 1, it suffices to show $0\leqslant\ln(1+2s)/(1-2s)-\mathfrak{U}_\lambda^-\leqslant C/\lambda$. The other part is similar. Fix $K\subset\subset K'\subset\subset\Omega\backslash\cup_{l=1}^n\{p_l\}\cup_{k=1}^m\{q_k\}$. By Lemma 4, we may assume that $\mathfrak{U}_\lambda^-\geqslant\ln(1+2s)/2(1-2s)$ on K'. For any fixed $x_0\in K$ and $r_1=\frac{1}{2}\mathrm{dist}(K,\partial K')$, let ζ be a smooth function with $0\leqslant\zeta\leqslant1$, $\zeta\equiv1$ in $B(x_0,r_1)$ and $\zeta\equiv0$ outside $B(x_0,2r_1)$. Then

$$\Delta\left[\zeta^2\left(e^{\mathfrak{U}_\lambda^-}-\frac{1+2s}{1-2s}\right)\right]=\nabla\left[2\zeta\nabla\zeta\left(e^{\mathfrak{U}_\lambda^-}-\frac{1+2s}{1-2s}\right)+\zeta^2 e^{\mathfrak{U}_\lambda^-}\nabla\mathfrak{U}_\lambda^-\right]$$

$$=2\zeta\Delta\zeta\left(e^{\mathfrak{U}_\lambda^-}-\frac{1+2s}{1-2s}\right)+2|\nabla\zeta|^2\left(e^{\mathfrak{U}_\lambda^-}-\frac{1+2s}{1-2s}\right)$$

$$+2\nabla\zeta^2\nabla\mathfrak{U}_\lambda^- e^{\mathfrak{U}_\lambda^-}+\zeta^2\Delta\left(e^{\mathfrak{U}_\lambda^-}-\frac{1+2s}{1-2s}\right)$$

$$\leqslant 2\zeta|\Delta\zeta|\left(\frac{1+2s}{1-2s}-e^{\mathfrak{U}_\lambda^-}\right)+2|\nabla\zeta^2||\nabla\mathfrak{U}_\lambda^-|e^{\mathfrak{U}_\lambda^-}+\zeta^2 e^{\mathfrak{U}_\lambda^-}|\nabla\mathfrak{U}_\lambda^-|^2+\zeta^2 e^{\mathfrak{U}_\lambda^-}\Delta\mathfrak{U}_\lambda^-$$

$$\leqslant 2\zeta|\Delta\zeta|\left(\frac{1+2s}{1-2s}-e^{\mathfrak{U}_\lambda^-}\right)+2\frac{1+2s}{1-2s}|\nabla\zeta^2||\nabla\mathfrak{U}_\lambda^-|+\zeta^2 e^{\mathfrak{U}_\lambda^-}|\nabla\mathfrak{U}_\lambda^-|^2$$

$$+\zeta^2 e^{\mathfrak{U}_\lambda^-}(1-2s)\lambda\frac{e^{u_\lambda}}{(1+e^{u_\lambda})^3}\left(e^{\mathfrak{U}_\lambda^-}-\frac{1+2s}{1-2s}\right)$$

$$\leqslant 2\zeta|\Delta\zeta|\left(\frac{1+2s}{1-2s}-e^{\mathfrak{U}_\lambda^-}\right)+2\frac{1+2s}{1-2s}|\nabla\zeta^2||\nabla\mathfrak{U}_\lambda^-|+\zeta^2 e^{\mathfrak{U}_\lambda^-}|\nabla\mathfrak{U}_\lambda^-|^2$$

$$+C\lambda\zeta^2\left(e^{\mathfrak{U}_\lambda^-}-\frac{1+2s}{1-2s}\right).$$

If we set

$$\xi=\lambda\zeta^2\left(\frac{1+2s}{1-2s}-e^{\mathfrak{U}_\lambda^-}\right),$$

then

$$-\frac{1}{\lambda}\Delta\xi+C\xi\leqslant 2\zeta|\Delta\zeta|\left(\frac{1+2s}{1-2s}-e^{\mathfrak{U}_\lambda^-}\right)+2\frac{1+2s}{1-2s}|\nabla\zeta^2||\nabla\mathfrak{U}_\lambda^-|+\zeta^2 e^{\mathfrak{U}_\lambda^-}|\nabla\mathfrak{U}_\lambda^-|^2.$$

Using Young's inequality, we have

$$-\frac{1}{\lambda}\Delta\xi+C\xi\leqslant C(1+|\nabla\mathfrak{U}_\lambda^-|^2).$$

Multiplying $\xi^{r'-1}$ for $r'>2$ and integrating by parts, we obtain

$$\frac{r'-1}{\lambda}\int_\Omega\xi^{r'-2}|\nabla\xi|^2+C\int_\Omega\xi^{r'}\leqslant C\int_\Omega(1+|\nabla\mathfrak{U}_\lambda^-|^2)\xi^{r'-1}$$

$$\leqslant C\left[\int_{B(x_0,2r_1)}(1+|\nabla\mathfrak{U}_\lambda^-|^2)^{r'}\right]^{1/r'}\left(\int_{B(x_0,2r_1)}\xi^{r'}\right)^{(r'-1)/r'}$$

$$\leqslant C\left[1+\left(\int_{K'}|\nabla\mathfrak{U}_\lambda^-|^{2r'}\right)^{1/r'}\right]\|\xi\|^{r'-1}_{L^{r'}(B(x_0,2r_1))}.$$

By Lemma 6 there exists s subsequence $\{\lambda_j\}$ such that

$$\|\xi\|_{L^{r'}(B(x_0,2r_1))} \leqslant C\left[1+\left(\int_{K'}|\nabla \mathfrak{U}_{\lambda_j}^-|^{2r'}\right)^{1/r'}\right] \leqslant C.$$

Applying this to (12), we get $\|\mathcal{V}_{\lambda_j}^-\|_{W^{2,r'}(K)} \leqslant C$ for $r'>2$, and $\|\nabla \mathcal{V}_{\lambda_j}^-\|_{L^\infty(K)} \leqslant C$. Since the maximum of ξ occurs at an interior point of K', say $\tilde{x}_j$,

$$\begin{aligned}
0 &\leqslant \sup_{K\cap B(x_0,r_1)} \lambda\left(\frac{1+2s}{1-2s} - e^{\mathfrak{U}_{\lambda_j}^-}\right) \\
&= \sup_{K\cap B(x_0,r_1)} \xi \\
&\leqslant \sup_{B(x_0,2r_1)} \xi \\
&\leqslant -\frac{1}{\lambda}\Delta\xi(\tilde{x}_j) + C\xi(\tilde{x}_j) \\
&\leqslant C(1+\sup_{K'}\nabla|\mathfrak{U}_{\lambda_j}^-|^2) \leqslant C.
\end{aligned}$$

Hence

$$\sup_{K\cap B(x_0,r_1)} \lambda\left(\frac{1+2s}{1-2s} - e^{\mathfrak{U}_{\lambda_j}^-}\right) \leqslant C.$$

Since $x_0 \in K$ is arbitrary and $\mathfrak{U}^- < \mathfrak{U}_{\lambda_j}^- < \ln(1+2s)/(1-2s)$, we have

$$\left\| \ln\frac{1+2s}{1-2s} - \mathfrak{U}_{\lambda_j}^- \right\|_{L^\infty(K)} \leqslant \frac{C}{\lambda_j}.$$

Partition asymptotics from one-dimensional quantum entropy and energy currents

Miles P. Blencowe[a] and Nicholas C. Koshnick

(Received 28 June 2000; accepted for publication 18 September 2001)

We give an alternative method to that of Hardy–Ramanujan–Rademacher to derive the leading exponential term in the asymptotic approximation to the partition function $p(n,a)$, defined as the number of decompositions of a positive integer n into integer summands, with each summand appearing at most a times in a given decomposition. The derivation involves mapping to an equivalent physical problem concerning the quantum entropy and energy currents of particles flowing in a one-dimensional (1D) channel connecting thermal reservoirs, and which obey Gentile's intermediate statistics with statistical parameter a. The method is also applied to partitions associated with Haldane's fractional exclusion statistics. © *2001 American Institute of Physics.* [DOI: 10.1063/1.1416195]

A classic result in the theory of partitions is the Hardy–Ramanujan–Rademacher formula for the unrestricted partition function $p(n,\infty)$, wherein the latter, combinatoric quantity is represented as a power series whose terms involve elementary functions of n.[1–3] This series yields the following asymptotic approximation:

$$p(n,\infty)\sim \frac{1}{4\sqrt{3}n}e^{\pi\sqrt{2/3}\sqrt{n}}. \tag{1}$$

A series representing $p(n,1)$, the number of decompositions of n into distinct summands, has also been derived (see, e.g., Sec. 24.2.2 of Ref. 4), yielding the asymptotic approximation

$$p(n,1)\sim \frac{1}{4(3^{1/4})n^{3/4}}e^{\pi\sqrt{1/3}\sqrt{n}}. \tag{2}$$

And more recently,[5] Hagis used the Hardy–Ramanujan–Rademacher method to derive a power series representation of $p(n,a)$ for arbitrary $a=1,2,...$, yielding the asymptotic approximation

$$p(n,a)\sim \frac{\sqrt{12}a^{1/4}}{(1+a)^{3/4}(24n)^{3/4}}e^{\pi\sqrt{2a/[3(1+a)]}\sqrt{n}}, \tag{3}$$

where $n\gg a$. As an example, for $a=4$ the number of partitions of $n=1000$ to five significant figures is 2.4544×10^{28}, while approximation (3) gives 2.4527×10^{28}, accurate to within 0.1%.

In the present work, we give an alternative and more direct derivation of the asymptotic approximation to $\ln p(n,a)$ which, from Eq. (3), is

$$\ln p(n,a)\sim \pi\sqrt{\frac{2a}{3(1+a)}}\cdot\sqrt{n}. \tag{4}$$

The derivation begins by considering a one-dimensional (1D) quantum channel which supports particles obeying Gentile's intermediate statistics[6] characterized by statistical parameter a, the

[a]Electronic mail: miles.p.blencowe@dartmouth.edu

maximum occupation number of particles in a single particle state, with $a=1$ describing fermions and $a=\infty$ bosons. The left end of the channel is connected to a particle source and the right end to a particle sink. The channel is dispersionless so that particle packets with different mean energies have the same velocity c and hence transmission time $\tau=L/c$, where L is the channel length. Imposing periodic boundary conditions on the channel length, the single-particle energies are $\epsilon_j=hf_j=hj/\tau$, $j=1,2,...$, where h is Planck's constant. The total energy E_n of a given Fock state is $E_n=\Sigma_j \epsilon_j n_j=nh/\tau$, where $n=\Sigma_{j=1}^{\infty} jn_j$, and $n_j \leqslant a$ is the occupation number of, say, the right-propagating mode j.

We now suppose that the source emits a finite number of particles with fixed total energy E_n. The maximum possible entropy of this collection of right-propagating particles subject to the fixed energy constraint is $S(n,a)=k_B \ln p(n,a)$. Thus, the problem to determine the asymptotic approximation to $\ln p(n,a)$ is equivalent to determining the asymptotic approximation to the entropy $S(n,a)$ of the just-described physical system. (see Sec. 4 of Ref. 7, where the same setup restricted to bosons was considered in the problem to determine the optimum capacity for classical information transmission down a quantum channel.)

The crucial next step is to consider a slightly different setup, in which the particle source and sink are replaced by two thermal reservoirs described by grand canonical ensembles, with the chemical potentials of the left and right reservoirs satisfying $\mu_L=\mu_R=0$, the temperature of the right reservoir $T_R=0$, and the temperature T_L of the left reservoir chosen such that the thermal-averaged energy current flowing in the channel satisfies $\overline{\dot{E}}(T_L,a)=E_n/\tau$. (Note that the chemical potentials are set to zero since there is no constraint on the thermal-averaged particle number.) With this choice, the thermal-averaged, channel entropy current $\overline{\dot{S}}(T_L,a)$ coincides with $S(n,a)/\tau$ in the thermodynamic limit E_n(equivalently n)$\rightarrow\infty$.

The advantage with using the latter, grand canonical ensemble description as opposed to the former, microcanonical ensemble description is the greater ease with which the energy and entropy currents can be calculated. The starting formula for the single channel energy current is

$$\overline{\dot{E}}(T,a)=\sum_{j=1}^{\infty} \epsilon_j[\overline{n}_a(\epsilon_j)/L]c, \tag{5}$$

where we have dropped the subscript on T_L, and where $\overline{n}_a(\epsilon)$ is the intermediate statistics thermal-averaged occupation number of the right-moving state with energy ϵ:[6]

$$\overline{n}_a(\epsilon)=\frac{1}{e^{\beta\epsilon}-1}-+\frac{a+1}{e^{\beta\epsilon(a+1)}-1}. \tag{6}$$

In the limit $L\rightarrow\infty$ (equivalently $\tau\rightarrow\infty$), we can replace the sum with an integral over j and, changing integration variables $j\rightarrow\epsilon=(h/\tau)j=(hc/L)j$, we have [c.f. Eq. (13) of Ref. 8]:

$$\overline{\dot{E}}(T,a)=\frac{1}{h}\int_0^{\infty} \mathrm{d}\epsilon\, \epsilon \overline{n}_a(\epsilon). \tag{7}$$

A formula for entropy current can be derived as follows. First note that the thermal-averaged occupation energy $\overline{\epsilon}=\epsilon\overline{n}_a(\epsilon)$ and the entropy $\overline{s}$ for a given mode with energy ϵ are related through the first law: $\mathrm{d}\overline{s}/\mathrm{d}T=(1/T)\mathrm{d}\overline{\epsilon}/\mathrm{d}T$. Integrating with respect to temperature and then summing over the right propagating channel modes, we obtain

$$\overline{\dot{S}}(T,a)=\frac{k_B}{h}\int_0^{\infty} \mathrm{d}\epsilon\, \epsilon \int_0^{\beta} \mathrm{d}\beta' \beta' \frac{\partial \overline{n}_a}{\partial \beta'}. \tag{8}$$

The integrals are straightforwardly carried out by noting from (6) that the thermal-averaged occupation energy $\overline{\epsilon}=\epsilon\overline{n}_a(\epsilon)$ of level ϵ for statistical parameter a is just the difference in the

thermal-averaged occupation energies of levels ϵ and $\epsilon(a+1)$ for bosons. Thus, we require only the integrals for the bosonic case: $\overleftarrow{E}(T,\infty)=\pi^2(k_BT)^2/(6h)$ and $\overleftarrow{S}(T,\infty)=\pi^2k_B^2T/(3h)$, giving

$$\overleftarrow{E}(T,a)=\left(1-\frac{1}{1+a}\right)\frac{\pi^2(k_BT)^2}{6h} \tag{9}$$

and

$$\overleftarrow{S}(T,a)=\left(1-\frac{1}{1+a}\right)\frac{\pi^2k_B^2T}{3h}. \tag{10}$$

Comparing powers of T appearing in Eqs. (9) and (10), and recalling that $\overleftarrow{E}(T,a)=E_n/\tau$ and $\overleftarrow{S}(T,a)\sim S(n,a)/\tau$, we learn immediately that $\ln p(n,a)\sim C(a)\sqrt{n}$, where the n-independent factor $C(a)$ is given by

$$C(a)=\frac{\sqrt{h}\overleftarrow{S}(T,a)}{k_B\sqrt{\overleftarrow{E}(T,a)}}. \tag{11}$$

Substituting in the expressions (9) and (10) for $\overleftarrow{E}$ and $\overleftarrow{S}$, respectively, we finally obtain $C(a)=\pi\sqrt{2a/[3(1+a)]}$, in agreement with Eq. (4).

We will now carry out the same steps as above for particles obeying Haldane's fractional exclusion statistics[9] to derive the asymptotic approximation to the logarithm of yet another type of partition function, $\tilde{p}(n,g)$, which also interpolates between the unrestricted and distinct partition functions [Eqs. (1) and (2), respectively]. Following the usual conventions, the statistics parameter is denoted by $g=1/a$ (so that $g=0$ describes bosons and $g=1$ fermions). Partitions associated with exclusion statistics are subject to additional constraints as compared with partitions associated with intermediate statistics (see the following).

The energy and entropy currents for particles obeying exclusion statistics are[10,11]

$$\overleftarrow{E}(T,g)=\frac{(k_BT)^2}{h}\int_0^\infty dx\, x\overline{n_g}(x) \tag{12}$$

and

$$\overleftarrow{S}(T,g)=-\frac{k_B^2T}{h}\int_0^\infty dx\{\overline{n_g}\ln\overline{n_g}+(1-g\overline{n_g})\ln(1-g\overline{n_g})-[1+(1-g)\overline{n_g}]\ln[1+(1-g)\overline{n_g}]\}, \tag{13}$$

where $x=\beta\epsilon$ and the thermal-averaged occupation number is[12]

$$\overline{n_g}(x)=[w(x)+g]^{-1}, \tag{14}$$

with the function $w(x)$ given by the implicit equation

$$w(x)^g[1+w(x)]^{1-g}=e^x. \tag{15}$$

Again, comparing powers of T appearing in Eqs. (12) and (13), we learn immediately that $\ln\tilde{p}(n,g)\sim\tilde{C}(g)\sqrt{n}$, where the n-independent factor $\tilde{C}(g)$ is given in terms of $\overleftarrow{E}$ and $\overleftarrow{S}$ as in Eq. (11). Substituting in the expressions for $\overleftarrow{E}$ and $\overleftarrow{S}$ and performing a change of variables from x to w,[10] Eq. (11) becomes after some algebra

$$\tilde{C}(g)=\frac{s(g)}{\sqrt{e(g)}}, \tag{16}$$

where

$$e(g)=\int_{w_g(0)}^{\infty} dw\,\frac{1}{w(1+w)}[(1-g)\ln(1+w)+g\ln w] \tag{17}$$

and

$$s(g)=\int_{w_g(0)}^{\infty} dw[\ln(1+w)/w-\ln w/(w+1)]. \tag{18}$$

Using the identity $s(g)=2e(g)$, Eq. (16) can be further simplified to

$$\tilde{C}(g)=\sqrt{2s(g)}. \tag{19}$$

Let us now describe some of the properties and consequences of result (19). Integral (18) can be rewritten in terms of dilogarithms[13] and only for certain choices of lower integration limit do closed-form solutions exist. For example, from (15) we have $w_{g=0}(0)=0$ and $w_{g=1}(0)=1$ and solving the respective integrals, we obtain $s(0)=\pi^2/3$ and $s(1)=\pi^2/6$. Substituting these values into (19), we indeed obtain the arguments of the exponentials in the asymptotic approximations to the unrestricted and distinct partition functions, Eqs. (1) and (2), respectively. It is tempting to speculate that closed-form solutions to the integral $s(g)$ exist only for $g=0$, 1/2, 1/3, 1/4, and 1 in the interval [0, 1], since it is only for these rational values that Eq. (15) can be solved analytically for the lower integration limit $w_g(0)$. For $g=1/2$, we have $w_{1/2}(0)=(-1+\sqrt{5})/2$ and $s(1/2)=\pi^2/5$, so that

$$\ln\tilde{p}(n,1/2)\sim\pi\sqrt{2/5}\cdot\sqrt{n}. \tag{20}$$

Note that $\tilde{C}_{g=1/2}(=\pi\sqrt{2/5})<C_{a=2}(=2\pi/3)$, signaling the fact that $\tilde{p}(n,g)<p(n,a=1/g)$ for $0<g<1$, a consequence of additional constraints on the allowed partitions associated with Haldane's statistics. These constraints are discussed in Ref. 14. The above-mentioned, closed-form solutions for $g=0$, $g=1/2$, and 1 were obtained by solving the integral $s(g)$ numerically and then noting that the result when divided by π^2 was rational. This method does not work for the $g=1/3$, 1/4 cases, however, owing to the complicated form of the lower limits $w_{1/3}(0)$ and $w_{1/4}(0)$ (they are roots of third and fourth degree polynomial equations, respectively). A more sophisticated method is required in order to determine whether or not closed-form solutions exist for these latter two cases.

We would like to thank Peter Hagis, Jr. and George Andrews for very helpful correspondence. Discussions with Makoto Itoh and Jay Lawrence are also gratefully acknowledged.

[13] Interestingly, if the chemical potential of the left reservoir is nonzero, then the lower integration range of Eq. (18) tends to zero in the degenerate limit so that the single channel entropy current is universal, i.e., independent of the particle statistics. In general, the formulation of thermodynamical quantities in terms of polylogarithms is a powerful method for revealing equivalences between different statistical systems. See M. H. Lee, Phys. Rev. (Received 25 May 2001; accepted for publication 30 August 2001)

Recently, an analytic method was developed to study in the large N limit non-Hermitian random matrices that are drawn from a large class of circularly symmetric non-Gaussian probability distributions, thus extending the existing Gaussian non-Hermitian literature. One obtains an explicit algebraic equation for the integrated density of eigenvalues from which the Green's function and averaged density of eigenvalues could be calculated in a simple manner. Thus, that formalism may be thought of as the non-Hermitian analog of the method due to Brézin, Itzykson, Parisi, and Zuber for analyzing Hermitian non-Gaussian random matrices. A somewhat surprising result is the so called "single ring" theorem, namely, that the domain of the eigenvalue distribution in the complex plane is either a disk or an annulus. In this article we extend previous results and provide simple new explicit expressions for the radii of the eigenvalue distribution and for the value of the eigenvalue density at the edges of the eigenvalue distribution of the non-Hermitian matrix in terms of moments of the eigenvalue distribution of the associated Hermitian matrix. We then present several numerical verifications of the previously obtained analytic results for the quartic ensemble and its phase transition from a disk shaped eigenvalue distribution to an annular distribution. Finally, we demonstrate numerically the "single ring" theorem for the sextic potential, namely, the potential of lowest degree for which the "single ring" theorem has nontrivial consequences. © *2001 American Institute of Physics.* [DOI: 10.1063/1.1412599]

I. INTRODUCTION

There has been considerable interest in random non-Hermitian matrices in recent years. Possible applications range over several areas of physics.[1–4] For some recent reviews see Ref. 5. One difficulty is that the eigenvalues of non-Hermitian matrices invade the complex plane, and, consequently, various methods developed over the years to deal with random Hermitian matrices are no longer applicable, as these methods typically all involve exploiting the powerful constraints of analytic function theory. (See in particular the paper by Brézin, Itzykson, Parisi, and Zuber.[6]) In Ref. 3, two of us proposed a "method of Hermitization," whereby a problem involving random non-Hermitian matrices can be reduced to a problem involving random Hermitian matrices, to which various standard methods (such as the diagrammatic method,[7] or the "renormalization group" method[8–11]) can be applied. An idea similar to the "method of Hermitization" was expressed independently in Ref. 2.

To our knowledge, the literature on random non-Hermitian matrices[1,2] has focused exclusively on Gaussian randomness. For instance, it has been known for over 30 years, from the work of Ginibre,[12] that for the Gaussian probability distribution $P(\phi)=(1/Z)\exp(-N\mathrm{tr}\phi^\dagger\phi)$ (here, as in the rest of this article, ϕ denotes an $N\times N$ complex random matrix with the limit $N\to\infty$ understood), the density of eigenvalues of ϕ is uniformly distributed over a disk of radius 1 in the complex plane.

Analytic determination of the density of eigenvalues of a non-Gaussian probability distribution of the form

$$P(\phi)=\frac{1}{Z}e^{-N\mathrm{tr}V(\phi^\dagger\phi)}, \tag{1.1}$$

where V is an arbitrary polynomial of its argument, was given for the first time in Ref. 4. Based on the method of Hermitization, it was shown in Ref. 4 that by a simple trick, the desired density of eigenvalues could be obtained with a minimal amount of work, by judiciously exploiting the existing literature on random Hermitian matrices.

Due to the symmetry of $P(\phi)$ under the transformation $\phi\to e^{i\alpha}\phi$, the density of eigenvalues is obviously rotational invariant. It was shown in Ref. 4 that the class of probability distributions of the form (1.1) exhibits a universal behavior in the sense that whatever the polynomial V was, the shape of the eigenvalue distribution in the complex plane was always either a disk or an annulus. This result was referred to in Ref. 4 as the "single ring theorem."

In a certain sense, the formalism developed in Ref. 4 may be thought of as the analog of the work of Brézin *et al.* for random Hermitian matrices;[6] they showed how the density of eigenvalues of Hermitian matrices φ taken from the probability distribution $P(\varphi)=(1/Z)\exp[-N\mathrm{tr}V(\varphi)]$ with V an arbitrary polynomial can be determined, and not just for the Gaussian case studied by Wigner and others,[13] in which $V=(\frac{1}{2})\mathrm{tr}\varphi^2$. An important simplifying feature of the analysis in Ref. 6 is that $P(\varphi)$ depends only on the eigenvalues of φ, and not on the unitary matrix that diagonalizes it. In contrast, the probability distribution (1.1) for non-Hermitian matrices depends explicitly on the GL(N) matrix S used to diagonalize $\phi=S^{-1}\Lambda S$, and S does not decouple. Remarkably, however, for the Gaussian $P(\phi)$, Ginibre[12] managed to integrate over S explicitly and derived an explicit expression for the probability distribution of the eigenvalues of ϕ. Unfortunately, it is not clear how to integrate over S and derive the expression for the eigenvalue probability distribution for non-Gaussian distributions of the form (1.1). In Ref. 4 this difficulty was circumvented by using the method of Hermitization.

As an explicit example, the case $V(\phi^\dagger\phi)=2m^2\phi^\dagger\phi+g(\phi^\dagger\phi)^2$ was studied in detail in Ref. 4. As should perhaps be expected in advance, the following behavior in the parameter space $m^2,g>0$ was found: for m^2 positive, the eigenvalue distribution was disklike (and nonuniform), generalizing Ginibre's work, but as $m^2\equiv-\mu^2$ was made more and more negative, a phase transition at the critical value

$$\mu_c^2=\sqrt{2g}$$

occurred, after which the disk fragmented into an annulus. The density of eigenvalues was calculated in Ref. 4 in detail.

The article is organized as follows: In Sec. II we summarize the "method of hermitization."[3] We present (without derivation) the general algorithm for finding the density of eigenvalues associated with (1.1) which was developed in Ref. 4, and also add some new insight into the mechanism behind the "single ring" theorem. We then formulate a novel simple criterion on the couplings in $V(\phi^\dagger\phi)$ to decide whether the shape of the eigenvalue distribution is a disk or an annulus. Finally, we discuss some generic features of the disk-annulus phase transition. In particular, we prove that the Green's function associated with the Hermitian matrix $\phi^\dagger\phi$ (which plays an important role in the "Hermitization algorithm" just mentioned) is continuous through the disk-annulus phase transition.

In Sec. III we provide simple new expressions for the outer radius R_{out} and for the inner radius R_{in} (in the annular phase) of the eigenvalue distribution of the non-Hermitian matrix ϕ, and for the corresponding boundary values $\rho(R_{\text{out}})$ and $\rho(R_{\text{in}})$ of its eigenvalue density, in terms of the moments

$$\langle \sigma^k \rangle = \int d\sigma \sigma^k \tilde{\rho}(\sigma) \quad (k=0,\pm 1,\ldots)$$

of the eigenvalue distribution $\tilde{\rho}(\sigma)$ of the Hermitian matrix $\phi^\dagger \phi$. Thus, we find that

$$R_{\text{out}}^2 = \langle \sigma \rangle,$$

and

$$\rho(R_{\text{out}}) = \frac{2R_{\text{out}}^2}{\langle \sigma^2 \rangle - \langle \sigma \rangle^2}.$$

We see that R_{out}^2 is simply the average of σ, and the density $\rho(R_{\text{out}})$ is inversely proportional to the variance of σ.

Similarly, we find that in the annular phase,

$$\frac{1}{R_{\text{in}}^2} = \left\langle \frac{1}{\sigma} \right\rangle$$

and

$$\rho(R_{\text{in}}) = \frac{2R_{\text{in}}^{-6}}{\langle \sigma^{-2} \rangle - \langle \sigma^{-1} \rangle^2}.$$

Thus, R_{in}^{-2} is simply the σ^{-1} moment of $\tilde{\rho}(\sigma)$, and the density $\rho(R_{\text{out}})$ is inversely proportional to the variance of σ^{-1}.

In Sec. IV we verify that the explicit analytic expressions in Ref. 4 concerning the quartic ensemble $V(\phi^\dagger \phi) = 2m^2 \phi^\dagger \phi + g(\phi^\dagger \phi)^2$ are consistent with the results of Sec. III. We also compare these analytic predictions with results of Monte Carlo simulations of the quartic ensemble for various values of m^2 and g. The numerical results we obtained for the eigenvalue distribution in the disk phase and in the annular phase, as well as some quantitative features of the disk-annulus transition, are in good agreement with the analytic predictions in Ref. 4.

The ''single ring theorem'' may seem surprising at first sight. Our explanation of why the single ring theorem is not that surprising rests upon the simple argument that fragmentation of the eigenvalue distribution of $\phi^\dagger \phi$ into several disjoint segments does not necessarily imply that the eigenvalues of ϕ trace out annuli obtained, loosely speaking, by revolving the segments of the eigenvalue distribution of $\phi^\dagger \phi$ into the complex plane (see the discussion in Sec. II). In Sec. V we carry a numerical check of the ''single ring'' theorem for the sextic potential $V(\phi^\dagger \phi) = m^2 \phi^\dagger \phi + (\lambda/2)(\phi^\dagger \phi)^2 + (g/3)(\phi^\dagger \phi)^3$, which is the potential of lowest degree for which the eigenvalues of $\phi^\dagger \phi$ may split into more than a single segment (in this case, two segments at the most). We generated numerically an ensemble in which the spectrum of $\phi^\dagger \phi$ is split into two separated segments, yet we found that the spectrum of ϕ is a disk, and not a configuration of a disk encircled by a concentric annulus, as one would perhaps naively expect by rotating the two-segment spectrum of $\phi^\dagger \phi$ in the complex plane.

In the Appendix we briefly review the multi-cut phase structure of matrix ensembles with generic $V(\phi^\dagger \phi)$, and then specialize to the phase structure of the sextic potential ensemble.

II. THE METHOD OF HERMITIZATION AND NON-GAUSSIAN ENSEMBLES

Here we very briefly summarize the "method of Hermitization" [3,4] in the form of an algorithm, followed by a general discussion of the phase structure of the eigenvalue distribution.

Let us first introduce some notations and definitions. The averaged density of eigenvalues

$$\rho(x,y)=\left\langle \frac{1}{N}\sum_i \delta(x-\mathrm{Re}\,\lambda_i)\,\delta(y-\mathrm{Im}\,\lambda_i)\right\rangle \tag{2.1}$$

of the non-Hermitian matrix ϕ may be determined from the the Green's function associated with ϕ, namely,

$$G(z,z^*)=\left\langle \frac{1}{N}\mathrm{tr}\,\frac{1}{z-\phi}\right\rangle=\int d^2x'\,\frac{\rho(x',y')}{z-z'}, \tag{2.2}$$

in terms of which[14]

$$\rho(x,y)=\frac{1}{\pi}\partial^*\,G(z,z^*). \tag{2.3}$$

The probability distributions (1.1) studied in this article are invariant under $\phi\to e^{i\alpha}\phi$, rendering

$$\rho(x,y)\equiv\rho(r)/2\pi \tag{2.4}$$

circularly invariant. Rotational invariance thus leads to a simpler form of the defining formula (2.2) for $G(z,z^*)$ which reads

$$\gamma(r)\equiv zG(z,z^*)=\int_0^r r'dr'\,\rho(r'), \tag{2.5}$$

and thus

$$\rho(r)=\frac{1}{r}\,\frac{d\gamma}{dr}. \tag{2.6}$$

Clearly, the quantity $\gamma(r)$, which can be thought of as the integrated eigenvalue density, is a positive monotonically increasing function, which satisfies the obvious "sum-rules"

$$\gamma(0)=0 \quad \text{and} \quad \gamma(\infty)=1. \tag{2.7}$$

In particular, observe that the first condition in (2.7) insures that no $\delta(x)\,\delta(y)$ spike arises in $\rho(x,y)$ when calculating it from (2.3) with $G(z,z^*)$ given by (2.5), as it should be.

It was shown in Ref. 4 that by applying a simple trick, the desired Green's function of a non-Hermitian random matrix ϕ could be obtained with a minimal amount of work, by judiciously exploiting the existing literature on random Hermitian matrices. The algorithm, according to Ref. 4, for finding the Green's function and the averaged eigenvalue density of a non-Hermitian random matrix ϕ drawn from a non-Gaussian ensemble $P(\phi)=(1/Z)e^{-N\mathrm{tr}V(\phi^\dagger\phi)}$ [Eq. (1.1)] is as follows:

Start with the Green's function

$$F(w)=\left\langle \frac{1}{N}\mathrm{tr}_{(N)}\frac{1}{w-\phi^\dagger\phi}\right\rangle\equiv\int_0^\infty\frac{\tilde\rho(\sigma)d\sigma}{w-\sigma}, \tag{2.8}$$

where

$$\tilde{\rho}(\mu)=\frac{1}{N}\langle \mathrm{tr}_{(N)}\,\delta(\mu-\phi^\dagger\phi)\rangle \tag{2.9}$$

is the averaged eigenvalue density of $\phi^\dagger\phi$. [Of course, $F(w)$ is already known in the literature on chiral and rectangular block random Hermitian matrices for the Gaussian distribution,[11,15–17] as well as for non-Gaussian probability distributions of the form (1.1) with an arbitrary polynomial potential $V(\phi^\dagger\phi)$.[18–20]] Then, the desired equation for $\gamma(r)\equiv zG(z,z^*)$ is

$$\gamma\left[r^2F\left(\frac{\gamma r^2}{\gamma-1}\right)-\gamma+1\right]=0. \tag{2.10}$$

Thus, given F one can solve for $\gamma(r)$ using this master equation.

Equation (2.10) is an algebraic equation for $\gamma(r)$ and thus may have several r dependent solutions. In constructing the actual $\gamma(r)$ one may have to match these solutions smoothly into a single function which increases monotonically from $\gamma(0)=0$ to $\gamma(\infty)=1$. An explicit nontrivial example of such a procedure is the construction of $\gamma(r)$ in the disk phase of the quartic ensemble.[4]

A remarkable property of (2.10) is that it has only two r-independent solutions: $\gamma=0$ and $\gamma=1$.[4] Since the actual $\gamma(r)$ increases monotonically from $\gamma(0)=0$ to $\gamma(\infty)=1$, we immediately conclude from this observation that there can be no more than a single void in the eigenvalue distribution. Thus, in the class of models governed by $P(\phi)=(1/Z)\,e^{-N\mathrm{tr}V(\phi^\dagger\phi)}$ [Eq. (1.1)], the shape of the eigenvalue distribution is either a disk or an annulus, whatever polynomial the potential $V(\phi^\dagger\phi)$ is. This result is the ''single ring theorem'' of Ref. 4.

The ''single ring theorem'' may appear counter-intuitive at first sight. Indeed, consider a potential $V(\phi^\dagger\phi)$ with several wells or minima. For deep enough wells, we expect the eigenvalues of $\phi^\dagger\phi$ to ''fall into the wells.'' Thus, one might suppose that the eigenvalue distribution of ϕ to be bounded by a set of concentric circles of radii $0\leqslant r_1<r_2<\cdots<r_{n_{\max}}$, separating annular regions on which $\rho(r)>0$ from voids (annuli in which $\rho(r)=0$.) *A priori*, it is natural to assume that the maximal number of such circular boundaries should grow with the degree of V, because V may then have many deep minima. Remarkably, however, according to the ''single ring theorem'' the number of these boundaries is two at the most.

To reconcile this conclusion with the *a priori* expectation just mentioned, note that while the eigenvalues of the Hermitian matrix $\phi^\dagger\phi$ may split into several disjoint segments along the positive real axis, this does not necessarily constrain the eigenvalues of ϕ itself to condense into annuli. Indeed, the Hermitian matrix $\phi^\dagger\phi$ can always be diagonalized $\phi^\dagger\phi=U^\dagger\Lambda^2U$ by a unitary matrix U, with $\Lambda^2=\mathrm{diag}(\lambda_1^2,\lambda_2^2,...,\lambda_N^2)$, where the λ_i are all real. This implies that $\phi=V^\dagger\Lambda U$, with V a unitary matrix as well. Thus, the complex eigenvalues of ϕ are given by the roots of $\det(z-\Lambda W)=0$, with $W=UV^\dagger$. Evidently, as W ranges over $U(N)$ (which is what we expect to happen in the generic case), the eigenvalues of ΛW could be smeared (in the sense that they would not span narrow annuli around the circles $|z|=|\lambda_i|$.)

The last argument in favor of the ''single ring theorem'' clearly breaks down when W fails to range over $U(N)$, which occurs when the unitary matrices U and V are correlated. For example, ϕ may be such that $W=UV^\dagger$ is block diagonal, with the upper diagonal block being a $K\times K$ unitary diagonal matrix $\mathrm{diag}(e^{i\omega_1},...,e^{i\omega_K})$ (and with K a finite fraction of N). In the extreme case $K=N$, in which W is completely diagonal, $W\equiv e^{i\omega}=\mathrm{diag}(e^{i\omega_1},...,e^{i\omega_N})$, we see that $\phi=U^\dagger e^{i\omega}\Lambda U$ is a *normal* matrix (i.e., $[\phi,\phi^\dagger]=0$), with eigenvalues $\mathrm{diag}(e^{i\omega_1}\lambda_1,...,e^{i\omega_N}\lambda_N)$. Thus, normal matrices, or partially normal matrices (i.e., the case $K<N$), evade the ''single ring'' theorem: if the first K eigenvalues $\lambda_1^2,\lambda_2^2,\ldots,\lambda_K^2$ of $\phi^\dagger\phi$ split into several disjoint segments along the positive real axis, the corresponding eigenvalues of ϕ will split into concentric annuli in the complex plane obtained by revolving those λ-segments.

As a concrete demonstration of the latter qualitative discussion consider (1.1) with ϕ a normal matrix. According to the previous paragraph, we may diagonalize our normal matrix as ϕ

$=U^{\dagger}ZU$ with complex eigenvalues $Z=\mathrm{diag}(z_1,...,z_N)$, and U a unitary matrix. Thus, ϕ may be considered as a Hermitian matrix whose eigenvalues were continued into the complex plane. Thus, the partition function associated with (1.1) for ϕ normal,[21]

$$Z=\int \prod_{k=1}^{N} d^2z_k \prod_{i<j} |z_i-z_j|^2 \exp -N\sum_i V(|z_i|^2), \tag{2.11}$$

is a trivial generalization of the partition function of Hermitian matrices, where the complex eigenvalues form a two dimensional Dyson gas. It is expressed purely in terms of the complex eigenvalues z_i, contrary to ensembles of complex matrices (1.1) with a generic potential V. [With the exception, of course, of Ginibre's ensemble $V\sim\phi^{\dagger}\phi$,[12] for which the diagonalizing $GL(N)$ matrix can be integrated out explicitly, yielding (2.11).] Clearly, if $V(|z|^2)$ had several well separated and deep minima, the z_i would fall into them, and in principle produce an arbitrary number of eigenvalue rings, depending on V. Thus, normal matrices evade the single ring theorem.

Normal, or partially normal matrices, are, of course, extremely rare in the ensembles of non-Hermitian matrices, studied in this article, and do not affect the "single ring" behavior of the bulk of matrices in the ensemble.

We end this section by showing how simple features of $F(w)$ indicate whether the domain of the eigenvalue distribution is a disk or an annulus. As is well known,[11,19,20] for V a polynomial of degree p, the Green's function $F(w)$ is given by

$$F(w)=\tfrac{1}{2}V'(w)-P(w)\sqrt{(w-a)(w-b)}, \tag{2.12}$$

where

$$P(w)=\sum_{k=-1}^{p-2} c_k w^k. \tag{2.13}$$

(Here we assume for simplicity that the eigenvalues of $\phi^{\dagger}\phi$ condense into a single segment $[a,b]$. Discussion of condensation of $\phi^{\dagger}\phi$ eigenvalues into more segments appears in the Appendix.) The real constants $0\leqslant a<b$ and c_k are then determined completely by the requirement that $F(w)\to 1/w$ as w tends to infinity, and by the condition that $F(w)$ has at most an integrable singularity as $w\to 0$. Thus, if $a>0$, inevitably $c_{-1}=0$. However, if $a=0$, then c_{-1} will be determined by the asymptotic behavior for w large.

According to the "single ring" theorem,[4] the eigenvalue distribution of ϕ is either a disk or an annulus. The behavior of $F(w)$ as $w\sim 0$ turns out to be an indicator as to which phase of the two the system is in, as we now show:

A. Disk phase

In the disk phase we expect that $\rho(0)>0$, as in Ginibre's case. Thus, from (2.6) $\rho(r)=(1/r)(d\gamma/dr)\equiv 2(d\gamma/dr^2)$ and from the first sum rule $\gamma(0)=0$ in (2.7) we conclude that

$$\gamma(r)\sim \tfrac{1}{2}\rho(0)r^2 \tag{2.14}$$

near $r=0$. Therefore, for r small, (2.10) yields

$$F\left(-\frac{\rho(0)r^4}{2}+\cdots\right)\sim -\frac{1}{r^2}, \tag{2.15}$$

namely, $F(w)\sim 1/\sqrt{w}$ for $w\sim 0$, as we could have anticipated from Ginibre's case.[22] This means that in the disk phase we must set $a=0$ in (2.12). Consequently, in the disk phase c_{-1} does not vanish. We can do even better: paying attention to the coefficients in (2.12) and (2.13) (with $a=0$) we immediately obtain from (2.15) that

$$c_{-1}=\sqrt{\frac{\rho(0)}{2b}}. \tag{2.16}$$

B. Annular phase

In the annular phase $\gamma(r)$ must clearly vanish identically in the inner void of the annulus. Thus, (2.10) implies that $F(w)$ cannot have a pole at $w=0$, and therefore from (2.12) we must have $c_{-1}\sqrt{ab}=0$. Thus, the annulus must arise for $c_{-1}=0$ (the other possible solution $a=0$, $c_{-1}\neq 0$ leads to a disk configuration with $\gamma=0$ only at $r=0$, as we just discussed.)

Thus, to summarize, in the disk phase F has the form

$$F_{\text{disk}}(w)=\frac{1}{2}V'(w)-\left(\sqrt{\frac{\rho(0)}{2b}}w^{-1}+c_0+c_1 w+\cdots+c_{p-2}w^{p-2}\right)\sqrt{w(w-b)}, \tag{2.17}$$

while in the annular phase it has the form

$$F_{\text{annulus}}(w)=\tfrac{1}{2}V'(w)-(c_0+c_1 w+\cdots+c_{p-2}w^{p-2})\sqrt{(w-a)(w-b)}. \tag{2.18}$$

Having determined $F(w)$ in this way, i.e., having determined the various unknown parameters in (2.17) or in (2.18), we substitute it into (2.10) and find $G(z,z^*)$. We can thus calculate the density of eigenvalues $\rho(r)$ explicitly for an arbitrary V.

We now turn to the disk-annulus phase transition. An important feature of this transition is that $F(w)$ is continuous through it. To see this we argue as follows: By tuning the couplings in V, we can induce a phase transition from the disk phase into the annular phase, or vice versa. Note, of course, that we can parametrize any point in the disk phase either by the set of couplings in V or by the set of parameters $\{c_{-1},c_0,\ldots,c_{p-2};b\}$ in (2.17). The "coordinate transformation" between these two sets of parameters is encoded in the asymptotic behavior of $F(w)$. Similarly, we can parametrize any point in the annular phase either by the set of couplings in V or by the set of parameters $\{c_0,c_1,\ldots,c_{p-2};a,b\}$ in (2.18). Due to the one-to-one relation (in a given phase, once we have established it is the stable one) between the couplings in V and the parameters in $F(w)-\frac{1}{2}V'(w)$ [namely, the c_n's and the locations of the branch points of $F(w)$], we can describe the disk-annulus transition in terms of the latter parameters (instead of the couplings in V). Clearly, the transition point is reached from the disk phase when $\rho(0)=0$, that is, when c_{-1} in (2.17) vanishes:

$$c_{-1}^{\text{crit}}=0. \tag{2.19}$$

Similarly, the transition point is reached from the annular phase when the lower branch point a in (2.18) vanishes. Thus, e.g., in a transition from the disk phase into the annular phase, $F_{\text{disk}}(w)$ in (2.17) would cross-over continuously into $F_{\text{annulus}}(w)$ in (2.18) through a critical form

$$F_{\text{crit}}(w)=\tfrac{1}{2}V'_{\text{crit}}(w)-(c_0^{\text{crit}}+c_1^{\text{crit}}w+\cdots+c_{p-2}^{\text{crit}}w^{p-2})\sqrt{w(w-b^{\text{crit}})}. \tag{2.20}$$

The continuity of $F(w)$ through the transition was demonstrated explicitly in Ref. 4 for the quartic ensemble $V(\phi^\dagger\phi)=2m^2\phi^\dagger\phi+g(\phi^\dagger\phi)^2$ (see also Sec. IV).

This discussion obviously generalizes to cases when $F(w)$ has multiple cuts, which correspond to condensation of the eigenvalues of $\phi^\dagger\phi$ into many segments. If $w=0$ is a branch point of $F(w)$, that is, if the lowest cut extends to the origin, we are in the disk phase,

$$F_{\text{disk}}(w)=\tfrac{1}{2}V'(w)-(c_{-1}w^{-1}+c_0+c_1 w+\cdots+c_{p-2}w^{p-2})\sqrt{w(w-b_1)\cdots(w-b_n)}, \tag{2.21}$$

with $0<b_1<\cdots<b_n$. The relation (2.16) then generalizes to

$$c_{-1}=\sqrt{\frac{\rho(0)}{2(-1)^{n+1}\Pi_{k=1}^{n}b_k}}. \tag{2.22}$$

Since c_{-1} must be real we conclude that such a configuration exists only for n odd.

If the lowest branch point in $F(w)$ is positive, we are in the annular phase with

$$F_{\text{annulus}}(w)=\tfrac{1}{2}V'(w)-(c_0+c_1 w+\cdots+c_{p-2}w^{p-2})\sqrt{(w-a)(w-b_1)\cdots(w-b_n)}. \tag{2.23}$$

The phase transition would occur when the couplings in $V(\phi^\dagger\phi)$ are tuned such that $F_{\text{disk}}(w)$ and $F_{\text{annulus}}(w)$ match continuously, as was described in the previous paragraph.

III. BOUNDARIES AND BOUNDARY VALUES

Remarkably, with a minimal amount of effort, and based on the mere definition of $F(w)$ [Eq. (2.8), which we repeat here for convenience],

$$F(w)=\left\langle \frac{1}{N}\,\mathrm{tr}_{(N)}\frac{1}{w-\phi^\dagger\phi}\right\rangle \equiv \int_0^\infty \frac{\tilde{\rho}(\sigma)d\sigma}{w-\sigma}, \tag{3.1}$$

we are able to derive simple expressions for the location of the boundaries of the eigenvalue distribution and also for the boundary values of $\rho(r)$ in terms of the moments of $\tilde{\rho}(\sigma)$, which, we remind the reader, is the density of eigenvalues for a Hermitian matrix problem.

To this end it is useful to rewrite our master formula (2.10) for $\gamma(r)$ as

$$wF(w)=\gamma \tag{3.2}$$

with

$$w=\frac{\gamma r^2}{\gamma-1}. \tag{3.3}$$

We start with the outer edge $r=R_{\text{out}}$ (either in the disk phase or in the annular phase.) Near the outer edge $\gamma\to 1-$, and thus $w\to-\infty$. We therefore expand $F(w)$ in powers of $1/w$ and obtain from (3.1)–(3.3)

$$\frac{\langle\sigma\rangle}{r^2}+\frac{\gamma-1}{\gamma r^4}\langle\sigma^2\rangle+\frac{(\gamma-1)^2}{\gamma^2 r^6}\langle\sigma^3\rangle+\cdots=\gamma, \tag{3.4}$$

where

$$\langle\sigma^k\rangle=\int_0^\infty \tilde{\rho}(\sigma)\sigma^k d\sigma \tag{3.5}$$

are the moments of $\tilde{\rho}(\sigma)$ (which is of course normalized to 1). For the class of models we are interested in here, all the moments $\langle\sigma^k\rangle$, $k\geqslant 0$ are clearly finite. [$\tilde{\rho}(\sigma)\equiv(1/\pi)\mathrm{Im}\,F(\sigma-i\epsilon)$ is supported along a finite segment (or segments), and its singularity at $\sigma=0$ is no worse than $\sigma^{-1/2}$.] Thus, at the outer edge $r=R_{\text{out}}$ [where of course $\gamma(R_{\text{out}})=1$], all terms with $\langle\sigma^k\rangle$, $k\geqslant 2$, drop out of (3.4) and we obtain

$$R_{\text{out}}^2=\langle\sigma\rangle. \tag{3.6}$$

Namely, R_{out}^2 is simply the first moment of $\tilde{\rho}(\sigma)$.

We now calculate the boundary value $\rho(R_{\text{out}})$. Approaching R_{out} from the inside, we substitute $\gamma=1-f$ and $r^2=R_{\text{out}}^2(1-\delta)$ (with $f,\delta\ll 1$) in (3.4). After some work we obtain $f=\langle\sigma\rangle^2/[\langle\sigma^2\rangle-\langle\sigma\rangle^2]\,\delta+\mathcal{O}(\delta^2)$, namely,

$$\gamma=1-\frac{\langle\sigma\rangle^2}{\langle\sigma^2\rangle-\langle\sigma\rangle^2}\,\delta+\mathcal{O}(\delta^2). \tag{3.7}$$

Thus, from $\rho(r)=2(d\gamma/dr^2)$ [Eq. (2.6)] and (3.6) we find

$$\rho(R_{\text{out}})=\frac{2R_{\text{out}}^2}{\langle\sigma^2\rangle-\langle\sigma\rangle^2}. \tag{3.8}$$

The density $\rho(R_{\text{out}})$ is inversely proportional to the variance of σ!

For the $\tilde{\rho}(\sigma)$ under consideration here, $\langle\sigma^2\rangle$, and consequently $\rho(R_{\text{out}})$, are always finite. Outside the boundary $\rho(r)$ vanishes identically, of course, and, thus, $\rho(r)$ always "falls off a cliff" at the boundary, for all probability distributions of the form (1.1) with V polynomial. It would be thus interesting to study circularly invariant matrix ensembles $P(\phi^\dagger\phi)$ such that the eigenvalue distribution $\tilde{\rho}(\sigma)$ of $\phi^\dagger\phi$ has a finite $\langle\sigma\rangle$ but an infinite $\langle\sigma^2\rangle$. Then $\rho(R_{\text{out}})$ would vanish. This would naturally raise the question whether in such situations, $\rho(r)$ behaves universally near the edge [that is, if near the edge it vanishes like $(R_{\text{out}}-r)^\epsilon$ with ϵ being some universal exponent]. We do not pursue this question further in this article.

We now turn to the annular phase, and focus on the inner edge $r=R_{\text{in}}$ of the annulus. According to the discussion at the end of Sec. II [see Eq. (2.18) and the discussion preceding it], $a>0$ in (2.12), and thus $F(w)$ is analytic in the domain $|w|<a$. Expanding (3.1) in powers of w, we obtain from (3.2)

$$\frac{1-\gamma}{r^2}-\left\langle\frac{1}{\sigma}\right\rangle=w\left\langle\frac{1}{\sigma^2}\right\rangle+w^2\left\langle\frac{1}{\sigma^3}\right\rangle+\cdots. \tag{3.9}$$

A little above the inner radius, into the annulus, clearly $\gamma\to 0$ and $w\to 0-$ in (3.3). Thus, setting $w=0$ in (3.9) we obtain

$$\frac{1}{R_{\text{in}}^2}=\left\langle\frac{1}{\sigma}\right\rangle. \tag{3.10}$$

R_{in}^{-2} is simply the σ^{-1} moment of $\tilde{\rho}(\sigma)$.

We can now calculate the boundary value $\rho(R_{\text{in}})$. Near the inner edge we parametrize $r^2=R_{\text{in}}^2(1+\delta)$ with $\delta\ll 1$ (and of course, $\gamma\ll 1$ to begin with). Since $\tilde{\rho}(\sigma)$ obviously vanishes for $\sigma<a$, all moments $\langle\sigma^{-k}\rangle$ in (3.9) are finite. Thus, dropping all terms with $\langle\sigma^{-k}\rangle$, $k\geqslant 3$, in (3.9), we obtain after some work

$$\gamma=R_{\text{in}}^{-4}\frac{\delta}{\langle\sigma^{-2}\rangle-\langle\sigma^{-1}\rangle^2}+\mathcal{O}(\delta^2). \tag{3.11}$$

It then follows from (2.6) and (3.10) that

$$\rho(R_{\text{in}})=\frac{2R_{\text{in}}^{-6}}{\langle\sigma^{-2}\rangle-\langle\sigma^{-1}\rangle^2}. \tag{3.12}$$

The density $\rho(R_{\text{out}})$ is inversely proportional to the variance of σ^{-1}.

From (2.12) [or (2.18)] we learn that in the annular phase $\tilde{\rho}_{\text{annulus}}(\sigma)\equiv(1/\pi)\text{Im}F(\sigma-i\epsilon)$ $=\text{polynomial}(\sigma)\sqrt{(\sigma-a)(b-\sigma)}$, $0<a<\sigma<b$ (and vanishes elsewhere.) Thus, $\langle 1/\sigma^k\rangle$ $\equiv\int_a^b(\tilde{\rho}(\sigma)/\sigma^k)d\sigma$, $k=1,2$, are finite. Therefore, $\rho_{\text{annulus}}(r)$ jumps from zero (in the inner void of

the annulus) to a finite value at the inner edge $R_{\rm in}$. Note, however, that when $a\to 0$, that is, in the annular to disk transition, $\langle 1/\sigma\rangle$ remains finite, but $\langle 1/\sigma^2\rangle$ diverges like $1/\sqrt{a}$. [For a particular example, see Eq. (4.18).] Thus, from (3.10) we see that $R_{\rm inner}(a=0)$, the *critical* inner radius, is finite. The annulus starts up with a finite inner radius. Also, in this limit, we see from (3.12) that $\rho(R_{\rm in})$ vanishes like $\sqrt{a}$. As we approach the annulus-disk transition, the discontinuity in $\rho(r)$ at the (finite) inner edge disappears.

We saw at the end of Sec. II [see Eqs. (2.17)–(2.20)] that $F(w)$ is continuous through the disk-annulus phase transition. Thus, our master formula $wF(w)=\gamma$ to determine $\gamma(r)$ [Eq. (3.2)] is also continuous through the transition. Consequently, $\rho(r)=(1/r)(d\gamma/dr)$ must remain continuous through the disk-annulus transition, and has (at the transition) the universal behavior described in the previous paragraph.

IV. PHASE TRANSITIONS IN THE QUARTIC ENSEMBLE

The disk-annulus transition in the quartic ensemble

$$V(\phi^\dagger\phi)=2m^2\phi^\dagger\phi+g(\phi^\dagger\phi)^2 \tag{4.1}$$

was studied in detail in Ref. 4. The annular eigenvalue distribution $\rho_{\rm annular}(r)$ and the disk eigenvalue distribution $\rho_{\rm disk}(r)$ for this ensemble were calculated explicitly in Ref. 4. According to the expressions given in Ref. 4, as the critical point is approached from the annular phase, $\rho_{\rm annular}(r)$ behaves precisely as described in the paragraph following Eq. (3.12) at the end of the previous section [see also Eq. (4.13), at $\mu=\mu_c$.] Also according to Ref. 4, as the critical point is approached from the disk phase, $\rho_{\rm disk}(r)$ gets completely depleted inside a region of radius $R_{\rm in}(\mu_c)$ [remaining continuous at $r=R_{\rm in}(\mu_c)$]. [See Eq. (4.20).] Thus, $\rho(r)$ for the quartic ensemble is continuous through the disk-annulus transition.

In this section we verify the expressions (3.6), (3.8), (3.10) and (3.12) for $R_{\rm out}$, $\rho(R_{\rm out})$, $R_{\rm in}$ and $\rho(R_{\rm in})$ for the quartic ensemble (4.1) against the explicit expressions for these quantities given in Ref. 4, and also provide ample numerical results concerning the disk phase, the annular phase, and the transition between them, in support of the analytical results. In what follows we have omitted many technical details that can be found in Ref. 4.

A. The disk phase

For $m^2>-\sqrt{2g}$ the density of eigenvalues is a disk. According to Ref. 4 we have

$$F(w)=m^2+gw-\left(\frac{c}{w}+g\right)\sqrt{w(w-b)} \tag{4.2}$$

with

$$c=\frac{2m^2+\sqrt{m^4+6g}}{3}\quad\text{and}\quad b=\frac{-2m^2+2\sqrt{m^4+6g}}{3g}. \tag{4.3}$$

According to Eqs. (5.8) and (5.9) in Ref. 4, the eigenvalue density in this phase is

$$\rho_{\rm disk}(r)=2m^2+4gr^2+2\left[\,\mathrm{sgn}\left(\frac{b}{4}-r^2\right)\right]\frac{bc^2-(m^2+2gr^2)[1+2(m^2r^2+gr^4)]}{\sqrt{[1+2(m^2r^2+gr^4)]^2-4bc^2r^2}} \tag{4.4}$$

inside a disk of radius $R_{\rm out}$, where

$$R_{\rm out}^2=\frac{bc^2-2m^2}{2g}=\frac{(m^4+6g)^{3/2}-m^2(m^4+9g)}{27g^2}. \tag{4.5}$$

Thus, from (4.4) and (4.5) we have[23]

$$\rho_{\rm disk}(R_{\rm out})=\frac{4g(bc^2-2m^2)}{2g-bc^2(bc^2-2m^2)}=\frac{4gR_{\rm out}^2}{1-2R_{\rm out}^2(gR_{\rm out}^2+m^2)}. \tag{4.6}$$

These results should be compared with the predictions of Sec. III. From (4.2) we can read-off the density of eigenvalues $\tilde{\rho}(\sigma)=(1/\pi)\mathrm{Im}\,F(\sigma-i\epsilon)$ of $\phi^\dagger\phi$ as

$$\tilde{\rho}(\sigma)=\frac{1}{\pi}\left(\frac{c}{\sigma}+g\right)\sqrt{\sigma(b-\sigma)} \tag{4.7}$$

for $0\leqslant\sigma\leqslant b$, and zero elsewhere. We can readily check that (4.7) is properly normalized to 1.

The first two moments of (4.7) are

$$\langle\sigma\rangle=\frac{1}{2}\left(\frac{b}{2}\right)^2\left(c+\frac{gb}{2}\right)=\frac{(m^4+6g)^{3/2}-m^2(m^4+9g)}{27g^2}, \tag{4.8}$$

and

$$\langle\sigma^2\rangle=\frac{1}{8}\left(\frac{b}{2}\right)^4\left(\frac{8c}{b}+5g\right)=\frac{27g^2+18gm^4+2m^8-2m^2(6g+m^4)^{3/2}}{54g^3}. \tag{4.9}$$

Thus,

$$\begin{aligned}\langle\sigma^2\rangle-\langle\sigma\rangle^2&=-\frac{b^3}{256}[4bc^2+bg(b^2g-10)+4c(b^2g-4)]\\&=\frac{297g^3+108g^2m^4-18gm^8-4m^{12}-2m^2(9g-2m^4)(6g+m^4)^{3/2}}{1458g^4}.\end{aligned} \tag{4.10}$$

Comparing (4.5) and (4.8) we immediately verify (3.6), $R_{\rm out}^2=\langle\sigma\rangle$. After some additional work, using (4.10) and (4.5) in (3.8), we can see that (3.8), namely, that $\rho(R_{\rm out})=2R_{\rm out}^2/(\langle\sigma^2\rangle-\langle\sigma\rangle^2)$, coincides with (4.6).

1. Numerical results for the disk phase

We have generated numerically random matrix ensembles corresponding to the quartic potential (4.1) in the disk phase, for $m^2=1$ fixed and for various values of the coupling g (and for various sizes of matrices), and measured $\rho_{\rm disk}(r)$ for these realizations.

The generation of the matrices was done by a standard Metropolis Monte Carlo approach. A random change had been suggested in the real and imaginary parts of one of the elements of ϕ and then the change in $V(\phi)$ was evaluated. This ''move'' was accepted unconditionally if V was decreased, and with probability $p=e^{-\Delta V}$ if V was increased. General theorems on Monte Carlo then guaranteed that the resulting probability distribution of ϕ was the desired one. After the matrices were generated, their eigenvalues were determined with a standard solver from the LAPACK library. We tuned the size of the suggested changes in ϕ so that the acceptance rate was about one-half, and monitored the equilibration and autocorrelation times to ensure our starting configuration had evolved properly and error bars were accurate. In particular, the local changes in ϕ made the matrices correlated over some number of random changes, however, local changes also allowed one to employ various tricks to evaluate the change in V rapidly.

In Fig. 1 we display our numerical results for $\rho_{\rm disk}(r)$ for 128×128 dimensional matrices, and compare them to the analytical large-N result (4.4) of Ref. 4. [As a trivial check of our numerical code, we also included in this figure the results for the Gaussian (Ginibre) ensemble.] Evidently, the agreement between the numerical and the analytical results is good. Note the finite-N effects near the edge of the disk.

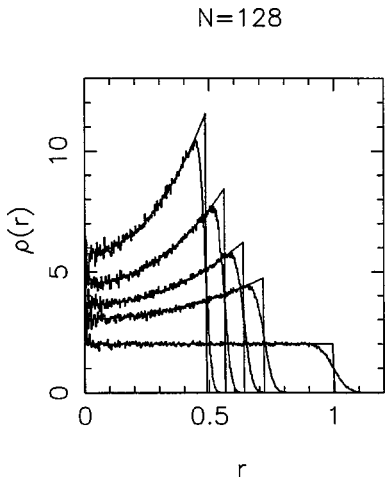

FIG. 1. Comparison between Monte Carlo measurements of the density of eigenvalues $\rho(r)$ of matrices ϕ of size 128×128, taken from the quartic ensemble $V(\phi^\dagger\phi)=2m^2\phi^\dagger\phi+g(\phi^\dagger\phi)^2$ with $m^2=0.5$ (disk phase) and for $g=0$, 0.5, 1, 2, 4 (g increases from bottom to top), compared to the analytical results of Ref. 4 (solid lines). At $g=0$ we obtain Ginibre's Gaussian ensemble with $V=\phi^\dagger\phi$, with its unit disk of eigenvalues.

B. The annular phase

For $m^2<-\sqrt{2g}$, the stable eigenvalue distribution is annular. For convenience, let us switch notations according to $m^2=-\mu^2$, and also write $\mu_c^2=\sqrt{2g}$.

According to Ref. 4 we have

$$F(w)=m^2+gw-g\sqrt{(w-a)(w-b)} \tag{4.11}$$

with

$$a=\frac{\mu^2}{g}-\sqrt{\frac{2}{g}} \quad \text{and} \quad b=\frac{\mu^2}{g}+\sqrt{\frac{2}{g}}. \tag{4.12}$$

We see that $a=(2/\mu_c^4)(\mu^2-\mu_c^2)$ which is positive for $\mu^2>\mu_c^2$, as it should be, by definition.

According to Eqs. (5.16)–(5.19) in Ref. 4, the eigenvalue density in this phase is

$$\rho_{\text{annulus}}(r)=8g\left(r^2-\frac{\mu^2}{2g}\right)=8g\left(r^2-\frac{\mu^2}{\mu_c^4}\right) \tag{4.13}$$

inside an annulus $R_{\text{in}}\leqslant r\leqslant R_{\text{out}}$, where

$$R_{\text{in}}^2=\frac{\mu^2+\sqrt{\mu^4-2g}}{2g}=\frac{\mu^2+\sqrt{\mu^4-\mu_c^4}}{\mu_c^4} \tag{4.14}$$

and

$$R_{\text{out}}^2=\frac{\mu^2}{g}=\frac{2\mu^2}{\mu_c^4}. \tag{4.15}$$

Thus, we see immediately that

$$\begin{aligned}\rho(R_{\text{in}})&=4\sqrt{\mu^4-\mu_c^4}\\ \rho(R_{\text{out}})&=4\mu^2.\end{aligned} \tag{4.16}$$

Note that $\rho(R_{\rm in})=0$ at $\mu=\mu_c$, as expected. Also note that the critical annulus has a finite inner radius: $R^2_{\rm in}(\mu_c)=1/\mu_c^2>0$.

We now compare these results with the predictions of Sec. III. From (4.11) we read-off the density of eigenvalues of $\phi^\dagger\phi$:

$$\tilde{\rho}(\sigma)=\frac{g}{\pi}\sqrt{(\sigma-a)(b-\sigma)} \tag{4.17}$$

for $a\leqslant\sigma\leqslant b$, and zero elsewhere. We can check that (4.17) is properly normalized to 1.

The relevant moments of (4.17) are

$$\begin{aligned}
\langle\sigma\rangle&=\frac{g}{2}\left(\frac{a+b}{2}\right)\left(\frac{b-a}{2}\right)^2=\frac{\mu^2}{g},\\
\langle\sigma^2\rangle&=\frac{g}{2}\left(\frac{b-a}{2}\right)^4\left[\left(\frac{b+a}{b-a}\right)^2+\frac{1}{4}\right]=\frac{\mu^4}{g^2}+\frac{1}{2g},\\
\left\langle\frac{1}{\sigma}\right\rangle&=\frac{g}{2}(\sqrt{b}-\sqrt{a})^2=\mu^2-\sqrt{\mu^4-2g}\\
\left\langle\frac{1}{\sigma^2}\right\rangle&=\frac{g}{2}\frac{(\sqrt{b}-\sqrt{a})^2}{\sqrt{ab}}=g\,\frac{\mu^2-\sqrt{\mu^4-2g}}{\sqrt{\mu^4-2g}}.
\end{aligned} \tag{4.18}$$

Comparing (4.14), (4.15) and the first and third equations in (4.18), we verify (3.6) and (3.10) straightforwardly.

Further, we find from (4.18) that

$$\begin{aligned}
\langle\sigma^2\rangle-\langle\sigma\rangle^2&=\frac{1}{2g}\\
\left\langle\frac{1}{\sigma^2}\right\rangle-\left\langle\frac{1}{\sigma}\right\rangle^2&=g-2\mu^4+\mu^2\frac{2\mu^4-3g}{\sqrt{\mu^4-2g}}.
\end{aligned} \tag{4.19}$$

Thus, comparing with (4.16) we find that

$$\frac{2R_{\rm out}^2}{\langle\sigma^2\rangle-\langle\sigma\rangle^2}=4\mu^2=\rho(R_{\rm out})$$

and

$$\frac{2R_{\rm in}^{-6}}{\langle\sigma^{-2}\rangle-\langle\sigma^{-1}\rangle^2}=4\sqrt{\mu^4-\mu_c^4}=\rho(R_{\rm in}),$$

and verify (3.8) and (3.12) for the annular phase.

1. Numerical results for the annular phase

In Figs. 2(a)–2(c) we display our numerical results for $\rho_{\rm annulus}(r)$ for matrices of various sizes, and compare them to the analytical large-N result (4.13) of Ref. 4. In these figures we hold $\mu^2=0.5$ fixed, and increase g from 0.025 to 0.1. (Here we have $\mu^2=0.5=\mu_c^2/2\sqrt{2g}$. Thus increasing g as indicated in the text brings us closer to the disk-annulus phase transition.)

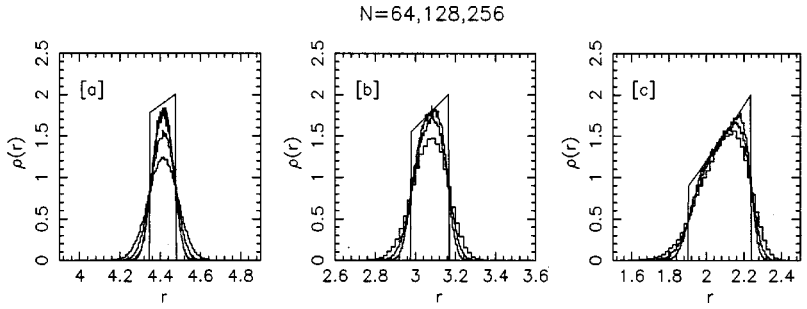

FIG. 2. Results of Monte Carlo measurements of the density of eigenvalues $\rho(r)$ of matrices ϕ of sizes corresponding to $N=64$, 128 and 256, taken from the quartic ensemble with $m^2=-\mu^2=-0.5$ (annular phase) for various values of the quartic coupling: $g=0.025$ in (a), $g=0.05$ in (b) and $g=0.1$ in (c). These are compared to the analytical results of Ref. 4 (solid lines). As N increases, the numerical results converge monotonically to the analytical results.

C. The disk-annulus phase transition

The phase boundary separating the disk phase and the annular phase in the m^2-g plane is the curve $m^2=-\sqrt{2g}$.

Consider approaching this boundary from within the disk phase by setting $m^2=-\sqrt{2g}+\delta$, with δ positive and small. Then, using (4.3), we find to first order in δ that $c=\delta/2$ and $b=2\sqrt{(2/g)}-\delta/g$. In particular, at the phase boundary itself $c=0$, in accordance with (2.19) and (2.20). It was shown in Ref. 4 that as one approaches the critical point $m^2=-\sqrt{2g}$ from the disk phase, the density of eigenvalues of ϕ approches the particularly simple critical configuration

$$\rho_{\mathrm{crit}}(r)=\begin{cases} 0, & r^2<1/\sqrt{2g} \\ 8g\left(r^2-\dfrac{1}{\sqrt{2g}}\right), & 1/\sqrt{2g}<r^2<\sqrt{2/g}. \end{cases} \tag{4.20}$$

Thus, as we decrease δ to zero, $\rho_{\mathrm{disk}}(r)$ [Eq. (4.4)] becomes increasingly depleted inside the disk $r^2<b(\delta)/4$, reaching complete depletion at $\delta=0$, at which point the disk breaks into an annulus. We also note that at the phase boundary (4.2) reads

$$F(w)=-\sqrt{2g}+gw-g\sqrt{w\left(w-2\sqrt{\frac{2}{g}}\right)}. \tag{4.21}$$

Consider now approaching the phase boundary $m^2=-\sqrt{2g}$ from within the annular phase. Thus, we set $\mu^2=\sqrt{2g}+\delta$, with δ positive and small. Then, since all the expressions in (4.12) are linear in μ^2, we find that $a=\delta/g$ and $b=2\sqrt{(2/g)}+\delta/g$. In particular, at the phase boundary itself $a=0$, and $b=1/\sqrt{2g}$. Therefore, at the phase boundary (4.11) reads

$$F(w)=-\sqrt{2g}+gw-g\sqrt{w\left(w-2\sqrt{\frac{2}{g}}\right)},$$

which coincides with (4.21). Thus, $F(w)$ (and consequently, the eigenvalue density of $\phi^\dagger\phi$) is also continuous at the transition, in accordance with (2.20).

Note from (4.14) and (4.15) that at the transition $R_{\mathrm{in}}^2=1/\mu_c^2=1/\sqrt{2g}$ is *finite*, and coincides with the radius (squared) of the depleted region in the disk configuration (4.20). Right at the transition, the disk breaks into an annulus with a finite hole! Note also that $R_{\mathrm{out}}^2=2/\mu_c^2=\sqrt{2/g}$, which coincides with the disk's R_{out}^2 at the phase boundary. Thus, at the phase boundary $\mu^2=\mu_c^2$ (4.13) coincides with (4.20), namely, $\rho(r)$ is continuous at the transition from the disk phase to the annular phase.

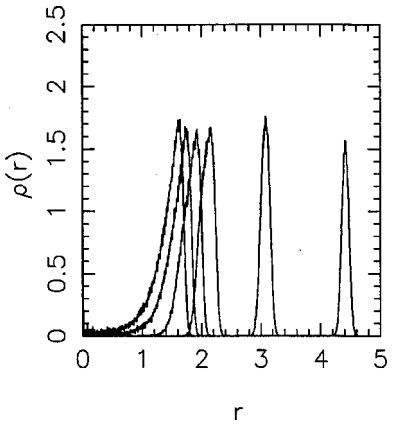

FIG. 3. Monte Carlo measurements of the density of eigenvalues $\rho(r)$ of matrices ϕ of size 128×128, taken from the quartic ensemble with $\mu^2=0.5$ and for $g=0.025$, 0.05, 0.1, 0.125, 0.15 and 0.175 (g increases from right to left). The first three profiles on the right (corresponding to the three lowest values of g) evidently belong to the annular phase. The fourth density profile from the right is the critical one (corresponding to $g_c=0.125$). Finally, the last two profiles (which correspond to the two higher values of g) belong to the disk configuration.

1. Numerical simulation of the disk-annulus phase transition

We have measured the density of eigenvalues $\rho(r)$ of matrices ϕ of size 128×128, taken from the the quartic ensemble with $\mu^2=0.5$ and for $g=0.025$, 0.05, 0.1, 0.125, 0.15 and 0.175. The results are displayed in Fig. 3.

For these values of g, we start in the annular phase at the lowest value of g. For our set of parameters we have $\mu^2=0.5=\mu_c^2/2\sqrt{2g}$. Thus, increasing g (while keeping μ^2 fixed at 0.5) brings us closer to the disk-annulus phase transition, which occurs (at large N) at $g_c=0.125$. Increasing g beyond that, puts us into the disk phase.

The first three profiles on the right in Fig. 3 belong to the annular phase. Their behavior is consistent with our discussion in Sec. IV B of the annular phase. Indeed, as g increases towards the transition point at $g_c=0.125$, these three graphs exhibit the expected decrease of $R_{\rm in}^2=(\mu^2+\sqrt{\mu^4-\mu_c^4})/\mu_c^4$ [Eq. (4.14), with $\mu_c^2=\sqrt{2g}$] and the decrease of $R_{\rm out}^2=2\mu^2/\mu_c^4$ [Eq. (4.15)].

The critical density profile, corresponding to $g_c=0.125$, is the fourth profile (from the right). For our choice of parameters, the theoretical boundary radii of the critical annulus, i.e., at $g=0.125$, are $R_{\rm in}^{\rm crit}=1/\mu_c=\sqrt{2}$ and $R_{\rm out}^{\rm crit}=\sqrt{2}/\mu_c=2$. These boundary values fit nicely with the features of the critical profile in Fig/ 3.

Finally, the last two profiles in Fig. 3 have pronounced tails extending to $r=0$ and thus belong to the disk phase.

V. PHASE TRANSITIONS IN THE SIXTH ORDER POTENTIAL AND THE "SINGLE RING" THEOREM

The sextic potential

$$V(\phi^\dagger\phi)=m^2\phi^\dagger\phi+\frac{\lambda}{2}(\phi^\dagger\phi)^2+\frac{g}{3}(\phi^\dagger\phi)^3 \tag{5.1}$$

is the potential of lowest degree in (1.1) for which the eigenvalues of $\phi^\dagger\phi$ may split into more then a single segment. In fact, it is easy to see that there can be at most two eigenvalue segments in the spectrum of $\phi^\dagger\phi$.

The qualitative features of the support of the eigenvalue density associated with (5.1) can be deduced by moving the cubic $V(x)=m^2x+(\lambda/2)x^2+(g/3)x^3$ around in the plane (i.e., by varying its couplings, fixing, say $g=1$), and concentrating on $x\geqslant0$. It is obvious from such considerations that there are three qualitatively different phases in the spectrum of $\phi^\dagger\phi$. In two of the

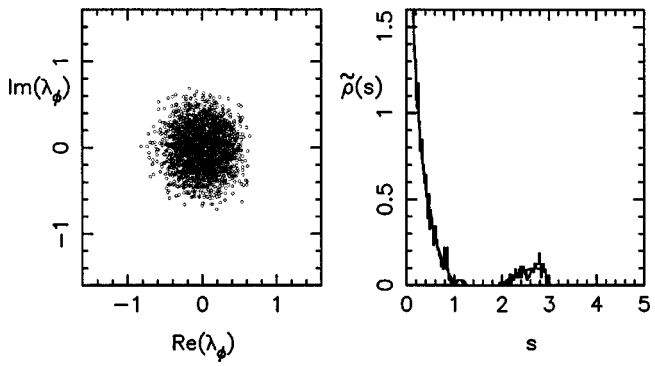

FIG. 4. Scatter plot of the eigenvalues of matrices ϕ of size 32×32, taken from (5.1) with $m^2=7.372$, $\lambda=-6.116$ and $g=1.372$ (left), and the corresponding density of eigenvalues $\tilde{\rho}(s)$ of $\phi^\dagger\phi$ (right). The solid line on the right is the analytical curve corresponding to (A22). The support of $\tilde{\rho}(s)$ is split into the two segments $\{0\leqslant s\leqslant a=1\}\cup\{b=2\leqslant s\leqslant c=3\}$, while the support of $\rho(r)$ on the left is manifestly a disk.

phases the eigenvalues s_i of $\phi^\dagger\phi$ live in a single segment. In one of these single segment phases, the segment includes the origin $(0\leqslant s\leqslant a)$, but in the other it does not $(0<a\leqslant s\leqslant b)$. Following the general discussion in the last part of Sec. II, we would expect that the spectrum of ϕ itself is a disk in the first case, and an annulus in the second case.

In the third phase of $\phi^\dagger\phi$, there are two segments, one of which hits the origin ($\{0\leqslant s\leqslant a\}\cup\{b\leqslant s\leqslant c\}$). (There is no two-segment phase of $\phi^\dagger\phi$ which does not include the origin.) Thus, according to the discussion in the last part of Sec. II, the non-Hermitian matrix ϕ is expected to be in the disk phase in this case (rather than having its eigenvalue fill in a disk surrounded by a concentric annulus), in accordance with the "single ring" theorem.

In this short section we limit our discussion to the two-segment phase of $\phi^\dagger\phi$. [A rather detailed sketch of the analytical conditions that determine the whole phase structure of the sextic ensemble (5.1) is given in the Appendix.] Our purpose here is to demonstrate numerically the "single ring" Theorem for the eigenvalue distribution of matrices ϕ taken from the sextic ensemble (5.1). To this end, we have to identify points well within the phase in which the eigenvalues of $\phi^\dagger\phi$ split into two segments.

We used the formalism of the Appendix to choose two ensembles in the two-segment phase of $\phi^\dagger\phi$, for which we verified that the eigenvalues of ϕ formed a disk. The results for these ensembles are displayed in Figs. 4 and 5.

Figure 4 shows the scatter plot of the eigenvalues of ϕ together with the density of eigenvalues $\tilde{\rho}(s)$ of $\phi^\dagger\phi$ for (5.1) with couplings $m^2=7.372$, $\lambda=-6.116$ and $g=1.372$. As can be seen on the right part of Fig. 4, for these couplings, the eigenvalues of $\phi^\dagger\phi$ live in two separated

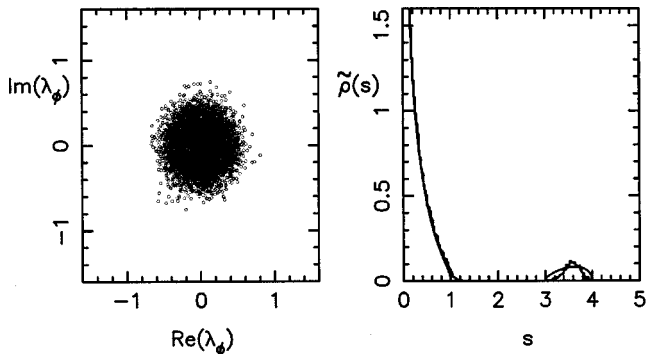

FIG. 5. Similar to Fig. 4, but with $m^2=6.403$, $\lambda=4.184$ and $g=0.713$. The support of $\tilde{\rho}(s)$ is split into the two segments $\{0\leqslant s\leqslant a=1\}\cup\{b=3\leqslant s\leqslant c=4\}$, while the support of $\rho(r)$ on the left remains a disk.

segments: $\{0\leqslant s\leqslant a=1\}\cup\{b=2\leqslant s\leqslant c=3\}$. The solid line there is the large N theoretical curve, which was plotted according to the analysis we have described in the Appendix [see the discussion following (A20)]. Evidently, the spectrum of ϕ is a disk, despite the split support of $\tilde{\rho}(s)$, in accordance with the ''single ring'' Theorem.

Figure 5 is similar to Fig. 4, but for (5.1) with couplings $m^2=6.403$, $\lambda=4.184$ and $g=0.713$, for which the eigenvalues of $\phi^\dagger\phi$ live in the segments $\{0\leqslant s\leqslant a=1\}\cup\{b=3\leqslant s\leqslant c=4\}$. The spectrum of ϕ remains a disk, even though the two segments of the support of $\tilde{\rho}(s)$ are more separated than in Fig. 4.

APPENDIX: THE PHASE DIAGRAM OF A GENERIC $V(\phi^\dagger\phi)$

In this Appendix we briefly review the necessary theoretical aspects of multi-cut phases of $\phi^\dagger\phi$. The first part of our discussion will apply for a generic polynomial $V(\phi^\dagger\phi)$. Then, in the second part of the Appendix, we will specialize to the sextic potential (5.1).

The following discussion is an adaptation and application of the ideas of Ref. 24 to non-Hermitian matrices. For a more detailed discussion of Hermitian and non-Hermitian random matrix ensembles with multi-cut eigenvalue distributions, see Ref. 25. [As a side remark, we mention at this point the recent interest in the surprising nonuniversal large distance behavior of the (smoothed) connected two-point function[26] in matrix models with multi-cut eigenvalue distributions.]

For practical reasons, we eliminate some (or all) of the couplings in $V(\phi^\dagger\phi)$ in terms of the end-points of the segments containing the eigenvalue distribution of $\phi^\dagger\phi$, and use the latter as (part of) the coordinates in the phase diagram. In this way we can find rather easily which couplings in $V(\phi^\dagger\phi)$ are needed to generate an eigenvalue distribution of $\phi^\dagger\phi$ with a prescribed set of support segments.

1. A generic potential $V(\phi^\dagger\phi)$

The saddle-point equation governing the Dyson gas of eigenvalues of $\phi^\dagger\phi$ is[19,20]

$$\mathrm{Re}\,F(s-i\epsilon)=\tfrac{1}{2}V'(s). \tag{A1}$$

By definition [see Eq. (2.8)]

$$F(w)=\frac{1}{N}\left\langle \mathrm{tr}_{(N)}\frac{1}{w-\phi^\dagger\phi}\right\rangle=\frac{1}{N}\sum_{i=1}^{N}\left\langle\frac{1}{w-s_i}\right\rangle \tag{A2}$$

(where s_i are the eigenvalues of $\phi^\dagger\phi$). Thus, as usual,

$$F(s-i\epsilon)=\mathrm{P.P.}\frac{1}{N}\sum_{j=1}^{N}\left\langle\frac{1}{s-s_j}\right\rangle+i\pi\tilde{\rho}(s), \tag{A3}$$

where $\tilde{\rho}(s)$ is the density of eigenvalues of $\phi^\dagger\phi$.

In order to study multi-cut configurations of $\tilde{\rho}(s)$, we also need the auxiliary function[24]

$$G(s)=\int_{a_1>0}^{s}d\mu(V'(\mu)-2F(\mu-i\epsilon)). \tag{A4}$$

In the last equation a_1 is the lowest branch point of $F(w)$. Thus, from (A3) and (A1), we see that for s real and in the support of eigenvalues,

$$G(s) = -2\pi i \int_{a_1}^{s} \tilde{\rho}(\mu) d\mu \tag{A5}$$

is pure imaginary. $-\mathrm{Im}\, G(s) = 2\pi\tilde{\rho}(s)$ is then positive and monotonically increasing (and reaches 2π when s hits the largest branch point).

Stability of multi-cut distributions. How do we know that a given distribution of eigenvalues is stable against migration of eigenvalues from one place to another? To answer this question, consider the Dyson gas energy functional

$$S_{\mathrm{eff}}[\tilde{\rho}] = \int_{s\geqslant 0} \tilde{\rho}(s) V(s) ds - \frac{1}{2} \int_{s,\mu\geqslant 0} \tilde{\rho}(s)\tilde{\rho}(\mu) \log(s-\mu)^2 \, ds d\mu. \tag{A6}$$

A general variation of (A6) under $\tilde{\rho}(s) \to \tilde{\rho}(s) + \delta\tilde{\rho}(s)$ is

$$\delta S_{\mathrm{eff}}[\tilde{\rho}] = \int_{s\geqslant 0} V(s)\, \delta\tilde{\rho}(s) ds - \int_{s,\mu\geqslant 0} \tilde{\rho}(\mu) \log(s-\mu)^2 \delta\tilde{\rho}(s) ds d\mu. \tag{A7}$$

Moving an eigenvalue from s_i to s_f corresponds to $\delta\tilde{\rho}(s) = (1/N)[\,\delta(s-s_f) - \delta(s-s_i)\,]$. Thus, from (A7) and (A4) (and after some work) we can show that such a move costs

$$\Delta S_{\mathrm{eff}}[\tilde{\rho}] = \frac{1}{N}[G(s_f) - G(s_i)] \tag{A8}$$

in energy.[24] Such a rearrangement of eigenvalues costs energy only if

$$\mathrm{Re}\, \Delta S_{\mathrm{eff}}[\tilde{\rho}] > 0\,, \tag{A9}$$

and therefore (A9) is the stability condition against such a rearrangement. Thus, a multi-cut $F(w)$, where the eigenvalues coalesce into n segments

$$[a_1, a_2] \cup [a_3, a_4] \cup \cdots \cup [a_{2n-1}, a_{2n}],$$

would be stable against migration of eigenvalues between neighboring cuts if and only if (A9) would hold for all neighboring pairs of cuts, and in both directions. Since $G(s)$ is real on the segments on the real axis that connect the cuts, this stability condition means

$$G(a_3) = G(a_2), \quad G(a_5) = G(a_4), \quad \ldots, \quad G(a_{2n-1}) = G(a_{2n-2}). \tag{A10}$$

In addition, of course, $\mathrm{Re}\, G(s) < 0$ cannot happen anywhere for $s \geqslant 0$. The $n-1$ equations (A10) comprise the desired stability condition for such an eigenvalue distribution. In addition to these conditions, we have to make sure that along the cuts themselves $-\mathrm{Im}\, G(s) > 0$, which is just the condition that $\tilde{\rho}(s)$ be positive.

The $n-1$ equations (A10), together with the obvious analytic properties of $F(w)$ and its asymptotic behavior

$$F(w) \sim \frac{1}{w} \tag{A11}$$

as $w \to \infty$, determine $F(w)$ uniquely. Indeed, as is well known, for a generic $V(\phi^\dagger\phi)$, in view of (A1) and (A11) (and as we discussed at the end of Sec. II), $F(w)$ (with n cuts) must be of the form

$$F(w)=\frac{1}{2}V'(w)-P(w)\sqrt{\prod_{l=1}^{2n}(w-a_l)}, \tag{A12}$$

where

$$P(w)=\frac{c_{-1}}{w}+\sum_{l=0}^{\deg V-n-1}c_l w^l. \tag{A13}$$

Here $a_1<a_2\cdots<a_{2n}$ and $c_{-1}\neq 0$ only if $a_1=0$ (see Sec. II). If $a_1>0$, then $c_{-1}=0$, and thus in such a case, there are $2n(a's)+(\deg V-n)(c's)=n+\deg V$ independent parameters in the expression (A12) for $F(w)$. On the other hand, there are $\deg V+1$ conditions from the asymptotic behavior (A11) plus additional $n-1$ conditions from (A10), which comprise a total of $\deg V+n$ conditions, equal to the number of unknown parameters. This balance remains if c_{-1} appears in the game as an unknown parameter, because then $a_1=0$, so that the number of parameters does not change. Finally, we have to remember to impose the positivity constraint

$$\tilde{\rho}(x)=\frac{1}{\pi}\mathrm{Im}\,F(x-i\epsilon)\geqslant 0, \tag{A14}$$

which translates into a set of inequalities among the a's and c's.

A convenient local parametrization of the phase diagram. Recall, that the phases of $\phi^\dagger\phi$ are specified by the number of segments in the support of $\tilde{\rho}(s)$, i.e., the number of cuts in $F(w)$ (and whether these cuts have $w=0$ as a branch point or not.) Thus, instead of the usual description of the phase structure in terms of the deg$V$ couplings in $V(\phi^\dagger\phi)$, our strategy is to use deg$V$ parameters out of the $2n$ branch-points $a_1,\ldots a_{,2n}$ of $F(w)$ and the deg$P$ coefficients c_k (with the total number deg$V$ first saturated by the a's in ascending order), which we refer to as "*phase coordinates,*" to express (in a given phase) the couplings appearing in $V(\phi^\dagger\phi)$ [such as m^2,λ and g in (5.1)], as well the as the c_k's and a_k's complementary to the phase coordinate parameter set. (See our discussion of the sextic potential in the next subsection for concrete examples of this parametrization.)

We have to be careful in giving the expressions for, say, the couplings of V, in terms of the phase coordinates. This because for a given configuration of $F(w)$, the equations from which we are to eliminate the couplings of V [such as the triad m^2,λ and g in (5.1)] as functions of the phase coordinates may have several solutions (in other words, the couplings in V are generally multivalued functions of the phase coordinates in a given phase). Thus, in a given phase, we must of course choose the parametrization of couplings in V which yields the minimal $S_{\mathrm{eff}}[\tilde{\rho}]$ appropriate for that phase.

This alternative parametrization is more convenient for our purposes in Sec. V. Indeed, once we are successful in expressing the couplings in V as functions of the phase coordinates, it will be very easy for us to tune the couplings in $V(\phi^\dagger\phi)$ to a generic point in a given phase and also to approach the phase boundaries in a controlled manner. In particular, phase transitions appear here, for example, when branch points collide and become equal (at some common real positive value a). This process removes two a's and thus closes one cut $(n\to n-1)$ but adds an additional term to $P(w)$. The number of unknown parameters drops by 1, but so does the number of stability conditions (A10). In the other direction, we can obviously reach the same coexistence point, by tuning the parameters of $P(w)$ to a point where it develops a linear factor $(w-a)=\sqrt{(w-a)^2}$ (with $a\geqslant 0$). Obviously, when these alternative phase coordinates approach a point on the coexistence surface from two different sides of the phase transition, the respective sets of couplings of V, expressed as sets of functions of the two phase coordinate patches, coincide. Thus, they lead to the same $S_{\mathrm{eff}}[\tilde{\rho}]$, which means that such a point is indeed a point on the phase boundary.

2. Results for the sextic potential

From (A12) and (5.1), the general form of $F(w)$ is

$$F(w)=\tfrac{1}{2}(m^2+\lambda w+gw^2)-P(w)\sqrt{\text{polynomial}}. \tag{A15}$$

a. Single cut, disk phase

Here

$$F(w)=\frac{1}{2}(m^2+\lambda w+gw^2)-\left(\frac{s}{w}+t+uw\right)\sqrt{w(w-a)}. \tag{A16}$$

There is a single cut, so (A10) is trivial in this case, and (A14) holds manifestly. We need only impose (A11). In the end, we find

$$\begin{aligned} u&=\frac{16-8as-2a^2t}{a^3},\\ g&=2u\\ \lambda&=2t-au=\frac{4a^2t+8as-16}{a^2},\\ m^2&=2s-at-\frac{a^2u}{4}=\frac{8as-a^2t-8}{2a}. \end{aligned} \tag{A17}$$

The phase coordinates are a, t and s.

b. Single cut, annular phase

We have

$$F(w)=\tfrac{1}{2}(m^2+\lambda w+gw^2)-(t+uw)\sqrt{(w-a)(w-b)}. \tag{A18}$$

Here $0<a<b$. Again, there is a single cut, so (A10) is trivial in this case too, and also (A14) holds manifestly. We need only impose (A11). In the end, we find

$$\begin{aligned} u&=\frac{16-2t(a-b)^2}{(a+b)(a-b)^2},\\ g&=2u,\\ \lambda&=2t-u(a+b)=4t-\frac{16}{(a-b)^2},\\ m^2&=-\frac{(a-b)^2}{4}u-t(a+b)=-\frac{4}{a+b}-t\frac{a^2+6ab+b^2}{2(a+b)}. \end{aligned} \tag{A19}$$

The phase coordinates are a, b and t.

c. Two cuts, disk phase

We have

$$F(w)=\frac{1}{2}(m^2+\lambda w+gw^2)-\left(\frac{s}{w}+t\right)\sqrt{w(w-a)(w-b)(w-c)}. \tag{A20}$$

Here $0<a<b<c$. Note that in this case we can trade the three couplings m^2, λ and g for the three branch points a, b and c. In this case there are two cuts, so for the first time (A10) is not trivial. We first impose (A11). We find

$$\begin{aligned} s &= \frac{8}{a^2+b^2+c^2-2(ab+ac+bc)} \\ &\quad -\frac{1}{2}\frac{a^3+b^3+c^3-a^2(b+c)-b^2(a+c)-c^2(a+b)+2abc}{a^2+b^2+c^2-2(ab+ac+bc)}t, \\ g &= 2t, \\ \lambda &= 2s-t(a+b+c), \\ m^2 &= -(a+b+c)s-\frac{a^2+b^2+c^2-2(ab+ac+bc)}{4}t. \end{aligned} \tag{A21}$$

We have yet to impose (A10), which is why t was not eliminated yet. Before doing that, we impose (A14). Our conventions are always to take each cut from the appropriate branch point to the left on the real axis. Thus, after some work, we find from (A20)

$$\pi\tilde{\rho}(x)=\operatorname{Im}F(x-i\epsilon)=\begin{cases} -\left(\dfrac{s}{x}+t\right)\sqrt{x(a-x)(b-x)(c-x)}, & 0<x<a, \\ +\left(\dfrac{s}{x}+t\right)\sqrt{x(x-a)(x-b)(c-x)}, & b<x<c, \\ 0 \quad \text{otherwise.} \end{cases} \tag{A22}$$

We have to impose (A14) on (A22). This means

$$\frac{s}{x}+t<0 \quad \text{for} \quad 0<x<a,$$

$$\frac{s}{x}+t>0 \quad \text{for} \quad b<x<c.$$

Thus, we must have

$$t>0 \quad \text{and} \quad -bt\leqslant s\leqslant -at<0, \tag{A23}$$

where s is given in (A21). (It is straightforward to check that these inequalities hold for the ensembles corresponding to Figs. 4 and 5 in Sec. V.) We are now ready to impose (A10). Here it simply means $G(a)=G(b)$, namely,

$$\int_a^b\left(\frac{s}{x}+t\right)\sqrt{x(x-a)(b-x)(c-x)}\,dx=0. \tag{A24}$$

Note from (A23) that $-b<s/t<-a$, and thus the factor multiplying the square root in (A24) flips its sign in the integration domain, so that the integral on the lhs of (A24) may vanish. The latter equation may be expressed in terms of the elliptic integrals

$$I(a,b,c)=\int_a^b \sqrt{x(x-a)(x-b)(x-c)}\,dx,$$
$$J(a,b,c)=\int_a^b \sqrt{x(x-a)(x-b)(x-c)}\,\frac{dx}{x}. \tag{A25}$$

Following the usual procedure, we may express I and J in terms of complete elliptic integrals in a straightforward manner. (We do not bother to write these expressions here, since for our purposes in Sec. V we evaluated I and J numerically.)

