At the formal level, all the statements considered in the BFV scheme have their counterparts in the BV formalism. We do not restate here the contents of 3.1–3.4 for the odd case and refer instead to Refs. 5 and 6. We only point out one important difference. Unlike the Hamiltonian picture, the Lagrangian one can be considered in the scope of a finite dimensional analog only formally. The finite dimensional configuration space (the space of field histories) does not correspond to any physically relevant system. Thus all the BV counterparts of the statements of the preceding section should be considered with some care. In particular, the BV quantization prescription requires the master action S to be a proper solution to the master equation. The condition imposed on the master action to be proper has no counterpart in the Hamiltonian picture. It implies that the corresponding configuration space is a proper *QP* manifold (which in general is not the case for the BFV phase space). In the finite dimensional case, this in turn implies that all the observables (the cohomology of $\mathbf{Q}$) are trivial (except those of a topological nature). The $\mathbf{Q}$ cohomology becomes nontrivial only when evaluated on space-time local functionals.[20,21]

IV. TOWERS OF BRACKETS

In this section, we study the possibility of a ''second'' zero-locus reduction, i.e., the reduction on a *QP* manifold which itself is the result of a zero-locus reduction. This leads to several well-known structures, including the classical Yang–Baxter equation.

4.1. A "second" zero-locus reduction. On a *QP* manifold $\mathcal{N}$ (which can be either even or odd), a coisotropic submanifold $\mathcal{L}\subset\mathcal{Z}_{\mathbf{Q}}$ (for example, a Lagrangian submanifold in $\mathcal{N}$) is a P manifold, i.e., is equipped with an (even or odd) Poisson structure (see 2.2.5). One can try to equip $\mathcal{L}$ with a compatible $\mathbf{Q}$ structure, thereby making it into a *QP* manifold. On a general *QP* manifold $\mathcal{N}$, there is no canonical structure inducing a $\mathbf{Q}$ operator on $\mathcal{L}$. Instead, we can look for a $\mathbf{Q}$ operator on $\mathcal{L}$ in the form $\mathbf{Q}_{\mathcal{L}}=\{H,\cdot\}_{\mathbf{Q}}$ where $\{,\}_{\mathbf{Q}}$ is the bracket given by (2.7) and H is a solution of the equation

$$\{H,H\}_{\mathbf{Q}}=0, \quad H\in\mathcal{F}_{\mathcal{L}}, \quad \mathrm{p}(H)=\mathrm{p}(\{,\}_{\mathbf{Q}})+1. \tag{4.1}$$

Whenever such an H is found, $\mathcal{L}$ becomes a *QP* manifold. With this $\mathbf{Q}$ structure, we can repeat the procedure, thereby producing a sequence of *QP* manifolds.

This construction can be restated in terms of differential Poisson algebras (the algebras of functions on *QP* manifolds). Even "more algebraically," we consider the case where a differential Poisson algebra arises from a *complex* endowed with a super-commutative associative multiplication and a Gerstenhaber-like multiplication (see the Appendix). To these differential Poisson algebras, we can then apply one or more zero-locus reduction steps, resulting in relations between different complexes.

4.2. Examples of the zero-locus reduction on an even QP manifold. Let $\mathcal{M}$ be a cotangent bundle $\mathcal{M}=T^*\mathcal{X}$. We then write (q^a,p_a) for local coordinates on $\mathcal{M}$ (which we take to be bosonic to avoid extra sign factors); the Poisson bracket then is $\{q^a,p_b\}=\delta^a_b$. We assume a Hamiltonian action of a Lie algebra $\mathfrak{a}$ on $\mathcal{M}$. For simplicity, we consider the Hamiltonian action that is the lift of an action on $\mathcal{X}$ via the vector fields $X_i=X_i^a(\partial/\partial q^a)$, with $[X_i,X_j]=C_{ij}^kX_k$. The generators of the Hamiltonian action on $\mathcal{M}$ are then given by $T_i=-p_aX_i^a(q)$. Applying the BFV scheme to the constraints T_i gives the BRST generator

$$\Omega=-p_aX_i^a(q)\,\theta^i-\tfrac{1}{2}C_{ij}^k\xi_k\theta^i\theta^j. \tag{4.2}$$

We now take the submanifold $\mathcal{L}\subset\mathcal{Z}_{\mathbf{Q}}$ (which is Lagrangian in $\mathcal{M}$) determined by $\theta^i=0$ and $p_a=0$ and view q^a and ξ_i as local coordinates on $\mathcal{L}$. The antibracket $(,)\equiv\{,\}_{\mathbf{Q}}$ from 2.2.5 is then given by

$$(\xi_i,\xi_j)=C_{ij}^k\xi_k,\quad (q^a,\xi_i)=-X_i^a. \tag{4.3}$$

Using this antibracket structure on $\mathcal{L}$, we consider the equation

$$(H,H)=0 \tag{4.4}$$

for an even function $H\in\mathcal{F}_{\mathcal{L}}$. Given a solution H, we can construct the odd nilpotent vector field $\mathbf{Q}=(H,\cdot)$ that makes $\mathcal{L}$ into a *QP* manifold.

We consider solutions to (4.4) of the form

$$H_{\mathrm{YB}}=-\tfrac{1}{2}r^{ij}\xi_i\xi_j, \tag{4.5}$$

where r is a skew-symmetric matrix with entries from $\mathcal{F}_{\mathcal{X}}$. Explicitly, Eq. (4.4) is the following generalization of the CYBE:

$$r^{l[i}C_{lm}^kr^{j]m}+X_l^ar^{l[i}\frac{\partial}{\partial q^a}r^{jk]}=0. \tag{4.6}$$

We now proceed with the next stage of the zero-locus reduction. The zero locus of the "Yang–Baxter differential" $\mathbf{Q}_{\mathrm{YB}}=(H_{\mathrm{YB}},\cdot)$ is determined by $r^{ij}\xi_j=0$. We choose a smaller submanifold $\mathcal{X}\subset\mathcal{Z}_{\mathbf{Q}_{\mathrm{YB}}}$ determined by $\xi_i=0$. Whenever (4.4) is satisfied, $\{\cdot,\cdot\}=(\cdot,\mathbf{Q}_{\mathrm{YB}}\cdot)$ is a Poisson bracket on $\mathcal{X}$. Explicitly, the Poisson brackets are given by

$$\{q^a,q^b\}=X_i^ar^{ij}X_j^b. \tag{4.7}$$

4.2.1. The classical Yang–Baxter equation. Antibracket (4.3) considered on q-independent functions coincides with the Schouten bracket on $\wedge\mathfrak{a}$ viewed as the Grassmann algebra generated by ξ_i. In the case where r^{ij} is a constant matrix, (4.6) becomes the CYBE,

$$r^{j[i}C_{jl}^kr^{m]l}=0. \tag{4.8}$$

For each r^{ij} satisfying (4.8), the corresponding differential $\mathbf{Q}_{\mathrm{YB}}$ (considered on $\wedge\mathfrak{a}$) is nothing but the cohomology differential of the Lie algebra complex with trivial coefficients (see Appendix A), for the Lie algebra defined on $\mathfrak{a}^*$ by the structure constants $F_k^{ij}=r^{il}C_{lk}^j-r^{jl}C_{lk}^i$.

4.2.2. The Sklyanin bracket. With $\mathcal{X}$ taken to be the Lie group corresponding to the Lie algebra $\mathfrak{a}$, we have two natural ways to define the action of $\mathfrak{a}$ on $\mathcal{X}$, by the left- and right-invariant vector fields L_i and R_i. Proceeding along the steps described in the previous paragraphs with X_i^a taken to be L_i^a or R_i^a, we arrive at two Poisson brackets on $\mathcal{X}$,

$$\{q^a,a^b\}_{\text{right}}=L_i^a r^{ij} L_j^b \quad \text{and} \quad \{q^a,q^b\}_{\text{left}}=R_i^a r^{ij} R_j^b, \tag{4.9}$$

which are compatible in view of $[R_i,L_j]=0$. The Poisson bracket

$$\{q^a,q^b\}_{\text{Sklyanin}}=\{q^a,q^b\}_{\text{right}}-\{q^a,q^b\}_{\text{left}} \tag{4.10}$$

makes the Lie group $\mathcal{X}$ into a Poisson–Lie group.

4.3. Zero-locus reduction on an odd QP manifold. To reformulate the above for an odd *QP* manifold, we construct the BV scheme starting with a manifold $\mathcal{X}$ with an $\mathfrak{a}$ action. The ξ_i variables are then even, and because of the symmetry properties, the ''tower of reductions'' is shorter than for odd ξ_i. We then introduce antifields q_a^*, ghosts θ^i, and their antifields ξ_i, with $(\theta^i,\xi_j)=\delta_j^i$ (where restored the traditional notation for the antibracket). The differential

$$\mathbf{Q}=(S,\cdot), \quad S=q_a^* X_i^a \theta^i - \tfrac{1}{2}\xi_k C_{ij}^k \theta^i \theta^j \tag{4.11}$$

corresponds to the quantization of a theory with the vanishing classical action.

We choose a Lagrangian subspace $\mathcal{L}\subset\mathcal{Z}_{\mathbf{Q}}$ determined by $\theta^i=0$ and $q_a^*=0$. In accordance with Sec. 2, the zero locus reduction induces a Poisson bracket $\{,\}_{\mathbf{Q}}$ on $\mathcal{L}$ with the nonvanishing components

$$\{\xi_i,\xi_j\}_{\mathbf{Q}}=C_{ij}^k\xi_k, \quad \{q^a,\xi_i\}_{\mathbf{Q}}=X_i^a. \tag{4.12}$$

Unless $\mathcal{X}$ is a *super*manifold, $\mathcal{L}$ is a purely even manifold, and therefore, the new generating equation with respect to the $\{,\}_{\mathbf{Q}}$-bracket has only the trivial solution. The tower of brackets is thus terminated.

We now recall that the *even* variables ξ_i generate the algebra of functions on $\mathfrak{a}^*$. Restricting ourselves to functions that are independent of the coordinates on $\mathcal{X}$, we see that (4.12) becomes the Berezin–Kirillov bracket on $\mathfrak{a}^*$,

$$\{f,g\}=f\frac{\overleftarrow{\partial}}{\partial\xi_i}\xi_k C_{ij}^k \frac{\partial}{\partial\xi_j}g. \tag{4.13}$$

4.3.1. Linear and nonlinear brackets. The bracket in (4.13) is ''linear'' in the sense of its explicit dependence on ξ_i. For a Lie algebra $\mathfrak{a}$, one can construct ''nonlinear'' brackets $(\overleftarrow{\partial}/\partial\xi_i)\Omega_{ij}(\partial/\partial\xi_j)$ on $\mathfrak{a}^*$, where the expansion of Ω_{ij} in ξ_i starts with $\xi_k C_{ij}^k$. For a given bracket of this form, a natural problem is whether it can be transformed into the Berezin–Kirillov bracket by a change of coordinates. With the help of the zero-locus reduction, this is solved as follows. The Poisson bracket is represented as the zero-locus reduction of the *canonical* antibracket on a *QP* manifold with $\mathbf{Q}$ determined by the Hamiltonian $H=\Omega_{ij}(\xi)\theta^i\theta^j$. The Jacobi identity for the Poisson bracket is rewritten as the master equation for H, and moreover, the terms containing higher powers of ξ_i are closed with respect to the differential $\mathbf{Q}_0=\{H_0,\cdot\}$, where $H_0=\xi_k C_{ij}^k\theta^i\theta^j$ is the ''linear'' part of the Hamiltonian. We thus have proved the fact known from other considerations (and in a more powerful analytic version).[22]

4.3.2. Corollary. *Let* $\Omega_{ij}(\xi)=\xi_k C_{ij}^k+\xi_k\xi_l C_{ij}^{kl}+\cdots$ *be the matrix of a Poisson bracket on* $\mathfrak{a}^*$, *where* C_{ij}^k *are the structure constants of a Lie algebra* $\mathfrak{a}$. *Then* $\Omega_{ij}(\xi)$ *can be reduced to the form* $\xi_k C_{ij}^k$ *by a change of variables* $\xi_i\mapsto f_i(\xi)$ *if the second cohomology group* $H^2(\mathfrak{a},\mathrm{S}\mathfrak{a})$ *of* $\mathfrak{a}$ *with coefficients in* $\mathrm{S}\mathfrak{a}$ *is trivial*.

Similar considerations in the BFV case lead to similar statements for the nonlinear antibracket.

V. Bi-*QP* MANIFOLDS

Up to now, we have studied *QP* manifolds whose differential corresponds to a *single* solution of the corresponding "master" equation. We now consider bi-*QP* manifolds.

5.1. A BFV-like formulation of the bialgebra complex. In the preceding section, we associated an even *QP* manifold with a vector space $\mathfrak{a}$ and a smooth manifold $\mathcal{M}=T^*\mathcal{X}$. Namely, a Lie algebra structure on $\mathfrak{a}$ and the vector fields X_i (giving an $\mathfrak{a}$-module structure on $\mathcal{F}_\mathcal{X}$) can be read off from a solution of the generating equation

$$\{\Omega,\Omega\}=0 \tag{5.1}$$

with the ansatz (4.2). The algebra of functions on the thus constructed *QP* manifold is $\mathfrak{A}=\mathrm{Hom}(\wedge\mathfrak{a},\wedge\mathfrak{a})\otimes\mathcal{F}_{T^*\mathcal{X}}$; we interpret $\mathrm{Hom}(\wedge\mathfrak{a},\wedge\mathfrak{a})$ as the algebra generated by the odd variables θ^i and ξ_j. The basic Poisson bracket relations are

$$\{\theta^i,\xi_j\}=\delta^i_j,\quad \{q^a,p_b\}=\delta^a_b, \tag{5.2}$$

where q, p are the standard local coordinates on the cotangent bundle $\mathcal{M}=T^*\mathcal{X}$. We have the solution

$$C=-p_aX^a_i(q)\,\theta^i-\tfrac{1}{2}\,\xi_kC^k_{ij}\theta^i\theta^j. \tag{5.3}$$

At the same time, every solution of (5.1) of the form

$$F=-p_aX^{ia}\xi_i-\tfrac{1}{2}\theta^kF^{ij}_k\xi_i\xi_j \tag{5.4}$$

determines a coalgebra structure on the vector space $\mathfrak{a}$, or equivalently, a Lie algebra structure on $\mathfrak{a}^*$, and makes $\mathcal{F}_\mathcal{X}$ into an $\mathfrak{a}^*$-module, with the vector fields $X^i=R^{ia}(\partial/\partial q^a)\in\mathrm{Vect}_\mathcal{X}$ representing the action of the basis elements of $\mathfrak{a}^*$. Then $\mathfrak{A}$ is equipped with Poisson bracket (5.2) and the differentials

$$\begin{aligned}
d_C&=\{C,\cdot\}\\
&=-\frac{1}{2}C^k_{ij}\theta^i\theta^j\frac{\partial}{\partial\theta^k}-\xi_kC^k_{ij}\theta^i\frac{\partial}{\partial\xi_j}-p_aX^a_i\frac{\partial}{\partial\xi_i}+\theta^iX^a_i\frac{\partial}{\partial q^a}-\theta^ip_aX^a_{i,b}\frac{\partial}{\partial p_b},\\
d_F&=\{F,\cdot\}\\
&=-\frac{1}{2}F^{ij}_k\xi_i\xi_j\frac{\partial}{\partial\xi_k}-\theta^kF^{ij}_k\xi_i\frac{\partial}{\partial\theta^j}-p_aX^{ia}\frac{\partial}{\partial\theta^i}+\xi_iX^{ia}\frac{\partial}{\partial q^a}-\xi_ip_aX^{ia}_{,b}\frac{\partial}{\partial p_b}.
\end{aligned} \tag{5.5}$$

We next impose the condition that the differentials be compatible, i.e.,

$$[d_C,d_F]=0\Leftrightarrow\{C,F\}=0. \tag{5.6}$$

5.1.1. Proposition: Condition (5.6) *implies that* ($\mathfrak{a}$, $\mathfrak{a}^*$, $\mathfrak{a}\oplus\mathfrak{a}^*$) *is a Manin triple,*[13] *with the Lie bracket on* $\mathfrak{a}\oplus\mathfrak{a}^*$ *given by*

$$[e_i,e_j]=C^k_{ij}e_k\quad [e^i,e^j]=F^{ij}_ke^k,\quad [e_i,e^j]=C^j_{ik}e^k+F^{jk}_ie_k. \tag{5.7}$$

where e_i *and* e^i *are dual bases in* $\mathfrak{a}$ *and* $\mathfrak{a}^*$ *respectively. Equivalently,* $\mathfrak{a}$ *is a Lie bialgebra. Moreover,* $\mathcal{F}_\mathcal{X}$ *is a module over the Lie algebra* $\mathfrak{a}\oplus\mathfrak{a}^*$.

The proof is straightforward.

That $\mathcal{F}_\mathcal{X}$ is a module over $\mathfrak{a}\oplus\mathfrak{a}^*$ means that under the mapping $e_i\mapsto X_i$, $e^i\mapsto X^i$, the following commutation relations between vector fields are satisfied:

$$[X_i,X_j]=C_{ij}^k X_k,\quad [X^i,X^j]=F_k^{ij}X^k,\quad [X_iX^j]=C_{ik}^j X^k+F_i^{jk}X_k. \tag{5.8}$$

It also follows from (5.6) that

$$X^{ia}X_i^b+X^{ib}X_i^a=0. \tag{5.9}$$

5.1.2. Zero locus reduction on a bi-*QP manifold*. We next consider the submanifolds of the zero loci, $\mathcal{L}_C\subset\mathcal{Z}_C$ and $\mathcal{L}_F\subset\mathcal{Z}_F$ defined by $(\theta^i=0,\ p_a=0)$ and $(\xi_i=0,\ p_a=0)$, respectively. Since $\mathcal{L}_C$ and $\mathcal{L}_F$ are coisotropic, we can apply Theorem 2.2.5. We thus have the respective antibrackets

$$\begin{aligned}&\{\xi_i,\xi_j\}_C=C_{ij}^k\xi_k,\quad \{\xi_i,q^q\}_C=Z_i^a,\\ &\{\theta^i,\theta^j\}_F=F_k^{ij}\theta^k,\quad \{\theta^i,q^a\}_F=X^{ia},\end{aligned} \tag{5.10}$$

on $\mathcal{L}_C$ and $\mathcal{L}_F$.

5.1.3. Proposition: The differential d_C induces a well-defined operator (vector field) $\overline{d}_C=d_C|_{\mathcal{L}_F}:\mathcal{F}_{\mathcal{L}_F}\to\mathcal{F}_{\mathcal{L}_F}$ and the differential d_F induces an operator $\overline{d}_F=d_F|_{\mathcal{L}_C}:\mathcal{F}_{\mathcal{L}_C}\to\mathcal{F}_{\mathcal{L}_C}$. Thus, $\mathcal{F}_{\mathcal{L}_F}(\mathcal{F}_{\mathcal{L}_C})$ is an odd differential Poisson algebra and $\mathcal{L}_F$ (respectively, $\mathcal{L}_C$) is an odd QP manifold.

Thus, the manifolds $\mathcal{L}_C$ and $\mathcal{L}_F$ are equipped with **Q** structures. We now proceed to the next step of the zero-locus reduction.

Recall that the submanifold $\mathcal{X}=\mathcal{L}_C\cap\mathcal{L}_F$ is determined by the equations $p_a=\xi_i=\theta^j=0$. It is easy to see that $\mathcal{X}$ is a coisotropic submanifold of $\mathcal{L}_C$ and also a coisotropic submanifold of $\mathcal{L}_F$. On $\mathcal{X}$, we then have the Poisson bracket

$$\{\cdot,\cdot\}_{\mathcal{X}}=\{\cdot,\overline{d}_F\cdot\}_C=\{\cdot,\overline{d}_C\cdot\}_F \tag{5.11}$$

or in the coordinate form

$$\{q^a,q^b\}_{\mathcal{X}}=X_i^aX^{ib}. \tag{5.12}$$

It follows from (5.9) that bracket (5.12) is skew-symmetric; the Jacobi identity follows from the compatibility of d_C and d_F.

5.1.4. Coboundary bialgebras. Up to this point, the situation was symmetric with respect to $\theta^i\leftrightarrow\xi_i$, but now we try to solve Eq. (5.6) for F. Namely, suppose that F is a coboundary

$$F=d_Cr=\{C,r\}, \tag{5.13}$$

where $r=r^{ij}\xi_i\xi_j$ and r^{ij} is taken to be a constant matrix. Then the condition $d_F^2=0$ yields

$$\{C,\{r,\{C,r\}\}\}=d_C\{r,d_Cr\}=0. \tag{5.14}$$

This is the generalized CYBE. An even stronger condition

$$\{r,d_Cr\}=\{r,r\}_C=0 \tag{5.15}$$

leads to the CYBE [see (4.4)].

5.2. Two differentials from a Lie algebra action. We now look at the bicomplex setting from a somewhat different point of view. Rather than associating a second differential with a coalgebra structure, we construct a pair of differentials for a single Lie algebra. This subject attracts one's attention because of its possibly deep relation to the extended BRST symmetry.[9,10] We now show that the bicomplex generalization of the zero locus reduction method induces the so-called non-Abelian triplectic antibrackets on the space of common zeroes of the differentials. The non-

Abelian triplectic antibrackets were introduced in Ref. 14, see also Ref. 23, as the structure underlying a possible generalization of the well-known Lagrangian version of the extended BRST quantization.

5.2.1. Left and right $\mathfrak{a}$ *actions*. We consider the left and the right actions of $\mathfrak{a}$ on $\mathcal{X}$. To illustrate the idea, we restrict ourselves to the case where $\mathcal{X}=\mathcal{G}$ is the Lie group corresponding to the Lie algebra $\mathfrak{a}$. Let the basis elements e_i of $\mathfrak{a}$ act on $\mathcal{G}$ via the left invariant vector fields L_i (which correspond to the right action) and via the right invariant vector fields R_i (which correspond to the left action). Obviously, $[L_i,R_j]=0$. Let q^a and p_a be the standard coordinates on $T^*\mathcal{G}$. Unlike in the case considered above, we introduce the doubled set of variables ξ_i^1, ξ_j^2, θ_1^k, and θ_2^l, $i, j, k, l=1,...,\dim \mathfrak{a}$, with the basic Poisson brackets

$$\{q^a,p_b\}=\delta_b^a, \quad \{\theta_1^i,\xi_j^1\}=\delta_j^i, \quad \{\theta_2^i,\xi_j^2\}=\delta_j^i. \tag{5.16}$$

The functions

$$\begin{aligned}\Omega^1&=-p_aR_i^a\theta_1^i-\tfrac{1}{2}\xi_k^1C_{ij}^k\theta_1^i\theta_1^j,\\ \Omega^2&=-p_aL_i^a\theta_2^i-\tfrac{1}{2}\xi_k^2C_{ij}^k\theta_2^i\theta_2^j,\end{aligned} \tag{5.17}$$

satisfy $\{\Omega^\alpha,\Omega^\beta\}=0$ for $\alpha,\beta=1,2$, as follows immediately from the commutativity of the left- and right-invariant vector fields. These generating functions give rise to the anticommuting differentials $\mathbf{Q}^a=\{\Omega^a,\cdot\}$, thereby providing $\mathcal{F}_{\text{ext}}$ with a bicomplex structure.

5.2.2. Zero-locus reduction in $\mathcal{F}_{\text{ext}}$ *and non-Abelian triplectic antibrackets*. We now apply the zero locus reduction along the lines of Sec. 2. We identify the zero-locus $\mathcal{Z}_{\mathbf{Q}^1}$ (respectively, $\mathcal{Z}_{\mathbf{Q}^2}$) of the differential $\mathbf{Q}^1$ (of $\mathbf{Q}^2$) determined by the equations $\theta_1^i=0$ and $p_a=0$ (respectively, $\theta_2^i=0$ and $p_a=0$). The intersection $\mathcal{L}=\mathcal{Z}_{\mathbf{Q}^1}\cap\mathcal{Z}_{\mathbf{Q}^2}$ is then endowed with a pair of compatible antibrackets. Identifying $\mathcal{F}_{\mathcal{L}}$ (functions on the intersection) with functions of q^a, ξ_i^1, and ξ_j^2, we have

$$\begin{aligned}\{\xi_i^1,q^a\}_{\mathbf{Q}^1}&=R_i^a, \quad \{\xi_i^1,\xi_j^1\}_{\mathbf{Q}^1}=C_{ij}^k\xi_k^1,\\ \{\xi_i^2,q^a\}_{\mathbf{Q}^2}&=L_i^a, \quad \{\xi_i^2,\xi_j^2\}_{\mathbf{Q}^2}=C_{ij}^k\xi_k^2,\end{aligned} \tag{5.18}$$

with all the other brackets vanishing. These are precisely the non-Abelian triplectic antibrackets from Ref. 14.

VI. CONCLUSIONS

Our results give a geometric interpretation to a number of structures involved in the BFV/BV formalism; the interpretation of the BRST cohomology in terms of the constraint surface geometry[24] can thus be extended in terms of geometry of a ''more invariant'' object—the zero locus $\mathcal{Z}_{\mathbf{Q}}$ that plays the role of the *extended constraint surface*. Although this is presently limited to the ghost number zero, it would be interesting to extend this interpretation to other ghost numbers. Another interesting application of the zero locus reduction consists in interpreting $\mathcal{Z}_{\mathbf{Q}}$ with the induced Poisson bracket in the BV formulation of a pure-gauge model as an extended phase space and the extended Poisson bracket in the BFV formulation of the same model.[25] As noted above, the zero-locus reduction applies to finite-dimensional models; it would be interesting to extend it to local field theory, for example, in the jet language formulation of the BRST formalism.[26]

APPENDIX: LIE ALGEBRA COHOMOLOGY AND THE (ANTI)BRACKET

Let $\mathfrak{a}$ denote a Lie algebra of dimension N and $\mathfrak{M}$ denote an $\mathfrak{a}$-module. We denote by

$$\wedge a = \bigoplus_{n=0}^{N} \wedge^n \mathfrak{a} \tag{A1}$$

the exterior algebra of the vector space $\mathfrak{a}$ and by $\mathsf{S}\mathfrak{a}$ the symmetric tensor algebra.

The cohomology complex of $\mathfrak{a}$ with coefficients in the module $\mathfrak{M}$ is

$$\mathsf{C}^*(\mathfrak{a},\mathfrak{M}) = \{\mathsf{Hom}(\wedge\mathfrak{a},\mathfrak{M}), d\}. \tag{A2}$$

Decomposition (A1) induces the grading $\mathsf{C}^*(\mathfrak{a},\mathfrak{M}) = \oplus_{n=0}^{N} C^n(\mathfrak{a},\mathfrak{M})$, where $C^n(\mathfrak{a},\mathfrak{M}) = \mathsf{Hom}(\wedge^n\mathfrak{a},\mathfrak{M})$. The differential d has the degree 1 and acts as $d: C^n(\mathfrak{a},\mathfrak{M}) \to C^{n+1}(\mathfrak{a},\mathfrak{M})$ via

$$(da)(g_1,\ldots,g_{n+1}) = \sum_{1\leqslant i<j\leqslant n+1} (-1)^{i+j-1} a([g_i,g_j],g_1,\ldots,\hat{g}_i,\ldots,\hat{g}_j,\ldots,g_{n+1})$$

$$+ \sum_{1\leqslant iLZn+1} (-1)^i g_i a(_1,\ldots,\hat{g}_i,\ldots,g_{n+1}), \quad a \in C^n(\mathfrak{a},\mathfrak{M}). \tag{A3}$$

In what follows we use the simplified notation $C^n = C^n(\mathfrak{a},\mathfrak{M})$.

Assume that $\mathfrak{a}$ is finite dimensional or graded, $\mathfrak{a} = \oplus_i \mathfrak{a}_i$, with finite dimensional homogeneous spaces $\mathfrak{a}_i$, and $\mathfrak{a}^*$ is by definition $\mathfrak{a}^* = \oplus_i \mathfrak{a}_i^*$, where $\mathfrak{a}_i^*$ are finite dimensional spaces dual to $\mathfrak{a}_i$. We then can identify the cohomology complex $\mathsf{C}^*(\mathfrak{a},\mathfrak{M})$ with $\wedge\mathfrak{a}^* \otimes \mathfrak{M}$ as follows. Let e_i be a basis in $\mathfrak{a}$, with $[e_i,e_j] = C_{ij}^k e_k$. Let also θ^i be the basis of $\mathfrak{a}^*$ dual to e_i. The Grassmann algebra generated by θ^i is then identified with $\wedge\mathfrak{a}^*$. To every cochain $x \in \mathsf{Hom}(\wedge^n\mathfrak{a},\mathfrak{M})$, we associate the element (with the summations implied)

$$\overline{x} = \frac{1}{n!} x(e_{i_1},\ldots,e_{i_n})\,\theta^{i_1}\cdots\theta^{i_n} \in \wedge\mathfrak{a}^* \otimes \mathfrak{M}. \tag{A4}$$

The differential d then acts on $\wedge\mathfrak{a}^* \otimes \mathfrak{M}$ as the differential operator

$$d = \frac{1}{2} C_{ij}^k \theta^i \theta^j \frac{\partial}{\partial \theta^k} - \theta^i X_i, \tag{A5}$$

where $X_i : \mathfrak{M} \to \mathfrak{M}$ is the action of $e_i \in \mathfrak{a}$ on $\mathfrak{M}$.

We next specialize to the coefficients in $\mathfrak{a}$ (viewed as the adjoint representation $\mathfrak{a}$-module). The complex is then endowed with the Gerstenhaber bracket[27] (see Ref. 28, and references therein),

$$\{\cdot,\cdot\}: C^n \otimes C^m \to C^{n+m-1}$$

given by

$$\{x,y\} = x\circ y - (-1)^{(m+1)(n+1)} y\circ x, \quad x \in C^n, \quad y \in C^m, \tag{A6}$$

where

$$(x\circ y)(a_1,\ldots,a_{n+m-1})$$

$$=\frac{1}{m!(n-1)!}\sum_{\sigma\in P_{n+m-1}}(-1)^{\sigma}x(a_{\sigma(1)},\ldots,a_{\sigma(n-1)},y(a_{\sigma(n)},\ldots,a_{\sigma(n+m-1)})). \tag{A7}$$

This makes $\mathrm{Hom}(\wedge\mathfrak{a},\mathfrak{a})$ into a graded differential Lie algebra.

Let ξ_i denote the basis of $\mathfrak{a}$ viewed as an $\mathfrak{a}$-module (equivalently, *coordinates* on $\mathfrak{a}^*$). For each cochain $x\in C^n$, we then expand $\overline{x}$ from (A4) as

$$\overline{x}=\frac{1}{n!}\xi_j x^j(e_{i_1},\ldots,e_{i_n})\,\theta^{i_1}\cdots\theta^{i_n} \tag{A8}$$

and rewrite the Gerstenhaber bracket as

$$\{\overline{x},\overline{y}\}=\overline{x\circ y}-(-1)^{(k+1)(l+1)}\overline{y\circ x},\quad \overline{x}\,\overline{y}=\overline{x}\frac{\overleftarrow{\partial}}{\partial\theta^i}\frac{\partial}{\partial\xi_i}\overline{y},\quad x\in C^k,\quad y\in C^l, \tag{A9}$$

where $\overleftarrow{\partial}/\partial\theta^i$ is the (right) derivative in the Grassmann algebra and the $\partial/\partial\xi_i$ operation is defined on the elements of form (A8) as the contraction with the element ξ_i^* of the dual basis in $\mathfrak{a}^*$. The differential then becomes

$$d=\left\{-\frac{1}{2}C_{ij}^k\xi_k\theta^i\theta^j,\cdot\right\}=\frac{1}{2}C_{ij}^k\theta^i\theta^j\frac{\partial}{\partial\theta^k}-\xi_k\theta^iC_{ij}^k\frac{\partial}{\partial\xi_j}. \tag{A10}$$

On the elements $\underline{a}$ as in (A8), the second term represents the adjoint action (in accordance with the above choice $\mathfrak{M}=\mathfrak{a}$). Equation (A9) suggests the interpretation of a Poisson/Batalin–Vilkovisky bracket. As it stands, however, (A9) can be neither of these, since no associative supercommutative multiplication has been defined on the cochains.

Superficially, the bracket in (A9) has the grade -1 since it maps as $C^m\times C^n\to C^{m+n-1}$, however the gradings of all the terms in the complex can be shifted by 1, after which the bracket becomes a grade-0 operation. On the other hand, an associative graded commutative multiplication defined on the complex would fix the grading, and (A9) would become either the Batalin–Vilkovisky or the Poisson bracket. Thus there are two remarkable possibilities to embed $\mathrm{C}^*(\mathfrak{a},\mathfrak{M})=\mathrm{C}^*(\mathfrak{a},\mathfrak{a})$ into a complex endowed with a multiplication: the complex

$$\mathrm{C}^*(\mathfrak{a},\mathrm{S}\mathfrak{a})=\wedge\mathfrak{a}^*\otimes\mathrm{S}\mathfrak{a} \tag{A11}$$

corresponding to the BV quantization, or the complex

$$\mathrm{C}^*(\mathfrak{a},\wedge\mathfrak{a})=\wedge\mathfrak{a}^*\otimes\wedge\mathfrak{a} \tag{A12}$$

corresponding to the BFV quantization. Geometrically, these two possibilities correspond to even and odd *QP* manifolds (see Definition 2.1).

Choosing $\mathfrak{M}=\mathrm{S}\mathfrak{a}$, we have the complex $\oplus_{m,n}\mathrm{Hom}(\wedge^m\mathfrak{a},\mathrm{S}^n\mathfrak{a})$, which can be viewed as the associative supercommutative algebra generated by the variables θ^i and ξ_j satisfying $\xi_i\xi_j-\xi_j\xi_i=0$, $\theta^i\theta^j+\theta^j\theta^i=0$, and $\theta^i\xi_j-\xi_j\theta^i=0$.[29] It then follows that (A9) can be extended to an odd bracket on this complex. The differential extends to $\mathrm{Hom}(\wedge\mathfrak{a},\mathrm{S}\mathfrak{a})$ by the same formula $d=\{C_0,\cdot\}$, $C_0=-\frac{1}{2}C_{ij}^k\xi_k\theta^i\theta^j$. The complex is endowed with the grading known as the *ghost number* in the BV quantization or as the Weyl complex grading in homology theory: for a cochain $x\in\mathrm{Hom}(\wedge^m\mathfrak{a},\mathrm{S}^n\mathfrak{a})$, one has $\mathrm{gh}(x)=m-2n$.

On the other hand, taking the coefficients to be the *exterior* algebra $\wedge\mathfrak{a}$, we can extend (A9) to an even bracket. With $\wedge\mathfrak{a}$ identified with the algebra generated by ξ_i viewed as *anticommuting variables* (with obvious modifications in the case where $\mathfrak{a}$ is a Lie *super*algebra, see Ref. 29, the bracket becomes the Poisson bracket on the space $\wedge\mathfrak{a}^*\otimes\wedge\mathfrak{a}$ (which is identified with functions of

θ^i and ξ_j; we also assume that $\xi_i\theta^j+\theta^j\xi_i=0$ in addition to $\xi_i\xi_j+\xi_j\xi_i=0$). The ghost number grading on this complex taken from the BFV quantization is $\mathrm{gh}(x)=m-n$ for an element $x \in \mathsf{Hom}(\wedge^m\mathfrak{a},\wedge^n\mathfrak{a})$.

The coefficients can be further extended (cf. Ref. 28) by $\mathfrak{M}=\mathcal{F}_{\mathcal{M}}$, the algebra of smooth functions on a manifold $\mathcal{M}$ such that $\mathfrak{a}$ acts on $\mathcal{F}_{\mathcal{M}}$ *by derivations* (vector fields on $\mathcal{M}$). We write X_i for the image of the basis elements of $\mathfrak{a}$ in $\mathrm{Vect}_{\mathcal{M}}$. In accordance with the BRST paradigm, one wishes the vector fields representing the action of $\mathfrak{a}$ on $\mathcal{M}$ to be Hamiltonian with respect to a bracket structure. For *even* ξ_i, this can be achieved by replacing $\mathcal{M}$ with the odd cotangent bundle $\Pi T^*\mathcal{M}$ and, thus, the algebra $\mathcal{F}_{\mathcal{M}}$ with the algebra $\mathcal{F}_{\Pi T^*\mathcal{M}}$ of smooth functions on the odd cotangent bundle. Then each vector field $V=V^a(\partial/\partial q^a)$ on $\mathcal{M}$ is generated by the canonical antibracket structure on $\Pi T^*\mathcal{M}$; the action of the basis elements $X_i=X_i^a(\partial/\partial q^a)$ on functions is given by the antibracket

$$X_iF=-\{X_i^aq_a^*,F\},\quad F\in\mathcal{F}_{\mathcal{M}}, \tag{A13}$$

with q_a^* being the standard coordinates on the fibers of $\Pi T^*\mathcal{M}$ (and the standard antibracket given by $\{q^a,q_b^*\}=\delta_b^a$).

For odd ξ_i, similarly, we can consider the functions $\mathcal{F}_{T^*\mathcal{M}}$ on the cotangent bundle, which allows the action of $\mathfrak{a}$ to be implemented by the bracket on $\mathcal{F}_{T^*\mathcal{M}}$ [the same formula (A13) for the bracket, where now q_a^* are the canonical coordinates on the fibers of $T^*\mathcal{M}$].

We note, however, that the differential

$$d=\{-\tfrac{1}{2}C_{ij}^k\xi_k\theta^i\theta^j,\cdot\}+\theta^i\{X_i^aq_a^*,\cdot\} \tag{A14}$$

in either of the complexes

$$\mathsf{C}^*_{\mathrm{odd}}(\mathfrak{a},\mathcal{M})=\mathsf{C}^*(\mathfrak{a},\mathsf{S}\mathfrak{a})\otimes\mathcal{F}_{\Pi T^*\mathcal{M}}, \tag{A15}$$

$$\mathsf{C}^*_{\mathrm{even}}(\mathfrak{a},\mathcal{M})=\mathsf{C}^*(\mathfrak{a},\wedge\mathfrak{a})\otimes\mathcal{F}_{T^*\mathcal{M}}, \tag{A16}$$

is *not* compatible with the bracket. Remarkably, the compatibility can be achieved by changing the differentials such that (A15) and (A16) become the well-known BV and BFV complexes used in the Lagrangian and Hamiltonian quantization of gauge theories. The term to be added to the differential is the Koszul differential involving precisely the same ''auxiliary'' variables ξ_i that were originally introduced to rewrite the Gerstenhaber bracket in the ''geometric'' form.

To conclude, we note that we have given a homological interpretation of the structures appearing in the BRST quantization in the example of a Lie algebra structure (i.e., in the case where the constraints or gauge generators form a Lie algebra). In the most general setting, the BRST charge and the master action in the BFV and BV cases, respectively, can be considered as the generating functions for the L_∞ algebras[8] (see also Ref. 4). From this general standpoint, the Lie algebra structure appears as a particular case.

[29] The relations between θ and ξ variables correspond to the case (tacitly implied in most of our formulas) where $\mathfrak{a}$ is a Lie algebra, not a superalgebra; then the Grassmann parities are simply $p(\xi_i)=0$ and $p(\theta^i)=1$. However, if $\mathfrak{a}$ is a Lie superalgebra, let $p(e_i)=\varepsilon_i$ be the Grassmann parities of its generators. Then $p(\xi_i)=\varepsilon_i$ and $p(\theta^i)=\varepsilon_i+1$, and therefore, $\xi_i\xi_j-(-1)^{\varepsilon_i\varepsilon_j}\xi_j\xi_i=0$, $\theta^i\theta^j-(-1)^{(\varepsilon_i+1)(\varepsilon_j+1)}\theta^j\theta^i=0$, and $\xi_i\theta^j-(-1)^{\varepsilon_i(\varepsilon_j+1)}\theta^j\xi_i=0$.

Ground state of a spin-1/2 charged particle in a two-dimensional magnetic field

(Received 8 September 2000; accepted for publication 30 March 2001)

It is investigated that the structure of the kernel of the Dirac–Weyl operator **D** of a charged particle in the magnetic-field $B=B_0+B_1$, given by the sum of a strongly singular magnetic field $B_0(\cdot)=\Sigma_\nu \gamma^\nu \delta(\cdot-\mathbf{a}_\nu)$ with some singular points $\mathbf{a}_\nu$ and a magnetic-field B_1 with a bounded support. Here the magnetic field B_1 may have some singular points with the order of the singularity less than 2. At a glance, it seems that, following ''Aharonov–Casher Theorem'' [Phys. Rev. A **19**, 2461 (1979)], the dimension of the kernel of **D**, dim ker **D**, is a function of one variable of the total magnetic flux $(=\Sigma_\nu \gamma_\nu+\int_{\mathbf{R}^2} B_1 dxdy)$ of B. However, since the influence of the strongly singular points works, dim ker **D** indeed is a function of several variables of the total magnetic flux and each of γ_ν's. © *2001 American Institute of Physics.* [DOI: 10.1063/1.1379312]

I. INTRODUCTION

In 1979, Y. Aharonov and A. Casher[1] investigated the dimension of the kernel of the Dirac–Weyl operator **D** for a spin-1/2 charged particle in a two-dimensional magnetic field. And after that, many authors[2–10] (and references therein) studied it with various situations.

Aharonov and Casher[1] treated the case when the magnetic-field B is a smooth function on $\mathbf{R}^2$. In this case, **D** is essentially selfadjoint operator on $C_0^\infty(\mathbf{R}^2)$, the space of smooth functions with compact supports, and dim ker **D** is equal to the largest natural number which is less than $|q\Phi|/2\pi-1$, where q is the charge of the particle and the quantity Φ is the total magnetic flux of B defined by $\Phi=\int_{\mathbf{R}^2} B dxdy$. This result is well known as ''Aharonov–Casher Theorem.''

In 1993, A. Arai[2] treated another case than theirs. His is the case when B is strongly singular, more precisely, B is equal to 0 except on some finite points $\mathbf{a}_\nu \in \mathbf{R}^2 (\nu=1,...,n)$ and can be written as the sum of delta functions with coefficients $\gamma_\nu (\nu=1,...,n)$ and their derivatives [see, Eq. (1)]. The total magnetic flux Φ of B is equal to $\Sigma_{\nu=1}^n \gamma_\nu$. He have proved that, for this situation, **D** is not essentially selfadjoint on $C_0^\infty(M)$ with $M=\mathbf{R}^2\backslash\{\mathbf{a}_1,\ldots,\mathbf{a}_n\}$, and that each dimension of the kernels of two selfadjoint extensions of **D** depends on not only Φ but also each of γ_ν's. (He also has given an explicit formula.[2]) This means that, if B is strongly singular, ''Aharonov–Casher Theorem'' is not valid for this case.

In our article, we argue the case when magnetic field is a mixture of the Aharonov–Casher type and the Arai type, i.e., the case when the configuration space has both smooth and singular magnetic fields. No one has treated this situation yet. The following question arises: which theorem determines dim ker **D**, Aharonov–Casher's theorem or Arai's? Roughly speaking, we prove that dim ker **D** can be expressed by a formula similar to Arai's one [see Theorem 11].

We imagine the following physical situations: (1) Consider observation of a quantized magnetic field[11] penetrating a type II superconducting film by an electron microscope, such as in Refs. 12–14. To get such a quantized magnetic field, one applies a magnetic field **H** to the type II

[a)]Electronic mail: hirokawa@math.okayama-u.ac.jp
[b)]Electronic mail: ogurisu@lagendra.s.kanazawa-u.ac.jp

superconducting film first, and strengthens **H** next within the mixed state, so-called Schubnikov phase, between the lower critical field $\mathbf{H}_{c1}$ and upper one $\mathbf{H}_{c2}$. Then, following Abrikosov's theory and some experiments, the magnetic fluxes start to enter cores (normal regions on the inside of vortexes) on the type II superconducting film, and the entered magnetic field has the form of the bundle of fluxons (flux quanta). Following Tonomura's explanation about the experiments,[14] when one raise temperature up to the neighborhood of the critical temperature T_c with fixed **H** within the Schubnikov phase, the roots of the lines of magnetic fluxes become thick and the fluxons suddenly start to move. And, at the temperature over T_c the film fills with the normal cores, and the superconducting state is broken, namely the state changes to normal state from superconducting state. To observe the quantized magnetic field, for instance, in the experiment[12] the electron incident from the emitter of the electron microscope skims low over the surface of the type II superconductor. We are interested in the magnetic field on the normal cores in the critical phase near T_c. Our simple setup tries to represent mathematically the fired electron for the observation of the magnetic field on the normal cores in the critical phase though, of course, the representation cannot describe perfectly the physical realistic situation. (2) When we observe the quantized magnetic fluxes of a superconductor with the electron fired from an electron microscope, the fired electron needs to keep straight on. The electron, however, sometimes meets another magnetic field caused by, for instance, another electron microscope. This magnetic field from another electron microscope may, indeed, give no influence on the object because of the Meissner effect, but the magnetic field, as a noise, hinders the electron in its keeping straight on. In spite of such a situation, experimenters have to observe the object, the quantized magnetic fluxes. Thus, we have to investigate theoretically how the noise of another magnetic field influences the electron for the observation of the quantized magnetic fluxes. We try that as a first simplified case in our article (see Remark 3).

The plan of this article is as follows: In Sec. II, we define **D** and prove some lemmas. In Sec. III, we prove ''Vanishing Theorem.'' In Sec. IV, we prove our main theorem, which states the dimension of the kernel of **D**.

II. PRELIMINARY

Our aim is to investigate the structure of the kernel of the Dirac–Weyl operator **D** of a charged spin-1/2 particle in the magnetic field $B=B_0+B_1$, the sum of a strongly singular magnetic field B_0 [see, Eq. (1) and Ref. 2] and a magnetic-field B_1 with a bounded support. As mentioned above, the magnetic-field B_1 may have some singular points with the order of the singularity less than 2.

In this article, we denote the charge of the particle by $q \in \mathbf{R}\backslash\{0\}$. We assume that B_0 and B_1 may be singular at the finite isolated points $\mathbf{a}_\nu=(a_{\nu_1},a_{\nu_2}) \in \mathbf{R}^2$, $\nu=1,...,n$, and we put

$$M=\mathbf{R}^2\backslash\{\mathbf{a}_1,\ldots,\mathbf{a}_n\}.$$

In the case when B_1 is equal to 0, our model is the same one as in Ref. 2.

A. Strongly singular part B_0 of B

We denote by B_0 the strongly singular part of the given magnetic field B. Let

$$B_0(\mathbf{z})=\sum_{\nu=1}^{n}\sum_{0\leqslant\alpha+\beta\leqslant m} C_{\alpha\beta}^{(\nu)} D_x^\alpha D_y^\beta \delta(\mathbf{z}-\mathbf{a}_\nu), \quad \mathbf{z}=(x,y)\in\mathbf{R}^2, \tag{1}$$

with a nonnegative integer m and real constants $C_{\alpha,\beta}^{(\nu)}$, where D_x and D_y are the distributional partial differential operators in x and y, respectively, and $\delta(\mathbf{z})$ is the Dirac delta distribution on $\mathbf{R}^2$. A gauge potential $\mathbf{A}_0(\mathbf{z})$ of B_0 is defined by an $\mathbf{R}^2$-valued function $\mathbf{A}_0=(A_{01},A_{02})$ on M so that

$$B_0(x,y)=D_xA_{02}(x,y)-D_yA_{01}(x,y),$$

in the sense of distribution on $\mathbf{R}^2$.

Let

$$\phi_0(\mathbf{z})=\sum_{\nu=1}^{n}\sum_{0\leqslant\alpha+\beta\leqslant m}\frac{C_{\alpha,\beta}^{(\nu)}}{2\pi}D_x^{\alpha}D_y^{\beta}\log|\mathbf{z}-\mathbf{a}_\nu|,$$

which satisfies

$$\Delta\phi_0(\mathbf{z})=B_0(\mathbf{z}),$$

in the sense of distribution on $\mathbf{R}^2$. Thus, we can choose

$$\mathbf{A}_0=(A_{01},A_{02})=(-D_y\phi_0,D_x\phi_0),$$

as a gauge potential of B_0. We use later some of the same symbols as in Ref. 2. Put

$$C_k^{(\nu)}=(-1)^k k!\sum_{\alpha=0}^{k}C_{\alpha,k-\alpha}^{(\nu)}i^{k-\alpha},\quad \gamma_\nu=C_{0,0}^{(\nu)}=C_0^{(\nu)}\ \text{ and }\ \Phi_0=\sum_{\nu=1}^{n}\gamma_\nu. \tag{2}$$

B. Remainder B_1 of B

Through this article, we suppose that the remainder B_1 of B satisfies that

$$B_1\in C_0^{\infty}(M)=\{f\in C^{\infty}(M);\ \text{supp}\ \ f\ \ \text{is bounded}\} \tag{3}$$

and that for arbitrary $\nu=1,...,n$, there exist constants $d_\nu>0$ and $\epsilon_\nu<2$ such that

$$|B_1(\mathbf{z})|\leqslant\frac{d_\nu}{|\mathbf{z}-\mathbf{a}_\nu|^{\epsilon_\nu}}\ \text{ near }\ \mathbf{z}=\mathbf{a}_\nu. \tag{4}$$

Let

$$\phi_1(\mathbf{z})=\frac{1}{2\pi}\int_{\mathbf{R}^2}B_1(\mathbf{z}')\log|\mathbf{z}-\mathbf{z}'|d\mathbf{z}'\ \text{ for }\ \mathbf{z}=(x,y)\in\mathbf{R}^2.$$

Then we have that $B_1(\mathbf{z})=\Delta\phi_1(\mathbf{z})$ on M. Since $B_1\in L^{\epsilon}(\mathbf{R}^2)$ with $1<\epsilon<2$, using Young's inequality, we can prove the following lemma.

Lemma 1: Let $B_1\in C_0^{\infty}(M)$ and suppose Eq. (4). Then $\phi_1\in C(\mathbf{R}^2)$.

We shall need the local boundedness of ϕ_1 on $\mathbf{R}^2$ as a conclusion of this lemma.

Let

$$\Phi_1=\int_{\mathbf{R}^2}B_1(\mathbf{z})d\mathbf{z}.$$

Since $B_1\in C_0^{\infty}(M)$ and Eq. (4), we have $B_1\in L^1(\mathbf{R}^2)$. Thus, Φ_1 has a finite value. Considering the boundedness of the support of B_1, we can prove the following lemma with calculating a little.

Lemma 2: Suppose $B_1\in C_0^{\infty}(M)$. Then

$$e^{\phi_1(\mathbf{z})}\sim|\mathbf{z}|^{\Phi_1}\ \ as\ \ \mathbf{z}\to\infty.$$

Remark: We write that $f(\mathbf{z})\sim g(\mathbf{z})$ as $\mathbf{z}\to\infty$ if and only if there exist positive constants, c and d, such that for all $|\mathbf{z}|$ large enough, $cf(\mathbf{z})\leqslant g(\mathbf{z})\leqslant df(\mathbf{z})$ holds.

Define an $\mathbf{R}^2$-valued function $\mathbf{A}_1=(A_{11},A_{12})$ on M by

$$\mathbf{A}(\mathbf{z})=(A_{11}(\mathbf{z}),A_{22}(\mathbf{z}))=(-\partial_y\phi_1(\mathbf{z}),\partial_x\phi_1(\mathbf{z})).$$

Here, $\partial_x=\partial/\partial x$ and $\partial_y=\partial/\partial y$. Then $\mathbf{A}_1$ is a gauge potential of B_1, i.e.,

$$B_1(x,y)=D_xA_{12}(x,y)-D_yA_{11}(x,y)$$

in the sense of distribution on $\mathbf{R}^2$.

Remark 3: For the sake of simplicity, we assume Eq. (3). P. Exner and the authors[10] *have proven that under the assumptions,* $B_1(x)=\mathcal{O}(|x|^{-2-\delta})$ *for some* $\delta>0$ *and* $B_1\in L^{1+\epsilon}_{\mathrm{loc}}(\mathbf{R}^2)$ *for some* $\epsilon>0$*, there exists a positive R such that*

$$|\phi_1(x)-\Phi_1\ln|x||<\epsilon|\ln x|,$$

for all $|x|>R$ *and* ϕ_1 *is continuous.* (*See, Prop. 2.2 and Prop. 2.5 in* Ref. 10.) *Since we do not need the compactness of the support of* B_1*, we can remove this restriction.*

C. The total magnetic-field *B*

From now on, using the notations in the previous subsections, we rewrite the given (total) magnetic field B as

$$B(\mathbf{z})=B_0(\mathbf{z})+B_1(\mathbf{z}),$$

and take

$$\mathbf{A}(\mathbf{z})=\mathbf{A}_0(\mathbf{z})+\mathbf{A}_1(\mathbf{z}),$$

as a gauge potential of B. We denote by Φ the total magnetic flux:

$$\Phi=\Phi_0+\Phi_1.$$

Let

$$\phi(\mathbf{z})=\phi_0(\mathbf{z})+\phi_1(\mathbf{z}).$$

Then we have

$$\mathbf{A}(\mathbf{z})=(-D_y\phi(\mathbf{z}),D_x\phi(\mathbf{z})).$$

D. Dirac–Weyl operators

In this subsection, we define the Dirac–Weyl operators with B_0 and B acting in $\mathbf{C}^2\otimes L^2(\mathbf{R}^2)$. Let σ_j, $j=1,2,3$, be the Pauli matrices:

$$\sigma_1=\begin{pmatrix}0&1\\1&0\end{pmatrix},\quad \sigma_2=\begin{pmatrix}0&-i\\i&0\end{pmatrix},\quad \sigma_3=\begin{pmatrix}1&0\\0&-1\end{pmatrix}.$$

We denote the domain of an operator T by *Dom(T).*

Let

$$p_1=-iD_x,\quad p_2=-iD_y,$$

be distributional differential operators acting in $L^2(\mathbf{R}^2)$. The velocity operator $\mathbf{P}_0=(P_{01},P_{02})$ with the gauge potential $\mathbf{A}_0$ is given by

$$P_{0j}=p_j-qA_{0j}\ \text{ with }\ \mathrm{Dom}(P_{0j})=C_0^\infty(M).$$

Define the Dirac–Weyl operator $Q_{\min}$ with the strongly singular magnetic-field B_0 by

$$Q_{\min}=\sigma_1P_{01}+\sigma_2P_{02}\ \text{ with }\ \mathrm{Dom}(Q_{\min})=\mathbf{C}^2\otimes C_0^\infty(M).$$

As the above equation, we often omit the tensorial sign, $\otimes$, between two operators. The velocity operator $\mathbf{P}=(P_1,P_2)$ with the gauge potential $\mathbf{A}$ is given by

$$P_j=p_j-q(A_{0j}+A_{1j}) \quad \text{with} \quad \mathrm{Dom}(P_j)=C_0^\infty(M).$$

Define the Dirac–Weyl operator $D_{\min}$ with the total magnetic field B by

$$D_{\min}=\sigma_1P_1+\sigma_2P_2 \quad \text{with} \quad \mathrm{Dom}(D_{\min})=\mathbf{C}^2\otimes C_0^\infty(M).$$

Note that $Q_{\min}$ is written in the form of

$$Q_{\min}=\begin{pmatrix} 0 & Q_- \\ Q_+ & 0 \end{pmatrix},$$

where

$$Q_\pm=P_{01}\pm iP_{02} \quad \text{with} \quad \mathrm{Dom}(Q_\pm)=C_0^\infty(M),$$

and $D_{\min}$ is written in the form of

$$D_{\min}=\begin{pmatrix} 0 & D_- \\ D_+ & 0 \end{pmatrix},$$

where

$$D_\pm=P_1\pm iP_2 \quad \text{with} \quad \mathrm{Dom}(D_\pm)=C_0^\infty(M).$$

The operators $Q_{\min}$ and $D_{\min}$ are symmetric, and thus, $Q_{\min}$ and $D_{\min}$ are closable. We denote by $\overline{Q}_{\min}$ and $\overline{D}_{\min}$ the closures of $Q_{\min}$ and $D_{\min}$, respectively.

Let

$$\mathbf{D}_1=\begin{pmatrix} 0 & D_+^* \\ \overline{D}_+ & 0 \end{pmatrix} \quad \text{and} \quad \mathbf{D}_2=\begin{pmatrix} 0 & \overline{D}_- \\ D_-^* & 0 \end{pmatrix},$$

be Dirac–Weyl operators with B acting in $\mathbf{C}^2\otimes L^2(\mathbf{R}^2)$. These are selfadjoint extensions of $D_{\min}$. In Sec. IV, it is proven that these do not coincide under some conditions.

Remark: In Ref. 2, for the two self-adjoint extensions $Q_{\min}^{(1)}$ and $Q_{\min}^{(2)}$ of the symmetric operator $Q_{\min}$ have been constructed in the same fashion as above. Under some conditions, these selfadjoint extensions are not coincided with each other.

E. Generalized kernel

In this subsection, we preliminary examine the generalized kernel (the space of generalized eigenvectors with eigenvalue 0) of $D_{\min}$ to identify the kernels of $\mathbf{D}_1$ and $\mathbf{D}_2$. We use the following natural identification of $\mathbf{R}^2$ and $\mathbf{C}$: Each $\mathbf{z}=(x,y)\in\mathbf{R}^2$ corresponds to $z=x+iy\in\mathbf{C}$ with the imaginary unit i. We set $\partial=(\partial/\partial x-i\partial/\partial y)/2$, $\overline{\partial}=(\partial/\partial x+i\partial/\partial y)/2$, and $a_\nu=a_{\nu_1}+ia_{\nu_2}$ for $\mathbf{a}_\nu=(a_{\nu_1},a_{\nu_2})$.

The following proposition shall be needed later.

Proposition 4: *The following identity as differential operators holds on* $C^\infty(M)$*:*

$$D_\pm=e^{\mp q\phi_1}Q_\pm e^{\pm q\phi_1}.$$

Proof: By direct computations, we have

$$Q_+=-2ie^{-q\phi_0}\overline{\partial}e^{+q\phi_0},$$

$$Q_- = -2ie^{+q\phi_0}\partial e^{-q\phi_0},$$

$$D_+ = -2ie^{-q\phi}\overline{\partial} e^{+q\phi},$$

$$D_- = -2ie^{+q\phi}\partial e^{-q\phi}$$

on $C^\infty(M)$. Thus, we obtain the desired result.

Let $\mathcal{D}(M)=C_0^\infty(M)$ and $\mathcal{D}'(M)$ be the space of distributions on M. We say that $f\in\mathcal{D}'(M)$ is a generalized eigenvector with eigenvalue 0 of an operator T on $C_0^\infty(M)$ if

$$\langle f,(Tg)^*\rangle = 0 \quad \text{for all } g\in C_0^\infty(M),$$

where $\langle\cdot,\cdot\rangle$ denotes the canonical bilinear form on $\mathcal{D}'(M)\times C_0^\infty(M)$. We denote by $S(T)$ the space of all the generalized eigenvectors with eigenvalue 0 of T. Note that $\ker \overline{D}_\pm \subset S(D_\pm)$.

For a function ψ on M, let

$$H_\psi(M)=\{e^{-q\psi}f;\ f \text{ is holomorphic on } M\},$$

$$H_\psi^q(M)=\{e^{q\psi}g;\ g \text{ is antiholomorphic on } M\}$$

The following lemma is Lemma 4.4 in Ref. 2.

Lemma 5: We have

$$S(Q_+)=H_{\phi 0}(M) \quad \text{and} \quad S(Q_-)=H_{\phi 0}^q(M).$$

The following lemma can be proven in the same way as in the proof of Lemma 4.4 in Ref. 2.

Lemma 6: We have

$$S(D_+)=H_\phi(M) \quad \text{and} \quad S(D_-)=H_\phi^q(M).$$

Note that $S(Q_{\min})=S(Q_+)\oplus S(Q_-)$ and $S(D_{\min})=S(D_+)\oplus S(D_-)$.

III. VANISHING THEOREM

In this section, we examine the vanishing theorem for Dirac–Weyl operators $\mathbf{D}_1$ and $\mathbf{D}_2$. Suppose that $B_1\in C_0^\infty(M)$ and that Eq. (4) holds. We need the following lemma proved by Arai.

Lemma 7 (Arai, Lemma 4.3 in Ref. 2): We have $\ker \overline{Q}_\pm=\{0\}$, i.e., $\ker \overline{Q}_{\min}=\{0\}$.

The following is the main theorem in this section.

Theorem 8 (Vanishing Theorem): Suppose that the multiplication operator $e^{q\phi_1}$ (*resp.* $e^{-q\phi_1}$) *acting in* $L^2(\mathbf{R}^2)$ *is bounded. Then*

$$\ker \overline{D}_+=\{0\}. \quad (\text{resp. } \ker \overline{D}_-=\{0\}.)$$

Remark: For ϵ in Remark 3, (i) if $q\Phi_1\leqslant -|q|\epsilon$, then $e^{q\phi_1}$ is bounded; (ii) if $e^{q\phi_1}$ is bounded, then $q\Phi_1\leqslant|q|\epsilon$.

Proof: Consider the case when $e^{q\phi_1}$ is bounded. By Proposition 4, we have

$$e^{q\phi_1}S(D_+)=S(Q_+). \tag{5}$$

Let $\Psi\in\ker \overline{D}_+$. Then there exists a sequence $\{\Psi_n;n\in\mathbf{N}\}\subset C_0^\infty(M)$ such that $\Psi_n\to\Psi$ and $D_+\Psi_n\to 0$ in $L^2(\mathbf{R}^2)$ as $n\to\infty$. Since $\Psi\in S(D_+)$, by Eq. (5) and the assumption

$$e^{q\phi_1}\Psi\in S(Q_+)\cap L^2(\mathbf{R}^2).$$

We have $e^{q\phi_1}\Psi_n\in C_0^\infty(M)$ for all $n\in\mathbf{N}$ and, since $e^{q\phi_1}$ is bounded, we have

$$e^{q\phi_1}\Psi_n \to e^{q\phi_1}\Psi \quad \text{in} \quad L^2(\mathbf{R}^2),$$

as $n\to\infty$. Moreover

$$\|Q_+ e^{q\phi_1}\Psi_n\| \leqslant \|e^{q\phi_1}\|\|e^{-q\phi_1}Q_+ e^{q\phi_1}\Psi_n\| = \|e^{q\phi_1}\|\|D_+\Psi_n\| \to 0,$$

as $n\to\infty$. Thus, $e^{q\phi_1}\Psi \in \mathrm{Dom}(\overline{Q}_+)$ and $\overline{Q}_+ e^{q\phi_1}\Psi = 0$. Therefore, by Lemma 7, $e^{q\phi_1}\Psi = 0$. Thus, we have $\Psi = 0$, which means $\ker \overline{D}_+ = \{0\}$. In the case when $e^{-q\phi_1}$ is bounded, we can obtain the desired result in the same way as above.

IV. KERNEL OF DIRAC–WEYL OPERATOR

In the previous section, in the case when $e^{q\phi_1}$ (resp. $e^{-q\phi_1}$) is bounded, we proved that $\ker \overline{D}_+ = \{0\}$ (resp. $\ker \overline{D}_- = \{0\}$). In this section, we examine $\ker \overline{D}_-$ and $\ker \overline{D}_+$, and we identify the kernels of the two selfadjoint extensions $\mathbf{D}_1$ and $\mathbf{D}_2$ in restricted cases, respectively.

Let $\mathbf{Z}_+$ be the set of nonnegative integers. We introduce the set

$$W_\pm(\Phi) = \left\{ (p,k_1,\ldots,k_n) \in \mathbf{Z}_+ \times \mathbf{Z}^n; p + \sum_{\nu=1}^{n} k_\nu < \pm\frac{q\Phi}{2\pi} - 1, \ \pm\ \frac{q\gamma_\nu}{2\pi} - 1 < k_\nu, \nu = 1,\ldots,n \right\},$$

and put

$$N_\pm(\Phi;n;q) = \#W_\pm(\Phi),$$

the number of the elements of $W_\pm(\Phi)$. Note that $N_-(\Phi;n;q) = N_+(\Phi;n;-q)$. Let

$$F(z) = -\frac{1}{2\pi}\sum_{\nu=1}^{n}\sum_{k=1}^{m}\frac{C_k^{(\nu)}}{k(z-a_\nu)^k}.$$

Here, the constants $C_k^{(\nu)}$ were defined by Eq. (2). For $(p_\pm,k_1,\ldots,k_n) \in \mathbf{Z}_+ \times \mathbf{Z}^n$, define functions on M by

$$\Omega^{+}_{p_+,k_1,\ldots,k_n}(\mathbf{z}) = \left(\prod_{\nu=1}^{n} |\mathbf{z}-\mathbf{a}_\nu|^{-q\gamma_\nu/2\pi}(z-a_\nu)^{k_\nu} \right) P_+(z)^{iq\Im F(z)},$$

$$\Omega^{-}_{p_-,k_1,\ldots,k_n}(\mathbf{z}) = \left(\prod_{\nu=1}^{n} |\mathbf{z}-\mathbf{a}_\nu|^{q\gamma_\nu/2\pi}(\overline{z}-\overline{a}_\nu)^{k_\nu} \right) P_-(\overline{z})^{-iq\Im\overline{F}(z)},$$

where $P_\pm$ is a polynomial of order $p_\pm$ such that $P_+(a_\nu) \neq 0$, $P_-(\overline{a}_\nu) \neq 0$, $\nu = 1,\ldots,n$.

Remark: The sets $W_\pm(\Phi_0)$ and the numbers $N_\pm(\Phi_0;n;q)$ are equal to $W_\pm$ and $N_\pm(n;q)$ given in Ref. 2, respectively, and these functions $\Omega^{\pm}_{p_\pm,k_1,\ldots,k_n}$ are the same ones given in Ref. 2.

First of all, we solve the differential equations $D_\pm\Omega = 0$ on M and examine when it is solutions Ω are in $L^2(M)$.

Lemma 9: (i) The functions $e^{\mp q\phi_1}\Omega^{\pm}_{p_\pm,k_1,\ldots,k_n}$ satisfy the partial differential equations

$$D_\pm e^{\mp q\phi_1}\Omega^{\pm}_{p_\pm,k_1,\ldots,k_n} = 0 \quad \text{on} \quad M,$$

respectively.

(ii) The functions $e^{\mp q\phi_1}\Omega^{\pm}_{p_\pm,k_1,\ldots,k_n}$ are in $L^2(\mathbf{R}^2)$ if and only if $(p_\pm,k_1,\ldots,k_n) \in W_\pm(\Phi)$, respectively.

Proof: By Lemma 4.6 (i) in Ref. 2, we have

$$Q_\pm\Omega^{\pm}_{p_\pm,k_1,\ldots,k_n} = 0 \quad \text{on} \quad M.$$

Thus, with Proposition 4, we obtain part (i). We prove part (ii). We have

$$|e^{-q\phi_1}\Omega^+_{p_+,k_1,\ldots,k_n}(\mathbf{z})| \sim \text{const}|\mathbf{z}|^{-(q\Phi/2\pi)+p_+ +\Sigma_{\nu=1}^n k_\nu},$$

as $|\mathbf{z}|\to\infty$, and

$$|e^{-q\phi_1}\Omega^+_{p_+,k_1,\ldots,k_n}(\mathbf{z})| \sim \text{const}|\mathbf{z}-\mathbf{a}_\nu|^{-(q\gamma_\nu/2\pi)+p_+},$$

as $\mathbf{z}\to\mathbf{a}_\nu$. Therefore, the desired assertion on $e^{-q\phi_1}\Omega^+_{p_+,k_1,\ldots,k_n}$ follows. Similarly we can prove the assertion on $e^{q\phi_1}\Omega^-_{p_-,k_1,\ldots,k_n}$.

Using this lemma, we can identify the kernels of $D^*_\pm$.

Theorem 10: *We have*

$$\ker D^*_- = \{e^{-q\phi_1}\Omega^+_{p,k_1,\ldots,k_n}; (p,k_1,\ldots,k_n)\in W_+(\Phi)\}, \tag{6}$$

where $\ker D^*_- = \{0\}$ *if* $W_+(\Phi)=\varnothing$, *and*

$$\ker D^*_+ = \{e^{q\phi_1}\Omega^-_{p,k_1,\ldots,k_n}; (p,k_1,\ldots,k_n)\in W_-(\Phi)\}, \tag{7}$$

where $\ker D^*_+ = \{0\}$ *if* $W_-(\Phi)=\varnothing$.

Proof: By Lemma 9, the sets on the right-hand side (rhs) of Eqs. (6) and (7) are included in $\ker D^*_-$ and $\ker D^*_+$, respectively. To prove the converse inclusion relations, let

$$\Omega=(\Omega_+,\Omega_-)\in \ker D^*_-\oplus\ker D^*_+.$$

Note that

$$\ker D^*_-\oplus\ker D^*_+ = \ker D^*_{\min} = \mathbf{C}^2\otimes L^2(\mathbf{R}^2)\cap S(D_{\min}).$$

Hence $\Omega\in S(D)$ and $\Omega_\pm\in L^2(\mathbf{R}^2)$. Therefore, by Lemma 6, there exists a holomorphic function f and an anti-holomorphic function g on M such that

$$\Omega_+ = e^{-q(\phi_1+\phi_0)}f, \quad \Omega_- = e^{q(\phi_1+\phi_0)}g.$$

We note that

$$\phi_0(\mathbf{z}) = \Re F(z) + \sum_{\nu=1}^n \frac{\gamma_\nu}{2\pi}\log|\mathbf{z}-\mathbf{a}_\nu|,$$

and $\phi_1\in C(\mathbf{R}^2)$. Thus, using the condition of that $\Omega_+\in L^2(\mathbf{R}^2)$, we see that f must be of the form

$$f(z) = e^{qF(z)}h(z),$$

with a meromorphic function h on $\mathbf{C}\cup\{\infty\}$ with possible poles at $z=a_\nu$, $\nu=1,\ldots,n$. Thus, Ω_+ has to take the form

$$\Omega_+ = e^{-q\phi_1}\Omega^+_{p,k_1,\ldots,k_n},$$

with some $(p,k_1,\ldots,k_n)\in\mathbf{Z}_+\times\mathbf{Z}^n$. By Lemma 9 (ii), $(p,k_1,\ldots,k_n)$ must be in $W_+(\Phi)$. Thus, Ω_+ is in the set on the rhs of Eq. (6). In the same way, we can prove that Ω_- is in the set on the rhs of Eq. (7).

Consequently, we obtain our main theorem.

Theorem 11: *(i) If* $e^{q\phi_1}$ *is bounded, we have*

$$\ker \mathbf{D}_1 = \left\{ \begin{pmatrix} 0 \\ e^{q\phi_1}\Omega^-_{p,k_1,\ldots,k_n} \end{pmatrix};\ (p,k_1,\ldots,k_n) \in W_-(\Phi) \right\}, \tag{8}$$

where $\ker \mathbf{D}_1 = \{0\}$ *if* $W_-(\Phi) = \varnothing$. *In particular,*

$$\dim\ \ker \mathbf{D}_1 = N_-(\Phi;n;q). \tag{9}$$

(ii) If $e^{-q\phi_1}$ *is bounded, we have*

$$\ker \mathbf{D}_2 = \left\{ \begin{pmatrix} e^{-q\phi_1}\Omega^+_{p,k_1,\ldots,k_n} \\ 0 \end{pmatrix};\ (p,k_1,\ldots,k_n) \in W_+(\Phi) \right\}, \tag{10}$$

where $\ker \mathbf{D}_2 = \{0\}$ *if* $W_+(\Phi) = \varnothing$. *In particular,*

$$\dim\ \ker \mathbf{D}_2 = N_+(\Phi;n;q). \tag{11}$$

Proof: Consider the part (i). By Theorem 8, we have

$$\ker \mathbf{D}_1 = \left\{ \begin{pmatrix} 0 \\ \Omega \end{pmatrix}; \Omega \in \ker \mathbf{D}_+^* \right\}.$$

Hence it follows from Lemma 9 that the set on the rhs of Eq. (8) is included in $\ker \mathbf{D}_1$. By Theorem 10, we obtain the converse inclusion relation. Therefore, we obtain Eq. (8). In the same way, we can obtain Eq. (10). We write as $(p,k_1,\ldots,k_n) = (p,\mathbf{k})$. Thus, $\{e^{\mp q\phi_1}\Omega^{\pm}_{p_j,\mathbf{k}_j}\}_{j=1}^{l}$ are linearly independent if and only if $(p_j,\mathbf{k}_j) \neq (p_i,\mathbf{k}_i)$, $i \neq j$, $i,j = 1,\ldots,l$. Thus, Eq. (9) and Eq. (11) follow.

Remark: In Theorem 4.7 (ii) in Ref. 2, both $W_\pm(\Phi)$ is empty for $n=1$. On the other hand, in our case, $W_\pm(\Phi)$ is not always empty. For instance, we can rewrite $W_\pm(\Phi)$ as

$$W_\pm(\Phi) = \left\{ (p,k_1) \in \mathbf{Z}_+ \times \mathbf{Z}; p + k_1 < \pm\frac{q}{2\pi}(\Phi_0 + \gamma_1) - 1 < \pm\frac{q}{2\pi}\Phi_0 - k_1 \right\},$$

for $n=1$, since $\Phi = \Phi_0 + \gamma_1$. Thus, if $k_1 > q\gamma_1/2\pi - 1$ and $q\Phi_0/2\pi \geqslant 1$, then $W_+(\Phi)$ is not empty and $W_-(\Phi) = \varnothing$. This is the difference caused by the effect of B_1. We remark that B_1 prevents the magnetic flux from locally quantization defined by Arai in Ref. 2.

As a corollary of Theorem 11, we have the following.

Corollary 12: Let $n \geqslant 2$ *and suppose that* $N_+(\Phi;n;q) + N_-(\Phi;n;q) \geqslant 1$. *Then* $D_{\min}$ *is not essentially selfadjoint.*

Proof: In this case, the two self-adjoint extensions $\mathbf{D}_1$ and $\mathbf{D}_2$ are not coincided with each other. Thus, $D_{\min}$ is not essentially selfadjoint.

Remark: In the same way as in the proof of Proposition 4.9 in Ref. 2, we can prove under some conditions that $N_\pm(\Phi_1;n;q) \geqslant 1$ and, thus, $D_{\min}$ is not essentially self-adjoint.

Intertwined isospectral potentials in an arbitrary dimension

Ş. Kuru,[a] A. Teğmen,[b] and A. Verçin[c]
Department of Physics, Ankara University, Faculty of Sciences, 06100, Tandoğan-Ankara, Turkey

(Received 5 March 2001; accepted for publication 8 May 2001)

The method of intertwining with n-dimensional (nD) linear intertwining operator $\mathcal{L}$ is used to construct nD isospectral, stationary potentials. It has been proven that the differential part of $\mathcal{L}$ is a series in Euclidean algebra generators. Integrability conditions of the consistency equations are investigated and the general form of a class of potentials respecting all these conditions have been specified for each $n=2, 3, 4, 5$. The most general forms of 2D and 3D isospectral potentials are considered in detail and construction of their hierarchies is exhibited. The followed approach provides coordinate systems which make it possible to perform separation of variables and to apply the known methods of supersymmetric quantum mechanics for 1D systems. It has been shown that in choice of coordinates and $\mathcal{L}$ there are a number of alternatives increasing with n that enlarge the set of available potentials. Some salient features of higher dimensional extension as well as some applications of the results are presented. © *2001 American Institute of Physics.*

I. INTRODUCTION

The method of intertwining provides a unified approach to constructing exactly solvable linear and nonlinear problems and their hierarchies in various fields of physics and mathematics.[1–5] This is closely connected with the supersymmetric (SUSY) methods such as Darboux's transformation, Schrödinger's factorization, and shape invariant potential concept which deal with pairs of Hamiltonians having the same energy spectra but different eigenstates.[6,7] In general, the object of the intertwining is to construct the so-called intertwining operator $\mathcal{L}$ which performs an intertwining between two given operators of the same type (differential, integral, matrix, or, operator-valued matrix operator, etc.). In the context of quantum mechanics $\mathcal{L}$ is taken to be a linear differential operator which intertwines two Hamiltonian operators H_0 and H_1 such that

$$\mathcal{L}H_0 = H_1\mathcal{L}. \tag{1}$$

Two simple and important facts that are at the heart of the usefulness of this method can be stated as follows: (i) If ψ^0 is an eigenfunction of H_0 with eigenvalue of E^0, then $\psi^1=\mathcal{L}\psi^0$ is an (unnormalized) eigenfunction of H_1 with the same eigenvalue E^0. Hence $\mathcal{L}$ transforms one solvable problem into another. (ii) When H_0 and H_1 are Hermitian (on some common function space) $\mathcal{L}^\dagger$ intertwines in the other direction $H_0\mathcal{L}^\dagger=\mathcal{L}^\dagger H_1$ and this in turn implies that $[H_0,\mathcal{L}^\dagger\mathcal{L}]=0=[\mathcal{L}\mathcal{L}^\dagger,H_1]$, where † and $[,]$ stand for Hermitian conjugation and commutator. Therefore , two hidden dynamical symmetry operators of H_0 and H_1 are immediately constructed in terms of $\mathcal{L}$.[5] These are dimension and form independent general properties of this method.[2] Despite this fact, like the above mentioned SUSY methods, the intertwining method is mostly studied in the context of one-dimensional (1D) systems where $\mathcal{L}$ is taken to be the first order differential operator and

[a]Electronic mail: kuru@science.ankara.edu.tr
[b]Electronic mail: tegmen@science.ankara.edu.tr
[c]Electronic mail: vercin@science.ankara.edu.tr

Hamiltonians are in the standard potential forms. Two additional properties that arise in that case are that;[8] (i) Every eigenfunction of H_0 (without regard to boundary conditions or normalizability) can be used to generate a transformation to a new solvable problem [see Eq. (20) below]. (ii) A direct connection to a SUSY algebra can be established by constructing a diagonal matrix Hamiltonian $H=\mathrm{diag}(H_0,H_1)$ and two nilpotent supercharges $Q^+=(Q^-)^\dagger$ such that the only nonvanishing element of Q^+ matrix is $Q^+_{21}=\mathcal{L}$. These obey the defining relations of the simplest SUSY algebra,

$$\{Q^+,Q^-\}=H, \quad (Q^+)^2=(Q^-)^2=0,$$

which imply $[H,Q^\pm]=0$ and emphasize in a compact algebraic form of the spectral equivalence of two 1D systems. In the nomenclature of the SUSY quantum mechanics $\mathcal{L}$ is known as the supercharge operator and its zeroth-order (in derivatives) term as the superpotential.

There are important studies in the literature which aim to generalize the SUSY methods beyond 1D problems. These can be classified as (i) curved-space approach[1,2,9] (for recent studies, see Ref. 10), and (ii) Matrix-Hamiltonian approach.[5,11–13] Both are based on the intertwining method and they mostly concentrate on extension to two dimensions.

The application of the first approach to quantum mechanics was motivated by Ref. 1 which deals with free particle propagation on a Lie group manifold (see also Ref. 14). Later on, this has been advanced to find the propagator of a free particle moving on an nD sphere[9] as well as to solve both ordinary and partial differential equations with applications to symmetric spaces.[2] These approaches are expected to produce solvable 1D n-particle problems from an nD free motion via some projection methods like that used in Refs. 15 and 16. The second approach, appeared for the first time in Ref. 11, performs the extension by preserving the connection with a SUSY algebra.[12,13] This inevitably restricts the consideration to two matrix Hamiltonian such that one of them has off-diagonal entries. Accordingly, a matrix with elements having higher order derivative terms participates as the intertwining operator. This approach establishes the equivalence of two matrix systems but does not establish spectral equivalence between two scalar Hamiltonians. To improve it in this regard, an algorithm called the polynomial SUSY in which $\{Q^+,Q^-\}$ is a polynomial of the H-matrix was introduced.[13]

The classification given above is by no means exhaustive; for instance one may find a nice method based on integral intertwining operator in Ref. 3 (Sec. II 8) to generate a hierarchy of 2D problems. We should also note that recently the intertwining method has been used for the nonstationary Schrödinger operator.[5,17,18]

The main purpose of this paper is to extend the intertwining method to an arbitrary dimension by applying it to a pair of nD systems characterized by Hamiltonian operators of potential form,

$$H_i=-\nabla^2+V_i, \quad i=0,1, \tag{2}$$

where the potentials V_i and eigenvalues of H_i are expressed in terms of $2m/\hbar^2$ and $\nabla^2=\Sigma_{j=1}^n\partial_j^2$ is the Laplace's operator of R^n. We shall use the Cartesian coordinates $\{x_k;k=1,\ldots,n\}$, the convention $\partial_k\equiv\partial/\partial x_k$, and the abbreviation $V_i\equiv V_i(x_1,\ldots,x_n)$ throughout the paper. We purpose the ansatz that $\mathcal{L}$ is the most general first-order linear operator,

$$\mathcal{L}=L_0+L_d=L_0+\sum_{k=1}^n L_k\partial_k, \tag{3}$$

where L_0,L_k are some functions of $\{x_k;k=1,\ldots,n\}$ which together with V_i are to be determined from consistency equations of Eq. (1). In terms of the vector field $\mathbf{L}=(L_1,\ldots,L_n)$ and nD gradient operator ∇ the operator $L_d=\Sigma_{k=1}^n L_k\partial_k$ will be usually written as $L_d=\mathbf{L}\cdot\nabla$, where "$\cdot$" denotes the usual Euclidean inner product.

In the next section by solving the first $n(n+1)/2$ consistency equations we will show that the operator L_d is a series in generators of the Euclidean algebra in n-dimension. There remain $n+1$ consistency equations which consist of n linear and 1 nonlinear partial differential equations.

Some particular solutions of these equations for an arbitrary n are presented in Sec. III. In Sec. IV we take up the integrability conditions of the remaining n linear equations in the context of the Frobenius integrability theory.[19] General forms of the potentials respecting all integrability conditions for $n=2,3,4,5$ are obtained in Sec. V. A detailed investigation of 2D and 3D isospectral potentials are given in Secs. VI, VII, VIII, where we also exhibit how to generate hierarchies of potentials.

II. INTERTWINING IN *N* DIMENSION: EUCLIDEAN ALGEBRA

In view of (2) and (3) the intertwining relation (1) can be written as

$$[\nabla^2, L_d] = -[\nabla^2, L_0] + [V_0, L_d] + P\mathcal{L}, \tag{4}$$

where $P = V_1 - V_0$. At a glimpse of the right-hand side of Eq. (4) and

$$[\nabla^2, L_d] = \sum_{j,k} (\partial_j^2 L_k)\partial_k + 2\sum_j (\partial_j L_j)\partial_j^2 + 2\sum_{j<k} (\partial_j L_k + \partial_k L_j)\partial_j\partial_k, \tag{5}$$

$$[\nabla^2, L_0] = (\nabla^2 L_0) + 2\sum_j (\partial_j L_0)\partial_j, \tag{6}$$

$$[V_0, L_d] = -(L_d V_0) = -\sum_j L_j(\partial_j V_0), \tag{7}$$

we see that the second order derivatives in Eq. (4) come, together with some first order derivatives, only from $[\nabla^2, L_d]$. Therefore by setting their coefficients to zero we obtain two sets of consistency equations,

$$\partial_j L_j = 0, \quad j = 1, \ldots, n; \quad \partial_j L_k + \partial_k L_j = 0, \quad j < k = 2, \ldots, n. \tag{8}$$

The first set gives $L_j = a_j + f_j(x)$, where a_j's are constants and $f_j(x)$ depends on all of x_k's except x_j. The second set determines f_j as $f_j = \Sigma_k c_{jk} x_k$, where c_{jk}'s are all constants and antisymmetric in j and k: $c_{jk} + c_{kj} = 0$. Hence,

$$L_j = a_j + \sum_k c_{jk} x_k. \tag{9}$$

These solutions make the first order derivative terms at the right-hand side of (5) vanish so that $[\nabla^2, L_d] = 0$. As a result of this the intertwining relation (4) simplifies to

$$[\nabla^2, L_0] = [V_0, L_d] + P(L_0 + L_d). \tag{10}$$

From (6), (7), and (10) we get, by equating the coefficients of the first and zeroth powers of derivatives,

$$2\partial_j L_0 = P L_j; \quad j = 1,2,\ldots,n, \tag{11}$$

$$(-\nabla^2 + P)L_0 = (L_d V_0). \tag{12}$$

These $n+1$ equations constitute a reduced form of the consistency conditions for three unknown functions L_0, V_0, and V_1. While Eq. (12) is nonlinear, Eqs. (11) are linear since all components of L_d have been found.

Equation (12) can be considered in the following way. By virtue of

$$\partial_j L_k = c_{kj}, \tag{13}$$

Eqs. (11) imply that

$$\nabla^2 L_0 = \tfrac{1}{2}(L_d P). \tag{14}$$

Combining this with (12) we arrive at

$$L_0 P = \tfrac{1}{2} L_d (V_1 + V_0), \tag{15}$$

which can be used instead of Eq. (12).

By defining

$$T_j = \partial_j, \quad L_{jk} = x_k \partial_j - x_j \partial_k, \tag{16}$$

and using (9), L_d can be written as

$$L_d = \sum_j a_j T_j + \sum_{j<k} c_{jk} L_{jk}. \tag{17}$$

The generators T_j's and L_{jk}'s obey the following commutation relations:

$$[T_j, T_k] = 0,$$

$$[T_j, L_{km}] = \delta_{jm} T_k - \delta_{jk} T_m, \tag{18}$$

$$[L_{jk}, L_{lm}] = \delta_{jm} L_{lk} - \delta_{jl} L_{mk} + \delta_{kl} L_{mj} - \delta_{km} L_{lj}.$$

These are the defining relations of $n(n+1)/2$ dimensional Euclidean algebra $e(n)$, also known as the algebra of rigid motion denoted by iso(n).[14,20] n translational generators T_j's form the invariant Abelian subalgebra $t(n)$ and $n(n-1)/2$ rotational generators L_{jk}'s form the semisimple subalgebra so(n). As is well known $e(n)$ is semidirect sum of $t(n)$ and so(n) and $\Sigma T_j^2 = \nabla^2$ is a Casimir operator of $e(n)$.

Now, we shall show that the above analysis includes and naturally generalizes the well known 1D case. It is evident that for $n=1$ we have $\mathcal{L} = L_0 + \partial_x$ and $P = 2L_0'(x)$, where we take $x \equiv x_1, a_1 = 1$ and we use the prime(s) to denote differentiation(s) with respect to the argument (when there is no risk of confusion the argument will be suppressed). In that case Eq. (15) yields $\partial_x(V_0 + L_0' - L_0^2) = 0$ from which we recover the well-known forms of the 1D partner potentials:

$$V_0 = L_0^2 - L_0' + b, \quad V_1 = L_0^2 + L_0' + b. \tag{19}$$

It is a standard procedure of 1D SUSY quantum mechanics to take the constant b and L_0 as $b = \lambda_1$ and $L_0(x) = -\partial_x[\ln \phi_1(x)]$. When these are substituted into the first equation of (19) we obtain $-\phi_1''(x) + V_0 \phi_1(x) = \lambda_1 \phi_1(x)$, that is, $\phi_1(x)$ is the eigenfunction of the Schrödinger's equation $-\phi''(x) + V_0 \phi(x) = \lambda \phi(x)$ corresponding to the eigenvalue $\lambda = \lambda_1$. Therefore the Schrödinger's equation remains covariant under the Darboux's transformations,

$$(\phi, V_0) \to (L\phi = \phi' - [\ln \phi_1]' \phi, \quad V_1 = V_0 - 2[\ln \phi_1]''). \tag{20}$$

Obviously, instead of ϕ_1, any other fixed eigenfunction can be used to generate a transformation to another new potential V_1. It is this fact which allows us to apply the Darboux's transformations successively and to construct a hierarchy of potentials for a given V_0.

We conclude this section by saying that for $n \geqslant 1$ the differential part of the intertwining operator is a series in generators of $e(n)$. In saying that we have identified the algebra generated by ∂_x with $e(1)$. A related result is that intertwined potentials have symmetry generators differential part of which are quadratic in the generator of $e(n)$, that is, they belong to universal enveloping algebra of $e(n)$. From now on we assume that a_j's and c_{jk}'s are real constants.

III. APPLICATIONS

Before proceeding further we consider some particular cases of Eqs. (11) and (12).

When $P=0$, Eqs. (11) and (15) give $L_0=$constant and $(L_d V_0)=0$. In view of Eq. (1) these imply, as an expected result, that $\mathcal{L}$ is a symmetry generator of $H_0=H_1$:$[H_0,\mathcal{L}]=0$.

Next we take P to be a constant such that $P=p_0\neq 0$. In that case the integrability conditions $\partial_j\partial_k L_0=\partial_k\partial_j L_0$ of Eqs. (11) require that $c_{jk}=0$ for all j,k which lead to $2L_0=p_0\mathbf{a}\cdot\mathbf{r}+2b$, where $\mathbf{r}=(x_1,\ldots,x_n)$ is the position vector and $\mathbf{a}$ represents the constant vector $\mathbf{a}=(a_1,\ldots,a_n)$. Taking the constant b as $b=\mathbf{a}\cdot\mathbf{b}$ we get from (15),

$$\mathbf{a}\cdot(p_0^2\mathbf{r}+2p_0\mathbf{b}-2\nabla V_0)=0,$$

which is solved by

$$V_0=\tfrac{1}{4}p_0^2r^2+p_0\mathbf{b}\cdot\mathbf{r}+g(x), \tag{21}$$

where $\mathbf{b}$ is a constant vector, $r^2=\Sigma_j x_j^2$, and $g(x)\equiv g(x_1,\ldots,x_n)$ is any differentiable function subjected to the constraint $\mathbf{a}\cdot\nabla g(x)=0$. One may take

$$g(x)=g(\mathbf{b}_{(1)}\cdot\mathbf{r},\ldots,\mathbf{b}_{(n-1)}\cdot\mathbf{r}), \tag{22}$$

such that $\mathbf{b}_{(j)}$'s are linearly independent vectors perpendicular to $\mathbf{a}$. Different choices of g define different systems which accept

$$\mathcal{L}^\dagger\mathcal{L}=-(\mathbf{a}\cdot\nabla)^2+[\mathbf{a}\cdot(\tfrac{1}{2}p_0\mathbf{r}+\mathbf{b})]^2-\tfrac{1}{2}p_0a^2, \tag{23}$$

as a common symmetry generator. Accordingly,

$$\mathcal{L}\mathcal{L}^\dagger=-(\mathbf{a}\cdot\nabla)^2+[\mathbf{a}\cdot(\tfrac{1}{2}p_0\mathbf{r}+\mathbf{b})]^2+\tfrac{1}{2}p_0a^2, \tag{24}$$

is a common symmetry generator for $V_1=V_0+p_0$. These also imply that $\mathcal{L}/a$ and $\mathcal{L}^\dagger/a$ are a pair of ladder operators for H_0,

$$[H_0,\mathcal{L}]=-p_0\mathcal{L},\quad [H_0,\mathcal{L}^\dagger]=p_0\mathcal{L}^\dagger,\quad [\mathcal{L},\mathcal{L}^\dagger]=p_0a^2.$$

As a result of these we recover the existence of harmonic oscillator like spectrum in the spectrum of a class of nD systems described by H_0 which contains many parameters and an arbitrary function.

Now we set all of c_{jk}'s to zero. From (11) and (15) we get $L_0=f(\zeta)$ and $P=f'(\zeta)$ where f is an arbitrary differentiable function of $\zeta=\mathbf{a}\cdot\mathbf{r}/2$. Defining

$$V_\pm=\frac{1}{a^2}f^2(\zeta)\pm\frac{1}{2}f'(\zeta), \tag{25}$$

we obtain, by virtue of (11) and (15),

$$V_0=\tfrac{1}{2}g(x)+V_-;\quad V_1=\tfrac{1}{2}g(x)+V_+, \tag{26}$$

where $g(x)$ may be taken as in (22). Observing that $V_\pm$ are form equivalent to (19) we can say that all the known techniques of 1D SUSY quantum mechanics can equally well be used in this case. For this application the intertwining operator is $\mathcal{L}=f(\zeta)+\mathbf{a}\cdot\nabla$ and the symmetry generators are

$$\mathcal{L}\mathcal{L}^\dagger=a^2V_+-(\mathbf{a}\cdot\nabla)^2,\quad \mathcal{L}^\dagger\mathcal{L}=a^2V_--(\mathbf{a}\cdot\nabla)^2. \tag{27}$$

IV. INTEGRABILITY CONDITIONS

In this section we concentrate on the integrability conditions of n linear equations given by (11). It turns out that once these conditions are well understood all the consistency equations can be tackled more easily.

By considering L_0 as the $(n+1)$th coordinate $x_{n+1}\equiv L_0$ of R^{n+1} and P as a function defined on it we introduce the 1-form,

$$\Omega = dL_0 - \tfrac{1}{2} P\Gamma, \tag{28}$$

on R^{n+1}. Here d stands for the exterior derivative and Γ denotes the 1-form,

$$\Gamma = \sum_{j=1}^{n} L_j dx_j, \tag{29}$$

on R^n. Now n linear equations given by (11) can be expressed as a single Pfaffian equation $\Omega = 0$. In the Frobenius theory, integrability of this Pfaffian equation amounts to being able to find a positive valued integrating factor f and a function g such that $\Omega = f dg$.[19] If this is possible, then $\Omega = 0$ and $dg = 0$ are equivalent Pfaffian equations and the solution (integral surface) of $\Omega = 0$ is the hypersurface $g =$ constant. According to the Frobenius theorem a necessary and sufficient condition for the existence of functions g and f is the fulfillment of the so-called Frobenius condition,

$$\Omega \wedge d\Omega = 0, \tag{30}$$

where $\wedge$ denotes the usual exterior product.

From (28) and (29) we have

$$d\Omega = -\frac{1}{2}\left[(\partial_{n+1} P) dL_0 \wedge d(P\Gamma) + \sum_{j=1}^{n} (\partial_j P) dx_j \wedge \Gamma + P d\Gamma \right],$$

and therefore

$$\Omega \wedge d\Omega = -\tfrac{1}{2}[dL_0 \wedge d(P\Gamma) - \tfrac{1}{2} P^2 \Gamma \wedge d\Gamma], \tag{31}$$

where d in $d(P\Gamma)$ and $d\Gamma$ stands for the exterior derivative of R^n. The Frobenius conditions (30) is therefore equivalent to the following two conditions:

$$d(P\Gamma) = 0, \tag{32}$$

$$\Gamma \wedge d\Gamma = 0, \tag{33}$$

provided that $P \neq 0$. Since both of these conditions are valid in R^n, P is defined on R^n.

The condition (32) gives $n(n-1)/2$ equations,

$$K_{jk} P = -2 c_{jk} P, \tag{34}$$

where

$$K_{jk} = L_j \partial_k - L_k \partial_j. \tag{35}$$

Observe that Eq. (34) can also be obtained from $\partial_j \partial_k L_0 = \partial_k \partial_j L_0$ and in deriving it we have used Eq. (13). The condition (33) could also be inferred from Eq. (32) upon exterior multiplication of $dP \wedge \Gamma + P d\Gamma = 0$ by Γ. It leads to $n(n-1)(n-2)/6$ equations,

$$L_{[j} c_{kl]} = 0, \tag{36}$$

where $j<k<l\leqslant n$ and the square bracket [ ] enclosing the subindexes means antisymmetrization. Equation (36) shows that any three of L_j's are linearly dependent, that is

$$L_j c_{kl}+L_k c_{lj}+L_l c_{jk}=0. \tag{37}$$

Making use of (9) this can be written as

$$a_{[j}c_{kl]}=\sum_m x_m c_{m[j}c_{kl]}. \tag{38}$$

This gives nothing in the case of $n=2$ because $\Gamma\wedge d\Gamma$ is a 3-form and therefore identically vanishes on R^2.

By a simple reasoning making use of the antisymmetry of c_{jk}'s we see that for $n=3$ the right-hand side of Eq. (38) vanishes identically and a single condition

$$\mathbf{L}\cdot\mathbf{c}=\mathbf{a}\cdot\mathbf{c}=0 \tag{39}$$

results. Here we have made use of the fact that in the case of $n=3$ we have

$$\mathbf{L}=\mathbf{a}+\mathbf{r}\times\mathbf{c}, \tag{40}$$

where $\mathbf{c}=(c_1,c_2,c_3)=(c_{23},c_{31},c_{12})$ and "$\times$" stands for the usual cross product of R^3. For $n\geqslant 4$ more care is needed. It is not hard to check that $c_{m[m}c_{kl]}=0$ for any n and hence for $n=4$ the terms $c_{1[j}c_{kl]},\ldots,c_{4[j}c_{kl]}$are equal to each other up to a sign "$-$". These imply that in the case of $n=4$, Eq. (38) restricts all the coordinates to some constant values. But, as is evident from Eq. (38), at the expense of constraining the form of L we can get rid of all these coordinate restrictions by imposing the conditions,

$$a_{[j}c_{kl]}=0; \quad j<k<l, \tag{41}$$

$$c_{m[j}c_{kl]}=0; \quad m=1,\ldots,n. \tag{42}$$

As is mentioned above in the case of $n=4$, Eqs. (42) give only one condition

$$c_{12}c_{34}+c_{13}c_{42}+c_{14}c_{23}=0,$$

and Eqs. (41) give conditions which reduce the total number of parameters. To see this more concretely we define the following four vectors:

$$\mathbf{c}_{(1)}=(0,c_{34},-c_{24},c_{23}), \quad \mathbf{c}_{(2)}=(c_{34},0,c_{41},-c_{31}),$$

$$\mathbf{c}_{(3)}=(c_{24},c_{41},0,c_{12}), \quad \mathbf{c}_{(4)}=(c_{23},c_{31},c_{12},0).$$

Now Eqs. (41) can be rewritten as $\mathbf{a}\cdot\mathbf{c}_{(j)}=0, j=1,2,3,4$. It is easy to check that, in view of Eq. (42), the determinant of the matrix formed by the components of the vectors $\mathbf{c}_{(j)}$'s has rank two. Therefore Eqs. (41) provide two of a_j's as free parameters, or, for a given $\mathbf{a}$ two constraints for c_{jk}'s. By taking into account also (42) we get seven free parameters: five c_{jk}'s and two a_j's, or, three c_{jk}'s and four a_j's. These can be chosen in many different ways. Moreover, one can also choose a lesser number of parameters without destroying the integrability conditions.

For the number of conditions implied by (41)–(42) exceeds the number of parameters the investigation is getting harder and harder for $n\geqslant 5$. But, in the case of $n=5$ one can keep again 5 of c_{jk}'s as free parameters by setting all a_j's to zero. In that case Eqs. (41) disappear and Eqs. (42) give 5 constraints which reduce the number of c_{jk}'s from 10 to 5. Note also that, as has been done in Sec. III, for $n\geqslant 2$ one can always set all c_{jk}'s to zero and keep n a_j's as parameters. In such a case condition (36) completely disappears.

TABLE I. In 3-dimension the special choices of parameters and corresponding coordinates. Note that in each case further choices are possible. For example, in the first three cases c_j which does not appear in the first column can be set to zero and instead of η, one can also use η_2, or η_3. As a completely different case in which all c_{jk}'s are zero has been presented in Sec. III for any $n>1$.

These remarks imply an important property of the intertwining method in higher dimensions; due to integrability conditions there are a number of choices in specifying $\mathcal{L}$. Evidently this fact enriches the set of intertwined potentials (see Table I in the case of $n=3$). In the next section by taking $c_{jk}\neq 0$ for at least a pair of j,k, we carry out an investigation which will enable us to find out the general forms of a class of potentials for $n=2,3,4,5$ endowed with mentioned richness for $n\geqslant 3$.

V. GENERAL FORM OF POTENTIALS

By making use of Eqs. (13), (35), and (37) one can easily verify the following relations:

$$\partial_m\left(\frac{L_i}{L_j}\right)=\frac{c_{ij}}{L_j^2}L_m, \tag{43}$$

$$K_{mn}\left(\frac{L_i}{L_j}\right)=0, \tag{44}$$

$$K_{mn}\left(\frac{1}{L_j^k}\right)=-k\frac{c_{mn}}{L_j^k}, \tag{45}$$

$$\mathbf{L}\cdot\nabla\left(\frac{L_i}{L_j}\right)=c_{ij}\frac{L^2}{L_j^2}, \tag{46}$$

$$\mathbf{L}\cdot\nabla g(L^2)=\left(2\sum_{ij} L_iL_jc_{ij}\right)g'(L^2)=0. \tag{47}$$

In Eq. (47), g is an arbitrary function of $L^2=\Sigma_jL_j^2$. Comparing Eqs. (43) and (11) we see that the general form of L_0 is

$$L_0=f\left(\frac{L_i}{L_j}\right), \tag{48}$$

provided that $c_{ij}\neq 0$. Then from any of Eqs. (11), P is found to be

$$P=\frac{2c_{ij}}{L_j^2}f'(\eta), \tag{49}$$

where $\eta=L_i/L_j$. Fortunately, Eqs. (44) and (45) imply that solution (49) respects all the integrability conditions given by (34).

The only equation that remained unsolved is Eq. (15) which is now as follows:

$$\mathbf{L}\cdot\nabla(V_1+V_0)=\frac{2c_{ij}}{L_j^2}\partial_\eta[f^2(\eta)]. \tag{50}$$

From (46) and (47) it is evident that the general solution of this equation is of the form,

$$V_1+V_0=h+2\frac{f^2(\eta)}{L^2}, \tag{51}$$

where $2f^2(\eta)/L^2$ accounts for the right-hand side of (50) and h is the general solution of the homogeneous equation,

$$\mathbf{L}\cdot\nabla h=0. \tag{52}$$

Hence, the general forms of V_0 and V_1 are, by combining (49) and (51),

$$V_0=\frac{1}{2}h+\frac{V_-}{L^2}, \tag{53}$$

$$V_1=\frac{1}{2}h+\frac{V_+}{L^2}, \tag{54}$$

where

$$V_\pm=f^2(\eta)\pm c_{ij}\frac{L^2}{L_j^2}f'(\eta). \tag{55}$$

As a result, the number of consistency equations has been reduced from $(n+1)(n+2)/2$ [the sum of the number of Eqs. (8), (11), and (12)] to 1, i.e., to Eq. (52). Geometrically, Eq. (52) means that at each point of the surface $h=$constant, $\mathbf{L}$ always lies on the local tangent space. Equivalently, $\mathbf{L}$ is always perpendicular to the (classical) force field determined by ∇h. On the other

hand, from group theoretical point of view Eq. (52) means that the common part of the intertwined potentials is invariant under the action of the Euclidean group $E(n)$, i.e., $e^{L_d}h=h$. For all these statements and the integrability conditions are dimension-dependent h must be determined in each case separately. The rest of the paper is devoted to a detailed investigation of $n=2$ and $n=3$ cases.

As our investigation for an arbitrary dimension is completed two remarks are in order. (i) The above analysis enables us to write down a class of nD isospectral potentials provided that at least one of c_{jk}'s is different from zero. For instance, if only $c_{jk}\neq 0$, then Eq. (37) implies that $L_m=0$ for $m\neq j,k$ and Eqs. (11) require L_0 to depend only on x_j and x_k. In such a case, after defining $\eta=L_j/L_k$ it remains to solve Eq. (52) to find suitable $n-1$ coordinate functions. (ii) When the number of nonzero c_{jk}'s is greater than one there are a number of choices [at most $n(n-1)/2$] for η. But, from Eq. (37) we see that these are all functionally dependent to each other. For example, in the case of $n=3$ we have three choices $\eta=L_1/L_2, \eta_2=L_1/L_3, \eta_3=L_2/L_3$ which obey the following relations:

$$\eta_3=\eta_2/\eta, \quad \eta_2 c_{23}+\eta_3 c_{31}=-c_{12}.$$

Instead of η_i one may choose one of the variables $\alpha_i=L_i/\mathbf{r}\cdot\mathbf{L}=L_i/\mathbf{r}\cdot\mathbf{a}$, or for $n=3,\sigma_i=L_i/(\mathbf{c}\times\mathbf{L})_i$. It is easy to verify that each of these satisfies relations similar to Eqs. (43)–(44) and (46) and enables us to express $L_0,P,V_\pm$ in terms of them. This freedom in the choice of coordinates once again manifests the largeness of the set of intertwined potentials. But, we should emphasize that these are all functionally dependent since the differential of any variable obeying (43) is proportional to $\Gamma=\mathbf{L}\cdot d\mathbf{r}$ and therefore $d\eta_i\wedge d\alpha_i=0$, etc. This also proves that as long as first order intertwining is concerned $V_\pm$ depend only on one variable.

VI. 2D ISOSPECTRAL POTENTIALS

In two dimensions we have $L_1=(a_1+cy)$ and $L_2=(a_2-cx)$, where $c=c_{12},x=x_1,y=x_2$. From Eq. (47) we see that, in terms of

$$\kappa=[L_1^2+L_2^2]^{1/2}=[(a_1+cy)^2+(a_2-cx)^2]^{1/2}, \tag{56}$$

the general solution of Eq. (52) is $h=h(\kappa)$, where h is an arbitrary differentiable function. Taking $\eta=L_1/L_2$ and noting that $L^2/L_2^2=1+\eta^2$, by Eqs. (53)–(55) the general forms of the 2D isospectral potentials are found to be

$$V_0=\frac{1}{2}h(\kappa)+\frac{V_-}{\kappa^2}, \quad V_1=\frac{1}{2}h(\kappa)+\frac{V_+}{\kappa^2}, \tag{57}$$

where

$$V_\pm=f^2(\eta)\pm c(1+\eta^2)f'(\eta). \tag{58}$$

In that case the intertwining operator is

$$\mathcal{L}=f(\eta)+(a_1+cy)\partial_x+(a_2-cx)\partial_y=f(\eta)+c(1+\eta^2)\partial_\eta. \tag{59}$$

As is well known, for a 2D stationary system the existence of a symmetry generator means that the system is completely integrable in the Liouville sense. Recalling that $\mathcal{L}^\dagger\mathcal{L}$ and $\mathcal{L}\mathcal{L}^\dagger$ are symmetry generators of H_0 and H_1, the potentials given by (57) are the most general forms of 2D integrable potentials which can be intertwined by a first order operator.

We shall now present some examples in which for some simple forms of V_- we consider the Riccati's equation (58) for dependent variable f and by solving it we construct the corresponding

potentials. As the simplest case we take $V_0=0$. This may happen in two different cases: (i) $h=0, V_-=0$, and (ii) $h=-2b/\kappa^2, V_-=b$, where b is a constant. In these cases (58) is a separable equation of the form,

$$f^2-c(1+\eta^2)f'=b, \tag{60}$$

which has the general solution,

$$f=(-b)^{1/2}\tan\left[\frac{(-b)^{1/2}}{c}(\tan^{-1}\eta-b_1)\right] \tag{61}$$

for $b<0$. This should be read as $f=b^{1/2}\tanh[(b^{1/2}/c)(b_1-\tan^{-1}\eta)]$ for $b>0$ and as $f=c(b_1-\tan^{-1}\eta)^{-1}$ for $b=0$, where b_1 is an integration constant. From (58) we have

$$V_1=2c^2[\kappa(b_1-\tan^{-1}\eta)]^{-2}, \tag{62}$$

for the case (i) and

$$V_1=-2b\left\{\kappa\cos\left[\frac{(-b)^{1/2}}{c}(\tan^{-1}\eta-b_1)\right]\right\}^{-2};$$

$$V_1=-2b\left\{\kappa\cosh\left[\frac{b^{1/2}}{c}(\tan^{-1}\eta-b_1)\right]\right\}^{-2}, \tag{63}$$

for the case (ii) corresponding to $b<0$ and $b>0$, respectively. As a result we have found a two parameter family of 2D potentials that are intertwined to 2D free motion. Note that for $b=-c^2, b_1=0$ we have $f=c\eta$ and

$$V_1=2c^2\frac{\eta^2+1}{\kappa^2}=\frac{2c^2}{(a_2-cx)^2}. \tag{64}$$

As another example, taking $V_-=b=-c^2$ and $h=(2c^2/\kappa^2)+2g(\kappa)$ in (57) leads us to the partner potentials,

$$V_0=g(\kappa), \quad V_1=g(\kappa)+2c^2\frac{1+\eta^2}{\kappa^2} \tag{65}$$

for $f=c\eta$. In particular, for $g(\kappa)=\kappa^2$, H_0 represents a 2D isotropic displaced harmonic oscillator and H_1 a 2D Calogero's type system for which

$$V_1=\frac{2c^2}{(a_2-cx)^2}+(a_2-cx)^2+(a_1+cy)^2. \tag{66}$$

In that case for any choice of $g(\kappa)$ we have $\mathcal{L}=c[\eta+(\eta^2+1)\partial_\eta]$. This explicitly shows that two different families of potentials, such as that given by (65) can be intertwined by the same $\mathcal{L}$. This is an important property that we do not have in one dimension. It is evident that this arises from the separability of the problem that we shall analyze in the next section. It is also worth mentioning that after a simple affine transformation of the coordinates and a restriction on c^2 one can easily recognize (66) as one of the four superintegrable the Smorodinsky–Winternitz 2D potentials.[21] The above particular example shows that this potential is intertwined to the harmonic oscillator and one of its symmetry generators is immediately obtained as $\mathcal{L}\mathcal{L}^\dagger$.

VII. SEPARATION OF VARIABLES AND HIERARCHY OF 2D POTENTIALS

The above analysis suggests the variables (κ,η) as a new coordinate system. This is a kind of the orthogonal polar coordinate system with displaced center in which we have

$$\nabla^2=\frac{c^2}{\kappa^2}\{\kappa\partial_\kappa(\kappa\partial_\kappa)+(1+\eta^2)\partial_\eta[(1+\eta^2)\partial_\eta]\}. \tag{67}$$

This implies that the eigenvalue equations of H_i accept the separation of variables in terms of (κ,η). In fact, this can be carried out in an easier way by introducing the coordinates

$$\rho=\frac{1}{c}\ln\kappa, \quad \xi=\frac{1}{c}\tan^{-1}\eta. \tag{68}$$

From (59) and (67) we get

$$\mathcal{L}=f(\xi)+\partial_\xi, \tag{69}$$

and $\nabla^2=e^{-2c\rho}(\partial_\rho^2+\partial_\xi^2)$. By defining

$$H_\rho=-\partial_\rho^2+\tfrac{1}{2}e^{2c\rho}h(\rho), \quad H_\pm=-\partial_\xi^2+V_\pm(\xi),$$

and

$$V_\pm=f^2(\xi)\pm f'(\xi), \tag{70}$$

the Hamiltonians can be written as

$$H_0=e^{-2c\rho}(H_\rho+H_-), \quad H_1=e^{-2c\rho}(H_\rho+H_+). \tag{71}$$

If we take $\psi^0(\rho,\xi)=R(\rho)U^0(\xi)$ the eigenvalue equation $H_0\psi^0(\rho,\xi)=E^0\psi^0(\rho,\xi)$ separates as follows:

$$H_-U^0(\xi)=MU^0(\xi), \tag{72}$$

$$(H_\rho-E^0e^{2c\rho})R(\rho)=-MR(\rho), \tag{73}$$

where M is the separation constant. For given E^0 ρ-equation for H_1 is the same as Eq. (73), but ξ-equation is $H_-U^1(\xi)=MU^1(\xi)$. $\mathcal{L}$ given by (69) intertwines only solutions of H_- to that of H_+ by $U^1(\xi)=\mathcal{L}U^0(\xi)$.

We shall now briefly describe how to generate a hierarchy of 2D isospectral potentials.

Taking $f(\xi)=-\phi'(\xi)/\phi(\xi)$ in Eq. (70) yields $V_-(\xi)=\phi''(\xi)/\phi(\xi)$. This is the same as Eq. (72) for $M=0$. Therefore, each solution of (72) with $M=0$ can be used to generate a transformation to a new problem with potential V_1. In fact, by keeping analogy with 1D SUSY methods we can do more than that. For this purpose let us take

$$V_-(\xi)=\mathcal{V}(\xi)-\mathcal{E}_n, \quad f(\xi)=-\frac{\phi_n'(\xi)}{\phi_n(\xi)}, \tag{74}$$

in Eq. (70) and suppose that the resulting stationary Schrödinger's equation,

$$[-\partial_\xi^2+\mathcal{V}(\xi)]\phi_n(\xi)=\mathcal{E}_n\phi_n(\xi) \tag{75}$$

is exactly solvable, where n is a quantum number labeling the eigenvalues and eigenfunctions. If together with (74) we take

$$h(\rho)=2e^{-2c\rho}[\mathcal{H}(\rho)+\mathcal{E}_n], \tag{76}$$

then from Eq. (57) V_i are found to be

$$V_0=e^{-2c\rho}[\mathcal{V}(\xi)+\mathcal{H}(\rho)],$$

$$V_1=e^{-2c\rho}\left[2\left(\frac{\phi_n'(\xi)}{\phi_n(\xi)}\right)^2+2\mathcal{E}_n-\mathcal{V}(\xi)+\mathcal{H}(\rho)\right].$$

In that case the separated equations of H_0 are

$$[-\partial_\xi^2+\mathcal{V}(\xi)]U_n^0(\xi)=(\mathcal{E}_n+M)U_n^0(\xi), \tag{77}$$

$$[-\partial_\rho^2+\mathcal{H}(\rho)-e^{2c\rho}E^0]R_n(\rho)=-(\mathcal{E}_n+M)R_n(\rho). \tag{78}$$

Let us choose M such that

$$\mathcal{E}_{n_\pm}=\mathcal{E}_n\pm M. \tag{79}$$

This amounts to the fact that ξ-equation of H_0 is the same as Eq. (75). Therefore, $U_n^0(\xi)=\phi_{n_+}(\xi)$ and $E^0,R_n(\rho)$ must be labeled by n_+. Accordingly Eq. (78) must be rewritten as

$$[-\partial_\rho^2+\mathcal{H}(\rho)-e^{2c\rho}E_{n_+}^0]R_{n_+}(\rho)=-\mathcal{E}_{n_+}R_{n_+}(\rho). \tag{80}$$

The eigenvalue equation of H_1 corresponding to the same $E_{n_+}^0$ can be separated such that the ρ-equation is the same as Eq. (80) and ξ-equation reads

$$\left[-\partial_\xi^2+2\left(\frac{\phi_n'(\xi)}{\phi_n(\xi)}\right)^2-\mathcal{V}(\xi)\right]U_{n_+}^1(\xi)=-\mathcal{E}_{n_-}U_{n_+}^1(\xi), \tag{81}$$

where

$$U_{n_+}^1(\xi)=\mathcal{L}U_{n_+}^0(\xi)=\left[-\frac{\phi_n'(\xi)}{\phi_n(\xi)}+\partial_\xi\right]\phi_{n_+}(\xi). \tag{82}$$

The function $\phi_n(\xi)$ that generates the transformation is annihilated by the action of $\mathcal{L}$, i.e., $\mathcal{L}\phi_n(\xi)=\{[\phi_n'(\xi)/\phi_n(\xi)]-\partial_\xi\}\phi_n(\xi)=0$. Hence, in the case of $M=0$ the function $U_n^1(\xi)$ corresponding to $\phi_n(\xi)$ can not be found in this way. But, by referring to a well-known theorem of the theory of ordinary differential equations U_n^1 can be constructed. This theorem says that if $y_0(x)$ is a particular nontrivial solution of the equation $a_0(x)y''+a_1(x)y'+a_2(x)y=0$, then the second solution y_1 linearly independent from y_0 is given by

$$y_1=y_0\int\frac{\exp[-\int(a_1(x)/a_0(x))\,dx]}{y_0^2}dx. \tag{83}$$

Adopting this theorem to Eq. (75), where $a_0=-1$ and $a_1=0$ the second solution linearly independent from $\phi_n(\xi)$ is found to be $Y(\xi)=\phi_n(\xi)\int d\xi/\phi_n^2(\xi)$. $\mathcal{L}$ generated by $\phi_n(\xi)$ applied to $Y(\xi)$ gives $Y_0(\xi)=\mathcal{L}Y(\xi)=-1/\phi_n(\xi)$. Inserting this (as y_0) into (83) yields the desired eigenfunction corresponding to $\phi_n(\xi)$,

$$U_n^1(\xi)=-\frac{1}{\phi_n(\xi)}\int\phi_n^2(\xi)d\xi.$$

As a result, changing the eigenfunction of Eq. (75) used to generate the transformation will lead us to a new eigenvalue problem given by Eq. (81). In that way a hierarchy of 2D isospectral potentials can be constructed.

VIII. 3D ISOSPECTRAL POTENTIALS

In order to find the general solution of Eq. (52) for $n=3$ we first recall the integrability condition (39) and the relation (40). Secondly we observe that the set $\{\mathbf{L},\mathbf{c},\mathbf{L}\times\mathbf{c}\}$ forms a right-handed (unnormalized) orthogonal moving frame which "moves" about fixed direction of $\mathbf{c}=(c_1,c_2,c_3)=(c_{23},c_{31},c_{12})$. By using $x=x_1, y=x_2, z=x_3$ we now introduce the variables,

$$\beta=\mathbf{r}\cdot\mathbf{c},$$

$$\gamma=\tfrac{1}{2}\mathbf{r}\cdot[(\mathbf{a}+\mathbf{L})\times\mathbf{c}]=\mathbf{r}\cdot(\mathbf{a}\times\mathbf{c})+\tfrac{1}{2}[(\mathbf{r}\cdot\mathbf{c})^2-c^2r^2], \tag{84}$$

$$\eta=\frac{L_1}{L_2}=\frac{a_1+c_3y-c_2z}{a_2-c_3x+c_1z}.$$

These obey the following relations:

$$(\mathbf{L}\cdot\nabla)\beta=\mathbf{L}\cdot\mathbf{c}=0, \tag{85}$$

$$(\mathbf{L}\cdot\nabla)\gamma=\mathbf{L}\cdot(\mathbf{L}\times\mathbf{c})=0, \tag{86}$$

$$(\mathbf{L}\cdot\nabla)\eta=p(\eta), \tag{87}$$

where $p(\eta)$ is a quadratic polynomial in η,

$$p(\eta)=c_3\frac{L^2}{L_2^2}=\frac{1}{c_3}[(c^2-c_2^2)\eta^2+2c_1c_2\eta+(c^2-c_1^2)], \tag{88}$$

and $c^2=c_1^2+c_2^2+c_3^2$. In deriving this we assumed $c_3\neq 0$ and made use of Eq. (37).

It is now easy to see that, in view of (85) and (86), the general solution of (52) is $h=h(\beta,\gamma)$ where $h:R^2\to R$ is an arbitrary differentiable function. On the other hand, from (53)–(55) the general forms of the potentials are

$$V_0=\frac{1}{2}h(\beta,\gamma)+\frac{V_-}{L^2},\quad V_1=\frac{1}{2}h(\beta,\gamma)+\frac{V_+}{L^2}, \tag{89}$$

where

$$V_\pm=f^2(\eta)\pm p(\eta)f'(\eta), \tag{90}$$

$$L^2=a^2-2\gamma. \tag{91}$$

Making use of Eqs. (84)–(87), $\mathcal{L}$ is found to be

$$\mathcal{L}=f(\eta)+(\mathbf{a}+\mathbf{r}\times\mathbf{c})\cdot\nabla=f(\eta)+p(\eta)\partial_\eta.$$

If instead of $\eta=L_1/L_2$ had we taken one of the variables

$$\eta_2=\frac{L_1}{L_3}=\frac{a_1+c_3y-c_2z}{a_3+c_2x-c_1y},\quad \eta_3=\frac{L_2}{L_3}=\frac{a_2-c_3x+c_1z}{a_3+c_2x-c_1y},$$

we would have obtained $(\mathbf{L}\cdot\nabla)\eta_j=p_j(\eta_j), j=2,3$ and $V_\pm=f_j^2(\eta_j)\pm p_j(\eta_j)f_j'(\eta_j)$, where

$$p_2(\eta_2)=-c_2\frac{L^2}{L_3^2}=-\frac{1}{c_2}[(c^2-c_3^2)\eta_2^2+2c_1c_3\eta_2+(c^2-c_1^2)],$$

$$p_3(\eta_3)=c_1\frac{L^2}{L_3^2}=\frac{1}{c_1}[(c^2-c_3^2)\eta_3^2+2c_2c_3\eta_3+(c^2-c_2^2)].$$

Without any change in the β,γ dependence merely $\mathcal{L}$ would have been changed as $\mathcal{L}=f_j(\eta_j)+p_j(\eta_j)\partial_{\eta_j}$.

As an application we again consider the simplest case $V_0=0$. Following an analysis similar to that made in Sec. VI one can easily verify that the following three different potentials:

$$V_1^{(1)}=\frac{2f_1^2}{L^2},$$

$$V_1^{(2)}=\frac{2}{L^2}\left[c^2+\frac{1}{4}p'^2(\eta)\right],$$

$$V_1^{(3)}=\frac{2}{L^2}\left\{c^2+\left[\frac{1}{2}p'(\eta)+\frac{p(\eta)}{b_1-\eta}\right]^2\right\},$$

are intertwined to 3D free motion, respectively, by

$$\mathcal{L}^{(1)}=f_1+p(\eta)\partial\eta,\quad \mathcal{L}^{(2)}=\tfrac{1}{2}p'(\eta)+p(\eta)\partial\eta,$$

$$\mathcal{L}^{(3)}=\left[\frac{1}{2}p'(\eta)+\frac{p(\eta)}{b_1-\eta}\right]+p(\eta)\partial\eta,$$

where $f_1=[b_1-(cc_3^2)^{-1}\tan^{-1}(p'(\eta)/2c)]^{-1}$ and b_1 is an integration constant. More generally, a two parameter family of potentials can be constructed by means of $f=(-b)^{1/2}\tan[(-b)^{1/2}(b_1+\int d\eta/p(\eta))]$.

We shall now show that in terms of (β,γ,η) the eigenvalue equations of H_i's accept separation of variables. Starting with

$$d\beta=\mathbf{c}\cdot d\mathbf{r},\quad d\gamma=(\mathbf{L}\times\mathbf{c})\cdot d\mathbf{r},\quad d\eta=\frac{c_3}{L_2^2}\mathbf{L}\cdot d\mathbf{r}, \tag{92}$$

one can easily write the differentials dx,dy,dz in terms of $d\beta,d\gamma,d\eta$. These are as follows:

$$d\mathbf{r}=\frac{1}{c^2}\mathbf{c}d\beta+\frac{1}{c^2L^2}(\mathbf{L}\times\mathbf{c})d\gamma+\frac{L_2^2}{c_3L^2}\mathbf{L}d\eta. \tag{93}$$

With the help of these relations the volume form $dV=dx\wedge dy\wedge dz$, the metric $ds^2=d\mathbf{r}\cdot d\mathbf{r}$, and ∇^2 are found to be

$$dV=\frac{1}{c^2p(\eta)}d\beta\wedge d\gamma\wedge d\eta, \tag{94}$$

$$ds^2=\frac{1}{c^2}(d\beta)^2+\frac{1}{c^2L^2}(d\gamma)^2+\frac{L_2^4}{c_3^2L^2}(d\eta)^2, \tag{95}$$

$$\nabla^2 = c^2[\partial_\beta^2 + \partial_\gamma(L^2\partial_\gamma)] + \frac{p(\eta)}{L^2}\partial_\eta[p(\eta)\partial_\eta]. \tag{96}$$

From Eq. (94) we infer that the Jacobian determinant of the transformation $(x,y,z)\to(\beta,\gamma,\eta)$ is $1/c^2p(\eta)$. On the other hand, Eq. (95) manifestly shows that the coordinate system (β,γ,η) is orthogonal. In virtue of (96) the eigenvalue equation $H_0\psi^0(\beta,\gamma,\eta)=E^0\psi^0(\beta,\gamma,\eta)$ separates, by taking $\psi^0(\beta,\gamma,\eta)=U^0(\beta,\gamma)R^0(\eta)$, as

$$H_{\beta\gamma}U^0(\beta,\gamma)=MU^0(\beta,\gamma), \quad H_\eta R^0(\eta)=-MR^0(\eta), \tag{97}$$

where M is a separation constant and

$$H_{\beta\gamma}=-c^2L^2[\partial_\beta^2+\partial_\gamma(L^2\partial_\gamma)]+L^2[\tfrac{1}{2}h(\beta,\gamma)-E^0], \tag{98}$$

$$H_\eta=-p(\eta)\partial_\eta[p(\eta)\partial_\eta]+f^2(\eta)-p(\eta)f'(\eta). \tag{99}$$

At this point we will be content with saying that by following the similar steps as for Sec. VII, one can construct a hierarchy of 3D isospectral potentials.

Finally we would like to emphasize that the 3D potentials we have found depend on six parameters such that a large number of potentials can be generated by setting some of them to zero, or, to some particular values. Possible choices of parameters are represented in Table I. The corresponding potentials can be read off from the expressions in the main text.

IX. CONCLUDING REMARKS

The main results of this study can be summarized as follows. We have studied a pair of nD Hamiltonians of potential forms that intertwine by first order operator $\mathcal{L}$ and proved that the differential part of $\mathcal{L}$ is an element of the Euclidean algebra $e(n)$. These imply that so-intertwined systems have symmetry operators whose differential parts belong to the enveloping algebra of $e(n)$. The integrability conditions of consistency equations are dimension dependent and therefore have been considered for each case separately. The general form of potentials have been specified for $n=2,3,4,5$, where only one linear partial differential equation which determines the common part of the potential remains unsolved. We have found the general solution of this equation in cases of $n=2$ and $n=3$.

Three distinctive features of the higher dimensional extension of the intertwining method are that: (i) The method suggests coordinate systems which allows us to do the separation of variables and to utilize, in one of the variable, all the methods of the 1D SUSY quantum mechanics. (ii) In the choice of this variable and $\mathcal{L}$ itself one has a number of alternatives increasing with n. This fact enlarges the set of available potentials for each $n\geqslant 3$. (iii) There exists families of potentials accepting the same intertwining operator.

2D and 3D isospectral potentials we have obtained involve two arbitrary functions. The former constitute the most general integrable potentials which admit first order intertwining. Particular forms of these potentials may be of special interest for various purposes. Having in mind the projection techniques which produce exactly solvable lower dimensional problems from the higher dimensional one-particle problems[15,16] our analysis in Secs. VI–VIII must be continued also for $n=4$ and $n=5$. As is implied by the last example of Sec. VI, it seems to be possible to investigate connections among the superintegrable potentials[21] as well as to construct related potentials by repeated Darboux's transformations in the context of the intertwining method. Velocity dependent, stationary, and nonstationary problems[22,23] can also be considered within our approach. Work on 2D and 3D isospectral potentials which are at the same time superintegrable is in progress.

ACKNOWLEDGMENTS

JOURNAL OF MATHEMATICAL PHYSICS VOLUME 42, NUMBER 8 AUGUST 2001

Functional differentiation, line integration, and departures from homogeneity of the single-particle kinetic energy functional for one-dimensional systems of *N* fermions

N. H. March
Department of Physics, University of Antwerp (RUCA), Antwerpen, Belgium and Oxford University, Oxford, England

L. M. Nieto[a)]

(Received 11 December 2000; accepted for publication 4 April 2001)

The differential virial theorem of March and Young for N fermions moving in a common one-dimensional potential energy $V(x)$ is here combined with the Euler equation of density functional theory expressing the constancy of the chemical potential throughout the entire inhomogeneous particle density. The functional derivative of the single-particle kinetic energy is thereby expressed directly in terms of the kinetic energy density; a line integral being involved in establishing the connection. This result is then used to establish a formula measuring departures from simple homogeneity of the kinetic energy functional: a matter of current interest in density functional theory. Finally, the general theory of the functional derivative of the single-particle kinetic energy with respect to the particle density is exemplified for the case of harmonic confinement of fermions in one dimension. [DOI: 10.1063/1.1379069]

I. BACKGROUND AND OUTLINE

Density functional theory is of considerable current interest in connection with atomic, molecular, and condensed matter physics.[1–3] The origins of the theory go back to Thomas[4] and Fermi,[5] whose work was formally completed by the theorem of Hohenberg and Kohn,[6] which states that the ground-state energy E of a many-fermion assembly of N interacting particles is a unique functional of the corresponding particle density n. Unfortunately, to date this functional remains unknown.

As background to the present study of the (single-particle) kinetic energy functional $T_s[n]$ of N fermions moving independently in a one-dimensional common potential $V(x)$, let us write immediately the Thomas–Fermi (TF) approximation to the ground-state energy $E_{\mathrm{TF}}[n]$, namely[7] (atomic units are used throughout)

$$E_{\mathrm{TF}}[n]=\frac{\pi^2}{6}\int_{-\infty}^{\infty} n^3(x)\,\mathrm{d}x+\int_{-\infty}^{\infty} n(x)\,V(x)\,\mathrm{d}x. \tag{1}$$

The variational principle underlying the density functional theory may be expressed as

$$\delta(E-N\mu)=0, \tag{2}$$

where δ represents variation with respect to the particle density $n(x)$ while μ is a Lagrange multiplier taking care of the normalization condition

a)Electronic mail: luismi@metodos.fam.cie.uva.es

$$\int_{-\infty}^{\infty} n(x)\,dx = N. \tag{3}$$

The physical significance of μ, as Hulthén[8] pointed out, is that it represents the chemical potential, which is constant throughout the entire inhomogeneous fermion particle density $n(x)$. Applying the general result (2) to the approximate Thomas–Fermi functional in Eq. (1) yields the well-known result

$$\mu = \frac{\pi^2}{2} n^2(x) + V(x), \tag{4}$$

which involves semiclassical approximations and therefore comes into its own when the microscopic system under consideration has many states with large quantum numbers occupied. Bohr's correspondence principle then assures us that in such a limit the predictions of a fully quantal theory will be usefully represented by semiclassical theory.

Generalizing Eq. (4) to such a formally exact quantal theory, one writes[9]

$$\mu = \frac{\delta T_s[n]}{\delta n(x)} + V(x). \tag{5}$$

Here $T_s[n]$ is the so-called single-particle kinetic energy functional of density functional theory, and though a much simpler (one-body) problem than that of $E[n]$ cited previously, it also remains an unknown functional to date. Obviously, by comparing Eqs. (4) and (5), we see that the functional derivative of the Thomas–Fermi kinetic energy in Eq. (1) (a ''local'' density approximation) is $(\pi^2/2)\, n^2(x)$.

It was von Weizsäcker[10] (W) who first recognized the need to correct the Thomas–Fermi kinetic energy function(al) in Eq. (1) by introducing a kinetic energy term dependent on the density gradient. His so-called inhomogeneity kinetic energy, T_W say, will be written in the following in terms of a kinetic energy density $t_W(x)$, as

$$T_W = \int_{-\infty}^{\infty} t_W(x)\,dx, \quad t_W(x) = \frac{1}{8}\frac{(n'(x))^2}{n(x)}. \tag{6}$$

In an early attempt to synthesize density matrix theory with what is now called density functional theory, March and Young[11] derived an approximate form of $T_s[n]$ which was the linear combination of $T_W[n]$ and $T_{\mathrm{TF}}[n]$ given by $T_W[n] + \gamma(N)\, T_{\mathrm{TF}}[n]$, where $\gamma(1) = 0$, since the von Weizsäcker form (6) is the exact single-particle kinetic energy functional for one level only occupied. Baltin[12,13] subsequently made generalizations of such results relating to the single-particle kinetic energy functional $T_s[n]$. Searches for improved approximations to $T_s[n]$ are continuing,[14–16] in order to use so-called ''orbital-free'' density functional theory, thereby bypassing the need to solve one-electron (Slater–Kohn–Sham) Schrödinger equations.[17,18] But even for formal properties of $T_s[n]$, such as its homogeneity or otherwise,[19] current interest remains, this area having been one of some controversy.[20] One of the purposes of this investigation is to settle the matter of (departures from simple) homogeneity of $T_s[n]$ for N fermions in one dimension.[21]

The outline of the present study is then as follows. In Sec. II the Euler Eq. (5) of density functional theory is combined with the differential virial theorem of March and Young[22] to allow by a single integration the functional derivative $\delta T_s[n]/\delta n(x)$ to be written in terms of the corresponding kinetic energy plus properties of the particle density $n(x)$. Section III is then concerned with using this result to discuss the homogeneity departures of the (formally exact) $T_s[n]$ in one dimension for an arbitrary number of fermions. Section IV is devoted to exemplifying the formally exact results of Secs. II and III particularly for the (exactly soluble) case of harmonic confinement.[23,24] Section V constitutes a summary, and includes some proposals for possible further studies in the general area of the nonlocal kinetic energy functional $T_s[n]$. In the

Appendix, the ''box'' model of finite length L is considered for N fermions. The thermodynamic limit of this model, the so-called semi-infinite gas, has been discussed earlier by one of us in this Journal[25] and has in fact been treated in d dimensions. For $d=1$, the Appendix contains a generalization of the differential equation for a spherical Bessel function, which incorporates all inhomogeneities in $n(x)$ due to the finite length L of the box.

II. FORMALLY EXACT FUNCTIONAL DERIVATIVE OF SINGLE-PARTICLE KINETIC ENERGY IN TERMS OF KINETIC ENERGY AND PARTICLE DENSITIES

The March–Young[22] differential virial theorem reads, for kinetic energy density $t_G(x)$ defined from the positive $(\text{grad}\,\psi)^2$ wave function form:

$$t_G'(x) = -\frac{1}{2}\; n(x)\,\frac{\mathrm{d}V(x)}{\mathrm{d}x} + \frac{n'''(x)}{8}. \tag{7}$$

This exact result was derived from the equation of motion for the first-order density matrix, which was then solved by expansion around the diagonal element, which is just the particle density $n(x)$. The near-diagonal behavior of the density matrix is precisely determined by the kinetic energy density $t_G(x)$ plus $n(x)$. An immediate check of Eq. (7) is to multiply both sides by x, and then to integrate over all x from $-\infty$ to ∞. The left-hand side, after integration by parts, then gives the total kinetic energy, while the first term on the right-hand side is in magnitude half the virial of the force $(-\mathrm{d}V/\mathrm{d}x)$. Since the $n'''(x)$ term in Eq. (7) makes no contribution, Eq. (7) contains correctly the (integral) quantum-mechanical virial theorem.

Following the force-balance equation approach used by Holas and March[26] in their derivation of the force $-\nabla V_{\mathrm{xc}}$ associated with the exchange–correlation potential $V_{\mathrm{xc}}(\mathbf{r})$ in terms of low-order density matrices, we rewrite Eq. (7) for the force $(-\mathrm{d}V/\mathrm{d}x)$ acting on the N fermions occupying singly the levels generated by the common potential $V(x)$. Then

$$n(x) = \sum_{m=1}^{N} \psi_m^*(x)\,\psi_m(x), \tag{8}$$

where the normalized wave functions $\psi_m(x)$ are, of course, generated by $V(x)$. One finds from Eq. (7) after multiplying by $2/n(x)$, the so-called force-balance equation

$$-\frac{\mathrm{d}V(x)}{\mathrm{d}x} = \frac{2\,t_G'(x)}{n(x)} - \frac{n'''(x)}{4n(x)}. \tag{9}$$

Next we appeal to the Euler equation of density functional theory,[9] which is a statement of the constancy of the chemical potential μ throughout the entire fermion particle density $n(x)$, however inhomogeneous this may be. With

$$T_s[n] = \int_{-\infty}^{\infty} t_G(x)\,\mathrm{d}x \tag{10}$$

one has for the functional derivative of the single-particle kinetic energy $T_s[n]$ the result quoted already in Eq. (5). Differentiating Eq. (5) with respect to x to exploit the constancy of μ, one can evidently rewrite Eq. (9) as

$$\left(\frac{\delta T_s[n]}{\delta n(x)}\right)' = \frac{2\,t_G'(x)}{n(x)} - \frac{n'''(x)}{4n(x)}. \tag{11}$$

We now proceed to integrate this Eq. (11) to obtain the desired expression for the functional derivative $\delta T_s/\delta n(x)$. The result, as is readily verified, can be expressed in the form

$$\frac{\delta T_s[n]}{\delta n(x)} = 2\frac{t_G(x)}{n(x)} - \frac{n'^2(x)}{8n^2(x)} - \frac{n''(x)}{4n(x)} + 2\int^x \frac{n'(s)}{n(s)}\left[\frac{t_G(s)-t_W(s)}{n(s)}\right]\mathrm{d}s \tag{12}$$

by repeated integration by parts. In Eq. (12) we have introduced the von Weizsäcker inhomogeneity kinetic energy density $t_W(x)$ defined in Eq. (6). From there, the following functional derivative is readily calculated as

$$\frac{\delta T_W}{\delta n(x)} = \frac{1}{8}\left[\frac{n'(x)}{n(x)}\right]^2 - \frac{n''(x)}{4n(x)}. \tag{13}$$

Using Eqs. (6) and (13) in Eq. (12) one reaches the general one-dimensional form of the functional derivative of $T_s[n]$ as

$$\frac{\delta\{T_s[n]-T_W[n]\}}{\delta n(x)} = 2\left[\frac{t_G(x)-t_W(x)}{n(x)}\right] + 2\int^x \frac{n'(s)}{n(s)}\left[\frac{t_G(s)-t_W(s)}{n(s)}\right]\mathrm{d}s, \tag{14}$$

which, for arbitrary N, is defined to within an N-dependent constant.

One immediate check of Eq. (14) is the case $N=1$, where $T_s=T_W$ and $t_G(x)=t_W(x)$. Evidently Eq. (14) is trivially satisfied, with no arbitrary constant left for this special case [compare Eq. (13)].

Of course, for a general potential $V(x)$, the kinetic energy $t_G(x)$ is not known solely in terms of the density $n(x)$. However, for the case of harmonic confinement, we shall return to Eq. (14) in Sec. IV.

III. DEPARTURES FROM HOMOGENEITY OF THE SINGLE-PARTICLE KINETIC ENERGY FUNCTIONAL $T_s[n]$ FOR N FERMIONS IN ONE DIMENSION

Having obtained $\delta T_s/\delta n(x)$ in Eq. (14), let us now consider the departures from homogeneity of the single-particle kinetic energy functional $T_s[n]$. Since the work of Liu and Parr,[20] this has been an area of considerable interest (see, e.g., Ref. 19) and also some degree of controversy.[21]

Let us start from the customary definition of homogeneity. A functional $F[n]$ is homogeneous of order α in $n(x)$ if

$$F[\lambda\, n] = \lambda^{\alpha} F[n]. \tag{15}$$

Let us immediately use the examples cited above of (a) Thomas–Fermi and (b) von Weizsäcker kinetic energies to explore the validity (or otherwise) of Eq. (15) when F becomes the single-particle kinetic energy functional $T_s[n]$.

A. Thomas–Fermi and von Weizsäcker functionals, $T_{\mathrm{TF}}[n]$ and $T_W[n]$

Using Eq. (1),

$$T_{\mathrm{TF}}[n] = \frac{\pi^2}{6}\int_{-\infty}^{\infty} n^3(x)\,\mathrm{d}x$$

and hence $T_{\mathrm{TF}}[\lambda\, n]=\lambda^3\, T_{\mathrm{TF}}[n]$. Therefore we see immediately that the functional $T_{\mathrm{TF}}[n]$ is homogeneous of order three.

Next let us consider again the von Weizsäcker functional already given in Eq. (6),

$$T_W[n] = \frac{1}{8}\int_{-\infty}^{\infty} \frac{(n'(x))^2}{n(x)}\,\mathrm{d}x.$$

It follows immediately that $T_W[\lambda n]=\lambda T_W[n]$ and hence $T_W[n]$ is homogeneous of order one, as already emphasized by Liu and Parr.[20] This means, since T_W is the exact functional for $N=1$, that for all confining potentials $V(x)$ the single-particle kinetic energy $T_s[n]$ has this exact homogeneity property in this special case.

B. Example of harmonic confinement of an arbitrary number of fermions

March, Senet, and Van Doren[24] have constructed the fully nonlocal single-particle kinetic energy $T_s[n]$ for harmonic confinement of N fermions. We quote their functional here:

$$T_s[n]=T_W[n]+\int_{-\infty}^{\infty} dx\, \xi(x)\, t_{\mathrm{TF}}(x), \tag{16}$$

where

$$t_{\mathrm{TF}}(x)=\frac{\pi^2}{6}\ n^3(x). \tag{17}$$

In Eq. (16), the function $\xi(x)$ is explicitly given in Ref. 24 as

$$\xi(x)=\xi(0)+\frac{3}{\pi^2}\int_0^x ds\ \frac{(n'(s))^3}{n^5(x)}. \tag{18}$$

Thus, introducing the kinetic energy term on the right-hand side of Eq. (1), it follows by inserting Eq. (18) into Eq. (16) that

$$T_s[n]=T_W[n]+\xi(0)\, T_{\mathrm{TF}}[n]+\frac{3}{\pi^2}\int_{-\infty}^{\infty} dx\, t_{\mathrm{TF}}(x)\int_0^x ds\ \frac{(n'(s))^3}{n^5(x)}. \tag{19}$$

But we have already discussed the order of homogeneity of T_{TF} and T_W in Sec. III A above, the orders being, respectively, three and one. The quantity $\xi(0)$ is itself a weak function of N, tending rapidly to a constant as N becomes large. The order of the final term in Eq. (19) is unity, and hence it is clear that $T_s[n]$ is not homogeneous. Thus it follows that while

$$\int_{-\infty}^{\infty} n(x)\ \frac{\delta T_s}{\delta n(x)}\,dx=T_s[n] \tag{20}$$

is true for $N=1$ (when $T_s\equiv T_W$), for N arbitrary there are departures from homogeneity until $N\to\infty$, when $T_s\to T_{\mathrm{TF}}$ and the order of homogeneity tends to three (see Sec. III A).

Thus, having demonstrated departures from homogeneity for a specific potential energy $V(x)=x^2/2$ representing harmonic confinement, it follows naturally that the general result (14) must reflect such departures, being true for arbitrary one-dimensional confining potentials $V(x)$.

IV. ILLUSTRATIONS OF GENERAL EQUATION (14)

In this section, we shall illustrate the functional derivative in Eq. (14) by reference to some specific cases. As a first example, let us take the two-level system, i.e., $N=2$, for an arbitrary confining potential $V(x)$.

A. Two-level system with arbitrary confining potential $V(x)$

Here we work out explicitly the example for a given potential $V(x)$ for two levels only occupied. We invoke the so-called Dawson–March[27] transformation in which the wave functions $\psi_1(x)$ and $\psi_2(x)$ associated with the two levels are written in terms of density ''amplitude'' $\sqrt{n(x)}$ and phase $\theta(x)$ as

$$\psi_1(x)=\sqrt{n(x)}\ \cos\theta(x), \quad \psi_2(x)=\sqrt{n(x)}\ \sin\theta(x), \tag{21}$$

leading, of course, to $n(x)=\psi_1^2(x)+\psi_2^2(x)$. It is then readily shown that the kinetic energy density $t_G(x)$ is given by

$$t_G(x)=t_W(x)+\frac{1}{2}n(x)\left(\frac{\mathrm{d}\theta(x)}{\mathrm{d}x}\right)^2. \tag{22}$$

The phase $\theta(x)$ is related to the particle density $n(x)$ by the nonlinear pendulumlike equation, with eigenvalue ϵ:

$$\theta''(x)+\frac{n'(x)}{n(x)}\theta'(x)+\epsilon\sin 2\theta(x)=0. \tag{23}$$

Introducing Eq. (22) into Eq. (14) yields almost immediately

$$\frac{\delta(T_s-T_W)}{\delta n(x)}=(\theta'(x))^2+\int^x\frac{n'(s)}{n(s)}(\theta'(s))^2\,\mathrm{ds}. \tag{24}$$

But multiplying Eq. (23) by $\theta'(x)$ and using the result for $n'(\theta')^2/n$ in Eq. (24) one can readily evaluate the integral to find, to within a constant of integration

$$\frac{\delta(T_s-T_W)}{\delta n(x)}=\frac{1}{2}(\theta'(x))^2+\frac{\epsilon}{2}\cos 2\theta(x). \tag{25}$$

This result Eq. (25) is now to be compared with Eq. (B10) of Holas *et al.*,[28] namely

$$\frac{\delta(T_s-T_W)}{\delta n(x)}=\frac{1}{2}(\theta'(x))^2+\frac{1}{2}\left(\theta''(x)+\frac{n'(x)}{n(x)}\theta'(x)\right)\tan\theta(x). \tag{26}$$

Again using Eq. (23) in the last term of this equation, it is readily verified that it agrees with our result Eq. (25) to within an additive constant. This completes the demonstration that Eq. (14) holds for all two-level systems with an arbitrary confining potential.

B. Large *N* limit with arbitrary confining potential *V*(*x*)

Here, from the studies, for example, of Lieb,[29] we know that the Thomas–Fermi method is asymptotically correct in the limit $N\to\infty$. Then, one can drop $n''(x)$ in the difference between t_G and t, this being expressed precisely in

$$t_G(x)=t(x)+\frac{n''(x)}{4}, \tag{27}$$

and can neglect the von Weizsäcker contribution relative to the Thomas–Fermi kinetic energy. Equation (14) then simplifies to read

$$\frac{\delta T_{\mathrm{TF}}}{\delta n(x)}=2\frac{t_{\mathrm{TF}}}{n(x)}+2\int^x\frac{n'(s)}{n(s)}\frac{t_{\mathrm{TF}}(s)}{n(s)}\mathrm{ds}+(\text{constant}). \tag{28}$$

But from Eq. (1), $t_{\mathrm{TF}}=(\pi^2/6)n^3(x)$, and hence Eq. (28) becomes

$$\frac{\delta T_{\mathrm{TF}}}{\delta n(x)}=2\frac{t_{\mathrm{TF}}}{n(x)}+\frac{\pi^2}{3}\int^x n'(s)\,n(s)\,\mathrm{ds}=3\frac{t_{\mathrm{TF}}(x)}{n(x)}+(\text{constant}), \tag{29}$$

which can be confirmed by direct appeal to Eqs. (1) and (4). Thus, for arbitrary potential $V(x)$, Eq. (14) is now confirmed asymptotically as $N\to\infty$.

C. Harmonic confinement: Arbitrary number *N* of fermions

The above-mentioned Thomas–Fermi example, applicable asymptotically in the limit of large N, has encouraged us to consider the harmonic confinement case treated in earlier work as a further example. Let us use the form of March, Senet, and Van Doren[24] for the kinetic energy density $t(x)$, namely [their Eq. (27)]:

$$t(x)=t_W(x)+\xi(x)t_{\mathrm{TF}}(x). \tag{30}$$

Here $\xi(x)$ is given by (18). Thus, it follows that

$$\xi'(x)=\frac{3}{\pi^2}\frac{(n'(x))^3}{n^5(x)}. \tag{31}$$

But differentiating Eq. (30) and substituting Eq. (31) for $\xi'(x)$ and Eq. (17) yields

$$3\xi(x)\,t_{\mathrm{TF}}(x)=\frac{n(x)}{n'(x)}[t'(x)-t'_W(x)]-\frac{1}{2}\frac{(n'(x))^2}{n(x)}. \tag{32}$$

Inserting this equation into Eq. (30) for $t(x)$ and using Eq. (6), one finds

$$3t(x)+t_W(x)=\frac{n(x)}{n'(x)}[t'(x)-t'_W(x)]. \tag{33}$$

But from Eq. (16) of Ref. 24

$$\frac{t'(x)}{n'(x)}=N-\frac{x^2}{2} \tag{34}$$

and therefore

$$3t(x)+t_W(x)=n(x)\left[N-\frac{x^2}{2}\right]-\frac{n(x)}{n'(x)}t'_W(x). \tag{35}$$

From here, and using Eq. (6)

$$t(x)+\frac{n(x)}{6}(x^2-2N)=-\frac{n''(x)}{12\,n(x)}, \tag{36}$$

or from Eq. (5)

$$\frac{3t(x)}{n(x)}+\frac{t_W(x)}{n(x)}+\frac{t'_W(x)}{n'(x)}=\frac{\delta T_s}{\delta n(x)}+K(N), \tag{37}$$

where $K(N)$ is a constant depending on the number of fermions.

Now again using Eq. (6)

$$\frac{t'_W(x)}{n'(x)}=\frac{1}{4}\frac{n''(x)}{n(x)}-\frac{1}{8}\left(\frac{n'(x)}{n(x)}\right)^2=-\frac{\delta T_W}{\delta n(x)}. \tag{38}$$

Thus Eq. (37) becomes

$$\frac{\delta T_s}{\delta n(x)} = -K(N) + \frac{3t(x)}{n(x)} + \frac{1}{4}\frac{n''(x)}{n(x)}, \tag{39}$$

which agrees with Eq. (35) of March, Senet, and Van Doren.[24] Thus

$$\left[\frac{\delta T_s}{\delta n(x)}\right]' = 3\frac{n(x)t'(x) - n'(x)t(x)}{n^2(x)} + \frac{1}{4}\frac{n(x)n'''(x) - n'(x)n''(x)}{n^2(x)} \tag{40}$$

and at this point we shall compare with the general Eq. (14) which yields by differentiation

$$\left[\frac{\delta T_s}{\delta n(x)}\right]' = 2\ \frac{t_G'(x) - t_W'(x)}{n(x)} + \left[\frac{\delta T_W}{\delta n(x)}\right]'. \tag{41}$$

Using the two equalities in Eq. (38) the last term in Eq. (41) becomes

$$\left[\frac{\delta T_W}{\delta n(x)}\right]' = \frac{2}{n(x)}\left[t_W'(x) - \frac{n'''(x)}{8}\right]. \tag{42}$$

Returning to the harmonic oscillator, using Eq. (27) in Eq. (40) yields

$$\left[\frac{\delta T_s}{\delta n(x)}\right]' = \frac{2}{n}(t_G' - t_W') + \frac{2}{n}t_W' - \frac{n'''}{4n} + \left[\frac{t'}{n} - \frac{3t\,n'}{n^2} - \frac{n'\,n''}{4n^2}\right]. \tag{43}$$

But the last term in brackets is readily seen to be zero using Eqs. (34) and (36). Therefore, Eq. (43) agrees completely with Eqs. (41) and (42), confirming once more the validity of the general Eq. (14).

V. SUMMARY AND POSSIBLE FUTURE DIRECTIONS

What has been demonstrated here is that the combination of the differential virial theorem (7) of March and Young with the Euler equation (5) of density functional theory allows the explicit expression (14) to be obtained for the functional derivative $\delta T_s/\delta n(x)$ of the single-particle kinetic energy $T_s[n]$. This Eq. (14) has, therefore, by measuring $T_s[n]$, and its kinetic energy density $t_G(x)$, from the von Weizsäcker counterparts $T_W[n]$ and $t_W(x)$, respectively, bypassed the process of functional differentiation by recourse to a line integration. This allows, in principle, a much more straightforward route to the functional derivative of $T_s[n]$. Of course, the general form of $[t_G(x) - t_W(x)]/n(x)$ is still lacking and therefore the illustrations of the validity of Eq. (14), set out in Sec. IV, have been either for models (e.g., harmonic confinement) or asymptotic for large particle number N but for arbitrary confining potential $V(x)$.

As to future directions, it would naturally be important to find other soluble models to add to the harmonic confinement example invoked extensively in Sec. IV. But in the case of a quite general potential $V(x)$ and an arbitrary number of fermions, Eq. (14) may perhaps afford an approximate route to the functional derivative, and hence to the desired differential equation for the ground-state density $n(x)$, given $V(x)$. It is presently only for such models as harmonic confinement that such a differential equation exists [see also the Appendix, especially Eqs. (A10) and (A11)], as derived by Lawes and March[23] in this case. The fact that one has a line integration in the final term of Eq. (14) makes it tempting to contemplate inserting an approximation for $[t_G(x) - t_W(x)]/n(x)$ in this term, possibly modeled on the harmonic confinement example already fully solved.

The final comments concern what has been until recently the vexed question of homogeneity of $T_s[n]$. The present argument, set out explicitly in Sec. III, and most precisely in Eq. (19) for admittedly the special case of harmonic confinement, can leave no possible doubt that $T_s[n]$ in one-dimensional N fermion problems is a linear combination of terms with different scaling properties as the density $n(x)$ goes to $\lambda\, n(x)$. Of course, in the case $N=1$, the von Weizsäcker

functional is the exact form of $T_s[n]$ and from well-known arguments $T_W[n]$ has homogeneity of order one. Again, in the asymptotic limit $N\to\infty$, the Thomas–Fermi kinetic energy functional in Eq. (1) is again homogeneous, but now of order three. For intermediate N, one must expect therefore departures from homogeneity, as clearly evidenced in the harmonic example set out in Eq. (19) where each of the three terms on the right-hand side has its own specific scaling properties with the parameter λ.

ACKNOWLEDGMENTS

It is a pleasure for N.H.M. to thank Professor J.A. Alonso for most generous hospitality during a visit to the University of Valladolid, which made possible this collaborative study. This work has been supported by the Spanish DGES (PB98-0370) and Junta de Castilla y León (CO2/199).

APPENDIX: KINETIC ENERGY AND PARTICLE DENSITY FOR FREE MOTION IN A BOX OF LENGTH *L*

In this Appendix we will calculate $t_G(x)$ and $n(x)$ for N fermions occupying singly the free particle levels for confinement in a box of length L, with normalized eigenfunctions $\psi_m(x)=\sqrt{2/L}\,\sin(m\pi x/L)$. In this case the particle density $n(x)$ is given by[30]

$$\begin{aligned} n(x) &= \frac{2}{L}\sum_{m=1}^{N}\sin^2\left[\frac{m\pi x}{L}\right] \\ &= \frac{1}{L}\left[N-\frac{\cos\left[\dfrac{(N+1)\pi x}{L}\right]\sin\left[\dfrac{N\pi x}{L}\right]}{\sin\left[\dfrac{\pi x}{L}\right]}\right] \\ &= \frac{1}{L}\left\{N+\sin^2\left[\frac{N\pi x}{L}\right]-\cot\left[\frac{\pi x}{L}\right]\sin\left[\frac{N\pi x}{L}\right]\cos\left[\frac{N\pi x}{L}\right]\right\}. \end{aligned} \tag{A1}$$

As N and L both tend to infinity in such a way that N/L tends to a finite value, $n_0\equiv k_f/\pi$ say, Eq. (A1) becomes

$$n(x)=n_0\left[1-\frac{\sin(2k_fx)}{2k_fx}\right]=n_0[1-j_0(2k_fx)], \tag{A2}$$

k_f being the wave number of the Fermi gas in this limit and $j_\ell(z)$ the spherical Bessel function of order ℓ. This result (A2) is the special case corresponding to one dimension ($d=1$) of the d-dimensional semi-infinite electron gas treated earlier by one of us in this Journal.[25]

The kinetic energy density corresponding to Eq. (A2) was also given in this earlier work in the ''thermodynamic'' limit discussed previously as

$$t(x)=t_0+\frac{k_f^2}{2}\,[n(x)-n_0]+\frac{k_f^3}{\pi}\,\frac{j_1(2k_fx)}{2k_fx}. \tag{A3}$$

The generalization of Eq. (A3) before passing to the thermodynamic limit, in the $(\mathrm{grad}\,\psi)^2$ wave function form of the kinetic energy $t_G(x)$ is evidently

$$t_G(x)=\frac{1}{2}\sum_{m=1}^{N}(\psi_m'(x))^2. \tag{A4}$$

Hence we find

$$t_G(x)=\frac{\pi^2}{L^3}\sum_{m=1}^{N} m^2\cos^2\left(\frac{m\pi x}{L}\right)$$

$$=\frac{\pi^2}{24L^3}\left\{\frac{6}{\sin\left[\frac{\pi x}{L}\right]}\left(N+N^2\sin^2\left[\frac{\pi x}{L}\right]\right)\cos\left[\frac{2N\pi x}{L}\right]\right.$$

$$\left.-3\,\frac{\cos\left[\frac{\pi x}{L}\right]}{\sin^3\left[\frac{\pi x}{L}\right]}\left(1-2N^2\sin^2\left[\frac{\pi x}{L}\right]\right)\sin\left[\frac{2N\pi x}{L}\right]+2N(N+1)(2N+1)\right\}. \tag{A5}$$

Except at the box "edges" $x=0$ and L,

$$t_G'(x)=\frac{n'''(x)}{8}, \tag{A6}$$

from the March-Young virial result. Using Eq. (A5) explicitly one finds the integral of Eq. (A6) as

$$t_G(x)=\frac{\pi^2}{12L^3}\;N(N+1)(2N+1)+\frac{n''(x)}{8}. \tag{A7}$$

Connection with the semi-infinite electron gas result[25] is readily established using the second-order differential equation for the spherical Bessel function.

This has stimulated us to construct a generalized differential equation for the exact density $n(x)$ without invoking the thermodynamic limit. The argument goes as follows. Using the definition from Eq. (A1) that

$$S(x)=n(x)-\frac{N}{L}-\frac{1}{2L}, \tag{A8}$$

where the last term is introduced to have a homogeneous equation [see Eq. (A10)] for $S(x)$, we have

$$\sin\left[\frac{\pi x}{L}\right]\;S(x)=-\frac{1}{2L}\;\sin\left[\frac{(2N+1)\pi x}{L}\right]. \tag{A9}$$

From here it is very easy to prove that the function $S(x)$ satisfies the following second-order linear differential equation

$$S''(x)+\left[\frac{2\pi/L}{\tan\left[\frac{\pi x}{L}\right]}\right]S'(x)+\left[\frac{4N(N+1)\pi^2}{L^2}\right]S(x)=0, \tag{A10}$$

which we will term a generalized spherical Bessel equation. If we consider now the thermodynamic limit in Eq. (A10) and we call $S_0(x)$ the resulting function from $S(x)$, one can immediately prove that $S_0(x)$ satisfies the following spherical Bessel equation:

$$S_0''(x)+\frac{2}{x}\;S_0'(x)+(2k_f)^2\;S_0(x)=0, \tag{A11}$$

the solution of which is essentially given by (A2). It seems to us somewhat remarkable that the major ''size effects'' due to the finite length L of the box enter Eq. (A10) through the factor $(2\pi/L)/\tan[\pi x/L]$ multiplying the first derivative of $S(x)$, the change in the coefficient $S(x)$ for finite N being minor in comparison. As $L\to\infty$ and $N\to\infty$, such that N/L tends to a finite limit n_0, the tangent factor with $0<x<L$ has a node at $L/2$ for finite box length which moves out to infinity, and the factor $2/x$ multiplying $S_0'(x)$ in the spherical Bessel equation (A11) is recovered.

(Received 14 March 2001; accepted for publication 8 May 2001)

A variationally improved Sturmian approximation for solving time-independent Schrödinger equation is developed. This approximation is used to obtain the energy levels of a quartic anharmonic oscillator, a quartic potential, and a Gaussian potential. The results are compared with those of the perturbation theory, the WKB approximation, and the accurate numerical values. © *2001 American Institute of Physics.* [DOI: 10.1063/1.1385374]

I. INTRODUCTION

Since the early days of quantum mechanics, the main technical tools for solving the time-independent Schrödinger equation have been the time-independent perturbation theory, the semiclassical or WKB approximation, and the variational method.[1,2] Starting form the late 1950s, physical chemists and nuclear physicists have explored the use of what is called the *Sturmian basis functions* in solving this equation for a variety of potentials arising in molecular and atomic physics.[3,4] Recently, Antonsen[5] and Szmytkowski and Zywicka-Mozeiko[6] have studied the harmonic oscillator Sturmian functions. The purpose of the present paper is to outline a general variationally improved Sturmian approximation scheme that provides a nonperturbative method of solving time-independent Schrödinger equation.

The organization of the paper is as follows. In Sec. II, we give the definition of the Sturmian basis vectors, derive their general properties, and discuss the conventional Sturmian approximation. In Sec. III we present an improved Sturmian approximation which makes use of the variational method. In Sec. IV we study the harmonic oscillator Sturmians and use them for the solution of time-independent Schrödinger equation in one dimension. In Sec. V we apply our general results to some concrete problems, and compare our results with those obtained using perturbation theory, the WKB approximation, and the highly accurate numerical investigations. In particular, we obtain the energy levels of a quartic anharmonic oscillator, a quartic potential, and a Gaussian potential. Finally, in Sec. VI we summarize our results and present our conclusions.

II. CONVENTIONAL STURMIAN APPROXIMATION

Consider the time-independent Schrödinger equation:

$$H|E,a\rangle = E|E,a\rangle, \tag{1}$$

where H is a self-adjoint Hamiltonian operator and a is a degeneracy label.

The method of Sturmian approximation is based on an expansion of the eigenvectors $|E,a\rangle$ in terms of solutions $|\phi_\nu,\alpha\rangle$ of the equation

$$(H_0+\beta_\nu V_0)|\phi_\nu,\alpha\rangle = \mathcal{E}|\phi_\nu,\alpha\rangle, \tag{2}$$

a)Electronic mail: amostafazadeh@ku.edu.tr

where H_0 and V_0 are self-adjoint operators, β_ν and $\mathcal{E}$ are real scalar parameters, and α is a degeneracy label. Note that in order to obtain $|\phi_\nu,\alpha\rangle$, one must fix $\mathcal{E}$ and solve Eq. (2) for $|\phi_\nu,\alpha\rangle$. Clearly, every solution $|\phi_\nu,\alpha\rangle$ would correspond to a choice for the value of the coupling constant β_ν.

Suppose that $H_0=\vec{p}^2/(2m)$ is the Hamiltonian for a free particle moving in the configuration space $\mathbb{R}^d$, $V_0=V_0(\vec{x})$ is a real interaction potential, and H is a standard Hamiltonian of the form

$$H=\frac{\vec{p}^2}{2m}+V(\vec{x}), \tag{3}$$

where $\vec{p}$ and $\vec{x}$ are momentum and position operators, respectively. If $V_0(\vec{x})$ tends to infinity as $|\vec{x}|\to\infty$, all the eigenstates of V_0 are bound states.[7] In this case, only for a discrete set of positive values of β_ν, can we find square-integrable solutions $|\phi_\nu,\alpha\rangle$ of Eq. (2). In this case, the label ν will take values in a discrete set which we shall choose to be $\{0,1,2,...\}$.

The only difference between Eq. (2) and the eigenvalue equation for the potential $\beta_\nu V_0(\vec{x})$ is that in the former $\mathcal{E}$ is a fixed parameter which can be arbitrarily chosen. Therefore, a solution of Eq. (2) corresponds to a pair $(\beta_\nu,|\phi_\nu,\alpha\rangle)$.

The vectors $|\phi_\nu,\alpha\rangle$ are called the *Sturmian basis vectors* or simply the *Sturmians*.[3] They satisfy certain orthonormality conditions which we shall derive below. We should, however, note that the square-integrable Sturmians do not generally constitute a complete set of basis vectors of the Hilbert space.[6] There are certain potentials V_0, such as the Coulomb potential, that lead to a complete set of square-integrable Sturmians.[8]

Let us first note that the defining equation (2) does not determine $|\phi_\nu,\alpha\rangle$ uniquely. This is reflected in the presence of the degeneracy label α. What is uniquely determined by Eq. (2) is the degeneracy subspace $\mathcal{H}_\nu$ spanned by $\{|\phi_\nu,1\rangle,|\phi_\nu,2\rangle,\ldots,|\phi_\nu,l_\nu\rangle\}$, where l_ν is the degree of degeneracy, i.e., the number of linearly independent solutions of Eq. (2) associated with a given (admissible) value of β_ν. Clearly, we can construct an orthonormal basis of $\mathcal{H}_\nu$ and choose the Sturmian vectors $|\phi_\nu,\alpha\rangle$ to be the basis vectors. In other words, without loss of generality, we can choose to work with the Sturmians $|\phi_\nu,\alpha\rangle$ satisfying

$$\langle\phi_\nu,\alpha|\phi_\nu,\gamma\rangle=\delta_{\alpha\gamma}, \tag{4}$$

where $\delta_{\alpha\gamma}$ denotes the Kronecker delta function. Clearly, any unitary transformation of $\mathcal{H}_\nu$ would lead to a new set of Sturmians satisfying (4). Therefore, the condition (4) reduces the freedom in the choice of the Sturmians $|\phi_\nu,\alpha\rangle$, but does not eliminate it.

Next, we evaluate the Hermitian adjoint of both sides of Eq. (2), change (ν,α) to (μ,γ), and take the inner product of both sides of the resulting equation with $|\phi_\nu,\alpha\rangle$. This yields

$$\beta_\mu\langle\phi_\mu,\gamma|V_0|\phi_\nu,\alpha\rangle=\langle\phi_\mu,\gamma|(\mathcal{E}-H_0)|\phi_\nu,\alpha\rangle. \tag{5}$$

We can compute the right-hand side of this equation using Eq. (2). Substituting the result in (5), we find

$$(\beta_\mu-\beta_\nu)\langle\phi_\mu,\gamma|V_0|\phi_\nu,\alpha\rangle=0. \tag{6}$$

If we define

$$N_\nu^{\gamma\alpha}:=\langle\phi_\nu,\gamma|V_0|\phi_\nu,\alpha\rangle, \tag{7}$$

then we can write Eq. (6) in the form

$$\langle\phi_\mu,\gamma|V_0|\phi_\nu,\alpha\rangle=N_\nu^{\gamma\alpha}\delta_{\mu\nu}. \tag{8}$$

Equation (8) is the desired orthogonality property of the Sturmians. We can further simplify Eq. (8), by noting that the $l_\nu \times l_\nu$ matrix N_ν formed by $N_\nu^{\gamma\alpha}$ is a Hermitian matrix. This means that we can choose $|\phi_\nu,\alpha\rangle$ in such a way that N_ν is a diagonal matrix. Making this choice, we have

$$N_\nu^{\alpha\gamma}=N_\nu^\alpha\delta_{\alpha\gamma}, \tag{9}$$

$$\langle\phi_\mu,\gamma|V_0(\vec{x})|\phi_\nu,\alpha\rangle=N_\nu^\alpha\delta_{\mu\nu}\delta_{\alpha\gamma}, \tag{10}$$

where N_α^ν, with $\alpha\in\{1,2,\ldots,l_\nu\}$, are eigenvalues of the matrix N_ν. Since N_ν is Hermitian, N_ν^α are real.

In summary, we can choose a set of Sturmian vectors $|\phi_\nu,\alpha\rangle$ which are eigenvectors of the matrices N_ν. Therefore, for each value of ν, $\{|\phi_\nu,1\rangle,\ldots,|\phi_\nu,l_\nu\rangle\}$ forms an orthonormal eigenbasis of N_ν in the degeneracy subspace $\mathcal{H}_\nu$. However, $|\phi_\nu,\alpha\rangle$ with different values of ν are not orthogonal. Instead, they satisfy a modified orthogonality condition, namely (10).

Now, let us expand a solution $|E,a\rangle$ of the Schrödinger equation (1), in a Sturmian basis corresponding to a solvable potential V_0, i.e., seek solutions of the form

$$|E,a\rangle=\sum_{\nu=0}^{\infty}\sum_{\alpha=1}^{l_\nu}C_\nu^\alpha|\phi_\nu,\alpha\rangle, \tag{11}$$

where C_ν^α are complex coefficients and ν is supposed to take discrete values 0,1,2,... . Note that if the Sturmians $|\phi_\nu,\alpha\rangle$ do not form a complete basis, then Eq. (11) yields the eigenvectors that belong to the span of $|\phi_\nu,\alpha\rangle$.

The *Sturmian approximation of order N* is the approximation in which one neglects all the coefficients C_ν^α in Eq. (11) but those with ν belonging to a subset $\mathcal{S}_{N+1}$ of non-negative integers of order $N+1$. Alternatively, in considering the Sturmian approximation of order N, one confines the range of the indices (of type) ν to a fixed finite set $\mathcal{S}_{N+1}$. In this way, the infinite sum $\Sigma_{\nu=0}^{\infty}\cdots$ in Eq. (11) is replaced by the finite sum $\Sigma_{\nu\in\mathcal{S}_{N+1}}\cdots$. We shall abbreviate the latter by Σ_ν. The set $\mathcal{S}_{N+1}$ may, in principle, be chosen arbitrarily. We will comment on this choice in Sec. III.

Substituting (11) in the Schrödinger equation (1) and making use of Eqs. (2) and (3), we find

$$\sum_\nu\sum_{\alpha=1}^{l_\nu}C_\nu^\alpha(E-\mathcal{E}-V+\beta_\nu V_0)|\phi_\nu,\alpha\rangle=0. \tag{12}$$

Now, evaluating the inner product of both sides of this equation with $|\phi_\mu,\gamma\rangle$ and using the orthogonality relation (10), we obtain

$$\sum_\nu\sum_{\alpha=1}^{l_\nu}[(E-\mathcal{E})T_{\mu\nu}^{\gamma\alpha}-(W_{\mu\nu}^{\gamma\alpha}-\beta_\nu N_\nu^\alpha\delta_{\mu\nu}\delta_{\gamma\alpha})]C_\nu^\alpha=0. \tag{13}$$

Here we have introduced

$$T_{\mu\nu}^{\gamma\alpha}:=\langle\phi_\mu,\gamma|\phi_\nu,\alpha\rangle, \tag{14}$$

$$W_{\mu\nu}^{\gamma\alpha}:=\langle\phi_\mu,\gamma|V|\phi_\nu,\alpha\rangle. \tag{15}$$

We can express Eq. (13) in a more compact form, if we use a single label for the pair (ν,α). Introducing $\mathcal{N}:=(\nu,\alpha)$ and $\mathcal{M}:=(\mu,\gamma)$, we write Eq. (13) in the form

$$\sum_{\mathcal{N}}[(E-\mathcal{E})T_{\mathcal{M}\mathcal{N}}-S_{\mathcal{M}\mathcal{N}}]C_{\mathcal{N}}=0, \tag{16}$$

where

$$T_{\mathcal{MN}}=T^{\gamma\alpha}_{\mu\nu},\quad S_{\mathcal{MN}}=W_{\mathcal{MN}}-\beta_\nu N_{\mathcal{N}}\delta_{\mathcal{MN}},\tag{17}$$

$$W_{\mathcal{MN}}=W^{\gamma\alpha}_{\mu\nu},\quad N_{\mathcal{N}}=N^{\alpha}_{\nu}.\tag{18}$$

Equations (16) form a linear system of homogeneous first order algebraic equations for $C_{\mathcal{N}}$. This system has a nontrivial solution provided that the determinant of the matrix of coefficients vanishes, i.e.,

$$\det[(E-\mathcal{E})T-S]=0.\tag{19}$$

Here T and S are matrices with entries $T_{\mathcal{MN}}$ and $S_{\mathcal{MN}}$, respectively.

Solving Eq. (19), we can express E in terms of $\mathcal{E}$, β_ν, and the Sturmians $|\phi_\nu,\alpha\rangle$. Now, we recall that for a fixed choice of V_0, the coupling constants β_ν and the corresponding Sturmians $|\phi_\nu,\alpha\rangle$ depend on the parameter $\mathcal{E}$. Therefore, Eq. (19) yields E as a function of $\mathcal{E}$. Furthermore, substituting the value of $E=E(\mathcal{E})$ obtained by solving (19) in (16) and solving for the coefficients $C_{\mathcal{N}}$, we obtain an expression for the eigenvector $|E,a\rangle$ that involves $\mathcal{E}$. As we discuss in the following section, the fact that the Sturmian approximation yields the eigenvalues and the eigenvectors of the Hamiltonian as functions of a free parameter seems to have been overlooked. This is mainly because there is a choice for the parameter $\mathcal{E}$ that simplifies the calculations.

It should also be emphasized that Eq. (19) is an algebraic equation of order $N+1$. Therefore, in general, it has $N+1$ solutions. This can be understood by noting that in the Sturmian approximation one actually approximates the Hilbert space by a finite-dimensional vector space. Consequently, the Hamiltonian is replaced with a matrix with a finite number of eigenvalues.

III. VARIATIONAL STURMIAN APPROXIMATION

In general, the accuracy of the Sturmian approximation depends on the following factors.
(1) *Choice of* V_0*:* In practice, V_0 must be one of the exactly solvable potentials. Therefore, the available choices for V_0 are few in number. For the potentials V with bound states, we can choose V_0 to be a harmonic oscillator potential. For example, for the quartic anharmonic oscillator

$$V(x)=\frac{k}{2}x^2+\epsilon x^4,\tag{20}$$

we shall take

$$V_0(x)=\frac{k}{2}x^2.\tag{21}$$

Similarly, for the Gaussian potential

$$V(x)=-\lambda e^{-\epsilon x^2/2},\tag{22}$$

we shall take

$$V_0(x)=\tfrac{1}{2}\lambda\epsilon x^2-\lambda.\tag{23}$$

This will enable us to compare the results of the Sturmian approximation with those of the perturbation theory, for in the limit $\epsilon\to 0$, $V(r)\to V_0(r)$. Note that multiplying V_0 by a positive real number does not change the results of the Sturmian approximation. This is simply because we can always absorb such a number in the definition of β_ν.
(2) *Choice of the Sturmians included in the sum (16):* This is also directly related to the choice of the potential V_0. If V_0 is obtained from V by a limiting process as in the case of the potentials (20)

and (22), then a natural choice for the computation of the nth energy eigenvalue E_n and the corresponding eigenvectors $|E_n,\alpha\rangle$ is to include the $|\phi_\nu,\alpha\rangle$ with ν equal or close to n. In particular, in the Sturmian approximation of order zero, we have

$$|E_n,a\rangle=\sum_{\alpha=1}^{l_n} C_n^\alpha|\phi_n,\alpha\rangle. \tag{24}$$

(3) *Choice of the parameter $\mathcal{E}$:* The conventional choice[4,5] for the parameter $\mathcal{E}$ is $\mathcal{E}=E$. This simplifies Eq. (19) considerably. The basic idea pursued in this paper is the fact that this simplification does not necessarily justify the conventional choice for $\mathcal{E}$.

It is well known[2] that the eigenvalue equation (1) is equivalent to the variational equation

$$\frac{\delta}{\delta\langle\psi|}\left(\frac{\langle\psi|H|\psi\rangle}{\langle\psi|\psi\rangle}\right)=0. \tag{25}$$

In other words, the eigenvalues E are the minima of the expectation value

$$\langle H\rangle:=\frac{\langle\psi|H|\psi\rangle}{\langle\psi|\psi\rangle},$$

and the eigenvectors are the vectors $|E\rangle=|E,a\rangle$ that minimize $\langle H\rangle$. This observation suggests that the most efficient choice for the parameter $\mathcal{E}$ appearing in the Sturmian approximation is the one that minimizes $E=E(\mathcal{E})$. Therefore, the most reliable Sturmian approximation is obtained by choosing $\mathcal{E}$ to be a solution of

$$\frac{dE}{d\mathcal{E}}=0. \tag{26}$$

If this equation does not have a solution, then one must either make another choice for the set $\mathcal{S}_{N+1}$ or proceed with a higher order Sturmian approximation.

IV. VARIATIONAL STURMIAN APPROXIMATION USING HARMONIC OSCILLATOR STURMIANS

Consider a quantum system with the configuration space $\mathbb{R}$, a standard Hamiltonian (3), and a real-valued potential $V=V(x)$. Suppose that the system has an infinite number of bound states with nondegenerate energy eigenvalues E_n. Here $n\in\{0,1,2,\ldots\}$ and E_0 stands for the ground state.

Now, consider the Sturmian basis vectors associated with a harmonic oscillator[5,6]

$$V_0=V_0(x)=\frac{k}{2}x^2. \tag{27}$$

In order to solve Eq. (2) for this choice of V_0, we introduce

$$\omega_\nu:=\left(\frac{\beta_\nu k}{m}\right)^{1/2}, \tag{28}$$

$$\alpha_\nu:=\frac{m\omega_\nu}{\hbar}, \tag{29}$$

$$a_\nu:=\left(\frac{\alpha_\nu}{2}\right)^{1/2}\left(x+\frac{ip}{\hbar\alpha_\nu}\right). \tag{30}$$

$$|l\rangle_\nu := \frac{1}{\sqrt{l!}} a_\nu^{\dagger l} |0\rangle_\nu, \tag{31}$$

where $|0\rangle_\nu$ is the normalized real ground state vector for a harmonic oscillator with mass m and frequency ω_ν. That is

$$\langle x|0\rangle_\nu := \left(\frac{\alpha_\nu}{\pi}\right)^{1/4} e^{-\alpha_\nu x^2/2}. \tag{32}$$

In view of the similarity of Eq. (2) with the eigenvalue equation for the potential $\beta_\nu V_0$, we can easily deduce that

$$\mathcal{E} = \hbar\omega_\nu(\nu + \tfrac{1}{2}), \tag{33}$$

$$|\phi_\nu\rangle = |\nu\rangle_\nu \tag{34}$$

where $\nu \in \{0,1,2,\ldots\}$.

We can invert Eqs. (33) and (28) to express ω_ν and β_ν in terms of $\mathcal{E}$. This yields

$$\omega_\nu = \frac{2\mathcal{E}}{\hbar(2\nu+1)}, \tag{35}$$

$$\beta_\nu = \frac{4m\mathcal{E}^2}{\hbar^2 k(2\nu+1)^2}. \tag{36}$$

Substituting Eq. (35) in (29), we have

$$\alpha_\nu = \frac{2m\mathcal{E}}{\hbar^2(2\nu+1)} = \frac{\alpha_0}{2\nu+1}. \tag{37}$$

Next, we compute the term $\beta_\nu N_\nu = \beta_\nu \langle \phi_\nu | V_0 | \phi_\nu \rangle$. We can use the properties of the annihilation operator a_ν, namely

$$a_\nu|l\rangle_\nu = \sqrt{l}\,|l-1\rangle_\nu, \quad a_\nu^\dagger|l\rangle_\nu = \sqrt{l+1}\,|l+1\rangle_\nu, \quad x = (2\alpha_\nu)^{-1/2}(a_\nu + a_\nu^\dagger), \tag{38}$$

and the orthonormality of $|l\rangle_\nu$ to compute

$${}_\nu\langle l|x^2|\nu\rangle_\nu = (2\alpha_\nu)^{-1}[(2\nu+1)\delta_{l,\nu} + \sqrt{(\nu+1)(\nu+2)}\,\delta_{l,\nu+2} + \sqrt{\nu(\nu-1)}\,\delta_{l,\nu-2}]. \tag{39}$$

In view of Eqs. (27) and (39), we obtain, after some remarkable simplifications,

$$\beta_\nu N_\nu = \frac{\mathcal{E}}{2}. \tag{40}$$

A. Variational Sturmian approximation of order zero

For the variational Sturmian approximation of order zero, $\nu = n$, and Eq. (19) takes the form

$$(E_n - \mathcal{E})T - S = 0, \tag{41}$$

where

$$T = \langle \phi_n | \phi_n \rangle = 1, \quad S = W - \beta_n N_n, \quad W = \langle \phi_n | V | \phi_n \rangle. \tag{42}$$

According to Eqs. (41), (42), and (40), the energy eigenvalues E_n are given by

$$E_n = W + \frac{\mathcal{E}}{2}. \tag{43}$$

Next, we fix the parameter $\mathcal{E}$ using Eq. (26). This requires the computation of $dW/d\mathcal{E}$. We first evaluate the variation of W,

$$\delta W = (\delta\langle\phi_n|)V|\phi_n\rangle + \langle\phi_n|V(\delta|\phi_n\rangle) = 2\langle\phi_n|V(\delta|\phi_n\rangle) = 2\sum_{l=0}^{\infty} {}_n\langle n|V|l\rangle_n\, {}_n\langle l|(\delta|n\rangle_n). \tag{44}$$

Here we have made use of Eq. (34), the fact that the Sturmians and the potential V are real and $|l\rangle_n$ form a complete set of basis vectors.

We can compute ${}_n\langle l|(\delta|n\rangle_n)$ using the eigenvalue equation

$$(H_0 + \beta_n V_0)|j\rangle_n = \mathcal{E}_j|j\rangle_n, \tag{45}$$

where $\mathcal{E}_j = \hbar\omega_n(j+1/2)$. Taking the variation of both sides of this equation and computing the inner product with $|l\rangle_n$, we find

$${}_n\langle l|\delta|j\rangle_n = \frac{{}_n\langle l|V_0|j\rangle_n(\delta\beta_n)}{\mathcal{E}_j - \mathcal{E}_l} \quad \text{for } l \neq j. \tag{46}$$

Furthermore, using the fact that the eigenfunctions $\langle x|l\rangle_n$ are real, we can easily show that

$${}_n\langle l|(\delta|l\rangle_n) = 0. \tag{47}$$

Equations (44), (46) and (47) reduce the computation of δW to that of

$${}_n\langle l|V_0|n\rangle_n = \frac{k}{2}\,{}_n\langle l|x^2|n\rangle_n. \tag{48}$$

We have already computed ${}_n\langle l|x^2|n\rangle_n$ in Eq. (39). Substituting this equation in Eq. (48) and using Eqs. (46) and (44), we find, after some remarkable cancellations,

$$\delta W = \left(\frac{\delta\mathcal{E}}{2\mathcal{E}}\right)[\sqrt{n(n-1)}\,{}_n\langle n|V|n-2\rangle_n - \sqrt{(n+1)(n+2)}\,{}_n\langle n|V|n+2\rangle_n]. \tag{49}$$

Now, in view of Eqs. (43) and (49),

$$\frac{dE_n}{d\mathcal{E}} = \left(\frac{1}{2\mathcal{E}}\right)[\sqrt{n(n-1)}\,{}_n\langle n|V|n-2\rangle_n - \sqrt{(n+1)(n+2)}\,{}_n\langle n|V|n+2\rangle_n] + \frac{1}{2}.$$

Substituting this equation in Eq. (26) yields

$$\mathcal{E} = \sqrt{(n+1)(n+2)}\,{}_n\langle n|V|n+2\rangle_n - \sqrt{n(n-1)}\,{}_n\langle n|V|n-2\rangle_n. \tag{50}$$

Note that the right-hand side of this equation also involves $\mathcal{E}$. This is because $|l\rangle_n$ depend on $\mathcal{E}$.

Using Eqs. (50) and (43) we can express the energy eigenvalue E_n in terms of V. This yields

$$E_n = {}_n\langle n|V|n\rangle_n + \tfrac{1}{2}[\sqrt{(n+1)(n+2)}\,{}_n\langle n|V|n+2\rangle_n - \sqrt{n(n-1)}\,{}_n\langle n|V|n-2\rangle_n]. \tag{51}$$

For the ground state $n=0$ and Eq. (51) reduces to

$$E_0 = {}_0\langle 0|V|0\rangle_0 + \frac{1}{\sqrt{2}}\,{}_0\langle 0|V|2\rangle_0. \tag{52}$$

Note that the vectors $|l\rangle_n$ appearing in Eqs. (51) and (52) are those of Eq. (31) with $\mathcal{E}$ being a solution of Eq. (50).

Equations (51) and (52) are of limited importance. In practice, one obtains the energy eigenvalue E_n by substituting the solution of Eq. (50) in Eq. (43).

The variational Sturmian approximation of order zero, as outlined above, is a valid approximation scheme, if Eq. (50) has a unique positive solution $\mathcal{E}$. If such a solution does not exist, one may attempt to construct higher order variational Sturmian approximations. As we shall see in Sec. V, for all the potentials that we have considered, Eq. (50) has a unique positive solution. This is very remarkable, for this equation turns out to be an algebraic equation of order three for the quartic anharmonic oscillator and the quartic potential, and of order four for the Gaussian potential.

B. Variational Sturmian approximation of order one

In the variational sturmian approximation of order one, the number of Sturmians contributing to the eigenvector $|E\rangle$ is two. We shall denote them by $|\phi_n\rangle$ and $|\phi_m\rangle$.

The matrices T and W are Hermitian 2×2 matrices. They can be written in the form

$$T=\begin{pmatrix} 1 & t^* \\ t & 1 \end{pmatrix}, \quad W=\begin{pmatrix} v_n & w^* \\ w & v_m \end{pmatrix}, \tag{53}$$

where we have used the fact that the Sturmians are normalized and introduced

$$t:=\langle \phi_m|\phi_n\rangle, \quad v_\nu:=\langle \phi_\nu|V|\phi_\nu\rangle, \quad w:=\langle \phi_m|V|\phi_n\rangle. \tag{54}$$

Next, we construct the matrix S. In view of Eqs. (17) and (53),

$$S=\begin{pmatrix} v_n-\beta_n N_n & w^* \\ w & v_m-\beta_m N_m \end{pmatrix}. \tag{55}$$

Note that because the Sturmians for the harmonic oscillator are real-valued, t and w are real-valued functions of the parameter $\mathcal{E}$. In particular, the matrices T, W, and S are real and symmetric.

Substituting Eqs. (53) and (55) in the Eq. (19), making use of Eq. (40), and simplifying the resulting expression, we find

$$A\left(E-\frac{\mathcal{E}}{2}\right)^2+B\left(E-\frac{\mathcal{E}}{2}\right)+C=0, \tag{56}$$

where

$$A:=1-t^2, \quad B:=t(t\mathcal{E}+2w)-(v_n+v_m), \quad C:=v_n v_m-\left(\frac{t\mathcal{E}}{2}+w\right)^2. \tag{57}$$

Note that the coefficients A, B, and C are functions of $\mathcal{E}$. Equation (56) can be easily solved to express E in terms of $\mathcal{E}$. The result is

$$E=E_\pm:=\frac{\mathcal{E}}{2}+\frac{-B\pm\sqrt{B^2-4AC}}{2A}. \tag{58}$$

The next step is to determine $\mathcal{E}$ using the variational principle, i.e., setting $dE/d\mathcal{E}=0$. The resulting formulas are complicated and we shall not include them here.

We conclude this section with the following remarks.

(1) As seen from Eq. (58), the first order Sturmian approximation leads to a pair of energy eigenvalues. For the potentials which are related to V_0 via a limiting process, one expects these two eigenvalues to be those labeled by m and n. That is, for $n<m$,

$$E_n=E_-, \quad E_m=E_+. \tag{59}$$

(2) In the variational Sturmian approximation of order one, there are two variational equations $dE_\pm/d\mathcal{E}=0$. It is not clear whether these equations lead to a unique minimum for $E_\pm(\mathcal{E})$ with a positive value for $\mathcal{E}$. As we shall show in the following sections, for all the specific examples that we have considered each of these equations lead to a unique minimum with a positive value for $\mathcal{E}$. Lack of such a solution may be interpreted as the failure of the variational Sturmian approximation of order one.

C. Variational Sturmian approximation of order two

In the variational Sturmian approximation of order two, one uses three Sturmians to expand the energy eigenvectors $|E\rangle$. We shall denote these by $|\phi_{n_l}\rangle$ where $n_l\in\mathcal{S}_3:=\{n_1,n_2,n_3\}$.

The matrices T, W, and S are given by

$$T=\begin{pmatrix} 1 & t_1^* & t_2^* \\ t_1 & 1 & t_3^* \\ t_2 & t_3 & 1 \end{pmatrix}, \quad W=\begin{pmatrix} v_3 & w_1^* & w_2^* \\ w_1 & v_2 & w_3^* \\ w_2 & w_3 & v_1 \end{pmatrix}, \tag{60}$$

$$S=\begin{pmatrix} v_3-\beta_{n_3}N_{n_3} & w_1^* & w_2^* \\ w_1 & v_2-\beta_{n_2}N_{n_2} & w_3^* \\ w_2 & w_3 & v_1-\beta_{n_1}N_{n_1} \end{pmatrix}, \tag{61}$$

where we have used the fact that $|\phi_{n_l}\rangle$ are normalized and introduced

$$t_1:=\langle\phi_{n_2}|\phi_{n_3}\rangle, \quad t_2:=\langle\phi_{n_1}|\phi_{n_3}\rangle, \quad t_3:=\langle\phi_{n_1}|\phi_{n_2}\rangle, \quad v_l:=\langle\phi_{n_l}|V|\phi_{n_l}\rangle, \tag{62}$$

$$w_1:=\langle\phi_{n_2}|V|\phi_{n_3}\rangle, \quad w_2:=\langle\phi_{n_1}|V|\phi_{n_3}\rangle, \quad w_3:=\langle\phi_{n_1}|V|\phi_{n_2}\rangle. \tag{63}$$

Because the harmonic oscillator Sturmian functions are real-valued, t_l, v_l, and w_l are real, and T, W, and S are real symmetric matrices.

In view of Eq. (40), we can write the secular equation (19) in the form

$$A\left(E-\frac{\mathcal{E}}{2}\right)^3+B\left(E-\frac{\mathcal{E}}{2}\right)^2+C\left(E-\frac{\mathcal{E}}{2}\right)+D=0, \tag{64}$$

where

$$A:=1-\sum_{l=1}^{3} t_l^2+2t_1t_2t_3, \tag{65}$$

$$B:=\sum_{l=1}^{3}\left[(t_l^2-1)v_l+2t_l\xi_l\right]-2(t_1t_2\xi_3+t_3t_1\xi_2+t_2t_3\xi_1), \tag{66}$$

$$C:=v_1v_2+v_2v_3+v_3v_1+2(t_1\xi_2\xi_3+t_3\xi_1\xi_2+t_2\xi_3\xi_1)-\sum_{l=1}^{3}(\xi_l^2+2t_lv_l\xi_l), \tag{67}$$

$$D := \sum_{l=1}^{3} v_l \xi_l^2 - 2\xi_1\xi_2\xi_3 - v_1 v_2 V_3, \tag{68}$$

$$\xi_l := \tfrac{1}{2} t_l \mathcal{E} + w_l. \tag{69}$$

Equation (64) has, in general, three solutions. The desired eigenvalues are the minima of these solutions corresponding to positive values of $\mathcal{E}$. Again for the cases where V is related to V_0 by a limiting process the minima of the solutions of Eq. (64) correspond to E_{n_1}, E_{n_2}, and E_{n_3}.

V. APPLICATIONS

In this section, we apply our general results to compute the energy eigenvalues of a quartic anharmonic oscillator, a quartic potential, and a Gaussian potential.

A. The quartic anharmonic oscillator

Consider the potential

$$V(x) = \frac{k}{2}x^2 + \epsilon x^4. \tag{70}$$

In order to obtain the energy levels of this potential using variational Sturmian approximation of order zero, we need to calculate ${}_n\langle n|V|l\rangle_n$. We first use Eqs. (38) to compute

$$\begin{aligned} {}_n\langle n|x^4|l\rangle_n = (2\alpha_n)^{-2}[&3(2n^2+2n+1)\delta_{l,n} + 4(n+1)\sqrt{(n+1)(n+2)}\,\delta_{l,n+2} \\ &+ 2(2n-1)\sqrt{n(n-1)}\,\delta_{l,n-2} + \sqrt{(n+1)(n+2)(n+3)(n+4)}\,\delta_{l,n+4} \\ &+ \sqrt{(n-3)(n-2)(n-1)n}\,\delta_{l,n-4}]. \end{aligned} \tag{71}$$

In view of this equation and Eqs. (39) and (70),

$$W = {}_n\langle n|V|n\rangle_n = \frac{(2n+1)k}{4\alpha_n} + \frac{3(2n^2+2n+1)\epsilon}{4\alpha_n^2}, \tag{72}$$

$${}_n\langle n|V|n+2\rangle_n = \sqrt{(n+1)(n+2)}\left(\frac{k}{4\alpha_n} + \frac{(n+1)\epsilon}{\alpha_n^2}\right), \tag{73}$$

$${}_n\langle n|V|n-2\rangle_n = \sqrt{n(n-1)}\left(\frac{k}{4\alpha_n} + \frac{(2n-1)\epsilon}{2\alpha_n^2}\right), \tag{74}$$

Next, we substitute Eqs. (73) and (74) in Eq. (50). Using Eq. (37), we then obtain

$$\mathcal{E}^3 - p_n\mathcal{E} - q_n = 0, \tag{75}$$

where

$$p_n := \left(\frac{\hbar^2 k}{m}\right)\left(n+\frac{1}{2}\right)^2, \quad q_n := \left(\frac{\hbar^4\epsilon}{2m^2}\right)\left(n+\frac{1}{2}\right)^2(11n^2+9n+4). \tag{76}$$

It is not difficult to show that Eq. (75) has a single positive solution [this is true for any positive p_n and q_n] given by[9]

$$\mathcal{E} = \left(\frac{q_n}{2}\right)^{1/3}(1+\sqrt{1-r_n})^{1/3} + \left(\frac{p_n}{3}\right)\left(\frac{2}{q_n}\right)^{1/3}(1+\sqrt{1-r_n})^{-1/3}, \tag{77}$$

TABLE I. First 10 energy levels of the Hamiltonian $H=p^2+x^2+(x^4/10)$ in units where $\hbar=1$. $E_n^{\#}$ are the highly accurate numerical values of Ref. 10. E_n are the values obtained using the zero order variational Sturmian approximation. $E_n^{\rm CSA}$ are the values obtained by the zero order conventional Sturmian approximation in Ref. 5. $E_n^{(0)}$ and $E_n^{(1)}$ are the energy eigenvalues obtained using the zero and first order perturbation theory, respectively.

where

$$r_n:=\frac{4p_n^3}{27q_n^2}=\left(\frac{8n+4}{11n^2+9n+4}\right)^2 r_0,\quad r_0:=\frac{mk^3}{108\hbar^2\epsilon^2}. \tag{78}$$

The right-hand side of Eq. (77) is manifestly real and positive for $r_n\leqslant 1$. It is not difficult to check that it is also real and positive for $r_n>1$. In fact, we can express $\mathcal{E}$ in the form

$$\mathcal{E}=2\sqrt{\frac{p_n}{3}}\cos\left(\frac{\phi_n}{3}\right)=\sqrt{\frac{k}{3m}}(2n+1)\cos\left(\frac{\phi_n}{3}\right), \tag{79}$$

where

$$\phi_n:=\tan^{-1}(\sqrt{r_n-1}). \tag{80}$$

Note that for $r_n<1$, ϕ_n is imaginary, but $\cos(\phi_n/3)$ is still real and positive.

Having fixed the parameter $\mathcal{E}$, we can determine the energy eigenvalues E_n using Eqs. (43) and (72). We first use Eqs. (37) and (79) to compute

$$\alpha_n=\left(\frac{2}{\hbar}\right)\sqrt{\frac{mk}{3}}\cos\left(\frac{\phi_n}{3}\right). \tag{81}$$

Then substituting this equation in Eq. (72) and using Eq. (43), we find

$$E_n=\left(\frac{\hbar}{24}\right)\sqrt{\frac{3k}{m}}(2n+1)\left[7+3\tan^2\left(\frac{\phi_n}{3}\right)\right]\cos\left(\frac{\phi_n}{3}\right)+\left(\frac{9\hbar^2\epsilon}{16mk}\right)(2n^2+2n+1)\left[1+\tan^2\left(\frac{\phi_n}{3}\right)\right]. \tag{82}$$

In particular, the ground state energy is given by

$$E_0=\left(\frac{\hbar}{24}\right)\sqrt{\frac{3k}{m}}\left[7+3\tan^2\left(\frac{\phi_0}{3}\right)\right]\cos\left(\frac{\phi_0}{3}\right)+\left(\frac{9\hbar^2\epsilon}{16mk}\right)\left[1+\tan^2\left(\frac{\phi_0}{3}\right)\right]. \tag{83}$$

In Table I, we list the numerical values obtained using Eq. (82) for the first 10 energy levels of a quartic anharmonic oscillator with $m=1/2$, $k=2$, $\epsilon=1/10$ in units where $\hbar=1$. This table also

TABLE II. Energy levels of the Hamiltonian $H=p^2+x^2+x^4/10$ obtained using the first order variational Sturmian approximation. δE_n stands for $|E_n-E_n^{\#}|/E_n^{\#}$.

includes the accurate numerical values of Ref. 10, the values obtained using the conventional Sturmian approximation and the zero and first order perturbation theory. [The zero and first order perturbation theory yield

$$E_n^{(0)}=\hbar(k/m)^{1/2}(n+1/2),\quad E_n^{(1)}=E_n^{(0)}+3\hbar^2\epsilon^2(2n^2+2n+1)/(4mk), \tag{84}$$

respectively.] The relative difference between the results of the variational Sturmian approximation of order zero with the highly accurate numerical results ($E_n^{\#}$) of Ref. 10, i.e., the quantity $|E_n-E_n^{\#}|/E_n^{\#}$, varies between 3.38×10^{-4} and 2.77×10^{-3}. For the ground state, this number is 1.53×10^{-3}. Even for the lowest lying energy levels where perturbation theory yields reliable results, the zero order variational Sturmian approximation produces more accurate values than both the zero and first order perturbation theory. As seen from Table I, the variational Sturmian approximation is better than the conventional Sturmian approximation.

In the remainder of this section we present the results obtained using the first and second order variational Sturmian approximation. The numerical results are respectively presented in Tables II and III.

As we explained in Sec. IV, in the variational Sturmian approximation of order one one chooses an indexing set $\mathcal{S}_2$ consisting of two Sturmians to be included in the expansion of the eigenvector $|E\rangle$. One then solves the corresponding secular equation (19), expresses the solutions $E_\pm$ in terms of the parameter $\mathcal{E}$, and finds the minima of $E_\pm(\mathcal{E})$. In general, $E_\pm$ are complicated functions of $\mathcal{E}$. However, it turns out that for all the cases that we considered $E_\pm$ has a unique minimum corresponding to a positive value of $\mathcal{E}$.

In order to choose the indexing set $\mathcal{S}_2$, we first note that the Sturmian functions $\langle x|\phi_n\rangle$ with even (respectively, odd) n are even (respectively odd) functions of x. We expect the energy eigenfunctions of the anharmonic oscillator (70) to have the same parity structure as the Sturmian functions. This, in particular, suggests that in the calculation of E_0 we should take $\mathcal{S}_2=\{0,2\}$.

For a quartic anharmonic oscillator with $m=1/2$, $k=2$, $\epsilon=1/10$, the first order variational Sturmian approximation corresponding to $\mathcal{S}_2=\{0,2\}$ yields $E_0=E_-=1.066\,14$ and $E_2=E_+=5.761\,17$. The value obtained for E_0 differs from the accurate numerical value by one part in 10^4. It is one order of magnitude better than the value obtained using the zero order variational Sturmian approximation. The value for E_2 is however less accurate. One may argue that the choice made for $\mathcal{S}_2$ is appropriate only for the ground state. In order to compute E_2 using the first order

TABLE III. Energy levels of the Hamiltonian $H=p^2+x^2+x^4/10$ obtained using the second order variational Sturmian approximation with the choice {0,2,4} for the indexing set $\mathcal{S}_3$. $E_n^{\#}$ are the highly accurate numerical values of Ref. 10.

n	$E_n^{\#}$	E_n	$\frac{\lvert E_n-E_n^{\#}\rvert}{E_n^{\#}}$
0	1.065 286	1.066 13	7.9×10^{-4}
2	5.750 52	5.752 75	8.3×10^{-4}
4	11.098 60	9.684 83	0.127

variational Sturmian approximation, one may alternatively choose $\mathcal{S}_2=\{2,4\}$. This choice yields $E_2=E_-=5.745\,58$ and $E_4=E_+=9.6637$. Again this value for E_2 is an order of magnitude better than the value obtained using the zero order variational Sturmian approximation, whereas the value for E_4 is less accurate. One can also try $\mathcal{S}_2=\{0,4\}$. As expected, this choice yields a less accurate value than the choices $\mathcal{S}_2=\{0,2\}$ and $\mathcal{S}_2=\{2,4\}$ for both E_0 and E_4.

For the calculation of the first excited state we choose $\mathcal{S}_2=\{1,3\}$. Then we find $E_1=E_-=3.309\,22$ and $E_3=E_+=8.372\,84$. Once again the first order variational Sturmian approximation of order one with the choice $\mathcal{S}_2=\{1,3\}$ yields a more accurate result for E_1 and a less accurate result for E_3.

In general, in the calculation of the energy levels E_n with $n\geqslant 2$, there are two alternative choices for the indexing set $\mathcal{S}_2$. In view of the parity properties of the eigenvectors, these are $\{n,n+2\}$ and $\{n-2,n\}$. The fact that there is no physical reason to distinguish between these two choices suggests that for these levels one should consider the second order variational Sturmian approximation with the choice $\mathcal{S}_3=\{n-2,n,n+2\}$.

Table III includes the results of the second order variational Sturmian approximation corresponding to the indexing set $\mathcal{S}_3=\{0,2,4\}$. This approximation yields more accurate values for E_0 than the zero and first order variational Sturmian approximations. However, contrary to our expectation the value obtained for E_2 is less accurate than the one given by the zero order approximation and the first order approximation with $\mathcal{S}_2=\{2,4\}$.

B. The quartic potential

Consider the quartic potential

$$V(x)=\epsilon x^4. \tag{85}$$

We can easily obtain the energy levels of this potential using the zero order variational Sturmian approximation by simply setting $k=0$ in our formulas for the quartic anharmonic oscillator. Substituting $k=0$ in (76), we can write Eq. (75) in the form

$$\mathcal{E}=q_n^{1/3}=\hbar\left(\frac{\hbar\epsilon}{2m^2}\right)^{1/3}\left[\left(n+\frac{1}{2}\right)^2(11n^2+9n+4)\right]^{1/3}. \tag{86}$$

In view of Eqs. (37), (43), (72), (86), and $k=0$, we have

$$\alpha_n=\hbar^{-1}(m\hbar\epsilon)^{1/3}\left(\frac{11n^2+9n+4}{2n+1}\right)^{1/3}, \tag{87}$$

$$E_n=\left(\frac{8n+4}{11n^2+9n+4}\right)^{2/3}\left(\frac{17}{7}n^2+\frac{15}{7}n+1\right)E_0, \tag{88}$$

$$E_0:=\frac{7\hbar}{8}\left(\frac{\hbar\epsilon}{2m^2}\right)^{1/3}. \tag{89}$$

In Table IV, we present the values obtained using Eq. (88) for the energy levels of a quartic potential with $m=1/2$ and $\epsilon=1$ in units where $\hbar=1$. This table also includes accurate numerical results $E_n^{\#}$ and the results of the zero and first order WKB approximation given in Refs. 11 and 12. The relative difference $|E_n-E_n^{\#}|/E_n^{\#}$ is about 0.04 for the ground state and ranges between 6.4×10^{-4} and 8.7×10^{-3} for the energy levels E_2,E_4,E_6,E_8,E_{10}, and E_{16}.

Table V includes the results of the first and second order variational Sturmian approximation for E_0,E_2, and E_4.

TABLE IV. Energy levels of the Hamiltonian $H=p^2+x^4$ in units where $\hbar=1$. $E_n^{\#}$ are the highly accurate numerical values of Refs. 11 and 12. E_n are the values obtained using the zero order variational Sturmian approximation. $E_n^{\mathrm{WKB}(0)}$ and $E_n^{\mathrm{WKB}(1)}$ are the values obtained using the zero and first order WKB approximation (Ref. 11), respectively.

C. The Gaussian potential

Consider the Gaussian potential

$$V(x)=-\lambda e^{-\epsilon x^2/2}. \tag{90}$$

In order to apply the results of Sec. IV to this potential, we write $V(x)=\tilde{V}(x)-\lambda$ where

$$\tilde{V}(x)=\lambda(1-e^{-\epsilon x^2/2}). \tag{91}$$

Then as ϵ tends to zero, $\tilde{V}(x)$ approaches to the harmonic oscillator potential (27) with $k=\lambda\epsilon$.

Clearly, the energy eigenvalues associated with V and $\tilde{V}$ are related by

$$E_n=\tilde{E}_n-\lambda. \tag{92}$$

In the following we use the zero order variational Sturmian approximation to obtain the ground state energy of the potential $\tilde{V}$. The excited energy levels can be obtained similarly.

We first note that for the ground state $n=0$, and Eq. (50) for the potential $\tilde{V}$ takes the form

$$\mathcal{E}=\sqrt{2}\,{}_0\langle 0|\tilde{V}|2\rangle_0=\sqrt{2}{}_0\langle 0|V|2\rangle_0=-\sqrt{2}\lambda\,{}_0\langle 0|e^{-\epsilon x^2/2}|2\rangle_0=-\sqrt{2}\lambda\int_{-\infty}^{\infty}{}_0\langle 0|x\rangle e^{-\epsilon x^2/2}\langle x|2\rangle_0\,dx. \tag{93}$$

We can evaluate the right-hand side of (93) using the well-known expression for the eigenfunctions of the harmonic oscillator, namely (32) and

$$\langle x|2\rangle_0=\left(\frac{\alpha_0}{4\pi}\right)^{1/4}(2\alpha_0x^2-1)e^{-\alpha_0x^2/2}. \tag{94}$$

TABLE V. Energy levels of the Hamiltonian $H=p^2+x^4$ obtained using the first and second order variational Sturmian approximation. N is the order of the approximation. $E_n^{\#}$ are the accurate numerical results reported in Ref. 11.

Substituting Eqs. (32) and (94) in Eq. (93) and performing the necessary calculations, we find

$$\mathcal{E}(\mathcal{E}+p)^3=\lambda^2p^2, \tag{95}$$

where

$$p:=\frac{\hbar^2\epsilon}{4m}. \tag{96}$$

Introducing

$$\eta:=1+\frac{\mathcal{E}}{p}, \tag{97}$$

we can write Eq. (95) in the form

$$f(\eta):=\eta^4-\eta^3-r=0, \tag{98}$$

where

$$r:=\frac{\lambda^2}{p^2}=\frac{16\lambda^2m^2}{\hbar^4\epsilon^2}. \tag{99}$$

It is not difficult to show that for all $r>0$, $f(\eta)$ has a single minimum at $\eta=3/4$. The minimum is $f(3/4)=-(27/256+r)<0$. Furthermore, $f(0)=f(1)=-r<0$ and $\lim_{\eta\to\infty}f(\eta)=\infty$. Therefore, $f(\eta)$ has a single positive root that is greater than 1. This root is given by

$$\eta_\star=\tfrac{1}{4}(1+2\xi+\sqrt{3-4\xi^2+\xi^{-1}}), \tag{100}$$

where

$$\xi:=\tfrac{1}{2}\sqrt{1-a+b},\quad a:=\tfrac{3}{2}\zeta(1+\sqrt{1+\zeta^3})^{1/3},$$

$$b:=\tfrac{3}{2}\zeta(-1+\sqrt{1+\zeta^3})^{1/3},\quad \zeta:=\frac{4}{3}(4r)^{1/3}.$$

In view of Eq. (97) and the fact that $\eta_0>1$, Eq. (95) has a single positive solution, namely

$$\mathcal{E}=p(\eta_\star-1). \tag{101}$$

Having obtained the parameter $\mathcal{E}$, we next compute

$$W={}_0\langle 0|\tilde{V}|0\rangle_0=\lambda(1-\sqrt{1-\eta_\star^{-1}}). \tag{102}$$

Here we have made use of Eqs. (32), (37), (91), (96), and (101). Substituting this equation and Eq. (101) in Eq. (43) and using Eqs. (92) and (99), we find the ground state energy of the Gaussian potential (90) to be

$$E_0=\tilde{E}_0-\lambda=-\lambda\left[\sqrt{1-\eta_\star^{-1}}+\frac{1-\eta_\star}{2\sqrt{r}}\right]. \tag{103}$$

In order to reveal the asymptotic behavior of E_0, we investigate the power series expansion of the right-hand side of Eq. (103).

For $r\gg 1$, i.e., $(\epsilon/\lambda)\to 0$,

$$E_0 = -\lambda[1 - r^{-1/4} + \tfrac{3}{8}r^{-1/2} - \tfrac{1}{32}r^{-3/4} - \tfrac{1}{128}r^{-1} + \mathcal{O}(r^{-5/4})]. \tag{104}$$

For $r \ll 1$, i.e., $(\epsilon/\lambda) \to \infty$,

$$E_0 = -\left(\frac{\lambda\sqrt{r}}{2}\right)[1 - r + 3r^2 - 13r^3 + 68r^4 + \mathcal{O}(r^5)]. \tag{105}$$

Therefore, for fixed λ,

$$\lim_{\epsilon \to 0^+} E_0 = -\lambda, \tag{106}$$

$$\lim_{\epsilon \to \infty} E_0 = \lim_{\epsilon \to \infty}\left[-\frac{4m^2\lambda^2}{\hbar^2\epsilon}\right] = 0^-, \tag{107}$$

and for fixed ϵ,

$$\lim_{\lambda \to 0^+} E_0 = \lim_{\lambda \to 0}\left[-\frac{4m^2\lambda^2}{\hbar^2\epsilon}\right] = 0^-, \tag{108}$$

$$\lim_{\lambda \to \infty} E_0 = -\infty. \tag{109}$$

Clearly, the asymptotic behavior of E_0, as given by Eqs. (106)–(109), agrees with the qualitative analysis of the eigenvalue problem for the Gaussian potential.

It is not difficult to see that in the limit $\epsilon \to 0$ perturbation theory provides reliable results. Writing the Gaussian potential (90) in the form

$$V = V_0 + \delta V, \tag{110}$$

with V_0 given by Eq. (23) and performing the standard calculations,[1] we find that the zero and first order perturbation theory yield, respectively,

$$E_0^{(0)} = -\lambda(1 - r^{-1/4}), \tag{111}$$

$$E_0^{(1)} = -\lambda(1 + r^{-1/4})^{-1/2} = -\lambda[1 - \tfrac{1}{2}r^{-1/4} + \tfrac{3}{8}r^{-1/2} - \tfrac{5}{16}r^{-3/4} + \mathcal{O}(r^{-1})]. \tag{112}$$

Here $E_0^{(l)}$ is the ground state energy for the Gaussian potential (90) obtained using the lth order perturbation theory.

Comparing Eq. (104) with Eqs. (111) and (112), one finds that in the pertubative region where $r \gg 1$, the variational Sturmian approximation of order zero agrees with the results of the perturbation theory. In fact, since by construction E_0 is the expectation value of the energy of the Sturmian $|\phi_0\rangle$, the fact that $E_0 < E_0^{(0)}$ shows that even in the pertubative region the variational Sturmian approximation of order zero is a better approximation than the zero order perturbation theory. By the same reasoning, because $E_0 > E_0^{(1)}$, the first order perturbation theory yields a better result. Note however that the wave function obtained in the first order perturbation theory is an infinite sum whereas the wave function in the zero order Sturmian approximation is given explicitly.

Another interesting limit is the delta function limit of the potential V where $\lambda = a\sqrt{\epsilon/(2\pi)}$, $\epsilon \to \infty$, and $V(x) \to -a\,\delta(x)$. Here a is a fixed coupling constant. In this limit $r \to 0$ and the ground state energy is given by Eq. (105) according to

$$E_0 = -\frac{ma^2}{\pi\hbar^2}. \tag{113}$$

This result has the same order of magnitude as the exact result:

$$E_0 = -\frac{ma^2}{2\hbar^2}. \tag{114}$$

VI. DISCUSSION AND CONCLUSION

We have outlined a variationally improved Sturmian approximation and applied our results to the harmonic oscillator Sturmians. For these Sturmians we could solve the associated variational problem in the zero order Sturmian approximation exactly. We have used our variational Sturmian approximation in the calculation of the energy levels of various potentials. We have shown that using a few harmonic oscillator Sturmians, one obtains quite reliable results. In general, the variational Sturmian approximation is a better approximation than the conventional Sturmian approximation.

Because the harmonic oscillator potential is a confining potential, we expect that the method is more suitable for the confining potentials such as the quartic anharmonic oscillator and the quartic potential. We can base this argument on a more quantitative reasoning by addressing the problem of classifying the potentials for which the Sturmian approximation is exact. It is not difficult to show that these potentials satisfy

$$V(\vec{x}) = E - \mathcal{E} + \left(\frac{\Sigma_{\nu=0}^{N} \Sigma_{\alpha} C_{\nu}^{\alpha} \beta_{\nu} \phi_{\nu,\alpha}(\vec{x})}{\Sigma_{\nu=0}^{N} C_{\nu}^{\alpha} \phi_{\nu,\alpha}(\vec{x})} \right) V_0(\vec{x}), \tag{115}$$

where E, $\mathcal{E}$, and C_{ν}^{α} are constants and $\phi_{\nu,\alpha}(\vec{x}) := \langle \vec{x} | \phi_{\nu}, \alpha \rangle$. Equation (115) follows from Eqs. (1), (2), (3), and (11).

For example, the potentials for which the first order harmonic oscillator Sturmian approximation with $\mathcal{S}_2 = \{0,2\}$ yields an exact eigenfunction are of the form

$$V(x) = E - \frac{\hbar^2 \alpha_0}{2m} + \left(\frac{\hbar^2 \alpha_0^2}{2m} \right) \left[\frac{e^{-2\alpha_0 x^2/5} + \left(\frac{\zeta}{5} \right)(2\alpha_0 x^2 - 5)}{e^{-2\alpha_0 x^2/5} + 5\zeta(2\alpha_0 x^2 - 5)} \right] x^2, \tag{116}$$

where α_0 is a real parameter with the dimension of (length)$^{-2}$ and ζ is a dimensionless real parameter. As seen from Eq. (116), these potentials tend to the harmonic oscillator potential for $|x| \to \infty$. In particular, as $|x| \to \infty$, $V \to \infty$. This asymptotic behavior is also valid for higher order harmonic oscillator Sturmian approximations. This observation shows that the harmonic oscillator Sturmian approximation is more reliable for confining potentials.

We conclude this paper with a couple of remarks.

(1) The variational principle used in the variational Sturmian approximation leads to an algebraic (nondifferential) equation for the parameter $\mathcal{E}$. The acceptable solutions for this equation are those which are real and positive. The fact that for all the cases we consider there is a unique real positive solution corresponding to each eigenvalue E_n is quite remarkable. This observation may be viewed as a consistency check for the Sturmian approximation.

(2) In our selection of the Sturmians in the first and higher order Sturmian approximation, we used the information about the parity properties of the Sturmians and the energy eigenfunctions. For example we ruled out the first order variational Sturmian approximation with $\mathcal{S}_2 = \{0,1\}$. If we perform the necessary calculations, we find that for this choice the functions t and w vanish identically and the matrices T and S are diagonal. Therefore, the secular equation (19) yields the same results as the zero order Sturmian approximation. This can also be seen from the results of Ref. 5.

Hartree approximation I: The fixed point approach

E. Prodan[a] and P. Nordlander
Rice University, Department of Physics—MS 61, 6100 Main Street, Houston, Texas 77005-1892

(Received 7 February 2001; accepted for publication 10 April 2001)

We consider the Hartree approximation at finite temperature. We give a justification of this approximation by using the methods of functional integration. For finite temperatures, a fixed point approach to solving the Hartree problem is proposed. For a class of two-body interactions and background potentials that includes the Coulomb interaction, we prove that the Hartree equation has a unique solution provided the coupling constant is small. We also prove a similar result for local density theory. © *2001 American Institute of Physics.* [DOI: 10.1063/1.1379747]

I. INTRODUCTION

For an interacting fermionic system, we consider the approximation that, diagrammatically, can be written as in Fig. 1. In solid state physics, this approximation is also called the Hartree approximation. This approximation is different from the classical Hartree approximation,[1–3] which neglects the Fermi–Dirac statistics for particles. In the following, we will refer to diagram 1 (including the Fermi–Dirac statistics) as the Hartree approximation. The equations for this approximation [see Eqs. (16) and (18)] are formally the same as the equations for the restricted classical Hartree approximation. Consider for example zero temperature. Then, in both cases, the equations are $(H_0+n*v)\,\eta_i=\lambda_i\eta_i$, where $n=\Sigma_i|\eta_i|^2$ is the density of particles and v is the two-body interaction. In the restricted classical Hartree approximation, the only constraint imposed on $\{\eta_i\}_i$ is that they are normalized.[4] These functions can be the same, for example. Thus, this constraint does not prevent particles from collapsing into a single state. This problem has been considered in Ref. 5 and classified as an open question. In a recent paper,[6] it was proven that indeed, for the restricted classical Hartree problem, particles do collapse into a single state under special conditions and the approximation reduces to a purely local density approximation. For what we here call the Hartree approximation, this collapse will not happen because of the Pauli exclusion principle, which only allows one particle in each state. We also mention that the classical Hartree approximation cannot be extended at finite temperatures. For this, one has to assume a statistics on the particles.

One can see that the Hartree approximation follows from the Hartree–Fock approximation if one omits the exchange diagram (Fig. 2). Let us mention a few reasons why the Hartree approximation is of interest. One reason for considering this approximation rather than the Hartree–Fock approximation is that the later one may give up to 100% error when applied to homogeneous electron gas.[7] Another reason is that analyzing diagram 1 is the first step towards a rigorous analysis of the solutions of the local density approximation. Also, we found that the Hartree approximation is equivalent to the Gaussian approximation.[8] Given the importance of the Gaussian approximation in the study of the bosonic quantum fields, this equivalence is another strong reason for considering the Hartree approximation. Finally, this approximation may be interesting because the symmetry breaking phenomenon is present. We found that, at low temperatures and in the absence of any background potential, the stable solution of the Hartree equation corresponds to a nonuniform, periodic density of particles.

We decided to divide our results in three parts, where three important aspects of this model are analyzed. Our analysis covers only the small limit of the coupling constants. In the first part, we

[a]Electronic mail: emprodan@rice.edu

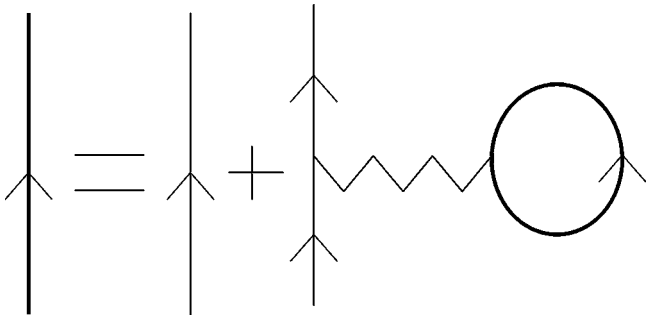

FIG. 1. The Hartree equation: the thick lines represents the exact propagator.

investigate the Hartree approximation for finite systems (i.e., finite volumes and finite number of particles). In the second part, we investigate the thermodynamic limit and in the third part we present the proof of a symmetry breaking within this model. This paper includes the first part. The main result is that, at finite temperatures, the Hartree equation can be formulated as a fixed point problem. The fixed point approach is used then to prove that there is a unique solution to the Hartree equations, provided the coupling constant is small enough. A similar result is proven for the local density theory. The fixed point approach has been advocated by some pedagogical text books[9] as a standard method for solving the Hartree or Hartree–Fock equations. Various iterative schemes have been proposed for finding this fixed point. In practice, all these iterative schemes may have convergence problems,[10–12] and there are only a few rigorous results about their convergency.[11–14] The fact that these schemes converge does not necessarily mean that the absolute minimum of the energy has been achieved. All one can say, in general, is that the absolute minimum exists.[4,5] The uniqueness is still an open problem.[15] To our knowledge, our result is the first step in this direction. Unfortunately, the result is valid only in the small limit of the coupling constants. Still, as we shall see, this limit is not trivial at all.

II. HARTREE APPROXIMATION FROM A FUNCTIONAL INTEGRAL POINT OF VIEW

We consider in this paper only spin independent interactions. Therefore, we will not take into account the spin degree of freedom. Let us consider a two-body interaction:

$$L_I=\frac{1}{2}\int \psi^\dagger(\vec{x})\psi^\dagger(\vec{y})v(\vec{x}-\vec{y})\psi(\vec{y})\psi(\vec{x})d\vec{x}\,d\vec{y}. \tag{1}$$

Suppose that the one particle system is described by a Hamiltonian $H_0:\mathcal{D}(H_0)\subset\mathcal{H}\to\mathcal{H}$, where $\mathcal{H}$ is a Hilbert space. In the Euclidean region (i.e., imaginary time), the system is described by the interacting measure:[16]

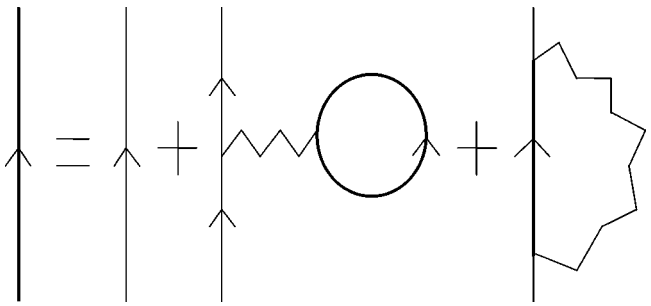

FIG. 2. The Hartree–Fock equation: the thick line represents the exact propagator.

$$d\mu = e^{-\mathcal{A}(\psi^\dagger,\psi)} d\mu_C \Big/ \int e^{-\mathcal{A}(\psi^\dagger,\psi)} d\mu_C, \tag{2}$$

where the action is given by

$$\mathcal{A}(\psi^\dagger,\psi) = \frac{1}{2}\int \psi^\dagger(\vec{x},\tau)\psi^\dagger(\vec{y},\tau')v(\vec{x}-\vec{y})\delta(\tau-\tau')\psi(\vec{y},\tau')\psi(\vec{x},\tau)d\vec{x}\,d\tau\,d\vec{y}\,\tau'. \tag{3}$$

The Grassmann Gaussian measure, μ_C, corresponds to covariance:

$$C = (\partial_\tau + H_0 - \mu)^{-1}. \tag{4}$$

The variable τ takes values in $I=[-\beta/2,\beta/2]$ and anti-periodic boundary conditions are imposed at $\pm\beta/2$. By using the anti-commutation relations (in the Euclidean region, ψ and $\psi^\dagger$ anti-commutes), the action can be written in the analogous form

$$\mathcal{A}(\psi^\dagger,\psi) = \frac{1}{2}\int [\hat{n}(\vec{x},\tau)-n(\vec{x})]v(\vec{x}-\vec{y})\delta(\tau-\tau')[\hat{n}(\vec{y},\tau')-n(\vec{y})]d\vec{x}\,d\tau\,d\vec{y}\,\tau'$$
$$+\int V_n(\vec{x})\hat{n}(\vec{x},\tau)d\vec{x}\,d\tau - E_n, \tag{5}$$

where $\hat{n}(\vec{x},\tau)=\psi^\dagger(\vec{x},\tau)\psi(\vec{x},\tau)$ is the density of particles operator, V_n and E_n are given by

$$V_n(\vec{x}) = \int v(\vec{x}-\vec{y})n(\vec{y})d\vec{y}, \tag{6}$$

$$E_n = \beta/2\int n(\vec{x})v(\vec{x}-\vec{y})n(\vec{y})d\vec{x}\,d\vec{y}, \tag{7}$$

and $n(\vec{x})$ is yet an unknown function. The way to the Hartree approximation is similar to the way to the Gaussian approximation for boson fields.[8] Our goal is to cancel the quadratic term of the action by a change of covariance and by normal ordering.

Proposition 1: Let C' be defined by

$$C' = (\partial_\tau + H_0 + V_n - \mu)^{-1}.$$

Then

$$d\mu = e^{-\mathcal{A}'(\psi^\dagger,\psi)} d\mu_{C'} \Big/ \int e^{-\mathcal{A}'(\psi^\dagger,\psi)} d\mu_{C'},$$

where

$$\mathcal{A}'(\psi^\dagger,\psi) = \frac{1}{2}\int (\hat{n}(x)-n(\vec{x}))v(x-y)(\hat{n}(y)-n(\vec{y}))dx\,dy,$$

and $v(x-y)\equiv v(\vec{x}-\vec{y})\delta(\tau-\tau')$. We denoted $x\equiv(\tau,\vec{x})$.

Proof: Let us consider an orthonormal basis $\{e_j\}_{j\in\mathbf{N}}$. For $f\in\mathcal{H}$, we use the notation

$$\psi(f) \equiv \int dx f(x)\psi(x). \tag{8}$$

The quadratic term can be expressed as

$$\int V_n(\vec{x})\hat{n}(x)dx=\Sigma_{i,j}\langle e_i, V_n(\vec{x})e_j\rangle \psi^\dagger(e_i)\psi(e_j). \tag{9}$$

We notice that this operator commutes with the field operator. Then we have successively

$$\begin{aligned} e^{-\int V_n(\vec{x})\hat{n}(x)dx}\, d\mu_C &= e^{-\Sigma_{i,j}\langle e_i, V_n e_j\rangle \psi^\dagger(e_i)\psi(e_j)}\frac{1}{\det C^{-1}}\, e^{-\Sigma_{i,j}\langle e_i, C^{-1}e_j\rangle \psi^\dagger(e_i)\psi(e_j)}\prod_{i,j} d\psi^\dagger(e_i)d\psi(e_j) \\ &= \frac{1}{\det C^{-1}}\, e^{-\Sigma_{i,j}\langle e_i(C^{-1}+V_n)e_j\rangle \psi^\dagger(e_i)\psi(e_j)}\prod_{i,j} d\psi^\dagger(e_i)d\psi(e_j) \\ &= \frac{\det[1+V_nC]}{\det C'^{-1}}\, e^{-\Sigma_{i,j}\langle e_i, C'^{-1}e_j\rangle \psi^\dagger(e_i)\psi(e_j)}\prod_{i,j} d\psi^\dagger(e_i)d\psi(e_j) \\ &= \det[1+V_nC]d\mu_{C'}. \end{aligned} \tag{10}$$

This is in fact the Gaussian identity for fermions. With this expression, the proposition follows immediately. ■

The next step is to observe that if

$$\langle \hat{n}(x)\rangle_{\mu_{C'}} \equiv \int \hat{n}(x)d\mu_{C'} = n(\vec{x}), \tag{11}$$

then

$$\hat{n}(x)-n(\vec{x})=:\psi^\dagger(x)\psi(x):_{\mu_{C'}}, \tag{12}$$

the normal ordering with respect to the measure $\mu_{C'}$. Condition (11) is a self-consistent equation for n and, as we shall see, it coincides with the Hartree equation. Let us summarize. We proved that, if (11) has a solution, the original interacting measure is equal to

$$d\mu = e^{-\mathcal{A}'(\psi^\dagger,\psi)}d\mu_{C_{\mathrm{H}}} \Big/ \int e^{-\mathcal{A}'(\psi^\dagger,\psi)}d\mu_{C_{\mathrm{H}}}, \tag{13}$$

where

$$\mathcal{A}'(\psi^\dagger,\psi)=\frac{1}{2}\int :\psi^\dagger(x)\psi(x):_{\mu_{C_{\mathrm{H}}}} v(x-y):\psi^\dagger(y)\psi(y):_{\mu_{C_{\mathrm{H}}}} dx\, dy. \tag{14}$$

The covariance C_{H} is constructed from the solution to the Hartree equations through Eq. (17). Indeed, a simple calculus shows

$$\langle \hat{n}(x)\rangle_{\mu_{C'}} = -C'(\vec{x},\tau;\vec{x},\tau+0). \tag{15}$$

If $\{\eta_i,\varepsilon_i\}_i$ is the set of eigenvectors and the corresponding eigenvalues of H_0+V_n:

$$\left(H_0+\int v(\vec{x}-\vec{y})n(\vec{y})d\vec{y}\right)\eta_i=\varepsilon_i\eta_i; \tag{16}$$

then

$$C'(\vec{x},\tau;\vec{x}',\tau')=\Sigma_i \eta_i(\vec{x})\,\eta_i(\vec{x}')^* e^{-\xi_i(\tau-\tau')}\begin{cases} 1-f_\beta(\xi_i), & \text{for } \tau\geqslant\tau', \\ -f_\beta(\xi_i), & \text{for } \tau<\tau', \end{cases} \tag{17}$$

where $\xi_i=\varepsilon_i-\mu$ and $f_\beta(x)=(1+e^{\beta x})^{-1}$ is the Fermi–Dirac distribution. Then Eq. (11) reduces to

$$n(\vec{x})=\Sigma_i f_\beta(\xi_i)|\eta_i(\vec{x})|^2. \tag{18}$$

One can recognize in (16) and (18) the usual Hartree equations. Thus, from the functional integral point of view, the Hartree approximation is just a convenient (probably the best) starting point for future expansions. This is because, due to the normal ordering in $\mathcal{A}'(\psi^\dagger,\psi)$, the tadpole diagrams are no longer present in any diagrammatic analysis beyond the Hartree approximation: they have been absorbed in the covariance C_{H}. We end this section by noticing that already condition (11) suggests a fixed point approach for this problem. This is developed in the next section.

III. THE FIXED POINT APPROACH

From now on, H_0 will be the sum of $-\frac{1}{2}\Delta_{\mathrm{D}}$ and a background potential U, defined over a finite box $\mathrm{vol}=[-a,a]^d\in R^d$, $d\geqslant 1$. We denoted by Δ_{D} the Laplace operator with Dirichlet boundary conditions (other boundary conditions can be also considered). Later calculations (Sec. IV) force us to define H_0 through the Kato–Relich theorem. More precisely, we need the same type of estimates as in the Kato–Relich theorem. Thus it is natural to define the Hamiltonian in this way. In the variational approach, is natural to define the Hamiltonian through the KLM theorem,[17] based on estimates on the symmetric quadratic forms which are needed anyway in this approach. The class of potentials included in the later case is larger than the class of potentials we can include in our approach. We start with the following result.

Proposition 2: Let $V\in L^p(\mathrm{vol})$, $p\geqslant\max\{2,(d+1)/2\}$. *Let* Λ *denote the lattice* $[(\pi/2a)Z_+]^d$, *where* Z_+ *is the set of strictly positive integers and let* $\Delta^d\vec{k}=(\pi/2a)^d$ *be the volume of its unit cell. Then, for* $f\in D(-\frac{1}{2}\Delta_{\mathrm{D}})$ *and* $z\notin R_+$ *:*

$$\|Vf\|_{L^2(\mathrm{vol})}\leqslant k_{p,z}\|V\|_{L^p(\mathrm{pol})}\|(-\tfrac{1}{2}\Delta_{\mathrm{D}}-z)f\|_{L^2(\mathrm{vol})}.$$

The constant is given by

$$k_{p,z}=[(\pi/2)^d\Sigma_{\vec{k}\in\Lambda}|\tfrac{1}{2}\vec{k}^2-z|^{-p}\Delta^d\vec{k}]^{1/p}.$$

Proof: This will be an extension of the estimates presented in Ref. 17 (p. 171) to the case when the boundary conditions are present. The eigenvalues and eigenstates of $-\frac{1}{2}\Delta_{\mathrm{D}}$ are labeled by a point of the lattice Λ:

$$\vec{k}=\left(\frac{\pi}{2a}n_1,\ldots,\frac{\pi}{2a}n_d\right). \tag{19}$$

They are given by

$$E_{\vec{k}}=\frac{1}{2}\vec{k}^2,\quad \phi_{\vec{k}}(x)=a^{-d/2}\prod_{i=1}^{d}\varphi_{n_i}(x_i/a), \tag{20}$$

where

$$\varphi_n(x)=\begin{cases}\sin(n\pi x/2), & \text{for } n=1,3,5,\ldots,\\ \cos(n\pi x/2), & \text{for } n=2,4,6,\ldots.\end{cases} \tag{21}$$

We denote by l^p the Banach space of p-summable infinite sequences. For $f\in L^2(\mathrm{vol})$, we denote by $\Sigma_{\vec{k}\in\Lambda}f_{\vec{k}}\phi_{\vec{k}}(x)$ its decomposition in the basis $\{\phi_{\vec{k}}\}_{\vec{k}\in\Lambda}$. We need to prove first a Hausdorf–Young type inequality, namely,

$$\|f\|_{L^q(\mathrm{vol})} \leqslant a^{-(d/2)(1/p-1/q)} \|\{f_{\vec{k}}\}_{\vec{k}\in\Lambda}\|_{l^p}, \quad \frac{1}{q}+\frac{1}{p}=1, q\geqslant 2. \tag{22}$$

This inequality follows from

$$\|f\|_{L^\infty(\mathrm{vol})} \leqslant a^{-d/2} \|\{f_{\vec{k}}\}_{\vec{k}\in\Lambda}\|_{l^1} \text{ and } \|f\|_{L^2(\mathrm{vol})} = \|\{f_{\vec{k}}\}_{\vec{k}\in\Lambda}\|_{l^2}, \tag{23}$$

which can be interpolated using the Riesz–Thorin theorem to get (22). Then, for an arbitrary $f \in D(-\frac{1}{2}\Delta_{\mathrm{D}})$ and $1/p+1/r=1/2$:

$$\begin{aligned} \|Vf\|_{L^2(\mathrm{vol})} &\leqslant \|V\|_{L^p(\mathrm{vol})} \|f\|_{L^r(\mathrm{vol})} \\ &\leqslant a^{-(d/2)(1/q-1/r)} \|V\|_{L^p(\mathrm{vol})} \|\{f_{\vec{k}}\}_{\vec{k}\in\Lambda}\|_{l^q}, \end{aligned} \tag{24}$$

with $1/r+1/q=1$. Moreover,

$$\begin{aligned} \|\{f_{\vec{k}}\}_{k\in\Lambda}\|_{l^q} &= \|\{(\tfrac{1}{2}\vec{k}^2-z)^{-1}(\tfrac{1}{2}\vec{k}^2-z) f_{\vec{k}}\}_{\vec{k}\in\Lambda}\|_{l^q} \\ &\leqslant \|\{(\tfrac{1}{2}\vec{k}^2-z)^{-1}\}_{\vec{k}\in\Lambda}\|_{l^s} \|\{(\tfrac{1}{2}\vec{k}^2-z) f_{\vec{k}}\}_{\vec{k}\in\Lambda}\|_{l^2} \\ &= \|\{(\tfrac{1}{2}\vec{k}^2-z)^{-1}\|_{\vec{k}\in\Lambda}\|_{l^s} \|(-\tfrac{1}{2}\Delta_{\mathrm{D}}-z) f\|_{L^2(\mathrm{vol})}, \end{aligned} \tag{25}$$

where $1/q=1/s+1/2$. In fact this constraint imposes $s=p$. We can conclude that

$$\|Vf\|_{L^2(\mathrm{vol})} \leqslant a^{-d/p} \|\{(\tfrac{1}{2}\vec{k}^2-z)^{-1}\}_{\vec{k}\in\Lambda}\|_{l^p} \|(-\tfrac{1}{2}\Delta_{\mathrm{D}}-z) f\|_{L^2(\mathrm{vol})}. \tag{26}$$

In the above relation, p must be greater than $(d+1)/2$ in order to have a finite right hand side. The starting constraint $1/p+1/r=1/2$ imposes $p\geqslant 2$ and this finishes the proof. ■

Proposition 3: Suppose the two-body interaction, v, belongs to $L^p(R^d)$. Then so it does V_n as long as $n \in L^1(\mathrm{vol})$.

Proof: Because the two-body interaction is given, in general, over R^d, we can extend $V_n = v*n$ over the entire R^d. Then, from the Young inequality,

$$\begin{aligned} \|V_n\|_{L^p(\mathrm{vol})} &\leqslant \|V_n\|_{L^p(R^d)} \\ &\leqslant \|v\|_{L^p(R^d)} \|\chi_{\mathrm{vol}} n\|_{L^1(R^d)} = \|v\|_{L^p(R^d)} \|n\|_{L^1(\mathrm{vol})}. \end{aligned} \tag{27}$$

■

From the above estimates, it seems that a natural class of potentials and two-body interactions will be L^p with $p\geqslant \max\{2,(d+1)/2\}$. For a given potential, we have, in general, to take care of its singularities and the way it decreases to infinity. We can separate them by dividing the potential in two: one part includes the singularities and the other part includes the behavior at infinity. Thus a more natural class of potentials will be L^p+L^q, where p must be small to include the singularities and q large to include different decays at infinity. In fact, based on our previous estimates, the optimal class will be L^m+L^∞, where $m=\max\{2,(d+1)/2\}$. We do not know if our estimates are optimal. However, for $d=3$, it follows from Ref. 17 [problem (14)] that L^2+L^∞ is indeed the maximal class of potentials for which the Kato–Relich theorem applies. Thus we will consider from now on that $U\in L^m(\mathrm{vol})+L^\infty(\mathrm{vol})$ and $v\in L^m(R^d)+L^\infty(R^d)$. This potential can be as singular as $|x|^{-(d-1)/2-\varepsilon}$ with $\varepsilon<1/2$. For $d=3$, this includes the Coulomb interaction. Along this paper, $\|\cdot\|$ will denote the operatorial norm on $L^2(\mathrm{vol})$.

Theorem 4: *Suppose the background and the two-body interaction satisfies the above conditions and let $U=U^{(1)}+U^{(2)}$ and $v=v^{(1)}+v^{(2)}$ be a decomposition in L^m+L^∞. Then we have the following.*

(i) $H_0=-\frac{1}{2}\Delta_{\mathrm{D}}+U$ and $H_n=H_0+V_n$ are self-adjoint on $D(-1/2\Delta_{\mathrm{D}})$.

(ii) H_0 and H_n have only pure punctual spectrum.

(iii) $\exp(-H_0)$ *is of trace class.*
(iv) For $z \notin \sigma_{H_0} \cup R_+$ *:*

$$\|V_n(H_0-z)^{-1}\| \leqslant K_1(z)\|n\|_{L^1(\mathrm{vol})},$$

where the constant is given by:

$$K_1(z)=k_{m,z}(1+\|U(H_0-z)^{-1}\|)\|v^{(1)}\|_{L^m(R^d)}+d(z,\sigma_{H_0})^{-1}\|v^{(2)}\|_{L^\infty(R^d)},$$

and

$$\|U(H_0-z)^{-1}\| \leqslant (1-k_{m,z}\|U^{(1)}\|_{L^m(\mathrm{vol})})^{-1}\{k_{m,z}\|U^{(1)}\|_{L^m(\mathrm{vol})}+d(z,\sigma_{H_0})^{-1}\|U^{(2)}\|_{L^\infty(\mathrm{vol})}\}.$$

Proof: (i) The affirmation follows from the Kato–Relich theorem.
(ii) Both operators have compact resolvents which can be easily seen from resolvent identity.
(iii) Using a technique that will be extensively used later, the affirmation follows from the fact that $\exp(\frac{1}{2}\Delta_D)$ is trace class operator.[18]
(iv) It easily follows from Propositions 1 and 2. ■

We are ready now to define the fixed point approach. If the total number of particles, N, is conserved, then we must impose the following constraint: $\|n\|_{L^1}=N$.

Proposition 5: In the above conditions, for $\beta<\infty$*, we have the following.*

(i) The map:

$$T: L^1(\mathrm{vol}) \to L^1(\mathrm{vol}),$$

$$L^1(\mathrm{vol}) \ni n \to T[n](\vec{x})=(1+e^{\beta(H_0+V_n-\mu_n)})^{-1}(\vec{x},\vec{x}),$$

is well defined. Here, μ_n *is the unique solution of*

$$N=\mathrm{Tr}(1+e^{\beta(H_0+V_n-\mu)})^{-1}.$$

(ii) The fixed points of T are solutions for the Hartree equation.

Proof: (*i*) The proof is based on the following classic result.[19]

Proposition 6: For A a trace class, self-adjoint operator and ϕ *a convex function on* $\sigma(A)$*, the following is true:*

$$\mathrm{Tr}\phi(A) \geqslant \sum_m \phi((\eta_m, A\eta_m)),$$

where $\{\eta_m\}_m$ *is any complete orthonormal set.*

We use $\|\cdot\|_1$ to denote the trace norm. Also, let us denote $\phi_{\mu,\beta}(t)\equiv(1+e^{\beta(t-\mu)})^{-1}$. For a large, positive α, let

$$\gamma_\alpha=\|V_n(H_0+\alpha)^{-1}\|, \tag{28}$$

which is a decreasing function of α. Consider $\{\eta_m,\varepsilon_m\}_m$, the eigenvectors and the corresponding eigenvalues of H_0+V_n. Then, if $\phi'_{\mu,\beta}(t)\equiv e^{-\beta(t-\mu)}$ and α is large enough:

$$
\begin{aligned}
\mathrm{Tr}\phi'_{\mu,\beta}(H_0) &= \mathrm{Tr}\phi'_{\mu+\alpha,\beta}(H_0+\alpha) \\
&\geqslant \sum_m \phi'_{\mu+\alpha,\beta}((\eta_m,(H_0+\alpha)\eta_m)) \\
&= \sum_m \phi'_{\mu+\alpha,\beta}[(\varepsilon_m+\alpha)\langle \eta_m,(H_0+\alpha)(H_0+\alpha+V_n)^{-1}\eta_m\rangle] \\
&= \sum_m \phi'_{\mu+\alpha,\beta}[(\varepsilon_m+\alpha)\langle \eta_m,(1+V_n(H_0+\alpha)^{-1})^{-1}\eta_m\rangle] \\
&\geqslant \sum_m \phi'_{\mu+\alpha,\beta}[(\varepsilon_m+\alpha)/(1-\gamma_\alpha)] \\
&\geqslant \sum_m \phi_{\mu+\alpha,\beta}[(\varepsilon_m+\alpha)/(1-\gamma_\alpha)] \\
&= \sum_m \phi_{(1-\gamma_\alpha)\mu-\alpha\gamma_\alpha,\beta/(1-\gamma_\alpha)}[\varepsilon_m] \\
&= \mathrm{Tr}\phi_{(1-\gamma_\alpha)\mu-\alpha\gamma_\alpha,\beta/(1-\gamma_\alpha)}[H_0+V_n]. \qquad (29)
\end{aligned}
$$

Taking

$$
\mu' = (\mu+\alpha\gamma_\alpha)/(1-\gamma_\alpha) \quad \text{and} \quad \beta' = (1-\gamma_\alpha)\beta, \qquad (30)
$$

we conclude that

$$
\|(1+e^{\beta(H_0+V_n-\mu)})^{-1}\|_1 < e^{\beta'\mu'}\,\mathrm{Tr}\exp(-\beta' H_0) < \infty. \qquad (31)
$$

Thus the equation (in μ)

$$
N = \mathrm{Tr}(1+e^{\beta(H_0+V_n-\mu)})^{-1}, \qquad (32)
$$

makes sense. One can check that the right hand side is a continuous, strict monotone increasing function of μ. Moreover, the right hand side goes to ∞ and 0 as μ goes to $\pm\infty$ respectively. Thus, Eq. (32) has a unique solution. Because $(1+e^{\beta(H_0+V_n-\mu_n)})^{-1}$ is a positive defined self-adjoint operator:

$$
\int (1+e^{\beta(H_0+V_n-\mu_n)})^{-1}(\vec{x},\vec{x})\,d\vec{x} = \|(1+e^{\beta(H_0+V_n-\mu_n)})^{-1}\|_1 < \infty, \qquad (33)
$$

from (31). This proves that $(1+e^{\beta(H_0+V_n-\mu_n)})^{-1}(\vec{x},\vec{x})$ exists as a $L^1(\mathrm{vol})$ function.

(*ii*) From spectral decomposition:

$$
T[n](\vec{x}) = \sum_m f\beta(\varepsilon_m-\mu_n)|\eta_m(\vec{x})|^2. \qquad (34)
$$

Thus the Hartree equation can be written as $n(\vec{x}) = T[n](\vec{x})$. ■

The condition $\beta<\infty$ is essential here. If H_0+V_n has degenerate eigenvalues, then it is not possible all the time to match the number of eigenvalues below the Fermi energy with N, whatever value the Fermi energy has. This is why, at zero temperature, one has to assume that H_0+V_n has only nondegenerate eigenvalues, which is not necessarily at finite temperatures. The fixed point approach for a classical Hartree approximation also encounters a similar problem.[5]

IV. THE SOLUTION OF THE HARTREE EQUATION

We investigate in this section the solutions of the Hartree equations. In many cases, a background charge, n_0, is present to assure the neutrality of the system: $\int n_0(\vec{x})d\vec{x}=N$. In this case, V_n is replaced by

$$V_n(\vec{x})\to V_{n-n_0}(\vec{x})=\lambda\int v(\vec{x}-\vec{y})(n(\vec{y})-n_0(\vec{y}))d\vec{y}, \tag{35}$$

where we inserted a scaling parameter λ. As we mentioned in the Introduction, a common way of solving the Hartree problem consists of the following. The density of particles in the absence of the two-body interaction (denoted here by n_1) is chosen as the starting point for Hartree iteration. Then one tests if the sequence $\{T^{\circ k}n_1\}_k$ converges. In our approach, the convergence must be in $L^1(\mathrm{vol})$.

Theorem 7: *If the two-body interaction satisfies the conditions enunciated at the beginning of the previous section, then, for* λ *small enough, the sequence* $\{T^{\circ k}n_1\}_k$ *converges to the unique solution of the Hartree equation.*

Remark: According to our estimates, the maximum value of the coupling constant depends on the number of particles and temperature. Only if one assumes special conditions like periodicity of the background potential, then one can prove (second part of this work) that this value does not depend on the number of particles. The dependency on temperature it is not due to our imperfect estimates. We will prove in third part that there is a symmetry breaking at zero temperature. Thus, the maximum value of the coupling constant for which the Hartree problem has a unique solution does go to zero at low temperatures, unless some special conditions are imposed (like nondegenerate eigenvalues, band gaps, etc.). The proof of the theorem is based on several propositions.

Proposition 8: Let n_1, $n_2\in L^1(\mathrm{vol})$ *and let us use the shortening:* $H_{n_{1,2}}=H_0+V_{n_{1,2}-n_0}$. *Then*

$$\|T[n_1]-T[n_2]\|_{L^1}\leqslant 2\|(1+e^{\beta(H_{n_1}-\mu_M)})^{-1/2}-(1+e^{\beta(H_{n_2}-\mu_M)})^{-1/2}\|(\|(1+e^{\beta(H_{n_1}-\mu_M)})^{-1/2}\|_1 + \|(1+e^{\beta(H_{n_2}-\mu_M)})^{-1/2}\|_1),$$

where $\mu_M=\max\{\mu_{n_1},\mu_{n_2}\}$.

Proof: Suppose $\mu_{n_2}\geqslant\mu_{n_1}$. We have, successively,

$$\begin{aligned}\|T[n_1]-T[n_2]\|_{L^1}&\leqslant\|(1+e^{\beta(H_{n_1}-\mu_{n_1})})^{-1}-(1+e^{\beta(H_{n_2}-\mu_{n_2})})^{-1}\|_1\\&\leqslant\|(1+e^{\beta(H_{n_1}-\mu_{n_1})})^{-1}-(1+e^{\beta(H_{n_1}-\mu_{n_2})})^{-1}\|_1\\&\quad+\|(1+e^{\beta(H_{n_1}-\mu_{n_2})})^{-1}-(1+e^{\beta(H_{n_2}-\mu_{n_2})})^{-1}\|_1.\end{aligned} \tag{36}$$

From

$$N=\mathrm{Tr}(1+e^{\beta(H_{n_1}-\mu_{n_1})})^{-1}=\mathrm{Tr}(1+e^{\beta(H_{n_2}-\mu_{n_2})})^{-1}, \tag{37}$$

it follows that

$$\begin{aligned}&\|(1+e^{\beta(H_{n_1}-\mu_{n_1})})^{-1}-(1+e^{\beta(H_{n_1}-\mu_{n_2})})^{-1}\|_1\\&\quad=\mathrm{Tr}\{(1+e^{\beta(H_{n_1}-\mu_{n_2})})^{-1}-(1+e^{\beta(H_{n_1}-\mu_{n_1})})^{-1}\}\\&\quad=\mathrm{Tr}\{(1+e^{\beta(H_{n_1}-\mu_{n_2})})^{-1}-(1+e^{\beta(H_{n_2}-\mu_{n_2})})^{-1}\}\\&\quad\leqslant\|(1+e^{\beta(H_{n_1}-\mu_{n_2})})^{-1}-(1+e^{\beta(H_{n_2}-\mu_{n_2})})^{-1}\|_1.\end{aligned} \tag{38}$$

At this step we can conclude that

$$\|T[n_1]-T[n_2]\|_{L^1}\leqslant 2\|(1+e^{\beta(H_{n_1}-\mu_{n_2})})^{-1}-(1+e^{\beta(H_{n_2}-\mu_{n_2})})^{-1}\|_1. \tag{39}$$

Then the proposition follows from the identity

$$\begin{aligned}(1+e^{\beta(H_{n_1}-\mu_{n_2})})^{-1}&-(1+e^{\beta(H_{n_2}-\mu_{n_2})})^{-1}\\ &=(1+e^{\beta(H_{n_1}-\mu_{n_2})})^{-1/2}\{(1+e^{\beta(H_{n_1}-\mu_{n_2})})^{-1/2}-(1+e^{\beta(H_{n_2}-\mu_{n_2})})^{-1/2}\}\\ &\quad+\{(1+e^{\beta(H_{n_1}-\mu_{n_2})})^{-1/2}-(1+e^{\beta(H_{n_2}-\mu_{n_2})})^{-1/2}\}(1+e^{\beta(H_{n_2}-\mu_{n_2})})^{-1/2},\end{aligned} \tag{40}$$

and the basic inequality $\|AB\|_1\leqslant\|A\|_1\|B\|_{L^2}$ or $\|A\|_{L^2}\|B\|_1$ for A trace class and B bounded, or *vice versa*. ■

We continue with the evaluation of the two terms that appear in the above proposition. Let us denote $\phi_{\mu,\beta}(t)=(1+e^{\beta(t-\mu)})^{-1/2}$. Because this function is convex for $t\geqslant\mu+\beta^{-1}\ln 2$, one can define a family of convex functions, $\overline{\phi}_{\mu,\beta}$, such that $\overline{\phi}_{\mu,\beta}(t)\geqslant\phi_{\mu,\beta}(t)$ for any μ, $t\in R$ and $\beta\in R_+$, with equality for t larger than some $t_c(\mu,\beta)>\mu+\beta^{-1}\ln 2$. Also, $\overline{\phi}_{\mu,\beta}(t)$ can be chosen continuous in the parameters μ and β, increasing with respect to μ and decreasing with respect to β.

Proposition 9: With the above notations, for α negative and $|\alpha|$ large enough,

$$\|(1+e^{(\beta H_0+\lambda V_{n-n_0}-\mu)})^{-1/2}\|_1\leqslant\mathrm{Tr}\overline{\phi}_{\mu',\beta'}(H_0),$$

where

$$\mu'=(\mu-\alpha K_1(\alpha)\xi)/(1-K_1(\alpha)\xi)$$

and

$$\beta'=(1-K_1(\alpha)\xi)\beta.$$

We used the notation $\xi\equiv\lambda\|n-n_0\|_{L^1(\mathrm{vol})}$.

Proof: Let $\{\eta_m,\varepsilon_m\}_m$ be the eigenvectors and the corresponding eigenvalues of $H_0+\lambda V_{n-n_0}$. Then we have successively,

$$\begin{aligned}\mathrm{Tr}\overline{\phi}_{\mu,\beta}(H_0)&=\mathrm{Tr}\overline{\phi}_{\mu-\alpha,\beta}(H_0-\alpha)\\ &\geqslant\sum_m\overline{\phi}_{\mu-\alpha,\beta}[\langle\eta_m,(H_0-\alpha)\eta_m\rangle]\\ &=\sum_m\overline{\phi}_{\mu-\alpha,\beta}[(\varepsilon_m-\alpha)\langle\eta_m,(H_0-\alpha)(H_0+\lambda V_{n-n_0}-\alpha)^{-1}\eta_m\rangle]\\ &=\sum_m\overline{\phi}_{\mu-\alpha,\beta}[(\varepsilon_m-\alpha)\langle\eta_m,(1+\lambda V_{n-n_0}(H_0-\alpha)^{-1})^{-1}\eta_m\rangle]\\ &\geqslant\sum_m\overline{\phi}_{\mu-\alpha,\beta}[(\varepsilon_m-\alpha)/(1-\lambda\|V_{n-n_0}(H_0-\alpha)^{-1}\|)]\\ &\geqslant\sum_m\overline{\phi}_{\mu-\alpha,\beta}[(\varepsilon_m-\alpha)/(1-\lambda K_1(\alpha)\|n-n_0\|_{L^1})]\\ &\geqslant\sum_m\phi_{\mu-\alpha,+gb}[(\varepsilon_m-\alpha)/(1-K_1(\alpha)\xi)]\\ &=\mathrm{Tr}\phi_{\mu-\alpha,\beta}[(H_n-\alpha)/(1-K_1(\alpha)\xi)].\end{aligned} \tag{41}$$

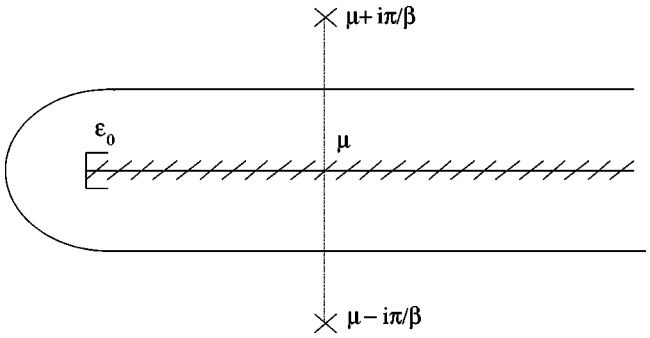

FIG. 3. Contour $\mathcal{C}$, used in Proposition 10. The poles of $(1+e^{\beta(z-\mu)})^{-1}$ at $\mu \pm i\pi/\beta$ are marked.

Replacing μ and β by μ' and β', the proposition follows. ■

An important remark is that the bound found in the above proposition is a continuous, increasing function of ξ and μ.

Proposition 10: For n_1, $n_2 \in L^1(\mathrm{vol})$ *the following is true:*

$$\|(1+e^{\beta(H_{n_1}-\mu)})^{-1/2}-(1+e^{\beta(H_{n_2}-\mu)})^{-1/2}\|_{L^2} \leqslant K_2(\mu,\beta,\xi)\lambda\|n_1-n_2\|_{L^1(\mathrm{vol})},$$

where ξ *denotes now* $\max\{\lambda\|n_1-n_0\|_{L^1},\lambda\|n_2-n_0\|_{L^1}\}$.

Proof: From

$$\begin{aligned}(1+e^{\beta(H_{n_1}-\mu)})^{-1/2}&-(1+e^{\beta(H_{n_2}-\mu)})^{-1/2}\\ &=\frac{\lambda}{2\pi i}\int_{\mathcal{C}}(1e^{\beta(z-\mu)})^{-1/2}(z-H_{n_1})^{-1}\\ &\quad\times(V_{n_1-n_0}-V_{n_2-n_0})(z-H_{n_2})^{-1}dz,\end{aligned} \tag{42}$$

where $\mathcal{C}$ is a curve in the complex plane that surrounds the spectrum of $H_{n_{1,2}}$ and $\phi_{\mu,\beta}$ is analytic inside of $\mathcal{C}$. Then

$$\begin{aligned}&\|(1+e^{\beta(H_{n_1}-\mu)})^{-1/2}-(1+e^{\beta(H_{n_2}-\mu)})^{-1/2}\|\\ &\quad\leqslant\frac{\lambda}{2\pi}\int_{\mathcal{C}}|dz||1+e^{\beta(z-\mu)}|^{-1/2}d(z,\sigma)^{-1}\|V_{n_1-n_2}(z-H_{n_2})^{-1}\|,\end{aligned} \tag{43}$$

where σ is the semi-axis starting from ε_0, the bottom of $\sigma_{H_{n_1}}\cup\sigma_{H_{n_2}}$. Choosing $\mathcal{C}$ as in Fig. 3, $d(z,\sigma)=\pi/(2\beta)$:

$$\begin{aligned}&\|(1+e^{\beta(H_{n_1}-\mu)})^{-1/2}-(1+e^{\beta(H_{n_2}-\mu)})^{-1/2}\|\\ &\quad\leqslant\frac{\lambda\beta}{\pi^2}\int_{\mathcal{C}}|dz||1+e^{\beta(z-\mu)}|^{-1/2}\|V_{n_1-n_2}(z-H_{n_2})^{-1}\|.\end{aligned} \tag{44}$$

Because Theorem 4 gives an estimate of $\|V_{n_1-n_2}(z-H_0)^{-1}\|$, one can try

$$\begin{aligned}&\|V_{n_1-n_2}(z-H_{n_2})^{-1}\|\\ &\quad=\|V_{n_1-n_2}(z-H_0)^{-1}(1-\lambda V_{n_2-n_0}(z-H_0)^{-1})^{-1}\|\\ &\quad\leqslant\|V_{n_1-n_2}(z-H_0)^{-1}\|/(1-\lambda\|V_{n_2-n_0}(z-H_0)^{-1}\|).\end{aligned} \tag{45}$$

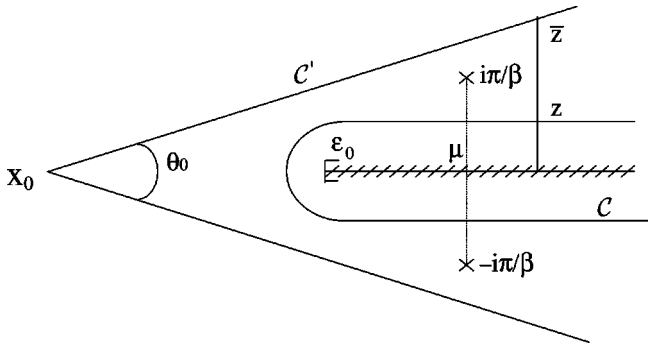

FIG. 4. Contour $\mathcal{C}'$ used in Proposition 10. It is shown, graphically, how $\overline{z}$ is chosen.

However, this will not work for two reasons. The first reason is that, for $d=3$, $k_{m,z}$ (defined in Proposition 2) diverges as $\mathrm{Re}\, z$ goes to infinity and $\mathrm{Im}\, z$ is kept finite, so it will diverge at the ends of $\mathcal{C}$. This can be seen for large volumes, when $k_{m,z}$ can be approximated by

$$k_{m,z}=\left[(2\pi)^{-d}\int_{R^d}|k^2/2-z|^{-2}d^dk\right]^{1/2}=\sqrt{\frac{S_{d-1}}{2^{2+d/2}\pi^{d-1}\rho^{2-d/2}\sin\theta/2}}, \tag{46}$$

where $z=\rho e^{i\theta}$ and S_d is the surface of the d dimensional sphere. The second reason is that, as the temperature decreases, we are forced to take the curve $\mathcal{C}$ closer and closer to the real axis to avoid the poles of $(1+e^{\beta(z-\mu)})^{-1}$ and to stay in the domain of analyticity of $(1+e^{\beta(z-\mu)})^{-1/2}$. In either case, $\lambda\|V_{n_2-n_0}(z-H_0)^{-1}\|$ becomes greater than one, for any finite value of λ. However, the following procedure solves the problem. Consider the curve $\mathcal{C}'$ as in Fig. 4. For $z\in\mathcal{C}$ we consider the line that passes through z and the closest point of σ to the z. Then, we associate to every $z\in\mathcal{C}$ a point $\overline{z}\in\mathcal{C}'$ defined by the intersection of this line with $\mathcal{C}'$. With the notations from Fig. 4, it is clear that $k_{\overline{z}}(\overline{z}\in\mathcal{C}')$ can be made smaller than any positive number by properly choosing x_0 and θ_0. This means that $K_1(\overline{z})$ (defined in Theorem 4) can be made as small as we want. Moreover, the following is true:

$$\begin{aligned}
&\|V_{n_1-n_2}(z-H_{n_2})^{-1}\|\\
&\quad=\|V_{n_1-n_2}(\overline{z}-H_{n_2})^{-1}(\overline{z}-H_{n_2})(z-H_{n_2})^{-1}\|\\
&\quad\leqslant\|V_{n_1-n_2}(\overline{z}-H_{n_2})^{-1}\|\sup_{x\in[\varepsilon_0,\infty)}(\overline{z}-x)/(z-x)\\
&\quad=\|V_{n_1-n_2}(\overline{z}-H_{n_2})^{-1}\|d(\overline{z},\sigma)/d(z,\sigma).
\end{aligned}\tag{47}$$

With the above remark, one can continue:

$$\begin{aligned}
\|V_{n_1-n_2}(z-H_{n_2})^{-1}\|&\leqslant\|V_{n_1-n_2}(\overline{z}-H_0)^{-1}\|\frac{d(\overline{z},\sigma)/d(z,\sigma)}{1-\|V_{n_2-n_0}(\overline{z}-H_0)^{-1}\|}\\
&\leqslant\frac{d(\overline{z},\sigma)}{d(z,\sigma)}\frac{K_1(\overline{z})}{1-K_1(\overline{z})\xi}\lambda\|n_1-n_2\|_{L^1(\mathrm{vol})}.
\end{aligned}\tag{48}$$

Thus we can conclude that

$$\begin{aligned}
&\|(1+e^{\beta(H_{n_1}-\mu)})^{-1/2}-(1+e^{\beta(H_{n_2}-\mu)})^{-1/2}\|\\
&\quad\leqslant K_2(\mu,\beta,\xi)\lambda\|n_1-n_2\|_{L^1(\mathrm{vol})},
\end{aligned}\tag{49}$$

where

$$K_2(\mu,\beta,\xi)=\frac{2\beta^2}{\pi^3}\int_{\mathcal{C}}|dz||1+e^{\beta(z-\mu)}|^{-1/2}\frac{d(\overline{z},\sigma)K_1(\overline{z})}{1-K_1(\overline{z})\xi}. \tag{50}$$

The divergence of $d(\overline{z},\sigma)$ as $\mathrm{Re}\,z\to\infty$ is canceled by the exponential decay of $|1+e^{\beta(z-\mu)}|^{-1/2}$. One can easily check that $K_2(\mu,\beta,\xi)$ is increasing with respect to μ and ξ. ■

The last estimate we need is a bound on μ_n. For this, we define a convex function, $\phi_{\mu,\beta}$ that goes below $(1+e^{\beta(t-\mu)})^{-1}$:

$$\phi_{\mu,\beta}(t)\leqslant(1+e^{\beta(t-\mu)})^{-1},\quad \text{for any } t,\mu\in R \quad\text{and}\quad \beta\in R_+. \tag{51}$$

This function needs to be convex only for $t\geqslant\varepsilon_0$, the bottom of $\sigma_{H_0+V_n}$. To be more explicit, let $g(t)$ be the linear function that, for $t\in[\varepsilon_0,\infty)$, goes below the Fermi–Dirac distribution, $\phi_{\mu,\beta}(t)=(1+e^{\beta(t-\mu)})^{-1}$, and it is as close as it is possible to $(1+e^{\beta(t-\mu)})^{-1}$. In this case, $g(t)$ is tangent to $(1+e^{\beta(t-\mu)})^{-1}$ in some point, t_c, and $g(\varepsilon_0)=\phi_{\mu,\beta}(\varepsilon_0)$. Then $\phi_{\mu,\beta}(t)$ can be chosen as $g(t)$ for $t\in[\varepsilon_0,t_c]$ and as $\phi_{\mu,\beta}(t)$ for $t>t_c$.

Proposition 11: The constraint $N=\mathrm{Tr}\phi_{\mu_n}(H_0+V_{n-n_0})$ imposes an upper limit on μ_n. An estimate of this limit can be found from the following implicit relation:

$$N\geqslant\mathrm{Tr}\phi_{\mu_n,\beta}((1+K_1(\alpha)\xi)H_0-\alpha K_1(\alpha)\xi),$$

where α is a negative number and $\xi=\lambda\|n-n_0\|_{L^1(\mathrm{vol})}$.

Proof: Let $\{\eta_m^0,\lambda_m\}_m$ be the set of eigenvectors and the corresponding eigenvalues of H_0. Then, for α negative and $|\alpha|$ large enough,

$$\begin{aligned}
N&=\mathrm{Tr}\phi_{\mu_n,\beta}[H_0+\lambda V_{n-n_0}]\\
&\geqslant\mathrm{Tr}\phi_{\mu_n}[H_0+\lambda V_{n-n_0}]\\
&\geqslant\sum_m\ \phi_{\mu_n,\beta}[\langle\eta_m^0,(H_0+\lambda V_{n-n_0})\eta_m^0\rangle]\\
&=\sum_m\ \phi_{\mu_n,\beta}[\langle\eta_m^0,(H_0+\lambda V_{n-n_0}-\alpha)\eta_m^0\rangle+\alpha]\\
&=\sum_m\ \phi_{\mu_n,\beta}[\langle\eta_m^0,(1+\lambda V_{n-n_0}(H_0-\alpha)^{-1})\eta_m^0\rangle(\lambda_m-\alpha)+\alpha]\\
&\geqslant\sum_m\ \phi_{\mu_n,\beta}[(1+\lambda K_1(\alpha)\|n-n_0\|_{L^1})(\lambda_m-\alpha)+\alpha]\\
&=\mathrm{Tr}\phi_{\mu_n,\beta}[(1+\lambda K_1(\alpha)\|n-n_0\|_{L^1})H_0-\alpha\lambda K_1(\alpha)\|n-n_0\|_{L^1}].
\end{aligned}\tag{52}$$

An important property of $\phi_{\mu,\beta}$ is that

$$\phi_{\mu,\beta}(t)>\phi_{\mu',\beta}(t),\quad \text{for } \mu>\mu'. \tag{53}$$

Also, $\phi_\mu(t)\to1$ as $\mu\to\infty$. This means that

$$\mathrm{Tr}\phi_{\mu_n,\beta}((1+K_1(\alpha)\xi)H_0-\alpha K_1(\alpha)\xi)\xrightarrow[\mu\to\infty]{}\infty, \tag{54}$$

monotonically, so that

$$N \geqslant \mathrm{Tr}\phi_{\mu_n,\beta}[(1+K_1(\alpha)\xi)H_0 - \alpha K_1(\alpha)\xi], \tag{55}$$

does impose an upper limit on μ_n. ■

Proof of Theorem 7: Let us consider an ε-ball around n_1:

$$n \in B_\varepsilon(n_1) \Leftrightarrow \|n-n_1\|_{L^1} \leqslant \varepsilon. \tag{56}$$

Let $\delta = \|n_0 - n_1\|_{L^1}$ and let us note that $B_\varepsilon(n_1) \subset B_{\varepsilon+\delta}(n_0)$. We are interested first to find those conditions in which $T[B_\varepsilon(n_1)] \subset B_\varepsilon(n_1)$. We denote $\xi \equiv \lambda(\varepsilon+\delta)$. From Proposition 11, it follows that, for $n \in B_{\varepsilon+\delta}(n_0)$,

$$\mathrm{Tr}\phi_{\mu_n,\beta}((1+K_1(\alpha)\xi)H_0 - \alpha K_1(\alpha)\xi) \leqslant N, \tag{57}$$

where α is a negative number. This shows that μ_n is bounded by some μ_M which is a function only of ξ. Moreover, $\mu_M(\xi)$ is an increasing function of ξ. Because $\overline{\phi}_{\mu,\beta}$ in Proposition 9 is increasing with respect to μ and decreasing with respect to β and $K_2(\mu,\beta,\xi)$ in Proposition 10 is increasing with respect to μ and ξ, it follows that, for any $n, n' \in B_{\varepsilon+\delta}(n_0)$,

$$\|T[n]-T[n']\|_{L^1} \leqslant 4\,\mathrm{Tr}\overline{\phi}_{\mu'_M(\xi),\beta'(\xi)}(H_0)K_2(\mu_M(\xi),\beta,\xi)\lambda\|n-n'\|_{L^1}, \tag{58}$$

where

$$\mu'_M(\xi) = (\mu_M(\xi) - \alpha K_1(\alpha)\xi)/(1-K_1(\alpha)\xi), \tag{59}$$

$$\beta'(\xi) = (1-K_1(\alpha)\xi)\beta. \tag{60}$$

Then, for $n \in B_\varepsilon(n_1)$,

$$\begin{aligned}\|T[n]-n_1\|_{L^1} &= \|T[n]-T[n_0]\|_{L^1} \\ &\leqslant 4\,\mathrm{Tr}\overline{\phi}_{\mu'_M(\xi),\beta'(\xi)}(H_0)K_2(\mu_M(\xi),\beta,\xi)\xi.\end{aligned} \tag{61}$$

If

$$4\,\mathrm{Tr}\overline{\phi}_{\mu'_M(\xi),\beta'(\xi)}(H_0)K_2(\mu_M(\xi),\beta,\xi)\xi \leqslant \varepsilon, \tag{62}$$

then $T[B_\varepsilon(n_1)] \subset B_\varepsilon(n_1)$. Moreover, if (62) is fulfilled, then T is a contraction on $B_\varepsilon(n_1)$. Indeed, for any $n, n' \in B_\varepsilon(n_1)$,

$$\begin{aligned}\|T[n]-T[n']\|_{L^1} &\leqslant 4\,\mathrm{Tr}\overline{\phi}_{\mu'_M(\xi),\beta'(\xi)}(H_0)K_2(\mu_M(\xi),\beta,\xi)\lambda\|n-n'\|_{L^1} \\ &\leqslant \frac{\varepsilon}{\varepsilon+\delta}\|n-n'\|_{L^1}.\end{aligned} \tag{63}$$

Because the left hand side of (62) is a continuous function of ξ which goes to zero as ξ goes to zero, it follows that, for any $\varepsilon > 0$, the condition (62) is fulfilled provided λ is small enough. In consequence, we proved that, for λ small enough, $B_\varepsilon(n_1)$ is invariant for T and T is a contraction on $B_\varepsilon(n_1)$. In consequence, T has a single fixed point in $B_\varepsilon(n_1)$. In particular, $\{T^{\circ k}n_1\}_k$ is convergent. Because any fixed point of T satisfies $\|n\|_{L^1} = N$, they belongs to $B_{2N}(n_1)$. Taking $\varepsilon = 2N$, the uniqueness on $L^1(\mathrm{vol})$ follows. ■

At the end, we consider the extension of the above result to the local density approximation.[20] Without going into detail, we want to prove the following proposition.

Proposition 12: Consider the conditions enunciated at the beginning of Sec. III. Then Theorem 7 is true if V_n is replaced with

$$V_n(\vec{x}) \to V_n^{\mathrm{tot}}(\vec{x}) = \lambda \left[\int v(\vec{x}-\vec{y}) n(\vec{y}) d\vec{y} + v_{\mathrm{xc}}(n(\vec{x})) \right],$$

where v_{xc} is a continuous, differentiable on R_+ less a finite number of points. Also, we ask that dv_{xc}/dn is uniformly bounded.

For $n>0$, the conditions we impose on v_{xc} are satisfied by most of the expressions used in local density functional calculations. For example, the potential proposed in Ref. 21 is continuous and differentiable on intervals. The new expression provided in Ref. 22 is differentiable on the entire $(0, \infty)$. Moreover, dv_{xc}/dn is uniformly bounded for large n. At small concentrations, v_{xc} behaves as $n^{1/3}$ which makes dv_{xc}/dn to diverge as $n \to 0$. Thus, one has to modify only the very low density behavior of v_{xc} in order to be in our conditions.

Sketch of proof: We prove first that $v_{\mathrm{xc}}(n)(H_0-z)^{-1}$ is a bounded operator for $n \in L^1(\mathrm{vol})$ and $z \notin \sigma_{H_0} \cup R_+$. Indeed, for $f \in \mathcal{D}(-\frac{1}{2}\Delta_B)$:

$$\| v_{\mathrm{xc}}(n) f \|_{L^2(\mathrm{vol})} \leqslant k_{p,z} \| v_{\mathrm{xc}}(n) \|_{L^p(\mathrm{vol})} \| (-\tfrac{1}{2}\Delta - z) f \|_{L^2(\mathrm{vol})}, \tag{64}$$

and

$$\begin{aligned} \| v_{\mathrm{xc}}(n) \|_{L^p(\mathrm{vol})} &= \left[\int_{\mathrm{vol}} \frac{v_{\mathrm{xc}}(n(\vec{x}))^p}{n(\vec{x})} n(\vec{x}) d\vec{x} \right]^{1/p} \\ &\leqslant \sup_{t \in R_+} \left\{ \frac{v_{\mathrm{xc}}(t)^p}{t} \right\} \| n \|_{L^1(\mathrm{vol})}^{1/p}. \end{aligned} \tag{65}$$

Choosing different values for p, $v_{\mathrm{xc}}(t)^p/t$ can be made uniformly bounded. In the case of homogeneous electron gas, p must be chosen 3. We notice that in this case, the estimate (65) remains true even if we do not modify the low density behavior of the exchange-correlation potential. Then, one can find a bound for $\| (1+e^{\beta(H_n-\mu)})^{-1/2} \|_1$ and μ_n exactly as in Propositions 9 and 11, respectively. A result similar to that of Proposition 10 can be proven by starting from

$$\begin{aligned} \langle f, [v_{\mathrm{xc}}(n) - v_{\mathrm{xc}}(n')] g \rangle &\leqslant \| v_{\mathrm{xc}}(n) - v_{\mathrm{xc}}(n') \|_{L^1} \| f \|_{L^\infty} \| g \|_{L^\infty}, \\ &\leqslant k_{m,z}^2 \| v_{\mathrm{xc}}(n) - v_{\mathrm{xc}}(n') \|_{L^1} \| (H_0 - z^*) f \|_{L^2} \| (H_0 - z) g \|_{L^2}, \end{aligned} \tag{66}$$

for any $f, g \in \mathcal{D}(H_0)$. We ignored the background potential for simplicity and notation. Thus,

$$\begin{aligned} &\langle (H_0 - z^*)^{-1} f, [v_{\mathrm{xc}}(n) - v_{\mathrm{xc}}(n')] (H_0 - z)^{-1} g \rangle \\ &\quad \leqslant k_{m,z}^2 \| v_{\mathrm{xc}}(n) - v_{\mathrm{xc}}(n') \|_{L^1} \| f \|_{L^2} \| g \|_{L^2}, \end{aligned} \tag{67}$$

for any $f, g \in L^2(\mathrm{vol})$, which shows that

$$\begin{aligned} &\| (H_0 - z)^{-1} [v_{\mathrm{xc}}(n) - v_{\mathrm{xc}}(n')] (H_0 - z)^{-1} \| \\ &\quad \leqslant k_{m,z}^2 \| v_{\mathrm{xc}}(n) - v_{\mathrm{xc}}(n') \|_{L^1} \\ &\quad = k_{m,z}^2 \int_{\mathrm{vol}} \left| \int_{n'(\vec{x})}^{n(\vec{x})} \frac{dv_{\mathrm{xc}}(t)}{dt} dt \right| d\vec{x} \\ &\quad \leqslant k_{m,z}^2 \sup_{t \in R_+} \left| \frac{dv_{\mathrm{xc}}(t)}{dt} \right| \| n - n' \|_{L^1}. \end{aligned} \tag{68}$$

If v_{xc} is not differentiable on a set of points, then the integral $\int_{n'(\vec{x})}^{n(\vec{x})} dt$ must be broken on the intervals. The result is the same with the only difference that the supremum is taken over R_+ less the points where the derivative is not defined. Then

$$
\begin{aligned}
&(1+e^{\beta(H_{n_1}-\mu)})^{-1/2}-(1+e^{\beta(H_{n_2}-\mu)})^{-1/2}\\
&\quad=\frac{\lambda}{2\pi i}\int_{\mathcal{C}}(1+e^{\beta(z-\mu)})^{-1/2}(z-H_{n_1})^{-1}V_{n_1-n_2}(z-H_{n_2})^{-1}dz\\
&\quad+\frac{\lambda}{2\pi i}\int_{\mathcal{C}}(1+e^{\beta(z-\mu)})^{-1/2}(z-H_{n_1})^{-1}\\
&\qquad\times[v_{\mathrm{xc}}(n_1)-v_{\mathrm{xc}}(n_2)](z-H_{n_2})^{-1}dz. \qquad (69)
\end{aligned}
$$

The first term can be bounded as before while the second one,

$$
\begin{aligned}
&\left\|\frac{\lambda}{2\pi i}\int_{\mathcal{C}}(1+e^{\beta(z-\mu)})^{-1/2}(z-H_{n_1})^{-1}[v_{\mathrm{xc}}(n_1)-v_{\mathrm{xc}}(n_2)](z-H_{n_2})^{-1}dz\right\|\\
&\quad\leqslant\frac{\lambda}{2\pi}\int_{\mathcal{C}}|dz|\,|1+e^{\beta(z-\mu)}|^{-1/2}\|(z-H_{n_1})^{-1}[v_{\mathrm{xc}}(n_1)-v_{\mathrm{xc}}(n_2)](z-H_{n_2})^{-1}\|\\
&\quad\leqslant\frac{\lambda}{2\pi}\int_{\mathcal{C}}|dz|\,|1+e^{\beta(z-\mu)}|^{-1/2}\frac{d(\bar{z},\sigma)^2/d(z,\sigma)^2}{(1-\|V_{n_1}^{\mathrm{tot}}(\bar{z}-H_0)^{-1}\|)(1-\|V_{n_2}^{\mathrm{tot}}(\bar{z}-H_0)^{-1}\|)}\\
&\qquad\times\|(\bar{z}-H_0)^{-1}[v_{\mathrm{xc}}(n_1)-v_{\mathrm{xc}}(n_2)](\bar{z}-H_0)^{-1}\|\\
&\quad\leqslant k_{m,z}^2\frac{\sup_{t\in R_+}dv_{\mathrm{xc}}(t)/dt}{2\pi}\int_{\mathcal{C}}|dz|\,|1+e^{\beta(z-\mu)}|^{-1/2}\\
&\qquad\times\frac{d(\bar{z},\sigma)^2/d(z,\sigma)^2}{(1-\|V_{n_1}^{\mathrm{tot}}(\bar{z}-H_0)^{-1}\|)(1-\|V_{n_2}^{\mathrm{tot}}(\bar{z}-H_0)^{-1}\|)}\|n_1-n_2\|_{L^1}, \qquad (70)
\end{aligned}
$$

where we use the same notation as in Proposition 10 and H_n represents $H_0+V_n^{\mathrm{tot}}$. Thus, Propositions 9 to 11 remain true when the exchange-correlation potential is considered and one can repeat the proof of Theorem 7. ■

The problem at low density comes from the fact that we were not able to find a suitable norm in which $n^{1/3}-n'^{1/3}$ is bounded by $\|n-n'\|_{L^1(\mathrm{vol})}$ as it is needed in the fixed point theorem. If one tries an L^p norm in (68) instead of the L^1 norm, then the best one can get is a bound proportional to $\|n-n'\|_{L^1(\mathrm{vol})}^{1/p}$ which is not enough. However, our result can be relevant for the general case, if one can prove that, after each iteration, $\|n\|_{L^\infty(\mathrm{vol})}$ is greater than the value from where the exchange-correlation potential has been artificially modified.

Hartree approximation II: The thermodynamic limit

E. Prodan[a] and P. Nordlander
Rice University, Department of Physics—MS 61, 6100 Main Street, Houston, Texas 77005-1892

(Received 7 February 2001; accepted for publication 10 April 2001)

We investigate the thermodynamic limit of the Hartree approximation for periodic background potentials and short range two-body interactions. We prove that, for any finite volume, the Hartree problem has a unique solution among the periodic densities of particles provided the coupling constant is smaller than a certain value. This value is independent of volume. We also prove that these solutions converge as the thermodynamic limit is considered. © *2001 American Institute of Physics.* [DOI: 10.1063/1.1379748]

I. INTRODUCTION

We continue our investigation[1] of the Hartree approximation at finite temperatures. As in Ref. 1, we neglect the spin degrees of freedom. In this paper, we analyze the thermodynamic limit of this model. Only the three dimensional case will be considered. Let us consider a periodic background potential: $u(\vec{x}+\vec{R})=u(\vec{x})$, for any $\vec{R}$ belonging to the infinite lattice:

$$\Gamma=\{\vec{y}\in R^3|\vec{y}=\Sigma_{i=1}^3 n^i\vec{\delta}_i,\ \ n_i\in\mathbf{Z}\},\tag{1}$$

where $\vec{\delta}_i$, $i=\overline{1,3}$, are three independent vectors. Let us consider a finite crystal, confined in

$$V=\{\vec{y}\in R^3|\vec{y}=\Sigma_{i=1}^3 x^i\vec{\delta}_i,\ \ x^i\leqslant K,\ \ i=\overline{1,3}\},\tag{2}$$

where K is a positive integer number. We denote its unit cell by

$$\text{cell}=\{\vec{y}\in R^3|\vec{y}=\Sigma_{i=1}^3 x^i\vec{\delta}_i,\ \ x^i\leqslant 1,\ \ i=\overline{1,3}\}.\tag{3}$$

The crystal is formed from K^3 cells. Let the independent particles be described by the Hamiltonian: $H_0=-\frac{1}{2}\Delta_p+u$, where Δ_p denotes the periodic Laplace operator on V. Suppose a two-body interaction, v, is given. The Hartree problem consists in finding the fixed points of the map:[1]

$$T:L^1(V)\to L^1(V),\ \ T[n](\vec{x})=(1+e^{\beta(H_n-\mu_n)})^{-1}(\vec{x},\vec{x}),\tag{4}$$

where

$$H_n=H_0+\lambda\int_V v(\vec{x}-\vec{y})n(\vec{y})d\vec{y}.\tag{5}$$

In (4), μ_n represents the unique solution of the equation (in μ): $N=\mathrm{Tr}(1+e^{\beta(H_n-\mu)})^{-1}$, N being the number of particles. Because the background potential is periodic, it seems natural to search for the fixed points of T among the periodic functions. However, the space of periodic functions is not invariant for T. This is because the potential,

[a]Electronic mail: emprodan@rice.edu

$$V_n(\vec{x}) = \int_V v(\vec{x}-\vec{y})n(\vec{y})d\vec{y}, \tag{6}$$

is not periodic even if the density n is. It will be periodic if the opposite faces of the crystal are identified. This is why we will consider that the particles are trapped on the torus: $\mathcal{T}=S_1\times S_2\times S_3$, where S_i are circles of length: $K\delta_i$. We denote the Laplace operator on $\mathcal{T}$ by the same Δ_p. The two-body interaction has to be modified because, on the torus, particles on different faces of the crystal will be closer to each other. Supposing that the two-body interactions is invariant under the spatial reflections, we can write the interaction between two particles, situated in two points, $\vec{x}$, $\vec{y}\in\mathcal{T}$, as

$$\tilde{v}(\vec{x},\vec{y}) = v(d_1(x_1-y_1),d_2(x_2-y_2),d_3(x_3-y_3)), \tag{7}$$

where $d_i(\cdot,\cdot)$ represents the distance on the circle S_i. We will replace this expression in (6). Our conditions are

- restricted to the unit cell, $u\in L^2(\text{cell})+L^\infty(\text{cell})$.
- the two-body interaction belongs to $L^2(R^3)+L^\infty(R^3)$.
- the two-body interaction is of short range: $|v(\vec{x})|<|\vec{x}|^{-3+\epsilon}$ for large $|\vec{x}|$, where $\epsilon>0$.

Thus, our class of background potential includes the Coulomb force, while the class of the two-body interactions includes only the screened Coulomb force. Assume now that N particles are trapped on the torus $\mathcal{T}$. We denote by N_0 the number of particles per unit cell: $N_0=N/K^3$. Our goal in this paper is to study the Hartree model in the limit $N\to\infty$, $K\to\infty$, when $N_0=N/K^3$ remains constant. Specifically, we prove that the conditions of the fixed point theorem are uniformly satisfied on the invariant set of periodic densities of particles as the thermodynamic limit is considered. The case of nonperiodic densities cannot be treated by the method presented here. For this periodic solution, we prove that the chemical potential, energy per unit volume and the density of particles have a well defined thermodynamic limit. We mention that, very recently, a similar analysis has been carried out for the classical Hartree approximation by Catto, Le Bris and Lions.[2]

II. PRELIMINARY RESULTS

Let us introduce first a few notations: $L^1_{\text{per}}(\mathcal{T})$ will denote the set of L^1 integrable functions over $\mathcal{T}$ with $f(\vec{x}+\vec{R})=f(\vec{x})$ for $\vec{R}\in\Gamma$. Also, let $\mathcal{C}=\{\Sigma_{i=1}^3 q^i\vec{\delta}_i, \mathbf{q}\in\Lambda\}$, where $\Lambda\equiv\{0,1,...,K-1\}$.[3] We also introduce a new scalar product. For two vectors: $v_{1,2}=\Sigma_{i=1}^3 v^i_{1,2}\vec{\delta}_i$, $\vec{v}_1\vec{v}_2$ will be by definition, $\Sigma_{i=1}^3 v^i_1 v^i_2$. Also, the norm of vectors will be calculated using this scalar product. The scalar product defined above will simplify the notation and will not play any other special role. To any point $\vec{x}\in R^3$, one can associate a point on the torus by considering the point in V with the coordinates: $\tilde{x}^i=x^i \bmod K\delta_i$, $i=\overline{1,3}$. In the following, all points in R^3 are considered modulo V.

As we already mentioned, if $n\in L^1_{\text{per}}(\mathcal{T})$, then $V_n(\vec{x}+\vec{R})=V_n(\vec{x})$ for any $\vec{R}\in\Gamma$. In this case, there exists a unitary transformation:

$$U: L^2(\mathcal{T})\to\oplus_{\mathbf{q}\in\Lambda}L^2(\text{cell}), \tag{8}$$

such that

$$U(-\tfrac{1}{2}\Delta_p+u+\lambda V_n)U^{-1}=\oplus_{\mathbf{q}\in\Lambda}[-\tfrac{1}{2}\Delta_{\mathbf{q}}+u+\lambda V_n]. \tag{9}$$

Here, $\Delta_{\mathbf{q}}$ denotes the Laplace operator over the unit cell, with the boundary conditions

$$f(\vec{x}+\vec{\delta}_j)=e^{i2\pi q^j/K}f(\vec{x}) \quad\text{and}\quad f'(\vec{x}+\vec{\delta}_j)=e^{i2\pi q^j/K}f'(\vec{x}), \tag{10}$$

for $\vec{x}$ and $\vec{x}+\vec{\delta}_j$ on the faces of the unit cell. The unitary transformation is given by

$$L^2(\mathcal{T}) \ni f \to (Uf)_{\mathbf{q}}(\vec{x}) = K^{-3} \sum_{\vec{R} \in \mathcal{C}} e^{-i\vec{R}\vec{\theta}_{\mathbf{q}}} f(\vec{x}+\vec{R}), \tag{11}$$

where $\vec{\theta}_{\mathbf{q}} = 2\pi K^{-1} \Sigma_{i=1}^{3} q^i \vec{\delta}_i$ for any $\mathbf{q} \in \Lambda$. We start now the analysis of $H_n^{(\mathbf{q})} = -1/2\Delta_{\mathbf{q}} + u + \lambda V_n$. In this section, if not specified, all the L^p norms are over the unit cell and $\|\cdot\|$ denotes the operatorial norm over L^2(cell).

Proposition 1: For $f \in \mathcal{D}(-\frac{1}{2}\Delta_{\mathbf{q}})$ *and* $a > 0$:

$$\|f\|_{L^\infty} \leqslant k_a \|(-\tfrac{1}{2}\Delta_{\mathbf{q}} + a) f\|_{L^2},$$

where k_a *is given by*

$$k_a = 1/(2\sqrt{2a}\,\pi) \sum_{\vec{R} \in \Gamma} e^{-\sqrt{2a}|\vec{R}|}.$$

It is only this place where $|\cdot|$ denotes the usual norm on R^3. Because the explicit expression of k_a will not play a special role in the following, we hope that the notation is not confusing.

Proof: Let $f \in \mathcal{D}(-\frac{1}{2}\Delta_{\mathbf{q}})$ and let us denote $g = (-\frac{1}{2}\Delta_{\mathbf{q}} + a) f$ and by $G_{\mathbf{q}}(\vec{x},\vec{y};a)$ the kernel of $(-\frac{1}{2}\Delta_{\mathbf{q}} + a)^{-1}$. Then

$$f(\vec{x}) = \left(\left(-\frac{1}{2}\Delta_{\mathbf{q}} + a \right)^{-1} g \right)(\vec{x}) = \int_{\text{cell}} G_{\mathbf{q}}(\vec{x},\vec{y};a) g(\vec{y})\, d\vec{y}, \tag{12}$$

which leads to

$$|f(\vec{x})| \leqslant \sup_{x \in \text{cell}} \int_{\text{cell}} |G_{\mathbf{q}}(\vec{x},\vec{y};a)|^2\, d\vec{y} \|g\|_{L^2}. \tag{13}$$

The kernel of $(-\frac{1}{2}\Delta_{\mathbf{q}} + a)^{-1}$ is given by

$$G_{\mathbf{q}}(\vec{x},\vec{y};a) = \sum_{\vec{R} \in \Gamma} e^{-i\vec{R}\vec{\theta}_{\mathbf{q}}} G(\vec{x}-\vec{y}+\vec{R};a), \tag{14}$$

where G is the kernel of $(-\frac{1}{2}\Delta + a)^{-1}$, Δ being the Laplace operator over R^3. Because G is a real, positive function,

$$\left| \sum_{\vec{R} \in \Gamma} e^{-i\vec{R}\vec{\theta}_{\mathbf{q}}} G(\vec{x}-\vec{y}+\vec{R};a) \right| \leqslant \sum_{\vec{R} \in \Gamma} G(\vec{x}-\vec{y}+\vec{R};a) = G_{\mathbf{0}}(\vec{x},\vec{y};a), \tag{15}$$

thus

$$\|f\|_{L^\infty} \leqslant \sup_{x \in \text{cell}} \int_{\text{cell}} |G_{\mathbf{0}}(\vec{x},\vec{y};a)|^2 d\vec{y} \left\| \left(-\frac{1}{2}\Delta_{\mathbf{q}} + a \right) f \right\|_{L^2}. \tag{16}$$

One can recognize

$$\int_{\text{cell}} |G_0(\vec{x},\vec{y};a)|^2 dy = \left(-\frac{1}{2}\Delta_{\mathbf{0}} + a \right)^{-2} (\vec{x},\vec{x}) \equiv C_{\mathbf{0}}(\vec{x},\vec{x};a). \tag{17}$$

If $C(\vec{x}-\vec{y};a)$, is the kernel of $(-\frac{1}{2}\Delta + a)^{-2}$, then

$$C_{\mathbf{0}}(\vec{x},\vec{y};a)=\sum_{\vec{R}\in\Gamma} C(\vec{x}-\vec{y}+\vec{R};a). \tag{18}$$

A simple calculus shows $C(\vec{x};a)=1/(2\sqrt{2a}\pi)e^{-\sqrt{2a}|\vec{x}|}$, which leads to

$$\|f\|_{L^\infty}\leqslant 1/(2\sqrt{2a}\pi)\sum_{\vec{R}\in\Gamma} e^{-\sqrt{2a}|\vec{R}|}\left\|\left(-\frac{1}{2}\Delta_{\mathbf{q}}+a\right)f\right\|_{L^2}. \tag{19}$$

■

Proposition 2: If $u\in L^\infty(\text{cell})+L^2(\text{cell})$, *then, for* $a>0$,

$$\|u(-\tfrac{1}{2}\Delta_{\mathbf{q}}+a)^{-1}\|<K_1(a),$$

where $K_1(a)$ *is a decreasing function.*

Proof: From previous theorem, for any $f\in\mathcal{D}(-\frac{1}{2}\Delta_{\mathbf{q}})$,

$$\|uf\|_{L^2}\leqslant\|u^{(1)}\|_{L^\infty}\|f\|_{L^2}+1/(2\sqrt{2a}\pi)\sum_{\vec{R}\in\Gamma} e^{-\sqrt{2a}|\vec{R}|}\|u^{(2)}\|_{L^2}\left\|\left(-\frac{1}{2}\Delta_{\mathbf{q}}+a\right)f\right\|_{L^2}, \tag{20}$$

which leads to

$$\begin{aligned}\left\|u\left(-\frac{1}{2}\Delta_{\mathbf{q}}+a\right)^{-1}f\right\|_{L^2}&\leqslant\|u^{(1)}\|_{L^\infty}\left\|\left(-\frac{1}{2}\Delta_{\mathbf{q}}+a\right)^{-1}f\right\|_{L^2}+1/(2\sqrt{2a}\pi)\sum_{\vec{R}\in\Gamma} e^{-\sqrt{2a}|\vec{R}|}\|u^{(2)}\|_{L^2}\|f\|_{L^2}\\&\leqslant\left\{a^{-1}\|u^{(1)}\|_{L^\infty}+1/(2\sqrt{2a}\pi)\sum_{\vec{R}\in\Gamma} e^{-\sqrt{2a}|\vec{R}|}\|u^{(2)}\|_{L^2}\right\}\|f\|_{L^2}.\end{aligned} \tag{21}$$

■

In the following, we denote the trace norm by $\|\cdot\|_1$.

Proposition 3: Let $n,n'\in L^1_{\text{per}}(\mathcal{T})$ *and* $\|n\|_{L^1(\mathcal{T})}=N$. *Then*

(i) $\|V_n(-\frac{1}{2}\Delta_{\mathbf{q}}+a)^{-1}\|\leqslant N_0K_2(a)$;

(ii) $\|(-\frac{1}{2}\Delta_{\mathbf{q}}+a)^{-1}V_{n'}(-\frac{1}{2}\Delta_{\mathbf{q}}+a)^{-1}\|_1\leqslant k_aK^{-3}\|v\|_{L^1(R^3)}\|n'\|_{L'(\mathcal{T})}$.

where K_2 *is independent of N and it is a decreasing function of a.*

Proof: (i) Let us denote by $\mathcal{N}$ the number of cells around the unit cell that have at least one point infinitely close to the unit cell. We divide the torus in $\text{vol}^{(1)}+\text{vol}^{(2)}$, where $\text{vol}^{(1)}$ comprises all these $\mathcal{N}$ cells plus the unit cell. Then

$$V_n(\vec{x})=\int_{\text{vol}^{(1)}}\tilde{v}(\vec{x},\vec{y})n(\vec{y})d\vec{y}+\int_{\text{vol}^{(2)}}\tilde{v}(\vec{x},\vec{y})n(\vec{y})d\vec{y}, \tag{22}$$

and let us analyze first the second term:

$$\int_{\text{vol}^{(2)}}\tilde{v}(\vec{x},\vec{y})n(\vec{y})d\vec{y}=\sum_{\vec{k}}\int_{\text{cell}(\vec{k})}\tilde{v}(\vec{x},\vec{y})n(\vec{y})d\vec{y}, \tag{23}$$

where the sum goes over all crystal cells in $\text{vol}^{(2)}$. Let us denote

$$\alpha_{\vec{k}}=\sup_{\substack{x\in\text{cell}\\ y\in\text{cell}(\vec{k})}}\tilde{v}(\vec{x},\vec{y}). \tag{24}$$

Then

$$\left| \int_{\mathrm{vol}^{(2)}} \tilde{v}(\vec{x},\vec{y}) n(\vec{y}) d\vec{y} \right| \leqslant \sum_{\vec{k}} \alpha_{\vec{k}} \int_{\mathrm{vol}(\vec{k})} |n(\vec{y})| d\vec{y} = N_0 \sum_{\vec{k}} \alpha_{\vec{k}}, \tag{25}$$

where we use the periodicity of n. For short range potentials considered in this paper,

$$\sum_{\vec{k}} \alpha_{\vec{k}} \leqslant \lim_{K\to\infty} \sum_{\vec{k}} \alpha_{\vec{k}} < \infty, \tag{26}$$

which means that the second term in (22) is a bounded operator:

$$\left\| \int_{\mathrm{vol}^{(2)}} \tilde{v}(\vec{x},\vec{y}) n(\vec{y}) d\vec{y} \right\| \leqslant N_0 A, \tag{27}$$

where A is independent of K. Let $v = v^{(1)} + v^{(2)}$ be the decomposition of v in $L^\infty(R^3) + L^2(R^3)$ and let

$$V_n^{(i)} = \int_{\mathrm{vol}^{(1)}} \tilde{v}^{(i)}(\vec{x},\vec{y}) n(\vec{y}) d\vec{y} = \int_{\mathrm{vol}^{(1)}} v^{(i)}(\vec{x}-\vec{y}) n(\vec{y}) d\vec{y}, \quad i = 1,2. \tag{28}$$

The second equality is true if we assume K sufficiently large. Then

$$\|V_n f\|_{L^2} \leqslant N_0 A \|f\|_{L^2} + \|V_n^{(1)}\|_{L^\infty} \|f\|_{L^2} + \|V_n^{(2)}\|_{L^2} \|f\|_{L^\infty}. \tag{29}$$

Denoting by χ_Ω the characteristic function for some $\Omega \in R^3$, it follows that

$$\begin{aligned} \|V_n^{(1)}\|_{L^\infty} \leqslant \|V_n^{(1)}\|_{L^\infty(R^3)} &= \|v^{(1)} * (n\chi_{\mathrm{vol}^{(1)}})\|_{L^\infty(R^3)} \\ &\leqslant \|v^{(1)}\|_{L^\infty(R^3)} \|n\chi_{\mathrm{vol}^{(1)}}\|_{L^1(R^3)} \\ &= (1+\mathcal{N}) N_0 \|v^{(1)}\|_{L^\infty(R^3)}, \end{aligned} \tag{30}$$

and

$$\begin{aligned} \|V_n^{(2)}\|_{L^2} \leqslant \|V_n^{(2)}\|_{L^2(R^3)} &= \|v^{(2)} * (n\chi_{\mathrm{vol}^{(1)}})\|_{L^2(R^3)} \\ &\leqslant \|v^{(2)}\|_{L^2(R^3)} \|n\chi_{\mathrm{vol}^{(1)}}\|_{L^1(R^3)} \\ &= (1+\mathcal{N}) N_0 \|v^{(2)}\|_{L^2(R^3)}. \end{aligned} \tag{31}$$

From (29) and Proposition 1,

$$\|V_n f\|_{L^2} \leqslant N_0 (A + (1+\mathcal{N}) \|v^{(1)}\|_{L^\infty(R^3)}) \|f\|_{L^2} + (1+\mathcal{N}) N_0 \|v^{(2)}\|_{L^2(R^3)} k_a \| (-\tfrac{1}{2}\Delta_{\mathbf{q}} + a) f\|_{L^2}, \tag{32}$$

which leads to

$$\|V_n (-\tfrac{1}{2}\Delta_{\mathbf{q}} + a)^{-1}\| \leqslant N_0 \{ (A + (1+\mathcal{N}) (\|v^{(1)}\|_{L^\infty(R^3)})/a + k_a \|v^{(2)}\|_{L^2(R^3)}) \}. \tag{33}$$

(ii) Using the polar decomposition, $V_n = S|V_n|$, it follows that

$$\begin{aligned} &\|(-\tfrac{1}{2}\Delta_{\mathbf{q}} + a)^{-1} V_n (-\tfrac{1}{2}\Delta_{\mathbf{q}} + a)^{-1}\|_1 \\ &\quad = \|V_n (-\tfrac{1}{2}\Delta_{\mathbf{q}} + a)^{-2}\|_1 = \|S|V_n| (-\tfrac{1}{2}\Delta_{\mathbf{q}} + a)^{-2}\|_1 \\ &\quad \leqslant \| |V_n| (-\tfrac{1}{2}\Delta_{\mathbf{q}} + a)^{-2}\|_1 = \| |V_n|^{1/2} (-\tfrac{1}{2}\Delta_{\mathbf{q}} + a)^{-2} |V_n|^{1/2}\|_1. \end{aligned}$$

Because $|V_n|^{1/2} (-\frac{1}{2}\Delta_{\mathbf{q}} + a)^{-2} |V_n|^{1/2}$ is a positive defined, self-adjoint operator:

$$
\begin{aligned}
&\| |V_n|^{1/2}(-\tfrac{1}{2}\Delta_{\mathbf{q}}+a)^{-2}|V_n|^{1/2}\|_1 \\
&\quad=\int_{\text{cell}} |V_n(\vec{x})^{1/2} C_{\mathbf{q}}(\vec{x},\vec{x};a)|V_n(\vec{x})|^{1/2}\,d\vec{x} \\
&\quad\leqslant \int_{\text{cell}} |V_n(\vec{x})| C_{\mathbf{0}}(\vec{x},\vec{x};a)\,d\vec{x} \\
&\quad= k_a \|V_n\|_{L^1} \\
&\quad= k_a K^{-3} \|V_n\|_{L^1(\mathcal{T})} \\
&\quad= k_a K^{-3} \int_{\mathcal{T}} d\vec{x} \left| \int_{\mathcal{T}} \tilde{v}(\vec{x},\vec{y}) n(\vec{y})\,dy \right| \\
&\quad\leqslant k_a K^{-3} \int_{\mathcal{T}} d\vec{y} |n(\vec{y})| \int_{\mathcal{T}} d\vec{x} |\tilde{v}(\vec{x},\vec{y})| \\
&\quad= k_a K^{-3} \int d\vec{x} |\tilde{v}(\vec{x},\vec{y})| \|n\|_{L^1(\mathcal{T})}, \qquad (34)
\end{aligned}
$$

because $\int d\vec{x}|\tilde{v}(\vec{x},\vec{y})|$ does not depend on $\vec{y}$. Finally, using: $\int_{\mathcal{T}} d\vec{x}|\tilde{v}(\vec{x},\vec{y})| \leqslant \|v\|_{L^1(R^3)} < \infty$, the affirmation follows. ■

From the above propositions, one can give an estimate of the bottom of σ_{H_n}, the spectrum of H_n. For $n \in L^1_{\text{per}}(\mathcal{T})$, $\|n\|_{L^1(\mathcal{T})} = N$, $H_n^{(\mathbf{q})} + a$ is invertible as soon as $K_1(a) + \lambda N_0 K_2(a) < 1$. Because we study the range of small coupling constants, we assume $\lambda < 1$. If ϵ_0 is the solution of $K_1(-\epsilon_0) + N_0 K_2(-\epsilon_0) = 1$, then $\inf\sigma(H_n) = \min \inf\sigma(H_n^{(\mathbf{q})}) \geqslant \epsilon_0$. What is important here is that this lower limit depends only on N_0, thus it is valid, uniformly, as the thermodynamic limit is considered. In next section, we will also need the following bound:

$$
\|(u + \lambda V_n)(-\tfrac{1}{2}\Delta_{\mathbf{q}} + a)^{-1}\| < K_1(a) + N_0 K_2(a) \equiv K_3(a), \qquad (35)
$$

if one considers $\lambda < 1$.

III. UNIFORM ESTIMATES

We start now to investigate if the conditions of the fixed point theorem are uniformly satisfied as the thermodynamic limit is considered. We start with upper and lower estimates on μ_n.

Proposition 4: For any $n \in L^1_{\text{per}}(\mathcal{T})$ with $\|n\|_{L^1(\mathcal{T})} = N$, there is an upper and a lower limit for μ_n that depend only on N_0.

Proof: Let us denote by $\phi_{\mu,\beta}$ the Fermi–Dirac distribution: $\phi_{\mu,\beta}(t) = (1 + e^{\beta(\tau-\mu)})^{-1}$. We consider a decreasing, convex function on $[\epsilon_0, \infty)$, $\underline{\phi}_{\mu,\beta}$, such that $\underline{\phi}_{\mu,\beta}(t) \leqslant (1 + e^{\beta(t-\mu)})^{-1}$ for all $\beta > 0$ and $\mu \in R$. The best choice of $\underline{\phi}_{\mu,\beta}$ was presented in Ref. 1. We add here that ϵ_0 depends only on N_0, so the definition of $\underline{\phi}_{\mu,\beta}$ depends only on N_0. If $(\eta_m^{\mathbf{q}}, \lambda_m^{\mathbf{q}})$ are the eigenvectors and the corresponding eigenvalues of $-\frac{1}{2}\Delta_{\mathbf{q}}$, then, for large, positive a,

$$
\begin{aligned}
N = \operatorname{Tr} \phi_{\mu_n,\beta}(H_n) &= \sum_{\mathbf{q}\in\Lambda} \operatorname{Tr} \phi_{\mu_n,\beta}(H_n^{(\mathbf{q})}) \\
&\geqslant \sum_{\mathbf{q}\in\Lambda} \operatorname{Tr} \underline{\phi}_{\mu_n,\beta}(H_n^{(\mathbf{q})}) \\
&\geqslant \sum_{\mathbf{q}\in\Lambda} \sum_m \underline{\phi}_{\mu_n,\beta}(\langle \eta_m^{\mathbf{q}}, H_n^{(\mathbf{q})} \eta_m^{\mathbf{q}} \rangle)
\end{aligned}
$$

$$\geqslant \sum_{\mathbf{q}\in\Lambda}\sum_{m} \underline{\phi}_{\mu_n,\beta}(\langle \eta_m^{\mathbf{q}}, (H_n^{(\mathbf{q})}+a)\,\eta_n^{\mathbf{q}}\rangle - a)$$

$$= \sum_{\mathbf{q}\in\Lambda}\sum_{m} \underline{\phi}_{\mu_n,\beta}\left((\lambda_m^{\mathbf{q}}+a)\left\langle \eta_m^{\mathbf{q}}, \left[1+(u+\lambda V_n)\left(-\frac{1}{2}\Delta_{\mathbf{q}}+a\right)^{-1}\right]\eta_m^{\mathbf{q}}\right\rangle - a\right)$$

$$\geqslant \sum_{\mathbf{q}\in\Lambda}\sum_{m} \underline{\phi}_{\mu_n,\beta}((\lambda_m^{\mathbf{q}}+a)(1+K_3(a)) - a)$$

$$\geqslant K^3 \inf_{q\in\Lambda} \mathrm{Tr}\,\underline{\phi}_{\mu_n,\beta}\left(\left(-\frac{1}{2}\Delta_{\mathbf{q}+a}\right)(1+K_3(a)) - a\right), \tag{36}$$

for $\lambda \leqslant 1$. In conclusion,

$$N_0 \geqslant \inf_{\vec{\theta}\in[0,2\pi)^3} \mathrm{Tr}\,\underline{\phi}_{\mu_n,\beta}((1+K_3(a))(-\tfrac{1}{2}\Delta_{\vec{\theta}}+a) - a). \tag{37}$$

Because $\underline{\phi}_{\mu,\beta}$ goes pointwise to 1 as μ goes to infinity, the above inequality imposes an upper limit on μ_n, that depends only on N_0. We consider now a decreasing convex function, $\overline{\phi}_{\mu,\beta}(t)$, such that $\overline{\phi}_{\mu,\beta}(t) \geqslant \phi_{\mu,\beta}(t)$ for any $\mu \in R$ and $\beta \in R_+$. If $(\chi_m^{\mathbf{q}}, \epsilon_m^{\mathbf{q}})$ are the eigenvectors and the corresponding eigenvalues of $H_n^{(\mathbf{q})}$, then

$$\mathrm{Tr}\,\overline{\phi}_{\mu,\beta}\left(-\frac{1}{2}\Delta_p\right) = \sum_{\mathbf{q}\in\Lambda} \mathrm{Tr}\,\overline{\phi}_{\mu,\beta}\left(-\frac{1}{2}\Delta_{\mathbf{q}}\right)$$

$$\geqslant \sum_{\mathbf{q}\in\Lambda}\sum_{m} \overline{\phi}_{\mu,\beta}(\langle \chi_m^{\mathbf{q}}, H_0^{(\mathbf{q})}\chi_m^{\mathbf{q}})\rangle$$

$$= \sum_{\mathbf{q}\in\Lambda}\sum_{m} \overline{\phi}_{\mu,\beta}(\langle \chi_m^{\mathbf{q}}, (H_n^{(\mathbf{q})} - u - \lambda V_n + a)\chi_m^{\mathbf{q}}\rangle - a)$$

$$= \sum_{\mathbf{q}\in\Lambda}\sum_{m} \overline{\phi}_{\mu,\beta}((\epsilon_m^{\mathbf{q}}+a)\langle \chi_m^{\mathbf{q}}, [1-(u+\lambda V_n)(H_n^{(\mathbf{q})}+a)^{-1}]\chi_m^{\mathbf{q}}\rangle - a)$$

$$\geqslant \sum_{\mathbf{q}\in\Lambda}\sum_{m} \overline{\phi}_{\mu,\beta}((\epsilon_m^{\mathbf{q}}+a)(1+K_3(a)(1-K_3(a))^{-1}) - a)$$

$$= \sum_{\mathbf{q}\in\Lambda}\sum_{m} \overline{\phi}_{\mu,\beta}((\epsilon_m^{\mathbf{q}}+a)(1-K_3(a))^{-1} - a)$$

$$= \sum_{\mathbf{q}\in\Lambda}\sum_{m} \overline{\phi}_{\mu,\beta}((\epsilon_m^{\mathbf{q}}+aK_3(a))/(1-K_3(a)))$$

$$\geqslant \sum_{\mathbf{q}\in\Lambda}\sum_{m} \phi_{\mu,\beta}((\epsilon_m^{\mathbf{q}}+aK_3(a))/(1-K_3(a)))$$

$$= \mathrm{Tr}\,\phi_{\mu,\beta}((H_n+aK_3(a))/(1-K_3(a))) = \mathrm{Tr}\,\phi_{\mu'',\beta''}(H_n), \tag{38}$$

where

$$\mu'' = \mu - aK_3(a) \quad \text{and} \quad \beta'' = \beta/(1-K_3(a)). \tag{39}$$

Replacing μ and β with

$$\mu' = \mu_n + aK_3(a) \quad \text{and} \quad \beta' = (1-K_3(a))\beta, \tag{40}$$

it follows that

$$\mathrm{Tr}\,\phi_{\mu',\beta'}(-\tfrac{1}{2}\Delta_p)\geqslant \mathrm{Tr}\,\phi_{\mu_n,\beta}(H_n)=N, \tag{41}$$

or

$$\sup_{\vec{\theta}\in[0,2\pi)^3}\mathrm{Tr}\,\overline{\phi}_{\mu',\beta'}(-\tfrac{1}{2}\Delta_{\vec{\theta}})\geqslant N_0, \tag{42}$$

which implies that $\mu'=\mu_n+aK_3(a)$ is greater than a certain finite value, which depends only on N_0. ■

We will denote the upper/lower limit of μ_n by μ_M/μ_m, respectively.

Theorem 5: *At finite temperature, there exists a constant* $\lambda_{\max}>0$, *independent of K, such that the map T is a contraction over the set* $\mathcal{S}=\{n\in L^1_{\mathrm{per}}(\mathcal{T}),\|n\|_{L^1(\mathrm{cell})}=N_0\}$, *for any K and* $\lambda<\lambda_{\max}$.

Proof: Supposing $\mu_{n_2}=\max\{\mu_{n_1},\mu_{n_2}\}$:

$$\begin{aligned}\|T[n_1]-T[n_2]\|_{L^1(T)}&\leqslant\|\hat{T}[n_1]-\hat{T}[n_2]\|_1\\&\leqslant 2\|(1+e^{\beta(H_{n_1}-\mu_{n_2})})^{-1}-(1+e^{\beta(H_{n_2}-\mu_{n_2})}\|_1\\&=2\sum_{\mathbf{q}\in\Lambda}\|(1+e^{\beta(H_n^{(\mathbf{q})}-\mu_{n_2})})^{-1}-(1+e^{\beta(H_n^{(\mathbf{q})}-\mu_{n_2})})^{-1}\|_1,\end{aligned} \tag{43}$$

where the first inequality can be proven as in Ref. 1. If $\mathcal{C}$ is a contour in the complex plane that surrounds $[\epsilon_0,\infty)$ and avoids the poles of $(1+e^{\beta(z-\mu_{n_2})})^{-1}$, then

$$\begin{aligned}&(1+e^{\beta(H_{n_1}^{(\mathbf{q})}-\mu_{n_2})})^{-1}-(1+e^{\beta(H_{n_2}^{(\mathbf{q})}-\mu_{n_2})})^{-1}\\&\quad=\frac{\lambda}{2\pi i}\int_{\mathcal{C}}dz(1+e^{\beta(z-\mu_{n_2})})^{-1}(z-H_{n_1}^{(\mathbf{q})})^{-1}V_{n_1-n_2}(z-H_{n_2}^{(\mathbf{q})})^{-1}\\&\quad=\frac{\lambda}{2\pi i}\int_{\mathcal{C}}dz(1+e^{\beta(z-\mu_{n_2})})^{-1}(H_{n_1}^{(\mathbf{q})}-z)^{-1}(H_{n_1}^{(q)}+a)\\&\qquad\times(H_{n_1}^{(\mathbf{q})}+a)^{-1}V_{n_1-n_2}(H_{n_2}^{(\mathbf{q})}+a)^{-1}(H_{n_2}^{(\mathbf{q})}+a)(z-H_{n_2}^{(\mathbf{q})})^{-1}.\end{aligned} \tag{44}$$

The contour $\mathcal{C}$ can be chosen independent of μ_{n_2}. Denoting

$$g_a(z)=\sup_{x\in[\epsilon_0,\infty)}|(x+a)/(x-z)|, \tag{45}$$

it follows that

$$\begin{aligned}&\|(1+e^{\beta(H_{n_1}^{(\mathbf{q})}-\mu_{n_2})})^{-1}-(1+e^{\beta(H_{n_2}^{(\mathbf{q})}-\mu_{n_2})})^{-1}\|_1\\&\quad\leqslant\frac{\lambda}{2\pi}\int_{\mathcal{C}}|dz||(1+e^{\beta(z-\mu_{n_2})})^{-1}|[g_a(z)/(1-K_3(a))]^2\\&\qquad\times\left\|\left(-\frac{1}{2}\Delta_{\mathbf{q}}+a\right)^{-1}V_{n_1-n_2}\left(-\frac{1}{2}\Delta_{\mathbf{q}}+a\right)^{-1}\right\|_1\\&\quad\leqslant\frac{\lambda k_a\|v\|_{L^1(R^3)}}{2\pi K^3(1-K_3(a))^2}\int_{\mathcal{C}}|dz||(1+e^{\beta(z-\mu_M)})^{-1}|g_a(z)^2\|n_1-n_2\|_{L^1(T)}.\end{aligned} \tag{46}$$

This, together with (43), leads to

$$\|T[n_1]-T[n_2]\|_{L^1(T)}\leqslant \lambda\gamma\|n_1-n_2\|_{L^1(T)}, \tag{47}$$

where

$$\gamma=\frac{k_a\|v\|_{L^1(R^3)}}{\pi(1-K_3(a))^2}\int_{\mathcal{C}}|dz||(1+e^{\beta(z-\mu_M)})^{-1}|g_a(z)^2, \tag{48}$$

in independent of K. ■

Because $\mathcal{S}$ is a closed, invariant set for T, the above result proves that, for $\lambda<\lambda_{\max}$, T has a unique fixed point in $\mathcal{S}$ for any K. In other words, the Hartree equation has a unique periodic solution for any finite volume. The result is valid only at finite temperatures, because γ diverges as the poles of $(1+e^{\beta(z-\mu_M)})^{-1}$ come closer and closer to the real axis (zero temperature limit). Of course, the zero temperature limit is well defined if $\mu_{m,M}$ are in a gap. We prove in the following that the chemical potential, $\{\mu_{T^{(om)}[n]}\}_m$, also converge to a well defined limit.

Lemma 6: For $\mu_{1,2}\in[\mu_m,\mu_M]$ *and* $n\in L^1_{\text{per}}(\mathcal{T})$, $\|n\|_{L^1(\mathcal{T})}=K^3N_0$, *the following are true:*
(i) $|\mu_1-\mu_2|\leqslant C^{-1}K^{-3}|\mathrm{Tr}(1+e^{\beta(H_n-\mu_1)})^{-1}-\mathrm{Tr}(1+e^{\beta(H_n-\mu_2)})^{-1}|$,
(ii) $K^{-3}|\mathrm{Tr}(1+e^{\beta(H_n-\mu_1)})^{-1}-\mathrm{Tr}(1+e^{\beta(H_n-\mu_2)})^{-1}\leqslant C'|\mu_1-\mu_2|$,
(iii) $K^{-3}|\mathrm{Tr}\,H_n(1+e^{\beta(H_n-\mu_1)})^{-1}-\mathrm{Tr}\,H_n(1+e^{\beta(H_n-\mu_2)})^{-1}|\leqslant C''|\mu_1-\mu_2|$,
where C *is a strictly positive constant and* C', $C''<\infty$. *All three constants do not depend on* K.

Proof: (i) Let us denote

$$F(\mu)=K^{-3}\,\mathrm{Tr}(1+e^{\beta(H_n-\mu)})^{-1}. \tag{49}$$

Then

$$\begin{aligned}\partial F/\partial\mu&=K^{-3}\beta e^{-\beta\mu}\,\mathrm{Tr}(1+e^{\beta(H_n-\mu)})^{-2}\\&\geqslant K^{-3}\beta e^{-\beta\mu_M}\,\mathrm{Tr}(1+e^{\beta(H_n-\mu_m)})^{-2}\\&=K^{-3}\beta e^{-\beta\mu_M}\sum_{\mathbf{q}\in\Lambda}\mathrm{Tr}(1+e^{\beta(H_n^{(\mathbf{q})}-\mu_m)})^{-2}.\end{aligned} \tag{50}$$

Considering a decreasing, convex function on $[\epsilon_0,\infty)$, $\underline{\phi}'_{\mu,\beta}(t)$, with the property

$$\underline{\phi}'_{\mu,\beta}(t)\leqslant(1+e^{\beta(t-\mu)})^{-2}\quad\text{for}\quad\beta\in R_+\quad\text{and}\quad\mu\in R, \tag{51}$$

it follows that

$$\begin{aligned}\partial F/\partial\mu&\geqslant K^{-3}\beta e^{-\beta\mu_M}\sum_{\mathbf{q}\in\Lambda}\mathrm{Tr}\,\underline{\phi}'_{\mu_m,\beta}(H_n^{(\mathbf{q})})\\&\geqslant K^{-3}\beta e^{-\beta\mu_M}\sum_{\mathbf{q}\in\Lambda}\sum_m\mathrm{Tr}\,\underline{\phi}'_{\mu_m,\beta}\left(\left\langle\eta_m^{\mathbf{q}},\left(-\frac{1}{2}\Delta_q+u+\lambda V_n\right)\eta_m^q\right\rangle\right)\\&\geqslant K^{-3}\beta e^{-\beta\mu_M}\sum_{\mathbf{q}\in\Lambda}\sum_m\mathrm{Tr}\,\underline{\phi}'_{\mu_m,\beta}((\lambda_m^{\mathbf{q}}+a)(1+K_3(a))-a)\\&\geqslant\beta e^{-\beta\mu_M}\inf_{\vec{\theta}\in[0,2\pi)^3}\mathrm{Tr}\,\underline{\phi}'_{\mu_m,\beta}\left(\left(-\frac{1}{2}\Delta_{\vec{\theta}}+a\right)(1+K_3(a))-a\right).\end{aligned} \tag{52}$$

The function $\underline{\phi}'_{\mu,\beta}$ can be chosen equal to $(1+e^{\beta(t-\mu)})^{-2}$ for t much larger than μ, in which case, (52) shows that $\partial F/\partial\mu\geqslant C>0$. Then

$$|F(n,\mu_1)-F(n,\mu_2)|=\int_{\min\{\mu_1,\mu_2\}}^{\max\{\mu_1,\mu_2\}}(\partial F/\partial\mu)d\mu>C|\mu_1-\mu_2|, \tag{53}$$

which proves the first affirmation.

(ii) One has

$$\partial F/\partial\mu = K^{-3}\beta e^{-\beta\mu}\sum_{\mathbf{q}\in\Lambda}\mathrm{Tr}(1+e^{\beta(H_n^{(\mathbf{q})}-\mu)})^{-2}. \tag{54}$$

If one considers a convex function on $[\epsilon_0,\infty)$ with the properties

$$\begin{aligned}\overline{\phi}'_{\mu,\beta}(t)&\geqslant(1+e^{\beta(t-\mu)})^{-2},\ \text{ for }\ \beta\in R_+\ \text{ and }\ \mu\in R,\\ \overline{\phi}'_{\mu,\beta}(t)&=(1+e^{\beta(t-\mu)})^{-2},\ \text{ for }\ t\gg\mu,\end{aligned} \tag{55}$$

one can evaluate the right hand side of (54) by following the same steps as in Proposition 4.

(iii) Consider

$$F'(\mu)=K^{-3}\,\mathrm{Tr}\,H_n(1+e^{\beta(H_n-\mu)})^{-1}, \tag{56}$$

with

$$\begin{aligned}\partial F'/\partial\mu &= K^{-3}\beta e^{-\beta\mu}\,\mathrm{Tr}\,H_n(1+e^{\beta(H_n-\mu)})^{-2}=K^{-3}\beta\mu e^{-\beta\mu}\,\mathrm{Tr}(1+e^{\beta(H_n-\mu)})^{-2}\\ &\quad+K^{-3}\beta e^{-\beta\mu}\,\mathrm{Tr}(H_n-\mu)(1+e^{\beta(H_n-\mu)})^{-2}.\end{aligned} \tag{57}$$

The first term has been estimated above. Because $\beta(t-\mu)(1+e^{\beta(t-\mu)})^{-2}$ is a convex function for $t\gg\mu$, we can find, again, a decreasing, convex function on $[\epsilon_0,\infty)$ such that

$$\begin{aligned}\overline{\phi}''_{\mu,\beta}(t)&\geqslant\beta(t-\mu)(1+e^{\beta(t-\mu)})^{-2},\quad \text{for }\ \beta\in R_+\ \text{ and }\ \mu\in R,\\ \overline{\phi}''_{\mu,\beta}(t)&=\beta(t-\mu)(1+e^{\beta(t-\mu)})^{-2},\quad \text{for }\ t\gg\mu.\end{aligned} \tag{58}$$

Then $|\partial F'/\partial\mu|$ can be bounded as in Proposition 4. ■

Theorem 7: *For any $n\in L^1_{\mathrm{per}}(\mathcal{T})$, $\|n\|_{L^1(\mathcal{T})}=K^3N_0$, the sequence $\{\mu_{\mathcal{T}^{\circ m}[n]}\}_m$ converges to a unique limit as m goes to infinity, provided $\lambda<\lambda_{\max}$. In other words, the chemical potential is well defined in the Hartree model, for any finite volume.*

Proof: For $n_{1,2}\in L^1_{\mathrm{per}}(T)$, $\|n_{1,2}\|=K^3N_0$:

$$\begin{aligned}|\mu_{n_1}-\mu_{n_2}|&\leqslant C^{-1}K^{-3}|\mathrm{Tr}(1+e^{\beta(H_{n_1}-\mu_{n_1})})^{-1}-\mathrm{Tr}(1+e^{\beta(H_{n_1}-\mu_{n_2})})^{-1}|\\ &=C^{-1}K^{-3}|\mathrm{Tr}(1+e^{\beta(H_{n_2}-\mu_{n_2})})^{-1}-\mathrm{Tr}(1+e^{\beta(H_{n_1}-\mu_{n_2})})^{-1}|\\ &\leqslant C^{-1}K^{-3}\|(1+e^{\beta(H_{n_2}-\mu_{n_2})})^{-1}-(1+e^{\beta(H_{n_1}-\mu_{n_2})})^{-1}\|_1\\ &<\frac{\lambda\gamma}{2C}\|n_1-n_2\|_{L^1(\mathrm{cell})}.\end{aligned} \tag{59}$$

This shows that

$$\lim_{m\to\infty}|\mu_{T^{\circ(m+p)}[n]}-\mu_{T^{\circ m}[n]}|\to 0, \tag{60}$$

for any positive p, so the sequence is convergent. Also, (59) shows that the limit does not depend on n. ■

A similar result can be proven for the energy. However, we will not present them here, because we will return in the next section to this problem. The following result will be useful for proving the thermodynamic limit.

Proposition 8: For any $K \in \mathbf{N}$, let E_K be the energy of the system in the Hartree approximation. Then there exists E_M, independent of K, such that $|E_K/K^3| < E_M < \infty$.

The affirmation can be proven by following the same steps as in Lemma 6.

IV. THE THERMODYNAMIC LIMIT

For a given K, we denote by n_K, μ_K, E_K the density of particles, chemical potential and the energy of the system in the Hartree approximation. We proved in the last section that these objects exist for any $K \in \mathbf{N}$ provided the coupling constant smaller than some $\lambda_{\max}$, independent of K. We will use the notation Λ_K, $\mathcal{T}_K$, T_K, $H_n^{(K)}$ to indicate that these objects correspond to some $K \in \mathbf{N}$. The estimates we use in this section are based on the following technical proposition which will be proven at the end of this section.

Proposition 9: For $n \in L^1_{\text{per}}(T)$, $\|n\|_{L^1(\text{cell})} = N_0$ and $\mu \in [\mu_m, \mu_M]$, let us consider

$$f_{1,2}:[0,2\pi)^3 \to \mathcal{L}_1, \begin{cases} f_1(\vec{\theta}) = (1 + e^{\beta(-1/2\Delta_{\vec{\theta}} + u + \lambda V_n - \mu)})^{-1} \\ f_2(\vec{\theta}) = (-\frac{1}{2}\Delta_{\vec{\theta}} + u + \lambda V_n) f_1(\vec{\theta}) \end{cases},$$

where $\mathcal{L}_1$ denotes the trace class operators defined over the unit cell. Then $f_{1,2}$ are continuous:

$$\|f_i(\vec{\theta}) - f_i(\vec{\theta}')\|_1 < ct.|\vec{\theta} - \vec{\theta}'|^{\epsilon}, \quad i = 1,2,$$

where ϵ is a strictly positive constant which depends only on N_0.

The thermodynamic limit of the physical parameters will follow from the lemma below.

Lemma 10: With the above notations:

$$\|n_{K+1} - n_K\|_{L^1(\text{cell})} \to 0, \quad \text{as } K \to \infty.$$

Proof: There is a unique extension of n_K over $\mathcal{T}_{K+1}$ such that n_K remains periodic. This extension will be denoted by the same n_K:

$$\begin{aligned} \|n_{K+1} - n_K\|_{L^1(\text{cell})} &= \|\sum_{m=1}^{\infty} (T_{K+1}^{\circ m}[n_K] - T_{K+1}^{\circ(m-1)}[n_K])\|_{L^1(\text{cell})} \\ &\leqslant \sum_{m=1}^{\infty} \|(T_{K+1}^{\circ m}[n_K] - T_{K+1}^{\circ(m-1)}[n_K])\|_{L^1(\text{cell})} \\ &\leqslant (1 - \lambda\gamma)^{-1} \|T_{K+1}[n_K] - n_K\|_{L^1(\text{cell})}. \end{aligned} \tag{61}$$

Let μ_{n_K} be the chemical potential corresponding to n_K, i.e.,

$$(K+1)^3 N_0 = \text{Tr}(1 + e^{\beta(H_{n_K}^{(K+1)} - \mu_{n_K})})^{-1}. \tag{62}$$

We prove first that

$$\delta_K = |\mu_K - \mu_{n_K}| \to 0, \quad \text{as } K \to \infty. \tag{63}$$

From Lemma 6:

$$\begin{aligned} |\mu_K - \mu_{n_K}| &\leqslant C^{-1}(K+1)^{-3} |\text{Tr}(1 + e^{\beta(H_{n_K}^{(K+1)} - \mu_K)})^{-1} - \text{Tr}(1 + E^{\beta(H_{n_K}^{(K+1)} - \mu_{n_K})})^{-1}| \\ &= C^{-1} |(K+1)^{-3} \text{Tr}(1 + e^{\beta(H_{n_K}^{(K+1)} - \mu_K)})^{-1} - N_0| \\ &= C^{-1} |(K+1)^{-3} \text{Tr}(1 + e^{\beta(H_{n_K}^{(K+1)} - \mu_K)})^{-1} - K^{-3} \text{Tr}(1 + e^{\beta(H_{n_K}^{(K)} - \mu_K)})^{-1}| \\ &\leqslant C^{-1}[(K+1)^3/K^3 - 1] N_0 + C^{-1}(K+1)^{-3} \end{aligned}$$

$$\times\Big|\sum_{\mathbf{q}\in\Lambda_{K+1}}\mathrm{Tr}(1+e^{\beta(H^{(K+1,\mathbf{q})}_{n_K}-\mu_K)})^{-1}-\sum_{\mathbf{q}\in\Lambda_K}\mathrm{Tr}(1+e^{\beta(H^{(K,\mathbf{q})}_{n_K}-\mu_K)})^{-1}\Big|$$

$$\leq C^{-1}[(K+1)^3/K^3-1]N_0+C^{-1}(K+1)^{-3}\sum_{q\in\partial\Lambda_{K+1}}\mathrm{Tr}(1+e^{\beta(H^{(K+1,\mathbf{q})}_{n_K}-\mu_K)})^{-1}$$

$$+C^{-1}(K+1)^{-3}\sum_{\mathbf{q}\in\Lambda_K}\big|\mathrm{Tr}(1+e^{\beta(H^{(K+1,\mathbf{q})}_{n_K}-\mu_K)})^{-1}-\mathrm{Tr}(1+e^{\beta(H^{(K,\mathbf{q})}_{n_K}-\mu_K)})^{-1}\big|$$

$$\leq C^{-1}N_0[(K+1)^3/K^3-1]+ct.(K+1)^{-1}$$

$$+C^{-1}(K+1)^{-3}\sum_{\mathbf{q}\in\Lambda_K}|f_1(2\pi\mathbf{q}/(K+1))-f_1(2\pi\mathbf{q}/K)|$$

$$\leq C^{-1}N_0[(K+1)^3/K^3-1]+ct.(K+1)^{-1}$$

$$+ct.C^{-1}(K+1)^{-3}\sum_{\mathbf{q}\in\Lambda_K}\left|\frac{2\pi\mathbf{q}}{K+1}-\frac{2\pi\mathbf{q}}{K}\right|^{\epsilon}$$

$$\leq C^{-1}N_0[(K+1)^3/K^3-1]+ct.(K+1)^{-1}+ct.C^{-1}(K+1)^{-\epsilon}, \tag{64}$$

which proves (63). Now

$$\begin{aligned}\|T_{K+1}[n_K]-n_K\|_{L^1(\mathrm{cell})}&=\|(1+e^{\beta(H^{(K+1)}_{n_K}-\mu_{n_K})})^{-1}(\vec{x},\vec{x})-(1+e^{\beta(H^{(K)}_{n_K}-\mu_K)})^{-1}(\vec{x},\vec{x})\|_{L^1(\mathrm{cell})}\\&\leq\|(1+e^{\beta(H^{(K)}_{n_K}-\mu_{n_K})})^{-1}(\vec{x},\vec{x})-(1+e^{\beta(H^{(K)}_{n_K}-\mu_K)})^{-1}(\vec{x},\vec{x})\|_{L^1(\mathrm{cell})}\\&\quad+\|(1+e^{\beta(H^{(K+1)}_{n_K}-\mu_{n_K})})^{-1}(\vec{x},\vec{x})-(1+e^{\beta(H^{(K)}_{n_K}-\mu_{n_K})})^{-1}(\vec{x},\vec{x})\|_{L^1(\mathrm{cell})}\\&\leq K^{-3}\|(1+e^{\beta(H^{(K)}_{n_K}-\mu_{n_K})})^{-1}-(1+e^{\beta(H^{(K)}_{n_K}-\mu_K)})^{-1}\|_1\\&\quad+\|(K+1)^{-3}\sum_{\mathbf{q}\in\Lambda_{K+1}}(1+e^{\beta(H^{(K+1,\mathbf{q})}_{n_K}-\mu_{n_K})})^{-1}(\vec{x},\vec{x})\\&\quad-K^{-3}\sum_{\mathbf{q}\in\Lambda_K}(1+e^{\beta(H^{(K,\mathbf{q})}_{n_K}-\mu_{n_K})})^{-1}(\vec{x},\vec{x})\|_{L^1,(\mathrm{cell})}.\end{aligned}\tag{65}$$

The first term, above, have been evaluated in Lemma 6, so we can continue:

$$\begin{aligned}\|T_{K+1}[n_K]-n_K\|_{L^1(\mathrm{cell})}&\leq C'|\mu_{n_K}-\mu_K|+|(K+1)^{-3}\\&\quad-K^{-3}\Big|\Big\|\sum_{\mathbf{q}\in\Lambda_{K+1}}(1+e^{\beta(H^{(K+1,\mathbf{q})}_{n_K}-\mu_{n_K})})^{-1}(\vec{x},\vec{x})\Big\|_{L^1(\mathrm{cell})}\\&\quad+K^{-3}\Big\|\sum_{\mathbf{q}\in\Lambda_{K+1}}(1+e^{\beta(H^{(K+1,\mathbf{q})}_{n_K}-\mu_{n_K})})^{-1}(\vec{x},\vec{x})\\&\quad-\sum_{\mathbf{q}\in\Lambda_K}(1+e^{\beta(H^{(K,\mathbf{q})}_{n_K}-\mu_{n_K})})^{-1}(\vec{x},\vec{x})\Big\|_{L^1(\mathrm{cell})}\\&\leq C'\delta_K+|1-K^{-3}/(K+1)^3|N_0+K^{-3}\sum_{\mathbf{q}\in\partial\Lambda_{K+1}}\|(1+e^{\beta(H^{(K+1,\mathbf{q})}_{n_K}-\mu_{n_K})})^{-1}\|_1\\&\quad+K^{-3}\sum_{\mathbf{q}\in\Lambda_K}\|(1+e^{\beta(H^{(K+1,\mathbf{q})}_{n_K}-\mu_{n_K})})^{-1}-(1+e^{\beta(H^{(K,\mathbf{q})}_{n_K}-\mu_{n_K})})^{-1}\|_1\end{aligned}$$

$$\leqslant C'\,\delta_K+\left|1-K^{-3}/(K+1)^3\right|N_0+ct.(K+1)^2/K^3$$
$$+K^{-3}\sum_{\mathbf{q}\in\Lambda_K}\left\|f_1\left(\frac{2\pi\mathbf{q}}{K+1}\right)-f_1\left(\frac{2\pi\mathbf{q}}{K}\right)\right\|_1$$
$$\leqslant C'\,\delta_K+\left|1-K^{-3}/(K+1)^3\right|N_0+ct.(K+1)^2/K^3$$
$$+ct.K^{-3}\sum_{\mathbf{q}\in\Lambda_K}K^{-\epsilon}(K+1)^{-\epsilon}|\mathbf{q}|^{\epsilon}$$
$$\leqslant C'\,\delta_K+\left|1-K^{-3}/(K+1)^3\right|N_0+ct.(K+1)^2/K^3+ct.(K+1)^{-\epsilon}, \quad (66)$$

which finishes the proof. ■

Theorem 11: *If n_K is viewed as a linear functional over L^∞(cell):*

$$\hat{n}_K(g)=\int_{\text{cell}} n_K(\vec{x})g(\vec{x})d\vec{x}, \quad g\in L^\infty(\text{cell}),$$

then we have the following.

(i) $\{\hat{n}_K\}_K$ converges weakly in L^∞(cell), i.e., $\{\hat{n}_K(g)\}_K$ converges for any $g\in L^\infty$(cell)*

(ii) The chemical potential converges in the thermodynamic limit.

(iii) The energy per unit volume converges in the thermodynamic limit.

Unfortunately, exactly for $p=1$ it occurs that $(L^p)^*\neq L^q$, where q is the Holder conjugate of p.[3] This means that we need additional information in order to prove that the thermodynamic limit of particle density is in L^1.

Proof: (i) One knows from the Banach–Alaoglu theorem[3] that the closed balls in L^∞(cell)* are compact in the weak topology. Because $\|\hat{n}_K\|=\|n_K\|_{L^1(\text{cell})}=N_0$, it follows that $\{\hat{n}_K\}_K$ must have at least one accumulation point. Due to the fact that

$$\|\hat{n}_{K+1}(g)-\hat{n}_K(g)\|\leqslant\|n_{K+1}-n_K\|_{L^1(\text{cell})}\|g\|_{L^\infty(\text{cell})}, \quad (67)$$

for any $g\in L^\infty$(cell), it follows from Lemma 10 that there must be one and only one accumulation point.

(ii) Because $\{\mu_K\}_K$ is confined in a compact set (see Proposition 4), this sequence has at least one point of accumulation. Using the results of Theorem 7 and Lemma 10, one has successively,

$$|\mu_{K+1}-\mu_K|\leqslant|\mu_{K+1}-\mu_{n_K}|+|\mu_{n_K}-\mu_K|\leqslant\gamma/(2C)|n_K-n_{K+1}|+\delta_K. \quad (68)$$

Then, from a previous theorem, we can conclude that $|\mu_{K+1}-\mu_K|\to 0$ as $K\to\infty$, which shows that there is one and only one accumulation point for $\{\mu_K\}_K$.

(iii) The energy per unit volume is also confined in a compact set (Proposition 8), $|E_K/K^3|<E_M$. Also,

$$\left|(K+1)^{-3}E_{K+1}-K^{-3}E_K\right|$$
$$=\left|((K+1)^{-3}-K^{-3})E_{K+1}+K^{-3}\,\mathrm{Tr}\,H^{(K+1)}_{n_{K+1}}(1+e^{\beta(H^{(K+1)}_{n_{K+1}}-\mu_{K+1})})^{-1}\right.$$
$$\left.-K^{-3}\,\mathrm{Tr}\,H^{(K)}_{n_K}(1+e^{\beta(H^{(K)}_{n_K}-\mu_K)})^{-1}\right|$$
$$\leqslant((K+1)^3/K^3-1)E_M+K^{-3}\Big|$$
$$\times\sum_{\mathbf{q}\in\Lambda_{K+1}}\mathrm{Tr}\,H^{(K+1,\mathbf{q})}_{n_{K+1}}(1+e^{\beta(H^{(K+1,\mathbf{q})}_{n_{K+1}}-\mu_{K+1})})^{-1}$$

$$
\begin{aligned}
&- \sum_{\mathbf{q}\in\Lambda_K} \mathrm{Tr}\, H_{n_K}^{(K,\mathbf{q})}(1+e^{\beta(H_{n_K}^{(K,\mathbf{q})}-\mu_K)})^{-1}\big| \\
\leqslant &((K+1)^3/K^3-1)E_M+K^{-3} \\
&\times \sum_{\mathbf{q}\in\partial\Lambda_{K+1}} \big|\mathrm{Tr}\, H_{n_{K+1}}^{(K+1,\mathbf{q})}(1+e^{\beta(H_{n_{K+1}}^{(K+1,\mathbf{q})}-\mu_{K+1})})^{-1}\big| \\
&+K^{-3}\sum_{\mathbf{q}\in\Lambda_K} \big\|H_{n_{K+1}}^{(K+1,\mathbf{q})}(1+e^{\beta(H_{n_{K+1}}^{(K+1,\mathbf{q})}-\mu_{K+1})})^{-1}-H_{n_K}^{(K,\mathbf{q})}(1+e^{\beta(H_{n_K}^{(K,\mathbf{q})}-\mu_K)})^{-1}\big\|_1 \\
\leqslant &((K+1)^3/K^3-1)E_M+6K^{-3}(K+1)^2E_M \\
&+K^{-3}\sum_{\mathbf{q}\in\Lambda_K} \big\|H_{n_{K+1}}^{(K+1,\mathbf{q})}(1+e^{\beta(H_{n_{K+1}}^{(K+1,\mathbf{q})}-\mu_{K+1})})^{-1}-H_{n_K}^{(K+1,\mathbf{q})}(1+e^{\beta(H_{n_K}^{(K+1,\mathbf{q})}-\mu_{K+1})})^{-1}\big\|_1 \\
&+K^{-3}\sum_{\mathbf{q}\in\Lambda_K} \big\|H_{n_K}^{(K+1,\mathbf{q})}(1+e^{\beta(H_{n_K}^{(K+1,\mathbf{q})}-\mu_{K+1})})^{-1} \\
&-H_{n_K}^{(K,\mathbf{q})}(1+e^{\beta(H_{n_K}^{(K,\mathbf{q})}-\mu_{K+1})})^{-1}\big\|_1 \\
&+K^{-3}\sum_{\mathbf{q}\in\Lambda_K} \big\|H_{n_K}^{(K,\mathbf{q})}(1+e^{\beta(H_{n_K}^{(K,\mathbf{q})}-\mu_{K+1})})^{-1}-H_{n_K}^{(K,\mathbf{q})}(1+e^{\beta(H_{n_K}^{(K,\mathbf{q})}-\mu_K)})^{-1}\big\|_1 \\
= &((K+1)^3/K^3-1)E_M+6K^{-3}(K+1)^2E_M+K^{-3}\sum_{\mathbf{q}\in\Lambda_K} \|H_{n_{K+1}}^{(K+1,\mathbf{q})}(1+e^{\beta(H_{n_{K+1}}^{(K+1,\mathbf{q})}-\mu_{K+1})})^{-1} \\
&-H_{n_K}^{(K+1,\mathbf{q})}(1+e^{\beta(H_{n_K}^{(K+1,\mathbf{q})}-\mu_{K+1})})^{-1}\|_1+K^{-3}\sum_{\mathbf{q}\in\Lambda_K}\left\| f_2\left(\frac{2\pi\mathbf{q}}{K+1}\right) \quad -f_2\left(\frac{2\pi\mathbf{q}}{K}\right)\right\|_1 \\
&+K^{-3}\sum_{\mathbf{q}\in\Lambda_K} \big\|H_{n_K}^{(K,\mathbf{q})}(1+e^{\beta(H_{n_K}^{(K,\mathbf{q})}-\mu_{K+1})})^{-1}-H_{n_K}^{(K,\mathbf{q})}(1+e^{\beta(H_{n_K}^{(K,\mathbf{q})}-\mu_K)})^{-1}\big\|_1 . \qquad (69)
\end{aligned}
$$

The third term, above, can be shown to be smaller than $\gamma'\|n_{K+1}-n_K\|_{L^1(\mathrm{cell})}$. To evaluate this term, we have to replace in Eq. (46) $(1+e^{\beta(z-\mu)})^{-1}$ by $z(1+e^{\beta(z-\mu)})^{-1}$. This will not affect the next equations, so the conclusion will be the same. The fourth term can be evaluated using the continuity of f_2 (Lemma 9) and the fifth term has been evaluated in Lemma 6. It follows that

$$
\big|(K+1)^{-3}E_{K+1}-K^{-3}E_K\big|\to 0, \quad \text{as } K\to\infty, \qquad (70)
$$

which implies that the sequence $\{E_K/K^3\}_K$ has one and only one accumulation point. ■

Proof of Lemma 9: Let us denote $H_{\vec{\theta}}=-1/2\Delta_{\vec{\theta}}+u+\lambda V_n$. By simple manipulations,

$$
\begin{aligned}
f_1(\vec{\theta})-f_1(\vec{\theta}') = &[e^{-\beta(H_{\vec{\theta}}-\mu)}-e^{-\beta(H_{\vec{\theta}'}-\mu)}]\mathrm{ch}^{-1}\,\beta/2(H_{\vec{\theta}}-\mu) \\
&+e^{-\beta(H_{\vec{\theta}'}-\mu)}[\mathrm{ch}^{-1}\,\beta/2(H_{\vec{\theta}}-\mu)-\mathrm{ch}^{-1}\,\beta/2(H_{\vec{\theta}'}-\mu)], \qquad (71)
\end{aligned}
$$

and

$$
\begin{aligned}
f_2(\vec{\theta})-f_2(\vec{\theta}') = &[H_{\vec{\theta}}e^{-\beta(H_{\vec{\theta}}-\mu)}-H_{\vec{\theta}'}e^{-\beta(H_{\vec{\theta}'}-\mu)}]\mathrm{ch}^{-1}\,\beta/2(H_{\vec{\theta}}-\mu)+H_{\vec{\theta}'}e^{-\beta(H_{\vec{\theta}'}-\mu)} \\
&\times[\mathrm{ch}^{-1}\,\beta/2(H_{\vec{\theta}}-\mu)-\mathrm{ch}^{-1}\,\beta/2(H_{\vec{\theta}'}-\mu)]. \qquad (72)
\end{aligned}
$$

Because $e^{-\beta(H_{\vec{\theta}}-\mu)}$, $H_{\vec{\theta}}e^{-\beta(H_{\vec{\theta}}-\mu)}$ and $\mathrm{ch}^{-1}\,\beta/2(H_{\vec{\theta}}-\mu)$ are bounded in $\mathcal{L}_1$, with a bound independent of $\vec{\theta}$, n and μ, the lemma follows if we prove the L^2 norm continuity of $g(H_{\vec{\theta}})$ with respect to $\vec{\theta}$, for $g(z)$ equal to $e^{-\beta(z-\mu)}$, $ze^{-\beta(z-\mu)}$ or $\mathrm{ch}^{-1}\,\beta/2(z-\mu)$. In all cases,

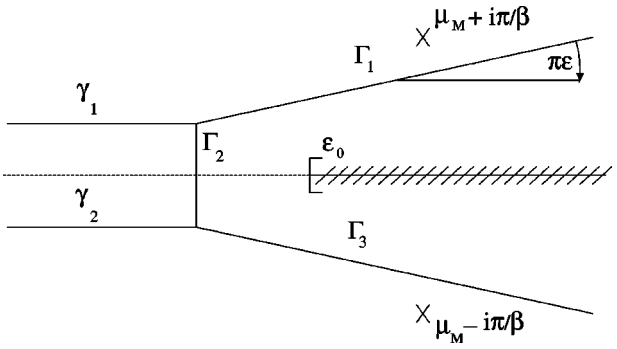

FIG. 1. The contour used in Lemma 9: $\Gamma=\Gamma_1\cup\Gamma_2\cup\Gamma_3$. The contour $\gamma=\gamma_1\cup\Gamma_2\cup\gamma_3$ is also used in Proposition 12. The poles of $\mathrm{ch}^{-1}\beta/2(z-\mu)$ at $\mu\pm i\pi/\beta$ limit the value of ϵ. The lowest limit of ϵ is obtained when $\mu=\mu_M$.

$$g(H_{\vec{\theta}})-g(H_{\vec{\theta}'})=\frac{1}{2\pi i}\int_{\Gamma}dz g(z)[(z-H_{\vec{\theta}})^{-1}-(z-H_{\vec{\theta}'})^{-1}], \tag{73}$$

where Γ is shown in Fig. 1.

Proposition 12: Let Γ be the contour shown in Fig. 1. In the conditions of Lemma 9, $(-\frac{1}{2}\Delta_{\vec{\theta}}+u+\lambda V_n-z)^{-1}$ is uniformly continuous with respect to $\vec{\theta}\in[0,2\pi)^3$, more exactly:

$$\|(-\tfrac{1}{2}\Delta_{\vec{\theta}}+u+\lambda V_n-z)^{-1}-(-\tfrac{1}{2}\Delta_{\vec{\theta}'}+u+\lambda V_n-z)^{-1}\|\leqslant ct.|\vec{\theta}-\vec{\theta}'|^{\epsilon},$$

for any $z\in\Gamma$, where $\epsilon>0$ and the ct. depends only on N_0.
We can conclude that

$$\|g(H_{\vec{\theta}})-g(H_{\vec{\theta}'})\|\leqslant ct.|\vec{\theta}-\vec{\theta}'|^{\epsilon}\frac{1}{2\pi}\int_{\Gamma}|dz||g(z)|, \tag{74}$$

and the lemma follows. ■

Proof of Proposition 12: Let us denote $u+\lambda V_n=U$. We prove first that

$$\|(-\tfrac{1}{2}\Delta_{\vec{\theta}}+U-z)^{-1}-(-\tfrac{1}{2}\Delta_{\vec{\theta}'}+U-z)^{-1}\|<ct.|\vec{\theta}-\vec{\theta}'|, \tag{75}$$

for any $z\in\gamma_1\cup\Gamma_2\cup\gamma_3$ (see Fig. 1). Because

$$\begin{aligned}(-\tfrac{1}{2}\Delta_{\vec{\theta}}+U-z)^{-1}-(-\tfrac{1}{2}\Delta_{\vec{\theta}'}+U-z)^{-1}=&(1+(-\tfrac{1}{2}\Delta_{\vec{\theta}}-z)^{-1}U)^{-1}[(-\tfrac{1}{2}\Delta_{\vec{\theta}}-z)^{-1}\\&-(-\tfrac{1}{2}\Delta_{\vec{\theta}'}-z)^{-1}](1+U(-\tfrac{1}{2}\Delta_{\vec{\theta}}-z)^{-1})^{-1},\end{aligned} \tag{76}$$

and the operators $(1+U(-\frac{1}{2}\Delta_{\vec{\theta}}-z)^{-1})^{-1}$ and $(1+(-\frac{1}{2}\Delta_{\vec{\theta}}-z)^{-1}U)^{-1}$ are uniformly bounded for $z\in\gamma_1\cup\Gamma_2\cup\gamma_3$ and the bound is independent of n (see Proposition 3), it is sufficient to prove that

$$\|(-\tfrac{1}{2}\Delta_{\vec{\theta}}-z)^{-1}-(-\tfrac{1}{2}\Delta_{\vec{\theta}'}-z)^{-1}\|<ct.|\vec{\theta}-\vec{\theta}'|. \tag{77}$$

If $G(\vec{x}-\vec{y};z)$ is the kernel of $(-\frac{1}{2}\Delta-z)^{-1}$, then

$$\left[\left(-\frac{1}{2}\Delta_{\vec{\theta}}+U-z\right)^{-1}-\left(-\frac{1}{2}\Delta_{\vec{\theta}'}+U-z\right)^{-1}\right](\vec{x},\vec{y})=\sum_{\vec{R}\in\Gamma}e^{-i\vec{R}\vec{\theta}'}(e^{-i\vec{R}(\vec{\theta}-\vec{\theta}')}-1)G(\vec{x}-\vec{y}+\vec{R};z). \tag{78}$$

Denoting by $\hat{A}_{\vec{R}}(z)$ the bounded operator on $L^2(\text{cell})$ corresponding to the kernel $G(\vec{x}-\vec{y}+\vec{R};z)$, then, for f and $g \in L^2(\text{cell})$, the following estimates are true:

$$\langle g,\hat{A}_{\vec{R}}(z)f\rangle=\langle \chi_{\text{cell}}g,(-\tfrac{1}{2}\Delta-z)^{-1}f_{\vec{R}}\rangle \leqslant |z|^{-1}\|g\|_{L^2(\text{cell})}\|f_{\vec{R}}\|_{L^2(R^3)}, \tag{79}$$

where $f_{\vec{R}}(\vec{x})=f(\vec{x}+\vec{R})$ for $\vec{x}+\vec{R}\in\text{cell}$ and zero otherwise. It is obvious that $\|f_{\vec{R}}\|_{L^2(R^3)}=\|f\|_{L^2(\text{cell})}$, which leads to $\|\hat{A}_{\vec{R}}(z)\|\leqslant|z|^{-1}$ which is a useful estimate for small $|\vec{R}|$. For large $|\vec{R}|$,

$$\begin{aligned}(\hat{A}_{\vec{R}}(z)f)(\vec{x})&=\int G(\vec{x}-\vec{y}+\vec{R};z)f(\vec{y})d\vec{y}\\ &\leqslant\sqrt{\int |G(\vec{x}-\vec{y}+\vec{R};z)|^2\,d\vec{y}}\,\|f\|_{L^2(\text{cell})}\leqslant\beta_{\vec{R}}(z)\sqrt{V_{\text{cell}}}\|f\|_{L^2(\text{cell})},\end{aligned} \tag{80}$$

where

$$\beta_{\vec{R}}(z)=\inf_{\vec{x},\vec{y}\in\text{cell}}|G(\vec{x}-\vec{y}+\vec{R};z)|. \tag{81}$$

This parameter exponentially decays as $|\vec{R}|\to\infty$, and it decreases as $\text{Re}\,z\to-\infty$. Thus

$$\|\hat{A}_{\vec{R}}(z)f\|_{L^2\text{cell}}\leqslant V_{\text{cell}}\sup_{z\in\gamma_1\cup\Gamma_2\cup\gamma_3}\beta_{\vec{R}}(z)\|f\|_{L^2(\text{cell})}. \tag{82}$$

From (77),

$$\left\|\left(-\frac{1}{2}\Delta_{\vec{\theta}}+U-z\right)^{-1}-\left(-\frac{1}{2}\Delta_{\vec{\theta}'}+U-z\right)^{-1}\right\|\leqslant|\vec{\theta}-\vec{\theta}'|\sum_{\vec{R}\in\Gamma}|\vec{R}|\|\hat{A}_{\vec{R}}(z)\|, \tag{83}$$

and the sum is convergent, because, for $\vec{R}$ large, one can use (82) while for the rest one can use (79). The sum converges due to exponential decay of $\beta_{\vec{R}}$. We turn now to investigate the case when $z\in\Gamma_1\cup\Gamma_3$. Because

$$\begin{aligned}&\|(-\tfrac{1}{2}\Delta_{\vec{\theta}'}+U-z)^{-1}-(-\tfrac{1}{2}\Delta_{\vec{\theta}'}+U-z)^{-1}\|\\ &\quad=\sup_{\|f\|,\|g\|=1}|\langle f,[(-\tfrac{1}{2}\Delta_{\vec{\theta}'}+U-z)^{-1}-(-\tfrac{1}{2}\Delta_{\vec{\theta}'}+U-z)^{-1}]g\rangle|,\end{aligned}$$

it will be sufficient to prove that

$$F(\vec{\theta},\vec{\theta}';z)\equiv\langle f,[(-\tfrac{1}{2}\Delta_{\vec{\theta}}+U-z)^{-1}-(-\tfrac{1}{2}\Delta_{\vec{\theta}'}+U-z)^{-1}]g\rangle, \tag{84}$$

satisfies

$$|F(\vec{\theta},\vec{\theta}';z)|<ct|\vec{\theta}-\vec{\theta}'|^{\epsilon},$$

for any $f, g\in L^2$ (cell), two unitary vectors. Now F is analytic on $\mathbf{C}\backslash[\epsilon_0,\infty)$ with respect to z and we just proved that $|F(z)|<ct.|\vec{\theta}-\vec{\theta}'|$, for $z\in\gamma_1$ and *ct.* independent of f and g. Then, from the two-constants theorem,[4] it follows that $|F(z)|<ct.|\vec{\theta}-\vec{\theta}'|^{\epsilon}$ for any $z\in\Gamma_1$, where $\pi\epsilon$ is the angle shown in Fig. 1. As is shown in Fig. 1, this angle depends only on the values of ϵ_0 and μ_M which, in turn, depend only on N_0. The same arguments apply for $z\in\Gamma_3$. ■

We consider a one dimensional fermionic gas confined on a circle of finite length. At finite temperatures, in the absence of any background potential, one can show that a constant density of particles is a solution to the Hartree equation, regardless of the type of interparticle interaction. Moreover, at finite temperatures and small coupling constants, our previous analysis shows that this is the only solution of the Hartree equations. We show in this paper that, at zero temperature, there is another solution, which has an asymptotic expansion: $n(x)=n_0(1+ct.\cos 2k_F x)+o(\lambda)$, where λ is the coupling constant. Moreover, this solution is stable while the trivial solution become unstable at zero temperature. © *2001 American Institute of Physics.* [DOI: 10.1063/1.1379749]

I. INTRODUCTION

Let us consider a spinless, one dimensional fermionic gas confined on a circle, $\mathcal{T}_L$, of length L. Let us initially neglect the interaction between particles. In the absence of any background potential, the ground state of the system is nondegenerate, while the excited states are all double degenerate. Suppose there are $2N$ particles trapped on $\mathcal{T}_L$, where N is an integer number. At zero temperature, these particles occupy the energetic levels in order, starting with the lowest energy. Then there is only one particle that occupies the last energetic level (Fig. 1). In other words, the Fermi energy coincides with a degenerate energy level. In this case, the density of particles is not defined, because the state of the particle on the last occupied energy level is not known. Let us analyze this in a little more detail. The energy levels of the noninteracting system are given by $E_m=1/2(2\pi m/L)^2$. Let E_K $(K=N)$ be the last occupied energy level. In this case, the Fermi energy is given by

$$\varepsilon_F=\tfrac{1}{2}k_F^2=\tfrac{1}{2}(2\pi K/L)^2\Rightarrow L/(\lambda_F/2)=2K, \tag{1}$$

or, in other words, the half of the Fermi wavelength divides the length of the crystal in an even number. Things become clearer if we look at H_0 as a periodic Hamiltonian, with period $\delta=\lambda_F/2=\pi/k_F$. We consider the usual unitary transformation:

$$U:L^2(\mathcal{T}_L)\rightarrow\bigoplus_{q=0}^{2K-1}L^2[0,\delta],$$

$$L^2(\mathcal{T}_L)\ni f\rightarrow(Uf)_q(x)=\frac{1}{\sqrt{2K}}\sum_{m=0}^{2K-1}e^{-i\theta_q m}f(x+m\delta), \tag{2}$$

where $\theta_q=2\pi(q/2K)$. In this case,

$$UH_0U^{-1}=\bigoplus_{q=0}^{2K-1}-\frac{1}{2}\left(\frac{d^2}{dx^2}\right)_{\theta_q}\equiv\bigoplus_{q=0}^{2K-1}H_0^{(q)}, \tag{3}$$

[a]Electronic mail: emprodan@rice.edu

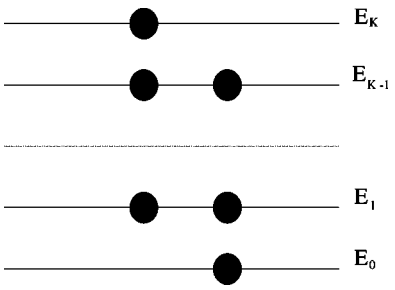

FIG. 1. The $2N$ particles occupy the lowest energetic levels. The last particle occupies a double degenerate level.

where $(d^2/dx^2)_{\theta_q}$ is the Laplace operator over $[0,\ \delta]$ with the boundary conditions:

$$f(\delta)=e^{i\theta_q}f(0) \quad \text{and} \quad f'(\delta)=e^{i\theta_q}f'(0). \tag{4}$$

Their eigenvalues and the corresponding eigenvectors are given by

$$\varepsilon_m^{(q,0)}=\tfrac{1}{2}(\omega_m+\theta_q/\delta)^2;\ \ \varphi_m^{(q,0)}(x)=\delta^{-1/2}e^{i(\omega_n+\theta_q/\delta)x}, \quad m\in\mathbf{Z}, \tag{5}$$

where $\omega_m=2\pi m/\delta$. We mention a few important properties of H_0^q.

(1) $H_0^{(q)}$ and $H_0^{(2K-q)}$ are anti-unitarily equivalent for $q=1,2,...,2K-1$, relative to the complex conjugation. This means that H_0^q and H_0^{2K-q} have the same eigenvalues and the corresponding eigenvectors are complex conjugate.

(2) For $q<K$, the ground state is defined by $m=0$. The ground state is given by

$$\varepsilon_0^{(q,0)}=\tfrac{1}{2}(\theta_q/\delta)^2;\ \ \varphi_0^{(q,0)}(x)=\delta^{-1/2}e^{i(\theta_q/\delta)x}. \tag{6}$$

The first excited state is $\varepsilon_{-1}^{(q,0)}$.

(3) For $q=K$, the ground state is degenerate:

$$\varepsilon_0^{(q=K,0)}=\varepsilon_{-1}^{(q=K,0)}=\tfrac{1}{2}(\pi/\delta)^2,$$
$$\varphi_0^{(q=K,0)}(x)=\delta^{-1/2}e^{i(\pi/\delta)x},\ \ \varphi_{-1}^{(q=K,0)}(x)=\varphi_0^{(q=K,0)}(x)^*. \tag{7}$$

(4) For $q>K$, the ground state is again nondegenerate:

$$\varepsilon_{-1}^{(q,0)}=\tfrac{1}{2}(-2\pi/\delta-\theta_q/\delta)^2;\ \ \varphi_{-1}^{(q,0)}(x)=\delta^{-1/2}e^{i(-2\pi/\delta+\theta_q/\delta)x}. \tag{8}$$

The first excited state is $\varepsilon_0^{(q,0)}$.

Then there is an alternative way of looking on the problem. As in Fig. 2, one can think that $2N-1$ particles occupy the nondegenerate ground states of $H_0^{(q\neq K,0)}$, while the last particle sits on the double degenerate ground state of $H_0^{(K,0)}$. Suppose, now, that a periodic potential is added:

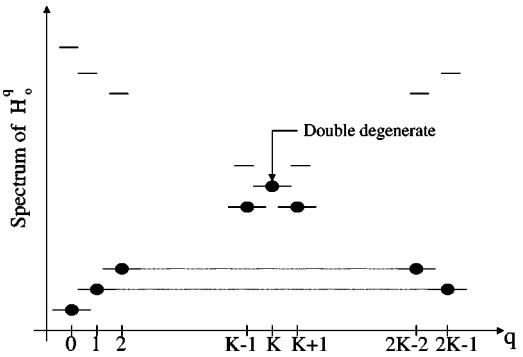

FIG. 2. The spectrum of $H_0^{(q)}$. The last particle occupies the double degenerate ground state of $H_0^{(K)}$.

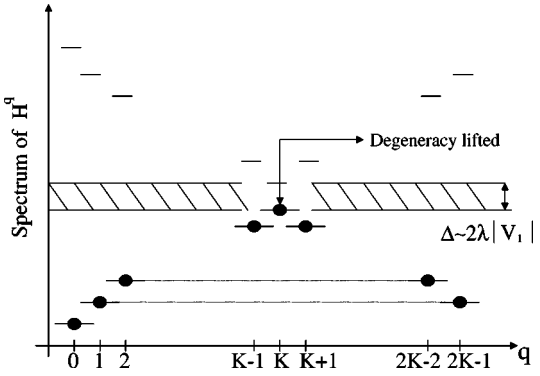

FIG. 3. The spectrum of $H_n^{(q)}$. The gap is opened due to the periodic potential.

$V(x+\delta)=V(x)$. If $V_1=\int_0^\delta e^{-i(2\pi/\delta)x}V(x)dx\neq 0$, perturbation theory shows that the degeneracy of the ground state of $H_0^{(K,0)}$ is lifted, or, in other words, a gap will open exactly at the Fermi energy. In this case, $H=H_0+V$ will be unitarily equivalent, through the same unitary transformation (1), to

$$UHU^{-1}=\bigoplus_{q=0}^{2K-1}\left[-\frac{1}{2}\left(\frac{d^2}{dx^2}\right)_{\theta_q}+V\right]\equiv\bigoplus_{q=0}^{2K-1}H^{(q)}. \tag{9}$$

In the limit of small coupling constants, the spectrum of these Hamiltonians can be pictured as in Fig. 3. Because the last occupied energy level is nondegenerate, the density of particles will be well defined at zero temperature. If $P^{(q)}$ is the projector onto the ground state of $H^{(q)}$, then the density of particles is given by

$$n(x)=\sum_{q=0}^{2K-1}(U^{-1}P^{(q)}U)(x,x)\Leftrightarrow n(x+m\delta)=\frac{1}{2K}\sum_{q=0}^{2K-1}P^{(q)}(x,x), \tag{10}$$

for $x\in[0,\delta]$ and any integer m. In the Hartree approximation, this periodic potential may come from a modulation of the particles density. Indeed, denoting by $|x,y|$ the distance between two points of the circle $\mathcal{T}$ and if v denotes the two-body interaction, then

$$H_n=H_0+\lambda\int_{\mathcal{T}}v(|x,y|)[n(y)-n_0]dy \tag{11}$$

is a periodic Hamiltonian. This happens because, if $n(x+\delta)=n(x)$,

$$\begin{aligned}V_n(x+\delta)&=\int_{\mathcal{T}}v(|x+\delta,y|)[n(y)-n_0]dy\\&=\int_{\mathcal{T}}v(|x,y-\delta|)[n(y)-n_0]dy\\&=\int_{\mathcal{T}}v(|x,y|)[n(y+\delta)-n_0]dy=V_n(x).\end{aligned} \tag{12}$$

Here we used $|x+t,y|=|x,y-t|$. We will consider in this paper that the real axis is winded around $\mathcal{T}$, thus, any point of the real axis may be considered also a point of the circle. In (11), a

background charge has been considered. Its effect is a constant added to the Hamiltonian. However, this will be useful because it cancels the zero-th Fourier coefficient of V_n. We use the following notations:

$$UH_nU=\bigoplus_{q=0}^{2K-1}\left[-\frac{1}{2}\left(\frac{d^2}{dx^2}\right)_{\theta_q}+\lambda V_n\right]\equiv\bigoplus_{q=0}^{2K-1}H_n^{(q)}. \tag{13}$$

The eigenvalues of $H_n^{(q)}$ will be denoted by $\varepsilon_m^{(q,n)}$ and the corresponding projectors by $P_m^{(q,n)}$. Also we will use in the next section $P_{0-1}^{(q,n)}$ to denote the projector for $\varepsilon_0^{(q,n)}$ and $\varepsilon_{-1}^{(q,n)}$. The notation implies that $\varepsilon_m^{(q,n)}$ are perturbations of $\varepsilon_m^{(q,n_0)}$. This is unambiguous for $q\neq K$. For $q=K$, there is an ambiguity about $\varepsilon_{0,-1}^{(K,n)}$ because the unperturbed eigenvalues are equal. Our convention will be that $\varepsilon_0^{(K,n)}$ denotes the lowest energy level of $H_n^{(K)}$. With the remarks above, it follows that the Hartree problem is well defined on the set:

$$\mathcal{S}_\epsilon=\left\{n\in L^1_{\rm per}(\mathcal{T}_L)\,\middle|\,\|n\|_{L^1(\mathcal{T})}=2N,\left|\frac{1}{\delta}\int_0^\delta e^{-i(2\pi/\delta)x}n(x)dx\right|>\epsilon\right\}, \tag{14}$$

for some $\epsilon>0$, because, for $n\in\mathcal{S}_\epsilon$, the first Fourier coefficient of V_n is nonzero, which means the gap is opened in the spectrum (at least in the range of small coupling constants) exactly at the Fermi energy, so the projector on the spectrum below Fermi energy is well defined. This means we can define the map

$$T:\mathcal{S}_\epsilon\to L^1_{\rm per}(\mathcal{T});\quad T[n](x)=P_{(-\infty,\epsilon_F)}(H_n)(x,x)=\sum_{q=0}^{2K-1}(U^{-1}P^{(q,n)}U)(x,x). \tag{15}$$

The value of ϵ is fixed, such that $\epsilon\ll 1/(4\delta K)$ for reasons that will be explained in the next section. The Hartree problem consists[1] of solving $n=T[n]$, which, as we shall see in the next sections, has a solution for λ small.

II. THE $\lambda\to 0^+$ LIMIT

We start by computing the asymptotic expansion of the map T. We will see that the perturbation of the degenerate ground state of $H_0^{(K)}$ has a nontrivial effect.

Proposition 1: The asymptotic expansion of T around $\lambda=0$ *is given by*

$$T[n](x+m\delta)=\frac{1}{\delta}+\frac{\lambda v_1}{2K\delta(\varepsilon_0^{(K,n)}-\varepsilon_{-1}^{(K,n)})}(n_1e^{i2\pi x/\delta}+n_{-1}e^{-i2\pi x/\delta})+o(\lambda),$$

for $x\in[0,\delta]$ *and any integer m. The Fourier coefficients are given by*

$$n_m=\frac{1}{\delta}\int_0^\delta e^{-i\omega_m x}n(x)dx\quad\text{and}\quad v_m=\int_{\mathcal{T}}e^{-i\omega_m(x-y)}v(|x,y|)dx.$$

Before proving this proposition, we need to compute the perturbed eigenvalues. In the classical perturbation theory,[2] one needs to calculate the projectors in order to find the corresponding perturbed eigenvalues. There is a direct way of finding the perturbed eigenvalues, without involving the projectors.

Proposition 2: If $v\in L^{(2)}(R)+L^\infty(R)$, *then the eigenvalues of* $H_n^{(K)}$ *are the solutions of the following equation (in E)*:

$$E-\varepsilon_0^{(K,n)}=\lambda M_{00}(E)\pm|\lambda M_{0,-1}(E)|,$$

where

$$M_{ij}(E)=\langle \varphi_i^{(K,n_0)},[1-\lambda V_n G_0^{(K,n_0)}(E)]^{-1}V_n\varphi_j^{(K,n_0)}\rangle$$

and $G_0^{(K,n_0)}(E)$ *is the bounded operator for* E *in a vicinity of* $\varepsilon_0^{(K,n_0)}=\varepsilon_{-1}^{(K,n_0)}$, *given by*

$$G_{0,-1}^{(K,n_0)}(E)=(E-H_0^{(K)})^{-1}-(E-\varepsilon_0^{(K,n_0)})^{-1}P_{0,-1}^{(K,n_0)}.$$

Proof: For $E\neq\varepsilon_0^{(K,n_0)}$ one has successively,

$$\begin{aligned}(E-H_0^{(K)}-\lambda V_n)&=[1-\lambda V_n(E-H_0^{(K)})^{-1}](E-H_0^{(K)})\\&=[1-\lambda V_n(E-\varepsilon_0^{(K,n_0)})^{-1}P_{0,-1}^{(K,n_0)}-\lambda V_n G_{0,-1}^{(K,n_0)}](E-H_0^{(K)})\\&=(1-\lambda V_n G_{0,-1}^{(K,n_0)})\\&\quad\times[1-\lambda(E-\varepsilon_0^{(K,n_0)})^{-1}(1-\lambda V_n G_{0,-1}^{(K,n_0)})^{-1}V_n P_{0,-1}^{(K,n_0)}](E-H_0^{(K)}).\end{aligned}\tag{16}$$

We used that $V_n G_{0,-1}^{(K,n_0)}$ is a bounded operator for E in a vicinity of $\varepsilon_0^{(K,n_0)}$, which easily follows from Ref. 3. Assuming that the perturbed eigenvalues are different from the unperturbed ones, we can conclude that $E-H_0^{(K)}-\lambda V_n$ is not invertible if and only if

$$\det[1-\lambda(E-\varepsilon_0^{(K,n_0)})^{-1}(1-\lambda V_n G_{0,-1}^{(K,n_0)})^{-1}V_n P_{0,-1}^{(K,n_0)}]=0.\tag{17}$$

For two trace class operators, $\det(1+AB)=\det(1+BA)$, which allows us to write

$$\det[1-\lambda(E-\varepsilon_0^{(K,n_0)})^{-1}P_{0,-1}^{(K,n_0)}(1-\lambda V_n G_{0,-1}^{(K,n_0)})^{-1}V_n P_{0,-1}^{(K,n_0)}]=0,\tag{18}$$

which is equivalent to

$$\det[P_{0,-1}^{(K,n_0)}-\lambda(E-\varepsilon_0^{(K,n_0)})^{-1}P_{0,-1}^{(K,n_0)}(1-\lambda V_n G_{0,-1}^{(K,n_0)})^{-1}V_n P_{0,-1}^{(K,n_0)}]=0.\tag{19}$$

This is just an ordinary determinant:

$$\det\begin{pmatrix}1-\lambda(E-\varepsilon_0^{(K,n_0)})^{-1}M_{00}(E) & -\lambda(E-\varepsilon_0^{(K,n_0)})^{-1}M_{01}(E)\\ -\lambda(E-\varepsilon_0^{(K,n_0)})^{-1}M_{01}(E)^* & 1-\lambda(E-\varepsilon_0^{(K,n_0)})^{-1}M_{-1-1}(E)\end{pmatrix}=0,\tag{20}$$

where we use the fact that $(1-\lambda V_n G_{0,-1}^{(K,n_0)})^{-1}V_n$ is self-adjoint ($\Rightarrow M_{-10}(E)=M_{0-1}(E)^*$). This can be seen by expanding this operator. Thus

$$E-\varepsilon_0^{(K,n_0)}=\lambda\frac{M_{00}(E)+M_{-1-1}(E)}{2}\pm\frac{|\lambda|}{2}\sqrt{(M_{00}(E)-M_{-1-1}(E))^2+4|M_{0-1}|^2}.\tag{21}$$

Because the kernel of the operator $(E-H_0^{(K)})^{-1}$ has no imaginary part for $E\in R$,[4] $(1-\lambda V_n G_{0,-1}^{(K,n_0)})^{-1}V_n$ commutes with the complex conjugation, C^*. Then $M_{00}(E)=M_{-1-1}(E)$. Indeed,

$$\begin{aligned}&\langle\varphi_0^{(K,n_0)},[1-\lambda V_n G_0^{(K,n_0)}(E)]^{-1}V_n\varphi_0^{(K,n_0)}\rangle\\&\quad=\langle C^*\varphi_{-1}^{(K,n_0)},[1-\lambda V_n G_0^{(K,n_0)}(E)]^{-1}V_n C^*\varphi_{-1}^{(K,n_0)}\rangle\\&\quad=\langle C^*\varphi_{-1}^{(K,n_0)},C^*[1-\lambda V_n G_0^{(K,n_0)}(E)]^{-1}V_n\varphi_{-1}^{(K,n_0)}\rangle\\&\quad=\langle[1-\lambda V_n G_0^{(K,n_0)}(E)]^{-1}V_n\varphi_{-1}^{(K,n_0)},\varphi_{-1}^{(K,n_0)}\rangle\end{aligned}$$

$$= \langle \varphi_{-1}^{(K,n_0)}, [1-\lambda V_n G_0^{(K,n_0)}(E)]^{-1} V_n \varphi_{-1}^{(K,n_0)} \rangle. \tag{22}$$

In the same way, it follows that $M_{0-1}(E)$ is a real number. In consequence, the equation for the perturbed eigenvalues is

$$E - \varepsilon_0^{(K,n_0)} = \lambda M_{00}(E) \pm |\lambda M_{0,-1}(E)|. \tag{23}$$

It is useful to give the asymptotic expansion of the eigenvalues. A simple calculus shows

$$M_{00}(E) = \langle \varphi_0^{(K,n_0)}, V_n \varphi_0^{(K,n_0)} \rangle + \lambda \langle \varphi_0^{(K,n_0)}, V_n G_0^{(K,n_0)}(E) V_n \varphi_0^{(K,n_0)} \rangle = o(\lambda), \tag{24}$$

because the background charge cancels the zero-th Fourier coefficient of V_n:

$$\begin{aligned} M_{0-1}(E) &= \langle \varphi_0^{(K,n_0)}, V_n \varphi_{-1}^{(K,n_0)} \rangle + o(\lambda) \\ &= \frac{1}{\delta} \int_0^{\delta} e^{-i\omega_1 x} V_n(x) dx + o(\lambda) \\ &= \frac{1}{\delta} \frac{1}{2K} \int_{\mathcal{T}} dx \int_{\mathcal{T}} dy e^{-i\omega_1 x} v(|x,y|)(n(y)-n_0) + o(\lambda) \\ &= \int_{\mathcal{T}} dx\, e^{-i\omega_1 (x-y)} v(|x,y|) \frac{1}{\delta} \int_0^{\delta} e^{-i\omega_1 y} n(y) = v_1 n_1 + o(\lambda). \end{aligned} \tag{25}$$

Finally,

$$\begin{aligned} \varepsilon_0^{(K,n)} &= \varepsilon_0^{(K,n_0)} - |\lambda v_1 n_1| + o(\lambda^2), \\ \varepsilon_{-1}^{(K,n)} &= \varepsilon_0^{(K,n_0)} + |\lambda v_1 n_1| + o(\lambda^2), \end{aligned} \tag{26}$$

Due to our notation, these eigenvalues are not analytic at $\lambda = 0$, because here they switch places such that $\varepsilon_0^{(K,n)}$ is always the lowest eigenvalue, as our notation requires. Equation (26) also shows that the perturbed eigenvalues are different by $\varepsilon_0^{(K,n_0)}$ for small λ, which means the assumption we made is true. ■

Proof of Proposition 1: Using resolvent calculus, it follows that

$$P^{(q,n)} = P_0^{(q,n_0)} + \lambda R^{(q,n)} \quad \text{for} \quad q < K, \tag{27}$$

where $R^{(q,n)}$ is a finite rank operator, uniformly bounded for λ in a vicinity of 0 and $n \in \mathcal{S}_\epsilon$. For $q = K$ we can write only

$$P_0^{(K,n)} + P_{-1}^{(q,n)} = P_0^{(K,n_0)} + P_{-1}^{(K,n_0)} + \lambda Q^{(K,n)}, \tag{28}$$

where, again, $Q^{(K,n)}$ is a finite rank operator, uniformly bounded for λ in a vicinity of 0 and $n \in \mathcal{S}_\epsilon$. If the eigenvalues of $H_n^{(K)}$ are known, then

$$(\varepsilon_0^{(K,n)} - \varepsilon_{-1}^{(K,n)}) P_0^{(K,n)} = P_{0,-1}^{(K,n)} (H_n^{(K)} - \varepsilon_{-1}^{(K,n)}) P_{0,-1}^{(K,n)}, \tag{29}$$

can be used to calculate the projector. Indeed, if one plugs in the right-hand side of (29) the expression (28),

$$\begin{aligned} (\varepsilon_0^{(K,n)} - \varepsilon_{-1}^{(K,n)}) P_0^{(K,n)} &= P_{0,-1}^{(K,n_0)} (H_n^{(K)} - \varepsilon_{-1}^{(K,n)}) P_{0,-1}^{(K,n_0)} + \lambda (\varepsilon_0^{(K,n)} - \varepsilon_{-1}^{(K,n)}) P_0^{(K,n)} Q^{(q,n)} \\ &\quad + \lambda Q^{(q,n)} (H_n^{(K)} - \varepsilon_{-1}^{(K,n)}) P_{0,-1}^{(K,n_0)}. \end{aligned} \tag{30}$$

We simplify the notation by

$$\hat{K}_0 \equiv (\varepsilon_0^{(K,n)} - \varepsilon_{-1}^{(K,n)})^{-1} P_{0,-1}^{(K,n_0)} (H_n^{(K)} - \varepsilon_{-1}^{(K,n)}) P_{0,-1}^{(K,n_0)}. \tag{31}$$

Then

$$P_0^{(K,n)}(1-\lambda Q^{(K,n)}) = \hat{K}_0 + \lambda (\varepsilon_0^{(K,n)} - \varepsilon_{-1}^{(K,n)})^{-1} Q^{(q,n)} (H_n^{(K)} - \varepsilon_{-1}^{(K,n)}) P_{0,-1}^{(K,n_0)}. \tag{32}$$

Using the identity

$$(1-\lambda Q^{(K,n)})^{-1} = 1 + \lambda Q^{(K,n)} (1-\lambda Q^{(K,n)})^{-1}, \tag{33}$$

we can finally give the asymptotic expansion of $P_0^{(K,n)}$:

$$P_0^{(K,n)} = \hat{K}_0 + \lambda R^{(K,n)}, \tag{34}$$

where

$$R^{(K,n)} = \left[\hat{K}_0 Q^{(K,n)} + Q^{(K,n)} \hat{K}_0 + \frac{\lambda}{\varepsilon_0^{(K,n)} - \varepsilon_{-1}^{(K,n)}} Q^{(K,n)} (P_{0,-1}^{(K,n_0)})^{\perp} V_n P_{0,-1}^{(K,n_0)} \right] \times (1-\lambda Q^{(K,n)})^{-1}, \tag{35}$$

is uniformly bounded for small λ and $n \in \mathcal{S}_\epsilon$. We can write now the asymptotic expansion of the map T:

$$T[n](x+m\delta) = \frac{1}{2K} \left[P_0^{(0,n_0)}(x,x) + 2 \sum_{q=1}^{K-1} P_0^{(q,n_0)}(x,x) + \hat{K}_0(x,x) + \lambda R'[n](x,x) \right]. \tag{36}$$

Because the operators $R^{(q,n)}$, $q = \overline{0,K}$, are of finite rank and uniformly bounded, it follows that $\lambda R'[n](x,x)$ actually goes to zero in $L^1(\mathcal{T})$ as λ goes to zero. Using the expressions for the projectors,

$$T[n](x+m\delta) = \frac{1}{\delta} + \frac{\lambda v_1}{2K(\varepsilon_0^{(K,n)} - \varepsilon_{-1}^{(K,n)})\delta} (n_1 e^{i2\pi x/\delta} + n_{-1} e^{-i2\pi x/\delta}) + \frac{2\varepsilon_0^{(K,n_0)} - \varepsilon_0^{(K,n)} - \varepsilon_{-1}^{(K,n)}}{2K(\varepsilon_0^{(K,n)} - \varepsilon_{-1}^{(K,n)})\delta} + \lambda R'[n](x,x), \tag{37}$$

where we also used $v_1 = v_{-1}$. The leading term is given by

$$\frac{1}{\delta} + \frac{\lambda v_1}{2K(\varepsilon_0^{(K,n)} - \varepsilon_{-1}^{(K,n)})\delta} (n_1 e^{i2\pi x/\delta} + n_{-1} e^{-i2\pi x/\delta}), \tag{38}$$

because the third term is of order λ, as it follows from Proposition 2. ■

We formulate now the principal result of this section.

Proposition 3: If the Hartree equation $n = T[n]$ has a solution for λ small, then this solution has a well defined limit as λ goes to zero, given by

$$\lim_{\lambda \to 0^+} n(x) = \frac{1}{\delta} \left[1 + \frac{1}{2K} \cos(2k_F x + \phi) \right],$$

provided $v_1 < 0$. The limit is in $L^1(\mathcal{T})$.

Proof: Because $R^{(q,n)}$, $q=0,1,...,K$, are of finite rank, uniformly bounded for $n\in\mathcal{S}_\epsilon$ and small λ, we have

$$\lim_{\lambda\to 0^+} n_\lambda(x)=\lim_{\lambda\to 0^+} T[n_\lambda](x)=\frac{1}{\delta}-\frac{1}{2K\delta}\frac{v_1}{2|v_1 n_1|}(n_1 e^{i2\pi x/\delta}+n_{-1}e^{-i2\pi x/\delta}), \tag{39}$$

where the limit is true in $L^1(\mathcal{T}_L)$. Writing $n_{\pm 1}=|n_1|e^{\pm i\phi}$:

$$\lim_{\lambda\to 0^+} n_\lambda(x)=\frac{1}{\delta}-\frac{1}{2K\delta}\frac{v_1}{|v_1|}\cos[2\pi x/\delta+\phi]. \tag{40}$$

On the other hand,

$$n(x)=n_0+2|n_1|\cos[2\pi x/\delta+\phi]+\sum_{|m|>1} n_m e^{i2\pi m x/\delta}, \tag{41}$$

which leads to $|n_1|=-v_1/(4K\delta|v_1|)$. This is the reason we chose $\epsilon<1/(4K\delta)$. Then there is a solution if and only if $v_1<0$. For example, an attractive, short range interaction will satisfy this condition. Assuming $v_1<0$,

$$\lim_{\lambda\to 0^+} n(x)=\frac{1}{\delta}\left[1+\frac{1}{2K}\cos(2k_F x+\phi)\right]. \tag{42}$$

■

The parameter ϕ is free, and it comes, basically, from the symmetry of the problem relative to the rotation of the circle $\mathcal{T}$. Specifically, if n is a solution of the Hartree equation so it is $n_\phi(x)=n(x+\phi)$.

III. THE $\lambda>0$ CASE

There is another symmetry that we will exploit in this section. Because the interparticle interaction depends only on the distance between particles, it follows that $V_n(-x)=V_n(x)$ whenever $n(-x)=n(x)$. Because the kinetic energy is symmetric relative to $x\to -x$ transformation, it follows that $T[n](-x)=T[n](x)$ whenever $n(-x)=n(x)$. In other words, the space of densities with this property is invariant under T. In this section, we restrict T to the intersection of $\mathcal{S}_\epsilon$ with the space of densities with this property. The new set is denoted by the same symbol $\mathcal{S}_\epsilon$. We mention that, for $n\in\mathcal{S}_\epsilon$, the Fourier coefficients of n are real numbers, which is a major advantage as we will see in the following. Let us analyze first the leading term of T.

Proposition 4: For small λ, *the leading term of the map T,*

$$T_0[n]=\frac{1}{\delta}+\frac{1}{2K\delta}\frac{\lambda v_1}{\varepsilon_0^{(K,n)}-\varepsilon_{-1}^{(K,n)}}(n_1 e^{i\omega_1 x}+n_{-1}e^{-i\omega_1 x}),$$

has a fixed point in $\mathcal{S}_\varepsilon$.

Proof: Restricted to $\mathcal{S}_\varepsilon$, T_0 becomes

$$T_0[n]=\frac{1}{\delta}+\frac{1}{2K\delta}\frac{\lambda v_1}{\varepsilon_0^{(K,n)}-\varepsilon_{-1}^{(K,n)}}2n_1\cos\omega_1 x. \tag{43}$$

Of course, the fixed point must be of the form $1/\delta+2n_1\cos\omega_1 x$, which leads to

$$\frac{1}{2K\delta}\lambda v_1/(\varepsilon_0^{(K,n)}-\varepsilon_{-1}^{(K,n)})=1. \tag{44}$$

We use the implicit function theorem to prove that, for small, positive λ, this equation has a solution, i.e., there is a $n_1(\lambda)$ such that (44) is satisfied. First we remember that, with our notation, $\varepsilon_{0,-1}^{(K,n)}$ are not analytic at $\lambda=0$. The eigenvalues were the solutions of the equations

$$E-\varepsilon_0^{(K,n_0)}=\lambda M_{00}(E)\pm|\lambda M_{0,-1}(E)|. \tag{45}$$

We will replace $\varepsilon_{0,-1}^{(K,n)}$ by $\varepsilon_{\pm}^{(K,n)}$ given by the solutions of the equations:

$$E-\varepsilon_0^{(K,n_0)}=\lambda(M_{00}(E)\pm M_{0-1}(E)). \tag{46}$$

The asymptotic expansion of $M_{0,-1}(E)$ was given in Proposition 2:

$$M_{0-1}(E)=v_1n_1+o(\lambda)<0, \tag{47}$$

for small λ and n_1 in a vicinity of the solution found last section, $\underline{n}_1=1/(4K\delta)$. This means $\varepsilon_{\pm}^{(K,n)}=\varepsilon_{0,-1}^{(K,n)}$ for $\lambda>0$ and $\varepsilon_{\mp}^{(K,n)}=\varepsilon_{0,-1}^{(K,n_0)}$ for $\lambda<0$. We consider the function

$$F(\lambda,n_1)=\frac{1}{2K\delta}\lambda v_1/(\varepsilon_+^{(K,n)}(\lambda)-\varepsilon_-^{(K,n)}(\lambda)). \tag{48}$$

For this particular expression of n, $V_n=2v_1n_1\cos\omega_1x$. If we denote by $\varepsilon_{\pm}(\xi)$ the eigenvalues of $H_0^{(K)}+2\xi v_1\cos\omega_1x$, then $\varepsilon_{\pm}^{(K,n)}(\lambda)=\varepsilon_{\pm}(\xi=\lambda v_1)$. Thus, if we define

$$\tilde{F}(\xi)=\frac{1}{2K\delta}\xi v_1/(\varepsilon_+(\xi)-\varepsilon_-(\xi)), \tag{49}$$

we can write $F(\lambda,n_1)=\tilde{F}(\lambda n_1)/n_1$. Now, $\tilde{F}$ is analytic for $\xi\neq0$, with a well defined limit as $\xi\to0$. This means that $\tilde{F}$ is analytic in a vicinity of 0 which implies that $F(\lambda,n_1)$ is analytic in both arguments, for λ in a vicinity of 0 and n_1 in a vicinity of $\underline{n}_1$. Moreover,

$$\frac{\partial F(\lambda,n_1)}{\partial n_1}=-\frac{1}{n_1^2}\tilde{F}(\lambda n_1)+\frac{\lambda}{n_1}\frac{d\tilde{F}}{d\xi}(\lambda n_1), \tag{50}$$

which leads to $\partial F(\lambda,n_1)/\partial n_1|_{\lambda=0,n_1=\underline{n}_1}=-1/\underline{n}_1\neq0$. Collecting all these results,

$$\begin{aligned}&F(\lambda,n_1),\text{analytic around } (0,\underline{n}_1);\\ &\left.\frac{\partial F(\lambda,n_1)}{\partial n_1}\right|_{(0,\underline{n}_1)}\neq0;\quad F(0,\underline{n}_1)=1,\end{aligned} \tag{51}$$

so the conditions of the analytic implicit function theorem are satisfied. This means there is an analytic solution $n_1(\lambda)$ such that $F(\lambda,n_1(\lambda))=1$, for small λ. Of course, for small λ, $n_1(\lambda)>\varepsilon$. Then the proposition follows from the fact that, for $\lambda>0$,

$$F(\lambda,n_1)=\frac{1}{2K\delta}\lambda v_1/(\varepsilon_0^{(K,n)}-\varepsilon_{-1}^{(K,n)}). \tag{52}$$

Let us denote by n_λ the fixed point of T_0. Next we prove that T_0 is a contraction in a vicinity of n_λ. We will make use of the following result.

Proposition 5: Let X, Y two Banach spaces. Let f: $X\to Y$ be a function such that

$$\lim_{t\to0}\|f(x+t(x-x'))-f(x)\|/t<\chi,$$

for any x, x′ with $\|x-x'\|=1$, and $x\in B_{2\varepsilon}(x_0)$. Then, for x, $x'\in B_\varepsilon(x_0)$,

$$\|f(x')-f(x)\|<\chi\|x-x'\|.$$

Proof: For $x, x' \in B_\varepsilon(x_0)$,

$$\begin{aligned}
&\|f(x')-f(x)\| \\
&\quad=\left\|\sum_{m=0}^{N-1}\left[f\left(x+\frac{(m+1)\|x-x'\|}{N}\frac{(x-x')}{\|x-x'\|}\right)-f\left(x+\frac{m\|x-x'\|}{N}\frac{(x-x')}{\|x-x'\|}\right)\right]\right\| \\
&\quad\leqslant\frac{\|x-x'\|}{N}\sum_{m=0}^{N-1}\left\|f\left(x_m+t_N\frac{(x-x')}{\|x-x'\|}\right)-f(x_m)\right\|/t_N,
\end{aligned} \tag{53}$$

where $t_N=\|x-x'\|/N$ and $x_m=x+m/N(x-x')$ belongs to $B_{2\varepsilon}(x_0)$. Taking the limit $N\to\infty$ and using the property given in the proposition, the affirmation follows easily. ■

Proposition 6: Let $\varepsilon>0$ such that $L^1_{\mathrm{per}}(\mathcal{T})\cap B_{2\varepsilon}(n_\lambda)\subset\mathcal{S}_\varepsilon$. Then, for $n, n'\in\mathcal{S}_\varepsilon\cap B_\varepsilon(n_\lambda)$:

$$\|T_0[n]-T_0[n']\|_{L^1}\leqslant\chi\|n-n'\|_{L^1},\quad \chi=o(\lambda).$$

Proof: We take X and Y in the last proposition as $L^1_{\mathrm{per}}(\mathcal{T})$. We want to calculate

$$\lim_{t\to0}\|(T_0[n+t(n'-n)]-T_0[n])/t\|_{L^1(\mathcal{T})}, \tag{54}$$

for $n\in L^1_{\mathrm{per}}(\mathcal{T}_L)\cap B_{2\varepsilon}(n_\lambda)$ and $n'\in L^1_{\mathrm{per}}(\mathcal{T}_L)$, with $\|n-n'\|=1$. The limit (54) makes sense because, for small t, $n+t(n'-n)\subset\mathcal{S}_\varepsilon$. Because

$$T_0[n+t(n'-n)](x)=\frac{1}{\delta}+\frac{v_1}{2K\delta}\frac{\lambda n_1+\lambda t(n_1'-n_1)}{\varepsilon_0^{(K)}(n+t(n'-n))-\varepsilon_{-1}^{(K)}(n+t(n'-n))}2\cos\omega_1 x, \tag{55}$$

it is natural to consider the Hamiltonian:

$$H(\lambda,\xi)=H_n^{(K)}+\xi\int_{\mathcal{T}}v(|x,y|)(n(y)-n'(y))dy, \tag{56}$$

which is an analytic perturbation of $H_n^{(K)}$ for ξ in a vicinity of 0. Let us denote its eigenvalues by $\varepsilon_\pm(\lambda,\xi)$. Considering

$$f(\lambda,\xi)\equiv[\lambda n_1+\xi(n_1'-n_1)]/[\varepsilon_+(\lambda,\xi)-\varepsilon_-(\lambda,\xi)], \tag{57}$$

the limit (54) can be expressed as

$$\lim_{t\to0}(T_0[n+t(n'-n)]-T_0[n])/t=\lambda\frac{v_1}{K\delta}\frac{\partial f}{\partial\xi}(\lambda,0)\cos\omega_1 x. \tag{58}$$

But

$$\partial_\xi f(\lambda,0)=[(n_1'-n_1)\Delta\varepsilon(\lambda,0)-\lambda n_1\,\partial_\xi\Delta\varepsilon(\lambda,0)]/\Delta\varepsilon(\lambda,0)^2, \tag{59}$$

where we denoted $\Delta\varepsilon(\lambda,\xi)=\varepsilon_+(\lambda,\xi)-\varepsilon_-(\lambda,\xi)$. From the asymptotic expansion of the eigenvalues given in Proposition 2,

$$\Delta\varepsilon(\lambda,\xi)=-2v_1[\lambda n_1+\xi(n_1'-n_1)]+o(\lambda^2,\lambda\xi,\xi^2), \tag{60}$$

which leads to

$$\partial_\xi f(\lambda,0)=\frac{(n_1'-n_1)(-2v_1\lambda n_1+o(\lambda^2))-\lambda n_1(-2v_1(n_1'-n_1)+o(\lambda))}{[-2v_1\lambda n_1+o(\lambda^2)]^2},$$

$$=\frac{o(\lambda^2)}{[-2v_1\lambda n_1+o(\lambda^2)]^2}. \tag{61}$$

For $n\in L^1_{\mathrm{per}}(\mathcal{T}_L)\cap B_{2\varepsilon}(n_\lambda)$, $n_1>\varepsilon$, in which case $\partial_\xi f(\lambda,0)$ has a finite limit as λ goes to zero. We can conclude that $\partial_\xi f(\lambda,0)$ is analytic for λ in the vicinity of zero. The proposition follows from (58). ■

The last result we need is the following proposition.

Proposition 7: For n, $n'\in\mathcal{S}_\varepsilon\cap B_\varepsilon(n_\lambda)$ and λ small,

$$\|R[n]-R[n']\|_{L^1(\mathcal{T})}\leqslant ct.\|n-n'\|_{L^1(\mathcal{T})},\quad ct.<\infty.$$

Proof: From Proposition 1,

$$R[n](x)=\frac{2\varepsilon_0^{(K,n_0)}-\varepsilon_0^{(K,n)}-\varepsilon_{-1}^{(K,n)}}{2K\lambda(\varepsilon_0^{(K,n)}-\varepsilon_{-1}^{(K,n)})}+(U^{-1}R^{(0,n)}U)(x,x)$$
$$+2\sum_{q=1}^{K-1}(U^{-1}R^{(q,n)}U)(x,x)+U^{-1}R^{(K,n)}U(x,x). \tag{62}$$

Let us analyze the first term denoted by $F[n]$ in the following. With the notations of the last proposition, we define

$$g(\lambda,\xi)=\frac{2\varepsilon_0^{(K,n_0)}-\varepsilon_+(\lambda,\xi)-\varepsilon_-(\lambda,\xi)}{2K\lambda(\varepsilon_+(\lambda,\xi)-\varepsilon_-(\lambda,\xi))}. \tag{63}$$

Then

$$\lim_{t\to 0}\|(F[n+t(n'-n)]-F[n])/t\|_{L^1(\mathcal{T})}=\lambda\,\partial_\xi g(\lambda,0)L, \tag{64}$$

and

$$\partial_\xi g(\lambda,0)=\frac{1}{2K\lambda}\,\frac{\Delta\varepsilon(\lambda,0)\partial_\xi\Delta'\varepsilon(\lambda,0)-\Delta'\varepsilon(\lambda,0)\partial_\xi\Delta\varepsilon(\lambda,0)}{\Delta\varepsilon(\lambda,0)^2}, \tag{65}$$

where $\Delta'\varepsilon(\lambda,\xi)=2\varepsilon_0^{(K,n_0)}-\varepsilon_+(\lambda,\xi)-\varepsilon_-(\lambda,\xi)$. From Proposition 2,

$$\Delta'\varepsilon(\lambda,\xi)=o(\lambda^2,\lambda\xi,\xi^2)\Rightarrow\partial_\xi\Delta'\varepsilon(\lambda,0)=o(\lambda). \tag{66}$$

We can conclude that

$$\lambda\,\partial_\xi g(\lambda,0)=\frac{1}{2K}\,\frac{o(\lambda^2)}{[-2v_1\lambda n_1+o(\lambda^2)]^2}, \tag{67}$$

which shows that $\lambda\,\partial_\xi g(\lambda,0)$ is analytic in a vicinity of 0. Then (64) together with Proposition 5 allows us to say

$$\|F[n']-F[n]\|_{L^1(\mathcal{T})}<ct.\|n'-n\|_{L^1(\mathcal{T})}. \tag{68}$$

Because $R^{(q,n)}$, $q=0,1,\ldots,K$, are self-adjoint operators:

$$\begin{aligned}\|(U^{-1}R^{(q,n)}U)(x,x)-(U^{-1}R^{(q,n')}U)(x,x)\|_{L^1(\mathcal{T})}&\leqslant\|(U^{-1}[R^{(q,n)}-R^{(q,n')}]U\|_1\\&=\|R^{(q,n)}-R^{(q,n')}\|_1.\end{aligned}\tag{69}$$

For $q<K$,

$$\begin{aligned}R^{(q,n)}-R^{(q,n')}=P_0^{(q,n')}(V_n-V_{n'})\sum_{m\neq 0}\frac{P_m^{(q,n)}}{\varepsilon_0^{(q,n')}-\varepsilon_m^{(q,n)}}\\+\sum_{m\neq 0}\frac{P_m^{(q,n')}}{\varepsilon_0^{(q,n)}-\varepsilon_m^{(q,n')}}(V_{n'}-V_n)P_0^{(q,n)},\end{aligned}\tag{70}$$

and we can write

$$\begin{aligned}\|R^{(q,n)}-R^{(q,n')}\|_1&\leqslant\left\|P_0^{(q,n')}(V_n-V_{n'})\sum_{m\neq 0}\frac{P_m^{(q,n)}}{\varepsilon_0^{(q,n')}-\varepsilon_m^{(q,n)}}\right\|_{L^2}\\&\quad+\left\|\sum_{m\neq 0}\frac{P_m^{(q,n')}}{\varepsilon_0^{(q,n)}-\varepsilon_m^{(q,n')}}(V_{n'}-V_n)P_0^{(q,n)}\right\|_{L^2}\\&=\left\|P_0^{(q,n')}(V_n-V_{n'})(H_n^{(q)}+a)^{-1}\sum_{m\neq 0}\frac{\varepsilon_m^{(q,n)}+a}{\varepsilon_0^{(q,n')}-\varepsilon_m^{(q,n)}}P_m^{(q,n)}\right\|_{L^2}\\&\quad+\left\|\sum_{m\neq 0}\frac{P_m^{(q,n')}}{\varepsilon_0^{(q,n)}-\varepsilon_m^{(q,n')}}(V_{n'}-V_n)(H_n^{(q)}+a)^{-1}(\varepsilon_0^{(q,n)}+a)P_0^{(q,n)}\right\|_{L^2}.\end{aligned}\tag{71}$$

From Ref. 3, we already know that

$$\|(V_{n'}-V_n)(H_n^{(q)}+a)^{-1}\|\leqslant K(a)\|n-n'\|_{L^1(\mathcal{T})},\tag{72}$$

which leads to

$$\|R^{(q,n)}-R^{(q,n')}\|_1\leqslant K(a)\left[\frac{\varepsilon_{-1}^{(q,n)}+a}{\varepsilon_{-1}^{(q,n)}-\varepsilon_0^{(q,n')}}+\frac{\varepsilon_0^{(q,n)}+a}{\varepsilon_{-1}^{(q,n')}-\varepsilon_0^{(q,n)}}\right]\|n-n'\|_{L^1(\mathcal{T})}.\tag{73}$$

Because $\varepsilon_m^{(q,n)}$ are analytic in λ, it follows that

$$\varepsilon_{-1}^{(q,n)}-\varepsilon_0^{(q,n')}=\varepsilon_{-1}^{(q,n_0)}-\varepsilon_0^{(q,n_0)}+o(\lambda)>0,\tag{74}$$

and

$$\varepsilon_{-1}^{(q,n')}-\varepsilon_0^{(q,n)}=\varepsilon_{-1}^{(q,n_0)}-\varepsilon_0^{(q,n_0)}+o(\lambda)>0,\tag{75}$$

for λ small and $q<K$. In this case, we can conclude from (73),

$$\|R^{(q,n)}-R^{(q,n')}\|_1\leqslant ct.\|n-n'\|_{L^1(\mathcal{T})},\quad ct<\infty.\tag{76}$$

The last operator in (62) has a relatively complicated expression:

$$R^{(K,n)}=\left[\hat{K}_0 Q^{(K,n)}+Q^{(K,n)}\hat{K}_0+\frac{\lambda}{\varepsilon_0^{(K,n)}-\varepsilon_{-1}^{(K,n)}}Q^{(K,n)}\right)(P_{0,-1}^{(K,n_0)})^{\perp}V_n P_{0,-1}^{(K,n_0)}]$$
$$\times(1-\lambda Q^{(K,n)})^{-1}, \tag{77}$$

where $\hat{K}_0=\hat{K}_0[n]$ is given by

$$\hat{K}_0[n]=\frac{\varepsilon_0^{(K,n_0)}-\varepsilon_{-1}^{(K,n)}}{\varepsilon_0^{(K,n)}-\varepsilon_{-1}^{(K,n)}}P_0^{(K,n_0)}+\frac{\varepsilon_{-1}^{(K,n_0)}-\varepsilon_{-1}^{(K,n)}}{\varepsilon_0^{(K,n)}-\varepsilon_{-1}^{(K,n)}}P_{-1}^{(K,n_0)} \tag{78}$$

However, when the difference $R^{(K,n)}-R^{(K,n')}$ is considered, we can form terms like $K_0[n]-K_0[n']$, $Q^{(K,n)}-Q^{(K,n')}$, $(V_n-V_{n'})P_{0,-1}^{(K,n_0)}$ and

$$\lambda/(\varepsilon_0^{(K,n)}-\varepsilon_{-1}^{(K,n)})-\lambda/(\varepsilon_0^{(K,n')}-\varepsilon_{-1}^{(K,n')}). \tag{79}$$

Moreover, because $K_0[n]=P_{0,-1}^{(K,n_0)}\hat{K}_0[n]P_{0,-1}^{(K,n_0)}$ we have to evaluate the L^2 norm instead of the trace class norm. The terms involved in K_0 have been already evaluated in Proposition 6 and above. Also, $Q^{(K,n)}-Q^{(K,n')}$ can be evaluated as we did above for $q<K$ and the third term can be evaluated using (72). The last term was evaluated in Proposition (6). ■

We are ready now to formulate the main result of this paper.

Theorem 8: *The Hartree equation has a solution in* $\mathcal{S}_\varepsilon\cap B_\varepsilon(n_\lambda)$.

Proof: We show first that $\mathcal{S}_\varepsilon\cap B_\varepsilon(n_\lambda)$ is invariant for T. For $n\in\mathcal{S}_\varepsilon\cap B_\varepsilon(n_\lambda)$,

$$\begin{aligned}\|T[n]-n_\lambda\|_{L^1(T)}&=\|T_0[n]-T_0[n_\lambda]+\lambda R[n]\|_{L^1(T)}\\&\leqslant\|T_0[n]-T_0[n_\lambda]\|_{L^1(T)}+\lambda\|R[n]\|_{L^1(T)}\\&\leqslant o(\lambda)\varepsilon+\lambda\|R[n]\|_{L^1(T)}\leqslant\varepsilon,\end{aligned} \tag{80}$$

if λ is small enough. We mention that, because n_λ is analytic and

$$n_\lambda\to\frac{1}{\delta}\left[1+\frac{1}{2K}\cos 2k_F x\right],\quad \text{as}\ \ \lambda\to 0, \tag{81}$$

we can choose ε independent of λ. We can prove also that T is a contraction on $\mathcal{S}_\varepsilon\cap B_\varepsilon(n_\lambda)$ for small λ. Indeed, for n, $n'\in B_\varepsilon(n_\lambda)$,

$$\begin{aligned}\|T[n]-T[n']\|_{L^1(T)}&\leqslant\|T_0[n]-T_0[n']\|_{L^1(T)}+\lambda\|R[n]-R[n']\|_{L^1(T)}\\&\leqslant o(\lambda)\|n-n'\|_{L^1(T)}+\lambda ct.\|n-n'\|_{L^1(T)}.\end{aligned} \tag{82}$$

The proposition follows from the fixed point theorem. ■

We remember that ε was defined such that for all $n\in B_{2\varepsilon}(n_\lambda)$, $n_1>\varepsilon$. The above result implies that the solution of the Hartree equation we proved to exist, is not uniform, i.e., the symmetry is broken. Moreover, as $\lambda\to 0$, we can take ε smaller and smaller which shows that the limit of this solution is well defined as λ goes to zero which is another way of proving the assertion of Theorem 3.

IV. THE THERMODYNAMIC LIMIT

We are not able yet to prove that the previous results are true in the thermodynamic limit. To see the difficulties that appear, let us analyze the $\lambda\to 0$ limit. As $K\to\infty$, $\varepsilon_0^{(K-q,n_0)}-\varepsilon_{-1}^{(K-q,n_0)}$ becomes smaller and smaller, for a fixed q. This means that these eigenvalues must be treated together in the perturbation theory. One can repeat the steps of Proposition 1 to show

$$P_0^{(K-q,n)}=(\varepsilon_0^{(K-q,n)}-\varepsilon_{-1}^{(K\text{-}q,n)})^{-1}P_{0,-1}^{(K-q,n_0)}(H_n^{(K-q)}-\varepsilon_{-1}^{(K-q,n)})P_{0,-1}^{(K-q,n_0)}+o(\lambda), \tag{83}$$

where the rest is bounded in the limit $K\to\infty$. We will use this expression for all $K/2<q<3K/2$. Then

$$T[n](x+m\delta)=1/\delta-\frac{1}{K}\sum_{q=0}^{q<K/2}\frac{\lambda v_1}{\varepsilon_{-1}^{(K-q,n)}-\varepsilon_0^{(K-q,n)}}2n_1\cos\omega_1 x+o(\lambda), \tag{84}$$

for $x\in[0,\delta]$ and an m integer. We can also apply Proposition 2 to compute $\varepsilon_{-1}^{(K-q,n}-\varepsilon_0^{(K-q,n)}$. Keeping the notation, but replacing

$$G_{0,-1}^{(K,n_0)}(E)\to G_{0,-1}^{(q,n_0)}=(E-H_0^{(q)})^{-1}-(E-\varepsilon_0^{(q,n_0)})P_0^{(q,n_0)}-(E-\varepsilon_{-1}^{(q,n_0)})P_{-1}^{(q,n_0)}, \tag{85}$$

it follows that

$$\varepsilon_{-1}^{(K-q,n)}-\varepsilon_0^{(K-q,n)}=2\sqrt{(\lambda M_{00}-\lambda M_{-1-1}-\Delta\varepsilon^{(K-q)})^2+4|M_{0-1}|^2}, \tag{86}$$

where

$$\Delta\varepsilon^{(K-q)}=\varepsilon_{-1}^{(K-q,n_0)}-\varepsilon_0^{(K-q,n_0)}=\frac{4\pi^2}{\delta^2}\frac{q}{K}. \tag{87}$$

Asymptotically,

$$\varepsilon_{-1}^{(K-q,n)}-\varepsilon_0^{(K-q,n)}=2\sqrt{\left(\frac{4\pi^2}{\delta^2}\frac{q}{K}\right)^2+4\lambda^2|n_1v_1|^2+o(\lambda^3)}. \tag{88}$$

In the limit $K\to\infty$, the leading therm of T is given by

$$\begin{aligned}T_0[n](x+m\delta)&=1/\delta-\lambda v_1\int_0^{1/2}\frac{dt}{2\sqrt{(4\pi^2/\delta^2t)^2+4\lambda^2|n_1v_1|^2}}2n_1\cos\omega_1x\\&=1/\delta-\frac{\lambda v_1\delta^2}{8\pi^2}\operatorname{arcosh}\left(\frac{\pi^2}{\lambda\delta^2|n_1v_1|}\right)2n_1\cos\omega_1x.\end{aligned} \tag{89}$$

The self-consistent equation leads to

$$n_1=\pi^2/\{\lambda|v_1|\delta^2\,\mathrm{sh}[-8\pi^2/(\lambda v_1\delta^2)]\}. \tag{90}$$

This means the band gap will be proportional to

$$\Delta\propto\mathrm{sh}[-8\pi^2/(\lambda v_1\delta^2)]^{-1}\approx 2\exp[-8\pi^2/(\lambda v_1\delta^2)], \tag{91}$$

a BCS like expression. This slow opening of the gap request sharper estimates in order to prove that T is a contraction.

V. CONCLUSIONS

It is easy to check that the map T becomes infinitely unstable as n_1 goes to zero. This means that the solution n constant is unstable. The key element for a successful expansion beyond the Hartree approximation (which we proved that it is equivalent to the Gaussian approximation) will be the stability of the solution. Also, the perturbed eigenvalues are smaller than the unperturbed ones. We have already proved this for $H_n^{(K)}$. For $q<K$, one can use:

$$\varepsilon_0^{(q,n)}\leqslant\langle\varphi_0^{(q,n_0)},H_n^{(q)}\varphi_0^{(q,n_0)}\rangle=\varepsilon_0^{(q,n_0)}, \tag{92}$$

where we used that the zero-th Fourier coefficient of V_n is zero. Then it follows that the total energy is smaller for the broken phase than for the unbroken one. Condition $v_1<0$ seems to rule out the phase transition for repulsive interactions. However, one expects that the phase transition to be there for these cases too. One can convince oneself that, in any local theory, the effective potential must be low where the density of particles is high for modulations of the particles density to occur. For repulsive interactions, the exchange-correlation potential is attractive. We proved in Ref. 3 that the fixed point approach works also for local density approximation provided the very low density behavior of the exchange-correlation potential, v_{xc}, is modified. Supposing that one can extend the analysis of this paper to the local density approximation, we can predict the following. Because $v_{\mathrm{xc}}(n)$ behaves as $n^{1/3}$ at low densities, the attractive term will dominate the repulsive Hartree term at low densities. This means that, for repulsive interactions and at low densities, the symmetry breaking will also be present.

(Received 7 February 2001; accepted for publication 27 March 2001)

Using the strong localization bounds obtained by the Aizenman–Molcanov method for a particle in a magnetic field and a disordered potential, we show that the zero-temperature Hall conductivity of a gas of such particles is quantized and constant as long as both Fermi energy and disorder coupling parameter vary in a region of strong localization of the corresponding two-dimensional phase diagram.
 [DOI: 10.1063/1.1379070]

I. INTRODUCTION

In quantum Hall effect experiments,[1] one measures the Hall resistance of an effectively two-dimensional electron gas. For a wide range of the experimental parameters (such as the magnetic field and the particle density), the Hall resistance is an integer multiple of the fundamental constant e^2/h (here e is the charge of an electron and h is Planck's constant). The two most remarkable facts of this so-called integer quantum Hall effect, namely, (1) the appearence of an integer number and (2) its stability with respect to changes of the parameters, can both be explained within a one-particle framework.[1,2] The integers are known to be of topological origin, whereas their stability is due to Anderson localization in the sample. Here we focus on this second issue and study a one-particle Hamiltonian $H^\lambda = H_0 + \lambda V$, $\lambda \in \mathbf{R}$, given by the sum of a free magnetic operator H_0 of the Harper type and a disordered potential V. We prove that in a region of the (λ,μ)-plane of coupling constant λ and Fermi level μ in which localization estimates hold, the Hall conductivity is constant and equal to an integer multiple of e^2/h.

II. MODELS AND RESULTS

A. Covariant operators

Let $(\Omega, T, \mathbf{Z}^2, \mathbf{P})$ be a dynamical system given by a compact probability space Ω endowed with a probability measure $\mathbf{P}$ which is invariant and ergodic with respect to the action T of the group $\mathbf{Z}^2$. A family $A = (A_\omega)_{\omega \in \Omega}$ of bounded operators on $l^2(\mathbf{Z}^2)$ is called covariant with respect to the action if it is weakly continuous (in ω) and it satisfies the covariance relation

$$U^n A_\omega U^{*n} = A_{T^n \omega}, \quad n \in \mathbf{Z}^2.$$

Here the magnetic translation operators U^n, $n = (n_x, n_y)$, acting on $l^2(\mathbf{Z}^2)$ are defined by

$$U^n \psi(m) = \exp\left(\frac{\imath}{2} \theta \, n \wedge m \right) \psi(m-n), \quad m = (m_x, m_y) \in \mathbf{Z}^2, \quad \psi \in l^2(\mathbf{Z}^2),$$

where $a \wedge n = a_x n_y - a_y n_x$ and θ is the magnetic flux per unit cell. Given a covariant operator family $A = (A_\omega)_{\omega \in \Omega}$, Birkhoff's ergodic theorem implies that its trace per unit volume

$$\mathcal{T}(A) = \lim_{\Lambda \to \mathbf{Z}^2} \frac{1}{|\Lambda|} \mathrm{Tr}_\Lambda (A_\omega) = \lim_{\Lambda \to \mathbf{Z}^2} \frac{1}{|\Lambda|} \sum_{n \in \Lambda} \langle 0 | A_{T^n \omega} | 0 \rangle,$$

is **P**-almost surely independent of $\omega \in \Omega$ and is equal to $\int d\mathbf{P}(\omega)\, \langle 0|A_\omega|0\rangle$. If X and Y denote the components of the position operator on $l^2(\mathbf{Z}^2)$, new covariant operator families $\nabla_x A$ and $\nabla_y A$ are defined by

$$(\nabla_x A)_\omega = \imath[X, A_\omega], \quad (\nabla_y A)_\omega = \imath[Y, A_\omega],$$

whenever the right-hand-sides are bounded operators. Let now $P=(P_\omega)_{\omega\in\Omega}$ be a covariant family of projection operators (i.e., $P_\omega^2 = P_\omega^* = P_\omega$). Its Chern number is defined by

$$\mathrm{Ch}(P) = 2\pi\imath\, \mathcal{T}(P[\nabla_x P, \nabla_y P]). \tag{1}$$

The Chern number is a topological invariant of the equivalence class of covariant projections defined by P. For further details and a more algebraic formulation of these notions, please consult.[2]

B. Hamiltonian and physical quantities

We consider disordered two-dimensional magnetic operators in the tight-binding appoximation on the rectangular lattice Hilbert space $l^2(\mathbf{Z}^2)$ which are of the form,

$$H_\omega^\lambda = H_0 + \lambda V_\omega, \quad V_\omega = \sum_{n\in\mathbf{Z}^2} \omega_n |n\rangle\langle n|. \tag{2}$$

Here $H_0 = H_0^*$ is a polynomial in the magnetic translations. The most simple nontrivial example is given by the Harper Hamiltonian $H_{\mathrm{Har}} = U^{(1,0)} + U^{(-1,0)} + U^{(0,1)} + U^{(0,-1)}$. Furthermore, $\omega = (\omega_n)_{n\in\mathbf{Z}^2}$ is a point in the space of disorder configurations given by the topological product $\Omega = [-1,1]^{\otimes \mathbf{Z}^2}$. We suppose that the ω_n's are independent and identically distributed random variables with a probability distribution ρ. The product measure $\mathbf{P} = \rho^{\otimes \mathbf{Z}^2}$ then defines a probability on Ω which is invariant and ergodic with respect to the shift action T of $\mathbf{Z}^2$ on Ω. Hence we dispose of a dynamical system $(\Omega, T, \mathbf{Z}^2, \mathbf{P})$ as in Sec. II A.

The family $H=(H_\omega^\lambda)_{\omega\in\Omega}$ and any function $f(H)$ of it (f measurable) are covariant. Given a Fermi level $\mu \in \mathbf{R}$, we consider the associated Fermi projection $P^{\lambda,\mu} = \chi_{(-\infty,\mu]}(H^\lambda)$, where $\chi_{(-\infty,\mu]}$ is the characteristic function of the interval $(-\infty,\mu]$. Whenever well-defined, its Chern number is linked to the bulk Hall conductivity $\sigma_\perp(\lambda,\mu)$ via the Kubo–Chern formula,[2]

$$\sigma_\perp(\lambda,\mu) = \frac{e^2}{h}\,\mathrm{Ch}(P^{\lambda,\mu}).$$

Furthermore we consider the density of states of H^λ, notably the probability measure $\mathcal{N}^\lambda$ defined by

$$\int d\mathcal{N}^\lambda(E)\, f(E) = \mathcal{T}(f(H^\lambda)), \quad f \in C_0(\mathbf{R}).$$

C. Localization regime

Here we shall study the quantities $\sigma_\perp(\lambda,\mu)$ and $\mathcal{N}^\lambda$ in the

Aizenman–Molcanov Localization Regime (AMLR): A spectral interval $\Delta \subset \mathbf{R}$ is in the AMLR for the covariant Hamiltonian $H=(H_\omega)_{\omega\in\Omega}$ if for any $s\in(0,1)$ there exist positive constants Λ and $c_{s,\epsilon}$ such that

$$\int d\mathbf{P}(\omega) |\langle n|(E+\imath\epsilon - H_\omega)^{-1}|m\rangle|^s \leq c_{s,\epsilon} e^{-\Lambda|n-m|} \tag{3}$$

for all $E\in\Delta$ and $\epsilon \neq 0$.

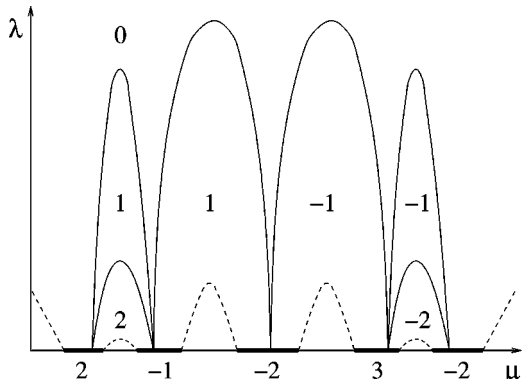

FIG. 1. Phase diagram for the Hall conductivity in a disordered Harper model with rational flux $\theta = 2\pi \cdot 3/5$ (following Ref. 7) The fat lines are the Bloch bands of the free Harper operator, each with its Chern number given below. These numbers can easily be calculated using the diophantine equation in Ref. 10. The solid lines show the critical energies separating the regions of the phase diagram with constant Chern number; this number is written inside each region. The dashed lines show the boundaries of the spectrum.

Under appropriate regularity conditions on the probability measure ρ (absolute continuity is sufficient), the AMLR is known to hold in the strong disorder regime (large λ) (Refs. 3, 4) as well as at the band edges in the weak disorder regime.[5,6] Furthermore note that the AMLR holds for a (**P**-almost sure) gap of the spectrum of H^λ by a standard Combes–Thomas argument. However, it is not known rigorously (as suggest, for example, the numerical calculations of Tan[7] discussed below) that the AMLR holds for all but a set of critical energies for the 2D magnetic models defined by Eq. (2).

D. Main result and phase diagram

Theorem 1: *Let* $\mathcal{R} \subset \{(\mu,\lambda) \in \mathbf{R}^2\}$ *be a connected set such that for every* λ *the set* $\Delta(\lambda) = \{\mu | (\mu,\lambda) \in \mathcal{R}\}$ *is an interval for which the* AMLR *holds for* H^λ. *Then:*

(i) The map $(\mu,\lambda) \in \mathcal{R} \mapsto \mathcal{N}^\lambda((-\infty,\mu])$ *is Hölder continuous for any exponent less than* 1/2;

(ii) $(\mu,\lambda) \in \mathcal{R} \mapsto \sigma_\perp(\lambda,\mu)$ *is constant and equal to an integer multiple of* q^2/h.

The fact that $\mu \mapsto \sigma_\perp(\lambda,\mu)$ is constant as long as μ varies in an interval for which the AMLR holds was already proven in Ref. 2 (see also Ref. 4). Hence the new result concerns constancy in λ. Concerning (i), the continuity of the DOS for fixed λ is well known (by Wegner estimate even absolute continuity[8]), so that again the main issue is continuity in λ. Even though $\lambda \mapsto H^\lambda$ is norm continuous, this is nontrivial because $\mathcal{N}^\lambda((-\infty,\mu])$ is expressed in terms of a discontinuous function of H^λ.

Theorem 1 (ii) combined with a recent work by Avron and Sadun[9] allows us to clarify the (μ,λ)-phase diagram (Fig. 1) which was obtained numerically by Tan[7] for the family of disordered Harper Hamiltonians $H_{\mathrm{Har}} + \lambda V_\omega$, where ρ is the uniform distribution on $[-1,1]$. There are regions where the Hall conductivity is constant. These regions correspond to a localization region, whereas the lines indicate critical lines where the Hall conductivity jumps. Generically, such jumps are by unity,[9] which is actually satisfied except on the line $\lambda = 0$ where the integrable character of Harper's equation leads to singularities in this respect.

Let us further note that at large disorder the whole spectrum belongs to the phase with vanishing Chern number and hence zero Hall conductance. This is compatible with the proof of AMLR for large disorder.[3] There is a corresponding result of Nakamura and Bellissard[11] for the continuous case showing that for fixed Fermi energy, there is a value of the disorder coupling constant λ_c such that for $\lambda > \lambda_c$ the Hall conductivity vanishes. In this situation, the current carrying lines do not annihilate as in Fig. 1, but bend towards higher energies.[12]

An interesting open problem is to show that the edge Hall conductivity as defined in Ref. 13 is well-defined and also remains constant in the regions of the above phase-diagram.

III. PROOFS

Let us denote the disorder average w.r.t. **P** by **E**. For technical reasons, we consider a covariant family $H^{(\nu)}=(H_\omega^{(\nu)})_{\omega\in\Omega}$ given by

$$H_\omega^{(\nu)}=H_\omega^{\lambda}+\nu\, W_\omega,$$

where $W=(W_\omega)_{\omega\in\Omega}$ is a family of uniformly bounded covariant operators which is diagonal in the basis $(|n\rangle)_{n\in\mathbf{Z}^2}$. If $W=V$, then $H^{(\nu)}=H^{\lambda+\nu}$, but we will also be interested in the case $W=1$ to study continuity in the energy. The following result also holds for a (magnetic) Anderson model in arbitrary dimension.

Lemma 1: Let f be a real, piecewise continuous and bounded function such that the discontinuities of f are within AMLR of $H^{(\nu)}$ for all $\nu\in[\nu_1,\nu_2]$. Then for any $s<1/2$,

$$\mathbf{E}(|\langle n|f(H_\omega^{(\nu_1)})|m\rangle-\langle n|f(H_\omega^{(\nu_2)})|m\rangle|)\leqslant c\,|\nu_1-\nu_2|^s\, e^{-\Lambda|n-m|}. \tag{4}$$

Proof: First let us recall the resolvent identity,

$$(z-H_\omega^{(\nu_1)})^{-1}-(z-H_\omega^{(\nu_2)})^{-1}=(\nu_1-\nu_2)\,(z-H_\omega^{(\nu_1)})^{-1}W_\omega(z-H_\omega^{(\nu_2)})^{-1}.$$

Now using the convexity inequality $|\Sigma_j x_j|^s\leqslant\Sigma_j|x_j|^s$ and the fact that W is diagonal and $|W_\omega(k)|\leqslant c$, one obtains therefore

$$\begin{aligned}&|\langle n|(z-H_\omega^{(\nu_1)})^{-1}|m\rangle-\langle n|(z-H_\omega^{(\nu_2)})^{-1}|m\rangle|^s\\&\quad\leqslant c|\nu_1-\nu_2|^s\sum_{k\in\mathbf{Z}^2}|\langle n|(z-H_\omega^{(\nu_1)})^{-1}|k\rangle|^s|\langle k|(z-H_\omega^{(\nu_2)})^{-1}|m\rangle|^s.\end{aligned}$$

This gives

$$\begin{aligned}&|\langle n|(z-H_\omega^{(\nu_1)})^{-1}|m\rangle-\langle n|(z-H_\omega^{(\nu_2)})^{-1}|m\rangle|\\&\quad\leqslant c|\nu_1-\nu_2|^s\sum_{k\in\mathbf{Z}^2}|\langle n|(z-H_\omega^{(\nu_1)})^{-1}|k\rangle|^s|\langle k|(z-H_\omega^{(\nu_2)})^{-1}|m\rangle|^s\\&\qquad\cdot(|\langle n|(z-H_\omega^{(\nu_1)})^{-1}|m\rangle|^{1-s}+|\langle n|(z-H_\omega^{(\nu_2)})^{-1}|m\rangle|^{1-s}).\end{aligned}$$

Now we use the bound $|\langle n|(z-H_\omega^{(\nu_{1,2})})^{-1}|m\rangle|\leqslant|\Im m(z)|^{-1}$, then take the disorder average and apply the Cauchy–Schwarz inequality in order to get

$$\begin{aligned}&\mathbf{E}(|\langle n|(z-H_\omega^{(\nu_1)})^{-1}|m\rangle-\langle n|(z-H_\omega^{(\nu_2)})^{-1}|m\rangle|)\\&\quad\leqslant c|\nu_1-\nu_2|^s|\Im m(z)|^{s-1}\cdot\sum_{k\in\mathbf{Z}^2}(\mathbf{E}(|\langle n|(z-H_\omega^{(\nu_1)})^{-1}|k\rangle|^{2s}))^{1/2}\\&\qquad\times(\mathbf{E}(|\langle k|(z-H_\omega^{(\nu_2)})^{-1}|m\rangle|^{2s}))^{1/2},\end{aligned}$$

so that replacing the AMLR bound we finally obtain by using for example the Young inequality,

$$\mathbf{E}(|\langle n|(z-H_\omega^{(\nu_1)})^{-1}|m\rangle-\langle n|(z-H_\omega^{(\nu_2)})^{-1}|m\rangle|)\leqslant c|\nu_1-\nu_2|^s|\Im m(z)|^{s-1}e^{-\Lambda|m-n|} \tag{5}$$

for $s<1/2$.

Now let f be an analytic function on an interval $\Delta=[E_l,E_r]$ the end points of which fall into the AMLR. Then we use holomorphic functional calculus in the following way:

$$f(H_\omega^{(\nu)}) = Q_f(H_\omega^{(\nu)} - E_r) - R_f(H_\omega^{(\nu)}) - Q_f(H_\omega^{(\nu)} - E_l) + R_f(H_\omega^{(\nu)})^*, \tag{6}$$

where

$$Q_f(z) = \int_{-1}^{1} \frac{dt}{2\pi} \frac{f(\imath t)}{\imath t - z}, \quad R_f(z) = \int_{E_l}^{E_r} \frac{dt}{2\pi} \frac{f(t)}{t - \imath - z}.$$

Because we are in the AMLR, the spectrum is pure-point and it is then well-known that E_l and E_r are almost surely not in the spectrum of $H_\omega^{(\nu)}$. Hence the intergrals in (6) are almost surely well-defined (a similar argument was already used in Ref. 4). Now we can estimate the differences for different coupling parameters ν,

$$\begin{aligned}
&\mathbf{E}(|\langle n|Q_f(H_\omega^{(\nu_1)} - E_r)|m\rangle - \langle n|Q_f(H_\omega^{(\nu_2)} - E_r)|m\rangle|) \\
&\quad \leqslant \left(\sup_{t' \in [-1,1]} |f(\imath t')| \right) \int_{-1}^{1} \frac{dt}{2\pi} \mathbf{E}(|\langle n|(z - H_\omega^{(\nu_1)})^{-1}|m\rangle - \langle n|(z - H_\omega^{(\nu_2)})^{-1}|m\rangle|) \\
&\quad \leqslant c\,|\nu_1 - \nu_2|^s \int_{-1}^{1} \frac{dt}{|t|^{1-s}} e^{-\Lambda|m-n|} \leqslant c'\,|\nu_1 - \nu_2|^s\, e^{-\Lambda|m-n|}.
\end{aligned} \tag{7}$$

Of course, the terms with E_l instead of E_r can be treated in the same way. Concerning the R_f-contributions in (6), let us first remark that a bound like (3) but with $s=1$ actually holds for all complex energies off the real axis (by a Combes–Thomas argument, cf. Ref. 4). Using this fact, one can either proceed as above or more directly use the resovent identity. We skip the details.

Combining these estimates, we see that (4) holds for an analytic function f on Δ. Because the above estimate is continuous w.r.t. the maximum norm on the space of continuous functions [cf. the bound (7), for example], a standard Stone–Weierstrass approximation argument allows us to obtain the same bound also for every continuous function f. Finally, for a piecewise continuous function we can treat each continuous part separately provided the points of discontinuity of f are within the AMLR. □

Proof of Theorem 1 (i): Because the indicator function χ_μ on the interval $(-\infty, \mu]$ is piecewise continuous and the discontinuity varies within the AMLR according to hypothesis, we can apply the above lemma with $W=V$ and $W=1$, respectively. With the notation $\mathcal{N}^\lambda(\mu) = \mathcal{N}^\lambda((-\infty,\mu])$, we therefore obtain

$$\begin{aligned}
|\mathcal{N}^{\lambda_1}(\mu_1) - \mathcal{N}^{\lambda_2}(\mu_2)| &\leqslant |\mathcal{N}^{\lambda_1}(\mu_1) - \mathcal{N}^{\lambda_2}(\mu_1)| + |\mathcal{N}^{\lambda_2}(\mu_1) - \mathcal{N}^{\lambda_2}(\mu_2)| \\
&\leqslant \mathbf{E}(|\langle 0|\chi_{\mu_1}(H^{\lambda_1})|0\rangle - \langle 0|\chi_{\mu_1}(H^{\lambda_2})|0\rangle|) \\
&\quad + \mathbf{E}(|\langle 0|\chi_{\mu_1}(H^{\lambda_2})|0\rangle - \langle 0|\chi_{\mu_1}(H^{\lambda_2} + \mu_2 - \mu_1)|0\rangle|) \\
&\leqslant c\,|\lambda_1 - \lambda_2|^s + c\,|\nu_1 - \nu_2|^s \quad (s < 1/2).
\end{aligned}$$

This gives the desired Hölder continuity. □

Proof of Theorem 1 (ii): As in Ref. 2, let us introduce a noncommutative Sobolov space as the set of all weakly continuous covariant operator families $A = (A_\omega)_{\omega \in \Omega}$ for which the norm

$$\|A\|_{\mathcal{S}}^2 = \mathcal{T}(|A|^2) + \mathcal{T}(|\nabla A|^2) \tag{8}$$

is finite (here $|\nabla A|^2 = |\nabla_x A|^2 + |\nabla_y A|^2$). Note that the Chern number (1) is continuous w.r.t. this norm. An important result of Ref. 2 is the following: if $t \mapsto P(t) \in \mathcal{S}$ is a one-parameter family of covariant projection operators which is continuous w.r.t. to the Sobolev norm $\|.\|_{\mathcal{S}}$, then $t \mapsto \mathrm{Ch}(P(t))$ is constant and equal to an integer. Hence it is sufficient to show that the map $(\mu, \lambda) \in \mathcal{R} \mapsto \|P^{\lambda,\mu}\|_{\mathcal{S}}$ is Hölder continuous. According to part (i) proven above, this actually holds for the $\mathcal{T}(|\,.\,|^2)$-part of the norm. For the second part, we begin with

$$|\mathcal{T}(|\nabla P^{\mu_1,\lambda_1}|^2)-\mathcal{T}(|\nabla P^{\mu_2,\lambda_2}|^2)|\leqslant \sum_{m\in\mathbf{Z}^2}|m|^2\,\mathbf{E}(||\langle 0|\chi_{\mu_1}(H^{\lambda_1})|m\rangle|^2-|\langle 0|\chi_{\mu_2}(H^{\lambda_2})|m\rangle|^2|). \tag{9}$$

Now the bound $|\langle 0|\chi_\mu(H^\lambda)|m\rangle|\leqslant 1$ implies that

$$||\langle 0|\chi_{\mu_1}(H^{\lambda_1})|m\rangle|^2-|\langle 0|\chi_{\mu_2}(H^{\lambda_2})|m\rangle|^2|\leqslant 2\,|\langle 0|\chi_{\mu_1}(H^{\lambda_1})|m\rangle-\langle 0|\chi_{\mu_2}(H^{\lambda_2})|m\rangle|,$$

so that an argument similar to that in the proof of (i) shows that

$$\mathbf{E}(||\langle 0|\chi_{\mu_1}(H^{\lambda_1})|m\rangle|^2-|\langle 0|\chi_{\mu_2}(H^{\lambda_2})|m\rangle|^2|)\leqslant c(|\lambda_1-\lambda_2|^s+|\mu_1-\mu_2|^s)\,e^{-\Lambda|m|}.$$

Inserting this into (9) allows us to conclude. □

Quantum Chern–Simons vortices on a sphere

Nuno M. Romão[a)]
Department of Applied Mathematics and Theoretical Physics, Centre for Mathematical Sciences, University of Cambridge, Wilberforce Road, Cambridge CB3 0WA, United Kingdom

(Received 7 November 2000; accepted for publication 4 April 2001)

The quantization of the reduced first-order dynamics of the nonrelativistic model for Chern–Simons vortices introduced by Manton is studied on a sphere of given radius. We perform geometric quantization on the moduli space of static solutions, using a Kähler polarization, to construct the quantum Hilbert space. Its dimension is related to the volume of the moduli space in the usual classical limit. The angular momenta associated with the rotational SO(3) symmetry of the model are determined for both the classical and the quantum systems. The results obtained are consistent with the interpretation of the solitons in the model as interacting bosonic particles. © *2001 American Institute of Physics*. [DOI: 10.1063/1.1379315]

I. INTRODUCTION

Over the past decade, much attention has been given to $(1+2)$-dimensional field theories including a Chern–Simons term. The pure Chern–Simons gauge theory, although still interesting both from the mathematical and the physical points of view, has no dynamics by itself. However, many interesting models for field dynamics can be obtained by adding to the Chern–Simons action Maxwell or Yang–Mills terms and/or interactions with other fields.[1] Some of these models have been shown to admit classical solitonic solutions (vortices), at least for critical or ''self-dual'' values of the parameters in the Lagrangian. These objects can be regarded as smeared-out particles which retain a characteristic size and superpose nonlinearly; unlike some types of solitons, they can also be assigned a pointlike core individually. In specific models, vortices often turn out to possess rather exotic properties, which may be relevant in applications. For example, models with abelian vortices have been important in attempts to explain phenomena in condensed matter theory such as superconductivity and the fractional quantum Hall effect.

In Ref. 2, Manton constructed a nonrelativistic Lagrangian for a U(1) gauge field minimally coupled to a complex scalar on the plane which describes vortex dynamics. The action for the gauge field includes a Chern–Simons term and the purely spatial part of the Maxwell action. The equations of motion for the field theory are first-order in time, and they admit the well-known Bogomol'nyĭ vortices[3] of the Ginzburg–Landau theory as static solutions, for special values of the parameters. Mathematically, Bogomol'nyĭ vortices are rather well understood, even though on general surfaces they cannot be constructed analytically. Their space of gauge equivalence classes splits into disjoint sectors $\mathcal{M}_N$ labeled by an integer vortex number $N \in \mathbb{Z}$, each $\mathcal{M}_N$ (the moduli space of N vortices) being a smooth $2|N|$-dimensional manifold. In his paper, Manton explored the dynamics of time-dependent fields by explicitly reducing the field theory Lagrangian to an effective (finite-dimensional) mechanical system on the moduli space $\mathcal{M}_N$. The Lagrangian equations of motion for the reduced system are again first-order in time, and so the moduli space is to be regarded as the phase space where a noncanonical Hamiltonian dynamics takes place. The symplectic form defining the dynamics, determined by the kinetic term, contains nontrivial information about the system; of course, it may still be written in canonical form locally, but not in a natural way. Time evolution is determined by the potential energy alone, which is supposed to be small so that the field configurations are still approximately Bogomol'nyĭ vortices. In the case of

a)Electronic-mail: N.M.Romao@damtp.cam.ac.uk

two vortices, the reduced system describes namely a rigid uniform rotation of the two vortex cores about their midpoint, with an angular velocity which is maximal when the distance between the two is roughly a vortex diameter.

If we place the vortices on a compact surface Σ, with a Riemannian metric and an orientation, rather than on the plane, the moduli spaces $\mathcal{M}_N$ also become compact. The metric on Σ fixes a complex structure, which in turn induces a complex structure on $\mathcal{M}_N$. This complex structure can be shown to be compatible with the symplectic form relevant for the dynamics, and so each $\mathcal{M}_N$ becomes a Kähler manifold. Compact Kähler phase spaces are optimal stages for geometric quantization.[4,5] The complex geometry supplies a natural (Kähler) polarization, for which the corresponding quantum Hilbert space turns out to be finite-dimensional. This approach to the quantization of the vortex system is to be included in a more general framework, pioneered by Gibbons and Manton in the context of BPS monopoles.[6] The idea is to probe the quantum behavior of solitons through geometric quantization of the reduced dynamics on the moduli space of static solutions, when such a space is available. In the more familiar situation of the Abelian Higgs model,[7] where the reduced system is of second order, there is a canonical Hamiltonian description of the classical dynamics and the quantization can be carried out using the vertical polarization of $T^*\mathcal{M}_N$, which leads to a truncated Schrödinger representation of the quantum system. The accuracy of the approximation involved is very difficult to assess, and the study of an example where the Schrödinger representation is not available, as is the case here, is of considerable interest. From the point of view of geometric quantization itself, it is fortunate that Manton's system seems to provide us with a nontrivial example where it may be put to work rather directly.

The main aim of the present work is to discuss the geometric quantization of Manton's reduced system of periodic vortex dynamics, when space is taken to be a sphere of a given radius R. In particular, we shall determine the dimension of the Hilbert space and construct the quantum operators corresponding to the conserved angular momenta determined by the natural action of SO(3).

Let us summarize how this paper is organized. In Sec. II, we describe the generalization of Manton's model to the case where the spatial surface is compact. In Sec. III, we gather some results concerning the moduli space of Bogomol'nyĭ vortices on a sphere and its use in the study of the field theory dynamics. The effective Lagrangian on the moduli space is constructed in Sec. IV. In Sec. V, we obtain conservation laws for both the field theory and the reduced dynamical system, and show that they are consistent. In Sec. VI, the setup for the geometric quantization of the reduced dynamics on the moduli space of static solutions is presented. The dimension of the Hilbert space of wavefunctions is computed in Sec. VII, and we show how to construct the quantum angular momentum operators in Sec. VIII. Finally, we discuss the results obtained and address some outstanding issues.

II. FIRST-ORDER CHERN–SIMONS VORTICES

We start by discussing the generalization of the model introduced by Manton[2] to the situation where space is compact. We shall consider time-periodic boundary conditions in the formulation of the variational principle, and accordingly we fix space–time to be of the form $S^1\times\Sigma$, where Σ is a compact and oriented two-dimensional riemannian manifold. In the remaining sections of this paper we will assume that Σ is a sphere, but for now this restriction is unnecessary. Since in two dimensions any metric is conformally flat, we can introduce a complex coordinate z locally on Σ and write

$$ds^2=dt^2-\Omega^2(z,\overline{z})dzd\overline{z}, \tag{1}$$

where t parametrises time.

Naively, the Lagrangian we would like to consider is

$$\mathcal{L}[A,\phi]=\gamma\left(\frac{i}{2}(\overline{\phi}D_t\phi-\phi\overline{D_t\phi})-A_t\right)\Omega^2+\mu(BA_t+2i(E_zA_{\bar{z}}-E_{\bar{z}}A_z))$$
$$-\left(\frac{1}{2}B^2\Omega^{-2}+(|D_z\phi|^2+|D_{\bar{z}}\phi|^2)+\frac{\lambda}{8}(1-|\phi|^2)^2\Omega^2\right). \tag{2}$$

This reduces to Manton's Lagrangian[2] without transport current if we take Σ to be the plane and set $\Omega^2=1$. Here, $A=A_tdt+A_zdz+A_{\bar{z}}d\bar{z}$ is the real-valued $U(1)$ gauge field, with curvature $F_A=dA=(E_zdz+E_{\bar{z}}d\bar{z})\wedge dt+(i/2)Bdz\wedge d\bar{z}$, and ϕ the Higgs scalar field. The covariant derivatives are $D_\nu\phi=\partial_\nu\phi-iA_\nu\phi$, where $\nu=t$, z or $\bar{z}$. Of course, $(i/2)\mathcal{L}$ is to be thought of as the coefficient of a three-form on some open subset of $S^1\times\Sigma$ where local expressions for the fields can be given, and the factors of Ω introduced in (2) are imposed by the natural interpretation given to the different terms.

To set up the classical field theory, we must give as global data a principal U(1) bundle P over $S^1\times\Sigma$. With respect to local trivializations, the gauge field is interpreted as a connection on this bundle, the Higgs field as a section of the complex line bundle associated to P by the defining representation, and $\overline{\phi}$ is a section of the bundle dual to this one. It is natural to restrict to the situation where P is the pull-back to $S^1\times\Sigma$ of a U(1) bundle on Σ; in particular, the transition functions will be time-independent. Topologically, U(1) bundles on a compact surface are classified by their first Chern class $N\in\mathbb{Z}$, which can be interpreted as the net number of units of quantized magnetic flux through space at any time,

$$\frac{i}{2}\oint_\Sigma Bdz\wedge d\bar{z}=2\pi N. \tag{3}$$

We may assume without loss of generality that the bundle we are considering over Σ can be trivialized on an open disc $U_1\subset\Sigma$ and on an open neighborhood U_2 of its complement, with $U_1\cap U_2$ being a very narrow annulus which for most purposes can be identified with its retraction ∂U_1. More precisely, we may have to consider sub-patches of U_2 to make sense of local data such as the relevant coordinate z, but this will not affect the discussion of the aspects related to the nontriviality of P which will be our main concern, because $P|_{U_2}$ is trivial. Thus we shall consider P to be defined by the homotopy class of a single transition function $f_{12}:\partial U_1\to U(1)$ whose degree is N, and we refrain from introducing partitions of unity to keep the discussion as simple as possible.

The term with coefficient μ is the Chern–Simons density $\mu A\wedge dA$. On the overlap of the two trivializing patches U_1, U_2,

$$A^{(1)}\wedge dA^{(1)}=A^{(2)}\wedge dA^{(2)}-if_{12}^{-1}df_{12}\wedge dA^{(2)},$$

where $A^{(j)}$ denotes the connection one-form on U_j, and so its values on the trivializing patches do not agree on the overlap $U_1\cap U_2$. So in general we cannot define an action by just using partitions of unity to patch together pieces of the Lagrangian given by (2), as we can do for gauge-invariant Lagrangians. Notice that the term proportional to A_t, although gauge-dependent, is unambiguously defined globally since we are assuming that the transition functions are time-independent. The most elegant way to define the Chern–Simons action is as the integral of the gauge-invariant second Chern form $\mu dA\wedge dA$, on any four-dimensional manifold M with boundary $\partial M=S^1\times\Sigma$. Here, A is a connection on a principal U(1) bundle on M which restricts to our bundle P on $S^1\times\Sigma$. There is no obstruction to the existence of such an extension of $P\to S^1\times\Sigma$, since in our case it would lie in the group $H_3(\mathbb{CP}^\infty;\mathbb{Z})$, which is trivial.[8] The action should be independent (mod 2π) of the choice of the manifold M and the bundle over it, and this imposes the constraint

$$\mu\in\frac{1}{4\pi}\mathbb{Z} \tag{4}$$

on the Chern–Simons coefficient. We shall write $\kappa := 4\pi\mu$.

The group of gauge transformations $\mathcal{G}$ consists of smooth maps from $S^1\times\Sigma$ to U(1). The connected component of the identity $\mathcal{G}^0$ is the subgroup of maps homotopic to the identity (the small gauge transformations), and the connected components of $\mathcal{G}$ are labeled by two-homology classes of space-time, dual to the one-cycles around which the gauge transformations have non-trivial winding:

$$\mathcal{G}/\mathcal{G}^0 \cong H_2(S^1\times\Sigma;\mathbb{Z}) \cong \mathbb{Z}\oplus\mathbb{Z}^{\oplus 2\mathsf{g}}. \tag{5}$$

Here, g is the genus of Σ, and we can choose for the generator σ of the first $\mathbb{Z}$ factor the class of a positively oriented copy of Σ at a particular instant. It can be shown[9] that a gauge transformation in the connected component of $\mathcal{G}$ labeled by a class whose first component in the above decomposition is $k\sigma$ has the effect of adding the term $2\pi\kappa k N$ to the Chern–Simons action, so that this action is gauge-invariant (mod 2π) if and only if the condition (4) holds.

It is possible to express the Chern–Simons action entirely in terms of the three-dimensional data by treating carefully the boundary terms of the four-dimensional Chern action introduced above.[9] The result is that we should add a correction to the sum of the integrals of the Chern–Simons bulk term appearing in (2) over U_1 and U_2. The correction term is the double integral

$$\mu i \oint_{S^1\times\partial U_1} f_{12}^{-1} df_{12} \wedge A^{(1)}. \tag{6}$$

We still have to ensure that the term proportional to A_t in the action is gauge-invariant (mod 2π). Under a gauge transformation g, A_t changes as

$$A_t \mapsto A_t - ig^{-1}\partial_t g.$$

If the class of g in the first factor of $\mathcal{G}/\mathcal{G}^0$ in (5) is $k\sigma$, then everywhere on Σ

$$i \oint_{S^1} g^{-1}\partial_t g\, dt = k,$$

and the change in the action is

$$-\frac{i}{2}\gamma k \oint_{\Sigma} \Omega^2 dz\wedge d\bar{z} = -\gamma k \,\mathrm{Vol}(\Sigma).$$

This will be in $2\pi\mathbb{Z}$ for all $k\in\mathbb{Z}$ if and only if we impose the constraint

$$\gamma\,\mathrm{Vol}(\Sigma) \in \mathbb{Z}. \tag{7}$$

The action for Manton's model on Σ can then be written as

$$S[A,\phi] = \sum_{j=1}^{2} \int_{S^1\times U_j} \mathcal{L}[A^{(j)},\phi^{(j)}]\, d^3x + \mu i \oint_{S^1\times\partial U_1} f_{12}^{-1} df_{12}\wedge A^{(1)}, \tag{8}$$

where we impose the constraints (4) and (7) to the classical parameters to ensure that e^{iS} is well defined and gauge invariant. To implement the variational principle, we consider variations δA, $\delta\phi$ and $\delta\overline{\phi}$ of the fields which are a one-form and sections of the bundles associated to P by the fundamental representation and its dual, respectively. As usual, the variation of the first (bulk) term in (8) yields after integration by parts

$$\delta S = \sum_{\psi}\sum_{j=1}^{2}\left\{\int_{S^1\times U_j}\left[\frac{\delta\mathcal{L}}{\delta\psi} - \partial_\nu\left(\frac{\delta\mathcal{L}}{\delta\partial_\nu\psi}\right)\right]\delta\psi\, d^3x + \int_{S^1\times U_j}\partial_\nu\left(\frac{\delta\mathcal{L}}{\delta\partial_\nu\psi}\,\delta\psi\right) d^3x\right\}. \tag{9}$$

Here, ψ is any of A_ν, ϕ, or $\overline{\phi}$, and the (j) subscripts have been suppressed. If we define on each U_j the one-form

$$\Psi := \Omega^{-2}\left(\frac{\delta\mathcal{L}}{\delta\partial_t\psi}\right)dt - \left(\frac{\delta\mathcal{L}}{\delta\partial_{\overline{z}}\psi}\right)dz - \left(\frac{\delta\mathcal{L}}{\delta\partial_z\psi}\right)d\overline{z},$$

and denote the Hodge star of (1) by $*$, then the last integral in the expression (9) can be written as

$$\int_{S^1\times U_j}\partial_\nu\left(\frac{\delta\mathcal{L}}{\delta\partial_\nu\psi}\,\delta\psi\right)d^3x = \oint_{S^1\times\partial U_j} *\Psi\ \delta\psi. \tag{10}$$

It is easy to verify by direct computation that, for the terms in $\mathcal{L}$ which are locally gauge-invariant, the contributions to the components of the two-form $*\Psi\,\delta\psi$ are just functions on each trivializing patch. Therefore, their corresponding $j=1,2$ contributions in (10) cancel as they should, since the boundaries ∂U_1 and ∂U_2 are very close but carry opposite orientations. For the term proportional to A_t, the values of the contributions on the $j=1,2$ patches also cancel because of our assumption of the time-independence of f_{12}. However, the Chern–Simons term has a nonvanishing contribution. Indeed,

$$\delta(A\wedge dA) = 2\,dA\wedge\delta A - d(A\wedge\delta A),$$

and so the sum of the $j=1,2$ contributions to (10) is

$$\mu\oint_{S^1\times\partial U_1}(A^{(1)}\wedge\delta A - A^{(2)}\wedge\delta A) = -\mu i\oint_{S^1\times\partial U_1} f_{12}^{-1}df_{12}\wedge\delta A,$$

which exactly cancels the variation of the correction (6) to the Chern–Simons bulk term. So we conclude that the stationarity of the action (8) is exactly expressed by the Euler–Lagrange equations for the naive Lagrangian (2) in each trivializing coordinate patch. They read

$$\gamma i D_0\phi = -(D_z D_{\overline{z}}\phi + D_{\overline{z}}D_z\phi)\Omega^{-2} - \frac{\lambda}{4}(1-|\phi|^2)\phi, \tag{11}$$

$$\partial_z(B\Omega^{-2}) = -iJ_z + 2\mu E_z, \tag{12}$$

$$2\mu B = \gamma(1-|\phi|^2)\Omega^2, \tag{13}$$

where the gauge-invariant supercurrent J_z is defined by

$$J_z := -\frac{i}{2}(\overline{\phi}D_z\phi - \phi\overline{D_{\overline{z}}\phi}). \tag{14}$$

We are making the assumption that these equations admit nonstatic time-periodic solutions which can be patched together on Σ. Notice that no higher than first-order time derivatives of the fields appear in (11)–(13). Equation (11) is a gauge-invariant nonlinear Schrödinger equation for ϕ, while (12) is a version of Ampère's law and (13) can be interpreted as a magnetic Gauss' law.

III. STATIC VORTICES ON A SPHERE

Static configurations are time-independent solutions of the field equations of motion with vanishing A_t. For them, our Lagrangian reduces to the Ginzburg–Landau energy functional $\mathcal{E}$, given by the last bracket in (2). Notice that this is also the functional relevant to the discussion of static solutions in the Abelian Higgs model. If $\lambda=1$, one can show that all the critical points of $\mathcal{E}$ satisfy the two-dimensional Bogomol'nyĭ equations[10] on Σ. For configurations with $N>0$, these read

$$D_{\bar{z}}\phi = 0, \tag{15}$$

$$2B = (1-|\phi|^2)\Omega^2, \tag{16}$$

and their solutions are known as vortices. If $N<0$, they are called antivortices and satisfy similar equations, with $D_{\bar{z}}$ replaced by D_z in (15), whereas a minus sign is introduced in (16). Solutions (A,ϕ) to the Bogomol'nyĭ equations for which (3) holds have energy $\mathcal{E}=|N|\pi$. Henceforth, we shall be interested in the $N>0$ case only. Write $\phi = e^{h/2+i\chi}$; the function h is gauge-invariant while χ (defined only modulo 2π) is not, and both are real. Equation (15) can be used to obtain A_z in terms of h and χ, and substitution in (16) yields

$$4\partial_z\partial_{\bar{z}}h - (e^h-1)\Omega^2 = 4\pi\sum_{r=1}^{N}\delta^{(2)}(z-z_r). \tag{17}$$

The solution to this equation provides all the information needed to reconstruct the fields on Σ; χ has to give the required winding properties of ϕ in each patch, but the gauge freedom leaves it otherwise undetermined.

The Bogomol'nyĭ equations were first studied on a compact Riemann surface Σ by Bradlow[11] (cf. also Ref. 12 and references therein). He showed existence and uniqueness of a solution satisfying (3) with the Higgs field having exactly N zeros (counted with well-defined multiplicities) in any configuration, provided

$$\mathrm{Vol}(\Sigma) > 4\pi N. \tag{18}$$

Thus, given the topological constraint (3), and if the bound (18) is satisfied, the moduli space of solutions to the Bogomol'nyĭ equations can be described as the symmetric product $\mathcal{M}_N = S^N\Sigma = \Sigma^N/\mathfrak{S}_N$, a smooth $2N$-manifold. These solutions can be interpreted as nonlinear superpositions of N indistinguishable vortices located at the zeros of the Higgs field (the vortex cores), which play the rôle of moduli.

For the rest of this paper, we shall restrict to the situation where Σ is a two-sphere of radius R, which for later convenience we assume to be centered at the origin of $\mathbb{R}^3$. We choose the open subsets U_1 and U_2 introduced in Sec. II to be discs around the North and South poles, respectively, where stereographic coordinates can be used. In the next Section, we will argue that actually we can shrink U_2 to a point, and focus entirely on a U_1 which covers all of Σ except the South pole. So we can parametrize the position of the vortices in the open dense U_1 by a coordinate z with inverse

$$z \mapsto R\left(\frac{z+\bar{z}}{1+|z|^2}, -i\frac{z-\bar{z}}{1+|z|^2}, \frac{1-|z|^2}{1+|z|^2}\right). \tag{19}$$

As usual, we write $z=\infty$ to refer to the South pole. In terms of this coordinate, the conformal factor in (1) is just

$$\Omega^2(z,\bar{z}) = \frac{4R^2}{(1+|z|^2)^2}. \tag{20}$$

The positions $z_1,\ldots,z_N$ of N vortices define coordinates almost everywhere on the moduli space. They are regular only in the subset of configurations for which all the zeros of ϕ are simple and none of them occur at the South pole. To parametrize the whole subset $V_0 \subset \mathcal{M}_N$ of static configurations with no zeros of the Higgs field at $z=\infty$, we can introduce instead the elementary symmetric polynomials in the N variables z_r

$$s_k := s_k^{[N]}(z_1,\ldots,z_N) = \sum_{1\leqslant j_1<\cdots<j_k\leqslant N} z_{j_1}\cdots z_{j_k}, \quad 1\leqslant k\leqslant N. \tag{21}$$

More generally, let $V_j \subset \mathcal{M}_N$ denote the subset of configurations with exactly j vortices at $z=\infty$; it is parametrized by the symmetric polynomials $s_k^{[N-j]}$ of the coordinates of the $N-j$ remaining vortices. Clearly, $\mathcal{M}_N = \amalg_{j=0}^N V_j$ gives a decomposition of $\mathcal{M}_N$ into $N+1$ disjoint $2(N-j)$-cells $V_j \cong \mathbb{C}^{N-j}$, and it is easy to verify that they are glued together so as to give $\mathcal{M}_N = \mathbb{CP}^N$.

Later on, it will be useful to consider the standard decomposition of the moduli space as union of affine pieces $\mathcal{M}_N = \cup_{j=0}^N W_j$, where the W_j are defined in terms of homogeneous coordinates as usual

$$W_j := \{(Y_0 : Y_1 : \cdots : Y_N) \mid Y_j \neq 0\} \cong \mathbb{C}^N.$$

We may set $W_0 = V_0$ say, and identify the s_k in (21) with the inhomogeneous coordinates of W_0,

$$s_k = y_k^{(0)} := \frac{Y_k}{Y_0}, \quad 1 \leqslant k \leqslant N.$$

Letting $s_0 := 1$, we can relate the inhomogeneous coordinates in the other W_j to the s_k by

$$y_k^{(j)} := \frac{Y_k}{Y_j} = \frac{s_k}{s_j}, \quad 0 \leqslant k \leqslant N, \quad k \neq j.$$

It is not hard to see that V_j is being identified with the $(N-j)$-plane $y_0^{(j)} = \cdots = y_{j-1}^{(j)} = 0$ in W_j.

We still need to introduce a further piece of notation. Near the position $z = z_r$ of an isolated vortex, $h = \log|\phi|^2$ can be expanded as[7,13]

$$h(z; z_1, \ldots, z_N) = \log|z - z_r|^2 + a_r + \frac{b_r}{2}(z - z_r) + \frac{\overline{b_r}}{2}(\overline{z} - \overline{z_r}) + O(|z - z_r|^2). \tag{22}$$

Here, a_r and b_r are functions of the positions $z_1, \ldots, z_N$ of all the N vortices. If $N=1$, spherical symmetry can be used to show that[14]

$$b_1 = -\frac{2\overline{z_1}}{1 + |z_1|^2}.$$

This function describes how the level curves of $|\phi|^2$, which consist of circles centered around the core of the vortex on the sphere, are distorted by the stereographic projection onto the z-plane. An analogous situation arises when we consider more generally the subvariety $\mathcal{M}_N^{\mathrm{co}} \subset \mathcal{M}_N$ of configurations of N coincident vortices. It is parametrized by the position $z = Z$ of the only zero of the Higgs field, whose modulus squared has a logarithm with an expansion identical to (22) around Z, but with a coefficient N before the logarithmic term; the coefficient of $\frac{1}{2}(z - Z)$ is then

$$b = -\frac{2N\overline{Z}}{1 + |Z|^2}. \tag{23}$$

When the positions of the N vortices do not coincide, there is an additional distortion to the $|\phi|^2$ contours caused by the mutual interactions, and this leads to nontrivial b_r coefficients in (22). It turns out that the functions b_r contain all the information about the interactions relevant for the kinetic term of the reduced mechanical system. This was also the case in Samols' analysis of the Abelian Higgs model.[7]

It will be useful later to relate the functions b_r to their pullbacks

$$T^* b_r(z_1, \ldots, z_N) := b_r(T(z_1), \ldots, T(z_N)),$$

under an isometry T of the sphere. This relationship is easy to obtain directly from the expansion (22) by requiring that h be invariant:

$$T^* b_r = \frac{b_r}{T'(z_r)} - \frac{T''(z_r)}{(T'(z_r))^2}. \tag{24}$$

If we interpret T as a (passive) change of coordinates, this equation can be regarded as the formula for the transformation of Christoffel symbols for an affine connection, as pointed out in Ref. 15. In fact, we shall define a natural unitary connection on a line bundle over the moduli space of static vortices. In the next Section, we show that this connection is the essential ingredient of the reduced Lagrangian for Manton's model. The functions b_r are part of the coefficients of the connection one-form, and they incorporate the interactions among the vortices at zero potential energy into the reduced dynamics.

IV. THE EFFECTIVE MECHANICAL SYSTEM

Ultimately, we are interested in understanding the dynamics of the field configurations, and this is a much harder problem than the study of static solutions. However, it is natural to expect that, for λ close to 1, slow-varying solutions of the field theory should be well approximated by static solutions evolving along the directions defined by the linearized Bogomol'nyĭ equations. This idea was introduced by Manton in the context of Yang–Mills–Higgs monopoles[16] and has proven very fruitful in many situations. For the Abelian Higgs model, a careful analysis by Stuart[17] showed that this so-called adiabatic approximation is exponentially accurate in the limit of small velocities, and that it holds even when the coupling differs slightly from the self-dual value $\lambda = 1$. The field dynamics of N vortices is reduced to an effective mechanical system on the moduli space $\mathcal{M}_N$. The relevant Lagrangian can be obtained by evaluating the Lagrangian for the field theory at static solutions with time-dependent moduli and then integrating out the space dependence. Samols[7] showed that the reduced dynamics at self-dual coupling corresponds to geodesic motion on the moduli space, with respect to a Kähler metric that encodes information about the local behavior of the Higgs field at its zeros; we shall explain this more precisely at the end of this Section. For general values of $\lambda \simeq 1$, the geodesic motion is distorted by conservative forces, which are absent at self-dual coupling.

In what follows, we shall study Manton's model within the adiabatic approximation, in the regime $\lambda \simeq 1$ and $\gamma = \mu$. The latter assumption enables one to obtain a neat expression for the reduced kinetic-energy term, as will be shown below. Notice that, when $\gamma = \mu$, Eq. (13) reduces to (16), and this raises our hope that the adiabatic picture is a good approximation to the field theory in this model, as Manton pointed out.[2] Another check is provided by the existence of consistent conservation laws, which we shall explore in Sec. V.

We shall follow the analysis in Ref. 2 to obtain the Lagrangian for the reduced mechanical system on the moduli space. When γ and μ are set to be equal, consistency of the conditions (4) and (7) is expressed by

$$\frac{\kappa}{4\pi}\mathrm{Vol}(\Sigma) = \kappa R^2 \in \mathbb{Z}. \tag{25}$$

The kinetic energy consists of the terms in (8) which contain time derivatives and A_t. After using (16), it can be written in the form

$$T = \frac{i\gamma}{2}\sum_{j=1}^{2} \int_{U_j} \mathrm{Im}(4A_{\bar{z}}\dot{A}_z - \bar{\phi}\dot{\phi}\Omega^2)\, dz \wedge d\bar{z},$$

where the overdots denote time derivatives and z is the relevant stereographic coordinate on each of the discs U_j. Notice that the correction to the naive Chern–Simons action has now been canceled by a boundary term coming from the bulk. In terms of the functions h and χ introduced in Sec. III, we can write

$$T=\frac{i\gamma}{2}\sum_{j=1}^{2}\int_{U_j}(2i(\partial_{\bar z}\zeta_z-\partial_z\zeta_{\bar z})+\partial_t(\partial_z h\partial_{\bar z}\chi+\partial_{\bar z}h\partial_z\chi)-\dot\chi\Omega^2)dz\wedge d\bar z, \tag{26}$$

where ζ_z, $\zeta_{\bar z}$ are the components of the one-form

$$\zeta=\dot\chi(d\chi+\star dh)+\tfrac{1}{4}\dot h\, dh$$

in each trivializing coordinate patch; here, $\star$ is the Hodge star of the metric on Σ. To evaluate (26), we cut discs of small radius ϵ around each vortex position (where the integrand is singular) and apply Stokes' theorem, letting $\epsilon\to 0$ at the end.

The only contributions to the integrals around ∂U_j come from the first term in (26), yielding

$$i\gamma\oint_{\partial U_1}\dot\chi f_{12}^{-1}df_{12},$$

where χ denotes the argument of $\phi^{(1)}$. If we choose U_2 small enough so that it does not overlap with any of the trajectories of the vortices, χ is globally defined on U_2. So this term is a total time derivative and can be discarded from the kinetic energy. No other contribution coming from the nontriviality of the bundle P arises, and hence we may safely shrink U_2 to the South pole, while $U_1\cong\mathbb{C}$ becomes dense in Σ. Henceforth, z shall always denote the coordinate in (19).

To describe the contributions coming from the neighborhood of the vortices, we write[2] near vortex r

$$\chi=\theta_r+\psi_r, \tag{27}$$

where θ_r is the polar angle in the z-plane with respect to z_r, and ψ_r is a function of the position of the vortices only. Of course, Eq. (27) assumes that the gauge freedom has been reduced in the neighborhood of the vortices. The analysis in Ref. 2 goes through unchanged to conclude that the contributions from the first two terms in (26) add up to

$$\pi\gamma\sum_{r=1}^{N}(2\dot\psi_r+ib_r\dot z_r-i\bar b_r\dot{\bar z}_r). \tag{28}$$

It follows from the expansion (22) that the coefficient b_r has a singularity when vortex r approaches another vortex $s\neq r$,

$$b_r(z_1,\ldots,z_N)=2\sum_{s\neq r}\frac{1}{z_r-z_s}+\tilde b_r(z_1,\ldots,z_N), \tag{29}$$

where $\tilde b_r$ is a smooth function. However, a gauge can be chosen for which each ψ_r is given by

$$\psi_r(z_1,\ldots,z_N)=\arg\prod_{s\neq r}^{N}(z_r-z_s)\pmod{2\pi},$$

and then

$$\sum_{r=1}^{N}\dot\psi_r=-i\sum_{r=1}^{N}\sum_{s\neq r}\left(\frac{\dot z_r}{z_r-z_s}-\frac{\dot{\bar z}_r}{\bar z_r-\bar z_s}\right)$$

exactly cancels the singularity from the b_r coefficients.

The last term in (26) yields again a contribution from the metric on Σ. Its time integral gives $-2\pi\gamma$ times the signed area enclosed by the trajectories of the vortices $z_r(t)$. In our local coordinate z, the area form can be expressed as

$$\omega_\Sigma = 2iR^2 \frac{dz\wedge d\overline{z}}{(1+|z|^2)^2} = iR^2 d\left(\frac{z d\overline{z} - \overline{z} dz}{1+|z|^2}\right) =: d\vartheta.$$

Therefore, we may write

$$-2\pi\gamma \oint_{S^1}\left(\int_\Sigma \dot{\chi}\omega_\Sigma\right)dt = -2\pi\gamma \oint_{S^1}\sum_{r=1}^N z_r^*\vartheta = 2i\pi\gamma R^2 \oint_{S^1}\sum_{r=1}^N \frac{\overline{z}_r\dot{z}_r - z_r\dot{\overline{z}}_r}{1+|z_r|^2}dt \tag{30}$$

and interpret the integrand in the last expression above as the relevant contribution to T.

Putting (28) and (30) together, we conclude that the kinetic-energy term in the effective Lagrangian is given by

$$T^{\mathrm{red}} = \pi i\gamma \sum_{r=1}^N \left[\left(2R^2\frac{\overline{z}_r}{1+|z_r|^2} + \tilde{b}_r\right)\dot{z}_r - \left(2R^2\frac{z_r}{1+|z_r|^2} + \overline{\tilde{b}_r}\right)\dot{\overline{z}}_r\right]. \tag{31}$$

Unfortunately, the potential energy is harder to deal with. It can be written as

$$\begin{aligned} V^{\mathrm{red}} &= N\pi + \frac{i}{16}(\lambda-1)\int_\Sigma (1-e^h)^2\Omega^2 dz\wedge d\overline{z} \\ &= N\pi\lambda - \frac{\pi}{2}(\lambda-1)R^2 + \frac{i}{16}(\lambda-1)\int_\Sigma e^{2h}\Omega^2 dz\wedge d\overline{z}. \end{aligned}$$

It does not seem possible to simplify the integral involving e^{2h} to a local expression in the moduli. Stuart has shown[18] that, for $N=2$, V^{red} can be approximated by a rational function of the distance between the two vortices, in the limit where Bradlow's bound (18) comes close to the equality.

The reduced Lagrangian $L^{\mathrm{red}} = T^{\mathrm{red}} - V^{\mathrm{red}}$ is first-order in the time derivatives, just as the field theory Lagrangian. So, as mentioned in the Introduction, the equations of motion already arise in Hamiltonian form and the moduli space is to be interpreted as a phase space. The potential energy V^{red} is the only contribution to the Hamiltonian, while the kinetic term determines a symplectic potential $\mathcal{A}$ in our coordinate patch W_0 for a noncanonical symplectic form on $\mathcal{M}_N$. Indeed, $T^{\mathrm{red}} = \mathcal{A}(d/dt)$ with d/dt the vector field determining time evolution, and $\mathcal{A}$ the real one-form

$$\mathcal{A} = \pi i\gamma \sum_{r=1}^N \left[\left(2R^2\frac{\overline{z}_r}{1+|z_r|^2} + \tilde{b}_r\right)dz_r - \left(2R^2\frac{z_r}{1+|z_r|^2} + \overline{\tilde{b}_r}\right)d\overline{z}_r\right]. \tag{32}$$

This one-form is regular throughout W_0. The equations of motion can be cast as

$$\iota_{\frac{d}{dt}}\omega = -dV^{\mathrm{red}},$$

where the (global) symplectic form $\omega = d\mathcal{A}$ is given on W_0 by

$$-\frac{4i}{\kappa}\omega = d\sum_{r=1}^{N}\left[\left(2R^2\frac{\overline{z_r}}{1+|z_r|^2}+\tilde{b}_r\right)dz_r-\left(2R^2\frac{z_r}{1+|z_r|^2}+\overline{\tilde{b}_r}\right)d\overline{z_r}\right]$$

$$=\sum_{r=1}^{N}\sum_{s\neq r}\left(\frac{\partial\tilde{b}_s}{\partial z_r}dz_r\wedge dz_s-\frac{\partial\overline{\tilde{b}_s}}{\partial\overline{z_r}}d\overline{z_r}\wedge d\overline{z_s}\right)$$

$$-\sum_{r,s=1}^{N}\left(\frac{\partial b_r}{\partial\overline{z_s}}+\frac{\partial\overline{b_s}}{\partial z_r}+\frac{4R^2\delta_{rs}}{(1+|z_r|^2)^2}\right)dz_r\wedge d\overline{z_s}.$$

Notice that we are allowed to replace b_r by $\tilde{b}_r$ in expressions like $\partial b_r/\partial\overline{z_s}$, since it is know from (29) that $b_r-\tilde{b}_r$ is holomorphic. Either of the two arguments given in Ref. 7 shows that locally

$$\tilde{b}_r=\frac{\partial\mathcal{B}}{\partial z_r}, \tag{33}$$

for a real function $\mathcal{B}$. Hence

$$\omega=-\frac{i\kappa}{2}\sum_{r,s=1}^{N}\left(\frac{2R^2\delta_{rs}}{(1+|z_r|^2)^2}+\frac{\partial\overline{b_s}}{\partial z_r}\right)dz_r\wedge d\overline{z_s}. \tag{34}$$

It is easily verified that Eq. (33) is equivalent to ω being a Kähler form on W_0 with respect to the complex structure on the moduli space induced by the one on Σ. Moreover, we conclude from (34) that it is proportional to the Kähler form ω_{Sam} of Samols' metric[7]

$$\omega=-\frac{\kappa}{2}\omega_{\mathrm{Sam}}. \tag{35}$$

It is a global (1,1)-form on $\mathcal{M}_N$ with respect to the complex structure defined by our coordinates. It becomes apparent that ω_{Sam} (or ω) is a central object in the reduced dynamics of both the Abelian Higgs model and Manton's model; but we should emphasize that it plays completely different rôles in the two contexts. In the Abelian Higgs model, ω_{Sam} is the (1,1)-form corresponding to a Kähler metric on the configuration space $\mathcal{M}_N$. In the Hamiltonian picture, the dynamics takes place on the cotangent bundle $T^*\mathcal{M}_N$ with its canonical (tautological) symplectic form, and time evolution is determined by the laplacian of Samols' metric, possibly with an extra potential term if we allow $\lambda\neq 1$. On the other hand, in Manton's system ω is the symplectic form of a Hamiltonian system on $\mathcal{M}_N$ itself, which has no time evolution unless the potential V^{red} is switched on. We can also interpret ω as the curvature of the one-form $\mathcal{A}$ in (32), which represents a unitary connection on a Hermitian line bundle over $\mathcal{M}_N$ in a local orthonormal frame. This point of view leads directly to the geometric quantization of Manton's system using the natural Kähler polarization, as we shall see in Sec. VI.

V. SYMMETRIES AND CONSERVED QUANTITIES

In this section, we analyze the symmetries of Manton's model on the sphere, following the similar analysis for the plane.[19] More precisely, we will study the isometries of the metric (1). We shall make standard use of Noether's theorem to obtain the corresponding conserved quantities in the Lagrangian formulations of both the field theory and the reduced mechanical system. The conserved quantities reduced to static solutions are interesting observables of the effective classical system of vortices, and later we will be concerned with their quantization.

A. Symmetries in the field theory

Here, we shall be concerned with the Lagrangian (2). When computing the Lie derivatives of the different terms along a vector field ξ, one obtains gauge-dependent quantities in general.

However, we can supplement the field variations under the flow of ξ by a gauge transformation by $e^{-i\alpha A(\xi)}$, where α is the flow parameter, so as to obtain gauge-invariant variations.[19] The whole operation can be interpreted as a covariant Lie derivative, in the spirit of the discussion in the Appendix of Ref. 18.

The simplest symmetry of the model is time translation, generated by ∂_t. The $\mathrm{O}(\alpha)$ variation of the Lagrangian is

$$\alpha\,\delta\mathcal{L}=\alpha[\,\partial_t(\mathcal{L}+\gamma A_t\Omega^2-\mu BA_t)+2\mu i(\partial_{\bar z}(A_tE_z)-\partial_z(A_tE_{\bar z}))\,],$$

where we included a gauge transformation by $e^{-i\alpha A_t}$ in the fields. Noether's theorem then gives the conserved density

$$\begin{aligned} j^t&=\sum_{\psi}\frac{\delta\mathcal{L}}{\delta\partial_t\psi}\,\delta\psi-\partial_t(\mathcal{L}+\gamma A_t\Omega^2-\mu BA_t)\\ &=\frac{1}{2}B^2\Omega^{-2}+(|D_z\phi|^2+|D_{\bar z}\phi|^2)+\frac{\lambda}{8}(1-|\phi|^2)^2\Omega^2. \end{aligned}$$

This is the density of potential energy, so we learn that V is a constant of motion. This result does not depend on the particular form (20) for the conformal factor of the metric, and so it is also valid for more general Σ.

The SO(3) action on the sphere Σ by rotations about axes through the origin of $\mathbb{R}^3$ provides conservation laws for angular momentum. In our coordinate z, this action is described by elliptic Möbius transformations with antipodal fixed points,

$$z\mapsto\frac{(e^{i\alpha}+|a|^2)z+a(1-e^{i\alpha})}{\bar a(1-e^{i\alpha})z+(1+|a|^2e^{i\alpha})}, \tag{36}$$

where $a\in\mathbb{C}$ and $\alpha\in\mathbb{R}$. We shall consider the effect of rotations $R^{(j)}_\alpha$ $(j=1,2,3)$ by an angle α about the three Cartesian axes, which correspond to taking $a=1,i,0$.

The variation of the Lagrangian under the rotation $R^{(1)}_\alpha$, to be supplemented by the gauge transformation $e^{-\frac{\alpha}{2}((1-z^2)A_z-(1-\bar z^2)A_{\bar z})}$, is given up to $\mathrm{O}(\alpha)$ by

$$\begin{aligned} \alpha\,\delta_{(1)}\mathcal{L}=\frac{\alpha}{2}i[\,&\partial_t[(\mu B-\gamma\Omega^2)((1-z^2)A_z-(1-\bar z^2)A_{\bar z})]\\ &-\partial_z[(1-z^2)\mathcal{L}+2\mu i((1-z^2)A_zE_{\bar z}-(1-\bar z^2)A_{\bar z}E_{\bar z})]\\ &+\partial_{\bar z}[(1-z^2)\mathcal{L}+2\mu i((1-\bar z^2)A_{\bar z}E_z-(1-z^2)A_zE_z)]\,], \end{aligned}$$

and the variations $\delta_{(2)}\mathcal{L}$, $\delta_{(3)}\mathcal{L}$ are given by similar expressions. The densities of the conserved quantities can then be shown to be

$$j^t_{(1)}=\frac{\gamma i}{2}((1-z^2)(J_z+A_z)-(1-\bar z^2)(J_{\bar z}+A_{\bar z}))\Omega^2,$$

$$j^t_{(2)}=-\frac{\gamma}{2}((1+z^2)(J_z+A_z)+(1+\bar z^2)(J_{\bar z}+A_{\bar z}))\Omega^2,$$

$$j^t_{(3)}=-\gamma i(z(J_z+A_z)-\bar z(J_{\bar z}+A_{\bar z}))\Omega^2,$$

where J_z is the supercurrent defined in (14). These densities are still not gauge invariant. As in Ref. 19, we can remedy this by adding to the vector field $X_{(k)}$ in $\delta_{(k)}\mathcal{L}=:\partial_\nu X^\nu_{(k)}$ a divergenceless vector field. So we substitute $X^\nu_{(k)}$ by $\widetilde X^\nu_{(k)}$ given by

$$\tilde{X}^t_{(k)} = X^t_{(k)} - \partial_z(\Lambda_{(k)}A_{\bar{z}}) + \partial_{\bar{z}}(\Lambda_{(k)}A_z),$$

$$\tilde{X}^z_{(k)} = X^z_{(k)} + \partial_t(\Lambda_{(k)}A_{\bar{z}}) - \partial_{\bar{z}}(\Lambda_{(k)}A_t),$$

$$\tilde{X}^{\bar{z}}_{(k)} = X^{\bar{z}}_{(k)} - \partial_t(\Lambda_{(k)}A_z) + \partial_z(\Lambda_{(k)}A_t),$$

using

$$(\Lambda_{(1)},\Lambda_{(2)},\Lambda_{(3)}) = -2i\gamma R^2\left(\frac{z+\bar{z}}{1+|z|^2}, -i\frac{z-\bar{z}}{1+|z|^2}, \frac{1-|z|^2}{1+|z|^2}\right).$$

The new densities $\tilde{j}^t_{(k)}$ are now gauge invariant, and their space integrals are the conserved quantities

$$M_1 = -\frac{\gamma}{4}\int_{\mathbb{C}}\left[((1-z^2)J_z - (1-\bar{z}^2)J_{\bar{z}})\Omega^2 + 2iR^2\frac{z+\bar{z}}{1+|z|^2}B\right]dz\wedge d\bar{z},$$

$$M_2 = \frac{\gamma i}{4}\int_{\mathbb{C}}\left[((1+z^2)J_z + (1+\bar{z}^2)J_{\bar{z}})\Omega^2 - 2iR^2\frac{z-\bar{z}}{1+|z|^2}B\right]dz\wedge d\bar{z},$$

$$M_3 = \frac{\gamma i}{2}\int_{\mathbb{C}}\left[i(zJ_z - \bar{z}J_{\bar{z}})\Omega^2 + 2R^2\frac{1-|z|^2}{1+|z|^2}B\right]dz\wedge d\bar{z},$$

which can be interpreted as angular momenta around the three independent axes. Although Noether's theorem determines the conserved quantities corresponding to a given symmetry generator only up to an additive constant, the requirement that M_k be the components of a Hamiltonian moment of SO(3) removes this ambiguity.

Just as on the plane,[19] the quantities M_k can be neatly written as moments of the vorticity of the system. This is defined to be the gauge-invariant real quantity

$$\mathcal{V} = 2i(\partial_{\bar{z}}J_z - \partial_z J_{\bar{z}}) + B,$$

which is well-defined and smooth everywhere on Σ. Typically, it approaches zero away from the vortex cores, where both the magnetic field and the supercurrent (and its derivatives) become negligible. We obtain

$$M_1 = \frac{i\gamma}{2}R^2\int_{\mathbb{C}}\frac{z+\bar{z}}{1+|z|^2}\mathcal{V}\,dz\wedge d\bar{z}, \tag{37}$$

$$M_2 = \frac{i\gamma}{2}R^2\int_{\mathbb{C}}\frac{(-i)(z-\bar{z})}{1+|z|^2}\mathcal{V}\,dz\wedge d\bar{z}, \tag{38}$$

$$M_3 = \frac{i\gamma}{2}R^2\int_{\mathbb{C}}\frac{1-|z|^2}{1+|z|^2}\mathcal{V}\,dz\wedge d\bar{z}. \tag{39}$$

The expressions in the integrands should be compared with the Cartesian coordinates on the sphere as given by Eq. (19). We can anticipate that $\mathbf{M}=(M_1,M_2,M_3)$ is a vector in $\mathbb{R}^3$ which contains information about a center of mass of the vortex configurations. In particular, when N vortices become coincident, we expect $\mathbf{M}$ to point in the direction of the core, given the circular symmetry of the fields.

B. Symmetries in the effective mechanical system

There is an action of SO(3) on $\mathbb{CP}^N$ by simultaneous rotation of the vortex positions z_r as in (36). It is generated by the vector fields

$$\xi_{(1)}=-\frac{i}{2}\sum_{r=1}^{N}\left((1-z_r^2)\frac{\partial}{\partial z_r}-(1-\overline{z}_r^2)\frac{\partial}{\partial\overline{z}_r}\right), \tag{40}$$

$$\xi_{(2)}=\frac{1}{2}\sum_{r=1}^{N}\left((1+z_r^2)\frac{\partial}{\partial z_r}+(1+\overline{z}_r^2)\frac{\partial}{\partial\overline{z}_r}\right), \tag{41}$$

$$\xi_{(3)}=i\sum_{r=1}^{N}\left(z_r\frac{\partial}{\partial z_r}-\overline{z}_r\frac{\partial}{\partial\overline{z}_r}\right), \tag{42}$$

which can be seen to extend smoothly to $\mathbb{CP}^N$ after changing coordinates from the z_r to the s_k defined in (21). The rotational symmetry yields three independent relations among the functions b_r, which we shall now derive. Notice that the fluxes of the vector fields $\xi_{(j)}$ are given by acting on each z_r by the rotations $R_\alpha^{(j)}$ introduced in Sec. V.A. The Lie derivatives of the b_r can be computed by making use of (24),

$$\pounds_{\xi_{(j)}}b_r=\lim_{\alpha\to 0}\frac{R_\alpha^{(j)*}b_r-b_r}{\alpha}.$$

We then find the following relations:

$$-\frac{i}{2}\sum_{s=1}^{N}\left((1-z_s^2)\frac{\partial b_r}{\partial z_s}-(1-\overline{z}_s^2)\frac{\partial b_r}{\partial\overline{z}_r}\right)=\pounds_{\xi_{(1)}}b_r=-i(1+z_rb_r), \tag{43}$$

$$\frac{1}{2}\sum_{s=1}^{N}\left((1+z_s^2)\frac{\partial b_r}{\partial z_s}+(1+\overline{z}_s^2)\frac{\partial b_r}{\partial\overline{z}_s}\right)=\pounds_{\xi_{(2)}}b_r=-(1+z_rb_r), \tag{44}$$

$$i\sum_{s=1}^{N}\left(z_s\frac{\partial b_r}{\partial z_s}-\overline{z}_s\frac{\partial b_r}{\partial\overline{z}_s}\right)=\pounds_{\xi_{(3)}}b_r=-ib_r. \tag{45}$$

Using (33), Eqs. (43) and (44) can be written as

$$\sum_{s=1}^{N}\left((1\mp z_s^2)\frac{\partial b_s}{\partial z_r}\mp(1\mp\overline{z}_s^2)\frac{\partial\overline{b}_s}{\partial z_r}\right)\mp 2(1+z_rb_r)=0,$$

which together imply that the quantity $\Sigma_{s=1}^{N}(2z_s+z_s^2b_s+\overline{b}_s)$ is constant for all vortex configurations. To find what this constant is, we remark that all the singular parts in (29) cancel in pairs in the sum over s, and that in the limit of coincidence of the vortices the functions $\tilde{b}_r$ in (29) tend to b in (23). In particular, when all the vortices are at $Z=0$

$$\sum_{r=1}^{N}b_r(0,\ldots,0)=0. \tag{46}$$

So we conclude that

$$\sum_{s=1}^{N}(2z_s+z_s^2b_s+\overline{b}_s)=0. \tag{47}$$

Similarly, Eq. (45) and its conjugate imply that the quantity $\Sigma_{r=1}^{N}(z_s b_s - \overline{z_s}\overline{b_s})$ is independent of the vortex positions. Using the explicit formula (23) for N coincident vortices, we then deduce that this constant has to be zero, obtaining

$$\sum_{s=1}^{N} z_s b_s \in \mathbb{R}. \tag{48}$$

We remark that Eqs. (47) and (48) are analogues of the statement that the sum of the b_r vanishes for any vortex configuration on the plane, as found by Samols[7] as a consequence of translational symmetry. In fact, this statement follows from (47) in the limit where all vortices approach the origin, and (46) may be regarded as a special case of it. Equation (48) is also valid for vortices on the plane, and is a consequence of the SO(2) symmetry, but it has not been noted before in the literature.

The SO(3) action on $\mathbb{CP}^N$ leaves the symplectic form (34) invariant, i.e.,

$$\pounds_{\xi}\omega = d\iota_{\xi}\omega = 0, \tag{49}$$

for all ξ generating a rotation. To establish this, we make use of the relations (47) and (48). For example, $\xi_{(3)}$ satisfies (49) if and only if

$$\frac{\partial}{\partial \overline{z_q}}\left[\sum_{s=1}^{N}\left(\overline{z_s}\frac{\partial \overline{b_s}}{\partial z_r} - z_s\frac{\partial b_s}{\partial z_r}\right) - b_r\right] = 0,$$

for all q and r, and this follows from (48) or the weaker statement (45). Since $H^1(\mathbb{CP}^N;\mathbb{R})$ is trivial, (49) implies that there exist globally defined functions M_j^{red} satisfying

$$\iota_{\xi_{(j)}}\omega = -dM_j^{\mathrm{red}}. \tag{50}$$

The functions M_j^{red} are determined from (50) only up to a constant, and the $\xi_{(j)}$ are their corresponding Hamiltonian vector fields. We can fix this constant by requiring that the M_j^{red} are the components of a moment map, i.e., that the SO(3) action is Hamiltonian[20]

$$\{M_i^{\mathrm{red}}, M_j^{\mathrm{red}}\} := \omega(\xi_{(i)}, \xi_{(j)}) = -\sum_{k=1}^{3}\epsilon_{ijk}M_k^{\mathrm{red}}. \tag{51}$$

The M_j^{red} turn out to be the conserved quantities corresponding to the rotational symmetry in the reduced mechanical system. Recall that the connection one-form $\mathcal{A}$ in (32) is a symplectic potential for ω, and thus Eq. (50) is equivalent to

$$\pounds_{\xi_{(j)}}\mathcal{A} = dW_j, \tag{52}$$

with

$$W_j = \mathcal{A}(\xi_{(j)}) - M_j^{\mathrm{red}}. \tag{53}$$

Equation (52) is the statement of rotational invariance of the U(1) connection represented by $\mathcal{A}$ (see Ref. 21 for a discussion in the more general situation of connections on bundles with nonabelian structure group). The reduced Lagrangian L^{red} has a kinetic term (31) of the form

$$T^{\mathrm{red}} = \sum_{r=1}^{N}\mathcal{A}_r\dot{z}_r + \text{c.c.},$$

and a rotationally invariant potential. Using (52), we can establish that

$$\pounds_{\xi_{(j)}} L^{\mathrm{red}} = \partial_t W_j \,, \tag{54}$$

and so Noether's theorem implies that M_j^{red} as given by (53) is a conserved quantity. Notice that W_j depends on the choice of symplectic potential for ω, whereas M_j^{red} does not—cf. Eqs. (52) and (50). We can determine M_j^{red} by integrating (50), or alternatively from (54) and (53). We shall follow the latter route, which provides a direct proof of the spherical symmetry of the reduced system. Using Eqs. (43)–(45), we find that

$$\pounds_{\xi_{(1)}} L^{\mathrm{red}} = -\pi\gamma(R^2 - N)\partial_t \sum_{r=1}^{N} (z_r - \overline{z_r}),$$

$$\pounds_{\xi_{(2)}} L^{\mathrm{red}} = \pi i \gamma(R^2 - N)\partial_t \sum_{r=1}^{N} (z_r + \overline{z_r}),$$

$$\pounds_{\xi_{(3)}} L^{\mathrm{red}} = 0 = -2\pi\gamma\partial_t(N(R^2 - N)).$$

The constant term after the time derivative in the last equation was chosen so that the conserved quantities M_j^{red} obey (51). Making use of the relations (47) and (48) for the functions b_r, they can be written as

$$M_1^{\mathrm{red}} = \frac{\kappa}{4} \sum_{r=1}^{N} \left(2R^2 \frac{z_r + \overline{z_r}}{1 + |z_r|^2} + b_r + \overline{b_r} \right), \tag{55}$$

$$M_2^{\mathrm{red}} = \frac{i\kappa}{4} \sum_{r=1}^{N} \left(-2R^2 \frac{z_r - \overline{z_r}}{1 + |z_r|^2} + b_r - \overline{b_r} \right), \tag{56}$$

$$M_3^{\mathrm{red}} = \frac{\kappa}{2} \sum_{r=1}^{N} \left(R^2 \frac{1 - |z_r|^2}{1 + |z_r|^2} - (z_r b_r + 1) \right). \tag{57}$$

A consistency check of the reduction procedure can be made by comparing the conserved angular momenta in the two pictures. To do this, we shall write the quantities M_k in Sec. V A for static solutions in terms of the moduli. This is most easily done from Eqs. (37)–(39), expressing the fields in terms of the function h and making use of Eqs. (17) and (22) to reduce each M_k to the moduli space, similarly to what we did for the Lagrangian in Sec. IV. For example, to obtain the expression for M_1 we start by writing

$$\begin{aligned} \frac{z + \overline{z}}{1 + |z|^2} \mathcal{V} &= \frac{2}{R^2} \frac{z + \overline{z}}{1 + |z|^2} \partial_z \left(\frac{\partial_{\overline{z}} h \, \partial_z \partial_{\overline{z}} h}{1 + |z|^2} \right) \\ &= \frac{4}{R^2} \partial_z \left((z + \overline{z}) \partial_z \left(\frac{(\partial_{\overline{z}} h)^2}{1 + |z|^2} \right) - \frac{(\partial_{\overline{z}} h)^2}{1 + |z|^2} \right) + \text{c.c.} \end{aligned}$$

and use Stokes' theorem to evaluate (37) as a sum of contour integrals along small discs C_r of radius ϵ around the vortex positions:

$$M_1 = \frac{\gamma i}{4} \sum_{r=1}^{N} \oint_{C_r} ((z + \overline{z})(\overline{z}(\partial_{\overline{z}} h)^2 + (1 + |z|^2)\partial_{\overline{z}} h \partial_z \partial_{\overline{z}} h) - (1 + |z|^2)(\partial_{\overline{z}} h)^2) d\overline{z} + \text{c.c.}\,.$$

Assuming that the vortices are isolated, we may write on C_r

$$\partial_z \partial_{\bar{z}} h = -\frac{R^2}{(1+|z_r|^2)^2} + \mathrm{O}(\epsilon^2),$$

$$\partial_{\bar{z}} h = \frac{e^{i\theta_r}}{\epsilon} + \frac{\overline{b_r}}{2} + \mathrm{O}(\epsilon),$$

and then obtain in the limit $\epsilon \to 0$

$$M_1 = \frac{\pi\gamma}{2} \sum_{r=1}^{N} \left(4R^2 \frac{z_r + \overline{z_r}}{1+|z_r|^2} + (1-z_r^2) b_r + (1-\overline{z_r}^2)\overline{b_r} - 2(z_r + \overline{z_r}) \right)$$
$$= \frac{\kappa}{4} \sum_{r=1}^{N} \left(2R^2 \frac{z_r + \overline{z_r}}{1+|z_r|^2} + b_r + \overline{b_r} \right),$$

where we made use of (47). Similarly, we find

$$M_2 = \frac{\pi\gamma i}{2} \sum_{r=1}^{N} \left(-4R^2 \frac{z_r - \overline{z_r}}{1+|z_r|^2} + (1+z_r^2) b_r - (1+\overline{z_r}^2)\overline{b_r} + 2(z_r - \overline{z_r}) \right)$$
$$= \frac{\kappa i}{4} \sum_{r=1}^{N} \left(-2R^2 \frac{z_r - \overline{z_r}}{1+|z_r|^2} + b_r - \overline{b_r} \right)$$

and

$$M_3 = \pi\gamma \sum_{r=1}^{N} \left(2R^2 \frac{1-|z_r|^2}{1+|z_r|^2} - (z_r b_r + \overline{z_r}\overline{b_r}) - 2 \right)$$
$$= \frac{\kappa}{2} \sum_{r=1}^{N} \left(R^2 \frac{1-|z_r|^2}{1+|z_r|^2} - (z_r b_r + 1) \right).$$

So each M_j agrees with M_j^{red}.

It is instructive to compare the conserved quantities that we have found for the sphere with the ones obtained for the plane.[19] On the plane, space isometries are described by the Euclidean group $E(2)$. Convenient generators are the translations along the x_1 and x_2 axes and the rotation about the origin, and their conserved quantities in the reduced picture were determined to be

$$P_1 = -\pi\gamma i \sum_{r=1}^{N} (Z_r - \overline{Z_r}), \tag{58}$$

$$P_2 = \pi\gamma \sum_{r=1}^{N} (Z_r + \overline{Z_r}), \tag{59}$$

$$M = 2\pi\gamma \sum_{r=1}^{N} \left(\frac{1}{2}|Z_r|^2 + B_r Z_r + \overline{B_r}\overline{Z_r} + 1 \right), \tag{60}$$

where Z_r denote the positions of the vortex cores, B_r the coefficients in an expansion equivalent to (22), and we removed the "red" superscripts. In the limit where the radius R is large and the vortices are close together, say in a small neighborhood of the North pole, one should expect that our M_k should be well approximated by quantities directly related to the ones in (58)–(60). Indeed, identifying $2Rz_r = Z_r$ we obtain from (55) to (57)

$$M_1 = -RP_2 + \pi\gamma R \sum_{r=1}^{N} (B_r + \overline{B}_r) + \mathrm{O}(|z_s|), \tag{61}$$

$$M_2 = RP_1 + \pi\gamma i R \sum_{r=1}^{N} (B_r - \overline{B}_r) + \mathrm{O}(|z_s|), \tag{62}$$

$$M_3 = 2\pi\gamma N R^2 - M + \mathrm{O}(|z_s|). \tag{63}$$

Since it is known[7] that $\Sigma_{r=1}^{N} B_r = 0$ [cf. Eq. (46)], we see that M_1, M_2 and P_1, P_2 are related as expected, but Eq. (63) for M_3 is rather surprising. It means that, as $R \to \infty$, M_3 becomes infinite, and we should subtract from it the quantity $2\pi\gamma N R^2$, itself infinite in the limit, to be able to compare it with the angular momentum in the plane, M. Notice that when (61)–(63) are inserted in (51), we obtain

$$\{P_1, P_2\} = 2\pi\gamma N - \frac{1}{R^2} M + \mathrm{O}(|z_s|).$$

Thus when $R \to \infty$ we recover the nonvanishing classical Poisson brackets for the linear momenta in the plane as calculated by Hassaïne *et al.*[22]

For N coincident vortices, we can make use of (23) to obtain the angular momentum vector in closed form:

$$\mathbf{M}^{[N]} = 2\pi\gamma N(R^2 - N)\left(\frac{Z + \overline{Z}}{1 + |Z|^2}, -i\frac{Z - \overline{Z}}{1 + |Z|^2}, \frac{1 - |Z|^2}{1 + |Z|^2} \right). \tag{64}$$

As before, Z denotes the position of the common core. If we take $N = 1$, (64) implies that a single vortex on Σ should be assigned a nonzero $\mathbf{M}$ vector. Its direction gives just the vortex position, and its conservation implies that the single vortex does not move (even if $\lambda \neq 1$), as expected. The length of $\mathbf{M}^{[1]}$ can be interpreted as a nonzero intrinsic angular momentum of the single vortex at rest. This was also a feature of the model in the plane, where a single vortex was found to have an intrinsic momentum $-2\pi\gamma$. This agrees with our result, provided that we subtract the "tail" momentum $2\pi\gamma N R^2$ as discussed above. It should be noted that on the sphere this intrinsic momentum is quantized, from the considerations in Sec. II—it is a half integer in units of $\hbar = 1$. On the plane, this feature is not apparent, since γ could take any value. More generally, a configuration of N coincident vortices has angular momentum $-2\pi\gamma N^2$ after subtraction of $2\pi\gamma N R^2$, and this is consistent with the results of Ref. 19.

VI. INGREDIENTS FOR GEOMETRIC QUANTIZATION

We would like to investigate the quantum version of the reduced mechanics in the framework of geometric quantization. We shall follow the conventions in Ref. 5 and refer to Ref. 23 for background on complex geometry. To construct the quantum system, we need to supplement the classical theory (specified by the phase space $\mathcal{M}_N = \mathbb{CP}^N$, endowed with the symplectic form ω) with a Hermitian line bundle L over $\mathcal{M}_N$. The wave functions in the quantum Hilbert space are particular sections of L.

To start with, we should verify whether our phase space is quantizable at all. This is equivalent to the integrality of the class represented by the closed form $\omega/(2\pi)$ in de Rham cohomology,

$$\frac{1}{2\pi}[\omega] \in H^2(\mathcal{M}_N; \mathbb{Z}) \subset H^2(\mathcal{M}_N; \mathbb{R}). \tag{65}$$

In general, this requirement leads to nontrivial constraints on the parameters of the classical theory—the Weil (pre)quantization conditions. If they are satisfied, we may regard $[\omega]/(2\pi)$ as the first Chern class of a smooth complex line bundle over $\mathcal{M}_N$, which is what we call the prequantum line bundle L.

Recall that $H^2(\mathbb{CP}^N;\mathbb{R})$ is cyclic and we can take as generator the first Chern class $\eta \in H^2(\mathbb{CP}^N;\mathbb{Z})$ of the hyperplane bundle of $\mathbb{CP}^N$. Then $[\omega]=2\pi\ell\eta$ for suitable $\ell\in\mathbb{R}$. To determine ℓ, we can refer to Eq. (35) and use the formula for the cohomology class of ω_{Sam} obtained by Manton.[14] (This formula has been generalized[15] for Σ of arbitrary genus.) For the benefit of the reader, we reproduce Manton's argument here. Let $\mathcal{M}_N^{\mathrm{co}}\subset\mathcal{M}_N$ be the subvariety of configurations of N coincident vortices. This is a projective line parametrized by the position Z of the zero of the Higgs field. Equation (23) implies that ω restricts to it as

$$\omega|_{\mathcal{M}_N^{\mathrm{co}}}=-i\kappa\frac{N(R^2-N)}{(1+|Z|^2)^2}dZ\wedge d\overline{Z}. \tag{66}$$

It is readily seen that $\mathcal{M}_N^{\mathrm{co}}$ is embedded as a projective curve of degree N in $\mathcal{M}_N$, and is thus homologous to $\pm N[\mathbb{CP}^1]$. Here, we denote by $[\mathbb{CP}^1]$ the homology class of a projective line inside $\mathcal{M}_N$, which is dual to η and a generator of $H_2(\mathcal{M}_N;\mathbb{Z})$. The integral of (66) over $\mathcal{M}_N^{\mathrm{co}}$ is just $-2\pi\kappa N(R^2-N)$, and so we conclude that $\ell=-\kappa(R^2-N)$,

$$\frac{1}{2\pi}[\omega]=\ell\eta=-\kappa(R^2-N)\eta. \tag{67}$$

Equation (65) is equivalent to ℓ being an integer,

$$\kappa(R^2-N)\in\mathbb{Z},$$

and this is weaker than the conditions $\kappa,\kappa R^2\in\mathbb{Z}$ that we already had to impose in (4) and (25) from considerations of gauge invariance (mod 2π) of the classical field theory action. We conclude that no further constraints arise from prequantization.

In geometric quantization, the prequantum line bundle L is to be equipped with a Hermitian metric and a unitary connection. The fact that $\mathbb{CP}^N$ is simply-connected implies that in our case L is uniquely determined as a smooth bundle by the symplectic structure, and so is the Hermitian metric and the connection $\mathcal{D}$. The basic idea in the standard construction of L is to interpret (real) symplectic potentials of ω as local expressions for the connection, and then use parallel transport to define local sections and construct the bundle.[5] A given symplectic potential determines a unique local section σ of L up to a phase of modulus one. The Hermitian metric is introduced by requiring that each σ is a local orthonormal frame

$$\langle\sigma,\sigma\rangle=1. \tag{68}$$

This is unambiguous since two symplectic potentials must differ by the exterior derivative of a real function u, and then the corresponding local sections are related by the factor e^{-iu}.

The wave functions in geometric quantization are defined as the L^2 polarized sections of L. By L^2 we mean square-integrable with respect to the Hermitian product (68) on the fibres and the symplectic measure $\omega^N/N!$ on the base $\mathcal{M}_N$. Roughly speaking, polarized means that they only depend on half of the real coordinates of the phase space, just as the wave functions in the Schrödinger representation of quantum mechanics only depend on the position and not on the momentum. More precisely, a polarization $\mathcal{P}$ is defined as a Lagrangian (i.e., maximally isotropic) integrable subbundle of the complexification $T_{\mathbb{C}}\mathcal{M}_N$ of the tangent bundle of the phase space, and the condition

$$\mathcal{D}_{\overline{X}}\psi=0,\quad \forall X\in\Gamma(\mathcal{M}_N,\mathcal{P}) \tag{69}$$

defines what is meant for a section ψ to be $\mathcal{P}$-polarized. When the classical dynamics takes place in a Kähler phase space, as is our case, there is a natural choice of polarization $\mathcal{P}$—namely, the one determined by the i-eigenspaces of the compatible complex structure. It is generated by the holomorphic vector fields in the local complex coordinates. The introduction of a Kähler polarization can be interpreted naturally in terms of complex geometry as follows. A connection on the prequantum line bundle defines a holomorphic structure for L: By definition, the holomorphic sections are the ones which are annihilated by the part of $\mathcal{D}$ that takes values in $\Omega^{(0,1)}(\mathcal{M}_N,L)$, which is defined from the complex structure in the base. But such sections are precisely the ones satisfying the condition (69) for the Kähler polarization. Thus, polarized sections of L are nothing but holomorphic sections with respect to the holomorphic structure on L induced by the unitary connection $\mathcal{D}$.

VII. THE QUANTUM HILBERT SPACE

The Picard variety of $\mathbb{CP}^N$ is trivial, and this implies that L is uniquely determined as a holomorphic line bundle by its first Chern class, which can be read off from (67). A classical result[24] on the sheaf cohomology of $\mathbb{CP}^N$ establishes that L admits nontrivial global holomorphic sections if and only if $\ell > 0$ (i.e., $\kappa < 0$), and then they form the vector space

$$H^0(\mathbb{CP}^N,\mathcal{O}(L)) \cong \mathbb{C}[Y_0,\ldots,Y_N]_\ell, \tag{70}$$

where the right-hand side denotes the homogeneous polynomials of degree ℓ in the $N+1$ variables Y_j. This gives a concrete way to realize L and its sections (up to multiplication by a constant in $\mathbb{C}^\times$). Recall that the local symplectic potential $\mathcal{A}$ in (32) for the connection $\mathcal{D}$ determines a nonvanishing local section $\sigma: W_0 \to L$. It is not holomorphic though, as $\mathcal{A}$ has a nonzero component in $\Omega^{(0,1)}(W_0)$. But we can obtain a holomorphic local section from it by using a nonunitary gauge transformation: Since

$$\mathcal{A} = 2\pi\gamma i \sum_{r=1}^{N} \left(2R^2 \frac{\overline{z_r}}{1+|z_r|^2} + \tilde{b}_r \right) dz_r - 2\pi\gamma i d\left(\frac{1}{2}\mathcal{B} + R^2 \sum_{r=1}^{N} \log(1+|z_r|^2) \right), \tag{71}$$

where $\mathcal{B}$ is defined up to an additive real constant by (33), we can define on W_0

$$\sigma^{(0)}(z_1\ldots,z_N) := \sigma(z_1\ldots,z_N) e^{-2\pi\gamma(\frac{1}{2}\mathcal{B} + R^2 \sum_{r=1}^{N} \log(1+|z_r|^2))}; \tag{72}$$

this is a holomorphic section of L on W_0. It is uniquely determined from σ up to a positive real constant, and thus from $\mathcal{A}$ up to a constant in $\mathbb{C}^\times$. It extends to a global section of L, vanishing in the complement of W_0; we identify it with the homogeneous polynomial Y_0^ℓ in (70). From it, we can define the sections

$$\sigma^{(j)} := \left(\frac{Y_j}{Y_0} \right)^\ell \sigma^{(0)} = (y_j^{(0)})^\ell \sigma^{(0)},$$

which trivialize L on each W_j, and determine the line bundle through the transition functions

$$\varphi_{ij} : W_i \cap W_j \to \mathbb{C}^\times$$

$$(y_1^{(i)},\ldots,y_N^{(i)}) \mapsto (y_j^{(i)})^\ell = \left(\frac{s_j}{s_i} \right)^{-\kappa(R^2-N)}.$$

On each W_j, global holomorphic sections of L are given by multiplying $\sigma^{(j)}$ by polynomials in the $y_k^{(j)}$ of degree less than or equal to ℓ.

The quantum Hilbert space $\mathcal{H}_{\mathcal{P}}$ is the space of holomorphic sections of L which are normalizable with respect to the inner product defined by the symplectic measure of $\mathcal{M}_N$ and the product on the fibres given by (68), as we said in Sec. VI. This inner product can be easily written down as an integral over the open dense W_0, where L is trivialized by $\sigma^{(0)}$, by making use of (34), (68) and (72). Since we are dealing with a compact phase space, all the holomorphic sections have finite norm, so the Hilbert space $\mathcal{H}_{\mathcal{P}}$ is $H^0(\mathbb{CP}^N,\mathcal{O}(L))$ itself, with dimension

$$\dim\mathcal{H}_{\mathcal{P}}=\binom{N+\ell}{\ell}. \tag{73}$$

All these quantum states belong to a single degenerate energy level when $\lambda=1$. Recall that in this situation the Hamiltonian vanishes and no motion occurs at the classical level.

We may interpret the expression (73) as giving the number of states in a quantum system of N interacting bosons. By interacting, we mean that the area available for the dynamics on the sphere is affected by the space which the vortices themselves occupy. Recall that Bradlow's bound (18) establishes that N vortices can only live on a sphere which has an area exceeding $4\pi N$. Heuristically, we can say that a single vortex occupies 4π units of area. So we can regard (73) as the formula for the number of states for a system of N bosons which can be assigned to any of the $(|\kappa|/4\pi)\cdot 4\pi(R^2-N)$ states corresponding to the room available on the sphere, after the total area of the vortices has been discounted. (For $\kappa=-1$, there is a similiar interpretation for (73) as the number of states of a system of N noninteracting fermions, but it breaks down for $\kappa\neq -1$.)

From the formula (67), it is immediate to compute the volume of the moduli space determined by the Kähler form ω:

$$\mathrm{Vol}_{\omega}(\mathcal{M}_N)=\frac{(2\pi|\kappa|(R^2-N))^N}{N!}=\frac{(2\pi\ell)^N}{N!}.$$

It is of course proportional to the volume determined by Samols' metric, as first computed by Manton.[14,15] This volume has been used to deduce the thermodynamics of an ideal gas of Abelian Higgs vortices at $\lambda=1$ in the framework of Gibbs' classical statistical mechanics. In Manton's model at $\lambda=1$, there is only a ground state as we noted above, and its degeneracy, in Gibbs' approximation, is given by

$$d_{\mathrm{Gibbs}}=\frac{1}{(2\pi\hbar)^N}\mathrm{Vol}(\mathcal{M}_N)=\frac{\ell^N}{N!}. \tag{74}$$

Notice that Planck's constant is $2\pi\hbar=2\pi$ in our units. Gibbs' partition function is simply $Z_{\mathrm{Gibbs}}=d_{\mathrm{Gibbs}}e^{-\beta N\pi}$. At $\lambda\neq 1$, the degeneracy is lifted but the formula above is still to be interpreted as the total number of states of the system. It is of interest to study the quotient

$$Q:=\frac{\dim\mathcal{H}_{\mathcal{P}}}{d_{\mathrm{Gibbs}}},$$

which gives information about how appropriate Gibbs' estimate for the number of states of the quantum system is. From (73) and (74), we find

$$Q=\frac{(N+\ell)!}{\ell^N\ell!}.$$

Using Stirling's formula for the gamma function, we obtain

$$Q=\left(1+\frac{N+1}{\ell}\right)^N\left(1+\frac{N}{\ell+1}\right)^{-\frac{1}{2}}\left[\left(1+\frac{N}{\ell+1}\right)^{\ell+1}e^{-N}\right]e^{J(N+\ell+1)-J(\ell+1)}, \tag{75}$$

where J is the asymptotic series

$$J(z)=\sum_{n=1}^{\infty}\frac{B_n}{(2n-1)2n}\frac{1}{z^{2n-1}}.$$

In the context of Chern–Simons theories, the classical approximation is described as the limit $|\kappa|\to\infty$; this is equivalent to keeping the coupling μ as constant and letting $\hbar\to 0$. So we keep N fixed and let $\ell\to\infty$ in the expression (75), and this gives indeed $Q\to 1$. We might also try to obtain a classical regime in a thermodynamical limit, where both N and the area of the sphere become very large, but keeping a finite (possibly small) density, which we might want to define as

$$\nu:=\frac{|\kappa|N}{\ell}=\frac{\dfrac{N}{R^2}}{\left(1-\dfrac{N}{R^2}\right)}.$$

But it follows from (75) that in this limit Q is infinite, however small ν is taken to be.

VIII. QUANTUM ANGULAR MOMENTA

From the prequantization data, it is possible to construct prequantum operators $\mathcal{P}(f)$ for any classical observable $f\in C^{\infty}(\mathcal{M}_N)$ as

$$\mathcal{P}(f):=-i\mathcal{D}_{\xi_f}+f. \tag{76}$$

Here, ξ_f is the Hamiltonian vector field of f with respect to ω, defined by

$$d\iota_{\xi_f}\omega=-df. \tag{77}$$

Equation (50) is of course a special case of (77), with $\xi_{M_j^{\mathrm{red}}}=\xi_{(j)}$. In general, the linear operator $\mathcal{P}(f)$ does not map polarized sections of L to polarized sections. It is easy to show that it does if and only if ξ_f preserves the polarization:

$$[\xi_f,\Gamma(\mathcal{M}_N,\mathcal{P})]\subset\Gamma(\mathcal{M}_N,\mathcal{P}). \tag{78}$$

Then we may interpret $\mathcal{P}(f)$ as the quantum operator corresponding to the observable f. In the Kähler case, (78) can be seen to be equivalent to ξ_f being the real part of a holomorphic vector field. This condition is true for the Hamiltonian vector fields (40)–(42) of the angular momenta in (55)–(57).

We can determine explicitly the action of the quantum operators on the wave functions Ψ in the quantum Hilbert space $\mathcal{H}_{\mathcal{P}}=H^0(\mathcal{M}_N,\mathcal{O}(L))$. In the holomorphic frame on W_0 provided by $\sigma^{(0)}$, one can write $\Psi=\Psi^{(0)}\sigma^{(0)}$ with

$$\Psi^{(0)}(z_1,\ldots,z_N)=\sum_{j_1+\cdots+j_N=0}^{\ell}\alpha_{j_1\cdots j_N}\prod_{k=1}^{N}s_k^{[N]}(z_1,\ldots,z_N)^{j_k}, \tag{79}$$

with $\alpha_{j_1\cdots j_N}\in\mathbb{C}$. The one-form representing $\mathcal{D}$ with respect to this frame can be read off from (71) to be

$$\mathcal{A}^{(0)}=2\pi\gamma i\sum_{r=1}^{N}\left(2R^2\frac{\overline{z_r}}{1+|z_r|^2}+\tilde{b}_r\right)dz_r.$$

Substitution in (76) now gives the local representatives of the quantum operators in the local frame $\sigma^{(0)}$. For example, for M_3 we obtain

$$\begin{aligned}\mathcal{P}(M_3) &= -i(\iota_{\xi_{(3)}} d - i\mathcal{A}^{(0)}(\xi_{(3)})) + M_3 \\ &= -i\iota_{\xi_{(3)}} d + \frac{\kappa}{2} N(R^2-1) - \kappa \sum_{r=1}^{N} \sum_{s\neq r}^{N} \frac{z_r}{z_r - z_s} \\ &= -i\iota_{\xi_{(3)}} d - \frac{N\ell}{2}.\end{aligned}$$

Acting on Ψ as in (79), this yields

$$\mathcal{P}(M_3)\Psi^{(0)} = \sum_{j_1+\cdots+j_N=0}^{\ell} \left(j_1 + 2j_2 + \cdots + Nj_N - \frac{N\ell}{2} \right) \alpha_{j_1\cdots j_N} \prod_{k=1}^{N} s_k^{[N]}(z_1,\ldots,z_N)^{j_k}. \quad (80)$$

From this expression, it is easy to read off the eigenvalues of $\mathcal{P}(M_3)$ as

$$-\frac{N\ell}{2}, -\frac{N\ell}{2}+1, \ldots, \frac{N\ell}{2},$$

together with their multiplicities. The same spectrum is obtained for $\mathcal{P}(M_1)$ and $\mathcal{P}(M_2)$.

For $N=1$ and a given negative $\kappa \in \mathbb{Z}$, we see that the Hilbert space $\mathcal{H}_{\mathcal{P}}$ yields the irreducible (projective) $(\ell+1)$-dimensional representation of SO(3) through the action of the generators M_j^{red}. The situation here is exactly equivalent to the geometric quantization of the spin degrees of freedom of a particle of spin $\ell/2$, which are described classically by a two-sphere of half-integer radius $\ell/2$ and the standard Fubini–Study symplectic form. More generally, for any N, it follows from (80) that the representation of SO(3) carried by $\mathcal{H}_{\mathcal{P}}$ is the Nth symmetric power $\text{Sym}^N(\ell + \mathbf{1})$; notice that ℓ itself depends on N. This indicates once again that the vortices in our model can be regarded as interacting bosons, as we have put forward in Sec. VII. It is worthwhile to emphasize how our approach differs from the usual treatment of a system of indistinguishable bosons in quantum mechanics. In the latter context, the N-particle sector of the Fock space is constructed as the Nth symmetric power of the Hilbert space of a single particle. In our situation, the N-particle sector is constructed directly from the quantization of a classical N-particle phase space.

IX. DISCUSSION

In this paper, we have investigated an effective quantization of Manton's model of first-order Chern–Simons vortices on a sphere Σ of radius R. We have seen that the nontrivial topology of the space manifold leads to the integer constraints (4) and (7) on the parameters γ and μ in the Lagrangian. The periodic motion in the classical field theory was reduced to a Hamiltonian system on the moduli space of N vortices imposing the condition $\gamma = \mu$. At the self-duality point $\lambda = 1$, the effective dynamics is frozen, whereas for $\lambda \simeq 1$ the vortices move slowly, preserving their energy and angular momenta. The energy is purely potential and depends on the relative position of the vortices only.

The angular momenta along the three Cartesian axes have been computed in Sec. V, both for the field theory and the reduced dynamics, and the two results were shown to be consistent. In the latter context, the expressions for the angular momenta can be simplified using the relations (47) and (48) for the functions b_r, which we derived from rotational symmetry. The angular momenta along the three independent directions fit together to form a moment map $\mathbf{M}^{\text{red}}$ which we can regard as taking values in an $\text{so}(3)^* \cong \mathbb{R}^3$ where the sphere Σ is embedded. The direction of the vector $\mathbf{M}^{\text{red}}$ gives a point on the sphere that can be interpreted as the center of mass of the configuration of N vortices. Notice that there is no natural notion of centroid for a configuration of N points on a sphere (unless they lie on the same great circle and are not equidistant). We might be tempted to define it for generic configurations as the direction of the sum of the points, regarded as vectors in an $\mathbb{R}^3$ containing the sphere. (This definition is better behaved if we replace the target

sphere by the elliptic plane by identifying antipodal points.) For a configuration of vortices, this centroid does not coincide with the direction of the angular momentum, as can be seen from our formula for $\mathbf{M}^{\mathrm{red}}$ in (55)–(57). We believe that, for configurations where the vortices are not symmetrically distributed, the areas of the sphere where vortices are most close together give a contribution to the angular momentum which is smaller than the one corresponding to taking the sum of the vortex positions; this is based on the fact that the total angular momentum of N coincident vortices is proportional to $N(R^2-N)$ rather than to N, as was shown at the end of Sec. V B. On the plane,[19] the total linear momentum in Manton's model is proportional to the ordinary centroid in $\mathbb{R}^2$ of the positions of the vortices.

A rather unexpected feature of the analysis in Sec. V is that the angular momentum of a given number of vortices grows with the square of the radius R of the sphere. In the limit where the vortices are kept close together and $R\to\infty$, the modulus of the angular momentum blows up, and it was found necessary to subtract the constant $2\pi\gamma NR^2$, which becomes infinite in the limit, in order to compare it with the angular momentum of the system of vortices on the plane. This constant was seen to be related to the central charge for the linear momentum Poisson algebra for Manton's model on the plane.

The geometric quantization of the reduced model is rather straightforward to set up. The prequantum line bundle is uniquely determined by the Kähler structure on the moduli space defined by the kinetic energy term. To construct it, we made use of an argument of Manton[14] to obtain the cohomology class of Samols' Kähler two-form on the moduli space of Bogomol'nyĭ vortices, which appears in the study of the Abelian Higgs model. It is presumed that the quantum system we have obtained approximates a finite truncation of the quantum field theory, in which most of the excitations are kept in the ground state. However, it is not clear how one should assess the validity of this approximation. For $\lambda=1$, the quantization of the reduced system yields a single degenerate energy level; this degeneracy is lifted when the potential becomes nontrivial, and in principle its spectrum can be determined using degenerate perturbation theory. In Sec. VII, we have computed the dimension of the quantum Hilbert space and it was shown that it approaches Gibbs' estimate for the number of quantum states, as determined by the volume of the moduli space, in the classical limit of large Chern–Simons coefficient. Another result which comes from the analysis of the quantized effective system is that the solitons in the model should be interpreted as interacting bosons with the characteristic size 4π, as explained in Sec. VII. The bosonic character of the vortices is also apparent from the analysis of the representations of $\mathrm{SO}(3)$ arising in the algebra of the quantum angular momentum operators. In Sec. VIII, we found that for N vortices the Hilbert space is the N-fold symmetric product of an irreducible representation of $\mathrm{SO}(3)$. This irreducible representation is the same as the one obtained from quantizing a single vortex on a sphere whose area is the one of the original sphere minus the total area occupied by N vortices.

ACKNOWLEDGMENTS

The idea of studying the Kähler quantization of Manton's model of Chern–Simons vortices was first suggested by G.W. Gibbons. I am thankful to Nick Manton for many helpful discussions. Semiclassical Coulomb differential excitation function: Asymptotic expansions

Michael D. Thorsley and Marita C. Chidichimo
Department of Applied Mathematics, University of Waterloo, Ontario N2L 3G1, Canada

(Received 13 November 2000; accepted for publication 16 March 2001)

We have obtained asymptotic expansions of the electric dipole ($E1$) *differential* excitation function for large values of the adiabaticity parameter ξ and for all values of the eccentricity (ε) of the projectile orbit. To accomplish this, we have developed a new asymptotic power series of exponential integrals related to the Airy integrals, introduced originally in a paper by Brussaard *et al.* [Ann. Phys. (N.Y.) **7**, 47 (1962)], in which asymptotic expansions of the *total* excitation function were derived. © *2001 American Institute of Physics.* [DOI: 10.1063/1.1379067]

I. INTRODUCTION

In the semiclassical treatment of the Coulomb excitation of positive ions[1,2] by nuclei, the incoming particle is assumed to follow a classical positive energy (Rutherford) orbit, while the excitation of the ion is handled using the techniques of first-order, time-dependent perturbation theory on the resulting time-varying Coulomb field. Expanding the interaction in multipoles and neglecting the penetration of the projectile into the target results, for each multipole order λ, in a problem which factors into two parts—a factor solely dependent on the properties of the target in question, which controls the strength of the interaction, and a differential excitation function $\mathrm{d}f_{E\lambda}(\varepsilon,\xi)/d\Omega$, which determines the angular distribution of the scattered projectile.

In the electric dipole ($E1$) case, the semiclassical Coulomb *differential* excitation function is expressible in the closed form,[3]

$$\frac{\mathrm{d}f_{E1}(\varepsilon,\xi)}{d\Omega}=\frac{\pi}{18}\varepsilon^4\{I^2_{1,-1}(\varepsilon,\xi)+I^2_{1,1}(\varepsilon,\xi)\}$$

$$=\frac{4\pi}{9}\xi^2\varepsilon^2\exp(\pm\pi|\xi|)\{(\varepsilon^2-1)K^2_{\mathrm{i}\xi}(|\xi|\varepsilon)+\varepsilon^2K'^2_{\mathrm{i}\xi}(|\xi|\varepsilon)\}, \tag{1.1}$$

for ξ finite. The Coulomb integrals are given by[4]

$$I_{1,\pm1}(\varepsilon,\xi)=-2\xi\exp(\pm\tfrac{1}{2}\pi|\xi|)[K'_{\mathrm{i}\xi}(|\xi|\varepsilon)\pm(1-\varepsilon^{-2})^{1/2}K_{\mathrm{i}\xi}(|\xi|\varepsilon)], \tag{1.2}$$

where the $(\pm)$ sign in the exponential correspond to attractive and repulsive potentials, respectively, $K_\nu(z)$ is the modified Bessel function and $K'_\nu(z)$ is its derivative with respect to its argument. The eccentricity ε of the hyperbolic orbit is related to the deflection angle θ of the projectile by $\varepsilon=\sin(\theta/2)^{-1}$. The nondimensional adiabaticity parameter ξ is defined by

$$\xi=Z_1Z_2\sqrt{\frac{M}{(E_i/Ry)}}[(E_i/E_f)^{1/2}-1], \tag{1.3}$$

where the indices *i* and *f* refer to the initial and the final states, respectively, E_i is the initial kinetic energy of relative motion, with Ry standing for rydberg (about 13.8 eV), Z_1 and Z_2 are the charge numbers of the projectile and the atomic system, M is the reduced mass of the system in electron mass units.

For heavy ions and $E_f \to 0$ (threshold energy), $\xi \to \infty$. The complexity of the way in which both the argument ($|\xi|\varepsilon$) and the order ($i\xi$) go to infinity simultaneously, without one being significantly larger than the other, results in a paucity of asymptotic expressions, valid over all angles. Only for ε very large ($\theta \approx 0$), or $\varepsilon \approx 1 (\theta \approx \pi)$, can an asymptotic expression from Ref. 5 be adequately applied.

In Ref. 6, the authors make use of a modification of the saddle-point method to obtain a large-ξ asymptotic expansion for the semiclassical Coulomb integrals, which is used to derive an asymptotic expression for the *total* excitation functions $f_{E\lambda}(\xi)$. Their method, however, can not be directly applied to the case of *differential* excitation functions $df_{E\lambda}(\varepsilon,\xi)/d\Omega$, since they make use of the stretched variable $\xi^{-1/3}\sqrt{\varepsilon^2-1}$, which limits the possibilities for evaluation of the final result to angles very near the backwards-scattering direction. In this section, we modify their result, sacrificing uniform validity of the resulting expansion, to obtain an asymptotic form for the semiclassical differential excitation function useful for large ξ in the $E1$ case, provided θ is not near π. We then apply the method of Ref. 6 more directly to obtain expressions when $\theta = \pi$ and $\theta \to \pi$.

Note that, because of our extensive use of results from Ref. 6, we use the convention of these authors in our definition of the semiclassical Coulomb integrals.

We used the symbolic computation program MAPLE VI (Ref. 7) to help us with the algebraic manipulations in this work.

II. METHOD OF STEEPEST DESCENTS

For the sake of clarity, we go over the details and principles involved in the method of steepest descents,[8] sketched briefly in Ref. 6. The semiclassical Coulomb integrals in the form applied in Ref. 6 are

$$I_{\lambda,\mu}(\varepsilon,\xi) = \int_{-\infty}^{\infty} e^{-i\xi(\varepsilon \sinh w + w)} \frac{[\cosh w + \varepsilon - i\sqrt{\varepsilon^2-1}\sinh w]^{\mu}}{[\varepsilon \cosh w + 1]^{\lambda+\mu}} dw, \tag{2.1}$$

where λ and μ are the quantum numbers describing the multipole transition.

In the $E1$ case, this expression simplifies to

$$I_{1,\pm 1}(\varepsilon,\xi) = \int_{-\infty}^{\infty} e^{-i\xi(\varepsilon \sinh w + w)} \frac{1}{\cosh w + \varepsilon \pm i\sqrt{\varepsilon^2-1}\sinh w} dw, \tag{2.2}$$

where we have used the identity,

$$(\varepsilon \cosh w + 1)^2 = (\varepsilon + \cosh w + i\sqrt{\varepsilon^2-1}\sinh w)(\varepsilon + \cosh w - i\sqrt{\varepsilon^2-1}\sinh w), \tag{2.3}$$

to simplify the result.

In the method of steepest descents, we divide the integrand up into an exponential function $\exp[\xi f(w)]$ and a slowly varying part $h_{\lambda,\mu}(w)$. Let $f(w) = -i(\varepsilon \sinh w + w)$ and $h_{\lambda,\mu}(w) = (\cosh w + \varepsilon \pm i\sqrt{\varepsilon^2-1}\sinh w)^{-1}$, which puts (2.1) in the standard form

$$I_{\lambda,\mu}(\varepsilon,\xi) = \int_{-\infty}^{\infty} e^{\xi f(w)} h_{\lambda,\mu}(w) dw. \tag{2.4}$$

The principle to be applied here is that, for large ξ, the most important part of the integral comes from a region of the integrand around the point where $\mathrm{Re}\, f(w)$ is at a maximum. For large ξ, the exponential factor will cause this region of the integrand to become larger than any other part.

Working against this effect, however, are the effects of the imaginary part of $f(w)$. As ξ becomes large, $\mathrm{Im}\, f(w)$ results in rapid oscillations, which integrate to zero. The result is that regions where $\mathrm{Im}\, f(w)$ changes most slowly are preferentially represented in the integral. Failure

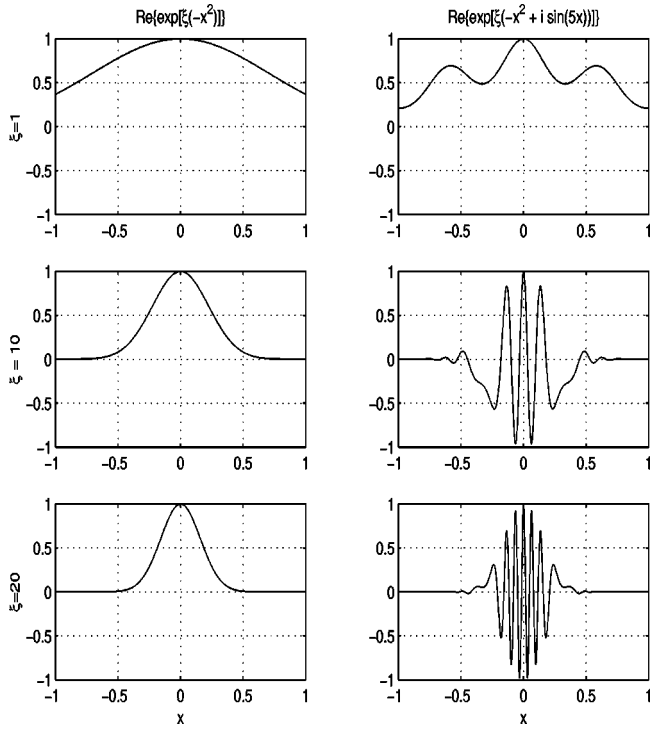

FIG. 1. Principle to be applied in the method of steepest descent. If the exponentiated function is purely real, the region around a maximum of this function becomes the most important part of the integral as $\xi\to\infty$. If it has an imaginary part, however, rapid oscillations eat into the peak as $\xi\to\infty$ and it is no longer obvious where the most important part of the integral is.

to resolve these two, possibly conflicting, influences can result in the difficulties shown in Fig. 1. To maximize the effect of Re $f(w)$, and minimize the effect of the oscillations caused by Im $f(w)$, we analytically extend $f(w)$ into the complex plane and make use of Cauchy's theorem to distort the path of integration through a stationary point of $f(w)$. Since $f(w)$ is analytic, the Cauchy–Riemann equations guarantee that both the real and imaginary parts of $f(w)$ are harmonic, and thus, must have a saddle point at this point.

We pick the path through the saddle point where Im $f(w)$ is constant and Re $f(w)$ decreases most rapidly on moving away from the saddle point. This choice, if it is possible to make it, amplifies the maximizing effect associated with Re $f(w)$, while minimizing the effect of the rapid oscillations resulting from Im $f(w)$.

In the case at hand, the stationary points are where $f'(w)=0$, or

$$\cosh w_0 = -\frac{1}{\varepsilon}. \tag{2.5}$$

We use the Eqs. (4.6.9), (4.6.12), and (4.5.8) of Ref. 9, and the triangle (see Fig. 2) to obtain

$$w_0 = \pm \mathrm{i}\arccos\left(\frac{1}{\varepsilon}\right) + (2k\mp 1)\pi\mathrm{i} = \pm \mathrm{i}\arctan(s) + (2k\mp 1)\pi\mathrm{i}, \tag{2.6}$$

where $s=\sqrt{\varepsilon^2-1}$. If we choose the plus sign and $k=0$, we obtain the saddle point we will use in this expansion. We will see that this choice allows us to avoid the complications associated with distorting the path of integration through a pole of the integrand. We want to verify that the saddle point we have selected, viz.,

$$w_0 = -\pi\mathrm{i} + \mathrm{i}\arctan(s), \tag{2.7}$$

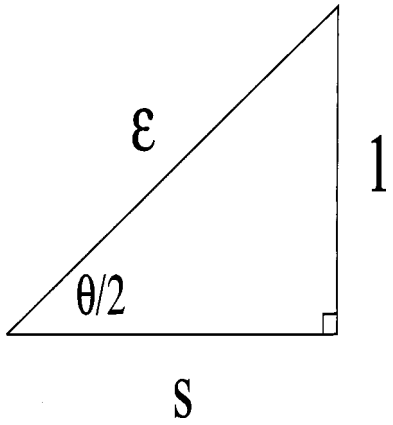

FIG. 2. Triangle used to deduce $\arccos(1/\varepsilon)=\arctan(s)$.

admits a path of steepest descent into which the real axis may be deformed. We notice that $\mathrm{Im}(f(w_0))=0$, so our path of integration must satisfy, for all $w=x+iy$,

$$0=\mathrm{Im}(f(w))=-\varepsilon\,\mathrm{Re}(\sinh w)-\mathrm{Re}(w)=-\varepsilon\,\sinh(x)\cos(y)-x, \tag{2.8}$$

whose solution is $x\equiv 0$, or

$$\cos(y)=\frac{-x}{\varepsilon\,\sinh(x)},$$

$$\begin{aligned} y&=\pm\arccos\left(-\frac{x}{\varepsilon\,\sinh(x)}\right)+2k\pi \\ &=\pm\arccos\left(\frac{x}{\varepsilon\,\sinh(x)}\right)+(2k\mp 1)\pi. \end{aligned} \tag{2.9}$$

Note that the imaginary part of $f(w)$, being zero along this path, means that we have not only reduced, but have in fact eliminated, the effect of oscillations for large ξ.

Along this path,

$$\lim_{x\to 0} y=\pm\arccos\left(\frac{1}{\varepsilon}\right)+(2k\mp 1)\pi, \tag{2.10}$$

which gives our w_0, if we select the positive sign and $k=0$,

$$y=\arccos\left(\frac{x}{\varepsilon\,\sinh(x)}\right)-\pi. \tag{2.11}$$

For this path, we have that $\lim_{x\to-\infty} y=-(\pi/2)$ for all ε. Because of this, along the path

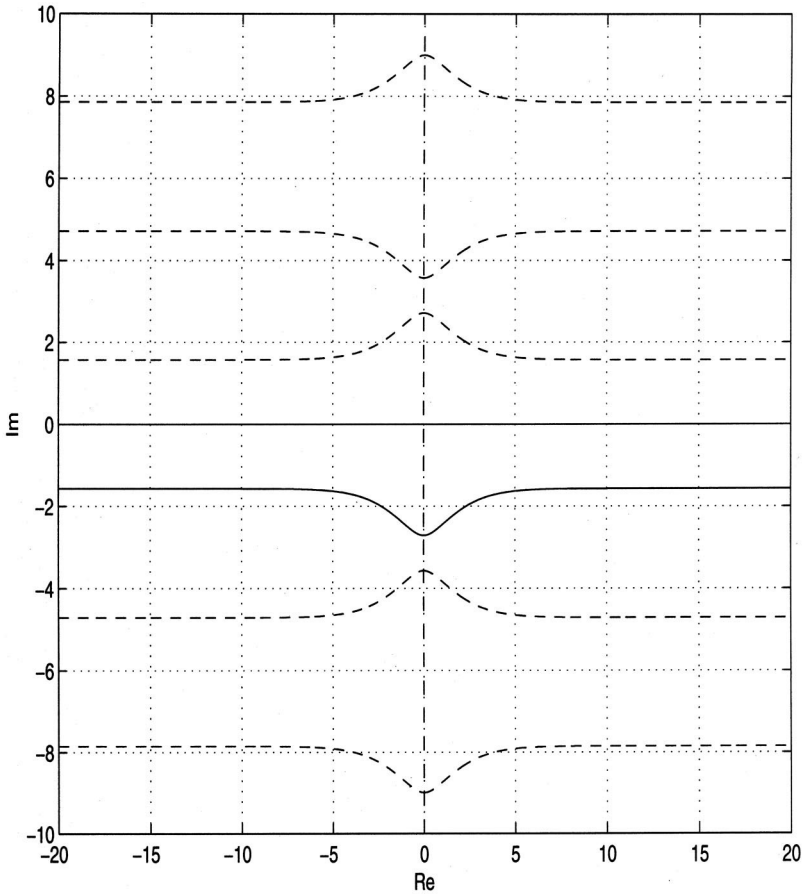

FIG. 3. Paths of steepest descent/ascent. The path that we use is plotted as a solid line, as is the real axis, while all others are plotted as dashed lines. $\varepsilon = 1.1$ in this figure.

$$\mathrm{Re}(f(w)) = \varepsilon \cosh(x)\sin(y) + y \to -\varepsilon \cosh(x) - \frac{\pi}{2} \to -\infty, \tag{2.12}$$

as $x \to \infty$. This confirms that the path we have chosen is a path of steepest descent (rather than one of steepest *ascent*), and also that the tails of the integrand (for a well-enough behaved $h_{\lambda,\mu}$) will decay exponentially, guaranteeing convergence of the integral in that regard.

This path is illustrated in Fig. 3.

We are now justified in expanding the integrand around this point. Letting $w = w_0 + \omega$,

$$\begin{aligned} f(w) &= -\mathrm{i}\varepsilon \sinh(w_0+\omega) - \mathrm{i}(w_0+\omega) \\ &= -\mathrm{i}\varepsilon[\sinh(w_0)\cosh(\omega) + \cosh(w_0)\sinh(\omega)] - \mathrm{i}(w_0+\omega) \\ &= -\mathrm{i}w_0 - \mathrm{i}\omega - s\cosh(\omega) + \mathrm{i}\sinh(\omega) \\ &= -\pi - [s - \arctan(s)] + \left[\mathrm{i}\left(\frac{\omega^3}{3!} + \frac{\omega^5}{5!} + \cdots\right) - s\left(\frac{\omega^2}{2!} + \frac{\omega^4}{4!} + \cdots\right)\right]. \end{aligned} \tag{2.13}$$

Similarly, we expand the parts of the slowly-varying part of the integrand,

$$\cosh w+\varepsilon+\mathrm{i}s\sinh w=\frac{1}{\varepsilon}\left\{2s^2+(-1+s^2)\left(\frac{\omega^2}{2!}+\frac{\omega^4}{4!}+\cdots\right)-2\mathrm{i}s\left(\omega+\frac{\omega^3}{3!}+\cdots\right)\right\}, \quad (2.14)$$

$$\cosh w+\varepsilon-\mathrm{i}s\sinh w=-\varepsilon\left\{\frac{\omega^2}{2!}+\frac{\omega^4}{4!}+\cdots\right\}, \quad (2.15)$$

$$\varepsilon\cosh w+1=-\left\{\frac{\omega^2}{2!}+\frac{\omega^4}{4!}+\cdots\right\}-\mathrm{i}s\left\{\omega+\frac{\omega^3}{3!}+\cdots\right\}. \quad (2.16)$$

The normal procedure of evaluating integrals of the form,

$$\int_c e^{-\xi f(x)}g(z)\mathrm{d}z, \quad (2.17)$$

by introducing a variable of integration along the new path of integration, fails here due to the presence of poles in the slowly-varying part of the integrand at the saddle point. The procedure used in Ref. 6 allows us to circumvent this problem.

After the distortion of the path of integration and the expansion about w_0 the integral becomes

$$I_{\lambda,\mu}(s,\xi)=e^{-\pi\xi}\exp[-\xi(s-\arctan s)]\int_{-\infty}^{\infty}\exp\left[\xi\left(-s\frac{\omega^2}{2}+\mathrm{i}\frac{\omega^3}{6}-\cdots\right)\right]h_{\lambda,\mu}(s,\omega)\mathrm{d}\omega. \quad (2.18)$$

The exponential term inside the integral gives an exponentially decaying factor ($\exp[-\xi s\omega^2/2]$) and an oscillatory factor ($\exp[\mathrm{i}\xi\omega^3/6]$). In order to have a Gaussian form for the integrand, we need the decaying factor to decay almost to zero, before the first root of the real part of the oscillatory factor (we do not worry about the imaginary part, since it is odd in ω and disappears upon integration anyway). Since the first such root is of order $\xi^{-(1/3)}$, when, s, which controls the rate of decay, becomes smaller than or comparable to $\xi^{-(1/3)}$, the integrand is no longer nearly Gaussian and has significant side lobes, as seen in Fig. 4.

The most significant part of the integral comes from the central lobe of the integrand, a neighborhood of $\omega=0$ with width of order $\xi^{-(1/3)}$. To stretch this region to a uniform width for all ξ, and to help isolate the powers of ξ to be used in the expansion, we perform the scale transformation $s\to s\xi^{-(1/3)}, \omega\to\omega\xi^{-(1/3)}$. Retaining the first two terms in the exponential and expanding the remainder gives

$$I_{\lambda,\mu}(s\xi^{-(1/3)},\xi)=e^{-\pi\xi}\exp[-\xi(s\xi^{-(1/3)}-\arctan(s\xi^{(-1/3)}))]\int_{-\infty}^{\infty}\exp\left[-s\frac{\omega^2}{2}+\mathrm{i}\frac{\omega^3}{6}\right]\exp\left[\xi^{-(2/3)}\left(-s\frac{\omega^4}{4!}+\mathrm{i}\frac{\omega^5}{5!}\right)+\cdots\right]h_{\lambda,\mu}(s\xi^{-(1/3)},\omega\xi^{-(1/3)})\xi^{-(1/3)}\mathrm{d}\omega. \quad (2.19)$$

Note that, unlike Ref. 6, we do not expand the arctangent in the exponential outside the integral, although we notice that the argument of this exponential stays finite, but nonzero, as $\xi\to\infty$, due to the cancellation of the first term in the Maclaurin series for the arctangent.

As was pointed out in Ref. 6, this transformation shows, that the appropriate expansion parameter is $u=\xi^{-(2/3)}$.

With the scale transformation in place, the components of the slowly-varying part transform as

$$\cosh w+\varepsilon+\mathrm{i}s\sinh w\to-\frac{u}{\varepsilon}\left[\frac{1}{2}(\omega^2+4\mathrm{i}s\omega-4s^2)\right]$$

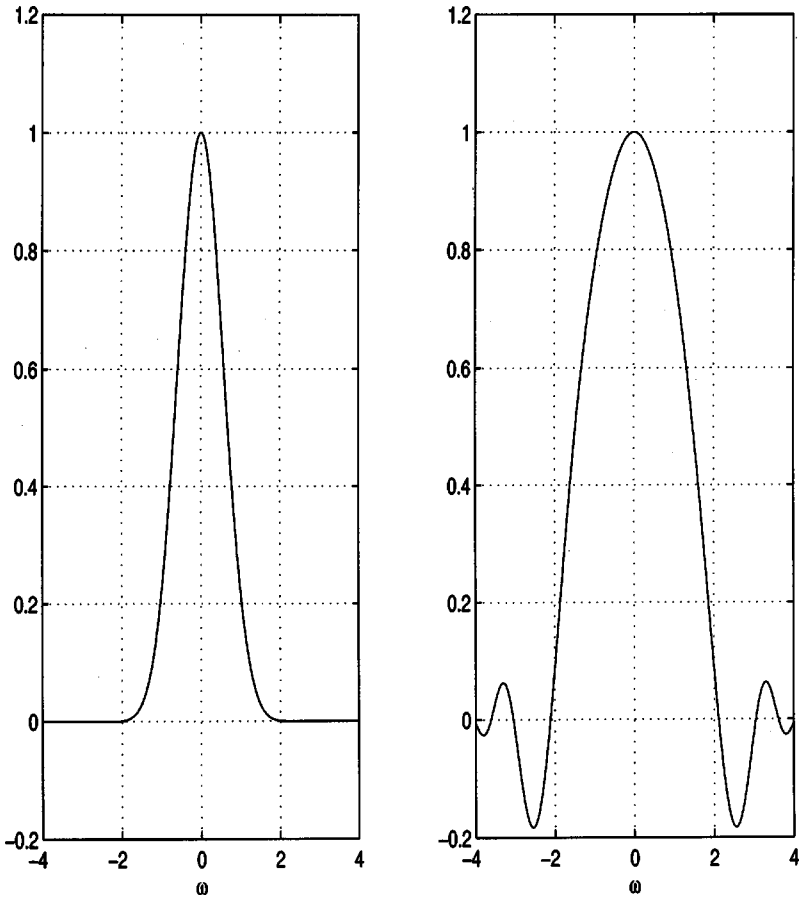

FIG. 4. Exponential factor in the integrand of Eq. (2.18). In the plot on the left ($\xi=1$, $s=3$) the decaying factor decays almost to zero before the oscillatory part has its first root resulting in a nearly Gaussian curve. In the plot on the right ($\xi=1$, $s=0.5$) the oscillatory part has several oscillations before the decaying part decays significantly resulting in several significant side lobes.

$$-\frac{u}{\varepsilon}\sum_{n=2}^{\infty}\frac{\omega^{2n-2}}{(2n)!}[\omega^2+4n\mathrm{i}s\omega-2n(2n-1)s^2]u^{n-1}, \tag{2.20}$$

$$\cosh w+\varepsilon-\mathrm{i}s\sinh w\rightarrow-u\varepsilon\sum_{n=1}^{\infty}\frac{\omega^{2n}}{(2n)!}u^{n-1}. \tag{2.21}$$

We have not expressed ε explicitly in terms of s, since at the end we will reverse the scale change anyway. However, it is important to realize that the scale change has affected ε, via its dependence on s through the relation $\varepsilon=\sqrt{s^2+1}\rightarrow\sqrt{s^2\xi^{-(2/3)}+1}$.

These transformed relations indicate that u is definitely the correct expansion parameter and that the integrands will consist of integral powers of ω and $\omega+2\mathrm{i}s$ modulated by the exponential factor $\exp[-s\omega^2/2-\mathrm{i}\omega^3/6]$. Brussaard *et al.*[6] introduced the following integral expressions:

$$Q_{k,m}(s)=\mathrm{i}^{-k-m}\int_{-\infty}^{\infty}\exp\left(-s\frac{\omega^2}{2}+\mathrm{i}\frac{\omega^3}{6}\right)\omega^k(\omega+2\mathrm{i}s)^m\mathrm{d}\omega, \tag{2.22}$$

which appear in the coefficients of the asymptotic expressions. It is necessary to derive some properties of these functions to aid in their evaluation. An extensive analysis of the properties and

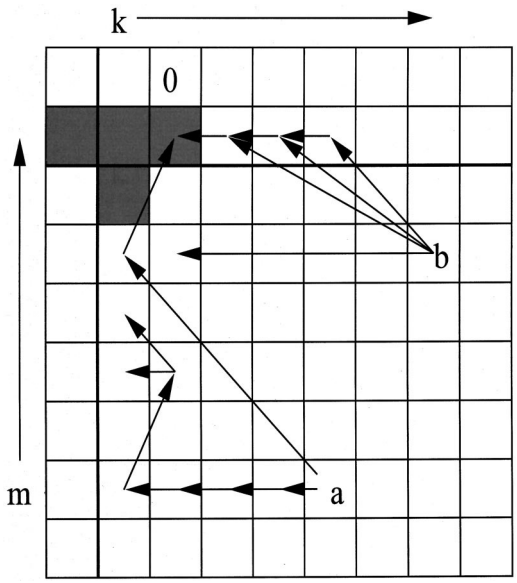

FIG. 5. Use of the recurrence relations to reduce the $Q_{k,-m}$ for $k,m>0$. If $k\leqslant m$ (a) we apply (A13) to express it in terms of $Q_{k,-m}$s with smaller k and then use (A4) to increase $-m$. If $k>m$ (b) we use the division algorithm on the integrand to express it in terms of the previous case and several $Q_{k,m}$ with $m=0$ which are handled easily using (A9)–(A11).

power series expansions of the $Q_{k,m}(s)$ are given in the Appendix. Notice that, in addition to the ascending power series provided by Ref. 6, which gives a good approximation for small values of s, in order to obtain an expression for the *differential* excitation function, we need asymptotic expressions valid for large s as well. Using a slight modification of an extension to Watson's lemma provided in Ref. 10 (p. 24ff) allows us to obtain an asymptotic power series for the four basic integrals $Q_{1,0}(s)$, $Q_{0,0}(s)$, $Q_{-1,0}(s)$, and $Q_{0,-1}(s)$.

III. SEMICLASSICAL COULOMB INTEGRALS

While the $Q_{k,m}(s)$ expressions, obtained using the stretched variable $s\xi^{-(1/3)}$ in Ref. 6, are useful for obtaining *total* excitation functions in the large-ξ limit (the dependence on the stretched variable is integrated out), reversing the scale change to obtain $I_{1,\pm1}(s,\xi)$ from $I_{1,\pm1}(s\xi^{-(1/3)},\xi)$, in order to obtain an expression for the differential excitation functions, proves to be much more difficult.

For very large ξ, we find that we must substitute a large value of s (i.e., make the inverse transformation $s\rightarrow s\xi^{1/3}$) in order to obtain a result for a moderate scattering angle. For this reason, we must consider s to be an asymptotically large variable, growing like $\xi^{1/3}$. Unfortunately, performing the expansion in *ascending* powers of s results in expansion coefficients that contain positive powers of s, in addition to the negative powers of ξ. As a result, we no longer have a guarantee, as we did for moderate s, that the terms decrease in size as $\xi\rightarrow\infty$. That is, we do not know, after truncating to two terms, that some higher term will not become more significant, as $\xi\rightarrow\infty$, due to a large power of s in the coefficient.

Instead, we will perform the expansion in negative powers of s, ensuring that the terms will be decreasing in size, as both ξ and s increase.

A. Orbital integrals $I_{1,+1}(s,\xi)$

We begin with the more complicated $\lambda=1$, $\mu=+1$ integral. Applying the inversion formula (Ref. 11, Sec. 20),

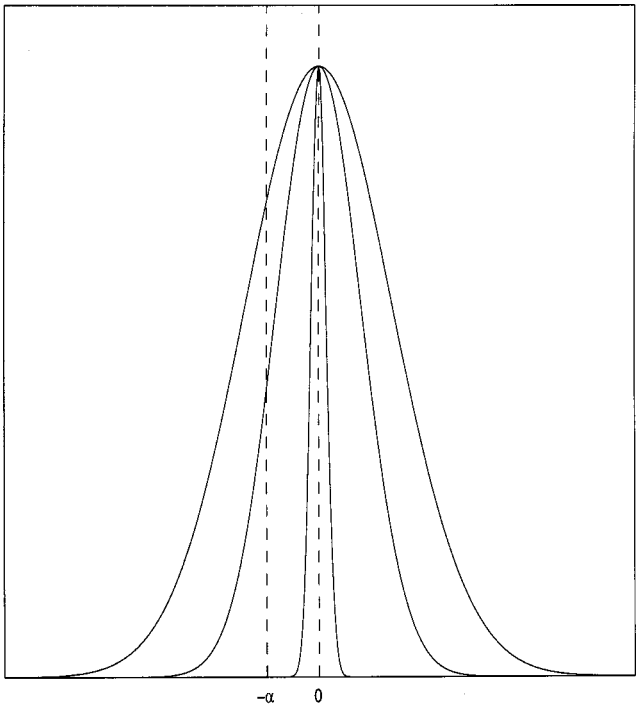

FIG. 6. Modulation factor of the integral (A34), e^{-xt^2}. If we select $-\alpha$ as our lower bound, no matter how small α is, for large enough x most of the integral is included. If we select 0 as our lower bound, only half of the integral is included no matter how large x is.

$$\left[\sum_{n=1}^{\infty} a_n u^{n-1}\right]^{-1} = \frac{1}{a_1} - \frac{a_2}{a_1^2}u + \left(\frac{a_2^2 - a_1 a_3}{a_1^3}\right)u^2 + \cdots, \tag{3.1}$$

to Eq. (2.20), gives the coefficients,

$$\frac{1}{a_1} = \frac{2}{(\omega + 2\mathrm{i}s)^2}\left(-\frac{\varepsilon}{u}\right), \tag{3.2}$$

$$-\frac{a_2}{a_1^2} = -\frac{2}{(\omega+2\mathrm{i}s)^2}\left[\frac{2}{4!}\frac{\omega^2(\omega+2\mathrm{i}s)(\omega+6\mathrm{i}s)}{(\omega+2\mathrm{i}s)^2}\right]\left(-\frac{\varepsilon}{u}\right)$$

$$= -\frac{1}{2}\frac{\omega^2}{(\omega+2\mathrm{i}s)^2}\left[1 + \frac{1}{3}\mathrm{i}\omega\frac{1}{s} - \frac{1}{6}\omega^2\frac{1}{s^2} - \cdots\right]\left(-\frac{\varepsilon}{u}\right), \tag{3.3}$$

$$\frac{a_2^2 - a_1 a_3}{a_1^3} = \frac{2}{(\omega+2\mathrm{i}s)^2}\left[\frac{\frac{1}{240}\omega^8 + \frac{1}{15}\mathrm{i}\omega^7 s - \frac{23}{60}\omega^6 s^2 - \frac{13}{15}\mathrm{i}\omega^5 s^3 + \frac{1}{6}\omega^4 s^4}{(\omega+2\mathrm{i}s)^4}\right]\left(-\frac{\varepsilon}{u}\right)$$

$$= \frac{1}{12}\frac{\omega^4}{(\omega+2\mathrm{i}s)^2}\left[1 + \frac{7}{10}\mathrm{i}\omega\frac{1}{s} - \frac{19}{40}\omega^2\frac{1}{s^2} + \cdots\right]\left(-\frac{\varepsilon}{u}\right). \tag{3.4}$$

This gives the following expansion for the slowly varying part of the integrand in negative powers of ξ (positive powers of u) and s:

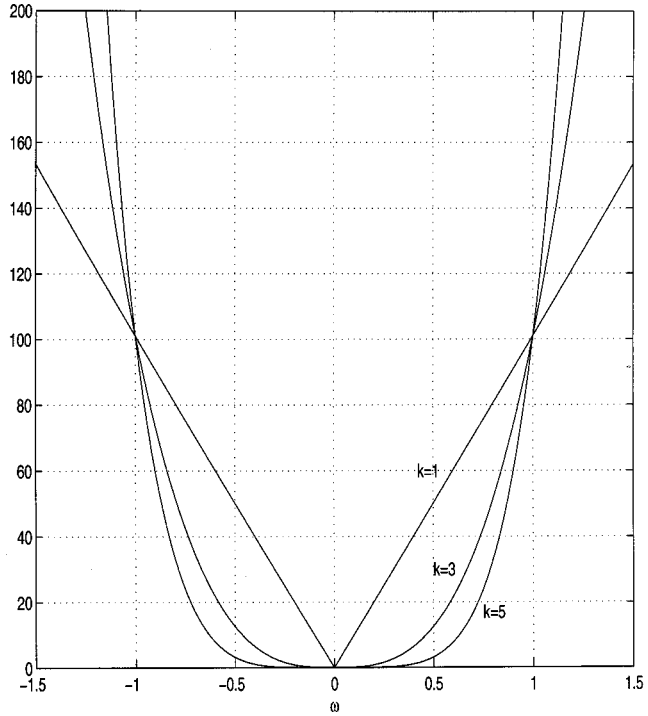

FIG. 7. Magnitude of the slowly-varying part of the integrand of Eq. (A48), $|\omega^k(\omega+2\mathrm{i}s)^m|$. As k gets larger, the slowly-varying part of the integrand is pushed out of the central part of the integral—all-important for large s—by the factor of ω^k. In this figure, $s=5$ and $m=2$.

$$h_{1,+1}(s\xi^{-(1/3)},\omega\xi^{-(1/3)})\sim-\frac{\varepsilon}{u}\left\{\frac{2}{(\omega+2\mathrm{i}s)^2}-\frac{1}{2}\frac{\omega^2}{(\omega+2\mathrm{i}s)^2}\left[1+\frac{1}{3}\mathrm{i}\omega\frac{1}{s}-\frac{1}{6}\omega^2\frac{1}{s^2}+\cdots\right]u\right.$$
$$\left.+\frac{1}{12}\frac{\omega^4}{(\omega+2\mathrm{i}s)^2}\left[1+\frac{7}{10}\mathrm{i}\omega\frac{1}{s}-\frac{19}{40}\omega^2\frac{1}{s^2}+\cdots\right]u^2\right\}. \tag{3.5}$$

We must now expand the exponential factor in the integral. Unlike the slowly-varying part, there is no convenient way to expand this factor as a descending power series in s, so we must settle for an ascending series. As we shall see, this compromise is an added complication, but not a fatal flaw in the technique,

$$\exp\left[\sum_{n=1}^{\infty}\left(-s\frac{\omega^{2n+2}}{(2n+2)!}+\mathrm{i}\frac{\omega^{2n+3}}{(2n+3)!}\right)u^n\right]$$
$$=\exp\left[\left(-s\frac{\omega^4}{4!}+\mathrm{i}\frac{\omega^5}{5!}\right)u+\left(-s\frac{\omega^6}{6!}+\mathrm{i}\frac{\omega^7}{7!}\right)u^2+\cdots\right]$$
$$\sim1+u\omega^4\left(-\frac{1}{24}s+\frac{1}{120}\mathrm{i}\omega\right)+u^2\omega^6\left[\left(\frac{\mathrm{i}\omega}{5040}-\frac{\omega^4}{28800}\right)\right.$$
$$\left.+\left(-\frac{1}{720}-\frac{\mathrm{i}\omega^3}{2880}\right)s+\frac{\omega^2}{1152}s^2\right]. \tag{3.6}$$

An important thing to realize about this expansion is that each term contains only powers of

s less than or equal to the corresponding power of u. When the scattering angle is held fixed, s grows like $\xi^{1/3}$. Since u decays like $\xi^{-(2/3)}$, this fact ensures that every positive power of s is cancelled asymptotically.

Now, forming the product of these terms, we obtain

$$\begin{aligned}
&\exp\left[\sum_{n=1}^{\infty}\left(-s\frac{\omega^{2n+2}}{(2n+2)!}+\mathrm{i}\frac{\omega^{2n+3}}{(2n+3)!}\right)u^n\right]h_{1,+1}(s\xi^{-(1/3)},\omega\xi^{-(1/3)})\\
&\quad\sim\frac{-\varepsilon}{u}\left\{\frac{2}{(\omega+2\mathrm{i}s)^2}+u\left[-\frac{1}{2}\frac{\omega^2}{(\omega+2\mathrm{i}s)^2}\left(1+\frac{1}{3}\mathrm{i}\omega\frac{1}{s}-\frac{1}{6}\omega^2\frac{1}{s^2}+\cdots\right)\right.\right.\\
&\qquad\left.+2\frac{\omega^4}{(\omega+2\mathrm{i}s)^2}\left(-\frac{1}{24}s+\frac{1}{120}\mathrm{i}\omega\right)\right]+u^2\left[\frac{1}{12}\frac{\omega^4}{(\omega+2\mathrm{i}s)^2}\left(1+\frac{7}{10}\mathrm{i}\omega\frac{1}{s}-\frac{19}{40}\omega^2\frac{1}{s^2}+\cdots\right)\right.\\
&\qquad+\frac{2\omega^6}{(\omega+2\mathrm{i}s)^2}\left(\left(\frac{\mathrm{i}\omega}{5040}-\frac{\omega^4}{28800}\right)+\left(-\frac{1}{720}-\frac{\mathrm{i}\omega^3}{2880}\right)s+\frac{\omega^2}{1152}s^2\right)\\
&\qquad\left.\left.-\frac{1}{2}\frac{\omega^6}{(\omega+2\mathrm{i}s)^2}\left(1+\frac{1}{3}\mathrm{i}\omega\frac{1}{s}-\frac{1}{6}\omega^2\frac{1}{s^2}+\cdots\right)\left(-\frac{1}{24}s+\frac{1}{120}\mathrm{i}\omega\right)\right]\right\}. \qquad (3.7)
\end{aligned}$$

After multiplying by the common exponential factor, and integrating with respect to ω, we find

$$\begin{aligned}
&\int_{-\infty}^{\infty}\exp\left[-s\frac{\omega^2}{2}+\mathrm{i}\frac{\omega^3}{6}\right]\exp\left[\sum_{n=1}^{\infty}\left(-s\frac{\omega^{2n+2}}{(2n+2)!}+\mathrm{i}\frac{\omega^{2n+3}}{(2n+3)!}\right)u^n\right]\\
&\quad\times h_{1,+1}(s\xi^{-(1/3)},\omega\xi^{-(1/3)})\xi^{-(1/3)}d\omega\\
&\quad\sim\frac{\varepsilon}{u}\xi^{-(1/3)}\left\{2Q_{0,-2}(s)+u\left[-\frac{s}{12}Q_{4,-2}(s)-\frac{1}{60}Q_{5,-2}(s)+\frac{1}{2}Q_{2,-2}(s)-\frac{1}{6s}Q_{3,-2}(s)\right.\right.\\
&\qquad\left.\left.+\frac{1}{12s^2}Q_{4,-2}(s)+\cdots\right]+u^2\left[\frac{s^2}{576}Q_{8,-2}(s)+\cdots\right]\right\}, \qquad (3.8)
\end{aligned}$$

where terms of low order in s are omitted.

It is not yet, however, a foregone conclusion that the first term in the expansion is asymptotically the largest, since in addition to the complication added by the positive powers of s, each of the $Q_{k,m}(s)$ decays at a different rate. Analysis is still required to determine the correct method of truncating this expansion.

Firstly, we realize that the relationship between the powers of u and s, noted in the expansion of the exponential factor, namely, that the highest power of s in the coefficient of u^n is equal to n, carries over to this expansion as well, which means that we can place asymptotic bounds on the contribution of later terms.

We note that, for large s and small u, the asymptotic order of the nth term [ignoring the asymptotic properties of the $Q_{k,m}(s)$] is $s^n u^n$. After performing the inverse scale change, $s \to s\xi^{1/3}$, and noting that $u=\xi^{-(2/3)}$, this order becomes $s^n\xi^{-(n/3)}$, for large ξ. So this factor, at least, decreases in size as n becomes larger.

Since, for all of the $Q_{k,m}(s)$ present in the expansion, $k>0$ and $m=-2$, by (A51) and (A52), we know that they all decay to zero as $s\to\infty$ at rate at least $s^{-(5/2)}\to s^{-(5/2)}\xi^{-(5/6)}$, so they cannot increase the asymptotic order of a term as $\xi\to\infty$.

This indicates that the contribution of the terms does, in fact, decrease as the series progresses. That is, for example, once the u^3 term is included, we know that we have the complete contribution of order ξ^{-1} and that no later term can give an asymptotic contribution larger than this.

This knowledge is sufficient to allow us to use the series (3.8) directly, without any further consideration, knowing that eventually, at least, the terms become asymptotically small. However, in the interests of efficiency, and since the coefficients are themselves infinite sums, we would like to isolate specifically the contribution from each power of ξ. We start by considering the constant term in Eq. (3.8) [see also Eq. (A41)],

$$2Q_{0,-2}(s)=Q_{1,0}(s)\sim\frac{\sqrt{2\pi}}{2}s^{-5/2}\quad\text{as}\quad s\to\infty,$$

$$2Q_{0,-2}(s\xi^{1/3})\sim\frac{\sqrt{2\pi}}{2}s^{-5/2}\xi^{-(5/6)}\quad\text{as}\quad\xi\to\infty. \tag{3.9}$$

This leading-order term attains the minimum possible decay rate as $s\to\infty$. Any contribution from the u^1 term must decay faster than this, since it also has to include the contribution from s and u, which must decay at least like $\xi^{-1/3}$.

To obtain a first-order correction to this result, we examine the higher-order asymptotic terms from the u^0 coefficient,

$$2Q_{0,-2}(s\xi^{1/3})\sim\sqrt{2\pi}\left[\frac{1}{2}s^{-5/2}\xi^{-(5/6)}-\frac{35}{48}s^{-11/2}\xi^{-(11/6)}\right]\quad\text{as}\quad\xi\to\infty. \tag{3.10}$$

To be part of the next-highest-order term, terms from the u^1 coefficient need to be of order $\xi^{-11/6}$ or higher. We examine each individually [see Eqs. (A51) and (A52)],

$$(s\xi^{1/3})uQ_{4,-2}(s\xi^{1/3})\sim\tfrac{3}{4}\sqrt{2\pi}s^{-7/2}\xi^{-11/6}\quad\text{as}\quad\xi\to\infty, \tag{3.11}$$

$$uQ_{5,-2}(s\xi^{1/3})\sim\tfrac{15}{4}\sqrt{2\pi}s^{-11/2}\xi^{-5/2}\quad\text{as}\quad\xi\to\infty, \tag{3.12}$$

$$uQ_{2,-2}(s\xi^{1/3})\sim-\tfrac{1}{4}\sqrt{2\pi}s^{-7/2}\xi^{-11/6}\quad\text{as}\quad\xi\to\infty, \tag{3.13}$$

$$\frac{u}{s\xi^{1/3}}Q_{3,-2}(s\xi^{1/3})\sim-\tfrac{3}{4}\sqrt{2\pi}s^{-11/2}\xi^{-5/2}\quad\text{as}\quad\xi\to\infty. \tag{3.14}$$

The terms from (3.11) and (3.13) contribute to the first-order correction.

The remaining terms from the u^1 coefficient we know do not contribute to the $\xi^{-11/6}$ term, since both the power of s they are divided by and the value of k increase from this point on in the series.

In the coefficient of the second-order term, the highest power of s is s^2, while all of the $Q_{k,m}$ have $k\geqslant 4$. Therefore, all of the terms must be asymptotically smaller than

$$u^2s^2Q_{4,-2}(s\xi^{1/3})\sim\tfrac{3}{4}\sqrt{2\pi}s^{-5/2}\xi^{-13/6}\quad\text{as}\quad\xi\to\infty, \tag{3.15}$$

meaning that none of these terms can contribute to the $\xi^{-11/6}$ term. Through similar reasoning, we see that higher-order terms in u can not contribute either.

Combining these terms, leads to the asymptotic expression [see also Eqs. (2.19) and (3.8)],

$$I_{1,+1}(s\xi^{-1/3},\xi)\sim\sqrt{2\pi}\xi^{1/3}e^{-\pi\xi}(1+s^2\xi^{-2/3})^{1/2}\exp[-\xi(s\xi^{-1/3}-\arctan(s\xi^{-1/3}))]$$
$$\times[\tfrac{1}{2}s^{-5/2}-\tfrac{35}{48}s^{-11/2}-\tfrac{3}{16}s^{-7/2}\xi^{-2/3}]\quad\text{as}\quad s\to\infty, \tag{3.16}$$

$$I_{1,+1}(s,\xi)\sim\sqrt{\frac{\pi}{2}}\,\xi^{-1/2}e^{-\pi\xi}s^{-5/2}(1+s^2)^{1/2}\exp[-\xi(s-\arctan(s))]$$
$$\times\left[1-\left(\frac{3}{8}+\frac{35}{24}s^{-2}\right)s^{-1}\xi^{-1}\right]\quad\text{as}\quad\xi\to\infty,\tag{3.17}$$

for the $\lambda=1$, $\mu=+1$ semiclassical Coulomb integral.

B. Orbital integrals $I_{1,-1}(s,\xi)$

Similar analysis of the $\mu=-1$ case is significantly easier, since the coefficients in the expansion of the slowly-varying part do not contain s.

Proceeding as before from

$$\cosh w+\varepsilon-\mathrm{i}s\sinh w\to-u\varepsilon\sum_{n=1}^{\infty}\frac{\omega^{2n}}{(2n)!}u^{n-1},\tag{3.18}$$

and applying the inversion formula (3.1) gives the coefficients

$$\frac{1}{a_1}=\frac{2}{\omega^2}\left(-\frac{1}{\varepsilon u}\right),\tag{3.19}$$

$$-\frac{a_2}{a_1^2}=-\frac{1}{6}\left(-\frac{1}{\varepsilon u}\right),\tag{3.20}$$

$$\frac{a_2^2-a_1a_3}{a_1^3}=\frac{1}{120}\omega^2\left(-\frac{1}{\varepsilon u}\right).\tag{3.21}$$

The absence of s in the coefficients simplifies the task greatly, since we no longer need to concern ourselves with expanding the coefficients in negative powers of s. This gives the asymptotic expression,

$$h_{1,-1}(s\xi^{-(1/3)},\omega\xi^{-(1/3)})\sim-\frac{1}{\varepsilon u}\left[\frac{2}{\omega^2}-\frac{1}{6}u+\frac{1}{120}\omega^2u^2\right].\tag{3.22}$$

Using again (3.6) gives

$$\exp\left[\sum_{n=1}^{\infty}\left(-s\frac{\omega^{2n+2}}{(2n+2)!}+\mathrm{i}\frac{\omega^{2n+3}}{(2n+3)!}\right)u^n\right]h_{1,-1}(s\xi^{-(1/3)},\omega\xi^{-(1/3)})$$
$$\sim-\frac{1}{\varepsilon u}\left\{\frac{2}{\omega^2}+u\left[\left(-\frac{1}{6}+\frac{\mathrm{i}\omega^3}{60}\right)-\frac{\omega^2}{12}s\right]\right.$$
$$\left.+u^2\left[\left(\frac{\omega^2}{120}-\frac{\mathrm{i}\omega^5}{1008}-\frac{\omega^8}{14400}\right)+\left(\frac{\omega^4}{240}-\frac{\mathrm{i}\omega^7}{1440}\right)s+\frac{\omega^6}{570}s^2\right]\right\}.\tag{3.23}$$

After multiplying the previous expression by $\exp(-s\omega^2/2+\mathrm{i}\omega^3/6)$ and integrating with respect to ω the result is

$$\int_{-\infty}^{\infty}\exp\left[-s\frac{\omega^2}{2}+\mathrm{i}\frac{\omega^3}{6}\right]\exp\left[\sum_{n=1}^{\infty}\left(-s\frac{\omega^{2n+2}}{(2n+2)!}+\mathrm{i}\frac{\omega^{2n+3}}{(2n+3)!}\right)u^n\right]$$
$$\times h_{1,-1}(s\xi^{-(1/3)},\omega\xi^{-(1/3)})\xi^{-(1/3)}d\omega$$

$$\sim \frac{\xi^{-1/3}}{\varepsilon u}\left\{2Q_{-2,0}(s)+\left[\frac{1}{6}Q_{0,0}(s)-\frac{1}{60}Q_{3,0}(s)-\frac{s}{12}Q_{2,0}(s)\right]u+\left[\frac{1}{120}Q_{2,0}(s)+\cdots\right]u^2\right\}. \tag{3.24}$$

The $\cdots$ in the last term includes only terms with $Q_{k,m}(s)$ with $k\geqslant 4$ and power of s at most s^2.

Again, we have a bound on the maximum possible order in ξ that allows us to use this expansion directly. For efficiency, we again want to isolate those terms of same order in ξ.

To obtain a leading order approximation, we make use of the recurrence relations (A11) and Eqs. (A41) and (A42),

$$Q_{-2,0}(s)=sQ_{0,0}(s)+\tfrac{1}{2}Q_{1,0}(s)\sim\sqrt{2\pi}s^{1/2}\quad \text{as}\ \ s\to\infty,$$

$$Q_{-2,0}(s\xi^{1/3})\sim\sqrt{2\pi}s^{1/2}\xi^{1/6}\quad \text{as}\ \ \xi\to\infty. \tag{3.25}$$

The higher-order terms all go to zero as $\xi\to\infty$, so they can not make a contribution exceeding this term.

We can now look for a first-order correction term. Expanding the previous result a little further gives

$$Q_{-2,0}(s\xi^{1/3})\sim\sqrt{2\pi}[s^{1/2}\xi^{1/6}+\tfrac{1}{24}s^{-5/2}\xi^{-5/6}]\quad \text{as}\ \ \xi\to\infty, \tag{3.26}$$

which leads us to believe that the next term in the series will have order $\xi^{-5/6}$. We look for terms of that order or lower in the u^1 term,

$$uQ_{0,0}(s\xi^{1/3})\sim\sqrt{2\pi}s^{-1/2}\xi^{-5/6}\quad \text{as}\ \ \xi\to\infty, \tag{3.27}$$

$$uQ_{3,0}(s\xi^{1/3})\sim-\tfrac{5}{2}\sqrt{2\pi}s^{-7/2}\xi^{-11/6}\quad \text{as}\ \ \xi\to\infty, \tag{3.28}$$

$$(s\xi^{1/3})uQ_{2,0}(s\xi^{1/3})\sim-\sqrt{2\pi}s^{-1/2}\xi^{-5/6}\quad \text{as}\ \ \xi\to\infty. \tag{3.29}$$

The terms from (3.27) and (3.29) contribute at this order.

We can see that no terms from the u^2 term contribute at this order, by noting that the terms consist of:

(a) $u^2Q_{2,0}(s\xi^{1/3})$ which decays like $s^{-3/2}\xi^{-11/6}$ as $\xi\to\infty$;

(b) Terms containing $Q_{k,m}$, where $k\geqslant 4$ and power of s at most 2. These all decay faster than

$$(s\xi^{1/3})^2u^2Q_{4,0}(s\xi^{1/3})\sim-3\sqrt{2\pi}s^{-1/2}\xi^{-3/2},\quad \xi\to\infty. \tag{3.30}$$

None of these can contribute to the $\xi^{-5/6}$ term.

Moreover, the u^3 or higher terms cannot contribute, since each contains a $u^3=\xi^{-2}$ factor and a power of s no greater than $s^3\to s^3\xi$. Since all of the $Q_{k,m}(s\xi^{-1/3})$ in this term decay as $\xi\to\infty$, this means that each term can contribute at no higher than the ξ^{-1} order.

So, finally [see also Eqs. (2.19) and (3.24)], as an expansion in the $\mu=-1$ case we have

$$I_{1,-1}(s\xi^{-1/3},\xi)\sim\sqrt{2\pi}\xi^{1/3}e^{-\pi\xi}(1+s^2\xi^{-2/3})^{-1/2}\exp[-\xi(s\xi^{-1/3}-\arctan(s\xi^{-1/3}))]$$
$$\times[2s^{1/2}+\tfrac{1}{12}s^{-5/2}+\tfrac{1}{4}s^{-1/2}\xi^{-2/3}],\quad \text{as}\ \ s\to\infty, \tag{3.31}$$

$$I_{1,-1}(s,\xi)\sim 2\sqrt{2\pi}\xi^{1/2}e^{-\pi\xi}s^{1/2}(1+s^2)^{-1/2}\exp[-\xi(s-\arctan(s))]$$
$$\times[1+(\tfrac{1}{8}+\tfrac{1}{24}s^{-2})s^{-1}\xi^{-1}],\quad \text{as}\ \ \xi\to\infty. \tag{3.32}$$

We notice that the leading order of the expansion for $\mu=-1$ is a full power of ξ larger than that for the $\mu=+1$ term, which means that we need to consider only the $\mu=-1$ term in the expansion for the differential excitation function, at least to leading order.

We also note that, while the leading-order term of the $\mu=-1$ expansion is well-behaved, the correction terms are singular at $s=0$, corresponding to the backscatter direction, as are *all* of the terms in the expansion for $\mu=+1$. Even using only the nonsingular leading order term of $I_{1,-1}$ gives the result of $df_{E1}(\theta=\pi)/d\Omega=0$, which we know to be wrong, so this case must be handled separately.

IV. DIFFERENTIAL EXCITATION FUNCTION

A. Parameter s bounded away from zero (θ bounded away from π)

Dismissing the $I_{1,+1}$ term as asymptotically much smaller than the $I_{1,-1}$ term, we obtain the following expression for the semiclassical excitation function for large ξ (repulsive potential),

$$\frac{df_{E1}}{d\Omega}(s,\xi)\sim\frac{4}{9}\pi^2\xi e^{-2\pi\xi}s(1+s^2)\exp[-2\xi(s-\arctan(s))]\times\{1+(\tfrac{1}{4}+\tfrac{1}{12}s^{-2})s^{-1}\xi^{-1}\},\quad \text{as}\ \ \xi\to\infty. \tag{4.1}$$

The behavior of the leading order of this expression is qualitatively similar to the semiclassical result, with the exception that it goes to 0 in the backscattering direction $\theta=\pi(s=0)$, while the semiclassical result remains a small positive number.

B. Parameter $s=0$ ($\theta=\pi$)

While the previous expansions are useful for s large (θ bounded away from π), the leading-order term for $df_{E1}(\theta=\pi)/d\Omega$ is 0 in this approximation, while all of the correction terms are singular for that direction. This situation arises, due to our use of large-s asymptotic expressions for the $Q_{k,m}(s)$, when, in the present case of $\theta=\pi$, we should be considering small values for the argument of these functions.

To obtain information about $\theta=\pi$, we need to follow the method of Ref. 6 and expand in ascending powers of s. As in the large-s case, however, we will not expand $\exp[-\xi(s-\arctan(s))]$ or ε in powers of ξ.

Our situation is simplified by the fact that, for the backscatter direction, the integral for $\mu=+1$ and the integral for $\mu=-1$ are exactly the same. Since the $\mu=-1$ case presents the simpler expansion, we shall use it, rather than bothering with the more complicated $\mu=+1$ expansion. In fact, we can derive it directly from the results of the previous section [Eq. (3.24)] and Eq. (2.19),

$$I_{1,-1}(s\xi^{-1/3},\xi)\sim\xi^{1/3}e^{-\pi\xi}(1+s^2\xi^{-2/3})^{-1/2}\exp[-\xi(s\xi^{-1/3}-\arctan(s\xi^{-1/3}))]\times\left\{2Q_{-2,0}(s)+u\left[\frac{1}{6}Q_{0,0}(s)-\frac{1}{60}Q_{3,0}(s)-\frac{s}{12}Q_{2,0}(s)\right]\right\},\quad \text{as}\ \ s\to0. \tag{4.2}$$

In taking the limit as $\xi\to\infty$, we see that there is some degeneracy in the expansion we get, since any constant value of s will give a result for backscatter at $\xi=\infty$. However, since we are seeking approximations for large, but finite ξ, it is best to pick $s=0$ to obtain the backscatter direction for all ξ.

We do not encounter, as we did in the $s\neq0$ case, the problem with differing asymptotic behavior of the $Q_{k,m}$, since, in this case, we are merely evaluating each of them at $s=0$.

We see that, in the leading order of Eq. (4.2) [see also Eqs. (A21), (A22), (A25)],

$$2Q_{-2,0}(0)=Q_{1,0}(0)=2^{2/3}3^{1/6}\Gamma(2/3), \tag{4.3}$$

and, in the first-order correction of Eq. (4.2),

$$Q_{0,0}(0)=2^{1/3}3^{1/6}\Gamma(1/3), \tag{4.4}$$

$$Q_{3,0}(0)=-2Q_{0,0}(0)=-2^{4/3}3^{-1/6}\Gamma(1/3), \tag{4.5}$$

which results in the expansion,

$$I_{1,-1}(0,\xi)\sim\xi^{1/3}e^{-\pi\xi}2^{2/3}3^{1/6}\Gamma(2/3)\left[1+\frac{1}{5}6^{-1/3}\frac{\Gamma(1/3)}{\Gamma(2/3)}\xi^{-2/3}\right], \quad \text{for } \xi^{2/3}\gg 1, \tag{4.6}$$

Using the equality of $I_{1,+1}(0,\xi)$ and $I_{1,-1}(0,\xi)$, gives the following expression for the $E1$ differential excitation function:

$$\begin{aligned}\frac{df_{E1}}{d\Omega}(0,\xi)&=\frac{1}{9}\pi I_{1,-1}^2(0,\xi)\\ &\sim\frac{2}{9}\pi 6^{1/3}\Gamma^2(2/3)\xi^{2/3}e^{-2\pi\xi}\left[1+\frac{2}{5}6^{-1/3}\frac{\Gamma(1/3)}{\Gamma(2/3)}\xi^{-2/3}\right], \quad \text{for } \xi^{2/3}\gg 1,\end{aligned} \tag{4.7}$$

and repulsive potentials.

The same result is obtained using Watson's asymptotic expansion of the Bessel functions $K_\nu(z)=\frac{1}{2}\pi\mathrm{i}\exp(\frac{1}{2}\nu\pi\mathrm{i})H_\nu^{(1)}(ze^{1/2\pi\mathrm{i}})$ in Eq. (1.1), whose order and argument are nearly equal (Sec. 8.42 of Ref. 5).

An interesting result is that, upon conversion to the attractive case through multiplication by $\exp(2\pi|\xi|)$ of Eqs. (4.1) and (4.7), we see that Eq. (4.1) still decays to 0, albeit at a slower rate, while Eq. (4.7) tends to infinity as $\xi\to\infty$. This is explained by the fact that, as $E_f\to 0$, those classical orbits, which come closer to the target, are more strongly emphasized. Those same orbits result in scattering angles near the backscatter direction. This effect is not seen in the repulsive case, since the classical orbits do not come arbitrarily close to the ion, making it increasingly unlikely for a transition to occur when $E_f\to 0$.

C. Parameter $s\to 0$ (i.e., $\theta\to\pi$)

The approach in the previous section can be extended to handle the case $\xi^{2/3}\gg 1$ and $s\xi^{1/3}\ll 1$ by using the small-argument expansions (A28)–(A33) for the $Q_{k,m}$ in Eq. (4.2) and in the equation

$$\begin{aligned}I_{1,1}(s\xi^{-1/3},\xi)\sim{}&\xi^{1/3}e^{-\pi\xi}(1+s^2\xi^{-2/3})^{1/2}\exp[-\xi(s\xi^{-1/3}-\arctan(s\xi^{-1/3}))]\\ &\times\left\{2Q_{0,-2}(s)+u\left[\frac{1}{6}Q_{2,-2}(s)-\frac{2}{3}sQ_{2,-3}(s)-\frac{s}{12}Q_{4,-2}(s)-\frac{1}{60}Q_{5,-2}(s)\right]\right\}.\end{aligned} \tag{4.8}$$

The results obtained are, for the relevant Coulomb integral,

$$I_{1,-1}(s,\xi)\sim\xi^{1/3}e^{-\pi\xi}2^{2/3}3^{1/6}\Gamma(2/3)\left\{1+\frac{1}{5}6^{-1/3}\frac{\Gamma(1/3)}{\Gamma(2/3)}\xi^{-2/3}+6^{-1/3}\frac{\Gamma(1/3)}{\Gamma(2/3)}(s\xi^{1/3})\right\} \tag{4.9}$$

and

$$I_{1,1}(s,\xi)\sim\xi^{1/3}e^{-\pi\xi}2^{2/3}3^{1/6}\Gamma(2/3)\left\{1+\frac{1}{5}6^{-1/3}\frac{\Gamma(1/3)}{\Gamma(2/3)}\xi^{-2/3}-6^{-1/3}\frac{\Gamma(1/3)}{\Gamma(2/3)}(s\xi^{1/3})\right\}, \tag{4.10}$$

and hence, for the repulsive potential excitation function,

$$\frac{df_{E1}}{d\Omega}(s,\xi)\sim\frac{2}{9}\pi 6^{1/3}\Gamma^2(2/3)\xi^{2/3}e^{-2\pi\xi}\left\{1+\frac{2}{5}6^{-1/3}\frac{\Gamma(1/3)}{\Gamma(2/3)}\xi^{-2/3}\right\}, \tag{4.11}$$

for $\xi^{2/3}\gg 1$ and $s\xi^{1/3}\ll 1$. The match between the exact semiclassical $E1$ differential excitation function [Eq. (1.1)] and the asymptotic expansions derived in this paper is shown in Fig. 8.

We would like to thank Dr. S. G. Davison, Dr. F. O. Goodman, Dr. L. U. Ancarani, and Dr. J. A. Tully for valuable discussions. This work was supported in part by the Natural Sciences and Engineering Research Council of Canada.

APPENDIX: PROPERTIES OF THE $Q_{K,M}(S)$

While, in general, the integral in (2.22) cannot be solved in closed form, there is one important case where a closed-form integral exists,

$$Q_{1,1}(s)=\left[2\mathrm{i}\exp\left(-s\frac{\omega^2}{2}+\mathrm{i}\frac{\omega^3}{6}\right)\right]_{\omega=-\infty}^{\infty}\equiv 0, \tag{A1}$$

for $s>0$. The principal-value prescription assigns a value of 0 at $s=0$ as well. The explicit knowledge of this case will help us to eliminate pathological cases in the recurrence relations we will derive presently.

For brevity, we will in general not write the explicit dependence of the $Q_{k,m}$ on its argument from this point on, unless it is absolutely necessary.

1. Recurrence relations for $Q_{k,m}$

Integration by parts provides several recurrence relations among these integrals that may be used to reduce the problem of evaluating any of the $Q_{k,m}$ to that of evaluating four basic integrals, $Q_{1,0}$, $Q_{0,0}$, $Q_{-1,0}$, and $Q_{0,-1}$.

Using integration by parts on the definition (2.22), assuming $m\neq -1$,

$$\begin{aligned}Q_{k,m}&=\mathrm{i}^{-k-m}\int_{-\infty}^{\infty}\exp\left[-s\frac{\omega^2}{2}+\mathrm{i}\frac{\omega^3}{6}\right]\omega^k(\omega+2\mathrm{i}s)^m\mathrm{d}\omega\\&=-\frac{\mathrm{i}^{-k-m}}{m+1}\left\{k\int_{-\infty}^{\infty}\exp\left[-s\frac{\omega^2}{2}+\mathrm{i}\frac{\omega^3}{6}\right]\omega^{k-1}(\omega+2\mathrm{i}s)^{m+1}\mathrm{d}\omega\right.\\&\quad\left.-\frac{\mathrm{i}}{2}\int_{-\infty}^{\infty}\exp\left[-s\frac{\omega^2}{2}+\mathrm{i}\frac{\omega^3}{6}\right]\omega^{k+1}(\omega+2\mathrm{i}s)^{m+2}\mathrm{d}\omega\right\}\\&=\frac{-k}{m+1}Q_{k-1,m+1}-\frac{1}{2(m+1)}Q_{k+1,m+2}.\end{aligned} \tag{A2}$$

Selecting other factors for the integration by parts, and now assuming $k\neq -1$, gives

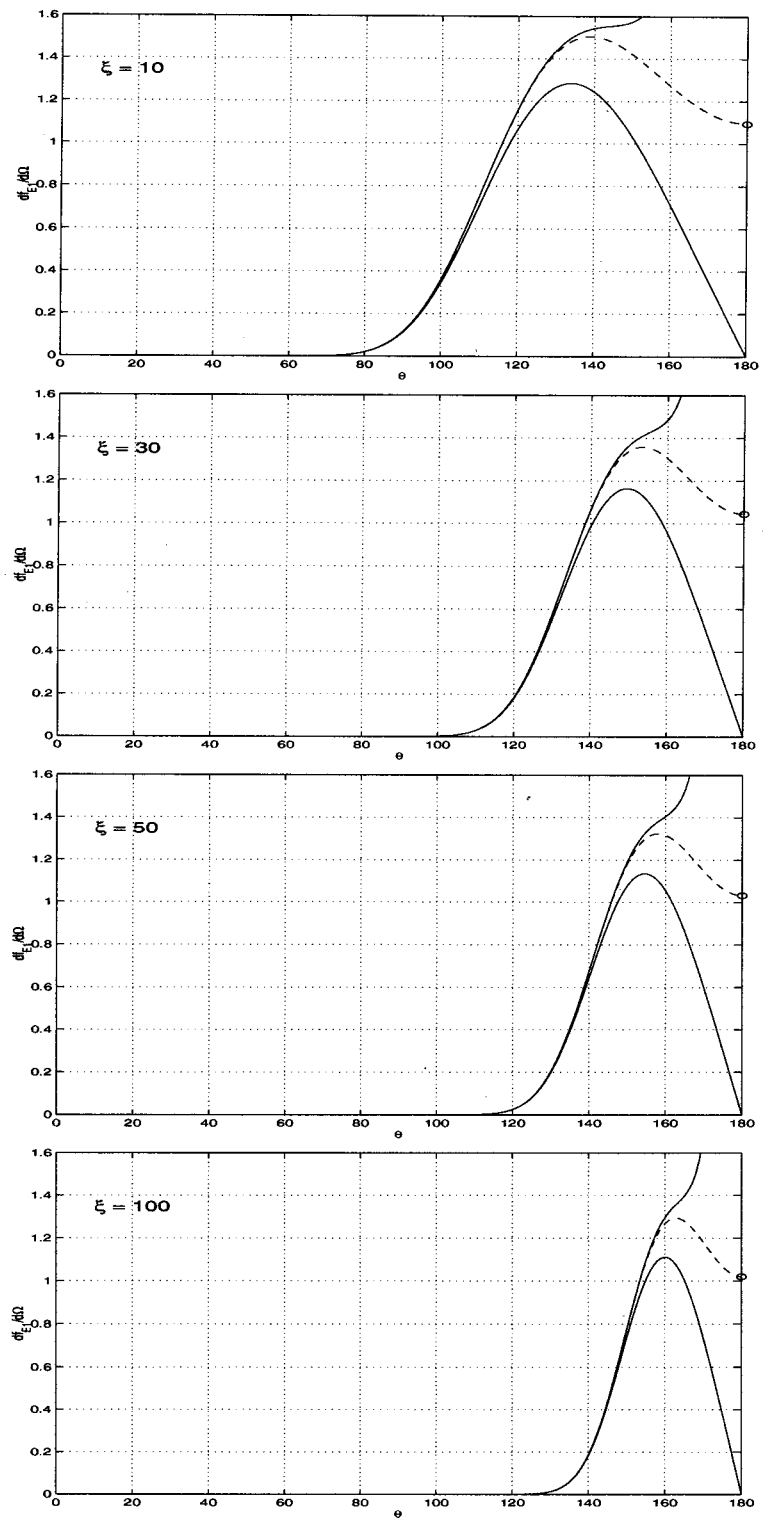

FIG. 8. Semiclassical approximation for large ξ. The function $(9/2\pi)\Gamma^{-2}(2/3)\exp(2\pi\xi)\mathrm{d}f_{E1}/\mathrm{d}\Omega$ is plotted as a function of θ for different values of the parameter ξ. Under this normalization, the plots for the attractive and repulsive cases are equivalent. The semiclassical expression (1.1) for $\lambda=1$ is shown as a dashed line while the one- and two-term asymptotic expression (4.1) is shown as solid lines. The two-terms asymptotic expression (4.7) for $\theta=\pi$ is shown as a circle.

$$
\begin{aligned}
Q_{k,m} &= \mathrm{i}^{-k-m}\int_{-\infty}^{\infty}\exp\left[-s\frac{\omega^2}{2}+\mathrm{i}\frac{\omega^3}{6}\right]\omega^k(\omega+2\mathrm{i}s)^m\mathrm{d}\omega \\
&= -\frac{\mathrm{i}}{k+1}\left\{m\int_{-\infty}^{\infty}\exp\left[-s\frac{\omega^2}{2}+\mathrm{i}\frac{\omega^3}{6}\right]\omega^{k+1}(\omega+2\mathrm{i}s)^{m-1}\mathrm{d}\omega\right. \\
&\quad \left.-\frac{\mathrm{i}}{2}\int_{-\infty}^{\infty}\exp\left[-s\frac{\omega^2}{2}+\mathrm{i}\frac{\omega^3}{6}\right]\omega^{k+2}(\omega+2\mathrm{i}s)^{m+1}\mathrm{d}\omega\right\} \\
&= -\frac{m}{k+1}Q_{k+1,m-1}-\frac{1}{2(k+1)}Q_{k+2,m+1}. \qquad \text{(A3)}
\end{aligned}
$$

While (A2) is valid only for $m\neq -1$ and (A3) is good only for $k\neq -1$, upon multiplying the former by $(m+1)$ and the latter by $(k+1)$, we find that we can transform one into the other by permuting indices, meaning both are valid for $(k,m)\neq(-1,-1)$. Knowing that $Q_{1,1}=0$, allows us to remove even this restriction, resulting in three recurrence relations for the $Q_{k,m}$ of general applicability (the two above, plus a third from permuting indices),

$$(m+1)Q_{k,m}=-kQ_{k-1,m+1}-\tfrac{1}{2}Q_{k+1,m+2}, \qquad \text{(A4)}$$

$$(k+1)Q_{k,m}=-mQ_{k+1,m-1}-\tfrac{1}{2}Q_{k+1,m+1}, \qquad \text{(A5)}$$

$$\tfrac{1}{2}Q_{k,m}=-(k-1)Q_{k-2,m-1}-(m-1)Q_{k-1,m-2}. \qquad \text{(A6)}$$

If $m=0$, we can derive other recurrence relations. If $k\neq -1$,

$$
\begin{aligned}
Q_{k,0} &= \mathrm{i}^{-k}\int_{-\infty}^{\infty}\exp\left[-s\frac{\omega^2}{2}+\mathrm{i}\frac{\omega^3}{6}\right]\omega^k\mathrm{d}\omega \\
&= -\frac{\mathrm{i}^{-k}}{k+1}\int_{-\infty}^{\infty}\left(-s\omega+\mathrm{i}\frac{\omega^2}{2}\right)\exp\left[-s\frac{\omega^2}{2}+\mathrm{i}\frac{\omega^3}{6}\right]\omega^{k+1}\mathrm{d}\omega \\
&= -\frac{s}{k+1}Q_{k+2,0}-\frac{1}{2(k+1)}Q_{k+3,0}. \qquad \text{(A7)}
\end{aligned}
$$

Similarly, if we multiply by $k+1$, we can extend to general applicability by noting that

$$
\begin{aligned}
-sQ_{1,0}-\frac{1}{2}Q_{2,0} &= \int_{-\infty}^{\infty}\exp\left[-s\frac{\omega^2}{2}+\mathrm{i}\frac{\omega^3}{6}\right]\omega\left(\mathrm{i}s+\frac{\omega}{2}\right)\mathrm{d}\omega \\
&= -\tfrac{1}{2}Q_{1,1}=0. \qquad \text{(A8)}
\end{aligned}
$$

Again, permuting indices gives three versions of this recurrence relation,

$$(k+1)Q_{k,0}=-sQ_{k+2,0}-\tfrac{1}{2}Q_{k+3,0}, \qquad \text{(A9)}$$

$$Q_{k,0}=-2sQ_{k-1,0}-2(k-2)Q_{k-3,0}, \qquad \text{(A10)}$$

$$sQ_{k,0}=-(k-1)Q_{k-2,0}-\tfrac{1}{2}Q_{k+1,0}. \qquad \text{(A11)}$$

While the three recurrence relations for $m=0$, (A9)–(A11) are quite readily applicable, the three more general relations, (A4)–(A6) are much more difficult to apply to obtain a combination of only the basic four $Q_{k,m}$. Another recurrence relation, derived from partial fractions aids us here, especially in the frequently-encountered case, when k is positive and m is negative.

From the binomial theorem,

$$(\omega+2\mathrm{i}s)^k=\sum_{j=0}^{k}\binom{k}{j}\omega^{k-j}(2\mathrm{i}s)^j$$

$$=\omega^k+\sum_{j=1}^{k}\binom{k}{j}\omega^{k-j}(2\mathrm{i}s)^j, \tag{A12}$$

so

$$Q_{k,-m}=\mathrm{i}^{-k+m}\int_{-\infty}^{\infty}\exp\left[-s\frac{\omega^2}{2}+\mathrm{i}\frac{\omega^3}{6}\right]\frac{\omega^k}{(\omega+2\mathrm{i}s)^m}\,\mathrm{d}\omega,$$

$$Q_{k,-m}=\mathrm{i}^{-k+m}\int_{-\infty}^{\infty}\exp\left[-s\frac{\omega^2}{2}+\mathrm{i}\frac{\omega^3}{6}\right]\frac{1}{(\omega+2\mathrm{i}s)^m}\left[(\omega+2\mathrm{i}s)^k-\sum_{j=1}^{k}\binom{k}{j}\omega^{k-j}(2\mathrm{i}s)^j\right]\mathrm{d}\omega,$$

$$=Q_{0,k-m}-\sum_{j=1}^{k}\binom{k}{j}(2s)^jQ_{k-j,-m}. \tag{A13}$$

This relation expresses a $Q_{k,-m}$ in terms of an integral with $k=0$ and several with the same value of m, but lower values of k. If $k\leqslant m$, this can be used repeatedly to obtain a result in terms of only the $Q_{k,-m}$ with $k=0$ and $m\geqslant 0$. In this situation, Eq. (A4) takes a simple form (one term drops out), which can be used to increase $-m$. Repeated application of (A13) and (A4) is guaranteed to be able to express any $Q_{k,m}$ with positive k and negative m in terms of $Q_{1,0}$, $Q_{0,0}$, and $Q_{0,-1}$.

If $k>m$, we use the division algorithm on the integrand to express it in terms of $Q_{k,-m}$ with $k<m$ and those with $m=0$, which are handled easily by (A9)–(A11).

The use of these recurrence relations is shown in Fig. 5.

2. Ascending power series for $Q_{k,m}$

Since we have reduced the problem of computing the general $Q_{k,m}$ to that of computing the four basic integrals $Q_{1,0}$, $Q_{0,0}$, $Q_{-1,0}$, and $Q_{0,-1}$, we now set ourselves to obtaining power series for these four integrals. We begin by expressing each of these in real form,

$$Q_{1,0}=2\int_0^{\infty}\exp\left(-s\frac{\omega^2}{2}\right)\omega\sin\left(\frac{\omega^3}{6}\right)\mathrm{d}\omega, \tag{A14}$$

$$Q_{0,0}=2\int_0^{\infty}\exp\left(-s\frac{\omega^2}{2}\right)\cos\left(\frac{\omega^3}{6}\right)\mathrm{d}\omega, \tag{A15}$$

$$Q_{-1,0}=\pi-2\int_0^{\infty}\exp\left(-s\frac{\omega^2}{2}\right)\frac{1}{\omega}\sin\left(\frac{\omega^3}{6}\right)\mathrm{d}\omega, \tag{A16}$$

$$Q_{0,-1}=4\int_0^{\infty}\exp\left(-s\frac{\omega^2}{2}\right)\frac{s}{\omega^2+4s^2}\cos\left(\frac{\omega^3}{6}\right)\mathrm{d}\omega-2\int_0^{\infty}\exp\left(-s\frac{\omega^2}{2}\right)\frac{\omega}{\omega^2+4s^2}\sin\left(\frac{\omega^3}{6}\right)\mathrm{d}\omega. \tag{A17}$$

The π-term in the expression for $Q_{-1,0}$ comes from distorting the path of integration around the pole in the integrand at $\omega=0$, while the remainder is the principal value of the the integral.