Finally, substituting these expressions in (A24) we obtain

$$s(t,a,b,c)J(a,b,c)+tI(a,b,c)=0, \tag{A26}$$

which we solve for t (recall from (A21) that s is merely linear in t, and also that $t>0$, in view of (A23).) Once $t(a,b,c)$ is known, we can go back to (A21) and evaluate $m^2(a,b,c)$, $\lambda(a,b,c)$ and $g(a,b,c)$ explicitly. Our phase coordinates in this case are thus a, b and c.

[14] We use the following notational conventions: for $z=x+iy$ we define $\partial \equiv \partial/\partial z = \frac{1}{2}(\partial/\partial x - i\,\partial/\partial y)$ so that $\partial z = 1$. Similarly, we define $\partial^* \equiv \partial/\partial z^* = \frac{1}{2}(\partial/\partial x + i\,\partial/\partial y)$, so that $\partial^* z^* = 1$ and also $\partial^*(1/z) = \pi\delta^{(2)}(z)$. Finally, we denote $|z| = r$.

[22] In the Gaussian case, $V=\phi^\dagger\phi$, we have $2\sqrt{w}F(w)=\sqrt{w}-\sqrt{w-4}$, whence the roots of (2.10) are $\gamma=0,1$ and r^2. We note that $\gamma=0$ is unphysical, $\gamma=r^2$ (i.e., $G=z^*$) corresponds to Ginibre's disk (Ref. 12), and $\gamma=1$ is the solution outside the disk.

[23] It is straightforward to show that $\mathrm{sgn}\,(b/4-R_{\mathrm{out}}^2)=-1$ in (4.4): just substitute $m^4=A^2\cos^2\alpha$ and $6g=A^2\sin^2\alpha$ and obtain that $R_{\mathrm{out}}^2-b/4=(A^3/108g^2)(1-\cos\alpha)^3$.

Analytical and geometrical information on certain dynamical systems **X** is obtained under the assumption that **X** is embedded into a certain real Lie algebra. [DOI: 10.1063/1.1412598]

I. INTRODUCTION

This article deals with the problem of extracting information of a three-dimensional dynamical system **X**, when **X** is embedded into a Lie algebra of 3-D vectorfields.

This approach is interesting since up to now, as we explain later in this work, the only case considered has been that in which the generators of the Lie algebra are **X** and a certain number of symmetries or pseudosymmetries of **X**. Such restriction is dropped in this article.

Let us explain this in more detail.

It is well known[1] that when a vectorfield **X** (v.f. in what follows) admits a symmetry vector, that is, a v.f. **S** satisfying

$$\mathcal{L}_{\mathbf{S}}(\mathbf{X})=0, \tag{1}$$

$\mathcal{L}_{\mathbf{S}}$ standing for the Lie derivative along the streamlines of **S**, useful consequences on the local and global structure of **X** can be obtained: existence of local and global first integrals, limit cycles of **X**,[2] etc.

Remember that (1) implies that the flow of the v.f. **S** acts on the set of solutions of the differential equations

$$\frac{d\mathbf{x}}{dt}=\mathbf{X}(\mathbf{x}). \tag{2}$$

In other words, the local flow of **S** transforms a solution of (2) into another solution of Eq. (2).

Sometimes the pair of v.f. $(\mathbf{X},\mathbf{S})$ does not satisfy Eq. (1) but the equations

$$\mathcal{L}_{\mathbf{S}}(\mathbf{X})=\lambda(\mathbf{x})\mathbf{X}, \tag{3}$$

$\lambda(\mathbf{x})$ being a function. In this case **S** is called a pseudosymmetry of **X**. The geometrical meaning of Eq. (3) is that the local flow of **S** conserves *not* the solutions of (2) but the trajectories on which these solutions lie (a trajectory of **X** is just an unparametrized solution of **X**).

Interesting geometric information on the trajectories of **X** when (3) holds can be found in Ref. 2.

Motivated by Eqs. (1) and (3) we consider in this article that **X** (a $\mathbb{R}^3$ v.f. from now on) is one of the generators of a Lie algebra $A_{2,2}$ of dimension two or $A_{3,3}$ of dimension three. That is,

$$[\mathbf{X},\mathbf{S}_1]=a_0\mathbf{X}+a_1\mathbf{S}_1,$$

$$a_0, a_1 \in \mathbb{R}, \tag{4}$$

$$\text{rank}(\mathbf{X}, \mathbf{S}_1) = 2 \quad \text{for any } \mathbf{x} \in \mathbb{R}^3,$$

in the first case, and

$$\begin{gathered} [\mathbf{X}, \mathbf{S}_1] = a_0 \mathbf{X} + a_1 \mathbf{S}_1 + a_2 \mathbf{S}_2, \\ [\mathbf{X}, \mathbf{S}_2] = b_0 \mathbf{X} + b_1 \mathbf{S}_1 + b_2 \mathbf{S}_2, \\ [\mathbf{S}_1, \mathbf{S}_2] = c_0 \mathbf{X} + c_1 \mathbf{S}_1 + c_2 \mathbf{S}_2, \\ a_i, b_i, c_i \in \mathbb{R}, \\ \text{rank}(\mathbf{X}, \mathbf{S}_1, \mathbf{S}_2) = 3 \quad \text{for any } \mathbf{x} \in \mathbb{R}^3, \end{gathered} \tag{5}$$

in the case of an algebra of type $A_{3,3}$.

Note that [,] stands for the Lie bracket of v.f. and $A_{i,j}$ $(i \geqslant j)$ stands for a Lie algebra with i generators (including $\mathbf{X}$) and rank $(\mathbf{X}, \mathbf{S}_1, .., \mathbf{S}_{i-1}) = j$.

We shall say that $\mathbf{X}$ belongs to a certain Lie algebra if $\mathbf{X}$ is one of its generators. For example, $\mathbf{X}$ belongs to the Lie algebras $A_{2,2}$ and $A_{3,3}$ defined by Eqs. (4) and (5).

Note that the case of pseudosymmetries corresponds to $a_1 = 0$ in Eq. (4) and $a_1 = a_2 = b_1 = b_2 = 0$ in Eq. (5).

We shall prove in what follows that when a dynamical system $\mathbf{X}$ belongs to a Lie algebra this information can be useful in order to get qualitative information on the orbits of $\mathbf{X}$.

This article is organized this way. Lie algebras of type $A_{2,2}$ are briefly considered in Sec. II, where their influence on $\mathbf{X}$ is studied. The structure constants of $A_{3,3}$ algebras are reduced to a finite number of canonical forms in Sec. III. The case of a v.f. $\mathbf{X}$ embedded into an $A_{3,3}$ Lie algebra is studied in Sec. IV. Illustrative examples are given in Sec. V, and some open problems are discussed in Sec. VI.

We end this section by motivating our study with some considerations of the significance and applicability of the idea of embedding a v.f. $\mathbf{X}$ into a Lie algebra.

We shall refer to the illustrative example of $A_{2,2}$ algebras [that is, algebras with two generators and rank equal 2: see Eq. (4)]. For these algebras Eq. (4) can be interpreted in two ways:

(i) as the structure equation of a Lie transformation (local) group G acting on $\mathbb{R}^3$ of generators $\mathbf{X}$ and $\mathbf{S}$, or
(ii) as the equations defining an involutive distribution[3,4] generated by $\mathbf{X}$ and $\mathbf{S}$.

The fact that a_0 and a_1 in Eq. (4) are real numbers instead of functions of $\mathbf{x} = (x_1, x_2, x_3)$ is a useful piece of information that should be taken into account.
Therefore the philosophy of this article is the following:

(i) get $\mathbf{X}$ (if you can, via computer packages, etc.) be embedded into the algebras $A_{r,3}(r \geqslant 3)$ or $A_{r,2}(r \geqslant 2)$ of some Lie transformation group G. We shall speak immediately about the difficulties of this process.
(ii) apply the techniques of this article in order to get information on some structures of $\mathbf{X}$, as first integrals, invariant sets, existence of partitions of $\mathbb{R}^3$ invariant under $\mathbf{X}$, integrability via quadratures, etc.

The most difficult point is, of course, the finding of the concrete embedding of $\mathbf{X}$. In fact it may even happen that (for structural reasons connected with the orbit structure of $\mathbf{X}$, strange or complicated limit behavior of the orbits when $t \to +\infty$) the embedding process will be a failure because it does not exist at all. For example, by topological reasons it is *impossible* to get an embedding of $\mathbf{X}$ into an algebra of type $A_{3,2}$ or $A_{2,2}$ if $\mathbf{X}$ is a dynamical system with an orbit which is an asymptotic "limit cycle" (orbit of type S^1 acting as limit set of neighboring orbits). Nevertheless, the dynamical system $\mathbf{X}$ could be embedded into an algebra of type $A_{3,3}$.

However, we have *not* been able to find analytical conditions, geometric structures, etc. such that if **X** satisfies them, then **X** cannot be embedded into an algebra of type $A_{3,3}$. Upto today open problems are to decide

(i) whether or not a given v.f. **X** can be embedded into a finite dimensional Lie algebra, and
(ii) whether or not a given v.f. **X** can be embedded into an algebra of type $A_{n,3}(n\geqslant 3)$, where n is a fixed natural number.

In general, the problem of studying the relation between the geometry of the orbits of **X** and the type of algebra into which **X** can or cannot be embedded seems to be a very difficult one.

In conclussion, this article could be of interest to people working in differential equations, dynamical systems, etc., and to all those normally handling symmetry techniques in differential equations since we offer here a certain generalization of them yielding, under some conditions, first integrals, invariant sets, integrability via quadratures, foliations of $\mathbb{R}^3$ invariant under **X**, etc.

II. $\mathbb{R}^3$ DYNAMICAL SYSTEMS EMBEDDED INTO A LIE ALGEBRA $A_{2,2}$

Let us now develop some consequences of the fact that our dynamical system **X** is embedded into a Lie algebra of type $A_{2,2}$, that is,

$$[\mathbf{X},\mathbf{S}_1]=a_0\mathbf{X}+a_1\mathbf{S}_1,$$
$$a_0,a_1\in\mathbb{R}, \tag{6}$$
$$\operatorname{rank}(\mathbf{X},\mathbf{S}_1)=2.$$

We shall now obtain from Eq. (6) consequences of several kinds concerning the orbit structure of **X**. Most of these results fail when the real constants a_0 and a_1 of (6) are substituted by real functions $a(\mathbf{x})$ and $b(\mathbf{x})$, $\mathbf{x}\in\mathbb{R}^3$. Therefore, most of these results cannot be obtained when **X** is embedded into a two-dimensional foliation instead of being embedded into a $A_{2,2}$ algebra.

From now on all the functions v.f.'s, and differential forms of this article are assumed to be analytic (C^w). See Refs. 3–5 for the theory and applications of differential forms.

A. First integrals of X

We obtain now first integrals of **X** via the construction of exact one-forms. The reader can have a look at this method when $a_0=a_1=0$ in Ref. 3.

Our assumptions are the following:
X belongs to a $A_{2,2}$ Lie algebra [see Eq. (6)] and

$$\operatorname{Div}\mathbf{X}=-a_1,\ \operatorname{Div}\mathbf{S}_1=a_0, \tag{7}$$

a_0 and a_1 being the real numbers of Eq. (6) and Div **Y** standing for

$$\operatorname{Div}\mathbf{Y}=\frac{\partial Y_1}{\partial x_1}+\frac{\partial Y_2}{\partial x_2}+\frac{\partial Y_3}{\partial x_3},$$
$$\mathbf{Y}=Y_1\partial_1+Y_2\partial_2+Y_3\partial_3. \tag{8}$$

$\operatorname{Div}\mathbf{Y}$ can be alternatively defined by $\mathcal{L}_Y\Omega_3=\operatorname{Div}\mathbf{Y}\cdot\Omega_3$, Ω_3 being the standard volume form $dx_1\wedge dx_2\wedge dx_3$ of $\mathbb{R}^3$.

Under these hypotheses the one-form w_1 defined by

$$w_1=i_{\mathbf{x}}i_{\mathbf{s}_1}\Omega_3 \tag{9}$$

is exact ($dw_1=0$) and we can write

$$w_1 = dI, \tag{10}$$

and since $i_x w_1 = 0$ we can write

$$\mathcal{L}_{\mathbf{x}}(I) = 0. \tag{11}$$

Therefore I is a global first integral of $\mathbf{X}$.

Note that I can never become a trivial constant, as this would imply $w_1 = 0$ (identically), getting a contradiction with the rank condition appearing in Eq. (6).

B. Independent first integrals

Let us now assume that I_1, I_2 are two independent first integrals of $\mathbf{S_1}$; this situation often appears in physics[6] as $\mathbf{S_1}$ usually is a v.f. easier to handle than $\mathbf{X}$ (isometries of $\mathbb{R}^3$ considered as Euclidean space, linear or affine v.f. and so on). Under this assumption let us see that the integration of $\mathbf{X}$ can be simplified.

Under these conditions Eq. (6) implies

$$-\mathcal{L}_{\mathbf{S_1}}\mathcal{L}_{\mathbf{X}}(I_i) = a_0 \mathcal{L}_{\mathbf{X}}(I_i), \quad i = 1,2, \tag{12}$$

and when $a_0 = 0$ we get

$$\mathcal{L}_{\mathbf{X}}(I_i) = \varphi_i(I_1, I_2), \tag{13}$$

that is, $\mathbf{X}$ projects to the $\mathbb{R}^3$ v.f.

$$\mathbf{X}_2 = \varphi_1(I_1, I_2)\partial_{I_1} + \varphi_2(I_1, I_2)\partial_{I_2}, \tag{14}$$

that is

$$\begin{aligned} \frac{dI_1}{dt} &= \varphi_1(I_1, I_2), \\ \frac{dI_2}{dt} &= \varphi_2(I_1, I_2). \end{aligned} \tag{15}$$

Therefore, the integration of $\mathbf{X}$ has been simplified.

We now summarize the results of this section: We have seen that it is, in general, impossible to get geometric information on the trajectories of the $\mathbb{R}^3$ v.f. $\mathbf{X}$ just by knowing that $\mathbf{X}$ belongs to a certain Lie algebra of v.f. More information concerning the v.f. of the Lie algebra is needed: see, for example, the requirements in (7).

A similar observation can be made in relation to the study of the pseudosymmetries of $\mathbf{X}$ [see Eq. (3)]. Namely, pseudosymmetries, *per se*, are insufficient in order to get first integrals and other geometric structures related to the trajectories of $\mathbf{X}$.

What is new in this section is the fact that we have shown the possibility of getting global geometric information on the trajectories of $\mathbf{X}$ when *no* pseudosymmetries are known but we have discovered that our dynamical system $\mathbf{X}$ is a generator of an $A_{2,2}$ algebra of vectorfields.

For brevity reasons we shall not study in the following sections algebras of type $A_{3,2}$, but just algebras of type $A_{3,3}$.

III. CLASSIFICATION OF $A_{3,3}$ ALGEBRAS

A classification list of the $A_{3,3}$ algebras is given now. The proof shall not be given and will be sent on request. As we can see the classification contains 18 different types. Note that the non-

written brackets between $\mathbf{X}$, $\mathbf{S_1}$ and $\mathbf{S_2}$ vanish and have been omitted. Nevertheless, all brackets have been written in the algebra of type number one (for esthetic reasons).

Any $A_{3,3}$ algebra can be obtained from those appearing in the list by means of linear combinations of type

$$\begin{aligned}
\mathbf{X}^* &= \alpha_0 \mathbf{X}, \\
\mathbf{S}_1^* &= \beta_0 \mathbf{X} + \beta_1 \mathbf{S}_1 + \beta_2 \mathbf{S}_2, \\
\mathbf{S}_2^* &= \gamma_0 \mathbf{X} + \gamma_1 \mathbf{S}_1 + \gamma_2 \mathbf{S}_2, \\
&\alpha_0, \beta_0, \gamma_0 \in \mathbb{R} \quad \alpha_0 \neq 0, \\
&\beta_1 \gamma_2 - \gamma_1 \beta_2 \neq 0.
\end{aligned} \tag{16}$$

These linear combinations arise as the generator $\mathbf{X}$ (representing the dynamical system) must be isolated in all the algebraic manipulations; otherwise a generator $\mathbf{X}^*$ could be obtained mixing the dynamics of $\mathbf{X}$ with the dynamics of the v.f. $\mathbf{S_1}$ and $\mathbf{S_2}$. Therefore, the orbit structure of $\mathbf{X}$ would be unrelated to the orbit structure of $\mathbf{X}^*$.

The 18 types of $A_{3,3}$ algebras are

(1) $[\mathbf{X},\mathbf{S_i}]=0$, $[\mathbf{S_1},\mathbf{S_2}]=0$, $i=1,2$;
(2) $[\mathbf{X},\mathbf{S_1}]=\mathbf{X}$;
(3) $[\mathbf{S_1},\mathbf{S_2}]=\mathbf{X}$;
(4) $[\mathbf{X},\mathbf{S_1}]=\mathbf{S_1}$;
(5) $[\mathbf{X},\mathbf{S_2}]=\mathbf{S_1}$, $[\mathbf{S_1},\mathbf{S_2}]=\alpha\mathbf{S_1}$, $\alpha\in\mathbb{R}$;
(6) $[\mathbf{S_1},\mathbf{S_2}]=\mathbf{S_1}$;
(7) $[\mathbf{X},\mathbf{S_2}]=\mathbf{X}$, $[\mathbf{S_1},\mathbf{S_2}]=\mathbf{X}+\alpha\mathbf{S_1}$, $\alpha\in\mathbb{R}\backslash\{0\}$;
(8) $[\mathbf{X},\mathbf{S_2}]=\mathbf{X}+\mathbf{S_1}$, $[\mathbf{S_1},\mathbf{S_2}]=\mathbf{X}$;
(9) $[\mathbf{X},\mathbf{S_2}]=\mathbf{S_1}$, $[\mathbf{S_1},\mathbf{S_2}]=-\mathbf{X}$;
(10) $[\mathbf{X},\mathbf{S_2}]=\mathbf{S_1}$, $[\mathbf{S_1},\mathbf{S_2}]=\mathbf{X}$;
(11) $[\mathbf{X},\mathbf{S_1}]=\mathbf{S_1}$, $[\mathbf{X},\mathbf{S_2}]=\alpha\mathbf{S_2}$, $\alpha\in\mathbb{R}\backslash\{0\}$;
(12) $[\mathbf{X},\mathbf{S_1}]=\mathbf{S_1}$, $[\mathbf{X},\mathbf{S_2}]=\mathbf{S_1}+\mathbf{S_2}$;
(13) $[\mathbf{X},\mathbf{S_1}]=\alpha\mathbf{S_1}+\mathbf{S_2}$, $[\mathbf{X},\mathbf{S_2}]=-\mathbf{S_1}+\alpha\mathbf{S_2}$, $\alpha\in\mathbb{R}\backslash\{0\}$;
(14) $[\mathbf{X},\mathbf{S_1}]=\mathbf{X}$, $[\mathbf{X},\mathbf{S_2}]=\mathbf{S_1}$, $[\mathbf{S_1},\mathbf{S_2}]=\mathbf{X}+\mathbf{S_2}$;
(15) $[\mathbf{X},\mathbf{S_1}]=\mathbf{S_2}$, $[\mathbf{X},\mathbf{S_2}]=-\mathbf{S_1}$, $[\mathbf{S_1},\mathbf{S_2}]=\mathbf{X}$;
(16) $[\mathbf{X},\mathbf{S_1}]=\mathbf{S_2}$, $[\mathbf{X},\mathbf{S_2}]=\mathbf{S_1}$, $[\mathbf{S_1},\mathbf{S_2}]=\mathbf{X}$;
(17) $[\mathbf{X},\mathbf{S_1}]=-\mathbf{S_1}-\mathbf{S_2}$, $[\mathbf{X},\mathbf{S_2}]=\mathbf{S_2}$, $[\mathbf{S_1},\mathbf{S_2}]=\mathbf{X}$; and
(18) $[\mathbf{X},\mathbf{S_1}]=-\mathbf{S_1}+\mathbf{S_2}$, $[\mathbf{X},\mathbf{S_2}]=\mathbf{S_2}$, $[\mathbf{S_1},\mathbf{S_2}]=\mathbf{X}$.

IV. INVARIANT SETS AND FIRST INTEGRALS WHEN THE DYNAMICAL SYSTEM IS EMBEDDED INTO AN $A_{3,3}$ ALGEBRA

We now show that it is possible to get first integrals, invariant sets and foliations invariant under $\mathbf{X}$ when $\mathbf{X}$ belongs to an $A_{3,3}$ algebra. Reduction of $\mathbf{X}$ to a two-dimensional v.f. is also possible (see Sec. IV C).

A. Global results

We get in this paragraph global results on $\mathbf{X}$ assuming that

$$\mathcal{L}_{\mathbf{X}} w_i = f(\mathbf{x}) w_i, \tag{17}$$

w_i being a C^∞ differential form of degree i ($i=1,2,3$).

Define the functions Δ_i via

$$\Delta_1 = i_{\mathbf{X}} i_{\mathbf{S}_1} i_{\mathbf{S}_2} w_3, \tag{18}$$

$$\Delta_2 = i_{\mathbf{X}} i_{\mathbf{S}_j} w_2, \quad j=1,2, \tag{19}$$

$$\Delta_3 = i_{\mathbf{S}_1} i_{\mathbf{S}_2} w_2, \tag{20}$$

$$\Delta_4 = i_{\mathbf{X}} w_1, \tag{21}$$

$$\Delta_5 = i_{\mathbf{S}_j} w_1, \quad j=1,2. \tag{22}$$

We then get under standard manipulations[4]

$$\mathcal{L}_{\mathbf{X}}(\Delta_i) = (f(\mathbf{x})+K)\Delta_i, \quad K \in \mathbb{R}, \tag{23}$$

where the real number K depends on the constants a_i, b_i, c_i $(i=0,1,2)$ defining the $A_{3,3}$ algebra [see Eq. (5)].

Now, Eq. (23) implies the following.

(i) When the set $\{\Delta_i=0\}$ is a differential manifold ($\nabla(\Delta_i)\neq \mathbf{0}$ for any $P\in\{\Delta_i=0\}$), then the set $\{\Delta_i=0\}$ is invariant under $\mathbf{X}$. See Example 1 in Sec. V.

(ii) When $f+K$ is a function of Δ_i (in particular when $f+K$ is a constant real number), then the sets $\{\Delta_i=\text{const}\}$ form a two-foliation invariant under $\mathbf{X}$.

(iii) When $f(\mathbf{x})$ is a trivial constant function and $f+K$ is equal to zero, then the function Δ_i is a global first integral of $\mathbf{X}$.

These results give useful information on the orbits of $\mathbf{X}$ and they have been obtained without problems in spite of the fact that $\mathbf{S_1}$ and $\mathbf{S_2}$ are, in general, not pseudosymmetries of $\mathbf{X}$.

See the examples on these results at the end of the article.

Note that the techniques of this section can be applied to *any* of the canonical algebras of the list in Sec. III.

B. Subalgebras

We now assume that our $A_{3,3}$ algebra contains two $A_{2,2}$ subalgebras satisfying

$$\begin{aligned} [\mathbf{X},\mathbf{S_1}] &= a\mathbf{X}+b\mathbf{S_1}, \\ [\mathbf{S_2},\mathbf{X}] &= a'\mathbf{X}+b'\mathbf{S_1}, \\ [\mathbf{S_2},\mathbf{S_1}] &= a''\mathbf{X}+b''\mathbf{S_1}, \\ a,a',a'',b,b',b'' &\in \mathbb{R}, \end{aligned} \tag{24}$$

or

$$\begin{aligned} [\mathbf{S}_1^*,\mathbf{S}_2^*] &= c\mathbf{S}_1^*+d\mathbf{S}_2^*, \\ [\mathbf{X},\mathbf{S}_1^*] &= c'\mathbf{S}_1^*+d'\mathbf{S}_2^*, \\ [\mathbf{X},\mathbf{S}_2^*] &= c''\mathbf{S}_1^*+d''\mathbf{S}_2^*, \\ c,c',c'',d,d',d'' &\in \mathbb{R}, \end{aligned} \tag{25}$$

or both [i.e., $A_{3,3}$ might contain a subalgebra satisfying Eq. (24) and another two-dimensional subalgebra satisfying Eq. (25)]. Note that $\{\mathbf{X},\mathbf{S_1}\}$ in the case of Eq. (24) and $\{\mathbf{S_1^*},\mathbf{S_2^*}\}$ in the case of Eq. (25) are ideals of dimension two of $A_{3,3}$.[7]

First of all, notice that we can apply the techniques of Sec. II to the pair $(\mathbf{X},\mathbf{S_1})$ of Eq. (24).

Note that Eqs. (24) are fulfilled by the algebras 1, 2, 3, 4, 5, 6, 7, 8, 9, 10 and 13 and Eqs. (25) are satisfied by the algebras 1, 4, 5, 6, 11, and 12.

On the other hand, algebras 13–18 satisfy neither Eqs. (24) nor Eqs. (25). The reader will have no difficulty in checking all these points.

We give now the geometric meaning of Eqs. (24) and (25). Calling $\mathcal{F}_2$ and $\mathcal{F}_2^*$ the two-foliations associated with the pairs $(\mathbf{X},\mathbf{S_1})$ and $(\mathbf{S_1^*},\mathbf{S_2^*})$, Eqs. (24) and (25) can be rewritten in the form

$$\mathcal{L}_{\mathbf{S_2}}(\mathcal{F}_2)\subset\mathcal{F}_2, \tag{26}$$

and

$$\mathcal{L}_{\mathbf{X}}(\mathcal{F}_2^*)\subset\mathcal{F}_2^*. \tag{27}$$

Accordingly, $\mathcal{F}_2$ and $\mathcal{F}_2^*$ can be locally integrated via the well known formulas[8]

$$\Delta^{-1}\cdot(i_{\mathbf{X}}i_{\mathbf{S_1}}\Omega_3)=dI,$$

$$\Omega_3=dx_1\wedge dx_2\wedge dx_3, \tag{28}$$

$$\Delta=i_{\mathbf{X}}i_{\mathbf{S_1}}i_{\mathbf{S_2}}\Omega_3,$$

and

$$\Delta^{-1}\cdot(i_{\mathbf{S_1^*}}i_{\mathbf{S_2^*}}\Omega_3)=dI^*, \tag{29}$$

I and I^* satisfying

$$\mathcal{L}_{\mathbf{X}}(I)=0 \tag{30}$$

and

$$\mathcal{L}_{\mathbf{X}}(I^*)=f(I^*) \tag{31}$$

for a certain function f.

The function I is, of course, a local integral of $\mathbf{X}$ and it globalizes to a $\mathbb{R}^3$ first integral of $\mathbf{X}$ when the function Δ of Eq. (28) never vanishes.

On the other hand, the geometrical meaning of Eq. (31) is that the local flow of $\mathbf{X}$ acts on the level sets of I^*. When the function f of (31) never vanishes, $\mathbf{X}$ is free from closed trajectories. If $f(I_0^*)=0$, then closed trajectories of $\mathbf{X}$ might appear on the level set $I^*=I_0^*$.

Note that I and I^* are genuine functions, not reducing to constant functions, since in an $A_{3.3}$ algebra the ranks of the pairs $(\mathbf{X},\mathbf{S})$ and $(\mathbf{S_1^*},\mathbf{S_2^*})$ cannot be lower than 2.

C. Results

We now get several results on the orbits of the dynamical system $\mathbf{X}$ assuming that a pair of first integrals common to $\mathbf{S_1}$ and $\mathbf{S_2}$ are known. For brevity's sake, the case of only a first integral I common to $\mathbf{S_1}$ and $\mathbf{S_2}$ shall not be studied.

See Ref. 6 for a similar use of a pair of first integrals of a symmetry of a $\mathbb{R}^3$ dynamical system related to the Bessel, Poisson–Boltzmann, Emden–Fowler and Fermi–Thomas equations. This

approach can be justified since in most of the applications the v.f. $\mathbf{S_i}$ are simple v.f.; often they are affine, or even linear v.f., and therefore the finding of their first integrals is, in general, not difficult.

Consider that

$$\mathcal{L}_{\mathbf{S_i}}(I_j)=0, \quad i,j=1,2 \tag{32}$$

that is I_1, I_2 are independent first integrals common to $\mathbf{S_1}, \mathbf{S_2}$. We then get via Eq. (5) ($c_0 \neq 0$)

$$\mathcal{L}_{\mathbf{X}}(I_i)=\varphi_i(I_1,I_2) \quad i=1,2. \tag{33}$$

Therefore $\mathbf{X}$ can be written in the form

$$\mathbf{X}=\varphi_1(x,y)\partial_1+\varphi_2(x,y)\partial_2. \tag{34}$$

Accordingly, $\mathbf{X}$ has been reduced to a $\mathbb{R}^2$ v.f.

V. EXAMPLES

Examples 1: Consider the conformal v.f.[4]

$$\mathbf{X}=(x_1^2-x_2^2-x_3^2)\partial_1+(2x_1x_2)\partial_2+(2x_1x_3)\partial_3 \tag{35}$$

and the v.f.

$$\begin{aligned}\mathbf{S}_1&=x_3\partial_2-x_2\partial_3,\\ \mathbf{S}_2&=x_1\partial_1+x_2\partial_2+x_3\partial_3,\end{aligned} \tag{36}$$

with commutation relations

$$[\mathbf{X},\mathbf{S_1}]=\mathbf{0}, \quad [\mathbf{X},\mathbf{S_2}]=-\mathbf{X}, \quad [\mathbf{S_1},\mathbf{S_2}]=\mathbf{0}. \tag{37}$$

By application of the results obtained in Secs. IV A and IV B we get

$$\Delta_1=i_{\mathbf{X}}i_{\mathbf{S_1}}i_{\mathbf{S_2}}(dx_1\wedge dx_2\wedge dx_3)=(x_2^2+x_3^2)(-x_1^2-x_2^2-x_3^2). \tag{38}$$

On the other hand,

$$\mathcal{L}_{\mathbf{X}}(\Delta_1)=6x_1\cdot\Delta_1. \tag{39}$$

Therefore, the set $\Delta_1=0$ is invariant under $\mathbf{X}$. Note that the set $\Delta_1=0$ is just the x_1-axis.

Let us now get a local first integral of $\mathbf{X}$ by application of the methods of Sec. IV B. In fact, computing $i_{\mathbf{X}}i_{\mathbf{S_1}}(dx_1\wedge dx_2\wedge dx_3)/\Delta_1$ we get the differential form

$$\frac{w_1}{\Delta_1}=\frac{2x_1dx_1}{-x_1^2-x_2^2-x_3^2}+\frac{(-x_2dx_2-x_3dx_3)(x_1^2-x_2^2-x_3^2)}{(x_2^2+x_3^2)(-x_1^2-x_2^2-x_3^2)}, \tag{40}$$

which is locally exact ($w_1/\Delta_1=dI$). Upon integration we get the local first integral I that can be reduced to

$$I'=\frac{x_2^2+x_3^2}{x_1^2+x_2^2+x_3^2}. \tag{41}$$

Example 2: Consider now the family of v.f.

$$\mathbf{X}=F(x_3)(x_1^2+x_2^2)^n x_1\partial_1+F(x_3)(x_1^2+x_2^2)^n x_2\partial_2+G(x_3)(x_1^2+x_2^2)^n\partial_3, \quad n=1,2,3,..., \tag{42}$$

where F and G are analytic and G vanishes on the set $Z(Z\subset\mathbb{R})$.

Let $\mathbf{S_i}$ $(i=1,2)$ be the v.f.

$$\begin{aligned}\mathbf{S_1}&=x_1\partial_1+x_2\partial_2,\\ \mathbf{S_2}&=x_2\partial_1-x_1\partial_2.\end{aligned} \tag{43}$$

The three v.f. $\mathbf{X},\mathbf{S_1},\mathbf{S_2}$ form a commutative algebra. By applying to them the techniques of Secs. IV A and IV B we get the invariant set

$$\Delta_1=G(x_3)(x_1^2+x_2^2)^{n+1}=0, \tag{44}$$

that is, the invariant sets

$$\begin{aligned}x_1^2+x_2^2&=0,\\ x_3&=z, \quad z\in Z.\end{aligned} \tag{45}$$

On the other hand, we can also write

$$\frac{w_1}{\Delta_1}=dI, \tag{46}$$

w_1 standing for the one-form

$$w_1=i_{\mathbf{x}}i_{\mathbf{s_2}}(dx_1\wedge dx_2\wedge dx_3). \tag{47}$$

We get in this way

$$I=\frac{1}{2}L(x_1^2+x_2^2)-\int\frac{F(x_3)}{G(x_3)}dx_3, \tag{48}$$

L standing for Neperian logarithm, that is, a local first integral of $\mathbf{X}$.

Example 3: We now give an example related to Sec. II B.

Let $H_i(x_1,x_2,x_3)$ be homogeneous polynomials of degrees d_1 and d_2. Define $\mathbf{X}$ and $\mathbf{S}$ viahe equations

$$\begin{aligned}\mathbf{X}&=\nabla H_1\wedge\nabla H_2+a_0(x_1\partial_1+x_2\partial_2+x_3\partial_3),\\ \mathbf{S}&=\nabla H_1\wedge\nabla H_2,\\ a_0&\in\mathbb{R}, \quad \nabla=\text{gradient operator}.\end{aligned} \tag{49}$$

The reader will check that

$$[\mathbf{X},\mathbf{S}]=b\mathbf{S}, \quad b\in\mathbb{R}. \tag{50}$$

Therefore the pair $(\mathbf{X},\mathbf{S})$ forms an $A_{2,2}$ algebra.

Since H_1 and H_2 are first integrals of $\mathbf{S}$, we get from (50)

$$\begin{aligned}\mathcal{L}_{\mathbf{x}}(H_1)&=\varphi_1(H_1,H_2),\\ \mathcal{L}_{\mathbf{x}}(H_2)&=\varphi_2(H_1,H_2),\end{aligned} \tag{51}$$

that is, **X** projects to the $\mathbb{R}^2$ v.f.

$$\varphi_1 \partial_{H_1} + \varphi_2 \partial_{H_2}. \tag{52}$$

Note that the v.f. **X** of (49) is not trivial, as it is *not* a homogeneous v.f.

Note also that any first integral $I(H_1, H_2)$ of the reduced differential equations (51) is a first integral of **X**.

Example 4: The considerations of Example 3 can be extended to nonhomogeneous functions in this way.

Let H_1 and H_2 be nonhomogeneous polynomials that can be transformed into homogeneous ones via a transformation of type

$$\begin{gathered} x_1 \to x_1^a, \\ x_2 \to x_2^b, \\ x_3 \to x_3^c, \\ a, b, c \in \mathbb{R}^+. \end{gathered} \tag{53}$$

For example, the pairs

$$H_1 = x_2 x_3, \quad H_2 = x_1^2 + x_2^2 + x_3$$

and

$$H_1 = x_2^2 + x_3^2, \quad H_2 = x_1^2 - x_3$$

become homogeneous under the transformations

$$x_1 \to x_1, \quad x_2 \to x_2, \quad x_3 \to {}^2_3$$

and

$$x_1 \to x_1 \quad x_2 \to {}^2_2, \quad x_3 \to x_3^2.$$

Under these circumstances the v.f. defined by

$$\begin{gathered} \mathbf{X} = \nabla H_1 \wedge \nabla H_2 + a_0 (x_1 \partial_1 + x_2 \partial_2 + x_3 \partial_3), \\ \mathbf{S} = \nabla H_1 \wedge \nabla H_2, \end{gathered} \tag{54}$$

commutes as in Eq. (50). Therefore, the conclusions in Example 3 are valid for the v.f. of Eq. (54). For example, the Lorenz dynamical system[9]

$$\mathbf{X}_L = \sigma(x_2 - x_1)\partial_1 + (-x_1 x_3 + r x_1 - x_2)\partial_2 + (x_1 x_2 - b x_3)\partial_3, \quad \sigma, r, b \in \mathbb{R}, \tag{55}$$

for the following particular values of the parameters,

$$\sigma = \tfrac{1}{2}, \quad r = 0, \quad b = 1,$$

forms an $A_{2,2}$ algebra, of the type discussed in this example, with the v.f.

$$\mathbf{S} = \nabla(x_2^2 + x_3^2) \wedge \nabla(x_1^2 - x_3) \tag{56}$$

as the reader can check.

Example 5: We end this section with a list of second order differential equations appearing in Physics (see in Ref. 6) admitting a symmetry vector **S** to which the methods of this article can be applied (see Sec. II B).

(5.1) $x^2y_{,xx}+xy_{,x}+x^2y=0$:

$$\text{Associated } \mathbf{X}\text{:}\mathbf{X}=\frac{-xu-x^2y}{x^2}\partial_u+u\partial_y+\partial_x \quad u=y_{,x}.$$

$$\text{Symmetry vector: } \mathbf{S}=y\partial_y+u\partial_u.$$

$$\text{Commutation relation: } [\mathbf{X},\mathbf{S}]=\mathbf{0}.$$

$$\text{First integrals of } \mathbf{S}\text{: } I_1=x, \quad I_2=u/y.$$

(5.2) $y_{,xx}+y_{,x}/x=e^y$.

$$\text{Associated } \mathbf{X}\text{: } \mathbf{X}=\left(e^y-\frac{u}{x}\right)\partial_u+u\partial_y+\partial_x, \quad u=y_{,x}.$$

$$\text{Symmetry vector: } \mathbf{X}=x\partial_x-2\partial_y-u\partial_u.$$

$$\text{Commutation relation: } [\mathbf{X},\mathbf{S}]=\mathbf{X}.$$

$$\text{First integrals of } \mathbf{S}\text{: } I_1=x^2e^y, \quad I_2=xu.$$

(5.3) $y_{,xx}+(2/x)y_{,x}+y^n=0$.

$$\text{Associated } \mathbf{X}\text{: } \mathbf{X}=\left(-y^n-\frac{2u}{x}\right)\partial_u+u\partial_y+\partial_x \quad u=y_{,x}.$$

$$\text{Symmetry vector: } \mathbf{S}=x\partial_x+\frac{2y}{1-n}\partial_y+\frac{1+n}{1-n}u\partial_u.$$

$$\text{Commutation relation: } [\mathbf{X},\mathbf{S}]=\mathbf{X}.$$

$$\text{First integrals of } \mathbf{S}\text{: } I_1=x^2y^{n-1}, \quad I_2=x^{n+1}u^{n-1}.$$

(5.4) $y_{,xx}=x^{-1/2}y^{3/2}$.

$$\text{Associated } \mathbf{X}\text{: } \mathbf{X}=(x^{-1/2}y^{3/2})\partial_u+u\partial_y+\partial_x, \quad u=y_{,x}.$$

$$\text{Symmetry vector: } \mathbf{S}=x\partial_x-3y\partial_y-4u\partial_u.$$

$$\text{Commutation relation: } [\mathbf{X},\mathbf{S}]=\mathbf{X}.$$

$$\text{First integrals of } \mathbf{S}\text{: } I_1=x^3y, \quad I_2=x^4u.$$

VI. FINAL REMARKS

We have seen that when a $\mathbb{R}^3$ dynamical system **X** lies inside an $A_{2,2}$, $A_{3,2}$ or $A_{3,3}$ algebra useful information on its trajectories can be obtained from this piece of information.

What happens when **X** can be embedded into a Lie algebra $A_{n,3}$ when $n>3$? Note that now the canonical forms of Sec. III are harder to obtain. On the other hand, $A_{n,3}$ might contain ideals I containing **X** of lower dimension n', reducing the problem to an algebra $A_{n',3}$ of lower dimension. If no ideal of this type can be found, we can always apply the techniques of Sec. IV A.

Considering only contractions of $\mathbf{X}$ and $\mathbf{S_i}$ with differential forms of type w_3, we can get in this way a whole set of functions Δ_{ij}:

$$\Delta_{ij}=i_X i_{S_i} i_{S_j} w_3, \quad i,j=1,...,n-1, \tag{57}$$

leading to the sets

$$\Delta_{ij}(x_1,x_2,x_3)=0 \tag{58}$$

that are invariant under $\mathbf{X}$ [at least near the points P on which (58) defines a differential manifold, that is $\nabla(\Delta_{ij})(P)\neq 0$].

Therefore, when n is high we can get, via Eq. (58), a collection of more and more sets invariant under $\mathbf{X}$.

An open problem is to study if the number N of invariant sets in (58) is bounded or not when n increases and whether or not these invariant sets accumulate (when N is unbounded). Does the topology of the trajectories of $\mathbf{X}$ ''feel'' that $\mathbf{X}$ is included in an $A_{n,3}$ algebra (without proper ideals) when n is large?

Another open problem meriting a separate study is this one: Assume that $\mathbf{X}$ is included among the generators of an $A_{\infty,3}$ algebra where $A_{\infty,3}$ is an infinite Lie algebra, free from finite or infinite proper ideals containing $\mathbf{X}$. Let us call them *simple* ∞-algebras.

Equation (57) can now be written in the form

$$\Delta_{ij}=i_X i_{S_i} i_{S_j} w_3, \tag{59}$$

and, therefore, invariant sets of $\mathbf{X}$ can be obtained this way.

The question arises again of classifying topologically the v.f. $\mathbf{X}$ that can be included in a simple $A_{\infty,3}$ algebra.

A final question is this one: can a dynamical system $\mathbf{X}$ embedded into a Lie algebra $A_{n,2}$, $A_{n,3}$ or $A_{\infty,2}$, $A_{\infty,3}$ possess a strange attractor?[9]

JOURNAL OF MATHEMATICAL PHYSICS VOLUME 42, NUMBER 12 DECEMBER 2001

Nonintegrable reductions of the self-dual Yang–Mills equations in a metric of plane wave type

Devendra A. Kapadia
Department of Mathematics, University of Pittsburgh, Pittsburgh, Pennsylvania 15260

(Received 26 January 2001; accepted for publication 29 August 2001)

Symmetry reductions of the self-dual Yang–Mills equations for SL(2,C) bundles with the background metric $ds^2=2\,du\,dv-dx^2+f^2(u)dy^2$ are considered. One of the field components in the reduced equations can be cast into Jordan normal form after gauge transformations. The reduced equations for the two possible normal forms are equivalent, respectively, to certain generalizations of the Korteweg–de Vries (KdV) equation and the nonlinear Schrödinger (NLS) equation. It is shown that the generalized KdV and NLS equations fail the Painlevé test except when the metric is flat. The generalized KdV equation is transformed to a simple form in the case when $f(u)=u^a$ and it is shown that one may obtain either the KdV equation or the cylindrical KdV equation by this method only when the metric is flat. [DOI: 10.1063/1.1412466]

I. INTRODUCTION

The self-dual Yang–Mills (SDYM) equations for bundles defined over flat spacetime play a unifying role in the theory of integrable systems. This is because many well-known integrable equations may be obtained as symmetry reductions of these equations (Ref. 1, Ref. 9). The twistor description of solutions of the SDYM equations in flat spacetime (Ref. 10) then leads to a twistor description of the reduced equations.

Our aim in this paper is to study reductions of the SDYM equations for bundles defined over an open subset U of R^4 with the metric

$$ds^2=2\,du\,dv-dx^2+f^2(u)dy^2, \tag{1}$$

where u, v, x, y are coordinates on U and f is a smooth function.

Before proceeding further, we would like to mention that metrics of the type (1) with the Lorentzian signature (obtained by changing the sign of the middle term) arise in the study of plane waves in general relativity. The geodesic and curvature properties of these metrics (e.g., the fact that they are conformally Einstein) are given in Ref. 5. For our purposes, it is enough to note that the metric (1) is flat if and only if f is a linear function of u. We will now explain our motivation for studying the problem.

In Ref. 11, Ward presented an integral formula for the general solution of the wave equation in a plane wave spacetime. This formula was subsequently generalized by Mason (Ref. 7) to show how it is that Maxwell's equation satisfies a kind of Huygen's principle in plane wave spacetimes. We were therefore interested in studying solutions of the SDYM equations in these spacetimes. As a first step, we decided to study reductions of the SDYM equations with the background metric (1) along the lines of Ref. 8.

Somewhat to our surprise, the generalized Korteweg–de Vries (KdV) and nonlinear Schrödinger (NLS) equations which resulted from the reduction procedure both failed the Painlevé PDE test (Ref. 12) formulated for these equations in Refs. 2 and 4, respectively, except in the case when the metric (1) is flat.

The plan for our paper is as follows. In Sec. II, we will derive the SDYM equations for an SL(2,C) bundle with the background metric (1). The metric possesses a large group of symme-

tries. We impose two of these symmetries, one timelike and the other null, on the bundle and, after a choice of gauge, we obtain the reduced SDYM equations in a form suitable for use in the later sections.

One of the components of the connection in the reduced SDYM equation may, after gauge transformations, be cast into Jordan normal form. The reduced equations corresponding to one choice of the normal form leads to a generalized KdV equation. This reduction is discussed in Sec. III where we also prove the nonintegrability of the generalized KdV equation. It has been known for some time that there is a formal relation between solutions of the KdV equation and solutions of the so-called cylindrical KdV equation (Refs. 3 and 6). In Sec. IV, we set $f(u)=u^a$ in the metric (1) and give a direct proof that the generalized KdV equation from Sec. III can be reduced either to the KdV equation or to the cylindrical KdV equation in exactly two cases, namely, $a=0,1$. These values of a correspond to the cases when the metric (1) is flat.

The second choice of the normal form mentioned above leads us to the generalized NLS equation in Sec. V. Once again, we show that this equation is nonintegrable except in the flat case. We note that it may very well be possible to obtain the cylindrical NLS equation by following the method described in Sec. IV but we have not done this ourselves.

We end this introduction by observing that in the case of the generalized KdV equation all quantities may be interpreted as being real and hence the gauge group is $\mathrm{SL}(2,R)$. The gauge group for the generalized NLS equation is SU(1,1).

II. THE REDUCED SDYM EQUATIONS

In this section, we will derive the reduced self-dual Yang–Mills equations for an $\mathrm{SL}(2,C)$ bundle E defined over U with the metric (1).

We begin by recalling that a connection on E is a linear differential operator D that maps sections of E to 1-forms with values in E. In a local trivialization, we may write D as

$$D=D_a\,dx^a, \tag{2}$$

where

$$D_a=\partial_a-\Phi_a\,. \tag{3}$$

In this expression ∂_a denotes the partial derivative with respect to the coordinate x^a and Φ_a belongs to the Lie algebra of $\mathrm{SL}(2,C)$ $(a=1,2,3,4)$.

The curvature of the connection D is a 2-form F with values in the Lie algebra of $\mathrm{SL}(2,C)$. It is given by

$$F=F_{ab}=[D_a,D_b]=\partial_a\Phi_b-\partial_b\Phi_a+[\Phi_a,\Phi_b], \tag{4}$$

where the brackets denote the appropriate commutator in each case.

Next, let g^{ab} denote the inverse of the matrix g_{ab} associated with the metric (1) and let Δ denote square root of the determinant of g_{ab}. Also, let ϵ_{abcd} denote the totally skew Levi–Civita tensor density. The connection D is said to be a solution of the SDYM equations if

$$F_{ab}=\tfrac{1}{2}\Delta\,\epsilon_{abcd}g^{ce}g^{df}F_{ef}\,. \tag{5}$$

We now choose an orientation by setting $\epsilon_{uvxy}=1$. Then it is easy to see that the SDYM equations for the metric (1) are as follows:

$$[D_x,D_y]=-f[D_u,D_v], \tag{6}$$

$$[D_u,D_y]=-f[D_u,D_x], \tag{7}$$

and

$$[D_v, D_y] = f[D_v, D_x]. \tag{8}$$

(We have suppressed the argument of f for the sake of convenience.)

Next, we know that the vectors $\partial/\partial x$ and $\partial/\partial v$ are Killing vectors for the metric (1). We now impose these symmetries on the bundle, i.e., we assume that the field components are independent of x and v. We also let

$$D_y = \partial_y - A, \quad D_v = \partial_v - B, \tag{9}$$

$$D_u = \partial_u - C, \quad D_x = \partial_x - D, \tag{10}$$

where A, B, C, and D belong to the Lie algebra of SL(2,C). Then the SDYM equations reduce to the following three equations:

$$\partial_y D + [D,A] = -f(-\partial_u B + [C,B]), \tag{11}$$

$$-\partial_u A + \partial_y C + [C,A] = -f(-\partial_u D + [C,D]), \tag{12}$$

and

$$\partial_y B + [B,A] = f[B,D]. \tag{13}$$

Finally, we impose the gauge condition

$$A = fD. \tag{14}$$

The equation (13) now reduces to

$$\partial_y B = 0. \tag{15}$$

Hence, B is a function of u alone. Using gauge transformations involving only u, we may reduce B to one of the following constant normal forms:

$$B = \begin{bmatrix} 0 & 0 \\ 1 & 0 \end{bmatrix} \quad \text{or} \quad B = \kappa \begin{bmatrix} 1 & 0 \\ 0 & -1 \end{bmatrix}, \tag{16}$$

where κ is a real or complex constant.

The equation (11) now reduces to

$$\partial_y D = -f[C,B] \tag{17}$$

and Eq. (12) reduces to

$$-f'D - 2f\partial_u D + \partial_y C + 2f[C,D] = 0, \tag{18}$$

where the prime denotes differentiation with respect to u.

We will use the two normal forms for B in Secs. III and V, respectively, in order to reduce the SDYM equations to the generalized KdV and Schrödinger equations, respectively.

III. REDUCTION TO THE GENERALIZED KdV EQUATION

We will begin this section by showing that if the field component B has the normal form

$$B = \begin{bmatrix} 0 & 0 \\ 1 & 0 \end{bmatrix} \tag{19}$$

then the equations (17) and (18) are equivalent to a generalized (variable coefficient) KdV equation. In order to do this, we assume that $\mathrm{tr}(BD)\neq 0$ and set

$$C=\begin{bmatrix} p & s \\ r & -p \end{bmatrix}, \quad D=\begin{bmatrix} q & 1 \\ h & -q \end{bmatrix}. \tag{20}$$

Then after some simplification, the equation (17) implies the following relations between h,p,q,s:

$$q_y=-fs, \quad h_y=2fp. \tag{21}$$

Hence, we must have

$$C=\begin{bmatrix} \dfrac{h_y}{2f} & -\dfrac{q_y}{f} \\ r & -\dfrac{h_y}{2f} \end{bmatrix}. \tag{22}$$

Finally, we consider the equation (18). If we substitute the matrices D and C from above into this equation, then a rather tedious calculation simplifies this equation to

$$\begin{bmatrix} -f'q-2fq_u+\dfrac{h_{yy}}{2f}-2hq_y-2fr & -f'-\dfrac{q_{yy}}{f}+2h_y+4qq_y \\ -f'h-2fh_u+r_y+4fqr-2hh_y & f'q+2fq_u-\dfrac{h_{yy}}{2f}+2fr+2hq_y \end{bmatrix}=0, \tag{23}$$

where the 0 on the right-hand side stands for the zero matrix of order 2. Using the equation given by (1, 2) entries on both sides, we see that h may be taken to be

$$h=\tfrac{1}{2}\left(f'y+\frac{q_y}{f}-2q^2\right). \tag{24}$$

Next, using the equation given by the (1,1) entries and the expression for h from (24) we see that r is given by the expression

$$r=-\frac{f'}{2f}q-q_u+\frac{q_{yyy}}{8f^3}-\frac{q_y^2}{f^2}-\frac{qq_{yy}}{2f^2}-\frac{f'yq_y}{2f}+\frac{q^2q_y}{f}. \tag{25}$$

Finally, if we substitute the expressions for h and r in the equation given by the (2,1) entries, we see that the function q must satisfy the equation

$$-[ff']'y-2q_{uy}-\frac{f'q_y}{f}-\frac{f'yq_{yy}}{f}+\frac{q_{yyyy}}{8f^3}-\frac{3q_yq_{yy}}{f^2}=0. \tag{26}$$

We now relabel the coordinates u and y as t and x, respectively. The equation (26) then reads

$$-[ff']'x-2q_{tx}-\frac{f'q_x}{f}-\frac{f'xq_{xx}}{f}+\frac{q_{xxxx}}{8f^3}-\frac{3q_xq_{xx}}{f^2}=0. \tag{27}$$

Next, let $q_x=u$. Then the function u must satisfy the generalized (variable coefficient) KdV equation

$$-[ff']'x-2u_t-\frac{f'u}{f}-\frac{f'xu_x}{f}+\frac{u_{xxx}}{8f^3}-\frac{3uu_x}{f^2}=0. \tag{28}$$

Now, according to Brugarino (Ref. 2), the KdV equation with nonuniformities, given by

$$u_t + a(t)u + (b(x,t)u)_x + c(t)uu_x + d(t)u_{xxx} + e(x,t) = 0 \tag{29}$$

has the Painlevé property if its coefficients satisfy the following compatibility condition:

$$b_t + (a - L(c))b + bb_x + db_{xxx} = 2ah + hL\left(\frac{d}{c^2}\right) + h' + ce + x\left[2a^2 + aL\left(\frac{d^3}{c^4}\right) + a' + L\left(\frac{d}{c}\right)L\left(\frac{d}{c^2}\right) + \frac{d}{dt}L\left(\frac{d}{c}\right)\right], \tag{30}$$

where L denotes the logarithmic derivative and $h(t)$ is an arbitrary function of t.

In order to apply this criterion, we first write the equation (28) as

$$\frac{[ff']'x}{2} + u_t + \left(\frac{f'xu}{2f}\right)_x - \frac{u_{xxx}}{16f^3} + \frac{3uu_x}{2f^2} = 0. \tag{31}$$

Then on comparison with the equation (29) we see that

$$a = 0, \quad b = \frac{f'x}{2f}, \quad c = \frac{3}{2f^2}, \quad d = -\frac{1}{16f^3}, \quad e = \frac{[ff']'x}{2}. \tag{32}$$

Using these expressions, the condition (30) reduces to

$$\frac{3f''x}{4f} = h\left(\frac{f'}{f}\right) + h'. \tag{33}$$

Clearly, we can find a suitable h if and only if $f'' = 0$, i.e., if and only if the metric is flat. Hence the generalized KdV equation (28) fails the Painlevé test in nonflat spacetimes.

IV. REDUCTION TO KdV/CYLINDRICAL KdV

We would now like to study the equation (28) in the special case when $f(t) = t^a$, where a is a fixed real number. We begin by transforming the dependent variable u as follows:

$$u \to t^{-(a+3\beta)/2}u + \beta t^{2a-1}x. \tag{34}$$

Here β is one of the (necessarily real) solutions of the quadratic equation

$$a(2a-1) + 2\beta(3a-1) + 3\beta^2 = 0. \tag{35}$$

After some simplification, the PDE (28) reduces to

$$u_t + \frac{a+3\beta}{2}t^{-1}xu_x - \frac{1}{16}t^{-3a}u_{xxx} + \frac{3}{2}t^{-5a+3\beta/2}uu_x = 0. \tag{36}$$

In order to eliminate the term in xu_x, we apply the coordinate transformation

$$x' = t^{-(a+3\beta)/2}x, \quad t' = t \tag{37}$$

and then we rename the variables x' and t' as x and t, respectively. The equation (36) transforms to

$$u_t - \tfrac{1}{16}t^{-(9a+9\beta)/2}u_{xxx} + \tfrac{3}{2}t^{-(3a+3\beta)}uu_x = 0. \tag{38}$$

Next we transform u as follows:

$$u \to t^{-(3a+3\beta)/2} u. \tag{39}$$

Then we get the equation

$$-\frac{3a+3\beta}{2} t^{9a+9\beta-2} 2u + t^{9a+9\beta} 2u_t - \frac{1}{16} u_{xxx} + \frac{3}{2} u u_x = 0. \tag{40}$$

The last two terms in this equation are the same as the dissipative and nonlinear terms in the KdV equation (for a particular choice of coefficients).

Next, consider the transformation

$$t' = t^{-(9a+9\beta-2)/2} \tag{41}$$

and rename t' as t. The equation (40) reduces to

$$-\frac{3}{2}(a+\beta)\frac{u}{t} - \frac{9a+9\beta-2}{2} u_t - \frac{u_{xxx}}{16} + \frac{3}{2} u u_x = 0. \tag{42}$$

We now observe that if $a+\beta=0$ (i.e., $\beta=-a$) then this equation is the KdV equation (for a particular choice of coefficients). Further, on substituting $\beta=-a$ in (35) we see that $a=0,1$. Thus, the equation (28) can be reduced to the KdV equation by this method only if the metric (1) is flat.

We now wish to study the possibility of choosing a and β such that the equation (42) reduces to the cylindrical KdV equation, which is given by

$$w_t - 6 w w_x + w_{xxx} + \frac{w}{2t} = 0. \tag{43}$$

Let

$$u = \alpha w, \quad t = \gamma t', \quad x' = \delta x \tag{44}$$

in (42) and rename the variables t' and x' as t and x, respectively. Then (42) transforms to

$$-\frac{3a+3\beta}{2}\frac{\alpha}{\gamma}\frac{w}{t} - \frac{9a+9\beta-2}{2}\frac{\alpha}{\gamma} w_t - \frac{\alpha\delta^3}{16} w_{xxx} + \frac{3}{2}\alpha^2 \delta w w_x = 0. \tag{45}$$

Comparing this equation with (43), we see that we must have

$$-\frac{3a+3\beta}{2}\frac{\alpha}{\gamma} = \frac{1}{2}, \quad -\frac{9a+9\beta-2}{2}\frac{\alpha}{\gamma} = 1, \tag{46}$$

$$\alpha\delta^3 = -16, \quad \alpha^2\delta = 4. \tag{47}$$

The last two equations yield real values for α and δ as required. It is also easy to see that the first pair of equations are consistent if and only if $a+\beta=\frac{2}{3}$. Substitution of this condition in (35) again yields $a=0,1$. To summarize, we have exhibited a procedure which reduces (28) either to the KdV equation or to the cylindrical KdV equation precisely in the cases when the metric (1) is flat.

We end this section by noting that for a general value of the exponent a in the function f, the above procedure yields the equation

$$w_t - 6 w w_x + w_{xxx} + \frac{\epsilon}{t} w = 0. \tag{48}$$

It can be shown (Ref. 1) that the ODE arising from a scaling similarity solution of this equation has a movable logarithmic branch point except if $\epsilon = 0, \frac{1}{2}$, i.e., when the equation is either the KdV or the cylindrical KdV equation. Hence the Painlevé ODE test predicts that the equation (48) is nonintegrable if $\epsilon \neq 0, \frac{1}{2}$.

V. REDUCTION TO GENERALIZED NLS

We now consider the reduced SDYM equations in the case when the field component B has the normal form

$$B = \kappa \begin{bmatrix} 1 & 0 \\ 0 & -1 \end{bmatrix}. \tag{49}$$

We begin by making the following ansatz for the components D and C:

$$D = \begin{bmatrix} 0 & \psi \\ -\tilde{\psi} & 0 \end{bmatrix}, \quad C = \begin{bmatrix} p & q \\ r & -p \end{bmatrix}. \tag{50}$$

Then the equation (17) reduces to

$$\begin{bmatrix} 0 & \psi_y \\ -\tilde{\psi}_y & 0 \end{bmatrix} = -f\kappa \begin{bmatrix} 0 & -2q \\ 2r & 0 \end{bmatrix}. \tag{51}$$

Thus, we must have

$$q = \frac{\psi_y}{2f\kappa}, \quad r = \frac{\tilde{\psi}_y}{2f\kappa}, \tag{52}$$

i.e.,

$$C = \begin{bmatrix} p & \dfrac{\psi_y}{2f\kappa} \\ \dfrac{\tilde{\psi}_y}{2f\kappa} & -p \end{bmatrix}. \tag{53}$$

We now substitute D and C into (18) to obtain the following equation after some calculation:

$$\begin{bmatrix} p_y & -f'\psi - 2f\psi_u + \dfrac{\psi_{yy}}{2f\kappa} \\ f'\tilde{\psi} + 2f\tilde{\psi}_u - \dfrac{\tilde{\psi}_{yy}}{2f\kappa} & -p_y \end{bmatrix} + \begin{bmatrix} -\dfrac{(\psi\tilde{\psi})_y}{\kappa} & 4fp\psi \\ 4fp\tilde{\psi} & \dfrac{(\psi\tilde{\psi})_y}{\kappa} \end{bmatrix} = 0. \tag{54}$$

Using the equation given by the (1,1) entries on both sides of (54), we see that we may take

$$p = \frac{\psi\tilde{\psi}}{\kappa}. \tag{55}$$

If we set $\kappa = i/2$ and $\tilde{\psi} = -\overline{\psi}$ (where $\overline{\psi}$ denotes the complex conjugate of ψ), then

$$p = 2i|\psi|^2. \tag{56}$$

We now substitute this expression for p in the equation given by the (1, 2) entries on both sides of (54) to get

$$-ff'\psi-2f^2\psi_u-i\psi_{yy}+8if^2|\psi|^2\psi=0. \tag{57}$$

This is a generalized (variable coefficient) NLS equation.

We now wish to reduce this equation to a form which is suitable for application of the Painlevé PDE test. We begin by transforming the dependent variable ψ as follows:

$$\psi\rightarrow\frac{\psi}{f}. \tag{58}$$

Then (57) reduces to

$$ff'\psi-2f^2\psi_u-i\psi_{yy}+8i|\psi|^2\psi=0. \tag{59}$$

Next, let

$$t=\int\frac{1}{2f^2(u)}du. \tag{60}$$

Then (59) transforms to

$$\frac{if_t\psi}{2f}-i\psi_t+\psi_{yy}+8|\psi|^2\psi=0. \tag{61}$$

Finally, if we apply the transformation

$$\psi\rightarrow-2\psi,\quad y'=4y,\quad t'=16t, \tag{62}$$

and rename t' as t and y' as x, then we get the required form of the generalized NLS equation:

$$-\frac{if_t}{2f}\psi+i\psi_t+\psi_{xx}-2|\psi|^2\psi=0. \tag{63}$$

Now, according to Clarkson (Ref. 4), the generalized nonlinear Schrödinger equation

$$i\psi_t+\psi_{xx}-2|\psi|^2\psi=a(x,t)\psi+b(x,t) \tag{64}$$

passes the Painlevé PDE test if and only if

$$a(x,t)=x^2\left(\frac{1}{2}\frac{d\beta}{dt}-\beta^2\right)+i\beta(t)+x\alpha_1(t)+\alpha_0(t) \tag{65}$$

and

$$b(x,t)\equiv0. \tag{66}$$

In our case, $\alpha_1(t)=\alpha_0(t)=b(x,t)\equiv0$ and $\beta(t)=f_t/2f$. Also since there is no quadratic term in x [in $a(x,t)$] we must have

$$\frac{1}{2}\frac{d\beta}{dt}-\beta^2=0, \tag{67}$$

i.e.,

$$\beta = -\frac{1}{2(t-t_0)} \tag{68}$$

which is easily seen to imply that

$$f = ku + l, \tag{69}$$

where k and l are constants.

We conclude that the generalized NLS equation (63) passes the Painlevé PDE test if and only if the metric (1) is flat.

VI. DISCUSSION

As mentioned by us in the introduction, the SDYM equations in flat space and the twistor description of these equations have deep connections with the theory of integrable systems. However, as the results in our paper indicate, the situation appears to be quite different when we study these equations in a (conformally) curved spacetime. Since our results were obtained for a specific class of metrics, it may be of interest to study reductions of the SDYM equations in other curved spacetimes.

ACKNOWLEDGMENTS

I would like to thank Professor George Sparling for suggesting the problem to me and also for valuable discussions and encouragement throughout the course of this work. I gratefully acknowledge the award of an Andrew Mellon Predoctoral Fellowship to me during the academic year 2000–2001.

JOURNAL OF MATHEMATICAL PHYSICS VOLUME 42, NUMBER 12 DECEMBER 2001

A family of integrable nonlinear equations of hyperbolic type

A. Tongas,[a] D. Tsoubelis,[b] and P. Xenitidis[c]
Department of Mathematics, University of Patras, 265 00 Patra, Greece

(Received 26 March 2001; accepted for publication 19 September 2001)

A new system of integrable nonlinear equations of hyperbolic type, obtained by a two-dimensional reduction of the anti-self-dual Yang–Mills equations, is presented. It represents a generalization of the Ernst–Weyl equation of General Relativity related to colliding neutrino and gravitational waves, as well as of the fourth order equation of Schwarzian type related to the KdV hierarchies, which was introduced by Nijhoff, Hone, and Joshi recently. An auto-Bäcklund transformation of the new system is constructed, leading to a superposition principle remarkably similar to the one connecting four solutions of the KdV equation. At the level of the Ernst–Weyl equation, this Bäcklund transformation and the associated superposition principle yield directly a generalization of the single and double Harrison transformations of the Ernst equation, respectively. The very method of construction also allows for revealing, in an essentially algorithmic fashion, other integrability features of the main subsystems, such as their reduction to the Painlevé transcendents. © *2001 American Institute of Physics.* [DOI: 10.1063/1.1416488]

I. INTRODUCTION

The main relationship between the anti-self-dual Yang–Mills equations (ASDYM) and integrable systems of partial differential equations (PDEs) stems from the fact that most well-known integrable systems arise as reductions of the ASDYM equations, or higher-dimensional generalizations of them, by imposing appropriate symmetry conditions.[1] We adopt that saying a system of equations is integrable means that the equations under consideration can be linearized directly, or they can be expressed as consistency conditions for the solution of a linear overdetermined system of PDEs of a certain type (Lax pair).

Of particular interest are the two-dimensional reductions, which are constructed using specific two-dimensional subgroups of the full group of conformal isometries of the four-dimensional complex Minkowski space. A prime example of this kind of reduction is provided by the Ernst equation of General Relativity, which forms the basis of stationary axisymmetric, cylindrical or plane symmetric solutions of the Einstein equations.[2–8] A comprehensive review of two-dimensional reductions of the ASDYM equations is presented in Ref. 8, where a general class of a two-dimensional group of conformal transformations, not necessarily translations, is considered. In all of the above reductions to the Ernst equation, at least one of the two conformal Killing vectors (CKVs) has a nontrivial lift to the twistor space and the formulation is adapted to the Yang matrix J.

In the present paper we consider, instead, a two-dimensional reduction of the ASDYM equations based on a pair of commuting CKVs which are left rotations and leave the α-planes through the origin invariant. It leads to a quite general system of integrable equations of hyperbolic type in two independent variables, which represents a generalization not only of the Ernst–Weyl equation for coupled gravitational and neutrino waves in General Relativity, but of the fourth order equation

[a]Electronic mail: tasos@math.upatras.gr
[b]Electronic mail: tsoubeli@math.upatras.gr
[c]Electronic mail: xeniti@math.upatras.gr

of Schwarzian type introduced by Nijhoff, Hone, and Joshi[9] recently, which is related to the KdV hierarchy.

More specifically, our reduction scheme uses **GL**$(2,\mathbb{C})$ as the gauge group and connection potentials that are matrices of unit rank. The general background, as well as the specific features, of the reduction process are presented in Sec. II. In the same section we present the end result of the reduction. It consists of a system of equations which, written in an invariant form, reads as follows:

$$\mathrm{d}\,(P+R)-*\mathrm{d}\,(P-R)=\frac{P-R}{\rho}\,((P-R)*\mathrm{d}U-\mathrm{d}\beta), \tag{1a}$$

$$\rho\mathrm{d}*\mathrm{d}U-\mathrm{d}\beta\wedge\mathrm{d}U=(P-R)\mathrm{d}U\wedge*\mathrm{d}U, \tag{1b}$$

$$\mathrm{d}*\mathrm{d}\rho=0,\quad \mathrm{d}*\mathrm{d}\beta=0. \tag{1c}$$

The complex functions U, P, R depend on the real coordinates u, v. The functions ρ, β are arbitrary real and complex solutions of the wave equation, respectively. The operator $*$ is a two-dimensional Hodge duality operator acting on one-forms as

$$*\mathrm{d}u=\mathrm{d}u,\quad *\mathrm{d}v=-\mathrm{d}v. \tag{1d}$$

The above system of equations can also be considered as the compatibility or integrability condition of a linear pair of equations parametrized by a complex parameter. This Lax pair of equations is presented in Sec. III, where it is shown that it can be derived algorithmically from the Lax pair of the ASDYM equations. In the same section we derive an auto-Bäcklund transformation of system (1), using the above Lax pair and the standard Gauss decomposition of **GL**$(2,\mathbb{C})$.

The restrictions

$$\rho=\tfrac{1}{2}(v-u),\quad \mathrm{d}\beta=n\,\mathrm{d}u+m\,\mathrm{d}v,\quad n,m\ \text{complex parameters}, \tag{2}$$

of the functions ρ and β, reduce system (1) to a potential form of the fourth order equation of Schwarzian type introduced recently by Nijhoff *et al.*,[9] which was called a regular partial differential equation (RPDE) by the above authors. Its importance stems from the fact that it is directly associated with the KdV hierarchies. The exact relation of the system (1) to the RPDE, as well as to the well-known Euler–Poisson–Darboux equation, is the object of Sec. IV. In the same section, we present a new family of fourth order equations which contains the RPDE among its members.

Imposing appropriate conditions on the variables P, R and β, on the other hand, turns the system (1) into the Ernst–Weyl equation,

$$\mathcal{R}e(E)(\mathrm{d}(\rho*\mathrm{d}E)-\mathrm{i}\,\mathrm{d}a\wedge\mathrm{d}E)=\rho\,\mathrm{d}E\wedge*\mathrm{d}E, \tag{3}$$

for colliding neutrino waves accompanied by gravitational waves.[10] The Ernst equation for colliding pure gravitational waves in a flat background is also obtained in this way, by applying further restrictions on β. The Neugebauer–Kramer involution arises naturally from the conditions imposed on system (1) and defines a map connecting the real components of two Ernst–Weyl equations.

The relation of system (1) to the Ernst and Ernst–Weyl equations is described in full detail in Sec. V. Section VI, on the other hand, is devoted to another integrability feature of the Ernst–Weyl and RPDE subsystems of the system (1), namely their reduction to Painlevé transcendents. More specifically, in Sec. VI we show how the relation between the Ernst–Weyl and the RPDE equations, established by their being members of the same system (1), facilitates the construction of group invariant solutions of the former based on the Painlevé transcendents from similar kinds of solutions of the latter equation.

The final section of the paper consists of the Perspectives, where an overall evaluation of the results obtained in the main body of the paper is presented, along with the description of various avenues for expanding the above results.

II. REDUCTION OF THE ASDYM EQUATIONS

In this section we present the first main result of this paper. It consists of the new integrable system given by (32), which is derived by a specific two-dimensional reduction of the ASDYM equations.

In order to make the presentation of our result self-contained, we first summarize in Sec. II A the general framework of the ASDYM equations. Then, in Sec. II B, we give the details of the reduction scheme that leads to the new integrable system of equations mentioned above.

A. General considerations

Throughout this section we shall follow the notation and conventions of Refs. 8, 11. Let $M=\mathbb{CM}$ denote the four-dimensional complex Minkowski spacetime and G a Lie group, called the gauge group, and $\mathfrak{g}$ the corresponding Lie algebra. In the finite-dimensional case G can be taken to be $\mathbf{GL}(N,\mathbb{C})$.

Let $P(M,G)$ be a principal bundle, $\{U_i\}$ an open covering of M and s_i a local section defined on each U_i. The Lie algebra valued one-form $\omega\in\mathfrak{g}\otimes T^*P$, called the connection one-form, and the two-form $\Omega\in\mathfrak{g}\otimes\Omega^2(P)$, called the curvature two-form, satisfy the Cartan structure equation,

$$\Omega=\mathrm{d}_P\omega+\omega\wedge\omega,$$

where d_P is the exterior derivative on P. The $\mathfrak{g}$-valued one-form (gauge potential) Φ_i is defined locally as the pull-back $\Phi_i=s_i^*\omega$ of the connection one-form ω and the $\mathfrak{g}$-valued two-form F_i, also called curvature two-form or (Yang–Mills) field strength, is defined by $\mathrm{F}_i=s_i^*\Omega$. If s, s' are local sections over U such that $s'(p)=s(p)g(p)$, $p\in U$, $g\in G$ then the corresponding local one-forms Φ and Φ' are related by

$$\Phi'=g^{-1}\Phi g+g^{-1}\,\mathrm{d}g, \tag{4}$$

where d is the exterior derivative on M. The potentials Φ and Φ' are said to be related through a gauge transformation and they are regarded as being equivalent. From the Cartan structure equation it follows that the curvature F can be expressed in terms of the gauge potential Φ as

$$\mathrm{F}=\mathrm{d}\Phi+\Phi\wedge\Phi. \tag{5}$$

Under gauge transformations (4) the local two-forms F and F′ are related by

$$\mathrm{F}'=g^{-1}\mathrm{F}g.$$

In double null coordinates $x^a=(w,z,\tilde{w},\tilde{z})$ the metric on $\mathbb{CM}$ is given by

$$\mathrm{d}s^2=2(\mathrm{d}z\,\mathrm{d}\tilde{z}-\mathrm{d}w\,\mathrm{d}\tilde{w}). \tag{6}$$

In this coordinate system the gauge potential Φ may be written as

$$\Phi=\Phi_w\,\mathrm{d}w+\Phi_z\,\mathrm{d}z+\Phi_{\tilde{w}}\,\mathrm{d}\tilde{w}+\Phi_{\tilde{z}}\,\mathrm{d}\tilde{z}, \tag{7}$$

where the components are $\mathfrak{g}$-valued functions. Φ is said to be anti-self-dual iff F is Hodge anti-self-dual with respect to the metric (6), i.e.,

$$\mathrm{F}=-*\mathrm{F}. \tag{8}$$

Choosing an orientation, condition (8) is equivalent to the ASDYM equations,

$$\partial_z \Phi_w - \partial_w \Phi_z + [\Phi_z, \Phi_w] = 0, \tag{9a}$$

$$\partial_{\tilde{z}} \Phi_{\tilde{w}} - \partial_{\tilde{w}} \Phi_{\tilde{z}} + [\Phi_{\tilde{z}}, \Phi_{\tilde{w}}] = 0, \tag{9b}$$

$$\partial_z \Phi_{\tilde{z}} - \partial_{\tilde{z}} \Phi_z - \partial_w \Phi_{\tilde{w}} + \partial_{\tilde{w}} \Phi_w + [\Phi_z, \Phi_{\tilde{z}}] - [\Phi_w, \Phi_{\tilde{w}}] = 0. \tag{9c}$$

These equations are the integrability conditions of the overdetermined linear system (Lax pair),[12,13]

$$(\partial_w + \Phi_w - \zeta(\partial_{\tilde{z}} + \Phi_{\tilde{z}}))\Psi = 0, \tag{10a}$$

$$(\partial_z + \Phi_z - \zeta(\partial_{\tilde{w}} + \Phi_{\tilde{w}}))\Psi = 0, \tag{10b}$$

where $\Psi(x^a;\zeta)$ is a G-valued function of the spacetime coordinates and the spectral parameter ζ.

B. The reduced equations

For a two-dimensional reduction of the ASDYM equations, one first chooses a two-dimensional subgroup H of the full group of conformal isometries of the Minkowski space. Then, one can reduce the number of the dependent variables by imposing algebraic constraints on the components of Φ, in a way which is consistent with the equations.

A general class of two-dimensional reductions is considered in Ref. 8 where H is generated by two conformal Killing vectors:

$$X = a\partial_w + b\partial_z + \tilde{a}\partial_{\tilde{w}} + \tilde{b}\partial_{\tilde{z}}, \quad Y = c\partial_w + d\partial_z + \tilde{c}\partial_{\tilde{w}} + \tilde{d}\partial_{\tilde{z}}, \tag{11}$$

where a, b, c, d and $\tilde{a}$, $\tilde{b}$, $\tilde{c}$, $\tilde{d}$ depend only on w, z and $\tilde{w}$, $\tilde{z}$, respectively. Both of the quadruples $\{X, Y, \partial_w, \partial_z\}$ and $\{X, Y, \partial_{\tilde{w}}, \partial_{\tilde{z}}\}$ should be linearly independent and the reduced metric on the orbits of H should be nondegenerate. These conditions assure a compatible reduction.

The most straightforward reduction of this form arises when the corresponding algebra $\mathfrak{h}$ is *Abelian*. We assume that this is the case and we further limit the choices of the components of X and Y by demanding that X and Y leave invariant the α-planes through the origin (the meaning of this requirement will become clear later) and are not a combination of translations. It turns out that these requirements are satisfied only by the commuting null CKVs,

$$X = w\partial_w + \tilde{z}\partial_{\tilde{z}}, \quad Y = z\partial_z + \tilde{w}\partial_{\tilde{w}}. \tag{12}$$

The invariant spacetime coordinates on the orbits of the two-dimensional group of conformal transformations generated by X, Y are arbitrary functions of the fractions $w/\tilde{z}$, $z/\tilde{w}$. Without loss of generality we choose the coordinates of the space of orbits S to be

$$u = \frac{w}{\tilde{z}}, \quad v = \frac{z}{\tilde{w}}, \tag{13}$$

and restrict ourselves to the ultrahyperbolic slice of $\mathbb{CM}$ where the spacetime coordinates are real. The metric induced on S is conformal to two-dimensional Minkowski spacetime in null coordinates, i.e.,

$$\mathrm{d}s^2 = \frac{2}{v-u}\,\mathrm{d}u\,\mathrm{d}v. \tag{14}$$

The invariance conditions of the potential Φ with respect to the algebra generated by X, Y are

$$\mathcal{L}_X \Phi = \mathcal{L}_Y \Phi = 0, \tag{15}$$

where $\mathcal{L}_X$ denotes the Lie derivative along X. Under these conditions, one can write the components of the gauge potential Φ in the form

$$\Phi_w=\frac{1}{w}A(u,v),\quad \Phi_z=\frac{1}{z}B(u,v),\quad \Phi_{\tilde{w}}=\frac{1}{\tilde{w}}\tilde{A}(u,v),\quad \Phi_{\tilde{z}}=\frac{1}{\tilde{z}}\tilde{B}(u,v). \tag{16}$$

We choose to work with the invariant gauge where $\tilde{A}$ and $\tilde{B}$ become the Higgs fields of X and Y, respectively. This means that $\tilde{A}$ and $\tilde{B}$ are contractions of the invariant gauge potential Φ with the vector fields X and Y, respectively, i.e., $\tilde{A}=X\lrcorner\Phi$, $\tilde{B}=Y\lrcorner\Phi$. In this gauge one can put $A=B=0$, whereupon the ASDYM equations (9) become

$$v\tilde{B}_{,v}-u\tilde{A}_{,u}+[\tilde{B},\tilde{A}]=0, \tag{17a}$$

$$\tilde{B}_{,v}-\tilde{A}_{,u}=0. \tag{17b}$$

Equation (17b) implies the existence of a matrix function $K(u,v)$ such that

$$\tilde{B}=K_{,u},\quad \tilde{A}=K_{,v}, \tag{18}$$

and hence Eq. (17a) becomes

$$(v-u)K_{,u\,v}+[K_{,u},K_{,v}]=0. \tag{19}$$

The remaining gauge freedom is $\tilde{A}\to g^{-1}\tilde{A}g$ and $\tilde{B}\to g^{-1}\tilde{B}g$ or, equivalently, $K\to g^{-1}Kg+c$ where g, c constant matrices.

Alternatively, one can look at (17a) as a sufficient condition of the existence of the matrix function J such that

$$\tilde{A}=-vJ^{-1}J_{,v},\quad \tilde{B}=-uJ^{-1}J_{,u}. \tag{20}$$

Then (17b) takes the following form:

$$(uJ^{-1}J_{,u})_{,v}-(vJ^{-1}J_{,v})_{,u}=0. \tag{21}$$

Introducing the functions ρ, σ by

$$\rho=\tfrac{1}{2}(v-u),\quad \sigma=\tfrac{1}{2}(v+u), \tag{22}$$

one can now write Eq. (19) in an invariant form, namely

$$\rho\,\mathrm{d}{*}\mathrm{d}K-\mathrm{d}K\wedge\mathrm{d}K=0. \tag{23}$$

In a similar fashion Eq. (21) takes the coordinate free form,

$$\mathrm{d}(\rho J^{-1}{*}\mathrm{d}J)=\mathrm{d}(\sigma J^{-1}\,\mathrm{d}J). \tag{24}$$

From the way the coordinates (u,v) were introduced one sees that a more general coordinate system is obtained via the coordinate transformation

$$u\to f(u),\quad v\to g(v), \tag{25}$$

i.e., by relabeling the null coordinates (u,v). Within this more general setting it follows that

$$\rho=\tfrac{1}{2}(g(v)-f(u)),\quad \sigma=\tfrac{1}{2}(g(v)+f(u)), \tag{26}$$

and the functions ρ, σ may be invariantly defined as conjugate solutions of the wave equation $d*d\rho=0$.

Now, Eq. (17) imply that

$$\partial_u(\mathrm{tr}\,\tilde{A}^k)=\partial_v(\mathrm{tr}\,\tilde{B}^k)=0, \text{ where } k=1,2,...,N-1. \tag{27}$$

Hence

$$\mathrm{tr}\,\tilde{A}^k=m_k(v), \quad \mathrm{tr}\,\tilde{B}^k=n_k(u). \tag{28}$$

To reduce the number of the dependent variables we restrict to the case where $N=2$ and $\tilde{A},\tilde{B}$ are matrix functions with

$$\mathrm{rank}\,\tilde{A}=\mathrm{rank}\,\tilde{B}=1. \tag{29}$$

With these algebraic constraints, $\tilde{A}$, $\tilde{B}$ may be written as

$$\tilde{A}=\begin{pmatrix} m(v)-RQ & Q \\ R(m(v)-RQ) & RQ \end{pmatrix}, \quad \tilde{B}=\begin{pmatrix} n(u)-PS & S \\ P(n(u)-PS) & PS \end{pmatrix}, \tag{30}$$

where P, Q, R, S are complex functions of (u,v). Inserting $\tilde{A}$ and $\tilde{B}$ given by (30) into the matrix equation (17b), one finds that the upper right element gives

$$Q_{,u}=S_{,v}, \tag{31}$$

which implies the existence of a function U such that $Q=U_{,v}$ and $S=U_{,u}$. In virtue of these relations, Eq. (17a) yields the following system of PDEs:

$$(g(v)-f(u))P_{,v}=(R-P)(m(v)+(P-R)U_{,v}), \tag{32a}$$

$$(g(v)-f(u))R_{,u}=(R-P)(n(u)-(P-R)U_{,u}), \tag{32b}$$

$$(g(v)-f(u))U_{,uv}=m(v)U_{,u}-n(u)U_{,v}+2(P-R)U_{,u}U_{,v}. \tag{32c}$$

This system will be denoted by

$$\Sigma(u,v,U,P,R;m(v),n(u))=0 \tag{33}$$

in the following. We close this section by pointing out that the remaining equation of system (17), namely Eq. (17b), is trivially satisfied when (33) holds.

III. THE REDUCED LAX PAIR AND AN AUTO-BÄCKLUND TRANSFORMATION

Linear (Lax pairs) and nonlinear (Bäcklund transformations) deformation problems are invaluable techniques for generating solutions of integrable equations. As a matter of fact these problems are so interrelated that one can in general derive Bäcklund transformations from the corresponding Lax pair (see, for example, Refs. 14, 15).

Most of the well-known integrable equations in two independent variables, such as the KdV and the sine-Gordon equations, admit a Lax pair of the form

$$d\Psi=\Omega\Psi, \tag{34}$$

where Ψ belongs in $\mathbf{SL}(2,\mathbb{R})$ and Ω is a $\mathfrak{sl}(2,\mathbb{R})$-valued one form. The associated equation arises from the integrability condition $d\Omega=\Omega\wedge\Omega$ and the particular way the independent and dependent variables enter into Ω. Using the Iwasawa decomposition of $\mathbf{SL}(2,\mathbb{R})$ for Ψ, one may construct a Bäcklund transformation associated with the given PDE.[15]

The system $\Sigma=0$ also admits a Lax pair of the form (34). It can be derived algorithmically from the Lax pair (10) of the ASDYM equations by applying the invariance conditions[16]

$$\mathcal{L}_X\Psi=\mathcal{L}_Y\Psi=0. \tag{35}$$

These conditions imply that Ψ depends only on the invariant coordinates u, v and the spectral parameter ζ. Taking into account (16) and putting $A=B=0$, we find that Eqs. (10) reduce to

$$\Psi_{,u}=\frac{1}{f(u)-\lambda}\tilde{B}\Psi, \tag{36a}$$

$$\Psi_{,v}=\frac{1}{g(v)-\lambda}\tilde{A}\Psi, \tag{36b}$$

where we have set $\lambda=-\zeta^{-1}$. It is now easily verified that the integrability condition $\Psi_{,uv}=\Psi_{,vu}$ leads to $\Sigma=0$. This means that Eqs. (36) constitute a Lax pair for the system $\Sigma=0$.

At this point it is worth noting that using (18) and (26), the Lax pair (36) may be written in an invariant form as

$$(\sigma-\lambda-\rho*)\mathrm{d}\Psi=\mathrm{d}K\,\Psi, \tag{37a}$$

where

$$(\sigma-\lambda-\rho*)^{-1}=\frac{(\sigma-\lambda+\rho*)}{(\sigma-\lambda)^2-\rho^2}. \tag{37b}$$

We point out that the linear system (37), or equivalently (36), includes the Lax pair used by Hauser and Ernst in solving the initial value problem for colliding plane gravitational waves.[17]

We are now ready to construct a Bäcklund transformation of the system $\Sigma=0$, using the Lax pair (36). To this end, we generalize the technique employed in the case where $\Psi\in\mathbf{SL}(2,\mathbb{R})$ by considering the Gauss decomposition of $\mathbf{GL}(2,\mathbb{C})$.[18] It allows us to write the spectral potential Ψ in the form

$$\Psi=L^{-1}T, \tag{38}$$

where T is an upper triangular matrix and L is a lower triangular one of the form

$$L=\begin{pmatrix}1 & 0\\ -\tilde{U} & 1\end{pmatrix}. \tag{39}$$

Substituting (38) into the Lax pair (36) we obtain the following linear system for the matrix function T:

$$T_{,u}T^{-1}=L_{,u}L^{-1}+\frac{1}{f(u)-\lambda}L\tilde{B}L^{-1}, \tag{40a}$$

$$T_{,v}T^{-1}=L_{,v}L^{-1}+\frac{1}{g(v)-\lambda}L\tilde{A}L^{-1}. \tag{40b}$$

The lower left elements of the the above system lead to the following Riccati system for the function $\tilde{U}$:

$$\tilde{U}_{,u}=\frac{P-\tilde{U}}{f(u)-\lambda}(n(u)-(P-\tilde{U})U_{,u}), \tag{41a}$$

$$\tilde{U}_{,v}=\frac{R-\tilde{U}}{g(v)-\lambda}(m(v)-(R-\tilde{U})U_{,v}). \tag{41b}$$

The integrability condition of (41) is satisfied if the system $\Sigma=0$ holds. In other words, (41) defines a Bäcklund map for the system $\Sigma=0$. Using such a map, one may construct an auto-Bäcklund transformation for the system under consideration in a manner presented in Ref. 14.

More specifically, solving Eqs. (41) for the derivatives of U we obtain

$$U_{,u}=\frac{1}{P-\tilde{U}}\left(n(u)-\frac{f(u)-\lambda}{P-\tilde{U}}\tilde{U}_{,u}\right), \tag{42a}$$

$$U_{,v}=\frac{1}{R-\tilde{U}}\left(m(v)-\frac{g(v)-\lambda}{R-\tilde{U}}\tilde{U}_{,v}\right). \tag{42b}$$

When Eqs. (32a), (32b) and (42) are satisfied, the integrability condition $U_{,uv}=U_{,vu}$ implies that $\tilde{U}$ satisfies the following equation:

$$(f(u)-g(v))\tilde{U}_{,uv}=n(u)\tilde{U}_{,v}-m(v)\tilde{U}_{,u}+2\left(\frac{f(u)-\lambda}{\tilde{U}-P}-\frac{g(v)-\lambda}{\tilde{U}-R}\right)\tilde{U}_{,u}\tilde{U}_{,v}. \tag{43}$$

If not stated otherwise, we will assume that $P\neq R$ in what follows. The particular case $P=R$ will be considered separately in the next section.

Equation (43) takes the form

$$(f(u)-g(v))\tilde{U}_{,uv}=n(u)\tilde{U}_{,v}-m(v)\tilde{U}_{,u}-2(\tilde{P}-\tilde{R})\tilde{U}_{,u}\tilde{U}_{,v}, \tag{44}$$

by introducing

$$\tilde{P}=W-\frac{f(u)-\lambda}{\tilde{U}-P},\quad \tilde{R}=W-\frac{g(v)-\lambda}{\tilde{U}-R}, \tag{45}$$

where $W=W(u,v)$ is an auxiliary function. Equation (44) is none other than Eq. (32c) with (U,P,R) replaced by $(\tilde{U},\tilde{P},\tilde{R})$. It suffices to determine W in such a way that the functions $(\tilde{U},\tilde{P},\tilde{R})$, defined by (41) and (45), satisfy $\Sigma(u,v,\tilde{U},\tilde{P},\tilde{R})=0$ whenever $\Sigma(u,v,U,P,R)=0$ holds. This requirement and the differential consequences of (45) result in

$$W=U, \tag{46}$$

up to a nonsignificant constant of integration. In conclusion, we have established the following.

Proposition 1: The algebro-differential system,

$$\tilde{U}_{,u}=\frac{P-\tilde{U}}{f(u)-\lambda}(n(u)-(P-\tilde{U})U_{,u}), \tag{47a}$$

$$\tilde{U}_{,v}=\frac{R-\tilde{U}}{g(v)-\lambda}(m(v)-(R-\tilde{U})U_{,v}), \tag{47b}$$

$$(\tilde{U}-P)(U-\tilde{P})=f(u)-\lambda, \tag{48}$$

$$(\tilde{U}-R)(U-\tilde{R})=g(v)-\lambda, \tag{49}$$

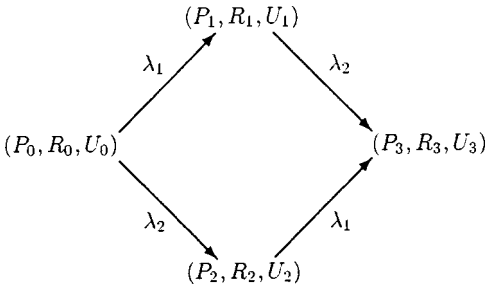

FIG. 1. Bianchi commuting diagram.

constitutes an auto-Bäcklund transformation for the system $\Sigma=0$.

By purely algebraic procedures Proposition 1 leads to the following permutability theorem.

Permutability theorem: *Let* (U_i,P_i,R_i), $i=1,2$, *be a solution of the system (32a)–(32c), generated by means of the Bäcklund transformation (47)–(49) from a known solution* (U_0,P_0,R_0) *via the Bäcklund parameters* λ_1 *and* λ_2, *respectively. Then there exists a new solution* (U_3,P_3,R_3) *which is given by*

$$(U_3-U_0)(U_2-U_1)=\lambda_2-\lambda_1, \tag{50a}$$

$$(P_3-P_0)(P_2-P_1)=\lambda_2-\lambda_1, \tag{50b}$$

$$(R_3-R_0)(R_2-R_1)=\lambda_2-\lambda_1, \tag{50c}$$

where (U_3,P_3,R_3) *is constructed according to* Fig. 1.

IV. NEW AND OLD EQUATIONS RELATED TO THE SYSTEM Σ

Many physically interesting integrable equations arise from the system $\Sigma=0$ by imposing further algebraic constraints on the independent and the dependent variables. This is illustrated in the following sections in terms of a new family of fourth order equations, which represents a generalization of the RPDE introduced by Nijhoff *et al.*[9] recently, the RPDE itself and the well-known Euler–Poisson–Darboux equation. The Ernst–Weyl equation is also contained in the system $\Sigma=0$ and is presented thoroughly in the next section.