As a preliminary to deriving power series for the four principal $Q_{k,m}$, we evaluate every integral of the form $Q_{k,0}$ at $s=0$. We note that

$$Q_{1,0}(0)=2\int_0^\infty \omega \sin\left(\frac{\omega^3}{6}\right)\mathrm{d}\omega. \tag{A18}$$

Making the substitution $v=\omega^{1/3}$ gives

$$Q_{1,0}(0)=\frac{2}{3}\int_0^\infty v^{-(1/3)}\sin\left(\frac{v}{3}\right)\mathrm{d}v. \tag{A19}$$

This is an example of a representation of the Gamma function [Ref. 12, Eq. 6.312(8)]

$$\Gamma(z)=\frac{b^z}{\mathrm{trig}\left(\frac{\pi}{2}z\right)}\int_0^\infty t^{z-1}\,\mathrm{trig}(bt)\mathrm{d}t, \tag{A20}$$

where trig(x) stands for either sin(x) or cos(x), for $b>0$, $0<\mathrm{Re}(z)<1$, which gives the integral in terms of the Gamma function,

$$Q_{1,0}(0)=2^{2/3}3^{1/6}\Gamma\left(\frac{2}{3}\right). \tag{A21}$$

Similarly,

$$\begin{aligned}Q_{0,0}(0)&=2\int_0^\infty \cos\left(\frac{\omega^3}{6}\right)\mathrm{d}\omega\\&=2^{(1/3)}3^{-(1/6)}\Gamma\left(\frac{1}{3}\right).\end{aligned} \tag{A22}$$

In contrast, $Q_{-1,0}$ is expressible in closed form without invoking a special function (although an intermediate step makes use of the sine integral function),

$$\begin{aligned}Q_{-1,0}(0)&=\pi-2\int_0^\infty \frac{1}{\omega}\sin\left(\frac{\omega^3}{6}\right)\mathrm{d}\omega\\&=\pi-\frac{2}{3}\int_0^\infty \frac{1}{v}\sin\left(\frac{v}{6}\right)\mathrm{d}v\\&=\pi-\frac{2}{3}\lim_{v\to\infty}\mathrm{Si}(v)=\frac{2\pi}{3}.\end{aligned} \tag{A23}$$

While not immediately useful, for completeness, we note that

$$Q_{0,-1}(0)=\mathrm{i}\int_{-\infty}^\infty \exp\left(\mathrm{i}\frac{\omega^3}{6}\right)\frac{1}{\omega}\mathrm{d}\omega=Q_{-1,0}(0)=\frac{2\pi}{3}. \tag{A24}$$

Using these known quantities and Eq. (A9) we obtain for positive k,

$$\begin{aligned}Q_{3n-1,0}(0)&=0 \quad n=1,2,3,4,...,\\Q_{3n,0}(0)&=(3n-1)!!!(-2)^nQ_{0,0}(0) \quad n=0,1,2,3,...,\\Q_{3n+1,0}(0)&=(3n-1)!!!(-2)^nQ_{1,0}(0) \quad n=0,1,2,3,...,\end{aligned} \tag{A25}$$

and, for negative k,

$$Q_{1-3n,0}(0)=\frac{1}{2^n(3n-2)!!!}Q_{1,0}(0) \quad n=0,1,2,3,...,$$

$$Q_{-3n,0}(0)=\frac{1}{2^n(3n-1)!!!}Q_{0,0}(0) \quad n=0,1,2,3,..., \tag{A26}$$

$$Q_{-1-3n,0}(0)=\frac{1}{2^n(3n-1)!!!}\frac{2\pi}{3} \quad n=0,1,2,3,...,$$

where the triple factorial is defined by

$$A!!!=A(A-3)(A-6)\cdots\left\{\begin{matrix}3\\2\\1\end{matrix}\right\}, \quad 0!!!=1. \tag{A27}$$

To obtain ascending power series for these four integrals, we write $\sin(\omega^3/6)$ and $\cos(\omega^3/6)$ in terms of $\exp(\pm i\omega^3/6)$ and we expand the part of the exponential in the integrand which contains s, namely,

$$\begin{aligned}
Q_{1,0}(s)&=-i\int_{-\infty}^{\infty}\exp\left[-s\frac{\omega^2}{2}+i\frac{\omega^3}{6}\right]\omega d\omega,\\
&=-i\int_{-\infty}^{\infty}\sum_{n=0}^{\infty}(-)^n\frac{s^n}{2^n n!}\exp\left(i\frac{\omega^3}{6}\right)\omega^{2n+1}d\omega\\
&=\sum_{n=0}^{\infty}\frac{s^n}{2^n n!}Q_{2n+1,0}(0)\\
&=Q_{1,0}(0)-sQ_{0,0}(0)+\sum_{n=1}^{\infty}\left\{Q_{1,0}(0)\frac{(6n-1)!!!}{(3n)!2^n}s^{3n}-Q_{0,0}(0)\frac{(6n+1)!!!}{(3n+1)!2^n}s^{3n+1}\right\}.
\end{aligned} \tag{A28}$$

Similarly,

$$\begin{aligned}
Q_{0,0}(s)&=\int_{-\infty}^{\infty}\exp\left[-s\frac{\omega^2}{2}+i\frac{\omega^3}{6}\right]d\omega\\
&=\sum_{n=0}^{\infty}\frac{s^n}{2^n n!}Q_{2n,0}(0)\\
&=Q_{0,0}(0)+\sum_{n=1}^{\infty}\left\{-Q_{1,0}(0)\frac{(6n-4)!!!}{(3n-1)!2^n}s^{3n-1}+Q_{0,0}(0)\frac{(6n-1)!!!}{(3n)!2^n}s^{3n}\right\},
\end{aligned} \tag{A29}$$

and

$$
\begin{aligned}
Q_{-1,0}(s) &= \mathrm{i}\int_{-\infty}^{\infty} \exp\left[-s\frac{\omega^2}{2}+\mathrm{i}\frac{\omega^3}{6}\right]\frac{1}{\omega}\,\mathrm{d}\omega \\
&= \sum_{n=0}^{\infty}\frac{s^n}{2^n n!}Q_{2n-1,0}(0) \\
&= \frac{2\pi}{3}+\frac{1}{2}sQ_{1,0}(0)-\frac{1}{4}s^2Q_{0,0}(0) \\
&\quad +\sum_{n=1}^{\infty}\left\{Q_{1,0}(0)\frac{(6n-1)!!!}{(3n+1)!2^{n+1}}s^{3n+1}-Q_{0,0}(0)\frac{(6n+1)!!!}{(3n+2)!2^{n+1}}s^{3n+2}\right\}. \qquad \text{(A30)}
\end{aligned}
$$

To apply the same procedure to $Q_{0,-1}$, we make use of the result

$$
\begin{aligned}
\exp\left(-s\frac{\omega^2}{2}\right)\frac{1}{\omega+2\mathrm{i}s} &= \sum_{m=0}^{\infty}\sum_{k=0}^{\infty}\left((-)^m\frac{s^m\omega^{2m}}{2^m m!}\right)\left(\frac{1}{\omega^{k+1}}(-2\mathrm{i}s)^k\right) \\
&= \sum_{m=0}^{\infty}\sum_{k=0}^{\infty}(-)^{m+k}\frac{\mathrm{i}^k}{2^{m-k}m!}s^{m+k}\omega^{2m-k-1}. \qquad \text{(A31)}
\end{aligned}
$$

We can change the order of summation to make one of the sums finite. Let $n=m+k$,

$$
\exp\left(-s\frac{\omega^2}{2}\right)\frac{1}{\omega+2\mathrm{i}s} = \sum_{n=0}^{\infty}\sum_{m=0}^{n}\frac{(-)^n\mathrm{i}^{n-m}}{2^{2m-n}m!}s^n\omega^{3m-n-1}, \qquad \text{(A32)}
$$

i.e., we have

$$
\begin{aligned}
Q_{0,-1}(s) &= \mathrm{i}\int_{-\infty}^{\infty}\exp\left[-s\frac{\omega^2}{2}+\mathrm{i}\frac{\omega^3}{6}\right]\frac{1}{\omega+2\mathrm{i}s}\,\mathrm{d}\omega \\
&= \int_{-\infty}^{\infty}\sum_{n=0}^{\infty}\sum_{l=0}^{n}\frac{(-)^n\mathrm{i}^{n-l+1}}{2^{2l+n}l!}s^n\omega^{3l-n-1}\mathrm{d}\omega \\
&= \sum_{n=0}^{\infty}\sum_{l=0}^{n}\frac{(-)^{l+n}}{2^{2l-n}l!}s^nQ_{3l-n-1,0}(0). \qquad \text{(A33)}
\end{aligned}
$$

Using the known forms for the $Q_{k,0}(0)$, (A25) and (A26), gives the result cited in Ref. 6. The first 30 coefficients of each of these power series are tabulated in Ref. 6.

3. Descending power series for $Q_{k,m}$

In addition to the ascending power series provided by Ref. 6, which give a good approximation for small values of s, to obtain an expression for the *differential* excitation function, we need asymptotic expressions valid for large s as well. Using a slight modification of an extension to Watson's lemma provided in Ref. 10 (pp. 24ff) allows us to obtain asymptotic power series for the four basic integrals.

Consider the function

$$
f(x)=\int_0^{\sqrt{T}}e^{-xt^2}\varphi(t)\,\mathrm{d}t \qquad \text{(A34)}
$$

(contrast this with the theorem in Ref. 10, where the integration starts at a small negative number).

Making the substitution $t=\tau^{1/2}$ yields

$$f(x)=\frac{1}{2}\int_0^T e^{-x\tau}\varphi(\tau^{1/2})\tau^{-(1/2)}\mathrm{d}\tau. \tag{A35}$$

Suppose that φ admits a Maclaurin series, $\sum_{n=0}^{\infty} a_n t^n$ for $t\in\mathcal{R}$, then

$$f(x)=\frac{1}{2}\int_0^T e^{-x\tau}\tau^{-(1/2)}(a_0+a_1\tau^{1/2}+a_2\tau+a_3\tau^{3/2}+\cdots)\mathrm{d}\tau. \tag{A36}$$

Interchanging the order of integration and summation, we can provide asymptotic forms for all of the terms in the series. We note here that, unlike in Ref. 10, we can not assume that the odd powered terms disappear,

$$\begin{aligned}\int_0^t e^{-x\tau}\tau^{-(1/2)}\mathrm{d}\tau&=\int_0^\infty e^{-x\tau}\tau^{-(1/2)}\mathrm{d}\tau-\int_T^\infty e^{-x\tau}\tau^{-(1/2)}\mathrm{d}\tau\\&=\frac{1}{\sqrt{x}}\int_0^\infty e^{-s}s^{-(1/2)}\mathrm{d}s+\mathcal{O}\left(\frac{e^{-xT}}{x}\right)\\&=\sqrt{\frac{\pi}{x}}+\mathcal{O}\left(\frac{e^{-xT}}{x}\right)\quad\text{as}\quad x\to\infty,\end{aligned} \tag{A37}$$

$$\int_0^T e^{-x\tau}\mathrm{d}\tau=\frac{1}{x}+\mathcal{O}\left(\frac{e^{-xT}}{x}\right), \tag{A38}$$

$$\begin{aligned}\int_0^T x^n e^{-x\tau}\mathrm{d}\tau&=\frac{1}{x^{n+1}}\int_0^\infty s^n e^{-s}\mathrm{d}s+\mathcal{O}\left(\frac{e^{-xT}}{x}\right)\\&=\frac{\Gamma(n+1)}{x^{n+1}}+\mathcal{O}\left(\frac{e^{-xT}}{x}\right);\quad n>0,\end{aligned} \tag{A39}$$

which gives the asymptotic form,

$$\begin{aligned}f(x)&\sim\frac{1}{2}a_0\int_0^T e^{-x\tau}\tau^{-(1/2)}\mathrm{d}\tau+\frac{1}{2}a_1\int_0^T e^{-x\tau}\tau\mathrm{d}\tau+\frac{1}{2}\sum_{n=2}^{\infty}a_n\int_0^T e^{-x\tau}\tau^{(n-1)/2}\mathrm{d}\tau\\&\sim\frac{a_0}{2}\sqrt{\frac{\pi}{x}}+\frac{a_1}{2}\frac{1}{x}+\sum_{n=2}^{\infty}\frac{a_n}{2}\frac{\Gamma\left(\frac{n+1}{2}\right)}{x^{(n+1)/2}}.\end{aligned} \tag{A40}$$

The remainder term of each integral being of higher asymptotic order than all of the other terms.

There are two main differences between this formula and that given in Ref. 10: (1) as it was already noted, the odd-powered terms do not disappear in this derivation, and (2) a factor of $\frac{1}{2}$ has been introduced. Both of these effects can be seen to be a result of replacing the negative lower bound, $-\alpha$ used in Ref. 10 with 0 used here.

As is seen in Fig. 6, since the modulation factor requires that parts of the integral near zero become more and more important as x becomes large, even if the lower bound on the integral is a very small negative number, for large enough x, the region from $-\infty$ to $-\alpha$ becomes insignificant and ''most'' of the integral is included. Since odd-powered terms are odd functions, they

integrate to 0. Taking the lower bound as 0 integrates only half the integrand, no matter how large x is, resulting in odd-powered terms that do not vanish and even-powered terms of half the magnitude given in Ref. 10.

We can now use this theorem to find asymptotic expressions for the four principal integrals $(x=s/2)$,

$$Q_{1,0}=2\int_0^\infty \exp\left(-\frac{s}{2}\omega^2\right)\omega\sin\left(\frac{\omega^3}{6}\right)\mathrm{d}\omega,$$

$$\varphi(\omega)=\omega\sin\left(\frac{\omega^3}{6}\right)=\frac{1}{6}\omega^4-\frac{1}{1296}\omega^{10}+\frac{1}{933120}\omega^{16}+\cdots,$$

$$Q_{1,0}\sim\frac{1}{6}\frac{\Gamma(\frac{5}{2})}{x^{5/2}}-\frac{1}{1296}\frac{\Gamma(\frac{11}{2})}{x^{11/2}}+\frac{1}{933120}\frac{\Gamma(\frac{17}{2})}{x^{17/2}}$$

$$=\sqrt{2\pi}\left[\frac{1}{2}s^{-(5/2)}-\frac{35}{48}s^{-(11/2)}+\frac{5005}{2304}s^{-(17/2)}\right], \tag{A41}$$

$$Q_{0,0}=2\int_0^\infty \exp\left(-\frac{s}{2}\omega^2\right)\cos\left(\frac{\omega^3}{6}\right)\mathrm{d}\omega,$$

$$\varphi(\omega)=\cos\left(\frac{\omega^3}{6}\right)=1-\frac{1}{72}\omega^6+\frac{1}{31104}\omega^{12}\cdots,$$

$$Q_{0,0}\sim\sqrt{2\pi}[s^{-(1/2)}-\tfrac{5}{24}s^{-(7/2)}+\tfrac{385}{1152}s^{-(13/2)}], \tag{A42}$$

$$Q_{-1,0}=\pi-2\int_0^\infty \exp\left(-\frac{s}{2}\omega^2\right)\frac{1}{\omega}\sin\left(\frac{\omega^3}{6}\right)\mathrm{d}\omega,$$

$$\varphi(\omega)=\frac{1}{\omega}\sin\left(\frac{\omega^3}{6}\right)=\frac{1}{6}\omega^2-\frac{1}{1296}\omega^8+\frac{1}{933120}\omega^{14}+\cdots,$$

$$Q_{-1,0}\sim\pi+\sqrt{2\pi}\left[-\frac{1}{6}s^{-(3/2)}+\frac{70}{843}s^{-(9/2)}-\frac{1001}{6912}s^{-(15/2)}\right]. \tag{A43}$$

Handling $Q_{0,-1}$ [Eq. (A17)] is a little more complicated, since there are two integrals involved, and both integrands depend on s in a more complicated way than simply through the exponential factor. We accommodate this by first expanding the s-dependent factor $(\omega^2+4s^2)^{-1}$ as a descending power series in s using

$$\frac{1}{\omega^2+4s^2}=\frac{1}{4s^2}-\frac{\omega^2}{16s^4}+\frac{\omega^4}{64s^6}+\cdots, \tag{A44}$$

and the expressions

$$
\begin{aligned}
I_1 &= 4\int_0^\infty \exp\left(-\frac{s}{2}\omega^2\right)\frac{s}{\omega^2+4s^2}\cos\left(\frac{\omega^3}{6}\right)\mathrm{d}\omega \\
&= \frac{1}{s}\int_0^\infty \exp\left(-\frac{s}{2}\omega^2\right)\cos\left(\frac{\omega^3}{6}\right)d\omega - \frac{1}{4s^3}\int_0^\infty \exp\left(-\frac{s}{2}\omega^2\right)\omega^2\cos\left(\frac{\omega^3}{6}\right)\mathrm{d}\omega \\
&\quad + \frac{1}{16s^5}\int_0^\infty \exp\left(-\frac{s}{2}\omega^2\right)\omega^4\cos\left(\frac{\omega^3}{6}\right)\mathrm{d}\omega + \cdots \\
&= \frac{1}{s}\int_0^\infty \exp\left(-\frac{s}{2}\omega^2\right)\left(1-\frac{1}{72}\omega^6+\frac{1}{31104}\omega^{12}+\cdots\right)\mathrm{d}\omega \\
&\quad - \frac{1}{4s^3}\int_0^\infty \exp\left(-\frac{s}{2}\omega^2\right)\left(\omega^2-\frac{1}{72}\omega^8+\frac{1}{31104}\omega^{14}+\cdots\right)\mathrm{d}\omega + \frac{1}{16s^5} \\
&\quad \times \int_0^\infty \exp\left(-\frac{s}{2}\omega^2\right)\left(\omega^4-\frac{1}{72}\omega^{10}+\frac{1}{31104}\omega^{16}+\cdots\right)\mathrm{d}\omega + \cdots \\
&\sim \sqrt{2\pi}\left[\tfrac{1}{2}s^{-(3/2)} - \tfrac{11}{48}s^{-(9/2)} + \tfrac{1021}{2304}s^{-(15/2)}\right],
\end{aligned}
\tag{A45}
$$

$$
\begin{aligned}
I_2 &= -2\int_0^\infty \exp\left(-\frac{s}{2}\omega^2\right)\frac{\omega}{\omega^2+4s^2}\sin\left(\frac{\omega^3}{6}\right)\mathrm{d}\omega \\
&= -\frac{1}{2s^2}\int_0^\infty \exp\left(-\frac{s}{2}\omega^2\right)\omega\sin\left(\frac{\omega^3}{6}\right)\mathrm{d}\omega + \frac{1}{8s^4}\int_0^\infty \exp\left(-\frac{s}{2}\omega^2\right)\omega^3\sin\left(\frac{\omega^3}{6}\right)\mathrm{d}\omega \\
&\quad + \frac{1}{32s^6}\int_0^\infty \exp\left(-\frac{s}{2}\omega^2\right)\omega^5\sin\left(\frac{\omega^3}{6}\right)\mathrm{d}\omega \\
&\sim \sqrt{2\pi}\left[-\tfrac{1}{8}s^{-(9/2)} + \tfrac{65}{192}s^{-(15/2)} - \tfrac{12145}{9216}s^{-(21/2)}\right].
\end{aligned}
\tag{A46}
$$

Therefore,

$$
Q_{0,-1} = I_1 + I_2 \sim \sqrt{2\pi}\left[\tfrac{1}{2}s^{-(3/2)} - \tfrac{17}{48}s^{-(9/2)} + \tfrac{1801}{2304}s^{-(15/2)}\right]. \tag{A47}
$$

All four of these asymptotic expansions enjoy a very rapid increase in the order of the terms, as each exponent is 3 less than the previous. The condition for these to be a good approximation is therefore not merely that s be large, but the much less restrictive $s^3 \gg 1$.

In principle, these asymptotic expansions may be used to obtain asymptotic expansions for any $Q_{k,m}$, since any $Q_{k,m}$ may be represented as a finite combination of these four basic functions. In practice, however, low-order terms frequently cancel and higher-order terms must be derived to get a useful expansion for these integrals. For this reason, we derive from first principles a leading-order asymptotic expression for these integrals in the more general case of $k \geqslant 0$. In this case, we can apply Murray's extension to Watson's lemma directly to the definition of $Q_{k,m}$,

$$
Q_{k,m} = \mathrm{i}^{-k-m}\int_{-\infty}^\infty \exp\left(-\frac{s}{2}\omega^2\right)\exp\left(\mathrm{i}\frac{\omega^3}{6}\right)\omega^k(\omega+2\mathrm{i}s)^m\mathrm{d}\omega. \tag{A48}
$$

When $k \geqslant 0$, the portion of the integrand outside the first exponential admits a Maclaurin series. While we cannot, in general, immediately apply Murray's extension, due to the dependence on s outside the exponential, we may expand $(\omega+2\mathrm{i}s)^m$ in a descending power series in s prefixed by a power of s,

$$(\omega+2\mathrm{i}s)^m=(2\mathrm{i}s)^m\left(1+\frac{\omega}{2\mathrm{i}s}\right)^m=(2\mathrm{i}s)^m\left(1+\frac{m\omega}{2\mathrm{i}s}+\cdots\right). \tag{A49}$$

Using this, we can expand the integral in terms of integrals suitable for applying Murray's extension,

$$\begin{aligned}Q_{k,m}&=\mathrm{i}^{-k-m}(2\mathrm{i}s)^m\int_{-\infty}^{\infty}\exp\left(-\frac{s}{2}\omega^2\right)\exp\left(\mathrm{i}\frac{\omega^3}{6}\right)\omega^k\left(1+\frac{m\omega}{2\mathrm{i}s}+\cdots\right)\mathrm{d}\omega\\&=\mathrm{i}^{-k-m}(2\mathrm{i}s)^m\int_{-\infty}^{\infty}\exp\left(-\frac{s}{2}\omega^2\right)\exp\left(\mathrm{i}\frac{\omega^3}{6}\right)\omega^k\mathrm{d}\omega+\mathrm{i}^{-k-m}m(2\mathrm{i}s)^{m-1}\\&\quad\times\int_{-\infty}^{\infty}\exp\left(-\frac{s}{2}\omega^2\right)\exp\left(\mathrm{i}\frac{\omega^3}{6}\right)\omega^{k+1}\mathrm{d}\omega+\cdots.\end{aligned} \tag{A50}$$

The later integrals (in the $\cdots$) do not contribute in the leading order, since they have both a higher leading-order power of ω in the integrand and a higher power of s in the denominator of the coefficient, both of which lower the leading order of the integral in s.

Since the leading order of $\exp(\mathrm{i}\omega^3/6)$ is 1, and only even-powered terms contribute asymptotically, only one of the integrals in (A50) contributes in the leading order, the first if k is even, and the second if k is odd.

If k is even, we have the asymptotic form,

$$Q_{k,m}\sim(-)^{k/2}\sqrt{2\pi}2^m[1\times3\times\cdots\times(k-1)]s^{-(k/2)+m-(1/2)}, \tag{A51}$$

and if k is odd

$$Q_{k,m}\sim(-)^{(k+1)/2}\sqrt{2\pi}m2^{m-1}[1\times3\times\cdots\times k]s^{-[(k+1)/2]+m-(1/2)}. \tag{A52}$$

There are several important things that we can learn from this expansion. First, if k is even and $m>(k/2)+(1/2)$, or if k is odd and $m>(k/2)+1$ the integrals actually increase without bound as $s\to\infty$. Secondly, as k becomes larger, the integral decays at a faster rate. This is to be expected, since, for large k, the factor of ω^k "forces" the slowly-varying part of the integrand away from 0—the most important part of the integral asymptotically (see Fig. 7). We will use this fact later to prove that higher-order terms in the expansion for the semiclassical Coulomb integrals are actually insignificant.

Armed with these facts, we are ready to tackle the $E1$ semiclassical Coulomb integrals.

JOURNAL OF MATHEMATICAL PHYSICS VOLUME 42, NUMBER 8 AUGUST 2001

Singular and nonsingular eigenvectors for the Gaudin model

Daniela Garajeu and Annamaria Kiss[a)]
CNRS Luminy, Centre de Physique Théorique, Case 907, F-13288 Marseille Cedex 9, France

(Received 12 March 2001; accepted for publication 28 March 2001)

We present a method to construct a basis of singular and nonsingular common eigenvectors for Gaudin Hamiltonians in a tensor product module of the Lie algebra $SL(2)$. The subset of singular vectors is completely described by analogy with covariant differential operators. The relation between singular eigenvectors and the Bethe Ansatz is discussed. In each weight subspace the set of singular eigenvectors is completed to a basis, by a family of nonsingular eigenvectors. We discuss also the generalization of this method to the case of an arbitrary Lie algebra. © *2001 American Institute of Physics.* [DOI: 10.1063/1.1379750]

I. INTRODUCTION

The Gaudin model[1] is an example of an integrable system in statistical quantum mechanics, associated to N spin particles with magnetic interaction, based on N independent and commuting Hamiltonians. As originally formulated, this model is related to the Lie algebra $SL(2)$. In this simplest case, the problem of the diagonalization of the Hamiltonians was partially solved. Using a constructive method, known as Bethe Ansatz, Gaudin[2] constructed a family of common eigenvectors for all Hamiltonians.

More generally, integrable systems can be associated to any semi-simple complex Lie algebra. For such systems, generalizations of the set of Gaudin Hamiltonians have been constructed.[3] The methods proposed for diagonalization of these Hamiltonians revealed remarkable connections between integrable models and two dimensional conformal field theories.

In Ref. 3, the structure of the Bethe vectors for the Gaudin model is related to the representation theory of affine Lie algebras. The diagonalization of Gaudin Hamiltonians is based on a concept of invariant functionals (correlation functions) on tensor products of representations of an affine Lie algebra at the critical level.

Another approach for the problem of diagonalization,[4,5] is related to the connection between eigenvectors of the Gaudin Hamiltonians and the solutions[6] of the Knizhnik–Zamolodchikov equations.[7] In this approach, the common eigenvectors are constructed inductively and each eigenvector leads to an integral solution of the KZ equations. Conversely, in Ref. 8 it was proved that in the quasi-classical limit, the first term of the asymptotic solutions of KZ equation leads to a common eigenvector of the Hamiltonians. In this case the Bethe equations for the Gaudin model appear as conditions of critical points.

In Sec. II we review some aspects concerning the Gaudin model, originally formulated for the Lie algebra $SL(2)$. We recall the expression of the N Hamiltonians, introduced by Gaudin. The space Ω of physical states is defined as a tensor product of N finite-dimensional highest weight representations of the Lie algebra $SL(2)$. It is decomposed as a direct sum of weight subspaces, i.e., $\Omega = \oplus \mathcal{V}_m$. We explain how the Bethe Ansatz works to construct common eigenvectors for Gaudin Hamiltonians in each eigenspace $\mathcal{V}_m$. However, this method cannot give all the common eigenvectors of Gaudin Hamiltonians. Therefore, supplementary common eigenvectors have to be determined.

a)Electronic mail: kiss@cpt.univ-mrs.fr

In Sec. III we give a general, recursive method to construct a basis of common eigenvectors in each invariant subspace $\mathcal{V}_m$. Knowing a basis of $\mathcal{V}_{m-1}$, we construct a family of linear independent common eigenvectors in $\mathcal{V}_m$, which are nonsingular. This family is completed to a basis of $\mathcal{V}_m$, by a basis of the subspace of singular vectors of $\mathcal{V}_m$. Using an analog of the Gordan operator,[9] we give a basis of $\mathrm{Sing}\,\mathcal{V}_m$. Finally, we show that the Bethe Ansatz gives a family of singular common eigenvectors for Gaudin Hamiltonians, but in some particular cases, this family could not be complete.

Section IV is devoted to a discussion of the generalized model associated to an arbitrary simple Lie algebra. We recall the generalization of the Gaudin Hamiltonians and explain how the Bethe Ansatz was generalized to construct common eigenvectors for these Hamiltonians. We show that Bethe equations, which appear as conditions that Bethe type vectors be common eigenvectors, are also conditions of singularity for them. This constructive method does not ensure the completeness of the system of eigenvectors.

II. GAUDIN MODEL AND THE $SL(2)$ LIE ALGEBRA

The Gaudin spin model is related to the Lie algebra $SL(2)$, with generators E, F and H satisfying the commutation relations:

$$[E,F]=H; \quad [H,E]=2E; \quad [H,F]=-2F.$$

For this Lie algebra we consider N finite-dimensional highest weight modules: $V_{\lambda_1},\ldots,V_{\lambda_N}$ with highest weights $\lambda_1,\ldots,\lambda_N$ and highest weight vectors $v_{\lambda_1},\ldots,v_{\lambda_N}$. The tensor product of these N modules constitutes the space of physical states for a system of N spin particles:

$$\Omega = V_{\lambda_1}\otimes\cdots\otimes V_{\lambda_N}.$$

The Lie algebra action on each vector $v=v_1\otimes\cdots\otimes v_N$ of this tensor module is defined as

$$\mathbf{X}\,v=\sum_{i=1}^{N} X^{(i)}v, \quad \forall X\in SL(2), \tag{1}$$

where $X^{(i)}$ denotes the operator on Ω which acts as X on the ith module and as the identity operator on all other factors:

$$X^{(i)}v_1\otimes\cdots\otimes v_N=v_1\otimes\cdots\otimes Xv_i\otimes\cdots\otimes v_N, \quad \forall v_1\otimes\cdots\otimes v_N\in\Omega. \tag{2}$$

For such a system of N spin particles, Gaudin proposed a set of N Hamiltonians defined on Ω, depending on N distinct, complex parameters $z_1,\ldots,z_N$:

$$\mathcal{H}_i(z_1,\ldots,z_N)=\sum_{j=1,j\neq i}^{N}\frac{1}{z_i-z_j}\left[\frac{1}{2}H^{(i)}H^{(j)}+E^{(i)}F^{(j)}+F^{(i)}E^{(j)}\right], \quad \forall i=1,\ldots,N. \tag{3}$$

All these operators commute:

$$[\mathcal{H}_i,\mathcal{H}_j]=0, \quad \forall i,j=1,\ldots,N,$$

but they are not independent, because $\Sigma_{i=1}^{N}\mathcal{H}_i=0$. It can easily be verified that among the N Gaudin Hamiltonians there are exactly $N-1$ which are independent. To integrate a system of N spin particles, with N degrees of freedom, the family of commuting operators is completed by the Cartan generator (also called the total spin operator), of which action on the tensor module is

$$\mathbf{H}\,v=\sum_{i=1}^{N} H^{(i)}v, \quad \forall v\in\Omega,$$

and which commutes with all Gaudin Hamiltonians.

For this family of N independent Hamiltonians which commute there is a complete system of common eigenvectors in Ω. Our goal is to construct a basis in Ω, of common eigenvectors of Gaudin Hamiltonians.

A. The structure of the space Ω

In order to analyze the structure of Ω it is useful to recall some elements of the theory of highest weight representations of the Lie algebra $SL(2)$. Such a representation is completely determined by a highest weight vector v_λ, on which the action of the algebra is given by

$$Hv_\lambda=\lambda v_\lambda, \quad Ev_\lambda=0,$$

and the representation space is generated by vectors:

$$\{v_n=F^n v_\lambda\}_{n\in\mathbb{N}}.$$

The action of the Lie algebra on these vectors is

$$Hv_n=(\lambda-2n)v_n, \tag{4}$$

$$Ev_n=n(\lambda-n+1)v_{n-1}, \tag{5}$$

$$Fv_n=v_{n+1}. \tag{6}$$

If the highest weight λ is not a positive integer, the representation is infinite dimensional and irreducible. If $\lambda\in\mathbb{N}$, then in $\{v_n=F^n v_\lambda\}_{n\in\mathbb{N}}$ there is an invariant subspace, generated by $\{v_{\lambda+1}, v_{\lambda+2}, \dots\}$ and the quotient representation is irreducible and finite dimensional, of dimension $\lambda+1$, generated by vectors $\{v_n=F^n v_\lambda\}_{n=0,\dots,\lambda}$. We denote V_λ this quotient representation, for which we have $F^n v_\lambda=0$ for all $n\geqslant\lambda+1$.

We will consider the space Ω as a tensor product of finite-dimensional representations V_λ, which is completely determined by the vector $v_0=v_{\lambda_1}\otimes\cdots\otimes v_{\lambda_N}$, called vacuum vector and is generated by vectors $\{F^{n_1}v_{\lambda_1}\otimes F^{n_2}v_{\lambda_2}\cdots\otimes F^{n_N}v_{\lambda_N}\}_{n_i=0,\dots,\lambda_i;i=1,\dots,N}$, with n_i operators F applied on the ith component. Such a vector can be written as a product of $m=n_1+n_2+\cdots+n_N$ operators of type (2), denoted

$$v_m^{(k_1,\dots,k_m)}=F^{(k_1)}F^{(k_2)}\cdots F^{(k_m)}v_0,$$

with $1\leqslant k_1\leqslant\cdots\leqslant k_m\leqslant N$. Note that for finite-dimensional representations, m can vary between 0 and a maximal value $m_{\max}=\Sigma_{i=1}^N\lambda_i$.

Note also the particular action of the Hamiltonians on the vacuum vector:

$$\mathbf{H}v_0=\left(\sum_{k=1}^N\lambda_k\right)v_0, \quad \mathcal{H}_i v_0=\left(\frac{1}{2}\sum_{j=1,j\neq i}^N\frac{\lambda_i\lambda_j}{z_i-z_j}\right)v_0. \tag{7}$$

The Cartan operator $\mathbf{H}$ has a privileged place in the family of commuting Hamiltonians. According to (4), it gives a gradation of the representation spaces V_{λ_i}, which induces a gradation of the tensor product module, on $\mathbf{H}$-invariant subspaces:

$$\Omega=\oplus_{m=0}^{m_{\max}}\mathcal{V}_m,$$

where $\mathcal{V}_m$ is a weight subspace, of weight $\Sigma_{i=1}^N\lambda_i-2m$, also called space of spin deviation m. It is generated by $\mathbf{H}$-eigenvectors:

$$\{v_m^{(k_1,\ldots,k_m)}=F^{(k_1)}\cdots F^{(k_m)}v_0\}_{1\leqslant k_1\leqslant\cdots\leqslant k_m\leqslant N}, \tag{8}$$

which we call states of spin deviation m:

$$\mathbf{H}F^{(k_1)}F^{(k_2)}\cdots F^{(k_m)}v_0=\left(\sum_{i=1}^{N}\lambda_i-2m\right)F^{(k_1)}F^{(k_2)}\cdots F^{(k_m)}v_0.$$

Note that for spin deviations $m\leqslant\min\{\lambda_1,\ldots,\lambda_N\}$, a subspace $\mathcal{V}_m$ has the dimension

$$\dim\mathcal{V}_m=\sum_{1\leqslant k_1\leqslant\cdots\leqslant k_m\leqslant N}1=\sum_{1\leqslant j_1<\cdots<j_m\leqslant N+m-1}1=C_{N+m-1}^{m}. \tag{9}$$

From the explicit form of the Gaudin Hamiltonians (3) and from the action (4)–(6) of the $SL(2)$ Lie algebra on the spaces V_{λ_i}, it follows that the weight subspaces $\mathcal{V}_m$ are invariant under the action of any $\mathcal{H}_i$. Therefore, in each subspace $\mathcal{V}_m$, we can construct a basis of common eigenvectors of $\mathcal{H}_i$.

B. The construction of common eigenvectors by Bethe Ansatz

Bethe Ansatz is a method to construct a family of common eigenvectors for Gaudin Hamiltonians in each invariant subspace $\mathcal{V}_m$, but this family is not a basis of $\mathcal{V}_m$.

Since $\mathcal{V}_m$ is generated by (8), any common eigenvector in $\mathcal{V}_m$ has the form

$$\psi_m=\sum_{k_1=1}^{N}\cdots\sum_{k_m=1}^{N}c_{k_1\cdots k_m}F^{(k_1)}\cdots F^{(k_m)}v_0.$$

The central idea of the Bethe method is to consider the coefficients $c_{k_1\cdots k_m}$ as rational complex functions:

$$c_{k_1\cdots k_m}=\frac{1}{w_1-z_{k_1}}\cdots\frac{1}{w_m-z_{k_m}},$$

depending on some unknown, distinct, complex parameters: $w_1,\ldots,w_m$. We call such a vector a Bethe vector. Hereafter we shortly present this method.

1. Bethe vectors of spin deviation m=1

The eigenspace $\mathcal{V}_1$ is generated by vectors $\{F^{(k)}v_0\}_{k=1,\ldots,N}$. A Bethe vector of spin deviation $m=1$ is defined as an expansion on this basis, with rational coefficients depending on one complex parameter w:

$$\psi_1(w)=\mathcal{F}(w)v_0,$$

where we denoted by $\mathcal{F}(w)$ the operator on Ω:

$$\mathcal{F}(w)=\sum_{k=1}^{N}\frac{1}{w-z_k}F^{(k)}. \tag{10}$$

Straightforward calculations give the commutator

$$[\mathcal{H}_i,\mathcal{F}(w)]=\mathcal{F}(w)\frac{H^{(i)}}{(w-z_i)}-\frac{F^{(i)}}{(w-z_i)}\sum_{k=1}^{N}\frac{H^{(k)}}{w-z_k}. \tag{11}$$

Applying this operator on v_0 and using (7) we obtain the action of a Gaudin Hamiltonian $\mathcal{H}_i$ on $\psi_1(w)$:

$$\mathcal{H}_i\,\psi_1(w)=\left(\frac{1}{2}\sum_{j=1;j\neq i}^{N}\frac{\lambda_i\lambda_j}{z_i-z_j}+\frac{\lambda_i}{w-z_i}\right)\psi_1(w)-\left(\sum_{k=1}^{N}\frac{\lambda_k}{w-z_k}\right)\frac{F^{(i)}}{w-z_i}v_0,$$

and we have the following lemma.

Lemma 1: Given N distinct complex numbers $\{z_i\}_{i=1,\ldots,N}$ *and fixed, positive, integer highest weights* $\{\lambda_i\}_{i=1,\ldots,N}$, *the Bethe vector* $\psi_1(w)$ *of spin deviation* $m=1$ *is an eigenvector for all Gaudin Hamiltonians:*

$$\mathcal{H}_i\,\psi_1(w)=s_i^1\,\psi_1(w),\quad \forall i=1,\ldots,N,$$

if the complex parameter w satisfies the condition

$$\sum_{k=1}^{N}\frac{\lambda_k}{w-z_k}=0, \tag{12}$$

called Bethe equation associated to $\mathcal{V}_1$. *The eigenvalue* s_i^1 *of* $\mathcal{H}_i$, *depends on the solution w of this equation:*

$$s_i^1(w)=\frac{1}{2}\sum_{j=1;j\neq i}^{N}\frac{\lambda_i\lambda_j}{z_i-z_j}+\frac{\lambda_i}{w-z_i}.$$

2. Bethe vectors of spin deviation m=2

The eigenspace $\mathcal{V}_2$ is generated by vectors $\{F^{(k_1)}F^{(k_2)}v_0\}_{1\leqslant k_1\leqslant k_2\leqslant N}$. A Bethe vector of spin deviation $m=2$ is defined as an expansion on this basis, with rational coefficients depending on two complex parameters w_1, w_2:

$$\psi_2(w_1,w_2)=\mathcal{F}(w_1)\mathcal{F}(w_2)v_0.$$

Remark that the order of the two operators $\mathcal{F}$ is not significant because they commute.

In order to compute the action of a Hamiltonian on this state, we have to commute $\mathcal{H}_i$ successively with the two operators $\mathcal{F}$. Using (11) we obtain the commutator formula:

$$[[\mathcal{H}_i,\mathcal{F}(w_1)],\mathcal{F}(w_2)]=\frac{2}{w_1-w_2}\left(\frac{F^{(i)}}{w_1-z_i}\mathcal{F}(w_2)-\frac{F^{(i)}}{w_2-z_i}\mathcal{F}(w_1)\right). \tag{13}$$

From (11) and (13) the action of a Gaudin Hamiltonian $\mathcal{H}_i$ on the state ψ_2 is

$$\begin{aligned}\mathcal{H}_i\,\psi_2(w_1,w_2)=&\left(\frac{1}{2}\sum_{j=1;j\neq i}^{N}\frac{\lambda_i\lambda_j}{z_i-z_j}+\frac{\lambda_i}{w_1-z_i}+\frac{\lambda_i}{w_2-z_i}\right)\psi_2(w_1,w_2)-\left(\sum_{k=1}^{N}\frac{\lambda_k}{w_1-z_k}+\frac{2}{w_2-w_1}\right)\\&\times\frac{F^{(i)}}{w_1-z_i}\psi_1(w_2)-\left(\sum_{k=1}^{N}\frac{\lambda_k}{w_2-z_k}+\frac{2}{w_1-w_2}\right)\frac{F^{(i)}}{w_2-z_i}\psi_1(w_1),\end{aligned}$$

and we have the following lemma.

Lemma 2: The Bethe vector $\psi_2(w_1,w_2)$ *of spin deviation* $m=2$ *is an eigenvector for all Gaudin Hamiltonians:*

$$\mathcal{H}_i\,\psi_2(w_1,w_2)=s_i^2\,\psi_2(w_1,w_2),\quad \forall i=1,\ldots,N,$$

if the complex parameters w_1, w_2 *satisfy the Bethe equations associated to* $\mathcal{V}_2$:

$$\sum_{k=1}^{N}\frac{\lambda_k}{w_1-z_k}+\frac{2}{w_2-w_1}=0,\quad \sum_{k=1}^{N}\frac{\lambda_k}{w_2-z_k}+\frac{2}{w_1-w_2}=0. \tag{14}$$

The eigenvalues s_i^2 *depend on the solutions* w_1, w_2 *of these equations:*

$$s_i^2(w_1,w_2)=\frac{1}{2}\sum_{j=1;j\neq i}^{N}\frac{\lambda_i\lambda_j}{z_i-z_j}+\frac{\lambda_i}{w_1-z_i}+\frac{\lambda_i}{w_2-z_i}.$$

3. Bethe vectors of spin deviation m

In the subspace $\mathcal{V}_m$, generated by vectors $\{F^{(k_1)}\cdots F^{(k_m)}v_0\}_{1\leqslant k_1\leqslant\cdots\leqslant k_m\leqslant N}$, a Bethe vector of spin deviation m is defined as an expansion with coefficients depending on m complex parameters $w_1,\ldots,w_m$:

$$\psi_m(w_1,\ldots,w_m)v_0=\mathcal{F}(w_1)\cdots\mathcal{F}(w_m)v_0. \tag{15}$$

The action of a Gaudin Hamiltonian $\mathcal{H}_i$ on this state is calculated by induction on m:

$$\begin{aligned}\mathcal{H}_i\,\psi_m(w_1,\ldots,w_m)v_0&=\mathcal{H}_i\,\mathcal{F}(w_m)\psi_{m-1}(w_1,\ldots,w_{m-1})v_0\\&=\mathcal{F}(w_m)\mathcal{H}_i\psi_{m-1}(w_1,\ldots,w_{m-1})v_0+\psi_{m-1}(w_1,\ldots,w_{m-1})\\&\quad\times[\mathcal{H}_i,\mathcal{F}(w_m)]v_0+[[\mathcal{H}_i,\mathcal{F}(w_m)],\psi_{m-1}(w_1,\ldots,w_{m-1})]v_0.\end{aligned}$$

The first term is computed from the induction hypothesis, the second from (11) and the last term from relation (13). Putting all together it follows that

$$\begin{aligned}\mathcal{H}_i\,\psi_m(w_1,\ldots,w_m)v_0=&\left(\frac{1}{2}\sum_{j=1;j\neq i}^{N}\frac{\lambda_i\lambda_j}{z_i-z_j}+\sum_{k=1}^{m}\frac{\lambda_i}{w_k-z_i}\right)\psi_m(w_1,\ldots,w_m)v_0\\&-\sum_{k=1}^{m}\left(\sum_{j=1}^{N}\frac{\lambda_j}{w_k-z_j}+\sum_{l=1;l\neq k}^{m}\frac{2}{w_l-w_k}\right)\frac{F^{(i)}}{w_k-z_i}\psi_{m-1}(\ldots,\hat{w}_k,\ldots)v_0,\end{aligned} \tag{16}$$

where $\psi_{m-1}(\ldots,\hat{w}_k,\ldots)$ denotes $\psi_{m-1}(w_1,\ldots,w_{k-1},w_{k+1},\ldots,w_m)$. Hence, we obtain the following theorem.

Theorem 3: *The Bethe vector* $\psi_m(w_1,\ldots,w_m)v_0$ *of spin deviation* m *is a common eigenvector for all Gaudin Hamiltonians:*

$$\mathcal{H}_i\,\psi_m(w_1,\ldots,w_m)v_0=s_i^m\,\psi_m(w_1,\ldots,w_m)v_0,\quad\forall i=1,\ldots,N,$$

if the complex parameters $w_1,\ldots,w_m$ *satisfy the Bethe equations associated to* $\mathcal{V}_m$:

$$\sum_{j=1}^{N}\frac{\lambda_j}{w_k-z_j}+\sum_{l=1;l\neq k}^{m}\frac{2}{w_l-w_k}=0,\quad\forall\,k=1,\ldots,m. \tag{17}$$

The eigenvalues s_i^m *depend on the solution of these equations:*

$$s_i^m(w_1,\ldots,w_m)=\frac{1}{2}\sum_{j=1;j\neq i}^{N}\frac{\lambda_i\lambda_j}{z_i-z_j}+\sum_{k=1}^{m}\frac{\lambda_i}{w_k-z_i}.$$

As observed in Ref. 10, the Bethe Ansatz does not give all the common eigenvectors of Gaudin Hamiltonians. Therefore, supplementary common eigenvectors have to be determined, which will be done in the following section.

III. A CONSTRUCTION OF A BASIS OF COMMON EIGENVECTORS FOR GAUDIN HAMILTONIANS

In this section we give a general method to construct a basis of common eigenvectors in each invariant subspace $\mathcal{V}_m$. This is a recursive method, which will be applied for subspaces $\mathcal{V}_m$, with $m \leqslant \min\{\lambda_1, \ldots, \lambda_N\}$. Knowing a basis of $\mathcal{V}_{m-1}$, we construct a family of linear independent common eigenvectors in $\mathcal{V}_m$, which are nonsingular. This family is completed to a basis of $\mathcal{V}_m$ by a basis of the subspace of singular vectors of $\mathcal{V}_m$.

There are two important properties of Gaudin Hamiltonians which are useful in this section, namely they commute with the operators **E** and **F**, on the tensor product module:

$$[\mathcal{H}_i, \mathbf{E}] = 0, \tag{18}$$

$$[\mathcal{H}_i, \mathbf{F}] = 0, \tag{19}$$

where **E** and **F** are defined by (1) as

$$\mathbf{E} = \sum_{i=1}^{N} E^{(i)}, \quad \mathbf{F} = \sum_{i=1}^{N} F^{(i)}.$$

Definition 4: We call $v^s \in \Omega$ a singular vector of Ω if the generator **E** *acts trivially on v^s,*

$$\mathbf{E}\, v^s = 0.$$

We denote Sing *V the subspace of singular vectors in V.*

It was shown in Ref. 11 that the dimension of the subspace $\mathrm{Sing}\,\mathcal{V}_m$ is

$$\dim(\mathrm{Sing}\,\mathcal{V}_m) = C^m_{m+N-2}. \tag{20}$$

Since according to (9), for $m \leqslant \min\{\lambda_1, \ldots, \lambda_N\}$ the dimension of the space $\mathcal{V}_m$ is C^m_{m+N-1}, it follows that a basis of $\mathrm{Sing}\,\mathcal{V}_m$ can be completed to a basis of $\mathcal{V}_m$, by a family of C^{m-1}_{m+N-2} nonsingular linear independent vectors. The space spanned by this family of nonsingular vectors is denoted $\mathrm{NonSing}\,\mathcal{V}_m$. Hence,

$$\mathcal{V}_m = \mathrm{Sing}\,\mathcal{V}_m \oplus \mathrm{NonSing}\,\mathcal{V}_m.$$

From the property (18) we obtain the following.

Lemma 5: $\mathrm{Sing}\,\mathcal{V}_m$ *is a C^m_{m+N-2}-dimensional vector subspace of $\mathcal{V}_m$ and it is $\mathcal{H}_i$-invariant:*

$$\mathcal{H}_i(\mathrm{Sing}\,\mathcal{V}_m) \subseteq \mathrm{Sing}\,\mathcal{V}_m, \quad \forall\, i = 1, \ldots, N.$$

Then $\mathrm{Sing}\,\mathcal{V}_m$ admits a basis formed by singular common eigenvectors of Gaudin Hamiltonians $\mathcal{H}_i$. Denote $\mathcal{B}^s_m$ this basis.

From the property (19) of the Gaudin Hamiltonians we can construct recursively a basis of common eigenvectors in $\mathrm{NonSing}\,\mathcal{V}_m$:

Proposition 6: The basis of common eigenvectors in $\mathrm{NonSing}\,\mathcal{V}_m$ *is obtained by the application of the operator* **F** *on all common eigenvectors (singular and nonsingular) which form the basis of the invariant subspace $\mathcal{V}_{m-1}$. Denote $\mathcal{B}^{ns}_m$ this basis:*

$$\mathcal{B}^{ns}_m = \mathbf{F}(\mathcal{B}_{m-1}),$$

where $\mathcal{B}_{m-1}$ is a basis of common eigenvectors of $\mathcal{V}_{m-1}$.

Proof: (1) The vectors of $\mathcal{B}^{ns}_m$ are linear independent. Indeed, for $m \leqslant \min\{\lambda_1, \ldots, \lambda_N\}$ the operator $\mathbf{F}: \mathcal{V}_{m-1} \to \mathcal{V}_m$ is injective, since $\mathrm{Ker}\,\mathbf{F} = \{0\}$. Moreover, the injectivity of **F** implies that the number of elements of the family $\mathcal{B}^{ns}_m$ is equal to the dimension of $\mathcal{V}_{m-1}$, namely C^{m-1}_{m+N-2}.

(2) The vectors of $\mathcal{B}_m^{ns}$ are common eigenvectors of $\mathcal{H}_i$. If $v_{m-1} \in \mathcal{B}_{m-1}$ is a common eigenvector:

$$\mathcal{H}_i v_{m-1} = a_{m-1}^i v_{m-1},$$

then, from the property (19) it follows that the vector $v_m = \mathbf{F} v_{m-1} \in \mathcal{B}_m^{ns}$ is also an eigenvector, with the same eigenvalue a_{m-1}^i.

(3) The vectors of $\mathcal{B}_m^{ns}$ are nonsingular.

Note first that in $\mathcal{V}_0$ there is only one vector, the vacuum vector v_0. Thus, there is one common eigenvector $v_1 = \mathbf{F} v_0$ in the family $\mathcal{B}_1^{ns}$, which is indeed nonsingular:

$$\mathbf{E} v_1 = \mathbf{E}\mathbf{F} v_0 = \mathbf{H} v_0 = \left(\sum_{i=1}^{N} \lambda_i \right) v_0 \neq 0.$$

Now suppose by induction that for all $k \leqslant m-1$, with $m \leqslant \min\{\lambda_1, \ldots, \lambda_N\}$, we have constructed a basis of $\mathcal{V}_k$ of the form $\mathcal{B}_k^s \cup \mathcal{B}_k^{ns}$, where $\mathcal{B}_k^{ns}$ is obtained by application of the operator $\mathbf{F}$ on vectors of the basis $\mathcal{B}_{k-1}$ of $\mathcal{V}_{k-1}$. Then for a vector v_m^{ns} of $\mathcal{B}_m^{ns}$ we have

$$\mathbf{E} v_m^{ns} = \mathbf{E}\mathbf{F} v_{m-1} = \mathbf{H} v_{m-1} + \mathbf{F}\mathbf{E} v_{m-1} = \left(\sum_{i=1}^{N} \lambda_i - 2(m-1) \right) v_{m-1} + \mathbf{F}\mathbf{E} v_{m-1}. \tag{21}$$

If v_{m-1} is singular, then the last term of (21) vanishes and v_m^{ns} is nonsingular, since

$$\sum_{i=1}^{N} \lambda_i - 2(m-1) \geqslant Nm - 2(m-1) > 0, \quad \forall\, N \geqslant 2.$$

If v_{m-1} is nonsingular, then by the induction hypothesis, there is a $k \in \{1, \ldots, m-1\}$ such that $v_{m-1} = \mathbf{F}^k v_{m-1-k}^s$ with v_{m-1-k}^s a common singular eigenvector of $\mathcal{B}_{m-1-k}^s$. Then relation (21) becomes

$$\mathbf{E} v_m^{ns} = (k+1) \left(\sum_{i=1}^{N} \lambda_i - 2(m-1) + k \right) v_{m-1} \neq 0, \quad \forall\, N \geqslant 2. \tag{22}$$

(4) The vectors of $\mathcal{B}_m^{ns}$ are linear independent of the singular vectors of the basis $\mathcal{B}_m^s$. Consider a null linear combination of the vectors $v_m^{ns}(i) \in \mathcal{B}_m^{ns}$ and $v_m^s(j) \in \mathcal{B}_m^s$:

$$\sum_i a(i)\, v_m^{ns}(i) + \sum_j b(j)\, v_m^s(j) = 0.$$

Applying the operator $\mathbf{E}$, the second sum (of singular vectors) vanishes. Hence,

$$\sum_i a(i)\, \mathbf{E} v_m^{ns}(i) = 0.$$

It follows from (22) that each vector $\mathbf{E} v_m^{ns}(i)$ is colinear with the vector $v_{m-1}(i)$, which form the basis of $\mathcal{V}_{m-1}$. Then, the coefficients $a(i)$ are all zero. Since $v_m^s(j)$ form also a basis, in $\mathrm{Sing}\, \mathcal{V}_m$, the coefficients $b(j)$ vanish too.

Properties (1)–(4) from above show that $\mathcal{B}_m^{ns} = \mathbf{F}(\mathcal{B}_{m-1})$ is a basis of $\mathrm{NonSing}\, \mathcal{V}_m$ and then $\mathcal{B}_m^{ns} \cup \mathcal{B}_m^s$ is a basis of common eigenvectors in $\mathcal{V}_m$. In this basis, the sub-family $\mathcal{B}_m^{ns}$ is completely determined by Proposition 6, whereas for the subset of singular vectors $\mathcal{B}_m^s$ we have only the existence Lemma 5 and not the structure. In the next section we will characterize the singular vectors of a tensor product module of $SL(2)$.

A. Singular vectors of the $SL(2)$ tensor modules

For a finite-dimensional highest weight module V_λ of the Lie algebra $SL(2)$ there is only one singular vector: the highest weight vector v_λ. Nevertheless, for tensor product modules $\Omega=\otimes_{i=1}^{N} V_{\lambda_i}$ the vacuum vector $v_0=\otimes_{i=1}^{N} v_{\lambda_i}$ is not the only singular vector. There exist singular vectors in every subspace $\mathcal{V}_m$.

1. The case N=2

Consider first $N=2$ and $\Omega=V_{\lambda_1}\otimes V_{\lambda_2}$ with the decomposition on invariant subspaces $\Omega=\oplus_{m=0}^{m_{\max}}\mathcal{V}_m$. In this case an invariant subspace $\mathcal{V}_m$ is generated by vectors:

$$\{F^k v_{\lambda_1}\otimes F^{m-k} v_{\lambda_2}\}_{k=0,m},$$

and the singular vectors of such a subspace are characterized by the following proposition.

Proposition 7: Let $\mathcal{V}_m$ be an invariant subspace of $\Omega=V_{\lambda_1}\otimes V_{\lambda_2}$, with $m\leqslant\min\{\lambda_1,\lambda_2\}$. Then a vector $v_m^s\in\mathcal{V}_m$,

$$v_m^s=\sum_{k=0}^{m} c_k F^k v_{\lambda_1}\otimes F^{m-k} v_{\lambda_2},$$

is singular if and only if the coefficients c_k satisfy the conditions

$$c_{k+1}(k+1)(k-\lambda_1)+c_k(m-k)(m-k-1-\lambda_2)=0,\quad \forall k=0,\ldots,m-1. \tag{23}$$

The proof is based on straightforward calculation using relation (5):

$$\begin{aligned}\mathbf{E}\, v_m^s &= E^{(1)} v_m^s + E^{(2)} v_m^s \\ &= \sum_{k=0}^{m-1}\{c_{k+1}(k+1)(\lambda_1-k)+c_k(m-k)(\lambda_2+k+1-m)\}F^k v_{\lambda_1}\otimes F^{m-k-1} v_{\lambda_2}.\end{aligned}$$

Remark that the conditions (23), satisfied by the coefficients c_k, coincide with the conditions determined in Ref. 12, satisfied by the coefficients of a bilinear differential operator which is projective covariant. The system (23) was solved in this article and for $m\leqslant\min\{\lambda_1,\lambda_2\}$ it admits a unique solution (up to a constant factor):

$$c_k=(-1)^k C_m^k\frac{(m-k-\lambda_2)_k}{(-\lambda_1)_k},\quad \forall\, k=0,\ldots,m,$$

with C_m^k the binomial coefficient and $(x)_i$ the Pochhammer symbol:

$$(x)_i=x(x+1)\cdots(x+i-1),\quad \forall\, i\in\mathbb{N}^*,\quad (x)_0=1.$$

By analogy with covariant differential operators, we introduce the bilinear operator P_m defined on the subspace $\mathcal{V}_m$ of $\Omega=V_{\lambda_1}\otimes V_{\lambda_2}$ by

$$P_m(v_1\otimes v_2)=\sum_{k=0}^{m}(-1)^k C_m^k\frac{(m-k-\lambda_2)_k}{(-\lambda_1)_k}F^k v_1\otimes F^{m-k} v_2, \tag{24}$$

which is analogous to the Gordan operator.

Conclusion: In the case of $N=2$ in every invariant subspace $\mathcal{V}_m$ with $m\leqslant\min\{\lambda_1,\lambda_2\}$ there is a unique singular vector (up to a constant factor) which is

$$v_m^s = P_m(v_{\lambda_1} \otimes v_{\lambda_2}) = \sum_{k=0}^{m} (-1)^k C_m^k \frac{(m-k-\lambda_2)_k}{(-\lambda_1)_k} F^k v_{\lambda_1} \otimes F^{m-k} v_{\lambda_2}.$$

2. The case N=3

Consider now $N=3$ and $\Omega = V_{\lambda_1} \otimes V_{\lambda_2} \otimes V_{\lambda_3}$ with its decomposition on invariant subspaces. In this case, a subspace $\mathcal{V}_m$ is generated by vectors:

$$\{F^{k_1} v_{\lambda_1} \otimes F^{k_2} v_{\lambda_2} \otimes F^{m-k_1-k_2} v_{\lambda_3}\}_{\substack{k_1=0,\ldots,m \\ k_2=0,\ldots,m-k_1}},$$

and the singular vectors of this subspace are characterized by the following result.

Proposition 8: Let $\mathcal{V}_m$ be an invariant subspace of $\Omega = V_{\lambda_1} \otimes V_{\lambda_2} \otimes V_{\lambda_3}$, with $m \leqslant \min\{\lambda_1, \lambda_2, \lambda_3\}$. Then a vector v_m^s of $\mathcal{V}_m$,

$$v_m^s = \sum_{k_1=0}^{m} \sum_{k_2=0}^{m-k_1} c_{k_1 k_2} F^{k_1} v_{\lambda_1} \otimes F^{k_2} v_{\lambda_2} \otimes F^{m-k_1-k_2} v_{\lambda_3}, \tag{25}$$

is singular if and only if the coefficients $c_{k_1 k_2}$ satisfy the conditions:

$$c_{k_1+1,k_2}(k_1+1)(k_1-\lambda_1) + c_{k_1,k_2+1}(k_2+1)(k_2-\lambda_2) + c_{k_1,k_2}(m-k_1-k_2)(m-k_1-k_2-1-\lambda_3) = 0, \tag{26}$$

$\forall\, k_1 = 0,\ldots,m-1, \quad \forall\, k_2 = 0,\ldots,m-1-k_1.$

The proof is analogous to that of $N=2$. As in the case $N=2$, we note that the system (26), which has to be satisfied by the coefficients of the development (25) in order that v_m^s be singular, coincides with the conditions given in Ref. 12 for the coefficients of a trilinear differential operator which is projective covariant. The system (26) was also solved in Ref. 12 and for $m \leqslant \min\{\lambda_1, \lambda_2, \lambda_3\}$ it admits $m+1$ linear independent solutions. In addition, it was shown that the space of covariant trilinear operators is generated only by successive applications of covariant bilinear operators.

Conclusion: In the case of $N=3$ in every subspace $\mathcal{V}_m$ with $m \leqslant \min\{\lambda_1, \lambda_2, \lambda_3\}$ there are $m+1$ linear independent singular vectors:

$$\dim(\mathrm{Sing}\, \mathcal{V}_m) = m+1.$$

Moreover, using the operator on Ω introduced in (27) we can construct a basis of $\mathrm{Sing}\, \mathcal{V}_m$, given by the vectors

$$\{v_m^s = \mathbf{P}_{3,k}(\mathbf{P}_{2,m-k}(v_{\lambda_1} \otimes v_{\lambda_2}) \otimes v_{\lambda_3})\}_{k=0,\ldots,m}.$$

3. General case

The results obtained for $N=2$ and $N=3$ can be generalized for an arbitrary N. For each $N \geqslant 2$, consider the space $\Omega = \Omega^N = \Omega^{N-1} \otimes \mathcal{V}_{\lambda_N}$, where $\Omega^{N-1} = \otimes_{i=1}^{N-1} \mathcal{V}_{\lambda_i}$ and define on Ω^N the operator

$$\mathbf{P}_{N,m}(v_1 \otimes v_2) = \sum_{k=0}^{m} (-1)^k C_m^k \frac{(m-k-\lambda_2)_k}{(-\lambda_1)_k} \mathbf{F}^k v_1 \otimes F^{m-k} v_2, \quad \forall\, v_1 \in \Omega^{N-1},\, v_2 \in \mathcal{V}_{\lambda_N}, \tag{27}$$

where $\mathbf{F} = \Sigma_{i=1}^{N-1} F^{(i)}$ is defined by (1) on Ω^{N-1}. Then we have the following.

Proposition 9: Let $\mathcal{V}_m$ be an invariant subspace of Ω^N with $m \leqslant \min\{\lambda_1,\ldots,\lambda_N\}$. Then in $\mathcal{V}_m$ there is a family of C^m_{m+N-2} linear independent singular vectors, given by the formula

$$v^s_m = \mathbf{P}_{N,k}(v^s_{m-k} \otimes v_{\lambda_N}), \quad k=0,\ldots,m, \tag{28}$$

where v^s_{m-k} is a singular vector of weight $\Sigma_{i=1}^{N-1}\lambda_i - 2(m-k)$ in the basis of the subspace Sing $\mathcal{V}_{m-k}$ *of* Ω^{N-1}.

The singularity of these vectors arises from straightforward calculation analogous to the case $N=2$.

These vectors are linear independent because v^s_{m-k} are the elements of the basis of the subspace Sing $\mathcal{V}_{m-k}$ of Ω^{N-1} and for different k the maximal number of operators F applied on the last component v_{λ_N} is different.

The fact that by this construction we obtain exactly C^m_{m+N-2} linear independent singular vectors, can be demonstrated by induction with respect to N: For $N=2$ and $N=3$ this number of singular vectors was already obtained. Suppose now that for an arbitrary N the number of linear independent singular vectors v^s_{m-k} in $\mathcal{V}_{m-k}$ is $C^{m-k}_{m-k+N-2}$. Then for $N+1$, the number of linear independent singular vectors obtained by the construction (28) is

$$\sum_{k=0}^{m} C^{m-k}_{m-k+N-2} = \sum_{j=0}^{m} C^j_{j+N-2} = C^m_{m+N-1}.$$

Proposition 9 allows to construct inductively a basis in Sing $\mathcal{V}_m$ which has the form

$$\{\mathbf{P}_{N,k_{N-1}}(\ldots \mathbf{P}_{3,k_2}(\mathbf{P}_{2,k_1}(v_{\lambda_1}\otimes v_{\lambda_2})\otimes v_{\lambda_3})\cdots \otimes v_{\lambda_N})\}_{\substack{k_i=0,\ldots,m \\ k_1+k_2+\cdots+k_{N-1}=m}}. \tag{29}$$

4. Remark

We point out that in this section we have considered invariant subspaces $\mathcal{V}_m$ of Ω with spin deviation m which does not exceed any of the N weights $\lambda_i \in \mathbb{N}$:

$$m \leqslant \min\{\lambda_1,\ldots,\lambda_N\}.$$

If m is greater than at least one of the weights λ_i, then in the set

$$\{F^{n_1}v_{\lambda_1}\otimes\cdots\otimes F^{n_N}v_{\lambda_N}\}_{n_1+\cdots+n_N=m},$$

there are elements for which the number of operators F acting on v_{λ_i} is greater then λ_i. These vectors are zero because for finite-dimensional irreducible representations of $SL(2)$ we have $F^n v_\lambda = 0$, $\forall\, n \geqslant \lambda+1$. Therefore in this case the dimension of the space $\mathcal{V}_m$ is less than C^m_{m+N-1} and depends on the weights λ which are less than m.

Moreover, if m exceeds one or more of the weights λ, the dimension of the space Sing $\mathcal{V}_m$ is also less than C^m_{m+N-2}. For example, in the case $N=2$, it was shown in Ref. 12 that for $m \leqslant m_{\max}=\lambda_1+\lambda_2$, but $m>\lambda_1$ and $m>\lambda_2$ there are two independent bilinear covariant differential operators, to which correspond singular vectors of the type

$$P_{m-(1+\lambda_1)}(F^{1+\lambda_1}v_{\lambda_1}\otimes v_{\lambda_2}) \quad \text{and} \quad P_{m-(1+\lambda_2)}(v_{\lambda_1}\otimes F^{1+\lambda_2}v_{\lambda_2}),$$

which are zero in the considered finite-dimensional irreducible representations of $SL(2)$. For an arbitrary N we claim that relation (29) still gives the basis of Sing $\mathcal{V}_m$ but some of the elements of the form (29) vanish. This fact implies the decreasing of the dimension of Sing $\mathcal{V}_m$.

B. Singular common eigenvectors and Bethe Ansatz

The basis (29) of $\mathrm{Sing}\,\mathcal{V}_m$ constructed in the previous section is not a basis of common eigenvectors. In this section we show that the Bethe eigenvectors constructed in Sec. II using the Bethe Ansatz are singular, but their number could be less than the dimension of $\mathrm{Sing}\,\mathcal{V}_m$. More precisely, the Bethe equations (17), which appear in the Bethe Ansatz as conditions that Bethe type vectors (15) be common eigenvectors of $\mathcal{H}_i$ are also conditions that Bethe type vectors be singular.

Proposition 10: If the distinct parameters $w_1,\ldots,w_m$ are solutions of the Bethe system:

$$\sum_{j=1}^{N}\frac{\lambda_j}{w_k-z_j}+\sum_{l=1;l\neq k}^{m}\frac{2}{w_l-w_k}=0,\quad \forall\, k=1,\ldots,m, \tag{30}$$

then the corresponding Bethe type vector $\psi_m(w_1,\ldots,w_m)\,v_0=\mathcal{F}(w_1)\cdots\mathcal{F}(w_m)v_0$ of $\mathcal{V}_m$ is a singular vector of the tensor product module Ω.

Proof: Using the commutators,

$$[\mathbf{E},\mathcal{F}(w)]=h(w)\quad \text{and}\quad [h(w_1),\mathcal{F}(w_2)]=\frac{2}{w_1-w_2}(\mathcal{F}(w_1)-\mathcal{F}(w_2)),$$

with $h(w)=\Sigma_{k=1}^{N}[1/(w-z_k)]\,H^{(k)}$, we obtain

$$\mathbf{E}\,\psi_m(w_1,\ldots,w_m)\,v_0=\sum_{i=1}^{m}\left(\sum_{k=1}^{m}\frac{\lambda_k}{w_i-z_k}+\sum_{\substack{k=1\\k\neq i}}^{N}\frac{2}{w_k-w_i}\right)\times\psi_{m-1}(w_1,\ldots,w_{i-1},w_{i+1},\ldots,w_m)\,v_0.$$

Therefore if the parameters $w_1,\ldots,w_m$ are solutions of the system (30), then $\psi_m(w_1,\ldots,w_m)$ is a singular vector.

The number of common Bethe eigenvectors is equal to the number of distinct solutions of the Bethe system (30). If they are C_{m+N-2}^{m} then they form a basis of $\mathrm{Sing}\,\mathcal{V}_m$. For $m=1$ and $m=2$ we can easily show that the number of complex solutions of the Bethe system is $N-1$ and $N(N-1)/2$, respectively, but we cannot say how many of them are distinct. For example, in the case $m=1$, $N=3$, the Bethe equation is equivalent to a second order equation. For some particular values of the parameters λ_i and z_i, $i=1,2,3$, this equation could have a double solution.

For arbitrary m and N, the number of solutions of the Bethe system seems to be C_{m+N-2}^{m} but to our knowledge there is no estimate of the number of distinct solutions. In any case, the Bethe Ansatz gives a family of singular common eigenvectors which could be completed, if necessary, to a basis of $\mathrm{Sing}\,\mathcal{V}_m$ with common eigenvectors constructed using the basis (29).

IV. THE GAUDIN MODEL FOR AN ARBITRARY SIMPLE LIE ALGEBRA *G*

Consider a simple Lie algebra G, of dimension d and rank r. Denote Δ the root system of G, Δ_+ the system of positive roots and Δ_0 the system of simple roots. The Cartan basis of G is formed by the Cartan generators $\{H_i\}_{i=1,\ldots,r}$, the generators of positive roots $\{E_\alpha\}_{\alpha\in\Delta_+}$ and the generators of negative roots $\{F_\alpha=E_{-\alpha}\}_{\alpha\in\Delta_+}$. The commutation relations are

$$[E_\alpha,F_\alpha]=\frac{2}{\langle\alpha,\alpha\rangle}H_\alpha;\quad [H,E_\alpha]=\alpha(H)E_\alpha;\quad [H,F_\alpha]=-\alpha(H)F_\alpha;$$

$$[E_\alpha,E_\beta]=N_{\alpha,\beta}E_{\alpha+\beta},\quad \forall\,\alpha,\beta\in\Delta\ \text{ such that }\ \alpha+\beta\in\Delta.$$

The Killing form of G defines a symmetrical, G-invariant, bilinear form $\langle,\rangle$ on G, which allows us to identify the Cartan sub-algebra $\mathcal{K}$ of G with its dual, by the isomorphism $\alpha(H)=\langle H_\alpha,H\rangle$, for all $H\in\mathcal{K}$. The scalar product on $\mathcal{K}$ induces a scalar product on its dual, which is nondegenerate,

$$\langle\alpha,\beta\rangle=\langle H_\alpha,H_\beta\rangle,$$

normalized such that $\langle\alpha_l,\alpha_l\rangle=2$ for a long root α_l.

All generators of G are orthogonal with respect to the bilinear form $\langle,\rangle$ except

$$\langle H_i,H_i\rangle=\tfrac{1}{2}\chi,\quad \forall i=1,\ldots,r,$$

$$\langle E_\alpha,F_\alpha\rangle=\frac{2}{\langle\alpha,\alpha\rangle},\quad \forall\alpha\in\Delta_+,$$

where $\chi=\Sigma_{i=1}^r\alpha_l^2(H_i)$ is the square of the length of a long root. Then, for the Cartan basis we can define the dual basis with respect to this bilinear form:

$$\tilde{H}_i=\frac{2}{\chi}H_i;\quad \tilde{E}_\alpha=\frac{\langle\alpha,\alpha\rangle}{2}F_\alpha;\quad \tilde{F}_\alpha=\frac{\langle\alpha,\alpha\rangle}{2}E_\alpha,$$

such that $\langle H_i,\tilde{H}_j\rangle=\delta_{ij}$ and $\langle E_\alpha,\tilde{E}_\beta\rangle=\langle F_\alpha,\tilde{F}_\beta\rangle=\delta_{\alpha\beta}$.

For this algebra, consider N finite-dimensional highest weight G-modules, $V_{\lambda_1},\ldots,V_{\lambda_N}$, with dominant integral highest weights $\lambda_1,\ldots,\lambda_N$ and highest weight vectors $v_{\lambda_1},\ldots,v_{\lambda_N}$. The tensor product module of these N G-modules is the space of physical states:

$$\Omega=V_{\lambda_1}\otimes\cdots\otimes V_{\lambda_N}.$$

Recall that the Lie algebra action on this tensor module is defined by (1).

The fundamental building blocks of the generalized Gaudin Hamiltonians are the quadratic generalized Casimir operators, defined on Ω as

$$\omega^{(ij)}=\sum_{a=1}^{d}I_a^{(i)}\tilde{I}_a^{(j)},\quad \forall\, i,j=1,\ldots,N, \tag{31}$$

where $\{I_a\}_{a=1,d}$ is a basis of G and $\{\tilde{I}_a\}_{a=1,d}$ its dual with respect to the scalar product, $\langle I_a,\tilde{I}_b\rangle=\delta_{ba}$. We recall two fundamental properties of these operators, which will be useful in this section.

(1) $\omega^{(ij)}$ are independent of the choice of the basis in G. In particular, in the Cartan basis they take the form

$$\omega^{(ij)}=\frac{2}{\chi}\sum_{l=1}^{r}H_l^{(i)}H_l^{(j)}+\sum_{\alpha\in\Delta_+}\frac{\langle\alpha,\alpha\rangle}{2}(E_\alpha^{(i)}F_\alpha^{(j)}+F_\alpha^{(i)}E_\alpha^{(j)});$$

(2) $\omega^{(ij)}$ commute with the action of the algebra on the tensor module:

$$[\omega^{(ij)},\mathbf{X}]=0,\quad \forall X\in G.$$

The operators $\omega^{(ij)}$ do not commute between themselves, but we can construct N linear combinations which commute.

Lemma 11: The operators $\omega_i:\Omega\to\Omega$, $i=1,\ldots,N$,

$$\omega_i=\sum_{j=1,j\neq i}^{N}c_{ij}\,\omega^{(ij)},$$

commute: $[\omega_i,\omega_j]=0$, $\forall i,j=1,\ldots,N$ *if and only if the coefficients* c_{ij} *satisfy the equations*

$$c_{ik}c_{jk}-c_{ik}c_{ji}-c_{jk}c_{ij}=0, \quad \forall\, i\neq j\neq k\neq i,\ \ i,j,k=1,\ldots,N. \tag{32}$$

In particular, if $z_1,\ldots,z_N$ are distinct complex parameters, the coefficients $c_{ij}=1/(z_i-z_j)$ fulfill the conditions (32). With these coefficients we can construct the following N operators on Ω:

$$\mathcal{H}_i=\sum_{i=1,i\neq j}^{N}\frac{1}{z_i-z_j}\omega^{(ij)}, \tag{33}$$

which are the generalized Gaudin Hamiltonians. They preserve the properties (1) and (2) of the operators $\omega^{(ij)}$. More precisely, if we consider the Cartan basis in G, we have

$$[\mathcal{H}_i,\mathbf{H}_\alpha]=0, \tag{34}$$

$$[\mathcal{H}_i,\mathbf{E}_\alpha]=0, \tag{35}$$

$$[\mathcal{H}_i,\mathbf{F}_\alpha]=0, \tag{36}$$

$\forall\, i=1,\ldots,N$; $\forall\,\alpha\in\Delta_+$, where $\mathbf{H}_\alpha=\Sigma_{i=1}^{N}H_\alpha^{(i)}$, $\mathbf{E}_\alpha=\Sigma_{i=1}^{N}E_\alpha^{(i)}$, $\mathbf{F}_\alpha=\Sigma_{i=1}^{N}F_\alpha^{(i)}$ are operators on the tensor product module, defined by (1). The generalized Gaudin Hamiltonians commute between themselves, but only $N-1$ of them are independent. Due to the property (34) we can complete this system by other r operators, the generators $\mathbf{H}_\alpha$ of the Cartan sub-algebra, which commute with all $\mathcal{H}_i$. For this family of independent and commuting Hamiltonians there is a complete system of common eigenvectors in Ω.

A. The structure of Ω

Since the space Ω is a tensor product of N highest weight representations V_λ of G, it is useful to recall some basic results concerning the theory of highest weight representations of Lie algebras.

Such a representation is completely determined by a highest weight vector v_λ, on which the action of the algebra is given by

$$H_\alpha v_\lambda=\langle\alpha,\lambda\rangle v_\lambda, \quad E_\alpha v_\lambda=0.$$

As in the $SL(2)$ case, the representation space V_λ is linearly generated only by monomials in generators of negative roots:

$$\{v^{n_1\cdots n_l}_{\alpha_1\cdots\alpha_l}=F^{n_1}_{\alpha_1}\cdots F^{n_l}_{\alpha_l}v_\lambda\}_{\alpha_i\in\Delta_+,n_i\in\mathbb{N}}, \tag{37}$$

but in this case, the monomials are ordered with respect to the roots, as showed by the Poincaré–Birkhoff–Witt theorem.[13] These vectors are eigenvectors for the Cartan generators:

$$H_\alpha v^{n_1\cdots n_l}_{\alpha_1\cdots\alpha_l}=\left(\langle\alpha,\lambda\rangle-\sum_{\beta\in\Delta_+}n_\beta\langle\alpha,\beta\rangle\right)v^{n_1\cdots n_l}_{\alpha_1\cdots\alpha_l}, \tag{38}$$

and the action of a positive root generator on monomials $v_\alpha^{n_\alpha}$ is

$$E_\alpha v_\alpha^{n_\alpha}=n_\alpha\left(2\frac{\langle\lambda,\alpha\rangle}{\langle\alpha,\alpha\rangle}-n_\alpha+1\right)v_\alpha^{n_\alpha-1}. \tag{39}$$

Concerning the dimension of a highest weight representation of G, recall that a weight λ is a dominant integral if

$$r_\alpha = 2\frac{\langle \lambda, \alpha\rangle}{\langle \alpha, \alpha\rangle} \in \mathbb{N}, \quad \forall\, \alpha \in \Delta_0 .$$

If the highest weight λ is not dominant integral, then the representation is infinite dimensional and irreducible. If the highest weight λ is dominant integral then there is an invariant subspace, generated by vectors $v^{n_1 \dots n_l}_{\alpha_1 \dots \alpha_l}$, with $n_\alpha \geqslant r_\alpha + 1$.[13] The quotient representation, denoted V_λ is an irreducible, finite-dimensional representation of G, generated by ordered monomials:

$$\{v^{n_1 \dots n_l}_{\alpha_1 \dots \alpha_l} = F^{n_1}_{\alpha_1} \dots F^{n_l}_{\alpha_l} v_\lambda\}_{\alpha_j \in \Delta_+, n_j = 0, \dots, r_{\alpha_j}}.$$

As in the $SL(2)$ case, the space Ω is a finite-dimensional tensor product module of G, completely determined by the vacuum vector $v_0 = v_{\lambda_1} \otimes \cdots \otimes v_{\lambda_N}$ and generated by ordered monomials:

$$F^{(k_1)}_{\alpha_1} F^{(k_2)}_{\alpha_2} \cdots F^{(k_m)}_{\alpha_m} v_0 ,$$

with $1 \leqslant k_i \leqslant N$. Note that for finite-dimensional representations, m can vary between 0 and a maximal value $m_{\max} = \Sigma_{i=1}^N \Sigma_{\alpha \in \Delta_+} r^i_\alpha$. Note also that the action of the Hamiltonians on the vacuum vector is

$$\mathbf{H}_\alpha v_0 = \left(\sum_{k=1}^N \langle \lambda_k, \alpha\rangle \right) v_0 , \quad \alpha \in \Delta_0 ,$$

$$\mathcal{H}_i v_0 = \left(\sum_{j=1, j\neq i}^N \frac{\langle \lambda_i, \lambda_j\rangle}{z_i - z_j} \right) v_0 , \quad i = 1, \dots, N.$$

As in the case of the Lie algebra $SL(2)$, the Cartan operators $\mathbf{H}_\beta$ have the particular role to give a gradation of the tensor product module:

$$\Omega = \oplus \mathcal{V}_\mu ,$$

on weight subspaces $\mathcal{V}_\mu$, of weight $\mu = \Sigma_{i=1}^N \lambda_i - \Sigma_{j=1}^m \gamma_j$, generated by $\mathbf{H}_\beta$ eigenvectors:

$$\mathbf{H}_\beta F^{(k_1)}_{\gamma_1} \cdots F^{(k_m)}_{\gamma_m} v_0 = \left(\sum_{i=1}^N \langle \lambda_i, \beta\rangle - \sum_{j=1}^m \langle \gamma_j, \beta\rangle \right) F^{(k_1)}_{\gamma_1} \cdots F^{(k_m)}_{\gamma_m} v_0 ,$$

with $\gamma_1, \dots, \gamma_m \in \Delta_+$ and $1 \leqslant k_i \leqslant N$. Since a positive root can be written as a sum of simple roots, with positive integer coefficients, in a unique way, the weight subspaces will be labeled by a family of simple roots: $\mathcal{V}_\mu = \mathcal{V}_{\alpha_1 \dots \alpha_s}$, with $\alpha_1 \dots \alpha_s \in \Delta_0$, not necessarily distinct and satisfying $\Sigma_{j=1}^m \gamma_j = \Sigma_{k=1}^s \alpha_k$. Hence

$$\Omega = \oplus \mathcal{V}_{\alpha_1 \dots \alpha_s}.$$

From the explicit form of the generalized Gaudin Hamiltonians (33) and from the action (37)–(39) of the Lie algebra on each module V_{λ_i}, it follows that the weight subspaces $\mathcal{V}_{\alpha_1 \dots \alpha_s}$ are invariant under the action of any $\mathcal{H}_i$. Therefore, in each subspace $\mathcal{V}_{\alpha_1 \dots \alpha_s}$, we can construct a basis of common eigenvectors of $\mathcal{H}_i$.

Unlike the case of the Lie algebra $SL(2)$, there is no result concerning the dimension of the invariant subspaces $\mathcal{V}_{\alpha_1 \dots \alpha_s}$ and neither for Sing $\mathcal{V}_{\alpha_1 \dots \alpha_s}$. However, using the properties (35) and (36), the recursive procedure presented in Sec. III can be generalized to construct in each subspace $\mathcal{V}_{\alpha_1 \dots \alpha_s}$ a family of common nonsingular eigenvectors, by applying operators $\mathbf{F}_{\alpha_i}$ on vectors of the sub-spaces $\mathcal{V}_{\alpha_1 \dots \alpha_{i-1} \alpha_{i+1} \dots \alpha_s}$. Concerning the subspace of singular vectors in

$\mathcal{V}_{\alpha_1 \ldots \alpha_s}$ we do not have a generalization of the result presented in Sec. III A, for the construction of a basis of singular vectors. The only result[4] concerning this problem is a generalization of the Bethe Ansatz, which we discuss hereafter.

B. Common eigenvectors in $\mathcal{V}_\alpha$

Consider a simple root α. The subspace $\mathcal{V}_\alpha$ of weight $\Sigma_{i=1}^N \lambda_i - \alpha$ is generated by vectors $\{F_\alpha^{(k)} v_0\}_{k=1,\ldots,N}$. A Bethe vector in this subspace is defined as an expansion on the basis, with rational coefficients depending on one complex parameter w:

$$\psi_1(w,\alpha)v_0 = \sum_{i=1}^N \frac{F_\alpha^{(i)}}{w-z_i} v_0 = \mathcal{F}(w,\alpha)v_0. \tag{40}$$

To give the action of a Hamiltonian $\mathcal{H}_i$ on this vector it is useful to calculate the commutator:

$$[\mathcal{H}_i, \mathcal{F}(w,\alpha)] = \mathcal{F}(w,\alpha)\frac{H_\alpha^{(i)}}{w-z_i} - \frac{F_\alpha^{(i)}}{w-z_i}\left(\sum_{j=1}^N \frac{H_\alpha^{(j)}}{w-z_j}\right) + \sum_{\beta\in\Delta_+,\beta>\alpha} \frac{\langle\beta,\beta\rangle}{2} N_{\beta,-\alpha}\left\{\mathcal{F}(w,\beta)\frac{E_{\beta-\alpha}^{(i)}}{w-z_i} - \frac{F_\beta^{(i)}}{w-z_i}\sum_{j=1}^N \frac{E_{\beta-\alpha}^{(j)}}{w-z_j}\right\}. \tag{41}$$

Applied on the vacuum vector all the terms of the last sum vanish and the action of a Gaudin Hamiltonian $\mathcal{H}_i$ on the vector (40) is

$$\mathcal{H}_i\psi_1(w,\alpha)v_0 = \left(\sum_{j=1;j\neq i}^N \frac{\langle\lambda_i,\lambda_j\rangle}{z_i-z_j} + \frac{\langle\alpha,\lambda_i\rangle}{w-z_i}\right)\psi_1(w,\alpha)v_0 - \left(\sum_{k=1}^N \frac{\langle\alpha,\lambda_k\rangle}{w-z_k}\right)\frac{F_\alpha^{(i)}}{w-z_i}v_0. \tag{42}$$

Hence we have the following.

Lemma 12: Given N complex numbers $\{z_i\}_{i=1,\ldots,N}$ *and dominant integral highest weights* $\{\lambda_i\}_{i=1,\ldots,N}$, *the Bethe vector* $\psi_1(w,\alpha)v_0$ *is an eigenvector for all Gaudin Hamiltonians:*

$$\mathcal{H}_i\,\psi_1(w,\alpha)v_0 = s_i^1(w,\alpha)\,\psi_1(w,\alpha)v_0, \quad \forall i=1,\ldots,N,$$

if the complex parameter w satisfies the Bethe equation:

$$\sum_{k=1}^N \frac{\langle\alpha,\lambda_k\rangle}{w-z_k} = 0. \tag{43}$$

The eigenvalue $s_i^1(w,\alpha)$ *of the Hamiltonian* $\mathcal{H}_i$ *depends on the solution of this equation:*

$$s_i^1(w,\alpha) = \sum_{j=1;j\neq i}^N \frac{\langle\lambda_i,\lambda_j\rangle}{z_i-z_j} + \frac{\langle\alpha,\lambda_i\rangle}{w-z_i}, \quad i=1,\ldots,N.$$

C. Common eigenvectors in $\mathcal{V}_{\alpha_1,\alpha_2}$

Consider two simple roots α_1 and α_2, which are not necessarily distinct. The subspace $\mathcal{V}_{\alpha_1,\alpha_2}$, of weight $\Sigma_{i=1}^N \lambda_i - \alpha_1 - \alpha_2$ is generated by vectors $\{F_{\alpha_1}^{(k_1)} F_{\alpha_2}^{(k_2)} v_0\}_{k_1,k_2=1,\ldots,N;\ k_1\neq k_2}$, with two generators of negative roots applied on two distinct components of v_0, but also by vectors $\{(F_{\alpha_1}F_{\alpha_2})^{(k)}v_0\}_{k=1,\ldots,N}$ and $\{(F_{\alpha_2}F_{\alpha_1})^{(k)}v_0\}_{k=1,\ldots,N}$ with two generators of negative roots applied on the same component of v_0. A Bethe vector in $\mathcal{V}_{\alpha_1,\alpha_2}$ is defined as an expansion on all these vectors, with some particular coefficients depending on two complex parameters w_1, w_2:

$$\psi_2(w_1,\alpha_1;w_2,\alpha_2)v_0=\sum_{k_1=1}^{N}\sum_{k_2\neq k_1}^{N}\frac{F_{\alpha_1}^{(k_1)}F_{\alpha_2}^{(k_2)}}{(w_1-z_{k_1})(w_2-z_{k_2})}v_0+\frac{1}{w_1-w_2}\sum_{k=1}^{N}\frac{(F_{\alpha_1}F_{\alpha_2})^{(k)}}{w_2-z_k}v_0$$
$$+\frac{1}{w_2-w_1}\sum_{k=1}^{N}\frac{(F_{\alpha_2}F_{\alpha_1})^{(k)}}{w_1-z_k}v_0.$$

As element of the representation space V_{λ_k}, one of the two last terms is not a good ordered monomial and we must write, for instance, $(F_{\alpha_2}F_{\alpha_1})^{(k)}=(F_{\alpha_1}F_{\alpha_2})^{(k)}+[F_{\alpha_2},F_{\alpha_1}]^{(k)}$. Then this vector can be also written in the following form, using the operators $\mathcal{F}$:

$$\psi_2(w_1,\alpha_1;w_2,\alpha_2)v_0=\mathcal{F}(w_1,\alpha_1)\mathcal{F}(w_2,\alpha_2)v_0+\frac{1}{w_1-w_2}\mathcal{F}(w_1,[F_{\alpha_1},F_{\alpha_2}])v_0. \tag{44}$$

In order to compute the action of a Hamiltonian $\mathcal{H}_i$ on the vector ψ_2, we use the result (41) and (42) to obtain

$$\mathcal{H}_i\,\psi_2(w_1,\alpha_1;w_2,\alpha_2)v_0=s_i^2(w_1,w_2)\psi_2(w_1,\alpha_1;w_2,\alpha_2)v_0$$
$$-f_1\left(\frac{F_{\alpha_1}^{(i)}}{w_1-z_i}\mathcal{F}(w_2,\alpha_2)+\frac{1}{w_1-w_2}\frac{[F_{\alpha_1}^{(i)},F_{\alpha_2}^{(i)}]}{w_1-z_i}\right)v_0$$
$$-f_2\left(\mathcal{F}(w_1,\alpha_1)\frac{F_{\alpha_2}^{(i)}}{w_2-z_i}+\frac{1}{w_1-w_2}\frac{[F_{\alpha_1}^{(i)},F_{\alpha_2}^{(i)}]}{w_1-z_i}\right)v_0,$$

where

$$s_i^2=\sum_{j=1;j\neq i}^{N}\frac{\langle\lambda_i,\lambda_j\rangle}{z_i-z_j}+\frac{\langle\alpha_1,\lambda_i\rangle}{w_1-z_i}+\frac{\langle\alpha_2,\lambda_i\rangle}{w_2-z_i},$$

$$f_1=\sum_{k=1}^{N}\frac{\langle\alpha_1,\lambda_k\rangle}{w_1-z_k}+\frac{\langle\alpha_1,\alpha_2\rangle}{w_2-w_1}\quad\text{and}\quad f_2=\sum_{k=1}^{N}\frac{\langle\alpha_2,\lambda_k\rangle}{w_2-z_k}+\frac{\langle\alpha_1,\alpha_2\rangle}{w_1-w_2}.$$

Note that the action of $\mathcal{H}_i$ on the second term of the vector (44) must be calculated separately, because (42) does not hold for the positive root $\alpha_1+\alpha_2$ which is no more simple. It follows from these considerations the following lemma.

Lemma 13: The Bethe vector $\psi_2(w_1,\alpha_1;w_2,\alpha_2)v_0$ is an eigenvector for all Gaudin Hamiltonians,

$$\mathcal{H}_i\,\psi_2(w_1,w_2)v_0=s_i^2\,\psi_2(w_1,\alpha_1;w_2,\alpha_2)v_0,$$

if the parameters w_1, w_2 satisfy the Bethe equations:

$$f_1=\sum_{k=1}^{N}\frac{\langle\alpha_1,\lambda_k\rangle}{w_1-z_k}+\frac{\langle\alpha_1,\alpha_2\rangle}{w_2-w_1}=0,\quad f_2=\sum_{k=1}^{N}\frac{\langle\alpha_2,\lambda_k\rangle}{w_2-z_k}+\frac{\langle\alpha_1,\alpha_2\rangle}{w_1-w_2}=0. \tag{45}$$

D. Common eigenvectors in $\mathcal{V}_{\alpha_1,\ldots,\alpha_m}$

For m simple roots $\alpha_1,\ldots,\alpha_m$, not necessarily distinct, the subspace $\mathcal{V}_{\alpha_1,\ldots,\alpha_m}$ of weight $\Sigma_{i=1}^{N}\lambda_i-\Sigma_{k=1}^{m}\alpha_k$ is generated by ordered monomials $F_{\gamma_1}^{(k_1)}\ldots F_{\gamma_n}^{(k_n)}v_0$ with $k_1,\ldots,k_n$

$=1,\ldots,N$ and $\gamma_1,\ldots,\gamma_n$ positive roots with $\Sigma_{i=1}^{n}\gamma_i=\Sigma_{k=1}^{m}\alpha_k$. In this general case it is difficult to define an appropriate Bethe type vector, with rational coefficients on the basis of $\mathcal{V}_{\alpha_1,\ldots,\alpha_m}$. In Ref. 4. a recursive procedure was proposed to define such a vector:

$$\psi_m(w_1,\alpha_1;\ldots;w_m,\alpha_m)v_0=\psi_{m-1}(w_1,\alpha_1;\ldots;w_{m-1},\alpha_{m-1})\mathcal{F}(w_m,\alpha_m)v_0+\sum_{j=1}^{m-1}\frac{1}{w_j-w_m}$$
$$\times\psi_{m-1}(w_1,\alpha_1;\ldots;w_j,[F_{\alpha_j},F_{\alpha_m}];\ldots;w_{m-1},\alpha_{m-1})v_0, \quad (46)$$

with $\psi_1(w,\alpha)=\mathcal{F}(w,\alpha)$. However, to our knowledge there is no proof that the action of a Hamiltonian $\mathcal{H}_i$ on the vector $\psi_m v_0$ is

$$\mathcal{H}_i\,\psi_m(w_1,\alpha_1;\ldots;w_m,\alpha_m)v_0=s_i^m\psi_m(w_1,\alpha_1;\ldots;w_m,\alpha_m)v_0-\sum_{k=1}^{m}f_k^m\overline{\psi}_m^k v_0, \quad (47)$$

with $\overline{\psi}_m^k$ some vectors in $\mathcal{V}_{\alpha_1,\ldots,\alpha_m}$ and

$$s_i^m=\sum_{j=1;j\neq i}^{N}\frac{\langle\lambda_i,\lambda_j\rangle}{z_i-z_j}+\sum_{k=1}^{m}\frac{\langle\alpha_k,\lambda_i\rangle}{w_k-z_i},\quad f_k^m=\sum_{j=1}^{N}\frac{\langle\alpha_k,\lambda_j\rangle}{w_k-z_j}+\sum_{l=1,l\neq k}^{m}\frac{\langle\alpha_k,\alpha_l\rangle}{w_l-w_k}.$$

Such a recursive construction of generalized Bethe vectors seems to be appropriate for inductive calculations, but for the action (47) of Hamiltonians on these vectors such a calculation raises some problems, as explained in Ref. 10. Similar problems occur if we intend to prove inductively that all Bethe eigenvectors are singular. For a small number of roots this can be done by direct calculation.

We call $v^s\in\Omega$ a singular vector of Ω if all the generators of simple roots $\mathbf{E}_\alpha$ act trivially on v^s:

$$\mathbf{E}_\alpha v^s=0.$$

Note first that $[E_\beta,F_\alpha]=\delta_{\alpha\beta}(2/\langle\alpha,\alpha\rangle)\forall\, i=1,\ldots,N;\ \forall\,\alpha\in\Delta_{+H_\alpha}$ for any simple roots α and β.

Consider now the weight subspace $\mathcal{V}_\alpha$. If β is a simple root we have

$$[E_\beta,\psi_1(w,\alpha)]=\delta_{\alpha\beta}\frac{2}{\langle\alpha,\alpha\rangle}\sum_{i=1}^{N}\frac{H_\alpha^{(i)}}{w-z_i}. \quad (48)$$

Hence,

$$E_\beta\psi_1(w,\alpha)v_0=\delta_{\alpha\beta}\frac{2}{\langle\alpha,\alpha\rangle}\left(\sum_{i=1}^{N}\frac{\langle\alpha,\lambda_i\rangle}{w-z_i}\right)v_0,\quad\forall\,\beta\in\Delta_0.$$

Therefore, if w is a solution of the Bethe equation (43), then $\psi_1(w,\alpha)\,v_0$ is a singular vector of $\mathcal{V}_\alpha$.

In order to calculate the action of a generator E_β of simple root on a generalized Bethe vector (44) of $\mathcal{V}_{\alpha_1,\alpha_2}$, we use (48) but also

$$[E_\beta,\psi_1(w,[F_{\alpha_1},F_{\alpha_2}])]=2\frac{\langle\alpha_1,\alpha_2\rangle}{\langle\beta,\beta\rangle}\{\delta_{\beta\alpha_2}\mathcal{F}(w,\alpha_1)-\delta_{\beta\alpha_1}\mathcal{F}(w,\alpha_2)\},$$

to obtain

$$E_\beta\psi_2(w_1,\alpha_1;w_2,\alpha_2)v_0=\delta_{\beta\alpha_1}\frac{2}{\langle\alpha_1,\alpha_1\rangle}\left\{\sum_{i=1}^{N}\frac{\langle\lambda_i,\alpha_1\rangle}{w_1-z_i}+\frac{\langle\alpha_1,\alpha_2\rangle}{w_2-w_1}\right\}\mathcal{F}(w_2,\alpha_2)v_0$$
$$+\delta_{\beta\alpha_2}\frac{2}{\langle\alpha_2,\alpha_2\rangle}\left\{\sum_{i=1}^{N}\frac{\langle\lambda_i,\alpha_2\rangle}{w_2-z_i}+\frac{\langle\alpha_1,\alpha_2\rangle}{w_1-w_2}\right\}\mathcal{F}(w_1,\alpha_1)v_0.$$

Therefore, if (w_1,w_2) is a solution of the Bethe equations (45), then $\psi_2(w_1,\alpha_1;w_2,\alpha_2)\,v_0$ is a singular vector of $\mathcal{V}_{\alpha_1,\alpha_2}$.

For Bethe vectors (46) depending on more than 3 simple roots we claim that the commutator of E_β with ψ_m is given by

$$[E_\beta,\psi_m(w_1,\alpha_1;\dots w_m,\alpha_m)]=\sum_{i=1}^{m}\delta_{\beta\alpha_i}\frac{2}{\langle\alpha_i,\alpha_i\rangle}\left\{\psi_{m-1}(\dots\widehat{w_i,\alpha_i};\dots)\sum_{j=1}^{N}\frac{H^{(j)}_{\alpha_i}}{w_i-z_j}\right.$$
$$\left.-\left(\sum_{j=1,j\neq i}^{m}\frac{\langle\alpha_i,\alpha_j\rangle}{w_i-w_j}\right)\psi_{m-1}(\dots\widehat{w_i,\alpha_i}\dots)\right\},$$

where $\psi_{m-1}(\dots\widehat{w_i,\alpha_i}\dots)$ denotes $\psi_{m-1}(\dots w_{i-1},\alpha_{i-1};w_{i+1},\alpha_{i+1}\dots)$. As for the action (47) of the Hamiltonians, there is no inductive proof of this relation. The action of E_β on the Bethe vector is then

$$E_\beta\psi_m(w_1,\alpha_1;\dots w_m,\alpha_m)v_0=\frac{2\,\delta_{\beta\alpha_i}}{\langle\beta,\beta\rangle}\left\{\sum_{j=1}^{N}\frac{\langle\alpha_i,\lambda_j\rangle}{w_i-z_j}-\sum_{\substack{k=1\\k\neq i}}^{m}\frac{\langle\alpha_i,\alpha_k\rangle}{w_i-w_k}\right\}\psi_{m-1}(\dots\widehat{w_i,\alpha_i}\dots)v_0.$$

Hence, the Bethe vector is singular if the parameters w satisfy the Bethe equations $f_k^m=0$, $\forall k=1,\dots,m$.

V. CONCLUSIONS

In this article we recall the Gaudin model associated to the Lie algebra $SL(2)$ and its partial diagonalization by the Bethe Ansatz.

We give a general recursive method to construct a basis of common eigenvectors in each invariant subspace $\mathcal{V}_m$. Knowing a basis of $\mathcal{V}_{m-1}$, we construct a family of nonsingular independent common eigenvectors in $\mathcal{V}_m$. This family is completed to a basis of $\mathcal{V}_m$, by a basis of the subspace of singular vectors of $\mathcal{V}_m$.

In order to describe the subspace $\mathrm{Sing}\,\mathcal{V}_m$, we establish a relation between singular vectors and covariant differential operators. This allows us to construct a basis of $\mathrm{Sing}\,\mathcal{V}_m$ using an analog of the Gordan operator. On the other hand we show that the Bethe Ansatz gives a family of singular common eigenvectors. If Bethe equations have a maximal number of distinct solutions, then Bethe eigenvectors form a basis of common eigenvectors in $\mathrm{Sing}\,\mathcal{V}_m$.

We discuss also the generalization of this method to the case of an arbitrary Lie algebra. We recall the generalization of the Gaudin Hamiltonians and of the Bethe Ansatz. The generalized Bethe vectors are defined recursively, but this definition allows neither to calculate the action of the Hamiltonians, nor to prove that Bethe eigenvectors are singular. For a small number of simple roots we prove by direct calculation that the Bethe equations are conditions that Bethe type vectors be singular and common eigenvectors. The recursive method to construct nonsingular common eigenvectors could also be generalized to the case of an arbitrary Lie algebra.

The Painlevé analysis for $N=2$ super Korteweg–de Vries equations

S. Bourque[a] and P. Mathieu[b]
Département de Physique, Université Laval, Québec G1K 7P4, Canada

(Received 6 July 2000; accepted for publication 9 March 2001)

The Painlevé analysis of a generic multiparameter $N=2$ extension of the Korteweg–de Vries (KdV) equation is presented. Unusual aspects of the analysis, pertaining to the presence of two fermionic fields, are emphasized. For the general class of models considered, we find that the only ones which manifestly pass the test are precisely the four known integrable supersymmetric KdV equations, including the SKdV_1 case. © *2001 American Institute of Physics.*
[DOI: 10.1063/1.1369641]

I. MOTIVATION AND SUMMARY OF THE RESULTS

Even in its simplest form, the Painlevé analysis,[1] as applied to a multiparameter class of equations, is a powerful tool for identifying those special values of the parameters for which the equations are potentially integrable.

However, for fermionic—and in particular, supersymmetric—extensions of known integrable systems, the application of the test is made a little tricky by the presence of fermionic fields[2,3] and actually very few systems have been fully studied so far (see also Ref. 4). For a single fermionic extension (with a fermionic field of degree 3/2 in the normalization where the degree of ∂_x is 1) of the Korteweg–de Vries (KdV) equation, which contains 3 free parameters, the test has selected the very two integrable nontrivial extensions of the KdV equation, namely, the Kuper–KdV (Ref. 5) (which is not invariant under supersymmetry) and the supersymmetric KdV (sKdV-the small s refers to $N=1$) equation[6,7,8]—the latter being called here the sKdV_3 equation for reasons explained below. There is an additional integrable supersymmetric system[6,9] which will be referred to, in the following, as the sKdV_0 equation. Although the latter is somewhat trivial in that the fermionic fields do not appear in the bosonic evolution equations (and for this reason it was excluded from the generic family considered in Ref. 2), this will not be an issue here.[10] That the integrability of these models had already been established by other means supports the validity of the application of the test, or more precisely, its reliability as an integrability indicator, in the presence of fermionic fields.

No similar studies have been performed for the extension of the KdV equation with two fermions and an additional bosonic field. Six such systems are known to be integrable: the three usual $N=2$ supersymmetric KdV (SKdV, the capital S is used for $N=2$) equations, i.e., the SKdV_a equation (where a is a free parameter in a second Hamiltonian formulation) for $a=-2$, 1, 4, [11,12,13] the $\mathrm{SKdV}_{\mathcal{O}}$ (where the subscript stands for ''odd'') equation,[14] which has an *odd* Poisson bracket formulation, the SKdV-B equation[15] and the osp(2, 2) KdV equation, the direct extension of the Kuper-KdV equation (which is thus not invariant under $N=2$ supersymmetry).[11,16] (See note added in proof.)

The details of the Painlevé analysis of these systems has never been presented in the literature. Actually, it has been claimed that for the SKdV_1 equation, the test is failed (see in particular the concluding remarks in Ref. 13). The particular interest for this case, at the time, was due to its conjectural integrability status for some years before the discovery of its Lax formulation in Ref. 13. But given that this system is now known to be integrable,[17] that it does not have the Painlevé

[a]Electronic mail: sbourque@phy.ulaval.ca
[b]Electronic mail: pmathieu@phy.ulaval.ca

property sounds as an extremely surprising statement. Clearly, the failure of the Painlevé test is not by itself a clear indication of nonintegrability. For instance, the equation might have to be somewhat transformed in order to successfully pass the test. However, in a multiparameter deformation of an equation, we definitely expect that if the test is satisfied for some values of the parameters (corresponding to a known integrable system), it should be equally satisfied for all other values of the parameters for which the equations are known to be integrable. But to rule on the $SKdV_1$ equation, we need to perform the test for the other cases too in order to see if, in the presence of two fermionic fields, it is again a reliable integrability indicator.

The natural expectation is that all six extended KdV equations known to be integrable should have the Painlevé property. However, precisely because there are two fermions, the test displays unusual features. This point in itself is certainly not surprising given some of the odd technical aspects of the test as applied to a single fermionic extension of the KdV equation.[2,3] Clearing up the status of the Painlevé property for the $SKdV_1$ equation was our first motivation for this work.

We present here the result of a ''complete'' Painlevé analysis for four supersymmetric integrable systems [excluding the SKdV-B equation by requiring an $O(2)$ invariance, see below]. More precisely, we perform a simplified analysis, in which, in addition to verifying the plain properties of a genuine pole behavior of the leading singularities and the integrality of the resonance positions, we only check the compatibility conditions at the non-negative resonances. The qualitative ''complete'' refers to the fact that we consider the full set of four evolution equations in each case. In addition to be rather complicated, even though the analysis is done with the simplified Kruskal ansatz,[18] it reveals an unusual feature: in two cases out of four (and this includes the $SKdV_1$ equation), in order to verify the last resonance conditions—whenever this resonance is bosonic—say, at level n, we need to solve the set of recursion equations at level $n+1$. In other words, at first sight the compatibility conditions are *not* satisfied. However, they involved some field components that get determined only at the next recursion level. But when this is done and the solutions are substituted back into the level n resonance relations, the compatibility conditions are found to be satisfied. We thus conclude that, in this context, the Painlevé test is still in par with the other integrability indicators.

A second motivation for this work was to initiate the search for new integrable $N=2$ extensions of the KdV equations by using the Painlevé property as a probing tool to test generic deformations of the known SKdV equations. In the present work we treat the most general deformation (which contains 4 free parameters) compatible with a natural $O(2)$ invariance.

Instead of starting with a brute force analysis of this four-parameter equation, we use a simple observation in order to constrain these parameters, which is that the reduction (by which we mean setting some fields equal to zero) of an integrable system has to be integrable. For instance, a clear signal of this integrability persistence is that, after the reduction of an integrable system, there remains an infinite number of conservation laws. In particular, the $N=1$ reduction of an integrable SKdV equation has to be either the $sKdV_3$ or $sKdV_0$ equations. This fixes two parameters and selects two classes of two-parameter equations. Another simplifying feature of the above observation is that the bosonic core of the full set of equations (obtained by setting the two fermionic fields equal to zero) must also be integrable. The analysis of such bosonic systems (here a system of two coupled evolution equations) is much easier and puts severe constraints on the remaining parameters. In fact, the bosonic core of the test is satisfied (modulo a technical restriction discussed below) for only four cases, which are precisely *the four known integrable supersymmetric systems*.

Our search for new systems is thus unsuccessful. The results suggest in particular, that (most probably) there are no integrable deformations of the $SKdV_{\mathcal{O}}$ equation.

The analysis of the complete fermionic systems is then performed case by case and the Painlevé property is verified in all four cases, as already mentioned.

We should point out a technical limitation of the present analysis, which is restricted to the study of the so-called *principal family*—in the terminology of Ref. 19. That means that we only look for non-negative resonances, in addition to the resonance at level $n=-1$. For a complete analysis, solutions with negative resonances must also be considered. The perturbative Painlevé

test[19] provides a method for investigating such solutions. However, there is no finite algorithm ensuring the absence of movable logarithms (only for the principal families one can guarantee that the system has the Painlevé property). As a result, the computations are much more involved. We intend to return to this question elsewhere. Here we only indicate the cases where the negative resonances occur but without further analysis. Our statements concerning the nonexistence of new integrable systems must thereby be tinged by this technical restriction.

The article is organized as follows: In Sec. II, we present the general class of $N=2$ supersymmetric equations to be studied and discuss the constraints resulting from integrability under truncation to $N=1$ supersymmetric equations. The general structure of the recursion relations is displayed in Sec. III. The delicate question of fixing the dominant resonance of the fermionic fields is discussed in full detail in Appendix B. In the following section, we present the essential results of the bosonic-core analysis, relegating the details to Appendix A. This analysis turns out to be rather involved, necessitating the consideration of a large number of special cases. Finally, Sec. V presents a brief discussion of the study of the equations incorporating the fermionic fields. Here we only present the salient features of the SKdV_1 case and briefly comment on the differences that occur in the other cases. Our conclusions are reported in Sec. VI.

II. THE GENERAL EQUATIONS AND THE $N=1$ CONSTRAINTS

The $N=1$ supersymmetrization of the KdV equation,

$$u_t=-u_{xxx}+6uu_x \tag{2.1}$$

is obtained by extending the u field to a fermionic superfield as

$$u(x)\to\phi(x,\theta)=\theta u(x)+\xi(x). \tag{2.2}$$

Here θ is a Grassmannian variable ($\theta^2=0$) and ξ is a fermionic field, $\xi(x)\xi(x')=-\xi(x')\xi(x)$. The direct supersymmetrization reads[6,20]

$$\phi_t=-\phi_{xxx}+c(\phi D\phi)_x+(6-2c)\phi_x(D\phi), \tag{2.3}$$

where c is a free parameter and D is the superderivative; $D=\theta\partial_x+\partial_\theta$ so that $D^2=\partial_x$. It turns out that this equation is integrable only if $c=0$ or 3.[6] We call the resulting equation the sKdV_c equation. Its component version reads

$$\begin{aligned} u_t&=-u_{xxx}+6uu_x-c\xi\xi_{xx},\\ \xi_t&=-\xi_{xxx}+(6-c)u\xi_x+cu_x\xi. \end{aligned} \tag{2.4}$$

For $c=0$ we see that ξ decouples from the first equation.[21]

The $N=2$ superextension is obtained by lifting u to a bosonic superfield defined as follows (with the time dependence being implicit):

$$\Phi(x,\theta_1,\theta_2)=\theta_2\theta_1u(x)+\theta_1\xi^{(2)}(x)+\theta_2\xi^{(1)}(x)+w(x). \tag{2.5}$$

$\xi^{(1)}$ and $\xi^{(2)}$ are two fermionic fields and w is a new bosonic field. Using the superderivatives,

$$D_i=\theta_i\partial_x+\partial_{\theta_i}\Rightarrow D_i^2=\partial_x\quad(i=1,2)\quad D_1D_2=-D_2D_1, \tag{2.6}$$

the most general version (subject to some restrictions to be specified shortly) of the $N=2$ extension of the KdV equation reads

$$\Phi_t=-\Phi_{xxx}+\alpha_1\Phi D_1D_2\Phi_x+\alpha_2\Phi_xD_1D_2\Phi+\frac{\alpha_3}{2}(D_1D_2\Phi^2)_x+\frac{\alpha_4}{3}(\Phi^3)_x. \tag{2.7}$$

This equation contains all possible terms that are compatible with an homogeneity requirement under a gradation defined by $\deg \Phi = 1$, $\deg D_i = 1/2$, and the $O(2)$ invariance, that is, invariance under the transformation $\Phi \to -\Phi$ and $D_1 \leftrightarrow D_2$. {For instance, terms like $[D_1(\Phi_x D_2 \Phi) - D_2(\Phi_x D_1 \Phi)]$ or $[D_1(\Phi D_2 \Phi_x) - D_2(\Phi D_1 \Phi_x)]$ or even $[(D_1\Phi)(D_2\Phi_x) - (D_2\Phi)(D_1\Phi_x)]$ are not independent, i.e., they are linear combinations of those already given.}

The $N=1$ reduction is obtained by setting

$$\Phi(x, \theta_1, \theta_2) = \theta_2 \phi(x, \theta_1) + \mathcal{F}(x, \theta_1) \tag{2.8}$$

and keeping only the linear terms in θ_2 with $\mathcal{F}=0$. All *integrable* versions of this four-parameter equation *must reduce* to the sKdV_c equation for either $c=0$ or 3. This fixes two parameters,

$$\alpha_1 = c, \quad \alpha_2 = 6 - c. \tag{2.9}$$

The other two are redefined as follows:

$$\alpha_3 = \alpha - 1, \quad \alpha_4 = \beta, \tag{2.10}$$

and we are left with two distinct two-parameter equations,

$$\Phi_t = -\Phi_{xxx} + c\Phi D_1 D_2 \Phi_x + (6-c)\Phi_x D_1 D_2 \Phi + \frac{\alpha - 1}{2}(D_1 D_2 \Phi^2)_x + \beta \Phi^2 \Phi_x \tag{2.11}$$

$(c = 0,3)$. In terms of component fields, it leads to four coupled equations,

$$\begin{aligned} u_t &= -u_{xxx} + 6uu_x - c\xi^{(i)}\xi^{(i)}_{xx} - cww_{xxx} - (6-c)w_x w_{xx} \\ &\quad - \frac{\alpha - 1}{2}(w^2)_{xxx} + \beta(uw^2)_x + 2\beta(\xi^{(2)}\xi^{(1)}w)_x, \\ \xi^{(i)}_t &= -\xi^{(i)}_{xxx} + cu_x\xi^{(i)} + (6-c)u\xi^{(i)}_x - c\epsilon_{ij}\xi^{(j)}_{xx}w - (6-c)\epsilon_{ij}\xi^{(j)}_x w_x \\ &\quad - (\alpha - 1)\epsilon_{ij}(\xi^{(j)}w)_{xx} + \beta(\xi^{(i)}w^2)_x, \\ w_t &= -w_{xxx} + cu_x w + (6-c)uw_x + (\alpha - 1)(uw + \xi^{(2)}\xi^{(1)})_x + \beta w^2 w_x \end{aligned} \tag{2.12}$$

with $i,j = 1, 2$ and $\epsilon_{12} = -\epsilon_{21} = 1$.

III. THE PAINLEVÉ ANALYSIS: RECURSION RELATIONS

We next proceed with the Painlevé analysis by solving the recursion equations in order to find those values of the parameters α and β for which the test is satisfied. In the present work, we content ourself with a minimal version of the test, which consists in verifying:

(1) That the leading singularity is an integer (i.e., polelike);
(2) The resonances occur at integer levels;
(3) The compatibility conditions are satisfied at the non-negative resonances.

We will further give all possible solutions with integer resonances but without further analysis of these last cases.

The expansion of the component fields about a movable singular manifold $\varphi(x,t)$ reads

$$u = \sum_{n=0}^{\infty} u_n \varphi^{n-p}, \quad \xi^{(i)} = \sum_{n=0}^{\infty} \xi^{(i)}_n \varphi^{n-r}, \quad w = \sum_{n=0}^{\infty} w_n \varphi^{n-q} \tag{3.1}$$

($i=1,2$). By symmetry, the value of the leading singularity must be the same for the two fermionic fields. To simplify the analysis, we will use the Kruskal's ansatz,

$$\varphi(x,t)=x-f(t),\ \ u_n=u_n(t),\ \ \xi_n^{(i)}=\xi_n^{(i)}(t),\ \ w_n=w_n(t). \tag{3.2}$$

The first step amounts to fix the leading singularity; we easily find that $p=2$, $q=1$. Note that this is a consequence of the SKdV degree-homogeneity already mentioned: setting $\deg(\partial_x)=1$, it follows that $\deg(u)=2$ and $\deg(w)=1$. Now since $\deg(\varphi)=\deg(x)=-1$ and u_0 and w_0 are constants, hence of degree zero, we thus conclude that $\deg(u)=2$ and $\deg(w)=1$ only if $p=2$ and $q=1$.

The determination of the leading singularity for the fermionic fields is a bit tricky (see for instance Ref. 3); it is shown in appendix B that $r=2$ is a solution and all other possible solutions do not pertain to a principal family. However, for the rest of this section, we leave r unspecified since the recursion relations themselves are needed to fix it, cf. Appendix B. Moreover, the precise value found for r depends explicitly on the first bosonic terms and these are fixed from the bosonic-core analysis.

A direct substitution of (3.1), (3.2) with $p=2$, $q=1$ into (2.12) leads to the general recursion formulas

$$\begin{aligned}
u_{n-3,t}+(n-4)u_{n-2}\varphi_t=&-(n-2)(n-3)(n-4)u_n+3(n-4)\\
&\times\sum_{m=0}^{n}u_{n-m}u_m-(\alpha-1+c)\sum_{m=0}^{n}(m-1)(m-2)(m-3)w_{n-m}w_m\\
&-\frac{1}{2}(3\alpha+3-c)(n-4)\sum_{m=0}^{n}(n-m-1)(m-1)w_{n-m}w_m+\beta(n-4)\\
&\times\sum_{m=0}^{n}\sum_{l=0}^{m}u_{u-m}w_{m-l}w_l+\frac{1}{2}c(n-4)\\
&\times\sum_{m=0}^{n+2r-3}(n+2r-3-2m)\xi^{(i)}_{n+2r-3-m}\xi^{(i)}_m+2\beta(n-4)\\
&\times\sum_{m=0}^{n+2r-3}\sum_{l=0}^{m}\xi^{(2)}_{n+2r-3-m}\xi^{(1)}_{m-l}w_l
\end{aligned}$$

$$\begin{aligned}
\xi^{(i)}_{n-3,t}+(n-r-2)\xi^{(i)}_{n-2}\varphi_t=&-(n-r)(n-r-1)(n-r-2)\xi^{(i)}_n\\
&+c\sum_{m=0}^{n}(n-m-2)u_{n-m}\xi^{(i)}_m+(6-c)\\
&\times\sum_{m=0}^{n}(m-r)u_{n-m}\xi^{(i)}_m+\beta(n-r-2)\\
&\times\sum_{m=0}^{n}\sum_{l=0}^{m}\xi^{(i)}_{n-m}w_{m-l}w_l-c\sum_{m=0}^{n}(n-m-r)(n-m-r-1)\\
&\times\epsilon_{ij}\xi^{(j)}_{n-m}w_m-(6-c)\sum_{m=0}^{n}(n-m-r)(m-1)\epsilon_{ij}\xi^{(j)}_{n-m}w_m\\
&-(\alpha-1)(n-r-1)(n-r-2)\sum_{m=0}^{n}\epsilon_{ij}\xi^{(j)}_{n-m}w_m
\end{aligned} \tag{3.3}$$

$$w_{n-3,t}+(n-3)w_{n-2}\varphi_t=-(n-1)(n-2)(n-3)w_n+c\sum_{m=0}^{n}(n-m-2)u_{n-m}w_m+(6-c)$$
$$\times\sum_{m=0}^{n}(m-1)u_{u-m}w_m+(\alpha-1)(n-3)\sum_{m=0}^{n}u_{n-m}w_m+\frac{1}{3}\beta(n-3)$$
$$\times\sum_{m=0}^{n}\sum_{l=0}^{m}w_{n-m}w_{m-l}w_l+(\alpha-1)(n-3)\sum_{m=0}^{n+2r-3}\xi^{(2)}_{n+2r-3-m}\xi^{(1)}_m.$$

Here n takes any integer value from $\min(3-2r,0)$ to ∞ (sticking to the principal family). It is understood that every field-component with a negative index is zero. For the system of equations to be integrable, the solution needs to contain a sufficient number of arbitrary functions. For the case under study, the system being composed of four coupled third order equations, there should be twelve arbitrary functions, six bosonic and six fermionic. With the leading singularities fixed, we need to determine those (recursion) levels n—the resonances—in (3.3) for which there are arbitrary functions. That clearly requires n to be an integer. At each such level, the equation must vanish identically without enforcing any constraints on the lower-order arbitrary functions. These are the compatibility conditions at the resonances. We then proceed in two steps. We first find all the possible values of the free parameters for which the bosonic-core system has the Painlevé property. Then, for those special parameters, we complete the analysis for the full system with the fermionic fields reintroduced.

IV. THE PAINLEVÉ ANALYSIS OF THE BOSONIC CORE

The bosonic-core analysis is the most important and also the most involved part of this work. It amounts to consider one-by-one a long sequence of special cases. Although the analysis is straightforward for most of them, there is a number of cases (that include cases in which the test is satisfied) for which this is not so. For this reason, a somewhat detailed presentation of all the possibilities is required. It is reported in Appendix A. For the ease of reading, we collect in this section the final results of this Appendix.

The only cases for which the Painlevé property of the bosonic core is fully satisfied are listed below. Note that the ''body'' (i.e., without the nilpotent part) values of u_0 and w_0 represent an important part of the data since it is necessary to fix uniquely the leading singularity of the fermionic fields. Here, $k=\pm i$,

(I) SKdV_{-2}

$c=3,\ \alpha=-2,\ \beta=-6,\ u_0=-1,\ w_0=k;$

(II) SKdV_1

$c=3,\ \alpha=1,\ \beta=3,\ u_0=1,\ w_0=k;$

(III) SKdV_4

$c=3,\ \alpha=4,\ \beta=12,\ u_0=\frac{1}{2},\ w_0=\frac{1}{2}k;$

(IV) $\mathrm{SKdV}_{\mathcal{O}}$

$c=0,\ \alpha=1,\ \beta=0,\ u_0=1,\ w_0=k;$

(V) SKdV_{-2} (''degenerate'' case)

$c=3,\ \alpha=-2,\ \beta=-6,\ u_0=2,\ w_0=0.$

Cases (I)–(V) are those with nonnegative resonances. For completeness, we also present all other possible solutions that are not in principal families. These are listed below. It is always understood that j_1, k_1, and k_2 are integers,

(VI) $c=3,\ \alpha=\frac{1}{2}j_1(j_1-3)-1,\ \beta=\frac{3}{2}j_1(j_1-3)-1,$

$$u_0=2, \qquad w_0=0$$

$$(j_1\geqslant 4);$$

(VII) $$c=3,\ \alpha=\frac{6k_1}{k_1(3-k_2)+k_2(k_2+1)-6}-2,$$

$$\beta=108\frac{k_1-2}{(k_1(3-k_2)+k_2(k_2+1)-6)^2},$$

$$u_0=\tfrac{1}{6}(k_1(3-k_2)+k_2(k_2+1)-6),$$

$$w_0=ku_0$$

$$(k_1\geqslant\max(5,2k_2+1),\ k_2\geqslant -1);$$

(VIII) $$c=3,\ \alpha=\frac{6k_1}{k_1(3-k_2)+k_2(k_2+1)-6}-2,$$

$$\beta=108\frac{k_1-2}{(k_1(3-k_2)+k_2(k_2+1)-6)^2},$$

$$u_0=\tfrac{1}{6}(k_1(3-k_2)+k_2(k_2+1)-6),$$

$$w_0=ku_0$$

$$(k_1\geqslant 5,\ k_2\leqslant -4);$$

(IX) $$c=3,\ \alpha=2\frac{7-k_1^2}{2+k_1^2},\quad \beta=\frac{108}{(2+k_1^2)^2},$$

$$u_0=\tfrac{1}{6}(2+k_1^2),\ w_0=ku_0$$

$$(k_1\geqslant 5);$$

(X) $$c=3,\ \alpha=-4\frac{k_1}{5k_1+6},\ \beta=108\frac{k_1}{(5k_1+6)^2},$$

$$u_0=\tfrac{5}{6}k_1+1, \qquad w_0=ku_0$$

$$(k_1\leqslant -7);$$

(XI) $$c=3,\ \alpha=-4\frac{k_1}{5k_1+6},\ \beta=108\frac{k_1}{(5k_1+6)^2},$$

$$u_0=\tfrac{5}{6}k_1+1, \qquad w_0=ku_0$$

$$(k_1\geqslant 3);$$

(XII) $c=0,\ \alpha=7,\ u_0=2,\ w_0=0;$

(XIII) $c=0,\ \alpha=1,\ u_0=2,\ w_0=0;$

(XIV) $c=0,\ \alpha=-\frac{7}{31},\ \beta=-\frac{78}{961},\ u_0=-31,\ w_0=ku_0;$

(XV) $c=0,\ \alpha=-\frac{5}{21},\ \beta=-\frac{6}{49},\ u_0=-21,\ w_0=ku_0;$

(XVI) $c=0,\ \alpha=-\frac{1}{7},\ \beta=\frac{15}{98},\ u_0=14,\ w_0=ku_0;$

(XVII) $c=0,\ \alpha=-\frac{7}{5},\ \beta=0,\ u_0=-5,\ w_0=ku_0.$

V. THE PAINLEVÉ ANALYSIS OF THE FULL FERMIONIC SYSTEMS OF THE FOUR INTEGRABLE $N=2$ SUPERSYMMETRIC SYSTEMS

In a second step, the Painlevé analysis is completed for the fermionic extension of the successful bosonic systems. We omit the details of the $\mathrm{SKdV}_{-2,4,\mathcal{O}}$ analysis and sketch some aspects of the analysis of the SKdV_1 equation.

A. Analysis of the SKdV_1 equation

In Appendix B, it is shown that the leading singularity of fermionic fields must be $r=2$ and that the following condition must hold:

$$\xi_0^{(2)}=k_0\xi_0^{(1)}, \tag{5.1}$$

where $k_0^2=-1$.[22] With this condition, (3.3) for $n=-1$, which reads

$$-30\alpha\xi_0^{(1)}\xi_0^{(2)}w_0=0,\ \ -4(\alpha-1)\xi_0^{(1)}\xi_0^{(2)}=0, \tag{5.2}$$

is automatically satisfied.

From the resonance equations obtained in Appendices A and B, the bosonic resonances must occurs at the roots of

$$(n+1)(n-1)(n-2)(n-3)(n-4)(n-6)=0 \tag{5.3}$$

corresponding to the arbitrariness of φ, w_1, w_2, w_3, u_4, and w_6, whereas the fermionic ones are determined by the roots of

$$n(n-2)^2(n-4)^2(n-6)=0 \tag{5.4}$$

corresponding to the arbitrariness of $\xi_0^{(1)}$, $\xi_2^{(1)}$, $\xi_2^{(2)}$, $\xi_4^{(1)}$, $\xi_4^{(2)}$, and $\xi_6^{(1)}$.

The introduction of the fermionic fields brings a little complexity right at the beginning of the analysis in that it is necessary to use both the $n=0$ and $n=1$ conditions in order to fix u_0, $\xi_0^{(i)}$, and w_0 unambiguously. Once this is settled, the remaining part of the analysis is straightforward, apart from the plain fact that the equations are rather complicated.

The most general solution to the recursion formulas at level $n=0$, for which the bosonic part reduces to the one found in the bosonic-core analysis (with constant k appearing in w_0 fixed to $k=-k_0$, as shown in Appendix B), is

$$u_0=1-\tfrac{2}{3}\lambda_0\xi_0^{(1)},\ \ \xi_0^{(2)}=k_0\xi_0^{(1)},$$

$$w_0=-k_0+\lambda_0\xi_0^{(2)},\ \ \xi_1^{(2)}=k_0\xi_1^{(1)}+\tfrac{4}{3}k_0\lambda_0+k_1\xi_0^{(2)}, \tag{5.5}$$

where $k_0^2=-1$, k_1 is a (even) constant, λ_0 is a fermionic constant, and $\xi_0^{(1)}$ is an arbitrary fermionic function.

In order to fix uniquely u_0 and w_0, we need to consider the equations for $n=1$. At this level, a substitution of (5.5) into the recursion equations leads to ($k_0^2=-1$)

$$u_0=1,\ \xi_0^{(1)}\text{arbitrary},\ \xi_0^{(2)}=k_0\xi_0^{(1)},\ w_0=-k_0,$$

$$u_1=0,\ \xi_1^{(1)}=0,\ \xi_1^{(2)}=0,\ w_1=0. \tag{5.6}$$

Pursuing the analysis of (3.3), one can verify that all the compatibility conditions at the various resonances are satisfied. Since the resulting equations are very long, this part of the analysis will be omitted. Notice that since the equation for w_6 depends upon the value of $\xi_7^{(i)}$ ($i=1,2$), we have to go up to level $n=7$ to fix completely the different nonarbitrary functions needed to verify this particular compatibility condition. The analysis for levels $n=5$ to $n=7$ is actually very complicated; the computations have been made with Maple (with the package Grassmann).

B. Comments on the other three cases

The analysis for the other three cases singled out by the bosonic-core analysis has also been performed successfully.

For the SKdV$_{-2}$ equation, only one of the two possible cases identified by the bosonic-core analysis is found to have the Painlevé property; this is case (I). The analysis for this case is not too difficult since the last resonance is fermionic, occurring at level $n=5$, so that we only have to push the analysis up to this level. The arbitrary functions are φ, $\xi_0^{(1)}$, u_1, $\xi_2^{(1)}$, u_3, $\xi_3^{(1)}$, w_3, u_4, $\xi_4^{(1)}$, $\xi_4^{(2)}$, w_4, and $\xi_5^{(1)}$.

For the so-called ''degenerate'' SKdV$_{-2}$ case (V), the Painlevé test immediately fails at the first level since both $\xi_0^{(1)}$ and $\xi_0^{(2)}$ need to be arbitrary and, at the same time, satisfy $\xi_0^{(1)}\xi_0^{(2)}=0$ [cf. (5.2)]. This condition is completely independent of the value of r.

For the SKdV$_4$ equation, the compatibility conditions are all verified and φ, $\xi_0^{(1)}$, w_1, $\xi_2^{(1)}$, u_3, $\xi_3^{(1)}$, w_3, u_4, $\xi_4^{(1)}$, $\xi_4^{(2)}$, u_5, and $\xi_5^{(1)}$ are found to be arbitrary. Notice that there are two resonances at level $n=5$, one of which being bosonic; the analysis must then be extended up to level $n=6$.

For the SKdV$_{\mathcal{O}}$ equation, the bosonic evolution equations decouple from the fermionic ones; this eliminates the necessity of extending the analysis to a higher level in order to check the compatibility condition at the highest resonance. With $r=2$ we find that φ, $\xi_0^{(1)}$, w_1, $\xi_2^{(1)}$, $\xi_2^{(2)}$, w_2, $\xi_3^{(1)}$, w_3, u_4, $\xi_4^{(1)}$, u_6, and $\xi_7^{(1)}$ are arbitrary hence it is not necessary to perform the test for other values of r (since we already know that the system SKdV$_{\mathcal{O}}$ has the Painlevé property).

VI. CONCLUSION

In this work, we have presented the Painlevé analysis (at least, a reduced form of it) for the complete set of bosonic and fermionic evolution equations pertaining to a general multiparameter family of $N=2$ supersymmetric equations. Such an analysis is interesting for a number of reasons. First, very few fermionic extensions of integrable systems have been analyzed from that point of view. The detailed analysis of specific examples is of a clear interest in view of confirming (or limiting or even, in principle, invalidating) the direct extension of the test to fermionic systems. The successful analysis presented here for four $N=2$ supersymmetric extensions of the KdV equation, known to be integrable from other methods, indeed confirms the validity of the naive extension of the test. This, in turn, gives credit to the test when viewed as an exploratory tool in the search for new integrable systems among a multiparameter class of equations. In that respect, the present results have not signaled the existence of a single new integrable equation (although new integrable systems could still in principle be revealed by an analysis that goes beyond the principal families).

Manifestly, that only a rather limited number of examples have been studied so far is partly due to the intrinsic complications of such computations (involving here four coupled nonlinear

equations); however, it is also due to the special complications brought by the fermionic fields themselves. In particular, even the determination of the leading singularity is somewhat problematic (and a simple degree-homogeneity requirement cannot be put forward). This particular question has been treated in great detail here. Another aspect of the present analysis is to have put in light unusual features of the verification of the compatibility conditions for systems involving fermions, unusual in that these conditions can be satisfied in some case only if higher-order recursion relations are solved.

For completeness, we have also checked the Painlevé property for the osp(2, 2) KdV equation, which is $O(2)$ symmetric but not supersymmetric, and found that it successfully passes the test. The equations take the form,

$$u_t=\partial_x[-u_{xx}+3u^2-12\xi^{(i)}\xi_x^{(i)}+24\xi^{(2)}\xi^{(1)}w+2(w_x)^2+2ww_{xx}-6uw^2+3w^4],$$

$$\begin{aligned}\xi_t^{(i)}=&-4\xi_{xxx}^{(i)}+3u_x\xi^{(i)}+6u\xi_x^{(i)}+6w^2\xi_x^{(i)}+6ww_x\xi^{(i)}-12\epsilon_{ij}\xi_{xx}^{(j)}w\\&-12\epsilon_{ij}\xi_x^{(j)}w_x-4\epsilon_{ij}\xi^{(j)}w_{xx}+6u\epsilon_{ij}\xi^{(j)}w-2\epsilon_{ij}\xi^{(j)}w^3\end{aligned}\tag{6.1}$$

with $w_t=0$. Since the w-evolution equation is trivial this field has no singularity; however, relying on the degree-homogeneity property, we have set $w=\Sigma_{n=0}^{\infty}w_n\varphi^{n-1}$ and $w_0=0$. Moreover, the fermionic fields are also singularity-free at the leading order; therefore, u is the only field having a leading singularity, which in itself is a rather uncommon feature.

We stress finally that the analysis has been presented here in terms of the component fields. Hence, we have not taken advantage of the economical superfield formalism. In fact, the Painlevé test has never been formulated in superspace. That would be a definite progress since it is only in such a case that we could face a more refined analysis that does not rely upon the simplified Kruskal ansatz. The benefit of such a generalization is the ability to make contact, in the early steps of the analysis, with Backlünd transformations and Lax pairs (see e.g., Ref. 23). We hope to report elsewhere on this topic.

Note added in proof. Apart from the cases mentioned in the third paragraph of Sec. I, there are two further integrable extensions of the KdV equation with an extra boson and two fermions also defined via the 'second' Hamiltonian structure equivalent to the classical superconformal algebra (see e.g., Eqs. (4.14)–(4.17) and (4.23)–(4.24) of F. Delduc, L. Gallot, E. Ivanov, Phys. Lett. B **396**, 122 (1997), hep-th/9611033). The first has $N=1$ supersymmetry and $O(2)$ invariance, while the second has no supersymmetry but it is $O(2)$ invariant (and it differs from the $osp(2,2)$ extension of the Kuper-KdV equation). We thank E. Ivanov for drawing our attention to this point.

APPENDIX A: ANALYSIS OF THE BOSONIC CORE

In this Appendix, we analyze the bosonic core of the generic supersymmetric KdV equations. This boils down to the study of the recursion formulas (3.3) in which we set all fermionic fields equal to zero: $\xi_n^{(i)}=0$ for $i=1,2$. Further references to (3.3) in this appendix are to be understood with this restriction, which transforms this system into a set of two coupled bosonic equations.

Before considering the general recursion equations and determining its resonances, we first analyze the recursion formulas at levels $n=0,1$ for the cases $c=0,3$, in order to impose as much constraints as possible in the very early steps of the analysis. For every solution found at those levels, we need to write the resonance equation in order to identify those cases that are potentially Painlevé admissible. Note however that a single solution to the $n=0,1$ relations can lead to more than one resonance equation; the different possibilities must then be analyzed one by one. The cases $c=0,3$ are studied separately.

1. The $c=3$ case

The recursion formulas (3.3), with $c=3$, can be written under the form,

$$A_1^1 u_n + A_2^1 w_n = F_n^1,$$

$$A_1^2 u_n + A_2^2 w_n = F_n^2, \tag{A1}$$

where

$$A_1^1(n) = [-(n-2)(n-3) + 6u_0 + \beta w_0^2](n-4),$$

$$A_2^1(n) = [-(\alpha+2)n^2 + (5\alpha+4)n - 6(\alpha+1) + 2\beta u_0](n-4)w_0,$$

$$A_1^2(n) = (\alpha+2)(n-3)w_0,$$

$$A_2^2(n) = [-(n-1)(n-2) + (\alpha+2)u_0 + \beta w_0^2](n-3), \tag{A2}$$

and F_n^1 and F_n^2 are functions of $u_0, u_1, \ldots, u_{n-1}$ and $w_0, w_1, \ldots, w_{n-1}$. There is a resonance when this system is not defined, that is, when

$$A(n) = \det|A_j^i(n)| = 0 \quad (i,j = 1,2). \tag{A3}$$

The substitution of α, β, u_0, and w_0 (whenever they are known) for each case identified will then yield the values of the resonance levels n. It should be stressed that we are particularly interested in cases in which there is a resonance at level $n=-1$ (corresponding to the arbitrariness of the singular manifold φ) with the other ones being integers $\geqslant 1$, unless either u_0 or w_0 is arbitrary, in which case we also need a resonance at level zero. The cases for which negative resonances appear will be given, but the search for movable logarithms will be omitted.

Here are the solutions of the recursion equations for levels $n=0,1$, the results of the resonance analysis and their compatibility conditions. When the test is not satisfied, we simply indicate the reason (and avoid repeating: therefore the test is not satisfied).

(i) $$u_0 = 0, \qquad u_1 = 0,$$

$$w_0 = 0, \quad w_1 \text{ arbitrary.}$$

This case can readily be eliminated given the absence of singularities. Similarly, cases (ii) and (iii) below could have been eliminated from the start since there are no singularities for the field w; however, being interested in a supersymmetric extension for the field u— which is thus the ''leading'' field—this restriction will not be imposed.

(ii) $$u_0 = 2, \quad u_1 = 0,$$

$$w_0 = 0, \quad w_1 = 0,$$

$$A(n) = (n+1)(n-3)(n-4)(n-6)(n^2 - 3n - 2(\alpha+1)).$$

Given that the two roots of the second order polynomial are j_1 and j_2, we thus have

$$j_2 = 3 - j_1, \quad \alpha = \tfrac{1}{2} j_1(j_1 - 3) - 1, \tag{A4}$$

and we can choose $j_1 \geqslant j_2$. Now since the coefficients at level 0 and 1 are fixed, a resonance at one of those levels would signal the presence of a movable logarithm. In consequence, there is no

solution in a principal family (with both j_1 and $j_2 \geqslant 0$) free from movable logarithms. The only other cases left are those for which $j_1 \geqslant 4$. For those cases, the compatibility conditions at level 6 are satisfied only for $\beta = 3\alpha$.

(iii) $\alpha = -2$,

$$u_0 = 2, \quad u_1 = 0,$$

$$w_0 = 0, \quad w_1 \text{ arbitrary},$$

$$A(n) = (n+1)(n-1)(n-2)(n-3)(n-4)(n-6).$$

The resonances correspond to the arbitrariness of $\varphi, w_1, w_2, w_3, u_4, u_6$. All compatibility conditions are verified without constraints on the parameters, except the one at level 6 which forces $\beta = 3\alpha = -6$. This will turn out to correspond to a nonintegrable solution of the recursion relations associated to the $\mathrm{SKdV}_{\alpha=-2}$ equation.

(iv) $\alpha = -1$,

$$u_0 \text{ not fixed yet or arbitrary}, \quad u_1 = 0,$$

$$w_0 = k\sqrt{\frac{3}{\beta}(u_0 - 2)}, \quad w_1 = 0,$$

$$A(n) = (n+1)n(n-3)(n-4)(n^2 - 9n - (u_0 - 20) - (3/\beta)(u_0 - 2)),$$

where (here and below) $k^2 = -1$. The resonance at level 0 would signal a movable logarithm if u_0 would have to be fixed. Moreover, $A(n)$ would need to be independent of u_0 for this coefficient to be arbitrary. This leads to $\beta = -3$ and

$$A(n) = (n+1)n(n-3)^2(n-4)(n-6). \tag{A5}$$

However, the compatibility conditions at level 3 are not satisfied.

(v) $\alpha = -1, \quad \beta = 3\left[\frac{u_0 - 2}{P}\right]$,

$$u_0 \text{ fixed by value of } \beta, \quad u_1 = 0,$$

$$w_0 = k\sqrt{P}, \quad w_1 = 0,$$

$$A(n) = (n+1)n(n-3)(n-4)[(n-1)(n-8) - 3u_0(u_0 - 2)],$$

with $P = 3(u_0)^2 - 7u_0 + 12$. The resonance at level 0 signals the presence of a movable logarithm.

(vi) $\alpha = -1, \quad \beta = -\frac{8}{3}$,

$$u_0 = -\tfrac{4}{3}, \quad u_1 = 0,$$

$$w_0 = \tfrac{1}{2}k\sqrt{15}, \quad w_1 = 0,$$

$$A(n) = (n+1)n(n-3)(n-4)\left[n^2 - 9n + \frac{211}{12}\right].$$

$A(n)$ has noninteger roots.

(vii) $\beta=3\left[\dfrac{(\alpha+2)u_0-2}{u_0^2}\right]$,

$$u_0 \text{ fixed by the value of } \beta, \quad u_1=0,$$

$$w_0=ku_0, \quad w_1=0,$$

$$A(n)=(n+1)(n-3)(n-4)(n-m)[n^2+(m-9)n+6(4-u_0-m)],$$

where $m=4-(\alpha+2)u_0$. Writing the two roots of the second order polynomial as j_1 and j_2, the general solution can be written (with k_1 and k_2 integers)

$$m=4-k_1, \ j_1=3+k_2, \ j_2=2+k_1-k_2, \ k_1\geqslant 2k_2+1 \tag{A6}$$

with

$$u_0=\tfrac{1}{6}(k_1(3-k_2)+k_2(k_2+1)-6),$$

$$\alpha=\frac{6k_1}{k_1(3-k_2)+k_2(k_2+1)-6}-2,$$

$$\beta=108\frac{k_1-2}{(k_1(3-k_2)+k_2(k_2+1)-6)^2}. \tag{A7}$$

The principal families are characterized by

$$-1\leqslant k_2\leqslant 2k_2+1\leqslant k_1\leqslant 2 \tag{A8}$$

for which the possible solutions are

vii.e	4	2	3	-2	-6	-1
vii.f	5	2	2	$-\frac{7}{5}$	$-\frac{81}{25}$	$-\frac{5}{3}$

Case vii.b can be eliminated since there are no singularities (and moreover $\alpha, \beta\to\infty$). For cases vii.a, c, d and f, the compatibility conditions at level $n=2,3,3,2$, respectively, are not satisfied. For vii.e all the conditions are satisfied so that this system passes the test (φ, u_1, u_3, w_3, u_4, and w_4 are all arbitrary functions). It corresponds to the bosonic core of the $\mathrm{SKdV}_{\alpha=-2}$ equation.
The only other solutions of interest (with negative resonances) are given by

vii.g	$k_1\geqslant\max(5,2k_2+1)$	$k_2\geqslant -1$
vii.h	$k_1\geqslant 5$	$k_2\leqslant -4$

(viii) $\beta=\frac{1}{3}(\alpha+2)^2$,

$$u_0=\frac{3}{\alpha+2}, \quad u_1=0,$$

$$w_0=ku_0, \quad w_1 \text{ arbitrary},$$

$$A(n)=(n+1)(n-1)(n-3)(n-4)(n^2-8n-6(u_0-3)).$$

We write the two roots of the quadratic term as

$$j_1=4-k_1, \ j_2=4+k_1, \ k_1\geqslant 1, \tag{A9}$$

with k_1 an integer and

$$u_0=\tfrac{1}{6}(2+k_1^2), \ \alpha=2\,\frac{7-k_1^2}{2+k_1^2}. \tag{A10}$$

The principal families (free from movable logarithms) are characterized by $k_1=1,2$ so that we have

	j_1	j_2	α	β	u_0
viii.a	2	6	1	3	1
viii.b	3	5	4	12	$\frac{1}{2}$

For viii.a and b, all the compatibility conditions are satisfied. Those systems describe the bosonic core of the $\mathrm{SKdV}_{\alpha=1}$ (with φ, w_1, w_2, w_3, u_4, and w_6 arbitrary) and $\mathrm{SKdV}_{\alpha=4}$ (with φ, w_1, u_3, w_3, u_4, and u_5 arbitrary) equations, respectively.
The other possible cases are those for which $k_1\geqslant 5$,

(ix) $\beta=-\frac{9}{8}\alpha(5\alpha+4)$,

$$u_0=\frac{4}{5\alpha+4}, \quad u_1=\frac{1}{2}\left(\frac{11\alpha+4}{\alpha+2}\right)kw_1,$$

$$w_0=ku_0, \quad w_1 \text{ arbitrary}.$$

Note however that in the singular case where $\alpha=-2$, $w_1=0$, and u_1 is arbitrary.

$$A(n)=(n+1)(n-1)(n-3)(n-4)(n+\tfrac{6}{5}u_0-\tfrac{16}{5})(n-\tfrac{6}{5}u_0-\tfrac{24}{5}).$$

We can write the two roots of the last two factors as

$$j_1=2-k_1, \quad j_2=6+k_1, \tag{A11}$$

with

$$u_0=\frac{5}{6}k_1+1, \quad \alpha=-4\,\frac{k_1}{5k_1+6}. \tag{A12}$$

The principal families (with $-4\leqslant k_1\leqslant 0$) are thus

	j_1	j_2	α	β	u_0
ix.a	2	6	0	0	1
ix.b	3	5	4	-108	$\frac{1}{6}$
ix.c	4	4	-2	$-\frac{27}{2}$	$-\frac{2}{3}$
ix.d	5	3	$-\frac{4}{3}$	-4	$-\frac{3}{2}$
ix.e	6	2	$-\frac{8}{7}$	$-\frac{108}{49}$	$-\frac{7}{3}$

The resonance conditions are not met at level $n=2,3,4,3,2$, respectively. The other solutions are

ix.f	$k_1 \leqslant -7$
ix.g	$k_1 \geqslant 3.$

When $c=3$, there are thus only 4 cases in principal families for which the Painlevé test is satisfied for the bosonic core of our multiparameter version of the SKdV equation. Those cases correspond to (I), (II), (III), and (V) in the list of Sec. IV. There is also some other cases with negative resonances. Those cases will be classified as (VI), (VII), (VIII), (IX), (X), and (XI).

2. The $c=0$ case

The recursion formulas (3.3) with $c=0$ take the form (A1) with

$$A_1^1(n)=[-(n-2)(n-3)+6u_0+\beta w_0^2](n-4),$$

$$A_2^1(n)=[-(\alpha-1)n(n+1)+6\alpha(n-1)+2\beta u_0](n-4)w_0,$$

$$A_1^2(n)=[(\alpha-1)(n-3)-6]w_0,$$

$$A_2^2(n)=-(n-1)(n-2)(n-3)+(\alpha-1)(n-3)u_0+6(n-1)u_0+\beta(n-3)w_0^2. \quad \text{(A13)}$$

The possible solutions of the resonance conditions are now listed in turn.

(i) $u_0=0, \quad u_1=0,$

$$w_0=0, \quad w_1 \text{ arbitrary.}$$

Again, this case is eliminated due to the absence of singularity but, as before, we will keep the cases (ii) and (iii) below even if w is not singular.

(ii) $u_0=2, \quad u_1=0,$

$$w_0=0, \quad w_1=0,$$

$$A(n)=(n+1)(n-4)(n-6)(n^3-6n^2+n-2\alpha(n-3)).$$

Writing the last factor under the form $(n-j_1)(n-j_2)(n-j_3)$, the constants j_1,j_2,j_3 must satisfy

$$j_1+j_2+j_3=6, \quad j_1j_2+(j_1+j_2)j_3=1-2\alpha, \quad j_1j_2j_3=-6\alpha, \quad \text{(A14)}$$

and we can choose $j_2 \leqslant j_3$. The second condition requires that α be an integer or half-integer so that the third condition allow us to choose $j_1 = 3m$, where m is an integer. This leads to the equation

$$9m(m-1) - 9(m-1) + (m-1)j_2 j_3 = 8. \tag{A15}$$

$m-1$ must thus be a divisor of 8. With this last condition, a case-by-case analysis leads to the only two possible solutions (which are not in principal families),

	j_1	j_2	j_3	α
ii.a	-1	1	6	1
ii.b	-3	2	7	7

Case (ii.a) can be eliminated since the resonance at level $n=1$ signals a movable logarithm.

(iii) $\alpha = 1$,

$$u_0 = 2, \quad u_1 = 0,$$

$$w_0 = 0, \quad w_1 \text{ arbitrary},$$

$$A(n) = (n+1)^2(n-1)(n-4)(n-6)^2.$$

This case is not a principal family solution but all positive resonances are verified.

(iv) $\alpha = 0$,

$$u_0 \text{ not fixed yet}, \quad u_1 = 0,$$

$$w_0 = k\sqrt{\frac{3}{\beta}(u_0 - 2)}, \quad w_1 = 0,$$

$$A(n) = (n+1)n(n-4)\left[n^3 - 12n^2 - \frac{1}{\beta}((3+5\beta)u_0 - 47\beta - 6)n - 9\frac{(1-3\beta)}{\beta}u_0 + 6\frac{(3-10\beta)}{\beta}\right]$$

(recall that $k = \pm i$). To fix the three roots of the cubic polynomial, u_0 must be fixed so that the resonance at level $n=0$ signals the presence of a movable logarithm.

(v) $\alpha = 0$,

$$u_0 = 12\left(\frac{1-\beta}{6-11\beta}\right), \quad u_1 = -(3\beta+2)\sqrt{\frac{3}{10}\left(\frac{1}{6-11\beta}\right)}kw_1,$$

$$w_0\sqrt{\frac{30}{6-11\beta}}k, \quad w_1 \text{ arbitrary},$$

$$A(n) = (n+1)n(n-1)(n-4)\left(n^4 - 11n + \frac{126-336\beta}{6-11\beta}\right).$$

There is a resonance at level $n=0$ but u_0 and w_0 are both fixed.

(vi) $\alpha=\dfrac{(\beta u_0-3)u_0+6}{3u_0}$,

$$u_0 \text{ fixed by the value of } \alpha, \quad u_1=0,$$

$$w_0=ku_0, \quad w_1=0,$$

$$A(n)=(n+1)(n-4)[n^2+(\tfrac{1}{3}\beta u_0^2-2u_0-5)n-\beta u_0^2+6]$$

$$\times[n^2-(\tfrac{1}{3}\beta u_0^2-2u_0+7)n-6u_0+2\beta u_0^2+12].$$

Writing

$$\beta u_0^2=k_1, \quad u_0=\tfrac{1}{2}k_2+\tfrac{1}{6}k_1,$$

the roots of the two quadratic polynomials j_1, j_2, j_3, and j_4 are the integers satisfying

$$j_1+j_2=5+k_2, \quad j_1j_2=6-k_1,$$

$$j_3+j_4=7-k_2, \quad j_3j_4=12+k_1-3k_2, \tag{A16}$$

and we choose $j_1\leqslant j_2$ and $j_3\leqslant j_4$. Introducing the auxiliary integers k_3 and k_4 such that

$$j_1=3+k_2-k_3, \quad j_2=2+k_3,$$

$$j_3=3+k_4-k_2, \quad j_4=4-k_4, \tag{A17}$$

with $2k_4+1\leqslant k_2\leqslant 2k_3-1$. The constraints can be written as

$$k_2(k_3+k_4+1)=0,$$

$$k_3+k_4=k_3^2+k_4^2,$$

$$k_4(k_4+k_4k_3-k_3^2-1)=k_1(1+k_3+k_4), \tag{A18}$$

so that the only possible solution is $(k_1,k_2,k_3,k_4)=(0,0,1,0)$ which correspond to

$$(j_1,j_2,j_3,j_4u_0,\alpha,\beta)=\left(2,3,3,4,0,\sim\frac{1}{u_0},\sim\frac{1}{u_0}\right).$$

However, the compatibility conditions at level $n=3$ are not satisfied.

(vii) $\alpha=\dfrac{3-2u_0}{u_0}$, $\beta=-3\left(\dfrac{u_0-1}{u_0^2}\right)$,

$$u_0 \text{ fixed by } \alpha \text{ and } \beta, \quad u_1=0,$$

$$w_0=ku_0, \quad w_1=0,$$

$$A(n)=(n+1)(n-1)(n-4)(n-m)[n^2+(m-11)n-2(2m-15)]$$

with $m=3(u_0+1)$. The two roots of the quadratic polynomial are

$$j_1,j_2=\frac{8-3u_0}{2}\mp\frac{1}{2}\sqrt{9u_0^2-8}. \tag{A19}$$

Since j_1, j_2 and m are integers, we must have $u_0 = \frac{1}{3}k_1$ with k_1 as an integer. This leads to the condition

$$9u_0^2 - 8 = k_1^2 - 8 = k_2^2, \tag{A20}$$

where k_2 is also an integer but this equation has a solution only when $k_1 = \pm 3$. With $k_1 = -3$, there should be a resonance at level $n = 0$ so that there is a movable logarithm. The only solution is thus $u_0 = 1$, which yields $m = 6$, $j_1 = 2$, $j_2 = 3$ and $\alpha = 1$, $\beta = 0$. All the resonance conditions are verified: φ, w_1, w_2, w_3, u_4, and u_6 are genuine arbitrary functions. Actually, this system is the bosonic core of the SKdV$_{\mathcal{O}}$ equation.

(viii) $$\alpha = \frac{1}{5}\left(\frac{4-u_0}{u_0}\right), \quad \beta = \frac{6}{5}\left(\frac{2u_0-3}{u_0^2}\right),$$

$$u_0 \text{ fixed by } \alpha \text{ and } \beta, \quad u_1 = -2\,\frac{9u_0-11}{9u_0+4}\,kw_1,$$

$$w_0 = ku_0, \qquad w_1 \text{ arbitrary},$$

$$A(n) = (n+1)(n-1)(n-4)(n-m)[n^2-(11-m)n+2m],$$

with $m = \frac{6}{5}(4-u_0)$. Writing the roots of the second order polynomial as j_1 and j_2, we thus have

$$j_1 + j_2 = m - 11, \quad j_1 j_2 = 2m \tag{A21}$$

and we choose $j_1 \leqslant j_2$. Elimination of m leads to the formula,

$$j_2 = \frac{26}{j_1+2} - 2, \tag{A22}$$

so that $2 + j_1$ must be a divisor of 26. We thus find that the only possible solutions are

	m	j_1	j_2	u_0	α	β
viii.a	42	-28	-3	-31	$-\frac{7}{31}$	$-\frac{78}{961}$
viii.b	30	-15	-4	-21	$-\frac{5}{21}$	$-\frac{6}{49}$
viii.c	0	0	11	4	0	$\frac{3}{8}$
viii.d	-12	-1	24	14	$-\frac{1}{7}$	$\frac{15}{98}$

Case (viii.c) can be eliminated since there are movable logarithms at level $n = 0$.

(ix) $$\alpha = \tfrac{1}{3}, \quad \beta = 0,$$

$$u_0 = \tfrac{3}{2}, \quad u_1 = -\tfrac{2}{7}kw_1,$$

$$w_0 = ku_0, \quad w_1 \text{ arbitrary},$$

$$A(n) = (n+1)(n-1)(n-3)(n-4)(n^2-8n+6).$$

$A(n)$ has noninteger roots.

(x) $\beta=0$,

$$u_0=\frac{2}{\alpha+1}, \quad u_1=0,$$

$$w_0=ku_0, \quad w_1=0,$$

$$A(n)=(n+1)(n-3)(n-4)(n-m)(n^2+(m-9)n+6),$$

with $m=2(2-u_0)$. The roots of the quadratic piece are

$$j_1,j_2=\frac{9-m}{2}\mp\frac{1}{2}\sqrt{m^2-18m+57} \tag{A23}$$

with $j_1\leqslant j_2$. We can write the quantity inside the square root as

$$m^2-18m+57=(m-9)^2-24=k_1^2, \tag{A24}$$

where k_1 must be an integer. In consequence, we must have $m=14$ or $m=4$. The choice $m=4$, $j_1=2$, $j_2=3$ leads to $\alpha\sim\infty$ and $u_0=w_0=u_1=0$ so that there are no singularities at all. The only possible case is thus

$$(m,j_1,j_2,u_0,\alpha,\beta)=(14,-3,-2,-5,-\tfrac{7}{5},0). \tag{A25}$$

(xi) $\alpha=0$, $\beta=0$,

$$u_0=2, \quad u_1=0,$$

$$w_0 \text{ arbitrary}, \quad w_1=0,$$

$$A(n)=(n+1)n(n-4)(n^3-12n^2+w_0^2n+37n-6+3w_0^2).$$

There is a resonance at level $n=0$ but u_0 is already fixed and w_0 cannot be arbitrary since it enters in the expression of the other resonances.

(xii) $\alpha=0$, $\beta=0$,

$$u_0=2, \quad u_1 \text{ arbitrary},$$

$$w_0=\sqrt{5}k, \quad w_1=\sqrt{5}ku_1,$$

$$A(n)=(n+1)n(n-1)(n-4)(n^2-11n+21).$$

There is a resonance at level $n=0$ while u_0 and w_0 are both fixed and moreover $A(n)$ has noninteger roots.

For $c=0$, we have thus found only one case in a principal family for which the bosonic core passes the test: this is case (IV) of Sec. IV. Some other possibilities can be identified as cases (XII)–(XVII).

APPENDIX B: LEADING SINGULARITY AND RESONANCE EQUATION FOR FERMIONIC FIELDS

The general recursion equations for the fermionic evolution equations can be written as [cf. (3.3)]

$$B_1^1(n)\xi_n^{(1)}+B_2^1(n)\xi_n^{(2)}=G_n^1,$$
$$B_1^2(n)\xi_n^{(1)}+B_2^2(n)\xi_n^{(2)}=G_n^2, \tag{B1}$$

where

$$B_1^1(n)=B_2^2(n)=-(n-r)(n-r-1)(n-r-2)-2cu_0+(6-c)(n-r)u_0+\beta(n-r-2)w_0^2,$$
$$B_1^2(n)=-B_2^1(n)=[c(n-r)(n-r-1)-(6-c)(n-r)+(\alpha-1)(n-r-1)(n-r-2)]w_0, \tag{B2}$$

r is the leading singularity exponent (so that $r\leqslant 0$ corresponds to no singularity) and G_n^i ($i=1,2$) are functions of $\varphi,u_0,\ldots,u_n,\xi_0^{(1,2)},\ldots,\xi_{n-1}^{(1,2)},w_0,\ldots,w_n$.

With $n=0$, we have

$$G_0^i=0,$$
$$B_1^1(0)=r(r+1)(r+2)-2cu_0-(6-c)ru_0-\beta(r+2)w_0^2, \tag{B3}$$
$$B_1^2(0)=[cr(r+1)+(6-c)r+(\alpha-1)(r+1)(r+2)]w_0.$$

Multiplying the first equation in (B1) with $n=0$ by $\xi_0^{(1)}$ and the second by $\xi_0^{(2)}$ yields (using $G_0^i=0$)

$$B_1^1(0)\xi_0^{(1)}\xi_0^{(2)}=B_1^2(0)\xi_0^{(1)}\xi_0^{(2)}=0. \tag{B4}$$

There are thus two possible types of solutions: either the two B_j^i coefficients vanish or $\xi_0^{(1)}\xi_0^{(2)}=0$, that is,

(1) $B_1^1(0)=B_1^2(0)=0$ (no relation between $\xi_0^{(1)}$ and $\xi_0^{(2)}$);

(2) $\xi_0^{(2)}=k_0\xi_0^{(1)}$ (with k_0 a bosonic constant).

The leading singularity is fixed by introducing the values found in the bosonic-core analysis (corresponding to the "body piece," i.e., without the nilpotent part, of the bosonic components) and verify the possible solutions for r.

Before pursuing, the exact meaning of this computation should be clarified. The goal is to fix the leading singularity of the fermionic field for those 5 particular cases for which the bosonic-core analysis manifestly shows the Painlevé property. We thus look for the solutions [type-(1) or (2)] of (B1) for the special values of the parameters c, α, β, u_0, and w_0 given in Sec. IV, appropriate to each possibility. The solutions with negative resonances will not be considered. Now, let us eliminate a possible source of ambiguity in our procedure; *a priori*, the values of u_0 and w_0 entering in (B1) should be those pertaining to the complete system, incorporating the fermions. However, as mentioned above, only the non-nilpotent parts are considered. The reason for this is that since the nilpotent piece can be eliminated by an appropriate multiplication, the bosonic core must also satisfy (B4).

The solutions to case (1) are

(I) $r=-2$,

(II) $r=0,-2$,

(III) $r=-2$,

(IV) $r=0$,

(V) $r=2,-2,-3$.

For case (2), Eq. (B1) for $n=0$ can be written

$$B_1^1(0)-k_0B_1^2(0)=0, \quad k_0^2B_1^1(0)+k_0B_1^2(0)=0. \tag{B5}$$

The compatibility of these equations forces $k_0^2=-1$ or $k_0=\pm i$. The constant $k=\pm i$ that appear in the expression of the bosonic component w_0 (cf. Sec. IV) can thus be either $k=\pm k_0$; both cases need thus to be considered (the precise relation being fixed by the resonance equations). We then find the following possible solutions for r:

$$\begin{aligned}
&\text{(I)} \quad k=+k_0: \quad r=2,-2,-3,\\
&\qquad k=-k_0: \quad r=0,-1,-2,\\
&\text{(II)} \quad k=+k_0: \quad r=0,-2,-4,\\
&\qquad k=-k_0: \quad r=2,0,-2,\\
&\text{(III)} \quad k=+k_0: \quad r=-1,-2,-3,\\
&\qquad k=-k_0: \quad r=2,0,-2,\\
&\text{(IV)} \quad k=+k_0: \quad r=0,-1,-2,\\
&\qquad k=-k_0: \quad r=2,0,-5,\\
&\text{(V)} \quad r=2,-2,-3.
\end{aligned}$$

Observe that the type-(1) solutions for r are recovered as the intersection of the two set of solutions in each case: this is clear since in case (1) we do not assume any special relation between k and k_0; it should then hold for all possibilities, in particular when $k=k_0$ and $-k_0$. In the following, we can thus restrict ourself to type-(2) solutions.

In order to uniquely fix the value of r (and, thereby, the value of k appropriate to each case), we must consider the resonance equations. Since the bosonic resonances are solutions of $A(n)=\det|A_j^i(n)|=0$, the fermionic resonances are necessarily given by

$$B(n)=\det|B_j^i(n)|=0 \quad (i,j=1,2). \tag{B6}$$

Inserting the values already found for r, u_0 and w_0, the roots of $B(n)$ should then lead to the resonance levels for the fermionic fields. The idea is to select r by requiring the corresponding polynomial $B(n)$ to have only integer roots. The explicit form of these polynomials is

$$\begin{aligned}
&\text{(I)} \quad r=2: \quad B(n)=n(n-2)(n-3)(n-4)^2(n-5),\\
&\qquad r=0: \quad B(n)=(n^5-4n^4-n^3+16n^2-12n+36)(n-2),\\
&\qquad r=-1: \quad B(n)=(n^5+n^4-7n^3-n^2+6n+54)(n-1),\\
&\qquad r=-2: \quad B(n)=(n^5+6n^4+7n^3-6n^2-8n+72)n,\\
&\qquad r=-3: \quad B(n)=(n^5+11n^4+41n^3+61n^2+30n+90)(n+1),\\
&\text{(II)} \quad r=2: \quad B(n)=n(n-2)^2(n-4)^2(n-6),\\
&\qquad r=0: \quad B(n)=(n^4-4n^3-4n^2+52n-54)n(n-2),\\
&\qquad r=-2: \quad B(n)=(n^4+4n^3-4n^2+56n-36)(n+2)n,
\end{aligned}$$

$$r=-4: \quad B(n)=(n^4+12n^3+44n^2+156n+54)(n+4)(n+2),$$

(III) $$r=2: \quad B(n)=n(n-2)(n-3)(n-4)^2(n-5),$$

$$r=0: \quad B(n)=(n^4-2n^3-5n^2+42n-18)(n-2)^2,$$

$$r=-1: \quad B(n)=(n^5+n^4-7n^3+53n^2-48n-\tfrac{81}{2})(n-1),$$

$$r=-2: \quad B(n)=(n^4+7n^3+14n^2+80n+108)n(n-1),$$

$$r=-3: \quad B(n)=(n^5+11n^4+41n^3+151n^2+210n-\tfrac{225}{2})(n+1),$$

(IV) $$r=2: \quad B(n)=n(n-2)^2(n-3)(n-4)(n-7),$$

$$r=0: \quad B(n)=(n+2)n^2(n-1)(n-2)(n-5),$$

$$r=-1: \quad B(n)=(n+3)(n+1)^2(n-1)n(n-4),$$

$$r=-2: \quad B(n)=(n+4)(n+2)^2(n+1)n(n-3),$$

$$r=-5: \quad B(n)=(n+7)(n+5)^2(n+4)(n+3)n,$$

(V) $$r=2: \quad B(n)=n^2(n-4)^2(n-5)^2,$$

$$r=-2: \quad B(n)=(n+4)^2n^2(n-1)^2,$$

$$r=-3: \quad B(n)=(n+5)^2(n+1)^2n^2.$$

We can already eliminate all cases for which there are noninteger roots. This leaves us with $r=2$ as the only possibility for cases (I), (II), and (III) while we have some other possibilities for cases (IV) and (V). However, we argue in Sec. V that for the other possibilities we can restrict to $r=2$ (moreover, this amounts to restrict the study to the principal families).

The situation concerning the leading fermionic singularity is thus somewhat peculiar: we essentially keep track of all possibilities and determine the particular values which ensure integer-valued resonances. Quite interestingly, the same value for r is singled out in all cases when we restrict to principal family solutions. Actually, this value corresponds precisely to the one that follows from a naive consideration where the fermionic terms, in the bosonic evolution equations, have a dominant singular behavior comparable to that of the leading bosonic terms.

[21] Notice that in Ref. 3, the following system has also been shown to have the Painlevé property $u_t=-u_{xxx}+6uu_x-3\xi\xi_{xx}$, $\xi_t=-\xi_{xxx}+6(u\xi)_x$. However, the change of variable $v=u-\xi\partial_x^{-1}\xi$ transforms it into [cf. D. Depireux and P. Mathieu, Phys. Lett. B **308**, 272 (1993)]. $v_t=-v_{xxx}+6vv_x$, $\xi_t=-\xi_{xxx}+6(v\xi)_x$, which is somewhat trivial (but clearly integrable) and manifestly not supersymmetric invariant.
[22] Notice that even if the Painlevé analysis breaks the $O(2)$ invariance, we are still free to choose the sign of k_0. Clearly, in a formulation in terms of the redefined fields $\xi^{(\pm)}=\xi^{(1)}\pm i\xi^{(2)}$, we would be free to take either $\xi_0^{(+)}$ or $\xi_0^{(-)}$ as an arbitrary function, the other being null.

(Received 13 November 2000; accepted for publication 2 April 2001)

We define the algebraic variety of almost intertwining matrices to be the set of triples (X,Y,Z) of $n\times n$ matrices for which $XZ=YX+T$ for a rank one matrix T. A surprisingly simple formula is given for tau functions of the KP hierarchy in terms of such triples. The tau functions produced in this way include the soliton and vanishing rational solutions. The induced dynamics of the eigenvalues of the matrix X are considered, leading in special cases to the Ruijsenaars–Schneider particle system. © *2001 American Institute of Physics.* [DOI: 10.1063/1.1379313]

I. INTRODUCTION

The KP hierarchy[1,2] is a well-studied system of integrable nonlinear partial differential equations with Lax form

$$\frac{\partial \mathcal{L}}{\partial t_i}=[\mathcal{L},\mathcal{L}_+^i], \quad i=1,2,3,...$$

for a monic, first-order pseudodifferential operator $\mathcal{L}$. In one of its formulations, the KP hierarchy is a set of bilinear equations for the "tau function" $\tau(t_1,t_2,t_3,t_4,\ldots)$ depending upon infinitely many "time variables" t_i $(i\in\mathbb{Z}_+)$. In this paper we will consider τ functions of the form:

$$\tau_M(t_1,t_2,\ldots):=\det(Xe^{g(Z)}+e^{g(Y)}), \tag{1}$$

where $M=(X,Y,Z)$ is a triple of $n\times n$ constant complex matrices and the function g is defined as

$$g(W):=\sum_{i=1}^{\infty} t_i W^i, \quad t_i\in\mathbb{C}. \tag{2}$$

(To avoid issues of convergence, we will here consider only the case in which all but a finite number of the parameters $t_i\in\mathbb{C}$ are nonzero.)

It is *not* true that (1) always gives the formula for a function which satisfies the KP hierarchy. For instance, as we shall see from Remark 2.2 and Theorem 3.1, in the 2×2 case formula (1) is only a tau function if $\det[(XZ-YX)(Y-Z)]=0$. On the other hand, among the solutions one can obviously write this way are the *one-soliton solutions* which are the natural generalizations in this context of the solitary wave from which the term "soliton" was coined by Zabusky and Kruskal.[3] The *standard* τ function for the one-soliton solution takes the form (1) where $M=(X,Y,Z)\in\mathbb{C}^3$ is any triple of scalar constants. (To exclude the degenerate cases we must further assume that X and $Y-Z$ are nonzero.) This τ function describes a single line soliton of the KP equation. More generally, one may be interested in τ functions of n-soliton solutions ("nonlinear superpositions" of n different line solitons) or their rational degenerations. These τ functions are usually written in a form that looks very different than (1).

a)Electronic mail: kasman@math.cofc.edu

Of course, when X, Y, and Z are scalar as in the one-soliton case, then the determinant which appears in (1) is unnecessary. However, the main result of this paper is that the n-soliton solutions also take the form (1) and that they arise in the case that X, Y, and Z are three $n\times n$ matrices satisfying the condition $\operatorname{rank}(XZ-YX)=1$. In fact, this same rank one condition provides not only the nondegenerate soliton solutions to the KP hierarchy but also their rational degenerations. Thus, we see that the one-soliton τ function is merely a special case of this much more general formula.

II. ALMOST-INTERTWINING MATRICES

It is common to say that an operator X intertwines the operators Y and Z if one has that

$$XZ=YX. \tag{3}$$

Definition 2.1: Given three $n\times n$ matrices X, Y and Z, we define the rank $\kappa(X,Y,Z)$ *to which* X intertwines Y and Z by the formula

$$\kappa(X,Y,Z)=\operatorname{rank}(XZ-YX)=n-\dim\ker(XZ-YX).$$

For fixed $k,n\in\mathbb{N}$ $(0\leqslant k\leqslant n)$ define

$$\mathcal{M}_n^k=\{(X,Y,Z)\,|\,\kappa(X,Y,Z)\leqslant k\}$$

to be the set of all triples of $n\times n$ matrices $M=(X,Y,Z)$ such that $\kappa(M)\leqslant k$.

In most instances, one expects to find that $\kappa(X,Y,Z)=n$, its maximum value. For $\kappa(X,Y,Z)$ to be lower means that X does, in fact, intertwine Y and Z on the positive dimensional subspace $\ker(XZ-YX)$. In particular, when $\kappa(X,Y,Z)=0$, then $XZ=YX$ and so X does actually intertwine the other two matrices. If Y and Z are not intertwined by X, then the best one could ask for would be for $\kappa(X,Y,Z)$ to be equal to one, and so it seems reasonable to say that they are almost intertwined in this case.

Remark 2.1: Note that a triple (X,Y,Z) is in $\mathcal{M}_n^k$ precisely when the $k\times k$ minor determinants of the matrix $XZ-YX$ all vanish. Consequently, $\mathcal{M}_n^k$ has the geometric structure of an affine algebraic variety in the $3n^2$-dimensional vector space of $n\times n$ matrix triples.

The following elementary observations will be used to establish the connection between almost intertwining matrices and solitons:

Lemma 2.1: • There is a natural $GL(n)\times GL(n)$ action on $\mathcal{M}_n^k$ given by

$$(G,H)\in GL(n)\times GL(n):\quad (X,Y,Z)\in\mathcal{M}_n^k\mapsto(GXH^{-1},GYG^{-1},HZH^{-1})\in\mathcal{M}_n^k,$$

which restricts on the diagonal to the natural $GL(n)$ action of simultaneous conjugation

$$G\in GL(n):\quad (X,Y,Z)\in\mathcal{M}_n^k\mapsto(GXG^{-1},GYG^{-1},GZG^{-1})\in\mathcal{M}_n^k.$$

• Let Λ and Ω be $n\times n$ matrices satisfying the commutation relationships

$$[\Lambda,Y]=0,\quad [\Omega,Z]=0,$$

then

$$\kappa(X,Y,Z)=\kappa(\Lambda X\Omega,Y,Z).$$

Proof: Both claims are easily verified by noting that $\kappa(X,Y,Z)\leqslant k$ if and only if

$$XZ=YX+\sum_{i=1}^{k} v_i\otimes w_i \tag{4}$$

for n-vectors $\{v_i\}$ and $\{w_i\}$ and that $\kappa(X,Y,Z)$ is exactly the minimum k for which such an equation exists. □

The main result of this section is the following lemma:

Lemma 2.2: Given three $n\times n$ matrices $\hat{X}$, Y and Z, let $H(a,b,c)\in\mathbb{C}[a,b,c]$ be the polynomial defined by

$$H(a,b,c)=H_1(a)H_2(b,c)-H_1(b)H_2(a,c)+H_1(c)H_2(a,b) \tag{5}$$

with

$$H_1(a)=\det(\hat{X}(aI-Z)+(aI-Y))$$

and

$$H_2(a,b)=(a-b)\det(\hat{X}(aI-Z)(bI-Z)+(aI-Y)(bI-Y)).$$

If $\kappa(\hat{X},Y,Z)\leqslant 1$ then $H(a,b,c)\equiv 0$ is the zero polynomial.

Proof: To say that $\kappa(\hat{X},Y,Z)\leqslant 1$ is equivalent to saying that there exist vectors v and w_1 such that

$$\hat{X}Z-Y\hat{X}=-vw_1^T. \tag{6}$$

[In the case $\kappa(\hat{X},Y,Z)=0$ one of these vectors is the zero vector.] Also, merely for the sake of convenience, we introduce the notation

$$Z_a=(aI-Z),\quad Y_a=(aI-Y)$$

and recall that adj(M) is the classical adjoint matrix [i.e., $\mathrm{adj}(M)=\det(M)M^{-1}$ if M is invertible].

Now, using (6) to eliminate "$\hat{X}Z$," one can rewrite $H_1(a)$, $H_2(a,b)$ as

$$H_1(a)=\det(Y_a(\hat{X}+I)+vw_1^T),\quad H_2(a,b)=(a-b)\det(Y_aY_b(\hat{X}+I)+Y_{a+b}vw_1^T+vw_2^T),$$

where $w_2^T=w_1^TZ$.

Next, since $H(a,b,c)$ depends on $\hat{X}$ polynomially, it is enough to prove that $H(a,b,c)=0$ for almost all $\hat{X}$. Let us assume that $\det(\hat{X}+I)=\gamma\neq 0$. Then we can eliminate reference to $\hat{X}$ by writing

$$H_1(a)=\gamma\det(Y_a+vu_1^T),\quad H_2(a,b)=\gamma(a-b)\det(Y_aY_b+Y_{a+b}vu_1^T+vu_2^T),$$

where

$$u_1^T=w_1\cdot(\hat{X}+I)^{-1},\quad u_2^T=w_2^T\cdot(\hat{X}+I)^{-1}.$$

Let us further rewrite $H_2(a,b)$ as

$$H_2(a,b)=(a-b)\gamma\det(Y_aY_b+Y_avu_1^T+vu_1^TY_b+v(u_2^T+u_1^TY))$$

$$=(a-b)\gamma\det((Y_a+vu_1^T)(Y_b+vu_1^T)+vu_2^T).$$

Finally, denote $Y-vu_1^T$ by M. We obtain

$$H_1(a)=\gamma\det(M_a),\quad H_2(a,b)=\gamma(a-b)\det(M_aM_b+vu_2^T).$$

Note that

$$\det(M_aM_b+vu_2^T)=\det(M_a)\det(M_b)+u_2^T\,\mathrm{adj}(M_aM_b)v=\gamma^{-2}H_1(a)H_1(b)(1+u_2^TM_a^{-1}M_b^{-1}v)$$

and since $[M_a, M_b]=0$ we also have that

$$M_a^{-1}M_b^{-1}=\frac{1}{a-b}(M_b^{-1}-M_a^{-1}).$$

Therefore,

$$\det(M_aM_b+vu_2^T)=\gamma^{-1}H_1(a)H_1(b)+\frac{H_1(a)(u_2^T\,\mathrm{adj}(M_b)v)-H_1(b)(u_2^T\,\mathrm{adj}(M_a)v)}{\gamma(a-b)}.$$

So, using the notation $p(a)=a\gamma^{-2}H_1(a)-\gamma^{-1}u^T\,\mathrm{adj}(M_a)v$, we see that $\det(M_aM_b+vu^T)$ is a Bezoutian of the form

$$\det(M_aM_b+vu^T)=\frac{p(a)H_1(b)-p(b)H_1(a)}{a-b}.$$

Substituting $H_2(a,b)=\gamma(p(a)H_1(b)-p(b)H_1(a))$ into the expression for $H(a,b,c)$ immediately yields $H\equiv 0$. □

Remark 2.2: The special case $n=2$ turns out to be surprisingly simple. A quick calculation verifies that for arbitrary 2×2 matrices $\hat{X}$, Y, and Z the polynomial $H(a,b,c)$ is given by the formula

$$H(a,b,c)=(a-b)(b-c)(c-a)\det[(\hat{X}Z-Y\hat{X})(Y-Z)].$$

III. TAU FUNCTIONS

A. Main theorem

It is easy to check that if $\kappa(M)=0$ then the formula for τ_M defined in (1) is a tau function of the KP hierarchy. In fact, in this case in which (3) is satisfied one has

$$\tau_M(t_1,t_2,t_3,\ldots)=\det(X+I)\exp\left(\sum_{i=1}^{\infty}\sum_{j=1}^{n}(\lambda_j^i)t_i\right),$$

where $\{\lambda_j\}$ are the eigenvalues of Y. Since the function

$$u(x,y,t)=2(\log\tau_M(x,y,t,0,0,\ldots))_{xx}=0$$

is the trivial solution to the KP equation, we say that τ_M is merely a gauge transformation of the trivial tau function.

Moreover, with g defined as in (2) and τ_M defined by (1), we observe that this is still a τ function in the case $\kappa(M)=1$. In fact, it is more interesting in this ''almost-intertwining'' case since we get nontrivial soliton and rational solutions in this way.

Theorem 3.1: If $\kappa(M)\leqslant 1$ for $M=(X,Y,Z)$ then the function

$$\tau_M(t_1,t_2,\ldots)=\det(Xe^{g(Z)}+e^{g(Y)}),\quad g(W)=\sum_{i=1}^{\infty}t_iW^i$$

is a tau function of the KP hierarchy with corresponding (stationary) Baker–Akhiezer function

$$\psi_M(x,z):=\frac{\det(X(zI-Z)e^{xZ}+(zI-Y)e^{xY})}{z^n\det(Xe^{xZ}+e^{xY})}e^{xz}.$$

Proof: Given the semi-infinite vector $\vec{t}=(t_1,t_2,t_3,\ldots)$, we use the notation $\tau_M(\vec{t})=\tau_M(t_1,t_2,\ldots)$. For an arbitrary constant a, we define the semi-infinite vector $[a]=(a,a^2/2,a^3/3,\ldots)$. Then, it is sufficient to prove that the continuous function $\tau(\vec{t})$ defined in (1) satisfies the Hirota equation in Miwa form[4,5]

$$0=(b-c)\tau(\vec{t}-[a^{-1}])\tau(\vec{t}-[b^{-1}]-[c^{-1}])-(a-c)\tau(\vec{t}-[b^{-1}])\tau(\vec{t}-[a^{-1}]-[c^{-1}])$$
$$+(a-b)\tau(\vec{t}-[c^{-1}])\tau(\vec{t}-[a^{-1}]-[b^{-1}]) \tag{7}$$

uniformly in a, b, and c and for all $\vec{t}$.

However, from the definition we see that

$$\begin{aligned}\tau(\vec{t}-[a^{-1}])&=\det(Xe^{g(Z)}e^{\ln(I-a^{-1}Z)}+e^{g(Y)}e^{\ln(I-a^{-1}Y)})\\&=a^{-n}\det(e^{g(Y)})\det(\hat{X}(aI-Z)+(aI-Y))\\&=a^{-n}\det(e^{g(Y)})H_1(a),\end{aligned}$$

where we have chosen $\hat{X}=e^{-g(Y)}Xe^{g(Z)}$ and used the notation of Lemma 2.2. Similarly,

$$(a-b)\tau(\vec{t}-[a^{-1}]-[b^{-1}])=a^{-n}b^{-n}\det(e^{g(Y)})H_2(a,b).$$

Consequently, (7) is equivalent to demonstrating that the polynomial $H(a,b,c)$ in Lemma 2.2 is zero in the case of this $\hat{X}$, Y, and Z. But, according to the second result in Lemma 2.1 we have that $\kappa(\hat{X},Y,Z)=\kappa(X,Y,Z)\leqslant 1$ and so Lemma 2.2 demonstrates that the Hirota equation is satisfied.

Once we know that τ_M is a tau function, the formula for ψ_M is derived from simply using the "famous Japanese formula,"[2]

$$\psi_M(x,z)=\frac{\tau_M(x-z^{-1},-z^{-2}/2,-z^{-3}/3,\ldots)}{\tau_M(x,0,0,\ldots)}e^{xz}.$$

Note that the numerator is simply $\tau_M(\vec{t}-[z^{-1}])$ with $\vec{t}=(x,0,0,\ldots)$. So, again expanding this in terms of the power series for the logarithm we derive the desired expression for ψ_M. □

Remark 3.1: Technically, although the function $\tau\equiv 0$ solves the bilinear equations of the KP hierarchy, it is not generally considered to be a tau function. [In particular, there is no associated operator $\mathcal{L}$ satisfying the Lax equation or function $u(x,y,t)$ satisfying the KP equation.] In the preceding we have not been careful to make certain that τ is nonzero. In fact, one can certainly choose $M\in\mathcal{M}_n^1$ so that $\tau_M=0$. Consequently, Theorem 3.1 should be understood to say that if τ_M is nonzero (which is generally the case) then it is a KP tau function.

Remark 3.2: Since the Baker–Akhiezer function ψ_M in Theorem 3.1 has the property that $z^ne^{-xz}\psi_M$ is a polynomial in z, it must be that τ_M is the tau function of a rank-one KP solution with a (singular) rational spectral curve. In particular, it must be a soliton solution or one of its rational degenerations. Well-known consequences[6–8] of this fact are the following:

Corollary 3.1: Let $K=K_M(t_1,t_2,t_3,\ldots,\partial_x)$ be the ordinary differential operator determined by simply substituting the formal symbol ∂_x in for z in the polynomial

$$K(t_1,t_2,\ldots,z)=\frac{\det(X(zI-Z)e^{g(Z)}+(zI-Y)e^{g(Y)})}{\det(Xe^{(Z)}+e^{g(Y)})}.$$

Then, equating x and t_1, $\mathcal{L}_M=K\partial_xK^{-1}$ satisfies the Lax equations

$$\frac{\partial}{\partial t_i}\mathcal{L}=[\mathcal{L},(\mathcal{L}^i)_+].$$

Moreover, the function

$$u(x,y,t) := \frac{\partial^2}{\partial x^2} \log \tau_M(x,y,t,0,0,\ldots)$$

satisfies the KP equation

$$\tfrac{3}{4} u_{yy} = (u_t - \tfrac{1}{4}(6uu_x + u_{xxx}))_x .$$

Remark 3.3: It is well known and easily verified (cf. Ref. 2) that multiplication by a function of the form $\exp(\Sigma \gamma_i t_i)$ takes one tau function to another having the same corresponding Lax operator $\mathcal{L}$. Such a change is often referred to as a "gauge transformation" in KP theory. Since $\det \exp g(Y)$ is a function of this form with $\gamma_i = \Sigma \lambda_j^i$ (where λ_j are the eigenvalues of Y counted according to multiplicity) it follows that:

Corollary 3.2: For $M = (X,Y,Z) \in \mathcal{M}_n^1$,

$$\hat{\tau}_M(t_1,t_2,\ldots) = \det(Xe^{g(Z)}e^{-g(Y)} + I)$$

is also a KP tau function differing from τ_M by only a gauge transformation.

Remark 3.4: Since the tau function and Baker–Akhiezer function are defined as they are by determinants of X, Y, and Z, simultaneously conjugating all three leaves the corresponding solution unchanged. Consequently, it would be possible to use Lemma 2.1 to take to quotient of $\mathcal{M}_n^1$ by the action of GL and then would be natural to define $\tau_{\overline{M}}$ for $\overline{M} \in \overline{\mathcal{M}_n^1} = \mathcal{M}_n^1 / GL(n)$.

B. Special cases

1. Gelfan'd–Dickii hierarchies (N-KdV)

The N-KdV or Gelfan'd–Dickii hierarchies are special classes of KP solutions for which $\mathcal{L}^N$ is an ordinary differential operator and hence is independent of the KP flows whose indices are multiples of N. In particular, we say a tau function is an N-KdV tau function if it factors as $\tau = f \cdot g$ where

$$\frac{\partial}{\partial t_{iN}} g = 0 \quad \forall i \in \mathbb{N}, \quad \frac{\partial}{\partial t_1} f = 0.$$

In other words, except for a factor independent t_1, τ is independent of t_j for all j that are multiples of N.

Let $\mathcal{M}_n^1(N)$ be the subset of $\mathcal{M}_n^1$,

$$\mathcal{M}_n^1(N) = \{(X,Y,Z) \in \mathcal{M}_n^1 : Y^N = Z^N\}.$$

Theorem 3.2: For $M \in \mathcal{M}_n^1(N)$, the corresponding tau function τ_M is a solution of the N-KdV hierarchy.

Proof: If we consider only the dependence upon t_1 and t_j (j a multiple of N) then

$$\begin{aligned}\tau_M &= \det(Xe^{t_1 Z + t_j Z^j} + e^{t_1 Y + t_j Y^j}) \\ &= \det(Xe^{t_1 Z + t_j Z^j} + e^{t_1 Y + t_j Z^j}) \\ &= \det(Xe^{t_1 Z} + e^{t_1 Y}) \det(e^{t_j Z^j}).\end{aligned}$$

□

For example, if we consider the restriction $Y = -Z$, then we are looking for matrix pairs (X,Z) satisfying

$$\operatorname{rank}(XZ+ZX)=1.$$

In this case, the formula (1) will produce a tau-function solution to the KdV hierarchy (independent of all even time flows). (Note that special cases have been considered elsewhere in the literature in the context of integrable particle systems.[9,10])

2. Solitons

The n-soliton solutions to the KP hierarchy are identified by these properties:

(1) The BA function $\psi(x,z)$ when multiplied by a degree n polynomial $q(z)=z^n+\cdots$ has the form

$$\vec{\psi}(x,z)=q(z)\,\psi(x,z)=\left(\sum_{i=1}^{n} a_i(x)z^i\right)e^{xz}.$$

(2) There are n independent linear ''conditions'' satisfied by $\overline{\psi}(x,z)$ of the form

$$\hat{\alpha}_i\overline{\psi}(x,\lambda_i)+\hat{\beta}_i\overline{\psi}(x,\mu_i)=0,\quad 1\leqslant i\leqslant n$$

(with $\lambda_i\neq\mu_i$).

These solutions can be constructed from $\mathcal{M}_n^1$ by choosing the point $M=(X,Y,Z)$ with

$$X_{ij}=\frac{\alpha_i}{\beta_j(\lambda_j-\mu_i)},\quad Y_{ij}=\mu_i\delta_{ij},\quad Z_{ij}=\lambda_i\delta_{ij}.$$

This can be verified, for instance, by noting that because $[Y,Z]=0$, the tau function $\hat{\tau}_M$ takes the form (cf. Corollary 3.2)

$$\hat{\tau}=\det(Xe^{g(Z)-g(Y)}+I).$$

For any index set $J\subset\{1,\ldots,n\}$, the principal minor of $Xe^{g(Z)-g(Y)}$ can be written as

$$\left(\prod_{i\in J}\frac{\alpha_i}{\beta_i}e^{g(\lambda_i)-g(\mu_i)}\right)\det\left(\frac{1}{\lambda_i-\mu_{i'}}\right)_{i,i'\in J}.$$

The latter determinant is a Cauchy determinant and is equal to

$$\prod_{i,i'\in J;i<i'}\frac{(\lambda_i-\lambda_{i'})(\mu_i-\mu_{i'})}{(\lambda_i-\mu_{i'})(\mu_i-\lambda_{i'})}\prod_{i\in J}\frac{1}{\lambda_i-\mu_i}.$$

Setting

$$c_i=\frac{\alpha_i}{\beta_i(\lambda_i-\mu_i)},$$

we obtain

$$\hat{\tau}=\sum_{J\subset\{1,\ldots,n\}}\prod_{i\in J}c_ie^{g(\lambda_i)-g(\mu_i)}\prod_{i,i'\in J;i<i'}\frac{(\lambda_i-\lambda_{i'})(\mu_i-\mu_{i'})}{(\lambda_i-\mu_{i'})(\mu_i-\lambda_{i'})},$$

which coincides with the known formula for this n-soliton solution of the KP hierarchy.[11]

3. Polynomial τ functions and rational solutions

Clearly, in the case that Y and Z are chosen to be nilpotent, the definition of τ_M produces a *polynomial* in the time variables t_i. It is perhaps of greater interest to note that one may also get tau functions that are—up to a gauge transformation—polynomial in t_1 but an infinite series if all t_i are considered.

For example, choosing

$$X=\begin{pmatrix}1&1&0\\1&0&0\\1&0&0\end{pmatrix},\quad Y=\begin{pmatrix}\lambda&1&0\\0&\lambda&1\\0&0&\lambda\end{pmatrix},\quad Z=\begin{pmatrix}\lambda&0&0\\1&\lambda&0\\0&1&\lambda\end{pmatrix}$$

leads to (after a gauge transformation to remove an exponential factor):

$$\tau(x,y,t,0,0,\ldots)$$

$$=1+(-3\lambda+3\lambda^2)t+\frac{9}{2}\lambda^4t^2+\frac{x^2}{2}+(6\lambda^3t+2\lambda-1)y+2\lambda^2y+(1+3\lambda^2t+2\lambda y)x.$$

Such solutions are well known and have been studied in previous papers.[6,8,12–14] However, one should especially compare the present approach with that of Wilson,[15] where these "vanishing rational KP solutions" are produced from matrix pairs (X,Z) satisfying $\operatorname{rank}(XZ-ZX+I)=1$. The main results in that paper concern the induced dynamics of the eigenvalues which behave as particles in a Calogero–Moser particle system. So, it may be of interest to similarly investigate the dynamics of the eigenvalues associated with almost-intertwining matrices.

IV. EIGENVALUE DYNAMICS

One of the most interesting things about the Ruijsenaars–Schneider (RS) particle system[9,16] is its connection to soliton tau functions. Specifically, certain KP tau functions can be written as

$$\tau(t_1,t_2,\ldots)=\det(X+I),$$

where $X=X(t_1,t_2,t_3,\ldots)$ is a matrix whose eigenvalues move according to the Ruijsenaars–Schneider Hamiltonian.

In this section we similarly study the dynamics of eigenvalues of time-dependent matrices in the context of almost-intertwining matrices to both reproduce and extend known results about the RS system and its connection to solitons.

A. Solitons and a matrix flow

Theorem 4.1: The vector fields V_i on the space of $n\times n$ matrix triples defined by

$$V_i(X_0,Y,Z)=(X_0Z^i-Y^iX_0,0,0) \tag{8}$$

are tangent to the manifold $\mathcal{M}_n^1$ and induce the flows in the variables t_i parametrized as

$$M_t=(X_t,Y,Z)=(e^{-g(Y)}X_0e^{g(Z)},Y,Z). \tag{9}$$

Proof: Note that the flows specified have the stated vector fields and that

$$X_tZ-YX_t=e^{-g(Y)}(X_0Z-YX_0)e^{g(Z)}$$

is a rank one matrix if X_0Z-YX_0 is. □

Remark 4.1: Given a parametrized flow $(X_t,Y,Z)\in\mathcal{M}_n^1$ as previously, the function $\hat{\tau}_M=(X_t+I)$ is another way to write the gauge transformed tau function from Corollary 3.2 with $M=(X_0,Y,Z)$.

B. General equations for eigenvalue dynamics

Given any matrices X_0, Y, Z such that $\kappa(X_0,Y,Z)=1$ let us define $X=X_t$ according to (9). If we denote the eigenvalues of X_t by $\{Q_i(t)\}$ $(1\leqslant i\leqslant n)$, to what extent can we describe their dynamics by intrinsic equations (depending only on Q_i and their derivatives)?

In what follows we will only be considering the flow under the first time parameter t_1, but will write simply t in order to simplify exposition and will use a ''dot'' to indicate differentiation with respect to this parameter.

We define vectors v and w by the formula

$$(X_0Z-YX_0)=vw^T \tag{10}$$

and so we have the equations of motion

$$\dot{X}=vw^T, \quad \dot{Y}=0, \quad \dot{Z}=0. \tag{11}$$

For convenience we introduce the (time-dependent) matrix U which diagonalizes X and the logarithms of the eigenvalues q_i

$$Q=UXU^{-1}=\begin{pmatrix} Q_1 & 0 & 0 & \cdots & \\ 0 & Q_2 & 0 & 0 & \cdots \\ 0 & 0 & Q_3 & 0 & \cdots \\ \vdots & & & \ddots & \end{pmatrix}, \quad q_i=\ln(Q_i) \tag{12}$$

and define in analogy to (10) the matrices and vectors

$$\hat{Y}=UYU^{-1}, \quad \hat{Z}=UZU^{-1}, \quad \hat{v}=Uv, \quad \hat{w}=wU^{-1} \tag{13}$$

so that

$$Q\hat{Z}-\hat{Y}Q=\hat{v}\hat{w}^T. \tag{14}$$

Note, in particular, that looking at an individual element of Eq. (14) yields

$$Q_i\hat{Z}_{ij}-Q_j\hat{Y}_{ij}=\hat{v}_j\hat{w}_i. \tag{15}$$

Now, defining $M=\dot{U}U^{-1}$ we have in analogy to (11)

$$\dot{Q}=[M,Q]+\hat{v}\hat{w}^T, \quad \hat{Y}=[M,\hat{Y}], \quad \hat{Z}=[M,\hat{Z}]. \tag{16}$$

Since Q and $\dot{Q}$ have no off diagonal elements, we get from (16) that

$$\dot{Q}_i=\hat{v}_i\hat{w}_i=\dot{q}_ie^{q_i}, \tag{17}$$

and

$$M_{ij}=\frac{\hat{v}_j\hat{w}_i}{Q_i-Q_j} \quad (i\neq j). \tag{18}$$

It turns out to be especially useful to write the equations of motion in terms of q_i rather than Q_i because then we find by multiplying (16) by Q^{-1} that

$$\begin{pmatrix} \dot{q}_1 & 0 & \cdots \\ \vdots & \ddots & \\ 0 & \cdots & \dot{q}_n \end{pmatrix} = \dot{Q}Q^{-1} = M - QMQ^{-1} + Q\hat{Z}Q^{-1} - \hat{Y}. \tag{19}$$

Since Q is diagonal, $M - QMQ^{-1}$ has no diagonal and $Q\hat{Z}Q^{-1} - \hat{Y}$ has the same diagonal as $\hat{Z} - \hat{Y}$ and so

$$\dot{q}_i = (\hat{Z} - \hat{Y})_{ii}. \tag{20}$$

Finally, we can differentiate (20) and use (15), (17), and (18) to find the equation of motion

$$\ddot{q}_i = ([M, \hat{Z} - \hat{Y}])_{ii} \tag{21}$$

$$= \sum_{k \neq i} (M_{ik}(\hat{Z}_{ki} - \hat{Y}_{ki}) - M_{ki}(\hat{Z}_{ik} - \hat{Y}_{ik})) \tag{22}$$

$$= \sum_{k \neq i} \left(\frac{\dot{Q}_i \dot{Q}_k}{Q_i(Q_i - Q_k)} + \frac{\hat{v}_k \hat{w}_i \hat{Z}_{k,i}}{Q_i} + \frac{\dot{Q}_i \dot{Q}_k}{Q_k(Q_k - Q_i)} + \frac{\hat{v}_i \hat{w}_k \hat{Z}_{ik}}{Q_k} \right) \tag{23}$$

$$= \sum_{k \neq i} \frac{\dot{Q}_i \dot{Q}_k (Q_i + Q_k) - (Q_i - Q_k)(Q_i \hat{v}_i \hat{w}_k \hat{Z}_{ik} - Q_k \hat{v}_k \hat{w}_i \hat{Z}_{ki})}{Q_i Q_k (Q_i - Q_k)}. \tag{24}$$

C. A special case

We can further simplify (24) assuming that $\hat{w}$ has no zero component. In that case, we can utilize additional freedom of conjugation by a diagonal matrix to leave Q unchanged but modify U.

In particular, if $\hat{w}$ is a vector with no zero component, then we can put it in a form where $w = (1,1,1,...,1)$ by multiplying U by the diagonal matrix with w_i's along its diagonal. Now, in this "gauge," we know that $\hat{w}_i = 1$ and so by (17) we know that $\hat{v}_i = \dot{Q}_i$. This then gives us that

$$\ddot{q}_i = \sum_{k \neq i} \frac{\dot{Q}_i \dot{Q}_k (Q_i + Q_k) - (Q_i - Q_k)(Q_i \dot{Q}_i \hat{Z}_{ik} - Q_k \dot{Q}_k \hat{Z}_{ki})}{Q_i Q_k (Q_i - Q_k)}.$$

Ideally, we would like to be able to completely eliminate $\hat{Z}_{ki}$ from this equation and have an "intrinsic" equation for the eigenvalues. It seems that this can only be done when certain additional simplifying assumptions are made.

Suppose that we are in the case that

$$-\lambda \hat{Y} + \hat{Z} = \gamma I \Rightarrow \hat{Z}_{ij} = \lambda \hat{Y}_{ij} \quad (i \neq j). \tag{25}$$

Combining Eqs. (15) and (25) we find that

$$\hat{Z}_{ij} = \frac{\lambda \hat{v}_j \hat{w}_i}{\lambda Q_i + Q_j} \quad (i \neq j).$$

Substituting this into (24) and again using (17) one finds the intrinsic equations of motion

$$\ddot{q}_i = (\lambda - 1)^2 \dot{Q}_i \sum_{k \neq i} \frac{\dot{Q}_k (Q_i + Q_k)}{(Q_i - Q_k)(\lambda Q_i - Q_k)(\lambda Q_k - Q_i)}. \tag{26}$$

Note that the equations are independent of γ. In the case $\lambda=-1$ the dynamics of (26) *is* the Ruijsenaars–Schneider model.[9]

V. COMMENTS AND CONCLUSIONS

It is interesting to note that restrictions on $\kappa(X,Y,Z)$ for triples of square matrices have arisen before in the context of integrable systems. For example, though the notations are different, the key operator identity used by Sakhnovich[17] is such a restriction. Perhaps there is a deep connection between the results of that work and this one, though the relationship is not immediately apparent to us. A more relevant result was obtained by Nijhoff and Chalykh,[18] who used the condition rank $(XZ-qZX)=1$ for invertible X and Z and scalar q to construct solutions to the q-difference KP hierarchy. It is reasonable to suppose that their result could now also be obtained as a discretization of the results in the present work in the special case $Y=qZ$. [Another matrix approach[19] to q-KP made use of the condition rank $(XY-qYX+I)=1$.]

The suggestive appearance of these spaces of matrices in such different contexts within the study of integrable systems might indicate that we should look more carefully at the manifolds $\mathcal{M}_n^k$. For instance, we have implicitly constructed a map from $\mathcal{M}_n^1$ to the infinite dimensional Grassmannian[2] Gr_1, and $\mathcal{M}_n^k$ naturally has the structure of an algebraic variety, but so far we have little understanding of the geometry.

Wilson[15] constructs an adelic Grassmannian and a Hilbert scheme from the set of matrices satisfying rank $([X,Z]+I)=1$. Moreover, the natural symmetry of this set which is manifested as the involution $(X,Z)\mapsto(Z^T,X^T)$ has significance both for the KP hierarchy (bispectrality) and the Calogero–Moser particle system (self-duality). So, it is reasonable to wonder how the obvious symmetries of $\mathcal{M}_n^k$ are reflected in the soliton solutions to the KP hierarchy. We have already noted that multiplying X by a function of Y on the left and a function of Z on the right corresponds to the KP flows. Note also that if $\kappa(X,Y,Z)=1$ and X is invertible then $\kappa(X^{-1},Z,Y)=1$ as well and that this triple corresponds to the same KP solution. (In particular, these two points in $\mathcal{M}_n^1$ get mapped to the same point in $\mathrm{Gr}^{\mathrm{rat}}$.) Similarly, if Y is invertible then $\kappa(Y,X,XZY^{-1})=1$, but it is not immediately apparent what symmetry of KP is analogous.

One alternative characterization of $\mathrm{Gr}^{\mathrm{rat}}$ is as the Grassmannian of finite dimensional subspaces of finitely supported distributions.[6] Specifically, to identify a point $W\in\mathrm{Gr}^{\mathrm{rat}}$ it is sufficient to identify the finitely supported distributions in z which annihilate the normalized Baker–Akhiezer function. We showed in Sec. III B 2 that in the case of nondegenerate solitons, the eigenvalues of Y and Z determine the support of the distributions and X determines the coefficients. We conjecture that this situation holds in general:

Conjecture 5.1: The support of the distributions annihilating $z^n\psi_M$ for $M=(X,Y,Z)\in\mathcal{M}_n^1$ is the set of eigenvalues of the matrices Y and Z with the highest derivative taken at a particular eigenvalue being bounded by the size of the corresponding Jordan blocks.

A Lax pair for the two dimensional Euler equation

Yanguang (Charles) Li[a)]
Department of Mathematics, University of Missouri, Columbia, Missouri 65211

(Received 4 December 2000; accepted for publication 22 March 2001)

A Lax pair for the 2D Euler equation is found. © *2001 American Institute of Physics.* [DOI: 10.1063/1.1378305]

I. A LAX PAIR FOR THE TWO DIMENSIONAL (2D) EULER EQUATION

This is to report that a Lax pair for the 2D Euler equation is found. We write the 2D Euler equation in the vorticity form,

$$\frac{\partial \Omega}{\partial t} + \{\Psi, \Omega\} = 0, \tag{1.1}$$

where Ω is the vorticity, Ψ is the stream function, and the bracket $\{\ \}$ is defined as

$$\{f,g\} = (\partial_x f)(\partial_y g) - (\partial_y f)(\partial_x g).$$

Let us denote the x-directional and the y-directional velocities by u and v, respectively. Then

$$u = -\frac{\partial \Psi}{\partial y}, \quad v = \frac{\partial \Psi}{\partial x}, \quad \Omega = \frac{\partial v}{\partial x} - \frac{\partial u}{\partial y}, \quad \Delta \Psi = \Omega.$$

The Lax pair is given as

$$\begin{aligned} L\varphi &= \lambda \varphi, \\ \partial_t \varphi + A\varphi &= 0, \end{aligned} \tag{1.2}$$

where

$$L\varphi = \{\Omega, \varphi\}, \ \ A\varphi = \{\Psi, \varphi\},$$

and λ is a complex constant, and φ is a complex-valued function. The compatibility condition of the Lax pair (1.2) gives the 2D Euler equation (1.1), i.e.,

$$\partial_t L = [L, A],$$

where $[L,A] = LA - AL$ gives the Lax representation of the 2D Euler equation (1.1).

Remark 1.1: With the recent development on chaos in partial differential equations,[1–3] *I am interested in building a dynamical system theory for 2D Euler equation under periodic boundary condition.*[4–6] *In particular, I am investigating the existence versus nonexistence of homoclinic structure. For such studies, it will be fundamentally important to find a Lax pair (if it exists) for the 2D Euler equation. Then I started with Zakharov's paper*.[7] *Zakharov proposed the Lax pair,*

$$\lambda D_1 \varphi + \{\Omega, \varphi\} = 0,$$

$$\partial_t \varphi + \lambda D_2 \varphi + \{S, \varphi\} = 0,$$

a)Electronic mail: cli@math.missouri.edu

where

$$D_1=\alpha\frac{\partial}{\partial x}+\beta\frac{\partial}{\partial y},\quad D_2=\gamma\frac{\partial}{\partial x}+\delta\frac{\partial}{\partial y},$$

α, β, γ, and δ are real constants, λ is a complex constant, S is a real-valued function, and φ is a complex-valued function. The compatibility condition of this Lax pair gives the following equation instead of the 2D Euler equation:

$$\frac{\partial\Omega}{\partial t}+\{S,\Omega\}=0,$$

$$D_1S=D_2\Omega.$$

(Notice the misprints in the English translation of the article.[7]*)*

Remark 1.2: The author is also aware of the Lax pair in the inverse Cauchy–Green tensor variable of the Lagrangian formulations of both 2D and 3D Euler equations found by Susan Friedlander and Misha Vishik.[8,9]

Finite-dimensional integrable systems related to the *n*-wave interaction equations

Qi-Yan Shi[a)]
School of Mathematical Sciences, Peking University, Beijing 100871, People's Republic of China

(Received 4 December 2000; accepted for publication 15 May 2001)

Under a constraint between the potentials and the eigenfunctions, Lax pairs and adjoint Lax pairs of a soliton hierarchy associated with the $n\times n$ generalized Zakharov–Shabat eigenvalue problem are transformed into a spatial finite-dimensional Hamiltonian system and a hierarchy of temporal finite-dimensional Hamiltonian systems. The Lax representations, *r*-matrix structure and integrals of motion are explicitly presented. These integrals of motion are functionally independent and in involution in pairs, which shows that these systems, especially the whole hierarchy of temporal finite-dimensional Hamiltonian systems, are Liouville integrable. © *2001 American Institute of Physics.* [DOI: 10.1063/1.1385565]

I. INTRODUCTION

Since the pioneer work on solitons by Zabusky and Kruskal[1] in the 1960s, many infinite-dimensional integrable systems were found. Flaschka[2] pointed out that finite-dimensional integrable systems can be produced by constraining the infinite-dimensional integrable systems on a finite-dimensional invariant manifold. Motivated by Flaschka's idea and J. Moser's work,[3] the technique of the nonlinearization of Lax pairs, or, more generally, symmetry constraint, was developed during the beginning of the 1990s.[4–7] This method has been applied to various soliton hierarchies associated with matrix eigenvalue problems, from which a considerable number of finite-dimensional Liouville integrable Hamiltonian systems have been obtained.[8–12] Recently, the basic idea was generalized to discuss the binary nonlinearization of Lax pairs and adjoint Lax pairs of soliton hierarchies.[13–15]

The present article is devoted to the binary nonlinearization of the $n\times n$ generalized Zakharov–Shabat eigenvalue problem. The obtained spatial finite-dimensional Hamiltonian system and a hierarchy of temporal finite- dimensional Hamiltonian systems are completely Liouville integrable.[16] In the next section, we construct a soliton hierarchy associated with the eigenvalue problem. In Sec. III, under the Bargmann constraint between the potentials and the eigenfunctions, a spatial finite-dimensional Hamiltonian system and a hierarchy of temporal finite-dimensional Hamiltonian systems are obtained by nonlinearization of Lax pairs and adjoint Lax pairs of the obtained soliton hierarchy. In Sec. IV, the Lax representations are deduced for the resulting finite-dimensional systems. A constant rational *r*-matrix structure is established from the Lax operator. In Sec. V, sufficiently many involutive integrals of motion are obtained; furthermore, they are proved to be functionally independent. Thus the Hamiltonian systems generated from Lax pairs and adjoint Lax pairs are completely integrable in the Liouville sense.

a)Electronic mail: qyshi@math.pku.edu.cn

II. THE SOLITON HIERARCHY

Let us consider the $n\times n$ generalized Zakharov–Shabat eigenvalue problem

$$\phi_x=U(u,\lambda)\phi,\phi=\begin{pmatrix}\phi_1\\ \vdots\\ \phi_n\end{pmatrix},\quad U=\begin{pmatrix}\alpha_1\lambda & u_{12} & \dots & u_{1n}\\ u_{21} & \alpha_2\lambda & \dots & u_{2n}\\ \vdots & \vdots & \ddots & \vdots\\ u_{n1} & u_{n2} & \dots & \alpha_n\lambda\end{pmatrix},\tag{2.1}$$

where the potential vector $u=(u_{12},u_{21},\dots,u_{1n},u_{n1},u_{23},u_{32},\dots,u_{n-1,n},u_{n,n-1})^T$, λ is a constant spectral parameter, and $\alpha_i,1\leqslant i\leqslant n$, are n distinct constants. We will derive the isospectral soliton hierarchy associated with (2.1). To do this we first solve the stationary zero-curvature equation:

$$V_x=[U,V],\quad V=(V_{ij})_{n\times n},\tag{2.2}$$

where $V=\Sigma_{l\geqslant 0}V_l\lambda^{-l},V_l=(V_{ij}^{(l)})_{n\times n}$. Equation (2.2) leads to the following recursion relations:

$$V_{iix}^{(0)}=0,\quad V_{ij}^{(0)}=0,\quad (i\neq j),$$

$$V_{ijx}^{(l)}+u_{ij}(V_{ii}^{(l)}-V_{jj}^{(l)})+\sum_{\substack{k=1\\k\neq i,j}}^{n}(u_{kj}V_{ik}^{(l)}-u_{ik}V_{kj}^{(l)})-(\alpha_i-\alpha_j)V_{ij}^{(l+1)}=0,\quad i\neq j,\tag{2.3}$$

$$V_{iix}^{(l)}=\sum_{\substack{k=1\\k\neq i}}^{n}(u_{ik}V_{ki}^{(l)}-u_{ki}V_{ik}^{(l)}),\quad 1\leqslant i,\quad j\leqslant n,\quad l\geqslant 0.$$

By (2.3) we have

$$V_{ii}^{(0)}=\beta_i,\quad V_{ij}^{(0)}=0,\quad i\neq j,$$

$$V_{ii}^{(1)}=0,\quad V_{ij}^{(1)}=\frac{\beta_i-\beta_j}{\alpha_i-\alpha_j}u_{ij},\quad i\neq j,$$

and require that

$$\beta_i\neq\beta_j(i\neq j),\quad V_{ij}^{(l)}|_{u=0}=0,\quad l\geqslant 1,$$

which means constants of integration are put to be zero. Then $V_{ij}^{(l)}$'s are uniquely determined by (2.3). For instance, it is easy to see that

$$V_{ij}^{(2)}=\frac{\beta_i-\beta_j}{(\alpha_i-\alpha_j)^2}u_{ijx}+\frac{1}{\alpha_i-\alpha_j}\sum_{\substack{k=1\\k\neq i,j}}^{n}\left(\frac{\beta_i-\beta_k}{\alpha_i-\alpha_k}-\frac{\beta_k-\beta_j}{\alpha_k-\alpha_j}\right)u_{ik}u_{kj},\quad i\neq j,$$

$$V_{ii}^{(2)}=\sum_{\substack{k=1\\k\neq i}}^{n}\frac{\beta_k-\beta_i}{(\alpha_k-\alpha_i)^2}u_{ik}u_{ki}.$$

Equations (2.3) can be equivalently written as the Lenard form

$$MG_{l-1}=JG_l,\tag{2.4}$$

$$G_{l-1}=(V_{21}^{(l)},V_{12}^{(l)},\dots,V_{n1}^{(l)},V_{1n}^{(l)},V_{32}^{(l)},V_{23}^{(l)},\dots,V_{n,n-1}^{(l)},V_{n-1,n})^T,\quad l\geqslant 1,$$

$$G_0=\Big(\frac{\beta_2-\beta_1}{\alpha_2-\alpha_1}u_{21},\frac{\beta_1-\beta_2}{\alpha_1-\alpha_2}u_{12},\ldots,\frac{\beta_n-\beta_1}{\alpha_n-\alpha_1}u_{n1},\frac{\beta_1-\beta_n}{\alpha_1-\alpha_n}u_{1n},$$

$$\frac{\beta_3-\beta_2}{\alpha_3-\alpha_2}u_{32},\frac{\beta_2-\beta_3}{\alpha_2-\alpha_3}u_{23},\ldots,\frac{\beta_n-\beta_{n-1}}{\alpha_n-\alpha_{n-1}}u_{n,n-1},\frac{\beta_{n-1}-\beta_n}{\alpha_{n-1}-\alpha_n}u_{n-1,n})^T,$$

with the condition $G_l|_{u=0}=0$. Here J and M are two skew-symmetric operators:

$$J=(J_{ij})_{(n^2-n)\times(n^2-n)}=\begin{pmatrix} J_{12} & & & & & 0\\ & \ddots & & & & \\ & & J_{1n} & & & \\ & & & J_{23} & & \\ & & & & \ddots & \\ 0 & & & & & J_{n-1,n}\end{pmatrix},$$

$$J_{ij}=\begin{pmatrix}0 & \alpha_i-\alpha_j\\ \alpha_j-\alpha_i & 0\end{pmatrix};$$

$M=(M_{ij})_{(n^2-n)\times(n^2-n)}$ with

$$M_{(k-1)(2n-k)+2r-1,(k-1)(2n-k)+2r-1}=2u_{k,k+r}\partial^{-1}u_{k,k+r},$$

$$M_{(k-1)(2n-k)+2r,(k-1)(2n-k)+2r}=2u_{k+r,k}\partial^{-1}u_{k+r,k},$$

$$M_{(k-1)(2n-k)+2r-1,(k-1)(2n-k)+2r}=\partial-2u_{k,k+r}\partial^{-1}u_{k+r,k},$$

$$M_{(k-1)(2n-k)+2r-1,(k-1)(2n-k)+2s-1}=u_{k,k+r}\partial^{-1}u_{k,k+s},$$

$$M_{(k-1)(2n-k)+2r-1,(k-1)(2n-k)+2s}=u_{k+s,k+r}-u_{k,k+r}\partial^{-1}u_{k+s,k},$$

$$M_{(k-1)(2n-k)+2r,(k-1)(2n-k)+2s}=u_{k+r,k}\partial^{-1}u_{k+s,k},$$

$$M_{(k-1)(2n-k)+2r,(k-1)(2n-k)+2s-1}=-u_{k+r,k+s}-u_{k+r,k}\partial^{-1}u_{k,k+s},$$

$$M_{(k-1)(2n-k)+2r-1,(k+p-1)(2n-k-p)+2(r-p)-1}=u_{k,k+r}\partial^{-1}u_{k+p,k+r},$$

$$M_{(k-1)(2n-k)+2r-1,(k+p-1)(2n-k-p)+2(r-p)}=-u_{k,k+p}-u_{k,k+r}\partial^{-1}u_{k+r,k+p},$$

$$M_{(k-1)(2n-k)+2r,(k+p-1)(2n-k-p)+2(r-p)}=u_{k+r,k}\partial^{-1}u_{k+r,k+p},$$

$$M_{(k-1)(2n-k)+2r,(k+p-1)(2n-k-p)+2(r-p)-1}=u_{k+p,k}-u_{k+r,k}\partial^{-1}u_{k+p,k+r},$$

$$M_{(k-1)(2n-k)+2r-1,(k+r-1)(2n-k-r)+2t}=u_{k,k+r}\partial^{-1}u_{k+r+t,k+r},$$

$$M_{(k-1)(2n-k)+2r-1,(k+r-1)(2n-k-r)+2t-1}=-u_{k,k+r+t}-u_{k,k+r}\partial^{-1}u_{k+r,k+r+t},$$

$$M_{(k-1)(2n-k)+2r,(k+r-1)(2n-k-r)+2t-1}=u_{k+r,k}\partial^{-1}u_{k+r,k+r+t},$$

$$M_{(k-1)(2n-k)+2r,(k+r-1)(2n-k-r)+2t}=u_{k+r+t,k}-u_{k+r,k}\partial^{-1}u_{k+r+t,k+r},$$

and

$$M_{ij}^*=-M_{ji},\qquad M_{ij}=0\qquad \text{for other}\quad ij,$$

where

$$k,r,s,p,t\geqslant 1,\quad k+r\leqslant n,\quad k+s\leqslant n,\quad k+r+t\leqslant n,\quad s\neq r,\quad k+p<r.$$

Now we consider the auxiliary problem of the spectral problem (2.1),

$$\phi_{t_m}=V^{(m)}\phi,\quad V^{(m)}=V^{(m)}(u,\lambda)=(\lambda^m V)_+,\quad m\geqslant 1, \tag{2.5}$$

where $()_+$ is the truncation containing only non-negative powers of λ. The compatibility condition between (2.1) and (2.5) leads to the zero-curvature equation, $U_{t_m}-V_x^{(m)}+[U,V^{(m)}]=0$. This implies the following soliton hierarchy,

$$u_{t_m}=K_m=JG_m=J\Phi^m G_0,\quad m\geqslant 1, \tag{2.6}$$

where $\Phi=J^{-1}M$. The first typical nonlinear system in the hierarchy is the famous *n*-wave interaction equations in one spatial dimension:[17]

$$u_{ijt_1}=\frac{\beta_i-\beta_j}{\alpha_i-\alpha_j}u_{ijx}+\sum_{\substack{k=1\\k\neq i,j}}^{n}\left(\frac{\beta_i-\beta_k}{\alpha_i-\alpha_k}-\frac{\beta_k-\beta_j}{\alpha_k-\alpha_j}\right)u_{ik}u_{kj},\quad i\neq j,\quad 1\leqslant i,\quad j\leqslant n.$$

III. FINITE-DIMENSIONAL HAMILTONIAN SYSTEMS

In this section, under the Bargmann constraint between the potentials and the eigenfunctions, the Lax pair and adjoint Lax pair of the soliton hierarchy (2.6) are nonlinearized to a spatial finite-dimensional Hamiltonian system and a hierarchy of temporal finite-dimensional Hamiltonian systems.

The system (2.6) has an adjoint Lax pair

$$\psi_x=-U^T(u,\lambda)\psi, \tag{3.1}$$

$$\psi_{t_m}=-V^{(m)T}(u,\lambda)\psi,\quad m\geqslant 1, \tag{3.2}$$

where $\psi=(\psi_1,\ldots,\psi_n)^T$. In fact, we easily verify that the compatibility condition between (3.1) and (3.2) leads to the same zero-curvature equation as that between Eqs. (2.1) and (2.5).

Let $\lambda_1,\lambda_2,\ldots,\lambda_N$ be N mutual distinct eigenvalues. The systems associated with (2.1) and (3.1) can be written in the form

$$\begin{aligned}(\phi_{1l},\ldots,\phi_{nl})_x&=(\phi_{1l},\ldots,\phi_{nl})U^T(u,\lambda_l),\\(\psi_{1l},\ldots,\psi_{nl})_x&=-(\psi_{1l},\ldots,\psi_{nl})U(u,\lambda_l),\end{aligned} \tag{3.3}$$

where $\phi_{il}=\phi_i(\lambda_l),\psi_{il}=\psi_i(\lambda_l),1\leqslant i\leqslant n,1\leqslant l\leqslant N$, are eigenfunctions. A direct caculation gives the functional gradient of the eigenvalue λ_l with regard to the potential vector u:

$$\begin{aligned}\frac{\delta\lambda_l}{\delta u}&=\left(\frac{\delta\lambda_l}{\delta u_{12}},\frac{\delta\lambda_l}{\delta u_{21}},\ldots,\frac{\delta\lambda_l}{\delta u_{1n}},\frac{\delta\lambda_l}{\delta u_{n1}},\frac{\delta\lambda_l}{\delta u_{23}},\frac{\delta\lambda_l}{\delta u_{32}},\ldots,\frac{\delta\lambda_l}{\delta u_{n-1,n}},\frac{\delta\lambda_l}{\delta u_{n,n-1}}\right)^T\\&=(\phi_{2l}\psi_{1l},\phi_{1l}\psi_{2l},\ldots,\phi_{nl}\psi_{1l},\phi_{1l}\psi_{nl},\phi_{3l}\psi_{2l},\phi_{2l}\psi_{3l},\ldots,\phi_{nl}\psi_{(n-1)l},\phi_{(n-1)l}\psi_{nl})^T.\end{aligned}$$

Such a gradient satisfies the following equation:

$$M\frac{\delta\lambda_l}{\delta u}=\lambda_l J\frac{\delta\lambda_l}{\delta u}. \tag{3.4}$$

Now we consider the Bargmann constraint

$$G_0=\sum_{l=1}^{N}\frac{\delta\lambda_l}{\delta u}, \tag{3.5}$$

which implies

$$u_{ij}=\frac{\alpha_i-\alpha_j}{\beta_i-\beta_j}\langle\Phi_i,\Psi_j\rangle, i\neq j, 1\leqslant i,j\leqslant n, \tag{3.6}$$

where $\langle .,.\rangle$ is the standard inner-product in $\mathcal{R}^N$, and $\Phi_i=(\phi_{i1},\phi_{i2},\ldots,\phi_{iN})^T$, and $\Psi_i=(\psi_{i1},\psi_{i2},\ldots,\psi_{iN})^T$, $1\leqslant i\leqslant n$. Substituting (3.6) in (3.3), we obtain a spatial finite-dimensional Hamiltonian system

$$\Phi_{ix}=\frac{\partial H}{\partial\Psi_i},\quad \Psi_{ix}=-\frac{\partial H}{\partial\Phi_i},\quad 1\leqslant i\leqslant n, \tag{3.7}$$

with the Hamiltonian

$$H=\sum_{i=1}^{n}\alpha_i\langle\Lambda\Phi_i,\Psi_i\rangle+\sum_{1\leqslant i,j\leqslant n}\frac{\alpha_i-\alpha_j}{\beta_i-\beta_j}\langle\Phi_i,\Psi_j\rangle\langle\Phi_j,\Psi_i\rangle,$$

where $\Lambda=\mathrm{diag}(\lambda_1,\lambda_2,\ldots,\lambda_N)$.

In the same way, we discuss the nonlinearization of the auxiliary spectral problem (2.5) and its adjoint one (3.2);

$$\begin{gathered}(\phi_{1l},\ldots,\phi_{nl})_{t_m}=(\phi_{1l},\ldots,\phi_{nl})V^{(m)T}(u,\lambda_l),\\ (\psi_{1l},\ldots,\psi_{nl})_{t_m}=-(\psi_{1l},\ldots,\psi_{nl})V^{(m)}(u,\lambda_l),\quad m\geqslant 1,\quad 1\leqslant l\leqslant N\end{gathered} \tag{3.8}$$

under the constraints (3.6) and the control of the spatial system (3.7).

First we do some caculations. By using (2.4), (3.4) and (3.5), we have

$$G_k=\sum_{l=1}^{N}\lambda_l^k\frac{\delta\lambda_l}{\delta u},$$

which is a special solution of (2.4) and can be written as follows:

$$\tilde{V}_{ij}^{(k)}=\langle\Lambda^{k-1}\Phi_i,\Psi_j\rangle,\quad i\neq j,\quad 1\leqslant i,\quad j\leqslant n,\quad k\geqslant 1. \tag{3.9}$$

Here and hereafter, an overtilde indicates the corresponding nonlinearized quantity. From (3.9) and the last relations of (2.3), we have

$$\tilde{V}_{ii}^{(k)}=\langle\Lambda^{k-1}\Phi_i,\Psi_i\rangle,\quad 1\leqslant i\leqslant n,\quad k\geqslant 1.$$

Thus

$$\tilde{V}_{ij}=V_{ij}^{(0)}+\sum_{k\geqslant 1}\langle\Lambda^{k-1}\Phi_i,\Psi_j\rangle\lambda^{-k},\quad 1\leqslant i,\quad j\leqslant n, \tag{3.10}$$

and

$$(\tilde{V}^{(m)}(\lambda_l))_{ij}=(\lambda_l^m\tilde{V}_{ij})_+=V_{ij}^{(0)}\lambda_l^m+\sum_{k=1}^{m}\langle\Lambda^{k-1}\Phi_i,\Psi_j\rangle\lambda_l^{m-k},\quad m\geqslant 1,\quad 1\leqslant i,\quad j\leqslant n.$$

The nonlinearized temporal systems of (3.8) under the constraints (3.6) and the control of the spatial system (3.7) are a hierarchy of temporal finite-dimensional Hamiltonian systems:

$$\Phi_{it_m}=\frac{\partial H_m}{\partial\Psi_i},\quad \Psi_{it_m}=-\frac{\partial H_m}{\partial\Phi_i},\quad m\geqslant 1,\quad 1\leqslant i\leqslant n,\tag{3.11}$$

with the Hamiltonian

$$H_m=\sum_{i=1}^{n}\beta_i\langle\Lambda^m\Phi_i,\Psi_i\rangle+\frac{1}{2}\sum_{i=1}^{n}\sum_{k=1}^{m}\langle\Lambda^{k-1}\Phi_i,\Psi_i\rangle\langle\Lambda^{m-k}\Phi_i,\Psi_i\rangle$$

$$+\sum_{1\leqslant i<j\leqslant n}\sum_{k=1}^{m}\langle\Lambda^{k-1}\Phi_i,\Psi_j\rangle\langle\Lambda^{m-k}\Phi_j,\Psi_i\rangle,\quad m\geqslant 1.$$

IV. LAX REPRESENTATIONS AND *r*-MATRIX

By (3.10), we have

$$\tilde{V}=\begin{pmatrix}\beta_1+\sum_{l=1}^{N}\frac{\phi_{1l}\psi_{1l}}{\lambda-\lambda_l} & \sum_{l=1}^{N}\frac{\phi_{1l}\psi_{2l}}{\lambda-\lambda_l} & \cdots & \sum_{l=1}^{N}\frac{\phi_{1l}\psi_{nl}}{\lambda-\lambda_l}\\ \sum_{l=1}^{N}\frac{\phi_{2l}\psi_{1l}}{\lambda-\lambda_l} & \beta_2+\sum_{l=1}^{N}\frac{\phi_{2l}\psi_{2l}}{\lambda-\lambda_l} & \cdots & \sum_{l=1}^{N}\frac{\phi_{2l}\psi_{nl}}{\lambda-\lambda_l}\\ \vdots & \vdots & \ddots & \vdots\\ \sum_{l=1}^{N}\frac{\phi_{nl}\psi_{1l}}{\lambda-\lambda_l} & \sum_{l=1}^{N}\frac{\phi_{nl}\psi_{2l}}{\lambda-\lambda_l} & \cdots & \beta_n+\sum_{l=1}^{N}\frac{\phi_{nl}\psi_{nl}}{\lambda-\lambda_l}\end{pmatrix}.\tag{4.1}$$

Under the condition (3.6), the following equations still hold:

$$\tilde{V}_x=[\tilde{U},\tilde{V}],\quad \tilde{V}_{t_m}=[\tilde{V}^{(m)},\tilde{V}],\quad m\geqslant 1,\tag{4.2}$$

which are the Lax representations of the spatial system (3.7) and temporal systems (3.11), respectively. Set $L(\lambda)=\tilde{V}$ and $A_m(\lambda)=\tilde{V}^{(m)}$, thus we have the following theorem.

Theorem 1: Equations (3.7) and (3.11) have the following Lax representations,

$$L(\lambda)_x=[A_0(\lambda),L(\lambda)],\tag{4.3}$$

$$L(\lambda)_{t_m}=[A_m(\lambda),L(\lambda)],\quad m\geqslant 1,\tag{4.4}$$

respectively, where

$$L(\lambda)=(L_{ij}(\lambda))_{n\times n}=\begin{pmatrix} \beta_1+\sum_{l=1}^{N}\frac{\phi_{1l}\psi_{1l}}{\lambda-\lambda_l} & \sum_{l=1}^{N}\frac{\phi_{1l}\psi_{2l}}{\lambda-\lambda_l} & \cdots & \sum_{l=1}^{N}\frac{\phi_{1l}\psi_{nl}}{\lambda-\lambda_l} \\ \sum_{l=1}^{N}\frac{\phi_{2l}\psi_{1l}}{\lambda-\lambda_l} & \beta_2+\sum_{l=1}^{N}\frac{\phi_{2l}\psi_{2l}}{\lambda-\lambda_l} & \cdots & \sum_{l=1}^{N}\frac{\phi_{2l}\psi_{nl}}{\lambda-\lambda_l} \\ \vdots & \vdots & \ddots & \vdots \\ \sum_{l=1}^{N}\frac{\phi_{nl}\psi_{1l}}{\lambda-\lambda_l} & \sum_{l=1}^{N}\frac{\phi_{nl}\psi_{2l}}{\lambda-\lambda_l} & \cdots & \beta_n+\sum_{l=1}^{N}\frac{\phi_{nl}\psi_{nl}}{\lambda-\lambda_l} \end{pmatrix},$$

$$A_0(\lambda)=\begin{pmatrix} \alpha_1\lambda & \frac{\alpha_1-\alpha_2}{\beta_1-\beta_2}\langle\Phi_1,\Psi_2\rangle & \cdots & \frac{\alpha_1-\alpha_n}{\beta_1-\beta_n}\langle\Phi_1,\Psi_n\rangle \\ \frac{\alpha_2-\alpha_1}{\beta_2-\beta_1}\langle\Phi_2,\Psi_1\rangle & \alpha_2\lambda & \cdots & \frac{\alpha_2-\alpha_n}{\beta_2-\beta_n}\langle\Phi_2,\Psi_n\rangle \\ \vdots & \vdots & \ddots & \vdots \\ \frac{\alpha_n-\alpha_1}{\beta_n-\beta_1}\langle\Phi_n,\Psi_1\rangle & \frac{\alpha_n-\alpha_2}{\beta_n-\beta_2}\langle\Phi_n,\Psi_2\rangle & \cdots & \alpha_n\lambda \end{pmatrix},$$

and for $m\geqslant 1$, $A_m=((A_m)_{ij})_{n\times n}$ has its entries as follows:

$$(A_m)_{ii}=\beta_i\lambda^m+\sum_{k=1}^{m}\langle\Lambda^{k-1}\Phi_i,\Psi_i\rangle\lambda^{m-k},$$

$$(A_m)_{ij}=\sum_{k=1}^{m}\langle\Lambda^{k-1}\Phi_i,\Psi_j\rangle\lambda^{m-k},\quad i\neq j.$$

Now we deal with the r-matrix relation for the Lax operator $L(\lambda)$. A simple caculation gives rise to

$$\{L_{ik}(\lambda),L_{jl}(\mu)\}=\begin{cases} 0, \text{ when } j\neq k, i\neq l \text{ or } i=j=k=l; \\ \frac{1}{\mu-\lambda}(L_{jk}(\lambda)-L_{jk}(\mu)), \text{ when } j\neq k, i=l; \\ \frac{1}{\mu-\lambda}(L_{il}(\mu)-L_{il}(\lambda)), \text{ when } j=k, i\neq l; \\ \frac{1}{\mu-\lambda}(L_{jj}(\lambda)-L_{jj}(\mu)-L_{ii}(\lambda)+L_{ii}(\mu)), \text{ when } j=k\neq i=l, \end{cases}$$

where the Poisson bracket is defined as

$$\{f,g\}=\sum_{i=1}^{n}\sum_{j=1}^{N}\left(\frac{\partial f}{\partial\phi_{ij}}\frac{\partial g}{\partial\psi_{ij}}-\frac{\partial f}{\partial\psi_{ij}}\frac{\partial g}{\partial\phi_{ij}}\right).$$

Using the notations in Ref. 18, $L_1(\lambda)=L(\lambda)\otimes I, L_2(\mu)=I\otimes L(\mu)$, where I is the $n\times n$ unit matrix, and $\{L_1(\lambda),L_2(\mu)\}$ is a $n^2\times n^2$ matrix composed of various Poisson brackets of the matrix elements of $L_1(\lambda)$ and $L_2(\mu)$, i.e., $\{L_1(\lambda),L_2(\mu)\}_{ij,kl}=\{L_{ik}(\lambda),L_{jl}(\mu)\}, 1\leqslant i,j,k,l\leqslant n$.

A direct computation can give us the following r-matrix formulation.

Theorem 2: Lax operator $L(\lambda)$ satisfies the r-matrix relation as follows:

$$\{L_1(\lambda),L_2(\mu)\}=\left[\frac{1}{\mu-\lambda}P,L_1(\lambda)+L_2(\mu)\right], \tag{4.5}$$

where P is the permutation matrix, $Px\otimes y=y\otimes x$.

It is easy to see that the r-matrix $r_{12}(\lambda,\mu)=[1/(\mu-\lambda)]P$ satisfies the classical Yang–Baxter equation:[18]

$$[r_{12},r_{13}]+[r_{12},r_{23}]+[r_{13},r_{23}]=0.$$

V. INTEGRALS OF MOTION AND THE LIOUVILLE INTEGRABILITY

In this section, we will construct the motion integrals of finite-dimensional Hamiltonian systems (3.7) and (3.11). These integrals of motion are verified to be in involution in pairs and functionally independent, which leads to the complete Liouville integrability of the systems.

Lemma: Let V be a solution of the stationary zero-curvature equation $V_y=[U,V](y=x$ or $t_m)$, then

(1) det$V$ is constant independent of the variable y, and
(2) the matrix $\mu I-V$ is also a solution of the stationary zero-curvature equation $V_y=[U,V]$, where μ is an arbitrary parameter.

Proof: The first result is known (see Ref. 19). The second one can be easily verified.

By the above lemma, we know that $\det(\mu I-L(\lambda))$ is a constant independent of the variables x and t_m. Expanding $\det(\mu I-L(\lambda))$ in power of μ, yields

$$\det(\mu I-L(\lambda))=\mu^n-\sigma_1(\lambda)\mu^{n-1}+\ldots+(-1)^n\sigma_n, \tag{5.1}$$

where

$$\sigma_\nu(\lambda)\equiv\mathrm{tr}\overset{\nu}{\wedge}L(\lambda),\quad 1\leqslant\nu\leqslant n. \tag{5.2}$$

For example,

$$\sigma_1(\lambda)=\mathrm{tr}\,L(\lambda),\quad \sigma_2(\lambda)=\tfrac{1}{2}((\mathrm{tr}L(\lambda))^2-\mathrm{tr}\,L^2(\lambda)),\ \ldots,\sigma_n(\lambda)=\det L(\lambda).$$

Therefore we obtain the following result.

Proposition: The functions $\sigma_\nu(\lambda),1\leqslant\nu\leqslant n$, are integrals of motion of the Hamiltonian systems (3.7) and (3.11).

According to the r-matrix theory,[20] from (4.5) we have

$$\{\mathrm{tr}\,L^i(\lambda),\mathrm{tr}\,L^j(\mu)\}=0,\quad 1\leqslant i,\quad j\leqslant n, \tag{5.3}$$

which insures the involution property of the integrals of motion obtained from expanding $\sigma_\nu(\lambda),1\leqslant\nu\leqslant n$, in powers of λ. Explicity,

$$\sigma_1(\lambda)=\sum_{i=1}^{n}\beta_i+\sum_{m=0}^{\infty}\lambda^{-m-1}F_m^{(1)},$$

$$\sigma_2(\lambda)=\sum_{1\leqslant i<j\leqslant n}\beta_i\beta_j+\sum_{m=0}^{\infty}\lambda^{-m-1}F_m^{(2)},$$

$$\sigma_3(\lambda)=\sum_{1\leqslant i<j<k\leqslant n}\beta_i\beta_j\beta_k+\sum_{m=0}^{\infty}\lambda^{-m-1}F_m^{(3)},$$

$$\ldots,$$

$$\sigma_n(\lambda)=\prod_{i=1}^{n}\beta_i+\sum_{n=0}^{\infty}\lambda^{-m-1}F_n^{(n)},$$

where

$$F_m^{(1)}=\sum_{i=1}^{n}\langle\Lambda^m\Phi_i,\Psi_i\rangle,\quad m\geqslant 0,$$

$$F_0^{(2)}=\sum_{p=1}^{n}\sum_{\substack{i=1\\ i\neq p}}^{n}\beta_i\langle\Phi_p,\Psi_p\rangle,$$

$$F_m^{(2)}=\sum_{p=1}^{n}\sum_{\substack{i=1\\ i\neq p}}^{n}\beta_i\langle\Lambda^m\Phi_p,\Psi_p\rangle+\sum_{1\leqslant i<j\leqslant n}\sum_{l=1}^{m}\begin{vmatrix}\langle\Lambda^{l-1}\Phi_i,\Psi_i\rangle & \langle\Lambda^{m-l}\Phi_i,\Psi_j\rangle\\ \langle\Lambda^{l-1}\Phi_j,\Psi_i\rangle & \langle\Lambda^{m-l}\Phi_j,\Psi_j\rangle\end{vmatrix},\quad m\geqslant 1,$$

$$F_0^{(3)}=\sum_{p=1}^{n}\sum_{\substack{1\leqslant i<j\leqslant n\\ i,j\neq p}}\beta_i\beta_j\langle\Phi_p,\Psi_p\rangle,$$

$$F_1^{(3)}=\sum_{p=1}^{n}\sum_{\substack{1\leqslant i<j\leqslant n\\ i,j\neq p}}\beta_i\beta_j\langle\Lambda\Phi_p,\Psi_p\rangle+\sum_{1\leqslant i<j\leqslant n}\sum_{\substack{k=1\\ k\neq i,j}}^{n}\beta_k\begin{vmatrix}\langle\Phi_i,\Psi_i\rangle & \langle\Phi_i,\Psi_j\rangle\\ \langle\Phi_j,\Psi_i\rangle & \langle\Phi_j,\Psi_j\rangle\end{vmatrix},$$

$$F_m^{(3)}=\sum_{p=1}^{n}\sum_{\substack{1\leqslant i<j\leqslant n\\ i,j\neq p}}\beta_i\beta_j\langle\Lambda^m\Phi_p,\Psi_p\rangle+\sum_{1\leqslant i<j\leqslant n}\sum_{\substack{l+t=m-1\\ l,t\geqslant 0}}\sum_{\substack{k=1\\ k\neq i,j}}^{n}\beta_k\begin{vmatrix}\langle\Lambda^l\Phi_i,\Psi_i\rangle & \langle\Lambda^t\Phi_i,\Psi_j\rangle\\ \langle\Lambda^l\Phi_j,\Psi_i\rangle & \langle\Lambda^t\Phi_j,\Psi_j\rangle\end{vmatrix}$$

$$+\sum_{1\leqslant i<j<k\leqslant n}\sum_{\substack{l+t+s=m-2\\ l,t,s\geqslant 0}}\begin{vmatrix}\langle\Lambda^l\Phi_i,\Psi_i\rangle & \langle\Lambda^t\Phi_i,\Psi_j\rangle & \langle\Lambda^s\Phi_i,\Psi_k\rangle\\ \langle\Lambda^l\Phi_j,\Psi_i\rangle & \langle\Lambda^t\Phi_j,\Psi_j\rangle & \langle\Lambda^s\Phi_j,\Psi_k\rangle\\ \langle\Lambda^l\Phi_k,\Psi_i\rangle & \langle\Lambda^t\Phi_k,\Psi_j\rangle & \langle\Lambda^s\Phi_k,\Psi_k\rangle\end{vmatrix},\quad m\geqslant 2,$$

$$\ldots,$$

$$F_m^{(n)}=\sum_{p=1}^{n}\prod_{\substack{i=1\\ i\neq p}}^{n}\beta_i\langle\Lambda^m\Phi_p,\Psi_p\rangle+\sum_{1\leqslant i<j\leqslant n}\sum_{\substack{l+t=m-1\\ l,t\geqslant 0}}\prod_{\substack{k=1\\ k\neq i,j}}^{n}\beta_k\begin{vmatrix}\langle\Lambda^l\Phi_i,\Psi_i\rangle & \langle\Lambda^t\Phi_i,\Psi_j\rangle\\ \langle\Lambda^l\Phi_j,\Psi_i\rangle & \langle\Lambda^t\Phi_j,\Psi_j\rangle\end{vmatrix}$$

$$+\sum_{1\leqslant i<j<k\leqslant n}\sum_{\substack{l+t+s=m-2\\ l,t,s\geqslant 0}}\prod_{\substack{r=1\\ r\neq i,j,k}}\beta_r\begin{vmatrix}\langle\Lambda^l\Phi_i,\Psi_i\rangle & \langle\Lambda^t\Phi_i,\Psi_j\rangle & \langle\Lambda^s\Phi_i,\Psi_k\rangle\\ \langle\Lambda^l\Phi_j,\Psi_i\rangle & \langle\Lambda^t\Phi_j,\Psi_j\rangle & \langle\Lambda^s\Phi_j,\Psi_k\rangle\\ \langle\Lambda^l\Phi_k,\Psi_i\rangle & \langle\Lambda^t\Phi_k,\Psi_j\rangle & \langle\Lambda^s\Phi_k,\Psi_k\rangle\end{vmatrix}$$

$$+\ldots+\sum_{\substack{l_1+\ldots+l_n=m-n\\ l_1,\ldots,l_n\geqslant 0}}\begin{vmatrix}\langle\Lambda^{l_1}\Phi_1,\Psi_1\rangle & \ldots & \langle\Lambda^{l_n}\Phi_1,\Psi_n\rangle\\ \vdots & \ddots & \vdots\\ \langle\Lambda^{l_1}\Phi_n,\Psi_1\rangle & \ldots & \langle\Lambda^{l_n}\Phi_n,\Psi_n\rangle\end{vmatrix},\quad m\geqslant n.$$

From (5.3) we instantly have the following:

Theorem 3: The functions $F_m^{(i)},1\leqslant i\leqslant n,m\geqslant 0$, are in involution in pairs, i.e., $\{F_k^{(i)},F_l^{(j)}\}=0,1\leqslant i,j\leqslant n,k,l\geqslant 0$.

Now we turn to prove the functional independence of integrals of motion over some region of $\mathcal{R}^{2nN}$. The functional independence means a sufficent number of integrals of motion, which is important but usually difficult to verify. For the case of 2×2 matrix eigenvalue problems, Cao *et al.*[21,22] presented a effective method: straightening Abel-Jacobi coordinates method. But this method cannot be used to the cases of higher order matrix spectral problems, since the ellipic coordinates of Hamiltonian systems resulted from higher order matrix spectral problems are not known yet. Here we use the direct method to prove the functional independence of integrals of motion.

Theorem 4: The nN one-forms $dF_m^{(i)}, 1\leqslant i\leqslant n, 0\leqslant m\leqslant N-1$, are linearly independent over some region of $\mathcal{R}^{2nN}$.

Proof: In the following, we adopt compact forms, for example,

$$\frac{\partial}{\partial \Psi_i}=\left(\frac{\partial}{\partial \psi_{i1}},\ldots,\frac{\partial}{\partial \psi_{iN}}\right)^T,\quad \Psi=(\Psi_1,\ldots,\Psi_n),$$

and denote

$$C_i=\begin{pmatrix} \phi_{i1} & \lambda_1\phi_{i1} & \ldots & \lambda_1^{N-1}\phi_{i1}\\ \phi_{i2} & \lambda_2\phi_{i2} & \ldots & \lambda_2^{N-1}\phi_{i2}\\ \vdots & \vdots & \ddots & \vdots\\ \phi_{iN} & \lambda_N\phi_{iN} & \ldots & \lambda_N^{N-1}\phi_{iN}\end{pmatrix}$$

$$\begin{vmatrix} \frac{\partial F_0^{(1)}}{\partial \Psi_1} & \cdots & \frac{\partial F_{N-1}^{(1)}}{\partial \Psi_1} & \frac{\partial F_0^{(2)}}{\partial \Psi_1} & \cdots & \frac{\partial F_{N-1}^{(2)}}{\partial \Psi_1} & \cdots & \frac{\partial F_0^{(n)}}{\partial \Psi_1} & \cdots & \frac{\partial F_{N-1}^{(n)}}{\partial \Psi_1}\\ \frac{\partial F_0^{(1)}}{\partial \Psi_2} & \cdots & \frac{\partial F_{N-1}^{(1)}}{\partial \Psi_2} & \frac{\partial F_0^{(2)}}{\partial \Psi_2} & \cdots & \frac{\partial F_{N-1}^{(2)}}{\partial \Psi_2} & \cdots & \frac{\partial F_0^{(n)}}{\partial \Psi_2} & \cdots & \frac{\partial F_{N-1}^{(n)}}{\partial \Psi_2}\\ \vdots & \ddots & \vdots & \vdots & \ddots & \vdots & \ddots & \vdots & \ddots & \vdots\\ \frac{\partial F_0^{(1)}}{\partial \Psi_n} & \cdots & \frac{\partial F_{N-1}^{(1)}}{\partial \Psi_n} & \frac{\partial F_0^{(2)}}{\partial \Psi_n} & \cdots & \frac{\partial F_{N-1}^{(2)}}{\partial \Psi_n} & \cdots & \frac{\partial F_0^{(n)}}{\partial \Psi_n} & \cdots & \frac{\partial F_{N-1}^{(n)}}{\partial \Psi_n}\end{vmatrix}_{\Psi=0}$$

$$=\begin{vmatrix} C_1 & \sum_{i=2}^{n}\beta_i C_1 & \sum_{2\leqslant i<j\leqslant n}\beta_i\beta_j C_1 & \cdots & \prod_{i=2}^{n}\beta_i C_1\\ C_2 & \sum_{\substack{i=1\\ i\neq 2}}^{n}\beta_i C_2 & \sum_{\substack{1\leqslant i<j\leqslant n\\ i,j\neq 2}}\beta_i\beta_j C_2 & \cdots & \prod_{\substack{i=1\\ i\neq 2}}^{n}\beta_i C_2\\ \vdots & \vdots & \vdots & \ddots & \vdots\\ C_n & \sum_{i=1}^{n-1}\beta_i C_n & \sum_{1\leqslant i<j\leqslant n-1}\beta_i\beta_j C_n & \cdots & \prod_{i=1}^{n-1}\beta_i C_n\end{vmatrix}$$

$$=\prod_{1\leqslant i<j\leqslant n}(\beta_i-\beta_j)\prod_{1\leqslant i<j\leqslant N}(\lambda_j-\lambda_i)^n\prod_{l=1}^{N}\prod_{k=1}^{n}\phi_{kl}$$

is not zero over the region $\Pi_{l=1}^{N}\Pi_{k=1}^{n}\phi_{kl}\neq 0$ of $\mathcal{R}^{2nN}$. Therefore, the nN one-forms $dF_m^{(i)}, 1\leqslant i\leqslant n, 0\leqslant m\leqslant N-1$, are linearly independent. The proof is finished.

A direct calculation shows that the Hamiltonian functions of systems (3.7) and (3.11) can be rewritten as follows:

$$H=\sum_{i=1}^{n}\gamma_i F_1^{(i)}+\sum_{1\leqslant i<j\leqslant n}\delta_{ij}\left(\sum_{k=1}^{n}(-1)^{k-1}\beta_i^{n-k}F_0^{(k)}\right)\cdot\left(\sum_{k=1}^{n}(-1)^{k-1}\beta_j^{n-k}F_0^{(k)}\right),$$

$$H_m=\sum_{i=1}^{n}\beta_i F_m^{(1)}-F_m^{(2)}+\frac{1}{2}\sum_{k=1}^{m}F_{k-1}^{(1)}F_{m-k}^{(1)},m\geqslant 1,$$

where

$$\gamma_p=\sum_{i=1}^{n}\left((-1)^{p+i}\alpha_i\beta_i^{n-p}\prod_{\substack{1\leqslant k<l\leqslant n\\ k,l\neq i}}(\beta_k-\beta_l)\right)\Big/\prod_{1\leqslant i<j\leqslant n}(\beta_i-\beta_j),$$

$$\delta_{ij}=\frac{\alpha_j-\alpha_i}{(\beta_i-\beta_j)^3\prod_{\substack{k=1\\ k\neq i,j}}^{n}(\beta_i-\beta_k)(\beta_j-\beta_k)}.$$

Hence we have

$$\{H,F_m^{(i)}\}=\{H_j,F_m^{(i)}\}=\{H,H_j\}=0,\quad 1\leqslant i\leqslant n,\quad 0\leqslant m\leqslant N-1,\quad j\geqslant 1.$$

Therefore the integrability of systems (3.7) and (3.11) is established resorting to Theorems 3 and 4.

Theorem 5: The finite-dimensional Hamiltonian systems (3.7) and (3.11) are completely integrable in the Liouville sense and their flows are commuting with each other.

2+1 gravity, chaos and time machines

Ingemar Bengtsson[a] and Johan Brännlund[b]
Fysikum, Stockholm University, Box 6730, S-113 85 Stockholm, Sweden

(Received 22 December 2000; accepted for publication 20 March 2001)

$2+1$ gravity for space–times with topology $\mathbf{R}\times\mathbf{T}^2$ has been much studied. We add a description of how to extend these space–times across a Cauchy horizon into a region where the torus becomes Lorentzian. The result is a one parameter family of tori given by a geodesic in the ''Teichmüller space'' of Lorentzian tori. We describe this in detail. We also point out that if the modular group is regarded as part of the gauge group then these space–times offer a nice toy model for the dynamics of Bianchi IX models; in the region where the tori are spacelike the dynamics is described exactly by a hyperbolic billiard. On the other hand the modular group acts ergodically on the Teichmüller space of Lorentzian tori. © *2001 American Institute of Physics.* [DOI: 10.1063/1.1378302]

I. INTRODUCTION

The subject of $2+1$ dimensional gravity looks *a priori* unpromising since—in the absence of matter—all space–times have constant curvature. Nevertheless it has been the subject of many investigations over the past twenty years or so. Indeed it is now widely recognized that it provides (when handled with taste!) surprisingly illuminating toy models of general relativity. Most of these investigations center on quantum gravity,[1] often from a Hamiltonian point of view, and as a result the space–time properties of the models are receiving somewhat less attention than we think that they deserve. Here we intend to present some properties of $2+1$ space–times with topology $\mathbf{R}\times\mathbf{T}^2$, regarded as quotients of Minkowski space. This perspective enables us to discuss what goes on in that region of space–time where the torus becomes Lorentzian and closed timelike curves appear; existing treatments[2,3] typically use the Hamiltonian ADM formalism and therefore do not go across the Cauchy horizon that bounds this region. The motivation for doing this is partly just curiosity, but partly a feeling that there is structure there which may well illuminate some features occurring in $3+1$ dimensions too—even if it will manifest itself in a different way in the latter case. Be that as it may a nice picture emerges; we can regard the entire space–time as a geodesic in the Teichmüller space of tori. This space is the familiar upper half plane in the Riemannian case, and it is $1+1$ dimensional de Sitter space in the Lorentzian case.

The second point that we wish to bring up is that if the modular group is regarded as part of the gauge group then these space–times offer a nice toy model for the chaotic behavior of Bianchi cosmologies. The dynamics of the latter has attracted attention for quite some time and many of its aspects are by now well understood. (There are many references, old,[4,5] new[6] and very new.[7]) In particular it is well known that the behavior of Bianchi IX models close to the singularity can be approximated by a hyperbolic billiard, which is an archetypical chaotic system. In the literature the situation is often described by saying that chaotic behavior appears when curvature becomes strong, although the precise meaning of the word ''chaotic'' here is a subject of some controversy. It is therefore of some interest that this kind of chaotic behavior appears in $2+1$ gravity with zero curvature, as a kind of global effect. A simplifying feature is that in our case the hyperbolic billiard captures the dynamics exactly.

As additional motivation we note that both the points we raise are important for quantization.

They also appear to be of interest in string theory—see Ref. 8, but beware of some misunderstandings in that reference.

The organization of the paper is as follows: In Sec. II we construct our space–times by taking quotients of a region of $2+1$ dimensional Minkowski space with the appropriate discrete isometry groups. This construction is well known.[9,10] In Sec. III we describe these space–times as a geodesic in a Teichmüller space; this is a new result as far as the region with closed timelike curves is concerned. Since the Teichmüller space of Lorentzian tori has caused some puzzlement in the past[11] we describe it in detail. In Sec. IV we describe the dynamics which results when taking the quotient of Teichmüller space with the modular group, and stress the analogy to mixmaster cosmology. We focus on the spectrum of closed geodesics since they are the skeleton on which chaos is built; actually a closed geodesic corresponds to a self-similar rather than a periodic space–time. Our account is intended to be pedagogical (and to be helpful in Sec. V); all the hard results are well known to mathematicians[12,13] and to workers in quantum chaos.[14] In Sec. V we discuss the action of the modular group on the Teichmüller space of Lorentzian tori. We show that it is ergodic. (In a general setting involving discrete groups acting on coset spaces formed from noncompact groups such phenomena are known to mathematicians, but our pedestrian treatment is original as far as we know.) In Sec. VI we sketch how our method works for locally de Sitter space–times,[15] and comment on the higher genus case. Our conclusions are in Sec. VII.

II. OUR SPACE–TIMES

Let $\mathbf{M}$ be a region of $2+1$ dimensional Minkowski space and Γ a free discrete isometry group acting in a properly discontinuous way on this region. We want to choose Γ so that the quotient space $\mathbf{M}/\Gamma$ has the topology of a torus cross the real line. For a simply connected M the quotient space has Γ as its fundamental group. Therefore Γ must be a free discrete group with two commuting generators. We also insist that the quotient space should contain a complete spacelike surface that is not crossed by any closed timelike (or null) curve. The solution to this problem is described, e.g., by Louko and Marolf.[10] As generators of the discrete group we choose $g_1=e^{\xi_1}$ and $g_2=e^{\xi_2}$, that is to say exponentials of the two linearly independent commuting Killing vectors,

$$\xi_1=\alpha J_{xt}+\beta P_y; \quad \xi_2=\gamma J_{xt}+\delta P_y; \quad \alpha\delta-\beta\gamma>0. \tag{1}$$

Here J_{xt} is a Lorentz boost, P_y is a translation and α,β,γ and δ are real numbers. This is the most general solution, except for the obvious static case that we ignore. The group Γ will contain all group elements of the form e^{ξ}, where

$$\xi=(n_1\alpha-n_2\gamma)J_{xt}+(n_1\beta-n_2\delta)P_y, \quad n_1,n_2\in\mathbf{Z}. \tag{2}$$

Here n_1 and n_2 are arbitrary integers. We observe that Γ will contain pure boosts if and only if β/δ is rational, and pure translations if and only if α/γ is rational. Note also that in any case the action of Γ on the line $x=t=0$ is problematic; if a pure boost is present it has a line of fixed points there, and if not the action of Γ on this line is ergodic. Hence we see why the covering space M is taken to be a subset of $2+1$ dimensional Minkowski space only.

Since the Killing vectors ξ_1 and ξ_2 commute they form surfaces, namely

$$t^2-x^2=\tau^2\equiv-\sigma^2, \tag{3}$$

where τ^2 is some constant (not necessarily positive; if it is not then σ^2 is positive). These surfaces are left invariant by the group Γ, they foliate Minkowski space, they are intrinsically flat and their mean curvature is constant. They turn into tori when we take the quotient with Γ. From now on we take M to be the union of regions I and II of Minkowski space, as defined in Fig. 1. This means that our quotient spaces will be geodesically incomplete. If we did not restrict M in this way we would obtain what Louko and Marolf[10] accurately describe as a ''modest generalization of Misner space;'' as far as we can see there is nothing interesting to say about this that goes beyond Misner's original observations[16] which is why we make the restriction. Since each invariant

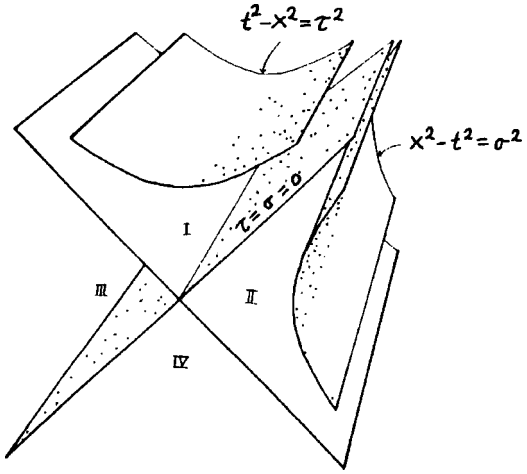

FIG. 1. $2+1$ dimensional Minkowski space divided into four wedge shaped regions, each of which is foliated by flat surfaces left invariant by Γ. Our covering space consists of regions I and II and our quotient space becomes a one parameter family of tori.

surface contributes a torus to the quotient space we now see that our space–times can be described as a one parameter family of flat tori; spacelike tori coming from region I and labeled by τ and Lorentzian tori coming from region II and labeled by σ. The Cauchy horizon $\tau=\sigma=0$ contributes a null torus.

III. A TRIP THROUGH TEICHMÜLLER SPACE

Our task now is to describe the one parameter family of flat tori that constitutes a space–time of the kind that we defined in Sec. II. We use the notation that $\xi_\alpha\xi^\alpha\equiv\|\xi\|^2\equiv\pm|\xi|^2$, where the sign depends on whether the vector is timelike or spacelike and $|\xi|$ is non-negative by definition. Let us first sketch what goes on in the region without closed timelike curves (where a Hamiltonian description is available[2,3]). At fixed τ the tori are built from parallelograms spanned by the generators ξ_1 and ξ_2. The angle between them is given by

$$\cos\theta=\frac{\xi_1\cdot\xi_2}{|\xi_1||\xi_2|}=\frac{\beta\delta+\alpha\gamma\tau^2}{\sqrt{\beta^2+\alpha^2\tau^2}\sqrt{\delta^2+\gamma^2\tau^2}}. \tag{4}$$

Therefore their area is a monotonically increasing function:

$$A=|\xi_1||\xi_2|\sin\theta=(\alpha\delta-\beta\gamma)\tau. \tag{5}$$

(The total area of the torus is the area of a parallelogram times a fixed numerical factor that can be chosen at will.) On the other hand the shape of the torus is changing in an interesting way. To describe it we introduce their Teichmüller space:

Definition: Teichmüller space is the moduli space of marked flat tori.

''Marked'' means that a particular pair of intersecting closed geodesics on the torus (namely the one that corresponds to our generators ξ_1 and ξ_2) has been singled out for special attention. The definition applies equally well to Riemannian and Lorentzian tori; in the former case it is well known that Teichmüller space can be regarded as the upper half plane, and that it is naturally equipped with the Poincaré metric,

$$ds^2=\frac{1}{y^2}(dx^2+dy^2). \tag{6}$$

This is hyperbolic space $\mathbf{H}^2$ and its isometry group is $PSL(2,\mathbf{R})$. We can assign a position in Teichmüller space to our tori if we first normalize our generators so that ξ_1 has length one and lies along the x-axis. Then the tip of ξ_2 will point at a unique point in the upper half plane, namely

$$(x,y)=\frac{|\xi_2|}{|\xi_1|}(\cos\theta,\sin\theta)=\frac{1}{\beta^2+\alpha^2\tau^2}(\beta\delta+\alpha\gamma\tau^2,(\alpha\delta-\beta\gamma)\tau). \tag{7}$$

Note that at this stage we use an auxiliary Euclidean metric on the coordinate plane to assign a point to ξ_2. We now have a curve parametrized by τ and it is elementary to show that this is a semi-circle meeting the boundary at right angles:

$$\left(x-\frac{\beta\gamma+\alpha\delta}{2\alpha\beta}\right)^2+y^2=\left(\frac{\alpha\delta-\beta\gamma}{2\alpha\beta}\right)^2. \tag{8}$$

This is a geodesic with respect to the natural metric. Hence the statement that the torus evolves along a geodesic in Teichmüller space. It should not be forgotten that it also grows in area. A minor calculation informs us that if we move a distance L along the geodesic, as measured by the Poincaré metric, then the area of the torus grows with a factor e^L. Note that this does not depend on the parameters describing the space–time, nor does it depend on where we are on the geodesic.

Now what happens when we pass the Cauchy horizon and enter region II? The first observation is that

$$\|\xi_1\|^2=\beta^2-\sigma^2\alpha^2. \tag{9}$$

Hence (unless ξ_1 is a pure translation or a pure boost) ξ_1 is spacelike in a region where $x^2-t^2=\sigma^2<\beta^2/\alpha^2$ and it is timelike when $x^2-t^2=\sigma^2>\beta^2/\alpha^2$. Let us refer to these regions as region IIa and IIb, respectively. To avoid misunderstandings, because the group Γ contains all the elements listed in Eq. (2) there are closed timelike geodesics through every point in region II, although the existence of closed null geodesics on the Cauchy horizon depends on whether δ/β is rational or not.

If we now try to mimic the construction of the Teichmüller space of Riemannian tori we run into a problem with the first step, which was to use a rotation to bring the generator ξ_1 into a standard position. We cannot use Lorentz transformations for the same purpose here: The Teichmüller space of Lorentzian tori splits into two components depending on whether ξ_1 is spacelike or timelike. We therefore use a different approach at first. By definition the Teichmüller space is the moduli space of marked flat Lorentzian tori.

Theorem 1: The Teichmüller space of Lorentzian tori has the topology $\mathbf{R}\times\mathbf{S}^1$. It is naturally equipped with the de Sitter metric.

Proof: To each oriented dyad of vectors there corresponds a unique flat marked Lorentzian torus. The set of such dyads is isomorphic to the group $SL(2,\mathbf{R})$. If we perform a Lorentz transformation of the dyad the torus is unchanged. Taking this into account we find a one-to-one correspondence between the Teichmüller space and the coset space $SL(2,\mathbf{R})/SO(1,1)$. But it is well known that this space has the stated topology. The de Sitter metric is natural because it is the maximally symmetric metric, and also because it arises if we take the perpendicular distance between the fibers, as measured by the standard metric on $SL(2,\mathbf{R})$.

Although well known the result is not quite trivial. The coset space $SO(2,1)/SO(1,1)$ has the topology of the Möbius strip, even though the group manifolds of $SO(2,1)$ and $SL(2,\mathbf{R})$ have the same topology. Let us give a sketch of the argument: we may, by analogy with the Euler angle parametrization of $\mathbf{S}^3$, introduce local coordinates θ,φ,γ on $SL(2,\mathbf{R})$ (aka $\mathbf{adS}_3$) as

$$X=\cos\frac{\theta}{2}\sinh\frac{\varphi-\gamma}{2},$$

$$Y=\sin\frac{\theta}{2}\sinh\frac{\varphi+\gamma}{2},$$

$$U=\cos\frac{\theta}{2}\cosh\frac{\varphi-\gamma}{2},$$

$$V=\sin\frac{\theta}{2}\cosh\frac{\varphi+\gamma}{2}. \tag{10}$$

The flat metric,

$$ds^2=dX^2+dY^2-dU^2-dV^2, \tag{11}$$

on the embedding space induces the metric

$$ds^2=\tfrac{1}{4}(-d\theta^2+d\varphi^2+d\gamma^2-2\,d\varphi\,d\gamma\cos\theta), \tag{12}$$

on $SL(2,\mathbf{R})$. The coordinate γ runs along the flow lines of the Killing field $J_{XU}+J_{YV}$ which generates $SO(1,1)$ transformations and we want to identify points along these lines. The metric on the resulting space, obtained from the orthogonal distance between the fibers, may be calculated using the threading approach of Boersma and Dray.[17] By identifying the metric in (12) with an Ansatz of the form

$$ds^2=M^2(d\gamma-M_i\,dx^i)^2+h_{ij}\,dx^i\,dx^j, \tag{13}$$

one obtains the metric

$$h=\tfrac{1}{4}(-d\theta^2+\sin^2\theta d\varphi^2), \tag{14}$$

for the quotient space $SL(2,\mathbf{R})/SO(1,1)$. This is precisely the metric for (part of) $\mathbf{adS}_2$ in a reasonably well known coordinate system; anti-de Sitter space and de Sitter space are identical in $1+1$ dimensions. It is also possible to do this calculation in global coordinates, at the expense of their not being adapted to the identification Killing field.

As it stands Theorem 1 is not very useful. To see what kind of curve our tori describe we need to know how to assign a point in Teichmüller space to a given marked torus. This understanding will be provided by the proof of Theorem 2, which will wind its way to the end of this section.

Theorem 2: The Teichmüller space of Lorentzian tori has the topology $\mathbf{R}\times\mathbf{S}^1$. The one parameter family of tori that represents a space–time (defined in Sec. II) is a timelike geodesic in this space provided that it is equipped with the de Sitter metric.

Proof: Our first step is to introduce coordinates (x,t). During the construction we use the flat Minkowski metric on this coordinate plane. Again we normalize the vectors so that ξ_1 points at (1,0). This is always possible provided that $\sigma^2<\beta^2/\alpha^2$. Since we know the scalar product of the vectors we find that the tip of ξ_2 points at the point

$$(x,t)=\frac{1}{\beta^2-\sigma^2\alpha^2}(\beta\delta-\alpha\gamma\sigma^2,-(\alpha\delta-\beta\gamma)\sigma). \tag{15}$$

We have therefore been able to arrange that this component of Teichmüller space is identical to the lower half plane. It is elementary to show that the points on this curve obey

$$\left(x-\frac{\beta\gamma+\alpha\delta}{2\alpha\beta}\right)^2-t^2=\left(\frac{\alpha\delta-\beta\gamma}{2\alpha\beta}\right)^2. \tag{16}$$

This is a hyperbola with its foci on the x-axis and it is a geodesic with respect to the metric,

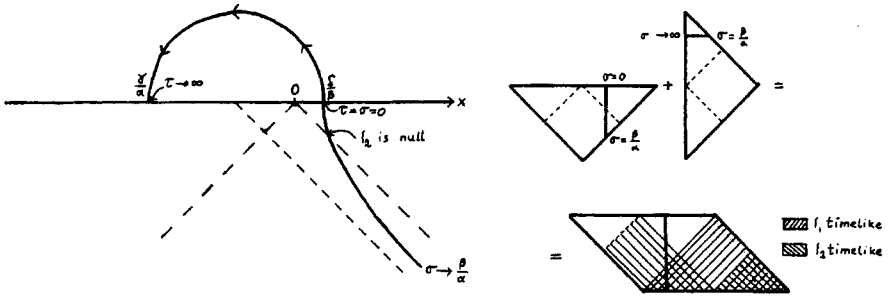

FIG. 2. The curve through Teichmüller space. In the upper half plane the torus is Riemannian. In the lower half plane the torus is Lorentzian but the generator ξ_1 is still spacelike. When ξ_1 is timelike we again obtain a half plane. The latter two half planes are conveniently depicted with conformal diagrams; adding them together so that the curve becomes smooth we obtain the conformal diagram of $1+1$ dimensional de Sitter space.

$$ds^2=\frac{1}{t^2}(dx^2-dt^2). \tag{17}$$

But this is in fact the de Sitter metric on a coordinate patch that covers ''one half'' of de Sitter space.

We can now draw a picture of the geodesic in Teichmüller space, where the Teichmüller space of Riemannian tori has been joined to its counterpart for Lorentzian tori across their conformal boundaries. Note that in the Lorentzian part of the picture the geodesic reaches infinite coordinate values at finite parameter values $\sigma^2=\beta^2/\alpha^2$. This is actually a good thing: We know that the coordinates we are using cover only a part of Teichmüller space. ''Infinity'' in the picture corresponds to a coordinate singularity that is caused by our assumption that ξ_1 is spacelike. (See Fig. 2.)

When ξ_1 is timelike we again introduce an infinite half plane, this time described by the coordinates t' and $x'>0$, and normalize the vectors so that ξ_1 points at $(t',x')=(1,0)$. We then find that ξ_2 points at

$$(t',x')=\frac{1}{\sigma^2\alpha^2-\beta^2}(\beta\delta-\alpha\gamma\sigma^2,(\alpha\delta-\beta\gamma)\sigma). \tag{18}$$

These points lie on the hyperbola,

$$\left(t'+\frac{\beta\gamma+\alpha\delta}{2\alpha\beta}\right)^2-x'^2=\left(\frac{\alpha\delta-\beta\gamma}{2\alpha\beta}\right)^2. \tag{19}$$

This is a geodesic with respect to the metric,

$$ds^2=\frac{1}{x'^2}(dt'^2-dx'^2). \tag{20}$$

This is again the metric on ''one half'' of de Sitter space. Since we now think of the conformal boundary as being timelike it may be more natural to think of it as anti-de Sitter space—but in $1+1$ dimensions de Sitter space and anti-de Sitter space coincide when we switch the meaning of space and time.

It remains to show that the two components of Teichmüller space can be glued together so that they form a de Sitter space, in such a way that the curve becomes a geodesic globally. For this purpose we observe that both $\mathbf{H}^2$ (the Teichmüller space of Riemannian tori) and $1+1$ dimensional de Sitter space can be isometrically mapped into surfaces in a $2+1$ dimensional Minkowski space with the metric

$$ds^2 = dX^2 + dY^2 - dU^2. \tag{21}$$

Explicitly we define an embedding of $\mathbf{H}^2$ by

$$X = \frac{x}{y}, \quad Y + U = \frac{1}{y}, \quad Y - U = -\frac{x^2 + y^2}{y}; \quad y > 0. \tag{22}$$

The surface is the upper sheet of the hyperboloid $X^2 + Y^2 - U^2 = -1$ and the induced metric is the one given in Eq. (6). The first component of the Teichmüller space of Lorentzian tori is embedded through

$$X = \frac{x}{t}, \quad Y + U = \frac{1}{t}, \quad Y - U = \frac{t^2 - x^2}{t}; \quad t > 0. \tag{23}$$

The surface is ''one half'' of the hyperboloid $X^2 + Y^2 - U^2 = 1$ and the induced metric is the one given in Eq. (17). The second component is embedded through

$$X = \frac{t'}{x'}, \quad Y + U = -\frac{1}{x'}, \quad Y - U = \frac{t'^2 - x'^2}{x'}; \quad x' > 0. \tag{24}$$

The surface is ''the other half'' of the hyperboloid $X^2 + Y^2 - U^2 = 1$ and the induced metric is the one given in Eq. (20).

A geodesic in $\mathbf{H}^2$, and a timelike geodesic in de Sitter space, is uniquely defined as the intersection of a hyperboloid with a timelike plane through the origin in the embedding space. The curve in Teichmüller space is given by Eqs. (8), (16) and (19). Therefore, to show that this curve is globally a timelike geodesic in de Sitter space we must find a spacelike vector k_α such that Eqs. (16) and (19) are equivalent to $k \cdot X = 0$. An elementary calculation shows that this is the case for the vector,

$$(k_X, k_Y, k_U) = (\alpha^2\delta^2 - \beta^2\gamma^2, \beta\delta(\alpha^2 + \gamma^2) - \alpha\gamma(\beta^2 + \delta^2), \quad \alpha\gamma(\beta^2 - \delta^2) + \beta\delta(\gamma^2 - \alpha^2)). \tag{25}$$

Equation (8) is also reproduced. This completes the proof that the curve is globally described by a timelike geodesic in de Sitter space.

IV. THE COGWHEELS OF CHAOS

In this section we restrict ourselves to region I (where there are no closed timelike curves), so that the evolution can be regarded as time evolution in a configuration space in the standard sense.[2,3] However, it is a moot point whether the configuration space should be taken to be Teichmüller space or the moduli space of (unmarked) flat tori. The latter space is in fact $\mathbf{H}^2/\Gamma_M$, where Γ_M is the modular group $PSL(2,\mathbf{Z})$ acting on the upper half plane through

$$z \to z' = \frac{az + b}{cz + d}; \quad ad - bc = 1, \tag{26}$$

where a, b, c and d are integers and $z = x + iy$. (To see that z and z' actually correspond to the same torus, consider a pair of intersecting closed geodesics on the torus and choose them to have the shortest circumference possible. The conformal structure can be characterized by the angle and relative lengths of this pair. A little experimentation shows that these are unaffected by a modular transformation.) The quotient space is the famous modular surface, usually described as the fundamental region of the group which is bounded by $r^2 \equiv x^2 + y^2 = 1$ and $x = \pm 1/2$. It is depicted in Fig. 3. Its area is finite and it is a smooth manifold except for two conical singularities occurring at the fixed points of the transformations S and ST, where S and T are the transformations

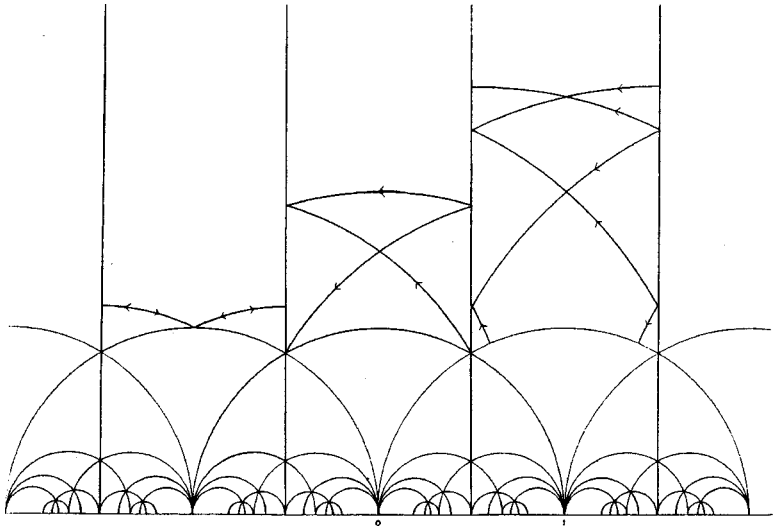

FIG. 3. The modular surface is the fundamental region of the modular group, with sides appropriately identified. The picture shows how the upper half plane is tesselated by copies of the fundamental region. In three of the copies we have drawn examples of closed geodesics ($N=3$ $x_+=[\dot{1}]$, $N=4$ $x_+=[\dot{1},\dot{2}]$ and $N=5$ $x_+=[\dot{1},\dot{3}]$ in the notation introduced below).

$$Sz=-\frac{1}{z},\quad Tz=z+1. \tag{27}$$

S and T generate the group and obey two relations, viz., $S^2=1$ and $(ST)^3=1$. Note that the transformation S acts by switching the elements in the oriented dyad that defines the torus.

The question whether the configuration space is $\mathbf{H}^2$ or $\mathbf{H}^2/\Gamma_M$ matters for the properties of the model but it is not a question of right or wrong, since we do not intend to compare the model to experiment anyway. Technically the modular group does not belong to the connected component of the gauge group so that both options are open as far as consistency is concerned. For thoughtful comments on this issue we refer to papers by Peldán[18] and Matschull;[19] here we choose the second option because it is an interesting one.

As shown by Artin[12] and Hedlund[20] the geodesic flow on the modular surface is ergodic (indeed they showed this at a time when the proper definition of an ergodic system was yet to be found—with today's definition we can say that the flow has the Bernoulli property, which is the strongest ergodic property around). From this point of view it has been much studied; Series has written a nice review with some entries to the technical literature.[13] Here we focus on one aspect of this flow, namely its closed orbits. We take the point of view that one can define ''chaos'' in a dynamical system by the requirement that the number of its unstable closed orbits rises exponentially as a function of length. This is not at all unreasonable; in fact this is the feature of chaotic systems that survives the transition to quantum theory (via the Gutzwiller trace formula, which connects the asymptotic properties of the spectrum of closed geodesics to the spectrum of the Laplacian). Since it is a simple matter of counting it is also a feature that survives the transition to diffeomorphism invariant systems—unlike Lyapounov exponents and the like that can be reparametrized away. To avoid confusion, note that—because the area of our tori is growing—a closed geodesic in moduli space actually corresponds to a self-similar rather than a periodic space–time.

The closed geodesics on the modular surface arise because any hyperbolic Möbius transformation—corresponding to an $SL(2,\mathbf{R})$ matrix whose trace has an absolute value larger than two—has a unique geodesic flowline connecting its pair of fixed points on the real axis. If this Möbius transformation is a modular transformation as well there are points on this geodesic that will be identified with each other, and a closed geodesic results. The distance L between a pair of neighboring identified points is easily computed. It is given by

$$2\cosh\frac{L}{2}=N, \tag{28}$$

where $N=|\mathrm{Tr}\,g|$ and g is the matrix corresponding to the modular transformation, so that $N=a+d$ if the transformation is written as in Eq. (26). Note that N can be used to label the conjugacy classes of $SL(2,\mathbf{R})$. This therefore is the length spectrum of the closed geodesics.

It takes more effort to understand how many closed geodesics there are. In group theoretical terms this is the problem to enumerate the conjugacy classes of $PSL(2,\mathbf{Z})$. There are only two conjugacy classes of elliptic elements, corresponding to the two fixed points on the boundary of the fundamental region. The number of conjugacy classes of hyperbolic elements on the other hand is a rapidly growing function of N. It is in fact known (see for instance Ref. 14) that when L is large the number n of closed geodesics with length l not exceeding L grows like

$$n(l\leqslant L)\sim\frac{e^L}{L}. \tag{29}$$

This settles it: The system is chaotic. It is however an instructive exercise to compute the number of closed geodesics ''from below'' with pedestrian methods, and this we will now proceed to do.

A geodesic in the upper half plane can be conveniently characterized by two real numbers, its starting point x_+ and its end point x_- on the real axis. To each geodesic we can associate a hyperbolic Möbius transformation whose fixed points are these two points. The geodesic projects to a closed geodesic on the modular surface if and only if this Möbius transformation belongs to the modular group, and there will be a unique such Möbius transformation of smallest trace associated to the closed geodesic (if $x=gx$ then $x=g^nx$; if $n>1$ the trace of g^n is greater than the trace of g and the corresponding geodesic is traversed several times—here we count only ''primitive'' closed geodesics). In equations then

$$x_\pm=\frac{ax_\pm+b}{cx_\pm+d}. \tag{30}$$

It follows that $x_\pm$ is a quadratic surd, that is to say a solution to a quadratic algebraic equation with integer coefficients whose discriminant is not a perfect square. The two solutions to this equation are

$$x_\pm=\frac{1}{2c}(a-d\pm\sqrt{N^2-4}), \tag{31}$$

where $N=a+d$ and we made use of the condition $ad-bc=1$. Note that the discriminant $D=N^2-4=4\sinh^2(L/2)$ according to Eq. (28). Since the surds occur in pairs the closed geodesics can in fact be labeled by just one real number, say its ''source'' x_+.

Next we introduce continued fractions.[21] A real number can be uniquely expressed in the form

$$x=a_0+\cfrac{1}{a_1+\cfrac{1}{a_2+\ldots}}\equiv[a_0,a_1,a_2,\ldots], \tag{32}$$

where all the partial quotients a_i are integers and all except possibly a_0 are positive. It is known that x is rational if and only if its continued fraction expansion is finite (i.e., the number of its partial quotients is finite), and it is a quadratic surd if and only if its continued fraction expansion eventually repeats, in which case it is called periodic. The beginning and end of the period is then marked with overdots, so that a quadratic surd of period length k is of the form $x=[a_0;a_1,\ldots a_{n-1},\dot{a}_n,\ldots,\dot{a}_{n+k-1}]$. This nice characterization of quadratic surds is interesting to us.

One piece of the technology of continued fractions should be mentioned, which is that they give rise to a sequence of approximations of x by rational numbers:

$$[a_0]=\frac{p_0}{q_0},\quad [a_0,a_1]=\frac{p_1}{q_1},\quad [a_0,a_1,a_2]=\frac{p_2}{q_2}, \tag{33}$$

and so on. Here p_n and q_n are polynomials in the partial quotients and by induction one can show that

$$p_n=a_n p_{n-1}+p_{n-2},\quad q_n=a_n q_n+q_{n-1}. \tag{34}$$

Note that p_n and q_n are monotonically increasing functions of n.

We want to count equivalence classes of geodesics under the modular group and therefore we will try to fix one member of each equivalence class. Now the modular group acts on a continued fraction in the following way:

$$x=[a_0,a_1,a_2,a_3,\dots]\to ST^{-a_0}x=-[a_1,a_2,a_3,\dots]\to ST^{a_1}ST^{-a_0}x=[a_2,a_3,\dots]. \tag{35}$$

It follows that we can remove the partial quotients in pairs. In particular it follows that we can choose x_+ to be a purely periodic continued fraction since we can always remove the initial sequence. Hence without loss of generality,

$$x_+=[\dot a_0,\dots,\dot a_{k-1}]. \tag{36}$$

If the period length k is even then x_+ is a fixed point of the group element,

$$g=ST^{a_{k-1}}\cdots\ ST^{a_1}ST^{-a_0}. \tag{37}$$

In terms of the polynomials introduced above it can be shown that

$$x_+=gx_+=\frac{q_{k-2}x_+-p_{k-2}}{-q_{k-1}x_++p_{k-1}}\Rightarrow N=|\mathrm{Tr}\,g|=p_{k-1}+q_{k-2}. \tag{38}$$

This is a useful fact since it means that N is a monotonically increasing function of the partial quotients. It also means that N will grow when the length of the period in the continued fraction grows, other things being equal.

The fixed point x_+ is in fact the source of the geodesic associated with g. This is so because g removes one period from the continued fraction, so that when g acts on an approximation to x_+ that is a rational number whose continued fraction expansion consists of a finite number of periods then g moves that rational number away from x_+. If the period length is odd then that g which leaves it fixed and has the smallest value of N is

$$g=ST^{a_{k-1}}\cdot\cdots\cdot ST^{a_0}ST^{-a_{k-1}}\cdot\cdots\cdot ST^{-a_0}. \tag{39}$$

It is convenient to regard continued fractions of odd period lengths as having even periods of twice the original length. According to a theorem of Galois' the corresponding sink (the other root of the quadratic equation) now obeys

$$Sx_-=-\frac{1}{x_-}=[\dot a_{k-1},\dots,\dot a_0]. \tag{40}$$

It is easy to show this since x_- is the source of the group element g^{-1}. The source and sink are now given in reduced form; this means that $x_+>1$ and $-1<x_-<0$.

Two geodesics in reduced form will give rise to the same closed geodesic on the modular surface if one can be obtained from the other by cyclic permutations of the pairs in the continued fraction expansion of their sources. This remaining ambiguity is easy to take care of, so that we

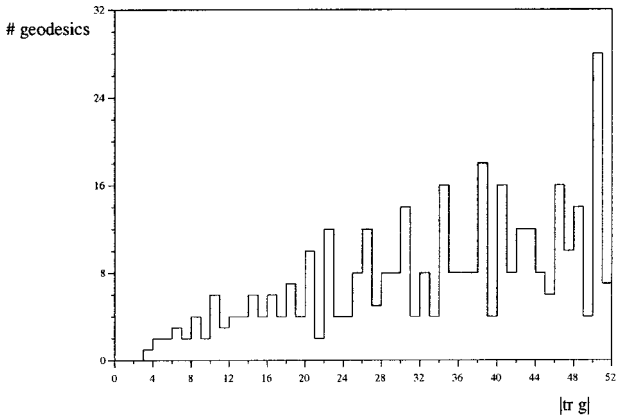

FIG. 4. Degeneracies of the length spectrum: The first 52 levels.

can now make a list of all closed geodesics corresponding to continued fraction expansions of a given period length. Moreover we know from Eq. (38) that the length of the geodesic is a monotonically increasing function of the partial quotients, so it is straightforward to compute the number of primitive closed geodesics of a length not exceeding some chosen reasonable number. The result of such a calculation is given in Fig. 4. Continuing this exercise on a computer one can see how Eq. (29) emerges. (Curiously we were unable to find this calculation in the accessible literature, although it has been done before.[22])

The conclusion is that $2+1$ gravity on the torus is a chaotic system according to the definition that we have adopted. Unlike the case of Bianchi models no approximation was involved. It may be felt that this chaos was introduced by sleight-of-hand since the system was in fact integrable before the modular group was declared to generate gauge symmetries. Indeed we are dealing with chaos of a very special kind, called ''arithmetical chaos.'' Although the system is chaotic in the sense that the number of closed orbits not exceeding a given length grows exponentially, it is also very special because there are huge degeneracies in the length spectrum (caused by the fact that the number of possible lengths grows much more slowly). Closer investigation reveals[14] that in such situations the level statistics of the Laplace operator shows some features that resemble integrable systems much more than they resemble a generic chaotic system (in particular the level repulsion that is typical of the latter is missing here) so the feeling is justified to some extent.

V. A LOOSE END

In the previous section we occupied ourselves with the action of the modular group on the Teichmüller space of Riemannian tori; the quotient space—the moduli space of Riemannian tori—is almost a smooth manifold since the modular group has only two elliptic conjugacy classes, and only the elliptic members of the modular group have fixed points in $\mathbf{H}^2$. The situation is dramatically different for the action of the modular group on the Teichmüller space of Lorentzian tori: Here every hyperbolic element of the modular group has fixed points inside the space, and we have already seen that there is an infinite number of inequivalent elements of this type.

The modular group is a subgroup of $PSL(2,\mathbf{R})=SO(2,1)$ and this is the isometry group of $\mathbf{H}^2$ and $1+1$ dimensional de Sitter space alike. The action of the generators of the modular group is as follows. The generator T gives rise to a ''null rotation'' generated by a Killing vector that becomes null along the coordinate singularity that separates the two parts of de Sitter space in the description we gave above; its fixed points lie on the conformal boundary. In the half plane coordinates it is simply a translation in the x-direction. The generator S is a spatial rotation of de Sitter space; it has no fixed points and cannot be described in a single coordinate patch of the type used above. If we think of S as effecting an interchange of the basis elements in the dyad that defines the torus we see that this must be so whenever one of the elements is spacelike and the

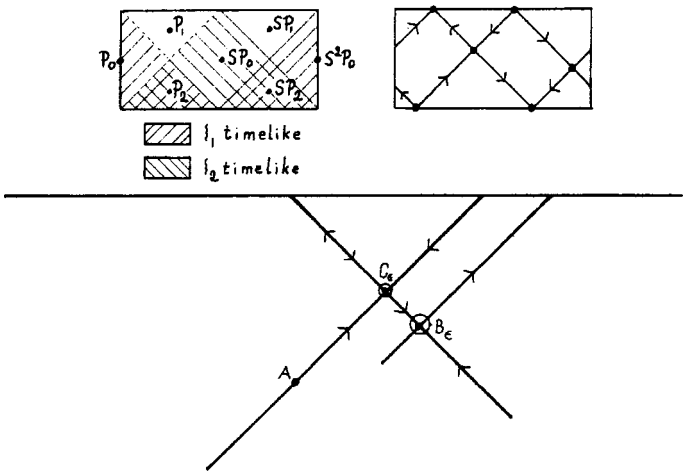

FIG. 5. The action of S on $1+1$ dimensional de Sitter space; also the null flow lines and the fixed points of a hyperbolic transformation; and a sketch of the proof (involving two different hyperbolic transformations) that the action of the modular group is ergodic.

other timelike—the generator S will then transform a point representing a spacelike ξ_1 (say) into a point in the other coordinate patch where ξ_1 is timelike. Figure 5 should be enough to make this clear.

Each hyperbolic element of the modular group has two fixed points inside de Sitter space, and two fixed points on each component of the conformal boundary separated from the fixed points in the interior by null lines that are left invariant by the transformation. The fixed points on the boundary are conjugate pairs of quadratic surds and conversely. This makes it easy to prove the next theorem.

Theorem 3: The action of the modular group on the Teichmüller space of Lorentzian tori is ergodic, in the sense that an arbitrary point can be transformed into an arbitrary coordinate neighborhood of any other point.

Proof: We must show that there is a modular transformation taking an arbitrary point A into a given neighborhood B_ϵ of another arbitrary point B. All neighborhoods are regarded as coordinate neighborhoods and we assume that the pair of points lies within some half plane coordinate patch. (There are exceptional pairs for which this fails, but they can easily be treated with an extension of the argument and will be ignored.)

We need to know that in any neighborhood of any point there is a hyperbolic modular transformation with a fixed point in that neighborhood. This will be so if, given any two points $x_\pm$ on the conformal boundary, we can find a conjugate pair of quadratic surds with one member arbitrarily close to each. But this is easy using the technology of the previous section. First modular transformations are used to show that it is enough to consider the case $x_+ > 1$, $-1 < x_- < 0$. Then one approximates x_+ and $-1/x_-$ with continued fractions to the desired accurary. The sequence of integers that gives the continued fraction approximating $-1/x_-$ is then reversed and added to the sequence that approximates x_+, and the resulting sequence is taken to be the period of a purely periodic continued fraction. Galois' theorem shows that we now have an approximation of x_+ whose conjugate surd approximates x_-. At the end we choose $x_\pm$ to be null separated from the given point. They intersect at a fixed point, and we are done.

With this understanding, draw null lines through A and B meeting each other at the point C. Choose a suitable neighborhood C_ϵ of C and a hyperbolic modular transformation with a fixed point in C_ϵ. Use this transformation to move the point A into C_ϵ. Then choose a hyperbolic modular transformation with a fixed point in B_ϵ and adjust the size of C_ϵ so that the second transformation moves C_ϵ into B_ϵ.

Except for a speculative remark in the conclusions we have nothing to say about what this means.

VI. OTHER SPACE–TIMES

The final issue is to what extent the results described above are peculiar to flat space–times and to the genus one case. We confine our remarks to region I, where there are no closed timelike curves and the tori are spacelike. Consider first locally de Sitter space–times. $2+1$ dimensional de Sitter space–time can be described as the hypersurface,

$$X^2+Y^2+Z^2-U^2=1, \tag{41}$$

embedded in a four dimensional Minkowski space (with U as its time coordinate). Alternatively, it is the maximally symmetric vacuum solution to Einstein's equations with a positive cosmological constant λ. Again we choose two commuting and linearly independent Killing vectors,

$$\xi_1=\alpha J_{ZU}+\beta J_{XY} \quad \xi_2=\gamma J_{ZU}+\delta J_{XY}. \tag{42}$$

They leave invariant the flat surfaces,

$$U^2-Z^2=\sinh^2\tau, \tag{43}$$

whose mean curvature is $K=4\cosh\tau$. Following the same steps as above we find that the invariant flat surfaces are turned into tori and that the evolution of the shape of these tori is given by a geodesic in Teichmüller space, with the interesting difference[15] that the evolution slows down and tends to a definite point in Teichmüller space as the parameter τ goes to infinity (while the area continues to grow). Explicitly,

$$(x,y)=\frac{1}{\alpha^2\tanh^2\tau+\beta^2}(\alpha\gamma\tanh^2\tau+\beta\delta,(\alpha\delta-\beta\gamma)\tanh\tau), \tag{44}$$

$$A=(\alpha\delta-\beta\gamma)\sinh\tau\cosh\tau. \tag{45}$$

The evolution stops because $\tanh\tau\to 1$ as $\tau\to\infty$. Note that this time the change of area as we move a distance L along the geodesic does depend on where we are on the geodesic. A subtlety should be mentioned also, namely that the universal covering space of the quotient spaces considered here is not, in general, de Sitter space itself but a ''larger'' incomplete space–time of constant curvature;[9,23] for the best explanation that we have to offer see Ref. 24.

Why does the evolution stop in the interior of Teichmüller space? The answer is in fact obvious: In the de Sitter case future infinity $\mathcal{J}$ is a spacelike surface transformed into itself by Γ. When we take the quotient we obtain an ''asymptotic torus'' with a definite conformal structure, and this is the endpoint of the geodesic in Teichmüller space. The area of this torus is not defined since $\mathcal{J}$ is equipped with a conformal structure only. At this point the reader may object that $\mathcal{J}$ is a sphere and that a discrete group like our Γ cannot act properly discontinuously on a sphere. This is true but irrelevant; in fact the covering space that we are using is not quite de Sitter space but an incomplete space–time obtained by removing two timelike lines from de Sitter space, and afterwards going to the universal covering space. This means that $\mathcal{J}$ is really a twice punctured sphere that has been ''unrolled'' to form a plane. This is explained in Fig. 7 in Ref. 24, where it can be seen that the invariant flat spacelike surfaces that were defined in the previous section do not encounter the timelike lines that were removed (except on $\mathcal{J}$ itself).

For the genus one case then we find that the chaotic behavior in the moduli space of tori is somehow ''washed away'' by the cosmological constant. It should however be noted that the flat torus universe is quite special in this regard. We can obtain locally flat space–times foliated by Riemann surfaces of higher genus by choosing Γ to be a discrete group—but this time not a free group—generated by noncommuting elements that in general are combinations of boosts and

translations. These space–times are conformally static when Γ consists of pure boosts. As time passes the boost parts will dominate the translations and the solution will tend to a conformally static solution, that is to a definite point inside Teichmüller space. (This has been demonstrated with full rigor.[25]) For the genus one case the evolution never stops for essentially the same reason; it is still true that eventually the boost part of the generators will dominate but now this means that the shape of the torus degenerates so that we approach the boundary of Teichmüller space.

VII. CONCLUSIONS

The main new results of this paper are the explicit description of the moduli space of Lorentzian tori as the union of two half planes constituting a $1+1$ dimensional de Sitter space, and the demonstration that the description of the $2+1$ dimensional locally flat torus universe as a geodesic in Teichmüller space is valid on both sides of the Cauchy horizon. We also emphasized the analogy between these $2+1$ dimensional space–times on the one hand, and mixmaster cosmology on the other. The difference between them is that the BKL approximation is exact in the former case. This is interesting because it shows that chaotic behavior in general relativity should not in general be blamed on strong gravitational fields.

There are some open ends. We did not describe the extension to a geodesically complete space–time, but this was mainly because it appears clear that this would give nothing new (compared to Misner's original work[16]). A more interesting open end is that the analogy to Bianchi IX cosmology holds only in the region where there are no closed timelike curves and the configuration space can be taken to be the moduli space of flat Riemannian tori, which is almost a smooth manifold. In the region with closed timelike curves we have to deal with the moduli space of Lorentzian tori, which is defined as the quotient of $1+1$ dimensional de Sitter space by the modular group. But—as we demonstrated—the action of the modular group is now ergodic, so that the resulting quotient space is not easily described even as a set. It is our understanding that the desire to describe sets of this type is one of the main motivations behind noncommutative geometry.[26] It would be marvelous if one could follow this lead in such a way that an analogy with the singularity in $3+1$ dimensional cosmologies could be drawn.

JOURNAL OF MATHEMATICAL PHYSICS VOLUME 42, NUMBER 8 AUGUST 2001

Time-dependent automorphism inducing diffeomorphisms in vacuum Bianchi cosmologies and the complete closed form solutions for types II and V

T. Christodoulakis,[a] G. Kofinas,[b] E. Korfiatis, G. O. Papadopoulos,[c] and A. Paschos
University of Athens, Physics Department Nuclear and Particle Physics Section, GR-15771 Athens, Greece

(Received 30 August 2000; accepted for publication 22 May 2001)

We investigate the set of space–time general coordinate transformations (GCTs) which leave the line element of a generic Bianchi-type geometry quasiform invariant; i.e., preserve manifest spatial homogeneity. We find that these GCTs, induce special time-dependent automorphic changes, on the spatial scale factor matrix $\gamma_{\alpha\beta}(t)$—along with corresponding changes on the lapse function $N(t)$ and the shift vector $N^{\alpha}(t)$. These changes, which are Bianchi-type dependent, form a group and are, in general, different from those induced by the group SAut(G) advocated in earlier investigations as the relevant symmetry group; they are used to simplify the form of the line element—and thus simplify Einstein's equations as well, without losing generality. As far as this simplification procedure is concerned, the transformations found are proved to be essentially unique. For the case of Bianchi types II and V, where the most general solutions are known, Taub's and Joseph's, respectively, it is explicitly verified that our transformations and only those, suffice to reduce the generic line element to the previously known forms. It thus becomes possible—for these types—to give in closed form the most general solution, containing all the necessary ''gauge'' freedom. © *2001 American Institute of Physics.*
[DOI: 10.1063/1.1386637]

I. INTRODUCTION

It is well known that spatial homogeneity reduces Einstein's field equations for pure gravity to a system of ten coupled ordinary differential equations (ODEs) with respect to time:[1] one equation quadratic in the velocities $\dot{\gamma}_{\alpha\beta}$ and algebraic in N^2 $(G_{00}=0)$, three linear in velocities and also algebraic in N^{α} $(G_{0i}=0)$, and the six spatial equations $(G_{ij}=0)$ which are linear in $\ddot{\gamma}_{\alpha\beta}$ and also involve $N,\dot{N},N^{\alpha},\dot{N}^{\alpha},\gamma_{\alpha\beta},\dot{\gamma}_{\alpha\beta}$.

In attempting to find solutions to this set of equations, it is natural—although seldom adopted in the literature—to solve the quadratic constraint for N^2 and the linear constraint equations for as many of the N^{α}'s as possible; then substitute into the remaining spatial equations. When this is done, the spatial equations can be solved for only $6-4=2$ independent accelerations $\ddot{\gamma}_{\alpha\beta}$. Only for Bianchi types II and III—a particular VI case—can we solve for $6-3=3$ accelerations, since only two of the three linear constraints are independent; but then in both of these cases, a linear combination of the N^{a}'s remains arbitrary and counterbalances the existence of the third independent acceleration. Thus, the general solution to the above-mentioned system of equations will, in every Bianchi type, involve four arbitrary functions of time, whose specification should, somehow, correspond to a choice of time and space coordinates—in complete analogy to the full pure

[a]Electronic mail: tchris@cc.uoa.gr
[b]Electronic mail: gkofin@phys.uoa.gr
[c]Electronic mail: gpapado@cc.uoa.gr

gravity, whereby four arbitrary functions of the space–time coordinates are expected to enter the general solution.

In the literature a different approach is more frequently met. It involves an *a priori* gauge choice of coordinate system: As far as time is concerned, one may set N to be either an explicit function of time, say 1 or t^2 etc., or some combination of $\gamma_{\alpha\beta}$'s—see (2.8). For the spatial coordinates, the depicted situation is more vague. In some works, N^α's are set to zero, in others, some N^α's are retained. In any case, most of these choices are considered as being more or less inequivalent and their connection to the well-known existence of Gauss-normal coordinates ($g_{00}=-1$, $g_{0i}=0$),[2] is not at all clear. When such a gauge choice has been made, the spatial equations can be solved for all six independent $\ddot{\gamma}_{\alpha\beta}(t)$. The constraint equations then become algebraic equations, restricting the initial data—needed to specify a particular solution of the spatial equations.

In both approaches, the ensuing equations are still too difficult to handle; thus further simplifying hypotheses are employed, such as $N^\alpha(t)=0$, leading to $\gamma_{\alpha\beta}=\mathrm{diag}((a^2(t),\, b^2(t),c^2(t)))$ for class A types, etc. For Bianchi types I and IX, the hypothesis $N^\alpha(t)=0$ and $\gamma_{\alpha\beta}=\mathrm{diag}((a^2(t),b^2(t),c^2(t)))$ is known to be linked to kinematics and/or dynamics—although in a, somewhat, vague way, see, e.g. Ref. 3 and Ryan in Ref. 1. In all other cases, this or any other simplifying hypothesis used is interpreted only as an ansatz to be tested at the end, i.e., after having solved all the (further simplified) equations. For example, to take an extreme case, diagonality of $\gamma_{\alpha\beta}(t)$ together with the vanishing of the shift vector is known to lead to incompatibility for Bianchi types IV, VII (class B),[4,5] as well as for the biaxial type VIII cases $(a^2,a^2,c^2),(a^2,b^2,a^2)$.[5] The diversity of the various ansatzen appearing in the literature causes a considerable degree of fragmentation.

It has long been suspected and/or known that automorphisms ought to play an important role in a unified treatment of this problem. The first mention goes back to Heekman and Schücking in Ref. 6. More recently, Jantzen (1979)[6] has used time-dependent automorphism matrices as a convenient parametrization of a general positive definite 3×3 scale factor matrix, $\gamma_{\alpha\beta}(t)$, in terms of a—desired—diagonal matrix. His approach is based on the orthonormal frame bundle formalism, and the main conclusion is (third of Jantzen (1982), p. 1138]:[6] "... *the special automorphism matrix group SAut(G), is the symmetry group of the ordinary differential equations, satisfied by the metric matrix* $\gamma_{\alpha\beta}$, *when no sources are present* ...." Later on, Samuel and Ashtekar[7] saw automorphisms, as a result of general coordinate transformations. Their space–time point of view has led them to consider the so-called "homogeneity preserving diffeomorphisms," and link them to topological considerations.

In this paper, we also take a spacetime point of view, and try to avoid the fragmentation by revealing those general coordinate transformations (GCTs) which enable us to simplify the line element (and therefore Einstein's equations), while at the same time preserving manifest spatial homogeneity. We are, thus, able to identify special automorphic transformations of $\gamma_{\alpha\beta}(t)$, along with corresponding—nontensorial, for the shift vector—changes of N,N^α which allow us to set $N^\alpha=0$ and bring $\gamma_{\alpha\beta}(t)$ to some irreducible, simple—though not unique—form.

The structure of the paper is as follows: In Sec. II, after establishing the existence of time-dependent automorphism inducing diffeomorphisms (AIDs), the general irreducible form of the line element for all Bianchi types is given, and a uniqueness theorem is proven. In Sec. III, attention is focused on Bianchi types II and V. Einstein's equations obtaining from the irreducible form of the line element are explicitly written down and completely integrated. The uniqueness of the transformations given in Sec. II is explicitly verified, with the aid of the well-known Taub's and Joseph's solution, respectively. As a result, we give the closed form of the most general line elements, satisfying Eq. (2.5). Finally, some concluding remarks are included in the discussion.

II. TIME-DEPENDENT AUTOMORPHISM INDUCING DIFFEOMORPHISMS

It is well known that the vacuum Einstein field equations can be derived from an action principle:

$$\mathcal{A}=\frac{-1}{16\pi}\int \sqrt{-{}^{(4)}g}{}^{(4)}R\ \mathrm{d}^4x \tag{2.1}$$

(we use geometrized units, i.e., $G=c=1$).

The standard canonical formalism[8] makes use of the lapse and shift functions appearing in the four-metric:

$$\mathrm{d}s^2=(N^iN_i-N^2)\mathrm{d}t^2+2N_i\ \mathrm{d}x^i\ \mathrm{d}t+g_{ij}\ \mathrm{d}x^i\ \mathrm{d}x^j. \tag{2.2}$$

From this line element the following set of equations obtains, expressed in terms of the extrinsic curvature:

$$K_{ij}=\frac{1}{2N}\left(N_{i|j}+N_{i|j}-\frac{\partial g_{ij}}{\partial t}\right),$$

$$H_0=\sqrt{g}(K_{ij}K^{ij}-K^2+R)=0, \tag{2.3a}$$

$$H_i=2\sqrt{g}(K^j_{i|j}-K_{|i})=0, \tag{2.3b}$$

$$\begin{aligned}\frac{1}{\sqrt{g}}\frac{\mathrm{d}}{\mathrm{d}t}[\sqrt{g}(K^{ij}-Kg^{ij})]=&-N\left(R^{ij}-\frac{1}{2}Rg^{ij}\right)-\frac{N}{2}(K_{kl}K^{kl}-K^2)g^{ij}\\&+2N(K^{ik}K^j_k-KK^{ij})-(N^{|ij}-N^{|l}_{|l}g^{ij})\\&+[(K^{ij}-Kg^{ij})N^l]_{|l}-N^i_{|l}(K^{lj}-Kg^{lj})-N^j_{|l}(K^{li}-Kg^{li}).\end{aligned} \tag{2.3c}$$

This set is equivalent to the ten Einstein's equations.

In cosmology, we are interested in the class of spatially homogeneous space–times, characterized by the existence of an m-dimensional isometry group of motions G, acting transitively on each surface of simultaneity Σ_t. When m is greater than three and there is no proper invariant subgroup of dimension three, the space–time is of the Kantowski–Sachs type[9] and will not concern us further. When m equals the dimension of Σ_t—which is 3—there exist three basis one-forms σ^α_i satisfying

$$\mathrm{d}\sigma^\alpha=C^\alpha_{\beta\gamma}\sigma^\beta\wedge\sigma^\gamma\Leftrightarrow\sigma^\alpha_{i,j}-\sigma^\alpha_{j,i}=2C^\alpha_{\beta\gamma}\sigma^\gamma_i\sigma^\beta_j, \tag{2.4a}$$

where $C^\alpha_{\beta\gamma}$ are the structure constants of the corresponding isometry group.

In this case there are local coordinates $t,\ x^i$ such that the line element in (2.2) assumes the form:

$$\mathrm{d}s^2=(N^\alpha(t)N_\alpha(t)-N^2(t))\mathrm{d}t^2+2N_\alpha(t)\sigma^\alpha_i(x)\ \mathrm{d}x^i\ \mathrm{d}t+\gamma_{\alpha\beta}\sigma^\alpha_i(x)\sigma^\beta_j(x)\ \mathrm{d}x^i\ \mathrm{d}x^j. \tag{2.4b}$$

Italic indices are spatial with range from 1 to 3. Greek indices number the different basis one-forms, take values in the same range, and are lowered and raised by $\gamma_{\alpha\beta}$, and $\gamma^{\alpha\beta}$, respectively.

A commitment concerting the topology of the three-surface is pertinent here, especially in view of the fact that we wish to consider diffeomorphisms;[7] we thus assume that G is simply connected and the three-surface Σ_t can be identified with G by singling out a point p of Σ_t, as the identity e, of G.

If we insert relations (2.4) into Eq. (2.3), we get the following set of ordinary differential equations for the Bianchi-type spatially homogeneous space–times:

$$E_0\doteq K^\alpha_\beta K^\beta_\alpha-K^2+R=0, \tag{2.5a}$$

$$E_\alpha \doteq K^\mu_\alpha C^\epsilon_{\mu\epsilon} - K^\mu_\epsilon C^\epsilon_{\alpha\mu} = 0, \tag{2.5b}$$

$$E^\alpha_\beta \doteq \dot{K}^\alpha_\beta - NKK^\alpha_\beta + NR^\alpha_\beta + 2N^\rho (K^\alpha_\nu C^\nu_{\beta\rho} - K^\nu_\beta C^\alpha_{\nu\rho}), \tag{2.5c}$$

where $K^\alpha_\beta = \gamma^{\alpha\rho} K_{\rho\beta}$ and

$$K_{\alpha\beta} = -\frac{1}{2N}(\dot{\gamma}_{\alpha\beta} + 2\gamma_{\alpha\nu} C^\nu_{\beta\rho} N^\rho + 2\gamma_{\beta\nu} C^\nu_{\alpha\rho} N^\rho), \tag{2.6}$$

$$\begin{aligned} R_{\alpha\beta} = {} & C^\kappa_{\sigma\tau} C^\lambda_{\mu\nu} \gamma_{\alpha\kappa} \gamma_{\beta\lambda} \gamma^{\sigma\nu} \gamma^{\tau\mu} + 2C^\lambda_{\alpha\kappa} C^\kappa_{\beta\lambda} + 2C^\mu_{\alpha\kappa} C^\nu_{\beta\lambda} \gamma_{\mu\nu} \gamma^{\kappa\lambda} \\ & + 2C^\lambda_{\beta\kappa} C^\mu_{\mu\nu} \gamma_{\alpha\lambda} \gamma^{\kappa\nu} + 2C^\lambda_{\alpha\kappa} C^\mu_{\mu\nu} \gamma_{\beta\lambda} \gamma^{\kappa\nu}. \end{aligned} \tag{2.7}$$

When $N^\alpha = 0$, Eq. (2.5c) reduces to the form of the equation given in Ref. 10. Equation set (2.5) forms what is known as a (complete) perfect ideal; that is, there are no integrability conditions obtained from this system. So, with the help of (2.5c), (2.6), and (2.7), it can explicitly be shown that the time derivatives of (2.5a) and (2.5b) vanish identically. The calculation is staightforward—although somewhat lengthy. It makes use of the Jacobi identity $C^\alpha_{\rho\beta} C^\rho_{\gamma\delta} + C^\alpha_{\rho\delta} C^\rho_{\beta\gamma} + C^\alpha_{\rho\gamma} C^\rho_{\delta\beta} = 0$, and its contracted form $C^\alpha_{\alpha\beta} C^\beta_{\gamma\delta} = 0$.

The vanishing of the derivatives of the four constrained equations: $E_0 = 0, E_\alpha = 0$, implies that these equations are first integrals of Eq. (2.5c)—moreover, with vanishing integration constants. Indeed, algebraically solving (2.5a) and (2.5b) for $N(t), N^\alpha(t)$, respectively and substituting in (2.5c), one finds that in all—but types II and III—Bianchi types, Eq. (2.5c) can be solved for only two of the six accelerations $\ddot{\gamma}_{\alpha\beta}$ present. In types II and III, the independent accelerations are three, since E_α are not independent and, thus, can be solved for only two of the three N^α's. But then in both of these cases, a linear combination of the N^a's remains arbitrary, and counterbalances the extra independent acceleration. Thus, in all Bianchi types, four arbitrary functions of time enter the general solution to the set of equations (2.5). Based on the intuition gained from the full theory, one could expect this fact to be a reflection of the only known covariance of the theory, i.e., of the freedom to make arbitrary changes of the time and space coordinates.

The rest of this section is devoted to the investigation of the existence, uniqueness, and properties of general coordinate transformations—containing four arbitrary functions of time, which on the one hand, must preserve the manifest spatial homogeneity of the line element (2.4b), and on the other hand, must be symmetries of Eq. (2.5). As far as time reparametrization is concerned the situation is pretty clear: If a transformation

$$t \to \tilde{t} = g(t) \Leftrightarrow t = f(\tilde{t}) \tag{2.8a}$$

is inserted in the line element (2.4b), it is easily inferred that[ ]

$$\gamma_{\alpha\beta}(t) \to \gamma_{\alpha\beta}(f(\tilde{t})) \equiv \tilde{\gamma}_{\alpha\beta}(\tilde{t}), \tag{2.8b}$$

$$\begin{aligned} N(t) &\to \pm N(f(\tilde{t})) \frac{\mathrm{d}f(\tilde{t})}{\mathrm{d}\tilde{t}} \equiv \tilde{N}(\tilde{t}), \\ N^\alpha(t) &\to N^\alpha(f(\tilde{t})) \frac{\mathrm{d}f(\tilde{t})}{\mathrm{d}\tilde{t}} \equiv \tilde{N}^\alpha(\tilde{t}). \end{aligned} \tag{2.8c}$$

Accordingly, K^α_β transforms under (2.8a) as a scalar and thus (2.5a), (2.5b) are also scalar equations while (2.5c) gets multiplied by a factor $\mathrm{d}f(\tilde{t})/\mathrm{d}\tilde{t}$. Thus, given a particular solution to Eq. (2.5), one can always obtain an equivalent solution by arbitrarily redefining time. Hence, we understand the existence of one arbitrary function of time in the general solution to Einstein's

equations (2.5). In order to understand the presence of the rest three arbitrary functions of time it is natural to turn our attention to the tranformations of the three spatial coordinates x^i. To begin with, consider the transformation:

$$\begin{aligned} &\tilde{t}=t\Leftrightarrow t=\tilde{t},\\ &\tilde{x}^i=g^i(x^j,t)\Leftrightarrow x^i=f^i(\tilde{x}^j,\tilde{t}). \end{aligned} \tag{2.9}$$

It is here understood that our previous assumption concerning the topology of G and the identification of Σ_t with G is valid for all values of the parameter t, for which the transformation is to be well defined.

Under these transformations, the line element (2.4b) becomes

$$\begin{aligned} ds^2=&\left[(N^\alpha N_\alpha-N^2)+\frac{\partial f^i}{\partial\tilde{t}}\frac{\partial f^j}{\partial\tilde{t}}\sigma_i^\alpha(f)\sigma_j^\beta(f)\gamma_{\alpha\beta}(\tilde{t})+2\sigma_i^\alpha(f)\frac{\partial f^i}{\partial\tilde{t}}N_\alpha(\tilde{t})\right]d\tilde{t}^2\\ &+2\sigma_i^\alpha(x)\frac{\partial x^i}{\partial\tilde{x}^m}\left[N_\alpha(\tilde{t})+\sigma_j^\beta(x)\frac{\partial x^j}{\partial\tilde{t}}\gamma_{\alpha\beta}(\tilde{t})\right]d\tilde{x}^m\ d\tilde{t}\\ &+\sigma_i^\alpha(x)\sigma_j^\beta(x)\gamma_{\alpha\beta}(\tilde{t})\frac{\partial x^i}{\partial\tilde{x}^m}\frac{\partial x^j}{\partial\tilde{x}^n}d\tilde{x}^m\ d\tilde{x}^n. \end{aligned} \tag{2.10}$$

Since our aim is to retain manifest spatial homogeneity of the line element (2.4b), we have to refer the form of the line element given in (2.10) to the old basis $\sigma_i^\alpha(\tilde{x})$ at the new spatial point $\tilde{x}^i$. Since σ_i^α (both at x^i and $\tilde{x}^i$) as well as $\partial x^i/\partial\tilde{x}^j$ are invertible matrices, there always exists a nonsingular matrix $\Lambda_\mu^\alpha(\tilde{x},\tilde{t})$ and a triplet $P^\alpha(\tilde{x},\tilde{t})$, such that

$$\begin{aligned} &\sigma_i^\alpha(x)\frac{\partial x^i}{\partial\tilde{x}^m}=\Lambda_\mu^\alpha(\tilde{x},\tilde{t})\sigma_m^\mu(\tilde{x}),\\ &\sigma_i^\alpha(x)\frac{\partial x^i}{\partial\tilde{t}}=P^\alpha(\tilde{x},\tilde{t}). \end{aligned} \tag{2.11}$$

The above-given relations must be regarded as definitions for the matrix Λ_μ^α and the triplet P^α. With these identifications the line element (2.10) assumes the following form:

$$\begin{aligned} ds^2=&[(N^\alpha N_\alpha-N^2)+P^\alpha(\tilde{x},\tilde{t})P^\beta(\tilde{x},\tilde{t})\gamma_{\alpha\beta}(\tilde{t})+2P^\alpha(\tilde{x},\tilde{t})N_\alpha(\tilde{t})]d\tilde{t}^2+2\Lambda_\mu^\alpha(\tilde{x},\tilde{t})\sigma_m^\mu(\tilde{x})[N_\alpha(\tilde{t})\\ &+P^\beta(\tilde{x},\tilde{t})\gamma_{\alpha\beta}(\tilde{t})]d\tilde{x}^m\ d\tilde{t}+\Lambda_\mu^\alpha(\tilde{x},\tilde{t})\Lambda_\nu^\beta(\tilde{x},\tilde{t})\gamma_{\alpha\beta}(\tilde{t})\sigma_m^\mu(\tilde{x})\sigma_n^\nu(\tilde{x})d\tilde{x}^m\ d\tilde{x}^n. \end{aligned} \tag{2.12}$$

If, following the spirit of Ref. 7, we wish the transformation (2.9) to be manifest homogeneity preserving, i.e., to have a well-defined, nontrivial action on $\gamma_{\alpha\beta}(t)$, $N(t)$, and $N^\alpha(t)$, we must impose the condition that $\Lambda_\mu^\alpha(\tilde{x},\tilde{t})$ and $P^\alpha(\tilde{x},\tilde{t})$ do not depend on the spatial point $\tilde{x}$, i.e., $\Lambda_\mu^\alpha=\Lambda_\mu^\alpha(\tilde{t})$ and $P^\alpha=P^\alpha(\tilde{t})$. Then (2.12) is written as

$$\begin{aligned} ds^2=&[(N^\alpha N_\alpha-N^2)+P^\alpha P^\beta\gamma_{\alpha\beta}+2P^\alpha N_\alpha]d\tilde{t}^2+2\Lambda_\mu^\alpha\sigma_m^\mu(\tilde{x})[N_\alpha+P^\beta\gamma_{\alpha\beta}]d\tilde{x}^m\ d\tilde{t}\\ &+\Lambda_\mu^\alpha\Lambda_\nu^\beta\gamma_{\alpha\beta}\sigma_m^\mu(\tilde{x})\sigma_n^\nu(\tilde{x})d\tilde{x}^m\ d\tilde{x}^n\\ \Rightarrow ds^2\equiv&(\tilde{N}^\alpha\tilde{N}_\alpha-\tilde{N}^2)d\tilde{t}^2+2\tilde{N}_\alpha(\tilde{t})\sigma_i^\alpha(\tilde{x})d\tilde{x}^i\ d\tilde{t}+\tilde{\gamma}_{\alpha\beta}(\tilde{t})\sigma_i^\alpha(\tilde{x})\sigma_j^\beta(\tilde{x})d\tilde{x}^i\ d\tilde{x}^j \end{aligned} \tag{2.13}$$

with the allocations

$$\tilde{\gamma}_{\alpha\beta}=\Lambda^{\mu}_{\alpha}\Lambda^{\nu}_{\beta}\gamma_{\mu\nu}, \tag{2.14a}$$

$$\tilde{N}_{\alpha}=\Lambda^{\beta}_{\alpha}(N_{\beta}+P^{\rho}\gamma_{\rho\beta}) \quad \text{and thus} \quad \tilde{N}^{\alpha}=S^{\alpha}_{\beta}(N^{\beta}+P^{\beta}), \tag{2.14b}$$

$$\tilde{N}=N \tag{2.14c}$$

(where $S=\Lambda^{-1}$).

Of course, the demand that Λ^{α}_{β} and P^{α} must not depend on the spatial point $\tilde{x}^{i}$, changes the character of (2.11) from identities to the following set of differential restrictions on the functions defining the transformation:

$$\frac{\partial f^{i}}{\partial\tilde{x}^{m}}=\sigma^{i}_{\alpha}(f)\Lambda^{\alpha}_{\beta}(\tilde{t})\sigma^{\beta}_{m}(\tilde{x}), \tag{2.15a}$$

$$\frac{\partial f^{i}}{\partial\tilde{t}}=\sigma^{i}_{\alpha}(f)P^{\alpha}(\tilde{t}). \tag{2.15b}$$

Equation (2.15) constitutes a set of first-order highly nonlinear PDEs for the unknown functions f^{i}. The existence of local solutions to these equations is guaranteed by Frobenius theorem[11] as long as the necessary and sufficient conditions

$$\frac{\partial}{\partial\tilde{x}^{j}}\left(\frac{\partial f^{i}}{\partial\tilde{x}^{m}}\right)-\frac{\partial}{\partial\tilde{x}^{m}}\left(\frac{\partial f^{i}}{\partial\tilde{x}^{j}}\right)=0,$$

$$\frac{\partial}{\partial\tilde{t}}\left(\frac{\partial f^{i}}{\partial\tilde{x}^{m}}\right)-\frac{\partial}{\partial\tilde{x}^{m}}\left(\frac{\partial f^{i}}{\partial\tilde{t}}\right)=0$$

hold. Through (2.15) and repeated use of (2.4a), these equations reduce, respectively, to

$$\Lambda^{\alpha}_{\mu}C^{\mu}_{\beta\gamma}=\Lambda^{\rho}_{\beta}\Lambda^{\sigma}_{\gamma}C^{\alpha}_{\rho\sigma}, \tag{2.16}$$

$$P^{\mu}C^{\alpha}_{\mu\nu}\Lambda^{\nu}_{\beta}=\tfrac{1}{2}\dot{\Lambda}^{\alpha}_{\beta}. \tag{2.17}$$

It is noteworthy that the solutions to (2.16) and (2.17)—by virtue of (2.14)—form a group, with composition law:

$$(\Lambda_3)^{\alpha}_{\beta}=(\Lambda_1)^{\alpha}_{\varrho}(\Lambda_2)^{\varrho}_{\beta},$$

$$(P_3)^{a}=(\Lambda_1)^{\alpha}_{\beta}(P_2)^{\beta}+(P_1)^{a},$$

where (Λ_1,P_1) and (Λ_2,P_2) are two successive transformations of the form (2.14). Note also that a constant automorphism is always a solution of (2.16), (2.17); indeed, $\Lambda^{a}_{\beta}(t)=\Lambda^{a}_{\beta}$ and $P^{a}(t)=0$ solve these equations. Thus, Λ^{a}_{β} and $P^{a}=0$ can be regarded as the remaining gauge symmetry, after one has fully used the arbitrary functions of time, appearing in a solution $\Lambda^{a}_{\beta}(t)$ and $P^{a}(t)$. Consequently one can, at first sight, regard all the arbitrary constants encountered when integrating (2.17) as absorbable in the shift, since the transformation law for the shift is then tensorial. This is certainly true as long as there is a nonzero initial shift. However, if one has used the independent functions of time, in order to set the shift zero, then the constants remaining within Λ^{a}_{β} are not absorbable. It is these kinds of constants that we explicitly present in the following when we give the solutions to (2.16) and (2.17) for all Bianchi types. A relevant nice discussion, distinguishing between genuine gauge symmetries (cf. arbitrary functions of time) and rigid sym-

metries (cf. arbitrary constants), is presented in Ref. 12. There a different definition of manifest homogeneity preserving diffeomorphisms—stronger than the one adopted in this work—is used, and results in only the inner automorphisms being allowed to acquire t dependence. In connection to this, it is interesting to observe that (2.16) and (2.17) give essentially the same results: Notice that $2P^{\mu}C^{\alpha}_{\mu\beta}$ is, by definition, the generator of inner automorphisms. Thus there is always a $\lambda^{\alpha}_{\beta}(t)\equiv\exp(2P^{\mu}C^{\alpha}_{\mu\beta})\in \mathrm{IAut(G)}$ satisfying (2.17). If we now parametrize the general solution to (2.16) and (2.17) by $\Lambda^{\alpha}_{\beta}(t)=\lambda^{\alpha}_{\varrho}(t)U^{\varrho}_{\beta}(t)$ and substitute in these relations, we deduce that the matrix U is a constant automorphism. This analysis is verified in the explicit solutions to (2.16) and (2.17) presented latter.

Equation (2.16) is satisfied if and only if $\Lambda^{\alpha}_{\beta}(t)$ is an element of the automorphism group of the Lie algebra determined by the $C^{\alpha}_{\beta\gamma}$. Equation (2.17) further restricts the form of $\Lambda^{\alpha}_{\beta}(t)$ and $P^{\alpha}(t)$, so that manifest spatial homogeneity is preserved despite the mixing of the old time and space coordinates in the new spatial coordinates $\tilde{x}^i$. Thus, it is appropriate to call transformations (2.9), satisfying conditions (2.15), (2.16), and (2.17), *time-dependent automorphism inducing diffeomorphisms*. The importance of automorphisms in Bianchi Cosmologies has been stressed in Ref. 6. The symmetry group of the differential equations, satisfied by $\gamma_{\alpha\beta}(t)$, advocated in these works of Jantzen *et al.*, is the unimodular matrices SAut(G). As we shall later see, we find another symmetry group, whose time-dependent part lies essentially in IAut(G) and thus coincides with SAut(G), only for class A Bianchi types VI, VII, VIII, and IX.

At this point it is natural to ask how this difference occurs. It is our opinion that the key elements on which the difference in the symmetry groups found rests are:

(a) The inhomogeneous transformation law (2.14b) for the shift. Indeed, Jantzen (1979), having adopted an orthonormal frame-bundle point of view, naturally assumes as his ''gauge'' transformation laws (2.14a) and (2.14c) and the tensorial law $\overline{N}^a=S^a_{\beta}N^{\beta}$, for the shift p. 221.

(b) The different definition and/or role reserved for the triplet $P^a(t)$; we define it as a sort of ''velocity'' of the transformation (2.9) in (2.15b) and use it in the inhomogeneous law (2.14b). On the other hand, Jantzen [1979), p. 221] uses the corresponding quantity $\omega^a(t)$ (the so called velocity of the automorphism frame to define a new time derivative $\partial/\partial\overline{t}=\partial/\partial t+\omega^a(t)\sigma^i_a(x)\partial/\partial x^i$.

(c) We concentrate on the symmetries of the ODEs (2.5), i.e., of *Eistein's equations written in the invariant base*, while Jantzen, as far as we understand, focuses on the symmetries of the PDEs (2.3), i.e., *of Einstein's equations, written in an arbitrary frame*.

In Ref. 7, the so-called homogeneity preserving diffeomorphisms are considered in relation to the topology of Σ_t. A time-independent version of (2.15), appears in Ref. 13, where all homogeneous three-geometries are classified in equivalence classes with respect to these ''frozen'' transformations. It is straightforward to check that $E_0, E_{\alpha}, E^{\alpha}_{\beta}$ transform—under (2.14)—as follows:

$$\tilde{E}_0=E_0,\quad \tilde{E}_{\alpha}=\Lambda^{\beta}_{\alpha}E_{\beta},\quad \tilde{E}^{\alpha}_{\beta}=S^{\alpha}_{\mu}\Lambda^{\nu}_{\beta}E^{\mu}_{\nu}. \tag{2.18}$$

This fact establishes the covariance of Eq. (2.5) under the ''gauge'' transformation (2.14), and implies that if $(N,N^{\alpha},\gamma_{\alpha\beta})$ is a solution to Einstein's equations, so will be the set $(\tilde{N},\tilde{N}^{\alpha},\tilde{\gamma}_{\alpha\beta})$—provided that (2.16) and (2.17) hold; in fact, as the preceding exposition proves, they will be the same equations expressed in different space–time coordinate systems. Out of the twelve quantities $\Lambda^{\alpha}_{\beta}(t)$ and $P^{\alpha}(t)$, conditions (2.16) and (2.17) leave us, as we are going to see, in every Bianchi type with three arbitrary functions of time. This fact, along with the time reparametrization covariance, completes our understanding of why four arbitrary functions of time enter the general solution to (2.5). Consequently, transformation (2.14), gives us the possibility to simplify the form of the line element, and thus of Einstein's equations without loss of generality. It is obvious that the simplification obtained is different for different Bianchi types, and even within a particular Bianchi type it is not unique—since one may ''spend'' the freedom of the three arbitrary functions in different ways.

A particularly interesting result is that the shift vector $\tilde{N}^\alpha$ can always be put to zero—perhaps at the expense of a more complicated $\tilde{\gamma}_{\alpha\beta}$. For the sake of completeness, we give in the following a detailed analysis of the space of solutions to (2.16) and (2.17), for each and every Bianchi type [solutions to (2.16), have been presented in Ref. 14].

To this end, recall that in three dimensions, the tensor $C^\alpha_{\beta\gamma}$ admits a unique decomposition in terms of a contravariant symmetric tensor density of weight -1, $m^{\alpha\beta}$ and a covariant vector $\nu_\alpha = \frac{1}{2}C^\rho_{\alpha\rho}$ as follows:[15]

$$C^\alpha_{\beta\gamma} = m^{\alpha\delta}\varepsilon_{\delta\beta\gamma} + \nu_\beta\delta^\alpha_\gamma - \nu_\gamma\delta^\alpha_\beta.$$

The contracted Jacobi identities imply that $m^{\alpha\beta}\nu_\beta = 0$, i.e., ν_α is a null eigenvector of the matrix $m^{\alpha\beta}$. Under a $GL(3,\Re)$ linear mixing of the basis one-forms $\sigma^\alpha \to \tilde{\sigma}^\alpha = S^\alpha_\beta\sigma^\beta$, the structure constant tensor transforms as

$$C^\alpha_{\beta\gamma} \to \tilde{C}^\alpha_{\beta\gamma} = S^\alpha_\mu \Lambda^\nu_\beta \Lambda^\rho_\gamma C^\mu_{\nu\rho}.$$

Accordingly, the $m^{\alpha\beta}$ and ν_α transform as

$$\tilde{m}^{\alpha\beta} = |S|^{-1} S^\alpha_\gamma S^\beta_\delta m^{\gamma\delta},$$

$$\tilde{\nu}_\alpha = \Lambda^\beta_\alpha \nu_\beta.$$

Λ (and thus S) is called a Lie algebra automorphism if $C^\alpha_{\beta\gamma} = \tilde{C}^\alpha_{\beta\gamma}$, i.e., if $\tilde{m}^{\alpha\beta}$ and $\tilde{\nu}_\alpha$ are equal to $m^{\alpha\beta}$ and ν_α, respectively. In this case the automorphism conditions become

$$m^{\alpha\beta} = |S|^{-1} S^\alpha_\gamma S^\beta_\delta m^{\gamma\delta}, \tag{2.19a}$$

$$\nu_\alpha = \Lambda^\beta_\alpha \nu_\beta. \tag{2.19b}$$

The different Bianchi types arise according to the rank and signature of $m^{\alpha\beta}$ and the vanishing or not of ν_α. Using (2.19), one can—straightforwardly—solve the system of Eqs. (2.16) and (2.17). We now present the form of $\Lambda^\alpha_\beta(t)$ and $P^\alpha(t)$ satisfying (2.16) and (2.17) as well as some irreducible form for $\gamma_{\alpha\beta}$ for each Bianchi type:

Type I: $m^{\alpha\beta} = 0, \nu_\alpha = 0$. This type has been exhaustively treated in the literature (Refs. 3 and 7). We only note that since all $C^\alpha_{\beta\gamma}$ are zero, (2.17) implies that $P^\alpha(t)$ is arbitrary and $\Lambda^\alpha_\beta(t)$ is constant. Then, (2.16) implies that Λ^α_β is an element of $GL(3,\Re)$. Thus, without loss of generality, one can set $N^\alpha = 0$ using (2.14b). A first integral of Eq. (2.5c) is then $\gamma^{\alpha\rho}\dot{\gamma}_{\rho\beta} = \vartheta^\alpha_\beta$, where ϑ^α_β is an arbitrary constant matrix. From this point, the standard textbooks[3] deduce (using algebraic arguments) a diagonal form: $\gamma_{\alpha\beta} = \mathrm{diag}(e^{\alpha t}, e^{\beta t}, e^{\gamma t})$ and then using Einstein's equations find the general solution, which depends on one essential parameter, as expected—see Table I.

Indeed, from (2.5c), one has 12 initial constants; 6 $\gamma_{\alpha\beta}$, and 6 $\dot{\gamma}_{\alpha\beta}$ at some t_0—according to Peano's theorem. The quadratic constraint equation (2.5a), reduces them to 10, and then, with the usage of constant automorphisms (which contain 9 Λ^α_β's), the number of the remaining essential constants (or essential parameters), is $10-9=1$.

Type II: $\mathrm{rank}(m)=1$ and $\nu_\alpha = 0$. Then, matrix $m^{\alpha\beta}$, can be cast to the form $m^{\alpha\beta} = \mathrm{diag}(1/2,0,0)$. Equations (2.16) and (2.17) give the following form for $\Lambda^\alpha_\beta(t)$:

$$\Lambda^\alpha_\beta(t) = \begin{pmatrix} \varrho_1\varrho_4 - \varrho_2\varrho_3 & x(t) & y(t) \\ 0 & \varrho_1 & \varrho_2 \\ 0 & \varrho_3 & \varrho_4 \end{pmatrix}, \quad (\varrho_1, \varrho_2, \varrho_3, \varrho_4 \text{ constants}).$$

The triplet $P^\alpha(t)$ assumes the following form:

TABLE I. The number of arbitrary constants appearing in general solution for each Bianchi type—vacuum model—is given (depicted in the first reference of Ref. 19, p. 21).

Bianchi type	No. of essential constants
I	1
II	2
VI_0, VII_0	3
VIII, IX	4
IV	3
V	1
VI_h $(h\neq -1/9)$	3
$VI_{-1/9}$	4
VII_h	3

$$P^{\alpha}(t)=\left(P(t), \frac{\varrho_1\dot{y}-\varrho_2\dot{x}}{\varrho_1\varrho_4-\varrho_2\varrho_3}, \frac{\varrho_3\dot{y}-\varrho_4\dot{x}}{\varrho_1\varrho_4-\varrho_2\varrho_3}\right).$$

The general solution to this type is Taub's solution,[16] which contains two essential parameters—see Table I.

Again, we can understand this number, using Peano's theorem and the arbitrary extra constants, appearing in Λ^{α}_{β}. Using $x(t)$ and $y(t)$, we start with 4 $\gamma_{\alpha\beta}$'s (i.e., we set $\gamma_{12}=\gamma_{13}=0$) and no shift. Thus the initial arbitrary constants are $2\times 4=8$. Out of these, the quadratic constraint equation (2.5a), removes 2, and 4 more are eliminated by the 4 ϱ's, contained in Λ^{α}_{β}. So, the remaining arbitrary constants are: $8-2-4=2$, in accordance with the number of expected essential parameters.

Type V: $\mathrm{rank}(m)=0$ and $\nu_{\alpha}\neq 0$. Then $m^{\alpha\beta}=0$ and we may choose $\nu_{\alpha}=-\frac{1}{2}\delta^3_{\alpha}$. Equations (2.16) and (2.17) give the following form for $\Lambda^{\alpha}_{\beta}(t)$:

$$\Lambda^{\alpha}_{\beta}(t)=\begin{pmatrix} \varrho_1P(t) & \varrho_2P(t) & x(t) \\ \varrho_3P(t) & \varrho_4P(t) & y(t) \\ 0 & 0 & 1 \end{pmatrix}, \quad (\varrho_1,\varrho_2,\varrho_3,\varrho_4 \text{ constants})$$

with $\varrho_1\varrho_4-\varrho_2\varrho_3=1$ and the triplet:

$$P^{\alpha}(t)=\left(x\left(\ln\frac{x}{P}\right)^{\cdot}, y\left(\ln\frac{y}{P}\right)^{\cdot}, \left(\ln\frac{1}{P}\right)^{\cdot}\right).$$

The general solution is also known as Joseph's solution (Ref. 17) with one essential parameter.

This number comes naturally within our method; using $x(t)$ and $y(t)$, one can eliminate γ_{13} and γ_{23}. Then, $P(t)$ can serve to set the subdeterminant of $\gamma_{\alpha\beta}$, equal to $(\gamma_{33})^2$. At this stage, we are left with 3 $\gamma_{\alpha\beta}$'s while the linear constraint equations (2.5b), imply that the shift is zero. Again, the quadratic constraint (2.5a) subtracts 2 arbitrary constants, and the constants contained in Λ^{α}_{β}, 3 more. Then, the result is $6-2-3=1$, essential constant.

Type IV: $\mathrm{rank}(m)=1$ and $\nu_{\alpha}\neq 0$. We may choose $m^{\alpha\beta}=\mathrm{diag}(1/2,0,0)$, $\nu_{\alpha}=-\frac{1}{2}\delta^3_{\alpha}$. Equations (2.16) and (2.17) give the following form for $\Lambda^{\alpha}_{\beta}(t)$:

$$\Lambda^{\alpha}_{\beta}(t)=\begin{pmatrix} P(t) & P(t)\ln[\kappa P(t)] & x(t) \\ 0 & P(t) & y(t) \\ 0 & 0 & 1 \end{pmatrix}, \quad (\kappa \text{ constant})$$

and the triplet

$$P^{\alpha}(t)=\left(x\left(\ln\frac{x}{P}\right)^{\cdot}-\dot{y},y\left(\ln\frac{y}{P}\right)^{\cdot},\left(\ln\frac{1}{P}\right)^{\cdot}\right).$$

In this type—which is a class B type—we can set $\gamma_{13}=\gamma_{23}=0$, using $x(t)$ and $y(t)$. At this stage, 2 of the 3 linear constraint equations imply $N^1=N^2=0$, while the third involves $P(t)$. Thus we can further, either set $N^3=0$—through (2.14b)—and retain a nonzero γ_{12}, or eliminate γ_{12}, at the expense of a nonvanishing N^3. It is well known that $N^3=0$ and $\gamma_{12}=0$ lead to incompatibility.[4]

We thus have the following counting of the essential parameters:

(a) When $\gamma_{12}\neq 0$ and $N^3=0$, we have $8-2$ (from the quadratic constraint) -2 (from the remaining linear equation) -1 (from the constant contained in Λ^{α}_{β}) $=3$.

(b) When $\gamma_{12}=0$ and $N^3\neq 0$, we have $6-2$ (from the quadratic constraint) -1 (from the constant contained in Λ^{α}_{β}) $=3$. Notice that here, the remaining linear constraint equation simply serves to define N^3 and thus does not remove any constant.

Type VI: (Including type III[19,18]) rank$(m)=2$, signature$(m)=$Lorentzian, and $\nu_{\alpha}\neq 0$. One convenient choice is $m^{\alpha\beta}=\mathrm{diag}(1,-1,0)$ and $\nu_{\alpha}=h\delta^{3}_{\alpha}$.

Note: In the standard texts, e.g., Ref. 15, the matrix $m^{a\beta}$ is given in a more complicated form, which carries part of the arbitrariness of the magnitude of the vector ν_{α}. In this work, we imply that $C^{\alpha}_{\beta\gamma}$ are given by their defining relation in terms of $\varepsilon_{\alpha\beta\gamma}$, $m^{\alpha\beta}$, ν_{α}.

For all values of $h\neq 0,\pm 1$, Eqs. (2.16) and (2.17) give the following form for $\Lambda^{\alpha}_{\beta}(t)$:

$$\Lambda^{\alpha}_{\beta}(t)=\begin{pmatrix} e^{-hP(t)}\lambda\ \cosh(P(t)) & e^{-hP(t)}\lambda\ \sinh(P(t)) & x(t)\\ e^{-hP(t)}\lambda\ \sinh(P(t)) & e^{-hP(t)}\lambda\ \cosh(P(t)) & y(t)\\ 0 & 0 & 1\end{pmatrix}$$

(λ constant)

while the triplet

$$P^{\alpha}(t)=\left(-\frac{(h^2-1)x(t)\dot{P}(t)+h\dot{x}(t)+\dot{y}(t)}{2(h^2-1)},-\frac{(h^2-1)y(t)\dot{P}(t)+h\dot{y}(t)+\dot{x}(t)}{2(h^2-1)},-\frac{\dot{P}(t)}{2}\right).$$

For $h=0$, class A, there are two solutions:

$$\Lambda^{\alpha}_{\beta}(t)=\begin{pmatrix} \lambda\ \cosh(P(t)) & \lambda\ \sinh(P(t)) & x(t)\\ \epsilon\lambda\ \sinh(P(t)) & \epsilon\lambda\ \cosh(P(t)) & y(t)\\ 0 & 0 & \epsilon\end{pmatrix}$$

(λ constant),

while the triplet

$$P^{\alpha}(t)=\left(\frac{\epsilon\dot{y}(t)-x(t)\dot{P}(t)}{2},\frac{\epsilon\dot{x}(t)-y(t)\dot{P}(t)}{2},-\frac{\epsilon\dot{P}(t)}{2}\right),$$

where $\epsilon=\pm 1$.

For $h=\pm 1$, class B, the solutions are

$$\Lambda^{\alpha}_{\beta}(t)=\begin{pmatrix} e^{-hP(t)}\lambda\ \cosh(P(t)) & e^{-hP(t)}\lambda\ \sinh(P(t)) & x(t)\\ e^{-hP(t)}\lambda\ \sinh(P(t)) & e^{-hP(t)}\lambda\ \cosh(P(t)) & c-hx(t)\\ 0 & 0 & 1\end{pmatrix}$$

$$(\lambda \text{ constant}),$$

while the triplet

$$P^{\alpha}(t)=\left(\Omega(t),\frac{2h\Omega(t)-c\dot{P}(t)+2hx(t)\dot{P}(t)+\dot{x}(t)}{2},\right.$$

$$\left.h\frac{e^{-hP(t)}\lambda\sinh(P(t))\dot{P}(t)-he^{-hP(t)}\lambda\cosh(P(t))\dot{P}(t)}{2e^{-hP(t)}\lambda\cosh(P(t))-2he^{-hP(t)}\lambda\sinh(P(t))}\right).$$

For each of the previously mentioned cases, we have the following.

(a) When $h=0$ (class A), $\gamma_{\alpha\beta}$ can be made diagonal and then the shift vanishes. Thus the counting of the essential parameters is: $6-2$ (from the quadratic constraint) -1 (from the constant, contained in Λ^{α}_{β}) $=3$.

(b) When $h=\pm 1$ (class B), using $x(t)$ and $P(t)$, we can eliminate γ_{13} and γ_{23}. So: $8-2$ (from the quadratic constraint) -2 (from the constants, contained in Λ^{α}_{β}) $=4$ is the number of the essential constants. Notice that the 3 linear constraint equations, are linearly dependent and thus, when $N^3=0$ through (2.14b), there is no linear constraint equation left, to remove any constants, hence the number 4.

(c) When $h\neq 0,\pm 1$, the counting algorithm is exactly the same, as in the type IV case.

Type VII: rank$(m)=2$, signature$(m)=$Euclidean and $\nu_{\alpha}\neq 0$. We may set $m^{\alpha\beta}=\text{diag}(-1,-1,0)$, $\nu_{\alpha}=h\delta^{3}_{\alpha}$. For all values of h, Eqs. (2.16) and (2.17) give the following form for $\Lambda^{\alpha}_{\beta}(t)$:

$$\Lambda^{\alpha}_{\beta}(t)=\begin{pmatrix}\lambda e^{hP(t)}\cos(P(t)) & \lambda e^{hP(t)}\sin(P(t)) & x(t)\\ -\lambda e^{hP(t)}\sin(P(t)) & \lambda e^{hP(t)}\cos(P(t)) & y(t)\\ 0 & 0 & 1\end{pmatrix}$$

$$(\lambda \text{ constant})$$

and the triplet

$$P^{\alpha}(t)=\left(\frac{x(t)\dot{P}(t)+h^2x(t)\dot{P}(t)-h\dot{x}(t)+\dot{y}(t)}{2(1+h^2)},\frac{y(t)\dot{P}(t)+h^2y(t)\dot{P}(t)-h\dot{y}(t)-\dot{x}(t)}{2(1+h^2)},\frac{\dot{P}(t)}{2}\right).$$

For the case $h=0$, there is another solution, except the one deduced from the previous, by setting $h=0$:

$$\Lambda^{\alpha}_{\beta}(t)=\begin{pmatrix}\lambda\cos(P(t)) & \lambda\sin(P(t)) & x(t)\\ \lambda\sin(P(t)) & -\lambda\cos(P(t)) & y(t)\\ 0 & 0 & -1\end{pmatrix}$$

$$(\lambda \text{ constant})$$

and the triplet

$$P^{\alpha}(t)=\left(\frac{x(t)\dot{P}(t)-\dot{y}(t)}{2},\frac{y(t)\dot{P}(t)+\dot{x}(t)}{2},-\frac{\dot{P}(t)}{2}\right).$$

Again, for each of the previously mentioned cases, we have the following.

(a) When $h=0$ (class A), $\gamma_{\alpha\beta}$ can be made diagonal and Eq. (2.5b) gives $N^a=0$. Thus: $6-2$ (from the quadratic constraint) -1 (from the constant, contained in Λ^{α}_{β}) $=3$ is the number of the essential constants.
(b) When $h\neq 0$, the counting algorithm is exactly the same, as in the type IV case.

For Bianchi Types VIII and IX, condition (2.17) does not impose any restriction on $\Lambda^{\alpha}_{\beta}(t)$*, but rather fixes completely the triplet* $P^a(t)$ *to be*

$$P^a=\frac{1}{4|m|}\varepsilon_{\beta\tau\kappa}m^{\alpha\beta}\Lambda^{\tau}_{\gamma}\dot{\Lambda}^{\kappa}_{\delta}m^{\gamma\delta}.$$

Type VIII: rank$(m)=3$, signature$(m)=$Lorentzian. A standard choice is $m^{\alpha\beta}=\eta^{\alpha\beta}=$diag $(-1,1,1)$. Since $|m^{\alpha\beta}|=-1$, (2.19a) implies that $|\Lambda^{\alpha}_{\beta}|=1$ and, thus, Λ^{α}_{β}'s are the isometries of the Minkowski metric, in three dimensions, i.e., the Lorentz boosts, with one timelike and two spacelike directions, times a rotation of the ''space'' plane. Thus, the automorphisms are characterized by the two components of the velocity vector, plus the rotation angle. The triplet, P^a, is

$$P^a=\tfrac{1}{2}(\Lambda^2_{\mu}\dot{\Lambda}^3_{\nu}\eta^{\mu\nu},-\Lambda^3_{\mu}\dot{\Lambda}^1_{\nu}\eta^{\mu\nu},-\Lambda^1_{\mu}\dot{\Lambda}^2_{\nu}\eta^{\mu\nu}).$$

It can be proven—see Appendix—that a positive definite matrix can be diagonalized by this automorphism group, i.e., we can set $\gamma_{\alpha\beta}=\mathrm{diag}(a^2(t),b^2(t),c^2(t))$. Then, from (2.5b), we will have $N^a=0$.

The number 4, of the expected essential parameters—see Table I—can be understood as follows: The time-dependent Lorentz transformation Λ^{α}_{β} can diagonalize $\gamma_{\alpha\beta}$. Thus, the counting: $6-2$ (from the quadratic constraint) $=4$.

Type IX: rank$(m)=3$, signature$(m)=$Euclidean. The standard choice is $m^{\alpha\beta}=\delta^{\alpha\beta}$. Since $|m^{\alpha\beta}|=1$, (2.19a) implies that $|\Lambda^{\alpha}_{\beta}|=1$ and, thus, Λ^{α}_{β}'s are the isometries of the Euclidean metric, in three dimensions, i.e., the orthogonal matrices, which are characterized by three parameters, e.g., the Euler angles. The triplet, P^a, is

$$P^a=\tfrac{1}{2}(\Lambda^2_{\mu}\dot{\Lambda}^3_{\nu}\delta^{\mu\nu},\Lambda^3_{\mu}\dot{\Lambda}^1_{\nu}\delta^{\mu\nu},\Lambda^1_{\mu}\dot{\Lambda}^2_{\nu}\delta^{\mu\nu}).$$

Since a positive definite symmetric matrix can be diagonalized by an element of—the connected to the identity component of—$O(3)$, we have that $\gamma_{\alpha\beta}(t)=\mathrm{diag}(a^2(t),b^2(t),c^2(t))$.[19] Then, from (2.5b), as is well known $N^{\alpha}=0$.

The counting yields—exactly as in type VIII: $6-2$ (from the quadratic constraint) $=4$, essential constants.

From the above-given analysis of the space of solutions to (2.16) and (2.17), we observe that in each Bianchi type, there are 3 arbitrary functions of time, as expected, for two reasons: First, because we are solving the integrability conditions for the existence of a time-dependent spatial diffeomorphism according to (2.9). Second, because as mentioned in the Sec. I, the system of Einstein's equations (2.5) has a gauge freedom of 4 arbitrary functions of time. But one of them, simply corresponds to time reparametrization, while the remaining 3 are the ones we found in the above-given analysis.

In the various Bianchi types, the 3 arbitrary functions are distributed differently among the components of $\Lambda^{a}_{\beta}(t)$ and $P^a(t)$. This fact, together with the different number of arbitrary constants appearing in Λ^{a}_{β} for each type, results in a different number of essential constants—expected by independent arguments[19] to appear in the general solutions to Einstein's equations (2.5)—see Table I.

We now conclude Sec. II by stating the following (uniqueness) Theorem: *"In a given—albeit arbitrary—Bianchi Type, let* γ_1, γ_2, *(in matrix notation) be solutions to Einstein's equations (2.5), then there is a matrix M of the form:* $M=\Lambda_1^{-1}\Sigma\Lambda_2$ *(where* Λ_1 *and* Λ_2 *are solutions to (2.16) and (2.17) and* Σ*, represents the irrelevant symmetries of the solution in its irreducible form) which connects them as:* $\gamma_2=M^T\gamma_1 M$*."*

Note: N, N^a are understood to be given from the quadratic and linear constraint equations (2.5a) and (2.5b).

The proof rests on the previously established facts:

(a) That the solutions to (2.16) and (2.17) suffice to reduce the generic $\gamma_{\alpha\beta}$ to a form that will contain the expected necessary number of essential constants, so as to be regarded as the most general one—for each and every Bianchi type.

(b) That for every given Bianchi type, the solutions to (2.16) and (2.17), form a group. Indeed, let γ_1, γ_2 be solutions to (2.5). Then there are Λ_1, Λ_2—along with P_1, P_2, respectively, if needed—solutions to (2.16) and (2.17), such that

$$\gamma_1 = \Lambda_1^T \gamma_{\text{irreducible}} \Lambda_1,$$

$$\gamma_2 = \Lambda_2^T \gamma_{\text{irreducible}} \Lambda_2,$$

where $\gamma_{\text{irreducible}}$, stands for the solution in a form exhibiting only the essential constants. From the first of these

$$\gamma_{\text{irreducible}} = (\Lambda_1^{-1})^T \gamma_1 \Lambda_1.$$

Since, by definition, $\gamma_{\text{irreducible}}$ is a symmetric matrix there are always nontrivial matrices Σ such that

$$\gamma_{\text{irreducible}} = \Sigma^T \gamma_{\text{irreducible}} \Sigma.$$

Substituting the last two relations for $\gamma_{\text{irreducible}}$ in the expression giving γ_2, we obtain:

$$\gamma_2 = (\Lambda_1^{-1} \Sigma \Lambda_2)^T \gamma_1 \Lambda_1^{-1} \Sigma \Lambda_2.$$

Q.E.D.

III. THE SPACE OF SOLUTIONS FOR TYPE II AND V CASES

In this section, we adopt the more conventional point of view; that of ''gauge'' fixing, before solving. As far as time is concerned, we adopt the ''gauge'' fixing condition $\tilde{N} = \sqrt{\tilde{\gamma}}$, since this simplifies the form of the equations. For the spatial coordinates, as explained in Sec. II, a choice of reference system amounts to a choice of time-dependent automorphism—along with a choice of $P^\alpha(t)$; thus, we select the form of $\tilde{\gamma}_{\alpha\beta}(t)$ to be such that the linear equation would imply $\tilde{N}^\alpha = 0$. In this ''gauge,'' Einstein's equations (2.5) read:

$$-\tilde{\gamma}^{\alpha\kappa}\tilde{\gamma}^{\beta\lambda}\dot{\tilde{\gamma}}_{\kappa\lambda}\dot{\tilde{\gamma}}_{\alpha\beta} + \left(\frac{\dot{\tilde{\gamma}}}{\tilde{\gamma}}\right)^2 - 4\tilde{\gamma}R = 0, \tag{3.1a}$$

$$C^{\epsilon}_{\alpha\mu}\tilde{\gamma}^{\mu\rho}\dot{\tilde{\gamma}}_{\rho\epsilon} - C^{\epsilon}_{\mu\epsilon}\tilde{\gamma}^{\mu\rho}\dot{\tilde{\gamma}}_{\rho\alpha} = 0, \tag{3.1b}$$

$$\ddot{\tilde{\gamma}}_{\alpha\beta} - \tilde{\gamma}^{\mu\nu}\dot{\tilde{\gamma}}_{\alpha\mu}\dot{\tilde{\gamma}}_{\beta\nu} - 2\tilde{\gamma}R_{\alpha\beta} = 0. \tag{3.1c}$$

Note that taking the trace of Eq. (3.1c), one arrives at

$$\left(\frac{\dot{\tilde{\gamma}}}{\tilde{\gamma}}\right)^{\cdot} - 2\tilde{\gamma}R = 0. \tag{3.2}$$

A somewhat useful result deriving from (3.2) is the following: $\tilde{\gamma} = ae^{\beta t}$ implies $\tilde{R} = 0$, which is incompatible for all but I Bianchi types.

We now present a realization of the method developed in Sec. II for the cases of type II and V Bianchi geometries. At this point, a word of caution is pertinent: It is evident—from the previously mentioned counting of the expected number of essential constants—that the well-known Taub's (type II) and Joseph's (type V) solutions are the most general for the respective cases.[18] Thus, we should not expect to find anything new in this respect. However, the thorough investigation of the complete space of solutions requires knowledge of the correct (gauge) symmetry group for Einstein's equations (2.5). In this respect, we shall directly show that transformations (2.14—as specified by conditions (2.16) and (2.16), applied to types II and V—are essentially the only (gauge) symmetries of these Bianchi geometries.

Note: From now on we drop the tildes from the various quantities for simplicity—except in some cases, where misunderstanding could occur.

A. Bianchi type II

As can be seen, from the results concerning type II, we can consider without loss of generality the time-dependent part $\gamma_{\alpha\beta}(t)$, of the three-metric to have the following form:

$$\gamma_{\alpha\beta}(t)=\begin{pmatrix} a(t) & 0 & 0 \\ 0 & b(t) & f(t) \\ 0 & f(t) & c(t) \end{pmatrix}.$$

It is interesting to observe that the freedom in arbitrary functions of time—contained in $\Lambda^{\alpha}_{\beta}(t)$—does not suffice to diagonalize $\gamma_{\alpha\beta}(t)$, i.e., to set $f(t)=0$, *a priori*. Yet, we know [see (3.16) and (3.17) in the following] that the diagonal Taub's metric is the irreducible form of the most general type II solution. The reconciliation of these two, seemingly conflicting facts, obtains only on mass shell; after we have completely solved (3.1), with $\gamma_{\alpha\beta}(t)$ given previously, $f(t)$ becomes linearly dependent upon $b(t)$ and $c(t)$, and we can, thus, gauge it away—utilizing the remaining freedom in arbitrary constants, contained in $\Lambda^{\alpha}_{\beta}(t)$.

Note: From now on, we drop the *t* symbol—for time dependence—from the various quantities, e.g., *a* stands for $a(t)$.

Inserting the form of $\gamma_{\alpha\beta}$ in Eq. (3.1b), we find that they vanish identically. We next consider the following quantity *q*, which is scalar under a general linear mixing $\sigma^{\alpha}\rightarrow\tilde{\sigma}^{\alpha}=S^{\alpha}_{\beta}\sigma^{\alpha}$ with $S^{\alpha}_{\beta}\in GL(3,\Re)$,

$$q=C^{\kappa}_{\mu\nu}C^{\lambda}_{\tau\sigma}\gamma_{\kappa\lambda}\gamma^{\mu\tau}\gamma^{\nu\sigma}=\frac{a^2}{2\gamma}=\frac{a}{2(bc-f^2)},$$

where γ, as usual, denotes the determinant of the matrix $\gamma_{\alpha\beta}$. Then, (2.7) gives the following nonzero components for the Ricci tensor $R_{\alpha\beta}$, and the Ricci scalar, *R:*

$$\begin{aligned} R_{11}&=-q\gamma_{11}, \\ R_{rs}&=q\gamma_{rs} \quad r,s=2,3, \\ R&=q. \end{aligned} \tag{3.3}$$

The (1,1) component of (3.1c) is an autonomous equation for the scale factor *a:*

$$\left(\frac{\dot{a}}{a}\right)^{\cdot}+a^2=0 \tag{3.4}$$

with a first integral

$$\left(\frac{\dot{a}}{a}\right)^2 + a^2 = \omega = \text{constant} > 0. \tag{3.5}$$

Using (3.2), (3.3), and (3.4), we get the equation for *q:*

$$\left(\frac{\dot{q}}{q}\right)^{\cdot} + 3a^2 = 0. \tag{3.6}$$

To obtain first integrals for (3.1c), let us define the new variables:

$$\begin{aligned} &\overline{\gamma}_{11} = q^{-1/3}\gamma_{11}, \quad \overline{\gamma}_{rs} = q^{1/3}\gamma_{rs}, \\ &\overline{\gamma}^{11} = q^{1/3}\gamma^{11}, \quad \overline{\gamma}^{rs} = q^{-1/3}\gamma_{rs}. \end{aligned} \tag{3.7}$$

Then:

$$\overline{\gamma} = \det(\overline{\gamma}_{\alpha\beta}) = q^{1/3}\gamma = \frac{a^2}{2}q^{-2/3}. \tag{3.8}$$

It is straightforward to see that, with the use of (3.7), and (3.3), (3.4), (3.6), the spatial Einstein's equations (3.1c) translate into the following simple, integrable, Kasner-like, equations, in terms of $\overline{\gamma}_{\alpha\beta}$:

$$(\overline{\gamma}^{\alpha\rho}\dot{\overline{\gamma}}_{\rho\beta})^{\cdot} = 0 \tag{3.9}$$

with first integrals:

$$\overline{\gamma}^{\alpha\rho}\dot{\overline{\gamma}}_{\rho\beta} = \vartheta^{\alpha}_{\beta}, \tag{3.10}$$

where

$$\vartheta^{\alpha}_{\beta} = \begin{pmatrix} \theta^1_1 & 0 & 0 \\ 0 & \theta & \varrho \\ 0 & \sigma & \pi \end{pmatrix}.$$

Taking the trace of (3.10), we obtain—by means of (3.8):

$$2\left(\frac{\dot{a}}{a} - \frac{1}{3}\frac{\dot{q}}{q}\right) = \vartheta^a_a = \theta^1_1 + \vartheta^s_s, \tag{3.11}$$

while the (1,1) component of (3.10), gives

$$\frac{\dot{a}}{a} - \frac{1}{3}\frac{\dot{q}}{q} = \theta^1_1. \tag{3.12}$$

Equations (3.11) and (3.12) imply that $\theta^1_1 = \vartheta^s_s = \theta + \pi$, so finally, the matrix ϑ becomes

$$\vartheta^{\alpha}_{\beta} = \begin{pmatrix} \theta + \pi & 0 & 0 \\ 0 & \theta & \varrho \\ 0 & \sigma & \pi \end{pmatrix}. \tag{3.13}$$

Using the relation $\gamma=a^2/(2q)$ (mentioned earlier), as well as (3.5), (3.6), (3.7), and (3.10), it is straightforward to see that the quadratic constraint equation (3.1a), becomes a relation among constants; that is:

$$\omega=2(\vartheta_s^s)^2+|\vartheta_s^r|. \tag{3.14}$$

Integrating (3.5), we get the scale factor *a:*

$$a(t)\doteq a=\frac{\sqrt{\omega}}{\cosh(\pm\sqrt{\omega}t)}. \tag{3.15}$$

From this relation and (3.12), we conclude that

$$q^{-1/3}a=a_0e^{\vartheta_s^s t},\quad a_0>0. \tag{3.16}$$

Now utilizing, in matrix notation, the relation $\overline{\gamma}\vartheta=\vartheta^T\overline{\gamma}$, which is the consistency requirement for (3.10) and (3.16), we deduce that classical solutions exist, only for matrices ϑ, with real eigenvalues and thus diagonalizable. Since (2.16) and (2.17) admit the solutions Λ_β^α=constant, $P^a=0$, we can invoke a constant mixing of ϑ, with a matrix of the form:

$$\Lambda=\begin{pmatrix}1&0&0\\0&\Lambda_2^2&\Lambda_3^2\\0&\Lambda_2^3&\Lambda_3^3\end{pmatrix}$$

and reduce it to a diagonal form. Then, we are essentially led to the diagonal Taub's solution:

$$\begin{aligned}\overline{\gamma}_{22}&=q^{1/3}b=e^{\theta t},\\ \overline{\gamma}_{33}&=q^{1/3}c=e^{\pi t}.\end{aligned} \tag{3.17}$$

At this point, it is interesting to observe that, if for some reason, we had not invoked this diagonalizing Λ, and instead proceeded with the general ϑ_s^r, we would have arrived at a reducible form of the solutions with a nonvanishing $\overline{\gamma}_{23}$. However, this off-diagonal element can be made to vanish through the action of the previously mentioned Λ.

Thus, we have shown that "gauge" transformations (2.14)—with (2.16) and (2.17), holding—suffice to reduce the most general line element, for the type II Bianchi model, to the known Taub's metric. According to the theorem stated at the end of Sec. II, these transformations are, essentially, unique. We are now going to explicitly verify it for the case at hand.

A convenient way to proceed is to start from Taub's form of the solution and ask ourselves; what is the form of the most general time-dependent automorphism $\Lambda_\beta^\alpha(t)$, which retains the form invariance of Einstein's equations (2.5)—written in the invariant basis. Since we know that Λ_2^1 and Λ_3^1 can be time dependent, we focus on a time-dependent matrix Λ, of the form:

$$\Lambda_\beta^\alpha=\begin{pmatrix}\varrho&0&0\\0&\varrho_1&\varrho_2\\0&\varrho_3&\varrho_4\end{pmatrix}, \tag{3.18}$$

where $\varrho=\varrho_1\varrho_4-\varrho_2\varrho_3$ and all ϱ's are time dependent.

Consider the transformation, induced by this Λ_β^α, on $\gamma_{\alpha\beta}^{\text{Taub}}$—in matrix notation:

$$\hat{\gamma}=\Lambda^T\gamma^{\text{Taub}}\Lambda. \tag{3.19}$$

The linear constraint equations (3.1b) still imply $\hat{N}^a=0$. As far as the time gauge fixing condition $N=\sqrt{\gamma}$ is concerned, we have $\sqrt{\hat{\gamma}}=|\Lambda|\sqrt{\gamma^{\text{Taub}}}$, $|\Lambda|>0$, and thus

$$N^{\text{Taub}}\,\mathrm{d}t^{\text{Taub}}=\hat{N}\,\mathrm{d}\hat{t}\Rightarrow \mathrm{d}\hat{t}\,|\Lambda|\sqrt{\gamma^{\text{Taub}}}=\sqrt{\gamma^{\text{Taub}}}\,\mathrm{d}t^{\text{Taub}}\Rightarrow \mathrm{d}\hat{t}\,\varrho^2=\mathrm{d}t^{\text{Taub}}.$$

Since we wish the transformation to be a symmetry of (2.5), and we have secured that $\hat{N}^a=0$, and selected $\hat{N}=\sqrt{\hat{\gamma}}$, the equation satisfied by $\hat{\gamma}_{\alpha\beta}$, would be exactly (3.1) and (3.2). Only the dot—defining the time derivative, with respect to Taub's time—must be replaced by a prime:

$$'\doteq\frac{\mathrm{d}}{\mathrm{d}\hat{t}}=\varrho^2(t^{\text{Taub}})\frac{\mathrm{d}}{\mathrm{d}t^{\text{Taub}}}=\varrho^2(t^{\text{Taub}})\times\dot{}\,. \tag{3.20}$$

Defining the corresponding scale quantities $\hat{\bar{\gamma}}_{\alpha\beta}$, according to (3.7) and (3.8) we must have the analogs of (3.10):

$$\hat{\bar{\gamma}}^{\alpha\rho}\hat{\bar{\gamma}}'_{\rho\beta}=\vartheta^{\alpha}_{\beta}. \tag{3.21}$$

Equation (3.2) reads:

$$\left(\frac{\hat{\gamma}'}{\hat{\gamma}}\right)'-2\hat{\gamma}\hat{R}=0. \tag{3.22}$$

It also holds that

$$\left(\frac{\dot{\gamma}_{\text{Taub}}}{\gamma_{\text{Taub}}}\right)\dot{}\,-2\gamma_{\text{Taub}}R_{\text{Taub}}=0. \tag{3.23}$$

Translating (3.22) in the t^{Taub} variable, and subtracting (3.23), we get

$$2(\varrho^2)\ddot{}+(\varrho^2)\dot{}\,\frac{\dot{\gamma}_{\text{Taub}}}{\gamma_{\text{Taub}}}=0,$$

which, with the help of $\gamma_{\text{Taub}}=a^2_{\text{Taub}}/2q$, (3.12) and $(\theta^1_1)^{\text{Taub}}=(\vartheta^s_s)^{\text{Taub}}$, becomes

$$2(\varrho^2)\ddot{}+(\varrho^2)\dot{}\left(2(\vartheta^s_s)^{\text{Taub}}-\frac{1}{3}\frac{\dot{q}}{q}\right)=0. \tag{3.24}$$

The (1,1) component of (3.21) is

$$\frac{\hat{\bar{\gamma}}_{11}'}{\hat{\bar{\gamma}}_{11}}=\vartheta^s_s,$$

where

$$\hat{\bar{\gamma}}_{11}=q^{-1/3}\hat{\gamma}_{11}=q^{-1/3}\varrho^2\gamma^{\text{Taub}}_{11}$$

and, thus, that component reads:

$$(\varrho^2)\dot{}+\varrho^2(\vartheta^s_s)^{\text{Taub}}=\vartheta^s_s. \tag{3.25}$$

Inserting the derivative of (3.25) into (3.24), we have

$$(\varrho^2)\cdot\frac{\dot{q}}{q}=0,$$

which in conjunction with (3.6) implies $\varrho^2=$constant. Without loss of generality, we can take $\varrho^2=1$. Henceforth, the time variable $\hat{t}$, may—and will—denote Taub's time. It is thus left for us to investigate the unimodular matrices:

$$\begin{pmatrix} 1 & 0 & 0 \\ 0 & \varrho_1 & \varrho_2 \\ 0 & \varrho_3 & \varrho_4 \end{pmatrix}$$

with $1=\varrho_1\varrho_4-\varrho_2\varrho_3$, and all ϱ's, are time dependent.

It can be proved that a convenient parametrization for this task is

$$\Lambda^{\alpha}_{\beta}=\begin{pmatrix} 1 & 0 & 0 \\ 0 & & \\ 0 & & \Lambda^{r}_{s} \end{pmatrix},$$

where

$$\Lambda^{r}_{s}=R^{r}_{m}L^{m}_{s},$$

$$L^{m}_{s}=\begin{pmatrix} \varphi(t) & \chi(t) \\ 0 & 1/\varphi(t) \end{pmatrix}$$

and R^{r}_{m} are the symmetries of the Taub's metric, i.e., $R^{T}\gamma^{\text{Taub}}R=\gamma^{\text{Taub}}$—in matrix notation—:

$$R=\begin{pmatrix} 1 & 0 & 0 \\ 0 & & \\ 0 & & R^{r}_{m} \end{pmatrix},$$

R^{r}_{m} being

$$R^{r}_{m}=\begin{pmatrix} \cos(\tilde{g}(t)) & \sin(\tilde{g}(t))e^{-(\kappa-\mu)t/2} \\ -\sin(\tilde{g}(t))e^{(\kappa-\mu)t/2} & \cos(\tilde{g}(t)) \end{pmatrix},$$

where $\tilde{g}(t)$ is an unspecified function of time and κ,μ, the eigenvalues of ϑ^{Taub}.

The system (3.21) gives the following equations for $\chi(t)$ and $\varphi(t)$:

$$2\frac{\dot{\varphi}}{\varphi}+\kappa=\theta+\sigma\frac{\chi}{\varphi}, \tag{3.26a}$$

$$\left(\frac{\chi}{\varphi}\right)^{\cdot}=-\sigma\left(\frac{\chi}{\varphi}\right)^{2}+(\pi-\theta)\frac{\chi}{\varphi}+\varrho, \tag{3.26b}$$

$$e^{(\kappa-\mu)t}(\dot{\chi}\varphi-\chi\dot{\varphi})=\frac{\sigma}{\varphi^2}, \tag{3.26c}$$

$$-2\frac{\dot{\varphi}}{\varphi}+\mu=\pi-\sigma\frac{\chi}{\varphi}. \tag{3.26d}$$

Equation (3.25), for the choice $\varrho^2=1$, gives $(\vartheta_s^s)^{\text{Taub}}=\vartheta_s^s$, and hence

$$\pi+\theta=\kappa+\mu. \tag{3.27}$$

It also implies $\hat{\overline{\gamma}}_{11}=\overline{\gamma}_{11}^{\text{Taub}}$, or $a(t)=a^{\text{Taub}}(t)$, as well as $\omega=\omega^{\text{Taub}}$, or, through (3.14),

$$2(\theta+\pi)^2+\pi\theta-\varrho\sigma=2(\kappa+\mu)^2+\kappa\mu \overset{3.27}{\rightarrow} 3.27\kappa\mu=\theta\pi-\varrho\sigma. \tag{3.28}$$

Out of the four differential equations (3.26), only the first three are independent—in view of (3.27). The solution to this system, for $\sigma\neq 0$, is given by

$$\frac{\chi}{\varphi}=k_1-\frac{\lambda^3c^4e^{-\lambda t}}{\sigma(1+\lambda^2c^4e^{-\lambda t})},\quad \lambda=\kappa-\mu \tag{3.29}$$

from Riccati (3.26b), where $k_1=(\pi-\theta+\lambda)/2\sigma$ is the constant special solution and

$$\varphi^2=\frac{\sigma}{\lambda^2c^2}(1+\lambda^2c^4e^{-\lambda t}),\quad \sigma>0. \tag{3.30}$$

Thus, it is easily seen that (3.29) and (3.30) make the matrix L_s^m to be written in the form $L_s^m=\Sigma_n^m\tilde{L}_s^n$, where

$$\Sigma_n^m=\begin{pmatrix}\cos(g(t)) & \sin(g(t))e^{-\lambda t/2}\\ \sin(g(t))e^{\lambda t/2} & -\cos(g(t))\end{pmatrix},$$

$$\tilde{L}_s^n=\begin{pmatrix}\varepsilon_1\dfrac{\sqrt{\sigma}}{\lambda c} & k_1\varepsilon_1\dfrac{\sqrt{\sigma}}{\lambda c}\\ \varepsilon_2c\sqrt{\sigma} & \left(k_1-\dfrac{\lambda}{\sigma}\right)\varepsilon_2c\sqrt{\sigma}\end{pmatrix}$$

with $(\varepsilon_1)^2=(\varepsilon_2)^2=1$, $(\sigma,c)>0$, and

$$\tan(g(t))=\frac{\varepsilon_2c^2\lambda}{\varepsilon_1}e^{-\lambda t/2}.$$

There are the special cases $\sigma=0$, or $\lambda=0$, which are easily seen to fall into the previous case.

Thus, in all cases, there always exist matrices Σ and $\tilde{L}$, such that the transformation matrix Λ_β^α can be written as

$$\Lambda_\beta^\alpha=\begin{pmatrix}1 & 0 & 0\\ 0 & & \\ 0 & R_m^r\Sigma_n^m\tilde{L}_s^n & \end{pmatrix}.$$

This concludes the verification of the Theorem stated at the end of Sec. II, since, indeed, R and Σ have trivial action on $\gamma_{\alpha\beta}^{\text{Taub}}$. It is therefore evident that the most general $\gamma_{\alpha\beta}$, $N(t)$, and $N^a(t)$, satisfying Eq. (2.5), are—in matrix notation:

$$\gamma_{\text{most general}}(t)=\Lambda^{T}(t)\,\gamma^{\text{Taub}}(h(t))\Lambda(t),$$

$$\Lambda=\begin{pmatrix} \varrho_1\varrho_4-\varrho_2\varrho_3 & x(t) & y(t) \\ 0 & \varrho_1 & \varrho_2 \\ 0 & \varrho_3 & \varrho_4 \end{pmatrix},$$

where the ϱ's are constant, and

$$N(t)=\sqrt{|\gamma_{\text{most general}}|}\dot{h}(t),$$

$$N^{\alpha}(t)=S^{\alpha}_{\beta}(t)P^{\beta}(h(t))\dot{h}(t),$$

$$P^{\beta}(h(t))=\left\{P(t),\frac{\varrho_1\dot{y}(t)-\varrho_2\dot{x}(t)}{(\varrho_1\varrho_4-\varrho_2\varrho_3)\dot{h}(t)},\frac{\varrho_3\dot{y}(t)-\varrho_4\dot{x}(t)}{(\varrho_1\varrho_4-\varrho_2\varrho_3)\dot{h}(t)}\right\},$$

$$S=\Lambda^{-1}(t),$$

$$\gamma^{\text{Taub}}(h(t))=\begin{pmatrix} a & 0 & 0 \\ 0 & \dfrac{e^{(2\kappa+\mu)h(t)}}{a} & 0 \\ 0 & 0 & \dfrac{e^{(\kappa+2\mu)h(t)}}{a} \end{pmatrix},$$

$$a=\frac{\sqrt{\omega}}{\cosh(\pm\sqrt{\omega}h(t))},$$

$$\omega=2(\kappa+\mu)^2+\kappa\mu,$$

where the fourth arbitrary function, $h(t)$, accounts for the time reparametrization covariance, i.e., permits us to depart from the time gauge fixing $N=\sqrt{\gamma}$.

B. Bianchi type V

As can be seen from the results of Sec. II concerning type V, we can consider—with the usage of time-dependent AIDs—the time-dependent part $\gamma_{\alpha\beta}(t)$, of the three-metric, to be of the form:

$$\gamma_{\alpha\beta}(t)=\begin{pmatrix} a(t) & b(t) & 0 \\ b(t) & c(t) & 0 \\ 0 & 0 & f(t) \end{pmatrix}$$

with $a(t)c(t)-b^2(t)=f^2(t)$. Again, as happens for type II, the form of the allowed transformation $\Lambda^{\alpha}_{\beta}(t)$ is such that one cannot set $b(t)=0$ *a priori*. Yet, we know—see (3.39) and (3.40) in the following—that the diagonal Joseph's metric is the irreducible form of the most general type V solution. This puzzle finds its resolution only on mass shell; after we have completely solved (3.1) with $\gamma_{\alpha\beta}(t)$ given previously, $b(t)$ becomes linearly dependent upon $a(t)$ and $c(t)$, and we can thus put it to zero—utilizing the remaining freedom in arbitrary constants, contained in $\Lambda^{\alpha}_{\beta}(t)$.

Note: From now on, we drop the t symbol—for time dependence—from the various quantities, e.g., a stands for $a(t)$.

Inserting the form of $\gamma_{\alpha\beta}$ in Eq. (3.1b), we find that they vanish identically. We next define the scalar—under a general linear mixing $\sigma^{\alpha}\to\tilde{\sigma}^{\alpha}=S^{\alpha}_{\beta}\sigma^{\alpha}$, with $S^{\alpha}_{\beta}\in GL(3,\Re)$—quantity *q:*

$$q=C^{\tau}_{\tau\mu}C^{\sigma}_{\sigma\nu}\gamma^{\mu\nu}=\frac{1}{f}.$$

The condition $ac-b^2=f^2$ now reads as: $ac-b^2=1/q^2$, or

$$\gamma=\frac{1}{q^3}. \tag{3.31}$$

Then, (2.7) gives

$$\begin{aligned} R_{\alpha\beta}&=2q\gamma_{\alpha\beta},\\ R&=6q. \end{aligned} \tag{3.32}$$

The (3,3) component of (3.1c) gives an autonomous equation for the scalar quantity *q:*

$$\left(\frac{\dot{q}}{q}\right)^{\cdot}+\frac{4}{q^2}=0 \tag{3.33}$$

with a first integral:

$$\left(\frac{\dot{q}}{q}\right)^2-\frac{4}{q^2}=\omega=\text{constant}. \tag{3.34}$$

Defining the scaled quantities:

$$\begin{aligned} \overline{\gamma}_{\alpha\beta}&=q\gamma_{\alpha\beta},\\ \overline{\gamma}^{\alpha\beta}&=\frac{1}{q}\gamma^{\alpha\beta},\\ |\overline{\gamma}|&=1, \end{aligned} \tag{3.35}$$

and using (3.32) and (3.33), Eq. (3.1c) is translated into the following form:

$$(\overline{\gamma}^{\alpha\rho}\dot{\overline{\gamma}}_{\rho\beta})^{\cdot}=0 \tag{3.36}$$

with first integrals:

$$\overline{\gamma}^{\alpha\rho}\dot{\overline{\gamma}}_{\rho\beta}=\vartheta^{\alpha}_{\beta}, \tag{3.37}$$

where

$$\vartheta^{\alpha}_{\beta}=\begin{pmatrix} \theta & \varrho & 0\\ \sigma & -\theta & 0\\ 0 & 0 & 0 \end{pmatrix}.$$

The form of the matrix, ϑ, has been derived using the form of $\overline{\gamma}_{\alpha\beta}$ and the property that $|\overline{\gamma}|=1$. Using (3.31), (3.34), and (3.37), the quadratic constraint (3.1a) becomes a relation among constants—as was expected—namely:

$$3\omega=\theta^2+\varrho\sigma. \tag{3.38}$$

The property $|\overline{\gamma}|=1$, together with the consistency requirement—in matrix notation—$\overline{\gamma}\vartheta=\vartheta^T\overline{\gamma}$, which follows from (3.37), enables us to conclude that classical solutions, exist only for those values of the parameters, θ, ϱ, σ, for which ϑ is diagonalizable, i.e., when $\theta^2+\varrho\sigma>0$.

Since the matrices Λ^α_β of the form:

$$\Lambda^\alpha_\beta=\begin{pmatrix}\varrho_1 & \varrho_2 & 0\\ \varrho_3 & \varrho_4 & 0\\ 0 & 0 & 1\end{pmatrix}$$

along with $P^a=0$, constitute the remaining gauge freedom, we can invoke such Λ^α_β to diagonalize ϑ^α_β and—at the same time—retain the shift, zero—see (2.14). Now with a diagonal ϑ^α_β, Eq. (3.37) essentially implies that $\overline{\gamma}_{\alpha\beta}$, is diagonal too.

A further integration of (3.34), yields

$$\frac{1}{f(t)}=q(t)=\begin{cases}\dfrac{2}{\sqrt{\omega}}\sinh(\pm\sqrt{\omega}t), & \omega>0\\ \pm 2t, & \omega=0\end{cases}\tag{3.39}$$

and thus we are led to the well-known Joseph's solution—through complete integration of (3.37)—for the diagonal case:

$$\begin{aligned}\overline{\gamma}_{11}&=qa=e^{\lambda t},\\ \overline{\gamma}_{22}&=qc=e^{-\lambda t},\\ 3\omega&=\lambda^2>0\end{aligned}\tag{3.40}$$

or the Milnor's solution,[18] when $\omega=0$—with the corresponding q.

Once again, it is interesting to observe that if, for some reason, we do not invoke this diagonalizing Λ^α_β and, instead, proceed with the general ϑ^α_β, we arrive at a reducible form of the solution, which contains a nonvanishing $\overline{\gamma}_{12}$. However, this off-diagonal element can be made to vanish through the action of the previously mentioned constant automorphism.

Thus, we have shown that the ''gauge'' transformations (2.14)—with (2.16) and (2.17) holding—suffice to reduce the most general line element for the type V Bianchi model to the known Joseph's metric, as predicted from the theorem, stated at the end of Sec. II. As we have done for the type II case, we are now going to explicitly verify that these transformations are essentially unique. To this end, let us consider the most general time-dependent automorphism, complementary to the time-dependent automorphism, described in Sec. II—for the type V case.

$$\Lambda^\alpha_\beta=\begin{pmatrix}A(t) & B(t) & 0\\ C(t) & F(t) & 0\\ 0 & 0 & 1\end{pmatrix}\tag{3.41}$$

with $A(t)F(t)-B(t)C(t)=1$. The action of such automorphism on $\gamma^{\text{Joseph}}_{\alpha\beta}$ is, in matrix notation,

$$\hat{\gamma}=\Lambda^T\gamma^{\text{Joseph}}\Lambda.$$

If we insert $\hat{\gamma}_{\alpha\beta}$ in the linear constraint equations (3.1b), we learn that $\hat{N}^a$ are also zero and, since, $|\hat{\gamma}_{\alpha\beta}|=|\Lambda|^2|\gamma^{\text{Joseph}}_{\alpha\beta}|=|\gamma^{\text{Joseph}}_{\alpha\beta}|$, we conclude that we are in the same temporal, as well as spatial, gauge. Therefore, $\hat{\gamma}_{\alpha\beta}$ will also satisfy Eq. (3.1c). Since Λ^α_β is an automorphism, it is a symmetry of q and, thus, if we define the scaled quantities:

$$\hat{\bar{\gamma}}_{\alpha\beta}=q\hat{\gamma}_{\alpha\beta}$$

they must satisfy the relations analogous to (3.37):

$$\hat{\bar{\gamma}}^{\alpha\rho}\hat{\bar{\gamma}}_{\rho\beta}=\vartheta^{\alpha}_{\beta}, \tag{3.42}$$

where

$$\vartheta^{\alpha}_{\beta}=\begin{pmatrix}\theta & \varrho & 0\\ \sigma & -\theta & 0\\ 0 & 0 & 0\end{pmatrix},$$

while $\bar{\gamma}^{\text{Joseph}}_{\alpha\beta}$ satisfies the following relations:

$$(\bar{\gamma}^{\alpha\rho})_{\text{Joseph}}(\bar{\gamma}_{\rho\beta})_{\text{Joseph}}=(\vartheta^{\alpha}_{\beta})_{\text{Joseph}},$$

where

$$(\vartheta^{\alpha}_{\beta})_{\text{Joseph}}=\begin{pmatrix}\lambda & 0 & 0\\ 0 & -\lambda & 0\\ 0 & 0 & 0\end{pmatrix}.$$

By virtue of (3.34), and since q is invariant, we get that $\omega=\omega^{\text{Joseph}}$, i.e.,

$$\theta^2+\varrho\sigma=\lambda^2. \tag{3.43}$$

In order to proceed with the integration of (3.42), it is convenient to parametrize Λ^{α}_{β} in (3.41) as follows:

$$\Lambda^{\alpha}_{\beta}=\begin{pmatrix}\Lambda^{r}_{s} & & 0\\ & & 0\\ 0 & 0 & 1\end{pmatrix}$$

with $\Lambda^{r}_{s}=R^{r}_{m}L^{m}_{s}$, where R^{r}_{m} is

$$\begin{pmatrix}e^{-\lambda t/2} & 0\\ 0 & e^{\lambda t/2}\end{pmatrix}\cdot\begin{pmatrix}\cos(g(t)) & \sin(g(t))\\ -\sin(g(t)) & \cos(g(t))\end{pmatrix}\cdot\begin{pmatrix}e^{\lambda t/2} & 0\\ 0 & e^{-\lambda t/2}\end{pmatrix},$$

i.e., the symmetries of the Joseph's metric; in matrix notation $R^{T}\gamma^{\text{Joseph}}R=\gamma^{\text{Joseph}}$ and L^{m}_{s} is

$$\begin{pmatrix}\varphi(t) & \tau(t)\\ 0 & 1/\varphi(t)\end{pmatrix}.$$

The system (3.42) gives the following differential equations for $\varphi(t)$ and $\tau(t)$:

$$2\frac{\dot{\varphi}}{\varphi}+\lambda=\theta+\sigma\frac{\tau}{\varphi}, \tag{3.44a}$$

$$\dot{\tau}\varphi-\tau\dot{\varphi}=\varrho\varphi^2-2\theta\varphi\tau-\sigma\tau^2, \tag{3.44b}$$

$$e^{2\lambda t}(\dot{\tau}\varphi-\tau\dot{\varphi})=\frac{\sigma}{\varphi^2}. \tag{3.44c}$$

The solution to this system, for $\sigma\neq 0$, leads to incompatibility of the form $\varphi^2=-e^2$, with e a function of time.

For $\sigma=0$, we get

$$\varphi(t)=c_1\exp\left(\frac{\theta-\lambda}{2}t\right),$$
$$\tau(t)=c_1\frac{\varrho}{2\theta}\exp\left(\frac{\theta-\lambda}{2}t\right) \tag{3.45}$$

with $c_1>0$, and from (3.43), for the case at hand, $\theta=\pm\lambda$. The case $\theta=\lambda$ trivially gives a constant matrix

$$L_s^m=\begin{pmatrix} c_1 & c_1\dfrac{\varrho}{2\lambda} \\ 0 & 1/c_1 \end{pmatrix}$$

while the case $\theta=-\lambda$ gives

$$L_s^m=\begin{pmatrix} 0 & e^{-\lambda t} \\ e^{\lambda t} & 0 \end{pmatrix}\cdot\begin{pmatrix} 0 & 1/c_1 \\ c_1 & -c_1\dfrac{\varrho}{2\lambda} \end{pmatrix}.$$

Since the first matrix in the product is a symmetry of $(\overline{\gamma}_{\alpha\beta})_{\text{Joseph}}$, we again conclude that the nontrivial action of Λ^α_β on $(\overline{\gamma}_{\alpha\beta})_{\text{Joseph}}$, is tantamount to the action of a constant matrix in accordance to the theorem of Sec. II.

Finally, the most general line element $(\gamma_{\alpha\beta},N,N^a)$ satisfying Einstein's equations (2.5) is thus given—in matrix notation—by

$$\gamma_{\text{most general}}(t)=\Lambda^T(t)\,\gamma^{\text{Joseph}}(h(t))\Lambda(t),$$

$$\Lambda=\begin{pmatrix} \varrho_1P(t) & \varrho_2P(t) & x(t) \\ \varrho_3P(t) & \varrho_4P(t) & y(t) \\ 0 & 0 & 1 \end{pmatrix},$$

where the ϱ's are constant, subject to the condition $\varrho_1\varrho_4-\varrho_2\varrho_3=1$ and

$$N(t)=\sqrt{|\gamma_{\text{most general}}|}\dot{h}(t),$$

$$N^\alpha(t)=S^\alpha_\beta P^\beta(h(t)),$$

$$P^\beta(h(t))=\left\{x(t)\left(\ln\frac{x(t)}{P(t)}\right)^{\cdot},y(t)\left(\ln\frac{y(t)}{P(t)}\right)^{\cdot},\left(\ln\frac{1}{P(t)}\right)^{\cdot}\right\},$$

$$S=\Lambda^{-1},$$

$$\gamma^{\text{Joseph}}(h(t))=\begin{pmatrix} \dfrac{e^{\lambda h(t)}}{q} & 0 & 0 \\ 0 & \dfrac{e^{-\lambda h(t)}}{q} & 0 \\ 0 & 0 & f \end{pmatrix},$$

$$\frac{1}{f(h(t))}=q(h(t))=\begin{cases} \dfrac{2}{\sqrt{\omega}}\sinh(\pm\sqrt{\omega}h(t)), & \omega>0 \\ \pm 2h(t), & \omega=0 \end{cases} \tag{3.46}$$

$$3\omega=\lambda^2,$$

where the fourth arbitrary function, $h(t)$, accounts for the time reparametrization covariance.

IV. DISCUSSION

In this work, we present an approach to the problem of solving Einstein's equations for the case of a generic Bianchi-type spatially homogeneous space–time. The approach is not plagued by the fragmentation characterizing the major part of the existing rich literature—which is inherited by the diversity of the various simplifying ansatzen, employed in each case. The key notion for avoiding this fragmentation is that of a time-dependent automorphism inducing diffeomorphism; that is, a general coordinate transformation (2.9), mixing space and time coordinates, whose action on the line element of a Bianchi geometry is described by relations (2.14)—viewed as ''gauge'' transformation laws for the dependent variables $\gamma_{\alpha\beta}(t)$, $N(t)$, and $N^{\alpha}(t)$. The investigation for the existence of such GCTs, leads to the necessary and sufficient conditions (2.16) and (2.17); hence the name time-dependent AIDs. In each and every Bianchi type, these conditions possess a nonempty set of solutions containing precisely three arbitrary functions of time. A choice of these arbitrary functions amounts exactly to a choice for the three spatial coordinates. Thus, the possibility is offered for simplifying Einstein equations—through a simplification of $\gamma_{\alpha\beta}, N^{\alpha}, N$—without running the risk of loss of generality or any sort of incompatibility.

Of course, the possible simplifications differ from one Bianchi type to another; even within the same Bianchi type, there are many possible simplifications—since one, can use the three arbitrary functions at will. This kinematical freedom, when combined with the dynamical information—furnished by the linear constraint equations—considerably simplifies the form of the line-element and thus of Einstein's equations, as well. A useful, in our opinion, irreducible form of the line element for each Bianchi type is given at the balance of Sec. II.

A statement that applies to all types is that, using two of the three arbitrary functions, the scale-factor matrix $\gamma_{\alpha\beta}(t)$ can always—*a priori*; i.e., before solving any classical equations of motion—be put into a so-called ''symmetric''[16] form, i.e., $\gamma_{13}=\gamma_{23}=0$. This applies also for type II, if we take instead of the standard form for the structure constants ($C^1_{23}=-C^1_{32}=1$, all others vanish) the equivalent version $C^3_{12}=-C^3_{21}=1$, all others vanish. If this ''symmetric'' form is then substituted into the linear equations, and the third arbitrariness is used, considerable restrictions among N^{α}'s and the remaining $\gamma_{\alpha\beta}$'s are obtained, as presented in detail at the end of Sec. II. Furthermore, with the help of the essential arbitrary constants in Λ^{α}_{β}, we can diagonalize $\gamma_{\alpha\beta}(t)$, on mass shell. For all Bianchi types, the shift vector N^{α} can always be set to zero—with the help of time-dependent AIDs, and the linear equations. One could, of course, rely on the well-known existence of Gauss-normal coordinates,[2] and argue that this should be true. However, in this work, the explicit realization of this fact is presented; what is more important is that the vanishing of N^{α} is accomplished without spoiling manifest spatial homogeneity. The interplay between line elements with and without shift, established through time-dependent AIDs—see (2.14b)—raises the

need to reexamine the set of existing solutions—with respect to physical equivalence, among each other. In particular, many tilded and untilded fluid solutions,[18] may proven to be GCT related, and thus physically indistinguishable.

Except for the three arbitrary functions of time, of considerable importance are also the (nonabsorbable in the shift) arbitrary constants, appearing in the solutions to (2.16) and (2.17). The number of these constants varies for different Bianchi types. The very interesting fact is that when this number is subtracted from the number of constants, given by Peano's theorem—after the freedom in arbitrary functions of time has been fully exhausted—the resulting number of the (finally) remaining constants equals, for each and every Bianchi type, the number of expected essential constants—see Ref. 19, p. 211. This permits us to conclude that the gauge symmetry transformations (2.14)—with (2.16) and (2.17), holding—are, essentially, unique. It is also noteworthy that the existence of these constant parameters helps to rectify a defect from which the previous approach of Jantzen is suffering; that of an uneven passage, from the lower to the higher Bianchi types, owing to the change of the dimension of the invoked symmetry group;[19] indeed, the arbitrary functions of time are thus varying with dim[SAut(G)], from 8 (type I), to 5 (types II and V), to 3 (higher types). This situation is rather unsatisfactory, since we know that the independent or dynamical degrees of freedom for the gravitational field are 2-per space point. Thus, in cosmology, we expect 2 independent functions of time—irrespective of Bianchi type.

In contrast to this state of affairs, the solutions to (2.16) and (2.17) contain exactly 3 arbitrary functions of time, which together with the arbitrary function—owing to the time reparametrization covariance of Eq. (2.5)—leave us with $6(\gamma_{\alpha\beta})-4=2$ arbitrary functions, in all Bianchi types. The required sensitivity of the method to the particular isometry group is represented by the extra constant parameters—as explained.

It is in this remarkable way that general relativity manages to encode the memory of spatial GCT covariance in the set of the reduced equations (2.5), where only functions of time and their derivatives appear. This encoding also persists in the actions—when these actions exist—and leads to important grouping of $\gamma_{\alpha\beta}$'s into the three solutions: $x^1=C^{\alpha}_{\mu\nu}C^{\beta}_{\rho\sigma}\gamma^{\mu\rho}\gamma^{\nu\sigma}\gamma_{\alpha\beta}$, $x^2=C^{\alpha}_{\beta\delta}C^{\delta}_{\nu\alpha}\gamma^{\beta\nu}$, $x^3=\gamma$ of the quantum linear constraints.[13,20] When a truly scalar Hamiltonian exists,[13,21] the wave function depends only on the q^i's:

$$q^1=\frac{m^{\alpha\beta}\gamma_{\alpha\beta}}{\sqrt{\gamma}},\quad q^2=\frac{(m^{\alpha\beta}\gamma_{\alpha\beta})^2}{2\gamma}-\frac{1}{4}C^{\alpha}_{\mu\nu}C^{\beta}_{\rho\sigma}\gamma^{\mu\rho}\gamma^{\nu\sigma}\gamma_{\alpha\beta},\quad q^3=\frac{m}{\sqrt{\gamma}},$$

which completely and irreducibly determine a spatial three-geometry.

To summarize, the system (2.5), admits solutions containing in each and every Bianchi type exactly four unspecified functions of time. One corresponds to the freedom of changing the time coordinate; three correspond to the freedom of changing the spatial coordinates via time-dependent AIDs. The action of such a transformation on the line element, and on the system of equations (2.5), is described by relations (2.14) and (2.18). Thus, one does not actually need to calculate the simplifying GCTs; one simply uses (2.14), simplifies the equations, solves them completely, and finally inverts the transformation, thereby obtaining the entire space of solutions. It is in this sense that the closed form of the line elements presented in Sec. III, exhaust the space of classical solutions—for the case of Bianchi types II and V.

ACKNOWLEDGMENTS

We would like to thank Professor M. A. H. MacCallum whose severe criticism on an earlier version of our work has helped us to clarify the issue of essential constants—in the context of the present work. He also brought to our attention the existing literature concerning the diagonalization of positive definite symmetric forms via the Lorentz group. The earlier version of this work is part of the 1995 PENED program ''Quantum and Classical Gravity—Black Holes'' (No. 512) supported by the General Secretariat for the Research and Technology of the Hellenic Department

of Industry, Research and Technology. Two of the authors (G.K. and A.P.) were partially supported by the Hellenic Fellowship Foundation (I.K.Y.) All authors, acknowledge financial support by the University of Athens' Special Account for the Research.

APPENDIX

In Ref. 22, the following Theorem is given:

"Let two symmetric forms A and B, be given, on a n-dimensional linear vector space V. If one of them—say A—is non singular, then there is a base in V in which both A and B, are diagonal, if and only if, the mapping $A^{-1}B$, possesses n-real eigenvalues."

Thus, if we take the pair $\gamma_{\alpha\beta}$, $\eta_{\alpha\beta}$, it suffices to prove that $\eta^{\alpha\varrho}\gamma_{\varrho\beta}$, has n-real eigenvalues. In what follows, for the sake of completeness, we give a proof of the entire statement that a positive definite matrix $\gamma_{\alpha\beta}$ can be diagonalized via the Lorentz group.

Theorem: Let γ be a positive definite $n\times n$ real matrix. Then, there exists a Lorentz matrix Λ, such that

$$\Lambda^T\gamma\Lambda=\Delta, \tag{A1}$$

where Δ a diagonal matrix.

Note: Since $\Lambda^T=\eta\Lambda^{-1}\eta$, where η is the Minkowski metric, (A1) may be written as

$$\Lambda^{-1}\eta\gamma\Lambda=\eta\Delta. \tag{A2}$$

In order to prove (A2) it is useful to write it equivalently using the notation employed with linear mappings. To do that, we consider an n-dimensional real linear space V with basis $(e_1,e_2,\ldots,e_n)$. The scalar product in this space is defined as $\langle,\rangle: VV\times V\rightarrow\Re$, with $\langle e_\alpha,e_\beta\rangle=\eta_{\alpha\beta}$. The matrix $\eta\gamma$ defines a mapping $f: V\rightarrow V$ through the relation:

$$f(e_\alpha)=\sum_{\beta=1}^{n}(\eta\gamma)_{\alpha\beta}e_\beta.$$

The following will prove useful later on:

(1) If $M\subseteq V$ then $V=M\oplus M^\perp$.[23]

(2) A mapping $f: V\rightarrow V$ is called self-dual, if $\langle f(x),y\rangle=\langle x,f(y)\rangle$ for every $x,y\in V$. We may prove that the mapping f defined through the matrix $\eta\gamma$ is self-dual. Indeed:

$$\left.\begin{aligned}\langle f(x),y\rangle=\langle y,f(x)\rangle=y^T\eta\eta\gamma x=y^T\gamma x\\ \langle x,f(y)\rangle=x^T\eta\eta\gamma y=x^T\gamma y=y^T\gamma x\end{aligned}\right\}$$

$$\Rightarrow\langle f(x),y\rangle=\langle x,f(x)\rangle.$$

(3) If $M\subseteq V$ is an invariant subspace of V with respect to a self-dual mapping f then $M^\perp$ is also an invariant subspace of V. Indeed, let $b\in M^\perp$ and $m\in M$. Since M is an invariant subspace, it follows that

$$f(m)\in M\Rightarrow\langle f(m),b\rangle=0\Rightarrow\langle m,f(b)\rangle=0\,\forall\, m\in M$$

$$\Rightarrow f(b)\in M^\perp.$$

Equation (A2) states the fact that there exists an orthonormal basis of V consisting of the eigenvalues of f. If (A2) holds then the nonvanishing elements of the real diagonal matrix $\eta\Delta$ will be eigenvalues of $\eta\gamma$. Thus, we have to prove that the eigenvalues of $\eta\gamma$ are real. Indeed, the following theorem holds:

Theorem: If γ is a positive definite symmetric matrix, then $\eta\gamma$ has real eigenvalues.

Proof: Let $\lambda=\alpha+\beta j,\ \beta\neq 0$ be a complex eigenvalue of $\eta\gamma$ and $u\neq 0$ the corresponding complex right eigenvector. Since η is invertible, there exists a $v=x+yj,\ x,y,\in\Re^n$ such that $u=\eta v$. We have

$$\eta\gamma u=\lambda u\Leftrightarrow\eta\gamma\eta v=\lambda\eta v\Leftrightarrow\eta\gamma\eta x=\alpha\eta x-\beta\eta y, \tag{A3}$$

$$\eta\gamma\eta y=\alpha\eta y+\beta\eta x. \tag{A4}$$

Equations (A3) and (A4) imply, respectively,

$$y^T\eta\gamma\eta x=\alpha\langle y,x\rangle-\beta\langle y,y\rangle,$$

$$x^T\eta\gamma\eta y=\alpha\langle x,y\rangle+\beta\langle x,x\rangle.$$

The last two equations have their left-hand sides equal (since $\eta\gamma\eta$ is symmetric), hence

$$\beta(\langle x,x\rangle+\langle y,y\rangle)=0\Rightarrow\langle y,y\rangle=-\langle x,x\rangle. \tag{A5}$$

Since γ is positive definite, $\eta\gamma\eta$ is positive definite as well. Then:

$$x^T\eta\gamma\eta x\geqslant^{(A3)}0\Rightarrow\alpha\langle x,x\rangle-\beta\langle x,y\rangle\geqslant 0, \tag{A6}$$

$$y^T\eta\gamma\eta y\geqslant^{(A4)}0\Rightarrow\alpha\langle y,y\rangle+\beta\langle y,x\rangle\geqslant^{(A5)}0\Rightarrow\alpha\langle x,x\rangle-\beta\langle x,y\rangle\leqslant 0. \tag{A7}$$

From (A6) and (A7) we get

$$\alpha\langle x,x\rangle=\beta\langle x,y\rangle \tag{A8}$$

Through (A5) and (A8), Eqs. (A3) and (A4) imply

$$x^T\eta\gamma\eta x=0,$$

$$y^T\eta\gamma\eta y=0,$$

and since $\eta\gamma\eta$ is positive definite we conclude that $x=0$ and $y=0$, i.e., $u=0$, contradicting our initial assumption $u\neq 0$. Therefore β has to vanish and thus we have proved the reality of λ.

For the eigenvectors of $\eta\gamma$, we can prove that they have a nonzero norm. Indeed, let x be an eigenvector of $\eta\gamma$, i.e.,

$$\eta\gamma x=\lambda x\Rightarrow\gamma x=\lambda\eta x\Rightarrow x^T\gamma x=\lambda x^T\eta x=\lambda\langle x,x\rangle.$$

Since γ is positive definite and $x\neq 0$ we have $x^T\gamma x>0$, so that $\langle x,x\rangle\neq 0$. We are now in position to prove a spectral theorem for a mapping f with real eigenvalues.

Theorem: If $f:V\rightarrow V$ is a self-dual mapping with real eigenvalues, then V has an orthonormal basis consisting of the eigenvectors of f.

Proof: Let λ be an eigenvalue of f, u the corresponding eigenvector, and $M=[u]$ the one-dimensional subspace spanned by u. Obviously, M is an invariant subspace of V with respect to f.

According to (1), we have $V=M\oplus M^{\perp}$. As implied by (2) and (3), $M^{\perp}$ is also an invariant subspace and thus f induces a self-dual mapping onto $M^{\perp}$. Hence, we can apply induction and show that

$$V=M_1\oplus M_2\oplus\ \ldots\ \oplus M_n,$$

where the M_α are one-dimensional invariant subspaces orthogonal to each other. Since u_α is an eigenvector of $\eta\gamma$, it holds that $\langle u,u\rangle\neq 0$, as proved previously. We can thus promote the orthogo-

nal basis to an orthonormal set $(\hat{u}_1,\hat{u}_2,\ldots,\hat{u}_n)$. The transformation connecting this orthonormal basis to the initial orthonormal basis $(e_1,e_2,\ldots,e_n)$ is the matrix Λ sought for in the first theorem, relations (A2) and (A1).

We apply Painlevé analysis to the Ricci-flat Einstein equations for a warped product with an arbitrary number of factors. We find that, as in the situation of the two factors examined [J. Geom. Phys. **38**, 183–206 (2001)], the cases when the total dimension is 10 or 11 are singled out by the analysis. © *2001 American Institute of Physics.* [DOI: 10.1063/1.1380441]

I. INTRODUCTION

In Ref. 1 we applied Painlevé analysis to investigate the integrability of certain cases of the Ricci-flat Einstein equations, including that of a warped product on two Einstein factors. In this paper, we consider the Ricci-flat equations for warped products with an arbitrary number of Einstein factors. More precisely, we study Riemannian metrics of the form

$$dt^2+f_1^2(t)g_1\oplus\cdots\oplus f_r^2(t)g_r, \tag{1.1}$$

where (Y_i,g_i) are Einstein manifolds with nonzero Einstein constant. We denote the dimension of Y_i by d_i and assume that $d_i>1$. We also let $n=\Sigma_{i=1}^r d_i$, so the metric (1.1) lives on a manifold with dimension $n+1$.

In Ref. 2 we introduced a Hamiltonian formulation of the cohomogeneity one Einstein equations based on a Hamiltonian of ADM type (cf. Ref. 3 or Appendix E of Ref. 4) on the cotangent bundle of the space of all invariant metrics of the principal orbit. This Hamiltonian formalism applies equally well in the special case of r-fold warped product metrics, where the principal orbits are replaced by the product $Y_1\times\cdots\times Y_r$ with *no* symmetry assumptions on the Y_i, as long as (Y_i,g_i) are Einstein. Using changes of variables analogous to those employed in Ref. 1, we deduce that the Ricci-flat Einstein equations for the r-fold warped product metrics (1.1) are equivalent to the Hamiltonian flow of

$$\overline{H}=\sum_{i,j=1}^{r} E_{ij}x_ix_jy_iy_j-\sum_{i=1}^{r} A_ix_i$$

subject to the constraint $\overline{H}=0$. Here A_i is the scalar curvature of the Einstein manifold Y_i, and

$$E_{ij}=1, \quad \text{for } i\neq j,$$

$$E_{ii}=1-\frac{1}{d_i}.$$

Introducing new variables $u_i=x_iy_i$, and rescaling the x_i to make $A_i=1$, Hamilton's equations for $\overline{H}$ now become

[a)]Electronic mail: dancer@maths.ox.ac.uk
[b)]Electronic mail: wang@mcmail.mcmaster.ca

$$x_i' = 2x_i\left(\sum_{j=1}^{r} E_{ij}u_j\right), \tag{1.2}$$

$$u_i' = x_i, \tag{1.3}$$

for $1 \leqslant i \leqslant r$. In the above, a prime denotes differentiation with respect to a variable s which is related to the variable t in (1.1) by

$$\frac{dt}{ds} = f_1(t)^{d_1}\cdots f_r(t)^{d_r},$$

i.e., the distortion of the volume relative to that of the background.

A summary of our analysis of (1.2)–(1.3) is given in Sec. V. We note that the case when (1.1) is replaced by a Lorentz metric with spacelike hypersurfaces is included in our analysis as the special case when all of the A_i are negative.

II. LEADING POWERS

We shall now analyze the equations (1.2)–(1.3). We first find the possible leading terms for a Painlevé expansion around a singularity at $s=0$. We set

$$x_i = \alpha_i s^{M_i} + \cdots, \quad u_i = \beta_i s^{N_i} + \cdots, \quad : \quad (i = 1,..,r),$$

where α_i and β_i are all nonzero. Without loss of generality, let $N_1 = \cdots = N_m < N_{m+1}, \ldots, N_r$.

As E is nondegenerate one of the sums $\Sigma_{j=1}^{m} E_{ij}\beta_j$ is nonzero, so upon examining the corresponding equation in (1.2) we deduce $N_1 \geqslant -1$, with equality if and only if $M_i \neq 0$. On the other hand, if some M_k is nonzero then $N_1 \leqslant -1$. So either $N_1 = -1$ or all $M_k = 0$. The latter possibility implies, from (1.3), that we have $N_k = 0$ or 1, and so we have no singularity at $s=0$, giving a contradiction.

Therefore we must have $N_1 = \cdots = N_m = -1$ and hence, from (1.3)

$$M_1 = \cdots = M_m = -2.$$

Now (1.2) implies

$$\sum_{j=1}^{m} E_{ij}\beta_j = -1 \quad : (i = 1,..., m).$$

These equations have solution

$$\beta_i = \frac{d_i}{1 - \Sigma_{j=1}^{m} d_j} \quad : (i = 1,..., m), \tag{2.1}$$

so for $i > m$ we see that $\Sigma_{j=1}^{m} E_{ij}\beta_j = \Sigma_{j=1}^{m} \beta_j$ is nonzero. Hence, from (1.2), all the M_i are nonzero.

Moreover, for $i = m+1,..., r$ we have

$$2\sum_{j=1}^{m} \beta_j = M_i \geqslant N_i - 1 > -2.$$

Comparing with (2.1) shows that we have a contradiction unless $m = r$.

We have established the following lemma.

Lemma 2.2: The leading terms are given by

$$N_i = -1, \quad M_i = -2 \quad : (i = 1,...,r),$$

$$\alpha_i = d_i/(n-1), \quad \beta_i = -d_i/(n-1) \quad : (i = 1,\ldots, r).$$

□

Remark 2.3: By changing to the variable $1/s$ and doing an analysis similar to that above, we can rule out the existence of Painlevé expansions around a singularity at infinity.

III. RESONANCES

We now look for expansions of the form

$$x_i = \sum_{j=0}^{\infty} \alpha_i^{(j)} s^{-2+j/Q}, \quad u_i = \sum_{j=0}^{\infty} \beta_i^{(j)} s^{-1+j/Q},$$

where Q is an integer to be determined later. Note that $\alpha_i^{(0)} = \alpha_i$, $\beta_i^{(0)} = \beta_i$. We write $\alpha^{(j)}$ for the column vector whose ith entry is $\alpha_i^{(j)}$.

It follows from a straightforward computation that the terms of the expansion must satisfy the recursion relation

$$\begin{pmatrix} \nu I_r & -\left(\frac{2}{n-1}\right)F \\ -I_r & (\nu-1)I_r \end{pmatrix} \begin{pmatrix} \alpha^{(j)} \\ \beta^{(j)} \end{pmatrix} = \begin{pmatrix} \tau^{(j)} \\ 0 \end{pmatrix}, \tag{3.1}$$

where I_r is the identity matrix of size r, $\nu = j/Q$, $F_{ij} = d_i E_{ij}$, and the ith entry of the vector $\tau^{(j)}$ is

$$2\sum_{k=1}^{r} E_{ik} \sum_{p=1}^{j-1} \alpha_i^{(p)} \beta_k^{(j-p)}.$$

We shall denote the matrix in (3.1) by $X(\nu)$.

We can write the recursion as

$$\left(\nu(\nu-1)I_r - \frac{2F}{n-1}\right)\beta^{(j)} = \tau^{(j)},$$

$$\alpha^{(j)} = (\nu-1)\beta^{(j)}.$$

The resonances, that is the values of ν for which the matrix $X(\nu)$ fails to be invertible, are therefore the roots of

$$\nu(\nu-1) = \lambda,$$

where λ ranges over the eigenvalues of $[2/(n-1)]F$. Moreover, the dimension of the kernel of $X(\nu)$ equals the dimension of the λ eigenspace.

Lemma 3.2: The eigenvalues of $[2/(n-1)]F$ *are 2 with multiplicity one and* $-2/(n-1)$ *with multiplicity* $r-1$. *In each case the dimension of the eigenspace equals the multiplicity.*

Proof: Observe that $F = D - I$ where $D_{ij} = d_i$. The eigenvalues of F are therefore -1 with multiplicity $r-1$ and $n-1$ with multiplicity one. The eigenspaces are, respectively, $\{(a_1,\ldots, a_r): \Sigma a_i = 0\}$ and the line spanned by $(d_1,\ldots, d_r)$.

As in Ref. 1 we deduce the following result. □

Lemma 3.3: (i) Two resonances are therefore always -1 *and 2. In these cases,* $\ker(X(\nu))$ *is one dimensional.*

(ii) The remaining resonances, that is, the roots of $\nu(\nu-1) = -2/(n-1)$, *are rational if and only if* $n = 9$ *or* 10 *(cf. Ref. 1).*

If $n = 9$ *these resonances are* 1/2; *if* $n = 10$, *they are* 1/3, 2/3.

For each of these resonances $\ker(X(\nu))$ *has dimension* $r-1$. □

IV. COMPATIBILITY CONDITIONS

We shall now look at the cases $n=9, 10$. To study the compatibility conditions we need to record the kernel of $X(\nu)^T$ where ν is a resonance. The kernel is given by the equations

$$\left(\nu(\nu-1)I_r-\frac{2}{n-1}F^T\right)\alpha=0,$$

$$\beta=\nu\alpha.$$

By Lemma 3.2, the $-2/(n-1)$ eigenspace of $2F^T/(n-1)$ is the hyperplane $\{(a_1,\ldots,a_r):\Sigma d_i a_i=0\}$ and the 2 eigenspace is spanned by $(1,\ldots,1)$. For compatibility, the right-hand side of (3.1) should be orthogonal to the kernel of $X(\nu)^T$.

In particular the compatibility condition at $\nu=2$ is $\Sigma_{i=1}^r \tau_i^{(2Q)}=0$, that is

$$\sum_{i,k=1}^{r} E_{ik}\sum_{p=1}^{2Q-1}\alpha_i^{(p)}\beta_k^{(2Q-p)}=0. \tag{4.1}$$

But using (3.1) we observe that

$$\begin{aligned}\sum_{p=1}^{2Q-1}\alpha_i^{(p)}\beta_k^{(2Q-p)}&=\sum_{p=1}^{2Q-1}\left(\frac{p}{Q}-1\right)\beta_i^{(p)}\beta_k^{(2Q-p)}\\&=\sum_{q=1}^{2Q-1}\left(1-\frac{q}{Q}\right)\beta_i^{(2Q-q)}\beta_k^{(q)}\\&=-\sum_{q=1}^{2Q-1}\alpha_k^{(q)}\beta_i^{(2Q-q)}.\end{aligned}$$

This shows that in (4.1) the terms with $i\neq k$ cancel in pairs and the terms with $i=k$ are 0. Hence the compatibility condition holds at $\nu=2$ if it holds at the earlier resonances.

Note also that at the first positive resonance the compatibility condition always holds because the right-hand side of (3.1) is 0 at that stage of the recursion.

If $n=9$, it is natural to take $Q=2$, so the positive resonances are at $j=1$ and $j=4$. We get one free parameter from the pole position, $r-1$ free parameters from the kernel of $X(1/2)$ and one further parameter from the resonance $j=4$.

If $n=10$, we take $Q=3$, so the positive resonances occur at $j=1, 2, 6$. Since the compatibility condition at $j=1$ automatically holds, we consider $j=2$. Now we have

$$\alpha^{(1)}=-\tfrac{2}{3}\beta^{(1)} \quad \text{and} \quad \sum_{i=1}^{r}\beta_i^{(1)}=0. \tag{4.2}$$

From the description of $\ker(X(2/3)^T)$ it follows that the compatibility condition at $j=2$ is given by

$$\sum_{i,j=1}^{r} v_i\beta_i^{(1)}E_{ij}\beta_j^{(1)}=0$$

for all $(v_1,\ldots,v_r)$ such that $d_1v_1+\cdots+d_rv_r=0$. This simplifies to

$$d_k\tau_i^{(2)}=d_i\tau_k^{(2)}, \quad 1\leqslant i,k\leqslant r,$$

or, equivalently,

$$d_i^2(\beta_k^{(1)})^2 = d_k^2(\beta_i^{(1)})^2.$$

After imposing these conditions we have at most one free parameter at $j=1$. More precisely, we have one free parameter if

$$\{d_1,\ldots,d_r\}=\{5,5\},\ \{5,3,2\},\ \text{or}\ \{3,3,2,2\},$$

and no free parameters otherwise.

The kernel of $X(2/3)$ gives us $r-1$ parameters at $j=2$. The pole position and the resonance at $j=6$ each contribute one further parameter.

Remark 4.3: The majorization argument in Ref. 1 carries over to prove convergence of our formal Painlevé expansion (we now take the constant κ in Ref. 1 to be $2\Sigma_{i,k=1}^{r}E_{ik}$).

V. SUMMARY

We summarize our results as follows.

Theorem 5.1: If $n\neq 9,10$ *then the only rational resonances are* -1 *and* 2.

If $n=9$ *we have a* $(r+1)$*-parameter Painlevé expansion in* $s^{1/2}$ *in a* $2r$*-dimensional system. Here* r *must be less than or equal to 4.*

If $n=10$ *we have an* $(r+2)$*-parameter Painlevé expansion in* $s^{1/3}$ *in a* $2r$*-dimensional system if*

$$\{d_1,\ldots,d_r\}=\{5,5\},\{2,3,5\},\ \text{or}\ \{2,2,3,3\}.$$

Otherwise we have a $(r+1)$*-parameter expansion. Here* r *is less than or equal to 5.* □

Remark 5.2: Recall that the Ricci-flat metric corresponding to a solution of our equations lives on a manifold of dimension $n+1$.

Remark 5.3: In all cases the constraint $\overline{H}=0$ has the effect of fixing the parameter at the top resonance.

Remark 5.4: The two-parameter expansion which always occurs (associated to the resonances $r=-1, 2$) comes from the special family of solutions with $d_j u_i = d_i u_j$ for all i,j. After imposing the Hamiltonian constraint, these solutions are just translations of

$$x_i=\frac{d_i}{(n-1)s^2},\quad u_i=\frac{-d_i}{(n-1)s}.$$

The corresponding Ricci-flat metric is the cone over the product of the Y_i (after the metrics g_i on Y_i have been rescaled by constant factors so that all have the same Einstein constant).

Remark 5.5: In the context of Theorem 4.23 in Ref. 2, the ordered basis $\hat{W}$ for the present case of r-fold warped product metrics may be taken to be $\{(-1, 0, \ldots, 0),\ldots, (0, \ldots, 0, -1)\}$, and one can readily check that when $r\geqslant 3$, all the hypotheses of that theorem are satisfied. Hence the associated Ricci-flat Hamiltonian system does not have nontrivial polynomial generalized first integrals.

On the other hand, the Ricci-flat Einstein equations for the warped product metrics (1.1) with $r=2$ are a subsystem of the system for arbitrary r, provided that the Ricci curvatures A_i/d_i of the factors that are grouped together are chosen to be equal. Therefore the nontrivial polynomial generalized first integrals found in Ref. 5 for the $r=2$ case give rise to explicit Ricci-flat metrics in some of the situations singled out in Theorem 5.1. Of course, these are not generalized integrals of the full system, as was just noted above. Solvability of the Ricci-flat warped product equations in these cases has independently been observed in Ref. 6 using different methods.

(Received 8 June 2000; accepted for publication 25 April 2001)

We propose a reformulation of the nonsymmetric gravitation theory (NGT) in the context of noncommutative geometry. It is shown that all of the Moffat's added terms in his new version of the NGT have a geometric origin. © *2001 American Institute of Physics.* [DOI: 10.1063/1.1385176]

I. INTRODUCTION

Despite the successes of the physical theories describing the fundamental interactions, they remain confronted to several fundamental difficulties which may require the introduction of new mathematical concepts. For this purpose, many theories have been explored like Kaluza–Klein theories, super-gravity, superstrings, etc.

Recently, a geometrical picture has been proposed by Connes[1–4] which consists in generalizing the classical differential geometry to a noncommutative one, and allows the accommodation of other types of spaces like discrete spaces in order to reformulate the standard model of elementary particles.

The success of noncommutative geometry (NCG) comes from the fact that it gives a geometric interpretation for the origin of the Higgs fields (in the standard model), namely as connections on a discrete space.

The reformulation of General Relativity in this framework was done by Chamseddine and collaborators[5,6] where they have considered a space–time given by a product of a 4-dimensional manifold and a two points discrete space. They have generalized the notion of cotangent space to the case of noncommutative geometry, and taken the Cartan structure equations.[7] The resulting action describes a scalar field coupled with gravity.[5,6] General Relativity[8,9] as a classical theory of gravity, was adopted as the correct theory of gravitation in regard to its experimental success, and its simple and elegant mathematical formalism.

Yet Einstein himself attempted to generalize his theory so as to include the fundamental interactions but endowed with a geometrical meaning. In his new theory he considered a more general nonsymmetric metric with the symmetric part corresponding to the metric of General Relativity, and the anti-symmetric one corresponding to the electromagnetic tensor field.

Since then, quite a few other theories inspired by General Relativity and based on a nonsymmetric metric $g_{\mu\nu}$ were proposed. One of those theories which has attracted a sustained interest is certainly the Nonsymmetric Gravitation theory (NGT) propounded by Moffat, and for which the antisymmetric part has a gravitational origin.[10–12]

However, NGT as proposed initially was not self-consistent, but suffered from perturbative problems in the skewon sector where the nonphysical modes happen to be coupled with the physical ones.

Recently, a new more consistent version of NGT was proposed, where the nonphysical modes are no longer coupled to the physical ones. Yet, this problem had been circumvented at the cost of adding by hand new terms to the action without any geometrical origin.[13]

In this work, we propose a new action for NGT which does not suffer from this defect. This

[a]Electronic mail: j.mimouni@eudoramail.com

is done by generalizing the scalar product defining the action as well as the Dirac operator.

In Sec. II, we generalize the formalism of noncommutative geometry for NGT. In Sec. III, we derive the new NGT action, and finally in Sec. IV we discuss our results and give our conclusions.

II. BASICS ON NGT AND NCG

NGT is a geometric theory of gravity based on a nonsymmetric metric $g_{\mu\nu}$. The best formulation of NGT is to use a hyperbolic complex space, where the metric $g_{\mu\nu}$ is written as

$$g_{\mu\nu}=g_{(\mu,\nu)}+g_{[\mu\nu]}=\tilde{g}_{\nu\mu}.$$

Here $\tilde{g}_{\mu\nu}$ stands for the hyperbolic complex conjugate of $g_{\mu\nu}$, $g_{(\mu\nu)}$ and $g_{[\mu\nu]}$ are the symmetric and the antisymmetric parts of $g_{\mu\nu}$, with $\varepsilon^2=1$.

One can also define the inverse $g^{\mu\nu}$ of the metric by[12]

$$g^{\mu\nu}g_{\mu\alpha}=g^{\nu\mu}g_{\alpha\mu}=\delta^{\nu}_{\mu}.$$

The fundamental object in NGT is the connection $W^{\lambda}_{\mu\nu}$ (which is of course nonsymmetric). The latter can be related to another one denoted by $\Gamma^{\lambda}_{\mu\nu}$ through the projective transformation:[12]

$$W^{\lambda}_{\mu\nu}=\Gamma^{\lambda}_{\mu\nu}-\tfrac{2}{3}\delta^{\lambda}_{\mu}W_{\nu},$$

where

$$W_{\mu}=\tfrac{1}{2}(W^{\alpha}_{\mu\alpha}-W^{\alpha}_{\alpha\mu}).$$

It is worth mentioning that the displacement field $\Gamma^{\lambda}_{\mu\nu}$ is defined by the parallel transport law for a vector A^{μ}:

$$\delta A^{\lambda}(x)=\Gamma^{\lambda}_{\mu\nu}A^{\mu}(x)dx^{\nu}.$$

A curvature and contracted curvature tensors $R^{\sigma}_{\mu\nu\rho}$ and $R_{\mu\nu}$, respectively, can be formed from the connection as

$$R^{\sigma}{}_{\mu\nu\rho}=W^{\sigma}{}_{\mu\nu,\rho}-W^{\sigma}{}_{\mu\rho,\nu}+W^{\sigma}{}_{\alpha\rho}W^{\alpha}{}_{\mu\nu}-W^{\sigma}{}_{\alpha\nu}W^{\alpha}{}_{\mu\rho},$$

$$R_{\mu\nu}(W)=W^{\alpha}_{\mu\nu,\alpha}-\tfrac{1}{2}(W^{\alpha}{}_{\mu\alpha,\nu}+W^{\alpha}{}_{\nu\alpha,\mu})+W^{\beta}{}_{\alpha\beta}W^{\alpha}{}_{\mu\nu}-W^{\beta}{}_{\alpha\nu}W^{\alpha}{}_{\mu\beta},$$

where we have used the notation $W^{\sigma}{}_{\mu\nu,\rho}=\partial_{\rho}W^{\sigma}{}_{\mu\nu}$.

As in general relativity, one can introduce a vierbein e^{a}_{μ} such that

$$g_{\mu\nu}=e^{a}_{\mu}\tilde{e}^{b}_{\nu}\eta_{ab},$$

with the orthogonality condition

$$e^{a}_{\mu}e^{\nu}_{a}=\delta_{\mu}{}^{\nu},\quad e_{a}{}^{\mu}e^{b}_{\mu}=\delta_{a}{}^{b},$$

where $\eta_{ab}=\mathrm{diag}(1,-1,-1,-1)$ is the Minkowski metric and $\tilde{e}^{b}_{\nu}$ denotes the hyperbolic complex conjugate of e^{b}_{ν}.

The vierbein satisfies the compatibility condition:

$$\nabla_{\sigma}e^{a}_{\mu}=e^{a}_{\mu,\sigma}+(\omega_{\sigma})^{a}_{b}e^{b}_{\mu}-W^{\nu}_{\sigma\mu}e^{a}_{\nu}=0,$$

where ω_{σ} is the NGT spin connection verifying the following hermiticity condition:[11]

$$(\tilde{\omega}_{\sigma})^{ab}=-(\omega_{\sigma})^{ba}.$$

Notice that in this holonomic coordinates, the curvature tensor $R^{\lambda}_{\sigma\mu\nu}$ is given by[11]

$$R^{\lambda}_{\sigma\mu\nu}=e^{\lambda}_{a}e^{b}_{\sigma}(R_{\mu\nu})^{a}{}_{b},$$

with

$$(R_{\mu\nu})^{a}{}_{b}=(\omega_{\nu})^{a}{}_{b}-(\omega_{\mu})^{a}{}_{b}+[\omega_{\mu},\omega_{\nu}]^{a}{}_{b}.$$

In NCG one can generalize the basic notions of connection, curvature, and torsion. This construction is based on the definition of the metric as an internal product on the cotangent space $T^{*}(M)$ (M is a compact manifold),[8]

$$g:M\to\otimes^{2}T^{*}(M),\quad x\to g_{x}\in T^{*}_{x}(M).$$

By analogy to the algebra of differential forms $\Lambda(M)$ on a manifold M, one can construct from a unitary, associative and involutive algebra $\mathcal{A}$, a Z-graded differential algebra $\Omega(\mathcal{A})$ defined by

$$\Omega(\mathcal{A}):=n\geqslant 0\oplus\Omega^{n}(\mathcal{A}),$$

$$\Omega^{n}(\mathcal{A})=\left\{i\sum\ a_{0}^{(i)}da_{1}^{(i)}\ldots da_{n}^{(i)},\quad a_{0}^{(i)},a_{1}^{(i)},\ldots,a_{n}^{(i)}\in\mathcal{A}\right\},$$

where d is a differential operator:

$$d:\Omega^{n}(\mathcal{A})\to\Omega^{n+1}(\mathcal{A})$$

[here $\Omega^{0}(\mathcal{A})=\mathcal{A}$ and $\Omega^{n}(\mathcal{A})$ is a bilateral A-module].

A connection on a vector fiber bundle $\mathcal{E}$ is by definition a linear application ∇ such that[5]

$$\nabla:\mathcal{E}\to\Omega(\mathcal{A})\otimes_{A}\mathcal{E},$$

with the following property:

$$\nabla(a\sigma)=da\otimes\sigma+a\,\nabla\sigma,\quad\forall a\in\mathcal{A},\quad\forall\sigma\in\mathcal{E}.$$

For each $\mathcal{A}$-left module $\mathcal{E}$, one can define a differential form space by

$$\Omega^{0}(\mathcal{E}):=\Omega(\mathcal{A})\otimes_{A}\mathcal{E}.$$

The curvature of ∇ is given by[5]

$$R(\nabla)=-\nabla^{2}:\mathcal{E}\to\Omega^{2}(\mathcal{A})\otimes_{A}\mathcal{E},$$

with

$$R(\nabla)(a\sigma)=aR(\nabla)(\sigma),\quad\forall a\in A,\quad\forall\sigma\in\mathcal{E}.$$

It is worth mentioning that if $\mathcal{A}$ is involutive then $\Omega(\mathcal{A})$ is involutive too:

$$(da)^{*}=-d(a^{*}),\quad(\alpha\beta)^{*}=\beta^{*}\alpha^{*},\quad\forall a\in A,\quad\forall\alpha,\beta\in\Omega(\mathcal{A}).$$

A connection ∇ is said to be unitary if for $\sigma,\tau\in\mathcal{E}$ one has[5]

$$d\langle\sigma,\tau\rangle=\langle\nabla\sigma,\tau\rangle-\langle\sigma,\nabla\tau\rangle,$$

where $\langle\cdot/\cdot\rangle$ is a Hermitian internal product:

$$\langle \cdot / \cdot \rangle : \mathcal{E} \times \mathcal{E} \to \mathcal{A}.$$

In NCG, the notion of a geodesic distance on M is given by the K-cycles of the algebra $\mathcal{A}$.[6] We remind the reader that a K-cycle $(\mathcal{A}, \mathcal{H}, \rho, \mathcal{D}, \Gamma)$ is defined by the following:

(1) A separable Hilbert space $\mathcal{H} = \mathcal{H}_+ \oplus \mathcal{H}_-$.
(2) A $*$-faithful representation ρ of $\mathcal{A}$ given by bounded operatos on $\mathcal{H}$.
(3) A self-adjoint operator $\mathcal{D}$ on $\mathcal{H}$ with the following properties:
(i) $[\mathcal{D}, \rho(a)] \in \mathrm{End}(\mathcal{H})$: a bounded operator on $\mathcal{H} (\forall a \in \mathcal{A})$.
(ii) The operator $\exp(-\varepsilon \mathcal{D}^2)$ is traceclass, $\forall \varepsilon > 0$.
(4) A self-adjoint operator Γ on $\mathcal{H}$ satisfying

$$\Gamma^* = \Gamma^{-1} = \Gamma, \{\Gamma, \mathcal{D}\} = 0, \quad \rho(a)\Gamma = \Gamma \rho(a), \quad \forall a \in \mathcal{A}.$$

Now, from a K-cycle, one can define an involutive representation π of $\Omega(\mathcal{A})$ as[5,6]

$$\pi(a_0 da_1 \ldots da_p) = \rho(a_0)[D, \rho(a_1)] \cdots [D, \rho(a_p)].$$

Then, we define the algebra of differential forms $\Omega_D(\mathcal{A}.)$ as

$$\Omega_D(\mathcal{A}.) := \pi(\Omega(A))/\pi(d \ \mathrm{Ker}\ \pi) = p \geqslant 0 \oplus \Omega_D^p(\mathcal{A}.),$$

$$\omega_D^p(\mathcal{A}.) := \pi(\omega^p(\mathcal{A}.))/\mathrm{Aux}^p,$$

where Aux^p is the space of auxiliary (junk forms) fields given by

$$\mathrm{Aux}^p) = \{\pi(d\omega) \in \pi(\Omega^p(\mathcal{A}.)); \ \ \omega(\omega) = 0 \ \ \text{and} \ \ \omega \in \Omega^{p-1}(\mathcal{A}.)\}.$$

This allows us to define a metric $\langle \cdot / \cdot \rangle$ as the internal product over the $\mathcal{A}$-left-module $\Omega_D^1(\mathcal{A}.)$ as[6]

$$\langle \cdot / \cdot \rangle : \Omega_D^1(\mathcal{A}) \times \Omega_D^1(\mathcal{A}) \to \mathcal{A}.$$

It is to be noted that $\Omega_D^1(\mathcal{A})$ plays the role of the cotangent space of the noncommutative space.[5]

Since $\Omega_D(\mathcal{A})$ is a Z-graded differential algebra, it can be used to define the connection ∇ on the cotangent space $\Omega_D^1(\mathcal{A})$:

$$\nabla : \Omega_D^1(\mathcal{A}) \to \Omega_D^1(\mathcal{A}) \otimes_A \Omega_D^1(\mathcal{A});$$

the curvature and the torsion are defined by

$$R(\nabla) = -\nabla^2 : \Omega_D^1(\mathcal{A}) \to \Omega_D^2(\mathcal{A}) \otimes_A \otimes_A \Omega_D^1(\mathcal{A})$$

and

$$T(\nabla) = d - m \circ \nabla : \nabla : \Omega_D^1(\mathcal{A}) \to \Omega_D^2(\mathcal{A}),$$

respectively. Here m denotes the forms product:

$$m : \Omega_D^1(\mathcal{A}) \times \Omega_D^1(\mathcal{A}) \to \Omega_D^2(\mathcal{A}), \quad (\omega, \eta) \to \omega, \eta, \quad \forall \omega, \eta \in \Omega_D^1(\mathcal{A}).$$

In order to get the Cartan structure equations, we suppose that $\Omega_D^1(\mathcal{A})$ is a trivial vector fiber space. Let $(E^A)_{1 \leqslant A \leqslant N}$ be a basis of the space $\Omega_D^1 \mathcal{A}$, and define $\Omega^{AB} \in \Omega_D^1(\mathcal{A})$ such that[5,7]

$$\nabla E^A = -B \sum \ \Omega^{AB} \otimes E^B, \quad A, B = 1, 2, \ldots, N.$$

The components R^{AB}, T^A of the curvature $R(\nabla)$ and the torsion $T(\nabla)$ are given by

$$R(\nabla)E^A = B\sum R^{AB}\otimes E^B, \quad A,B=1,2,...,N,$$

$$T^A = T(\nabla).E^A, \quad A=1,2,...,N.$$

Now, using the definition of $R(\nabla)$ and $T(\nabla)$, we get the (noncommutative) Cartan structure equations:[5,7]

$$R^{AB} = d\Omega^{AB} + C\sum \Omega^{AC}\Omega^{CB},$$

$$T^A = dE^A + B\sum \Omega^{AB}E^B.$$

III. GENERALIZED NONCOMMUTATIVE GEOMETRY APPROACH

In order to reformulate NGT in the context of NCG, we have to generalize the Dirac operator with the following form:[6]

$$D = \begin{pmatrix} \gamma^a\otimes E_a^\mu\partial_\mu\otimes 1 & \gamma^5\otimes M_{12}\otimes K_{12} \\ \gamma^5\otimes M_{21}\otimes K_{21} & \gamma^a\otimes E_a^\mu\partial_\mu\otimes 1 \end{pmatrix} = \begin{pmatrix} \gamma^a E_a^\mu\partial_\mu & \gamma^5 M_{12}K_{12} \\ \gamma^5 M_{21}K_{21} & \gamma^a E_a^\mu\partial_\mu \end{pmatrix}. \tag{1}$$

The diagonal elements of the Dirac operator is a compact form which means

$$\gamma^a\otimes E_a^\mu\partial_\mu\otimes 1 = \gamma^a e_a^\mu\partial_\mu\otimes M\otimes 1 + \gamma^a\tilde{e}_a^\mu\partial_\mu\otimes\tilde{M}\otimes 1,$$

with

$$M = \begin{pmatrix} 0 & 1 \\ 0 & 0 \end{pmatrix} \quad \text{and} \quad \tilde{M} = \begin{pmatrix} 0 & 0 \\ 1 & 0 \end{pmatrix},$$

where E_a^μ is a 2×2 matrix characterizing the vierbein and defined by

$$E_a^\mu = (E_a^\mu)^* = E_a^{\mu *} = \begin{pmatrix} 0 & e_a^\mu \\ \tilde{e}_a^\mu & 0 \end{pmatrix}, \tag{2}$$

with M_{12}, M_{21} (resp., K_{12}, K_{21}) are 2×2 (resp., $N\times N$) matrices. It is worth mentioning that the γ^a's are the ordinary Dirac matrices in the flat four-dimensional space–time and are defined as[6]

$$\begin{gathered} \gamma^{a*} = -\gamma^a, \quad \{\gamma^a,\gamma^b\} = \gamma^a\gamma^b + \gamma^b\gamma^a = -2\delta^{ab}, \\ \gamma^{ab} = \tfrac{1}{2}[\gamma^a,\gamma^b], \quad \gamma^{(ab)} = \tfrac{1}{2}\{\gamma^a,\gamma^b\} = -\delta^{ab}. \end{gathered} \tag{3}$$

In order to have a self-adjoint Dirac operator as it is required to be, one has to set the conditions:

$$K_{21}^* = K_{12} = K \tag{4}$$

and

$$M_{12} = M_{21}^* = M. \tag{5}$$

Concerning the algebra $\mathcal{A}$, it is defined as

$$\mathfrak{a}=C^{\infty}_{\mathbb{R}}(X)\otimes(M_2(\mathbb{K})\oplus M_2(\mathbb{K}))=C^{\infty}_{\mathbb{R}}(X,M_2(\mathbb{K}))\oplus C^{\infty}_{\mathbb{R}}(X,M_2(\mathbb{K})), \tag{6}$$

$$\mathcal{A}=\{a^{(1)}+\alpha^{(2)};\alpha^{(i)}\in C^{\infty}_{\mathbb{R}}(X,M_2(\mathbb{K})),\ \ i=1,2\}, \tag{7}$$

with

$$C^{\infty}_{\mathbb{R}}(X,M_2(\mathbb{K}))=C^{\infty}_{\mathbb{R}}(X)\otimes M_2(\mathbb{K}),$$

where $C^{\infty}_{\mathbb{R}}(X)$ denotes the space of infinite differentiable real functions on a manifold X and $M_2(\mathbb{K})$ the set of 2×2 hyperbolic complex matrices. (We can state that the space X is a spin manifold, and replace the Dirac operator $e^{\mu}_a\partial_\mu$ by $e^{\mu}_a\nabla_\mu$, where $\nabla_\mu=\partial_\mu+\omega_\mu$ without changing the results. The reason is that the spin connection ω_μ commutes with the elements of the algebra $\mathcal{A}$.)

In what follows, we restrict ourselves to a subalgebra $\mathcal{B}$ of $\mathcal{A}$ such that

$$\mathcal{B}=\left\{\alpha\in\mathcal{A}/\alpha=\alpha^{(1)}+\alpha^{(2)},\alpha^{(i)}=\begin{pmatrix}a^{(i)} & 0\\ 0 & a^{(i)}\end{pmatrix},\quad a^{(i)}\in C^{\infty}_{\mathbb{R}}(X,\mathbb{K}),\quad i=1,2\right\}. \tag{8}$$

Then one can choose the following representation:

$$\pi(\alpha)=\pi(\alpha^{(1)}+\alpha^{(2)})=\begin{pmatrix}1\otimes\alpha^{(1)}\otimes 1 & 0\\ 0 & 1\otimes\alpha^{(2)}\otimes 1\end{pmatrix}=\begin{pmatrix}\alpha^{(1)} & 0\\ 0 & \alpha^{(2)}\end{pmatrix}. \tag{9}$$

The algebra acts by left multiplication on the following Hilbert space $\mathcal{H}$:[6]

$$\mathcal{H}=\mathcal{H}_1\mathcal{H}_2,$$

where

$$\mathcal{H}_i=L^2(S,dv)\otimes_R K^2\otimes_R K^N, \tag{10}$$

and R, K denote the rings of real and hyperbolic complex numbers, respectively and S is the spinors space, dv is the volume element on X.

For the 1-forms space denoted by $\Omega^1_D(\mathcal{B})$, one has as a representation,

$$\Omega^1_D(\mathcal{B})=\pi(\Omega^1(\mathcal{B}))=\left\{\pi(\omega)=\pi\left(i\sum\ \alpha_i\delta\beta_i\right)=i\sum\ \pi(\alpha_i)[D,\pi(\beta_i)]\right\}. \tag{11}$$

Straightforward calculations give

$$\pi(\omega)=\begin{pmatrix}\gamma^a E^{\mu}_a\omega^{(1)}_{\mu} & \gamma^5 K_{12}\Phi_{12}\\ \gamma^5 K_{21}\Phi_{21} & \gamma^a E^{\mu}_a\omega^{(2)}_{\mu}\end{pmatrix}, \tag{12}$$

where

$$\omega^{(m)}_{\mu}=i\sum\ \alpha^{(m)}_i\,\partial_\mu\beta^{(m)}_i,\quad m=1,2 \tag{13}$$

and

$$\Phi_{mn}=\phi_{mn}M_{mn}, \tag{14}$$

with

$$\phi_{mn}=\sum_i\ (\alpha_i^{(m)}\beta_i^{(n)})-1,\quad m\neq n=1,2, \tag{15}$$

together with the normalization condition:

$$\sum_i\ \alpha_i^{(1)}\beta_i^{(1)}=\sum_i\ \alpha_i^{(2)}\beta_i^{(2)}=1. \tag{16}$$

Now, in order to get a representation $\Omega_D^2(\mathcal{B})$ of the 2-forms space $\Omega^2(\mathcal{B})$ without the junks forms (auxiliary fields), one has to set

$$\Omega_D^2(\mathcal{B})=\pi(\Omega_D^2(\mathcal{B}))/\mathrm{Aux}^2, \tag{17}$$

where Aux^2 is the space of the auxiliary fields defined as

$$\mathrm{Aux}^2=\{\pi(\delta\omega)/\pi(\omega)=0\},\quad \omega\in\Omega^1(\mathcal{B}), \tag{18}$$

with

$$\pi(\delta\omega)=i\sum\ \pi(\delta\alpha_i\,\delta\beta_i)=i\sum\ [D,\pi(\alpha_i)][D,\pi(\beta_i)]. \tag{19}$$

Direct but lengthy calculations lead to

$$\pi(\delta\omega)_{11}=\gamma^a\gamma^bE_a^\mu E_b^\nu(\partial_\mu\omega_\nu^{(1)}-X_{\mu\nu}^{(1)})+K_{12}K_{21}M_{12}M_{21}(\phi_{12}+\phi_{21}),$$

$$\pi(\delta\omega)_{22}=\gamma^a\gamma^bE_a^\mu E_b^\nu(\partial_\mu\omega_\nu^{(2)}-X_{\mu\nu}^{(2)})+K_{21}K_{12}M_{21}M_{12}(\phi_{21}+\phi_{12}),$$

$$\pi(\delta\omega)_{12}=K_{12}\gamma^a\gamma^5(E_a^\mu M_{12}(\partial_\mu\phi_{12}+\omega_\mu^{(1)})-M_{12}E_a^\mu\omega_\mu^{(2)}-[E_a^\mu,M_{12}]Y_\mu^{(12)}),$$

$$\pi(\delta\omega)_{21}=K_{21}\gamma^a\gamma^5(E_a^\mu M_{21}(\partial_\mu\phi_{21}+\omega_\mu^{(2)})-M_{21}E_a^\mu\omega_\mu^{(1)}-[E_a^\mu,M_{21}]Y_\mu^{(21)}),$$

where the hyperbolic complex functions $X_{\mu\nu}^{(m)}$ and $Y_\mu^{(mn)}$ are given by

$$X_{\mu\nu}^{(m)}=i\sum\ \alpha_i^{(m)}\partial_\mu\,\partial_\nu\beta_i^{(m)},\quad m=1,2,$$

and

$$Y_\mu^{(mn)}=i\sum\ \alpha_i^{(m)}\,\partial_\mu\beta_i^{(n)},\quad m\neq n=1,2. \tag{20}$$

After some simplifications, we obtain the following expression for Aux^2:

$$\mathrm{Aux}^2=\begin{pmatrix}\gamma^a\gamma^bE_a^\mu E_b^\nu X_{\mu\nu}^{(1)} & K\gamma^a\gamma^5[E_a^\mu,M_{12}]Y_\mu\\ K^*\gamma^a\gamma^5[E_a^\mu,M_{21}]Z_\mu & \gamma^a\gamma^bE_a^\mu E_b^\nu X_{\mu\nu}^{(2)}\end{pmatrix}, \tag{21}$$

where $X_{\mu\nu}^{(1)}=X_{\nu\mu}^{(1)}$, $X_{\mu\nu}^{(2)}=X_{\nu\mu}^{(2)}$, Y_μ,Z_μ are arbitrary hyperbolic complex functions.

The curvature tensor $R^{AB}(A,B=\overline{1,5})$ is defined by[6,7]

$$R^{AB}=d\Omega^{AB}+C\sum\ \Omega^{AC}\Omega^{CB}, \tag{22}$$

where the components of the connection $\Omega^{AB}\in\Omega_D^1(\mathcal{B})$ are given by

$$(\Omega^{AB})_{mn}=\gamma^a E_a^\mu \omega_\mu^{(m)AB},\quad m=1,2,$$
$$(\Omega^{AB})_{mn}=\gamma^5 K_{mn} M_{mn}^{AB}\phi_{mn},\quad m\neq n=1,2. \tag{23}$$

Setting

$$M_{12}=\begin{pmatrix}0&1\\0&0\end{pmatrix},\quad M_{21}=M_{12}^*=\begin{pmatrix}0&0\\1&0\end{pmatrix},\quad \tau=\begin{pmatrix}1&0\\0&0\end{pmatrix},\quad \overline{\tau}=\begin{pmatrix}0&0\\0&1\end{pmatrix} \tag{24}$$

and

$$E_a^\mu E_b^\nu=\eta_{ab}^{\mu\nu}\mathbf{1}-\varepsilon g_{ab}^{\mu\nu}\tau_3, \tag{25}$$

with:

$$\eta_{ab}^{\mu\nu}=(\alpha_a^\mu\alpha_b^\nu-\beta_a^\mu\beta_b^\nu)=+\eta_{ba}^{\nu\mu},$$
$$g_{ab}^{\mu\nu}=\alpha_a^\mu\beta_b^\nu-\beta_a^\mu\alpha_b^\nu=-g_{ba}^{\nu\mu},$$
$$\tau-\overline{\tau}=\tau_3,$$

and

$$\alpha_a^\mu=\tfrac{1}{2}(e_a^\mu+\tilde{e}_a^\mu),$$
$$\beta_a^\mu=\tfrac{1}{2}\varepsilon(e_a^\mu-\tilde{e}_a^\mu),$$

we obtain the following expressions for the component of R^{AB}:

$$R_{11}^{AB}=\tfrac{1}{2}(\gamma^{ab}\eta_{ab}^{\mu\nu}\mathbf{1}+\varepsilon g_{ab}^{\mu\nu}\delta_{ab}\tau_3)R_{\mu\nu}^{(1)AB}-\tfrac{1}{2}(\mathrm{Tr}(K.K^*)-2(K.K^*)\tau)H_{12}^{AB},$$
$$R_{22}^{AB}=\tfrac{1}{2}(\gamma^{ab}\eta_{ab}^{\mu\nu}\mathbf{1}+\varepsilon g_{ab}^{\mu\nu}\delta_{ab}\tau_3)R_{\mu\nu}^{(2)AB}-\tfrac{1}{2}(\mathrm{Tr}(K.K^*)-2(K^*.K)\overline{\tau})H_{21}^{AB},$$
$$R_{12}^{AB}=\tfrac{1}{2}K.\gamma^a\gamma^5\tilde{e}_a^\mu(\nabla_\mu\phi_{12}^{AB}-(\phi_{12}^{AC}\omega_\mu^{(2)CB}+\omega^{(2)AB})),$$
$$R_{21}^{AB}=\tfrac{1}{2}K.^*\gamma^a\gamma^5 e_a^\mu(\nabla_\mu\phi_{21}^{AB}-(\phi_{21}^{AC}\omega_\mu^{(1)CB}+\omega_\mu^{(1)AB})),$$

where

$$R_{\mu\nu}^{(m)AB}=\partial_\mu\omega_\nu^{(m)AB}+C\sum\ \omega_\mu^{(m)AC}\omega_\nu^{(m)CB}-(\mu\leftrightarrow\nu)=-R_{\nu\mu}^{(m)AB},\quad m=1,2,$$
$$\gamma^{ab}=\tfrac{1}{2}[\gamma^a,\gamma^b],$$
$$H_{12}^{AB}=C\sum\ \phi_{12}^{AC}\phi_{21}^{CB}+\phi_{12}^{AB}+\phi_{21}^{AB},$$
$$H_{21}^{AB}=C\sum\ \phi_{21}^{AC}\phi_{12}^{CB}+\phi_{21}^{AB}+\phi_{12}^{AB},$$
$$\nabla_\mu\phi_{12}^{AB}=\partial_\mu\phi_{12}^{AB}+C\sum\ \omega_\mu^{(1)AC}\phi_{12}^{CB}+\omega_\mu^{(1)AB},$$

$$\nabla_\mu \phi_{21}^{AB} = \partial_\mu \phi_{21}^{AB} + C \sum \omega_\mu^{(2)AC} \phi_{21}^{CB} + \omega_\mu^{(2)AB}.$$

As for the torsion T^A $(A = \overline{1,5})$, it is defined by[6,7]

$$T^A = d\xi^A + B \sum \Omega^{AB}.\xi^B,$$

where the generators ξ^A are

$$\xi^a = \gamma^b E_b^\mu \tilde{e}_\mu^a \otimes \mathbf{1},$$

$$\xi^{a*} = -\gamma^b E_b^\mu e_\mu^a \otimes \mathbf{1} = -\tilde{\xi}$$

and

$$\xi^5 = \begin{pmatrix} 0 & \gamma^5 K M_{21} \\ -\gamma^5 K^* M_{21} & 0 \end{pmatrix} = -\xi^{5*} = -\tilde{\xi}^5.$$

Using the fact that

$$d\xi^a = \gamma^b \gamma^c E_b^\mu E_c^\nu \partial_\mu \tilde{e}_\nu^a \otimes \mathbf{1},$$

$$d\xi^5 = 0,$$

the components of T^A, which are orthogonal to the auxiliary fields space, take the form

$$(T^a)_{11} = (\gamma^{cd} \eta_{cd}^{\mu\nu} \mathbf{1} + \varepsilon g^{\mu\nu} \tau_3)(\partial_\mu \tilde{e}_\nu^a + \omega_\mu^{(1)ab} \tilde{e}_\nu^b) + \tfrac{1}{2}(\mathrm{Tr}(K.K^*) - 2(K.K^*)\tau)\phi_{12}^{a5},$$

$$(T^a)_{22} = (\gamma^{cd} \eta_{cd}^{\mu\nu} \mathbf{1} + \varepsilon g^{\mu\nu} \tau_3)(\partial_\mu \tilde{e}_\nu^a + \omega_\mu^{(2)ab} \tilde{e}_\nu^b) - \tfrac{1}{2}(\mathrm{Tr}(K.K^*) - 2(K^*.K)\overline{\tau})\phi_{21}^{a5},$$

$$(T^a)_{12} = +K.\gamma^d \gamma^5 \tilde{e}_d^\mu \omega_\mu^{(1)a5} - K\gamma^d \gamma^5 \tilde{e}_d^\mu (\omega_\mu^{(1)a5} + \tilde{e}_\mu^b \phi_{12}^{ab})\tau,$$

$$(T^a)_{21} = -K.^* \gamma^d \gamma^5 e_d^\mu \omega_\mu^{(2)a5} + K^* \gamma^d \gamma^5 e_d^\mu (\omega_\mu^{(2)a5} - \tilde{e}_\mu^b \phi_{21}^{ab})\overline{\tau},$$

and

$$(T^5)_{11} = (\gamma^{cd} \eta_{cd}^{\mu\nu} \mathbf{1} + \varepsilon g^{\mu\nu} \tau_3) \omega_\mu^{(1)5b} \tilde{e}_\nu^b + \tfrac{1}{2}(\mathrm{Tr}(K.K^*) - 2(K.K^*)\tau)\phi_{12}^{55},$$

$$(T^5)_{22} = (\gamma^{cd} \eta_{cd}^{\mu\nu} \mathbf{1} + \varepsilon g^{\mu\nu} \tau_3) \omega_\mu^{(2)5b} \tilde{e}_\nu^b - \tfrac{1}{2}(\mathrm{Tr}(K.K^*) - 2(K^*.K)\overline{\tau})\phi_{21}^{55},$$

$$(T^5)_{12} = K\gamma^d \gamma^5 \tilde{e}_d^\mu \omega_\mu^{(1)55} - K\gamma^d \gamma^5 \tilde{e}_d^\mu (\omega_\mu^{(1)55} + \tilde{e}_\mu^b \phi_{12}^{5b})\tau,$$

$$(T^5)_{21} = -K^* \gamma^d \gamma^5 e_d^\mu \omega_\mu^{(2)55} + K^* \gamma^d \gamma^5 e_d^\mu (\omega_\mu^{(2)55} - \tilde{e}_\mu^b \phi_{21}^{5b})\overline{\tau}.$$

IV. THE NEW NGT ACTION

In order to get the action $\mathfrak{I}$, one has to use the following form:[5]

$$\mathfrak{I} = \tfrac{1}{2}(E^A E^{B*} - E^{B*} E^A, R^{BA}), \tag{26}$$

where $(,)$ denotes the generalized scalar product defined as

$$(E^A E^{B*} - E^{B*} E^A, R^{BA}) = \int d^4x \sqrt{e\tilde{e}}\ \mathrm{Tr}_K \cdot \mathrm{tr}((E^B E^{A*} - E^{A*} E^B) R^{BA}), \tag{27}$$

and (Tr_K) is the trace over the K matrices, while (tr) is the trace over the Clifford algebra. The E^A's are the generators of a subspace of the 1-form space $\Omega^1_D(A)$ defined by

$$\pi(\omega) = i \sum \pi(\alpha_i)[D, \pi(\beta_i)], \tag{28}$$

with

$$\alpha_i \in A, \quad \beta_i \in \mathcal{B}, \alpha_i = \alpha_i^{(1)} \oplus \alpha_i^{(2)}, \quad \beta_i = \beta_i^{(1)} \oplus \beta_i^{(2)}.$$

After some simplifications, one obtains

$$\pi(\omega) = \begin{pmatrix} \gamma^a \omega_\mu^{(1)} E_a^\mu & \gamma^5 K \Phi_{12} M_{12} \\ \gamma^5 K^* \Phi_{21} M_{12} & \gamma^a \omega_\mu^{(2)} E_a^\mu \end{pmatrix}, \tag{29}$$

where now the generators of this subspace are expressed by

$$E^a = \gamma^b e_\mu^a \tau E_b^\mu \otimes \mathbf{1} = \gamma^a M_{12} \otimes \mathbf{1},$$

$$\tilde{E}^a = \gamma^b \tilde{e}_\mu^a \overline{\tau} E_b^\mu \otimes \mathbf{1} = \gamma^a M_{21} \otimes \mathbf{1},$$

$$E^5 = \begin{pmatrix} 0 & \gamma^5 K M_{12} \\ -\gamma^5 K^* M_{21} & 0 \end{pmatrix} = \tilde{E}^5.$$

It is worth mentioning that if we use the generators ξ^A of the space $\Omega^1_D(\mathcal{B})$,

$$\xi^a = \gamma^b E_b^\mu \tilde{e}_\mu^a \otimes \mathbf{1} = \begin{pmatrix} 0 & \gamma^b e_b^\mu \tilde{e}_\mu^a \\ \gamma^a & 0 \end{pmatrix} \otimes \mathbf{1},$$

to define the action, we get two contributions to the action: one coming from the term $\gamma^b \tilde{e}_b^\mu \tilde{e}_\mu^a = \gamma^a$ and which gives the NGT action, and the other one from the term $\gamma^b e_b^\mu \tilde{e}_\mu^a$ giving a meaningless contribution. This is however not the case for the generators E^A where the matrix $\tau = \left(\begin{smallmatrix} 1 & 0 \\ 0 & 0 \end{smallmatrix}\right)$ in the expression of E^a ensures the absence of such terms in the action.

According to the above mentioned remark, we cannot use only the algebra $\mathcal{B}$ because we need the generators E^A to define the action, which are elements of the space $\Omega^1_D(\mathcal{A})$. Also we can use only the algebra $\mathcal{A}$, but because the matrix E_a^μ in the Dirac operator does not commute with the elements of the algebra $\mathcal{A}$, this will give a complicated expression for the space of 1- and 2-forms, and the elimination of the auxiliary fields will be very tedious. Then, in order to get the usual expression for the tensor $R_{\mu\nu}^{(m)ab}$, we must impose that the connection forms Ω^{AB} lie in the space $\Omega^1_D(\mathcal{B})$. This is why we have used the algebra $\mathcal{B}$ to define the space of 1- and 2-forms, the curvature tensor, the torsion, and using the algebra $\mathcal{A}$ to define the generators E_a^μ.

Using the generalized scalar product (0.27), the equation (26) is rewritten as

$$\begin{aligned} \mathfrak{I} = \int d^4x \sqrt{e\tilde{e}} \Big\{ & -\frac{1}{2}(2\eta_{ab}^{\mu\nu} - \varepsilon \delta_{ab} g^{\mu\nu})(R_{\mu\nu}^{(1)ba} + R_{\mu\nu}^{(2)ba}) + \frac{1}{2}\mathrm{Tr}(K.K^*)(\phi_{12}^{aB}\phi_{21}^{Ba} - \phi_{21}^{aB}\phi_{12}^{Ba}) \\ & + \frac{1}{2}\mathrm{Tr}(K.K^*)\tilde{e}_a^\mu(\nabla_\mu \phi_{12}^{a5} - \phi_{12}^{aB}\omega_\mu^{(2)B5} - \omega_\mu^{(2)a5}) \\ & + \frac{1}{2}\mathrm{Tr}(K.K^*)e_a^\mu(\nabla_\mu \phi_{21}^{5a} - \phi_{21}^{5B}\omega_\mu^{5B}\omega_\mu^{(1)Ba} - \omega_\mu^{(1)5a}) \Big\}. \end{aligned}$$

Imposing the weak conditions

$$\mathrm{Tr}_k(T^a)=0, \quad T^5\neq 0,$$

where Tr denotes the trace over $K^2\otimes K^N$, one gets the following constraints:

$$\omega_\mu^{(1)ab}=\omega_\mu^{(2)ab}, \tag{30}$$

$$\omega_\mu^{(2)a5}=\omega_\mu^{(2)5a}=\omega_\mu^{(1)a5}=\omega_\mu^{(1)5a}=0, \tag{31}$$

$$\phi_{12}^{ab}=\phi_{21}^{ab}=0, \tag{32}$$

$$\phi_{12}^{a5}=\phi_{21}^{5a}\Rightarrow\phi_{21}^{5a}=\phi_{12}^{5a}. \tag{33}$$

Moreover, by making use of the fact that T^A must be orthogonal to the space Aux^2, we get the following relations:

$$\begin{aligned}
&\omega_\mu^{(2)a5}-\tilde{e}_\mu^b\phi_{21}^{ab}=0,\\
&\omega_\mu^{(1)a5}+\tilde{e}_\mu^b\phi_{12}^{ab}=0,\\
&\omega_\mu^{(2)55}-\tilde{e}_\mu^b\phi_{21}^{5b}=0,\\
&\omega_\mu^{(1)55}+\tilde{e}_\mu^b\phi_{12}^{5b}=0,
\end{aligned} \tag{34}$$

which allows us to express the ϕ_{mn}^{Ab} fields in terms of the $\omega_\mu^{(m)A5}$ fields in the action.

Taking into account both the compatibility and the unitarity conditions:

$$\begin{aligned}
&\nabla_\sigma\tilde{e}_\mu^a=\partial_\sigma\tilde{e}_\mu^a+\omega_\sigma^{ab}\tilde{e}_\mu^b-W_{\sigma\mu n}^\lambda\tilde{e}_\lambda^a=0,\\
&(\Omega^{AB})^*=\Omega^{BA},
\end{aligned} \tag{35}$$

we end up with

$$\tilde{\omega}_\mu^{(1)AB}=-\omega_\mu^{(1)BA}, \quad \tilde{\omega}_\mu^{(2)AB}=-\omega_\mu^{(2)BA},$$

$$\tilde{\phi}_{12}^{AB}=\phi_{21}^{BA}, \quad \tilde{\phi}_{21}^{AB}=\phi_{12}^{BA}, \quad \tilde{R}_{\mu\nu}^{AB}=-R_{\mu\nu}^{BA}.$$

Using these various constraints, the action takes the simplified form

$$\mathfrak{I}=\int d^4x\sqrt{e\tilde{e}}\,\mathfrak{L},$$

with

$$\mathfrak{L}=G^{\mu\nu}R_{\mu\nu}-\varepsilon g_{ab}^{\mu\nu}R_{\mu\nu}^{ba}+\tfrac{1}{4}\,\mathrm{Tr}(K.K^*)(G^{(\mu\nu)}W_\mu W_\nu+G^{[\mu\nu]}\partial_\mu W_\nu). \tag{36}$$

Notice that one can also add the following cosmological term J to the action (2.37):

$$J=\frac{\alpha}{2}(E^AE^{B^*}-E^{B^*}E^A,\xi^A\xi^{B^*}), \tag{37}$$

which becomes after simple calculations,

$$J=\alpha\int \sqrt{e\tilde{e}}d^4x(-2G^{[\mu\nu]}G_{[\mu\nu]}-2\ \mathrm{Tr}(K\cdot K^*)-8-G^{\mu\nu}_{ab}G^{ab}_{\nu\mu}). \tag{38}$$

Here α is an arbitrary constant.

Consequently, the total NGT action takes the following form:

$$\mathfrak{I}_{\mathrm{NGT}}=\int d^4x\sqrt{e\tilde{e}}\mathfrak{L}_{\mathrm{NGT}},$$

with

$$\mathfrak{L}_{\mathrm{NGT}}=\mathfrak{L}_{\acute{g}\mathrm{eom}}+\mathfrak{L}_{\mathrm{skew}}+\mathfrak{L}_c+\mathfrak{L}_W,$$

where

$$\text{Body Math}\quad \mathfrak{L}_{\mathrm{geom}}=G^{\mu\nu}R_{\mu\nu}-\tfrac{1}{4}\mathrm{Tr}(K\cdot K^*)G^{[\mu\nu]}W_{[\mu,\nu]}-\varepsilon g^{\mu\nu}_{ab}R^{ba}_{\mu\nu},$$

$$\text{Body Math}\quad \mathfrak{L}_W=\tfrac{1}{4}\mathrm{Tr}(K\cdot K^*)G^{(\mu\nu)}W_\mu W_\nu,$$

$$\text{Body Math}\quad \mathfrak{L}_{\mathrm{skew}}=-2\alpha G^{[\mu\nu]}G_{[\mu\nu]},$$

$$\text{Body Math}\quad \mathfrak{L}_c=-2\alpha\,\mathrm{Tr}(K\cdot K^*)-8\alpha-\alpha G^{\mu\nu}_{ab}G^{ab}_{\nu\mu},$$

and $G^{(\mu\nu)}$ (resp., $G^{[\mu\nu]}$) is the symmetric (resp., antisymmetric) part of $G^{\mu\nu}$. Notice that if one redefines the connection W_μ such that

$$(\tfrac{2}{3}-\tfrac{1}{4}\mathrm{Tr}(K\cdot K^*))W_\mu=\tfrac{2}{3}\overline{W}_\mu, \tag{39}$$

and using the fact that[12,13]

$$R_{\mu\nu}(W)=R_{\mu\nu}(\Gamma)+\tfrac{2}{3}W_{[\mu,\nu]}, \tag{40}$$

one obtains the following geometrical term $\mathfrak{L}_{\mathrm{geom}}$:

$$\mathfrak{L}_{\mathrm{geom}}=G^{\mu\nu}R_{\mu\nu}(\overline{W})-\varepsilon g^{\mu\nu}_{ab}R^{ba}_{\mu\nu},$$

where $\overline{W}^{\lambda}_{\mu\nu}$ is defined as

$$\overline{W}^{\lambda}_{\mu\nu}=\Gamma^{\lambda}_{\mu\nu}-\tfrac{2}{3}\delta^{\lambda}_{\mu}\overline{W}_\nu. \tag{41}$$

Setting $x=-\mathrm{Tr}(K\cdot K^*)$, one can write

$$\mathfrak{L}_W=\tfrac{1}{4}\mathrm{Tr}(K\cdot K^*)G^{(\mu\nu)}W_\mu W_\nu=-f(x)G^{(\mu\nu)}\overline{W}_\mu\overline{W}_\nu, \tag{42}$$

where

$$f(x)=\frac{1}{9}\frac{x}{(\frac{2}{3}+\frac{1}{4}x)^2}. \tag{43}$$

Now, it is worth mentioning that the term $\mathfrak{L}_W$ used in the Moffat's NGT Lagrangian has the form

$$\mathfrak{L}_W=\tfrac{1}{2}\sigma G^{(\mu\nu)}\overline{W}_\mu\overline{W}_\nu, \tag{44}$$

where σ was taken in an *ad-hoc* fashion to be equal to $-1/3$ for consistency with physics.

Notice that in our model, this value of σ comes out rather naturally since $1/2\sigma$ corresponds to the maximum of the $f(x)$ interaction coefficient.

V. CONCLUSIONS

In this work, we have been able to reformulate NGT in the formalism of noncommutative geometry without recourse to an additional scalar field (as it is the case for General Relativity). Moreover, all the terms which were put by hand by Moffat in his modified NGT action for physics consistency, were derived explicitly in our theory, with the added benefit of gaining some deeper geometrical insight. In particular, we have been able to attach a geometrical meaning to the coupling constant:

$$\mathfrak{L}_W = -f(x)G^{(\mu\nu)}\overline{W}_\mu\overline{W}_\nu,$$

where the value which maximizes our $f(x)$ corresponds exactly to the one chosen by Moffat.

Friedmann limits of rotating hypersurface–homogeneous dust models

Andrzej Krasiński[a)]
N. Copernicus Astronomical Center and School of Sciences, Polish Academy of Sciences, Bartycka 18, 00 716 Warszawa, Poland

(Received 13 February 2001; accepted for publication 21 March 2001)

The existence of Friedmann limits is systematically investigated for all the hypersurface–homogeneous rotating dust models, presented in previous papers by this author. Limiting transitions that involve a change of the Bianchi type are included. Except for stationary models that obviously do not allow it, the Friedmann limit expected for a given Bianchi type exists in all cases. Each of the three Friedmann models has parents in the rotating class; the $k=+1$ model has just one parent class, the other two each have several parent classes. The type IX class is the one investigated in 1951 by Gödel. For each model, the consecutive limits of zero rotation, zero tilt, zero shear, and spatial isotropy are explicitly calculated. [DOI: 10.1063/1.1378304]

I. MOTIVATION AND SUMMARY OF THE METHOD

In previous papers[1–3] a complete set of all metric forms was derived that can represent hypersurface–homogeneous rotating dust models. For each case, the generators of the symmetry algebra were found, the Bianchi type determined, and the metric form resulting from the Killing equations was explicitly presented. That classification was more detailed than the Bianchi classification because all possible orientations of the symmetry orbits in the spacetime were allowed, i.e., the orbits could be spacelike, timelike or null.

In a later paper,[4] one of the Bianchi type V models was investigated. Among the problems considered there was the question whether the model can reproduce the $k=-1$ Friedmann model in the limit of zero rotation, $\omega\to 0$. Since the coordinates that are well-suited to the classification are not suitable at all for considering the limit $\omega\to 0$, this limit could be taken only after a coordinate change and reparametrization of the metric.

In the present paper, the existence of the Friedmann limits is systematically investigated for all the other cases found in the classification in Refs. 1–3. The Bianchi type is allowed to change in the limiting transition. In all Bianchi type I cases the velocity field is tangent to the symmetry orbits, i.e., those models have matter density constant along the flow, and no expanding Friedmann model can be a subcase there. The same is true for the Bianchi type II from Ref. 1 and for both the subcases of case 1.1.1.2 in Ref. 2 which are of type III. In all the other cases the Friedmann limits that can be expected for a given Bianchi type do indeed exist.

The specialization to the Friedmann metrics is possible in so many cases because there is a free parameter in them that determines the tilt of the orbits with respect to the velocity field (with various values of the tilt parameter, the orbits may be spacelike, timelike or null). Whenever a Friedmann limit exists, the orbits are made orthogonal to the velocity field (''untilted'') during the limiting transition.

In order to make this paper readable independently of the other ones, the basic facts are briefly recalled here. More details can be found in Ref. 1.

The velocity field of a rotating dust, u^α, defines three scalar functions $\tau(x), \eta(x)$ and $\xi(x)$ such that

a)Electronic mail: akr@camk.edu.pl

$$u_\alpha = \tau_{,\alpha} + \eta\xi_{,\alpha}. \tag{1.1}$$

These functions (whose existence follows from the equations of motion via the Darboux theorem[1]) are determined up to the transformations:

$$\tau = \tau' - S(\xi', \eta'), \quad \xi = F(\xi', \eta'), \quad \eta = G(\xi', \eta'), \tag{1.2}$$

where the functions F and G obey

$$F_{,\xi'}G_{,\eta'} - F_{,\eta'}G_{,\xi'} = 1, \tag{1.3}$$

and then S is determined by

$$S_{,\xi'} = GF_{,\xi'} - \eta', \quad S_{,\eta'} = GF_{,\eta'}. \tag{1.4}$$

[Eq. (1.3) is the integrability condition of (1.4).]

Then, the continuity equation, $(nu^\alpha)_{;\alpha} = 0$, where n is the number density of the dust particles, implies that there exists one more function $\zeta(x)$ such that

$$\sqrt{-g}nu^\alpha = \varepsilon^{\alpha\beta\gamma\delta}\xi_{,\beta}\eta_{,\gamma}\zeta_{,\delta}, \tag{1.5}$$

where g is the determinant of the metric tensor and $\varepsilon^{\alpha\beta\gamma\delta}$ is the Levi-Civita symbol. The function ζ is determined up to the transformations

$$\zeta = \zeta' + T(\xi', \eta'), \tag{1.6}$$

where T is an arbitrary function.

The following relations hold then:

$$\begin{gathered} u^\alpha\tau_{,\alpha} = 1, \quad u^\beta\xi_{,\beta} = u^\beta\eta_{,\beta} = u^\beta\zeta_{,\beta} = 0, \\ \frac{\partial(\tau, \eta, \xi, \zeta)}{\partial(x^0, x^1, x^2, x^3)} = \sqrt{-g}n \neq 0. \end{gathered} \tag{1.7}$$

This shows that $\{\tau, \xi, \eta, \zeta\}$ can be chosen as coordinates, with τ being the time coordinate. They are called the Plebański coordinates. Denoting $\{\tau, \xi, \eta, \zeta\} = \{x^0, x^1, x^2, x^3\} = \{t, x, y, z\}$, we obtain for the velocity field u^α, the metric tensor $g_{\alpha\beta}$, the rotation tensor $\omega_{\alpha\beta}$ and the rotation vector w^α in these coordinates

$$\begin{gathered} u_\alpha = \delta^\alpha{}_0, \quad u_\alpha = \delta^0{}_\alpha + y\,\delta^1{}_\alpha, \\ g_{00} = 1, \quad g_{01} = y, \quad g_{02} = g_{03} = 0, \quad g \equiv \det(g_{\alpha\beta}) = -n^{-2}, \\ w^\alpha = n\,\delta^\alpha_3, \quad \omega_{\alpha\beta} = -\omega_{\beta\alpha} = \tfrac{1}{2}\,\delta^1{}_\alpha\delta^2{}_\beta. \end{gathered} \tag{1.8}$$

It is the last property that makes the limiting transition $\omega \to 0$ impossible without a coordinate transformation and reparametrization.

In these coordinates, if any Killing field is allowed by the metric it must be of the form

$$k^\alpha = (C + \phi - y\,\phi_{,y})\,\delta^\alpha{}_0 + \phi_{,y}\delta^\alpha{}_1 - \phi_{,x}\delta^\alpha{}_2 + \lambda\,\delta^\alpha{}_3, \tag{1.9}$$

where C is an arbitrary constant and $\phi(x,y)$ and $\lambda(x,y)$ are arbitrary functions. If $\phi_{,\alpha} \neq 0$ (i.e., ϕ is not constant on an open set), then the coordinates can be adapted to k^α within the Plebański class [by Eqs. (1.2)–(1.4) and (1.6)] so that

$$k^\alpha = \delta^\alpha{}_1. \tag{1.10}$$

The metric then becomes independent of x, and the coordinates preserving (1.10) are determined up to the transformations:

$$t'=t-\int yH_{,y}dy+A, \quad x'=x+H(y), \quad y'=y, \quad z'=z+T(y), \tag{1.11}$$

where A is an arbitrary constant and H,T are arbitrary functions.

If $\phi_{,\alpha}=0$, then the form of the Killing field $k^\alpha=C\delta^\alpha{}_0+\lambda\delta^\alpha{}_3$, is invariant under (1.2)–(1.6) and the Plebański coordinates cannot be adapted to k^α. The property $\phi=$const is equivalent to the following invariant relation:

$$k^\alpha=Cu^\alpha+(\lambda/n)w^\alpha, \tag{1.12}$$

i.e., k^α is then spanned on the velocity field and the rotation field.

If three Killing fields exist, then each of them can either be of the special type (1.12) or of the general type (1.9). One of the general-type Killing fields can always be transformed to the form (1.10) by (1.2)–(1.6).

This observation gives rise to a complete classification of all hypersurface–homogeneous space–times that are possible for a rotating dust. When all three Killing fields are of the special type (1.12), the symmetry orbits are two-dimensional, and this case is not considered. When two Killing fields are of the special type, while the third one is general, there exist two classes of metrics (Bianchi types I and II) that were derived in Ref. 1. When one Killing field is of the special type, while the two others are general, all Bianchi types except VIII and IX appear (Ref. 2). When all three Killing fields are of the general type, all the Bianchi types appear, some of them hidden as limits of more general types (Ref. 3). The multitude of cases is a consequence of the many possible alignments or misalignments among the three Killing fields and the velocity and rotation fields.

When the Bianchi classification is introduced, the generators of symmetry are scaled to standard forms such that all nonzero structure constants (except the free parameters in types VI_h and VII_h) become equal either to $+1$ or to -1. In general, though, they are arbitrary constants, and in the general form each of those constants can be allowed to become zero. In this way, the more special Bianchi types can be obtained from the more general ones by going to the zero limit with some of the structure constants. The resulting hierarchy of Bianchi types is well-known, and is shown in Fig. 1 (adapted from Ref. 5) for easy reference. The specializations that are possible can be instantly guessed from the values of the a, n_1, n_2, and n_3 parameters for the different Bianchi types. Type III cannot be specialized to IV or V because, with the arbitrary values of the parameters n_2 and n_3, the parameter a is determined by $a=\sqrt{-n_2n_3}$.

Another well-known result[6] is the placement of different Robertson–Walker geometries within the Bianchi classes. This is also recalled for easy reference. Since we are considering only dust models, we will call these geometries the Friedmann models and Friedmann limits of the rotating models.

The $k=0$ model is a subcase of the Bianchi types I and VII_0 (the two Bianchi algebras have different bases, but share common orbits).

The $k=-1$ model is a subcase of the Bianchi types V and VII_h.

The $k=+1$ model is a subcase of the Bianchi type IX.

When considering each case of the classification from Refs. 1–3, one has to recognize from Fig. 1 which of the four types {I, V, VII_0, VII_h, IX} could possibly be contained in it as a subcase and then the appropriate specialization of the arbitrary constants and functions in the model has to be considered. This procedure will be presented in more detail in Sec. II, later it will be applied without detailed explanations.

It will turn out that only the stationary models have no Friedmann limit. In every nonstationary case, the Friedmann limit indicated by the Bianchi type indeed exists. Note that the limits are found for the metrics, without taking into account the Einstein equations. This is why a nonsta-

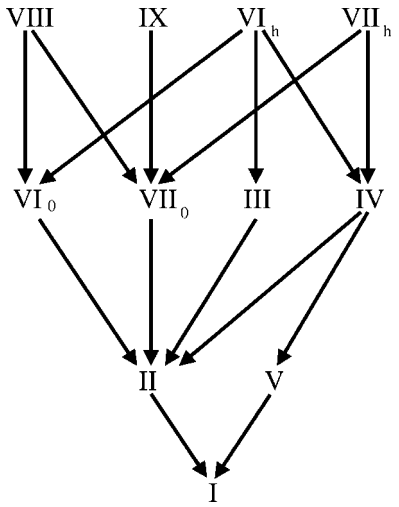

FIG. 1. The diagram shows how the different Bianchi types can be specialized by taking the zero limit of one or more of the structure constants. This allows to recognize (by the rules given at the end of Sec. I), which Friedmann models can possibly be contained as limits in a given class—see text. All the possibilities are actually realized in the collection considered in the paper.

tionary type II metric exists in the collection, and is found to admit the $k=0$ Friedmann limit, even though it is known[7,8] that spatially homogeneous type II dust solutions must have zero rotation, see Sec. III.

Now we shall systematically go over all the cases presented in Refs. 2 and 3. The two cases from Ref. 1 are immediately seen to admit no Friedmann limit: In both of them, the velocity field of the dust is spanned on the Killing fields [see Eqs. (7.7) and (7.8) in Ref. 1], so the particle number density n will obey $n_{,\alpha}u^{\alpha}=0$. Hence, these cases cannot contain any expanding Friedmann model because in the latter $n_{,\alpha}u^{\alpha}\neq 0$.

Each of the models presented in Refs. 2 and 3 that allows a Friedmann limit will be first transformed to the Plebański coordinates (most of them were found in coordinates adapted to the Killing fields that are not in the Plebański class). Then, each model will be transformed by a coordinate transformation and reparametrization of the metric functions and constants to such a form in which the limit of zero rotation can be calculated explicitly. Then, the Friedmann limits will be calculated by consecutively imposing on the metric the conditions of zero rotation, zero tilt, zero shear, and spatial isotropy (i.e., constant curvature in the three-spaces orthogonal to the dust flow). This last condition is not superfluous, even though dust with zero rotation and zero shear must be a Friedmann model in consequence of the Einstein equations.[9] It is conceivable that no Friedmann limit would exist at all in some classes. However, this does not happen, and a spatially isotropic subcase will be found to exist in all cases. The corresponding limits of the Killing fields, where nontrivial, will be also calculated and the Bianchi type of the limit determined.

Since on each of the underlying manifolds five vector fields exist (velocity, rotation, and the three Killing fields), the five vectors must be linearly dependent at each point. This linear relation allows to identify in each case the parameter that determines the tilt of the velocity field with respect to the symmetry orbits—see Sec. V. It turns out that this tilt parameter is always simply proportional to that defined by King and Ellis.[8]

II. THE CASES 1.1.1 OF REF. 2

We begin with case 1.1.1.1., which is of Bianchi type III.

The transformation from the coordinates used in Eq. (2.18) of Ref. 2 (that were adapted to the Killing fields) to the Plebański coordinates is given by Eq. (2.16) in Ref. 2 (where $\{t',x',Y,Z\}$ are

the coordinates of (2.18), and $\{t,x,y,z\}$ are the Plebański coordinates). The transformed metric is

$$
\begin{gathered}
g_{00}=1, \quad g_{01}=y, \quad g_{02}=g_{03}=0, \\
g_{11}=\left(\frac{Y}{2\lambda_3}\right)^2+\frac{1}{2\lambda_3^2}YZ+h_{11}-\frac{b}{\lambda_3}h_{12}Y+\left(\frac{1}{2}bY\right)^2 h_{22}, \\
g_{12}=h_{12}-\tfrac{1}{2}b\lambda_3 Y h_{22}, \quad g_{13}=C_3 h_{13}-\tfrac{1}{2}b^2 C_3 Y h_{23}, \\
g_{22}=\lambda_3^2 h_{22}, \quad g_{23}=bC_3\lambda_3 h_{23}, \quad g_{33}=(bC_3)^2 h_{33},
\end{gathered}
\tag{2.1}
$$

where b, C_3 and λ_3 are arbitrary constants, Y and Z are given by:

$$
Y=-b\lambda_3 t+\lambda_3 y+bC_3 z, \quad Z=b\lambda_3 t+\lambda_3 y-bC_3 z, \tag{2.2}
$$

and all the h_{ij}, $i,j=1,2,3$ are arbitrary functions of Z. The first line of Eq. (2.1) will be the same in all the other metrics transformed to the Plebański coordinates, so it will not be repeated from now on. Since the argument of h_{ij} is determined (by the Killing equations) only up to a constant factor, we are allowed to rescale it by an arbitrary factor. For considering the limit $\omega\to 0$, it will be convenient to assume that the argument of h_{ij} is

$$
T:=Z/(b\lambda_3)=t+y/b-(C_3/\lambda_3)z. \tag{2.3}
$$

This presupposes that $b\lambda_3\neq 0$, but this condition is included in the definition of case 1.1.1.1. The limit $\lambda_3=0$ can be taken into account after a simple reparametrization, and it leads to a stationary solution. The subcase $b=0$ is degenerate, and it belongs to the 1.1.2 family.

As seen from the last formula in (1.8), the simplest way to let $\omega\to 0$ is to transform y as follows:

$$
y=\omega_0\tilde{y}, \tag{2.4}
$$

and then let $\omega_0\to 0$, so that the only nonzero component of rotation in the new coordinates becomes

$$
\omega'_{12}=\omega_0\tilde{y}\xrightarrow[\omega_0\to 0]{}0. \tag{2.5}
$$

Then, however, the components g'_{12}, g'_{22}, and g'_{23} of the transformed metric would simultaneously go to zero, and the metric would become degenerate ($g=0$). To avoid this, h_{22} must be rescaled as follows:

$$
h_{22}=H_{22}/\omega_0^2. \tag{2.6}
$$

Then $g'_{12}=\omega_0 h_{12}-\frac{1}{2}b\lambda_3 Y H_{22}/\omega_0$ would become infinite in the limit $\omega_0\to 0$. To avoid this, h_{12} must be reset so that the infinity is cancelled. Since all h_{ij} depend on T, not on Y, this can be done as follows:

$$
h_{12}=H_{12}/\omega_0-\tfrac{1}{2}(b\lambda_3)^2 T H_{22}/\omega_0^2. \tag{2.7}
$$

The first term in (2.7) contains the ω_0 in the denominator for greater generality, so that $g'_{12}\xrightarrow[\omega_0\to 0]{}H_{12}\neq 0$. Then, to cancel the infinities in g_{11}, the function h_{11} must be reset as follows:

$$
h_{11}=H_{11}-\tfrac{1}{4}b^4(\lambda_3 T)^2 H_{22}/\omega_0^2-b^2 T h_{12}. \tag{2.8}
$$

The reparametrization (2.4), (2.6)–(2.8) would be sufficient to make the limit $\omega_0 \to 0$ of the metric (2.1) nondegenerate. However, the hypersurfaces $t = \text{const}$, that become orthogonal to the velocity field u^α in the limit $\omega_0 \to 0$, would not yet coincide with the hypersurfaces of constant matter density. In the Plebański coordinates, as seen from (1.8), the matter density obeys $g = -n^{-2}$, and so n would depend on $(t - C_3 z/\lambda_3)$ in the limit $\omega_0 \to 0$, i.e., the model would still be tilted. To untilt it, we must let $C_3 \to 0$, and this requires at least one more rescaling. It will be convenient to redefine C_3 as follows

$$C_3 = \omega_0 c, \tag{2.9}$$

so that the untilting occurs simultaneously with $\omega \to 0$. Then we must rescale h_{33}

$$h_{33} = H_{33}/\omega_0^2. \tag{2.10}$$

For greater generality, we will also rescale h_{23}

$$h_{23} = H_{23}/\omega_0^2, \tag{2.11}$$

and then h_{13} must be reset as follows:

$$h_{13} = H_{13}/\omega_0 - \tfrac{1}{2} b^3 \lambda_3 T H_{23}/\omega_0^2. \tag{2.12}$$

The transformation (2.4), applied to (2.1) together with all the subsequent reparametrizations, results in the following metric:

$$\begin{gathered}
g_{00} = 1, \quad g_{01} = \omega_0 \tilde{y}, \quad g_{02} = g_{03} = 0, \\
g_{11} = \frac{1}{4\lambda_3^2}[b\lambda_3 t(-2\lambda_3 \tilde{y} + 2bcz)\omega_0 + (\lambda_3 \tilde{y} + bcz)(3\lambda_3 \tilde{y} - bcz)\omega_0^2] \\
- \frac{1}{4}(bt)^2 + H_{11} - 2b\tilde{y} H_{12} + (b\lambda_3 \tilde{y})^2 H_{22}, \\
g_{12} = H_{12} - b\lambda_3^2 \tilde{y} H_{22}, \quad g_{13} = cH_{13} - b^2 c \lambda_3 \tilde{y} H_{23}, \\
g_{22} = \lambda_3^2 H_{22}, \quad g_{23} = bc\lambda_3 H_{23}, \quad g_{33} = (bc)^2 H_{33},
\end{gathered} \tag{2.13}$$

where the H_{ij} depend only on t. Here, similarly as in (2.1), the first line will be the same for every metric, and so it will not be repeated from now on.

The metric (2.13) still has nonzero shear. If a Friedmann model is to result from it, the shear must be set to zero. The coordinates $\{t,x,y,z\}$ in (2.13) are now comoving and synchronous, so zero shear means that

$$g_{ij} = G_{ij}(x,y,z) R^2(t), \tag{2.14}$$

i.e., all the components of the metric must depend on time only through the same factor $R^2(t)$. This means:

$$\begin{gathered}
H_{11}(t) = \tfrac{1}{4} b^2 t^2 - C_{11} R^2(t), \\
\text{other } H_{ij}(t) = -C_{ij} R^2(t),
\end{gathered} \tag{2.15}$$

where C_{ij} are unknown constants. With no loss of generality, it may be assumed that

$$C_{33} = 1. \tag{2.16}$$

The metric (2.13) with H_{ij} as in (2.15) and (2.16) will represent a Friedmann model when the hypersurfaces $t=\text{const}$ are spaces of constant curvature. In order to calculate this curvature, it is convenient to introduce the new constants D_{11}, D_{12}, and D_{22} by

$$D_{22}{}^2 := C_{22} - C_{23}{}^2, \quad D_{12} := (C_{12} - C_{13}C_{23}/b)/(\lambda_3 D_{22}),$$
$$D_{11}{}^2 := C_{11} - C_{13}{}^2/b^2 - D_{12}{}^2. \tag{2.17}$$

The correct signs for $D_{11}{}^2$ and $D_{22}{}^2$ are guaranteed by the signature of (2.13). Then (2.13) may be written as follows:

$$\begin{aligned} \mathrm{d}s^2 = {} & \mathrm{d}t^2 - (D_{11}R\,\mathrm{d}x)^2 - R^2[(D_{12} - b\lambda_3 D_{22}y)\mathrm{d}x + \lambda_3 D_{22}\mathrm{d}y]^2 \\ & - R^2[(C_{13}/b - b\lambda_3 C_{23}y)\mathrm{d}x + \lambda_3 C_{23}\mathrm{d}y + bc\,\mathrm{d}z]^2, \end{aligned} \tag{2.18}$$

and the curvature tensor for the spaces $t=\text{const}$ may be easily calculated using the orthonormal set of differential forms suggested by (2.18). The curvature tensor is

$$R^{12}{}_{12} = \tfrac{3}{4}F^2G^2 + F^2, \quad R^{13}{}_{13} = R^{23}{}_{23} = -\tfrac{1}{4}F^2G^2, \tag{2.19}$$

where

$$F := b/(D_{11}R), \quad G := C_{23}/D_{22}. \tag{2.20}$$

The Riemann tensor (2.19) will represent constant curvature when $R^{12}{}_{12} = R^{13}{}_{13}$. This implies $b=0$, which seems to be a singular limit of (2.18). However, the limit $b\to 0$ may be easily incorporated into (2.18) by the following reparametrization:

$$C_{13} = D_{13}b, \quad c = C/b. \tag{2.21}$$

After this, the Riemann tensor of the space $t=\text{const}$ still has the same form (2.19)–(2.20). With $b=0$, $R^{ij}{}_{kl} \equiv 0$, i.e., (2.18) represents then the $k=0$ Friedmann model. This is the Friedmann limit of the metric (2.1), as expected for Bianchi type III.

In this case, the coordinates of the Friedmann limit are similar to those usually used (they are the nonorthogonal Cartesian coordinates for the flat space $t=\text{const}$). This will not be so in most other cases—the coordinate representation of the resulting Friedmann limit will be rather exotic, and calculating the Riemann tensor of the subspace $t=\text{const}$ will be the simplest way to check that it is the Friedmann metric indeed.

The Killing fields for the metric (2.1) are (see Ref. 2)

$$k^\alpha_{(1)} = \delta^\alpha_1, \quad k^\alpha_{(2)} = \mathrm{e}^{bx}(\delta^\alpha_0 - b\,\delta^\alpha_2), \quad k^\alpha_{(3)} = C_3\delta^\alpha_0 + \lambda_3\delta^\alpha_3. \tag{2.22}$$

As seen from Fig. 1, the algebra of type III can be specialized only to types II and I, and so the $k=0$ Friedmann limit is the only one of the three that can be expected here. Note that the Killing field $k_{(2)}$ will have a meaningful limit $\omega\to 0$, $b\to 0$ only if the two limits are tuned so that $\omega_0/b \xrightarrow[\omega_0\to 0]{} 0$ (for example, $b = B\sqrt{\omega_0}$). Then $l^\alpha_{(2)} := (\omega_0/b)k^\alpha_{(2)} \xrightarrow[\omega_0\to 0]{} \delta^\alpha{}_2$, which is indeed a Killing field of (2.18) with $b=0$. The algebra $\{k_{(1)}, l_{(2)}, k_{(3)}\}$ becomes then Bianchi type I when $\omega_0 = 0$, as expected.

The reasoning behind the reparametrizations, and the subsequent calculation of the limits of zero rotation, zero tilt, zero shear, and constant curvature of the spaces $t=\text{const}$, follows the same scheme in all the other cases. Therefore, it will be presented in less detail from now on. In some of the cases, the reparametrization that untilts the limit $\omega\to 0$ is a necessary condition for cancelling the infinities introduced by the earlier reparametrizations.

The other two subcases of case 1.1.1 in Ref. 2, i.e., cases 1.1.1.2.1 [Eq. (3.16)] and 1.1.1.2.2 [Eq. (3.32)] are immediately seen to allow no Friedmann limit. For both of them, the Killing fields are given by (2.22) above with $\lambda_3=0$. As seen from (1.8), the Killing field $k_{(3)}$ coincides then with the velocity field of dust, and so both these models are stationary.

In fact, the last of (2.22) is the linear relation among the five vectors mentioned at the end of Sec. I, because it is equivalent to (1.12). Since with $\lambda_3=0$ the velocity becomes one of the Killing fields, i.e., becomes tangent to the symmetry orbits, λ_3 is the tilt parameter. More on this—see Sec. V.

III. CASES 1.1.2 OF REF. 2

The case 1.1.2.1 is again of Bianchi type III. The transformation back from the coordinates of Eq. (4.6) in Ref. 2 (adapted to two Killing fields) to the Plebański coordinates is given by (4.4) in Ref. 2, with the roles of $\{x^\alpha\}$ and $\{x'^\alpha\}$ interchanged. The transformed metric is

$$g_{11}=-2(c/a)y-(c/a)^2+Y^2h_{11}-2(c/a)\lambda_3 Yh_{13}+(c\lambda_3/a)^2h_{33},$$

$$g_{12}=h_{12}-\frac{c\lambda_3}{aY}h_{23},\quad g_{13}=C_3Yh_{13}-(c/a)\lambda_3C_3h_{33}, \tag{3.1}$$

$$g_{22}=h_{22}/Y^2,\quad g_{23}=C_3h_{23}/Y,\quad g_{33}=C_3^2h_{33},\quad Y:=ay+c,$$

where a, c and λ_3 are arbitrary constants and h_{ij} are arbitrary functions of the variable

$$T:=t-C_3z/\lambda_3. \tag{3.2}$$

The reparametrization that will allow setting the rotation and tilt to zero is

$$(y,C_3)=\omega_0(\tilde{y},D),$$

$$h_{11}=H_{11}+(\lambda_3/a)^2H_{33}/\omega_0^2,\quad h_{12}=H_{12}/\omega_0+(\lambda_3/a)H_{23}/\omega_0^2,$$

$$h_{13}=H_{13}+(\lambda_3/a)H_{33}/\omega_0^2,\quad (h_{22},h_{23},h_{33})=(H_{22},H_{23},H_{33})/\omega_0^2. \tag{3.3}$$

The reparametrized metric (without the limit $\omega_0\to 0$ taken yet) is

$$g_{11}=-(c/a)^2-2(c/a)\omega_0\tilde{y}+\tilde{Y}^2H_{11}-2(c/a)\lambda_3\tilde{Y}H_{13}+(\lambda_3\tilde{y})^2H_{33},$$

$$g_{12}=H_{12}+(\lambda_3\tilde{y}/\tilde{Y})H_{23},\quad g_{13}=D\omega_0\tilde{Y}H_{13}+D\lambda_3\tilde{y}H_{33}, \tag{3.4}$$

$$g_{22}=H_{22}/\tilde{Y}^2,\quad g_{23}=DH_{23}/\tilde{Y},\quad g_{33}=D^2H_{33},\quad \tilde{Y}=a\omega_0\tilde{y}+c.$$

Similarly as before, in the limit $\omega_0\to 0$ the H_{ij} will depend only on t, and the subsequent limit of zero shear is $H_{11}=-C_{11}R^2(t)+(c/a)^2$, other $H_{ij}(t)=-C_{ij}R^2(t)$, $C_{33}=1$. Proceeding exactly as in Sec. II, we then find that the hypersurfaces $t=\text{const}$ will have constant curvature when $\lambda_3\to 0$; the resulting limit is the Friedmann $k=0$ model, as expected for type III. The limits $C_3\to 0$ and $\lambda_3\to 0$ should be tuned so that $C_3/\lambda_3 \xrightarrow[\omega_0\to 0]{} 0$, e.g., $\lambda_3=L_3\omega_0{}^{1/2}$.

The case 1.1.2.2 [Eqs. (4.12)–(4.33) in Ref. 2] is of Bianchi type II. It is known from the paper by Ozsváth,[7] and from Theorem 3.1 by King and Ellis,[8] that dust models of type II have zero rotation. However, that thesis was proven with use of the Einstein equations in Ref. 7 and of the Ellis evolution equations[9] in Ref. 8, that include consequences of the Einstein equations. In the approach of Refs. 1–3, the Einstein equations were not used. Moreover, the constant λ_3 plays the role of the tilt parameter here—with $\lambda_3=0$, the metric becomes stationary (the orbits of the symmetry group become timelike and tangent to the velocity field of the dust), and this case is not

covered in Refs. 7 and 8. This is why the case 1.1.2.2 could show up in our consideration. This observation implies a warning: The existence of a Friedmann limit of the metric does not guarantee that the Einstein equations will allow a rotating generalization of a given Bianchi type of the corresponding Friedmann model. A rotating dust solution and the Friedmann solution may turn out to be two disjoint subclasses within that type.

The metric [Eq. (4.13) from Ref. 2] transformed back to the Plebański coordinates [by the inverse of (4.4) from Ref. 2] is

$$\begin{gathered} g_{11}=h_{11}+2\lambda_3 y h_{13}+y^2(1+\lambda_3^2 h_{33}), \\ g_{12}=h_{12}+\lambda_3 y h_{23}, \quad g_{13}=C_3(h_{13}+\lambda_3 y h_{33}), \\ (g_{22},g_{23},g_{33})=(h_{22},C_3 h_{23},C_3^2 h_{33}), \end{gathered} \tag{3.5}$$

where the h_{ij} are arbitrary functions of the T from (3.2). The limit of zero rotation and zero tilt is achieved after the reparametrization

$$\begin{gathered} (y,C_3)=\omega_0(\tilde{y},D), \\ (h_{12},h_{13})=(H_{12},H_{13})/\omega_0, \quad (h_{22},h_{23},h_{33})=(H_{22},H_{23},H_{33})/\omega_0^2, \end{gathered} \tag{3.6}$$

and the reparametrized metric is

$$\begin{gathered} g_{11}=(\omega_0\tilde{y})^2+h_{11}+2\lambda_3\tilde{y}H_{13}+(\lambda_3\tilde{y})^2 H_{33}, \\ g_{12}=H_{12}+\lambda_3\tilde{y}H_{23}, \quad g_{13}=D(H_{13}+\lambda_3\tilde{y}H_{33}), \\ (g_{22},g_{23},g_{33})=(H_{22},DH_{23},D^2H_{33}). \end{gathered} \tag{3.7}$$

The $k=0$ Friedmann limit will result now when $\omega_0=0$, $H_{ij}=-C_{ij}R^2$, and $\lambda_3=0$.

The theorem by King and Ellis mentioned above implies that $\omega_0=0$ will follow when (3.7) is substituted in the Einstein equations.

The Killing fields for the metric (3.1) are

$$\begin{gathered} k^\alpha_{(1)}=\delta^\alpha{}_1, \quad k^\alpha_{(3)}=C_3\delta^\alpha{}_0+\lambda_3\delta^\alpha{}_3, \\ k^\alpha_{(2)}=cx\,\delta^\alpha{}_0+ax\,\delta^\alpha{}_1-(ay+c)\,\delta^\alpha{}_2+(c\lambda_3/C_3)x\,\delta^\alpha{}_3. \end{gathered} \tag{3.8}$$

[The Killing fields for (3.5) result when $a=0$ above.] After the reparametrization (3.3), in the limit $\omega_0\to 0$, the basis (3.8) becomes

$$\begin{gathered} k^\alpha_{(1)}=\delta^\alpha{}_1, \quad l^\alpha_{(3)}:=(1/\lambda_3)k^\alpha_{(3)} \xrightarrow[\omega_0\to 0]{} \delta^\alpha{}_3, \\ l^\alpha_{(2)}=-(\omega_0/c)k^\alpha_{(2)} \xrightarrow[\omega_0\to 0]{} \delta^\alpha{}_2-(\lambda_3/D)x\,\delta^\alpha{}_3. \end{gathered} \tag{3.9}$$

In the Friedmann limit $\lambda_3\to 0$, the generators (3.9) become a Bianchi type I algebra.

IV. CASES 1.2 AND 2 OF REF. 2

All of these allow both the $k=0$ and the $k=-1$ Friedmann limits.

Case 1.2.1.1 is of Bianchi type VI_h with the free parameter $(b^2+f^2)/(b^2-f^2)$ (there is a typo in Ref. 2). In this case [Eqs. (5.6)–(5.7) in Ref. 2], the transformation back to the Plebański coordinates is given by (5.5) from Ref. 2, with the roles of x^α and x'^α interchanged. The resulting metric is

$$g_{11}=h_{11}-2bt(y-bh_{12})-2Zh_{13}+(bt)^2(b^2h_{22}-1)-2b^2tZh_{23}+Z^2h_{33},$$

$$g_{12}=h_{12}+b^2th_{22}-Zh_{23},\quad g_{13}=h_{13}+b^2th_{23}-Zh_{33}, \tag{4.1}$$

$$(g_{22},g_{23},g_{33})=(h_{22},h_{23},h_{33}),\quad Z:=fz,$$

where b and f are arbitrary constants, and h_{ij} are arbitrary functions of

$$T=t+y/b. \tag{4.2}$$

The limit of zero rotation (that will automatically untilt the model) is achieved by the reparametrization

$$y=\omega_0\tilde{y},\quad h_{22}=H_{22}/\omega_0^2,\quad h_{23}=H_{23}/\omega_0,$$

$$h_{11}=H_{11}+(bT)^2-2b^2Th_{12}-b^4T^2H_{22}/\omega_0^2, \tag{4.3}$$

$$h_{12}=H_{12}/\omega_0-b^2TH_{22}/\omega_0^2,\quad h_{13}=H_{13}-b^2TH_{23}/\omega_0,$$

and the reparametrized metric is

$$g_{11}=(\omega_0\tilde{y})^2+H_{11}-2b\tilde{y}H_{12}-2ZH_{13}+(b\tilde{y})^2H_{22}+2b\tilde{y}ZH_{23}+Z^2h_{33},$$

$$g_{12}=H_{12}-b\tilde{y}H_{22}-ZH_{23},\quad g_{13}=H_{13}-b\tilde{y}H_{23}-Zh_{33}, \tag{4.4}$$

$$(g_{22},g_{23},g_{33})=(H_{22},H_{23},h_{33}).$$

With $\omega_0=0$, the shearfree limit will result when all $h_{ij}=-C_{ij}R^2(t)$, and then the $k=-1$ Friedmann model results when $b=f\neq 0$. The $k=0$ Friedmann limit results when $b=f=0$. This is the first instance where the coordinates of the $k=-1$ Friedmann limit come out rather exotic. From now on, this will be the rule.

The Killing fields for the metric (4.1)–(4.2) are

$$k^\alpha_{(1)}=\delta^\alpha{}_1,\quad k^\alpha_{(2)}=e^{bx}(\delta^\alpha{}_0-b\,\delta^\alpha{}_2),\quad k^\alpha_{(3)}=e^{fx}\delta^\alpha{}_3. \tag{4.5}$$

In the $k=-1$ Friedmann limit that will result by the first of (4.3) and $b=f$, $k^\alpha_{(1)}$ remains unchanged, $k^\alpha_{(3)}$ becomes $e^{bx}\delta^\alpha{}_{(3)}$, while $k^\alpha_{(2)}$ is replaced by

$$l^\alpha_{(2)}=(-\omega_0/b)k^\alpha_{(2)}\xrightarrow[\omega_0\to 0]{}\ e^{bx}\delta^\alpha{}_2. \tag{4.6}$$

This is of Bianchi type V, and in the further limit $b=f=0$ it becomes type I.

In the case 1.2.1.2 [Eq. (5.10) in Ref. 2], which is of type IV, the transformation back to the Plebański coordinates is given by Eq. (5.9) there. The whole further calculation is similar to (4.1)–(4.4) above. Instead of the last formula in (4.1) we have

$$Z:=ct+bz, \tag{4.7}$$

where c is one more arbitrary constant, and in (4.3) we have:

$$h_{11}=H_{11}+(bT)^2-2b^2Th_{12}+2cTH_{13}-b^4T^2H_{22}/\omega_0^2+(cT)^2h_{33},$$

$$h_{12}=H_{12}/\omega_0-b^2TH_{22}/\omega_0^2+cTH_{23}/\omega_0,\quad h_{13}=H_{13}-b^2TH_{23}/\omega_0+cTh_{33}. \tag{4.8}$$

The reparametrized metric is

$$g_{11}=(\omega_0\tilde{y})^2(1+c^2h_{33}/b^2)+2c\omega_0\tilde{y}(H_{13}/b-\tilde{y}H_{23}-zh_{33})+H_{11}-2b\tilde{y}H_{12}$$
$$-2bzH_{13}+(b\tilde{y})^2H_{22}+2b^2\tilde{y}zH_{23}+(bz)^2h_{33},$$

$$g_{12}=\omega_0(c/b)\tilde{y}H_{23}+H_{12}-b\tilde{y}H_{22}-bzH_{23}, \tag{4.9}$$

$$g_{13}=\omega_0(c/b)\tilde{y}h_{33}+H_{13}-b\tilde{y}H_{23}-bzh_{33}, \quad (g_{22},g_{23},g_{33})=(H_{22},H_{23},H_{33}).$$

The limit $\omega_0\to 0$ of (4.9) is the same as the limit $\omega_0\to 0$ of (4.4) with $b=f$. Hence, the $k=-1$ Friedmann limit will result from (4.9) when $\omega_0=0$ and $h_{ij}=-C_{ij}R^2(t)$, without any further limitations. The $k=0$ Friedmann limit will result when $b=0$ in addition.

For the case 1.2.2.1 [Eqs. (5.17) and (5.18) in Ref. 2], which is of Bianchi type VI_h, the subcase $C=j+a=0$ is identical to the subcase $c=0$ of case 1.2.2.2, and so the Friedmann limits will be the same (see below).

The case 1.2.2.2 [Eq. (5.19) in Ref. 2], which is of Bianchi type IV, allows the special case $c=0$, where the Bianchi type becomes V. This special case was investigated in detail in Ref. 4, and it was shown there how the $k=-1$ Friedmann limit is obtained. In order to obtain the $k=0$ Friedmann limit, one has to apply the following transformation and rescaling to Eq. (3.5) in Ref. 4:

$$y=\mathrm{e}^{\alpha u}, \quad K=\tilde{K}/\alpha, \tag{4.10}$$

and then take the limit $\alpha\to 0$.

All the subcases of case 2 in Ref. 2 have matter density constant along the dust flow: In case 2.1.1 (type I) and both cases 2.1.2 (types II and I), the velocity field is tangent to the symmetry orbits, in case 2.2 (type I), the velocity field coincides with one of the Killing fields. Therefore, no Friedmann limits will exist there.

With this, all cases of Ref. 2 are exhausted.

V. CASE 1.1.1.1 OF REF. 3

In the cases considered in Ref. 3, each of the three Killing vectors is linearly independent of the velocity and rotation. However, the five vectors existing in each four-dimensional tangent space to the manifold cannot form a linearly independent set. The three-dimensional space spanned by the Killing vectors, K_3, must intersect with the two-dimensional plane spanned by the velocity and rotation, H_2, along at least one direction. In the models of Ref. 1, the whole H_2 plane was a subspace of the K_3 space. In consequence, the velocity was a linear combination of the Killing vectors, and so those models were stationary. In the models of Ref. 2, considered up to now, the plane H_2 and the space K_3 intersected along the direction of the Killing vector $k^\alpha_{(3)}=C_3u^\alpha+(\lambda_3/n)w^\alpha$. From now on, the line of intersection will not coincide with any Killing direction. Hence, in each case an equation of the following form will have to hold:

$$a_1k^\alpha_{(1)}+a_2k^\alpha_{(2)}+a_3k^\alpha_{(3)}=b_1u^\alpha+b_2w^\alpha, \tag{5.1}$$

where a_i and b_i are functions on the manifold. Note that if $b_2=0$, then the velocity field is tangent to the symmetry orbits, and in consequence such a model has zero expansion and matter-density independent of the comoving time (the metric may depend on the time only because in general the metric has shear). Hence, b_2 is a measure of the tilt of the velocity field with respect to the orbits. Its relation to the tilt defined by King and Ellis[8] will be explained below [see after Eq. (5.6)].

The case 1.1.1.1, given by Eqs. (2.28) and (2.29) in Ref. 3, is of Bianchi type VI_h. The transformation back to the Plebański coordinates is given by Eq. (2.27) in Ref. 3, and the result is

$$
\begin{aligned}
g_{11}&=\frac{f^2(b+f)}{b^2(b-f)}U^2-2\frac{f}{b-f}U(ft+y)+h_{11}-2Vh_{12}-2\frac{f\gamma}{b\beta(b-f)}Uh_{13}+V^2h_{22}\\
&\quad+2\frac{f\gamma}{b\beta(b-f)}UVh_{23}+\left[\frac{f\gamma}{b\beta(b-f)}\right]^2U^2h_{33},\\
g_{12}&=V/b^2+h_{12}-Vh_{22}-\frac{f\gamma}{b\beta(b-f)}Uh_{23},\\
g_{13}&=h_{13}-Vh_{23}-\frac{f\gamma}{b\beta(b-f)}Uh_{33},\\
g_{22}&=-1/b^2+h_{22},\quad (g_{23},g_{33})=(h_{23},h_{33}),
\end{aligned}
\tag{5.2}
$$

where b, f, β and γ are arbitrary constants, the h_{ij} are arbitrary functions of the argument:

$$T=t+y/b-\beta(b-f)z/\gamma, \tag{5.3}$$

and U and V stand for

$$U=bt+y,\quad V=bft+(b+f)y. \tag{5.4}$$

The Killing fields for the metric (5.2) are:

$$
\begin{aligned}
k^\alpha_{(1)}&=\delta^\alpha_1,\quad k^\alpha_{(2)}=\mathrm{e}^{fx}\{\delta^\alpha_0-f\delta^\alpha_2+[\gamma/(b\beta)]\delta^\alpha_3\},\\
k^\alpha_{(3)}&=\mathrm{e}^{bx}(-\delta^\alpha_0+b\delta^\alpha_2).
\end{aligned}
\tag{5.5}
$$

From (1.8) it follows then that:

$$b\mathrm{e}^{-fx}k^\alpha_{(2)}+f\mathrm{e}^{-bx}k^\alpha_{(3)}=(b-f)u^\alpha+[\gamma/(n\beta)]w^\alpha. \tag{5.6}$$

This is the Eq. (5.1) specified for the case 1.1.1.1. As remarked above, when $\gamma=0$, the velocity field becomes tangent to the symmetry orbits. [With $\gamma\to0$, the argument of h_{ij} given by (5.2) has to be redefined so that it becomes $Z=\gamma T \xrightarrow[\gamma\to0]{} -\beta(b-f)z$.]

This means that the parameter (γ/β) is a measure of the tilt of the velocity field with respect to the symmetry orbits. Indeed, the measure of tilt defined by King and Ellis[8] is proportional to (γ/β). They defined the hyperbolic angle of tilt $\overline{\beta}$ by

$$\cosh\overline{\beta}=u^\alpha n_\alpha \tag{5.7}$$

(the difference in sign from their paper is a consequence of the difference in signature), where n_α is the unit vector normal to the orbits of symmetry. This definition of $\overline{\beta}$ makes sense only when both u^α and n^α are timelike vectors; the cases of n^α being null or spacelike are not considered in Ref. 8. However, $u^\alpha n_\alpha$ is a measure of the tilt also for nontimelike n^α. In particular, when u^α is tangent to the symmetry orbits, $u^\alpha n_\alpha=0$. The vector n^α is related to the Killing fields by

$$n_\alpha=N_\alpha/\sqrt{-g_{\mu\nu}N^\mu N^\nu}:=N_\alpha/\|N\|, \tag{5.8}$$

where

$$N_\alpha=\frac{1}{\sqrt{-g}}\varepsilon_{\alpha\beta\gamma\delta}k^\beta_{(1)}k^\gamma_{(2)}k^\delta_{(3)}. \tag{5.9}$$

In our case then

$$u^\alpha n_\alpha = \|N\|^{-1} N_\alpha u^\alpha = \frac{1}{\|N\|\sqrt{-g}} \mathrm{e}^{(b+f)x} \gamma/\beta. \tag{5.10}$$

Analogs of (5.1) and (5.6) will exist in every case considered from now on. In the models of Ref. 2, considered up to now, where the Killing field $k^\alpha_{(3)}$ always had the form $k^\alpha_{(3)} = C_3 u^\alpha + (\lambda_3/n) w^\alpha$, λ_3 was a measure of the tilt.

For calculating the limit of zero rotation and zero shear, the following reparametrization is useful:

$$\begin{gathered}
(y,\beta) = \omega_0(\tilde{y},B), \quad h_{22} = H_{22}/\omega_0^2, \quad h_{23} = H_{23}/\omega_0, \\
h_{11} = (fT)^2 + H_{11} + 2bfTh_{12} + 2(f^2/D)Th_{13}/\omega_0 - (bfT)^2 H_{22}/\omega_0^2 \\
- 2(bf^3/D)T^2 H_{23}/\omega_0^2 - (f^4/D^2)T^2 h_{33}/\omega_0^2, \\
h_{12} = H_{12}/\omega_0 + bfTH_{22}/\omega_0^2 + (f^2/D)TH_{23}/\omega_0^2, \\
h_{13} = H_{13} + bfTH_{23}/\omega_0 + (f^2/D)Th_{33}/\omega_0, \\
D := f(b-f)B/\gamma.
\end{gathered} \tag{5.11}$$

The reparametrized metric is

$$\begin{gathered}
g_{11} = -2\,ftW\omega_0 + [(Dz)^2 - 2(f/b)\tilde{y}W]\omega_0^2 + H_{11} - 2bWH_{12} \\
- 2\,fzH_{13} + (bW)^2 H_{22} + 2bfzWH_{23} + (fz)^2 H_{33}, \\
g_{12} = (ft/b)\omega_0 + [(b+f)/b^2]\tilde{y}\omega_0^2 + H_{12} - bWH_{22} - fzH_{23}, \\
g_{13} = H_{13} - bWH_{23} - fzh_{33}, \\
(g_{22}, g_{23}, g_{33}) = (H_{22}, H_{23}, h_{33} = H_{33}), \quad W := y + Dz.
\end{gathered} \tag{5.12}$$

The $k=-1$ Friedmann limit results now from (5.12) when $\omega_0 = 0$ (after which all h_{ij} depend only on t), and

$$H_{ij} = -C_{ij}R^2(t), \quad C_{33} = 1, \quad b = f. \tag{5.13}$$

[The last of (5.13) implies $D=0$.] The $k=0$ Friedmann limit results when in addition

$$b = f = 0. \tag{5.14}$$

The reparametrization (5.11) transforms the Killing fields $k^\alpha_{(2)}$ and $k^\alpha_{(3)}$ from (5.5) as follows:

$$\begin{gathered}
l^\alpha_{(2)} = (b\beta/\gamma)k^\alpha_{(2)} \xrightarrow[\omega_0 \to 0]{} \mathrm{e}^{fx}[-(bf\beta/\gamma)\delta^\alpha{}_{(2)} + \delta^\alpha{}_{(3)}] \\
l^\alpha_{(3)} = (\omega_0/b)k^\alpha_{(3)} \xrightarrow[\omega_0 \to 0]{} \mathrm{e}^{bx}\delta^\alpha{}_{(2)}.
\end{gathered} \tag{5.15}$$

In the $k=-1$ Friedmann limit ($b=f$), together with $k^\alpha_{(1)}$, this becomes a Bianchi type V algebra, and in the $k=0$ Friedmann limit ($b=f=0$), it becomes type I.

VI. CASE 1.1.1.2 OF REF. 3

This case is given by Eqs. (3.7)–(3.11) in Ref. 3. It is of Bianchi type VIII or VI_0 (when $g \neq 0$ or $g=0$, respectively), so only the $k=0$ Friedmann limit may exist here. The limit of zero rotation and zero tilt can be considered without transforming the metric back to the Plebański form, but the three subcases have to be considered separately.

The Killing fields in this case are

$$k^\alpha_{(1)}=\delta^\alpha_1, \quad k^\alpha_{(3)}=\mathrm{e}^{\alpha_1 x}\delta^\alpha_2,$$
$$k^\alpha_{(2)}=\mathrm{e}^{-\alpha_1 x}[2gy\,\delta^\alpha_1+\alpha_1(gy^2+2B)\,\delta^\alpha_2+\delta^\alpha_3]. \tag{6.1}$$

The analog of Eq. (5.1) is

$$k^\alpha_{(2)}-\alpha_1(gy^2+2B)\mathrm{e}^{-2\alpha_1 x}k^\alpha_{(3)}-2gy\mathrm{e}^{-\alpha_1 x}k^\alpha_{(1)}=\mathrm{e}^{-\alpha_1 x}[4Bu^\alpha+(8c\gamma\alpha_1/n)w^\alpha], \tag{6.2}$$

and, consequently, the King–Ellis measure of tilt is

$$\sqrt{-g}N_\alpha u^\alpha=\alpha_1, \tag{6.3}$$

[N_α is given by (5.8)].

The argument of the arbitrary functions in the metric is

$$T=t+y/\alpha_1-\frac{B}{2c\gamma\alpha_1}z. \tag{6.4}$$

In case I ($gB\neq 0$), the reparametrization needed is

$$y=\omega_0\tilde{y}, \quad B=\omega_0{}^{3/4}\tilde{B}, \quad \alpha_1=\omega_0^{1/4}a_1, \tag{6.5}$$

$$(h_{13},k_{13})=(G_{13},K_{13})\omega_0, \quad h_{22}=G_{22}/\omega_0^2. \tag{6.6}$$

The full reparametrized metric, with $\omega_0\neq 0$, is rather complicated here, so only the limit $\omega_0\to 0$ will be quoted:

$$\mathrm{d}s^2=\mathrm{d}t^2+h_{11}\mathrm{d}x^2+G_{22}\mathrm{d}y^2-\frac{h_{33}}{2\tilde{B}a_1}\mathrm{d}y\mathrm{d}z+h_{33}\mathrm{d}z^2. \tag{6.7}$$

The $k=0$ Friedmann limit results when further $h_{11}=G_{22}=h_{33}=-R^2(t)$.

As seen from (6.1), the symmetry group becomes Bianchi type I in the limit $\omega_0\to 0$ after the reparametrization (6.4) [the Killing field $k_{(3)}$ has to be replaced by $l_{(3)}=\omega_0 k_{(3)}$ in order that the limit is nonsingular].

In case II ($B=0$), Eq. (6.5) remains unchanged, while (6.6) is replaced by

$$(h_{12},h_{23})=(G_{12},G_{23})\omega_0, \quad h_{22}=G_{22}/\omega_0^2. \tag{6.8}$$

The limit $\omega_0\to 0$ of the reparametrized metric is:

$$\mathrm{d}s^2=\mathrm{d}t^2+h_{11}\mathrm{d}x^2+2G_{12}\mathrm{d}x\mathrm{d}y+2h_{13}\mathrm{d}x\mathrm{d}z+G_{22}\mathrm{d}y^2+h_{33}\mathrm{d}z^2, \tag{6.9}$$

where all the metric components depend only on t. The $k=0$ Friedmann limit is here

$$G_{12}=h_{13}=0, \quad h_{11}=G_{22}=h_{33}=-R^2(t). \tag{6.10}$$

In case III ($g=0$, Bianchi type VI_0), the $k=0$ Friedmann limit results again by (6.5), (6.8), (6.9) and (6.10).

Note two typos in Sec. III of Ref. 3: In (3.7) the correct formula for w^α is

$$w^\alpha=\frac{n\alpha_1}{2c\gamma\Delta}(-4B\delta_0^\alpha+\delta_3^\alpha)=\frac{n}{8c\gamma\alpha_1}(-4B\delta_0^\alpha+\delta_3^\alpha), \tag{6.11}$$

and in (3.10), the correct formula for g_{23} is

$$g_{23}=-2gzh_{13}+h_{23}-\alpha_1 gz^2h_{33}. \tag{6.12}$$

VII. CASE 1.1.2.1 OF REF. 3

This model is of Bianchi type VII_h, and is given by Eqs. (4.19)–(4.23) in Ref. 3. Two formulas in (4.23) had typos, the correct expressions are

$$\begin{aligned} g_{12}&=\mathrm{e}^{(b+f)x/2}[Wh_{12}-(\gamma/D)(b+f)\cos(Dx/2)h_{13}],\\ g_{22}&=\mathrm{e}^{(b+f)x}\{[\gamma^2(b+f)^2h_{33}/D^2+1]\cos^2(Dx/2)\\ &\quad -2(\gamma/D)(b+f)\cos(Dx/2)Wh_{23}+W^2h_{22}\}. \end{aligned} \tag{7.1}$$

The transformation back to the Plebański coordinates is given by (4.21) in Ref. 3, and the resulting metric is

$$\begin{aligned} g_{11}&=y^2+h_{11}+2Uh_{12}-2(\gamma/D)(b+f)yh_{13}+U^2h_{22}\\ &\quad -2(\gamma/D)(b+f)yUh_{23}+[(\gamma/D)(b+f)y]^2h_{33},\\ g_{12}&=-2h_{12}+2(\gamma/D)h_{13}-2Uh_{22}+2(\gamma/D)Uh_{23}+2(\gamma/D)(b+f)yh_{23}-2(\gamma/D)^2(b+f)yh_{33},\\ g_{13}&=h_{13}+Uh_{23}-(\gamma/D)(b+f)yh_{33}, \end{aligned} \tag{7.2}$$

$$g_{22}=4h_{22}-8(\gamma/D)h_{23}+4(\gamma/D)^2h_{33},\quad g_{23}=-2h_{23}+2(\gamma/D)h_{33},$$

$$g_{33}=h_{33},\quad U:=\tfrac{1}{2}[(b+f)^2+D^2]t+2(b+f)y,$$

where b, f D, and γ are arbitrary constants, and h_{ij} are arbitrary functions of the variable

$$T=t+\frac{2y}{b+f}+\frac{D}{\gamma(b+f)}z. \tag{7.3}$$

The Killing fields for the metric (7.2) are

$$\begin{aligned} k^\alpha_{(1)}&=\delta^\alpha_1,\quad k^\alpha_{(2)}=e^{(b+f)x/2}[\cos(Dx/2)\,\delta^\alpha_0-\tfrac{1}{2}W\delta^\alpha_2-\gamma\sin(Dx/2)\,\delta^\alpha_3],\\ k^\alpha_{(3)}&=e^{(b+f)x/2}[\sin(Dx/2)\,\delta^\alpha_0-\tfrac{1}{2}V\delta^\alpha_2+\gamma\cos(Dx/2)\,\delta^\alpha_3],\\ W&:=(b+f)\cos(Dx/2)-D\sin(Dx/2),\\ V&:=D\cos(Dx/2)+(b+f)\sin(Dx/2). \end{aligned} \tag{7.4}$$

The analog of (5.1) is here

$$Vk^\alpha_{(2)}-Wk^\alpha_{(3)}=De^{(b+f)x/2}u^\alpha-\frac{\gamma}{n}(b+f)e^{(b+f)x/2}w^\alpha, \tag{7.5}$$

and the King–Ellis measure of the tilt is:

$$\sqrt{-g}u^{\alpha}N_{\alpha}=-\tfrac{1}{2}(b+f)\gamma e^{(b+f)x}. \tag{7.6}$$

Equation (7.5) shows that with $\gamma(b+f)=0$, the model should be nonexpanding. This is so indeed, but in order to be able to consider the subcase $\gamma(b+f)\to 0$, we have to take $\gamma(b+f)T$ as the argument of h_{ij} in (7.2) instead of the T given by (7.3).

We define

$$E:=(b+f)^2+D^2, \tag{7.7}$$

and then the reparametrization needed for the limit of zero rotation and zero tilt is

$$\begin{gathered}(y,D)=\omega_0(\tilde{y},d),\quad h_{22}=H_{22}/\omega_0^2,\quad h_{23}=H_{23}/\omega_0,\\ h_{11}=H_{11}-ETH_{12}/\omega_0+(\tfrac{1}{2}ET)^2H_{22}/\omega_0^2,\\ h_{12}=H_{12}/\omega_0-\tfrac{1}{2}ETH_{22}/\omega_0^2,\quad h_{13}=H_{13}-\tfrac{1}{2}ETH_{23}/\omega_0.\end{gathered} \tag{7.8}$$

After the reparametrization we have

$$S_{1,2}:=b+f+\varepsilon_{1,2}(\omega_0 d)^2/(b+f)\xrightarrow[\omega_0\to 0]{} b+f,\quad \varepsilon_1=+1,\varepsilon_2=-1,$$

$$\Sigma:=S_2\tilde{y}-\tfrac{1}{2}(d/\gamma)S_1 z,$$

$$\begin{aligned}g_{11}&=(\omega_0 y)^2+H_{11}+2\Sigma H_{12}-2(\gamma/d)(b+f)\tilde{y}H_{13}+\Sigma^2H_{22}\\&\quad-2(\gamma/d)(b+f)\tilde{y}\Sigma H_{23}+[(\gamma/d)(b+f)\tilde{y}]^2h_{33},\\ g_{12}&=-2H_{12}+2(\gamma/d)H_{13}-2\Sigma H_{22}+2(\gamma/d)\tilde{y}H_{23}\\&\quad+2(\gamma/d)(b+f+\Sigma)H_{23}-2(\gamma/d)^2(b+f)\tilde{y}h_{33},\\ g_{13}&=H_{13}+\tilde{y}\Sigma H_{23}-(\gamma/d)(b+f)\tilde{y}h_{33},\\ g_{22}&=4H_{22}-8(\gamma/d)H_{23}+4(\gamma/d)^2h_{33},\\ g_{23}&=-2H_{23}+2(\gamma/d)h_{33},\quad g_{33}=h_{33}:=H_{33}.\end{aligned} \tag{7.9}$$

In the limit $\omega_0\to 0$, all the H_{ij} will depend only on t. The limit of zero shear is then obtained by

$$H_{ij}=-C_{ij}R^2(t),\quad C_{33}=1. \tag{7.10}$$

To obtain the Friedmann limits, a further reparametrization of the constants C_{ij} is necessary. We define

$$\begin{gathered}C_{23}=D_{23}+\gamma/d,\quad {D_{22}}^2=C_{22}-{C_{23}}^2,\\ D_{12}=(C_{12}-C_{13}C_{23})/D_{22},\quad {D_{11}}^2=C_{11}-{C_{13}}^2-{D_{12}}^2.\end{gathered} \tag{7.11}$$

The metric (7.9) may then be written

$$ds^2=dt^2-(D_{11}R\,dx)^2-R^2\left\{\left[-D_{12}-(b+f)D_{22}\left(\tilde{y}-\frac{d}{2\gamma}z\right)\right]dx+2D_{22}d\tilde{y}\right\}^2$$
$$-R^2\left\{\left[C_{13}+(b+f)D_{23}\tilde{y}-\frac{1}{2}(b+f)\left(1+\frac{d}{\gamma}D_{23}\right)z\right]dx-2D_{23}d\tilde{y}+dz\right\}^2, \qquad (7.12)$$

The $k=-1$ Friedmann limit results now when $d=0$, the $k=0$ limit results when $b+f=0$ in addition. The first of (7.11) was necessary to eliminate γ/d from (7.9) so that the limit $d\to 0$ could be subsequently taken.

We have found above [after Eq. (7.6)] that $b+f=0$ corresponds to zero expansion. This is so when $b+f\to 0$ with other parameters unchanged. In considering the $k=0$ Friedmann limit, $b+f$ is set to zero after the limit $d\to 0$ had already been taken. In order to make these two limits compatible, we have to assume that $b+f\to 0$ slowly enough so that $D/(b+f)\to 0$ and $y/(b+f)\to 0$. With the reparametrization (7.8), this is achieved when $b+f=B\omega_0^{\varepsilon}$, where $0<\varepsilon<1$.

After the reparametrization (7.8), in the limit $\omega_0\to 0$, the Killing fields become

$$k^{\alpha}_{(1)}=\delta^{\alpha}{}_{(1)}, \quad l^{\alpha}_{(2)}=-[2\omega_0/(b+f)]k^{\alpha}_{(2)} \xrightarrow[\omega_0\to 0]{} e^{(b+f)x/2}\delta^{\alpha}{}_{(2)}$$

$$l^{\alpha}_{(3)}=(1/\gamma)k^{\alpha}_{(3)} \xrightarrow[\omega_0\to 0]{} e^{(b+f)x/2}\left\{-\frac{d}{2\gamma}\left[1+\frac{1}{2}(b+f)x\right]\delta^{\alpha}{}_{(2)}+\delta^{\alpha}{}_{(3)}\right\}. \qquad (7.13)$$

This is a Bianchi type IV algebra, and in the Friedmann limits $k=-1$ $(d=0)$ and $k=0$ $(d=b+f=0)$ it becomes type V and I, respectively.

VIII. CASE 1.1.2.2 OF REF. 3, BIANCHI TYPE IX SUBCASE

The case 1.1.2.2 contains three different subcases that are of Bianchi types IX, VIII, and VII_0. The type IX subcase requires some adaptation of the formulas given in Ref. 3.

For type IX, $g/c>0$. Then, as seen from Eq. (5.16) in Ref. 3, $B/c<0$, or else (5.16) would lead to a contradiction. These two inequalities imply that $gB<0$, while Eqs. (5.26) and (5.27) in Ref. 3 are adapted to the case $gB>0$. Hence, a re-adaptation of these formulas to type IX is necessary first. We define

$$B:=-\overline{B}, \quad \lambda=i\overline{\lambda}, \quad k_{12}=i\overline{k_{12}}, \quad k_{23}=i\overline{k_{23}} \qquad (8.1)$$

(the overbars simply denote new symbols that will be real), so that instead of (5.16), (5.23), (5.26), and (5.27) from Ref. 3, we obtain

$$K=\frac{1}{2D}\left(\frac{2\overline{B}-gy^2}{c}\right)^{1/2}, \quad \delta^2:=(\overline{B}/D)^2+(2c\gamma)^2, \quad \overline{\lambda^2}:=\frac{g\overline{B}}{8\delta^4D^2},$$

$$R=2cD^2y/(\overline{B}K), \quad \int K^{-3}R\,dy=\frac{4c^2D^4}{g\overline{B}K^2}, \qquad (8.2)$$

$$v=\overline{B}t+2cD\gamma z, \quad U=h_{12}\sin(2\overline{\lambda}v)+\overline{k_{12}}\cos(2\overline{\lambda}v),$$

$$g_{11}=y^2+K^2H_{11}+4\frac{c\gamma D}{\overline{B}}yKH_{13}+8\frac{(c\gamma D)^2}{g\overline{B}}H_{33},$$

$$g_{12}=H_{12}+2\frac{c\gamma D}{\overline{B}K}yH_{23}, \quad g_{13}=KH_{13}+2\frac{c\gamma D}{\overline{B}}yH_{33}, \qquad (8.3)$$

$$g_{22}=H_{22}/K^2,\quad g_{23}=H_{23}/K,\quad g_{33}=H_{33},$$

$$H_{11}=-\frac{cD^2}{2\delta^2\overline{\lambda}}U+h_{11},\quad H_{12}=h_{12}\cos(2\overline{\lambda}v)-\overline{k_{12}}\sin(2\overline{\lambda}v),$$

$$H_{13}=-\frac{cD^2}{2\delta^2\overline{\lambda}}[h_{23}\sin(\overline{\lambda}v)+\overline{k_{23}}\cos(\overline{\lambda}v)],$$

$$H_{22}=2\frac{\delta^2\overline{\lambda}}{cD^2}U+\frac{g\overline{B}}{2c^2D^6}h_{11}+\frac{8c\gamma^2}{\overline{B}D^2}h_{33},\tag{8.4}$$

$$H_{23}=h_{23}\cos(\overline{\lambda}v)-\overline{k_{23}}\sin(\overline{\lambda}v),\quad H_{33}=h_{33},$$

where $\overline{B}$, c, D, g, and γ are arbitrary constants, and all the h_{ij}, $\overline{k_{12}}$, and $\overline{k_{23}}$ are arbitrary functions of the argument

$$T=t-\frac{\overline{B}}{2cD\gamma}z.\tag{8.5}$$

Equations (8.2)–(8.5) are written in the Plebański coordinates.

The Killing fields for metrics (8.3) and (8.4) are

$$k^\alpha_{(1)}=\delta^\alpha_1,$$

$$k^\alpha_{(2)}=\cos(Dx/2)\left[(K-yK_{,y})\delta^\alpha_0+K_{,y}\delta^\alpha_1+\frac{\gamma}{DK}\delta^\alpha_3\right]+\frac{1}{2}DK\sin(Dx/2)\delta^\alpha_2,$$

$$k^\alpha_{(3)}=\sin(Dx/2)\left[(K-yK_{,y})\delta^\alpha_0+K_{,y}\delta^\alpha_1+\frac{\gamma}{DK}\delta^\alpha_3\right]-\frac{1}{2}DK\cos(Dx/2)\delta^\alpha_2.\tag{8.6}$$

(Note: the first commutator in Eq. (5.20) in Ref. 3 should have a minus on the right-hand side.) The analog of (5.1) here is

$$\cos(Dx/2)k^\alpha_{(2)}+\sin(Dx/2)k^\alpha_{(3)}-K_{,y}k^\alpha_{(1)}=(K-yK_{,y})u^\alpha+[\gamma/(DKn)]w^\alpha.\tag{8.7}$$

In agreement with this, the King–Ellis measure of tilt is here

$$\sqrt{-g}N_\alpha u^\alpha=\gamma/2.\tag{8.8}$$

Note that

$$K_{,y}=-\frac{gy}{4cD^2K},\quad K-yK_{,y}=\frac{\overline{B}}{2cD^2K}.\tag{8.9}$$

The case presently considered is the only one of type IX in the whole classification. Therefore,

(1) This is the only place where the $k=+1$ Friedmann model will appear as a limit;
(2) The models represented by Eqs. (8.2)–(8.6) include those considered by Gödel.[10] (Ours are in fact more general because the tilt of the symmetry orbits with respect to the velocity field is an arbitrary parameter here.) We shall deal with this point further on.

For later considerations, it will be convenient to reparametrize the metric (8.4) once more, as follows:

$$\begin{gathered}\overline{G}:=(h_{12}{}^2+\overline{k_{12}}{}^2)^{1/2},\quad h_{12}=-\overline{G}\sin(2\beta),\quad \overline{k_{12}}=\overline{G}\cos(2\beta),\\ F:=(h_{23}{}^2+\overline{k_{23}}{}^2)^{1/2},\quad h_{23}=F\cos(\alpha),\quad \overline{k_{23}}=F\sin(\alpha),\end{gathered}\tag{8.10}$$

where $\overline{G}$, F, α, and β are new functions of the T given by (8.3); and also to transform the coordinate y by

$$y=\sqrt{2\overline{B}/g}\cos(\vartheta).\tag{8.11}$$

From now on, the x^2-coordinate will be ϑ. Then, in order to set the rotation and the tilt to zero, the following further reparametrization is needed:

$$\overline{B}=b\omega_0^2,\quad \gamma=h\omega_0,\quad \overline{G}=G/\omega_0,\quad h_{11}=G_{11}/\omega_0^2.\tag{8.12}$$

Let us note that

$$\overline{\lambda}v=\frac{\sqrt{bg}D(\omega_0 bt+2cDhz)}{2\sqrt{2}[(\omega_0 b)^2+(2cDh)^2]}\xrightarrow[\omega_0\to 0]{}\frac{\sqrt{bg}}{4\sqrt{2}ch}z.\tag{8.13}$$

The metric (8.5), reparametrized by (8.10)–(8.12), becomes

$$\begin{aligned}g_{11}&=\frac{2b}{g}\cos^2\vartheta\omega_0^2+\frac{2b}{4cD^2}G_{11}\sin^2\vartheta-4\frac{chD^3}{g}\sqrt{\frac{2c}{b}}F\sin(\overline{\lambda}v+\alpha)\sin\vartheta\cos\vartheta\\&\quad-D\sqrt{\frac{b}{2g}}G\cos(2\overline{\lambda}v+2\beta)\sin^2\vartheta+8\frac{(chD)^2}{bg}h_{33},\\ g_{12}&=\sqrt{2b/g}G\sin(2\overline{\lambda}v+2\beta)\sin\vartheta-4\sqrt{2}(chD^2/g)\sqrt{c/b}F\cos(\overline{\lambda}v+\alpha)\cos\vartheta,\\ g_{13}&=2\sqrt{2}\frac{chD}{\sqrt{bg}}h_{33}\cos\vartheta-D^2\sqrt{\frac{c}{g}}F\sin(\overline{\lambda}v+\alpha)\sin\vartheta,\\ g_{22}&=2\frac{b}{cD^4}G_{11}+32\frac{(ch)^2}{bg}h_{33}+2\sqrt{2}\frac{1}{D}\sqrt{\frac{b}{g}}G\cos(2\overline{\lambda}v+2\beta),\\ g_{23}&=-2D\sqrt{\frac{c}{g}}F\cos(\overline{\lambda}v+\alpha),\quad g_{33}=h_{33}.\end{aligned}\tag{8.14}$$

In the limit $\omega_0\to 0$, the velocity field $u^\alpha=\delta^\alpha{}_0$ will have zero shear when

$$\begin{gathered}\alpha=\text{const},\quad \beta=\text{const},\\ (G,F,G_{11},h_{33})=-(C_{12},C_{23},C_{11},1)R^2(t).\end{gathered}\tag{8.15}$$

With use of (8.13) it may be verified now that the $k=+1$ Friedmann limit will result from (8.14) and (8.15) when $\omega_0\to 0$ and

$$C_{12}=C_{23}=C_{11}=0.\tag{8.16}$$

The resulting representation of the Friedmann model (again an exotic one) is identical, up to rescalings of coordinates, to the one derived by Behr[11]

$$ds^2=dt^2-R^2(t)\left[8\frac{(chD)^2}{bg}dx^2+4\sqrt{2}\frac{chD}{\sqrt{bg}}\cos\vartheta\,dx\,dz+32\frac{(ch)^2}{bg}d\vartheta^2+dz^2\right]. \tag{8.17}$$

The $k=0$ Friedmann model will result from this after the transformation–reparametrization

$$\vartheta=\arccos(ky),\quad h=H/k,\quad x=kx', \tag{8.18}$$

in the limit $k\to 0$.

For the $k=+1$ Friedmann limit, the algebra of the Killing fields (8.6), suitably transformed by use of (8.9), (8.11), and (8.12), is still of Bianchi type IX. For the $k=0$ limit, the algebra $\{l_{(1)},l_{(2)},l_{(3)}\}:=k\{k_{(1)},k_{(2)},k_{(3)}\}$ is of Bianchi type I when $k\to 0$.

As stated above, the class of models defined by (8.2)–(8.5) must contain the one considered by Gödel in Ref. 10. This is so because two of Gödel's assumptions (dust source and nonzero rotation) place his class within our collection, and the third assumption (compact spaces $t=\text{const}$, i.e., Bianchi type IX; the Bianchi classification and terminology had not yet been in common use in Gödel's time) uniquely points to the subcase I of our case 1.1.2.2. Gödel presented several properties of these models in the form of theorems, but mostly without proofs and almost without formulas. It would be an interesting exercise to see how Gödel's theorems apply to the explicitly given metric (8.2)–(8.5).

In particular, one of his statements seems to need a refinement. He said that there exist ∞^8 rotating solutions satisfying all his requirements. This means that the collection of all solutions of the Einstein equations for (8.2)–(8.5) should be labeled by eight arbitrary constants. One can understand how this happens from Ref. 4, where the Einstein equations were investigated for an equally general Bianchi type V class. Of the six unknown functions in the initial metric, one (h_{33} in Ref. 4) is determined by an algebraic relation, two of the Einstein equations are of first order and can be used to eliminate two more functions, and then the remaining three functions obey equations of second order. This gives eight constants indeed. However, the tilt parameter [γ in (8.7) and (8.8)] is one more arbitrary constant that is contained in the metric even before the Einstein equations are considered.

Rotating dust models of Bianchi type IX were considered by Behr,[11] with simplifying assumptions about the metric. Similarly as in Ref. 4, the main conclusion seems to be that whatever one does with the Einstein equations, no solution comes within sight.

IX. CASE 1.1.2.2 OF REF. 3, BIANCHI TYPES VIII AND VII$_0$

The subcase of case 1.1.2.2 that corresponds to the Bianchi type VIII is defined by

$$g/c<0, \tag{9.1}$$

in Eqs. (5.16)–(5.27) in Ref. 3. Then, B/c and, consequently, Bg can have any sign at this point. Only the $k=0$ Friedmann model can be contained as a subcase here.

The cases $Bg\neq 0$ and $Bg=0$ have to be considered separately. When $Bg\neq 0$, we take Eqs. (5.23)–(5.28) in Ref. 3 with the following specializations:

$$h_{12}=k_{12}=h_{23}=k_{23}=0,$$

$$B=b\omega_0^2,\quad (\gamma,y)=(h,\tilde{y})\omega_0,\quad h_{11}=G_{11}/\omega_0^2. \tag{9.2}$$

Then

$$K=\omega_0\tilde{K},\quad \tilde{K}=\frac{1}{2D}\sqrt{-\frac{g\tilde{y}^2+2b}{c}},$$

$$g_{11}=(\omega_0\tilde{y})^2-8\frac{(cDh)^2}{bg}h_{33}+\tilde{K}^2G_{11},$$

$$g_{12}=0,\quad g_{13}=-2(cDh/b)\tilde{y}h_{33}, \tag{9.3}$$

$$g_{22}=\tilde{K}^{-2}\left(-\frac{bg}{2c^2D^6}G_{11}-8\frac{ch^2}{bD^2}h_{33}\right),\quad g_{23}=0,\quad g_{33}=h_{33}.$$

It is now seen that the proper signature will result only when

$$b/c>0. \tag{9.4}$$

In order to obtain the $k=0$ Friedmann model from (9.3), we then rescale the constants again as follows:

$$b=b_0\sqrt{g},\quad D=dg^{1/4},\quad h=Hg^{3/4}, \tag{9.5}$$

and take the limit $g\to 0$. The limiting metric is

$$\mathrm{d}s^2=\mathrm{d}t^2+G_{11}\left(\frac{b_0}{2cd^2}\mathrm{d}x^2+\frac{1}{d^4}\mathrm{d}\tilde{y}^2\right)+h_{33}\mathrm{d}z^2, \tag{9.6}$$

and in the limit of zero shear, $G_{11}=C_{11}h_{33}=-C_{11}R^2(t)$, this becomes the $k=0$ Friedmann model indeed.

The Killing fields for this case are given by (8.6). After the rescalings (9.2) and (9.5), the following basis of the symmetry algebra is obtained:

$$k^\alpha_{(1)}=\delta^\alpha{}_1,$$

$$l^\alpha_{(2)}=\sqrt{\frac{b_0}{2cg}}\frac{1}{H}k^\alpha_{(3)}\xrightarrow[g\to 0]{}\frac{1}{4cH}\left(-\frac{\tilde{y}}{d}\delta^\alpha{}_1+\frac{1}{2}b_0dx\,\delta^\alpha{}_2\right)+\delta^\alpha{}_3, \tag{9.7}$$

$$l^\alpha_{(3)}=-2\sqrt{\frac{2c}{b_0}}g^{-1/4}k^\alpha_{(3)}\xrightarrow[g\to 0]{}\delta^\alpha{}_2.$$

This is of Bianchi type VII_0.

When $Bg=0$, and the Bianchi type is VIII, we must have:

$$B=0\neq g. \tag{9.8}$$

The metric is then found from Eqs. (5.28) and (5.23)–(5.26) in Ref. 3, suitably adapted. With $B=0$, the arbitrary functions depend only on t. The metric needs then to be rescaled as follows:

$$(\gamma,y)=(h,\tilde{y})\omega_0,\quad (h_{12},h_{13},h_{23})=(G_{12},G_{13},G_{23})/\omega_0,\quad h_{11}=G_{11}/\omega_0^2 \tag{9.9}$$

and the result of the rescaling is

$$g_{11}=(\omega_0\tilde{y})^2-\frac{g\tilde{y}^2}{4cD^2}G_{11}+\frac{Dg}{8ch}\tilde{y}^2zG_{12}-2\sqrt{-c/g}hG_{13}-\frac{g^2}{2^5c^2h}\sqrt{-c/g}(\tilde{y}z)^2G_{13}$$
$$-\frac{D^4g}{2^6ch^2}(\tilde{y}z)^2h_{22}+\frac{1}{4}D^2\tilde{y}zG_{23}+\left(\frac{Dg}{2^4ch}\right)^2(\tilde{y}z)^3G_{23}+4\left(\frac{cDh}{g\tilde{y}}\right)^2h_{33}$$
$$+\frac{1}{8}(Dz)^2h_{33}+\left(\frac{Dg}{2^5ch}\tilde{y}z^2\right)^2h_{33},$$

$$g_{12}=G_{12}-\frac{g}{2cD}\sqrt{-c/g}zG_{13}-\frac{D^3}{4h}zh_{22}+2\frac{cDh}{g\tilde{y}}G_{23}$$
$$+3\frac{Dg}{2^5ch}\tilde{y}z^2G_{23}+2\frac{cDh}{g\tilde{y}^2}zh_{33}+\frac{Dg}{2^5ch}z^3h_{33},$$

$$g_{13}=\frac{1}{2D}\sqrt{-g/c}\tilde{y}G_{13}+\frac{Dg}{2^5ch}\tilde{y}^2zG_{23}+2\frac{cDh}{g\tilde{y}}h_{33}+\frac{Dg}{2^5ch}\tilde{y}z^2h_{33}, \tag{9.10}$$

$$g_{22}=-4\frac{cD^2}{g\tilde{y}^2}h_{22}+2(z/\tilde{y})G_{23}+(z/\tilde{y})^2h_{33},$$

$$g_{23}=G_{23}+(z/\tilde{y})h_{33},\quad g_{33}=h_{33}.$$

In the limit $\omega_0\to0$ one term in g_{11} disappears and the h_{ij} depend only on t. The shearfree limit is then attained when

$$G_{ij}=-C_{ij}R^2(t),\quad h_{33}=-R^2(t),\quad h_{22}=-C_{22}R^2(t). \tag{9.11}$$

To find the Friedmann limit we then assume that

$$C_{12}=C_{13}=C_{23}=0,\quad h=HD,\quad g=-cG^2D^2, \tag{9.12}$$

where H and G are new constants (the last definition takes into account that $g/c<0$ in type VIII), and let $\omega_0\to0$, $D\to0$. The resulting metric is:

$$\mathrm{d}s^2=\mathrm{d}t^2-C_{11}\left(\frac{1}{2}G\tilde{y}R\right)^2\mathrm{d}x^2-C_{22}\left(2\frac{R}{G\tilde{y}}\right)^2\mathrm{d}\tilde{y}^2-R^2\left(-2\frac{H}{G^2\tilde{y}}\mathrm{d}x+\frac{z}{\tilde{y}}\mathrm{d}\tilde{y}+\mathrm{d}z\right)^2. \tag{9.13}$$

The $k=0$ Friedmann limit results from this when

$$\tilde{y}=\mathrm{e}^{ku},\quad C_{22}=(D_{22}/k)^2,\quad k\to0. \tag{9.14}$$

With (9.8), (9.9), and (9.12), the Killing fields become

$$k^\alpha_{(1)}=\delta^\alpha_1,$$

$$k^\alpha_{(2)}=\frac{1}{2}G\cos(Dx/2)\,\delta^\alpha_1+\frac{1}{4}GD\tilde{y}\sin(Dx/2)\,\delta^\alpha_2+\frac{2H}{G\tilde{y}}\cos(Dx/2)\,\delta^\alpha_3,$$

$$k^\alpha_{(3)}=\frac{1}{2}G\sin(Dx/2)\,\delta^\alpha_1-\frac{1}{4}GD\tilde{y}\cos(Dx/2)\,\delta^\alpha_2+\frac{2H}{G\tilde{y}}\sin(Dx/2)\,\delta^\alpha_3. \tag{9.15}$$

Before the limit $D\to0$ can be taken, $k_{(3)}$ needs to be redefined by $k'_{(3)}=(1/D)k_{(3)}$. The basis in the limit becomes

$$k^{\alpha}_{(1)}=\delta^{\alpha}_{1}, \quad k^{\alpha}_{(2)}=\frac{1}{2}G\,\delta^{\alpha}_{1}+\frac{2H}{G\tilde{y}}\,\delta^{\alpha}_{3},$$

$$k'^{\alpha}_{(3)}=\frac{1}{4}Gx\,\delta^{\alpha}_{1}-\frac{1}{4}G\tilde{y}\,\delta^{\alpha}_{2}+\frac{Hx}{G\tilde{y}}\,\delta^{\alpha}_{3}. \tag{9.16}$$

This is of type VI_0. We now transform $\tilde{y}$ by (9.10), and redefine $k'_{(3)}$ once more

$$l^{\alpha}_{(3)}=-(4k/G)k'^{\alpha}_{(3)}. \tag{9.17}$$

In the limit $k\to 0$, the following basis then results:

$$k^{\alpha}_{(1)}=\delta^{\alpha}_{1}, \quad k^{\alpha}_{(2)}=\frac{1}{2}G\,\delta^{\alpha}_{1}+\frac{2H}{G}\,\delta^{\alpha}_{3}, \quad l^{\alpha}_{(3)}=\delta^{\alpha}_{2} \tag{9.18}$$

(u being now the x^2), which is clearly of Bianchi type I.

Finally, when the Bianchi type is VII_0 (i.e., $g=0$), the metric results by a simple specialization of Eqs. (5.23)–(5.25) and (5.28) in Ref. 3. In this case necessarily $b/c<0$ and

$$K=\frac{1}{D}\sqrt{\frac{-b}{2c}}=\text{const.} \tag{9.19}$$

The rescaling that will allow to calculate the limit $\omega_0\to 0$ is

$$(B,y)=(b,\tilde{y})\omega_0^2, \quad D=d\omega_0,$$

$$(h_{12},h_{23})=(G_{12},G_{23})/\omega_0, \quad h_{22}=G_{22}/\omega_0^2. \tag{9.20}$$

The argument of the arbitrary functions must then be redefined so that it becomes:

$$\tilde{u}=u/(2cD\gamma)=t+\frac{B}{2cD\gamma}z \xrightarrow[\omega_0\to 0]{} t. \tag{9.21}$$

The limit $\omega\to 0$ of the metric is then:

$$\mathrm{d}s^2=\mathrm{d}t^2-\frac{b}{2cd^2}h_{11}\mathrm{d}x^2-2G_{12}\mathrm{d}x\mathrm{d}\tilde{y}+\frac{2}{d}\sqrt{\frac{-b}{2c}}h_{13}\mathrm{d}x\mathrm{d}z$$
$$-2\frac{cd^2}{b}C_{22}\mathrm{d}\tilde{y}^2+2G_{23}\mathrm{d}\tilde{y}\mathrm{d}z+h_{33}\mathrm{d}z^2. \tag{9.22}$$

The $k=0$ Friedmann limit results from here when shear is set to zero, i.e., when $g_{ij}=-C_{ij}R^2(t)$.

The basis of the Killing fields in the limit $\omega_0\to 0$ is found as follows:

$$k^{\alpha}_{(1)}=\delta^{\alpha}_{1}, \quad l^{\alpha}_{(2)}=\lim_{\omega_0\to 0}\left(\frac{K\omega_0}{d\gamma}k^{\alpha}_{2}\right)=\delta^{\alpha}_{3}, \quad l^{\alpha}_{(3)}=\lim_{\omega_0\to 0}\left(-\frac{2}{dK}\omega_0 k^{\alpha}_{3}\right)=\delta^{\alpha}_{2}. \tag{9.23}$$

X. CASES 2.1 OF REF. 3

In the case 2.1.1 the transformation back to the Plebański coordinates is the inverse of (7.16) in Ref. 3, and when applied to (7.18) there, it gives the following metric:

$$g_{11}=y^2-(y+V)^2+h_{11}+(b+f)[(y+V)h_{12}+(\gamma/c)Vh_{13}]$$
$$+\tfrac{1}{4}(b+f)^2[(y+V)^2h_{22}+2(\gamma/c)V(y+V)h_{23}+(\gamma V/c)^2h_{33}],$$

$$g_{12}=\frac{2}{b+f}(y+V)-h_{12}-\frac{1}{2}(b+f)[(y+V)h_{22}+(\gamma/c)Vh_{23}], \tag{10.1}$$

$$g_{13}=h_{13}+\tfrac{1}{2}(b+f)[(y+V)h_{23}+(\gamma/c)Vh_{33}],$$

$$g_{22}=-4/(b+f)^2+h_{22},\quad g_{23}=-h_{23},\quad g_{33}=h_{33},$$

where

$$V:=\tfrac{1}{2}(b+f)t+y, \tag{10.2}$$

and the arbitrary functions h_{ij} depend on

$$T:=t+\frac{2y}{b+f}+\frac{2c}{\gamma(b+f)}z. \tag{10.3}$$

[Note two typos in Ref. 3: In Eq. (7.18), the coefficient of Wh_{23} in g_{22} is 2γ, not $2b$, and in (7.17), in the formula for u^α, there should be a (W/c) in front of $\delta^\alpha{}_0$.] The Killing fields for this metric are

$$k^\alpha_{(1)}=\delta^\alpha_1,\quad k^\alpha_{(2)}=e^{(b+f)x/2}\{cx\,\delta^\alpha_0-c[1+\tfrac{1}{2}(b+f)x]\delta^\alpha_2+\gamma\delta^\alpha_3\},$$
$$k^\alpha_{(3)}=e^{(b+f)x/2}[\delta^\alpha_0-\tfrac{1}{2}(b+f)\delta^\alpha_2], \tag{10.4}$$

and they form a Bianchi type IV algebra.

The analog of (5.5) is

$$k^\alpha_{(2)}-\frac{2c}{b+f}[1+\tfrac{1}{2}(b+f)x]k^\alpha_{(3)}=e^{(b+f)x/2}\left(\frac{2c}{b+f}u^\alpha+\frac{\gamma}{n}w^\alpha\right), \tag{10.5}$$

and the King–Ellis measure of tilt is

$$\sqrt{-g}u^\alpha N_\alpha=-\tfrac{1}{2}(b+f)\gamma e^{(b+f)x}. \tag{10.6}$$

The redefinitions needed to make the limit $\omega_0\to 0$ finite are

$$(y,c)=\omega_0(\tilde{y},C),$$

$$h_{11}=H_{11}-\tfrac{1}{2}(b+f)^2T[h_{12}+(\gamma/c)h_{13}]-\tfrac{1}{16}(b+f)^4T^2[H_{22}/\omega_0^2+2(\gamma/c)H_{23}/\omega_0+(\gamma/c)^2h_{33}],$$

$$h_{12}=H_{12}/\omega_0-\tfrac{1}{4}(b+f)^2T[H_{22}/\omega_0^2+(\gamma/c)H_{23}/\omega_0],$$

$$h_{13}=H_{13}-\tfrac{1}{4}(b+f)^2T[H_{23}/\omega_0+(\gamma/c)h_{33}],$$
$$h_{22}=H_{22}/\omega_0^2,\quad h_{23}=H_{23}/\omega_0, \tag{10.7}$$

and the resulting metric is

$$g_{11}=(\omega_0\tilde{y})^2-[\tfrac{1}{2}(b+f)t+2\omega_0\tilde{y}]^2+H_{11}+(b+f)[YH_{12}-zH_{13}]$$
$$+\tfrac{1}{4}(b+f)^2[Y^2H_{22}-2YzH_{23}+z^2H_{33}],$$

$$g_{12}=\omega_0 t+\frac{4\omega_0^2}{b+f}\tilde{y}-H_{12}-\tfrac{1}{2}(b+f)[YH_{22}-zH_{23}],$$

$$g_{13}=H_{13}+\tfrac{1}{2}(b+f)[YH_{23}-zH_{33}], \tag{10.8}$$

$$g_{22}=H_{22}-4\omega_0^2/(b+f)^2, \quad g_{23}=-H_{23}, \quad g_{33}=h_{33}=H_{33},$$

$$Y:=\tilde{y}-Cz/\gamma.$$

In the limit $\omega_0\to 0$, all H_{ij} become functions of t, and the Killing fields become

$$k^\alpha_{(1)}=\delta^\alpha_1,$$

$$l^\alpha_{(2)}=\lim_{\omega_0\to 0}k^\alpha_{(2)}=e^{(b+f)x/2}\{-C[1+\tfrac{1}{2}(b+f)x]\delta^\alpha_2+\gamma\delta^\alpha_3\}, \tag{10.9}$$

$$l^\alpha_{(3)}=\lim_{\omega_0\to 0}\left(-\frac{2}{b+f}\omega_0 k^\alpha_{(3)}\right)=e^{(b+f)x/2}\delta^\alpha_2,$$

still of type IV.

The shearfree limit of (10.8) is

$$H_{11}=-C_{11}R^2(t)+[\tfrac{1}{2}(b+f)t]^2,$$

$$\text{other} \quad H_{ij}=-C_{ij}R^2(t), \quad C_{33}=1. \tag{10.10}$$

The $k=-1$ Friedmann model will then result when $C=0$ (and, consequently, $Y=\tilde{y}$), the $k=0$ Friedmann model will result when $b+f=0$, with no condition on C. Both limits can be easily taken also in the Killing fields (10.9), with $C=0$ they become of type V, with $b+f=0$ they become of type I.

The case 2.1.2 was shown in Ref. 3 to be included in 2.1.1 as a subcase.

XI. CASE 2.2.1.1 OF REF. 3

This case includes two subcases, $\mathcal{A}\neq 0$ and $\mathcal{A}=0$, given by Eqs. (9.11)–(9.15) in Ref. 3. Both are of Bianchi type VIII. The coordinates used there are those of Plebański.

With $\mathcal{A}\neq 0$, Eqs. (9.14) in Ref. 3 are adapted to the case $\mathcal{A}<0$. However, when $\mathcal{A}<0$, the limit of constant curvature in the spaces $t=\text{const}$ has a wrong signature. Therefore, the formulas must be re-adapted to $\mathcal{A}>0$. This is the result:

$$g_{11}=y^2\left(\frac{U}{\sqrt{2\mathcal{A}}}+\frac{\gamma V}{\mathcal{A}\sqrt{2\mathcal{A}}}+h_{11}\right),$$

$$g_{12}=h_{12}\cos(2\lambda v)-k_{12}\sin(2\lambda v)+\frac{\gamma}{2\mathcal{A}}[h_{23}\cos(\lambda v)-k_{23}\sin(\lambda v)],$$

$$g_{13}=y\left(\frac{V}{\sqrt{2\mathcal{A}}}+\frac{\gamma}{2\mathcal{A}}h_{33}\right), \quad g_{22}=y^{-2}\left(-\sqrt{2\mathcal{A}}U+2\mathcal{A}h_{11}-\frac{\gamma^2}{2\mathcal{A}}h_{33}\right), \tag{11.1}$$

$$g_{23}=y^{-1}[h_{23}\cos(\lambda v)-k_{23}\sin(\lambda v)],\quad g_{33}=H_{33}=h_{33},$$

$$U:=h_{12}\sin(2\lambda v)+k_{12}\cos(2\lambda v),\quad V:=h_{23}\sin(\lambda v)+k_{23}\cos(\lambda v),$$

$$\lambda^2=2\mathcal{A}/(4\mathcal{A}^2+\gamma^2)^2,\quad v=2\mathcal{A}t+\gamma z,$$

and the h_{ij} are arbitrary functions of

$$T=t-2\mathcal{A}z/\gamma. \tag{11.2}$$

The Killing fields for (11.1) are

$$k^\alpha_{(1)}=\delta^\alpha_1,\quad k^\alpha_{(2)}=(2\mathcal{A}/y)\,\delta^\alpha_0+(-\mathcal{A}/y^2+x^2/2)\,\delta^\alpha_1-xy\,\delta^\alpha_2+(\gamma/y)\,\delta^\alpha_3,$$

$$k^\alpha_{(3)}=x\,\delta^\alpha_1-y\,\delta^\alpha_2. \tag{11.3}$$

The analog of (5.1) is

$$(\mathcal{A}/y^2+x^2/2)k^\alpha_{(1)}+k^\alpha_{(2)}-xk^\alpha_{(3)}=(2\mathcal{A}/y)u^\alpha+\frac{\gamma}{yn}w^\alpha, \tag{11.4}$$

and the King–Ellis measure of tilt is

$$\sqrt{-g}u^\alpha N_\alpha=\gamma. \tag{11.5}$$

The redefinitions needed to make the limit $\omega_0\to 0$ of (11.1) finite are

$$(y,\gamma)=\omega_0(\tilde{y},h),\quad \mathcal{A}=\tfrac{1}{2}(a\omega_0)^2,$$

$$h_{11}=H_{11}/\omega_0^2,\quad (h_{12},k_{12})=(H_{12},K_{12})/\omega_0. \tag{11.6}$$

Note that with (11.6) we have

$$\lambda v \xrightarrow[\omega_0\to 0]{} az/h. \tag{11.7}$$

The reparametrized metric is

$$\begin{aligned}
g_{11}&=\tilde{y}^2\{2hV/a^3+H_{11}+a^{-1}[H_{12}\sin(2\lambda v)+K_{12}\cos(2\lambda v)]\},\\
g_{12}&=(h/a^2)[h_{23}\cos(\lambda v)-k_{23}\sin(\lambda v)]+H_{12}\cos(2\lambda v)-K_{12}\sin(2\lambda v),\\
g_{13}&=(\tilde{y}/a)(V+hh_{33}/a),\\
g_{22}&=\tilde{y}^{-2}\{-a[H_{12}\sin(2\lambda v)+K_{12}\cos(2\lambda v)]+a^2H_{11}-(h/a)^2H_{33}\},\\
g_{23}&=\tilde{y}^{-1}[h_{23}\cos(\lambda v)-k_{23}\sin(\lambda v)],\quad g_{33}=H_{33}=h_{33}.
\end{aligned} \tag{11.8}$$

In the limit $\omega_0\to 0$, all the arbitrary functions will depend only on t.

The $k=0$ Friedmann limit follows from (11.8) when the following further specialization and transformation is made:

$$\begin{aligned}
&h_{33}=-R^2(t),\quad H_{11}=-(C_{11}+h^2)R^2(t)/a^4,\\
&H_{12}=K_{12}=h_{23}=k_{23}=0,\quad x=a^2x',\quad \tilde{y}=e^{au},
\end{aligned} \tag{11.9}$$

and then the limit $a\to 0$ is taken. The metric becomes then

$$ds^2=dt^2-R^2[C_{11}(dx'^2+du^2)+(g\,dx+dz)^2], \tag{11.10}$$

which is clearly the $k=0$ Friedmann model.

The rescaling (11.6), followed by $\omega_0\to 0$, and the rescaling (11.9), followed by $a\to 0$ transform the Killing fields (11.3) into an almost-standard Bianchi type I basis ($k^\alpha_{(1)}$ has to be replaced by $l^\alpha_{(1)}=a^2k^\alpha_{(1)}$, and $k^\alpha_{(3)}$ has to be replaced by $l^\alpha_{(3)}=ak^\alpha_{(3)}$ before taking the limit $a\to 0$).

The case $\mathcal{A}=0$ is given by Eqs. (9.11) and (9.15) in Ref. 3. The rescalings needed there are

$$y=\omega_0\tilde{y},\quad h_{11}=G_{11}/\omega_0^2,\quad (h_{12},h_{13})=(G_{12},G_{13})/\omega_0. \tag{11.11}$$

The arbitrary functions h_{ij} depend only on t from the beginning. The limit $\omega_0\to 0$ of the rescaled metric is

$$\begin{aligned}ds^2=&dt^2+\tilde{y}^2G_{11}dx^2+2(zG_{13}+G_{12})dx\,d\tilde{y}+2\tilde{y}G_{13}dx\,dz+\tilde{y}^{-2}(h_{22}+2zh_{23}+z^2h_{33})d\tilde{y}^2\\&+2\tilde{y}^{-1}(h_{23}+zh_{33})d\tilde{y}\,dz+h_{33}dz^2.\end{aligned} \tag{11.12}$$

The $k=0$ Friedmann model results now when

$$\begin{gathered}G_{12}=G_{13}=0,\quad G_{11}=-C_{11}R^2(t),\\ h_{ij}=-C_{ij}R^2,\quad C_{33}=1,\quad C_{22}=1/a^2,\\ \tilde{y}=e^{au},\quad a\to 0.\end{gathered} \tag{11.13}$$

The Killing fields need not be reconsidered because $\mathcal{A}=0$ is an allowed subcase for (11.3).

XII. CASES 2.2.1.2 OF REF. 3

In considering these cases, we first have to correct two errors. The first error is that the arbitrary constant y_0 actually must be equal to zero in all the formulas. The second error is that one subcase was overlooked—it needs special treatment and is not included in the formulas given in Sec. X of Ref. 3. This special case is defined by

$$g=0, \tag{12.1}$$

and consequently $\mu_1=0$ and $\mu_2=j$. It is because of $\mu_1=0$ that some of the formulas do not apply to this case.

The conclusion that

$$a=0,\quad c=1, \tag{12.2}$$

can be achieved by a change of the basis of the Killing fields is still valid. With (12.1) and (12.2), the solutions of Eqs. (10.2) and (10.3) in Ref. 3 are

$$P=-jy+M,\quad L_3=\gamma, \tag{12.3}$$

where j, M, and γ are arbitrary constants. The resulting Killing fields are [by (10.6) from Ref. 3]

$$\begin{gathered}k^\alpha_{(1)}=\delta^\alpha_1,\quad k^\alpha_{(2)}=Mx\,\delta^\alpha_0-jx\,\delta^\alpha_1+(jy-M)\,\delta^\alpha_2+\gamma x\,\delta^\alpha_3,\\ k^\alpha_{(3)}=M\,\delta^\alpha_0-j\,\delta^\alpha_1+\gamma\delta^\alpha_3,\end{gathered} \tag{12.4}$$

and they form a Bianchi type III algebra.

The coordinates are still those of Plebański at this point, so u^α and w^α and $g_{0\alpha}$ have their standard forms. The solution of the Killing equations is

$$g_{11}=(2M/j)y-(M/j)^2+(jy-M)^2h_{11}+2(\gamma/j)(jy-M)h_{13}+(\gamma/j)^2h_{33},$$

$$g_{12}=h_{12}+\frac{\gamma h_{23}}{j(jy-M)},\quad g_{13}=(jy-M)h_{13}+(\gamma/j)h_{33},$$

$$g_{22}=h_{22}/(jy-M)^2,\quad g_{23}=h_{23}/(jy-M),\quad g_{33}=h_{33}, \tag{12.5}$$

where the h_{ij} are arbitrary functions of the argument

$$T=t-(M/\gamma)z. \tag{12.6}$$

The Killing fieds (12.4) are a subcase of the general expression that will apply to the whole case 2.2.1.2 collection. The analog of (5.1) will be given further on for the whole class.

The rescalings needed to find the nonrotating limit of (12.5) and (12.6) are

$$(y,M)=\omega_0(\tilde{y},m),\quad h_{11}=H_{11}/\omega_0^2,$$

$$(h_{12},h_{13})=(H_{12},H_{13})/\omega_0. \tag{12.7}$$

The rescaled metric is

$$g_{11}=(2m/j)\omega_0^2\tilde{y}-(m\omega_0/j)^2+(j\tilde{y}-m)^2H_{11}+2(\gamma/j)(j\tilde{y}-m)H_{13}+(\gamma/j)^2h_{33},$$

$$g_{12}=H_{12}+\frac{\gamma h_{23}}{j(j\tilde{y}-m)},\quad g_{13}=(j\tilde{y}-m)H_{13}+(\gamma/j)h_{33},$$

$$g_{22}=H_{22}/(j\tilde{y}-m)^2,\quad g_{23}=h_{23}/(j\tilde{y}-m),\quad g_{33}=h_{33}. \tag{12.8}$$

The $k=0$ Friedmann limit is now obtained from (12.8) when shear is set to zero [$h_{ij}=-C_{ij}R^2(t)$, $C_{33}=1$], and in addition

$$\gamma=hj,\quad j\to 0. \tag{12.9}$$

In order to make the limits $\omega_0\to 0$ and $j\to 0$ compatible, it has to be assumed that $j\propto\omega_0^\alpha$, where $0<\alpha<1$, e.g., $\alpha=1/2$. The Killing fields (12.4) become then an almost-standard Bianchi type I basis in the limit $\omega_0\to 0$, but $k^\alpha_{(3)}$ has to be replaced by $l^\alpha_{(3)}={\omega_0}^{-1/2}k^\alpha_{(3)}$.

The case 2.2.1.2 consists of three subcases, each of a different Bianchi type. The subcase $g<j^2/4$ is of Bianchi type VI_h, with the free parameter $j/(j^2-4g)^{1/2}$. However, the parametrization of the metric used in Ref. 3 is inconvenient for calculating the Friedmann limit. It will be more convenient to rewrite it in the parametrization in which μ_1 and μ_2 appear symmetrically. Therefore, instead of (10.15)–(10.17) from Ref. 3, we will use the following formulas:

$$U:=M\cosh(DY)+N\sinh(DY),\quad V:=M\sinh(DY)+N\cosh(DY),$$

$$D:=(j^2/4-g)^{1/2},\quad \Gamma:=\frac{\gamma}{D(M^2-N^2)},$$

$$P=\mathrm{e}^{-jY/2}U,\quad y=-\frac{j}{2g}P-\frac{D}{g}\mathrm{e}^{-jY/2}V,$$

$$g_{11}=y^2+h_{11}P^2+2\Gamma\mathrm{e}^{-jY}UVh_{13}+(\gamma\Gamma/D)\mathrm{e}^{-jY}h_{33}, \tag{12.10}$$

$$g_{12}=h_{12}+\Gamma(V/U)h_{23},\quad g_{13}=h_{13}P+\Gamma e^{-jY/2}Vh_{33},$$

$$g_{22}=h_{22}/P^2,\quad g_{23}=h_{23}/P,\quad g_{33}=h_{33},$$

where j, g, M, N, and γ are arbitrary constants, y is one of the coordinates, Y is just a parameter used to represent $P(y)$, and h_{ij} are arbitrary functions of the coordinate z. Since the coordinates used in (12.10) are not those of Plebański, the u^α and $g_{0\alpha}$ do not have their standard forms, they are given by Eqs. (10.9) in Ref. 3. The transformation back to the Plebański coordinates is the inverse of (10.8) in Ref. 3, after which we obtain

$$g_{12}=gth_{11}+h_{12}+\Gamma gt\left(V/U-\frac{1}{2}j/D\right)h_{13}+\Gamma(V/U)h_{23}-\Gamma^2 gt\left(1+\frac{jV}{2DU}\right)h_{33},$$

$$g_{22}=P^{-2}\{(gt)^2h_{11}+2gth_{12}-(j\Gamma g/D)t(gth_{13}+h_{23})+h_{22}+g(\Gamma gt/D)^2h_{33}\},\quad (12.11)$$

$$g_{23}=(1/P)\left\{gth_{13}+h_{23}-\frac{j\Gamma gt}{2D}h_{33}\right\},$$

with g_{11}, g_{13}, and g_{33} being the same as in (12.10). The h_{ij} depend now on

$$T=t+\frac{D}{\Gamma g}z. \quad (12.12)$$

The Killing fields corresponding to (12.11) and (12.12) [and to all the other subcases of case (2.2.1.2)] are

$$k^\alpha_{(1)}=\delta^\alpha_1,\quad k^\alpha_{(2)}=x(P-yP_{,y})\delta^\alpha_0+xP_{,y}\delta^\alpha_1-P\delta^\alpha_2+x(\gamma/P)e^{-jY}\delta^\alpha_3,$$
$$k^\alpha_{(3)}=(P-yP_{,y})\delta^\alpha_0+P_{,y}\delta^\alpha_1+(\gamma/P)e^{-jY}\delta^\alpha_3. \quad (12.13)$$

The analog of (5.1) (again valid for all the subcases) is

$$k^\alpha_{(3)}-P_{,y}k^\alpha_{(1)}=(P-yP_{,y})u^\alpha+\frac{\gamma}{nP}e^{-jY}w^\alpha, \quad (12.14)$$

and the King–Ellis measure of tilt is

$$\sqrt{-g}u^\alpha N_\alpha=-\gamma e^{-jY}. \quad (12.15)$$

The rescalings needed to make the limit $\omega_0\to 0$ finite are

$$(M,N,\gamma)=(m,n,h)\omega_0,\quad h_{11}=H_{11}/\omega_0^2,\quad h_{13}=H_{13}/\omega_0. \quad (12.16)$$

In consequence of this we have

$$(y,P,U,V)=(\tilde{y},\tilde{P},\tilde{U},\tilde{V})\omega_0, \quad (12.17)$$

where the symbols with a tilde are obtained from those on the left by replacing $(M,N)\to(m,n)$, and they do not depend on ω_0. Also, from now on Y will be used as the x^2-coordinate in place of y, so

$$dy=\omega_0\tilde{P}dY. \quad (12.18)$$

The rescalings (12.16) have to be accompanied by the following redefinitions of other functions in the metric:

$$h_{12}=-gTH_{11}/\omega_0^2+H_{12}/\omega_0+\frac{j\Gamma gT}{2D\omega_0}H_{13}+\Gamma^2 gTh_{33},$$

$$h_{22}=-(gT)^2H_{11}/\omega_0^2-2gTh_{12}+H_{22}+\frac{j\Gamma g}{D}(gT^2H_{13}/\omega_0+Th_{23})-g(\Gamma gT/D)^2h_{33},$$

$$h_{23}=-gTH_{13}/\omega_0+H_{23}+\frac{j\Gamma gT}{2D}h_{33}. \tag{12.19}$$

The metric resulting after the redefinitions and the coordinate transformation is

$$\tilde{\Gamma}:=\frac{h}{D(m^2-n^2)},$$

$$g_{11}=(\omega_0\tilde{y})^2+H_{11}\tilde{P}^2+\tilde{\Gamma}e^{-jY}[2\tilde{U}\tilde{V}H_{13}-(h/D)h_{33}],$$

$$g_{12}=\tilde{P}\{H_{12}-(D/\tilde{\Gamma})zH_{11}+(j/2-D\tilde{V}/\tilde{U})zH_{13}+\tilde{\Gamma}[(\tilde{V}/\tilde{U})H_{23}+(D+\tfrac{1}{2}j\tilde{V}/\tilde{U})zh_{33}]\},$$

$$g_{13}=H_{13}\tilde{P}+\tilde{\Gamma}e^{-jY/2}\tilde{V}h_{33}, \tag{12.20}$$

$$g_{22}=(Dz/\tilde{\Gamma})^2H_{11}-(D/\tilde{\Gamma})(2zH_{12}+jz^2H_{13})+H_{22}+jzH_{23}+gz^2h_{33},$$

$$g_{23}=-(D/\tilde{\Gamma})zH_{13}+H_{23}+(j/2)zh_{33},\quad g_{33}=h_{33}=H_{33}.$$

In the limit $\omega_0\to 0$, all the H_{ij} will depend only on t.

The limit of zero shear is then, as usual, $H_{ij}=-C_{ij}R^2(t)$, $C_{33}=1$, and the $k=-1$ Friedmann limit results from (12.20) when, in addition

$$h=HD,\quad C_{13}=0,\quad D\to 0. \tag{12.21}$$

With $D=0$ we have $\tilde{U}=m$, $\tilde{V}=n$. The, again rather exotic, representation of the limiting Friedmann model is

$$\begin{aligned}ds^2=&dt^2-R^2(t)(mD_{11}e^{-jY/2}dx+D_{12}dY)^2-(D_{22}RdY)^2\\&-R^2\left[e^{-jY/2}\frac{Hn}{m^2-n^2}dx+(C_{23}+jz/2)dY+dz\right]^2,\end{aligned} \tag{12.22}$$

where

$$D_{11}{}^2:=C_{11}{}^2-\left(\frac{H}{m^2-n^2}\right)^2,\quad D_{12}:=C_{12}/D_{11},$$

$$D_{22}{}^2:=C_{22}-C_{23}{}^2-D_{12}{}^2. \tag{12.23}$$

The $k=0$ Friedmann limit results from (12.22) when $j=0$.

The rescaling (12.16) and the limit $\omega_0\to 0$ transform the Killing fields as follows:

$$\begin{aligned}k^\alpha_{(1)}&=\delta^\alpha_1,\quad k^\alpha_{(2)}=(-j/2+D\tilde{V}/\tilde{U})x\delta^\alpha_1-\delta^\alpha_2+(h/\tilde{U})xe^{-jY/2}\delta^\alpha_3,\\k^\alpha_{(3)}&=(-j/2+D\tilde{V}/\tilde{U})\delta^\alpha_1+(h/\tilde{U})e^{-jY/2}\delta^\alpha_3,\end{aligned} \tag{12.24}$$

the algebra still being of type VI_h.

The further rescaling (12.21) and the limit $D\to 0$ transform (12.24) into a Bianchi type V algebra, but $k^\alpha_{(3)}$ has to be replaced by

$$l^\alpha_{(3)}=D^{-1}\left(k^\alpha_{(3)}+\frac{j}{2}k^\alpha_{(1)}\right)\xrightarrow[D\to 0]{}(n/m)\,\delta^\alpha_1+(H/m)\mathrm{e}^{-jY/2}\delta^\alpha_3. \tag{12.25}$$

When $j=0$ on top of $D\to 0$, the Bianchi type reduces to I.

The subcase with $g>j^2/4$ (Bianchi type VII_h with the free parameter $j/(4g-j^2)^{1/2}$) is given by Eqs. (10.18) and (10.19) in Ref. 3, with $y_0=0$. It is transformed back to the Plebański coordinates by the inverse of (10.8) there, and the result is very similar to our (12.10) and (12.11). Only the definitions of U, V, and y, and a few signs in the metric are different

$$D=(g-j^2/4)^{1/2},\quad \Gamma:=\frac{\gamma}{D(M^2+N^2)},$$

$$U:=M\cos(DY)+N\sin(DY),\quad V:=M\sin(DY)-N\cos(DY),$$

$$P=e^{-jY/2}U,\quad y=-\frac{j}{2g}P+\frac{D}{g}\mathrm{e}^{-jY/2}V,$$

$$\begin{aligned}
g_{11}&=y^2+h_{11}P^2+2\Gamma e^{-jY}UVh_{13}+(\gamma\Gamma/D)\mathrm{e}^{-jY}h_{33},\\
g_{12}&=gth_{11}+h_{12}+\Gamma gt\left(V/U+\frac{1}{2}j/D\right)h_{13}+(\Gamma V/U)h_{23}+\Gamma^2 gt\left(1+\frac{jV}{2DU}\right)h_{33},\\
g_{13}&=h_{13}P+\Gamma\mathrm{e}^{-jY/2}Vh_{33},\\
g_{22}&=P^{-2}[(gt)^2h_{11}+2gth_{12}+(j\Gamma/D)gt(gth_{13}+h_{23})+h_{22}+g(\Gamma gt/D)^2h_{33}],\\
g_{23}&=P^{-1}\left(gth_{13}+h_{23}+\frac{j\Gamma gt}{2D}h_{33}\right),\quad g_{33}=h_{33}.
\end{aligned} \tag{12.26}$$

The h_{ij} are here functions of the argument

$$T=t-\frac{D}{\Gamma g}z. \tag{12.27}$$

The redefinitions in the constants and functions needed here are again (12.16) and (12.17) together with

$$\begin{aligned}
h_{12}&=-gTH_{11}/\omega_0^2+H_{12}/\omega_0-\frac{j\Gamma gT}{2D\omega_0}H_{13}-\Gamma^2 gTh_{33},\\
h_{22}&=-(gT)^2H_{11}/\omega_0^2-2gTh_{12}+H_{22}-(j\Gamma g/D)(gT^2H_{13}/\omega_0+Th_{23})-g(\Gamma gT/D)^2h_{33},\\
h_{23}&=-gTH_{13}/\omega_0+H_{23}-\frac{j\Gamma gT}{2D}h_{33}.
\end{aligned} \tag{12.28}$$

The metric resulting after all the redefinitions is

$$\tilde{\Gamma} := \frac{h}{D(m^2+n^2)},$$

$$g_{11} = (\omega_0 \tilde{y})^2 + H_{11}\tilde{P}^2 + \tilde{\Gamma} e^{-jY}[2\tilde{U}\tilde{V}H_{13} + (h/D)h_{33}],$$

$$g_{12} = \tilde{P}[(D/\tilde{\Gamma})zH_{11} + H_{12} + (j/2 + D\tilde{V}/\tilde{U})zH_{13} + (\tilde{\Gamma}\tilde{V}/\tilde{U})H_{23} + \tilde{\Gamma}(D + \tfrac{1}{2}j\tilde{V}/\tilde{U})zh_{33}], \tag{12.29}$$

$$g_{13} = H_{13}\tilde{P} + \tilde{\Gamma} e^{-jY/2}\tilde{V}h_{33},$$

$$g_{22} = (Dz/\tilde{\Gamma})^2 H_{11} + (D/\tilde{\Gamma})(2zH_{12} + jz^2 H_{13}) + H_{22} + jzH_{23} + gz^2 h_{33},$$

$$g_{23} = (D/\tilde{\Gamma})zH_{13} + H_{23} + (j/2)zh_{33}, \quad g_{33} = h_{33} = H_{33}.$$

Just as before, in the limit $\omega_0 \to 0$ the H_{ij} will depend only on t, and the shearfree limit is found in the same way: $H_{ij} = -C_{ij}R^2$, $C_{33} = 1$.

The $k = -1$ Friedmann limit is now obtained in two ways: either

$$h = HD, \quad D \to 0, \tag{12.30}$$

or

$$C_{11} = C_{13} = 0. \tag{12.31}$$

In the first case the Friedmann limit is

$$ds^2 = dt^2 - R^2(t)(mD_{11}e^{-jY/2}dx + D_{12}dY)^2 - (D_{22}R\,dY)^2$$
$$- R^2[e^{-jY/2}(mC_{13} + n\tilde{\Gamma})dx + (C_{23} + jz/2)dY + dz]^2, \tag{12.32}$$

where

$$D_{11}{}^2 := C_{11}{}^2 - C_{13}{}^2 + H^2/(m^2+n^2)^2, \tag{12.33}$$

D_{12} and D_{22} being the same as in (12.23).

In the second case, the $k = -1$ Friedmann limit is

$$ds^2 = dt^2 - R^2(t)[D_{11}e^{-jY/2}\tilde{U}dx + (D_{12} + Dz)dY]^2 - (D_{22}R\,dY)^2$$
$$- R^2[e^{-jY/2}\tilde{V}\tilde{\Gamma}dx + (C_{23} + jz/2)dY + dz]^2, \tag{12.34}$$

where D_{11} is defined as in (12.33), but with $C_{11} = C_{13} = 0$.

The Killing fields before redefinitions are still given by (12.13), but, in consequence of the different definitions of P and y in the present subcase, the Bianchi type is VII_h. In the Friedmann limit defined by (12.31), the Killing fields are transformed only by (12.16) and (12.17) followed by $\omega_0 \to 0$, and they still form a type VII_h algebra. When (12.30) is imposed on top of (12.16) and (12.17) and $\omega_0 \to 0$, the Killing fields become the same as the limit $D \to 0$ of (12.24) and (12.25), i.e., the Bianchi type becomes V. This is an illustration of the fact, mentioned in Sec. I, that the $k = -1$ Robertson–Walker geometry is a subcase of two Bianchi types simultaneously, they are exactly V and VII_h.

In both cases, the $k=0$ Friedmann limit follows from (12.32) and (12.34) when $j=0$. In the first case, the algebra of the Killing fields becomes type I, in the second case it becomes type VII_0, which is another illustration of the same kind of duality.

Finally, the third subcase of case 2.2.1.2 is given by Eqs. (10.20) and (10.21) in Ref. 3, with $y_0=0$. There is one more typo there, the correct formula for y is

$$y=-2P/j-4M\mathrm{e}^{-jY/2}/j^2. \tag{12.35}$$

This one is of Bianchi type IV. When transformed back to the Plebański coordinates [by the inverse of (10.8) in Ref. 3], it becomes

$$\begin{gathered}
P=e^{-jY/2}(MY+N),\\
g_{11}=y^2+h_{11}P^2-2(\gamma/M)e^{-jY/2}Ph_{13}+(\gamma/M)^2\mathrm{e}^{-jY}h_{33},\\
g_{12}=(jt/2)^2h_{11}+h_{12}+\frac{j^3\gamma t}{8M^2}h_{13}-\frac{\gamma}{M(MY+N)}\left(\frac{1}{4}j^2th_{13}+h_{23}+\frac{j^3\gamma t}{8M^2}h_{33}\right),\\
g_{13}=h_{13}P-(\gamma/M)\mathrm{e}^{-jY/2}h_{33},\\
g_{22}=P^{-2}\left[\left(\frac{1}{4}j^2t\right)^2h_{11}+\frac{1}{2}j^2th_{12}+\frac{j^5\gamma t^2}{16M^2}h_{13}+h_{22}+\frac{j^3\gamma t}{4M^2}h_{23}+\left(\frac{j^3\gamma t}{8M^2}\right)^2h_{33}\right],\\
g_{23}=P^{-1}\left(\frac{1}{4}j^2th_{13}+h_{23}+\frac{j^3\gamma t}{8M^2}h_{33}\right),\quad g_{33}=h_{33},
\end{gathered} \tag{12.36}$$

where the h_{ij} are arbitrary functions of

$$T=t-\frac{4M^2}{j^2\gamma}z. \tag{12.37}$$

The redefinitions needed to calculate the limit $\omega_0\to 0$ are

$$\begin{gathered}
(M,N,\gamma)=(m,n,h)\omega_0,\quad h_{11}=H_{11}/\omega_0^2,\quad h_{13}=H_{13}/\omega_0,\\
h_{12}=-\frac{1}{4}j^2TH_{11}/\omega_0^2+H_{12}/\omega_0-\frac{j^3hT}{8(m\omega_0)^2}H_{13},\\
h_{22}=-(j^2T/4)^2H_{11}/\omega_0^2-\frac{1}{2}j^2Th_{12}-\frac{j^5hT^2}{(4m\omega_0)^2}H_{13}+H_{22}-\frac{j^3hT}{4m^2\omega_0}h_{23}-\left(\frac{j^3hT}{8m^2\omega_0}\right)^2h_{33},\\
h_{23}=-\frac{1}{4}j^2TH_{13}/\omega_0+H_{23}-\frac{j^3hT}{8m^2\omega_0}h_{33}.
\end{gathered} \tag{12.38}$$

We will denote, as before, $(y,P)=\omega_0(\tilde{y},\tilde{P})$, and choose Y as the new x^2-coordinate, so that $\mathrm{d}y=\omega_0\tilde{P}\mathrm{d}Y$. The metric that results is

$$g_{11}=(\omega_0\tilde{y})^2+H_{11}\tilde{P}^2-2(h/m)\mathrm{e}^{-jY/2}\tilde{P}H_{13}+(h/m)^2\mathrm{e}^{-jY}h_{33},$$

$$g_{12}=\tilde{P}\{(m^2/h)zH_{11}+H_{12}+(j/2)zH_{13}-(mY+n)^{-1}[mzH_{13}+(h/m)H_{23}+\tfrac{1}{2}(jh/m)zh_{33}]\},$$

$$g_{13}=H_{13}\tilde{P}-(h/m)\mathrm{e}^{-jY/2}h_{33}, \tag{12.39}$$

$$g_{22}=(m^2z/h)^2H_{11}+2(m^2/h)zH_{12}+(jm^2/h)z^2H_{13}+H_{22}+jzH_{23}+(jz/2)^2h_{33},$$

$$g_{23}=(m^2/h)zH_{13}+H_{23}+(j/2)zh_{33},\quad g_{33}=h_{33}=H_{33}.$$

In the limit $\omega_0\to 0$, the H_{ij} will depend only on t.

The $k=-1$ Friedmann limit is now obtained when

$$H_{ij}=-C_{ij}R^2(t),\quad h=Hm,\quad m\to 0. \tag{12.40}$$

The $k=0$ limit will result when $j=0$ in addition.

XIII. THE CASES 2.2.2 OF REF. 3

The case 2.2.2.1.1 is given by Eqs. (11.11) and (11.12) in Ref. 3. The transformation back to the Plebańnski coordinates is the inverse of (11.10), and the transformed metric is

$$g_{11}=y^2h_{11},\quad g_{12}=(jt/a)(1-h_{11})+h_{12}-\mathcal{A}jth_{13},$$

$$g_{13}=B(j+a)yh_{13},$$

$$g_{22}=\left(\frac{jt}{ay}\right)^2(h_{11}-1)-2\frac{jt}{ay^2}h_{12}+2\mathcal{A}\frac{(jt)^2}{ay^2}h_{13}+h_{22}/y^2-2(\mathcal{A}jt/y^2)h_{23}+(\mathcal{A}jt/y)^2h_{33}, \tag{13.1}$$

$$g_{23}=B(j+a)\left(-\frac{jt}{ay}h_{13}+h_{23}/y-\frac{\mathcal{A}jt}{y}h_{33}\right),\quad g_{33}=B^2(j+a)^2h_{33},$$

where a, $\mathcal{A}$, B, and j are arbitrary constants, and the h_{ij} are arbitrary functions of the argument

$$T=t+\frac{B(j+a)}{\mathcal{A}a}z. \tag{13.2}$$

The Killing fields for the metric (13.1) are

$$k^\alpha_{(1)}=\delta^\alpha_1,\quad k^\alpha_{(2)}=x\delta^\alpha_1-y\delta^\alpha_2,$$

$$k^\alpha_{(3)}=y^{-j/a}[B(j/a+1)\delta^\alpha_0-Bj(ay)^{-1}\delta^\alpha_1-\mathcal{A}\delta^\alpha_3], \tag{13.3}$$

and they form a Bianchi type VI_h algebra, with the free parameter $(j-a)/(j+a)$. The analog of (5.1) is

$$k^\alpha_{(3)}-Bj(ay)^{-1}k^\alpha_{(1)}=y^{-j/a}[B(j/a+1)u^\alpha-(\mathcal{A}/n)w^\alpha], \tag{13.4}$$

and the King-Ellis measure of tilt is

$$\sqrt{-g}u^\alpha N_\alpha=\mathcal{A}y^{1-j/a}. \tag{13.5}$$

By a simple transformation of the z coordinate we can achieve the same result as if

$$B(j+a)=1, \tag{13.6}$$

and we will assume this now.

The redefinitions needed to calculate the limit $\omega_0 \to 0$ are

$$\begin{gathered} y=\omega_0\tilde{y}, \quad \mathcal{A}=A/\omega_0, \quad h_{11}=H_{11}/\omega_0^2, \quad h_{13}=H_{13}/\omega_0, \\ h_{12}=-(j/a)T+(jT/a)H_{11}/\omega_0^2+H_{12}/\omega_0+AjTH_{13}/\omega_0^2, \\ h_{22}=(jT/a)^2(1-H_{11}/\omega_0^2)+2(jT/a)h_{12}-2(Aj^2T^2/a)H_{13}/\omega_0^2+H_{22} \\ +2AjTh_{23}/\omega_0-(AjT)^2h_{33}/\omega_0^2, \\ h_{23}=(jT/a)H_{13}/\omega_0+H_{23}+AjTh_{33}/\omega_0. \end{gathered} \tag{13.7}$$

The redefined metric is

$$\begin{gathered} g_{11}=\tilde{y}^2H_{11}, \quad g_{12}=\frac{j}{a^2A}z(H_{11}-\omega_0^2)+H_{12}+(j/a)zH_{13}, \quad g_{13}=\tilde{y}H_{13}, \\ g_{22}=\tilde{y}^{-2}\left[\left(\frac{jz}{a^2A}\right)^2(H_{11}-\omega_0^2)+2\frac{j}{a^2A}zH_{12}+2\frac{j^2}{a^3A}z^2H_{13}+H_{22}+2(j/a)zH_{23}+(jz/a)^2h_{33}\right], \\ g_{23}=\tilde{y}^{-1}\left[\frac{j}{a^2A}zH_{13}+H_{23}+(j/a)zh_{33}\right], \quad g_{33}=h_{33}=H_{33}. \end{gathered} \tag{13.8}$$

In the limit $\omega_0 \to 0$, the H_{ij} will depend only on t. The $k=-1$ Friedmann limit will then result when

$$H_{ij}=-C_{ij}R^2(t), \quad j=-a, \quad A\to\infty. \tag{13.9}$$

The $k=0$ Friedmann limit will result when

$$\begin{gathered} H_{ij}=-C_{ij}R^2(t), \quad C_{13}=j=0, \quad C_{22}=(D_{22}/k)^2, \\ \tilde{y}=\mathrm{e}^{ku}, \quad k\to 0. \end{gathered} \tag{13.10}$$

The limit (13.9) transforms the Killing fields (13.3) into a Bianchi type V algebra, provided $k^\alpha_{(3)}$ is redefined to $k'^\alpha_{(3)}=-(\omega_0^{j/a}/\mathcal{A})k^\alpha_{(3)}$, and the limits $A\to\infty$ and $j=-a$ are tuned so that $A(j+a)\to\infty$ [for example, $A=\alpha/(j+a)$ and $\alpha\to\infty$]. The limit (13.10) will transform (13.3) into a type I algebra, but $k^\alpha_{(3)}$ has to be redefined as above, and in addition $k^\alpha_{(2)}$ has to be redefined to $k'^\alpha_{(3)}=kk^\alpha_{(2)}$.

The formulas for the case 2.2.2.1.2 simply follow from those above. This case has a completely different outlook only in the coordinates adapted to the Killing fields that were used in Ref. 3. When transformed to the Plebański coordinates, it becomes the subcase of (13.1) given by

$$B(j+a)=1, \quad j=-a, \quad \mathcal{A}=\mathcal{A}_1/a, \tag{13.11}$$

where the $\mathcal{A}_1$ defined above stands in place of the $\mathcal{A}$ from Eq. (11.17) in Ref. 3. Then the redefinitions needed are (13.7) with $\mathcal{A}_1=A/\omega_0$ and $j=-a$, and the redefined metric is

$$\begin{gathered} g_{11}=\tilde{y}^2H_{11}, \quad g_{12}=-(z/A)(H_{11}-\omega_0^2)+H_{12}-zH_{13}, \quad g_{13}=\tilde{y}H_{13}, \\ g_{22}=\tilde{y}^{-2}[(z/A)^2(H_{11}-\omega_0^2)-2(z/A)H_{12}+2(z^2/A)H_{13}+H_{22}-2zH_{23}+z^2h_{33}], \\ g_{23}=\tilde{y}^{-1}[-(z/a)H_{13}+H_{23}-zh_{33}], \quad g_{33}=h_{33}=H_{33}. \end{gathered} \tag{13.12}$$

The $k=-1$ Friedmann limit results now by (13.9) when $\omega_0=0$, and the $k=0$ Friedmann limit results from (13.12) when

$$\omega_0=0, \quad H_{ij}=-C_{ij}R^2(t), \quad (\tilde{y},z)=(e^{ku},e^{kv}),$$

$$(H_{12},H_{13})=(G_{12},G_{13})/k, \quad (H_{22},H_{23},H_{33})=(G_{22},G_{23},G_{33})/k^2, \quad k\to 0. \tag{13.13}$$

The Killing field $k^\alpha_{(3)}$ is different here

$$k^\alpha_{(3)}=y\,\delta^\alpha{}_0-\ln y\,\delta^\alpha{}_1-\mathcal{A}y\,\delta^\alpha{}_3, \tag{13.14}$$

while the two others are as in (13.3). The case 2.2.2.1.2 required a separate consideration in Ref. 3 only because of the logarithm term in the Killing field. In calculating the limits $\omega_0\to 0$ and $A\to\infty$, this vector field has to be redefined similarly as before. For calculating the $k=0$ Friedmann limit, $k^\alpha_{(3)}$ and $k^\alpha_{(2)}$ have to be redefined by $(k'^\alpha_{(2)},k'^\alpha_{(3)})=k(k^\alpha_{(2)},k^\alpha_{(3)}) \xrightarrow[k\to 0]{} (-\delta^\alpha{}_2,-\mathcal{A}\delta^\alpha{}_3)$.

Finally, the case 2.2.2.2 from Ref. 3 [Eqs. (11.18)–(11.27)] is of Bianchi type I, with the velocity field being tangent to the symmetry orbits, so it has no Friedmann limit at all.

XIV. SUMMARY

All the metrics derived in Refs. 1–3, that correspond to rotating hypersurface–homogeneous dust models, have been checked here for the existence of a Friedmann limit. It was found that such a limit exists for all those cases listed in Refs. 2 and 3, where the matter-density is not constant along the flow. However, in at least one class (see Sec. III), the Friedmann model will have no rotating parent solution, but will instead be a separate subclass.

Along the way, the nonstationary metrics were all transformed to such a form, in which the limit of zero rotation can be explicitly calculated. The transformation–reparametrization leading to this form is nonsingular and invertible in each case, but it becomes singular when $\omega\to 0$. The limits $\omega=0$ all have nonzero shear. Thus, a whole collection of metrics generalizing those of Friedmann was found that can be used in studying spatially homogeneous exact perturbations of the latter.

The Class A Bianchi-type metrics (those in which the structure constants have the property $C^a{}_{ac}=0$) are known to admit a Lagrangian–Hamiltonian formulation.[12] Those of them that obey the Einstein equations with a rotating dust source (types VI_0, VII_0, VIII, and IX) were studied by Ozsváth.[7,13] The Lagrangians and Hamiltonians were explicitly found in Refs. 7 and 13, and the Einstein equations in the Hamiltonian form were then transformed to such variables, in which they become analytic. This should prove the existence of solutions.

Two more papers, specifically devoted to rotating spatially homogeneous dust solutions, are those of Behr[11] (where a subclass of type IX models was investigated) and of this author[4] (discussing a subclass of type V models). In both of these, the Einstein equations were transformed, simplified, investigated for known limiting cases and for Lie symmetries, but no explicit solutions were found. A (hopefully) complete overview of other solutions with rotating matter source is given at the end of Ref. 3.

It is hoped that the present paper will be helpful in picking out those models for future investigation that promise interesting physics or geometry.

(Received 3 July 2000; accepted for publication 21 March 2001)

According to 't Hooft [Class. Quantum. Grav. **16**, 3263 (1999)], quantum gravity can be postulated as a dissipative deterministic system, where quantum states at the ''atomic scale'' can be understood as equivalence classes of primordial states governed by a dissipative deterministic dynamics law at the ''Planck scale.'' In this paper, it is shown that for a quantum system to have an underlying deterministic dissipative dynamics, the time variable should be discrete if the continuity of its temporal evolution is required. Besides, the underlying deterministic theory also imposes restrictions on the energy spectrum of the quantum system. It is also found that quantum symmetry at the ''atomic scale'' can be induced from 't Hooft's coarse graining classification of primordial states at the ''Planck scale.'' © *2001 American Institute of Physics.* [DOI: 10.1063/1.1380250]

I. INTRODUCTION

Recently, Gerard't Hooft postulated that there should be a dissipative deterministic theory underlying quantum gravity at the so-called ''Planck scale.'' [1,2] In his theory, the generic quantum mechanics is no longer the crucial starting point. Rather, a deterministic theory with dissipation of information at the ''Planck scale'' is needed to derive quantum mechanics at the ''atomic scale.'' It seems that this viewpoint can solve problems concerning locality and causality in the so-called Planck scale physics such as quantum gravity, which are quite different from those in the usual quantum field theories in some flat background space–time based on the holographic principle in quantum gravity theory.[3]

In 't Hooft's opinion, at the ''atomic scale'' quantum states are equivalence classes of primordial states at the ''Planck scale.'' In Ref. 4, this point of view was illustrated through a simple model. According to 't Hooft, if we only care about the temporal evolution of equivalence classes, the information within each equivalence class could be ignored. Then from a non-time-reversible evolution, which characterizes a deterministic process with dissipation at the ''Planck scale,'' we can obtain a time-reversible evolution of the properly defined equivalence classes of primordial states. Taking the equivalence classes to be quantum states we are then able to introduce a reversible evolution law at the ''atomic scale.'' Apparently, here the central problem is how to classify the Planck scale states with respect to a deterministic evolution. 't Hooft's solution to this problem is as follows. He argues that two Planck scale states are equivalent at the ''atomic scale'' if, after some finite time interval, they evolve into the same state. This leads to a natural definition of equivalence classes: Two states are in the same equivalence class if and only if they evolve into the same state after some finite time interval. Then, quantum states are identified with these equivalence classes.