A. The generalized RPDE

The system $\Sigma=0$ leads to a fourth order PDE for the function U solely in the following manner. First, one may solve Eq. (32c) for the difference $P-R$ to obtain

$$P-R=\mathcal{A}[U]:=\frac{1}{2}\left(2\rho\frac{U_{,uv}}{U_{,u}U_{,v}}+\frac{n(u)}{U_{,u}}-\frac{m(v)}{U_{,v}}\right), \tag{51}$$

where ρ is given by (26). Taking the partial derivative of both sides of (51) with respect to u and using Eq. (32b), we arrive at an expression for $P_{,u}$ involving the derivatives of U only. The latter expression and (32a) form a linear first order system for P which takes the following form:

$$P_{,u}=-\frac{\mathcal{A}}{2\rho}(n(u)-\mathcal{A}U_{,u})+\partial_u\mathcal{A},$$

$$P_{,v}=-\frac{\mathcal{A}}{2\rho}(m(v)+\mathcal{A}U_{,v}).$$

The compatibility condition $P_{,uv}=P_{,vu}$ leads to the equation

$$\partial_u\left(\partial_v\mathcal{A}+\frac{\mathcal{A}^2}{\rho}U_{,v}+m(v)\frac{\mathcal{A}}{\rho}\right)+\partial_v\left(\partial_u\mathcal{A}+\frac{\mathcal{A}^2}{\rho}U_{,u}-n(u)\frac{\mathcal{A}}{\rho}\right)=0. \tag{52}$$

This equation, when written out explicitly, reads as

$$\begin{aligned}U_{,uuvv}=&U_{,uuv}\left(-\frac{\rho_{,v}}{\rho}+\frac{U_{,vv}}{U_{,v}}+\frac{U_{,uv}}{U_{,u}}\right)+U_{,uvv}\left(-\frac{\rho_{,u}}{\rho}+\frac{U_{,uu}}{U_{,u}}+\frac{U_{,uv}}{U_{,v}}\right)-U_{,uu}U_{,vv}\frac{U_{,uv}}{U_{,u}U_{,v}}\\&+U_{,uu}\left(\frac{n(u)^2}{4\rho^2}\frac{U_{,v}^2}{U_{,u}^2}+\frac{\rho_{,v}}{\rho}\frac{U_{,uv}}{U_{,u}}-\frac{U_{,uv}^2}{U_{,u}^2}\right)+U_{,vv}\left(\frac{m(v)^2}{4\rho^2}\frac{U_{,u}^2}{U_{,v}^2}+\frac{\rho_{,u}}{\rho}\frac{U_{,uv}}{U_{,v}}-\frac{U_{,uv}^2}{U_{,v}^2}\right)\\&-\frac{n(u)^2}{8\rho^3}\frac{U_{,v}}{U_{,u}}(\rho_{,v}U_{,u}-\rho_{,u}U_{,v}+2\rho U_{,uv})+\frac{m(v)^2}{8\rho^3}\frac{U_{,u}}{U_{,v}}(\rho_{,v}U_{,u}-\rho_{,u}U_{,v}-2\rho U_{,uv})\\&+\frac{1}{2\rho}U_{,uv}^2\left(\frac{\rho_{,u}}{U_{,u}}+\frac{\rho_{,v}}{U_{,v}}\right)-\frac{n(u)n'(u)}{4\rho^2}\frac{U_{,v}^2}{U_{,u}}-\frac{m(v)m'(v)}{4\rho^2}\frac{U_{,u}^2}{U_{,v}}.\end{aligned} \tag{53}$$

This is a new integrable equation which generalizes the RPDE, as it will be clear from the following section. It will be referred to as the generalized RPDE (GRPDE). In order to clarify its relation to the system $\Sigma=0$, we first introduce a shorthand notation whereby Eq. (53) is written in the form

$$\mathcal{R}(u,v,U;m(v),n(u))=0. \tag{54}$$

In a manner to be explained shortly, one is led to similar equations for the functions P, R, starting from the system $\Sigma=0$. More specifically, these functions satisfy the fourth order equations

$$\mathcal{R}(u,v,P;m(v),n(u)-2\rho_{,u})=0, \tag{55}$$

and

$$\mathcal{R}(u,v,R;m(v)+2\rho_{,v},n(u))=0, \tag{56}$$

respectively. Thus, it becomes clear that the system $\Sigma=0$ represents an involution of a triad of GRPDEs. The members of this triad differ only by specific changes in the parameter functions $m(v)$ and $n(u)$.

Returning to the derivation of Eqs. (55), (56), let us first note that one may eliminate the derivatives of U from the system $\Sigma=0$ by solving (32a) and (32b) for $U_{,v}$ and $U_{,u}$, respectively. Using compatibility conditions and (32c), one then ends up with the following system for P, R:

$$P_{,uv}=\frac{2}{P-R}P_{,u}P_{,v}+\frac{m(v)}{2\rho}P_{,u}+\frac{n(u)-2\rho_{,u}}{2\rho}P_{,v}, \tag{57a}$$

$$R_{,uv}=\frac{2}{R-P}R_{,u}R_{,v}-\frac{m(v)+2\rho_{,v}}{2\rho}R_{,u}-\frac{n(u)}{2\rho}R_{,v}. \tag{57b}$$

It is now a matter of straightforward, but lengthy, calculations to decouple the above system and arrive to Eqs. (55), (56) for P and R, respectively.

At this point, it is worth noting that Eqs. (57) may be combined to yield[19]

$$(\rho SS_{,u})_{,v}+(\rho SS_{,v})_{,u}+\tau_{,u}S_{,v}+\tau_{,v}S_{,u}=0, \tag{58}$$

where

$$\tau:=\sigma+\beta, \tag{59a}$$

and S is a 2×2 matrix defined by

$$S=\frac{1}{R-P}\begin{pmatrix} P+R & -2 \\ 2PR & -(P+R)\end{pmatrix}. \tag{59b}$$

The matrix equation (58) represents a complexified hyperbolic version of the stationary Loewner–Konopelchenko–Rogers (LKR) system[20] proposed by Schief[21] as a 2×2 real matrix representation of the Ernst–Weyl equation in stationary, axisymmetric spacetimes. It should be pointed out that LKR systems have proven to be a repository of mathematically and physically interesting integrable equations in $2+1$-dimensions, including a $2+1$-dimensional Ernst-type equation, introduced by Schief recently.[22]

B. The RPDE

By choosing

$$f(u)=u, \quad g(v)=v \tag{60a}$$

and

$$m(v)=m, \quad n(u)=n, \tag{60b}$$

where n, m are complex parameters, Eq. (53) becomes

$$\begin{aligned} U_{,uuvv}=&U_{,uuv}\left(\frac{1}{u-v}+\frac{U_{,vv}}{U_{,v}}+\frac{U_{,uv}}{U_{,u}}\right)+U_{,uvv}\left(\frac{1}{v-u}+\frac{U_{,uu}}{U_{,u}}+\frac{U_{,uv}}{U_{,v}}\right)-U_{,uu}U_{,vv}\frac{U_{,uv}}{U_{,u}U_{,v}} \\ &+U_{,uu}\left(\frac{n^2}{(u-v)^2}\frac{U_{,v}^2}{U_{,u}^2}-\frac{1}{u-v}\frac{U_{,uv}}{U_{,u}}-\frac{U_{,uv}^2}{U_{,u}^2}\right)+U_{,vv}\left(\frac{m^2}{(u-v)^2}\frac{U_{,u}^2}{U_{,v}^2}+\frac{1}{u-v}\frac{U_{,uv}}{U_{,v}}-\frac{U_{,uv}^2}{U_{,v}^2}\right) \\ &+\frac{n^2}{2(u-v)^3}\frac{U_{,v}}{U_{,u}}(U_{,u}+U_{,v}+2(v-u)U_{,uv})-\frac{m^2}{2(u-v)^3}\frac{U_{,u}}{U_{,v}}(U_{,u}+U_{,v}+2(u-v)U_{,uv}) \\ &+\frac{1}{2(u-v)}U_{,uv}^2\left(\frac{1}{U_{,u}}-\frac{1}{U_{,v}}\right), \end{aligned} \tag{61}$$

which is the RPDE introduced by Nijhoff *et al.*[9] recently. Its importance stems from the fact that it is a generating equation for the whole hierarchy of the KdV equation. We presented several aspects of the integrability of the RPDE in Ref. 23.

C. The EPD equation

By choosing

$$P=R, \tag{62}$$

and referring to Eqs. (32a), (32b), we find that

$$P=c, \quad c \ \text{constant}. \tag{63}$$

Without loss of generality we set $c=0$. This can be achieved by performing a gauge transformation on $\tilde{A}$, $\tilde{B}$ by $g=\left(\begin{smallmatrix}1 & 0\\ -c & 1\end{smallmatrix}\right)$, whereupon one obtains equivalent Higgs fields with $P=R=0$. Within this setting, the system $\Sigma=0$ reduces to a single linear, second order PDE for U,

$$U_{,uv}=\frac{1}{f(u)-g(v)}(n(u)U_{,v}-m(v)U_{,u}), \tag{64}$$

which is known as the *Euler–Poisson–Darboux* (EPD) equation. From this point of view, the EPD equation may be considered as a linearization of the system $\Sigma=0$.

The substitution $\psi=\tilde{U}^{-1}$ transforms the Riccati equations (41) into the linear system,

$$\psi_{,u}=\frac{n(u)}{f(u)-\lambda}\psi+\frac{U_{,u}}{f(u)-\lambda}, \tag{65a}$$

$$\psi_{,v}=\frac{m(v)}{g(v)-\lambda}\psi+\frac{U_{,v}}{g(v)-\lambda}. \tag{65b}$$

It can be easily verified that the integrability condition $U_{,uv}=U_{,vu}$ and the system (65) lead to

$$\psi_{,uv}=\frac{1}{f(u)-g(v)}(n(u)\psi_{,v}-m(v)\psi_{,u}). \tag{66}$$

A comparison of this with Eq. (64) shows that the system (65) represents an auto-Bäcklund transformation for the EPD equation. The linearity of the same system in ψ indicates that it is also a Lax pair for the EPD equation.

Restricting $U(u,v),m(v),n(u)$ to be real functions of their arguments and choosing

$$n(u)=-\tfrac{1}{2}f'(u),\quad m(v)=-\tfrac{1}{2}g'(v),$$

Eq. (64) becomes

$$2U_{,uv}+\frac{\rho_{,u}}{\rho}U_{,v}+\frac{\rho_{,v}}{\rho}U_{,u}=0,\quad \rho=\frac{1}{2}(g(v)-f(u)). \tag{67}$$

This particular form of the EPD equation governs the collision of two plane gravitational waves with *collinear polarization*[24] in the context of Einstein's General Relativity. The reduced Lax pair (65) becomes the Lax pair used in Ref. 25 for solving the corresponding initial value problem.

V. REDUCTION TO THE ERNST–WEYL EQUATION

One of the most extensively studied problems in General Relativity is the collision of two plane gravitational waves. The Ernst–Weyl equation describes the collision of neutrino waves accompanied by gravitational waves.[10] The latter equation, which reduces to the famous Ernst equation when the neutrino fields vanish everywhere, arises naturally by applying appropriate reality conditions to the system $\Sigma=0$. Our reduction scheme unifies many aspects of the integrability of the Ernst equation like the Hauser–Ernst Lax pair, Neugebauer–Kramer involution, and the Harrison Bäcklund transformation and gives analogous generalizations for the Ernst–Weyl equation.

A. The reality conditions

The system $\Sigma=0$ may be written in the following invariant form:

$$\mathrm{d}(P+R)-*\mathrm{d}(P-R)=\frac{P-R}{\rho}((P-R)*\mathrm{d}U-\mathrm{d}\beta), \tag{68a}$$

$$\rho\mathrm{d}*\mathrm{d}U-\mathrm{d}\beta\wedge\mathrm{d}U=(P-R)\mathrm{d}U\wedge*\mathrm{d}U, \tag{68b}$$

where

$$\rho=\tfrac{1}{2}(g(v)-f(u))\quad\text{and}\quad \mathrm{d}\beta=n(u)\mathrm{d}u+m(v)\mathrm{d}v. \tag{69}$$

Here, we have used the Poincaré lemma to express the one-form $n(u)\mathrm{d}u+m(v)\mathrm{d}v$ as the exterior derivative of a scalar complex function β.

Let us now impose the reality condition,

$$P=-R^{\star}, \tag{70}$$

on (68) with $\star$ denoting complex conjugation. Furthermore, in order to make contact with the notation employed in General Relativity,[26] let us introduce the complex potentials $E,\mathcal{E}$ by

$$\mathcal{E}=\mathcal{F}+\mathrm{i}\chi=P, \quad E=F+\mathrm{i}\omega=U, \tag{71}$$

where $\mathrm{i}=\sqrt{-1}$ and $\mathcal{F}$, F and χ, ω are the real and imaginary parts, respectively, of $\mathcal{E}$, E. In the same fashion, we split the one-form $\mathrm{d}\beta$ into real and imaginary part by setting

$$\mathrm{d}\beta=\mathrm{d}\delta+\mathrm{i}\mathrm{d}a, \tag{72}$$

where a, δ are real solutions of the wave equation. Inserting these into Eq. (68a), the system separates into a real and an imaginary part:

$$\mathrm{d}\mathcal{F}=\frac{\mathcal{F}}{\rho}*\mathrm{d}\delta-\frac{2\mathcal{F}^2}{\rho}\mathrm{d}F \tag{73a}$$

and

$$\mathrm{d}\,\chi=\frac{2\mathcal{F}^2}{\rho}*\mathrm{d}\,\omega-\frac{\mathcal{F}}{\rho}\mathrm{d}a, \tag{73b}$$

respectively. Equation (68b) on the other hand becomes

$$\rho\mathrm{d}*\mathrm{d}E-\mathrm{d}\beta\wedge\mathrm{d}E=2\mathcal{F}\mathrm{d}E\wedge*\mathrm{d}E. \tag{74}$$

The integrability condition $\mathrm{d}^2\mathcal{F}=0$ of Eq. (73a) yields

$$2\mathcal{F}(\mathrm{d}\rho-*\mathrm{d}\delta)\wedge\mathrm{d}F=\mathrm{d}\rho\wedge*\mathrm{d}\delta, \tag{75}$$

which is satisfied for general real functions $\mathcal{F},F$ of (u,v) if

$$\mathrm{d}\delta=*\mathrm{d}\rho=-\mathrm{d}\sigma. \tag{76}$$

Consequently,

$$\mathrm{d}\beta=*\mathrm{d}\rho+\mathrm{i}\mathrm{d}a. \tag{77}$$

Then, Eq. (73a) can be integrated to give

$$\mathcal{F}F=\frac{\rho}{2}, \tag{78}$$

by setting the integration constant equal to zero. The integrability condition of Eq. (73b) is satisfied when Eqs. (74), (77) and (78) hold. In view of (77) and (78), Eq. (74) becomes

$$\mathcal{R}e(E)(\mathrm{d}(\rho*\mathrm{d}E)-\mathrm{i}\ \mathrm{d}a\wedge\mathrm{d}E)=\rho\,\mathrm{d}E\wedge*\mathrm{d}E. \tag{79}$$

Equivalently we may apply the reality condition (70) to the system (57). This condition is compatible with the system for general function $\mathcal{E}$ of (u,v) when (77) holds. In this case, the system (57) reduces to the following single second order PDE for $\mathcal{E}$:

$$\mathcal{R}e(\mathcal{E})(\mathrm{d}(\rho*\mathrm{d}\mathcal{E})+\mathrm{i}*\mathrm{d}a\wedge\mathrm{d}\mathcal{E})=\rho\,\mathrm{d}\mathcal{E}\wedge*\mathrm{d}\mathcal{E}. \tag{80}$$

Hence, the above considerations lead to the following.
Proposition 2: The conditions

$$P=-R^{\star} \tag{81a}$$

and

$$m(v)=-\rho_{,v}+\mathrm{i}\,a_{,v}, \quad n(u)=\rho_{,u}+\mathrm{i}\,a_{,u} \tag{81b}$$

reduce the system (68) and equivalently the system (57) to

$$\mathcal{R}e(E)(\mathrm{d}(\rho*\mathrm{d}E)-\mathrm{i}\,\mathrm{d}a\wedge\mathrm{d}E)=\rho\,\mathrm{d}E\wedge*\mathrm{d}E, \tag{82}$$

$$\mathcal{R}e(\mathcal{E})(\mathrm{d}(\rho*\mathrm{d}\mathcal{E})+\mathrm{i}*\mathrm{d}a\wedge\mathrm{d}\mathcal{E})=\rho\,\mathrm{d}\mathcal{E}\wedge*\mathrm{d}\mathcal{E}, \tag{83}$$

respectively, where E and $\mathcal{E}$ are related through the involution

$$\mathcal{F}F=\frac{\rho}{2}, \quad \mathrm{d}\chi=\frac{2\mathcal{F}^2}{\rho}*\mathrm{d}\omega-\frac{\mathcal{F}}{\rho}\mathrm{d}a. \tag{84}$$

- When $\mathrm{d}a=0$, Eq. (82) becomes the Ernst equation for colliding plane pure gravitational waves in a flat background. The map given by (84) which connects two solutions $(E,\mathcal{E})$ of the Ernst equation, is known as the *Neugebauer–Kramer involution*.[27]
- When $\mathrm{d}a\neq 0$, Eq. (82) is the Ernst–Weyl equation for colliding plane neutrino waves accompanied by gravitational waves. The form of the function a is specified by the initial profile of the neutrino waves on the null hypersurfaces $u=0$, $v=0$. After solving Eq. (82) for E, the neutrino fields and the metric components can be found by quadrature. It should be mentioned here that, in the present case, the spacetime metric is not of the block diagonal form and the two Killing vectors characterizing the plane symmetry of the spacetime are not surface-forming. The map given by (84), connecting solutions of the two different Ernst–Weyl equations (82) and (83), may be viewed as a *generalization of the Neugebauer–Kramer involution.*

The considerations in Sec. IV indicate that the solutions $(E,\mathcal{E})$ of the Ernst–Weyl equations (82), (83) also satisfy

$$\mathcal{R}(u,v,E;-\rho_{,v}+\mathrm{i}\,a_{,v},\rho_{,u}+\mathrm{i}\,a_{,u})=0 \tag{85a}$$

and

$$\mathcal{R}(u,v,\mathcal{E};-\rho_{,v}+\mathrm{i}\,a_{,v},-\rho_{,u}+\mathrm{i}\,a_{,u})=0, \tag{85b}$$

respectively. Thus, the solution space of the Ernst–Weyl equation is imbedded into the solution space of Eq. (53) for the specific choices of $m(v),n(u)$ given by (81b).

B. Reduction of the auto-Bäcklund transformation

Finding exact solutions of Einstein's field equations is quite a difficult task. This is mainly due to the nonlinearity of the field equations. Another reason is that the solutions should respect various types of boundary (side) conditions. In stationary axisymmetric spacetimes for example, the corresponding metric should be asymptotically flat. For colliding wave solutions, on the other hand, the metric must satisfy appropriate junction conditions across the wavefront surfaces. There-

fore, solution generating techniques, such as the inverse scattering transform and Bäcklund transformations, become invaluable methods in finding exact solutions or determining global properties of the field equations (for a survey of results see Ref. 28).

In this section we show how the auto-Bäcklund transformation (47)–(49) of the system $\Sigma=0$ can be reduced to a Bäcklund transformation for the Ernst–Weyl equation. Moreover, we establish the relation of this reduction to the well-known Harrison Bäcklund transformation[29] for the Ernst equation.

To this end, let us first denote by $\mathcal{D}$ the solution space of the system $\Sigma=0$ and by $\mathcal{D}_E\subset\mathcal{D}$ the corresponding space of the Ernst–Weyl equation. Then, the auto-Bäcklund transformation B, defined by (47)–(49), may be viewed as a symmetry transformation in $\mathcal{D}$. In order to construct the reduced Bäcklund transformation for the Ernst–Weyl equation we require $B(\mathcal{D}_E)\subset\mathcal{D}_E$. This requirement implies that the new functions should satisfy the system $\Sigma=0$ *and* conditions (81). Following the notation of the previous section, we shall denote in what follows $\tilde{P}$ by $\tilde{\mathcal{E}}$ and $\tilde{U}$ by $\tilde{E}$.

Under the above conditions the auto-Bäcklund transformation (47)–(49) takes the following form:

$$\tilde{E}_{,u}=\frac{\mathcal{E}-\tilde{E}}{f(u)-\lambda}(\rho_{,u}+\mathrm{i}\,a_{,u}-(\mathcal{E}-\tilde{E})E_{,u}), \tag{86a}$$

$$\tilde{E}_{,v}=\frac{\mathcal{E}^{\star}+\tilde{E}}{g(v)-\lambda}(\rho_{,v}-\mathrm{i}\,a_{,v}-(\mathcal{E}^{\star}+\tilde{E})E_{,v}), \tag{86b}$$

$$(\tilde{E}-\mathcal{E})(E-\tilde{\mathcal{E}})=f(u)-\lambda, \tag{87a}$$

$$(\tilde{E}+\mathcal{E}^{\star})(E+\tilde{\mathcal{E}}^{\star})=g(v)-\lambda. \tag{87b}$$

One can now easily verify the following fact. Starting with a pair of potentials $(E,\mathcal{E})$ related as in (84), then the system (86), (87) delivers a new pair of potentials $(\tilde{E},\tilde{\mathcal{E}})$ which satisfy the same relation.

In order to establish the connection of the above Bäcklund transformation to the one proposed by Harrison, let us first note that in terms of $(E,\mathcal{E})$ the first of Eqs. (84) reads as

$$(E+E^{\star})(\mathcal{E}+\mathcal{E}^{\star})=2\rho. \tag{88}$$

Then, combining (87a), (87b) and (88) one finds that

$$\left|\frac{\tilde{\mathcal{E}}+E^{\star}}{\tilde{\mathcal{E}}-E}\right|^2=\gamma, \tag{89}$$

where $|\,|$ stands for the modulus of a complex number and γ is defined by

$$\gamma:=\frac{g(v)-\lambda}{f(u)-\lambda}. \tag{90}$$

Introducing the function α via

$$\alpha:=\frac{\tilde{\mathcal{E}}+E^{\star}}{\tilde{\mathcal{E}}-E}, \tag{91}$$

we can write Eq. (89) as

$$\alpha\,\alpha^{\star}=\gamma, \tag{92}$$

and Eqs. (87), (91) as

$$\widetilde{E}=\frac{\gamma-\alpha}{\gamma-1}\mathcal{E}+\frac{1-\alpha}{\gamma-1}\mathcal{E}^{\star}, \tag{93a}$$

$$\widetilde{\mathcal{E}}=\frac{\alpha}{\alpha-1}E+\frac{1}{\alpha-1}E^{\star}, \tag{93b}$$

respectively. Finally, Eqs. (86) take the following form:

$$\alpha_{,u}=\alpha(\alpha-1)\frac{E_{,u}}{E+E^{\star}}+(\alpha-\gamma)\frac{E^{\star}_{,u}}{E+E^{\star}}+\frac{\alpha}{2}(\gamma-1)\frac{\rho_{,u}-\mathrm{i}\,a_{,u}}{\rho}, \tag{94a}$$

$$\alpha_{,v}=(\alpha-1)\frac{E^{\star}_{,v}}{E+E^{\star}}+\frac{\alpha}{\gamma}(\alpha-\gamma)\frac{E_{,v}}{E+E^{\star}}+\frac{\alpha}{2\gamma}(\gamma-1)\frac{\rho_{,v}-\mathrm{i}\,a_{,v}}{\rho}. \tag{94b}$$

The converse also holds. More specifically, let us suppose that a pair of potentials $(E,\mathcal{E})$ satisfying Eqs. (82), (84) is given. Then, the members of the Ricatti system (94) for the auxiliary function $\alpha(u,v)$ are compatible and can be integrated to yield a solution which satisfies the condition (92). Moreover, Eqs. (93) deliver a new pair of potentials $(\widetilde{E},\widetilde{\mathcal{E}})$ which *also* satisfy the generalized version of the Neugebauer–Kramer involution. The system (92)–(94) constitutes a generalization of the *single Harrison transformation* for the Ernst equation, to which it reduces when $\mathrm{d}a=0$. We would like to point out that the above novel construction is purely algebraic and yields *explicit* expressions for the new potentials. As far as we are aware only implicit expressions for the new potentials occur in the literature. Let it also be noted that if one considers each member of the pair $(E,\mathcal{E})$ separately, then the relations (92)–(94b) must be viewed as an auto- or hetero-Bäcklund transformation, depending on whether $\mathrm{d}a$ equals 0 or not, respectively. This follows from the fact that E and $\mathcal{E}$ satisfy Eqs. (82) and (83), respectively, which are identical or different depending on whether $\mathrm{d}a$ vanishes or not.

Returning to the considerations of the paragraph preceding the last one, we note that one has to apply the transformation (92)–(94) twice in order to decouple the new potentials. This can be achieved by using the superposition principle (50) in the form resulting by applying the reality conditions. This form is given by

$$E_3=E_0+\frac{\lambda_2-\lambda_1}{E_2-E_1}, \tag{95a}$$

$$\mathcal{E}_3=\mathcal{E}_0+\frac{\lambda_2-\lambda_1}{\mathcal{E}_2-\mathcal{E}_1}. \tag{95b}$$

The potentials $E_i,\mathcal{E}_i$, $i=1,2$, appearing in these relations are determined by

$$E_i=\frac{\gamma_i-\alpha_i}{\gamma_i-1}\mathcal{E}_0+\frac{1-\alpha_i}{\gamma_i-1}\mathcal{E}_0^{\star},$$

$$\mathcal{E}_i=\frac{\alpha_i}{\alpha_i-1}E_0+\frac{1}{\alpha_i-1}E_0^{\star}.$$

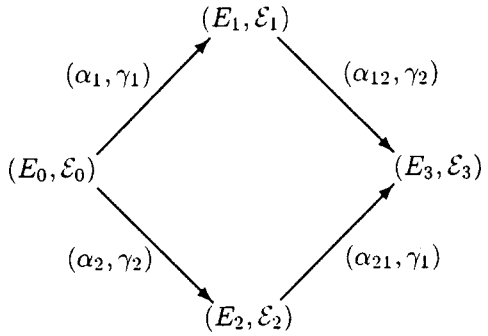

FIG. 2. Commuting diagram for the Harrison transformation.

Here, the γ_i's are defined by (92) with λ replaced by λ_i and the α_i's are obtained from the system (94) by replacing γ by γ_i. Using these expressions, Eqs. (95) reads as

$$E_3=E_0+\frac{(\gamma_2-\gamma_1)(E_0+E_0^\star)}{\gamma_1-\gamma_2-(1-\gamma_2)\alpha_1+(1-\gamma_1)\alpha_2}, \tag{96a}$$

$$\mathcal{E}_3=\mathcal{E}_0-\frac{\gamma_2-\gamma_1}{\alpha_2-\alpha_1}\frac{(1-\alpha_1)(1-\alpha_2)}{(1-\gamma_1)(1-\gamma_2)}(\mathcal{E}_0+\mathcal{E}_0^\star). \tag{96b}$$

Equations (96) represent the double Harrison transformation and are valid for both cases, $da=0$ and $da\neq 0$.

In the Bianchi commuting diagram given in Fig. 2 one can focus on the auxiliary functions α_i's instead of the potentials $(E_i,\mathcal{E}_i)$. Then the superposition principle is expressed by the following relations among the α's:

$$\frac{\alpha_{12}}{\alpha_{21}}=\frac{\alpha_2}{\alpha_1}, \tag{97}$$

where

$$\alpha_{12}=\frac{1}{\alpha_1}\frac{\alpha_1\alpha_2(\gamma_2-\gamma_1)+\alpha_1\gamma_2(\gamma_1-1)+\alpha_2\gamma_1(1-\gamma_2)}{\gamma_1-\gamma_2+\alpha_1(\gamma_2-1)+\alpha_2(1-\gamma_1)}. \tag{98}$$

VI. REDUCTIONS TO THE PAINLEVÉ TRANSCENDENTS

Similarity reductions of the Ernst equation to Painlevé transcendents have been of particular interest for a long time. More recently Schief[21] has shown that the Ernst–Weyl equation for stationary axially symmetric spacetimes [the elliptic analog of Eq. (82)] admits similarity reductions to Painlevé III, V, and VI. His reduction procedure to Painlevé III and V is based on solving the system of ordinary differential equations (ODEs) resulting from the application of the invariance conditions. For the reduction to Painlevé VI, however, the author resorts to a different approach, based on a matrix formulation of the Ernst–Weyl equation, motivated by the Loewner system. In this section, we present a reduction of the hyperbolic Ernst–Weyl equation (82) by a method which exploits the relation of the latter equation to the RPDE and the straightforward manner in which the symmetry group of the RPDE leads to Painlevé's transcendents.

As we have shown,[23] the RPDE admits straightforward similarity reductions to Painlevé III, V, and VI in full form. This was done by considering the invariant solutions under the optimal system of one-dimensional subalgebras of the Lie point symmetries of the RPDE. The link between the RPDE and the Ernst–Weyl equation is the system $\Sigma=0$. Specifically, in Sec. IV, it was shown that the RPDE may be given in involutive form by system (32) with the choices

$$f(u)=u, \quad g(v)=v, \quad m(v)=m, \quad n(u)=n. \tag{99}$$

Within the above setting, the Ernst–Weyl equation arises from the system $\Sigma=0$ by requiring that

$$P=-R^{\star}, \quad m=-\tfrac{1}{2}+\mathrm{i}a_1, \quad n=-\tfrac{1}{2}+\mathrm{i}a_2, \tag{100}$$

where a_1, a_2 are real constants.

On the basis of the above connection, we shall search for invariant solutions of the Ernst–Weyl equation that follow from imposing conditions (100) on corresponding invariant solutions of the RPDE. As we shall immediately show, this can best be achieved by first prolonging the symmetries of the RPDE to symmetries of the system $\Sigma=0$. For illustration purposes, we shall restrict our presentation to invariant solutions that are related to the full Painlevé V and VI cases, only. To make the presentation self-contained, we first summarize briefly the Lie point symmetries of the RPDE.

The Lie point symmetry group of the RPDE consists of transformations leaving the dependent variables unaffected (base transformations) and transformations acting on the dependent variables only (vertical transformations). The base transformations act on $(u,v)\in\mathbb{R}^2$ by

$$(u,v)\rightarrow(\lambda u+\epsilon,\lambda v+\epsilon), \quad \lambda\in\mathbb{R}^{+}, \ \epsilon\in\mathbb{R}, \tag{101}$$

and the generators are given by the vector fields

$$\partial_u+\partial_v, \quad u\partial_u+v\partial_v. \tag{102}$$

The group of vertical transformations is the most general group of transformations acting locally effectively on a one-dimensional complex manifold and is given by

$$U\rightarrow\frac{aU+b}{cU+d}, \quad \begin{pmatrix} a & b \\ c & d \end{pmatrix}\in\mathbf{SL}(2,\mathbb{C}). \tag{103}$$

The corresponding generators are the vector fields

$$\partial_U, \quad U\partial_U, \quad U^2\partial_U. \tag{104}$$

A. Reduction to Painlevé V

The group invariant solutions of the RPDE under the symmetry generator,

$$\partial_u+\partial_v+2\mu U\partial_U, \tag{105}$$

have the form

$$U(u,v)=S(y)\exp(\mu(u+v)), \quad y=u-v. \tag{106}$$

The prolongation of the vector field (105) in the P and R directions which yields a symmetry of the system $\Sigma=0$ reads as

$$\partial_u+\partial_v+2\mu U\partial_U-2\mu(P\partial_P+R\partial_R). \tag{107}$$

This implies that the invariant form of the functions P and R is

$$P(u,v)=p(y)\exp(-\mu(u+v)), \quad R(u,v)=r(y)\exp(-\mu(u+v)), \tag{108}$$

respectively. Inserting (106), (108) into the system $\Sigma=0$ we get the following system of ODEs:

$$(S'-\mu S)(p-r)^2-m(p-r)-y(p'+\mu p)=0, \tag{109a}$$

$$(S'+\mu S)(p-r)^2-n(p-r)+y(r'-\mu r)=0, \tag{109b}$$

$$yS''+2(p-r)S'^2-(m+n)S'-2\mu^2(p-r)S^2-\mu(m-n+\mu y)S=0. \tag{109c}$$

By a simple differentiation and elimination process applied to system (109), one ends up with a fourth order ODE for the function S, which can be integrated once leading to

$$y^2S(S'^2-\mu^2S^2)S'''-y^2SS'S''^2+y(-yS'^3+SS'^2+3\mu^2yS^2S'-\mu^2S^3)S''-yS'^4+\mu(m^2-n^2+\mu y)S^2S'^2+\mu^2[2(m^2+n^2)-\mu^2y^2]S^3S'+\mu^3(m^2-n^2)S^4-lyS'^2-\mu^2S^2)^2=0, \tag{110}$$

where l is the constant of integration. For later use, we note that, using system (109), the above first integral can be written in the following remarkably simple form:

$$2y\frac{(pr)'}{(p-r)^2}+(m-n)\frac{p+r}{p-r}+1+l=0. \tag{111}$$

Setting

$$\frac{S'(y)}{S(y)}=\mu\frac{1+G(y)}{1-G(y)}, \tag{112}$$

Eq. (110) becomes

$$\mathcal{P}_V\left(G,y;\frac{n^2}{2},-\frac{m^2}{2},2\mu l,-2\mu^2\right)=0. \tag{113}$$

Here $\mathcal{P}_V(G,y;\alpha,\beta,\gamma,\delta)=0$, with α, β, γ and δ arbitrary complex parameters, stands for the full Painlevé V equation, i.e.,

$$-G''+\left(\frac{1}{2G}+\frac{1}{G-1}\right)G'^2-\frac{1}{y}G'+\alpha\frac{G(G-1)^2}{y^2}+\beta\frac{(G-1)^2}{y^2G}+\gamma\frac{G}{y}+\delta\frac{G(G+1)}{G-1}=0. \tag{114}$$

Having determined S in the manner described above, one can return to system (109) to find the following explicit expressions for the functions p, r:

$$p(y)=\frac{yG'+nG^2-(l+2n+1-2\mu y)G+l+n+1}{4\mu S(1-G)}, \tag{115a}$$

$$r(y)=\frac{yG'-(l+m+1)G^2+(l+2m+1+2\mu y)G-m}{4\mu SG(1-G)}. \tag{115b}$$

At this point it is worth noting that using Eqs. (112), (113) and (115), one can easily verify that the functions W, V defined by

$$\frac{p'(y)}{p(y)}=\mu\frac{W(y)+1}{W(y)-1},\quad \frac{r'(y)}{r(y)}=\mu\frac{V(y)+1}{V(y)-1}, \tag{116}$$

satisfy

$$\mathcal{P}_V\left(W,y;\frac{(n+1)^2}{2},-\frac{m^2}{2},2\mu(l+1),-2\mu^2\right)=0, \tag{117a}$$

$$\mathcal{P}_V\left(V,y;\frac{n^2}{2},-\frac{(m+1)^2}{2},2\mu(l+1),-2\mu^2\right)=0, \tag{117b}$$

respectively. Thus, one may consider Eqs. (115) as Bäcklund transformations among the Painlevé V equations (113), (117).

Restricting our considerations to solutions of the Ernst–Weyl equation, we need to take conditions (100) into account. Under these conditions, Eqs. (108) imply that

$$p=-r^\star, \quad \mu=\mu^\star, \tag{118a}$$

while (111) yields

$$l=l^\star. \tag{118b}$$

Hence, the corresponding similarity solutions of the Ernst–Weyl equation (82) are determined by the potential

$$E=S(y)\exp(\mu(u+v)), \quad y=u-v, \tag{119}$$

where S is given by Eq. (112). In the latter, G represents a solution of the Painlevé equation (113), with

$$n=-\tfrac{1}{2}+\mathrm{i}a_1, \quad m=-\tfrac{1}{2}+\mathrm{i}a_2, \quad l=l^\star, \quad \mu=\mu^\star. \tag{120}$$

The analogous similarity solutions of the Ernst–Weyl equation (83) are specified by the potential

$$\mathcal{E}=p(y)\exp(-\mu(u+v)), \quad y=u-v, \tag{121}$$

where p is determined by the first of Eqs. (116). In the latter, W stands for a solution of the Painlevé equation (117a), with n, m, l, and μ satisfying the conditions (120) above.

B. Reduction to Painlevé VI

In a similar manner one may construct solutions of the Ernst–Weyl equation from the Painlevé VI transcendents, i.e., solutions of the ODE,

$$\begin{aligned}-G''+\frac{1}{2}\left(\frac{1}{G}+\frac{1}{G-1}+\frac{1}{G-y}\right)G'^2-\left(\frac{1}{y}+\frac{1}{y-1}+\frac{1}{G-y}\right)G'\\ +\frac{G(G-1)(G-y)}{y^2(y-1)^2}\left(\alpha+\beta\frac{y}{G^2}+\gamma\frac{y-1}{(G-1)^2}+\delta\frac{y(y-1)}{(G-y)^2}\right)=0,\end{aligned} \tag{122}$$

where α, β, γ, and δ arbitrary complex parameters, which will be denoted by $\mathcal{P}_{VI}(G,y;\alpha,\beta,\gamma,\delta)=0$ in the following.

The solutions of the RPDE which are invariant under the symmetry generated by the vector field

$$u\partial_u+v\partial_v+2\mu U\partial_U, \tag{123}$$

have the form

$$U(u,v)=S(y)(uv)^\mu, \quad y=u/v. \tag{124}$$

The prolongation of the vector field (123) in the P, R directions leading to a symmetry of system $\Sigma=0$ reads as

$$u\partial_u+v\partial_v+2\mu U\partial_U+(1-2\mu)(P\partial_P+R\partial_R). \tag{125}$$

This implies that the invariant form of the functions P and R is

$$P(u,v)=p(y)(uv)^{-\mu+1/2},\quad R(u,v)=r(y)(uv)^{-\mu+1/2}, \tag{126}$$

respectively. Inserting (124), (126) into the system $\Sigma=0$ we obtain the following system of ODEs:

$$y^{1/2}(\mu S-yS')(p-r)^2+(m+(\mu-\tfrac{1}{2})(y-1))p-mr+(y-1)yp'=0, \tag{127a}$$

$$y^{1/2}(\mu S+yS')(p-r)^2+(ny-(\mu-\tfrac{1}{2})(y-1))r-nyp+(y-1)yr'=0, \tag{127b}$$

$$(1-y)y^2S''+2y^{1/2}(p-r)(\mu^2S^2-y^2S'^2)+y(m+(n-1)y+1)S'+\mu(m-ny+\mu(y-1))S=0. \tag{127c}$$

Through a lengthy but straightforward process of differentiation and elimination one ends up with a fourth order ODE for the function S. The latter may be integrated once leading to a third order equation which is omitted because of its length. We note, however, that this first integral can be written in the following simple form by using system (127):

$$(1-2\mu)\frac{y^2-1}{(p-r)^2}(pr)'-2y\frac{(y-1)^2}{(p-r)^2}p'r'+\frac{(2\mu-1)^2}{2(p-r)^2}\left(p^2+r^2-\frac{1+y^2}{y}pr\right)$$

$$+(m-n)(1-2\mu)\frac{p+r}{p-r}+\frac{1}{2}(m-n)^2=l,\quad l\ \text{constant}. \tag{128}$$

Substituting

$$\frac{S'(y)}{S(y)}=\frac{\mu}{y}\frac{y+G(y)}{y-G(y)} \tag{129}$$

into the omitted third order ODE for S, we find that G satisfies the full Painlevé equation,

$$\mathcal{P}_{VI}\left(G,y;\frac{n^2}{2},-\frac{m^2}{2},l,\frac{1-4\mu^2}{2}\right)=0. \tag{130}$$

Once S is determined by solving the differential equations (129), (130), one can find the functions p, r algebraically using system (127). The explicit expressions for these functions are given by

$$p(y)=\frac{y^2(y-1)^2G'^2+\Gamma G^2(G-1)G'+A_i(y,m,n)G^i}{8\,\mu\,(2\mu-1)\,y^{1/2}(y-G)\,(G-1)\,G\,S}, \tag{131a}$$

$$r(y)=\frac{y^2(y-1)^2G'^2+\Gamma yG(G-1)G'+B_i(y,m,n)G^i}{8\,\mu\,(2\mu-1)\,y^{1/2}(y-G)\,(G-1)\,G\,S}, \tag{131b}$$

where summation over the repeated index $i=0,\ldots,4$ is understood and the coefficients A_i, B_i and Γ are given by

$$A_0(y,m,n)=-m^2y^2,$$

$$A_1(y,m,n)=y[(m^2-2l+(n-2\mu+1)^2)y+2m^2],$$

$$A_2(y,m,n)=-(n-2\mu+1)^2y^2-2(m^2-2l+(n-2\mu+1)^2)y+(1-2\mu)^2-m^2,$$

$$A_3(y,m,n)=2(n-2\mu+1)^2y+m^2+2n^2-2l-(n+2\mu-1)^2,$$

$$A_4(y,m,n)=-n(n-4\mu+2),$$

$$B_i(y,m,n)=y^2A_{4-i}(y^{-1},n,m),\quad i=0,\ldots,4,$$

$$\Gamma=2(2\mu-1)y(y-1).$$

As in the previous case, one may use Eqs. (129), (130) and (131) to verify that the functions W, V defined by

$$\frac{p'(y)}{p(y)}=\frac{1-2\mu}{2y}\frac{y+W(y)}{y-W(y)},\quad \frac{r'(y)}{r(y)}=\frac{1-2\mu}{2y}\frac{y+V(y)}{y-V(y)},\tag{132}$$

satisfy

$$\mathcal{P}_{VI}\left(W,y;\frac{(n+1)^2}{2},-\frac{m^2}{2},l,2\mu(1-\mu)\right)=0,\tag{133a}$$

$$\mathcal{P}_{VI}\left(V,y;\frac{n^2}{2},-\frac{(m+1)^2}{2},l,2\mu(1-\mu)\right)=0,\tag{133b}$$

respectively. Hence, one may view Eqs. (131) as defining Bäcklund transformations among the Painlevé VI equations (130) and (133).

Taking into account conditions (100), one is restricted to solutions of the Ernst–Weyl equation. Equations (126) imply that

$$p=-r^\star,\quad \mu=\mu^\star,\tag{134}$$

while Eq. (128) gives

$$l=l^\star.\tag{135}$$

Hence the invariant solutions of the Ernst–Weyl equation (82) are of the form

$$E=S(y)(uv)^\mu,\quad y=u/v,\tag{136}$$

where S is given by integrating (129) and G satisfies (130) with

$$n=-\tfrac{1}{2}+\mathrm{i}a_1,\quad m=-\tfrac{1}{2}+\mathrm{i}a_2,\quad l=l^\star,\quad \mu=\mu^\star.\tag{137}$$

Last, the similarity solutions of the Ernst–Weyl equation (83) have the form

$$\mathcal{E}=p(y)(uv)^{-\mu+1/2},\quad y=u/v,\tag{138}$$

where p is given by integrating the first equation of (132) and W satisfies (133a) with n, m, l, and μ given by (137).

VII. PERSPECTIVES

We presented a two-dimensional reduction of the ASDYM equations which leads to a novel system of integrable equations. This system incorporates the well-known Ernst–Weyl equation, as well as a significant generalization of the fourth order hyperbolic equation proposed by Nijhoff *et al.*[9] recently as the generating PDE for the KdV hierarchy. We have also constructed a Lax pair

and an auto-Bäcklund transformation for the above system and similarity solutions based on the Painlevé V and VI transcendents. Our reduction scheme unifies many aspects of integrability of the Ernst equation, like the Ernst–Hauser deformation problem, the Neugebauer–Kramer involution, the single and double-Harrison Bäcklund transformations, and gives analogous generalizations to the Ernst–Weyl equation. All these aspects follow algorithmically from the new system and the associated Lax pair, by imposing purely algebraic and compatibility conditions. Moreover, our reduction scheme allows for an easier construction of solutions to the Ernst–Weyl equation related to Painlevé transcendents by Lie group techniques. Using the reduction scheme presented in this paper and higher-dimensional gauge groups than $\mathbf{GL}(2,\mathbb{C})$, one should obtain integrable systems which incorporate the Ernst–Maxwell–Weyl equations, or even more general integrable equations describing the interaction of the gravitational field with other sources.[30,31]

(Received 27 September 2000; accepted for publication 29 August 2001)

Maxwell's equations can be obtained in generalized coordinates by considering the electromagnetic field as an external agent. The work presented here shows how to obtain the electrodynamics for a charged particle in generalized coordinates eliminating the concept of external force. Based on Kaluza's formalism, the one presented here extends the 5×5 metric into a 6×6 space–time giving enough room to include magnetic monopoles in a very natural way. © *2001 American Institute of Physics.* [DOI: 10.1063/1.1412463]

I. INTRODUCTION

Over 70 years ago, T. Kaluza developed a theory unifying electromagnetism and gravitation by working in a five-dimensional manifold.[1,2] In his work, influences of an electrical charge in space are treated as sources of curvature in a similar way as mass does in Einstein's theory of general relativity. With this formalism, Maxwell's equations can be obtained in Cartesian coordinates in a rather simple way. In generalized coordinates, only four out of eight (three for each rotational and one for each divergence) Maxwell equations can be recovered correctly–those with sources. The problem resides in the asymmetrical way in which each pair of equations, with and without sources, are obtained *if Kaluza's formalism is applied*. The equations with sources are obtained by means of the field equation, while the homogeneous ones have to be deduced from an identity which yields incorrect results unless the metric is Cartesian. A more conventional method for obtaining Maxwell equations consists in using Bianchi's identities.[3] Although it yields correct results using any metric, the electromagnetic field is treated as an external ''source'' by including it in the stress tensor. Kaluza's method, and consequently the one presented here, have the advantage of considering charge as a space curvature, thus following the tenets of general relativity.

In this work we propose an alternative method for treating charge and mass as curvature sources. This method is not only consistent with Kaluza's but also represents a generalization of it, by considering his 5×5 metric included in a larger one. A larger space also has enough room to establish a generalized theory in which magnetic monopoles can be introduced in a very natural way.

This paper is divided as follows. Section II contains a brief summary of Kaluza's theory without specifying any metric, as presented in his original article. In Sec. III, through a simplified example, the cause for the incorrectness of the inhomogeneous equations is explored. Section IV proposes an alternative to the theory, making a symmetrical generalization of the metric used before as a way of obtaining Maxwell equations using only Einstein's field equation. Section V goes deeper into the interpretation of the 6×6 space–time and finally in Sec. VI we discuss the implications of this formalism.

II. KALUZA'S THEORY

Kaluza's formalism generates Maxwell's equations as well as the equations of motion for charged particles by working with a 5×5 metric defined as

$$g_{\mu\nu}=\begin{bmatrix} g_{11} & g_{12} & g_{13} & g_{14} & A_1 \\ g_{21} & g_{22} & g_{23} & g_{24} & A_2 \\ g_{31} & g_{32} & g_{33} & g_{34} & A_3 \\ g_{41} & g_{42} & g_{43} & g_{44} & \dfrac{1}{c}\phi \\ A_1 & A_2 & A_3 & \dfrac{1}{c}\phi & g_{55} \end{bmatrix}. \tag{1}$$

The 4×4 metric consisting of $g_{\mu\nu}$ elements with subscripts running from 1 to 4 has to be a solution of Einstein's equations, while the fifth column and row contain the four-vector electromagnetic potential A_ν, the first three components being the ones of the usual potential vector and the fourth the scalar potential ϕ. The fifth element g_{55} is undefined in Kaluza's article, but, as this extra dimension is considered as a spatial type one, g_{55} can be set equal to a constant taken to be equal to one in the case of a Minkowski metric.

The position and velocity vectors to consider in this formalism are defined as follows:

$$x^\nu=\begin{bmatrix} x^1 \\ x^2 \\ x^3 \\ ct \\ x^5 \end{bmatrix}, \tag{2}$$

$$v^\nu=\begin{bmatrix} v^1 \\ v^2 \\ v^3 \\ c \\ \dfrac{q}{m} \end{bmatrix}. \tag{3}$$

The fact that the time derivative of the fifth position coordinate is taken to be equal to the charge–mass ratio arises from comparing the equation of motion for a charged particle moving under Lorentz's force

$$\frac{\mathrm{d}^2x^\alpha}{\mathrm{d}t^2}=\frac{q}{m}\left[\varepsilon^\alpha_{\beta\gamma}\frac{\mathrm{d}x^\beta}{\mathrm{d}t}B^\gamma+E^\gamma\right] \tag{4}$$

with the one obtained by restricting the particle to move through a geodesic in this space namely,

$$\frac{\mathrm{d}^2x^\alpha}{\mathrm{d}s^2}+\Gamma^\alpha_{\mu\nu}\frac{\mathrm{d}x^\mu}{\mathrm{d}s}\frac{\mathrm{d}x^\nu}{\mathrm{d}s}=0. \tag{5}$$

Indeed Eq. (4) may be obtained from Eq. (5) only if $v^5=q/m$. An extra condition must be taken into account in order to recover electrodynamics within this framework. Such condition is usually referred to as the cylindrical condition,[1] namely

$$\frac{\partial}{\partial x^5}=0 \tag{6}$$

makes any derivative with respect to the fifth component equal to zero. The only justification for this restriction is that it leads to the correct Maxwell's equations.

The structural similarity between curls and Christoffel symbols, $\Gamma^{\alpha}_{\mu\nu}$, suggests a proportionality between the latter and the components of the electromagnetic field.[1] These symbols, taking $g^{ij}=\delta^{ij}$ (latin indices run from 1 to 3), are computed as follows:

$$\Gamma^{\alpha}_{\mu\nu}=\frac{1}{2}g^{\alpha\lambda}\left(\frac{\partial g_{\mu\lambda}}{\partial x^{\nu}}+\frac{\partial g_{\nu\lambda}}{\partial x^{\mu}}-\frac{\partial g_{\mu\nu}}{\partial x^{\lambda}}\right), \tag{7}$$

$$\Gamma^{\alpha}_{\mu 5}=\Gamma^{\alpha}_{5\mu}=\frac{1}{2}\,g^{\alpha\lambda}\left(\frac{\partial g_{5\lambda}}{\partial x^{\mu}}-\frac{\partial g_{\mu 5}}{\partial x^{\lambda}}\right)=F^{\alpha}_{\mu}, \tag{8}$$

where F^{α}_{μ}, the elements of the field tensor, are defined as

$$F^{\alpha}_{\mu}=\begin{bmatrix} 0 & B_z & -B_y & -\frac{1}{c}E_x \\ -B_z & 0 & B_x & -\frac{1}{c}E_y \\ B_y & -B_x & 0 & -\frac{1}{c}E_z \\ \frac{1}{c}E_x & \frac{1}{c}E_y & \frac{1}{c}E_z & 0 \end{bmatrix}. \tag{9}$$

In this scheme, Maxwell's inhomogeneous equations may be obtained through Einstein's field equation

$$G^{\alpha\beta}=\kappa T^{\alpha\beta} \tag{10}$$

since the energy momentum tensor $T^{\alpha\beta}$ now has a fifth column and row containing the electric current

$$T^{\alpha 5}=T^{5\alpha}=\rho_0 v^{\alpha} v^{5}=\begin{bmatrix} \rho_0 v^1 \frac{q}{m} \\ \rho_0 v^2 \frac{q}{m} \\ \rho_0 v^3 \frac{q}{m} \\ \rho_0 c \frac{q}{m} \\ \rho_0 \frac{q^2}{m^2} \end{bmatrix}=J^{\alpha} \tag{11}$$

and K is the coupling constant. The homogeneous equations can be derived, as suggested by Kaluza, from the identity

$$F^{\lambda\alpha,\beta}+F^{\alpha\beta,\lambda}+F^{\beta\lambda,\alpha}=0, \tag{12}$$

which arises from applying the cylindrical condition [Eq. (6)], to the identity

$$(\Gamma^{\alpha}_{\beta\lambda}+\Gamma^{\beta}_{\lambda\alpha}+\Gamma^{\lambda}_{\alpha\beta})_{,\mu}=\Gamma^{\alpha,\beta}_{\mu\lambda}+\Gamma^{\beta,\lambda}_{\mu\alpha}+\Gamma^{\lambda,\alpha}_{\mu\beta} \tag{13}$$

taking $\mu=5$.

In Cartesian coordinates this mechanism yields the complete set of Maxwell's equations. However, if one works in generalized coordinates, Eq. (13) does not correspond to the correct sourceless electromagnetic equations, a fact which will be shown in Sec. III. A strong objection can be primarily made to Eq. (13). Christoffel symbols by themselves are not tensors and, although some combinations of them are, Eq. (13) is not tensorial, in contrast with Eq. (10) which has tensors in both sides.

Summarizing, the theory has its weak point in the way sourceless equations are obtained. On the other hand, the mechanism by which inhomogeneous equations are derived, Einstein's field equation, is irrefutable and far more elegant.

III. FIVE DIMENSIONS AND GENERALIZED COORDINATES

In this section we give the necessary arguments to circumvent the objection raised in Sec. II regarding the derivation of Maxwell's sourceless equations following Kaluza's procedure. To do so and for the sake of simplicity we shall take as an example a Minkowski space with spherical symmetry. The covariant and contravariant metric tensors are thus given by

$$g_{\mu\nu}=\begin{bmatrix} 1 & 0 & 0 & 0 & A_1 \\ 0 & r^2 & 0 & 0 & r^2A_2 \\ 0 & 0 & r^2\sin^2\theta & 0 & r^2\sin^2\theta A_3 \\ 0 & 0 & 0 & -1 & -\frac{1}{c}\phi \\ A_1 & r^2A_2 & r^2\sin^2\theta A_3 & -\frac{1}{c}\phi & 1 \end{bmatrix}, \tag{14}$$

$$g^{\mu\nu}=\begin{bmatrix} 1 & 0 & 0 & 0 & -A_1 \\ 0 & \frac{1}{r^2} & 0 & 0 & -A_2 \\ 0 & 0 & \frac{1}{r^2\sin^2\theta} & 0 & -A_3 \\ 0 & 0 & 0 & -1 & \frac{1}{c}\phi \\ -A_1 & -A_2 & -A_3 & \frac{1}{c}\phi & 1 \end{bmatrix}. \tag{15}$$

In this metric, which is similar to the one used in Kaluza's article, the two metric tensors are inverse discarding quadratic terms. This means that (14) is the inverse of (15) only if second-order terms are eliminated. This approximation seems to be correct since it was also used in Kaluza's article with a Cartesian metric. Geometric coefficients must be added to the components of the electromagnetic potential which simply implies working in physical coordinates in order to obtain geometric terms and coefficients in the equations. If A^{ten}_{ν} are tensorial components of a vector, its physical components are computed as follows

$$A^{\text{phys}}_{\nu}=\sqrt{g_{\nu\nu}}A^{\text{ten}}_{\nu}. \tag{16}$$

It has to be pointed out that with these metric coefficients g^{ij}, permutations of indices in the Christoffel symbols of Eq. (13) do not *only* yield a change in sign as with a Cartesian metric in which $g^{ij}=\delta^{ij}$ with i and j running from 1 to 3, but also metric coefficients relate these permutations. Moreover,

$$\Gamma^{\alpha}_{\beta 5}=-\frac{g^{\alpha\alpha}}{g^{\beta\beta}}\Gamma^{\beta}_{\alpha 5} \tag{17}$$

gives a relation between permutations of indices in Christoffel symbols which makes Eq. (13) dependent on the value given to the indices unless the metric is Cartesian, resulting in more than four incorrect equations since each permutation of indices leads to an equation with different coefficients.

To clarify these statements let us take, for example, the third component of

$$\varepsilon^{\nu\beta\gamma}\left(\frac{\partial E_{\beta}}{\partial x^{\gamma}}-\frac{\partial E_{\gamma}}{\partial x^{\beta}}\right)=-\frac{1}{c}\frac{\partial B^{\nu}}{\partial t}. \tag{18}$$

In the space we are working in, both sides of Eq. (18) in terms of electromagnetic potentials should read

$$-\frac{2}{r\sin\theta}\frac{\partial A_2}{\partial t}-\frac{1}{\sin\theta}\frac{\partial^2 A_2}{\partial t\partial r}-\frac{1}{r^2\sin\theta}\frac{\partial^2 A_1}{\partial t\partial\theta}, \tag{19}$$

while Eq. (13), taking $\alpha=4$, $\beta=2$, $\lambda=1$, and $\mu=5$, turns out to be

$$-r\frac{\partial A_2}{\partial t}-\frac{1}{cr^3}\frac{\partial\phi}{\partial\theta}+\frac{\partial^2 A_1}{\partial\theta\partial t}+\frac{1}{2}(1-r^2)\frac{\partial^2 A_2}{\partial r\partial t}+\frac{1}{2c}\left(1+\frac{1}{r^2}\right)\frac{\partial^2\phi}{\partial r\partial\theta}=0, \tag{20}$$

which can be written as

$$\frac{1}{2r}\frac{\partial^2 A_2}{\partial r\partial t}-\frac{1}{cr^4}\frac{\partial\phi}{\partial\theta}+\frac{1}{2cr}\left(1+\frac{1}{r^2}\right)\frac{\partial^2\phi}{\partial r\partial\theta}=\frac{\partial A_2}{\partial t}+\frac{r}{2}\frac{\partial^2 A_2}{\partial r\partial t}-\frac{1}{2r}\frac{\partial^2 A_1}{\partial\theta\partial t}. \tag{21}$$

Equation (21) is obviously wrong. In Eq. (18), no derivatives of the scalar potential should appear since its right-hand side is a time derivative of **B** which is only in terms of the vector potential. The left-hand side contains the rotational of the gradient of ϕ which is equal to zero. Similar results are obtained by changing the indices for the rest of the equations. These equations are derived in Appendix A.

On the other hand, the inhomogeneous Maxwell equations are correctly recovered using Einstein's field equation as was mentioned. This induces us to reformulate the theory in order to be able to obtain electromagnetic equations, within Kaluza's formalism, based *only* on Einstein's field equation without having to invoke the cylindrical condition to work on the geometrical identity given by Eq. (13).

IV. KALUZA'S FORMALISM IN SIX DIMENSIONS

The alternative presented here for Kaluza's formalism is based on a 6×6 metric. This space–time can thus be considered as an extension of Kaluza's case. To proceed we define the following metric tensors with components accounting for spherical symmetry namely

$$g_{\mu\nu}=\begin{bmatrix} 1 & 0 & 0 & 0 & A_1 & Z_1 \\ 0 & r^2 & 0 & 0 & r^2A_2 & r^2Z_2 \\ 0 & 0 & r^2\sin^2\theta & 0 & r^2\sin^2\theta A_3 & r^2\sin^2\theta Z_3 \\ 0 & 0 & 0 & -1 & -\frac{1}{c}\phi & -\frac{1}{c}\eta \\ A_1 & r^2A_2 & r^2\sin^2\theta A_3 & \frac{1}{c}\phi & 1 & g_{56} \\ Z_1 & r^2Z_2 & r^2\sin^2\theta Z_3 & -\frac{1}{c}\eta & g_{65} & 1 \end{bmatrix}, \tag{22}$$

$$g^{\mu\nu}=\begin{bmatrix} 1 & 0 & 0 & 0 & -A_1 & -Z_1 \\ 0 & \frac{1}{r^2} & 0 & 0 & -A_2 & -Z_2 \\ 0 & 0 & \frac{1}{r^2\sin^2\theta} & 0 & -A_3 & -Z_3 \\ 0 & 0 & 0 & -1 & \frac{1}{c}\phi & \frac{1}{c}\eta \\ -A_1 & -A_2 & -A_3 & \frac{1}{c}\phi & 1 & g_{56} \\ -Z_1 & -Z_2 & -Z_3 & \frac{1}{c}\eta & g_{65} & 1 \end{bmatrix}. \tag{23}$$

The structure of these tensors is proposed to maintain symmetry between the fifth and sixth dimensions. The quantities Z_n and η are left unspecified for the time being but will be interpreted later when the role that each one plays in the equations becomes clear. Also $g_{56}=g_{65}$ is left unsettled but it has to be proposed as time independent in order to recover the conventional definitions for the fields (see Appendix B). The position and velocity vectors are proposed, just following Kaluza, as follows:

$$x^\nu=\begin{bmatrix} r \\ \theta \\ \varphi \\ ct \\ x^5 \\ x^6 \end{bmatrix}, \tag{24}$$

$$v^\nu=\begin{bmatrix} v^1 \\ v^2 \\ v^3 \\ c \\ \frac{q}{m} \\ \frac{dx^6}{dt} \end{bmatrix}. \tag{25}$$

The equation of motion to be considered in this formalism is that of a particle under the influence of a generalized Lorentz's force, namely

$$\frac{\mathrm{d}^2x^\alpha}{\mathrm{d}t^2}=\frac{q}{m}\left[\varepsilon^{\alpha}_{\beta\gamma}\frac{\partial x^\beta}{\partial t}B^\gamma+E^\alpha\right]+\frac{g}{m}\left[\varepsilon^{\alpha}_{\beta\gamma}\frac{\partial x^\beta}{\partial t}E^\gamma-B^\alpha\right]. \tag{26}$$

This space is a more general one and has enough room to work in a generalized scheme as will soon be shown. Here g stands for the magnetic charge. The Christoffel symbols that appear in the equation of a geodesic [Eq. (5)] in this space are to be compared with the coefficients of velocity components and charge in Eq. (26).

On the other hand, with the proposed metric Christoffel symbols can also be computed from definition (7). The symbols to be proportional to the electromagnetic field components are shown here as they arise directly by introducing the elements of the metric tensors (22) and (23) in definition (7). These symbols, in terms of potentials, become

$$\Gamma^\mu_{\beta 5}=g^{\mu\alpha}(A_{\beta,\alpha}-A_{\alpha,\beta}+Z_\alpha g_{56,\beta}), \tag{27}$$

$$\Gamma^\mu_{\beta 6}=g^{\mu\alpha}(Z_{\beta,\alpha}-Z_{\alpha,\beta}+A_\alpha g_{56,\beta}). \tag{28}$$

Comparing the symbols obtained from the geodesic and Eq. (26) with the ones obtained directly from their definition, expressions for electric and magnetic fields arise. Since we now have two sets of Christoffel symbols, there are two expressions for each field (see Appendix B),

$$E^\nu=-\frac{\partial\phi}{\partial x^\nu}-\frac{\partial A_\nu}{\partial t}, \tag{29}$$

$$E^\nu=\varepsilon^{\nu\beta\gamma}\left(\frac{\partial Z_\beta}{\partial x^\gamma}-\frac{\partial Z_\gamma}{\partial x^\beta}\right)+M^\nu, \tag{30}$$

$$B^\nu=-\frac{\partial\eta}{\partial x^\nu}-\frac{\partial Z_\nu}{\partial t}, \tag{31}$$

$$B^\nu=\varepsilon^{\nu\beta\gamma}\left(\frac{\partial A_\beta}{\partial x^\gamma}-\frac{\partial A_\gamma}{\partial x^\beta}\right)+Q^\nu, \tag{32}$$

where the vectors M^ν and Q^ν are defined as

$$M^\nu=\begin{bmatrix} Z_2\dfrac{\partial g_{56}}{\partial x^3} \\ Z_3\dfrac{\partial g_{56}}{\partial x^1} \\ Z_1\dfrac{\partial g_{56}}{\partial x^2} \end{bmatrix}, \quad Q^\nu=\begin{bmatrix} A_2\dfrac{\partial g_{56}}{\partial x^3} \\ A_3\dfrac{\partial g_{56}}{\partial x^1} \\ A_1\dfrac{\partial g_{56}}{\partial x^2} \end{bmatrix}. \tag{33}$$

These vectors are irrotational and since curls are solenoidal vectors, expressions (30) and (32) are in accordance with a generalized Helmolhtz theorem for tensors.[4] The duality in Faraday's tensor has been previously exhibited[4] as based in this theorem but dual expressions for the fields are now introduced. Vectorial fields can always be decomposed as a sum of a solenoidal vector field and an irrotational one which validates expressions (30) and (32). Thus two sets of symmetrical expressions for the fields are obtained—one of these sets being the expressions of the decomposition mentioned in the previous line. The implications of Eqs. (29)–(32) will be discussed in Sec. V.

Within this framework, the complete set of Maxwell equations can be derived (Appendix C). The inhomogeneous equations are obtained in the same way as in Sec. III. The new quantity Q^{ν} is irrotational and does not affect the structure of $\varepsilon^{\nu\beta\gamma}((\partial B_{\beta}/\partial x^{\gamma})-(\partial B_{\gamma}/\partial x^{\beta}))$ while the other equation with sources is identically obtained provided the same definition for E is used. The sourceless equations are obtained once again by means of Einstein's field equation

$$R^{6\beta}=\kappa T^{6\beta}, \tag{34}$$

since the energy momentum tensor now has one additional column and row

$$T^{6\beta}=T^{6\beta\alpha}=\rho_0 v^{\beta}v^{6}=\begin{bmatrix} \rho_0 v^{1}\dfrac{\mathrm{d}x^{6}}{\mathrm{d}t} \\ \rho_0 v^{2}\dfrac{\mathrm{d}x^{6}}{\mathrm{d}t} \\ \rho_0 v^{3}\dfrac{\mathrm{d}x^{6}}{\mathrm{d}t} \\ \rho_0 c\dfrac{\mathrm{d}x^{6}}{\mathrm{d}t} \\ \rho_0\left(\dfrac{\mathrm{d}x^{6}}{\mathrm{d}t}\right)^{2} \end{bmatrix}=K^{\beta}. \tag{35}$$

In Appendix C it is proved that Eq. (34) leads to the four missing Maxwell equations with some extra terms that make the complete set of equations symmetric. This new terms will be interpreted in Sec. V.

Thus, the purpose of this section is accomplished. The mechanism for obtaining both homogeneous and inhomogeneous equations is the same. This makes the theory completely symmetric and the cylindrical condition not so fundamental for the recovery of Maxwell's equations.

V. IMPLICATIONS OF THE SIXTH DIMENSION

In Kaluza's theory, the fifth dimension is associated with electric charge. As electric charge generates curvature in space, it becomes intuitive that the sixth dimension is a curvature source similar to it. The complete set of equations (the equation of motion and Maxwell relations) as is obtained in this formalism is given by

$$\frac{\mathrm{d}^2x^{\alpha}}{\mathrm{d}t^2}=\frac{q}{m}\left[\varepsilon^{\alpha}_{\beta\gamma}\frac{\mathrm{d}x^{\beta}}{\mathrm{d}t}B^{\gamma}+E^{\alpha}\right]+\frac{g}{m}\left[\varepsilon^{\alpha}_{\beta\gamma}\frac{\mathrm{d}x^{\beta}}{\mathrm{d}t}E^{\gamma}-B^{\alpha}\right], \tag{36}$$

$$\nabla\times\mathbf{E}=-\frac{1}{c}\frac{\partial\mathbf{B}}{\partial t}-\mathbf{K}, \tag{37}$$

$$\nabla\times\mathbf{B}=\frac{\partial\mathbf{E}}{\partial t}+\mu_0\mathbf{J}, \tag{38}$$

$$\nabla\cdot\mathbf{E}=\frac{\rho}{\varepsilon_0}\frac{q}{m}, \tag{39}$$

$$\nabla \cdot \mathbf{B} = \mu_0 \rho \frac{g}{m}. \tag{40}$$

This finally confirms that the sixth dimension is associated with a magnetic charge g. Equations (37) and (40) show the presence of magnetic charge and it's associated magnetic current **K**. These equations are completely symmetric as the new definitions (29)–(32) for electric and magnetic fields result in this formalism. The new potentials Z_α and η can be interpreted as electromagnetic potentials. Z_α plays the role of an electric vector potential and η a scalar magnetic potential. Both appear in these definitions but do not affect the behavior of charged particles since they do not introduce extra effects in the equations. The magnetic charge and current terms in the equations arise exclusively from the extra column in the energy–momentum tensor $T^{6\beta}$. To recover the equations without these extra terms, it is sufficient to make the magnetic charge equal to zero, $dx^6/dt = 0$, just as was done with the fifth component of the position vector to recover the equations of motion for a particle without electrical charge.

Also, from the combination of Eqs. (29)–(32) and Maxwell's equations one can easily obtain four wave equations for potentials, provided a Lorentz's gauge for the new four vector potential is considered. In the procedure, continuity relations for electric and magnetic charge are obtained.

The role of the vectors M^ν and Q^ν [Eq. (33)] becomes clear by taking a closer look at definitions (30) and (32). In these expressions, the fields are decomposed as a curl plus a vector which is irrotational. In order to obtain both Maxwell equations that feature charge density as a source, one has to calculate the divergence of both fields. In the procedure, the divergence of the rotational term vanishes since curls are solenoidal vectors leaving alone the divergence of M^ν and Q^ν, which should then be proportional to the charge densities. If these vectors do not appear in the definitions, the result would be solenoidal magnetic and *electric* fields meaning that neither magnetic *nor electric* charges exist. The spatial derivatives of the metric elements $g_{56} = g_{65}$ appear in M^ν and Q^ν which makes its value fundamental since if it is proposed as a constant, these vectors would be equal to zero with the consequences mentioned before.

VI. CONCLUSIONS

Many decades ago Kaluza proposed a way to unify electromagnetic and gravitational theories. His formalism, although very useful and elegant, shows a weak point in the way a pair of Maxwell's equations are obtained. Moreover, this mechanism does not give correct results when working in generalized coordinates, which are necessary to get the correct physics of most systems.

The alternative presented here is a similar formalism which consists in working in a larger space–time. The new extra dimension makes it possible to use Einstein's field equation twice and all the equations can be correctly recovered. Even in the absence of this curvature source, the extra dimension remains necessary.

In addition to leading to the complete and correct set of Maxwell equations, this formalism allows the introduction of magnetic charge in a very elegant and natural way. The metric and ensuing procedure are proposed based only on a symmetrical way of treating electric and magnetic fields. As a result, magnetic charge effects arise in the theory in the same way as electric effects do. Also, following the same procedure as in conventional electromagnetism, wave equations for potentials in the presence of magnetic charge can be obtained without having to introduce any singularity in space, as done in other works.[5]

Some approximations have been made in order to verify the equations that emerge from the classical treatment of electromagnetism. First of all, the metric used neglects quadratic terms. These terms may introduce additional measurable effects. In Kaluza's work, the basic hypothesis of a small electric charge–mass ratio has to be considered. In the formalism presented here a similar assumption has to be made about the magnetic charge–mass ratio. This is of course a mere conjecture since no magnetic monopoles have yet been detected.

The correct set of equations in generalized coordinates can also be obtained using Bianchi's identities. We consider the formalism presented here more elegant since charges and electromagnetic potentials are included in the geometrical description of space–time and no external forces or fields have to be introduced. Electromagnetic effects are consequences of space configuration. Kaluza's theory has been found to be very useful for the formulation of magnetohydrodynamics equations in the context of irreversible process thermodynamics[6] and in the development of gauge theories[2] so that we consider fundamental the reformulation of the theory in generalized coordinates to treat problems with different spatial symmetries.

APPENDIX A

Sourceless Maxwell's equations in vectorial notation read:

$$\nabla \times \mathbf{E} = -\frac{1}{c}\frac{\partial \mathbf{B}}{\partial t}, \tag{A1}$$

$$\nabla \cdot \mathbf{B} = 0. \tag{A2}$$

To write Eq. (A1) in terms of potentials, first we express the vector potential A_ν and the gradient of the scalar potential ϕ in physical coordinates:

$$A_\nu^{\text{phys}} = \begin{bmatrix} A_1 \\ rA_2 \\ r\sin\theta A_3 \end{bmatrix}, \tag{A3}$$

$$\nabla \phi^{\text{phys}} = \begin{bmatrix} \dfrac{\partial \phi}{\partial r} \\ \dfrac{1}{r}\dfrac{\partial \phi}{\partial \theta} \\ \dfrac{1}{r\sin\theta}\dfrac{\partial \phi}{\partial \varphi} \end{bmatrix}. \tag{A4}$$

The electric field is then

$$E^\nu = \begin{bmatrix} -\dfrac{\partial A_1}{\partial t} - \dfrac{\partial \phi}{\partial r} \\ -\dfrac{\partial (rA_2)}{\partial t} - \dfrac{1}{r}\dfrac{\partial \phi}{\partial \theta} \\ -\dfrac{\partial (r\sin\theta A_3)}{\partial t} - \dfrac{\partial \phi}{\partial \varphi} \end{bmatrix}. \tag{A5}$$

To calculate the curl of **E**, the following determinant has to be expanded:

$$\nabla \times \mathbf{E} = \frac{1}{r^2 \sin\theta} \begin{vmatrix} \vec{r} & r\vec{\theta} & r\sin\theta\vec{\varphi} \\ \dfrac{\partial}{\partial r} & \dfrac{\partial}{\partial \theta} & \dfrac{\partial}{\partial \varphi} \\ E^1 & rE^2 & r\sin\theta E^3 \end{vmatrix}. \tag{A6}$$

The third component of the $\nabla \times \mathbf{E}$ is then

$$\frac{r\sin\theta}{r^2\sin\theta}\left[\frac{\partial}{\partial r}\left(r\left(-\frac{\partial(rA_2)}{\partial t}-\frac{1}{r}\frac{\partial\phi}{\partial\theta}\right)\right)-\frac{\partial}{\partial\theta}\left(-\frac{\partial A_1}{\partial t}-\frac{\partial\phi}{\partial r}\right)\right]\vec{\varphi}. \tag{A7}$$

After some algebra Eq. (A7) reduces to

$$-2\frac{\partial A_2}{\partial t}-r\frac{\partial^2 A_2}{\partial t\partial r}+\frac{1}{r}\frac{\partial^2 A_1}{\partial t\partial\theta}. \tag{A8}$$

Equation (A8) has to be divided by $\sqrt{g_{33}}$ to return the expression to its tensorial components which finally results in Eq. (19). Note that in Eq. (A8) the scalar potential does not appear, which agrees with the property of the gradient being irrotational.

On the other hand, the left-hand side of Eq. (13), with $\alpha=4$, $\beta=2$, $\lambda=1$, and $\mu=5$ should be equal to zero because of the cylindrical condition [Eq. (6)]:

$$(\Gamma^4_{21}+\Gamma^2_{14}+\Gamma^1_{42})_{,5}=0, \tag{A9}$$

which means

$$\Gamma^{4,2}_{51}+\Gamma^{2,1}_{54}+\Gamma^{1,4}_{52}=0. \tag{A10}$$

The Christoffel symbols involved in Eq. (A9) are computed as follows:

$$\Gamma^4_{51}=\frac{1}{2}g^{44}\left(\frac{\partial g_{54}}{\partial x^1}+\frac{\partial g_{14}}{\partial x^5}-\frac{\partial g_{51}}{\partial x^4}\right)=\frac{1}{2c}\frac{\partial A_1}{\partial t}+\frac{1}{2c}\frac{\partial\phi}{\partial r}, \tag{A11}$$

$$\Gamma^2_{54}=\frac{1}{2}g^{22}\left(\frac{\partial g_{52}}{\partial x^4}+\frac{\partial g_{42}}{\partial x^5}-\frac{\partial g_{54}}{\partial x^2}\right)=\frac{1}{2cr^2}\frac{\partial(r^2A_2)}{\partial t}+\frac{1}{2cr^2}\frac{\partial\phi}{\partial\theta}, \tag{A12}$$

$$\Gamma^1_{52}=\frac{1}{2}g^{11}\left(\frac{\partial g_{51}}{\partial x^2}+\frac{\partial g_{21}}{\partial x^5}-\frac{\partial g_{52}}{\partial x^1}\right)=\frac{1}{2}\frac{\partial A_1}{\partial\theta}-r^2\frac{\partial A_2}{\partial r}-2rA_2. \tag{A13}$$

Introducing the previous results in Eq. (A10) we obtain an incorrect expression for Eq. (A1), namely

$$-\frac{r}{c}\frac{\partial A_2}{\partial t}-\frac{1}{2cr^3}\frac{\partial\phi}{\partial\theta}+\frac{1}{c}\frac{\partial^2 A_1}{\partial\theta\partial t}+\frac{1}{2c}(1-r^2)\frac{\partial^2 A_2}{\partial r\partial t}+\frac{1}{2c}\left(1+\frac{1}{r^2}\right)\frac{\partial^2\phi}{\partial r\partial\theta}=0. \tag{A14}$$

APPENDIX B

The equation for the geodesic is

$$\frac{d^2x^\alpha}{ds^2}+\Gamma^\alpha_{\mu\nu}\frac{dx^\mu}{ds}\frac{dx^\nu}{ds}=0. \tag{B1}$$

In the six-dimensional space proposed the first of the three equations in the geodesic turns out as follows:

$$\frac{d^2r}{dt^2}+\Gamma^1_{5\nu}\frac{q}{m}\frac{dx^\nu}{ds}+\Gamma^1_{6\nu}\frac{g}{m}\frac{dx^\nu}{ds}=0, \tag{B2}$$

which after expanding the sums over ν reads

$$\frac{d^2r}{dt^2}+\Gamma^1_{51}\frac{q}{m}\frac{dx^1}{ds}+\Gamma^1_{52}\frac{q}{m}\frac{dx^2}{ds}+\Gamma^1_{53}\frac{q}{m}\frac{dx^3}{ds}+\Gamma^1_{54}\frac{q}{m}\frac{dx^4}{ds}+\Gamma^1_{61}\frac{g}{m}\frac{dx^1}{ds}+\Gamma^1_{62}\frac{g}{m}\frac{dx^2}{ds}+\Gamma^1_{63}\frac{g}{m}\frac{dx^3}{ds}$$
$$+\Gamma^1_{64}\frac{g}{m}\frac{dx^4}{ds}=0. \tag{B3}$$

On the other hand, the first component of the equation of motion under a generalized Lorentz's [Eq. (26)] force is

$$\frac{d^2r}{dt^2}=\frac{q}{m}\frac{dx^2}{dt}B_3-\frac{q}{m}\frac{dx^3}{dt}B_2+\frac{q}{m}E_1+\frac{g}{m}\frac{dx^2}{dt}E_3-\frac{g}{m}\frac{dx^3}{dt}E_2-\frac{g}{m}B_1. \tag{B4}$$

Then the relationship between the Christoffel symbols and the components of the electromagnetic field should be, for Eq. (B4),

$$\Gamma^1_{51}=0, \tag{B5}$$

$$\Gamma^1_{52}=B_3, \tag{B6}$$

$$\Gamma^1_{53}=-B_2, \tag{B7}$$

$$\Gamma^1_{54}=\frac{1}{c}E_1, \tag{B8}$$

and

$$\Gamma^1_{61}=0, \tag{B9}$$

$$\Gamma^1_{62}=E_3, \tag{B10}$$

$$\Gamma^1_{63}=-E_2, \tag{B11}$$

$$\Gamma^1_{64}=-\frac{1}{c}B_1. \tag{B12}$$

Calculating the symbols Γ^1_{52} and Γ^1_{64} directly from the definition (7) we have

$$\Gamma^1_{52}=\frac{1}{2}g^{11}\left(\frac{\partial g_{51}}{\partial x^2}-\frac{\partial g_{52}}{\partial x^1}\right)+\frac{1}{2}g^{16}\frac{\partial g_{56}}{\partial x^2}=\frac{1}{2}\left(\frac{\partial A_1}{\partial x^2}-\frac{\partial A_2}{\partial x^1}\right)+\frac{1}{2}Z_1\frac{\partial g_{56}}{\partial x^2}=B_3, \tag{B13}$$

$$\Gamma^1_{64}=\frac{1}{2}g^{11}\left(\frac{\partial g_{61}}{\partial x^4}-\frac{\partial g_{64}}{\partial x^1}\right)+\frac{1}{2}g^{15}\frac{\partial g_{56}}{\partial x^4}=\frac{1}{2}\left(\frac{\partial Z_1}{\partial x^4}+\frac{1}{c}\frac{\partial \eta}{\partial x^1}\right)=-\frac{1}{c}B_1. \tag{B14}$$

In Eq. (B14) the quantity g_{56} is supposed as time independent in order to recover the conventional definition of the magnetic field. Equations (B13) and (B14) exhibit how the magnetic field can be represented in two different ways [Eqs. (32) and (31)]. Similar results, now verifying Eqs. (29) and (30), are obtained by computing Γ^1_{54} and Γ^1_{62} from definition (7) namely,

$$\Gamma^1_{54}=\frac{1}{2}g^{11}\left(\frac{\partial g_{51}}{\partial x^4}-\frac{\partial g_{54}}{\partial x^1}\right)+\frac{1}{2}g^{16}\frac{\partial g_{56}}{\partial x^4}=\frac{1}{2}\left(\frac{\partial A_1}{\partial x^4}+\frac{1}{c}\frac{\partial \phi}{\partial x^1}\right)=\frac{1}{c}E_1, \tag{B15}$$

$$\Gamma^1_{62}=\frac{1}{2}g^{11}\left(\frac{\partial g_{61}}{\partial x^2}-\frac{\partial g_{62}}{\partial x^1}\right)+\frac{1}{2}g^{15}\frac{\partial g_{65}}{\partial x^2}=\frac{1}{2}\left(\frac{\partial Z_1}{\partial x^2}-\frac{\partial Z_2}{\partial x^1}\right)+\frac{1}{2}A_1\frac{\partial g_{65}}{\partial x^2}=E_3. \tag{B16}$$

APPENDIX C

In this appendix it is shown how the complete set of correct Maxwell's equations is obtained only by means of Einstein's equation. In the first part, equations with sources are obtained. This procedure can be carried out in a 5×5 space–time giving the same results, since the Christoffel symbols required for the following operations are the ones with one index equal to 5.

Einstein's field equation relates Ricci's tensor with the mass–energy tensor. If we assume the curvature scalar to be zero, the field equation turns out as follows:

$$R_{\mu\nu}=\kappa T_{\mu\nu}, \tag{C1}$$

where Ricci's tensor is defined as[7]

$$R_{\mu\nu}=\Gamma^{n}_{\mu\nu,n}+\Gamma^{n}_{mn}\Gamma^{m}_{\mu\nu}-\Gamma^{n}_{\mu m}\Gamma^{m}_{\nu n}. \tag{C2}$$

In order to obtain the inhomogeneous equations, let us take $\mu=5$ and let ν run from 1 to 4,

$$R_{51}=\frac{\cot\theta}{r}A_2+\frac{1}{2}\frac{\partial^2A_1}{\partial t^2}+\frac{1}{r}\frac{\partial A_3}{\partial\varphi}-\frac{\csc^2\theta}{r^2}\frac{\partial^2A_1}{\partial\varphi^2}-\frac{\cot\theta}{2r^2}\frac{\partial A_1}{\partial\theta}+\frac{1}{r}\frac{\partial A_2}{\partial\theta}$$
$$-\frac{1}{2r^2}\frac{\partial^2A_1}{\partial\theta^2}+\frac{\cot\theta}{2}\frac{\partial A_2}{\partial r}+\frac{1}{2c}\frac{\partial^2\phi}{\partial r\partial t}+\frac{1}{2}\frac{\partial^2A_3}{\partial r\partial\varphi}+\frac{1}{2}\frac{\partial^2A_2}{\partial r\partial\theta}, \tag{C3}$$

$$R_{52}=-A_2+\frac{r^2}{2}\frac{\partial^2A_2}{\partial t^2}+\cot\theta\frac{\partial A_3}{\partial\varphi}-\frac{\csc^2\theta}{2}\frac{\partial^2A_2}{\partial\varphi^2}+\frac{1}{2c}\frac{\partial^2\phi}{\partial\theta\partial t}$$
$$+\frac{1}{2}\frac{\partial^2A_3}{\partial\theta\partial\varphi}-2r\frac{\partial A_2}{\partial r}+\frac{1}{2}\frac{\partial^2A_1}{\partial r\partial\theta}-\frac{r^2}{2}\frac{\partial^2A_2}{\partial r^2}, \tag{C4}$$

$$R_{53}=\frac{r^2}{2}\sin^2\theta\frac{\partial^2A_3}{\partial t^2}-\frac{\cot\theta}{2}\frac{\partial A_2}{\partial\varphi}+\frac{1}{2c}\frac{\partial^2\phi}{\partial\varphi\partial t}-\frac{3}{2}\cos\theta\sin\theta\frac{\partial A_3}{\partial\theta}+\frac{1}{2}\frac{\partial^2A_2}{\partial\theta\partial\varphi}$$
$$-\frac{1}{2}\sin^2\theta\frac{\partial^2A_3}{\partial\theta^2}-2r\sin^2\theta\frac{\partial A_3}{\partial r}+\frac{1}{2}\frac{\partial^2A_1}{\partial r\partial\varphi}-\frac{r^2}{2}\sin^2\theta\frac{\partial^2A_3}{\partial r^2}, \tag{C5}$$

$$R_{54}=\frac{1}{2r}\frac{\partial A_1}{\partial t}+\frac{\cot\theta}{2}\frac{\partial A_2}{\partial t}+\frac{1}{2}\frac{\partial^2A_3}{\partial\varphi\partial t}+\frac{\csc^2\theta}{2cr^2}\frac{\partial^2\phi}{\partial\varphi^2}+\frac{\cot\theta}{2cr^2}\frac{\partial\phi}{\partial\theta}+\frac{1}{2}\frac{\partial^2A_2}{\partial\theta\partial t}$$
$$+\frac{1}{2cr^2}\frac{\partial^2\phi}{\partial\theta^2}+\frac{1}{2cr}\frac{\partial\phi}{\partial r}+\frac{1}{2}\frac{\partial^2A_1}{\partial r\partial t}+\frac{1}{2c}\frac{\partial^2\phi}{\partial r^2}. \tag{C6}$$

If each one of these equations is equaled with its corresponding element of the energy–momentum tensor $T_{\mu5}$ [Eq. (11)], Maxwell's equations with sources are correctly recovered.

To obtain the homogeneous equations, the sixth row of Ricci's tensor has to be calculated. The procedure is exactly the same as the one to obtain the inhomogeneous equations and the results are

$$R_{61}=\frac{\cot\theta}{r}Z_2+\frac{1}{2}\frac{\partial^2Z_1}{\partial t^2}+\frac{1}{r}\frac{\partial Z_3}{\partial\varphi}-\frac{\csc^2\theta}{r^2}\frac{\partial^2Z_1}{\partial\varphi^2}-\frac{\cot\theta}{2r^2}\frac{\partial Z_1}{\partial\theta}+\frac{1}{r}\frac{\partial Z_2}{\partial\theta}$$
$$-\frac{1}{2r^2}\frac{\partial^2Z_1}{\partial\theta^2}+\frac{\cot\theta}{2}\frac{\partial Z_2}{\partial r}+\frac{1}{2c}\frac{\partial^2\eta}{\partial r\partial t}+\frac{1}{2}\frac{\partial^2Z_3}{\partial r\partial\varphi}+\frac{1}{2}\frac{\partial^2Z_2}{\partial r\partial\theta}, \tag{C7}$$

$$R_{62}=-Z_2+\frac{r^2}{2}\frac{\partial_2^2 Z}{\partial t^2}+\cot\theta\frac{\partial Z_3}{\partial\varphi}-\frac{\csc^2\theta}{2}\frac{\partial^2 Z_2}{\partial\varphi^2}+\frac{1}{2c}\frac{\partial^2\eta}{\partial\theta\partial t}$$
$$+\frac{1}{2}\frac{\partial_3^2 Z}{\partial\theta\partial\varphi}-2r\frac{\partial Z_2}{\partial r}+\frac{1}{2}\frac{\partial_1^2 Z}{\partial r\partial\theta}-\frac{r^2}{2}\frac{\partial_2^2 Z}{\partial r^2}, \tag{C8}$$

$$R_{63}=\frac{r^2}{2}\sin^2\theta\frac{\partial^2 Z_3}{\partial t^2}-\frac{\cot\theta}{2}\frac{\partial Z_2}{\partial\varphi}+\frac{1}{2c}\frac{\partial^2\eta}{\partial\varphi\partial t}-\frac{3}{2}\cos\theta\sin\theta\frac{\partial Z_3}{\partial\theta}+\frac{1}{2}\frac{\partial^2 Z_2}{\partial\theta\partial\varphi}$$
$$-\frac{1}{2}\sin^2\theta\frac{\partial^2 Z_3}{\partial\theta^2}-2r\sin^2\theta\frac{\partial Z_3}{\partial r}+\frac{1}{2}\frac{\partial^2 Z_1}{\partial r\partial\varphi}-\frac{r^2}{2}\sin^2\theta\frac{\partial^2 Z_3}{\partial r^2}, \tag{C9}$$

$$R_{64}=\frac{1}{2r}\frac{\partial Z_1}{\partial t}+\frac{\cot\theta}{2}\frac{\partial Z_2}{\partial t}+\frac{1}{2}\frac{\partial^2 Z_3}{\partial\varphi\partial t}+\frac{\csc^2\theta}{2cr^2}\frac{\partial^2\eta}{\partial\varphi^2}+\frac{\cot\theta}{2cr^2}\frac{\partial\eta}{\partial\theta}+\frac{1}{2}\frac{\partial^2 Z_2}{\partial\theta\partial t}$$
$$+\frac{1}{2cr^2}\frac{\partial^2\eta}{\partial\theta^2}+\frac{1}{2cr}\frac{\partial\eta}{\partial r}+\frac{1}{2}\frac{\partial^2 Z_1}{\partial r\partial t}+\frac{1}{2c}\frac{\partial^2\eta}{\partial r^2}. \tag{C10}$$

If we introduce expressions (30) and (31) as definitions for **E** and **B** respectively, and set each of the previous equations [(C7) to (C10)] equal to its corresponding element in the energy–momentum tensor $T_{\mu 6}$, Eqs. (37) and (40) are obtained. For example, to prove Eq. (C9) corresponds to the third component of Eq. (37) we will calculate the third component or the curl of the electric field using the alternative expression in Eq. (30). First, the vector potential Z_β has to be expressed in its physical components as follows:

$$Z_\nu^{\text{phys}}=\begin{bmatrix} Z_1 \\ rZ_2 \\ r\sin\theta Z_3 \end{bmatrix}. \tag{C11}$$

The curl of Z_ν^{phys} is calculated by expanding following the determinant:

$$\nabla\times\mathbf{Z}=\frac{1}{r^2\sin\theta}\begin{vmatrix} \vec{r} & r\vec{\theta} & r\sin\theta\vec{\varphi} \\ \frac{\partial}{\partial r} & \frac{\partial}{\partial\theta} & \frac{\partial}{\partial\varphi} \\ Z_1 & r(rZ_2) & r\sin\theta(r\sin\theta Z_3) \end{vmatrix}$$
$$=\frac{1}{r^2\sin\theta}\begin{bmatrix} r^2\frac{\partial\sin^2\theta Z_3}{\partial\theta}-r^2\frac{\partial Z_2}{\partial\varphi} \\ r\left(\frac{\partial Z_1}{\partial\varphi}-\sin^2\theta\frac{\partial r^2 Z_3}{\partial r}\right) \\ r\sin\theta\left(\frac{\partial r^2 Z_2}{\partial r}-\frac{\partial Z_1}{\partial\theta}\right) \end{bmatrix}$$
$$=\begin{bmatrix} \sin\theta\frac{\partial Z_3}{\partial\theta}+2\cos\theta Z_3-\csc\theta\frac{\partial Z_2}{\partial\varphi} \\ \frac{1}{r\sin\theta}\frac{\partial Z_1}{\partial\varphi}-r\sin\theta\frac{\partial Z_3}{\partial r}-2\sin\theta Z_3 \\ r\frac{\partial Z_2}{\partial r}+2Z_2-\frac{1}{r}\frac{\partial Z_1}{\partial\theta} \end{bmatrix}. \tag{C12}$$

Since M^ν is irrotational, $\nabla\times\mathbf{E}=\nabla\times(\nabla\times\mathbf{Z})$, which is calculated as follows:

$$\nabla\times\mathbf{E}=\frac{1}{r^2\sin\theta}\begin{vmatrix}\vec{r} & r\vec{\theta} & r\sin\theta\vec{\varphi}\\ \dfrac{\partial}{\partial r} & \dfrac{\partial}{\partial\theta} & \dfrac{\partial}{\partial\varphi}\\ [\nabla\times\mathbf{Z}]^1 & r[\nabla\times\mathbf{Z}]^2 & r\sin\theta[\nabla\times\mathbf{Z}]^3\end{vmatrix}. \tag{C13}$$

The third component of the last equation reads

$$\frac{1}{r}\left[\frac{\partial}{\partial r}\left(r\left(\frac{1}{r\sin\theta}\frac{\partial Z_1}{\partial\varphi}-r\sin\theta\frac{\partial Z_3}{\partial r}-2\sin\theta Z_3\right)\right)-\frac{\partial}{\partial\theta}\left(\sin\theta\frac{\partial Z_3}{\partial\theta}+2\cos\theta Z_3-\csc\theta\frac{\partial Z_2}{\partial\varphi}\right)\right], \tag{C14}$$

which after some algebraic manipulation turns out as follows:

$$\frac{1}{r\sin\theta}\frac{\partial^2 Z_1}{\partial r\partial\varphi}-r\sin\theta\frac{\partial^2 Z_3}{\partial r^2}-4\sin\theta\frac{\partial Z_3}{\partial r}-\frac{\sin\theta}{r}\frac{\partial^2 Z_3}{\partial\theta^2}$$
$$-\frac{3\cos\theta}{r}\frac{\partial Z_3}{\partial\theta}-\frac{\cos\theta}{r\sin^2\theta}\frac{\partial Z_2}{\partial\varphi}+\frac{\csc\theta}{r}\frac{\partial^2 Z_2}{\partial\theta\partial\varphi}. \tag{C15}$$

Expression (C15) is the third physical component of the curl of the electric field. To obtain the third component of Eq. (37), also $-(1/c)(\partial\mathbf{B}/\partial t)-\mathbf{K}$ has to be in physical components which implies multiplying by $r\sin\theta$. Then, to make it clear that Eq. (C15) corresponds to (37) it has to be expressed in the following way:

$$\frac{1}{r\sin\theta}\left(\frac{\partial^2 Z_1}{\partial r\partial\varphi}-r^2\sin^2\theta\frac{\partial^2 Z_3}{\partial r^2}-4r\sin^2\theta\frac{\partial Z_3}{\partial r}-\sin^2\theta\frac{\partial^2 Z_3}{\partial\theta^2}\right.$$
$$\left.-\frac{3}{2}\sin 2\theta\frac{\partial Z_3}{\partial\theta}-\frac{\cos\theta}{\sin\theta}\frac{\partial Z_2}{\partial\varphi}+\frac{\partial^2 Z_2}{\partial\theta\partial\varphi}\right). \tag{C16}$$

This finally proves that Eqs. (C7)–(C10) correspond to the missing Maxwell's equations (37) and (40). These equations include magnetic sources.

It is important to point out, once again, that to obtain Maxwell's equations without magnetic sources it is sufficient to make $dx^6/dt=0$ which implies $T_{\mu 6}=0$.

JOURNAL OF MATHEMATICAL PHYSICS VOLUME 42, NUMBER 12 DECEMBER 2001

Electromagnetic propagators in hyperbolic Robertson–Walker cosmologies

Roman Tomaschitz[a)]
Department of Physics, Hiroshima University, 1-3-1 Kagami-yama, Higashi-Hiroshima 739-8526, Japan

(Received 15 August 2000; accepted for publication 5 September 2001)

Green functions (retarded, advanced, Feynman and Dyson propagators) are calculated for the electromagnetic field in Robertson–Walker cosmologies with hyperbolic 3-manifolds as spacelike slices. The starting point is the Proca equation, i.e., the Maxwell field with a finite photon mass for infrared regularization, in a static cosmology with simply connected hyperbolic 3-sections. The time and space components of the resolvent kernel are scalar and vectorial point-pair invariants, respectively, and this symmetry allows for an explicit evaluation in the spectral representation. It is found that the quantum propagators have a logarithmic infrared singularity, which drops out in the zero curvature limit. Retarded and advanced Green functions remain well defined in the limit of zero photon mass, and they admit a simple generalization, by conformal scaling, to expanding 3-spaces. In cosmologies with multiply connected hyperbolic 3-manifolds as spacelike sections, the four enumerated propagators are constructed by means of Poincaré series. The spectral decomposition of the Green functions is given in terms of Eisenstein series for a certain class of open hyperbolic 3-spaces, including those with Schottky covering groups corresponding to solid handle-bodies as spacelike slices. [DOI: 10.1063/1.1413522]

I. INTRODUCTION

This is a study of vectorial Green functions in hyperbolic Robertson–Walker (RW) cosmology. I will keep the introduction short, given the length of the paper, and given that it is a very technical paper too. No applications are discussed; the usefulness of Green functions in cosmology is documented in two standard reviews,[1,2] which mainly focus on quantum field theory, and my motivation to write this paper is time-symmetric wave propagation in the cosmological absorber theory of Wheeler and Feynman,[3,4] which, however, will not be addressed here. Electromagnetic Green functions in RW cosmologies with hyperbolic 3-sections have not been studied so far. There do exist a great many investigations on vector equations in Riemannian spaces, but they are either of a general nature, and hence not really explicit, or approximate, cf. the reviews cited above. I also note that the spaces considered in this paper are not asymptotically flat, and the high symmetry of the hyperbolic 3-space together with the conformal coupling of the electromagnetic field to the background geometry makes it possible to avoid the Riemann curvature tensor. Green functions for scalar fields on hyperbolic spaces, that is, the resolvent kernel of the Laplace–Beltrami operator, have been exhaustively studied[5–10] (as far as one can go without specifying the covering group), but not so the resolvent kernels of vector operators, though, in two dimensions, there were attempts also in this regard.[7,8]

In Sec. II, the Proca equation is discussed (including spectral resolution and differential equations for the resolvent kernel) in a static RW cosmology with simply connected hyperbolic 3-sections. This equation is tantamount to electrodynamics with a finite photon mass,[11] but the mass parameter is regarded in this paper as a mere technical regularization of the Feynman and

a)Electronic mail: roman@fusion.sci.hiroshima-u.ac.jp

Dyson propagators, which turn out to be infrared divergent, a curvature effect. In Sec. III, the longitudinal time component (a scalar point-pair invariant) of the resolvent kernel is calculated, as well as the time component G_{00} of the real-space Green function, obtained by a Fourier transform. As in Minkowski space, the retarded and advanced Green functions and the two quantum propagators are defined by the choice of the integration path in the Fourier transform of the resolvent kernel.

In Sec. IV, the spatial resolvent kernel, a vectorial point-pair invariant, is calculated, and in Sec. V we study its Fourier transform, that is, the space components G_{ij} of the Green function on the 4-manifold. (The space–time mixing components G_{i0} vanish for symmetry reasons.) Explicit expressions for all four real-space propagators are given, and their infrared behavior and the Minkowski space limit (curvature radius of the 3-space to infinity) is explained. At the end of Sec. V, the time scaling of the two classical propagators (with zero photon mass) is discussed in RW cosmologies with arbitrary expansion factor.

In Sec. VI, we study Green functions on open, multiply connected hyperbolic manifolds (geometrically finite, without cusps) by periodizing the propagators calculated in the previous sections with the covering group. We focus on manifolds with $\delta(\Lambda)<1$ [$\delta(\Lambda)$: Hausdorff dimension of the limit set of the covering group], so that the Green functions can be defined by Poincaré series without the use of analytic continuation. There are three appendices, all dealing with the calculation of matrix elements, which are reduced to convolutions of Poisson kernels and Feynman integrals. The orthogonality and completeness relations, and the various spectral measures used in Secs. III and IV are calculated there. The paper is more or less self-contained, the notation is mainly that of Ref. 5, which is also the approach to hyperbolic Green functions followed here.

II. THE PROCA EQUATION IN A STATIC RW COSMOLOGY WITH NEGATIVELY CURVED 3-SECTIONS

We consider a static RW line element, $ds^2=-d\tau^2+d\sigma^2$, where $d\sigma^2$ is the line element of hyperbolic space, corresponding to the metric $\gamma_{ij}=t^{-2}\delta_{ij}$ in the Poincaré half-space model H^3 [with Cartesian coordinates (z, t), $t>0$, $z:=z_1+iz_2$], or to $\gamma_{ij}=4(1-|\mathbf{x}|^2)^{-2}\delta_{ij}$ in the ball model $B^3(|\mathbf{x}|<1)$, cf. Ref. 12. The field equations read

$$F^{\alpha\beta}{}_{;\beta}+\mu^2A^\alpha=j^\alpha, \tag{2.1}$$

where $F_{\alpha\beta}=A_{\beta,\alpha}-A_{\alpha,\beta}$, and we have included a photon mass μ for the infrared regularization of quantum propagators. We find in H^3, with $x^i=(z_1,z_2,t)$,

$$F_0{}^\beta{}_{;\beta}\equiv-t^2A_{0,n,n}+tA_{0,3}-tA_{3,0}+t^2A_{n,n,0}, \tag{2.2}$$

$$F_i{}^\beta{}_{;\beta}\equiv A_{i,0,0}-t^2A_{i,n,n}+tA_{3,i}-tA_{i,3}-A_{0,0,i}+t^2A_{n,n,i}. \tag{2.3}$$

[Greek indices run from 0 to 3, Latin ones from 1 to 3, unless explicitly stated otherwise. Whenever a Latin subscript is attached twice to the same vector, ordinary summation is implied, e.g., in (2.2) and (2.3), summation over n.] In (2.1), we could substitute $F^{\alpha\beta}{}_{;\beta}\equiv-A^{\alpha;\beta}{}_{;\beta}+R^\alpha{}_\beta A^\beta+A^\beta{}_{;\beta}{}^{,\alpha}$, but it is better to avoid Christoffel symbols and the Ricci tensor.

The Lorentz condition, $A^\alpha{}_{;\alpha}=0$, is a consequence of (2.1) and current conservation, and we find, by differentiation,

$$\begin{gathered}-A_{0,0}+t^2A_{n,n}-tA_3=0,\ \ A_{0,0,0}-t^2A_{n,n,0}+tA_{3,0}=0,\\ A_{0,0,i}-t^2A_{n,n,i}+tA_{3,i}-2t\delta_{3i}A_{n,n}+\delta_{3i}A_3=0.\end{gathered} \tag{2.4}$$

Using (2.4), we write the field Eqs. (2.1)–(2.3) as

$$A_{0,0,0}-\Delta_{H^3}A_0+\mu^2A_0=j_0,\ \ \Delta_{H^3}:=t^2\Delta_{E^3}-t\partial/\partial t, \tag{2.5}$$

$$A_{i,0,0}-\Delta_{H^3}A_i-2t(A_{i,3}-A_{3,i})-2t\,\delta_{3i}A_{n,n}+\delta_{3i}A_3+\mu^2A_i=j_i\,, \tag{2.6}$$

where Δ_{H^3}, is the scalar Laplace–Beltrami operator of H^3, and Δ_{E^3} is the Euclidean Laplace operator in Cartesian coordinates $x^i=(z_1,z_2,t)$. In this way we obtain separate equations for the space and time components of A_α.

Analogously to (2.2) and (2.3), we find in the ball model B^3,

$$F_0{}^{\beta}{}_{;\beta}\equiv-(1/4)(1-|\mathbf{x}|^2)^2(A_{0,n,n}-A_{n,n,0})+(1/2)(1-|\mathbf{x}|^2)x^n(A_{n,0}-A_{0,n}), \tag{2.7}$$

$$F_i{}^{\beta}{}_{;\beta}\equiv A_{i,0,0}-A_{0,0,i}-(1/4)(1-|\mathbf{x}|^2)^2(A_{i,n,n}-A_{n,n,i})-(1/2)(1-|\mathbf{x}|^2)x^n(A_{n,i}-A_{i,n}). \tag{2.8}$$

The Lorentz condition reads as

$$-A_{0,0}+(1/2)(1-|\mathbf{x}|^2)x^nA_n+(1/4)(1-|\mathbf{x}|^2)^2A_{n,n}=0, \tag{2.9}$$

to be differentiated with respect to space and time variables as in (2.4), and the separated field equations are

$$A_{0,0,0}-\Delta_{B^3}A_0+\mu^2A_0=j_0\,, \tag{2.10}$$

$$A_{i,0,0}-\Delta_{B^3}A_i+(1/2)(1-|\mathbf{x}|^2)(2x^n(A_{i,n}-A_{n,i})-A_i+2x_iA_{n,n})+x_ix^nA_n+\mu^2A_i=j_i\,, \tag{2.11}$$

$$\Delta_{B^3}:=\frac{(1-|\mathbf{x}|^2)^2}{4}\left(\Delta_{E^3}+\frac{2}{1-|\mathbf{x}|^2}x_n\frac{\partial}{\partial x_n}\right). \tag{2.12}$$

In H^3, a set of transversal modes propagating along the t-semiaxis is readily found, Eqs. (2.4)–(2.6) (with $j_\mu=0$) are solved by

$$A_1=t^{is}e^{-i\omega\tau},\ \ A_0=A_2=A_3=0,\ \ \omega^2=s^2+\mu^2, \tag{2.13}$$

and the same with A_1 and A_2 interchanged. The longitudinal modes traveling along the t-semiaxis read

$$A_3=t^{is}e^{-i\omega\tau},\ \ A_1=A_2=0,\ \ A_0=-i(1-is)\omega^{-1}tA_3\,,\ \ \omega^2=s^2+1+\mu^2. \tag{2.14}$$

The time component A_0 is inferred from the Lorentz condition in (2.4), and one should also stress that the dispersion relation is different from the transversal modes.

A complete set of eigenfunctions can be generated by applying certain symmetry transformations of H^3 [Möbius transformations $\alpha_\xi(z)=(z-\xi)^{-1}$, lifted into H^3, cf. Ref. 12] to the plane waves (2.13) and (2.14). The dispersion relations remain unaltered, and we find, with $A_\mu=(A_0,\mathbf{A})$ and $i=1,2$, cf. Ref. 13,

$$\begin{gathered}A_0^{T_i}=0,\ \ \mathbf{A}^{T_i}(z,t;\xi,s)=\mathbf{a}^{T_i}(z,t;\xi,s)e^{-i\omega\tau},\\ A_0^L(z,t;\xi,s)=-i\omega^{-1}(1-is)P^{1+is}(z,t;\xi)e^{-i\omega\tau},\end{gathered} \tag{2.15}$$

$$\begin{gathered}\mathbf{A}^L(z,t;\xi,s)=\mathbf{a}^L(z,t;\xi,s)e^{-i\omega\tau},\\ \mathbf{a}^L(z,t;\xi,s):=\frac{P^{2+is}(z,t;\xi)}{t^2}\begin{pmatrix}-2t(z_1-\xi_1)\\ -2t(z_2-\xi_2)\\ |z-\xi|^2-t^2\end{pmatrix},\ \ P(z,t;\xi):=\frac{t}{|z-\xi|^2+t^2},\end{gathered} \tag{2.16}$$

$$\mathbf{a}^{T_1}(z,t;\xi,s) := \frac{P^{2+is}(z,t;\xi)}{t^2}\begin{pmatrix} -(z_1-\xi_1)^2+(z_2-\xi_2)^2+t^2 \\ -2(z_1-\xi_1)(z_2-\xi_2) \\ -2t(z_1-\xi_1)\end{pmatrix},$$
$$\mathbf{a}^{T_2}(z,t;\xi,s) := \frac{P^{2+is}(z,t;\xi)}{t^2}\begin{pmatrix} -2(z_1-\xi_1)(z_2-\xi_2) \\ -(z_2-\xi_2)^2+(z_1-\xi_1)^2+t^2 \\ -2t(z_2-\xi_2)\end{pmatrix}. \tag{2.17}$$

[$z := (z_1,z_2)$, $\xi := (\xi_1,\xi_2)$; it is useful to use complex notation as at the beginning of this section.] We have chosen the normalization $\mathbf{a}^{T_i}(z,t;\xi,s)\cdot\mathbf{a}^{T_i}(z,t;\xi,-s)=(P/t)^2$, and the same for the longitudinal component, and these vectors form an orthogonal triad; the $\mathbf{a}^{T_{1,2}}$ generate the tangent planes of the horospheres[12] $P(z,t;\xi)=\text{const.}$, and $\mathbf{a}^L$ is proportional to the gradient of P.

The main part of this paper is based on the representation,

$$\mathbf{a}^L = \frac{1}{1+is}\begin{pmatrix} \dfrac{\partial P^{1+is}}{\partial z_1} \\ \dfrac{\partial P^{1+is}}{\partial z_2} \\ \dfrac{\partial P^{1+is}}{\partial t}\end{pmatrix},\quad \mathbf{a}^{T_1} = \frac{1}{1+is}\begin{pmatrix} \dfrac{-1}{4is}D_{12}P^{is}+(1+is)P^{2+is} \\ \dfrac{-1}{2is}\dfrac{\partial^2 P^{is}}{\partial z_1\partial z_2} \\ \dfrac{\partial P^{1+is}}{\partial z_1}\end{pmatrix},$$
$$\mathbf{a}^{T_2} = \frac{1}{1+is}\begin{pmatrix} \dfrac{-1}{2is}\dfrac{\partial^2 P^{is}}{\partial z_1\partial z_2} \\ \dfrac{-1}{4is}D_{21}P^{is}+(1+is)P^{2+is} \\ \dfrac{\partial P^{1+is}}{\partial z_2}\end{pmatrix},\quad D_{ij} := \frac{\partial^2}{\partial z_i^2}-\frac{\partial^2}{\partial z_j^2}, \tag{2.18}$$

and we will assume the identity,

$$\frac{\partial P^{1+is}}{\partial t} = (1+is)P^{2+is}\left(\frac{1}{tP}-2\right) \tag{2.19}$$

substituted into the third component of $\mathbf{a}^L$, so that no t-derivatives appear in the eigenvectors. The z_i-derivatives in (2.18) may also be replaced by ξ_i-derivatives, via the substitution $\partial/\partial z_i \to -\partial/\partial\xi_i$. When performing integrations over eigenfunctions, we will pull the differential operators in front of the integral signs, so that we are left with convolutions of Poisson kernels, which can be calculated by Feynman parametrization; this is the purpose of (2.18).

Finally, the eigenvectors (2.17) can be written as

$$(\mathbf{a}^L(z,t;\xi,s))^t = (0,0,1)[\alpha'_\xi(z,t)]P^{is}(z,t;\xi),$$
$$(\mathbf{a}^{T_1})^t = (1,0,0)[\alpha'_\xi]P^{is},\quad (\mathbf{a}^{T_2})^t = (0,-1,0)[\alpha'_\xi]P^{is}, \tag{2.20}$$

where $[\alpha'_\xi]$ denotes the Jacobian of the Möbius transformation $\alpha_\xi(z)=(z-\xi)^{-1}$ lifted into the half-space. The superscript t denotes transposition of the row-vectors (2.17), and ordinary matrix multiplication is assumed on the right-hand side of these equations. In Ref. 13, we derived

$$(\mathbf{a}^L(\gamma(z,t);\xi,s))^t[\gamma'(z,t)] = |\gamma^{-1\prime}\xi|^{is}(0,0,|\gamma^{-1\prime}\xi|)[\alpha'_{\gamma^{-1}\xi}(z,t)]P^{is}(z,t;\gamma^{-1}\xi),$$
$$(\mathbf{a}^{T_1}(\gamma;\xi,s))^t[\gamma'] = |\gamma^{-1\prime}\xi|^{is}(\mathrm{Re}(\gamma^{-1\prime}\xi),-\mathrm{Im}(\gamma^{-1\prime}\xi),0)[\alpha'_{\gamma^{-1}\xi}(z,t)]P^{is}(z,t;\gamma^{-1}\xi), \tag{2.21}$$

$$(\mathbf{a}^{T_2}(\gamma;\xi,s))^t[\gamma']=|\gamma^{-1\prime}\xi|^{is}(-\mathrm{Im}(\gamma^{-1\prime}\xi),-\mathrm{Re}(\gamma^{-1\prime}\xi),0)[\alpha'_{\gamma^{-1}\xi}(z,t)]P^{is}(z,t;\gamma^{-1}\xi),$$

where $\gamma^{-1}\xi$ is the Möbius transformation γ^{-1} acting in the complex plane, and $\gamma^{-1\prime}\xi$ denotes its ξ-derivative. Introducing a circulary polarized basis for the transversal components,

$$\sqrt{2}\mathbf{a}^{T_L}:=\mathbf{a}^{T_1}+i\mathbf{a}^{T_2},\quad \sqrt{2}\mathbf{a}^{T_R}:=\mathbf{a}^{T_1}-i\mathbf{a}^{T_2},$$
$$\mathbf{a}^{T_L}\overline{\mathbf{a}^{T_L}}+\mathbf{a}^{T_R}\overline{\mathbf{a}^{T_R}}=\mathbf{a}^{T_1}\overline{\mathbf{a}^{T_1}}+\mathbf{a}^{T_2}\overline{\mathbf{a}^{T_2}}, \tag{2.22}$$

we find

$$[\gamma'(z,t)]^t\mathbf{a}^L(\gamma(z,t);\xi,s)=|\gamma^{-1\prime}\xi|^{1+is}\mathbf{a}^L(z,t;\gamma^{-1}\xi,s),$$
$$[\gamma']^t\mathbf{a}^{T_L}(\gamma;\xi)=|\gamma^{-1\prime}\xi|^{is}\overline{\gamma^{-1\prime}\xi}\mathbf{a}^{T_L}(\gamma^{-1}\xi), \tag{2.23}$$
$$[\gamma']^t\mathbf{a}^{T_R}(\gamma;\xi)=|\gamma^{-1\prime}\xi|^{is}\gamma^{-1\prime}\xi\mathbf{a}^{T_R}(\gamma^{-1}\xi),$$

with $[\gamma']^t\mathbf{a}:=\mathbf{a}_i[\gamma']_{ij}$. ($T_{L,R}$ stands for left and right transversal polarization, respectively.) As for the time component of the longitudinal modes in (2.16), we use[5,6]

$$P^{1+is}(\gamma(z,t);\xi)=|\gamma^{-1\prime}\xi|^{1+is}P^{1+is}(z,t;\gamma^{-1}\xi), \tag{2.24}$$

which is the scalar analog to (2.23). These symmetries are crucial in constructing the eigenfunctions of (2.5) and (2.6) on multiply connected manifolds, as well as the spectral representation of the resolvent, cf. Sec. VI.

Next we derive the differential equations for the propagators of the Proca Eq. (2.1). We start with a bivector $G_{\alpha\alpha'}(x,x')$ on the 4-manifold; primed indices refer to the primed variable, and we define $F^G_{\alpha\alpha'\beta}(x,x'):=G_{\beta\alpha';\alpha}-G_{\alpha\alpha';\beta}$, which is evidently a second rank skew tensor with respect to x, and a vector with respect to x'. The covariant differentiations may be replaced by ordinary ones, as usual in $F_{\alpha\beta}$. Likewise, in the divergence $F^{G\ \ \beta}_{\alpha\alpha'\ ;\beta}$, the primed index and the primed variable are regarded as dummy parameters in the differentiation procedure. Green functions are defined as solutions of

$$F^{G\ \ \beta}_{\alpha\alpha'\ ;\beta}+\mu^2G_{\alpha\alpha'}=(-g)^{-1/2}\delta(x-x')g_{\alpha\alpha'}, \tag{2.25}$$

$(-g)^{-1/2}\delta$ denotes the Dirac function on the 4-manifold. The variable in the metric and the determinant on the right-hand side may be x or x', given the support of the δ-function. Clearly, $G_{\alpha\alpha'}(x,x')$ is an inverting kernel, since

$$A_\alpha=\int G_{\alpha\alpha'}(x,x')j^{\alpha'}(x')\sqrt{-g(x')}dx' \tag{2.26}$$

solves the field Eq. (2.1) according to

$$F_{\alpha\ \ ;\beta}^{\ \ \beta}+\mu^2A_\alpha=\int(F^{G\ \ \beta}_{\alpha\alpha'\ ;\beta}+\mu^2G_{\alpha\alpha'})j^{\alpha'}(x')\sqrt{-g(x')}dx'=j_\alpha. \tag{2.27}$$

We consider, formally, the Fourier transform

$$G_{\alpha\alpha'}(\tau;\mathbf{x},\mathbf{x}')=(2\pi)^{-1}\int_{-\infty}^{+\infty}d\omega e^{-i\omega\tau}\hat{G}_{\alpha\alpha'}(\omega;\mathbf{x},\mathbf{x}'), \tag{2.28}$$

and find, with (2.10) and (2.11),

$$-\Delta_{B^3}\hat{G}_{00}(\omega;\mathbf{x},\mathbf{y})+(\mu^2-\omega^2)\hat{G}_{00}=-(1/8)(1-|\mathbf{y}|^2)^3\delta(\mathbf{x}-\mathbf{y}), \tag{2.29}$$

$$-\Delta_{B^3}\hat{G}_{ij}(\omega;\mathbf{x},\mathbf{y})+(1/2)(1-|\mathbf{x}|^2)(2x^n(\hat{G}_{ij,n}-\hat{G}_{nj,i})-\hat{G}_{ij}+2x_i\hat{G}_{nj,n})+x_ix^n\hat{G}_{nj}$$
$$+(\mu^2-\omega^2)\hat{G}_{ij}=(1/2)(1-|\mathbf{y}|^2)\,\delta(\mathbf{x}-\mathbf{y}). \tag{2.30}$$

We have here slightly changed notation, writing $\mathbf{y}$ instead of $\mathbf{x}'$, and all differentiations are with respect to the variable $\mathbf{x}$. In (2.28), we write as a shortcut τ instead of $\tau-\tau'$. $\hat{G}_{00}$ and $\hat{G}_{ij}$ are scalar and vectorial point-pair invariants on the 3-space, respectively, cf. Ref. 13, and (6.3) and (6.4). (The first index always refers to $\mathbf{x}$ and the second to $\mathbf{y}$.) To achieve the symmetry $\hat{G}_{\mu\nu}(\omega;\mathbf{x},\mathbf{y})=\hat{G}_{\nu\mu}(\omega;\mathbf{y},\mathbf{x})$, we put the space–time mixing components to zero, that is $\hat{G}_{0j}$ and $\hat{G}_{i0}$, which satisfy the homogeneous Eqs. (2.29) and (2.30), respectively. Equations analogous to (2.29) and (2.30) hold in the half-space model H^3,

$$-\Delta_{H^3}\hat{G}_{00}(\omega;z,t;z_0,t_0)+(\mu^2-\omega^2)\hat{G}_{00}=-t^3\delta(t-t_0)\,\delta(z-z_0), \tag{2.31}$$

$$-\Delta_{H^3}\hat{G}_{ij}(\omega;z,t;z_0,t_0)-2t(\hat{G}_{ij,3}-\hat{G}_{3j,i})-2t\,\delta_{3i}\hat{G}_{nj,n}+\delta_{3i}\hat{G}_{3j}+(\mu^2-\omega^2)\hat{G}_{ij}$$
$$=t\,\delta(t-t_0)\,\delta(z-z_0). \tag{2.32}$$

[t is the coordinate in the half-space H^3 orthogonal to the complex plane; cosmic time is denoted by τ.] In Secs. III and IV, we will solve (2.31) and (2.32), respectively, and figure out the boundary conditions, in terms of pole coefficient and decay at infinity. In Secs. II and V, we will discuss the Fourier transform (2.28), specify the integration paths encircling the singularities of the resolvent, and calculate the propagators, i.e., the general solution of Eq. (2.25).

III. THE SCALAR TIME COMPONENT OF THE GREEN FUNCTION

The differential equations for the time-time component $\hat{G}_{00}$ of the resolvent kernel only involve the Laplace–Beltrami operator (2.29) or (2.31), and accordingly $\hat{G}_{00}$ transforms as a scalar under spatial coordinate transformations. We put $\mathbf{y}=0$ in (2.29), define $\lambda:=\mu^2-\omega^2$ as spectral parameter, and look for spherically symmetric solutions $\psi(\lambda,r)$ of $(-\Delta_{B^3}+\lambda)\psi(\lambda,r)=0$ or

$$\frac{-(1-r^2)^2}{4}\left[\psi''+2\left(\frac{1}{r}+\frac{r}{1-r^2}\right)\psi'\right]+\lambda\psi=0. \tag{3.1}$$

Two independent solutions of (3.1) are

$$\psi_{\pm}(\lambda,r)=(1-r^2)^{1+\sqrt{1+\lambda}}r^{-1}((1+r)^{-2\sqrt{1+\lambda}}\pm(1-r)^{-2\sqrt{1+\lambda}}), \tag{3.2}$$

and we assume $\mathrm{Re}\,\sqrt{1+\lambda}>0$. Since $\hat{G}_{00}(\omega;\mathbf{x},\mathbf{0})$ is spherically symmetric, it is a linear combination of the two solutions (3.2). As for boundary conditions, in the limit $r\to 0$, the asymptotic solution of Eq. (2.29) is $\hat{G}_{00}(\omega;r,\mathbf{0})\sim -1/(8\pi r)$, which follows from the Poisson equation $\Delta_{E^3}r^{-1}=-4\pi\delta(\mathbf{x})$. The second integration constant is chosen in a way that $\hat{G}_{00}(\omega;\mathbf{x},\mathbf{0})$ decays as fast as possible at infinity, that is, for $r\to 1$. Accordingly,

$$\hat{G}_{00}(\omega;\mathbf{x},\mathbf{0})=-\frac{1}{8\pi r}(1-r^2)^{1+\sqrt{1+\lambda}}(1+r)^{-2\sqrt{1+\lambda}}. \tag{3.3}$$

The Green function with pole at $\mathbf{y}$ is obtained by the substitution[5]

$$\mathbf{x}\to T_{\mathbf{y}}\mathbf{x}:=\frac{(1-|\mathbf{y}|^2)\mathbf{x}-(1-2\mathbf{x}\cdot\mathbf{y}+|\mathbf{x}|^2)\mathbf{y}}{1-2\mathbf{x}\cdot\mathbf{y}+|\mathbf{x}|^2|\mathbf{y}|^2}. \tag{3.4}$$

$T_{\mathbf{y}}$ is a Möbius transformation in B^3 that maps an arbitrary point $\mathbf{y}$ into the origin. In fact, $\hat{G}_{00}(\omega;T_{\mathbf{y}}\mathbf{x},\mathbf{0})$ is a solution of (2.29), denoted in the following by $\hat{G}_{00}(\omega;\mathbf{x},\mathbf{y})$, because (2.29) is invariant with respect to the symmetry group of B^3. The absolute value of (3.4) relates to the point-pair invariant[5,12] $L(\mathbf{x},\mathbf{y})$ as

$$|T_{\mathbf{y}}\mathbf{x}|=\sqrt{\frac{L(\mathbf{x},\mathbf{y})}{1+L(\mathbf{x},\mathbf{y})}},\quad L(\mathbf{x},\mathbf{y}):=\frac{|\mathbf{x}-\mathbf{y}|^2}{(1-|\mathbf{x}|^2)(1-|\mathbf{y}|^2)}. \tag{3.5}$$

By substituting $r=|T_{\mathbf{y}}\mathbf{x}|$ into (3.3), we find the Green function with pole at $\mathbf{y}$, cf. Refs. 5, 6, and 10,

$$\hat{G}_{00}(\omega;\mathbf{x},\mathbf{y})=-\frac{1}{8\pi}\frac{1}{\sqrt{L(1+L)}}\rho_+^{-\sqrt{1+\lambda}}(L)=-\frac{1}{4\pi}\frac{e^{-\sqrt{1+\lambda}d}}{\sinh d}, \tag{3.6}$$

$$\rho_\pm(L):=1+2L\pm 2\sqrt{L(L+1)},\quad \rho_+=1/\rho_-,\quad d:=\log\rho_+(L), \tag{3.7}$$

with $\lambda=\mu^2-\omega^2$ and $\mathrm{Re}\,\sqrt{1+\lambda}>0$. We have here also introduced the hyperbolic distance function $d(\mathbf{x},\mathbf{y})$ in B^3, and we will frequently make use of the identities,

$$(1/2)(\rho_++\rho_-)=\cosh d=1+2L, \tag{3.8}$$

$$(1/2)(\rho_+-\rho_-)=\sinh d=2\sqrt{L(L+1)}, \tag{3.9}$$

$$e^{-d}=\rho_-=\frac{1-\sqrt{L/(1+L)}}{1+\sqrt{L/(1+L)}}. \tag{3.10}$$

The Green function $\hat{G}_{00}(\omega;z,t;z_0,t_0)$ in the half-space model H^3, cf. (2.31), is obtained by the substitution,

$$L(\mathbf{x},\mathbf{y})\to L(z,t;z_0,t_0):=\frac{|z-z_0|^2+(t-t_0)^2}{4tt_0} \tag{3.11}$$

in (3.6) and (3.7). This follows from the isometry[12] $H^3\leftrightarrow B^3$,

$$x^i=(|z|^2+(1+t)^2)^{-1}(2z_1,2z_2,|z|^2+t^2-1), \tag{3.12}$$

with $z=z_1+iz_2$. The identities (3.6)–(3.10) also hold in H^3, with the distance function $d(z,t;z_0,t_0)$ defined by the third equation in (3.7).

Next we compile the spectral representation[6,10] of $\hat{G}_{00}(\omega;z,t;z_0,t_0)$,

$$\begin{aligned}\hat{G}_{00}(\omega;z,t;z_0,t_0)&=-\int_{R^2\times R^+}d\sigma(\xi,s)\frac{P^{1+is}(z,t;\xi)P^{1-is}(z_0,t_0;\xi)}{s^2+1+\lambda}\\&=-\frac{1}{2\pi^3}\int_0^\infty\frac{k(s,d)}{s^2+1+\lambda}s^2ds,\end{aligned} \tag{3.13}$$

$$k(s,d):=\int_{R^2}P^{1+is}(z,t;\xi)P^{1-is}(z_0,t_0;\xi)d\xi=\frac{\pi}{2}\frac{\sin(s\log\rho_+(L))}{s\sqrt{L(1+L)}}=\pi\frac{\sin(sd)}{s\sinh(d)}, \tag{3.14}$$

with $\lambda(\omega)=\mu^2-\omega^2$. The spectral measure, $d\sigma(\xi,s)$, is defined in (A13) (with the convergence factor dropped). Equation (3.13) readily follows from the completeness relation (A14), in conjunction with $-\Delta_{H^3}P^{1+is}=(s^2+1)P^{1+is}$, cf. (B12), and (2.31). The integral in (3.14) is calcu-

lated in (A7), and $\rho_{\pm}(L)$ is defined in (3.7). As $\hat{G}_{00}$ depends on the space variables only via the point-pair invariant L or the distance function d, we will write $\hat{G}_{00}(\omega,d)$; in this way we get model independent formulas, i.e., independent of the coordinate representation H^3, B^3, or any other.

Next we turn to the time dependent Green functions. The retarded Green function is denoted by G^{+}_{00}, the advanced one by G^{-}_{00}, the Feynman propagator by G^{+}_{F00}, and the Dyson propagator by $G_{\overline{F}00}$; they can be defined by certain contour integrations, and we use the conventions, though not quite the notation, of Ref. 14. The propagators relate to $\hat{G}_{00}(\omega,d)$ in (3.6) via (2.28),

$$G^{\pm}_{(F)00}(\tau,d) = -\frac{1}{8\pi^2}\int_{-\infty}^{+\infty} d\omega e^{-i\omega\tau}\frac{\exp(-\sqrt{1+\lambda^{\pm}_{(F)}(\omega)}d)}{\sinh d}, \tag{3.15}$$

$$\lambda^{\pm}(\omega) := \mu^2 - (\omega^2 \pm 2i\varepsilon\omega), \quad \lambda^{\pm}_{F}(\omega) := \mu^2 - (\omega^2 \pm i\varepsilon). \tag{3.16}$$

The ε-terms indicate the path of integration for the respective propagators. We find, via (3.13) and (3.14),

$$G^{\pm}_{(F)00}(\tau,d) = -\frac{1}{4\pi^4}\int_0^{\infty} I^{\pm}_{(F)}(s,\tau)k(s,d)s^2 ds,$$

$$I^{\pm}_{(F)}(s,\tau) := \int_{-\infty}^{+\infty} g^{\pm}_{(F)}(s,\omega)\exp(-i\omega\tau)d\omega, \tag{3.17}$$

$$g^{\pm}(s,\omega) := (\omega_0^2 - \omega^2 \mp 2i\varepsilon\omega)^{-1}, \quad g^{\pm}_{F}(s,\omega) := (\omega_0^2 - \omega^2 \mp i\varepsilon)^{-1},$$

with $\omega_0(s) := \sqrt{s^2+1+\mu^2}$, and $\omega_0 > 0$. A standard integration[14] gives

$$I^{\pm}(s,\tau) = \mp \pi i \omega_0^{-1}(e^{i\omega_0\tau} - e^{-i\omega_0\tau})\theta(\pm\tau), \quad I^{\pm}_{F}(s,\tau) = \pm\pi i\omega_0^{-1}e^{\mp i\omega_0|\tau|}. \tag{3.18}$$

Defining

$$\tilde{G}_{00}(\tau,d) := -\frac{1}{4\pi^4}\int_0^{\infty}\tilde{I}(s,\tau,\varepsilon)k(s,d)s^2 ds, \quad \tilde{I}(s,\tau,\varepsilon) := \omega_0^{-1}e^{-(i\tau+\varepsilon)\omega_0}, \tag{3.19}$$

we may write the propagators as linear combinations of $\tilde{G}_{00}(\pm\tau,d)$,

$$G^{\pm}_{00}(\tau,d) = \pm\pi i\,\theta(\pm\tau)(\tilde{G}_{00}(\tau,d) - \tilde{G}_{00}(-\tau,d)), \quad G^{\pm}_{F00}(\tau,d) = \pm\pi i\tilde{G}_{00}(\pm|\tau|,d). \tag{3.20}$$

The integral in (3.19) is likewise standard,[15] and we find

$$\tilde{G}_{00}(\tau;L) = -\frac{d}{4\pi^3}\frac{\Delta(\tau,d)}{\sinh d},$$
$$\Delta(\tau,d) := \frac{\sqrt{\mu^2+1}K_1(\sqrt{\mu^2+1}\sqrt{d^2-\tau^2+2i\tau\varepsilon})}{\sqrt{d^2-\tau^2+2i\tau\varepsilon}}. \tag{3.21}$$

Next we separate the pole part of $\Delta(\tau,d)$, and then perform the limit $\varepsilon\to 0$. We note[15]

$$K_1(\pm ix) = -(\pi/2)(J_1(x) \mp iN_1(x)), \quad x>0, \tag{3.22}$$

$$K_1(z) = z^{-1} + O(z\log z), \quad J_1(z) = z/2 + O(z^3),$$

$$N_1(z) = -(2/\pi)z^{-1} + O(z\log z). \tag{3.23}$$

Hence,

$$\Delta(\tau,d)=\frac{1}{d^2-\tau^2+2i\varepsilon\tau}-\frac{1}{d^2-\tau^2}+\hat{\delta}_K+\frac{\pi}{2}(\hat{\delta}_N+i\varepsilon(\tau)\hat{\delta}_J), \tag{3.24}$$

$$\hat{\delta}_K:=\theta(d^2-\tau^2)\sqrt{\mu^2+1}\frac{K_1(\sqrt{\mu^2+1}\sqrt{d^2-\tau^2})}{\sqrt{d^2-\tau^2}}, \tag{3.25}$$

$$\hat{\delta}_{J,N}:=\theta(\tau^2-d^2)\sqrt{\mu^2+1}\frac{(J_1,N_1)(\sqrt{\mu^2+1}\sqrt{\tau^2-d^2})}{\sqrt{\tau^2-d^2}}, \tag{3.26}$$

where $\varepsilon(\tau):=\mathrm{sign}(\tau)$ (not to be confused with the ε-regularization). The distributions (3.21) and (3.24) are identical. The second term in (3.24) is a principal value, and we arrive, by making use of the second formula in (A10), at

$$\Delta(\tau,d)=-i\pi\delta(d^2-\tau^2)\varepsilon(\tau)+\hat{\delta}_K+(\pi/2)(\hat{\delta}_N+i\varepsilon(\tau)\hat{\delta}_J). \tag{3.27}$$

Piecing together the above formulas, we find the retarded/advanced Green functions and the Feynman/Dyson propagators as

$$G^{\pm}_{00}(\tau,d)=-\frac{1}{2\pi}\frac{d\,\theta(\pm\tau)}{\sinh d}\left(\delta(d^2-\tau^2)-\frac{1}{2}\hat{\delta}_J\right), \tag{3.28}$$

$$G^{\pm}_{F00}(\tau,d)=-\frac{1}{4\pi}\frac{d}{\sinh d}\left(\delta(d^2-\tau^2)-\frac{1}{2}\hat{\delta}_J\pm\frac{i}{2}\left(\hat{\delta}_N+\frac{2}{\pi}\hat{\delta}_K\right)\right). \tag{3.29}$$

In the limit of vanishing photon mass, the classical propagators read

$$G^{\pm}_{00}(\tau,d;\mu=0)=-\frac{1}{2\pi}\frac{c^2}{R^2}\frac{d\,\theta(\pm\tau)}{\sinh(d/R)}\times\left(R\,\delta(d^2-c^2\tau^2)-\frac{1}{2}\frac{\theta(c^2\tau^2-d^2)}{\sqrt{c^2\tau^2-d^2}}J_1(R^{-1}\sqrt{c^2\tau^2-d^2})\right); \tag{3.30}$$

we have here restored the natural units, R is the curvature radius of the 3-space. The limit $\mu\to 0$ can also be carried out in (3.29), but the spatial components of the quantum propagators get singular, see after (5.18).

Remark: In (2.1), (2.26), and (2.27), the restoration of the units requires the substitution $j^\alpha\to c^{-1}j^\alpha$, and, for nonvanishing photon mass, $\mu:=mc/\hbar$. Moreover, $j^0=:\rho$ is the charge density of dimension $\sqrt{\hbar c}/R^3$. The components of the static RW-metric read in natural units $g_{00}=-c^2$ and $g_{ij}=(R/t)^2\delta_{ij}$, or $g_{ij}=4(1-|\mathbf{x}|^2/R^2)^{-2}\delta_{ij}$, $|\mathbf{x}|<R$. Dimensionally, $j^k\sim cj^0$, $A^k\sim cA^0\sim\sqrt{\hbar c}/R$, and $G_{00}\sim c^2G_{ij}\sim c^2/R^2$.

In the ball model B^3, the Minkowski space limit of (3.21) is recovered for $R\to\infty$. To this end, we restore the units in (3.21), analogously to (3.30). For $R\to\infty$, $d\sigma^2_{B^3}\sim 4d\mathbf{x}^2$, so that $d\sim 2|\mathbf{x}-\mathbf{y}|$, and the asymptotic limit of the point-pair invariant (3.5) is $\sqrt{L}\sim R^{-1}|\mathbf{x}-\mathbf{y}|$. Also, $\mu^2+1=(mc/\hbar)^2+R^{-2}$, see the Remark above. A rescaling of the space coordinates, $\mathbf{x}\to\mathbf{x}/2$, then gives

$$\tilde{G}_{00}(\tau,d;R\to\infty)\sim-\frac{\mu}{4\pi^3}\frac{K_1(\mu\sqrt{|\mathbf{x}-\mathbf{y}|^2-\tau^2+2i\tau\varepsilon})}{\sqrt{|\mathbf{x}-\mathbf{y}|^2-\tau^2+2i\tau\varepsilon}}. \tag{3.31}$$

Inserting this into (3.28) and (3.29), we recover of course the Minkowski results.[14]

Remark: The Green functions $G^{\pm}_{(F)00}(\tau,d)$ also happen to be the propagators of the minimally coupled Klein–Gordon equation, solving

$$(\Box-\mu^2)G^{\pm}_{(F)00}(\tau,d(\mathbf{x},\mathbf{y}))=c^{-1}\delta_{B^3}(\mathbf{x},\mathbf{y})\,\delta(\tau), \tag{3.32}$$

with the d'Alembertian $\Box=-\partial^2/\partial\tau^2+\Delta_{B^3}$. [The dimension of $G^{\pm}_{(F)00}$ is here $1/R^2$, so that we have to divide the right-hand side of (3.30) by c^2.] We may also couple the scalar field to the Ricci scalar, via the wave operator $\Box-\mu^2-\xi\hat{R}$. As the background geometry is static, the Ricci scalar is constant, $\hat{R}=-6$, cf. (5.28). Obviously, $G^{\pm}_{(F)00}(\tau,d)$ also applies to this case, with a redefinition of the mass parameter, as long as $\mu^2+\xi\hat{R}+1\geqslant 0$. Conformal coupling is achieved for $\mu=0$ and $\xi=1/6$. We will return to the conformally coupled Klein–Gordon equation, when we discuss electromagnetic propagators in an expanding background geometry, at the end of Sec. V.

IV. THE SPATIAL RESOLVENT KERNEL

The transversal and longitudinal components of the spatial resolvent kernel, $\hat{R}_{ij}:=\hat{R}^T_{ij}+\hat{R}^L_{ij}$, of the Proca equation are defined by

$$\hat{R}^T_{ij}(z,t;z',t';\lambda):=\int_{R^2\times R^+}\sum_{k=1,2}\mathbf{a}^{T_k}_i(z,t;\xi,s)\overline{\mathbf{a}^{T_k}_j(z',t';\xi,s)}\frac{d\sigma^T(\xi,s)}{s^2+\lambda}, \tag{4.1}$$

$$\hat{R}^L_{ij}(z,t;z',t';\lambda):=\int_{R^2\times R^+}\mathbf{a}^L_i(z,t;\xi,s)\overline{\mathbf{a}^L_j(z',t';\xi,s)}\frac{d\sigma^L(\xi,s)}{s^2+1+\lambda}. \tag{4.2}$$

The eigenvectors $\mathbf{a}^{T_{1,2},L}$ are listed in (2.18) and (2.19). In the spectral measures $d\sigma^{T,L}$, cf. (B13), the ε-regularizator can be dropped, as the integrals (4.1) and (4.2) are already convergent, unlike those in the completeness relation (B14). (As in Sec. III, we write the resolvent kernel with a roof, to distinguish it from its Fourier transform, when studying time-dependent Green functions on the 4-manifold in Sec. V.) If we put $\lambda=\mu^2-\omega^2$, then $\hat{R}_{ij}$ formally satisfies Eq. (2.32), which is an immediate consequence of the completeness relation (B.14). The vectorial space component of the (time independent) Green function of the Proca equation is thus

$$\hat{G}_{ij}(\omega;z,t;z_0,t_0)=\hat{R}_{ij}(z,t;z_0,t_0;\lambda=\mu^2-\omega^2). \tag{4.3}$$

The time dependent Green function on the 4-manifold is then obtained by means of the Fourier transform (2.28), studied in Sec. V. The purpose of this section is to find an explicit formula for the kernel (4.3). A complex spectral parameter λ is needed to define the integration paths in (2.28), which in turn define the propagators, cf. (3.17). In the following we assume Re $\sqrt{\lambda}>0$, as well as Re $\sqrt{\lambda+1}>0$.

At first we calculate the kernels (4.1) and (4.2) for $z=z'=0$, and then restore these variables by a symmetry argument. To this end we need the matrix elements

$$C^{T_k}_{ij}(t,t';s):=\int_{R^2}\mathbf{a}^{T_k}_i(0,t;\xi,s)\overline{\mathbf{a}^{T_k}_j(0,t';\xi,s)}d\xi,\quad C^T_{ij}:=C^{T_1}_{ij}+C^{T_2}_{ij},\quad C^L_{ij}:=\int_{R^2}\mathbf{a}^L_i\overline{\mathbf{a}^L_j}d\xi, \tag{4.4}$$

calculated in Appendix C. The nonvanishing matrix elements of the kernels (at $z=z'=0$) read, for $\beta=t'/t>1$,

$$\hat{R}^T_{11}(0,t;0,t';\lambda)=\int_0^\infty C^T_{11}(t,t';s)\,\frac{s^2+1}{s^2+\lambda}\,\frac{ds}{2\pi^3}=\frac{\beta}{2\pi(\beta^2-1)^3\lambda}\,\frac{1}{tt'}(4\beta^2(\beta^{-\sqrt{\lambda}}-1)$$
$$+(\beta^4-1)\sqrt{\lambda}\beta^{-\sqrt{\lambda}}+(\beta^2-1)^2\lambda\beta^{-\sqrt{\lambda}}), \tag{4.5}$$

$$\hat{R}^L_{11}=\int_0^\infty C^L_{11}(s)\,\frac{s^2}{s^2+1+\lambda}\,\frac{ds}{2\pi^3}=\frac{\beta^2}{\pi(\beta^2-1)^3\lambda}\,\frac{1}{tt'}$$
$$\times(2\beta-(\beta^2+1)\beta^{-\sqrt{1+\lambda}}-(\beta^2-1)\sqrt{1+\lambda}\beta^{-\sqrt{1+\lambda}}), \tag{4.6}$$

$$\hat{R}_{11}:=\hat{R}^T_{11}+\hat{R}^L_{11}=\frac{\beta}{2\pi(\beta^2-1)^3\lambda}\,\frac{1}{tt'}(4\beta^{2-\sqrt{\lambda}}+(\beta^4-1)\sqrt{\lambda}\beta^{-\sqrt{\lambda}}+(\beta^2-1)^2\lambda\beta^{-\sqrt{\lambda}}$$
$$-2\beta(\beta^2+1)\beta^{-\sqrt{1+\lambda}}-2\beta(\beta^2-1)\sqrt{1+\lambda}\beta^{-\sqrt{1+\lambda}}), \tag{4.7}$$

$$\hat{R}^{(T,L)}_{22}=\hat{R}^{(T,L)}_{11}, \tag{4.8}$$

$$\hat{R}^T_{33}:=\int_0^\infty C^T_{33}(s)\,\frac{s^2+1}{s^2+\lambda}\,\frac{ds}{2\pi^3}=\frac{2\beta^2}{\pi(\beta^2-1)^3\lambda}\,\frac{1}{tt'}$$
$$\times((\beta^2+1)(1-\beta^{-\sqrt{\lambda}})-(\beta^2-1)\sqrt{\lambda}\beta^{-\sqrt{\lambda}}), \tag{4.9}$$

$$\hat{R}^L_{33}:=\int_0^\infty C^L_{33}(s)\,\frac{s^2}{s^2+1+\lambda}\,\frac{ds}{2\pi^3}=\frac{\beta}{2\pi(\beta^2-1)^3\lambda}\,\frac{1}{tt'}(-4\beta(\beta^2+1)+(\beta^2-1)^2\lambda\beta^{-\sqrt{1+\lambda}}$$
$$+2(\beta^4-1)\sqrt{1+\lambda}\beta^{-\sqrt{1+\lambda}}+2(\beta^2+1)^2\beta^{-\sqrt{1+\lambda}}), \tag{4.10}$$

$$\hat{R}_{33}:=\hat{R}^T_{33}+\hat{R}^L_{33}=\frac{\beta}{2\pi(\beta^2-1)^3\lambda}\,\frac{1}{tt'}(-4(\beta^2+1)\beta^{1-\sqrt{\lambda}}-4(\beta^2-1)\sqrt{\lambda}\beta^{1-\sqrt{\lambda}}$$
$$+(\beta^2-1)^2\lambda\beta^{-\sqrt{1+\lambda}}+2(\beta^4-1)\sqrt{1+\lambda}\beta^{-\sqrt{1+\lambda}}+2(\beta^2+1)^2\beta^{-\sqrt{1+\lambda}}). \tag{4.11}$$

Replacing on the right-hand side of Eqs. (4.5)–(4.11) β by $1/\beta$, we obtain the kernels for $\beta=t'/t<1$. If we put $t'=1$, and $t=1-2r$, and calculate the leading order of $\hat{R}_{11}$ and $\hat{R}_{33}$ for $r\to 0$, we find $\hat{R}_{11}\sim\hat{R}_{33}\sim 1/(8\pi r)$, and $\hat{R}^L_{11}\sim 1/(16\pi r)$.

Next we will restore the z and z'-variables, assumed zero in (4.5)–(4.11). This can be done by symmetry, of course. The goal is to find the Green function $\hat{G}^{B^3}_{ij}(\omega;\mathbf{x},\mathbf{x}')$ with pole at $\mathbf{x}'$ in the Poincaré ball B^3, cf. (2.30). [We will frequently switch between the ball (B^3) and half-space (H^3) models of hyperbolic geometry, cf. Sec. II, and we will indicate that by a superscript.] $\hat{G}^{B^3}_{ij}$ transforms as a bivector, $\hat{G}^{B^3}_{ij}(\omega;\mathbf{x},\mathbf{x}')dx^i dx'^j$; we map B^3 onto H^3 via the isometry (3.12), and use the same transformation for the primed coordinates x'^i and (z',t'), so that $\mathbf{x}'=0$ is mapped onto $(z'=0,\ t'=1)$. In the B^3-model, the Green function with pole at the origin is spherically symmetric, $\hat{G}^{B^3}_{ij}(\omega;\mathbf{x},\mathbf{0})=f(\omega;|\mathbf{x}|)\,\delta_{ij}+g(\omega;|\mathbf{x}|)x_i x_j$. We map $\hat{G}^{B^3}_{ij}(\omega;\mathbf{x},\mathbf{x}')dx^i dx'^j$ into H^3, and then consider the special coordinate values $\mathbf{x}'=0$, $x^{1,2}=0$, $x^3=(t-1)(t+1)^{-1}$, $z=z'=0$, $t'=1$, with arbitrary $t>0$. [From now on we also put $t'=1$ in the components (4.5)–(4.11) of the resolvent kernel $\hat{R}_{ij}$, in particular $\beta=1/t$.] At these special coordinate values, the result of this transformation is $\hat{R}_{11}dz_1dz'_1+\hat{R}_{22}dz_2dz'_2+\hat{R}_{33}dtdt'$. [If $t>1$, we have to replace β by $1/\beta$ in (4.5)–(4.11), as mentioned above.] Moreover,

$$dx^i dx'^i=(1+t)^{-2}(dz_k dz'_k+dtdt'),\quad x^i x^j dx^i dx'^j=\frac{(t-1)^2}{(t+1)^4}dtdt'. \tag{4.12}$$

(We do not distinguish between x^i and x_i; the i and j-summations are from 1 to 3, the k-summation is from 1 to 2. Also note, that x^j in the second formula is not primed.) Accordingly, we may identify

$$f(\omega;|\mathbf{x}|)=(1+t)^2\hat{R}_{11},\quad g(\omega;|\mathbf{x}|)=\frac{(1+t)^4}{(1-t)^2}(\hat{R}_{33}-\hat{R}_{11}), \tag{4.13}$$

where $t=(1-|\mathbf{x}|)(1+|\mathbf{x}|)^{-1}$ if $t<1$, and $t=(1-|\mathbf{x}|)^{-1}(1+|\mathbf{x}|)$ if $t>1$. In this way we have determined the Green function $\hat{G}^{B^3}_{ij}(\omega;\mathbf{x},\mathbf{0})$ in B^3, with pole at the origin.

Remarks: We have put $t'=1$ in $\hat{R}_{ij}$ for the t-dependence of $t\hat{R}_{ij}$ to be solely via $\beta=1/t$. Equations (4.5)–(4.11) only hold for $\beta>1$, so that we have to choose $t=(1-|\mathbf{x}|)(1+|\mathbf{x}|)^{-1}$, if we use (4.7) and (4.11) in (4.13). As consistency check, the same result is obtained for $f(\omega;|\mathbf{x}|)$ and $g(\omega;|\mathbf{x}|)$, if we insert into (4.13) $\hat{R}_{ij}$ calculated for $\beta<1$ as indicated after (4.11). Then we have to identify $t=(1-|\mathbf{x}|)^{-1}(1+|\mathbf{x}|)$. As pointed out in (4.3), the spectral variable in $\hat{R}_{ij}$ relates to the frequency as $\lambda=\mu^2-\omega^2$.

Next we calculate, by a further symmetry argument, the Green function $\hat{G}^{B^3}_{ij}(\omega;\mathbf{x},\mathbf{y})$ in B^3 with pole at an arbitrary point $\mathbf{y}$. We write for the moment $\hat{\mathbf{x}}$ instead of $\mathbf{x}$, so that $\hat{G}^{B^3}_{ij}(\omega;\hat{\mathbf{x}},\mathbf{0})=f(\omega;|\hat{\mathbf{x}}|)\delta_{ij}+g(\omega;|\hat{\mathbf{x}}|)\hat{x}_i\hat{x}_j$, which is to be regarded as a vector field depending on a dummy index j, solving the vector Eq. (2.30). Whenever we apply a Möbius transformation (i.e., a symmetry transformation of hyperbolic space) to this vector field, it will still solve the invariant Eq. (2.30). We consider the Möbius transformation (3.4), $\hat{\mathbf{x}}=T_{\mathbf{y}}\mathbf{x}$. The components of this transformation can be written in terms of the point-pair invariant $L(\mathbf{x},\mathbf{y})$, cf. (3.5),

$$\frac{\hat{x}_j}{1-|\mathbf{y}|^2}=-\frac{1}{2}\frac{1}{1+L}\frac{\partial L(\mathbf{x},\mathbf{y})}{\partial y_j}, \tag{4.14}$$

and the Jacobian, $\hat{x}_{j,i}:=\partial\hat{x}_j/\partial x_i$, reads as

$$\frac{\hat{x}_{j,i}}{1-|\mathbf{y}|^2}=\frac{1}{2}\frac{1}{(1+L)^2}\left(\frac{\partial L}{\partial x_i}\frac{\partial L}{\partial y_j}-(1+L)\frac{\partial^2 L}{\partial x_i\partial y_j}\right). \tag{4.15}$$

By means of the identities,

$$|\hat{\mathbf{x}}|^2=\frac{L}{1+L}=\frac{|\mathbf{x}-\mathbf{y}|^2}{1-2\mathbf{x}\cdot\mathbf{y}+|\mathbf{x}|^2|\mathbf{y}|^2}, \tag{4.16}$$

$$\frac{1}{1+L}\frac{\partial L}{\partial y_i}\frac{\partial L}{\partial y_i}=\frac{4}{(1-|\mathbf{y}|^2)^2}L, \tag{4.17}$$

we readily find

$$\frac{\hat{x}_k\hat{x}_{k,i}\hat{x}_j}{1-|\mathbf{y}|^2}=-\frac{1}{4}\frac{1}{(1+L)^3}\frac{\partial L}{\partial x_i}\frac{\partial L}{\partial y_j}. \tag{4.18}$$

[Summation over i in (4.17) and k in (4.18) is implied.] Applying the transformation $\hat{\mathbf{x}}=T_{\mathbf{y}}\mathbf{x}$ to $\hat{G}^{B^3}_{ij}(\omega;\hat{\mathbf{x}},\mathbf{0})d\hat{x}_i$, we find

$$\hat{G}^{B^3}_{ij}(\omega;\hat{\mathbf{x}},\mathbf{0})d\hat{x}_i=(1-|\mathbf{y}|^2)\hat{G}^{B^3}_{ij}(\omega;\mathbf{x},\mathbf{y})dx_i, \tag{4.19}$$

$$\hat{G}^{B^3}_{ij}(\omega;\mathbf{x},\mathbf{y}):=f(\omega;|\hat{\mathbf{x}}|)\frac{\hat{x}_{j,i}}{1-|\mathbf{y}|^2}+g(\omega;|\hat{\mathbf{x}}|)\frac{\hat{x}_k\hat{x}_{k,i}\hat{x}_j}{1-|\mathbf{y}|^2}, \tag{4.20}$$

and more explicitly, by inserting (4.16), (4.15), and (4.18),

$$\hat{G}^{B^3}_{ij}(\omega;\mathbf{x},\mathbf{y})=\rho_-\hat{R}_{11}\left(\frac{(1+2L)}{L(L+1)}L_{,i}L_{,j}-2L_{,i,j}\right)-\rho_-\hat{R}_{33}\frac{1}{L(L+1)}L_{,i}L_{,j}, \tag{4.21}$$

with $\rho_-=1+2L-2\sqrt{L(L+1)}$ as defined in (3.7). The index i denotes differentiation with respect to x_i, the index j means differentiation with respect to y_j, and $\hat{R}_{11}$ and $\hat{R}_{33}$ are defined in (4.7) and (4.11), with $t'=1$ and $t=1/\beta=\rho_-=\sqrt{\rho_-/\rho_+}$. Note that $\hat{G}^{B^3}_{ij}(\omega;\mathbf{x},\mathbf{y})$ solely depends on the point-pair invariant $L(\mathbf{x},\mathbf{y})$ and the spectral parameter $\lambda=\mu^2-\omega^2$ (via $\hat{R}_{11}$ and $\hat{R}_{33}$). In the definition (4.20), we have also used a normalization factor $(1-|\mathbf{y}|^2)^{-1}$, to achieve the symmetry $\hat{G}^{B^3}_{ij}(\omega;\mathbf{x},\mathbf{y})=\hat{G}^{B^3}_{ji}(\omega;\mathbf{y},\mathbf{x})$. By construction, $\hat{G}^{B^3}_{ij}(\omega;\mathbf{x},\mathbf{y})$ satisfies the vector Eq. (2.30), with the vector index i corresponding to the argument $\mathbf{x}$. $\hat{G}^{B^3}_{ij}(\omega;\mathbf{x},\mathbf{y})dx_i dy_j$ transforms as a bivector under arbitrary coordinate transformations $\mathbf{x}=h(\mathbf{x}')$, $\mathbf{y}=h(\mathbf{y}')$, and $L(\mathbf{x},\mathbf{y})$ is of course a biscalar. So it is clear how to map $\hat{G}^{B^3}_{ij}(\omega;\mathbf{x},\mathbf{y})$ into the H^3-model; we just have to replace in (4.21) $L(\mathbf{x},\mathbf{y})$ by the H^3-point-pair invariant (3.11). [The biscalars $L(\mathbf{x},\mathbf{y})$ and $L(z,t;z',t')$ relate via the isometry (3.12).]

We also have to check that $\hat{G}^{B^3}_{ij}(\omega;\mathbf{x},\mathbf{y})$ has the right pole. We find in the B^3-model, from (4.21) and the discussion following (4.11),

$$\hat{G}^{B^3}_{ij}(\omega;\mathbf{x},\mathbf{y})\sim\frac{1}{2\pi}\frac{1}{1-|\mathbf{y}|^2}\frac{1}{|\mathbf{x}-\mathbf{y}|}\delta_{ij}, \tag{4.22}$$

which solves

$$-\frac{1}{4}(1-|\mathbf{x}|^2)^2\Delta_{E^3}\hat{G}^{B^3}_{ij}=\gamma_{ij}\frac{1}{\sqrt{\gamma}}\delta(\mathbf{x}-\mathbf{y}), \tag{4.23}$$

where $\gamma_{ij}=4(1-|\mathbf{x}|^2)^{-2}\delta_{ij}$ is the B^3-metric and γ is its determinant. In fact, Eq. (2.30) boils down to (4.23) in leading asymptotic order.

We rewrite $\hat{G}^{B^3}_{ij}(\omega;\mathbf{x},\mathbf{y})$ in terms of the hyperbolic distance function $d(\mathbf{x},\mathbf{y})$, cf. (3.8)–(3.10). As in (4.21), the indices i and j denote differentiation with respect to the first and second argument, respectively. By differentiating Eq. (3.8), we readily find

$$d_{,i}d_{,j}\sinh^2 d=4L_{,i}L_{,j},\quad d_{,i}d_{,j}\cosh d+d_{,i,j}\sinh d=2L_{,i,j}. \tag{4.24}$$

We may now write, instead of (4.21),

$$\hat{G}_{ij}(\omega;\mathbf{x},\mathbf{y})=-e^{-d}(\hat{R}_{11}\sinh d\,d_{,i,j}+\hat{R}_{33}d_{,i}d_{,j}), \tag{4.25}$$

and in (4.7) and (4.11) we put $t'=1$ and $t=1/\beta=e^{-d}$, so that

$$\hat{R}_{11}=\frac{e^d}{4\pi\lambda\sinh^3 d}(e^{-\sqrt{\lambda}d}(1+\lambda\sinh^2 d+\sqrt{\lambda}\sinh d\cosh d)-e^{-\sqrt{1+\lambda}d}(\cosh d+\sqrt{1+\lambda}\sinh d)). \tag{4.26}$$

$$\hat{R}_{33}=\frac{-e^d}{2\pi\lambda\sinh^3 d}(e^{-\sqrt{\lambda}d}(\cosh d+\sqrt{\lambda}\sinh d)-e^{-\sqrt{1+\lambda}d}(\cosh^2 d+(\lambda/2)\sinh^2 d + \sqrt{1+\lambda}\sinh d\cosh d)), \tag{4.27}$$

with $\mathrm{Re}\,\sqrt{\lambda}>0$, and $\mathrm{Re}\,\sqrt{\lambda+1}>0$. The Green function $\hat{G}_{ij}(\omega;\mathbf{x},\mathbf{y})$, explicitly defined by (4.25)–(4.27) depends on the space arguments only via the hyperbolic distance function $d(\mathbf{x},\mathbf{y})$. We have dropped the B^3-superscript, as Eqs. (4.25)–(4.27) are valid in every model of hyperbolic geom-

etry, e.g., in the half-space model H^3, where $d(\mathbf{x},\mathbf{y})$ is to be replaced by the H^3-distance function $d(z,t;z_0,t_0)$, defined by (3.10) and (3.11). As special case, we note the Green function (4.25) with pole at $\mathbf{y}=0$ in the B^3-model,

$$\hat{G}^{B^3}_{ij}(\omega;|\mathbf{x}|,\mathbf{0})=\frac{4\hat{R}_{11}}{(1+r)^2}\,\delta_{ij}+\frac{4(\hat{R}_{33}-\hat{R}_{11})}{(1+r)^2}\,\frac{x_i x_j}{r^2}, \tag{4.28}$$

where $\hat{R}_{11}$ and $\hat{R}_{33}$ are defined by (4.26) and (4.27) and the substitutions

$$\sinh d=\frac{2r}{1-r^2},\quad \cosh d=\frac{1+r^2}{1-r^2},\quad e^d=\frac{1+r}{1-r}, \tag{4.29}$$

cf. (3.5) and (3.8)–(3.10).

Finally we give a direct proof of the completeness relation (B14), which is a good consistency check for the rather lengthy calculations in this section and Appendix C. We start with (4.25), but use for $\hat{R}_{11}$ and $\hat{R}_{33}$ the integral representations in (4.1) and (4.2), with the $(s^2+\lambda)^{-1}$ and $(s^2+1+\lambda)^{-1}$ factors dropped. Instead, we include into these integrals the convergence factor $e^{-\varepsilon s}$ that appears in the spectral measures (B13). In short, by replacing in (4.25) $\hat{R}_{ij}$ by

$$\hat{S}_{ij}:=\frac{1}{2\pi^3}\int_0^\infty ds e^{-\varepsilon s}((s^2+1)C^T_{ij}(s)+s^2C^L_{ij}(s)), \tag{4.30}$$

cf. (4.4) and (C.8), we may write the completeness relation (B14) as

$$-e^{-d}(\hat{S}_{11}\sinh d\, d_{,i,j}+\hat{S}_{33}d_{,i}d_{,j})=\gamma_{ij}\gamma^{-1/2}\delta(\mathbf{x}-\mathbf{y}). \tag{4.31}$$

It is here understood, that the substitutions $t'=1$ and $t=1/\beta=e^{-d}$, as indicated after (4.25), are carried out in the $C^{T,L}_{ij}$-coefficients. It is not difficult to verify (4.31). The various s-integrations in $\hat{S}_{11}$ and $\hat{S}_{33}$ are all standard in the limit $\varepsilon\to 0$. [We put $\varepsilon=0$ whenever the integrals over the individual trigonometric functions in the $C^{T,L}_{ij}$-coefficients converge without regularization, cf. (C8).] We find, with $d\sim 2\sqrt{L}$ for $\mathbf{x}\to\mathbf{y}$,

$$\hat{S}_{11}=4\pi\frac{\beta^2\log\beta}{\beta^2-1}\,\frac{\varepsilon}{(\varepsilon^2+\log^2\beta)^2}=\frac{1}{\pi^2}\,\frac{\varepsilon}{(\varepsilon^2+4L)^2}, \tag{4.32}$$

which is an ε-representation of the δ-function, $\gamma^{-1/2}\delta(\mathbf{x}-\mathbf{y})$, in hyperbolic space, cf. (A16). Moreover, at $\mathbf{x}=\mathbf{y}$,

$$L_{,i,j}=\frac{-2}{(1-|\mathbf{y}|^2)^2}\,\delta_{ij}+O(x_ix_j),\quad L_{,i}L_{,j}=O(x_ix_j), \tag{4.33}$$

and it is easy to check, that the $O(x_ix_j)$-terms entering in (4.31) via (4.24) do not give a contribution for $\varepsilon\to 0$, which proves (4.31) and hence the completeness relation (B14).

V. TIME DEPENDENT GREEN FUNCTIONS

In this section we focus on the Fourier integral (2.28) for the spatial component of the Green function, calculated in (4.25)–(4.27). The time component of the Green function has already been Fourier transformed in Sec. III, cf. (3.15)–(3.30), and a similar procedure is applied in this section to the spatial Fourier component (4.25). The integration paths in (2.28) are specified by substituting for λ in (4.25) one of the four ε-regularizations $\lambda^{\pm}_{(F)}(\omega)$ defined in (3.16). $\lambda^{\pm}$ refers to

retarded (+) and advanced Green functions, and $\lambda_F^{\pm}$ to Feynman (+) and Dyson propagators. Also note that we assumed in the derivation of (4.25) Re $\sqrt{\lambda}>0$, and Re $\sqrt{\lambda+1}>0$. We write the matrix elements (4.26) and (4.27) as

$$\hat R_{11}(\lambda,d)=\frac{e^d}{4\pi\sinh^3 d}\bigg(-\int_0^d\frac{e^{-\sqrt{\lambda}x}}{\sqrt{\lambda}}dx+\frac{e^{-\sqrt{\lambda}d}}{\sqrt{\lambda}}\sinh d\cosh d+e^{-\sqrt{\lambda}d}\sinh^2 d \\ +\int_0^d e^{-\sqrt{1+\lambda}x}\sinh x\,dx\bigg), \tag{5.1}$$

$$\hat R_{33}(\lambda,d)=\frac{e^d}{2\pi\sinh^3 d}\bigg(\cosh d\int_0^d\frac{e^{-\sqrt{\lambda}x}}{\sqrt{\lambda}}dx-\frac{e^{-\sqrt{\lambda}d}}{\sqrt{\lambda}}\sinh d-\cosh d\int_0^d e^{-\sqrt{1+\lambda}x}\sinh x\,dx \\ +\frac{1}{2}e^{-\sqrt{1+\lambda}d}\sinh^2 d\bigg), \tag{5.2}$$

and substitute

$$\frac{e^{-\sqrt{\lambda}d}}{\sqrt{\lambda}}=\frac{2}{\pi}\int_0^\infty\frac{\cos(sd)}{s^2+\lambda}ds,\quad e^{-\sqrt{\lambda}d}=\frac{2}{\pi}\int_0^\infty\frac{s\sin(sd)}{s^2+\lambda}ds, \tag{5.3}$$

and the same with $\lambda\to\lambda+1$, and $d\to x$. (We do not interchange the s and d-integrations here.) Next we define,

$$R^{\pm}_{(F)ij}(\tau,d):=\frac{1}{2\pi}\int_{-\infty}^{\infty}d\omega e^{-i\omega\tau}\hat R_{ij}(\lambda^{\pm}_{(F)}(\omega),d), \tag{5.4}$$

so that retarded and advanced Green functions and Feynman and Dyson propagators read, according to (4.25),

$$G^{\pm}_{(F)ij}(\tau;\mathbf{x},\mathbf{y}):=-e^{-d}(R^{\pm}_{(F)11}(\tau,d)\sinh d\,d_{,i,j}+R^{\pm}_{(F)33}(\tau,d)d_{,i}d_{,j}). \tag{5.5}$$

This complements the time component $G^{\pm}_{(F)00}(\tau,d)$ in (3.15). To evaluate (5.4), we interchange s and ω-integrations. The ω-integration can be carried out as in (3.17) and (3.18), and we arrive at

$$R^{\pm}_{(F)11}(\tau,d)=\frac{e^d}{4\pi\sinh^3 d}\bigg(-\int_0^d S^{\pm}_{0(F)}(\tau,x;\mu)dx+S^{\pm}_{0(F)}(\tau,d;\mu)\sinh d\cosh d \\ +S^{\pm}_{1(F)}(\tau,d;\mu)\sinh^2 d+\int_0^d S^{\pm}_{1(F)}(\tau,x;\sqrt{1+\mu^2})\sinh x\,dx\bigg), \tag{5.6}$$

$$R^{\pm}_{(F)33}(\tau,d)=\frac{e^d}{2\pi\sinh^3 d}\bigg(\cosh d\int_0^d S^{\pm}_{0(F)}(\tau,x;\mu)dx-S^{\pm}_{0(F)}(\tau,d;\mu)\sinh d \\ -\cosh d\int_0^d S^{\pm}_{1(F)}(\tau,x;\sqrt{1+\mu^2})\sinh x\,dx+\frac{1}{2}S^{\pm}_{1(F)}(\tau,d;\sqrt{1+\mu^2})\sinh^2 d\bigg). \tag{5.7}$$

Here, $S^{\pm}_{i(F)}(\tau,d;\mu)$ and $S^{\pm}_{i(F)}(\tau,d;\sqrt{1+\mu^2})$ are defined by

$$S^{\pm}_{0(F)}(\tau,d;\mu):=\frac{1}{\pi^2}\int_0^\infty\cos(sd)I^{\pm}_{(F)}(\omega_0,\tau)ds,$$

$$S^{\pm}_{1(F)}(\tau,d;\mu) := \frac{1}{\pi^2}\int_0^\infty s\,\sin(sd) I^{\pm}_{(F)}(\omega_0,\tau)\,ds, \tag{5.8}$$

$$I^{\pm}(\omega_0,\tau) := \mp \pi i \omega_0^{-1}(e^{i\omega_0\tau} - e^{-i\omega_0\tau})\,\theta(\pm\tau),\quad I^{\pm}_F(\omega_0,\tau) := \pm \pi i \omega_0^{-1} e^{\mp i\omega_0|\tau|},$$

with $\omega_0 := \sqrt{s^2+\mu^2}$, and $\mathrm{Re}\,\omega_0 > 0$. Sometimes we will write ω_0^T for ω_0, the frequency of the transversal modes; the longitudinal frequency relates to the spectral parameter via $\omega_0^L := \sqrt{s^2+1+\mu^2}$, $\mathrm{Re}\,\omega_0^L > 0$. Evidently, $S^{\pm}_{i(F)}(\tau,d;\sqrt{1+\mu^2})$ is obtained by replacing in (5.8) ω_0 by ω_0^L. The terms in (5.6) and (5.7) depending on $S^{\pm}_{i(F)}(\tau,d;\mu)$ stem from the transversal modes in the spectral resolution, cf. the derivation of (4.26) and (4.27), whereas the terms containing $S^{\pm}_{i(F)}(\tau,d;\sqrt{1+\mu^2})$ are generated by the longitudinal modes. Clearly, $S_1 = -\partial S_0/\partial d$. The coefficients (5.8) are calculated via an integral representation of modified Bessel functions,[15] quite analogously to the scalar case (3.19) and (3.20),

$$S^{\pm}_i(\tau,d;\mu) = \pm \pi i(\tilde{S}_i(\tau,d;\mu) - \tilde{S}_i(-\tau,d;\mu))\,\theta(\pm\tau), \tag{5.9}$$

$$S^{\pm}_{iF}(\tau,d;\mu) = \pm \pi i \tilde{S}_i(\pm|\tau|,d;\mu), \tag{5.10}$$

where we have defined

$$\tilde{S}_0(\tau,d;\mu) := \frac{1}{\pi^2}\int_0^\infty \cos(sd)\tilde{I}(\omega_0,\tau)\,ds = \frac{1}{\pi^2} K_0(\mu\sqrt{d^2+(i\tau+\varepsilon)^2}), \tag{5.11}$$

$$\tilde{S}_1(\tau,d;\mu) := \frac{1}{\pi^2}\int_0^\infty s\,\sin(sd)\tilde{I}(\omega_0,\tau)\,ds = \frac{\mu d}{\pi^2}\,\frac{K_1(\mu\sqrt{d^2+(i\tau+\varepsilon)^2})}{\sqrt{d^2+(i\tau+\varepsilon)^2}}, \tag{5.12}$$

with $\tilde{I}(\omega_0,\tau) := \omega_0^{-1} e^{-(i\tau+\varepsilon)\omega_0}$, and the same with $\mu \to \sqrt{1+\mu^2}$. Performing the limit $\varepsilon \to 0$, cf. (3.21)–(3.27), we find

$$\begin{aligned}\tilde{S}_0(\tau,d;\mu) = {} & \frac{1}{\pi^2}\,\theta(d^2-\tau^2) K_0(\mu\sqrt{d^2-\tau^2}) - \frac{1}{2\pi}\,\theta(\tau^2-d^2) \\ & \times (N_0(\mu\sqrt{\tau^2-d^2}) + i\varepsilon(\tau) J_0(\mu\sqrt{\tau^2-d^2})),\end{aligned} \tag{5.13}$$

$$\begin{aligned}\tilde{S}_1(\tau,d;\mu) = {} & -\frac{i}{\pi} d\,\varepsilon(\tau)\,\delta(d^2-\tau^2) + \frac{\mu d}{\pi^2}\,\frac{\theta(d^2-\tau^2)}{\sqrt{d^2-\tau^2}} K_1(\mu\sqrt{d^2-\tau^2}) \\ & + \frac{\mu d}{2\pi}\,\frac{\theta(\tau^2-d^2)}{\sqrt{\tau^2-d^2}} (N_1(\mu\sqrt{\tau^2-d^2}) + i\varepsilon(\tau) J_1(\mu\sqrt{\tau^2-d^2})),\end{aligned} \tag{5.14}$$

and the $\tilde{S}_i(\tau,d;\sqrt{1+\mu^2})$ are obtained by the substitution $\mu \to \sqrt{1+\mu^2}$, of course; $\varepsilon(\tau)$ is the sign function. In the calculation of (5.13) and (5.14), we used the second and third formula in (A10), as well as (3.22) and (3.23), and[15]

$$K_0(\pm ix) = -(\pi/2)(N_0(x) \pm i J_0(x)),\quad x > 0, \tag{5.15}$$

$$\begin{aligned}K_0(z) &= -\gamma - \log(z/2) + O(z^2\log z),\quad J_0(z) = 1 + O(z^2), \\ N_0(z) &= (2/\pi)(\gamma + \log(z/2)) + O(z^2\log z).\end{aligned} \tag{5.16}$$

The integrals in (5.6) and (5.7) are calculated via (5.9) and (5.10), by making use of (5.13) and (5.14),

$$\int_0^d \tilde{S}_0(\tau,x;\mu)dx=\frac{1}{\pi^2}\,\theta(d^2-\tau^2)\int_0^{\sqrt{d^2-\tau^2}}\frac{K_0(\mu y)ydy}{\sqrt{\tau^2+y^2}}-\frac{1}{2\pi}\bigg(\theta(\tau^2-d^2)\int_{\sqrt{\tau^2-d^2}}^{|\tau|}$$
$$+\theta(d^2-\tau^2)\int_0^{|\tau|}\bigg)(N_0(\mu y)+i\varepsilon(\tau)J_0(\mu y))\,\frac{ydy}{\sqrt{\tau^2-y^2}}, \tag{5.17}$$

$$\int_0^d \tilde{S}_1(\tau,x;\sqrt{1+\mu^2})\sinh x\,dx=-\frac{i}{2\pi}\,\theta(d^2-\tau^2)\varepsilon(\tau)\sinh|\tau|+\frac{\sqrt{\mu^2+1}}{\pi^2}\,\theta(d^2-\tau^2)$$
$$\times\int_0^{\sqrt{d^2-\tau^2}}K_1(\sqrt{\mu^2+1}y)\sinh\sqrt{\tau^2+y^2}dy+\frac{\sqrt{\mu^2+1}}{2\pi}$$
$$\times\bigg(\theta(\tau^2-d^2)\int_{\sqrt{\tau^2-d^2}}^{|\tau|}+\theta(d^2-\tau^2)\int_0^{|\tau|}\bigg)(N_1(\sqrt{\mu^2+1}y)$$
$$+i\varepsilon(\tau)J_1(\sqrt{\mu^2+1}y))\sinh\sqrt{\tau^2-y^2}dy. \tag{5.18}$$

In the $\theta(d^2-\tau^2)$-terms, there are singularities in K_1 and N_1 for $y\to 0$, cf. (3.23), which, however, cancel each other. As a consistency check, we note $\int_0^d\tilde{S}_1^T(\tau,x)dx=\tilde{S}_0^T(\tau,0)-\tilde{S}_0^T(\tau,d)$, which can readily be verified by $(J_0',N_0',K_0')(z)=-(J_1,N_1,K_1)(z)$. The integrals in (5.17) and (5.18) are of indefinite type and cannot be further evaluated in closed form, but this representation is sufficiently explicit to reveal the singularity and asymptotic structure and in particular the support of the propagators. The most surprising feature is perhaps, that the Feynman and Dyson propagators defined by (5.10) have an infrared singularity for $\mu\to 0$. Hence, for the electromagnetic field, these propagators are ill-defined by the standard contour integration, unless one uses some kind of infrared regularization such as a finite photon mass. This is an effect of the space curvature; if one approximates in (5.6) and (5.7), in the limit of large curvature radius, $\cosh d\sim 1$, and $\sinh d\sim d$, then the $\log\mu$ singularities stemming from N_0 and K_0 cancel each other. (Throughout the calculations, we have put the curvature radius of the 3-space equal to one, but it can readily be restored by dimensional considerations, see below.) In retarded and advanced Green functions, cf. (5.9), the $\log\mu$-singularities cancel without performing this curvature limit. It would be interesting to investigate whether the infrared divergence of the quantum propagators can affect the emission probability of soft photons.[16] If so, one could possibly draw inferences on the curvature sign.

Making use of (5.13), (5.14), (5.17), and (5.18), we readily find

$$S_0^{\pm}(\tau,d;\mu)=\theta(\pm\tau)\,\theta(\tau^2-d^2)J_0(\mu\sqrt{\tau^2-d^2}),$$
$$S_1^{\pm}(\tau,d;\mu)=2d\,\theta(\pm\tau)\,\delta(d^2-\tau^2)-\mu d\,\theta(\pm\tau)\,\frac{\theta(\tau^2-d^2)}{\sqrt{\tau^2-d^2}}J_1(\mu\sqrt{\tau^2-d^2}), \tag{5.19}$$

$$\int_0^d S_0^{\pm}(\tau,x;\mu)dx=\theta(\pm\tau)\bigg(\theta(\tau^2-d^2)\int_{\sqrt{\tau^2-d^2}}^{|\tau|}+\theta(d^2-\tau^2)\int_0^{|\tau|}\bigg)J_0(\mu y)\,\frac{ydy}{\sqrt{\tau^2-y^2}}, \tag{5.20}$$

$$\int_0^d S_1^{\pm}(\tau,x;\sqrt{1+\mu^2})\sinh x\,dx$$
$$=\theta(\pm\tau)\,\theta(d^2-\tau^2)\sinh|\tau|-\sqrt{\mu^2+1}\,\theta(\pm\tau)$$
$$\times\bigg(\theta(\tau^2-d^2)\int_{\sqrt{\tau^2-d^2}}^{|\tau|}+\theta(d^2-\tau^2)\int_0^{|\tau|}\bigg)J_1(\sqrt{\mu^2+1}y)\sinh\sqrt{\tau^2-y^2}dy,$$

and the $S_i^{\pm}(\tau,d;\sqrt{1+\mu^2})$ are obtained by the substitution $\mu\to\sqrt{1+\mu^2}$. The retarded and advanced Green functions $G_{ij}^{\pm}(\tau;\mathbf{x},\mathbf{y})$ of a massive vector field are thus given by (5.5)–(5.7), with (5.19) and (5.20) inserted. The analogous coefficients for the Feynman propagator read as

$$S_{0F}^{+}(\tau,d;\mu)=\frac{i}{\pi}\,\theta(d^2-\tau^2)K_0(\mu\sqrt{d^2-\tau^2})+\frac{1}{2}\,\theta(\tau^2-d^2)(J_0(\mu\sqrt{\tau^2-d^2})-iN_0(\mu\sqrt{\tau^2-d^2})),$$

$$\begin{aligned}S_{1F}^{+}(\tau,d;\mu)&=d\,\delta(d^2-\tau^2)+\frac{i\mu d}{\pi}\,\frac{\theta(d^2-\tau^2)}{\sqrt{d^2-\tau^2}}K_1(\mu\sqrt{d^2-\tau^2})\\&\quad-\frac{\mu d}{2}\,\frac{\theta(\tau^2-d^2)}{\sqrt{\tau^2-d^2}}(J_1(\mu\sqrt{\tau^2-d^2})-iN_1(\mu\sqrt{\tau^2-d^2})),\end{aligned}\tag{5.21}$$

$$\begin{aligned}\int_0^d S_{0F}^{+}(\tau,x;\mu)dx&=\frac{i}{\pi}\,\theta(d^2-\tau^2)\int_0^{\sqrt{d^2-\tau^2}}\frac{K_0(\mu y)y\,dy}{\sqrt{\tau^2+y^2}}+\frac{1}{2}\Bigg(\theta(\tau^2-d^2)\int_{\sqrt{\tau^2-d^2}}^{|\tau|}+\theta(d^2-\tau^2)\\&\quad\times\int_0^{|\tau|}\Bigg)(J_0(\mu y)-iN_0(\mu y))\,\frac{y\,dy}{\sqrt{\tau^2-y^2}},\end{aligned}\tag{5.22}$$

$$\begin{aligned}\int_0^d S_{1F}^{+}(\tau,x;\sqrt{1+\mu^2})\sinh x\,dx&=\frac{1}{2}\,\theta(d^2-\tau^2)\sinh|\tau|+\frac{i}{\pi}\sqrt{\mu^2+1}\,\theta(d^2-\tau^2)\\&\quad\times\int_0^{\sqrt{d^2-\tau^2}}K_1(\sqrt{\mu^2+1}y)\sinh\sqrt{\tau^2+y^2}\,dy-\frac{1}{2}\sqrt{\mu^2+1}\\&\quad\times\Bigg(\theta(\tau^2-d^2)\int_{\sqrt{\tau^2-d^2}}^{|\tau|}+\theta(d^2-\tau^2)\int_0^{|\tau|}\Bigg)(J_1(\sqrt{\mu^2+1}y)\\&\quad-iN_1(\sqrt{\mu^2+1}y))\sinh\sqrt{\tau^2-y^2}\,dy.\end{aligned}$$

The coefficients for the Dyson propagator are obtained by complex conjugation, $S_{iF}^{-}(\tau,d;\mu)=\overline{S_{iF}^{+}(\tau,d;\mu)}$.

In the retarded and advanced propagators, the limit $\mu\to 0$ can be performed, and we find

$$\begin{aligned}G_{ij}^{\pm}(\tau;\mathbf{x},\mathbf{y};\mu=0)&=-e^{-d/R}(R_{11}^{\pm}(\tau,d;\mu=0)\sinh(d/R)Rd_{,i,j}\\&\quad+R_{33}^{\pm}(\tau,d;\mu=0)d_{,i}d_{,j}),\end{aligned}\tag{5.23}$$

with the matrix elements, cf. (5.19) and (5.20),

$$\begin{aligned}R_{11}^{\pm}(\tau,d;\mu=0)&=\frac{e^{d/R}\theta(\pm\tau)}{4\pi R^2\sinh^3(d/R)}\Bigg[2dR\sinh^2\Big(\frac{d}{R}\Big)\delta(d^2-c^2\tau^2)+\theta(c^2\tau^2-d^2)\\&\quad\times\Bigg(-\frac{d}{R}+\sinh\frac{d}{R}\cosh\frac{d}{R}-\frac{1}{R}\int_{\sqrt{c^2\tau^2-d^2}}^{c|\tau|}J_1(y/R)\sinh(R^{-1}\sqrt{c^2\tau^2-y^2})dy\Bigg)\\&\quad+\theta(d^2-c^2\tau^2)\Bigg(-\frac{c|\tau|}{R}+\sinh\frac{c|\tau|}{R}\\&\quad-\frac{1}{R}\int_0^{c|\tau|}J_1(y/R)\sinh(R^{-1}\sqrt{c^2\tau^2-y^2})dy\Bigg)\Bigg],\end{aligned}\tag{5.24}$$

$$R^{\pm}_{33}(\tau,d;\mu=0)=\frac{e^{d/R}\theta(\pm\tau)}{2\pi R^2\sinh^3(d/R)}\Bigg[dR\sinh^2\!\left(\frac{d}{R}\right)\delta(d^2-c^2\tau^2)+\theta(c^2\tau^2-d^2)$$
$$\times\Bigg(\frac{d}{R}\cosh\frac{d}{R}-\sinh\frac{d}{R}-\frac{d}{2}\sinh^2\!\left(\frac{d}{R}\right)\frac{J_1(R^{-1}\sqrt{c^2\tau^2-d^2})}{\sqrt{c^2\tau^2-d^2}}$$
$$+\cosh\!\left(\frac{d}{R}\right)\frac{1}{R}\int_{\sqrt{c^2\tau^2-d^2}}^{c|\tau|}J_1(y/R)\sinh(R^{-1}\sqrt{c^2\tau^2-y^2})\,dy\Bigg)+\theta(d^2-c^2\tau^2)$$
$$\times\cosh\frac{d}{R}\left(\frac{c|\tau|}{R}-\sinh\frac{c|\tau|}{R}+\frac{1}{R}\int_0^{c|\tau|}J_1(y/R)\sinh(R^{-1}\sqrt{c^2\tau^2-y^2})\,dy\right)\Bigg]. \tag{5.25}$$

We have here restored the natural units, the curvature radius R of the 3-space, and c. [The exponentials drop out, of course, we just have them included to be consistent with the previous notation, and they are also convenient when considering the $d\to\infty$ asymptotics, see after (6.14).] In the B^3-model, we recover for $R\to\infty$ the Green functions in Minkowski space, cf. the discussion preceding (3.31). In fact, $dd_{,i,j}+d_{,i}d_{,j}\sim-4\delta_{ij}$, so that (5.23) boils down to

$$G^{\pm}_{ij}(\tau;\mathbf{x},\mathbf{y};\mu=0,\ R\to\infty)\sim\frac{1}{2\pi}4\delta_{ij}\theta(\pm\tau)\delta(4|\mathbf{x}-\mathbf{y}|^2-c^2\tau^2), \tag{5.26}$$

supported only at the light cone. By a rescaling of the space coordinates, one can get rid of the two factors of 4. One can sometimes switch from negative to positive curvature just by analtyic continuation in the curvature radius, and it would be interesting to check in how far this persists here.

Up to now we considered a static RW cosmology [expansion factor $a(\tau)=1$]; the retarded and advanced electromagnetic Green functions as defined by (3.30) and (5.23) remain valid, with minor modifications, in a general RW cosmology, $ds^2=-d\tau^2+a^2(\tau)d\sigma^2$. In the spectral elementary waves (2.15) and (2.16), we have to substitute $\tau\to\int_{\tau_0}^{\tau}a^{-1}(\tau)d\tau$ into the exponentials, so that the frequencies of the transversal and longitudinal waves scale as $|s|a^{-1}(\tau)$ and $\sqrt{s^2+1}a^{-1}(\tau)$, respectively. In addition, the longitudinal time component A^L_0 in (2.16) has to be rescaled by a factor $a^{-1}(\tau)$. In the Green functions (3.30) and (5.23), we have to perform the same substitution for the time variable, and then to scale $G^{\pm}_{00}$ by a factor $(a(\tau)a(\tau_0))^{-1}$. These modifications only apply to the massless case, $\mu=0$, as a consequence of the conformal coupling of the electromagnetic field. If the rest mass is finite, a time separation of (2.4)–(2.6) is still possible, so that the time independent part of the spectral problem, in particular the resolvent kernel calculated in Secs. III and IV, also applies to a RW cosmology with arbitrary expansion factor without modifications. However, the time dependence of the eigenfunctions is then not any more exponential as in (2.15) and (2.16), and has to be calculated from scratch, and the integral transform (2.28) relating the time dependent Green functions to the resolvent kernel must be modified accordingly. In a Milne universe with linear expansion factor, $a(\tau)=(c/R)\tau$, it should be possible to obtain quite explicit formulas for the massive propagators.[17]

Remark: The time component $G^{\pm}_{00(F)}(\mu^2=-1)$, if scaled in the indicated way with the expansion factor, also defines the propagators of the conformally coupled Klein–Gordon equation, as discussed at the end of Sec. III. The limit $\mu^2\to-1$ can easily be carried out in (3.25) and (3.26). By a standard scaling argument[2] applied to (3.32), we find

$$(\Box-\hat{R}/6)G^{\pm}_{00(F)}(\tau,d;\mu^2=-1)=a^{-3}(\tau)\delta_{B^3}(\mathbf{x},\mathbf{y})\delta(\tau), \tag{5.27}$$

where $\Box$ is the d'Alembertian of the RW-line element, and

$$\hat{R} := 6\left(\frac{-1}{a^2} + \frac{\ddot{a}}{a} + \frac{\dot{a}^2}{a^2}\right) \tag{5.28}$$

is the Ricci scalar. The spectral elementary waves, solving $(\Box - \hat{R}/6)\psi = 0$, read

$$\psi = a^{-1}(\tau)\exp\left(\pm is\int a^{-1}(\tau)d\tau\right)P^{1+is}, \tag{5.29}$$

with the Poisson kernel P as defined in (2.17).

VI. GREEN FUNCTIONS IN RW COSMOLOGIES WITH MULTIPLY CONNECTED HYPERBOLIC 3-SPACE

We start with the time independent Green functions $\hat{G}_{00}(\omega;\mathbf{x},\mathbf{y})$, cf. (3.6) and $\hat{G}_{ij}(\omega;\mathbf{x},\mathbf{y})$, cf. (4.25). For λ, we substitute $\lambda^{\pm}_{(F)}(\omega)$ as in (3.16) and write accordingly, in the B^3-model, $\hat{G}^{\pm}_{(F)00}(\omega;\mathbf{x},\mathbf{y})$ and $\hat{G}^{\pm}_{(F)ij}(\omega;\mathbf{x},\mathbf{y})$, as at the beginning of Sec. V. We will switch between the B^3 and H^3-models whenever convenient; in the H^3-model, we write $\hat{G}^{\pm}_{(F)\alpha\beta}(\omega;z,t;z_0,t_0)$. Green functions on multiply connected hyperbolic manifolds can formally be obtained by periodizing B^3 or H^3-Green functions with the covering group Γ,

$$\hat{G}^{\Gamma\pm}_{(F)00}(\omega;\mathbf{x},\mathbf{y}) := \sum_{\gamma\in\Gamma}\hat{G}^{\pm}_{(F)00}(\omega;\gamma\mathbf{x},\mathbf{y}), \tag{6.1}$$

$$\hat{G}^{\Gamma\pm}_{(F)ij}(\omega;\mathbf{x},\mathbf{y}) := \sum_{\gamma\in\Gamma}\hat{G}^{\pm}_{(F)kj}(\omega;\gamma\mathbf{x},\mathbf{y})[\gamma'\mathbf{x}]_{ki}; \tag{6.2}$$

the scalar case (6.1) is well documented.[6,9,10,18] The Jacobian $[\gamma'\mathbf{x}]$ in (6.2) is readily calculated by making use of the representation[5] $\gamma(\mathbf{x}) = kT_{\gamma^{-1}(\mathbf{0})}\mathbf{x}$, with a constant matrix $k\in\mathrm{SO}(3)$; the Jacobian of $T_{\mathbf{y}}\mathbf{x}$ is given in (4.15).

The hard part is of course to show that the series (6.1) and (6.2) converge, see after (6.11). We restrict this investigation to hyperbolic manifolds that admit a finitely sided fundamental polyhedron without parabolic cusp singularities. The covering group Γ is a Kleinian group,[19–24] a discrete subgroup of $\mathrm{SL}(2,C)/\{\pm id\}$ acting via 3D Möbius transformations in B^3 or H^3. Γ is finitely generated, and does not contain parabolic (or elliptic) elements. As for the Hausdorff dimension δ of the limit set of Γ, the manifold is open if $0\leqslant\delta<2$, so that the fundamental polyhedron has faces on the boundary of H^3; it is compact if $\delta=2$, in this case the fundamental polyhedron does not touch the boundary. The domain defined by the polyhedral faces on the boundary is denoted by f; it is a fundamental domain of Γ acting via Möbius (i.e., linear fractional) transformations in the complex plane. Examples for open hyperbolic manifolds are solid handle-bodies with Schottky covering groups;[19] the limit sets of these groups are Cantor sets with $0<\delta<1$. Another class of open hyperbolic manifolds are thickened Riemann surfaces, hollow handle bodies, with (quasi-) Fuchsian[20] covering groups, whose limit sets are closed Jordan curves with Hausdorff dimensions $1\leqslant\delta<2$. As mentioned, the faces of the fundamental polyhedron corresponding to the surfaces of these 3D handle bodies lie on the boundary at infinity of hyperbolic space, i.e., in the complex plane, if we use the H^3-model, and so these manifolds are open. In the following only manifolds with $0\leqslant\delta<1$ are considered, to assure the convergence of the series (6.1) and (6.2).

The periodization in (6.1) and (6.2) may as well be with respect to $\mathbf{y}$, because $\hat{G}^{\pm}_{(F)00}$ and $\hat{G}^{\pm}_{(F)ij}$ are scalar and vectorial point-pair invariants, respectively,

$$\hat{G}^{\pm}_{(F)00}(\omega;\gamma\mathbf{x},\gamma\mathbf{y}) = \hat{G}^{\pm}_{(F)00}(\omega;\mathbf{x},\mathbf{y}), \tag{6.3}$$

$$\hat{G}^{\pm}_{(F)ij}(\omega;\gamma\mathbf{x},\gamma\mathbf{y})[\gamma'\mathbf{x}]_{im}[\gamma'\mathbf{y}]_{jn}=\hat{G}^{\pm}_{(F)mn}(\omega;\mathbf{x},\mathbf{y}),$$
$$\hat{G}^{\pm}_{(F)kn}(\omega;\gamma\mathbf{x},\mathbf{y})[\gamma'\mathbf{x}]_{km}=\hat{G}^{\pm}_{(F)mk}(\omega;\mathbf{x},\gamma^{-1}\mathbf{y})[\gamma^{-1\prime}\mathbf{y}]_{kn}. \tag{6.4}$$

These symmetries hold for every Möbius transformation in B^3, unrelated to the covering group Γ, because $\hat{G}^{\pm}_{(F)00}$ and $\hat{G}^{\pm}_{(F)ij}$ are functions of the scalar point-pair invariant $L(\mathbf{x},\mathbf{y})$, and the vectorial invariants $\partial L/\partial x_i \partial L/\partial y_j$ and $\partial^2 L/\partial x_i \partial y_j$. The periodization (6.1) and (6.2) may be replaced by a Γ-periodization with respect to $\mathbf{y}$ (and j). To see this, we replace in (6.3) and (6.4) $\mathbf{x}$ by $\gamma^{-1}\mathbf{x}$, and because the summation in (6.1) and (6.2) is over the whole group, we may replace there γ by γ^{-1}. By a similar reasoning, (6.3) and (6.4) still holds for the periodized functions (6.1) and (6.2), provided $\gamma\in\Gamma$.