Most recently we made clear the mathematical structure of 't Hooft's theory using quotient space construction and related concepts.[5] Let the primordial states span a linear space. We find that

[a)]Electronic mail: suncp@itp.a.c.cn

the equivalence classes defined by 't Hooft can be identified with the cosets of the invariant subspace spanned by those primordial states annihilated by the time-evolution operator. Thus the Hilbert space of quantum states is just the corresponding quotient space and the time-reversible evolution at the ''atomic scale'' can naturally be induced on the quotient space by the dissipative deterministic evolution operator. Following this line, in this paper, we will make a further analysis of the mathematical aspect of 't Hooft's theory and then discuss some physical consequences implied in the theory. We will also probe the spectral structure of finite dimensional quantum system with an underlying deterministic structure and extend 't Hooft's idea to study quantum symmetry problem.

II. SOME MATHEMATICAL RESULTS

In this section we present some mathematical results closely related to the 't Hooft equivalence class theory. In the following, I, J stand for index sets not necessarily finite; if V_1 is a subspace of $V, v \in V$, the element $v+V_1$ in the quotient space V/V_1 is denoted by $\overline{v}$. All the vector spaces to be considered are over the complex number field. Physically, one should bear in mind that V will be the linear space spanned by so-called primordial states at the ''Planck scale'' (see the following). For convenience, we list the mathematical definitions of some concepts appearing in 't Hooft's theory as follows.

Definition 1: A linear operator $T \in \mathrm{End}(V)$ is called deterministic if there exists a basis $\{v_i | i \in I\}$ of V on which T acts in the following way: $\forall i \in I$, $\exists i' \in I$ s.t. $Tv_i = v_{i'}$. Such a basis is called a T-deterministic basis. If, moreover, T is singular (noninvertible), then it is called dissipative deterministic.

Remark 1: In 't Hooft theory, T represents a deterministic time-evolution process (with dissipation) at the ''Planck scale.''

Definition 2: An injective map from a set to itself is called a permutation of the set. A linear operator $T \in \mathrm{End}(V)$ is called a permutation operator if there exists a basis of V on which T act as a permutation.

Definition 3: A linear operator on a vector space is called unitarizable if there exists an inner product on the vector space such that it is unitary relative to it.

Remark 2: Physically, time-reversible evolution is described by a unitary operator, and a reversible but not unitarizable operator usually does not correspond to any practical evolution in quantum mechanics.

Definition 4: Let V and W be two vector spaces, $T \in \mathrm{End}(V)$ and $S \in \mathrm{End}(W)$. If there exists an isomorphism φ between V and W such that $\varphi T = S\varphi$, T and S are called equivalent.

Having prepared the above-given definitions, we now state one of our central results.

Proposition 1: Let V be a vector space, $T \in \mathrm{End}(V)$ is dissipative deterministic and V_1 is a T-invariant subspace such that the induced operator $\overline{T}$ on the quotient space V/V_1 is nonsingular, then $\overline{T}$ is a permutation operator; conversely, if $S \in \mathrm{End}(V)$ is a permutation operator, then there exists a vector space V', a dissipative deterministic operator $S' \in \mathrm{End}(V')$, and an S'-invariant subspace V_1' of V' such that the induced operator $\overline{S'} \in \mathrm{End}(V'/V_1')$ is equivalent to S.

Proof: Let $\{v_i | i \in I\}$ be a T-deterministic basis. Then there exists a subset $J \subset I$ such that $\{\overline{v_i} | i \in J\}$ is a basis of V/V_1. By definition

$$\overline{T}\,\overline{v_i} = \overline{Tv_i} = \overline{v_{i'}}, \quad (i, i' \in I). \tag{1}$$

As $\overline{T}$ is nonsingular, we clearly see that $\overline{T}$ acts as a permutation on the basis $\{\overline{v_i} | i \in J\}$. This proves the first half of the proposition. For the second half, let $\{v_i | i \in I\}$ be a basis of V on which S acts as a permutation, take an arbitrary element $w \notin V$, and define

$$V' = \mathrm{span}\{v_i, w | i \in I\},$$

$V_1'=V$. Define $S'\in \mathrm{End}(V')$ such that $S'|_V=S$ and $S'w=0$. It is then trivial to verify that S' is dissipative deterministic and $\overline{S'}$ is equivalent to S. The proposition is thus proved.

Remark 3: This proposition, as we will see in the following, tells us that 't Hooft 's underlying dissipative deterministic dynamic law at the ''Planck scale'' can only produce very special time-reversible evolution at the ''atomic scale.''

Keep the notations in the above-given proposition. We have the following corollary.

Corollary: If V/V_1 is finite dimensional, then $\overline{T}$ is unitarizable.

Proof: According to the proposition, there is a basis of V/V_1 on which $\overline{T}$ acts as a permutation. If $\dim V/V_1<\infty$, $\overline{T}$ is periodic, namely, there exists a positive integer n such that $\overline{T}^n=1$. Let p be its period. Choose an arbitrary inner product $(,)$ on V/V_1 and define a new inner product $\langle,\rangle$ as follows:

$$\langle\overline{v},\overline{w}\rangle=\sum_{j=1}^{p}(\overline{T}^j\overline{v},\overline{T}^j\overline{w}),\quad \forall\overline{v},\overline{w}\in V/V_1. \tag{2}$$

It is then easy to show that $\overline{T}$ is unitary relative to the inner product $\langle,\rangle$.

Proposition 1 shows us that an invertible linear operator can be induced from a deterministic operator T if and only if it is a permutation operator. The following proposition characterizes the permutation operator on a finite dimensional space.

Proposition 2: Let V be a finite dimensional vector space, $T\in\mathrm{End}(V)$. T is a permutation operator if and only if it is diagonalizable and its eigenvalues can be grouped into some classes, say, $\Delta_{n_1},\Delta_{n_2},\cdots,\Delta_{n_r}$, such that Δ_{n_j} $(j=1,2,\cdots,r)$ exactly consists of the n_j n_jth roots of unity with the same multiplicity.

Proof: Let $\{v_i|i=1,2,\cdots,n\}$ be a basis on which T acts as a permutation. First, suppose T is a cyclic permutation of the basis, namely, we have

$$Tv_1=v_2,Tv_2=v_3,\cdots,Tv_{n-1}=v_n,Tv_n=v_1. \tag{3}$$

Then T is a periodic operator of period n, and its minimal polynomial is λ^n-1. Consequently, T is diagonalizable and its eigenvalues are $\exp(i\,2k\pi/n)$ $(k=1,2,\cdots,n)$, the nth roots of unity. Now let T act as a general permutation on the basis. We notice that the basis elements can be grouped into some classes on each of which T acts as a cyclic permutation. Thus the ''only if'' part of the proposition easily follows.

Conversely, suppose T is diagonalizable and its eigenvalues can be grouped into some classes $\Delta_{n_1},\Delta_{n_2},\cdots,\Delta_{n_r}$ in such a way that Δ_{n_j} $(j=1,2,\cdots,r)$ exactly consists of the n_j n_jth roots of unity with multiplicity m_j. Then there is a basis $\{v_{k,l}^j|j=1,2,\cdots,r;\ k=1,2,\cdots,n_j;\ l=1,2,\cdots,m_j\}$ such that

$$Tv_{k,l}^j=\exp\left(i\frac{2k\pi}{n_j}\right)v_{k,l}^j. \tag{4}$$

Define the subspace $V_{j,l}$ of V as follows:

$$V_{j,l}=\mathrm{span}\{v_{k,l}^j|k=1,2,\cdots,n_j\}.$$

Clearly, we have

$$V=\sum_{j=1}^{r}\sum_{l=1}^{m_j}\oplus V_{j,l}$$

and from the proof of the "only if" part we know in each subspace $V_{j,l}$ there is a basis on which T acts as a cyclic permutation of order m_j. Put together, these bases of the subspaces form a basis of V on which T acts as a permutation. This proves the "if" part of the proposition.

III. DYNAMICS FROM 'T HOOFT'S THEORY

In this section we focus on the physical aspect of 't Hooft's theory, but our analysis depends on the above-mentioned mathematical results.

In 't Hooft's theory, primordial states at the "Planck scale" need not form a linear space. Generally they can be denoted by a set $\Sigma=\{\phi_i|i\in I\}$. *The underlying deterministic evolution is a transformation U (usually depending on time) of* Σ *to itself. If U has no inverse it is called a dissipative deterministic evolution*. Obviously, it can be represented by a matrix with the entries 0 or 1 if I is a finite set. As U is an evolution operator, we write it as $U=U(t_f,t_i)$ by convention. Physically, it represents the evolution in the time interval $[t_i,t_f]$. Certainly the evolution should satisfy the so-called semigroup condition

$$U(t_f,t_m)U(t_m,t_i)=U(t_f,t_i),$$
$$U(t,t)=1. \tag{5}$$

If U is singular, it describes deterministic process with dissipation. As a matter of fact, under such an evolution some states will disappear and some states will evolve into the same state, or in other words, some states with a different past may have the same deterministic fate. 't Hooft thinks that if two states evolve in such a way that their futures are identical they should represent the same state at the "atomic scale." In this view, he divides the elements of Σ into equivalence classes, ϕ_{i_1} and $\phi_{i_2}(i_1,i_2\in I)$ being in the same equivalence class if they are evolved into the same state after finite time interval. Denote by $\Xi=\{\overline{\phi_j}|j\in J\}$ the set of the equivalence classes. Then 't Hooft postulates that the space of quantum states is spanned by $\{\overline{\phi_j}|j\in J\}$ and claims that the reduced evolution on the space of quantum states is reversible. We can mathematically reformulate 't Hooft's theory as follows.[5] We assume that the evolution operator $U(t_2,t_1)$ only depends on the difference of t_2 and t_1, i.e., we can write $U(t_2,t_1)=U(t_2-t_1)$. This is in the spirit of 't Hooft's original construction. Then the evolution at the "Planck scale" is determined by the operator $U(t,0)\triangleq U(t)$. Let V be the vector space spanned by $\{\phi_i|i\in I\}$. Then $U(t)$ can be extended to a *deterministic operator* on V. We call V the space of primordial states in spite of the fact that generally it contains elements which are not states. Let V_1 denote the subspace of V consisting of the vectors annihilated by $U(t)$ at some t, namely, a vector v belongs to V_1 if and only if there exists some $U(t)$ such that $U(t)v=0$. Then it follows that *the space of quantum states is none other than the quotient space*

$$Q=V/V_1=\{|\phi\rangle\triangleq\phi+V_1|\phi\in V\}$$

and a nonsingular evolution law of the quantum states naturally follows from $U(t)$. Let $\overline{v}\equiv|\nu\rangle$ denote the equivalence class containing v. We notice that V_1 is invariant under $U(t)$. Thus $U(t)$ induces a natural action on the quotient space Q. We denote the induced operator by $\overline{U(t)}$, then we have

$$\overline{U(t)}\,\overline{v}=\overline{U(t)v}. \tag{6}$$

The following simple result is easy to prove.

Proposition 3: $\overline{U(t)}$ is nonsingular.

In fact, if $\overline{U(t)}\,\overline{v}=\overline{0}$, then $U(t)v\in V_1$. Thus there exists some t' such that $U(t')U(t)v=0$. It then follows that

$$U(t')U(t)v=U(t'+t)v=0. \tag{7}$$

By definition this means $v \in V_1$, i.e., $\overline{v}=\overline{0}$. This proves the nonsingularity of $\overline{U(t)}$.

Remark 4: In Refs. 1 and 2, 't Hooft just claims the nonsingularity of the induced evolution operator. But it should be pointed out that if the condition $U(t_2,t_1)=U(t_2-t_1)$ is not satisfied the induced evolution $\overline{U(t_2,t_1)}$ might be singular if we still use 't Hooft's principle to classify the primordial states.

We are now in a position to discuss a consequence of 't Hooft's theory. The basis consisting of the equivalence classes is called the primordial basis by 't Hooft. In our notations, $\{\overline{\phi_j}|j \in J\}$ is the primordial basis and $\overline{U(t)}$ is a (dissipative) deterministic operator on V. As we have proved the nonsingularity of $\overline{U(t)}$, it follows from Proposition 1 that $\overline{U(t)}$ is a permutation operator which acts as a permutation on the primordial basis. Then we easily observe that if we require $\overline{U(t)}$ to be continuous with respect to t, the time variable should be discrete. For example, if J is a finite set, or in other words, the quantum Hilbert space is finite dimensional, the induced evolution operator $\overline{U(t)}$ is represented as a matrix with the entries 0 or 1 with respect to the primordial basis. Clearly, it could not be continuous if the time variable is not discrete.

IV. SPECTRUM AND HAMILTONIAN

Let us turn to consider restrictions on the energy spectrum of quantum system imposed by the underlying determinism. Due to the arguments in the last paragraph, we assume the time variable to be discrete. Without losing generality, let the time t take values in Z^+, the set of non-negative integers. The deterministic evolution and the induced evolution of the quantum system is then completely determined by the operator $U(1)$. Suppose $\overline{U(1)}$ is unitary. It is then can be written as $\overline{U(1)}=e^{-iH}$, where H is a Hermitian operator describing the Hamiltonian of the quantum system. Now if the quantum system is finite dimensional it follows from Proposition 2 that the eigenvalues of $\overline{U(1)}$ are of the form $e(-i\,2k\pi/n)$. Thus we have the following

Proposition 4: The eigenvalues of H corresponding to the induced evolution $\overline{U(1)}=e^{-iH}$ of quantum states lie in the set

$$\left\{ \frac{2k\pi}{n} \pm 2m\pi \middle| k,n,m \in Z^+ \right\}.$$

Remark 5: We have seen that evolutions that can be induced from dissipative deterministic evolutions at the ''Planck scale'' belong to a special class. First, there is a rather strict restriction on the corresponding Hamiltonian H. Second, if a quantum system with an underlying deterministic structure as is described by 't Hooft is initially in the state represented by an element of the primordial basis then the evolution will never cause coherent superposition of quantum states. As these drawbacks are inherent in the theory, to remove them we have to generalize the underlying dynamic law at the ''Planck scale.''

Another conclusion that can be drawn from Proposition 1 is that 't Hooft's theory is closely related to the hidden variable theory. Since $\overline{U(t)}$ acts as a permutation on the primordial basis of the space of quantum states, an operator that is diagonal now with respect to this basis will continue to be diagonal in the future. Such an operator could thus be thought to represent a hidden variable. This suggests that a quantum system with an underlying dissipative deterministic mechanism might permit some kind of hidden variable theory. The corollary to Proposition 2 also shows us that if $U(t)$ is a dissipative deterministic such that the quotient space V/V_1 is finite dimensional $\overline{U(t)}$ can be made unitary by properly introducing an inner product. Then $\overline{U(t)}$ can be regarded as an evolution operator for a quantum system. But on the other hand, such inner product is not at all unique. Since a correct quantum theory requires a Hilbert space with properly defined inner product to define probability, this is really a problem if we wish to derive quantum dynamics from a dissipative deterministic evolution, not just to interpret a given quantum system as governed by an underlying deterministic mechanism. So a gap remains to be bridged between the so-called Planck scale physics and the atomic scale physics in 't Hooft's theory.

Before passing to discuss quantum symmetry we would like to present a simple quantum system which has some characteristics of a deterministic system as shown previously. We consider the following quantum system: A spinless free particle in the one-dimensional region $[0,L]$ with the boundary condition $\psi(0,t)=\psi(L,t)$, where $\psi(x,t)$ is the wave function. The Hilbert space of the system is

$$\mathcal{H}=\{\psi\in\mathcal{L}^2[0,L]\psi(0)=\psi(L)\}.$$

Clearly,

$$\Delta=\left\{\exp\left(i\frac{2k\pi}{L}x\right)k=0,\pm1,\pm2,\cdots\right\}$$

is a basis of $\mathcal{H}$. In the case of extreme relativity, the Hamiltonian of the system is $H=-i\hbar c(d/dx)$, *where c* is the speed of light. Define $\overline{U(t)}=e^{-iHt}$. We have

$$\overline{U(t)}\exp\left(i\frac{2k\pi}{L}x\right)=\exp\left(-i2k\pi\frac{\hbar c}{L}t\right)\exp\left(i\frac{2k\pi}{L}x\right). \tag{8}$$

We observe that if we take the time to be discrete, it is then possible to define a time unit such that the one step evolution acts on Δ in the following way:

$$\overline{U(1)}\exp\left(i\frac{2k\pi}{L}x\right)=\exp\left(i\frac{2k\pi}{L}x\right).$$

We then see that this system might be regarded as a deterministic system and Δ might serve as primordial basis for the system. If we normalize $\hbar c/L$ as one energy unit, then the energy spectrum of the system is $\{2k\pi|k=0,\pm1,\pm2,...\}$. This is consistent with our previous discussion.

Remark 6: It should be pointed out that the above-mentioned simple example is essentially the same as the example of massless neutrinos discussed in Ref. 1.

V. QUANTUM SYMMETRY BY COARSE GRAINING

As shown previously, 't Hooft's classification of primordial states implies a scheme for coarse graining. Usually, for a large close system a coarse graining process can result in quantum dissipation and decoherence in the subsystem.[6] But here the converse seems to be the case: Coarse graining (or classification) can lead to a unitary dynamics for the effective system even if the evolution of primordial system is not time reversible. Since ''symmetry dominates dynamics,'' it is rather natural to probe the role of coarse graining in generating symmetry at the ''atomic scale.''

Let a deterministic system be described by an evolution operator $\overline{U(t)}$, and let $\{\overline{\phi_j}|j\in J\}$ be the primordial basis for the system. Denote by P^J the permutation group of the set J. According to Proposition 1, $\overline{U(t)}$ is a permutation operator and can be identified with an element of P^J. By definition, the group of quantum symmetry consists of those unitary operators on the state space that commute with the evolution operator. If we require that these unitary operators be induced from deterministic operators on the space of primordial states, it then follows from Proposition 1 that they belong to the centralizer of $\overline{U(t)}$ in P^J. If the space of quantum states is finite dimensional, by the trick of redefining inner product as is used in the proof of the corollary to Proposition 1, we can show that there exists an inner product such that both $\overline{U(t)}$ and the operators in its centralizer in P^J are unitary operators. Thus in this case it might be reasonable to take the group of quantum symmetry to be the centralizer of $\overline{U(t)}$ in P^J. Anyway, the symmetry group is a discrete group.

We have seen that if we adhere to the principle that things happening in the space of primordial states bear the mark of determinism, then logically, things happening in the space of quantum states bear the mark of discreteness. To change the situation we need to loosen the restriction of

determinism in the strict sense of this word used by 't Hooft. Let us conclude this paper with a short discussion of quantum symmetry derived from a not necessarily deterministic operator on the space of primordial states. Let V be the space of primordial states and $S \in \mathrm{End}(V)$ satisfies $SV_1 \subset V_1$.

Proposition 5: $\overline{U(t)S} - \overline{SU(t)} = 0$ if and only if there exists some t' such that

$$U(t')(U(t)S - SU(t)) = 0. \tag{9}$$

The proof of this result is immediate. It directly follows from Eq. (9) that $(U(t)S - SU(t))V \subset V_1$ (cf. Sec. III). In other words, we have

$$\overline{U(t)S} - \overline{SU(t)} = 0. \tag{10}$$

This proves the ''if'' part. The ''only if'' part can be proved by reversing the deduction.

If the time is discrete and takes values in Z^+, then the evolution at the ''Planck scale'' is determined by $U(1) \triangleq U$. Notice that $U^n = U(n)$ in this case. It follows that Eq. (9) is equivalent to

$$U^n(US - SU) = 0 \tag{11}$$

for some positive integer n. Let us take 't Hooft's example in Ref. 1 to illustrate the above-mentioned idea. We have

$$U = \begin{pmatrix} 0 & 1 & 0 & 1 \\ 1 & 0 & 0 & 0 \\ 0 & 0 & 1 & 0 \\ 0 & 0 & 0 & 0 \end{pmatrix}. \tag{12}$$

Let $e_1 = (1\,0\,0\,0)^T$, $e_2 = (0\,1\,0\,0)^T$, $e_3 = (0\,0\,1\,0)^T$, $e_4 = (0\,0\,0\,1)^T$. Then

$$\overline{U} = \begin{pmatrix} 0 & 1 & 0 \\ 1 & 0 & 0 \\ 0 & 0 & 1 \end{pmatrix}$$

with respect to the basis $\{\overline{e_i} | i = 1,2,3\}$. The general matrix T that commutes with $\overline{U}$ is of the form

$$T = \begin{pmatrix} a & b & c \\ b & a & c \\ j & j & k \end{pmatrix}.$$

Suppose $SV_1 \subset V_1$. Then the general solution of Eq. (11) is

$$S = \begin{pmatrix} a & b & c & b \\ b-m & f & g & f \\ j & j & k & j \\ m & a-f & c-g & a-f \end{pmatrix}.$$

It is clear that for each T commuting with $\overline{U}$ there exists S such that $\overline{S} = T$. In fact, as $\overline{e_2} = \overline{e_4}$, the above S has the representation

$$\overline{S}=\begin{pmatrix} a & b & c \\ b & a & c \\ j & j & k \end{pmatrix} \tag{13}$$

with respect to the basis $\{\overline{e_i}|i=1,2,3\}$. Mathematically, this is a trivial fact. On the other hand, we have

$$US-SU=\begin{pmatrix} 0 & 0 & 0 & 0 \\ a-f & m & c-g & m \\ 0 & 0 & 0 & 0 \\ -a+f & -m & -c+g & -m \end{pmatrix}.$$

This simply means that for $\overline{S}$ to commute with $\overline{U}$, S does not necessarily commute with U.

In the representation where $\overline{U}$ is diagonal we have

$$\overline{U}=\begin{pmatrix} 1 & 0 & 0 \\ 0 & 1 & 0 \\ 0 & 0 & -1 \end{pmatrix}.$$

Thus the matrix T that commutes with $\overline{U}$ takes a block diagonal form. It then follows that the symmetry group of the system is $U(2)\times U(1)$. But if we impose the restriction that S is a deterministic operator, as is required by determinism, it then turns out that the set of nonsingular $\overline{S}$ commuting with $\overline{U}$ is $\{1,\overline{U}\}$, the centralizer of $\overline{U}$ in P^3.

To sum up, if we loosen the restriction of determinism it is possible to induce quantum symmetry from transformations on the space of primordial states through a procedure of coarse graining as shown previously. On the other hand, quantum symmetry at the ''atomic scale'' does not necessitate symmetry at the ''Planck scale.''

We prove the existence of nondecaying real solutions of the mKP-I equation, vanishing for $x\to+\infty$, and we obtain asymptotic formulas as $t\to\infty$ in the form of an infinite series of asymptotic solitons with curved lines of constant phase and varying amplitude and width. © *2001 American Institute of Physics.*
[DOI: 10.1063/1.1329155]

I. INTRODUCTION

Investigations of long-time asymptotic behavior of nondecaying at infinity solutions of nonlinear evolution equations in $2+1$ dimensions (two spatial and one time variables) are closely related to the corresponding investigations in $1+1$ dimensions. A. V. Gurevich and L. P. Pitaevsky studied in 1973 the nondecaying solution of the Korteweg–de Vries (KdV) equation, which describes the evolution of the initial step-function $u(x,0)$:[1,2]

$$u_t-6uu_x+u_{xxx}=0,$$

$$u(x,0)=\begin{cases}0 & \text{if } x>0,\\ -c^2 & \text{if } x\leqslant 0.\end{cases}$$

They applied the Whitham method to construct an approximation of this solution by a cnoidal wave with slowly varying parameters, and detected the presence of many strong solitonlike oscillations on the front of the solution for large time. This approximate solution satisfies the KdV equation with error vanishing for $t\to+\infty$. Thus, they conjectured that solutions of the Cauchy problem with initial steplike data split into an infinite sequence of solitons for $t\to\infty$.

However, this conjecture seemed to contradict the idea that solitons were generated by the discrete spectrum of the L-operator since a Schrödinger operator whose potential is a step-function has no discrete spectrum.

The situation was clarified in 1975 by E. Ya. Khruslov in Ref. 3. He showed that these solitonlike oscillations are not generated by the discrete spectrum but by the continuous spectrum of multiplicity one of the Schrödinger operator, i.e., the L-operator of the KdV equation. Later on, these solitons were called ''asymptotic solitons.'' An analogous phenomenon of splitting of nondecaying at infinity initial data into infinite series of solitons was then found for other integrable nonlinear equations (nonlinear Schrödinger equation, sine–Gordon equation, modified Korteweg–de Vries equation and the Toda lattice).[4–8]

In Refs. 9–12, the method proposed by E. Ya. Khruslov in Ref. 3 was extended to the investigation of the asymptotic behavior of nondecaying solutions of the Kadomtsev–Petviashvili (KP) equation for $t\to\infty$. Within the framework of the Zakharov–Shabat scheme,[13] the solutions of the KP equation, vanishing for $x\to\infty$ and bounded for any fixed x,y,t, were obtained, and their

a)Electronic mail: anne@math.jussieu.fr

large-time asymptotic form was proved to be an infinite series of solitons with curved lines of constant phase in a neighborhood of the front for $t\to\infty$. These asymptotic solitons were called ''curved asymptotic solitons.'' Recently,[14] V. E. Zakharov also considered a curved soliton of the KP–II equation, but in another space-time domain.

Our goal is to prove the phenomenon of splitting of nondecaying solutions of the modified Kadomtsev–Petviashvili–I (mKP-I) equation into an infinite series of solitons for $t\to\infty$. The mKP equation was introduced by B. G. Konopelchenko in Ref. 15 as a natural two-dimensional generalization of the modified Korteweg–de Vries (mKdV) equation, and it has the form

$$v_t+\frac{1}{4}v_{xxx}-\frac{3}{2}\alpha^2\left(v_xv^2-v_x\int_x^\infty v_y\,dx'+\frac{1}{2}\int_x^\infty v_{yy}\,dx'\right)=0,$$

where $v=v(x,y,t)$ and

$$\alpha=\begin{cases}1 & \text{for the mKP-II equation,}\\ i & \text{for the mKP-I equation.}\end{cases}$$

This equation was integrated by the $\overline{\partial}$-method (see Ref. 16), and both ''lump solutions'' [vanishing as $(x^2+y^2)^{-1}$] and ''plane solitons'' were obtained.

A scheme of integration of the mKP equation by the inverse scattering method, which is an analog of the Zakharov–Shabat method for the KP equation, was introduced in Ref. 11. According to this scheme, a solution has the form

$$v(x,y,t)=\frac{1}{\alpha}\frac{\mathrm{d}}{\mathrm{d}x}\ln\left(1+\int_x^\infty K(x,s,y,t)\mathrm{d}s\right),\tag{1.1}$$

where the function $K(x,s,y,t)$ is a solution of the Marchenko integral equation

$$K(x,z,y,t)+F(x,z,y,t)+\int_x^\infty K(x,\xi,y,t)F(\xi,z,y,t)\mathrm{d}\xi=0\tag{1.2}$$

viewed as an equation with respect to z, with x,y,t as parameters. The kernel $F(x,z,y,t)$ of (1.2) satisfies the system of linear differential equations

$$\begin{cases}F_t+F_{xxx}+F_{zzz}=0,\\ \alpha F_y+F_{xx}-F_{zz}=0.\end{cases}\tag{1.3}$$

A large class of solutions of (1.3) for $\alpha=i$ can be found by the Fourier method as follows:

$$F(x,z,y,t)=\int\int_\Omega \exp[ip(x-z)-q(x+z)+2qf(p,q,Y)t]\mathrm{d}\mu(p,q),\tag{1.4}$$

where $f(p,q,Y)=q^2-3p^2+2pY$, $Y=y/t$, and the measure $\mathrm{d}\mu(p,q)$ $(p+iq\in\mathbb{C})$ is defined on a set $\Omega\subset\mathbb{C}$.

In Sec. II we introduce two functions $C(s)$ and $g(s)$, and using them we construct a set Ω and a measure $\mathrm{d}\mu$ of a special form. Then we prove that the scheme (1.1)–(1.4) determines the existence of a nondecaying real solution of the mKP-I equation, vanishing for $x\to\infty$ and bounded for any fixed x,y,t.

In Sec. III we state and prove the theorem about splitting of the solutions in a neighborhood of the front into a series of solitons of the form

$$v_n(x,y,t)=-\frac{2q_0(Y)^2}{p_0(Y)+\sqrt{p_0^2(Y)+q_0^2(Y)}\cosh[2q_0(Y)\kappa_n(x,y,t)]},$$

$$\kappa_n(x,y,t)=x-C(Y)t+\frac{1}{2q_0(Y)}(\ln t^{n+1/2}-\ln g(Y)-\ln \phi_n(Y)),$$

where the domain of investigations and the functions $q_0(Y)$, $p_0(Y)$, $\phi_n(Y)$ are completely determined by the functions $C(Y)$ and $g(Y)$.

In Sec. IV we give two examples of curved asymptotic solitons. For example, if $C(Y)=Y^2/3+b^2$, then $q_0(Y)=b$, $p_0(Y)=Y/3$.

II. EXISTENCE OF SOLUTIONS OF THE mKP–I EQUATION

To construct a mKP-I solution by the scheme (1.1)–(1.4) we must define the set Ω in (1.4) and the measure $d\mu(p,q)$ over this set. For this goal we introduce two positive functions $C(s)$ and $g(s)$ which play an important role in the construction of the solution and in the investigation of its asymptotic behavior. We introduce the following conditions.

Condition A: The function $C(s):\mathbb{R}\to\mathbb{R}^+$ is C^∞ and such that

$$C(s)>s^2/3+\delta^2 \quad (\delta=\text{const}>0),$$
$$C''(s)>0. \tag{2.1}$$

Condition B: The set $\Omega\subset\mathbb{R}^2$ has the form

$$\Omega=\{(p,q)\,|\,-\infty<p<\infty,\ 0<\varepsilon\leqslant q\leqslant h(p)\}, \tag{2.2}$$

where $q=h(p)$ is the envelope of the family of hyperbolas

$$f(p,q,s)=C(s), \tag{2.3}$$

which touch it at the point

$$(p_0(s),q_0(s))=(C'(s)/2,\ \sqrt{C(s)+\tfrac{3}{4}(C'(s))^2-sC'(s)}). \tag{2.4}$$

Remark: Conditions A and B imply that

$$C(s)=\max_{(p,q)\in\Omega} f(p,q,s), \tag{2.5}$$

and for any $s\in\mathbb{R}$ this maximum is attained at a unique point, $(p_0(s),q_0(s))$.

Condition C: The function $g(s):\mathbb{R}\to\mathbb{R}^+$ is of class C^∞ and such that the real positive function $\tilde g(p,q)\in C^\infty$, $\tilde g(p_0(s),q_0(s))=g(s)$, satisfies the inequality

$$\forall a=\text{const}>0:\quad \int\int_\Omega e^{a(q+|p|)}\tilde g(p,q)\,dp\,dq<\infty. \tag{2.6}$$

Condition D: The measure $d\mu$ has the form

$$d\mu(p,q)=\tilde g(p,q)\sqrt{\frac{p-iq}{p+iq}}\,dp\,dq. \tag{2.7}$$

Lemma 1: Assume that Conditions A–D are fulfilled. Then the scheme (1.1)–(1.4) determines a smooth real solution of the mKP-I equation vanishing as $x\to\infty$ and bounded for all fixed x,y,t.

Proof: Define an operator $\hat F$ acting in $L^2[x,\infty)$ by the formula

$$[\hat F h](z)=\int_x^\infty F(s,z,y,t)h(s)\,ds,$$

where the kernel F is given by (1.4). The function $h(s)$ depends on the parameters y,t as well. Since

$$\|\hat{F}\|^2_{L^2[x,\infty)} = \int_x^\infty \int_x^\infty |F(x,z,y,t)|^2 \mathrm{d}s\mathrm{d}z$$
$$\leqslant \frac{1}{4\varepsilon^2} \int \int_\Omega \tilde{g}(p,q)\mathrm{d}p\mathrm{d}q \int \int_\Omega \exp[4q(|x|+f(p,q,Y))t]\tilde{g}(p,q)\mathrm{d}p\mathrm{d}q$$
$$\leqslant \frac{1}{4\varepsilon^2} \int \int_\Omega \tilde{g}(p,q)\mathrm{d}p\mathrm{d}q \int \int_\Omega e^{aq}\tilde{g}(p,q)\mathrm{d}p\mathrm{d}q,$$

condition C gives $\|\hat{F}\|_{L^2[x,\infty)}<\infty$, i.e., $\hat{F}$ is a Hilbert–Schmidt operator. Hence, $\hat{F}$ is a compact operator.[17]

The adjoint operator $\hat{F}^*$ is given by

$$[\hat{F}^*\psi](z) = \int_x^\infty \overline{F(z,s,y,t)}\psi(s)\mathrm{d}s,$$

where

$$\overline{F(z,x,y,t)} = \int \int_\Omega \exp[ip(x-z)-q(x+z)+4pqy-2q(3p^2-q^2)t] \sqrt{\frac{p-iq}{p+iq}}\, \tilde{g}(p,q)\mathrm{d}p\mathrm{d}q.$$

Let us consider the homogeneous equation

$$\psi+\hat{F}^*\psi=0. \tag{2.8}$$

Multiplying (2.8) with $\overline{\psi}$, we obtain by integration

$$\|\psi\|^2 - \int \int_\Omega \tilde{g}(p,q)\frac{p}{\sqrt{p^2+q^2}} e^{-2q(3p^2-q^2)t+4pqy} \left| \int_x^\infty e^{(ip-q)s}\psi(s)\mathrm{d}s \right|^2 \mathrm{d}p\mathrm{d}q$$
$$= i \int \int_\Omega \tilde{g}(p,q)\frac{q}{\sqrt{p^2+q^2}} e^{-2q(3p^2-q^2)t+4pqy} \left| \int_x^\infty e^{(ip-q)s}\psi(s)\mathrm{d}s \right|^2 \mathrm{d}p\mathrm{d}q.$$

Since $q>0$, $\tilde{g}(p,q)>0$, the right-hand side of this equation is $\neq 0$. Therefore, Eq. (2.8) has only the trivial solution. Then, Fredholm's theory[17] implies that Eq. (1.2) is solvable for any x,y,t.

According to (1.4) and conditions C and D, $F(x,z,y,t)$ is a C^∞ function with respect to all variables. We can show[18] that the function $K(x,z,y,t)$ is C^∞, too.

Since the set Ω lies inside the upper half-plane ($q\geqslant\varepsilon>0$), $F(x,z,y,t)$ vanishes exponentially as $x+z\to\infty$. Therefore $K(x,z,y,t)$ and its derivatives vanish exponentially also as $x\to+\infty$.

Now let us address the formula (1.1) for the mKP-1 solution. First of all we will show that $K(\cdot,s,\cdot,\cdot)\in L^1[x,\infty)$. Conditions C and D allow us to show that $\|F(\cdot,s,\cdot,\cdot)\|_{L^1(x,\infty)}<\infty$. Now (1.2) implies that the function

$$\Phi(x,a,y,t) = \int_a^\infty K(x,z,y,t)\mathrm{d}z \quad (a\geqslant x)$$

satisfies

$$\Phi(x,a,y,t) + \int_x^\infty \Phi(x,s,y,t)D(s,a,x,y,t)\mathrm{d}s = B(x,a,y,t) \tag{2.9}$$

with

$$B(x,a,y,t)=-\frac{A(x,a,y,t)}{1+A(x,x,y,t)},$$

$$D(s,a,x,y,t)=A_s(s,a,y,t)-\frac{A(x,a,y,t)}{1+A(x,x,y,t)}A_s(s,x,y,t),$$

$$A(x,a,y,t)=\int_a^\infty F(x,z,y,t)\mathrm{d}z,$$

where $A_s(x,a,y,t)=(\partial/\partial s)\,A(s,a,y,t)$. Since $\mathrm{Re}\,A(x,x,y,t)=0$, the kernel $D(s,a,x,y,t)$ and the right-hand side of (2.9) are well defined. Equation (2.9) is a Volterra equation with respect to a and x,y,t are parameters. Application of the successive approximation method to (2.9) gives

$$|\Phi(x,x,y,t)|<\infty. \tag{2.10}$$

Hence, $K(\cdot,s,\cdot,\cdot)\in L^1[x,\infty)$.

Let us show now that

$$\int_x^\infty K(x,s,y,t)\mathrm{d}s\neq -1.$$

Suppose that $\int_x^\infty K(x,s,y,t)\mathrm{d}s=-1$. Then it follows immediately from (2.9) that $\Phi(x,a,y,t)$ satisfies the homogeneous integral equation

$$\Phi(x,a,y,t)+\int_x^\infty \Phi(x,s,y,t)A_s(s,a,y,t)\mathrm{d}s=0. \tag{2.11}$$

We can easily show by the above method that for any $a\geqslant x$ this equation has only the trivial solution. Therefore, $\int_x^\infty K(x,s,y,t)\mathrm{d}s\neq -1$, and (1.1) has sense.

Now we shall prove that the constructed mKP-I solution is real-valued. Analysis of (1.1) implies that it is sufficient to show that

$$\frac{\partial}{\partial x}(2\,\mathrm{Re}\,\Phi(x,x,y,t)+|\Phi(x,x,y,t)|^2)=0. \tag{2.12}$$

First of all, note that

$$\overline{A(x,z)}=-A(z,x). \tag{2.13}$$

Consider the equation conjugated to (2.9). After multiplication of (2.9) by $(\partial/\partial a)\,\Phi(x,a,y,t)$ and integration with respect to a from x to $+\infty$ we obtain

$$\begin{aligned} g(\Phi)=\Phi(x,x,y,t)(A(x,x,y,t)+1)+A(x,x,y,t)(\overline{\Phi(x,x,y,t)}+1)+A(x,x,y,t)|\Phi(x,x,y,t)|^2 \\ +\left((\hat{A}\Phi(x,a,y,t),\Phi(x,a,y,t))-\int_x^\infty \overline{\Phi(x,a,y,t)}\Phi_a(x,a,y,t)\mathrm{d}a\right)=0, \end{aligned} \tag{2.14}$$

where $\hat{A}:L^2[x,\infty)\to L^2[x,\infty)$ has the form

$$(\hat{A}\varphi)(s)=\int_x^\infty \overline{A_{sa}}(s,a)\,\varphi(a)\mathrm{d}a$$

and $(\cdot,\cdot)$ denotes the scalar product in $L^2[x,\infty)$. It follows from (2.13) and (2.14) that

$$g(\Phi)+\overline{g(\Phi)}=2\,\mathrm{Re}\,\Phi(x,x,y,t)+|\Phi(x,x,y,t)|^2=0.$$

□

III. LARGE-TIME ASYMPTOTIC BEHAVIOR OF NONDECAYING SOLUTIONS OF THE mKP–I EQUATION

Our goal is to investigate the long-time asymptotic behavior of the solution of the mKP-I equation defined in Sec. II.

Definition 1: Let $M>0$. Denote by $G_M(t)\subset\mathbb{R}^2$ the domain

$$G_M(t)=\left\{(x,y)\in\mathbb{R}^2\,\middle|\,-\infty<y<\infty,t>t_0(M),x>C(Y)t-\frac{M}{2q_0(Y)}\ln t;Y=\frac{y}{t}\right\}.$$

We call $G_M(t)$ the neighborhood of the front of the solution.

We shall study the behavior of the mKP-I solution in such domains.

Theorem 1 describes the large-time asymptotic behavior of the solutions of the mKP-I equation defined by Lemma 1.

Theorem 1: *Assume that conditions A–D are fulfilled. Then, in the domain $G_M(t)$, the solution $v(x,y,t)$ of the mKP-I equation constructed by the scheme (1.1)–(1.3) has for $t\to\infty$ the asymptotic behavior*

$$v(x,y,t)=-\sum_{n=1}^{[M-1]}v_n(x,y,t)+O\left(\frac{1}{t^{1/2-\varepsilon_1}}\right)\quad(0<\varepsilon_1<\tfrac{1}{2}),\tag{3.1}$$

where

$$v_n(x,y,t)=-\frac{2q_0(Y)^2}{p_0(Y)+\sqrt{p_0^2(Y)+q_0^2(Y)}\cosh[2q_0(Y)\kappa_n(x,y,t)]},$$

$$\kappa_n(x,y,t)=x-C(Y)t+\frac{1}{2q_0(Y)}(\ln t^{n+1/2}-\ln g(Y)-\ln\phi_n(Y)),$$

$$\phi_n(Y)=\frac{(C(Y)+3(C'(Y))^2-4YC'(Y)+Y^2)^n(C''(Y))^{n-1/2}Q^{(n)}\Gamma^{(n)}}{2^{5n-1/2}((n-1)!)^2(C(Y)+3/4(C'(Y))^2-YC'(Y))^{(10n-5)/4}Q^{(n-1)}\Gamma^{(n-1)}},$$

and $\Gamma^{(n)},Q^{(n)}>0$ are the determinants of the $n\times n$ matrices with the entries

$$\Gamma^{(n)}_{i+1,k+1}=\Gamma\left(\frac{i+k+1}{2}\right)(1+(-1)^{i+k}),$$

$$Q^{(n)}_{i+1,k+1}=\Gamma(i+k+1),\quad i,k=0,\ldots,n-1.$$

The asymptotic behavior (3.1) is uniform with respect to x and y in $G_M(t)$ for any fixed $M>2$.

Proof: Let us indicate the key points of the proof. It consists of three steps.

First we show that for $t\to\infty$ the kernel $F(x,z,y,t)$ of the integral equation (1.2) is represented as the sum of a degenerate kernel and a kernel with a small operator norm in the space $L^2(x,\infty)$.

At the second step we prove that the degenerate kernel gives the main contribution in the asymptotic behavior of the solution of Eq. (1.2).

The third step consists of an analysis of the expression (1.1) for the solution $v(x,y,t)$ as $t\to\infty$, where the function $K(x,z,y,t)$ is a solution of the Marchenko integral equation with degenerate kernel.

To investigate the kernel $F(x,z,y,t)$ of the Marchenko equation for $t\to\infty$ [see (1.4)], we set

$$x=C(Y)t+\xi, \quad z=C(Y)t+\zeta,$$

and define

$$\tilde{F}(\xi,\zeta,y,t)=F(\xi+C(Y)t,\zeta+C(Y)t,y,t).$$

Then

$$\tilde{F}(\xi,\zeta,y,t)=\int\int_{\Omega}\exp[ip(\xi-\zeta)-q(\xi+\zeta)-2q(C(Y)-f(p,q,Y))t]\mathrm{d}\mu.$$

For sufficiently small $\varepsilon'>0$, let us consider the curve

$$2q(f(p,q,Y)-C(Y))+\varepsilon'=0. \tag{3.2}$$

This curve defines a partition of the domain Ω into two subdomains $O_{\varepsilon'}$ and $\Omega_{\varepsilon'}$ so that $\Omega=\overline{O_{\varepsilon'}}\cup\Omega_{\varepsilon'}$. Here $O_{\varepsilon'}$ lies between the curve $q=h(p)$ and curve (3.2), moreover $(p_0(Y),q_0(Y))\in O_{\varepsilon'}$. The set $\Omega_{\varepsilon'}$ is the complementary set of $\overline{O_{\varepsilon'}}$ in Ω. According to this decomposition, the kernel (1.4) is the sum of two kernels which we denote by $F_1(x,z,y,t)$ and $F_2(x,z,y,t)$, respectively.

Let us make a change of variables by setting

$$r=2q(C(Y)-f(p,q,Y)) \tag{3.3}$$

in the kernel $F_1(x,z,y,t)$ related to integration over the set $O_{\varepsilon'}$. Let u be the projection of the radius vector directed from the point $(p_0(Y),q_0(Y))$ to the point $(p,q)\in O_{\varepsilon'}$ on the tangent to the curve $q=h(p)$ at the point $(p_0(Y),q_0(Y))$ or, which is the same, on the tangent to the curve $f(p,q,Y)=C(Y)$ at the same point. We have

$$u=\frac{3p_0(Y)-Y}{\sqrt{q_0^2(Y)+(3p_0(Y)-Y)^2}}(q-q_0(Y))+\frac{q_0(Y)}{\sqrt{q_0^2(Y)+(3p_0(Y)-Y)^2}}(p-p_0(Y)). \tag{3.4}$$

The system (3.3) and (3.4) has a unique solution with respect to $(p,q)\in O_{\varepsilon'}$ for $0<\varepsilon'<\min(4\delta^3,\delta-\varepsilon)$. Therefore the variables p and q can be expressed via the variables r and u in $O_{\varepsilon'}$. We can choose the number ε' such that the following Taylor series converge absolutely:

$$p(r,u)=p_0+k_1r+k_2u+k_3ur+k_4r^2+k_5u^2+\cdots,$$

$$q(r,u)=q_0+\lambda_1r+\lambda_2u+\lambda_3ur+\lambda_4r^2+\lambda_5u^2+\cdots,$$

where k_n and λ_n are the coefficients of the corresponding Taylor series. The first of them have the form

$$k_1(Y)=\frac{3p_0(Y)-Y}{4q_0(Y)(q_0^2(Y)+(3p_0(Y)-Y)^2)},$$

$$k_2(Y)=\frac{q_0(Y)}{\sqrt{q_0^2(Y)+(3p_0(Y)-Y)^2}},$$

$$\lambda_1(Y)=-\frac{1}{4q_0(Y)(q_0^2(Y)+(3p_0(Y)-Y)^2)},$$

$$\lambda_2(Y)=\frac{3p_0(Y)-Y}{\sqrt{q_0^2(Y)+(3p_0(Y)-Y)^2}}.$$

For $n>2$ we can obtain the coefficients k_n and λ_n in an explicit form after n–times differentiation of (3.3) and (3.4) with respect to r and u. The equation $q=h(p)$ can be written in the variables r and u in $O_{\varepsilon'}$. Condition A $[C''(Y)\neq 0]$ implies that the curves $f(p,q,Y)=C(Y)$ and $q=h(p)$ have a contact of the first order. Therefore $q=h(p)$ takes the form $u=u(r)$ with

$$u=\pm a(Y)\sqrt{r}+b(Y)r+\cdots,$$

where

$$\begin{aligned}a(Y)&=\left[\frac{q_0^2(Y)+(3p_0(Y)-Y)^2}{4q_0(Y)(3q_0^2(Y)-(3p_0(Y)-Y)^2-h'(p_0(Y))q_0^3(Y))}\right]^{1/2}\\&=\left(\frac{(C(Y)+3(C'(Y))^2-4YC'(Y)+Y^2)C''(Y)}{8(C(Y)+3/4(C'(Y))^2-YC'(Y))^{3/2}}\right)^{1/2}.\end{aligned}\tag{3.5}$$

With the new variables u and r and the notation

$$E_0(\xi,\zeta,Y)=e^{ip_0(Y)(\xi-\zeta)-q_0(Y)(\xi+\zeta)},$$

we write the function $\tilde{F}_1(\xi,\zeta,y,t)=F_1(\xi+C(Y)t,\zeta+C(Y)t,y,t)$ as follows:

$$\begin{aligned}\tilde{F}_1(\xi,\zeta,y,t)=E_0(\xi,\zeta,Y)\int_0^{\varepsilon}dr\int_{-a\sqrt{r}+\cdots}^{a\sqrt{r}+\cdots}du\,j(r,u,Y)\tilde{g}(r,u,Y)\sqrt{\frac{p-iq}{p+iq}}\\\times e^{i(p-p_0)(\xi-\zeta)-(q-q_0)(\xi+\zeta)-rt},\end{aligned}\tag{3.6}$$

where $j(r,u,Y)=j(p(r,u,Y),q(r,u,Y))$ is the Jacobian corresponding to the change of variables $(p,q)\to(r,u)$.

Let us expand the integrand in (3.6) into a series with respect to the powers of r and u in the neighborhood of the point $(p_0(Y),q_0(Y))$ $(u=0,r=0)$:

$$\begin{aligned}&j(r,u,Y)\tilde{g}(r,u,Y)\sqrt{\frac{p-iq}{p+iq}}e^{i(p-p_0(Y))(\xi-\zeta)-(q-q_0(Y))(\xi+\zeta)}\\&=\sum_{n=0}^{\infty}\sum_{j=0}^{n}\sum_{l=0}^{j}\sum_{m=0}^{n-j}\zeta^j\xi^{n-j}r^{l+m}u^{n-l-m}\varphi_{n,j,l,m}(Y)(1+\psi_n(r,u)),\end{aligned}$$

with

$$\begin{aligned}\varphi_{n,j,l,m}(Y)=\frac{(-1)^{n-m}}{l!m!(n-j-m)!(j-l)!}\sqrt{\frac{p_0(Y)-iq_0(Y)}{p_0(Y)+iq_0(Y)}}(ik_1(Y)+\lambda_1(Y))^l(ik_2(Y)\\+\lambda_2(Y))^{j-l}(ik_1(Y)-\lambda_1(Y))^m(\lambda_2(Y)-ik_2(Y))^{n-j-m}g(Y)j_0(Y),\end{aligned}$$

and

$$\begin{aligned}j_0(Y)=j(0,0,Y)=\frac{1}{4q_0(Y)\sqrt{q_0^2(Y)+(3p_0(Y)-Y)^2}},\\g(Y)=\tilde{g}(0,0,Y),\end{aligned}\tag{3.7}$$

the functions $\psi_n(r,u)$ satisfying the inequalities $|\psi_n(r,u)| \leqslant An(r+|u|)$.

Integrating with respect to u and r, we obtain

$$\tilde{F}_1(\xi,\zeta,y,t) = E_0(\xi,\zeta,Y) \sum_{n=0}^{N-1} \sum_{j=0}^{N-n-1} \zeta^n \xi^j \frac{\psi_{nj}(Y)}{t^{(n+j+3)/2}} (1+\delta_n(t)) + \Delta_N(\xi,\zeta,y,t),$$

where

$$\psi_{nj}(Y) = \sqrt{\frac{p_0(Y)-iq_0(Y)}{p_0(Y)+iq_0(Y)}} \frac{g(Y)j_0(Y)a^{n+j+1}(Y)}{2n!j!} \Gamma\left(\frac{n+j+1}{2}\right)(1+(-1)^{n+j})(ik_2(Y) + \lambda_2(Y))^n(\lambda_2(Y)-ik_2(Y))^j, \tag{3.8}$$

and

$$|\delta_n(t)| \leqslant \frac{B_{nj}}{\sqrt{t}},$$

$$|\Delta_N| \leqslant AE_0(\xi,\zeta,y,t) \sum_{j=0}^{N} \frac{|\zeta^j \xi^{N-j}|}{t^{(N+3)/2}}. \tag{3.9}$$

The bound (3.9) is valid for $|\xi|<|\zeta|<t^{1/4}$.

In the domain $\zeta > \xi > -(1/2q_0)\ln t^M$, we have the following bound for the function $\Delta_N(\xi,\zeta,y,t)$ as $t>t_0(M)$

$$\int_x^\infty \int_x^\infty |\Delta_N(s,z,y,t)|^2 \mathrm{d}s\mathrm{d}z \leqslant \frac{A(N)}{t^{1/2-\varepsilon_1}} \quad (0<\varepsilon_1<\tfrac{1}{2}), \tag{3.10}$$

where $A(N) \leqslant e^{N+3}/(N+3)^{N+3}2^{N+4}$ and $N=[2M-3]$.

Consider the operator

$$[\hat{F}_2 h](z) = \int_x^\infty F_2(s,z,y,t)h(s)\mathrm{d}s$$

in the space $L^2[x,\infty)$. We estimate the function $|F_2(s,z,y,t)|^2$ as follows:

$$\begin{aligned} |F_2(s,z,y,t)|^2 &= \left| \int\int_{\Omega_{\varepsilon'}} e^{ip(x-z)-q(x+z)+4pqy-2q(3p^2-q^2)t} \mathrm{d}\mu \right|^2 \\ &\leqslant \left(\int\int_{\Omega_{\varepsilon'}} g(p,q)\mathrm{d}p\mathrm{d}q \right)\left(\int\int_{\Omega_{\varepsilon'}} e^{-2q(s+z)+4qf(p,q,Y)t} \tilde{g}(p,q)\mathrm{d}p\mathrm{d}q \right) \\ &\leqslant A \int\int_{\Omega_{\varepsilon'}} e^{-2q(s+z)+4qf(p,q,Y)t} \tilde{g}(p,q)\mathrm{d}p\mathrm{d}q. \end{aligned}$$

Taking into account that $C(Y)-f(p,q,Y) \geqslant \varepsilon'/2q$ $[(p,q)\in\Omega_{\varepsilon'},\ q\geqslant\varepsilon>0]$, we have the following estimate for the norm of $\hat{F}_2$ for $x>C(Y)t-(\varepsilon'/2\varepsilon)t$:

$$\int_x^\infty \int_x^\infty |F_2(s,z,y,t)|^2 \mathrm{d}s\mathrm{d}z = O(e^{-\varepsilon' t}). \tag{3.11}$$

Therefore inside the domain

$$\zeta > \xi > -\frac{1}{2q_0(Y)} \ln t^M, \quad Y = \frac{y}{t}, \quad -\infty < y < \infty,$$

and for $t \to \infty$, the kernel $\tilde{F}(\xi,\zeta,y,t)$ has the form

$$\tilde{F}(\xi,\zeta,y,t) = \tilde{F}_N(\xi,\zeta,y,t) + \tilde{G}(\xi,\zeta,y,t),$$

where $(N=[2M-3])$

$$\tilde{F}_N(\xi,\zeta,y,t) = e^{ip_0(\xi-\zeta)-q_0(\xi+\zeta)} \sum_{n=0}^{N-1} \sum_{j=0}^{N-n-1} \zeta^n \xi^j \frac{\psi_{nj}(Y)}{t^{(n+j+3)/2}}, \tag{3.12}$$

and the functions $\psi_{nj}(Y)$ defined in (3.8) are bounded. Taking into account (3.9)–(3.11), we can conclude that the function $G(s,z,y,t)$ admits a uniform estimate with respect to y $(-\infty < y < \infty)$:

$$\int_x^\infty \int_x^\infty |G(s,z,y,t)|^2 ds\,dz = O\left(\frac{1}{t^{1/2-\varepsilon_1}}\right) \quad (0 < \varepsilon_1 < 1/2). \tag{3.13}$$

We show that after replacing the kernel $F(x,z,y,t)$ by the degenerate kernel $F_N(x,z,y,t)$ we can obtain an asymptotic representation of the solution $K(x,z,y,t)$ of the Marchenko integral equation (1.2) up to $O(t^{-1/2+\varepsilon_1})$ $(0 < \varepsilon_1 < \frac{1}{2})$ for $t \to \infty$. Set

$$x = C(Y)t + \xi, \quad z = C(Y)t + \zeta,$$

and consider the domain

$$\zeta > \xi > -\frac{1}{2q_0(Y)} \ln t^M,$$

where M is an arbitrary positive number. Let us introduce the operators

$$(\hat{F}_N f)(z) = \int_x^\infty F_N(s,z,y,t) f(s) ds,$$

$$(\hat{G}_N f)(z) = \int_x^\infty G_N(s,z,y,t) f(s) ds,$$

in the space $L^2[x,\infty)$. The degenerate kernel

$$F_N(x,z,y,t) = \tilde{F}_N(x - C(Y)t, z - C(Y)t, y, t)$$

$(N=[2M-3])$ is defined in (3.12) with $\xi = x - C(Y)t$ and $\zeta = z - C(Y)t$, and $\psi_{nj}(Y)$ are defined by (3.8). The function $G_N(x,z,y,t)$ is the difference between $F(x,z,y,t)$ defined in (1.4) and $F_N(x,z,y,t)$:

$$G_N = F - F_N.$$

Now (1.2) takes the form

$$(I + \hat{F}_N) f + \hat{G}_N f = h_N + g_N, \tag{3.14}$$

where $f=K(x,z,y,t)$, $h_N=-F_N(x,z,y,t)$, and $g_N=-G_N(x,z,y,t)$. According to (3.13) we easily obtain the following estimates for the norms of the operator $\hat{G}_N$ and the vector g_N in $L^2[x,\infty)$ for $\zeta>\xi>-[1/2q_0(Y)]\ln t^M$:

$$\|\hat{G}_N\|\leqslant A_1 t^{-1/2+\varepsilon_1},$$
$$\|\hat{g}_N\|\leqslant A_1 t^{-1/2+\varepsilon_1} \quad (A_1=\text{const},\ 0<\varepsilon_1<\tfrac{1}{2}). \tag{3.15}$$

The operator $I+\hat{F}_N$ is the direct sum of two operators, $I_1+\hat{F}_N$ and I_2. The first one acts in the subspace H_1 of $L^2[x,\infty)$ generated by the vectors $e^{(ip_0-q_0)z}$, $ze^{(ip_0-q_0)z}$, $\ldots$, $z^{N-1}e^{(ip_0-q_0)z}$. The second, I_2 $(I=I_1\oplus I_2)$, acts in the orthogonal complement $H_2=L^2[x,\infty)\ominus H_1$ of H_1. Since we have $\hat{F}_N=\hat{F}-\hat{G}$ and since $I+\hat{F}$ is invertible, we derive that also $I+\hat{F}_N$ is invertible in $L^2[x,\infty)$, and

$$\|(I+\hat{F}_N)^{-1}\|_{L^2[x,\infty)}\leqslant A_2<\infty. \tag{3.16}$$

We shall look for a solution of (3.14) in the form $f=\phi_N+\psi_N$, ϕ_N being the solution of the equation $(I+\hat{F}_N)\phi_N=h_N$. The latter observation implies that ψ_N satisfies the equation

$$(I+\hat{F}_N)\psi_N=g_N-\hat{G}_N\phi_N.$$

According to (3.16), we have

$$\|\psi_N\|\leqslant A_2(\|g_N\|+\|\hat{G}_N\|\cdot\|\psi_N\|).$$

Below we shall show that ϕ_N is uniformly bounded with respect to y, t and $\xi>-[1/2q_0(Y)]\ln t^M$ in the space $L^2[x,\infty)\cap L^1[x,\infty)$. This fact and (3.15) allow us to conclude that

$$f(z)=\phi_N(z)+O(t^{-1/2+\varepsilon_1}), \quad 0<\varepsilon_1<\tfrac{1}{2}. \tag{3.17}$$

The replacement of the kernel F by the degenerate kernel F_N in the equation (1.2) and the substitutions $x=C(Y)t+\xi$ and $z=C(Y)t+\zeta$ allow us to obtain as an integral equation for the function $K_N(\xi,\zeta,y,t)=K(\xi+C(Y)t,\zeta+C(Y)t,y,t)$ $(\zeta>\xi)$,

$$K_N(\xi,\zeta,y,t)+F_N(\xi,\zeta,y,t)+\int_\xi^\infty K_N(\xi,s,y,t)F_N(s,\zeta,y,t)\,ds=0, \tag{3.18}$$

where F_N is given by (3.12).

According to (1.1) and (3.17), we have the following asymptotic expression of $v(x,y,t)$ in the domain $x>C(Y)t-(1/2q_0)\ln t^M$:

$$v(x,y,t)=\left(-i\frac{\partial}{\partial\xi}\ln\left\{1+\int_\xi^\infty K_N(\xi,s,y,t)\,ds\right\}\right)\Bigg|_{\xi=x-C(Y)t}+O(t^{-1/2+\varepsilon_1}). \tag{3.19}$$

We shall look for a solution of the equation (3.18) in the form

$$K_N(\xi,\zeta,y,t)=\sum_{n=0}^{N-1}\gamma_n(\xi,Y,t)\zeta^n e^{-(ip_0+q_0)\zeta}. \tag{3.20}$$

By substituting (3.20) into (3.18) we obtain the system of algebraic equations for the functions $\gamma_n(\xi,Y,t)$ $(n=0,\ldots,N-1)$:

$$\gamma_n+\sum_{m=0}^{N-1}\gamma_m\sum_{j=0}^{N-n-1}\frac{\psi_{nj}(Y)}{t^{(n+j+3)/2}}\int_\xi^\infty s^{j+m}e^{-2q_0s}\mathrm{d}s=-\sum_{j=0}^{N-n-1}\frac{\psi_{nj}(Y)}{t^{(n+j+3)/2}}\xi^j e^{(ip_0-q_0)\xi}. \quad (3.21)$$

The solution of these equations has the form

$$\gamma_n=\frac{\det[I+A(\xi,y,t)]^{(l)}}{\det[I+A(\xi,y,t)]},$$

where I is the identity matrix, $A(\xi,y,t)$ is the matrix with the entries $(n,m=0,\ldots,N-1)$,

$$[A]_{n+1,m+1}=\sum_{j=0}^{N-n-1}\frac{\psi_{nj}}{t^{(n+j+3)/2}}I_{j+m}, \quad (3.22)$$

$$I_{j+m}=\int_\xi^\infty s^{j+m}e^{-2q_0s}\mathrm{d}s.$$

The matrix $[I+A(\xi,y,t)]^{(l)}$ is obtained via the substitution of the column of the right-hand sides of the system (3.21) instead of the lth column of the matrix $[I+A(\xi,y,t)]$. The functions ψ_{nj} are defined by (3.8).

The substitution of $\gamma_n(\xi,Y,t)$ into (3.20) gives

$$K_N(\xi,\zeta,y,t)=\sum_{n=0}^{N-1}\frac{\det(I+A)^{(n)}}{\det(I+A)}\zeta^n e^{-(ip_0+q_0)\zeta}.$$

To obtain $v(x,y,t)$ we calculate the integral

$$\int_\xi^\infty K(\xi,s,y,t)\mathrm{d}s=e^{-(ip_0+q_0)\xi}\sum_{n=0}^{N-1}\gamma_n(\xi,y,t)\sum_{i=0}^{n}\frac{\xi^i n!}{i!(ip_0+q_0)^{n-i+1}}$$

and we substitute it into (3.19). One has

$$v(x,y,t)=-i\frac{\mathrm{d}}{\mathrm{d}\xi}\ln\left(1+\sum_{n=0}^{N-1}\frac{\det(I+A(\xi,y,t))^{(n)}}{\det(I+A(\xi,y,t))}\sum_{i=0}^{n}\frac{\xi^i n!e^{-(ip_0+q_0)\xi}}{i!(ip_0+q_0)^{n-i+1}}\right)\Bigg|_{\xi=x-C(Y)t}+O(t^{-1/2+\varepsilon_1}). \quad (3.23)$$

Hence the investigation of the long-time behavior of $v(x,y,t)$ reduces to the study of the determinant formula (3.23) for $t\to\infty$.

We introduce the following notation:

$$G(\xi,y,t)=\sum_{n=0}^{N-1}\frac{\det(I+A(\xi,y,t))^{(n)}}{\det(I+A(\xi,y,t))}\sum_{i=0}^{n}\frac{\xi^i n!e^{-(ip_0+q_0)\xi}}{i!(ip_0+q_0)^{n-i+1}}.$$

The function G can be represented in the form

$$G(\xi,y,t)=\frac{1}{ip_0+q_0}\frac{\partial}{\partial\xi}\ln\det(I+A(\xi,y,t))+\sum_{n=1}^{N-1}\frac{\det(I+A(\xi,y,t))^{(n)}}{\det(I+A(\xi,y,t))}\sum_{i=0}^{n}\frac{\xi^i n!e^{-(ip_0+q_0)\xi}}{i!(ip_0+q_0)^{n-i+1}}.$$

The asymptotic analysis of the function $\det(I+A(\xi,y,t))$ for $t\to\infty$ gives us

$$\det(I+A(\xi,y,t))=1+\sum_{n=1}^{N}\frac{\Delta_n(\xi,y,t)}{t^{n(n+2)/2}}e^{-2nq_0\xi},$$

where

$$\Delta_n(\xi,y,t)=\frac{P_nW_n}{(2q_0)^n}\left[1+O_N\left(\frac{1}{\sqrt{t}}\right)\right],$$

where P_n are the determinants of the $n\times n$ matrices whose entries are the integrals

$$[P_n]_{jk}=2q_0\int_\xi^\infty s^{j+k}e^{-2q_0s}\mathrm{d}s,$$

and W_n are the determinants of the $n\times n$ matrices with the entries

$$[W_n]_{ik}=\psi_{ik}.$$

Besides,

$$W_n=\frac{(q_2^2+p_2^2)^{n(n-1)/2}a^{n^2}}{2^n\Pi_{k=0}^{n-1}(k!)^2}\left(\frac{ip_0+q_0}{ip_0-q_0}\right)^{n/2}(j_0g)^n\Gamma^{(n)}, \tag{3.24}$$

where

$$[\Gamma^{(n)}]_{i+1,k+1}=(1+(-1)^{k+i})\Gamma\left(\frac{k+i+1}{2}\right).$$

It is easy to verify that P_n and $\Gamma^{(n)}$ are the Gram determinants of the two systems of functions $(k=0,\ldots,n-1)$

$$u_k=e^{-\xi/2}\xi^k,\quad \xi>0,$$

$$u_k=\sqrt{2}x^ke^{-x^2/2},\quad -\infty<x<+\infty,$$

respectively. Therefore $\Gamma^{(n)},\ P_n\neq 0$, and $(0\leqslant i,k\leqslant n-1)$

$$P_n=\det\|\Gamma(i+k+1)(2q_0)^{-i-k}\|.$$

Since in the region $\zeta>\xi>(1/2q_0)\ln t^M$ the determinant Δ_n does not vanish [the operator $(I+\hat{F})^{-1}$ is bounded], it is easy to see that $\Gamma^{(n)},P_n>0$.

Let us cover the domain $G_M(t)$ $(M>2)$ by the subdomains

$$a_1=\left\{(\xi,t)\,\middle|\,\xi>-\frac{1}{2q_0}\ln t^{2+\varepsilon}\right\},$$

$$a_n=\left\{(\xi,t)\,\middle|\,-\frac{1}{2q_0}\ln t^{n+1+\varepsilon}<\xi<-\frac{1}{2q_0}\ln t^{n-\varepsilon}\right\},\quad n=2,\ldots,m-1,$$

$$a_m=\left\{(\xi,t)\,\middle|\,-\frac{1}{2q_0}\ln t^{(N+3)/2}<\xi<-\frac{1}{2q_0}\ln t^{m-\varepsilon}\right\},$$

where $m=[(N+1)/2]$. If (ξ,t) belongs to a_n, one has

$$\det(I+A)=\left(\frac{W_{n-1}P_{n-1}e^{-2(n-1)q_0\xi}}{(2q_0)^{n-1}t^{(n-1)(n+1)/2}}+\frac{W_nP_ne^{-2nq_0\xi}}{(2q_0)^nt^{n(n+2)/2}}\right)\left[1+O\left(\frac{1}{\sqrt{t}}\right)\right] \tag{3.25}$$

as $t\to\infty$.

One can represent $G(\xi,y,t)$ in the form

$$G(\xi,y,t)=\frac{1}{(ip_0+q_0)\det(I+A)}\left\{\frac{\partial}{\partial\xi}\det(I+A(\xi,y,t))+\sum_{n=1}^{N-1}\det(I+A(\xi,y,t))^{(n)}\sum_{i=0}^{n}\frac{\xi^i n!e^{-(ip_0+q_0)\xi}}{i!(ip_0+q_0)^{n-i+1}}\right\}.$$

The analysis of the matrices $(I+A)^{(n)}$ for $t\to\infty$ gives us an asymptotic representation for $G(\xi,y,t)$ inside a_n:

$$G(\xi,y,t)=\frac{2q_0}{(ip_0+q_0)(W_{n-1}P_{n-1}+P_nT_ne^{-2q_0\xi})}\{W_{n-1}S_{n-1}+S_nT_ne^{-2q_0\xi}\},$$

where

$$\begin{aligned}T_n&=\frac{W_n}{2q_0t^{n+1/2}},\\ S_n&=-(R_n+nP_n),\\ R_n&=\sum_{k=1}^{n-1}\frac{k!}{(ip_0+q_0)^k}P_n^{(k)},\\ R_1&=0,\end{aligned}\tag{3.26}$$

$P_n^{(k)}$ being the determinant of the matrix obtained from the matrix P_n by replacing the $(k+1)$th column by the transpose of $(1,0,\ldots,0)$.

It follows from (3.19) that

$$v(x,y,t)=\frac{1}{i}\frac{\partial}{\partial\xi}\ln(1+G(\xi,y,t))\Big|_{\xi=x-C(Y)t}=\frac{1}{i}\frac{G_\xi}{1+G}\Big|_{\xi=x-C(Y)t}.\tag{3.27}$$

Let us calculate the numerator and the denominator in (3.27):

$$\begin{aligned}G_\xi(\xi,y,t)&=\frac{4q_0^2}{ip_0+q_0}\frac{T_nW_{n-1}(P_nS_{n-1}-S_nP_{n-1})e^{-2q_0\xi}}{(W_{n-1}P_{n-1}+T_nP_ne^{-2q_0\xi})^2},\\ 1+G(\xi,y,t)&=\frac{W_{n-1}F_{n-1}+T_nF_ne^{-2q_0\xi}}{(ip_0+q_0)(W_{n-1}P_{n-1}+P_nT_ne^{-2q_0\xi})},\end{aligned}\tag{3.28}$$

where

$$F_n=(ip_0+q_0)P_n+2q_0S_n.\tag{3.29}$$

After substitution of (3.28) into (3.27) we obtain

$$v(x,y,t)\sim-\frac{2iq_0^2(S_nP_{n-1}-P_nS_{n-1})}{\frac{1}{2}(P_nF_{n-1}+F_nP_{n-1})+\sqrt{P_nP_{n-1}F_nF_{n-1}}\cosh\{2q_0(x-C(Y)t)-\ln\varphi_n\}},$$

where

$$\varphi_n=\frac{T_n}{W_{n-1}}\sqrt{\frac{P_nF_n}{P_{n-1}F_{n-1}}}. \tag{3.30}$$

One can prove that

$$(ip_0+q_0)P_{n-1}F_n=(ip_0-q_0)P_nF_{n-1}. \tag{3.31}$$

Equations (3.29) and (3.31) give us the following relations:

$$\begin{aligned} F_nP_{n-1}&=(ip_0-q_0)(S_{n-1}P_n-S_nP_{n-1}),\\ F_{n-1}P_n&=(ip_0+q_0)(S_{n-1}P_n-S_nP_{n-1}). \end{aligned} \tag{3.32}$$

Let us write the sum and the product of the relations in (3.32):

$$F_nP_{n-1}+P_nF_{n-1}=2ip_0(S_{n-1}P_n-S_nP_{n-1}),$$

$$F_nF_{n-1}P_nP_{n-1}=-(q_0^2+p_0^2)(S_{n-1}P_n-S_nP_{n-1})^2.$$

Then the function $v(x,y,t)$ has the following form:

$$v(x,y,t)=-\sum_{n=1}^{[(N+1)/2]}\frac{2q_0^2}{p_0+\sqrt{p_0^2+q_0^2}\cosh[2q_0(x-C(Y)t)-\ln\varphi_n(Y,t)]},$$

where $\varphi_n(Y,t)$ is defined by (3.30).

It follows from (3.26) and (3.31) that

$$\frac{T_n}{W_{n-1}}=\frac{1}{2q_0t^{n+1/2}}\frac{W_n}{W_{n-1}},\quad \frac{P_nF_n}{P_{n-1}F_{n-1}}=\frac{P_n^2}{P_{n-1}^2}\frac{ip_0-q_0}{ip_0+q_0},$$

i.e.,

$$\varphi_n(Y,t)=\frac{1}{2q_0t^{n+1/2}}\sqrt{\frac{ip_0-q_0}{ip_0+q_0}}\ \frac{P_nW_n}{P_{n-1}W_{n-1}}. \tag{3.33}$$

In view of condition D and (3.33), one can represent the function φ_n as

$$\varphi_n(Y,t)=\frac{1}{2q_0(Y)t^{n+1/2}}\frac{g(Y)j_0(Y)a^{2n-1}(Y)(k_2^2+\lambda_2^2)^{n-1}P_n\Gamma^{(n)}}{2P_{n-1}\Gamma^{(n-1)}}.$$

Thus, the asymptotic behavior of the solution $v(x,y,t)$ of the mKP-I equation for $t\to\infty$ is given by

$$v(x,y,t)=-\sum_{n=1}^{[M-1]}v_n(x,y,t)+O\left(\frac{1}{t^{1/2-\varepsilon_1}}\right),$$

with

$$v_n(x,y,t)=\frac{2q_0^2(Y)}{p_0+\sqrt{p_0^2+q_0^2}\cosh[2q_0(Y)(x-C(Y)t+(1/2q_0)(\ln t^{n+1/2}-\ln g(Y)-\ln\phi_n(Y)))]},$$

where

$$\phi_n(Y)=\frac{j_0(Y)a^{2n-1}(Y)Q^{(n)}\Gamma^{(n)}}{2(2q_0(Y))^{2(n-1)}[(n-1)!]^2Q^{(n-1)}\Gamma^{(n-1)}}>0, \tag{3.34}$$

and $Q^{(n)}$, $\Gamma^{(n)}$ are the determinants $(0\leqslant i,k\leqslant n-1)$

$$Q^{(n)}=\det\|\Gamma(i+k+1)\|,$$

$$\Gamma^{(n)}=\det\left\|(1+(-1)^{k+i})\Gamma\left(\frac{k+i+1}{2}\right)\right\|.$$

Using condition B, (3.7) and (3.5) we can also write $\phi_n(Y)$ as

$$\phi_n(Y)=\frac{(C(Y)+3(C'(Y))^2-4YC'(Y)+Y^2)^n(C''(Y))^{n-1/2}Q^{(n)}\Gamma^{(n)}}{2^{5n-1/2}((n-1)!)^2(C(Y)+3/4(C'(Y))^2-YC'(Y))^{(10n-5)/4}Q^{(n-1)}\Gamma^{(n-1)}}.$$

So, the mKP-I equation solution $v(x,y,t)$ determined by (1.1)–(1.3) splits into a series of curved solitons whose width and amplitude depend on Y. Since all the factors in $\phi_n(Y)$ are positive, $v_n(x,y,t)$ are regular. These asymptotic solitons diverge with a velocity proportional to $\ln t$ when t increases. The theorem is proved. □

IV. EXAMPLES OF ASYMPTOTIC SOLITONS FOR THE mKP-I EQUATION

In this section we consider two special examples of solutions of the mKP-I equation, which generate asymptotic solitons of different forms in the neighborhood of the front of the mKP-I solution for $t\to\infty$. First of all we have to choose a function $C(Y)$ satisfying condition A. After that we have to construct a set Ω satisfying condition B.

Suppose

$$C(Y)=aY^2+b^2,\quad a\geqslant\tfrac{1}{3},\quad b>\delta>0. \tag{4.1}$$

The family of hyperbolas $f(p,q,Y)=C(Y)$ has the envelope $q=h(p)=\sqrt{b^2+(3-1/a)p^2}$, and touch it at the point $(p_0(Y),q_0(Y))$ given by $(-\infty<Y<\infty)$

$$p_0(Y)=aY,$$

$$q_0(Y)=\sqrt{b^2+a(3a-1)Y^2}.$$

We choose Ω of the form

$$\Omega=\{(p,q)\in\mathbb{R}^2|-\infty<p<\infty,h(p)\geqslant q\geqslant\varepsilon>0\}.$$

Thus conditions A and B are fulfilled.

Now we have to determine two functions $g(Y)$ and $\tilde{g}(p,q)$ satisfying condition C, and to construct a measure $\mathrm{d}\mu$ satisfying condition D. We choose

$$g(Y)=\exp(-q_0^2(Y)-p_0^2(Y)),\quad \tilde{g}(p,q)=\exp(-q^2-p^2),$$

and

$$\mathrm{d}\mu(p,q)=\exp(-q^2-p^2)\sqrt{\frac{p-iq}{p+iq}}\,\mathrm{d}p\,\mathrm{d}q.$$

Thus all conditions of Theorem 1 are fulfilled.

A. First example

We take $a=\frac{1}{3}$ in (4.1). Then

$$p_0(Y)=Y/3,\quad q_0(Y)=b,$$

$$h(p)=b, \quad g(Y)=\exp(-b^2-Y^2/9).$$

According to Theorem 1, inside the domain ($M\geqslant 2$)

$$G_M(t)=\left\{(x,y)\in\mathbb{R}^2 \middle| t>t_0(M), -\infty<y<\infty, x>\frac{y^2}{3t}+b^2t-\frac{M}{2b}\ln t\right\}$$

the solution of the mKP-I equation constructed by (1.1)–(1.3) has as $t\to\infty$ the asymptotic behavior ($0<\varepsilon_1<\frac{1}{2}$)

$$v(x,y,t)=-\sum_{n=1}^{[M-1]}\frac{6b^2}{Y+\sqrt{Y^2+9b^2}\cosh\psi_n(x,y,t)}+O(t^{-1/2+\varepsilon_1}). \tag{4.2}$$

This is a sequence of $[M-1]$ solitons with constant amplitude and constant phase lines of the form

$$\psi_n(x,y,t)=b\left(x-\frac{y^2}{3t}\left(1-\frac{1}{3bt}\right)-b^2t\right)+\frac{1}{2}(\ln t^{n+1/2}+b^2-\ln\varphi_n), \tag{4.3}$$

where

$$\varphi_n=\frac{Q^{(n)}\Gamma^{(n)}}{2^{4n}3^{n-1/2}b^{(6n-5)/2}((n-1)!)^2Q^{(n-1)}\Gamma^{(n-1)}},$$

and $\Gamma^{(n)}$, $Q^{(n)}$ are the determinants of the $n\times n$ matrices whose entries $(i,k=0,\ldots,n-1)$ are given by

$$\begin{aligned}\Gamma^{(n)}_{i+1,k+1}&=\Gamma\left(\frac{i+k+1}{2}\right)(1+(-1)^{i+k}),\\ Q^{(n)}_{i+1,k+1}&=\Gamma(i+k+1).\end{aligned} \tag{4.4}$$

It is easy to derive from (4.3) that all asymptotic solitons have constant amplitude and shifts of phases, and neighboring solitons diverge with velocity proportional to $\ln t$ when the time increases.

B. Second example

We take $a=1$ in (4.1). Then

$$p_0(Y)=Y, \quad q_0(Y)=\sqrt{b^2+2Y^2},$$

$$h(p)=\sqrt{b^2+2p^2}, \quad g(Y)=\exp(-b^2-3Y^2).$$

According to Theorem 1, as $t\to\infty$ inside the domain ($M>2$)

$$G_M(t)=\left\{(x,y)\in\mathbb{R}^2 \middle| t>t_0(M), -\infty<y<\infty, x>\frac{y^2}{t}+b^2t-\frac{M}{2b}\ln t\right\}$$

the solution of the mKP-I equation given by (1.1)–(1.3) has the asymptotic behavior

$$v(x,y,t)=-\sum_{n=1}^{[M-1]}\frac{2(b^2+2Y^2)}{Y+\sqrt{b^2+3Y^2}\cosh^2\psi_n(x,y,t)}+O(t^{-1/2+\varepsilon_1}), \tag{4.5}$$

where

$$\psi_n(x,y,t)=\sqrt{b^2+2Y^2}\left(x-\frac{y^2}{t}\left(1-\frac{3}{2\sqrt{b^2t^2+2y^2}}\right)-b^2t\right)+\frac{1}{2}(\ln t^{n+1/2}+b^2-\ln\varphi_n(Y))$$

with

$$\varphi_n=\frac{(b^2+6Y^2)^nQ^{(n)}\Gamma^{(n)}}{2^{4n}((n-1)!)^2(b^2+2Y^2)^{(10n-5)/4}Q^{(n-1)}\Gamma^{(n-1)}},$$

and $Q^{(n)}$, $\Gamma^{(n)}$ are given by (4.4).

Therefore in this case the curved asymptotic solitons (4.5) have nonconstant amplitudes, widths and phases.

(Received 7 October 2000; accepted for publication 22 January 2001)

In order to determine the region where the Borel sum of a Wentzel–Kramers–Brillouin (WKB) solution ψ of an mth order ($m \geqslant 3$) ordinary differential equation $P\psi = 0$ with polynomial coefficients is well defined, we apply the steepest descent method to the Laplace integral of a WKB solution $\hat{\psi}$ of $\hat{P}\hat{\psi} = 0$, with $\hat{P}$ denoting the Laplace transform of P. As a counterpart of the connection formula for $\hat{\psi}$, we introduce a new notion of the exact steepest descent path, which is the union of bifurcated steepest descent paths. Both theoretical and computer-assisted experimental studies are given to show the importance of this notion. © *2001 American Institute of Physics.* [DOI: 10.1063/1.1368138]

I. INTRODUCTION

No algorithmic way of describing Stokes regions, i.e., domains where the Borel sum of a Wentzel–Kramers–Brillouin (WKB) solution is well defined, is known for higher order ordinary differential equations with a large parameter.[1] The main difficulty lies in the necessity of ''new Stokes curves,'' which emanate from possible crossing points of Stokes curves, as Berk, Nevins, and Roberts[2] first observed in discussing a connection formula for WKB solutions. Berk *et al.* further presented a charming idea of applying the steepest descent method to the inverse Fourier transform of a WKB solution for the Fourier-transformed operator. (See also Watanabe–Sanuki–Watanabe[3] for some related subject.) They have confirmed that this approach is effective near saddle points of the integrand,[4] but they have observed several troubles if a steepest descent path hits a turning point of the Fourier-transformed operator.[5]

The principal aim of this paper is to examine the idea of Berk *et al.* from the viewpoint of the exact WKB analysis, i.e., with the Borel resummation of WKB solutions[6–8] (see also Berry–Howls[9] for a related subject ''hyperasymptotics''), and to propose a new notion, ''an exact steepest descent path,'' which naturally fits in with the Borel resummation method. We then present some examples which illustrate how the previously mentioned troubles are naturally resolved by the use of exact steepest descent paths. We note that the notion of an exact steepest descent path is introduced here to exactly take into account the effect of exponentially small terms pertaining to Stokes phenomena of WKB solutions; this explains why we have succeeded in resolving the troubles that Berk *et al.* encountered far away from saddle points.

II. NOTATIONAL PRELIMINARIES

The operators we study in this paper are supposed to have the following form:

$$P = \sum_{\substack{0 \leqslant j \leqslant m \\ 0 \leqslant k \leqslant n}} a_{jk} x^k \eta^{m-j} \left(\frac{\mathrm{d}}{\mathrm{d}x} \right)^j, \tag{1}$$

[a)]Dedicated to the memory of the late Professor Tosio Kato.
[b)]Electronic mail: aoki@math.kindai.ac.jp
[c)]Electronic mail: takei@kurims.kyoto-u.ac.jp

where a_{jk} is a constant and η is a large parameter. Let $\hat{\psi}(\xi,\eta)$ denote the Laplace transform of a function $\psi(x,\eta)$, i.e.,

$$\psi(x,\eta)=\int e^{\eta x\xi}\,\hat{\psi}(\xi,\eta)\mathrm{d}\xi, \tag{2}$$

and let $\hat{P}$ denote the Laplace transform of P, i.e.,

$$\hat{P}=\sum a_{jk}\,\eta^{m-k}\left(-\frac{\mathrm{d}}{\mathrm{d}\xi}\right)^k\xi^j. \tag{3}$$

[For the sake of simplicity of the notations we use the Laplace transform instead of the Fourier transform, that is, we use $e^{\eta x\xi}$ instead of $e^{i\eta x\xi}$. We also assume $m\geqslant n$, as our purpose is to analyze the structure of WKB solutions of a higher order operator P in terms of the exact WKB analysis for $\hat{P}$.] In what follows we let $p(x,\xi)$ denote

$$\sum_{\substack{0\leqslant j\leqslant m\\ 0\leqslant k\leqslant n}} a_{jk}\,x^k\,\xi^j. \tag{4}$$

Solving the equation $p(x,\xi)=0$ in the form $x=x_k(\xi)$ $(k=1,\ldots,n)$, we obtain n WKB solutions $\hat{\psi}_k(\xi,\eta)$ of the equation $\hat{P}\hat{\psi}=0$ so that they have the following form:

$$\hat{\psi}_k=\exp\left(\eta\int^{\xi}(-x_k(\xi))\mathrm{d}\xi+\cdots\right)\Big/\sqrt{\eta}. \tag{5}$$

Here the normalization factor $\eta^{-1/2}$ is introduced for the sake of convenience in handling its Borel transform, and $\cdots$ designates terms with nonpositive powers of η.

Thus the object we are interested in is of the form

$$\varphi=\int\exp\left(\eta\left(x\xi-\int^{\xi}x_k(\xi)\mathrm{d}\xi\right)+\cdots\right)\Big/\sqrt{\eta}\,\mathrm{d}\xi. \tag{6}$$

The specification of the path of integration in (6) will be given in Sec. III. As $\hat{\psi}_k$ and φ are formal series in η^{-1}, their meaning should be given, say, by the Borel resummation. Hence we introduce operators P_B and $\hat{P}_B$, respectively, by

$$P_B=\sum a_{jk}\,x^k\frac{\partial^j}{\partial x^j}\frac{\partial^{m-j}}{\partial y^{m-j}} \tag{7}$$

and

$$\hat{P}_B=\sum a_{jk}\frac{\partial^{m-k}}{\partial\tilde{y}^{m-k}}\left(-\frac{\partial}{\partial\xi}\right)^k\xi^j. \tag{8}$$

It then follows from the definition of the Borel transformation that

$$\hat{P}_B\,\hat{\psi}_{k,B}=0 \tag{9}$$

for the Borel transform $\hat{\psi}_{k,B}$ of $\hat{\psi}_k$. Note that the Borel transform $\hat{\psi}_{k,B}$ is computed after applying the Taylor expansion of $\exp(\cdots)$; it then has the form,

$$\left(\exp\left(-\eta\int^{\xi}x_k(\xi)\mathrm{d}\xi\right)\right)(c_0+c_1\eta^{-1}+c_2\eta^{-2}+\cdots)\Big/\sqrt{\eta} \tag{10}$$

and hence its Borel transform is, by definition,

$$\sum_{l=0}^{\infty} \frac{c_l}{\Gamma(l+1/2)} \left(\tilde{y} - \int^{\xi} x_k(\xi) \mathrm{d}\xi \right)^{l-1/2}. \tag{11}$$

It also follows from the definition that the Borel resummed WKB solution $\hat{\psi}_k$ is given by

$$\hat{\psi}_k = \int \exp(-\eta \tilde{y}) \hat{\psi}_{k,B}(\xi, \tilde{y}) \mathrm{d}\tilde{y}, \tag{12}$$

where the integration is performed along the path

$$\tilde{y} = \int_{\hat{a}}^{\xi} x_k(\xi) \mathrm{d}\xi + v, \quad v \geqslant 0. \tag{13}$$

Here $\hat{a}$ is an arbitrarily fixed point to normalize $\hat{\psi}_k$.[10]

So far we have discussed WKB solutions $\hat{\psi}_k$ of the equation $\hat{P}\hat{\psi} = 0$. It is clear that, if we solve the equation $p(x, \xi) = 0$ in the form $\xi = \xi_j(x)$ $(j = 1, \ldots, m)$ we obtain m WKB solutions $\psi_j(x, \eta)$ $(j = 1, \ldots, m)$ of $P\psi = 0$ in the form

$$\psi_j = \exp\left(\eta \int^{x} \xi_j(x) \mathrm{d}x + \cdots \right) \Big/ \sqrt{\eta}, \tag{14}$$

or possibly with another normalization factor η^{-1} instead of $\eta^{-1/2}$, as we will see in Sec. III. Its Borel transform $\psi_{j,B}$ is obtained in the same manner as shown previously.

III. LOCAL CORRESPONDENCE BETWEEN $\hat{\psi}_{k,B}$ AND $\psi_{j,B}$ NEAR A SADDLE POINT

Let us first fix the path of integration in (6); as $\hat{\psi}_k(\xi, \eta)$ has been given its meaning through the Borel resummation, we have only to fix the path of integration in ξ-space. We stipulate that the ξ-integration should be performed along a steepest descent path for $\mathrm{Re}\, f_k$ that passes through a saddle point of f_k with f_k being $x\xi - \int_{\hat{a}}^{\xi} x_k(\xi) \mathrm{d}\xi$. A saddle point ξ_* of f_k satisfies $x = x_k(\xi_*)$, and hence $\xi_* = \xi_j(x)$ holds for some j. Barring the accidental coincidence of ξ_* with a turning point of $\hat{P}$, we find

$$\left. \frac{\mathrm{d}x_k(\xi)}{\mathrm{d}\xi} \right|_{\xi = \xi_j(x)} \neq 0 \tag{15}$$

and hence

$$\left. \frac{\partial^2 f_k}{\partial \xi^2} \right|_{\xi = \xi_j(x)} \neq 0. \tag{16}$$

Thus the ξ-integration is performed along the path described by

$$f_k(x, \xi) = f_k(x, \xi_j(x)) - u^2, \quad u: \text{ real}, \tag{17}$$

i.e.,

$$\left(x\xi - \int_{\hat{a}}^{\xi} x_k(\xi) \mathrm{d}\xi \right) - \left(x\xi_j(x) - \int_{\hat{a}}^{\xi_j(x)} x_k(\xi) \mathrm{d}\xi \right) = -u^2, \quad u: \text{ real}. \tag{18}$$

Fixing the path of integration in (6) in this way, and substituting the Borel sum of $\hat{\psi}_k$ into the integrand, we rewrite the integral (6), by introducing $y=\tilde{y}-x\xi$, in the following way:

$$\varphi=\int\int \exp(-\eta y)\,\hat{\psi}_{k,B}(\xi,y+x\xi)\mathrm{d}y\,\mathrm{d}\xi. \tag{19}$$

Here the domain of integration is described by relation (18) and

$$y=-x\xi_j(x)+\int_{\hat{a}}^{\xi_j(x)} x_k(\xi)\mathrm{d}\xi+v+u^2, \tag{20}$$

which follows from (13) and (18). To see the geometric meaning of (20), let $s(x)$ denote

$$-x\xi_j(x)+\int_{\hat{a}}^{\xi_j(x)} x_k(\xi)\mathrm{d}\xi. \tag{21}$$

Then we find

$$\frac{\mathrm{d}s(x)}{\mathrm{d}x}=-\xi_j(x)-x\frac{\mathrm{d}\xi_j}{\mathrm{d}x}+x_k(\xi_j(x))\frac{\mathrm{d}\xi_j}{\mathrm{d}x}=-\xi_j(x). \tag{22}$$

Thus (20) is rewritten as

$$y=-\int_a^x \xi_j(x)\mathrm{d}x+v+u^2, \tag{23}$$

where a is a fixed point. If we set $w=v+u^2$, the positivity assumption on v entails $u^2\leqslant w$. Hence ξ obeying relation (18) can range only over a compact set for a fixed pair (x,w) $(w\geqslant 0)$. Therefore the integral

$$\chi(x,y)=\int \hat{\psi}_{k,B}(x,y+x\xi)\mathrm{d}\xi \tag{24}$$

is well defined if y satisfies

$$y=-\int_a^x \xi_j(x)\mathrm{d}x+w,\quad w\geqslant 0 \tag{25}$$

and if the ξ-integration is done along the path described by (18). Thus the integral (6) can be written as

$$\int \exp(-\eta y)\chi(x,y)\mathrm{d}y, \tag{26}$$

where y ranges over the half-line $\{y\in\mathbb{C};y=-\int_a^x\xi_j(x)\mathrm{d}x+w,w\geqslant 0\}$. We shall further confirm that $\chi(x,y)$ is the Borel transform of a WKB solution of the equation $P\psi=0$. In view of the particular form of the integral (26), we will then be convinced that the integral (6) should play an important role in describing the domain on which the Borel sum of a WKB solution of $P\psi=0$ is well defined.

In order to verify that χ is the Borel transform of a WKB solution of $P\psi=0$, let us first show $P_B\chi=0$ by the integration by parts. In fact, we have

$$P_B\chi=\sum a_{jl}x^l\left(\frac{\partial}{\partial x}\right)^j\left(\frac{\partial}{\partial y}\right)^{m-j}\int \hat{\psi}_{k,B}(\xi,y+x\xi)\mathrm{d}\xi$$
$$=\sum a_{jl}\int \xi^j\left(\frac{\partial}{\partial y}\right)^{j+m-j}x^l\,\hat{\psi}_{k,B}(\xi,y+x\xi)\mathrm{d}\xi$$
$$=\sum a_{jl}\int \xi^j\left(\frac{\partial}{\partial y}\right)^{m-l}\left(x\frac{\partial}{\partial y}\right)^l\hat{\psi}_{k,B}(\xi,y+x\xi)\mathrm{d}\xi$$
$$=\sum a_{jl}\left(\frac{\partial}{\partial y}\right)^{m-l}\int \left(\frac{\partial}{\partial\zeta}\right)^l(\xi^j\hat{\psi}_{k,B}(\xi,y+x\zeta))\Big|_{\zeta=\xi}\mathrm{d}\xi. \tag{27}$$

By repeatedly using the following identity

$$\frac{\partial}{\partial\xi}(\xi^j\varphi(\xi,y+x\xi))=\frac{\partial}{\partial\xi}(\xi^j\varphi(\xi,y+x\zeta))\Big|_{\zeta=\xi}+\frac{\partial}{\partial\zeta}(\xi^j\varphi(\xi,y+x\zeta))\Big|_{\zeta=\xi} \tag{28}$$

together with the integration by parts applied to the integral interpreted as contour integral, we find

$$P_B\chi=\sum a_{jl}\left(\frac{\partial}{\partial y}\right)^{m-l}\int \left(-\frac{\partial}{\partial\xi}\right)^l(\xi^j\hat{\psi}_{k,B}(\xi,y+x\zeta))\Big|_{\zeta=\xi}\mathrm{d}\xi=0, \tag{29}$$

as

$$\hat{P}_B\hat{\psi}_{k,B}(\xi,y)=\Sigma a_{jl}\left(\frac{\partial}{\partial y}\right)^{m-l}\left(-\frac{\partial}{\partial\xi}\right)^l\xi^j\hat{\psi}_{k,B}(\xi,y)=0.$$

Furthermore a mathematical theory[11] tells us that $\chi(x,y)$ has a singularity of the form $\alpha(x,y)\log(y+\int_a^x\xi_j(x)\mathrm{d}x)+\beta(x,y)$ with α and β holomorphic near $y=-\int_a^x\xi_j(x)\mathrm{d}x$, as $\hat{\psi}_{k,B}(\xi,\tilde{y})$ has the singularity of the form $\tilde{\alpha}(\xi,\tilde{y})(\tilde{y}-\int_a^\xi x_k(\xi)\mathrm{d}\xi)^{-1/2}+\tilde{\beta}(\xi,\tilde{y})$ with $\tilde{\alpha}$ and $\tilde{\beta}$ holomorphic near $\tilde{y}=\int_a^\xi x_k(\xi)\mathrm{d}\xi$. This result combined with the relation $P_B\chi=0$ entails that χ is the Borel transform of a WKB solution of $P\psi=0$ that has the form $\exp(\eta\int_a^x\xi_j(x)\mathrm{d}x+\cdots)/\eta$.

Summing up, the integral (6) relates $\hat{\psi}_{k,B}$ to $\psi_{j,B}$ unless extra singularities become relevant to the domain of integration specified by (13) and (18). As we will see in Sec. IV, other singularities of $\hat{\psi}_{k,B}(\xi,y)$ really sneak into the domain in question if the steepest descent path (18) crosses a Stokes curve for $\hat{P}$. In this sense, the discussion in this section concerns the local correspondence of $\hat{\psi}_{k,B}$ and $\psi_{j,B}$ near the saddle point $\xi=\xi_j(x)$. It is worth noting that this correspondence is what mathematicians call ''the quantized Legendre transformation'' with a generating function $\delta(y-\tilde{y}+x\xi)\mathrm{d}\xi\,\mathrm{d}\tilde{y}$.[12]

IV. CORRESPONDENCE OF WKB SOLUTIONS IN THE LARGE: INTRODUCTION OF THE NOTION OF EXACT STEEPEST DESCENT PATHS

When the steepest descent path for $\mathrm{Re}\,f_k$ given in Sec. III that passes through the saddle point $\xi=\xi_j(x)$ crosses a Stokes curve for $\hat{P}$, say at $\xi=\xi_0$, the singularity of $\hat{\psi}_{k,B}(\xi,\tilde{y})$ located at $\tilde{y}=\int_a^\xi x_{k'}(\xi)\mathrm{d}\xi(k'\neq k)$ may become relevant to the integral (19) by the definition of a Stokes curve in the exact WKB analysis.[10] If $\hat{\psi}_k$ is dominant over $\hat{\psi}_{k'}$ along the Stokes curve, the integral (19) will acquire an additional exponentially small term as a consequence of the ''connection formula.'' To give the concrete description of the added term is the purpose of this section. Our description is based on a precise computation done for the case where P is a harmonic oscillator.[13]

As the exact WKB analysis is complete only for the second-order operators, we now assume that $n=2$, i.e., $\hat{P}$ is of the second order. (Practically speaking, we can deal with more general

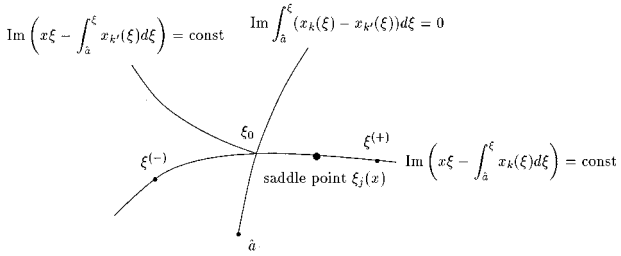

FIG. 1. Crossing of a steepest descent path and a Stokes curve.

operators. See, e.g., example 2 in Sec. V.) When $\hat{P}$ is of second order, we can, and really do, choose $\hat{a}$, the end point of the integral, to be the turning point from which the Stokes curve in question emanates so that $\hat{\psi}_k$ has the form

$$(-\eta x_k(\xi)+\cdots)^{-1/2}\exp\left(\int_{\hat{a}}^{\xi}(-\eta x_k(\xi)+\cdots)\mathrm{d}\xi\right), \tag{30}$$

where $\cdots$ designates terms with odd (and negative) powers of η. We also note that the Stokes curve in question is given by

$$\mathrm{Im}\int_{\hat{a}}^{\xi}(x_k(\xi)-x_{k'}(\xi))\mathrm{d}\xi=0 \tag{31}$$

(cf. Fig. 1). Normalizing $\hat{\psi}_{k'}$ in the same manner as done for $\hat{\psi}_k$, the dominant (Borel resummed) term $\hat{\psi}_k$ acquires an exponentially small term

$$\pm i\hat{\psi}_{k'} \tag{32}$$

when it crosses the Stokes curve (31).[14] The sign depends on the configuration of the steepest descent path and the Stokes curve, and we assume without loss of the generality that the sign is $+$. This exponentially small term appears as a consequence of the fact that at $\xi=\xi_0$ the singularity of $\hat{\psi}_{k,B}(\xi,\tilde{y})$ located at $\tilde{y}=\int_{\hat{a}}^{\xi}x_{k'}(\xi)\mathrm{d}\xi$ hits the path of integration (13) that defines the Borel sum of $\hat{\psi}_k(\xi,\eta)$. Otherwise stated, if we define u_0 and v_0, respectively, by

$$u_0^2=-x\xi_0+\int_{\hat{a}}^{\xi_0}x_k(\xi)\mathrm{d}\xi+x\xi_j(x)-\int_{\hat{a}}^{\xi_j(x)}x_k(\xi)\mathrm{d}\xi \tag{33}$$

and

$$v_0=\int_{\hat{a}}^{\xi_0}(x_{k'}(\xi)-x_k(\xi))\mathrm{d}\xi, \tag{34}$$

then the integrand of (19) finds a new singularity on its domain of integration when $(u,v)=(u_0,v_0)$. Note that $v_0\geqslant 0$ holds because of the fact that ξ_0 is on the Stokes curve in question together with the fact that $\hat{\psi}_k$ is dominant over $\hat{\psi}_{k'}$ there. To fix the configuration of several points to be discussed in the following, we assume $u_0<0$. To analyze the integral (24) with the explicit use of ξ-variable (rather than the u-variable) we introduce the symbol $\xi^{(\pm)}$ to denote the end points of the integral (24). For the sake of definiteness we suppose that $\xi^{(-)}$ corresponds to u that is negative and smaller than u_0. Note also that ξ_0 corresponds to u_0. If we let ξ_* denote the singular point of $\hat{\psi}_{k,B}(\xi,\tilde{y})$ that is described by $\tilde{y}=\int_{\hat{a}}^{\xi}x_{k'}(\xi)\mathrm{d}\xi$, our task is then to describe concretely the integral I obtained by the integration from ξ_0 to ξ_* in Fig. 2(b).

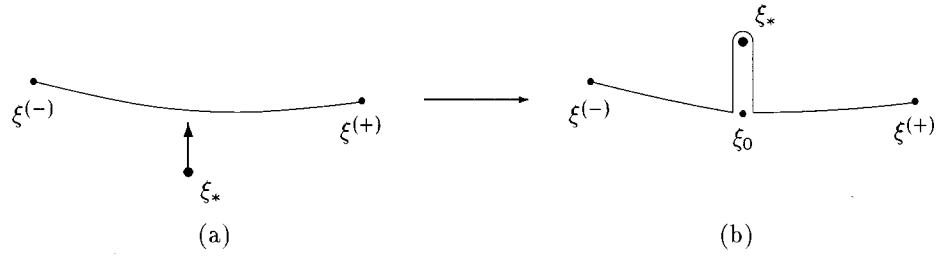

FIG. 2. Singular point ξ_* of $\hat{\psi}_{k,B}(\xi,\tilde{y})$ hitting the path of integration.

In view of the connection formula (32), this integral should be related to $i\hat{\psi}_{k',B}$. To find the precise form of the relation let us consider the following integral (35) with the domain of integration prescribed by (36) and (37) in the following; in what follows we show that the integral I is coincident with the integral (35) with this particular choice of the domain of integration. This integral was first found in the course of concrete computations for harmonic oscillators:[13]

$$i\int\int \exp(\eta(x\xi-\tilde{y}))\hat{\psi}_{k',B}(\xi,\tilde{y})\mathrm{d}\xi\mathrm{d}\tilde{y}=i\int \exp(-\eta y)\left(\int \hat{\psi}_{k',B}(\xi,y+x\xi)\mathrm{d}\xi\right)\mathrm{d}y, \tag{35}$$

where the domain of integration is given by

$$\tilde{y}=\int_{\hat{a}}^{\xi} x_{k'}(\xi)\mathrm{d}\xi+\tilde{v}, \quad \tilde{v}\geqslant 0 \tag{36}$$

and

$$x\xi-\int_{\hat{a}}^{\xi} x_{k'}(\xi)\mathrm{d}\xi-x\xi_0+\int_{\hat{a}}^{\xi_0} x_{k'}(\xi)\mathrm{d}\xi=-\tilde{u}, \quad \tilde{u}\geqslant 0. \tag{37}$$

The geometric meaning of (37) is worth mentioning: ξ obeying (37) is on the steepest descent path for $\mathrm{Re}\, f_{k'}$ with

$$f_{k'}\underset{\mathrm{def}}{=}x\xi-\int_{\hat{a}}^{\xi} x_{k'}(\xi)\mathrm{d}\xi$$

that passes through the point $\xi=\xi_0$. Note that ξ_0 is not a saddle point of $f_{k'}$. Let us now try to find where ξ ranges for fixed x and y; it is clear that

$$y=\tilde{y}-x\xi=-x\xi_0+\int_{\hat{a}}^{\xi_0} x_{k'}(\xi)\mathrm{d}\xi+\tilde{u}+\tilde{v} \tag{38}$$

follows from (36) and (37). Since we know by (22) that

$$-x\xi_j(x)+\int_{\hat{a}}^{\xi_j(x)} x_k(\xi)\mathrm{d}\xi=-\int_a^x \xi_j(x)\mathrm{d}x \tag{39}$$

holds for some a, we can rewrite (38) as follows:

$$y=-\int_a^x \xi_j(x)\mathrm{d}x+x\xi_j(x)-\int_{\hat{a}}^{\xi_j(x)} x_k(\xi)\mathrm{d}\xi-x\xi_0+\int_{\hat{a}}^{\xi_0} x_{k'}(\xi)\mathrm{d}\xi+\tilde{u}+\tilde{v}. \tag{40}$$

On the other hand, (33) and (34) entail

$$-x\xi_0+\int_{\hat{a}}^{\xi_0}x_{k'}(\xi)\mathrm{d}\xi+x\xi_j(x)-\int_{\hat{a}}^{\xi_j(x)}x_k(\xi)\mathrm{d}\xi=u_0^2+v_0. \tag{41}$$

Hence we find

$$y=-\int_a^x\xi_j(x)\mathrm{d}x+w,\quad w=w_0+\tilde{u}+\tilde{v}, \tag{42}$$

where w_0 denotes $u_0^2+v_0$. Since $\tilde{v}$ is supposed to be non-negative, the ξ-integration in (35) is done over the region

$$0\leqslant\tilde{u}\leqslant w-w_0. \tag{43}$$

Let us now consider the geometric meanings of the points corresponding to $\tilde{u}=0$ or $\tilde{u}=w-w_0$. Clearly $\xi=\xi_0$ is the point corresponding to $\tilde{u}=0$. Let ξ'_* denote the point that corresponds to $\tilde{u}=w-w_0$. Then it follows from the definition of $\tilde{u}$ that

$$x\xi'_x-\int_{\hat{a}}^{\xi'_*}x_{k'}(\xi)\mathrm{d}\xi=x\xi_0-\int_{\hat{a}}^{\xi_0}x_{k'}(\xi)\mathrm{d}\xi-(w-w_0). \tag{44}$$

Using the definition of w_0, we find this is equal to

$$x\xi_j(x)-\int_{\hat{a}}^{\xi_j(x)}x_k(\xi)\mathrm{d}\xi-w, \tag{45}$$

which has another expression

$$\int_a^x\xi_j(x)\mathrm{d}x-w \tag{46}$$

by (39). Thus we find

$$x\xi'_*-\int_{\hat{a}}^{\xi'_*}x_{k'}(\xi)\mathrm{d}\xi=\int_a^x\xi_j(x)\mathrm{d}x-w=-y \tag{47}$$

by (42), that is, ξ'_* is a point satisfying the relation (47) on the steepest descent path for $\mathrm{Re}\,f_{k'}$ that emanates from $\xi=\xi_0$. Summing up, we can rewrite the integral (35) as follows:

$$\int_L\exp(-\eta y)\left(\int_{\xi_0}^{\xi'_*}i\hat{\psi}_{k',B}(\xi,y+x\xi)\,\mathrm{d}\xi\right)\mathrm{d}y, \tag{48}$$

where $L=\{y\in\mathbb{C};y=-\int_a^x\xi_j(x)\mathrm{d}x+w,w\geqslant w_0\}$.

Before relating this integral with the connection formula for $\hat{P}$, we note the following property of ξ'_*; relation (47) implies that, at $\xi=\xi'_*$, $\tilde{y}=y+x\xi$ attains the value $\int_{\hat{a}}^{\xi'_*}x_{k'}(\xi)\mathrm{d}\xi$. This is a singular point of $\hat{\psi}_{k',B}(\xi,\tilde{y})$, which coincides with a singular point of $\hat{\psi}_{k,B}(\xi,\tilde{y})$ that is described by $\int_{\hat{a}}^{\xi_*}x_{k'}(\xi)\mathrm{d}\xi$, i.e., the singularity considered in Fig. 2. Thus ξ'_* is actually equal to ξ_*, an end point of the integral I we encountered in Fig. 2. Otherwise stated, the point $\xi=\xi_*$ also lies on the steepest descent path for $\mathrm{Re}\,f_{k'}$ that emanates from ξ_0. Hence the integral I in question is expressed as

$$\int_\gamma\hat{\psi}_{k,B}(\xi,y+x\xi)\mathrm{d}\xi, \tag{49}$$

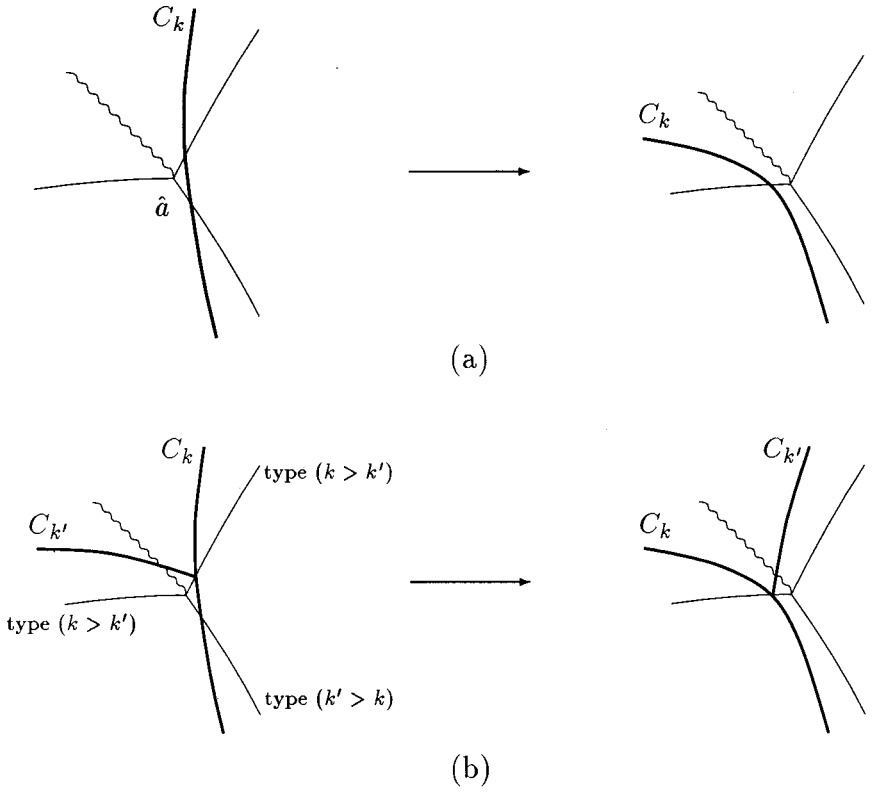

FIG. 3. Schematic illustration of a change of configurations of ordinary steepest descent paths (a) and of exact ones (b) when they hit a simple turning point $\hat{a}$; a lightfaced line and a wiggly line, respectively, designate a Stokes curve and a cut [defining the Riemann surface of $x_k(\xi)$].

where γ denotes a path of integration that starts from ξ_0 and comes back to ξ_0 by encircling the portion of the steepest descent path for $\mathrm{Re}\, f_{k'}$ whose boundaries are ξ_0 and ξ_*. Now let us recall the precise meaning of the connection formula (32) in the exact WKB analysis:[10] if we let $\Delta\hat{\psi}_{k,B}$ denote the discontinuity of $\hat{\psi}_{k,B}(\xi,\tilde{y})$ along the cut $\{\tilde{y}\in\mathbb{C};\tilde{y}=\int_a^\xi x_{k'}(\xi)\mathrm{d}\xi+\tilde{v},\tilde{v}\geqslant 0\}$, then

$$\Delta\hat{\psi}_{k,B}=i\hat{\psi}_{k',B}. \tag{50}$$

Since $(\Delta\hat{\psi}_{k,B})(\xi,y+x\xi)$ is coincident with the integrand of integral (49) because of the choice of the path γ, the integral I is equal to integral (48) by (50). Therefore we conclude that the concrete form of the integral I is given by the integral (35) whose domain of integration is specified by (36) and (37).

The discussion given in this section tells us that, if we consider the integral (24) globally with respect to y, we are forced to consider not only the steepest descent path C_k for $\mathrm{Re}\, f_k$ passing through the saddle point of f_k but also another steepest descent path $C_{k'}$ for $\mathrm{Re}\, f_{k'}$ that is bifurcated from C_k at the crossing point of C_k and a Stokes curve for $\hat{P}$. The necessity of integration over a portion of C_k' and the connection formula for WKB solutions of $\hat{P}\hat{\psi}=0$ are two sides of the same coin, and hence the integral along C_k and that along $C_{k'}$ are, so to speak, equal partners. Therefore, if $C_{k'}$ hits some saddle point, say $\xi=\xi_l(x)$, then some anomalies should be observed in the Borel sum of WKB solutions of the starting equation $P\psi=0$, that is, the point x should be on a Stokes curve for P, ordinary or new. Thus we are led to the ''exact steepest descent path ansatz,'' or ''ESDP ansatz'' for short, which is given in the following. To state the ESDP ansatz,

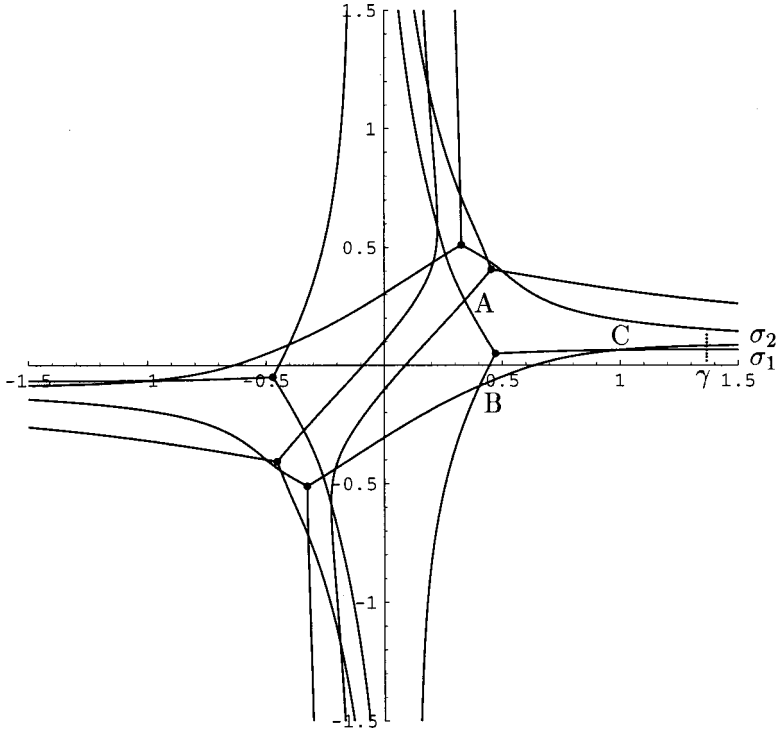

FIG. 4. Stokes curves of Eq. (51).

we prepare the following definition of an exact steepest descent path. There we use the terminology "a Stokes curve of type $(k>k')$" to mean that $\hat{\psi}_k$ is dominant over $\hat{\psi}_{k'}$ along the Stokes curve.

Definition of an exact steepest descent path: Let f_l denote $x\xi-\int_a^\xi x_l(\xi)\mathrm{d}\xi$. An exact steepest descent path C is, by definition, the union of portions of steepest descent paths obtained by the following procedure.

Start with a steepest descent path C_k of $\mathrm{Re}\, f_k$ for some k that passes through a saddle point. If C_k crosses a Stokes curve (for $\hat{P}$) of type $(k>k')$, consider the steepest descent path $C_{k'}$ for $\mathrm{Re}\, f_{k'}$ which starts from the crossing point. If $C_{k'}$ crosses another Stokes curve of type $(k'>k'')$, consider another steepest descent path $C_{k''}$ for $\mathrm{Re}\, f_{k''}$ in the same manner, and so on.

Exact steepest descent path ansatz: *Stokes phenomena for Borel resummed WKB solutions of* $P\psi=0$ *are observed at* x *if and only if an exact steepest descent path connects two saddle points* $\xi_k(x)$ *and* $\xi_l(x)$.

It is evident that this ansatz is a natural generalization of the results[15,16] obtained for a Laplace-type operator P (i.e., an operator whose Laplace transform is of the first order). We also note that the ESDP ansatz is validated by the reasoning given in this section in a most basic situation, that is, when the operator $\hat{P}$ is of the second order and when a steepest descent path passing through a saddle point crosses only one Stokes curve for $\hat{P}$; with this observation we believe that the above-mentioned ansatz should be true in general.

Remark 1: Introduction of exact steepest descent paths automatically resolves the spurious changes of topological configurations of steepest descent paths that occur when they hit a turning

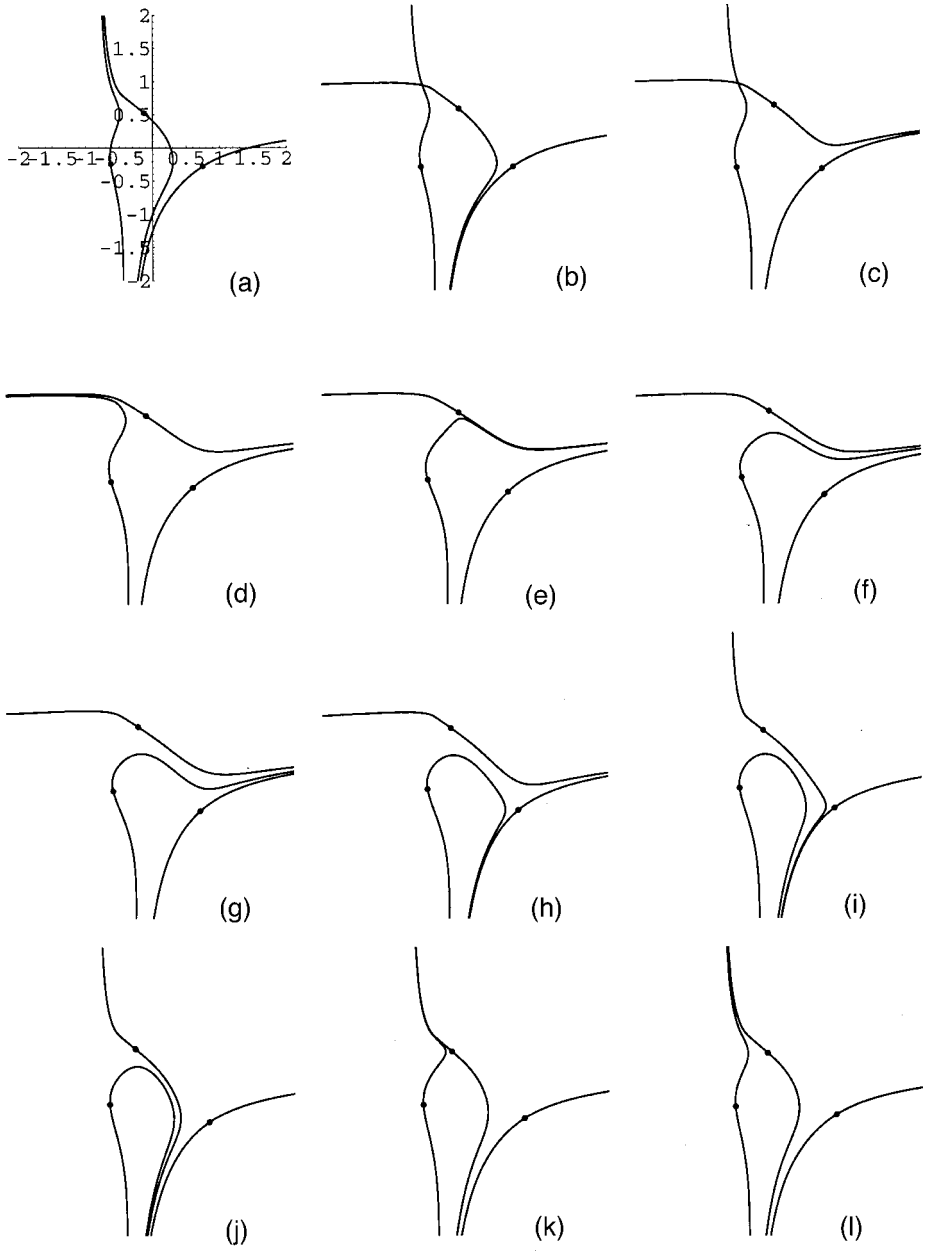

FIG. 5. Ordinary steepest descent paths around the crossing point A.

point of $\hat{P}$. For example, as is shown in Fig. 3, when a steepest descent path C_k hits a simple turning point $\hat{a}$, no topological change of configurations occurs for the exact steepest descent path $C_k \cup C_{k'}$ although the shape of C_k itself changes abruptly.[17]

V. COMPUTER-ASSISTED STUDY OF THE EXACT STEEPEST DESCENT PATH ANSATZ

The purpose of this section is to present a computer-assisted study of the ESDP ansatz in some illuminating examples. See our previous paper[18] for some more detailed explanation of the figures given in the following. We also note that the above-mentioned paper contains discussions on some

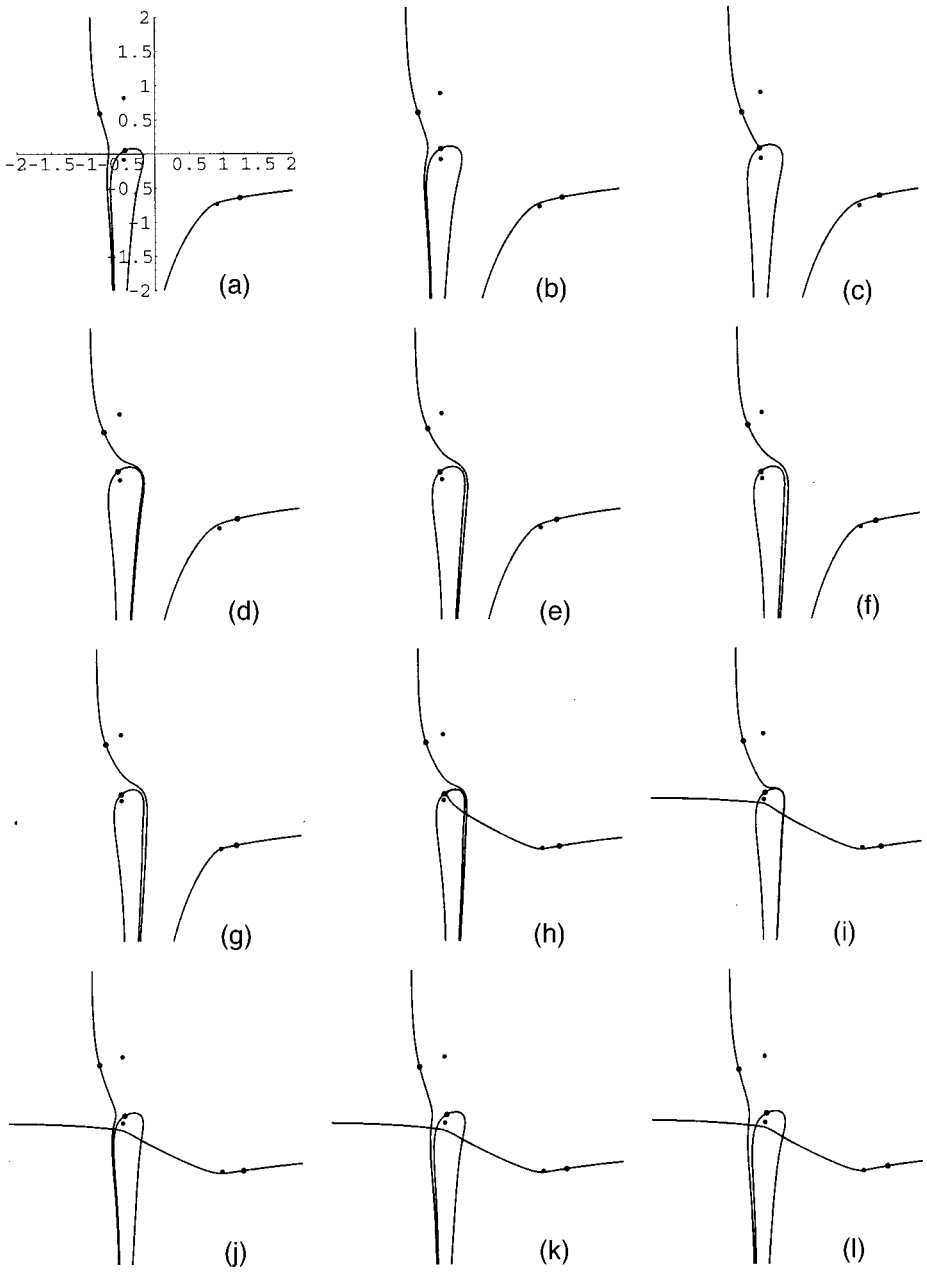

FIG. 6. Ordinary steepest descent paths around the crossing point B.

other less peculiar examples; the examples given in the following are the most illuminating ones among them. All computations are done using MATHEMATICA (ver. 3.0.1 or 4.0.2.1).

Example 1: Consider the following equation:

$$\left(\frac{\mathrm{d}^3}{\mathrm{d}x^3}+\eta^2(i-4x^2)\frac{\mathrm{d}}{\mathrm{d}x}+\eta^3\left(\frac{i}{2}-x^2\right)\right)\psi=0. \tag{51}$$

If we draw ordinary Stokes curves (i.e., if we ignore temporarily new turning points and new Stokes curves), we obtain Fig. 4.

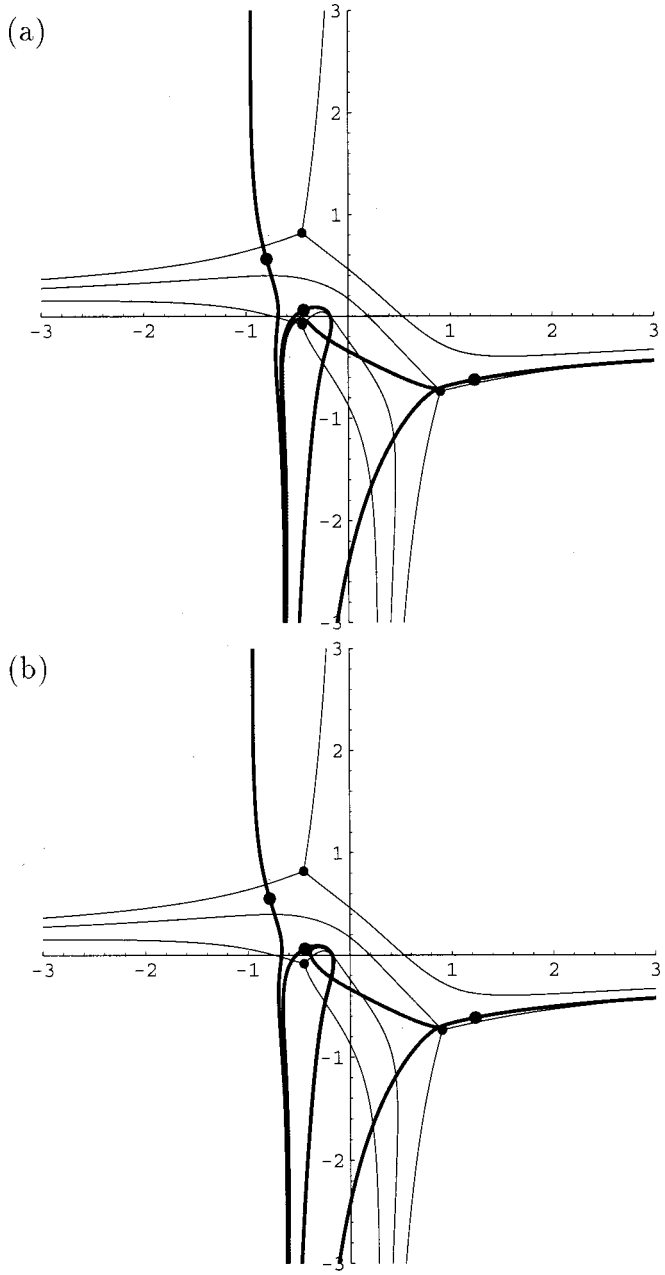

FIG. 7. Exact steepest descent paths for $x=0.459\,36-0.067\,718\,i$ (a) and for $x=0.455\,97-0.060\,089\,4\,i$ (b).

(i) Let us consider the problem near the point A where two Stokes curves cross; let x_k ($k=0,1,\ldots,11$) denote the point

$$c+0.05e^{\pi ik/6}, \tag{52}$$

where c stands for the coordinate of A, and consider the ordinary steepest descent paths for the integral (19) [or rather (6)] with $x=x_k$. With the aid of a computer we find Fig. 5, where Figs. 5(a), 5(b), . . . , 5(l) illustrate the configuration for $x=x_0$, x_1, . . . , x_{11}, respectively. We seek a topological change of configurations which occurs when a steepest descent path hits another saddle point. (The change that occurs when a steepest descent path hits a turning point is spurious

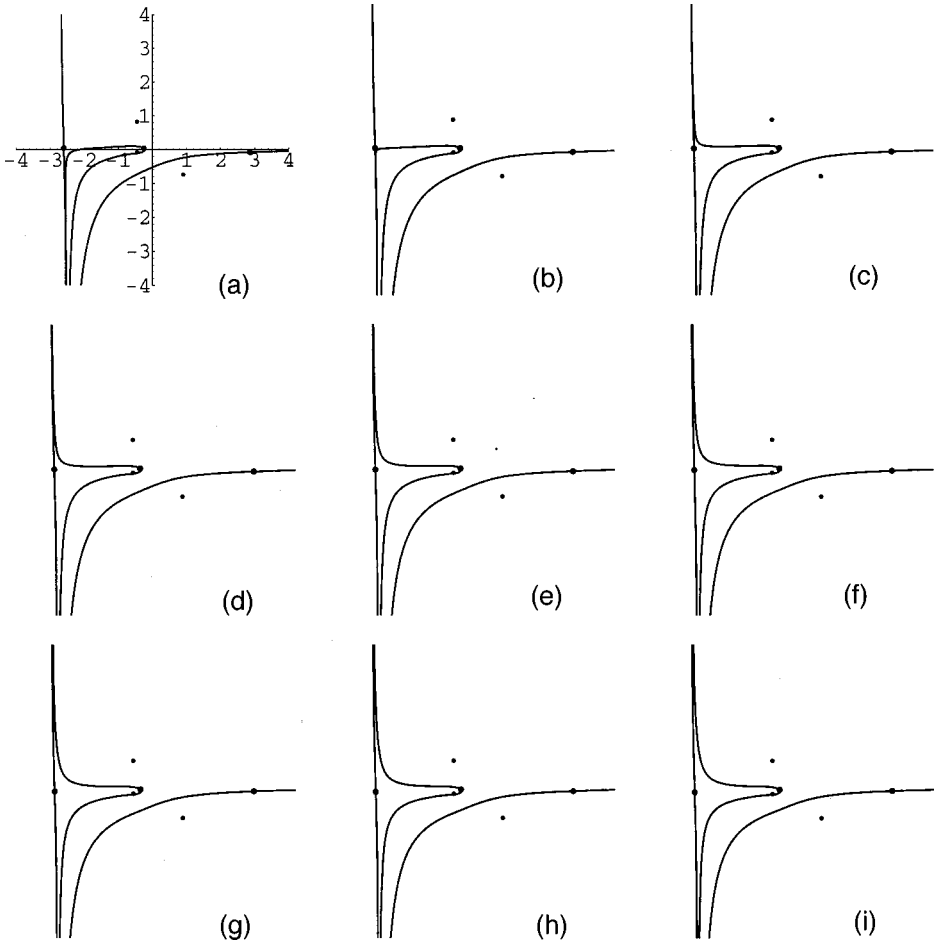

FIG. 8. Ordinary steepest descent paths for the point x_k on the path γ.

and should be ignored; cf. Remark 1 in Sec. IV.) We then observe five changes of the configuration of this kind: between $x=x_1$ and $x=x_2$, around $x=x_4$, between $x=x_7$ and $x=x_8$, around $x=x_{10}$, and between $x=x_6$ and $x=x_7$. Each of the first four corresponds to one of four portions of Stokes curves meeting at the point A, while the fifth change that occurs between $x=x_6$ and $x=x_7$ can be attributed to a new Stokes curve passing through the ordered crossing point A (in the sense of Berk *et al.*[2]). Thus the (ordinary) steepest descent method applied to the integral (6) correctly detects Stokes curves in this case.

(ii) In spite of the success shown in (i), the method fails near B, another crossing point of Stokes curves in Fig. 4. Choosing c to be the coordinate of the point B, we find Fig. 6 that shows the configuration of the ordinary steepest descent paths for the integral (6). In Fig. 6 one can observe only three relevant topological changes of the configuration: around $x=x_2$, around $x=x_7$, and between $x=x_8$ and $x=x_9$. However, the reasoning of Berk *et al.*[19,20] indicates that three Stokes segments meet at a point only if one of them or all of them are actually irrelevant to Stokes phenomena. Otherwise stated, the ordinary steepest descent method applied to the integral (6) cannot correctly detect the Stokes phenomena in this case.

Contrary to this failure, if we use exact steepest descent paths, then we can correctly detect the points where the Stokes phenomena occur, as Fig. 7 shows. Figure 7 visualizes the movement between $x=x_0$ and $x=x_1$ of configuration of the exact steepest descent paths of the integral (19); in order not to make the figures too complicated, some irrelevant paths are omitted. The heavy line designates the *exact* steepest descent path, which plays a crucially important role.

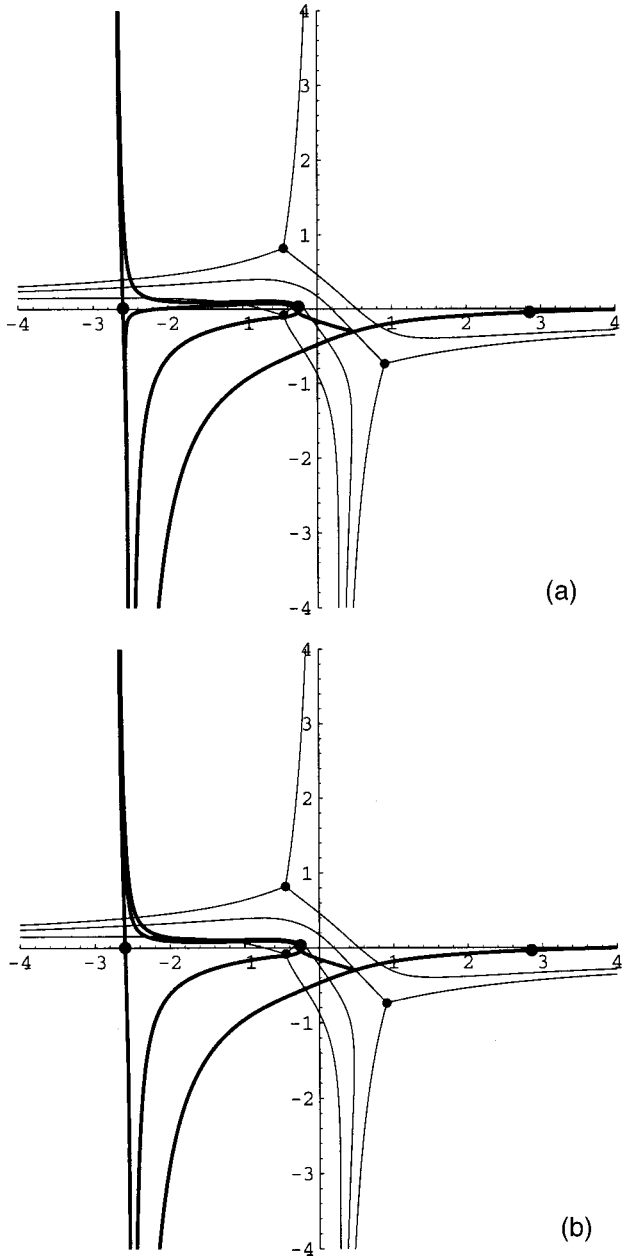

FIG. 9. (i) Exact steepest descent paths for $x=1.37+0.074\,75\,i$ (a) and for $x=1.37+0.08\,i$ (b). (ii) Exact steepest descent paths for $x=1.37+0.085\,25\,i$ (c) and for $x=1.37+0.0905\,i$ (d). (ii bis) Added exact steepest descent paths for $x=1.37+0.085\,25\,i$ (c′) and for $x=1.37+0.0905\,i$ (d′).

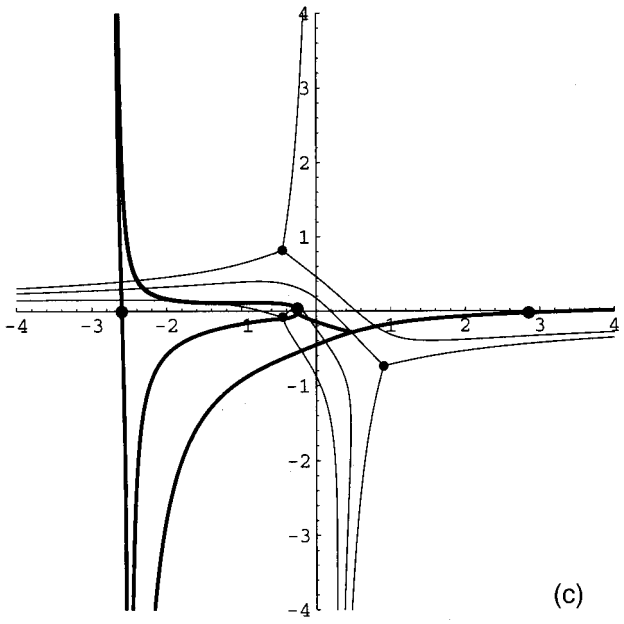
(iii) Additional evidence strongly in support of the ESDP ansatz can be found near the point C, where two Stokes curves cross. Let $x_k(k=0,1,\ldots,8)$ denote the point $1.37+\sqrt{-1}(0.059+0.005\,25k)$; these points lie on the path γ that is designated by a dotted line in Fig. 4. Then we find Fig. 8, where Figs. 8(a), . . . , 8(i) describe the configuration of ordinary steepest descent paths for $x=x_0, \ldots, x_8$, respectively. In Fig. 8 we observe a topological change of the configuration only near $x=x_1$, which evidently corresponds to the situation where γ crosses an ordinary Stokes curve σ_1 in Fig. 4; we cannot observe any changes that might be attributed to the crossing of γ and another ordinary Stokes curve σ_2 or a possibly relevant new Stokes curve σ_0 emanating from the crossing point C.



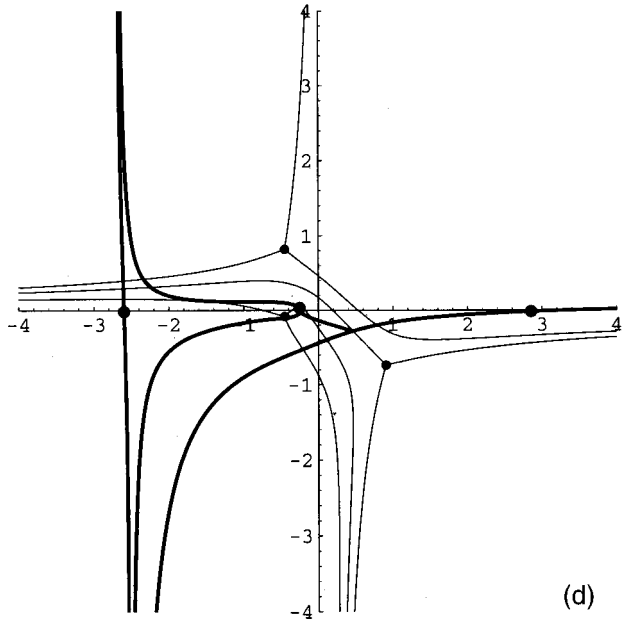


FIG. 9 (*Continued.*)

Let us now add an exact steepest descent path to Figs. 8(d) and 8(e); the resulting figures are, respectively, Figs. 9(a) and 9(b). In contrast with Figs. 8(d) and 8(e), they clearly show a topological difference of configurations. This topological change that occurs between $x=x_3$ and $x=x_4$ corresponds to the crossing of γ and a new Stokes curve σ_0 that emanates from C.

Similarly we find Figs. 9(c) and 9(d) by adding an exact steepest descent path, respectively, to Figs. 8(f) and 8(g). They again show a topological change of configurations, which occurs between $x=x_5$ and $x=x_6$. (As Figs. 9(c) and 9(d) seem to be too complicated to decipher, we also present Fig. 9(c′) and Fig. 9(d′) which contain only the added exact steepest descent path, so that the reader's attention may be concentrated upon it.) This change that occurs between $x=x_5$ and $x=x_6$ corresponds to the crossing of γ and the ordinary Stokes curve σ_2.

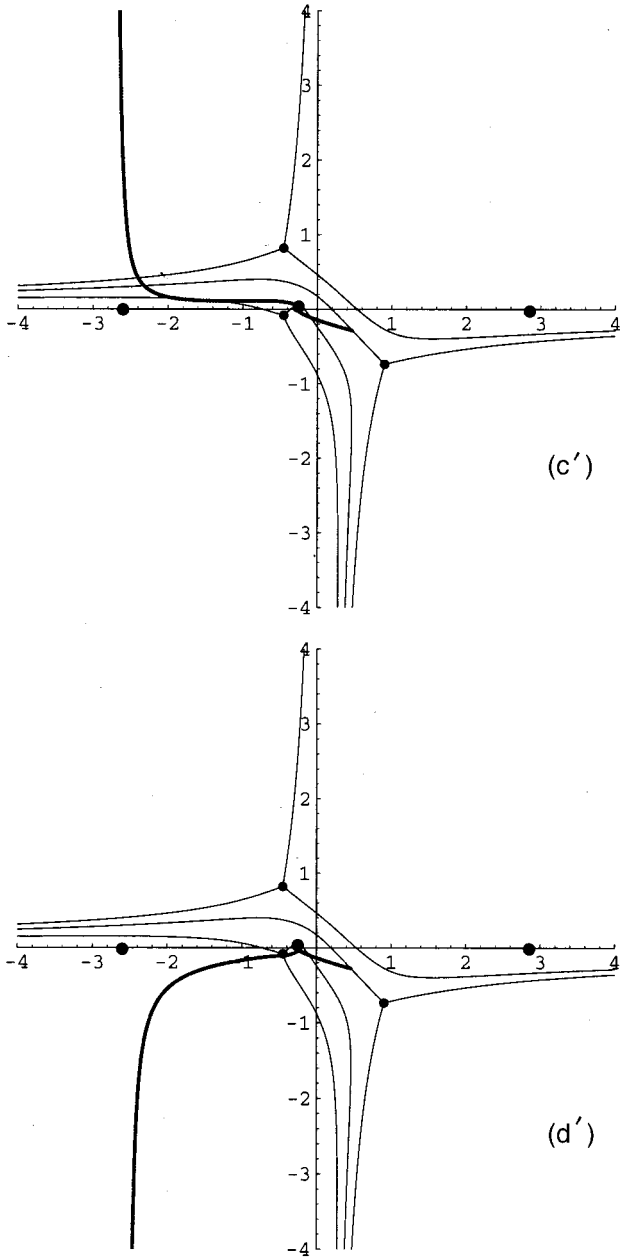

FIG. 9 (*Continued.*)

Thus the addition of an exact steepest descent path neatly explains delicate issues concerning the Stokes phenomena near point C.

Example 2: In order to show that the ESDP ansatz may be valid even if $\hat{P}$ is of higher order, let us study the following Carroll–Hioe equation:

$$\frac{d^3\psi}{dx^3}+2i(r_1+r_2+r_3)\eta x\frac{d^2\psi}{dx^2}+\{-4(r_1r_2+r_2r_3+r_3r_1)\eta^2x^2+2ic_1\eta$$
$$+\tfrac{1}{4}[(\Omega_{12})^2+(\Omega_{23})^2]\eta^2\}\frac{d\psi}{dx}+\{-8ir_1r_2r_3\eta^3x^3-4c_2\eta^2x$$
$$+\tfrac{1}{2}[(\Omega_{12})^2r_3+(\Omega_{23})^2r_1]\eta^3x\}\psi=0, \tag{53}$$

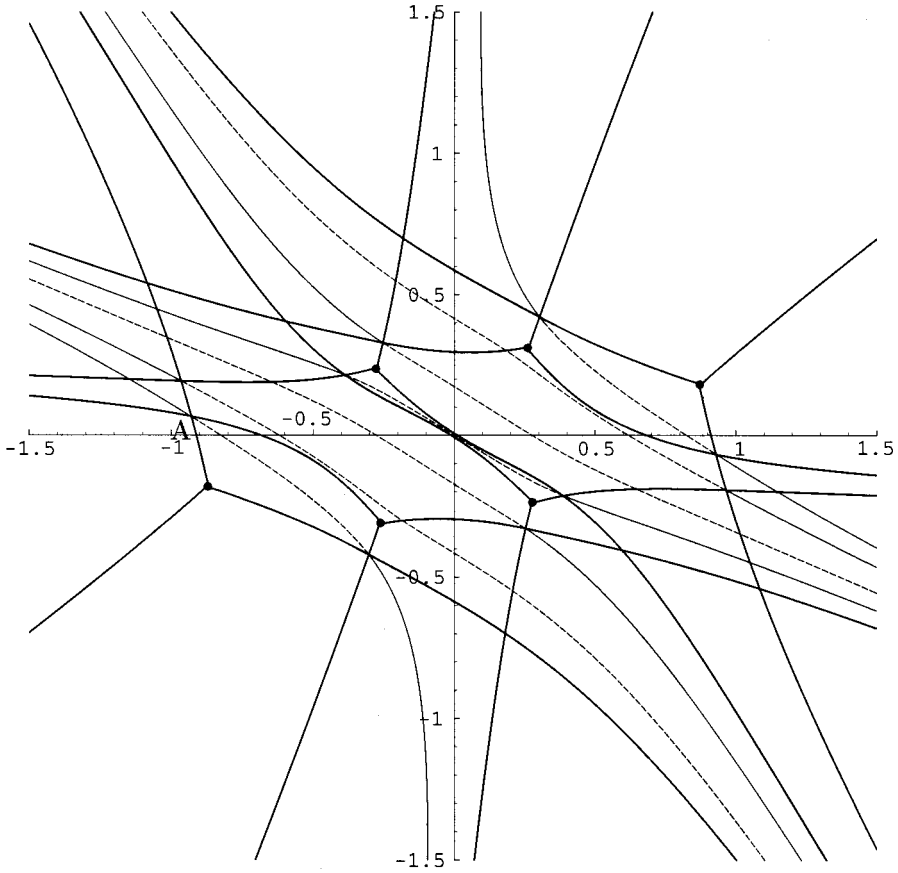

FIG. 10. Stokes geometry for Eq. (53).

where $r_1, r_2, r_3, \Omega_{12}, \Omega_{23}, c_1$, and c_2 are some parameters. In what follows all figures are drawn for the following values of these parameters: (there is no particular meaning in this choice)

$$r_1 = -2+i, \quad r_2 = \tfrac{1}{2}+2i, \quad r_3 = 1-2i, \tag{54}$$

$$\Omega_{12} = -3+4i, \quad \Omega_{23} = 1-3i, \quad \text{and}$$

$$c_1 \text{ and } c_2 \text{ are arbitrarily fixed.}$$

Although $\hat{P}$ is of the third order, Carroll–Hioe ingeniously gave an integral representation of solutions of (53). Hence we can describe the complete Stokes geometry for (53) by analyzing the integral again with the aid of a computer.[21] The result is shown in Fig. 10. (A dotted line indicates that no Stokes phenomena occur across that portion of the curve.)

Choosing c in (52) to be the coordinate of the point A in Fig. 10, we illustrate the configuration of ordinary steepest descent paths for the integral that represents a solution of (53) and the integral (6), respectively, in Figs. 11 and 12. In Fig. 12 we cannot observe any topological change of the configuration caused by the interaction of steepest descent paths and saddle points between $x = x_3$ and $x = x_4$, which is observed in Fig. 11. If we use exact steepest descent paths in addition to ordinary ones, the topological change can be observed in Fig. 13, which describes the behavior between $x = x_3$ and $x = x_4$.

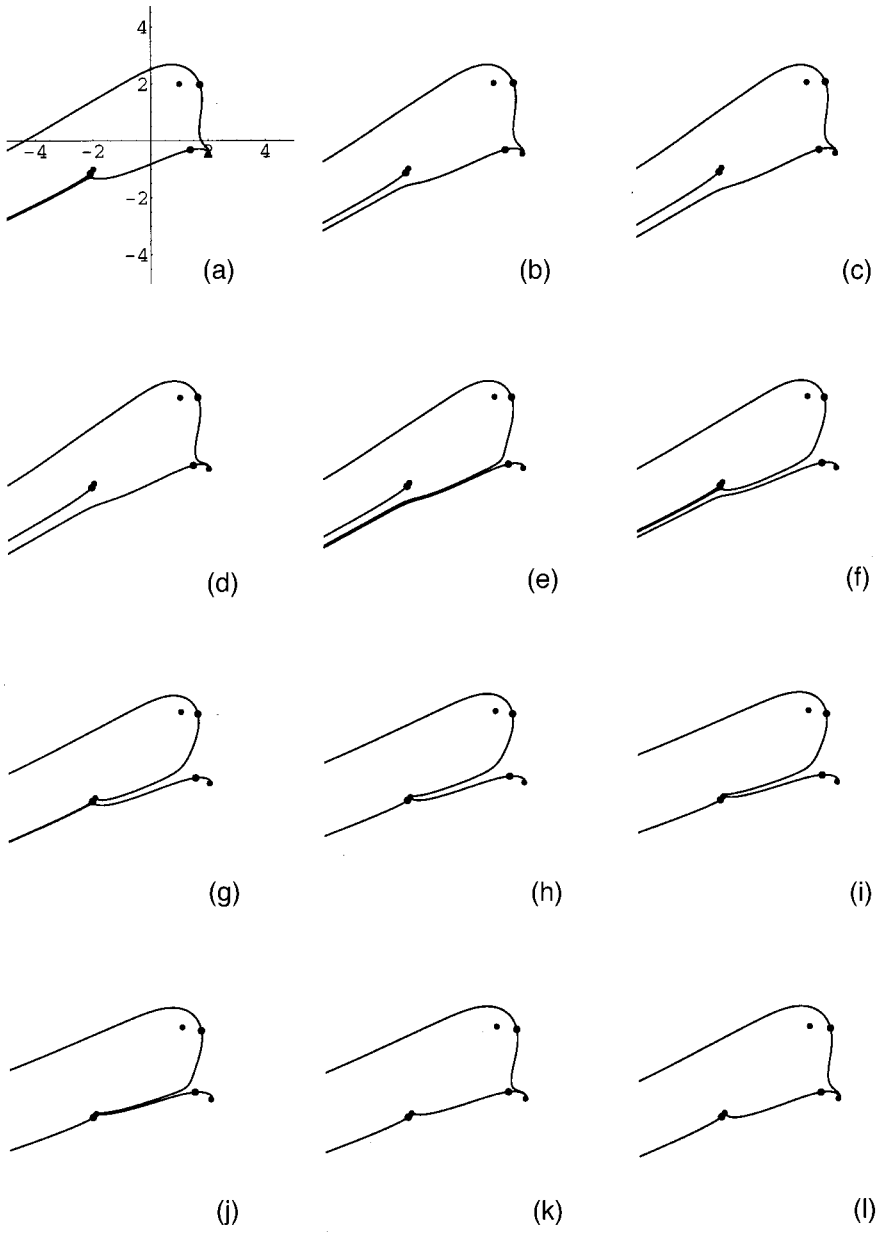

FIG. 11. Ordinary steepest descent paths for the integral representing a solution around the crossing point A.

VI. CONCLUDING REMARKS

As several examples in Sec. V have shown, the ESDP ansatz is a new and powerful proposition in WKB analysis. In particular, we note the disappearance of a pathological change of configurations of steepest descent paths which is observed when an ordinary steepest descent path hits a turning point for $\hat{P}$ (see Remark 1 in Sec. IV), if we use exact steepest descent paths; the effect of a turning point is automatically built in the definition of an exact steepest descent path through its interrelationship with a Stokes curve that emanates from the turning point. This fact nicely fits in with the fact that a turning point is not a singular point of the equation $\hat{P}\hat{\psi}=0$; the singularity at a turning point that appears in the WKB expansion is a spurious one to disappear by the Borel resummation.

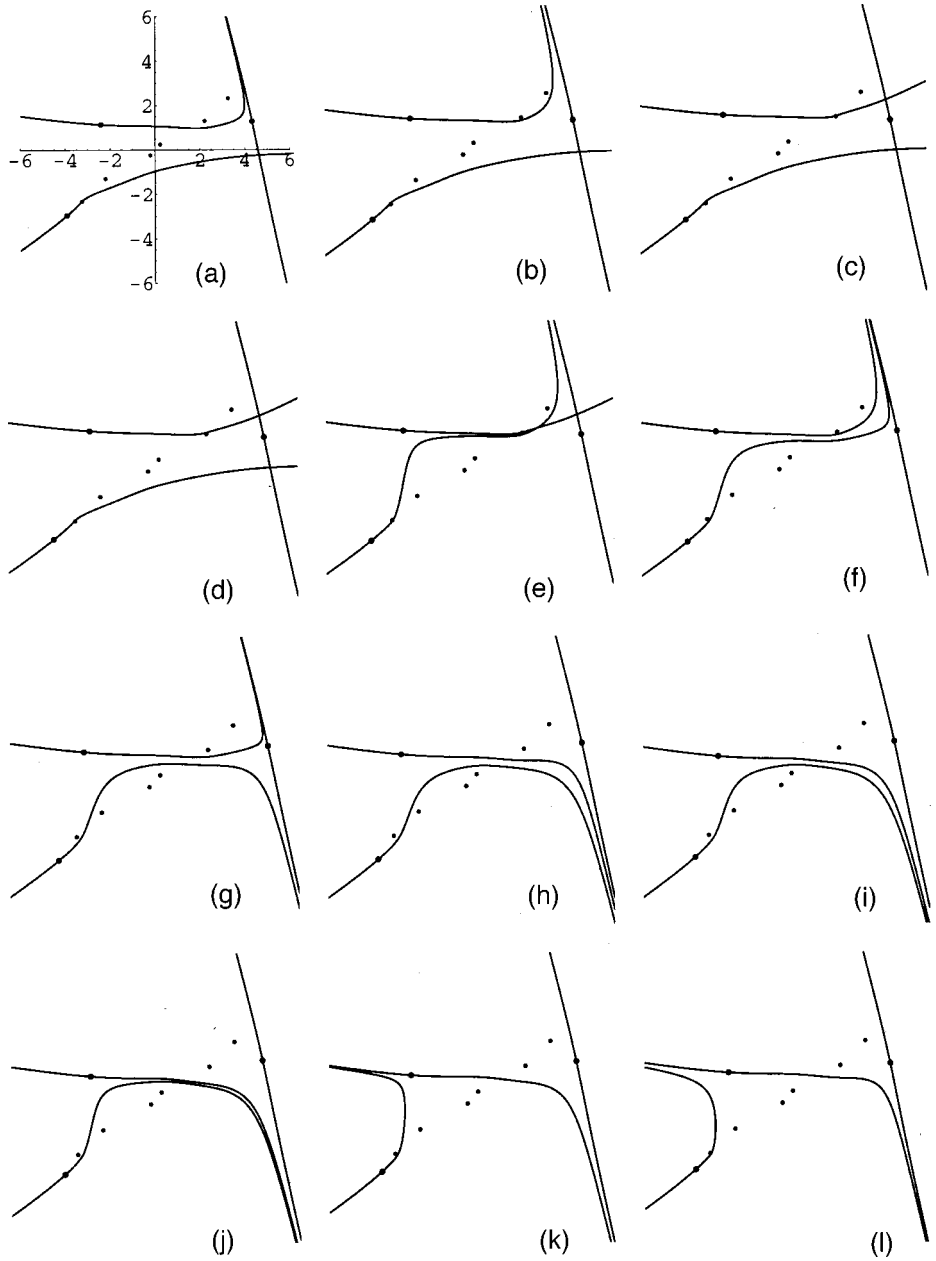

FIG. 12. Ordinary steepest descent paths for the integral (6) around the crossing point A.

Another important implication of the ESDP ansatz is that Stokes phenomena for the operator P occur only on a Stokes curve of the form (62). The reasoning is as follows: Suppose that a Stokes phenomenon is observed at x. The ESDP ansatz then asserts that

$$\mathrm{Im}\left(x\xi_j(x) - \int_{\hat{a}}^{\xi_j(x)} x_k(\xi)\mathrm{d}\xi \right) = \mathrm{Im}\left(x\xi_0 - \int_{\hat{a}}^{\xi_0} x_k(\xi)\mathrm{d}\xi \right), \tag{55}$$

$$\mathrm{Im}\left(x\xi_{j'}(x) - \int_{\hat{a}}^{\xi_{j'}(x)} x_{k'}(\xi)\mathrm{d}\xi \right) = \mathrm{Im}\left(x\xi_0 - \int_{\hat{a}}^{\xi_0} x_{k'}(\xi)\mathrm{d}\xi \right), \tag{56}$$

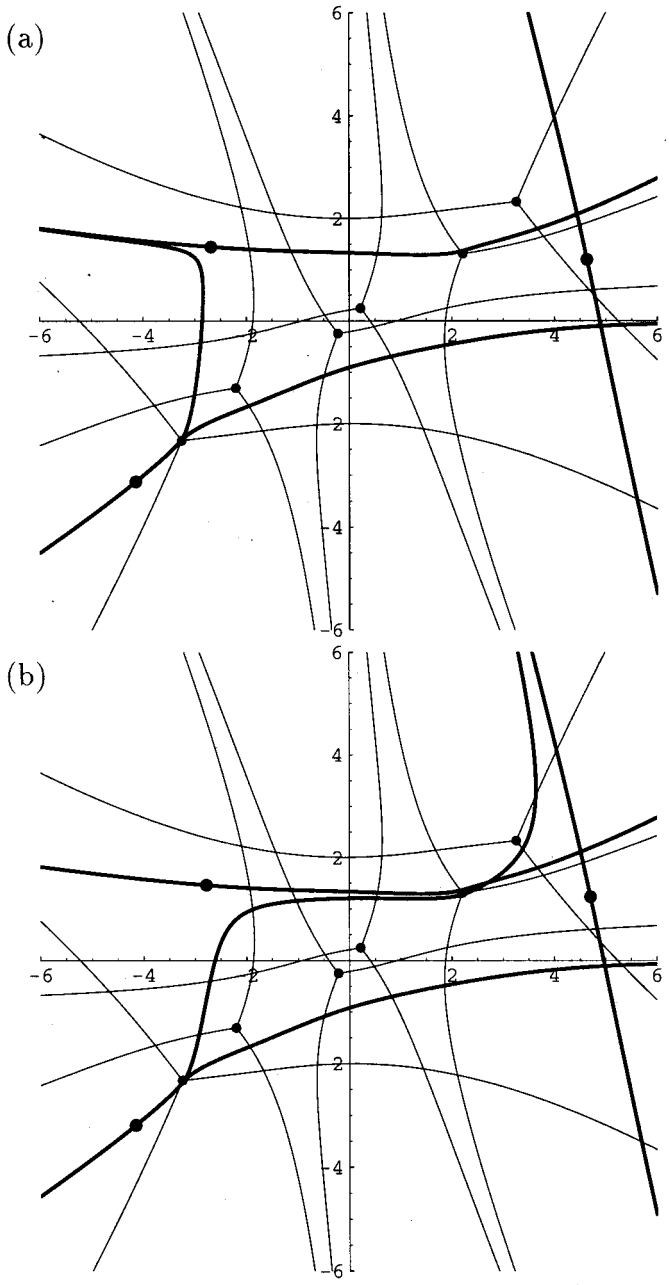

FIG. 13. Exact steepest descent paths for $x=-0.978\,776+0.247\,106\,i$ (a) and for $x=-0.998\,081+0.247\,106\,i$ (b).

and

$$\mathrm{Im}\int_{\hat{a}}^{\xi_0}(x_k(\xi)-x_{k'}(\xi))\mathrm{d}\xi=0 \tag{57}$$

hold for some $j,j',k,$ and k', a turning point $\hat{a}$ and some ξ_0, where $x_k(\xi)$ and $x_{k'}(\xi)$ solve the equation $p(x,\xi)=0$ given by (4) and $\xi_j(x)$ and $\xi_{j'}(x)$ also solve the same equation in ξ. Let us suppose that $\mathcal{R}=\{(x,\xi)\in\mathbb{C}^2:p(x,\xi)=0\}$ is nonsingular and that $x_k(\xi)$, etc., are situated with a turning point a of P as in Fig. 14. Here we note that relations (55) and (56) are slightly weaker

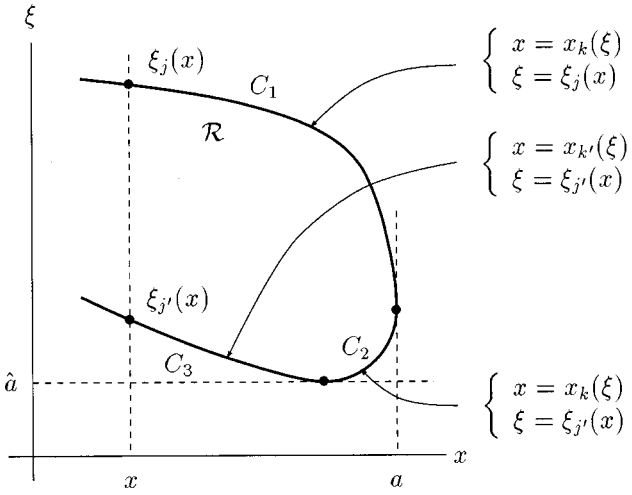

FIG. 14. Schematic illustration of $\mathcal{R}=\{(x,\xi):p(x,\xi)=0\}$.

than the actual situation that the ESDP ansatz requires to occur, because a level surface of $\mathrm{Im}\, f_k$ or $\mathrm{Im}\, f_{k'}$ is not necessarily connected. As we see in the following, these weaker conditions still suffice to entail the required relation (62).

Integration of the one-form $\mathrm{d}(x\xi)=x\mathrm{d}\xi+\xi\mathrm{d}x$ on the portion C_1 in Fig. 14 gives us

$$x\xi_j(x)-a\xi_j(a)=\int_{\xi_j(a)}^{\xi_j(x)}x_k(\xi)\mathrm{d}\xi+\int_a^x\xi_j(x)\mathrm{d}x. \tag{58}$$

Similar calculations on the portions C_2 and C_3, respectively, lead to

$$a\xi_{j'}(a)-x_k(\hat{a})\hat{a}=\int_{\hat{a}}^{\xi_{j'}(x)}x_k(\xi)\mathrm{d}\xi+\int_{x_k(\hat{a})}^{a}\xi_{j'}(x)\mathrm{d}x \tag{59}$$

and

$$x_{k'}(\hat{a})\hat{a}-x\xi_{j'}(x)=\int_{\xi_{j'}(x)}^{\hat{a}}x_{k'}(\xi)\mathrm{d}\xi+\int_x^{x_{k'}(\hat{a})}\xi_{j'}(x)\mathrm{d}x. \tag{60}$$

Combining these relations, we obtain

$$x\xi_j(x)-x\xi_{j'}(x)=\int_{\hat{a}}^{\xi_j(x)}x_k(\xi)\mathrm{d}\xi+\int_{\xi_{j'}(x)}^{\hat{a}}x_{k'}(\xi)\mathrm{d}\xi+\int_a^x\xi_j(x)\mathrm{d}x+\int_x^a\xi_{j'}(x)\mathrm{d}x. \tag{61}$$

Considering the imaginary part of the relation (61) together with (55), (56), and (57), we conclude

$$\mathrm{Im}\int_a^x(\xi_j(x)-\xi_{j'}(x))\mathrm{d}x=0. \tag{62}$$

This relation enhances our belief in the ESDP ansatz.

An application of solvable structures to classical and nonclassical similarity solutions

M. A. Barco[a)]
Keon Park, Victoria 3073, Australia

(Received 2 October 2000; accepted for publication 1 March 2001)

Using exterior differential systems, we extend work by Harrison and Estabrook for deriving similarity solutions of hyperbolic and parabolic partial differential equations (PDEs). We use exterior calculus results to show that a symmetry (isovector) of the differential ideal corresponding to some hyperbolic or parabolic PDE can be used to generate a Cauchy characteristic vector field of a restricted exterior differential system defined on some four-dimensional regular submanifold of the first jet bundle. We then show that this restricted differential ideal has a Frobenius integrable annihilating space, which can be used to yield a similarity solution of the PDE by applying results from Lie and Cartan on integrating Frobenius integrable vector field distributions via symmetry. We also give an extension to conditional symmetries. © *2001 American Institute of Physics.* [DOI: 10.1063/1.1368845]

I. INTRODUCTION

Given a nonlinear partial differential equation (PDE), a so-called ''similarity solution'' is one which is invariant under some group action. Pioneered by Lie,[1] techniques for using symmetries to find similarity solutions have been around for a long time, and in recent times authors such as Bluman and Cole,[2] Bluman and Kumei,[3] Olver,[4–6] and Stephani[7] have provided modern discussions on various aspects of this similarity solution approach to PDEs.

This work considers a single second-order hyperbolic or parabolic PDE of one dependent variable u and two independent variables x^1,x^2 of the form

$$f_1\frac{\partial^2 u}{\partial(x^1)^2}+f_2\frac{\partial^2 u}{\partial(x^2)^2}+f_3\frac{\partial^2 u}{\partial x^1 x^2}=k, \tag{1}$$

where f_1,f_2,f_3,k are smooth functions of $x^1,x^2,u,\partial u/\partial x^1$, $\partial u/\partial x^2$. Although exterior differential systems[8–12] are of most use in studying systems of nonlinear partial differential equations, we examine in this paper their application to similarity solutions of (1) along similar lines to Harrison and Estabrook.[13] We also give an alternative interpretation of the underlying geometric significance of such solutions.

Since this paper is essentially concerned with algorithms based on symmetry for extracting similarity solutions of (1), we assume throughout that given a second-order hyperbolic or parabolic PDE of the form in (1) and symmetry vector field, there exists a local smooth similarity solution. This also means that if we apply the Cartan–Kuranishi theorem,[14] we will obtain after a finite number of prolongations an involutive system of PDEs.

Our work also makes use of results from Lie[15] and Cartan[16,17] for integrating Frobenius integrable vector field distributions with solvable symmetry structures, which has in recent times been extended by Basarab-Horwath,[18] Duzhin and Lychagin,[19] Hartl and Athorne,[20] and Sherring and Prince.[21] With particular emphasis on results in Ref. 21, we establish in Secs. V and VII two algorithms based entirely on symmetry for generating similarity solutions of second order hyperbolic or parabolic PDEs of the type in (1), which avoids the usual requirement of having to solve

a)Electronic mail: M.Barco@latrobe.edu.au

some ordinary differential equation once the similarity variable is known. Finally, we briefly examine conditional symmetries. Using such symmetries we extend earlier results in this paper to give a technique for generating the so-called ''nonclassical'' [6,22,23] similarity solutions, which once again avoids the need to solve any ordinary differential equation.

II. BACKGROUND

It is assumed throughout this paper that for natural numbers n and m, U^n and V^m are, respectively, some open, convex neighborhoods of $\mathbb{R}^n$ and $\mathbb{R}^m$, with coordinates $x^1,\ldots,x^n$ and $z^1,\ldots,z^m$. On the κth jet bundle $J^\kappa(U^n,V^m)$, we say that the set of exterior differential p-forms $\Lambda^p(J^\kappa(U^n,V^m))$ is a section of the bundle of all homogeneous differential forms $\Lambda(J^\kappa(U^n,V^m))$. We define $\mathfrak{X}(J^\kappa(U^n,V^m))$ to be the module of smooth vector fields over $C^\infty(J^\kappa(U^n,V^m))$. Given some $\omega\in\Lambda^p(J^\kappa(U^n,V^m))$, its *kernel* is defined by $\ker(\omega)=\{X\in\mathfrak{X}(J^\kappa(U^n,V^m)):X\lrcorner\omega=0\}$. We assume that on their domains of definition, all vector field distributions are of constant dimension, and unless otherwise stated as in Secs. VI and VII, all mappings and differential one-forms are of constant rank.

The *Cauchy characteristic* space of a differential ideal I generated by some finite collection of differential forms is denoted $A(I)$, and contains all vector fields $X\in\mathfrak{X}(J^\kappa(U^n,V^m))$ such that $X\lrcorner I\subset I$. A vector field $X\in\mathfrak{X}(J^\kappa(U^n,V^m))$ is said to be a *symmetry* (isovector) of I if it satisfies the condition involving the Lie derivative that $\mathcal{L}_X I\subset I$. A vector field $X\in\mathfrak{X}(J^\kappa(U^n,V^m))$ is a *symmetry* of a vector field distribution $D\subset\mathfrak{X}(J^\kappa(U^n,V^m))$ if $\mathcal{L}_X D\subset D$. We say that a vector field is a *nontrivial* symmetry if, in terms of a differential ideal, it is not Cauchy characteristic, or in terms of a vector field distribution, it is not in the distribution.

We also assume throughout this paper that unless otherwise stated, M^q is some open, convex q-dimensional neighborhood of $J^\kappa(U^n,V^m)$. Since by the inverse function theorem, parametrizing immersions mapping onto regular submanifolds are locally diffeomorphic, we also assume all neighborhoods U^n, V^m, and M^q are chosen such that this holds. Thus for the differential map $\Psi_*:\mathfrak{X}(M^r)\to\mathfrak{X}(M^s)$, we can therefore assume for each $Y\in\mathfrak{X}(M^r)$ that Ψ_*Y is a well-defined vector field, and the following property holds:

$$\Psi_*[Y_1,Y_2]=[\Psi_*Y_1,\Psi_*Y_2] \tag{2}$$

for any $Y_1,Y_2\in\mathfrak{X}(M^r)$. We also make use of the following theorem found in Sternberg[24] that we use in Sec. III:

Theorem 1: Let $\Psi:M^r\to M^s$ *be a one-to-one immersion. Then for all* $Y\in\mathfrak{X}(F(M^r))$ *there exists* $X\in\mathfrak{X}(M^r)$ *such that* $\Psi_*X=Y$.

Here we write $\mathfrak{X}(\Psi(M^r))$ to mean the module of vector fields tangent to $\Psi(M^r)$. At Ψ is one-to-one, this notation is unambiguous.

The pull-back map $\Psi^*:\Lambda(M^s)\to\Lambda(M^r)$ has the following properties:

$$(\Psi^*\omega)(Y_1,\ldots,Y_k)=\Psi^*(\omega(\Psi_*Y_1,\ldots,\Psi_*Y_k)), \tag{3}$$

for any $\omega\in\Lambda^k(M^s)$, $Y_1,\ldots,Y_k\in\mathfrak{X}(M^r)$, and

$$\Psi^*\circ\mathrm{d}\omega^1=d\circ\Psi^*\omega^1, \tag{4}$$

$$\Psi^*(\omega^1\wedge\omega^2)=(\Psi^*\omega^1)\wedge(\Psi^*\omega^2), \tag{5}$$

for any $\omega^1,\omega^2\in\Lambda(M^s)$. Given any smooth $\Phi:M^q\to M^r$ and $\omega\in\Lambda^1(M^s)$, we also have the following composition property:

$$(\Psi\circ\Phi)^*\omega=\Phi^*(\Psi^*\omega). \tag{6}$$

III. DIFFERENTIAL IDEAL REPRESENTATION OF PDEs

Working in the second jet bundle $J^2(U^2,V^1)$ with coordinates $x^1,x^2,z^1,z^1_1,z^1_2,\ z^1_{11},z^1_{12},z^1_{22}$, we define

$$F:=f_1z^1_{11}+f_2z^1_{22}+f_3z^1_{12}-k,$$

along with the contact forms

$$C^1:=\mathrm{d}z^1-z^1_1\,\mathrm{d}x^1-z^1_2\,\mathrm{d}x^2,$$

$$C^1_1:=\mathrm{d}z^1_1-z^1_{11}\,\mathrm{d}x^1-z^1_{12}\,\mathrm{d}x^2,$$

$$C^1_2:=\mathrm{d}z^1_2-z^1_{12}\,\mathrm{d}x^1-z^1_{22}\,\mathrm{d}x^2.$$

We can express a solution surface of the PDE in (1) as a two-dimensional integral manifold (immersion) of the differential ideal

$$I_F:=\langle C^1,C^1_1,C^1_2,\mathrm{d}C^1_1,\mathrm{d}C^1_2,F\,\mathrm{d}x^1\wedge\mathrm{d}x^2\rangle,$$

such that the transverse condition $\mathrm{d}x^1\wedge\mathrm{d}x^2\neq 0$ holds on its tangent space. Note that $\mathrm{d}C^1\equiv 0 \mod C^1_1,C^1_2$. Also, Lemma 1.1 in Ref. 25 implies

$$\mathrm{d}(F\,\mathrm{d}x^1\wedge\mathrm{d}x^2)\equiv 0 \mod C^1,C^1_1,C^1_2,\mathrm{d}C^1_1,\mathrm{d}C^1_2.$$

It is well known that an integral manifold in the second jet bundle which annihilates all the contact forms that generate the second-order contact system is the image of the two-jet of some smooth map $f:U^2\to V^1$ if and only if $\mathrm{d}x^1\wedge dx^2\neq 0$ on the tangent space of the integral manifold (see, e.g., Theorem 2.3.1 in Stormark[26]). If, in addition, the integral manifold annihilates F, then the two-jet is that of some local solution of the PDE in (1).

Our principal result of this section is the following:

Theorem 2:

$$I_F=\langle C^1,C^1_1,C^1_2,\mathrm{d}C^1_1,\mathrm{d}C^1_2,L\rangle,$$

where

$$L:=f_1\,\mathrm{d}z^1_1\wedge\mathrm{d}x^2-f_2\,\mathrm{d}z^1_2\wedge\mathrm{d}x^1+f_3\,\mathrm{d}z^1_2\wedge\mathrm{d}x^2-k\,\mathrm{d}x^1\wedge\mathrm{d}x^2.$$

Proof:

$$F\,\mathrm{d}x^1\wedge\mathrm{d}x^2=(f_1z^1_{11}+f_2z^1_{22}+f_3z^1_{12}-k)\mathrm{d}x^1\wedge\mathrm{d}x^2.$$

Now

$$f_1z^1_{11}\,\mathrm{d}x^1\wedge\mathrm{d}x^2=f_1(z^1_{11}\,\mathrm{d}x^1+z^1_{12}\,\mathrm{d}x^2)\wedge\mathrm{d}x^2=f_1(\mathrm{d}z^1_1-C^1_1)\wedge\mathrm{d}x^2,$$

$$f_2z^1_{22}\,\mathrm{d}x^1\wedge\mathrm{d}x^2=-f_2(z^1_{21}\,\mathrm{d}x^1+z^1_{22}\,\mathrm{d}x^2)\wedge\mathrm{d}x^1=-f_2(\mathrm{d}z^1_2-C^1_2)\wedge\mathrm{d}x^1,$$

$$f_3z^1_{12}\,\mathrm{d}x^1\wedge\mathrm{d}x^2=f_3(z^1_{12}\,\mathrm{d}x^1+z^1_{22}\,\mathrm{d}x^2)\wedge\mathrm{d}x^2=f_3(\mathrm{d}z^1_2-C^1_2)\wedge\mathrm{d}x^2.$$

Hence

$$F\,\mathrm{d}x^1\wedge\mathrm{d}x^2\equiv f_1\,\mathrm{d}z^1_1\wedge\mathrm{d}x^2-f_2\,\mathrm{d}z^1_2\wedge\mathrm{d}x^1+f_3\,\mathrm{d}z^1_2\wedge\mathrm{d}x^2-k\,\mathrm{d}x^1\wedge\mathrm{d}x^2 \mod C^1_1,C^1_2\equiv L \mod C^1_1,C^1_2.$$

From this we obtain

$$\mathrm{d}L \equiv \mathrm{d}(F\,\mathrm{d}x^1 \wedge \mathrm{d}x^2) \bmod C_1^1, C_2^1, \mathrm{d}C_1^1, \mathrm{d}C_2^1,$$

$$\equiv 0 \bmod C^1, C_1^1, C_2^1, \mathrm{d}C_1^1, \mathrm{d}C_2^1,$$

■

using Lemma 1.1 in Ref. 25.

Remark: In a similar fashion, it is easy to show that

$$I_F = \langle C^1, C_1^1, C_2^1, \mathrm{d}C_1^1, \mathrm{d}C_2^1, L^\dagger \rangle,$$

where

$$L^\dagger := f_1\,\mathrm{d}z_1^1 \wedge \mathrm{d}x^2 - f_2\,\mathrm{d}z_2^1 \wedge \mathrm{d}x^1 - f_3\,\mathrm{d}z_1^1 \wedge \mathrm{d}x^1 - k\,\mathrm{d}x^1 \wedge \mathrm{d}x^2.$$

In our work, we deal mostly with L, however all results equally apply to $L^\dagger$.

We define

$$I_{\bar{F}} := \langle C^1, C_1^1, C_2^1, \mathrm{d}C_1^1, \mathrm{d}C_2^1, L \rangle.$$

Technically speaking, $I_{\bar{F}} := I_F$ (by Theorem 2), and the notation $I_{\bar{F}}$ might appear redundant. However we will use $I_{\bar{F}}$ as a brief way of referring to the particular choice of generators $C^1, C_1^1, C_2^1, \mathrm{d}C_1^1, \mathrm{d}C_2^1, L$.

Now L (containing all the information specific to the PDE) does not depend on any second-order terms $z_{11}^1, z_{12}^1, z_{22}^1$. Therefore, we may modify our problem to that of finding two-dimensional integral manifolds of a *reduced* differential ideal $I_{\bar{F}}^r$ defined by

$$I_{\bar{F}}^r := \langle C^1, \mathrm{d}C^1, L, \mathrm{d}L \rangle, \tag{7}$$

defined on the first jet bundle $J^1(U^2, V^1)$. We note that since $\mathrm{d}L$ is a three-form, all two-dimensional integral manifolds of $I_{\bar{F}}^r$ will trivially annihilate $\mathrm{d}L$, so this differential form can therefore be ignored in all calculations.

IV. SIMILARITY SOLUTION APPROACHES

Given a Lie point symmetry $X \in \mathfrak{X}(U^2 \times V^1)$ of the PDE in (1), a similarity solution of the PDE is a local solution that remains unchanged under the one-parameter group action of the symmetry. The most well-known procedure for using X to generate a corresponding similarity solution basically involves determining the two functionally independent invariants $\gamma^1, \gamma^2 \in C^\infty(U^2 \times V^1)$ of X and finding a solution of (1) that is some function of these invariants. Doing so, one essentially obtains from (1) a second-order ODE expressed in terms of γ^1, γ^2, known as the ''reduced'' differential equation. In the general case for PDE problems of n independent variables, the reduced equation retains the same order of the PDE but is of $n-1$ independent variables.

An alternative and equivalent approach to finding similarity solutions is discussed by Olver in Ref. 6 where one searches for a common solution of the overdetermined system of PDEs given by (1) and the first-order quasilinear PDE obtained from

$$X^{(1)} \lrcorner C^1 = 0, \tag{8}$$

where z^1 and z_1^1, z_2^1 are replaced with u and its respective first partial derivatives. Here we assume (8) gives a valid PDE and the Lie point symmetry X is not, for example, $\partial/\partial z^1$. The PDE derived from (8) is known as the *characterizing invariance system* (or *invariant surface condition*) corresponding to X, and is typically solved first using invariant coordinates to give a solution in terms

of an arbitrary function. Then, by inserting this solution into (1), a reduced differential equation for the arbitrary function is derived. Once this is solved, a similarity solution is obtained once more.

In this paper we do not follow either of the above-mentioned procedures, but instead choose to adopt another approach formulated by Harrison and Estabrook[13] that uses exterior calculus and differential ideals. This is discussed in the following.

Suppose we are given some differential ideal I_F^r on $J^1(U^2,V^1)$ corresponding to some second-order PDE of the form in (1). If a vector field $V\in\mathfrak{X}(J^1(U^2,V^1))$ is a symmetry of I_F^r, then

$$\mathcal{L}_V C^1=\lambda_1 C^1, \tag{9}$$

and

$$\mathcal{L}_V L=\alpha^1\wedge C^1+\lambda_2\,\mathrm{d}C^1+\lambda_3 L, \tag{10}$$

for some $\lambda_1,\lambda_2,\lambda_3\in C^\infty(J^1(U^2,V^1))$ and $\alpha^1\in\Lambda^1(J^1(U^2,V^1))$. Applying the property that $\mathcal{L}_V(\mathrm{d}\omega)=\mathrm{d}(\mathcal{L}_V\omega)$ for any differential form ω, we can use (9) and (10) to derive corresponding symmetry expressions for the remaining two generators of I_F^r. A key property of the Harrison and Estabrook approach is that the symmetry algebra of I_F^r includes the Lie point symmetry algebra of (1). We state this fact without proof, however in Ref. 27 it is proved for differential ideals where the PDE is left as a zero-form generator of the ideal. Since we are dealing with PDEs of one dependent variable, the determining equations derived from (9) and (10) should also be able to establish any so-called contact symmetries of the PDE in (1).

Suppose then that we are given some symmetry V of I_F^r [or the first prolongation of some Lie point symmetry of (1)]. In the Harrison and Estabrook approach to generating similarity solutions of (1), the differential ideal I_F^r is augmented with $V\lrcorner C^1$, $V\lrcorner\mathrm{d}C^1$, $V\lrcorner L$, and $V\lrcorner\mathrm{d}L$. One then looks for a two-dimensional integral manifold of the augmented ideal

$$\langle C^1,\mathrm{d}C^1,L,\mathrm{d}L,V\lrcorner C^1,V\lrcorner\mathrm{d}C^1,V\lrcorner L,V\lrcorner\mathrm{d}L\rangle, \tag{11}$$

defined on $J^1(U^2,V^1)$, which also satisfies the transverse condition.

The symmetry conditions in (9) and (10) can be used to easily prove that (11) is a differential ideal, and it is clear that V is a Cauchy characteristic vector field of the differential ideal. Though this obvious latter fact has also been noted by Estabrook,[28] we show in Lemma 3 in the following that for hyperbolic and parabolic PDEs of the form in (1), there exists a more useful extension of this result.

Finally, we can simplify (11) in the following way: It is not hard to establish from using (9) and (10) that (11) is equal to

$$\langle C^1,\mathrm{d}C^1,L,\mathrm{d}L,V\lrcorner C^1,\mathrm{d}(V\lrcorner C^1),V\lrcorner L,\mathrm{d}(V\lrcorner L)\rangle. \tag{12}$$

In Sec. V we examine (12) more closely and show that two further reductions are possible.

V. FIRST MAIN RESULT

The class of second-order PDEs we deal with is those for which L is decomposable, or equivalently, $L\wedge L=0$ using Theorem 1.7 in Bryant *et al.*[8] Although L defined in Theorem 2 is obviously not decomposable for some choices of f_1,f_2,f_3, and k, we will see later in Sec. VIII that for all hyperbolic and parabolic PDEs of the form in (1) we are able to add to L some multiple of $\mathrm{d}C^1$ which is then decomposable.

Assuming then without loss that L is decomposable, we have

$$0=Y\lrcorner(L\wedge L)=2(Y\lrcorner L)\wedge L,$$

for any $Y \in \mathfrak{X}(J^1(U^2,V^1))$, so that if $Y \lrcorner L \neq 0$, then $L=(Y \lrcorner L)\wedge\omega$ for some $\omega \in \Lambda^1(J^1(U^2,V^1))$. Therefore, for decomposable L, any integral manifold of

$$\langle C^1, \mathrm{d}C^1, V \lrcorner C^1, \mathrm{d}(V \lrcorner C^1), V \lrcorner L, \mathrm{d}(V \lrcorner L)\rangle \tag{13}$$

is an integral manifold of (12) (the two differential ideals are equal for decomposable L). Here V is the symmetry of I_F^r described in Sec. IV. We shall make use of this condition on L in our two main results, Theorem 4 in this section and Theorem 9 in Sec. VII.

Since $V \lrcorner C^1$ is a smooth function generator of (13), we can make a further simplification to this differential ideal by pulling it back onto the regular submanifold of $J^1(U^2,V^1)$ described by $V \lrcorner C^1=0$, and confine our work to this region of $J^1(U^2,V^1)$. Suppose that the equation $V \lrcorner C^1 =0$ describes a four-dimensional regular submanifold of $J^1(U^2,V^1)$, which we parametrize by the immersion $\Phi: M^4 \to J^1(U^2,V^1)$. Then denoting the pull-back of (13) onto M^4 by

$$J_F^r := \langle \Phi^* C^1, d\circ\Phi^* C^1, \Phi^*(V \lrcorner L), d\circ\Phi^*(V \lrcorner L)\rangle, \tag{14}$$

we have the following lemma:

Lemma 3: Let $V \in \mathfrak{X}(J^1(U^2,V^1))$ be a symmetry of I_F^r. If the equation $V \lrcorner C^1=0$ describes a four-dimensional regular submanifold of $J^1(U^2,V^1)$, which we parametrize by the immersion $\Phi: M^4 \to J^1(U^2,V^1)$, then there exists $W \in \mathfrak{X}(M^4)$ with the property that W is a Cauchy characteristic vector field of J_F^r.

Proof: Let $\Phi: M^4 \to J^1(U^2,V^1)$ be a corresponding immersion mapping onto the regular submanifold of $J^1(U^2,V^1)$ described by $V \lrcorner C^1=0$. It is clear that the tangent space of $\Phi(M^4) \subset J^1(U^2,V^1)$ spans the annihilating space of $\mathrm{d}(V \lrcorner C^1)$. From contracting the symmetry condition in (9) with V we obtain, at any point in $\Phi(M^4)$,

$$V \lrcorner \mathrm{d}(V \lrcorner C^1) = \lambda_1 (V \lrcorner C^1) = 0.$$

Hence V is in the tangent space of $\Phi(M^4)$. Applying Theorem 1, there exists a vector field $W \in \mathfrak{X}(M^4)$ such that $\Phi_* W = V$.

We now proceed to show that W is a Cauchy characteristic vector field of J_F^r by examining each generator of the differential ideal. First,

$$W \lrcorner \Phi^* C^1 = \Phi^*(\Phi_* W \lrcorner C^1) = 0, \tag{15}$$

where for the first equality we have used the property in (3), and for the second, we have made use of the fact that the pull-back of $V \lrcorner C^1$ by Φ is zero.

Next, we have that

$$W \lrcorner \Phi^* \circ \mathrm{d}C^1 = \Phi^*(\Phi_* W \lrcorner \mathrm{d}C^1) = \Phi^*(V \lrcorner \mathrm{d}C^1), \tag{16}$$

once again using (3). Now

$$\begin{aligned} \Phi^*(V \lrcorner \mathrm{d}C^1) &= \Phi^*(\lambda_1 C^1 - \mathrm{d}(V \lrcorner C^1)), \\ &= (\Phi^* \lambda_1)\Phi^* C^1 - d\circ\Phi^*(V \lrcorner C^1), \\ &= (\Phi^* \lambda_1)\Phi^* C^1 \in J_F^r, \end{aligned} \tag{17}$$

where in the first line we have inserted the symmetry condition in (9), and in the second, we have used properties (4) and (5). Combining the end result in (17) with (16) and (4) then gives

$$W \lrcorner d\circ\Phi^* C^1 \in J_F^r. \tag{18}$$

We also have from (3),

$$W \lrcorner \Phi^*(V \lrcorner L) = \Phi^*(\Phi_* W \lrcorner V \lrcorner L) = \Phi^*(V \lrcorner V \lrcorner L) = 0. \tag{19}$$

In a similar fashion,

$$W \lrcorner \Phi^* \circ \mathrm{d}(V \lrcorner L) = \Phi^*(\Phi_* W \lrcorner \mathrm{d}(V \lrcorner L)) = \Phi^*(V \lrcorner \mathrm{d}(V \lrcorner L)). \tag{20}$$

The symmetry condition in (10) yields

$$\begin{aligned} V \lrcorner \mathrm{d}(V \lrcorner L) &= V \lrcorner (\alpha^1 \wedge C^1 + \lambda_2 \, \mathrm{d}C^1 + \lambda_3 L - V \lrcorner \mathrm{d}L), \\ &= (V \lrcorner \alpha^1) C^1 - (V \lrcorner C^1) \alpha^1 + \lambda_2 (V \lrcorner \mathrm{d}C^1) + \lambda_3 (V \lrcorner L). \end{aligned}$$

Pulling this back by Φ, then using (5) and $\Phi^*(V \lrcorner C^1) = 0$ followed by (17) gives

$$\Phi^*(V \lrcorner \mathrm{d}(V \lrcorner L)) = (\Phi^*(V \lrcorner \alpha^1)) \Phi^* C^1 + (\Phi^* \lambda_2) \Phi^*(V \lrcorner \mathrm{d}C^1) + (\Phi^* \lambda_3) \Phi^*(V \lrcorner L) \in J_F^r, \tag{21}$$

so that combining this result with (20) and (4), we obtain

$$W \lrcorner \mathrm{d} \circ \Phi^*(V \lrcorner L) \in J_F^r. \tag{22}$$

Therefore (15), (18), (19), and (22) imply that $W \lrcorner J_F^r \subset J_F^r$. □

From Lemma 3 we obtain the first of our major new results:

Theorem 4: *Given some second-order PDE of the form in* (1) *whose corresponding L is decomposable, let* $V \in \mathfrak{X}(J^1(U^2, V^1))$ *be a symmetry of* I_F^r. *Suppose the equation* $V \lrcorner C^1 = 0$ *describes a four-dimensional regular submanifold of* $J^1(U^2, V^1)$, *and denote* $\Phi : M^4 \to J^1(U^2, V^1)$ *as a corresponding immersion mapping onto this submanifold. With*

$$D_F^r := (\mathrm{sp}\{\Phi^* C^1, \Phi^*(V \lrcorner L)\})^\perp,$$

if $\Phi^*(C^1 \wedge (V \lrcorner L)) \neq 0$, *then* $\Phi_* D_F^r$ *generates a two-dimensional integral manifold of* I_F^r. *If, in addition,* $\mathrm{d}x^1 \wedge \mathrm{d}x^2 \neq 0$ *on* $\Phi_* D_F^r$, *then the integral manifold is the image of the one-jet of some local solution of the PDE in (1).*

Proof: We know from the proof of Lemma 3 that $V = \Phi_* W$ for some $W \in \mathfrak{X}(M^4)$. Since $\Phi^*(C^1 \wedge (V \lrcorner L)) \neq 0$, it follows that D_F^r is two dimensional. From Lemma 3, W is a Cauchy characteristic vector field of the differential ideal J_F^r defined in (14), which implies $[W, Y] \in D_F^r$ for all $Y \in D_F^r$.[29,26] Hence D_F^r is Frobenius integrable. Since it is assumed Φ is diffeomorphic onto its image, $\Phi_* D_F^r$ is well defined. Now let $Z_1, Z_2 \in \Phi_* D_F^r$. This means

$$Z_1 = \Phi_* P_1, \quad Z_2 = \Phi_* P_2,$$

for some $P_1, P_2 \in D_F^r$. Using (2) and the fact that D_F^r is Frobenius integrable, we then get

$$[Z_1, Z_2] = [\Phi_* P_1, \Phi_* P_2] = \Phi_* [P_1, P_2] \in \Phi_* D_F^r,$$

so $\Phi_* D_F^r$ is Frobenius integrable.

Suppose that $\Psi : M^2 \to M^4$ is an immersion mapping onto any leaf of the foliation of M^4 generated by D_F^r. Thus $\Psi^* J_F^r = 0$. Using (6),

$$(\Phi \circ \Psi)^* C^1 = \Psi^*(\Phi^* C^1) = 0, \tag{23}$$

and from (4),

$$(\Phi\circ\Psi)^*(\mathrm{d}C^1)=\mathrm{d}((\Phi\circ\Psi)^*C^1)=0. \tag{24}$$

By assumption, $\Phi^*(C^1\wedge(V\lrcorner L))\neq 0$. This implies $V\lrcorner L\neq 0$. Since L is decomposable, we have $L=(V\lrcorner L)\wedge\omega$ for some $\omega\in\Lambda^1(J^1(U^2,V^1))$. Concentrating on $V\lrcorner L$,

$$0=\Psi^*(\Phi^*(V\lrcorner L))=(\Phi\circ\Psi)^*(V\lrcorner L),$$

which gives

$$\Psi^*(\Phi^*L)=\Psi^*((\Phi^*(V\lrcorner L))\wedge(\Phi^*\omega))=((\Phi\circ\Psi)^*(V\lrcorner L))\wedge((\Phi\circ\Psi)^*\omega)=0. \tag{25}$$

Hence from (23), (24), and (25), it then follows that $(\Phi\circ\Psi)^*I_F^r=0$. If the transverse condition holds, then $\Phi\circ\Psi(M^2)=j^1h(U^2)$ for some $h\in C^\infty(U^2,V^1)$, with h as some local solution of (1). □

Remark: In order to satisfy the transverse requirement, the symmetry V in Theorem 4 must necessarily satisfy the condition $\mathrm{d}(V\lrcorner C^1)\wedge\mathrm{d}x^1\wedge\mathrm{d}x^2\neq 0$. If this is not the case, then $\Phi^*(\mathrm{d}x^1\wedge\mathrm{d}x^2)=0$, and hence *for all* Ψ, $(\Phi\circ\Psi)^*(\mathrm{d}x^1\wedge\mathrm{d}x^2)=0$. Consequently the transverse requirement fails.

We illustrate Theorem 4 with the following example:

Example 5: Consider the heat equation

$$\frac{\partial^2 u}{\partial(x^1)^2}=\frac{\partial u}{\partial x^2}. \tag{26}$$

Defined on $J^1(U^2,V^1)$ we have

$$I_F^r=\langle C^1,\mathrm{d}C^1,L,\mathrm{d}L\rangle,$$

where $F=z^1_{11}-z^1_2$ and $L=(\mathrm{d}z^1_1-z^1_2\,\mathrm{d}x^1)\wedge\mathrm{d}x^2$. Now

$$V:=x^1\frac{\partial}{\partial x^1}+2x^2\frac{\partial}{\partial x^2}$$

is a Lie point symmetry of (26), and we use its first prolongation $V^{(1)}$, where

$$V^{(1)}=x^1\frac{\partial}{\partial x^1}+2x^2\frac{\partial}{\partial x^2}-z^1_1\frac{\partial}{\partial z^1_1}-2z^1_2\frac{\partial}{\partial z^1_2},$$

as our nontrivial symmetry of I_F^r.

Applying Theorem 4, we define the four-dimensional regular submanifold $M^4\subset J^1(U^2,V^1)$ by the locus of

$$V^{(1)}\lrcorner C^1=-x^1z^1_1-x^2z^1_2=0.$$

In a simplified manner without explicitly introducing an immersion, we assume M^4 has coordinates x^1,x^2,z^1,z^1_1 with $x^2\neq 0$, so that on M^4,

$$\begin{aligned} C^1&=\mathrm{d}z^1-z^1_1\,\mathrm{d}x^1+\frac{z^1_1x^1}{2x^2}\mathrm{d}x^2,\\ V^{(1)}\lrcorner L&=-z^1_1x^1\,\mathrm{d}x^1+z^1_1\left(\frac{(x^1)^2}{2x^2}-1\right)\mathrm{d}x^2-2x^2\,\mathrm{d}z^1_1, \end{aligned} \tag{27}$$

with

$$J_{\overline{F}}^{r}=\langle C^1,\mathrm{d}C^1,V^{(1)}\lrcorner L,\mathrm{d}(V^{(1)}\lrcorner L)\rangle,$$

also defined on M^4. From Theorem 4 we have that $D_{\overline{F}}^{r}\subset\mathfrak{X}(M^4)$ generated by the annihilating space of the equations in (27) is Frobenius integrable. It is easy to show that on $D_{\overline{F}}^{r}$, the transverse condition $\mathrm{d}x^1\wedge\mathrm{d}x^2\neq 0$ holds, so we expect to get some local solution to the heat equation. Then applying Proposition 4.7 in Sherring and Prince[21] with a solvable structure of two symmetries, where $X_2:=\partial/\partial z^1\in\mathfrak{X}(M^4)$ is a nontrivial symmetry of $D_{\overline{F}}^{r}$, $X_1:=z_1^1(\partial/\partial z_1^1)\in\mathfrak{X}(M^4)$ is a nontrivial symmetry of $D_{\overline{F}}^{r}\oplus\mathrm{sp}\{X_2\}$, and defining

$$\Omega:=\left(\mathrm{d}z^1-z_1^1\,\mathrm{d}x^1+\frac{z_1^1x^1}{2x^2}\mathrm{d}x^2\right)\wedge\left(-z_1^1x^1\,\mathrm{d}x^1+z_1^1\left(\frac{(x^1)^2}{2x^2}-1\right)\mathrm{d}x^2-2x^2\,\mathrm{d}z_1^1\right),$$

we find

$$\frac{X_2\lrcorner\Omega}{X_1\lrcorner X_2\lrcorner\Omega}=\mathrm{d}\left(\ln(z_1^1\sqrt{x^2})+\frac{(x^1)^2}{4x^2}\right),$$

$$\frac{X_1\lrcorner\Omega}{X_2\lrcorner X_1\lrcorner\Omega}\equiv\mathrm{d}\left(z^1-2z_1^1\sqrt{x^2}\exp\left(\frac{(x^1)^2}{4x^2}\right)\int\exp(-\xi^2)\mathrm{d}\xi\right)\bmod\frac{X_2\lrcorner\Omega}{X_1\lrcorner X_2\lrcorner\Omega},$$

where $\xi:=x^1/(2\sqrt{x^2})$. Putting

$$\ln(z_1^1\sqrt{x^2})+\frac{(x^1)^2}{4x^2}=c^1,$$

and

$$z^1-2z_1^1\sqrt{x^2}\exp\left(\frac{(x^1)^2}{4x^2}\right)\int\exp(-\xi^2)\mathrm{d}\xi=c^2,$$

for any constants c^1,c^2, we obtain

$$u=2\exp(c^1)\int\exp(-\xi^2)\mathrm{d}\xi$$

as our local similarity solution of the heat equation corresponding to V.

We close this section with a warning that there will exist situations when applying Theorem 4 will yield a distribution $\Phi_*D_{\overline{F}}^{r}$ that is not transverse, even with $\mathrm{d}(V\lrcorner C^1)\wedge\mathrm{d}x^1\wedge\mathrm{d}x^2\neq 0$. In such cases we must abandon the above-mentioned approach and look to use elements of $I_{\overline{F}}^{r}$ that are in a sense singular. This is explained in full in Sec. VI.

VI. A SINGULAR APPROACH

Consider a differential ideal $I:=\langle\alpha^1,\alpha^2\rangle$ defined on some open, convex neighborhood $U^4\subset\mathbb{R}^4$ with coordinates $x^1,\ldots,x^4$, generated by two linearly independent one-forms $\alpha^1,\alpha^2\in\Lambda^1(U^4)$. Suppose that for each $i\in\{1,2\}$, $\mathrm{d}\alpha^i\equiv 0\bmod\alpha^1,\alpha^2$, i.e., $\ker(\alpha^1\wedge\alpha^2)$ is Frobenius integrable. Here, we choose to work with a two-dimensional Pfaffian system defined on a four-dimensional space because the material in the following section on second-order hyperbolic or parabolic PDEs of the type in (1) is precisely of this nature, but all results that follow in this section can easily be extended to arbitrary dimensions.

For integrating the Frobenius integrable distribution $\ker(\alpha^1\wedge\alpha^2)$ using solvable symmetry structures, we can use Proposition 4.7 in Sherring and Prince[21] to find some functions $f_1^1,f_2^1,f_1^2,f_2^2,g^1,g^2\in C^\infty(U^4)$ such that

$$f_1^1\alpha^1+f_2^1\alpha^2=\mathrm{d}g^1,$$
$$f_1^2\alpha^1+f_2^2\alpha^2=\mathrm{d}g^2. \tag{28}$$

If, on U^4, the functions g^1,g^2 are of constant maximal rank two, then the equations $g^1=c^1,g^2=c^2$ describe a two-dimensional regular submanifold of U^4. Let $\Psi:M^2\to U^4$ be an immersion mapping onto this submanifold. If, in addition, the determinant

$$\Psi^*\begin{vmatrix} f_1^1 & f_2^1 \\ f_1^2 & f_2^2 \end{vmatrix}\neq 0$$

on M^2, then (28) and the fact that $\Psi^*(\mathrm{d}g^1)=0=\Psi^*(\mathrm{d}g^2)$ imply $\Psi^*\alpha^1=0=\Psi^*\alpha^2$. Hence Ψ is a two-dimensional integral manifold of I, for arbitrary constant functions c^1,c^2.

The problem with the above ''regular'' approach used in Theorem 4 for dealing with a PDE of the form in (1) is that if the submanifold generated by $\Phi_*D_F^r$ is not transverse, then the method fails to give us a local solution with u as some smooth function of x^1,x^2.

Our goal in this section and the next is to provide an alternative approach for finding two-dimensional integral manifolds of I, which includes the above-mentioned situation as a subclass, as well as applies to PDE problems when $\Phi_*D_F^r$ *may or may not* be transverse. We will also see that the trade-off for this extra flexibility is that there is no direct computational approach using solvable symmetry structures, however using the Frobenius integrable nature of $\ker(\alpha^1\wedge\alpha^2)$ (or $\Phi_*D_F^r$ in Theorem 4) we do come close.

Consider then the following obvious extension to the above-given discussion:

Theorem 6: *With α^1,α^2 and I defined as noted previously, let there exist $f_1^1,f_2^1,f_1^2,f_2^2,g^{11},g^{12},g^{21},g^{22}\in C^\infty(U^4)$ such that*

$$f_1^1\alpha^1+f_2^1\alpha^2=g^{11}\,\mathrm{d}g^{12},$$
$$f_1^2\alpha^1+f_2^2\alpha^2=g^{21}\,\mathrm{d}g^{22}. \tag{29}$$

Suppose that for some $p,q\in\{1,2\}$, the equations

$$g^{1p}=\begin{cases} 0 & \text{if } p=1,\\ c^1 & \text{otherwise,}\end{cases}\qquad g^{2q}=\begin{cases} 0 & \text{if } q=1,\\ c^2 & \text{otherwise,}\end{cases}$$

for some constants c^1,c^2 describe a two-dimensional regular submanifold of U^4, and let $\Psi:M^2\to U^4$ be an immersion mapping onto this submanifold. If, on M^2, the determinant

$$\Psi^*\begin{vmatrix} f_1^1 & f_2^1 \\ f_1^2 & f_2^2 \end{vmatrix}\neq 0, \tag{30}$$

then Ψ is a two-dimensional integral manifold of I.

For PDE problems, Theorem 6 will be used to find alternative (hopefully transverse) integral manifolds of I to those found with the usual approach reviewed at the start of this section. Unfortunately there is no algorithmic technique (without involving ODEs) for establishing (29) by means other than following direct one using Proposition 4.7 in Sherring and Prince[21] that incorporates symmetry:

Suppose then we apply Proposition 4.7 with $X_2\in\mathfrak{X}(U^4)$ as a nontrivial symmetry of $\ker(\alpha^1\wedge\alpha^2)$, and $X_1\in\mathfrak{X}(U^4)$ as a nontrivial symmetry of $\mathrm{sp}\{X_2\}\oplus\ker(\alpha^1\wedge\alpha^2)$. We then obtain

$$\frac{X_2 \lrcorner (\alpha^1 \wedge \alpha^2)}{X_1 \lrcorner X_2 \lrcorner (\alpha^1 \wedge \alpha^2)} = \mathrm{d}g^{12},$$
$$\frac{X_1 \lrcorner (\alpha^1 \wedge \alpha^2)}{X_2 \lrcorner X_1 \lrcorner (\alpha^1 \wedge \alpha^2)} = \mathrm{d}g^{22} - X_1(g^{22})\mathrm{d}g^{12}, \tag{31}$$

for some $g^{12}, g^{22} \in C^\infty(U^4)$. This gives integral manifolds of I defined by $g^{12} = c^1$, $g^{22} = c^2$ for constants c^1, c^2. Suppose these are not transverse. Rearranging the equations in (31) gives

$$\begin{aligned}(X_2 \lrcorner \alpha^2)\alpha^1 - (X_2 \lrcorner \alpha^1)\alpha^2 &= (X_2 \lrcorner X_1 \lrcorner (\alpha^1 \wedge \alpha^2))\mathrm{d}g^{12},\\ ((X_1 + X_1(g^{22})X_2) \lrcorner \alpha^2)\alpha^1 - ((X_1 + X_1(g^{22})X_2) \lrcorner \alpha^1)\alpha^2 &= (X_1 \lrcorner X_2 \lrcorner (\alpha^1 \wedge \alpha^2))\mathrm{d}g^{22}.\end{aligned} \tag{32}$$

Now applying Theorem 6 with the equations in (32), we set

$$g^{11} = -g^{21} = X_2 \lrcorner X_1 \lrcorner (\alpha^1 \wedge \alpha^2).$$

We cannot choose $p = 2, q = 2$ since by assumption these integral manifolds of I are not transverse. We also cannot choose $p = 1, q = 1$ because $g^{11} = -g^{21}$ implies we do not obtain a regular two-dimensional submanifold of U^4. This is clearly due to the constant maximal rank two requirement failing. Therefore we require that at least one of the two remaining (p,q) combinations satisfy the rank two condition. Finally, the equation in (30) must also be satisfied, i.e.,

$$\Psi^* \begin{vmatrix} X_2 \lrcorner \alpha^2 & -X_2 \lrcorner \alpha^1 \\ (X_1 + X_1(g^{22})X_2) \lrcorner \alpha^2 & -(X_1 + X_1(g^{22})X_2) \lrcorner \alpha^1 \end{vmatrix} \neq 0.$$

The following is a modification of Theorem 6, which shows that if we are given just one of the equations in (29) (found for example by inspection, or using Proposition 4.7 in Sherring and Prince[21] as in the above), then the other can be determined using a symmetry:

Theorem 7: *With α^1, α^2 and I defined as noted previously, let there exist $f_1^1, f_2^1, g^{11}, g^{12} \in C^\infty(U^4)$ such that*

$$f_1^1 \alpha^1 + f_2^1 \alpha^2 = g^{11}\,\mathrm{d}g^{12}. \tag{33}$$

Suppose that for some $p \in \{1,2\}$, the equation

$$g^{1p} = \begin{cases} 0 & \text{if } p = 1, \\ c^1 & \text{otherwise,} \end{cases} \tag{34}$$

for some constant c^1 describes a three-dimensional regular submanifold of U^4. Let $\Theta: M^3 \to U^4$ denote an immersion mapping onto this submanifold, and let $X \in \mathfrak{X}(M^3)$ be a nontrivial symmetry of $\Theta^*(f_1^2 \alpha^1 + f_2^2 \alpha^2)$, for some $f_1^2, f_2^2 \in C^\infty(U^4)$. Then there exist $\bar{g}^{21}, \bar{g}^{22} \in C^\infty(M^3)$ such that

$$\Theta^*(f_1^2 \alpha^1 + f_2^2 \alpha^2) = \bar{g}^{21}\,\mathrm{d}\bar{g}^{22}.$$

Further suppose that, for some $q \in \{1,2\}$, the equation

$$\bar{g}^{2q} = \begin{cases} 0 & \text{if } q = 1, \\ c^2 & \text{otherwise,} \end{cases}$$

for some constant c^2 describes a two-dimensional regular submanifold of M^3. With $\Psi: M^2 \to M^3$ denoting an immersion mapping onto this submanifold, if

$$(\Theta\circ\Psi)^*\begin{vmatrix} f_1^1 & f_2^1 \\ f_1^2 & f_2^2 \end{vmatrix} \neq 0, \tag{35}$$

on M^2, *then* $\Theta\circ\Psi$ *is a two-dimensional integral manifold of* I.

Proof: Since for each $i\in\{1,2\}$, $\mathrm{d}\alpha^i \equiv 0 \bmod \alpha^1,\alpha^2$, it follows that with

$$\beta^1 := f_1^1\alpha^1 + f_2^1\alpha^2,$$

$$\beta^2 := f_1^2\alpha^1 + f_2^2\alpha^2,$$

we have for each $i\in\{1,2\}$, $d\beta^i \equiv 0 \bmod \beta^1,\beta^2$ for arbitrary choice of $f_1^1, f_2^1, f_1^2, f_2^2 \in C^\infty(U^4)$. Let β^1 satisfy (33) for some f_1^1, f_2^1 and some $g^{11}, g^{12} \in C^\infty(U^4)$, and for some $p\in\{1,2\}$, let the immersion $\Theta: M^3 \to U^4$, defined as in the theorem, map onto the regular submanifold of U^4 given by (34). Then $\Theta^*\beta^1 = 0$, so that

$$\mathrm{d}(\Theta^*\beta^2) = \Theta^*(\mathrm{d}\beta^2) = (\Theta^*\mu_1)\Theta^*\beta^1 + (\Theta^*\mu_2)\Theta^*\beta^2 \equiv 0 \bmod \Theta^*\beta^2,$$

for some $\mu_1,\mu_2 \in C^\infty(U^4)$. Let $X\in\mathfrak{X}(M^3)$ be a nontrivial symmetry of $\Theta^*\beta^2$. Hence from Proposition 4.7 in Sherring and Prince[21] (or even Theorem 2.1 in the same paper), we obtain

$$\mathrm{d}\left(\frac{\Theta^*\beta^2}{X\lrcorner(\Theta^*\beta^2)}\right) = 0.$$

Therefore

$$\Theta^*\beta^2 = (X\lrcorner(\Theta^*\beta^2))\mathrm{d}\overset{2}{g}{}^{22},$$

for some $\overset{2}{g}{}^{22} \in C^\infty(M^3)$. We set $\overset{2}{g}{}^{21} = X\lrcorner(\Theta^*\beta^2)$ and choose $\overset{2}{g}{}^{2q}$ such that it is of constant maximal rank one on M^3. Hence with Ψ defined as in the theorem, we have

$$(\Theta\circ\Psi)^*\beta^1 = 0 = (\Theta\circ\Psi)^*\beta^2.$$

By the assumption in (35), it is then clear that $\Theta\circ\Psi$ is a two-dimensional integral manifold of I. □

Remark: The functions f_1^2, f_2^2 in Theorem 7 are not quite arbitrary: First they must be chosen so that

$$\Theta^*\begin{vmatrix} f_1^1 & f_2^1 \\ f_1^2 & f_2^2 \end{vmatrix} \neq 0,$$

on M^3, or else (35) fails for any Ψ. Then once Ψ is known, (35) must be checked.

Certainly the difficult part in applying Theorem 7 is in establishing (33). Once this is done however, the remaining assumptions in the theorem simply involve two maximal rank conditions, one nonzero determinant condition and one nontrivial symmetry.

Another observation we can make regarding Theorem 7 is that $\ker(\alpha^1\wedge\alpha^2)$ must be Frobenius integrable. Of course, even if $\ker(\alpha^1\wedge\alpha^2)$ is not Frobenius integrable, singular two-dimensional integral manifolds of I may still exist.

The following example illustrates Theorem 7:

Example 8: Suppose on some suitably chosen U^4 where $x^2 \neq 0$, $I := \langle \alpha^1, \alpha^2 \rangle$ with

$$\alpha^1 := \mathrm{d}x^3 + \frac{x^1}{2x^2}\mathrm{d}x^1 - x^4\,\mathrm{d}x^2,$$

$$\alpha^2 := \left(2x^2x^4 - \frac{(x^1)^2}{2x^2} + 1\right)\mathrm{d}x^2.$$

It is easy to show that for all $i \in \{1,2\}$, $d\alpha^i \equiv 0 \bmod \alpha^1, \alpha^2$, and so $\ker(\alpha^1 \wedge \alpha^2)$ is Frobenius integrable.

We begin with the ''regular'' approach to integrating $\ker(\alpha^1 \wedge \alpha^2)$ reviewed at the beginning of this section. Simple inspection (or Proposition 4.7 in Sherring and Prince[21]) yields

$$\alpha^1 \wedge \alpha^2 = \left(2x^2x^4 - \frac{(x^1)^2}{2x^2} + 1 \right) d\left(x^3 + \frac{(x^1)^2}{4x^2} \right) \wedge dx^2.$$

Hence if the equations

$$x^2 = c^1, \quad x^3 + \frac{(x^1)^2}{4x^2} = c^2,$$

for arbitrary constants c^1, c^2 are constant maximal rank two on some suitably chosen neighborhood of U^4, then they describe a two-dimensional foliation of the neighborhood, where each leaf is a regular submanifold that is an integral manifold of I.

We now look to apply Theorem 7 in order to generate different two-dimensional integral manifolds of I. Applying the theorem, suppose we choose $f_1^1 := 0$, $f_2^1 := 1$, and

$$g^{11} := 2x^2x^4 - \frac{(x^1)^2}{2x^2} + 1, \quad g^{12} := x^2,$$

so that (33) holds. We set

$$g^{11} = 0. \tag{36}$$

We also choose $f_1^2 := 1$, $f_2^2 := 0$. Again without explicitly introducing an immersion, and pulling-back α^1 onto M^3 defined by (36) with coordinates for M^3 given by x^1, x^2, x^3, we find (on M^3)

$$\alpha^1 = dx^3 + \frac{x^1}{2x^2} dx^1 + \frac{1}{2x^2} \left(1 - \frac{(x^1)^2}{2x^2} \right) dx^2,$$

which, from Theorem 7, is closed modulo itself. Applying Theorem 2.1 in Ref. 21 with $\partial/\partial x^3$ as a nontrivial symmetry of α^1, we get

$$\alpha^1 = d\left(x^3 + \ln(\sqrt{x^2}) + \frac{(x^1)^2}{4x^2} \right),$$

so

$$\overline{g}^{21} = 1, \quad \overline{g}^{22} = x^3 + \ln(\sqrt{x^2}) + \frac{(x^1)^2}{4x^2}.$$

Hence our only choice is to set

$$\overline{g}^{22} = c^3,$$

where c^3 is an arbitrary constant function. On a suitable neighborhood of U^4 the equations

$$2x^2x^4 - \frac{(x^1)^2}{2x^2} + 1 = 0, \quad x^3 + \ln(\sqrt{x^2}) + \frac{(x^1)^2}{4x^2} = c^3 \tag{37}$$

are of constant maximal rank two, and it is easy to see from above that the nonzero determinant condition in (35) holds. Hence the equations in (37) describe a two-dimensional regular submanifold of the neighborhood of U^4, that is an integral manifold of I. Note that the two-dimensional

leaves described by (37) do not generate a foliation of the neighborhood. Rather, the three-dimensional regular submanifold of the neighborhood described by the equation on the left in (37) is foliated by the two-dimensional leaves generated by the equation on the right.

VII. A SINGULAR APPLICATION

In this section we use Theorem 7 to provide an alternative to Theorem 4 when the transverse requirement fails for $\Phi_* D_F^r$. The following result is the second of our major results:

Theorem 9: *Given some second-order PDE of the form in (1) whose corresponding L is decomposable, let* $V \in \mathfrak{X}(J^1(U^2,V^1))$ *be a symmetry of* I_F^r. *Suppose the equation* $V \lrcorner C^1 = 0$ *describes a four-dimensional regular submanifold of* $J^1(U^2,V^1)$, *and let* $\Phi: M^4 \to J^1(U^2,V^1)$ *denote an immersion mapping onto this submanifold. Further suppose* $\Phi^*(C^1 \wedge (V \lrcorner L)) \neq 0$, *and we have applied Theorem 7, with* $\alpha^1 := \Phi^* C^1$ *and* $\alpha^2 := \Phi^*(V \lrcorner L)$, *thus generating some smooth* $g^{1p}, \overline{g}^{2q}$ *and immersions* $\Theta: M^3 \to J^1(U^2,V^1)$ *and* $\Psi: M^2 \to M^3$, *as in the theorem. If*

$$(\Phi \circ \Theta \circ \Psi)^*(\mathrm{d}x^1 \wedge \mathrm{d}x^2) \neq 0, \tag{38}$$

then $\Phi \circ \Theta \circ \Psi(M^2)$ *is the image of the one-jet of some local solution of the PDE in (1).*

Proof: Using Lemma 3, we have on M^4 that

$$D_F^r := (\mathrm{sp}\{\Phi^* C^1, \Phi^*(V \lrcorner L)\})^\perp$$

is Frobenius integrable. Applying Theorem 7 to J_F^r defined in (14) then generates a two-dimensional integral manifold of J_F^r given by

$$\Theta \circ \Psi: M^2 \to M^4.$$

At this point the proof becomes very similar to that of Theorem 4. As L is decomposable, we find that

$$\Phi \circ \Theta \circ \Psi: M^2 \to J^1(U^2,V^1)$$

is a two-dimensional integral manifold of I_F^r. The condition in (38) is a transverse requirement. It is then clear that the image of $\Phi \circ \Theta \circ \Psi$ is equal to the image of the one-jet of some local solution of the PDE in (1). ■

Remark 1: Theorem 9 can obviously be modified by replacing Theorem 7 with Theorem 6.

Remark 2: While Theorem 9 does not require that $\Phi_* D_F^r$ be transverse, a transverse requirement must still be introduced, but at a later stage.

The following example attempts to clarify Theorem 9:

Example 10: Consider the potential Burgers' equation

$$\frac{\partial u}{\partial x^2} - \frac{\partial^2 u}{\partial (x^1)^2} - \left(\frac{\partial u}{\partial x^1} \right)^2 = 0. \tag{39}$$

Defined on $J^1(U^2,V^1)$ we have

$$I_F^r = \langle C^1, \mathrm{d}C^1, L, \mathrm{d}L \rangle,$$

where $F = z_2^1 - z_{11}^1 - (z_1^1)^2$ and $L = ((z_2^1 - (z_1^1)^2)\mathrm{d}x^1 - \mathrm{d}z_1^1) \wedge \mathrm{d}x^2$. Now

$$V := 2x^2 \frac{\partial}{\partial x^1} - x^1 \frac{\partial}{\partial z^1}$$

is a Lie point symmetry of (39), and we use its first prolongation $V^{(1)}$, where

$$V^{(1)}=2x^2\frac{\partial}{\partial x^1}-x^1\frac{\partial}{\partial z^1}-\frac{\partial}{\partial z_1^1}-2z_1^1\frac{\partial}{\partial z_2^1},$$

as our nontrivial symmetry of I_F^r.

Applying Theorem 9, we define M^4 to be the four-dimensional regular submanifold of $J^1(U^2,V^1)$ given by the locus of

$$V^{(1)}\lrcorner C^1=-x^1-2x^2z_1^1=0.$$

We assume M^4 has coordinates x^1,x^2,z^1,z_2^1 with $x^2\neq 0$, so that on M^4 we have

$$C^1=\mathrm{d}z^1+\frac{x^1}{2x^2}\mathrm{d}x^1-z_2^1\mathrm{d}x^2,$$

$$V^{(1)}\lrcorner L=\left(2x^2z_2^1-\frac{(x^1)^2}{2x^2}+1\right)\mathrm{d}x^2.$$

It is clear that the transverse condition does not hold on the two-dimensional annihilating space of $\mathrm{sp}\{C^1,V^{(1)}\lrcorner L\}$ defined on M^4, so we will look to use Theorem 7. In applying this result, we refer to Example 8 which makes use of the theorem with x^3 replacing z^1 and x^4 replacing z_2^1 so that $\alpha^1=C^1$ and $\alpha^2=V^{(1)}\lrcorner L$. From the example, we then get that

$$u=-\ln(\sqrt{x^2})-\frac{(x^1)^2}{4x^2}+c^3,$$

for any constant c^3 is a similarity solution of (39) corresponding to V.

VIII. DECOMPOSABILITY EXAMINED

Theorems 4 and 9 appear to be restricted by the requirement that L (or $L^\dagger$) be decomposable. However, since $\mathrm{d}C^1$ is in I_F^r, we may look to add some multiple $b\in J^1(U^2,V^1)$ of $\mathrm{d}C^1$ to L so that $L+b\,\mathrm{d}C^1$ is decomposable.

Without loss, working this time with $L^\dagger$, we define the following two-form:

$$\Omega^\dagger:=L^\dagger+b\mathrm{d}C^1,$$

where b is for the moment any smooth function on the first jet bundle $J^1(U^2,V^1)$. The following lemma gives a simple quadratic condition on b in order that $\Omega^\dagger\wedge\Omega^\dagger=0$, so that $\Omega^\dagger$ is decomposable by Theorem 1.7 in Ref. 8.

Lemma 11: With $\Omega^\dagger:=L^\dagger+b\mathrm{d}C^1$, if

$$b=\frac{-f_3\pm\sqrt{f_3^2-4f_1f_2}}{2},$$

with $f_3^2-4f_1f_2\geqslant 0$, *then* $\Omega^\dagger$ *is decomposable.*

Proof:

$$(L^\dagger+b\,\mathrm{d}C^1)^2=(L^\dagger)^2+2b\,\mathrm{d}C^1\wedge L^\dagger+b^2(\mathrm{d}C^1)^2,$$

and

$$(\mathrm{d}C^1)^2 = 2\,\mathrm{d}z_1^1 \wedge \mathrm{d}x^1 \wedge \mathrm{d}z_2^1 \wedge \mathrm{d}x^2,$$

$$(L^\dagger)^2 = -2\,f_1 f_2\,\mathrm{d}z_1^1 \wedge \mathrm{d}x^2 \wedge \mathrm{d}z_2^1 \wedge \mathrm{d}x^1,$$

$$\mathrm{d}C^1 \wedge L^\dagger = f_3\,\mathrm{d}z_2^1 \wedge \mathrm{d}x^2 \wedge \mathrm{d}z_1^1 \wedge \mathrm{d}x^1.$$

Hence

$$(L^\dagger + b\,\mathrm{d}C^1)^2 = 2(b^2 + bf_3 + f_1 f_2)\,\mathrm{d}z_1^1 \wedge \mathrm{d}x^1 \wedge \mathrm{d}z_2^1 \wedge \mathrm{d}x^2.$$

It follows that if

$$b = \frac{-f_3 \pm \sqrt{f_3^2 - 4f_1 f_2}}{2},$$

where b is real on $J^1(U^2, V^1)$, then $\Omega^\dagger \wedge \Omega^\dagger = 0$, and therefore by Theorem 1.7 in Ref. 8, $\Omega^\dagger$ is decomposable. □

Proved in a similar way to Lemma 11, we have the following for L:

Lemma 12: With: $\Omega := L + b\,\mathrm{d}C^1$, *if*

$$b = \frac{f_3 \pm \sqrt{f_3^2 - 4f_1 f_2}}{2},$$

with $f_3^2 - 4f_1 f_2 \geqslant 0$, *then* Ω *is decomposable*.

The requirement that the discriminant in Lemmas 11 and 12 remains non-negative on $J^1(U^2, V^1)$ (or on some suitable neighborhood), coincides exactly with the condition found widely in the literature that the second-order PDE in (1) be hyperbolic or parabolic. Hence, if the PDE is of one of these two types, then we are always able to determine a decomposable Ω (or $\Omega^\dagger$). Thus we can apply Theorems 4 and 9 by simply replacing the L in these two theorems with Ω. We illustrate with an example.

Example 13: Consider the nonlinear wave equation:

$$\frac{\partial^2 u}{\partial (x^2)^2} = u \frac{\partial^2 u}{\partial (x^1)^2}. \tag{40}$$

In terms of coordinates of $J^1(U^2, V^1)$, this equation admits the point symmetry

$$V := x^2 \frac{\partial}{\partial x^2} - 2z^1 \frac{\partial}{\partial z^1},$$

whose first prolongation is

$$V^{(1)} = x^2 \frac{\partial}{\partial x^1} - 2z^1 \frac{\partial}{\partial z^1} - 2z_1^1 \frac{\partial}{\partial z_1^1} - 3z_2^1 \frac{\partial}{\partial z_2^1}.$$

Working with L, we have

$$L = -z^1\,\mathrm{d}z_1^1 \wedge \mathrm{d}x^2 - \mathrm{d}z_2^1 \wedge \mathrm{d}x^1,$$

which is clearly not decomposable. From Lemma 12, we find that $L \pm \sqrt{z^1}\,\mathrm{d}C^1$ is decomposable. Taking the positive option gives

$$\Omega_+ := L + \sqrt{z^1}\,\mathrm{d}C^1$$
$$= (\mathrm{d}z_2^1 - \sqrt{z^1}\mathrm{d}z_1^1) \wedge (\sqrt{z^1}\,\mathrm{d}x^2 - \mathrm{d}x^1).$$

Applying Theorem 4, we define the four-dimensional regular submanifold $M^4 \subset J^1(U^2, V^1)$ by the locus of

$$V^{(1)} \lrcorner C^1 = -x^2 z_2^1 - 2z^1 = 0.$$

Let M^4 have coordinates x^1, x^2, z^1, z_1^1 with $x^2 \neq 0$. Then we have on M^4,

$$C^1 = \mathrm{d}z^1 - z_1^1\,\mathrm{d}x^1 + \frac{2z^1}{x^2}\mathrm{d}x^2,$$

$$V^{(1)} \lrcorner \Omega_+ = \left(-\frac{6z^1}{x^2} - 2\sqrt{z^1} z_1^1 \right) \mathrm{d}x^1 + \left(\frac{4(z^1)^{3/2}}{x^2} + 2z^1 z_1^1 \right) \mathrm{d}x^2 + 2\sqrt{z^1}\,\mathrm{d}z^1 + x^2 z^1\,\mathrm{d}z_1^1.$$

It is easy to show that the transverse condition holds on the two-dimensional annihilating space of $\mathrm{sp}\{C^1, V^{(1)} \lrcorner \Omega_+\}$ defined on M^4. By inspection,

$$X_1 := \frac{\partial}{\partial x^1} \in \mathfrak{X}(M^4)$$

is a nontrivial symmetry of $C^1 \wedge (V^{(1)} \lrcorner \Omega_+)$ (pulled-back onto M^4). Using the Lie symmetry analysis software package DIMSYM,[30] we find

$$X_2 := -\frac{1}{(x^2)^2}\frac{\partial}{\partial z^1} \in \mathfrak{X}(M^4)$$

is another nontrivial symmetry of $C^1 \wedge (V^{(1)} \lrcorner \Omega_+)$, which also commutes with X_1. Therefore, taking advantage of this situation and applying Theorems 4.1 and 5.1 in Ref. 21 gives the two closed forms

$$\frac{X_1 \lrcorner (C^1 \wedge (V^{(1)} \lrcorner \Omega_+))}{X_2 \lrcorner X_1 \lrcorner (C^1 \wedge (V^{(1)} \lrcorner \Omega_+))} = \mathrm{d}\left(\frac{(x^2)^4 (z_1^1)^2}{12} - (x^2)^2 z^1 \right),$$

$$\frac{X_2 \lrcorner (C^1 \wedge (V^{(1)} \lrcorner \Omega_+))}{X_1 \lrcorner X_2 \lrcorner (C^1 \wedge (V^{(1)} \lrcorner \Omega_+))} = \mathrm{d}\left(x^1 - \frac{(x^2)^2 z_1^1}{6} \right).$$

Putting

$$\frac{(x^2)^4 (z_1^1)^2}{12} - (x^2)^2 z^1 = c^1, \quad x^1 - \frac{(x^2)^2 z_1^1}{6} = c^2,$$

for any constants c^1, c^2, we obtain

$$u = \frac{3(x^1 - c^2)^2 - c^1}{(x^2)^2}$$

as our similarity solution of the nonlinear wave equation in (40) corresponding to V.

IX. CONDITIONAL SYMMETRIES

Following Olver,[6] Stephani,[7] or Bluman and Cole,[23] a *conditional symmetry* $V \in \mathfrak{X}(U^2 \times V^1)$ of some second-order PDE in (1) is defined as a Lie point symmetry of the overdetermined system of PDEs given by (1) and the first-order quasilinear PDE obtained from

$$V^{(1)} \lrcorner C^1 = 0. \tag{41}$$

In this section we show that all results in the previous sections still hold true if instead of the symmetry being the first prolongation of some point symmetry of (1) it is the first prolongation of some conditional symmetry.

We define

$$\hat{I}^r_F := \langle C^1, \mathrm{d}C^1, L, \mathrm{d}L, (V^{(1)} \lrcorner C^1)\mathrm{d}x^1 \wedge \mathrm{d}x^2, \mathrm{d}(V^{(1)} \lrcorner C^1) \wedge \mathrm{d}x^1 \wedge \mathrm{d}x^2 \rangle,$$

defined on the first jet bundle $J^1(U^2, V^1)$. It is clear from Sec. III that the image of any two-dimensional integral manifold of $\hat{I}^r_F$ that satisfies the transverse condition will be that of some one-jet solution map of the overdetermined system of PDEs given by (1) and (41).

If V is a conditional symmetry of (1), then it follows from the discussion in Sec. IV that

$$\mathcal{L}_{V^{(1)}} \hat{I}^r_F \subset \hat{I}^r_F.$$

Explicitly,

$$\mathcal{L}_{V^{(1)}} C^1 = \lambda_1 C^1, \tag{42}$$

as well as

$$\mathcal{L}_{V^{(1)}} L = \alpha^1 \wedge C^1 + \lambda_2 \, \mathrm{d}C^1 + \lambda_3 L + \lambda_4 ((V^{(1)} \lrcorner C^1)\mathrm{d}x^1 \wedge \mathrm{d}x^2), \tag{43}$$

and finally,

$$\mathcal{L}_{V^{(1)}}((V^{(1)} \lrcorner C^1)\mathrm{d}x^1 \wedge \mathrm{d}x^2) = \alpha^2 \wedge C^1 + \lambda_5 \, \mathrm{d}C^1 + \lambda_6 L + \lambda_7 ((V^{(1)} \lrcorner C^1)\mathrm{d}x^1 \wedge \mathrm{d}x^2), \tag{44}$$

for some $\lambda_1, \ldots, \lambda_7 \in C^\infty(J^1(U^2, V^1))$ and $\alpha^1, \alpha^2 \in \Lambda^1(J^1(U^2, V^1))$.

Suppose in terms of first jet bundle coordinates the equation in (41) describes a four-dimensional regular submanifold of $J^1(U^2, V^1)$, which we parametrize by the immersion $\Phi: M^4 \to J^1(U^2, V^1)$. It is then obvious that

$$\Phi^* \hat{I}^r_F = \Phi^* I^r_F.$$

Without loss, we can assume L is decomposable, so that $L = (V^{(1)} \lrcorner L) \wedge \omega$ for some $\omega \in \Lambda^1(J^1(U^2, V^1))$ (assume $V^{(1)} \lrcorner L \neq 0$). Suppose we now wish to repeat the proof of Lemma 3, where in the lemma,

(1) I^r_F is replaced by $\hat{I}^r_F$,
(2) V is replaced by the first prolongation of our conditional symmetry $V^{(1)}$,
(3) the symmetry conditions in (9) and (10) are replaced by those in (42) and (43).

Now it is not hard to see that the lemma still holds true, since the pull-back of (43) by Φ forces the final term on the right to vanish. Thus when pulled-back by Φ, the two sets of equations given in item (3) are in identical form. Hence from the lemma there exists some Cauchy characteristic vector field $W \in \mathfrak{X}(M^4)$ of J^r_F with the property that $\Phi_* W = V^{(1)}$. Consequently, with the same three substitutions given previously, Theorems 4 and 9 hold.

Finally, the equation in (44) is not used in the proof of any of our results. Therefore it appears that in order for us to use symmetries of $\hat{I}_F^r$ to derive nonclassical similarity solutions, vector fields from the symmetry algebra of $\hat{I}_F^r$ are not strictly necessary. One essentially only requires vector fields that satisfy (42) and (43).

Using a conditional symmetry, we now illustrate Theorem 4 with the following example.

Example 14: Consider the heat equation given in (26). From Stephani,[7] it has the conditional symmetry

$$V := \tan(x^1)\frac{\partial}{\partial x^1} + \frac{\partial}{\partial x^2},$$

whose first prolongation is given by

$$V^{(1)} = \tan(x^1)\frac{\partial}{\partial x^1} + \frac{\partial}{\partial x^2} - z_1^1 \sec^2(x^1)\frac{\partial}{\partial z_1^1}.$$

From Example 5, L is decomposable. Applying Theorem 4, we define the four-dimensional regular submanifold $M^4 \subset J^1(U^2, V^1)$ by the locus of

$$V^{(1)} \lrcorner C^1 = -z_1^1 \tan(x^1) - z_2^1 = 0.$$

Letting M^4 have coordinates x^1, x^2, z^1, z_1^1, we pull-back C^1 and $V^{(1)} \lrcorner L$ so that (on M^4),

$$C^1 = \mathrm{d}z^1 - z_1^1\,\mathrm{d}x^1 + z_1^1 \tan(x^1)\mathrm{d}x^2,$$

$$V^{(1)} \lrcorner L = -z_1^1 \tan x^1\,\mathrm{d}x^1 - z_1^1\,\mathrm{d}x^2 - \mathrm{d}z_1^1.$$

It can be shown that on M^4, $\ker(C^1 \wedge (V^{(1)} \lrcorner L))$ is a two-dimensional Frobenius integrable distribution that satisfies the transverse condition. By inspection,

$$\frac{\partial}{\partial x^2}, \frac{\partial}{\partial z^1} \in \mathfrak{X}(M^4),$$

are two commuting nontrivial symmetries of $C^1 \wedge (V^{(1)} \lrcorner L)$. Hence by Propositions 4.1 and 5.1 in Ref. 21 we obtain the two closed forms

$$\frac{\dfrac{\partial}{\partial x^2} \lrcorner (C^1 \wedge (V^{(1)} \lrcorner L))}{\dfrac{\partial}{\partial z^1} \lrcorner \dfrac{\partial}{\partial x^2} \lrcorner (C^1 \wedge (V^{(1)} \lrcorner L))} = \mathrm{d}(z^1 - z_1^1 \tan(x^1)),$$

$$\frac{\dfrac{\partial}{\partial z^1} \lrcorner (C^1 \wedge (V^{(1)} \lrcorner L))}{\dfrac{\partial}{\partial x^2} \lrcorner \dfrac{\partial}{\partial z^1} \lrcorner (C^1 \wedge (V^{(1)} \lrcorner L))} = \mathrm{d}\left(\ln\left| \frac{z_1^1}{\cos(x^1)} \right| + x^2 \right).$$

Putting

$$z^1 - z_1^1 \tan(x^1) = c^1, \quad \ln\left| \frac{z_1^1}{\cos(x^1)} \right| + x^2 = c^2,$$

for any constants c^1 and c^2 yields

$$u = \sin(x^1)\exp(c^2 - x^2) + c^1$$

as our local nonclassical similarity solution of the wave equation corresponding to the conditional symmetry V.

X. COMMENTS AND CONCLUSIONS

Our main results, Theorems 4 and 9, combined with Lemmas 11 and 12 show how one may use solvable symmetry structures to extract classical and nonclassical similarity solutions of second-order hyperbolic or parabolic PDEs of the form in (1). While the two theorems assume L (or $L^\dagger$) is decomposable, it is hardly a restriction. This is because the discriminant in the two lemmas remains non-negative on some neighborhood precisely when the PDE is hyperbolic or parabolic. Hence, we are always able to apply Theorems 4 and 9 by replacing the given nondecomposable L with a suitable decomposable Ω, which is simply some linear combination of L and $\mathrm{d}C^1$. For Theorem 4 there is a risk that the resulting two-dimensional Frobenius integrable distribution does not satisfy the transverse requirement. If this is the case, then the approach described in the theorem must be abandoned, and we are forced to use the slightly more sophisticated Theorem 9.

Finally, while our work has focused solely on the generation of similarity solutions in the absence of boundary conditions, there is scope for further work with such conditions. As a possible starting point, we know from Theorems 4 and 9 that given a symmetry V, we obtain uniqueness of solution up to two and one arbitrary constants, respectively. We leave such research as the topic of another paper.

Classical Lie subalgebras of the Lie algebra of matrix differential operators on the circle

Carina Boyallian[a] and Jose I. Liberati[b]
CIEM-FAMAF Universidad Nacional de Córdoba, 500 Córdoba, Argentina

(Received 15 November 2000; accepted for publication 28 March 2001)

We give a complete description of the anti-involutions of the algebra $\mathcal{D}^N$ of $N \times N$-matrix differential operators on the circle, preserving the principal $\mathbb{Z}$ gradation. We obtain, up to conjugation, two families $\sigma_{\pm,m}$ with $1 \leqslant m \leqslant N$, getting two families $\mathcal{D}^N_{\pm,m}$ of simple Lie subalgebras fixed by $-\sigma_{\pm,m}$. We also give a geometric realization of $\sigma_{\pm,m}$, concluding that $\mathcal{D}^N_{+,m}$ is a subalgebra of $\mathcal{D}^N$ of type $o(m,n)$ and $\mathcal{D}^N_{-,m}$ is a subalgebra of $\mathcal{D}^N$ of type $osp(m,n)$ (ortho-symplectic). Finally, we study the conformal algebras associated with $\mathcal{D}^N_{+,m}$ and $\mathcal{D}^N_{-,m}$. © *2001 American Institute of Physics.* [DOI: 10.1063/1.1380252]

I. INTRODUCTION

Certain subalgebras of the Lie algebra $\mathcal{D}$ of differential operators on the circle were considered in Ref. 1, where they showed that there are two, up to conjugation, anti-involution $\sigma_\pm$ on $\mathcal{D}$, which preserve the principal gradation, and they obtained in this way two different Lie subalgebras fixed by $-\sigma_\pm$. The main goal of the present paper is to extend the results in Ref. 1 to the matrix case, where the picture seems to be rather more complicated and richer.

We give a complete description of the anti-involutions of the algebra $\mathcal{D}^N$ (whose central extension is usually denoted by $W^N_{1+\infty}$), of $N \times N$-matrix differential operators on the circle, preserving the principal $\mathbb{Z}$ gradation. We obtain, up to conjugation, two families $\sigma_{\pm,m}$ with $1 \leqslant m \leqslant N$, getting two families $\mathcal{D}^N_{\pm,m}$ of Lie subalgebras fixed by $-\sigma_{\pm,m}$, and we show that these subalgebras are simple. Then, we give a geometric realization of $\sigma_{\pm,m}$, concluding that $\mathcal{D}^N_{+,m}$ is a subalgebra of $\mathcal{D}^N$ of type $o(m,n)$ and $\mathcal{D}^N_{-,m}$ is a subalgebra of $\mathcal{D}^N$ of type $osp(m,n)$ (ortho-symplectic).

Finally, we study the conformal algebra associated with $\mathcal{D}^N_{+,m}$. Following the notation in Ref. 2, recall that $\mathcal{D}^N$ is a formal distribution algebra with the family of pairwise local formal distributions $\mathcal{F}=\{J^n_A(z)=\delta(t-z)(-\partial_t)^n \otimes A : n \in \mathbb{Z}_+, A \in \mathrm{Mat}_N\mathbb{C}\}$ (see Ref. 2, Example 2.10), and the associated associative (respectively, Lie) conformal algebra is $\mathrm{Cend}_N=\overline{\mathcal{F}}$ (respectively, gc_N). When we try to extend the anti-involutions $\sigma_{+,m}$ on $\mathcal{D}^N$ to the associative conformal algebra Cend_N we find some problems. If we apply $\sigma_{+,m}$ to the fields J^k_A, we have that $\sigma_{+,m}(\mathcal{F}) \not\subset \overline{\mathcal{F}}$, except in the degenerated case $m=0$. Using the notion of Γ-twisted and Γ-formal distribution algebras (Γ is a group) introduced in Refs. 3 and 4, we are able to characterize the conformal subalgebras of gc_N associated with $\mathcal{D}^N_{+,m}$ and $\mathcal{D}^N_{-,m}$. In the case of $\mathcal{D}^N_{+,m}$, we get the conformal orthogonal subalgebra oc_N of gc_N with a $\mathbb{Z}_2$-gradation, and in the other case, $\mathcal{D}^N_{-,m}$, the associated conformal algebra is gc_N with a $\mathbb{Z}_2 \times \mathbb{Z}_2$ action given by a $\mathbb{Z}_2$-gradation and an action of $\mathbb{Z}_2$ (multiplicative) by semilinear automorphisms.

In Ref. 5, the representation theory of the central extension of $\mathcal{D}^N(W^N_{1+\infty})$ was studied and it may be interesting to develop the representation theory for this new family of simple Lie subalgebras (see Ref. 1 for the special case $N=1$).

The paper is organized as follows. In Sec. II we review the Lie algebra $\mathcal{D}^N$ and classify the anti-involutions of $\mathcal{D}^N$ preserving the principal $\mathbb{Z}$-gradation of $\mathcal{D}^N$. In Sec. III, we describe the Lie

[a]Electronic mail: boyallia@mate.uncor.edu
[b]Electronic mail: liberati@mate.uncor.edu

subalgebras $\mathcal{D}^{\mathcal{N}}_{\pm,\mathfrak{m}}$. In Sec. IV we prove that $\mathcal{D}^{\mathcal{N}}_{\pm,\mathfrak{m}}$ are simple. In Sec. V, we obtain a geometric realization of $\sigma_{+,m}$. In Sec. VI we study the conformal subalgebra associated with $\mathcal{D}^{\mathcal{N}}_{+\mathfrak{m}}$, and in Sec. VII, the conformal subalgebra associated with $\mathcal{D}^{\mathcal{N}}_{-,\mathfrak{m}}$.

We are very grateful to Victor Kac for useful discussions and suggestions about this paper, and for introducing us to this subject, particularly what we have learned about the symbol map and the identification $gc_n = Mat\mathbb{C}[\partial,x]$ from his lectures at MIT in Spring'98, used in Sec. VI and VII.

II. ANTI-INVOLUTIONS OF $\mathcal{D}^N$

Let N be a positive integer. Denote by $\mathcal{D}^N_{\text{as}}$ the associative algebra of all regular matrix differential operators on $\mathbb{C}^\times$, i.e., the operators on $\mathbb{C}^N[t,t^{-1}]$ of the form

$$E = e_k(t)\partial_t^k + e_{k-1}(t)\partial_t^{k-1} + \cdots + e_0(t),$$

$$\text{where } e_i(t) \in \text{Mat}_N\mathbb{C}[t,t^{-1}]. \tag{2.1}$$

Here and in the following we denote by $\text{Mat}_N R$ the associative algebra of all $N\times N$ matrices over an algebra R. It is more convenient to write the differential operators as linear combinations of elements of the form $t^k f(D)A$, where f is a polynomial, $D = t\partial_t$, $k\in\mathbb{Z}$, and $A\in\text{Mat}_N\mathbb{C}$. The product in $\mathcal{D}^N_{\text{as}}$ is then given by

$$(t^r f(D)A)(t^s g(D)B) = t^{r+s} f(D+s)g(D)AB. \tag{2.2}$$

Let $\mathcal{D}^N$ denote Lie algebra obtained from $\mathcal{D}^N_{\text{as}}$. The bracket in $\mathcal{D}^N$ may be conveniently calculated by the following formula:

$$[t^r f(D)A, t^s g(D)B] = t^{r+s}(f(D+s)g(D)AB - f(D)g(D+r)BA). \tag{2.3}$$

The elements $t^k D^m E_{ij}$ $(k\in\mathbb{Z}, m\in\mathbb{Z}_+, i,j=1,...,N)$ form a basis of $\mathcal{D}^N$. Here and in the following E_{ij} is the standard basis of $\text{Mat}_N\mathbb{C}$. Define the *weight* wt on $\mathcal{D}^N$ by

$$\text{wt}\, t^k f(D)E_{ij} = kN + i - j. \tag{2.4}$$

This gives us the *principal* $\mathbb{Z}$-gradation of $\mathcal{D}^N_{\text{as}}$ and $\mathcal{D}^N$: $\mathcal{D}^N = \oplus_{j\in\mathbb{Z}}\mathcal{D}^N_j$, and so we have the triangular decomposition

$$\mathcal{D}^N = \mathcal{D}^N{}_+ \oplus \mathcal{D}^N{}_0 \oplus \mathcal{D}^N{}_-,$$

where $\mathcal{D}^N{}_\pm = \oplus_{j\in\pm N}\mathcal{D}^N{}_j$.

An *anti-involution* σ of $\mathcal{D}^N_{\text{as}}$ is an involutive antiautomorphism of $\mathcal{D}^N_{\text{as}}$, i.e., $\sigma^2 = I$, $\sigma(aX + bY) = a\sigma(X) + b\sigma(Y)$ and $\sigma(XY) = \sigma(Y)\sigma(X)$, for all $a,b\in\mathbb{C}, X,Y\in\mathcal{D}^N_{\text{as}}$.

In order to classify the anti-involutions of $\mathcal{D}^N_{\text{as}}$ preserving its principal gradation, we shall need the following notation. Define for each $m = 1,...,N$, the permutation π_m in S_N given by

$$\begin{array}{ccccccccccc} 1 & 2 & \dots & m-1 & m & m+1 & \dots & N-1 & N \\ \downarrow & \downarrow & & \downarrow & \downarrow & \downarrow & & \downarrow & \downarrow \\ m & m-1 & \dots & 2 & 1 & N & \dots & m+2 & m+1 \end{array}. \tag{2.5}$$

Let us fix $m = 1,...,N$, $f\in\mathbb{C}$ and $c = \{c_{i,j}\}$, $c_{i,j}\in\mathbb{C}, i>j$, we define $\sigma = \sigma_{\pm,f,c,m}$ by the following formulas:

$$\sigma(E_{ii}) = E_{\pi_m(i),\pi_m(i)},$$

$$\sigma(DE_{ii}) = (-D + f - \delta_{i>m})E_{\pi_n(i),\pi_m(i)},$$

$$\sigma(tE_{ii}) = \pm tE_{\pi_m(i),\pi_m(i)}, \tag{2.6}$$

$$(i>j) \quad \sigma(E_{i,j}) = \begin{cases} c_{i,j}E_{\pi_m(j),\pi_m(i)} & \text{if } \pi_m(i) \leqslant N-i+j \\ tc_{i,j}E_{\pi_m(j),\pi_m(i)} & \text{if } N-i+j < \pi_m(i) \end{cases},$$

$$(i<j) \quad \sigma(E_{i,j}) = \begin{cases} t^{-1}c_{j,i}^{-1}E_{\pi_m(j),\pi_m(i)} & \text{if } \pi_m(i) \leqslant j-i \\ c_{j,i}^{-1}E_{\pi_m(j),\pi_m(i)} & \text{if } \pi_m(i) > j-i \end{cases},$$

where

$$\delta_{i>m} = \begin{cases} 1 & \text{if } i>m, \\ 0 & \text{if } i \leqslant m. \end{cases}$$

Theorem 1: Let $m=1,...,N$, $f \in \mathbb{C}$, and $c=\{c_{i,j}\}$, $c_{i,j} \in \mathbb{C}$, $i>j$. Then $\sigma=\sigma_{\pm,f,c,m}$ defined on generators by (2.6) extends to an anti-involution on $\mathcal{D}_{\text{as}}^N$ which preserves the principal $\mathbb{Z}$-gradation if and only if

$$c_{i,j} = c_{i,i-1}c_{i-1,i-2}\ldots c_{j+1,j}, \tag{2.7a}$$

and

$$\begin{cases} c_{i,j}c_{\pi_m(j),\pi_m(i)} = 1 & \text{if } \pi_m(i) \leqslant N-i+j, \\ c_{i,j}c^{-1}_{\pi_m(i),\pi_m(j)} = \pm 1 & \text{if } \pi_m(i) > N-i+j. \end{cases} \tag{2.7b}$$

Moreover, any anti-involution σ of $\mathcal{D}_{\text{as}}^N$ which preserves the principal $\mathbb{Z}$-gradation is one of them.

The proof of this Theorem is certainly more difficult than the one given in Ref. 1 for $N=1$, and it will be given in several steps. We mainly use the relations between the generators $E_{i,j}$ and the involutive property of σ.

Proof: Step 1. Since σ should preserve the principal $\mathbb{Z}$-gradation, we have $\sigma(E_{i,i}) = \Sigma_{j=1}^N Q_{i,j}(D)E_{j,j}$. But $\sigma(E_{i,i}) = \sigma(E_{i,i}E_{i,i}) = \Sigma_{j=1}^N (Q_{i,j}(D))^2 E_{j,j}$. Therefore, if $Q_{i,j}(D) \neq 0$, then $Q_{i,j}(D) \equiv 1$. Note that $Q_{i,j}$ is independent of D. Now, $E_{i,i} = \sigma^2(E_{i,i}) = \Sigma_{k,j=1}^N Q_{i,j}Q_{j,k}E_{k,k}$, then $\delta_{i,k} = \Sigma_{j=1}^N Q_{i,j}Q_{j,k}$. So, for each i there exist a unique j_i such that $Q_{i,j_i}Q_{j_i,i} = 1$, then $Q_{j_i,i} = 1$. On the other hand, we also have $Q_{j_i,i}Q_{i,k} = 0$ for any $k \neq j_i$, then $Q_{i,k} = 0$ for any $k \neq j_i$, obtaining that $\sigma(E_{i,i}) = E_{j_i,j_i}$. Due to the injectivity of $\sigma, \pi(i) := j_i$ is a permutation in S_N, and since σ is an involution, we have $\pi^2 = id$.

Similar ideas will be used in the following steps.

Step 2. Again, using that σ should preserve the principal $\mathbb{Z}$-gradation, we may assume that $\sigma(DE_{i,i}) = \Sigma_{j=1}^N P_{i,j}(D)E_{j,j}$. We have

$$\begin{aligned} \sigma(DE_{i,i}) &= \sigma(DE_{i,i}E_{i,i}) = \sigma(E_{i,i})\sigma(DE_{i,i}) \\ &= E_{\pi(i),\pi(i)}\left(\sum_{j=1}^N P_{i,j}(D)E_{i,j}\right) \\ &= P_{i,\pi(i)}(D)E_{\pi(i),\pi(i)}. \end{aligned} \tag{2.8}$$

Therefore, $\sigma(DE_{i,i}) = P_i(D)E_{\pi(i),\pi(i)}$ with $P_i(D) = P_{i,\pi(i)}(D)$. Now, let us write $P_i(D) = \overline{P}_i(D) + \dot{P}_i$, where $\dot{P}_i$ stands for the constant term of $P_i(D)$. Thus,

$$\begin{aligned} DE_{i,i} &= \sigma^2(DE_{i,i}) = \sigma(P_i(D)E_{\pi(i),\pi(i)}) \\ &= \sigma((\overline{P}_i(D)+\dot{P}_i)E_{\pi(i),\pi(i)}) \\ &= \overline{P}_i(\sigma(DE_{\pi(i),\pi(i)})) + \dot{P}_i\sigma(E_{\pi(i),\pi(i)}) \\ &= (\overline{P}_i(P_{\pi(i)}(D)) + \dot{P}_i)E_{i,i}. \end{aligned}$$

So, we have $D=\overline{P}_i(P_{\pi(i)}(D))+\dot{P}_i$. Thus, $P_i(D)=a_iD+f_i$ with $a_i\cdot a_{\pi(i)}=1$ and $a_i\cdot f_{\pi(i)}+f_i=0$.

Step 3. Let us suppose that $\sigma(tE_{i,i})=t\Sigma_{l=1}^{N}T_{i,l}(D)E_{l,l}$. Using a similar argument to the one used in (2.8), we can deduce that $T_{i,k}(D)\equiv 0$ if $k\neq\pi(i)$. As before, we denote $T_i(D)=T_{i,\pi(i)}\times(D)$. Again, let us write $T_i(D)=\overline{T}_i(D)+\dot{T}_i$, where $\dot{T}_i$ stands for the constant term of $T_i(D)$. Thus,

$$\begin{aligned} tE_{i,i} = \sigma^2(tE_{i,i}) &= \sigma(tT_i(D)E_{\pi(i),\pi(i)}) \\ &= \sigma((tE_{\pi(i),\pi(i)})(\overline{T}_i(D)+\dot{T}_i)E_{\pi(i),\pi(i)}) \\ &= [\overline{T}_i(\sigma(DE_{\pi(i),\pi(i)})) + \dot{T}_i\sigma E_{\pi(i),\pi(i)}]\sigma(tE_{\pi(i),\pi(i)}) \\ &= (\overline{T}_i(T_{\pi(i)}(a_{\pi(i)}D+f_{\pi(i)})) + \dot{T}_i)tT_{\pi(i)}(D)E_{i,i} \\ &= t((\overline{T}_i(T_{\pi(i)}(a_{\pi(i)}(D+1)+f_{\pi(i)})) + \dot{T}_i)T_{\pi(i)}(D))E_{i,i}. \end{aligned}$$

Thus, $1=T_{\pi(i)}(D)\ (\overline{T}_i(T_{\pi(i)}(a_{\pi(i)}(D+1)+f_{\pi(i)}))+\dot{T}_i)$. Then $\deg(T_i)=0$ for all i, and $T_i\cdot T_{\pi(i)}=1$.

Step 4. Suppose $i>j$. Considering the $\mathbb{Z}$-gradation, we have that $\sigma(E_{i,j})=\Sigma_{l=1}^{N-i+j}C_l^{ij}(D)E_{l+i-j,l}+\Sigma_{l=N-i+j+1}^{N}tC_l^{ij}(D)E_{l+i-j-N,l}$. Since, $\sigma(E_{l,l}E_{i,j})=\sigma(E_{i,j})\sigma(E_{l,l})=\sigma(E_{i,j})E_{\pi(l),\pi(l)}$, we can deduce $C^{i,j}_{\pi(l)}(D)=0$ for all $l\neq i$. Let $C^{i,j}(D)=C^{i,j}_{\pi(i)}(D)$. Therefore, we have

$$\sigma(E_{i,j})=\begin{cases} C^{i,j}(D)E_{\pi(i)+i-j,\pi(i)} & \text{if } \pi(i)\leqslant N-i+j \\ tC^{i,j}(D)E_{\pi(i)+i-j-N,\pi(i)} & \text{if } \pi(i)\geqslant N-i+j+1. \end{cases} \tag{2.9}$$

Similarly, if $i<j$ and

$$\sigma(E_{i,j})=\sum_{l=1}^{j-i}t^{-1}S_l^{ij}(D)E_{N+l+i-j,l}+\sum_{l=j-i+1}^{N}S_l^{ij}(D)E_{l+i-j,l},$$

we deduce that $S^{i,j}_{\pi(l)}(D)=0$ for all $l\neq i$. Thus, denoting $S^{i,j}(D):=S^{ij}_{\pi(i)}(D)$, we have

$$\sigma(E_{i,j})=\begin{cases} S^{i,j}(D)E_{\pi(i)+i-j,\pi(i)} & \text{if } \pi(i)\geqslant j-i+1 \\ t^{-1}S^{i,j}(D)E_{\pi(i)+i-j+N,\pi(i)} & \text{if } \pi(i)\leqslant j-i. \end{cases} \tag{2.10}$$

Let $i>j$ and $k=i-j$, since σ is an involution we have if $\pi(i)\leqslant N-i+j$:

$$E_{i,j}=\sigma^2(E_{i,j})=\sigma(C^{i,j}(D)E_{\pi(i)+k,\pi(i)})=\sigma(C^{i,j}(D)E_{\pi(i)+k,\pi(i)+k}E_{\pi(i)+k,\pi(i)})$$

using (2.9), we must have $\pi(\pi(i)+k)+k\leqslant N-k$, otherwise we get t in the right-hand side above, so $E_{i,j}=C^{\pi(i)+k,\pi(i)}(D)C^{i,j}(a_{\pi(i)+k}D+f_{\pi(i)+k})E_{\pi(\pi(i)+k)+k,\pi(\pi(i)+k)}$. Then, $c_{i,j}:=C^{i,j}(D)$ are constant, $j=\pi(\pi(i)+k)$ and $c_{i,j}\cdot c_{\pi(j),\pi(i)}=1$, using $\pi^2=id$.

If $\pi(i)\geqslant N-i+j+1$, in the same way, using simultaneously (2.9) and (2.10) and taking care of the t that appears in $\sigma(E_{i,j})$ we have $d_{\pi(j),\pi(i)}:=S^{\pi(j),\pi(i)}(D)$ are constant, $j=\pi(\pi(i)+k-N)$, and $1=c_{i,j}\cdot d_{\pi(j),\pi(i)}\cdot b_{\pi(j)}$.

Consider $i<j$ and take $k=i-j$, by the same argument, if $\pi(i)\geqslant -k+1$ then we have $d_{i,j}:=S^{i,j}(D)$ are constant, $j=\pi(\pi(i)+k)$, and $d_{i,j}\cdot d_{\pi(j),\pi(i)}=1$.

And, if $\pi(i)\leqslant -k$ then we have $j=\pi(\pi(i)+N+k)$ and $d_{i,j}\cdot c_{\pi(j),\pi(i)}\cdot b^{-1}_{\pi(j)}=1$.

Step 5. Let $i>j$, then by step 1, $E_{\pi(i),\pi(i)}=\sigma(E_{i,i})=\sigma(E_{i,j}\cdot E_{j,i})=\sigma(E_{j,i})\cdot\sigma(E_{i,j})$, and using (2.9) and (2.10) we get

$$d_{j,i}\cdot c_{i,j}=1. \tag{2.11}$$

Now, let us determine the permutation π. Again, we have for $i=2,\ldots,N$, $E_{\pi(i),\pi(i)}=\sigma(E_{i,i})=\sigma(E_{i,i-1}\cdot E_{i-1,i})=\sigma(E_{i-1,i})\cdot\sigma(E_{i,i-1})$. Now, rewriting (2.9) and (2.10) for this case, we have

$$\sigma(E_{i,i-1})=\begin{cases} c_{i,i-1}E_{\pi(i)+1,\pi(i)} & \text{if } \pi(i)<N \\ tc_{i,i-1}E_{1,N} & \text{if } \pi(i)=N, \end{cases} \tag{2.12}$$

$$\sigma(E_{i-1,i})=\begin{cases} d_{i-1,i}E_{\pi(i-1)-1,\pi(i-1)} & \text{if } \pi(i-1)>1 \\ t^{-1}d_{i-1,i}E_{N,1} & \text{if } \pi(i-1)=1. \end{cases} \tag{2.13}$$

Let i_0 be such that $\pi(i_0)=N$. From these equations, it is easy to see that

$$\pi(i_0-1)=1, \text{ and } \pi(i-1)=\pi(i)+1 \quad \text{for any } i\neq i_0. \tag{2.14}$$

Since π is a bijective map, we conclude that π must be π_m given in (2.5) where $m=i_0-1$.

Step 6. In this step we will characterize the constants a_i, f_i, and b_i defined in steps 2 and 3.

Let us start with a_i. We have

$$\begin{aligned} -b_i tE_{\pi(i),\pi(i)} &= -\sigma(E_{i,i}) \\ &= [\sigma(DE_{i,i}),\sigma(tE_{i,i})] \\ &= [(a_iD+f_i)E_{\pi(i),\pi(i)},b_itE_{\pi(i),\pi(i)}] \\ &= b_ia_itE_{\pi(i),\pi(i)}. \end{aligned}$$

So, $a_i=-1$ for all i. Since $tE_{i+1,i+1}\cdot E_{i+1,i}=E_{i+1,i}\cdot tE_{i,i}$, applying σ to both sides and using (2.12) we deduce that $b_{i+1}=b_i$. In step 3 we showed that $b_i\cdot b_{\pi(i)}=1$, then $b_i=\pm 1$.

Finally, by applying the same argument to $DE_{i+1,i+1}\cdot E_{i+1,i}=E_{i+1,i}\cdot DE_{i,i}$, we get $f_{i_0}=f_{i_{0-1}}-1$, and if $i\neq i_0$ then $f_i=f_{i-1}(1<i)$. Thus $f:=f_1=\cdots=f_{i_{0-1}}$ and $f-1=f_{i_0}=\cdots=f_N$, getting in this way all the conditions in our theorem and all the equations in (2.7).

On the other hand, it is straightforward to check that σ defined by (2.6) is indeed anti-involution of $\mathcal{D}^N_{\text{as}}$, finishing the proof. ■

Let us study conditions (2.7a) and (2.7b) in more detail. By (2.7a), all the coefficients $c_{i,j}$ are completely determined by

$$c_i:=c_{i+1,i}, \quad i=1,\ldots,N-1, \tag{2.15}$$

and condition (2.7b) is equivalent to $c_i\cdot c_{\pi_m(i+1)}=1(i\neq m)$, and $\pm 1=c_m\cdot(c_{N,1})^{-1}=c_m\cdot\Pi_i(c_i)^{-1}=\Pi_{i\neq m}(c_i)^{-1}$. Observe that the permutation π_m is basically given by two simple permutations of the sets $\{1,\ldots,m\}$ and $\{m+1,\ldots,N\}$. Thus Eq. (2.7b) reduces to

$$c_ic_{m-i}=1 \quad (1\leqslant i<m), \quad c_{m+i}c_{N-i}=1 \quad (1\leqslant i<N-m), \quad \pm 1=\prod_{i\neq m} c_i. \tag{2.16}$$

Let $N=n+m$. If m (respectively, n) is even, we have $\Pi_{i<m}c_i=c_{(m-1)/2}$ and $(c_{(m-1)/2})^2=1$ (respectively, $\Pi_{i>m}c_i=c_{m+(n-1)/2}$ and $(c_{m+(n-1)/2})^2=1$); we shall call the coefficient $c_{(m-1)/2}$ (respectively, $c_{m+(n-1)/2}$) a fixed point. If m or n are odd, the corresponding products are equal to 1. Therefore, we have

Case −:

If N is even and

(1) m even, then there are two fixed points and one of them must be 1 and the other one equal to -1.
(2) m odd, then there are no fixed points and the last condition in (2.16) is impossible. Thus *there is no anti-involution in this case*.

If N is odd, then m or n is even and we have only one fixed point that must be equal to -1.

Case +:

For any N, the last condition in (2.16) will be satisfied if we take the (possible) fixed points equal to 1.

III. LIE SUBALGEBRAS $\mathcal{D}^N_{\pm,m}$.

Let $\mathcal{D}^N_{\pm,f,c,m}$ denote the Lie subalgebra of $\mathcal{D}^N$ fixed by $-\sigma_{\pm,f,c,m}$, namely

$$\mathcal{D}^N_{\pm,f,c,m}=\{a\in\mathcal{D}^N|\,\sigma_{\pm,f,c,m}(a)=-a\}. \tag{3.1}$$

Now, we shall study the relation among $\mathcal{D}^N_{\pm,f,c,m}$ for different data $(\pm,f,c,m)$. Let $s\in\mathbb{C}$, denote by Θ_s the automorphism of $\mathcal{D}^N_{\text{as}}$ given by $\Theta_s(A)=A$, $\Theta_s(tI)=tI$ and $\Theta_s(DI)=(D+s)I$, where I stands for the identity matrix. Clearly Θ_s preserves the principal $\mathbb{Z}$-gradation of $\mathcal{D}^N_{\text{as}}$. Let $\sigma_f:=\sigma_{\pm,f,c,m}$, then we have

$$\sigma_f\cdot\Theta_s=\sigma_{f+s}=\Theta_s\cdot\sigma_f. \tag{3.2}$$

Similarly, let $r=\{r_{i,j}\}$ $(i>j)$ satisfying (2.7a) and (2.7b). Denote by Γ_r the automorphism of $\mathcal{D}^N_{\text{as}}$ defined by $\Gamma_r(tI)=tI$, $\Gamma_r(DI)=DI$, $\Gamma_r(E_{i,i})=E_{i,i}$, $\Gamma_r(E_{i,j})=r_{i,j}E_{i,j}$ $(i>j)$, and $\Gamma_r(E_{i,j})=(r_{i,j})^{-1}E_{i,j}$ $(i<j)$. Let $\sigma_c:=\sigma_{\pm,f,c,m}$, then we have

$$\sigma_c\cdot\Gamma_r=\sigma_{c\cdot r}=\Gamma_{r^{-1}}\cdot\sigma_c, \tag{3.3}$$

where $(c\cdot r)_{i,j}:=c_{i,j}r_{i,j}$ and $(r^{-1})_{i,j}=r_{i,j}^{-1}$. Observe that $c\cdot r$ and r^{-1} also satisfy (2.7a) and (2.7b). Using (3.2) and (3.3), we have:

Lemma 1: (cf. Ref. 1, Lemma 2.2) (a) The Lie algebras $\mathcal{D}^N_{\pm,f,c,m}$ are all isomorphic for different $f\in\mathbb{C}$. In fact, we have $\Theta_s(\mathcal{D}^N_{\pm,f,c,m})=\mathcal{D}^N_{\pm,f-2s,c,m}$.

(b) $\Gamma_r(\mathcal{D}^N_{\pm,f,c,m})=\mathcal{D}^N_{\pm,f,c\cdot r^{-2},m}$.

Due to Lemma 1 we may choose a Lie algebra among $\mathcal{D}^N_{\pm,f,c,m}$, but we must keep in mind the analysis of the fixed points for the cases $+$ and $-$ that we made before.

We will fix $f=0$. In this way, we have a normalization similar to the one taken in Ref. 1.

Due to Lemma 1(b), it is possible to change c by $c\cdot r^{-2}$. Thus we can take $c_i=1$, except for the fixed points that are 1 or -1, and they should keep the sign. Denote by $\sigma_{\pm,m}$ and $\mathcal{D}^N_{\pm,m}$ the anti-involution $\sigma_{\pm,f,c,m}$ and the Lie subalgebra $\mathcal{D}^N_{\pm,f,c,m}$, respectively, with this choice of f and c.

Remark 1: Observe that $\mathcal{D}^N_{\pm,m}$ is naturally isomorphic to $\mathcal{D}^N_{\pm,N-m}$.

In order to give an explicit description of this family of subalgebras, we need some notation. For any matrix $A\in\text{Mat}_{m\times n}(\mathbb{C})$, define

$$(A^\dagger)_{i,j}=A_{n+1-j,m+1-i}, \tag{3.4}$$

i.e., the transpose with respect to the other diagonal. Recall the anti-involutions on $\mathcal{D}:=\mathcal{D}^1$ given in Ref. 1:

$$\dot{\sigma}_{\pm,b}(t^k f(D)) = (\pm t)^k f(-D-k+b) \quad (b \in \mathbb{C}). \tag{3.5}$$

We extend $\dot{\sigma}_{\pm,b}$ to a map on $\mathrm{Mat}_{m\times n}(\mathcal{D}) = \mathcal{D} \otimes \mathrm{Mat}_{m\times n}(\mathbb{C})$ by taking $[\dot{\sigma}_{\pm,b}(A)]_{i,j} = \dot{\sigma}_{\pm,b}(A_{i,j})$.

Case +:

We define the following maps on $\mathrm{Mat}_{m\times n}(\mathcal{D})$:

$$\begin{aligned} A^{\dagger_1} &= \dot{\sigma}_{+,0}(A^\dagger), \quad B^{\dagger_2} = t^{-1}\dot{\sigma}_{+,0}(B^\dagger), \\ C^{\dagger_3} &= t\dot{\sigma}_{+,-1}(C^\dagger), \quad F^{\dagger_4} = \dot{\sigma}_{+,-1}(F^\dagger). \end{aligned} \tag{3.6}$$

Then the anti-involution $\sigma_{+,m}$ on $\mathcal{D}^N = \mathcal{D} \otimes \mathrm{Mat}_N(\mathbb{C})$ is explicitly given by

$$\sigma_{+,m}\begin{pmatrix} A & B \\ C & F \end{pmatrix} = \begin{pmatrix} A^{\dagger_1} & C^{\dagger_3} \\ B^{\dagger_2} & F^{\dagger_4} \end{pmatrix}, \tag{3.7}$$

where $A \in \mathrm{Mat}_{m\times m}(\mathcal{D})$, $B \in \mathrm{Mat}_{m\times n}(\mathcal{D})$, $C \in \mathrm{Mat}_{n\times m}(\mathcal{D})$, and $F \in \mathrm{Mat}_{n\times n}(\mathcal{D})$. And

$$\mathcal{D}^N_{+,m} = \left\{ \begin{pmatrix} A & B \\ -B^{\dagger_2} & F \end{pmatrix} : A + A^{\dagger_1} = 0 \ \text{ and } \ F + F^{\dagger_4} = 0 \right\}. \tag{3.8}$$

Observe that condition $\sigma_{+,m}(a) = -a$ implies $C^{\dagger_3} = -B$ and $B^{\dagger_2} = -C$, and these two conditions are equivalent since $(B^{\dagger_2})^{\dagger_3} = B$. It is also possible to prove that $\mathcal{D}^N_{+,m}$ is a Lie subalgebra of $\mathcal{D}^N$ by direct computations, using that $\dagger_1$ and $\dagger_4$ are antiautomorphism, and the identities $B^{\dagger_2} = t^{-1}B^{\dagger_1}$, $F^{\dagger_4} = tF^{\dagger_3}$, $(B^{\dagger_2})^{\dagger_1} = Bt^{-1}$, etc. Observe that ^{†_2} and ^{†_3} are not antiautomorphism. The following identities are also useful

$$\begin{aligned} \dot{\sigma}_{\pm,0}(t^{-1}\dot{\sigma}_{\pm,0}(\cdot)) &= \pm(\cdot)t^{-1}, \\ \dot{\sigma}_{\pm,-1}(t^{-1}\dot{\sigma}_{\pm,0}(\cdot)) &= \pm t^{-1}(\cdot), \end{aligned} \tag{3.9}$$

Case −:

Since the situation N even and m (also n) odd is impossible, we may suppose, due to the symmetry, that n is even.

Now, consider the following maps on $\mathrm{Mat}_{m\times n}(\mathcal{D})$:

$$\begin{aligned} A^{*1} &:= \dot{\sigma}_{-,0}(A^\dagger), \\ B^{*2} = (B_1|B_2)^{*2} &:= t^{-1}\dot{\sigma}_{-,0}\begin{pmatrix} -B_2^\dagger \\ B_1^\dagger \end{pmatrix}, \\ C^{*3} = \begin{pmatrix} C_1 \\ C_2 \end{pmatrix}^{*3} &:= t\dot{\sigma}_{-,-1}(-C_2^\dagger | C_1^\dagger), \\ F^{*4} = \begin{pmatrix} F_1 & F_2 \\ F_3 & F_4 \end{pmatrix}^{*4} &:= \dot{\sigma}_{-,-1}\begin{pmatrix} F_4^\dagger & -F_2^\dagger \\ -F_3^\dagger & F_1^\dagger \end{pmatrix}, \end{aligned} \tag{3.10}$$

where B_i are $m\times p$, with $n = 2p$, C_i are $p\times m$, and F_i are $p\times p$.

Then the anti-involution $\sigma_{-,m}$ on $\mathcal{D}^N$ is explicitly given by

$$\sigma_{-,m}\begin{pmatrix} A & B \\ C & F \end{pmatrix} = \begin{pmatrix} A^{*1} & C^{*3} \\ B^{*2} & F^{*4} \end{pmatrix}, \tag{3.11}$$

where $A \in \mathrm{Mat}_{m\times m}(\mathcal{D})$, $B \in \mathrm{Mat}_{m\times n}(\mathcal{D})$, $C \in \mathrm{Mat}_{n\times m}(\mathcal{D})$, and $F \in \mathrm{Mat}_{n\times n}(\mathcal{D})$. And

$$\mathcal{D}^N_{-,m}=\left\{\begin{pmatrix} A & B \\ -B^{*2} & F\end{pmatrix}: A+A^{*1}=0 \text{ and } F+F^{*4}=0\right\}. \tag{3.12}$$

Note that we have again that condition $\sigma_{-,m}(a)=-a$ implies $C^{*3}=-B$ and $B^{*2}=-C$, and these two conditions are equivalent since $(B^{*2})^{*3}=B$. Again, it is also possible to prove that $\mathcal{D}^N_{-,m}$ is a Lie subalgebra of $\mathcal{D}^N$ by direct computations, using that $*_1$ and $*_4$ are antiautomorphism. Observe that $*_2$ and $*_3$ are not antiautomorphism.

Observe that we may replace † by T (usual transpose) in (3.6)–(3.8) and we get another family of involutions (denoted by $\sigma^T_{+,m}$) that do not preserve the principal $\mathbb{Z}$-gradation, and the corresponding subalgebras are not $\mathbb{Z}$-graded subalgebras of $\mathcal{D}^N$, but they are isomorphic to the others. Namely, using that $A^\dagger=JA^TJ^{-1}$ where

$$J=\begin{pmatrix} 0 & \cdots & 1 \\ \vdots & 1 & \vdots \\ 1 & \cdots & 0\end{pmatrix} \tag{3.13}$$

we get $\mathrm{Ad}_{J_{m,n}}\circ\sigma^T_{+,m}=\sigma_{+,m}$, where

$$J_{m,n}=\begin{pmatrix} J_m & 0 \\ 0 & J_n\end{pmatrix}$$

and J_n is the $n\times n$ matrix J. In the same way, we may replace † by T in (3.10), getting another family of involutions denoted by $\sigma^T_{-,m}$, and they produce subalgebras isomorphic to the others. More precisely, we have $\mathrm{Ad}_{J_{m,p,p}}\circ\sigma^T_{-,m}=\sigma_{-,m}$, where

$$J_{m,p,p}=\begin{pmatrix} J_m & 0 & 0 \\ 0 & J_p & 0 \\ 0 & 0 & J_p\end{pmatrix}.$$

IV. GENERATORS OF $\mathcal{D}^N_{\pm,m}$

In this section we give a detailed description of the generators of $\mathcal{D}^N_{\pm,m}$. Then we show that these subalgebras are simple Lie algebras.

Let us denote by $\mathbb{C}[w]^{(1)}$ the set of all odd polynomials in $\mathbb{C}[w]$, and by $\mathbb{C}[w]^{(0)}$ the set of all even polynomials in $\mathbb{C}[w]$. And let $\overline{k}=0$ if k is an odd integer and $\overline{k}=1$ if k is even.

Note that $\mathcal{D}^N_{\pm,m}=\{x-\sigma_{\pm,m}(x): x\in\mathcal{D}^N\}$ and observe that by (3.5)

$$\dot\sigma_{\pm,b}(t^kf(D_k))=(\pm t)^kf(-D_k),$$

where $D_k=D+(k-b)/2$. Therefore, by (3.6) and (3.10) the following is a set of generators of $\mathcal{D}^N_{\pm,m}$.

From now on we will use the description of the elements in the subalgebras used in (3.8) and (3.12).

- Corresponding to the block A, that is $1\leqslant i,\ j\leqslant m$ and $b=0$ ($D_k=D+k/2$):
  First consider case $+$,
  $$\{t^k(f(D_k)E_{i,m+1-j}-f(-D_k)E_{j,m+1-i}): k\in\mathbb{Z}, f\in\mathbb{C}[x], 1\leqslant i<j\leqslant m\}$$
  for the case $-$,
  $$\{t^k(f(D_k)E_{i,m+1-j}-(-1)^kf(-D_k)E_{j,m+1-i}): k\in\mathbb{Z}, f\in\mathbb{C}[x], 1\leqslant i<j\leqslant m\}$$
  and the generators on the opposite diagonal for the case $+$ are
  $$\{t^kf(D_k)E_{i,m+1-i}: k\in\mathbb{Z}, f\in\mathbb{C}[x]^{(1)}, 1\leqslant i\leqslant m\}$$

and for the case $-$ are

$$\{t^k f(D_k)E_{i,m+1-i} : k\in\mathbb{Z}, f\in\mathbb{C}[x]^{\overline{(k)}}, 1\leqslant i\leqslant m\}.$$

- Corresponding to the blocks $B-C$ $(b=0)$:
  First consider case $+$. Here we have
  $$\{t^k(f(D_k)E_{i,m+j}-t^{-1}f(-D_k)E_{N+1-j,m+1-i}) : k\in\mathbb{Z},\ f\in\mathbb{C}[x],\ 1\leqslant i\leqslant m,\ \text{and}\ 1\leqslant j\leqslant N-m\}.$$
  And for the case $-$,
  $$\{t^k(f(D_k)E_{i,m+j}-(-1)^k t^{-1}f(-D_k)E_{N+1-j,m+1-i}) : k\in\mathbb{Z},\ f\in\mathbb{C}[x],\ 1\leqslant i\leqslant m,\ \text{and}\ 1\leqslant j\leqslant p\},$$
  $$\{t^k(f(D_k)E_{i,m+j}+(-1)^k t^{-1}f(-D_k)E_{N+1-j,m+1-i}) : k\in\mathbb{Z},\ f\in\mathbb{C}[x],\ 1\leqslant i\leqslant m,\ \text{and}\ p+1\leqslant j\leqslant N-m\}.$$
- Corresponding to the blocks F $(b=-1$ and $D_k=D+(k+1)/2)$:
  Case $+$:
  $$\{t^k(f(D_k)E_{m+i,N+1-j}-f(-D_k)E_{m+j,N+1-i}) : k\in\mathbb{Z},\ f\in\mathbb{C}[x],\ 1\leqslant i<j\leqslant N-m\} \tag{4.1}$$

and the generators on the opposite diagonal are

$$\{t^k f(D_k)E_{m+i,N+1-i} : k\in\mathbb{Z},\ f\in\mathbb{C}[x]^{(1)},\ 1\leqslant i\leqslant N-m\}. \tag{4.2}$$

For the case $-$ they are

$$\{t^k(f(D_k)E_{m+i,m+j}-(-1)^k f(-D_k)E_{N+1-j,N+1-i}) : k\in\mathbb{Z},\ f\in\mathbb{C}[x],\ 1\leqslant i,j\leqslant p\},$$

$$\{t^k(f(D_k)E_{m+i,N+1-j}+(-1)^k f(-D_k)E_{m+j,N+1-i}) : k\in\mathbb{Z},\ f\in\mathbb{C}[x],\ 1\leqslant i<j\leqslant p\},$$

$$\{t^k(f(D_k)E_{N+1-i,m+j}+(-1)^k f(-D_k)E_{N+1-j,m+i}) : k\in\mathbb{Z},\ f\in\mathbb{C}[x],\ 1\leqslant i<j\leqslant p\}$$

and the generators on the opposite diagonal are

$$\{t^k f(D_k)E_{m+i,N+1-i} : k\in\mathbb{Z},\ f\in\mathbb{C}[x]^{\overline{(k+1)}},\ 1\leqslant i\leqslant N-m\}.$$

Using the above-given description we can prove the following
Theorem 2: The Lie algebras $\mathcal{D}^N_{\pm,m}$ are simple.
Since this is a rather technical proof, we refer to the Appendix.

V. GEOMETRIC REALIZATION OF $\sigma_{\pm,m}$

In this section we give a geometric realization of $\sigma_{\pm,f,m}$, for arbitrary f. The algebra $\mathcal{D}^N$ acts on the space $V=\mathbb{C}^N[t,t^{-1}]$ and one has two bilinear forms on V:

$$B_\pm(h,g)=\mathrm{Res}_t\, h^T J_\pm g, \tag{5.1}$$

where

$$J_+=\begin{pmatrix} t^{-f-1}J_m & 0 \\ 0 & t^{-f}J_n \end{pmatrix},\quad J_-=\begin{pmatrix} t^{-f-1}J_m & 0 & 0 \\ 0 & 0 & t^{-f}J_p \\ 0 & -t^{-f}J_p & 0 \end{pmatrix}\circ\Phi$$

with $\Phi: V\to V$ given by $\Phi(h(t))=h(-t)$, $h(t)\in V$, and J_m as in (3.13). Observe that $V=\mathbb{C}^m[t,t^{-1}]\times\mathbb{C}^n[t,t^{-1}]$ is an orthogonal decomposition of V. Now, consider the following proposition.

Proposition 1: (a) The bilinear forms $B_{\pm}$ are nondegenerated and B_{+} is symmetric. If f is even (respectively, odd) then B_{-} is symmetric (respectively, skew-symmetric).

(b) For any $L \in \mathcal{D}^N$ and $h,g \in V$ we have

$$B_{\pm}(Lh,g) = B_{\pm}(h,\sigma_{\pm,f,m}(L)g), \tag{5.2}$$

that is, L and $\sigma_{\pm,f,m}(L)$ are adjoint operators with respect to $B_{\pm}$.

Proof: (a) The statements that $B_{\pm}$ are nondegenerated and B_{+} is symmetric are straightforward. Let us see B_{-}:

$$\begin{aligned}
B_{-}(t^k e_i, t^l e_j) &= \mathrm{Res}_t\, e_i^T \begin{pmatrix} (-1)^l t^{k+1-f-1} J_m & 0 & 0 \\ 0 & 0 & (-1)^l t^{k+l-f} J_p \\ 0 & (-1)^l t^{k+l-f}(-J_p) & 0 \end{pmatrix} e_j \\
&= e_i^T \begin{pmatrix} (-1)^l \delta_{k+l-f,0} J_m & 0 & 0 \\ 0 & 0 & (-1)^l \delta_{k+l-f,-1} J_p \\ 0 & (-1)^l \delta_{k+l-f,-1}(-J_p) & 0 \end{pmatrix} e_j \\
&= (-1)^f e_j^T \begin{pmatrix} (-1)^k \delta_{k+l-f,0} J_m & 0 & 0 \\ 0 & 0 & (-1)^k \delta_{k+l-f,-1} J_p \\ 0 & (-1)^k \delta_{k+l-f,-1}(-J_p) & 0 \end{pmatrix} e_i \\
&= (-1)^f B_{-}(t^l e_j, t^k e_i).
\end{aligned}$$

Therefore, if f is even B_{-} is symmetric and if f is odd B_{-} is skew-symmetric.

(b) Let $L = t^k p(D)\left(\begin{smallmatrix} A & B \\ C & F \end{smallmatrix}\right)$, $h = t^r e_p$, and $g = t^s e_q$ be as shown previously. We will consider only the $+$ case. The $-$ case is completely analogous being careful with the definition of J_{-}. Then recall that

$$\sigma_{+,m,f}(L)(g) = t^{s+k} \begin{pmatrix} p(-k-s+f)A^{\dagger} & tp(-k-s+f-1)C^{\dagger} \\ t^{-1}p(-k-s+f)B^{\dagger} & p(-k-s+f-1)F^{\dagger} \end{pmatrix} e^q$$

and $L(h) = t^{k+r} p(r) \left(\begin{smallmatrix} A & B \\ C & F \end{smallmatrix}\right) e_p$. Let us compute,

$$\begin{aligned}
B_{+}(L(t^r e_p), t^s e_q) &= \mathrm{Res}_t\, t^{k+r} p(r) e_p^T \begin{pmatrix} A & B \\ C & F \end{pmatrix}^T \begin{pmatrix} t^{-f-1} J_m & 0 \\ 0 & t^{-f} J_n \end{pmatrix} t^s e_q \\
&= (p,q)\text{entry}\ \ p(r) \begin{pmatrix} \delta_{k+r+s-f,0} A^T J_m & \delta_{k+r+s-f,-1} C^T J_n \\ \delta_{k+r+s-f,0} B^T J_m & \delta_{k+r+s-f,-1} F^T J_n \end{pmatrix}.
\end{aligned} \tag{5.3}$$

On the other hand, we have

$$\begin{aligned}
B_{+}(h, \sigma_{+,f,m}(L)g) &= \mathrm{Res}_t\, t^{r+s+k} e_p^T \begin{pmatrix} t^{-f-1} J_m 0 & \\ 0 & t^{-f} J_n \end{pmatrix} \\
&\quad \cdot \begin{pmatrix} p(-k-s+f)A^{\dagger} & tp(-k-s+f-1)C^{\dagger} \\ t^{-1}p(-k-s+f)B^{\dagger} & p(-k-s+f-1)F^{\dagger} \end{pmatrix} e_q \\
&= \begin{pmatrix} \delta_{k+r+s-f,0} p(-k-s+f) J_m A^{\dagger} & \delta_{k+r+s-f,-1} p(-k-s+f-1) J_m C^{\dagger} \\ \delta_{k+r+s-f,0} p(-k-s+f) J_n B^{\dagger} & \delta_{k+r+s-f,-1} p(-k-s+f-1) J_n F^{\dagger} \end{pmatrix}_{p,q}.
\end{aligned} \tag{5.4}$$

Now, comparing (5.3) with (5.4) we finish the proof. ■

Remark 2: Analogously, we can define the following nondegenerate bilinear forms on V (in this case we consider $f=0$ for simplicity):

$$B_{\pm}^{T}(h,q)=\mathrm{Res}_t\, h^T J_{\pm,T} g,$$

where

$$J_{+,T}=\begin{pmatrix} t^{-1}I_m & 0 \\ 0 & I_n \end{pmatrix}, \quad J_{-,T}=\begin{pmatrix} t^{-1}I_m & 0 & 0 \\ 0 & 0 & I_p \\ 0 & -I_p & 0 \end{pmatrix}\circ\Phi$$

with I_m the $m\times m$ identity matrix, and it is easy to see that they satisfy

$$B_{\pm}(Lh,g)=B_{\pm}(h,\sigma_{\pm,m}^{T}(L)g),$$

where $\sigma_{\pm,m}^{T}$ were defined in (3.13). Therefore, we can claim that $\mathcal{D}_{+,m}^{N}$ is a subalgebra of $\mathcal{D}^N$ of type $o(m,n)$ and $\mathcal{D}_{-,m}^{N}$ is a subalgebra of $\mathcal{D}^N$ of type $osp(m,n)$ (orthogonal-symplectic).

VI. CONFORMAL ALGEBRA ASSOCIATED WITH $\mathcal{D}_{+,m}^{N}$

In this section we will study the conformal algebra associated with $\mathcal{D}_{+,m}^{N}$. We will follow the notation on Ref. 2. Recall that $\mathcal{D}^N=\mathcal{D}^1\otimes_{\mathbb{C}}\mathrm{Mat}_N\mathbb{C}$, viewed as an associative algebra is a formal distribution algebra with the family of pairwise local formal distributions

$$\mathcal{F}=\{J_A^n(z)=J^n(z)\otimes A: n\in\mathbb{Z}_+, A\in\mathrm{Mat}_N\mathbb{C}\},$$

where $J^n(z)=\Sigma_{j\in\mathbb{Z}}t^j(-\partial_t)^n z^{-j-1}=\delta(t-z)(-\partial_t)^n$, cf. Ref. 2, example 2.10. Recall that given a collection of mutually local formal distributions $\mathcal{F}$, the closure $\overline{\mathcal{F}}$ is defined as the minimal $\mathbb{C}[\partial]$-module closed under all nth products, $n\in\mathbb{Z}_+$ (see Ref. 2, pp. 39).

The associated associative conformal algebra is

$$\mathrm{Cend}_N=\oplus_{n\in Z_+}\mathbb{C}[\partial]J^n\otimes\mathrm{Mat}_N\mathbb{C}$$

with λ-product

$$J_{A\,\lambda}^{k}J_B^l=\sum_{j=0}^{k}\binom{k}{j}(\lambda+\partial)^j J_{AB}^{k+l-j}.$$

We will denote by gc_N the conformal (associative) algebra Cend_N viewed as a Lie conformal algebra with the λ-bracket

$$[J_{A\,\lambda}^{k}J_B^l]=\sum_{j=0}^{k}\binom{k}{j}(\lambda+\partial)^j J_{AB}^{k+l-j}-\sum_{j=0}^{l}\binom{l}{j}(-\lambda)^j J_{BA}^{k+l-j}. \tag{6.1}$$

For simplicity, we will introduce the following bijective map that we learn from Kac's lectures at MIT (Spring'98), called the *symbol*,

$$\mathrm{Symb}: \quad gc_N \quad \to\mathrm{Mat}_N[\partial,x],$$

$$\sum_k A_k(\partial)J^k\mapsto\sum_k A_k(\partial)x^k,$$

where $A_k(\partial)\in\mathrm{Mat}_N(\mathbb{C}[\partial])$. The transferred λ-bracket is

$$A(\partial,x)_\lambda B(\partial,x)=A(-\lambda,x+\lambda+\partial)B(\lambda+\partial,x)-B(\lambda+\partial,-\lambda+x)A(-\lambda,x).$$

Now, we will try to extend the anti-involutions $\sigma_{+,m}$ on $\mathcal{D}^N$ to the conformal algebra Cend_N (here we return to our normalization $f=0$ made in Sec. III). When we apply $\sigma_{+,m}$ to the fields J_A^k we find some problems. In order to show this we will need the following formulas:

$$\dot\sigma_{+,0}(\partial_t)=-t\partial_t t^{-1}, \quad \dot\sigma_{+,-1}(\partial_t)=-\partial_t \tag{6.2}$$

and

$$\dot\sigma_{+,b}(\delta(t-z))=\delta(t-z) \quad \text{for any } b. \tag{6.3}$$

If $1\leqslant i,\ j\leqslant m$, using (3.6):

$$\begin{aligned}
\sigma_{+,m}(J^1_{E_{ij}}(z))&=\sigma_{+,m}(\delta(t-z)(-\partial_t)E_{ij})\\
&=\dot\sigma_{+,0}(\delta(t-z)(-\partial_t))E_{m+1-j,m+1-i}\\
&=\dot\sigma_{+,0}(-\partial_t)\dot\sigma_{+,0}(\delta(t-z))E_{m+1-j,m+1-i}\\
&=t\partial_t t^{-1}\delta(t-z)E_{m+1-j,m+1-i}\\
&=(\delta(t-z)\partial_t+t(t^{-1}\delta(t-z))')E_{m+1-j,m+1-i}\\
&=(\delta(t-z)\partial_t-t^{-1}\delta(t-z)+\delta_t'(t-z))E_{m+1-j,m+1-i}\\
&=-J^1_{E_{m+1-j,m+1-i}}(z)-t^{-1}J^0_{E_{m+1-j,m+1-i}}(z)-\partial_z J^0_{E_{m+1-j,m+1-i}}(z).
\end{aligned} \tag{6.4}$$

Warning: The second term in the last line of (6.4) has an extra t^{-1}.
And if $1\leqslant i,\ j\leqslant N-m$,

$$\begin{aligned}
\sigma_{+,m}(J^1_{E_{m+i,m+j}}(z))&=\dot\sigma_{+,-1}(\delta(t-z)(-\partial_t))E_{N+1-j,N+1-i}\\
&=\partial_t\delta(t-z)E_{N+1-j,N+1-i}\\
&=(\delta(t-z)\partial_t+\delta_t'(t-z))E_{N+1-j,N+1-i}\\
&=-J^1_{E_{N+1-j,N+1-i}}(z)-\partial_z J^0_{E_{N+1-j,N+1-i}}(z).
\end{aligned} \tag{6.5}$$

In the same way, for $1\leqslant i\leqslant m$ and $1\leqslant j\leqslant N-m$ we have

$$\sigma_{+,m}(J^1_{E_{i,m+j}}(z))=-t^{-1}(J^1_{E_{N+1-j,m+1-i}}(z)+\partial_z J^0_{E_{N+1-j,m+1-i}}(z)). \tag{6.6}$$

and for $1\leqslant i\leqslant N-m$ and $1\leqslant j\leqslant m$, we get

$$\sigma_{+,m}(J^1_{E_{m+i,j}}(z))=-t(J^1_{E_{m+1-j,N+1-i}}(z)+\partial_z J^0_{E_{m+1-j,N+1-i}}(z))-J^0_{E_{m+1-j,N+1-i}}(z). \tag{6.7}$$

Remark 3: (a) From (6.4) and (6.6) to (6.7), we observe that

$$\sigma_{+,m}(\mathcal{F})\not\subset\overline{\mathcal{F}}.$$

We will return to this point later.

(b) From (6.5) and using symbol, we have that

$$\sigma_{+,m}\begin{pmatrix} 0 & 0 \\ 0 & F(\partial,x) \end{pmatrix} = \begin{pmatrix} 0 & 0 \\ 0 & F^{\dagger}(\partial,-\partial-x) \end{pmatrix}.$$

So if we consider the degenerated case $m=0$, we have $\sigma_{+,0}(A)=\dot{\sigma}_{+,-1}(A^{\dagger})$ getting in this way an anti-involution on gc_N. In terms of symbol, the corresponding conformal subalgebra fixed by $-\sigma_{+,0}$, which is usually denoted by oc_N, is the linear $\mathbb{C}$-span of

$$\overline{A(\partial,x)} := A(\partial,x) - \sigma_{+,0}(A(\partial,x)) = A(\partial,x) - A(\partial,-\partial-x)$$

with $A \in \mathrm{Mat}_N$ and the corresponding λ-bracket given by

$$[\overline{A(\partial,x)}_{\lambda}\ \overline{B(\partial,x)}] = \overline{A(-\lambda,\lambda+\partial+x)B(\lambda+\partial,x)} - \overline{B(\lambda+\partial,-\lambda+x)A(-\lambda,-\lambda+x)}$$
$$- \overline{A^{\dagger}(-\lambda,-\partial-x)B(\lambda+\partial,x)} + \overline{B(\lambda+\partial,-\lambda+x)A^{\dagger}(-\lambda,\lambda-x)}.$$

(c) In the case $N=1$ we have the same picture as in Ref. 1, where the fields $W^n(w) := \delta(t-z)(-\partial_t)^n + (-1)^{n+1}(-\partial_t)^n\delta(t-z)$, are introduced. Transferred in terms of symbol, $w^n = x^n - (-\partial-x)^n$ and the λ-bracket is simply (cf. Ref. 1, pp. 131–132)

$$[w^n{}_{\lambda} w^m] = (-\lambda-\partial-w)^n w^m - (\partial-w)^m w^n - (w+\partial)^n w^m + (\lambda-w)^m(-\lambda+w)^n.$$

Let us return to Remark 3(a). Consider the Lie algebra of matrix differential operators with constant coefficients $\mathfrak{g} := \mathrm{Mat}_N\mathbb{C}[\partial]$.

Now, for each $0 \leqslant m \leqslant N$, we have a $\mathbb{Z}_2$-gradation in $\mathfrak{g} = \mathfrak{g}_0 \oplus \mathfrak{g}_1$ where,

$$\mathfrak{g}_0 = \begin{pmatrix} \mathrm{Mat}_m\mathbb{C}[\partial] & 0 \\ 0 & \mathrm{Mat}_{N-m}\mathbb{C}[\partial] \end{pmatrix},$$

$$\mathfrak{g}_1 = \begin{pmatrix} 0 & \mathrm{Mat}_{m\times N-m}\mathbb{C}[\partial] \\ \mathrm{Mat}_{N-m\times m}\mathbb{C}[\partial] & 0 \end{pmatrix}.$$

Let us consider the Lie algebra $\mathcal{D}^{N,1/2}$ of matrix differential operators with coefficients in $\mathbb{C}[t^{1/2},t^{-1/2}]$, which can be seen as

$$\mathcal{D}^{N,1/2} = \mathbb{C}[t^{1/2},t^{-1/2}] \otimes \mathfrak{g}.$$

Consider the following subalgebra of $\mathcal{D}^{N,1/2}$:

$$\mathcal{D}^{N,1/2}_m = \mathbb{C}[t^1,t^{-1}] \otimes \mathfrak{g}_0 \oplus t^{1/2}\mathbb{C}[t^1,t^{-1}] \otimes \mathfrak{g}_1.$$

This is a *twisted* $\mathcal{D}^N$ algebra. Let us define the isomorphism $T_m : \mathcal{D}^{N,1/2} \to \mathcal{D}^{N,1/2}$ given by

$$T_m(A) = \begin{pmatrix} t^{-1/2}I_m & 0 \\ 0 & I_{N-m} \end{pmatrix} A \begin{pmatrix} t^{1/2}I_m & 0 \\ 0 & I_{N-m} \end{pmatrix}.$$

Note that T_m restricted to $\mathcal{D}^N$ gives us an isomorphism between $\mathcal{D}^N$ and $\mathcal{D}^{N,1/2}_m$. Via this isomorphism we translate $\sigma_{+,m}$ to $\mathcal{D}^{N,1/2}_m$, getting $T_m \circ \sigma_{+,m} \circ T_m^{-1} = \sigma_*$ where

$$\sigma_*\begin{pmatrix} A & B \\ C & F \end{pmatrix} = \dot{\sigma}_{+,-1}\begin{pmatrix} A^{\dagger} & C^{\dagger} \\ B^{\dagger} & F^{\dagger} \end{pmatrix}.$$

Observe that σ_* is equivalent to the involution defining oc_N extended to $\mathcal{D}^{N,1/2}_m$. Take the subalgebra $\mathcal{D}^{N,1/2}_{m,\sigma_*}$ of $\mathcal{D}^{N,1/2}_m$ fixed by $-\sigma_*$. This is isomorphic to $\mathcal{D}^N_{+,m}$.

Following the notation in Ref. 3, $\mathcal{D}_m^{N,1/2}$ gives rise to $1/2\mathbb{Z}$-twisted formal distributions algebra with local family

$$\mathcal{F}_m=\left\{ J_{A_i}^{n,i/2}(z):=J^{n,i/2}(z)\otimes A_i:=\sum_{k\in\mathbb{Z}} t^{k+i/2}(-\partial_t)^n z^{-k-1-i/2}A_i : A_i\in(\mathrm{Mat}_N\mathbb{C})_i,\ \ i\in\mathbb{Z}_2\right\}$$

where

$$\begin{aligned}(\mathrm{Mat}_N\mathbb{C})_0&=\left\{\begin{pmatrix} A & 0\\ 0 & F\end{pmatrix}: A\in \mathrm{Mat}_m\mathbb{C}, F\in \ \mathrm{Mat}_{N-m}\mathbb{C}\right\},\\ (\mathrm{Mat}_N\mathbb{C})_1&=\left\{\begin{pmatrix} 0 & B\\ C & 0\end{pmatrix}: B\in \mathrm{Mat}_{m\times N-m}\mathbb{C}, C\in \mathrm{Mat}_{N-m\times m}\mathbb{C}\right\}.\end{aligned}\tag{6.8}$$

Observe that $J_{A_i}^{n,i/2}(z)=\delta_{i/2}(z-t)(-\partial)^n A_i$, where $\delta_{i/2}(z-t)=\Sigma_{k\in\mathbb{Z}} t^{k+i/2}z^{-k-1-i/2}$.