The spectral representation of $\hat{G}^{\Gamma\pm}_{(F)\alpha\beta}$ is readily derived in the half-space model H^3. Starting with the scalar time component, we define the Eisenstein series[6,9,10]

$$E(z,t;\xi,1+is):=\sum_{\gamma\in\Gamma} P^{1+is}(\gamma(z,t);\xi)=\sum_{\gamma\in\Gamma}|\gamma'\xi|^{1+is}P^{1+is}(z,t;\gamma\xi), \tag{6.5}$$

where we used the symmetry (2.24), which also implies

$$E(\gamma(z,t);\xi,1+is)=E(z,t;\xi,1+is),\quad |\gamma'\xi|^{1+is}E(z,t;\gamma\xi,1+is)=E(z,t;\xi,1+is), \tag{6.6}$$

for $\gamma\in\Gamma$. In the first equation in (2.16), we substitute the series (6.5) for P^{1+is}, which amounts to periodizing the H^3-eigenfunctions with respect to the hyperbolic lattice. The series (6.5) converges for the indicated covering groups (with $\delta<1$), see after (6.11). It is easy to see, that the orthogonality and completeness relations (A12) and (A14) remain valid for $E(z,t;\xi,1\pm is)$ with some obvious modifications; apart from replacing $P^{1\pm is}$ by $E(z,t;\xi,1\pm is)$, the domain of integration (H^3) in (A12) has to be restricted to a fundamental polyhedron F of the covering group, and in (A14) the domain of integration ($R^2\times R^+$) is restricted to $f\times R^+$, where f is a fundamental domain of Γ in the complex plane. [The formal procedures to show this, and to derive (6.7) and (6.10) below, are quite similar to those indicated in (6.24) and (6.25).] It should be stressed, that these statements are only safe for the specified covering groups. For example, the series (6.5) diverges for covering groups as defined after (6.2) with $\delta\geqslant 1$, and analytic continuation is needed to define it for real s. This is not only a technicality, because bound states emerge in addition to the continuous spectrum,[6] and the set (6.5) is not complete.

If $\delta<1$, the completeness relation (A14) holds with the indicated modifications, and we may write, analogously to (3.13),

$$\hat{G}^{\Gamma\pm}_{(F)00}(\omega;z,t;z_0,t_0)=-\int_{f\times R^+} d\sigma(\xi,s)\,\frac{E(z,t;\xi,1+is)E(z_0,t_0;\xi,1-is)}{s^2+1+\lambda^{\pm}_{(F)}(\omega)}, \tag{6.7}$$

with the spectral measure defined in (A13). The formal identity of (6.7) with (6.1) can be easily shown by means of the completeness relation and the spectral representation (3.13) in the covering space, along the lines of (6.24) and (6.25).

The spatial component of the resolvent kernel admits a similar representation. The vectorial analog to (6.5) reads as[13]

$$\mathbf{a}_j^{\Gamma T_L}(z,t;\xi,s):=\sum_{\gamma\in\Gamma}\mathbf{a}_i^{T_L}(\gamma(z,t);\xi,s)[\gamma'(z,t)]_{ij}=\sum_{\gamma\in\Gamma}|\gamma'\xi|^{is}\overline{\gamma'\xi}\,\mathbf{a}_j^{T_L}(z,t;\gamma\xi,s),$$
$$\mathbf{a}_j^{\Gamma T_R}(z,t;\xi,s):=\sum_{\gamma\in\Gamma}|\gamma'\xi|^{is}\gamma'\xi\,\mathbf{a}_j^{T_R}(z,t;\gamma\xi,s), \tag{6.8}$$
$$\mathbf{a}_j^{\Gamma L}(z,t;\xi,s):=\sum_{\gamma\in\Gamma}|\gamma'\xi|^{1+is}\mathbf{a}_j^{L}(z,t;\gamma\xi,s),$$

with the invariance property, cf. (6.6),

$$\mathbf{a}_i^{\Gamma T_L}(\gamma(z,t);\xi,s)[\gamma'(z,t)]_{ij}=\mathbf{a}_j^{\Gamma T_L}(z,t;\xi,s)=|\gamma'\xi|^{is}\overline{\gamma'\xi}\mathbf{a}_j^{\Gamma T_L}(z,t;\gamma\xi,s), \tag{6.9}$$

and analogous relations hold for the right circular and longitudinal polarizations. These Eisenstein series are obtained by periodizing the circularly polarized transversal vectors $\mathbf{a}_j^{T_{L,R}}$ as defined in (2.22), and the longitudinal vector $\mathbf{a}_j^L$ in (2.20). The symmetries (2.23) have been invoked in (6.8) and (6.9). Again, for the indicated covering groups (with $\delta<1$), these series converge for real s, see the discussion following (6.11). The spatial components of the eigenfunctions in (2.15) and (2.16) get periodized (and circularly polarized) by replacing there $\mathbf{a}_j^{T_k,L}$ by (6.8), and then they solve again the Γ-invariant Eq. (2.6). The vectors in (6.8) are orthogonal, cf. (B4)–(B6), and the completeness relation (B14) stays valid with the substitutions $\mathbf{a}^{T_k,L}\to\mathbf{a}^{\Gamma T_{L,R},L}$ and the above-mentioned restriction of the domain of integration to a fundamental domain. Accordingly, the spectral resolution of the matrix elements (4.1) and (4.2) reads

$$\begin{aligned}\hat{R}_{ij}^{\Gamma T}(z,t;z_0,t_0;\lambda)&:=\int_{f\times R^+}\sum_{k=L,R}\mathbf{a}_i^{\Gamma T_k}(z,t;\xi,s)\overline{\mathbf{a}_j^{\Gamma T_k}(z_0,t_0;\xi,s)}\frac{d\sigma^T(\xi,s)}{s^2+\lambda},\\ \hat{R}_{ij}^{\Gamma L}(z,t;z_0,t_0;\lambda)&:=\int_{f\times R^+}\mathbf{a}_i^{\Gamma L}(z,t;\xi,s)\overline{\mathbf{a}_j^{\Gamma L}(z_0,t_0;\xi,s)}\frac{d\sigma^L(\xi,s)}{s^2+1+\lambda},\end{aligned} \tag{6.10}$$

and the spectral representation of the periodized spatial Green function is thus found as

$$\hat{G}_{(F)ij}^{\Gamma\pm}(\omega;z,t;z_0,t_0)=\hat{R}_{ij}^{\Gamma T}(z,t;z_0,t_0;\lambda_{(F)}^{\pm}(\omega))+\hat{R}_{ij}^{\Gamma L}(z,t;z_0,t_0;\lambda_{(F)}^{\pm}(\omega)). \tag{6.11}$$

[The k-summation in $\hat{R}_{ij}^{\Gamma T}$ is over left and right circular polarizations, which may as well be replaced by linearly polarized states, according to (2.22).] The spectral measures in (6.10) remain as defined in (B13), but the domain of the ξ-integration is restricted to a fundamental domain f in the complex plane.

The Poisson kernel $P(z,t;\gamma\xi)$ as well as the components of the vectors $\mathbf{a}^{T_{L,R},L}(z,t;\gamma\xi,s)$ are bounded for $\gamma\in\Gamma$, and hence the convergence abscissa of the Eisenstein series (6.5) and (6.8) coincides with that of the Poincaré series $\Sigma_{\gamma\in\Gamma}|\gamma'\xi|^{1+is}$. (The limit set is the set of accumulation points of the orbit $\gamma\xi$, by the way.) As for the covering groups indicated after (6.2), this series is known to converge only for $\mathrm{Re}(1+is)>\delta$, cf. Ref. 6.

To obtain the convergence behavior of the Poincaré series (6.1) and (6.2), we need an estimate on $\hat{G}_{(F)\alpha\beta}^{\pm}(\omega;\mathbf{x},\mathbf{y})$ [defined by (3.6) and (4.25)] for $d\to\infty$, which means for $|\mathbf{x}|\to1$, and $\mathbf{y}$ fixed, or vice versa. For the time component, this is easily settled, $\hat{G}_{00}(\omega;\mathbf{x},\mathbf{y})=O(\exp(-(1+\tilde{\varepsilon})d(\mathbf{x},\mathbf{y})))$, with $\tilde{\varepsilon}:=\mathrm{Re}\,\sqrt{1+\lambda}$, cf. (3.6). When calculating the real space Green functions (3.15), the limit $\tilde{\varepsilon}\to0$ is attained.

Next we turn to the $d\to\infty$ asymptotics of the space component and the Jacobian in (6.2). In the B^3-model, we can readily calculate $(\log L)_{,i,j}$, cf. (3.5), in the limit $|\mathbf{x}|\to1$,

$$\frac{L_{,i,j}}{L}-\frac{L_{,i}L_{,j}}{L^2}\sim\frac{-4}{1-2\mathbf{xy}+\mathbf{y}^2}\left(\frac{1}{2}\,\delta_{ij}-\frac{(x_i-y_i)(x_j-y_j)}{1-2\mathbf{xy}+\mathbf{y}^2}\right). \tag{6.12}$$

[As in (4.21), i means differentiation with respect to x_i, and j with respect to y_j.] Likewise, for $|\mathbf{x}|\to1$,

$$\frac{L_{,i}L_{,j}}{L^2}\sim\frac{4x_i(2y_j(1-\mathbf{xy})-x_j(1-\mathbf{y}^2))}{(1-\mathbf{x}^2)(1-\mathbf{y}^2)(1-2\mathbf{xy}+\mathbf{y}^2)}. \tag{6.13}$$

Moreover, we find from (4.24), for $L\to\infty$,

$$d_{,i}d_{,j}\sim L_{,i}L_{,j}/L^2=O(L),$$
$$\sinh(d)d_{,i,j}\sim 2L_{,i,j}-2\frac{L_{,i}L_{,j}}{L}+\frac{L_{,i}L_{,j}}{L^2}=O(L), \tag{6.14}$$

Clearly, $L\sim e^d/4$, so that $e^{-d}d_{,i}d_{,j}=O(1)$, as well as $e^{-d}\sinh(d)d_{,i,j}=O(1)$, for $d\to\infty$. Accordingly, $\hat{R}_{11}=O(e^{-\sqrt{\lambda}d})$, and $\hat{R}_{33}=O(e^{-\sqrt{1+\lambda}d})$, cf. (4.26) and (4.27), and hence the asymptotics of the Green function (4.25) is evident, $\hat{G}_{ij}(\omega;\mathbf{x},\mathbf{y})=O(\exp(-\tilde{\varepsilon}d(\mathbf{x},\mathbf{y})))$, with $\tilde{\varepsilon}:=\min(\mathrm{Re}\,\sqrt{\lambda},\mathrm{Re}\,\sqrt{1+\lambda})>0$. In the integration procedures for the time dependent Green functions, cf. (5.4) and (3.16), the limit $\tilde{\varepsilon}\to 0$ is again reached. In (6.2), the estimate for $\hat{G}_{ij}$ has still to be multiplied with the estimate for the Jacobian $[\gamma'\mathbf{x}]$.

As for the Jacobian $\hat{x}_{j,i}$ of $T_{\mathbf{y}}\mathbf{x}$, cf. (4.15), we find, for fixed $\mathbf{x}$ and $|\mathbf{y}|\to 1$, $\hat{x}_{j,i}=O(1-|\mathbf{y}|)$. We write $\gamma(\mathbf{x})=kT_{\gamma^{-1}(\mathbf{0})}\mathbf{x}$, with an orthogonal matrix k, as pointed out after (6.2). We thus obtain, for $|\gamma^{-1}(\mathbf{0})|\to 1$, the estimate $[\gamma'\mathbf{x}]_{mn}=O(1-|\gamma^{-1}\mathbf{0}|)$. Using $L(\mathbf{0},\gamma(\mathbf{y}))=L(\gamma^{-1}(\mathbf{0}),\mathbf{y})$, we find $[\gamma'\mathbf{x}]_{mn}=O(1-|\gamma\mathbf{y}|)$, for $|\gamma\mathbf{y}|\to 1$, with fixed $\mathbf{x}$ and $\mathbf{y}$, for every Kleinian group, and so we may write $[\gamma'\mathbf{x}]_{mn}=O(\exp(-d(\mathbf{y},\gamma\mathbf{x})))=O(\exp(-d(\gamma\mathbf{y},\mathbf{x})))$. (The geometric reasoning underlying such estimates, also with regard to uniformity in fundamental domains, is explained in Ref. 5.) We conclude, that the convergence of the series (6.1) and (6.2) is decided by the convergence of $\Sigma_{\gamma\in\Gamma}\exp(-d(\gamma\mathbf{x},\mathbf{y}))$, uniformly in $\lambda=\lambda^{\pm}_{(F)}(\varepsilon,\omega)$, for real ω and $\varepsilon\to 0$. The Poincaré series $\Sigma_{\gamma\in\Gamma}\exp(-\alpha d(\gamma\mathbf{x},\mathbf{y}))$ and $\Sigma_{\gamma\in\Gamma}|\gamma'\xi|^{\alpha}$ have the same abscissa of convergence. Accordingly, in the case of the covering groups specified after (6.2), we can use the series (6.1) and (6.2) only if $\delta<1$, which also happens to be the criterion for the convergence of the Eisenstein series (6.5) and (6.8).

The time-dependent Green function on the 4-manifold is defined as the Fourier transform of (6.1) and (6.2), cf. (2.28), (3.15), and (5.4),

$$G^{\Gamma\pm}_{(F)\alpha\beta}(\tau;\mathbf{x},\mathbf{y})=(2\pi)^{-1}\int_{-\infty}^{+\infty}d\omega e^{-i\omega\tau}\hat{G}^{\Gamma\pm}_{(F)\alpha\beta}(\omega;\mathbf{x},\mathbf{y}). \tag{6.15}$$

By formally interchanging summation and integration, we find

$$G^{\Gamma\pm}_{(F)00}(\tau;\mathbf{x},\mathbf{y})=\sum_{\gamma\in\Gamma}G^{\pm}_{(F)00}(\tau;\gamma\mathbf{x},\mathbf{y}), \tag{6.16}$$

$$G^{\Gamma\pm}_{(F)ij}(\tau;\mathbf{x},\mathbf{y})=\sum_{\gamma\in\Gamma}G^{\pm}_{(F)kj}(\tau;\gamma\mathbf{x},\mathbf{y})[\gamma'\mathbf{x}]_{ki}, \tag{6.17}$$

which means periodization of the real space Green functions defined in (3.28), (3.29), and (5.5)–(5.7). The convergence of the series (6.16) and (6.17) can be estimated as above, $G^{\pm}_{(F)00}(\tau;\mathbf{x},\mathbf{y})=O(e^{-d})$, uniformly in τ, for $|\mathbf{x}|\to 1$ and fixed $\mathbf{y}$, which follows from (3.28), (3.29), the asymptotics of the Bessel functions there, and (A10). Likewise, $G^{\pm}_{(F)ij}(\tau;\mathbf{x},\mathbf{y})=O(1)$, which follows from (5.5)–(5.7) and (5.19)–(5.22). The Jacobian in (6.17) is $O(e^{-d})$, so that we end up, like above, with $\Sigma_{\gamma\in\Gamma}e^{-d}$, as series determining the convergence of (6.16) and (6.17). Hence, for geometrically finite covering groups, without parabolic and elliptic elements, and with $\delta<1$, the propagators on the hyperbolic manifold are obtained by periodizing the corresponding Green functions in the covering space. Clearly, the symmetry (6.3) and (6.4) also applies to $G^{\Gamma\pm}_{(F)\alpha\beta}(\tau;\mathbf{x},\mathbf{y})$, for $\gamma\in\Gamma$.

Finally we point out a method to obtain wave solutions on the multiply connected manifold, that does not make explicit use of the periodized Green functions. This is not only useful for $\delta\geqslant 1$, when the above series fail to converge, but also if $\delta<1$, because the series $\Sigma_{\gamma\in\Gamma}|\gamma'\xi|^{\alpha}$ is not known for its rapid convergence.[21] Wave fields satisfying the field Eqs. (2.1) on the multiply connected 4-manifold are obtained as

$$A^{\Gamma}_{\alpha}(\tau,\mathbf{x})=\int_{F\times R} G^{\Gamma}_{\alpha\alpha'}(\tau-\tau';\mathbf{x},\mathbf{x}')j^{\Gamma\alpha'}(\tau',\mathbf{x}')dV_{B^3}d\tau' \tag{6.18}$$

analogously to (2.26). The spatial integration is over a fundamental polyhedron F, and $G^{\Gamma}_{\alpha\alpha'}$ denotes a linear combination of the propagators $G^{\Gamma\pm}_{(F)\alpha\beta}$, with coefficients adding up to unity, so that $G^{\Gamma}_{\alpha\alpha'}$ solves (2.25). The current is periodic with respect to the covering group,

$$j^{\Gamma 0}(\tau,\gamma\mathbf{x})=j^{\Gamma 0}(\tau,\mathbf{x}),\ \ [\gamma'\mathbf{x}]^{-1ik}j^{\Gamma k}(\tau,\gamma\mathbf{x})=j^{\Gamma i}(\tau,\mathbf{x}), \tag{6.19}$$

and so is the resulting vector potential,

$$A^{\Gamma}_{0}(\tau,\gamma\mathbf{x})=A^{\Gamma}_{0}(\tau,\mathbf{x}),\ \ A^{\Gamma}_{k}(\tau,\gamma\mathbf{x})[\gamma'\mathbf{x}]_{ki}=A^{\Gamma}_{i}(\tau,\mathbf{x}), \tag{6.20}$$

as $G^{\Gamma}_{\alpha\alpha'}$ admits the symmetries stated in (6.3) and (6.4) for $\gamma\in\Gamma$. The current density $j^{\Gamma\alpha}(\tau,\mathbf{x})$ is usually obtained by periodizing a density $j^{\alpha}(\tau,\mathbf{x})$ in B^3 or H^3,

$$j^{\Gamma 0}(\tau,\mathbf{x})=\sum_{\gamma\in\Gamma} j^{0}(\tau,\gamma\mathbf{x}),\ \ j^{\Gamma i}(\tau,\mathbf{x})=\sum_{\gamma\in\Gamma}[\gamma'\mathbf{x}]^{-1ik}j^{k}(\tau,\gamma\mathbf{x}). \tag{6.21}$$

Alternatively to (6.18), we may periodize the wave field

$$A_{\alpha}(\tau,\mathbf{x})=\int_{B^3\times R} G_{\alpha\alpha'}(\tau-\tau';\mathbf{x},\mathbf{x}')j^{\alpha'}(\tau',\mathbf{x}')dV_{B^3}d\tau', \tag{6.22}$$

where $G_{\alpha\alpha'}$ is again a linear combination of the propagators $G^{\pm}_{(F)\alpha\beta}$ in the covering space, so that

$$A^{\Gamma}_{0}(\tau,\mathbf{x})=\sum_{\gamma\in\Gamma} A_0(\tau,\gamma\mathbf{x}),\quad A^{\Gamma}_{i}(\tau,\mathbf{x})=\sum_{\gamma\in\Gamma} A_k(\tau,\gamma\mathbf{x})[\gamma'\mathbf{x}]_{ki}\,. \tag{6.23}$$

This periodization is formally equivalent to (6.18), by way of (6.21), (6.16), and (6.17),

$$\sum_{\gamma\in\Gamma} A_0(\tau,\gamma\mathbf{x})=\sum_{\gamma\in\Gamma}\sum_{\beta\in\Gamma}\int_{F\times R} G_{00}(\tau-\tau';\beta^{-1}\gamma\mathbf{x},\mathbf{x}')j^{0}(\tau',\beta\mathbf{x}')dV_{B^3}(\mathbf{x}')d\tau', \tag{6.24}$$

$$\begin{aligned}\sum_{\gamma\in\Gamma} A_k(\tau,\gamma\mathbf{x})[\gamma'\mathbf{x}]_{ki}=&\sum_{\gamma\in\Gamma}\sum_{\beta\in\Gamma}\int_{F\times R} G_{ab}(\tau-\tau';\beta^{-1}\gamma\mathbf{x},\mathbf{x}')\\ &\times[\beta^{-1\prime}(\gamma\mathbf{x})]_{ak}[\gamma'\mathbf{x}]_{ki}[\beta^{-1\prime}(\beta\mathbf{x}')]_{bm}j^{m}(\tau',\beta\mathbf{x}')dV_{B^3}(\mathbf{x}')d\tau'.\end{aligned} \tag{6.25}$$

Here we at first used $B^3=\cup_{\beta\in\Gamma}\beta(F)$, and then the invariance of the hyperbolic volume element, $dV_{B^3}(\beta\mathbf{x})=dV_{B^3}(\mathbf{x})$, as well as the point-pair invariance (6.3) and (6.4). The first two Jacobians in (6.25) can be replaced by $[(\beta^{-1}\gamma)'\mathbf{x}']_{ai}$, and the third by $[\beta'\mathbf{x}']^{-1bm}$. (As for Jacobians in Poincaré series, we do not distinguish between sub- and superscripts and avoid mixed indices; the summation convention applies whenever two indices are equal.) Next we pull the $\gamma\in\Gamma$ summation under the integral sign. As this summation is over the whole group Γ, we may drop the β^{-1} in $G_{\alpha\beta}$ and in the Jacobian, and obtain in this way $G^{\Gamma}_{\alpha\alpha'}$. The periodized current $j^{\Gamma\alpha}$ is finally recovered by pulling the $\beta\in\Gamma$ summation under the integral sign. In (6.23), no explicit use is made of the Green functions (6.16) and (6.17) on the 4-manifold.

ics, Bangalore. The hospitality and stimulating atmosphere of the Center for Nonlinear Dynamics, Bharathidasan University, Trichy, the Institute of Mathematical Sciences, Madras, and the Tata Institute of Fundamental Research, Bombay, are likewise gratefully acknowledged.

APPENDIX A: ORTHOGONALITY, COMPLETENESS, AND THE RESOLVENT KERNEL FOR THE LONGITUDINAL TIME COMPONENT

We calculate the resolvent kernel (3.14), and the spectral measure for the time component of the eigenvectors (2.16). The results obtained in this appendix are not new, and a more detailed account on the spectral theory of the hyperbolic Laplace–Beltrami operator, without explicit use of distributions, can be found in Refs. 9 and 10. I include this appendix, because the scalar Green function happens to be the time component of the electromagnetic propagators, and the integral (A1) is also a prerequisite for the calculation of the spatial resolvent kernel in Appendix B.

The key convolution of H^3-spectral theory is

$$C_{\alpha,\beta}(z_1,t_1;z_2,t_2)=\int_{R^2}(|z_1-\xi|^2+t_1^2)^{-\alpha}(|z_2-\xi|^2+t_2^2)^{-\beta}d\xi, \tag{A1}$$

with $z_i\in R^2$, and $t_i>0$. The exponents are complex numbers, and the convergence properties of this integral will turn out in the course of the calculation. We shift the integration variable, and use a Feynman parametrization for both factors, $x^{-\gamma}=\Gamma^{-1}(\gamma)\int_0^\infty s^{\gamma-1}e^{-xs}ds$. Then the ξ-integration gets Gaussian, and we obtain

$$C_{\alpha,\beta}=\frac{\pi}{\Gamma(\alpha)\Gamma(\beta)}\int_0^\infty\int_0^\infty ds_1ds_2\frac{s_1^{\alpha-1}s_2^{\beta-1}}{s_1+s_2}\exp\left(-\frac{|z_1-z_2|^2s_1s_2}{s_1+s_2}-s_1t_1^2-s_2t_2^2\right). \tag{A2}$$

Next we perform the transformation $s_1=us$, $s_2=(1-u)s$, $0\leqslant s\leqslant\infty$, $0\leqslant u\leqslant 1$, with the Jacobian $s=s_1+s_2$. The s-integration is trivial, and we are left with

$$C_{\alpha,\beta}=\pi\Gamma(\alpha+\beta-1)\Gamma^{-1}(\alpha)\Gamma^{-1}(\beta)\int_0^1 duu^{\alpha-1}(1-u)^{\beta-1}(|z_1-z_2|^2u(1-u)+ut_1^2+(1-u)t_2^2)^{1-(\alpha+\beta)}. \tag{A3}$$

We may write, by means of the transformation $y=(t_1/t_2)u(1-u)^{-1}$,

$$\begin{aligned}C_{\alpha,\beta}t_1^\alpha t_2^\beta&=\int_{R^2}P^\alpha(z_1,t_1;\xi)P^\beta(z_2,t_2;\xi)d\xi\\&=\frac{\pi\Gamma(\alpha+\beta-1)}{\Gamma(\alpha)\Gamma(\beta)}t_2^{2-\alpha-\beta}\int_0^\infty\frac{dyy^{\alpha-1}(1+(t_2/t_1)y)^{\alpha+\beta-2}}{(1+2(1+2L)y+y^2)^{\alpha+\beta-1}},\end{aligned} \tag{A4}$$

with the H^3-Poisson kernel and the Selberg point-pair invariant,

$$P(z,t;\xi):=\frac{t}{|z-\xi|^2+t^2},\quad L(z_1,t_1;z_2,t_2):=\frac{|z_1-z_2|^2+(t_1-t_2)^2}{4t_1t_2}, \tag{A5}$$

respectively. We specify $\alpha+\beta=2$, and writing L for $L(z_1,t_1;z_2,t_2)$, we find

$$C_{\alpha,2-\alpha}t_1^\alpha t_2^{2-\alpha}=\frac{\pi}{4}\frac{1}{1-\alpha}\frac{\rho_+^{1-\alpha}-\rho_-^{1-\alpha}}{\sqrt{L(1+L)}}, \tag{A6}$$

with $\rho_\pm:=1+2L\pm2\sqrt{L(L+1)}$, cf. (3.7). Finally, we put $\alpha=1+is$, and obtain the kernel (3.14) as

$$k(s,d) := C_{1+is,1-is} t_1^{1+is} t_2^{1-is} = \pi \frac{\sin(sd)}{s \sinh(d)}, \tag{A7}$$

with the hyperbolic distance function $d = \log \rho_+(L)$.

The scalar orthogonality relation for the longitudinal time component in (2.16) can be derived from

$$\begin{aligned} \tilde{\delta}(\xi,\xi';\alpha,\beta;\varepsilon) &= \int_0^\infty dt C_{\alpha,\beta}(\xi,t;\xi',t) t^{\alpha+\beta-3+\varepsilon} \\ &= \frac{\pi}{2} \frac{\Gamma(\alpha+\beta-1)}{\Gamma(\alpha)\Gamma(\beta)} |\xi-\xi'|^{\varepsilon-\alpha-\beta} \\ &\quad \times B\left(\frac{\alpha-\beta+\varepsilon}{2}, \frac{\beta-\alpha+\varepsilon}{2}\right) B\left(\frac{\alpha+\beta-2+\varepsilon}{2}, \frac{\alpha+\beta-\varepsilon}{2}\right). \end{aligned} \tag{A8}$$

We used here the representation (A3) and interchanged integrations. We put $\alpha = 1+is$, $\beta = 1-it$, and write

$$\delta(\xi,\xi';s,t) := \tilde{\delta}(\xi,\xi';1+is,1-it;\varepsilon) = \frac{\pi}{s^2} |\xi-\xi'|^{\varepsilon-2+i(t-s)} \frac{i\varepsilon}{t-s+i\varepsilon}, \tag{A9}$$

where we have dropped higher orders in ε. $\delta(\xi,\xi';s,t)$ is a distribution concentrated at $\xi=\xi'$, $t=s$. Next we note two ε-representations of the Dirac δ-function, as well as two other well known formulas frequently used in this paper, cf. Ref. 25,

$$\delta(x) = \frac{1}{\pi} \frac{\varepsilon}{x^2+\varepsilon^2}, \quad \mp \pi i \delta(x) = \frac{1}{x \pm i\varepsilon} - P\frac{1}{x}, \quad \pm \pi i \theta(-x) = \log(x \pm i\varepsilon) - \log|x|,$$

$$\delta(d^2-\tau^2) = (2d)^{-1}(\delta(d-\tau) + \delta(d+\tau)). \tag{A10}$$

By integrating over a test function in $R^2 \times R^+$, and making use of the first formula in (A10), one can easily show that

$$\delta(\xi,\xi';s,t) = 2\pi^3 s^{-2} \delta(\xi-\xi') \delta(s-t). \tag{A11}$$

$\delta(\xi-\xi')$ is the Dirac function in R^2. The orthogonality relation for the time component of the vectors (2.16), which satisfy the homogeneous scalar Eq. (2.5), now follows from (A1), (A8), (A9), and (A11),

$$\int_{H^3} dV_{H^3} P^{1+is}(z,t;\xi) P^{1-it}(z,t;\xi') = 2\pi^3 s^{-2} \delta(\xi-\xi') \delta(s-t). \tag{A12}$$

The H^3-volume element is $dV_{H^3} = t^{-3} dt dz_1 dz_2$. Accordingly, we find the spectral measure

$$d\sigma(\xi,s) := (2\pi^3)^{-1} s^2 e^{-\varepsilon s} d\xi ds \tag{A13}$$

on $R^2 \times R^+$. A convergence factor $e^{-\varepsilon s}$ is included to obtain an ε-representation of the δ-function via the completeness relation; a principal value as regularization is likewise possible.[10] The eigenfunctions P^{1+is} satisfy $-\Delta_{H^3} P^{1+is} = (s^2+1) P^{1+is}$.

Once the spectral measure is found, one can write down the completeness relation,

$$\int_{R^2 \times R^+} d\sigma(\xi,s) P^{1+is}(z,t;\xi) P^{1-is}(z_0,t_0;\xi) = \delta_{H^3}(z,t;z_0,t_0), \tag{A14}$$

or, more explicitly,

$$\delta(L,\varepsilon):=(2\pi^3)^{-1}\int_0^\infty k(s,d(L))e^{-\varepsilon s}s^2ds=\frac{1}{2\pi^2}\,\frac{\log\rho_+}{\sqrt{L(1+L)}}\,\frac{\varepsilon}{(\log^2\rho_++\varepsilon^2)^2}. \tag{A15}$$

If we expand in $\sqrt{L}$ and drop terms vanishing for $\varepsilon\to 0$, we find an ε-representation of the δ-function in hyperbolic space,

$$\delta(L(z,t;z_0,t_0),\varepsilon)=\frac{1}{\pi^2}\,\frac{\varepsilon}{(\varepsilon^2+4L)^2}=\delta_{H^3}(z,t;z_0,t_0), \tag{A16}$$

with L as in (A5). This can easily be checked by integration with a test function, preferably in the B^3-model; $\delta_{B^3}(\mathbf{x};\mathbf{x}_0)$ is obtained by replacing in (A16) $L(z,t;z_0,t_0)$ by the B^3-invariant $L(\mathbf{x},\mathbf{x}_0)$ as defined in (3.5). We may of course assume $\mathbf{x}_0=0$, because L is invariant with respect to the symmetry group of B^3, which includes the transformations (3.4), and then use polar coordinates and a Taylor expansion of the test function $f(\mathbf{x})$ in $\int_{B^3}dV_{B^3}f(\mathbf{x})\delta_{B^3}(\mathbf{x};\mathbf{x}_0)=f(\mathbf{x}_0)$; the B^3-volume element is $dV_{B^3}=8(1-|\mathbf{x}|^2)^{-3}d^3\mathbf{x}$.

APPENDIX B: TRANSVERSAL AND LONGITUDINAL SPECTRAL MEASURES FOR THE SPATIAL COMPONENT OF THE PROCA EQUATION

To calculate the space component of the resolvent kernel, we need the spectral measure in the completeness relation for the eigenvectors $\mathbf{a}^{T_{1,2},L}$, cf. (2.18) and (2.19), which can be extracted from the orthogonality relation derived in this appendix. The basic integral in this relation was already calculated in (A8),

$$\int_{H^3}P^\alpha(z,t;\xi)P^\beta(z,t;\xi')dzt^\gamma dt=\frac{\pi}{2}\,\frac{|\xi-\xi'|^{3-\alpha-\beta+\gamma}}{\Gamma(\alpha)\Gamma(\beta)\Gamma(3+\gamma)}\Gamma\left(\frac{\alpha-\beta+\gamma+3}{2}\right)\Gamma\left(\frac{3-\alpha+\beta+\gamma}{2}\right)$$
$$\times\Gamma\left(\frac{\alpha+\beta+\gamma+1}{2}\right)\Gamma\left(\frac{\alpha+\beta-\gamma-3}{2}\right), \tag{B1}$$

with the Poisson kernel P as defined in (A5) and arbitrary complex numbers α, β, and γ. (At this point there is no need to discuss convergence, though this is not hard to do; H^3 means here of course $R^2\times R^+$.) The orthogonality relation can be derived by differentiating this formula with respect to $\xi:=(\xi_1,\xi_2)$ and $\xi':=(\xi_1',\xi_2')$. Defining $e:=\varepsilon+i(s'-s)$, we find in leading asymptotic order, for $s'\to s$ and $\varepsilon\to 0$,

$$\int_{H^3}P^{is}(z,t;\xi)P^{-is'}(z,t;\xi')dzt^{-1+\varepsilon}dt\sim\frac{2\pi s^2}{e\overline{e}(1+e/2)}|\xi-\xi'|^{2+e},$$

$$\int_{H^3}P^{1+is}P^{1-is'}dzt^{-1+\varepsilon}dt\sim-\frac{\pi}{e}|\xi-\xi'|^e,$$

$$\int_{H^3}P^{2+is}P^{2-is'}dzt^{-1+\varepsilon}dt\sim\frac{\pi}{2(s^2+1)}(1+\overline{e}/2)|\xi-\xi'|^{-2+e}, \tag{B2}$$

$$\int_{H^3}P^{2+is}P^{-is'}dzt^{-1+\varepsilon}dt=\int P^{is}P^{2-is'}dzt^{-1+\varepsilon}dt\sim-\frac{\pi}{e}|\xi-\xi'|^e,$$

which readily follows from (B1), by expanding the Γ-functions.

In the eigenvectors (2.18), we may replace the z-differentiations by ξ-differentiations, $\partial/\partial z_i\to-\partial/\partial\xi_i$. [Note that in this appendix $z=(z_1,z_2)$, whereas in Appendix A the z_i are themselves complex.] We define $D_{ij}:=\partial^2/\partial\xi_i^2-\partial^2/\partial\xi_j^2$, and analogously D'_{ij} for ξ', so that

$$
\begin{aligned}
&D_{12}D'_{12}|\xi-\xi'|^{2+e}=(e+2)e[4(e-1)|\xi-\xi'|^{e-2}+((\xi_1-\xi'_1)^2\\
&\quad-(\xi_2-\xi'_2)^2)^2(e-2)(e-4)|\xi-\xi'|^{e-6}],\\
&\frac{\partial^4}{\partial\xi_1\partial\xi_2\partial\xi'_1\partial\xi'_2}|\xi-\xi'|^{2+e}=(e+2)e((e-1)|\xi-\xi'|^{e-2}+(\xi_1-\xi'_1)^2\\
&\qquad\times(\xi_2-\xi'_2)^2(e-2)(e-4)|\xi-\xi'|^{e-6}),\\
&D_{12}|\xi-\xi'|^e=D'_{12}|\xi-\xi'|^e=e(e-2)((\xi_1-\xi'_1)^2-(\xi_2-\xi'_2)^2)|\xi-\xi'|^{e-4},\\
&\frac{\partial^2}{\partial\xi_1\partial\xi'_1}|\xi-\xi'|^e=-e|\xi-\xi'|^{e-2}-e(e-2)(\xi_1-\xi'_1)^2|\xi-\xi'|^{e-4}.
\end{aligned}
\tag{B3}
$$

We thus find, by combining (2.18), (B2), and (B3),

$$
\begin{aligned}
&\int_{H^3}\mathbf{a}^{T_1}(s,\xi)\cdot\overline{\mathbf{a}^{T_1}(s',\xi')}dzt^{-1+\varepsilon}dt\\
&\quad=\frac{1}{(1+is)(1-is')}\left(\frac{1}{16ss'}D_{12}P^{is}(\xi)D'_{12}P^{-is'}(\xi')+(1+is)\right.\\
&\qquad\times(1-is')P^{2+is}(\xi)P^{2-is'}(\xi')+\frac{1+is}{4is'}P^{2+is}(\xi)D'_{12}P^{-is'}(\xi')\\
&\qquad-\frac{1-is'}{4is}P^{2-is'}(\xi')D_{12}P^{is}(\xi)+\frac{1}{4ss'}\frac{\partial^2}{\partial\xi_1\partial\xi_2}P^{is}(\xi)\frac{\partial^2}{\partial\xi'_1\partial\xi'_2}P^{-is'}(\xi')\\
&\qquad\left.+\frac{\partial}{\partial\xi_1}P^{1+is}(\xi)\frac{\partial}{\partial\xi'_1}P^{1-is'}(\xi')\right)\\
&\quad=\frac{\pi}{(s^2+1)}\frac{\varepsilon}{\bar{e}}|\xi-\xi'|^{e-2}=\int\mathbf{a}^{T_2}\cdot\overline{\mathbf{a}^{T_2}}dzt^{-1+\varepsilon}dt.
\end{aligned}
\tag{B4}
$$

We dropped here the (z,t)-arguments in the eigenfunctions and Poisson kernels. The t^{-1}-factor in the integral derives from the hyperbolic metric $\gamma_{ij}=t^{-2}\delta_{ij}$, via $\gamma^{ij}a_ia_j\sqrt{\gamma}$, and the ε-regularization is used to obtain an ε-representation of the δ-functions in the orthogonality relation. In fact, by integrating over a test function, one can readily show that

$$
(\varepsilon/\bar{e})|\xi-\xi'|^{e-2}=2\pi^2\delta(\xi-\xi')\delta(s-s'),
\tag{B5}
$$

with $\bar{e}:=\varepsilon-i(s'-s)$. Similarly, for the longitudinal vectors in (2.18),

$$
\begin{aligned}
&\int_{H^3}\mathbf{a}^{L}(s,\xi)\cdot\overline{\mathbf{a}^{L}(s',\xi')}dzt^{-1+\varepsilon}dt\\
&\quad=\frac{1}{(1+is)(1-is')}\left(\frac{\partial}{\partial\xi_1}P^{1+is}(\xi)\frac{\partial}{\partial\xi'_1}P^{1-is'}(\xi')+\frac{\partial}{\partial\xi_2}P^{1+is}(\xi)\frac{\partial}{\partial\xi'_2}P^{1-is'}(\xi')\right)\\
&\qquad+\frac{1}{t^2}P^{1+is}(\xi)P^{1-is'}(\xi')+4P^{2+is}(\xi)P^{2-is'}(\xi')-\frac{2}{t}P^{1+is}(\xi)P^{2-is'}(\xi')\\
&\qquad-\frac{2}{t}P^{2+is}(\xi)P^{1-is'}(\xi')=\frac{\pi}{s^2}\frac{\varepsilon}{\bar{e}}|\xi-\xi'|^{e-2}.
\end{aligned}
\tag{B6}
$$

Here we used (B2), (B3), and in addition,

$$\int_{H^3} P^{1+is}P^{1-is'}dzt^{-3+\varepsilon}dt\sim\frac{\pi\varepsilon}{\overline{es}s'}|\xi-\xi'|^{e-2},$$

$$\int_{H^3} P^{1+is}P^{2-is'}dzt^{-2+\varepsilon}dt\sim\frac{\pi}{2}\frac{\varepsilon}{(1-is')is'}|\xi-\xi'|^{e-2}, \tag{B7}$$

$$\int_{H^3} P^{2+is}P^{1-is'}dzt^{-2+\varepsilon}dt\sim-\frac{\pi}{2}\frac{\varepsilon}{(1+is)is}|\xi-\xi'|^{e-2},$$

which follows from (B1) for $s'\to s$ and $\varepsilon\to 0$. Equations (B4) and (B6), with (B5) substituted, constitute the orthogonality relations for the vector fields (2.18), if complemented by $\mathbf{a}^{Ti}(z,t;\xi,s)\cdot\mathbf{a}^{L}(z,t;\xi',s')\equiv 0$. The orthogonality of the longitudinal and transversal subspaces can readily be checked via (2.17), or via (2.18) and (2.19) and the following identities for the Poisson kernel,

$$\frac{\partial^2 P^\alpha}{\partial z_1\partial z_2}=\frac{\alpha}{1+\alpha}\frac{1}{P^{2+\alpha}}\frac{\partial P^{1+\alpha}}{\partial z_1}\frac{\partial P^{1+\alpha}}{\partial z_2}, \tag{B8}$$

$$D_{ij}P^\alpha=\frac{\alpha}{1+\alpha}\frac{1}{P^{2+\alpha}}\left(\left(\frac{\partial P^{1+\alpha}}{\partial z_i}\right)^2-\left(\frac{\partial P^{1+\alpha}}{\partial z_j}\right)^2\right), \tag{B9}$$

$$\left(\frac{\partial P^{1+\alpha}}{\partial z_1}\right)^2+\left(\frac{\partial P^{1+\alpha}}{\partial z_2}\right)^2=4(1+\alpha)^2P^{4+2\alpha}\left(\frac{1}{tP}-1\right), \tag{B10}$$

$$\frac{\partial P^{1+\alpha}}{\partial t}\frac{\partial P^{1+\beta}}{\partial t}+\frac{\partial P^{1+\alpha}}{\partial z_i}\frac{\partial P^{1+\beta}}{\partial z_i}=(1+\alpha)(1+\beta)\frac{P^{2+\alpha+\beta}}{t^2}, \tag{B11}$$

$$-\Delta_{H^3}P^\alpha(z,t;\xi)=\alpha(2-\alpha)P^\alpha(z,t;\xi). \tag{B12}$$

α and β are complex constants; the Laplace–Beltrami operator Δ_{H^3} is defined in (2.5), and the D_{ij} are defined either with z_i-derivatives as in (2.18) or with ξ_i-derivatives as after (B2); summation over i is implied in (B11).

The spectral measures for the transversal and longitudinal components can be read off from (B4)–(B6),

$$d\sigma^T(\xi,s):=\frac{s^2+1}{2\pi^3}e^{-\varepsilon s}d\xi ds,\quad d\sigma^L(\xi,s):=\frac{s^2}{2\pi^3}e^{-\varepsilon s}d\xi ds, \tag{B13}$$

the domain of integration is $R^2\times R^+$. As in (A13), we have included a convergence factor $e^{-\varepsilon s}$ needed in the completeness relation,

$$\int_{R^2\times R^+}\sum_{k=1,2}\mathbf{a}_i^{T_k}(z,t;\xi,s)\overline{\mathbf{a}_j^{T_k}(z',t';\xi,s)}d\sigma^T(\xi,s)$$
$$+\int_{R^2\times R^+}\mathbf{a}_i^{L}(z,t;\xi,s)\overline{\mathbf{a}_j^{L}(z',t';\xi,s)}d\sigma^L(\xi,s)=\gamma_{ij}\delta_{H^3}(z,t;z',t'), \tag{B14}$$

where δ_{H^3} denotes the δ-function in H^3, as defined in (A16). A check of this relation, by explicit calculation of the integrals, is given at the end of Sec. IV.

APPENDIX C: MATRIX ELEMENTS APPEARING IN THE SPATIAL RESOLVENT KERNEL

We will calculate the matrix elements (4.4), that is $C_{ij}^{T_k}:=\int_{R^2}\mathbf{a}_i^{T_k}\overline{\mathbf{a}_j^{T_k}}d\xi$, $C_{ij}^{T}:=C_{ij}^{T_1}+C_{ij}^{T_2}$, and $C_{ij}^{L}:=\int_{R^2}\mathbf{a}_i^{L}\overline{\mathbf{a}_j^{L}}d\xi$, with eigenfunctions as defined in (2.18) and (2.19), at $z=z'=0$. We consider, at first for arbitrary z and z', cf. (A4),

$$K(a,b;L;t,t'):=\int_{R^2}P^a(z,t;\xi)P^b(z',t';\xi)d\xi$$
$$=\frac{\pi\Gamma(a+b-1)}{\Gamma(a)\Gamma(b)}t'^{2-a-b}\int_0^\infty\frac{dyy^{a-1}(1+(t'/t)y)^{a+b-2}}{(1+2(1+2L)y+y^2)^{a+b-1}},\tag{C1}$$

with the H^3-point-pair invariant $L(z,t;z',t')$ as in (3.11), and define

$$K(a,b):=K(a,b;L;t,t')\big|_{z=z'=0},\quad K'(a,b):=\partial K(a,b;L;t,t')/\partial L\big|_{z=z'=0},\tag{C2}$$

and analogously $K''(a,b)$, where a and b are arbitrary complex numbers, so that the integrals converge. It is understood that the L-differentiation is carried out before the y-integration in (C1), to take care of the poles of $\Gamma(a+b-1)$. In the following, we put $\beta:=t'/t$, so that, at $z=z'=0$, $1+2(1+2L)y+y^2=(1+\beta y)(1+\beta^{-1}y)$. We also introduce the shortcuts $L_{,i}=\partial L/\partial z_i\big|_{z=z'=0}$ and $L_{,i'}=\partial L/\partial z_i'\big|_{z=z'=0}$, with $z=:(z_1,z_2)$ and $z'=:(z_1',z_2')$, and analogously for higher order derivatives. Evidently, $z_{1,2}$-derivatives of $K(a,b;L;t,t')$ at $z=z'=0$ are obtained via $\partial K/\partial z_i=:K_{,i}=K'(a,b)L_{,i}$, etc. We will only use $z_{1,2}$ and $z_{1,2}'$-derivatives, always at $z=z'=0$; t and t'-derivatives are not needed in the following. The only nonvanishing derivatives of L are $L_{,i,j}=(2tt')^{-1}\delta_{ij}$, $L_{,i,j'}=-(2tt')^{-1}\delta_{ij'}$, and $L_{,i',j'}=(2tt')^{-1}\delta_{i'j'}$. Accordingly, the only nonvanishing $z_{1,2}$-derivatives of $K(a,b;L;t,t')$ at $z=z'=0$ are, up to the fourth order

$$K_{,1,1}(a,b)=K_{,2,2}=(2tt')^{-1}K'(a,b),$$
$$K_{,1,1,2,2}=(2tt')^{-2}K''(a,b),\quad K_{,1,1,1,1}=K_{,2,2,2,2}=3K_{,1,1,2,2}.\tag{C3}$$

The indicated indices may of course be permuted. An index may also be replaced by the same primed index; in this case a minus sign has to be added on the right-hand side, e.g., $K_{,1,1',2,2}=-K_{,1,1,2,2}$, $K_{,1,1',2',2}=K_{,1,1,2,2}$, etc., since $\partial/\partial z_i=-\partial/\partial z_i'$ when applied to L.

With these preparations, the matrix elements (4.4) can be readily calculated. We use the representation (2.18), (2.19) for the eigenfunctions, interchange differentiations, and integrations, and do some bookkeeping by means of (C1)–(C3). In this way we find the nonvanishing matrix elements as

$$C_{11}^{T_1}=\frac{1}{16s^2(s^2+1)}\frac{K''(0,0)}{t^2t'^2}+K(2,2),$$
$$C_{22}^{T_1}=\frac{1}{16s^2(s^2+1)}\frac{K''(0,0)}{t^2t'^2},\quad C_{33}^{T_1}=\frac{-1}{2(s^2+1)}\frac{K'(1,1)}{tt'},$$
$$C_{11}^{T_2}=C_{22}^{T_1},\quad C_{22}^{T_2}=C_{11}^{T_1},\quad C_{11}^{L}=C_{22}^{L}=C_{33}^{T_2}=C_{33}^{T_1},\tag{C4}$$
$$C_{33}^{L}=\frac{K(1,1)}{tt'}+4K(2,2)-2\frac{K(1,2)}{t}-2\frac{K(2,1)}{t'}.$$

Next we define

$$\kappa(l,m,n;s):=\int_0^\infty\frac{dyy^{l+is}}{(1+\beta y)^m(1+\beta^{-1}y)^n},\tag{C5}$$

with $\beta:=t'/t$, so that

$$K(1,1)=\pi\frac{\kappa(0,1,1;s)}{\Gamma(1+is)\Gamma(1-is)},\quad K(1,2)=\frac{1}{t'}\frac{\pi\kappa(0,1,2;s)}{\Gamma(1+is)\Gamma(2-is)},$$

$$K(2,1)=\frac{1}{t'}\frac{\pi\kappa(1,1,2;s)}{\Gamma(2+is)\Gamma(1-is)},\quad K(2,2)=\frac{1}{t'^2}\frac{2\pi\kappa(1,1,3;s)}{\Gamma(2+is)\Gamma(2-is)},\tag{C6}$$

$$K'(1,1)=\frac{-4\pi\kappa(1,2,2;s)}{\Gamma(1+is)\Gamma(1-is)},\quad K''(0,0)=t'^2\frac{16\pi\kappa(1,3,1;s)}{\Gamma(is)\Gamma(-is)}.$$

As a consistency check, we note the symmetry

$$K(2,2;\beta\to\beta^{-1})=\frac{K''(0,0;\beta)}{8t'^4s^2(s^2+1)}.$$

The integrals (C6) are elementary,

$$K(1,1)=\frac{\pi}{is}\frac{\beta}{\beta^2-1}(\beta^{is}-\beta^{-is}),$$

$$K(1,2)=\frac{\pi}{is(1-is)}\frac{\beta}{(\beta^2-1)^2}\frac{1}{t'}(\beta^{2+is}-\beta^{2-is}-is\beta^{is}(\beta^2-1)),$$

$$K(2,1)=-\frac{\pi}{is(1+is)}\frac{\beta^2}{(\beta^2-1)^2}\frac{1}{t'}(\beta^{is}-\beta^{-is}-is\beta^{is}(\beta^2-1)),$$

$$K(2,2)=-\frac{2\pi}{(s^2+1)}\frac{\beta^4}{(\beta^2-1)^3}\frac{1}{t'^2}\frac{\beta^{is}-\beta^{-is}}{is}+\frac{\pi}{(s^2+1)}\frac{\beta^{2+is}}{(\beta^2-1)^2}\frac{1}{t'^2}((\beta^2+1)-is(\beta^2-1)),\tag{C7}$$

$$K'(1,1)=-4\pi\frac{\beta^2(\beta^2+1)}{(\beta^2-1)^3}\frac{\beta^{is}-\beta^{-is}}{is}+\frac{4\pi\beta^2}{(\beta^2-1)^2}(\beta^{is}+\beta^{-is}),$$

$$K''(0,0)=\frac{16\pi\beta^2}{(\beta^2-1)^3}t'^2is(\beta^{is}-\beta^{-is})+\frac{8\pi s^2\beta^{-is}}{(\beta^2-1)^2}t'^2((\beta^2+1)+is(\beta^2-1)).$$

Collecting terms, we obtain the nonvanishing matrix elements $C_{ij}^{T,L}$ in (4.4) as

$$C_{11}^T=C_{22}^T=\frac{\pi\beta}{(\beta^2-1)^3(s^2+1)}\frac{1}{tt'}$$
$$\times\left(-4\beta^2\frac{\beta^{is}-\beta^{-is}}{is}+(\beta^4-1)(\beta^{is}+\beta^{-is})-(\beta^2-1)^2is(\beta^{is}-\beta^{-is})\right),$$

$$C_{33}^T=C_{11}^L=C_{22}^L=\frac{2\pi\beta^2}{(\beta^2-1)^3(s^2+1)}\frac{1}{tt'}\left((\beta^2+1)\frac{\beta^{is}-\beta^{-is}}{is}-(\beta^2-1)(\beta^{is}+\beta^{-is})\right),\tag{C8}$$

$$C_{33}^L=\frac{\pi\beta}{(\beta^2-1)^3(s^2+1)}\frac{1}{tt'}$$
$$\times\left(-(\beta^4+6\beta^2+1)\frac{\beta^{is}-\beta^{-is}}{is}-(\beta^2-1)^2is(\beta^{is}-\beta^{-is})+2(\beta^4-1)(\beta^{is}+\beta^{-is})\right).$$

What remains is to substitute (C8) into the resolvent kernel (4.1) and (4.2), and to perform the *s*-integrations, which are likewise elementary, cf. (4.5)–(4.11).

Combinatorial identities for binary necklaces from exact ray-splitting trace formulas

R. Blümel[a] and Yu. Dabaghian
Department of Physics, Wesleyan University, Middletown, Connecticut 06459-0155

(Received 4 December 2000; accepted for publication 4 September 2001)

Based on an exact trace formula for a one-dimensional ray-splitting system, we derive novel combinatorial identities for cyclic binary sequences (Pólya necklaces).
 [DOI: 10.1063/1.1413226]

I. INTRODUCTION

Wave propagation in systems with sharp interfaces is a fundamental problem in the natural sciences and engineering. Well-known examples include light waves impinging on a water–air interface or sound waves propagating in layered media.[1] All these systems have one feature in common: The splitting of the incident wave into reflected and transmitted components. In the geometrical optics limit of small wave lengths, incident, reflected, and transmitted waves are described by rays. The rays are split at the interface; hence the name ''ray-splitting systems'' [2] for the whole class of wave systems with sharp interfaces. Ray-splitting systems have recently attracted attention in the context of acoustic, quantum, and electromagnetic wave chaos.[2–10] It was shown that the mere presence of a ray-splitting boundary can drive an otherwise regular system into chaos.[2–4] It was also shown that ray-splitting systems produce corrections to the Weyl formula[11,12] for the average density of states that can be computed analytically.[5,6] The most conspicuous consequence of ray splitting is the existence of non-Newtonian periodic orbits in a ray-splitting system that contribute substantially to the fluctuating part of the level density.[3,4,7–9] The existence of non-Newtonian orbits in a dielectric-loaded Bunimovich ray-splitting stadium was demonstrated experimentally.[7–9] In addition it has been shown recently that exact trace formulas exist for a class of one-dimensional ray-splitting systems.[9,10] These formulas were derived using results from quantum graph theory.[13,14] Considering the two-point correlation function of the spectra of special quantum graphs, Schanz and Smilansky were able to derive novel combinatorial identities.[15] This was possible by deriving the two-point correlation function in two independent ways, (i) directly using input from the quantum spectrum and (ii) using the exactness of the trace formula. Motivated by the methods of Kottos, Schanz, and Smilansky[13–15] we show that novel combinatorial identities for binary Pólya necklaces[16,17] are obtained directly by comparing the spectral density of analytically solvable quantum graphs with their exact periodic orbit expansion.

The plan of this paper is as follows: In Sec. II we present our model system, a one-dimensional ray-splitting system, whose spectrum can be obtained analytically. We present an exact periodic-orbit expansion of its level density expressed as a generalized Fourier sum over binary Pólya necklaces. In Sec. III we outline our method for obtaining exact combinatorial identities for binary necklaces derived from analytically solvable cases of the one-dimensional ray-splitting system. In Sec. IV we present two worked examples that yield two infinite sets of combinatorial identities. In Sec. V we discuss our results and conclude the paper.

II. SPECTRUM

Denote by E_n the spectrum of the one-dimensional scaled Schrödinger equation

$$-\psi''(x)+V_\lambda(E,x)\psi(x)=E\psi(x), \tag{1}$$

[a]Electronic mail: rblumel@wesleyan.edu

where

$$V_\lambda(E,x)=\begin{cases}0, & \text{for } 0<x\leqslant a\\ \lambda E, & \text{for } a<x<1,\\ \infty, & \text{for } x\notin(0,1)\end{cases} \tag{2}$$

and $\psi(x)\equiv 0$ for $x\notin(0,1)$. Scaling potentials of the form (2) arise naturally in many ray-splitting systems, for instance in dielectric-loaded cavities.[5,7–9] In this paper we concentrate on the case $E>V_\lambda(E,x)$ for all x. Then, without restriction of generality, the scaling constant λ can be assumed to satisfy $0\leqslant\lambda<1$. Define $E=k^2$, then the spectrum of (1) is determined by

$$\sin[k(\sigma_L+\sigma_R)]-r\sin[k(\sigma_L-\sigma_R)]=0, \tag{3}$$

where $\sigma_L=a$, $\sigma_R=\eta(1-a)$, $\eta=\sqrt{1-\lambda}$, and $r=(1-\eta)/(1+\eta)$ is the reflection coefficient. For the derivations below it is useful to define the transmission coefficient $t=\sqrt{1-r^2}$. Therefore, the reflection and transmission coefficients satisfy the relation

$$r^2+t^2=1. \tag{4}$$

Since in this paper we focus on the case $0\leqslant\lambda<1$, both r and t are real and positive and range between 0 and 1. Possible quantum phases incurred at reflection or transmission events are treated explicitly and separately [see, e.g., (6) below]. They are not included in r or t.

We now discuss an alternative method of solving the quantum dynamics in the potential (2). This method is based on coding the periodic orbits with the help of symbol strings. We denote a bounce off $x=0$ by the letter $\mathcal{L}$ and a bounce off $x=1$ by the letter $\mathcal{R}$. Words formed with these two letters code for periodic orbits in (2). The word $\mathcal{L}$, for instance, codes for the non-Newtonian orbit that bounces between $x=0$ and $x=a$ (above-barrier reflection orbit). The word $\mathcal{LR}$ codes for the (Newtonian) orbit that bounces between $x=0$ and $x=1$. Since a periodic orbit represented by the word w cycles through the letters of w without a well-defined beginning or end, two words w and w' are equivalent in our context, and code for the same periodic orbit, if they are of the same length (i.e., they consist of the same number of symbols) and their respective symbol sequences are identical up to cyclic permutations. Sequences of objects that are identical up to cyclic permutations are called (Pólya) necklaces.[16,17] If the number of objects they consist of is two, they are called binary necklaces. Apparently, therefore, the periodic orbits of (2) can be coded with the help of binary necklaces over the symbols $\mathcal{L}$ and $\mathcal{R}$. It is remarkable that for (2) every Newtonian or non-Newtonian periodic orbit can be mapped one-to-one onto a binary necklace. In other words, "pruning" is not necessary for the binary necklaces relevant for (2). Every binary necklace defines a possible periodic orbit of (2) and vice versa.

Given two letters, for instance $\mathcal{L}$ and $\mathcal{R}$, we can form 2^ℓ words of length ℓ. But, in general, many of these words will be cyclically equivalent, and correspond to the same necklace. So, how many necklaces of length ℓ are there? This question is answered by the following formula. There are exactly[17]

$$N(\ell)=\frac{1}{\ell}\sum_{n|\ell}\phi(n)2^{\ell/n}, \tag{5}$$

binary necklaces of length ℓ, where the symbol "$n|\ell$" denotes "n is a divisor of ℓ," and $\phi(n)$ is Euler's totient function defined as the number of positive integers smaller than n and relatively prime to n with $\phi(1)=1$ as a useful convention. Thus the first four totients are given by $\phi(1)=1$, $\phi(2)=1$, $\phi(3)=2$, and $\phi(4)=2$. We illustrate (5) with two examples for $\ell=1$ and $\ell=2$. There are two necklaces for $\ell=1$, $\mathcal{L}$ and $\mathcal{R}$. Applying (5) to this problem, we verify $N(1)=\phi(1)\times 2=2$. There are three necklaces of length 2, $\mathcal{LL}$, $\mathcal{LR}$, and $\mathcal{RR}$; again verified by (5), $N(2)=[\phi(1)\times 4+\phi(2)\times 2]/2=3$.

Given a binary necklace w, we define the following integer-valued functions on w: $n_{\mathcal{R}}(w)$ counts the number of $\mathcal{R}$s in w, $n_{\mathcal{L}}(w)$ counts the number of $\mathcal{L}$s, $n(w)=n_{\mathcal{L}}(w)+n_{\mathcal{R}}(w)$, $\chi(w)$ is the sum of $n(w)$ and the number of $\mathcal{R}$-pairs in w, $\alpha(w)$ counts all occurrences of $\mathcal{R}$-pairs or $\mathcal{L}$-pairs, $\beta(w)$ counts all occurrences of $\mathcal{RL}$ or $\mathcal{LR}$ and $\gamma(w)$ is defined as $\gamma(w)=2n_{\mathcal{L}}(w)+n_{\mathcal{R}}(w)$. Note that the counting of $\mathcal{R}$-pairs, $\mathcal{L}$-pairs, $\mathcal{LR}$- or $\mathcal{RL}$-combinations is to be understood cyclically, i.e., for example, $\alpha(\mathcal{R})=1$ and $\beta(\mathcal{LR})=2$. Next we define the set W_p of prime necklaces as the ones that cannot be written as a periodic concatenation of substrings. As shown recently,[10] there exists an exact periodic orbit expansion for the spectral density of (1) in terms of prime binary necklaces

$$\rho(k)=\overline{\rho}+\frac{1}{2\pi}\sum_{w\in W_p} S_w \sum_{\substack{\nu=-\infty \\ \nu\neq 0}}^{\infty} [(-1)^{\chi(w)} r^{\alpha(w)} t^{\beta(w)}]^{|\nu|} e^{i\nu S_w k}, \quad k>0, \tag{6}$$

where

$$S_w=2[n_{\mathcal{R}}(w)\sigma_R+n_{\mathcal{L}}(w)\sigma_L], \tag{7}$$

is the action of the primitive periodic orbit coded by the prime binary necklace w and $\overline{\rho}=(\sigma_L+\sigma_R)/\pi$ is the average level density.

III. METHOD

For special values of the parameters of the potential well (2) it is possible to solve (3) analytically, thus obtaining directly the density of states $\rho(k)$. Equating the explicit expression for $\rho(k)$ with the necklace expansion (6), one obtains combinatorial identities for binary necklaces. An illustrative example is the case $a=1$, for which the spectral density of (1) is given by

$$\rho(k)=\sum_{m=-\infty}^{\infty}\delta(k-\pi m). \tag{8}$$

In this case there exists only one primitive necklace, $\mathcal{LR}$, and the necklace expansion of (6) yields

$$\rho(k)=\frac{1}{\pi}\sum_{\nu=-\infty}^{\infty} e^{2i\nu k}. \tag{9}$$

Equating (8) and (9) yields the well-known Poisson formula.

A comment is in order here. For every finite a the necklace expansion (6) involves an infinite sum over prime periodic necklaces. At $a=1$ this sum collapses to a single term. One may ask the question how this singular limit arises. The answer is the following. For every finite a the actions of the right-hand lobes of the periodic orbits of (6) is finite. At $a=1$, these actions are zero. Consequently, all necklaces that represent *different* prime periodic orbits for $a\neq 1$ become *repetitions* of the Newtonian periodic orbit $\mathcal{LR}$ at $a=1$. This is the reason for the existence of only a single prime periodic orbit ($\mathcal{LR}$) at $a=1$.

Apart from trivial and well-known identities such as (8) and (9) above, (6) is a rich source of new and nontrivial combinatorial identities for binary necklaces. Specific examples are discussed in Sec. III. Here we outline the general method.

Equation (3) can be written as

$$\sin(\omega_1 k)-r\sin(\omega_2 k)=0, \tag{10}$$

where $\omega_1=\sigma_L+\sigma_R$ and $\omega_2=\sigma_L-\sigma_R$. A negative ω_2 corresponds to a mirror reflection of $V_\lambda(E,x)$ with respect to $x=1/2$. Thus, because of $\sigma_L,\sigma_R\geqslant 0$, and without loss of generality, we may assume $\omega_1\geqslant\omega_2\geqslant 0$.

In case ω_1 and ω_2 are rationally related, i.e., $\omega_1/\omega_2=p/q$, $p\geqslant q\in\mathbf{N}$ and p,q relatively prime, (10) is reduced to the algebraic equation

$$\sin(p\omega k)-r\sin(q\omega k)=0, \tag{11}$$

where $\omega_1=p\omega$ and $\omega_2=q\omega$. Using the formula

$$\sin(nx)=\sin(x)U_{n-1}(\cos(x)), \tag{12}$$

where $U_{n-1}(x)$ is the Chebyshev polynomial of the second kind, one obtains

$$\sin(\omega k)[U_{p-1}(\cos\omega k)-rU_{q-1}(\cos\omega k)]=0. \tag{13}$$

It follows immediately from (13) that in the case of rationally related ω_1 and ω_2 there always exists a sequence of roots $k_n^{(0)}=\pi n/\omega$. The remaining roots are determined by

$$U_{p-1}(x)-rU_{q-1}(x)=0, \tag{14}$$

where $x=\cos(\omega k)$. Since every root x_j of (14) gives rise to a periodic sequence of eigenvalues, $\cos(\omega k_n^{(j)})=x_j$, $j=1,2,\ldots,p-1$, together with the sequence $k_n^{(0)}$ the spectrum of (10) consists of p (possibly degenerate) periodic sequences of roots. Whenever (14) can be solved analytically, the density of states

$$\rho(k)=\sum_{j=0}^{p-1}\sum_{n=-\infty}^{\infty}\delta(k-k_n^{(j)}), \tag{15}$$

is known explicitly and together with (6) leads to a host of combinatorial identities for binary necklaces. Two examples are presented in the following section.

IV. COMBINATORIAL IDENTITIES

Example 1: For $\sigma_L=\sigma_R$ equation (3) becomes

$$\sin(2ka)=0, \tag{16}$$

with the solutions $k_n=\pi n/(2a)$. Note that there is no r-dependence in (16). The density of states is given by

$$\rho(k)=\sum_{n=-\infty}^{\infty}\delta\left(k-\frac{\pi n}{2a}\right)=\frac{2a}{\pi}\sum_{m=-\infty}^{\infty}e^{4imak}. \tag{17}$$

According to (7) and due to $\sigma_L=\sigma_R$, S_w depends only on the binary length of w and is given by $S_w=2an(w)$. Thus the sum (6) can be written as

$$\rho(k)=\frac{2a}{\pi}+\frac{a}{\pi}\sum_{\substack{m=-\infty\\ m\neq 0}}^{\infty}\sum_{w\cdot\nu\in W_{|m|}}n(w)[(-1)^{\chi(w)}r^{\alpha(w)}t^{\beta(w)}]^{\nu}e^{2imka}, \tag{18}$$

where W_n denotes the set of all length-n binary necklaces w, w is the shortest primitive code-piece *in* w and ν is the number of its repetitions in w. Comparing the series (17) and (18), we see that odd-length and even-length binary necklaces satisfy the sum rules

$$\sum_{w\cdot\nu\in W_{2m-1}}n(w)[(-1)^{\chi(w)}r^{\alpha(w)}t^{\beta(w)}]^{\nu}=0,\quad m=1,2,\ldots \tag{19}$$

and

TABLE I. List of the three cyclically nonequivalent binary necklaces of length 2 together with their primitives (w) and repetition indices (ν). Some properties of the primitives, such as their lengths (n), number of $\mathcal{R}$ or $\mathcal{L}$ pairs (α), number of transmissions (β), their weighted lengths (γ) and their phases (χ) are also listed.

j	w_j	w_j	ν_j	$n(w_j)$	$\alpha(w_j)$	$\beta(w_j)$	$\gamma(w_j)$	$\chi(w_j)$
1	$\mathcal{LL}$	$\mathcal{L}$	2	1	1	0	2	1
2	$\mathcal{LR}$	$\mathcal{LR}$	1	2	0	2	3	2
3	$\mathcal{RR}$	$\mathcal{R}$	2	1	1	0	1	2

$$\frac{1}{2}\sum_{w\cdot\nu\in W_{2m}} n(w)[(-1)^{\chi(w)}r^{\alpha(w)}t^{\beta(w)}]^{\nu}=1,\quad m=1,2,\ldots\ . \tag{20}$$

At first glance it may seem surprising that (20) is a constant for all r. The solution lies in the relation (4). When properly ordered according to powers of r and t, it turns out that (i) individual terms in (20) are of the form $r^{2p}t^{2q}$, where $p+q=m$ and (ii) the coefficients in front of the term $r^{2p}t^{2q}$ in (20) turn out to be binomial coefficients. Thus, for given m, the left-hand side of (20) reduces to $(r^2+t^2)^m$, which, according to (4) is equal to 1 for any choice of r. This explains why the seemingly variable left-hand side of (20) is nevertheless a constant. Thus we obtain from (20) the following infinite set of combinatorial identities for even-length binary necklaces:

$$\frac{1}{2}\sum_{w\cdot\nu\in W_{2m}} n(w)(-1)^{\nu\cdot\chi(w)}\delta_{\nu\cdot\alpha(w)/2,s}=\binom{m}{s},\quad s=0,\ldots,m,\quad m=1,2,\ldots, \tag{21}$$

where $\delta_{i,j}$ is the Kronecker symbol.

In order to illustrate (21) let us first focus on the case $m=1$. According to (5) there are exactly three cyclically nonequivalent necklaces of binary length 2 given by $\mathrm{w}_1=\mathcal{LL}$, $\mathrm{w}_2=\mathcal{LR}$, $\mathrm{w}_3=\mathcal{RR}$. The necklaces w_1 and w_3 are not primitive. The necklace w_1 is a twofold repetition of the primitive necklace $w_1=\mathcal{L}$. Thus $\nu_1=2$. An analogous consideration for w_3 yields $w_3=\mathcal{R}$ and $\nu_3=2$. The necklace w_2 is primitive. Therefore, $w_2=\mathrm{w}_2=\mathcal{LR}$ and $\nu_2=1$. The three necklaces w_j, $j=1,2,3$, are listed in Table I. Also listed are their primitives w_j, the repetition indices ν_j, and the values of the functions $n(w_j)$, $\alpha(w_j)$, $\beta(w_j)$, $\gamma(w_j)$, and $\chi(w_j)$.

We are now ready to check (21). For $m=1$ we have two choices for s: $s=0$ and $s=1$. For $s=0$ we have to scan the three words w_j, $j=1,2,3$, for $\nu_j\alpha(w_j)/2=s=0$. According to the entries in Table I, only w_2 qualifies and the sum on the left-hand side of (21) reduces to the single term

$$\frac{1}{2}n(w_2)(-1)^{\nu_2\chi(w_2)}=1=\binom{1}{0}. \tag{22}$$

This shows that (21) is indeed true for the simplest case $m=1$, $s=0$. For the case $m=1$, $s=1$ we have to check Table I for occurrences with $\nu_j\alpha(w_j)/2=1$. This is fulfilled for the necklaces w_1 and w_3. We obtain

$$\frac{1}{2}[n(w_1)(-1)^{\nu_1\chi(w_1)}+n(w_3)(-1)^{\nu_3\chi(w_3)}]=1=\binom{1}{1}. \tag{23}$$

This shows that (21) also works for $m=1$, $s=1$.

Testing (21) for $m=2$ involves finding all nonequivalent necklaces of binary length 4. According to (5) there are exactly six. All six necklaces are listed in Table II together with their properties. For $m=2$ we have three possibilities for s: $s=0,1,2$. For $s=0$ we have to check Table II for necklaces that fulfill $\nu_j\alpha(w_j)/2=0$. Only w_4 qualifies. We obtain $n(w_4)/2=1$, which equals $\binom{2}{0}$, the binomial coefficient on the right-hand side of (21). For $s=1$ we have to check for $\nu_j\alpha(w_j)/2=1$. We find three candidates: w_2, w_3, and w_5. This time we have to be careful when summing the three terms on the left-hand side of (21), since $\nu_3\chi(w_3)=5$. Therefore, the second

TABLE II. List of the six cyclically nonequivalent binary necklaces of length 4. The meaning of the columns is the same as in Table I.

j	w_j	w_j	ν_j	$n(w_j)$	$\alpha(w_j)$	$\beta(w_j)$	$\gamma(w_j)$	$\chi(w_j)$
1	$\mathcal{LLLL}$	$\mathcal{L}$	4	1	1	0	2	1
2	$\mathcal{LLLR}$	$\mathcal{LLLR}$	1	4	2	2	7	4
3	$\mathcal{LLRR}$	$\mathcal{LLRR}$	1	4	2	2	6	5
4	$\mathcal{LRLR}$	$\mathcal{LR}$	2	2	0	2	3	2
5	$\mathcal{LRRR}$	$\mathcal{LRRR}$	1	4	2	2	5	6
6	$\mathcal{RRRR}$	$\mathcal{R}$	4	1	1	0	1	2

term in (21) contributes with a minus sign. We obtain $[n(w_2)-n(w_3)+n(w_5)]/2=2$, which equals $\binom{2}{1}$, the corresponding binomial coefficient on the right-hand side of (21). Two necklaces, w_1 and w_6, contribute in the case $s=2$ and again satisfy (21).

Example 2: Suppose now that $\sigma_L=2\sigma_R$. In this case (3) becomes

$$\sin(ka/2)[4\cos^2(ka/2)-r-1]=0. \tag{24}$$

This equation has three sets of solutions

$$k_n^{(j)}=\frac{2j}{a}\arccos(\varphi)+\frac{2\pi n}{a},\quad j=-1,0,1, \tag{25}$$

where $\varphi=\sqrt{1+r}/2$. The density of states is

$$\begin{aligned}\rho(k)&=\sum_{j=-1}^{1}\sum_{m=-\infty}^{\infty}\delta\left(k+\frac{2j}{a}\arccos(\varphi)-\frac{2\pi m}{a}\right)\\&=\frac{a}{2\pi}\sum_{j=-1}^{1}\sum_{n=-\infty}^{\infty}e^{in[ak+2j\,\arccos(\varphi)]}\\&=\frac{a}{2\pi}\sum_{n=-\infty}^{\infty}e^{inak}[2T_{2n}(\varphi)+1],\end{aligned} \tag{26}$$

where $T_n(x)\equiv\cos(n\arccos x)$ are the Chebyshev polynomials of the first kind.[18] Equating (26) order-by-order with the necklace expansion (6) we obtain the sum rules

$$\begin{aligned}&\sum_{w\in W_p}\sum_{\nu=1}^{\infty}\gamma(w)[(-1)^{\chi(w)}r^{\alpha(w)}(1-r^2)^{\beta(w)/2}]^{\nu}\delta_{\nu\gamma(w),m}\\&\quad=1+\sum_{j=0}^{m}\frac{2m(-1)^j}{2m-j}\binom{2m-j}{j}(1+r)^{m-j},\quad m=1,2,\ldots\ .\end{aligned} \tag{27}$$

We used formula 22:6:1 of Ref. 18 for the Chebyshev polynomials in (26).

Ordering (27) according to powers of r, (27) can be reformulated as a combinatorial theorem on the set of binary necklaces, in which $\mathcal{L}$ beads weigh twice as much as $\mathcal{R}$ beads:

$$\begin{aligned}&\sum_{w\in W_p,C}\gamma(w)(-1)^{[2m\chi(w)+s\gamma(w)-m\alpha(w)]/[2\gamma(w)]}\binom{\dfrac{m\beta(w)}{2\gamma(w)}}{\dfrac{s\gamma(w)-m\alpha(w)}{2\gamma(w)}}\\&\quad=\delta_{s,0}+\sum_{j=0}^{m-s}\frac{2m(-1)^j}{2m-j}\binom{2m-j}{j}\binom{m-j}{s},\quad s=0,1,\ldots m,\quad m=1,2,\ldots\ .\end{aligned} \tag{28}$$

The condition C in the sum (28) is $C=\gamma(w)\,|\,m\wedge s-m\alpha(w)/\gamma(w)$ even. The sum on the left-hand side of (28) may be empty. In this case the sum is defined to be zero.

Let us check (28) with the help of a few examples. First we focus on the case $m=1$, $s=0$. In order to fulfill the first part of the condition C in (28) we need $\gamma=1$. This, in turn, requires to find a necklace with $n_{\mathcal{L}}=0$ and $n_{\mathcal{R}}=1$. There is just one such necklace, namely $\mathcal{R}$. But it does not fulfill the second part of C. Therefore, the sum on the left-hand side of (28) is empty, and the left-hand side is zero. The right-hand side adds up to $1+1-2=0$ and confirms (28) for this special case. For $s=1$ we find again that $\mathcal{R}$ is the only choice for w. But this time the second part of C is fulfilled and the left-hand side of (28) is

$$\gamma(\mathcal{R})(-1)^{[2\chi(\mathcal{R})+\gamma(\mathcal{R})-\alpha(\mathcal{R})]/[2\gamma(\mathcal{R})]}\begin{pmatrix}\beta(\mathcal{R})/[2\gamma(\mathcal{R})]\\ [\gamma(\mathcal{R})-\alpha(\mathcal{R})]/[2\gamma(\mathcal{R})]\end{pmatrix}=1. \tag{29}$$

We used $\alpha(\mathcal{R})=1$, $\beta(\mathcal{R})=0$, $\gamma(\mathcal{R})=1$, and $\chi(\mathcal{R})=2$. For $m=1$, $s=1$ the right-hand side of (28) consists of just one term, which turns out to be 1 as well. Thus we checked that (28) works for $m=1$. With the help of Tables I and II, other special cases may be checked as well.

V. DISCUSSION AND CONCLUSIONS

The work presented here is closely related to the theory of quantum graphs.[13–15] While the quantum graphs considered by Kottos, Schanz, and Smilansky[13–15] correspond to the case of zero potential on the bonds and delta potentials on the vertices, the step potentials considered in this paper correspond to constant potentials on the bonds and potential steps at the vertices. Thus, although the methods employed in this paper are essentially those used previously by Kottos, Schanz, and Smilansky, we obtain a different class of combinatorial identities that apply to cyclic binary codes (Pólya necklaces). Another difference concerns the derivation of identities. While Kottos, Schanz, and Smilansky use a route that involves two-point correlation functions, we show that novel combinatorial identities can be obtained directly from the periodic orbit expansions of explicitly solvable cases. These minor differences notwithstanding the central idea for generating entirely new classes of combinatorial identities is the same: Combinatorial identities can be obtained whenever a quantum system admits of (i) an explicit analytical solution and (ii) an exact periodic orbit expansion.

In addition to the two examples presented above, there exist many other cases in which (14) can be reduced to a low-order polynomial that can be solved by elementary means. Examples are the cases $p=3$, $q=2$ or $p=5$, $q=3$. Both cases can be treated in complete analogy to Example 2 above, and result in novel sum rules and combinatorial identities.

Recently we proved[10] that exact trace formulas exist for one-dimensional square wells with an arbitrary number of potential steps inside. Following the methods outlined above, our results can be generalized immediately to obtain novel combinatorial identities for necklaces with more than two types of beads.

I. INTRODUCTION

Recent developments in string theory have revealed the need to study generalizations of supersymmetry which lie beyond the realm of existing classifications of space–time supersymmetry algebras. Space–time supersymmetry algebras are $\mathbb{Z}_2$-graded super Lie algebras $\mathfrak{g}=\mathfrak{g}_0\oplus\mathfrak{g}_1$ having even $\mathfrak{g}_0$ and odd $\mathfrak{g}_1$ subspaces, where the even part $\mathfrak{g}_0=\langle M\rangle\oplus\langle P\rangle\oplus\mathfrak{h}$ includes the generators of spacetime Lorentz transformations M, translations P, and a subspace of additional ''internal symmetries'' $\mathfrak{h}$. The usual relation between spin and statistics implies that generators of $\mathfrak{g}_1$ transform as half-integer spin representations under the Lorentz transformations. Traditional classifications of spacetime supersymmetries were based on assumptions arising from the additional requirement that the supersymmetries act on either S-matrix elements[1] or on some physical Hilbert space of particle states.[2] In particular these restrict the maximum spin of the generators to be one and require the internal symmetries to be ''central'' in the sense that they commute with all other generators. Moreover, in four dimensional space–time, the realization of these algebras on physical states restricts finite dimensional representations to contain fields of spin less than or equal to two and the maximal number N of independent supercharges in $\mathfrak{g}_1$ to eight.

There are several instances in which spacetime supersymmetries and representations more general than those allowed in traditional settings occur. In M-theory, for instance, the internal symmetries $\mathfrak{h}$ do not commute with the Lorentz generators (see e.g., Ref. 3). In N-extended super self-dual theories in four dimensional Euclidean space, finite dimensional representations containing fields of spin higher than two do occur and there are consistent theories for any choice of N.[4] In $N=2$ string theory,[5] the absence of the usual relation between spin and statistics gives rise to a realization of a purely even variant of supersymmetry[6] on an infinite dimensional space of string states. There are indications that this statistics-twisted version of supersymmetry is related to an $N\to\infty$ extension of the super Poincaré algebra, which has a realization on an $N=\infty$ self-dual Yang–Mills supermultiplet.[4] These examples show that there seems to be room for the study of more general superalgebras containing the (N-extended) super Poincaré algebra or the super de Sitter algebra as a subalgebra or as a contraction. The work of Fradkin and Vasiliev (e.g., Ref. 7) on higher spin superalgebras on anti de Sitter space is also noteworthy in this respect. The present paper is a further contribution in this direction.

In a series of recent papers[8] we recently developed an approach to the study of generalized super-Poincaré algebras containing generators having spins higher than one. We showed that, contrary to common belief, such superalgebras indeed exist and are realizable in terms of vector

[a)]Electronic mail: devchand@math.uni-bonn.de
[b)]Electronic mail: Jean.Nuyts@umh.ac.be

fields on generalized superspaces having coordinates of higher spin which commute or anticommute in accordance with their statistics. We constructed numerous examples of generalized superalgebras with generators having spins up to two.

In the present paper, we address ourselves to another type of generalization, concerning the question of higher multiplicities of certain representations in the superalgebra. Theories with N supercharges are of special interest. In these, there does not seem to be any principle which distinguishes some of the supercharges from the others and field theories containing such supercharges are usually taken to be invariant under permutation of the supercharges. In this paper, we impose this permutation invariance at the level of the superalgebra, introducing what we will call *democratic superalgebras*. Our purpose here is not a complete classification of possibilities; rather, we aim to show that under the imposition of *democracy*, even in the widely familiar four-dimensional case, an investigation of super Jacobi identities yields some potentially interesting democratic spacetime superalgebras which lie beyond known classifications. The main novel feature which arises in our approach is that the algebra of Lorentz scalars $\mathfrak{h}$ generated by the superderivations is no longer either Abelian or in the center of $\mathfrak{g}$. Although democracy implies the Coleman–Mandula requirement[9] that the scalars commute with (even) translations, they possibly rotate spinor derivations among themselves.

II. DEMOCRATIC SUPERALGEBRAS

A. Four-dimensional space–time supersymmetry

Since our aim is to generalize traditional discussions and since our considerations are purely algebraic, we restrict ourselves to the general complex setting. The question of the appropriate real form depends in any case on the signature of the space–time on which the superalgebra is to be realized; and this depends on the specific context of the application. We consider the Lorentz group to be SO(4,$\mathbb{C}$), with complex generators $M_{\alpha\beta}, M_{\dot\alpha\dot\beta}$, where there is of course no conjugation between dotted and undotted spinor indices.

We shall consider $\mathbb{Z}_2$-graded N-extended complex supersymmetry algebras of the form $\mathfrak{g} = \mathfrak{g}_0 \oplus \mathfrak{g}_1$, with even part

$$\mathfrak{g}_0 = \langle M_{\alpha\beta}, M_{\dot\alpha\dot\beta}, \nabla_{\alpha\dot\alpha} \rangle \oplus \mathfrak{h}, \tag{1}$$

where $\nabla_{\alpha\dot\alpha}$ denotes the derivative vector fields generating translations, and $\mathfrak{h}$ is the subspace of internal symmetries,

$$\mathfrak{h} = \left\langle Y^i, Z^{ij} = -Z^{ji};\ \sum_i Y^i = 0,\ \sum_i Z^{ij} = 0,\ i,j = 1,\ldots,N \right\rangle, \tag{2}$$

spanned by a set of Lorentz scalar generators, $(N-1)$ Y's and $(N-1)(N-2)/2$ Z's.

The odd subspace $\mathfrak{g}_1$ is spanned by N copies of the two types of spinor representations of so(4,$\mathbb{C}$), namely, the $2N$ fermionic operators $\nabla^i_\alpha, \nabla^i_{\dot\alpha}$ $(i = 1,\ldots,N)$, which together with the bosonic vectorial operator $\nabla_{\alpha\dot\beta}$, form the set of superderivations acting on an N-extended superspace. We denote the vector space of superderivations,

$$\mathcal{D} = \langle \nabla_{\alpha\dot\beta}, \nabla^i_\alpha, \nabla^i_{\dot\alpha} \rangle = \mathcal{D}_0 \oplus \mathcal{D}_1,$$

where the even and odd parts are spanned by the vector and spinor derivations, respectively. The vector space $\mathcal{D}$ may be extended to include vector fields having higher spins on the lines of the consideration in Ref. 8. For simplicity, however, we restrict ourselves here, to the consideration of operators having spin less than or equal to one.

We shall assume that all the elements in $\mathfrak{g}$ have commutation or anticommutation relations in agreement with their statistics and with covariance under the Lorentz transformations with generators $M_{\alpha\beta}$, $M_{\dot\alpha\dot\beta}$, $\alpha, \beta, \dot\alpha, \dot\beta = 1,2$ satisfying

$$
\begin{aligned}
&[M_{\alpha\beta},M_{\gamma\delta}]=\epsilon_{\beta\gamma}M_{\alpha\delta}+\epsilon_{\alpha\gamma}M_{\beta\delta}+\epsilon_{\beta\delta}M_{\alpha\gamma}+\epsilon_{\alpha\delta}M_{\beta\gamma},\\
&[M_{\dot\alpha\dot\beta},M_{\dot\gamma\dot\delta}]=\epsilon_{\dot\beta\dot\gamma}M_{\dot\alpha\dot\delta}+\epsilon_{\dot\alpha\dot\gamma}M_{\dot\beta\dot\delta}+\epsilon_{\dot\beta\dot\delta}M_{\dot\alpha\dot\gamma}+\epsilon_{\dot\alpha\dot\delta}M_{\dot\beta\dot\gamma},\\
&[M_{\alpha\beta},M_{\dot\gamma\dot\delta}]=0.
\end{aligned}
\tag{3}
$$

Lorentz covariance, in particular, determines all commutators of the basic operators with the M, namely,

$$
\begin{aligned}
&[M_{\alpha\beta},\nabla^i_\gamma]=\epsilon_{\alpha\gamma}\nabla^i_\beta+\epsilon_{\beta\gamma}\nabla^i_\alpha,\ [M_{\alpha\beta},\nabla^i_{\dot\gamma}]=0,\ [M_{\alpha\beta},Y_i]=0,\ [M_{\alpha\beta},Z^{ij}]=0,\\
&[M_{\dot\alpha\dot\beta},\nabla^i_{\dot\gamma}]=\epsilon_{\dot\alpha\dot\gamma}\nabla^i_{\dot\beta}+\epsilon_{\dot\beta\dot\gamma}\nabla^i_{\dot\alpha},\ [M_{\dot\alpha\dot\beta},\nabla^i_\gamma]=0,\ [M_{\dot\alpha\dot\beta},Y_i]=0,\ [M_{\dot\alpha\dot\beta},Z^{ij}]=0.
\end{aligned}
\tag{4}
$$

Given these commutation rules, all Jacobi identities involving at least two M's are automatically satisfied. Lorentz covariance also yields restrictions on the (anti)commutators of any two elements of $\mathfrak{g}$. These guarantee that the Jacobi identities involving at least one M are also automatically satisfied.

The spinor derivations $\nabla^i_\alpha,\nabla^i_{\dot\alpha}$ are taken to transform under some group of automorphisms T of the superalgebra $\mathfrak{g}$,

$$
T\nabla^i_\alpha T^{-1}=U^i_j\nabla^j_\alpha,\ \ T\nabla^i_{\dot\alpha}T^{-1}=V^i_j\nabla^j_{\dot\alpha},
\tag{5}
$$

where the matrices U,V are representations of the group element T. In this paper, we make particular use of discrete transformations, taking U and V to be permutation matrices on the index i. When the automorphism group is continuous, the action of the group can be expressed in the form of commutation relations with the generators of the group: for instance, the scalar generators Y or Z which appear in (32)–(37).

We shall also allow the possibility of generating scalars by anticommuting spinor derivations, e.g., $\{\nabla^i_\alpha,\nabla^j_\beta\}\sim\epsilon_{\alpha\beta}Z^{ij}$. Traditionally,[1] such Lorentz scalars are always taken to be central with respect to $\mathcal{D}$. In our approach we do not *a priori* restrict the Lorentz scalars to be central. In fact they rotate the spinor derivations $\nabla^i_\alpha,\nabla^i_{\dot\alpha}$ just as the automorphisms (5). This is the main source of our novel examples of spacetime supersymmetries.

B. Democracy

1. Permutation invariants

We shall impose what we call democracy: we require the supercommutation relations to be invariant under the combined permutations of the i-indices of ∇^i_α and of $\nabla^i_{\dot\alpha}$. The group generating democracy S_N is the diagonal group of two groups of permutations acting independently on the two sets of spinors, with permutation matrices $U=V$ in (5).

The Clebsch–Gordon coefficients of the democratic group may be described as follows. The permutation invariant coupling among p $(p>1)$ i type indices can be associated to Young-type diagrams. Given a Young diagram with p $(p>0)$ boxes denoted $[m]=[m_1,m_2,\ldots,m_p]$, with m_j boxes in the jth row $(\Sigma_j m_j=p, m_{i+1}\leqslant m_i)$, we associate with it a p-index tensor $\theta^{i_1i_2\cdots i_p}_{[m_1m_2\cdots m_p]}$ defined by

$$
\theta^{\overbrace{i_1\ldots i_{m_1}}^{m_1}\overbrace{j_1\ldots j_{m_2}}^{m_2}\overbrace{k_1\ldots k_{m_3}}^{m_3}\cdots}_{[m_1m_2\ldots m_p]}=1 \quad \text{if } i_1=\ldots=i_{m_1},\ j_1=\ldots=j_{m_2},\ k_1=\ldots=k_{m_3},\ldots=0 \quad \text{otherwise.}
\tag{6}
$$

Note that these tensors clearly do not have the standard Young diagram symmetries. From these θ tensors, by permuting indices, all the invariant tensors of the permutation group can be constructed. For a Young-type diagram with p boxes, if n_l is the number of rows having length $m_k = l$, the number of independent invariant tensors is given by $p!/(\Pi_k m_k! \Pi_l n_l!)$.

Some of these tensors have a simple interpretation in terms of the familiar Kronecker tensor δ^{ij}. In particular,

$$\theta^{ij}_{[2]} = \delta^{ij}, \quad \theta^{ijkl}_{[22]} = \delta^{ij}\delta^{kl}, \quad \theta^{ijklmn}_{[222]} = \delta^{ij}\delta^{kl}\delta^{mn}, \tag{7}$$

correspond to the invariant tensors of so(N). These are special cases of the identities,

$$\theta^{i_1\cdots i_{m_1} i_{m_1+1}\cdots i_{m_1+m_2}\cdots}_{[m_1 m_2 m_3\cdots]} = \theta^{i_1\cdots i_{m_1}}_{[m_1]}\theta^{i_{m_1+1}\cdots i_{m_1+m_2}}_{[m_2]}\theta^{\cdots}_{[m3]}\cdots. \tag{8}$$

One further useful identity (with summation over repeated indices assumed) is

$$\theta^{i}_{[1]}\theta^{ijk\cdots}_{[m]} = \theta^{jk\cdots}_{[m-1]}, \tag{9}$$

which is valid for all $m>0$ if we define

$$\theta_{[0]} := N. \tag{10}$$

2. Trace conditions

We note that the tensor $\theta^{i}_{[1]}$ can be used to decompose tensors into their permutation irreducible parts. In particular, a vector V^i has two irreducible components given by the scalar projection S,

$$S = \theta^{j}_{[1]} V^j \tag{11}$$

and its complementary piece, of dimension $N-1$,

$$Y^j = V^i - \frac{1}{N}\theta^{i}_{[1]} S. \tag{12}$$

Similarly, a general antisymmetric tensor T^{ij} can be decomposed under the permutation group into two irreducible pieces. A piece of the form Y^j is obtained by the projection

$$Y^j = \theta^{i}_{[1]} T^{ij}, \tag{13}$$

which satisfies

$$\theta^{j}_{[1]} Y^j = 0. \tag{14}$$

The other irreducible piece Z^{ij}, of dimension $(N-1)(N-2)/2$, can be defined by

$$Z^{ij} = T^{ij} - \frac{1}{N}(\theta^{i}_{[1]} Y^j - \theta^{j}_{[1]} Y^i) \tag{15}$$

and satisfies

$$\theta^{i}_{[1]} Z^{ij} = 0. \tag{16}$$

We will generically call conditions imposed on the structure constants which guarantee the irreducibility of the relevant tensors *trace conditions*. The tensors Y in (12) and Z in (15) will be called *trace-free*.

Since the Y^k and the Z^{kl} need to satisfy the trace-free conditions (16) and (14), it is convenient to use some partially trace-free combinations of the invariant θ-tensors with certain symmetries,

$$
\begin{aligned}
t^{ij}_{[2]} &:= \theta^{ij}_{[2]} - \frac{1}{N}\theta^{ij}_{[11]}, \\
t^{ijk}_{[21]} &:= \theta^{ijk}_{[21]} - \frac{1}{N}\theta^{ijk}_{[111]}, \\
t^{ijk}_{[3]} &:= \theta^{ijk}_{[3]} - \frac{1}{N}(\theta^{kji}_{[21]} + \theta^{ijk}_{[21]} + \theta^{ikj}_{[21]}), \\
t^{ijkl}_{[22]} &:= \theta^{ijkl}_{[22]} - \theta^{kjil}_{[22]} - \frac{1}{N}(\theta^{ijkl}_{[211]} - \theta^{kjil}_{[211]} - \theta^{ilkj}_{[211]} + \theta^{klij}_{[211]}),
\end{aligned}
\tag{17}
$$

$$
\begin{aligned}
t^{ijklm}_{[32]} &:= \theta^{jklim}_{[32]} - \theta^{ikljm}_{[32]} - \theta^{jkmil}_{[32]} + \theta^{ikmjl}_{[32]} - \frac{1}{N}(\theta^{jklim}_{[311]} - \theta^{ikljm}_{[311]} - \theta^{jkmil}_{[311]} + \theta^{ikmjl}_{[311]}) \\
&\quad + \frac{1}{N}(\theta^{jmilk}_{[221]} - \theta^{imjlk}_{[221]} + \theta^{jkilm}_{[221]} - \theta^{ikjlm}_{[221]} - \theta^{jkiml}_{[221]} + \theta^{ikjml}_{[221]} - \theta^{lkimj}_{[221]} + \theta^{lkjmi}_{[221]} + \theta^{mkilj}_{[221]} \\
&\quad - \theta^{mkjli}_{[221]}) - \frac{3}{N^2}(\theta^{jmkil}_{[2111]} - \theta^{imkjl}_{[2111]} - \theta^{jlkim}_{[2111]} + \theta^{ilkjm}_{[2111]}),
\end{aligned}
$$

$$
\begin{aligned}
t^{jkmiln}_{[222]} &:= \theta^{jkmiln}_{[222]} - \theta^{ikmjln}_{[222]} - \theta^{jlmikn}_{[222]} + \theta^{ilmjkn}_{[222]} - \theta^{jknilm}_{[222]} + \theta^{iknjlm}_{[222]} + \theta^{jlnikm}_{[222]} - \theta^{ilnjkm}_{[222]} - \frac{1}{N}(\theta^{jkmiln}_{[2211]} \\
&\quad - \theta^{ikmjln}_{[2211]} - \theta^{jlmikn}_{[2211]} + \theta^{ilmjkn}_{[2211]} - \theta^{jknilm}_{[2211]} + \theta^{iknjlm}_{[2211]} + \theta^{jlnikm}_{[2211]} - \theta^{ilnjkm}_{[2211]} - \theta^{limkjn}_{[2211]} + \theta^{kimljn}_{[2211]} \\
&\quad + \theta^{ljmkin}_{[2211]} - \theta^{kjmlin}_{[2211]} + \theta^{linkjm}_{[2211]} - \theta^{kinljm}_{[2211]} - \theta^{ljnkim}_{[2211]} + \theta^{kjnlim}_{[2211]} + \theta^{jmknil}_{[2211]} - \theta^{imknjl}_{[2211]} - \theta^{jmlnik}_{[2211]} \\
&\quad + \theta^{imlnjk}_{[2211]} - \theta^{jnkmil}_{[2211]} + \theta^{inkmjl}_{[2211]} + \theta^{jnlmik}_{[2211]} - \theta^{inlmjk}_{[2211]}).
\end{aligned}
$$

These satisfy the useful identities,

$$t^{jnim}_{[22]} + t^{jmin}_{[22]} \equiv 0, \tag{18}$$

$$t^{jkmiln}_{[222]} + t^{jmnilm}_{[222]} \equiv 0, \tag{19}$$

$$t^{ij}_{[2]} t^{km}_{[2]} - t^{kj}_{[2]} t^{im}_{[2]} - \tfrac{1}{2} t^{knip}_{[22]} t^{pjnm}_{[22]} \equiv 0, \tag{20}$$

$$t^{minl}_{[22]} t^{lqjp}_{[22]} - t^{mjnl}_{[22]} t^{lqip}_{[22]} + \tfrac{1}{2} t^{ikjl}_{[22]} t^{mkpnlq}_{[222]} \equiv 0, \tag{21}$$

$$t^{ijk}_{[3]} t^{knm}_{[3]} - t^{njk}_{[3]} t^{kim}_{[3]} + \frac{1}{2N} t^{npiq}_{[22]} t^{qjpm}_{[22]} \equiv 0, \tag{22}$$

$$t^{kmin}_{[22]} t^{njmp}_{[22]} + t^{kmjn}_{[22]} t^{minp}_{[22]} + t^{imjn}_{[22]} t^{nkmp}_{[22]} \equiv 0, \tag{23}$$

$$t^{qimpjn}_{[222]} t^{nkrmls}_{[222]} + t^{qkmpln}_{[222]} t^{jmrins}_{[222]} + t^{jkmiln}_{[222]} t^{qmspnr}_{[222]} \equiv 0. \tag{24}$$

C. The supercommutators of the superderivations

Using the invariant θ and t tensors, the most general permutation invariant and Lorentz covariant supercommutation relations of the superderivations may be expressed,

$$\{\nabla^i_\alpha,\nabla^j_{\dot\alpha}\}=(a_2 t^{ij}_{[2]}+a_{11}\theta^{ij}_{[11]})\nabla_{\alpha\dot\alpha}, \tag{25}$$

$$\{\nabla^i_\alpha,\nabla^j_\beta\}=(b_2 t^{ij}_{[2]}+b_{11}\theta^{ij}_{[11]})M_{\alpha\beta}+\epsilon_{\alpha\beta}b_{21}(t^{ikj}_{[21]}-t^{jki}_{[21]})Y^k+\epsilon_{\alpha\beta}b_{22}t^{ikjl}_{[22]}Z^{kl}, \tag{26}$$

$$\{\nabla^i_{\dot\alpha},\nabla^j_{\dot\beta}\}=(\overline{b}_2 t^{ij}_{[2]}+\overline{b}_{11}\theta^{ij}_{[11]})M_{\dot\alpha\dot\beta}+\epsilon_{\dot\alpha\dot\beta}\overline{b}_{21}(t^{ikj}_{[21]}-t^{jki}_{[21]})Y^k+\epsilon_{\dot\alpha\dot\beta}\overline{b}_{22}t^{ikjl}_{[22]}Z^{kl}, \tag{27}$$

$$[\nabla^i_\alpha,\nabla_{\beta\dot\beta}]=\epsilon_{\alpha\beta}(c_2 t^{ij}_{[2]}+c_{11}\theta^{ij}_{[11]})\nabla^j_{\dot\beta}, \tag{28}$$

$$[\nabla^i_{\dot\alpha},\nabla_{\beta\dot\beta}]=\epsilon_{\dot\alpha\dot\beta}(\overline{c}_2 t^{ij}_{[2]}+\overline{c}_{11}\theta^{ij}_{[11]})\nabla^j_\beta, \tag{29}$$

$$[\nabla_{\alpha\dot\alpha},\nabla_{\beta\dot\beta}]=r(\epsilon_{\alpha\beta}M_{\dot\alpha\dot\beta}+\epsilon_{\dot\alpha\dot\beta}M_{\alpha\beta}). \tag{30}$$

Comments:

(a) The equations involving Y^i and $Z^{ij}=-Z^{ji}$ on the right-hand side have been written so as to exhibit manifestly the irreducibility of these operators. In particular, use of the partially trace-free invariant tensors as coefficients automatically yields Y^i satisfying (14) and Z^{ij} satisfying (16), since using these tensors guarantees that the relevant term vanishes when one replaces Z^{kl} by $\theta^k_{[1]}V^l$ and independently Y^k by $\theta^k S$.

(b) For the ∇^i_α and the $\nabla^i_{\dot\alpha}$, we have not separated the permutation-irreducible tensors explicitly. However, the tensors t from (17) have been chosen to correspond to the decomposition into the irreducible pieces.

(c) That the two terms on the right-hand side of (30) always have the same coefficient, can be easily deduced from the Jacobi identity for three $\nabla_{\alpha\dot\alpha}$'s. The parameter r distinguishes the two main classes of supersymmetry algebras we shall consider: The contraction to the $r=0$ case corresponds to the *algebras of super-Poincaré type* and for $r\neq 0$ we obtain *algebras of the super de Sitter type*. We shall not consider algebras of superconformal type, which have a second element transforming as a Lorentz vector, the generator of conformal transformations.

(d) The right-hand sides involve the most general Lorentz covariant terms. This guarantees that Jacobi identities involving one M are automatically satisfied.

(e) The fifteen complex parameters $\{a_2,a_{11}\}$, $\{b_2,b_{11},b_{21},b_{22}\}$, $\{\overline{b}_2,\overline{b}_{11},\overline{b}_{21},\overline{b}_{22}\}$, $\{c_2,c_{11}\}$, $\{\overline{c}_2,\overline{c}_{11}\}$, and $\{r\}$ are *a priori* independent. They are to be chosen so as to satisfy the super Jacobi identities, which we shall consider in the next section.

D. The action of $\mathfrak{h}$ on the superderivations

The most general commutation relations of the Lorentz scalar operators Y and Z with the superderivations compatible with Lorentz and permutation covariance, e.g.,

$$[Y^i,\nabla^j_\alpha]=(d_3\theta^{ijk}_{[3]}+d^a_{21}\theta^{ijk}_{[21]}+d^b_{21}\theta^{ikj}_{[21]}+d^c_{21}\theta^{kji}_{[21]}+d_{111}\theta^{ijk}_{[111]})\nabla^k_\alpha, \tag{31}$$

on imposition of the trace conditions, yield the following eight-parameter set of relations involving the partially trace-free tensors (17):

$$[Y^i,\nabla^j_\alpha]=(d_3 t^{ijk}_{[3]}+d^a_{21}t^{ijk}_{[21]}+d^b_{21}t^{ikj}_{[21]})\nabla^k_\alpha, \tag{32}$$

$$[Y^i,\nabla^j_{\dot\alpha}]=(\overline{d}_3 t^{ijk}_{[3]}+\overline{d}^a_{21}t^{ijk}_{[21]}+\overline{d}^b_{21}t^{ikj}_{[21]})\nabla^k_{\dot\alpha}, \tag{33}$$

$$[Y^i,\nabla_{\alpha\dot\alpha}]=0, \tag{34}$$

$$[Z^{ij},\nabla^k_\alpha]=f_{22}t^{jkil}_{[22]}\nabla^l_\alpha, \tag{35}$$

$$[Z^{ij},\nabla^{k}_{\dot\alpha}]=\overline{f}_{22}t^{jkil}_{[22]}\nabla^{l}_{\dot\alpha}, \tag{36}$$

$$[Z^{ij},\nabla_{\alpha\dot\alpha}]=0. \tag{37}$$

We note that the Coleman–Mandula-type relation, $[\mathfrak{h},\mathcal{D}_0]=0$, is an immediate consequence of the trace conditions. However, the internal symmetry can still act nontrivially on the odd derivations.

E. The commutators in $\mathfrak{h}$

The subalgebra of the Y's and Z's has the Lorentz and permutation covariant form satisfying the trace-conditions,

$$[Y^{i},Y^{j}]=g_{22}t^{imjn}_{[22]}Z^{mn}, \tag{38}$$

$$[Z^{ij},Y^{k}]=h_{22}t^{jkil}_{[22]}Y^{l}+h_{32}t^{jklim}_{[32]}Z^{lm}, \tag{39}$$

$$[Z^{ij},Z^{kl}]=k_{222}t^{jkmiln}_{[222]}Z^{mn}. \tag{40}$$

In fact the Jacobi identities always imply that $h_{32}=0$ (see below). This reduces the number of parameters to three, which are constrained by the Jacobi identities.

III. DEMOCRATIC LIE ALGEBRAS $\mathfrak{g}$

The *a priori* Lorentz covariant commutators of our N-extended democratic algebras must satisfy super Jacobi identities which guarantee that the products of the underlying operators are associative. We shall now consider the constraints imposed on the parameters in (25)–(30), (32)–(37), (38)–(40) by the super Jacobi identities. Let us first recall that, by construction, all the Jacobi identities involving at least one M are automatically satisfied. We begin with the subalgebra $\mathfrak{h}$.

A. Democratic Lie algebras $\mathfrak{h}$

To find all possible S_N democratic algebras containing the $N(N-1)/2$ generators Y and Z, the Jacobi identities for (38)–(40) need to be satisfied. These yield the following four conditions on the four parameters g_{22}, h_{22}, h_{32}, k_{222}:

$$\begin{aligned} &h_{32}h_{22}=h_{32}k_{222}=0,\\ &h_{22}(h_{22}-2k_{222})=0,\\ &Ng_{22}(h_{22}-2k_{222})-2h_{32}^{2}=0. \end{aligned} \tag{41}$$

They generally imply that $h_{32}=0$, leaving the conditions

$$h_{22}(h_{22}-2k_{222})=0,\quad g_{22}(h_{22}-2k_{222})=0. \tag{42}$$

These equations lead to a classification in five distinct categories:
(**1a**) Abelian $\mathfrak{h}$: all the scalar operators commute

$$g_{22}=h_{22}=k_{222}=0 \tag{43}$$

and the Y and Z can still be renormalized freely.
(**1b**) The Z's commute, they commute with the Y's but the commutators of the Y's generate the Z's. By renormalization of the Z's or the Y's, we find

$$g_{22}=1,\quad h_{22}=k_{222}=0. \tag{44}$$

(**2**) The Z's form an so$(N-1)$ algebra, with $N-1$ commuting Y's which moreover are so$(N-1)$ scalars, i.e., do not transform under the Z. Using the normalization freedom, we may write

$$g_{22}=h_{22}=0, \quad k_{222}=1. \tag{45}$$

(**3a**) The inhomogeneous so$(N-1)$ case. By normalization of the Z's, the parameters can be brought to

$$g_{22}=0, \quad h_{22}=2, \quad k_{222}=1. \tag{46}$$

The Y's behave as a vector under so$(N-1)$ and commute. They behave as momenta with respect to so$(N-1)$ and hence this corresponds to an inhomogeneous so$(N-1)$ algebra. The normalizations of the Y's can still be adjusted freely.

(**3b**) The so(N) case. We clearly have as many Y and Z operators as there are generators of so(N), which is indeed a particular democratic Lie algebra $\mathfrak{h}$. In this case, by suitable renormalizations of the Y's and the Z's, the parameters can be brought to their so(N) values, which we normalize as

$$g_{22}=1, \quad h_{22}=2, \quad k_{222}=1. \tag{47}$$

That these values correspond to so(N) can be seen as follows. The commutation relations of the $N(N-1)/2$ generators $M^{ij}=M^{ji}$ of so(N) are usually written as,

$$[M^{ij},M^{kl}]=\theta^{jk}_{[2]}M^{il}-\theta^{ik}_{[2]}M^{jl}-\theta^{jl}_{[2]}M^{ik}+\theta^{il}_{[2]}M^{jk}.$$

Defining projections

$$V^j=\theta^k_{[1]}M^{kj}, \quad T^{jk}=M^{jk}-\frac{1}{N}(\theta^j_{[1]}V^k\theta^k_{[1]}V^j), \tag{48}$$

we obtain that the subset of the T operators alone form a democratic so$(N-1)$ subalgebra [with $(N-1)(N-2)/2$ independent operators] of the so(N) algebra. The $N-1$ independent V operators transform as a vector under the so$(N-1)$ subalgebra. The V and the T satisfy precisely the commutation relations (38)–(40) satisfied by Y and Z, respectively, with

$$g_{22}=-\frac{N}{2}, \quad h_{22}=1, \quad k_{222}=\frac{1}{2}. \tag{49}$$

Since there are possible arbitrary democratic rescalings of V with respect to Y and of T with respect to Z, the algebra of the Y's and the Z's corresponds to an so(N) algebra provided (47) holds.

B. Supersymmetry algebras $\mathfrak{g}$

The full discussion for the rest of the super Jacobi identities is rather intricate. We discuss the full set of solutions in the Appendix, discussing the main features here.

We have chosen to discuss the general solution of the Jacobi identities in terms of two criteria:

(1) The first criterion is related to the appearance of the term $\theta^{ij}_{[2]}\nabla_{\alpha\dot\alpha}$ in the anticommutators of ∇^i_α with $\nabla^j_{\dot\alpha}$ (parameter a_2) and of the Y's in the anticommutator of two ∇_a's (parameter b_{21}) or of two $\nabla_{\dot\alpha}$'s (parameter $\overline{b_{21}}$).
(2) The second criterion reveals the structure of the algebra $\mathfrak{h}$ of the Lorentz scalar elements as discussed in the preceding section.

We use the values of the parameters a_2, b_{21}, and $\overline{b_{21}}$ as the basis of our classification. It follows from (25), (26) and (27) that, if any of these three parameters is nonzero, it may be

renormalized to one by rescaling the three superderivations democratically. Hence, using also the fact that we have a natural symmetry under the interchange of the dotted and undotted operators, we are led to six independent classes of superalgebras:

$$\begin{aligned}
&\text{Class A:}\ \ a_2=1,\ \ b_{21}=1,\ \ \overline{b}_{21}=1,\\
&\text{Class B:}\ \ a_2=1,\ \ b_{21}=1,\ \ \overline{b}_{21}=0,\\
&\text{Class C:}\ \ a_2=0,\ \ b_{21}=1,\ \ \overline{b}_{21}=1,\\
&\text{Class D:}\ \ a_2=1,\ \ b_{21}=0,\ \ \overline{b}_{21}=0,\\
&\text{Class E:}\ \ a_2=0,\ \ b_{21}=1,\ \ \overline{b}_{21}=0,\\
&\text{Class F:}\ \ a_2=0,\ \ b_{21}=0,\ \ \overline{b}_{21}=0,
\end{aligned} \tag{50}$$

which we discuss in detail in the Appendix. Classes *B* and *E* are *chiral*, not having the mirror symmetry under the chirality interchanges between dotted and undotted indices ($\alpha\leftrightarrow\dot{\alpha},\ldots$) and between the parameters $c\leftrightarrow\overline{c},\ldots$ (for existing unbarred-barred pairs). The two further classes,

$$\begin{aligned}
&\text{Class B}':\ \ a_2=1,\ \ b_{21}=0,\ \ \overline{b}_{21}=1,\\
&\text{Class E}':\ \ a_2=0,\ \ b_{21}=0,\ \ \overline{b}_{21}=1,
\end{aligned} \tag{51}$$

can clearly be obtained trivially from the *B* and *E* classes by performing the above chirality exchanges; and we do not explicitly discuss these.

Within the above classes, the discussion is subdivided according to the values of k_{222} and h_{22}, corresponding to the division in Sec. III A,

$$\begin{aligned}
&\text{Case 1:}\ \ k_{222}=0,\ \ h_{22}=0,\\
&\text{Case 2:}\ \ k_{222}=1,\ \ h_{22}=0,\\
&\text{Case 3:}\ \ k_{222}=1,\ \ h_{22}=2.
\end{aligned} \tag{52}$$

C. Some solutions of the super Jacobi identities

In this section, we discuss the main noteworthy features revealed by our approach. Let us consider Case A3 from the Appendix:

$$\{\nabla^i_\alpha,\nabla^j_{\dot\alpha}\}=(t^{ij}_{[2]}+a_{11}\theta^{ij}_{[11]})\nabla_{\alpha\dot\alpha}, \tag{53}$$

$$\{\nabla^i_\alpha,\nabla^j_\beta\}=4(b_{22}t^{ij}_{[2]}+a_{11}\overline{b}_{22}\theta^{ij}_{[11]})M_{\alpha\beta}+\epsilon_{\alpha\beta}((t^{ikj}_{[21]}-t^{jki}_{[21]})Y^k+b_{22}t^{ikjl}_{[22]}Z^{kl}), \tag{54}$$

$$\{\nabla^i_{\dot\alpha},\nabla^j_{\dot\beta}\}=4(\overline{b}_{22}t^{ij}_{[2]}+a_{11}b_{22}\theta^{ij}_{[11]})M_{\dot\alpha\dot\beta}+\epsilon_{\dot\alpha\dot\beta}((t^{ikj}_{[21]}-t^{jki}_{[21]})Y^k+\overline{b}_{22}t^{ikjl}_{[22]}Z^{kl}), \tag{55}$$

$$[\nabla^i_\alpha,\nabla_{\beta\dot\beta}]=4\epsilon_{\alpha\beta}\left(b_{22}t^{ij}_{[2]}+\frac{\overline{b}_{22}}{N}\theta^{ij}_{[11]}\right)\nabla^j_{\dot\beta}, \tag{56}$$

$$[\nabla^i_{\dot\alpha},\nabla_{\beta\dot\beta}]=4\epsilon_{\dot\alpha\dot\beta}\left(\overline{b}_{22}t^{ij}_{[2]}+\frac{b_{22}}{N}\theta^{ij}_{[11]}\right)\nabla^j_{\beta}, \tag{57}$$

$$[\nabla_{\alpha\dot\alpha},\nabla_{\beta\dot\beta}]=16b_{22}\overline{b}_{22}(\epsilon_{\alpha\beta}M_{\dot\alpha\dot\beta}+\epsilon_{\dot\alpha\dot\beta}M_{\alpha\beta}), \tag{58}$$

$$[Y^i,\nabla_{\alpha\dot\alpha}]=0, \tag{59}$$

$$[Z^{ij},\nabla_{\alpha\dot\alpha}]=0, \tag{60}$$

$$[Y^i,\nabla^j_\alpha]=4\left(\overline{b}_{22}a_{11}t^{ikj}_{[21]}-\frac{b_{22}}{N}t^{ijk}_{[21]}\right)\nabla^k_\alpha, \tag{61}$$

$$[Y^i,\nabla^j_{\dot\alpha}]=4\left(b_{22}a_{11}t^{ikj}_{[21]}-\frac{\overline{b}_{22}}{N}t^{ijk}_{[21]}\right)\nabla^k_{\dot\alpha}, \tag{62}$$

$$[Z^{ij},\nabla^k_\alpha]=2t^{jkil}_{[22]}\nabla^l_\alpha, \tag{63}$$

$$[Z^{ij},\nabla^k_{\dot\alpha}]=2t^{jkil}_{[22]}\nabla^l_{\dot\alpha}, \tag{64}$$

$$[Y^i,Y^j]=-4a_{11}b_{22}\overline{b}_{22}t^{imjn}_{[22]}Z^{mn}, \tag{65}$$

$$[Z^{ij},Y^k]=2t^{jkil}_{[22]}Y^l, \tag{66}$$

$$[Z^{ij},Z^{kl}]=t^{jkmiln}_{[222]}Z^{mn}. \tag{67}$$

The main unusual features displayed by this algebra are:

(1) Nontrivial action of the subalgebra $\mathfrak{h}$ on the vector space of superderivations $\mathcal{D}$;
(2) Non-Abelian subalgebra of the Lorentz scalar generators;
(3) Occurrence of the a_{11} term in (53).

The above example is of super de Sitter-type. A chiral super Poincaré-type example, also displaying these interesting features, is given by Case B3:

$$\{\nabla^i_\alpha,\nabla^j_{\dot\alpha}\}=(t^{ij}_{[2]}+a_{11}\theta^{ij}_{[11]})\nabla_{\alpha\dot\alpha}, \tag{68}$$

$$\{\nabla^i_\alpha,\nabla^j_\beta\}=(4b_{22}t^{ij}_{[2]}+Nc_{11}a_{11}\theta^{ij}_{[11]})M_{\alpha\beta}+\epsilon_{\alpha\beta}((t^{ikj}_{[21]}-t^{jki}_{[21]})Y^k+b_{22}t^{ikjl}_{[22]}Z^{kl}), \tag{69}$$

$$\{\nabla^i_{\dot\alpha},\nabla^j_{\dot\beta}\}=0, \tag{70}$$

$$[\nabla^i_\alpha,\nabla_{\beta\dot\beta}]=\epsilon_{\alpha\beta}(4b_{22}t^{ij}_{[2]}+c_{11}\theta^{ij}_{[11]})\nabla^j_{\dot\beta}, \tag{71}$$

$$[\nabla^i_{\dot\alpha},\nabla_{\beta\dot\beta}]=0, \tag{72}$$

$$[\nabla_{\alpha\dot\alpha},\nabla_{\beta\dot\beta}]=0, \tag{73}$$

$$[Y^i,\nabla_{\alpha\dot\alpha}]=0, \tag{74}$$

$$[Z^{ij},\nabla_{\alpha\dot\alpha}]=0, \tag{75}$$

$$[Y^i,\nabla^j_\alpha]=\left(-\frac{4}{N}b_{22}t^{ijk}_{[21]}+Na_{11}c_{11}t^{ikj}_{[21]}\right)\nabla^k_\alpha, \tag{76}$$

$$[Y^i,\nabla^j_{\dot\alpha}]=(-c_{11}t^{ijk}_{[21]}+4a_{11}b_{22}t^{ikj}_{[21]})\nabla^k_{\dot\alpha}, \tag{77}$$

$$[Z^{ij},\nabla^k_\alpha]=2t^{jkil}_{[22]}\nabla^l_\alpha, \tag{78}$$

$$[Z^{ij},\nabla^k_{\dot\alpha}]=2t^{jkil}_{[22]}\nabla^l_{\dot\alpha}, \tag{79}$$

$$[Y^i,Y^j]=-Na_{11}c_{11}b_{22}t^{imjn}_{[22]}Z^{mn}, \tag{80}$$

$$[Z^{ij},Y^k]=2t^{jkil}_{[22]}Y^l, \tag{81}$$

$$[Z^{ij},Z^{kl}]=t^{jkmiln}_{[222]}Z^{mn}. \tag{82}$$

IV. CONCLUSION

The inclusion of multiplicities in our program,[8] extending in a Lorentz covariant way the algebra of coordinates and derivatives, has been shown to exhibit interesting new features and a rather rich structure of solutions for the super Jacobi identities. In order to obtain explicit solutions, we have chosen to restrict ourselves in this article to a set of operators of spin less than or equal to one and to impose *democracy*. Within these restricted hypotheses, we have been able to classify fully the allowed superalgebras of derivations and superderivations. Apart from the well-known examples,[1,2] new and potentially interesting cases have been uncovered.

ACKNOWLEDGMENTS

This work has been supported in part by the TMR European Network ''Integrability, nonperturbative effects and symmetry in quantum field theory'' (Contract No. FMRX-CT96-0012). One of the authors (J.N.) wishes to thank the Theory Division at CERN where part of this work was carried through in April 2000 and the other (C.D.) thanks the MPI für Mathematik, Bonn and the Sonderforschungsbereich SFB 256, Mathematisches Institut der Universität Bonn for hospitality during the performance of this work.

APPENDIX

With classes (A–F) defined in (50) and subcases (1–3) defined by (52) the full classification of the democratic supersymmetry algebras is given below.

1. Class A

Imposing the super Jacobi identities together with the class A constraints, $a_2=1$, $b_{21}=1$, $\overline{b_{21}}=1$, yields the relations,

$$\{\nabla^i_\alpha,\nabla^j_{\dot\alpha}\}=(t^{ij}_{[2]}+a_{11}\theta^{ij}_{[11]})\nabla_{\alpha\dot\alpha}, \tag{A1}$$

$$\{\nabla^i_\alpha,\nabla^j_\beta\}=4k_{222}(b_{22}t^{ij}_{[2]}+a_{11}\overline{b}_{22}\theta^{ij}_{[11]})M_{\alpha\beta}+\epsilon_{\alpha\beta}((t^{ikj}_{[21]}-t^{jki}_{[21]})Y^k+b_{22}t^{ikjl}_{[22]}Z^{kl}), \tag{A2}$$

$$\{\nabla^i_{\dot\alpha},\nabla^j_{\dot\beta}\}=4k_{222}(\overline{b}_{22}t^{ij}_{[2]}+a_{11}b_{22}\theta^{ij}_{[11]})M_{\dot\alpha\dot\beta}+\epsilon_{\dot\alpha\dot\beta}((t^{ikj}_{[21]}-t^{jki}_{[21]})Y^k+\overline{b}_{22}t^{ikjl}_{[22]}Z^{kl}), \tag{A3}$$

$$[\nabla^i_\alpha,\nabla_{\beta\dot\beta}]=4\epsilon_{\alpha\beta}k_{222}\left(b_{22}t^{ij}_{[2]}+\frac{\overline{b}_{22}}{N}\theta^{ij}_{[11]}\right)\nabla^j_{\dot\beta}, \tag{A4}$$

$$[\nabla^i_{\dot\alpha},\nabla_{\beta\dot\beta}]=4\epsilon_{\dot\alpha\dot\beta}k_{222}\left(\overline{b}_{22}t^{ij}_{[2]}+\frac{b_{22}}{N}\theta^{ij}_{[11]}\right)\nabla^j_\beta, \tag{A5}$$

$$[\nabla_{\alpha\dot\alpha},\nabla_{\beta\dot\beta}]=16b_{22}\overline{b}_{22}k^2_{222}(\epsilon_{\alpha\beta}M_{\dot\alpha\dot\beta}+\epsilon_{\dot\alpha\dot\beta}M_{\alpha\beta}), \tag{A6}$$

$$[Y^i,\nabla_{\alpha\dot\alpha}]=0, \tag{A7}$$

$$[Z^{ij},\nabla_{\alpha\dot\alpha}]=0, \tag{A8}$$

$$[Y^i,\nabla^j_\alpha]=4k_{222}\left(\overline{b}_{22}a_{11}t^{ikj}_{[21]}-\frac{b_{22}}{N}t^{ijk}_{[21]}\right)\nabla^k_\alpha, \tag{A9}$$

$$[Y^i,\nabla^j_{\dot\alpha}]=4k_{222}\left(b_{22}a_{11}t^{ikj}_{[21]}-\frac{\overline{b}_{22}}{N}t^{ijk}_{[21]}\right)\nabla^k_{\dot\alpha}, \tag{A10}$$

$$[Z^{ij},\nabla^k_\alpha]=h_{22}t^{jkil}_{[22]}\nabla^l_\alpha, \tag{A11}$$

$$[Z^{ij},\nabla^k_{\dot\alpha}]=h_{22}t^{jkil}_{[22]}\nabla^l_{\dot\alpha}, \tag{A12}$$

$$[Y^i,Y^j]=-4a_{11}b_{22}\overline{b}_{22}k_{222}t^{imjn}_{[22]}Z^{mn}, \tag{A13}$$

$$[Z^{ij},Y^k]=h_{22}t^{jkil}_{[22]}Y^l, \tag{A14}$$

$$[Z^{ij},Z^{kl}]=k_{222}t^{jkmiln}_{[222]}Z^{mn}, \tag{A15}$$

with the space of class A superalgebras defined by solutions of the system of quadratic equations,

$$\begin{aligned} &b_{22}(2k_{222}-h_{22})=0,\\ &\overline{b}_{22}(2k_{222}-h_{22})=0,\\ &h_{22}(2k_{222}-h_{22})=0. \end{aligned} \tag{A16}$$

We find three subcases [see (52)]

Case A1: Since $h_{22}=k_{222}=0$, the parameters a_{11}, b_{22}, and $\overline{b}_{22}$ are free. This includes the standard super Poincaré algebra with Abelian algebra $\mathfrak{h}$ of central charges.

Case A2: Here a_{11} is free, $k_{222}=1$ and all other parameters are zero. There is an so$(N-1)$ subalgebra [see (45)] of the Z's which decouples.

Case A3: This is a much less trivial case (see Sec. III C) and the full so(N) algebra (49) is included in the algebra. The independent parameters are a_{11}, b_{22}, $\overline{b}_{22}$ while $h_{22}=2$, $k_{222}=1$.

2. Class B

This class is *chiral* of super Poincaré-type: $a_2=1$, $b_{21}=1$, $\overline{b}_{21}=0$. It has relations

$$\{\nabla^i_\alpha,\nabla^j_{\dot\alpha}\}=(t^{ij}_{[2]}+a_{11}\theta^{ij}_{[11]})\nabla_{\alpha\dot\alpha}, \tag{B1}$$

$$\{\nabla^i_\alpha,\nabla^j_\beta\}=(4b_{22}k_{222}t^{ij}_{[2]}+Nc_{11}a_{11}\theta^{ij}_{[11]})M_{\alpha\beta}+\epsilon_{\alpha\beta}((t^{ikj}_{[21]}-t^{jki}_{[21]})Y^k+b_{22}t^{ikjl}_{[22]}Z^{kl}), \tag{B2}$$

$$\{\nabla^i_{\dot\alpha},\nabla^j_{\dot\beta}\}=\epsilon_{\dot\alpha\dot\beta}\overline{b}_{22}t^{ikjl}_{[22]}Z^{kl}, \tag{B3}$$

$$[\nabla^i_\alpha,\nabla_{\beta\dot\beta}]=\epsilon_{\alpha\beta}(4b_{22}k_{222}t^{ij}_{[2]}+c_{11}\theta^{ij}_{[11]})\nabla^j_{\dot\beta}, \tag{B4}$$

$$[\nabla^i_{\dot\alpha},\nabla_{\beta\dot\beta}]=0, \tag{B5}$$

$$[\nabla_{\alpha\dot\alpha},\nabla_{\beta\dot\beta}]=0, \tag{B6}$$

$$[Y^i,\nabla_{\alpha\dot\alpha}]=0, \tag{B7}$$

$$[Z^{ij},\nabla_{\alpha\dot\alpha}]=0, \tag{B8}$$

$$[Y^i,\nabla^j_\alpha]=\left(-\frac{4}{N}b_{22}k_{222}t^{ijk}_{[21]}+Na_{11}c_{11}t^{ikj}_{[21]}\right)\nabla^k_\alpha, \tag{B9}$$

$$[Y^i,\nabla^j_{\dot\alpha}]=(-c_{11}t^{ijk}_{[21]}+4a_{11}b_{22}k_{222}t^{ikj}_{[21]})\nabla^k_{\dot\alpha}, \tag{B10}$$

$$[Z^{ij},\nabla^k_\alpha]=h_{22}t^{jkil}_{[22]}\nabla^l_\alpha, \tag{B11}$$

$$[Z^{ij},\nabla^k_{\dot\alpha}]=h_{22}t^{jkil}_{[22]}\nabla^l_{\dot\alpha}, \tag{B12}$$

$$[Y^i,Y^j]=-Na_{11}c_{11}b_{22}t^{imjn}_{[22]}Z^{mn}, \tag{B13}$$

$$[Z^{ij},Y^k]=h_{22}t^{jkil}_{[22]}Y^l, \tag{B14}$$

$$[Z^{ij},Z^{kl}]=k_{222}t^{jkmiln}_{[222]}Z^{mn}. \tag{B15}$$

Here the parameters are constrained by the system of equations,

$$\begin{aligned}&\overline{b}_{22}h_{22}=\overline{b}_{22}k_{222}=0,\\ &b_{22}(2k_{222}-h_{22})=0,\\ &h_{22}(2k_{222}-h_{22})=0,\end{aligned} \tag{B16}$$

defining the space of class B superalgebras. They are all of chiral super Poincaré-type. There are three subcases of solutions [see (52)]:

Case B1: The parameters a_{11}, b_{22}, $\overline{b}_{22}$, and c_{11} are free, $h_{22}=k_{222}=0$. The Z's are central, not the Y's.

Case B2: The parameters a_{11}, and c_{11} are free, $k_{222}=1$ and the remaining are zero. The subalgebra $\mathfrak{h}$ contains the so$(N-1)$ of the Z's which decouples. The subalgebra of the Y's is Abelian.

Case B3: The parameters a_{11}, b_{22}, and c_{11} are free, $h_{22}=2$, $k_{222}=1$, $\overline{b}_{22}=0$ (see Sec. III C).

3. Class C

This class contains super algebras of the de Sitter-type. They allow contractions to super Poincaré-type algebras by setting c_2 and/or $\overline{c}_2$ to zero. The relations $a_2=0$, $b_{21}=1$, $\overline{b}_{21}=1$ yield the superbrackets,

$$\{\nabla^i_\alpha,\nabla^j_{\dot\alpha}\}=a_{11}\theta^{ij}_{[11]}\nabla_{\alpha\dot\alpha}, \tag{C1}$$

$$\{\nabla^i_\alpha,\nabla^j_\beta\}=a_{11}\overline{c}_2\theta^{ij}_{[11]}M_{\alpha\beta}+\epsilon_{\alpha\beta}((t^{ikj}_{[21]}-t^{jki}_{[21]})Y^k+b_{22}t^{ikjl}_{[22]}Z^{kl}), \tag{C2}$$

$$\{\nabla^i_{\dot\alpha},\nabla^j_{\dot\beta}\}=a_{11}c_2\theta^{ij}_{[11]}M_{\dot\alpha\dot\beta}+\epsilon_{\dot\alpha\dot\beta}((t^{ikj}_{[21]}-t^{jki}_{[21]})Y^k+\overline{b}_{22}t^{ikjl}_{[22]}Z^{kl}), \tag{C3}$$

$$[\nabla^i_\alpha,\nabla_{\beta\dot\beta}]=\epsilon_{\alpha\beta}\left(c_2t^{ij}_{[2]}+\frac{\overline{c}_2}{N}\theta^{ij}_{[11]}\right)\nabla^j_{\dot\beta}, \tag{C4}$$

$$[\nabla^i_{\dot\alpha},\nabla_{\beta\dot\beta}]=\epsilon_{\dot\alpha\dot\beta}\left(\overline{c}_2t^{ij}_{[2]}+\frac{c_2}{N}\theta^{ij}_{[11]}\right)\nabla^j_\beta, \tag{C5}$$

$$[\nabla_{\alpha\dot\alpha},\nabla_{\beta\dot\beta}]=c_2\overline{c}_2(\epsilon_{\alpha\beta}M_{\dot\alpha\dot\beta}+\epsilon_{\dot\alpha\dot\beta}M_{\alpha\beta}), \tag{C6}$$

$$[Y^i,\nabla_{\alpha\dot\alpha}]=0, \tag{C7}$$

$$[Z^{ij},\nabla_{\alpha\dot{\alpha}}]=0, \tag{C8}$$

$$[Y^i,\nabla^j_\alpha]=a_{11}\overline{c}_2 t^{ikj}_{[21]}\nabla^k_\alpha, \tag{C9}$$

$$[Y^i,\nabla^j_{\dot{\alpha}}]=a_{11}c_2 t^{ikj}_{[21]}\nabla^k_{\dot{\alpha}}, \tag{C10}$$

$$[Z^{ij},\nabla^k_\alpha]=h_{22}t^{jkil}_{[22]}\nabla^l_\alpha, \tag{C11}$$

$$[Z^{ij},\nabla^k_{\dot{\alpha}}]=h_{22}t^{jkil}_{[22]}\nabla^l_{\dot{\alpha}}, \tag{C12}$$

$$[Y^i,Y^j]=-a_{11}b_{22}\overline{c}_2 t^{imjn}_{[22]}Z^{mn}, \tag{C13}$$

$$[Z^{ij},Y^k]=h_{22}t^{jkil}_{[22]}Y^l, \tag{C14}$$

$$[Z^{ij},Z^{kl}]=k_{222}t^{jkmiln}_{[222]}Z^{mn}. \tag{C15}$$

Here the parameters are constrained by the system of equations

$$\begin{gathered}\overline{b}_{22}c_2-b_{22}\overline{c}_2=0,\\ b_{22}h_{22}=b_{22}k_{222}=0,\\ \overline{b}_{22}h_{22}=\overline{b}_{22}k_{222}=0,\\ a_{11}\overline{c}_2 b_{22}(2k_{222}-h_{22})=0,\\ h_{22}(2k_{222}-h_{22})=0.\end{gathered} \tag{C16}$$

We find three subcases [see (52)]:

Case C1: We have $h_{22}=k_{222}=0$ while a_{11} is free and b_{22}, $\overline{b}_{22}$, c_2, $\overline{c}_2$, are constrained by the condition

$$\overline{b}_{22}c_2=b_{22}\overline{c}_2. \tag{C17}$$

The Z's are central charges.

Case C2: The parameters a_{11}, c_2, $\overline{c}_2$ are free, $k_{222}=1$ and the remaining are zero. The subalgebra $\mathrm{so}(N-1)\subset\mathfrak{h}$ of the Z's decouples.

Case C3: The parameters a_{11}, c_2, $\overline{c}_2$ are free, $h_{22}=2$, $k_{222}=1$, and $b_{22}=\overline{b}_{22}=0$.

4. Class D

This has $a_2=1$, $b_{21}=0$, $\overline{b}_{21}=0$, yielding

$$\{\nabla^i_\alpha,\nabla^j_{\dot{\alpha}}\}=(t^{ij}_{[2]}+a_{11}\theta^{ij}_{[11]})\nabla_{\alpha\dot{\alpha}}, \tag{D1}$$

$$\{\nabla^i_\alpha,\nabla^j_\beta\}=\epsilon_{\alpha\beta}b_{22}t^{ikjl}_{[22]}Z^{kl}, \tag{D2}$$

$$\{\nabla^i_{\dot{\alpha}},\nabla^j_{\dot{\beta}}\}=\epsilon_{\dot{\alpha}\dot{\beta}}\overline{b}_{22}t^{ikjl}_{[22]}Z^{kl}, \tag{D3}$$

$$[\nabla^i_\alpha,\nabla_{\beta\dot{\beta}}]=0, \tag{D4}$$

$$[\nabla^i_{\dot{\alpha}},\nabla_{\beta\dot{\beta}}]=0, \tag{D5}$$

$$[\nabla_{\alpha\dot{\alpha}},\nabla_{\beta\dot{\beta}}]=0, \tag{D6}$$

$$[Y^i,\nabla_{\alpha\dot{\alpha}}]=0, \tag{D7}$$

$$[Z^{ij},\nabla_{\alpha\dot{\alpha}}]=0, \tag{D8}$$

$$[Y^i,\nabla^j_\alpha]=(d_3 t^{ijk}_{[3]}+d^a_{21}t^{ijk}_{[21]}-N\overline{d}^a_{21}a_{11}t^{ikj}_{[21]})\nabla^k_\alpha, \tag{D9}$$

$$[Y^i,\nabla^j_{\dot{\alpha}}]=(-d_3 t^{ijk}_{[3]}+\overline{d}^a_{21}t^{ijk}_{[21]}-Na_{11}d^a_{21}t^{ikj}_{[21]})\nabla^k_{\dot{\alpha}}, \tag{D10}$$

$$[Z^{ij},\nabla^k_\alpha]=f_{22}t^{jkil}_{[22]}\nabla^l_\alpha, \tag{D11}$$

$$[Z^{ij},\nabla^k_{\dot{\alpha}}]=f_{22}t^{jkil}_{[22]}\nabla^l_{\dot{\alpha}}, \tag{D12}$$

$$[Y^i,Y^j]=g_{22}t^{imjn}_{[22]}Z^{mn}, \tag{D13}$$

$$[Z^{ij},Y^k]=h_{22}t^{jkil}_{[22]}Y^l, \tag{D14}$$

$$[Z^{ij},Z^{kl}]=k_{222}t^{jkmiln}_{[222]}Z^{mn}. \tag{D15}$$

The remaining parameters must satisfy the 18 equations,

$$d_3b_{22}=0,\ d_3\overline{b}_{22}=0,\ d_3f_{22}=0,\ d_3h_{22}=0, \tag{D16}$$

$$b_{22}f_{22}=0,\ b_{22}h_{22}=0,\ b_{22}k_{222}=0,\ b_{22}a_{11}\overline{d}^a_{21}=0, \tag{D17}$$

$$\overline{b}_{22}f_{22}=0,\ \overline{b}_{22}h_{22}=0,\ \overline{b}_{22}k_{222}=0,\ \overline{b}_{22}a_{11}d^a_{21}=0, \tag{D18}$$

$$h_{22}(h_{22}-2k_{222})=0,\ g_{22}(h_{22}-2k_{222})=0,\ f_{22}(f_{22}-2k_{222})=0, \tag{D19}$$

$$d^a_{21}(f_{22}-h_{22})=0,\ \overline{d}^a_{21}(f_{22}-h_{22})=0,\ d_3^2+2Nf_{22}g_{22}+N^3a_{11}d^a_{21}\overline{d}^a_{21}=0. \tag{D20}$$

We find seven essentially different subcases [see (52)]:

Case D1a: The parameter g_{22} is free while $h_{22}=k_{222}=b_{22}=\overline{b}_{22}=f_{22}=0$ and a_{11}, d_3, d^a_{21}, $\overline{d}^a_{21}$, satisfy the condition

$$a_{11}d^a_{21}\overline{d}^a_{21}+\frac{d_3^2}{N^3}=0. \tag{D21}$$

Case D1b: The parameters $b_{22}\neq 0$, d^a_{21} and g_{22} are free, a_{11} and $\overline{d}^a_{21}$ are constrained by

$$\overline{d}^a_{21}a_{11}=0 \tag{D22}$$

and the remaining parameters are zero.

Case D1c: The parameters $b_{22}\neq 0$, $\overline{b}_{22}\neq 0$, g_{22} are free, a_{11}, d^a_{21}, $\overline{d}^a_{21}$ satisfy the conditions

$$d^a_{21}a_{11}=0,\quad \overline{d}^a_{21}a_{11}=0, \tag{D23}$$

and the remaining parameters are zero.

Case D2a: Here $k_{222}=1$, the parameters a_{11}, d_3, d^a_{21}, $\overline{d}^a_{21}$ satisfy the condition (D21) and the remaining parameters are zero.

Case D2b: All the parameters are zero except $k_{222}=1$, $f_{22}=2$ and a_{11} which is free.

Case D3a: All the other parameters are zero except $k_{222}=1$, $h_{22}=2$ and a_{11}, g_{22} which are free.

Case D3b: All the parameters are zero except $k_{222}=1$, $h_{22}=2$, $f_{22}=2$ and g_{22}, a_{11}, d^a_{21}, $\overline{d}^a_{21}$ satisfy

$$4g_{22}+N^2a_{11}d^a_{21}\overline{d}^a_{21}=0.$$

5. Class E

Imposing $a_2=0$, $b_{21}=1$, $\overline{b}_{21}=0$, we obtain the chiral superalgebra,

$$\{\nabla^i_\alpha,\nabla^j_{\dot\alpha}\}=a_{11}\theta^{ij}_{[11]}\nabla_{\alpha\dot\alpha}, \tag{E1}$$

$$\{\nabla^i_\alpha,\nabla^j_\beta\}=Na_{11}c_{11}\theta^{ij}_{[11]}M_{\alpha\beta}+\epsilon_{\alpha\beta}((t^{ikj}_{[21]}-t^{jki}_{[21]})Y^k+b_{22}t^{ikjl}_{[22]}Z^{kl}), \tag{E2}$$

$$\{\nabla^i_{\dot\alpha},\nabla^j_{\dot\beta}\}=\epsilon_{\dot\alpha\dot\beta}\overline{b}_{22}t^{ikjl}_{[22]}Z^{kl}, \tag{E3}$$

$$[\nabla^i_\alpha,\nabla_{\beta\dot\beta}]=\epsilon_{\alpha\beta}(c_2t^{ij}_{[2]}+c_{11}\theta^{ij}_{[11]})\nabla^j_{\dot\beta}, \tag{E4}$$

$$[\nabla^i_{\dot\alpha},\nabla_{\beta\dot\beta}]=0, \tag{E5}$$

$$[\nabla_{\alpha\dot\alpha},\nabla_{\beta\dot\beta}]=0, \tag{E6}$$

$$[Y^i,\nabla_{\alpha\dot\alpha}]=0, \tag{E7}$$

$$[Z^{ij},\nabla_{\alpha\dot\alpha}]=0, \tag{E8}$$

$$[Y^i,\nabla^j_\alpha]=Na_{11}c_{11}t^{ikj}_{[21]}\nabla^k_\alpha, \tag{E9}$$

$$[Y^i,\nabla^j_{\dot\alpha}]=a_{11}c_2t^{ikj}_{[21]}\nabla^k_{\dot\alpha}, \tag{E10}$$

$$[Z^{ij},\nabla^k_\alpha]=h_{22}t^{jkil}_{[22]}\nabla^l_\alpha, \tag{E11}$$

$$[Z^{ij},\nabla^k_{\dot\alpha}]=\overline{f}_{22}t^{jkil}_{[22]}\nabla^l_{\dot\alpha}, \tag{E12}$$

$$[Y^i,Y^j]=-Na_{11}c_{11}b_{22}t^{imjn}_{[22]}Z^{mn}, \tag{E13}$$

$$[Z^{ij},Y^k]=h_{22}t^{jkil}_{[22]}Y^l, \tag{E14}$$

$$[Z^{ij},Z^{kl}]=k_{222}t^{jkmiln}_{[222]}Z^{mn}. \tag{E15}$$

Here a_{11} and c_{11} are free and the remaining parameters satisfy the constraints,

$$b_{22}\overline{f}_{22}=b_{22}h_{22}=b_{22}k_{222}=0, \tag{E16}$$

$$\overline{b}_{22}c_2=\overline{b}_{22}\overline{f}_{22}=\overline{b}_{22}h_{22}=\overline{b}_{22}k_{222}=0, \tag{E17}$$

$$h_{22}(h_{22}-2k_{222})=\overline{f}_{22}(\overline{f}_{22}-2k_{222})=c_2(\overline{f}_{22}-h_{22})=0. \tag{E18}$$

We find six essentially different subcases:

Case E1a: The parameters $h_{22}=k_{222}=\overline{f}_{22}=c_2=0$, and a_{11}, b_{22}, $\overline{b}_{22}$, c_{11} are free.

Case E1b: The parameters $h_{22}=k_{222}=\overline{f}_{22}=\overline{b}_{22}=0$, and a_{11}, b_{22}, c_2, c_{11} are free.

Case E2a: Here $k_{222}=1$, a_{11}, c_{11}, and c_2 are free and the remaining parameters are zero.
Case E2b: Here $k_{222}=1$, $\overline{f}_{22}=2$, a_{11}, c_{11} are free and the remaining parameters are zero.
Case E3a: Here $k_{222}=1$, $h_{22}=2$, a_{11}, c_{11} are free and the remaining parameters are zero.
Case E3b: Here $k_{222}=1$, $h_{22}=2$, $\overline{f}_{22}=2$, a_{11}, c_{11}, c_2 are free and the remaining parameters are zero.

6. Class F

Class F has the following basic relations, $a_2=0$, $b_{21}=0$, $\overline{b}_{21}=0$, which yield the superalgebra

$$\{\nabla^i_\alpha,\nabla^j_{\dot\alpha}\}=a_{11}\theta^{ij}_{[11]}\nabla_{\alpha\dot\alpha}, \tag{F1}$$

$$\{\nabla^i_\alpha,\nabla^j_\beta\}=\epsilon_{\alpha\beta}b_{22}t^{ikjl}_{[22]}Z^{kl}, \tag{F2}$$

$$\{\nabla^i_{\dot\alpha},\nabla^j_{\dot\beta}\}=\epsilon_{\dot\alpha\dot\beta}\overline{b}_{22}t^{ikjl}_{[22]}Z^{kl}, \tag{F3}$$

$$[\nabla^i_\alpha,\nabla_{\beta\dot\beta}]=\epsilon_{\alpha\beta}(c_2t^{ij}_{[2]}+c_{11}\theta^{ij}_{[11]})\nabla^j_{\dot\beta}, \tag{F4}$$

$$[\nabla^i_{\dot\alpha},\nabla_{\beta\dot\beta}]=\epsilon_{\dot\alpha\dot\beta}(\overline{c}_2t^{ij}_{[2]}+\overline{c}_{11}\theta^{ij}_{[11]})\nabla^j_\beta, \tag{F5}$$

$$[\nabla_{\alpha\dot\alpha},\nabla_{\beta\dot\beta}]=c_2\overline{c}_2(\epsilon_{\alpha\beta}M_{\dot\alpha\dot\beta}+\epsilon_{\dot\alpha\dot\beta}M_{\alpha\beta}), \tag{F6}$$

$$[Y^i,\nabla_{\alpha\dot\alpha}]=0, \tag{F7}$$

$$[Z^{ij},\nabla_{\alpha\dot\alpha}]=0, \tag{F8}$$

$$[Y^i,\nabla^j_\alpha]=(d_3t^{ijk}_{[3]}+d^a_{21}t^{ijk}_{[21]}+d^b_{21}t^{ikj}_{[21]})\nabla^k_\alpha, \tag{F9}$$

$$[Y^i,\nabla^j_{\dot\alpha}]=(\overline{d}_3t^{ijk}_{[3]}+\overline{d}^a_{21}t^{ijk}_{[21]}+\overline{d}^b_{21}t^{ikj}_{[21]})\nabla^k_{\dot\alpha}, \tag{F10}$$

$$[Z^{ij},\nabla^k_\alpha]=f_{22}t^{jkil}_{[22]}\nabla^l_\alpha, \tag{F11}$$

$$[Z^{ij},\nabla^k_{\dot\alpha}]=\overline{f}_{22}t^{jkil}_{[22]}\nabla^l_{\dot\alpha}, \tag{F12}$$

$$[Y^i,Y^j]=g_{22}t^{imjn}_{[22]}Z^{mn}, \tag{F13}$$

$$[Z^{ij},Y^k]=h_{22}t^{jkil}_{[22]}Y^l, \tag{F14}$$

$$[Z^{ij},Z^{kl}]=k_{222}t^{jkmiln}_{[222]}Z^{mn}. \tag{F15}$$

For $k_{222}=h_{22}=0$, i.e., case F1, we will limit ourselves to giving the conditions which have to be fulfilled. In the cases F2, F3 where $k_{222}=1$, we give a more precise discussion. There are many subcases which we have classified as follows:

$$\begin{aligned}&\text{subcase a: } a_{11}\neq 0,\\ &\text{subcase b: } a_{11}=0,\ f_{22}=0,\ \overline{f}_{22}=0,\\ &\text{subcase c: } a_{11}=0,\ f_{22}=2,\ \overline{f}_{22}=0,\\ &\text{subcase d: } a_{11}=0,\ f_{22}=2,\ \overline{f}_{22}=2.\end{aligned} \tag{F16}$$

With this in mind, we find nine essentially different subcases.

Case F1: With $h_{22}=k_{222}=0$, which implies $f_{22}=\overline{f}_{22}=0$, the 20 conditions to be fulfilled are

$$\begin{gathered}
b_{22}d^b_{21}=0, \quad b_{22}d_3=0,\\
\overline{b}_{22}\overline{d}^b_{21}=0, \ \overline{b}_{22}\overline{d}_3=0,\\
a_{11}c_2=0, \ a_{11}c_{11}=0,\\
a_{11}\overline{c}_2=0, \ a_{11}\overline{c}_{11}=0,\\
a_{11}d^a_{21}=0, \ a_{11}\overline{d}^a_{21}=0,\\
c_2\overline{c}_2-N^2c_{11}\overline{c}_{11}=0, \ \overline{b}_{22}c_2-b_{22}\overline{c}_2=0,\\
c_2(\overline{d}_3-d_3)=0, \ \overline{c}_2(\overline{d}_3-d_3)=0,\\
c_2\overline{d}^a_{21}-Nc_{11}d^a_{21}=0, \ \overline{c}_2\overline{d}^b_{21}-N\overline{c}_{11}d^b_{21}=0,\\
c_2d^b_{21}-Nc_{11}\overline{d}^b_{21}=0, \ \overline{c}_2d^a_{21}-N\overline{c}_{11}\overline{d}^a_{21}=0,\\
d_3^2-N^2d^a_{21}d^b_{21}=0, \ \overline{d}_3^2-N^2\overline{d}^a_{21}\overline{d}^b_{21}=0.
\end{gathered} \tag{F17}$$

This leads to a rather long, easy but uninteresting discussion which we will not give.

Case F2a: Here $k_{222}=1$, $a_{11}\neq 0$, d^b_{21}, $\overline{d}^b_{21}$, f_{22}, and $\overline{f}_{22}$ satisfy the following conditions:

$$\begin{gathered}
f_{22}(f_{22}-2)=0, \quad \overline{f}_{22}(\overline{f}_{22}-2)=0,\\
f_{22}d^b_{21}=0, \quad \overline{f}_{22}\overline{d}^b_{21}=0,
\end{gathered} \tag{F18}$$

and the remaining parameters are zero.

Case F2b: Here $k_{222}=1$, c_2, c_{11}, $\overline{c}_2$, $\overline{c}_{11}$, d^a_{21}, d^b_{21}, d_3, $\overline{d}^a_{21}$, $\overline{d}^b_{21}$, $\overline{d}_3$ satisfy the conditions,

$$\begin{gathered}
c_2\overline{c}_2-N^2c_{11}\overline{c}_{11}=0,\\
c_2(\overline{d}_3-d_3)=0, \ \overline{c}_2(\overline{d}_3-d_3)=0,\\
c_2\overline{d}^a_{21}-Nc_{11}d^a_{21}=0, \ \overline{c}_2\overline{d}^b_{21}-N\overline{c}_{11}d^b_{21}=0,\\
c_2d^b_{21}-Nc_{11}\overline{d}^b_{21}=0, \ \overline{c}_2d^a_{21}-N\overline{c}_{11}\overline{d}^a_{21}=0,\\
d_3^2-N^2d^a_{21}d^b_{21}=0, \ \overline{d}_3^2-N^2\overline{d}^a_{21}\overline{d}^b_{21}=0,
\end{gathered} \tag{F19}$$

and the remaining parameters are zero.

Case F2c: All the parameters are zero except $k_{222}=1$, $f_{22}=2$ and c_{11}, $\overline{c}_{11}$, $\overline{d}_3$, $\overline{d}^a_{21}$, and $\overline{d}^b_{21}$ which satisfy

$$\begin{gathered}
c_{11}\overline{c}_{11}=0, \ \overline{d}_3^2-N^2\overline{d}^a_{21}\overline{d}^b_{21}=0,\\
c_{11}\overline{d}^b_{21}=0, \ \overline{c}_{11}\overline{d}^a_{21}=0.
\end{gathered} \tag{F20}$$

Case F2d: All the parameters are zero except $k_{222}=1$, $f_{22}=\overline{f}_{22}=2$ and c_2, c_{11}, $\overline{c}_2$, $\overline{c}_{11}$ which satisfy the condition,

$$c_2\bar{c}_2 - N^2 c_{11}\bar{c}_{11} = 0. \tag{F21}$$

Case F3a: All the parameters are zero except $k_{222}=1$, $h_{22}=2$, $a_{11}\neq 0$, and d^b_{21}, $\bar{d}^b_{21}$, f_{22}, $\bar{f}_{22}$, and g_{22} which satisfy the conditions,

$$\begin{gathered} f_{22}(f_{22}-2)=0,\ \ \bar{f}_{22}(\bar{f}_{22}-2)=0, \\ d^b_{21}(f_{22}-2)=0,\ \ \bar{d}^b_{21}(\bar{f}_{22}-2)=0, \\ f_{22}g_{22}=0,\ \ \bar{f}_{22}g_{22}=0. \end{gathered} \tag{F22}$$

Case F3b: All the parameters are zero except for $k_{222}=1$, $h_{22}=2$, g_{22}, and c_2, c_{11}, $\bar{c}_2$, and $\bar{c}_{11}$ which satisfy the condition,

$$c_2\bar{c}_2 - N^2 c_{11}\bar{c}_{11} = 0. \tag{F23}$$

Case F3c: All the parameters are zero except $k_{222}=1$, $h_{22}=2$, $f_{22}=2$, and c_{11}, $\bar{c}_{11}$, d^a_{21}, and d^b_{21} which satisfy the conditions,

$$c_{11}\bar{c}_{11}=0, \quad c_{11}d^a_{21}=0, \quad \bar{c}_{11}d^b_{21}=0, \tag{F24}$$

and the dependent parameter,

$$g_{22}=\frac{N}{4}d^a_{21}d^b_{21}. \tag{F25}$$

Case F3d: All the parameters are zero except for $k_{222}=1$, $h_{22}=2$, $f_{22}=\bar{f}_{22}=2$, and c_{11}, c_2, $\bar{c}_{11}$, $\bar{c}_2$, d^a_{21}, d^b_{21} $\bar{d}^a_{21}$, and $\bar{d}^b_{21}$ which satisfy the conditions,

$$\begin{gathered} c_2\bar{d}^a_{21} - N c_{11} d^a_{21} = 0,\ \ \bar{c}_2\bar{d}^b_{21} - N\bar{c}_{11}d^b_{21} = 0, \\ c_2 d^b_{21} - N c_{11}\bar{d}^b_{21} = 0,\ \ \bar{c}_2 d^a_{21} - N\bar{c}_{11}\bar{d}^a_{21} = 0, \\ c_2\bar{c}_2 - N^2 c_{11}\bar{c}_{11} = 0,\ \ d^a_{21}d^b_{21} - \bar{d}^a_{21}\bar{d}^b_{21} = 0, \end{gathered} \tag{F26}$$

and the dependent parameter,

$$g_{22}=\frac{N}{4}d^a_{21}d^b_{21}. \tag{F27}$$

(Received 3 January 2001; accepted for publication 17 August 2001)

We consider the connections between sums of spherical wave functions over lattices, layers, and lines. The differences between sums over lattices and those over a doubly periodic constituent layer are expressed in terms of series with exponential convergence. Correspondingly, sums over the layer can be regarded as composed of a sum over a central line, and another sum over displaced lines exhibiting exponential convergence. We exhibit formulas which can be used to calculate accurately and efficiently sums of spherical waves over lattices, layers, and lines, which in turn may be used to construct quasiperiodic Green's functions for the Helmholtz equation, of use in scattering problems for layers and lines of spheres, and for finding the Bloch modes of lattices of spheres. We illustrate the numerical accuracy of our expressions. © *2001 American Institute of Physics.*

I. INTRODUCTION

We discuss here sums of spherical waves, solutions of the Helmholtz equation which arise naturally in scattering problems for systems of spheres. The systems on which we focus are periodic collections, with the spheres arranged either along a line, or in doubly periodic fashion in a plane, or in triply periodic fashion in a lattice. If the sums over the basis of spherical waves can be evaluated accurately and efficiently, then they can be used to construct quasiperiodic Green's functions, of use in integral equation treatments of wave scattering problems.[1] The conventional basis used for the calculation of such Green's functions is of course plane waves, but for systems composed of spherical scatterers, the natural basis to employ is composed of spherical waves, and its use delivers advantages of rapidity of convergence, and accuracy in the implementation of boundary conditions, particularly important in cases of high contrast between the media between and within the spheres.[2]

For the case of the Schrödinger equation, sums of spherical waves over lattices arise in the well-known Korringa–Kohn–Rostoker (KKR) method for calculation of Bloch functions,[3–5] where they are referred to as matrix elements. However, their lineage predates the KKR formulation, as they were perhaps first introduced by Appel,[6] and were considered in an important paper by Rayleigh,[7] which has motivated much of our work utilizing them. We have established[8] convenient formulas which may be used to calculate quasiperiodic sums of spherical waves over arbitrary lattices of spheres. Such sums are useful in finding Bloch modes in lattices, e.g., in calculating their photonic band structures.[9,10]

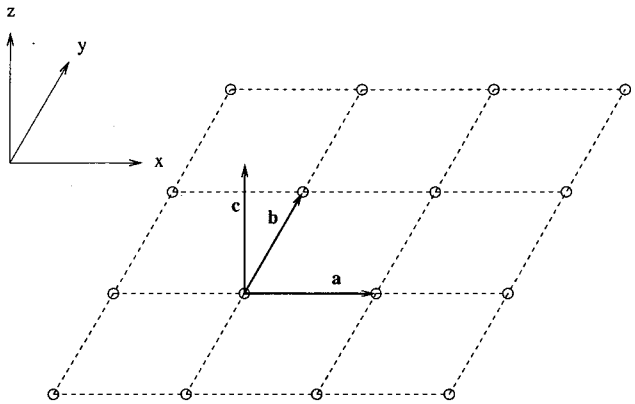

FIG. 1. A general array in the Oxy plane, characterized by (not necessarily orthogonal) basis vectors **a** and **b**, is made into a lattice using a third basis vector **c** along the Oz axis.

An important structure in three dimensions is the doubly periodic monolayer of spheres.[11] If sums of spherical waves over this structure can be calculated, and from them the quasiperiodic Green's functions, then efficient formulations can be constructed for the scattering by monolayers. These may be used in what Stefanou, Karathanos, and Modinos[10] call ''layer KKR methods,'' and enable the investigation of problems of wave localization by three-dimensional random systems, and of homogenization in them. We have carried out such investigations[11,12] of two-dimensional systems using sums over cylindrical wave functions.

Here we will investigate quasiperiodic sums of spherical wave functions over singly periodic, doubly periodic, and triply periodic sets of points. We will use Fourier methods, which have recently been employed by a number of groups,[13–17] and which enable convenient linkages to be established between wave functions summed over periodic sets, and constituent sets of lower dimension. As we have stressed,[11,12,17] these linkages are important in enabling a deeper understanding of the Bloch theorem, when applied to bases of functions other than plane waves. They also have computational advantages, in that the sums over lower dimension, when added to exponentially convergent series, generate those over a higher dimension.

We will begin by considering the sums of spherical waves over lattices. We will break up such sums into those over a central monolayer, and monolayers lying in positive and negative half spaces. The latter will be reduced to rapidly evaluable and quickly convergent series. We will next consider the central monolayer, and regard it as being composed of a set of displaced lines. Once again, we will obtain sums over the central line, and lines in the positive and negative half planes, with the latter being able to be simply and efficiently evaluated.

II. LATTICE AND LAYER SUMS

We consider the lattice shown in Fig. 1. It is characterized by basis vectors for a layer $\mathbf{a}=(a,0,0)$ and $\mathbf{b}=(b_x,b_y,0)$, with the third basis vector being taken to lie along the Oz axis: $\mathbf{c}=(0,0,c)$, with $c>0$. The general lattice vector is specified by a triplet of integers $p=(p_a,p_b,p_c)$:

$$\mathbf{R}_p=p_a\mathbf{a}+p_b\mathbf{b}+p_c\mathbf{c}=\mathbf{R}_{\mathbf{p}\perp}+p_c\mathbf{c}, \tag{1}$$

where we will introduce a unit vector to characterize direction: $\mathbf{R}_p=R_p\hat{\mathbf{R}}_p$. The lattice sums for the Helmholtz equation depend on a scalar parameter, k—the wave number, and a vector parameter, $\mathbf{k}_0$—the Bloch vector or quasiperiodicity vector. The sum of order n,m for the lattice is defined in terms of a superposition of the appropriately phased (n,m)th order solution of the Helmholtz equation, evaluated at the nodes of the lattice:

$$S_{nm}^{L}=\sum_{p\neq(0,0,0)} h_n^{(1)}(kR_p)Y_{nm}(\hat{\mathbf{R}}_p)\exp(i\mathbf{k}_0\cdot\mathbf{R_p}), \tag{2}$$

where $h_n^{(1)}$ represents the spherical Bessel function of the third kind (the Hankel function),[18] and multiplies the spherical harmonic angular function Y_{nm}. Note that the lattice point at the origin is excluded from the sum, and this distinguishes the central layer $p_c=0$ from those in the positive and negative half spaces $\mathbf{R}_p^+$ with $p_c>0$ and $\mathbf{R}_p^-$ with $p_c<0$.

In previous work,[11,12,17] we have established expressions from which the lattice sums may be evaluated:

$$S_{nm}^{L}=S_{nm}^{Lj}+iS_{nm}^{Ly}=-1/\sqrt{4\pi}\,\delta_{n,0}\delta_{m,0}+iS_{nm}^{Ly}, \tag{3}$$

where, using an asterisk to denote conjugation,

$$\begin{aligned}(-1)^m S_{n,-m}^{Ly} j_{n+q}(k\xi)=&-1/\sqrt{4\pi}\,\delta_{n,0}\delta_{m,0}[y_q(k\xi)+w_q(k\xi)]\\&-\frac{4\pi}{kV}i^n\sum_h\left(\frac{k}{Q_h}\right)^q\frac{j_{n+q}(Q_h\xi)}{Q_h^2-k^2}Y_{nm}^*(\hat{\mathbf{Q}}_h).\end{aligned} \tag{4}$$

Here, q is an arbitrary positive integer, representing the order of summation acceleration, while ξ is an arbitrary length, bounded from above by the shortest length of any integral combination of **a**, **b**, and **c**, and V is the volume of the unit cell. Also, $\mathbf{Q}_h$ denotes the general element of the space of reciprocal lattice vectors $\mathbf{K_h}$ translated by the quasiperiodicity vector $\mathbf{k}_0$, with its magnitude being Q_h and its direction being characterized by the unit vector $\hat{\mathbf{Q}}_h$. The function w_q removes the divergent part at the origin of the spherical Bessel function y_q:[19]

$$w_q(\xi)=\frac{1}{2\sqrt{\pi}}\sum_{p=0}^{q-1}\frac{\Gamma(q-p+1/2)}{p!}\left(\frac{2}{k\xi}\right)^{q-2p+1}. \tag{5}$$

These expressions give the S_{nm}^{L} as sums over a triplet of integers in reciprocal space.

We will now relate the lattice sums to those over the central layer, and the positive and negative half spaces:

$$S_{nm}^{L}=S_{nm}^{\mathrm{ML}}+S_{nm}^{L+}+S_{nm}^{L-}. \tag{6}$$

The monolayer term is the focus of interest in Eq. (6) and we will seek to establish simple expressions for the positive $(p_c>0)$ and negative $(p_c<0)$ half space sums.

Our basic tool will be Fourier transform expressions for spherical waves given by Wittmann.[19] These expressions contain a preferred coordinate z, and if $z>0$:

$$h_n^{(1)}(kr)Y_{nm}(\hat{\mathbf{r}})=\frac{1}{2\pi i^n}\int Y_{nm}(\hat{\mathbf{k}})\exp(i\mathbf{k}\cdot\mathbf{r})\frac{d\mathbf{K}}{\gamma k}. \tag{7}$$

Here the integral is from minus infinity to infinity in the two components K_x and K_y of the vector **K**, while γ is a function of K_x and K_y:

$$\gamma=\sqrt{k^2-K^2}, \tag{8}$$

with the square root being taken to be positive imaginary if $K>k$. The corresponding expression for $z<0$ is

$$h_n^{(1)}(kr)Y_{nm}(\hat{\mathbf{r}})=\frac{1}{2\pi(-i)^n}\int Y_{nm}(\hat{\mathbf{k}})\exp(-i\mathbf{k}\cdot\mathbf{r})\frac{d\mathbf{K}}{\gamma k}. \tag{9}$$

Convenient expressions for evaluating the Y_{nm} are

$$Y_{nm}(\hat{\mathbf{k}}) = (-1)^m K_{nm}(k_x/k + ik_y/k)^m P_n^{(m)}(k_z/k), \tag{10}$$

for positive m, and

$$Y_{n,-m}(\hat{\mathbf{k}}) = K_{nm}(k_x/k - ik_y/k)^m P_n^{(m)}(k_z/k), \tag{11}$$

where

$$K_{nm} = \sqrt{\frac{2n+1}{4\pi}\frac{(n-m)!}{(n+m)!}}. \tag{12}$$

The function $P_n^{(m)}$ is defined to be the mth derivative of the nth Legendre polynomial:

$$P_n^{(m)}(x) = \frac{\mathrm{d}^m}{\mathrm{d}x^m} P_n(x). \tag{13}$$

Note that $P_n^{(m)}$ differs from the associated Legendre function in the absence of a prefactor involving a power of the square root function. Expressions (10)–(13) are well adapted to our purpose here since they pose no problems with branch cuts for evanescent orders (k_z imaginary).

We use these expressions now to evaluate S_{nm}^{L+}, assuming $m>0$. Writing $\mathbf{k}_0 = \mathbf{k}_{0\perp} + k_{0z}\hat{\mathbf{z}}$,

$$S_{nm}^{L+} = \sum_{p_c=1}^{\infty} \exp(ik_{0z}p_c c)\frac{K_{nm}(-1)^m}{2\pi i^n}\int \frac{\mathrm{d}\mathbf{K}}{\gamma k}\left(\frac{k_x + ik_y}{k}\right)^m P_n^{(m)}(\gamma/k)$$

$$\times \exp(i\gamma p_c c)\sum_{\mathbf{R}_{p\perp}} \exp[i(\mathbf{K}+\mathbf{k}_{0\perp})\cdot\mathbf{R}_{p\perp}]. \tag{14}$$

If $\mathbf{Q}_{h\perp}$ denotes the set of integer combinations of the two reciprocal lattice basis vectors lying in the xy plane, and $\mathcal{A}$ denotes the area of the unit cell in that plane, we have

$$\sum_{\mathbf{R}_{p\perp}} \exp[i(\mathbf{K}+\mathbf{k}_{0\perp})\cdot\mathbf{R}_{p\perp}] = \frac{4\pi^2}{\mathcal{A}}\sum_{\mathbf{Q}_{h\perp}} \delta(\mathbf{K}+\mathbf{k}_{0\perp}-\mathbf{Q}_{h\perp}). \tag{15}$$

Let us define

$$\mathbf{Q}_{h\perp}^{-} = -\mathbf{k}_{0\perp} + \mathbf{Q}_{h\perp} = Q_{hx}^{-}\hat{\mathbf{x}} + Q_{hy}^{-}\hat{\mathbf{y}}, \tag{16}$$

so that

$$S_{nm}^{L+} = \frac{2\pi K_{nm}(-1)^m}{\mathcal{A} i^n}\sum_{p_c=1}^{\infty}\sum_{\mathbf{Q}_{h\perp}^{-}} \frac{\exp[i(k_{0z}+\gamma)p_c c]}{\gamma k}\left(\frac{Q_{hx}^{-} + iQ_{hy}^{-}}{k}\right)^m P_n^{(m)}(\gamma/k). \tag{17}$$

We stress that factors involving γ cannot be moved outside the sum over $\mathbf{Q}_{h\perp}^{-}$, since γ depends implicitly on the transverse reciprocal lattice vector. Note that the individual terms in the sum over p_c have physical interest: They would be needed if one wished to evaluate the Green's function due to a quasiperiodic set of spherical wave sources in a plane, with the field point being shifted along the z axis from the source plane.

The final step in the evaluation for the positive half space is to sum the geometrical progression in Eq. (17):

TABLE I. Convergence of the series in (18), for $n=1$, with the truncation order $p_{\max}$, for the data: $k_{0x}=0.37$, $k_{0y}=0.79$, $k_{0z}=0.48$, $k=2\pi/7.69$, $a_x=1.00$, $b_x=0.65$, $b_y=0.81$, $c_z=0.94$, $q=4$.

	$m=-1$	$m=0$	$m=+1$
2–10	$3.88\times10^{-7}-i\,1.21\times10^{-7}$	$-4.97\times10^{-7}+i\,1.03\times10^{-6}$	$-1.45\times10^{-7}-i\,3.80\times10^{-7}$
5–10	$1.78\times10^{-14}-i\,7.11\times10^{-15}$	$-2.31\times10^{-14}+i\,4.93\times10^{-14}$	$-3.55\times10^{-15}-i\,2.13\times10^{-14}$
10+	$18.5309+i\,2.002\,73$	$8.756\,54-i\,3.034\,16$	$13.4095-i\,12.9531$
10−	$-13.4095-i\,12.9531$	$8.756\,54+i\,3.034\,16$	$-18.5309+i\,2.002\,73$
S^L	$9.499\,23-i\,20.4461$	$17.5131+i\,0.$	$-9.499\,23-i\,20.4461$
S^{ML}	$4.377\,86-i9.495\,68$	$-3.82\times10^{-7}-i\,3.11\times10^{-15}$	$-4.377\,86-i\,9.495\,68$

$$S_{nm}^{L+}=\frac{-2\pi K_{nm}(-1)^m}{\mathcal{A}i^n}\sum_{\mathbf{Q}_{h\perp}^-}\frac{1}{\gamma k}\left(\frac{Q_{hx}^-+iQ_{hy}^-}{k}\right)^m\frac{1}{1-\exp[-i(k_{0z}+\gamma)c]}P_n^{(m)}(\gamma/k). \tag{18}$$

The evaluation for the negative half space proceeds along similar lines, bearing in mind the differences between Eqs. (7) and (9). The result is

$$S_{nm}^{L-}=\frac{-2\pi K_{nm}(-1)^m}{\mathcal{A}(-i)^n}\sum_{\mathbf{Q}_{h\perp}^+}\frac{1}{\gamma k}\left(\frac{Q_{hx}^++iQ_{hy}^+}{k}\right)^m\frac{1}{1-\exp[-i(-k_{0z}+\gamma)c]}P_n^{(m)}(\gamma/k), \tag{19}$$

where

$$\mathbf{Q}_{h\perp}^+=\mathbf{k}_{0\perp}+\mathbf{Q}_{h\perp}=Q_{hx}^+\hat{\mathbf{x}}+Q_{hy}^+\hat{\mathbf{y}}. \tag{20}$$

Given these results, it is possible to employ Eq. (6) in two ways: to proceed from the two-dimensional sum S_{nm}^{ML} via these exponential correction terms to the three-dimensional sum S_{nm}^L, or to proceed by subtraction in the opposite direction. Here we follow the latter course, since we have the aim of providing results to validate the expressions for the monolayer sums derived in Sec. III.

In Table I, we give numerical values illustrating the rapid convergence of the sum in Eq. (18). For the data chosen, summation between -10 and 10 along both axes in reciprocal space is entirely adequate, and so the rows labeled $2-10$ and $5-10$ give the differences arising for summation between -2 and 2 and -10 and 10 (which are of order 10^{-6}), and between -5 and 5 and -10 and 10 (which are of order 10^{-14}). The next two rows give the values of $S_{1,m}^{L+}$ and $S_{1,m}^{L-}$. The last two rows give the values of $S_{1,m}^L$ from Eqs. (3) and (4), and of $S_{1,m}^{\mathrm{ML}}$ from Eq. (6). Note that in Eq. (6), the lattice sums S^L depend on k_z, while the monolayer sums do not.

III. LAYER AND LINE SUMS

Let us now proceed to construct the monolayer sums by regarding them as made up of the addition of sums along lines. It is convenient to choose these lines to be parallel to the Ox axis, and to preserve exponential convergence by having the lines displaced along the Oz axis. What this means is that the coordinates we use in this section are in fact rotated coordinates $Ox'y'z'$ relative to those of Sec. II. This rotation of course affects the monolayer sum values, and we will discuss the necessary corrections in Sec. IV.

The analog to Eq. (6) here is

$$S_{nm}^{\mathrm{ML}}=S_{nm}^C+S_{nm}^{\mathrm{ML}+}+S_{nm}^{\mathrm{ML}-}, \tag{21}$$

where the terms on the right-hand side correspond to the central chain ($z=0$) and to the contributions from $z>0$ and $z<0$, respectively.

We start with the central chain, along which $x=pa\hat{\mathbf{x}}$, $y=z=0$. Hence, this sum depends only on k_{0x}:

$$S_{nm}^{C}=\sum_{p\neq 0} h_n^{(1)}(k|p|a)Y_{nm}(\mathrm{sign}(p),0,0)\exp(ik_{0x}pa). \tag{22}$$

Using the normal expression for the spherical harmonic function,[18] we find

$$S_{nm}^{C}=K_{nm}P_n^m(0)\sum_{p=1}^{\infty} h_n^{(1)}(kpa)[\exp(ik_{0x}pa)+(-1)^m\exp(-ik_{0x}pa)]. \tag{23}$$

Here $P_n^m(0)$ denotes the normal associated Legendre function, evaluated at the origin, an analytic quantity.[18]

We replace the function $h_n^{(1)}$ by an integral using Eq. (7):

$$h_n^{(1)}(kpa)Y_{n0}(0,0,1)=h_n^{(1)}(kpa)\sqrt{\frac{2n+1}{4\pi}}P_n(1)=\frac{1}{2\pi i^n}\int Y_{n0}(\hat{\mathbf{k}})\frac{\exp(i\gamma pa)}{\gamma k}\mathrm{d}\mathbf{K}. \tag{24}$$

The sums over p are geometric progressions, which lead to

$$S_{nm}^{C}=\frac{-1}{2\pi i^n}\sqrt{\frac{(n-m)!}{(n+m)!}}P_n^m(0) \times\int\frac{Y_{n0}(\hat{\mathbf{k}})\mathrm{d}\mathbf{K}}{\gamma k}\left\{\frac{1}{1-\exp[-i(\gamma+k_{0x})a]}+\frac{(-1)^m}{1-\exp[-i(\gamma-k_{0x})a]}\right\}. \tag{25}$$

We can express Y_{n0} simply:

$$Y_{n0}(\hat{\mathbf{k}})=\sqrt{\frac{(2n+1)}{4\pi}}P_n(\gamma/k), \tag{26}$$

and evaluate the integral over $\mathbf{K}$ using polar coordinates to arrive at

$$S_{nm}^{C}=\frac{-K_{nm}P_n^m(0)}{i^n}\int_0^{\infty}\frac{KP_n(\gamma/k)\mathrm{d}K}{\gamma k}\left\{\frac{1}{1-\exp[-i(\gamma+k_{0x})a]}+\frac{(-1)^m}{1-\exp[-i(\gamma-k_{0x})a]}\right\}. \tag{27}$$

This gives the sum over the central line as an exponentially convergent integral. The integrand can have singularities at points corresponding to Wood anomalies, where diffracted orders pass off,[1] but these can be eliminated by rotating the contour by 45° below the real K axis.[15]

In Fig. 2 we compare the result of direct summation over progressively larger regions with the result of numerical integration of Eq. (27). Direct summation yields a result which oscillates with a slowly decreasing amplitude, but it is clear that the analytic result lies at the centroid of the oscillations.

We continue with the evaluation of sums over the positive half plane:

$$S_{nm}^{\mathrm{ML}+}=\sum_{\mathbf{R}_p^+} h_n^{(1)}(kR_p^+)Y_{nm}(\hat{\mathbf{R}}_p^+)\exp(i\mathbf{k}_0\cdot\mathbf{R}_p^+), \tag{28}$$

where $\mathbf{R}_p^+=p_a\mathbf{a}+p_c\mathbf{c}$, and where $\mathbf{c}=c_x\hat{\mathbf{x}}+c_z\hat{\mathbf{z}}$. Hence, using the integral expressions for the spherical wave functions:

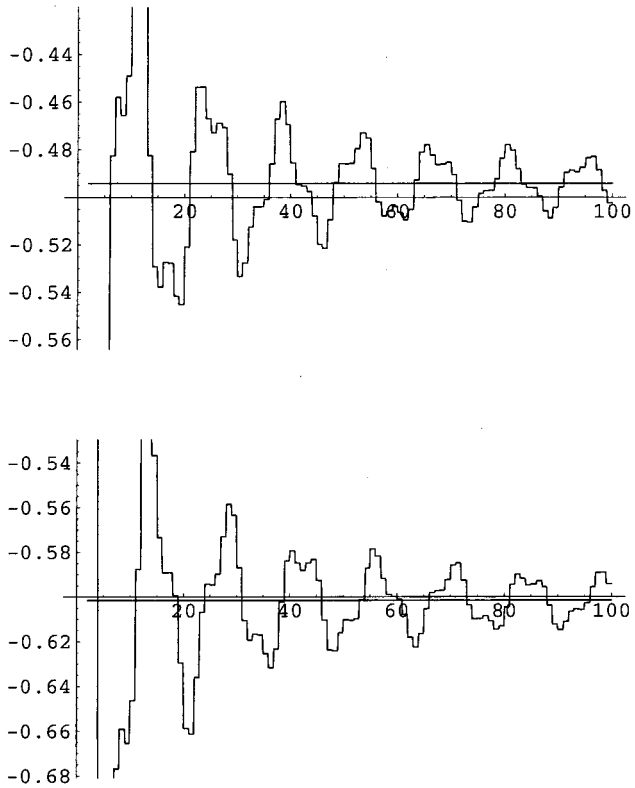

FIG. 2. A comparison of direct summation of S_{11}^{C} as a function of the size of the summation region with the result of Eq. (27) (horizontal line) for the real (top) and imaginary (bottom) parts. The data are: $k_{0x}=0.37$, $k_{0z}=-0.79$, $k=2\pi/7.69$, $a_x=1.00$, $c_x=-0.65$, $c_z=0.81$.

$$S_{nm}^{\mathrm{ML}+}=\sum_{p_{\mathbf{c}}=1}^{\infty}\exp[ip_c(c_xk_{0x}+c_zk_{0z})]\times\frac{1}{2\pi i^n}\int\frac{Y_{nm}(\hat{\mathbf{k}})\,\mathrm{d}\mathbf{K}}{\gamma k}$$
$$\times\exp[ip_c(c_xk_x+c_z\gamma)]\sum_{p_a=-\infty}^{\infty}\exp[ip_aa(k_x+k_{0x})]. \tag{29}$$

The sum over p_a gives rise to a sum of delta functions corresponding to $k_x=-k_q$, with q ranging over all integral values, and $k_q=k_{0x}+2\pi q/a$. We are left with a sum over q replacing the integral over k_x, and we combine the integrands from positive and negative k_y values, to give

$$S_{nm}^{\mathrm{ML}+}=\frac{1}{i^na}\sum_{q=-\infty}^{\infty}\int_0^{\infty}\frac{K_{nm}\mathrm{d}k_y}{\gamma k}P_n^{(m)}(\gamma/k)\times\left[\left(\frac{k_q-ik_y}{k}\right)^m+\left(\frac{k_q+ik_y}{k}\right)^m\right]$$
$$\times\sum_{p_c=1}^{\infty}\exp\{ip_c[c_x(k_{0x}-k_q)+c_z(k_{0z}+\gamma)]\}. \tag{30}$$

The summand here gives the contribution to the monolayer sum from a single line in $p_c>0$. Summing the geometrical progression over all such lines, we find

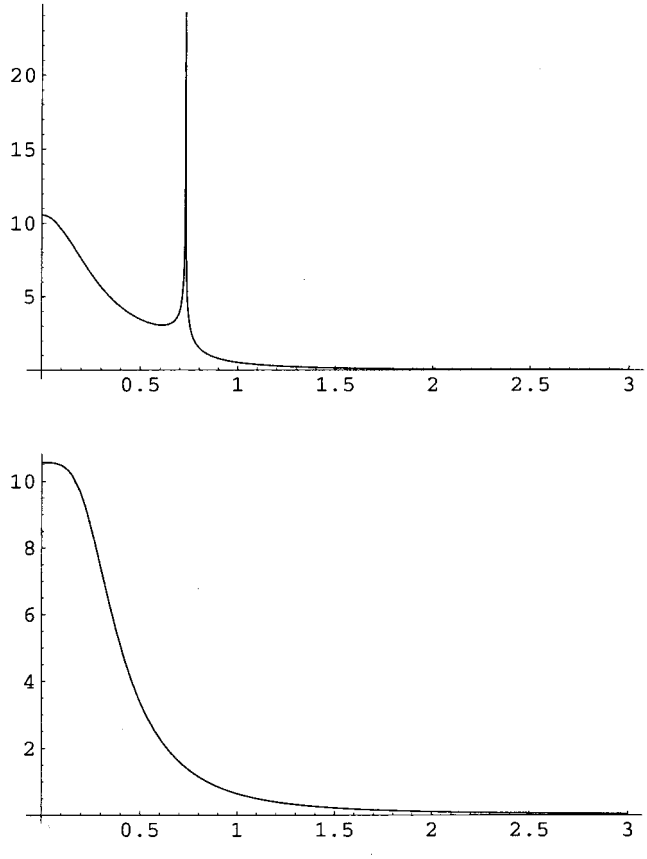

FIG. 3. Plots of the unshifted (top) and shifted (bottom) integrands in Eq. (31) for $n=1,m=1$ and for the data of Fig. 2.

$$S_{nm}^{\mathrm{ML}+}=\frac{-K_{nm}}{i^n a}\sum_{q=-\infty}^{\infty}\int_0^{\infty}\frac{\mathrm{d}k_y}{\gamma k}P_n^{(m)}(\gamma/k)$$
$$\times\left[\left(\frac{k_q-ik_y}{k}\right)^m+\left(\frac{k_q+ik_y}{k}\right)^m\right]\frac{1}{1-\exp-i[c_x(k_{0x}-k_q)+c_z(k_{0z}+\gamma)]}. \tag{31}$$

Once again, this contains an integral which should be evaluated over a line oriented at 45° below the real K axis. A comparison of the integrand in Eq. (31) plotted along the real axis and the line at $-45°$ is given in Fig. 3. Note how the integrable singularity evident in the former is smoothed out in the latter. For the case shown, the summation in Eq. (31) was carried out over q between -5 and 5, with this being entirely adequate for graphical accuracy.

A similar treatment may be applied to evaluate the lower half plane contribution:

$$S_{nm}^{\mathrm{ML}-}=\frac{-(-1)^m K_{nm}}{(-i)^n a}\sum_{q=-\infty}^{\infty}\int_0^{\infty}\frac{\mathrm{d}k_y}{\gamma k}P_n^{(m)}(\gamma/k)$$
$$\times\left[\left(\frac{k_q-ik_y}{k}\right)^m+\left(\frac{k_q+ik_y}{k}\right)^m\right]\frac{1}{1-\exp-i[c_x(-k_{0x}+k_q)+c_z(-k_{0z}+\gamma)]}. \tag{32}$$

IV. LATTICE SUMS AND ROTATIONS

We have described two different methods of arriving at the monolayer sums: working down from three-dimensional sums, and putting together one-dimensional sums. In order to verify that

TABLE II. Monolayer sums from Eq. (6), S_{nm}^{ML6}, after rotation using Eq. (35), S'^{ML6}_{nm}, and from Eq. (21), S_{nm}^{ML21}.

n,m	S_{nm}^{ML6}	S'^{ML6}_{nm}	S_{nm}^{ML21}
0,0	$-0.282\,095-i\,7.300\,57$	$-0.282\,095-i\,7.300\,57$	$-0.282\,095-i\,7.300\,57$
1,−1	$4.377\,86-i\,9.495\,68$	$4.377\,86+i\,2.70\times10^{-7}$	$4.377\,85+i\,4.7\times10^{-12}$
1,0	$-3.82\times10^{-7}-i\,3.11\times10^{-15}$	$-13.4289-i\,2.22\times10^{-15}$	$-13.4290+i\,2.1\times10^{-12}$
1,1	$-4.377\,86-i\,9.495\,68$	$-4.377\,86+i\,2.70\times10^{-7}$	$-4.377\,85+i\,4.7\times10^{-12}$
2,−2	$10.9071-i\,7.051\,39$	$-3.70\times10^{-9}-i\,8.444\,55$	$+1.2\times10^{-10}-i\,8.444\,74$
2,−1	$-1.5\times10^{-8}-i\,3.7\times10^{-9}$	$1.5\times10^{-8}-i\,10.9071$	$-3.4\times10^{-11}+i\,10.9081$
2,0	$0.+i\,8.032\,45$	$3.6\times10^{-15}+4.619\,93$	$2.4\times10^{-10}+i\,4.6183$
2,1	$-1.5\times10^{-8}+i\,3.7\times10^{-9}$	$1.5\times10^{-8}+i\,10.9071$	$3.4\times10^{-11}+i\,10.9081$
2,2	$-10.9071-i\,7.051\,39$	$3.70\times10^{-9}-i\,8.444\,55$	$-1.2\times10^{-10}-i\,8.444\,74$

the two methods agree, we need take into account that the axes used in Secs. II and III are rotated with respect to each other. The effect of rotations on the S_{nm}^{ML} is, from their definition, just the same as their effect on the spherical harmonic functions Y_{nm}. We follow the discussion of Rose[20] concerning the rotational properties of Y_{nm}.

We characterize the rotation by Euler angles α, β, and η. We call the axes of Sec. II the original set, and those of Sec. III the rotated or primed set. Then our transformation equations are

$$x=x',\quad z=y',\quad y=-z', \tag{33}$$

so that the Euler angles of interest are

$$\alpha=-\pi/2,\quad \beta=\pi/2,\quad \eta=\pi/2. \tag{34}$$

Under a rotation, then, S_{lm} is transformed into

$$S'_{lm}=\sum_{m'} D^{l}_{m'm}(\alpha,\beta,\eta)S_{lm'}, \tag{35}$$

where, if $m'\geqslant m$,

$$D^{l}_{m'm}(\alpha,\beta,\eta)=\exp(-im'\alpha)d^{l}_{m'm}(\beta)\exp(-im\eta), \tag{36}$$

and

$$d^{l}_{m'm}(\beta)=\sqrt{(l+m)!(l-m)!(l+m')!(l-m')!}\times\sum_{p}(-1)^{p}\frac{(\cos\beta/2)^{2l+m-m'-2p}(-\sin\beta/2)^{m'-m+2p}}{(l-m'-p)!(l+m-p)!(l+m'-m)!p!}. \tag{37}$$

For $m'<m$, we use

$$d^{l}_{m'm}(\beta)=(-1)^{m'-m}d^{l}_{mm'}(\beta). \tag{38}$$

In Table II we show the application of Eq. (35) to rotate the monolayer sums from the coordinate system of Sec. II to that of Sec. III. The results show good agreement between the two methods for evaluating the sums: subtractively, using the lattice sums as the starting point, and additively, building on the chain sums. The small differences between the two methods grow with order of sums, and reflect the fact that calculations were carried out in MATHEMATICA, with integration points and summation terms being limited because of computation time restrictions. Note the differing symmetry properties between the sums S^{ML} and S'^{ML}, arising because of the differences between the Legendre functions for angles of 0° and 90°.

V. AN ANALYTIC RESULT FOR MONOLAYER SUMS

The monolayer sums may be divided into two parts: one associated with functions j_n, which are finite at the origin, and the other with functions y_n, which are singular at the origin. We will now show that the former may be evaluated analytically.

We consider

$$\mathcal{J}_{nm}^{\mathrm{ML}}=\sum_{\mathbf{R}_p\neq(0,0)} j_n(kR_p)Y_{nm}(\hat{\mathbf{R}}_p)\exp(i\mathbf{k}_0\cdot\mathbf{R_p}), \tag{39}$$

or, adding and subtracting a term from the origin,

$$\mathcal{J}_{nm}^{\mathrm{ML}}=-\frac{1}{\sqrt{4\pi}}\delta_{n,0}\delta_{m,0}+\sum_{\mathbf{R}_p}\frac{1}{4\pi i^n}\int Y_{nm}(\hat{\mathbf{k}})d\hat{\mathbf{k}}\exp[i(\mathbf{k}_0+\mathbf{k})\cdot\mathbf{R}_p]. \tag{40}$$

We take the sum over $\mathbf{R}_p$ inside the integral, and recognize that the exponential term generates a delta function, whose argument requires that the part of $\mathbf{k}_0+\mathbf{k}$ in the monolayer plane, or $\mathbf{k}_{0\perp}+\mathbf{k}_\perp$, matches a reciprocal lattice vector $\mathbf{Q}_h$. Denoting by $\mathcal{A}$ the area of the unit cell in the array, we obtain

$$\mathcal{J}_{nm}^{\mathrm{ML}}=-\frac{1}{\sqrt{4\pi}}\delta_{n,0}\delta_{m,0}+\frac{\pi}{\mathcal{A}i^n}\sum_{\mathbf{Q}_h}\int Y_{nm}(\hat{\mathbf{k}})\mathrm{d}\hat{\mathbf{k}}\delta[(\mathbf{k}_{0\perp}+\mathbf{k}_\perp)-\mathbf{Q}_h]. \tag{41}$$

Now, $\mathbf{Q}_{h\perp}^{-}=-\mathbf{k}_{0\perp}+\mathbf{Q}_h$, and $\mathbf{K}_\perp$ can equal $\mathbf{Q}_{h\perp}^{-}$ only if $h\in\Omega$, the set of propagating orders which can be diffracted by the monolayer. The final steps in the argument are to recognize that to a given $\mathbf{Q}_{h\perp}^{-}$ there are two three-dimensional wave vectors $(\mathbf{Q}_{h\perp}^{-},Q_{h\|})$ and $(\mathbf{Q}_{h\perp}^{-},-Q_{h\|})$, with associated unit vectors $\hat{\mathbf{Q}}_{h\perp}^{-+}$ and $\hat{\mathbf{Q}}_{h\perp}^{--}$, and to evaluate the Jacobian corresponding to the change of integration vector from $\hat{\mathbf{k}}$ to its part in the monolayer plane. The result is

$$\mathcal{J}_{nm}^{\mathrm{ML}}=-\frac{1}{\sqrt{4\pi}}\delta_{n,0}\delta_{m,0}+\frac{\pi}{k\mathcal{A}i^n}\sum_{h\in\Omega}[Y_{nm}(\hat{Q}_{h\perp}^{-+})+Y_{nm}(\hat{Q}_{h\perp}^{--})]/Q_{h\|}^{-}. \tag{42}$$

We validate this result with numerical evidence given in Fig. 4. This shows that $\mathcal{J}^{\mathrm{ML}}$ is an oscillating function of the size of the summation region in real space, but that Eq. (42) accurately predicts the center line of the oscillations.