Define $\mathrm{symb}(J_{A_i}^{n,i/2})=xA_i$ where $A_i\in\mathrm{Mat}_N(\mathbb{C})_i, i\in\{0,1\}$. Under this identification, the associated $\mathbb{Z}_2$-graded conformal algebra is

$$gc_{N,m}:=(\mathrm{Mat}_N\mathbb{C}[\partial,x])_0\oplus(\mathrm{Mat}_N\mathbb{C}[\partial,x])_1$$

with λ-product

$$[A_i(\partial,x)_\lambda B_j(\partial,x)]=A_i(-\lambda,\lambda+\partial+x)B_j(\lambda+\partial,x)-B_j(\lambda+\partial,-\lambda+x)A_i(-\lambda,x).$$

Therefore, $gc_{N,m}$ is simply $gc_N=\mathrm{Mat}_N(\mathbb{C}[\partial,x])$ endowed with a $\mathbb{Z}_2$-gradation that comes from the $\mathbb{Z}_2$-gradation in $\mathrm{Mat}_N(\mathbb{C})$ given by (6.8).

It is easy to see that $\sigma_*(\mathcal{F}_m)\subset\mathcal{F}_m$, getting in this way the $\mathbb{Z}_2$-graded conformal subalgebra $oc_{N,m}$ of $gc_{N,m}$ fixed by $-\sigma_*$. Obviously, we can see $oc_{N,m}$ as oc_N with a $\mathbb{Z}_2$-gradation, or as the $\mathbb{Z}_2$-graded conformal algebra associated with the $1/2\mathbb{Z}$-twisted formal distribution algebra $\mathcal{D}_{m,\sigma_*}^{N,1/2}$.

VII. CONFORMAL ALGEBRA ASSOCIATED WITH $\mathcal{D}_{-,m}^N$

In this section we will study the conformal algebra associated with $\mathcal{D}_{-,m}^N$. As in Sec. VI we will follow the notation in Refs. 2 and 3. Recall that in the + case, we first considered the degenerated case $\sigma_{+,0}$ (that is $m=0$) where we obtained a formal distribution algebra structure on $\mathcal{D}_{+,0}^N$, but in the case $1\leqslant m<N$ we obtained a $1/2\mathbb{Z}$-*twisted* formal distribution algebra. Similarly, in the case −, we will first consider the degenerated case $m=N$. Here we are forced to take the Lie algebra $\mathcal{D}_{-,N}^N$ as $\mathbb{Z}_2$-local formal distribution algebra, and in the case $1\leqslant m<N$ we get a double structure, that is $1/2\mathbb{Z}$-*twisted* and $\mathbb{Z}_2$-*local* formal distribution algebra.

Let $m=N$. Here $\sigma_{-,N}(A)=\dot\sigma_{-,0}(A^\dagger)$. In the case of $N=1$ we get the Lie algebra $\mathcal{D}^-$ considered in Ref. 1. In this paper as in our case the most convenient choice is the isomorphic subalgebra $\mathcal{D}_-^N$ which is the subalgebra of $\mathcal{D}^N$ fixed by $-\sigma_-:=-\dot\sigma_{-,-1}(A^\dagger)$ (because $\dot\sigma_{-,-1}(\partial_t)=\partial_t$ and $\dot\sigma_{-,-1}(t)=-t$).

Let us consider as before the fields $J_A^n(z)\in\mathcal{F}$ [cf. (6.1)]. Therefore, we have that

$$\sigma_-(J_A^n(z))=\sigma_-(\delta(z-t)(-\partial_t)^n A)=(-\partial_t)^n\delta(z+t)A^\dagger$$

with $\delta(z+t)=z^{-1}\Sigma_{k\in\mathbb{Z}}(-t/z)^k$. This motivates one to consider the family

$$\mathcal{F}^\pm=\{J_A^{n,\pm1}(z):=\delta(z\pm t)(-\partial_t)^n A: n\in\mathbb{Z}_+ \ \text{ and } \ A\in\mathrm{Mat}_n\mathbb{C}\},$$

which is a family of pairwise $\mathbb{Z}_2$-local formal distributions, (here $\mathbb{Z}_2=\{1,-1\}$), with OPE ($\alpha,\beta\in\mathbb{Z}_2$):

$$[J_A^{m,\alpha}(z),J_B^{n,\beta}(w)]=\sum_{k=0}^{m}\sum_{r=0}^{k}\binom{m}{k}\binom{k}{r}\beta^k(\partial_w^r J_{AB}^{m+n-k,\beta}(w))\partial_w^{k-r}\delta(z-\alpha\beta^{-1}w)$$

$$-\sum_{l=0}^{n}\binom{n}{l}(-\beta)^l J_{BA}^{m+n-l,\beta}(w)\partial_w^l\delta(z-\alpha\beta^{-1}w).$$

As in Sec. VII in Ref. 3, we introduce the following operator on the space of formal distributions: $T_\alpha(a(z))=\alpha a(\alpha z)$, with $\alpha\in\mathbb{Z}_2$. Note that $\mathcal{F}^{\pm}$ is closed under all T_α. Therefore, if we take $\mathrm{symb}(J_A^{1,1})=xA$ and $\mathrm{symb}(J_A^{1,-1})=yA$, then $(\mathcal{D}_-^N,\mathcal{F}^{\pm})$ gives rise to a conformal algebra

$$R=\overline{\mathcal{F}^{\pm}}\simeq gc_N\oplus gc_N=\mathrm{Mat}_N(\mathbb{C}[\partial,x])\oplus\mathrm{Mat}_N(\mathbb{C}[\partial,y]),$$

since the λ-bracket is

$$[A(\partial,x)_\lambda B(\partial,x)]=A(-\lambda,\lambda+\partial+x)B(\lambda+\partial,x)-B(\lambda+\partial,-\lambda+x)A(-\lambda,x),$$

$$[A(\partial,y)_\lambda B(\partial,y)]=A(-\lambda,-\lambda-\partial+y)B(\lambda+\partial,y)-B(\lambda+\partial,\lambda+y)A(-\lambda,y),$$

and $[A(\partial,x)_\lambda B(\partial,y)]=0$. The $\mathbb{Z}_2$-action on it by semilinear automorphisms (this is $\alpha T_\alpha\partial=\partial T_\alpha$ and $T_\alpha([x_\lambda y])=[T_\alpha(x)_{\alpha\lambda}T_\alpha(y)]$), is given by $T_{-1}(A(\partial,x))=A(\partial,y)$ and $T_{-1}(A(\partial,y))=A(\partial,x)$.

Now, we have that

$$\begin{aligned}\sigma_-(A(\partial,x))&=A^\dagger(\partial,y-\partial),\\ \sigma_-(A(\partial,y))&=A^\dagger(\partial,x+\partial).\end{aligned}\tag{7.1}$$

Thus, the subalgebra fixed by $-\sigma_-$ is the $\mathbb{C}$-linear span of $\overline{A(\partial,x)}:=A(\partial,x)-A^\dagger(\partial,y-\partial)$, (observe that $\overline{A(\partial,y)}=-\overline{A(\partial,x+\partial)}$).

The λ-bracket is

$$[\overline{A(\partial,x)}_\lambda B(\partial,x)]=\overline{A(-\lambda,x+\lambda+\partial)B(\lambda+\partial,x)}-\overline{B(\lambda+\partial,-\lambda+x)A(-\lambda,x)}.$$

Note that it is easy to show that

$$T_{-1}(\overline{A(\partial,x)})=-(\overline{A^\dagger(-\partial,x+\partial)}).$$

Therefore, the associated conformal subalgebra is isomorphic to gc_N with a $\mathbb{Z}_2$-action by semilinear automorphisms given by $T_1=id$ and T_{-1}.

Remark 4: Observe that we can collapse to the case $N=1$, getting gc_1 as the $\mathbb{Z}_2$-conformal algebra associated with the Lie algebra $\mathcal{D}_-$ in Ref. 1.

Now, let us consider $1\leqslant m<N$. In this case we need to combine the $1/2\mathbb{Z}$-twisted and the $\mathbb{Z}_2$-local notions.

As in Sec. VI, consider the Lie algebra of matrix differential operators with constant coefficients $\mathfrak{g}:=\mathrm{Mat}_N\mathbb{C}[\partial]$. For each $0\leqslant m\leqslant N$, we take the $\mathbb{Z}_2$-gradation in $\mathfrak{g}=\mathfrak{g}_0\oplus\mathfrak{g}_1$ as before.

Let us consider the Lie algebra $\mathcal{D}^{N,1/2}$ of matrix differential operators with coefficients in $\mathbb{C}[t^{1/2},t^{-1/2}]$, and consider the following subalgebra:

$$\mathcal{D}_m^{N,1/2}=\mathbb{C}[t^1,t^{-1}]\otimes\mathfrak{g}_0\oplus t^{1/2}\mathbb{C}[t^1,t^{-1}]\otimes\mathfrak{g}_1.$$

This is a twisted $\mathcal{D}^N$ algebra. Let us define the isomorphism $T_m:\mathcal{D}^{N,1/2}\to\mathcal{D}^{N,1/2}$ given by

$$T_m(A)=\begin{pmatrix} \sqrt{i}t^{-1/2}I_m & 0 \\ 0 & I_{N-m}\end{pmatrix} A \begin{pmatrix} \frac{1}{\sqrt{i}}t^{1/2}I_m & 0 \\ 0 & I_{N-m}\end{pmatrix}.$$

Note that T_m restricted to $\mathcal{D}^N$ gives us an isomorphism between $\mathcal{D}^N$ and $\mathcal{D}_m^{N,1/2}$. Via this isomorphism we translate $\sigma_{-,m}$ to $\mathcal{D}_m^{N,1/2}$, getting $T_m\circ\sigma_{-,m}\circ T_m^{-1}=\sigma_*$ where

$$\sigma_*(A)=\hat{\sigma}_{-,-1}A^{\ddagger},$$

with $A\in \mathrm{Mat}_N\mathbb{C}$ and

$$A^{\ddagger}=\begin{pmatrix} A_1 & B_1 & B_2 \\ C_1 & F_1 & F_2 \\ C_2 & F_3 & F_4\end{pmatrix}^{\ddagger}=\begin{pmatrix} A_1^{\dagger} & -C_2^{\dagger} & C_1^{\dagger} \\ -B_2^{\dagger} & F_4^{\dagger} & -F_2^{\dagger} \\ B_1^{\dagger} & -F_3^{\dagger} & F_1^{\dagger}\end{pmatrix}.$$

Take the subalgebra $\mathcal{D}_{m,\sigma_*}^{N,1/2}$ of $\mathcal{D}_m^{N,1/2}$ fixed by $-\sigma_*$. This is isomorphic to $\mathcal{D}_{-,m}^N$.

Following the notation in Ref. 3, $\mathcal{D}_m^{N,1/2}$ gives rise to a $1/2\mathbb{Z}$-twisted and $\mathbb{Z}_2$-local formal distributions algebra with the family

$$\mathcal{F}=\left\{ J_{A_i}^{n,i/2,\pm 1}(z):=J^{n,i/2,\pm 1}(z)\otimes A_i:=\sum_{k\in\mathbb{Z}}(\pm t)^{k+i/2}(-\partial_t)^n z^{-k-1-i/2}A_i : A_i\in(\mathrm{Mat}_N\mathbb{C})_i, i\in\mathbb{Z}_2\right\}.$$

Observe that $J_{A_i}^{n,i/2,\pm 1}(z)=\delta_{i/2}(z-(\pm 1)t)(-\partial)^n A_i$ where

$$\delta_{i/2}(z-(\pm 1)t)=\sum_{k\in\mathbb{Z}}((\pm 1)t)^{k+i/2}z^{-k-1-i/2}.$$

Its OPE is ($\alpha,\beta\in\mathbb{Z}_2$):

$$[J_{A_i}^{m,i/2,\alpha}(z),J_{A_j}^{n,i/2,\beta}(w)]=-\sum_{s=0}^{n}\binom{n}{s}(-\beta)^s J_{A_jA_i}^{m+n-s,(i+j)/2,\beta}(w)\partial_w^s\delta_{i/2}(z-\alpha\beta^{-1}w)$$
$$+\sum_{r=0}^{m}\sum_{k=0}^{r}\binom{m}{r}\binom{r}{k}\beta^r(\partial_w^k J_{A_iA_j}^{m+n-r,(i+j)/2,\beta}(w))\partial_w^{r-k}\delta_{i/2}(z-\alpha\beta^{-1}w).$$

Now we also introduce the following operator on the space of $1/2\mathbb{Z}$-twisted and $\mathbb{Z}_2$-local formal distributions: $T_\alpha(a(z))=\alpha a(\alpha z)$, with $\alpha\in\mathbb{Z}_2$. Note that $\mathcal{F}_m$ is closed under all T_α.

Thus, introducing $\mathrm{symb}(J_{A_i}^{1,i/2,1})=xA_i$ and $\mathrm{symb}(J_{A_i}^{1,i/2,-1})=yA_i$ with $A_i\in(\mathrm{Mat}_N\mathbb{C})_i$, $i\in\mathbb{Z}_2=\{0,1\}$, we have that the associated $\mathbb{Z}_2$-graded conformal algebra

$$gc_{N,m}:=\overline{\mathcal{F}_m}=\bigoplus_{i\in\mathbb{Z}_2}((\mathrm{Mat}_N\mathbb{C}[\partial,x])_i\oplus(\mathrm{Mat}_N\mathbb{C}[\partial,y])_i)$$

with λ-bracket

$$[A_i(\partial,x)_\lambda B_j(\partial,x)]=A_i(-\lambda,\lambda+\partial+x)B_j(\lambda+\partial,x)-B_j(\lambda+\partial,-\lambda+x)A_i(-\lambda,x),$$

$$[A_i(\partial,y)_\lambda B_j(\partial,y)]=A_i(-\lambda,-\lambda-\partial+y)B_j(\lambda+\partial,y)-B_j(\lambda+\partial,\lambda+y)A_i(-\lambda,y),$$

and $[A_i(\partial,x)_\lambda B_j(\partial,y)]=0$. Again, the $\mathbb{Z}_2$-action on it by semilinear automorphism is given by $T_{-1}(A_i(\partial,x))=A_i(\partial,y)$ and $T_{-1}(A_i(\partial,y))=A_i(\partial,x)$.

Therefore, $gc_{N,m} \simeq gc_N \oplus gc_N \simeq \mathrm{Mat}_N\mathbb{C}[\partial,x] \oplus \mathrm{Mat}_N\mathbb{C}[\partial,y]$ endowed with a $\mathbb{Z}_2$-gradation and a $\mathbb{Z}_2$-action by semilinear automorphisms given by T_{-1}.

It is easy to see that (in terms of symbol) we have for $i \in \mathbb{Z}_2$,

$$\sigma_*(A_i(\partial,x)) = A_i^{\ddagger}(\partial,y-\partial),$$

$$\sigma_*(A_i(\partial,y)) = A_i^{\ddagger}(\partial,x+\partial).$$

Thus, we consider the $-\sigma_*$-fixed subalgebra which is the $\mathbb{C}$-linear span of $\overline{A_i(\partial,x)} := A_i(\partial,x) - A_i^{\ddagger}(\partial,y-\partial)$.

The λ-bracket is $(i,j \in \mathbb{Z}_2)$

$$[\overline{A_i(\partial,x)}_\lambda \overline{B_j(\partial,x)}] = \overline{A_i(-\lambda,x+\lambda+\partial)B_j(\lambda+\partial,x)} - \overline{B_j(\lambda+\partial,-\lambda+x)A_i(-\lambda,x)}.$$

Therefore, the conformal subalgebra associated with $\mathcal{D}^N_{-,m}$ is isomorphic to gc_N with a $\mathbb{Z}_2 \times \mathbb{Z}_2$-action given by a $\mathbb{Z}_2$-gradation (that comes from the $\mathbb{Z}_2$ gradation in $\mathrm{Mat}_N\mathbb{C}$) and $\mathbb{Z}_2$-action by semilinear automorphism given by $T_1 = id$ and T_{-1}.

APPENDIX

Here we will prove

Theorem 2: The Lie algebras $\mathcal{D}^N_{\pm,m}$ are simple.

Proof: We will give the proof only for the case $\mathcal{D}^N_{+,m}$, since the other is completely analogous. We are going to use the description in terms of generators given in Sec. IV. Since the proof is rather technical, some details will only be sketched. Assume that $b=1$. Let us define

$$X = \begin{pmatrix} \left(D-\frac{1}{2}\right)I_m & 0 \\ 0 & DI_{N-m} \end{pmatrix} \in \mathcal{D}^N_{+,m}. \tag{A1}$$

Note that $(k \in \mathbb{Z})$

$$\mathrm{ad}(X)\left(t^k f\left(D+\frac{k-1}{2}\right)A = kt^k f\left(D+\frac{k-1}{2}\right)A, \right. \tag{A2a}$$

where $A = \left(\begin{smallmatrix} A_1 & 0 \\ 0 & 0 \end{smallmatrix}\right)$. Similarly, if $F = \left(\begin{smallmatrix} 0 & 0 \\ 0 & F_1 \end{smallmatrix}\right)$, we have that

$$\mathrm{ad}(X)\left(t^k f\left(D+\frac{k}{2}\right)F\right) = kt^k f\left(D+\frac{k}{2}\right)F \tag{A2b}$$

and if $BC = \left(\begin{smallmatrix} 0 & B \\ t^{-1}C & 0 \end{smallmatrix}\right)$, we get

$$\mathrm{ad}(X)\left(t^k f\left(D+\frac{k-1}{2}\right)BC\right) = \left(k-\frac{1}{2}\right)t^k f\left(D+\frac{k-1}{2}\right)BC. \tag{A2c}$$

Let $\mathcal{J}$ be a nonzero ideal of $\mathcal{D}^N_{+,m}$ and let $v\in\mathcal{J}$ and $v=v^A+v^{BC}+v^F$, with v^A+v^F of the form $\left(\begin{smallmatrix}* & 0\\ 0 & *\end{smallmatrix}\right)$, and v^{BC} of the form $\left(\begin{smallmatrix}0 & *\\ * & 0\end{smallmatrix}\right)$.

By [(A2a)–(A2c)] we may assume that $v^A+v^F\in\mathcal{J}$ and $v^{BC}\in\mathcal{J}$. So, since $[I_m,v^A+v^F]\in\mathcal{J}$ we have that $v^A\in\mathcal{J}$ and similarly we can show that $v^F\in\mathcal{J}$.

We are going to show that if $v^A\in\mathcal{J}, v^A\neq 0$, then $E_{i,m+1-j}\pm E_{j,m+1-i}\in\mathcal{J}$ and $E_{i,m+1-i}\in\mathcal{J}$ with $1\leqslant i,j\leqslant m$. Analogous arguments will work finely for the remaining blocks, and the details are left to the reader. Therefore we can conclude that $\mathcal{J}=\mathcal{D}^N_{+,m}$.

Take $v^A\neq 0$ in $\mathcal{J}$. By (A2a), we may suppose $v^A=t^kA(D)=t^k\Sigma_{1\leqslant p,j\leqslant m}\,a_{pj}(D)E_{p,j}$ with A of the form $\left(\begin{smallmatrix}* & 0\\ 0 & 0\end{smallmatrix}\right)$.

Assume that $a_{i,s}(D)\neq 0$. Thus,

$$\left[\left(D-\frac{1}{2}\right)E_{i,m+1-i},t^kA(D)\right]=t^k\sum_{1\leqslant j\leqslant m}\left\{\left(D+k-\frac{1}{2}\right)a_{m+1-i,j}(D)E_{i,j}-\left(D-\frac{1}{2}\right)a_{j,i}(D)E_{j,m+1-i}\right\}. \tag{A3}$$

Now take $Y=t^{-k}(E_{r,s}-E_{m+1-s,m+1-r})\in\mathcal{D}^N_{+,m}$ with $s\neq m+1-r$, $s\neq i$ and $r\neq m+1-i$. Computing $\mathrm{ad}(Y)$ of (A3) we get

$$\begin{aligned}(D-\tfrac{1}{2})[&a_{m+1-i,m+1-s}(D-k)E_{i,m+1-r}-a_{i,s}(D)E_{r,m+1-i}\\&+a_{m+1-r,i}(D)E_{m+1-s,m+1-i}-a_{m+1-i,r}(D-k)E_{i,s}]\end{aligned} \tag{A4}$$

and again, $\mathrm{ad}((D-1/2)E_{m+1-r,r})$ $(r\neq m+1-r,\ r\neq i)$, applied to (A4), gives us

$$-(D-\tfrac{1}{2})^2[a_{m+1-i,m+1-s}(D-k)E_{i,r}+a_{s,i}(D)E_{m+1-r,m+1-i}]\in\mathcal{J} \tag{A5}$$

with $a_{s,i}(D)\neq 0$. In particular, (A5) belongs to $\mathcal{D}^N_{+,m}$, thus we have that

$$a_{m+1-i,m+1-s}(D)=-a_{s,i}(-D-k+1). \tag{A6}$$

Therefore, we may assume that $-(D-1/2)^2[f(D)E_{i,r}+f(-D-k+1)E_{m+1-r,m+1-i}]\in\mathcal{J}$ for some $f\neq 0$.

Note that $E_{pq}-E_{m+1-q,m+1-p}\in\mathcal{D}^N_{+,m}$ for any $1\leqslant p,q\leqslant m$. If we pick different values for p and q it is easy to show that

$$-(D-\tfrac{1}{2})^2[f(D)E_{p,q}+f(-D-k+1)E_{m+1-q,m+1-p}]\in\mathcal{J}, \tag{A7}$$

for arbitrary values of p and q. Note in particular, if $p=m+1-q$ we get an element on the diagonal (cf. with description of generators in Sec. IV).

Now to finish the proof, we only need to show we can lower the degree of $f(D)$ in (A7). But again, since $t(E_{ll}-E_{m+1-l,m+1-l})\in\mathcal{D}^N_{+,m}$ for $1\leqslant l\leqslant m$, and if we compute the bracket between (A7) and $t(E_{p,p}-E_{m+1-p,m+1-p})$, and the bracket between (A7) and $t(E_{q,q}-E_{m+1-q,m+1-q})$ and then the difference between them we have that

$$t((f(D+1)-f(D))E_{p,q}+(g(D)-g(D-1))E_{m+1-q,m+1-p})\in\mathcal{J}.$$

Thus we get an element in the ideal with lower degree in D, but we have increased the degree in t. Using the argument in (A4), we can again lower the degree in t. This process will eventually end, showing that $E_{p,q}\pm E_{m+1-q,m+1-p}$. □

(Received 23 October 2000; accepted for publication 30 March 2001)

We study the completeness/incompleteness properties of a system of exponentials $\mathcal{E}_\Lambda=\{e^{\pi\lambda z};\ \lambda\in\Lambda\}$, viewed as elements of the Bargmann–Fock space of entire functions. We assume that the index set Λ is a realization of a random point field in $\mathbb{C}$ (the support of a random measure). We prove that the properties are determined by the density of the field, i.e., by the mean number of the field points per unit area. We also discuss certain implications and motivations of our results, in particular, the jumps of the integrated density of states of the Landau Hamiltonian with the random potential, equal to the sum of point scatters. © *2001 American Institute of Physics.* [DOI: 10.1063/1.1379311]

I. INTRODUCTION: PROBLEM AND RESULTS

The probabilistic approach to classical questions on exponential systems gives a new insight and leads to new results combining the methods of probability theory, function theory, and also to some applications. We mention here[1,2] which study the frame property and also completeness of random exponential systems and also[3,4] devoted to expansions in random exponential systems as well as signal analysis applications.

In this paper we study completeness of the random systems of exponentials

$$\mathcal{E}_\Lambda=\{e^{\pi\lambda z};\ \lambda\in\Lambda\}, \tag{1.1}$$

in the Bargmann–Fock space $B^2(\mathbb{C})$ for the case when the index set Λ is a realization of an ergodic point field in $\mathbb{C}$ or is a random perturbation of a periodic lattice in $\mathbb{C}$. Questions of such type appear naturally in time frequency analysis and also in spectral analysis of the Schrödinger operator with random potential. We refer the reader to the end of this introduction for a more detailed survey, now we recall the basic notions and formulate the main results of the article.

We consider the Hilbert space $B^2(\mathbb{C})$ of entire functions defined by the inner product

$$\langle f,g\rangle_{B^2(\mathbb{C})}:=\int_{\mathbb{C}}\int f(z)\overline{g(z)}e^{-\pi|z|^2}\,dm_z, \tag{1.2}$$

where dm_z is the plane Lebesgue measure. We shall consider random sets Λ "uniformly" distributed through the complex plane $\mathbb{C}$. Such sets can be defined in two different ways.

Let $(\Omega,\mathcal{F},\mathbf{P})$ be a probability space and $\mu(\cdot,\omega)$ be an integer-valued random measure in $\mathbb{C}$, i.e., for each Borel set $\Delta\subset\mathbb{C}$, $\mu(\Delta,\cdot)$ is a random variable and also, for $\omega\in\Omega$, $\mu(\cdot,\omega)$ is a locally bounded integer-valued Borel measure.

[a)]On leave from Department of Mathematics, University Paris 7, France; electronic mail: pastur@cpt.univ-mrs.fr

To each $\omega\in\Omega$ one may associate the support of $\mu(\cdot,\omega)$, i.e., a discrete set

$$\Lambda_\omega=\{\lambda\in\mathbb{C};\ \mu(\{\lambda\},\omega)>0\},\tag{1.3}$$

such that

$$\mu(\cdot,\omega)=\sum_{\lambda\in\Lambda_\omega}\mu(\{\lambda\},\omega)\,\delta_\lambda(\cdot),\tag{1.4}$$

where δ_λ is the unit measure located at the point λ. In what follows we assume for simplicity that $\mu(\{\lambda\},\omega)=1$ for all $\lambda\in\Lambda_\omega$ with probability 1.

For $g=(m,n)\in\mathbb{Z}^2$ we denote $Q_g=\{x+iy;\ x\in[m,m+1),\ y\in[n,n+1)\}$, and $\mu_g(\omega)=\mu(Q_g,\omega)$. Let **E** and **Var** stand for mathematical expectation and variance in $(\Omega,\mathcal{F},\mathbf{P})$ respectively.

In Sec. III we assume that the family of random variables $\{\mu_g(\omega);\ g\in\mathbb{Z}^2\}$ is a point process in $\mathbb{R}^2$ homogeneous with respect to the group of motions generated by rotations by $\pm\pi/2$ around the origin and translations by integers along the coordinate axis (see, e.g., Ref. 5, Ch. 10, and Ref. 6, p. 17). In particular all random variables μ_g are identically distributed, and we assume that there exists the mathematical expectation

$$\mathbf{E}\mu_g=C<\infty.\tag{1.5}$$

C is called the *density* of the random field $\{\mu_g\}_{g\in\mathbb{Z}^2}$. We also assume that the random field $\{\mu_g\}_{g\in\mathbb{Z}^2}$ satisfies the following decay and mixture conditions:

(**a**) For some $\delta>0$

$$\mathbb{E}\,\mu_{(0,0)}^{2+\delta}<+\infty.\tag{1.6}$$

(**b**) There exist δ, satisfying (1.6), and a positive nondecreasing and slow varying function $h(x)$, $x\geqslant 0$, satisfying the conditions

$$h(0)=1,\quad \sum_{n=1}^{\infty}\frac{1}{n(h(n))^{1/(6+2\delta)}}<\infty,\tag{1.7}$$

and such that

$$\sup_{n\to\infty}\frac{h(n)}{n^{1+\delta}}\mathbf{E}\left|\sum_{j=1}^{n}(\mu_{(j,0)}-C)\right|^{2+\delta}<\infty.\tag{1.8}$$

Recall that a function $h:\mathbb{R}\to\mathbb{R}_+$ is called *slow varying* if, for each $t>0$, $\lim_{x\to\infty}h(tx)/h(x)=1$,

The condition (**b**) looks somewhat cumbersome. Nevertheless it is in fact a mixture condition and seems to be reflecting the general case. This fact is discussed in more details in Sec. V, where we show that the Poisson and generalized Poisson counting measures in $\mathbb{C}$ (see, e.g., Ref. 5, Ch. 10 and Ref. 6, pp. 27–29) having finite moment of order $2+\delta$, measures satisfying ϕ-mixture condition (see definition in Sec. V), as well as measures generated by random independent perturbations of points of a square lattice (see Sec. IV), satisfy this condition.

In Sec. III we prove

Theorem 1.1: *Let Λ_ω be the support of the random measure (1.4) satisfying conditions (1.5)–(1.8). Then the system (1.1) with $\Lambda=\Lambda_\omega$ is complete with probability 1 if $C>1$ and is incomplete with probability 1 if $C<1$.*

Another version of the problem is when the random set Λ_ω is a random perturbation of a lattice in $\mathbb{C}$, i.e., when Λ_ω is of the form

$$\Lambda_\omega=\{\lambda_g(\omega)=ma+ina+\xi_g(\omega);\ g\in\mathbb{Z}^2\},\tag{1.9}$$

where $\{\xi_g; g\in\mathbb{Z}^2\}$ are independent complex-valued centered random variables on a probability space $(\Omega,\mathcal{F},\mathbf{P})$ and $a>0$ is the lattice parameter. Even in the case when all $\{\xi_g; g\in\mathbb{Z}^2\}$ are identically distributed one encounters difficulties when checking condition (**b**) for the corresponding random field (see Theorem 4.1 below). For nonidentically distributed ξ_g's the random point field [i.e., respective measure, defined as in (1.4)] is no longer homogeneous (with respect to the group $\mathbb{Z}^2$). That is why we will consider this case separately.

Theorem 1.2: *Let $\{\xi_g(\omega); g\in\mathbb{Z}\}$ be independent and continuously distributed complex random variables. Assume that $\mathbf{E}\xi_g=0, \forall g\in\mathbb{Z}$ and that for some $\delta>0$*

$$\sup_{g\in\mathbb{Z}^2}\mathbf{E}\,|\xi_g|^{2+\delta}=K<\infty \tag{1.10}$$

[cf. (1.6)]. Then the system (1.1) with $\Lambda=\Lambda_\omega$ and Λ_ω given by (1.9) is complete with probability 1 if $a<1$, and is incomplete with probability 1 if $a>1$.

Remarks: (1) The restriction that all $\xi_g(\omega)$ are continuously distributed may be weakened. We need this condition just to guarantee that with probability 1 the points from Λ_ω are pair-wise different;

(2) this theorem generalizes the well known result for the periodic lattice ($\xi_g=0,\forall g\in\mathbb{Z}^2$), dating back to von Neumann (see Refs. 7 and 8).

As in the classical case (see, e.g., Ref. 9) the completeness theorems for sets of exponential functions can be reduced to constructing and then estimating of entire functions whose zero set is the set of exponents. In the case of the Bargmann–Fock space (1.2) this approach is based on the relation

$$\langle f(\cdot), e^{\pi\bar{\lambda}\cdot}\rangle_{B^2(\mathbb{C})}=f(\lambda), \tag{1.11}$$

valid for each function $f\in B^2(\mathbb{C})$ and $\lambda\in\mathbb{C}$, see, e.g., Ref. 10 (note that unlike[10] we use the inner product (1.2) in which the second factor is complex conjugate). Study of entire functions with randomly located zeros is the main technical content of this article. We believe it has its own intrinsic interest.

Completeness of the exponential system (1.1) in the Bargmann–Fock space $B^2(\mathbb{C})$ defined by (1.2) is equivalent to completeness in $L^2(\mathbb{R})$ of the Gabor system of windowed exponentials

$$\mathcal{G}_\Lambda=\{e_{i\sqrt{2\pi}\lambda}(t);\lambda\in\Lambda\}, \tag{1.12}$$

where, for $\zeta=\mu+i\nu\in\mathbb{C}$

$$e_\zeta(t)=e^{i\mu t-(t-\nu)^2/2},\quad t\in\mathbb{R} \tag{1.13}$$

[see formula (1.17) below]. Since the classic work[7] these systems became a standard tool for time-frequency analysis of nonbandlimited signals. In fact, it was von Neumann who first studied the Gabor systems corresponding to lattices with parameter $a>0$, i.e., to the sets

$$L_a=\{ma+ina;(m,n)\in\mathbb{Z}^2\} \tag{1.14}$$

(see Refs. 7 and 8 for a history survey as well as for various developments and applications). It was proved that such a system is infinitely redundant (overcomplete) in $L^2(\mathbb{R})$ for $a<1$ and is incomplete and has an infinite deficiency if $a>1$. The frame property of $\mathcal{G}_\Lambda$ with Λ given by (1.14) has been considered in Refs. 10–13. The results of Refs. 11 and 13 yield in particular that $\mathcal{G}_{L_a}$ constitute a frame in $L^2(\mathbb{R})$ for all $a<1$. Using the approach from Ref. 1 one can find that the frame property is lost for (generic) random perturbations of the lattice. Below we prove that the completeness–incompleteness property is more robust and survives after random perturbations of the lattice. We refer also to Refs. 14 and 15 where similar question of completeness–incompleteness of (deterministic) exponential systems have been considered.

Systems (1.1) of exponential functions and the Gabor systems (1.12) are connected by the inverse Bargmann transform see, e.g., Ref. 10

$$\mathcal{B}^{-1}: f \mapsto (\mathcal{B}^{-1} f)(t) = -\frac{1}{\pi^{1/4}} \int \int_{\mathbb{C}} f(z) e^{\sqrt{2\pi} t\bar{z} - \pi \bar{z}^2/2 - t^2/2} e^{-\pi |z|^2} dm_z. \tag{1.15}$$

The Bargmann transform itself is defined as

$$\mathcal{B}: \varphi \mapsto (\mathcal{B}\varphi)(z) = \frac{1}{\pi^{1/4}} \int_{\mathbb{R}} \varphi(t) e^{\sqrt{2\pi} tz - \pi z^2/2 - t^2/2} dt. \tag{1.16}$$

It is known (see, e.g., Ref. 10) that $\mathcal{B}^{-1}$ is a unitary mapping between $B^2(\mathbb{C})$ and $L^2(\mathbb{R})$, and for $\lambda = \mu + i\nu \in \mathbb{C}$

$$(\mathcal{B}^{-1} e^{\pi \bar{\lambda} \cdot})(t) = \frac{1}{\pi^{1/4}} e^{i\pi\mu\nu + \pi|\lambda|^2/2} e_{i\sqrt{2\pi}\lambda}(t). \tag{1.17}$$

Relations (1.11), and (1.15)–(1.17) allow one to interpret the previous theorems on the completeness properties of random exponential systems $\mathcal{E}_\omega = \{e^{\pi\lambda z}; \lambda \in \Lambda_\omega\}$, as those on the completeness of random Gabor systems $\mathcal{G}_\omega = \{e_{i\sqrt{2\pi}\lambda}; \lambda \in \Lambda_\omega\}$. Indeed, relation (1.11) identifies the functions $f \in B^2(\mathbb{C})$ annihilating $\mathcal{E}_\omega$ as just the functions vanishing on Λ_ω, while $\mathcal{B}^{-1}$ of (1.15) transforms statements about completeness–incompleteness of $\mathcal{E}_\omega$ into those about $\mathcal{G}_\omega$.

Let $C^\sharp$ denote the density C of the random measure (1.4) or the inverse a^{-2} of the area a^2 of the elementary square of the lattice (1.14). Then we can reformulate our results above as follows.

Theorem 1.3: *Under assumptions of Theorems 1.1 and 1.2 the random Gabor system* $\mathcal{G}_\omega$ *given by (1.12) with* Λ_ω *from (1.3) or from (1.9) is complete with probability 1 in* $L^2(\mathbb{R})$ *if* $C^\sharp > 1$ *and is incomplete if* $C^\sharp < 1$.

Another motivation (application) of the problem studied in this paper is related to the spectral analysis of the Schrödinger operator H with a constant magnetic field and with a random potential V, and to respective branches of the solid-state theory. This operator acts in $L^2(\mathbb{R}^2)$ and one of important problems is to find criteria for the presence of jumps of the integrated density of states (IDS) of the operator at energies equal the Landau levels. The Landau levels comprise the spectrum of the Landau Hamiltonian H_0, the Schrödinger operator with a constant magnetic field and zero potential. The levels are of the form $E_n = n + 1/2$, $n = 0, 1, \ldots$ and all have infinite multiplicity. The IDS of the Landau Hamiltonian is the piece-wise constant function having equal jumps at all E_n. Presence of jumps of the IDS of the Schrödinger operator $H = H_0 + V$ with a constant magnetic field and an electric field given by the potential V depends on the nature of the electric field and on its relative strength with respect to the magnetic field (see Ref. 6 for a general definition of the IDS of random differential operators and Refs. 16–20 for this property of the IDS and its use in solid state theory and in spectral theory).

In the case when the magnetic field is strong enough it is widely accepted that one can replace the Schrödinger operator H acting in $L^2(\mathbb{R}^2)$ by its projection on the eigenspace of the Landau level, that is most close to the energy interval considered. In the case when it is the lowest Landau level E_0 the corresponding eigenfunctions are

$$\psi_m(w) = (2^{m+1}\pi m!)^{-1/2} w^m \exp\{-|w|^2/4\}, \quad m = 0,1,\ldots, w \in \mathbb{C},$$

(see, e.g., Ref. 16), and the orthogonal projection P_0 onto the respective eigenspace $\mathcal{L}_0$ is an integral operator with the kernel

$$P_0(w,\zeta) = (2\pi)^{-1} \exp\{-|w|^2/4 - |\zeta|^2/4 + w\bar{\zeta}/2\}. \tag{1.18}$$

As a result the projection of H onto $\mathcal{L}_0$ has the form $P_0 H P_0 = E_0 P_0 + K$, where the operator K is defined by the kernel

$$K(w_1,w_2)=\int_{\mathbb{R}^2} P_0(w_1,x+iy)V(x,y)P_0(x+iy,w_2)dxdy. \tag{1.19}$$

In the case where V is the sum of contributions of the single site impurity potentials of zero radius, whose positions are $z_j=x_j+y_j, j=1, 2, \ldots$ the operator K becomes

$$K(w_1,w_2)=\sum_{j\geqslant 1} P_0(w_1,z_j)\overline{P_0(w_2,z_j)}. \tag{1.20}$$

Thus, the range of the nontrivial part of the projection P_0HP_0 is the span in $B^2(\mathbb{C})$ of the exponential system indexed by the set $\{z_j\}_{j\geqslant 1}$, and after changing the scale in $\mathbb{C}$ we obtain the system (1.1), where Λ is the set of the coordinates of impurities in this scale. We conclude that in this case the jump in the IDS is present if the system (1.1) is strongly incomplete. More precisely, for Λ_ω given by (1.3) or (1.9) denote

$$\Lambda_\omega(t)=\{\lambda\in\Lambda_\omega;\ |\lambda|<t\},\quad \mathcal{E}_{\omega,t}=\{\exp\{\pi\lambda z\};\ \lambda\in\Lambda_\omega(t)\},\quad X_{\omega,t}=\operatorname{Span}\mathcal{E}_{\omega,t}. \tag{1.21}$$

Set $\nu(t,\omega)=\#\Lambda_\omega(t)$. Then for almost all $\omega\,\nu(t,\omega)<\infty$ for any $t>0$, the system $\mathcal{E}_{\omega,t}$ consists of linearly independent functions, and $\dim X_{\omega,t}=\nu(t,\omega)$. Denote by $P_{\omega,t}$ the orthogonal projection onto $X_{\omega,t}$. Then $\operatorname{Tr}P_{\omega,t}=\dim X_{\omega,t}=\nu(t,\omega)$ and by ergodic theorem

$$\lim_{t\to\infty}\frac{1}{\pi t^2}\operatorname{Tr}P_{\omega,t}=\lim_{t\to\infty}\frac{\nu(t,\omega)}{\pi t^2}=C^\sharp, \tag{1.22}$$

where $C^\sharp=C$ in the case of (1.3) and $C^\sharp=a^{-2}$ in the case of (1.9).

According to Ref. 6 the quantity

$$1-\lim_{t\to\infty}\frac{1}{\pi t^2}\operatorname{Tr}P_{\omega,t},$$

can be interpreted as the jump of the IDS of the projection P_0HP_0 of the Schrödinger operator on the lowest Landau level, i.e., the relative number (per unit area) of those states of the Landau level that are not affected by the random potential. Then the right-hand side of (1.22) tells us that the jump is equal to $1-C^\sharp$, if $C^\sharp<1$. This conclusion is in agreement with the exactly solvable case of the Poisson random measure (1.4)[21] (see also Ref. 18). It was found that in this case the jump is equal to $(1-C)_+$, where $x_+=\max\{x,0\}$. An analogous spectral phenomenon has been known for the long time in the random matrix theory.[22] All these phenomena have the same geometric origin: Nonzero ''relative'' dimension of the null space of respective operator because of homogeneity of the distribution of random points.

All formulas above are written in the dimensionless units. Let us pass for a moment to the dimension-ful units. Then the set Λ_ω induces the length scale L which equals either the reciprocal square root of the (dimension-ful) concentration of points of (1.3) or the lattice parameter a of (1.9). Denote B the magnetic field and $\Phi=BL^2$ the magnetic flux through a piece of the plane of linear size L. Then our criterion implies that the macroscopic number of states of the lowest Landau level unaffected by impurities exists if $\Phi/\Phi_0>1$, where $\Phi_0=hc/e$ is the flux quantum.

For the relation of these questions to the interpretation of the integer Hall effect, see Ref. 16. A similar results for nonrandom sets Λ that are certain perturbations of the periodic lattice were obtained in Ref. 23.

It can be seen from the proof of Theorems 1.1 and 1.2 as well as from arguments of papers[18,23] that the mathematical mechanism of existence of a finite fraction of the Landau states unaffected by the point impurities located at points of a set Λ is that these eigenfunctions have zeros at all points of this set. A similar but simpler phenomenon is known in the case of the one-dimensional Schrödinger operator with the point scatterers (see, e.g., Ref. 20, Sec. 10.3). Since, however, in

this case the spectrum is of multiplicity 1, the only effect that this mechanism produces is coincidence of the asymptotic form of the IDS and of the Lyapunov exponent at the band edges with those of the periodic potential (in particular, the absence of the Lifshitz tails). On the other hand, in the two-dimensional case, according to arguments of Ref. 23, the fraction of states unaffected by the potential consists of delocalized states.

The quantity $C^\sharp$ can be viewed as the relative (per unit area) dimension of the system $\mathcal{E}_\omega$ given by (1.1) with $\Lambda=\Lambda_\omega$ and Λ_ω from (1.3) or from (1.9) or of $\mathcal{G}_\omega$ given by (1.12) with the same Λ_ω. This interpretation allows us to view $|1-C^\sharp|$ as a quantitative characteristic of incompleteness (the relative defect) of systems $\mathcal{E}_\omega$ and $\mathcal{G}_\omega$ in the case when $C^\sharp<1$ and of overcompleteness (the relative redundancy) in the case when $C^\sharp>1$. Indeed, if $\mathcal{E}_\omega$ (or $\mathcal{G}_\omega$) is complete and $C^\sharp>1$, then for any $C_1^\sharp$ such that $1<C_1^\sharp<C^\sharp$ the respective $\mathcal{E}_\omega$ (or $\mathcal{G}_\omega$) is also complete (overcomplete). An analogous statement is valid for $C^\sharp<1$. Thus $C^\sharp$ is also a quantitative characteristic of stability of completeness (overcompleteness) and incompleteness of the random system $\mathcal{E}_\omega$ (or $\mathcal{G}_\omega$), in agreement with the respective results for the case (1.14).[8]

The article is organized as follows. Section II contains some preliminary facts from the probability theory and the function theory. In Sec. III we prove Theorem 1.1 by considering separately the cases when the density of the random field is above and below the threshold $C=1$. In Sec. IV we consider the case (1.9) when the random field is generated by random perturbations of a lattice. In the last Sec. V we discuss various mixing conditions for random fields and compare them with restrictions imposed in this article.

II. AUXILIARY FACTS

In what follows we need to estimate the number of points from Λ_ω of (1.3) in special domains in $\mathbb{C}$. Denote

$$S(t;\theta_1,\theta_2)=\{z;\,|z|<t,\ \theta_1\leqslant\arg z<\theta_2\},\quad (t>0,\,0\leqslant\theta_1<\theta_2\leqslant 2\pi)$$

and

$$N(t;\theta_1,\theta_2)=\#\{Q_g\subset S(t;\theta_1,\theta_2)\}.$$

We have evidently

$$N(t;\theta_1,\theta_2)=\tfrac{1}{2}(\theta_2-\theta_1)t^2+O(t),\quad t\to\infty. \tag{2.1}$$

Given a discrete set $\Lambda\subset\mathbb{C}$ we denote

$$\nu(t,\theta_1,\theta_2;\Lambda)=\#\{\Lambda\cap S(t;\theta_1,\theta_2)\}$$

and

$$\tilde{\nu}(t,\theta_1,\theta_2;\Lambda)=\#\{\Lambda\cap(\cup_{Q_g\subset S(t;\theta_1,\theta_2)}Q_g)\}.$$

Lemma 2.1: Let (1.5)–(1.8) be fulfilled. Then, for each pair (θ_1,θ_2), $0\leqslant\theta_1<\theta_2\leqslant 2\pi$, *we have with probability 1*

$$\lim_{t\to\infty}\frac{1}{N(t;\theta_1,\theta_2)}\tilde{\nu}(t,\theta_1,\theta_2;\Lambda_\omega)=C. \tag{2.2}$$

Proof: It suffices to prove (2.2) only for $t=k$, $k\in\mathbb{N}$. Denote

$$X_k=\tilde{\nu}(k,\theta_1,\theta_2;\Lambda_\omega)/N(k;\theta_1,\theta_2).$$

Consider the random variables

$$Y_m(\omega)=\mu(S(k;\theta_1,\theta_2)\cap\cup_{l\in\mathbb{Z}}Q_{(l,m)},\omega),\quad m\in\mathbb{Z}.$$

We have

$$\tilde{\nu}(k,\theta_1,\theta_2;\Lambda_\omega)=\sum_{m=-k}^{k}Y_m,$$

Since $h(k)$ is a slowly varying function, $f(k):=k^{1+\delta}/h(k)$ is a nondecreasing function for $k\geqslant k_0$, for some $k_0>0$. Conditions (1.5)–(1.8) now yield

$$\mathbf{E}\,|Y_m-\mathbf{E}\,Y_m|^{2+\delta}\leqslant \text{const}\,k^{1+\delta}/h(k),\quad |m|\leqslant k, \tag{2.3}$$

where const does not depend on k. Therefore, for any $\varepsilon>0$

$$\sum_{k=1}^{\infty}\mathbf{P}\,(|X_k-C|>\varepsilon)<\infty. \tag{2.4}$$

Indeed, combining the Chebyshev and Minkowski inequalities (see, e.g., Ref. 24, pp. 190 and 192) with (2.3) we obtain

$$\begin{aligned}(\mathbf{P}(|X_k-C|>\varepsilon))^{1/(2+\delta)}&\leqslant\frac{\text{const}}{\varepsilon k^2}\left(\mathbf{E}\left|\sum_{m=-k}^{k}(Y_m-\mathbf{E}\,Y_m)\right|^{2+\delta}\right)^{1/(2+\delta)}\\&\leqslant\frac{\text{const}}{\varepsilon k^2}\sum_{m=-k}^{k}(\mathbf{E}\,|Y_m-\mathbf{E}\,Y_m|^{2+\delta})^{1/(2+\delta)}\\&\leqslant\frac{\text{const}}{\varepsilon k}\left(\frac{k^{1+\delta}}{h(k)}\right)^{1/(2+\delta)},\end{aligned}$$

so that

$$\mathbf{P}\,(|X_k-C|>\varepsilon)\leqslant\frac{\text{const}}{\varepsilon^{2+\delta}kh(k)},\quad k\in\mathbb{N}.$$

Now (2.4) follows from (1.7) and by the Borel-Cantelli lemma (see, e.g., Ref. 24, p. 254) we obtain that with probability 1 $X_k\to C$ as $k\to\infty$. ■

Remark: In the general case of an ergodic point field the lemma follows directly from the respective ergodic theorem (see, e.g., Ref. 25, Corollary 6.4.2). We give above a proof based on conditions (1.6)–(1.8), because in this case we need not to assume ergodicity.

We also need the following statements from the complex analysis. For $t>0$ we denote $\mathbb{D}_t=\{z\in\mathbb{C};|z|\leqslant t\}$.

Proposition 2.2: (Jensen formula, see, e.g., Ref. 9, p. 14) Let $R_0>0$ and let the function $f(z)$ be holomorphic in $\mathbb{D}_{R_0}$ with $f(0)\neq 0$. Then, for any $R<R_0$, we have

$$\int_0^R\frac{\nu_f(t)}{t}dt=\frac{1}{2\pi}\int_0^{2\pi}\log|f(\mathrm{Re}^{i\theta})|\,d\theta-\log|f(0)|, \tag{2.5}$$

where $\nu_f(t)$ is the number of zeros of $f(z)$ in $\mathbb{D}_t$.

This assertion is used in order to compare the growth of the entire function, whose zero set coincides with the set Λ_ω.

In order to study entire functions with a given zero set we need additional notation. Given a discrete set $\Lambda\subset\mathbb{C}$ we consider its counting functions for disks and sectors:

$$\nu(t)=\#\{\lambda\in\Lambda;\,|\lambda|<t\},\quad \nu(t,\theta,\vartheta)=\#\{\lambda\in\Lambda;\,|\lambda|<t,\,\theta<\arg\lambda<\vartheta\},\tag{2.6}$$

where $t>0$ and $0\leqslant\theta<\vartheta<2\pi$.

Proposition 2.3: Let C be a positive constant and Λ be a point set in $\mathbb{C}$. Assume that for each pair (θ,ϑ), $0\leqslant\theta<\vartheta<2\pi$, there exist the limits

$$\lim_{t\to\infty}\frac{\nu(t,\theta,\vartheta)}{t^2}=C\frac{\vartheta-\theta}{2},\tag{2.7}$$

and

$$\lim_{t\to\infty}\sum_{\lambda\in\Lambda\cap\mathbb{D}_t}\frac{1}{\lambda^2}=:\tau_\Lambda\exp\{i\theta_\Lambda\},\quad \tau_\Lambda>0,\ \theta_\Lambda\in(0,2\pi).\tag{2.8}$$

Then the infinite product

$$f(z)=\prod_{\lambda\in\Lambda}(1-z/\lambda)\exp\{z/\lambda+z^2/2\lambda^2\}$$

converges uniformly on each compact set in $\mathbb{C}$ and

$$r^{-2}\log|f(re^{i\theta})|=\frac{\pi}{2}C+\tau_\Lambda\cos 2(\theta-\theta_\Lambda)+\mathrm{O}(1),\quad r\to\infty$$

for all $z=r\exp\{i\theta\}$ outside of a union of disks of radius ε centered at the points $\lambda\in\Lambda$.

This assertion is a special case of Theorem 2,[9] Ch. 2 for $\rho\equiv 2$ and constant angular density. Existence of the limit (2.8) is a manifestation of a certain isotropy in the distribution of zeros of the entire function f.

III. PROOF OF THEOREM 1.1

We first consider the case when the density is above the threshold $C=1$.

Theorem 3.1: *Assume that conditions of Theorem 1.1 are fulfilled and $C>1$. Then the system $\mathcal{E}_\omega$ defined by (1.1) with $\Lambda=\Lambda_\omega$ is complete in $B^2(\mathbb{C})$ with probability 1.*

Proof: Let Ω' be the set of those Λ_ω for which the limiting relation (2.2) is valid. According to Lemma 2.1 $P(\Omega')=1$. We will prove that the system $\mathcal{E}_\omega$ is complete for all $\omega\in\Omega'$. Assume that the opposite is true. Then, according to (1.11) there exists a nonzero function $g\in B^2(\mathbb{C})$, having Λ_ω as its zero set. Since $f(z)=\overline{g(\overline{z})}\in B^2(\mathbb{C})$ if and only if $g\in B^2(\mathbb{C})$, here and below we ignore transition to conjugate exponents $\overline{\lambda}$, $\lambda\in\Lambda_\omega$.

Assume for simplicity that $0\notin\Lambda_\omega$. Denote $\nu(\tau;\omega)=\nu(0,2\pi,\tau;\omega)$. The Jensen formula (2.5) yields

$$\int_0^t\frac{\nu(\tau,\omega)}{\tau}\,d\tau=\frac{1}{2\pi}\int_0^{2\pi}\log|f(te^{i\theta},\omega)|\,d\theta+\mathrm{O}(1),\quad t\to\infty.\tag{3.1}$$

Combining (2.1) and (2.2) we see that with probability 1

$$\liminf_{t\to\infty}\frac{1}{t^2}\int_0^t\frac{\nu(\tau,\omega)}{\tau}\,d\tau\geqslant C'\pi/2$$

for some $C'>1$. On the other hand the Cauchy inequality yields that, for each $\varepsilon>0$

$$f(z,\omega)\in B^2(\mathbb{C})\Rightarrow|f(z,\omega)|\leqslant\mathrm{const}\exp\{(\pi+\varepsilon)|z|^2/2\},\quad z\in\mathbb{C}.$$

Therefore

$$\limsup_{t\to\infty}\frac{1}{2\pi t^2}\int_0^{2\pi}\log|f(te^{i\theta},\omega)|\,d\theta\leqslant(\pi+\varepsilon)/2 \quad \text{for} \quad \omega\in\Omega'.$$

Fix ε such that $\pi C'>\pi+\varepsilon$. Dividing the both sides of (3.1) by t^2 and passing to the limit as $t\to\infty$, we get a contradiction. ■

Now the case of density below the threshold.

Theorem 3.2: *Assume that the conditions of Theorem 1.1 are fulfilled and $C<1$. Then the system $\mathcal{E}_\omega$ defined by* (1.1) *with $\Lambda=\Lambda_\omega$ is incomplete in $B^2(\mathbb{C})$ with probability 1.*

Proof: We need to construct, for almost all $\omega\in\Omega$, a nonzero function $f_\omega\in B^2(\mathbb{C})$ vanishing on Λ_ω. The construction consists of several steps.

First we will check that the hypothesis of Proposition 2.3 is fulfilled. Indeed, by Lemma 2.1 we have, with probability 1

$$\exists\lim_{t\to\infty}\frac{1}{t^2}\mu(S(t;\theta_1,\theta_2),\omega)=C\frac{\theta_2-\theta_1}{2},$$

for any $0\leqslant\theta_1<\theta_2\leqslant2\pi$. Take a sequence $\{\theta_j\}$ which is dense in $[0,2\pi]$. Then, for almost all $\omega\in\Omega$

$$\exists\lim_{t\to\infty}\frac{\nu(t,\theta_l,\theta_j;\Lambda_\omega)}{t^2}=C\frac{\theta_j-\theta_l}{2} \quad \text{for} \quad \theta_l<\theta_j,$$

which implies that, for almost all $\omega\in\Omega$, the similar relation

$$\exists\lim_{t\to\infty}\frac{\nu(t,\vartheta,\vartheta';\Lambda_\omega)}{t^2}=C\frac{\vartheta'-\vartheta}{2}, \tag{3.2}$$

holds for arbitrary $\vartheta,\vartheta'\in[0,2\pi]$, $\vartheta'>\vartheta$. Indeed,

$$\limsup_{t\to\infty}\frac{\nu(t,\vartheta,\vartheta';\Lambda_\omega)}{t^2}\leqslant\inf_{\theta_l<\vartheta,\ \vartheta'<\theta_j}\lim_{t\to\infty}\frac{\nu(t,\theta_l,\theta_j;\Lambda_\omega)}{t^2}=C\frac{\vartheta'-\vartheta}{2}$$

and

$$\liminf_{t\to\infty}\frac{\nu(t,\vartheta,\vartheta';\Lambda_\omega)}{t^2}\geqslant\sup_{\vartheta<\theta_l,\ \theta_j<\vartheta'}\lim_{t\to\infty}\frac{\nu(t,\theta_l,\theta_j;\Lambda_\omega)}{t^2}=C\frac{\vartheta'-\vartheta}{2}$$

which yields (2.7).

Now denote $\hat{\mathbb{D}}_t=\cup_{Q_g\subset\mathbb{D}_t}Q_g$. We need the following:

Lemma 3.3: Under the conditions of Theorem 1.1 the limit

$$\delta_\omega=\lim_{t\to\infty}\sum_{\lambda\in\Lambda_\omega\cap\hat{\mathbb{D}}_t}\frac{1}{\lambda^2}, \tag{3.3}$$

exists with probability 1.

We mention that relation (3.3) is slightly different from the corresponding statement (2.8) in the hypothesis of Proposition 2.3, in which all points in the disk $\mathbb{D}_t$ (not only those in $\hat{\mathbb{D}}_t$) are taken into account. It is readily seen that the transition from $\mathbb{D}_t$ to $\hat{\mathbb{D}}_t$ does not alter the statement of Proposition 2.3.

Suppose this lemma be already proved. Then, by Proposition 2.3, the product

$$\Pi_\omega(z)=\prod_{\lambda\in\Lambda_\omega}(1-z/\lambda)\exp\left\{\frac{z}{\lambda}+\frac{z^2}{2\lambda^2}\right\},$$

is compact-wise convergent and, for any $\varepsilon>0$, the function

$$f_\omega(z)=\exp\{-\delta_\omega z^2\}\Pi_\omega(z),$$

satisfies with probability 1

$$|f_\omega(z)|\leqslant\exp\left\{\left(\frac{\pi}{2}C+\varepsilon\right)|z|^2\right\}.$$

for sufficiently large $|z|$. Hence, for almost all $\omega\in\Omega$, f_ω belongs to $B^2(\mathbb{C})$.

Clearly $f_\omega(\lambda)=0$ for $\lambda\in\Lambda_\omega$ so that we obtain at least one such function. This proves Theorem 3.2.

Proof of Lemma 3.3: We need an auxiliary fact. For each $n\in\mathbb{Z}$, set

$$h_1(|n|)=(h(|n|))^{1/(6+2\delta)}\quad\text{and}\quad N_n=[|n|/h_1(|n|)]. \tag{3.4}$$

Consider rectangular strips of two kinds:

$$H_{m,s}=\bigcup_{(m-1)N_s\leqslant l<mN_s}Q_{l,s}\quad\text{and}\quad V_{m,s}=\bigcup_{(m-1)N_s\leqslant l<mN_s}Q_{s,l},\quad m,s\in\mathbb{Z}. \tag{3.5}$$

We need those $H_{m,s}$ and $V_{m,s}$ that belong to the sectors

$$D_1:=\{z;\pi/4\leqslant\arg z\leqslant 3\pi/4\}\cup\{z;5\pi/4\leqslant\arg z\leqslant 7\pi/4\} \tag{3.6}$$

and

$$D_2:=\{z;-\pi/4\leqslant\arg z\leqslant\pi/4\}\cup\{z;3\pi/4\leqslant\arg z\leqslant 5\pi/4\}, \tag{3.7}$$

respectively.

The estimate below follows from (1.8).

$$\mathbf{E}\left|\sum_{l=0}^{N_s-1}(\mu_{(l,0)}(\omega)-C)\right|^{2+\delta}\leqslant\text{const}\,(|s|+1)^{1+\delta}/h(|s|),\quad s\in\mathbb{Z}. \tag{3.8}$$

Indeed, for $|s|\geqslant s_0>0$

$$\left(\mathbf{E}\left|\sum_{l=0}^{N_s-1}(\mu_{(l,0)}(\omega)-C)\right|^{2+\delta}\right)^{1/(2+\delta)}\leqslant\left(\mathbf{E}\left|\sum_{l=0}^{|s|}(\mu_{(l,0)}(\omega)-C)\right|^{2+\delta}\right)^{1/(2+\delta)}$$
$$+\left(\mathbf{E}\left|\sum_{l=N_s}^{|s|}(\mu_{(l,0)}(\omega)-C)\right|^{2+\delta}\right)^{1/(2+\delta)}:=\Sigma_1+\Sigma_2.$$

According to (1.8) we have $\Sigma_1\leqslant\text{const}(|s|^{1+\delta}/h(|s|))^{1/(2+\delta)}$. In addition, taking into account that $h(n)$ is a slowly varying function we obtain

$$\Sigma_2=\left(\mathbf{E}\left|\sum_{l=0}^{|s|-N_s}(\mu_{(l,0)}(\omega)-C)\right|^{2+\delta}\right)^{1/(2+\delta)}\leqslant\text{const}\left(\frac{|s|^{1+\delta}}{h(|s|-N_s)}\right)^{1/(2+\delta)}\leqslant\text{const}\left(\frac{|s|^{1+\delta}}{h(|s|)}\right)^{1/(2+\delta)}.$$

We deduce (3.8) from the two last estimates.

For each $m,s\in\mathbb{Z}$ the left-hand side of (3.8) coincides with

$$\mathbf{E}\,|\mu(H_{m,s},\omega)-CN_s|^{2+\delta}. \tag{3.9}$$

The corresponding random variables $\mu(H_{m,s},\omega)$ and $\mu(V_{m,s},\omega)$ satisfy the inequality given by the following:

Lemma 3.4: For all but maybe a finite number of sets $H_{m,s}\subseteq D_1$ defined by (3.5)–(3.7) the inequality

$$|\mu(H_{m,s},\omega)-CN_s|\leqslant(|s|+1)/h_1^2(|s|),$$

holds with probability 1. A similar relation holds for $\mu(V_{m,s},\omega)$, where $V_{m,s}\subseteq D_2$ is defined in (3.5)–(3.7).

Proof: Let $B_{m,s}=\{\omega;|\mu(H_{m,s},\omega)-CN_s|>(|s|+1)/h_1^2(|s|)\}$. The Chebyshev inequality yields

$$\mathbf{P}\,(B_{m,s})\leqslant\frac{h_1^{4+2\delta}(|s|)}{(|s|+1)^{2+\delta}}\mathbf{E}\,|\mu(H_{m,s},\omega)-\mathbf{E}\,\mu(H_{m,s},\omega)|^{2+\delta}. \tag{3.10}$$

Applying (3.8) to the right-hand side of this inequality we obtain

$$\mathbf{P}\,(B_{m,s})\leqslant\text{const}\frac{h_1(|s|)^{4+2\delta}}{(|s|+1)h(|s|)},\quad B_{m,s}\subseteq D_1. \tag{3.11}$$

Since, for each fixed s, the number of the rectangles $H_{m,s}$ under consideration does not exceed $2h_1(|s|)$, we obtain, using (3.11) and (1.7)

$$\sum_{B_{m,s}\subseteq D_1}\mathbf{P}\,(B_{m,s})\leqslant\sum_{s=-\infty}^{\infty}\sum_{|m|\leqslant 2h_1(|s|)}\mathbf{P}\,(B_{m,s})\leqslant\sum_{s=-\infty}^{\infty}\frac{\text{const}}{(|s|+1)(h(|s|))^{1/(6+2\delta)}}<\infty. \tag{3.12}$$

Now the Borel–Cantelli lemma applied to the events $B_{m,s}$ yields the statement of Lemma 3.4 for the random variables $\mu(H_{m,s},\omega)$. The random variables $\mu(V_{m,s},\omega)$ are considered in a similar way. ∎

Now we continue the proof of Lemma 3.3. Denote $K_n=\{z;-n\leqslant\Re z<n,-n\leqslant\Im z<n\}$, $n\in\mathbb{N}$, the square of side length n centered in the origin and let $K_{n(t)}$ be the biggest such square in $\mathbb{D}_t$. Lemma 3.3 follows from the two statements:

(i) For almost all $\omega\in\Omega$ there exists the limit

$$\lim_{t\to\infty}\sum_{\lambda\in\Lambda_\omega\cap K_{n(t)}}\frac{1}{\lambda^2}, \tag{3.13}$$

(ii)

$$\lim_{t\to\infty}\sum_{\lambda\in\Lambda_\omega\cap(\mathbb{D}_t\setminus K_{n(t)})}\frac{1}{\lambda^2}=0. \tag{3.14}$$

In order to prove (3.13) it suffices to pick up a sequence $b_s\geqslant 0$ so that

$$\sum_{s=1}^{\infty}b_s<\infty\quad\text{and, for almost all }\omega\in\Omega,\quad\left|\sum_{\lambda\in\Lambda_\omega\cap(K_{s+1}\setminus K_s)}\frac{1}{\lambda^2}\right|\leqslant b_s. \tag{3.15}$$

Let $H_{m,s}$, $V_{m,s}\subset K_{s+1}\setminus K_s$ and $N(H_{m,s}),N(V_{m,s})$ be the numbers of points from Λ_ω in $H_{m,s},V_{m,s}$ respectively. Let, for definiteness, $N(H_{m,s})\leqslant N(V_{m,s})$. Split the set $\Lambda_\omega\cap V_{m,s}$ into two parts $\Lambda_\omega\cap V_{m,s}=\Lambda_\omega^{(1)}(V_{m,s})\cup\Lambda_\omega^{(2)}(V_{m,s})$ so that $\#\Lambda_\omega^{(1)}(V_{m,s})=N(H_{m,s})$ and $\Lambda_\omega^{(1)}(V_{m,s})\cap\Lambda_\omega^{(2)}(V_{m,s})=\varnothing$.

We estimate the sum

$$\sigma_{m,s,\omega}=\sum_{\lambda\in\Lambda_\omega\cap(H_{m,s}\cup V_{m,s})}\frac{1}{\lambda^2}=\left(\sum_{\lambda\in\Lambda_\omega\cap(H_{m,s}\cup\Lambda_\omega^{(1)}(V_{m,s}))}+\sum_{\lambda\in\Lambda_\omega^{(2)}(V_{m,s})}\right)\frac{1}{\lambda^2}:=\sigma_{m,s,\omega}^{(1)}+\sigma_{m,s,\omega}^{(2)}.$$

If $\lambda_1\in H_{m,s}$ and $\lambda_2\in V_{m,s}$, then

$$\left(\frac{1}{\lambda_1^2}+\frac{1}{\lambda_2^2}\right)\leqslant\frac{A}{(|s|+1)^2h_1(|s|)},\tag{3.16}$$

where A depends on h only. Therefore

$$|\sigma_{m,s,\omega}^{(1)}|\leqslant\frac{AN(H_{m,s})}{(|s|+1)^2h_1(|s|)}.\tag{3.17}$$

By Lemma 3.4 we have for almost all $\omega\in\Omega$

$$N(H_{m,s})\leqslant CN_s+(|s|+1)/h_1^2(|s|)\leqslant(C+1)(|s|+1)/h_1(|s|)\tag{3.18}$$

and

$$|\sigma_{m,s,\omega}^{(1)}|\leqslant A(C+1)/((|s|+1)h_1^2(|s|)).\tag{3.19}$$

Applying Lemma 3.4 once again we obtain that the number of summands in $\sigma_{m,s,\omega}^{(2)}$ does not exceed $2(|s|+1)/h_1^2(|s|)$. Therefore

$$|\sigma_{m,s,\omega}^{(2)}|\leqslant\sum_{\lambda\in\Lambda_\omega^{(2)}(V_{m,s})}\frac{1}{|\lambda|^2}\leqslant 8/((|s|+1)h_1^2(|s|)).\tag{3.20}$$

Consider the sum $\Sigma_{m,s}\sigma_{m,s,\omega}$, where the summation is taken over all (m,s) satisfying $H_{m,s}\subset K_{s+1}\backslash K_s$. Inequalities (3.19) and (3.20) yield

$$\left|\sum_{m,s}\sigma_{m,s,\omega}\right|\leqslant 4h_1(|s|)\left(\frac{A(C+1)}{(|s|+1)h_1^2(|s|)}+\frac{8}{(|s|+1)h_1^2(|s|)}\right)=\frac{4A(C+1)+32}{(|s|+1)h_1(|s|)}\tag{3.21}$$

for almost all $\omega\in\Omega$. It remains to remark that the domain $K_{s+1}\backslash K_s$ is covered by the strips $H_{m,s}$ and $V_{m,s}$ up to for ''angles'' whose contribution may be estimated in a similar way.

Now (3.15) holds with

$$b_s=(4A(C+1)+32)((|s|+1)h_1(|s|))^{-1},$$

which, in turn, yields (3.13). The proof of (3.14) is similar, and we omit it. Lemma 3.3 is proved.

IV. RANDOM PERTURBATIONS OF A LATTICE

In this section we consider the case when the random set of points is generated by independent random perturbation of a periodic lattice, i.e., we prove Theorem 1.2. We will follow the same strategy as in the proof of Theorem 1.1. In addition in this section we do not demand random perturbations to be identically distributed.

Proof of Theorem 1.2: Denote $z_g=ma+ina$, $g=(m,n)\in\mathbb{Z}^2$, take $\alpha=1-\delta/(3+\delta)$, and consider the truncated random variables

$$\xi_g^*=\begin{cases}\xi_g, & \text{if} \quad |\xi_g|\leqslant|z_g|^\alpha\\ 0, & \text{if} \quad |\xi_g|>|z_g|^\alpha.\end{cases}$$

The Chebyshev inequality yields

$$\mathbf{P}(|\xi_g|>|z_g|^{\alpha})\leqslant \frac{\mathbf{E}\,|\xi_g|^{2+\delta}}{|z_g|^{2+\delta/(3+\delta)}},$$

whence, by (1.10)

$$\sum_{g\in\mathbb{Z}^2}\mathbf{P}(|\xi_g|>|z_g|^{\alpha})<\infty. \tag{4.1}$$

Now by the Borel–Cantelli lemma for almost all $\omega\in\Omega$ we have that $\xi_g^*=\xi_g$ for all but maybe a finite number of g's.

Next we have to check the hypothesis of Proposition 2.3 in our setting. That is, that the limits in (3.2) and (3.3) exist with probability 1. Then the function

$$f(z,\omega)=\exp\{-\delta_\omega z^2\}\prod_{\lambda\in\Lambda_\omega}G(z/\lambda;2),$$

belongs to $B^2(\mathbb{C})$. It suffices to check (3.2) and (3.3) for $\lambda_g^*(\omega)=ma+ina+\zeta_g^*$ instead of λ_g. The first of these relations comes from a direct calculation. The second one follows from:

$$\sum_{|\lambda_g^*|<t}\frac{1}{(\lambda_g^*)^2}-\sum_{|z_g|<t-t^a}\frac{1}{z_g^2}=\sum_{|z_g|<t-t^a}\left\{\frac{1}{(\lambda_g^*)^2}-\frac{1}{z_g^2}\right\}+\sum_{|z_g|>t-t^a,\ |\lambda_g^*|<t}\frac{1}{(\lambda_g^*)^2}:=S_1(t)+S_2(t).$$

It is easy to see that with probability 1 $S_2\to 0$ as $t\to\infty$. Besides, $S_1(t)$ approaches with probability 1 a limit as $t\to\infty$. This follows from the fact that the corresponding limit for unperturbed points (clearly) exists and from estimates of the perturbations. The proof of the second part is, in essence, a repetition of the proof of Theorem 1.1. Theorem 1.2 is proved.

We formulate now without proof a statement about a general property of a random field generated by a random perturbations of a lattice. In this statement restrictions on the sequence of random perturbations $\{\xi_g\}$ are more strict than in Theorem 1.2, but even then the proof is rather complicated. We do not know whether it is possible to weaken these restrictions. We formulate this result because (we believe) the study of random perturbations of deterministic sets has its own interest.

Theorem 4.1: *Let $\{\xi_g\,;\,g\in\mathbb{Z}^2\}$ be a sequence of independent, identically, and continuously distributed complex-valued random variables and*

$$\mathbf{E}\,|\xi_g|^{5+\Delta}<\infty,$$

for some $\Delta>0$. Consider the random set of points

$$\Lambda_\omega=\{\lambda=z_g+\xi_g\,;\,g\in\mathbb{Z}^2\}\subset\mathbb{C}, \tag{4.2}$$

here $z_g=ma+ina$ for $g=(m,n)$. Then the corresponding random field $\{\mu_g(\omega),g\in\mathbb{Z}^2\}$, $\mu_g(\omega)=\#\{\Lambda_\omega\cap Q_g\}$ satisfies condition (**b**) *of Section 1 with $\delta=2$ and $h(x)=\exp\{(\log_+x)^{1/2}\}$.*

Recall that $\log_+x:=\max(0,\log x)$.

V. RANDOM FIELDS WITH MIXING CONDITION

In this section we study conditions (**a**), (**b**) on the random field, which were imposed in Secs. I and II. Our goal is to show that in essence these are conditions of mixing and also that, in the most of typical situations, they are satisfied. We use here the notation of Sec. I. Thus, everywhere below we assume that $(\Omega,\mathcal{F},\mathbf{P})$ is a probability space and $\{\mu(\cdot,\omega);\,g\in\mathbb{Z}^2\}$ is defined by the relations

$$\mu_g(\omega)=\mu(Q_g,\omega),\quad g=m+in\in\mathbb{Z}^2,$$

$$Q_g:=\{x+iy;\, x\in[m,m+1),\, m\in[n,n+1)\}.$$

Theorem 5.1: *Let a random field* $\{\mu_g;\, g\in\mathbb{Z}^2\}$ *be homogeneous with respect to translations by integers along the coordinate axis and rotations by* $\pm\pi/2$. *Assume that the* μ_g*'s satisfy (1.6) and are independent. Then condition (***b***) is also valid.*

The theorem is a direct consequence of the following

Proposition 5.2: (Rosental, see e.g., Ref. 26, Ch. 3) Let $X_1,\ldots,X_n$ *be independent random variables with* $\mathbf{E}\,X_k=0, k=1,\ldots,n$ *and* $p>0$. *Denote*

$$M_{n,p}=\sum_{k=1}^{n}\mathbf{E}\,|X_k|^p,\quad B_n=\sum_{k=1}^{n}\mathbf{E}\,X_k^2.$$

Then

$$\mathbf{E}\left|\sum_{k=1}^{n}X_k\right|^p\leqslant C(p)(M_{n,p}+B_n^{p/2}),$$

where $C(p)$ *depends on p only.*

Proof of Theorem 5.1: Condition (**b**) with $h(x)=\exp\{(\log_+x)^{1/2}\}$ follows directly if one applies the proposition to the random variables $X_k=\mu_{(k,0)}-\mathbf{E}\,\mu_{(k,0)}$ and $p=2+\delta$, where δ is given in (1.6). ■

Remark: In particular all the Poisson and generalized the Poisson measures in $\mathbb{C}$ (see, e.g., Ref. 6, pp. 27–29) with a finite moment of order $2+\delta$ satisfy conditions (**a**) and (**b**) of Section I.

Now we compare condition (**b**) with the standard mixture condition. Denote by Σ the σ-algebra generated by all Q_g, $g\in\mathbb{Z}^2$. For each $Q^{(1)},Q^{(2)}\in\Sigma$ we denote by $\mathcal{F}_1,\mathcal{F}_2$ the σ-algebras generated by $\mu(Q^{(1)},\cdot)$ and $\mu(Q^{(2)},\cdot)$, respectively. We say that the random field $\{\mu_g(\omega);\, g\in\mathbb{Z}^2\}$ satisfies the ϕ-mixture condition, if

$$\phi(\tau):=\sup_{\operatorname{dist}(Q^{(1)},Q^{(2)})\geqslant\tau}\{|\mathbf{P}(B/A)-\mathbf{P}(B)|;\, A\in\mathcal{F}_1,B\in\mathcal{F}_2\}\to 0,\quad \text{as}\quad \tau\to\infty,$$

here "dist" denotes the usual Euclidean distance in $\mathbb{C}$.

Theorem 5.3: *Let the random field* $\{\mu_g(\omega);\, g\in\mathbb{Z}^2\}$ *be homogeneous with respect to integer translations along the coordinate axis and rotations by* $\pm\pi/2$. *Assume that the field satisfies condition* (**a**) *the* ϕ*-mixture condition, and also that*

$$\mathbf{Var}\,\mu(\Delta_n)\to\infty\quad \text{as}\quad n\to\infty,$$

for any sequence $\{\Delta_n\}$ *of Borelian sets in* $\mathbb{C}$ *such that* $mes(\Delta_n)\to\infty$. *Then the random field* $\{\mu_g(\omega);\, g\in\mathbb{Z}^2\}$ *satisfies condition* (**b**).

This statement is an immediate consequence of the following facts.

Proposition 5.4: (Ref. 27, Ch. 18) Let a stationary sequence $\{X_k\}$ *satisfy the* ϕ*-mixing condition. Assume that* $\mathbf{E}\,|X_k|^{2+\delta}<\infty$, *for some* $\delta>0$, *and also that* $\mathbf{Var}\,(X_1+\cdots+X_n)\to\infty$ *as* $n\to\infty$. *Then, for some constant* A_1

$$\mathbf{E}\left|\sum_{k=1}^{n}X_k-\sum_{k=1}^{n}\mathbf{E}\,X_k\right|^{2+\delta}\leqslant A_1(\mathbf{Var}(X_1+\cdots+X_n))^{1+\delta/2}. \tag{5.1}$$

Proposition 5.5: (Ref. 27, Ch. 18) Let a stationary sequence $\{X_k\}$ *satisfy the* ϕ*-mixing condition and also* $\lim_{n\to\infty}\mathbf{Var}\,(X_1+\cdots+X_n)\to\infty$ *as* $n\to\infty$. *Then*

$$\mathbf{Var}\,(X_1+\cdots+X_n)=nh(n), \tag{5.2}$$

where $h(n)$ is slowly varying function with respect to the argument $n \in \mathbb{Z}_+$. The function f can be continued to the whole real axis as a slowly varying one.

It can be mentioned that the ϕ-mixing condition for the random field $\{\mu_g(\omega); g \in \mathbb{Z}^2\}$ yields the ϕ-mixing condition for the random variables $\mu_{(1,0)}, \mu_{(2,0)}, \ldots$ and thus deduce condition (**b**) with $h(x) = \exp\{(\log_+ x)^{1/2}\}$ directly from these theorems.

(Received 27 October 2000; accepted for publication 27 February 2001)

We discuss measures on spaces of unparametrized paths related to the Wiener measure. These measures arise naturally in the study of one-dimensional gravity coupled to scalar fields. Two kinds of discrete approximations are defined, the piecewise linear and the hypercubic approximations. The convergence of these approximations in the sense of weak convergence of measures is proven. We describe a family of sets of unparametrized paths that are analogous to cylinder sets of parametrized paths. Integrals over some of these sets are evaluated in terms of Dirichlet propagators in bounded regions. © *2001 American Institute of Physics.* [DOI: 10.1063/1.1368367]

I. INTRODUCTION

In quantum field theory and string theory one frequently encounters the problem of integrating over geometrical objects, e.g., Riemannian manifolds or Riemannian manifolds with some additional structure. One wishes to define a measure on sets of geometrical objects and integrate functions that are independent of the coordinates used to describe the objects. The prime example of a theory where this problem arises is the path integral quantization of general relativity where one attempts to give meaning to expressions of the form

$$\langle F\rangle = \int e^{-S(g)} F([g]) D[g],$$

where g is a Riemannian metric on a manifold M, $[g]$ is the equivalence class of g under diffeomorhisms of M,F is a function, and $S(g)$ is a diffeomorphism invariant action functional, e.g., the Einstein–Hilbert action.[1,2] Giving a mathematical meaning to expressions of this form is largely an unsolved problem but some headway has been made, mainly in two dimensions, see Ref. 3 and references therein.

One of the strategies used in physics to deal with functional integrals of this type is to introduce discretizations of the geometrical objects under consideration and try to prove convergence of the discretization as a cutoff parameter, e.g., a lattice spacing, is taken to zero. It inspires confidence in the results obtained when different discretizations lead to identical continuum results. This approach is described in detail in the monograph.[3]

For one-dimensional objects, i.e., when the functional integral is over paths, the situation is radically different from the higher dimensional analogs, since we have measures on parametrized paths in $\mathbb{R}^d$ (e.g., the Wiener measure) that are mathematically well understood and give rise to measures on unparametrized paths as we shall discuss in the following. We study two different discretizations of integrals over unparametrized paths and show that the discrete measures converge to the appropriate continuum measure.

[b)]Electronic mail: thjons@raunvis.hi.is

In ordinary quantum field theory applications of random paths it is often the convergence of regularized propagators that is of main interest and various results in this vein have been known for a long time. Our main interest is the convergence of the underlying measures on unparametrized paths, whereas convergence of propagators merely means convergence of the total volume of the measures. Corresponding problems in nonrelativistic quantum mechanics normally involve only parametrized paths. In this case various aspects of discrete approximations pertaining to the Wiener measure on paths parametrized by a finite time interval have been discussed by many authors, see, e.g., Ref. 4 and references therein. For recent related work on discrete approximations to Wiener measure on Riemannian manifolds we refer to Refs. 5 and 6.

This paper is organized as follows. In Sec. II we introduce the models of discretized random paths we wish to study and give a proof of pointwise convergence of the lattice propagator to the continuum propagator, that will be needed later. In Sec. III we define the appropriate path spaces, the continuum measures and the discretized measures. In Sec. IV we use standard tools of probability theory to prove the convergence of the discretized measures. In Sec. V we determine a family of sets of unparametrized paths that generates the Borel sets of unparametrized paths and plays a role similar to the one played by cylinder sets for the Wiener measure. Finally, in Sec. VI we apply the results of the previous sections to evaluate the measure of some of these sets.

II. PROPAGATORS

Let Δ denote the Laplacian in $\mathbb{R}^d$. It is well known that the Euclidean propagator

$$G(x,y)=2(-\Delta+m^2)^{-1}(x,y) \tag{1}$$

of a scalar particle of mass $m>0$ in $\mathbb{R}^d$ has the path integral representation

$$G(x,y)=\int_{\omega:x\to y} e^{-m|\omega|}D\omega, \tag{2}$$

where ω is a path from x to y in $\mathbb{R}^d$ and $|\omega|$ denotes its length. The most straightforward interpretation of the formal expression on the right-hand side of Eq. (2) is obtained by regarding it as a limit of lattice propagators. We replace $\mathbb{R}^d$ by the hypercubic lattice $a\mathbb{Z}^d$ with lattice spacing a and define a lattice propagator as

$$G^a(x,y)=a^{2-d}\sum_{\omega:x\to y} e^{-m(a)|\omega|} \tag{3}$$

for $x,y\in a\mathbb{Z}^d$ where the sum is over all lattice paths from x to y. The prefactor a^{2-d} is dictated by dimensional considerations and the dependence of the parameter $m(a)$ (lattice mass) on a is determined by the requirement that $G^a(x,y)$ converge to $G(x,y)$ as $a\to 0$.

Using translation invariance we may set $G(x,y)=G(x-y)$ and $G^a(x,y)=G^a(x-y)$. The Fourier transform of the lattice propagator is then

$$\widehat{G^a}(k)=a^d\sum_{x\in a\mathbb{Z}^d} G^a(x)e^{-ik\cdot x}=e^{am(a)}\left(m^2+2a^{-2}\sum_{j=1}^{d}(1-\cos(ak_j))\right)^{-1}, \tag{4}$$

where $k\in[-\pi/a,\pi/a]^d$ and $m(a)$ is given by

$$e^{am(a)}=2d+m^2a^2. \tag{5}$$

Evidently this implies the desired uniform convergence in momentum space

$$d^{-1}\widehat{G^a}(k)\to 2(k^2+m^2)^{-1}=\hat{G}(k) \tag{6}$$

as $a\to 0$, for any $k\in\mathbb{R}^d$.

Pointwise convergence in space–time can be obtained as follows. We extend the lattice propagator from $a\mathbb{Z}^d$ to a smooth function on $\mathbb{R}^d$ by setting

$$G^a(x)=\frac{1}{(2\pi)^d}\int_{[-\pi/a,\pi/a]^d}\widehat{G^a}(k)e^{-ik\cdot x}\,\mathrm{d}k \tag{7}$$

for any $x\in\mathbb{R}^d$. For $\alpha=(\alpha_1,\ldots,\alpha_d)$, where the α_i's are non-negative integers, let

$$\partial^\alpha=\prod_{i=1}^{d}\frac{\partial^{\alpha_i}}{\partial x_i^{\alpha_i}}.$$

Defining $\widehat{G^a}(k)=0$ outside $[-\pi/a,\pi/a]^d$ it is easily verified that

$$\partial^\alpha\widehat{G^a}(k)\to\partial^\alpha\hat{G}(k)$$

uniformly on $\mathbb{R}^d$ for any multi-index α. Moreover, there is a constant c_α such that

$$|\partial^\alpha\widehat{G^a}(k)|\leqslant c_\alpha(k^2+m^2)^{-1-|\alpha|/2}, \tag{8}$$

where $|\alpha|=\alpha_1+\cdots+\alpha_d$. Thus, choosing $|\alpha|>d$, the right-hand side of Eq. (8) is integrable so the dominated convergence theorem together with Fourier inversion implies that

$$d^{-1}x^\alpha G^a(x)\to x^\alpha G(x) \tag{9}$$

as $a\to 0$, where $x^\alpha=x_1^{\alpha_1}\ldots x_d^{\alpha_d}$. In particular,

$$d^{-1}G^a(x)\to G(x) \tag{10}$$

for $x\neq 0$.

There is another path integral representation of the propagator $G(x,y)$ introduced in Ref. 7 whose analog for surfaces has played an important role in string theory in recent years.[8] The alternative representation is given by

$$G(x,y)=\int_{\omega:x\to y}\exp\left(-\frac{1}{2}\int(|\dot{\omega}|^2e^{-1}+m^2e)\mathrm{d}t\right)D\omega De, \tag{11}$$

where the integration is over paths ω in $\mathbb{R}^d$ from x to y and over intrinsic metrics e on the paths. An intrinsic metric on the path is simply a positive definite function defined on the path. In order to give a meaning to Eq. (11), we note an important common feature of the two action functionals

$$S_1(\omega)=m|\omega|=m\int|\dot{\omega}|\mathrm{d}t \tag{12}$$

and

$$S_2(\omega,e)=\frac{1}{2}\int(|\dot{\omega}|^2e^{-1}+m^2e)\mathrm{d}t, \tag{13}$$

which occur in the path integrals (2) and (11). The actions are invariant under reparametrizations

$$t'=\varphi(t),\quad \omega'(t')=\omega(t),\quad e'(t')=\frac{e(t)}{\dot{\varphi}(t)}, \tag{14}$$

where φ is an increasing diffeomorphism between intervals. Thus the path integrations in Eqs. (2) and (11) should be regarded as being taken over diffeomorphism classes of paths in the first case

and over diffeomorphism classes of paths and metrics in the second one. The standard method for dealing with functional integration over such orbit spaces is the so-called Faddeev–Popov procedure. We discuss the orbit spaces and the appropriate measures on them more thoroughly in Sec. III. For the moment we note that any pair (ω,e) can uniquely be reparametrized to (ω',e') such that the parameter interval of the latter is $[0, 1]$ and the metric e' is constant on $[0, 1]$ and equal to the volume

$$T\equiv\int e(t)\mathrm{d}t \tag{15}$$

of e, which is parametrization independent. It follows that the path integral (11) is effectively an integral over T and over paths ω parametrized on $[0, 1]$. An interpretation of (11) is then obtained by subdividing $[0,1]$ into N subintervals of length N^{-1} and letting ω be an N-step piecewise linear path $x=x_0\to x_1\to\cdots\to x_N=y$ for which

$$\int_0^1|\dot\omega|^2\,\mathrm{d}t=\frac{1}{N}\sum_{i=0}^{N-1}\left(\frac{x_{i+1}-x_i}{N^{-1}}\right)^2=N\sum_{i=0}^{N-1}(x_{i+1}-x_i)^2.$$

Setting

$$a^2=\frac{T}{N}$$

we have

$$\begin{aligned}H^a(x,y)&\equiv\frac{a^2}{(2\pi a^2)^{d/2}}\sum_{N=1}^{\infty}\int\prod_{i=1}^{N-1}\frac{dx_i}{(2\pi a^2)^{d/2}}\exp\left(-\frac{1}{2}\sum_{i=0}^{N-1}\frac{|x_{i+1}-x_i|^2}{a^2}-\frac{1}{2}m^2a^2N\right)\\&=a^2\sum_{N=1}^{\infty}(2\pi a^2N)^{-d/2}\exp\left(-\frac{|x-y|^2}{2a^2N}-\frac{1}{2}m^2a^2N\right)\\&\to\int_0^{\infty}(2\pi T)^{-d/2}\exp\left(-\frac{|x-y|^2}{2T}-\frac{1}{2}m^2T\right)dT=G(x,y)\end{aligned}\tag{16}$$

for $x\neq y$, as $a\to0$. Hence, the function $H^a(x,y)$ defined here provides a discrete approximation to $G(x,y)$. In the same way as for the hypercubic lattice approximation we show in Sec. IV that the measures on piecewise linear paths defined by the approximation H^a converge to a continuum path measure which attributes a proper meaning to Eq. (11).

III. THE CONTINUUM MEASURES AND DISCRETE APPROXIMATIONS

As noted in Sec. II the appropriate space to integrate over in Eqs. (2) and (11) consists of equivalence classes of paths under reparametrizations. In this section we define those orbit spaces and the relevant measures.

A. Piecewise linear paths

It is convenient to start with Eq. (11) and for notational and technical simplicity to consider first paths with only one fixed end point x. Let $\Gamma(x)$ be the space consisting of pairs (e,ω) where $e:[0,1]\to\mathbb{R}$ is a positive continuous function and $\omega:[0,1]\to\mathbb{R}^d$ is continuous with $\omega(0)=x$. Let $\mathrm{Diff}_+[0,1]$ denote the set of all increasing diffeomorphisms of the unit interval. As remarked in Sec. II there is a unique $\varphi\in\mathrm{Diff}_+[0,1]$ such that the reparameterized pair (e',ω') defined by Eq. (14) has $e'=T$ where T is a constant. Hence we conclude that

$$\tilde\Gamma(x)\equiv\Gamma(x)/\mathrm{Diff}_+[0,1]=\mathbb{R}_+\times\Omega(x),$$

where $\Omega(x)$ denotes the set of continuous paths $\omega:[0,1]\to\mathbb{R}^d$ with $\omega(0)=x$.

Let us define a metric $\tilde{d}$ on $\tilde{\Gamma}(x)$ by

$$\tilde{d}((T,\omega),(T',\omega'))=|T-T'|+d(\omega,\omega'),$$

where d is the standard uniform metric on $\Omega(x)$ defined by

$$d(\omega,\omega')=\sup\{|\omega(s)-\omega'(s)|:s\in[0,1]\}.$$

Equipped with $\tilde{d}$ the set $\tilde{\Gamma}(x)$ becomes a separable metric space. The discussion of probability measures and their convergence properties is particularly convenient on complete metric spaces (see, e.g., Ref. 9). Since $\Omega(x)$ with the metric d is complete we can complete $\tilde{\Gamma}(x)$ by adjoining $0\times\Omega(x)$. This will be assumed in the following. All measures on $\tilde{\Gamma}(x)$ that will be considered vanish identically on $0\times\Omega(x)$.

On $\Omega(x)$ we have the family of Wiener measures $W_x^t, t>0$, defined on the Borel subsets of $\Omega(x)$. Here t denotes the variance of the measure. We note that W_x^t is uniquely defined by the characteristic functions of its finite dimensional distributions which are given for $0<t_1<t_2<\cdots<t_n\leqslant 1$ by

$$\begin{aligned}p^t_{t_1,\ldots,t_n}(\xi_1,\ldots,\xi_n)&=\int \exp(i\xi_1\cdot\omega(t_1)+\cdots+i\xi_n\cdot\omega(t_n))\,\mathrm{d}W_x^t(\omega)\\&=\int\prod_{i=1}^n \mathrm{d}x_i(2\pi t(t_i-t_{i-1}))^{-d/2}\exp\left(-\frac{|x_i-x_{i-1}|^2}{2t(t_i-t_{i-1})}+i\xi_i\cdot x_i\right)\\&=\exp\left(-\frac{t}{2}\sum_{i=1}^n (t_i-t_{i-1})(\xi_i+\cdots+\xi_n)^2+ix\cdot(\xi_1+\cdots+\xi_n)\right),\end{aligned}\tag{17}$$

where $\xi_1,\ldots,\xi_n\in\mathbb{R}^d$, $t_0=0$, and $x_0=x$.

For a Borel set $B\subseteq\tilde{\Gamma}(x)$ we let

$$B_t=\{\omega:(t,\omega)\in B\}\quad\text{for}\quad t>0,$$

and define the measure W_x on $\tilde{\Gamma}(x)$ by

$$W_x(B)=\int_0^\infty e^{-(1/2)m^2t}W_x^t(B_t)\,\mathrm{d}t.$$

The above-given definition requires $t\to W_x^t(B_t)$ to be a measurable function. Rather than proving this directly we show that this must be the case by giving an alternative definition of W_x. First, let $x=0$ and consider the product M of Lebesgue measure on $\mathbb{R}_+$ and W_0^1 on $\Omega(0)$, i.e.,

$$\mathrm{d}M(t,\omega)=\mathrm{d}t\,\mathrm{d}W_0^1(\omega).$$

Defining a homeomorphism h of $\mathbb{R}_+\times\Omega(0)$ onto itself by $h(t,\omega)=(t,t^{-1/2}\omega)$ and observing that

$$W_0^t(A)=W_0^1(t^{-1/2}A)$$

for Borel sets $A\subseteq\Omega(0)$, it follows that we have a measure W_0 on $\tilde{\Gamma}(0)$ given by

$$W_0(B)=\int_B e^{-(1/2)m^2t}d(M\circ h)(t,\omega),$$

where the measure $M\circ h$ on $\mathbb{R}_+\times\Omega(0)$ is defined by $(M\circ h)(B)=M(h(B))$ for Borel sets $B\subseteq\mathbb{R}_+\times\Omega(0)$. This shows that W_0 is well defined. For arbitrary x we obtain W_x as the translation of W_0 by x.

To set up the discrete approximation to W_x, given by Eq. (16) for the propagator, let $\tilde{\Gamma}_{a,N}(x)\subseteq\tilde{\Gamma}(x)$ be the set of pairs (T,ω), where $T=a^2N$ and ω is an N-step piecewise linear path $x=x_0\to x_1\to\cdots\to x_N$ such that the step $x_{i-1}\to x_i$ is parametrized linearly by the interval $[(i-1)/N,i/N]$. Define the measure $W_{x,a,N}$ on $\tilde{\Gamma}(x)$ supported on $\tilde{\Gamma}_{a,N}(x)$ by

$$dW_{x,a,N}(T,\omega)=\prod_{i=1}^{N} dx_i(2\pi a^2)^{-d/2}\exp\left(-\frac{1}{2a^2}|x_i-x_{i-1}|^2\right). \tag{18}$$

For $N=0$ we let $W_{x,a,0}$ be the Dirac measure at the trivial (constant) path. The approximating measure $W_{x,a}$ on $\tilde{\Gamma}(x)$ is supported on the set

$$\tilde{\Gamma}_a(x)\equiv\bigcup_{N=0}^{\infty}\tilde{\Gamma}_{a,N}(x)$$

and defined by

$$W_{x,a}=(1-e^{-(1/2)m^2a^2})\sum_{N=0}^{\infty}e^{-(1/2)m^2a^2N}W_{x,a,N}. \tag{19}$$

The normalization factor in Eq. (19) has been chosen such that $W_{x,a}$ is a probability measure, whereas the volume of W_x is $W_x(\tilde{\Gamma}(x))=2/m^2$. We prove the following result in the next section.

Theorem III.1: $W_{x,a}\to m^2/2W_x$ as $a\to 0$.

Here and in the following convergence of measures is in the sense of *weak convergence*, i.e.,

$$\int f\,dW_{x,a}\to\int f\,dW_x \quad \text{as} \quad a\to 0,$$

for all bounded continuous functions f on $\tilde{\Gamma}(x)$.

B. Lattice paths

Next let us discuss the measure pertaining to Eq. (2). The relevant orbit space is now

$$\tilde{\Omega}(x)=\Omega(x)/\mathrm{Diff}_+[0,1]=\{[\omega]:\omega\in\Omega(x)\},$$

where $[\omega]=\{\omega\circ\varphi|\varphi\in\mathrm{Diff}_+[0,1]\}$. The quotient space $\tilde{\Omega}(x)$ inherits in a standard fashion a pseudometric $\bar{d}$ from the metric d on $\Omega(x)$, given by

$$\bar{d}([\omega],[\omega'])=\inf\{d(\omega,\omega'\circ\varphi):\varphi\in\mathrm{Diff}_+[0,1]\}.$$

Here the term pseudometric means that $\bar{d}([\omega],[\omega'])=0$ may occur even if $[\omega]\neq[\omega']$. For example, we have $\bar{d}([\omega],[\omega\circ f])=0$ whenever $f:[0,1]\to[0,1]$ is a uniform limit of increasing diffeomorphisms. This defect is eliminated by taking a further quotient setting

$$\bar{\Omega}(x)=\{\bar{\omega}:\omega\in\Omega(x)\},$$

where $\bar{\omega}=\{[\omega']:\bar{d}([\omega],[\omega'])=0\}$. Then $\bar{d}$ defines a metric on $\bar{\Omega}(x)$, and it is straightforward to verify that $\bar{\Omega}(x)$ is a complete separable metric space.

It is not hard to see that the same space $\overline{\Omega}(x)$ results from the above-mentioned construction if, e.g., we replace $\mathrm{Diff}_+[0,1]$ by the group $\mathrm{Homeo}_+[0,1]$ of increasing homeomorphisms of the unit interval. Let us also note that evidently the quotient map $\pi:\Omega(x)\to\overline{\Omega}(x)$ is continuous.

The measure W_x on $\tilde{\Gamma}(x)=\mathbb{R}_+\times\Omega(x)$ constructed in Sec. III A gives rise to a measure V'_x on $\Omega(x)$ by integration over the t variable,

$$V'_x(A)=W_x(\mathbb{R}_+\times A)=\int_0^\infty e^{-(1/2)m^2t}W_x^t(A)\,dt$$

for Borel sets $A\subseteq\Omega(x)$. Transporting this measure to $\overline{\Omega}(x)$ by π we obtain a measure V_x given by

$$V_x(\overline{A})=V'_x(\pi^{-1}(\overline{A})).$$

This measure is defined on those sets $\overline{A}$ for which $\pi^{-1}(\overline{A})$ is a Borel set. This σ-algebra contains the Borel algebra of $\overline{\Omega}(x)$ since π is continuous and we claim that the measure so defined is the appropriate one to associate to Eq. (2).

In order to define the corresponding lattice approximation let $\Omega_{a,N}(x)$ denote the set of parametrized paths in $x+a\mathbb{Z}^d$ with N steps, such that the ith step is linearly parametrized by $[(i-1)/N,i/N]$. Here x is an arbitrary point in $\mathbb{R}^d$. We let the discrete measure $V'_{x,a,N}$ on $\Omega(x)$, supported on $\Omega_{a,N}(x)$ be defined by

$$V'_{x,a,N}(\omega)=e^{-\beta_0 N}\quad\text{for}\quad\omega\in\Omega_{a,N}(x),\tag{20}$$

where $\beta_0=\log 2d$, i.e., $V'_{x,a,N}$ is a normalized counting measure.

Furthermore, in correspondence with Eqs. (3) and (5) we define the measure $V'_{x,a}$ on $\Omega(x)$ supported on

$$\Omega_a(x)\equiv\bigcup_{N=0}^{\infty}\Omega_{a,N}(x)$$

by

$$V'_{x,a}=(1-e^{-(1/2d)m^2a^2})\sum_{N=0}^{\infty}e^{-(1/2d)m^2a^2N}V'_{x,a,N}.\tag{21}$$

Here, $V'_{x,a,0}$ denotes the Dirac measure at the trivial path in $\Omega(x)$, and the normalization has been chosen such that $V'_{x,a}$ is a probability measure.

Similarly, we define

$$\overline{\Omega}_{a,N}(x)=\pi(\Omega_{a,N}(x))$$

and

$$\overline{\Omega}_a(x)=\pi(\Omega_a(x))=\bigcup_{N=0}^{\infty}\overline{\Omega}_{a,N}(x).$$

Correspondingly we define the transported measures $V_{x,a,N}$ and $V_{x,a}$ given by

$$V_{x,a,N}(\overline{A})=V'_{x,a,N}(\pi^{-1}(\overline{A}))\tag{22}$$

and

$$V_{x,a}(\overline{A}) = (1-e^{-(1/2d)m^2a^2}) \sum_{N=0}^{\infty} e^{-(1/2d)m^2a^2N} V_{x,a,N}(\overline{A}) \tag{23}$$

for Borel sets $\overline{A} \subseteq \overline{\Omega}(x)$. With these definitions we then have

Theorem III.2: $V_{x,a} \to (m^2/2)V_x$ as $a \to 0$.

This result is proven in the subsequent section as a consequence of the stronger result $V'_{x,a} \to (m^2/2)V'_x$ as $a \to 0$.

C. Paths with two fixed end points

Let us briefly discuss paths with both end points x,y fixed. It is straightforward to introduce analogs to the spaces defined previously for paths with one fixed end point. We shall use the same notation except that x is everywhere replaced by x,y. On $\Omega(x,y)$ the family of Wiener measures $W^t_{x,y}, t>0$, is defined by the characteristic functions

$$\begin{aligned} q^t_{t_1,\ldots,t_n}(\xi_1,\ldots,\xi_n) &= \int \exp(i\xi_1\cdot\omega(t_1)+\cdots+i\xi_n\cdot\omega(t_n))\mathrm{d}W^t_{x,y}(\omega) \\ &= \int \prod_{i=1}^{n} \mathrm{d}x_i (2\pi t(t_i-t_{i-1}))^{-d/2} \exp\left(-\frac{|x_i-x_{i-1}|^2}{2t(t_i-t_{i-1})} + i\xi_i\cdot x_i\right) \\ &\quad \times (2\pi t(1-t_n))^{-d/2} \exp\left(-\frac{|y-x_n|^2}{2t(1-t_n)}\right) \\ &= Z^t_{x,y} \exp\left(-\frac{t}{2}\sum_{i=1}^{n}(t_i-t_{i-1})(\xi_i+\cdots+\xi_n)^2 - \left(\sum_{i=1}^{n} t_i\xi_i\right)^2 \right. \\ &\quad \left. + i\sum_{i=1}^{n}(t_iy+(1-t_i)x)\xi_i\right), \end{aligned} \tag{24}$$

where

$$Z^t_{x,y} = (2\pi t)^{-d/2} e^{-|x-y|^2/2t},$$

the volume of $W^t_{x,y}$, is simply the heat kernel.

We then define the measure $W_{x,y}$ on $\tilde{\Gamma}(x,y)$ for $x \neq y$ by

$$W_{x,y}(B) = \int_0^\infty e^{-(1/2)m^2t} W^t_{x,y}(B_t)\mathrm{d}t,$$

where $B \subseteq \tilde{\Gamma}(x,y)$ is a Borel set and $B_t \subseteq \Omega(x,y)$ is defined as previously. The fact that this expression is well defined is shown in a similar way as for W_x by first noting that

$$W^t_{0,0}(A) = t^{-d/2} W^1_{0,0}(t^{-1/2}A)$$

for Borel sets $A \subseteq \Omega(0,0)$, and then using

$$W^t_{x,y}(A) = \exp\left(-\frac{|x-y|^2}{2t}\right) W^1_{0,0}(A-\omega_{x,y}),$$

where $\omega_{x,y}$ is the linear path from x to y and A is a Borel subset of $\Omega(x,y)$. The last relation is a direct consequence of Eq. (24).

Having defined $W_{x,y}$ the measures $V'_{x,y}$ and $V_{x,y}$ are defined in a similar way as V'_x and V_x.

The piecewise linear approximation is defined in analogy with Eq. (19) by

$$W_{x,y,a}=(1-e^{-(1/2)m^2a^2})\sum_{N=0}^{\infty} e^{-(1/2)m^2a^2N}W_{x,y,a,N}, \tag{25}$$

where

$$\mathrm{d}W_{x,y,a,N}(T,\omega)=\prod_{i=1}^{N} \mathrm{d}x_i(2\pi a^2)^{-d/2}\exp\left(-\frac{1}{2a^2}|x_i-x_{i-1}|^2\right) \tag{26}$$

for an N-step piecewise linear path $\omega: x=x_0\to x_1\to\cdots\to x_{N-1}\to x_N=y$. Here $W_{x,y,a,1}$ is the Dirac measure $\delta_{(1,\omega_0)}$, where ω_0 is the linear path from x to y, and $T=a^2N$ as before.

Similarly, the hypercubic approximation is defined for $x\neq y, x-y\in a\mathbb{Z}^d$ by

$$V'_{x,y,a}=(1-e^{-m^2a^2})\sum_{N=1}^{\infty} e^{-m^2a^2N}V'_{x,y,a,N}, \tag{27}$$

where

$$V'_{x,y,a,N}(\omega)=a^{-d}e^{-\beta_0 N} \quad \text{for} \quad \omega\in\Omega_{a,N}(x,y), \tag{28}$$

and $V_{x,y,a}$ is obtained by transporting to $\overline{\Omega}(x,y)$ by the quotient map π. Since in all cases we are interested in the limit $a\to 0$ we shall assume $0<a<1$.

It should be noted that in contrast to the case of paths with one fixed end point, the approximating measures defined here are not probability measures. The volume of $W_{x,y,a,N}$ is obtained by explicit computation and equals

$$Z_{x,y}^{a^2N}=(2\pi a^2N)^{-d/2}e^{-|x-y|^2/2a^2N}, \tag{29}$$

which by insertion into (25) immediately shows that the volume of $W_{x,y,a}$ equals $(1-e^{-(1/2)m^2a^2})a^{-2}H^a(x,y)$ and converges to $(m^2/2)G(x,y)$ as $a\to 0$ according to Eq. (16). Similarly, the volume of $V_{x,y}$ equals $(1-e^{-(1/2d)m^2a^2})a^{-2}G^a(x,y)$ and converges to $(m^2/2)G(x,y)$ as $a\to 0$ according to Eq. (10). On the other hand, the volume of $W_{x,y}$ and of $V_{x,y}$ both equal $G(x,y)$. The convergence of volumes extends to the following result.

Theorem III.3: $W_{x,y,a}\to(m^2/2)W_{x,y}$ and $V_{x,y,a}\to(m^2/2)V_{x,y}$ as $a\to 0$ for $x\neq y$.

The proof is given in Sec. IV.

IV. CONVERGENCE OF THE APPROXIMATIONS

In a complete separable metric space M there is a standard two-step procedure for proving convergence of a family $m_a, a>0$, of Borel probability measures to a measure m. The first step is to verify that $m_a, a>0$, is a *tight* (or *precompact*) family. This means that for every $\eta>0$ there exists a compact set $K\subseteq M$ such that $m_a(K)\geqslant 1-\eta$ for all $a>0$. The second step is to show that

$$\int_M f\,\mathrm{d}m_a\to\int_M f\,\mathrm{d}m \tag{30}$$

as $a\to 0$ for a collection of functions that determine the measure in the sense that if the integrals of these functions coincide for two measures then the measures coincide. Of course, the first step is superfluous if one can establish the convergence (30) for all bounded continuous functions f. But this only happens rarely. Generally, the first step ensures that every sequence m_{a_n} from the given family has a convergent subsequence, and the second step then implies that its limit is independent of the chosen sequence or subsequence. For the spaces $\Omega(x)$ and $\Omega(x,y)$ the second step can be

accomplished by proving convergence of the characteristic functions of the finite dimensional distributions. For the spaces $\tilde{\Gamma}(x)$ and $\tilde{\Gamma}(x,y)$ a little more is required as we discuss in the following.

In the following four lemmas we show that the approximations introduced in Sec. III form tight families.

Lemma IV.1: $W_{x,a}, 0<a<1$, is a tight family of measures on $\tilde{\Gamma}(x)$.

Proof: The following is an adaptation of the corresponding argument for the piecewise linear approximations to the measure W_x^t (see Ref. 9). According to the Arzela–Ascoli theorem the sets of compact closure in $\Omega(x)$ are the equicontinuous ones. Defining the modulus of continuity

$$m(\omega,\delta)=\sup\{|\omega(s)-\omega(t)|:|s-t|<\delta\} \quad \text{for} \quad \delta>0, \quad \omega\in\Omega(x),$$

it follows that complements to sets of the form

$$C=\bigcup_{n=1}^{\infty}\left\{\omega: m(\omega,\delta_n)>\frac{1}{n}\right\} \tag{31}$$

have compact closures in $\Omega(x)$ for an arbitrary sequence $\{\delta_n\}$ of positive numbers. We observe that by Eq. (19)

$$W_{x,a}([t_0,+\infty)\times\Omega(x))<\eta \quad \text{if} \quad t_0>-m^{-2}\log\eta \tag{32}$$

for any $\eta>0$ and all $a>0$. In order to prove the lemma it therefore suffices to show that for any $\eta,\varepsilon,t_0>0$ there exists a $\delta>0$ such that

$$W_{x,a}([0,t_0]\times\{\omega\in\Omega(x):m(\omega,\delta)>\varepsilon\})<\eta \tag{33}$$

for all $a>0$.

By Eq. (19) it follows that Eq. (33) holds if

$$W_{x,a,N}(\{(a^2N,\omega)\in\tilde{\Gamma}(x):m(\omega,\delta)>\varepsilon\})<\eta \quad \text{for} \quad a^2N\leq t_0. \tag{34}$$

But for a,N as in Eq. (34) we have

$$\begin{aligned} W_{x,a,N}(\{(a^2N,\omega):m(\omega,\delta)>\varepsilon\}) &= W_{x,1,N}\left(\left\{(N,\omega):m(\omega,\delta)>\frac{\varepsilon}{a}\right\}\right) \\ &\leq W_{x,1,N}\left(\left\{(N,\omega):m(\omega,\delta)>\frac{\varepsilon\sqrt{N}}{\sqrt{t_0}}\right\}\right). \end{aligned} \tag{35}$$

Hence, it suffices to show, for given $\eta,\varepsilon>0$, that

$$W_{x,1,N}(\{(N,\omega):m(\omega,\delta)>\varepsilon\sqrt{N}\})<\eta, \tag{36}$$

if δ is small enough. This is a well-known result (see, e.g., Ref. 9, pp. 62–63). For later reference we briefly recall the argument.

First, note that since paths contributing to (36) are linear on each interval $[(i-1)/N,i/N]$ we have

$$m_N(\omega,\delta)\equiv\max\left\{\left|\omega\left(\frac{i}{N}\right)-\omega\left(\frac{j}{N}\right)\right|:0\leq i,j\leq N,\left|\frac{i}{N}-\frac{j}{N}\right|<\delta\right\}\geq\frac{1}{3}m(\omega,\delta)$$

for $N \geqslant \delta^{-1}$. Note also that by uniform continuity of $\omega \in \Omega(x)$ the inequality (36) is fulfilled for sufficiently small δ for each individual N, so we need not worry about small N. Hence we may replace $m(\omega,\delta)$ in (36) by $m_N(\omega,\delta)$, and we may assume $\delta = M^{-1}$, where $M \in \mathbb{N}$ and $N \geqslant M$.

Next, given $N \geqslant M$, we choose integers $0 = k_0 < k_1 < \cdots < k_M = N$ such that any subinterval $[i/N, j/N]$ of $[0,1]$ of length $\leqslant \delta$ is contained in one of the intervals $[k_l/N, (k_{l+2}/N]$ and such that the latter intervals are all of length $\leqslant 3\delta$. It follows that

$$
\begin{aligned}
&W_{x,1,N}(\{(N,\omega): m(\omega,\delta) > \varepsilon\sqrt{N}\}) \\
&\qquad \leqslant \sum_{l=0}^{M-2} W_{x,1,N}\left(\left\{(N,\omega): \max_{k_l \leqslant k \leqslant l+2} \left|\omega\left(\frac{k_l}{N}\right) - \omega\left(\frac{k}{N}\right)\right| > \frac{\varepsilon}{6}\sqrt{N}\right\}\right) \\
&\qquad \leqslant \sum_{l=0}^{M-2} W_{x,1,N}\left(\left\{(N,\omega): \max_{k_l \leqslant k \leqslant k_{l+2}} \left|\omega\left(\frac{k_l}{N}\right) - \omega\left(\frac{k}{N}\right)\right| \right.\right. \\
&\qquad\qquad \left.\left. > \frac{\delta^{-1/2}\varepsilon}{6\sqrt{3}}\sqrt{k_{l+2} - k_l}\right\}\right).
\end{aligned}
$$

Due to statistical independence of the steps in ω and translation invariance, we have

$$
\begin{aligned}
&W_{x,1,N}\left(\left\{(N,\omega) \in \tilde{\Gamma}(x): \max_{k_l \leqslant k \leqslant k_{l+2}} \left|\omega\left(\frac{k_l}{N}\right) - \omega\left(\frac{k}{N}\right)\right| > \alpha\right\}\right) \\
&\qquad = W_{0,1,k_{l+2}-k_l}\left(\left\{(k_{l+2}-k_l,\omega) \in \tilde{\Gamma}(0): \max_{k_l \leqslant k \leqslant k_{l+2}} \left|\omega\left(\frac{k}{k_{l+2}-k_l}\right)\right| > \alpha\right\}\right)
\end{aligned}
$$

for $\alpha > 0$. Combining this with the previous inequality we conclude that it is sufficient to show for given $\eta > 0$ the existence of $\delta > 0$ such that for all $N \in \mathbb{N}$,

$$
\delta^{-1} W_{0,1,N}\left(\left\{(N,\omega): \max\left\{\left|\omega\left(\frac{i}{N}\right)\right| \middle| 0 \leqslant i \leqslant N\right\} > \delta^{-1/2}\sqrt{N}\right\}\right) < \eta.
$$

This inequality is a consequence of the Chebychev inequality and the uniform boundedness in N of the moments of $N^{-1/2}|\omega(1)|$ with respect to the measure $W_{0,1,N}$. The details may be found in Ref. 9 □

Lemma IV.2: $V'_{x,a}, 0 < a < 1$, is a tight family of measures on $\Omega(x)$.

Proof: This is obtained by an argument similar to the one given previously. First, applying the Arzela–Ascoli theorem one concludes that it is sufficient to prove for given $\eta, \varepsilon > 0$ that

$$
V'_{x,a}(\{\omega \in \Omega(x): m(\omega,\delta) > \varepsilon\}) < \eta \tag{37}
$$

for small enough δ. Second, since the contribution of terms with $a^2 N \geqslant t_0$ in (21) is less than or equal to $\eta/2$ if $t_0 \geqslant -m^2 \log \eta/2$ we conclude as previously that it is sufficient to show the existence of a $\delta > 0$ such that for all $N \in \mathbb{N}$,

$$
V'_{x,1,N}(\{\omega \in \Omega(x): m(\omega,\delta) > \varepsilon\sqrt{N}\}) < \eta. \tag{38}
$$

The proof of this fact parallels the one for piecewise linear paths referred to previously, and uses only the statistical independence of the steps in a path together with the uniform boundedness in N of the moments of $N^{-1/2}|\omega(1)|$ with respect to the measure $V'_{x,1,N}$. We omit the details of the argument. □

Lemma IV.3: $W_{x,y,a}, 0 < a < 1$, is a tight family of measures on $\tilde{\Gamma}(x,y)$ for $x \neq y$.

Proof: By definition tightness of the family $W_{x,y,a}, a>0$, means tightness of the corresponding family of normalized measures. Since, however, the volume of $W_{x,y,a}$ converges to the volume of $\frac{1}{2}m^2 W_{x,y}$ as $a\to 0$, as noted previously, we need not worry about normalization.

We note first that the volume of $W_{x,y,a,N}$ given by (29) is uniformly bounded in a and N. Hence, in (25) the sum over $N\leqslant s_0 a^{-2}$ or over $N\geqslant t_0 a^{-2}$ can be made arbitrarily small for sufficiently small s_0 or sufficiently large t_0, respectively. By the same arguments as in the first part of the proof of Lemma IV.1 it is sufficient to demonstrate the existence of a $\delta>0$ such that

$$W_{x,y,a,N}(\{(a^2N,\omega)\in\tilde{\Gamma}(x,y): m(\omega,\delta)>\varepsilon\})<\eta \quad \text{for} \quad s_0\leqslant a^2N\leqslant t_0, \tag{39}$$

for given $\eta,\varepsilon,s_0,\ t_0>0$.

We may as before replace $m(\omega,\delta)$ by $m_N(\omega,\delta)$. Assuming $\delta<\frac{1}{3}$ and setting $N_1=[\frac{2}{3}N]+1$, $N_2=[\frac{1}{3}N]$ (where $[\alpha]$ denotes the integer part of α), any subinterval of $[0,\ 1]$ of length δ is contained in either $[0,N_1/N]$ or in $[N_2/N,1]$. Hence, we have

$$\begin{aligned} &W_{x,y,a,N}(\{(a^2N,\omega): m_N(\omega,\delta)>\varepsilon\}) \\ &\quad\leqslant W_{x,y,a,N}(\{(a^2N,\omega): m_N^1(\omega,\delta)>\varepsilon\}) + W_{x,y,a,N}(\{(a^2N,\omega): m_N^2(\omega,\delta)>\varepsilon\}), \end{aligned} \tag{40}$$

where we have set

$$m_N^1(\omega,\delta)=\max\left\{\left|\omega\left(\frac{i}{N}\right)-\omega\left(\frac{j}{N}\right)\right|: 0\leqslant i,j\leqslant N_1, \left|\frac{i}{N}-\frac{j}{N}\right|<\delta\right\}$$

and

$$m_N^2(\omega,\delta)=\max\left\{\left|\omega\left(\frac{i}{N}\right)-\omega\left(\frac{j}{N}\right)\right|: N_2\leqslant i,j\leqslant N, \left|\frac{i}{N}-\frac{j}{N}\right|<\delta\right\}.$$

By definition of $W_{x,y,a,N}$ we have

$$W_{x,y,a,N}(\{(a^2N,\omega): m_N^1(\omega,\delta)>\varepsilon\})=\int_{\mathbb{R}^d} \mathrm{d}u\ Z_{u,y}^{a^2(N-N_1)} W_{x,u,a,N_1}(\{(a^2N_1,\omega): m_{N_1}(\omega,\delta)>\varepsilon\}). \tag{41}$$

Here $a^2(N-N_1)\geqslant a^2(\frac{1}{3}N-1)\geqslant\frac{1}{6}s_0$ (assuming $N\geqslant 6$) so

$$Z_{u,y}^{a^2(N-N_1)}\leqslant(\tfrac{1}{3}\pi s_0)^{-d/2}.$$

Using this estimate together with

$$\mathrm{d}W_{x,a,N}(a^2N,\omega)=\mathrm{d}\omega(1)\mathrm{d}W_{x,\omega(1),a,N}(\omega) \quad \text{for} \quad \omega\in\Omega(x)$$

in Eq. (41) we obtain

$$W_{x,y,a,N}(\{(a^2N,\omega): m_N^1(\omega,\delta)>\varepsilon\})\leqslant(\tfrac{1}{3}\pi s_0)^{-d/2} W_{x,a,N_1}(\{(a^2N_1,\omega): m_{N_1}(\omega,\delta)>\varepsilon\}).$$

Finally, using $a^2N_1\leqslant\frac{2}{3}t_0$ we conclude from the proof of Lemma IV.1 that $W_{x,a,N_1}(\{(a^2N_1,\omega): m_{N_1}(\omega,\delta)>\varepsilon\})$ can be made arbitrarily small for $a^2N\leqslant t_0$ if δ is chosen small enough.

The second term in (40) can be treated similarly, and the lemma is proven. □

Lemma IV.4: $V'_{x,y,a}, 0<a<1$, is a tight family of measures on $\Omega(x,y)$ for $x\neq y$.

Proof: Only a few modifications of the previous proof are needed.

For the volume $Z_{x,y,1,N}$ of $W_{x,y,1,N}$ we have the following result, which is rather easily derived from its Fourier representation (see, e.g., Ref. 10, pp. 76–77):

$$\lim_{N\to\infty}((2\pi N/d)^{d/2}Z_{x,y,1,N}-e^{-|x-y|^2/2N/d})=0$$

uniformly in $x-y\in\mathbb{Z}^d$. For the volume $Z_{x,y,a,N}$ of $W_{x,y,a,N}$ this means

$$\lim_{N\to\infty}((2\pi a^2N/d)^{d/2}Z_{x,y,a,N}-e^{-|x-y|^2/2Nd^2/d})=0 \tag{42}$$

uniformly in $x-y\in a\mathbb{Z}^d$ and $0<a<1$.

As a first consequence of (42) we note that $Z_{x,y,a,N}$ is uniformly bounded in a,N for $a^2N\geqslant t_0$ for any given $t_0>0$ large enough. It follows that in Eq. (25) the sum over $N\geqslant t_0a^{-2}$ can be made arbitrarily small [when applied to any Borel set in $\Omega(x,y)$] by choosing t_0 large enough.

A second consequence is that for any $s_0>0$

$$(1-e^{-(1/2d)m^2a^2})\sum_{a^2N\geqslant s_0}^{\infty}e^{-(1/2d)m^2a^2N}Z_{x,y,a,N}\to\frac{m^2}{2d}\int_{s_0}^{\infty}Z_{x,y}^{t/d}e^{-(1/2d)m^2t}\mathrm{d}t$$
$$=\frac{m^2}{2}\int_{s_0/d}^{\infty}Z_{x,y}^{t}e^{-(1/2)m^2t}\,\mathrm{d}t$$

as $a\to0$. On the other hand, as we know from Sec. II,

$$(1-e^{-(1/2d)m^2a^2})\sum_{N=0}^{\infty}e^{-(1/2d)m^2a^2N}Z_{x,y,a,N}\to\frac{m^2}{2}G(x,y)=\frac{m^2}{2}\int_{0}^{\infty}Z_{x,y}^{t}e^{-(1/2)m^2t}\,\mathrm{d}t$$

as $a\to0$. Hence we conclude that the sum in Eq. (25) over $a^2N\leqslant s_0$ can be made arbitrarily small for all $a<a_0$ for some $a_0>0$. Replacing s_0 by $\min\{s_0,a_0^2\}$ we can arrange that $a_0=1$.

It now follows as in the previous proof that it suffices to show for given $\eta,\varepsilon,s_0,t_0>0$ that there exists $\delta>0$ such that

$$V'_{x,y,a,N}(\{\omega:m_N(\omega,\delta)>\varepsilon\})<\eta\quad\text{for}\quad s_0<a^2N<t_0.$$

Following the proof of Lemma 4.3 we have the estimate

$$V'_{x,y,a,N}(\{(a^2N,\omega):m_N(\omega,\delta)>\varepsilon\})$$
$$\leqslant V'_{x,y,a,N}(\{(\omega):m_N^1(\omega,\delta)>\varepsilon\})+V'_{x,y,a,N}(\{(\omega):m_N^2(\omega,\delta)>\varepsilon\}). \tag{43}$$

By definition of $V'_{x,y,a,N}$ we can write

$$V'_{x,y,a,N}(\{(\omega):m_N^1(\omega,\delta)>\varepsilon\}=\sum_{u\in a\mathbb{Z}^d}Z_{u,y,a,N-N_1}V'_{x,u,a,N_1}(\{(\omega):m_{N_1}(\omega,\delta)>\varepsilon\}.$$

From Eq. (42) and $a^2(N-N_1)\geqslant\frac{1}{6}s_0$ it follows that $Z_{u,y,a,N-N_1}$ is uniformly bounded in x,y,a,N for $a^2N\geqslant s_0$ and $n\geqslant N_0$ for some $N_0\in\mathbb{N}$. Letting C denote such an upper bound, we have

$$V'_{x,y,a,N}(\{(\omega):m_N^1(\omega,\delta)>\varepsilon\}\leqslant C\sum_{u\in a\mathbb{Z}^d}V'_{u,x,a,N_1}((\{(\omega)m_{N_1}(\omega,\delta)>\varepsilon\}$$
$$=CV'_{x,a,N_1}((\{(\omega):m_{N_1}(\omega,\delta)>\varepsilon\}. \tag{44}$$

From the proof of Lemma 4.2 it now follows as previously that the right-hand side of (44) can be made arbitrarily small for $a^2N \leq t_0$ if δ is chosen sufficiently small. Estimating the second term in (43) similarly and noting again that the case $N<N_0$ can be taken care of separately, the proof of the lemma is complete. □

We are now ready to give proofs of the convergence theorems stated in Sec. III. In view of the preceding lemmas and the remarks at the beginning of this section it is sufficient in each case to prove convergence on a measure determining class of functions.

Proof of Theorem III.1: For $0<t_1<\cdots<t_n\leq 1$ and $s\in\mathbb{R}$, $\xi_1,\ldots,\xi_n\in\mathbb{R}^d$ we define the characteristic function $p_{a;t_1,\ldots,t_n}$ of $W_{x,a}$ by

$$p_{a;t_1,\ldots,t_n}(s,\xi_1,\ldots,\xi_n)=\int_{\tilde{\Gamma}(x)} e^{i(st+\xi_1\cdot\omega(t_1)+\cdots+\xi_n\cdot\omega(t_1))}\mathrm{d}W_{x,a}(t,\omega), \tag{45}$$

and similarly the characteristic function $p_{t_1,\ldots,t_n}$ of W_x. We claim it is sufficient to show that $p_{a;t_1,\ldots,t_n}\to(m^2/2)p_{t_1,\ldots,t_n}$ pointwise as $a\to 0$, for arbitrary $0<t_1<\cdots<t_n\leq 1$. In order to see this, it is enough to verify that the measure W_x on $\tilde{\Gamma}(x)$ is determined by its characteristic functions. Let f be a smooth function on $\mathbb{R}_+\times R^{nd}$ with compact support. Multiplying $p_{t_1,\ldots,t_n}$ by the Fourier transform of f at $(s,\xi_1,\ldots,\xi_n)$ and integrating over $(s,\xi_1,\ldots,\xi_n)\in\mathbb{R}^{nd+1}$ gives by Fubini's theorem $\int_{\tilde{\Gamma}(x)} f(t,\omega(t_1),\ldots,\omega(t_n))\mathrm{d}W_{x,a}(t,\omega)$. A simple limiting argument then shows that measures of sets of the form $\{(t,\omega):(t,\omega(t_1),\ldots,\omega(t_n))\in C\}$, where $C\subseteq\mathbb{R}_+\times\mathbb{R}^{nd}$ is closed, are determined by the characteristic functions. Since sets of this form generate the Borel algebra in $\tilde{\Gamma}(x)$ the claim follows.

Given N let $1\leq N_1\leq\ldots\leq N_n\leq N$ be such that $t_i\in](N_i-1)/N,N_i/N]$ and set $t_i'=N_i/N$. By an explicit computation, replacing the intermediate times t_i by t_i' in the piecewise linear paths, one finds

$$\int_{\tilde{\Gamma}(x)} e^{i(st+\xi_1\cdot\omega(t_1)+\cdots+\xi_n\cdot\omega(t_n))}\mathrm{d}W_{x,a,N}(t,\omega)=C_{a,N}p^{a^2N}_{t_1',\ldots,t_n'}(s,\xi_1,\ldots,\xi_n).$$

The quantity $C_{a,N}$ which depends on the time differences t_i-t_i' tends to 1 uniformly in N as $a\to 0$. Using the expression (17) for $p^t_{t_1,\ldots,t_n}(s,\xi_1,\ldots,\xi_n)$ it follows easily that

$$\begin{aligned}p_{a;t_1,\ldots,t_n}(s,\xi_1,\ldots,\xi_n)&=(1-e^{-(1/2)m^2a^2})\sum_{N=0}^{\infty} C_{a,N}e^{-(1/2)m^2a^2N}e^{isa^2N}p^{a^2N}_{t_1',\ldots,t_n'}(s,\xi_1,\ldots,\xi_n)\\&\to\frac{m^2}{2}p_{t_1,\ldots,t_n}(s,\xi_1,\ldots,\xi_n)\end{aligned}$$

as $a\to 0$.

Proof of Theorem III.2: We do this by proving the stronger result that $V'_{x,a}\to(m^2/2)V'_x$ as $a\to 0$. It follows by the same argument as given in the beginning of the previous proof that it is enough to prove convergence of the characteristic function

$$\begin{aligned}p'_{\alpha;t_1,\ldots,t_n}(\xi_1,\ldots,\xi_n)&=\int_{\Omega(x)} e^{i(\xi_1\cdot\omega(t_1)+\cdots+\xi_n\cdot\omega(t_n))}\mathrm{d}V'_{x,a}(t,\omega)\\&=(1-e^{-(1/2)m^2a^2})\sum_{N=0}^{\infty} e^{-(1/2)m^2a^2N}\sum_{\omega\in\Omega_{a,N}(x)} e^{-\beta_0 N}e^{i(\xi_1\cdot\omega(t_1)+\cdots+\xi_n\cdot\omega(t_n))}\end{aligned}$$

to $(m^2/2)p_{t_1,\ldots,t_n}$ as $a\to 0$ for arbitrary $0<t_1<\cdots<t_n\leq 1$. Furthermore, we can assume $x=0$, since translation by x only gives rise to a factor $e^{ix\cdot(\xi_1+\cdots+\xi_n)}$ in the characteristic functions. Defining N_i and t_i' as in the preceding proof we have

$$
\begin{aligned}
&p'_{a;t_1,\ldots,t_n}(\xi_1,\ldots,\xi_n)\\
&\quad=(1-e^{-(1/2d)m^2a^2})\sum_{N=0}^{\infty} e^{-(1/2d)m^2a^2N}\prod_{i=1}^{n}\left(\frac{1}{d}\sum_{\nu=1}^{d}\cos a(\xi_i+\cdots+\xi_n)_\nu\right)^{N_i-N_{i-1}}\\
&\quad=(1-e^{-(1/2d)m^2a^2})\sum_{N=0}^{\infty} e^{-(1/2d)m^2a^2N}\prod_{i=1}^{n}\left(\frac{1}{d}\sum_{\nu=1}^{d}\cos a(\xi_i+\cdots+\xi_n)_\nu\right)^{(t'_i-t'_{i-1})N},
\end{aligned}
$$

where ν labels the components of the ξ variables and $N_0=0$. Finally, using

$$
\left(\frac{1}{d}\sum_{\nu=1}^{d}\cos a(\xi_i+\cdots+\xi_n)_\nu\right)^{s/a^2}\to e^{-(s/2d)(\xi_i+\cdots+\xi_n)^2}
$$

as $a\to 0$, an application of the dominated convergence theorem shows that

$$
p'_{a;t_1,\ldots,t_n}(\xi_1,\ldots,\xi_n)\to\frac{m^2}{2}\int_0^\infty \mathrm{d}t\, e^{(1/2)m^2t}\exp\left(-\frac{t}{2}\sum_{i=1}^{n}(t_i-t_{i-1})(\xi_i+\cdots+\xi_n)^2\right)
$$

as $a\to 0$, which is the desired result.

Proof of Theorem III.3: The convergence $W_{x,y,a}\to W_{x,y}$ follows by essentially the same proof as of Theorem III.1. Similarly the convergence $V_{x,y,a}\to V_{x,y}$ is obtained by trivial modifications of the proof of Theorem III.2. Details are left to the reader.

V. CYLINDER SETS

In this section we define a class of sets of geometric paths which generate the Borel algebra and play a role similar to the one played by cylinder sets in the theory of parametrized paths. We will see in Sec. VI that the measure of these sets can be calculated in a particularly simple way.

A natural condition to put on a parametrized path ω is that the path be located in a particular subset A of $\mathbb{R}^d$ at a given time t, i.e., $\omega(t)\in A$. For geometric paths a condition of this type is meaningless but a similar one which has a well-defined meaning is the condition that a geometric path $\overline{\omega}$ hit a set A. This means that $\overline{\omega}\cap A\neq\varnothing$, i.e., if ω is a parametrization of $\overline{\omega}$ then there is a time t such that $\omega(t)\in A$. More generally, we can require that a geometric path hit a number of sets in a particular order and/or stay away from other sets. In the following we define a certain class of sets defined by such conditions. Other definitions are possible but we find this class simple to work with.

We consider paths with two fixed end points x and y. Let $A_1,\ldots,A_n$ be subsets of $\mathbb{R}^d$ and let $\overline{\omega}\in\overline{\Omega}(x,y)$ with parametrization $\omega:[0,1]\to\mathbb{R}^d$. Define

$$
\begin{aligned}
\tau_1&=\sup\{t\geqslant 0:\omega([0,t])\subseteq A_1\},\\
\tau_2&=\sup\{t\geqslant \tau_1:\omega([\tau_1,t])\subseteq A_2\},\\
&\vdots\\
\tau_n&=\sup\{t\geqslant \tau_{n-1}:\omega([\tau_{n-1},t])\subseteq A_n\},
\end{aligned}
$$

where by convention $\sup\varnothing=1$. We then define $Z(A_1,\ldots,A_n)$ as the set of all geometric paths $\overline{\omega}\in\overline{\Omega}(x,y)$ such that

$$
\tau_1<\tau_2<\cdots<\tau_{n-1}<\tau_n=1.
$$

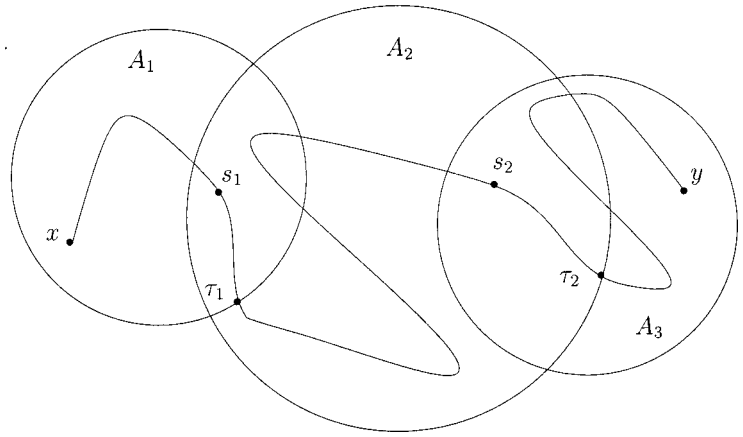

FIG. 1. An illustration of the times s_i and τ_i in the case of $n=3$.

This defining property is easily seen to be independent of the parametrization ω chosen for $\overline{\omega}$. In fact, $\overline{\omega}\in Z(A_1,\ldots,A_n)$ exactly if it starts at $x\in A_1$, stays inside A_1 until it leaves A_1 at a point $x_1=\omega(\tau_1)\in A_2$, then stays in A_2 until it leaves at a point $x_2=\omega(\tau_2)\in A_3$ and so on until it leaves A_{n-1} at a point $x_{n-1}=\omega(\tau_{n-1})\in A_n$ and then finally stays in A_n until it ends at $y\in\overline{A_n}$. The values of the escape times τ_i depend of course on the parametrization but their ordering and the points x_i are independent of parametrization.

Proposition 5.1: Let $A_1,\ldots,A_n\subseteq\mathbb{R}^d$ be open sets such that $x\in A_1$ and $y\in A_n\backslash\overline{A}_{n-1}$. Furthermore, assume

$$A_{i-1}\cap\partial A_i\cap A_{i+1}=\varnothing \tag{46}$$

for $i=2,\ldots,n-1$. Then $Z(A_1,\ldots,A_n)$ is an open subset of $\overline{\Omega}(x,y)$.

Proof: Let $\overline{\omega}\in Z(A_1,\ldots,A_n)$. Choose a parametrization ω for $\overline{\omega}$. Since the sets A_i are open we can choose $s_i<\tau_i$ such that $\omega([s_i,\tau_i])\subseteq A_{i+1}$, see Fig. 1. By the definition of the τ_i's it follows that $\omega([s_i,s_{i+1}])\subseteq A_{i+1}$ for $i=0,1,\ldots,n-1$, setting $s_0=0$.

Let $r_i>0$ be the distance from the compact set $\omega([s_i,s_{i+1}])$ to the boundary of A_{i+1}, $i=0,1,\ldots,n-1$, and set $r=\min_i r_i$. Now take a geometric path $\overline{\omega'}$ at a distance smaller than r from $\overline{\omega}$. Then there exists a parametrization $\omega':[0,1]\to\mathbb{R}^d$ of $\overline{\omega'}$ such that

$$\sup_{t\in[0,1]}|\omega(t)-\omega'(t)|<r.$$

In particular it follows that

$$\omega'([s_i,s_{i+1}])\subseteq A_{i+1}.$$

By the assumption (46) we may from the outset choose the s_i's such that $\omega(s_{i+1})\notin A_i$. Choosing r smaller, if necessary, we can also assume that r is smaller than the smallest of the distances from $\omega(s_{i+1})$ to A_i, $i=1,2,\ldots,n$. Hence, $\omega'(s_{i+1})\notin A_i$. On the other hand $\omega'(s_i)\in A_i$ so ω' leaves the set A_i at a time $\tau_i'\in[s_i,s_{i+1}]$. It follows that $\tau_1'<\tau_2'<\ldots\tau_n'=1$ so $\overline{\omega'}\in Z(A_1,\ldots,A_n)$. □

The condition (46) was essential in the above-given argument because otherwise the paths might never enter the interior of $A_i\backslash A_{i-1}$ for some i. But (46) can be replaced by a weaker condition as we now explain.

Let A be an open set in $\mathbb{R}^d$. We say that a geometric path $\overline{\omega}$ is *tangent to the boundary of A* at $x\in\partial A$ if there is a parametrization ω of $\overline{\omega}$ such that $\omega(t_0)=x$ and there is an $\varepsilon>0$ such that $\omega(t)\in\overline{A}$ for $0<|t-t_0|<\varepsilon$. We claim that any path in $Z(A_1,\ldots,A_n)$ which is nowhere tangent to

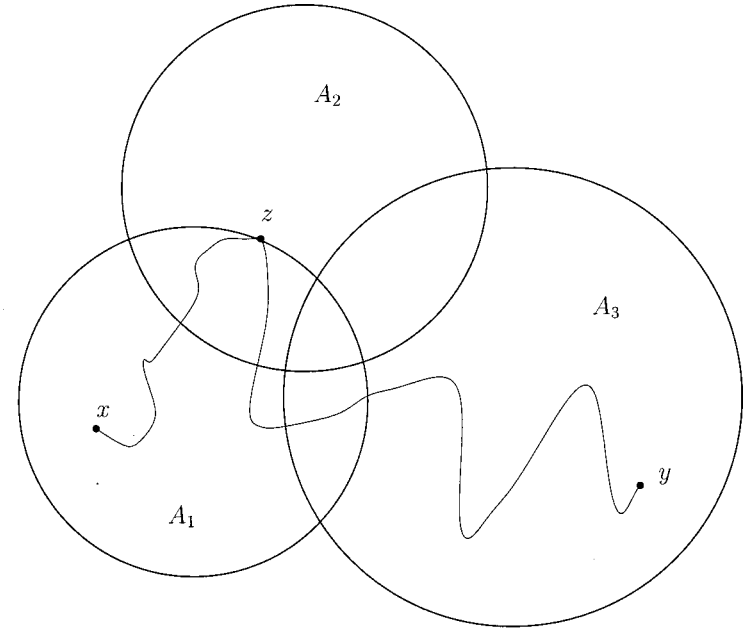

FIG. 2. A path from x to y which is tangent to A_1 at the point z. There are paths arbitrarily close to this path which are not in $Z(A_1,A_2,A_3)$.

any of the boundaries ∂A_i is an interior point of the set $Z(A_1,\ldots,A_n)$. This can be seen as follows: In addition to the s_i's, choose numbers $s_i' \in [0,1]$ such that $\tau_i < s_i' < s_i$ and $\omega(s_i') \notin \overline{A_i}$. Now choose $r>0$ smaller than each of the distances from $\omega(s_i')$ to $\overline{A_i}$. It then follows that a path $\overline{\omega'}$ within a distance r from $\overline{\omega}$ leaves A_i somewhere between s_i and s_i' and hence $\overline{\omega'} \in Z(A_1,\ldots,A_n)$ as before.

It is not hard to see that if $\overline{\omega} \in Z(A_1,\ldots,A_n)$ is tangent to one of the ∂A_i's then $\overline{\omega} \in \partial Z(A_1,\ldots,A_n)$, i.e., there are paths arbitrarily close to $\overline{\omega}$ that are not in $Z(A_1,\ldots,A_n)$, see Fig. 2.

We do not have a proof that the sets $Z(A_1,\ldots,A_n)$ are measurable for general open sets $A_1,\ldots,A_n$. We avoid this problem simply by taking the closures of these sets. We denote the closures by $\overline{Z}(A_1,\ldots A_n)$.

Proposition 5.2: The sets $\overline{Z}(A_1,\ldots,A_n)$ where the A_i's are open balls generate the Borel algebra of geometric paths.

Proof: We will show that any open set in $\overline{\Omega}(x,y)$ can be written as a countable union of $\overline{Z}$ sets. Given $\overline{\omega} \in \overline{\Omega}(x,y)$ and $\varepsilon>0$ we show that there are open balls $A_1,\ldots,A_n$ such that $\overline{\omega} \in \overline{Z}(A_1,\ldots,A_n)$ and $\overline{Z}(A_1,\ldots,A_n)$ is contained in a ball in $\overline{\Omega}(x,y)$ of radius ε centered on $\overline{\omega}$. Moreover, the A_i's can be taken to have rational centers and radii. It follows then by a standard argument that the $\overline{Z}$ sets generate the Borel algebra.

Let $\overline{\omega} \in U$ where $U \subseteq \overline{\Omega}(x,y)$ is open. Choose a rational number ε so that $\varepsilon < \frac{1}{2}\overline{d}(\overline{\omega},\partial U)$. Let A_1 be an open ball of radius ε centered at x. If $\overline{\omega}$ is not contained in A_1 let $x_1 \in \mathbb{R}^d$ be the point where $\overline{\omega}$ leaves A_1 for the first time, i.e., if $\omega:[0,1]\to\mathbb{R}^d$ is a parametrization of $\overline{\omega}$, then $x_1 = \omega(\tau_1)$, where

$$\tau_1 = \sup\{t \in [0,1]: \omega([0,t]) \subseteq A_1\}$$

as before. Take a point y_1 with rational coordinates such that $|x_1 - y_1| < \varepsilon/3$. Let A_2 be a ball of radius ε centered at y_1. If $\overline{\omega}$ stays inside A_2 after it leaves A_1 at x_1 the construction is finished; otherwise let x_2 be the point where $\overline{\omega}$ leaves A_2 for the first time after it left A_1 and x_1 and define

y_2 and A_3 in a way analogous to the one used to define y_1 and A_2. The construction continues in this way until we obtain a set A_n inside which $\overline{\omega}$ stays after it leaves A_{n-1}. The construction has to end after a finite number of steps since any parametrization ω of $\overline{\omega}$ is a uniformly continuous map.

From the above-given construction it is clear that $\overline{\omega} \in Z(A_1,\ldots,A_n)$. Moreover, if $\overline{\omega'}$ is another path in $Z(A_1,\ldots,A_n)$ then $\overline{d}(\overline{\omega},\overline{\omega'}) \leqslant 2\varepsilon$ because we can choose a parametrization ω' of $\overline{\omega'}$ such that the τ_i's coincide for ω and ω' and hence, for any $t \in [0,1]$, $\omega(t)$ and $\omega'(t)$ both belong to the same $A_j, j=1,\ldots,n$. We conclude that $Z(A_1,\ldots,A_n)$ and hence $\overline{Z}(A_1,\ldots,A_n)$ is contained in a closed ball in $\overline{\Omega}(x,y)$ of radius 2ε centered on $\overline{\omega}$. This ball is contained in U and the proof is complete. □

We remark that the proof of the above-mentioned result can of course be adapted to the case where the sets A_i are boxes in $\mathbb{R}^d$ rather than balls.

VI. INTEGRATING OVER CYLINDER SETS

In this section we show that the lattice approximation to the measure of the $\overline{Z}$ sets converges and we derive some formulas for the measure of these sets in terms of Dirichlet propagators.

Let A be a bounded set in $\mathbb{R}^d$ with a smooth boundary. Let x and y be two different points in the interior of A. We recall that the Dirichlet Green function for $\frac{1}{2}(-\Delta + m^2)$ with data on ∂A, denoted $G_A^D(x,y)$, is given by the Wiener integral over all paths from x to y that avoid ∂A. This fact is established in, e.g., Ref. 11 for the corresponding heat kernel and hence follows for the propagator by integrating over time.

In the following discussion the end points x and y will be kept fixed and for simplicity we denote the measure $V_{x,y}$ by μ. Accordingly we can write

$$G_A^D(x,y) = \int_{\overline{Z}(A)} \mathrm{d}\mu = \mu(\overline{Z}(A)). \tag{47}$$

We are interested in generalizing this formula to the case of $\overline{Z}(A_1,\ldots,A_n)$ with $n>1$ and showing that

$$\lim_{a\to 0} V_{x,y,a}(\overline{Z}(A_1,\ldots,A_n)) = \mu(\overline{Z}(A_1,\ldots,A_n)). \tag{48}$$

In order to minimize technical complications let us assume that the sets A_i are boxes so their boundaries are contained in hyperplanes.

Let us consider a family of boxes $A_1,\ldots,A_n$ in $\mathbb{R}^d$ with the property that the intersection of any two different boundaries ∂A_i and ∂A_j has codimension 2 or greater, i.e., the boundaries never overlap. Let us define O_1 as the collection of all paths in $\overline{\Omega}(x,y)$ that are somewhere tangent to one of the hyperplanes that make up the boundaries of the A_i's. Let O_2 be the collection of all paths in $\overline{\Omega}(x,y)$ that meet one or more of the intersections $\partial A_i \cap \partial A_j$, $i \neq j$. Put $O = O_1 \cup O_2$. It can be checked that the set of paths that are somewhere tangent to a given hyperplane is a measurable set with measure zero. It has measure zero since the probability that a Wiener path intersects a hyperplane exactly once in a time interval is zero, see, e.g., Ref. 12, Chap. 12. The set O_2 is easily seen to be closed and hence measurable. Its measure is zero since the codimension of the intersections $\partial A_i \cap \partial A_j$ is greater than 1. Thus, O is a measurable set with measure 0. The boundary of $Z(A_1,\ldots,A_n)$ consists of paths for which either two of the τ_i 's coincide or the path is tangent to one of the boundaries ∂A_i. Hence, $\partial\overline{Z}(A_1,\ldots,A_n) \subseteq \partial Z(A_1,\ldots,A_n) \subseteq O$. *We can therefore conclude from Ref. 9 Theorem 2.1 that the convergence (48) takes place for boxes* and the argument can be extended to the case of A_i's with piecewise smooth boundaries.

Let us now turn to the calculation of the measure of the $\overline{Z}$ sets. Let A be as before. Since $G_A^D(x,z) = 0$ for $z \in \partial A$ we have

$$\int_{\partial A}\frac{\partial}{\partial n}(G_A^D(x,z)G(z,y))\mathrm{d}S=\int_{\partial A}\frac{\partial G_A^D}{\partial n}(x,z)G(z,y)\mathrm{d}S, \tag{49}$$

where $\partial/\partial n$ is the normal derivative to ∂A with respect to z. Let Y_A be the collection of all paths from x to y which hit the boundary ∂A. An application of the divergence theorem and Eq. (47) lead to

$$\mu(Y_A)=\int_{\partial A}\frac{\partial G_A^D}{\partial n}(x,z)G(z,y)\mathrm{d}S. \tag{50}$$

More generally, it can be argued that

$$P_A(z)=\frac{\partial G_A^D}{\partial n}(x,z)G(z,y) \tag{51}$$

is [up to the constant factor $\mu(Y_A)$] the *conditional probability density* that a path from x to y which hits the boundary ∂A hits it for the first time at the point $z\in\partial A$, and $P_A(z)$ is given by an integral over all paths from x to y which hit the boundary of A and hit it for the first time in z.

It is convenient to extend the Dirichlet Green functions G_A^D to all of $\mathbb{R}^d$ such that they are 0 outside A. Let us now consider the case $x\in A_1$, $y\in A_2\backslash A_1$, $A_1\cap A_2\neq\varnothing$. Then the measure of $\overline{Z}(A_1,A_2)$ is the integral over all paths from x to y which leave A_1 for the first time at a point $z\in\partial A_1\cap A_2$ and stay in A_2 after they leave A_1. The integral over these paths is obtained by analogy with Eq. (50) as

$$\mu(\overline{Z}(A_1,A_2))=\int_{\partial A_1}\frac{\partial G_{A_1}^D}{\partial n}(x,z)G_{A_2}^D(z,y)\mathrm{d}S \tag{52}$$

and

$$\frac{\partial G_{A_1}^D}{\partial n}(x,z)\frac{G_{A_2}^D(z,y)}{\mu(\overline{Z}(A_1,A_2)}} \tag{53}$$

is the conditional probability density that a path in $\overline{Z}(A_1,A_2)$ leaves A_1 for the first time in the point z.

It is straightforward to generalize the above-mentioned considerations to the case of arbitrary n, i.e., $\overline{Z}(A_1,\ldots,A_n)$. By the Markov property of the Brownian paths we have

$$\mu(\overline{Z}(A_1,\ldots,A_n))=\int_{\partial A_1}\cdots\int_{\partial A_{n-1}}\prod_{i=1}^{n-1}\frac{\partial G_{A_i}^D}{\partial n_i}(z_{i-1},z_i)G_{A_n}^D(z_{n-1},y)\mathrm{d}S_1\ldots\mathrm{d}S_{n-1}, \tag{54}$$

where we have set $z_0=x$ and $\partial/\partial n_i$ denotes the normal derivative to ∂A_i with respect to z_i. In this integral formula z_i is the point where the path first leaves A_i after hitting $A_1,\ldots,A_{i-1}$ in that order.

We note that for $n=1$ the convergence (48), i.e., the convergence of the lattice approximations to the Dirichlet propagators is well known for sufficiently nice sets A. This convergence can also be proved directly without the use of measure theory. We also note that all the integration formulas given previously have clear lattice analogs for arbitrary n.

VII. CONCLUSION

We have in this paper defined integration over geometric paths and studied natural discretized measures on spaces of such paths. Two different discretizations were discussed, one with a metric degree of freedom and one without. We have proven the convergence of the discretized measures

and thereby in particular established the convergence of the discrete approximations to the integrals over paths that one is normally interested in for physics applications. We furthermore introduced, in the case without a metric degree of freedom, a natural class of sets of geometric paths which play the role of cylinder sets and generate the Borel algebra and we have shown how to calculate the measure of these sets in terms of Dirichlet propagators.

One, perhaps disappointing but not entirely unexpected, outcome of our analysis is that no technical simplifications are obtained by considering only parametrization independent quantities, i.e., by restricting to inherently physical degrees of freedom. In particular, it is hard to get a technical handle on geometric paths without introducing parametrizations to calculate with as is usually done in theories with a local gauge invariance.

One of the main motivations for this study was to obtain some insight into the corresponding problem for random surfaces. The random surface case is far more difficult than the one considered in this paper since the measures on parametrized surfaces which correspond to Wiener measure on paths are not well understood. Some of the ideas we have discussed here can be carried over to embedded surfaces but modifications would be needed since points on a geometric surface cannot be ordered like the points on a geometric path. For nonimbedded surfaces a new approach is required. In the absence of imbedding degrees of freedom, points on the surface have to be identified in terms of intrinsic geometric degrees of freedom like curvature. How to do this in a systematic fashion is far from obvious.

It is well-known that the equations for a simple fluid can be cast into what is called their Lagrange formulation. We introduce a notion of a generalized Lagrange formulation, which is applicable to a wide variety of systems of partial differential equations. These include numerous systems of physical interest, in particular, those for various material media in general relativity. There is proved a key theorem, to the effect that, if the original (Euler) system admits an initial-value formulation, then so does its generalized Lagrange formulation. © *2001 American Institute of Physics.* [DOI: 10.1063/1.1364502]

I. INTRODUCTION

Consider a simple perfect fluid in general relativity. That is, fix a space-time—a 4-dimensional manifold M with metric g_{ab} of Lorentz signature $(-,+,+,+)$. The fluid is described thereon by two fields, a unit timelike vector field u^a (which is interpreted as the velocity field of the fluid), and a scalar field ρ (which is interpreted as its mass density). These fields must satisfy the fluid equations,

$$(\rho+p)u^m\nabla_m u^a=-(g^{am}+u^a u^m)\nabla_m p, \tag{1}$$

$$\nabla_m(\rho u^m)=-p\nabla_m u^m. \tag{2}$$

Here p is specified as some fixed function of ρ, the function of state.

This treatment is usually called the Euler formulation of a fluid. Its characteristic feature is that the fluid is described by means of fields on space–time. That is, the ''independent variable'' in this formulation—the thing the fields are functions of—is the event of space-time. There is an alternative treatment of a fluid, called the Lagrange formulation, in which we ''move with the fluid, rather than remain fixed in space–time.'' In other words, the independent variable in this formulation is the fluid-element, and so the fluid is described by fields that are functions on the manifold of fluid-elements.[1]

Each of these two formulations has its advantages. The Euler formulation is less tightly tied down to the fluid itself, and so is usually more convenient when other systems—which would naturally be described with reference to space–time—are involved. In particular, the Euler formulation is normally used for a fluid in interaction with other fields, as, for example, in the Einstein-fluid system. The Lagrange formulation, by contrast, tends to be more convenient when one wishes to identify and follow individual fluid elements. For example, the Lagrange formulation might be used to describe a fluid object with a boundary. The boundary, in this formulation,

[a)]Electronic mail: geroch@midway.uchicago.edu
[b)]Fellowship of the Regional Center, France. Electronic mail: nagy@gargan.math.univ-tours.fr
[c)]Member of CONICET. Electronic mail: reula@fis.uncor.edu

would be fixed once and for all at the beginning (by designating those fluid-elements that constitute the boundary) as part of the kinematical structure. In the Euler formulation of such an object, by contrast, the boundary would be ''dynamical.''

How are the Euler and Lagrange formulations related to each other? Certainly, the two are physically equivalent, i.e., they represent mere mathematical reformulations of the same physics. That is, all physical predictions will be the same, no matter which formulation is used; and, at least in principle, either formulation could be used to solve any given problem. Indeed, one might be tempted to go further than this, to view them as related by a mere coordinate transformation on the manifold of independent variables. But such a viewpoint would be misleading, for the ''coordinate transformation'' between the two sets of variables involves the dynamics of the system. Thus, for example, from the standpoint of the Euler formulation the Lagrange formulation represents a curious mixing of kinematics with dynamics.

These mathematical differences in fact go even deeper. It is well-known that the equations for a perfect fluid in the Euler formulation, Eqs. (1)–(2), have a well-posed initial-value formulation.[3] But the corresponding equations in the Lagrange formulation—at least, those obtained directly, by simply ''transforming'' the Euler equations—do not.[5] However, it has been shown by Friedrich, in Ref. 17, that, at least for a certain fluid system in general relativity, there *can* be introduced a Lagrange formulation having also an initial-value formulation. It is necessary, in Friedrich's treatment, to introduce a substantial number of additional fields (including a frame-field) together with additional equations on those fields. What is not so transparent, however, is the mechanism behind this treatment. Precisely what features of these fluid systems are needed for such a deterministic Lagrange formulation?

Our purpose in this paper is to introduce and explore a certain, broad, geometrical setting for the Lagrange formulation of systems of partial differential equations.

In Sec. II, we introduce that setting. Our framework is systems of partial differential equations that are first-order and quasi-linear (i.e., involving only first derivatives of the fields, and those only linearly)—a framework that includes virtually every partial differential equation in physics. Given any such system—provided only that it has among its fields a distinguished vector field—we write out a new system, its ''Lagrange formulation.'' The key idea of this scheme is what one might expect: Include, among the dynamical variables of the new system, what were the independent variables of the original system. It turns out that, in order to execute this scheme, it is normally necessary to introduce additional dynamical variables and equations. We give a general scheme for choosing these variables. The key result of this section is the following: Given any system of partial differential equations having a distinguished vector field as above, and also having an initial-value formulation, then a certain version of its Lagrange formulation also has an initial-value formulation.

In Sec. III, we give some examples of this scheme. We apply the present scheme not only to ordinary fluids, but also to various other types of material systems, including dissipative fluids and elastic solids. This scheme is also applicable when such material systems are undergoing interaction, e.g., when they are coupled to an electromagnetic or gravitational field. Finally, we show in Sec. III how Friedrich's original system fits within the present framework.

A number of related mathematical issues are discussed in the appendices. In Appendix A, we describe a general procedure for modifying any system of partial differential equations by ''taking derivatives'' of the fields of that system. This procedure, it turns out, is crucial for casting systems into a form in which our Lagrange formulation can be applied. In Appendix B, we review a few facts about the initial-value formulation of systems of partial differential equations. (For a more detailed treatment, see, for example, Ref. 2.)

II. LAGRANGE FORMULATION

Fix a first-order, quasilinear system of partial differential equations. That is, let there be given a fiber bundle, consisting of some base manifold M, some bundle manifold $\mathcal{B}$, and some smooth projection mapping $\mathcal{B}\overset{\pi}{\to}M$. Typically, M will be the 4-dimensional manifold of space–time

events (but it could be any smooth manifold). By the *fiber* over a point x of M, we mean the set of all points y of $\mathcal{B}$ such that $\pi(y)=x$. Think of the fiber over $x\in M$ as ''the set of possible field-values at x.'' Then $\mathcal{B}$ is interpreted as the set of ''all possible choices of field-values at all points of M,'' and π as the mapping that assigns, to each such choice, the underlying point of M. Thus, point y of $\mathcal{B}$ could be written as $y=(x,\phi)$, with $x\in M$ and ϕ in the fiber over x. The action of the projection mapping would then be given by $\pi(x,\phi)=x$. Typically, the fiber over a point $x\in M$ will be some collection of tensors, with given index structure (possibly subject to various algebraic conditions), at x, whence $\mathcal{B}$ will be a manifold of all such tensor-collections at all points of M. In this case, $\mathcal{B}$ is called a *tensor bundle*. However, $\mathcal{B}$ could in general be any smooth manifold, subject only to the local-product condition in the definition of a fiber bundle.[6]

By a *cross-section* of such a bundle we mean a smooth mapping $M\overset{\phi}{\rightarrow}\mathcal{B}$ such that $\pi\circ\phi$ is the identity map on M. In other words, a cross-section assigns, to each point x of M, a point of the fiber over x; i.e., it assigns a ''field-value'' at each point of M. In the case of a tensor bundle, a cross-section is simply a certain collection of smooth tensor fields on M. Our partial differential equation will be an equation on this map, linear in its first derivative. In order to write out this equation, we introduce two smooth fields, ${k^{Aa}}_{\alpha}$ and j^{A}, on $\mathcal{B}$. Since these are fields on $\mathcal{B}$, they depend on point $y=(x,\phi)$ of $\mathcal{B}$, i.e., they depend on a choice of ''point x of the base manifold, as well as field-value ϕ at that point.'' The index ''α'' on ${k^{Aa}}_{\alpha}$ is a tensor index in $\mathcal{B}$ at the point, $y\in\mathcal{B}$, at which this field is evaluated; the index ''a'' is a tensor index in M at the corresponding point, $\pi(y)$, of the base manifold. The index ''A,'' on both ${k^{Aa}}_{\alpha}$ and j^{A}, lies in some new vector space (which will turn out, shortly, to be the vector space of equations). Finally, our partial differential equation, on a cross-section ϕ, is

$$ {k^{Aa}}_{\alpha}(\nabla\phi)_{a}{}^{\alpha}=j^{A}. \tag{3}$$

This equation is to be imposed at each point $x\in M$, with the fields k and j evaluated at $\phi(x)\in\mathcal{B}$, i.e., on the cross-section. Here, $(\nabla\phi)_{a}{}^{\alpha}$ denotes the derivative of the map ϕ [i.e., a map from tangent vectors in M at x to tangent vectors in $\mathcal{B}$ at $\phi(x)$]. The index ''A'' in Eq. (3) is free, i.e., Eq. (3) represents a number of scalar equations equal to the dimension of the vector space in which ''A'' lies.

Here is an example. Fix a 4-dimensional manifold M, together with a Lorentz-signature metric g_{ab} on this M. Let $\mathcal{B}$ be the 8-manifold consisting of triples, (x,u^{a},ρ), where x is a point of M, u^{a} is a unit timelike vector at x, and ρ is a number. Let $\pi(x,u^{a},\rho)=x$. This is a fiber bundle; in fact, a tensor bundle. The fiber over a point $x\in M$ consists of (u^{a},ρ), a vector at x together with a number. A cross-section of this bundle is represented by smooth fields, u^{a} and ρ, on M. Let the equations, on such a cross-section, be (1)–(2), where $p(\rho)$ is some given, fixed function of one variable, and ∇_{a} is the derivative operator defined by the space–time metric g_{ab}. This is a first-order, quasilinear system of partial differential equations, i.e., the equations are linear in the first derivatives of the fields. The vector space of equations, in this example, has dimension four. This system, of course, describes a simple perfect fluid in general relativity.

We shall now introduce a technique that transforms a given first-order, quasilinear system of partial differential equations—provided that system lies within a certain class—into a new first-order, quasilinear system of partial differential equations. This new system will be called the *Lagrange formulation* of the original. While the new system will differ in many respects from the original one—e.g., it will have a different base manifold, a different bundle manifold, and a different number of equations—the two will be intimately related to each other. In particular, it will turn out that there is a natural correspondence between the solutions of the original system and those of its Lagrange formulation.

In order to apply this technique to a given system of equations, it is necessary that that system satisfy the following condition: Among the various fields of the system there must be distinguished one consisting of a nowhere-vanishing vector field on the base manifold M. This condition means, then, that the fields of our system take the form (u^{a},φ), where u^{a} represents the

nowhere-vanishing vector field on M, and φ represents ''the rest of the fields.'' Thus, given a system that has, among its various fields, no vector field at all, then we shall be unable to write out any Lagrange formulation for it; and if it has several vector fields, then we must, at this stage, distinguish a particular one. We shall denote by $B \overset{\pi}{\to} M$ the bundle in which the rest of the fields, the φ, lie, and use Greek indices for tensors in the manifold B. Note that these are *different* from the Greek indices, e.g., in Eq. (3), for tensors in the manifold $\mathcal{B}$. The equation for our system may now be written as

$$k'^{Aa}{}_{b}\nabla_a u^b + k''^{Aa}{}_{\alpha}(\nabla\varphi)_a{}^{\alpha} = j^A, \tag{4}$$

where $k'^{Aa}{}_{b}$, $k''^{Aa}{}_{\alpha}$, and j^A are all functions of u^a, φ, and point of M. In Eq. (4), the ∇_a in the first term can be any derivative operator on M; and the form of j^A depends, of course, on what operator has been chosen. We could, for example, simply fix, once and for all, some derivative operator ∇_a, and use it to write Eq. (4). Should it happen that the manifold M comes equipped with a kinematical metric (i.e., one not included among the physical fields φ), then it is often convenient to use its derivative operator in Eq. (4). This possibility is available, e.g., for systems representing fluids in special relativity, or in general relativity with a fixed background metric. In fact, we could even choose the derivative operator ∇_a in Eq. (4) to depend on the fields (u^a, φ) themselves, provided only that its dependence on these fields is algebraic, rather than through their derivatives. We now obtain the Lagrange formulation of this system.

For the base manifold of the Lagrange formulation, we choose any manifold $\hat{M}$ having the same dimension as M. Tensors over this $\hat{M}$ will be denoted by lower-case Latin indices with hats. We also fix, once and for all on this manifold $\hat{M}$, a nowhere-vanishing vector field, $\hat{u}^{\hat{a}}$. This $\hat{u}^{\hat{a}}$ is a purely kinematical object, i.e., it is fixed right at the beginning, and will not be subject to any dynamical equations.

We next specify the bundle manifold, $\hat{\mathcal{B}}$, of the Lagrange formulation. Fix a point, $\hat{x}$, of the base manifold $\hat{M}$. Let the fiber over this point consist of a triple, $(x, \varphi, \kappa_{\hat{a}}{}^{b})$, where (i) x is a point of M, the base manifold of the original system, (ii) φ is a point of the fiber over x in B, the bundle manifold for the original system, and (iii) $\kappa_{\hat{a}}{}^{b}$ is an invertible tensor, where the index ''$\hat{a}$'' refers to tensors in $\hat{M}$ at the point $\hat{x} \in \hat{M}$ and the index ''b'' refers to tensors in M at the point $x \in M$. A more detailed discussion of these three objects follows.

(i) The points (x) of the base manifold M of the original system become, in its Lagrange formulation, *field-values*. In the case of a simple perfect fluid, for example, each point of the original base manifold M represents an event of space–time; while each point of the new base manifold $\hat{M}$ represents ''a particular fluid-element at a particular moment of its life.'' Thus, in the Lagrange formulation of such a fluid, x will be a field over $\hat{x}$, a field that specifies ''which event in space–time that particular fluid-element occupies at that particular moment.''

(ii) The field-values, the φ, of the original system become field-values also in its Lagrange formulation. But there is one important change: What were fields over M in the original system become, in its Lagrange formulation, fields over $\hat{M}$. Thus, were the fields collected in φ all tensor fields on M, then the corresponding fields in the Lagrange formulation would depend on point $\hat{x}$ of $\hat{M}$, but would continue to be tensors in the tangent space at the point x of M.[7] In the case of a simple perfect fluid, this step amounts, physically, to ''attaching the density ρ to the fluid element, rather than to the point of space–time.''

(iii) There is introduced a new object, $\kappa_{\hat{a}}{}^{b}$, an invertible two-point tensor, with one index at $\hat{x} \in \hat{M}$, the other at $x \in M$. Nothing analogous was present in the original system. Denote the inverse of $\kappa_{\hat{a}}{}^{b}$ by $\overline{\kappa}_{b}{}^{\hat{a}}$, so we have $\kappa_{\hat{a}}{}^{b}\overline{\kappa}_{b}{}^{\hat{c}} = \delta_{\hat{a}}{}^{\hat{c}}$ and $\overline{\kappa}_{b}{}^{\hat{a}}\kappa_{\hat{a}}{}^{c} = \delta_{b}{}^{c}$. The role of this tensor $\kappa_{\hat{a}}{}^{b}$ is, as we shall see, to preserve the first-order character of the final system of

equations. Note that the dynamical field u^a in the original system has disappeared entirely: There is no analog of it as a dynamical field in the Lagrange formulation.

Next note that the pair (x,φ), where x is a point of M and φ is a point of the fiber in B over x, is precisely the same thing as a point of the bundle manifold B. Call that point (for later convenience) $\hat{\varphi}$, so we have $\hat{\varphi}=(x,\varphi)\in B$. Then we may recover the point x of the original base-manifold from the point $\hat{\varphi}\in B$ using the projection π: We have $x=\pi(\hat{\varphi})$. Thus, our construction of the bundle manifold $\hat{\mathcal{B}}$ for the Lagrange formulation could have been stated as follows: The fiber over point $\hat{x}\in\hat{M}$ consists of a pair, $(\hat{\varphi},\kappa_{\hat{a}}{}^{b})$, where $\hat{\varphi}$ is a point of the manifold B, and $\kappa_{\hat{a}}{}^{b}$ is an invertible tensor with one index at $\hat{x}\in\hat{M}$, the other at $\pi(\hat{\varphi})\in M$.

We have now completed the specification of the fiber bundle in which the Lagrange formulation of our system will be written. The base manifold, $\hat{M}$, is some new manifold, of the same dimension as M, while the bundle manifold $\hat{\mathcal{B}}$ is such that the fiber over $\hat{x}\in\hat{M}$ consists of a pair, $(\hat{\varphi},\kappa_{\hat{a}}{}^{b})$, where $\hat{\varphi}\in B$, and $\kappa_{\hat{a}}{}^{b}$ is a certain 2-point tensor. A cross-section of this bundle, then, is a smooth map (a map we also denote by $\hat{\varphi}$) that assigns, to each point $\hat{x}\in\hat{M}$, a point $\hat{\varphi}$ of B together with a suitable tensor $\kappa_{\hat{a}}{}^{b}$. On such a cross-section, we now impose the following equations:

$$(\nabla(\pi\circ\hat{\varphi}))_{\hat{a}}{}^{b}=\kappa_{\hat{a}}{}^{b}, \tag{5}$$

$$\nabla_{[\hat{c}}(\kappa_{\hat{a}]}{}^{b})=f_{\hat{c}\hat{a}}{}^{b}, \tag{6}$$

$$k'^{Aa}{}_{b}\overline{\kappa}_{a}^{\hat{d}}\nabla_{\hat{d}}(\kappa_{\hat{c}}{}^{b}\hat{u}^{\hat{c}})+k''^{Aa}{}_{\alpha}\overline{\kappa}_{a}^{\hat{c}}(\nabla\hat{\varphi})_{\hat{c}}{}^{\alpha}=j^{A}. \tag{7}$$

These are the equations of the Lagrange formulation. In Eq. (5), the combination $\pi\circ\hat{\varphi}$ is a map from $\hat{M}$ to M, for $\hat{\varphi}$ goes from $\hat{M}$ to B, and π from B down to M. Equation (5) asserts that the derivative of this map is precisely the tensor $\kappa_{\hat{a}}{}^{b}$. Thus, this equation provides the geometrical meaning of the field $\kappa_{\hat{a}}{}^{b}$. Note that invertibility of $\kappa_{\hat{a}}{}^{b}$ in Eq. (5) implies that the map $\pi\circ\hat{\varphi}$ from $\hat{M}$ to M is a local diffeomorphism between these two manifolds. It was to achieve this feature that we originally choose $\hat{M}$ to have the same dimension as M. Equation (6) is merely the curl[8] of Eq. (5). Any derivative[9] may be used on the left in Eq. (6), but the exact form of the function $f_{\hat{c}\hat{a}}{}^{b}$ [of $(\hat{\varphi},\kappa_{\hat{a}}{}^{b})$] that appears on the right will depend on which derivative was chosen. This situation is analogous to that of Eq. (4). Equation (7) is the translation of the equation of the original system (4) to our new system. Here, everywhere in the fields $f_{\hat{c}\hat{a}}{}^{b}$, $k'^{Aa}{}_{b}$, $k''^{Aa}{}_{\alpha}$, and j^{A} there is to be substituted the combination ''$\kappa_{\hat{a}}{}^{b}\hat{u}^{\hat{a}}$'' for ''$u^{b}$;'' and ''$\hat{\varphi}$'' for ''$\varphi$.'' In Eq. (7), this ''replacement'' takes place even inside the derivative. Note that the field u^{b} of the original system has now disappeared entirely, having been replaced by the image of the kinematical field $\hat{u}^{\hat{b}}$ under the mapping $\pi\circ\hat{\varphi}$.

Thus, beginning with any first-order, quasilinear system of partial differential equations of the form (4), we obtain a new system of equations, its Lagrange formulation, of the form (5)–(7). The Lagrange formulation has a completely new base space, but fields and equations that echo those of the original system.

We now claim the following: Every solution of the Lagrange formulation gives rise, at least locally, to a solution of the original system. Indeed, let $(\hat{\varphi},\kappa_{\hat{a}}{}^{b})$ be fields satisfying (5)–(7). Then, as we have seen, $\pi\circ\hat{\varphi}$ is a local diffeomorphism between $\hat{M}$ and M. We now introduce the following two fields on M: $u^{b}=(\nabla(\pi\circ\hat{\varphi}))_{\hat{a}}{}^{b}\hat{u}^{\hat{a}}$, and $\varphi=\hat{\varphi}\circ(\pi\circ\hat{\varphi})^{-1}$. That is, we let u^{b} and φ be the images of $\hat{u}^{\hat{b}}$ and $\hat{\varphi}$, respectively, under the diffeomorphism $\pi\circ\hat{\varphi}$. Then these fields, (u^{b},φ), on M satisfy the system (4), as is immediate from Eqs. (5), (7). We next claim that the converse also holds: Every solution of the original system gives rise, at least locally, to a solution of its Lagrange formulation. Indeed, let (u^{b},φ) be fields satisfying (4). Choose any manifold $\hat{M}$ with the same dimension as that of M, and any nowhere-vanishing vector field $\hat{u}^{\hat{a}}$ thereon. Now let $\hat{\varphi}$ be

a diffeomorphism between $\hat{M}$ and the cross-section, $\varphi[M]$, such that $(\pi\circ\hat{\varphi})$ sends $\hat{u}$ to u; and then define $\kappa_{\hat{a}}{}^{b}$ by Eq. (5). Then these fields $(\hat{\varphi},\kappa_{\hat{a}}{}^{b})$ on $\hat{M}$ will satisfy Eqs. (5)–(7) [the first two by construction, the last by Eq. (4)].

Thus, the original system and its Lagrange formulation are identical as to solutions. But the two systems are quite different as to form. Their base manifolds, $\hat{M}$ and M, although of the same dimension, differ in their geometry. The manifold $\hat{M}$ must be endowed with a fixed, kinematical ''velocity field,'' $\hat{u}^{\hat{a}}$, while M has no such kinematical field. On the other hand, various kinematical fields that might have been specified over M (such as a Lorentz metric) yield no analogous kinematical fields[10] on $\hat{M}$. Furthermore, the fields of the two systems differ in several respects. Beginning with the fields of the original system, we must delete the dynamical field u^{a}, while adding ''point of M'' as well as the invertible tensor $\kappa_{\hat{a}}{}^{b}$, to obtain the fields of the Lagrange formulation. Finally, the equations for the two systems differ in that, for the Lagrange formulation, there must be introduced one new equation (5) on the derivative of the ''point of M,'' as well as is the curl (6) of this new equation.

What we have described above is precisely what is usually done in writing down the Lagrange formulation for a fluid. For example, consider again the simple perfect fluid, with fields (u^{a},ρ) on M and Eqs. (1)–(2). Its Lagrange formulation consists of fields[11,12] $(x,\kappa_{\hat{b}}{}^{a},\hat{\rho})$ on $\hat{M}$, with equations consisting of (5), (6), and

$$(\hat{\rho}+p(\hat{\rho}))\hat{u}^{\hat{c}}\nabla_{\hat{c}}(\kappa_{\hat{m}}{}^{a}\hat{u}^{\hat{m}})+(g^{am}+\hat{u}^{\hat{c}}\kappa_{\hat{c}}{}^{a}\hat{u}^{\hat{n}}\kappa_{\hat{n}}{}^{m})\overline{\kappa}_{m}{}^{\hat{b}}\nabla_{\hat{b}}p(\hat{\rho})=0, \tag{8}$$

$$\hat{u}^{\hat{b}}\nabla_{\hat{b}}\hat{\rho}+(\hat{\rho}+p(\hat{\rho}))\overline{\kappa}_{a}{}^{\hat{b}}\nabla_{\hat{b}}(\kappa_{\hat{m}}{}^{a}\hat{u}^{\hat{m}})=0. \tag{9}$$

We now return to the general case. It turns out that the procedure given above—starting with a system and ending with its Lagrange formulation—suffers from a serious difficulty. In general, the equations of the Lagrange formulation, (5)–(7), will fail to have an initial-value formulation, even if the original system, (4), did have such a formulation. For example, the system (5)–(6), (8)–(9) has no initial-value formulation, although the system (1)–(2) of course does. But it turns out that this difficulty does not arise—i.e., the Lagrange formulation does inherit an initial-value formulation from the original system—provided the original system satisfies the following condition: There can be derived from Eq. (4) an expression for the derivative of the vector field u^{a}, without contractions, back in terms of the various fields of the system. In other words, it must be possible to cast Eq. (4) into the form

$$\nabla_{a}u^{b}=w_{a}{}^{b}, \tag{10}$$

$$k''^{Aa}{}_{\alpha}(\nabla\varphi)_{a}{}^{\alpha}=j'^{A}, \tag{11}$$

where $w_{a}{}^{b}$, $k''^{Aa}{}_{\alpha}$, and j'^{A} are functions of (x,u^{a},φ), i.e., are functions of the point of B and the vector u^{a}. In Eq. (10), ∇_{a} can, again, be any derivative operator on the manifold M; and the form of $w_{a}{}^{b}$ depends, of course, on what operator has been chosen. Note that, once we have derived from Eq. (4) an equation of the form (10), then it is easy to cast the equations that remain into the form (11): Simply use Eq. (10) to remove all u-derivatives from Eq. (4). Indeed, we have $j'^{A}=j^{A}-k'^{Aa}{}_{b}w_{a}{}^{b}$.

The equations for systems of physical interest typically do *not* take the form of Eqs. (10)–(11), i.e., they do not express the derivative of u^{a} in terms of the other fields. For example, Eqs. (1)–(2) do not have this form. But it turns out that there is a simple, general procedure by which *any* first-order, quasilinear system of partial differential equations having a preferred vector field u^{a} can be recast so as to take the form (10)–(11). This procedure, called taking the *derivative system*, is spelled out in Appendix A. It consists of modifying the original system by introducing additional fields, which represent the derivatives of the original fields, as well as additional equations on those fields. The result of taking the derivative system is to produce a new system of

partial differential equations, having, in an appropriate sense, identical solutions to the original. Applied to a system in which a preferred vector field u^a has been distinguished, it produces a system in which $\nabla_a u^b$ is expressed back in terms of the fields of the system. Furthermore, applied to any system having an initial-value formulation, the derivative system also has an initial-value formulation.

As an example of this procedure, we return to the system, (1)–(2), for a simple perfect fluid in general relativity. For the distinguished nowhere-vanishing vector field in this case, we choose, of course, the velocity field u^a of the fluid. The result of taking the derivative system of this system is the following. The fields consist of $(u^a,\rho,w_a{}^b,v_a)$, where u^a is a unit timelike vector field, ρ a positive scalar field, $w_a{}^b$ a tensor field satisfying $g_{ab}u^a w_c{}^b=0$, and v_a a vector field, all subject to the algebraic conditions

$$(\rho+p)u^m w_m{}^a+(g^{am}+u^a u^m)(\partial p/\partial\rho)v_m=0, \tag{12}$$

$$u^m v_m+(\rho+p)w_m{}^m=0. \tag{13}$$

On these fields is imposed the following system of first-order, quasilinear partial differential equations:

$$\nabla_a u^b=w_a{}^b, \tag{14}$$

$$\nabla_{[a}w_{b]}{}^c=R_{abm}{}^c u^m, \tag{15}$$

$$\nabla_a\rho=v_a, \tag{16}$$

$$\nabla_{[a}v_{b]}=0. \tag{17}$$

Note what has happened here. We have introduced two new fields, $w_a{}^b$ and v_a. The ''interpretation'' of $w_a{}^b$ [via (14)] is as the derivative of u^b; and of v_a [via (16)] as the derivative of ρ. The original fluid equations, (1)–(2), have been converted into algebraic conditions, (12)–(13), on these new fields. That is, the original fluid equations serve merely to define the bundle of fields for this new system. Finally, the new system contains two other equations, Eqs. (15) and (17), that are merely the curls of Eqs. (14) and (16), respectively.

In short, our ''procedure'' has done nothing of substance. But note that, starting with a system (1)–(2), which fails to express $\nabla_a u^b$ in terms of the fields of the system, our procedure produces a new system satisfying, via (14), this condition. Furthermore—and this is perhaps the striking feature—the system (14)–(17) inherits from the original fluid system, (1)–(2), its initial-value formulation.

The key result of this section is the following: *Consider any system (4) of partial differential equations in which there has been selected a preferred vector field u^a. Let (i) that system have an initial-value formulation, and (ii) the equations of that system express the derivative of u^a in terms of the fields of the system [as in (10)–(11)]. Then the Lagrange formulation of that system also admits an initial-value formulation.*

First note that the Lagrange formulation of the system (10)–(11) consists of Eqs. (5)–(6), together with

$$\overline{\kappa}_a{}^{\hat{c}}\nabla_{\hat{c}}(\kappa_{\hat{m}}{}^b\hat{u}^{\hat{m}})=w_a{}^b, \tag{18}$$

$$k''^{Aa}{}_{\alpha}\overline{\kappa}_a{}^{\hat{b}}(\nabla\hat{\varphi})_{\hat{b}}{}^{\alpha}=j'^A. \tag{19}$$

As discussed in Appendix B, in order that a general first-order, quasilinear system of partial differential equations have an initial-value formulation it is necessary that it satisfy three conditions: (i) the system admits a hyperbolization; (ii) all the constraints of the system are integrable,

and (iii) the system has the correct number of equations relative to the number of its unknowns. What these conditions mean is also explained in Appendix B. We check these three conditions in turn.

Let the original system, Eqs. (10)–(11), admit a hyperbolization. Then the construction that, applied to Eqs. (10)–(11) to obtain a bilinear expression in $\delta\varphi^{\alpha}$ yields, when applied to Eqs. (18)–(19), a corresponding bilinear expression in $\delta\hat{\varphi}^{\hat{\alpha}}$. Next, contract Eq. (6) with $\hat{u}^{\hat{c}}$ and use Eq. (18) to obtain an equation expressing $\hat{u}^{\hat{m}}\nabla_{\hat{m}}\kappa_{\hat{a}}{}^{b}$ algebraically in terms of the fields. From this there follows immediately an appropriate bilinear expression in $\delta\kappa_{\hat{a}}{}^{b}$. Finally, a bilinear expression in δx arises from Eq. (5). These three bilinear expressions, taken together, represent a hyperbolization for the system (5)–(6), (18)–(19).

Every constraint of the original system (10)–(11) gives rise to a constraint of its Lagrange formulation; and, furthermore, if these constraints of the original system are integrable, then so are the corresponding constraints of the Lagrange formulation.[13] This assertion is immediate from the fact that Eqs. (18) and (19) mimic Eqs. (10) and (11), respectively. But, it turns out, there are two additional classes of constraints for the system of the Lagrange formulation. The first class arises from taking the curl of each side of Eq. (5). These constraints are certainly integrable, and, indeed, the corresponding integrability conditions are precisely Eq. (6). The second class of constraints arises from taking the curl of each side of Eq. (6). These constraints are also integrable, and indeed their integrability conditions are identities, simply from the way Eq. (6) was obtained. We conclude, thus, that a system of the form (10)–(11) having all its constraints integrable leads to a Lagrange formulation (5)–(6) (18)–(19), also having all its constraints integrable.

Finally, in order to check the third condition, we introduce the following integers. Denote by n the dimension of the base space M (the number of independent variables of the system), by u the dimension of the fibers in the bundle B (the number of unknowns represented by φ), by e the dimension of the vector space in which the index ''A'' of Eq. (11) lies, and by c the dimension of the space of vectors of the form $w_m c^m{}_A$, as $c^m{}_A$ runs over constraints for Eq. (11). Then, for the original system, we have the number of unknowns is given by $u_0=u+n$ (the term ''n'' arising from the field u^a); the number of equations is given by $e_0=n^2+e$ [these terms arising from Eqs. (10) and (11), respectively]; and the number of effective constraints is given by $c_0=n(n-1)+c$ [these terms arising from the constraints of Eqs. (10) and (11), respectively]. For the Lagrange formulation, on the other hand, we have: the number of unknowns is given by $u_L=u+n+n^2$ (the term ''n'' arising from the field ''point of M,'' the term ''n^2'' from the field $\kappa_{\hat{a}}{}^{b}$); the number of equations is given by $e_L=n^2+n^2(n-1)/2+n^2+e$ [these terms arising from Eqs. (5)–(6), (18)–(19), respectively]; and the dimension of the space of effective constraints is given by $c_L=n(n-1)+n(n-1)(n-2)/2+n(n-1)+c$ [these terms arising from the constraints of Eqs. (5)–(6), (18)–(19), respectively]. It is easy to check from these formulas that $e_0-c_0=u_0$ implies $e_L-c_L=u_L$. In other words, if the original system has the appropriate number of equations relative to its number of unknowns, then so does its Lagrange formulation.

Thus, we have shown a system of the form (10)–(11) having an initial-value formulation gives rise to a Lagrange formulation also with an initial-value formulation.

III. EXAMPLES

In this section, we introduce various examples of physical systems, the partial differential equations that describe them, and the Lagrange formulations of those partial differential equations.

One such example, the simple perfect fluid, has been discussed already in Sec. II. The fields, on space–time, M, g_{ab}, consist of a unit timelike vector field u^a (interpreted as the fluid velocity) and a positive scalar field ρ (interpreted as the mass density); and the equations are (1)–(2), where $p(\rho)$ is some fixed function (the function of state), which specifies the type of fluid under consideration. This is the Euler formulation. In order to achieve a Lagrange formulation for this system, the first step is to modify these equations so that the derivative of u^a, without contractions, is expressed in terms of the other fields. This was achieved by taking the derivative system: We introduced two new (tensor) fields, $w_a{}^b$ and v_a, subject to the algebraic conditions (12)–(13). We

then imposed on the total set of fields, $(u^a, \rho, w_a{}^b, v_a)$, the partial differential equations (14)–(17). This new system (14)–(17) is, by virtue of Eq. (14), of the required form, and, in addition, it inherits from the original system, (1)–(2), its initial-value formulation. To this system, (14)–(17), we may therefore apply the methods of Sec. II to obtain its Lagrange formulation. There result fields $(x, \hat{\rho}, \hat{w}_a{}^b, \hat{v}_a, \kappa_{\hat{a}}{}^b)$ on $\hat{M}$, subject to the equations (5)–(7). This new system, as demonstrated in Sec. II, again has an initial-value formulation.

There is a natural generalization of this simple perfect-fluid system to a much broader class of fluids. Fix some smooth manifold S, the points of which will, shortly, be interpreted as representing ''local, internal, states of the fluid.'' Also fix any space–time (M, g_{ab}). Let the fields, on this space–time, consist of a unit, timelike vector field, u^a (again interpreted as the velocity field of the fluid), together with a second field, φ, which is valued in S (and which is interpreted as giving the local state of the fluid at each point of space–time). Thus, φ is a mapping, $M \stackrel{\varphi}{\rightarrow} S$. As an example, the simple perfect-fluid system discussed above is the special case in which S is a 1-manifold (whose points are labeled by a coordinate ρ, whence φ reduces to the density field ρ). That is, our simple perfect fluid is one whose local state is completely characterized by the value of the density.

We next wish to write equations on these fields. To this end, fix two tangent vector fields, V^α and T^α, and one covector field, F_α, on the manifold S, where we have introduced Greek indices[14] to represent tensors in S. The physical interpretations of these fields will be given shortly. Let the equations for this system be

$$u^a \nabla_a u^b + (g^{ab} + u^a u^b)(\nabla \varphi)_a{}^\alpha F_\alpha = 0, \tag{20}$$

$$u^a (\nabla \varphi)_a{}^\alpha + V^\alpha \nabla_a u^a + T^\alpha = 0. \tag{21}$$

The first equation gives the fluid acceleration in terms of the derivative of the fluid state. We may interpret the field F_α, which acts by driving the fluid, as an ''effective force.'' The second equation gives the time rate of change of the fluid state in terms of that state and the divergence of u^a.[15] We may interpret the fields V^α and T^α, respectively, as giving the rate of change of fluid state under small volume-changes of a sample of that fluid, and under allowing a sample of that fluid to evolve in time. The simple perfect fluid, for example, has $F_\alpha = (\rho + p)^{-1} \nabla_\alpha p$, $V^\alpha = (\rho + p) \partial/\partial\rho$, and $T^\alpha = 0$ [for these choices reproduce Eqs. (1)–(2)]. Another familiar example is the perfect fluid with 2-dimensional manifold S of internal states, where the additional degree of freedom is represented by a conserved particle-number n. In this case, F_α is given by the same expression as above, V^α by $(\rho + p) \partial/\partial\rho|_n + n\, \partial/\partial n|_\rho$, and again T^α by 0. A more exotic example is that of a fluid consisting of several species of particles, between which chemical reactions can take place as the fluid evolves. In this case, we would have $\dim(S) > 2$ (the additional degrees of freedom describing the chemical composition of the fluid) and T^α nonzero (representing the rate and direction of the chemical reactions).

When does the system above satisfy the three properties, as discussed in Appendix B, for having an initial-value formulation? Two of these properties are immediate: Clearly, this system has no constraints, and the dimension of its space of equations is the same [namely, $\dim(S) + 3$] as the dimension of its space of fields. As for the third condition, this system, it turns out, admits a hyperbolization if and only if[16] $V^\alpha F_\alpha > 0$ everywhere on S. Note that, in the explicit examples given above, the combination $V^\alpha F_\alpha$ is precisely the square of the sound speed.

We now have a system of equations (20)–(21), having a preferred vector field, u^a, and, subject only to the inequality $V^\alpha F_\alpha > 0$, having an initial-value formulation. So, we may apply to this system the results of Appendix A and Sec. II. The first step is to take the derivative system (Appendix A). The result of this step is to include, in addition to the fields u^a, φ above, two new fields, $w_a{}^b$ (with $u_b w_a{}^b = 0$) and $\zeta_a{}^\alpha$, subject to the algebraic conditions $u^a w_a{}^b + (g^{ab} + u^a u^b) \zeta_a{}^\alpha F_\alpha = 0$ and $u^a \zeta_a{}^\alpha + V^\alpha w_a{}^a + T^\alpha = 0$. [These algebraic conditions reflect Eqs. (20)–(21).] The equations on these fields for the derivative system are given by

$$\nabla_a u^b = w_a{}^b, \tag{22}$$

$$\nabla_{[a} w_{b]}{}^c = R_{abd}{}^c u^d, \tag{23}$$

$$(\nabla \varphi)_a{}^\alpha = \zeta_a{}^\alpha, \tag{24}$$

$$\nabla_{[a} \zeta_{b]}{}^\alpha = 0. \tag{25}$$

This system indeed has a preferred vector field, u^a; has among its equations one [Eq. (22)] that expresses the derivative of this u^a algebraically in terms of the fields; and has an initial-value formulation [by virtue of that for Eqs. (20)–(21)]. So, we may, as described in Sec. II, take the Lagrange formulation of this system. There results a new system of partial differential equations, (5)–(7), again having an initial-value formulation.

Even the broad class of generalized fluids above does not include all possible types. For example, there exist fluids manifesting dissipative effects, such as heat-flow and viscosity. One description of such a fluid in relativity (Refs. 18–21) proceeds as follows. The fields consist of a unit timelike vector field u^a (interpreted as the fluid 4-velocity), two scalar fields, ρ and n (interpreted, respectively, as the fluid mass density and particle-number density), a vector field q_a satisfying $u^a q_a = 0$ (interpreted as the heat-flow vector), and a symmetric tensor field τ_{ab} satisfying $u^a \tau_{ab} = 0$ (interpreted as the stress tensor). Thus, the space of field-values at each point of M is 14-dimensional. The equations on these fields consist of (i) vanishing of the divergence of nu^a (conservation of particle number), (ii) vanishing of the divergence of $(\rho + p)u^a u^b + pg^{ab} + 2u^{(a} q^{b)} + \tau^{ab}$ (conservation of stress-energy), and (iii) a certain system of nine additional equations that, effectively, governs the dynamical evolution of q^a and τ^{ab}. It turns out that the resulting system, consisting of (i)–(iii), has an initial-value formulation: Specifically, it has a hyperbolization and no constraints. Furthermore—and this is perhaps surprising—this system of equations can be so chosen that it reduces, in an appropriate limit, to the familiar Navier–Stokes system for a dissipative fluid. [The Navier–Stokes dissipation coefficients—the thermal conductivity and viscosity—arise from within the nine equations (iii).] Here, in any case, is a system of equations with a preferred vector field u^a—a system, therefore, to which the present methods can be applied. Thus, we take the derivative system, as described in Appendix A, and then the Lagrange formulation, as described in Sec. II. There results a Lagrange formulation for a dissipative, relativistic fluid.

There exist still other types of material systems, e.g., some that are not fluids at all. Consider, for example, the elastic solid. In one treatment[22] of such a system in relativity, the fields consist of a unit timelike vector field u^a (the material 4-velocity), a positive function ρ (the mass density of the material), and a symmetric tensor field h_{ab} satisfying $h_{ab} u^b = 0$. This h_{ab} represents the geometry of the material as it was ''frozen in'' at the time the material originally solidified: It describes the shape to which the material would ''like to return.'' Thus, the combination $h_{ab} - (g_{ab} + u_a u_b)$, the difference between this natural geometry and the actual spatial geometry in which the material currently finds itself, is interpreted as the strain of the solid material. The equations on these fields are $\mathcal{L}_u h_{ab} = 0$ (the vanishing of the Lie derivative of h_{ab}, interpreted as asserting that the material remembers, over time, its frozen-in geometry), and $\nabla_b(\rho u^a u^b + \tau^{ab}) = 0$, (interpreted as the conservation of stress-energy, whence τ^{ab} is interpreted as the stress of the material). Here, τ^{ab} is to be given as some fixed function of h_{ab}, g_{ab}, and u^a. This is the stress–strain relation. Provided this stress–strain relation is chosen appropriately, the final system, it turns out, has an initial-value formulation: Specifically, it has a hyperbolization and no constraints. Again, we have a system to which the present methods can be applied. There results a Lagrange formulation for an elastic solid.

There are, presumably, a variety of other systems of equations, representing ''materials'' of various sorts, having, among their fields, a preferred 4-velocity. Examples might include the systems for a plasma, for a superconductor, or for a solid (such as ice) that is able to flow. These systems, too, will have Lagrange formulations.

These various material systems may, of course, interact with their environment in a variety of ways, e.g., electromagnetically, gravitationally, or through contact forces. What impact do such interactions have on their Lagrange formulations?

Consider, as an example, the fluid of Eqs. (20)–(21) interacting electromagnetically. This charged-fluid system is described by fields consisting of the original fluid variables, u^a and φ, together with an antisymmetric (electromagnetic) tensor field F_{ab}. The equations on these fields consist of Eq. (20), modified by the inclusion of a term on the right of the form $\mu F^b{}_a u^a$, Eq. (21)[23] and Maxwell's equations,

$$\nabla^b F_{ab} = \sigma u_a , \tag{26}$$

$$\nabla_{[a} F_{bc]} = 0. \tag{27}$$

Here, the μ in the first equation and the σ in Eq. (26) must be given as fixed fields on the manifold S of fluid states. The field σ describes how the fluid drives the electromagnetic field, and so is interpreted as the charge density. We require that it satisfy charge conservation: $V^\alpha \nabla_\alpha \sigma = \sigma$, $T^\alpha \nabla_\alpha \sigma = 0$. The field μ, which describes how the electromagnetic field drives the fluid, might be called the specific charge density. [For a normal fluid, σ and μ are in ratio $(\rho + p)$.] Here, in any case, is a list of fields, together with a system of equations on those fields. This system has an initial-value formulation, which it inherits from the separate initial-value formulations for the original fluid system [(20)–(21)] and for Maxwell's equations. We wish to take the Lagrange formulation for this system. Since the system does not express the derivative of u^a in terms of the other fields, the first step is to take the derivative system. But note that, in taking the derivative system, it is necessary to introduce, not only the new fields $w_a{}^b$ and $\zeta_a{}^\alpha$ that represent [via Eqs. (22) and (24), respectively] the derivatives of u^b and φ, but also the field ζ_{abc} that represents [via Eq. (A5)] the derivative of F_{ab}. One might have hoped that it would be possible, exploiting somehow the fact that our system of equations splits naturally into ''fluid equations'' and ''Maxwell-field equations,'' to avoid introducing the additional field ζ_{abc}. Unfortunately, this seems not to be the case. This issue is discussed briefly in Appendix A. In any case, this derivative system has the appropriate form (a preferred vector field u^a, whose derivative is expressed in terms of the fields of the system), and an initial-value formulation (which it inherits from that of the original coupled system). So, we may apply the methods of Sec. II. Thus, there is a Lagrange formulation for a charged fluid, but it requires the introduction of a further field ζ_{abc}, representing the derivative of the Maxwell field.

In a similar way, we may write down the Lagrange formulation for a charged dissipative fluid, a charged elastic solid, etc. In each of these cases, it is necessary to introduce the auxiliary field ζ_{abc}.

The situation for gravitational interactions is similar. Consider, again, the fluid of (20)–(21), now interacting gravitationally. The interacting system is described by fields consisting of the original fluid variables, u^a and φ, together with the variables for gravitation: a Lorentz-signature metric g_{ab}, and a derivative operator, ∇_a. The equations of this system consist of Eqs. (20)–(21),[24] the equation $\nabla_a g_{bc} = 0$, and Einstein's equation,

$$G_{ab} = T_{ab} , \tag{28}$$

where G_{ab} is the Einstein tensor. Here, T_{ab} is some fixed symmetric tensor function of g_{ab} and the fluid variables (which we interpret as the stress-energy tensor of the fluid). It plays a role analogous to that of the functions μ and σ for electromagnetic interactions. We demand of this tensor function that, as a consequence of Eqs. (20)–(21), it be conserved.[25] This system of equations does *not* have an initial-value formulation, in the sense we are using this term. But this is merely a consequence of the fact that our sense of this term is overly restrictive, in that it does not tolerate the diffeomorphism freedom characteristic of all systems in general relativity. In a physical sense, i.e., once the diffeomorphism freedom has been treated properly, the fluid-Einstein system does, of course, have an initial-value formulation. Now take the derivative system of this system. Note that

in doing so we must, as in the electromagnetic case, include also fields to represent the derivatives of the gravitational fields.[26] Take the Lagrange formulation of the result. The resulting system, again, will not have an initial-value formulation in our restrictive sense, but it will have such a formulation when the diffeomorphism-freedom is properly taken into account. We conclude, then, that there does exist a Lagrange formulation for a gravitating fluid, but that it requires that we introduce further fields to represent the derivatives of the gravitational fields.

In a similar way, we may write down the Lagrange formulation for a gravitating dissipative fluid, a gravitating elastic solid, etc. In each case, it is necessary to introduce fields representing the derivatives of the gravitational fields; and in each case the Lagrange formulation retains the initial-value formulation of the original system.

A similar treatment is available for systems consisting of two or more different materials in interaction. In these cases, there will be two or more 4-velocity fields present, and we shall have to select one to be that with respect to which the Lagrange formulation is taken.

The treatment of systems in which several interactions are turned on simultaneously, e.g., the charged gravitating fluid, is similar.

Finally, we briefly characterize, within the present framework, Friedrich's[17] original example of a relativistic Lagrange formulation. Begin with the system for a gravitating fluid, as described above, for the case in which the fluid has a 2-dimensional manifold S of local states, i.e., that in which $T^\alpha = 0$ and $V^\alpha = (\rho + p)\partial/\partial\rho|_n + n\partial/\partial n|_\rho$. For this system, first take the derivative system, and then the Lagrange formulation. The result of this process—after three, essentially cosmetic, further modifications—is precisely Friedrich's original example. The three further modifications are the following.

(1) Introduce, already in the original Einstein-fluid system, before taking the derivative system, a 3-dimensional space of additional variables, consisting of three unit vector fields, x^a, y^a, and z^a, that are required to be orthogonal to each other and to the 4-velocity u^a. On these fields, impose the equations that they be Fermi-transported by u^a. The introduction of these fields with these equations does not interfere with the initial-value formulation. These fields, which have no direct physical significance, are introduced to facilitate the writing of various equations.
(2) After taking the derivative system, but before passing to the Lagrange formulation, suppress half of the field $\zeta_a{}^\alpha$, which represents the derivative of the fluid state.[27] While such suppression of variables will in general destroy the initial-value formulation for a system, it turns out that, in this particular instance, it does not. Thus, the essential effect of this modification is to reduce by four the number of independent variables.
(3) Write the final equations, after passing to the Lagrange formulation, not in terms of the specific fields listed above, but rather in terms of others that are algebraic functions of these. This choice of variables—choice of ''coordinates'' on the bundle space—is, of course, a matter of convenience.

IV. CONCLUSION

We have introduced a scheme that takes a first-order, quasilinear system of partial differential equations and produces from it a new first-order, quasilinear system, its ''Lagrange formulation.'' The key requirement, on a given system of equations, in order that this scheme be applicable to it is that that system have, among its fields, some nowhere-vanishing vector field. Why this special role of a vector field? Could, for example, a similar scheme be developed based on some other geometrical object(s)? It turns out that there are two special features of vector fields that we used in the construction of the Lagrange formulation.

First, nowhere-vanishing vector fields on manifolds are locally homogeneous. This means the following. Let there be given any manifold M, any nowhere-vanishing vector field u^a thereon, and any point $x \in M$; and, similarly, some other manifold $\hat{M}$ (of the same dimension), vector field $\hat{u}^{\hat{a}}$ and point $\hat{x} \in \hat{M}$. Then there always exists a diffeomorphism between neighborhoods of x and $\hat{x}$

that sends u^a to $\hat{u}^{\hat{a}}$. In other words, nowhere-vanishing vector fields are ''locally all the same:'' They carry no local structure. We used this fact in Sec. II in order to replace u^a on M by some kinematical field $\hat{u}^{\hat{a}}$ on $\hat{M}$.

Second, by virtue of the appearance of the vector field $\hat{u}^{\hat{a}}$ on the left in Eq. (18), the system (6), (18) for the two-point tensor $\kappa_{\hat{a}}{}^{b}$ admits a hyperbolization. We used this fact in Sec. II in order to achieve a hyperbolization, and consequently an initial-value formulation, for the entire system (5)–(6), (18)–(19).

It appears that, given any other geometrical structure manifesting these two features, then there could be developed a ''Lagrange formulation'' based on it. It is only necessary to make three key modifications in Sec. II (all involving replacing the vector field by the totality of fields in the new geometrical structure): (i) Replace Eq. (10) by equations for the derivatives of all the fields of the geometrical structure; (ii) endow the base manifold $\hat{M}$ of the Lagrange formulation with kinematical fields consisting of all the fields of the geometrical structure; and (iii) replace Eq. (18) by the corresponding equation involving all the fields of the geometrical structure. Unfortunately, it is not so easy to find geometrical structures having the two features described above, in part because they are somewhat in opposition to each other: The first feature, local homogeneity, prefers fewer fields, relatively devoid of structure; while the second feature, hyperbolicity of (6), (18), prefers many fields, of rich structure.

There are a variety of geometrical structures that are locally homogeneous. Examples include: two commuting, pointwise independent vector fields; a nowhere-vanishing, curl-free 1-form; a symplectic structure; a flat, Lorentz-signature metric. Examples of geometrical structures that yield a hyperbolization for (6), (18) are somewhat less plentiful. One simple class consists of those in which the geometrical structure is comprised of a nowhere-vanishing vector field u^a, together with any additional fields of whatever type. For structures in this class, a hyperbolization for (6), (18) (suitably generalized) is guaranteed already by the presence of the vector field u^a in the structure.

Here is an application of these ideas. Consider the geometrical structure consisting of a nowhere-vanishing vector field u^a, together with a nowhere-vanishing 3-form, ω_{abc}, that has zero curl and is annihilated by u^a. This structure satisfies both of the features above—it is locally homogeneous, and it gives rise to a hyperbolization for (6), (18). So, this geometrical structure could serve as the basis for a Lagrange formulation. In fact, this formulation is appropriate for a physical system, namely that of a fluid with a 2-dimensional manifold of internal states, as discussed in Sec. III. Identify u^a with the velocity field of the fluid, and ω_{abc} with the particle-number density, via $\omega_{abc}=n\epsilon_{abcd}u^d$.

It is curious that the original system and its Lagrange formulation, while so similar with regard to their solutions, are completely different with regard to their initial-value formulations. Indeed, as we have seen in Sec. II, it is frequently the case that the original system of equations (4) has an initial-value formulation, while its Lagrange formulation, (5)–(7), does not. Perhaps there is some more natural or more general notion of ''initial-value formulation'' that would resolve this disparity.

APPENDIX A: DERIVATIVE SYSTEMS

Fix, once and for all, a first-order, quasilinear system of partial differential equations, as described in Sec. II. That is, fix a fiber bundle, with bundle manifold $\mathcal{B}$, base manifold M, and projection mapping $\mathcal{B}\overset{\pi}{\rightarrow}M$, together with smooth fields $k^{Aa}{}_{\alpha}, j^A$ on the bundle manifold $\mathcal{B}$. Our system of equations, on a cross-section, $M\overset{\phi}{\rightarrow}\mathcal{B}$, of this fiber bundle, is given by

$$k^{Aa}{}_{\alpha}(\nabla\phi)_a{}^{\alpha}=j^A. \tag{A1}$$

We shall now construct from this system a new first-order, quasilinear system of partial differential equations. The idea is to "take one derivative" (with respect to the point of M) of Eq. (A1).

The first step is to introduce the appropriate bundle of fields for the new system. Let the base manifold again be M. But now let the fiber, over a point $x \in M$, consist of all pairs, $(\phi, \zeta_a{}^\alpha)$, where ϕ is point of $\mathcal{B}$ satisfying $\pi(\phi) = x$ and $\zeta_a{}^\alpha$ is a tensor at ϕ satisfying

$$k^{Aa}{}_\alpha \zeta_a{}^\alpha = j^A. \tag{A2}$$

Thus, ϕ is merely a point of the fiber over $x \in M$, in the original bundle $\mathcal{B}$. It represents a set of "values for the original fields" at x. The tensor $\zeta_a{}^\alpha$ represents a set of "values for the derivatives of the original fields." In order that a given $\zeta_a{}^\alpha$ be a viable candidate for these derivatives, it must satisfy Eq. (A2), the algebraic equation that results from replacing $(\nabla\phi)_a{}^\alpha$ in Eq. (A1) by $\zeta_a{}^\alpha$. We impose this algebraic condition on ζ in the very construction of the new bundle (as opposed, e.g., to introducing it later as an "algebraic constraint"). In short, the *dynamics* [Eq. (A1)] of the original system goes into the *kinematics* [Eq. (A2)] of the new system. Call the bundle space of this new fiber bundle $\mathcal{B}'$. Thus, the dimension of the fibers of $\mathcal{B}'$ is given by: (dim fibers of $\mathcal{B}$) $(1 + \dim(M))$-(dim vector space of equations in $\mathcal{B}$).

Consider, as an example, Maxwell's equations. Then M is a 4-dimensional manifold, with fixed smooth metric g_{ab} of Lorentz signature. For the bundle $\mathcal{B}$, the fiber over $x \in M$ consists of all antisymmetric tensors, F_{bc}, at x. Equation (A1) is Maxwell's equations: $g^{ab}\nabla_a F_{bc} = 0$, $\nabla_{[a}F_{bc]} = 0$. For this example, the new bundle, $\mathcal{B}'$, has, as its fiber over $x \in M$, the collection of all pairs, (F_{bc}, ζ_{abc}), with symmetries $F_{bc} = F_{[bc]}, \zeta_{abc} = \zeta_{a[bc]}$, and with ζ satisfying the algebraic conditions [Eq. (A2)] $g^{ab}\zeta_{abc} = 0, \zeta_{[abc]} = 0$. Thus, the fibers of $\mathcal{B}$ have dimension six, those of $\mathcal{B}'$ dimension twenty-two.

Returning to the general case, the second step is to introduce appropriate equations on this bundle. A cross-section of the bundle $\mathcal{B}'$ consists of fields $\phi, \zeta_a{}^\alpha$ on M. On such a cross-section, we impose the following system of partial differential equations:

$$(\nabla\phi)_a{}^\alpha = \zeta_a{}^\alpha, \tag{A3}$$

$$\nabla_{[a}\zeta_{b]}{}^\alpha = f_{ab}{}^\alpha. \tag{A4}$$

Equation (A3) provides the "interpretation" of ζ, as the derivative of ϕ. The $f_{ab}{}^\alpha$ on the right of (A4) is some field on $\mathcal{B}'$ [i.e., some function of (x, ϕ, ζ)], whose exact form depends on what derivative operator is used on the left side of that equation. The general rule is that Eq. (A4) to be the result of taking the curl of Eq. (A3). For example, if ϕ is represented by tensor fields over M, if ζ is represented by the tensor fields obtained by taking the covariant derivatives (with respect to some fixed derivative operator on M) of those fields, and if that same derivative operator is used on the left in Eq. (A4), then f will consist of certain terms involving ϕ and the curvature tensor of that derivative operator. If, on the other hand, all bundles are taken as simple products, and all derivatives are taken using the corresponding (flat) connection, then $f_{ab}{}^\alpha = 0$. Note that we have *not* included in our system the derivative of Eq. (A2). The reason is that Eq. (A2) has already been included at the algebraic level in the construction of the bundle $\mathcal{B}'$. Its derivative is thus an identity in $\mathcal{B}'$. On the other hand, we *do* include in our system Eq. (A4), even though it merely results from taking a derivative of Eq. (A3). In short, all algebraic conditions on fields are included in the construction of the bundle,[28] while all differential conditions on fields are included in the equations on a cross-section of that bundle. We note that the system of Eqs. (A3)–(A4) is indeed first-order and quasilinear.

Consider again the example, above, of Maxwell's equations. Then a cross-section of bundle $\mathcal{B}'$ consists of smooth fields, F_{bc}, ζ_{abc}, satisfying everywhere the symmetries and algebraic conditions given above. The equations, (A3)–(A4), on such a cross-section become, respectively,

$$\nabla_a F_{bc} = \zeta_{abc}, \tag{A5}$$

$$\nabla_{[d}\zeta_{a]bc} = 2R_{da[b}{}^{m}F_{c]m}. \tag{A6}$$

Given a system, consisting of bundle $\mathcal{B}$ and partial differential equations (A1), then by its *derivative system* we mean the system, consisting of bundle $\mathcal{B}'$ and partial differential equations (A3)–(A4), constructed above. Note that every solution of the original system gives rise to a solution of its derivative system [by merely setting $\zeta_a{}^{\alpha} = (\nabla\phi)_a{}^{\alpha}$]. Conversely, every solution of the derivative system gives rise to a solution of the original system (by merely ignoring ζ). The two systems of partial differential equations are, in this sense, ''equivalent as to solutions.'' But they are not ''equivalent as to form,'' a feature we exploit in Sec. II.

We next turn to the issue of the existence of an initial-value formulation for these systems. As discussed in Appendix B, we say that a general first-order quasilinear system (A1) of partial differential equations admits an *initial-value formulation* provided it satisfies the following three conditions: (i) the system admits a hyperbolization; (ii) all constraints of the system are integrable; and (iii) the system has the correct number of equations relative to the number of its unknowns. See Appendix B for the details of what these conditions mean. A key property of the derivative system is the following: *If the original system, (A1) admits an initial-value formulation, then so does its derivative system, (A3)–(A4).* We check the three conditions in turn.

Let the original system (A1) admit a hyperbolization (say, $h_{\beta A}$, with w_a). Then, we claim, so does its derivative system. Indeed, the corresponding bilinear expression [on a pair of tangent vectors, represented as $(\delta\phi^{\alpha}, \delta\zeta_a{}^{\alpha})$ and $(\delta'\phi^{\alpha}, \delta'\zeta_a{}^{\alpha})$] is given by

$$w_m h_{\alpha A} k^{Am}{}_{\beta}[\overset{+}{g}{}^{ab}\delta\zeta_a{}^{\alpha}\delta'\zeta_b{}^{\beta} + \delta\phi^{\alpha}\delta'\phi^{\beta}], \tag{A7}$$

where $\overset{+}{g}{}^{ab}$ is any positive-definite metric field on M. It is apparently not known whether the converse is true, i.e., whether the existence of a hyperbolization for the derivative system, (A3)–(A4), implies the existence of a hyperbolization for the original system (A1). Simple examples suggest that this is a reasonable conjecture.

Integrable constraints of the system (A1) do *not* lead to constraints of the corresponding derivative system. Rather, they lead to a reduction in the number of effective equations. Indeed, let $c^b{}_A$ be any constraint. Then the result of contracting Eq. (A4) with $c^a{}_A k^{Ab}{}_{\alpha}$ is an identity: It holds automatically, by virtue of Eq. (A2). Thus, each constraint for the system (A1) reduces by one the number of effective equations represented by Eqs. (A3)–(A4).

What, then, *are* the constraints of the derivative system (A3)–(A4)? These fall into two classes. The first class consists of those constraints that correspond to taking the curl of Eq. (A3). These constraints are of course integrable: Their integrability conditions are precisely (A4). The second class of constraints consists of those that correspond to taking the curl of Eq. (A4). These constraints, too, are integrable, by virtue of the fact that Eq. (A4) is itself a curl. Not all of these constraints, it turns out, are in general algebraically independent.

Let us return to our original partial differential equation (A1). Denote by n the dimension of the base manifold M (the ''number of independent variables''), by u the dimension of the fibers in the bundle $\mathcal{B}$ (the ''number of unknown functions''), and by e the dimension of the vector space of equations, (A1). Further, denote by $\hat{c}$ the dimension of the vector space of constraints, and, for fixed nonzero covector w_a, by c the dimension of the space of vectors of the form $w_a c^a{}_A$, as $c^a{}_A$ runs over the constraints. Then, as discussed in Appendix B, the condition that the original system (A1) have the ''correct number of equations'' becomes $e - c = u$. We turn now to the derivative system (A3)–(A4). The number of its unknowns is given by $u' = u + (nu - e)$ (the two terms representing the numbers of unknowns contained in the fields ϕ and ζ, respectively). The number of its equations is given by $e' = nu + [un(n-1)/2 - \hat{c}]$ [the two terms representing the number of effective equations in (A3) and (A4)], respectively. Finally, the number of effective constraints of the derivative system is given by $c' = u(n-1) + [(n-1)(n-2)u/2 + c - \hat{c}]$, (the two terms rep-

resenting the number of effective constraints in (A3) and (A4), respectively[29]). From these formulas, it is easy to check: If $e-c=u$, then $e'-c'=u'$. In other words, if the original system has the correct number of equations, then so does the derivative system.

We conclude, then, that, beginning with a system (A1) having an initial-value formulation, its derivative system, (A3)–(A4), also has an initial-value formulation.

The construction above of the derivative system is useful because it permits a large class of systems of partial differential equations to be cast into a form to which the Lagrange formulation of Sec. II can be applied. But, unfortunately, passing to the derivative system and then to the Lagrange formulation is often a cumbersome procedure. The reason is that the derivative system requires the introduction of additional fields to represent the derivatives of *all* the fields of the original system—even of those fields only remotely related to the one real interest: the velocity field. The result is a large number of extraneous fields. More useful would be a construction that goes only part way to the full derivative system—one that introduces additional fields to represent the derivatives of only *some* of the original fields, leaving the remaining ones intact. It turns out that, while there are one or two systems (e.g., that for dust) for which a smaller derivative system along these lines is available, for the vast majority of systems of partial differential equations of physical interest there is none. Here, briefly, is why.

First, we must designate which of the dependent variables (the fields represented by ϕ) are to be derived and which not. This is done by writing the original bundle, $\mathcal{B}$, as a product of two bundles, $\mathcal{B}'$ and $\mathcal{B}''$, with the same base space[30] M. The bundle $\mathcal{B}'$ carries the fields whose derivatives will be represented by new variables, while $\mathcal{B}''$ carries the remaining fields. A cross-section ϕ of $\mathcal{B}$ consists precisely of a pair, (ϕ',ϕ''), where ϕ' is a cross-section of the bundle $\mathcal{B}'$, and ϕ'' is a cross-section of the bundle $\mathcal{B}''$. In terms of these variables, Eq. (A1) becomes

$$k'^{Aa}{}_{\alpha'}(\nabla\phi')_a{}^{\alpha'}+k''^{Aa}{}_{\alpha''}(\nabla\phi'')_a{}^{\alpha''}=j^A, \tag{A8}$$

where primed Greek indices denote tensors in $\mathcal{B}'$, and double-primed in $\mathcal{B}''$. Here, the fields k', k'' and j are all functions on $\mathcal{B}$, i.e., are functions of (x,ϕ',ϕ''). We now proceed just as with the derivative system. Introduce a new fiber bundle, with base manifold again M, but with fiber over $x\in M$ consisting of certain triples, $(\phi',\zeta_a{}^{\alpha'},\phi'')$. There must now be imposed on such triples all those algebraic conditions that flow from (A8). This is done as follows. At each point, denote by V the vector space of μ_A satisfying $\mu_A k''^{Aa}{}_{\alpha''}=0$. That is, V captures "those equations in (A8) that contain no derivative of ϕ''." We now demand, in order that a triple $(\phi',\zeta_a{}^{\alpha'},\phi'')$ give rise to a point of the fiber, the following: For every $\mu_A\in V$, $\mu_A k'^{Aa}{}_{\alpha'}\zeta_a{}^{\alpha'}=\mu_A j^A$. This is the fiber bundle for our new system. Let the equations of the new system be

$$(\nabla\phi)_a{}^{\alpha'}=\zeta_a{}^{\alpha'}, \tag{A9}$$

$$\nabla_{[a}\zeta_{b]}{}^{\alpha'}=f_{ab}{}^{\alpha'}, \tag{A10}$$

$$\nu_A k'^{Aa}{}_{\alpha'}\zeta_a{}^{\alpha'}+\nu_A k''^{Aa}{}_{\alpha''}(\nabla\phi'')_a{}^{\alpha''}=\nu_A j^A. \tag{A11}$$

In (A11), ν_A is any vector in some fixed subspace complementary to the subspace V. In other words, Eq. (A11) reflects those equations of (A8) that do involve the derivative of ϕ''.

The system (A9)–(A11) is, certainly, a first-order, quasilinear system of partial differential equations; and it has as its variables precisely the ones we intended, namely $(\phi',\zeta_a{}^{\alpha'},\phi'')$. But, unfortunately, this system is subject to a variety of maladies—and these can arise even if the original system was quite well-behaved. For example—and this happens frequently—there can be constraints for the system (A9)–(A11) that are hidden in Eq. (A11), and thus do not arise from any constraints for the original system, (A8). Furthermore, these new constraints are not in general integrable. One could attempt to include the integrability conditions of these new constraints as new equations for the system. But two further problems can arise. First, some integrability con-

ditions can turn out to be mere algebraic equations on the fields, $(\phi', \zeta_a{}^{\alpha'}, \phi'')$. The only way to ''include'' such equations is to start over, introducing a new bundle right from the beginning. Second, some integrability conditions can turn out to be quadratic, rather than linear, in the field-derivatives. These cannot simply be ''included''—at least, not if we wish to retain a quasilinear system. The system (A9)–(A11) can also manifest a number of other types of difficulties, e.g., the absence of a hyperbolization or the wrong number of equations. There appears to be no simple, general condition that guarantees that Eqs. (A9)–(A11) lead to a system with an initial-value formulation.

As an example of this construction consider again the simple fluid, (1)–(2). Let $\mathcal{B}'$ be the bundle whose fiber consists only of the variable u^a; and $\mathcal{B}''$ the bundle whose fiber consists only of the variable ρ. In this example, the vector space V, capturing those equations in (1)–(2) involving no derivative of ρ, is zero-dimensional. The corresponding new bundle space, then, is that whose fiber, over $x \in M$, consists of $(u^a, w_b{}^a, \rho)$, with u^a unit timelike and $w_b{}^a$ satisfying $g_{ac}u^c w_b{}^a = 0$ (unit-ness of u^a). The equations for the new system, in this example, are

$$\nabla_b u^a = w_b{}^a, \tag{A12}$$

$$\nabla_{[a} w_{b]}{}^c = R_{abd}{}^c u^d, \tag{A13}$$

$$(g^{am} + u^a u^m)\nabla_m p + (\rho + p) u^m w_m{}^a = 0, \tag{A14}$$

$$u^m \nabla_m \rho + (\rho + p) w_m{}^m = 0. \tag{A15}$$

This system has a new constraint [obtained by combining Eqs. (A14) and (A15) to obtain an expression for $\nabla_m \rho$, and then taking its curl], which turns out not to be integrable. But its integrability condition turns out to be quasilinear in field-derivatives, and so may be included as a further equation of the system. The resulting system in this case (but not for the case of an even slightly more complicated fluid) actually admits a hyperbolization.

APPENDIX B: INITIAL-VALUE FORMULATION

Consider a first-order, quasilinear system of partial differential equations, as described in Sec. II. That is, we have a fiber bundle, with base manifold M, bundle manifold $\mathcal{B}$, and projection mapping $\mathcal{B} \overset{\pi}{\to} M$. The system of partial differential equations, on a cross-section, $M \overset{\phi}{\to} \mathcal{B}$, of this bundle, is given by Eq. (3). We are concerned here with the issue of under what circumstances such a system admits an initial-value formulation, i.e., a formulation in which the fields are first specified on some ''initial surface'' in M, and are then determined elsewhere in M by Eq. (3) itself.

The key to achieving such a formulation is an object called a *hyperbolization* of the system (3), a field $h_{\beta A}$ on the bundle manifold $\mathcal{B}$ having the properties described below. Consider, for (x, ϕ) any point of the bundle manifold $\mathcal{B}$, w_m any covector at $x \in M$, and $\delta\phi^\alpha, \delta'\phi^\alpha$ any two vectors at $(x, \phi) \in \mathcal{B}$ tangent to the fiber (''vertical''), the expression

$$w_m h_{\beta A} k^{Am}{}_\alpha \delta\phi^\alpha \delta'\phi^\beta. \tag{B1}$$

We demand, in order that this $h_{\beta A}$ be a hyperbolization, that, everywhere in $\mathcal{B}$, this expression be symmetric in $\delta\phi^\alpha, \delta'\phi^\alpha$ for all w_m, and positive-definite (i.e., positive for any nonzero $\delta'\phi^\beta = \delta\phi^\beta$) for some w_m. The most direct way to specify a hyperbolization for a system of partial differential equations is simply to give the bilinear expression (B1). Such an expression indeed defines a hyperbolization provided it is symmetric and positive-definite, as described above, and furthermore, that it is some multiple of the result of replacing, in the left side of Eq. (3), ''$(\nabla\phi)_a{}^\alpha$'' by ''$w_a\, \delta\phi^\alpha$.'' As an example, consider the system, (1)–(2), for a simple perfect fluid. Consider the bilinear expression

$$\delta' u^a[(\rho+p)(u^m w_m) g_{ab}\delta u^b + (\partial p/\partial\rho) w_a \delta\rho] + (\partial p/\partial\rho)(\rho+p)^{-1}\delta'\rho[(\rho+p)\delta u^m w_m + u^m w_m \delta\rho]. \tag{B2}$$

We note that this expression is symmetric under interchange of the two vectors $(\delta\rho, \delta u^a)$ and $(\delta'\rho, \delta' u^a)$, and that [provided $(\rho+p)>0$ and $1\geqslant(\partial p/\partial\rho)>0$] it is positive-definite whenever w_m is future-directed timelike. Furthermore, this expression arises, as described above, from Eqs. (1)–(2). This bilinear expression, then, specifies a hyperbolization for this system.

Let there be given a hyperbolization, $h_{\alpha A}$, for the system (3). Then this object gives rise to an initial-value formulation for a portion of that system, in the following manner. Fix initial data, consisting of a submanifold T of M of codimension one (an ''initial surface'') together with a cross-section ϕ_0 over this submanifold (''data'' on that surface), such that at each point of T, the normal to T is one of the vectors w_m for which the bilinear expression (B1) is positive-definite (the surface is ''noncharacteristic''). Then, in some neighborhood of the submanifold T, there exists one and only one solution ϕ of the system

$$h_{\beta A} k^{Aa}{}_{\alpha} (\nabla\phi)_a{}^{\alpha} = h_{\beta A} j^A, \tag{B3}$$

such that $\phi=\phi_0$ on T. Note that we do not guarantee a solution of the entire system (3), but rather only of those components that are involved in the hyperbolization. While the proof of this theorem is technically difficult, the key idea is to construct, using the hyperbolization, an energy integral, which is positive-definite, and, effectively, conserved.

Denote by u the number of unknowns of the system (3) (i.e., the dimension of the fibers in $\mathcal{B}$), and by e the number of equations (i.e., the dimension of the vector space in which the index ''A'' lies). Then the mere existence of a hyperbolization for this system already implies $e\geqslant u$ (i.e., that there are at least as many equations as unknowns). Should it happen that this inequality is an equality, i.e., that $e=u$, then it follows that the hyperbolization tensor $h_{\alpha A}$ is invertible, and so that the system (B3) exhausts the original system of equations (3). Thus, in this case we are done: We have achieved our full initial-value formulation. In the example of the simple perfect fluid above, for instance, we have $e=u=4$, and so the hyperbolization (B2) gives rise to an initial-value formulation for the fluid system (1)–(2). Unfortunately, in many cases of interest we have the strict inequality $e>u$, i.e., there are additional equations in (3) that are not accounted for in (B3). Such ''additional equations'' are dealt with in the following manner.

By a *constraint* of the system, (3), of partial differential equations, at a point of $\mathcal{B}$, we mean a tensor $c^a{}_A$ at that point such that the tensor $c^a{}_A k^{Ab}{}_{\alpha}$ is antisymmetric in the indices ''a,b.'' This definition has two facets. First, each constraint gives rise to an integrability condition. Fix a constraint field, $c^a{}_A$, and a solution ϕ of Eq. (3). Contract both sides of Eq. (3) with $c^b{}_A$, and apply to both sides some derivative operator, ∇_b, on M. Then, by the constraint-condition, terms involving second derivatives of ϕ vanish, leaving an algebraic equation (indeed, a polynomial of degree at most two) in the first derivative, $(\nabla\phi)_a{}^{\alpha}$, of ϕ. The constraint field is said to be *integrable* if this equation is an algebraic consequence of Eq. (3), i.e., if the difference of its two sides is the product of some expression (at most linear in field-derivatives) and the difference of the two sides of (3). The lack of integrability of a constraint generally indicates that ''not all the equations have been included in the original system (3).'' As to the second facet, each constraint gives rise to a compatibility condition on initial data. Fix constraint field, $c^a{}_A$, solution ϕ of Eq. (3), and submanifold T of M of codimension one. Then, at each point of T, we have

$$n_m c^m{}_A k^{Aa}{}_{\alpha} (\nabla\phi)_a{}^{\alpha} = n_m c^m{}_A j^A, \tag{B4}$$

where n_m is the normal to T at that point. But, by virtue of the constraint-condition, the index ''a'' in the tensor $n_m c^m{}_A k^{Aa}{}_{\alpha}$ is tangent to T. Thus, Eq. (B4) takes the derivative of ϕ only in directions tangent to T, and so it refers only to the value of ϕ on T, i.e., only to the initial data on T. In short, Eq. (B4) represents a compatibility condition on initial data. If these compatibility conditions were not satisfied, then we would have have no hope of finding a corresponding

solution of Eq. (3). As an example, consider the Maxwell equation $\nabla_{[a}F_{bc]}=0$. This equation has a constraint. The corresponding integrability condition, obtained by taking the curl of this equation, is an identity, and so this constraint is integrable. The compatibility condition (B4) on initial data becomes, in this example, $\nabla\cdot B=0$.

In the case in which $e>u$, i.e., in which the system (3) has more equations than unknowns, two further conditions must be imposed on the system. The first is that all the constraints be integrable. The second is that $e-c=u$, where c denotes the dimension of the vector space of vectors of the form $w_m c^m{}_A$, for fixed w_m, as $c^m{}_A$ runs through all the constraints. This last condition means that any additional equations in (3) that are not included already in (B3) are accounted for, effectively, by constraints. It states that (3) has the ''correct number of equations'' for its unknowns. In the case of Maxwell's equations, for example, all the constraints are integrable, as we have already remarked; and we have $e=8$, $c=2$, and $u=6$, so there is indeed the correct number of equations. That is, the two further conditions above are satisfied in this example.

Consider now a first-order, quasilinear system of partial differential equations that satisfies the three conditions given above. That is, let the system (i) admit a hyperbolization, (ii) have all its constraints integrable, and (iii) have the correct number of equations, as described above. It seems likely that such a system—possibly with some mild further conditions—must always manifest an initial-value formulation in some suitable sense. That is, we would expect that, given initial data for the system on a suitable surface T, satisfying on T the compatibility conditions (B4), then there exists a unique corresponding solution of Eq. (3) in a neighborhood of T. A key piece of evidence prompting this expectation is the following. There certainly exists a solution of Eq. (B3) manifesting the initial data, as we have already seen. Consider next the left sides of Eq. (B4) (as $c^m{}_A$ varies over all constraints). These expressions of course vanish on T, and, by virtue of the conditions (ii) and (iii) above, satisfy a system of equations that express the ''time-derivatives'' (off T) of these expressions in terms of their ''space-derivatives'' (within T). Naively, we might expect that, as a consequence, these expressions must vanish in a neighborhood of T. But the vanishing of these expressions implies, again by condition (iii) above, that Eq. (3) itself is satisfied everywhere in a neighborhood of T. Indeed, in all physical examples of which we are aware—including all those discussed in this paper—this naive expectation is in fact borne out. Unfortunately, there is, apparently, no general theorem to this effect. Nevertheless, we shall, for convenience, use the expression ''having an initial-value formulation'' to describe systems of partial differential equations that satisfy the three conditions, (i)–(iii), above.

[1] See, for example, R. Courant and K. O. Friedrichs, *Supersonic Flow and Shock Waves* (Interscience, New York, 1948), for the Euler and Lagrange formulations of non-relativistic perfect fluids, and Appendix A of Ref. 2 for the Euler formulation of a relativistic perfect fluid.

[3] For the case of the Einstein-Euler system, for example, see Sec. 4.2 of Ref. 4, and references therein.

[4] H. Friedrich and A. Rendall, ''The Cauchy problem for the Einstein equations,'' in *Einstein's Field Equations and their Physical Interpretation*, edited by B. G. Schmidt (Springer-Verlag, Berlin, 2000), available as gr-qc/0002074.

[5] In fact, some care must be taken, in the Lagrange formulation, even to say what ''initial-value formulation'' means, in light of the fact that the independent variables are not the usual space-time events, through which evolution normally proceeds.

[6] Recall that this condition requires, essentially, that, locally in M, $\mathcal{B}$ can be written as a product, $M\times F$, of M with some other fixed manifold F, in such a way that the projection mapping π becomes the projection to the M-factor in this product. This condition guarantees, e.g., that, locally, all the fibres of the bundle are diffeomorphic with this fixed manifold F, and so with each other.

[7] Note that we can, in this case, convert these to ordinary tensors on the manifold $\hat{M}$ by using $\kappa_{\hat{a}}{}^b$ and its universe. This, a mere ''coordinate transformation'' on the fibres, changes nothing, in particular, not the final partial differential equations of the Lagrange formulation.

[8] For convenience, we shall always include within our system *all* first-order equations on the fields of the system, even those that arise from differentiating other equations of the system.

[9] These derivatives may be characterized in the following manner. Consider the bundle with base space $\hat{M}$ and fibre over $\hat{x}\in\hat{M}$ consisting of a pair, $(x,\kappa_{\hat{a}}{}^b)$, where $x\in M$ and $\kappa_{\hat{a}}{}^b$ is a tensor with indices at x and $\hat{x}$. Then a choice of connection in this bundle gives rise to an operator $\nabla_{\hat{a}}$ for use in the left side of Eq. (6).

[10] A Lorentz metric on M, for example, becomes, on $\hat{M}$, an algebraic function of the fields (namely, just of x) of the Lagrange formulation.

[11] In the notation of (5)–(7), we have $\varphi=(x,\rho)$, and $\hat{\varphi}=(x,\hat{\rho})$.

[12] There is an unfortunate complication here, involving the normalization condition, $u^a u^b g_{ab}=-1$, on u^a. It is awkward simply to carry this condition through the Lagrange formulation. But there are several other ways—none very elegant—to deal with it. Perhaps the simplest is to rewrite the fluid equations from the outset [by inserting, strategically, factors of $(u^a u^b g_{ab})$] in such a way that, while retaining their initial-value formulation, they no longer require this normalization condition. Then take the Lagrange formulation of these new equations.

[13] Note in particular that the original system, (10)–(11), always possesses the constraints arising from the curl of Eq. (10). Thus, if the constraints of this system are to be integrable, this curl-equation must have been included in the system (10)–(11).

[14] These are not to be confused with the indices for tensors on the bundle space, used extensively in Sec. II.

[15] Note that the last two terms on the left in Eq. (21) constitute the most general expression (involving u^a and φ) quasilinear in the derivative of u^a.

[16] For "if," suppose that $V^\alpha F_\alpha>0$ everywhere on S. It follows that there exists a positive-definite metric field, $g_{\alpha\beta}$, on the manifold S such that $V^\alpha g_{\alpha\beta}=F_\beta$ everywhere. Choose one (e.g., the sum of $F_\alpha F_\beta/(F_\gamma V^\gamma)$ and a suitable positive semi-definite tensor $h_{\alpha\beta}$ that annihilates V^α) and consider the bilinear expression

$$-(w_m u^m)[g_{ab}\delta u^a \delta' u^b + g_{\alpha\beta}\delta\varphi^\alpha \delta'\varphi^\beta] - w_m F_\alpha [\delta u^m \delta'\varphi^\alpha + \delta' u^m \delta\varphi^\alpha].$$

This bilinear expression indeed arises, as described in Appendix B, from Eqs. (20)–(21), and is indeed positive-definite (for w_m sufficiently close to u_m). So, this bilinear expression gives rise to a hyperbolization. The converse is easy.

R. Acad. Sci. Paris **276**, 1317–1320 (1973); and also G. Pichon, "Théorèmes d'existence pour les équations des milieux élastiques," J. Math. Pures Appl. **45**, 395–409 (1966). For a brief summary of this subject, see Ref. 4.

[23] There could also be included on the right side of this equation terms algebraic in the electromagnetic and other fields. Such terms would represent, e.g., an effect of the electromagnetic field on the rates of chemical reactions.

[24] Note that there are no expressions, algebraic in the gravitational fields, that could be introduced on the right in these equations. This is a reflection of "the equivalence principle."

[25] The most general candidate for such a stress-energy (i.e., the most general algebraic function of our fields, having the correct index-structure) is given by $T_{ab}=(\rho+p)u_a u_b + p g_{ab}$, where ρ,p are some functions on the manifold S of fluid states. When does there exist such a T^{ab} that, in addition, is conserved, $\nabla_b T^{ab}=0$, by virtue of the field equations (20)–(21)? It is not difficult to check that (assuming $V^\alpha F_\alpha>0$; and demanding $\rho+p>0$) a necessary and sufficient condition is that the fields F_α, V^α, and T^α on S satisfy the following three equations: $F_{[\alpha}\nabla_\beta F_{\gamma]}=0$, $T^\alpha K_\alpha=0$, and $\nabla_{[\alpha}(K_{\beta]}+F_{\beta]}=0$, where we have set $K_\alpha=(2V^\beta\nabla_{[\beta}F_{\alpha]}+F_\alpha)/(V^\gamma F_\gamma)$.

[26] In the resulting system, there will initially be two versions of "the derivative of the metric g_{ab}," one being the original derivative operator ∇_a, and the other arising (via g_{ab}) through passage to the derivative system. These two versions are then to be set equal to each other, via Eq. (A2). A similar phenomenon occurs, e.g., on taking the derivative system of the Klein-Gordon system.

[27] This "suppression" proceeds, in more detail, as follows. Choose on the 2-manifold S, a function s (which is interpreted in Ref. 17 as the entropy per particle) satisfying $V^\alpha\nabla_\alpha s=0$. Now delete the field $\zeta_a{}^\alpha$ everywhere, by replacing the component $\zeta_a{}^\alpha\nabla_\alpha s$ of $\zeta_a{}^\alpha$ by some new field f_a, and the remaining components of $\zeta_a{}^\alpha$ by $(\nabla\varphi)_a{}^\alpha$. To the resulting system add those further equations that are required for integrability of the constraints.

[28] In fact, there is, at this level of generality, a possible anomaly with the system (A3)–(A4). In some cases, further *algebraic* conditions on the fields can follow from Eq. (A4). In fact, this anomaly will never arise in systems of interest, because it is precluded by the requirement, which we shall impose shortly, that all constraints of the original system (A1), be integrable.

[29] The number of effective constraints of Eq. (A4) is the dimension of the vector space of tensors $\Lambda^{ab}{}_\alpha$ satisfying $\Lambda^{ab}{}_\alpha=\Lambda^{[ab]}{}_\alpha$ and $w_a\Lambda^{ab}{}_\alpha=0$ (namely, $(n-1)(n-2)u/2$), minus the dimension of the vector space of such tensors of the form $c^a{}_A k^{Ab}{}_\alpha$ for $c^a{}_A$ a constraint (namely, $\hat{c}-c$).

[30] Recall that the product of two bundles, with the same base space M, is the bundle, again with the base space M, whose fibre, over point $x\in M$, is given by the product of the fibres, over x, in the separate bundles.

Reduction of Sasakian manifolds

(Received 7 February 2001; accepted for publication 9 May 2001)

We show that the contact reduction can be specialized to Sasakian manifolds. We prove that the Sasakian reduction is compatible with the Kähler reduction both in the cone construction and in the Boothby–Wang fibration. In particular, applying Futaki's results, we obtain a sufficient condition for the reduced space of a regular Sasakian–Einstein manifold to be Sasakian–Einstein. We present examples of Sasakian–Einstein manifolds obtained by S^1 reduction of standard Sasakian spheres. © *2001 American Institute of Physics.* [DOI: 10.1063/1.1386636]

I. INTRODUCTION

The reduction technique was naturally extended from symplectic to contact structures by Geiges in Ref. 1 and Albert in Ref. 2. On the other hand, Boyer, Galicki and B. Mann defined in Ref. 3 a moment map for 3-Sasakian manifolds, thus extending the reduction procedure for nested metric contact structures. Quite surprisingly, a reduction scheme for Sasakian manifolds (contact manifolds endowed with a compatible Riemannian metric satisfying a curvature condition), was still missing.

In this note, based on the preprint,[4] we fill the gap by defining a Sasakian moment map and constructing the associated reduced space (compare with Ref. 5; here we focus on the Riemannian aspects). We then relate Sasakian reduction to Kähler reduction *via* the Kähler cone over a Sasakian manifold and *via* the Boothby–Wang fibration. Further, we derive a condition, similar to Futaki's, for the reduced manifold of a regular Sasakian–Einstein manifold to be Sasakian–Einstein. We end this paper with some completely worked examples of the S^1-reduction of standard Sasakian spheres. Most of the reduced Sasakian structures that we obtain are Einstein. Some of them are among the examples considered in Ref. 6, however our methods allow a much simpler check of the Einstein condition.

Sasakian manifolds seem to be more and more important in superconformal field theories, being connected with the Maldacena conjecture. One of our examples, a S^1 bundle over $S^2 \times S^2$, already appeared in Ref. 7, where the Kähler reduction of the cone over a Sasakian manifold is implicitly used.

II. SASAKIAN MANIFOLDS

In this section we briefly recall the notion of a Sasakian manifold. The definition we give is not the standard one, but is suited for our purpose. For more details, we refer to Refs. 8 and 9.

Definition 2.1: A *Sasakian* manifold is a $(2n+1)$-dimensional Riemannian manifold (N,g) endowed with a unitary Killing vector field ξ such that the curvature tensor of g satisfies the equation

$$R(X,\xi)Y = \eta(Y)X - g(X,Y)\xi, \tag{2.1}$$

where η is the metric dual 1-form of ξ: $\eta(X) = g(\xi,X)$.

[a)]Electronic mail: geogran@math.uconn.edu
[b)]Electronic mail: lornea@imar.ro

Let $\varphi=\nabla\xi$, where ∇ is the Levi-Civita connection of g. The following formulas are then easily deduced:

$$\varphi\xi=0, \quad g(\varphi Y,\varphi Z)=g(Y,Z)-\eta(Y)\eta(Z), \quad d\eta(X,Y)=g(\phi X,Y). \tag{2.2}$$

It can be seen that η is a contact form on N, whose Reeb field is ξ (it is also called the characteristic vector field). Moreover, the restriction of φ to the contact distribution $\eta=0$ is an almost complex structure satisfying the ''integrability'' condition (called normality) $[\varphi,\varphi]+2\,d\eta\otimes\xi=0$.

The simplest example is the standard sphere $S^{2n+1}\subset\mathbb{C}^{n+1}$, with the metric induced by the flat one of $\mathbb{C}^{n+1}$. The characteristic Killing vector field is $\xi_p=-i\vec{p}$, i being the imaginary unit; this is the standard Sasakian structure of the odd sphere. Other Sasakian structures on the sphere can be obtained by D-homothetic transformations (cf. Ref. 10). Also, the unit sphere bundle of any real space form is Sasakian.

More generally, the quantization bundle of a compact Kähler manifold naturally carries a Sasakian structure. The converse construction, possible when the characteristic field is regular, is known as the Boothby–Wang fibration. Precisely, the following result (the metric part is due to Morimoto and Hatakeyama) is available (cf. Refs. 11 or 9).

Theorem 2.1: Let (P,h) be a Hodge manifold. There exists a principal circle bundle $\pi:N\to P$ and a connection form η in it, with curvature from the pull-back of the Kähler form of P, which is a contact form on S. Let ξ be the vector field dual to η with respect to the metric $g=\pi^*h+\eta\otimes\eta$. Then (N,g,ξ) is Sasakian.

The following equivalent definition puts Sasakian geometry into the framework of holonomy groups. Let $C(N)=N\times\mathbb{R}_+$ be the cone over (N,g). Endow it with the warped-product cone metric $C(g)=r^2g+dr^2$. Let $R_0=r\,\partial r$ and define on $C(N)$ the complex structure J acting like this (with obvious identifications): $JY=\varphi Y-\eta(Y)R_0$, $JR_0=\xi$. We have the following.

Theorem 2.2 Ref. 9: (N,g,ξ) is Sasakian if and only if the cone over N $(C(N),C(g),J)$ is Kählerian.

III. MAIN RESULTS

A. Direct construction

In this section we show that the contact map defined in Ref. 1 is compatible with the Sasakian metric and the contact reduced space is indeed Sasakian.

Theorem 3.1: Let (N,g,ξ) be a compact $2n+1$-dimensional Sasakian manifold and G a compact d-dimensional Lie group acting on N by contact isometries. Suppose $0\in\mathfrak{g}^*$ is a regular value of the associated moment map μ. Then the reduced space $M=N//G:=\mu^{-1}(0)/G$ is a Sasakian manifold of dimension $2(n-d)+1$.

Proof: By Ref. 1, the contact moment map $\mu:N\to\mathfrak{g}^*$ is defined by

$$<\mu(x),\underline{X}>=\eta(X),$$

for any $\underline{X}\in\mathfrak{g}$ and X the corresponding field on N. We know that the reduced space is a contact manifold, *loc. cit.* Hence we only need to check that (1) the Riemannian metric is projected on M and (2) the field ξ projects to a unitary Killing field on M such that the curvature tensor of the projected metric satisfies formula (2.1).

To this end, we first describe the metric geometry of the Riemannian submanifold $\mu^{-1}(0)$.

Let $\{\underline{X}_1,\ldots,\underline{X}_d\}$ be a basis of $\mathfrak{g}$ and let $\{X_1,\ldots,X_d\}$ be the corresponding vector fields on N. Since 0 is a regular value of μ, $\{X_{ix}\}$ is a linearly independent system in each $T_x\mu^{-1}(0)$. From the very definition of the moment map we have $\eta_p(X_i)=\mu(p)(X_i)=0$, hence $X_i\perp\xi$. As G acts by contact isometries, we have

$$\mathcal{L}_{X_i}g=0, \quad \mathcal{L}_{X_i}\eta=0 \quad i=1,\ldots,d. \tag{3.1}$$

Note that these also imply $[X_i,\xi]=\mathcal{L}_{X_i}\xi=0$.

We observe that $\mu^{-1}(0)$ is an isometrically immersed submanifold of N (we denote the induced metric also with g) whose tangent space in each point is described by $Y\in T_x\mu^{-1}(0)$ if and only if $d\mu_x(Y)=0$. Hence, by the definition of the moment map, the vector fields ξ and X_i are tangent to $\mu^{-1}(0)$. Moreover, for any Y tangent to $\mu^{-1}(0)$, one has $g(\varphi X_i,Y)=d\eta(Y,X_i)=d\mu(Y)=0$; hence the vector fields $\{X_i\}$ produce a local basis (not necessarily orthogonal) of the normal bundle of $\mu^{-1}(0)$. The shape operators $A_i:=A_{\varphi X_i}$ of this submanifold in N are computed as follows [we let ∇, ∇^N be the Levi Civita covariant derivatives of $\mu^{-1}(0)$, resp. N]:

$$\begin{aligned} g(A_iY,Z)&=-g(\nabla^N_Y(\|X_i\|^{-1}\varphi X_i),Z)=-g(Y(\|X_i\|^{-1})\varphi X_i,Z)-g(\|X_i\|^{-1}\nabla^N_Y(\varphi X_i),Z)\\ &=-\|X_i\|^{-1}g(\nabla^N_Y(\varphi X_i),Z)=-\|X_i\|^{-1}g(\nabla^N_Y(\varphi)X_i+\varphi\nabla^N_YX_i,Z)\\ &=-\|X_i\|^{-1}g(\eta(X_i)Y-g(X_i,Y)\xi+\varphi\,\nabla^N_YX_i,Z)\\ &=\|X_i\|^{-1}\{g(X_i,Y)\,\eta(Z)-g(\varphi\,\nabla^N_YX_i,Z\}. \end{aligned}\tag{3.2}$$

In particular, for the corresponding quadratic second fundamental forms we get

$$h_i(Y,\xi)=\|X_i\|^{-1}g(X_i,Y),\quad h_i(\xi,\xi)=0.\tag{3.3}$$

Consequently, one easily obtains the following: *the restriction of the vector field ξ is Killing on $\mu^{-1}(0)$ too*.

Using the Gauss equation of a submanifold,

$$R^N(X,Y,Z,W)=R^{\mu^{-1}(0)}(X,Y,Z,W)+g(h(X,Z),h(Y,W))-g(h(X,W),h(Y,Z)),$$

and the formula (3.2) we now compute the needed part of the curvature tensor of $\mu^{-1}(0)$ at a fixed point $p\in\mu^{-1}(0)$. We take X,Y,Z orthogonal to ξ_p and obtain

$$\begin{aligned} g(R^{\mu^{-1}(0)}(X,\xi)Y,Z)-g(R^N(X,\xi)Y,Z)&=-\sum_{i=1}^{d}\|X_i\|^{-2}\{h_i(X,Y)h_i(\xi,Z)-h_i(X,Z)h_i(\xi,Y)\}\\ &=-\sum_{i=1}^{d}\|X_i\|^{-2}\{g(X_i,Z)g(\nabla^N_XX_i,\varphi Y)\\ &\quad-g(X_i,Y)g(\nabla^N_XX_i,\varphi Z)\} \end{aligned}\tag{3.4}$$

(note that $\nu_i=\|X_i\|^{-1}\varphi X_{ip}$ are chosen to be orthonormal in p; this is always possible pointwise by an appropriate choice of the initial $\underline{X}_i$).

Now let $\pi:\mu^{-1}(0)\to M$ and endow M with the projection g^M of the metric g such that π becomes a Riemannian submersion. This is possible because G acts by isometries. In this setting, the vector fields X_i span the vertical distribution of the submersion, while ξ is horizontal and projectable (because $\mathcal{L}_{X_i}\xi=0$). Denote with ζ its projection on M. ζ is obviously unitary. To prove that ζ is Killing on M, we just observe that $\mathcal{L}_\zeta g(Y,Z)=\mathcal{L}_\xi g(Y^h,Z^h)$, where Y^h denotes the horizontal lift of Y. Finally, to compute the values $R^M(X,\zeta)Y$ of the curvature tensor of g^M, we use the O'Neill formula [cf. Ref. 12 Eq. (9.28f)]:

$$\begin{aligned} g^M(R^M(X,\zeta)Y,Z)&=g(R^{\mu^{-1}(0)}(X^h,\xi)Y^h,Z^h)+g(A(X^h,\xi),A(Y^h,Z^h))-g(A(\xi,Y^h),A(X^h,Z^h))\\ &\quad+g(A(X^h,Z^h),A(\xi,Z^h)), \end{aligned}$$

where X,Y,Z are unitary, normal to ζ and the O'Neill (1,2) tensor A is defined as: $A(Z^h,X^h)$ = vertical part of $\nabla_{Z^h}X^h$. Using the Gauss formula and (3.3), we obtain

$$g(\nabla_{Z^h}\xi, X_i) = g(\varphi Z^h, X_i) = -g(Z^h, \varphi X_i) = 0;$$

hence $\nabla_{Z^h}\xi$ has no vertical part and $A(Z^h,\xi)=0$. Thus

$$R^M(X,\zeta)Y = R^{\mu^{-1}(0)}(X^h,\xi)Y^h = R^N(X^h,\xi)Y^h$$

because of (3.4) and the fact that X^h, Y^h are normal to all X_i. Hence

$$R^M(X,\zeta)Y = g(\xi,Y^h)X^h - g(X^h,y^h)\xi = g^M(\zeta,Y)X - g^M(X,Y)\zeta,$$

which proves that (M,g^M,ζ) is a Sasakian manifold. □

B. Compatibility with the cone construction

In the following we relate Sasakian reduction to Kähler reduction by using the cone construction. Roughly speaking, we prove that reduction and taking the cone are commuting operations.

Let $\omega = dr \wedge \eta + r^2\, d\eta$ be the Kähler form of the cone $C(N)$ over a Sasakian manifold (N,g,ξ). If ρ_t are the translations acting on $C(N)$ by $(x,r)\mapsto(x,tr)$, then the vector field $R_0 = r\,\partial r$ is the one generated by $\{\rho_t\}$. Moreover, the following two relations are useful:

$$\mathcal{L}_{R_0}\omega = \omega, \quad \rho_t^*\omega = t\omega. \tag{3.5}$$

Suppose that a compact Lie group G acts on $C(N)$ by holomorphic isometries, commuting with ρ_t. This ensures a corresponding action of G on N. In fact, we can consider $G \cong G\times\{Id\}$ acting as $(g,(x,r))\times(gx,r)$.

Suppose that a moment map $\Phi: C(N)\to\mathfrak{g}$ exists.

As above, let $\{\underline{X}_1,\ldots,\underline{X}_d\}$ be a basis of $\mathfrak{g}$ and let $\{X_1,\ldots,X_d\}$ be the corresponding vector fields on $C(N)$. We see that X_i are independent on r, hence can be considered as vector fields on N. Furthermore, the commutation of G with ρ_t implies

$$\Phi(\rho_t(p)) = t\Phi(p). \tag{3.6}$$

Now we imbed N in the cone as $N\times\{1\}$ and let $\mu := \Phi|_{N\times\{1\}}$. This is the moment map of the action of G on N. To see this, recall the definition of the symplectic moment map $\Phi = (\Phi_1,\ldots,\Phi_d)$: Φ_i is given up to constant by $d\Phi_i(Y) = \omega(X_i,Y)$. Here we uniquely determine Φ_i by imposing the condition $\eta(X_i) = \Phi|_{N\times\{1\}}$. This immediately implies that the Reeb field of N is orthogonal to the vector fields X_i since $g(\xi,X_i) = \eta(X_i) = 0$. As G acts by isometries on $C(N)$, we may project the cone metric to a metric on $N//G\times\mathbb{R}_+$ which we denote by g_0. Then $g_0(Y,Z) = C(g)(Y^h,Z^h)$, where Y^h, Z^h are the unique vector fields on $\Phi^{-1}(0)$ orthogonal to all of X_i which project on Y, Z (we call them horizontal).

Let $P = \Phi^{-1}(0)/G$ be the reduced Kähler manifold. The key remark is that because of (3.6), $\Phi^{-1}(0)$ is the cone $N'\times\mathbb{R}_+$ over $N' = \{x\in N; (x,1)\in\Phi^{-1}(0)\}$. Moreover, since the actions of G and ρ_t commute, one has an induced action of G on N'. Then

$$\Phi^{-1}(0)/G \cong (N'\times\mathbb{R}_+)/G \cong N'/G\times\mathbb{R}_+.$$

The manifold $N'//G\times\mathbb{R}_+$ is Kähler, as the reduction of a Kähler manifold, but we still have to check that this Kähler structure is a cone one. For the more general, symplectic case, this was done in Ref. 13. Let g_0 be the reduced Kähler metric and g' be the Sasakian reduced metric on $N'//G$. It is easily seen that the lift of g_0 to $\Phi^{-1}(0)$ coincides with the lift of the cone metric $r^2g' + dr^2$ on horizontal fields. This implies that the cone metric coincides with g_0.

Summing up we have proved the following.

Theorem 3.2: Let (N,g,ξ) be a Sasakian manifold and let $(C(N),\ C(g),J)$ be the Kähler cone over it. Let a compact Lie group G act by holomorphic isometries on $C(N)$ and commuting with the action of the 1-parameter group generated by the field R_0. If a moment map with regular

value 0 exists for this action, then a moment map with regular value 0 exists also for the induced action of G on N. Moreover, the reduced space $C(N)//G$ is the Kähler cone over the reduced Sasakian manifold $N//G$.

The advantage of defining the Sasakian reduction *via* Kähler reduction, as done in Ref. 3 for 3-Sasakian manifolds, is the avoiding of curvature computations. However, as we shall see, the direct construction is easily applicable.

C. Compatibility with the Boothby–Wang fibration and obtaining Sasakian–Einstein spaces by reduction

Let (N,g,ξ) be a compact Sasakian manifold with a regular characteristic vector field and let $\pi:N\to P$ be the corresponding Boothby–Wang fibration over the Hodge base P. Let G be a compact Lie group acting on N by Sasakian transformations. By (3.1), it preserves the fibers of π; hence it induces an action by Kähler transformations on P. If we denote with ${}^N\mu$, ${}^P\mu$ the corresponding moment maps, using the relation (cf. Theorem 2.1) $g(X,\varphi Y)=\pi^*\omega(X,Y)$ and the definitions of the respective moment maps, it is easy to see that we have an S^1 subbundle ${}^N\mu^{-1}(0)\to{}^P\mu^{-1}(0)$ and an S^1 bundle $N//G\to P//G$. Finally one can check that 0 is a regular value for an induced moment map on the base using the relation

$$d\,{}^N\mu(X)=d\,\eta(X,\cdot)=\pi^*\omega(X,\cdot)=\pi^*d\,{}^P\mu$$

The details being easily settled, we can state the following.

Proposition 3.1: Let G be a compact Lie group acting by Sasakian transformations on the total space of a Boothby–Wang fibration $\pi:N\to P$. Then there exists a Boothby–Wang fibration of the reduced spaces $N//G\to P//G$.

On the other hand, if the Hodge base of a Boothby–Wang fibration is Kähler–Einstein, then the total space is Sasakian–Einstein, as proved in Ref. 9. According to Futaki (cf. Ref. 14, Corollary 7.3.4), if one reduces a Kähler–Einstein manifold, the reduced space is still Einstein if and only if the length of the multivector $X_1\wedge\cdots\wedge X_d$ is constant on the level set of the moment map. Hence, one way to obtain Sasakian–Einstein metrics *via* reduction is to start with a regular Sasakian–Einstein manifold and with a Sasakian action inducing on the Hodge base a Kähler action of Futaki's type. The precise result is the following.

Theorem 3.3: Let G be a compact Lie group acting by Sasakian transformations on the regular Sasakian–Einstein manifold N having 0 as a regular value of the corresponding moment map μ. If the length of the multivector $X_1\wedge\cdots\wedge X_d$ is constant on $\mu^{-1}(0)$ then the reduced space is Sasakian–Einstein.

Proof: First observe that the Boothby–Wang fibration $\pi:N\to P$ has a Kähler–Einstein base, with positive Ricci curvature, according to Ref. 9, Theorem 2.5(iv). Now, from the equations (3.1) we see that the S^1 action on $\mu^{-1}(0)$ commutes with the G-action. In particular the multivector $X_1\wedge\cdots\wedge X_d$ is projectable to $\mu^{-1}(0)/S^1$ for the projection $\pi:\mu^{-1}(0)\to\mu^{-1}(0)/S^1$. In view of the preceding section, this is a restriction of the Boothby–Wang fibration to the corresponding zero-sets of the moment maps on N and P, respectively. Since it is a Riemannian submersion and X_i are orthogonal to ξ, the lengths of the projected vectors are preserved, as well as the length of the projected multivector. Now we can apply Futaki's result (Ref. 14, Corollary 7.3.4) in order to conclude that the base for the reduced Boothby–Wang fibration $N//G\to P//G$ is Kähler–Einstein. Then, again according to Ref. 9, Theorem 2.5(iv), the reduced Sasakian manifold is Sasakian–Einstein. □

We apply this result in the examples of the last section.

In the same spirit, combining Ref. 9, Theorem 2.5(iii) (stating that the base of the Boothby–Wang fibration is Fano if and only if the Ricci curvature of the total space is >-2) and Ref. 14, Corollary 7.3.3 (asserting that the reduced space of a Fano manifold is again Fano), we obtain the following.

Proposition 3.2: Let G be a compact Lie group acting by Sasakian transformations on the regular Sasakian–Einstein manifold N having 0 as a regular value of the corresponding moment map μ. Then N has Ricci curvature Ric>-2 if and only if $N//G$ has Ricci curvature Ric>-2.

IV. EXAMPLES: S^1 ACTIONS ON SASAKIAN SPHERES

Example 4.1: Let us start with $S^7\subset\mathbb{C}^4$ with its standard Sasakian structure. Let the complex coordinates of $\mathbb{C}^4$ be $(z_0,\ldots,z_3)$, with $z_j=x_j+iy_j$. The contact form on S^7 can then be written as

$$\eta=\sum_{j=0}^{3}(x_j\,dy_j-y_j\,dx_j),$$

and its Reeb field is

$$\xi=\sum_{j=0}^{3}(x_j\,\partial y_j-y_j\,\partial x_j).$$

Let S^1 act on S^7 by $e^{it}\mapsto(e^{-it}z_0,e^{-it}z_1,e^{it}z_2,e^{it}z_3)$. The associated field of this action is (in real coordinates)

$$X_0=-(x_0\,\partial y_0-y_0\,\partial x_0)-(x_1\,\partial y_1-y_1\,\partial x_1)+(x_2\,\partial y_2-y_2\,\partial x_2)+(x_3\,\partial y_3-y_3\,\partial x_3).$$

The moment map $\mu:S^7\to\mathbb{R}$ reads as

$$\mu(z)=\eta_z(X_0)=-|z_0|^2-|z_1|^2+|z_2|^2+|z_3|^2,$$

with zero level set

$$\{z\in S^7;\ \ |z_0|^2+|z_1|^2=|z_2|^2+|z_3|^2\}=S^3\left(\frac{1}{\sqrt{2}}\right)\times S^3\left(\frac{1}{\sqrt{2}}\right).$$

Clearly μ is nondegenerate on $\mu^{-1}(0)$.

The reduced space can be identified with $S^3\times S^3/S^1$ which, by Ref. 6, is diffeomorphic with $S^2\times S^3$. [In this case, one can also avoid the topological arguments in Ref. 6 and identify the reduced space by observing that the following diffeomorphism of $S^3\times S^3$: $(z_0,z_1,z_2,z_3)\mapsto(z_0z_3+\overline{z_1z_2},z_0z_2-\overline{z_1z_3},z_2,z_3)$ is equivariant with respect to the previous S^1 action which, restricted to the second factor of the product, is the usual action inducing the Hopf fibration; *mille grazie* to Rosa Gini and Maurizio Parton for letting us know it (Ref. 15).]

The reduced Sasakian structure obtained in this way on $S^2\times S^3$ is directly checked to be Einstein and to project on the Kähler Einstein metric of $\mathbb{C}P^1\times\mathbb{C}P^1$ making the fiber map be a Riemannian submersion. As by Ref. 6 such an Einstein metric is unique, our reduced Sasakian structure coincides with the Sasakian structure found in Ref. 16 viewing $S^2\times S^3$ as a minimal submanifold of S^7, the total space of the pull-back over $\mathbb{C}P^1\times\mathbb{C}P^1$ of the Hopf bundle $S^7\to\mathbb{C}P^3$. The same Einstein–Sasakian metric on $S^2\times S^3$ also appears in Ref. 10, constructed by a different approach. In Example 4.3 we will generalize this structure by making use of Theorem 3.2.

Example 4.2: Consider again S^7 as the starting Sasakian manifold, but let S^1 act by $e^{it}\mapsto(e^{-kit}z_0,e^{it}z_1,e^{it}z_2,e^{it}z_3)$, $k\in\mathbb{Z}_+$. Now $\mu^{-1}(0)\cong S^1(\sqrt{k/k+1})\times S^5(\sqrt{1/k+1})$. In order to identify the reduced space, we regard the k:1 mapping,

$$S^1\times S^5\ni(z_0,z_1,z_2,z_3)\mapsto((z_0)^{-k},z_1,z_2,z_3)\in S^1\times S^5.$$

It induces a k:1 map from $M=S^1\times S^5/S^1$, where S^1 acts diagonally, to the reduced space $\mu^{-1}(0)/S^1$ with the action given above. As in Ref. 15, the map

$$(z_0,\ldots,z_3)\mapsto(z_0,\overline{z_0}z_1,\overline{z_0}z_2,\overline{z_0}z_3)$$

is an equivariant diffeomorphism of $S^1\times S^5$, equivariant with respect to the diagonal action of S^1 and the action of S^1 on the first factor. Hence M is diffeomorphic to S^5 and the reduced Sasakian space is $S^5/\mathbb{Z}_k$. Again, we shall see below that the metric is actually Sasakian–Einstein and it is the same as that found in Ref. 6.

Example 4.3: In general, consider the weighted action of S^1 on $S^{2n-1}\subset\mathbb{C}^n$ by

$$(e^{it},(z_0,\ldots,z_{n-1}))\mapsto(e^{\lambda_0 it}z_0,\ldots,e^{\lambda_n it}z_{n-1}),$$

where $(\lambda_0,\ldots,\lambda_{n-1})\in\mathbb{Z}^n$. The associated moment map,

$$\mu(z)=\lambda_0|z_0|^2+\cdots+\lambda_n|z_{n-1}|^2,$$

is regular on $\mu^{-1}(0)$ for any $(\lambda_0,\ldots,\lambda_{n-1})$ such that $\lambda_0\cdots\lambda_{n-1}\neq 0$, $(\lambda_0,\ldots,\lambda_{n-1})=1$ and at least two λ's have different signs (compare with the 3-Sasakian case where the weights obey to more restrictions; cf. Ref. 3).

Now take $\lambda_0=\cdots=\lambda_k=a$ and $\lambda_{k+1}=\cdots=\lambda_{n-1}=-b$, $a,b\in\mathbb{Z}_+$ relatively prime. Then $\mu^{-1}(0)\cong S^{2k+1}(\sqrt{a/a+b})\times S^{2(n-k)-1}(\sqrt{b/a+b})$. Moreover the length of the induced vector field X_0 on μ^{-1} is easily calculated to be $(a^2+b^2)/2$. Now we can apply Theorem 3.2 to deduce that the reduced metric is Sasakian–Einstein. Note that the induced metric on $\mu^{-1}(0)$ coincides with the product metric of the standard metrics of the two factors. Moreover we see that the reduced space is diffeomorphic with an S^1 factor of the above product of spheres given by the following action:

$$(e^{it},(x,y))\mapsto(e^{iat}x,e^{-ibt}y).$$

One can now adapt the arguments of Ref. 6, Corollary 2.2 and prove that the reduced spaces are S^1 bundles over $\mathbb{C}P^k\times\mathbb{C}P^{n-k-1}$ and, for $1\leqslant k$, $4<n$, they are not homeomorphic to each other in general. These are the examples considered in Ref. 6. However, for $k=1$, $n=2$, the reduced space is always diffeomorphic with $S^2\times S^3$. Hence, one obtains an infinite family of Sasakian structures on $S^2\times S^3$.

ACKNOWLEDGMENTS

Some of the results in this article were communicated at the 2nd Meeting on Quaternionic Structures in Mathematics and Physics, Rome 1999. This research was initiated during the authors visit at the *Abdus Salam International Center for Theoretical Physics*, Trieste, in summer 1999. The authors thank the Institute for support and excellent environment. The second author also acknowledges financial and technical support from the *Erwin Schrödinger Institute*, Vienna, in September 1999, during the "Special holonomies" semester. (Received 10 November 2000; accepted for publication 16 April 2001)

There is a decomposition of a Lie algebra for open matrix chains akin to the triangular decomposition. We use this decomposition to construct unitary irreducible representations. All multiple meson states can be retrieved this way. Moreover, they are the only states with a finite number of non-zero quantum numbers with respect to a certain set of maximally commuting linearly independent quantum observables. Any other state is a tensor product of a multiple meson state and a state coming from a representation of a quotient algebra that extends and generalizes the Virasoro algebra. We expect the representation theory of this quotient algebra to describe physical systems at the thermodynamic limit. © *2001 American Institute of Physics.* [DOI: 10.1063/1.1384866]

I. INTRODUCTION

Theories with matrix degrees of freedom are of wide interest in physics. Quantum chromodynamics (QCD) is an important example. Each gluon field carries two color indices. They can be treated as row and column indices of a matrix field. A typical term in the action of a physical theory is constructed by multiplying matrix fields together and taking the trace of the resulting product; this serves to preserve gauge invariance. M(atrix)-theory,[1] a candidate for a unified theory of gravitational, strong and electroweak interactions, is another major example. In this model, the matrices describe the positions of D0-branes and their relative distances noncommutatively.[2]

So far, the most successful calculational tool for both theories is perturbative analysis, whose approximation assumptions are valid in the high-energy regime of QCD and the classical limit of M-theory. Indeed, there is an excellent agreement between perturbative QCD predictions and measurements of high-energy scattering experiments among quarks and gluons. (See Ref. 3, for instance, for a general introduction and further literature on the subject.) Perturbative M-theory calculations of scattering processes among M-theory objects are, by and large, in good agreement with classical supergravity, too. (References 4 and 5 are two recent reviews on the subject. Additional literature can be found therein.) To study important low-energy phenomena of QCD like color confinement, hadron spectrum or the parton distribution of a nucleon, or large quantum effects of supergravity, however, it is necessary to develop nonperturbative methods.

As we have just noted, both QCD and M-theory are intrinsically matrix models. Little is known about the ramifications of the matrix nature, though many researchers believe that this is the key to a deeper understanding of the physics of a matrix model. One approach is to study its symmetry. This consists in identifying a symmetry of a generic matrix model, expressing the symmetry in terms of a Lie algebra (or quantum group) and developing a representation theory for the Lie algebra.

[a)]Electronic mail: jakobsen@math.ku.dk
[b)]Electronic mail: lee@math.ku.dk

Numerous examples have demonstrated the fruitfulness of studying representation theories. To name but a few, the representation theory of so(3) shapes the energy spectra of physical systems with rotational symmetry; the representation theory of the Poincaré algebra enables us to classify massless fundamental particles;[3] even more remarkably, the so(4) symmetry of the hydrogenic atom dictates its energy spectrum completely.[6]

Perhaps the most prominent example in recent years is the Virasoro algebra, a Lie algebra describing two-dimensional conformal symmetry. Its representation theory reveals how the reducibility of a highest weight representation depends on the values of c, the central charge, and h, the eigenvalue of the highest weight state under the action of L_0, the energy operator. We can use these irreducible representations to describe compactified string theory.[7] We can also use a small number of highest weight reducible representations to build up a so-called minimal model describing a physical system at criticality like the Ising model and the three-state Potts model.[8] In addition, the representation theory renders us a character formula

$$\mathrm{Tr}\exp\left[2\pi\mathrm{i}\tau\left(L_0-\frac{c}{24}\right)\right]=\frac{q^{h+(1-c)/24}}{\eta(\tau)},$$

where τ is a complex variable, Tr means a sum over all states of highest weight representation and $\eta(\tau)$ is the Dedekind function

$$\eta(\tau)=\exp\left(\frac{\pi\mathrm{i}\tau}{12}\right)\prod_{n=1}^{\infty}(1-\exp(2\pi\mathrm{i}n\tau)).$$

If we interpret τ as the ratio between two complex periods along two linearly independent directions on a torus, this character formula becomes nothing but the holomorphic part of the partition function of a conformal field theory on a torus.[9] Thus we can solve for the thermodynamics of this system.

In Ref. 10, Rajeev and one of us gave an exposition on the basic properties of a newly discovered Lie algebra $\hat{G}_{\Lambda,\Lambda_F}$ for open matrix chains in the large-N limit.[11] (By an open matrix chain we mean a state produced by the action of a product of a row vector, several square matrices and a column vector of creation operators on the vacuum.) They can be interpreted as mesons in QCD, discretized open strings in a string-bit model[12] or one-dimensional open quantum spin chain systems. The relation of this Lie algebra with another Lie algebra for closed matrix chains was discussed at length in Ref. 13. We would like to build upon the results of Ref. 10, and work out a representation theory for it. In this article, we will present first results on the subject.

As noted in Ref. 13, $\hat{G}_{\Lambda,\Lambda_F}$ can be broken down into a direct sum of subalgebras in a manner similar to the triangular decomposition of a semi-simple Lie algebra. Just as a traditional triangular decomposition gives rise to lowest weight representations, this decomposition for $\hat{G}_{\Lambda,\Lambda_F}$ leads to interesting representations generated by a weight vector, which we will call a lowest weight vector. The corresponding representation will be called a lowest weight representation. It can be made irreducible by quotienting out the maximal subrepresentation. Some lowest weight vectors produce unitary representations.

Since the Cartan subalgebra we have found for $\hat{G}_{\Lambda,\Lambda_F}$ is simultaneously a maximally commutative subalgebra, we can treat it as a linear space generated by a maximally commuting set of linearly independent quantum observables. A lowest weight vector is then a quantum eigenstate of this set of quantum observables, and the lowest weight a set of quantum numbers. An interesting result we are going to show is that *if only a finite number of these quantum numbers are nonzero, then this eigenstate must be, in the context of QCD, a multiple meson state. Any state with an infinite number of nonzero quantum numbers must be a tensor product of a multiple meson and a state coming from an irredicible representation of a certain quotient algebra which extends and generalizes the Virasoro algebra*. Already for the case $\Lambda=1$ the quotient algebra is quite inter-

TABLE I. Some basis vectors of the grand string algebra. They form an overcomplete set of generators for the open string algebra. Λ and Λ_F are positive integers. λ_1, λ_2, λ_3 and λ_4 are positive integers between 1 and Λ_F inclusive. $\dot{I}$ and $\dot{J}$ are finite empty or nonempty sequences of integers, each of which is between 1 and Λ inclusive. I and J are finite nonempty sequences of integers, each of which is between 1 and Λ inclusive. $\bar{\Xi}$ and Ξ are operators acting on two different Λ_F-dimensional Hilbert spaces, and f, l, r and σ are operators acting on the same infinite-dimensional Hilbert spaces. All three Hilbert spaces were introduced in Ref. 10. (There is some abuse of notations here for the sake of future convenience; strictly speaking, the more proper notations $\bar{\Xi}^{\lambda_1}_{\lambda_2}\otimes l^{\dot{I}}_{\dot{J}}\otimes 1$, $1\otimes r^{\dot{I}}_{\dot{J}}\otimes \Xi^{\lambda_1}_{\lambda_2}$ and $1\otimes\sigma^{I}_{J}\otimes 1$ for the operators of the second, third and fourth kind, respectively, refer to the defining representation.)

Operator of which kind	Expression
first	$\bar{\Xi}^{\lambda_1}_{\lambda_2}\otimes f^{\dot{I}}_{\dot{J}}\otimes \Xi^{\lambda_3}_{\lambda_4}$
second	$\bar{\Xi}^{\lambda_1}_{\lambda_2}\otimes l^{\dot{I}}_{\dot{J}}$
third	$r^{\dot{I}}_{\dot{J}}\otimes \Xi^{\lambda_1}_{\lambda_2}$
fourth	σ^{I}_{J}
any	X, $X^{\dot{I}}_{\dot{J}}$ or $Y^{\dot{I}}_{\dot{J}}$

esting. Specifically, it is an extension of the Virasoro algebra by an infinite Heisenberg algebra.[14] We expect the representation theory of the quotient algebra to describe physical systems at the thermodynamic limit.

This article is organized as follows. We will review without proofs the definition of $\hat{G}_{\Lambda,\Lambda_F}$ and its basis properties in Sec. II, further details of which can be found in Refs. 10 and 13. We will work out two useful bases for the Lie algebra in Sec. III, and its Cartan subalgebra and root vectors in Sec. IV. (The reader is advised to read only the statements of the propositions in these two sections on a first reading, and return to them later on if he or she is interested in the details.) We will define the notion of a Verma-like module and the associated Hermitian form in Sec. V, and use this to identify the representation spaces of multiple meson states in Sec. VI and other states which are related to the quotient algebra in Sec. VII.

We follow Refs. 15 and 16 in the usage of Lie algebra terminologies.

II. DEFINITIONS

Two Lie algebras were defined in Ref. 13: the grand string algebra and the open string algebra. The latter is our major interest in this article, and was defined as a quotient of the former. We will briefly review them in this section. Further details of the notations and formalism can be found in Refs. 10 and 13. One agreement we need to make with the reader now is that *unless otherwise specified, the summation convention will not be adopted.*

The elements of the grand string algebra were originated from operators acting on closed or open matrix chains (which are sometimes called closed or open singlet states). Some of them are shown in Table I. A physical observable is a linear combination of such operators. An operator of the first kind replaces a whole open singlet state with a finite linear combination of open single states; an operator of the second kind replaces the conjugate and the adjacent adjoint partons of an open singlet state with a finite linear combination of open singlet states with possibly other conjugate and adjoint partons; an operator of the third kind is similar to the second kind in action except that it acts on the end with a fundamental parton; an operator of the fourth kind propagates

an open singlet state to a finite linear combination of open singlet states in each of which a middle segment of adjacent adjoint partons in the original state is replaced with a possibly different sequence of adjoint partons.

Note that *as operators acting on closed or open matrix chains, the operators tabulated are not linearly independent; as elements of the grand string algebra, however, they are linearly independent*. Listed below are the Lie brackets of the grand string algebra between

(1) an operator of the first kind and any operator:

$$[\overline{\Xi}^{\lambda_1}_{\lambda_2}\otimes f^{\dot I}_{\dot J}\otimes\Xi^{\lambda_3}_{\lambda_4},\overline{\Xi}^{\lambda_5}_{\lambda_6}\otimes f^{\dot K}_{\dot L}\otimes\Xi^{\lambda_7}_{\lambda_8}]=\delta^{\lambda_5}_{\lambda_2}\delta^{\dot K}_{\dot J}\delta^{\lambda_7}_{\lambda_4}\overline{\Xi}^{\lambda_1}_{\lambda_6}\otimes f^{\dot I}_{\dot L}\otimes\Xi^{\lambda_3}_{\lambda_8}-\delta^{\lambda_1}_{\lambda_6}\delta^{\dot I}_{\dot L}\delta^{\lambda_3}_{\lambda_8}\overline{\Xi}^{\lambda_5}_{\lambda_2}\otimes f^{\dot K}_{\dot J}\otimes\Xi^{\lambda_7}_{\lambda_4},\quad(1)$$

$$[\overline{\Xi}^{\lambda_1}_{\lambda_2}\otimes f^{\dot I}_{\dot J}\otimes\Xi^{\lambda_3}_{\lambda_4},\overline{\Xi}^{\lambda_5}_{\lambda_6}\otimes l^{\dot K}_{\dot L}]=\delta^{\lambda_5}_{\lambda_2}\overline{\Xi}^{\lambda_1}_{\lambda_6}\otimes\sum_{\dot J_1\dot J_2=\dot J}\delta^{\dot K}_{\dot J_1}f^{\dot I}_{\dot L\dot J_2}\otimes\Xi^{\lambda_3}_{\lambda_4}-\delta^{\lambda_1}_{\lambda_6}\overline{\Xi}^{\lambda_5}_{\lambda_2}\otimes\sum_{\dot I_1\dot I_2=\dot I}\delta^{\dot I_1}_{\dot L}f^{\dot K\dot I_2}_{\dot J}\otimes\Xi^{\lambda_3}_{\lambda_4},\quad(2)$$

$$[\overline{\Xi}^{\lambda_1}_{\lambda_2}\otimes f^{\dot I}_{\dot J}\otimes\Xi^{\lambda_3}_{\lambda_4},r^{\dot K}_{\dot L}\otimes\Xi^{\lambda_5}_{\lambda_6}]=\delta^{\lambda_5}_{\lambda_4}\overline{\Xi}^{\lambda_1}_{\lambda_2}\otimes\sum_{\dot J_1\dot J_2=\dot J}\delta^{\dot K}_{\dot J_2}f^{\dot I}_{\dot J_1\dot L}\otimes\Xi^{\lambda_3}_{\lambda_6}-\delta^{\lambda_3}_{\lambda_6}\overline{\Xi}^{\lambda_1}_{\lambda_2}\otimes\sum_{\dot I_1\dot I_2=\dot I}\delta^{\dot I_2}_{\dot L}f^{\dot I_1\dot K}_{\dot J}\otimes\Xi^{\lambda_5}_{\lambda_4},\quad(3)$$

and

$$[\overline{\Xi}^{\lambda_1}_{\lambda_2}\otimes f^{\dot I}_{\dot J}\otimes\Xi^{\lambda_3}_{\lambda_4},\sigma^{K}_{L}]=\overline{\Xi}^{\lambda_1}_{\lambda_2}\otimes\left(\sum_{\dot J_1\dot J_2\dot J_3=\dot J}\delta^{K}_{\dot J_2}f^{\dot I}_{\dot J_1L\dot J_3}-\sum_{\dot I_1\dot I_2\dot I_3=\dot I}\delta^{\dot I_2}_{L}f^{\dot I_1K\dot I_3}_{\dot J}\right)\otimes\Xi^{\lambda_3}_{\lambda_4};\quad(4)$$

(2) an operator of the second kind and an operator of the second, third or fourth kind:

$$\begin{aligned}[\overline{\Xi}^{\lambda_1}_{\lambda_2}\otimes l^{\dot I}_{\dot J},\overline{\Xi}^{\lambda_3}_{\lambda_4}\otimes l^{\dot K}_{\dot L}]=&\delta^{\lambda_3}_{\lambda_2}\overline{\Xi}^{\lambda_1}_{\lambda_4}\otimes\left(\delta^{\dot K}_{\dot J}l^{\dot I}_{\dot L}+\sum_{\dot J_1\dot J_2=\dot J}\delta^{\dot K}_{\dot J_1}l^{\dot I}_{\dot L\dot J_2}+\sum_{\dot K_1\dot K_2=\dot K}\delta^{\dot K_1}_{\dot J}l^{\dot I\dot K_2}_{\dot L}\right)\\&-\delta^{\lambda_1}_{\lambda_4}\overline{\Xi}^{\lambda_3}_{\lambda_2}\otimes\left(\delta^{\dot I}_{\dot L}l^{\dot K}_{\dot J}+\sum_{\dot L_1\dot L_2=\dot L}\delta^{\dot I}_{\dot L_1}l^{\dot K}_{\dot J\dot L_2}+\sum_{\dot I_1\dot I_2=\dot I}\delta^{\dot I_1}_{\dot L}l^{\dot K\dot I_2}_{\dot J}\right),\end{aligned}\quad(5)$$

$$[\overline{\Xi}^{\lambda_1}_{\lambda_2}\otimes l^{\dot I}_{\dot J},r^{\dot K}_{\dot L}\otimes\Xi^{\lambda_3}_{\lambda_4}]=\overline{\Xi}^{\lambda_1}_{\lambda_2}\otimes\left(\sum_{\substack{\dot J_1\dot J_2=\dot J\\ \dot K_1\dot K_2=\dot K}}\delta^{\dot K_1}_{\dot J_2}f^{\dot I\dot K_2}_{\dot J_1\dot L}-\sum_{\substack{\dot I_1\dot I_2=\dot I\\ \dot L_1\dot L_2=\dot L}}\delta^{\dot I_2}_{\dot L_1}f^{\dot I_1\dot K}_{\dot J\dot L_2}\right)\otimes\Xi^{\lambda_3}_{\lambda_4},\quad(6)$$

and

$$\begin{aligned}[\overline{\Xi}^{\lambda_1}_{\lambda_2}\otimes l^{\dot I}_{\dot J},\sigma^{K}_{L}]=\overline{\Xi}^{\lambda_1}_{\lambda_2}\otimes\Bigg(&\delta^{K}_{\dot J}l^{\dot I}_{L}+\sum_{K_1K_2=K}\delta^{K_1}_{\dot J}l^{\dot I K_2}_{L}+\sum_{\dot J_1\dot J_2=\dot J}\delta^{K}_{\dot J_2}l^{\dot I}_{\dot J_1L}+\sum_{\dot J_1\dot J_2=\dot J}\delta^{K}_{\dot J_1}l^{\dot I}_{\dot L\dot J_2}+\sum_{\substack{\dot J_1\dot J_2=\dot J\\ K_1K_2=K}}\delta^{K_1}_{\dot J_2}l^{\dot I K_2}_{\dot J_1L}\\&+\sum_{\dot J_1\dot J_2\dot J_3=\dot J}\delta^{K}_{\dot J_2}l^{\dot I}_{\dot J_1L\dot J_3}-\delta^{\dot I}_{L}l^{K}_{\dot J}-\sum_{L_1L_2=L}\delta^{\dot I}_{L_1}l^{K}_{\dot J L_2}-\sum_{\dot I_1\dot I_2=\dot I}\delta^{\dot I_2}_{L}l^{\dot I_1K}_{\dot J}-\sum_{\dot I_1\dot I_2=\dot I}\delta^{\dot I_1}_{L}l^{K\dot I_2}_{\dot J}\\&-\sum_{\substack{L_1L_2=L\\ \dot I_1\dot I_2=\dot I}}\delta^{\dot I_2}_{L_1}l^{\dot I_1K}_{\dot J\dot L_2}-\sum_{\dot I_1\dot I_2\dot I_3=\dot I}\delta^{\dot I_2}_{L}l^{\dot I_1K\dot I_3}_{\dot J}\Bigg);\end{aligned}\quad(7)$$

(3) an operator of the third kind and an operator of the third or fourth kind:

$$[r^{\dot I}_{\dot J}\otimes\Xi^{\lambda_1}_{\lambda_2},r^{\dot K}_{\dot L}\otimes\Xi^{\lambda_3}_{\lambda_4}]=\delta^{\lambda_3}_{\lambda_2}\Bigg(\delta^{\dot K}_{\dot J}r^{\dot I}_{\dot L}+\sum_{J_1J_2=\dot J}\delta^{\dot K}_{J_2}r^{\dot I}_{J_1\dot L}+\sum_{K_1K_2=\dot K}\delta^{\dot K_2}_{\dot J}r^{K_1\dot I}_{\dot L}\Bigg)\otimes\Xi^{\lambda_1}_{\lambda_4}$$
$$-\delta^{\lambda_1}_{\lambda_4}\Bigg(\delta^{\dot I}_{\dot L}r^{\dot K}_{\dot J}+\sum_{L_1L_2=\dot L}\delta^{\dot I}_{L_2}r^{\dot K}_{L_1\dot J}+\sum_{I_1I_2=\dot I}\delta^{\dot I_2}_{\dot L}r^{I_1\dot K}_{\dot J}\Bigg)\otimes\Xi^{\lambda_3}_{\lambda_2}\tag{8}$$

and

$$[r^{\dot I}_{\dot J}\otimes\Xi^{\lambda_1}_{\lambda_2},\sigma^K_L]=\Bigg(\delta^K_{\dot J}r^{\dot I}_L+\sum_{K_1K_2=K}\delta^{K_2}_{\dot J}r^{K_1\dot I}_L+\sum_{J_1J_2=\dot J}\delta^K_{J_2}r^{\dot I}_{J_1L}+\sum_{J_1J_2=\dot J}\delta^K_{J_1}r^{\dot I}_{LJ_2}+\sum_{\substack{J_1J_2=\dot J\\K_1K_2=K}}\delta^{K_2}_{J_1}r^{K_1\dot I}_{LJ_2}$$
$$+\sum_{J_1J_2J_3=\dot J}\delta^K_{J_2}r^{\dot I}_{J_1LJ_3}-\delta^{\dot I}_Lr^K_{\dot J}-\sum_{L_1L_2=L}\delta^{\dot I}_{L_2}r^K_{L_1\dot J}-\sum_{I_1I_2=\dot I}\delta^{I_2}_Lr^{I_1K}_{\dot J}-\sum_{I_1I_2=\dot I}\delta^{I_1}_Lr^{KI_2}_{\dot J}$$
$$-\sum_{\substack{L_1L_2=L\\I_1I_2=\dot I}}\delta^{I_1}_{L_2}r^{KI_2}_{L_1\dot J}-\sum_{I_1I_2I_3=\dot I}\delta^{I_2}_Lr^{I_1KI_3}_{\dot J}\Bigg)\otimes\Xi^{\lambda_1}_{\lambda_2};\tag{9}$$

(4) two operators of the fourth kind:

$$[\sigma^I_J,\sigma^K_L]=\delta^K_J\sigma^I_L+\sum_{J_1J_2=J}\delta^K_{J_2}\sigma^I_{J_1L}+\sum_{K_1K_2=K}\delta^{K_1}_J\sigma^{IK_2}_L$$
$$+\sum_{\substack{J_1J_2=J\\K_1K_2=K}}\delta^{K_1}_{J_2}\sigma^{IK_2}_{J_1L}+\sum_{J_1J_2=J}\delta^K_{J_1}\sigma^I_{LJ_2}+\sum_{K_1K_2=K}\delta^{K_2}_J\sigma^{K_1I}_L+\sum_{\substack{J_1J_2=J\\K_1K_2=K}}\delta^{K_2}_{J_1}\sigma^{K_1I}_{LJ_2}$$
$$+\sum_{J_1J_2J_3=J}\delta^K_{J_2}\sigma^I_{J_1LJ_3}+\sum_{K_1K_2K_3=K}\delta^{K_2}_J\sigma^{K_1IK_3}_L-(I\leftrightarrow K,J\leftrightarrow L)+\cdots.\tag{10}$$

The ellipses in the last equation represent terms which cannot be written in terms of the operators listed in Table I; they play no role in the open string algebra, to be introduced immediately.

As the elements of the grand string algebra come from phyiscal observables of open matrix chains, it should not be surprising the open matrix chains provide a representation of the grand string algebra, albeit not a faithful one. As we mentioned in the Introduction, an open matrix chain can be abstractly written as $\overline{\phi}^{\lambda_1}\otimes s^{\dot K}\otimes\phi^{\lambda_2}$. $\overline{\phi}^1$, $\overline{\phi}^2$,…, and $\overline{\phi}^{\Lambda_F}$ span a Λ_F-dimensional vector space; ϕ^1, ϕ^2,…, and ϕ^{Λ_F} span another Λ_F-dimensional vector space; and all vectors of the form s^K span an infinite-dimensional vector space. Let $\mathcal{T}_o$ be the vector space consisting of finite linear combinations of open matrix chains. The actions of the four kinds of operators on an open matrix chain are given by

$$\overline{\Xi}^{\lambda_1}_{\lambda_2}\otimes f^{\dot I}_{\dot J}\otimes\Xi^{\lambda_3}_{\lambda_4}(\overline{\phi}^{\lambda_5}\otimes s^{\dot K}\otimes\phi^{\lambda_6})=\delta^{\lambda_5}_{\lambda_2}\delta^{\dot K}_{\dot J}\delta^{\lambda_6}_{\lambda_4}\overline{\phi}^{\lambda_1}\otimes s^{\dot I}\otimes\phi^{\lambda_3},\tag{11}$$

$$\overline{\Xi}^{\lambda_1}_{\lambda_2}\otimes l^{\dot I}_{\dot J}(\overline{\phi}^{\lambda_3}\otimes s^{\dot K}\otimes\phi^{\lambda_4})=\delta^{\lambda_3}_{\lambda_2}\sum_{\dot K_1\dot K_2=\dot K}\delta^{\dot K_1}_{\dot J}\overline{\phi}^{\lambda_1}\otimes s^{\dot I\dot K_2}\otimes\phi^{\lambda_4},\tag{12}$$

$$r^{\dot I}_{\dot J}\otimes\Xi^{\lambda_1}_{\lambda_2}(\overline{\phi}^{\lambda_3}\otimes s^{\dot K}\otimes\phi^{\lambda_4})=\delta^{\lambda_4}_{\lambda_2}\sum_{\dot K_1\dot K_2=\dot K}\delta^{\dot K_2}_{\dot J}\overline{\phi}^{\lambda_3}\otimes s^{\dot K_1\dot I}\otimes\phi^{\lambda_1},\tag{13}$$

and

$$\sigma_J^I(\overline{\phi}^{\lambda_1}\otimes s^{\dot{K}}\otimes\phi^{\lambda_2})=\overline{\phi}^{\lambda_1}\otimes\left(\sum_{\dot{K}_1K_2\dot{K}_3=\dot{K}}\delta_J^{K_2}s^{\dot{K}_1I\dot{K}_3}\right)\otimes\phi^{\lambda_2}. \tag{14}$$

$\mathcal{T}_o$ is a representation space for the grand string algebra.

Definition 1: The Lie algebra denoted as $\hat{G}_{\Lambda,\Lambda_F}$ in Ref. 10 and later on called the open string algebra in Ref. 13 is defined as the quotient of the grand string algebra by the annihilator of the representation $\mathcal{T}_o$. We will call $\mathcal{T}_o$ the defining representation.

Equations (1), (5), (8) and (10) show that the space generated by each kind of operator forms a subalgebra of the open string algebra. The four subalgebras were denoted by $F_{\Lambda,\Lambda_F}=\mathrm{gl}(\Lambda_F)\otimes F_\Lambda\otimes\mathrm{gl}(\Lambda_F)$, $\mathrm{gl}(\Lambda_F)\otimes\hat{L}_\Lambda$, $\hat{R}_\Lambda\otimes\mathrm{gl}(\Lambda_F)$ and $\hat{\Sigma}_\Lambda$, respectively, in Ref. 10. In addition, Eqs. (1)–(4) tell us that $\mathrm{gl}(\Lambda_F)\otimes F_\Lambda\otimes\mathrm{gl}(\Lambda_F)$ is a proper ideal isomorphic to $\mathrm{gl}(\infty)$, and Eqs. (1)–(9) tell us that all the operators of the first three kinds together span a bigger proper ideal $\hat{M}_{\Lambda,\Lambda_F}$.

For future convenience, let us introduce some more operators of the fourth kind acting on the defining representation space. They are $\sigma_\varnothing^\varnothing$, $\sigma_\varnothing^I$ and $\sigma_J^\varnothing$, and are defined by

$$\sigma_\varnothing^\varnothing(\overline{\phi}^{\lambda_1}\otimes s^{\dot{K}}\otimes\phi^{\lambda_2})\equiv(\#(\dot{K})+1)\,\overline{\phi}^{\lambda_1}\otimes s^{\dot{K}}\otimes\phi^{\lambda_2}, \tag{15}$$

$$\sigma_\varnothing^I(\overline{\phi}^{\lambda_1}\otimes s^{\dot{K}}\otimes\phi^{\lambda_2})\equiv\sum_{\dot{K}_1\dot{K}_2=\dot{K}}\overline{\phi}^{\lambda_1}\otimes s^{\dot{K}_1I\dot{K}_2}\otimes\phi^{\lambda_2} \tag{16}$$

and

$$\sigma_J^\varnothing(\overline{\phi}^{\lambda_1}\otimes s^{\dot{K}}\otimes\phi^{\lambda_2})\equiv\sum_{\dot{K}_1K_2\dot{K}_3=\dot{K}}\delta_J^{K_2}\overline{\phi}^{\lambda_1}\otimes s^{\dot{K}_1\dot{K}_3}\otimes\phi^{\lambda_2}. \tag{17}$$

Though these operators look completely new, they are actually elements of the open string algebra, as can be seen from the following identities which are now fully general:

$$\sigma_{\dot{J}}^{\dot{I}}=\sum_{i=1}^{\Lambda}\sigma_{i\dot{J}}^{i\dot{I}}+\sum_{\lambda=1}^{\Lambda_F}\overline{\Xi}_\lambda^\lambda\otimes l_{\dot{J}}^{\dot{I}}=\sum_{j=1}^{\Lambda}\sigma_{\dot{J}j}^{\dot{I}j}+\sum_{\lambda=1}^{\Lambda_F}r_{\dot{J}}^{\dot{I}}\otimes\Xi_\lambda^\lambda. \tag{18}$$

The reader can check the validity of Eq. (18) by verifying that the left and right hand sides have the same action on any open matrix chain.

Without recourse to Eq. (18), there is a representation of $\sigma_J^\varnothing$ directly in terms of matrix annihilation operators as shown in the following formula, where the summation convention for color indices is adopted:

$$\sigma_J^\varnothing=\frac{1}{N^{(b-2)/2}}a_{\nu_b}^{\nu_{b-1}}(j_b)a_{\nu_{b-1}}^{\nu_{b-2}}(j_{b-1})\cdots a_{\nu_1}^{\nu_b}(j_1). \tag{19}$$

We know of no representation of $\sigma_\varnothing^\varnothing$ or $\sigma_\varnothing^I$ in terms of matrix annihilation or creation operators without using Eq. (18).

Sometimes we will use the generic notation $X_{\dot{J}}^{\dot{I}}$ or $Y_{\dot{J}}^{\dot{I}}$ to refer to $\overline{\Xi}_{\lambda_2}^{\lambda_1}\otimes f_{\dot{J}}^{\dot{I}}\otimes\Xi_{\lambda_4}^{\lambda_3}$, $\overline{\Xi}_{\lambda_2}^{\lambda_1}\otimes l_{\dot{J}}^{\dot{I}}$, $r_{\dot{J}}^{\dot{I}}\otimes\Xi_{\lambda_2}^{\lambda_1}$ or $\sigma_{\dot{J}}^{\dot{I}}$, ignoring λ_1, λ_2, λ_3 and λ_4.

III. BASES

The operators listed in Table I do not form a basis for the open string algebra because they are overcomplete. In this section, we will work out two bases which will be of use in future discussions. Readers who are not interested in the details may read only the statements of Propositions 1 and 2, and then move on directly to the next section.

Before we start, we need to recall a lexicographic ordering for integer sequences from Ref. 13. We will use it to construct another one for a basis of the open string algebra. (Both orderings are denoted as $>$ as there is no danger of confusion.)

Definition 2: We designate $\dot{I}>\dot{J}$ *if either*

(1) $\#(\dot{I})>\#(\dot{J})$*; or*
(2) $\#(\dot{I})=\#(\dot{J})=a\neq 0$*, and there exists an integer* $r\leqslant a$ *such that* $i_1=j_1$, $i_2=j_2,\ldots,$ $i_{r-1}=j_{r-1}$ *and* $i_r>j_r$.

Definition 3: Here is a lexicographic ordering for a basis of the open string algebra.

(1) $X^{\dot{I}}_{\dot{J}}>Y^{\dot{K}}_{\dot{L}}$ *if*
  (a) $\#(\dot{I})-\#(\dot{J})>\#(\dot{K})-\#(\dot{L})$*; or*
  (b) $\#(\dot{I})-\#(\dot{J})=\#(\dot{K})-\#(\dot{L})$ *and* $\#(\dot{I})+\#(\dot{J})>\#(\dot{K})+\#(\dot{L})$*; or*
  (c) $\#(\dot{I})=\#(\dot{K})$, $\#(\dot{J})=\#(\dot{L})$ *and* $\dot{J}>\dot{L}$*; or*
  (d) $\dot{J}=\dot{L}$, $\#(\dot{I})=\#(\dot{K})$ *and* $\dot{I}>\dot{K}$*;*
(2) $\sigma^{\dot{I}}_{\dot{J}}>r^{\dot{I}}_{\dot{J}}\otimes\Xi^{\lambda_1}_{\lambda_2}>\overline{\Xi}^{\lambda_3}_{\lambda_4}\otimes l^{\dot{I}}_{\dot{J}}>\overline{\Xi}^{\lambda_5}_{\lambda_6}\otimes f^{\dot{I}}_{\dot{J}}\otimes\Xi^{\lambda_7}_{\lambda_8}$*;*
(3) $\overline{\Xi}^{\lambda_1}_{\lambda_2}\otimes f^{\dot{I}}_{\dot{J}}\otimes\Xi^{\lambda_3}_{\lambda_4}>\overline{\Xi}^{\lambda_5}_{\lambda_6}\otimes f^{\dot{I}}_{\dot{J}}\otimes\Xi^{\lambda_7}_{\lambda_8}$ *if*
  (a) $\lambda_2\lambda_4>\lambda_6\lambda_8$ *as concatenated sequences; or*
  (b) $\lambda_2\lambda_4=\lambda_6\lambda_8$ *and* $\lambda_1\lambda_3>\lambda_5\lambda_7$*;*
(4) $\overline{\Xi}^{\lambda_1}_{\lambda_2}\otimes l^{\dot{I}}_{\dot{J}}>\overline{\Xi}^{\lambda_3}_{\lambda_4}\otimes l^{\dot{I}}_{\dot{J}}$ *if*
  (a) $\lambda_2>\lambda_4$*; or*
  (b) $\lambda_2=\lambda_4$ *and* $\lambda_1>\lambda_3$*;*
(5) $r^{\dot{I}}_{\dot{J}}\otimes\Xi^{\lambda_1}_{\lambda_2}>r^{\dot{I}}_{\dot{J}}\otimes\Xi^{\lambda_3}_{\lambda_4}$ *if*
  (a) $\lambda_2>\lambda_4$*; or*
  (b) $\lambda_2=\lambda_4$ *and* $\lambda_1>\lambda_3$.