VI. THE MONOLAYER GREEN'S FUNCTION

We now present the expression which may be used to evaluate the Green's function G_{ML}, given the monolayer sums. G_{ML} satisfies

$$(\nabla^2+k^2)G_{\mathrm{ML}}(\mathbf{r})=-\sum_p \delta(\mathbf{r}-\mathbf{R}_{p\perp})e^{i\mathbf{k_0}\cdot\mathbf{R}_{p\perp}}. \tag{43}$$

The solution may be expressed in terms of spherical Hankel functions[2]

$$G_{\mathrm{ML}}(\mathbf{r})=\frac{ik}{4\pi}\sum_p h_0^{(1)}(k|\mathbf{r}-\mathbf{R}_{p\perp}|)e^{i\mathbf{k_0}\cdot\mathbf{R}_{p\perp}}. \tag{44}$$

The term for $\mathbf{R}_{p\perp}=0$ is separated from the sum, with all other terms being expanded using the addition theorem for spherical waves.[2] The result is

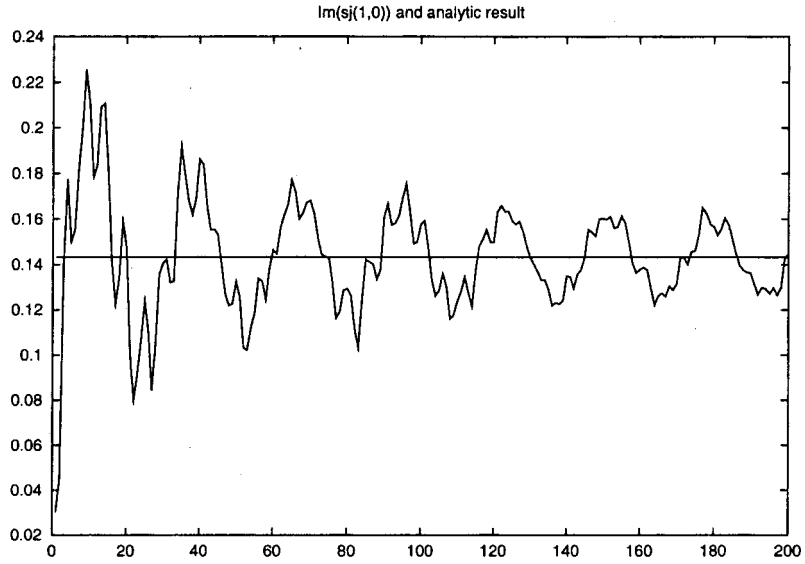

FIG. 4. A comparison of direct summation of $\mathrm{Im}(\mathcal{J}_{11}^{\mathrm{ML}})$ as a function of the size of the summation region with the result of Eq. (39) (horizontal line). The data are: $k=2\pi/0.69$, angles of incidence in polar form: $\theta=23°$, $\psi=37.18°$, $a_x=1.00$, $c_x=0.65$, $c_z=0.81$.

$$G_{\mathrm{ML}}(\mathbf{r})=\frac{ik}{4\pi}h_0^{(1)}(kr)+ik\sum_{n,m}(-1)^m S_{n,-m}^{\mathrm{ML}} j_l(kr)Y_{n,m}(\theta,\phi), \tag{45}$$

with θ, ϕ denoting the polar angles of $\mathbf{r}$.

The expression (45) converges like a geometric series whose radius of convergence is the smaller of a and b. If this is not sufficient to cover the unit parallelogram, then the origin of coordinates may be moved to another array point, with the monolayer sums being rephased appropriately.

VII. CONCLUSIONS

We have explored the connections between sums of spherical waves over lines, layers, and lattices. These connections are of interest numerically, in permitting the efficient and accurate construction of Green's functions for the fundamental alignments of spherical particles. They are also of interest theoretically, since they permit the construction of multipole Bloch methods, for example, to go from the scattering matrix of a sheet of spheres to the Bloch modes of a corresponding lattice of spheres. We will explore their applications in future studies of localization and homogenization in layered sphere systems.

(Received 14 December 2000; accepted for publication 18 September 2001)

We prove the following result on the generalized fractal dimensions $D_q^{\pm}$ of a probability measure μ on $\mathbb{R}^n$. Let g be a complex-valued measurable function on $\mathbb{R}^n$ satisfying the following conditions: (1) g is rapidly decreasing at infinity, (2) g is continuous and nonvanishing at (at least) one point, (3) $\int g \neq 0$. Define the partition function $\Lambda_a(\mu,q)=a^{n(q-1)}\|g_a * \mu\|_q^q$, where $g_a(x)=a^{-n}g(a^{-1}x)$ and $*$ is the convolution in $\mathbb{R}^n$. Then for all $q>1$ we have $D_q^{\pm}=1/(q-1)\lim_{r\to 0}\,^{\sup}_{\inf} \times[\log \Lambda_a\mu(r,q)/\log r]$. © *2001 American Institute of Physics.*

I. INTRODUCTION

Since the apparition of the fractal formalism in the late 1970s, there has been a huge amount of literature devoted to the different definitions of the fractal dimensions of probability measures (see, e.g., Refs. 1 and 2 for reviews). Roughly speaking, there are two types of fractal dimensions: the pointwise dimensions, which give essentially the local Hölder exponents of the measure, and the global ones, which can be seen as regularity indices in a scale of Besov spaces. Both families of dimensions are related to one another by the so-called multifractal formalism. The global dimensions were originally introduced by Renyi[3] and rediscovered by Hentschel and Procaccia in their seminal paper;[4] they are a generalization of the usual fractal dimension or capacity, and are therefore called ''generalized fractal dimensions.'' They are obtained by a box-counting algorithm, which amounts to partitioning the space in elementary cells and suming up powers of the individual contributions to the measure into what is called a partition function. There are several variants of this definition, according to the kind of covering that is chosen (grids, balls, redundant, nonredundant, etc.) and the kind of partition function (discrete or continuous). First used in the context of chaos and dynamical systems, the generalized fractal dimensions have regained interest in the framework of quantum diffusion in the presence of fractal spectra. After the pioonering work of Guarneri[5] many relations were established between the diffusive behavior of quantum wave packets and the generalized fractal dimensions (see, e.g., Refs. 6–9 for some recent results).

In order to simplify the numerous definitions and unify the results arising in dimension theory, it is important to find equivalences between the different approaches. This has been the aim of some recent works (e.g., Refs. 10–12, 2). In this short note we show that the generalized fractal dimensions can be obtained by replacing the boxes by arbitrary rapidly decaying complex-valued functions in the partition function, provided only these functions have nonzero mean.

II. THE GENERALIZED FRACTAL DIMENSIONS

Let μ be a probability Borel measure on $\mathbb{R}^n$ and consider a partition of the space in a grid of cubes $\mathcal{Q}(x_j,r)$ of center x_j and side $2r$. For $q \geqslant 0$, form the following partition function:

a)Electronic mail: caguerin@loe.u-3mrs.fr

$$\Lambda_1\mu(r,q)=\sum_j \mu(\mathcal{Q}(x_j,r))^q. \tag{2.1}$$

The so-called Rényi dimensions $D_q^{\pm}$ (Ref. 4) of the measure μ are defined as the limiting exponents of the last function as $r\to 0$, precisely:

$$D_q^{\pm}=\frac{\tau_q^{\pm}}{q-1}, \quad q\neq 1 \tag{2.2}$$

with

$$\tau_q^{\pm}=\lim_{r\to 0} \begin{matrix}\sup\\ \inf\end{matrix} \frac{\log \Lambda_1\mu(r,q)}{\log r}. \tag{2.3}$$

This normalization recasts the dimensions on the unit interval, $0\leqslant D_q^{\pm}\leqslant 1$, at least for $q>1$ (see Ref. 12 for a detailed discussion). Note that (2.2) is not defined for $q=1$. Hentschel and Proccacia[4] have shown heuristically the existence of the limit $q\to 1$, thereby defining $D_1^{\pm}$ by continuity. A rigorous analysis[12] however, shows that $D_q^{\pm}$ are only left- and right-continuous about $q=1$, with a possible discontinuity. The dimension $D_0^{\pm}$ is the usual fractal dimension or capacity. The dimension $D_2^{\pm}$ is known as the correlation dimension. A continuous version[4,10] of the partition function (2.1) is

$$\Lambda_2\mu(r,q)=\int_{\mathbb{R}^n}\mu(\mathcal{B}(x,r))^{q-1}\,\mathrm{d}\mu(x), \tag{2.4}$$

where $\mathcal{B}(x,r)$ is the ball of center x and radius r. The corresponding limiting exponents, defined after (2.2) and (2.3), are called *generalized fractal dimensions*. Note that the integration is performed against the measure μ, which is possibly singular. A more tractable definition consists in integrating versus the Lebesgue measure, by formally replacing $\mathrm{d}\mu(x)$ by the absolutely continuous measure $r^{-n}\mu(\mathcal{B}(x,r))$:

$$\Lambda_3\mu(r,q)=r^{-n}\int_{\mathbb{R}^n}\mu(\mathcal{B}(x,r))^q\mathrm{d}x. \tag{2.5}$$

Although more convenient, this formula seems to be less popular in the literature. The equivalence of definitions (2.1) and (2.4) has been shown in Ref. 13 for $q>1$ (also rewritten in Ref. 2, p. 184), and the equivalence of (2.1) and (2.5) follows by an obvious adaptation of the proof. The equivalence for $0<q<1$ has been proved more recently.[12] We thus have, for all $q>0 (q\neq 1)$, three equivalent definitions of the generalized fractal dimensions:

$$D_q^{\pm}=\frac{1}{q-1}\lim_{r\to 0} \begin{matrix}\sup\\ \inf\end{matrix} \frac{\log \Lambda_{j\mu}(r,q)}{\log r}, \quad j=1,2,3. \tag{2.6}$$

III. MAIN RESULT

As we are going to show, the balls or boxes used to define the partition functions $\Lambda_j\mu$ can be replaced by arbitrary measurable functions, provided the latter are rapidly decreasing. This is very natural for non-negative functions, which can be seen as smooth cutoff functions, but less obvious for complex or signed functions. For any measurable complex-valued function g on $\mathbb{R}^n$ denote by $g_a(x)=a^{-n}g(a^{-1}x)$, $a>0$, its dilated version and define the partition function

$$\Lambda_a(\mu,q)=a^{n(q-1)}\|g_a*\mu\|_q^q=a^{n(q-1)}\int \mathrm{d}b|g_a*\mu(b)|^q,$$

where the asterisk $(*)$ stands for the convolution:

$$g_a*\mu(b)=\int g_a(b-x)\mathrm{d}\mu(x),$$

We start by recalling a useful rule of computation for the limiting exponents. A proof of this result can be found in Ref. 14, for example.

Lemma 3.1: Let s be a non-negative measurable function. Then

$$\liminf_{t\to 0}\frac{\log s(t)}{\log t}=\sup\{\gamma: st(t)\leqslant O(t^{\gamma}),\ t\to 0\},$$

$$\limsup_{t\to 0}\frac{\log s(t)}{\log t}=\inf\{\gamma: t^{\gamma}\leqslant O(s(t)),\ t\to 0\}.$$

Next we consider the case of non-negative functions.

Lemma 3.2: Let g be a non-negative measurable function g on $\mathbb{R}^n$ which is continuous and nonvanishing at (at least) one point and rapidly decreasing at infinity. Then for all $q>1$ we have

$$D_q^{\pm}=\frac{1}{q-1}\lim_{r\to 0}\ \sup_{\inf}\ \frac{\log \Lambda_a\mu(r,q)}{\log r}. \tag{3.1}$$

Proof: First note that we do not change the limit (3.1) on replacing g by a translated and rescaled version $\lambda g(\alpha t-\beta)$. Since g remains positive in some neighborhood of, say, t_0, we can rescale g in such a way that $ch\leqslant g\leqslant Ch$, where h is some non-negative function with $h(t)=1$ for $t\in[-1,1]$ and c,C are two positive constants. Hence it suffices to prove the lemma for such a function h. Let $\epsilon>0$. For all $a>0$ small enough and $b\in\mathbb{R}$ we have

$$\begin{aligned}|h_a*\mu(b)|&=\int h_a(t)\mathrm{d}\mu(b-t)\\ &\geqslant\int_{|t|\leqslant a^{1+\epsilon}} h_a(t)\mathrm{d}\mu(b-t)\\ &\geqslant a^{-n}\min_{|t|\leqslant a^{\epsilon}}\{h(t)\}\mu(\mathcal{B}(b,a^{1+\epsilon}))\\ &\geqslant a^{-n}\mu(\mathcal{B}(b,a^{1+\epsilon})).\end{aligned}$$

Integrating over b this yields to

$$\|h_a*\mu\|_q^q\geqslant a^{(1-q)n+\epsilon n}\Lambda_3\mu(a^{1+\epsilon},q). \tag{3.2}$$

The reverse estimation is more touchy. For all $\epsilon>0$ we have

$$\begin{aligned}|h_a*\mu(b)|&\leqslant\int_{|t|\leqslant a^{1-\epsilon}}|h_a(t)|\mathrm{d}\mu(b-t)+\int_{|t|>a^{1-\epsilon}}|h_a(t)|\mathrm{d}\mu(b-t)\\ &\leqslant a^{-n}\|g\|_{\infty}\mu(\mathcal{B}(b,a^{1-\epsilon}))+\int_{|t|>a^{1-\epsilon}}|h_a(t)|\mathrm{d}\mu(b-t)\end{aligned}$$

and thus

$$\|h_a*\mu\|_q^q\leqslant C_q a^{(1-q)n-\epsilon n}\Lambda_3\mu(a^{1-\epsilon},q)+C_q\int \mathrm{d}b\left(\int_{|b-t|>a^{1-\epsilon}} h_a(b-t)\mathrm{d}\mu(t)\right)^q \tag{3.3}$$

for some constant C_q. We have to show that the contribution of the second term is negligible. By Jensen's inequality, we have for all $q>1$,

$$\left(\int_{|t|>a^{1-\epsilon}} h_a(t)\mathrm{d}\mu(b-t)\right)^q \leqslant \left(\int_{|b-t|>a^{1-\epsilon}} \mathrm{d}\mu(t)\right)^{q-1} \int_{|b-t|>a^{1-\epsilon}} h_a^q(b-t)\mathrm{d}\mu(t).$$

Thus, calling $I(a)$ the second term on the right-hand side of (3.3), we have

$$\begin{aligned} I(a) &\leqslant C_q \int \mathrm{d}b \int_{|t|>a^{1-\epsilon}} h_a^q(t)\mathrm{d}\mu(b-t) \\ &= C_q \int_{|t|>a^{1-\epsilon}} h_a^q(t) \int \mathrm{d}\mu(b-t) = C_q a^{(1-q)n} \int_{|t|>a^{-\epsilon}} g^q(t), \end{aligned}$$

where we use the finiteness of μ to exchange the integrals. Now since g is rapidly decreasing at infinity, the tails of its integrals also and thus $I(a)\leqslant O(a^\infty), a\to 0$. Since (3.2) and (3.3) hold for arbitrarily small ϵ, the conclusion follows from Lemma 3.1. □

Note: A proof of this result in the case $0<q<1$ has been given in Ref. 12, Theorem A.1.

We now can state the main result:

Theorem 3.3: *Let g be a complex-valued measurable function on $\mathbb{R}^n$ satisfying the following conditions:*

(1) g is rapidly decreasing at infinity,
(2) g is continuous and nonvanishing at (at least) one point,
(3) $\int g \neq 0$.

Then for all $q>1$ we have

$$D_q^{\pm} = \frac{1}{q-1} \lim_{r\to 0} \begin{matrix}\sup \\ \inf\end{matrix} \frac{\log \Lambda_a \mu(r,q)}{\log r}. \tag{3.4}$$

This will be an easy consequence of the following lemma.

Lemma 3.4: Let g be a rapidly decreasing complex-valued measurable function such that $\int g \neq 0$. Then there exists a non-negative function ϕ in $\mathcal{S}(\mathbb{R}^n)$ (the Schwartz space of infinitely differentiable rapidly decreasing functions) and a complex-valued function $\psi \in \mathcal{S}(\mathbb{R}^n)$ such that $\phi = g^* \psi$.

Proof: Let $\hat{g}$ be the notation for the Fourier transform of a L^1 function g:

$$\hat{g}(k) = \int e^{-ikx} g(x)\mathrm{d}x.$$

Without restriction we may suppose $|\int g| = |\hat{g}(0)| = 1$. Since $\hat{g}$ is a continuous function, we can find some neighborhood $V = B(0,\epsilon)$ about the origin in which $|\hat{g}|>1/2$ on V. Now take a smaller neighborhood $V' = B(0,\epsilon/2)$ and some nonzero $h \in C_0^\infty(\mathbb{R}^n)$ with support in V'. Define ϕ by its Fourier transform: $\hat{\phi} = h * \tilde{h}$, where $\tilde{h}(x) = \overline{h}(-x)$ and $\overline{h}$ is the complex conjugate of h. Then support $(\hat{\phi}) \subset V$ and $\phi = |\hat{h}|^2$ is a non-negative function in $\mathcal{S}(\mathbb{R}^n)$. It remains to construct ψ. This can be done by setting $\hat{\psi} = \hat{\phi}/\hat{g}$ on V, $\hat{\psi} = 0$ elsewhere. The two functions then satisfy $\phi = g * \psi$ and ψ is in $\mathcal{S}(\mathbb{R}^n)$ for $\hat{\psi}$ is in $C_0^\infty(\mathbb{R}^n)$. □

Proof (of Theorem 3.3): Take two functions ϕ and ψ as in Lemma 3.4. Then for all $q>1$, we have by Young's inequality:

$$\|\mu * \phi_a\|_q = \|(\mu * g_a) * \psi_a\|_q \leqslant \|\mu * g_a\|_q \|\psi\|_1.$$

On the other hand,

$$\|\mu * g_a\|_q \leqslant \|\mu * |g_a|\|_q .$$

Both functions ϕ and $|g|$ fulfill the hypothesis of Lemma 3.2. The partition functions $a^{n(q-1)}\|\mu * \phi_a\|_q$ and $a^{n(q-1)}\|\mu * |g_a|\|_q$ therefore satisfy (2.6), and since they "sandwich" $\Lambda_a(\mu,q)$, the conclusion follows. □

Filtered random variables, bialgebras, and convolutions

Romuald Lenczewski[a)]
Institute of Mathematics, Wrocław University of Technology, Wybrzeze Wyspianskiego 27, 50-370 Wrocław, Poland

(Received 6 March 2001; accepted for publication 29 August 2001)

We introduce the *filtered *-bialgebra* which is a multivariate generalization of the unital *-bialgebra $\mathbf{C}\langle X,X',P\rangle$ of polynomials in noncommuting variables $X=X^*$, $X'^*=X'$ and a projection $P=P^*=P^2$, endowed with the coproduct $\Delta(X)=X\otimes 1+1\otimes X$, $\Delta(X')=X'\otimes P+P\otimes X'$, with P being group-like. We study the associated convolutions, random walks and *filtered random variables*. The GNS representations of the limit states lead to *filtered fundamental operators* which are the CCR fundamental operators on the multiple symmetric Fock space $\Gamma(\mathcal{H})$ over $\mathcal{H}=L^2(\mathbf{R}^+,\mathcal{G})$, where $\mathcal{G}$ is a separable Hilbert space, multiplied by appropriate projections. The importance of filtered random variables and fundamental operators stems from the fact that by addition and strong limits one obtains from them the main types of noncommutative random variables and fundamental operators, respectively, regardless of the type of noncommutative independence. © *2001 American Institute of Physics.* [DOI: 10.1063/1.1412465]

I. INTRODUCTION

In this work we introduce and study basic noncommutative random variables, from which the main types of noncommutative random variables can be constructed regardless of the notion of independence.

The basic idea of introducing filtered random variables is pretty straightforward and has its origin in the definition of the convolution of measures and the associated states. Let $\mathbf{C}[X]$ be the unital *-algebra of polynomials in $X^*=X$, with the coproduct

$$\Delta(X)=X\otimes 1+1\otimes X. \tag{1.1}$$

If ϕ, ψ are states on $\mathbf{C}[X]$, then

$$\phi\star_c\psi=\phi\otimes\psi\circ\Delta$$

gives the convolution of states corresponding to the classical convolution of measures.

In order to define a quantum deformation of this simple model, we replace the unit in the coproduct (1.1) by a projection P to get

$$\Delta(X')=X'\otimes P+P\otimes X',\quad \Delta(P)=P\otimes P. \tag{1.2}$$

Then, for given state ϕ on $\mathbf{C}[X']$, we define its noncommutative extension $\tilde{\phi}$ to $\mathbf{C}\langle X',P\rangle$, which is the free product $\mathbf{C}[X']*\mathbf{C}[P]$ with identified units, by

$$\tilde{\phi}(P^{\alpha}Y^{n_1}PY^{n_2}P\cdots Y^{n_k}P^{\beta})=\phi(Y^{n_1})\phi(Y^{n_2})\cdots\phi(Y^{n_k}),$$

where $\alpha,\beta\in\{0,1\}$ and $n_1,\ldots,n_k\in\mathbf{N}$, called the Boolean extension.[1] The convolution

$$\tilde{\phi}\uplus\tilde{\psi}=\tilde{\phi}\otimes\tilde{\psi}\circ\Delta,$$

a)Electronic mail: lenczew@im.pwr.wroc.pl

where Δ is given by (1.2), gives a quantum analog of the classical convolution of states, called the Boolean convolution. Note that by introducing P, which plays a similar role to the q-commuting operators in q-deformed Hopf *-algebras[2,3] and *-bialgebras,[4] we can deal with tensor coproducts (for a different formalism, see Ref. 5). The same holds for the m-free and free products of states.

This new convolution is very important since its generalization to the multivariate case, when restricted to suitable *-bialgebras, gives also m-free and free convolutions.[1,6] In the multivariate case we study the unital *-algebra $\hat{\mathcal{B}}$ over $\mathbf{C}$ generated by $X_k(\sigma)$, $P(\sigma)$ $k\in\mathbf{N}$, $\sigma\in\mathcal{P}(\mathbf{N})$, where $\mathcal{P}(\mathbf{N})$ is the power set of $\mathbf{N}$, with the involution given by $X_k(\sigma)=X_k^*(\sigma)$, $P(\sigma)^*=P(\sigma)$, and subject to the relations

$$P(\sigma)P(\tau)=P(\sigma\cap\tau),\quad P(\varnothing)=1,$$

$$P(\sigma)X_k(\tau)=X_k(\tau)P(\sigma)\quad \text{iff}\ \ k\in\sigma,$$

i.e., $P(\sigma)$'s are projections which ''partially commute'' with the variables $X_k(\sigma)$. When equipped with the coproduct and the counit

$$\hat{\Delta}(X_k(\sigma))=X_k(\sigma)\otimes P(\sigma)+P(\sigma)\otimes X_k(\sigma),$$

$$\hat{\Delta}(P(\sigma))=P(\sigma)\otimes P(\sigma),\quad \hat{\epsilon}(X_k(\sigma))=0,\quad \hat{\epsilon}(P(\sigma))=1,$$

the algebra $\hat{\mathcal{B}}$ becomes a unital *-bialgebra called *filtered *-bialgebra*. Therefore, we are in the position to study random walks[7] and stochastic processes over *-bialgebras.[4,8]

We take a suitable state $\hat{\phi}$ on $\hat{\mathcal{B}}$, which is obtained by lifting the tensor product state $\tilde{\phi}^{\otimes\infty}$ on $\otimes_{k=1}^{\infty}\mathbf{C}\langle Y_k,P_k\rangle$ to $\hat{\mathcal{B}}$ through the mapping which sends each $X_k(\sigma)$ onto Y_k and $P(\sigma)$ onto the tensor product of P_k's with $k\in\sigma$, where $Y_k^*=Y_k$ and P_k a projection. The state $\hat{\phi}$ is our noncommutative, ''filtered'' analog of the classical product measure (σ's play the role of filters due to ''partial commutations'').

The corresponding convolution central limit theorem (or discrete random walk), which plays the role of a noncommutative analog of the classical multivariate central limit theorem, gives, under the usual normalization, pointwise convergence of the Nth convolution power

$$\hat{\phi}^{\star N}=\hat{\phi}^{\otimes N}\circ\hat{\Delta}^{N-1},$$

where $\hat{\Delta}^{N-1}$ is the $N-1$th iteration of the coproduct $\hat{\Delta}$.

The summands produced by iterating the coproduct are called *filtered random variables* and can be viewed as quantum analogs of independent *random vectors*. It is important to note that by taking suitable linear combinations (strongly convergent series on the GNS pre-Hilbert space) of filtered random variables we obtain m-free (free) random variables. Thus all three basic notions of quantum independence in the axiomatic theory[9,10] (tensor, free, and Boolean) are covered by this scheme.

By considering random walks with continuous time, or stochastic processes over the filtered *-bialgebra, we obtain in the limit the vacuum expectation state in the multiple symmetric Fock space $\Gamma(\mathcal{H})$, where

$$\mathcal{H}=L^2(\mathbf{R}^+)\otimes\mathcal{G}$$

and $\mathcal{G}$ is a separable Hilbert space called the multiplicity space. The GNS representation leads to *filtered fundamental operators* which are the CCR fundamental operators on $\Gamma(L^2(\mathbf{R}^+)\otimes\mathcal{G})$, multiplied by projections $P^{(\sigma)}$, is the second quantization of the canonical projection onto subspaces of $L^2(\mathbf{R}^+)\otimes\mathcal{G}$ built from the modes (called *colors*) which belong to the set σ.

Fundamental operators associated with different notions of independence can be expressed in terms of the filtered ones. In particular, one can define bounded extensions to $\Gamma(L^2(\mathbf{R}^+)\otimes\mathcal{G})$ of

m-free creation and annihilation operators[11] as strongly convergent series of filtered creation and annihilation operators, respectively. This formalism enables us not only to embed the free (or, full) Fock space over $L^2(\mathbf{R}^+)$ in $\Gamma(\mathcal{H})$, but also decompose $\Gamma(\mathcal{H})$ into an orthogonal sum of subspaces which are isomorphic to the free Fock space.

The corresponding *filtered stochastic calculus* is developed in Ref. 12 and it is, in fact, a generalization of the Hudson–Parthasarathy calculus[13] (see also Ref. 14) on multiple symmetric Fock spaces[15] and includes a new version of the free calculus, originally developed for the Cuntz algebra,[16] as well as gives calculi for the hierarchy of *m*-free Brownian motions.[6] In that context, see also Refs. 17 and 18.

In Sec. II we introduce the filtered *-bialgebra which sets the framework for a unified approach to noncommutative probability. This leads to filtered random variables, which are introduced in the more general setting of unital *-algebras in Sec. III. Their combinatorics and the recurrence relation for the product state is given in Sec. IV. Convolution limit theorems are proved in Sec. V. In Sec. VI we introduce the filtered fundamental operators. These are used for the GNS construction of the limit of a sequence of random walks on the filtered *-bialgebra in Sec. VII. In Sec. VIII we determine the combinatorics of general filtered white noises. In Sec. IX we study in more detail extensions of the *m*-free and free creation and annihilation operators to all of $\Gamma(\mathcal{H})$. A free Fock space decomposition of $\Gamma(\mathcal{H})$ is established.

We denote all scalar products by $\langle .,. \rangle$ and identify operators and their ampliations if no confusion arises.

II. FILTERED BIALGEBRA AND CONVOLUTION

In this section we discuss the bialgebra in our construction and the associated convolution. For general background on this, we refer the reader to Refs. 4 and 7.

For simplicity, consider first the unital *-algebra $\mathbf{C}[X]$ of polynomials in the variable $X = X^*$ endowed with the coproduct

$$\Delta : \mathbf{C}[X] \to \mathbf{C}[X] \otimes \mathbf{C}[X]$$

given by

$$\Delta(X) = X \otimes 1 + 1 \otimes X \tag{2.1}$$

and the counit $\epsilon : \mathbf{C}[X] \to \mathbf{C}$ given by $\epsilon(X) = 0$. This coproduct leads to the *classical convolution* of measures and thus classical convolution of states.

Namely, if ϕ, ψ are states on $\mathbf{C}[X]$ associated with measures μ, ν on the real line, i.e.,

$$\phi(X^n) = \int_{\mathbf{R}} x^n \, \mathrm{d}\mu(x), \quad \psi(X^n) = \int_{\mathbf{R}} x^n \, \mathrm{d}\nu(x),$$

then the convolution of states

$$\phi \star_c \psi = \phi \otimes \psi \circ \Delta$$

corresponds to the classical convolution of measures $\mu \star_c \nu$ in the sense that

$$\phi \star_c \psi(X^n) = m_n(\mu \star_c \nu),$$

where $m_n(\mu \star_c \nu)$ is the nth moment of the measure $\mu \star_c \nu$.

The coproduct is a convenient tool to produce independent random variables.[7] Namely, by applying successive iterations of Δ to X, we obtain

$$\Delta^{N-1}(X) = \sum_{k=1}^{N} j_{l,N}(X),$$

where $\Delta^N := (\mathrm{id}\otimes\Delta^{N-1})\circ\Delta$ for $N>1$ with $\Delta^1=\Delta$, and the summands

$$j_{l,N}(X)=1^{\otimes(l-1)}\otimes X\otimes 1^{\otimes(N-l)},\quad 1\leqslant l\leqslant N,$$

can be viewed as independent random variables with respect to the state $\phi^{\otimes N}$.

The so-called *Boolean convolution* can be obtained by considering the unital*-algebra of polynomials in two noncommuting self-adjoint variables $\mathbf{C}\langle X',P\rangle$, where P is a projection, with the coproduct

$$\Delta:\mathbf{C}\langle X',P\rangle\to\mathbf{C}\langle X',P\rangle\otimes\mathbf{C}\langle X',P\rangle,$$

given by

$$\Delta(X')=X'\otimes P+P\otimes X',\quad \Delta(P)=P\otimes P, \tag{2.2}$$

and the counit $\epsilon(X')=0$, $\epsilon(P)=1$. It can be shown that this coproduct gives the Boolean convolution of states and thus the Boolean convolution of measures.[19] This follows from the hierarchy of freeness construction,[1] but a direct proof will be presented in the following.

Definition 2.1: If ϕ is a state on $\mathbf{C}[Y]$, where $Y^*=Y$, then its *Boolean extension* is the state on $\mathbf{C}\langle Y,P\rangle$, where P is a projection, given by the linear extension of

$$\tilde{\phi}(P^{\alpha}Y^{n_1}PY^{n_2}P\cdots Y^{n_k}P^{\beta})=\phi(Y^{n_1})\phi(Y^{n_2})\cdots\phi(Y^{n_k}), \tag{2.3}$$

where $\alpha,\beta\in\{0,1\}$ and $n_1,\ldots,n_k\in\mathbf{N}$, with $\tilde{\phi}(P)=1$. If ϕ is a state on the unital *-algebra $\mathcal{A}$, then its Boolean extension $\tilde{\phi}$ to the free product $\tilde{\mathcal{A}}=\mathcal{A}*\mathbf{C}[P]$ (units identified) is defined in an analogous way.

The Boolean extension of a state is a state since it is obtained as the Boolean product of the state ϕ on $\mathbf{C}[Y]$ and the unital *-homomorphism h on $\mathbf{C}[P]$ given by $h(P)=h(1)=1$.

In order to have a unified model for both convolutions it is now enough to incorporate both coproducts (2.1) and (2.2) into one scheme. This is done as follows. The unital *-algebra $\mathcal{B}=\mathbf{C}\langle X,X',P\rangle$ where $X=X^*$, $X'=X'^*$ and P is a projection, endowed with the coproduct $\Delta:\mathcal{B}\to\mathcal{B}\otimes\mathcal{B}$ and counit $\epsilon:\mathcal{B}\to\mathbf{C}$ given by

$$\Delta(X)=X\otimes 1+1\otimes X,\quad \Delta(X')=X'\otimes P+P\otimes X',$$

$$\Delta(P)=P\otimes P,\quad \epsilon(X)=\epsilon(X')=0,\quad \epsilon(P)=1$$

(in other words, X is primitive, X' is P-primitive, and P is group-like), becomes a unital *-bialgebra. Both classical and Boolean convolutions are recovered from $(\mathcal{B},\Delta,\epsilon)$, as we show in the following.

Proposition 2.2: Let $\eta:\mathcal{B}\to\mathbf{C}\langle Y,P\rangle$, where $Y=Y^*$ and $P^2=P=P^*$, be the linear and multiplicative extension of

$$\eta(X)=\eta(X')=Y,\quad \eta(P)=P,\quad \eta(1)=1$$

and, for states ϕ, ψ on $\mathbf{C}[Y]$, let $\phi_0=\tilde{\phi}\circ\eta$, $\psi_0=\tilde{\psi}\circ\eta$ with the convolution

$$\phi_0\star\psi_0=\phi_0\otimes\psi_0\circ\Delta, \tag{2.4}$$

where Δ is the coproduct for $\mathcal{B}$. Then the restrictions of $\phi_0\star\psi_0$ to $\mathbf{C}[X]$ and $\mathbf{C}[X']$, respectively, agree with $\phi\star_c\psi$ and $\phi\uplus\psi$, respectively.

Proof: Recall[19] that the Boolean convolution of states ϕ, ψ on $\mathbf{C}[X]$ and $\mathbf{C}[X']$, respectively, is defined to be the state $\phi\uplus\psi$ on $\mathbf{C}[Y]$ given by the linear extension of $\phi\uplus\psi(Y^n)=\phi*^B\psi((X+X')^n)$, where $\phi*^B\psi$ is the Boolean product of states on the free product $\mathbf{C}[X]*\mathbf{C}[X']$.

Note that ϕ_0 and ψ_0 are states since η is a unital *-homomorphism. That the restriction of the convolution (2.4) to $\mathbf{C}[X]$ gives classical convolution is obvious. In turn, the statement concerning the Boolean convolution follows from the fact that the subalgebras $\mathbf{C}[Y]\otimes P, P\otimes\mathbf{C}[Y]$ of $\mathbf{C}\langle Y,P\rangle\otimes\mathbf{C}\langle Y,P\rangle$ are Boolean independent with respect to the state $\tilde{\phi}\otimes\tilde{\psi}$. This fact can be easily seen from the following calculation:

$$\tilde{\phi}\otimes\tilde{\psi}(Y^{k_1}\otimes P)(P\otimes Y^{n_2})(Y^{k_2}\otimes P)(P\otimes Y^{n_2})\cdots)=\hat{\phi}\,(Y^{k_1}PY^{k_2}P\cdots)\hat{\psi}\,(PY^{n_1}PY^{n_2}\cdots)$$
$$=\phi(Y^{k_1})\psi(Y^{n_1})\phi(Y^{k_2})\psi(Y^{n_2})\cdots.$$

A more general setting of the Boolean product of states was given in Ref. 1. □

The quadruple $(\mathcal{B},\Delta,\epsilon,\phi_0)$ can be called the *random walk* (we follow Majid[7] in this terminology) on the *pair of quantum planes*. Note that on the quantum probability space level we may also study the pair $(\mathbf{C}\langle Y,P\rangle,\tilde{\phi})$, which corresponds to (polynomial functions on) a *pair of quantum real lines*.

Let us consider now the multivariate generalization of the *-bialgebra $\mathcal{B}$. In classical probability, the multivariate case in an algebraic formulation would be reached if we considered the unital *-algebra $\mathbf{C}[X_k;k\in\mathbf{N}]$ of polynomials in commuting variables $(X_k)_{k\in\mathbf{N}}$, with the classical coproduct

$$\Delta(X_k)=X_k\otimes 1+1\otimes X_k \tag{2.5}$$

and the counit $\epsilon(X_k)=0$.

Let us now define a quantum analog of this multivariate *-bialgebra, of which the bialgebra $\mathcal{B}$ is the ''one-dimensional'' version. Thus, introduce the unital *-algebra

$$\hat{\mathcal{B}}=\mathbf{C}\langle X_k(\sigma),P(\sigma);\ k\in\mathbf{N},\sigma\in\mathcal{P}(\mathbf{N})\rangle/J,$$

where $X_k(\sigma)=X_k^*(\sigma)$, $P(\sigma)^*=P(\sigma)$, $\mathcal{P}(\mathbf{N})$ is the power set of $\mathbf{N}$ and J is the two-sided ideal generated by the relations

$$P(\sigma)P(\sigma')=P(\sigma\cap\sigma'),\quad P(\varnothing)=1, \tag{2.6}$$

$$P(\sigma)X_k(\tau)=X_k(\tau)P(\sigma)\quad \text{iff}\ \ k\in\sigma, \tag{2.7}$$

i.e., the projection associated with the set σ (we call σ a *filter*) ''filters through'' the variables $X_k(\sigma)$ if the index $k\in\sigma$.

Proposition 2.3: The algebra $\hat{\mathcal{B}}$, equipped with the coproduct $\hat{\Delta}:\hat{\mathcal{B}}\to\hat{\mathcal{B}}\otimes\hat{\mathcal{B}}$ and the counit $\hat{\epsilon}:\hat{\mathcal{B}}\to\mathbf{C}$ given by

$$\hat{\Delta}(X_k(\sigma))=X_k(\sigma)\otimes P(\sigma)+P(\sigma)\otimes X_k(\sigma), \tag{2.8}$$

$$\hat{\Delta}(P(\sigma))=P(\sigma)\otimes P(\sigma),\quad \hat{\epsilon}(X_k(\sigma))=0,\quad \hat{\epsilon}(P(\sigma))=1 \tag{2.9}$$

*for all k and σ, is a unital *-bialgebra called filtered *-bialgebra.*

Proof: The coproduct and the counit preserve relations (2.6) and (2.7). □

By iterating this coproduct, called *filtered coproduct*, we obtain the sum

$$\hat{\Delta}^{N-1}(X_k(\sigma))=\sum_{l=1}^{N}\hat{j}_{l,N}(X_k(\sigma)) \tag{2.10}$$

of $P(\sigma)$-deformed random variables

$$\hat{j}_{l,N}(X_k(\sigma))=P(\sigma)^{\otimes l-1}\otimes X_k(\sigma)\otimes P(\sigma)^{\otimes(N-l)}, \tag{2.11}$$

where $\sigma \in \mathcal{P}(\mathbf{N})$, $k \in \mathbf{N}$, $1 \leqslant l \leqslant N$, $N \in \mathbf{N}$.

When we go over from quantum groups to quantum probability spaces, we identify $X_k(\sigma)$'s for all different σ and fixed k, as we did by using the map η in the "one-dimensional" case of Proposition 2.2. This is done in order to include different notions of independence in one scheme. For that purpose, we consider the mapping

$$\hat{\eta}: \ \hat{\mathcal{B}} \to \bigotimes_{k=1}^{\infty} \mathbf{C}\langle Y_k, P_k \rangle \tag{2.12}$$

given by the linear and multiplicative extension of

$$\hat{\eta}(P(\sigma)) = P_1^{r_1} \otimes P_2^{r_2} \otimes \cdots \otimes P_k^{r_k} \otimes \cdots, \tag{2.13}$$

$$\hat{\eta}(X_k(\sigma)) = 1_1 \otimes 1_2 \otimes \cdots \otimes 1_{k-1} \otimes Y_k \otimes 1_{k+1} \otimes \cdots, \tag{2.14}$$

where $\mathbf{C}\langle Y_k, P_k \rangle$ is the kth copy of $\mathbf{C}\langle Y, P \rangle$ and $r_k = 0$ if $k \in \sigma$, whereas $r_k = 1$ if $k \notin \sigma$. The infinite tensor product is taken with respect to the set $\{1_k, P_k, k \in \mathbf{N}\}$ (see Ref. 11 for the formal definition).

It can be seen that η is a unital *-homomorphism. Therefore, for a given state ϕ on $\mathbf{C}[Y]$, the functional

$$\hat{\phi} = \tilde{\phi}^{\otimes \infty} \circ \hat{\eta}, \tag{2.15}$$

is a state on $\hat{\mathcal{B}}$. It plays the role of a noncommutative analog of a vector state in classical probability. A generalization to vector states corresponding to products of different measures is immediate. It is enough to take

$$\hat{\phi} = \bigotimes_{k=1}^{\infty} \tilde{\phi}_k \circ \hat{\eta}, \tag{2.16}$$

where ϕ_k is a state on $\mathbf{C}[Y_k]$, $k \in \mathbf{N}$.

When we take (2.15) [or, (2.16)], the quadruple $(\hat{\mathcal{B}}, \hat{\Delta}, \hat{\epsilon}, \hat{\phi})$ will give our stationary *filtered random walk*, using the terminology of Majid,[7] which carries two structures, that of the unital *-bialgebra and that of the quantum probability space. The corresponding convolution of states

$$\hat{\phi} \star \hat{\psi} = \hat{\phi} \otimes \hat{\psi} \circ \hat{\Delta} \tag{2.17}$$

(or, products of states) will be called the *filtered convolution*. One of the main motivations to study the filtered *-bialgebras, convolutions, random walks, and stochastic processes comes from the following result (cf. Ref. 1).

Proposition 2.4: If $\hat{\phi}$ *and* $\hat{\psi}$ *are of the form* (2.16) *and* i *is the unital* *-*homomorphism*

$$i: \mathbf{C}\langle X_k, k \in \mathbf{N} \rangle \to \hat{\mathcal{B}}, \quad i(X_k) = X_k(\mathbf{N}),$$

then $\hat{\phi} \star \hat{\psi} \circ i$ *agrees with the classical convolution of products of states. If* $\hat{\phi}$ *and* $\hat{\psi}$ *are of the form* (2.15) *and* $i^{(m)}$ *denotes the unital* *-*homomorphism*

$$i^{(m)}: \mathbf{C}[X] \to \hat{\mathcal{B}}, \quad i^{(m)}(X) = \sum_{k=1}^{m} (X_k(k) - X_k(k-1))$$

where $X_k(p) = X_k(\{1, \ldots, p-1\})$, *then* $\hat{\phi} \star \hat{\psi} \circ i^{(m)}$ *agrees with the additive m-free convolution of states* $\phi \star_m \psi$ *on* $\mathbf{C}[X]$, $1 \leqslant m < \infty$. *The pointwise limit* $\lim_{m \to \infty} \hat{\phi} \star \hat{\psi} \circ i^{(m)}$ *agrees with the free convolution.*

Proof: The statement concerning the classical convolution of products of states is obvious since $P(\mathbf{N})=1$. In turn, the second part of the proposition is nontrivial and follows from the construction of *m*-free product states and the associated *-bialgebras (see Ref. 1, Sec. 5, where we also refer the reader for the definition of the *m*-free convolution). □

Since $\mathbf{C}\langle Y,P\rangle$ can be viewed as a *quantum pair of real lines*, on the quantum probability space level we can interpret our object of interest as (polynomial functions on) the product of infinitely many quantum pairs of real lines, which is our noncommutative analog of $\mathbf{R}^{\infty}$. On the bialgebra level, we have a bigger object since every variable X_k admits a family of different convolutions.

III. FILTERED RANDOM VARIABLES

In this section we introduce filtered random variables which are our noncommutative analogs of independent random vectors in the general setting of arbitrary unital *-algebras.

In analogy to the classical case, we obtain them by iterating the coproduct $\hat{\Delta}$ as in (2.10). Then, we embed $\hat{j}_{l,N}(X_k(\sigma))$ into $\hat{\mathcal{B}}^{\infty}$ to get

$$P(\sigma)^{\otimes(l-1)}\otimes X_k(\sigma)\otimes P(\sigma)^{\otimes\infty} \tag{3.1}$$

and generalize these to the arbitrary unital *-algebras. In order to do that, write (3.1) as the product

$$(1^{\otimes(l-1)}\otimes X_k(\sigma)\otimes 1^{\otimes\infty})(P(\sigma)^{\otimes(l-1)}\otimes 1\otimes P(\sigma)^{\otimes\infty})$$

of an ampliation of $X_k(\sigma)$ into $\hat{\mathcal{B}}^{\otimes\infty}$ and a projection indexed by σ. This shows that the definitions given in the following are a natural generalization of those of Sec. II.

Let $(\mathcal{A}_l)_{l\in L}$ be a family of unital *-algebras with units 1_l and let $(\phi_l)_{l\in L}$ be the corresponding family of states. Consider a noncommutative probability space $(\hat{\mathcal{A}}_1,\hat{\Phi}_1)$, where

$$\hat{\mathcal{A}}_1=\bigotimes_{l\in L}\hat{\mathcal{A}}_l^{\otimes\infty},\quad \hat{\Phi}_1=\bigotimes_{l\in L}\hat{\phi}_l^{\otimes\infty},$$

and $\tilde{\mathcal{A}}_l=\mathcal{A}_l*\mathbf{C}[P_l]$ is the free product with identified units, P_l being a projection, whereas $\tilde{\phi}$ is the Boolean extension of ϕ (Definition 2.1). The infinite tensor products are understood as in Ref. 11, with the canonical involution. This noncommutative probability space will be called the *multiple probability space* associated with the considered family of probability spaces since each of them appears infinitely many times in the considered tensor products. We will refer to those copies as *colors*. Roughly speaking, $\tilde{\mathcal{A}}_l^{\otimes\infty}$ and $\tilde{\phi}_l^{\otimes\infty}$ correspond to $\otimes_{k=1}^{\infty}\mathbf{C}\langle Y_k,P_k\rangle$ and $\tilde{\phi}^{\otimes\infty}$ for each $l\in L$, respectively, of Sec. II.

If $(\mathcal{H}_l,\pi_l,\Omega_l)$ is the GNS triple for the pair $(\mathcal{A}_l,\phi_l)$, then $(\mathcal{H}_l,\tilde{\pi}_l,\Omega_l)$ is the GNS triple for $(\tilde{\mathcal{A}}_l,\tilde{\phi}_l)$, $l\in L$, where $\tilde{\pi}_l$ agrees with π_l on $\mathcal{A}_l$ and $\tilde{\pi}_l(P_l)$ is the projection onto the cyclic vector Ω_l. For convenience, we can identify $x\in\mathcal{A}_l$ with $\pi_l(x)$, P_l with P_{Ω_l} and ϕ_l with the expectation state $\langle\Omega_l,.\Omega_l\rangle$ (see Ref. 11).

Guided by (3.1), from projections P_m we construct projections $\mathbf{P}(l,\sigma)$ to be elementary tensors in $\hat{\mathcal{A}}_1$ with components

$$\mathbf{P}(l,\sigma)_{m,k}=\begin{cases}P_m & \text{if } m\neq l \text{ and } k\notin\sigma\\ 1_m & \text{otherwise,}\end{cases}$$

where $\sigma\in\mathcal{P}(\mathbf{N})$ and $l\in L$. In the case when $\sigma=\{1,...,r-1\}$, we will write $\mathbf{P}(l,r)=\mathbf{P}(l,\sigma)$.

Definition 3.1: By *filtered random variables* we will understand elements of $\hat{\mathcal{A}}_1$ which are of the form

$$\mathbf{XP}, \tag{3.2}$$

where $\mathbf{X}=\mathbf{X}(l,k)$ is the (l,k)th ampliation of $x\in\mathcal{A}_l$ into $\hat{\mathcal{A}}_l$ and $\mathbf{P}=\mathbf{P}(l,\sigma)$, where $l\in L$, $k\in\mathbf{N}$, $\sigma\in\mathcal{P}(\mathbf{N})$. In particular, the unit $\mathbf{1}=\otimes_{l\in L}1_l^{\otimes\infty}$ is a filtered random variable.

If $L=\mathbf{N}$, filtered random variables can be represented as infinite matrices. Assume that k numbers the rows and l numbers the columns. For instance, for $x\in\mathcal{A}_2$, $\mathbf{X}=\mathbf{X}(2,3)$, and $\mathbf{P}=\mathbf{P}(2,4)$ we have

$$\mathbf{XP}=\begin{pmatrix} 1_1 & 1_2 & 1_3 & \cdots \\ 1_1 & 1_2 & 1_3 & \cdots \\ 1_1 & x & 1_3 & \cdots \\ P_1 & 1_2 & P_3 & \cdots \\ P_1 & 1_2 & P_3 & \cdots \\ . & . & . & \cdots \end{pmatrix}.$$

Note that if $L=\mathbf{N}$, multiplication of filtered random variables corresponds to Schur's multiplication of matrices.

Definition 3.2: Let $\tilde{\mathcal{A}}$ be the unital *-subalgebra of $\hat{\mathcal{A}}_1$ generated by all filtered random variables and let $\hat{\Phi}=\hat{\Phi}_1|\hat{\mathcal{A}}$. The noncommutative probability space $(\hat{\mathcal{A}},\hat{\Phi})$ will be called the *filtered probability space* associated with $(\mathcal{A}_l,\phi_l)_{l\in L}$ and the state $\hat{\phi}$ will be called the *filtered product* of $(\phi_l)_{l\in L}$. The unital *-subalagebras of $\hat{\mathcal{A}}$,

$$\hat{\mathcal{A}}_l=\langle\mathbf{XP}|\mathbf{X}=\mathbf{X}(l,k),\mathbf{P}=\mathbf{P}(l,\sigma),x\in\mathcal{A}_l,k\in\mathbf{N},\ \sigma\in\mathcal{P}(\mathbf{H})\rangle,\quad l\in L,$$

will be called *filtered with respect* to $\hat{\Phi}$.

Example 1: Let $*_{l\in L}\mathcal{A}_l$ denote the free product of $(\mathcal{A}_l)_{l\in L}$ with nonidentified units. Fix $k\in\mathbf{N}$, $\sigma\in\mathcal{P}(\mathbf{N})$ and define a *-homomorphism

$$j^{(k,\sigma)}:\quad *_{l\in L}\mathcal{A}_l\to\hat{\mathcal{A}}$$

as the linear extension of

$$j^{(k,\sigma)}(x_1\cdots x_n)=\mathbf{X}_1(l_1,k)\mathbf{P}(l_1,\sigma)\cdots\mathbf{X}_n(l_n,k)\mathbf{P}(l_n,\sigma)$$

for $x_i\in\mathcal{A}_{l_i}$, $l_1\neq l_2\neq\cdots\neq l_n$. Let us define the mapping

$$i:\quad *_{l\in L}\mathcal{A}_l\to\bigotimes_{l\in L}\mathcal{A}_l$$

as the linear extension of

$$i(x_1\cdots x_n)=i_{l_1}(x_1)\cdots i_{l_n}(x_n),$$

where i_l are canonical *-homomorphic embeddings of $\mathcal{A}_l$ into $\bigotimes_{l\in L}\mathcal{A}_l$. Then,

$$\hat{\Phi}\circ j^{(k,\sigma)}=\begin{cases}\otimes_{l\in L}\phi_l\circ i & \text{if } k\in\sigma\\ *^B_{l\in L}\phi_l & \text{if } k\notin\sigma\end{cases}$$

where $*^B_{l\in L}\phi_l$ denotes the Boolean (or, one-free) product of states $(\phi_l)_{l\in L}$ on $*_{l\in L}\mathcal{A}_l$. In other words, for fixed k, σ, the set $\{\mathbf{X}(l,k)\mathbf{P}(l,\sigma):l\in L\}$ is a family of tensor independent r.v. if $k\in\sigma$ and Boolean independent r.v. if $k\notin\sigma$ (see Ref. 1).

Example 2: As we showed in Ref. 1, the Boolean product is just the first-order approximation of the free product of states in free probability.[20] Higher order approximations given by the

modified hierarchy of m-free products[11] (the case with nonidentified units of the usual hierarchy of freeness[1]) can also be obtained from the filtered product. Namely, let $m \in \mathbf{N}$, and define

$$\overline{j^{(m)}}: \quad *_{l\in L}\mathcal{A}_l \to \hat{\mathcal{A}}$$

as the linear extension of

$$\overline{j^{(m)}}(x_1 \cdots x_n) = \overline{j_{l_1}^{(m)}}(x_1) \cdots \overline{j_{l_n}^{(m)}}(x_n),$$

where $x_i \in \mathcal{A}_{l_i}$, $l_1 \neq l_2 \neq \cdots \neq l_n$, and

$$\overline{j_l^{(m)}}(x) = \sum_{k=1}^{m} \mathbf{X}(l,k)(\mathbf{P}(l,k) - \mathbf{P}(l,k-1)) \tag{3.3}$$

for $x \in \mathcal{A}_l$. Then

$$\hat{\Phi} \circ \overline{j^{(m)}} = *_{l\in L}^{(m)} \phi_l,$$

where $*_{l\in L}^{(m)} \phi_l$ denotes the modified m-free product of states. If $m=\infty$, the series given by the representation of (3.3) converges strongly on the GNS pre-Hilbert space (see Ref. 11). Moreover,

$$\overline{j_l^{(\infty)}}(\mathbf{1}_l) = \mathbf{1}, \quad l \in L$$

and thus $\hat{\Phi} \circ \overline{j^{(\infty)}}$ is well defined on the free product of $\mathcal{A}_l$, $l \in L$, with identified units and agrees on it with the free product of states (for details, see Ref. 11). Thus, the variables $\overline{j_l^{(m)}}(x)$, $x \in \mathcal{A}_l$, $l \in L$, are m-free random variables for $m \in \mathbf{N}$ and free random variables if $m=\infty$.

IV. COMBINATORICS

Let us now introduce a new class of partitions which is crucial to the combinatorics of filtered random variables.

Definition 4.1: Let $\vec{k}=(k_1,\ldots,k_n)$ and $\vec{\sigma}=(\sigma_1,\ldots,\sigma_n)$ be color and filter tuples of natural numbers and sets of natural numbers, respectively. A partition $R=\{R_1,\ldots,R_q\}$ of the set $\{1,...,n\}$ will be called $(\vec{k},\vec{\sigma})$-*adapted* if and only if it satisfies the conditions

(A1) $\forall 1 \leqslant q \leqslant n \forall i,j \in R_q, \quad k_i = k_j$

(A2) If $i<m<j$, where $i,j \in R_q$ and $m \notin R_q$, then $k_i = k_j \in \sigma_m$.

The collection of all $(\vec{k},\vec{\sigma})$-adapted partitions (pair partitions) will be denoted by $\mathcal{P}_n(\vec{k},\vec{\sigma})$ ($\mathcal{P}_n^{\text{pair}}(\vec{k},\vec{\sigma})$). The partitions of $\{1,\ldots,n\}$ which are not $(\vec{k},\vec{\sigma})$-adapted will be called $(\vec{k},\vec{\sigma})$-*nonadapted*.

In other words, $\mathcal{P}_n(\vec{k},\vec{\sigma})$ is the subset of all partitions $\mathcal{P}_n$ of $\{1,...,n\}$ which are adapted to the tuples $\vec{k}$ and $\vec{\sigma}$ in the following sense: (A1) colors corresponding to the elements of the same block have to match, (A2) between the elements of a given block there are no filters associated with other blocks which separate them. In particular, if $k_i=k$, $\sigma_i=\sigma$ for all $1 \leqslant i \leqslant n$, then the two extreme cases are given by

$$\mathcal{P}_n(\vec{k},\vec{\sigma}) = \begin{cases} \mathcal{P}_n & \text{if } k \in \sigma \\ \mathcal{P}_n^{\text{int}} & \text{if } k \notin \sigma, \end{cases}$$

where $\mathcal{P}_n^{\text{int}}$ denotes the interval partitions of $\{1,\ldots,n\}$. In turn, if $\sigma_i = \mathbf{N}$ for all $i=1,...,n$, then

$$\mathcal{P}_n(\vec{k},\vec{\sigma}) = \mathcal{P}_n(\vec{k}),$$

where $\mathcal{P}_n(\vec{k})$ denotes all partitions R of the set $\{1,\ldots,n\}$ such that $k_i=k_j$ iff i,j belong to the same block of R (this corresponds to the classical multivariate case).

Definition 4.2: If R is $(\vec{k},\vec{\sigma})$-nonadapted, then the unique coarsest subpartition of R which is $(\vec{k},\vec{\sigma})$-adapted will be denoted by $R(\vec{k},\vec{\sigma})$.

Examples: Consider the partition

$$R=\{\{1,3,5\},\{2,4\}\}$$

of {1, ..., 5} and let the color tuple be given by $\vec{k}=(1,1,2,1,1)$. Then R is not $(\vec{k},\vec{\sigma})$-adapted for any $\vec{\sigma}$ since it does not satisfy (A1). If we take now the filter tuple $\vec{\sigma}=(\sigma_1,\ldots,\sigma_5)$ given by $\sigma_i=\{1,\ldots,r_i-1\}$, with $r_1=r_3=r_5=1$, $r_2=r_4=2$, then

$$R(\vec{k},\vec{\sigma})=\{\{1\},\{2\},\{3\},\{4\},\{5\}\}.$$

In turn, if we take $\vec{\tau}=(\tau_1,\ldots,\tau_5)$, where $\tau_i=\{1,\ldots,s_i-1\}$ and $s_1=s_5=1$ and $s_2=s_3=s_4=2$, then

$$R(\vec{k},\vec{\tau})=\{\{1,5\},\{2,4\},\{3\}\}.$$

We will see that partitions which are not $(\vec{k},\vec{\sigma})$-adapted are less important since they do not survive in the limit theorems. Therefore, there is an analogy with the crossing and noncrossing partitions in free probability, the $(\vec{k},\vec{\sigma})$-adapted playing a similar role to noncrossing partitions, whereas the non-$(\vec{k},\vec{\sigma})$-adapted behave like crossing partitions.

Let us give a recurrence formula for moments of filtered random variables, or ''filtered moments.'' It is convenient to introduce the following notions.

Definition 4.3: Given a tuple of pairs $((l_1,k_1),\ldots(l_n,k_n))$, we will say that (l_j,k_j) is a *singleton* if $(l_j,k_j)\neq(l_i,k_i)$ for all $i\neq j$. If $(l_i,k_i)=(l_j,k_j)$ for $i<j$ such that there is no $i<r<j$ for which $(l_r,k_r)=(l_i,k_i)$ and there exists $i<m<j$ such that $l_m\neq l_i$ and $k_i\notin\sigma_m$, then we will say that the filter σ_m *separates* (l_i,k_i) and (l_j,k_j).

Proposition 4.4: Let $\mathbf{X}_i:=\mathbf{X}(l_i,k_i)$, $\mathbf{P}_i:=\mathbf{P}(l_i,\sigma_i)$, $1\leqslant i\leqslant n$, *where* $x_i\in\mathcal{A}_{l_i}$, $l_i\in L$, $k_i\in\mathbf{N}$, $\sigma_i\in\mathcal{P}(\mathbf{N})$, *with* $n\in\mathbf{N}$, *and* $(l_1,k_1)\neq(l_2,k_2)\neq\ldots\neq(l_n,k_n)$. *Then*

$$\hat{\Phi}(\mathbf{X}_1\mathbf{P}_1\mathbf{X}_2\mathbf{P}_2\cdots\mathbf{X}_n\mathbf{P}_n)=\hat{\Phi}(\mathbf{X}_1\mathbf{P}_1)\hat{\Phi}(\mathbf{X}_2\mathbf{P}_2\cdots\mathbf{X}_n\mathbf{P}_n)$$

if (l_1,k_1) *is a singleton, or if there exists a filter* σ_m *which separates* (l_1,k_1) *and* (l_r,k_r), *where* r *is the first index for which* $(l_1,k_1)=(l_r,k_r)$, *and otherwise*

$$\hat{\Phi}(\mathbf{X}_1\mathbf{P}_1\mathbf{X}_2\mathbf{P}_2\cdots\mathbf{X}_n\mathbf{P}_n)=\hat{\Phi}(\mathbf{X}_2\mathbf{P}_2\cdots\mathbf{X}_1\mathbf{X}_r\mathbf{P}_r\cdots\mathbf{X}_n\mathbf{P}_n).$$

Proof: These formulas follow from the definition of filtered random variables. □

Proposition 4.5: Under the assumptions of Proposition 4.4,

$$\hat{\Phi}(\mathbf{X}_1\mathbf{P}_1\cdots\mathbf{X}_n\mathbf{P}_n)=\hat{\Phi}(\mathbf{X}_{B_1})\cdots\hat{\Phi}(\mathbf{X}_{B_r})=\phi_{l(B_1)}(x_{B_1})\cdots\phi_{l(B_r)}(x_{B_r}),$$

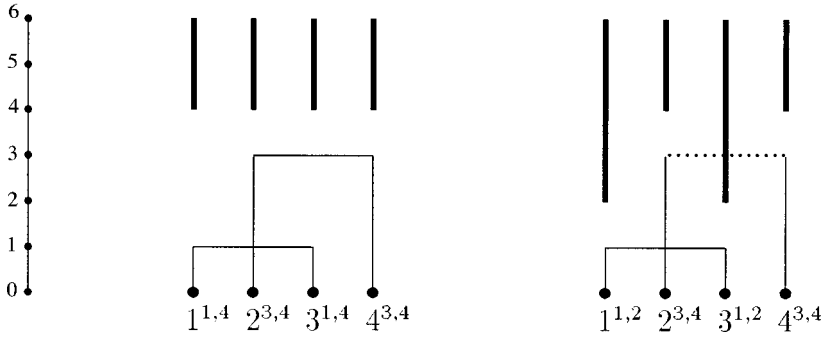
where R *is the partition associated with the tuple* $(l_1,\ldots,l_n)$, $B_1,\ldots,B_r$ *are the blocks of* $R(\vec{k},\vec{\sigma})$, $\mathbf{X}_B=\Pi_{j\in B}\mathbf{X}_j$ *and* $x_B=\Pi_{j\in B}x_j$ *are products taken in the natural order, and* $l(B)$ *is the index* $l\in L$ *associated with block* B.

Proof: This is a straightforward consequence of Proposition 4.4 and the fact that if $j_1,\ldots,j_r$ are elements of the same block $B\in R(\vec{k},\vec{\sigma})$, then

$$\hat{\Phi}(\mathbf{X}_{j_1}\mathbf{P}_{j_1}\cdots\mathbf{X}_{j_r}\mathbf{P}_{j_r})=\hat{\Phi}(\mathbf{X}_{j_1}\cdots\mathbf{X}_{j_r})=\phi_{l(B)}(x_{j_1}\cdots x_{j_r}).$$

(Definition 4.2 is crucial here.) □

Example: Let $L=\mathbf{N}$ and take $x_1,x_3\in\mathcal{A}_1$ and $x_2,x_4\in\mathcal{A}_2$. Then the partition $R=\{\{1,3\},\{2,4\}\}$ is associated with the tuple $(l_1,l_2,l_3,l_4)=(1,2,1,2)$. Let us consider two cases of color and filter tuples: (i) $\vec{k}=(1,3,1,3)$, $\vec{\sigma}=(4,4,4,4)$ and (ii) $\vec{m}=(1,3,1,3)$, $\vec{\tau}=(2,4,2,4)$. Then the corresponding "filtered moments" can be obtained by refinement of R and represented in terms of diagrams. By $p^{k,r}$ we understand the number p associated with color k and filter $\{1,...,r-1\}$.



In the diagrams, thick lines represent complements of filters, thin vertical lines represent the color (if the color is k, then their height is equal to k units on the axis shown), thin horizontal lines show connections between numbers which form a block, and the dotted line in the second diagram shows a connection (between 1 and 3) which is not realized (the filter $\tau_3=\{1\}$ "blocks" connections between colors $\geqslant 2$). The corresponding moments are given by

$$\text{(i)}\quad \phi_1(x_1x_3)\phi_2(x_2x_4),\quad \text{(ii)}\quad \phi_1(x_1x_3)\phi_2(x_2)\phi_2(x_4),$$

respectively. This simple example shows how a filter may kill certain connections in the "classical" partition R—this is the effect of "quantum" (filtered) independence.

V. CONVOLUTION LIMIT THEOREMS

In this section we will prove the central limit theorem and Poisson's limit theorem for filtered convolutions of states on the bialgebra $\hat{\mathcal{B}}$. We choose the convolution formulation for clarity of exposition, but the general case, based on the filtered product of states, is done in an analogous fashion.

The combinatorics of filtered convolution powers

$$\hat{\phi}^{\star N}=\hat{\phi}^{\otimes N}\circ\hat{\Delta}^{N-1},$$

where $N\in\mathbf{N}$, is given by Lemma 5.1. To a large extent we follow our approach for the convolution powers of q-deformed states on $U_q(su(2))$ given in Ref. 2.

Lemma 5.1: Let $\vec{k}=(k_1,\ldots,k_n)$, $\vec{\sigma}=(\sigma_1,\ldots,\sigma_n)$, *where* $k_i\in\mathbf{N}$, $\sigma_i\in\mathcal{P}(\mathbf{N})$, $1\leqslant i\leqslant n$, *and let* $N\in\mathbf{N}$. *Then*

$$\hat{\phi}^{\star N}(X_{k_1}(\sigma_1)\cdots X_{k_n}(\sigma_n))=\sum_{p=1}^{n}(N)_p\sum_{R=\{R_1,\ldots,R_p\}\in\mathcal{P}_n}\prod_{B\in R(\vec{k},\vec{\sigma})}\hat{\phi}(X_B),\tag{5.1}$$

where $(N)_p=N(N-1)\cdots(N-p+1)$ *and* $X_B=\pi_{i\in B}X_{k_i}(\sigma_i)$ *for the block* B *of the partition* $R(\vec{k},\vec{\sigma})$, *with the product taken in the natural order*.

Proof: Denote $X_1=X_{k_1}(\sigma_1),\ldots,X_n=X_{k_n}(\sigma_n)$. Using the notation of (2.11), we have

$$\hat{\phi}^{\star N}(X_1\cdots X_n)=\sum_{l_1,\ldots l_n=1}^{n}\hat{\phi}^{\otimes N}(\hat{j}_{l_1,N}(X_1)\cdots\hat{j}_{l_n,N}(X_n))$$

and

$$\hat{j}_{l_1,N}(X_1)\cdots\hat{j}_{l_n,N}(X_n)=\prod_{m=1}^{n} P(\sigma_m)^{\otimes(l_m-1)}\otimes X_m\otimes P(\sigma_m)^{\otimes(N-l_m)}.$$

The tuple $(l_1,\ldots,l_n)$ defines a partition R of the set $\{1,\ldots,n\}$ in the usual way. Namely, if $\{l_1,\ldots,l_n\}=\{k_1,\ldots,k_r\}$, where k_j's are all different, then $R_j=\{i:l_i=k_j\}$. Thus, from (2.15) we get

$$\hat{\phi}^{\otimes N}(\hat{j}_{l_1,N}(X_1)\cdots\hat{j}_{l_n,N}(X_n))=\prod_{i=1}^{r}\hat{\phi}(\xi_i^R(X_1\cdots X_n))$$

where ξ_i^R is a multiplicative extension of the mapping

$$\xi_i^R(X_p)=\begin{cases}P(\sigma_p) & \text{if } p\notin R_i\\ X_p & \text{if } p\in R_i\,.\end{cases}$$

Now, if $1\leqslant r\leqslant n$, then for each partition R consisting of r blocks, there are $(N)_r$ tuples $(l_1,\ldots,l_n)$ which give the same contribution $\Pi_i^r\hat{\phi}(\xi_i^R(X_1\cdots X_n))$ (the same combinatorial argument is presented in Ref. 2 in more detail). Thus

$$\hat{\phi}^{\star N}(X_1\cdots X_n)=\sum_{r=1}^{n}(N)_p\sum_{R=\{R_1,\ldots,R_p\}}\prod_{i=1}^{r}\hat{\phi}(\xi_{i=1}^R(X_1\cdots X_n)).$$

Finally, note that

$$\prod_{j=1}^{r}\hat{\phi}(\xi_i^R(X_1\cdots X_n))=\hat{\phi}(X_{B_1})\cdots\hat{\phi}(X_{B_r}),$$

where $B_1,\ldots,B_r$ are blocks of the partition $R(\vec{k},\vec{\sigma})$ since every block R_j of R splits up into subblocks for which all k_i's are the same and are not separated by any filters due to the way $\tilde{\phi}$ separates words. It is also worth noting that $\hat{\phi}(X_B)=\phi(X^{\#B})$ where # stands for the number of elements. □

In order to state the central limit theorem, let us introduce the gradation on $\hat{\mathcal{B}}$ given by $d(X_k(\sigma))=1$ and $d(P(\sigma))=0$ for all k and σ. Then, for $N\in\mathbf{N}$, define

$$D_{1/\sqrt{N}}(W)=\frac{1}{N^{d(W)/2}}W,$$

where W is a word in $\hat{\mathcal{B}}$ and $d(W)$ is its degree.

Corollary 5.2: Consider a family of states ϕ_N on $\mathbf{C}[Y]$, where $N\in\mathbf{N}$ and suppose that the limits

$$\lim_{N\to\infty}\phi_N(Y^k)=Q(k)$$

exist and are finite for all $k\in\mathbf{N}$. Then

$$\lim_{N\to\infty}\hat{\phi}_N^{\star N}(X_{k_1}(\sigma_1)\cdots X_{k_n}(\sigma_n))=\sum_{R\in\mathcal{P}_n(\vec{k},\vec{\sigma})}\prod_{B\in R}Q(\#B),\tag{5.2}$$

where $\#B$ is the number of elements in the block B.

Proof: It is an immediate consequence of Lemma 5.1 since if $R \in \mathcal{P}_n \backslash \mathcal{P}_n(\vec{k},\vec{\sigma})$, then the number of blocks in $R(\vec{k},\vec{\sigma})$ is strictly greater than the number of blocks in R which makes the contribution from R disappear as $N \to \infty$. □

Theorem 5.3 (central limit theorem): *Let* $k_i \in \mathbf{N}$, $\sigma_i \in \mathcal{P}(\mathbf{N})$, $i=1,\ldots,n$. *Suppose that* $\hat{\phi}(X_{k_i}(\sigma_i))=0$ *and* $\hat{\phi}(X_{k_i}^2(\sigma_i))=1$ *for* $i=1,...,n$. *If n is even, then*

$$\lim_{N\to\infty} \hat{\phi}^{\star N} \circ D_{1/\sqrt{N}}(X_{k_1}(\sigma_1)\cdots X_{k_n}(\sigma_n)) = |\mathcal{P}_n^{\mathrm{pair}}(\vec{k},\vec{\sigma})| \tag{5.3}$$

and, if n is odd, the limit vanishes.

Proof: It is enough to use Lemma 5.1 and notice that if there is a singleton in R, then there is no contribution from such a partition to the right-hand side of (5.1). In turn, if there are no singletons, then $(N)_p/N^{n/2} \to 0$ unless $2p=n$. That means that in the limit only pair-partitions may give a nonzero contribution. However, note that those pair partitions which are not $(\vec{k},\vec{\sigma})$-adapted give zero since in that case the number of blocks of $R(\vec{k},\vec{\sigma})$ is strictly greater than the number of blocks of R and $\Pi_{B\in R(\vec{k},\vec{\sigma})}\hat{\phi}(X_B)=0$ by the mean zero assumption.

Example 1: Note that if $\sigma_i=\mathbf{N}$ for all $1\leqslant i\leqslant n$ and all n, we obtain $|\mathcal{P}_n^{\mathrm{pair}}(\vec{k})|$ on the right-hand side of (5.3) which gives the moments of the classical multivariate Gaussian law.

Example 2: Here we give some one-dimensional examples. If $k_i=k$ and $\sigma_i=\sigma$ for $1\leqslant i\leqslant n$ and all n, then we obtain the Gaussian law if $k\in\sigma$ and the one-free (or, Boolean) central limit law corresponding to the discrete measure $\mu^{(1)}=1/2(\delta_{-1}+\delta_1)$ if $k\notin\sigma$. In turn, if we take

$$\Delta^{(m)} = \hat{\Delta} \circ \overline{j^{(m)}}, \tag{5.4}$$

where $\overline{j^{(m)}}$ is given by (3.3), we obtain the m-free coproduct defined in Ref. 1, for which the convolution powers tend to the m-free central limit laws and approximate pointwise the Wigner semicircle law for $m=\infty$. For details, see Ref. 6.

Theorem 5.4 (Poisson's limit theorem): *Under the assumptions of Corollary 5.2, suppose that* $Q(k)=\lambda$ *for all* $k\in\mathbf{N}$, *where* $\lambda>0$. *Then*

$$\lim_{N\to\infty} \hat{\phi}_N^{\star N}(X_{k_1}(\sigma_1)\cdots X_{k_n}(\sigma_n)) = \sum_{R\in\mathcal{P}_n(\vec{k},\vec{\sigma})} \lambda^{b(R)} \tag{5.5}$$

where $b(R)$ *is the number of blocks of R.*

Proof: It is an immediate consequence of Corollary 5.2. □

Example 1: Let us first give some one-dimensional examples. Again, if $k_i=k$ and $\sigma_i=\sigma$ for $1\leqslant i\leqslant n<\infty$, then we obtain the classical Poisson law for $k\in\sigma$ and the one-free (or Boolean) Poisson law for $k\notin\sigma$ corresponding to the discrete measure $\mu_\lambda^{(1)}=1/(1+\lambda)(\delta_0+\lambda\delta_{1+\lambda})$. Considering linear combinations of sample sums as in the preceeding example, we obtain the m-free Poisson laws for $m\in\mathbf{N}$ and the free Poisson law[21] for $m=\infty$ (see Ref. 6).

Example 2: If we take $\hat{\phi}$ given by (2.16), i.e., corresponding to the product of measures, then we can generalize Lemma 5.1 and Corollary 5.2 to the effect that if $\lim_{N\to\infty}\phi_{s,N}(Y^k)=\lambda_s$ where $\lambda_s>0$, $s\in\mathbf{N}$, then the right-hand side of (5.5) takes the form

$$\sum_{R\in\mathcal{P}_n(\vec{k},\vec{\sigma})} \lambda_{s_1}\lambda_{s_2}\cdots\lambda_{s_p},$$

where $s_1,\ldots,s_p$ correspond to the blocks $B_1,\ldots,B_p$ of the partition $R(\vec{k},\vec{\sigma})$ and denote their colors [which are the same within one block by (A1) of Definition 4.1]. These moments are the moments of the multivariate classical Poisson law.

VI. FILTERED FUNDAMENTAL OPERATORS

In this section we recall basic facts concerning multiple symmetric Fock spaces over $\mathcal{K}\equiv L^2(\mathbf{R}^+)$, which will be the underlying space for the filtered fundamental processes.

Let $\mathcal{G}$ be a separable Hilbert space with a countably infinite fixed orthonormal basis $(e_n)_{n\in\mathbf{N}}$. It is called the *multiplicity space*. By a *multiple symmetric Fock space* over $\mathcal{K}$ we understand the symmetric Fock space over $\mathcal{H}=L^2(\mathbf{R}^+,\mathcal{G})\cong L^2(\mathbf{R}^+)\otimes\mathcal{G}\equiv\mathcal{K}\otimes\mathcal{G}$, namely

$$\Gamma(\mathcal{H})=\mathbf{C}\Omega\oplus\bigoplus_{n=1}^{\infty}\mathcal{H}^{\circ n}$$

where $\mathcal{H}^{\circ n}$ denotes the nth symmetric tensor power of $\mathcal{H}$ and Ω is the vacuum vector, with the scalar product given by $\langle\Omega,\Omega\rangle=1$, $\langle\Omega,u\rangle=0$ and

$$\langle u_1\circ\cdots\circ u_n,v_1\circ\cdots\circ v_m\rangle=\delta_{n,m}\frac{1}{n!}\sum_{\sigma\in\mathbf{S}_n}\langle u_1,v_{\sigma(1)}\rangle\cdots\langle u_n,v_{\sigma(n)}\rangle,$$

where

$$u_1\circ\cdots\circ u_n=\frac{1}{n!}\sum_{\sigma\in\mathbf{S}_n}u_{\sigma(1)}\otimes\cdots\otimes u_{\sigma(n)}$$

and $\mathbf{S}_n$ denotes the symmetric group of order n.

Denote by $\mathcal{H}^{(\sigma)}$ the linear subspace of $\mathcal{H}$ spanned by all $u\in\mathcal{H}$ of the form

$$u=\sum_{k\in\sigma}u^{(k)}\otimes e_k,$$

where $\sigma\in\mathcal{P}(\mathbf{N})$. In particular, we put $\mathcal{H}^{(\varnothing)}=\{0\}$. The set σ will be called a *filter* and the associated canonical projection will be denoted $\pi^{(\sigma)}:\mathcal{H}\to\mathcal{H}^{(\sigma)}$ with $v^{(\sigma)}=\pi^{(\sigma)}v$ for any $v\in\mathcal{H}$. Then let $P^{(\sigma)}:\Gamma(\mathcal{H})\to\Gamma(\mathcal{H}^{(\sigma)})$ be the second quantization of $\pi^{(\sigma)}$. Thus, if $\varepsilon(v)$ is an exponential vector in $\Gamma(\mathcal{H})$, i.e.,

$$\varepsilon(v)=\bigoplus_{n=0}^{\infty}\frac{1}{\sqrt{n!}}v^{\otimes n}$$

with $v^{\otimes 0}=\Omega$, we have $P^{(\sigma)}\varepsilon(u)=\varepsilon(u^{(\sigma)})$.

Of special importance will be subspaces $\mathcal{H}^{(r)}$ of $\mathcal{H}$ spanned by all $u\in\mathcal{H}$ of the form

$$u=\sum_{k=1}^{r-1}u^{(k)}\otimes e_k,$$

where $r>1$, i.e., here $\sigma=\{1,...,r-1\}$; we set $\mathcal{H}^{(1)}=\{0\}$. In $\Gamma(\mathcal{H})$, we will use the *finite particle domain* $\Gamma_0(\mathcal{H})$, i.e., the linear space generated by vectors of the form

$$v_1\circ v_2\circ\cdots\circ v_n,$$

where $v_1,\ldots,v_n\in\mathcal{H}$, $n\in\mathbf{N}$.

Since $\mathcal{H}$ can be viewed as a direct sum of infinitely many copies of $\mathcal{K}$ and we need some convenient terminology concerning the numbering of those copies, we will refer to them as *colors*. Thus, in the direct sum decomposition

$$\mathcal{H}=\bigoplus_{k\in\mathbf{N}}\mathcal{K}\otimes e_k$$

the kth summand will be associated with the kth color and we will say that nonzero vectors from that summand are of kth color. In addition, to the zero vector we assign the 0th color.

By *filtered creation and annihilation operators* we will understand operators given by

$$a^{(\sigma)*}(f\otimes e_k)=a^*(f\otimes e_k)P^{(\sigma)}, \tag{6.1}$$

$$a^{(\sigma)}(f\otimes e_k)=P^{(\sigma)}a(f\otimes e_k), \tag{6.2}$$

respectively, where $a^*(f\otimes e_k)$ and $a(f\otimes e_k)$ are the usual boson creation and annihilation operators.[14] Thus, filtered creation operators first "filter out particles of colors which are not in σ and then create a particle of given color," whereas the filtered annihilation operators "first annihilate a particle of a given color and then filter out particles of colors which are not in σ."

In addition, we define

$$a^{(k,\sigma)\circ}=a^{(k)\circ}P^{(\sigma\cup\{k\})} \tag{6.3}$$

and call *filtered number operators*. In an analogous fashion one can define exchange operators.

Proposition 6.1: The finite particle domain $\Gamma_0(\mathcal{H})$ is contained in the domains of filtered fundamental operators. Furthermore, the following relations hold:

$$a^{(\sigma)}(f\otimes e_k)(v_1\circ v_2\circ\cdots\circ v_n)=\frac{1}{\sqrt{n}}\sum_{j=1}^{n}\langle f,v_j^{(k)}\rangle v_1^{(\sigma)}\circ\cdots\circ\check{v}_j\circ\cdots\circ v_n^{(\sigma)},$$

$$a^{(\sigma)*}(f\otimes e_k)(v_1\circ v_2\circ\cdots\circ v_n)=\sqrt{n+1}(f\otimes e_k)\circ v_1^{(\sigma)}\circ\cdots\circ v_n^{(\sigma)},$$

$$a^{(k,\sigma)\circ}(v_1\circ v_2\circ\cdots\circ v_n)=\sum_{j=1}^{n}v_1^{(\sigma)}\circ\cdots(v_j^{(k)}\otimes e_k)\circ\cdots\circ v_n^{(\sigma)}$$

with $a^{(\sigma)}(f\otimes e_k)\Omega=0$, $a^{(\sigma)*}(f\otimes e_k)\Omega=f\otimes e_k$ *and* $a^{(k,\sigma)0}\Omega=0$, *where* $v_1,\ldots,v_n\in\mathcal{H}$, $k\in\mathbf{N}$, $\sigma\in\mathcal{P}(\mathbf{N}),n\in\mathbf{N}$.

Proof: The first statement follows from the definitions (6.1)–(6.3) and an analogous property of the canonical (CCR) operators and the fact that the projections $P^{(\sigma)}$ leave the finite particle domain invariant. Similarly, the relations follow immediately from the analogous formulas for the canonical (CCR) operators (we use Hudson–Parthasarathy's normalization). □

Lemma 6.2: Filtered creation and annihilation operators satisfy the following relations on the finite particle domain:

$$a^{(\sigma)}(f\otimes e_k)a^{(\tau)*}(g\otimes e_l)-a^{(\tau)*}(g\otimes e_l)a^{(\sigma)}(f\otimes e_k)P^{(\tau)}]_{\{l\in\sigma\}}=\delta_{k,l}\langle f,g\rangle P^{(\sigma\cap\tau)}$$

for any $k,\ l\in\mathbf{N},\ \sigma,\ \tau\in\mathcal{P}(\mathbf{N}),\ f,\ g\in\mathcal{K}$.

Proof: In the proof given below we understand that the equations hold on the finite particle domain, but it remains valid on the whole intersection of the domains of the considered filtered operators. Using canonical commutation relations (CCR) of the form

$$a(f\otimes e_k)a^*(g\otimes e_l)-a^*(g\otimes e_l)a(f\otimes e_k)=\delta_{k,l}\langle f,g\rangle,$$

we obtain

$$\begin{aligned}a^{(\sigma)}(f\otimes e_k)a^{(\tau)*}(g\otimes e_l)&=P^{(\sigma)}a(f\otimes e_k)a^*(g\otimes e_l)P^{(\tau)}\\&=P^{(\sigma)}a^*(g\otimes e_l)a(f\otimes e_k)P^{(\tau)}+\delta_{k,l}\langle f,g\rangle P^{(\sigma\cap\tau)}.\end{aligned}$$

Now, note that if $l\notin\sigma$, then

$$P^{(\sigma)}a^*(g\otimes e_l)a(f\otimes e_k)P^{(\tau)}=0$$

and we obtain

$$a^{(\sigma)}(f\otimes e_k)a^{(\tau)*}(g\otimes e_l)=\delta_{k,l}\langle f,g\rangle P^{(\sigma\cap\tau)}.$$

Consider now the case $l\in\sigma$. Then

$$\begin{aligned}&P^{(\sigma)}a^*(g\otimes e_l)a(f\otimes e_k)P^{(\tau)}-a^*(g\otimes e_l)P^{(\sigma\cap\tau)}a(f\otimes e_k)P^{(\tau)}\\&\quad=a^*(g\otimes e_l)(P^{(\sigma)}-P^{(\sigma\cap\tau)})a(f\otimes e_k)P^{(\tau)}\end{aligned}$$

since $P^{(\sigma)}$ commutes with $a^*(g\otimes e_l)$ for $l\in\sigma$. Note that if $\sigma\subseteq\tau$, then $P^{(\sigma)}=P^{(\sigma\cap\tau)}$ and thus the above expression vanishes. In turn, if $\tau\subseteq\sigma$, then $P^{(\sigma)}-P^{(\sigma\cap\tau)}=P^{(\sigma)}-P^{(\tau)}$. However,

$$P^{(\tau)}:\quad\Gamma(\mathcal{H})\to\Gamma(\mathcal{H}^{(\tau)}).$$

and $a(f\otimes e_k)$ leaves $\Gamma(\mathcal{H}^{(\tau)})$ invariant, hence when we apply $P^{(\sigma)}-P^{(\tau)}$, we can see that the above-mentioned expression also vanishes. Therefore, if $l\in\sigma$, we obtain

$$\begin{aligned}&a^{(\sigma)}(f\otimes e_k)a^{(\tau)*}(g\otimes e_l)-a^*(g\otimes e_l)P^{(\sigma\cap\tau)}a(f\otimes e_k)P^{(\tau)}\\&\quad=a^{(\sigma)}(f\otimes e_k)a^{(\tau)*}(g\otimes e_l)-a^{(\tau)*}(g\otimes e_l)a^{(\sigma)}(f\otimes e_k)P^{(\tau)}\\&\quad=\langle f,g\rangle\delta_{k,l}P^{(\sigma\cap r)}.\end{aligned}$$

Combining the two cases $l\in\sigma$ and $l\notin\sigma$ ends the proof. □

Let us finally define the fundamental processes associated with the filtered fundamental operators introduced in this section. They will appear in Secs. VII and VIII when finding GNS realizations of limit states. They will also serve as integrators in the filtered calculus developed in Ref. 12. Thus, in connection with (6.1)–(6.3), let

$$A_t^{(k,\sigma)*}=a^{(\sigma)*}(\chi_{[0,1]}\otimes e_k),\tag{6.4}$$

$$A_t^{(k,\sigma)}=a^{(\sigma)}(\chi_{[0,t]}\otimes e_k),\tag{6.5}$$

$$A_t^{(k,\sigma)^\circ}=\lambda(I_{[0,t]}\otimes|e_k\rangle\langle e_k|)P^{(\sigma\cup\{k\})},\tag{6.6}$$

$$A_t^{(0,\sigma)}=tP^{(\sigma)},\tag{6.7}$$

where $t\geqslant 0, k\in\mathbf{N},\sigma\in\mathcal{P}(\mathbf{N})$, $I_{[0,t]}$ denotes the operator of multiplication by the characteristic function $\chi_{[0,t]}$ on $L^2(\mathbf{R}^+)$, and $\lambda(H)$ denotes the differential second quantization of $H\in\mathcal{B}(\mathcal{H})$. The families of processes given by (6.4)–(6.7) will be called *filtered creation, annihilation, number*, and *time processes*, respectively. When speaking of all of them, we will call them *filtered fundamental processes*. By *filtered Brownian motion* we will understand the unital *-algebra generated by filtered creation and annihilation operators indexed by time intervals.[2]

VII. RANDOM WALK ON THE FILTERED BIALGEBRA

In this section we show that a limit of continuous-time random walks on the filtered *-bialgebra gives the filtered Brownian motion. This gives a multivariate Brownian motion on the multiple symmetric Fock space which satisfies the properties required by the axioms for white noise on *-bialgebras[1,4] and includes quantum Brownian motions for different types of independence. For the first quantum version of the Wiener process, see Ref. 22. We follow the notation used in Ref. 23 for the random walk on $U_q(su(2))$.

Instead of $\hat{\mathcal{B}}$, we choose to work with a slightly more general unital *-bialgebra $\hat{\mathcal{C}}$, also called filtered *-bialgebra, which is defined to be the unital *-algebra over $\mathbf{C}$ generated by $X_k(\sigma)$, $X_k^*(\sigma)$, and $P(\sigma)$, where $k\in\mathbf{N},\sigma\in\mathcal{P}(\mathbf{N})$ subject to relations (2.6) and (2.7), where $P(\sigma)$ is a

projection for each $\sigma \in \mathcal{P}(\mathbf{N})$ [this of course also means that $P(\sigma)$ commutes with $X_k^*(\tau)$ for $k \in \sigma$], with the coproduct in which $X_k(\sigma)$ and $X_k^*(\sigma)$ are both $P(\sigma)$-primitive and $P(\sigma)$ is group-like [cf. (2.8) and (2.9)].

Let $k \in \mathbf{N}, \sigma \in \mathcal{P}(\mathbf{N}), N \in \mathbf{N}$, and consider a sequence of continuous-time random walks on $\hat{\mathcal{C}}$ given by

$$\hat{\Delta}_{s,t}^N(X_k^\natural(\sigma)) = \sum_{l=N_s+1}^{N_t} P(\sigma)^{\otimes(l-1)} \otimes X_k^\natural(\sigma) \otimes P(\sigma)^{\otimes\infty}, \tag{7.1}$$

$$\hat{\Delta}_{s,t}^N(P(\sigma)) = 1^{\otimes N_s} \otimes P(\sigma)^{\otimes(N_t - N_s)} \otimes 1^{\otimes\infty}, \tag{7.2}$$

where $0 \leqslant s \leqslant t < \infty$, $N_t = E[tN]$, $E[x] = n$ for $n \leqslant x < n+1$, with $X_k^\natural(\sigma) \in \{X_k(\sigma), X_k^*(\sigma)\}$.

It is easy to check that for each pair (s, t) and natural number N, the mapping

$$\hat{\Delta}_{s,t}^N : \hat{\mathcal{C}} \to \hat{\mathcal{C}}^{\otimes\infty}$$

given by the linear and multiplicative extension of (7.1) and (7.2) is a unital *-homomorphism and the triple $(\hat{\mathcal{C}}^{\otimes\infty}, (\Delta_{s,t}^N)_{0 \leqslant s \leqslant t}, \hat{\phi}^{\otimes\infty})$ satisfies for each $N \in \mathbf{N}$ the properties required from a stochastic process over the bialgebra $\hat{\mathcal{C}}$ given in Ref. 8. In particular,

$$\hat{\Delta}_{s,t}^N \star \hat{\Delta}_{t,r}^N = \hat{\Delta}_{s,r}^N$$

for all $0 \leqslant s \leqslant t \leqslant r$, where $\hat{\Delta}_{s,t}^N \star \hat{\Delta}_{t,r}^N = M \circ (\hat{\Delta}_{s,t}^N \otimes \hat{\Delta}_{t,r}^N) \circ \hat{\Delta}$ with $M(a \otimes b) = ab$. For details on stochastic processes over *-bialgebras see Refs. 4 and 8.

In this *-bialgebra formulation, further preparations are similar to those which lead to the central limit theorem. Namely, for a given state ϕ on $\mathbf{C}\langle Y, Y^* \rangle$ we denote by $\tilde{\phi}$ its Boolean extension to $\mathbf{C}\langle Y, Y^*, P \rangle$, where P is a projection and we set $\hat{\phi} = \tilde{\phi}^{\otimes\infty} \circ \eta$, where

$$\eta : \hat{\mathcal{C}} \to \bigotimes_{k=1}^{\infty} \mathbf{C}\langle Y_k, Y_k^*, P_k \rangle$$

is defined by the *-multiplicative extension of formulas (2.13) and (2.14).

In the following we will study the limit of distributions of the mixed moments of (7.1) as $N \to \infty$ and find the GNS representation of the limit state. Let us remark that more general sample sums indexed by $f \in L_c^2(\mathbf{R}^+)$ can also be given and the proofs of this section will still hold.

Theorem 7.1: *Let* $Z_i = X_{k_i}(\sigma_i)$, $Z_i^* = X_{k_i}^*(\sigma_i)$, *where* $k_i \in \mathbf{N}, \sigma_i \in \mathcal{P}(\mathbf{N})$, $i = 1,...,n$. *Suppose that* $\hat{\Phi} = \hat{\Phi}^{\otimes\infty}$ *with* $\phi(Y) = 0$ *and the only nonvanishing second-order moment of* ϕ *is given by* $\phi(YY^*) = 1$. *Then*

$$\lim_{N \to \infty} N^{-n/2} \hat{\Phi}(\hat{\Delta}_{s_1,t_1}^N(Z_1^\natural) \cdots \hat{\Delta}_{s_n,t_n}^N(Z_n^\natural)) = \varphi(a^{(\sigma_1)^\natural}(v_1) \cdots a^{(\sigma_n)^\natural}(v_n)),$$

where $Z_i^\natural \in \{Z_i, Z_i^*\}$, $v_i = \chi_{[s_i,t_i]} \otimes e_{k_i}$, $i = 1,...,n$, *and* $\varphi(.) = \langle \Omega, .\Omega \rangle$ *is the vacuum expectation in* $\Gamma(\mathcal{H})$.

Proof: From the general invariance principle[24] and the combinatorics of the filtered central limit theorem it follows that for even $n = 2p$ we have

$$\mathrm{LHS} = \sum_{R \in \mathcal{P}_{2p}^{\mathrm{pair}}(\vec{k}, \vec{\sigma})} \delta(R) \prod_{m=1}^{p} \langle v_{\alpha(m)}, v_{\beta(m)} \rangle,$$

where the blocks of R consist of two-element sets $\{\alpha(i),\beta(i)\}$, with $\alpha(i)<\beta(i)$, $i=1,...,p$ and $\delta(R)=1$ if for the given partition R we have $Z^{\natural}_{\alpha(i)}=Z_{\alpha(i)}$ and $Z^{\natural}_{\beta(i)}=Z^{*}_{\beta(i)}$ and otherwise $\delta(R)=0$. It is clear that if n is odd, then LHS$=0$.

It is clear that RHS$=0$ if n is odd, too—it is enough to use the properties of creation and annihilation operators following from Proposition 6.1. Therefore assume that $n=2p$. Next, notice that in order that LHS$=$RHS it is enough to show the following claim:

$$\varphi(a_1^{\natural}\cdots a_n^{\natural})=\sum_{R\in\mathcal{P}_{2p}^{\mathrm{pair}}(\vec{k},\vec{\sigma})}\delta(R)\prod_{m=1}^{p}\langle v_{\alpha(m)},v_{\beta(m)}\rangle$$

where, for simplicity, we denote $a_j^{\natural}=a^{\sigma_j\natural}(v_j)$.

We begin with the simplest case, i.e.,

$$\varphi(a_1a_2^{*}\cdots a_{2p-1}a_{2p}^{*})=\langle v_1,v_2\rangle\langle v_3,v_4\rangle\cdots\langle v_{2p-1},v_{2p}\rangle=\sum_{R\in\mathcal{P}_{2p}^{\mathrm{pair}}(\vec{k},\vec{\sigma})}\delta(R)\prod_{m=1}^{p}\langle v_{\alpha(m)},v_{\beta(m)}\rangle,$$

the second expression being formally written as a sum since we have at most one partition contributing to it. This is the beginning of an induction procedure. Namely, it is enough to show that from the claim being true for all expectations of orders $\leqslant 2p-2$ and for $\varphi(a_1^{\natural}\cdots a_i^{*}a_{i+1}\cdots a_{2p}^{\natural})$ it follows that it also holds for the expectation of the form $\varphi(a_1^{\natural}\cdots a_{i+1}a_i^{*}\cdots a_{2p}^{\natural})$.