Note that changing the basis changes the lexicographic ordering also.

Proposition 1: The following set $\mathcal{B}_0$ *of elements forms a basis for the open string algebra:*

(1) all $\overline{\Xi}^{\lambda_1}_{\lambda_2}\otimes f^{\dot{I}}_{\dot{J}}\otimes\Xi^{\lambda_3}_{\lambda_4}$ *such that* $\lambda_1+\lambda_2>2$ *and* $\lambda_3+\lambda_4>2$*;*
(2) all $\overline{\Xi}^{\lambda_1}_{\lambda_2}\otimes l^{\dot{I}}_{\dot{J}}$ *such that* $\lambda_1\neq 1$ *or* $\lambda_2\neq 1$*;*
(3) all $r^{\dot{I}}_{\dot{J}}\otimes\Xi^{\lambda_1}_{\lambda_2}$ *such that* $\lambda_1\neq 1$ *or* $\lambda_2\neq 1$*; and*
(4) all $\sigma^{\dot{I}}_{\dot{J}}$.

This proposition is a consequence of the following two lemmas.

Lemma 1: $\mathcal{B}_0$ *is a linearly independent set.*

Proof: We will prove this by *ad absurdum*. Consider an arbitrary sum X of a finite number of the elements listed in Proposition 1. Write down X according to the following

Convention: The numerical coefficient of $\sigma^{\dot{I}}_{\dot{J}}$ in X is written as $c(\sigma^{\dot{I}}_{\dot{J}})$. The coefficients of other operators are written similarly. (By definition, only a finite number of the coefficients are nonzero.)

Assume that this sum X is identically equal to zero. There are now several possibilities.

Consider first the case in which some $c(\sigma^{\dot{I}}_{\dot{J}})\neq 0$ in the sum X, which can then be written as

$$\sum_{i=1}^{p} c(\sigma^{\dot{I}_i}_{\dot{J}_i})\sigma^{\dot{I}_i}_{\dot{J}_i}+\cdots,$$

where p is a finite positive integer, $\dot{J}_1=\dot{J}_2=\cdots=\dot{J}_q<\dot{J}_{q+1}\leqslant\cdots\leqslant\dot{J}_p$ for some integer $q\leqslant p$, $\dot{I}_r\neq\dot{I}_s$ for $1\leqslant r,s\leqslant q$ such that $r\neq s$, and the ellipses denote terms involving operators of other kinds. Then acting the sum on $\overline{\phi^1}\otimes s^{\dot{J}_1}\otimes\phi^1$ yields

$$\sum_{i=1}^{q} c(\sigma^{\dot{I}_i}_{\dot{J}_1})\overline{\phi^1}\otimes s^{\dot{I}_i}\otimes\phi^1+\cdots,$$

where the ellipses consist of terms proportional to $\overline{\phi^{\lambda_1}}\otimes s^{\dot{K}}\otimes\phi^{\lambda_2}$, where $\lambda_1>1$ or $\lambda_2>1$. This is manifestly nonzero, a contradiction. Hence there is no operator of the form $\sigma^{\dot{I}}_{\dot{J}}$ in the sum.

Similarly, considering the action of the sum on a state of the form $\overline{\phi^\rho}\otimes s^K\otimes\phi^1$ will rule out the presence of any $\overline{\Xi}^{\lambda_1}_{\lambda_2}\otimes l^{\dot{I}}_{\dot{J}}$ in the sum. Then considering $\overline{\phi^1}\otimes s^{\dot{K}}\otimes\phi^\rho$ will rule out any $r^{\dot{I}}_{\dot{J}}\otimes\Xi^{\lambda_1}_{\lambda_2}$. Finally, considering $\overline{\phi^{\rho_1}}\otimes s^{\dot{K}}\otimes\phi^{\rho_2}$ will eliminate all $\overline{\Xi}^{\lambda_1}_{\lambda_2}\otimes f^{\dot{I}}_{\dot{J}}\otimes\Xi^{\lambda_3}_{\lambda_4}$. Consequently, no element of $\mathcal{B}_0$ can appear in the sum to make it identically zero, and $\mathcal{B}_0$ is linearly independent. Q.E.D.

Lemma 2: Any element of the open string algebra can be written as a finite sum of the elements listed in Proposition 1.

Proof: This follows from the following formulas, which the reader can check one by one by verifying that the actions of the left and right hand sides of any equation below on any open matrix chain are the same:

$$\sum_{\lambda=1}^{\Lambda_F}\overline{\Xi}^{\lambda}_{\lambda}\otimes r^I_J=\sigma^I_J-\sum_{j=1}^{\Lambda}\sigma^{Ij}_{Jj};\tag{20}$$

$$\sum_{\lambda=1}^{\Lambda_F} l^I_J\otimes\Xi^{\lambda}_{\lambda}=\sigma^I_J-\sum_{i=1}^{\Lambda}\sigma^{iI}_{iJ};\tag{21}$$

$$\sum_{\lambda_3=1}^{\Lambda_F}\overline{\Xi}^{\lambda_1}_{\lambda_2}\otimes f^{\dot{I}}_{\dot{J}}\otimes\Xi^{\lambda_3}_{\lambda_3}=\overline{\Xi}^{\lambda_1}_{\lambda_2}\otimes l^{\dot{I}}_{\dot{J}}-\sum_{j=1}^{\Lambda}\overline{\Xi}^{\lambda_1}_{\lambda_2}\otimes l^{\dot{I}\dot{j}}_{\dot{J}j};\tag{22}$$

and

$$\sum_{\lambda_1=1}^{\Lambda_F}\overline{\Xi}^{\lambda_1}_{\lambda_1}\otimes f^{\dot{I}}_{\dot{J}}\otimes\Xi^{\lambda_2}_{\lambda_3}=r^{\dot{I}}_{\dot{J}}\otimes\Xi^{\lambda_2}_{\lambda_3}-\sum_{i=1}^{\Lambda} r^{i\dot{I}}_{i\dot{J}}\otimes\Xi^{\lambda_2}_{\lambda_3}.\tag{23}$$

Q.E.D.

Remark 1: Equations (20)–(23) may now be taken as a set of defining relations for the open string algebra, though there is a little redundancy in them.

We now give a different basis for the open string algebra. We will use it to construct ''Verma-like modules.''

Proposition 2: The following set $\mathcal{B}_4$ of elements form a basis for the open string algebra:

(1) all $\overline{\Xi}^{\lambda_1}_{\lambda_2}\otimes f^{\dot{I}}_{\dot{J}}\otimes\Xi^{\lambda_3}_{\lambda_4}$;

(2) all $\overline{\Xi}^{\lambda_1}_{\lambda_2}\otimes l^{\dot{I}}_{\dot{J}}$ such that the last integers in $\dot{I}$ *and* $\dot{J}$ *are not simultaneously 1;*

(3) all $r^{\varnothing}_{\varnothing}\otimes\Xi^{\lambda_1}_{\lambda_2}$ *such that* $\lambda_1\neq 1$ *or* $\lambda_2\neq 1$*;*
(4) all $r^{I}_{\varnothing}\otimes\Xi^{\lambda_1}_{\lambda_2}$ *such that* $\lambda_1\neq 1$, $\lambda_2\neq 1$ *or the first integer of* I *is not 1;*
(5) all $r^{\varnothing}_{J}\otimes\Xi^{\lambda_1}_{\lambda_2}$ *such that* $\lambda_1\neq 1$, $\lambda_2\neq 1$ *or the first integer of* J *is not 1;*
(6) all $r^{I}_{J}\otimes\Xi^{\lambda_1}_{\lambda_2}$ *such that the first integers in* I *and* J *are not simultaneously 1; and*
(7) all $\sigma^{\dot{I}}_{\dot{J}}$ *such that the first integers in* I *and* J *are not simultaneously 1 and the last integers in* I *and* J *are not simultaneously 1 either.*

Proof (sketched): This follows from Lemma 1 by extensive use of Eqs. (20)–(23) and by insisting that all the elements $\overline{\Xi}^{\lambda_1}_{\lambda_2}\otimes f^{\dot{I}}_{\dot{J}}\otimes\Xi^{\lambda_3}_{\lambda_4}$ should occur in the basis. Observe that the recundancy in the mentioned equations in the present setting is due to the fact that the elements $\sigma^{1\dot{I}1}_{\varnothing}$, $\sigma^{\varnothing}_{1\dot{J}1}$, and $\Sigma_i\sigma^{i}_{i}$ occur both in Eq. (20) and in Eq. (21). The reader can find a more detailed and thoroughly rigorous proof in Ref. 17.

IV. CARTAN SUBALGEBRA AND ROOT VECTORS

We are going to work out a Cartan subalgebra and the root vectors associated with it for the open string algebra. We will need these results in future sections. Once again those who are not interested in details may only read the statements of the propositions in this section, and move on to the next section directly.

Proposition 3: All $\overline{\Xi}^{\lambda_1}_{\lambda_1}\otimes f^{\dot{I}}_{\dot{I}}\otimes\Xi^{\lambda_2}_{\lambda_2}$, *all* $\overline{\Xi}^{\lambda}_{\lambda}\otimes l^{\dot{I}}_{\dot{I}}$, *all* $r^{\dot{I}}_{\dot{I}}\otimes\Xi^{\lambda}_{\lambda}$ *and all* $\sigma^{\dot{I}}_{\dot{I}}$ *form an overcomplete set of generators of a Cartan subalgebra* G^{00} *of the open string algebra.*[18]

Proof: In terms of the basis $\mathcal{B}_0$, what we need to show is that

(1) all $\overline{\Xi}^{\lambda_1}_{\lambda_1}\otimes f^{\dot{I}}_{\dot{I}}\otimes\Xi^{\lambda_2}_{\lambda_2}$ such that $\lambda_1\neq 1$ and $\lambda_2\neq 1$,
(2) all $\overline{\Xi}^{\lambda}_{\lambda}\otimes l^{\dot{I}}_{\dot{I}}$, such that $\lambda\neq 1$,
(3) all $r^{\dot{I}}_{\dot{I}}\otimes\Xi^{\lambda}_{\lambda}$ such that $\lambda\neq 1$, and
(4) all $\sigma^{\dot{I}}_{\dot{I}}$

form a basis for this Cartan subalgebra. It is obvious that G^{00} is commutative and, *a fortiori*, nilpotent. Consider an element X of the normalizer of G^{00}. Let us express X in terms of the basis $\mathcal{B}_0$ using the Convention in the proof of Lemma 1. Consider the following.

Case 1: There exist in X *terms of the form* $c(\sigma^{\dot{I}_i}_{\dot{J}_i})\sigma^{\dot{I}_i}_{\dot{J}_i}$ *such that* i *is a positive integer not larger than* p, $\dot{I}_i\neq\dot{J}_i$, $c(\sigma^{\dot{I}_i}_{\dot{J}_i})\neq 0$ *for each* i *and* $c(\sigma^{\dot{I}}_{\dot{J}})=0$ *for any other* $\dot{I}$ *and* $\dot{J}$ *such that* $\dot{I}\neq\dot{I}_i$ *or* $\dot{J}\neq\dot{J}_i$ *for each* i. *Without loss of generality, we can further assume that either*

$$\dot{I}_1\leqslant\dot{I}_i \quad and \quad \dot{I}_1\leqslant\dot{J}_i \tag{24}$$

for each value of i, *or*

$$\dot{J}_1\leqslant\dot{I}_i \quad and \quad \dot{J}_1\leqslant\dot{J}_i \tag{25}$$

for each value of i.

If Eq. (24) is true, then

$$[\overline{\Xi}^{1}_{1}\otimes f^{\dot{I}_1}_{\dot{I}_1}\otimes\Xi^{1}_{1},X]=c(\sigma^{\dot{I}_1}_{\dot{J}_1})\overline{\Xi}^{1}_{1}\otimes f^{\dot{I}_1}_{\dot{J}_1}\otimes\Xi^{1}_{1}+\cdots, \tag{26}$$

which clearly does not belong to G^{00}. If instead Eq. (25) is true, then

$$[\bar{\Xi}^1_1 \otimes f^{\dot{J}_1}_{\dot{J}_1} \otimes \Xi^1_1, X] = -c(\sigma^{\dot{I}_1}_{\dot{J}_1})\bar{\Xi}^1_1 \otimes f^{\dot{I}_1}_{\dot{J}_1} \otimes \Xi^1_1 + \cdots, \tag{27}$$

which clearly does not belong to G^{00} either. Thus there is no term proportional to $\sigma^{\dot{I}}_{\dot{J}}$ in X such that $\dot{I} \neq \dot{J}$.

Similar arguments by contradiction enable us to rule out all other cases listed below.

Case 2: There exist in X terms of the form $c(r^{\dot{I}_i}_{\dot{J}_i} \otimes \Xi^{\lambda_i}_{\rho_i}) r^{\dot{I}_i}_{\dot{J}_i} \otimes \Xi^{\lambda_i}_{\rho_i}$ *such that the following four conditions hold:*

(1) i *is a positive integer not larger than p;*
(2) $\dot{I}_i \lambda_i \neq \dot{J}_i \rho_i$ *for each i;*
(3) $c(r^{\dot{I}_i}_{\dot{J}_i} \otimes \Xi^{\lambda_i}_{\rho_i}) \neq 0$ *for each i; and*
(4) $c(r^{\dot{I}}_{\dot{J}} \otimes \Xi^{\lambda}_{\rho}) = 0$ *for any other* $\dot{I}$, $\dot{J}$, λ *and* ρ *such that* $\dot{I}\lambda \neq \dot{I}_i \lambda_i$ *or* $\dot{J}\rho \neq \dot{J}_i \rho_i$ *for each i.*

Without loss of generality, we can further assume that for all values of i, either

$$\dot{I}_1 \lambda_1 \leqslant \dot{I}_i \lambda_i \quad \text{and} \quad \dot{I}_1 \lambda_1 \leqslant \dot{J}_i \rho_i \tag{28}$$

for each value of i, *or*

$$\dot{J}_1 \rho_1 \leqslant \dot{I}_i \lambda_i \quad \text{and} \quad \dot{J}_1 \rho_1 \leqslant \dot{J}_i \rho_i \tag{29}$$

for each value of i.

Case 3: There exist in X terms of the form $c(\bar{\Xi}^{\lambda_i}_{\rho_i} \otimes l^{\dot{I}_i}_{\dot{J}_i}) \bar{\Xi}^{\lambda_i}_{\rho_i} \otimes l^{\dot{I}_i}_{\dot{J}_i}$ *such that the following four conditions hold:*

(1) i *is a positive integer not larger than p;*
(2) $\dot{I}_i \lambda_i \neq \dot{J}_i \rho_i$ *for each i;*
(3) $c(\bar{\Xi}^{\lambda_i}_{\rho_i} \otimes l^{\dot{I}_i}_{\dot{J}_i}) \neq 0$ *for each i; and*
(4) $c(\bar{\Xi}^{\lambda}_{\rho} \otimes l^{\dot{I}}_{\dot{J}}) = 0$ *for any other* $\dot{I}$, $\dot{J}$, λ *and* ρ *such that* $\dot{I}\lambda \neq \dot{I}_i \lambda_i$ *or* $\dot{J}\rho \neq \dot{J}_i \rho_i$ *for each i.*

(5) Case 4: There exist in X terms of the form $c(\bar{\Xi}^{\lambda_i}_{\rho_i} \otimes f^{\dot{I}_i}_{\dot{J}_i} \otimes \Xi^{\alpha_i}_{\beta_i}) \bar{\Xi}^{\lambda_i}_{\rho_i} \otimes f^{\dot{I}_i}_{\dot{J}_i} \otimes \Xi^{\alpha_i}_{\beta_i}$ *such that the following four conditions hold:*

(1) i *is a positive integer not larger than p;*
(2) $\dot{I}_i \lambda_i \alpha_i \neq \dot{J}_i \rho_i \beta_i$ *for each i;*
(3) $c(\bar{\Xi}^{\lambda_i}_{\rho_i} \otimes f^{\dot{I}_i}_{\dot{J}_i} \otimes \Xi^{\alpha_i}_{\beta_i}) \neq 0$ *for each i; and*
(4) $c(\bar{\Xi}^{\lambda}_{\rho} \otimes f^{\dot{I}}_{\dot{J}} \otimes \Xi^{\alpha}_{\beta}) = 0$ *for any other* $\dot{I}$, $\dot{J}$, λ, ρ, α *and* β *such that* $\dot{I}\lambda\alpha \neq \dot{I}_i \lambda_i \alpha_i$ *or* $\dot{J}\rho\beta \neq \dot{J}_i \rho_i \beta_i$ *for each i.*

Q.E.D.

Proposition 4: A necessary and sufficient condition for a vector of the open string algebra to be an eigenvector with respect to the Cartan subalgebra G^{00} *is that this vector is proportional to* $\bar{\Xi}^{\lambda_1}_{\lambda_2} \otimes f^{\dot{I}}_{\dot{J}} \otimes \Xi^{\lambda_3}_{\lambda_4}$, *where* $\dot{I}\lambda_1\lambda_3 \neq \dot{J}\lambda_2\lambda_4$.[19]

Proof: The sufficient part is obvious. Let us prove the necessary part. Write down the eigenvector V in terms of the basis set $\mathcal{B}_0$ according to the Convention in the proof of Lemma 1. It is

clear that V contains no term proportional to an element in $\mathcal{B}_0$. Now consider Case 1 in the proof of Proposition 3. If Eq. (24) is true, then Eq. (26) tells us that $V \in F_{\Lambda,\Lambda_F}$; if Eq. (25) is true instead, then Eq. (27) still yields the same conclusion that $V \in F_{\Lambda,\Lambda_F}$.

Next consider Case 2 in the proof of Proposition 3 together with the additional assumption that $c(\sigma^{\dot{I}}_{\dot{J}})=0$ for all $\dot{I}$ and $\dot{J}$. An argument similar to the one in the preceding paragraph shows that $V \in F_{\Lambda,\Lambda_F}$. We reach the same conclusion even if we consider Case 3 in the proof of Proposition 3 together with the additional assumptions that $c(\sigma^{\dot{I}}_{\dot{J}})=0$ and $c(r^{\dot{I}}_{\dot{J}} \otimes \Xi^{\lambda}_{\rho})=0$ for all $\dot{I}$, $\dot{J}$, λ and ρ.

We therefore conclude that in all cases, $V \in F_{\Lambda,\Lambda_F}$. Now, we know that F_{Λ,Λ_F} is isomorphic to gl(∞) whose properties then lead to the necessary part of this proposition. Q.E.D.

V. VERMA-LIKE MODULES

Verma modules are a valuable tool for constructing nontrivial unitary lowest weight irreducible representations of familiar Lie algebras like the Virasoro algebra. We are going to adopt the same approach to construct unitary lowest weight irreducible representations for the open string algebra. This algebra, however, differs from the Virasoro algebra in one important aspect—its Cartan subalgebra and the associated root vectors do not span the whole open string algebra. This implies there cannot be any triangular decomposition of the open string algebra in the traditional sense. Nevertheless, there is still a decomposition very similar to the triangular decomposition, and we can use this other decomposition as a starting point to define a module which resembles a Verma module. We will call this a Verma-like module.

It was noted in Ref. 13 that the subalgebra $\hat{\Sigma}_{\Lambda}$ admits a decomposition into subalgebras of ''raising,'' ''diagonal'' and ''lowering'' operators. Indeed, we will see shortly that the open string algebra can be $\mathbb{Z}$-graded.

Let $\#(\dot{I})$ be the number of integers in $\dot{I}$ and $\tilde{G}^m$ be a subspace of the grand string algebra spanned by all operators of any form shown in Table I (and all operators of the fifth kind not mentioned in Sec. II) such that $\#(\dot{I})-\#(\dot{J})=m$ or $\#(I)-\#(J)=m$. Then the grand string algebra is a direct sum of $\tilde{G}^m$ for all integral values of m. Furthermore, the reader can check from the Lie brackets of the grand string algebra, all of which can be found in Ref. 13 and most of which were reproduced in Sec. II, that

$$[\tilde{G}^m,\tilde{G}^n] \subseteq \tilde{G}^{m+n}.$$

Hence, the set of all $\tilde{G}^m$ provides a $\mathbb{Z}$-grading for the grand string algebra. Moreover, the defining representation is, in a natural way, a graded representation for the grand string algebra with the grade of $\overline{\phi}^{\lambda_1} \otimes s^{\dot{K}} \otimes \phi^{\lambda_2}$ equal to $\#(\dot{K})$. Recall from Definition 1 that the open string algebra is the quotient of the grand string algebra by the annihilator of this graded representation. It follows that the open string algebra is also $\mathbb{Z}$-graded:

$$\hat{G}_{\Lambda,\Lambda_F} = \bigoplus_{m=-\infty}^{\infty} G^m \tag{30}$$

with G^m being the image of $\tilde{G}^m$ under the quotient operation and satisfying

$$[G^m,G^n] \subseteq G^{m+n}. \tag{31}$$

The Cartan subalgebra G^{00} is a subalgebra of G^0. Let G^{0+} be the subspace of G^0 spanned by all operators of any form shown in Table I such that $\dot{I}\lambda_1\lambda_3 > \dot{J}\lambda_2\lambda_4$, $\dot{I}\lambda_1 > \dot{J}\lambda_2$, $\dot{I} > \dot{J}$ or $I > J$. Then G^{0+} is a subalgebra of G^0.[13] Likewise, let G^{0-} be the subspace of G^0 spanned by all

operators of any form shown in Table I such that $\dot{J}\lambda_2\lambda_4 > \dot{I}\lambda_1\lambda_3$, $\dot{J}\lambda_2 > \dot{I}\lambda_1$, $\dot{J} > \dot{I}$ or $J > I$. Then G^{0-} is another subalgebra of G^0. Moreover, we have $G^0 = G^- \oplus G^{00} \oplus G^+$. Consider

$$G^+ \equiv G^{0+} \oplus \left(\bigoplus_{m=1}^{\infty} G^m \right) \tag{32}$$

and

$$G^- \equiv G^{0-} \oplus \left(\bigoplus_{m=-\infty}^{-1} G^m \right). \tag{33}$$

It follows from the fact that G^{0+} is a subalgebra of G^0 and Eq. (31) that G^+ is a subalgebra of the open string algebra. Likewise, G^- is another subalgebra of $\hat{G}_{\Lambda,\Lambda_F}$. Then

$$\hat{G}_{\Lambda,\Lambda_F} = G^+ \oplus G^{00} \oplus G^-. \tag{34}$$

Let us now construct a module for the open string algebra using Eq. (34). Consider the universal enveloping algebra $\mathcal{U}(\hat{G}_{\Lambda,\Lambda_F})$ of the open string algebra. Let $h_I(\lambda_1;\dot{I};\lambda_2)$, $h_{II}(\lambda;\dot{I})$, $h_{III}(\dot{I};\lambda)$ and $h_{IV}(\dot{I})$ be fixed functions on an integer sequence $\dot{I}$ and, with the exception of h_{IV}, the positive integer(s) λ_1, λ_2 or λ also. The subscripts tell us the kinds of operators with which the functions are associated. Construct the left ideal $\mathcal{I}$ of $\mathcal{U}(\hat{G}_{\Lambda,\Lambda_F})$ generated by

(1) all elements in G^-,
(2) all $\overline{\Xi}^{\lambda_1}_{\lambda_1} \otimes f^{\dot{I}}_{I} \otimes \Xi^{\lambda_2}_{\lambda_2} - h_I(\lambda_1;\dot{I};\lambda_2)\cdot \mathbf{1}$ with $\mathbf{1}$ being the identity element of $\mathcal{U}(\hat{G}_{\Lambda,\Lambda_F})$,
(3) all $\overline{\Xi}^{\lambda}_{\lambda} \otimes l^{\dot{I}}_{I} - h_{II}(\lambda;\dot{I})\cdot \mathbf{1}$ such that $\overline{\Xi}^{\lambda}_{\lambda} \otimes l^{\dot{I}}_{I} \in \mathcal{B}_4$,
(4) all $r^{\dot{I}}_{I} \otimes \Xi^{\lambda}_{\lambda} - h_{III}(\dot{I};\lambda)\cdot \mathbf{1}$ such that $r^{\dot{I}}_{I} \otimes \Xi^{\lambda}_{\lambda} \in \mathcal{B}_4$ and
(5) all $\sigma^{\dot{I}}_{I} - h_{IV}(\dot{I})\cdot \mathbf{1}$ such that $\sigma^{\dot{I}}_{I} \in \mathcal{B}_4$.

The values of all h_I, h_{II}, h_{III} and h_{IV} listed above can be freely chosen. Fix the values of these four functions on other arguments by the succeeding equations in all of which $\dot{K}_0$ stands for the empty sequence and $\dot{K}_n = K_n$ stands for the sequence 11...1 with n integers for $n > 0$:

$$h_{II}(\lambda_1;\dot{I}K_n) = h_{II}(\lambda_1;\dot{I}) - \sum_{p=0}^{n-1} \sum_{j=2}^{\Lambda} h_{II}(\lambda_1;\dot{I}\dot{K}_p j) - \sum_{p=0}^{n-1} \sum_{\lambda_2=1}^{\Lambda_F} h_I(\lambda_1;\dot{I}\dot{K}_p;\lambda_2), \tag{35}$$

where λ_1 is any positive integer not larger than Λ_F, n is any positive integer, and $\dot{I}$ is any integer sequence such that either it is empty or its last integer is larger than 1 [cf. Eq. (22)];

$$h_{III}(K_n\dot{I};\lambda_2) = h_{III}(\dot{I};\lambda_2) - \sum_{p=0}^{n-1} \sum_{i=2}^{\Lambda} h_{III}(i\dot{K}_p\dot{I};\lambda_2) - \sum_{p=0}^{n-1} \sum_{\lambda_1=1}^{\Lambda_F} h_I(\lambda_1;\dot{K}_p\dot{I};\lambda_2), \tag{36}$$

where n is positive, and either

(1) $\dot{I}$ is empty and $\lambda_2 \neq 1$, or
(2) $\dot{I}$ is nonempty and the first integer of $\dot{I}$ is not 1

[cf. Eq. (23)];

$$h_{III}(\dot{K}_n;1)=\sum_{\lambda=1}^{\Lambda_F} h_{II}(\lambda;\varnothing)-\sum_{\lambda=2}^{\Lambda_F} h_{III}(\varnothing;\lambda)-\sum_{p=0}^{n-1}\sum_{i=2}^{\Lambda} h_{III}(i\dot{K}_p;1)-\sum_{p=0}^{n-1}\sum_{\lambda=1}^{\Lambda_F} h_I(\lambda_1;\dot{K}_p;1), \tag{37}$$

where n is any non-negative integer [cf. Eqs. (22) and (23)];

$$h_{IV}(K_n\dot{I})=h_{IV}(\dot{I})-\sum_{p=0}^{n-1}\sum_{i=2}^{\Lambda} h_{IV}(i\dot{K}_p\dot{I})-\sum_{p=0}^{n-1}\sum_{\lambda=1}^{\Lambda_F} h_{II}(\lambda;\dot{K}_p\dot{I}), \tag{38}$$

where n is any positive integer, $\dot{I}$ is either empty or has both its first and last integers larger than 1, and the values of h_{II} can either be freely chosen or determined from Eq. (35) [cf. Eq. (20)];

$$h_{IV}(IK_n)=h_{IV}(I)-\sum_{p=0}^{n-1}\sum_{j=2}^{\Lambda} h_{IV}(I\dot{K}_pj)-\sum_{p=0}^{n-1}\sum_{\lambda=1}^{\Lambda_F} h_{III}(I\dot{K}_p;\lambda), \tag{39}$$

where n is a positive integer, I is a nonempty sequence whose first and last integers are both larger than 1, and the values of h_{III} can either be freely chosen or determined from Eq. (36) or (37) [cf. Eq. (21)];

$$h_{IV}(K_m\dot{I}K_n)=h_{IV}(K_m\dot{I})-\sum_{p=0}^{n-1}\sum_{j=2}^{\Lambda} h_{IV}(K_m\dot{I}\dot{K}_pj)-\sum_{p=0}^{n-1}\sum_{\lambda=1}^{\Lambda_F} h_{III}(K_m\dot{I}\dot{K}_p;\lambda), \tag{40}$$

where both m and n are positive integers, $\dot{I}$ is a nonempty integer sequence whose first and last integers are both larger than 1, the values of h_{III} could be determined from Eq. (36) or (37), and those of h_{IV} could be determined from Eq. (38) [cf. Eqs. (20)–(23)]. The four functions $h=(h_I,h_{II},h_{III},h_{IV})$ determined in this way will be called a *lowest weight*. (Clearly, the four functions are *not* linearly indepedent.) That $\mathcal{B}_4$ is a basis of the open string algebra then implies that $\mathcal{I}$ is spanned by G^- and all elements of the form

$$\bar{\Xi}^{\lambda_1}_{\lambda_1}\otimes f^{\dot{I}}_{\dot{I}}\otimes\Xi^{\lambda_2}_{\lambda_2}-h_I(\lambda_1;\dot{I};\lambda_2)\cdot\mathbf{1},$$

$$\bar{\Xi}^{\lambda}_{\lambda}\otimes l^{\dot{I}}_{\dot{I}}-h_{II}(\lambda_1;\dot{I})\cdot\mathbf{1},$$

$$r^{\dot{I}}_{\dot{I}}\otimes\Xi^{\lambda}_{\lambda}-h_{III}(\dot{I};\lambda)\cdot\mathbf{1}$$

or

$$\sigma^{\dot{I}}_{\dot{I}}-h_{IV}(\dot{I})\cdot\mathbf{1}.$$

Define $\mathcal{M}$ to be $\mathcal{U}/\mathcal{I}$. $\hat{G}_{\Lambda,\Lambda_F}$ acts on $\mathcal{M}$ by left multiplication and so $\mathcal{M}$ is a valid representation of $\hat{G}_{\Lambda,\Lambda_F}$. Let $|v_h\rangle$ be the image of $\mathbf{1}$ in $\mathcal{M}$. Then

$$G^-|v_h\rangle=0;$$

$$\bar{\Xi}^{\lambda_1}_{\lambda_1}\otimes f^{\dot{I}}_{\dot{I}}\otimes\Xi^{\lambda_2}_{\lambda_2}|v_h\rangle=h_I(\lambda_1;\dot{I};\lambda_2)|v_h\rangle;$$

$$\bar{\Xi}^{\lambda}_{\lambda}\otimes l^{\dot{I}}_{\dot{I}}|v_h\rangle=h_{II}(\lambda;\dot{I})|v_h\rangle; \tag{41}$$

$$r_{I}^{\dot{I}}\otimes\Xi_{\lambda}^{\lambda}|v_h\rangle=h_{III}(\dot{I};\lambda)|v_h\rangle;$$

$$\sigma_{I}^{\dot{I}}|v_h\rangle=h_{IV}(\dot{I})|v_h\rangle.$$

We will call any $|v_h\rangle$ satisfying Eq. (41) a *lowest weight vector*. (Note that not all elements in G^+ can be written as finite linear combinations of root vectors of G^{00} and so this notion of a lowest weight vector is different from the traditional one.) The Poincaré–Birkhoff–Witt theorem implies that $|v_h\rangle$ together with all the elements in $\mathcal{M}$ of the form

$$E(v_h)=\prod_{p=1}^{n} X_{J_p}^{\dot{I}_p}|v_h\rangle, \tag{42}$$

where n is any positive integer, $X_{J_p}^{\dot{I}_p}\in G^+$ for each value of p and the product is arranged in the reverse of the lexicographic ordering in Definition 3, forms a basis for $\mathcal{M}$. The *expectation value* of $E(v_h)$, which we will denote as $\langle E(v_h)\rangle$, is the coefficient of $|v_h\rangle$ in the expression for $E(v_h)$ written in this basis. We will call $\mathcal{M}$ a *Verma-like module*. (Again if G^+ and G^- were spanned by root vectors, $\mathcal{M}$ would be a Verma module.)

A *lowest weight representation* of the open string algebra is a Verma-like module or a quotient of it. (We called it a highest weight representation in Ref. 20.) In general, a lowest weight representation is not irreducible. If there is a maximal subrepresentation of a Verma-like module, the resulting quotient representation will be an irreducible lowest weight representation.

To establish the notion of unitarity for lowest weight representations, we introduce a number of auxiliary notions as follows. Define an antilinear anti-involution ω on $\hat{G}_{\Lambda,\Lambda_F}$ by

$$\begin{aligned}
\omega(\overline{\Xi}_{\lambda_2}^{\lambda_1}\otimes f_{J}^{\dot{I}}\otimes\Xi_{\lambda_4}^{\lambda_3})&=\overline{\Xi}_{\lambda_1}^{\lambda_2}\otimes f_{I}^{\dot{J}}\otimes\Xi_{\lambda_3}^{\lambda_4};\\
\omega(\overline{\Xi}_{\lambda_2}^{\lambda_1}\otimes l_{J}^{\dot{I}})&=\overline{\Xi}_{\lambda_1}^{\lambda_2}\otimes l_{I}^{\dot{J}};\\
\omega(r_{j}^{\dot{I}}\otimes\Xi_{\lambda_2}^{\lambda_1})&=r_{I}^{\dot{j}}\otimes\Xi_{\lambda_1}^{\lambda_2};\\
\omega(\sigma_{J}^{I})&=\sigma_{I}^{J}.
\end{aligned} \tag{43}$$

(Readers who know how these four kinds of operators were introduced in Refs. 10 and 13 should be aware that this antilinear anti-involution is nothing but the Hermitian conjugation of creation and annihilation operators of partons.) This antilinear anti-involution of $\hat{G}_{\Lambda,\Lambda_F}$ extends straightforwardly to an antilinear anti-involution of its universal enveloping algebra $\mathcal{U}(\hat{G}_{\Lambda,\Lambda_F})$.

From now on, we assume all the weight functions to be real. This allows us to define a sesquilinear form $\langle\cdot|\cdot\rangle$ on two elements $E_1(v_h)$ and $E_2(v_h)$ of $\mathcal{M}$, both of which are of the form Eq. (42), by

$$\langle E_1(v_h)|E_2(v_h)\rangle\equiv\langle(\omega(E_1)E_2)(v_h)\rangle. \tag{44}$$

Since $\langle\omega(E)(v_h)\rangle$ is the complex conjugate of $\langle E(v_h)\rangle$, $\langle\cdot|\cdot\rangle$ is a Hermitian form of $\mathcal{M}$. Moreover, it is clearly contravariant.

A lowest weight representation is *unitary* if its Hermitian form is positive definite. Of course, a Verma-like module is not unitary in general. Nevertheless, by a judicious choice of weight functions, it is possible to obtain unitary quotient representations with the help of this Hermitian form. In this case we call the Verma-like module *unitarizable*.

VI. TENSOR PRODUCTS OF THE DEFINING REPRESENTATION

Recall the defining representation in Sec. II. It is unitary and irreducible. More unitary irreducible representations can be obtained from the defining representation by taking its tensor products. Can they be obtained from Verma-like modules? We will answer this question in the form of a theorem. To state it, we need the following.

Definition 4: A Verma-like module is said to be approximately finite if its lowest weight function h satisfies the following conditions:[21]

(1) $h_I(\lambda_1;\dot{I};\lambda_2)-h_I(\lambda_3;\dot{J};\lambda_4)$ *is a non-negative integer if* $J\lambda 3\lambda 4>I\lambda 1\lambda 2$*;*
(2) $h_{II}(\lambda;\dot{I})=\Sigma_{i_1,\lambda_1}h_I(\lambda;\dot{I}\dot{I}_1;\lambda_1)$*;*
(3) $h_{III}(\dot{I};\lambda)=\Sigma_{\lambda_1,i_1}h_I(\lambda_1;\dot{I}_1\dot{I};\lambda)$*; and*
(4) $h_{IV}(\dot{I})=\Sigma_{\lambda_1,i_1,i_2,\lambda_2}h_I(\lambda_1;\dot{I}_1\dot{I}\dot{I}_2;\lambda_2)$.

(By convergence and unitarity, only a finite number of summands can be nonzero in each of the last three equations.)

Theorem 1: *The following statements pertaining to a unitary irreducible representation of open string algebra are equivalent:*

(1) The representation is a tensor product of the defining representation.
(2) The representation is the quotient of an approximately finite Verma-like module by its maximal subrepresentation.
(3) The representation is the quotient of a Verma-like module in which h_I, h_{II}, h_{III} *and* h_{IV} *are all nonzero only on a finite number of arguments by its maximal subrepresentation.*
(4) The representation is the quotient of a Verma-like module in which h_{IV} *is nonzero only on a finite number of arguments by its maximal subrepresentation.*[22]

Moreover, the maximal subrepresentations in the above statements are the radical of the Hermitian form of the Verma-like module.

There are some interesting physical interpretations of this theorem. In the context of QCD, a tensor product of the defining representation is a space consisting of multiple meson states. Theorem 1 thus reflects once again a long-established fact that in the large-N limit, one cannot break an open string into several, or combine several open strings to one.[23] Furthermore, the proof of Proposition 3 clearly shows that G^{00} is a maximally commutative subalgebra of $\hat{G}_{\Lambda,\Lambda_F}$. We may thus think of G^{00} as a linear space generated by a maximally commuting set of linearly independent quantum observables, of which the lowest weight state is an eigenstate with all its eigenvalues, or quantum numbers, given by the weight functions. If this state has only a finite number of nonzero quantum numbers, any other state generated by it will have a finite number of nonzero quantum numbers, too. Consequently, the above theorem implies that if an eigenstate, lowest weight or not, has only a finite number of nonzero quantum numbers with respect to these quantum observables, then this eigenstate must be a multiple meson state.

Before embarking on the proof of the equivalences, let us make some simple observations which have, as consequences, among other things, the statements about the Hermitian form in the theorem.

Lemma 3: The maximal subrepresentation of a unitarizable Verma-like module is the radical of the Hermitian form.

Proof: If we quotient out by the radical of the Hermitian form in the Verma module we get a representation with a nondegenerate Hermitian form (still contravariant of course). *A priori* it might seem possible that this representation could have a proper unitary quotient. However, exactly due to the unitarity assumption, if there exists a nonzero maximal proper invariant subspace I such that the quotient by it is unitary, then in fact the quotient must be equivalent to $I^{\perp}$. But since the space is cyclic, this is possible only if $I=0$, which is a contradiction. Q.E.D.

Lemma 4: If for a given weight h there exists a contravariant unitary lowest (or highest) weight module V_h, then it is unique.

Proof: Let $|v_h\rangle$ denote the lowest weight vector and let A_h denote the annihilator of $|v_h\rangle$ in the envelopping algebra $\mathcal{U}$. Then $V_h \simeq \mathcal{U}/A_h$ and by Lemma 3, A_h is equal to the set of $Y \in \mathcal{U}$ for which $Y|v_h\rangle = 0 \Leftrightarrow \langle Y(v_h)|Y(v_h)\rangle = 0$. By contravariance, the latter condition is expressible entirely in terms of the Lie algebra structure and h. Q.E.D.

We will now prove Theorem 1 by a series of lemmas in which (*1*), (*2*), (*3*), and (*4*), stand for the four enumerated statements in Theorem 1.

Lemma 5: (1)⇒(2).

Proof: First of all we observe that the defining representation $\mathcal{T}_o$ is obviously approximately finite. Indeed, it is elementary to verify that the following identities hold in $\mathcal{T}_o$:

$$\overline{\Xi}^{\lambda_1}_{\lambda_2} \otimes l^{\dot{I}}_{\dot{J}} = \sum_{\lambda_3=1}^{\Lambda_F} \sum_{\dot{K}} \overline{\Xi}^{\lambda_1}_{\lambda_2} \otimes f^{\dot{I}\dot{K}}_{\dot{J}\dot{K}} \otimes \Xi^{\lambda_3}_{\lambda_3}, \tag{45}$$

$$r^{\dot{I}}_{\dot{J}} \otimes \Xi^{\lambda_3}_{\lambda_4} = \sum_{\lambda_1=1}^{\Lambda_F} \sum_{\dot{K}} \overline{\Xi}^{\lambda_1}_{\lambda_1} \otimes f^{\dot{K}\dot{I}}_{\dot{K}\dot{J}} \otimes \Xi^{\lambda_3}_{\lambda_4} \tag{46}$$

and

$$\sigma^{\dot{I}}_{\dot{J}} = \sum_{\lambda_1,\lambda_2=1}^{\Lambda_F} \sum_{\dot{K}_1,\dot{K}_2} \overline{\Xi}^{\lambda_1}_{\lambda_2} \otimes f^{\dot{K}_1\dot{I}\dot{K}_2}_{\dot{K}_1\dot{J}\dot{K}_2} \otimes \Xi^{\lambda_2}_{\lambda_2} \tag{47}$$

for all $\dot{I}$, $\dot{J}$, λ_1, λ_2, λ_3, and λ_4. It is clear that the tensor product $\mathcal{T}_o^d = \mathcal{T}_o \otimes \mathcal{T}_o \otimes \cdots \otimes \mathcal{T}_o$ (d copies) will have the same property. Furthermore, any Young symmetrizer c_γ will define an invariant subspace and a nonzero weight vector v_γ which is annihilated by any subalgebra $gl(N)^- \subset gl(\infty) \equiv gl(\Lambda_F) \otimes F_\Lambda \otimes gl(\Lambda_F)$.

Let

$$\gamma = (\gamma_1, \gamma_2, \dots) \quad \text{with } \gamma_1 \geqslant \gamma_2 \geqslant \cdots \geqslant \gamma_n \geqslant 0 = \gamma_{n+1} = \gamma_{n+2} = \cdots$$

such that $d = \gamma_1 + \gamma_2 + \cdots + \gamma_n$. Again, by looking at the subalgebras gl(N) it follows that $c_\gamma(\mathcal{T}_o)$ carries an irreducible representation. That v_γ is annihilated by all of G^- and forms a one-dimensional representation for G^{00} is equally clear. The lowest weight is given by the formulas

$$h_I(1;\varnothing;1) = \gamma_1,$$

$$h_I(1;\varnothing;2) = \gamma_2,$$

$$\vdots$$

$$h_I(1;\varnothing;\Lambda_F) = \gamma_{\Lambda_F},$$

$$h_I(2;\varnothing;1) = \gamma_{\Lambda_F+1},$$

$$\vdots$$

$$h_I(\Lambda_F;\varnothing;\Lambda_F) = \gamma_{\Lambda_F\Lambda_F},$$

$$h_I(1;1;1) = \gamma_{\Lambda_F\Lambda_F+1},$$

$$\vdots$$

$$h_I(1;1;\Lambda_F)=\gamma_{\Lambda_F\Lambda_F+\Lambda_F},$$

$$h_I(2;1;1)=\gamma_{\Lambda_F\Lambda_F+\Lambda_F+1},$$

$$\vdots$$

$$h_I(\Lambda_F;1;\Lambda_F)=\gamma_{2\Lambda_F\Lambda_F},$$

$$h_I(1;2;1)=\gamma_{2\Lambda_F\Lambda_F+1},$$

$$\vdots$$

$$h_I(\Lambda_F;\Lambda;\Lambda_F)=\gamma_{\Lambda\Lambda_F\Lambda_F},$$

$$h_I(1;11;1)=\gamma_{\Lambda\Lambda_F\Lambda_F+1},$$

$$\vdots$$

$$h_I(\rho_1;\dot{K};\rho_2)=\gamma_n$$

and (48)

$$h_I(\lambda_1;\dot{I};\lambda_2)=0 \quad \text{if} \quad \dot{I}\lambda_1\lambda_2>\dot{K}\rho_1\rho_2.$$

Equations (45)–(47) clearly also hold in $c_\gamma(\mathcal{T}_o)$. Q.E.D.

Lemma 6: (2)⇒(1).

Proof: Let h_I be given in terms of a γ as in Eq. (48). Then, since it is nonzero only on a finite number of arguments, γ defines a Young symmetrizer c_γ. Consider $c_\gamma(\mathcal{T}_o)$. It is easy to see that this space has the right lowest weight. By Lemma 4 it is unique. Q.E.D.

Lemma 7: (2)⇒(3).

Proof: According to Definition 4, only a finite number of the summands in the formula

$$h_{IV}(\varnothing)=\sum_{\lambda_1,\dot{I}_1,\dot{I}_2,\lambda_2} h_I(\lambda_1;\dot{I}_1\dot{I}_2;\lambda_2)$$

are nonzero, so there exists an integer sequence $\dot{K}$ such that $h_I(\lambda_1;\dot{I};\lambda_2)=0$ for any λ_1 and λ_2 if $\dot{I}>\dot{K}$. Then $h_{II}(\lambda;\dot{I})=h_{III}(\dot{I};\lambda)=h_{IV}(I)=0$ if $\dot{I}>\dot{K}$. In particular, h_{II}, h_{III} and h_{IV} are nonzero on a finite number of arguments only. Q.E.D.

Lemma 8: If $\dot{I}\lambda_1\lambda_3>\dot{J}\lambda_2\lambda_4$, then $h_I(\lambda_2;\dot{J};\lambda_4)-h_I(\lambda_1;\dot{I};\lambda_3)$ is a non-negative integer.

Observe that this result is completely general: any unitary irreducible representation of the open string algebra constructed from a Verma-like module satisfies the first condition in Definition 4.

Proof: Let $\dot{I}$ and $\dot{J}$ be arbitrarily chosen integer sequences, and λ_1, λ_2, λ_3 and λ_4 arbitrarily chosen positive integers not greater than Λ_F. Notice that

$$\overline{\Xi}^{\lambda_1}_{\lambda_2}\otimes f^{\dot{I}}_{\dot{J}}\otimes\Xi^{\lambda_3}_{\lambda_4},\ \overline{\Xi}^{\lambda_1}_{\lambda_1}\otimes f^{\dot{I}}_{\dot{I}}\otimes\Xi^{\lambda_3}_{\lambda_3}-\overline{\Xi}^{\lambda_2}_{\lambda_2}\otimes f^{\dot{J}}_{\dot{J}}\otimes\Xi^{\lambda_4}_{\lambda_4} \text{ and } \overline{\Xi}^{\lambda_2}_{\lambda_1}\otimes f^{\dot{J}}_{\dot{I}}\Xi^{\lambda_4}_{\lambda_3},$$

where $\dot{I}\lambda_1\lambda_3>\dot{J}\lambda_2\lambda_4$, span a subalgebra of the open string algebra. This subalgebra is isomorphic to sl(2,$\mathbb{C}$). We therefore deduce from the representation theory of sl(2,$\mathbb{C}$) that $h_I(\lambda_2;\dot{J};\lambda_4)-h_I(\lambda_1;\dot{I};\lambda_3)$ must be a nonnegative integer. Q.E.D.

Lemma 9: (3)⇒(2).

Proof: Since there are only a finite number of arguments on which h_I does not vanish, Lemma 8 implies that there exists an integer sequence $\dot{K}\rho_1\rho_2$ such that

(1) $h_I(\rho_1;\dot{K};\rho_2)>0$;
(2) $h_I(\lambda_1;\dot{I};\lambda_2)=0$ if $\dot{I}\lambda_1\lambda_2>\dot{K}\rho_1\rho_2$; and
(3) $0<h_I(\lambda_1;\dot{I};\lambda_2)\leqslant h_I(\lambda_3;\dot{J};\lambda_4)$ if $\dot{K}\rho_1\rho_2>\dot{I}\lambda_1\lambda_2>\dot{J}\lambda_3\lambda_4$.

In other words, Eq. (48) with the partition γ holds.

We will move on to show that h_{II} satisfies Definition 4. The proofs for h_{III} and h_{IV} are similar. Let $\dot{K}_1\rho_3$ be the integer sequence such that $h_{II}(\rho_3;\dot{K}_1)>0$ and $h_{II}(\lambda;\dot{I})=0$ if $\dot{I}\lambda>\dot{K}_1\rho_3$. Then Eq. (22) implies that

$$\sum_{\lambda} h_I(\rho_3;\dot{K}_1;\lambda)=h_{II}(\rho_3;\dot{K}_1)-\sum_{i} h_{II}(\rho_3;\dot{K}_1 i)>0.$$

Hence $\dot{K}_1\rho_3\leqslant\dot{K}\rho_1$. $\dot{K}_1\rho_3<\dot{K}\rho_1$ is impossible or else

$$\sum_{\lambda} h_I(\rho_1;\dot{K};\lambda)=h_{II}(\rho_1;\dot{K})-\sum_{i} h_{II}(\rho_1;\dot{K}i)=0,$$

a contradiction. Thus $\rho_3=\rho_1$ and $\dot{K}_1=\dot{K}$. That h_{II} satisfies Definition 4 now follows from the fact that $h_{II}(\lambda;\dot{I})$ is a sum of

(1) all $h_I(\lambda;\dot{I}\dot{I}_1;\lambda_1)$ where λ_1 can take on any value and $\dot{I}_1$ is an integer sequence such that $\dot{I}\dot{I}_1\lambda<\dot{K}\rho_1$,
(2) all $h_{II}(\lambda;\dot{I}\dot{I}_1 i)$ where $\dot{I}_1 i$ is any integer sequence such that $\dot{I}\dot{I}_1\lambda<\dot{K}\rho_1$ but $\dot{I}\dot{I}_1 i\lambda>\dot{K}\rho_1$,

and the fact that the summands in the second family vanish identically. Q.E.D.

Lemma 10: (3)⇒(4).

Proof: Trivial. Q.E.D.

Lemma 11: $h_{II}(\lambda_2;\dot{J})-h_{II}(\lambda_1;\dot{I})\geqslant 0$ *and* $h_{III}(\dot{J};\lambda_2)-h_{III}(\dot{I};\lambda_1)\geqslant 0$ *if* $\dot{I}\lambda_1>\dot{J}\lambda_2$.

Proof: This comes from the inequalities

$$\langle v_h|(\bar{\Xi}^{\lambda_2}_{\lambda_1}\otimes l^{\dot{J}}_{\dot{I}})(\bar{\Xi}^{\lambda_1}_{\lambda_2}\otimes l^{\dot{I}}_{\dot{J}})|v_h\rangle\geqslant 0$$

and

$$\langle v_h|(r^{\dot{J}}_{\dot{I}}\otimes\Xi^{\lambda_2}_{\lambda_1})(r^{\dot{I}}_{\dot{J}}\otimes\Xi^{\lambda_1}_{\lambda_2})|v_h\rangle\geqslant 0.$$

Q.E.D.

Lemma 12: (4)⇒(3).

Proof: Let $\dot{K}$ be an integer sequence such that $h_{IV}(\dot{K})>0$ and $h_{IV}(\dot{I})=0$ for any $\dot{I}>\dot{K}$. Equations (20)–(23) imply that for this $\dot{I}$,

$$\sum_{\lambda_1,\lambda_2=1}^{\Lambda_F} h_I(\lambda_1;\dot{I};\lambda_2)=h_{IV}(\dot{I})-\sum_{i=1}^{\Lambda} h_{IV}(i\dot{I})-\sum_{j=1}^{\Lambda} h_{IV}(\dot{I}j)+\sum_{i,j=1}^{\Lambda} h_{IV}(i\,\dot{I}j)=0. \tag{49}$$

Assume that some $h_I(\lambda_1;\dot{I};\lambda_2)\neq 0$ in Eq. (49). Then there exist two integers ρ_1 and ρ_2 such that $h_I(\rho_1;\dot{I};\rho_2)<0$. By Lemma 8, $h_I(\lambda_3;\dot{J};\lambda_4)<0$ if $\dot{J}>\dot{I}$. Hence for this $\dot{J}$,

$$0>\sum_{\lambda_3,\lambda_4=1}^{\Lambda_F} h_I(\lambda_3;\dot{J};\lambda_4)=h_{IV}(\dot{J})-\sum_{i=1}^{\Lambda} h_{IV}(i\dot{J})-\sum_{j=1}^{\Lambda} h_{IV}(\dot{J}j)+\sum_{i,j=1}^{\Lambda} h_{IV}(i\dot{J}j)=0,$$

a contradiction. We thus conclude that $h_I(\lambda_1;\dot{I};\lambda_2)=0$ for any integer sequence $\dot{I}$ such that $\dot{I}>\dot{K}$ and any integers λ_1 and λ_2. In particular, h_I is nonzero on a finite number of arguments only. A similar argument using Lemma 11 shows that h_{II} and h_{III} are nonzero on a finite number of arguments only. Q.E.D.

VII. OTHER UNITARY IRREDUCIBLE REPRESENTATIONS

Now that we have identified a class of unitary irreducible representations, it is natural for us to ask what other unitary irreducible representations look like. One crucial observation is that not only are the above tensor product representations faithful representations of the full open string algebra, but also they are completely determined by the ideal $\mathrm{sl}(\infty)=[\mathrm{gl}(\infty),\mathrm{gl}(\infty)]$, where $\mathrm{gl}(\infty)=F_{\Lambda,\Lambda_F}$, and are the only representations that remain faithful and unitary as representations of this ideal. This suggests that other unitary irreducible representations can be obtained as unitary lowest weight representations from the quotient algebra by $\mathrm{sl}(\infty)$, i.e., as "truly infinite" (t.i.) representations of the open string algebra—lowest weight representations in which $\mathrm{sl}(\infty)$ acts trivially. Indeed, it turns out that we have the following.

Theorem 2: *Any unitary irreducible lowest weight representation of the open string algebra is a tensor product of a unitary irreducible approximately finite representation and a unitary irreducible lowest weight representation in which any element of* $\mathrm{sl}(\infty)$ *acts as the* 0 *operator*.[24]

Together with the physical interpretation of Theorem 1, this result implies that if a lowest weight state has an infinite number of nonzero quantum numbers, it must be a tensor product of a multiple meson state and a state in a representation of the quotient algebra. As remarked in the Introduction, the quotient algebra extends and generalizes the Virasoro algebra. Already for the case $\Lambda=1$ the quotient algebra is quite interesting. Specifically, it is an extension of the Virasoro algebra by an infinite Heisenberg algebra.[14] Physically speaking, $\mathrm{sl}(\infty)$ consists of finite-size-effect operators. Studying the quotient algebra is thus equivalent to studying a physical system which is free of finite-size effects. Hence, we expect the representation theory of the quotient algebra to describe the physics of open matrix chains at the thermodynamic limit.

Let h be the weight function of an arbitrary unitary lowest weight representation $\mathcal{R}$ of the open string algebra, and $|v_h\rangle$ its lowest weight vector (somewhat abusing notation, we do not distinguish between the space and the representation). Our task is to produce two representations $\mathcal{R}_{a.f.}$ and $\mathcal{R}_{t.i.}$ such that $\mathcal{R}_{a.f.}$ is approximately finite, $\mathcal{R}_{t.i.}$ comes from the quotient algebra [is trivial on $\mathrm{sl}(\infty)$], and $\mathcal{R}=\mathcal{R}_{t.i.}\otimes\mathcal{R}_{a.f.}$. As usual, we do this by proving a succession of lemmas.

Lemma 13: In the first two equations below, assume that $\dot{I}\lambda_1>\dot{J}\lambda_2$, *and in the third assume that* $\dot{I}>\dot{J}$. *Let*

$$\bar{\Xi}^{\lambda_1}_{\lambda_2}\otimes\tilde{l}^{\dot{I}}_{\dot{J}}\equiv\bar{\Xi}^{\lambda_1}_{\lambda_2}\otimes l^{\dot{I}}_{\dot{J}}-\sum_{\lambda_3=1}^{\Lambda_F}\sum_{\dot{K}}\bar{\Xi}^{\lambda_1}_{\lambda_2}\otimes f^{\dot{I}\dot{K}}_{\dot{J}\dot{K}}\otimes\Xi^{\lambda_3}_{\lambda_3}, \tag{50}$$

$$\tilde{r}^{\dot{I}}_{\dot{J}}\otimes\Xi^{\lambda_1}_{\lambda_2}\equiv r^{\dot{I}}_{\dot{J}}\otimes\Xi^{\lambda_1}_{\lambda_2}-\sum_{\lambda_3=1}^{\Lambda_F}\sum_{\dot{K}}\bar{\Xi}^{\lambda_3}_{\lambda_3}\otimes f^{\dot{K}\dot{I}}_{\dot{K}\dot{J}}\otimes\Xi^{\lambda_1}_{\lambda_2}, \tag{51}$$

and

$$\tilde{\sigma}^{\dot{I}}_{\dot{J}}\equiv\sigma^{\dot{I}}_{\dot{J}}-\sum_{\lambda_1,\lambda_2=1}^{\Lambda_F}\sum_{\dot{K},\dot{L}}\bar{\Xi}^{\lambda_1}_{\lambda_1}\otimes f^{\dot{K}\dot{I}\dot{L}}_{\dot{K}\dot{J}\dot{L}}\otimes\Xi^{\lambda_2}_{\lambda_2}. \tag{52}$$

Then $\bar{\Xi}^{\lambda_1}_{\lambda_2}\otimes\tilde{l}^{\dot{I}}_{\dot{J}}|v_h\rangle$, $\tilde{r}^{\dot{I}}_{\dot{J}}\otimes\Xi^{\lambda_1}_{\lambda_2}|v_h\rangle$ *and* $\tilde{\sigma}^{\dot{I}}_{\dot{J}}|v_h\rangle$ *have finite norms.*

Proof: We will show that $\tilde{\sigma}^{\dot{I}}_{\dot{J}}|v_h\rangle$ has a finite norm. The rest of the lemma can be proved by a simpler version of the following argument.

For any non-negative integer p, consider the operator

$$\tilde{\sigma}^{\dot{I}}_{\dot{J}}(p)=\sigma^{\dot{I}}_{\dot{J}}-\sum_{\lambda_1,\lambda_2=1}^{\Lambda_F}\sum_{\substack{\dot{K},\dot{L}\\ \#(\dot{K}\dot{L})\leqslant p}}\bar{\Xi}^{\lambda_1}_{\lambda_1}\otimes f^{\dot{K}\dot{I}\dot{L}}_{\dot{K}\dot{J}\dot{L}}\otimes\Xi^{\lambda_2}_{\lambda_2}. \tag{53}$$

Certainly it is well defined because there are only a finite number of summands in Eq. (53). [We can define $\tilde{l}^{\dot{I}}_{\dot{J}}(p)$ and $\tilde{r}^{\dot{I}}_{\dot{J}}(p)$ similarly.] Let

$$s(\dot{I},\dot{J},\dot{K},\dot{L})=\sum_{\dot{K}',\dot{L}'}\delta^{\dot{K}\dot{I}\dot{L}}_{\dot{K}'\dot{I}\dot{L}'}\delta^{\dot{K}\dot{J}\dot{L}}_{\dot{K}'\dot{J}\dot{L}'}.$$

Clearly, s is a positive integer. Since

$$[\tilde{\sigma}^{\dot{I}}_{\dot{J}}(p),f^{\dot{K}'\dot{J}\dot{L}'}_{\dot{K}'\dot{I}\dot{L}'}]=0 \tag{54}$$

for $\#(\dot{K}'\dot{L}')\leqslant p$,

$$\langle v_h|\tilde{\sigma}^{\dot{J}}_{\dot{I}}(p)\tilde{\sigma}^{\dot{I}}_{\dot{J}}(p)|v_h\rangle=\langle v_h|\sigma^{\dot{J}}_{\dot{I}}\sigma^{\dot{I}}_{\dot{J}}|v_h\rangle-\sum_{\lambda_1,\lambda_2=1}^{\Lambda_F}\sum_{\substack{\dot{K},\dot{L}\\ \#(\dot{K}\dot{L})\leqslant p}}s(\dot{I},\dot{J},\dot{K},\dot{L})(h_I(\lambda_1;\dot{K}\dot{J}\dot{L};\lambda_2)$$

$$-h_I(\lambda_1;\dot{K}\dot{I}\dot{L};\lambda_2)), \tag{55}$$

which, in turn, is non-negative owing to unitarity. That p can be arbitrarily large and Lemma 8 together then imply that for any fixed nonempty integer sequences $\dot{I}$ and $\dot{J}$, only a finite number of

$$h_I(\lambda_1;\dot{K}\dot{J}\dot{L};\lambda_2)-h_I(\lambda_1;\dot{K}\dot{I}\dot{L};\lambda_2),$$

where λ_1 and λ_2 are arbitrary positive integers not larger than Λ_F, and $\dot{K}$ and $\dot{L}$ are empty or nonempty integer sequences, are nonzero. As a result,

$$\sum_{\substack{\dot{K},\dot{L}\\ \#(\dot{K}\dot{L})>q_0}}\bar{\Xi}^{\lambda_1}_{\lambda_1}\otimes f^{\dot{K}\dot{I}\dot{L}}_{\dot{K}\dot{J}\dot{L}}\otimes\Xi^{\lambda_2}_{\lambda_2}|v_h\rangle=0 \tag{56}$$

for some positive integer q_0 because its norm vanishes. Thus $\tilde{\sigma}^{\dot{I}}_{\dot{J}}|v_h\rangle$ has a finite norm. Q.E.D.

Define $\mathcal{R}_f$ to be the subspace of $\mathcal{R}$ generated by the actions of elements of $\mathrm{gl}(\Lambda_F)\otimes F_\Lambda\otimes\mathrm{gl}(\Lambda_F)$ on the lowest weight vector $|v_h\rangle$. For brevity, let $\tilde{X}$ denote any one of the operators defined in Eqs. (50)–(52). It now follows easily that $\tilde{X}v$ is well defined for any $v\in\mathcal{R}_f$.

Lemma 14: For any $v\in\mathcal{R}_f$ and any $F\in\mathrm{gl}(\Lambda_F)\otimes F_\Lambda\otimes\mathrm{gl}(\Lambda_F)$,

$$\tilde{X}Fv=F\tilde{X}v.$$

Proof: Any $F\in\mathrm{gl}(\Lambda_F)\otimes F_\Lambda\otimes\mathrm{gl}(\Lambda_F)$ commutes, for fixed $\dot{I},\dot{J}$, with everything in $\mathrm{gl}(\Lambda_F)\otimes F_\Lambda\otimes\mathrm{gl}(\Lambda_F)$ of the form $\bar{\Xi}^{\lambda_1}_{\lambda_1}\otimes f^{\dot{K}\dot{I}\dot{L}}_{\dot{K}\dot{J}\dot{L}}\otimes\Xi^{\lambda_2}_{\lambda_2}$ except possibly finitely many. The claim now follows by a simple computation as in the proof of the previous lemma. Q.E.D.

Corollary 1: Let $\tilde{X}^{\dot{I}_p}_{\dot{J}_p}$ *stand for either* $\overline{\Xi}^{\lambda_1}_{\lambda_2}\otimes\tilde{l}^{\dot{I}}_{\dot{J}}$, $\tilde{r}^{\dot{I}}_{\dot{J}}\otimes\Xi^{\lambda_1}_{\lambda_2}$ or $\tilde{\sigma}^{\dot{I}}_{\dot{J}}$. *Then*

$$\prod_{p=1}^{n}\tilde{X}^{\dot{I}_p}_{\dot{J}_p}|v_h\rangle \tag{57}$$

has a finite norm for any value of n.

Proof: This follows directly from Lemmas 13 and 14. Q.E.D.

It follows from Lemmas 13 and 14 and Corollary 1 that $\tilde{l}$, $\tilde{r}$ and $\tilde{\sigma}$ are well-defined operators on a lowest weight module.

Lemma 15: There exist $\alpha\in\mathbb{R}$ *and* $N\in\mathbb{N}$ *such that* $h_I(\lambda_1;I;\lambda_2)=\alpha$ *for all* λ_1 *and* λ_2 *provided* $\#(I)\geqslant N$.

Proof: Observe that since $\dot{I}>\dot{J}$, (55) implies more generally for any $\lambda_1,\lambda_2,\lambda_3,\lambda_4$ that (the non-negative integer)

$$(h_I(\lambda_1;\dot{K}\dot{J}\dot{L};\lambda_2)-h_I(\lambda_3;\dot{K}\dot{I}\dot{L};\lambda_4))$$

can be nonzero for at most finitely many $\dot{K},\dot{L}$. As a special case of this, notice that for any $i=1,\ldots,\Lambda_F$, only a finite number of

$$h_I(\lambda_1;\dot{K}\dot{L};\lambda_2)-h_I(\lambda_3;\dot{K}\{i\}\dot{L};\lambda_4)$$

are nonzero. Hence, there exists an $N\in\mathbb{N}$ such that for any U with $\#(U)\geqslant N$, any $\lambda_1,\lambda_2,\lambda_3,\lambda_4,\lambda_5,\lambda_6$, and any indices $1\leqslant i,j\leqslant\Lambda_F$, $h_I(\lambda_1;U;\lambda_2)=h_I(\lambda_3;U\{i\};\lambda_4)=h_I(\lambda_5;\{j\}U;\lambda_6)$. But since for any two sequences U,V with $\#(U)=\#(V)=N$ there is a sequence W such that both U and V occur as segments of W, it follows that we must have $h_I(\lambda_1;U;\lambda_2)=h_I(\lambda_3;V;\lambda_4)$. Q.E.D.

We can now define the two spaces $\mathcal{R}_{t.i.}$ (the truly infinite) and $\mathcal{R}_{a.f.}$ (the almost finite).

Definition 5: Let α *be as in Lemma 15, set* $h^{a.e.}_I=h_I-\alpha$, *and let* $h^{a.e.}_{II}$, $h^{a.e.}_{III}$, *and* $h^{a.e.}_{IV}$ *be defined from* $h^{a.e.}_I$ *as in Definition 4.* $\mathcal{R}_{a.f.}$ *then is defined as the lowest weight representation having this lowest weight. Similarly,* $\mathcal{R}_{t.i.}$ *is defined to be the lowest weight representation given by the lowest weight* $(h^q_I,h^q_{II},h^q_{III},h^q_{IV})$ *with* $h^q_I\equiv\alpha$, *and* $h^q_W=h_W-h^{a.e.}_W$ *for* $W=II,III,IV$.

In the following we shall, among other things, consider elements $f^{\dot{I}}_{\dot{J}}$, with $\dot{I}>\dot{J}$ acting in $\mathcal{R}_f$ or in $\mathcal{R}_{a.f.}$. We will use the same symbol for these actions since the two spaces are, in fact, equal as vector spaces. As representations of $\mathrm{gl}(\Lambda_F)\otimes F_\Lambda\otimes\mathrm{gl}(\Lambda_F)$ they differ by a tensor product of a one-dimensional representation (defined by α) and this is trivial on said elements. Furthermore, in the representation $\mathcal{R}_{t.i.}$ each $f^{\dot{I}}_{\dot{J}}$, with $\dot{I}>\dot{J}$, acts trivially since by construction they must annihilate the lowest weight vector while at the same time having commutators with the other generators that again yield elements $f^{\dot{K}}_{\dot{L}}$, with $\dot{K}>\dot{L}$.

Proof of Theorem 2: Let $X^{\dot{I}_p}_{\dot{J}_p}$ stand for either $\overline{\Xi}^{\lambda_1}_{\lambda_2}\otimes l^{\dot{I}}_{\dot{J}}$, $r^{\dot{I}}_{\dot{J}}\otimes\Xi^{\lambda_1}_{\lambda_2}$ or $\sigma^{\dot{I}}_{\dot{J}}$ and likewise $\tilde{X}^{\dot{I}_p}_{\dot{J}_p}$ stand for either $\overline{\Xi}^{\lambda_1}_{\lambda_2}\otimes\tilde{l}^{\dot{I}}_{\dot{J}}$, $\tilde{r}^{\dot{I}}_{\dot{J}}\otimes\Xi^{\lambda_1}_{\lambda_2}$ or $\tilde{\sigma}^{\dot{I}}_{\dot{J}}$. It follows that $\mathcal{R}_{t.i.}$ is generated by operators from $X^{\dot{I}_p}_{\dot{J}_p}$. Further, it follows from Lemmas 13 and 14 and Corollary 1 that any element of $\mathcal{R}$ can be written as a finite linear combination of elements of the form

$$\prod_{p=1}^{n}\tilde{X}^{\dot{I}_p}_{\dot{J}_p}\prod_{p=1}^{n_I}\overline{\Xi}^{\lambda^{(I)}_p}_{\rho^{(I)}_p}\otimes f^{\dot{I}^{(I)}_p}_{\dot{J}^{(I)}_p}\otimes\Xi^{\eta^{(I)}_p}_{\zeta^{(I)}_p}|v_h\rangle, \tag{58}$$

where the two products are arranged in such a way that in each product, the factors follow the lexicographic ordering from Definition 3 with σ, r and l replaced with $\tilde{\sigma}$, $\tilde{r}$ and $\tilde{l}$, respectively.

Denote the lowest weight vector of $\mathcal{R}_{t.i.}$ by $v_{t.i.}$ and the lowest weight vector of $\mathcal{R}_{a.f.}$ by $v_{a.f.}$. Assume they are both unit vectors in their respective spaces. We can then define a surjection from $\mathcal{R}_{t.i.}\otimes\mathcal{R}_f$ to $\mathcal{R}$ by mapping

$$\left(\prod_{p=1}^{n} X^{\dot{I}_p}_{\dot{J}_p} v_{t.i.}\right)\otimes\left(\prod_{p=1}^{n_I} \overrightarrow{\Xi}^{(I)}_{\rho^{(I)}_p p}\otimes f^{\dot{I}^{(I)}_p}_{\dot{j}^{(I)}_p}\otimes \Xi^{\eta^{(I)}_p}_{\zeta^{(I)}_p} v_{a.f.}\right) \tag{59}$$

to the one shown in Eq. (58). Because of Lemma 14 and the above remarks, this is easily seen to be a map that preserves the respective inner products. By looking at the images of $\mathcal{R}_{t.i.}\otimes v_{a.f.}$ and $v_{t.i.}\otimes\mathcal{R}_{a.f.}$ it follows that $\mathcal{R}_{t.i.}$ and $\mathcal{R}_{a.f.}$ are unitary. The irreducibility is obvious, cf. Lemma 4. Q.E.D.

(Received 23 February 2001; accepted for publication 30 March 2001)

There are three fine gradings of the simple Lie algebra of type B_2 over the complex number field. They provide a basic information about the structure of the algebra. In the paper an explicit description of all fine gradings is given in terms of the four-dimensional symplectic [sp(4, $\mathbb{C}$)] and five-dimensional orthogonal [o(5, $\mathbb{C}$)] representations of the algebra. In addition, the real forms of B_2 are considered. It is shown which of the fine gradings survive the restriction to each of the real forms. These results should be useful in defining various sets of additive quantum numbers for systems with such symmetries, for systematic study of grading preserving contractions of this Lie algebra, and generally for choosing bases which reflect structural properties of the Lie algebra.
[DOI: 10.1063/1.1383788]

I. INTRODUCTION

The motivation for studying specific gradings of simple Lie algebras with complex or real parameters is often linked with applications. Among the infinity of possible decompositions of the algebra as a linear space into the direct sum of subspaces, there are a few decompositions particularly ''compatible'' with the structure of the given algebra, the so-called grading decompositions.[1] (Two decompositions are considered to be different only if they are nonconjugate under the action of the automorphism group of the Lie algebra.) Some of the gradings are coarse: the Lie algebra is decomposed in a small number of grading subspaces. The coarsest nontrivial ones are the $\mathbb{Z}_2$ gradings. Their role, for example, in defining the compact and noncompact part of real forms of complex algebras is well known. The opposite extreme are the fine gradings decomposing the algebra into as many subspaces as possible. Every simple Lie algebra with complex parameters admits a fine grading called root or Cartan decomposition. Corresponding bases of the algebra and of its representation spaces (defined up to a normalization by the grading) have been the work horses of the theory and applications even if the underlying grading property is usually not emphasized. For example, the Lie algebra sl(2, $\mathbb{C}$) has precisely two such gradings, each defining one basis (called also generators) of sl(2, $\mathbb{C}$). Practically no other bases are used in the theory or in the numerous applications. The basis of the root decomposition is often denoted by L_+, L_0, L_-, the other ones are the Pauli matrices. In both cases the generators are determined by the grading up to a nonzero normalization constant.

For simple Lie algebras of higher ranks fine gradings may not decompose the algebra into subspaces which are all of dimension one. Then the corresponding bases are defined only partially

by the grading. Well known is the example of the root decomposition/grading of sl(3, $\mathbb{C}$). Two ''diagonal'' generators have to be chosen by other considerations, while the remaining six are given by the grading. Possible choice of additive quantum numbers is another use of the fine gradings. The grading subspaces are eigenspaces of the grading group, the eigenvalues being the quantum numbers. A maximal set of additive quantum numbers is given by several elements of the grading group which have sufficiently many distinct eigenvalues to label the grading subspaces.

A grading of a Lie algebra L is a structural property of L resulting from the presence of an Abelian subgroup of diagonable automorphisms in the group of automorphism of L. Between the coarsest trivial grading, corresponding to the identity element of the automorphism group, to the finest gradings, there are many intermediate gradings. A complete list of such gradings has not been put together even for the rank 2 simple Lie algebras. Description of fine gradings makes such a task much simpler.

There are other motivations for studying the gradings of simple Lie algebras one can bring forward besides the choice of bases and the additive quantum numbers.

Our motivation originated in the study of graded contractions of simple Lie algebras.[2] Unlike the standard Wigner–Inonü contractions,[3] here one requires that a suitably chosen grading is preserved during the contraction/deformation process. It allows one to consider, separately from the general problem of all deformations of a given Lie algebra, only those deformations which are of interest for a problem at hand. Typically it makes it easy to keep any subalgebra of importance free of deformations (see, for example, Ref. 4). Finally it makes it possible to deform the action of the Lie algebra in the representation spaces so that one has a representation of the deformed algebra.[5] Another possible application of graded contractions allows one to link the very difficult task of classification of isomorphism classes of solvable Lie algebras to much simpler (though also difficult) problems of classification of isomorphism classes of equidimensional nilpotent Lie algebras.[6]

Yet another curious possibility of applications of fine gradings is implied in Ref. 7. The relevant observation made there is that the Drinfel–Jimbo quantum algebra arises as a q-deformation of the universal enveloping algebra U(so(n)) in the basis given by the root decomposition (see, for example, Ref. 8). In Ref. 7 an analogous but very different deformation is based on another fine grading of so(n). It is quite natural to ask the question about q-deformations for every fine grading of so(n), not only the two mentioned in Ref. 7.

In this paper we consider the rank 2 simple Lie algebra B_2 (equivalently also denoted C_2). In the physics literature it is frequently specified by one of its two lowest dimensional representations. It then is called either sp(4, $\mathbb{C}$) or o(5, $\mathbb{C}$). Our notations for the real forms of B_2 are the following. The compact one is written either as usp(4) or as o(5); the real form with 6 compact and 4 noncompact generators is shown as usp(2, 2) and o(4, 1); the last real form with 4 compact and 6 non-compact generators is denoted either by sp(4, $\mathbb{R}$) or by o(3, 2). According to Ref. 9 there are three fine gradings of B_2 which are not equivalent under the group of automorphisms of B_2. One of them is the well known root decomposition, the second one in our list is new, the basis given by the third fine grading in our list, at least in its o(5, $\mathbb{C}$)-version, has been often used in physics literature without reference to any grading. The second and third gradings each define an orthogonal (with respect to the Killing form) basis of B_2. In the first case, the root decomposition goes far in defining a basis but there is one subspace (Cartan subalgebra) which is of dimension 2. There is no grading of the algebra which would allow one to split the two-dimensional subspace into two one-dimensional ones. Any such splitting is not a grading.

Applications of the real forms of B_2 are too numerous to be mentioned here. Let us just mention that among their orthogonal realizations there are the Lie algebras of the de Sitter groups, that some real forms of the symplectic realization have been intensively applied in the recent years in nuclear physics, and also in quantum optics.[10–13]

Fine gradings are in correspondence with the maximal Abelian diagonable (MAD) subgroups of the automorphism groups of Lie algebras. The MAD-groups of B_2 as well as of other classical Lie algebras were classified in Ref. 14. Similar results for the real forms are found in Ref. 15. Given the 1–1 correspondence between the MAD-groups and the fine gradings, the existence of

the fine gradings which we are to describe here can be inferred from there. However, such a task is relatively laborious. Therefore we are undertaking to provide an explicit description of the fine gradings for the low rank simple Lie algebras which are most often encountered in applications. Fine gradings of sl(3, $\mathbb{C}$) are found in Ref. 9; there are four of them.

The paper is organized as follows: After the preliminaries in Sec. II, we consider the two representations of B_2 one by one and derive explicitly the fine gradings in terms of matrices $\mathbb{C}^{5\times5}$ for o(5, $\mathbb{C}$) (Sec. III) and matrices $\mathbb{C}^{4\times4}$ for sp(4, $\mathbb{C}$) (Sec. IV). The gradings for both representations are given in Tables II, IV, and VI. In Sec. V we consider the real forms of the Lie algebra. There are 3 fine gradings of o(3, 2) and sp(4, $\mathbb{R}$), two fine gradings of o(4, 1) and usp(2, 2), and only one fine grading for the compact algebras o(5) and usp(4). The gradings are presented in Tables IX–XX. Note that we use the same letters for corresponding basis elements of the Lie algebra in 4 and 5 dimensions; their normalizations are not the same [cf. (2) below].

II. PRELIMINARIES

A grading of Lie algebra L is a decomposition of L into a direct sum of linear subspaces $\Gamma: L=\oplus_{i\in I}L_i$ which satisfies the following property:

$$\text{For any pair of indices } i,j\in I \text{ there exists } k\in I \text{ such that } 0\subseteq[L_i,L_j]\subseteq L_k. \tag{1}$$

Throughout the paper we use a shorthand notation when writing expressions like $[L_i,L_j]$. It should be read as the commutator of any element of L_i with any element of L_j. It is often convenient to set up the indices additively, so that $k=i+j$. Note that if $[L_i,L_j]=0$, then $k\in I$ is not defined.[16,17]

A grading which cannot be further refined is called *fine*. In this article we describe explicitly the fine gradings of two isomorphic simple algebras over $\mathbb{C}$, namely, o(5, $\mathbb{C}$) and sp(4, $\mathbb{C}$). More precisely we are dealing here with three irreducible representations of the Lie algebra B_2: the four-dimensional one which we call sp(4, $\mathbb{C}$), the one of dimension five calling it o(5, $\mathbb{C}$), and the adjoint representation of dimension ten, namely, the algebra acting on itself.

As long as one is interested only in the gradings of B_2, i.e., decomposition into the direct sums of grading subspaces, particular normalization of basis elements of each subspace is of little importance. However, in applications one often needs to fix a normalization of bases. It is done using the scalar product in the Lie algebra (Killing form). For any $x,y\in B_2$ and for any matrix representation $\phi(B_2)$, one has the scalar product of (x,y),

$$(x,y)l_\phi=\mathrm{tr}\ \phi(x)\phi(y), \tag{2}$$

where l_ϕ is a representation-dependent integer-valued numerical constant called the (second) index of the representation ϕ. Values of l_ϕ for the representations of simple Lie algebras are generally well known.[18] In particular, for the irreducible representations of B_2 of dimensions 4, 5, and 10, they are 2, 4, 12, respectively.

Skew-symmetric 5×5 matrices represent the 10-dimensional complex vector space of o(5, $\mathbb{C}$),

$$\mathrm{o}(5,\mathbb{C})=\{X\in\mathbb{C}^{5\times5}\,|\,X+X^T=0\}=\left\{\left.\begin{pmatrix}0&a&b&c&d\\-a&0&e&f&g\\-b&-e&0&h&j\\-c&-f&-h&0&k\\-d&-g&-j&-k&0\end{pmatrix}\right|\ a,\ldots,k\in\mathbb{C}\right\}. \tag{3}$$

The isomorphic Lie algebra sp(4, $\mathbb{C}$) can be realized as the complex vector space of matrices,

$$\mathrm{sp}(4,\mathbb{C})=\left\{X\in\mathbb{C}^{4\times4}\middle|X\begin{pmatrix}0&I_2\\-I_2&0\end{pmatrix}+\begin{pmatrix}0&I_2\\-I_2&0\end{pmatrix}X^T=0\right\}$$

$$=\left\{\begin{pmatrix}m&n&p&q\\r&s&q&t\\u&v&-m&-r\\v&w&-n&-s\end{pmatrix}\middle|\,m,\ldots,w\in\mathbb{C}\right\}.$$

Since our algebras are simple, we can use results deduced in Ref. 1. If L is a simple Lie algebra over $\mathbb{C}$, then fine gradings of L are in the one-to-one correspondence with the maximal Abelian groups of diagonable automorphisms (MAD-groups). It is known that groups of automorphisms of $\mathrm{o}(5,\mathbb{C})$ and $\mathrm{sp}(4,\mathbb{C})$ are formed by inner automorphisms only, i.e., by automorphisms of the form,

$$\mathrm{Ad}_A X := A^{-1}XA \tag{4}$$

for any X belonging to the Lie algebra, and where A is an element of the corresponding Lie group. Technically our problem in this paper is to find, for suitably chosen A, the eigenvalues and eigenvectors of the transformations (4) of $X\in B_2$. In order to describe the group of automorphisms Aut $\mathrm{o}(5,\mathbb{C})$ and Aut $\mathrm{sp}(4,\mathbb{C})$, we introduce the Lie groups of orthogonal and symplectic matrices,

$$\mathrm{O}(5,\mathbb{C})=\{A\in\mathbb{C}^{5\times5}|AA^T=I\},\quad \mathrm{Sp}(4,\mathbb{C})=\{A\in\mathbb{C}^{4\times4}|AJA^T=J\},$$

where $J=\left(\begin{smallmatrix}0&I_2\\-I_2&0\end{smallmatrix}\right)$.

The automorphism groups are formed by the transformations (4),

$$\text{Aut }\mathrm{o}(5,\mathbb{C})=\{\mathrm{Ad}_A|A\in\mathrm{O}(5,\mathbb{C})\},\quad \text{Aut }\mathrm{sp}(4,\mathbb{C})=\{\mathrm{Ad}_A|A\in\mathrm{Sp}(4,\mathbb{C})\}. \tag{5}$$

In Ref. 14 it is shown that there exist three nonconjugate MAD-groups in Aut $\mathrm{o}(5,\mathbb{C})$, and similarly in Aut $\mathrm{sp}(4,\mathbb{C})$. In order to describe the three MAD-groups explicitly, we have to provide A in (4) as the matrices $\mathbb{C}^{5\times5}$ and $\mathbb{C}^{4\times4}$ respectively.

The MAD-groups $\mathcal{G}_1,\mathcal{G}_2,\mathcal{G}_3$ of Aut $\mathrm{o}(5,\mathbb{C})$ are given as subgroups of Aut $\mathrm{o}(5,\mathbb{C})$, where the following matrices A are used in (4):

$$\mathcal{G}_1:\quad A=(\varepsilon)\oplus\begin{pmatrix}\cos\varphi_1&\sin\varphi_1\\-\sin\varphi_1&\cos\varphi_1\end{pmatrix}\oplus\begin{pmatrix}\cos\varphi_2&\sin\varphi_2\\-\sin\varphi_2&\cos\varphi_2\end{pmatrix},\quad \varepsilon=\pm1,\ \varphi_1,\varphi_2\in\mathbb{C},$$

$$\mathcal{G}_2:\quad A=\mathrm{diag}(\varepsilon_1,\varepsilon_2,\varepsilon_3)\oplus\begin{pmatrix}\cos\varphi&\sin\varphi\\-\sin\varphi&\cos\varphi\end{pmatrix},\qquad \varepsilon_i=\pm1,\ \varphi\in\mathbb{C},$$

$$\mathcal{G}_3:\quad A=\mathrm{diag}(\varepsilon_1,\varepsilon_2,\varepsilon_3,\varepsilon_4,\varepsilon_5),\qquad \varepsilon_i=\pm1.$$

Correspondingly, the MAD-groups $\mathcal{H}_1,\mathcal{H}_2,\mathcal{H}_3$ of Aut $\mathrm{sp}(4,\mathbb{C})$ are given by

$$\mathcal{H}_1:\quad A=\mathrm{diag}(\alpha,\beta,\alpha^{-1},\beta^{-1}),\qquad \alpha,\beta\in\mathbb{C},$$

$$\mathcal{H}_2:\quad A=\begin{pmatrix}\alpha&0\\0&\alpha^{-1}\end{pmatrix}\otimes\sigma_k=\begin{pmatrix}\alpha\sigma_k&0\\0&\alpha^{-1}\sigma_k\end{pmatrix},\quad k=0,1,2,3,\ \alpha\in\mathbb{C},$$

$$\mathcal{H}_3:\quad A=\sigma_j\otimes\sigma_k,\qquad j,k=0,1,2,3,$$

where $\sigma_0=\left(\begin{smallmatrix}1&0\\0&1\end{smallmatrix}\right)$, $\sigma_1=\left(\begin{smallmatrix}0&1\\1&0\end{smallmatrix}\right)$, $\sigma_2=\left(\begin{smallmatrix}0&1\\-1&0\end{smallmatrix}\right)$, $\sigma_3=\left(\begin{smallmatrix}1&0\\0&-1\end{smallmatrix}\right)$.

According to Ref. 1, a grading $\Gamma: L=\oplus_{i\in I}L_i$ is fine iff Γ is a decomposition into eigenspaces of elements of a MAD-group $\mathcal{G}$. Since the decomposition of a finite-dimensional Lie algebra has only finite number of nonempty subspaces, we need only one or several elements of $\mathcal{G}$ even if the group $\mathcal{G}$ is infinite. The choice of such "grading elements" is far from unique. Our choice of grading elements is shown later.

It follows from the definition of a grading, that there is a partial binary operation defined on the index set I,

$$(i,j)\to k \quad \text{if} \quad 0\neq[L_i,L_j]\subseteq L_k. \tag{6}$$

Clearly this operation is closely related to the choice of labeling subscripts of the grading subspaces L_j. Since the grading subspaces are eigenspaces of the chosen grading elements, it is natural to use their eigenvalues for the labeling. Thus if L_i is the eigenspace of $\mathrm{Ad}_A\in\mathcal{G}$ corresponding to λ_i and L_j is the eigenspace corresponding to λ_j, and $[L_i,L_j]\neq 0$, then $[L_i,L_j]$ is the eigenspace corresponding to the eigenvalue $\lambda_i\lambda_j$. This fact enables one to embed I, equipped with operation (6), into an Abelian group. The multiplicative group is replaced by an additive one by putting $\lambda_j=e^{a_j}$ and using just the exponents as labels.

III. FINE GRADINGS OF o(5, $\mathbb{C}$)

For easier recording of the results, we use constant matrices E_{ij} and $M_{ij}\in\mathbb{C}^{5\times 5}$,

$$(E_{ij})_{rs}=\delta_{ir}\delta_{js}, \quad M_{ij}=E_{ij}-E_{ji}. \tag{7}$$

Their commutation relations are

$$[E_{jk},E_{mn}]=\delta_{km}E_{jn}-\delta_{jn}E_{mk},$$

$$[M_{pq},M_{rs}]=\delta_{qr}M_{ps}+\delta_{ps}M_{qr}-\delta_{qs}M_{pr}-\delta_{pr}M_{qs}.$$

A. The fine grading of o(5, $\mathbb{C}$) corresponding to $\mathcal{G}_1$

Since $\mathcal{G}_1$ is an Abelian group depending on two continuous complex parameters φ_1 and φ_2, it is a maximal torus of O(5, $\mathbb{C}$) so that the corresponding grading is a root decomposition of o(5, $\mathbb{C}$). If $\mathrm{Ad}_{A_1}\in\mathcal{G}_1$ is used in (4),

$$A_1=(1)\oplus\begin{pmatrix}\cos\varphi_1 & \sin\varphi_1\\ -\sin\varphi_1 & \cos\varphi_1\end{pmatrix}\oplus\begin{pmatrix}\cos\varphi_2 & \sin\varphi_2\\ -\sin\varphi_2 & \cos\varphi_2\end{pmatrix},$$

then the Lie algebra o(5, $\mathbb{C}$) is decomposed into nine subspaces: one two-dimensional (Cartan subalgebra) and 8 one-dimensional (root) subspaces.

The eigenvectors $X_1,\ldots,X_{10}$ are given in terms of matrices M_{jk},

$$X_1=\iota M_{23}+\iota M_{45}, \qquad X_2=\iota M_{23}-\iota M_{45},$$

$$X_3=M_{14}-\iota M_{15}, \qquad X_4=M_{24}+M_{35}+\iota(M_{25}-M_{34}),$$

$$X_5=M_{12}-\iota M_{13}, \qquad X_6=M_{24}-M_{35}+\iota(-M_{25}-M_{34}),$$

$$X_7=M_{24}-M_{35}+\iota(M_{25}+M_{34}), \quad X_8=M_{12}+\iota M_{13},$$

TABLE I. The correspondence between eigenvectors X_k from (8) and the eigenvalues λ of Ad_{A_1}.

λ	1	1	$e^{\iota\varphi_2}$	$e^{\iota(\varphi_1-\varphi_2)}$	$e^{\iota\varphi_1}$	$e^{\iota(\varphi_1+\varphi_2)}$	$e^{-\iota(\varphi_1+\varphi_2)}$	$e^{-\iota\varphi_1}$	$e^{-\iota(\varphi_1-\varphi_2)}$	$e^{-\iota\varphi_2}$
X_k	X_1	X_2	X_3	X_4	X_5	X_6	X_7	X_8	X_9	X_{10}

TABLE II. Grading subspaces for $\mathbb{Z}_9$-grading of o(5, $\mathbb{C}$) and sp(4, $\mathbb{C}$). For definition of X_i see (8) and (11), respectively.

L_0	L_1	L_2	L_3	L_4	L_5	L_6	L_7	L_8
$\mathbb{C}X_1+\mathbb{C}X_2$	$\mathbb{C}X_3$	$\mathbb{C}X_4$	$\mathbb{C}X_5$	$\mathbb{C}X_6$	$\mathbb{C}X_7$	$\mathbb{C}X_8$	$\mathbb{C}X_9$	$\mathbb{C}X_{10}$

$$X_9=M_{24}+M_{35}+\iota(-M_{25}+M_{34}),\quad X_{10}=M_{14}+\iota M_{15}. \tag{8}$$

Any linear combinations of X_1 and X_2 with coefficients in $\mathbb{C}$ are compatible with this grading. The presence of $\iota=\sqrt{-1}$ in the linear combinations (8) cannot be avoided as long as o(5, $\mathbb{C}$) is spanned by antisymmetric matrices [cf. (3)].

Putting $\varphi_1=2\pi/3$ and $\varphi_2=2\pi/9$ in Table I, we can see that the index set I is the additive group $\mathbb{Z}_9$. Thus we get the decomposition and the commutation relations,

$$\text{o}(5,\mathbb{C})=\oplus_{k=0}^{8}L_k,\quad 0\neq[L_k,L_j]\subseteq L_{k+j\ (\mathrm{mod}\ 9)}$$

with the grading subspaces L_k given in Table II.

The Cartan subalgebra in this case is L_0. In order to recognize the root spaces among $L_1,\ldots,L_8$, we have to fix a choice of simple roots of the Lie algebra B_2 and identify the correspondence between the eigenvalues λ_k of Ad_{A_1} and the roots. Let γ_1,γ_2 denote the short and long simple root respectively. A possible choice is $\gamma_1=\varphi_2$ and $\gamma_2=\varphi_1-\varphi_2$. The two nonsimple positive roots are then $\gamma_1+\gamma_2=\varphi_1$ and $2\gamma_1+\gamma_2=\varphi_1+\varphi_2$.

B. The fine grading of o(5, $\mathbb{C}$) corresponding to $\mathcal{G}_2$

Decomposing o(5, $\mathbb{C}$) simultaneously into eigenspaces of $\mathrm{Ad}_{A_1},\mathrm{Ad}_{A_2}\in\mathcal{G}_2$, where

$$A_1=\mathrm{diag}(1,1,-1)\oplus\begin{pmatrix}\cos\varphi & \sin\varphi\\ -\sin\varphi & \cos\varphi\end{pmatrix},\quad A_2=\mathrm{diag}(1,-1,-1)\oplus\begin{pmatrix}\cos\varphi & \sin\varphi\\ -\sin\varphi & \cos\varphi\end{pmatrix},$$

we obtain a grading into 10 one-dimensional subspaces which are the linear hulls of matrices,

$$Y_1=M_{45},\quad Y_2=M_{12},\quad Y_3=M_{23},\quad Y_4=M_{13},$$

$$Y_5=M_{14}+\iota M_{15},\quad Y_6=M_{24}+\iota M_{25},\quad Y_7=M_{34}+\iota M_{35},$$

$$Y_8=M_{14}-\iota M_{15},\quad Y_9=M_{24}-\iota M_{25},\quad Y_{10}=M_{34}-\iota M_{35}, \tag{9}$$

which correspond to the pair λ_1 and λ_2 of eigenvalues of Ad_{A_1} and Ad_{A_2}, respectively (Table III).

Putting $\varphi=2\pi/3$, we embed the index set I into the additive group $\mathbb{Z}_2\times\mathbb{Z}_2\times\mathbb{Z}_3$, see Table IV. The commutation relations thus are

$$\text{o}(5,\mathbb{C})=\oplus_{(i,j,k)}L_{(i,j,k)},$$

$$0\neq[L_{(i,j,k)},L_{(p,q,r)}]=L_{(i+p,j+q,k+r)}\ (\mathrm{mod}\ 2,\mathrm{mod}\ 2,\mathrm{mod}\ 3).$$

C. The fine grading of o(5, $\mathbb{C}$) corresponding to $\mathcal{G}_3$

Another way to obtain a decomposition of o(5, $\mathbb{C}$) into 10 one-dimensional grading subspaces is using $\mathrm{Ad}_{A_1},\mathrm{Ad}_{A_2},\mathrm{Ad}_{A_3},\mathrm{Ad}_{A_4}\in\mathcal{G}_3$. We set

$$A_1=\mathrm{diag}(1,-1,-1,1,1),\quad A_2=\mathrm{diag}(1,1,1,1,-1),$$

$$A_3=\mathrm{diag}(1,1,1,-1,1),\quad A_4=\mathrm{diag}(1,1,-1,-1,-1).$$

We have the eigenvectors

$$Z_1=M_{23},\quad Z_2=M_{14},\quad Z_3=M_{15},\quad Z_4=M_{45},\quad Z_5=M_{35},$$

$$Z_6=M_{25},\quad Z_7=M_{12},\quad Z_8=M_{34},\quad Z_9=M_{13},\quad Z_{10}=M_{24}, \tag{10}$$

which correspond to the tetrads of eigenvalues $\lambda_1,\ldots,\lambda_4$ shown in Table V. The tetrads are subsets of the multiplicative form of the group $(\mathbb{Z}_2)$.[4] Labeling of grading subspaces by additive form of this group is in Table VI.

The grading decomposition and the commutation relation thus are

$$\text{o}(5,\mathbb{C})=\oplus_{(i,j,k,m)}L_{(i,j,k,m)},$$

$$0\neq[L_{(i,j,k,m)},L_{(p,q,r,s)}]=L_{(i+p,j+q,k+r,m+s)\ (\mathrm{mod}\ 2,\mathrm{mod}\ 2,\mathrm{mod}\ 2,\mathrm{mod}\ 2)}.$$

IV. FINE GRADINGS OF sp(4, $\mathbb{C}$)

Since Lie algebra sp(4, $\mathbb{C}$) is isomorphic to the algebra o(5, $\mathbb{C}$), their fine gradings are isomorphic as well. We shall denote the subspaces of the three fine gradings of sp(4, $\mathbb{C}$) again by $\mathbb{C}X_i$, $\mathbb{C}Y_i$, and $\mathbb{C}Z_i$ respectively, in such a way that the subspaces in sp(4, $\mathbb{C}$) and o(5, $\mathbb{C}$) with the same notation correspond to each other via isomorphism between these two algebras. Therefore the assignment of indices for subspaces of the gradings in Tables II, IV, and VI is valid for fine gradings of sp(4, $\mathbb{C}$) as well.

A. The fine grading of sp(4, $\mathbb{C}$) corresponding to $\mathcal{H}_1$

A decomposition of sp(4, $\mathbb{C}$) into one two-dimensional and eight one-dimensional subspaces is obtained using $\mathrm{Ad}_{A_1}\in\mathcal{H}_1$, $A_1=\mathrm{diag}(\alpha,\beta,\alpha^{-1},\beta^{-1})$. The presence of two continuous parameters α and β reveals that A_1 stands for the maximal torus. Hence the grading we find in this case is the root decomposition. The eigenvectors are

TABLE V. Four eigenvalues labeling multiplicatively the basis (10) in o(5, $\mathbb{C}$) and the basis (13) in sp(4, $\mathbb{C}$).

$$X_1=\begin{pmatrix}1&0&0&0\\0&0&0&0\\0&0&-1&0\\0&0&0&0\end{pmatrix},\quad X_2=\begin{pmatrix}0&0&0&0\\0&1&0&0\\0&0&0&0\\0&0&0&-1\end{pmatrix},\quad X_3=\begin{pmatrix}0&0&0&0\\0&0&0&0\\0&1&0&0\\1&0&0&0\end{pmatrix},$$

$$X_4=\begin{pmatrix}0&0&0&0\\0&0&0&1\\0&0&0&0\\0&0&0&0\end{pmatrix},\quad X_5=\begin{pmatrix}0&0&0&0\\1&0&0&0\\0&0&0&-1\\0&0&0&0\end{pmatrix},\quad X_6=\begin{pmatrix}0&0&0&0\\0&0&0&0\\1&0&0&0\\0&0&0&0\end{pmatrix},$$

$$X_7=\begin{pmatrix}0&0&1&0\\0&0&0&0\\0&0&0&0\\0&0&0&0\end{pmatrix},\quad X_8=\begin{pmatrix}0&1&0&0\\0&0&0&0\\0&0&0&0\\0&0&-1&0\end{pmatrix},\quad X_9=\begin{pmatrix}0&0&0&0\\0&0&0&0\\0&0&0&0\\0&1&0&0\end{pmatrix},$$

$$X_{10}=\begin{pmatrix}0&0&0&1\\0&0&1&0\\0&0&0&0\\0&0&0&0\end{pmatrix}. \tag{11}$$

Corresponding eigenvalues are shown in Table VII.

Putting $\alpha=\exp((4\pi/9)\iota), \beta=\exp((16\pi/9)\iota)$, and having the same dependence of L_i on X_j as in the case of $o(5, \mathbb{C})$-decomposition under $\mathcal{G}_1$, the index set I is again embedded into $\mathbb{Z}_9$ (see Table II). Let us now make explicit the relation between the eigenvalues and the roots of B_2. Suppose again γ_1 and γ_2 are, respectively, the short and long simple root of B_2. Then a possible choice is to put

$$\gamma_1=\ln(\alpha\beta)=\ln\alpha+\ln\beta,\quad \gamma_2=\ln\beta^{-2}=-2\ln\beta.$$

The two nonsimple short and long positive roots are then, respectively,

$$\gamma_1+\gamma_2=\ln(\alpha\beta\cdot\beta^{-2})=\ln\alpha-\ln\beta,\quad 2\gamma_1+\gamma_2=\ln(\alpha^2\beta^2\cdot\beta^{-2})=2\ln\alpha.$$

Similarly one finds the negative roots. Cartan subalgebra is generated by X_1 and X_2.

TABLE VII. The correspondence between eigenvectors X_k from (11) and the eigenvalues of Ad_{A_1}.

λ	1	1	$\alpha\beta$	β^{-2}	$\alpha\beta^{-1}$	α^2	α^{-2}	$\alpha^{-1}\beta$	β^2	$\alpha^{-1}\beta^{-1}$
Eigenvectors	X_1	X_2	X_3	X_4	X_5	X_6	X_7	X_8	X_9	X_{10}

TABLE VIII. Correspondence between eigenvalues of Ad_{A_1} and Ad_{A_2} and eigenvectors (12).

λ_1	1	1	−1	−1	α^{-2}	α^{-2}	$-\alpha^{-2}$	α^2	α^2	$-\alpha^2$
λ_2	1	−1	1	−1	α^{-2}	$-\alpha^{-2}$	$-\alpha^{-2}$	α^2	$-\alpha^2$	$-\alpha^2$
Eigenvectors	Y_1	Y_2	Y_3	Y_4	Y_5	Y_6	Y_7	Y_8	Y_9	Y_{10}

B. The fine grading of sp(4, $\mathbb{C}$) corresponding to $\mathcal{H}_2$

Now let us put $A_1=\left(\begin{smallmatrix}\alpha & 0\\ 0 & \alpha^{-1}\end{smallmatrix}\right)\otimes\sigma_3$, and $A_2=\left(\begin{smallmatrix}\alpha & 0\\ 0 & \alpha^{-1}\end{smallmatrix}\right)\otimes\sigma_2$. A pair of automorphisms $\mathrm{Ad}_{A_1},\mathrm{Ad}_{A_2}\in\mathcal{H}_2$ decomposes sp(4, $\mathbb{C}$) again into ten one-dimensional subspaces. The eigenvectors are the following:

$$Y_1=\begin{pmatrix}1&0&0&0\\0&1&0&0\\0&0&-1&0\\0&0&0&-1\end{pmatrix},\quad Y_2=\begin{pmatrix}1&0&0&0\\0&-1&0&0\\0&0&-1&0\\0&0&0&1\end{pmatrix},\quad Y_3=\begin{pmatrix}0&1&0&0\\-1&0&0&0\\0&0&0&1\\0&0&-1&0\end{pmatrix},$$

$$Y_4=\begin{pmatrix}0&1&0&0\\1&0&0&0\\0&0&0&-1\\0&0&-1&0\end{pmatrix},\quad Y_5=\begin{pmatrix}0&0&1&0\\0&0&0&1\\0&0&0&0\\0&0&0&0\end{pmatrix},\quad Y_6=\begin{pmatrix}0&0&1&0\\0&0&0&-1\\0&0&0&0\\0&0&0&0\end{pmatrix},$$

$$Y_7=\begin{pmatrix}0&0&0&1\\0&0&1&0\\0&0&0&0\\0&0&0&0\end{pmatrix},\quad Y_8=\begin{pmatrix}0&0&0&0\\0&0&0&0\\1&0&0&0\\0&1&0&0\end{pmatrix},\quad Y_9=\begin{pmatrix}0&0&0&0\\0&0&0&0\\1&0&0&0\\0&-1&0&0\end{pmatrix},$$

$$Y_{10}=\begin{pmatrix}0&0&0&0\\0&0&0&0\\0&1&0&0\\1&0&0&0\end{pmatrix}. \tag{12}$$

Corresponding eigenvalues are shown in Table VIII.

Putting $\alpha=\exp((\pi/3)\iota)$ enables us to label eigenspaces by indices from the group $\mathbb{Z}_2\times\mathbb{Z}_2\times\mathbb{Z}_3$ as found in Table IV.

C. The fine grading of sp(4, $\mathbb{C}$) corresponding to $\mathcal{H}_3$

The second way to decompose sp(4, $\mathbb{C}$) into ten one-dimensional eigenspaces is using four automorphisms $\mathrm{Ad}_{A_1},\mathrm{Ad}_{A_2},\mathrm{Ad}_{A_3},\mathrm{Ad}_{A_4}\in\mathcal{H}_3$, where $A_1=\sigma_3\otimes\sigma_0$, $A_2=\sigma_0\otimes\sigma_3$, $A_3=\sigma_0\otimes\sigma_1$, and $A_4=\sigma_1\otimes\sigma_0$. We get the eigenvectors

$$Z_1=\begin{pmatrix}1&0&0&0\\0&1&0&0\\0&0&-1&0\\0&0&0&-1\end{pmatrix},\quad Z_2=\begin{pmatrix}1&0&0&0\\0&-1&0&0\\0&0&-1&0\\0&0&0&1\end{pmatrix},\quad Z_3=\begin{pmatrix}0&1&0&0\\1&0&0&0\\0&0&0&-1\\0&0&-1&0\end{pmatrix},$$

$$Z_4=\begin{pmatrix} 0 & 1 & 0 & 0 \\ -1 & 0 & 0 & 0 \\ 0 & 0 & 0 & 1 \\ 0 & 0 & -1 & 0 \end{pmatrix},\quad Z_5=\begin{pmatrix} 0 & 0 & 0 & 1 \\ 0 & 0 & 1 & 0 \\ 0 & 1 & 0 & 0 \\ 1 & 0 & 0 & 0 \end{pmatrix},\quad Z_6=\begin{pmatrix} 0 & 0 & 0 & 1 \\ 0 & 0 & 1 & 0 \\ 0 & -1 & 0 & 0 \\ -1 & 0 & 0 & 0 \end{pmatrix},$$

$$Z_7=\begin{pmatrix} 0 & 0 & 1 & 0 \\ 0 & 0 & 0 & 1 \\ 1 & 0 & 0 & 0 \\ 0 & 1 & 0 & 0 \end{pmatrix},\quad Z_8=\begin{pmatrix} 0 & 0 & 1 & 0 \\ 0 & 0 & 0 & -1 \\ 1 & 0 & 0 & 0 \\ 0 & -1 & 0 & 0 \end{pmatrix},\quad Z_9=\begin{pmatrix} 0 & 0 & 1 & 0 \\ 0 & 0 & 0 & 1 \\ -1 & 0 & 0 & 0 \\ 0 & -1 & 0 & 0 \end{pmatrix},$$

$$Z_{10}=\begin{pmatrix} 0 & 0 & 1 & 0 \\ 0 & 0 & 0 & -1 \\ -1 & 0 & 0 & 0 \\ 0 & 1 & 0 & 0 \end{pmatrix}. \tag{13}$$

The correspondence with the tetrads of eigenvalues is given in Table V.

The relation between eigenvectors Z_i and grading subspaces labeled by elements of the group $\mathbb{Z}_2\times\mathbb{Z}_2\times\mathbb{Z}_2\times\mathbb{Z}_2$ is shown in Table VI.

V. FINE GRADINGS OF REAL FORMS OF o(5, $\mathbb{C}$) AND sp(4, $\mathbb{C}$)

The real forms of o(5, $\mathbb{C}$) are determined by nonsingular Hermitian matrices $E\in \mathrm{O}(5,\mathbb{C})$ as follows:

$$\mathrm{o}(5-k,k)=\{X\in \mathrm{o}(5,\mathbb{C})\,|\,XE=-EX^{+}\}, \tag{14}$$

where E has $5-k$ positive and k negative eigenvalues, $k=0,1,2$. Two Hermitian orthogonal matrices with the same number of positive and negative eigenvalues (i.e., matrices with the same signatures) give two isomorphic real forms.

Real forms of sp(4, $\mathbb{C}$) are of two types. The first one is

$$\mathrm{sp}(4,\mathbb{R})=\{X\in \mathrm{sp}(4,\mathbb{C})\,|\,X=\overline{X}\},$$

where the overbar denotes complex conjugation, and the second type of real forms corresponds to Hermitian matrices $E\in \mathrm{Sp}(4,\mathbb{C})$,

$$\mathrm{usp}(4-2k,2k)=\{X\in \mathrm{sp}(4,\mathbb{C})\,|\,XE=-EX^{+}\}, \tag{15}$$

where E has $4-2k$ positive and $2k$ negative eigenvalues, $k=0,1$.

Since o(5, $\mathbb{C}$) and sp(4, $\mathbb{C}$) are isomorphic Lie algebras, we have the isomorphic pairs of real forms. More precisely,

$$\mathrm{o}(5)\sim\mathrm{usp}(4),\quad \mathrm{o}(4,1)\sim\mathrm{usp}(2,2),\quad \mathrm{o}(3,2)\sim\mathrm{sp}(4,\mathbb{R}). \tag{16}$$

Let us consider a MAD-group $\mathcal{K}$ on a real form $L_{\mathbb{R}}$ of a complex Lie algebra L. Any automorphism $g\in\mathcal{K}$ can be uniquely extended from $L_{\mathbb{R}}$ to L. Obviously such extensions are diagonable, their spectrum is real, and they mutually commute. Therefore $\mathcal{K}$ is a subgroup of some MAD-group $\mathcal{G}$ of complex Lie algebra L. If we denote by $\mathcal{G}^{\mathbb{R}}$ those automorphisms of $\mathcal{G}$ which have real spectrum, then $\mathcal{K}\subseteq\mathcal{G}^{\mathbb{R}}\subseteq\mathcal{G}$. It is proven in Ref. 15 that for any MAD-group $\mathcal{K}$ on a real form of classical Lie algebra L with the exception of o(8, $\mathbb{C}$) there exists a MAD-group $\mathcal{G}$ on L such that $\mathcal{K}=\mathcal{G}^{\mathbb{R}}$.

For any MAD-group $\mathcal{G}$ on o(n, $\mathbb{C}$) with n odd there exists a simple criteria how to decide for which real form o($n-k,k$) the group $\mathcal{G}^{\mathbb{R}}$ is a MAD-group on o($n-k,k$).

Theorem: *Let $\mathcal{G}$ be a MAD-group on* o(n, $\mathbb{C}$), *n odd, and let E be a Hermitian orthogonal matrix with $n-k$ positive and k negative eigenvalues. Then $\mathcal{G}^{\mathbb{R}}$ is a MAD-group on* $\mathrm{o}(n-k,k)=\{X\in\mathrm{o}(n,\mathbb{C})\,|\,XE=-EX^{+}\}$ *if and only if*

$$AEA^{+}=E \quad \text{for any} \quad \mathrm{Ad}_A\in\mathcal{G}^{\mathbb{R}}. \tag{17}$$

Note that automorphisms Ad_A of Aut o(n, $\mathbb{C}$) with

$$A=\mathrm{diag}(\varepsilon_1,\ldots,\varepsilon_s)\oplus\begin{pmatrix}\cos\varphi_1 & \sin\varphi_1\\ -\sin\varphi_1 & \cos\varphi_1\end{pmatrix}\oplus\cdots\oplus\begin{pmatrix}\cos\varphi_p & \sin\varphi_p\\ -\sin\varphi_p & \cos\varphi_p\end{pmatrix},\quad \varepsilon_j=\pm1,\quad \varphi_j\in\mathbb{C}$$

has the real spectrum if and only if $\varphi_j=\iota\psi_j$, $\psi_j\in\mathbb{R}$ for all $j=1,...,p$. In this case the matrix A has the form,

$$A=\mathrm{diag}(\varepsilon_1,\ldots,\varepsilon_3)\oplus\begin{pmatrix}\cosh\psi_1 & \iota\sinh\psi_1\\ -\iota\sinh\psi_1 & \cosh\psi_1\end{pmatrix}\oplus\cdots\oplus\begin{pmatrix}\cosh\psi_p & \iota\sinh\psi_p\\ -\iota\sinh\psi_p & \cosh\psi_p\end{pmatrix},$$

where $\varepsilon_j=\pm1$, $\psi_j\in\mathbb{R}$.

Therefore, $\mathcal{G}_3^{\mathbb{R}}=\mathcal{G}_3$, and for the description $\mathcal{G}_1^{\mathbb{R}}$ and $\mathcal{G}_2^{\mathbb{R}}$ we have to choose those automorphisms from $\mathcal{G}_1,\mathcal{G}_2$, for which parameters φ_1,φ_2, and φ, resp., belong to $\iota\mathbb{R}$.

A. Fine gradings of o(3, 2)

Let us apply the theorem to o(5, $\mathbb{C}$) and MAD-groups $\mathcal{G}_1,\mathcal{G}_2,\mathcal{G}_3$. If we choose $E=\mathrm{diag}(1,1,-1,1,-1)$, then the condition (17) is satisfied for $\mathcal{G}_1^{\mathbb{R}},\mathcal{G}_2^{\mathbb{R}},\mathcal{G}_3^{\mathbb{R}}$. Hence we can conclude that o(3, 2) has three MAD-groups.

Thus we find three find gradings of o(3, 2). Using $E=\mathrm{diag}(1,1,-1,1,-1)$ in (14),

$$\mathrm{o}(3,2)=\left\{\begin{pmatrix}0 & a & \iota b & c & \iota d\\ -a & 0 & \iota e & f & \iota g\\ -\iota b & -\iota e & 0 & \iota h & j\\ -c & -f & -\iota h & 0 & \iota k\\ -\iota d & -\iota g & -j & -\iota k & 0\end{pmatrix}\;\middle|\; a,\ldots,k\in\mathbb{R}\right\}.$$

Indeed, all subspaces of gradings of complex Lie algebra o(5, $\mathbb{C}$) corresponding to $\mathcal{G}_i$ contain elements belonging to o(3, 2). The gradings of the real form o(3, 2) are found in Tables IX, X, XI in terms of the bases (8), (9), and (10) of o(5, $\mathbb{C}$).

B. Fine gradings of o(4, 1)

The groups $\mathcal{G}_2^{\mathbb{R}}$ and $\mathcal{G}_3^{\mathbb{R}}$ satisfy (17) with the matrix $E=\mathrm{diag}(1,1,1,1,-1)$, but there exists no orthogonal Hermitian matrix E with one negative and four positive eigenvalues such that $\mathcal{G}_1^{\mathbb{R}}$ and E fulfill (17). Therefore the real form o(4, 1) has only two fine gradings corresponding to $\mathcal{G}_2^{\mathbb{R}}$ and $\mathcal{G}_3^{\mathbb{R}}$. For the definition of the real form o(4, 1) we use the matrix $E=\mathrm{diag}(1,1,1,1,-1)$, and thus the real form is given as

TABLE IX. Grading of o(3, 2) corresponding to $\mathcal{G}_1^{\mathbb{R}}$; X_i are form (8).

L_0	L_1	L_2	L_3	L_4	L_5	L_6	L_7	L_8

$\iota\mathbb{R}Y_1$	$\mathbb{R}Y_2$	$\iota\mathbb{R}Y_3$	$\iota\mathbb{R}Y_4$	$\mathbb{R}Y_5$	$\mathbb{R}Y_6$	$\iota\mathbb{R}Y_7$	$\mathbb{R}Y_8$	$\mathbb{R}Y_9$	$\iota\mathbb{R}Y_{10}$

$$\mathrm{o}(4,1)=\left\{\left.\begin{pmatrix} 0 & a & b & c & \iota d \\ -a & 0 & e & f & \iota g \\ -b & -e & 0 & h & \iota j \\ -c & -f & -h & 0 & \iota k \\ -\iota d & -\iota g & -\iota j & -\iota k & 0 \end{pmatrix}\right| a,\ldots,k\in\mathbb{R}\right\}.$$

The fine gradings of o(4, 1) are found in Tables XII and XIII.

C. Fine gradings of o(5)

The compact real form o(5) has only one fine grading, since only $\mathcal{G}_3^{\mathbb{R}}$ with $E=\mathrm{diag}(1,1,1,1,1)$ satisfies the condition (17).

For the definition of the compact real form o(5) we use the matrix $E=\mathrm{diag}(1,1,1,1,1)$, and thus the real form is given as

$$\mathrm{o}(5)=\{X\in\mathbb{R}^{5\times 5}\,|\,X+X^T=0\}.$$

The only fine grading possible on this real form is in Table XIV.

D. Fine gradings of real forms of sp(4, $\mathbb{C}$)

In order to describe the fine gradings of the real forms of sp(4, $\mathbb{C}$), we make use of the isomorphisms (16). It follows from the description of gradings of real forms of o(5, $\mathbb{C}$) that there exist three nonconjugate MAD-groups in the case of sp(4, $\mathbb{R}$), two MAD-groups for usp(2, 2), and one MAD-group for the compact real form usp(4). All the fine gradings of the real forms of sp(4, $\mathbb{C}$) are presented in Tables XV–XX, respectively.

We realize the real form sp(4, $\mathbb{R}$) as

$$\mathrm{sp}(4,\mathbb{R})=\left\{\left.\begin{pmatrix} m & n & p & q \\ r & s & q & t \\ u & v & -m & -r \\ v & w & -n & -s \end{pmatrix}\right| m,\ldots,w\in\mathbb{R}\right\}=\{X\in\mathbb{R}^{4\times 4}\,|\,XJ+JX^T=0\}.$$

Choosing $E=\begin{pmatrix} 0 & 0 & 0 & -1 \\ 0 & 0 & 1 & 0 \\ 0 & 1 & 0 & 0 \\ -1 & 0 & 0 & 0 \end{pmatrix}$ in (15), we obtain

Finally, the compact form (corresponding to $E=I$ in (15)) is written as

$$\mathrm{usp}(4)=\left\{\begin{pmatrix} \iota m & n+\iota r & p+\iota u & q+\iota v \\ -n+\iota r & \iota s & q+\iota v & t+\iota w \\ -p+\iota u & -q+\iota v & -\iota m & n-\iota r \\ -q+\iota v & -t+\iota w & -n-\iota r & -\iota s \end{pmatrix} \middle| \; m,\ldots,w\in\mathbb{R}\right\}.$$

VI. CONCLUDING REMARKS

Let us add the following remarks to the applications and problems mentioned in the Introduction.

(1) The way from the general classification of MAD-groups[15,14] to specific gradings of Lie algebras is relatively laborious, as we have exemplified in this paper. It would be interesting to provide explicit fine gradings for several other low rank Lie algebras of interest in physics besides the one or two which are well known. It is known that there are four fine gradings of sl(3, $\mathbb{C}$),[9] five for the nonsimple o(4, $\mathbb{C}$), eight in the case of sl(4, $\mathbb{C}$) or o(6, $\mathbb{C}$), and something up to that number for their real forms.

(2) The intermediate gradings found between the extremes of a fine grading and the trivial grading (by the identity element), are also useful. Most of the gradings used in graded contractions of Lie and superalgebras[2,5] are not the fine ones. The intermediate gradings should be useful in typical symmetry breaking situations where an important subalgebra needs to be preserved. This is a situation which often arises in graded contractions. There all deformations other than those of the subalgebra are admissible for consideration (see, for example, Ref. 4).

A full list of possible ''minimal'' refinements of gradings, starting from no grading at all (grading by the identity of the automorphism group) and proceeding step-by-step to the fine ones, is nowhere to be found for any simple Lie algebra of rank$\geqslant 2$ over $\mathbb{C}$. Closest to that are the coarsenings of the root decomposition of sl(3, $\mathbb{C}$) in Ref. 19.

(3) A comprehensive description of gradings of representation spaces by MAD-groups would be very useful. Here we have dealt with the three lowest representations of B_2. Note that for grading of an algebra and for a few of its representations, one does not need to use the whole MAD-group; suitably chosen elements of it provide enough of eigenvalues to distinguish grading subspaces. We have seen, for example, that for the root decomposition of B_2, it was sufficient to use a cyclic subgroup $\mathbb{Z}_9$ of the torus instead of the whole maximal torus. Generally one has to use the whole MAD-group for grading of all the representation spaces.

There is an additional complication to that in case of the simple Lie algebras of types A_n, B_n, C_n, D_n when $n>1$, and for E_6, and E_7. In those cases any MAD-group has to be Abelian in its action on the Lie algebra (adjoint action), and on the representations of the congruence class zero. On other irreducible representations, elements of a MAD-group may commute only up to the center of the corresponding Lie group. Consequently, not all elements of some MAD-groups can be simultaneously diagonalized in such representations. However, even then one could consider

reducible representations formed by the direct sum of pairs of irreducible contragredient representations (the only exception would be o(8, $\mathbb{C}$)) and diagonalize the whole MAD-group on it.

Gradings of representation spaces by a maximal torus are well known. They are called weight decompositions.

(4) For a given grading of a simple Lie algebra, in particular for the fine gradings, it is interesting to find also its normalizer in the group of automorphisms. Except for the root decomposition, little was known about the normalizers until recently.[9] Clearly the MAD-group is part of the normalizer which transforms each grading subspace into itself. More interesting are the elements of the normalizer which permute the grading subspaces.[16,17] They would, for example, transform equal valued Clebsch–Gordan coefficients among themselves provided one uses bases consisting of eigenvectors of the grading group in representation spaces.

(5) It is known that B_2 has two independent Casimir operators, one of degree 2 and one of degree 4. It would be interesting to compare their expressions written in the three bases provided by fine gradings. Perhaps one could get some better information about the spectrum of the operator of degree 4.

(6) One of the basic structures underlying the theory of semisimple Lie algebras and their representations are the root and weight lattices.[20] They are defined using the maximal torus which is one of the MAD-groups. What would be the analog of the lattices for some other MAD-groups?

Similarity reduction, generalized symmetries and integrability of Belov–Chaltikian and Blaszak–Marciniak lattice equations

R. Sahadevan[a] and S. Khousalya
Ramanujan Institute for Advanced Study in Mathematics, University of Madras, Chepauk, Chennai-600 005, Tamilnadu, India

(Received 4 December 2000; accepted for publication 22 March 2001)

The Lie point symmetries of Belov–Chaltikian (BC) and Blaszak–Marciniak (BM) lattice equations is derived. Using the symmetries similarity reduction for both BC and BM lattice equations is obtained and show that each of the reduced equation possesses Lax representation and satisfies the singularity confinement criteria (a discrete version of the Painlevé property) indicating their integrability. Two particular solutions of both the reduced equations are given explicitly. A systematic investigation for nonclassical symmetries of BC and BM lattice equations is carried out. Further, a sequence of conserved densities and generalized symmetries of both BC and BM lattice equation are derived explicitly. The existence of a sequence of such symmetries is a predictor for integrability. © *2001 American Institute of Physics.* [DOI: 10.1063/1.1378306]

I. INTRODUCTION

The study of discrete nonlinear systems governed by differential–difference, difference, lattice equations, and mappings has attracted considerable attention in recent years.[1–5] Several analytical but adhoc methods such as inverse scattering technique,[1,6] singularity confinement criteria,[7] symmetries approach,[5,8–12] Hirota bilinearization,[13] symplectic structure and construction of integrals of motion,[14] etc.[15] have been proposed to deal with discrete nonlinear systems towards its complete integrability, linearizability, and solvability. Among them the extended algorithmic Lie symmetries approach initiated by Maeda[8] and others[5,9,10,16] provides an efficient tool to construct similarity as well as exact solution of discrete nonlinear equations besides deriving its group theoretical aspects. Also, the Lie symmetries approach enables one to determine conditions at which the autonomous nonlinear difference equation can be transformed into linear difference equations. It was shown that an autonomous difference equation of arbitrary order and with one or more independent variables can be linearized by a point transformation if and only if it admits a symmetry vector field whose coefficient is the product of two functions, one of the dependent variable and one of the independent variables.[17] Furthermore the symmetry approach provides an effective tool to determine conditions on the parameters at which the nonlinear partial differential–difference or lattice equations possess a sequence of generalized or higher order or Lie Backlund symmetries. If a nonlinear partial differential–difference or lattice equations admits a sequence of generalized symmetries then it is expected to be integrable. Once the generalized symmetries are explicitly known it is quite often possible to find the recursion operator. If the recursion operator is hereditary then the equation will possess infinitely many symmetries. If the operator is hereditary and factorizable then the equation has infinitely many conserved quantities.

In this article we consider two new interesting integrable coupled lattice equations namely, Belov–Chaltikian (BC) lattice equation[18] given by

[a]Electronic mail: riasm@md3.vsnl.net.in

$$\frac{du_n}{dt}=u_n(u_{n+1}-u_{n-1})+v_{n-1}-v_n, \tag{1a}$$

$$\frac{dv_n}{dt}=v_n(u_{n+2}-u_{n-1}), \tag{1b}$$

and Blaszak–Marciniak (BM) lattice equation[19] defined by

$$\frac{du_n}{dt}=w_{n+1}-w_{n-1}, \tag{2a}$$

$$\frac{dv_n}{dt}=u_{n-1}w_{n-1}-u_nw_n, \tag{2b}$$

$$\frac{dw_n}{dt}=w_n(v_n-v_{n+1}), \tag{2c}$$

where $u_n=u(n,t)$, $v_n=v(n,t)$, $w_n=w(n,t)$, t is a continuous variable and n is a discrete variable. It is appropriate to mention that the BC lattice equation (1) was first found in the study of lattice analogues of W-algebras[20] while the BM lattice equation (2) was derived as an application of r-matrix formalism to the algebra of shift operators.[21,22] Also both BC and BM lattice equations (1) and (2) have rich mathematical structures such as biHamiltonian structure, Backlund transformation, bilinear form, soliton solution, and nonlinear superposition formula. The purpose of this paper is to derive group theoretical properties of BC and BM lattice equations (1) and (2) and investigate its relation with integrability.

The plan of the paper is as follows: In Sec. II, the Lie point symmetries of Belov–Chaltikian (BC) and Blaszak–Marciniak (BM) lattice equations is derived. Using the symmetries similarity reduction for both BC and BM lattice equations is obtained and show that each of the reduced equation possesses Lax representation and satisfies the singularity confinement criteria (a discrete version of the Painlevé property) indicating their integrability. Two particular solutions of both the reduced equations is given explicitly. In Sec. III, a systematic investigation for nonclassical symmetries of BC and BM lattice equations is carried out. In Sec. IV, a sequence of conserved densities and generalized symmetries of both BC and BM lattice equation are derived explicitly. The existence of a sequence of such symmetries is a predictor for integrability. In Sec. V, we give a brief details of our results.

II. SIMILARITY REDUCTION, LAX REPRESENTATION, AND SINGULARITY CONFINEMENT CRITERIA

A. Belov–Chaltikian lattice equation

Consider a one parameter (ϵ) continuous local Lie group of transformations,

$$n^*=n+\epsilon\xi_1+O(\epsilon^2), \quad t^*=t+\epsilon\xi_2+O(\epsilon^2), \tag{3a}$$

$$u^*_{n^*}=u_n+\epsilon\xi_3+O(\epsilon^2), \quad v^*_{n^*}=v_n+\epsilon\xi_4+O(\epsilon^2), \tag{3b}$$

where $\xi_i=\xi_i(n,t,u_n,v_n)$, $i=1,2,3,4$, are infinitesimals and the associated infinitesimal generator is

$$Y=\xi_1(n,t)\frac{\partial}{\partial n}+\xi_2(n,t)\frac{\partial}{\partial t}+\xi_3(n,t)\frac{\partial}{\partial u_n}+\xi_4(n,t)\frac{\partial}{\partial v_n}, \tag{3c}$$

where we have not indicated the explicit dependence of u_n and v_n in ξ_i's. The reader should realize that although usually the independent variable n in this equation is taken to be integer, here we allow n to be any real number. BC equation (1) is invariant under the transformations (3) if

$$\frac{du^*_{n^*}}{dt^*} = u^*_{n^*}(u^*_{n^*+1} - u^*_{n^*-1}) + v^*_{n^*-1} - v^*_{n^*}, \tag{4a}$$

$$\frac{dv^*_{n^*}}{dt^*} = v^*_{n^*}(u^*_{n^*+2} - u^*_{n^*-1}) \tag{4b}$$

provided u_n and v_n satisfy Eqs. (1a) and (1b). Making use of the expressions for $du^*_{n^*}/dt^*$, $dv^*_{n^*}/dt^*$, $u^*_{n^*+1}$, $u^*_{n^*-1}$, $u^*_{n^*+2}$, and $v^*_{n^*-1}$[10,12] in Eq. (4) we obtain the following invariance equation:

$$\xi_{3t} + (\xi_{3u_n} - \xi_{2t})\frac{du_n}{dt} = (u_{n+1} - u_{n-1})\xi_3 + u_n(\xi_3(n+1) - \xi_3(n-1)) + \xi_4(n-1) - \xi_4(n) \tag{5a}$$

and

$$\xi_{4t} + (\xi_{4v_n} - \xi_{2t})\frac{dv_n}{dt} = v_n(\xi_3(n+2) - \xi_3(n-1)) + (u_{n+2} - u_{n-1})\xi_4(n), \tag{5b}$$

where $\xi_{3t} = \partial\xi_3/\partial t$, $\xi_{3u_n} = \partial\xi_3/\partial u_n$, etc.

Substituting Eqs. (1a) and (1b) into (5a) and (5b) we obtained a overdetermined system of equations and solving we get

$$\xi_1(n,t) = \alpha, \quad \xi_2(n,t) = -\beta t + \gamma, \quad \xi_3(n,t) = \beta u_n, \quad \xi_4(n,t) = 2\beta v_n, \tag{6}$$

where α, β, γ are arbitrary constants and so the infinitesimal generator (3c) takes the following form:

$$Y = \alpha\frac{\partial}{\partial n} + (-\beta t + \gamma)\frac{\partial}{\partial t} + \beta u_n\frac{\partial}{\partial u_n} + 2\beta v_n\frac{\partial}{\partial v_n}. \tag{7}$$

Here the generators Y_1, Y_2, Y_3 become

$$Y_1 = -t\frac{\partial}{\partial t} + u_n\frac{\partial}{\partial u_n} + 2v_n\frac{\partial}{\partial v_n}, \quad Y_2 = \frac{\partial}{\partial t}, \quad Y_3 = \frac{\partial}{\partial n}$$

and the commutator relation satisfies

$$[Y_1, Y_2] = Y_2, \quad [Y_1, Y_3] = 0, \quad [Y_2, Y_3] = 0$$

indicating that the underlying symmetry algebra of (1) is nilpotent.

Next, the similarity variable and the similarity transformation associated with the above set of symmetries $(\xi_1, \xi_2, \xi_3, \xi_4)$, given in (6) can be obtained by solving the characteristic equation

$$\frac{dn}{\xi_1} = \frac{dt}{\xi_2} = \frac{du_n}{\xi_3} = \frac{dv_n}{\xi_4}. \tag{8}$$

The similarity variable η and similarity transformations $v(\eta)$ and $\omega(\eta)$ are

$$\eta = n + \frac{\alpha}{\beta}\log(-\beta t + \gamma), \tag{9a}$$

$$v(\eta) = (-\beta t + \gamma)u_n, \quad \omega(\eta) = (-\beta t + \gamma)^2 v_n, \tag{9b}$$

and so the BC lattice equation (1) reduces into

$$\beta v(\eta) - \alpha \frac{dv}{d\eta} = v(\eta)[v(\eta+1) - v(\eta-1)] + \omega(\eta-1) - \omega(\eta) \tag{10a}$$

and

$$2\beta\omega(\eta) - \alpha \frac{d\omega}{d\eta} = \omega(\eta)[v(\eta+2) - v(\eta-1)]. \tag{10b}$$

It is straightforward to check that the Lax representation for BC lattice equation takes the following form

$$\frac{dQ(n,t)}{dt} = -u_{n-1}Q(n,t) + Q(n-1,t), \tag{11a}$$

$$\lambda Q(n,t) = Q(n+1,t) + u_n Q(n+2,t) + v_n Q(n+3,t), \tag{11b}$$

where λ is a spectral parameter. It is easy to check that the compatibility condition leads to BC lattice equation. After some calculation we find that the reduced equation (10) admits the following Lax representation:

$$\left(-\alpha\frac{d}{d\eta} + \beta\zeta\frac{d}{d\zeta}\right)R(\eta,\zeta) = (\beta\eta - v(\eta-1))R(\eta,\zeta) + R(\eta-1,\zeta), \tag{12a}$$

$$\zeta R(\eta,\zeta) = R(\eta+1,\zeta) + v(\eta)R(\eta+2,\zeta) + \omega(\eta)R(\eta+3,\zeta), \tag{12b}$$

where ζ is a spectral parameter. The compatibility condition of Eqs. (12a) and (12b) gives the reduced equations (10a) and (10b).

It was conjectured that every ordinary differential equation obtained by an exact reduction of nonlinear partial differential equation solvable by inverse scattering transform is of Painlevé type or satisfies the Painlevé property.[23] The above conjecture also holds good for integrable nonlinear partial differential difference equations as well.[10,24] We show below that the reduced equations (10) of BC lattice equation (1) satisfies the singularity confinement criteria[7] which can be viewed as a discrete version of the Painlevé property. Rewriting Eqs. (10a) and (10b) as

$$\omega(\eta) = \omega(\eta-1) + v(\eta)[v(\eta+1) - v(\eta-1) - \beta] + \alpha\frac{dv}{d\eta} \tag{13a}$$

and

$$v(\eta+2) = v(\eta-1) + 2\beta - \frac{c}{\omega}\frac{d\omega}{d\eta}. \tag{13b}$$

From Eqs. (13a) and (13b) it is clear that there exists three distinct singularities:

(i) $\omega(\eta) = 0, \quad v(\eta) \neq 0;$
(ii) $\omega(\eta) = 0, \quad v(\eta) = 0;$
(iii) $\omega(\eta) \neq 0, \quad v(\eta) = 0.$

Let us first consider case (i). For a given value of η_0, $\omega(\eta_0)=0$, $v(\eta_0)\neq 0$, $v(\eta_0+1)\neq 0$, $v(\eta_0-1)\neq 0$, $\omega(\eta_0-1)\neq 0$. In order to derive various iterations of $v(\eta)$ and $\omega(\eta)$ we choose $\omega(\eta)=C_1(\eta)\tau(\eta)$ and expand equations for $\omega(\eta_0+1)$, $\omega(\eta_0+2)$, $v(\eta_0+3)$, $v(\eta_0+4)$ in a Laurent series. After a detailed calculation we find the following:

$$v(\eta_0+1)=finite, \omega(\eta_0+1)=finite+O\left(\frac{1}{\tau}\right),$$

$$v(\eta_0+2)=O\left(\frac{1}{\tau}\right), \quad \omega(\eta_0+2)=finite,$$

$$v(\eta_0+3)=O\left(\frac{1}{\tau}\right), \quad \omega(\eta_0+3)=finite,$$

$$v(\eta_0+4)=finite, \quad \omega(\eta_0+4)=finite.$$

Hence the singularity confinement criteria is satisfied for the case (i). Similar conclusion can also be arrived at for the cases (ii) and (iii). Thus the similarity reduction of BC lattice equation (1) is expected to be integrable.

Moreover equations (10a,b) admit the following two particular solutions for the case $\beta=0$:

(i) Soliton solution

$$v(\eta)=\frac{B^2k}{\alpha(e^{-k}-e^{k})}\frac{[1+e^{k\left(\eta+\frac{(2\delta-1)}{2}+\frac{A}{2B}\right)}][1+e^{k\left(\eta+\frac{(2\delta-1)}{2}-\frac{A}{2B}\right)}]}{[1+e^{k(\eta+\delta)}][1+e^{k(\eta-1+\delta)}]}, \tag{14a}$$

$$\omega(\eta)=\frac{(A^2+B^2-10\alpha^2)k}{3(e^{k}-e^{-k})}\frac{[1+e^{k(\eta+2+\delta)}][1+e^{k(\eta-2+\delta)}]}{[1+e^{k(\eta+1+\delta)}][1+e^{k(\eta-1+\delta)}]}. \tag{14b}$$

(ii) Rational solution

$$v(\eta)=\frac{-B^2\left(2\eta+2\delta-1+\frac{A}{B}\right)\left(2\eta+2\delta-1-\frac{A}{B}\right)}{8\alpha(\eta+\delta)(\eta+\delta-1)}, \tag{15a}$$

$$\omega(\eta)=\frac{(A^2+B^2-10\alpha^2)[(\eta+\delta)^2-4]}{6[(\eta+\delta)^2-1]}, \tag{15b}$$

where $A^2=9\alpha^2+3\beta_1$, $B^2=\alpha^2+3\beta_1$ and k, δ are arbitrary parameters.

B. Blaszak–Marciniak (BM) lattice equation

Consider a one parameter (ϵ) continuous local Lie group of tansformations

$$n^*=n+\epsilon\phi_1+O(\epsilon^2), \quad t^*=t+\epsilon\phi_2+O(\epsilon^2), \tag{16a}$$

$$u_{n^*}^*=u_n+\epsilon\phi_3+O(\epsilon^2), \quad v_{n^*}^*=v_n+\epsilon\phi_4+O(\epsilon^2), \quad w_{n^*}^*=w_n+\epsilon\phi_5+O(\epsilon^2), \tag{16b}$$

where $\phi_i=\phi_i(n,t,u_n,v_n,w_n)$, $i=1,2,3,4,5$ are infinitesimals and the associated infinitesimal generator is

$$Z=\phi_1(n,t)\frac{\partial}{\partial n}+\phi_2(n,t)\frac{\partial}{\partial t}+\phi_3(n,t)\frac{\partial}{\partial u_n}+\phi_4(n,t)\frac{\partial}{\partial v_n}+\phi_5(n,t)\frac{\partial}{\partial w_n}. \tag{17}$$

The BM lattice (2) is invariant under the transformations (16) if

$$\frac{du_{n*}^{*}}{dt^{*}}=w_{n*+1}^{*}-w_{n*-1}^{*}, \tag{18a}$$

$$\frac{dv_{n*}^{*}}{dt^{*}}=u_{n*-1}^{*}w_{n*-1}^{*}-u_{n*}^{*}w_{n*}^{*}, \tag{18b}$$

$$\frac{dw_{n*}^{*}}{dt^{*}}=w_{n*}^{*}(v_{n*}^{*}-v_{n*+1}^{*}), \tag{18c}$$

provided u_n, v_n, w_n satisfy Eqs. (2a)–(2c). Making use of the experssions for du_{n*}^{*}/dt^{*}, dv_{n*}^{*}/dt^{*}, dw_{n*}^{*}/dt^{*}, w_{n*+1}^{*}, w_{n*-1}^{*}, u_{n*-1}^{*}, and v_{n*+1}^{*} [10,12] in Eq. (18) we obtain the following invariance equation:

$$\phi_{3t}+(\phi_{3u_n}-\phi_{2t})\frac{du_n}{dt}=\phi_5(n+1)-\phi_5(n-1), \tag{19a}$$

$$\phi_{4t}+(\phi_{4v_n}-\phi_{2t})\frac{dv_n}{dt}=u_{n-1}\phi_5(n-1)+\phi_3(n-1)w_{n-1}-u_n\phi_5(n)-\phi_3(n)w_n, \tag{19b}$$

and

$$\phi_{5t}+(\phi_{5w_n}-\phi_{2t})\frac{dw_n}{dt}=w_n(\phi_4(n)-\phi_4(n+1))+(v_n-v_{n+1})\phi_5(n), \tag{19c}$$

where $\phi_{3t}=\partial\phi_3/\partial t$, $\phi_{3u_n}=\partial\phi_3/\partial u_n$, etc.

Substituting Eqs. (2a)–(2c) in (19a)–(19c) we obtained a overdetermined system of equations and solving we get

$$\phi_1(n,t)=\alpha_1, \quad \phi_2(n,t)=-\beta_1 t+\gamma_1, \tag{20a}$$

$$\phi_3(n,t)=\frac{\beta_1}{2}u_n, \quad \phi_4(n,t)=\beta_1 v_n, \quad \phi_5(n,t)=\frac{3\beta_1}{2}w_n, \tag{20b}$$

where α_1, β_1, γ_1 are arbitrary constants and so the infinitesimal generator (17) becomes

$$Z=\alpha_1\frac{\partial}{\partial n}+(-\beta_1 t+\gamma_1)\frac{\partial}{\partial t}+\frac{\beta_1}{2}u_n\frac{\partial}{\partial u_n}+\beta_1 v_n\frac{\partial}{\partial v_n}+\frac{3\beta_1}{2}w_n\frac{\partial}{\partial w_n}. \tag{21}$$

Here the generators Z_1, Z_2, Z_3 become

$$Z_1=-t\frac{\partial}{\partial t}+\frac{1}{2}u_n\frac{\partial}{\partial u_n}+v_n\frac{\partial}{\partial v_n}+\frac{3}{2}w_n\frac{\partial}{\partial w_n}, \quad Z_2=\frac{\partial}{\partial t}, \quad Z_3=\frac{\partial}{\partial n}, \tag{22}$$

and the commutator relation satisfies

$$[Z_1,Z_2]=Z_2, \quad [Z_1,Z_3]=0, \quad [Z_2,Z_3]=0,$$

indicating that the underlying symmetry algebra of (2) is nilpotent.

Proceeding as before for the BC lattice equation, we obtain the following similarity variable θ and the similarity transformations $\mu(\theta)$, $v(\theta)$, and $\omega(\theta)$

$$\theta = n + \frac{\alpha_1}{\beta_1}\log(-\beta_1 t + \gamma_1), \tag{23a}$$

$$\mu(\theta) = (-\beta_1 t + \gamma_1)^{1/2} u_n, \quad v(\theta) = (-\beta_1 t + \gamma_1) v_n, \quad \omega(\theta) = (-\beta_1 t + \gamma_1)^{3/2} w_n \tag{23b}$$

and so the BM lattice equation (2) reduces to

$$\frac{\beta_1}{2}\mu(\theta) - \alpha_1 \frac{d\mu}{d\theta} = \omega(\theta+1) - \omega(\theta-1), \tag{24a}$$

$$\beta_1 v(\theta) - \alpha_1 \frac{dv}{d\theta} = \mu(\theta-1)\omega(\theta-1) - \mu(\theta)\omega(\theta), \tag{24b}$$

and

$$\frac{3\beta_1}{2}\omega(\theta) - \alpha_1 \frac{d\omega}{d\theta} = \omega(\theta)(v(\theta) - v(\theta+1)). \tag{24c}$$

The Lax representation for BM lattice equation is

$$\frac{dQ_1(n,t)}{dt} = -\frac{1}{2} v_{n+1} Q_1(n,t) + w^{1/2}(n+1) Q_1(n+1,t), \tag{25a}$$

$$\begin{aligned}(\lambda_1 + v_{n+1}) Q_1(n,t) = {} & w^{1/2}(n) u_n Q_1(n-1,t) + w^{1/2}(n+1) Q_1(n+1,t) \\ & + w^{1/2}(n) w^{1/2}(n-1) Q_1(n-2,t),\end{aligned} \tag{25b}$$

where λ_1 is a spectral parameter. This leads to the following Lax representation for the reduced equation (24):

$$\left(\alpha_1 \frac{d}{d\theta} + \beta_1 \zeta_1 \frac{d}{d\zeta_1}\right) R_1(\theta,\zeta_1) = \frac{\beta_1 \theta}{4} R_1(\theta,\zeta_1) + \frac{1}{2} v(\theta+1) R_1(\theta,\zeta_1) - \omega^{1/2}(\theta+1) R_1(\theta+1,\zeta_1), \tag{26a}$$

$$\begin{aligned}(\zeta_1 + v(\theta+1)) R_1(\theta,\zeta_1) = {} & \omega^{1/2}(\theta)\mu(\theta) R_1(\theta-1,\zeta_1) + \omega^{1/2}(\theta+1) R_1(\theta+1,\zeta_1) \\ & + \omega^{1/2}(\theta)\omega^{1/2}(\theta-1) R_1(\theta-2,\zeta_1),\end{aligned} \tag{26b}$$

where ζ_1 is a spectral parameter. The compatibility condition of Eqs. (26a) and (26b) gives the reduced equation (24).

In order to check the singularity confinement criterion we rewrite the reduced Eqs. (24a)–(24c) into

$$v(\theta+1) = v(\theta) - \frac{3\beta_1}{2} + \frac{\alpha_1}{\omega}\frac{d\omega}{d\theta}, \tag{27a}$$

$$\omega(\theta+1) = \omega(\theta-1) + \frac{\beta_1}{2}\mu(\theta) - \alpha_1 \frac{d\mu}{d\theta}, \tag{27b}$$

$$\mu(\theta+1) = \frac{1}{\omega(\theta+1)}\left[\mu(\theta)\omega(\theta) - \beta_1 v(\theta+1) + \alpha_1 \frac{dv(\theta+1)}{d\theta}\right]. \tag{27c}$$

It is clear from the above equations that there exist seven distinct singularities. We have checked that the singularity confinement criteria is satisfied in all the seven cases. Thus the similarity reduction of BM lattice equation (2) is expected to be integrable.

Equations (24a)–(24c) also admit the following two particular solutions ($\beta_1=0$):

(i) Soliton solution

$$\mu(\theta)=\frac{2\alpha_1^2k_1}{A_2B_1^2(e^{k_1}-e^{-k_1})}\frac{[1+e^{k_1(\theta+\delta_1-B_1)}][1+e^{k_1(\theta+\delta_1+B_1)}]}{[1+e^{k_1(\theta+\delta_1+1)}][1+e^{k_1(\theta+\delta_1-1)}]}, \tag{28a}$$

$$v(\theta)=\frac{2\alpha_1k_1}{(B_2^2-1)(e^{k_1}-e^{-k_1})}\frac{\left[1+e^{k_1\frac{(\theta+2\delta_1-B_2+1)}{2}}\right]\left[1+e^{k_1\frac{(\theta+2\delta_1+B_2+1)}{2}}\right]}{[1+e^{k_1(\theta+\delta_1)}][1+e^{k_1(\theta+\delta_1-1)}]}, \tag{28b}$$

$$\omega(\theta)=\frac{2A_2k_1}{(e^{k_1}-e^{-k_1})}\frac{[1+e^{k_1(\theta+\delta_1+1)}][1+e^{k_1(\theta+\delta_1-1)}]}{[1+e^{k_1(\theta+\delta_1)}][1+e^{k_1(\theta+\delta_1)}]}. \tag{28c}$$

(ii) Rational solution

$$\mu(\theta)=\frac{\alpha_1^2}{A_2B_1^2}\frac{(\theta+\delta_1-B_1)(\theta+\delta_1+B_1)}{(\theta+\delta_1-1)(\theta+\delta_1+1)}, \tag{29a}$$

$$v(\theta)=\frac{\alpha_1(2\theta+2\delta_1-B_2+1)(2\theta+2\delta_1+B_2+1)}{(B_2^2-1)(\theta+\delta_1)(\theta+\delta_1-1)}, \tag{29b}$$

$$\omega(\theta)=\frac{A_2[(\theta+\delta_1)^2-1]}{(\theta+\delta_1)^2}, \tag{29c}$$

where $B_1^2=\alpha_1^3/\alpha_1^3+2A_2^2$, $B_2^2=1+4\alpha_1/A_1$ and k_1, δ_1 are arbitrary parameters.

III. NONCLASSICAL SYMMETRIES

A. Belov–Chaltikian lattice equation (BC)

In this section we investigate whether nonclassical symmetries (also referred to as conditional symmetries) for BC lattice equation (1) exists or not. In order to derive the nonclassical symmetries we consider two conditional constrained equations at first

$$T\frac{du_n}{dt}+X\frac{du_n}{dn}-U=0, \tag{30a}$$

$$T\frac{dv_n}{dt}+X\frac{dv_n}{dn}-V=0, \tag{30b}$$

where T,X,U,V are some undetermined functions of t, n, u_n, and v_n. Now we apply the standard algorithm that provides the symmetry algebra. The vector field has the form

$$S=T\frac{\partial}{\partial t}+X\frac{\partial}{\partial n}+U\frac{\partial}{\partial u_n}+V\frac{\partial}{\partial v_n}. \tag{31}$$

We consider two different cases: $T\neq0$, $X=0$, and $T\neq0$, $X\neq0$

Case 1: $T\neq0,X\neq0$

With no loss of generality we put $T=1$ in Eqs. (30) and (31). Making use of Eq. (1) we write Eqs. (30a) and (30b) as

$$U-X\frac{du_n}{dn}=u_n[u_{n+1}-u_{n-1}]+v_{n-1}-v_n, \tag{32a}$$

$$V-X\frac{dv_n}{dn}=v_n[u_{n+2}-u_{n-1}]. \tag{32b}$$

Proceeding further we obtain the following invariance equation

$$\left(X\frac{\partial U}{\partial t}-U\frac{\partial X}{\partial t}\right)+\left(\frac{\partial X}{\partial t}+X\frac{\partial U}{\partial u_n}\right)[u_n(u_{n+1}-u_{n-1})+v_{n-1}-v_n]$$
$$=X[u_n(U_{n+1}-U_{n-1})+U_n(u_{n+1}-u_{n-1})+V_{n-1}-V_n], \tag{33a}$$

$$\left(X\frac{\partial V}{\partial t}-V\frac{\partial X}{\partial t}\right)+\left(\frac{\partial X}{\partial t}+X\frac{\partial V}{\partial v_n}\right)[v_n(u_{n+2}-u_{n-1})]$$
$$=X[v_n(U_{n+2}-U_{n-1})+V_n(u_{n+2}-u_{n-1})]. \tag{33b}$$

We then obtain an overdetermined system of equations and solving them yields

$$X=\frac{1}{-at+b},\quad U=\frac{au_n}{-at+b},\quad V=\frac{2av_n}{-at+b}, \tag{34}$$

where a,b are arbitrary constants and so the vector field S becomes

$$S=\frac{1}{-at+b}\frac{\partial}{\partial n}+\frac{au_n}{-at+b}\frac{\partial}{\partial u_n}+\frac{2av_n}{-at+b}\frac{\partial}{\partial v_n}+\frac{\partial}{\partial n}.$$

Let us compare the nonclassical symmetries of BC lattice equation with classical ones. We now multiply Eq. (30) and the corresponding vector field (31) by $(-at+b)$ and obtain

$$S_1=\frac{\partial}{\partial n}+(-at+b)\frac{\partial}{\partial t}+au_n\frac{\partial}{\partial u_n}+2av_n\frac{\partial}{\partial v_n}. \tag{35}$$

Case 2: $T\neq 0, X=0$

Here the invariant surface conditions (30a) and (30b) becomes

$$T\frac{du_n}{dt}=U,\quad T\frac{dv_n}{dt}=V. \tag{36}$$

Substituting the above equation (36) in (1) we obtain

$$U=Tu_n(u_{n+1}-u_{n-1})+v_{n-1}-v_n, \tag{37a}$$

$$V=Tv_n(u_{n+2}-u_{n-1}). \tag{37b}$$

Applying classical Lie algorithm to the above equation (37) yields

$$T\frac{\partial U}{\partial t}+U\left(\frac{\partial U}{\partial u_n}-\frac{\partial T}{\partial t}\right)=T[u_n(U_{n+1}-U_{n-1})+U_n(u_{n+1}-u_{n-1})+V_{n-1}-V_n], \tag{38a}$$

$$T\frac{\partial V}{\partial t}+V\left(\frac{\partial V}{\partial v_n}-\frac{\partial T}{\partial t}\right)=T[v_n(U_{n+2}-U_{n-1})+V_n(u_{n+2}-u_{n-1})]. \tag{38b}$$

Solving the above equation (38), we obtain

$$T=-a_1t+b_1,\quad U=a_1u_n,\quad V=2a_1v_n, \tag{39}$$

where a_1,b_1 are arbitrary constants and so the conditional symmetry generator is

$$S_1=(-a_1t+b_1)\frac{\partial}{\partial t}+a_1u_n\frac{\partial}{\partial u_n}+2a_1v_n\frac{\partial}{\partial v_n}. \tag{40}$$

For cases (1) and (2) we conclude that no nonclassical symmetries exist for BC lattice equation (1).

B. Blaszak–Marciniak lattice

We also investigate the nonclassical symmetries for BM lattice by proceeding in a similar manner as for BC lattice. There are two different cases: $\tilde{T}\neq 0,\tilde{X}\neq 0$ and $\tilde{T}\neq 0,\tilde{X}=0$.

Case 1: $\tilde{T}\neq 0,\tilde{X}\neq 0$

Invariant surface condition is

$$\tilde{T}\frac{du_n}{dt}+\tilde{X}\frac{du_n}{dn}-\tilde{U}=0, \tag{41a}$$

$$\tilde{T}\frac{dv_n}{dt}+\tilde{X}\frac{dv_n}{dn}-\tilde{V}=0, \tag{41b}$$

$$\tilde{T}\frac{dw_n}{dt}+\tilde{X}\frac{dw_n}{dn}-\tilde{W}=0. \tag{41c}$$

With no loss of generality we put $\tilde{T}=1$ in Eq. (41). Making use of Eq. (2) we write Eq. (41) as

$$\tilde{U}-\tilde{X}\frac{du_n}{dn}=w_{n+1}-w_{n-1}, \tag{42a}$$

$$\tilde{V}-\tilde{X}\frac{dv_n}{dn}=u_{n-1}w_{n-1}-u_nw_n, \tag{42b}$$

$$\tilde{W}-\tilde{X}\frac{dw_n}{dn}=w_n(v_n-v_{n+1}). \tag{42c}$$

Proceeding further we obtain the following invariance equation:

$$\left[\tilde{X}\frac{\partial\tilde{U}}{\partial t}-\tilde{U}\frac{\partial\tilde{X}}{\partial t}\right]+\left(\frac{\partial\tilde{X}}{\partial t}+\tilde{X}\frac{\partial\tilde{U}}{\partial u_n}\right)(w_{n+1}-w_{n-1})=\tilde{X}[\tilde{W}(n+1)-\tilde{W}(n-1)], \tag{43a}$$

$$\left(\tilde{X}\frac{\partial\tilde{V}}{\partial t}-\tilde{V}\frac{\partial\tilde{X}}{\partial t}\right)+\left(\frac{\partial\tilde{X}}{\partial t}+\tilde{X}\frac{\partial\tilde{V}}{\partial v_n}\right)(u_{n-1}w_{n-1}-u_nw_n)$$
$$=\tilde{X}[\tilde{U}(n-1)w_{n-1}+u_{n-1}\tilde{W}(n-1)-\tilde{U}(n)w_n-u_n\tilde{W}(n)], \tag{43b}$$

$$\left(\tilde{X}\frac{\partial\tilde{W}}{\partial t}-\tilde{W}\frac{\partial\tilde{X}}{\partial t}\right)+\left(\frac{\partial\tilde{X}}{\partial t}+\tilde{X}\frac{\partial\tilde{W}}{\partial w_n}\right)[w_n(v_n-v_{n+1})]=\tilde{X}[\tilde{W}(v_n-v_{n+1})+w_n(\tilde{V}(n)-\tilde{V}(n+1))]. \tag{43c}$$

We then obtain an overdetermined system of equations and solving them yields

$$\tilde{X}=\frac{1}{-a_2t+b_2},\quad \tilde{U}=\frac{a_2u_n}{2(-a_2t+b_2)},\quad \tilde{V}=\frac{a_2v_n}{-a_2t+b_2},\quad \tilde{W}=\frac{3a_2w_n}{2(-a_2t+b_2)}, \tag{44a}$$

where a_2,b_2 are arbitrary constants and so the vector field S_2 becomes

$$S_2=\frac{1}{-a_2t+b_2}\frac{\partial}{\partial n}+\frac{a_2u_n}{2(-a_2t+b_2)}\frac{\partial}{\partial u_n}+\frac{a_2v_n}{-a_2t+b_2}\frac{\partial}{\partial v_n}+\frac{3a_2w_n}{2(-a_2t+b_2)}\frac{\partial}{\partial w_n}\frac{\partial}{\partial t}. \tag{44b}$$

We compare the nonclassical symmetries of BM lattice equation with the classical one (20a) and (20b). Multiplying Eq. (41) by $(-a_2t+b_2)$ we see that the vector field (44b) reduces into

$$S_2=\frac{\partial}{\partial n}+(-a_2t+b_2)\frac{\partial}{\partial t}+\frac{1}{2}a_2u_n\frac{\partial}{\partial u_n}+a_2v_n\frac{\partial}{\partial v_n}+\frac{3}{2}a_2w_n\frac{\partial}{\partial w_n}. \tag{45}$$

Case 2: $\tilde{T}\neq 0,\tilde{X}=0$

Here the invariant surface condition (41) becomes

$$\tilde{T}\frac{du_n}{dt}-\tilde{U}=0,\quad \tilde{T}\frac{dv_n}{dt}-\tilde{V}=0,\quad \tilde{T}\frac{dw_n}{dt}-\tilde{W}=0. \tag{46}$$

As a result Eq. (2) becomes

$$\tilde{U}=\tilde{T}[w_{n+1}-w_{n-1}], \tag{47a}$$

$$\tilde{V}=\tilde{T}[u_{n-1}w_{n-1}-u_nw_n], \tag{47b}$$

$$\tilde{W}=\tilde{T}[w_n(v_n-v_{n+1})]. \tag{47c}$$

Applying classical Lie algorithm we obtain the following invariant equation:

$$\tilde{T}\frac{\partial\tilde{U}}{\partial t}+\tilde{U}\left(\frac{\partial\tilde{U}}{\partial u_n}-\frac{\partial\tilde{T}}{\partial t}\right)=\tilde{T}[\tilde{W}(n+1)-\tilde{W}(n-1)], \tag{48a}$$

$$\tilde{T}\frac{\partial\tilde{V}}{\partial t}+\tilde{V}\left(\frac{\partial\tilde{V}}{\partial v_n}-\frac{\partial\tilde{T}}{\partial t}\right)=\tilde{T}[u(n-1)\tilde{W}(n-1)+\tilde{U}(n-1)w(n-1)-\tilde{U}(n)w_n-u_n\tilde{W}(n)], \tag{48b}$$

$$\tilde{T}\frac{\partial\tilde{W}}{\partial t}+\tilde{W}\left(\frac{\partial\tilde{W}}{\partial w_n}-\frac{\partial\tilde{T}}{\partial t}\right)=\tilde{T}[\tilde{W}(v_n-v_{n+1})+w_n(\tilde{V}(n)-\tilde{V}(n+1))]. \tag{48c}$$

Solving the above equation (48) gives

$$\tilde{T}=-a_3t+b_3,\quad \tilde{U}=\frac{a_3u_n}{2},\quad \tilde{V}=a_3v_n,\quad \tilde{W}=\frac{3a_3w_n}{2}, \tag{49}$$

where a_3 and b_3 are arbitrary constants and so the conditional symmetry generator is

$$S_2=(-a_3t+b_3)\frac{\partial}{\partial t}+\frac{a_3u_n}{2}\frac{\partial}{\partial u_n}+a_3v_n\frac{\partial}{\partial v_n}+\frac{3}{2}a_3w_n\frac{\partial}{\partial w_n}. \tag{50}$$

Thus it is clear from the cases (1) and (2) that there exists no nonclassical symmetries for BM lattice equation (2) as well.

IV. CONSERVED DENSITIES AND GENERALIZED SYMMETRIES

A. Belov–Chaltikian (BC) lattice equation

It is known that there exists a deep connection between the generalized symmetries and integrability of nonlinear evolution equations.[5] More precisely, if a nonlinear partial differential difference or lattice equations admits a sequence of generalized symmetries, then it is expected to be integrable. The generalized or higher order or Lie Backlund symmetries were computed for nonlinear partial differential equations by different authors in different context[25] and demonstrated

its relation with integrability. For nonlinear partial differential–difference or lattice equations attempt was made to derive polynomial generalized symmetries by different groups.[5,26–28] However, it is not clear how to compute nonpolynomial generalized symmetries. Yet the nonexistence of polynomial generalized symmetries or conserved quantities does not preclude integrability. We wish to note that the evaluation of generalized symmetries for nonlinear differential difference equations is a tedious and cumbersome work. In fact, there exists several software to compute polynomial generalized symmetries and conserved densities. For example, using a package in Mathematica, Goktas, and Hereman[5] have demonstrated that under what conditions on the parameters given nonlinear evolution equations including lattice equations admit a sequence of generalized symmetries and conserved densities.[5,28,29] In this paper we derive, the generalized symmetries and conserved densities for BC and BM lattice equations (1) and (2) without using any software package.

Let us first derive the conserved densities for the BC lattice equation (1) which is invariant under the scaling symmetry

$$(t,u_n,v_n)\rightarrow(\lambda t,\lambda^{-1}u_n,\lambda^{-2}v_n), \tag{51}$$

where λ is an arbitrary parameter. Thus u_n and v_n corresponds to one and two derivatives with respect to t, respectively. In otherwords

$$u_n\sim\frac{d}{dt},\quad v_n\sim\frac{d^2}{dt^2}.$$

In order to derive the conserved densities, Eqs. (1a) and (1b) should have the same rank. To start with we consider the form of conserved density with rank 2. We remind that if ρ_n is a conserved density for a nonlinear differential–difference, difference, or lattice equation then

$$\frac{d\rho_n}{dt}=J_n-J_{n+1}, \tag{52}$$

where J_n is the flux.

Forming all monomials of u_n,v_n with rank 2 yields the list $\Phi=\{u_n,u_n^2,v_n\}$. Introducing the necessary t derivatives leads to $\{u_n^2,v_n,u_nu_{n+1},u_nu_{n-1},v_{n-1}\}$. Using $u_nu_{n+1}\equiv u_nu_{n-1}$, $v_n\equiv v_{n-1}$, we obtain $I=\{u_n^2,v_n,u_nu_{n+1}\}$. Then the conserved density can be obtained by considering a linear combination of the terms in I

$$\rho_n=c_1u_n^2+c_2v_n+c_3u_nu_{n+1}, \tag{53}$$

where c_1,c_2,c_3 are constants. Differentiating equation (53) with respect to t and making use of Eqs. (1a) and (1b) we get

$$\begin{aligned}\frac{d\rho_n}{dt}=&(2c_1-c_3)u_n^2u_{n+1}+(2c_1-c_3)u_{n+1}v_n+(c_3-2c_1)u_nv_n-(c_2+c_3)u_nv_{n+1}+(c_2\\&+c_3)u_{n+2}v_n+(c_3-2c_1)u_nu_{n+1}^2+[J_n-J_{n+1}],\end{aligned} \tag{54}$$

with flux

$$J_n=2c_1u_nv_{n-1}-c_3u_nu_{n+1}u_{n-1}+c_3u_{n+1}v_{n-1}-c_2v_nu_{n-1}-2c_1u_n^2u_{n-1}. \tag{55}$$

By definition (52), the monomials outside the square brackets in (54) must vanish. This yields $2c_1-c_3=0$,$c_2+c_3=0$. We see that there are two equations for three unknowns. Choosing $c_1=1/2$, we obtain $c_2=-1$, $c_3=1$ and so the conserved density with rank 2, $\rho_n^{(2)}$ and the associated flux becomes

$$\rho_n^{(2)}=\tfrac{1}{2}u_n^2-v_n+u_nu_{n+1},$$

$$J_n^{(2)}=u_nv_{n-1}-u_nu_{n+1}u_{n-1}+u_{n+1}v_{n-1}+v_nu_{n-1}-u_n^2u_{n-1}.$$

Next we compute the conserved density of rank 3. As before forming all monomials of u_n and v_n with rank 3 yields the list $\phi=\{u_n,u_n^2,u_n^3,v_n,u_nv_n\}$. Introducing the necessary t derivatives and rescaling we obtain

$$I=\{u_n^3,u_nv_n,u_n^2u_{n+1},u_{n+1}^2u_n,u_{n+1}v_n,u_nu_{n+1}u_{n+2},u_nv_{n+1},u_{n+2}v_n,u_{n+1}v_{n-1},v_nu_{n-1}\}.$$

Then the conserved density can take the form

$$\rho_n=c_4u_n^3+c_5u_nv_n+c_6u_n^2u_{n+1}+c_7u_nu_{n+1}^2+c_8u_{n+1}v_n+c_9u_nu_{n+1}u_{n+2}+c_{10}u_nv_{n+1}+c_{11}u_{n+2}v_n+c_{12}u_{n+1}v_{n-1}+c_{13}v_nu_{n-1}. \tag{56}$$

Differentiating equation (56) with respect to t, making use of Eqs. (1a) and (1b) and by definition (52), we obtain $c_4=1/3,c_5=-1,c_6=1,c_7=1,c_8=-1,c_9=1,c_{10}=-1,c_{11}=-1,c_{12}=c_{13}=0$, and so the conserved density with rank 3, $\rho_n^{(3)}$ and the associated flux is

$$\rho_n^{(3)}=\tfrac{1}{3}u_n^3+(u_nu_{n+1}-v_n)(u_n+u_{n+1}+u_{n+2})-u_nv_{n+1},$$

$$\begin{aligned}J_n^{(3)}=&u_{n-1}(2u_n+u_{n+1}+u_{n+2})(v_n-u_nu_{n+1})+u_nv_{n-1}(u_n+2u_{n+1})-v_{n-1}(v_n+v_{n+1})\\&+u_{n+1}v_{n-1}(u_{n+2}+u_{n+1})+u_nu_{n-1}(v_{n+1}-u_n^2).\end{aligned}$$

Since the derivation of the conserved density of rank 4 involves more number of terms we give below only the result

$$\begin{aligned}\rho_n^{(4)}=&\tfrac{1}{4}u_n^4+u_n^3u_{n+1}+\tfrac{3}{2}u_n^2u_{n+1}^2+u_nu_{n+1}^2(u_{n+1}+u_{n+2})+u_nu_{n+1}u_{n+2}(u_n+u_{n+1}+u_{n+2}+u_{n+3})\\&+\tfrac{1}{2}v_n^2+v_nv_{n-1}-u_nv_n(u_n+u_{n+1}+u_{n-1}+u_{n+2})-u_nv_{n-1}(u_n+u_{n+1}+u_{n-2})\\&-v_nu_{n-1}(u_n+u_{n-2}+u_{n+2})-u_nu_{n+1}(v_n+v_{n-1})-u_n^2(v_{n+1}+v_{n-2})\\&+v_n(v_{n+2}-u_{n+2}u_{n+3}),\end{aligned}$$

$$\begin{aligned}J_n^{(4)}=&u_n^3v_{n-1}-u_n^4u_{n-1}-u_n^3v_{n-2}-2v_{n-1}^2u_n-v_{n-1}^2u_{n+1}-v_{n-1}^2u_{n-2}-u_nu_{n-1}u_{n+1}u_{n+2}u_{n+3}\\&-u_{n+1}^3u_nu_{n-1}-2u_n^2u_{n+1}v_{n-2}-3u_n^2u_{n+1}^2u_{n-1}+2u_n^2u_{n-1}v_{n-1}+u_{n-1}u_{n-2}u_{n-3}v_n\\&+u_nu_{n-1}u_{n-2}v_{n+1}+u_{n+1}u_nu_{n-1}v_{n+2}+u_nu_{n-1}u_{n-2}v_n+u_nu_{n-1}u_{n+1}v_{n+1}\\&+u_{n+1}u_{n-1}u_{n-2}v_n+u_nu_{n+2}u_{n-1}v_{n+1}+2u_nu_{n+1}u_{n-1}v_n-u_nu_{n-1}u_{n+2}v_n\\&-2u_nu_{n-1}u_{n+2}u_{n+1}^2-2u_n^2u_{n+2}u_{n+1}u_{n-1}-u_{n+2}^2u_nu_{n+1}u_{n-1}+2u_nu_{n+1}u_{n-1}v_{n-1}\\&+u_{n+1}u_{n+2}u_{n+3}v_{n-1}+u_{n+1}u_{n+2}u_{n-1}v_n+u_{n-2}^2u_{n-1}v_n-v_nv_{n-2}u_{n-2}-v_{n+1}v_{n-1}u_{n-1}\\&+u_{n-1}^2u_nv_{n+1}+u_n^2u_{n-1}v_n-v_{n-1}v_{n-3}u_n-v_nv_{n-2}u_{n+1}-v_{n+1}v_{n-1}u_{n+2}+u_{n+2}v_nv_{n-1}\\&-v_nv_{n-3}u_{n-1}-v_{n+1}v_{n-2}u_n-v_{n+2}v_{n-1}u_{n+1}+u_{n+2}^2u_{n+1}v_{n-1}-v_nv_{n-2}u_{n+2}\\&-v_{n+1}v_{n-1}u_{n+3}+u_{n-1}^2u_{n+2}v_n+u_n^2u_{n-3}v_{n-2}+u_{n+1}^2u_{n-2}v_{n-1}+u_nu_{n-2}^2v_{n-1}\\&+u_{n+1}u_{n-1}^2v_n+2u_n^2u_{n-1}v_{n-2}+u_{n+1}^2u_nv_{n-1}-u_nv_{n-1}v_{n-2}+v_nv_{n-1}u_{n-2}+v_nv_{n-2}u_{n-1}\\&+v_{n-1}v_{n+1}u_n+4u_{n-1}^2u_nv_n-3v_nv_{n-1}u_{n-1}+u_n^2u_{n-2}v_{n-1}+v_nu_{n+1}^2u_{n-1}+2u_n^2u_{n+1}v_{n-1}\end{aligned}$$

$$+2u_n^2u_{n-1}v_{n-1}+4u_n^2u_{n-1}v_{n+1}.$$

Proceeding in a similar manner one can compute conserved densities ρ_n with rank $\geqslant 5$.

Next we derive the generalized symmetries for the BC lattice equation (1) which is invariant under the dilation symmetry

$$(t,u_n,v_n)\rightarrow(\lambda^{-1}t,\lambda u_n,\lambda^2 v_n),$$

where λ is an arbitrary parameter. Thus u_n and v_n corresponds to one and two derivatives with respect to t, respectively. We first derive generalized symmetries of BC lattice equation with ranks (2) and (3) denoted by $G_1^{(1)}$ and $G_1^{(2)}$. Forming all the monomials in u_n and v_n of rank 2 and 3 gives the following:

$L_1=\{u_n,u_n^2,v_n\}, L_2=\{u_n,u_n^2,u_n^3,v_n,u_nv_n\}$.

We then introduce the necessary t derivatives in each monomial of L_1. Making use of Eqs. (1a) and (1b) we obtain

$$\frac{d^0}{dt^0}(u_n^2)=u_n^2,\quad \frac{d^0}{dt^0}(v_n)=v_n,\quad \frac{d}{dt}(u_n)=u_n(u_{n+1}-u_{n-1})+v_{n-1}-v_n,$$

and a set:

$$R_1=\{u_n^2,v_n,u_nu_{n+1},u_nu_{n-1},v_{n-1}\}.$$

Similarly, based on the monomials in L_2, we get

$$\begin{aligned}R_2=\{&u_n^3,u_nv_n,v_nu_{n+2},v_nu_{n-1},u_n^2u_{n+1},u_n^2u_{n-1},u_nv_{n-1},u_nu_{n+1}u_{n+2},\\&u_nv_{n+1},u_nu_{n-1}u_{n-2},u_nv_{n-2},u_nu_{n+1}^2,u_nu_{n+1}u_{n-1},u_{n+1}v_{n-1},\\&u_{n+1}v_n,u_nu_{n-1}^2,u_{n-1}v_{n-1},v_{n-1}u_{n-2}\}.\end{aligned}$$

Then the generalized symmetry can be obtained by considering linear combination of the terms in R_1 and R_2

$$G_1^{(1)}=c_1u_n^2+c_2v_n+c_3u_nu_{n+1}+c_4u_nu_{n-1}+c_5v_{n-1}, \tag{57a}$$

$$\begin{aligned}G_1^{(2)}=&c_6u_n^3+c_7u_nv_n+c_8v_nu_{n+2}+c_9v_nu_{n-1}+c_{10}u_n^2u_{n+1}+c_{11}u_n^2u_{n-1}+c_{12}u_nv_{n-1}\\&+c_{13}u_nu_{n+1}u_{n+2}+c_{14}u_nv_{n+1}+c_{15}u_nu_{n-1}u_{n-2}+c_{16}u_nv_{n-2}+c_{17}u_nu_{n+1}^2\\&+c_{18}u_nu_{n+1}u_{n-1}+c_{19}u_{n+1}v_{n-1}+c_{20}u_{n+1}v_n+c_{21}u_nu_{n-1}^2+c_{22}u_{n-1}v_{n-1}+c_{23}v_{n-1}u_{n-2},\end{aligned} \tag{57b}$$

where c_i, $i=1,2,\ldots,23$ are arbitrary constants.

To determine the coefficients c_i, $i=1,2,\ldots,23$ we introduce a lattice equation

$$\frac{du}{d\tau}=G_1^{(1)},\quad \frac{dv}{d\tau}=G_2^{(1)}. \tag{58}$$

Now by the compatibility condition of (1) and (58) we obtain

$$D_tG_1^{(1)}=D_\tau F_1,\quad D_tG_2^{(1)}=D_\tau F_2, \tag{59}$$

where $D_t=d/dt$, F_1, and F_2 are the right-hand side terms of Eqs. (1a) and (1b). We solve the above equation (59) and eliminate $\dot{u}_{n+1}$, $\dot{u}_{n-1}$, $\dot{v}_{n+1}$, $\dot{v}_{n-1}$, etc. then using Eq. (1) the nonzero coefficients are

$$c_2=-c_3=c_4=-c_5=c_9=-c_8,$$

we choose $c_8=1$ the symmetry is

$$G_1^{(1)}=u_n(u_{n+1}-u_{n-1})+v_{n-1}-v_n,$$
$$G_2^{(1)}=v_n(u_{n+2}-u_{n-1}).$$

Proceeding in a similar fashion described earlier we computed the generalized symmetries with ranks (3) and (4)

$$\begin{aligned}
G_2^{(1)}=&c_1u_n^3+c_2u_nv_n+c_3u_{n+2}v_n+c_4u_{n-1}v_n+c_5u_n^2u_{n+1}+c_6u_n^2u_{n-1}+c_7u_nv_{n-1}\\
&+c_8u_nu_{n+1}u_{n+2}+c_9u_nv_{n+1}+c_{10}u_nu_{n-1}u_{n-2}+c_{11}u_nv_{n-2}+c_{12}u_nu_{n+1}^2+c_{13}u_nu_{n+1}u_{n-1}\\
&+c_{14}u_{n+1}v_{n-1}+c_{15}u_{n+1}v_n+c_{16}u_nu_{n-1}^2+c_{17}u_{n-1}v_{n-1}+c_{18}v_{n-1}u_{n-2},\\
G_2^{(2)}=&c_{19}u_n^4+c_{20}v_n^2+c_{21}u_n^2v_n+c_{22}u_n^3u_{n+1}+c_{23}u_n^3u_{n-1}+c_{24}u_n^2v_{n-1}+c_{25}u_nu_{n+2}v_n\\
&+c_{26}u_nu_{n-1}v_n+c_{27}u_nu_{n+1}v_n+c_{28}v_nv_{n-1}+c_{29}u_n^2u_{n+1}^2+c_{30}u_n^2u_{n-1}^2+c_{31}u_n^2u_{n+1}u_{n-1}\\
&+c_{32}u_nu_{n+1}v_{n-1}+c_{33}u_nu_{n-1}v_{n-1}+c_{34}u_n^2u_{n+1}u_{n+2}+c_{35}u_n^2v_{n+1}+c_{36}u_n^2u_{n-1}u_{n-2}\\
&+c_{37}u_n^2v_{n-2}+c_{38}v_{n-1}^2+c_{39}u_nu_{n-2}v_{n-1}+c_{40}u_{n+2}^2v_n+c_{41}u_{n-1}^2v_n+c_{42}u_{n+2}u_{n-1}v_n\\
&+c_{43}u_{n+2}u_{n+3}v_n+c_{44}u_{n+1}u_{n+2}v_n+c_{45}v_nv_{n+1}+c_{46}v_nv_{n+2}+c_{47}u_{n-1}u_{n-2}v_n\\
&+c_{48}v_nv_{n-2}+c_{49}u_nu_{n+1}^3+c_{50}u_nu_{n+1}^2u_{n-1}+c_{51}u_{n+1}^2v_{n-1}+c_{52}u_{n+1}^2v_n+c_{53}u_nu_{n-1}^2u_{n+1}\\
&+c_{54}u_{n+1}u_{n-1}v_{n-1}+c_{55}u_{n+1}u_{n-1}v_n+c_{56}u_nu_{n-1}^3+c_{57}u_{n-1}^2v_{n-1}+c_{58}u_nu_{n+1}^2u_{n+2}\\
&+c_{59}u_nu_{n+1}v_{n+1}+c_{60}u_nu_{n+1}u_{n-1}u_{n-2}+c_{61}u_nu_{n+1}v_{n-2}+c_{62}u_nu_{n+1}u_{n-1}u_{n+2}\\
&+c_{63}u_nu_{n-1}v_{n+1}+c_{64}u_nu_{n-1}^2u_{n-2}+c_{65}u_nu_{n-1}v_{n-2}+c_{66}u_{n+1}u_{n-2}v_{n-1}\\
&+c_{67}u_{n-1}u_{n-2}v_{n-1}+c_{68}u_nu_{n+1}u_{n+2}u_{n+3}+c_{69}u_nu_{n+1}v_{n+2}+c_{70}u_{n+1}u_{n+2}v_{n-1}\\
&+c_{71}u_nu_{n+2}^2u_{n+1}+c_{72}u_nu_{n+2}v_{n+1}+c_{73}u_nu_{n+3}v_{n+1}+c_{74}v_{n+1}v_{n-1}\\
&+c_{75}u_nu_{n-1}u_{n-2}u_{n-3}+c_{76}u_nu_{n-1}v_{n-3}+c_{77}u_nu_{n-1}v_{n-2}+c_{78}u_nu_{n-2}^2u_{n-1}\\
&+c_{79}u_nu_{n-2}v_{n-2}+c_{80}v_{n-1}v_{n-2}+c_{81}u_nu_{n-3}v_{n-2}+c_{82}u_{n-2}^2v_{n-1}+c_{83}u_{n-2}u_{n-3}v_{n-1}\\
&+c_{84}v_{n-1}v_{n-3}.
\end{aligned}$$

As before replacing $G_1^{(1)}$ by $G_2^{(1)}$ and $G_2^{(1)}$ by $G_2^{(2)}$ in the compatibility condition (59) we find the nonzero coefficients,

$$\begin{aligned}
-c_2=&-c_3=c_5=-c_6=c_7=c_8=-c_9=-c_{10}=c_{11}=c_{12}=-c_{15}=-c_{16}=c_{17}=c_{18}=-c_{26}\\
&=c_{28}=c_{40}=-c_{41}=c_{44}=-c_{45}=-c_{46}=-c_{47}=c_{48}=c_{43}.
\end{aligned}$$

By choosing $c_{43}=-1$, we obtain the symmetry as

$$\begin{aligned}
G_2^{(1)}=&(v_n-u_nu_{n+1})(u_n+u_{n+1}+u_{n+2})+(u_nu_{n-1}-v_{n-1})(u_n+u_{n-1}+u_{n-2})\\
&-u_n(v_{n-2}-v_{n+1}),\\
G_2^{(2)}=&u_{n-1}v_n(u_n+u_{n-1}+u_{n-2})-u_{n+2}v_n(u_{n+1}+u_{n+2}+u_{n+3})\\
&+v_n(v_{n+1}+v_{n+2}-v_{n-1}-v_{n-2}).
\end{aligned}$$

It is straightforward to compute the generalized symmetries of higher order and, therefore, we refrain from presenting details of the symmetries.

B. Blaszak–Marciniak (BM) lattice equation

Following the procedure adopted for BC lattice equation we find that BM lattice equation also admits a sequence of conserved densities and generalized symmetries. The results are

$$\rho_n^{(1)}=v_n, J_n^{(1)}=u_{n-1}w_{n-1},$$

$$\rho_n^{(2)}=\tfrac{1}{2}v_n^2+u_nw_n, J_n^{(2)}=u_{n-1}w_{n-1}v_n-w_nw_{n-1},$$

$$\rho_n^{(3)}=\tfrac{1}{3}v_n^3+u_nv_nw_n+u_nw_nv_{n+1}-w_nw_{n-1},$$

$$J_n^{(3)}=v_n^2u_{n-1}w_{n-1}-w_nw_{n-1}v_{n-1}-w_nw_{n-1}v_n+u_nu_{n-1}w_nw_{n-1},$$

$$\rho_n^{(4)}=\tfrac{1}{4}v_n^4+\tfrac{1}{2}u_n^2w_n^2+u_nu_{n-1}w_nw_{n-1}-w_nw_{n+1}v_n-w_nw_{n+1}v_{n+1}-w_nw_{n-1}v_{n+1}+u_nw_nv_nv_{n+1}$$
$$+u_nw_nv_{n+1}^2+u_nv_n^2w_n,$$

$$J_n^{(4)}=2u_nu_{n-1}w_nw_{n-1}v_n-w_nw_{n-1}v_n^2+v_n^3u_{n-1}w_{n-1}-w_{n-1}^2u_{n-1}w_n-u_nw_nw_{n-1}w_{n-2}$$
$$+u_nu_{n-1}w_nw_{n-1}v_{n-1}-v_{n-1}v_{n+1}w_nw_{n-1}-w_nw_{n-1}v_nv_{n+1}-w_n^2w_{n-1}u_n,$$

$$G_3^{(1)}=w_{n+1}-w_{n-1},\quad G_3^{(2)}=u_{n-1}w_{n-1}-u_nw_n,\quad G_3^{(3)}=w_n(v_n-v_{n+1}),$$

and

$$G_4^{(1)}=w_{n-1}(v_n+v_{n-1})-w_{n+1}(v_{n+1}+v_{n+2}),$$

$$G_4^{(2)}=u_nw_n(v_n+v_{n+1})-u_{n-1}w_{n-1}(v_n+v_{n-1})+w_{n-1}w_{n-2}-w_nw_{n+1},$$

$$G_4^{(3)}=w_n(v_{n+1}^2-v_n^2)+w_n(w_{n+1}u_{n+1}-w_{n-1}u_{n-1}).$$

V. CONCLUSION

Using classical Lie symmetry approach we derive Lie symmetries and similarity reduction of BC and BM lattice equations. We have also shown that the reduced equation possesses different integrability properties such as Lax representation, singularity confinement criterion. Moreover, the reduced equations admit two interesting particular solutions. Also we have checked that both BC and BM lattice equation do not admit nonclassical symmetries. Furthermore, we have shown for both BC and BM lattice equations that there exists a sequence of conserved densities and generalized symmetries a characteristic of integrable systems governed by nonlinear partial differential, differential–difference equations. It is of interest to investigate whether any other integrability properties such as master symmetries, hereditary operators, etc. of BC and BM lattice equations exists or not which is under investigation.

(Received 9 June 2000; accepted for publication 19 January 2001)

Invariant integrals on Hopf superalgebras, in particular, the classical and quantum Lie supergroups, are studied. The uniqueness (up to scalar multiples) of a left integral is proved, and a $\mathbb{Z}_2$-graded version of Maschke's theorem is discussed. A construction of left integrals is developed for classical and quantum Lie supergroups. Applied to several classes of examples the construction yields the left integrals in explicit form. © *2001 American Institute of Physics.*

I. INTRODUCTION

This article studies invariant integrals on Hopf superalgebras. We shall focus on the Hopf superalgebras of functions on classical Lie supergroups and their quantum counterparts, developing aspects of the general theory of integrals on them, and also establishing an explicit construction of such integrals.

An important feature of classical and quantum Lie superalgebras is that their finite-dimensional representations are not completely reducible. This imposes severe restrictions on the possible integrals on the corresponding classical and quantum Lie supergroups. We shall extensively investigate this fact, arriving at a result which may be regarded as a $\mathbb{Z}_2$-graded version of Maschke's theorem in an infinite-dimensional setting.

Recall that if the dual of a given finite-dimensional Hopf algebra is semisimple, then a generalization of Maschke's theorem (see Refs. 1 and 2) applies, and the invariant integral on the Hopf algebra can be obtained by considering a Peter–Weyl type basis of the Hopf algebra. Such a construction of integrals fails badly in the supersymmetric setting [except for $\mathrm{OSP}(1|2n)$ and $\mathrm{OSP}_q(1|2n)$]. Here we develop an explicit construction of integrals, which can be implemented on classical Lie supergroups and also on type I quantum supergroups. The construction can also be adapted to produce integrals on quantum groups at roots of unity.

The study of this article is motivated by the great importance of the Haar measure in the theory of locally compact Lie groups. The first place we know of where integrals in the sense of Hopf algebra theory have shown up is Hochschild's proof of Tannaka's duality theorem for compact groups.[3] Later on they played an important role in the structure theory of finite-dimensional Hopf algebras (for example, see Refs. 4–7).

With the appearance of quantum groups and quantum algebras, it became obvious that integrals have to play an important role there, too. In fact, the quantum Haar functional is a basic tool in the C^*-algebra approach to quantum groups,[8] and it can also be used to introduce topologies on Hopf algebras which originally are defined by purely algebraic means.[9] Correspondingly, there are various attempts to define integration on quantum groups, quantum spaces and their braided generalizations (see Ref. 10 and the references therein).

In principle, the braided case includes Hopf superalgebras as a special example, but it seems worthwhile to investigate the super case separately. Needless to say, there is a huge literature dealing with the integration on supermanifolds and supergroups, but a theory of integrals on Hopf

superalgebras seems to be missing. This will be the topic of the present work. We hope that integrals will also prove to be useful in the further investigation of the structure and representations of quantum supergroups, and that our results will shed some new light on the integration over classical, i.e., undeformed Lie supergroups.

At present, we know of only one related work.[11] In that reference, integrals on quantum supergroups of the special linear type are constructed by means of the R-matrix formalism. However, even for the $\mathrm{SL}_q(m|n)$ quantum supergroups the techniques used and the results derived in that paper are totally different from those to be presented here [even though, because of the uniqueness theorem to be proved in Sec. II, the integrals on $\mathrm{SL}_q(m|n)$ constructed here and in Ref. 11 must be proportional].

The organization of the article is as follows. In Sec. II we develop some general theory of integrals on Hopf superalgebras and establish results generalizing Maschke's theorem. In Sec. III we study classical Lie supergroups. A general construction of integrals is developed, and applied to the type I Lie supergroups, and also the type II Lie supergroups $\mathrm{OSP}(1|2n)$ and $\mathrm{OSP}(3|2)$. In Sec. IV we extend the results to the quantum setting, obtaining a method for constructing integrals on quantum supergroups. As examples, the type I quantum supergroups are studied in detail. Section V contains a brief discussion of our results. Finally, in the Appendix we have collected some information on the finite dual of $U(\mathfrak{gl}(1))$.

We close this introduction by recalling some conventions related to $\mathbb{Z}_2$-graded algebraic structures. The two elements of $\mathbb{Z}_2$ are denoted by $\overline{0}$ and $\overline{1}$. Unless stated otherwise, all gradations considered in this work will be $\mathbb{Z}_2$-gradations. For any superspace, i.e., $\mathbb{Z}_2$-graded vector space $V=V_{\overline{0}}\oplus V_{\overline{1}}$, we define the gradation index $[\,]$: $V_{\overline{0}}\cup V_{\overline{1}}\to\mathbb{Z}_2$ by $[x]=\alpha$ if $x\in V_\alpha$, where $\alpha\in\mathbb{Z}_2$. All algebraic notions and constructions are to be understood in the super sense, i.e., they are assumed to be consistent with the $\mathbb{Z}_2$-gradations and to include the appropriate sign factors.

II. INTEGRALS ON HOPF SUPERALGEBRAS

Let $\mathcal{A}$ be a Hopf superalgebra with comultiplication Δ, counit ε, and antipode S. A left integral $\int^l$ on $\mathcal{A}$ is an element of $\mathcal{A}^*$, such that

$$\left(\mathrm{id}_{\mathcal{A}}\otimes\int^l\right)\Delta=\mathbb{1}_{\mathcal{A}}\int^l. \tag{1}$$

Equivalently, this means that

$$a^*\cdot\int^l=a^*(\mathbb{1}_{\mathcal{A}})\int^l,\quad \forall a^*\in\mathcal{A}^*, \tag{2}$$

where the dot denotes the multiplication in $\mathcal{A}^*$ deduced from Δ. A right integral $\int^r\in\mathcal{A}^*$ on $\mathcal{A}$ is defined by a similar requirement

$$\left(\int^r\otimes\ \mathrm{id}_{\mathcal{A}}\right)\Delta=\mathbb{1}_{\mathcal{A}}\int^r. \tag{3}$$

Let $\mathcal{A}^{\mathrm{aop,cop}}$ be the Hopf superalgebra opposite to $\mathcal{A}$ both regarded as an algebra and a coalgebra. Then a linear form $\int\in\mathcal{A}^*$ is a left/right integral on $\mathcal{A}$ if and only if it is a right/left integral on $\mathcal{A}^{\mathrm{aop,cop}}$. In particular, if the antipode S of $\mathcal{A}$ (and hence of $\mathcal{A}^{\mathrm{aop,cop}}$) is invertible, then $S^{\pm1}$ are isomorphisms of $\mathcal{A}$ onto $\mathcal{A}^{\mathrm{aop,cop}}$, and hence $\int$ is a left integral on $\mathcal{A}$ if and only if $\int S^{\pm1}$ are right integrals on $\mathcal{A}$. Thus we only need to consider left integrals (or right integrals).

We have the following result:

Theorem 1: *The dimension of the space of left integrals on $\mathcal{A}$ is not greater than 1. In particular, any integral on $\mathcal{A}$ is even or odd.*

Proof: The proof is carried out by reducing the problem to the classical nongraded case. In principle, this can be viewed as an application of Majid's bosonization,[12] but for the present simple case the technique has been known for quite some time.

For notational convenience (and for reasons that will become obvious at the end of this proof) we define a map

$$\tau:\mathbb{Z}_2\times\mathbb{Z}_2\to\mathbb{C}$$

by

$$\tau(\alpha,\beta)=(-1)^{\alpha\beta},\quad \forall\,\alpha,\beta\in\mathbb{Z}_2.$$

Let $\mathbb{C}\mathbb{Z}_2$ be the group Hopf algebra of $\mathbb{Z}_2$. The canonical basis elements will be denoted by g_α, $\alpha\in\mathbb{Z}_2$. In particular, we have

$$g_\alpha g_\beta=g_{\alpha+\beta},\quad \forall\,\alpha,\beta\in\mathbb{Z}_2.$$

Then

$$\overline{\mathcal{A}}=\mathcal{A}\otimes\mathbb{C}\mathbb{Z}_2$$

is made into a usual Hopf algebra by means of the following definitions (where $a,b\in\mathcal{A}$ and $\alpha,\beta\in\mathbb{Z}_2$):
product:

$$(a\otimes g_\alpha)(b\otimes g_\beta)=\tau(\alpha,[b])\,ab\otimes g_{\alpha+\beta},$$

coproduct (in Sweedler's notation):

$$\overline{\Delta}(a\otimes g_\alpha)=\sum_{(a)}(a_{(1)}\otimes g_{[a_{(2)}]+\alpha})\otimes(a_{(2)}\otimes g_\alpha),$$

counit:

$$\overline{\varepsilon}(a\otimes g_\alpha)=\varepsilon(a),$$

antipode:

$$\overline{S}(a\otimes g_\alpha)=\tau([a],\alpha+[a])\,S(a)\otimes g_{-\alpha-[a]}.$$

Now let s be a left integral on $\mathcal{A}$, i.e., a linear form $s\in\mathcal{A}^*$ such that

$$(\mathrm{id}_{\mathcal{A}}\otimes s)\Delta=\mathbb{1}_{\mathcal{A}}\,s,$$

and let us assume that s is homogeneous of degree σ. Recall that $\otimes$ denotes the tensor product in the *graded* sense. Nevertheless, it is easy to see that the equation above is equivalent to

$$\sum_{(a)}a_{(1)}s(a_{(2)})=s(a)\,\mathbb{1}_{\mathcal{A}},\quad \forall\,a\in\mathcal{A},$$

i.e., it takes the same form as in the nongraded case.

Define the linear form t_σ on $\mathbb{C}\mathbb{Z}_2$ by

$$t_\sigma(g_\alpha)=\delta_{\sigma,\,\alpha},\quad \forall\,\alpha\in\mathbb{Z}_2.$$

Then

$$\overline{s} = s \otimes t_\sigma$$

(nongraded tensor product) is a left integral on $\overline{\mathcal{A}}$. We prove this by showing that $\overline{s}$ satisfies the equation analogous to that given above for s: For all $a \in \mathcal{A}$ and $\alpha \in \mathbb{Z}_2$, we have

$$\begin{aligned}
(\mathrm{id}_{\overline{\mathcal{A}}} \otimes \overline{s})(\overline{\Delta}(a \otimes g_\alpha)) &= (\mathrm{id}_{\overline{\mathcal{A}}} \otimes \overline{s}) \sum_{(a)} (a_{(1)} \otimes g_{[a_{(2)}]+\alpha}) \otimes (a_{(2)} \otimes g_\alpha) \\
&= \sum_{(a)} (a_{(1)} \otimes g_{[a_{(2)}]+\alpha})\, s(a_{(2)})\, t_\sigma(g_\alpha) \\
&= \sum_{(a)} (a_{(1)} \otimes g_{-\sigma+\alpha})\, s(a_{(2)})\, t_\sigma(g_\alpha) \\
&= \left(\sum_{(a)} a_{(1)} s(a_{(2)}) \right) \otimes g_0\, t_\sigma(g_\alpha) \\
&= s(a) t_\sigma(g_\alpha)\, 1\!\!1_{\mathcal{A}} \otimes g_0 \\
&= \overline{s}(a \otimes g_\alpha)\, 1\!\!1_{\mathcal{A}} \otimes g_0,
\end{aligned}$$

as required.

Now let us suppose that $s \neq 0$ and that s' is a second nonzero integral on $\mathcal{A}$ which is homogeneous of degree σ'. Then $\overline{s} = s \otimes t_\sigma$ and $\overline{s'} = s' \otimes t_{\sigma'}$ are nonzero integrals on $\overline{\mathcal{A}}$. According to Sullivan's theorem on the uniqueness of integrals on ordinary (nongraded) Hopf algebras (see Refs. 13 and 2) these integrals must be proportional. This implies that $\sigma = \sigma'$ (otherwise, t_σ and $t_{\sigma'}$ would be linearly independent) and hence that s and s' are proportional.

Finally, let $s \in \mathcal{A}^*$ be an arbitrary linear form on $\mathcal{A}$, and let $s = \Sigma_{\sigma \in \mathbb{Z}_2} s_\sigma$, with $s_\sigma \in (\mathcal{A}^*)_\sigma$, be its decomposition into homogeneous components. Obviously, s is a left integral on $\mathcal{A}$ if and only if all of the s_σ are. Applying the foregoing result to the s_σ, we conclude that, for a left integral s, at most one of the s_σ can be different from zero, i.e., that s is homogeneous. This proves the theorem.

The reader will notice that the same proof applies to arbitrary color Hopf algebras (and this was the other reason to introduce the map τ).

The uniqueness result of the theorem enables us to investigate how a left integral behaves under ''right translations.'' Thus, let $\int$ be a nontrivial left integral on $\mathcal{A}$. We know that the linear form $\int$ is homogeneous, let γ be its degree. We consider the linear map

$$g: \mathcal{A} \to \mathcal{A}, \quad g = \left(\int \otimes \mathrm{id} \right) \Delta.$$

Obviously, it is homogeneous of degree γ and not equal to zero (otherwise, $\varepsilon\, g = \int$ would be equal to zero). Using the coassociativity of the coproduct, it is easy to check that

$$(g \otimes \mathrm{id})\Delta = \Delta\, g, \tag{4}$$

$$(\mathrm{id} \otimes g)\Delta = j\, g, \tag{5}$$

where

$$j: \mathcal{A} \to \mathcal{A} \otimes \mathcal{A}, \quad j(a) = 1\!\!1_{\mathcal{A}} \otimes a$$

is the right canonical injection of $\mathcal{A}$ into $\mathcal{A} \otimes \mathcal{A}$.

Now let $a^* \in \mathcal{A}^*$ be an arbitrary homogeneous linear form on $\mathcal{A}$. Equation (5) implies that $a^*\, g$ is a left integral on $\mathcal{A}$ and hence proportional to $\int$. In particular, $a^*\, g$ vanishes on the kernel

of $\int$. Since this is true for all homogeneous elements $a^* \in \mathcal{A}^*$, it follows that g itself vanishes on the kernel of $\int$. Consequently, there exists a unique element $a_0 \in \mathcal{A}$ such that

$$g(a) = \left\langle \int , a \right\rangle a_0, \quad \forall a \in \mathcal{A},$$

and a_0 is even. Equation (4) now means that

$$\Delta(a_0) = a_0 \otimes a_0 .$$

Since a_0 is nonzero (because g is nonzero), we see that a_0 is a grouplike element of $\mathcal{A}$. Thus we have proved the following proposition.

Proposition 1: Let $\int$ be a nontrivial left integral on a Hopf superalgebra $\mathcal{A}$. Then there exists a unique even grouplike element $a_0 \in \mathcal{A}$ such that

$$\left(\int \otimes \mathrm{id} \right) \Delta = a_0 \int .$$

In particular, $\int$ is also a right integral if and only if $a_0 = \mathbb{1}_{\mathcal{A}}$.

Let V be a finite-dimensional $\mathbb{Z}_2$-graded right $\mathcal{A}$-comodule, and let

$$\omega : V \to V \otimes \mathcal{A}$$

be its structure map (which, according to our general conventions, is supposed to be even). The antipode of $\mathcal{A}$ enables one to introduce a right $\mathcal{A}$-comodule structure on the dual space V^* of V, with the structure map

$$\overline{\omega} : V^* \to V^* \otimes \mathcal{A}$$

uniquely defined by

$$\langle v^*, w \rangle \mathbb{1}_{\mathcal{A}} = (\langle , \rangle \otimes M)(\mathrm{id}_{V^*} \otimes T \otimes \mathrm{id}_{\mathcal{A}}) \overline{\omega}(v^*) \otimes \omega(w), \quad \forall v^* \in V^*, w \in V,$$

where T is the flipping map, M denotes the multiplication in $\mathcal{A}$ and $\langle , \rangle$ is the dual space pairing. It follows that $\mathrm{End}(V) = V \otimes V^*$ has a natural right $\mathcal{A}$-comodule structure

$$\delta : \mathrm{End}(V) \to \mathrm{End}(V) \otimes \mathcal{A}.$$

For later use we note that a map $g \in \mathrm{End}(V)$ is a comodule endomorphism of V if and only if it is even and coinvariant, i.e., it satisfies

$$\delta(g) = g \otimes \mathbb{1}_{\mathcal{A}} .$$

If $\int$ is a left integral on $\mathcal{A}$, we define the linear map

$$\Phi = \left(\mathrm{id} \otimes \int \right) \delta : \mathrm{End}(V) \to \mathrm{End}(V).$$

Consider $\Phi(m) \in \mathrm{End}(V)$ for any $m \in \mathrm{End}(V)$. Left invariance of $\int$ immediately leads to

$$\delta(\Phi(m)) = \Phi(m) \otimes \mathbb{1}_{\mathcal{A}};$$

that is, we have the following.

Lemma 1: $\mathrm{Im}\,\Phi$ *is contained in the subspace of coinvariant elements of* $\mathrm{End}(V)$.

Now we consider the case when V contains a sub-comodule V_1. Let $P \in \mathrm{End}(V)$ be a projection onto V_1, i.e., $\mathrm{Im}\,P = V_1$ and $P^2 = P$. It can be easily shown that $\Phi(P)$ satisfies

$$\Phi(P)V\subset V_1 \quad \text{and} \quad \Phi(P)v_1=v_1\int 1_{\mathcal{A}}, \quad \forall v_1\in V_1.$$

Suppose now that $\int 1_{\mathcal{A}}\neq 0$. This implies that $\int$ is even. Thus $\Phi(P)$ is even as well, and hence it is a comodule endomorphism of V. It follows that $\mathrm{Ker}\,\Phi(P)$ is a comodule complement of V_1 in V. Since this holds for any finite-dimensional right $\mathcal{A}$-comodule V and any of its subcomodules, we conclude that all finite-dimensional right $\mathcal{A}$-comodules are completely reducible. Using the basic fact that all finitely generated comodules are finite-dimensional, it follows by means of standard arguments (known, for example, from the general theory of semisimple modules over rings) that all (not necessarily finite-dimensional) right $\mathcal{A}$-comodules are completely reducible.

Conversely, let $\mathcal{A}$ be a Hopf superalgebra such that all right $\mathcal{A}$-comodules are completely reducible. In particular, $\mathcal{A}$ regarded as a right $\mathcal{A}$-comodule with structure map Δ is completely reducible. Let $\mathcal{A}_0$ be a comodule complement of $\mathbb{C}1_{\mathcal{A}}$ in $\mathcal{A}$. Then any linear form $\int^r$ on $\mathcal{A}$ with kernel $\mathcal{A}_0$ is a right(!) integral on $\mathcal{A}$ such that $\int^r 1_{\mathcal{A}}\neq 0$. Applying the foregoing to $\mathcal{A}^{\mathrm{aop,cop}}$ and $\int^r$ (which is a left integral on $\mathcal{A}^{\mathrm{aop,cop}}$) we conclude that all left $\mathcal{A}$-comodules are completely reducible and that $\mathcal{A}$ also has a left integral $\int^l$ such that $\int^l 1_{\mathcal{A}}\neq 0$. It should be noted that according to Larson[6] analogous results hold for Hopf algebras, comodules and integrals living in an arbitrary tensor category.

Actually, much more can be said. Let $\{V(\lambda)|\lambda\in\Lambda\}$ be a complete representative set of all finite-dimensional right $\mathcal{A}$-comodules, where Λ is some index set. Among these, there is a one-dimensional comodule, $V(0)$, say, such that under the coaction, $v\mapsto v\otimes 1_{\mathcal{A}}$. We call $V(0)$ the trivial $\mathcal{A}$-comodule. For each $V(\lambda)$, we choose a basis $\{v_a^{(\lambda)}|a=1,2,\ldots,\dim V(\lambda)\}$. Then under the coaction of $\mathcal{A}$, we have

$$\omega(v_a^{(\lambda)})=\sum_b v_b^{(\lambda)}\otimes t_{ba}^{(\lambda)},$$

and the $t_{ab}^{(\lambda)}$ form a Peter-Weyl type of basis for $\mathcal{A}$. If $\int$ denotes the linear form on $\mathcal{A}$ defined by

$$\int 1_{\mathcal{A}}=1, \quad \int t_{ab}^{(\lambda)}=0, \quad \forall\lambda\neq 0,$$

then $\int$ is both a left and right integral on $\mathcal{A}$ and, obviously, it is even.

Summarizing part of our results, we have proved the following generalization of the well-known Maschke's theorem to the case of Hopf superalgebras (see Refs. 1, 6, and 2).

Proposition 2: The Hopf superalgebra $\mathcal{A}$ admits a left integral $\int$ with $\int 1_{\mathcal{A}}\neq 0$ if and only if all right $\mathcal{A}$-comodules are completely reducible.

In the present work we are mainly interested in the case where $\mathcal{A}$ is a sub-Hopf-superalgebra of the finite dual $\mathcal{U}^\circ$ of a Hopf superalgebra $\mathcal{U}$. The comultiplication, counit, and antipode of $\mathcal{U}$ will also be denoted by Δ, ε, and S, respectively. In this case, if V is a right $\mathcal{A}$-comodule, then V also has a natural left $\mathcal{U}$-module structure defined by

$$x\,v=(-1)^{[x][v]}(\omega(v))(x), \quad \forall x\in\mathcal{U}, v\in V.$$

We denote by $\mathcal{U}-\mathrm{Mod}_r$ the collection of all the left $\mathcal{U}$-modules obtained from finite-dimensional right $\mathcal{A}$-comodules, which forms a monoidal category. The above proposition is equivalent to the following statement: The category $\mathcal{U}-\mathrm{Mod}_r$ is semisimple if and only if $\mathcal{A}$ admits a left integral which does not vanish on the identity.

Let us close this section by the following simple remark. As above, let $\mathcal{A}$ be a sub-Hopf-superalgebra of $\mathcal{U}^\circ$. The even grouplike elements of $\mathcal{U}^\circ$ are exactly the characters of $\mathcal{U}$, i.e., the superalgebra homomorphisms of $\mathcal{U}$ into $\mathbb{C}$. By convention, $\mathcal{A}$ always contains the unit element of $\mathcal{U}^\circ$, i.e., the counit $\varepsilon_{\mathcal{U}}$ of $\mathcal{U}$. This is the so-called trivial character of $\mathcal{U}$. Now Proposition 1 implies the following lemma.

Lemma 2: Suppose that $\mathcal{A}$ does not contain any non-trivial character of $\mathcal{U}$. Then every left integral on $\mathcal{A}$ is also a right integral.

III. INTEGRALS ON CLASSICAL SUPERGROUPS

Let $\mathfrak{g}=\mathfrak{g}_{\bar{0}}\oplus\mathfrak{g}_{\bar{1}}$ be a finite-dimensional Lie superalgebra,[14,15] where $\mathfrak{g}_{\bar{0}}$ and $\mathfrak{g}_{\bar{1}}$ are the even and odd subspaces respectively. We take $\mathcal{U}$ to be the enveloping algebra $U(\mathfrak{g})$ of $\mathfrak{g}$. $U(\mathfrak{g})$ contains the enveloping algebra $U(\mathfrak{g}_{\bar{0}})$ of the Lie subalgebra $\mathfrak{g}_{\bar{0}}$ as a subalgebra. We denote $U(\mathfrak{g}_{\bar{0}})$ by $\mathcal{U}_e$, and let

$$\mathcal{I}: \mathcal{U}_e \to \mathcal{U}$$

be the embedding, which is a Hopf superalgebra map. It is well-known that the dual $\mathcal{I}^*$ of $\mathcal{I}$ induces a Hopf superalgebra map

$$\mathcal{P}: \ \mathcal{U}^\circ \to \mathcal{U}_e^\circ,$$

which is given by

$$\langle \mathcal{P}(a), u\rangle = \langle a\,, \mathcal{I}(u)\rangle, \quad \forall a \in \mathcal{U}^\circ, \quad u \in \mathcal{U}_e\,.$$

In the present work, a Lie supergroup will be defined in terms of its Hopf superalgebra of functions, i.e., we proceed as in the usual definition of quantum groups[16] or quantum supergroups[17] (for a related treatment of supergroups, see Refs. 18 and 19). More precisely, if $\mathfrak{g}$ is a Lie superalgebra, the superalgebra of functions on a Lie supergroup associated to $\mathfrak{g}$ will be a sub-Hopf-superalgebra $\mathcal{A}$ of $\mathcal{U}^\circ = U(\mathfrak{g})^\circ$, subject to the condition that $\mathcal{A}$ be dense in $U(\mathfrak{g})^*$. Actually, in our discussion of integrals, this latter property will not be used.

Thus, let $\mathcal{A}$ be a sub-Hopf-superalgebra of $\mathcal{U}^\circ$. We set

$$\mathcal{P}(\mathcal{A}) = \mathcal{A}_e\,,$$

which is a Hopf subalgebra of $\mathcal{U}_e^\circ$. Then there exist the following natural Hopf superalgebra maps (which are injective if $\mathcal{A}$ is dense in $\mathcal{U}^*$ and, consequently, $\mathcal{A}_e$ is dense in $\mathcal{U}_e^*$):

$$\nu: U(\mathfrak{g}) \to \mathcal{A}^\circ,$$

$$x \mapsto \nu(x), \ \ \langle \nu(x), a\rangle = (-1)^{[x][a]}\langle a, x\rangle, \quad \forall a \in \mathcal{A}; \tag{6}$$

$$\nu_e : \mathcal{U}_e \to \mathcal{A}_e^\circ,$$

$$u \mapsto \nu_e(u) = \tilde{u}\,, \ \ \langle \tilde{u}, a_0\rangle = \langle a_0\,, u\rangle, \quad \forall a_0 \in \mathcal{A}_e\,;$$

$$\hat{\mathcal{I}} = \nu\mathcal{I}: \mathcal{U}_e \to \mathcal{A}^\circ,$$

$$u \mapsto \hat{u}\,, \ \ \langle \hat{u}, a\rangle = \langle \tilde{u}, \mathcal{P}(a)\rangle = \langle \mathcal{P}(a), u\rangle = \langle a, \mathcal{I}(u)\rangle, \quad \forall a \in \mathcal{A}. \tag{7}$$

Let

$$\int_0 : \mathcal{A}_e \to \mathbb{C}$$

be a left integral on $\mathcal{A}_e$ with $\int_0 \mathbb{1}_{\mathcal{A}_e} = 1$. The existence of $\int_0$ depends on properties of $\mathfrak{g}_{\bar{0}}$ and $\mathcal{A}_e$. In the case when $\mathfrak{g}_{\bar{0}}$ is semisimple or reductive as a Lie algebra, such an $\int_0$ is known to exist and is right invariant as well. (However, see the Appendix about the reductive case.)

Lemma 3: The linear form $\int_0 \mathcal{P}: \mathcal{A} \to \mathbb{C}$ is left invariant with respect to $\mathcal{U}_e$ in the sense that

$$\hat{\mathcal{I}}(u)\cdot\left(\int_0\mathcal{P}\right)=\varepsilon(u)\int_0\mathcal{P},\quad \forall u\in\mathcal{U}_e.$$

Proof: Lemma 3 can be confirmed by a direct calculation. For any $u\in\mathcal{U}_e$ and $a\in\mathcal{A}$, we have

$$\begin{aligned}\left\langle \hat{u}\cdot\left(\int_0\mathcal{P}\right),a\right\rangle&=\sum_{(a)}\langle\hat{u},a_{(1)}\rangle\int_0\mathcal{P}(a_{(2)})\\&=\sum_{(a)}\langle\tilde{u},\mathcal{P}(a_{(1)})\rangle\int_0\mathcal{P}(a_{(2)})\\&=\left\langle\tilde{u}\otimes\int_0,\Delta\mathcal{P}(a)\right\rangle\\&=\left\langle\tilde{u}\cdot\int_0,\mathcal{P}(a)\right\rangle=\varepsilon(u)\int_0\mathcal{P}(a).\end{aligned}$$

Let $J=\mathcal{U}\mathfrak{g}_0^-$. By using the Poincaré–Birkhoff–Witt theorem for Lie superalgebras,[15] one immediately sees the following.

Lemma 4: The subspace J is a left ideal of $\mathcal{U}$ with finite codimension.

Consequently, the quotient space $\mathcal{U}/J$ is a left $\mathcal{U}$-module in the standard fashion:

$$x(y+J)=xy+J,\quad \forall x\in\mathcal{U},\ \ y+J\in\mathcal{U}/J.$$

Note that this module is isomorphic to the $\mathcal{U}$-module induced from the trivial $\mathcal{U}_e$-module. According to the usual definition, an element $z+J\in\mathcal{U}/J$, with $z\in\mathcal{U}$, is said to be invariant (under the action of $\mathcal{U}$) if

$$x(z+J)=\varepsilon(x)z+J,\quad \forall x\in\mathcal{U}.$$

Let $z+J$ be any invariant of this type, and let $\nu(z)$ be the image of z in $\mathcal{A}^\circ$ under the natural Hopf superalgebra map (6). Then we have the following theorem.

Theorem 2: *The linear form $\int=\nu(z)\cdot\int_0\mathcal{P}$ is a left integral on $\mathcal{A}$ and does not depend on the choice of the representative for $z+J$. If $z\notin J$ and if the matrix elements of the $\mathcal{U}$-module $\mathcal{U}/J$ belong to $\mathcal{A}$, the integral $\int$ is not equal to zero.*

Remark: The definition of $\int$ involves implicitly the comultiplication of $\mathcal{A}$. For any $a\in\mathcal{A}$,

$$\int a=\left\langle\nu(z)\otimes\int_0\mathcal{P},\ \ \Delta(a)\right\rangle.$$

Proof of Theorem 2: It follows from Lemma 3 that for any $X_0\in\mathfrak{g}_0^-$, $\nu(X_0)\cdot\int_0\mathcal{P}=0$. As ν is an algebra homomorphism, $\nu(y)\cdot\int_0\mathcal{P}=0$ for all $y\in J$. This proves the second part of the theorem. Now the invariance property of $z+J$ leads to

$$\nu(x)\cdot\int=\varepsilon(x)\int,\quad \forall x\in\mathcal{U}.$$

This implies Eq. (1). [Indeed, since $\mathcal{A}$ is contained in $\mathcal{U}^*$, it is sufficient to check Eq. (2) for all $a^*=\nu(x),\ x\in\mathcal{U}$.]

To prove the last part of the theorem, we choose a homogeneous basis $(v_i)_{1\leqslant i\leqslant r}$ of $\mathcal{U}/J$ such that $v_1=1_{\mathcal{U}}+J$. Let π be the representation of $\mathcal{U}$ in $\mathcal{U}/J$, and let $\pi_{i,j}$ be the matrix elements of π with respect to the basis (v_i), i.e.,

$$\pi(x)v_j=\sum_{i=1}^{r}\pi_{i,j}(x)v_i \quad \text{if } x\in\mathcal{U},\ 1\leqslant j\leqslant r.$$

Since v_1 is $\mathcal{U}_e$-invariant, we have

$$\pi_{i,1}(x)=\varepsilon_{\mathcal{U}_e}(x)\,\delta_{i,1} \quad \text{if } x\in\mathcal{U}_e,\ 1\leqslant i\leqslant r.$$

This implies that

$$\int\pi_{i,1}=(-1)^{[v_i]}\pi_{i,1}(z), \quad 1\leqslant i\leqslant r$$

(recall that we are assuming that $\int_0\mathbb{1}_{\mathcal{A}_e}=1$). Since $z\notin J$ and since

$$z+J=\pi(z)v_1=\sum_{i=1}^{r}\pi_{i,1}(z)v_i,$$

at least one of the matrix elements $\pi_{i,1}(z)$ must be different from zero. This proves the theorem.

We notice that

$$\int\mathbb{1}_{\mathcal{A}}=\varepsilon(z)\int_0\mathbb{1}_{\mathcal{A}_e}.$$

Taking for granted that $\int_0\mathbb{1}_{\mathcal{A}_e}$ is different from zero, we see that $\int\mathbb{1}_{\mathcal{A}}\neq 0$ if and only if $\varepsilon(z)\neq 0$.

Remark: Suppose that the Lie algebra $\mathfrak{g}_0^-$ is reductive, and that the adjoint representation of the center of $\mathfrak{g}_0^-$ in $\mathfrak{g}_1^-$ is diagonalizable. Then the subspace of $\mathcal{U}$-invariant elements of $\mathcal{U}/J$ is at most one-dimensional. This follows at once from Theorems 1 and 2, applied to a suitable sub-Hopf-superalgebra $\mathcal{A}$ of $\mathcal{U}^\circ$ (see the Appendix).

Let us now consider examples.

Example 1: The Berezin integral

Consider the purely odd Lie superalgebra $\mathfrak{g}=\mathfrak{g}_1^-$ with the basis $\{\xi_i,\ i=1,2,\ldots,n\}$ and with the super bracket

$$[\xi_i,\xi_j]=0, \quad \forall i,j.$$

Obviously, $\mathcal{U}=U(\mathfrak{g})$ is the Grassmann algebra on the n generators ξ_i, and $\mathcal{U}_e=\mathbb{C}\mathbb{1}_{\mathcal{U}}$. It is well-known that $\mathcal{U}$ has the basis

$$\Xi_{j_1\cdots j_l}=\xi_{j_1}\cdots\xi_{j_l}, \quad 1\leqslant j_1<\cdots<j_l\leqslant n,$$

where the $l=0$ element is understood to be the unity. The Hopf structure of $\mathcal{U}$ is the standard one for enveloping algebras of Lie superalgebras.

Introduce a basis $\{\Theta_{i_1\cdots i_k},\ 1\leqslant i_1<\cdots<i_k\leqslant n,\ 0\leqslant k\leqslant n\}$ for $\mathcal{U}^*$ (the $k=0$ case corresponds to the unit element) such that

$$\langle\Theta_{i_1\cdots i_k},\Xi_{j_1\cdots j_l}\rangle=(-1)^{(1/2)\,k(k-1)}\delta_{kl}\,\delta_{i_1j_1}\cdots\delta_{i_kj_k},$$

and set

$$\theta_i=\Theta_i, \quad i=1,2,\ldots,n.$$

The cocommutativity of $\mathcal{U}$ implies that

$$\theta_i\theta_j+\theta_j\theta_i=0, \quad \forall i,j.$$

It is also easy to show that

$$\Theta_{i_1\cdots i_k}=\theta_{i_1}\cdots\theta_{i_k},\quad i_1<\cdots<i_k.$$

As a Hopf superalgebra, $\mathcal{U}^*$ has the unique comultiplication such that

$$\Delta(\theta_i)=\theta_i\otimes\mathbb{1}+\mathbb{1}\otimes\theta_i,$$

the counit is fixed by

$$\varepsilon(\theta_i)=0,$$

and the antipode is specified by

$$S(\theta_i)=-\theta_i.$$

Since $(\mathcal{U}^*)^*\cong\mathcal{U}$ in this case, we make the identification. It is obvious that $\int_0\mathcal{P}=\mathbb{1}_{\mathcal{U}}$. Moreover, the $\mathcal{U}$-invariant elements of $\mathcal{U}$ are the scalar multiples of $\Xi_{1\,2\,\cdots\,n}$. Thus upon choosing an appropriate normalization we obtain the unique integral

$$\int=(-1)^{(1/2)\,n(n-1)}\xi_1\xi_2\cdots\xi_n,$$

which yields the standard Berezin integral on the Grassmanian algebra $\mathcal{U}^*$:

$$\int\theta_{i_1}\theta_{i_2}\cdots\theta_{i_k}=0,\quad \text{if } k<n,$$

$$\int\theta_1\theta_2\cdots\theta_n=1.$$

To explain the left (and right) invariance of $\int$ in more familiar terms, note that if $P(\theta)$ is any polynomial in the θ_i's, then

$$\Delta P(\theta)=P(\theta\otimes\mathbb{1}+\mathbb{1}\otimes\theta).$$

Left invariance of the integral means

$$\left(\mathrm{id}\otimes\int\right)\Delta(P(\theta))=\int P(\theta).$$

One may write $\mathbb{1}\otimes\theta_i$ as θ_i, and denote $\theta_i\otimes\mathbb{1}$ by λ_i, which is regarded as an independent Grassmann number. The above equation states that

$$\int_\theta P(\theta+\lambda)=\int P(\theta),$$

where the subscript θ on the left hand side indicates the fact that the ''integration'' is carried out over the θ's. The last equation is nothing but the translational invariance of the Berezin integral.

Example 2: The Lie supergroup $\mathrm{SL}(m|n)$

Let $\mathfrak{g}$ denote the Lie superalgebra $\mathfrak{sl}(m|n)$, which we shall regard as a subalgebra of the general linear Lie superalgebra $\mathfrak{gl}(m|n)$. Let $\{E_{ab}\,|\,a,b=1,2,\ldots,m+n\}$ be the standard homogeneous basis of $\mathfrak{gl}(m|n)$, which satisfies the commmutation relations

$$[E_{ab},E_{cd}]=\delta_{bc}E_{ad}-(-1)^{[E_{ab}][E_{cd}]}\delta_{da}E_{cb},$$

where $[\cdot,\cdot]$ should be understood as the graded brackets, namely, it is symmetric when both arguments are odd, and antisymmetric otherwise.

The standard basis for $\mathfrak{g}$ then is given by

$$E_{ab}, \quad a\neq b; \quad h_a=E_{aa}-(-1)^{\delta_{am}}E_{a+1,\,a+1}, \quad a<m+n.$$

The maximal even subalgebra of $\mathfrak{g}$ is $\mathfrak{g}_{\bar{0}}=\mathfrak{sl}(m)\oplus\mathfrak{sl}(n)\oplus\mathfrak{gl}(1)$. Let $\mathfrak{g}_{\bar{1}+}$ be the odd subalgebra spanned by $E_{i\mu}$, $i\leqslant m$, $\mu>m$, and $\mathfrak{g}_{\bar{1}-}$ be that spanned by $E_{\mu i}$. Then $\mathfrak{g}$ is the direct sum $\mathfrak{g}=\mathfrak{g}_{\bar{1}-}\oplus\mathfrak{g}_{\bar{0}}\oplus\mathfrak{g}_{\bar{1}+}$ (as vector spaces). Under the Lie superbracket,

$$\begin{gathered}[\mathfrak{g}_{\bar{1}+},\mathfrak{g}_{\bar{1}+}]=\{0\}, \quad [\mathfrak{g}_{\bar{1}-},\mathfrak{g}_{\bar{1}-}]=\{0\},\\ [\mathfrak{g}_{\bar{0}},\mathfrak{g}_{\bar{1}\pm}]\subset\mathfrak{g}_{\bar{1}\pm}, \quad [\mathfrak{g}_{\bar{1}+},\mathfrak{g}_{\bar{1}-}]\subset\mathfrak{g}_{\bar{0}}.\end{gathered} \tag{8}$$

Next, we observe that $U(\mathfrak{g}_{\bar{1}+})$ and $U(\mathfrak{g}_{\bar{1}-})$ are both isomorphic to the Grassmann algebra on mn generators. The subspaces of the highest Grassmann degree in $U(\mathfrak{g}_{\bar{1}+})$ and $U(\mathfrak{g}_{\bar{1}-})$ are both one-dimensional. We choose the following bases for them, respectively,

$$\mathbb{E}=\mathbb{E}_m\,\mathbb{E}_{m-1}\cdots\mathbb{E}_1, \quad \mathbb{F}=\mathbb{F}_1\,\mathbb{F}_2\cdots\mathbb{F}_m,$$

where

$$\mathbb{E}_i=E_{i,m+1}\,E_{i,m+2}\cdots E_{i,m+n},$$

$$\mathbb{F}_i=E_{m+n,i}\,E_{m+n-1,i}\cdots E_{m+1,i}.$$

Then we have

$$[X,\mathbb{E}]=[X,\mathbb{F}]=0, \quad \forall X\in\mathfrak{g}_{\bar{0}},$$

$$\xi_+\mathbb{E}=0, \quad \forall\xi_+\in\mathfrak{g}_{\bar{1}+},$$

$$\xi_-\mathbb{F}=0, \quad \forall\xi_-\in\mathfrak{g}_{\bar{1}-},$$

$$\xi_-\mathbb{E}-(-1)^{mn}\mathbb{E}\,\xi_-\in U(\mathfrak{g})\mathfrak{g}_{\bar{0}}, \quad \forall\xi_-\in\mathfrak{g}_{\bar{1}-}.$$

Defining

$$\Gamma=\mathbb{E}\,\mathbb{F},$$

it follows that

$$X\Gamma\in U(\mathfrak{g})\mathfrak{g}_{\bar{0}}, \quad \forall X\in\mathfrak{g}.$$

Let t be the defining representation of $\mathfrak{sl}(m|n)$, with

$$t(E_{ab})=e_{ab}, \quad a\neq b,$$

$$t(h_a)=e_{aa}-(-1)^{\delta_{am}}e_{a+1,\,a+1},$$

where the e_{ab}'s are the matrix units, and let t_{ab}, $a,b=1,2,\ldots,m+n$, be the elements of $\mathcal{U}^\circ = U(\mathfrak{g})^\circ$ defined by

$$(t_{ab}(x))_{a,\,b=1}^{m+n} = t(x), \quad \forall x \in U(\mathfrak{g}).$$

Moreover, let $\overline{t}$ be the dual representation of t, and let us similarly introduce the matrix elements $\overline{t}_{ab} \in U(\mathfrak{g})^\circ$ of $\overline{t}$. We note that

$$\sum_c \overline{t}_{ca} t_{cb} (-1)^{([a]+[c])([b]+\overline{1})} = \delta_{ab}.$$

The standard comultiplication on $U(\mathfrak{g})$ is super cocommutative. Therefore the finite dual $U(\mathfrak{g})^\circ$ is a super commutative Hopf superalgebra. The matrix elements t_{ab} and $\overline{t}_{ab}$ of the vector representation and the dual vector representation generate a sub-Hopf-superalgebra $\mathcal{A}$ of $U(\mathfrak{g})^\circ$, with the comultiplication

$$\Delta(t_{ab}) = \sum_c t_{ac} \otimes t_{cb} (-1)^{([a]+[c])([c]+[b])},$$

$$\Delta(\overline{t}_{ab}) = \sum_c \overline{t}_{ac} \otimes \overline{t}_{cb} (-1)^{([a]+[c])([c]+[b])},$$

the counit $\varepsilon(t_{ab}) = \varepsilon(\overline{t}_{ab}) = \delta_{ab}$, and the involutary antipode $S(t_{ab}) = (-1)^{[a]([a]+[b])} \overline{t}_{ba}$, where

$$[a] = \begin{cases} \overline{0}, & a \leqslant m, \\ \overline{1}, & a > m. \end{cases}$$

An important fact is the following.

Proposition 3: The subspace $\mathcal{A}$ is dense in $U(\mathfrak{sl}(m|n))^*$.

Proof: This follows from a slight strengthening of a theorem which in the nongraded case is due to Harish-Chandra. Let V be a finite-dimensional graded vector space and let $\mathfrak{g}$ be a graded subalgebra of the Lie superalgebra $\mathfrak{sl}(V)$. We regard V as a $\mathfrak{g}$-module. Arguing as in the nongraded case (see the proof of Theorem 2.5.7 in Ref. 20) one can easily prove that for any nonzero element $x \in U(\mathfrak{g})$ there exists an integer $r \geqslant 0$ such that x acts nontrivially on $V^{\otimes r}$. Actually, there is a minor complication: Dixmier's proof only applies if $\dim V_{\overline{0}} \neq \dim V_{\overline{1}}$. But if $\dim V_{\overline{0}} = \dim V_{\overline{1}}$, we can embed V into $W = V \oplus \mathbb{C}$, where $\mathbb{C}$ is regarded as a trivial $\mathfrak{g}$-module. Then his arguments apply to W, and the tensorial powers of W are isomorphic to direct sums of tensorial powers of V. This proves the proposition.

As at the beginning of this section, let $\mathcal{P}$ be the dual of the embedding of $U(\mathfrak{g}_{\overline{0}})$ in $U(\mathfrak{g})$. We have

$$\mathcal{P}(t_{i\mu}) = \mathcal{P}(t_{\mu i}) = \mathcal{P}(\overline{t}_{i\mu}) = \mathcal{P}(\overline{t}_{\mu i}) = 0, \quad 1 \leqslant i \leqslant m, \quad m < \mu \leqslant m+n.$$

Set

$$\mathcal{A}_e = \mathcal{P}(\mathcal{A}).$$

Then $\mathcal{A}_e$ has a Peter-Weyl type basis in terms of the matrix elements of irreducible finite-dimensional representations of $\mathfrak{sl}(m) \oplus \mathfrak{sl}(n) \oplus \mathfrak{gl}(1)$. Thus it follows from the discussion of the last section that there exists a unique normalized left integral

$$\int_0 : \ \mathcal{A}_e \to \mathbb{C},$$

which also turns out to be right invariant (see the Appendix). Denote by $\nu(\Gamma) \in \mathcal{A}^\circ$ the image of Γ under the natural embedding $U(\mathfrak{g}) \to \mathcal{A}^\circ$. Recalling Lemma 2, we have the following theorem.

Theorem 3: *The linear form $\int = \nu(\Gamma) \cdot \int_0 \mathcal{P}$ is a nontrivial left and right integral on $\mathcal{A}$.*

To see that $\int$ is indeed nontrivial, we consider $\int \Theta \overline{\Theta}$, where

$$\Theta_i = t_{i,m+n} t_{i,\, m+n-1} \cdots t_{i,m+1},$$

$$\overline{\Theta}_i = \overline{t}_{i,m+n} \overline{t}_{i,m+n-1} \cdots \overline{t}_{i,m+1}, \quad i = 1, 2, \ldots, m,$$

$$\Theta = \Theta_m \Theta_{m-1} \cdots \Theta_1,$$

$$\overline{\Theta} = \overline{\Theta}_m \overline{\Theta}_{m-1} \cdots \overline{\Theta}_1.$$

We have

$$\int \Theta \overline{\Theta} = \langle \Theta \overline{\Theta}, \mathbb{E}\mathbb{F} \rangle \int_0 \mathcal{P}(\det(t_{\mu\nu}) \det(\overline{t}_{\mu\nu}))^m.$$

As

$$\det(t_{\mu\nu}) \det(\overline{t}_{\mu\nu})(u) = \varepsilon(u), \quad \forall u \in U(\mathfrak{g}_0^-),$$

we immediately obtain

$$\int_0 \mathcal{P}(\det(t_{\mu\nu}) \det(\overline{t}_{\mu\nu}))^m = 1.$$

By induction we can show that

$$\langle \Theta \overline{\Theta}, \mathbb{E}\mathbb{F} \rangle = (-1)^{mn(mn+1)/2},$$

hence

$$\int \Theta \overline{\Theta} = (-1)^{mn(mn+1)/2}.$$

Example 3: The Lie supergroup $\mathrm{OSP}(2|2n)$

The Lie superalgebras $\mathfrak{g} = \mathfrak{osp}(2|2n)$ form the other series of type I (basic classical) Lie superalgebras besides $\mathfrak{sl}(m|n)$. They share many properties with the latter. In particular, the odd subspace of $\mathfrak{osp}(2|2n)$ is a direct sum of $\mathfrak{g}_{1+}^-$ and $\mathfrak{g}_{1-}^-$. Both $U(\mathfrak{g}_{1+}^-)$ and $U(\mathfrak{g}_{1-}^-)$ are isomorphic to the Grassmann algebra on $2n$ generators. The maximal even subalgebra of $\mathfrak{osp}(2|2n)$ is $\mathfrak{sp}(2n) \oplus \mathfrak{gl}(1)$, and $\mathfrak{g}_0^-$ and $\mathfrak{g}_{1\pm}^-$ satisfy relations of the same form as (8).

The subspaces of $U(\mathfrak{g}_{1\pm}^-)$ of the highest Grassmann degree are both one-dimensional. We choose bases $\mathbb{E}$ and $\mathbb{F}$ for them, respectively, and set $\Gamma = \mathbb{E}\mathbb{F}$. Then

$$X\Gamma \in U(\mathfrak{g})\mathfrak{g}_0^-, \quad \forall X \in \mathfrak{g}.$$

Let t be the defining representation of $\mathfrak{osp}(2|2n)$. It is known that t is self-dual. Introduce the matrix elements of t,

$$t_{ab} \in U(\mathfrak{g})^\circ, \quad a, b = 1,2,\ldots,2n+2,$$

with t_{ij} and $t_{\mu\nu}$ being even, and $t_{i\mu}$ and $t_{\mu i}$ odd, where $i,j=1,2$; $\mu,\nu=3,4,\ldots,2n+2$.

Proposition 4: The elements t_{ab} generate a sub-Hopf-superalgebra $\mathcal{A}$ of $U(\mathfrak{osp}(2|2n))^\circ$, and $\mathcal{A}$ is dense in $U(\mathfrak{osp}(2|2n))^*$.

Proof: This follows from the proof of Proposition 3.

Set $\mathcal{A}_e=\mathcal{P}(\mathcal{A})$. Then $\mathcal{A}_e$ admits a unique (up to scalar multiples) left integral $\int_0$. Denoting by $\nu(\Gamma)$ the canonical image of Γ in $\mathcal{A}^\circ$, we have

Theorem 4: *The linear form $\int=\nu(\Gamma)\cdot\int_0\mathcal{P}$ is a nontrivial left and right integral on $\mathcal{A}$.*

The $t_{i\mu}$ and $t_{\mu i}$ generate a Grassmann algebra contained in $\mathcal{A}$. We take Θ to be a nonzero element of the highest degree in this Grassmann algebra. Then direct computations can show that

$$\int\Theta\neq 0.$$

Example 4: The Lie supergroup OSP$(1|2n)$

Let us start with the simplest case, $n=1$. The Dynkin diagram of $\mathfrak{osp}(1|2)$ is just ●, and the simple Chevalley generators are $\{e,f,h\}$, where e and f are odd while h is even, with the commutation relations

$$[h,e]=e,\ [h,f]=-f,\ [e,f]=h.$$

It is important to observe that $[e,e]=E$, $[f,f]=F$ and h span an $\mathfrak{sl}(2)$ subalgebra, which is the maximal even subalgebra $\mathfrak{osp}(1|2)_{\bar 0}$. This is a general feature of any type II superalgebra, where some simple generators of the maximal even subalgebra are generated by odd elements. We denote $\mathfrak{g}=\mathfrak{osp}(1|2)$, $\mathfrak{g}_{\bar 0}=\mathfrak{sl}(2)\subset\mathfrak{osp}(1|2)$, $\mathcal{U}=U(\mathfrak{g})$ and $\mathcal{U}_e=U(\mathfrak{g}_{\bar 0})$.

Now

$$\mathbb{1}+ef+\mathcal{U}\mathfrak{g}_{\bar 0}^-$$

is an invariant of the left $\mathcal{U}$-module $\mathcal{U}/\mathcal{U}\mathfrak{g}_{\bar 0}^-$, and we have the left and right integral

$$\int\ =\nu(\mathbb{1}+ef)\cdot\int_0\mathcal{P}:\mathcal{U}^\circ\to\mathbb{C},$$

where $\int_0:\mathcal{U}_e^\circ\to\mathbb{C}$ is the standard Haar functional on $\mathcal{U}_e^\circ$. Consider $\int\mathbb{1}_{\mathcal{U}^\circ}$. We have

$$\int\mathbb{1}_{\mathcal{U}^\circ}=\langle\mathbb{1}_{\mathcal{U}^\circ},\mathbb{1}+ef\rangle\int_0\mathcal{P}(\mathbb{1}_{\mathcal{U}^\circ})=\int_0\mathbb{1}_{\mathcal{U}_e^\circ}\neq 0.$$

That is, the integral does not vanish on the identity element of $\mathcal{U}^\circ$. It follows from the discussion of Sec. II that all finite-dimensional representations of $\mathfrak{osp}(1|2)$ are completely reducible, which, of course, is a well-known fact.

The general case can be treated similarly. We do not go into details but only mention that an even element $u_0\in\mathcal{U}=U(\mathfrak{osp}(1|2n))$ such that $\varepsilon(u_0)\neq 0$ and such that $u_0+\mathcal{U}\mathfrak{g}_{\bar 0}^-$ is invariant in $\mathcal{U}/\mathcal{U}\mathfrak{g}_{\bar 0}^-$ has been constructed by Djoković and Hochschild in Ref. 21. Moreover, they have proved the following theorem:

Let $\mathfrak{g}$ be a finite-dimensional Lie superalgebra over a field of characteristic zero. Then all finite-dimensional representations of $\mathfrak{g}$ are completely reducible if and only if the following two conditions are satisfied.

(1) The Lie algebra $\mathfrak{g}_{\bar 0}^-$ is semisimple.
(2) There is an element u_0 in $U(\mathfrak{g})$ such that $u_0+U(\mathfrak{g})\mathfrak{g}_{\bar 0}^-$ is an invariant element of $U(\mathfrak{g})/U(\mathfrak{g})\mathfrak{g}_{\bar 0}^-$ and satisfies $\varepsilon(u_0)\neq 0$.

Visibly, in the cited reference the element u_0 has been a decisive tool in the proof that all finite-dimensional representations of $\mathfrak{osp}(1|2n)$ are completely reducible. It is remarkable that in

the present work it serves to construct a left integral on $\mathcal{U}^\circ$ which does not vanish on the unit element, a result which, in turn, implies the complete reducibility of the $\mathcal{U}^\circ$-comodules and hence of the finite-dimensional $\mathcal{U}$-modules.

Example 5: The Lie supergroup OSP$(3|2)$

Let $\mathfrak{g}$ denote the Lie superalgebra $\mathfrak{osp}(3|2)$. It is the simplest of those orthosymplectic Lie superalgebras which are not of type I and not one of the special algebras $\mathfrak{osp}(1|2n)$. Its maximal even subalgebra is $\mathfrak{g}_{\bar{0}}=\mathfrak{so}(3)\oplus\mathfrak{sp}(2)$. The $\mathfrak{g}$-module $U(\mathfrak{g})/U(\mathfrak{g})\mathfrak{g}_{\bar{0}}$ will be denoted by W. We shall also need the quadratic Casimir element $C\in U(\mathfrak{g})$ and the corresponding Casimir operator C_W acting on W.

In the subsequent investigation of the $\mathfrak{g}$-module W we are going to use the classification of finite-dimensional irreducible $\mathfrak{g}$-modules obtained by Van der Jeugt in Ref. 22. Both the $\mathfrak{g}$-modules and the $\mathfrak{g}_{\bar{0}}$-modules are characterized by a pair of numbers $p,q\in\{0,\frac{1}{2},1,\frac{3}{2},\ldots\}$. By a slight abuse of notation, we denote the corresponding $\mathfrak{g}$-module by $[p,q]$, and the corresponding $\mathfrak{g}_{\bar{0}}$-module by (p,q). [We remark that p is associated in the obvious way to $\mathfrak{so}(3)$ and q to $\mathfrak{sp}(2)$.]

A version of the Poincaré–Birkhoff–Witt theorem implies that W, regarded as a $\mathfrak{g}_{\bar{0}}$-module, is isomorphic to the Grassmann algebra constructed over $\mathfrak{g}_{\bar{1}}$. Using the representation theory of $\mathfrak{sl}(2)$, we conclude that the $\mathfrak{g}_{\bar{0}}$-module W decomposes into the direct sum of the modules contained in the following list, where the first line gives the Grassmann degree to which the modules underneath belong.

$$
\begin{array}{ccccccc}
0 & 1 & 2 & 3 & 4 & 5 & 6 \\
(0,0) & (1,\tfrac{1}{2}) & (1,1) & (2,\tfrac{1}{2}) & (1,1) & (1,\tfrac{1}{2}) & (0,0) \\
 & & (2,0) & (1,\tfrac{1}{2}) & (2,0) & & \\
 & & (0,0) & (0,\tfrac{3}{2}) & (0,0) & &
\end{array}
$$

Comparison with the lower-dimensional irreducible $\mathfrak{g}$-modules then shows that for a Jordan-Hölder sequence of the $\mathfrak{g}$-module W the irreducible quotients must be isomorphic to the following modules:

$$
[0,\tfrac{3}{2}],\ [1,1],\ [1,\tfrac{1}{2}],\ [0,0],\ [0,0].
$$

For the convenience of the reader and for later use, we also note how these modules decompose into irreducible $\mathfrak{g}_{\bar{0}}$-submodules, moreover, in the first column we give the eigenvalue of the quadratic Casimir operator (normalized as in Ref. 22) in these modules:

$$
\begin{aligned}
-6 \quad & [0,\tfrac{3}{2}]\cong(0,\tfrac{3}{2})\oplus(1,1)\oplus(1,\tfrac{1}{2})\oplus(0,0) \\
0 \quad & [1,1]\cong(1,1)\oplus(1,\tfrac{1}{2})\oplus(2,\tfrac{1}{2})\oplus(2,0) \\
2 \quad & [1,\tfrac{1}{2}]\cong(1,\tfrac{1}{2})\oplus(2,0)\oplus(0,0) \\
0 \quad & [0,0]\cong(0,0)
\end{aligned}
$$

Note that at this point it is obvious that the $\mathfrak{g}$-module W is not completely reducible: It is generated, as a $\mathfrak{g}$-module, by a $\mathfrak{g}_{\bar{0}}$-invariant element; the multiplicity of $(0,0)$ in the $\mathfrak{g}_{\bar{0}}$-module W is equal to 4, but the length of the $\mathfrak{g}$-module W (i.e., the number of irreducible quotients of a Jordan-Hölder sequence) is equal to 5.

The eigenvalues given previously imply that the primary decomposition of W with respect to C_W takes the following form:

$$
W=W_{-6}\oplus W_2\oplus W_0, \tag{9}
$$

where W_r, $r\in\{-6,2,0\}$, is the primary subspace of W corresponding to the eigenvalue r of C_W. Of course, the W_r's are $\mathfrak{g}$-submodules of W. Regarded as $\mathfrak{g}$-modules, we have

$$W_{-6}\cong[0,\tfrac{3}{2}],\quad W_2\cong[1,\tfrac{1}{2}],$$

whereas W_0 has a Jordan-Hölder sequence of the form

$$W_0\supset W_0'\supset W_0''\supset\{0\},$$

where one of the three modules W_0/W_0', W_0'/W_0'', W_0'' is isomorphic to $[1,1]$, while the other two are trivial one-dimensional. In any case we have

$$C_W(W_0)\subset W_0', \tag{10}$$

$$C_W(W_0')\subset W_0'', \tag{11}$$

$$C_W(W_0'')=\{0\}. \tag{12}$$

We stress that while W_{-6} and W_2 are eigenspaces of C_W, this is not so for W_0. In fact, we shall see that the restriction of C_W to W_0 is not equal to zero but only nilpotent.

Lemma 5: The subspace $C_W(W_0)$ of W_0 is either a trivial one-dimensional $\mathfrak{g}$-submodule of W_0 or else it is equal to $\{0\}$.

Proof: In the subsequent discussion, it is important to keep the following fact in mind:
(*) The $\mathfrak{g}$-module $[1,1]$ does not contain a trivial $\mathfrak{g}_0^-$-submodule.
There are three cases to consider.

(a) The module W_0/W_0' is isomorphic to $[1,1]$. This case is not possible since W_0, like W_2, is generated by a $\mathfrak{g}_0^-$-invariant element which, under the present assumption and because of (*), would have to belong to W_0'.

(b) The module W_0'/W_0'' is isomorphic to $[1,1]$. In this case, W_0'' consists of $\mathfrak{g}$-invariant elements, hence the existence of nonzero $\mathfrak{g}$-invariant elements in W_0 is obvious. However, we want to find an explicit expression for them, and a first step towards this end is the lemma. According to Eq. (11) we have $C_W(W_0')\subset W_0''$. Using Eq. (12) and recalling (*), we can even conclude that $C_W(W_0')=\{0\}$. Thus C_W induces a $\mathfrak{g}$-module map $W_0/W_0'\to W_0$, and this implies our claim. Actually, it is easy to see that $C_W(W_0)\subset W_0''$.

(c) The module W_0'' is isomorphic to $[1,1]$. Equation (12) says that $C_W(W_0'')=\{0\}$, hence C_W induces a $\mathfrak{g}$-module map $W_0'/W_0''\to W_0'$ which, according to Eq. (11), is even a map into W_0''. Invoking (*) we conclude that $C_W(W_0')=\{0\}$, and our claim follows as in part (b). This proves the lemma.

Let us now recall the decomposition (9) of W and also the fact that the $\mathfrak{g}$-module W is generated by the element $\mathbb{1}_{U(\mathfrak{g})}+U(\mathfrak{g})\mathfrak{g}_0^-$. Then the lemma above can be rephrased as follows: Either the element

$$z=C(C-2)(C+6)\in U(\mathfrak{g})$$

belongs to $U(\mathfrak{g})\mathfrak{g}_0^-$, or else $z+U(\mathfrak{g})\mathfrak{g}_0^-$ is a nontrivial invariant element of $U(\mathfrak{g})/U(\mathfrak{g})\mathfrak{g}_0^-$.

Thus all that remains to be shown is that z does not belong to $U(\mathfrak{g})\mathfrak{g}_0^-$. This is an easy consequence of the Poincaré–Birkhoff–Witt (PBW) theorem, which allows us to construct a suitable basis of W. Actually, the task can be simplified, as follows. The Casimir element C can be decomposed (in various ways) into the sum of two pieces,

$$C=C_o+C_e,$$

where C_o is quadratic in the elements of $\mathfrak{g}_{\bar{1}}^-$, and where C_e belongs to $U(\mathfrak{g}_{\bar{0}}^-)$. Since C commutes with all elements of $U(\mathfrak{g})$, it follows that

$$z \in C_o(C_o-2)(C_o+6)+U(\mathfrak{g})\mathfrak{g}_{\bar{0}}^-,$$

and hence we can replace z by

$$z_o=C_o(C_o-2)(C_o+6).$$

Applying Theorem 2 to z or z_o and recalling Lemma 2 we obtain a nonzero left and right integral on $U(\mathfrak{osp}(3|2))^\circ$.

IV. INTEGRALS ON QUANTUM SUPERGROUPS

We shall extend the construction of integrals on classical supergroups to quantum supergroups at generic q. Recall that the Drinfeld-Jimbo quantum superalgebra $U_q(\mathfrak{g})$ associated with a simple basic classical Lie superalgebra $\mathfrak{g}$ is usually defined with respect to the distinguished simple root system of $\mathfrak{g}$ where only one odd simple root exists. By removing the odd simple generators (but retaining the corresponding Cartan generator), one obtains a graded quantum subalgebra $U_q(\mathfrak{g}_0)\subset U_q(\mathfrak{g})$, where $\mathfrak{g}_0\subset\mathfrak{g}$ is an even subalgebra of $\mathfrak{g}$, which is a reductive Lie algebra. We stress that while for the basic classical Lie superalgebras of type I we have $\mathfrak{g}_0=\mathfrak{g}_{\bar{0}}^-$, this is *not* the case for type II.

An important fact is that $U_q(\mathfrak{g}_0)$ forms a Hopf subalgebra of $U_q(\mathfrak{g})$, with its structure inherited from the latter. We have the following Hopf superalgebra maps:

$$\mathcal{I}:\ U_q(\mathfrak{g}_0)\to U_q(\mathfrak{g}),$$

$$\mathcal{P}:\ U_q(\mathfrak{g})^\circ\to U_q(\mathfrak{g}_0)^\circ,$$

where $\mathcal{I}$ is the natural embedding and $\mathcal{P}$ is induced from its dual $\mathcal{I}^*$.

A quantum supergroup associated with $U_q(\mathfrak{g})$ is defined by specifying its superalgebra of functions $\mathcal{A}$, where $\mathcal{A}$ should meet two basic requirements, namely, it forms a sub-Hopf-superalgebra of $U_q(\mathfrak{g})^\circ$, and it is dense in $U_q(\mathfrak{g})^*$. In general, $\mathcal{A}$ is generated by the matrix elements of some finite-dimensional irreducible representations of $U_q(\mathfrak{g})$. The structure of $\mathcal{A}$ associated with a type I quantum superalgebra has been extensively studied. The fact that $\mathcal{A}$ is dense in $U_q(\mathfrak{g})^*$ implies that the natural Hopf superalgebra maps

$$\nu:\ U_q(\mathfrak{g})\to\mathcal{A}^\circ,$$

$$\hat{\mathcal{I}}=\nu\mathcal{I}:\ U_q(\mathfrak{g}_0)\to\mathcal{A}^\circ,$$

are embeddings.

Denote $\mathcal{A}_e=\mathcal{P}(\mathcal{A})$. Then $\mathcal{A}_e$ separates points of $U_q(\mathfrak{g}_0)$, i.e., it is dense in $U_q(\mathfrak{g}_0)^*$. Furthermore, $\mathcal{A}_e$ admits a Peter-Weyl type basis in terms of the matrix elements of finite-dimensional irreducible representations of $U_q(\mathfrak{g}_0)$, and there exists a unique (up to scalar multiples) left integral

$$\int_0:\ \mathcal{A}_e\to\mathbb{C},$$

which also turns out to be right invariant, and it is nonvanishing on $1_{\mathcal{A}_e}$.

Similar to the classical case, we consider

$$\int_0\mathcal{P}:\ \mathcal{A}\to\mathbb{C},$$

which is clearly left invariant with respect to $U_q(\mathfrak{g}_0)$, i.e.,

$$\hat{\mathcal{I}}(u)\cdot\int_0\mathcal{P}=\varepsilon(u)\int_0\mathcal{P},\quad \forall u\in U_q(\mathfrak{g}_0).$$

Let K denote the ideal of $U_q(\mathfrak{g}_0)$ defined by

$$K=\{u\in U_q(\mathfrak{g}_0)|\ \varepsilon(u)=0\},$$

where ε is the counit of $U_q(\mathfrak{g})$. Then

$$J=U_q(\mathfrak{g})K \tag{13}$$

is a left ideal of $U_q(\mathfrak{g})$.

Lemma 6: If $\mathfrak{g}$ *is one of the Lie superalgebras* $\mathfrak{sl}(m|n)$ *or* $\mathfrak{osp}(2|2n)$ (*i.e., if* $\mathfrak{g}$ *is basic classical of type I*), *the left ideal* J *has finite codimension in* $U_q(\mathfrak{g})$.

Proof: This follows immediately from the PBW theorems for these quantum superalgebras established in Refs. 23 and 24.

Clearly $U_q(\mathfrak{g})/J$ forms a left $U_q(\mathfrak{g})$-module under the natural action

$$x(y+J)=xy+J,\quad \forall x,y\in U_q(\mathfrak{g}).$$

Let $z+J$ be an invariant of $U_q(\mathfrak{g})/J$, i.e., $x(z+J)=\varepsilon(x)z+J$, $\forall x\in U_q(\mathfrak{g})$. Nontrivial invariants of this kind exist for type I quantum superalgebras, as we will see later. However, we doubt that the type II quantum superalgebras admit such invariants, as in this case J is expected to have infinite codimension.

Theorem 5: *Let* $\int=\nu(z)\cdot\int_0\mathcal{P}$. *Then* $\int$ *is a left integral on* $\mathcal{A}$, *that does not depend on the representative of* $z+J$. *As before,* $\nu(z)$ *is the image of* z *under the natural embedding* $U_q(\mathfrak{g})\rightarrow\mathcal{A}^\circ$.

Proof: The proof goes in the same way as in the classical case.

Example 6: *The quantum supergroup* $\mathrm{SL}_q(m|n)$

We study the quantum supergroup $\mathrm{SL}_q(m|n)$. The quantum superalgebra $U_q(\mathfrak{sl}(m|n))$ is generated by the simple and the Cartan generators

$$E_{a,a+1},\quad E_{a+1,a},\quad k_a^{\pm1},\quad a=1,2,\ldots,m+n-1,$$

subject to the standard relations. (Here $k_a=K_aK_{a+1}^{-1}$ in the notation of Ref. 23.) The generators $E_{m,m+1}$ and $E_{m+1,m}$ are odd, while all the others are even. Define recursively

$$E_{ab}=E_{ac}E_{cb}-q_c^{-1}E_{cb}E_{ac},$$

$$E_{ba}=E_{bc}E_{ca}-q_cE_{ca}E_{bc},\quad a<c<b,$$

where $q_c=q^{(-1)^{[c]}}$. The vector representation t of $U_q(\mathfrak{sl}(m|n))$ is given by

$$t(E_{a,a\pm1})=e_{a,a\pm1},$$

$$t(k_a)=q_a^{e_{aa}}q_{a+1}^{-e_{a+1,a+1}}=1+(q_a-1)e_{aa}+(q_{a+1}^{-1}-1)e_{a+1,a+1}.$$

We shall denote the dual vector representation by $\overline{t}$, and let

$$t_{ab},\ \overline{t}_{ab}\in U_q(\mathfrak{sl}(m|n))^\circ,\quad a,b=1,2,\ldots,m+n,$$

be the matrix elements of t and $\bar{t}$, respectively. Then the superalgebra $\mathcal{A}$ of functions on the quantum supergroup $\mathrm{SL}_q(m|n)$ is defined to be the subalgebra of $U_q(\mathfrak{sl}(m|n))^\circ$ generated by the t_{ab}, $\bar{t}_{ab}$. In Ref. 25 the following was shown.

Proposition 5: The algebra $\mathcal{A}$ is a sub-Hopf-superalgebra of $U_q(\mathfrak{sl}(m|n))^\circ$ and is dense in $U_q(\mathfrak{sl}(m|n))^*$.

The quantum even subalgebra $U_q(\mathfrak{g}_0)$ is $U_q(\mathfrak{sl}(m)\oplus\mathfrak{gl}(1)\oplus\mathfrak{sl}(n))$ with generators

$$k_a^{\pm 1},\ E_{b,b+1},\ E_{b+1,b},\quad a,b=1,2,\ldots,m+n-1,\quad b\neq m.$$

The images of t and $\bar{t}$ under $\mathcal{P}$ give rise to representations of $U_q(\mathfrak{g}_0)$, with

$$\mathcal{P}(t)=\begin{pmatrix}\mathcal{P}(t_{ij}) & 0\\ 0 & \mathcal{P}(t_{\mu\nu})\end{pmatrix},\quad \mathcal{P}(\bar{t})=\begin{pmatrix}\mathcal{P}(\bar{t}_{ij}) & 0\\ 0 & \mathcal{P}(\bar{t}_{\mu\nu})\end{pmatrix}.$$

The matrix elements of these representations generate $\mathcal{A}_e$, which forms a Hopf subalgebra of $U_q(\mathfrak{g}_0)^\circ$. On $\mathcal{A}_e$ there exists a unique left integral $\int_0$ which annihilates the matrix elements of all nontrivial irreducible representations and satisfies

$$\int_0 \mathbb{1}_{\mathcal{A}_e}=1.$$

Introduce

$$\mathbb{E}_i=E_{i,m+1}\ E_{i,m+2}\cdots E_{i,m+n},$$

$$\mathbb{F}_i=E_{m+n,i}\ E_{m+n-1,i}\cdots E_{m+1,i},$$

$$\mathbb{E}=\mathbb{E}_m\,\mathbb{E}_{m-1}\cdots\mathbb{E}_1,$$

$$\mathbb{F}=\mathbb{F}_1\,\mathbb{F}_2\cdots\mathbb{F}_m,$$

$$\Gamma=\mathbb{E}\,\mathbb{F}.$$

Lemma 7: Let J be defined as in (13). Then the image of Γ under the canonical map $U_q(\mathfrak{sl}(m|n))\to U_q(\mathfrak{sl}(m|n))/J$ is an invariant.

Proof: In Ref. 23 it was shown that

$$k_a\Gamma=\Gamma\,k_a,\quad \forall a,$$

$$[E_{c,c+1},\mathbb{E}]=[E_{c,c+1},\mathbb{F}]=0,\quad c\neq m,$$

$$[E_{c+1,c},\mathbb{E}]=[E_{c+1,c},\mathbb{F}]=0,\quad c\neq m.$$

It is also clear that

$$E_{m,m+1}\Gamma=0.$$

This immediately leads to

$$E_{i,m+1}\Gamma=0,\quad \forall i\leqslant m.$$

What remains to be shown is that

$$E_{m+1,m}\Gamma\in J. \tag{14}$$

By using the fact that $E_{m+1,m}$ q-anticommutes with all $E_{\mu,i}$, $\mu \geqslant m+1$, $i \leqslant m$, and $(E_{m+1,m})^2 = 0$, we have

$$E_{m+1,m}\,\mathbb{F} = 0.$$

Thus

$$E_{m+1,m}\Gamma = [E_{m+1,m}, \mathbb{E}]\,\mathbb{F}.$$

To determine the right hand side, we need the following commutation relations:

$$[E_{m+1,m}, \mathbb{E}_i] = q^{m+n-2} E_{i,m+2} E_{i,m+3} \cdots E_{i,m+n} k_m E_{i,m}, \quad i < m,$$

$$[E_{i,m}, \mathbb{E}_j] = 0, \quad i > j.$$

Now

$$[E_{m+1,m}, \Gamma] = [E_{m+1,m}, \mathbb{E}_m]\,\mathbb{E}_{m-1} \cdots \mathbb{E}_1\,\mathbb{F},$$

where $[E_{m+1,m}, \mathbb{E}_m]$ can be easily calculated to yield

$$[E_{m+1,m}, \mathbb{E}_m] = \frac{k_m - k_m^{-1}}{q - q^{-1}} E_{m,m+2} \cdots E_{m,m+n} + \sum_{\alpha=2}^{n} (-1)^{\alpha} q^{-(n-\alpha)} E_{m,m+1} \cdots \hat{E}_{m,m+\alpha} \cdots E_{m,m+n} E_{m+1,m+\alpha} k_\alpha^{-1},$$

with $\hat{E}_{m,m+\alpha}$ indicating that $E_{m,m+\alpha}$ is removed from the second term. By using

$$E_{m+1,m+\alpha}\,\mathbb{E}_i - q^{-2}\,\mathbb{E}_i\,E_{m+1,m+\alpha} = 0, \quad i = 1,2,\ldots,m, \quad \alpha = 2,3,\ldots,n,$$

we immediately see that (14) indeed holds.

Let $\nu: U_q(\mathfrak{g}) \to \mathcal{A}^\circ$ be the natural embedding.

Theorem 6: *There exists the following nontrivial left integral on* $\mathcal{A}$*:*

$$\int = \nu(\Gamma) \cdot \int_0 \mathcal{P}.$$

Example 7: The quantum supergroup $\mathrm{OSP}_q(2|2n)$.

We denote by $\mathfrak{g}$ the Lie superalgebra $\mathfrak{osp}(2|2n)$ and recall that in this case $\mathfrak{g}_0 = \mathfrak{g}_0^-$ is the maximal even subalgebra $\mathfrak{sp}(2n) \oplus \mathfrak{gl}(1)$ of $\mathfrak{g}$. Introduce the $(n+1)$-dimensional Minkowski space $\mathfrak{h}^*$ with a basis $\{\delta_i \mid i = 0,1,2,\ldots,n\}$ and the bilinear form $(,): \mathfrak{h}^* \times \mathfrak{h}^* \to \mathbb{C}$ defined by

$$(\delta_i, \delta_j) = -(-1)^{\delta_{0,i}}\,\delta_{i,j}, \quad \forall i,j.$$

Then the simple roots can be expressed as $\alpha_i = \delta_i - \delta_{i+1}$, $0 \leqslant i < n$, $\alpha_n = 2\delta_n$, with α_0 being the unique odd simple root. A convenient version of the Cartan matrix $A = (a_{ij})_{i,j=0}^{n}$ is $a_{ij} = 2(\alpha_i, \alpha_j)/(\alpha_i, \alpha_i)$, $\forall i > 0$, $a_{0,j} = (\alpha_0, \alpha_j)$. The quantum superalgebra $U_q(\mathfrak{g})$ is the universal complex superalgebra with generators $\{k_i^{\pm 1}, e_i, f_i, i \in \mathbb{N}_n\}$, $\mathbb{N}_n = \{0,1,2,\ldots,n\}$, where e_0 and f_0 are odd and the rest are even. The defining relations are

$$k_i k_j = k_j k_i, \quad k_i k_i^{-1} = k_i^{-1} k_i = \mathbb{1},$$

$$k_i e_j k_i^{-1} = q_i^{a_{ij}/2} e_j, \quad k_i f_j k_i^{-1} = q_i^{-a_{ij}/2} f_j,$$

$$[e_i,f_j]=\delta_{ij}(k_i^2-k_i^{-2})/(q_i-q_i^{-1}),\quad i,j\in\mathbb{N}_n,$$

$$(e_0)^2=(f_0)^2=0,$$

$$\sum_{\mu=0}^{1-a_{ij}}(-1)^\mu\begin{bmatrix}1-a_{ij}\\ \mu\end{bmatrix}_{q_i}e_i^{1-a_{ij}-\mu}e_je_i^\mu=0,\quad i\neq 0,$$

$$\sum_{\mu=0}^{1-a_{ij}}(-1)^\mu\begin{bmatrix}1-a_{ij}\\ \mu\end{bmatrix}_{q_i}f_i^{1-a_{ij}-\mu}f_jf_i^\mu=0,\quad i\neq 0,$$

where $\left[\begin{smallmatrix}m\\ n\end{smallmatrix}\right]_q$ is a q-binomial coefficient. As is well-known, the quantum superalgebra $U_q(\mathfrak{g})$ has the structure of a Hopf superalgebra. Note that $\{e_i, f_i, k_i^{\pm 1}\mid i=1,2,\ldots,n\}$ generate a Hopf subalgebra $U_q(\mathfrak{sp}(2n))\subset U_q(\mathfrak{g})$. Together with $\{k_0^{\pm 1}\}$, they generate $U_q(\mathfrak{g}_0)=U_q(\mathfrak{sp}(2n)\oplus\mathfrak{gl}(1))$.

Define the odd elements

$$\psi_1=e_0,$$

$$\psi_{i+1}=\psi_ie_i-qe_i\psi_i,\quad 1\leqslant i<n,$$

$$\psi_{-n}=\psi_ne_n-q^2e_n\psi_n,$$

$$\psi_{-i}=\psi_{-i-1}e_i-qe_i\psi_{-i-1},\quad 1\leqslant i<n;$$

$$\phi_0=f_0,$$

$$\phi_{i+1}=f_i\phi_i-q^{-1}\phi_if_i,\quad 1\leqslant i<n,$$

$$\phi_{-n}=f_n\phi_n-q^{-2}\phi_nf_n,$$

$$\phi_{-i}=f_i\phi_{-i-1}-q^{-1}\phi_{-i-1}f_i,\quad 1\leqslant i<n,$$

which satisfy the following relations

$$\psi_{\pm i}\psi_{\pm j}+q^{\pm 1}\psi_{\pm j}\psi_{\pm i}=0,\quad i\leqslant j,$$

$$\psi_i\psi_{-j}+q\psi_{-j}\psi_i=0,\quad \forall i\neq j,$$

$$\psi_n\psi_{-n}+q^2\psi_{-n}\psi_n=0,$$

$$\psi_{-i-1}\psi_{i+1}+\psi_{i+1}\psi_{-i-1}+q\psi_{-i}\psi_i+q^{-1}\psi_i\psi_{-i}=0,\quad i<n;$$

$$\psi_je_i-q^{(\alpha_i,\delta_0-\delta_j)}e_i\psi_j=\delta_{ij}\psi_{i+1},\quad \forall i,j,$$

$$\psi_{-j}e_i-q^{(\alpha_i,\delta_0+\delta_j)}e_i\psi_{-j}=\delta_{i+1,j}\psi_{-i+1},\quad i>1,$$

and also similar relations for $\phi_{\pm i}$, where ψ_{n+1} and ϕ_{n+1} are understood as ψ_{-n} and ϕ_{-n}, respectively. Let

$$E_{1,2}=e_1,$$

$$E_{1,i+1}=E_{1,i}e_i-qe_iE_{1,i},\quad 1<i<n,$$

$$E_{1,\bar{n}}=E_{1,n}e_n-q^2e_nE_{1,n},$$

$$E_{1,\bar{i}}=E_{1,\overline{i+1}}e_i-qe_iE_{1,\overline{i+1}},\quad 1<i<n,$$

$$E_{1,\bar{1}}=E_{1,\bar{2}}e_1q^{-1}-qe_1E_{1,\bar{2}},$$

where we have introduced the notation $\bar{\bar{i}}=-i$. Then

$$\{\psi_i,f_0\}=E_{1,i}k_0^{-2},\quad \{\psi_{-i},f_0\}=E_{1,\bar{i}}k_0^{-2}.$$

Define

$$\mathbb{E}=\psi_1\psi_2\cdots\psi_n\psi_{-n}\psi_{-n+1}\cdots\psi_{-1},$$

$$\mathbb{F}=\phi_{-1}\phi_{-2}\cdots\phi_{-n}\phi_n\phi_{n-1}\cdots\phi_1,$$

$$\Gamma=\mathbb{E}\,\mathbb{F}.$$

We have the following lemma.

Lemma 8: Let J be defined as in (13). Then

(i) $[v,\mathbb{E}]=[v,\mathbb{F}]=0,\ \forall v\in U_q(\mathfrak{sp}(2n))\subset U_q(\mathfrak{g}_0)$,
(ii) $[u,\Gamma]=0,\ \forall u\in U_q(\mathfrak{g}_0)$,
(iii) $x\Gamma\in\varepsilon(x)\Gamma+J,\ \forall x\in U_q(\mathfrak{g})$.

Of particular importance for us is the vector representation t of $U_q(\mathfrak{g})$. Introduce the index $a=i$ or $\bar{i}$, with $i=0,1,\ldots,n$, $\bar{i}=\bar{0},\bar{1},\ldots,\bar{n}$. We have

$$t(e_0)=e_{0,1}+e_{\bar{1},\bar{0}},\quad t(f_0)=e_{1,0}-e_{\bar{0},\bar{1}},$$

$$t(e_i)=e_{i,i+1}-e_{\overline{i+1},\bar{i}},\quad t(f_i)=e_{i+1,i}-e_{\bar{i},\overline{i+1}},\quad 1\leqslant i<n,$$

$$t(e_n)=e_{n,\bar{n}},\quad t(f_n)=e_{\bar{n},n},$$

$$t(k_i)=q_i^{H_i/2},\quad 0\leqslant i\leqslant n,$$

where

$$H_0=\delta_0^*+\delta_1^*,$$

$$H_i=\delta_i^*-\delta_{i+1}^*,\quad 0<i<n,$$

$$H_n=\delta_n^*;$$

$$\delta_i^*=e_{i,i}-e_{\bar{i},\bar{i}},\quad 0\leqslant i\leqslant n.$$

Let $t_{ab}\in U_q(\mathfrak{g})^\circ,\ a,b=0,1,\ldots,n,\bar{0},\bar{1},\ldots,\bar{n},$ be the matrix elements of the vector representation t,

$$\langle t_{ab},x\rangle=t(x)_{ab},\quad \forall x\in U_q(\mathfrak{g}).$$

We will take the algebra $\mathcal{A}$ of functions on $\mathrm{OSP}_q(2|2n)$ to be the subalgebra of $U_q(\mathfrak{g})^\circ$ generated by the elements t_{ab}. In Ref. 26 we have shown the following.

Proposition 6: The algebra $\mathcal{A}$ is a sub-Hopf-superalgebra of $\mathcal{U}_q(\mathfrak{osp}(2|2n))^\circ$ and is dense in $\mathcal{U}_q(\mathfrak{osp}(2|2n))^*$.

As usual, let $\mathcal{P}: U_q(\mathfrak{g})^\circ \to U_q(\mathfrak{g}_0)^\circ$ be the map induced by the dual of the embedding $\mathcal{I}: U_q(\mathfrak{g}_0) \to U_q(\mathfrak{g})$, let $\nu: U_q(\mathfrak{g}) \to \mathcal{A}^\circ$ be the canonical map, and let $\hat{\mathcal{I}} = \nu \mathcal{I}$. Set $\mathcal{A}_e = \mathcal{P}(\mathcal{A})$. Then $\mathcal{A}_e$ admits a left integral $\int_0$, which we normalize by setting $\int_0 1_{\mathcal{A}_e} = 1$. Now

$$\int_0 \mathcal{P}: \mathcal{A} \to \mathbb{C}$$

is a well-defined linear map, which is left invariant with respect to $U_q(\mathfrak{g}_0) \subset U_q(\mathfrak{g})$:

$$\hat{\mathcal{I}}(u) \cdot \int_0 \mathcal{P} = \varepsilon(u) \int_0 \mathcal{P}, \quad \forall u \in U_q(\mathfrak{g}_0).$$

We define

$$\int = \nu(\Gamma) \cdot \int_0 \mathcal{P}.$$

Theorem 7: *The linear form $\int: \mathcal{A} \to \mathbb{C}$ is a left integral on $\mathcal{A}$.*
Consider $\int \Lambda$, where

$$\Lambda = t_{\bar{1}\,0} \cdots t_{\bar{n}\,0} t_{n\,\bar{0}} \cdots t_{1\,\bar{0}} t_{\bar{1}\,0} \cdots t_{\bar{n}\,0} t_{n\,0} \cdots t_{1\,0}.$$

Using the following property of the Hopf superalgebra homomorphism $\mathcal{P}$,

$$\mathcal{P}(t_{a\,0}) = \mathcal{P}(t_{a\,\bar{0}}) = 0, \quad \forall a \neq 0, \bar{0},$$

$$\mathcal{P}(t_{0\,\bar{0}}) = \mathcal{P}(t_{\bar{0}\,0}) = 0,$$

we have

$$\int \Lambda = \langle \Lambda, \Gamma \rangle \int_0 \mathcal{P}((t_{\bar{0}\,\bar{0}})^{2n} (t_{0\,0})^{2n}).$$

Now

$$\mathcal{P}(t_{\bar{0}\,\bar{0}} t_{0\,0}) = \mathcal{P}(t_{0\,0} t_{\bar{0}\,\bar{0}}) = 1_{U_q(\mathfrak{g}_0)^\circ},$$

thus

$$\int \Lambda = \langle \Lambda, \Gamma \rangle,$$

which does not vanish if its $q \to 1$ limit is nonzero. A brute force calculation shows

$$|\langle \Lambda, \Gamma \rangle| \to 1, \text{ as } q \to 1.$$

V. DISCUSSION

In the present work we have introduced and investigated the integrals on Hopf superalgebras, with special emphasis on the classical and quantum supergroups. In the undeformed case, there is obviously one problem that we have not solved completely, namely, to prove the existence of nonzero integrals for all of the basic classical Lie supergroups. However, in the meantime we have shown that nonzero integrals exist for a large class of Lie supergroups, including the classical simple ones. For further details, we refer the reader to Ref. 27.

In the quantum case, we have only been able to treat the type I supergroups. In particular, we could not say anything about most of the orthosymplectic quantum supergroups. There are clear indications that our method will not work (or, at least, has to be modified) in this case. However, one should remember that, at present, only very little is known about the orthosymplectic quantum supergroups anyway.

ACKNOWLEDGMENTS

The present work was started during a visit of the first-named author to the Department of Pure Mathematics at the University of Adelaide; it was continued when both authors attended the seminar and workshop on Cooperative Phenomena in Statistical Physics, held at the Max Planck Institute for Physics of Complex Systems in Dresden; and it was finished during a visit of the first-named author to the Department of Mathematics at the University of Queensland, Brisbane. The kind invitations to these institutes and the hospitality extended there are gratefully acknowledged.

APPENDIX: DESCRIPTION OF $U(\mathfrak{gl}(1))^\circ$

In Example 2 of Sec. III we need to choose a (left) integral on

$$\mathcal{A}_e \subset \mathcal{U}_e^\circ,$$

where

$$\mathcal{U}_e = U(\mathfrak{g}_{\bar{0}}) = U(\mathfrak{sl}(m) \oplus \mathfrak{sl}(n) \oplus \mathfrak{g}(1)) \cong U(\mathfrak{sl}(m)) \otimes U(\mathfrak{sl}(n)) \otimes U(\mathfrak{gl}(1)),$$

and hence

$$\mathcal{U}_e^\circ \cong U(\mathfrak{sl}(m))^\circ \otimes U(\mathfrak{sl}(n))^\circ \otimes U(\mathfrak{gl}(1))^\circ$$

(the isomorphisms are to be interpreted in the Hopf algebra sense). According to the discussion in Sec. II, the Hopf algebras $U(\mathfrak{sl}(n))^\circ$ are sufficiently well understood. In particular, there is a unique (up to scalar multiples) left integral on $U(\mathfrak{sl}(n))^\circ$, which turns out to be right invariant as well. For $\mathfrak{osp}(2|2n)$ and for the quantum counterparts the situation is similar. Correspondingly, in the present appendix we would like to comment on $U(\mathfrak{gl}(1))^\circ$. Needless to say, the results to be presented are well-known,[28,29] and we summarize them here in order to clarify some slightly subtle issues.

The Lie algebra $\mathfrak{gl}(1)$ is one-dimensional, hence $U(\mathfrak{gl}(1))$ is isomorphic (as a Hopf algebra) to the polynomial algebra $\mathbb{C}[X]$ in one indeterminate X. The Hopf algebra structure is the one known from enveloping algebras: The structure maps are uniquely fixed by the equations

$$\Delta(X) = X \otimes 1 + 1 \otimes X,$$

$$\varepsilon(X) = 0,$$

$$S(X) = -X.$$

It follows that

$$\Delta(X^r) = \sum_{s=0}^{r} \binom{r}{s} X^s \otimes X^{r-s},$$

for all integers $r \geqslant 0$.

The finite dual $\mathbb{C}[X]^\circ$ of $\mathbb{C}[X]$ can be described as follows. Define, for any element $a \in \mathbb{C}$ and any integer $r \geqslant 0$, the linear form u_a^r on $\mathbb{C}[X]$ by

$$\langle u_a^r, P\rangle = \left.\frac{d^r P}{dX^r}\right|_{X=a}, \quad \forall P \in \mathbb{C}[X].$$

Using some elementary algebra, it is not difficult to prove that these linear forms, with a and r as described above, form a basis of the vector space $\mathbb{C}[X]^\circ$. The multiplication in $\mathbb{C}[X]^\circ$ is given by

$$u_a^r u_b^s = u_{a+b}^{r+s},$$

in particular, the unit element is equal to u_0^0 (which is the counit of $\mathbb{C}[X]$), the coproduct is given by

$$\Delta(u_a^r) = \sum_{s=0}^{r} \binom{r}{s} u_a^s \otimes u_a^{r-s},$$

the counit by

$$\varepsilon(u_a^r) = \delta_{r,0},$$

and the antipode by

$$S(u_a^r) = (-1)^r u_{-a}^r,$$

where, in all cases, $a, b \in \mathbb{C}$ and $r, s \geqslant 0$ are integers.

Let us next recall that the dual $\mathbb{C}[X]^*$ of the vector space $\mathbb{C}[X]$ can be identified (in various ways) with the space of formal power series $\mathbb{C}[[Y]]$ in one indeterminate Y. If the dual pairing

$$\langle\,,\rangle : \mathbb{C}[[Y]] \times \mathbb{C}[X] \to \mathbb{C}$$

is chosen such that

$$\left\langle \sum_{n\geqslant 0} c_n Y^n, X^r \right\rangle = r!\, c_r, \quad \forall r,$$

then the coalgebra structure of $\mathbb{C}[X]$ induces just the usual algebra structure on $\mathbb{C}[[Y]]$. Using this identification, the corresponding injection

$$\mathbb{C}[X]^\circ \to \mathbb{C}[[Y]]$$

is given by

$$u_a^r \to Y^r \exp(aY),$$

which immediately gives the product rule for the u_a^r's. Similarly, we find

$$\Delta(Y^r \exp(aY)) = (Y\otimes 1 + 1\otimes Y)^r (\exp(aY)\otimes \exp(aY)).$$

Under the canonical embedding of $\mathbb{C}[[Y]]\otimes\mathbb{C}[[Y]]$ into $\mathbb{C}[[Y\otimes 1, 1\otimes Y]]$, the algebra of formal power series in $Y\otimes 1$ and $1\otimes Y$, the right hand side of this equation can be written in the form

$$(Y\otimes 1 + 1\otimes Y)^r \exp(a(Y\otimes 1 + 1\otimes Y)).$$

In this sense, the coproduct in $\mathbb{C}[X]^\circ$ is fixed by the simple rule

$$\Delta(Y) = Y\otimes 1 + 1\otimes Y,$$

just as for $\mathbb{C}[X]$.

Let us now turn to the object of our main concern, the integrals. It is easy to see that on $\mathbb{C}[X]^\circ$ a nontrivial integral does not exist. However, there is a way out. Obviously, the elements u_a^0, $a \in \mathbb{C}$, span a Hopf subalgebra $\mathcal{K}$ of $\mathbb{C}[X]^\circ$, and the linear form $\int$ on $\mathcal{K}$, defined by

$$\int u_a^0 = \delta_{a,0}, \quad \forall a \in \mathbb{C},$$

is a left and right integral on $\mathcal{K}$. Note that the u_a^0's are exactly the characters of the algebra $\mathbb{C}[X]$, i.e., the grouplike elements of $\mathbb{C}[X]^\circ$, and that $\mathcal{K}$ is isomorphic to the group Hopf algebra of the additive group $\mathbb{C}$.

Now we recall that, for an arbitrary algebra A (associative, with unit element), the finite dual A° consists exactly of the matrix elements (regarded as linear forms on A) of the representations of A. (Here and in the following, all representations are assumed to be finite-dimensional.) It is easy to see that the matrix elements of the completely reducible representations of $\mathbb{C}[X]$ (i.e., the representations for which the image of X is diagonalizable) belong to $\mathcal{K}$, whereas the other elements of $\mathbb{C}[X]^\circ$ stem from those representations which are not completely reducible. Note that, once again, the close relationship between complete reducibility and the existence of nontrivial integrals shows up.

Returning to the situation at the beginning of this appendix, we have to assume that

$$\mathcal{A}_e \subset U(\mathfrak{sl}(m))^\circ \otimes U(\mathfrak{sl}(n))^\circ \otimes \mathcal{K}.$$

According to the foregoing discussion, this corresponds to the requirement to consider only those representations of $\mathfrak{g} = \mathfrak{sl}(m|n)$ for which the one-dimensional center of $\mathfrak{g}_0^-$ is represented by diagonalizable operators, which is usually assumed anyway.

(Received 18 December 2000, accepted for publication 26 March 2001)

We consider a special class of pseudo-Riemannian metrics that admit integrals in involution. A necessary and sufficient conditions for the complete integrability of the geodesic flows of the corresponding metrics is proved. Any of the metrics we consider lies in a big family (hierarchy) of metrics that also admit integrals in involution. Many classical and new examples of completely integrable metrics lie in such hierarchies. © *2001 American Institute of Physics.*
[DOI: 10.1063/1.1379068]

I. INTRODUCTION

The main purpose of the present paper is to prove the Liouville integrability of a class of pseudo-Riemannian metrics. The main idea of the proof of the involutivity of the corresponding first integrals is based on the observation that the metrics we consider lie in a big family (hierarchy) of metrics that also admit first integrals. The technique we use allows us to extend the main results proven in Refs. 1–5 to the case of pseudo-Riemannian metrics. In the present paper the word ''metric'' means *pseudo-Riemannian metric*, i.e., nondegenerate symmetric tensor field of type (0,2). The positive definite metrics are called Riemannian metrics.

Suppose that g and $\overline{g}$ are smooth metrics given on the smooth n-dimensional manifold M^n.

Definition 1: The metrics g and $\overline{g}$ are called geodesically equivalent *if they have the same geodesics (considered as unparemetrized curves).*

Having the metric g and $\overline{g}$ on M^n define the operator,

$$A(g,\overline{g})_j^i \stackrel{\text{def}}{=} \left|\frac{\det \overline{g}}{\det g}\right|^{1/(n+1)} \overline{g}^{i\alpha} g_{\alpha j}. \tag{1}$$

Consider the one-parameter family of functions on the tangent bundle TM^n given by the formula

$$K_c(g,\overline{g})(\xi) \stackrel{\text{def}}{=} \det(A+c\mathbf{1})g((A+c\mathbf{1})^{-1}\xi,\xi), \tag{2}$$

where c is a real parameter $A \stackrel{\text{def}}{=} A(g,\overline{g})$ and $\xi \in TM^n$. The functions K_c are well-defined on the whole manifold M^n for all real parameters c. Moreover, it can be easily seen that

$$K_c(\xi) = I_{n-1}(\xi)c^{n-1} + I_{n-2}(\xi)c^{n-2} + \cdots + I_0(\xi) \tag{3}$$

and $I_{n-1}(\xi) = g(\xi,\xi)$.

Theorem 1: *If the metrics g and $\overline{g}$ are geodesically equivalent, then the functions from the one-parameter family (2) are in involution with respect to the symplectic structure $\omega_g \stackrel{\text{def}}{=} FL_g^* \omega$, where $FL_g: TM \to T^*M$ is the Legendre transformation corresponding to the metric g and ω is the canonical symplectic structure on the cotangent bundle T^*M^n.*

Remark 1: Formula (3) shows that if some function F commutes with K_c for n different values of the parameter c, then these functions commute for all values of the parameter c. Moreover, F commutes with the coefficients $I_k (k=0,\ldots,n-1)$. As a corollary we obtain that the functions I_k $(k=0,\ldots,n-1)$ are in involution, and therefore, they are integrals of the geodesic flow of the metric g.

Suppose that the the metrics g and $\overline{g}$ are geodesically equivalent.

Definition 2: The number

$$r(g,\overline{g})\overset{\text{def}}{=}\max_{\xi\in TM^n}\ \mathrm{rk}\{d_\xi I_0,\ldots,d_\xi I_{n-1}\} \tag{4}$$

is called rank of the geodesic equivalence of the pair g and $\overline{g}$.

An equivalent definition in terms of the invariants of the operator $A(g,\overline{g})$ is given in Sec. III B (Definition 4). Indeed, denote by $r(g,\overline{g})(x)$ the degree of the minimal polynomial of the operator $A(g,\overline{g})|_x$. We prove in Sec. III B that $r(g,\overline{g})=\max_{x\in M^n} r(g,\overline{g})(x)$.

The smooth functions $F_1,\ldots,F_k$ given on the manifold V^m are called *functionally independent* if the set of points $x\in V^m$ where the differentials $d_xF_1,\ldots,d_xF_k$ are linearly independent is dense in V^m.

Theorem 2: *Suppose that the manifold M^n is connected and let the rank of the geodesic equivalence of the pair of geodesically equivalent metrics g and $\overline{g}$ is r; then there exist r quadratic in velocities functions $B_1(\xi),\ldots,B_r(\xi)$, $\xi\in TM$, such that the next three conditions are satisfied:*

(a) the functions $B_1,\ldots,B_r$ are pairwise commuting integrals of the geodesic flow of the metric g;

(b) the functions $B_1,\ldots,B_r$ are functionally independent on TM;

(c) for every fixed value of the parameter c there exist r constants $\alpha_1,\ldots,\alpha_r$ (depending on c) such that $K_c(\xi)=\Sigma_{i=1}^r\alpha_iB_i(\xi)$.

The functions $B_1,\ldots,B_r$ can be taken in the form $B_k=^{\text{def}}I_{i_k}$ where $0\leqslant i_k\leqslant n-1$ are some specially chosen different integer numbers.

Remark 2: Actually, in Theorem 2 we can take $B_1=^{\text{def}}I_{n-1},\ldots,B_r=^{\text{def}}I_{n-r}$. Another system of functions that satisfy conditions (a), (b), and (c) of Theorem 2 can be obtained if we put $B_1=^{\text{def}}K_{c_1},\ldots,B_r=^{\text{def}}K_{c_r}$ where $c_1,\ldots,c_r$ are arbitrary taking different real constants such that the integrals $K_{c_k}(k=1,\ldots,r)$ are not identically equal to zero.

Remark 3: It follows from Theorem 2 that the set of the points $x\in M^n$, where the degree of the minimal polynomial of the operator $A(g,\overline{g})|_x$ coincides with the rank of the geodesic equivalence $r(g,\overline{g})$ is open and dense in M^n.

Remark 4: Theorem 1 generalizes the classical results proved by Dini, Painlevé, Levi-Civita, and Liouville that the geodesic flows of the geodesically equivalent metrics g and $\overline{g}$ admit first integrals (see Refs. 6 and 7). The fact that the geodesic flows of the metrics g and $\overline{g}$ admit globally defined functionally independent integrals in involution (provided the metric g is positive definite) was first proven in Refs. 1 and 2 (see also Refs. 3, 4, and 5). Theorem 1 and Theorem 2 generalize all these results.

Corollary 1: Suppose that the metrics g and $\overline{g}$ are geodesically equivalent. If the differentials $d_{\xi_0}I_{n-1},\ldots,d_{\xi_0}I_0$ are linearly independent at some point $\xi_0\in TM^n$, then the rank of the geodesic equivalence of the pair g and $\overline{g}$ is equal to n and the geodesics flow of the metrics g and $\overline{g}$ are completely integrable.

Theorem 3: *Suppose that the metrics g and $\overline{g}$ are nontrivially geodesically equivalent (i.e., $g\neq\mathrm{const}\,\overline{g}$); then the rank $r(g,\overline{g})$ of the geodesic equivalence of the pair g and $\overline{g}$ is greater than or equal to two and any of the geodesic flows of the metrics g and $\overline{g}$ admits a first integral that is functionally independent of the energy almost everywhere on TM^n.*

The paper is organized as follows: In Sec. II we give the definition of the geodesic hierarchies and prove that the functions given by formula (2) are integrals of the geodesic flow of the metric g. In Sec. III we prove theorems 1, 2, and 3. Combining all these results we prove in Sec. III C Theorem 7 that assigns to any pair of geodesically equivalent metrics a hierarchy of functions in involution. In Sec. IV we apply the results obtained in the previous sections to a special case of geodesic equivalence in $\mathbf{R}^n$. Constructing the corresponding *projective hierarchy* we prove Theorems 8, 9, 10, and 11. As a corollary from Theorem 9 we obtain the theorem that was proven in

Ref. 1 (and independently in Ref. 8) that the standard ellipsoid admits a nontrivial geodesic equivalence. Theorem 9 shows that the same result is true also for the hyperboloids. Moreover, there exists a geodesic family of metrics dg_c^2 [given by formula (60)] having the property that the restriction of dg_c^2 to any of the quadrics from a fixed confocal family gives a metric that is geodesically equivalent to the restriction of the standard Euclidean metric on the same quadric. In Sec. IV we prove that the Euclidean metric in $\mathbf{R}^n$, the hyperbolic plane, and the analog of the Poisson sphere that corresponds to the Clebsch case of motion of the rigid body lie in the projective hierarchy. As corollaries we obtain the results proven in Ref. 4. A pseudo-Riemannian analog of the results proven in Ref. 4 is given. In Sec. IV B we find a family of functions in involution in $T^*\mathbf{R}^n$. The family contains the integrals obtained by Uhlenbeck in Ref. 9 and Moser in Ref. 10 as a particular case.

Throughout the paper together with the common tensor notations (with or without indices) we use the next convention. Let b be a bilinear form given on the manifold M^n. The formula $\xi \mapsto b(.,\xi)$ $(\xi \in TM^n)$ gives a fiberwise transformation of the bundles $TM^n \to T^*M^n$ that we denote by the same letter. Vice versa, any fiberwise linear transformation $K: TM^n \to T^*M^n$ gives a bilinear form by the formula $K(\xi,\eta) = {}^{\text{def}}\langle K\eta, \xi\rangle$, where the brackets $\langle .,. \rangle$ denote the standard pairing between vectors and covectors. If b is nondegenerate, then b^{-1} denotes the inverse transformation, i.e., $b^{-1}: T^*M^n \to TM^n$. Let A be a fiberwise linear transformation of the tangent bundle, i.e., $A \in \Gamma(\mathrm{Hom}(TM^n, TM^n))$. Denote by A' the transformation of the cotangent bundle T^*M^n given by the formula $p \mapsto \langle p, A(.)\rangle$. Let a be a nondegenerate bilinear form given on the manifold M^n. Using the previous duality we treat the compositions bA, $A'b$ or Aa^{-1} as bilinear forms on the corresponding bundles.

II. GEODESIC FAMILIES AND HIERARCHIES

This section has an informative character. In the first part we prove that the functions given by formula (2) are integrals of the geodesic flow of the metric g. In the second part we give the notion of the geodesic hierarchy. The existence of hierarchies is essential in the proof of the commutativity of the integrals given by formula (2).

A. Geodesic families

We follow the ideas presented in Ref. 11. Consider the one-parameter family of metrics

$$g_c(g,\overline{g})(\xi,\eta) = {}^{\text{def}} \frac{1}{\det(A + c\mathbf{1})} g((A + c\mathbf{1})^{-1}\xi, \eta), \tag{5}$$

where c is a real parameter $A = {}^{\text{def}} A(g,\overline{g})$ and $\xi, \eta \in TM^n$. The metric g_c is well-defined at the points of M^n where the operator $(A + c\mathbf{1})$ is invertible.

Theorem 4: *Suppose that the metric g_c is well-defined on some open subset $U \subset M^n$ for some fixed value of the parameter c; then the metrics g and g_c are geodesically equivalent on U.*

Remark 5: If the manifold M^n is compact, then the operator $(A + c\mathbf{1})$ is invertible on M^n for all sufficiently big parameters c.

Proof of Theorem 4: To prove the theorem we need the next lemma.

Lemma 1:

(1) Suppose that the pseudo-Riemannian metrics g and $\overline{g}$ are geodesically equivalent; then the tensors a_{ij} and λ_i,

$$a_{ij} = {}^{\text{def}} A_i^\alpha g_{\alpha j}, \tag{6}$$

$$\lambda_i = {}^{\text{def}} -A_i^\alpha \psi_\alpha, \tag{7}$$

where $(n+1)\psi_i=\frac{1}{2}\partial_i \ln|\overline{g}/g|$, $g=\det(g_{ij})$, *and the operator A is given by formula (1) satisfy the equation*

$$a_{ij,k}=\lambda_i g_{jk}+\lambda_j g_{ik}. \tag{8}$$

Here $a_{ij,k}$ *denotes the covariant derivative* $\nabla_k a_{ij}$, *where* ∇ *is the Levi-Civita connection corresponding to the metric g.*

(2) Conversely, if a nondegenerate symmetric tensor field a_{ij} *and an 1-form* λ_i *satisfy Eq. (8), then the metric*

$$\overline{g}_{ij}\overset{\text{def}}{=}\left(\frac{\hat{g}}{g}\right)\hat{g}_{ij}, \tag{9}$$

where $\hat{g}_{ij}\overset{\text{def}}{=}g_{i\alpha}a^{\alpha\beta}g_{\beta j}$, *is geodesically equivalent to g.*

The statement of this lemma is proven (under the condition of ''nontriviality'' of the geodesic equivalence) in Ref. 12. A geodesic equivalence is said to be ''nontrivial'' if the covector field ψ_k is not identically equal to zero. Nevertheless, the proof proposed in Ref. 12 passes also in our case.

Remark 6: To avoid any confusion recall that we use the expression "nontrivial geodesic equivalence" in a slightly different sense. In our terminology the metrics g and $\overline{g}$ *are "nontrivially geodesically equivalent" if* $g\neq \text{const}\,\overline{g}$.

Let us return to the proof of Theorem 4. Suppose that the metrics g and $\overline{g}$ are geodesically equivalent. It follows from Lemma 1 that the form a_{ij} given by formula (6) satisfies Eq. (8). Using the obvious relation that $\nabla g=0$ we see that the tensor field $a_c\overset{\text{def}}{=}a+cg$, where the constant c is the same as in the statement of the theorem, also satisfies Eq. (8). Moreover, $a_c\overset{\text{def}}{=}g(A+c\mathbf{1})$ is nondegenerate and applying the inverse part of Lemma 1 we obtain that the metrics g and

$$\overline{g}_c\overset{\text{def}}{=}\frac{\det \hat{g}_c}{\det g}\hat{g}_c \tag{10}$$

$$=\frac{\det(g(A+c\mathbf{1})^{-1})}{\det g}g(A+c\mathbf{1})^{-1} \tag{11}$$

$$=\frac{1}{\det(A+c\mathbf{1})}g(A+c\mathbf{1})^{-1} \tag{12}$$

are geodesically equivalent. Theorem 4 is proved.

As a corollary of Theorem 4 we obtain the next proposition.

Proposition 1: If the metrics g and $\overline{g}$ *are geodesically equivalent, then the functions given by formula (2) are integrals of the geodesic flow of the metric g.*

This theorem was proven by Levi-Civita in the case of positive definite metric g under some additional assumption (see Ref. 6). Actually, he proved the result under the assumption that the number of the roots (without their multiplicities) of the characteristic polynomial $\det(\overline{g}-\lambda g)=0$ is a constant. Remark that in the case of positive definite metric g all roots of the characteristic polynomial are real. Another proof was given by Liouville (see Ref. 6). A proof from a symplectic point of view is given in Refs. 1 and 2 (see also Ref. 13).

Proof of Proposition 1: We follow Ref. 11. Let us fix some point $x_0\in M^n$. It is clear that there exists an open neighborhood $U(x_0)$ of the point x_0 and an interval $(-\epsilon,\epsilon)$ such that the metric g_c given by formula (5) is well-defined on $U(x_0)$ for $c\in(-\epsilon,\epsilon)$. It follows from Theorem 4 that the metrics g and $\overline{g}_c$ are geodesically equivalent. We need the next proposition proved by Painlevé (see Ref. 6).

Proposition 2: If the metrics g and $\overline{g}$ *are geodesically equivalent, then the function given by the formula,*

$$I_0(g,\overline{g})(\xi)\overset{\text{def}}{=}\left|\frac{\det g}{\det \overline{g}}\right|^{2/(n+1)}\overline{g}(\xi,\xi), \tag{13}$$

where $\xi\in TM^n$, *is an integral of the geodesic flow of the metric* g.

One can find the proof of this proposition in Ref. 14 (see Sec. IV A).

Let us return to the proof of Proposition 1. The metrics g and g_c are geodesically equivalent. It follows from Proposition 2 that the function,

$$I_0(g,g_c)\overset{\text{def}}{=}\left|\frac{\det g}{\det g_c}\right|^{2/n+1} g_c \tag{14}$$

$$=\det(A+c\mathbf{1})^2\frac{1}{\det(A+c\mathbf{1})}g(A+c\mathbf{1})^{-1} \tag{15}$$

$$=\det(A+c\mathbf{1})g(A+c\mathbf{1})^{-1} \tag{16}$$

is an integral of the geodesic flow of the metric g on $U(x_0)$ for all $c\in(-\epsilon,\epsilon)$. It follows from Remark 1 that the functions given by formula (2) are integrals of the geodesic flow of the metric g on $U(x_0)$. Finally, recall that the point x_0 was arbitrary chosen. This completes the proof of Proposition 1.

B. Geodesic hierarchies

Suppose that g and $\overline{g}$ are metrics given on the manifold M^n. Denote by A the operator $A=^{\text{def}}A(g,\overline{g})$ given by formula (1). We need the next theorem proven in Ref. 15.

Theorem 5: *If the metrics* g *and* $\overline{g}$ *are geodesically equivalent, then for any integer number* k *the metrics* gA^k *and* $\overline{g}A^k$ *are also geodesically equivalent.*

Therefore, having a pair of geodesically equivalent metrics g and $\overline{g}$ we obtain a sequence of pairs of geodesically equivalent metrics that is called *geodesic hierarchy* of the pair g and $\overline{g}$. To describe the hierarchy we use the next formal diagram,

$$\begin{array}{ccc}
\downarrow & & \downarrow \\
g^{(-1)} & \overset{g.e.}{\leftrightarrow} & \overline{g}^{(-1)} \\
\downarrow & & \downarrow \\
g & \overset{g.e.}{\leftrightarrow} & \overline{g} \\
\downarrow & & \downarrow \\
g^{(1)} & \overset{g.e.}{\leftrightarrow} & \overline{g}^{(1)} \\
\downarrow & & \downarrow \\
g^{(2)} & \overset{g.e.}{\leftrightarrow} & \overline{g}^{(2)} \\
\downarrow & & \downarrow ,
\end{array}$$

where $g^{(k)}=^{\text{def}}gA^k$ and $\overline{g}^{(k)}=^{\text{def}}\overline{g}A^k$ $(k\in\mathbf{Z})$. The main properties of the geodesic hierarchies are investigated in Ref. 11. Some generalizations of the construction are given in Ref. 3. In Refs. 4, 5 the construction of the geodesic hierarchy is applied for constructing new examples of geodesically equivalent metrics and completely integrable systems.

III. INVOLUTIVITY OF THE INTEGRALS

The main purpose of the present section is to prove the involutivity of the integrals given by formula (2), provided the metrics g and $\overline{g}$ are geodesically equivalent. We prove Theorem 1 and 2.

A. Hierarchies and involutivity

Suppose that the metrics g and $\overline{g}$ are geodesically equivalent. Let us fix an arbitrary point $x_0 \in M^n$. It is clear that there exist an open neighborhood $U(x_0)$ of the point x_0 and an interval $(-\epsilon,\epsilon)$, $\epsilon>0$, such that the operator $(A+c\mathbf{1})|_x$ is invertible if $x \in U(x_0)$ and $c \in (-\epsilon,\epsilon)$. Consider the one-parameter family $g_c \stackrel{\text{def}}{=} g_c(g,\overline{g})$, $c \in (-\epsilon,\epsilon)$ [see formula (5)], of geodesically equivalent metrics on $U(x_0)$. Let us fix some $\kappa \in (-\epsilon,\epsilon)$. The metrics g and g_κ are geodesically equivalent on $U(x_0)$. Consider the next subsequence from the geodesic hierarchy of the pair g and g_κ,

$$\begin{array}{ccc}
\downarrow & & \downarrow \\
g & \overset{g.e.}{\leftrightarrow} & g_\kappa \\
\downarrow & & \downarrow \\
g^{(1)} & \overset{g.e.}{\leftrightarrow} & g_\kappa^{(1)} \\
\downarrow & & \downarrow \\
g^{(2)} & \overset{g.e.}{\leftrightarrow} & g_\kappa^{(2)} \\
\downarrow & & \downarrow,
\end{array}$$

where $g^{(l)} \stackrel{\text{def}}{=} gA(g,g_\kappa)^l$ and $g_\kappa^{(l)} \stackrel{\text{def}}{=} g_\kappa A(g,g_\kappa)^l$. The metrics $g^{(2)}$ and $g_\kappa^{(2)}$ are geodesically equivalent. It can be easily seen that $A(g,g_\kappa)=A+\kappa\mathbf{1}$. Hence, $g_\kappa^{(2)} \stackrel{\text{def}}{=} g_\kappa A(g,g_\kappa)^2 = 1/\det(A+\kappa\mathbf{1})\, g(A+\kappa\mathbf{1})$. Let us consider the one-parameter family of integrals $K_\alpha(g_\kappa^{(2)},g^{(2)})$ of the geodesic flow of the metric $g_\kappa^{(2)}$. A direct computation shows that $A(g_\kappa^{(2)},g^{(2)})=(A+\kappa\mathbf{1})^{-1}$. Applying the Legendre transformation corresponding to the metric $g_\kappa^{(2)}$ we obtain that the functions,

$$g_\kappa^{(2)-1} = \det(A+\kappa\mathbf{1})(A+\kappa\mathbf{1})^{-1} g^{-1} \tag{17}$$

and

$$K_\alpha(g_\kappa^{(2)},g^{(2)}) \stackrel{\text{def}}{=} \det((A+\kappa\mathbf{1})^{-1}+\alpha\mathbf{1})((A+\kappa)^{-1}+\alpha\mathbf{1})^{-1} g_\kappa^{(2)-1} \tag{18}$$

$$= \det(\alpha A+(\kappa\alpha+1)\mathbf{1})(\alpha A+(\kappa\alpha+1)\mathbf{1})^{-1} g^{-1} \tag{19}$$

are in involution with respect to the canonical symplectic structure on T^*M^n. Remark that after applying the Legendre transformation corresponding to the metric g the family of integrals (2) takes the form $K_c(g,\overline{g})=\det(A+c)(A+c)^{-1}g^{-1}$, where c is an arbitrary real parameter. Hence, the Poisson bracket $\{K_\kappa,K_{\kappa+1/\alpha}\}$ vanishes for all $\alpha\neq 0$ and $\kappa \in (-\epsilon,\epsilon)$. Fixing n different real numbers $\kappa_i \in (\epsilon,\epsilon)$, $i=1,\ldots,n$, $\kappa_i \neq \kappa_j$ $(i\neq j)$, we obtain that $\{K_{\kappa_i},K_c\}=0$ for all real values of the parameter c. Finally, recall that $K_\mu = I_{n-1}\mu^{n-1}+I_{n-2}\mu^{n-2}+\cdots+I_0$. The last equality and the nondegeneracy of the corresponding Vandermonde determinant show that the functions I_l $(l=1,\ldots,n)$ are linear combinations with constant coefficients of the functions K_{κ_i} $(i=1,\ldots,n)$. Therefore, the integrals given by formula (2) are in involution on $T^*U(x_0)$. The point x_0 was taken arbitrary. This proves Theorem 1.