Suppose that $k_i\notin\sigma_{i+1}$. Then

$$\begin{aligned}\varphi(a_1^{\natural}\cdots a_{i+1}a_i^{*}\cdots a_{2p}^{\natural})&=\langle v_i,v_{i+1}\rangle\varphi(a_1^{\natural}\cdots P^{(\sigma_i\cap\sigma_{i+1})}\cdots a_{2p}^{\natural})\\&=\sum_{R\in\mathcal{P}_{2p}^{\mathrm{pair}}(\hat{k},\hat{\sigma}|i,i+1)}\delta(R)\prod_{m=1}^{p}\langle v_{\sigma(m)},v_{\beta(m)}\rangle,\end{aligned}$$

where $\mathcal{P}_n^{\mathrm{pair}}(\hat{k},\hat{\sigma}|i,i+1)$ denotes all $(\hat{k},\hat{\sigma})$-adapted pair partitions with

$$\hat{k}=(k_1,\ldots,k_{i+1},k_i,\ldots,k_n),\quad \hat{\sigma}=(\sigma_1,\ldots,\sigma_{i+1},\sigma_i,\ldots,\sigma_n)$$

in which $(i,i+1)$ forms a pairing. The first equality follows from filtered relations of Lemma 6.2, whereas the second–from the inductive assumption and the fact that if $k_i\notin\sigma_{i+1}$, then

$$\forall R\in\mathcal{P}_{2q}^{\mathrm{pair}}(\hat{k},\hat{\sigma})\exists R'\in\mathcal{P}_{2q-2}^{\mathrm{pair}}(\zeta_{i,i+1}(\vec{k},\vec{\sigma})):\quad R=R'\cup\{(i,i+1)\},$$

where $\zeta_{i,i+1}(\vec{k},\vec{\sigma})=(\tilde{k},\tilde{\sigma})$, with

$$\tilde{k}=(k_1,\ldots,k_{i-1},k_{i+2},..,k_n),\quad \tilde{\sigma}=(\sigma_1,\ldots,\sigma_{i-1},\zeta(\sigma_{i+2}),\ldots,\zeta(\sigma_n)),$$

and

$$\zeta(\sigma_l)=\begin{cases}\sigma_l\cap\sigma_i\cap\sigma_{i+1} & \text{if } (s,l) \text{ is a pairing for } s<i\\ \sigma_l & \text{otherwise,}\end{cases}$$

where $i+2\leqslant l\leqslant n$.

In turn, if $k_i\in\sigma_{i+1}$, then using Lemma 6.2 again, we obtain

$$\varphi(a_1^{\natural}\cdots a_{i+1}a_i^{*}\cdots a_{2p}^{\natural})=\langle v_{i+1},v_i\rangle\varphi(a_1^{\natural}\cdots P^{(\sigma_i\cap\sigma_{i+1})}\cdots a_{2p}^{\natural})+\varphi(a_1^{\natural}\cdots a_i^{*}a_{i+1}P^{(\sigma_i)}\cdots a_{2p}^{\natural}).$$

By the inductive assumption and similar arguments as above, the first term gives

$$\sum_{R\in\mathcal{P}_{2p}^{\mathrm{pair}}(\hat{k},\hat{\sigma}|i,i+1)}\delta(R)\prod_{m=1}^{p}\langle v_{\alpha(m)},v_{\beta(m)}\rangle,$$

whereas the second, a sum over all the remaining partitions from $\mathcal{P}_n^{\mathrm{pair}}(\hat{k},\hat{\sigma})$ [it is disjoint from the first since $(i,i+1)$ cannot form a pairing as in the associated creation-annihilation pair the annihilation operator follows the creation operator], namely

$$\sum_{R\in\mathcal{P}_{2p}^{\mathrm{pair}}(\hat{k},\hat{\sigma})\setminus\mathcal{P}_{2p}^{\mathrm{pair}}(\hat{k},\hat{\sigma}|i,i+1)}\delta(R)\prod_{m=1}^{p}\langle v_{\alpha(m)},v_{\beta(m)}\rangle$$

by the inductive assumption. Note that the projection $P^{(\sigma_i)}$, which follows the annihilation operator in the second term, ensures that the annihilation operator $a^{(\sigma_{i+1})}(v_{i+1})$ in the original expression cannot be paired off with any creation operator (standing to the right of this annihilation operator) of color $k\notin\sigma_i$.

Now adding those two expressions, we can see that the claim holds for

$$\varphi(a_1^{\natural}\cdots a_{i+1}a_i^{*}\cdots a_{2p}^{\natural}),$$

which finishes the proof. □

Example: If $k_i=k$, $\sigma_i=\sigma$ for $1\leqslant i\leqslant n$ and arbitrary n, then we obtain the CCR Brownian motion if $k\in\sigma$ and Boolean Brownian motion if $k\notin\sigma$. By taking linear combinations of sample sums corresponding to m-free (free) independent random variables, we obtain the m-free (free) Brownian motion.[6]

VIII. FILTERED WHITE NOISE

In this section we define the general notion of filtered white noise, determine its combinatorics, and study the example of filtered Poisson white noises. Our approach largely parallels that used by Speicher[21] for free white noise.

Definition 8.1: Let $\mathrm{Int}(\mathbf{R}^+)$ denote the intervals in $\mathbf{R}^+$. An s-dimensional *filtered white noise* consists of a unital *-algebra $\mathcal{C}$, a state ρ on $\mathcal{C}$, and a family of finitely additive mappings $\mathrm{Int}(\mathbf{R}^+)\to\mathcal{C}$,

$$I\to(c_I(k,\sigma;1),\ldots,c_I(k,\sigma;s)),\quad k\in\mathbf{N},\quad \sigma\in\mathcal{P}(\mathbf{N})$$

such that

(i) for any pairwise disjoint intervals $I(1),\ldots,I(n)$,

$$\rho(c_{I(l_1)}(k_1,\sigma_1;q_1)\cdots c_{I(l_n)}(k_n,\sigma_n;q_n))=\rho(c_{B_1})\cdots\rho(c_{B_r}),\tag{8.1}$$

where $B_1,\ldots,B_r$ are the blocks of $R(\vec{k},\vec{\sigma})$, with R being the partition associated with $(l_1,\ldots,l_n)$ and c_B denotes the product, taken in the natural order, of $c_{I(l_i)}(k_i,\sigma_i;q_i)$'s for $i\in B$,

(ii) the distribution $\rho_I=\rho|\mathcal{C}_I$ depends only on the Lebesgue measure of the interval I, where $\mathcal{C}_I$ denotes the unital *-algebra generated by $c_I(k,\sigma;q)$, $k\in\mathbf{N}$, $\sigma\in\mathcal{P}(\mathbf{N})$, and $1\leqslant q\leqslant s$.

Lemma 8.2: Let $(\mathcal{C},\rho,(c_I(k,\sigma;1),\ldots,c_I(k,\sigma;n))_{I\in\mathrm{Int}(\mathbf{R}^+),k\in\mathbf{N},\sigma\in\mathcal{P}(\mathbf{N})})$ *be as s-dimensional filtered white noise and let* $c_t(k,\sigma)=c_{[0,t)}(k,\sigma)$ *for* $k\in\mathbf{N}$, $\sigma\in\mathcal{P}(\mathbf{N})$. *Then*

$$\rho(c_t(k_1,\sigma_1;q_1)\cdots c_t(k_n;\sigma_n;q_n))=\sum_{R\in\mathcal{P}_n(\vec{k},\vec{\sigma})}\prod_{B\in R}Q_t(B),$$

where

$$Q_t(B)=Q_t(k,(\sigma_i)_{i\in B},(q_i)_{i\in B})=\lim_{N\to\infty}\rho(c_{t/N}(k,\sigma_{i(1)};q_{i(1)})\cdots c_{t/N}(k,\sigma_{i(r)};q_{i(s)}))$$

and $B=\{i(1),\ldots,i(m)\}$ *with* $i(1)<\cdots<i(m)$ *with* $k=k(B)=k_{i(j)}$ *for all* $i(j)\in B$.

Proof: By additivity of the filtered white noise, we can split up each $c_t^{(k,\sigma;q)}$ into a sum of N summands:

$$c_t(k,\sigma;q)=\sum_{l=1}^{N} c_{I(l)}(k,\sigma;q),$$

where $I(l)=[(l-1)t/N,lt/N)$. Moreover, the summands have the same distributions.

Now, note that from (8.1) it follows that we can use the same combinatorial argument as in Corollary 5.2 providing the limits

$$\begin{aligned}Q_t(B)&=\lim_{N\to\infty} N\rho(c_{I(l)}(k,\sigma_1;q_{i(1)})\cdots c_{I(l)}(k,\sigma_r;q_{i(r)}))\\&=\lim_{N\to\infty} N\rho(c_{I(1)}(k,\sigma_1;q_{i(1)})\cdots c_{I(1)}(k,\sigma_r;q_{i(r)}))\end{aligned}$$

exist for all l, $k\in\mathbf{N}$, $i_1,\ldots,i_r$, $1\leqslant r\leqslant n$, where $k=k(B)$ and the dependence of the limit on k, $\sigma_{i(1)},\ldots,\sigma_{i(r)}$ and $q_{i(1)},\ldots,q_{i(r)}$ is suppressed. Existence of such limits follows from an induction procedure which is analogous to that in the free case.[21] □

Example: A two-dimensional filtered Gaussian noise is obtained from $c_t(k,\sigma;1)=A_t^{(k,\sigma)}$, $c_t(k,\sigma;2)=A_t^{(k,\sigma)*}$, given by (6.4) and (6.5), for any $k\in\mathbf{N}$, $\sigma\in\mathcal{P}(\mathbf{N})$, $t\geqslant 0$ with $\rho=\varphi$, the vacuum expectation in $\Gamma(\mathcal{H})$. Then

$$\varphi(c_t(k_1,\sigma_1;q_1)\cdots c_t(k_n,\sigma_n;q_n))=\begin{cases}\Sigma_{R\in\mathcal{P}_n^{\mathrm{pair}}(\vec{k},\vec{\sigma})}\Pi_{B\in R}Q_t(B) & n \text{ even}\\ 0 & n \text{ odd},\end{cases}$$

where the generator Q_t does not depend on $k(B)$ and σ_i's and is given by

$$Q_t(B)=Q_t(i(1),i(2))=\begin{cases}t & \text{if } q_{i(1)}=1,\ q_{i(2)}=2\\ 0 & \text{otherwise.}\end{cases}$$

Note that the filtered Gaussian noise was obtained before as the GNS representation of the limit state of the invariance principle (in a slightly more general version).

In the following we will find the expectations of the filtered (multivariate) Poisson noise constructed from filtered fundamental processes given by (6.4)–(6.7), which is also a way to justify the correctness of our definition of filtered number operators (6.3).

Theorem 8.3: *For any* $k\in\mathbf{N}$, $\sigma\in\mathcal{P}(\mathbf{N})$, *and* $t\geqslant 0$, *let*

$$\Lambda_t^{(k,\sigma)}=A_t^{(k,\sigma)}+A_t^{(k,\sigma)*}+A_t^{(k,\sigma)\circ}+A_t^{(0,\sigma)} \tag{8.2}$$

and let φ *be the vacuum expectation state in* $\Gamma(\mathcal{H})$. *Then*

$$\varphi(\Lambda_t^{(k_1,\sigma_1)}\cdots\Lambda_t^{(k_n,\sigma_n)})=\sum_{R\in\mathcal{P}_n(\vec{k},\vec{\sigma})} t^{b(R)},$$

where, $k_1,\ldots,k_n\in\mathbf{N},\sigma_1,\ldots,\sigma_n\in\mathcal{P}(\mathbf{N})$, *and* $b(R)$ *is the number of blocks of* R.

Proof: First of all, notice that if $I(1),\ldots,I(r)$ are disjoint intervals in $\mathbf{R}^+$, then

$$\varphi(\Lambda_{I(l_r)}^{(k_1,\sigma_1)}\ldots\Lambda_{I(l_r)}^{(k_r,\sigma_r)})=\varphi(\Lambda_{B_1})\ldots\varphi(\Lambda_{B_r}),$$

where $\Lambda_{[s,t)}=\Lambda_t-\Lambda_s$ and $B_1,\ldots,B_r$ are the blocks of $R(\vec{k},\vec{\sigma})$, with R being the partition associated with the tuple $(l_1,\ldots,l_n)$. This fact follows from the continuous tensor product decomposition of $\Gamma(\mathcal{H})$ with respect to time and the fact that all summands of $\Lambda_{I(l)}^{(k,\sigma)}$ have the form $a(I(l))p(I(l),\sigma)$, where $p(I(l),\sigma)$ plays the role of $\mathbf{P}(l,\sigma)$ in (3.1), whereas $a(I(l))$ is an elementary tensor which has units at all sites associated with $I(m)$'s for $m\neq l$. Note that they are not filtered random variables in the sense of Definition 3.1, however (8.1) still holds. Moreover, the distribution $\phi_I=\phi|\mathcal{C}_I$, where $\mathcal{C}_I$ is the unital *-algebra generated by $\Lambda_I^{(k,\sigma)}$, $k\in\mathbf{N}$, $\sigma\in\mathcal{P}(\mathbf{N})$, depends only on the Lebesgue measure $\lambda(I)$ of I since every expectation is in fact a polynomial in the length of I. This can be seen by using Proposition 6.1.

In view of Lemma 8.2, it suffices to show that

$$\lim_{N\to\infty}\varphi(\Lambda_{t/N}^{(k,\sigma_1)}\cdots\Lambda_{t/N}^{(k,\sigma_n)})=t$$

for any $k\in\mathbf{N}$ and $\sigma_1,\ldots,\sigma_n\in\mathcal{P}(\mathbf{N})$.

Looking at the action of the fundamental filtered operators on the finite particle domain (Proposition 6.1), we can see that in the considered expectation each creation-annihilation pair as well as each time operator produce t, whereas each number operator produces an integer. Therefore, we obtain

$$\varphi(\Lambda_t^{(k,\sigma)})=\varphi(A_t^{(0,\sigma)})=t,$$

$$\varphi(\Lambda_t^{(k,\sigma_1)}\Lambda_t^{(k,\sigma_2)})=\varphi(A_t^{(k,\sigma_1)}A_t^{(k,\sigma_2)*})+o(t)$$

$$\varphi(\Lambda_t^{(k,\sigma_1)}\cdots\Lambda_t^{(k,\sigma_n)})=\varphi(A_t^{(k,\sigma_1)}A_t^{(k,\sigma_2)\circ}\cdots A_t^{(k,\sigma_{n-1})\circ}A_t^{(k,\sigma_n)*})+o(t)=t+o(t)$$

for $n>2$ and any $k\in\mathbf{N},\sigma_1,\ldots,\sigma_n\in\mathcal{P}(\mathbf{N})$. Hence

$$\lim_{N\to\infty}N\varphi(\Lambda_{t/N}^{(k,\sigma_1)}\cdots\Lambda_{t/N}^{(k,\sigma_n)})=t,$$

which enables us to use Lemma 8.4 and obtain the desired form of the expectation. □

The above theorem gives the combinatorics of the filtered Poisson noise, defined by (8.1). As it contains infinitely many colors and filters, this combinatorics involves multivariate expectations (when speaking of a one-dimensional noise we mean one "type" of operator, although it has infinitely many "copies"). It can be noted that if $k\in\sigma$, then $\Lambda_t^{(k,\sigma)}$ for fixed k and σ gives classical Poisson white noise and if $k\notin\sigma$, then $\Lambda_t^{(k,\sigma)}$ gives Boolean (or, one-free) Poisson white noise (cf. Theorem 5.4). Moreover, m-free and free Poisson white noises are obtained from linear combinations of the same type as in (3.3) and (5.4). In general, also on the level of white noise, filtered Gaussian and Poisson's white noises are also the building blocks of other Gaussian and Poisson's white noises since the latter can be obtained from the former by addition or strong limits.

IX. A FREE FOCK SPACE DECOMPOSITION OF $\Gamma(\mathcal{H})$

In this section we embed the free and m-free Fock spaces over $\mathcal{K}$, denoted by $\mathcal{F}(\mathcal{K})$, $\mathcal{F}^{(m)}(\mathcal{K})$, $m\in\mathbf{N}$, respectively, in the multiple symmetric Fock space $\Gamma(\mathcal{H})$, where $\mathcal{H}=\mathcal{K}\otimes\mathcal{G}$, and extend the m-free and free creation and annihilation operators to bounded operators on $\Gamma(\mathcal{H})$. We assume that $\mathcal{K}=L^2(\mathbf{R}_+)$.

Let us introduce the following linear combinations of filtered creation and annihilation operators, respectively:

$$l^{(m)*}(f)=\sum_{k=1}^{m}(a^{(k)*}(f\otimes e_k)-a^{(k-1)*}(f\otimes e_k)), \tag{9.1}$$

$$l^{(m)}(f)=\sum_{k=1}^{m}(a^{(k)}(f\otimes e_k)-a^{(k-1)}(f\otimes e_k)), \tag{9.2}$$

where $m\in\mathbf{N}$. We will call $l^{(m)*}(f)$, $l^{(m)}(f)$, the *extended m-free creation and annihilation operators*, respectively. In order to compare them with the *m*-free creation and annihilation operators $a^{(m)*}(f)$, $a^{(m)}(f)$ introduced in Ref. 6, let us recall the definition of the latter.

First, the *m-free Fock space* over κ is the truncation of order *m* of the free Fock space, namely

$$\mathcal{F}^{(m)}(\mathcal{K})=\mathbf{C}\omega_m\oplus\bigoplus_{k=1}^{m}\kappa^{\otimes k},$$

where ω_m is the vacuum unit vector, with the canonical scalar product. The *m-free creation operators* are then given by

$$a^{(m)*}(f):\mathcal{F}^{(m)}(\mathcal{K})\to\mathcal{F}^{(m)}(\mathcal{K}),$$

$$a^{(m)*}(f)f_1\otimes\cdots\otimes f_n=\begin{cases}f\otimes f_1\otimes\cdots\otimes f_n & \text{if } 1\leqslant n<m\\ 0 & \text{if } n=m\end{cases}$$

with $a^{(m)*}(f)\omega_m=f$ and the *m-free annihilation operators*

$$a^{(m)}(f):\mathcal{F}^{(m)}(\mathcal{K})\to\mathcal{F}^{(m)}(\mathcal{K}),$$

$$a^{(m)}(f)f_1\otimes\cdots\otimes f_n=\langle f,f_1\rangle f_2\otimes\cdots\otimes f_n$$

if $1\leqslant n\leqslant m$ and $a^{(m)}(f)\omega_m=0$. Note that $a^{(m)*}(f)$, $a^{(m)}(f)$ are bounded on $\mathcal{F}^{(m)}(\mathcal{K})$ since they are truncations of order *m* of free creation and annihilation operators $a^*(f)$, $a(f)$ on the free Fock space $\mathcal{F}(\mathcal{K})$, respectively. We will see in the following that $l^{(m)*}(f)$, $l^{(m)}(f)$ are bounded extensions of $a^{(m)*}(f)$, $a^{(m)}(f)$, $f\in\mathcal{K}$, respectively, to $\Gamma(\mathcal{H})$.

If we set $m=\infty$ in the formulas for extended *m*-free creation and annihilation operators, we obtain operators which we denote $l^*(f)$ and $l(f)$, respectively, which will be called *extened free creation and annihilation operators*. They, too, are bounded extensions of free creation and annihilation operators $a^*(f)$, $a(f)$, $f\in\mathcal{K}$, to all of $\Gamma(\mathcal{H})$, respectively.

Thus, we identify two notations: $l^{(\infty)*}(f)\equiv l^*(f)$, $l^{(\infty)}(f)\equiv l(f)$, $f\in\mathcal{K}$. In that context we will understand that $P^{(\infty)}\equiv I$. In general, in this section we will often assume for convenience that $m\in\mathbf{N}^*=\mathbf{N}\cup\{\infty\}$. However, certain results will be stated for $m=\infty$ separately in order to single out the free case.

Remark: On the finite particle domain $\Gamma_0(\mathcal{H})$, spanned by Ω and vectors of the form

$$(f_1\otimes e_{k_1})\circ\cdots\circ(f_n\otimes e_{k_n})$$

where $f_1,\ldots,f_n\in\mathcal{K}$, $k_1\leqslant k_2\leqslant\cdots\leqslant k_n$, $n\in\mathbf{N}$, the series given by (9.1) and (9.2) for $m=\infty$ are strongly convergent since only a finite number of terms do not vanish when acting on vectors of finite "color support" and thus given well-defined operators with domains dense in $\Gamma(\mathcal{H})$. A similar feature was exhibited by the series representation of free random variables obtained from the construction of the hierarchy of freeness.[1,11] We will see in the following that they have bounded extensions to $\Gamma(\mathcal{H})$.

Let us first determine the action of *m*-free creation and annihilation operators on $\Gamma_0(\mathcal{H})$.

Proposition 9.1: Let $f,f_1,\ldots,f_n\in\mathcal{K}$ and $k_1\leqslant k_2\leqslant\cdots\leqslant k_n$, $m\in\mathbf{N}^*$. Then

$$l^{(m)*}(f)(f_1\otimes e_{k_1})\circ\cdots\circ(f_n\otimes e_{k_n})=\mathbb{1}_{\{m\geqslant k_n+1\}}\sqrt{(n+1)}(f_1\otimes e_{k_1})\circ\cdots\circ(f_n\otimes e_{k_n})\circ(f\otimes e_{k_n+1})$$

$$l^{(m)}(f)(f_1\otimes e_{k_1})\circ\cdots\circ(f_n\otimes e_{k_n})=\mathbb{1}_{\{m\geqslant k_n\}}\frac{1}{\sqrt{n}}\langle f,f_n\rangle\delta_{k_n,k_{n-1}+1}(f_1\otimes e_{k_1})\circ\cdots\circ(f_{n-1}\otimes e_{k_{n-1}})$$

where we set $k_0=0$, *with the action on the vacuum vector given by* $l^{(m)*}(f)\Omega=f\otimes e_1$ *and* $l^{(m)}(f)\Omega=0$.

Proof: Note that

$$a^{(k)*}(f\otimes e_k)-a^{(k-1)*}(f\otimes e_k)=a^*(f\otimes e_k)P^{[k-1]},$$

$$a^{(k)}(f\otimes e_k)-a^{(k-1)}(f\otimes e_k)=P^{[k-1]}a(f\otimes e_k)$$

where

$$P^{[k-1]}(f_1\otimes e_{k_1})\circ\cdots\circ(f_n\otimes e_{k_n})=\delta_{k-1,k_n}(f_1\otimes e_{k_1})\circ\cdots\circ(f_n\otimes e_{k_n})$$

since $P^{[k-1]}=P^{(k)}-P^{(k-1)}$ and $k_j\leqslant k_n$ for all $j=1,...,n$. Thus,

$$\begin{aligned}l^{(m)*}(f)(f_1\otimes e_{k_1})\circ\cdots\circ(f_n\otimes e_{k_n})&=\sum_{k=1}^{m}a^*(f\otimes e_k)P^{[k-1]}(f_1\otimes e_{k_1})\circ\cdots\circ(f_n\otimes e_{k_n})\\&=\sum_{k=1}^{m}\delta_{k-1,k_n}a^*(f\otimes e_k)(f_1\otimes e_{k_1})\circ\cdots\circ(f_n\otimes e_{k_n})\\&=\mathbb{1}_{\{m\geqslant k_n+1\}}\sqrt{n+1}(f_1\otimes e_{k_1})\circ\cdots\circ(f_n\otimes e_{k_n})\circ(f\otimes e_{k_n+1}).\end{aligned}$$

The action of the annihilation operators is derived in a similar manner. □

Corollary 9.2: In particular, if $m=\infty$, *we obtain*

$$l^*(f)(f_1\otimes e_{k_1})\circ\cdots\circ(f_n\otimes e_{k_n})=\sqrt{(n+1)}(f_1\otimes e_{k_1})\circ\cdots\circ(f_n\otimes e_{k_n})\circ(f\otimes e_{k_n+1}),$$

$$l(f)(f_1\otimes e_{k_1})\circ\cdots\circ(f_n\otimes e_{k_n})=\frac{1}{\sqrt{n}}\langle f,f_n\rangle\delta_{k_n,k_{n-1}+1}(f_1\otimes e_{k_1})\circ\cdots\circ(f_{n-1}\otimes e_{k_{n-1}})$$

with the action on the vacuum vector given by $l^*(f)\Omega=f\otimes e_1$ *and* $l(f)\Omega=0$.

Theorem 9.3: *For any* $m\in\mathbf{N}^*$ *and* $f,g\in\mathcal{K}$, *the operators* $l^{(m)*}(f)$ and $l^{(m)}(f)$ *have unique bounded extensions to* $\Gamma(\mathcal{H})$, *are adjoints of each other, and satisfy the following relation:*

$$l^{(m)}(g)l^{(m)*}(f)=\langle g,f\rangle P^{(m)}.$$

Proof: By Proposition 9.1 we have

$$l^{(m)}(f)l^{(m)*}(g)(f_1\otimes e_{k_1})\circ\cdots\circ(f_n\otimes e_{k_n})=\mathbb{1}_{\{m\geqslant k_n+1\}}\langle f,g\rangle(f_1\otimes e_{k_1})\circ\cdots\circ(f_n\otimes e_{k_n}),$$

where $k_1\leqslant k_2\leqslant\cdots\leqslant k_n$, which proves that the relation holds on $\Gamma_0(\mathcal{H})$. It is also elementary to show that

$$\langle l^{(m)}(f)x,y\rangle=\langle x,l^{(m)*}(f)y\rangle$$

for $x,y\in\Gamma_0(\mathcal{H})$. Now, note that

$$\|l^{(m)*}(f)(f_1\otimes e_{k_1})\circ\cdots\circ(f_n\otimes e_{k_n})\|^2=\mathbb{1}_{\{m\geqslant k_n+1\}}\|f\|^2\|f_1\otimes e_{k_1})\circ\cdots\circ(f_n\otimes e_{k_n})\|^2$$

hence $l^{(m)*}(f)$ has a unique bounded extension to $\Gamma(\mathcal{H})$ of norm $\|l^{(m)*}(f)\|=\|f\|$ and thus the annihilation operator $l^{(m)}(f)$ also has a unique bounded extension to $\Gamma(\mathcal{H})$ of norm $\|l^{(m)}(f)\| =\|f\|$. □

Acting with the m-free creation and annihilation operators on Ω, $m\in\mathbf{N}$, and taking the closure, we recover a subspace isomorphic to the m-free Fock space $\mathcal{F}^{(m)}(\mathcal{K})$. Thus, denote by $\tilde{\mathcal{F}}^{(m)}(\mathcal{K})$ the closure of the space $\tilde{\mathcal{F}}_0^{(m)}(\mathcal{K})$ spanned by Ω and vectors of the form

$$(f_n\otimes e_1)\circ\cdots\circ(f_1\otimes e_n)$$

where $f_1,\ldots,f_n\in\mathcal{K}$, $1\leqslant n\leqslant m$ if m is finite. Similarly, denote by $\tilde{\mathcal{F}}(\mathcal{K})$ the closure of $\tilde{\mathcal{F}}_0(\mathcal{K})$ spanned by vectors of the above form with arbitrary $n\in\mathbf{N}$. We obtain

$$\langle(f_n\otimes e_1)\circ\cdots\circ(f_1\otimes e_n)\rangle,(g_m\otimes e_1)\circ\cdots\circ(g_1\otimes e_m)\rangle=\delta_{n,m}\frac{1}{n!}\langle f_1,g_1\rangle\cdots\langle f_n,g_n\rangle$$

by the orthogonality of $e_1,\ldots,e_n$.

Corollary 9.4: The m-free Fock space $\mathcal{F}^{(m)}(\mathcal{K})$ is *is isomorphic to* $\tilde{\mathcal{F}}^{(m)}(\mathcal{K})$. *The free Fock space* $\mathcal{F}(\mathcal{K})$ *is isomorphic to* $\tilde{\mathcal{F}}(\mathcal{K})$.

Proof: The unitary isomorphism from $\mathcal{F}_0(\mathcal{K})$ to $\tilde{\mathcal{F}}_0(\mathcal{K})$ is given by

$$f_1\otimes\cdots\otimes f_n\rightarrow\sqrt{n!}(f_n\otimes e_1)\circ\cdots\circ(f_1\otimes e_n)$$

and thus extends uniquely to $\mathcal{F}(\mathcal{K})$ [its restrictions give the results for $\mathcal{F}^{(m)}(\mathcal{K})$]. □

Thus, for each $m\in\mathbf{N}$, we obtain the filtration

$$\tilde{\mathcal{F}}^{(1)}(\mathcal{K})<\cdots<\tilde{\mathcal{F}}^{(m)}(\mathcal{K})<\cdots<\tilde{\mathcal{F}}(\mathcal{K})$$

in which $\tilde{\mathcal{F}}^{(m)}(\mathcal{K})$ is an invariant subspace for the C^*-algebra

$$\mathcal{C}^{(m)}=C^*\langle\mathbf{1},l^{(m)*}(f)|f\in\mathcal{K}\rangle$$

and $\tilde{\mathcal{F}}(\mathcal{K})$ is an invariant subspace for the C^*-algebra

$$\mathcal{C}=C^*\langle\mathbf{1},l^*(f)|f\in\mathcal{K}\rangle.$$

Moreover, each $\tilde{\mathcal{F}}(\mathcal{K})$ is only one copy of the free Fock space in $\Gamma(\mathcal{K})$ and it turns out that one can decompose $\Gamma(\mathcal{H})$ into a countable direct sum of subspaces isomorphic to the free Fock space and invariant under $\mathcal{C}$. In the sequel we will concentrate on this decomposition, in other words on what is "between" $\tilde{\mathcal{F}}(\mathcal{K})$ and $\Gamma(\mathcal{H})$.

In order to determine this, we need to take a closer look at the kernel of the annihilation operators. Let $\{d_n\}_{n=1}^{\infty}$ be an orthonormal basis in $\mathcal{K}$. Note that the set consisting of Ω and vectors of the form

$$(d_{i_1}\otimes e_{k_1})\circ\cdots\circ(d_{i_n}\otimes e_{k_n}),$$

where $k_1\leqslant k_2\leqslant\cdots\leqslant k_n$ and $i_r\leqslant i_{r+1}$ whenever $k_{i_r}=k_{i_{r+1}}$, is an orthogonal basis in $\Gamma(\mathcal{H})$ (the ordering of indices is used for convenience, which is possible due to the fact that the product is symmetrized). Denote by $\hat{\mathcal{D}}$ the subset of this basis consisting of Ω and vectors of the above form for which $k_n\neq k_{n-1}+1$, i.e., the last two vectors are of identical colors or their colors differ by more than 1 if $n>1$, and the last color is not equal to 1 if $n=1$. By normalizing the vectors from $\hat{\mathcal{D}}$ we get

$$\mathcal{D}=\{x/\|x\|\ |x\in\hat{\mathcal{D}}\},$$

which is an orthonormal set. Let $\mathcal{D}^{(m)}=\mathcal{D}\cap\Gamma^{m+1)}$, where $\Gamma^{m+1)}=\Gamma(\mathcal{H}^{(m+1)})$. We understand that $\mathcal{D}^{(\infty)}=\mathcal{D}$.

Proposition 9.5: $\mathcal{D}^{(m)}\subseteq\ker l^{(m)}(f)$ *for any* $m\in\mathbf{N}^*$ *and* $f\in\mathcal{K}$.

Proof: This follows from Proposition 9.1 due to the presence of $\delta_{k_n,k_{n-1}+1}$ on the right-hand side of the formula for the annihilation operators. □

Proposition 9.6: Let $m\in\mathbf{N}^*$. *Then*

$$\sum_{s=1}^{\infty} l^{(m)*}(d_s)l^{(m)}(d_s)=I-P_{[\mathcal{D}^{(m)}]\oplus\Gamma^{(m}}$$

where $P_{[D^{(m)}]\otimes\Gamma^{(m}}$ *is the projection onto* $[D^{(m)}]\otimes\Gamma^{(m}$ *and* $\Gamma^{(m}=\Gamma(\mathcal{H}\ominus\mathcal{H}^{(m+1)})$. *In particular,*

$$\sum_{s=1}^{\infty} l^*(d_s)l(d_s)=I-P_{[\mathcal{D}]}$$

thus $\mathcal{C}\cong\mathcal{O}_\infty$, *where* $\mathcal{O}_\infty$ *is the Cuntz algebra.*

Proof: It can be seen from Theorem 9.3 that

$$l^{(m)*}(d_s)l^{(m)}(d_s)=Q_s,$$

where Q_s is the projection onto the subspace spanned by vectors of the form

$$(d_{s_1}\otimes e_{k_1})\circ\cdots\circ(d_{s_{n-1}}\otimes e_{k_{n-1}})\circ(d_s\otimes e_{k_n})$$

where $k_1\leqslant\cdots\leqslant k_{n-1}=k_n-1<k_n\leqslant m$ (cf. Ref. 25). These subspaces are pairwise orthogonal and span the orthogonal complement of $[\mathcal{D}^{(m)}]\oplus\Gamma^{(m}$, which proves the first formula. The second formula is just a special case when $m=\infty$ and, together with Theorem 9.3, it implies that the C^*-algebra generated by $l^*(f), f\in\mathcal{K}$, is isomorphic to the Cuntz algebra $\mathcal{O}_\infty$ since $\mathcal{K}$ is countably separable. □

Let us introduce the following notation on $\Gamma_0(\mathcal{H})$:

$$u\odot w=u_1\circ\cdots\circ u_r\circ w_1\circ\cdots\circ w_n$$

where $u=u_1\circ\cdots\circ u_r$, $w=w_1\circ\cdots\circ w_n$.

Proposition 9.7: If $x=x_1\circ\cdots\circ x_r$, $z=z_1\circ\cdots\circ z_r$, $u=u_1\circ\cdots\circ u_n$, $v=v_1\circ\cdots\circ v_n$, *where* $x_i,z_i\in\mathcal{H}_1$, $1\leqslant i\leqslant r$ *and* $z_j, v_j\in\mathcal{H}_2$, $1\leqslant j\leqslant n$, *and* $\mathcal{H}_1$, $\mathcal{H}_2$ *are two orthogonal subspaces of* $\mathcal{H}$, *then*

$$\langle x\odot u,z\odot v\rangle=\frac{r!n!}{(r+n)!}\langle x,z\rangle\langle u,v\rangle.$$

Proof: Using the orthogonality of $\mathcal{H}_1$ and $\mathcal{H}_2$ and the formula for the scalar product in $\Gamma(\mathcal{H})$, we obtain

$$\begin{aligned}\langle x\odot u,z\odot v\rangle&=\frac{1}{(r+n)!}\sum_{\sigma\in S_r}\sum_{\tau\in S_n}\langle x_1,z_{\sigma(1)}\rangle\cdots\langle x_r,z_{\sigma(r)}\rangle\langle u_1,v_{\tau(1)}\rangle\cdots\langle u_n,v_{\tau(n)}\rangle\\&=\frac{r!n!}{(r+n)!}\langle x,z\rangle\langle u,v\rangle.\end{aligned}$$

□

The C^*-algebra $\mathcal{C}$ is a C^*-subalgebra of $\mathcal{B}(\Gamma(\mathcal{H}))$. Denote the faithful representation of $\mathcal{C}$ on $\Gamma(\mathcal{H})$ by π. Since $[\mathcal{C}x]$ is for each $x\in\mathcal{D}$ a closed subspace of $\Gamma(\mathcal{H})$, which is invariant under each

operator A in $\mathcal{C}$, the mapping $A \to A|[\mathcal{C}x]$ is a cyclic representation of $\mathcal{C}$ on $[\mathcal{C}x]$ with cyclic vector x. Denote this representation by π_x. We will show in the following that π is a direct sum of cyclic representations π_x, $x \in \mathcal{D}$.

Theorem 9.8: *The multiple symmetric Fock space has the direct sum decomposition*

$$\Gamma(\mathcal{H}) = \bigoplus_{x \in \mathcal{D}} [\mathcal{C}x]$$

where $[\mathcal{C}x] \cong \mathcal{F}(\mathcal{K})$, *according to which*

$$\pi = \bigoplus_{x \in \mathcal{D}} \pi_x,$$

where $\pi_x \cong \rho$, *and* ρ *is the free Fock space representation of* $\mathcal{C}$.

Proof: If $x = \hat{x}/\|x\| \in \mathcal{D}$, where $\hat{x}$ is of the form

$$\hat{x} = (d_1 \otimes e_{k_1}) \circ \cdots \circ (d_{i_r} \otimes e_{k_r})$$

with $k_r = l$, then $[\mathcal{C}x]$ is the closed subspace of $\Gamma(\mathcal{H})$ spanned by vectors of the form

$$x \odot (f_n \otimes e_{l+1}) \circ \cdots \circ (f_1 \otimes e_{l+n})$$

where $f_1, \ldots, f_n \in \mathcal{K}$. Clearly, $[\mathcal{C}x]$ is invariant under $\mathcal{C}$. Let us show that for each $x \in \mathcal{D}$, $[\mathcal{C}x] \cong \mathcal{F}(\mathcal{K})$.

For that purpose, define the linear mapping

$$U_x : \mathcal{F}_0(\mathcal{K}) \to [\mathcal{C}x]$$

by

$$U_x(\omega) = x,$$

$$U_x(f_1 \otimes \cdots \otimes f_n) = \sqrt{\frac{(r+n)!}{r!}}\, x \odot (f_n \otimes e_{l+1}) \circ \cdots \circ (f_1 \otimes e_{l+n}).$$

An elementary computation shows that U_x is scalar-product preserving and therefore has a unique extension to $\mathcal{F}(\mathcal{K})$. It is not hard to see that $[\mathcal{C}x] \perp [\mathcal{C}x']$ for $x \neq x'$ and that $\Gamma(\mathcal{H})$ is a direct sum of $[\mathcal{C}x]$ for all $x \in \mathcal{D}$.

It remains to be shown that U_x intertwines between π_x and the free Fock space representation ρ of $\mathcal{C}$ on $\mathcal{F}(\mathcal{K})$. We have

$$\pi_x(l^*(f)) U_x(\omega) = \sqrt{r+1}\, x \odot (f \otimes e_{r+1}) = U_x(f) = U_x \rho(l^*(f))\omega$$

and

$$\pi_x(l^*(f)) U_x(f_1 \otimes \cdots \otimes f_n) = \sqrt{\frac{(r+n+1)!}{r!}} \times x \odot (f_n \otimes e_{l+1}) \circ \cdots \circ (f_1 \otimes e_{l+n}) \circ (f \otimes e_{l+n+1})$$

$$= U_x(f \otimes f_1 \otimes \cdots \otimes f_n) = U_x \rho(l^*(f))(f_1 \otimes \cdots \otimes f_n)$$

for any $f_1, \ldots, f_n, f \in \mathcal{K}, n \geq 1$. Similarly, $\pi_x(l(f)) U_x \Omega = l(f)x = 0 = U_x \rho(l(f))\Omega$ and

$$\pi_x(l(f)) U_x(f_1 \otimes \cdots \otimes f_n) = U_x \rho(l(f))(f_1 \otimes \cdots \otimes f_n).$$

Therefore $\pi_x(a) U_x = U_x \rho(a)$ also for any $a \in \mathcal{C}$. This finishes the proof. □

Let us finally define *extended m-free number operators*. Guided by the definitions of extended creation and annihilation operators, we set

$$l^{(m)\circ}=\sum_{k=1}^{m}(a^{(k,k)\circ}-a^{(k,k-1)\circ}),$$

where $m\in\mathbf{N}^*$ and $a^{(k,r)\circ}=a^{(k,\sigma)\circ}$ for $\sigma=\{1,...,r-1\}$ and $a^{(k,\sigma)\circ}$ is given by (6.3). Let us determine the action of extended number operators on the finite particle domain.

Proposition 9.9: Let $f_1,\ldots,f_n\in\mathcal{K}$, $k_1\leqslant\cdots\leqslant k_n$, $m\in\mathbf{N}^*$. *The finite particle domain* $\Gamma_0(\mathcal{H})$ *is contained in the domains of extended m-free number operators and*

$$l^{(m)\circ}(f_1\otimes e_{k_1})\circ\cdots\circ(f_n\otimes e_{k_n})=\begin{cases}N_{k_n}(f_1\otimes e_{k_1})\circ\cdots\circ(f_n\otimes e_{k_n}) & \text{if } k_j+1=k_n\leqslant m \text{ for } j<n\\ 0 & \text{otherwise,}\end{cases}$$

where $N_k=\#\{i|k_i=k\}$.

Proof: The proof is elementary and therefore will be omitted. □

In other words, $l^{(m)\circ}$ "counts" particles of the highest color k_n if that one is smaller or equal to m and the second highest color is equal to k_n-1. Otherwise, the extended free number operator gives zero. In particular, on $\tilde{\mathcal{F}}_0^{(m)}(\mathcal{K})$ we obtain

$$l^{(m)\circ}\Omega=0,$$

$$l^{(m)\circ}(f_1\otimes e_n)\circ\cdots\circ(f_n\otimes e_1)=(f_1\otimes e_n)\circ\cdots\circ(f_n\otimes e_1)$$

for $1\leqslant n\leqslant m$.

It can be seen that, contrary to the case of extended m-free creation and annihilation operators, the operators $l^{(m)\circ}$ are not bounded on $\Gamma(\mathcal{H})$. Clearly, they are bounded on $\tilde{\mathcal{F}}^{(m)}(\mathcal{H})$ and, in fact, it can be shown that they are bounded on $[Cx]$ for each $x\in\mathcal{D}$.

Order-automorphisms of the set of bounded observables

Lajos Molnár[a)]

(Received 13 July 2001; accepted for publication 4 September 2001)

Let H be a complex Hilbert space and denote by $B_s(H)$ the set of all self-adjoint bounded linear operators on H. In this article we describe the form of all bijective maps (no linearity or continuity is assumed) on $B_s(H)$ which preserve the order $\leqslant$ in both directions. © *2001 American Institute of Physics.*
[DOI: 10.1063/1.1413224]

I. INTRODUCTION AND STATEMENTS OF THE RESULTS

In the Hilbert space framework of quantum mechanics the bounded observables are represented by self-adjoint bounded linear operators. If H denotes the underlying Hilbert space, then these operators form the set $B_s(H)$ on which usually several operations and relations are considered. The automorphisms of $B_s(H)$ with respect to those operations and/or relations are, just as with any algebraic structure in mathematics, of remarkable importance.

First of all, $B_s(H)$ with the usual addition, scalar multiplication and Jordan product forms a Jordan algebra. It is a well-known result that the corresponding automorphisms of $B_s(H)$ are implemented by unitary or antiunitary operators of H (see, for example, Ref. 1, where the automorphisms of some other important structures appearing in the probabilistic aspects of quantum mechanics are also treated).

The aim of this article is to determine another class of automorphisms of $B_s(H)$. Namely, we equip the set $B_s(H)$ with the usual order among self-adjoint operators. That is, for any $A,B \in B_s(H)$, we write $A \leqslant B$ if $\langle Ax,x\rangle \leqslant \langle Bx,x\rangle$ holds for every $x \in H$. Alternatively, in the language of quantum mechanics, the bounded observable A is said to be less than or equal to the bounded observable B if the expected value of A in any state is less than or equal to the expected value of B in the same state. The relation $\leqslant$ is no doubt an important one among observables.

In what follows we determine all the automorphisms of $B_s(H)$ as a partially ordered set with the relation $\leqslant$ (this is done in the main result of the paper, Theorem 2) and also present some corollaries (Corollaries 3 and 4) that we believe have physical meaning.

We begin with the following proposition on which the proof of our main result rests. Let H be a complex Hilbert space and let $B(H)^+$ denote the cone of all positive operators on H (that is, the set of all $A \in B_s(H)$ for which $\langle Ax,x\rangle \geqslant 0$ holds for every $x \in H$). Our first result describes the form of all bijective maps on $B(H)^+$ which preserve the order $\leqslant$ in both directions.

Theorem 1: *Assume that* $\dim H > 1$. *Let* $\phi: B(H)^+ \to B(H)^+$ *be a bijective map with the property that*

$$A \leqslant B \Leftrightarrow \phi(A) \leqslant \phi(B)$$

holds whenever $A,B \in B(H)^+$. *Then there exists an invertible bounded either linear or conjugate-linear operator* $T: H \to H$ *such that* ϕ *is of the form*

$$\phi(A) = TAT^* \quad (A \in B(H)^+).$$

a)Electronic mail: molnarl@math.klte.hu

After having proved this result, it will be easy to deduce the main result of the article that follows.

Theorem 2: *Suppose that* $\dim H>1$. *Let* $\phi:B_s(H)\to B_s(H)$ *be a bijective map with the property that*

$$A\leqslant B\Leftrightarrow \phi(A)\leqslant \phi(B)$$

holds whenever $A,B\in B_s(H)$. *Then there exists an operator* $X\in B_s(H)$ *and an invertible bounded either linear or conjugate-linear operator* $T:H\to H$ *such that* ϕ *is of the form*

$$\phi(A)=TAT^*+X \quad (A\in B_s(H)).$$

This result has some corollaries that seem worth mentioning. In the first one we determine the form of all bijective transformations on $B_s(H)$ which preserve the order and the commutativity in both directions (in quantum mechanics, instead of commutativity they usually use the word compatibility for this important concept).

Corollary 3: Assume that $\dim H>1$. *Let* $\phi:B_s(H)\to B_s(H)$ *be a bijective map which preserves the order and the commutativity in both directions. Then there is an either unitary or antiunitary operator* $U:H\to H$, *a positive scalar* λ, *and a real number* μ *such that* ϕ *is of the form*

$$\phi(A)=\lambda UAU^*+\mu I \quad (A\in B_s(H)).$$

The next corollary describes all the bijective maps on $B_s(H)$ which preserve the order and the complementarity in both directions (two observables are called complementary if the range of any nontrivial projection from the range of the spectral measure of the first observable has zero intersection with the range of any nontrivial projection from the range of the spectral measure of the second observable). Although this latter concept is in some sense opposite to compatibility, as it turns out below we still have the same form for ϕ as above.

Corollary 4: Suppose that $\dim H>1$. *Let* $\phi:B_s(H)\to B_s(H)$ *be a bijective map which preserves the order and the complementarity in both directions. Then there is an either unitary or antiunitary operator* $U:H\to H$, *a positive scalar* λ, *and a real number* μ *such that* ϕ *is of the form*

$$\phi(A)=\lambda UAU^*+\mu I \quad (A\in B_s(H)).$$

Finally, our last corollary characterizes those bijective maps on $B_s(H)$ which preserve the order and the orthogonality in both directions [two operators $A,B\in B_s(H)$ are called orthogonal if $AB=0$ which is just equivalent to the mutual orthogonality of the ranges of A and B].

Corollary 5: Assume that $\dim H>1$. *Let* $\phi:B_s(H)\to B_s(H)$ *be a bijective map which preserves the order and the orthogonality in both directions. Then there is an either unitary or antiunitary operator* $U:H\to H$, *and a positive scalar* λ *such that* ϕ *is of the form*

$$\phi(A)=\lambda UAU^* \quad (A\in B_s(H)).$$

Closing this section we note that all the above statements could be conversed, that is, if a map ϕ is of any of the above forms, then it necessarily preserves the corresponding properties.

II. PROOFS

This section is devoted to the proofs of our results. We begin with the following auxiliary results. If A is a bounded linear operator, then rng A denotes its range. The rank of A is, by definition, the algebraic dimension of rng A and it is denoted by rank A. For any $A\in B(H)^+$, $\sqrt{A}$ stands for the unique positive linear operator whose square is A.

Lemma 1: Let $A,B\in B(H)^+$ *be such that* rank $A=1$ *and* rank $B<\infty$. *We have* $\lambda A\leqslant B$ *for some positive scalar* λ *if and only if* $\operatorname{rng}A\subset\operatorname{rng}B$.

Proof: We recall the following nice result of Busch and Gudder (Ref. 2, Theorem 3): if $B\in B(H)^+$, $x\in H$, and P is the rank-1 projection projecting onto the subspace generated by x, then

we have $\lambda P \leqslant B$ for some positive scalar λ if and only if x is in the range of $\sqrt{B}$. As in our case B is a finite rank operator, it follows from the spectral theorem that $\mathrm{rng}\, B = \mathrm{rng}\, \sqrt{B}$. Since the positive rank-1 operators are exactly the positive scalar multiples of rank-1 projections, we obtain the assertion. □

Lemma 2: Let $A \in B(H)^+$ *and* $n \in \mathbb{N}$. *We have* rank $A > n+1$ *if and only if there are operators* $E,F \in B(H)^+$ *such that* $E,F \leqslant A$, rank $E = n$, rank $F > 1$ *and there is no* $G \in B(H)^+$ *of rank 1 with* $G \leqslant E,F$.

Proof: Suppose that rank $A > n+1$. We assert that there exists a finite rank operator $A' \in B(H)^+$ such that $A' \leqslant A$ and rank $A' > n+1$. In case A is of finite rank, this is trivial. If A is compact and not of finite rank, then by the spectral theorem of compact self-adjoint operators we can verify our claim very easily. Finally, if A is noncompact, then using the spectral theorem of self-adjoint operators and the properties of the spectral integral, we can find an infinite rank projection P on H and a positive scalar λ such that $\lambda P \leqslant A$ from which the existence of an appropriate operator A' follows.

Clearly, A' can be written as the sum of positive scalar multiples of pairwise orthogonal rank-1 projections. Let E be the sum of the first n terms in this sum and let F be the sum of the remaining part. It is easy to see that E,F have the required property. In fact, the nonexistence of G follows from Lemma 1.

To prove the converse, suppose that there are operators $E,F \in B(H)^+$ with the properties formulated in the lemma. It follows from the relation $E,F \leqslant A$ that E,F are of finite rank and $\mathrm{rng}\, E$, $\mathrm{rng}\, F \subset \mathrm{rng}\, A$. As there is no positive rank-1 operator G with $G \leqslant E,F$, by Lemma 1 we have $\mathrm{rng}\, E \cap \mathrm{rng}\, F = \{0\}$. So, rng A contains two subspaces with trivial intersection the sum of whose dimensions is greater than $n+1$. This shows that rank $A > n+1$, completing the proof of the lemma. □

Now, we are in a position to prove our first theorem.

Proof of Theorem 1: We first remark that our proof is based on a beautiful result of Rothaus (Ref. 3) concerning the automatic linearity of bijective maps between closed convex cones in normed spaces preserving order in both directions. In Ref. 3 conclusions of that kind were reached under some quite restrictive assumptions. In our present situation, that is, when the normed space in question is an operator algebra, those assumptions are fulfilled exactly when the underlying Hilbert space H is finite dimensional. Accordingly, the main point of our proof is to reduce the problem to the finite dimensional case. This is in fact what we are going to do next.

Clearly, $\phi(0) = 0$. We prove that ϕ preserves the rank of operators. In fact, we show that the assertion that

$$\text{rank } A = k \Leftrightarrow \text{rank}\, \phi(A) = k$$

$(k = 1,\ldots,n)$ holds for every $n \in \mathbb{N}$. To begin, as for the case $n = 1$, we remark that a nonzero operator $A \in B(H)^+$ is of rank 1 if and only if the operator interval $[0,A]$ is total under the partial ordering $\leqslant$, that is, every two elements of it are comparable. Suppose that our assertion is true for some $n \in \mathbb{N}$. We show that in that case it holds also for $n+1$. Let $A \in B(H)^+$ be of rank $n+1$. By our assumption of induction, it follows that the rank of $\phi(A)$ is at least $n+1$. Suppose that rank $\phi(A) > n+1$. Using Lemma 2 and the order preserving property of ϕ we obtain that rank $A > n+1$, which is a contradiction. Therefore, we have rank $\phi(A) = n+1$. Referring to the fact that ϕ^{-1} shares the same properties as ϕ, we obtain the desired assertion.

We now prove that if $A_1,\ldots,A_n \in B(H)^+$ are of rank 1, then their ranges are linearly independent if and only if the ranges of $\phi(A_1),\ldots,\phi(A_n)$ are, too. [A system of one-dimensional subspaces in H of n members is called linearly independent if they cannot be included in an $(n-1)$-dimensional subspace.] This statement is clear for $n = 1$. Suppose that it holds for n and prove that it then necessarily holds also for $n+1$. Let $A_1,\ldots,A_n,A_{n+1}$ be rank-1 operators with linearly independent ranges and assume that this is not the case with the ranges of $\phi(A_1),\ldots,\phi(A_n),\phi(A_{n+1})$. Then these ranges can be included in an at most n-dimensional subspace implying that there is a rank-n operator $B \in B(H)^+$ such that $\phi(A_1),\ldots,\phi(A_{n+1}) \leqslant B$. By

the rank-preserving property of ϕ we have a rank-n operator $A \in B(H)^+$ such that $A_1,\ldots A_n, A_{n+1} \leqslant A$. By Lemma 1 this implies that $\mathrm{rng}\, A_1,\ldots,\ \mathrm{rng}\, A_{n+1} \subset \mathrm{rng}\, A$ and it follows that the ranges of $A_1,\ldots,A_{n+1}$ can be included in an n-dimensional subspace of H which is a contradiction. This verifies our claim.

Fix rank-1 operators $A_1,\ldots,A_n \in B(H)^+$ with linearly independent ranges which generate the n-dimensional subspace H_n of H. Denote by H_n' the n-dimensional subspace of H generated by the ranges of $\phi(A_1),\ldots,\phi(A_n)$. We assert that an operator $T \in B(H)^+$ acts on H_n if and only if $\phi(T)$ acts on H_n'. (We say that an operator T acts on the closed subspace M of H if M is an invariant subspace of T and T is zero on the orthogonal complement of M.) This will follow from the following observation: the positive finite rank operator T acts on H_n if and only if for every rank-1 operator A for which the ranges of $A_1,\ldots,A_n,A$ are linearly independent we have $A \not\leqslant T$. To see this, suppose that T acts on H_n. If $A \leqslant T$, then we have $\mathrm{rng}\, A \subset \mathrm{rng}\, T \subset H_n$ implying that the ranges of $A_1,\ldots,A_n,A$ cannot be linearly independent. This gives us the necessity. As for the sufficiency, suppose that T does not act on H_n. Then there exists a unit vector x in the range of T which does not belong to H_n. On the other hand, as $x \in \mathrm{rng}\, T$, by Lemma 1 it follows that a positive scalar multiple of the rank-1 projection projecting onto the subspace generated by x is less than or equal to T. This gives us a rank-1 operator A for which the ranges of $A_1,\ldots,A_n,A$ are linearly independent and we have $A \leqslant T$. This proves our claim.

So, for any n-dimensional subspace H_n of H, there exists an n-dimensional subspace H_n' of H such that for every $T \in B(H)^+$, T acts on H_n if and only if $\phi(T)$ acts on H_n'. This gives rise to a bijective transformation ψ on the cone $M_n(\mathbb{C})^+$ of all positive $n \times n$ complex matrices which preserves the order in both direction. (Here positivity is used in the operator theoretical sense, so our concept of positivity is just the same as positive semidefiniteness in matrix theory.)

Since ϕ preserves the rank, it follows that ψ preserves the rank-n matrices in both directions. The set of all such matrices is just the interior of $M_n(\mathbb{C})^+$ in the real normed space of all $n \times n$ Hermitian matrices. Now, the result (Ref. 3, Proposition 2) of Rothaus on the linearity of order preserving maps can be applied and it gives us that ψ is linear on the set of all rank-n elements in $M_n(\mathbb{C})^+$. We show that ψ is linear on the whole set $M_n(\mathbb{C})^+$. Pick $A, B \in M_n(\mathbb{C})^+$. Then there are sequences $(A_k),(B_k)$ of rank-n elements in $M_n(\mathbb{C})^+$ which are monotone decreasing with respect to the order $\leqslant$ and $A_k \to A$, $B_k \to B$. It is clear that the equalities $A = \inf_k A_k$, $B = \inf_k B_k$ and $A + B = \inf_k (A_k + B_k)$ hold in the partially ordered set $M_n(\mathbb{C})^+$. By the order preserving property of ψ we obtain that $\psi(A) = \inf_k \psi(A_k)$, $\psi(B) = \inf_k \psi(B_k)$ and $\psi(A+B) = \inf_k \psi(A_k + B_k)$. The sequences $\psi(A_k)$, $\psi(B_k)$, $\psi(A_k + B_k)$ are monotone decreasing and bounded below. By Vigier's theorem (Ref. 5 4.1.1. Theorem) they necessarily converge (strongly) to their infima. Now, by the partial additivity property of ψ which has been obtained previously as a consequence of Rothaus's result, we have

$$\psi(A+B) = \lim_k \psi(A_k + B_k) = \lim_k \psi(A_k) + \lim_k \psi(B_k) = \psi(A) + \psi(B).$$

So, ψ is additive on $M_n(\mathbb{C})^+$ and one can prove in the same way that it is positive homogeneous as well. Since every pair of finite rank elements in $B(H)^+$ can be embedded into a matrix space $M_n(\mathbb{C})^+$, we deduce that ϕ is additive and positive homogeneous on the set of all finite rank elements in $B(H)^+$.

Since every finite sum $\Sigma_i \lambda_i P_i$, where the λ_i's are positive numbers and the P_i's are projections of not necessarily finite rank, is the strong limit of a monotone increasing net of finite rank elements in $B(H)^+$, one can prove in a very similar way to that shown earlier that ϕ is additive and positive homogeneous on the set of all such finite sums. Finally, using the fact that every operator in $B(H)^+$ is the norm limit of a monotone increasing sequence of operators of the form $\Sigma_i \lambda_i P_i$ (this follows from the spectral theorem), repeating the previously stated argument once again, we obtain that ϕ is additive and positive homogeneous.

Extend ϕ from $B(H)^+$ to $B(H)_s$ in the obvious way, that is, define $\tilde{\phi}(T) = \phi(A) - \phi(B)$ for every $T \in B_s(H)$ and $A, B \in B(H)^+$ for which $T = A - B$. It is easy to check that $\tilde{\phi}: B(H)_s$

$\to B(H)_s$ is a linear transformation which preserves the order in both directions. To see the less trivial part of this last assertion, suppose that $T \in B_s(H)$, $T=A-B$, $A,B \in B(H)^+$ are such that $0 \leqslant \tilde{\phi}(T)=\phi(A)-\phi(B)$. This implies that $\phi(B) \leqslant \phi(A)$ which yields $B \leqslant A$, that is, we have $0 \leqslant T$. The linear transformation $\tilde{\phi}$ is surjective since $B(H)^+$ is included in its range. Moreover, it is injective as well which follows from the fact that $\tilde{\phi}$ preserves the order in both directions. Now, if one further extends $\tilde{\phi}$ to a linear transformation on the algebra $B(H)$ of all bounded linear operators on H, one gets a linear bijection of the C^*-algebra $B(H)$ which preserves the order in both directions. Due to a well-known result of Kadison (Ref. 4, Corollary 5) every such transformation sending the identity to itself is a Jordan *-automorphism. Therefore, the linear transformation

$$A \mapsto \sqrt{\phi(I)}^{-1} \phi(A) \sqrt{\phi(I)}^{-1}$$

is a Jordan *-automorphism of $B(H)$. But these transformations of $B(H)$ are well known to be implemented by unitary-antiunitary operators (see, for example, Ref. 1). It is now easy to infer that ϕ is of the desired form. This completes the proof of the theorem. □

Our main result is now easy to prove.

Proof of Theorem 2: Let $X=\phi(0)$ and consider the transformation

$$\psi: A \mapsto \phi(A)-X.$$

Clearly, ψ is a bijection of $B_s(H)$ preserving the order in both directions. So, without loss of generality we can assume that $\phi(0)=0$. Now, restricting ϕ onto $B(H)^+$ we have a bijection of $B(H)^+$ which preserves the order in both directions. So, we can apply Theorem 1 and obtain that there exists an invertible bounded either linear or conjugate-linear operator $T: H \to H$ for which we have

$$\phi(A)=TAT^* \quad (A \in B(H)^+). \tag{1}$$

It remains to show that this equality holds also for every $A \in B_s(H)$. Let $B \in B_s(H)$ be arbitrary but fixed. Then there exists a constant $K \in \mathbb{R}$ such that $K \leqslant B$ (for example, one can choose $K=-\|B\|$). Consider the transformation

$$A \mapsto \phi(A+K)-\phi(K)$$

on $B(H)^+$. Just as above, this transformation is a bijective map on $B(H)^+$ which preserves the order in both directions. Therefore, there exists an invertible bounded either linear or conjugate-linear operator $S: H \to H$ such that

$$\phi(A+K)-\phi(K)=SAS^* \quad (A \in B(H)^+). \tag{2}$$

If $A \geqslant -K,0$, then by (1) we have

$$T(A+K)T^*-\phi(K)=SAS^*. \tag{3}$$

Considering this equality for another A' with $A' \geqslant -K,0$, we see that

$$T(A-A')T^*=S(A-A')S^*.$$

As the difference $A-A'$ can be an arbitrary self-adjoint operator, we obtain that $TCT^*=SCS^*$ holds for every $C \in B_s(H)$. It now follows from (3) that

$$T(A+K)T^*-\phi(K)=SAS^*=TAT^*,$$

where $A \in B_s(H)$, $A \geqslant -K,0$. This yields $\phi(K)=TKT^*=SKS^*$. We deduce from (2) that

$$\phi(A+K)=SAS^*+\phi(K)=TAT^*+TKT^*=T(A+K)T^*$$

holds for every $A\in B(H)^+$. Choosing $A=B-K\geqslant 0$, we have

$$\phi(B)=TBT^*.$$

This completes the proof. □

We now turn to the proofs of the corollaries.

Proof of Corollary 3: By Theorem 2 there is an invertible bounded either linear or conjugate-linear operator T on H such that

$$\phi(A)=TAT^*+\phi(0)\quad (A\in B_s(H)).$$

Since 0 is commuting with every $A\in B_s(H)$, the same is true for $\phi(0)$. This gives us that $\phi(0)$ is a scalar operator, that is, there is a $\mu\in\mathbb{R}$ such that $\phi(0)=\mu I$. Similarly, we have a constant $\lambda\in\mathbb{R}$ such that $TT^*=\phi(I)-\phi(0)=\lambda I$. It is trivial that λ is necessarily positive and then we obtain that the operator $T/\sqrt{\lambda}$ is either unitary or antiunitary. □

Proof of Corollary 4: It is easy to see that $A\in B_s(H)$ is complementary with every $B\in B_s(H)$ if and only if A is scalar. Hence, ϕ preserves the scalar operators and one can apply the argument in the proof of Corollary 4 to get the desired form of ϕ. □

In the proof of Corollary 5 we make use of the following notation. If $x,y\in H$, then $x\otimes y$ denotes the operator defined by $(x\otimes y)z=\langle z,y\rangle x$ $(z\in H)$.

Proof of Corollary 5: Since 0 is the only operator in $B_s(H)$ which is orthogonal to every operator, we infer that $\phi(0)=0$. By Theorem 2 we have an invertible bounded either linear or conjugate-linear operator T on H such that $\phi(A)=TAT^*$ holds for every $A\in B_s(H)$. Without serious loss of generality we can suppose that T is linear. It now follows that for every $A,B\in B_s(H)$ with $AB=0$ we have $\phi(A)\phi(B)=0$ which implies that $AT^*TB=0$. Choosing nonzero orthogonal vectors $x,y\in H$, for $A=x\otimes x$ and $B=y\otimes y$ we get $x\otimes Tx\cdot Ty\otimes y=0$ which yields $\langle T^*Tx,y\rangle=\langle Tx,Ty\rangle=0$. So, we have $\langle T^*Tx,y\rangle=0$ whenever $\langle x,y\rangle=0$. This clearly implies that for every $x\in H$ there is a scalar λ_x such that $T^*Tx=\lambda_x x$. In another expression, the operators T^*T and I are locally linearly dependent. It is a folk result (whose proof requires only elementary linear algebra) that in that case the operators T^*T and I are necessarily linearly dependent, that is, there exists a scalar $\lambda\in\mathbb{R}$ such that $T^*T=\lambda I$. Now, the proof can be completed as in the proof of Corollary 3. □

An expansion of the hypergeometric function in Bessel functions

Bengt Nagel[a)]
Mathematical Physics, Department of Physics, Royal Institute of Technology, SCFAB, S-10691 Stockholm, Sweden

(Received 21 June 2001; accepted for publication 14 September 2001)

An expansion of the hypergeometric function ${}_2F_1(a,b,c+1;-z^2/4ab)$ in Bessel functions of argument z is derived. This expansion can be used to obtain an asymptotic expansion of the hypergeometric function for large absolute values of a and b. © *2001 American Institute of Physics.* [DOI: 10.1063/1.1415431]

I. INTRODUCTION AND SUMMARY

In a recent article[1] the authors derived the first terms of an asymptotic expansion of the hypergeometric function ${}_2F_1(a,b,c+1;-z^2/4ab)$ for large values of the parameters a and b, including second-order terms in $1/a$ and $1/b$, and involving Bessel functions $J_\nu(z)$ of orders c up to $c+4$ in integer steps. The result was obtained by a direct expansion of the a and b dependent coefficients in the power series definition of ${}_2F_1$. Going to higher orders would probably become very complicated. The resulting expansion was used in an analysis of the connection between the quantal and the semiclassical treatments of Coulomb excitation of atomic systems by passing charged particles.

In this note we show that the above-mentioned asymptotic expansion can be derived (in principle to arbitrary order) by rearranging a convergent expansion of the hypergeometric function in Bessel functions. This expansion is obtained by applying the standard integral representation of the gamma function to the factors $(a)_n=\Gamma(a+n)/\Gamma(a)$ and $(b)_n$ in the coefficients of the power series representation of the hypergeometric function. The expansion is

$$\frac{(z/2)^c}{\Gamma(c+1)}\,{}_2F_1(a,b,c+1;-z^2/4ab)=\sum_{\nu=0}^{\infty}\frac{1}{\nu!}\,{}_3F_0(-\nu,a,b;1/ab)(z/2)^\nu J_{c+\nu}(z), \tag{1}$$

where

$${}_3F_0(-\nu)={}_3F_0(-\nu,a,b;1/ab)=\sum_{n=0}^{\nu}\frac{(-\nu)_n}{n!}(a)_n(b)_n/(ab)^n \tag{2}$$

is a generalized hypergeometric polynomial. It is easily seen that ${}_3F_0(0)=1$, ${}_3F_0(-1)=0$, and that ${}_3F_0(-\nu)$ for $\nu\geqslant 2$ is a symmetric polynomial in $1/a$ and $1/b$ of degree $2(\nu-1)$ with constant term 0 and the two highest degree terms coming from the last term in the sum in (2):

$$(-1)^\nu[(\nu-1)!]^2[1/(ab)^{\nu-1}+\{1+1/2+\cdots+1/(\nu-1)\}(1/a^{\nu-1}b^{\nu-2}+1/a^{\nu-2}b^{\nu-1})]. \tag{3}$$

It is less trivial to find the degree and value of the first nonvanishing term. We do this by using a saddle point asymptotic estimate—a and b large—in the double integral representation of ${}_3F_0$. The result is different for even and odd ν:

a)Electronic mail: nagel@theophys.kth.se

$$ {}_3F_0(-2\kappa)\approx\frac{\Gamma(2\kappa+1)}{2^\kappa\Gamma(\kappa+1)}(1/a+1/b)^\kappa, \tag{4}$$

$$ {}_3F_0(-2\kappa-1)\approx\frac{\Gamma(2\kappa+1)}{2^{\kappa-1}\Gamma(\kappa)}[(1/a^2+1/b^2)/3+1/ab)](1/a+1/b)^{\kappa-1}. \tag{5}$$

This means that in reordering (1) into an expansion (possibly only asymptotic) after increasing powers of $1/a$ and $1/b$ the nth order terms, of the form $1/a^{n-\mu}b^\mu+1/a^\mu b^{n-\mu}$, contain Bessel functions of orders $c+[(n+3)/2]$ up to $c+2n$ ($[m]$ denotes the integer part of m). As an example we give the expansion including third-order terms in $1/a$ and $1/b$ [see (18)].

The asymptotic behavior of the terms on the right-hand side of (1) as $\nu\to\infty$ turns out to be the same as the behavior of the terms in the power series expansion of the left-hand side. The series is thus convergent provided $|z^2/4ab|<1$, and under this condition (1) is a valid expansion for all (possibly complex) z, a, and b, as follows from standard theorems on integration of series term by term, and on analytic continuation of series of holomorphic functions. It should be pointed out that the series obtained for the asymptotics in $1/a$ and $1/b$ might be only asymptotic, since its derivation involves a rearrangement of the convergent series using an increasing number of terms.

Finally it should be remarked that (1) is an example of what is called a modified Neumann series expansion of a function in a series of Bessel functions.[2,3] This means that the coefficients ${}_3F_0$ can also be derived from the general formula expressing the coefficients of the Bessel function expansion in terms of the power series coefficients of the function that one expands [see, e.g., Ref. 3, p. 66, (18)–(20)]. This presupposes that one knows which function to expand, and thus the derivation given here leads in a more natural way to the expansion of ${}_2F_1$ with the argument $-z^2/4ab$. Anyhow, it is very likely that the expansion (1) is already given somewhere in the enormous literature on Bessel functions, although it does not seem to occur in any of the standard handbooks.

II. DERIVATION OF FORMULAS (1)–(5)

Let us first derive the expansion (1). We start from the power series expansion of the relevant hypergeometric function,:

$$ F\equiv{}_2F_1(a,b,c+1;-z^2/4ab)=\sum_{n=0}^{\infty}\frac{(a)_n(b)_n}{(c+1)_n n!}(-z^2/4ab)^n. \tag{6}$$

We assume of course the convergence condition $|z^2/4ab|<1$, and shall also assume a and b real and positive, sometimes even large and going to infinity. Establishing relation (1) under these conditions we can use analytic continuation of both sides to extend the validity to general a and b.

Introducing the standard gamma function integral representation in the factors $(a)_n$ and $(b)_n$ in (6), and making a variable change $s=ax$, thus

$$ (a)_n=\frac{1}{\Gamma(a)}\int_0^\infty \mathrm{d}s\, e^{-s}s^{a+n-1}=\frac{a^{a+n}}{\Gamma(a)}\int_0^\infty \mathrm{d}x\, e^{-ax}x^{a+n-1},\ \text{etc.}, \tag{7}$$

we can interchange summation and integration and perform the summation to get

$$ F=\frac{a^a b^b}{\Gamma(a)\Gamma(b)}\int\int \mathrm{d}x\,\mathrm{d}y e^{-a(x-\ln x)-b(y-\ln y)}(xy)^{-1}\,{}_0F_1(c+1;-xy\,z^2/4), \tag{8}$$

where

$$ {}_0F_1(c+1;-u^2/4)=\sum_{n=0}^{\infty}\frac{1}{(c+1)_n n!}(-u^2/4)^n=\frac{\Gamma(c+1)}{(u/2)^c}J_c(u). \tag{9}$$

This relation, added to the following ''asymptotic expansion'' argument, motivates the choice of expanding the original F function with the argument $-z^2/4ab$. The function $f(x)=x-\ln x$ in the exponent of (8) goes from $+\infty$ at $x=0$ through a minimum 1 at $x=1$ to $+\infty$ at $x=\infty$. So if we want to study the behavior of the integral for large a and b we should obviously expand around $x=y=1$, which is a two-dimensional saddle point if we extend x and y to complex variables. We have $f(x)=1+(x-1)^2/2-(x-1)^3/3+\cdots$, so an asymptotic estimate (to be performed later) should use the new variables $\xi=\sqrt{a}(x-1)$, $\eta=\sqrt{b}(y-1)$. But first we shall establish formula (1) by expanding the ${}_0F_1$ function around $-z^2/4$, putting $-xyz^2/4=-z^2/4-(xy-1)z^2/4$. From the power series expansion one easily derives for the nth derivative ${}_0F_1^{(n)}(c+1;x)={}_0F_1(c+n+1;x)/(c+1)_n$. The Taylor expansion of ${}_0F_1$ around $-z^2/4$ then gives, with Bessel functions on the right-hand side,

$$ {}_0F_1(c+1;-xy\,z^2/4)=\frac{\Gamma(c+1))}{(z/2)^c}\sum_{\nu=0}^{\infty}\frac{1}{\nu!}(1-xy)^{\nu}(z/2)^{\nu}J_{c+\nu}(z). \tag{10}$$

Introducing (10) in (8), interchanging integration and summation, expanding the factor $(1-xy)^{\nu}$ in each term, and performing the integrations, we finally get the formulas (1) and (2), where as an intermediate result we get for ${}_3F_0$ the integral representation

$$ {}_3F_0(-\nu,a,b;1/ab)=\frac{a^a b^b}{\Gamma(a)\,\Gamma(b)}\int\int \mathrm{d}x\mathrm{d}y e^{-a(x-\ln x)-b((y-\ln y)}(xy)^{-1}(1-xy)^{\nu}. \tag{11}$$

It may be noted that (10), written for the Bessel function on the left-hand side:

$$ J_c(\varsigma z)=\varsigma^c\sum_{\nu=0}^{\infty}\frac{(1-\varsigma^2)^{\nu}}{\nu!}(z/2)^{\nu}J_{c+\nu}(z), \tag{12}$$

is the multiplication theorem for the Bessel function.[4]

Before we derive the lowest order expressions (4) and (5) for ${}_3F_0(-\nu)$, we shall establish the convergence of the expansion (1) provided $|z^2/4ab|<1$. So we should evaluate the asymptotic behavior as $\nu\to\infty$ of the factors on the right-hand side of (1). For the Bessel function the first term in the series expansion dominates, $J_{c+\nu}(z)\approx(z/2)^{c+\nu}/\Gamma(c+\nu+1)$. To make the asymptotic estimate for ${}_3F_0(-\nu)$ we use the integral representation (11) and observe that for large ν the main contribution to the integral comes from large x and y, so we can put $(1-xy)^{\nu}=(-xy)^{\nu}(1-\nu/xy+\cdots)\approx(-xy)^{\nu}$. The double integral can then be simply computed and we get ${}_3F_0(-\nu)\approx(-1)^{\nu}(a)_{\nu}(b)_{\nu}/(ab)^{\nu}$, not surprisingly just the last term in the expansion (2) of ${}_3F_0(-\nu)$. Altogether we get

$$ \frac{1}{\nu!}{}_3F_0(-\nu)(z/2)^{\nu}J_{c+\nu}(z)\approx\frac{(z/2)^c}{\Gamma(c+1)}\frac{(a)_{\nu}(b)_{\nu}}{(c+1)_{\nu}\,\nu!}(-z^2/4ab)^{\nu}. \tag{13}$$

So the asymptotic behavior of the terms of the series on the right-hand side of (1) is the same as the terms in the series expansion of the function on the left-hand side. Using basic theorems on integration of convergent function series it is then easy to establish the validity of (1) under the condition $|z^2/4ab|<1$, and furthermore a and b real and positive. But using analytic continuation of the functions of a and b (and even c) on both sides, we can conclude the validity of (1) for all a, b, and z satisfying $|z^2/4ab|<1$.

Let us now study the polynomial ${}_3F_0(-\nu)$ in $1/a$ and $1/b$. The series (2) can be written

$$ {}_3F_0(-\nu)=\sum_{n=0}^{\nu}(-1)^n\binom{\nu}{n}K_n, \tag{14}$$

where

$$K_{n+1}=(1+n/a)(1+n/b)\,K_n, K_0=1 \tag{15}$$

can be used for recursive calculation of ${}_3F_0(-\nu)$. Going from n to $n+1$ increases the polynomial degree in K_n by two units, so the two highest degree terms in ${}_3F_0$ come from the coefficient K_ν and are easily shown to be of the form given in (3). That ${}_3F_0(-\nu)$ has constant term 0 for $\nu \geqslant 1$ follows from the fact that all K_n have constant term 1. To study the first nonvanishing term in the series expansion seems less useful; instead we study the first term in an asymptotic expansion of the integral representation (11). In the standard spirit of asymptotic estimate by expansion around the saddle point $x=y=1$ we introduce, as already mentioned, the variables $\xi=\sqrt{a}(x-1)$, $\eta=\sqrt{b}(y-1)$, extend the integrations in these variables from $-\infty$ to $+\infty$, and find the lowest order term that is even in both variables (since odd terms give zero contribution from symmetry). To keep track of orders we put $a=mu$, $b=mw$, where m is large. There is a difference between the cases even or odd ν, $=2\kappa$, or $2\kappa+1$; in the even case the whole contribution comes from the leading term in the expansion of $(xy-1)^\nu \approx (\xi/\sqrt{u}+\eta/\sqrt{w})^\nu/m^{\nu/2}$, but for the odd case the next term comes in, and we also have to expand the third degree terms in the exponent and the factor $1/xy$. Doing this we get the expression

$$(-1)^\nu {}_3F_0(-\nu)\approx\frac{(a/e)^a(b/e)^b}{\Gamma(a)\Gamma(b)\sqrt{ab}}\int\int \mathrm{d}\xi\,\mathrm{d}\eta e^{-\xi^2/2-\eta^2/2}[\ldots], \tag{16}$$

where

$$[\ldots]=\left[1-\frac{1}{\sqrt{m}}\left(\frac{1}{\sqrt{u}}(\xi-\xi^3/3)+\frac{1}{\sqrt{w}}(\eta-\eta^3/3)\right)\right]\frac{1}{m^{\nu/2}}\left[(\xi/\sqrt{u}+\eta/\sqrt{w})^\nu+\nu\frac{1}{\sqrt{m}}(\xi/\sqrt{u}+\eta/\sqrt{w})^{\nu-1}\xi\eta/\sqrt{uw}\right]. \tag{17}$$

Expanding to the relevant lowest integer order of $1/m$ and performing the elementary integrations we finally get the results (4) or (5).

Expansion of ${}_2F_1$ to order three in $1/a$ and $1/b$ involves values of ν from 0 to 6. Here only ${}_3F_0(-4)$ contributes with terms not covered by the results given in (3), (4), or (5), namely the next lowest degree terms. The final result is

$$\begin{aligned}\frac{(z/2)^c}{\Gamma(c+1)}{}_2F_1(a,b,c+1;-z^2/4ab)=J_c(z)+\frac{1}{2}(1/a+1/b)(z/2)^2J_{c+2}(z)+(1/a^2+1/b^2)&\left[-\frac{1}{3}(z/2)^3J_{c+3}(z)+\frac{1}{8}(z/2)^4J_{c+4}(z)\right]\\+1/ab&\left[\frac{1}{2}(z/2)^2J_{c+2}(z)-(z/2)^3J_{c+3}(z)+\frac{1}{4}(z/2)^4J_{c+4}(z)\right]\\+\quad(1/a^3+1/b^3)&\left[\frac{1}{4}(z/2)^4J_{c+4}(z)-\frac{1}{6}(z/2)^5J_{c+5}(z)\right.\\&\left.+\frac{1}{48}(z/2)^6J_{c+6}(z)\right]+(1/a^2b+1/ab^2)\left[-(z/2)^3J_{c+3}(z)\right.\end{aligned}$$

$$+\frac{7}{4}(z/2)^4 J_{c+4}(z)-\frac{2}{3}(z/2)^5 J_{c+5}(z)+\frac{1}{16}(z/2)^6 J_{c+6}(z)\Bigg]$$
$$+\cdots. \tag{18}$$

(Received 16 April 2001; accepted for publication 10 August 2001)

The radiation from a pulsed source distribution can be described by a spectrum of time-dependent plane waves or of spherical waves (multipoles). These two fundamental representations are based on the slant stack transform and on the time-dependent multipole moment, respectively. In this article, we present a direct transformation relating these two representations. © *2001 American Institute of Physics.* [DOI: 10.1063/1.1407282]

I. INTRODUCTION

In recent years there is a growing interest in the generation, detection and processing of ultra-wideband short-pulse fields, with emphasis on application pertaining to local interrogation and sensing of the propagation environment or to source-synthesis of collimated short-pulse beam fields. (For further discussions and references the readers are referred to Ref. 1.) Because of the broad frequency band of these fields, the conventional use of frequency domain techniques is often less efficient and physically less transparent than a direct solution in the space–time domain where the fields are well localized. The fundamental time-dependent field representations, namely the Green's function integral, the plane-wave spectrum, and the spherical waves (multipoles) expansion, have been thoroughly investigated recently with emphasis on their causal properties.[1–3] (For completeness, field representations based on spectral expansion using pulsed-beam basis functions should also be mentioned. Their main advantages are the spectral compactness and the use of local propagators; for further references, see Ref. 1) The results have been used in various applications, pertaining to time-domain antenna analysis in the *radiation* zone[4–6] and in the *reactive* zone,[7,8] to inverse scattering[9–11] and inverse source[12] problems, and to fast algorithms for numerical solution of time-dependent scattering problems.[13–15]

In the present article we derive a direct transformation relating the time-domain plane-wave and spherical-wave representations. This is done in Sec. III following a review in Sec. II of these representations.

The prototype problem considered is the radiation of the scalar field $u(\mathbf{r},t)$ in a uniform medium with wave speed c, satisfying the time-dependent wave equation

$$\left(\nabla^2-\frac{1}{c^2}\frac{\partial^2}{\partial t^2}\right)u(\mathbf{r},t)=-q(\mathbf{r},t), \tag{1}$$

where $\mathbf{r}=(x,y,z)\in\mathbb{R}^3$ and $t\in\mathbb{R}$. It is assumed that the source distribution $q(\mathbf{r},t)$ is confined in a volume V bounded within a sphere of radius R_0 centered at the origins and within the time window $t\in(0,T)$. The solution to (1) may be expressed by the well-known Green's function integration. Here, however, the emphasis is on the time-dependent plane waves and multipole representations.

II. BACKGROUND

A. The slant stack transform and time-dependent plane wave representations

The slant stack transform (SST) of a scalar volume source $q(\mathbf{r},t)$ is defined as

$$\tilde{q}(\mathbf{s},\tau)=\int_V dV\,\delta(\tau+c^{-1}\mathbf{s}\cdot\mathbf{r})*q(\mathbf{r},\tau) \tag{2a}$$

$$=\int_V dV q(\mathbf{r},\tau+c^{-1}\mathbf{s}\cdot\mathbf{r}), \tag{2b}$$

where $\tau\in\mathbb{R}$, $\mathbf{s}\in\mathbb{R}^3$, and $*$ denotes a temporal convolution. From (2a), the SST is identified as a Radon projection of $q(\mathbf{r},t)$ in the 4D space $(\mathbf{r},t)$, while (2b) is obtained by performing the τ convolution. Alternatively, performing the spatial integration in (2a) first, the SST can be expressed as two cascaded operations [Ref. 1, Eqs. (3.11) and (3.12)]

$$\mathcal{P}_q(\hat{\mathbf{s}};\sigma,\tau)=\int d^2r\, q(\mathbf{r},\tau)|_{\hat{\mathbf{s}}\cdot\mathbf{r}=\sigma} \tag{3a}$$

$$\tilde{q}(\mathbf{s},\tau)=\int d\sigma\,\mathcal{P}_q(\hat{\mathbf{s}};\sigma,\tau+|\mathbf{s}|\sigma/c), \tag{3b}$$

where (3a) is a spatial Radon projection of $q(\mathbf{r},\tau)$ at planes normal to the spectral direction $\hat{\mathbf{s}}\equiv\mathbf{s}/|\mathbf{s}|$ (unit vectors are denoted by over circles), while in (3b) these projections are stacked with a progressive time delay $\mathbf{s}\cdot\mathbf{r}/c$ associated with a planar front that propagates along the $\mathbf{s}$ axis at the spectral speed $v(\mathbf{s})=c/|\mathbf{s}|$.

The SST extracts the time-dependent plane-wave information of the source, hence the field can be recovered as a superposition of the SST constituents $\tilde{q}(\mathbf{s},\tau)$ via the inverse SST [Ref. 1, Eqs. (3.10)]. One option, which applies both inside and outside the source region, is an integration in the entire 3D $\mathbf{s}$ domain [Ref. 1, Eq. (3.17)]. This involves SST constituents that propagate in all directions $\hat{\mathbf{s}}$ and in all spectral speeds $v(\mathbf{s})=c/|\mathbf{s}|$ [see (3b)].

Outside the source region, on the other hand, the full 3D spectral representation may be contracted to a 2D representation on the unit-sphere $|\mathbf{s}|=1$, involving only plane-wave constituents with wave speed c. There are two options for such formulations: In the **Weyl-type** representation, the field synthesis involves both *propagating* and *evanescent* spectra, identified by *real* and *complex* $\mathbf{s}$, respectively (with $|\mathbf{s}|=1$ in both cases). The incorporation of complex $\mathbf{s}$ requires an extension of the SST to complex time variables, an operation that is performed systematically via the analytic signal formulation [Ref. 1. Eqs. (4.13) and (4.14)]. The resulting integral representation is *strictly causal*, i.e., it vanishes prior to the wave arrival. The **Wittaker-type** representation, on the other hand, involves only the propagating part of the SST spectrum. It is valid only for $t>T$ after the source has turned off, while for $t<T$ it yields noncausal contributions [Ref. 1, Eqs. (7.13) and (7.14)] (see also Ref. 16). For $t>T$ it is given by

$$u(\mathbf{r},t)=\frac{-1}{8\pi^2}\partial_{ct}\int_{4\pi} d^2s\,\tilde{q}(\mathbf{s}\cdot t-c^{-1}\mathbf{s}\cdot\mathbf{r}), \tag{4}$$

where here and henceforth $\mathbf{s}$ is a unit vector whose Cartesian coordinates are given by $(\sin\alpha\cos\beta,\sin\alpha\sin\beta,\cos\alpha)$, i.e., $\int_{4\pi} d^2s=\int_0^{\pi}\sin\alpha\,d\alpha\int_{-\pi}^{\pi}d\beta$. Finally, it is noted that in the far radiation zone the field has the form

$$u(\mathbf{r},t)\sim(4\pi r)^{-1}\tilde{q}(\hat{\mathbf{r}},t-r/c), \tag{5}$$

where $r=|\mathbf{r}|$ and $\hat{\mathbf{r}}=\mathbf{r}/r$. Thus the time-dependent radiation pattern is determined by the SST constituent $\mathbf{s}=\hat{\mathbf{r}}$ in the $\mathbf{r}$ direction.

B. Spherical wave (multipoles) expansion

The spherical wave solutions of the *homogeneous* wave equation are given by[17]

$$\varphi_\nu(\mathbf{r},t)=(-1)^n 2\pi\frac{c}{r}[P_n(ct/r)p(ct/r)]Y_\nu(\mathring{\mathbf{r}}), \tag{6}$$

where $\mathring{\mathbf{r}}$ is a unit vector in the $\mathbf{r}$ direction, identified by the spherical angles (θ, ϕ), and $Y_\nu(\mathring{\mathbf{r}})$ are the *real* spherical harmonics defined, for the triple index $\nu=(n,m,s)$ with $s=1,2$, $n=0,1,...$, and $m=0,1,...n$, by

$$\begin{Bmatrix} Y_{n,m,1}(\mathring{\mathbf{r}}) \\ Y_{n,m,2}(\mathring{\mathbf{r}}) \end{Bmatrix} = y_{nm}P_n^m(\cos\theta)\begin{Bmatrix} \cos \\ \sin \end{Bmatrix} m\phi. \tag{7}$$

with $y_{nm}=\sqrt{\varepsilon_m(2n+1)/4\pi}\sqrt{(n-m)!/(n+m)!}$ and the Neumann symbol $\varepsilon_m=1$ or 2 for $m=0$ or $m>0$, respectively. P_n^m and $P_n^0=P_n$ are the associate Legendre functions and polynomials, respectively (Ref. 18, Chap. 8), and $p(x)$ is a rectangular pulse, $p(x)=1$ for $|x|\leqslant 1$ and 0 otherwise. The solutions in (6) may readily be verified by solving the time-dependent wave equation in spherical coordinates, and are the Fourier transform of the frequency domain solutions $4\pi\cdot(-i)^n j_n(kr)Y_\nu(\mathring{\mathbf{r}})$ where $j_n(kr)$ is the spherical Bessel function (Ref. 18, Chap. 10).

The spherical wave expansion of the Green's function is (see also Ref. 17)

$$g(\mathbf{r},\mathbf{r}',t)=\delta(t-c^{-1}|\mathbf{r}-\mathbf{r}'|)/4\pi|\mathbf{r}-\mathbf{r}'| \tag{8}$$

$$=\sum_\nu \varphi_\nu(\mathbf{r}_<,t)*\psi_\nu(\mathbf{r}_>,t), \tag{9}$$

where $(\mathbf{r}_<,\mathbf{r}_>)=(\mathbf{r}',\mathbf{r})$ or $(\mathbf{r},\mathbf{r}')$ if $r'\leqslant r$, respectively, and the spherical propagators are

$$\psi_\nu(\mathbf{r},t)=(4\pi r)^{-1}Y_\nu(\mathring{\mathbf{r}})\partial_t[P_n(ct/r)H(t-r/c)]. \tag{10}$$

H being the Heaviside function, $H(x)=0$ or 1 for $x\lessgtr 0$, respectively. ψ_ν are the inverse Fourier transforms of the frequency domain propagators $(4\pi)^{-1}i^{n+1}kh_n^{(1)}(kr)Y_\nu(\mathring{\mathbf{r}})$. The $n=0$, 1, 2 terms of $\partial_t[P_n(ct/r)H(t-r/c)]$ in (10) are, respectively, $\delta(t-r/c)$, $\delta(t-r/c)+(c/r)H(t-r/c)$, and $\delta(t-r/c)+3[(c/r)+(c/r)^2(t-r/c)]H(t-r/c)$.

Substituting (9) into the Green's function solution of (1), $u=\int_V d^3r'q[\mathbf{r}'\cdot t-|\mathbf{r}-\mathbf{r}'|/c]/4\pi|\mathbf{r}-\mathbf{r}'|$, we may express the radiated field for $r>R_0$ as

$$u(\mathbf{r},t)=\sum_\nu \psi_\nu(\mathbf{r},t)*q_\nu(t), \tag{11}$$

where the multipole moment $q_\nu(t)$ of the volume source $q(\mathbf{r},t)$ are given by

$$q_\nu(\tau)=\langle\varphi_\nu(\mathbf{r},t),q(\mathbf{r},t)\rangle=\int_V dV\,\varphi_\nu(\mathbf{r},t)*q(\mathbf{r},t). \tag{12a}$$

Performing the integral, they may also be calculated via [Ref. 2, Eq. (3.25)]

$$q_\nu(t)=2\pi\frac{1}{2^n n!}\int_V dV\,Y_\nu(\mathring{\mathbf{r}})(r/c)^n\partial_t^n\int_{-1}^1 d\eta\,(1-\eta^2)^n q(\mathbf{r},t+\eta r/c). \tag{12b}$$

Finally, noting that $\psi_\nu\to(4\pi r)^{-1}Y_\nu(\mathring{\mathbf{r}})\delta(t-r/c)$ for $r\to\infty$ we find for the far radiation field (Ref. 2, Sec. 3b)

$$u(\mathbf{r},t)\sim\frac{1}{4\pi r}\sum_{\nu}\ q_{\nu}(\tau)Y_{\nu}(\mathring{\mathbf{r}}),\tag{13}$$

which is an alternative to the SST result in (5).

III. NEW RESULTS: THE TIME-DEPENDENT PLANE-WAVE–MULTIPOLE TRANSFORM

The time-dependent plane wave kernel that propagate in the **s** direction can be expanded in terms of multipoles (spherical waves) as

$$\delta(t+c^{-1}\mathbf{s}\cdot\mathbf{r})=\sum_{\nu}\ Y_{\nu}(\mathbf{s})\varphi_{\nu}(\mathbf{r},t).\tag{14}$$

The inverse relation, namely the time-dependent plane wave expansion of a multipole field, has the form of a Whittaker's expansion [see (4)]:

$$\varphi_{\nu}(\mathbf{r},t)=\int_{4\pi}d^2s\ \delta(t+c^{-1}\mathbf{s}\cdot\mathbf{r})Y_{\nu}(\mathbf{s}).\tag{15}$$

Equations (14) and (15) form a transform pair relating plane waves and spherical waves

Proof: The proof of (14) is based on the frequency domain relation[19]

$$e^{ik\mathbf{s}\cdot\mathbf{r}}=4\pi\sum_{\nu}\ i^n j_n(kr)Y_{\nu}(\mathring{\mathbf{r}})Y_{\nu}(\mathbf{s}),\tag{16}$$

which is transformed to the time domain using $4\pi(-i)^n j_n(kr)Y_{\nu}(\mathring{\mathbf{r}})\Rightarrow\varphi_{\nu}(\mathbf{r},t)$, $e^{ik\mathbf{s}\cdot\mathbf{r}}\Rightarrow\delta(t-c^{-1}\mathbf{s}\cdot\mathbf{r})$ and $Y_{\nu}(-\mathbf{s})=(-)^n Y_{\nu}(\mathbf{s})$. To prove (15) we multiply both sides of (14) by $Y_{\nu'}(\mathbf{s})$ and utilize the orthogonality relation $\int_{4\pi}d^s Y_{\nu}(\mathbf{s})Y_{\nu'}(\mathbf{s})=\delta_{\nu,\nu'}$, where $\delta_{\nu,\nu'}$ is the Kronecker's delta.

A. Applications: The relation between the SST and the multiple expansion

The transform relations above can be used to derive direct transform relations between the time-dependent multipole functions and the SST of the source distribution. Indeed, inserting (14) into (2a), using the definition in (12a), we obtain a *spherical waves synthesis of the SST*

$$\tilde{q}(\mathbf{s},t)=\sum_{\nu}\ Y_{\nu}(\mathbf{s})q_{\nu}(t).\tag{17}$$

Alternatively, inserting (15) in (12a) results in the *SST expansion of the multipole moment*

$$q_{\nu}(t)=\int_{4\pi}d^2s\ \tilde{q}(\mathbf{s},t)Y_{\nu}(\mathbf{s}).\tag{18}$$

Thus, based on Eqs. (14) and (15), one may rederive much of the spherical wave expansion theory of Sec. II B as a projection of the plane-wave transform theory of Sec. II A. In particular, (17) and (18) comply with the equivalence of the time-dependent radiation patterns in (5) and (13).