B. The rank of the family of integrals

Suppose that the metrics g and $\overline{g}$ are geodesically equivalent. Consider the family of integrals $K_c=K_c(g,\overline{g})$ given by formula (2).

Remark 7: Let V be a vector space. It is useful for us to identify the linear space of the quadratic forms on V and the space of the symmetric bilinear forms on V.

For every fixed c the integral K_c gives a smooth section of the vector bundle $\mathrm{Symm}(T^*M^n \otimes T^*M^n)$. Let us fix a point $x\in M^n$ and a vector $\xi\in T_xM^n$. Consider the curves $\gamma_x:\mathbf{R} \to \mathrm{Symm}(T_x^*M^n\otimes T_x^*M^n)$ and $\gamma_x(\xi):\mathbf{R}\to T_x^*M^n$ given by the formulas

$$\gamma_x : c\mapsto K_c|_x \in \mathrm{Symm}(T_x^*M^n\otimes T_x^*M^n) \tag{20}$$

and

$$\gamma_x(\xi): c\mapsto K_c(.,\xi)\in T_x^*M^n. \tag{21}$$

Denote by $\mathrm{Span}(\gamma_x)$ the linear subspace in $\mathrm{Symm}(T_x^*M^n\otimes T_x^*M^n)$ of minimal dimension that contains the image of the curve γ_x. Denote by $\mathrm{Span}(\gamma_x(\xi))$, $\xi\in T_xM^n$, the linear subspace in $T_x^*M^n$ of minimal dimension that contains the image of the curve $\gamma_x(\xi)$. Consider the numbers

$$r_\gamma(x) \overset{\text{def}}{=} \max_{\xi\in T_xM^n} \dim \mathrm{Span}(\gamma_x(\xi)) \tag{22}$$

and

$$R_\gamma(x) \overset{\text{def}}{=} \dim \mathrm{Span}(\gamma_x). \tag{23}$$

Recall that $K_c=I_{n-1}c^{n-1}+I_{n-2}c^{n-2}+\cdots+I_0$.

Lemma 2: The next two statements are satisfied:

(1)

$$R_\gamma(x)=\mathrm{rk}\{I_{n-1}|_x,\ldots,I_0|_x\} \tag{24}$$

and

$$r_\gamma(x)=\max_{\xi\in T_xM^n} \mathrm{rk}\{I_{n-1}|_x(.,\xi),\ldots,I_0|_x(.,\xi)\}; \tag{25}$$

(2) the equality $r_\gamma(x)=\mathrm{rk}\{I_{n-1}|_x(.,\xi),\ldots,I_0|_x(.,\xi)\}$ *is satisfied in an open dense subset in* T_xM^n.

Proof of Lemma 2: The first item of the lemma is obvious. Indeed, it follows from formula (3) that the vector space spanned on the forms $I_{n-1}|_x,\ldots,I_0|_x\in\mathrm{Symm}(T_x^*M^n \otimes T_x^*M^n)$ contains $\mathrm{Span}(\gamma_x)$. Let us fix n different real numbers $c_1,\ldots,c_n$ and consider the forms $K_{c_1}|_x,\ldots,K_{c_n}|_x\in\mathrm{Span}(\gamma_x)$. Using formula (3) and the nondegeneracy of the Vandermonde determinant corresponding to the numbers $c_1,\ldots,c_n$ we see that $I_k|_x\in\mathrm{Span}(\gamma_x)$. Therefore, $\mathrm{Span}(I_{n-1}|_x,\ldots,I_0|_x)=\mathrm{Span}(\gamma_x)$. The same arguments show that $\mathrm{Span}(I_{n-1}|_x(.,\xi),\ldots,I_0|_x(.,\xi))=\mathrm{Span}(\gamma_x(\xi))$.

Let us prove the second item of the lemma. Fixing a basis in T_xM^n consider the $n\times n$-matrix constructing from the coefficients of the linear forms $I_{n-1}|_x(.,\xi),\ldots,I_0|_x(.,\xi)\in T_x^*M^n$. Formula (25) shows that there exists a nondegenerate minor of size $r_\gamma(x)\times r_\gamma(x)$ of this matrix. The corresponding determinant is a homogeneous polynomial of degree $r_\gamma(x)$ in the variables $(\xi_1,\ldots,\xi_n)$, where ξ_i are the coordinates of the vector $\xi\in T_xM^n$. Therefore, the considered minor is nondegenerate in an open dense subset in T_xM^n. Lemma 2 is proved.

Let λ be an eigenvalue of the operator $A|_x$ [see formula (1)]. Denote by $J_{r_1}(\lambda),\ldots,J_{r_k}(\lambda)$ $(1\leqslant r_1\leqslant\cdots\leqslant r_k)$ the Jordan's blocks corresponding to this eigenvalue. The numbers r_i $(i=1,\ldots,k)$ denote the size of the Jordan's blocks. By definition, the Jordan's blocks of size one are numbers, i.e., $J_1(\lambda)=\lambda$. The maximal size r_k of the Jordan's blocks is called *r-number of the eigenvalue* λ [we will denote it by $r(\lambda)$.]

Proposition 3:

(1) The numbers $r_\gamma(x)$ *and* $R_\gamma(x)$ *coincide. Denote by* $r(g,\overline{g})(x)$ *the number* $r(x)=^{\text{def}}r_\gamma(x)=R_\gamma(x)$*;*

(2) Denote by $\lambda_1,\ldots,\lambda_m$ *the eigenvalues of the operator* $A|_x$ *(i.e., the roots of the characteristic polynomial* $\chi_{A|_x}(\lambda)=^{\text{def}}\det(A|_x-\lambda\mathbf{1})$ *without their multiplicities). Then,*

$$r(x)=\sum_{i=1}^{m} r(\lambda_i). \tag{26}$$

In other words $r(x)$ *coincides with the degree of the minimal polynomial of the operator* $A|_x$.

Definition 3: The number $r(x)=r(g,\overline{g})(x)$ *is called* rank of the geodesic equivalence of the pair g and $\overline{g}$ at the point x.

Definition 4: The number $r(g,\overline{g})=^{\text{def}}\max_{x\in M^n} r(g,\overline{g})(x)$ *is called* rank of the geodesic equivalence of the pair g and $\overline{g}$.

Proof of Proposition 3: Without loss of generality it can be assumed that the curves γ_x and $\gamma_x(\xi)$ are given by the formulas

$$c\mapsto(A|_x+c\mathbf{1}_x)^{-1}\in\mathrm{Hom}(T_xM^n,T_xM^n) \tag{27}$$

and

$$c\mapsto(A|_x+c\mathbf{1}_x)^{-1}(\xi)\in T_xM^n, \tag{28}$$

respectively. Moreover, instead of these curves consider their "complexifications" $\gamma_x^{\mathbf{C}}: c\mapsto(A|_x^{\mathbf{C}}+c\mathbf{1}_x)^{-1}\in\mathrm{Hom}^{\mathbf{C}}(T_x^{\mathbf{C}}M^n,T_x^{\mathbf{C}}M^n)$ and $\gamma_x^{\mathbf{C}}(\xi): c\mapsto(A|_x^{\mathbf{C}}+c\mathbf{1}_x)^{-1}(\xi)\in T_x^{\mathbf{C}}M^n$, $\xi\in T_x^{\mathbf{C}}M^n$, where $c\in\mathbf{C}\backslash\{-\lambda_1,\ldots,-\lambda_m\}$ and $A|_x^{\mathbf{C}}$ is the complexification of the operator $A|_x$. By $\mathbf{1}_x$ we denote the identity operator in T_xM^n and $T_x^{\mathbf{C}}M^n$. It is clear that $R_\gamma(x)$ coincides with the complex dimension of the minimal (complex)linear subspace in $\mathrm{Hom}^{\mathbf{C}}(T_x^{\mathbf{C}}M^n,T_x^{\mathbf{C}}M^n)$ that contains the image of the curve $\gamma_c^{\mathbf{C}}$. Analogically, $r_\gamma(x)=\max_{\xi\in T_x^{\mathbf{C}}M^n}\dim_{\mathbf{C}}\mathrm{Span}^{\mathbf{C}}(\gamma_c^{\mathbf{C}}(\xi))$, where $\mathrm{Span}^{\mathbf{C}}(\gamma_c^{\mathbf{C}}(\xi))$ denotes the linear subspace in $T_x^{\mathbf{C}}M^n$ of minimal dimension that contains the image of the curve $\gamma_x^{\mathbf{C}}(\xi)$. Let us fix a basis in $T_x^{\mathbf{C}}M^n$ such that the operator $A|_x^{\mathbf{C}}$ has a Jordan's normal form, i.e., in coordinates, $A|_x^{\mathbf{C}}=\mathrm{diag}(J_\alpha(\lambda_1),\ldots,J_\beta(\lambda_m))$, where $\lambda_1,\ldots,\lambda_m$ are the eigenvalues of the operator and $J_r(\lambda)$ denotes a Jordan's block of size r corresponding to the eigenvalue λ. We have that

$$(A|_x^{\mathbf{C}}+c\mathbf{1}_x)^{-1}=\mathrm{diag}(J_\alpha(\lambda_1+c)^{-1},\ldots,J_\beta(\lambda_m+c)^{-1}). \tag{29}$$

Remark that

$$J_r(\lambda)^{-1}=\begin{bmatrix} 1/\lambda & -1/\lambda^2 & \cdots & (-1)^{r+1}/\lambda^r \\ 0 & 1/\lambda & \cdots & (-1)^r/\lambda^{r-1} \\ \vdots & & \ddots & \vdots \\ 0 & 0 & \cdots & 1/\lambda \end{bmatrix}.$$

Let ω_k $(k=1,\ldots,m)$ be a small circle around the eigenvalue λ_k such that the corresponding disk doesn't contain other eigenvalues. Consider the operators

$$M_k^l=(-1)^{l+1}\frac{1}{2\pi i}\oint_{\omega_k}(\lambda_k-z)^l(A|_x^{\mathbf{C}}-z\mathbf{1})^{-1}dz, \tag{30}$$

where $k=1,\dots,m;\ l=0,\dots,r(\lambda_k)-1$.

Lemma 3: The operators M_k^l $(k=1,\dots,m;\ l=0,\dots,r(\lambda_k)-1)$ form a basis of the linear space of minimal dimension that contains the image of the curve $\gamma_x^{\mathbf{C}}$.

Proof of Lemma 3: It follows from the form of the integrand in formula (30) that the operators M_k^l lie in any linear space that contains the image of the curve $\gamma_x^{\mathbf{C}}$. Formula (29) and Cauchy formula show that M_k^l $(k=1,\dots,m;\ l=1,\dots,r(\lambda_k))$ are linearly independent and the vector space spanned on them contains the image of the curve $\gamma_x^{\mathbf{C}}$. Lemma 3 is proved.

It follows from Lemma 3 that $R_\gamma(x)=\Sigma_{i=1}^m r(\lambda_i)$. The second item of Proposition 3 is proved. The first item can be easily proved by direct calculations using the simple form of the operators M_k^l in the Jordan's basis. Proposition 3 is proved.

Remark 8: Suppose that $r=r(g,\overline{g})(x)$. It follows from formula (29) that

$$T(c)|_x\overset{\text{def}}{=}(\lambda_1+c)^{r(\lambda_1)}\ \cdots(\lambda_m+c)^{r(\lambda_m)}(A|_x^{\mathbf{C}}+c\mathbf{1}_x)^{-1} \tag{31}$$

$$=P_{r-1}|_x c^{r-1}+P_{r-2}|_x c^{r-2}\cdots+P_0|_x. \tag{32}$$

It is clear that the forms $P_{r-1}|_x,\dots,P_0|_x$ are linearly independent. Therefore, if we take r real constants $c_1,\dots,c_r$ $(c_i\neq c_j(i\neq j))$, then the forms $T(c_1)|_x,\dots,T(c_r)|_x$ are linearly independent. Formula (2) shows that

$$K_c|_x=(\lambda_1+c)^{n_1-r(\lambda_1)}\ \cdots(\lambda_m+c)^{n_m-r(\lambda_m)}gT(c)|_x, \tag{33}$$

where n_k denotes the multiplicity of λ_k in the characteristic polynomial of the operator $A|_x$. Hence, if $K_{c_i}|_x\neq 0$ $(i=1,\dots,r)$, then the forms $K_{c_1}|_x,\dots,K_{c_r}|_x$ give a basis of the linear space of minimal dimension that contains the image of the curve $\gamma_x^{\mathbf{C}}$. It follows from formula (33) that the forms $I_{n-1}|_x,\dots,I_{n-r}|_x$ give another basis.

Theorem 6: *Suppose that the manifold M^n is connected and the rank of the geodesic equivalence of the pair g and $\overline{g}$ (given by Definition 4) is r; then there exist r quadratic in velocities functions $B_1(\xi),\dots,B_r(\xi)$, $\xi\in TM$, such that the next three conditions are satisfied:*

(a) The functions $B_1,\dots,B_r$ are pairwise commuting integrals of the geodesic flow of the metric g;

(b) The functions $B_1,\dots,B_r$ are functionally independent on TM;

(c) For every fixed value of the parameter c there exists r constants $\alpha_1,\dots,\alpha_r$ (depending on c) such that $K_c(\xi)=\Sigma_{i=1}^r\alpha_i B_i(\xi)$.

The functions $B_1,\dots,B_r$ can be taken in the form $B_k\overset{\text{def}}{=}I_{i_k}$, where $0\leqslant i_k\leqslant n-1$ are some specially chosen different integer numbers.

Remark 9: Actually, in Theorem 6 we can take $B_1\overset{\text{def}}{=}I_{n-1},\dots,B_r\overset{\text{def}}{=}I_{n-r}$. Another system of functions that satisfy conditions (a), (b), and (c) of Theorem 6 can be obtained if we put $B_1\overset{\text{def}}{=}K_{c_1},\dots,B_r\overset{\text{def}}{=}K_{c_r}$ where $c_1,\dots,c_r$ are arbitrarily taking different real constants such that the integrals K_{c_k} $(k=1,\dots,r)$ are not identically equal to zero.

Remark 10: It follows from Theorem 6 and Remark 8 that for every point x on the manifold M^n the dimension of the linear space spanned on the quadratic forms $B_1|_x,\dots,B_r|_x$ coincides with the rank of the geodesic equivalence of the pair g and $\overline{g}$ at x. Indeed, it follows from item (c) of Theorem 6 that $I_{n-i}=\Sigma_{i=1}^r\alpha_i^l B_l$ $(i=1,\dots,r)$, where (α_i^l) is a constant matrix. If x is a point of maximal rank [i.e., $r(g,\overline{g})(x)=r$], then $I_{n-1}|_x,\dots,I_{n-r}|_x$ are linearly independent. Therefore, $B_1|_x,\dots,B_r|_x$ are also linearly independent and the matrix (α_i^l) is nondegenerate.

Proof of Theorem 6: Suppose that the metrics g and $\overline{g}$ are geodesically equivalent.

Definition 5: A point $x_0 \in M^n$ is called stable *if the rank of the geodesic equivalence $r(g,\overline{g})\times(x)$ is equal to some constant s in an open neighborhood of the point x_0. In this case we say that x_0 is a stable point of rank s.*

Definition 6: A point $x_0 \in M^n$ is called singular *if it is not stable.*

Denote by $\mathcal{M}(g,\overline{g})$ the set of the stable points on M^n.

Lemma 4: The set of the stable points $\mathcal{M}(g,\overline{g})$ is everywhere dense in M^n.

Proof of Lemma 4: Let us fix a point $x_0 \in M^n$. It follows from Lemma 2 that $r(x)$ coincides with the dimension of the vector space spanned on the forms $I_{n-1}|_x, \ldots, I_0|_x \in \mathrm{Symm}(T_x^* M^n \otimes T_x^* M^n)$. It gives that the inequality $r(x) \geqslant r(x_0)$ is satisfied in an open neighborhood of x_0. Therefore, *if x_0 is a singular point, then every open neighborhood of x_0 contains a point y such that $r(y) > r(x_0)$.*

Suppose that the open set V consists of singular points. Let us take a point $p_1 \in V$. The point p_1 is singular. Hence, there is a point $p_2 \in V$ such that $r(p_2) > r(p_1)$. But the point p_2 is also singular. Applying the last argument several times we see that there exists a singular point $p_k \in V$ such that $r(p_k) = n$. From another side it is clear that the points of maximal rank are stable. This is a contradiction. Lemma 4 is proved.

Let us return to the proof of Theorem 6. Denote by r the rank of the geodesic equivalence of the pair g and $\overline{g}$. First of all, let us prove a local variant of Theorem 6.

Lemma 5: Suppose that x_0 is a stable point of rank s; then there exists an open neighborhood $U(x_0)$ of the point x_0 and quadratic in velocities functions $B_1, \ldots, B_s$ such that statements (a), (b), and (c) of Theorem 6 are satisfied. Moreover, for every point $x \in U(x_0)$, the set of the points $\xi \in T_x M^n$, are linearly independent is open and dense in $T_x M^n$.

Proof of Lemma 5: Suppose that $x_0 \in M^n$ is a stable point of rank s. It follows from Lemma 2 that we can choose s different integer numbers $0 \leqslant i_k \leqslant n-1$ $(k=1,\ldots,s)$ (see also Remark 8) such that the forms $I_{i_1}|_{x_0}, \ldots, I_{i_s}|_{x_0}$ are linearly independent. Let us define $B_1 = {}^{\mathrm{def}} I_{i_1}, \ldots, B_s = {}^{\mathrm{def}} I_{i_s}$. It is clear that the forms $B_k|_x$ $(k=1,\ldots,s)$ are linearly independent for every x from an open neighborhood $U(x_0)$ of the point x_0. We can take $U(x_0)$ such that $r(g,\overline{g})(x) = r$ on $U(x_0)$. Remark that the set of the points $\xi \in TU(x_0)$ where the differentials $d_\xi B_k$ $(k=1,\ldots,s)$ are linearly independent is open and dense in $TU(x_0)$. Moreover, the intersection of this set with any tangent plane $T_x U(x_0)$ is open and dense in $T_x U(x_0)$. Indeed, it follows from Lemma 2 that the set of the points $\xi \in T_x M^n$ where the differentials $d_\xi(B_k|_{T_x M^n}) = 2B_k(.,\xi)$ $(k=1,\ldots,s)$ are linearly independent is open and dense subset in $T_x M^n$.

Let us fix a real constant c and consider the form K_c. We have that $K_c(\xi) = \Sigma_{k=1}^s \alpha_k(x) B_k(\xi)$, $\xi \in TU(x_0)$, where $\alpha_k(x)$ are smooth functions on $U(x_0)$. Denote by E_g the energy function $E_g(\xi) = {}^{\mathrm{def}} \frac{1}{2} g(\xi,\xi)$. We have $0 = \{E_g, K_c\} = \Sigma_{k=1}^s \{E_g, \alpha_k\} B_k$. Hence, the Poisson brackets $\{E_g, \alpha_k\}$ vanish. It gives that α_k $(k=1,\ldots,s)$ are constants. Lemma 5 is proved.

Let us prove item (b) of Theorem 6.

Lemma 6: Let x and y be two points on M^n connected by a geodesic line and let $D(y)$ be an open neighborhood of the point y. Suppose that the set of the points $\xi \in T_x M^n$, where the differentials $d_\xi B_1, \ldots, d_\xi B_r$ are linearly independent is open and dense in $T_x M^n$; then there exists a point $y' \in D(y)$ such that the set of the points $\eta \in T_{y'} M^n$ where the differentials $d_\eta B_1, \ldots, d_\eta B_r$ are linearly independent is open and dense in $T_{y'} M^n$.

Proof of Lemma 6: Without loss of generality it can be assumed that y is a stable point of rank $r(y) = r_1$. Therefore, we can find an open neighborhood $V(y) \subset D(y)$ of the point y where the rank $r(u) = r_1$ $(u \in V(y))$ and the statements of Lemma 5 are satisfied. In particular, there exist functionally independent on $TV(y)$ functions $Q_1, \ldots, Q_{r_1}$ such that $B_k = \Sigma_{i=1}^{r_1} \beta_k^i Q_i$, where β_k^i are some constants. Therefore,

$$dB_k = \sum_{i=1}^{r_1} \beta_k^i dQ_i. \tag{34}$$

The points x and y can be connected by a geodesic. It can be easily seen that there exists a vector

$\xi \in T_x M^n$ such that $\exp(\xi) \in V(y)$ and the differentials $d_\xi B_k$ $(k=1,\ldots,r)$ are linearly independent. Using the fact that the functions B_k are integrals of the geodesic flow of the metric g we see that the differentials $d_w B_k$, where $w =^{\text{def}} d/dt\,|_{t=1} \exp(t\xi) \in TV(y)$, are linearly independent. Let us take $y' =^{\text{def}} \exp(\xi)$. It follows from formula (34) that $d_w B_k = \Sigma_{i=1}^{r_1} \beta_k^i d_w Q_i$. The last equality is possible only if the rank of the matrix (β_k^i) is equal to r and $r_1 \geqslant r$. By definition $r \geqslant r_1$. Hence, the square matrix (β_k^i) is nondegenerate. Therefore, dB_k $(k=1,\ldots,r)$ are linearly independent at the same points where dQ_k $(k=1,\ldots,r_1)$ are linearly independent. Finally, the statement of Lemma 6 follows from Lemma 5. Lemma 6 is proved.

Let us fix a point $x_0 \in M^n$. Suppose that x_0 is a stable point of rank r. Consider the functions $B_1,\ldots,B_r$ given by Lemma 5. These functions are invariantly defined on the whole manifold M^n (by definition, $B_k =^{\text{def}} I_{i_k}$). Assume that there exists an open set W in TM^n such that if $\xi \in W$ then the differentials $d_\xi B_k$ $(k=1,\ldots,r)$ are linearly dependent. Let us take a point $y_0 \in \pi(W)$, where $\pi: TM^n \to M^n$ denotes the natural projection on M^n. Provided the manifold M^n is connected, we can choose a sequence of points $x_0, x_1, \ldots, x_N = y_0$ and open neighborhoods $W(x_0), W(x_1), \ldots, W(x_N), W(x_N) \subseteq \pi(W)$ of these points such that any two points $u \in W(x_i)$ and $v \in W(x_{i+1})$ can be connected by a geodesic $(0 \leqslant i \leqslant N-1)$. Applying Lemma 6 successively we obtain that there exists a point $y_0' \in \pi(W)$ such that the set of the points $\eta \in T_{y_0'} M^n$ where the differentials $d_\eta B_1, \ldots, d_\eta B_r$ are linearly independent is open and dense in $T_{y_0'} M^n$. This is a contradiction. Item (b) is proved.

It follows from item (b) and Lemma 5 that the forms $B_k|_x$ $(k=1,\ldots,r)$ are linearly independent for every fixed x from an open and dense subset $\mathcal{K}$ in M^n. Indeed, the assumption that these forms are linearly dependent for every fixed x from an open subset in M^n implies (see Lemma 5) that there exists an open subset U in M^n such that $\Sigma_{i=1}^r \beta_i B_i = 0$ on U, where β_i are some constants. This contradicts to item (b). It is clear that for any two points $x \in \mathcal{K}$ and $y \in \mathcal{K}$ there exists a sequence $\{\xi_i\}_{i=1}^{N-1} \subset T\mathcal{K}$, $\xi_1 \in T_x M^n$, such that for every fixed $1 \leqslant i \leqslant N-1$ the differentials $d_{\xi_i} B_1, \ldots, d_{\xi_i} B_r$ are linearly independent and $\exp(\xi_i) = x_{i+1}$ $(i=1,\ldots,N-1)$, $x_N = y_0$. Let us fix a value c and consider the integral K_c given by formula (2). As in the proof of Lemma 5 we see that there exist open neighborhoods $U(x_1), \ldots, U(x_N)$ of the points $x_1, \ldots, x_N$, respectively, such that $K_c(\xi) = \Sigma_{s=1}^r \alpha_i^s B_s(\xi)$, where α_i^k are constants and $\xi \in TU(x_i)$ $(i=1,\ldots,N)$. We have $d_{\xi_1} K_c = \Sigma_{s=1}^r \alpha_1^s d_{\xi_1} B_s$. From another side,

$$d_{\xi_1} K_c = d_{\zeta^1(\xi_1)} K_c \circ \zeta_*^1 \tag{35}$$

$$= \sum_{s=1}^r \alpha_2^s d_{\zeta^1(\xi_1)} B_s \circ \zeta_*^1 \tag{36}$$

$$= \sum_{s=1}^r \alpha_2^s d_{\xi_1} B_s, \tag{37}$$

where $\zeta^t: TM^n \to TM^n$ denotes the geodesic flow corresponding to the metric g. The linear independence of the differentials $dB_1, \ldots, dB_r$ at ξ_1 shows that $\alpha_1^s = \alpha_2^s$ $(s=1,\ldots,r)$. Applying this constriction successively we obtain that $\alpha_1^s = \alpha_2^s = \cdots = \alpha_N^s$ $(s=1,\ldots,r)$. Therefore, $K_c = \Sigma_{s=1}^r \alpha_1^s B_s$ on $\mathcal{K}$. Using the fact that $\mathcal{K}$ is open and dense in M^n we prove item (c). This completes the proof of Theorem 6.

Remark 11: It follows from Theorem 6 that all stable points on M^n have the same rank.

As a simple corollary from Theorem 6 we obtain the next proposition.

Proposition 4: The rank of the geodesic equivalence of the pair g and $\overline{g}$ coincides with the number,

$$\rho \overset{\text{def}}{=} \max_{\xi \in TM^n} \operatorname{rk}\{d_\xi I_0, \ldots, d_\xi I_{n-1}\}. \tag{38}$$

Finally, Theorem 2 and Theorem 3 follow directly from Theorem 6 and Proposition 4.

Remark 12: Let g be a metric and $A \in \Gamma(\operatorname{Hom}(TM^n, TM^n))$ be an operator given on the manifold M^n. Suppose that the one-parameter family of functions on TM^n,

$$K_c(g,A) = \text{def}\det(A + c\mathbf{1})g(A + c\mathbf{1})^{-1} \tag{39}$$

$$= I_{n-1}(g,A)c^{n-1} + I_{n-2}(g,A)c^{n-2} + \cdots + I_0(g,A) \tag{40}$$

are integrals of the geodesic flow of the metric g. Denote by $r(g,A)(x)$ the degree of the minimal polynomial of the operator $A|_x$. Let $r = r(g,A) = \overset{\text{def}}{} \max_{x \in M^n} r(g,A)(x)$. It can be easily seen that statements (b) and (c) of Theorem 6 still hold. Moreover, the number $r(g,A)$ coincides with the number,

$$\rho(g,A) \overset{\text{def}}{=} \max_{\xi \in TM^n} \operatorname{rk}\{d_\xi I_0, \ldots, d_\xi I_{n-1}\}. \tag{41}$$

Theorem 6 admits us to prove the next corollary.

Corollary 2: Suppose that the metrics g and $\overline{g}$ are geodesically equivalent. Suppose in addition that the manifold M^n is connected and let $x_0 \in M^n$ be a point of maximal rank [i.e., $r(g,\overline{g}) \times (x_0) = r(g,\overline{g})$]. Denote by $m(\lambda)$ the multiplicity of the eigenvalue λ of the operator $A(g,\overline{g})|_{x_0}$ and let $r(\lambda)$ be the corresponding r-number (see Sec. III B); then if $m(\lambda) - r(\lambda) > 0$ the value λ is an eigenvalue of the operator $A(g,\overline{g})|_x$ for every point x on M^n.

Proof of Corollary 2: Let $\lambda \in \mathbf{C}$ be an eigenvalue of the operator $A(g,\overline{g})|_{x_0}$ such that $m(\lambda) - r(\lambda) > 0$. It follows from Theorem 6 that

$$K_\lambda = \sum_{k=1}^{r} \alpha_k I_{n-k}, \tag{42}$$

where $\alpha_1, \ldots, \alpha_r$ are constants. Formula (33) shows that $K_\lambda|_{x_0} = 0$. From another side, the forms $I_{n-1}|_{x_0}, \ldots, I_{n-r}|_{x_0}$ are linearly independent (see Remark 8). Therefore, $\alpha_i = 0$ $(i = 1, \ldots, r)$ and $K_\lambda \equiv 0$ on M^n. Finally, the statement of the corollary follows from formula (33). Corollary 2 is proved.

Combining Corollary 2 and Theorem 6 we obtain the next criterion.

Proposition 5: The integrals given by formula (2) are enough for the complete integrability of the geodesic flow of the metric g iff the equation $K_\lambda \equiv 0$ (on M^n) does not have a constant solution $\lambda \in \mathbf{C}$.

C. Associated hierarchy of functions in involution

Combining theorems 1, 2, and 5 we obtain the next theorem.

Theorem 7: *Suppose that the metrics g and $\overline{g}$ are geodesically equivalent. For every integer l consider the family of functions on T^*M^n,*

$$K_\alpha^{(l)}(g,\overline{g}) \overset{\text{def}}{=} \det(A + \alpha\mathbf{1})(A + \alpha\mathbf{1})^{-1} A^{-l} g^{-1} \tag{43}$$

$$= I_{n-1}^{(l)} \alpha^{n-1} + I_{n-2}^{(l)} \alpha^{n-2} + \cdots + I_0^{(l)}, \tag{44}$$

where $A=A(g,\overline{g})$ is given by formula (1). Then the functions $I^{(l)}_{n-1},\dots,I^{(l)}_0$ are in involution with respect to the canonical symplectic structure on T^*M^n. If the rank of the geodesic equivalence of the pair g and $\overline{g}$ is r, then the functions $I^{(l)}_{n-1},\dots,I^{(l)}_{n-r}$ are functionally independent.

Proof of Theorem 7: Let us consider the geodesic hierarchy of the pair g and $\overline{g}$,

$$\begin{array}{ccc} \downarrow & & \downarrow \\ g^{(l-1)} & \overset{g.e.}{\leftrightarrow} & \overline{g}^{(l-1)} \\ \downarrow & & \downarrow \\ g^{(l)} & \overset{g.e.}{\leftrightarrow} & \overline{g}^{(l)} \\ \downarrow & & \downarrow, \end{array}$$

where $g^{(l)}=^{\text{def}}gA^l$, $\overline{g}^{(l)}=^{\text{def}}\overline{g}A^l$, and l is a fixed integer number. It follows from formula (1) that $A(g^{(l)},\overline{g}^{(l)})=A(g,\overline{g})$. Therefore, the one-parameter family of functions

$$K_\alpha(g^{(l)},\overline{g}^{(l)})\overset{\text{def}}{=}\det(A+\alpha\mathbf{1})(A+\alpha\mathbf{1})^{-1}g^{(l)-1} \tag{45}$$

$$=\det(A+\alpha\mathbf{1})(A+\alpha\mathbf{1})^{-1}A^{-l}g^{-1} \tag{46}$$

are in involution with respect to the canonical symplectic structure on T^*M^n. It is clear that the rank of the geodesic equivalence of the pair $g^{(l)}$ and $\overline{g}^{(l)}$ is the same as the rank of the geodesic equivalence of the initial pair g and $\overline{g}$. Theorem 7 is proved.

IV. PROJECTIVE HIERARCHY

Let us consider the projective space $\mathbf{RP}^n=^{\text{def}}\{(x_1:\cdots:x_{n+1})\}$ and fix the affine chart $\mathbf{R}^n\cong\{x_{n+1}=1\}\hookrightarrow\mathbf{R}^{n+1}$. Any nondegenerate linear transformation L of $\mathbf{R}^{n+1}$ gives a projective transformation of $\mathbf{RP}^n$ that acts on the affine chart $\mathbf{R}^n$ as a linear-fractional transformation that we denote by μ_L. If the projective transformation μ_L is not an affine transformation, then it is a partially defined transformation that is not defined over a hyperplane Z_L in $\mathbf{R}^n$. It is clear that if a straight line l is not contained in Z_L, then the image $\mu_L(l)$ is a straight line.

Let us consider the projective transformation of the plane $\mathbf{R}^n$ given by the formula,

$$\mu:\begin{cases} x_1 & \mapsto & (\lambda_1x_1)/x_n \\ & \vdots & \\ x_{n-1} & \mapsto & (\lambda_{n-1}x_{n-1})/x_n \\ x_n & \mapsto & \lambda_n-\lambda_n/x_n \end{cases},$$

where λ_i $(i=1,\dots,n)$ are nonzero constants. Consider the metric $dg^2=^{\text{def}}\epsilon_1dx_1^2+\cdots\epsilon_ndx_n^2$ on $\mathbf{R}^n$, where $\epsilon_i=\pm1$. The geodesics of the metric g are straight lines. Denote by $\overline{g}$ the pullback μ^*g. Remark that the metric $\overline{g}$ is not defined over the hyperplane $Z=^{\text{def}}\{x_n=0\}$. It is clear that the metrics g and $\overline{g}$ are geodesically equivalent on $\mathcal{D}=^{\text{def}}\mathbf{R}^n\backslash Z$. Our aim is to compute the geodesic hierarchy corresponding to the pair of geodesically equivalent metrics g and $\overline{g}$. We have

$$d\overline{g}^2\overset{\text{def}}{=}\mu^*(dg^2)=\epsilon_1\lambda_1^2\left(\frac{x_ndx_1-x_1dx_n}{x_n^2}\right)^2+\cdots\epsilon_{n-1}\lambda_{n-1}^2\left(\frac{x_ndx_{n-1}-x_{n-1}dx_n}{x_n^2}\right)^2+\epsilon_n\lambda_n^2\left(\frac{dx_n}{x_n^2}\right)^2. \tag{47}$$

Let us compute the operator $A=^{\text{def}}A(g,\overline{g})$. We need the next simple lemmas.

Lemma 7: Consider the matrix,

$$C \overset{\text{def}}{=} \overline{a} \otimes \overline{a} + b, \tag{48}$$

where $b = {}^{\text{def}}\mathrm{diag}(b_1, \ldots, b_n)$, $b_i \neq 0$ $(i = 1, \ldots, n)$, $\overline{a} = {}^{\text{def}}(a_1, \ldots, a_n)'$ *(the symbol* $'$ *denotes the transposition of a matrix) and* $\overline{a} \otimes \overline{a}$ *stands for the matrix* $\overline{a}\overline{a}'$. *Then the inverse matrix* C^{-1} *is given by the formula*

$$C^{-1} = b^{-1} - \frac{1}{D}(b^{-1}\overline{a}) \otimes (b^{-1}\overline{a}), \tag{49}$$

where $D = {}^{\text{def}}\langle b^{-1}\overline{a}, \overline{a}\rangle + 1$ *and* $\langle \overline{x}, \overline{y}\rangle = {}^{\text{def}}\sum_{i=1}^{n} x_i y_i$. *Moreover,* $\det C = (\Pi_{k=1}^{n} b_k) D$.

Proof of Lemma 7: The proof is by direct calculation. We have

$$(\overline{a}\overline{a}' + b)\left(b^{-1} - \frac{1}{D}(b^{-1}\overline{a})(b^{-1}\overline{a})' \right) \tag{50}$$

$$= \overline{a}(\overline{a}' b^{-1}) + E - \frac{\langle \overline{a}, b^{-1}\overline{a}\rangle}{D}\overline{a}(b^{-1}\overline{a})' - \frac{1}{D}\overline{a}(b^{-1}\overline{a})' = E, \tag{51}$$

where E denotes the unit matrix. Lemma 7 is proved.

Lemma 8: Consider the matrix,

$$C_0 \overset{\text{def}}{=} \overline{a} \otimes \overline{a} + \mathrm{diag}(b_1, \ldots, b_{n-1}, 0), \tag{52}$$

where $b_i \neq 0$ $(i = 1, \ldots, n-1)$. *Then the inverse matrix* C_0^{-1} *is given by the formula,*

$$C_0^{-1} = \frac{1}{a_n^2}\left\{ \sum_{i=1}^{n-1} \frac{a_n^2}{b_i} E_{ii} + \left(\sum_{i=1}^{n-1} \frac{a_i^2}{b_i} + 1 \right) E_{nn} - \sum_{i=1}^{n-1} \frac{a_n a_i}{b_i} E_{in} - \sum_{i=1}^{n-1} \frac{a_n a_i}{b_i} E_{ni} \right\}, \tag{53}$$

where the matrix E_{ij} *has elements* $e_{kl} = {}^{\text{def}}\delta_{ki}\delta_{lj}$ $(k, l = 1, \ldots, n)$. *We have that* $\det C_0 = (\Pi_{k=1}^{n-1} b_k) a_n^2$.

Lemma 8 easily follows from Lemma 7 and the formula $C_0^{-1} = \lim_{\alpha \to +0}(C_0 + \alpha)^{-1}$.

Denote by $\overline{G}$ the matrix corresponding to the metric $\overline{g}$, i.e., the Gramian of the metric g. Taking $\overline{a} = \overline{x}$ $(\overline{x} = {}^{\text{def}}(x_1, \ldots, x_n))$, $b_i = (\epsilon_n \lambda_n^2)/(\epsilon_i \lambda_i^2)$ $(i = 1, \ldots, n-1)$, and applying Lemma 8 we see that

$$\overline{G}^{-1} = \frac{x_n^2}{\epsilon_n \lambda_n^2}\left(\overline{x} \otimes \overline{x} + \mathrm{diag}\left(\frac{\epsilon_n \lambda_n^2}{\epsilon_1 \lambda_1}, \ldots, \frac{\epsilon_n \lambda_n^2}{\epsilon_{n-1}\lambda_{n-1}}, 0 \right) \right). \tag{54}$$

As a corollary we obtain that $\det \overline{G} = (-1)^s (\Pi_{i=1}^{n} \lambda_i^2)/x_n^{2n+2}$, where s is the signature of the metric g. Finally, combining (1) and (54) we obtain (up to a multiplication on a constant) that

$$A(g, \overline{g}) = \left(\overline{x} \otimes \overline{x} + \mathrm{diag}\left(\frac{\epsilon_n \lambda_n^2}{\epsilon_1 \lambda_1^2}, \ldots, \frac{\epsilon_n \lambda_n^2}{\epsilon_{n-1}\lambda_{n-1}^2}, 0 \right) \right) \mathcal{E}, \tag{55}$$

where $\mathcal{E} = {}^{\text{def}}\mathrm{diag}(\epsilon_1, \ldots, \epsilon_n)$. Denote for simplicity,

$$\mathcal{A} \overset{\text{def}}{=} \overline{x} \otimes \overline{x} + \mathrm{diag}\left(\frac{\epsilon_n \lambda_n^2}{\epsilon_1 \lambda_1^2}, \ldots, \frac{\epsilon_n \lambda_n^2}{\epsilon_{n-1}\lambda_{n-1}^2}, 0 \right). \tag{56}$$

We have $A = \mathcal{A}\mathcal{E}$.

It follows from Theorem 4 that the one-parameter family of metrics $g_c(g,\overline{g})=^{\text{def}}1/[\det(A+c\mathbf{1})]\,g(A+c\mathbf{1})^{-1}$ are geodesically equivalent to g. We have

$$G_c=^{\text{def}}\frac{1}{\det(\mathcal{A}\mathcal{E}+cE)}\,\mathcal{E}(\mathcal{A}\mathcal{E}+cE)^{-1} \tag{57}$$

$$=\frac{(-1)^s}{\det(\mathcal{A}+c\mathcal{E})}(\mathcal{A}+c\mathcal{E})^{-1}, \tag{58}$$

where G_c denotes the Gramian of the metric g_c. It follows from Lemma 7 that up to a multiplication on a constant we have

$$dg_c^2=\left\{D_c\left(\frac{\epsilon_1 dx_1^2}{d_1+c}+\cdots+\frac{\epsilon_{n-1}dx_{n-1}^2}{d_{n-1}+c}+\frac{\epsilon_n dx_n^2}{c}\right)-\left(\frac{\epsilon_1 x_1 dx_1}{d_1+c}+\cdots+\frac{\epsilon_{n-1}x_{n-1}dx_{n-1}}{d_{n-1}+c}+\frac{\epsilon_n x_n dx_n}{c}\right)^2\right\}/D_c^2, \tag{59}$$

where $d_k=^{\text{def}}\epsilon_n\lambda_n^2/\lambda_k^2$ and

$$D_c=^{\text{def}}\frac{\epsilon_1 x_1^2}{d_1+c}+\cdots+\frac{\epsilon_{n-1}x_{n-1}^2}{d_{n-1}+c}+\frac{\epsilon_n x_n^2}{c}+1. \tag{60}$$

Remark 13: The metric dg_c^2 is not defined on the quadric $Z_c=^{\text{def}}\{D_c=0\}$. The most of the metrics we consider in the present section are not defined on a hypersurface. Nevertheless, from now on when we say that some metrics are geodesically equivalent we mean they are geodesically equivalent in the domain where both of them are defined.

It follows from Theorem 1 that the quadratic forms

$$dK_c^2=D_c\left(\frac{\epsilon_1 dx_1^2}{d_1+c}+\cdots+\frac{\epsilon_{n-1}dx_{n-1}^2}{d_{n-1}+c}+\frac{\epsilon_n dx_n^2}{c}\right)-\left(\frac{\epsilon_1 x_1 dx_1}{d_1+c}+\cdots+\frac{\epsilon_{n-1}x_{n-1}dx_{n-1}}{d_{n-1}+c}+\frac{\epsilon_n x_n dx_n}{c}\right)^2 \tag{61}$$

are pairwise commuting integrals of the geodesic flow of the metric dg^2 on every of the half-planes $\{x_n>0\}$ and $\{x_n<0\}$. The quadratic forms K_c are smoothly defined on the whole $\mathbf{R}^n$. Therefore, they are pairwise commuting integrals of the geodesic flow the metric dg^2 on $\mathbf{R}^n$.

Let us compute the rank of the geodesic equivalence of the pair g and $\overline{g}$. Suppose that $d_i\neq d_j$ $(i\neq j)$ and $d_i\neq 0$ $(i=1,\ldots,n-1)$. Consider the characteristic polynomial,

$$\chi_A(c)=^{\text{def}}\det(\mathcal{A}\mathcal{E}+cE) \tag{62}$$

$$=\prod_{k=1}^{n}(d_k+c)\left\{\frac{\epsilon_1 x_1^2}{d_1+c}+\cdots+\frac{\epsilon_{n-1}x_{n-1}^2}{d_{n-1}+c}+\frac{\epsilon_n x_n^2}{c}+1\right\}, \tag{63}$$

where we put $d_n=0$. It is clear that the polynomial $\chi_A(c)|_{(x=0)}$ has n different roots. Therefore, the rank of the geodesic equivalence of the pair dg^2 and $d\overline{g}^2$ is n (see Remark 12). Let us fix some real constant c and consider the metric dg_c^2 given by formula (59). The formula $A(g,g_c)=A(g,\overline{g})+c$ shows that the rank of the geodesic equivalence of the pair g and g_c is also n. We have proved the next theorem.

Theorem 8: *The metric $dg^2=^{\text{def}}\Sigma_{i=1}^n\epsilon_i dx_i^2$ and the metrics given by formula (59) are geodesically equivalent. If $d_i\neq d_j$ $(i\neq j)$ and $d_i\neq 0$ $(i=1,\ldots,n-1,)$, then the rank of the geodesic equivalence of the pair dg^2 and dg_c^2 is n.*

The metrics dg_c^2 given by formula (59) have a very special property given by the next theorem.

Theorem 9: *Consider the Euclidean case, i.e.* $\epsilon_i=1$ $(i=1,\dots,n)$. *Suppose that* $d_i\neq d_j$ $(i\neq j)$ *and* $d_i\neq 0$ $(i=1,\dots,n-1)$. *Then the restriction of the metrics* dg_c^2 *given by formula (59) on every quadric* Q_α $(\alpha\neq c)$ *from the confocal family* $Q_\alpha=^{\text{def}}\{D_\alpha=0\}$ *is geodesically equivalent to the restriction of the standard Euclidean metric* dg^2 *on* Q_α.

As a corollary we obtain the theorem proved in Ref. 1 and independently in Ref. 8 that the standard ellipsoid admits a nontrivial geodesic equivalence. Theorem 9 shows that the same result is true for the hyperboloids.

Proof of Theorem 9: Suppose that $dg^2=\Sigma_{i=1}^n dx_i^2$. Let us fix a point $\overline{x_0}=(x_1^0,\dots,x_n^0)\in\mathbf{R}^n$ such that $x_1^0\cdots x_n^0\neq 0$. It can be easily seen that there exists n different real constants $\alpha_1,\dots,\alpha_n$ such that $Q_{\alpha_1}(\overline{x_0})=0,\dots,Q_{\alpha_n}(\overline{x_0})=0$. It follows from formula (61) that

$$K_{\alpha_l}|_{\overline{x}_0}=-(d_{\overline{x}_0}Q_{\alpha_l})^2/4. \tag{64}$$

The forms $d_{\overline{x}_0}Q_{\alpha_l}$ are linearly independent. Therefore, $r(g,\overline{g})(\overline{x_0})=n$. Formula (3) and the nondegeneracy of the corresponding Vandermonde determinant show that the forms $I_0|_{\overline{x}_0},\dots,I_{n-1}|_{\overline{x}_0}$ are simultaneously diagonalizable in the dual to the forms $d_{\overline{x}_0}Q_{\alpha_l}$ $(l=1,\dots,n)$ frame. The form I_{n-1} is conformally equivalent to the metric g and the form I_0 is conformally equivalent to $\overline{g}$. Hence, the gradients (with respect to the metric g) $\nabla_{\overline{x}_0}Q_{\alpha_1},\dots,\nabla_{\overline{x}_0}Q_{\alpha_n}$ coincide with the principal directions of the metrics $g|_{\overline{x}_0}$ and $\overline{g}|_{\overline{x}_0}$. Finally, the statement of the theorem follows from Levi-Civita's theorem about the local form of the Riemannian metrics that permit geodesic equivalence (see Refs. 6, 11, 3). Theorem 9 is proved.

A. Projective hierarchy of geodesically equivalent metrics

Let $\{(x_1,\dots,x_n)\}$ be the coordinates in $\mathbf{R}^n$. Let us fix a value κ of the parameter c in formula (57). Using Theorem 5 we obtain that for every integer k the metrics given by the formulas,

$$dg_\kappa^{(k)2}=^{\text{def}}\langle\mathcal{E}(\mathcal{A}\mathcal{E}+\kappa E)^k d\overline{x},d\overline{x}\rangle \tag{65}$$

and

$$d\overline{g}_\kappa^{(k)2}=^{\text{def}}\frac{1}{\det(\mathcal{A}\mathcal{E}+\kappa E)}\langle\mathcal{E}(\mathcal{A}\mathcal{E}+\kappa E)^{k-1}d\overline{x},d\overline{x}\rangle, \tag{66}$$

where $d\overline{x}=(dx_1,\dots,dx_n)$, $\langle\overline{\xi},\overline{\eta}\rangle=^{\text{def}}\Sigma_{i=1}^n\xi_i\eta_i$,

$$\mathcal{A}=^{\text{def}}\overline{x}\otimes\overline{x}+\operatorname{diag}(\epsilon_1 d_1,\dots,\epsilon_{n-1}d_{n-1},0), \tag{67}$$

$$\mathcal{E}=^{\text{def}}\operatorname{diag}(\epsilon_1,\dots,\epsilon_n),\quad \epsilon_i=\pm 1, \tag{68}$$

are geodesically equivalent.

Theorem 10: *Let* κ *be a fixed real constant. For every fixed integer* k *the metrics given by formulas (65) and (66) are geodesically equivalent. Provided that* $d_i\neq d_j$ $(i\neq j)$ *and* $d_i\neq 0$ $(i=1,\dots,n-1)$ *the rank of the geodesic equivalence is* n.

Remark 14: The metric $d\overline{g}_\kappa^{(2)2}$, *provided* $\mathcal{E}=E$, *is isometric to the analog of the Poisson sphere corresponding to the Clebsch case of motion of the rigid body (see Sec. III B in Ref. 4).*

Remark 15: Using Lemma 8 we obtain that up to a multiplication on a constant,

$$d\overline{g}_\kappa^{(1)2}|_{(\kappa=0)}=\frac{1}{x_n^2}\sum_{i=1}^n\epsilon_i dx_i^2. \tag{69}$$

This is a canonical form of the metrics with constant negative curvature. The metric $dg_{\kappa}^{(1)2}|_{(\kappa=0)}=\langle \mathcal{E}\mathcal{A}\mathcal{E}d\overline{x},d\overline{x}\rangle$ *is geodesically equivalent to* $d\overline{g}_{\kappa}^{(1)2}|_{(\kappa=0)}$. *The metric* $dg_{\kappa}^{(1)2}|_{(\kappa=0)}$ *is smoothly defined on the whole* $\mathbf{R}^n$.

B. Projective hierarchy of functions in involution

Let $\{(x_1,\ldots,x_n)\}$ be the coordinates in $\mathbf{R}^n$. Denote by $(x_1,\ldots,x_n;p_1,\ldots,p_n)$ the corresponding coordinates in $T^*\mathbf{R}^n$. Applying Theorem 7 we obtain the next theorem.

Theorem 11: *For every fixed real* κ *and every fixed integer number* l *the one-parameter family of functions on* $T^*\mathbf{R}^n$ *given by the formula* $K_{\alpha}^{(l)}(\overline{p})=^{\text{def}}\langle K_{\alpha}^{(l)}\overline{p},\overline{p}\rangle$, *where* $\overline{p}=^{\text{def}}(p_1,\ldots,p_n)$, $\langle\overline{\xi},\overline{\eta}\rangle=^{\text{def}}\Sigma_{i=1}^{n}\xi_i\eta_i$,

$$K_{\alpha}^{(l)}\overset{\text{def}}{=}\det(\mathcal{A}\mathcal{E}+\alpha E)(\mathcal{A}\mathcal{E}+\alpha E)^{-1}(\mathcal{A}\mathcal{E}+\kappa E)^{-l}\mathcal{E} \tag{70}$$

$$=I_{n-1}^{(l)}(\kappa)\alpha^{n-1}+I_{n-2}^{(l)}(\kappa)\alpha^{n-2}+\cdots+I_{0}^{(l)}(\kappa) \tag{71}$$

and the matrices $\mathcal{A}$ *and* $\mathcal{E}$ *are given by formulas (67) and (68), are in involution with respect to the canonical symplectic structure on* $T^*\mathbf{R}^n$. *If* $d_i\neq d_j$ $(i\neq j)$ *and* $d_i\neq 0$ $(i=1,\ldots,n-1)$, *then the functions* $I_0^{(l)},\ldots,I_{n-1}^{(l)}$ *are functionally independent on* $T^*\mathbf{R}^n$.

Remark 16: If we take $l=0$ *and* $\mathcal{E}=E$ *we derive the integrals obtained by Uhlenbeck in Ref. 9. Another way of obtaining these integrals was proposed by Moser in Ref. 10. The families of functions in involution given by Theorem 11 generalize all these results.*

Remark 17: The case $l=-1$, $\kappa=0$, *gives a family of pairwise commuting functions* $I_0^{(-1)},\ldots,I_{n-1}^{(-1)}$ *on* T^*M^n. *The function* $I_{n-1}^{(-1)}$ *coincides with the Hamiltonian of the metric given by formula (69). Therefore, the functions* $I_0^{(-1)},\ldots,I_{n-1}^{(-1)}$ *on* T^*M^n *are complete family of integrals of the geodesic flow of the hyperbolic plane.*

JOURNAL OF MATHEMATICAL PHYSICS VOLUME 42, NUMBER 8 AUGUST 2001

Trefoil symmetries I. Clover extensions beyond Coleman–Mandula theorem

L. A. Wills-Toro[a)]
Mathematics Department, University of Hawaii/Manoa, 2565 The Mall, Honolulu, Hawaii 96822-2273, and Departamento de Física, Universidad de Antioquia, A.A. 1226 Medellín, Colombia, and Departamento de Física de Partículas, Universidad de Santiago de Compostela, 15706 Santiago de Compostela, Spain

(Received 3 July 2000; accepted for publication 12 April 2001)

A graded minimal Lie algebraic extension of the space–time symmetry is constructed involving only spin-1 multiplets as novel generators. The extension involves $\mathbb{Z}_4\times\mathbb{Z}_4$ graded parameters and generators. It provides a bosonic analog to supersymmetry since the composition of *three* symmetric vector charges produces a space–time translation. There arise three noncommutative four-dimensional manifolds with pseudometric. © *2001 American Institute of Physics.*
[DOI: 10.1063/1.1383561]

I. INTRODUCTION

A thorough analysis and account of the algebraic manipulations leading to symmetry transformations with desired invariant properties can reveal unexpected underlying grading structures. These gradings in turn can enable noncommutative (and even nonassociative) novel extensions whose plausibility has been largely overlooked[1,2]

In theoretical physics, the addition is sometimes tacitly constrained to elements of the ''same type.'' Besides the account of involved units of measure (dimensional analysis), eventually certain ''apparently ad hoc'' constraints play a role. Such constraints are called superselection rules. We will observe that to a certain extent such constraints might be casted by requiring a fixed underlying grading structure.

The extension of the real numeric field $\mathbb{R}$ to the complex, quaternion, octonion, and Cayley numbers abandons sequentially linear ordered field, commutativity, associativity, and division ring property. This line of extension maintains the addition operation between any two numbers. The addition in physical models can be, nevertheless, constrained to parameters of the ''same type,'' i.e., to ''homogeneous sums'' in a certain sense. Accordingly, certain desirable properties can be maintained for constrained use of the addition operation. We land in the realm of some sort of graded projective rings in which certain properties might be relaxed while maintaining all desirable features of the underlying ''number structure.''

The latter considerations lead to the introduction of graded parameters (parameter≡measure of a symmetry transformation, i.e., an angle, a length, etc.)[3] and to graded groups of transformations and graded Lie algebras.[1,2] In this case, the numbers will be replaced by parameters which will be ''designed'' for matching the features of the observed symmetries.

We are aware of the powerful connection among continuous symmetries and conserved quantities. The most general extensions of the external or space–time symmetries of the S matrix have been studied by Coleman and Mandula[4] and by Haag, Łopuszańnski, and Sohnius[5] using, respectively, group and supergroup structures and quite general and well-motivated assumptions in the quantum field theory realm. We are going to relax one underlying assumption to obtain an extension of the Coleman–Mandula theorem: *We do not assume that all symmetry generators should be acted on through commutators under Poincaré transformations*. We will find, already at this step, traces of the would-be internal symmetries (perhaps after a breaking of the obtained graded

a)Electronic mail: law@math.hawaii.edu

symmetry). This work is a continuation of the program started in Ref. 6 where several technical difficulties could be overcome. In fact, there seems to exist multiple possible paths for constructing novel extensions. We have stated in *italics* each of the assumptions characterizing the extension presented here.

The careful study of the underlying grading structure of the Poincaré group (Sec. III) has opened the possibility of considering gradings of a different sort than those used by supersymmetry. It has been found that besides $\mathbb{Z}_2$-gradings there are $\mathbb{Z}_2\times(\mathbb{Z}_{4N}\times\mathbb{Z}_{4N})$-gradings ($N\in\mathbb{N}$) compatible with the symmetries of the Poincaré group of special relativity.[1] Here we will study exhaustively a particular line of extension which is self-bosonic, i.e., we select here *only the bosonic part of the* $\mathbb{Z}_2$*-grading factor*. In this sense, we consider that our results go beyond Coleman–Mandula no-go theorem.

We consider here a $\mathbb{Z}_4\times\mathbb{Z}_4$ graded extension of the Poincaré algebra in which there are three symmetric-vector generators $P_{(1)}$, $P_{(2)}$, $P_{(3)}$ which can be composed via $(\frac{1}{2},\frac{1}{2})\otimes(\frac{1}{2},\frac{1}{2})\otimes(\frac{1}{2},\frac{1}{2})=(\frac{1}{2},\frac{1}{2})\oplus\cdots$ to produce the (standard) space–time translation multiplet $P_{(0)}$,

$$[\![P_{(1)},[\![P_{(2)},P_{(3)}]\!]]\!]\sim P_{(0)}.$$

The double brackets stand for q-commutators respecting the grading assignments of their entries, and $P_{(0)}=(P_0,P_1,P_2,P_3)$ is the translation four-vector.

To a certain extent, this is a bosonic counterpart of the supersymmetric extensions in which two fermionic charges are composed via $(\frac{1}{2},0)\otimes(0,\frac{1}{2})=(\frac{1}{2},\frac{1}{2})$ to produce the translation $P_{(0)}$,

$$[\![Q_{(0)},\overline{Q}_{(0)}]\!]\sim P_{(0)}.$$

The introduction of graded fermionic charges in a $\mathbb{Z}_2\times(\mathbb{Z}_4\times\mathbb{Z}_4)$-graded extension is done in a forthcoming paper, where the graded fermionic charges $\overline{Q}_{(1)}$, $Q_{(2)}$, $\overline{Q}_{(3)}$ can be composed to produce a susy generator $Q_{(0)}$,

$$[\![\overline{Q}_{(1)},[\![Q_{(2)},\overline{Q}_{(3)}]\!]]\!]\sim Q_{(0)}.$$

We call *trefoil symmetries* all the graded Lie algebras with involution that extend the Poincaré algebra. Those trefoil symmetries involving only $\mathbb{Z}_4\times\mathbb{Z}_4$-graded parameters and only novel multiplets of integer spin will be called *clover extensions*, and correspond to the simplest extensions beyond the Coleman–Mandula no-go theorem. The new ingredient leading to supersymmetry was the spin-$\frac{1}{2}$ irreps. The new ingredients leading to the clover extensions are the integer spin irreps of novel graded classes. Supersymmetry results from the nontrivial cohomology of the odd supertranslation group. The trefoil and clover extensions result from the nontrivial cohomology of a group grading which extends a grading of the Poincaré algebra.

We explore here a *minimal* $(\mathbb{Z}_4\times\mathbb{Z}_4;q)$*-graded extension in which the new symmetry generators build up symmetric and antisymmetric vector multiplets*. Such an extension will be called *minimal vector clover extension*. In the second paper of this series another minimal extension will be obtained in which the new generators are symmetric vectors and scalar charges. In the third paper of this series we will explore an extension simultaneously involving the previous minimal extensions as particular cases and address the introduction of dimensionless symmetry charges which are candidates for internal symmetries after graded symmetry breaking. In the fourth paper we study the graded superspace formalism for building concrete representations. In the fifth paper we study covariant constraints, the diverse representations, and their relations. The last two papers of this series address the simplest supermultiplets and their possible quantum actions, and study Casimir operators associated with the extensions. An immediate aim there is to present a natural relation between spin one (Yang–Mills?) and spin zero (Higgs?) fields. Further stages of this research will be devoted to the introduction of spin $\frac{1}{2}$ multiplets of generators, their connection to internal symmetry groups, the local realization of the presented symmetries and graded supergravity.

This paper is structured in the following way. Section II provides a quick introduction to graded continuous symmetries. Section III reviews the features of the suited group gradings for extending the Poincaré algebra. Section IV introduces the irreducible multiplets we need for constructing the extended Poincaré algebra and gives the corresponding self-, dual-, and complex-conjugated representations. In Sec. V we present the general structure of the searched extension, its underlying assumptions, and the strategy for its obtention. In Sec. VI we study the Jacobi identities and obtain the desired $(\mathbb{Z}_4\times\mathbb{Z}_4;q)$-graded Lie algebraic extension of the Poincaré algebra. Section VII gives the concluding remarks.

II. GRADED CONTINUOUS SYMMETRIES

To each parameter (or generator) we associate an index which is a group element that reveals the properties of these type of parameters (or generators) under addition, product (q-commutators), permutation of factors (or q-commutator entries), and alteration of parentheses (or q-commutators). A couple $(\mathbb{I};q)$ is called a *faithful associative group grading over* $\mathbb{C}$ if it satisfies that $\mathbb{I}$ is an Abelian group[2] and

$$q:\mathbb{I}\times\mathbb{I}\to\mathbb{C}\backslash\{0\}:\quad(\tilde a,\tilde e)\mapsto q_{(\tilde a,\tilde e)}=:q_{\tilde a,\tilde e}\in\mathbb{C}\{0\},\tag{2.1}$$

$$q_{\tilde a,\tilde e}=(q_{\tilde e,\tilde a})^{-1},\quad q_{\tilde a+\tilde e,\tilde c}=q_{\tilde a,\tilde c}q_{\tilde e,\tilde c}\quad\forall\tilde a,\tilde e,\tilde c\in\mathbb{I},\tag{2.2}$$

$$q_{\tilde o,\tilde a}=1,\quad\tilde o\text{ neutral element of }\mathbb{I},\quad\forall\tilde a\in\mathbb{I},\tag{2.3}$$

$$\tilde a\neq\tilde e\Rightarrow\exists\tilde c\in\mathbb{I}:q_{\tilde a,\tilde c}\neq q_{\tilde e,\tilde c}.\tag{2.4}$$

If additionally, the couple $(\mathbb{I};q)$ satisfies that there exists an involution $(\,.\,)^\star$ in $\mathbb{I}$ such that

$$q_{\tilde a^\star,\tilde e^\star}=(q^*_{\tilde a,\tilde e})^{-1},$$

where $(.)^*$ is complex conjugation, then we call $(\mathbb{I};q)$ a faithful associative group grading *with involution*. Some examples thereof are given as follows.

Example 1. $(\mathbb{Z}_2;q^{\mathbb{Z}_2})$-grading or supergrading:

$$\{\mathbb{Z}_2;+\},\quad\mathbb{Z}_2=\{0,1\},$$

$$+:\mathbb{Z}_2\times\mathbb{Z}_2\to\mathbb{Z}_2;\quad(a_0,e_0)\mapsto(a_0+e_0)\bmod 2,$$

$$q^{\mathbb{Z}_2}:\mathbb{Z}_2\times\mathbb{Z}_2\to\mathbb{C}\backslash\{0\};\quad(a_0,e_0)\mapsto q^{\mathbb{Z}_2}_{a_0,e_0}=\mathrm{e}^{\mathrm{i}\pi a_0e_0}.$$

Example 2. $(\mathbb{Z}_4\times\mathbb{Z}_4;q)$-grading:

$$\{\mathbb{Z}_4\times\mathbb{Z}_4;+\},\quad\mathbb{Z}_4\times\mathbb{Z}_4=\{(m,n);\quad n,m=0,1,2,3\}$$

$$(n,m)+(n',m'):=((n+n')\bmod 4,(m+m')\bmod 4)$$

$$q_{(n,m),(n',m')}:=\mathrm{e}^{(\mathrm{i}\pi/2)(nm'-n'm)}.$$

This type of grading has been called Weil grading[3] since it reproduces the structure of the Weil pairings used in the arithmetic of elliptic curves. It manifests close resemblance to the Dirac–Schwinger–Zwanziger condition,[7] which will be discussed elsewhere.

Example 3. $(\mathbb{Z}_2\times(\mathbb{Z}_4\times\mathbb{Z}_4);q^{\mathbb{Z}_2}q)$-grading:

$$(q^{\mathbb{Z}_2}q)_{(a_0,(n,m)),(a_0',(n',m'))}:=q^{\mathbb{Z}_2}_{a_0,a_0'}q_{(n,m),(n',m')}.$$

We consider now a set of parameters $\mathbb{P}=\{\beta_{\tilde{a}},\beta'_{\tilde{e}},\dots\}$ which builds up an $(\mathbb{I};q)$-*graded parameter algebra*, i.e., the parameters are $\mathbb{I}$-graded, and have a binary product which is q-commutative and associative (for more general cases see Ref. 2): $(\mathbb{I};q)$ is a faithful associative group grading,

$$(\beta_{\tilde{a}}\beta'_{\tilde{e}}) \text{ has index } \tilde{a}+\tilde{e} \quad \forall \beta_{\tilde{a}},\beta'_{\tilde{e}}\in\mathbb{P} \quad (\mathbb{I}\text{-grading}),$$

$$(\beta_{\tilde{a}}\beta'_{\tilde{e}})=q_{\tilde{a},\tilde{e}}(\beta'_{\tilde{e}}\beta_{\tilde{a}}) \quad \forall \beta_{\tilde{a}},\beta'_{\tilde{e}}\in\mathbb{P} \quad (q\text{-commutative}),$$

$$(\beta_{\tilde{a}}(\beta'_{\tilde{e}}\beta''_{\tilde{c}}))=((\beta_{\tilde{a}}\beta'_{\tilde{e}})\beta''_{\tilde{c}}) \quad \forall \beta_{\tilde{a}};\beta'_{\tilde{e}},\beta''_{\tilde{c}}\in\mathbb{P} \quad (\text{associative}).$$

The $(\mathbb{I};q)$-graded parameters are the measures (i.e., angles, lengths, etc.) of graded continuous symmetry transformations

$$g(\beta)=g(\beta_{-\tilde{a}_1},\beta_{-\tilde{a}_2},\dots,\beta_{-\tilde{a}_n})=\exp(\mathrm{i}\beta_{-\tilde{a}_j}Q_{\tilde{a}_j}). \tag{2.5}$$

The graded symmetry generators $Q_{\tilde{a}_j}$ constitute a novel structure known as ϵ-colored,[8] or $(\mathbb{I};q)$-graded Lie algebra.[1] (For more general extensions involving nonassociative parameters see Ref. 2). We call $\{\mathbb{L};+,[\![.,.]\!]\}$ an $(\mathbb{I};q)$-*graded Lie algebra over* $\mathbb{C}$ iff $0\in\mathbb{L}\neq\{0\}$, $(\mathbb{I};q)$ is a faithful associative group grading, and there exist an application S_t and a binary operation $[\![.,.]\!]$ satisfying the following five axioms.

Axiom 1: S_t assigns an index to each nonvanishing generator in $\mathbb{L}$, the generators carrying the same index build up a vector space, $(\mathbb{I};q)$ is the minimal allowed group grading:

$$S_t:\mathbb{L}\backslash\{0\}\to\mathbb{I}, \quad Q_{\tilde{a}}\mapsto S_t(Q_{\tilde{a}})=\tilde{a},$$

$$\mathbb{I} \text{ is generated by } S_t(\mathbb{L}\backslash\{0\}),$$

$$\mathbb{L}_{\tilde{a}}=\{0\}\cup S_t^{-1}(\tilde{a}) \text{vector space over } \mathbb{C} \quad \forall\tilde{a}\in\mathbb{I},$$

$$\mathbb{L}=\cup_{\tilde{a}\in\mathbb{I}}\ \mathbb{L}_{\tilde{a}}.$$

Axiom 2: $[\![.,.]\!]$ is a closed binary, $\mathbb{I}$-graded operation:

$$[\![.,.]\!]:\mathbb{L}\times\mathbb{L}\to\mathbb{L}, \quad (Q_{\tilde{a}},Q'_{\tilde{e}})\mapsto[\![Q_{\tilde{a}},Q'_{\tilde{e}}]\!]\in\mathbb{L},$$

$$[\![\mathbb{L}_{\tilde{a}},\mathbb{L}_{\tilde{e}}]\!]\subseteq\mathbb{L}_{\tilde{a}+\tilde{e}} \quad (\mathbb{I}\text{-grading}).$$

Axiom 3: $[\![.,.]\!]$ is q-antisymmetric:

$$[\![Q_{\tilde{a}},Q'_{\tilde{e}}]\!]=-q_{\tilde{a},\tilde{e}}[\![Q'_{\tilde{e}},Q_{\tilde{a}}]\!], \quad \forall Q_{\tilde{a}},Q'_{\tilde{e}}\in\mathbb{L}.$$

Axiom 4: $[\![.,.]\!]$ is bilinear with respect to the vector space structures:

$$[\![Q_{\tilde{a}}+yQ''_{\tilde{a}},Q'_{\tilde{e}}]\!]=[\![Q_{\tilde{a}},Q'_{\tilde{e}}]\!]+y[\![Q''_{\tilde{a}},Q'_{\tilde{e}}]\!], \quad \forall Q_{\tilde{a}},Q''_{\tilde{a}},Q'_{\tilde{e}}\in\mathbb{L}, \quad \forall y\in\mathbb{C}.$$

Axiom 5: $[\![.,.]\!]$ is q-Jacobi associative (q-Leibnitz rule):

$$[\![Q_{\tilde{a}},[\![Q'_{\tilde{e}},Q''_{\tilde{c}}]\!]]\!]=[\![[\![Q_{\tilde{a}},Q'_{\tilde{e}}]\!],Q''_{\tilde{c}}]\!]+q_{\tilde{a},\tilde{e}}[\![Q'_{\tilde{e}},[\![Q_{\tilde{a}},Q''_{\tilde{c}}]\!]]\!], \quad \forall Q_{\tilde{a}},Q'_{\tilde{e}},Q''_{\tilde{c}}\in\mathbb{L}.$$

If we adopt an extra axiom:

Axiom 6: There exist involutions $(.)^*$, $(.)^\star$, $\overline{(.)}$, in $\mathbb{C}$, $\mathbb{I}$, and $\mathbb{L}$, respectively, such that $(\mathbb{I};q)$ is a group grading with involution, and fulfilling

$$\overline{(yQ_a)}=y^*\overline{Q}_{a^\star},$$

$$\overline{[\![Q_{\tilde a},Q'_{\tilde e}]\!]}=[\![\overline{Q}'_{\tilde e^\star},\overline{Q}_{\tilde a^\star}]\!] \quad \forall Q_{\tilde a},Q'_{\tilde e}\in\mathbb{L},$$

$$\overline{(y\beta_{-\tilde a}Q_{\tilde a})}=y^*\overline{Q}_{\tilde a^\star}\overline{\beta}_{-\tilde a^\star} \quad \forall Q_{\tilde a}\in\mathbb{L},\ \forall\beta_{-\tilde a}\in\mathbb{P},$$

then the $\mathbb{L}$ is called an $(\mathbb{I};q)$-graded Lie algebra over $\mathbb{C}$ **with involution**. *We adopt here the trivial involution* $(.)^\star$ in $\mathbb{I}$, i.e. $(.)^\star=$identity. Obviously $(\tilde a^\star)^\star=\tilde a$.

The products $\beta_{-\tilde a}Q_{\tilde a}$ of an $(\mathbb{I};q)$-graded parameter $\beta_{-\tilde a}$ by an $(\mathbb{I};q)$-graded Lie algebra generator $Q_{\tilde a}$ are (plain) Lie algebra generators in an analogous way as the product $\theta^\alpha Q_\alpha$ of a Grassmann parameter by a fermionic supersymmetry charge constitutes a Lie algebra generator. The mixture of parameters and generators is governed by

$$\begin{aligned}\beta_{-\tilde a}Q'_{\tilde e}&=q_{-\tilde a,\tilde e}Q'_{\tilde e}\beta_{-\tilde a},\\ [\beta_{-\tilde a}Q_{\tilde a},\beta'_{-\tilde e}Q'_{\tilde e}]&=\beta'_{-\tilde e}\beta_{-\tilde a}[\![Q_{\tilde a},Q'_{\tilde e}]\!].\end{aligned} \tag{2.6}$$

III. GROUP GRADINGS FOR EXTENDING POINCARÉ ALGEBRA

A given Lie algebra can be extended to an $(\mathbb{I};q)$-graded Lie algebra in which the group $\mathbb{I}$ respects the underlying gradings of the given Lie algebra. The underlying gradings are in close relation to the Levi decomposition and the roots of the Lie algebra. The underlying gradings of the Poincaré algebra and their suited graded extensions have been studied in Ref. 1. We briefly illustrate these results. The Lorentz algebra M can be written

$$[M_{\mu\nu},M_{\rho\sigma}]=\mathrm{i}(g_{\mu\sigma}M_{\nu\rho}+g_{\nu\rho}M_{\mu\sigma}-g_{\mu\rho}M_{\nu\sigma}+g_{\nu\sigma}M_{\mu\rho}), \tag{3.1}$$

where $g=\mathrm{diag}\,(1,-1,-1,-1)$ is the Minkowski pseudometric. Changing variables we can write

$$\begin{aligned}J_i&\equiv\tfrac{1}{2}\epsilon_{ijk}M^{jk},\quad \hat J_i\equiv M^{0i}\\ [J_i,J_j]&=\mathrm{i}\epsilon_{ijk}J_k,\\ [J_i,\hat J_j]&=\mathrm{i}\epsilon_{ijk}\hat J_k,\\ [\hat J_i,\hat J_j]&=-\mathrm{i}\epsilon_{ijk}J_k.\end{aligned} \tag{3.2}$$

After a complexification we obtain the decomposition of this semisimple Lie algebra M into simple factors

$$\begin{aligned}T_{(0)i}&\equiv\tfrac{1}{2}(J_i+\mathrm{i}\hat J_i),\quad \overline{T}_{(0)i}\equiv\tfrac{1}{2}(J_i-\mathrm{i}\hat J_i),\\ [T_{(0)i},T_{(0)j}]&=\mathrm{i}\epsilon_{ijk}T_{(0)k},\\ [T_{(0)i},\overline{T}_{(0)j}]&=0,\\ [\overline{T}_{(0)i},\overline{T}_{(0)j}]&=\mathrm{i}\epsilon_{ijk}\overline{T}_{(0)k}.\end{aligned} \tag{3.3}$$

$$M\approx su(2)\oplus su(2).$$

To study the underlying grading of the Poincaré algebra we assume that *both the generators* $M_{\mu\nu}$ *and the generators* $T_{(0)i}$ *and* $\overline{T}_{(0)i}$ *can be adopted for generating the Lorentz group, and also that both Casimir operators of the Poincaré algebra carry the trivial index*. This leads to the following index assignment:

$$
\begin{gathered}
S_t(P^0_{(0)})=\tilde{a}_0,\\
S_t(M_{23})=S_t(J_1)=S_t(\hat{J}_1)=S_t(M_{01})=S_t(P^1_{(0)})=\tilde{a}_1,\\
S_t(M_{31})=S_t(J_2)=S_t(\hat{J}_2)=S_t(M_{02})=S_t(P^2_{(0)})=\tilde{a}_2\\
S_t(M_{12})=S_t(J_3)=S_t(\hat{J}_3)=S_t(M_{03})=S_t(P^3_{(0)})=\tilde{a}_3,
\end{gathered}
\tag{3.4}
$$

where $P^\mu_{(0)}$ are the translation generators and $\tilde{a}_0=\tilde{o}$ is the neutral element of the grading group $\mathbb{I}$. From the algebraic relations (3.1)–(3.3) and the Poincaré algebra relations involving the translation generators we obtain

$$
\begin{gathered}
q_{\tilde{a}_\mu,\tilde{a}_\nu}=1, \quad \forall \quad \mu,\nu=0,1,2,3,\\
\tilde{a}_1+\tilde{a}_2=\tilde{a}_3, \quad \tilde{a}_2+\tilde{a}_3=\tilde{a}_1, \quad \tilde{a}_3+\tilde{a}_1=\tilde{a}_2.
\end{gathered}
\tag{3.5}
$$

This implies that the grading group $\{\tilde{a}_0,\tilde{a}_1,\tilde{a}_2,\tilde{a}_3\}$ underlying the Poincaré algebra (with the adopted assumptions) is $\mathbb{Z}_2\times\mathbb{Z}_2$, the Klein group. This coincides with the group of discrete transformations that builds the full Poincaré group. Now,

$$
\tilde{a}_\mu+\tilde{a}_\mu=\tilde{o}\Rightarrow\tilde{a}_\mu=-\tilde{a}_\mu \quad \forall\mu=0,1,2,3. \tag{3.6}
$$

From (2.2) and (2.3) we obtain

$$
1=q_{\tilde{o},\tilde{c}}=q_{\tilde{a}_\nu+\tilde{a}_\nu,\tilde{c}}=q_{\tilde{a}_\nu,\tilde{c}}q_{\tilde{a}_\nu,\tilde{c}}=1 \quad \forall\tilde{c}\in\mathbb{I},
$$

hence

$$
q_{\tilde{a}_\nu,\tilde{c}}\in\{+1,-1\}, \quad \forall \quad \tilde{c}\in\mathbb{I}, \quad \forall \quad \nu=0,1,2,3. \tag{3.7}
$$

Accordingly, *the algebraic relations involving Poincaré generators can only be of commutator type or anticommutator type*.

We adopt a model for the q-application in which the indices with a tilde have the form

$$
\begin{gathered}
\tilde{c}=(c_0,[(c_1,c_2)]), \quad \tilde{u}=(u_0,[(u_1,u_2)]),\\
q_{\tilde{c},\tilde{u}}:=\exp\{\mathrm{i}\pi c_0u_0\}\exp\left\{\frac{\mathrm{i}\pi}{2N}(c_1u_2-c_2u_1)\right\}.
\end{gathered}
\tag{3.8}
$$

The first components c_0, u_0 turn out to belong to $\mathbb{Z}_2$ and the last components $[(c_1,c_2)]$, $[(u_1,u_2)]$ constitute equivalence classes of bivectors in a plane which satisfy quantization relations in the areas they subtend. Relations (3.3)–(3.5) lead to the conclusion that the allowed group gradings have the form $\mathbb{Z}_2\times(\mathbb{Z}_{4N}\times\mathbb{Z}_{4N})$, $N\in\mathbb{N}$ and the previously mentioned example 3 is just the simplest ($N=1$) novel grading compatible with the Poincaré algebra.[1] In this study we will leave the $\mathbb{Z}_2$ factor aside since we are looking for a self-bosonic extension beyond the Coleman–Mandula no-go theorem. A future paper will study an extension beyond the Haag–Lopuszański–Sohnius no-go theorem. Since we are not considering here the $\mathbb{Z}_2$-grading factor we adopt as indices with a tilde the elements associated with the group $\mathbb{Z}_4\times\mathbb{Z}_4$. The group elements associated with the Poincaré group turn out to build the $\mathbb{Z}_2\times\mathbb{Z}_2$ subgroup:

TABLE I. Addition table of the group $\mathbb{Z}_4\times\mathbb{Z}_4$.

+	(0)0	(0)1	(0)2	(0)3	(1)0	(1)1	(1)2	(1)3	(2)0	(2)1	(2)2	(2)3	(3)0	(3)1	(3)2	(3)3

(3,1)≡(3)3	(3)3	(3)1	(3)0	(3)2	(2)0	(2)3	(2)1	(2)2	(1)3	(1)1	(1)0	(1)2	(0)1	(0)2	(0)0	(0)3

$$
\begin{aligned}
&S_t(x^0)=S_t(P^0_{(0)})=\tilde{o}=\tilde{a}_0=(0,0)\equiv(0)_0,\\
&S_t(x^1)=S_t(P^1_{(0)})=S_t(M^{01})=S_t(M^{23})=\tilde{a}_1=(2,0)\equiv(0)_1,\\
&S_t(x^2)=S_t(P^2_{(0)})=S_t(M^{02})=S_t(M^{31})=\tilde{a}_2=(0,2)\equiv(0)_2,\\
&S_t(x^3)=S_t(P^3_{(0)})=S_t(M^{03})=S_t(M^{12})=\tilde{a}_3=(2,2)\equiv(0)_3.
\end{aligned}
\tag{3.9}
$$

It is easy to verify that this choice satisfies relations (3.5)–(3.7) under the group grading given in example 2. Observe that the index assignment does not enter into conflict with the relations used in special relativity, quantum mechanics, and QFT. For instance,

$$S_t(x^2P^3_{(0)}-x^3P^2_{(0)})=\tilde{a}_2+\tilde{a}_3=\tilde{a}_1=S_t(M^{23}).$$

Notice that we have two different ways for designating group elements: the first way are couples (n,m), where $n,m=0,1,2,3$; the second way which will become clear shortly, has the form $(f)_s$ where f indicates the class, and s indicates the element of the class. In order to visualize the grading structure we provide in Table I the addition table of the group $\mathbb{Z}_4\times\mathbb{Z}_4$ and in Table II the q-function for every couple of group elements. The values in Table II have to be identified with q (line, column).

In Tables I and II we have divided the 16 group elements into four classes. The class (0) contains the indices associated with the Poincaré generators $\{\tilde{a}_0,\tilde{a}_1,\tilde{a}_2,\tilde{a}_3\}=\{(0)_0,(0)_1,(0)_2,(0)_3\}$. Classes (1), (2), and (3) contain indices which remain in the same class when you add elements of class (0). This fact indicates that classes (0)–(3) provide the sets of indices available for building novel invariant multiplets of generators.

From Table I we obtain Table III for the addition of class indices $(\mathbb{Z}_4\times\mathbb{Z}_4)/(\mathbb{Z}_2\times\mathbb{Z}_2)\approx\mathbb{Z}_2\times\mathbb{Z}_2$. We write $(i\dagger j)$ instead of $(i)\dagger(j)$.

IV. GRADED SPIN IRREPS OF GENERATORS

We consider an extension $\mathbb{L}$ of the Poincaré algebra. The generators of $\mathbb{L}$ are assumed to be arranged into multiplets which transform linearly under the action of the generators of the Lorentz Lie subalgebra. Candidates for defining invariant multiplets are divided into four classes since the

TABLE II. q-function for $\mathbb{Z}_4\times\mathbb{Z}_4$.

$q^{\mathbb{Z}_4\times\mathbb{Z}_4}$	(0)0	(0)1	(0)2	(0)3	(1)0	(1)1	(1)2	(1)3	(2)0	(2)1	(2)2	(2)3	(3)0	(3)1	(3)2	(3)3

(1,1)≡(3)1	1	−1	−1	1	−i	i	i	−i	i	−i	i	−i	1	1	−1	−1
(1,3)≡(3)2	1	−1	−1	1	i	−i	−i	i	i	−i	i	−i	−1	−1	1	1
(3,1)≡(3)3	1	−1	−1	1	−i	i	i	−i	−i	i	−i	i	−1	−1	1	1

sets of indices $\{(0)_0,(0)_1,(0)_2,(0)_3\}$, $\{(1)_0,(1)_1,(1)_2,(1)_3\}$, $\{(2)_0,(2)_1,(2)_2,(2)_3\}$, $\{(3)_0,(3)_1,(3)_2,(3)_3\}$ remain invariant under addition of indices of the set $\{(0)_0,(0)_1,(0)_2,(0)_3\}$ associated with the Poincaré generators. That is why *we will consider for each spin four types of multiplets*. There arise three novel four-dimensional manifolds besides the Minkowski manifold. The coordinates of the Minkowski space carry indices of the class (0) according to (3.9). The three novel manifolds are noncommutative and have a metric structure (also spin-$\frac{1}{2}$ structures can be defined in those novel manifolds). *We assume here that a generalized spin-statistics theorem holds, in which self-bosonic generators transform under integer spin representations*. We consider multiplets of generators $a_{(f)s}$ of classes $(f)=(0),(1),(2),(3)$. The index s stands for the different components of each multiplet (except for spin-0 singlets not to be discussed here). The corresponding dual multiplets are written $a_{(f)}{}^{s}$, and the complex-conjugated and dual complex-conjugated multiplets are given by $\overline{a}_{(f)\dot{s}}$ and $\overline{a}_{(f)}{}^{\dot{s}}$. All these multiplets transform linearly under Lorentz generators:

$$[\![T_{(0)i},a_{(f)s}]\!]=-\mathrm{i}\sigma^{a}(i,f)_{s}{}^{t}a_{(f)t}, \tag{4.1}$$

$$[\![T_{(0)i},a_{(f)}{}^{s}]\!]=\mathrm{i}q_{(0)i,(f)s}\,a_{(f)}{}^{t}\,\sigma^{a}(i,f)_{t}{}^{s}, \tag{4.2}$$

$$[\![\overline{T}_{(0)i},\overline{a}_{(f)\dot{s}}]\!]=-\mathrm{i}q_{(0)i,(f)s}\,\overline{a}_{(f)\dot{t}}\,\overline{\sigma^{a}}(i,f)^{\dot{t}}{}_{\dot{s}}, \tag{4.3}$$

$$[\![\overline{T}_{(0)i},\overline{a}_{(f)}{}^{\dot{s}}]\!]=\mathrm{i}\overline{\sigma^{a}}(i,f)^{\dot{s}}{}_{\dot{t}}\,\overline{a}_{(f)}{}^{\dot{t}}, \tag{4.4}$$

TABLE III. Addition of class indices $\mathbb{Z}_2\times\mathbb{Z}_2$.

†	(0)	(1)	(2)	(3)
(0)	(0)	(1)	(2)	(3)
(1)	(1)	(0)	(3)	(2)
(2)	(2)	(3)	(0)	(1)
(3)	(3)	(2)	(1)	(0)

where $\overline{a_{(f)s}}=\overline{a}_{(f)\dot{s}}$, $\overline{a_{(f)}{}^{s}}=\overline{a}_{(f)}{}^{\dot{s}}$ and we have adopted the already described notation for the indices. We write $(f)s$ to indicate the sth index of the class (f). From the involution of (4.1) we obtain (using the property of q-commutators under involution, Axiom 6)

$$\overline{[\![T_{(0)i},a_{(f)s}]\!]}=[\![\overline{a}_{(f)\dot{s}},\overline{T}_{(0)i}]\!]$$

$$=\mathrm{i}\overline{a}_{(f)\dot{t}}\sigma^{a}(i,f)_{s}^{*t}.$$

Using (4.3) we conclude finally

$$\overline{\sigma^{a}}(i,f)^{\dot{t}}{}_{\dot{s}}=\sigma^{a}(i,f)_{s}^{*\,t}. \tag{4.5}$$

Analogously, under involution of (4.2) we again obtain (4.5). We now study which shall be the structure of the σ-matrices. We use the following Jacobi identity

$$[\![T_{(0)j},[\![T_{(0)k},a_{(f)s}]\!]]\!]=[\![[\![T_{(0)j},T_{(0)k}]\!],a_{(f)s}]\!]+q_{(0)j,(0)k}[\![T_{(0)k},[\![T_{(0)j},a_{(f)s}]\!]]\!].$$

Using (3.3) and (4.1) we obtain

$$[\mathrm{i}\sigma^{a}(j,f),\mathrm{i}\sigma^{a}(k,f)]=\mathrm{i}\epsilon_{jkl}(\mathrm{i}\sigma^{a}(l,f)), \tag{4.6}$$

where the commutator has the usual meaning. Accordingly, the matrices $\mathrm{i}\sigma^{a}(j,f)_{s}{}^{t}$ and $-\mathrm{i}[\sigma^{a}(j,f)^{\mathrm{tr}}]^{t}{}_{s}$ are standard representations of angular momenta. Analogously, using the Jacobi identity for the triple $\overline{T}_{(0)j}$, $\overline{T}_{(0)k}$, $\overline{a}_{(f)\dot{s}}$ we obtain

$$[-\mathrm{i}q_{(0)j,(f)}\overline{\sigma^{a}}(j,f),-\mathrm{i}q_{(0)k,(f)}\overline{\sigma^{a}}(k,f)]=\mathrm{i}\epsilon_{jkl}(-\mathrm{i}q_{(0)l,(f)}\overline{\sigma^{a}}(l,f)). \tag{4.7}$$

Hence, $-\mathrm{i}q_{(0)j,(f)}\overline{\sigma^{a}}(j,f)$ and $\mathrm{i}q_{(0)j,(f)}\overline{\sigma^{a}}(j,f)^{\mathrm{tr}}$ are also standard representations of angular momenta. We write $q_{(0)j,(f)}$ instead of $q_{(0)j,(f)s}$ since they are independent of the index s. It is easy to verify that $a_{(f)}{}^{s}a_{(f)s}$ (summation only over s throughout the multiplet) and $\overline{a}_{(f)\dot{s}}\overline{a}_{(f)}{}^{\dot{s}}$ are invariant quadratic products. For example:

$$[\![T_{(0)j},a_{(f)}{}^{s}a_{(f)s}]\!]=[\![T_{(0)j},a_{(f)}{}^{s}]\!]a_{(f)s}+q_{(0)j,(f)}\,a_{(f)}{}^{s}[\![T_{(0)j},a_{(f)s}]\!]=0.$$

We study now the "metric" structure $\epsilon^{a}(f)^{us}$, $\epsilon^{a}(f)_{us}$ connecting the self-representation $a_{(f)s}$ and the dual-self-representation $a_{(f)}{}^{s}$:

$$\epsilon^{a}(f)^{us}\,a_{(f)s}=a_{(f)}{}^{u}, \tag{4.8}$$

$$\epsilon^{a}(f)_{ds}\,a_{(f)}{}^{s}=a_{(f)d}. \tag{4.9}$$

We *assume* that these "metrics" carry trivial index $\tilde{o}$ and thus:

$$[\![T_{(0)j},a_{(f)}{}^{u}]\!]=\epsilon^{a}(f)^{ud}[\![T_{(0)j},a_{(f)d}]\!]$$

$$=\mathrm{i}a_{(f)}{}^{v}(-\epsilon^{a}(f)^{ud}\,\sigma^{a}(j,f)_{d}{}^{t}\,\epsilon^{a}(f)_{tv}).$$

Comparing this with Eq. (4.2) we obtain

$$\sigma^{a}(j,f)_{v}{}^{u}=-q_{(f),(0)j}\,\epsilon^{a}(f)^{ud}\sigma^{a}(j,f)_{d}^{t}\epsilon^{a}(f)_{tv}.$$

In matricial notation

$$\sigma^{a}(j,f)^{\mathrm{tr}}=-q_{(f),(0)j}\epsilon^{\uparrow a}(f)\sigma^{a}(j,f)\epsilon^{\downarrow a}(f), \tag{4.10}$$

where $\epsilon^{\uparrow a}(f)$ and $\epsilon^{\downarrow a}(f)$ stand for the metric with indices up and down respectively. Analogously, we define a ''metric'' structure among the complex-conjugated representation and its dual:

$$\overline{\epsilon^{a}}(f)^{\dot{u}\dot{s}}\,\overline{a}(f)_{\dot{s}}=\overline{a}(f)^{\dot{u}}, \tag{4.11}$$

$$\overline{\epsilon^{a}}(f)_{\dot{d}\dot{s}}\,\overline{a}_{(f)}{}^{\dot{s}}=\overline{a}_{(f)\dot{d}}, \tag{4.12}$$

which leads in matricial notation to

$$\overline{\sigma^{a}}(j,f)^{\mathrm{tr}}=-q_{(0)j,(f)}\overline{\epsilon^{\downarrow a}}(f)^{\mathrm{tr}}\overline{\sigma^{a}}(j,f)\overline{\epsilon^{\uparrow a}}(f)^{\mathrm{tr}}. \tag{4.13}$$

We classify now the spin representations according to their eigenvalues with respect to the Casimir operators of the Lorentz algebra: $\Sigma T_{(0)i}T_{(0)i}$ and $\Sigma\overline{T}_{(0)i}\overline{T}_{(0)i}$. A multiplet $a_{(f)s}$ is said to be in the (s_l,s_r)-spin representation if

$$\begin{aligned}\left[\!\left[\sum_{i=1}^{3} T_{(0)i}T_{(0)i}, a_{(f)s}\right]\!\right]&=s_l(s_l+1)a_{(f)s},\\ \left[\!\left[\sum_{i=1}^{3} \overline{T}_{(0)i}\overline{T}_{(0)i}, a_{(f)s}\right]\!\right]&=s_r(s_r+1)a_{(f)s}.\end{aligned} \tag{4.14}$$

The total spin is given by s_l+s_r. We are now going to list the irreps of integer total spin one.

A. Spin (1,0) and (0,1) irreps

An example of a multiplet of spin (1,0) and spin (0,1) of class (0) is given by the triplets $T_{(0)i}$ and $\overline{T}_{(0)i}$, respectively. We have to select then triples of indices of each one of the three remaining classes to define their spin (1,0) and (0,1) irreps. There are in principle no *a priori* reasons for selecting three indices out of the four available in each class. The metric structure they lead to is not the main aspect for making the choice. In fact, it is easy to check that the actual choice of the representation is responsible for the resulting metric. In the case of the class (0) triplets we see that the underlying metric is Euclidean. In the zero class we adopt the last three indices of the class (0) for the triplet. We adopt the same choice of the remaining three classes. Hence we adopt indices $\{(0)_1,(0)_2,(0)_3\}$, $\{(1)_1,(1)_2,(1)_3\}$, $\{(2)_1,(2)_2,(2)_3\}$, $\{(3)_1,(3)_2,(3)_3\}$ for the multiplets, i.e.,

$$S_t(T_{(f)j})=S_t(\overline{T}_{(f)j})=(f)j;\quad j=1,2,3, \tag{4.15}$$

where we denote the generic multiplet of spin (1,0) and class (f) by $T_{(f)}$ and the generic multiplet of spin (0,1) and class (f) by $\overline{T}_{(f)}$. The Lorentz generators $T_{(0)}$ and $\overline{T}_{(0)}$ form triplets for which

$$\sigma^{T}(j,0)_{k}{}^{l}=-\epsilon_{jkl},\quad \overline{\sigma^{T}}(j,0)^{l}{}_{k}=-\epsilon_{jkl}. \tag{4.16}$$

In order to match the grading properties according to Axiom 2 of $(\mathbb{I};q)$-graded Lie algebras, the texture of the σ-matrices is not free, and has to account for the equality of the indices in both sides of the q-commutator relations (4.1)–(4.4). An adequate choice for the σ^{T}-matrices is given in Table IV with $\overline{\sigma^{T}}(j,f)=\sigma^{T}(j,f)^{*\,\mathrm{tr}}$.

We can determine candidates for the metric in each one of these spin-1 multiplets. From relation (4.10) we have

$$\begin{aligned}\sigma^{T}(j,f)^{\mathrm{tr}}&=-q_{(f),(0)j}\epsilon^{\uparrow T}(f)\sigma^{T}(j,f)\epsilon^{\downarrow T}(f)\\ &=-(2\delta_{f0}+2\delta_{fj}-1)\epsilon^{\uparrow T}(f)\sigma^{T}(j,f)\epsilon^{\downarrow T}(f).\end{aligned} \tag{4.17}$$

It is easy to verify that a possible choice is given by

TABLE IV. σ^T matrices.

(f)	Spin(1,0)	$\sigma^T(1,f)$	$\sigma^T(2,f)$	$\sigma^T(3,f)$
(0)	$T_{(0)}$	$\begin{bmatrix} 0 & 0 & 0 \\ 0 & 0 & -1 \\ 0 & 1 & 0 \end{bmatrix}$	$\begin{bmatrix} 0 & 0 & 1 \\ 0 & 0 & 0 \\ -1 & 0 & 0 \end{bmatrix}$	$\begin{bmatrix} 0 & -1 & 0 \\ 1 & 0 & 0 \\ 0 & 0 & 0 \end{bmatrix}$
(1)	$T_{(1)}$	$\begin{bmatrix} 0 & 0 & 0 \\ 0 & 0 & -1 \\ 0 & 1 & 0 \end{bmatrix}$	$\begin{bmatrix} 0 & 0 & 1 \\ 0 & 0 & 0 \\ -1 & 0 & 0 \end{bmatrix}$	$\begin{bmatrix} 0 & -1 & 0 \\ 1 & 0 & 0 \\ 0 & 0 & 0 \end{bmatrix}$
(2)	$T_{(2)}$	$\begin{bmatrix} 0 & -1 & 0 \\ 1 & 0 & 0 \\ 0 & 0 & 0 \end{bmatrix}$	$\begin{bmatrix} 0 & 0 & 0 \\ 0 & 0 & -1 \\ 0 & 1 & 0 \end{bmatrix}$	$\begin{bmatrix} 0 & 0 & 1 \\ 0 & 0 & 0 \\ -1 & 0 & 0 \end{bmatrix}$
(3)	$T_{(3)}$	$\begin{bmatrix} 0 & 0 & 1 \\ 0 & 0 & 0 \\ -1 & 0 & 0 \end{bmatrix}$	$\begin{bmatrix} 0 & -1 & 0 \\ 1 & 0 & 0 \\ 0 & 0 & 0 \end{bmatrix}$	$\begin{bmatrix} 0 & 0 & 0 \\ 0 & 0 & -1 \\ 0 & 1 & 0 \end{bmatrix}$

$$\epsilon^{\uparrow T}(0)=\epsilon^{\downarrow T}(0)=\begin{bmatrix} -1 & 0 & 0 \\ 0 & -1 & 0 \\ 0 & 0 & -1 \end{bmatrix}, \tag{4.18}$$

$$\epsilon^{\uparrow T}(i)=\epsilon^{\downarrow T}(i)=\begin{bmatrix} 1 & 0 & 0 \\ 0 & -1 & 0 \\ 0 & 0 & -1 \end{bmatrix}, \tag{4.19}$$

for $i=1,2,3$. Anagously, by using Eq. (4.13) we obtain

$$\overline{\epsilon}^{\uparrow \overline{T}}(0)=\overline{\epsilon}^{\downarrow \overline{T}}(0)=\begin{bmatrix} -1 & 0 & 0 \\ 0 & -1 & 0 \\ 0 & 0 & -1 \end{bmatrix}, \tag{4.20}$$

$$\overline{\epsilon}^{\uparrow \overline{T}}(i)=\overline{\epsilon}^{\downarrow \overline{T}}(i)=\begin{bmatrix} 1 & 0 & 0 \\ 0 & -1 & 0 \\ 0 & 0 & -1 \end{bmatrix}, \tag{4.21}$$

for $i=1,2,3$. Here we find a curious difference between the familiar class (0) triplets and the triplets for the novel three classes. This difference could be avoided by an alternative representation presented in Table VII. Although the metrics turn out to be Euclidean in this case, it is found that these alternative irreps are not suited for allowing the desired extensions. We come latter to this point.

B. Spin $(\frac{1}{2},\frac{1}{2})$ irreps

An example of spin $(\frac{1}{2},\frac{1}{2})$ irrep of class (0) is given by the translation multiplet $P_{(0)\mu}$, which leads to

$$\sigma^P(j,0)_\mu{}^\nu=-\frac{i}{2}(\delta_{0\mu}\delta_j^\nu+\delta_{j\mu}\delta_0^\nu)+\frac{1}{2}(\epsilon^{mkl}\delta_{l\mu}\delta_k^\nu\delta_{mj}), \tag{4.22}$$

TABLE V. σ^P-matrices.

(f)	Spin $(\frac{1}{2},\frac{1}{2})$	$\sigma^P(1,f)$	$\sigma^P(2,f)$	$\sigma^P(3,f)$
(0)	$P_{(0)}$	$\frac{1}{2}\begin{bmatrix} 0 & -\mathrm{i} & 0 & 0 \\ -\mathrm{i} & 0 & 0 & 0 \\ 0 & 0 & 0 & -1 \\ 0 & 0 & 1 & 0 \end{bmatrix}$	$\frac{1}{2}\begin{bmatrix} 0 & 0 & -\mathrm{i} & 0 \\ 0 & 0 & 0 & 1 \\ -\mathrm{i} & 0 & 0 & 0 \\ 0 & -1 & 0 & 0 \end{bmatrix}$	$\frac{1}{2}\begin{bmatrix} 0 & 0 & 0 & -\mathrm{i} \\ 0 & 0 & -1 & 0 \\ 0 & 1 & 0 & 0 \\ -\mathrm{i} & 0 & 0 & 0 \end{bmatrix}$
(1)	$P_{(1)}$	$\frac{1}{2}\begin{bmatrix} 0 & -\mathrm{i} & 0 & 0 \\ -\mathrm{i} & 0 & 0 & 0 \\ 0 & 0 & 0 & -1 \\ 0 & 0 & 1 & 0 \end{bmatrix}$	$\frac{1}{2}\begin{bmatrix} 0 & 0 & -\mathrm{i} & 0 \\ 0 & 0 & 0 & 1 \\ -\mathrm{i} & 0 & 0 & 0 \\ 0 & -1 & 0 & 0 \end{bmatrix}$	$\frac{1}{2}\begin{bmatrix} 0 & 0 & 0 & -\mathrm{i} \\ 0 & 0 & -1 & 0 \\ 0 & 1 & 0 & 0 \\ -\mathrm{i} & 0 & 0 & 0 \end{bmatrix}$
(2)	$P_{(2)}$	$\frac{1}{2}\begin{bmatrix} 0 & 0 & 0 & -\mathrm{i} \\ 0 & 0 & -1 & 0 \\ 0 & 1 & 0 & 0 \\ -\mathrm{i} & 0 & 0 & 0 \end{bmatrix}$	$\frac{1}{2}\begin{bmatrix} 0 & -\mathrm{i} & 0 & 0 \\ -\mathrm{i} & 0 & 0 & 0 \\ 0 & 0 & 0 & -1 \\ 0 & 0 & 1 & 0 \end{bmatrix}$	$\frac{1}{2}\begin{bmatrix} 0 & 0 & -\mathrm{i} & 0 \\ 0 & 0 & 0 & 1 \\ -\mathrm{i} & 0 & 0 & 0 \\ 0 & -1 & 0 & 0 \end{bmatrix}$
(3)	$P_{(3)}$	$\frac{1}{2}\begin{bmatrix} 0 & 0 & -\mathrm{i} & 0 \\ 0 & 0 & 0 & 1 \\ -\mathrm{i} & 0 & 0 & 0 \\ 0 & -1 & 0 & 0 \end{bmatrix}$	$\frac{1}{2}\begin{bmatrix} 0 & 0 & 0 & -\mathrm{i} \\ 0 & 0 & -1 & 0 \\ 0 & 1 & 0 & 0 \\ -\mathrm{i} & 0 & 0 & 0 \end{bmatrix}$	$\frac{1}{2}\begin{bmatrix} 0 & -\mathrm{i} & 0 & 0 \\ -\mathrm{i} & 0 & 0 & 0 \\ 0 & 0 & 0 & -1 \\ 0 & 0 & 1 & 0 \end{bmatrix}$

$$q_{(0)j,(0)}\overline{\sigma^P}(j,0)^{\nu}{}_{\mu}=\frac{\mathrm{i}}{2}(\delta_{0\mu}\delta^{\nu}_{j}+\delta_{j\mu}\delta^{\nu}_{0})+\frac{1}{2}(\epsilon^{mkl}\delta_{l\mu}\delta^{\nu}_{k}\delta_{mj}). \tag{4.23}$$

Again, the textures of the $\sigma^P(j,f)$ and $\overline{\sigma^P}(j,f)$ matrices are imposed by the addition Table I and a suited choice of spin $(\frac{1}{2},\frac{1}{2})$ irreps for the different classes is given in Table V for generic spin $(\frac{1}{2},\frac{1}{2})$ four-vectors $P_{(f)}$ with $\overline{\sigma^P}(j,f)=\sigma^P(j,f)^{*\mathrm{tr}}$.

We observe again that the $\sigma^P(j,f)$ and $\overline{\sigma^P}(j,f)$ matrices are obtained by suited permutations of the matrices obtained for the class (0) in order to match the adequate textures. We can determine candidates for the metric in each one of these spin $(\frac{1}{2},\frac{1}{2})$ irreps. From relation (4.10) we have

$$\begin{aligned}\sigma^P(j,f)^{\mathrm{tr}}&=-q_{(f),(0)j}\epsilon^{\uparrow P}(f)\sigma^P(j,f)\epsilon^{\downarrow P}(f)\\&=-(2\delta_{f0}+2\delta_{fj}-1)\epsilon^{\uparrow P}(f)\sigma^P(j,f)\epsilon^{\downarrow P}(f).\end{aligned} \tag{4.24}$$

From this we can adopt

$$\epsilon^{\uparrow P}(0)=\epsilon^{\downarrow P}(0)=\begin{bmatrix} 1 & 0 & 0 & 0 \\ 0 & -1 & 0 & 0 \\ 0 & 0 & -1 & 0 \\ 0 & 0 & 0 & -1 \end{bmatrix}, \tag{4.25}$$

$$\epsilon^{\uparrow P}(i)=\epsilon^{\downarrow P}(i)=\begin{bmatrix} -1 & 0 & 0 & 0 \\ 0 & 1 & 0 & 0 \\ 0 & 0 & -1 & 0 \\ 0 & 0 & 0 & -1 \end{bmatrix} \tag{4.26}$$

for $i=1,2,3$. This is consistent with the $P_{(f)}$ multiplets as real representations [a further metric can accomplish (4.24) for $j=1,2,3$, $\epsilon^{\uparrow P}(j)=\sigma_2\otimes\mathrm{i}\sigma_2$, with σ_2 the standard Pauli matrix, but this leads

TABLE VI. Structure of the extension. $j=1,2,3$; $\mu=0,1,2,3$.

Spin → / ↓ Naive dim	(1,0)	$(\frac{1}{2},\frac{1}{2})$	(0,1)
1		$P_{(0)\mu}$	
2/3	$T_{(1)j}, T_{(2)j}, T_{(3)j}$		$\overline{T}_{(1)j}, \overline{T}_{(2)j}, \overline{T}_{(3)j}$
1/3		$P_{(1)\mu}, P_{(2)\mu}, P_{(3)\mu}$	
0	$T_{(0)j}$		$\overline{T}_{(0)j}$

to a nonreal invariant metric]. The pseudometrics in (4.25) and (4.26) reveal that the difference between the familiar class (0) multiplets and the novel multiplets persists. The difference could be again avoided by an alternative representation presented in the Appendix, table VIII. In this case, the ''metrics'' turn out to be Minkowskian, but it is found that these alternative irreps are not suited for the desired extensions.

V. GENERAL STRUCTURE OF THE EXTENSION

In this section we are going to give an outline of the structure of the aimed extension. We are looking for a novel extension of the Poincaré algebra in which, in analogous fashion as accomplished by supersymmetry, a translation can be composed by iteration of further symmetry transformations. We are going to *assume* all throughout this work that the *Clebsch–Gordan theorem* holds for graded multiplets. In order to produce a spin $(\frac{1}{2},\frac{1}{2})$ class (0) charge $P_{(0)}$ we can use three spin $(\frac{1}{2},\frac{1}{2})$-irreps, since

$$(\tfrac{1}{2},\tfrac{1}{2})\otimes(\tfrac{1}{2},\tfrac{1}{2})\otimes(\tfrac{1}{2},\tfrac{1}{2})=(\tfrac{1}{2},\tfrac{1}{2})\otimes((0,0)\oplus(1,0)\oplus(0,1)\oplus(1,1))$$

$$=(\tfrac{1}{2},\tfrac{1}{2})\oplus\ldots.$$

We will start with three spin $(\frac{1}{2},\frac{1}{2})$-irreps $P_{(1)}, P_{(2)}, P_{(3)}$ of naive dimension 1/3 so that they can compose a spin $(\frac{1}{2},\frac{1}{2})$-irrep $P_{(0)}$ of naive dimension 1: the translation multiplet. We introduce spin-1 multiplets necessary for some nontrivial minimal extension accomplishing

$$[\![P_{(1)},[\![P_{(2)},P_{(3)}]\!]]\!]\sim P_{(0)}. \tag{5.1}$$

We are going to implement three steps for building the extension. In order to have (5.1) we need to have a nontrivial result for $[\![P_{(i)},P_{(j)}]\!]$ with $i\neq j$; $i,j=1,2,3$. This implies that we need multiplets in the following direct sum of representations:

$$(\tfrac{1}{2},\tfrac{1}{2})\otimes(\tfrac{1}{2},\tfrac{1}{2})=(0,0)\oplus(1,0)\oplus(0,1)\oplus(1,1).$$

In a forthcoming paper we discuss the introduction of spin (0,0) singlets at this point. We will adopt in the first step only candidates of spin (1,0) and (0,1) of naive dimension 2/3: the spin (1,0)-triplets $T_{(i)}$; $i=1,2,3$, and the spin (0,1)-triplets $\overline{T}_{(i)}$; $i=1,2,3$. We can picture the structure of the aimed extension in the diagram given in Table VI.

In the second step we consider the composition of a space–time translation via $[\![T_{(k)},P_{(k)}]\!]\sim P_{(0)}$ or $[\![\overline{T}_{(k)},P_{(k)}]\!]\sim P_{(0)}$. In the last step we study the consistency of the previous two steps using the graded Jacobi identities.

VI. GRADED EXTENSION OF THE POINCARÉ ALGEBRA

We already observed that the Lie product of two spin $(\frac{1}{2},\frac{1}{2})$-irreps will be expressed in terms of spin (1,0)-triplets $T_{(1)}, T_{(2)}, T_{(3)}$ and (0,1)-triplets $\overline{T}_{(1)}, \overline{T}_{(2)}, \overline{T}_{(3)}$ all of them of naive dimension 2/3:

TABLE VII. $\sigma^{\tilde{T}}$-matrices.

(f)	Spin(1,0)	$\sigma^{\tilde{T}}(1,f)$	$\sigma^{\tilde{T}}(2,f)$	$\sigma^{\tilde{T}}(3,f)$
(1)	$\tilde{T}_{(1)}$	$\begin{bmatrix} 0 & 0 & 0 \\ 0 & 0 & 1 \\ 0 & -1 & 0 \end{bmatrix}$	$\begin{bmatrix} 0 & 0 & -\mathrm{i} \\ 0 & 0 & 0 \\ -\mathrm{i} & 0 & 0 \end{bmatrix}$	$\begin{bmatrix} 0 & -\mathrm{i} & 0 \\ -\mathrm{i} & 0 & 0 \\ 0 & 0 & 0 \end{bmatrix}$
(2)	$\tilde{T}_{(2)}$	$\begin{bmatrix} 0 & -\mathrm{i} & 0 \\ -\mathrm{i} & 0 & 0 \\ 0 & 0 & 0 \end{bmatrix}$	$\begin{bmatrix} 0 & 0 & 0 \\ 0 & 0 & 1 \\ 0 & -1 & 0 \end{bmatrix}$	$\begin{bmatrix} 0 & 0 & -\mathrm{i} \\ 0 & 0 & 0 \\ -\mathrm{i} & 0 & 0 \end{bmatrix}$
(3)	$\tilde{T}_{(3)}$	$\begin{bmatrix} 0 & 0 & -\mathrm{i} \\ 0 & 0 & 0 \\ -\mathrm{i} & 0 & 0 \end{bmatrix}$	$\begin{bmatrix} 0 & -\mathrm{i} & 0 \\ -\mathrm{i} & 0 & 0 \\ 0 & 0 & 0 \end{bmatrix}$	$\begin{bmatrix} 0 & 0 & 0 \\ 0 & 0 & 1 \\ 0 & -1 & 0 \end{bmatrix}$

$$[\![P_{(i)\mu},P_{(j)\nu}]\!]=\eta^{r}(i,j)_{\mu\nu}T_{(i\dagger j)r}+\hat{\eta}^{\dot{r}}(i,j)_{\mu\nu}\overline{T}_{(i\dagger j)\dot{r}} \tag{6.1}$$

for $i\neq j$. Now, using the involution and q-antisymmetry, and the reality of the $P_{(i)}$-irreps

$$\overline{[\![P_{(i)\mu},P_{(j)\nu}]\!]}=[\![P_{(j)\nu},P_{(i)\mu}]\!]=-q_{(j)\nu,(i)\mu}[\![P_{(i)\mu},P_{(j)\nu}]\!]$$

we obtain

$$\begin{aligned} -q_{(j)\nu,(i)\mu}\eta^{r}(i,j)_{\mu\nu}&=\eta^{r}(j,i)_{\nu\mu}=\hat{\eta}^{\dot{r}}(i,j)^{*}_{\mu\nu},\\ -q_{(j)\nu,(i)\mu}\hat{\eta}^{\dot{r}}(i,j)_{\mu\nu}&=\hat{\eta}^{\dot{r}}(j,i)_{\nu\mu}=\eta^{r}(i,j)^{*}_{\mu\nu}. \end{aligned} \tag{6.2}$$

Consider now the Jacobi identities obtained from the triple $T_{(0)l}$, $P_{(i)\mu}$, $P_{(j)\nu}$:

$$[\![T_{(0)l},[\![P_{(i)\mu},P_{(j)\nu}]\!]]\!]=[\![[\![T_{(0)l},P_{(i)\mu}]\!],P_{(j)\nu}]\!]+q_{(0)l,(i)}[\![P_{(i)\mu},[\![T_{(0)l},P_{(j)\nu}]\!]]\!]. \tag{6.3}$$

Using the identities (6.1) and (4.1) we obtain

$$\begin{aligned} \eta^{r}(i,j)_{\mu\nu}(-\mathrm{i}\sigma^{T}(l,i\dagger j)_{r}{}^{n}T_{(i\dagger j)n})=&-\mathrm{i}\sigma^{P}(l,i)_{\mu}{}^{\rho}(\eta^{n}(i,j)_{\rho\nu}T_{(i\dagger j)n}+\hat{\eta}^{\dot{n}}(i,j)_{\rho\nu}\overline{T}_{(i\dagger j)\dot{n}})\\ &+-\mathrm{i}q_{(0)l,(i)}\sigma^{P}(l,j)_{\nu}{}^{\delta}(\eta^{n}(i,j)_{\mu\delta}T_{(i\dagger j)n}+\hat{\eta}^{\dot{n}}(i,j)_{\mu\delta}\overline{T}_{(i\dagger j)\dot{n}}). \end{aligned}$$

With $T_{(i\dagger j)\dot{n}}$ and $\overline{T}_{(i\dagger j)\dot{n}}$ being linearly independent we obtain:

$$\begin{aligned} \sigma^{P}(l,i)_{\mu}{}^{\rho}\hat{\eta}^{\dot{n}}(i,j)_{\rho\nu}+(2\delta_{li}-1)\hat{\eta}^{\dot{n}}(i,j)_{\mu\rho}\sigma^{P}(l,j)_{\nu}{}^{\rho}&=0,\\ \sigma^{P}(l,i)_{\mu}{}^{\rho}\eta^{n}(i,j)_{\rho\nu}+(2\delta_{li}-1)\eta^{n}(i,j)_{\mu\rho}\sigma^{P}(l,j)_{\nu}{}^{\rho}&=\eta^{r}(i,j)_{\mu\nu}\sigma^{T}(l,i\dagger j)_{r}{}^{n}. \end{aligned} \tag{6.4}$$

In analogous fashion, for the triple $\overline{T}_{(0)l}$, $P_{(i)\mu}$, $P_{(j)\nu}$ we obtain further equations:

$$\begin{aligned} \overline{\sigma}^{P}(l,i)^{\rho}{}_{\mu}\eta^{n}(i,j)_{\rho\nu}+(2\delta_{lj}-1)\eta^{n}(i,j)_{\mu\rho}\overline{\sigma}^{P}(l,j)^{\rho}{}_{\nu}&=0,\\ \overline{\sigma}^{P}(l,j)^{\rho}{}_{\nu}\hat{\eta}^{\dot{n}}(i,j)_{\mu\rho}+(2\delta_{lj}-1)\hat{\eta}^{\dot{n}}(i,j)_{\rho\nu}\overline{\sigma}^{P}(l,i)^{\rho}{}_{\mu}&=\hat{\eta}^{\dot{r}}(i,j)_{\mu\nu}\overline{\sigma^{T}}(l,i\dagger j)^{\dot{n}}{}_{\dot{r}}. \end{aligned} \tag{6.5}$$

Using Table I we can determine the allowed textures for the arrays $\eta^{n}(i,j)$ and $\hat{\eta}^{\dot{n}}(i,j)$. We can now use Eqs. (6.2)–(6.5) and use the matrices $\sigma^{\tilde{T}}$ and $\overline{\sigma^{\tilde{T}}}$ for the triplets $\tilde{T}_{(i)}$ and $\tilde{\tilde{T}}_{(i)}$ in Table VII and obtain that using these alternative irreps there are not nontrivial η and $\hat{\eta}$ matrices. This fact is independent of the usage of irreps $P_{(i)}$ in Table V or the alternative $\tilde{P}_{(i)}$ in

Table VIII in the Appendix. Hence, in order *to allow for nontrivial* η and $\hat{\eta}$ matrices *we adopt* triplets $T_{(i)}$ and $\overline{T}_{(i)}$ given by the irreps in Table IV and irreps $P_{(i)}$ given in Table V. Using these multiplets and Eqs. (6.2)–(6.5), for $ijk \in \{123,231,312\}$, we obtain

$$\eta^1(i,j)=a_k\begin{bmatrix}1&0&0&0\\0&0&0&1\\0&-1&0&0\\0&0&1&0\end{bmatrix},\quad \eta^2(i,j)=a_k\begin{bmatrix}0&\mathrm{i}&0&0\\0&0&1&0\\-\mathrm{i}&0&0&0\\0&0&0&-1\end{bmatrix},$$
$$\eta^3(i,j)=a_k\begin{bmatrix}0&0&0&\mathrm{i}\\\mathrm{i}&0&0&0\\0&0&1&0\\0&1&0&0\end{bmatrix}, \tag{6.6}$$

and the further matrices are obtained using (6.2).

We could consider the composition of repeated $P_{(i)}$ charges: $[\![P_{(i)\mu},P_{(i)\nu}]\!]$. These would lead to the consideration of spin (1,0) and spin(0,1) multiplets of class (0), but they are excluded by the Coleman–Mandula theorem.

We are now ready to go to the second step of our extension. Since we want (5.1) to hold, we have

$$[\![T_{(k)r},P_{(l)\mu}]\!]=\delta_{kl}K_r(l)^{\nu}_{\mu}P_{(0)\nu}, \tag{6.7}$$

$$[\![\overline{T}_{(k)\dot{r}},P_{(l)\mu}]\!]=\delta_{kl}\hat{K}_{\dot{r}}(l)^{\nu}_{\mu}P_{(0)\nu}. \tag{6.8}$$

From the properties of involution and q-anticommutation it follows

$$\hat{K}_{\dot{r}}(l)^{\nu}_{\mu}=-q_{(l)r,(l)\mu}K_r(l)^{\nu}_{\mu}{}^*. \tag{6.9}$$

From the triples $T_{(0)l}$, $T_{(k)j}$, $P_{(k)\mu}$ and $\overline{T}_{(0)l}$, $T_{(k)j}$, $P_{(k)\mu}$ we obtain

$$K_j(k)^{\nu}_{\mu}\overline{\sigma}^{P}(l,0)^{\rho}{}_{\nu}=\overline{\sigma}^{P}(l,k)^{\nu}{}_{\mu}K_j(k)^{\rho}_{\nu}, \tag{6.10}$$

$$K_j(k)^{\nu}_{\mu}\sigma^{P}(l,0)_{\nu}{}^{\rho}=(2\delta_{lk}-1)\sigma^{P}(l,k)_{\mu}{}^{\nu}K_j(k)^{\rho}_{\nu}+\sigma^{T}(l,k)_j{}^{m}K_m(k)^{\rho}_{\mu}. \tag{6.11}$$

Using Eqs. (6.9)–(6.11) we obtain

$$K_1(1)=b_1\begin{bmatrix}1&0&0&0\\0&1&0&0\\0&0&1&0\\0&0&0&1\end{bmatrix},\quad K_2(1)=b_1\begin{bmatrix}0&0&0&\mathrm{i}\\0&0&1&0\\0&-1&0&0\\\mathrm{i}&0&0&0\end{bmatrix},$$
$$K_3(1)=b_1\begin{bmatrix}0&0&-\mathrm{i}&0\\0&0&0&1\\-\mathrm{i}&0&0&0\\0&-1&0&0\end{bmatrix},$$

$$K_1(2)=b_2\begin{bmatrix}1&0&0&0\\0&0&1&0\\0&0&0&1\\0&1&0&0\end{bmatrix},\quad K_2(2)=b_2\begin{bmatrix}0&\mathrm{i}&0&0\\0&0&0&1\\0&0&-1&0\\\mathrm{i}&0&0&0\end{bmatrix},$$

$$K_3(2)=b_2\begin{bmatrix}0&0&0&-\mathrm{i}\\0&1&0&0\\-\mathrm{i}&0&0&0\\0&0&-1&0\end{bmatrix},$$

$$K_1(3)=b_3\begin{bmatrix}1&0&0&0\\0&0&0&1\\0&1&0&0\\0&0&1&0\end{bmatrix},\quad K_2(3)=b_3\begin{bmatrix}0&0&\mathrm{i}&0\\0&1&0&0\\0&0&0&-1\\\mathrm{i}&0&0&0\end{bmatrix},\tag{6.12}$$

$$K_3(3)=b_3\begin{bmatrix}0&-\mathrm{i}&0&0\\0&0&1&0\\-\mathrm{i}&0&0&0\\0&0&0&-1\end{bmatrix},$$

the $\hat{K}$-matrices are obtained using (6.9).

We are now ready to go to the last consistency condition. We use the triple $P_{(1)\rho}$, $P_{(2)\mu}$, $P_{(3)\nu}$ and the corresponding Jacobi identity to obtain

$$\begin{aligned}0=&q_{(1)\rho,(2)\mu+(3)\nu}\eta^r(2,3)_{\mu\nu}K_r(1)^\sigma_\rho+q_{(2)\mu,(3)\nu}\eta^{r*}(2,3)_{\mu\nu}K^*_r(1)^\sigma_\rho+\eta^r(1,2)_{\rho\mu}K_r(3)^\sigma_\nu\\&+q_{(1)\rho,(2)\mu+(3)\nu}q_{(2)\mu,(3)\nu}\eta^{r*}(1,2)_{\rho\mu}K^*_r(3)^\sigma_\nu+q_{(1)\rho+(2)\mu,(3)\nu}\eta^r(3,1)_{\nu\rho}K_r(2)^\sigma_\mu\\&+q_{(1)\rho,(2)\mu}\eta^{r*}(3,1)_{\nu\rho}K^*_r(2)^\sigma_\mu.\end{aligned}\tag{6.13}$$

From Table II we see that

$$q_{(2)\mu,(3)\nu}=q_{(3)\mu,(1)\nu}=q_{(1)\mu,(2)\nu}=\begin{bmatrix}\mathrm{i}&-\mathrm{i}&-\mathrm{i}&\mathrm{i}\\-\mathrm{i}&\mathrm{i}&\mathrm{i}&-\mathrm{i}\\\mathrm{i}&-\mathrm{i}&-\mathrm{i}&\mathrm{i}\\-\mathrm{i}&\mathrm{i}&\mathrm{i}&-\mathrm{i}\end{bmatrix}_{\mu\nu}.\tag{6.14}$$

Using (6.13) and (6.14) we obtain the following consistency conditions:

$$a_1b_1+a_2b_2+a_3b_3+\mathrm{i}(a_1^*b_1^*+a_2^*b_2^*+a_3^*b_3^*)=0,\tag{6.15}$$

$$a_1b_1-\mathrm{i}a_1^*b_1^*=a_2b_2-\mathrm{i}a_2^*b_2^*=a_3b_3-\mathrm{i}a_3^*b_3^*.\tag{6.16}$$

We can parametrize these constraints in the following way

$$a_1b_1+a_2b_2+a_3b_3=\frac{3}{2}r_0(1-\mathrm{i}),\quad r_0\in\mathbb{R},\tag{6.17}$$

$$a_jb_j-\mathrm{i}a_j^*b_j^*=r_0(1-\mathrm{i}),\quad j=1,2,3.\tag{6.18}$$

A particular nontrivial solution to the constraints is given by

$$a_j=a, \quad b_j=b(1-\mathrm{i}), \quad a,b\in\mathbb{R}\backslash\{0\}, \quad r_0=2ab, \quad j=1,2,3. \tag{6.19}$$

The reader might find it surprising that nontrivial solutions of the structure constants have to be strictly complex, and might expect some conflict with the reality of the compounded translations. Consider for instance the following two triple q-commutators leading to nontrivial translations:

$$[\![P_{(1)0},[\![P_{(2)2},P_{(3)1}]\!]]\!]=(a_1b_1-\mathrm{i}a_1^*b_1^*)P_{(0)0}, \tag{6.20}$$

$$[\![P_{(3)2},[\![P_{(1)2},P_{(2)0}]\!]]\!]=(\mathrm{i}a_3b_3+a_3^*b_3^*)P_{(0)3}. \tag{6.21}$$

The resulting complex coefficients have exactly the required shape, since involution produces the same changes in both sides of (6.20) and (6.21):

$$\overline{[\![P_{(1)0},[\![P_{(2)2},P_{(3)1}]\!]]\!]}=[\![[\![P_{(3)1},P_{(2)2}]\!],P_{(1)0}]\!]=\mathrm{i}[\![P_{(1)0},[\![P_{(2)2},P_{(3)1}]\!]]\!], \tag{6.22}$$

$$\overline{[\![P_{(3)2},[\![P_{(1)2},P_{(2)0}]\!]]\!]}=[\![[\![P_{(2)0},P_{(1)2}]\!],P_{(3)2}]\!]=-\mathrm{i}[\![P_{(3)2},[\![P_{(1)2},P_{(2)0}]\!]]\!]. \tag{6.23}$$

Now, the corresponding (q-commuting) parameters for transformations (6.20) and (6.21) can be found recalling (2.5) and (2.6) and fulfill under involution:

$$\overline{\beta_{-(3)1}\beta_{-(2)2}\beta_{-(1)0}}=-\mathrm{i}\beta_{-(3)1}\beta_{-(2)2}\beta_{-(1)0}, \tag{6.24}$$

$$\overline{\beta_{-(2)0}\beta_{-(1)2}\beta_{-(3)2}}=\mathrm{i}\beta_{-(2)0}\beta_{-(1)2}\beta_{-(3)2}. \tag{6.25}$$

It is curious that due to the noncommutativity, the product of ''real'' (self-involutive) parameters produce complex behavior. The products

$$\beta_{-(3)1}\beta_{-(2)2}\beta_{-(1)0}[\![P_{(1)0},[\![P_{(2)2},P_{(3)1}]\!]]\!],$$

$$\beta_{-(2)0}\beta_{-(1)2}\beta_{-(3)2}[\![P_{(3)2},[\![P_{(1)2},P_{(2)0}]\!]]\!],$$

provide actually real (self-involutive) contributions, as required.

VII. CONCLUSIONS

We have started the construction of graded Lie algebraic extensions with involution of the Poincaré algebra, which we call generically *trefoil symmetries*. Those trefoil symmetries which involve only $\mathbb{Z}_4\times\mathbb{Z}_4$-graded parameters and novel generators of integer spin have been called *clover extensions*. We have obtained a $(\mathbb{Z}_4\times\mathbb{Z}_4;q)$-graded Clover extension $\mathbb{L}$ of the Poincaré algebra. In particular we call this extension *minimal vector clover extension*, for very apparent reasons. In this extension a space–time translation is obtained through the composition of three symmetric vectors which might be interpreted as translations in three novel noncommutative four-dimensional manifolds with a pseudometric.

The Poincaré algebra:

$$\begin{gathered}[\![T_{(0)i},T_{(0)j}]\!]=\mathrm{i}\epsilon_{ijk}T_{(0)k}, \quad [\![T_{(0)i},\overline{T}_{(0)j}]\!]=0, \quad [\![\overline{T}_{(0)i},\overline{T}_{(0)j}]\!]=\mathrm{i}\epsilon_{ijk}\overline{T}_{(0)k},\\ [\![T_{(0)i},P_{(o)\nu}]\!]=-\mathrm{i}\sigma^P(i,0)_\nu{}^\rho P_{(0)\rho}, \quad [\![\overline{T}_{(0)i},P_{(0)\nu}]\!]=-\mathrm{i}q_{(0)i,(0)\nu}P_{(0)\rho}\,\overline{\sigma}^P(i,0)^\rho{}_\nu, \qquad (7.1)\\ [\![P_{(0)\mu},P_{(0)\nu}]\!]=0,\end{gathered}$$

for which the q-commutators coincide with commutators, extends for $f,i,j,k,l=1,2,3$ through the *minimal vector clover extension:*

$$[\![T_{(0)i},P_{(f)\nu}]\!]=-\mathrm{i}\sigma^{P}(i,f)_{\nu}{}^{\rho}P_{(f)\rho},\quad [\![\overline{T}_{(0)i},P_{(f)\nu}]\!]=-\mathrm{i}q_{(0)i,(f)\nu}P_{(f)\rho}\,\overline{\sigma}^{P}(i,f)^{\rho}{}_{\nu},\quad (7.2)$$

$$[\![T_{(0)i},T_{(f)s}]\!]=-\mathrm{i}\sigma^{T}(i,f)_{s}{}^{t}T_{(f)t},\quad [\![\overline{T}_{(0)i},T_{(f)s}]\!]=0,$$

$$[\![T_{(0)i},\overline{T}_{(f)\dot{s}}]\!]=0,\quad [\![\overline{T}_{(0)i},\overline{T}_{(f)\dot{s}}]\!]=-\mathrm{i}q_{(0)i,(f)s}\,\overline{T}_{(f)}{}^{\dot{t}}\,\overline{\sigma^{T}}(i,f)^{\dot{t}}{}_{\dot{s}},\quad (7.3)$$

$$[\![P_{(0)\mu},P_{(f)\nu}]\!]=0,\quad [\![P_{(f)\mu},P_{(f)\nu}]\!]=0,\quad (7.4)$$

$$[\![P_{(0)\mu},T_{(f)t}]\!]=0,\quad [\![P_{(0)\mu},\overline{T}_{(f)s}]\!]=0,\quad (7.5)$$

$$[\![T_{(i)s},T_{(j)t}]\!]=0,\quad [\![T_{(i)s},\overline{T}_{(j)\dot{t}}]\!]=0,\quad [\![\overline{T}_{(i)\dot{s}},\overline{T}_{(j)\dot{t}}]\!]=0,\quad (7.6)$$

$$[\![P_{(i)\mu},P_{(j)\nu}]\!]=\eta^{r}(i,j)_{\mu\nu}T_{(i\dagger j)r}+\hat{\eta}^{\dot{r}}(i,j)_{\mu\nu}\overline{T}_{(i\dagger j)\dot{r}};\quad i\neq j,\quad (7.7)$$

$$\begin{aligned}[\![T_{(k)r},P_{(l)\mu}]\!]&=\delta_{kl}K_{r}(l)_{\mu}^{\nu}P_{(0)\nu},\\ [\![\overline{T}_{(k)\dot{r}},P_{(l)\mu}]\!]&=\delta_{kl}\hat{K}_{\dot{r}}(l)_{\mu}^{\nu}P_{(0)\nu}.\end{aligned}\quad (7.8)$$

The σ-matrices are given in Table IV and V. The η-matrices are given in (6.6). The K-matrices are given in (6.12). These matrices are constrained by the conditions (6.17) and (6.18). A particular choice respecting the symmetry among the novel classes is given by (6.19).

Relations (7.1)–(7.8) provide a $(\mathbb{Z}_4\times\mathbb{Z}_4;q)$-graded Lie algebra $\mathbb{L}$ with involution, which extends nontrivially the Poincaré algebra.

A very important feature of the obtained extension is that *this extension does not correspond to any cumbersome deformation of the conformal extension and related series since there the (scalar) dilatation operator cannot be excluded.*

This extension is minimal in the sense that no extra generators are needed for the closure of the algebra, and the omission of some generator would either damage the closure of the graded algebra, or would not provide an actual nontrivial extension of the Poincaré algebra.

The obtained constraints on the structure constants reveal that the isotropy and homogeneity of the space–time can be maintained in this extension: there are particular choices of the structure constants that maintain the profound symmetry behind the three novel classes.

The grading indices used by the novel generators provide a sort of triple replication of the way in which the class (0) indices are used by the Poincaré algebra: The Poincaré algebra uses once the index $(0)_0$ and three times each index $(0)_j$, for $j=1,2,3$. The novel generators of class (i) use once the index $(i)_0$ and three times each index $(i)_j$, for $j=1,2,3$. The Poincaré algebra has ten parameters (and generators) and the obtained extension has $10+3\times10=40$ parameters (and generators). There are further minimal extensions that can be nontrivially coupled to generators of this extension.

The index structure has certain attractive patterns. The class (0) builds up a $\mathbb{Z}_2\times\mathbb{Z}_2$ group, which might be connected to the discrete transformations of time reversal and space inversion. According to Table III the novel classes reproduce this Klein group structure as well. The three novel classes can be composed to arrive at the class (0). We discuss in further stages of this series the extent to which we could expect a connection to color charges, to the 1/3 electric charges of quarks, to the lepton and quarks family structure, or to the family generations. Observe for now that we have 16 Weyl fermions in each family, 12 of them are quarks and 4 leptons, which maintain some analogy with the structure of the $\mathbb{Z}_4\times\mathbb{Z}_4$-grading and its classes. The naive extensions of these symmetries, and the study of inner automorphism will provide the way for relating internal and external symmetries. The presence of spin 1 generators in the extension suggest superfields that might connect gauge and Higgs fields. Gravitation will be involved in this research

TABLE VIII. $\sigma^{\tilde{P}}$-matrices.

(f)	Spin $(\frac{1}{2},\frac{1}{2})$	$\sigma^{\tilde{P}}(1,f)$	$\sigma^{\tilde{P}}(2,f)$	$\sigma^{\tilde{P}}(3,f)$
(1)	$\tilde{P}_{(1)}$	$\frac{1}{2}\begin{bmatrix} 0 & -\mathrm{i} & 0 & 0 \\ -\mathrm{i} & 0 & 0 & 0 \\ 0 & 0 & 0 & -1 \\ 0 & 0 & 1 & 0 \end{bmatrix}$	$\frac{1}{2}\begin{bmatrix} 0 & 0 & 1 & 0 \\ 0 & 0 & 0 & -\mathrm{i} \\ -1 & 0 & 0 & 0 \\ 0 & -\mathrm{i} & 0 & 0 \end{bmatrix}$	$\frac{1}{2}\begin{bmatrix} 0 & 0 & 0 & -1 \\ 0 & 0 & -\mathrm{i} & 0 \\ 0 & -\mathrm{i} & 0 & 0 \\ 1 & 0 & 0 & 0 \end{bmatrix}$
(2)	$\tilde{P}_{(2)}$	$\frac{1}{2}\begin{bmatrix} 0 & 0 & 0 & -1 \\ 0 & 0 & -\mathrm{i} & 0 \\ 0 & -\mathrm{i} & 0 & 0 \\ 1 & 0 & 0 & 0 \end{bmatrix}$	$\frac{1}{2}\begin{bmatrix} 0 & -\mathrm{i} & 0 & 0 \\ -\mathrm{i} & 0 & 0 & 0 \\ 0 & 0 & 0 & -1 \\ 0 & 0 & 1 & 0 \end{bmatrix}$	$\frac{1}{2}\begin{bmatrix} 0 & 0 & 1 & 0 \\ 0 & 0 & 0 & -\mathrm{i} \\ -1 & 0 & 0 & 0 \\ 0 & -\mathrm{i} & 0 & 0 \end{bmatrix}$
(3)	$\tilde{P}_{(3)}$	$\frac{1}{2}\begin{bmatrix} 0 & 0 & 1 & 0 \\ 0 & 0 & 0 & -\mathrm{i} \\ -1 & 0 & 0 & 0 \\ 0 & -\mathrm{i} & 0 & 0 \end{bmatrix}$	$\frac{1}{2}\begin{bmatrix} 0 & 0 & 0 & -1 \\ 0 & 0 & -\mathrm{i} & 0 \\ 0 & -\mathrm{i} & 0 & 0 \\ 1 & 0 & 0 & 0 \end{bmatrix}$	$\frac{1}{2}\begin{bmatrix} 0 & -\mathrm{i} & 0 & 0 \\ -\mathrm{i} & 0 & 0 & 0 \\ 0 & 0 & 0 & -1 \\ 0 & 0 & 1 & 0 \end{bmatrix}$

by considering further extensions or local versions of flat graded symmetries. The reader might inquire for a sort of echo of grading in the Kepler symmetry relating the cube of the semimajor axes with the square of the periods of revolution in planetary motion.

Typesetting assistance and comments from L. A. Sánchez, D. Aristizábal, and D. E. Jaramillo are acknowledged.

APPENDIX

Here we present some spin representations whose metrics are formally identical to those of the class (0). Nevertheless, it turns out that these representations are not suited for allowing nontrivial extensions of the Poincaré algebra.

1. Alternative spin (1,0) and (0,1) irreps

We can construct an alternative representation to the spin (1,0) and (0,1) irreps presented in Table IV. Consider for instance the allowed choice given in Table VII with $\overline{\sigma^{\tilde{T}}}(j,f) = \sigma^{\tilde{T}}(j,f)^{*\mathrm{tr}}$. In this case the metrics turn out to be Euclidean. $\epsilon^{\uparrow\tilde{T}}(f) = \overline{\epsilon^{\uparrow\tilde{T}}}(f) = \mathrm{diag}(-1,-1,-1)$. Nevertheless, it is found in the main text that these alternative irreps are not suited for allowing nontrivial extensions of external symmetries.

2. Alternative spin $(\frac{1}{2},\frac{1}{2})$ irreps

We can construct an alternative representation to the spin $(\frac{1}{2},\frac{1}{2})$ irreps presented in Table V. Consider for instance the choice given in Table VIII with $\overline{\sigma^{\tilde{P}}}(j,f) = \sigma^{\tilde{P}}(j,f)^{*\mathrm{tr}}$. In this case, the "metrics" turn out to be Minkowskian: $\epsilon^{\uparrow\tilde{P}}(f) = \mathrm{diag}(1,-1,-1,-1) = \epsilon^{\downarrow\tilde{P}}(f)$. Again, it is found that these alternative irreps are not suited for the desired symmetry extensions.

(Received 3 July 2000; accepted for publication 12 April 2001)

We construct a novel graded extension of the Poincaré group with integer spin multiplets as novel generators. The extension involves $\mathbb{Z}_4\times\mathbb{Z}_4$ graded parameters and produce space–time translations through the composition of novel symmetric vector and scalar multiplets. © *2001 American Institute of Physics.*

I. INTRODUCTION

Grading structures suited for extending the Poincaré group were determined long ago[1] and even more general realms have been found for constructing continuous symmetries.[2] This is the second paper in a series on graded extensions of the Poincaré group beyond the Coleman–Mandula no-go theorem.[3] The study of novel symmetries beyond those of special relativity and supersymmetry has started addressing graded Lie algebraic extensions with involution which have been called *trefoil symmetries*.[4] Those trefoil symmetries which are $(\mathbb{Z}_4\times\mathbb{Z}_4;q)$-graded and involve only multiplets of generators of integer spin have been called *clover symmetries* and correspond to the simplest extensions beyond the Coleman–Mandula no-go theorem.

In Ref. 4 the reader can find a review on grading groups, graded parameter, and graded Lie algebras, on the grading groups suited for extending the external symmetries of the special relativity, and a minimal $(\mathbb{Z}_4\times\mathbb{Z}_4;q)$-graded extension of the Poincaré algebra which involved only spin-1 multiplets as novel generators, which has been called *minimal vector clover symmetry*. Our aim is to present another extension called *minimal scalar clover symmetry*, since the novel generators are only symmetric vector and scalar multiplets. *We will maintain all throughout this work all the conventions stated in Ref. 4*. We look for a $(\mathbb{Z}_4\times\mathbb{Z}_4;q)$-graded Lie algebra with involution which contains the Poincaré algebra. The novel algebra has three symmetric-vector generators $P_{(1)}$, $P_{(2)}$, $P_{(3)}$ of naive dimension 1/3. We want them to compose via

$$(\tfrac{1}{2},\tfrac{1}{2})\otimes(\tfrac{1}{2},\tfrac{1}{2})\otimes(\tfrac{1}{2},\tfrac{1}{2})=(\tfrac{1}{2},\tfrac{1}{2})\oplus\ \ldots \tag{1.1}$$

to produce the (standard) space–time translation multiplet $P_{(0)}$,

$$[\![P_{(1)},[\![P_{(2)},P_{(3)}]\!]]\!]\sim P_{(0)}\,. \tag{1.2}$$

a)Electronic mail: law@math.hawaii.edu

The double brackets stand for q-commutators respecting the grading assignments of its entries, and $P_{(0)}=(P_0,P_1,P_2,P_3)$ stands for the translation four-vector. The Lorentz generators will be written in terms of the spin (1,0) triplet $T_{(0)}$ and the spin (0,1) triplet $\overline{T}_{(0)}$ as presented in Ref. 4. In order to have (1.2) we need a nontrivial result for $[\![P_{(i)},P_{(j)}]\!]$ with $i\neq j$; $i,j=1,2,3$. Hence, we need multiplets in the following direct sum of representations:

$$(\tfrac{1}{2},\tfrac{1}{2})\otimes(\tfrac{1}{2},\tfrac{1}{2})=(0,0)\oplus(1,0)\oplus(0,1)\oplus(1,1).$$

We will discuss here the introduction of spin (0,0) singlets at this point:

$$[\![P_{(i)},P_{(j)}]\!]\sim E_{(i\dagger j)}+\overline{E}_{(i\dagger j)};\quad i\neq j;\quad i,j=1,2,3. \tag{1.3}$$

The novel scalars $E_{(f)s}$ have naive dimension 2/3.

This work is structured in the following way. Section II introduces the required novel irreducible multiplets. Section III gives an outline of the general structure of the aimed extension. In Sec. IV we study the Jacobi identities and obtain the desired $(\mathbb{Z}_4\times\mathbb{Z}_4;q)$-graded Lie algebraic extension of the Poincaré algebra. Section V inquires about the introduction of dimensionless scalar charges. Section VI gives the concluding remarks.

II. GRADED SPIN IRREPS OF GENERATORS

We consider multiplets of generators $a_{(f)s}$ of classes $(f)=(0),(1),(2),(3)$. The index s stands for the different components of each multiplet except for spin-0 singlets. The dual multiplets are written $a_{(f)}{}^{s}$, and the corresponding complex-conjugated and dual complex-conjugated-multiplets are given by $\overline{a}_{(f)\dot{s}}$ and $\overline{a}_{(f)}{}^{\dot{s}}$. All these multiplets transforms linearly under Lorentz generators:

$$[\![T_{(0)i},a_{(f)s}]\!]=-\mathrm{i}\sigma^a(i,f)_s{}^t a_{(f)t}, \tag{2.1}$$

$$[\![T_{(0)i},a_{(f)}{}^{s}]\!]=\mathrm{i}q_{(0)i,(f)s}\,a_{(f)}{}^{t}\,\sigma^a(i,f)_t{}^{s}, \tag{2.2}$$

$$[\![\overline{T}_{(0)i},\overline{a}_{(f)\dot{s}}]\!]=-\mathrm{i}q_{(0)i,(f)s}\,\overline{a}_{(f)\dot{t}}\,\overline{\sigma^a}(i,f)^{\dot{t}}{}_{\dot{s}}, \tag{2.3}$$

$$[\![\overline{T}_{(0)i},\overline{a}_{(f)}{}^{\dot{s}}]\!]=\mathrm{i}\overline{\sigma^a}(i,f)^{\dot{s}}{}_{\dot{t}}\,\overline{a}_{(f)}{}^{\dot{t}}, \tag{2.4}$$

where $\overline{a_{(f)s}}=\overline{a}_{(f)\dot{s}}$, $\overline{a_{(f)}{}^{s}}=\overline{a}_{(f)}{}^{\dot{s}}$. From the involution we obtain

$$\overline{\sigma^a}(i,f)^{\dot{t}}{}_{\dot{s}}=\sigma^a(i,f)^{*\,t}_{s}. \tag{2.5}$$

From the Jacobi identity

$$[\![T_{(0)j},[\![T_{(0)k},a_{(f)s}]\!]]\!]=[\![[\![T_{(0)j},T_{(0)k}]\!],a_{(f)s}]\!]+q_{(0)j,(0)k}[\![T_{(0)k},[\![T_{(0)j},a_{(f)s}]\!]]\!]$$

we obtain

$$[\mathrm{i}\sigma^a(j,f),\mathrm{i}\sigma^a(k,f)]=\mathrm{i}\epsilon_{jkl}(\mathrm{i}\sigma^a(l,f)), \tag{2.6}$$

where the commutator has the usual meaning. Accordingly, the matrices $\mathrm{i}\sigma^a(j,f)_s{}^t$ and $-\mathrm{i}[\sigma^a(j,f)^{\mathrm{tr}}]^t{}_s$ are standard representations of angular momenta. Analogously, using the Jacobi identity for the triple $\overline{T}_{(0)j}$, $\overline{T}_{(0)k}$, $\overline{a}_{(f)\dot{s}}$ we obtain

$$[-\mathrm{i}q_{(0)j,(f)}\overline{\sigma^a}(j,f),-\mathrm{i}q_{(0)k,(f)}\overline{\sigma^a}(k,f)]=\mathrm{i}\epsilon_{jkl}(-\mathrm{i}q_{(0)l,(f)}\overline{\sigma^a}(l,f)). \tag{2.7}$$

Hence, $-\mathrm{i}q_{(0)j,(f)}\overline{\sigma^a}(j,f)$ and $\mathrm{i}q_{(0)j,(f)}\overline{\sigma^a}(j,f)^{\mathrm{tr}}$ are also standard representations of angular momenta. It is easy to verify that $a_{(f)}{}^s a_{(f)_s}$ (summation only over s through the multiplet) and $\overline{a}_{(f)\dot{s}}\overline{a}_{(f)}{}^{\dot{s}}$ are invariant quadratic products.

The "metrics" $\epsilon^a(f)^{us}$ and $\epsilon^a(f)_{us}$ connect the self-representation $a_{(f)s}$ and the dual-self-representation $a_{(f)}{}^s$:

$$\epsilon^a(f)^{us}\, a_{(f)s} = a_{(f)}{}^u, \tag{2.8}$$

$$\epsilon^a(f)_{ds}\, a_{(f)}{}^s = a_{(f)d}. \tag{2.9}$$

These "metrics" carry trivial index $\tilde{o}$, and fulfill in matricial notation

$$\sigma^a(j,f)^{\mathrm{tr}} = -q_{(f),(0)j}\epsilon^{\uparrow a}(f)\sigma^a(j,f)\epsilon^{\downarrow a}(f), \tag{2.10}$$

where $\epsilon^{\uparrow a}(f)$ and $\epsilon^{\downarrow a}(f)$ stand for the metric with indices up and down, respectively. Analogously, we define a "metric" between the complex-conjugated-representation and its dual:

$$\overline{\epsilon^a}(f)^{\dot{u}\dot{s}}\overline{a}(f)_{\dot{s}} = \overline{a}(f)^{\dot{u}}, \tag{2.11}$$

$$\overline{\epsilon^a}(f)_{\dot{d}\dot{s}}\overline{a}_{(f)}{}^{\dot{s}} = \overline{a}_{(f)\dot{d}}, \tag{2.12}$$

which leads in matricial notation to

$$\overline{\sigma^a}(j,f)^{\mathrm{tr}} = -q_{(0)j,(f)}\overline{\epsilon}^{\downarrow\overline{a}}(f)^{\mathrm{tr}}\overline{\sigma^a}(j,f)\overline{\epsilon}^{\uparrow\overline{a}}(f)^{\mathrm{tr}}. \tag{2.13}$$

We classify now the spin representations according to their eigenvalues with respect to the Casimir operators of the Lorentz algebra: $\Sigma T_{(0)i}T_{(0)i}$ and $\Sigma\overline{T}_{(0)i}\overline{T}_{(0)i}$. A multiplet $a_{(0)s}$ is said to be in the (s_l,s_r)-spin representation if

$$\begin{aligned}\left[\!\left[\sum_{i=1}^{3} T_{(0)i}T_{(0)i}, a_{(f)s}\right]\!\right] &= s_l(s_l+1)a_{(f)s},\\ \left[\!\left[\sum_{i=1}^{3} \overline{T}_{(0)i}\overline{T}_{(0)i}, a_{(f)s}\right]\!\right] &= s_r(s_r+1)a_{(f)s}.\end{aligned} \tag{2.14}$$

The total spin is given by s_l+s_r. We are now going to list the irreps of integer total spin not greater than one.

A. Spin $(\frac{1}{2},\frac{1}{2})$ irreps

We consider spin $(\frac{1}{2},\frac{1}{2})$ multiplets $P_{(f)s}$; $f=0,1,2,3$. The four-vector $P_{(0)s}$ is the space–time translation. The textures of the $\sigma^P(j,f)$ and $\overline{\sigma^P}(j,f)$ matrices are fixed by the graded structure and a suited choice of spin $(\frac{1}{2},\frac{1}{2})$ irreps for the different classes is given in Table I for generic spin $(\frac{1}{2},\frac{1}{2})$ four-vectors $P_{(f)}$ with $\overline{\sigma^P}(i,f)=\sigma^P(i,f)^{*\mathrm{tr}}$.

From relation (2.10) we can adopt

$$\epsilon^{\uparrow P}(0)=\epsilon^{\downarrow P}(0)=\begin{bmatrix}1&0&0&0\\0&-1&0&0\\0&0&-1&0\\0&0&0&-1\end{bmatrix}, \tag{2.15}$$

TABLE I. σ^P-matrices.

(f)	Spin $(\frac{1}{2},\frac{1}{2})$	$\sigma^P(1,f)$	$\sigma^P(2,f)$	$\sigma^P(3,f)$
(0)	$P_{(0)}$	$\frac{1}{2}\begin{bmatrix} 0 & -i & 0 & 0 \\ -i & 0 & 0 & 0 \\ 0 & 0 & 0 & -1 \\ 0 & 0 & 1 & 0 \end{bmatrix}$	$\frac{1}{2}\begin{bmatrix} 0 & 0 & -i & 0 \\ 0 & 0 & 0 & 1 \\ -i & 0 & 0 & 0 \\ 0 & -1 & 0 & 0 \end{bmatrix}$	$\frac{1}{2}\begin{bmatrix} 0 & 0 & 0 & -i \\ 0 & 0 & -1 & 0 \\ 0 & 1 & 0 & 0 \\ -i & 0 & 0 & 0 \end{bmatrix}$
(1)	$P_{(1)}$	$\frac{1}{2}\begin{bmatrix} 0 & -i & 0 & 0 \\ -i & 0 & 0 & 0 \\ 0 & 0 & 0 & -1 \\ 0 & 0 & 1 & 0 \end{bmatrix}$	$\frac{1}{2}\begin{bmatrix} 0 & 0 & -i & 0 \\ 0 & 0 & 0 & 1 \\ -i & 0 & 0 & 0 \\ 0 & -1 & 0 & 0 \end{bmatrix}$	$\frac{1}{2}\begin{bmatrix} 0 & 0 & 0 & -i \\ 0 & 0 & -1 & 0 \\ 0 & 1 & 0 & 0 \\ -i & 0 & 0 & 0 \end{bmatrix}$
(2)	$P_{(2)}$	$\frac{1}{2}\begin{bmatrix} 0 & 0 & 0 & -i \\ 0 & 0 & -1 & 0 \\ 0 & 1 & 0 & 0 \\ -i & 0 & 0 & 0 \end{bmatrix}$	$\frac{1}{2}\begin{bmatrix} 0 & -i & 0 & 0 \\ -i & 0 & 0 & 0 \\ 0 & 0 & 0 & -1 \\ 0 & 0 & 1 & 0 \end{bmatrix}$	$\frac{1}{2}\begin{bmatrix} 0 & 0 & -i & 0 \\ 0 & 0 & 0 & 1 \\ -i & 0 & 0 & 0 \\ 0 & -1 & 0 & 0 \end{bmatrix}$
(3)	$P_{(3)}$	$\frac{1}{2}\begin{bmatrix} 0 & 0 & -i & 0 \\ 0 & 0 & 0 & 1 \\ -i & 0 & 0 & 0 \\ 0 & -1 & 0 & 0 \end{bmatrix}$	$\frac{1}{2}\begin{bmatrix} 0 & 0 & 0 & -i \\ 0 & 0 & -1 & 0 \\ 0 & 1 & 0 & 0 \\ -i & 0 & 0 & 0 \end{bmatrix}$	$\frac{1}{2}\begin{bmatrix} 0 & -i & 0 & 0 \\ -i & 0 & 0 & 0 \\ 0 & 0 & 0 & -1 \\ 0 & 0 & 1 & 0 \end{bmatrix}$

$$\epsilon^{\uparrow P}(i)=\epsilon^{\downarrow P}(i)=\begin{bmatrix} -1 & 0 & 0 & 0 \\ 0 & 1 & 0 & 0 \\ 0 & 0 & -1 & 0 \\ 0 & 0 & 0 & -1 \end{bmatrix}, \quad i=1,2,3, \tag{2.16}$$

which is consistent with the $P_{(f)}$ multiplets as real representations.

B. Spin (0,0) irreps

The spin (0,0) irreps are one-dimensional and are just characterized by vanishing σ-matrices, i.e., they are Lorentz invariant. A scalar siglet $E_{(\mu)\rho}$ means just that it carries index $(\mu)\rho$. In this case the subindex ρ *is not to be interpreted as a multiplet index.*

III. GENERAL STRUCTURE OF THE EXTENSION

We are going to implement three steps for building a novel extension. We will consider in the first step the composition of spin (0,0) singlets $E_{(f)s}$ of naive dimension 2/3 via $[\![P_{(i)},P_{(j)}]\!] \sim E_{(i\dagger j)}+\overline{E}_{(i\dagger j)}$ with $i\neq j$; $i,j=1,2,3$. We can picture the structure of the aimed extension in the diagram given in Table II.

In the second step we consider the composition of a space–time translation via $[\![E_{(k)},P_{(k)}]\!] \sim P_{(0)}$ or $[\![\overline{E}_{(k)},P_{(k)}]\!]\sim P_{(0)}$. In the last step we study the consistency of the previous two steps using the graded Jacobi-identities.

IV. GRADED EXTENSION OF THE POINCARÉ ALGEBRA

We already observed that the product of two spin-$(\frac{1}{2},\frac{1}{2})$ irreps will be expressed in terms of scalar singlets $E_{(k)\sigma},\overline{E}_{(k)\sigma}$ of naive dimension 2/3:

$$[\![P_{(i)\mu},P_{(j)\nu}]\!]=C^{\sigma}(i,j)_{\mu\nu}E_{(i\dagger j)\sigma}+\hat{C}^{\sigma}(i,j)_{\mu\nu}\overline{E}_{(i\dagger j)\sigma}, \tag{4.1}$$

TABLE II. Structure of the extension. $j=1,2,3$; μ, $s=0,1,2,3$.

	Spin		
Naive dim	(1,0)	$(\frac{1}{2},\frac{1}{2})$ / (0,0)	(0,1)
1		$P_{(0)\mu}$	
2/3		$E_{(1)0},E_{(2)0},E_{(3)0},\overline{E}_{(1)0},\overline{E}_{(2)0},\overline{E}_{(3)0}$	
1/3		$P_{(1)\mu},P_{(2)\mu},P_{(3)\mu}$	
0	$T_{(0)j}$	$(G_{(0)0},\overline{G}_{(0)0})$	$\overline{T}_{(0)j}$

for $i\neq j$, $i,j=1,2,3$. Now, using the involution and q-antisymmetry, and the reality of the $P_{(i)}$- irreps

$$\overline{[\![P_{(i)\mu},P_{(j)\nu}]\!]}=[\![P_{(j)\nu},P_{(i)\mu}]\!]=-q_{(j)\nu,(i)\mu}[\![P_{(i)\mu},P_{(j)\nu}]\!]$$

we obtain

$$-q_{(j)\nu,(i)\mu}C^{\sigma}(i,j)_{\mu\nu}=C^{\sigma}(j,i)_{\nu\mu}=\hat{C}^{\sigma}(i,j)^{*}_{\mu\nu}. \tag{4.2}$$

Consider now the Jacobi identities obtained from the triple $T_{(0)l}$, $P_{(i)\mu}$, $P_{(j)\nu}$:

$$[\![T_{(0)l},[\![P_{(i)\mu},P_{(j)\nu}]\!]]\!]=[\![[\![T_{(0)l},P_{(i)\mu}]\!],P_{(j)\nu}]\!]+q_{(0)l,(i)}[\![P_{(i)\mu},[\![T_{(0)l},P_{(j)\nu}]\!]]\!]. \tag{4.3}$$

Using the identities (4.1) and (2.1) we obtain

$$\begin{aligned}0=&-\mathrm{i}\sigma^{P}(l,i)_{\mu}{}^{\rho}(C^{\sigma}(i,j)_{\rho\nu}E_{(i\dagger j)\sigma}+\hat{C}^{\sigma}(i,j)_{\rho\nu}\overline{E}_{(i\dagger j)\sigma})\\&+-\mathrm{i}q_{(0)l,(i)}\sigma^{P}(l,j)_{\nu}{}^{\delta}(C^{\sigma}(i,j)_{\mu\delta}E_{(i\dagger j)\sigma}+\hat{C}^{\sigma}(i,j)_{\mu\delta}\overline{E}_{(i\dagger j)\sigma}).\end{aligned}$$

With $E_{(i\dagger j)s}$ and $\overline{E}_{(i\dagger j)s}$ being linearly independent we obtain

$$\sigma^{P}(l,i)_{\mu}{}^{\rho}C^{\sigma}(i,j)_{\rho\nu}+(2\delta_{li}-1)C^{\sigma}(i,j)_{\mu\rho}\sigma^{P}(l,j)_{\nu}{}^{\rho}=0. \tag{4.4}$$

In analogous fashion, for the triple $\overline{T}_{(0)l}$, $P_{(i)\mu}$, $P_{(j)\nu}$ we obtain further equations:

$$\overline{\sigma}^{P}(l,i)^{\rho}{}_{\mu}C^{\sigma}(i,j)_{\rho\nu}+(2\delta_{lj}-1)C^{\sigma}(i,j)_{\mu\rho}\overline{\sigma}^{P}(l,j)^{\rho}{}_{\nu}=0. \tag{4.5}$$

Using the table of the grading group $\mathbb{Z}_4\times\mathbb{Z}_4$ we can determine the allowed textures for the arrays $C^{\sigma}(i,j)$, $\hat{C}^{\sigma}(i,j)$. We can now use Eqs. (4.2)–(4.5) and the σ-matrices in Table I to obtain for $ijk\in\{123,231,312\}$:

$$C^0(i,j)=c_{k0}\begin{bmatrix}0&0&1&0\\0&\mathrm{i}&0&0\\0&0&0&\mathrm{i}\\1&0&0&0\end{bmatrix},\quad C^1(i,j)=c_{k1}\begin{bmatrix}1&0&0&0\\0&0&0&-1\\0&1&0&0\\0&0&1&0\end{bmatrix},$$
$$C^2(i,j)=c_{k2}\begin{bmatrix}0&1&0&0\\0&0&-\mathrm{i}&0\\1&0&0&0\\0&0&0&-\mathrm{i}\end{bmatrix},\quad C^3(i,j)=c_{k3}\begin{bmatrix}0&0&0&1\\-1&0&0&0\\0&0&-\mathrm{i}&0\\0&\mathrm{i}&0&0\end{bmatrix}. \tag{4.6}$$

The further matrices are obtained using (4.2).

We are now ready to go to the second step of our extension. Since we want (1.2) to hold, we have two ways for arriving at this stage:

$$[\![E_{(f)\sigma},P_{(l)\mu}]\!]=\delta_{fl}S_\sigma(l)^\nu_\mu P_{(0)\nu}, \tag{4.7}$$

$$[\![\overline{E}_{(f)\sigma},P_{(l)\mu}]\!]=\delta_{fl}\hat{S}_\sigma(l)^\nu_\mu P_{(0)\nu}, \tag{4.8}$$

for $l\in 1,2,3$. From the properties of involution and q-anticommutation it follows

$$\hat{S}_\sigma(l)^\nu_\mu=-q_{(l)\sigma,(l)\mu}S_\sigma(l)^{\nu *}_\mu. \tag{4.9}$$

From the triples $T_{(0)l}$, $E_{(k)s}$, $P_{(k)\mu}$ and their corresponding Jacobi identities we obtain

$$S_\sigma(k)^\nu_\mu\sigma^P(l,0)_\nu{}^\rho=(2\delta_{lk}-1)\sigma^P(l,k)_\mu{}^\delta S_\sigma(k)^\rho_\delta, \tag{4.10}$$

$$S_\sigma(k)^\nu_\mu\overline{\sigma}^P(l,0)^\rho{}_\nu=\overline{\sigma}^P(l,k)^\delta{}_\mu S_\sigma(k)^\rho_\delta. \tag{4.11}$$

Using Eqs. (4.10) and (4.11) we obtain

$$S_i(k)=0\quad\forall i\neq 0, \tag{4.12}$$

$$S_0(1)=s_{10}\begin{bmatrix}0&1&0&0\\1&0&0&0\\0&0&0&-\mathrm{i}\\0&0&\mathrm{i}&0\end{bmatrix},\quad S_0(2)=s_{20}\begin{bmatrix}0&0&1&0\\1&0&0&0\\0&-\mathrm{i}&0&0\\0&0&0&-\mathrm{i}\end{bmatrix},$$
$$S_0(3)=s_{30}\begin{bmatrix}0&0&0&1\\1&0&0&0\\0&0&-\mathrm{i}&0\\0&\mathrm{i}&0&0\end{bmatrix}. \tag{4.13}$$

Accordingly, only through the singlets $E_{(l)0}$; $l=1,2,3$ we might expect to produce a space–time translation. *Since we are looking for a minimal extension, we leave aside from now on the scalars* $E_{(l)j}$; $l,j=1,2,3$.

We are now ready to go to the last consistency condition. We use the triple $P_{(1)\rho}$, $P_{(2)\mu}$, $P_{(3)\nu}$ and the corresponding Jacobi identity to obtain

$$\begin{aligned}0=&q_{(1)\rho,(2)\mu+(3)\nu}C^\delta(2,3)_{\mu\nu}S_\delta(1)^\sigma_\rho+C^\delta(1,2)_{\rho\mu}S_\delta(3)^\sigma_\nu\\&+q_{(1)\rho+(2)\mu,(3)\nu}C^\delta(3,1)_{\nu\rho}S_\delta(2)^\sigma_\mu.\end{aligned} \tag{4.14}$$

From the group grading $(\mathbb{Z}_4\times\mathbb{Z}_4;q)$ we have:[4]

$$q_{(2)\mu,(3)\nu}=q_{(3)\mu,(1)\nu}=q_{(1)\mu,(2)\nu}=\begin{bmatrix} \mathrm{i} & -\mathrm{i} & -\mathrm{i} & \mathrm{i} \\ -\mathrm{i} & \mathrm{i} & \mathrm{i} & -\mathrm{i} \\ \mathrm{i} & -\mathrm{i} & -\mathrm{i} & \mathrm{i} \\ -\mathrm{i} & \mathrm{i} & \mathrm{i} & -\mathrm{i} \end{bmatrix}_{\mu\nu}. \tag{4.15}$$

Equations (4.14) and (4.15) lead to the consistency conditions

$$c_{j0}s_{j0}-\mathrm{i}c^*_{j0}s^*_{j0}=0, \quad j\in 1,2,3. \tag{4.16}$$

We can parametrize these constraints in the following way:

$$c_{10}\ \ s_{10}=t_1(1+\mathrm{i}), \quad c_{20}s_{20}=t_2(1+\mathrm{i}), \quad c_{30}s_{30}=t_3(1+\mathrm{i}), \tag{4.17}$$

$$t_1,t_2,t_3\in\mathbb{R}.$$

It is easy to construct particular solutions that maintain the symmetry among the novel multiplet classes (and thus the homogeneity and isotropy of space–time). Consider for instance the particular choice satisfying the constraints in (4.17):

$$c_{j0}=c, \quad s_{j0}=s(1+\mathrm{i}), \quad c,s\in\mathbb{R}\backslash\{0\}, \quad j=1,2,3\,. \tag{4.18}$$

Hence, there exist nontrivial solutions to the coefficients c_{j0},s_{j0}; $j=1,2,3$. This *does not imply* that we can compose a space–time translation $P_{(0)}$ just with the symmetric four-vectors $P_{(i)}$ (and the scalar fields $E_{(i)0}$) via the triple composition $[\![P_{(1)},[\![P_{(2)},P_{(3)}]\!]]\!]$ as originally aimed in (1.2). The contributions to this triple q-commutator turn out to be proportional to $c_{10}s_{10}-\mathrm{i}c^*_{10}s^*_{10}$, which vanish according to (4.16). We *can* nevertheless compose a space–time translation via $[\![E_{(l)0},P_{(l)}]\!]$ or via $[\![\overline{E}_{(l)0},P_{(l)}]\!]$, and this fact provides authentically a minimal extension of the Poincaré algebra by itself.

The class (0)-indices are used by the Poincaré algebra in the following way: once the index $(0)_0$ and three times each index $(0)_j$, for $j=1,2,3$. The novel generators of the class (i), $i=1,2,3$ use three times the index $(i)_0$ (since $E_{(i)0}$ is complex) and once each index $(i)_j$, for $j=1,2,3$. The Poincaré algebra has ten parameters (and generators) and the minimal extension presented here has $10+3\times3+3\times3=28$ parameters (and generators).

In order to maintain a symmetric usage of the indices of the different classes for the spin (0,0) and spin $(\frac{1}{2},\frac{1}{2})$ multiplets, the previous considerations suggest the introduction of two charges of index (0)0 of spin (0,0). This question will be addressed in Sec. V.

V. INTRODUCING DIMENSIONLESS SCALAR GENERATORS

A very appealing idea arises when considering novel extensions of the Poincaré algebra, since elusive connections between internal and external symmetries might be revealed. Particularly interesting is the introduction of dimensionless scalar generators since they are naively the most expedite candidates for internal symmetry generators. We introduce scalar dimensionless singlets $G_{(\rho)\mu}$, where $\rho,\mu=0,1,2,3$ and we will select only the ones which are effectively nontrivially connected to the extension obtained Sec. IV.

The generators $G_{(\rho)\mu}$ are scalar, and thus have trivial q-commutation relations with the Lorentz generators. If these scalar generators have nontrivial q-commutation relations with the mentioned extension, they have nontrivial relations with the multiplets $P_{(i)}$; $i=1,2,3$, since *all* the novel generators of the extension as well as the space–time translations are obtained from compositions of objects obtained in turn from the composition of the multiplets $P_{(i)}$.

We expect that the multiplets $P_{(i)}$; $i=1,2,3$ might constitute representations of the subgroup built by the novel scalar singlets. These scalars satisfy the q-commutation relations

$$[\![G_{(\rho)\mu},G_{(\sigma)\nu}]\!]=-\mathrm{i}\zeta_{\mu}(\rho,\sigma)_{\nu}{}^{\kappa}G_{(\rho\dagger\sigma)\kappa}. \tag{5.1}$$

The structure constants build up the adjoint representation, hence the matrix

$$D^{G}(G_{(\rho)\mu})=-\mathrm{i}\zeta_{\mu}(\rho,\sigma)^{\mathrm{tr}} \tag{5.2}$$

constitutes a representation D^{G} of the generator $G_{(\rho)\mu}$. Now, the multiplets $P_{(i)}$; $i=1,2,3$ build up representations of the group generated by $G_{(\rho)\mu}$. We should have

$$[\![G_{(\rho)\mu},P_{(i)\nu}]\!]=-\mathrm{i}\Lambda_{\mu}(\rho,i)_{\nu}{}^{\sigma}P_{(\rho\dagger i)\sigma}. \tag{5.3}$$

Using the Jacobi identities associated with the triples $G_{(\rho)\mu}$, $G_{(\alpha)\xi}$, $P_{(j)\nu}$, we obtain

$$\Lambda_{\mu}(\rho,\alpha\dagger j)^{\mathrm{tr}}\Lambda_{\xi}(\alpha,j)^{\mathrm{tr}}-q_{(\rho)\mu,(\alpha)\xi}\Lambda_{\xi}(\alpha,\rho\dagger j)^{\mathrm{tr}}\Lambda_{\mu}(\rho,j)^{\mathrm{tr}}=\zeta_{\mu}(\rho,\alpha)_{\xi}{}^{\kappa}\Lambda_{\kappa}(\rho\dagger\alpha,j)^{\mathrm{tr}}. \tag{5.4}$$

Hence, $-\mathrm{i}\Lambda_{\mu}(\rho,i)^{\mathrm{tr}}$ constitutes a representation D^{P} of the algebra generated by $G_{(\rho)\mu}$:

$$D^{P}(G_{(\rho)\mu})=-\mathrm{i}\Lambda_{\mu}(\rho,i)^{\mathrm{tr}}. \tag{5.5}$$

Using the Jacobi identity associated with the triples $T_{(0)r}$, $G_{(\rho)\mu}$, $P_{(i)\nu}$ and $\overline{T}_{(0)r}$, $G_{(\rho)\mu}$, $P_{(i)\nu}$ we obtain, respectively, for $\mu=0,1,2,3$:

$$\Lambda_{\mu}(0,i)=l(0i)_0\begin{bmatrix}\mathrm{i}&0&0&0\\0&\mathrm{i}&0&0\\0&0&\mathrm{i}&0\\0&0&0&\mathrm{i}\end{bmatrix},\quad l(0i)_1\begin{bmatrix}0&\mathrm{i}&0&0\\\mathrm{i}&0&0&0\\0&0&0&-1\\0&0&1&0\end{bmatrix},$$
$$l(0i)_2\begin{bmatrix}0&0&\mathrm{i}&0\\0&0&0&1\\\mathrm{i}&0&0&0\\0&-1&0&0\end{bmatrix},\quad l(0i)_3\begin{bmatrix}0&0&0&\mathrm{i}\\0&0&-1&0\\0&1&0&0\\\mathrm{i}&0&0&0\end{bmatrix}. \tag{5.6}$$

For $(i,j)\in\{12,23,31\}$ we obtain, respectively, for $\mu=0,1,2,3$:

$$\Lambda_{\mu}(i,j)=l(ij)_0\begin{bmatrix}0&\mathrm{i}&0&0\\0&0&-1&0\\-\mathrm{i}&0&0&0\\0&0&0&-1\end{bmatrix},\quad l(ij)_1\begin{bmatrix}0&0&0&\mathrm{i}\\-\mathrm{i}&0&0&0\\0&0&1&0\\0&1&0&0\end{bmatrix},$$
$$l(ij)_2\begin{bmatrix}0&0&\mathrm{i}&0\\0&1&0&0\\0&0&0&-1\\\mathrm{i}&0&0&0\end{bmatrix},\quad l(ij)_3\begin{bmatrix}\mathrm{i}&0&0&0\\0&0&0&-\mathrm{i}\\0&-\mathrm{i}&0&0\\0&0&\mathrm{i}&0\end{bmatrix}, \tag{5.7}$$

$$\Lambda_\mu(j,i)=l(ji)_0\begin{bmatrix}0&\mathrm{i}&0&0\\0&0&0&1\\0&0&1&0\\-\mathrm{i}&0&0&0\end{bmatrix},\quad l(ji)_1\begin{bmatrix}0&0&\mathrm{i}&0\\-\mathrm{i}&0&0&0\\0&-1&0&0\\0&0&0&-1\end{bmatrix},$$
$$l(ji)_2\begin{bmatrix}\mathrm{i}&0&0&0\\0&0&-\mathrm{i}&0\\0&0&0&\mathrm{i}\\0&-\mathrm{i}&0&0\end{bmatrix},\quad l(ji)_3\begin{bmatrix}0&0&0&\mathrm{i}\\0&-1&0&0\\\mathrm{i}&0&0&0\\0&0&1&0\end{bmatrix}. \tag{5.8}$$

We now consider the introduction of $G_{(\rho)\mu}$ generators in the presence of $P_{(i)}$ and $E_{(\alpha)0}$ multiplets. According to (4.1) and (5.3), the scalar charges $E_{(\alpha)0}$ should transform as a (product) representation, hence we have

$$[\![G_{(\rho)\mu},E_{(\alpha)0}]\!]=-\mathrm{i}\epsilon_\mu(\rho,\alpha)E_{(\rho\dagger\alpha)0}. \tag{5.9}$$

Using Eq. (4.1) and the Jacobi identity for the triple $G_{(\rho)\mu}$, $P_{(i)\sigma}$, $P_{(j)\nu}$ we obtain

$$C^0(i,j)_{\sigma\nu}\epsilon_\mu(\rho,i\dagger j)=\Lambda_\mu(\rho,i)_\sigma{}^\tau C^0(i\dagger\rho,j)_{\tau\nu}+q_{(\rho)\mu,(i)\sigma}C^0(i,\rho\dagger j)_{\sigma\omega}\Lambda_\mu(\rho,j)_\nu{}^\omega. \tag{5.10}$$

The relation (5.10) provides nontrivial solutions only for the complex singlet $G_{(0)0}$ [and since we want to determine dimensionless scalars with a nontrivial relation with the extension, we exclude the further (decoupled) scalars from now on]:

$$[\![G_{(0)0},P_{(i)\nu}]\!]=l(0i)_0P_{(i)\nu}, \tag{5.11}$$

$$[\![G_{(0)0},E_{(k)0}]\!]=-l(0k)_0E_{(k)0}, \tag{5.12}$$

$$[\![G_{(0)0},\overline{E}_{(k)0}]\!]=-l(0k)_0\overline{E}_{(k)0}. \tag{5.13}$$

Now, the charge $G_{(0)0}$ is complex, and in terms of its components (5.11)–(5.13) read

$$\begin{aligned}[\![\mathrm{Re}\,G_{(0)0},P_{(i)\nu}]\!]&=\mathrm{i}\,\mathrm{Im}(l(0i)_0)P_{(i)\nu},\\ [\![\mathrm{Im}\,G_{(0)0},P_{(i)\nu}]\!]&=-\mathrm{i}\,\mathrm{Re}(l(0i)_0)P_{(i)\nu},\end{aligned} \tag{5.14}$$

$$\begin{aligned}[\![\mathrm{Re}\,G_{(0)0},E_{(k)0}]\!]&=-\mathrm{i}\,\mathrm{Im}(l(0k)_0)E_{(k)0},\\ [\![\mathrm{Im}\,G_{(0)0},E_{(k)0}]\!]&=\mathrm{i}\,\mathrm{Re}(l(0k)_0)E_{(k)0},\end{aligned} \tag{5.15}$$

$$\begin{aligned}[\![\mathrm{Re}\,G_{(0)0},\overline{E}_{(k)0}]\!]&=-\mathrm{i}\,\mathrm{Im}(l(0k)_0)\overline{E}_{(k)0},\\ [\![\mathrm{Im}\,G_{(0)0},\overline{E}_{(k)0}]\!]&=\mathrm{i}\,\mathrm{Re}(l(0k)_0)\overline{E}_{(k)0}.\end{aligned} \tag{5.16}$$

The nontrivial coupling constants associated with the surviving scalar dimensionless complex charge $G_{(0)0}$ satisfy

$$l(01)_0+l(02)_0+l(03)_0=0. \tag{5.17}$$

This indicates just that according to relations (4.7) and (4.8), the charge of $P_{(0)}$ is vanishing as is required by the Coleman–Mandula theorem. Hence, we can think on the charge $G_{(0)0}$ as an additive charge.

We can now give an explicit and particular choice of the charges $\mathrm{Im}\, l(0i)_0$ and $\mathrm{Re}\, l(0i)_0$ that maintains the symmetries among the multiplets $P_{(1)}$, $P_{(2)}$, $P_{(3)}$. We can adopt for the values of $l(0i)_0$ three complex numbers symmetrically oriented in the complex plane:

$$l(01)_0 = l, \quad l(02)_0 = l e^{i2\pi/3}, \quad l(03)_0 = l e^{i4\pi/3}, \quad l \in \mathbb{R}. \tag{5.18}$$

We observe that the relations (5.14)–(5.16) could be interpreted as presenting $\mathrm{Re}\, G_{(0)0}$ and $\mathrm{Im}\, G_{(0)0}$ as a sort of U(1)-generators. The charges $G_{(0)0}$ and $\overline{G}_{(0)0}$ swap under involution. It is, nevertheless, not excluded that these generators might have nontrivial relations with further scalar charges. From relations (5.4) we conclude in particular,

$$[\![\mathrm{Re}\, G_{(0)0}, \mathrm{Im}\, G_{(0)0}]\!] = 0. \tag{5.19}$$

We observe that only the scalar charges $G_{(0)0}$, $\overline{G}_{(0)0}$ provide an authentic further enhancement of the clover extension obtained in Sec. IV.

VI. CONCLUSIONS

We have continued the study of graded Lie algebraic extensions with involution of the space–time symmetries, which has been called generically *trefoil symmetries*. We have inquired for a novel *clover extension*, i.e., a trefoil symmetry which is $\mathbb{Z}_4 \times \mathbb{Z}_4$-graded and involve only novel generators of integer spin. We have obtained a $(\mathbb{Z}_4 \times \mathbb{Z}_4; q)$-graded clover extension $\mathbb{L}'$ of the Poincaré algebra in which a space–time translation can be obtained through the composition of symmetric vectors (which might be interpreted as translations in three novel noncommutative four-dimensional manifolds with a pseudometric) and scalar fields. In particular, call this extension the *minimal scalar clover Extension*.

The Poincaré algebra:

$$\begin{gathered}
[\![T_{(0)i}, T_{(0)j}]\!] = i\epsilon_{ijk} T_{(0)k}, \quad [\![T_{(0)i}, \overline{T}_{(0)j}]\!] = 0, \quad [\![\overline{T}_{(0)i}, \overline{T}_{(0)j}]\!] = i\epsilon_{ijk} \overline{T}_{(0)k}, \\
[\![T_{(0)i}, P_{(0)\nu}]\!] = -i\sigma^P(i,0)_\nu{}^\rho P_{(0)\rho}, \quad [\![\overline{T}_{(0)i}, P_{(0)\nu}]\!] = -i q_{(0)i,(0)\nu} P_{(0)\rho} \overline{\sigma}^P(i,0)^\rho{}_\nu, \\
[\![P_{(0)\mu}, P_{(0)\nu}]\!] = 0,
\end{gathered} \tag{6.1}$$

extends for $f,i,j,k,l = 1,2,3$ through the *minimal scalar clover extension*

$$[\![T_{(0)i}, P_{(f)\nu}]\!] = -i\sigma^P(i,f)_\nu{}^\rho P_{(f)\rho}, \quad [\![\overline{T}_{(0)i}, P_{(f)\nu}]\!] = -i q_{(0)i,(f)\nu} P_{(f)\rho} \overline{\sigma}^P(i,f)^\rho{}_\nu,$$

$$[\![T_{(0)i}, E_{(f)0}]\!] = 0, \quad [\![\overline{T}_{(0)i}, E_{(f)0}]\!] = 0, \tag{6.2}$$

$$[\![T_{(0)i}, \overline{E}_{(f)0}]\!] = 0, \quad [\![\overline{T}_{(0)i}, \overline{E}_{(f)0}]\!] = 0,$$

$$[\![P_{(0)\mu}, P_{(f)\nu}]\!] = 0, \quad [\![P_{(f)\mu}, P_{(f)\nu}]\!] = 0, \tag{6.3}$$

$$[\![P_{(0)\mu}, E_{(f)0}]\!] = 0, \quad [\![P_{(0)\mu}, \overline{E}_{(f)0}]\!] = 0, \tag{6.4}$$

$$\begin{gathered}
[\![E_{(i)0}, E_{(j)0}]\!] = 0, \quad [\![E_{(i)0}, \overline{E}_{(j)0}]\!] = 0, \\
[\![\overline{E}_{(i)0}, \overline{E}_{(j)0}]\!] = 0,
\end{gathered} \tag{6.5}$$

$$[\![P_{(i)\mu}, P_{(j)\nu}]\!] = C^0(i,j)_{\mu\nu} E_{(i\dagger j)0} + \hat{C}^0(i,j)_{\mu\nu} \overline{E}_{(i\dagger j)0}, \quad i \neq j, \tag{6.6}$$

$$[\![E_{(f)0}, P_{(l)\mu}]\!] = \delta_{fl} S_0(l)^\nu_\mu P_{(0)\nu}, \tag{6.7}$$

$$[\![\overline{E}_{(f)0},P_{(l)\mu}]\!]=\delta_{fl}\hat{S}_0(l)^{\nu}_{\mu}P_{(0)\nu}. \tag{6.8}$$

The σ-matrices are given in Table I. The C^0-matrices are given in (4.6). The S_0-matrices are given in (4.13). These matrices are constrained by the consistency conditions (4.16) and (4.17). A particular choice respecting the symmetry among the novel classes is given by (4.18). Relations (6.1)–(6.8) provide a $(\mathbb{Z}_4\times\mathbb{Z}_4;q)$-graded Lie algebra $\mathbb{L}'$ with involution, which extends nontrivially the Poincaré algebra.

The obtained extension does not correspond to any cumbersome deformation of the conformal extension and related series since there the scalar dilatation operator *does not* commute with the space–time translation.

The obtained extension is minimal in the sense that no extra generators are needed for the closure of the algebra, and the omission of some generator would either damage the closure of the graded algebra, would damage the symmetry among the novel classes, or would not provide an actual nontrivial extension of the Poincaré algebra. The structure constants can be chosen so that no anisotropy or inhomogeneity is introduced to the space–time.

The obtained extension *cannot* compose a space–time translation $P_{(0)}$ via the triple composition $[\![P_{(1)},[\![P_{(2)},P_{(3)}]\!]]\!]$ as originally aimed since the parameter constraints (4.16) annihilate their contributions. Nevertheless, we *can* compose a space–time translation via $[\![E_{(l)0},P_{(l)}]\!]$ or via $[\![\overline{E}_{(l)0},P_{(l)}]\!]$, and this provides an authentic extension of the Poincaré algebra.

The introduction of dimensionless scalar charges has been also addressed and it has been found that scalar charges $\mathrm{Re}\,G_{(0)0}$ and $\mathrm{Im}\,G_{(0)0}$ can have nontrivial relations with the novel generators of the obtained minimal scalar clover extension. This constitutes the *dimensionless scalar enhancement*:

$$[\![\mathrm{Re}\,G_{(0)0},\mathrm{Im}\,G_{(0)0}]\!]=0, \tag{6.9}$$

$$\begin{aligned}[\![\mathrm{Re}\,G_{(0)0},P_{(i)\nu}]\!]&=\mathrm{i}\,\mathrm{Im}(l(0i)_0)P_{(i)\nu},\\ [\![\mathrm{Im}\,G_{(0)0},P_{(i)\nu}]\!]&=-\mathrm{i}\,\mathrm{Re}(l(0i)_0)P_{(i)\nu},\end{aligned} \tag{6.10}$$

$$\begin{aligned}[\![\mathrm{Re}\,G_{(0)0},E_{(k)0}]\!]&=-\mathrm{i}\,\mathrm{Im}(l(0k)_0)E_{(k)0},\\ [\![\mathrm{Im}\,G_{(0)0},E_{(k)0}]\!]&=\mathrm{i}\,\mathrm{Re}(l(0k)_0)E_{(k)0},\end{aligned} \tag{6.11}$$

$$\begin{aligned}[\![\mathrm{Re}\,G_{(0)0},\overline{E}_{(k)0}]\!]&=-\mathrm{i}\,\mathrm{Im}(l(0k)_0)\overline{E}_{(k)0},\\ [\![\mathrm{Im}\,G_{(0)0},\overline{E}_{(k)0}]\!]&=\mathrm{i}\,\mathrm{Re}(l(0k)_0)\overline{E}_{(k)0}.\end{aligned} \tag{6.12}$$

The nontrivial structure constants satisfy:

$$l(01)_0+l(02)_0+l(03)_0=0, \tag{6.13}$$

According to relations (4.7) and (4.8), the charge of $P_{(0)}$ is vanishing as required by the Coleman–Mandula theorem. Clearly, the charge $G_{(0)0}=\mathrm{Re}\,G_{(0)0}+\mathrm{i}\,\mathrm{Im}\,G_{(0)0}$ is an additive charge.

The class (0)-indices are used by the Poincaré algebra in the following way: once the index $(0)_0$ and three times each index $(0)_j$, for $j=1,2,3$. The novel generators of the minimal scalar clover extension (6.2)–(6.8) of the class (i), $i=1,2,3$ use three times the index $(i)_0$ (since $E_{(i)0}$ is complex) and once each index $(i)_j$, for $j=1,2,3$. The Poincaré algebra has ten parameters (and generators) and the minimal extension presented here has $10+3\times3+3\times3=28$ parameters (and generators). The enhancement of the minimal scalar clover extension using scalar dimensionless charges (6.9)–(6.12) makes symmetric the usage of indices for spin (0,0) and spin $(\frac{1}{2},\frac{1}{2})$ multiplets in the four different classes and completes an algebra with 30 generators. Nevertheless, only class (0) indices are used for spin (1,0) and (1,0) multiplets.

This situation allows one to conjecture an extension that makes symmetric usage of spin multiplets in all the classes. Such an extension would use exactly three times each one of the elements of the grading group $\mathbb{Z}_4 \times \mathbb{Z}_4$, and would involve the minimal vector clover and minimal scalar clover extensions as particular cases. This is exactly the content of the next contribution in this paper series. The connection of the already obtained extensions with known internal symmetries will be discussed as well in the further parts of this paper series.

(Received 3 July 2000; accepted for publication 12 April 2001)

We aim to approach a trefoil symmetry involving $(\mathbb{Z}_4\times\mathbb{Z}_4;q)$-graded parameters, multiplets of generators of integer spin <2 with naive dimensions in the interval $[0,1]$. The resulting full clover extension involves as particular subalgebras the minimal clover extensions previously obtained. We address the introduction of further scalar, dimensionless multiplets, and central charges. They could provide connections among external and internal symmetries, perhaps after some graded symmetry breaking. © *2001 American Institute of Physics.*

I. INTRODUCTION

The isospin interaction distinguishes between left and right $\frac{1}{2}$-spin multiplets. This observation suggests deep connections among external and internal symmetries. The present work addresses a possible channel for relating nontrivially internal and external symmetries.

There have been found two minimal nontrivial extensions[1,2] of the external symmetries of special relativity using $\mathbb{Z}_4\times\mathbb{Z}_4$-gradings and novel multiplets of integer spin. They correspond to extensions beyond the the Coleman–Mandula no-go theorem[3] since some of its assumptions were relaxed: On the one hand the novel symmetries are governed by $(\mathbb{Z}_4\times\mathbb{Z}_4;q)$-graded Lie groups, with generator structure given by a $(\mathbb{Z}_4\times\mathbb{Z}_4;q)$-graded Lie algebra with involution. On the other hand, the algebraic relations combining the generators of the Poincaré algebra and the novel generators can be either of commutator or anticommutator type.[4,1]

In the present work we are going to study a more general extension involving the previously obtained as particular cases. We aim in particular at the trefoil symmetry involving $(\mathbb{Z}_4\times\mathbb{Z}_4;q)$-graded parameters, multiplets of generators of integer spin <2 with naive dimensions in the interval $[0,1]$. We introduce novel generators that match naturally with the leitmotif of the previous extensions: the production of space–time translations $P_{(0)}$ via the composition of three symmetric vector charges:

$$[\![P_{(1)},[\![P_{(2)},P_{(3)}]\!]]\!]\sim P_{(0)}. \tag{1.1}$$

The double brackets stand for q-commutators[5] respecting the grading assignments of its entries, and $P_{(0)}=(P_0,P_1,P_2,P_3)$ translation four-vector. The Lorentz generators will be written in terms of the spin (1,0) triplet $T_{(0)}$ and the spin (0,1) triplet $\overline{T}_{(0)}$ as presented in Ref. 1.

We will maintain all throughout this work all the conventions stated in Refs. 1 and 2. In the first of these works we made a review on grading groups, graded parameter and graded Lie algebras, on the grading groups suited for extending the external symmetries of the special relativity. There, we constructed the so-called minimal vector clover extension, which is a $(\mathbb{Z}_4\times\mathbb{Z}_4;q)$-graded extension of the Poincaré algebra which involved only spin-1 multiplets as novel generators. This minimal extension succeeded in producing a space–time translation through the composition of three symmetric vector multiplets as in Eq. (1.1). In the second refereed work the

a)Electronic mail: law@math.hawaii.edu

so-called minimal scalar clover extension was obtained, which can produce a space–time translation through the composition of a symmetric vector generator and scalar generators.

We are interested now mainly in two aspects: First, we want to identify the constraints on the structure constants due to the simultaneous presence of the minimal extensions obtained so far. Second, we want to determine candidates for the would-be internal symmetries after a graded symmetry breaking. This is actually the most appealing aim of this paper: the identification of clues that might present more naturally the internal symmetries we observe in nature.

This work is structured in the following way. In Sec. II we study an extension involving simultaneously the novel multiplets of generators of the previously determined minimal extensions and study the constraints arising on their structure constants. In Sec. III we discuss the introduction of generators that could induce internal symmetries after a breaking of the graded symmetry. Section IV studies the introduction of scalar multiplets naively dimensionless, which are naturally candidates for would-be generators of internal symmetries after graded symmetry breaking. In Sec. V we study the introduction of nondimensionless scalar multiplets and discuss their relations with dimensionless scalar multiplets. In Sec. VI we consider the introduction of dimensionless antisymmetric vector multiplets. In Sec. VII we review the obtained results and give the concluding remarks.

II. MERGED EXTENSION

In analogous fashion as accomplished by supersymmetry, we are looking here for a novel extension of the Poincaré algebra in which a translation can be composed by the iteration of further symmetry transformations. In order to produce a spin-$(\frac{1}{2},\frac{1}{2})$ class (0) space–time translation multiplet $P_{(0)}$ we can use three spin-$(\frac{1}{2},\frac{1}{2})$ irreps $P_{(1)},P_{(2)},P_{(3)}$ as in Eq. (1.1), since

$$(\tfrac{1}{2},\tfrac{1}{2})\otimes(\tfrac{1}{2},\tfrac{1}{2})\otimes(\tfrac{1}{2},\tfrac{1}{2})=(\tfrac{1}{2},\tfrac{1}{2})\oplus\ldots. \tag{2.1}$$

In order to have a nontrivial right-hand side of (1.1) we need a nontrivial result for $[\![P_{(i)},P_{(j)}]\!]$ with $i\neq j$; $i,j=1,2,3$. Accordingly, such extension has to involve multiplets of generators in the right-hand side direct summation:

$$(\tfrac{1}{2},\tfrac{1}{2})\otimes(\tfrac{1}{2},\tfrac{1}{2})=(0,0)\oplus(1,0)\oplus(0,1)\oplus(1,1). \tag{2.2}$$

In Ref. 1 we studied the minimal extension involving generators with representations $(1,0)\oplus(0,1)$ of dimension 2/3 at this point, while in Ref. 2 we studied the introduction of spin (0,0) singlets of dimension 2/3. We study now the simultaneous introduction of both spin 1 and spin 0 multiplets. The fist step will study the constraints on the algebraic relation:

$$[\![P_{(i)\mu},P_{(j)\nu}]\!]=C^{\sigma}(i,j)_{\mu\nu}E_{(i\dagger j)\sigma}+\hat{C}^{\sigma}(i,j)_{\mu\nu}\overline{E}_{(i\dagger j)\sigma}+\eta^{r}(i,j)_{\mu\nu}T_{(i\dagger j)r}+\hat{\eta}^{\dot{r}}(i,j)_{\mu\nu}\overline{T}_{(i\dagger j)\dot{r}},\quad i\neq j. \tag{2.3}$$

Now, using the involution and q-antisymmetry, and the reality of the $P_{(i)}$-irreps

$$\overline{[\![P_{(i)\mu},P_{(j)\nu}]\!]}=[\![P_{(j)\nu},P_{(i)\mu}]\!]=-q_{(j)\nu,(i)\mu}[\![P_{(i)\mu},P_{(j)\nu}]\!] \tag{2.4}$$

we obtain

$$\begin{aligned}
-q_{(j)\nu,(i)\mu}C^{\sigma}(i,j)_{\mu\nu}&=C^{\sigma}(j,i)_{\nu\mu}=\hat{C}^{\sigma}(i,j)^{*}_{\mu\nu},\\
-q_{(j)\nu,(i)\mu}\eta^{r}(i,j)_{\mu\nu}&=\eta^{r}(j,i)_{\nu\mu}=\hat{\eta}^{\dot{r}}(i,j)^{*}_{\mu\nu},\\
-q_{(j)\nu,(i)\mu}\hat{\eta}^{\dot{r}}(i,j)_{\mu\nu}&=\hat{\eta}^{\dot{r}}(j,i)_{\nu\mu}=\eta^{r}(i,j)^{*}_{\mu\nu}.
\end{aligned} \tag{2.5}$$

Consider now the Jacobi identities obtained from the triple $T_{(0)l}$, $P_{(i)\mu}$, $P_{(j)\nu}$:

$$[\![T_{(0)l},[\![P_{(i)\mu},P_{(j)\nu}]\!]]\!]=[\![[\![T_{(0)l},P_{(i)\mu}]\!],P_{(j)\nu}]\!]+q_{(0)l,(i)}[\![P_{(i)\mu},[\![T_{(0)l},P_{(j)\nu}]\!]]\!]. \tag{2.6}$$

Using the identities (2.3) and the σ-matrices associated with the Lorentz transformations of the novel multiplets irreps, we obtain

$$\begin{aligned}\eta^r(i,j)_{\mu\nu}(-\mathrm{i}\sigma^T(l,i\dagger j)_r{}^n T_{(i\dagger j)n})=&-\mathrm{i}\sigma^P(l,i)_\mu{}^\rho(C^\sigma(i,j)_{\rho\nu}E_{(i\dagger j)\sigma}+\hat{C}^\sigma(i,j)_{\rho\nu}\overline{E}_{(i\dagger j)\sigma}\\&+\eta^n(i,j)_{\rho\nu}T_{(i\dagger j)n}+\hat{\eta}^{\dot n}(i,j)_{\rho\nu}\overline{T}_{(i\dagger j)\dot n})-\mathrm{i}q_{(0)l,(i)}\sigma^P(l,j)_\nu{}^\delta\\&\times(C^\sigma(i,j)_{\mu\delta}E_{(i\dagger j)\sigma}+\hat{C}^\sigma(i,j)_{\mu\delta}\overline{E}_{(i\dagger j)\sigma}+\eta^n(i,j)_{\mu\delta}T_{(i\dagger j)n}\\&+\hat{\eta}^{\dot n}(i,j)_{\mu\delta}\overline{T}_{(i\dagger j)\dot n}).\end{aligned}$$

With $E_{(i\dagger j)s}$, $\overline{E}_{(i\dagger j)s}$, $T_{(i\dagger j)n}$, and $\overline{T}_{(i\dagger j)n}$ being linearly independent we obtain

$$\begin{aligned}&\sigma^P(l,i)_\mu{}^\rho C^\sigma(i,j)_{\rho\nu}+(2\delta_{li}-1)C^\sigma(i,j)_{\mu\rho}\sigma^P(l,j)_\nu{}^\rho=0,\\&\sigma^P(l,i)_\mu{}^\rho\hat{\eta}^{\dot n}(i,j)_{\rho\nu}+(2\delta_{li}-1)\hat{\eta}^{\dot n}(i,j)_{\mu\rho}\sigma^P(l,j)_\nu{}^\rho=0,\\&\sigma^P(l,i)_\mu{}^\rho\eta^n(i,j)_{\rho\nu}+(2\delta_{li}-1)\eta^n(i,j)_{\mu\rho}\sigma^P(l,j)_\nu{}^\rho=\eta^r(i,j)_{\mu\nu}\sigma^T(l,i\dagger j)_r{}^n.\end{aligned} \tag{2.7}$$

In analogous fashion, for the triple $\overline{T}_{(0)l}$, $P_{(i)\mu}$, $P_{(j)\nu}$ we obtain further equations:

$$\begin{aligned}&\overline{\sigma}^P(l,i)^\rho{}_\mu C^\sigma(i,j)_{\rho\nu}+(2\delta_{lj}-1)C^\sigma(i,j)_{\mu\rho}\overline{\sigma}^P(l,j)^\rho{}_\nu=0,\\&\overline{\sigma}^P(l,i)^\rho{}_\mu\eta^n(i,j)_{\rho\nu}+(2\delta_{lj}-1)\eta^n(i,j)_{\mu\rho}\overline{\sigma}^P(l,j)^\rho{}_\nu=0,\\&\overline{\sigma}^P(l,j)^\rho{}_\nu\hat{\eta}^{\dot n}(i,j)_{\mu\rho}+(2\delta_{lj}-1)\hat{\eta}^{\dot n}(i,j)_{\rho\nu}\overline{\sigma}^P(l,i)^\rho{}_\mu=\hat{\eta}^{\dot r}(i,j)_{\mu\nu}\overline{\sigma^T}(l,i\dagger j)^{\dot n}{}_{\dot r}.\end{aligned} \tag{2.8}$$

We observe that these equations do not differ from those obtained for the C- and η-arrays at this step in the previously obtained minimal extensions,[1,2] hence for $ijk\in\{213,321,132\}$:

$$C^0(i,j)=c_{k0}\begin{bmatrix}0&0&1&0\\0&\mathrm{i}&0&0\\0&0&0&\mathrm{i}\\1&0&0&0\end{bmatrix}, \tag{2.9}$$

$$\begin{aligned}&\eta^1(i,j)=a_k\begin{bmatrix}1&0&0&0\\0&0&0&1\\0&-1&0&0\\0&0&1&0\end{bmatrix},\quad \eta^2(i,j)=a_k\begin{bmatrix}0&\mathrm{i}&0&0\\0&0&1&0\\-\mathrm{i}&0&0&0\\0&0&0&-1\end{bmatrix},\\&\eta^3(i,j)=a_k\begin{bmatrix}0&0&0&\mathrm{i}\\\mathrm{i}&0&0&0\\0&0&1&0\\0&1&0&0\end{bmatrix}.\end{aligned} \tag{2.10}$$

The further matrices are obtained using (2.5).

We are now ready to go to the second step of our extension. Since we want (1.1) to hold, we have two ways for arriving at this stage—through the singlets E or through the triplets T:

$$[\![E_{(f)\sigma},P_{(l)\mu}]\!]=\delta_{fl}S_\sigma(l)^\nu_\mu P_{(0)\nu}, \tag{2.11}$$

$$[\![\overline{E}_{(f)\sigma},P_{(l)\mu}]\!]=\delta_{fl}\hat{S}_{\sigma}(l)^{\nu}_{\mu}P_{(0)\nu}, \tag{2.12}$$

$$[\![T_{(k)r},P_{(l)\mu}]\!]=\delta_{kl}K_{r}(l)^{\nu}_{\mu}P_{(0)\nu}, \tag{2.13}$$

$$[\![\overline{T}_{(k)r},P_{(l)\mu}]\!]=\delta_{kl}\hat{K}_{r}(l)^{\nu}_{\mu}P_{(0)\nu}. \tag{2.14}$$

From the properties of involution and q-anticommutation it follows

$$\hat{S}_{\sigma}(l)^{\nu}_{\mu}=-q_{(l)\sigma,(l)\mu}S_{\sigma}(l)^{\nu}_{\mu}{}^{*}, \tag{2.15}$$

$$\hat{K}_{r}(l)^{\nu}_{\mu}=-q_{(l)r,(l)\mu}K_{r}(l)^{\nu}_{\mu}{}^{*}. \tag{2.16}$$

From the triples $T_{(0)l}$, $E_{(k)s}$, $P_{(k)\mu}$ and $\overline{T}_{(0)l}$, $E_{(k)s}$, $P_{(k)\mu}$ and their corresponding Jacobi identities we obtain

$$\begin{aligned} &S_{\sigma}(k)^{\nu}_{\mu}\sigma^{P}(l,0)_{\nu}{}^{\rho}=(2\delta_{lk}-1)\sigma^{P}(l,k)_{\mu}{}^{\delta}S_{\sigma}(k)^{\rho}_{\delta},\\ &S_{\sigma}(k)^{\nu}_{\mu}\overline{\sigma}^{P}(l,0)^{\rho}{}_{\nu}=\overline{\sigma}^{P}(l,k)^{\delta}{}_{\mu}S_{\sigma}(k)^{\rho}_{\delta}. \end{aligned} \tag{2.17}$$

From the triples $T_{(0)l}$, $T_{(k)j}$, $P_{(k)\mu}$ and $\overline{T}_{(0)l}$, $T_{(k)j}$, $P_{(k)\mu}$ we obtain

$$K_{j}(k)^{\nu}_{\mu}\overline{\sigma}^{P}(l,0)^{\rho}{}_{\nu}=\overline{\sigma}^{P}(l,k)^{\nu}{}_{\mu}K_{j}(k)^{\rho}_{\nu}, \tag{2.18}$$

$$K_{j}(k)^{\nu}_{\mu}\sigma^{P}(l,0)_{\nu}{}^{\rho}=(2\delta_{lk}-1)\sigma^{P}(l,k)_{\mu}{}^{\nu}K_{j}(k)^{\rho}_{\nu}+\sigma^{T}(l,k)_{j}{}^{m}K_{m}(k)^{\rho}_{\mu}. \tag{2.19}$$

We observe that the obtained equations coincide with the constraints for the S- and K-arrays at this step in the previously obtained minimal extensions,[1,2] hence we have

$$S_{i}(k)=0 \quad \forall i\neq 0, \tag{2.20}$$

$$\begin{aligned} &S_{0}(1)=s_{10}\begin{bmatrix}0&1&0&0\\1&0&0&0\\0&0&0&-\mathrm{i}\\0&0&\mathrm{i}&0\end{bmatrix}, \quad S_{0}(2)=s_{20}\begin{bmatrix}0&0&1&0\\1&0&0&0\\0&-\mathrm{i}&0&0\\0&0&0&-\mathrm{i}\end{bmatrix},\\ &S_{0}(3)=s_{30}\begin{bmatrix}0&0&0&1\\1&0&0&0\\0&0&-\mathrm{i}&0\\0&\mathrm{i}&0&0\end{bmatrix}, \end{aligned} \tag{2.21}$$

$$K_1(1)=b_1\begin{bmatrix}1&0&0&0\\0&1&0&0\\0&0&1&0\\0&0&0&1\end{bmatrix},\quad K_2(1)=b_1\begin{bmatrix}0&0&0&\mathrm{i}\\0&0&1&0\\0&-1&0&0\\\mathrm{i}&0&0&0\end{bmatrix},$$

$$K_3(1)=b_1\begin{bmatrix}0&0&-\mathrm{i}&0\\0&0&0&1\\-\mathrm{i}&0&0&0\\0&-1&0&0\end{bmatrix},$$

$$K_1(2)=b_2\begin{bmatrix}1&0&0&0\\0&0&1&0\\0&0&0&1\\0&1&0&0\end{bmatrix},\quad K_2(2)=b_2\begin{bmatrix}0&\mathrm{i}&0&0\\0&0&0&1\\0&0&-1&0\\\mathrm{i}&0&0&0\end{bmatrix},\tag{2.22}$$

$$K_3(2)=b_2\begin{bmatrix}0&0&0&-\mathrm{i}\\0&1&0&0\\-\mathrm{i}&0&0&0\\0&0&-1&0\end{bmatrix},$$

$$K_1(3)=b_3\begin{bmatrix}1&0&0&0\\0&0&0&1\\0&1&0&0\\0&0&1&0\end{bmatrix},\quad K_2(3)=b_3\begin{bmatrix}0&0&\mathrm{i}&0\\0&1&0&0\\0&0&0&-1\\\mathrm{i}&0&0&0\end{bmatrix},$$

$$K_3(3)=b_3\begin{bmatrix}0&-\mathrm{i}&0&0\\0&0&1&0\\-\mathrm{i}&0&0&0\\0&0&0&-1\end{bmatrix}.$$

The $\hat{S}$- and $\hat{K}$-matrices are obtained using (2.15) and (2.16). We are now ready to go to the last consistency condition. We use the triplet $P_{(1)\rho}$, $P_{(2)\mu}$, $P_{(3)\nu}$ and the corresponding Jacobi identity to obtain:

$$\begin{aligned}0=&q_{(1)\rho,(2)\mu+(3)\nu}\eta^r(2,3)_{\mu\nu}K_r(1)^\sigma_\rho+q_{(2)\mu,(3)\nu}\eta^{r*}(2,3)_{\mu\nu}K^*_r(1)^\sigma_\rho\\&+q_{(1)\rho,(2)\mu+(3)\nu}C^\delta(2,3)_{\mu\nu}S_\delta(1)^\sigma_\rho+\eta^r(1,2)_{\rho\mu}K_r(3)^\sigma_\nu\\&+q_{(1)\rho,(2)\mu+(3)\nu}q_{(2)\mu,(3)\nu}\eta^{r*}(1,2)_{\rho\mu}K^*_r(3)^\sigma_\nu+C^\delta(1,2)_{\rho\mu}S_\delta(3)^\sigma_\nu\\&+q_{(1)\rho+(2)\mu,(3)\nu}\eta^r(3,1)_{\nu\rho}K_r(2)^\sigma_\mu+q_{(1)\rho,(2)\mu}\eta^{r*}(3,1)_{\nu\rho}K^*_r(2)^\sigma_\mu\\&+q_{(1)\rho+(2)\mu,(3)\nu}C^\delta(3,1)_{\nu\rho}S_\delta(2)^\sigma_\mu.\end{aligned}\tag{2.23}$$

From the q-application of the $(\mathbb{Z}_4\times\mathbb{Z}_4;q)$ group grading,[4,1] we have

$$q_{(2)\mu,(3)\nu}=q_{(3)\mu,(1)\nu}=q_{(1)\mu,(2)\nu}=\begin{bmatrix} \mathrm{i} & -\mathrm{i} & -\mathrm{i} & \mathrm{i} \\ -\mathrm{i} & \mathrm{i} & \mathrm{i} & -\mathrm{i} \\ \mathrm{i} & -\mathrm{i} & -\mathrm{i} & \mathrm{i} \\ -\mathrm{i} & \mathrm{i} & \mathrm{i} & -\mathrm{i} \end{bmatrix}_{\mu\nu}. \tag{2.24}$$

Equations (2.23) and (2.24) lead to the following set of independent constraints:

$$a_1b_1+a_2b_2+a_3b_3+\mathrm{i}(a_1^*b_1^*+a_2^*b_2^*+a_3^*b_3^*)=0, \tag{2.25}$$

$$c_{10}s_{10}-\mathrm{i}c_{10}^*s_{10}^*=a_2b_2-\mathrm{i}a_2^*b_2^*-a_3b_3+\mathrm{i}a_3^*b_3^*, \tag{2.26}$$

$$c_{20}s_{20}-\mathrm{i}c_{20}^*s_{20}^*=a_3b_3-\mathrm{i}a_3^*b_3^*-a_1b_1+\mathrm{i}a_1^*b_1^*, \tag{2.27}$$

$$c_{30}s_{30}-\mathrm{i}c_{30}^*s_{30}^*=a_1b_1-\mathrm{i}a_1^*b_1^*-a_2b_2+\mathrm{i}a_2^*b_2^*. \tag{2.28}$$

Adding the last three constraints we obtain

$$c_{10}s_{10}+c_{20}s_{20}+c_{30}s_{30}-\mathrm{i}(c_{10}^*s_{10}^*+c_{20}^*s_{20}^*+c_{30}^*s_{30}^*)=0. \tag{2.29}$$

The constraints (2.25)–(2.28) can be parametrized in the following way;

$$a_1b_1-\mathrm{i}a_1^*b_1^*=\tfrac{1}{3}(3r_0-r_2+r_3)(1-\mathrm{i}), \tag{2.30}$$

$$a_2b_2-\mathrm{i}a_2^*b_2^*=\tfrac{1}{3}(3r_0-r_3+r_1)(1-\mathrm{i}), \tag{2.31}$$

$$a_3b_3-\mathrm{i}a_3^*b_3^*=\tfrac{1}{3}(3r_0-r_1+r_2)(1-\mathrm{i}), \tag{2.32}$$

$$c_{10}s_{10}-\mathrm{i}c_{10}^*s_{10}^*=r_1(1-\mathrm{i}), \tag{2.33}$$

$$c_{20}s_{20}-\mathrm{i}c_{20}^*s_{20}^*=r_2(1-\mathrm{i}), \tag{2.34}$$

$$c_{30}s_{30}-\mathrm{i}c_{30}^*s_{30}^*=r_3(1-\mathrm{i}), \tag{2.35}$$

$$r_1+r_2+r_3=0, \quad r_0,r_1,r_2,r_3\in\mathbb{R}. \tag{2.36}$$

These constraints show that we have actually choices of structure constants that go beyond the naive superposition of the two minimal extensions in Refs. 1 and 2. It is easy to get convinced that the presence of scalar fields can lead to an apparent asymmetry among the structure constants associated with the three classes (1), (2), and (3) unless we take $r_1=r_2=r_3=0$. This suggests that we can exhibit a particular choice of structure constants that maintain the symmetry among the three novel families, which is exactly a superposition of the particular choices presented in the minimal extensions:[1,2]

$$a_j=a, \quad b_j=b(1-\mathrm{i}), \quad a,b\in\mathbb{R}\backslash\{0\}, \quad j=1,2,3. \tag{2.37}$$

$$c_{j0}=c, \quad s_{j0}=s(1+\mathrm{i}), \quad c,s\in\mathbb{R}\backslash\{0\}, \quad j=1,2,3. \tag{2.38}$$

We observe that although the scalar fields are not strictly necessary for a consistent algebraic extension with a nontrivial generation of a space–time translation via (1.1), they can be involved without introducing any asymmetry between the novel classes, and therefore without introducing any anisotropy or inhomogeneity. In future stages of this research the presence of the scalar fields might be relevant for the cancellation of anomalies or for obtaining would-be internal symmetries. As already noticed in Refs. 1 and 2, since the scalar fields can be consistently excluded from the

TABLE I. Structure of the merged extension. $j=1,2,3$; $\mu=0,1,2,3$.

	Spin		
Naive dim	(1,0)	$(\frac{1}{2},\frac{1}{2})$ / (0,0)	(0,1)

extension and the novel scalar generators q-commute with the space–time translations then *the merged extension does not correspond to any cumbersome deformation of the conformal extension*.

We can picture the structure of the merged extension in the diagram given in Table I. One latter comment is in order about the obtained extension. The elements of the group $\mathbb{Z}_4\times\mathbb{Z}_4$ are used as indices for generators in the following way: Each index of the classes (1), (2), and (3) has been used three times. In the class (0) all the indices have been used three times except the neutral index $(0)_0$ which was used just once. We observe also that the antisymmetric vectors $T_{(j)}$, $\overline{T}_{(j)}$ for $j=1,2,3$ are accompanied by a couple of scalars $E_{(j)0}$, $\overline{E}_{(j)0}$ also of dimension 2/3. The dimensionless antisymmetric vector $T_{(0)}$, $\overline{T}_{(0)}$ might have an associated complex couple of scalars $G_{(0)0}$, $\overline{G}_{(0)0}$. This question will be answered in Sec. IV.

III. SEARCHING FOR CANDIDATES FOR INTERNAL SYMMETRIES

We now turn the attention to the inclusion of further generators to the extension previously obtained. We recognize different candidates for the would-be internal symmetry generators perhaps after some sort of graded symmetry breaking (analogous to supersymmetry breaking):

(1) the dimensionless scalar generators,
(2) the nondimensionless scalar generators,
(3) invariant forms of nonscalar generators (such as $T_{(i)1}T_{(i)1}-T_{(i)2}T_{(i)2}-T_{(i)3}T_{(i)3}$; $i=1,2,3$) that might survive as symmetry generators after graded symmetry breaking.

We will investigate in Sec. IV the introduction of scalar dimensionless singlets $G_{(\rho)\mu}$, where $\rho,\mu=0,1,2,3$. We will ask in Sec. V for the introduction of nondimensionless scalar central charges $Z_{(\rho)\mu}$, where $\rho,\mu=0,1,2,3$. In Sec. VI we ask for the introduction of dimensionless antisymmetric vectors $\mathbf{T}_{(i)}$ and $\overline{\mathbf{T}}_{(i)}$. This will finish our survey of enhancements of the obtained extension.

IV. DIMENSIONLESS SCALAR GENERATORS

Particular interest is paid to the dimensionless scalar generators since they are naively the most expedite candidates for internal symmetry generators perhaps after some sort of graded symmetry breaking. We introduce scalar dimensionless singlets $G_{(\rho)\mu}$, where $\rho,\mu=0,1,2,3$ and we will select the ones which are effectively nontrivially connected to the extension obtained in Sec. III.

The generators $G_{(\rho)\mu}$ have trivial q-commutation relations with the Lorentz generators, since they are scalar. If these scalar generators have nontrivial q-commutation relations with the mentioned extension, they have nontrivial relations with the multiplets $P_{(i)}$; $i=1,2,3$, since *all* the novel generators of the extension as well as the space–time translations are obtained from the composition of the multiplets $P_{(i)}$.

We expect that the multiplets $P_{(i)}$; $i=1,2,3$ might constitute representations of the subgroup built by the novel scalar singlets. These scalars satisfy the q-commutation relations

$$[\![G_{(\rho)\mu},G_{(\sigma)\nu}]\!]=-\mathrm{i}\zeta_{\mu}(\rho,\sigma)_{\nu}{}^{\kappa}G_{(\rho\dagger\sigma)\kappa}. \tag{4.1}$$

The structure constants build up the adjoint representation, hence the matrix

$$D^{G}(G_{(\rho)\mu})=-\mathrm{i}\zeta_{\mu}(\rho,\sigma)^{\mathrm{tr}} \tag{4.2}$$

constitutes a representation D^{G} of the generator $G_{(\rho)\mu}$. Now, the multiplets $P_{(i)}$; $i=1,2,3$ build up representations of the group generated by $G_{(\rho)\mu}$. We should have

$$[\![G_{(\rho)\mu},P_{(i)\nu}]\!]=-\mathrm{i}\Lambda_{\mu}(\rho,i)_{\nu}{}^{\sigma}P_{(\rho\dagger i)\sigma}. \tag{4.3}$$

Using the Jacobi identities associated with the triples $G_{(\rho)\mu}$, $G_{(\alpha)\xi}$, $P_{(j)\nu}$, we obtain

$$\Lambda_{\mu}(\rho,\alpha\dagger j)^{\mathrm{tr}}\Lambda_{\xi}(\alpha,j)^{\mathrm{tr}}-q_{(\rho)\mu,(\alpha)\xi}\Lambda_{\xi}(\alpha,\rho\dagger j)^{\mathrm{tr}}\Lambda_{\mu}(\rho,j)^{\mathrm{tr}}=\zeta_{\mu}(\rho,\alpha)_{\xi}{}^{\kappa}\Lambda_{\kappa}(\rho\dagger\alpha,j)^{\mathrm{tr}}. \tag{4.4}$$

Hence, $-\mathrm{i}\Lambda_{\mu}(\rho,i)^{\mathrm{tr}}$ constitutes a representation D^{P} of the algebra generated by $G_{(\rho)\mu}$:

$$D^{P}(G_{(\rho)\mu})=-\mathrm{i}\Lambda_{\mu}(\rho,i)^{\mathrm{tr}}. \tag{4.5}$$

Using the Jacobi identity associated with the triples $T_{(0)r}$, $G_{(\rho)\mu}$, $P_{(i)\nu}$ and $\overline{T}_{(0)r}$, $G_{(\rho)\mu}$, $P_{(i)\nu}$ we obtain, respectively, for $\mu=0,1,2,3$:

$$\begin{aligned}&\Lambda_{\mu}(0,i)=l(0i)_0\begin{bmatrix}\mathrm{i}&0&0&0\\0&\mathrm{i}&0&0\\0&0&\mathrm{i}&0\\0&0&0&\mathrm{i}\end{bmatrix},\quad l(0i)_1\begin{bmatrix}0&\mathrm{i}&0&0\\\mathrm{i}&0&0&0\\0&0&0&-1\\0&0&1&0\end{bmatrix},\\&l(0i)_2\begin{bmatrix}0&0&\mathrm{i}&0\\0&0&0&1\\\mathrm{i}&0&0&0\\0&-1&0&0\end{bmatrix},\quad l(0i)_3\begin{bmatrix}0&0&0&\mathrm{i}\\0&0&-1&0\\0&1&0&0\\\mathrm{i}&0&0&0\end{bmatrix}.\end{aligned} \tag{4.6}$$

For $(i,j)\in\{12,23,31\}$ we obtain, respectively, for $\mu=0,1,2,3$:

$$\begin{aligned}&\Lambda_{\mu}(i,j)=l(ij)_0\begin{bmatrix}0&\mathrm{i}&0&0\\0&0&-1&0\\-\mathrm{i}&0&0&0\\0&0&0&-1\end{bmatrix},\quad l(ij)_1\begin{bmatrix}0&0&0&\mathrm{i}\\-\mathrm{i}&0&0&0\\0&0&1&0\\0&1&0&0\end{bmatrix},\\&l(ij)_2\begin{bmatrix}0&0&\mathrm{i}&0\\0&1&0&0\\0&0&0&-1\\\mathrm{i}&0&0&0\end{bmatrix},\quad l(ij)_3\begin{bmatrix}\mathrm{i}&0&0&0\\0&0&0&-\mathrm{i}\\0&-\mathrm{i}&0&0\\0&0&\mathrm{i}&0\end{bmatrix},\end{aligned} \tag{4.7}$$

$$\Lambda_\mu(j,i)=l(ji)_0\begin{bmatrix}0&\mathrm{i}&0&0\\0&0&0&1\\0&0&1&0\\-\mathrm{i}&0&0&0\end{bmatrix},\quad l(ji)_1\begin{bmatrix}0&0&\mathrm{i}&0\\-\mathrm{i}&0&0&0\\0&-1&0&0\\0&0&0&-1\end{bmatrix},$$
$$l(ji)_2\begin{bmatrix}\mathrm{i}&0&0&0\\0&0&-\mathrm{i}&0\\0&0&0&\mathrm{i}\\0&-\mathrm{i}&0&0\end{bmatrix},\quad l(ji)_3\begin{bmatrix}0&0&0&\mathrm{i}\\0&-1&0&0\\\mathrm{i}&0&0&0\\0&0&1&0\end{bmatrix}. \tag{4.8}$$

We will study first the compatibility of this group structure $G_{(\rho)\mu}$ with the triplets $T_{(i)}$ and $\overline{T}_{(i)}$ and afterwards we study the compatibility with the scalar singlets $E_{(\alpha)\xi}$. Since the triplets $T_{(i)}$ and $\overline{T}_{(i)}$ are obtained by the composition of multiplets $P_{(i)}$, we expect that the triplets $T_{(i)}$ and $\overline{T}_{(i)}$ constitute representations of the algebra generated by $G_{(\rho)\mu}$:

$$[\![G_{(\rho)\mu},T_{(i)a}]\!]=-\mathrm{i}\tau_\mu(\rho,i)_a{}^bT_{(\rho\dagger i)b}, \tag{4.9}$$

$$[\![G_{(\rho)\mu},\overline{T}_{(i)a}]\!]=-\mathrm{i}\hat{\tau}_\mu(\rho,i)^b{}_a\overline{T}_{(\rho\dagger i)b}. \tag{4.10}$$

Using the Jacobi identity for the triples $T_{(l)c}$, $G_{(\rho)\mu}$, $\overline{T}_{(k)a}$ we obtain, respectively, for $\mu=0,1,2,3$:

$$\tau_\mu(0,1)=t(01)_0\begin{bmatrix}\mathrm{i}&0&0\\0&\mathrm{i}&0\\0&0&\mathrm{i}\end{bmatrix},\quad t(01)_1\begin{bmatrix}0&0&0\\0&0&-1\\0&1&0\end{bmatrix},$$
$$t(01)_2\begin{bmatrix}0&0&1\\0&0&0\\-1&0&0\end{bmatrix},\quad t(01)_3\begin{bmatrix}0&-1&0\\1&0&0\\0&0&0\end{bmatrix}, \tag{4.11}$$

$$\tau_\mu(0,2)=t(02)_0\begin{bmatrix}\mathrm{i}&0&0\\0&\mathrm{i}&0\\0&0&\mathrm{i}\end{bmatrix},\quad t(02)_1\begin{bmatrix}0&-1&0\\1&0&0\\0&0&0\end{bmatrix},$$
$$t(02)_2\begin{bmatrix}0&0&0\\0&0&-1\\0&1&0\end{bmatrix},\quad t(02)_3\begin{bmatrix}0&0&1\\0&0&0\\-1&0&0\end{bmatrix}, \tag{4.12}$$

$$\tau_\mu(0,3)=t(03)_0\begin{bmatrix}\mathrm{i}&0&0\\0&\mathrm{i}&0\\0&0&\mathrm{i}\end{bmatrix},\quad t(03)_1\begin{bmatrix}0&0&1\\0&0&0\\-1&0&0\end{bmatrix},$$
$$t(03)_2\begin{bmatrix}0&-1&0\\1&0&0\\0&0&0\end{bmatrix},\quad t(03)_3\begin{bmatrix}0&0&0\\0&0&-1\\0&1&0\end{bmatrix}. \tag{4.13}$$

For $(ij)\in\{12,23,31\}$:

$$\tau_\mu(i,j)=t(ij)_0\begin{bmatrix}0&-1&0\\0&0&0\\0&0&-1\end{bmatrix},\quad t(ij)_1\begin{bmatrix}0&0&0\\0&1&0\\-1&0&0\end{bmatrix},$$
$$t(ij)_2\begin{bmatrix}1&0&0\\0&0&-1\\0&0&0\end{bmatrix},\quad t(ij)_3\begin{bmatrix}0&0&-\mathrm{i}\\-\mathrm{i}&0&0\\0&\mathrm{i}&0\end{bmatrix}, \tag{4.14}$$

$$\tau_\mu(j,i)=t(ji)_0\begin{bmatrix}0&0&1\\0&1&0\\0&0&0\end{bmatrix},\quad t(ji)_1\begin{bmatrix}0&0&0\\-1&0&0\\0&0&-1\end{bmatrix},$$
$$t(ji)_2\begin{bmatrix}0&-\mathrm{i}&0\\0&0&\mathrm{i}\\-\mathrm{i}&0&0\end{bmatrix},\quad t(ji)_3\begin{bmatrix}-1&0&0\\0&0&0\\0&1&0\end{bmatrix}. \tag{4.15}$$

Observe that these results are analogous to the down-right 3×3 submatrices of the corresponding Λ_μ matrices in Eqs. (4.6)–(4.8). Using the identity (2.3) we obtain for the Jacobi identity associated with the triple $G_{(\rho)\mu}$, $P_{(i)\mu}$, $P_{(j)\nu}$ the constraints

$$\Lambda_\sigma(\rho,i)_\mu{}^\lambda\eta^r(\rho\dagger i,j)_{\lambda\nu}-q_{(\rho)\sigma,(i)\mu}\eta^r(i,j\dagger\rho)_{\mu\lambda}\Lambda_\sigma(\rho,j)_\nu{}^\lambda=\eta^s(i,j)_{\mu\nu}\tau_\sigma(\rho,i\dagger j)_s{}^r, \tag{4.16}$$

$$\Lambda_\sigma(\rho,i)_\mu{}^\lambda\hat\eta^r(\rho\dagger i,j)_{\lambda\nu}-q_{(\rho)\sigma,(i)\mu}\hat\eta^r(i,j\dagger\rho)_{\mu\lambda}\Lambda_\sigma(\rho,j)_\nu{}^\lambda=\hat\eta^s(i,j)_{\mu\nu}\hat\tau_\sigma(\rho,i\dagger j)_s{}^r. \tag{4.17}$$

From (4.16) we obtain the independent constraints

$$l(01)_0+l(02)_0=t(03)_0,$$
$$l(02)_0+l(03)_0=t(01)_0, \tag{4.18}$$
$$l(03)_0+l(01)_0=t(02)_0,$$

$$l(01)_1=-l(02)_1=-l(03)_1,$$
$$l(01)_2=-l(02)_2=l(03)_2, \tag{4.19}$$
$$l(01)_3=l(02)_3=-l(03)_3,$$

$$t(0i)_j=0;\quad \text{for } i,j=1,2,3, \tag{4.20}$$

$$l(12)_\sigma=l(23)_\sigma=l(31)_\sigma=0\quad\text{for } \sigma\neq2,$$
$$l(21)_\sigma=l(32)_\sigma=l(13)_\sigma=0\quad\text{for } \sigma\neq3, \tag{4.21}$$

$$t(12)_\sigma=t(23)_\sigma=t(31)_\sigma=0\quad\text{for } \sigma\neq3,$$
$$t(21)_\sigma=t(32)_\sigma=t(13)_\sigma=0\quad\text{for } \sigma\neq2, \tag{4.22}$$

$$a_2 l(12)_2 = a_3 t(13)_2,$$
$$a_3 l(23)_2 = a_1 t(21)_2, \tag{4.23}$$
$$a_1 l(31)_2 = a_2 t(32)_2,$$
$$a_3 l(13)_3 = a_2 t(12)_3,$$
$$a_1 l(21)_3 = a_3 t(23)_3, \tag{4.24}$$
$$a_2 l(32)_3 = a_1 t(31)_3.$$

Now using Eqs. (2.12) and (2.14) and the Jacobi identities for the triple $G_{(\rho)\sigma}$, $T_{(k)j}$, $P_{(l)\mu}$ we obtain the constraint

$$\tau_\sigma(\rho,k)_j{}^n \delta_{\rho\dagger k,l} K_n(l)^r_\mu + q_{(\rho)\sigma,(k)j} \Lambda_\sigma(\rho,l)_\mu{}^\nu \delta_{\rho\dagger l,k} K_j(k)^r_\nu = 0, \tag{4.25}$$

where we *assumed* that $P_{(0)}$ should be a invariant (q-commute) under the algebra generated by the $G_{(\rho)\sigma}$ according to an extrapolation of Coleman–Mandula theorem. (This is strictly a part of this theorem for the charges $G_{(0)\sigma}$). From the constraints (4.25) we obtain

$$t(0i)_0 = -l(0i)_0; \quad \text{for } i=1,2,3, \tag{4.26}$$

$$b_j l(0i)_j = t(0i)_j = 0 \quad \text{for } i,j=1,2,3, \tag{4.27}$$

$$b_3 l(12)_2 = -b_2 t(13)_2,$$
$$b_1 l(23)_2 = -b_3 t(21)_2, \tag{4.28}$$
$$b_2 l(31)_2 = -b_1 t(32)_2,$$
$$b_2 l(13)_2 = -b_3 t(12)_3,$$
$$b_3 l(21)_2 = -b_1 t(23)_3, \tag{4.29}$$
$$b_1 l(32)_2 = -b_2 t(31)_3.$$

From Eqs. (4.18)–(4.24) and (4.26)–(4.29) we obtain, for a nontrivial extension with $a_i b_i \neq 0$; $i=1,2,3$, the result:

$$l(ij)_\rho = t(ij)_\rho = 0, \quad i,j=1,2,3, \quad i \neq j, \quad \rho = 0,1,2,3, \tag{4.30}$$

$$l(0j)_k = 0, \quad j,k=1,2,3. \tag{4.31}$$

Hence, the only scalar dimensionless charge nontrivially related to the self-bosonic extension with $T_{(i)}$ ($\overline{T}_{(i)}$) triplets is just the singlet $G_{(0)0}$ ($\overline{G}_{(0)0}$). The nontrivial coupling constants associated with the surviving scalar dimensionless complex charge $G_{(0)0}$ satisfy

$$l(01)_0 + l(02)_0 + l(03)_0 = 0, \tag{4.32}$$

$$t(0i)_0 = -l(0i)_0, \quad i=1,2,3. \tag{4.33}$$

Hence, we can think on the charge $G_{(0)0}$ as an additive charge. The resulting relations

$$[\![G_{(0)0}, P_{(i)\nu}]\!] = l(0i)_0 P_{(i)\nu}, \tag{4.34}$$

$$[\![G_{(0)0}, T_{(k)a}]\!] = -l(0k)_0 T_{(k)a}, \tag{4.35}$$

$$[\![G_{(0)0}, \overline{T}_{(k)a}]\!] = -l(0k)_0 \overline{T}_{(k)a}, \tag{4.36}$$

indicate just that according to relation (1.1), the charge of $P_{(0)}$ is vanishing as it was required. Now, the charge $G_{(0)0}$ is complex $G_{(0)0}=\mathrm{Re}\,G_{(0)0}+\mathrm{i}\,\mathrm{Im}\,G_{(0)0}$, and in terms of its components (4.34)–(4.36) read

$$\begin{aligned}[\![\mathrm{Re}\,G_{(0)0},P_{(i)\nu}]\!]&=\mathrm{i}\,\mathrm{Im}(l(0i)_0)P_{(i)\nu},\\ [\![\mathrm{Im}\,G_{(0)0},P_{(i)\nu}]\!]&=-\mathrm{i}\,\mathrm{Re}(l(0i)_0)P_{(i)\nu},\end{aligned}\tag{4.37}$$

$$\begin{aligned}[\![\mathrm{Re}\,G_{(0)0},T_{(k)a}]\!]&=-\mathrm{i}\,\mathrm{Im}(l(0k)_0)T_{(k)a},\\ [\![\mathrm{Im}\,G_{(0)0},T_{(k)a}]\!]&=\mathrm{i}\,\mathrm{Re}(l(0k)_0)T_{(k)a},\end{aligned}\tag{4.38}$$

$$\begin{aligned}[\![\mathrm{Re}\,G_{(0)0},\overline{T}_{(k)a}]\!]&=-\mathrm{i}\,\mathrm{Im}(l(0k)_0)\overline{T}_{(k)a},\\ [\![\mathrm{Im}\,G_{(0)0},\overline{T}_{(k)a}]\!]&=\mathrm{i}\,\mathrm{Re}(l(0k)_0)\overline{T}_{(k)a}.\end{aligned}\tag{4.39}$$

We now consider the introduction of $G_{(\rho)\mu}$ generators in the presence of $P_{(i)}$ and $E_{(\alpha)0}$ multiplets. We expect that according to (2.3) and (2.10) we have

$$[\![G_{(\rho)\mu},E_{(\alpha)0}]\!]=-\mathrm{i}\epsilon_{\mu}(\rho,\alpha)E_{(\rho\dagger\alpha)0}.\tag{4.40}$$

Using Eq. (2.3) and the Jacobi identity for the triple $G_{(\rho)\mu}$, $P_{(i)\sigma}$, $P_{(j)\nu}$ we obtain

$$C^0(i,j)_{\sigma\nu}\epsilon_{\mu}(\rho,i\dagger j)=\Lambda_{\mu}(\rho,i)^{\tau}_{\sigma}C^0(i\dagger\rho,j)_{\tau\nu}+q_{(\rho)\mu,(i)\sigma}C^0(i,\rho\dagger j)_{\sigma\omega}\Lambda_{\mu}(\rho,j)^{\omega}_{\nu}.\tag{4.41}$$

Again, we obtain nontrivial relations only for the complex singlet $G_{(0)0}$:

$$[\![G_{(0)0},E_{(k)0}]\!]=-l(0k)_0E_{(k)0},\tag{4.42}$$

$$[\![G_{(0)0},\overline{E}_{(k)0}]\!]=-l(0k)_0\overline{E}_{(k)0},\tag{4.43}$$

which in terms of its components read

$$\begin{aligned}[\![\mathrm{Re}\,G_{(0)0},E_{(k)0}]\!]&=-\mathrm{i}\,\mathrm{Im}(l(0k)_0)E_{(k)0},\\ [\![\mathrm{Im}\,G_{(0)0},E_{(k)0}]\!]&=\mathrm{i}\,\mathrm{Re}(l(0k)_0)E_{(k)0},\end{aligned}\tag{4.44}$$

$$\begin{aligned}[\![\mathrm{Re}\,G_{(0)0},\overline{E}_{(k)0}]\!]&=-\mathrm{i}\,\mathrm{Im}(l(0k)_0)\overline{E}_{(k)0},\\ [\![\mathrm{Im}\,G_{(0)0},\overline{E}_{(k)0}]\!]&=\mathrm{i}\,\mathrm{Re}(l(0k)_0)\overline{E}_{(k)0}.\end{aligned}\tag{4.45}$$

We can now give an explicit and particular choice of the charges $\mathrm{Im}\,l(0i)_0$ and $\mathrm{Re}\,l(0i)_0$ that maintains the symmetries among the multiplets $P_{(1)}$, $P_{(2)}$, $P_{(3)}$. We can adopt for the values of $l(0i)_0$ three complex numbers symmetrically oriented in the complex plane:

$$l(01)_0=l,\quad l(02)_0=l\mathrm{e}^{\mathrm{i}2\pi/3},\quad l(03)_0=l\mathrm{e}^{\mathrm{i}4\pi/3},\quad l\in\mathbb{R}.\tag{4.46}$$

We observe that the relations (4.34) and (4.45) could be interpreted as presenting $\mathrm{Re}\,G_{(0)0}$ and $\mathrm{Im}\,G_{(0)0}$ as a sort of U(1)-generators. The charges $G_{(0)0}$ and $\overline{G}_{(0)0}$ swap under involution. It is, nevertheless, not excluded that these generators might have nontrivial relations with further scalar charges. From relation (4.5) we conclude that this scalar charges commute among them. In particular

$$[\![\mathrm{Re}\,G_{(0)0},\mathrm{Im}\,G_{(0)0}]\!]=0.\tag{4.47}$$

TABLE II. Full clover extension. $j=1,2,3;\ \mu=0,1,2,3$.

Naive dim	Spin (1,0)	Spin $(\frac{1}{2},\frac{1}{2})$	Spin (0,1)
1		$P_{(0)\mu}$	
2/3	$T_{(1)j}, T_{(2)j}, T_{(3)j}$	$E_{(1)0}, E_{(2)0}, E_{(3)0}, \overline{E}_{(1)0}, \overline{E}_{(2)0}, \overline{E}_{(3)0},$	$\overline{T}_{(1)j}, \overline{T}_{(2)j}, \overline{T}_{(3)j}$
1/3		$P_{(1)\mu}, P_{(2)\mu}, P_{(3)\mu}$	
0	$T_{(0)j}$	$G_{(0)0}, \overline{G}_{(0)0}$	$\overline{T}_{(0)j}$

A more explicit role of these scalar charges might be exhibited when introducing graded spinor charges for instance. We discuss possible interpretations of the novel scalar charges in the last section.

We observe that only the scalar charges $G_{(0)0}$, $\overline{G}_{(0)0}$ provide an authentic further enhancement of the merged extension obtained in the Sec. III. The structure of the obtained extension is presented graphically in Table II below, this extension will be called the **full clover extension**. The usage of the grading group elements for this symmetry presents a truly democratic pattern: each group element in $\mathbb{Z}_4\times\mathbb{Z}_4$ is used as generator index three times, and there is the same number spin representations (multiplets of generators) in each class.

V. CENTRAL CHARGES

We consider first extra scalar charges $Z_{(k)\nu}$, with $k=1,2,3;\ \mu=0,1,2,3$ produced by the combination of the multiplets $P_{(1)}$, $P_{(2)}$, $P_{(3)}$:

$$[\![P_{(i)\mu},P_{(j)\nu}]\!]=C^{\sigma}(i,j)_{\mu\nu}E_{(i\dagger j)\sigma}+\hat{C}^{\sigma}(i,j)_{\mu\nu}\overline{E}_{(i\dagger j)\sigma}+\eta^{r}(i,j)_{\mu\nu}T_{(i\dagger j)r}+\hat{\eta}^{\dot{r}}(i,j)_{\mu\nu}\overline{T}_{(i\dagger j)\dot{r}}$$
$$+D^{\sigma}(i,j)_{\mu\nu}Z_{(i\dagger j)\sigma}+\hat{D}^{\sigma}(i,j)_{\mu\nu}\overline{Z}_{(i\dagger j)\sigma},\quad i\neq j. \tag{5.1}$$

Using relation (2.4), we obtain

$$-q_{(j)\nu,(i)\mu}D^{\sigma}(i,j)_{\mu\nu}=D^{\sigma}(j,i)_{\nu\mu}=\hat{D}^{\sigma}(i,j)^{*}_{\mu\nu}. \tag{5.2}$$

Using the Jacobi identities for the triple $T_{(0)l}$, $P_{(i)\mu}$, $P_{(j)\nu}$ and the triple $\overline{T}_{(0)l}$, $P_{(i)\mu}$, $P_{(j)\nu}$ we obtain

$$\sigma^{P}(l,i)^{\rho}_{\mu}D^{\sigma}(i,j)_{\rho\nu}+(2\delta_{li}-1)D^{\sigma}(i,j)_{\mu\rho}\sigma^{P}(l,j)^{\rho}_{\nu}=0, \tag{5.3}$$

$$\overline{\sigma}^{P}(l,i)^{\rho}{}_{\mu}D^{\sigma}(i,j)_{\rho\nu}+(2\delta_{lj}-1)D^{\sigma}(i,j)_{\mu\rho}\overline{\sigma}^{P}(l,j)^{\rho}{}_{\nu}=0. \tag{5.4}$$

The grading structure determines the allowed textures for the arrays $D^{\sigma}(i,j)$, $\hat{D}^{\sigma}(i,j)$. From Eqs. (5.2)–(5.4) for $ijk\in\{123,231,312\}$, we obtain:

$$D^0(i,j)=d_{k0}\begin{bmatrix}0&0&1&0\\0&\mathrm{i}&0&0\\0&0&0&\mathrm{i}\\1&0&0&0\end{bmatrix},\quad D^1(i,j)=d_{k1}\begin{bmatrix}1&0&0&0\\0&0&0&-1\\0&1&0&0\\0&0&1&0\end{bmatrix},$$
$$D^2(i,j)=d_{k2}\begin{bmatrix}0&1&0&0\\0&0&-\mathrm{i}&0\\1&0&0&0\\0&0&0&-\mathrm{i}\end{bmatrix},\quad D^3(i,j)=d_{k3}\begin{bmatrix}0&0&0&1\\-1&0&0&0\\0&0&-\mathrm{i}&0\\0&\mathrm{i}&0&0\end{bmatrix}. \tag{5.5}$$

The further matrices are obtained using (5.2).

The central charges $Z_{(k)\nu},\overline{Z}_{(k)\nu}$ q-commute with all the generators of the clover extension obtained in Sec. II since the scalars that have nontrivial relations have been taken into account by the scalar couples $E_{(j)0},\overline{E}_{(j)0}$. Therefore their name of central charges:

$$[\![Z_{(k)\nu},Y]\!]=0,\quad [\![\overline{Z}_{(k)\nu},Y]\!]=0,$$
$$\forall Y=P_{(\mu)\nu},T_{(\mu)j},\overline{T}_{(\mu)j},E_{(j)0},\overline{E}_{(j)0},\quad \mu,\nu=0,1,2,3,\quad j,k=1,2,3. \tag{5.6}$$

Nevertheless, under the presence of the dimensionless scalars $G_{(0)0},\overline{G}_{(0)0}$ introduced in Sec. IV, these central charges acquire some nontrivial q-commutation relations:

$$[\![G_{(0)0},Z_{(k)\nu}]\!]=-l(0k)_0Z_{(k)\nu}, \tag{5.7}$$

$$[\![G_{(0)0},\overline{Z}_{(k)\nu}]\!]=-l(0k)_0\overline{Z}_{(k)\nu},\quad k=1,2,3. \tag{5.8}$$

The production of a scalar singlets $Z_{(0)\mu}$, with $\mu=0,1,2,3$ is considered when we compose repeated $P_{(i)}$ charges:

$$[\![P_{(i)\mu},P_{(i)\nu}]\!]=D^\sigma(i,i)_{\mu\nu}Z_{(0)\sigma}+\hat{D}^\sigma(i,i)_{\mu\nu}\overline{Z}_{(0)\sigma}. \tag{5.9}$$

We do not consider spin (1,0) and spin(0,1) multiplets of class (0) in (5.9) since they are excluded by the Coleman–Mandula theorem. We observe that the introduction of the scalar $Z_{(0)\mu}$ endanger the interpretation of the $P_{(i)}$ charges as translations in the novel four-dimensional noncommutative manifolds. From the Jacobi identities we obtain equations identical to (5.3) and (5.4) with $i=j$, whose solutions are

$$D^0(i,i)=\overline{d}_{i0}\begin{bmatrix}0&1&0&0\\-1&0&0&0\\0&0&0&-\mathrm{i}\\0&0&\mathrm{i}&0\end{bmatrix},\quad D^1(i,i)=\overline{d}_{i1}\begin{bmatrix}1&0&0&0\\0&-1&0&0\\0&0&1&0\\0&0&0&1\end{bmatrix},$$
$$D^2(i,i)=\overline{d}_{i2}\begin{bmatrix}0&0&0&1\\0&0&\mathrm{i}&0\\0&\mathrm{i}&0&0\\1&0&0&0\end{bmatrix},\quad D^3(i,i)=\overline{d}_{i3}\begin{bmatrix}0&0&1&0\\0&0&0&-\mathrm{i}\\1&0&0&0\\0&-\mathrm{i}&0&0\end{bmatrix}. \tag{5.10}$$

The further matrices are obtained using (5.2).

The central charges $Z_{(0)\nu}$, $\overline{Z}_{(k)\nu}$ also q-commute with all the generators of the merged extension obtained in Sec. II:

$$[\![Z_{(0)\nu},Y]\!]=0, \quad [\![\overline{Z}_{(0)\nu},Y]\!]=0,$$
$$\forall Y=P_{(\mu)\nu},T_{(\mu)j},\overline{T}_{(\mu)j},E_{(j)0},\overline{E}_{(j)0}, \quad \mu,\nu=0,1,2,3,j=1,2,3. \tag{5.11}$$

Nevertheless, under the presence of the dimensionless scalars $G_{(0)0}$, $\overline{G}_{(0)0}$ introduced in Sec. IV, the central charges $Z_{(0)\nu}$, $\overline{Z}_{(0)\nu}$ for $D^{\mu}(i,i)$ nonvanishing for $\mu=0,1,2,3;i=1,2,3$ imply:

$$[\![G_{(0)0},Z_{(0)\nu}]\!]=2\,l(0i)_0 Z_{(0)\nu}, \tag{5.12}$$

$$[\![G_{(0)0},\overline{Z}_{(0)\nu}]\!]=2\,l(0i)_0 \overline{Z}_{(0)\nu}, \tag{5.13}$$

$$2\,l(01)_0=2\,l(02)_0=2\,l(03)_0=0. \tag{5.14}$$

In order to circumvent this fact, we could introduce central charges $Z^i_{(0)\nu}$ with $i=1,2,3$ in Eq. (5.9) instead of the charges $Z_{(0)\nu}$. In this case, Eqs. (5.12) and (5.13) for $Z^i_{(0)\nu}$ instead of $Z_{(0)\nu}$ do not lead to Eq. (5.14).

We conclude this section observing that it is possible to introduce central charges $Z_{(k)\nu}$, $\overline{Z}_{(k)\nu}$ with $k=1,2,3$; $\nu=0,1,2,3$ and central charges $Z^i_{(0)\nu}$, $\overline{Z^i}_{(0)\nu}$ with $i=1,2,3$; $\mu=0,1,2,3$ of naive dimension 2/3 in the enhanced merged extension of Sec. IV. Nevertheless, we do not recognize so far a systematic in the usage of group grading indices by such central charges (at least as clear as it was obtained by the enhanced merged extension). The presence of the central charges $Z^i_{(0)\nu}$ would damage the interpretation of the charges $P_{(i)\mu}$ as translations in flat noncommutative four-dimensional manifolds. The role of the central charges might become clear when studying local versions of these symmetries toward novel gravity models.

VI. DIMENSIONLESS ANTISYMMETRIC VECTORS

We can also consider the introduction of dimensionless triplets $\mathbf{T}_{(i)}$ and $\overline{\mathbf{T}}_{(i)}$ of spin (1,0) and spin (0,1), respectively, such that they satisfy relations of the sort:

$$[\![\mathbf{T}_{(f)i},\mathbf{T}_{(g)j}]\!]=\Sigma^k(f,g)_{ij}\mathbf{T}_{(f\dagger g)k}.$$

Using the q-commutativity property we have

$$-q_{(f)j,(g)k}\Sigma^l(g,f)_{kj}=\Sigma^l(f,g)_{jk}.$$

After considering the necessary Jacobi identities associated with the triple $T_{(0)i}$, $\mathbf{T}_{(f)j}$, $\mathbf{T}_{(g)k}$ we obtain

$$\Sigma^l(f,g)\sigma^T(i,h)_l{}^n=\sigma^T(i,f)\Sigma^n(f,g)+q_{(0)i,(f)j}\Sigma^n(f,g)\sigma^T(i,g)^{\mathrm{tr}}. \tag{6.1}$$

Solving the equations above we obtain that there are no nontrivial connections between the proposed dimensionless antisymmetric vector generators:

$$\Sigma^k(f,g)_{ij}=0, \quad \forall i,j,k,f,g=1,2,3.$$

Hence, there is no place for extra dimensionless antisymmetric vectors.

VII. CONCLUSIONS

We have completed the construction of a very particular type of graded Lie algebraic extension of the Poincaré algebra with involution. The obtained trefoil symmetry is a $(\mathbb{Z}_4\times\mathbb{Z}_4;q)$-graded extension with multiplets of generators of spin <2 which belong to what has been called clover extensions. The obtained extension will be called the *full clover extension*, or simply the *clover extension*. It includes as particular cases the minimal vector clover extension and

the minimal scalar clover extension (also with dimensionless scalars). The clover extension corresponds to what would be $N=1$ supersymmetry for the $\mathbb{Z}_2$-supergradings. Replication of the clover extensions can also be considered but lie outside of the scope of the present work.

The Poincaré algebra:

$$\begin{gathered}
[\![T_{(0)i},T_{(0)j}]\!]=\mathrm{i}\epsilon_{ijk}T_{(0)k},\quad [\![T_{(0)i},\overline{T}_{(0)j}]\!]=0,\quad [\![\overline{T}_{(0)i},\overline{T}_{(0)j}]\!]=\mathrm{i}\epsilon_{ijk}\overline{T}_{(0)k},\\
[\![T_{(0)i},P_{(o)\nu}]\!]=-\mathrm{i}\sigma^{P}(i,0)_{\nu}{}^{\rho}P_{(0)\rho},\quad [\![\overline{T}_{(0)i},P_{(0)\nu}]\!]=-\mathrm{i}q_{(0)i,(0)\nu}P_{(0)\rho}\overline{\sigma}^{P}(i,0)^{\rho}{}_{\nu},\qquad (7.1)\\
[\![P_{(0)\mu},P_{(0)\nu}]\!]=0,
\end{gathered}$$

for which the q-commutators coincide with commutators, extends for $f,i,j,k,l=1,2,3$ through the *full clover extension*:

$$\begin{gathered}
[\![T_{(0)i},P_{(f)\nu}]\!]=-\mathrm{i}\sigma^{P}(i,f)_{\nu}{}^{\rho}P_{(f)\rho},\quad [\![\overline{T}_{(0)i},P_{(f)\nu}]\!]=-\mathrm{i}q_{(0)i,(f)\nu}P_{(f)\rho}\overline{\sigma}^{P}(i,f)^{\rho}{}_{\nu},\\
[\![T_{(0)i},T_{(f)s}]\!]=-\mathrm{i}\sigma^{T}(i,f)_{s}{}^{t}T_{(f)t},\quad [\![\overline{T}_{(0)i},T_{(f)s}]\!]=0,
\end{gathered}\qquad (7.2)$$

$$[\![T_{(0)i},\overline{T}_{(f)\dot{s}}]\!]=0,\quad [\![\overline{T}_{(0)i},\overline{T}_{(f)\dot{s}}]\!]=-\mathrm{i}q_{(0)i,(f)s}\overline{T}_{(f)\dot{t}}\overline{\sigma^{T}}(i,f)^{\dot{t}}{}_{\dot{s}},\qquad (7.3)$$

$$[\![T_{(0)i},E_{(f)0}]\!]=0,\quad [\![\overline{T}_{(0)i},E_{(f)0}]\!]=0,\qquad (7.4)$$

$$[\![T_{(0)i},\overline{E}_{(f)0}]\!]=0,\quad [\![\overline{T}_{(0)i},\overline{E}_{(f)0}]\!]=0,\qquad (7.5)$$

$$[\![T_{(0)i},G_{(0)0}]\!]=0,\quad [\![\overline{T}_{(0)i},G_{(0)0}]\!]=0,\qquad (7.6)$$

$$[\![T_{(0)i},\overline{G}_{(0)0}]\!]=0,\quad [\![\overline{T}_{(0)i},\overline{G}_{(0)0}]\!]=0,\qquad (7.7)$$

$$[\![P_{(0)\mu},P_{(f)\nu}]\!]=0,\qquad (7.8)$$

$$[\![P_{(0)\mu},T_{(f)t}]\!]=0,\quad [\![P_{(0)\mu},\overline{T}_{(f)s}]\!]=0,\qquad (7.9)$$

$$[\![P_{(0)\mu},E_{(f)0}]\!]=0,\quad [\![P_{(0)\mu},\overline{E}_{(f)0}]\!]=0,\qquad (7.10)$$

$$[\![P_{(0)\mu},G_{(0)0}]\!]=0,\quad [\![P_{(0)\mu},\overline{G}_{(0)0}]\!]=0,\qquad (7.11)$$

$$[\![T_{(i)s},T_{(j)t}]\!]=0,\quad [\![T_{(i)s},\overline{T}_{(j)\dot{t}}]\!]=0,\quad [\![\overline{T}_{(i)\dot{s}},\overline{T}_{(j)\dot{t}}]\!]=0,\qquad (7.12)$$

$$[\![E_{(i)0},E_{(j)0}]\!]=0,\quad [\![E_{(i)0},\overline{E}_{(j)0}]\!]=0,\quad [\![\overline{E}_{(i)0},\overline{E}_{(j)0}]\!]=0,\qquad (7.13)$$

$$[\![T_{(i)s},E_{(j)0}]\!]=0,\quad [\![T_{(i)s},\overline{E}_{(j)0}]\!]=0,\qquad (7.14)$$

$$[\![\overline{T}_{(i)\dot{s}},E_{(j)0}]\!]=0,\quad [\![\overline{T}_{(i)\dot{s}},\overline{E}_{(j)0}]\!]=0,\qquad (7.15)$$

$$[\![P_{(f)\mu},P_{(f)\nu}]\!]=0,\qquad (7.16)$$

$$[\![P_{(i)\mu},P_{(j)\nu}]\!]=C^{\sigma}(i,j)_{\mu\nu}E_{(i\dagger j)\sigma}+\hat{C}^{\sigma}(i,j)_{\mu\nu}\overline{E}_{(i\dagger j)\sigma}+\eta^{r}(i,j)_{\mu\nu}T_{(i\dagger j)r}+\hat{\eta}^{\dot{r}}(i,j)_{\mu\nu}\overline{T}_{(i\dagger j)\dot{r}},\quad i\neq j\qquad (7.17)$$

$$[\![T_{(k)r},P_{(l)\mu}]\!]=\delta_{kl}K_{r}(l)_{\mu}^{\nu}P_{(0)\nu},\qquad (7.18)$$

$$[\![\overline{T}_{(k)\dot{r}},P_{(l)\mu}]\!]=\delta_{kl}\hat{K}_{\dot{r}}(l)^{\nu}_{\mu}P_{(0)\nu}. \tag{7.19}$$

$$[\![E_{(f)\sigma},P_{(l)\mu}]\!]=\delta_{fl}S_{\sigma}(l)^{\nu}_{\mu}P_{(0)\nu}, \tag{7.20}$$

$$[\![\overline{E}_{(f)\sigma},P_{(l)\mu}]\!]=\delta_{fl}\hat{S}_{\sigma}(l)^{\nu}_{\mu}P_{(0)\nu}, \tag{7.21}$$

$$[\![G_{(0)0},\overline{G}_{(0)0}]\!]=0, \tag{7.22}$$

$$[\![G_{(0)0},P_{(i)\nu}]\!]=l(0i)_0P_{(i)\nu},\quad [\![\overline{G}_{(0)0},P_{(i)\nu}]\!]=-l(0i)^{*}_0P_{(i)\nu}, \tag{7.23}$$

$$[\![G_{(0)0},T_{(k)a}]\!]=-l(0k)_0T_{(k)a},\quad [\![\overline{G}_{(0)0},T_{(k)a}]\!]=l(0k)^{*}_0T_{(k)a}, \tag{7.24}$$

$$[\![G_{(0)0},\overline{T}_{(k)a}]\!]=-l(0k)_0\overline{T}_{(k)a},\quad [\![\overline{G}_{(0)0},\overline{T}_{(k)a}]\!]=l(0k)^{*}_0\overline{T}_{(k)a}. \tag{7.25}$$

The σ-matrices associated with the different spin representations were given in Ref. 1 The η- and C-matrices are given in (2.9) and (2.10). The K- and S-matrices are given in (2.21) and (2.22). These matrices are constrained by the conditions (2.25)–(2.28), or equivalently to the constraints (2.30)–(2.36). A particular choice respecting the symmetry among the novel classes is given by (2.37) and (2.38). The l-structure constants fulfill the constraint (4.32). A particular choice respecting the symmetry among the novel classes is given in (4.46). The obtained constraints on the structure constants reveal that no anisotropy or inhumogeneity should be introduced to the space–time through this extension since there are particular choices of the structure constants that maintain the profound symmetry behind the three novel classes.

The naive dimensions and spin representations of the full clover extension are presented diagramatically in Table II. This extension has 48 generators, three for each one of the 16 elements of the grading group $\mathbb{Z}_4\times\mathbb{Z}_4$. Both the minimal vector clover extension and the full clover extension make a democratic usage of the grading indices.

In the full clover extension each class has exactly a couple (conjugate pair) of scalar singlets, a symmetric vector and a couple (conjugate pair) of antisymmetric vectors. This structure gives a taste of what could be the structure of graded superfields. The minimal vector clover extension exhibits what might be a constrained version of such graded superfields, each class involving only a symmetric vector and a couple (conjugate pair) of antisymmetric vectors. The same type of comment might be done for the minimal scalar clover extension. We observe already that a relation among vector and scalar multiplets is suggested, whose relevance for a relation among gauge and Higgs fields is discussed in a forthcomming publication.

Since the product of each generator by its corresponding graded parameter builds a Lie algebra generator, we might inquire about which could be the Lie algebra and Lie groups associated with the presented extensions. The full clover extension has 48 generators, so it might be related to the Lie algebras A_6 $(u(7),su(7),su(p,q)$ for $p+q=7$, $sl(7,\mathbb{R}))$ or with $sl(5,\mathbb{C})$. The minimal vector clover extension enhanced with the two dimensionless scalars is a subalgebra of dimension 42, so it might be related to the Lie algebras $so(7,\mathbb{C}),o(7,\mathbb{C})$ or $sp(3,\mathbb{C})$. The minimal vector clover extension with dimension 40 has the same dimension of the supergraded de Sitter algebra $osp(5|4)$, but there the space–time translations no longer commute, while here they do. The minimal scalar clover extension enhanced with the two dimensionless scalars has dimension 30, so it might be related to the Lie algebra $sl(4,\mathbb{C})$. The minimal scalar clover extension has dimension 28, so it might be related to the Lie algebras $D_4(o(8),so(8),so(p,q)$ for $p+q=8,so^{*}(8))$ or $so(6,\mathbb{C}),o(6,\mathbb{C})$.

The introduction of central charges has also been addressed, although all scalar charges in the full clover extension might be seen as central charges as well. In particular we considered the introduction of scalar charges $Z_{(k)\nu},\overline{Z}_{(k)\nu}$ with $k=1,2,3$; $\nu=0,1,2,3$ and $Z^{i}_{(0)\nu}$, $\overline{Z}^{i}_{(0)\nu}$ with $i=1,2,3$; $\mu=0,1,2,3$ of naive dimension 2/3, by replacing relations (7.16) and (7.17) with

$$[\![P_{(i)\mu},P_{(i)\nu}]\!]=D^{\sigma}(i,i)_{\mu\nu}Z^{i}_{(0)\sigma}+\hat{D}^{\sigma}(i,i)_{\mu\nu}\overline{Z}^{i}_{(0)\sigma}, \tag{7.26}$$

$$[\![P_{(i)\mu},P_{(j)\nu}]\!]=C^{\sigma}(i,j)_{\mu\nu}E_{(i\dagger j)\sigma}+\hat{C}^{\sigma}(i,j)_{\mu\nu}\overline{E}_{(i\dagger j)\sigma}+\eta^{r}(i,j)_{\mu\nu}T_{(i\dagger j)r}+\hat{\eta}^{\dot{r}}(i,j)_{\mu\nu}\overline{T}_{(i\dagger j)\dot{r}}$$
$$+D^{\sigma}(i,j)_{\mu\nu}Z_{(i\dagger j)\sigma}+\hat{D}^{\sigma}(i,j)_{\mu\nu}\overline{Z}_{(i\dagger j)\sigma}, \quad i\neq j, \tag{7.27}$$

where the D-matrices are given in (5.5) and (5.10). These central charges q-commute with all the generators of the full clover extension with the exception of the dimensionless scalars:

$$[\![G_{(0)0},Z_{(k)\nu}]\!]=-l(0k)_{0}Z_{(k)\nu}, \tag{7.28}$$

$$[\![G_{(0)0},\overline{Z}_{(k)\nu}]\!]=-l(0k)_{0}\overline{Z}_{(k)\nu}, \quad k=1,2,3. \tag{7.29}$$

$$[\![G_{(0)0},Z^{i}_{(0)\nu}]\!]=2\,l(0i)_{0}Z^{i}_{(0)\nu}, \tag{7.30}$$

$$[\![G_{(0)0},\overline{Z}^{i}_{(0)\nu}]\!]=2\,l(0i)_{0}\overline{Z}^{i}_{(0)\nu}, \quad i=1,2,3. \tag{7.31}$$

It was remarked that the introduction of the central charges $Z^{i}_{(0)\nu}$, $\overline{Z}^{i}_{(0)\nu}$ damage or at least modify the interpretation of the $P_{(i)\mu}$ multiplets as translations in the noncommutative manifold, since they would no longer q-commute among them, as naively expected from a translation. It was also remarked that there is no place for introducing extra dimensionless antisymmetric vectors nontrivially connected with the clover extension. We do not recognize either any naive ''democratic'' pattern in the usage of group indices for these central charges.

Note added in proof. Central charges q-commuting with all the full clover extension generators can be included in the right-hand side of Eqs. (4.47) and (7.22).

By using Cheng–Yau's self-adjoint operator $\Box$, we study the space-like hypersurfaces in the de Sitter spaces and obtain some general rigidity results. © *2001 American Institute of Physics.* [DOI: 10.1063/1.1386638]

I. INTRODUCTION

Let $M_p^{n+p}(c)$ be an $(n+p)$-dimensional connected semi-Riemannian manifold of constant curvature c whose index is p. It is called an indefinite space form of index p and simply a space form when $p=0$. If $c>0$, we call it a de Sitter space of index p, and denote it by $S_p^{n+p}(c)$. The study of space-like hypersurfaces in de Sitter space has recently been of substantial interest from both physics and mathematical points of view. Akutagawa[1] and Ramanathan[2] investigated space-like hypersurfaces in a de Sitter space and proved independently that a complete space-like hypersurface in a de Sitter space with constant mean curvature is totally umbilical if the mean curvature H satisfies $H^2 \leqslant c$ when $n=2$ and $n^2H^2<4(n-1)c$ when $n\geqslant 3$. Later, Cheng[3] generalized this result to general submanifolds in a de Sitter space.

On the other hand, Cheng and Ishikawa[4] have recently shown that the totally umbilical round spheres are the only compact space-like hypersurfaces in $S_1^{n+1}(1)$ with constant scalar curvature $R<n(n-1)$. Some other authors, such as Liu,[5] Li,[6] and Zheng,[7,8] have also obtained interesting results related to the characterization of the totally umbilical round spheres as the only compact space-like hypersurfaces in the de Sitter space with constant scalar curvature.

In the present paper, we would like to use Cheng-Yau's self-adjoint operator $\Box$ to study the space-like hypersurfaces in the de Sitter spaces and get some very interesting general rigidity results.

II. PRELIMINARIES

Let S_1^{n+1} be an $(n+1)$-dimensional de Sitter space of constant curvature 1 whose index is 1. Let M be an n-dimensional compact space-like hypersurface in S_1^{n+1}. We choose a local field of semi-Riemannian orthonormal frames $e_1, \ldots, e_{n+1}$ in S_1^{n+1} such that at each point of M, $e_1, \ldots, e_n$ span the tangent space of M and form an orthonormal frame there. We use the following convention on the range of indices:

$$1\leqslant A,B,C, \ldots \leqslant n+1; \quad 1\leqslant i,j,k, \ldots \leqslant n.$$

Let $\omega_1, \ldots, \omega_{n+1}$ be its dual frame field so that the semi-Riemannian metric of S_1^{n+1} is given by $d\overline{s^2}=\Sigma_i \omega_i^2-\omega_{n+1}^2=\Sigma_A \epsilon_A \omega_A^2$, where $\epsilon_i=1$ and $\epsilon_{n+1}=-1$. Then the structure equations of S_1^{n+1} are given by

$$d\omega_A=\sum_B \epsilon_B \omega_{AB} \wedge \omega_B, \quad \omega_{AB}+\omega_{BA}=0, \tag{1}$$

a)Electronic mail: xmliu@dlut.edu.cn

$$d\omega_{AB}=\sum_{C}\ \epsilon_C\omega_{AC}\wedge\omega_{CB}-\frac{1}{2}\sum_{C,D}\ K_{ABCD}\omega_C\wedge\omega_D\,, \tag{2}$$

$$K_{ABCD}=\epsilon_A\epsilon_B(\,\delta_{AC}\delta_{BD}-\delta_{AD}\delta_{BC}). \tag{3}$$

Restrict these form to M^n, we have

$$\omega_{n+1}=0, \tag{4}$$

the Riemannian metric of M^n is written as $ds^2=\Sigma_i\,\omega_i^2$. From Cartan's lemma we can write

$$\omega_{n+1i}=\sum_{j}\ h_{ij}\omega_j\,,\quad h_{ij}=h_{ji}\,. \tag{5}$$

From these formulas, we obtain the structure equations of M:

$$\mathrm{d}\omega_i=\sum_{j}\ \omega_{ij}\wedge\omega_j\,,\quad \omega_{ij}+\omega_{ji}=0, \tag{6}$$

$$\mathrm{d}\omega_{ij}=\sum_{k}\ \omega_{ik}\wedge\omega_{kj}-\frac{1}{2}\sum_{k,l}\ R_{ijkl}\omega_k\wedge\omega_l\,, \tag{7}$$

$$R_{ijkl}=(\,\delta_{ik}\delta_{jl}-\delta_{il}\delta_{jk})-(h_{ik}h_{jl}-h_{il}h_{jk}), \tag{8}$$

where R_{ijkl} are the components of the curvature tensor of M and

$$h=\sum_{i,j}\ h_{ij}\omega_i\otimes\omega_j \tag{9}$$

is the second fundamental form of M. We also have

$$R_{ij}=(n-1)\,\delta_{ij}-nHh_{ij}+\sum_{k}\ h_{ik}h_{kj}\,, \tag{10}$$

$$n(n-1)(R-1)=-n^2H^2+|h|^2, \tag{11}$$

where R is the normalized scalar curvature, and H the mean curvature.

Define the first and the second covariant derivatives of h_{ij}, say h_{ijk} and h_{ijkl} by

$$\sum_{k}\ h_{ijk}\omega_k=dh_{ij}+\sum_{k}\ h_{kj}\omega_{ki}+\sum_{k}\ h_{ik}^{\alpha}\omega_{kj}\,, \tag{12}$$

$$\sum_{l}\ h_{ijkl}\omega_l=dh_{ijk}+\sum_{m}\ h_{mjk}\omega_{mi}+\sum_{m}\ h_{imk}\omega_{mj}+\sum_{m}\ h_{ijm}\omega_{mk}\,. \tag{13}$$

Then we have the Codazzi equation

$$h_{ijk}=h_{ikj}\,, \tag{14}$$

and the Ricci's identity

$$h_{ijkl}-h_{ijlk}=\sum_{m}\ h_{mj}R_{mikl}+\sum_{m}\ h_{im}R_{mjkl}\,. \tag{15}$$

For indefinite Riemannian manifolds in detail, refer to O'Neill.[9]

For a C^2-function f defined on M^n, we defined its gradient and Hessian f_{ij} by

$$df=\sum_i f_i\omega_i, \quad \sum_j f_{ij}\omega_j=df_i+\sum_j f_j\omega_{ji}. \tag{16}$$

We know that $f_{ij}=f_{ji}$ by exterior differentiation of (16).

Let $\phi=\Sigma_{ij}\phi_{ij}\omega_i\otimes\omega_j$ be a symmetric tensor defined on M^n, where

$$\phi_{ij}=nH\delta_{ij}-h_{ij}. \tag{17}$$

Following Cheng–Yau,[10] we introduce an operator $\Box$ associated with ϕ acting on any C^2-function f by

$$\Box f=\sum_{i,j}\phi_{ij}f_{ij}=\sum_{i,j}(nH\delta_{ij}-h_{ij})f_{ij}. \tag{18}$$

Since ϕ_{ij} is divergence-free, it follows[10] that the operator $\Box$ is self-adjoint relative to the L^2 inner product of M^n, i.e.,

$$\int_M f\Box g=\int_M g\Box f. \tag{19}$$

We can choose a local frame field $e_1,\ldots,e_n$ at any point $p\in M$, such that $h_{ij}=\lambda_i\delta_{ij}$ at p, by use of (18) and (11), we have

$$\Box(nH)=nH\Delta(nH)-\sum_i\lambda_i(nH)_{ii}$$

$$=\frac{1}{2}\Delta(nH)^2-\sum_i(nH)_i^2-\sum_i\lambda_i(nH)_{ii}$$

$$=-\frac{1}{2}n(n-1)\Delta R+\frac{1}{2}\Delta|h|^2-n^2|\nabla H|^2-\sum_i\lambda_i(nH)_{ii}. \tag{20}$$

On the other hand, through a standard calculation by use of (14) and (15), we get

$$\frac{1}{2}\Delta|h|^2=\sum_{i,j,k}h_{ijk}^2+\sum_i\lambda_i(nH)_{ii}+\frac{1}{2}\sum_{i,j}R_{ijij}(\lambda_i-\lambda_j)^2. \tag{21}$$

Putting (21) into (20), we have

$$\Box(nH)=-\frac{1}{2}n(n-1)\Delta R+|\nabla h|^2-n^2|\nabla H|^2+\frac{1}{2}\sum_{i,j}R_{ijij}(\lambda_i-\lambda_j)^2. \tag{22}$$

Now we assume that M^n is compact (without boundary) and we obtain the following formula by integrating (22) and by noting $\int_M\Delta R=0$ and $\int_M\Box(nH)=0$

$$\int_{M^n}\left[|\nabla h|^2-n^2|\nabla H|^2+\frac{1}{2}\sum_{i,j}R_{ijij}(\lambda_i-\lambda_j)^2\right]=0. \tag{23}$$

From (8), we have $R_{ijij}=1-\lambda_i\lambda_j$, $i\neq j$, and by putting this into (23), we obtain

$$\int_{M^n}\left[|\nabla h|^2-n^2|\nabla H|^2+n|h|^2-n^2H^2+|h|^4-nH\sum_i \lambda_i^3\right]=0. \tag{24}$$

Let $\mu_i=\lambda_i-H$ and $|Z|^2=\Sigma_i \mu_i^2$, we have

$$\sum_i \mu_i=0, \quad |Z|^2=|h|^2-nH^2, \tag{25}$$

$$\sum_i \lambda_i^3=\sum_i \mu_i^3+3H|Z|^2-nH^3. \tag{26}$$

From (24) to (26), we get

$$\int_{M^n}\left[|\nabla h|^2-n^2|\nabla H|^2+|Z|^2(n-nH^2+|Z|^2)-nH\sum_i \mu_i^3\right]=0. \tag{27}$$

We need the following algebraic lemma due to M. Okumura.[11,12]

Lemma 2.1: Let μ_i, $i=1,\ldots,n$, be real numbers such that $\Sigma_i \mu_i=0$ and $\Sigma_i \mu_i^2=\beta^2$, where $\beta=$constant$\geqslant 0$. Then

$$-\frac{n-2}{\sqrt{n(n-1)}}\beta^3\leqslant\sum_i \mu_i^3\leqslant\frac{n-2}{\sqrt{n(n-1)}}\beta^3, \tag{28}$$

and the equality holds in (28) if and only if at least $(n-1)$ of the μ_i are equal.

By use of Lemma 2.1, we have

$$\int_{M^n}\left[|\nabla h|^2-n^2|\nabla H|^2+(|h|^2-nH^2)\left(n-2nH^2+|h|^2-\frac{n(n-2)}{\sqrt{n(n-1)}}H\sqrt{|h|^2-nH^2}\right)\right]\leqslant 0. \tag{29}$$

III. MAIN RESULTS

Now consider the quadratic form

$$Q(u,t)=u^2-\frac{n-2}{\sqrt{n-1}}ut-t^2.$$

By the orthogonal transformation

$$\begin{cases}\overline{u}=\dfrac{1}{\sqrt{2n}}\{(1+\sqrt{n-1})u+(1-\sqrt{n-1})t\},\\ \overline{t}=\dfrac{1}{\sqrt{2n}}\{(\sqrt{n-1}-1)u+(\sqrt{n-1}+1)t\},\end{cases}$$

$Q(u,t)$ turns into

$$Q(u,t)=\frac{n}{2\sqrt{n-1}}(\overline{u}^2-\overline{t}^2),$$

where $\overline{u}^2+\overline{t}^2=u^2+t^2$.

Take $u=|Z|$, $t=\sqrt{n}H$, then

$$
\begin{aligned}
&n-nH^2-\frac{n(n-2)}{\sqrt{n(n-1)}}H|Z|+|Z|^2\\
&\quad=n+Q(u,t)=nc+\frac{n(\overline{u^2}-\overline{t^2})}{2\sqrt{n-1}}\\
&\quad=n+\frac{n(-\overline{u^2}-\overline{t^2})}{2\sqrt{n-1}}+\frac{n\overline{u^2}}{\sqrt{n-1}}\\
&\quad\geqslant n-\frac{n}{2\sqrt{n-1}}|h|^2. \qquad (30)
\end{aligned}
$$

From (30) and (29) we have

$$
0\geqslant\int_{M^n}\left\{(|\nabla h|^2-n^2|\nabla H|^2)+|Z|^2\left[n-\frac{n}{2\sqrt{n-1}}|h|^2\right]\right\}. \qquad (31)
$$

Therefore we have the following result.

Theorem 3.1: Let M be an n-dimensional ($n\geqslant 3$) compact space-like hypersurface in an $(n+1)$-dimensional de Sitter space S_1^{n+1}. If

$$
|\nabla h|^2\geqslant n^2|\nabla H|^2, \qquad (32)
$$

and

$$
0\leqslant|h|^2\leqslant 2\sqrt{n-1}, \qquad (33)
$$

then M is a totally umbilical hypersurface.

Proof: By the assumption of theorem, the right-hand side is non-negative. Thus, either $|Z|^2\equiv 0$, that is , M is totally umbilical; or

$$
|h|^2=2\sqrt{n-1}. \qquad (34)
$$

In the latter case, equality holds in Lemma 2.1, and it follows that M has at most two distinct constant principle curvatures. We conclude that M is totally umbilical from the compactness of M. This completes the proof of Theorem 3.1.

Lemma 3.1: Let M be an n-dimensional compact space-like hypersurface in an $(n+1)$-dimensional de Sitter space S_1^{n+1}. Suppose that the normalized scalar curvature $R=$constant and $R\leqslant 1$. Then $|\nabla h|^2\geqslant n^2|\nabla H|^2$.

Proof: From (11),

$$
-n^2H^2+\sum_{i,j}h_{ij}^2=n(n-1)(R-1).
$$

Taking the covariant derivative of the above-given expression, and using the fact $R=$constant, we get

$$
n^2HH_k=\sum_{i,j}h_{ij}h_{ijk}.
$$

By Cauchy–Schwarz inequality, we have

$$\sum_k n^4H^2(H_k)^2=\sum_k\left(\sum_{i,j}h_{ij}h_{ijk}\right)^2\leqslant\left(\sum_{i,j}h_{ij}^2\right)\sum_{i,j,k}h_{ijk}^2, \tag{35}$$

that is

$$n^4H^2\|\nabla H\|^2\leqslant|h|^2|\nabla h|^2. \tag{36}$$

On the other hand, from $R\leqslant 1$, we have $n^2H^2-|h|^2\geqslant 0$. Thus

$$H^2|\nabla h|^2\geqslant n^2H^2|\nabla H|^2$$

and Lemma 3.1 follows.

From Theorem 3.1 and Lemma 3.1, we have

Corollary 3.1: Let M be an n-dimensional ($n\geqslant 2$) compact space-like hypersurface with constant normalized scalar curvature R in an $(n+1)$-dimensional de Sitter space S_1^{n+1}. If $R\leqslant 1$ and

$$0\leqslant|h|^2\leqslant 2\sqrt{n-1}, \tag{37}$$

then M is a totally umbilical hypersurface.

Lemma 3.2: Let M be an n-dimensional compact space-like hypersurface in an $(n+1)$-dimensional de Sitter space S_1^{n+1}. Suppose that the normalized scalar curvature R is proportional to the mean curvature H of M, that is

$$R=aH, \tag{38}$$

where a is any constant. Then $|\nabla h|^2\geqslant n^2|\nabla H|^2$.

Proof: By use of Gauss equation $-n^2H^2+|h|^2=n(n-1)(R-1)$ and the assumption (38), we have

$$|h|^2=n^2H^2-n(n-1)(1-aH). \tag{39}$$

Taking the covariant derivative of (39), we have for every k

$$2\sum_{i,j}h_{ij}h_{ijk}=(2n^2H+n(n-1)a)H_k.$$

It follows that

$$4|h|^2|\nabla h|^2\geqslant 4\sum_k\left(\sum_{i,j}h_{ij}h_{ijk}\right)^2=(2n^2H+n(n-1)a)^2|\nabla H|^2. \tag{40}$$

By (38) and (39), we have

$$\begin{aligned}&(2n^2H+n(n-1)a)^2-4n^2|h|^2\\&\quad=(4n^4H^2+n^2(n-1)^2a^2+4n^3(n-1)Ha)-n^2(4n^2H^2-4n(n-1)(1-aH))\\&\quad=n^2(n-1)((n-1)a^2+4n)>0.\end{aligned} \tag{41}$$

Combining (40) with (41), we have $|\nabla h|^2\geqslant n^2|\nabla H|^2$. This completes the proof of Lemma 3.2.

From Theorem 3.1 and Lemma 3.2, we have

Corollary 3.2: Let M be an n-dimensional ($n\geqslant 2$) compact space-like hypersurface in an $(n+1)$-dimensional de Sitter space S_1^{n+1}. Suppose that the normalized scalar curvature R is proportional to the mean curvature H of M, that is, there exists a constant a such that

$$R=aH, \tag{42}$$

If

$$0\leqslant|h|^2\leqslant 2\sqrt{n-1}, \tag{43}$$

then M is a totally umbilical hypersurface.

Theorem 3.2: Let M be an n-dimensional ($n\geqslant 3$) compact space-like hypersurface in an $(n+1)$-dimensional de Sitter space S_1^{n+1}. If M has non-negative sectional curvature and

$$|\nabla h|^2\geqslant n^2|\nabla H|^2, \tag{44}$$

then M is a totally umbilical hypersurface.

Proof: If M has non-negative sectional curvature, $R_{ijij}\geqslant 0$, so the assumptions of Theorem 3.2 imply that the right-hand side of (23) is non-negative, thus we have

$$\frac{1}{2}\sum_{i,j} R_{ijij}(k_i-k_j)^2=0. \tag{45}$$

In the same way as Nomizu–Smyth's,[13] it follows that M has at most two distinct constant principle curvatures. We conclude that M is totally umbilical from the compactness of M. This completes the proof of Theorem 3.2.

From Theorem 3.2 and Lemma 3.1, we have

Corollary 3.3 (Ref. 8): Let M be an n-dimensional ($n\geqslant 2$) compact space-like hypersurface with constant normalized scalar curvature R and $R\leqslant 1$ in an $(n+1)$-dimensional de Sitter space S_1^{n+1}. If M has non-negative sectional curvature, then M is a totally umbilical hypersurface.

From Theorem 3.2 and Lemma 3.2, we have

Corollary 3.4: Let M be an n-dimensional ($n\geqslant 2$) compact space-like hypersurface in an $(n+1)$-dimensional de Sitter space S_1^{n+1}. If M has non-negative sectional curvature and the normalized scalar curvature R is proportional to the mean curvature H of M, that is, there exists a constant a such that

$$R=aH, \tag{46}$$

then M is a totally umbilical hypersurface.

Comment on "Method of handling the divergences in the radiation theory of sources that move faster than their waves" [J. Math. Phys. 40, 4331 (1999)]

J. H. Hannay
H. H. Wills Physics Laboratory, University of Bristol, Tyndall Avenue, Bristol BS8 1TL, England

(Received 7 October 2000; accepted for publication 12 April 2001)

The "method" in question[1] has repeatedly led to results which I proved false in 1996 by a short, transparent, and rigorous theorem.[2] Even shorter is the remark here that inspection of the standard formula for the electromagnetic field suffices to prove the results of the "method" false. © *2001 American Institute of Physics.*
[DOI: 10.1063/1.1384865]

The "method of handling the divergences in the radiation theory of sources that move faster than their waves"[1] has repeatedly led to results claiming unexpectedly strong waves from such sources.[2–8] In response to these claims I noted in 1996 a rigorous upper bound on the intensity of such waves which they violated.[9] My disproof is, in turn, referenced several times in Ref. 1, with comment as to where I must have erred. That I have not could be demonstrated by reproducing my bound theorem here. It is short and transparent, but I have repeated it before.[10] Even shorter is the following remark exploiting standard electromagnetism.[11] It shows that if, as is assumed in the "method,"[1–9] the source distribution in question is *finite in extent, bounded in magnitude, and smooth*, then the intensity of waves from it cannot possibly decay less slowly than $1/r^2$. This therefore proves that the $1/r$ intensity decay claimed to result from the "method" must be false.

The standard electromagnetic formula for the magnetic field at the origin as an integral over all space is[11]

$$\mathbf{B}=\frac{\mu_0}{4\pi}\int\frac{[\operatorname{curl}\mathbf{j}]}{r}\mathrm{d}^3\mathbf{r} \tag{1}$$

where the square brackets $[\bullet]$ stand for "retarded value of." (Importantly $[\operatorname{curl}\mathbf{j}]\neq\operatorname{curl}[\mathbf{j}]$.) Rigorously then, if the origin is outside some fixed ball enclosing all source currents $\mathbf{j}$, we have

$$|\mathbf{B}|\leqslant\frac{\mu_0}{4\pi}(\max|\operatorname{curl}\mathbf{j}|)\times\frac{(\text{Volume of ball})}{(\text{Min distance } r \text{ from the origin to the ball surface})}. \tag{2}$$

That is $|\mathbf{B}|\leqslant\text{const}/r$, or the intensity $|\mathbf{B}^2|\leqslant\text{const}/r^2$. The assumption of smoothness of $\mathbf{j}$ ensures that the constant is finite, not infinite, and the inverse square law is thus proved on this basis, contrary to the $1/r$ claim. No mention of the nature of the source "motion" (fast or slow) is necessary; the source distribution variation is smooth but otherwise general.

If (1) is considered in need of justification, then this is supplied by my earlier disproof.[9,10] Finally, the only criticism in Ref. 1 of my disproof which was not already refuted in Ref. 10 is the note of Ref. 11 of Ref. 1. This note gets the logic backwards; justification is required to make any *restriction* on the domain of integration, not the other way round.

Comment on "Uncertainty principle for proper time and mass" [J. Math. Phys 40, 1237 (1999)]

R. A. Krikorian[a)]
Collège de France, Institut d'Astrophysique-98bis Bd Arago, 75014 Paris, France

(Received 2 November 2000; accepted for publication 26 February 2001)

Kudaka and Matsumoto derive the uncertainty relation $c^2\Delta m\Delta\tau\approx h$ between the proper time τ and rest mass m of a material particle by adopting for the description of the particle the Lagrangian $L=M(\dot{\tau}-c^{-1}\sqrt{-g_{\mu\nu}\dot{x}^\mu\dot{x}^\nu})+eA_\mu(x)\dot{x}^\mu$, defined on the enlarged space (x^μ,τ,M), where M is an additional dynamical variable. A key step in the derivation of their uncertainty relation is the identification of the variable M with the rest mass m. Adopting the point of view of variational analysis, we show that such an identification goes against the relativistic requirement of the path dependence of proper time. © *2001 American Institute of Physics.*
[DOI: 10.1063/1.1367329]

In a recent paper entitled "Uncertainty principle for proper time and mass," Kudaka and Matsumoto[1] contend that the uncertainty relation

$$c^2\Delta m\Delta\tau\approx h \tag{1}$$

between the rest mass m and the proper time τ of a particle can be derived if, instead of the usual relativistic Lagrangian

$$\mathrm{L}_o=-mc\sqrt{-g_{\mu\nu}\dot{x}^\mu\dot{x}^\nu}+eA_\mu(x)\dot{x}^\mu, \tag{2}$$

one uses for the description of the particle a Lagrangian L which, besides the space–time coordinates $x^\mu(\mu=1,2,3,4)$, is dependent on both the proper time τ and an additional dynamical variable denoted M, and is defined by

$$\mathrm{L}=M(\dot{\tau}-c^{-1}\sqrt{-g_{\mu\nu}\dot{x}^\mu\dot{x}^\nu})+eA_\mu(x)\dot{x}^\mu, \tag{3}$$

the dot denoting differentiation with respect to an arbitrary parameter λ. A key step in their derivation of the uncertainty relation (1) is the identification of the dynamical variable M with the rest mass m. For this purpose, the authors consider the following Euler–Lagrange (EL) equations

$$\frac{\mathrm{d}}{\mathrm{d}\lambda}\frac{\partial\mathrm{L}}{\partial\dot{X}^A}-\frac{\partial\mathrm{L}}{\partial X^A}=0,\quad X^A=(x^\mu,\tau,M),\quad (A=1,\ldots,6), \tag{4}$$

or equivalently in explicit form

$$\dot{M}=0, \tag{5}$$

$$\dot{\tau}=c^{-1}\sqrt{-g_{\mu\nu}\dot{x}^\mu\dot{x}^\nu}, \tag{6}$$

$$\frac{\mathrm{d}}{\mathrm{d}\lambda}\left(\frac{M}{c}\frac{g_{\rho\mu}\dot{x}^\mu}{\sqrt{-g_{\mu\nu}\dot{x}^\mu\dot{x}^\nu}}+eA_\rho(x)\right)-\frac{M}{2c}\frac{g_{\mu\nu,\rho}\dot{x}^\mu\dot{x}^\nu}{\sqrt{-g_{\mu\nu}\dot{x}^\mu\dot{x}^\nu}}-eA_{\mu,\rho}(x)\dot{x}^\mu=0 \tag{7}$$

a)Electronic mail: Krikorian@iap.fr

and note that Eq. (7), with the aid of Eqs. (5) and (6), may be written in the form

$$\frac{M}{c^2}[\ddot{x}^\rho+\Gamma^\rho_{\mu\nu}\dot{x}^\mu\dot{x}^\nu]=ef^{\rho\mu}\dot{x}_\mu, \tag{8}$$

where $\Gamma^\rho_{\mu\nu}$ and $f_{\mu\nu}=A_{\nu,\mu}-A_{\mu,\nu}$ are respectively the Christoffel symbols of the second kind and the skew-symmetric electromagnetic tensor, the dot denoting now differentiation with respect to proper time τ. Comparison with the equation of motion

$$m[\ddot{x}^\rho+\Gamma^\rho_{\mu\nu}\dot{x}^\mu\dot{x}^\nu]=ef^{\rho\mu}\dot{x}_\mu \tag{9}$$

derived from the relativistic Lagrangian L_o shows that the two equations coincide if the dynamical variable M is identified with the rest energy mc^2 of the particle. From Eq. (5) it follows that the above identification is justified only in the case where M is a non-null constant. This fact is taken for granted by the authors and no discussion of the conditions ensuring this demand is presented. Moreover, from the point of view of variational analysis the EL equations, as a necessary condition for an extremum, are deduced from the first variation of a functional. The formal application, by the authors, of the EL equations (5)–(7) without specifying the form of the functional defined by the Lagrangian L and without saying precisely what extremum problem or variational principle is being considered, raises the question of the meaning and validity of this identification. The purpose of this comment is to show that the identification of the dynamical variable M with the rest mass goes against the relativistic requirement of the path dependence of proper time. Such a conclusion is reached if, by analogy with Hamilton's principle, we suppose that the Lagrangian L, as integrand, serves to define the parametric integral on the enlarged space (x^μ,τ,M)

$$J_{\mathrm{L}}=\int_{\lambda_1}^{\lambda_2}[M(\dot{\tau}-c^{-1}\sqrt{-g_{\mu\nu}\dot{x}^\mu\dot{x}^\nu})+eA_\mu(x)\dot{x}^\mu]d\lambda. \tag{10}$$

The integral is taken along the curve C joining the points P_1, P_2 corresponding to the parameter values λ_1 and λ_2, respectively, and which is representable in the form of the sextuple $X^A(\lambda)=(x^\mu(\lambda),\tau(\lambda),M(\lambda))$, with $\dot{X}^A(\lambda)$ vanishing nowhere on $[\lambda_1,\lambda_2]$, i.e., regular representation of the curve C. An important property of the functional J_L is that its value is independent of the particular parameter chosen. The Euler condition for the functional J_L assumes the form of the EL equations (5)–(7), in the absence of side conditions. This result is established by considering the problem of extremizing J_L as a nonparametric problem in the space (λ,x^μ,τ,M).[2,3] The Euler condition ensures that the extremizing curve g defined by the sextuple $\overline{X^A}(\lambda)=(\overline{x^\mu}(\lambda),\overline{\tau}(\lambda),\overline{M}(\lambda))$ lies entirely on the hypersurface $M=\text{const}$. It remains to specify under which end conditions the functional J_L is to be extremized. We shall see that in order to comply with the relativistic demand of the path dependence of proper time we must treat an extremum problem with variable end point. For such a problem, besides the Euler necessary condition, a second necessary condition, known as the transversality condition, must be satisfied.

For purpose of reference let us briefly recall Morse's formulation of this condition[2a,b]. Let points P_1, P_2 near the intial and final end points $\overline{P}_1$, $\overline{P}_2$ of the extremal g be given by functions

$$X^{AS}=(x^{\mu s},\tau^s,M^s)=X^{AS}(\alpha_1,\ldots,\alpha_r)\quad(s=1,2;1\leqslant r\leqslant 2m,m=4+2) \tag{11}$$

for values of the parameters (α) near (0). The functions appearing in Eq. (11) are assumed to be of class C^2 near $(\alpha)=(0)$. The end points $\overline{P}_1$, $\overline{P}_2$ of g being given by the values of the functions (11) for $(\alpha)=(0)$, i.e., $\overline{X^A}(\lambda_s)=X^{AS}(0)$ $(s=1.2)$. Curves neighboring the extremal g whose end points are given by the functions (11) are called terminally admissible or just admissible, in the absence of side conditions. The regular r dimensional manifold $X^{AS}=X^{AS}(\alpha)$ is known as the terminal manifold. The assumption of regularity meaning that the functional matrix

$$\left|\frac{\partial X^{AS}(0)}{\partial \alpha_h}\right| \quad (s=1,2;h=1,\ldots,r) \tag{12}$$

is of rank r. In the case of two end point manifolds M_1 and M_2 with respective dimensions p and q with $r=p+q$, meeting g at $\overline{P}_1$, $\overline{P}_2$, respectively, one sets

$$(\alpha_1,\ldots,\alpha_r)=(\rho_1,\ldots,\rho_p;\sigma_1,\ldots,\sigma_q), \tag{13}$$

and condition (11) takes the form

$$X^{A1}=X^{A1}(\rho_1,\ldots,\rho_p), \quad X^{A2}=X^{A2}(\sigma_1,\ldots,\sigma_q). \tag{14}$$

The curve g defined by the sextuple $\overline{X}^A(\lambda)$ and the set $(\alpha)=(0)$ will afford an extremum to the functional J_L relative to the neighboring curves of class C^1 if, besides the EL equations (5)–(7), the transversality condition (15) is satisfied:

$$[\mathrm{L}_{\dot{X}^A} dX^{AS}]_{s=1}^{s=2}=0, \quad (\alpha)=0, \tag{15}$$

where $(X,\dot{X})$ must be taken on g at the respective end points of g. Condition (15) is an identity in $d\alpha_h$ when the differentials dX^{AS} are expressed in terms of $d\alpha_h$. Without loss of generality we may assume that the end condition, at the first end point, fixes X^{A1} at $\overline{P}_1$. In this case the tranversality condition (15) reduces to

$$\left[\mathrm{L}_{\dot{X}^A}\frac{\partial X^{AS}(0)}{\partial \sigma_q}\right]^{s=2}=0. \tag{16}$$

Substitution of the expression of $\mathrm{L}_{\dot{X}}$ in (16) gives

$$\overline{M}(\lambda_2)\tau_q^2(0)+\left(\frac{\overline{M}(\lambda)g_{\mu\nu}\dot{\overline{x}}^{\nu}(\lambda)}{\sqrt{-g_{\mu\nu}\dot{\overline{x}}^{\mu}(\lambda)\dot{\overline{x}}^{\nu}(\lambda)}}+eA_{\mu}(\overline{x}(\lambda))\right)_{\lambda=\lambda_2} x_q^{\mu 2}(0)=0, \tag{17}$$

where the subscript q attached to τ^2 or $x^{\mu 2}$ means differentiation with respect to σ_q.

The second end point X^{A2} cannot be fixed at $\overline{P}_2$ otherwise the space–time projections of the admissible curves $X^A(\lambda)$, $\lambda_1\leqslant\lambda\leqslant\lambda_2$, contained within the future sheet of the null cone with vertex E_1, projection of the point $\overline{P}_1$, would all have the prescribed value $\overline{\tau}(\lambda_2)$ at their second end point; this would contradict the relativistic demand of the path dependence of proper time. Accordingly τ^2 must be left undetermined while $x^{\mu 2}$ can be set equal to the space–time coordinates $\overline{x}^{\mu}(\lambda_2)$ of $\overline{P}_2$. On account of this result it follows that along the extremal g the constant value taken by the dynamical variable M is equal to zero and thus it cannot be identified with the rest mass m. This conclusion remains valid in the general case where both τ^2 and $x^{\mu 2}$ are left undetermined at the second end point.

Krikorian asserts the following.

(1) The Lagrangian

$$\mathrm{L}=M(\dot{\tau}-c^{-1}\sqrt{-g_{\mu\nu}\dot{x}^{\mu}\dot{x}^{\nu}})+eA_{\mu}(x)\dot{x}^{\mu} \tag{1}$$

which we used for the description of a clock[1] is singular in a sense.

(2) When one considers the variational problem for such a singular Lagrangian, "the transversality condition"[2] must be taken into account in addition to the Euler condition.

(3) If both of these two conditions are taken into account for the Lagrangian L, it follows that the value of the variable M must be equal to zero along extremal curves. Therefore our conclusion[1] that the variable M can be identified with the rest mass of the particle is not correct. The objective of this response is to question the second of his assertions.

Let us consider a simple Lagrangian

$$\mathrm{L}'=-mc\sqrt{(\dot{x}^0)^2-(\dot{x}^1)^2} \tag{2}$$

for the description of a particle with rest mass m, where the dynamical variables are the space–time coordinates (x^0,x^1) (assuming one-dimensional space for simplicity) and the dot denotes the differential with respect to the proper time τ. The Euler–Lagrange equations are

$$\ddot{x}^0=\ddot{x}^1=0. \tag{3}$$

The Lagrangian L' is singular in the sense that

$$\det(\partial^2\mathrm{L}'/\partial\dot{x}^{\mu}\partial\dot{x}^{\nu})=0. \tag{4}$$

The Lagrangian L is also singular in this sense, and, in our judgment, this is the reason Krikorian asserts that the transversality condition must be taken into account when we consider the variational problem for the Lagrangian L.

Following his assertion, let us consider an extremal $x^{\mu}(\tau)(\tau_1\leqslant\tau\leqslant\tau_2)$ for the Lagrangian L' which, besides the Euler condition, satisfies the transversality condition. Without loss of generality we may assume that the first end point is fixed. In this case the transversality condition reduces to

$$\dot{x}^0(\tau_2)=0 \quad \text{or} \quad \dot{x}^1(\tau_2)=0. \tag{5}$$

Combining the condition (5) with the Euler condition (3), we are led to the conclusion that

$$\dot{x}^1(\tau)=0 \quad (\text{for all } \tau). \tag{6}$$

That is to say, only a very limited class of motions is admissible if we consider the variational problem for the Lagrangian L' under the transversality condition.

On the other hand, there is a general method[3] by which we can formulate Hamilton's principle for such a singular Lagrangian. When we apply the method to the Lagrangian L', we can actually describe all free motions of the relativistic particle. That is to say, at least for the Lagrangian L', there is no need to introduce the transversality condition and to limit the extent of the admissible motions. We dealt with the variational problem for the Lagrangian L by this method and got a set of motion equations which seems to be very reasonable.

Our question is then why we have to introduce an extra condition which limits the extent of the admissible motions when there is a method by which we can adequately represent Hamilton's principle and derive a set of reasonable motion equations.

From classical to quantum mechanics: "How to translate physical ideas into mathematical language"

H. Bergeron[a)]
LURE Bat. 209D, Centre Universitaire Paris-Sud-BP34-91898 Orsay Cedex, France

(Received 3 January 2001; accepted for publication 16 May 2001)

Following previous works by E. Prugovečki [Physica A **91A**, 202 (1978) and *Stochastic Quantum Mechanics and Quantum Space–time* (Reidel, Dordrecht, 1986)] on common features of classical and quantum mechanics, we develop a unified mathematical framework for classical and quantum mechanics (based on L^2-spaces over classical phase space), in order to investigate to what extent quantum mechanics can be obtained as a simple modification of classical mechanics (on both logical and analytical levels). To obtain this unified framework, we split quantum theory in two parts: (i) general quantum axiomatics (a system is described by a state in a Hilbert space, observables are self-adjoints operators, and so on) and (ii) quantum mechanics proper that specifies the Hilbert space as $L^2(\mathbf{R}^n)$; the Heisenberg rule $[\mathbf{p}_i,\mathbf{q}_j]=-i\hbar\delta_{ij}$ with $\mathbf{p}=-i\hbar\nabla$, the free Hamiltonian $\mathbf{H}=-\hbar^2\Delta/2m$ and so on. We show that general quantum axiomatics (up to a supplementary "axiom of classicity") can be used as a nonstandard mathematical ground to formulate physical ideas and equations of ordinary classical statistical mechanics. So, the question of a "true quantization" with "$\hbar$" must be seen as an independent physical problem not directly related with quantum formalism. At this stage, we show that this nonstandard formulation of classical mechanics exhibits a new kind of operation that has no classical counterpart: this operation is related to the "quantization process," and we show why quantization physically depends on group theory (the Galilei group). This analytical procedure of quantization replaces the "correspondence principle" (or canonical quantization) and allows us to map classical mechanics into quantum mechanics, giving all operators of quantum dynamics and the Schrödinger equation. The great advantage of this point of view is that quantization is based on concrete physical arguments and not derived from some "pure algebraic rule" (we exhibit also some limit of the correspondence principle). Moreover spins for particles are naturally generated, including an approximation of their interaction with magnetic fields. We also recover by this approach the semi-classical formalism developed by E. Prugovečki [*Stochastic Quantum Mechanics and Quantum Space–time* (Reidel, Dordrecht, 1986)]. © *2001 American Institute of Physics.* [DOI: 10.1063/1.1386410]

I. INTRODUCTION

From the beginning of quantum mechanics, different methods have been developed to link classical and quantum formalisms. One of the most famous is the Wigner–Weyl transformation that allows one to recover the semi-classical limit of quantum mechanics in phase space.[1] This operation associates to each quantum operator **a** a function in phase space $a(p,q)$ in such a way that at the lowest order in $\hbar$ (zeroth order), the quantum evolution of $a(p,q)$ reduces to the classical one.

From this point of view, quantization is mathematically a deformation of the Abelian algebra of functions in phase space into a noncommutative algebra using the so-called $*_h$-product that replaces standard multiplication[2] [$a(p,q)*_h b(p,q)$ corresponds to the operator product $\mathbf{a}\cdot\mathbf{b}$].

a)Electronic mail: bergeron@lure.u-psud.fr

Although the Wigner–Weyl transformation is algebraically very powerful, it is not completely satisfactory from a physical point of view, because all quantum densities **D** are not mapped into true probability densities[3] $\rho(p,q)$ (positive functions). Nevertheless, this formalism is very useful, and not only in nonrelativistic mechanics, since it can be extended to special relativity.[4]

The Wigner–Weyl transformation is not the unique way to obtain a semi-classical formula. Such kind of formula also occurs using a coherent state splitting.[5,6] Moreover, we have already proved that we can define Hamiltonian-dependent coherent states that allow us to obtain exact quantum results with a semi-classical formula,[7] and this approach preserves positivity [a quantum density **D** is associated with a true classical probability density $\rho(p,q)$]. This formalism with coherent states can be also extended to relativity.[6,8]

All these procedures have the nice property of giving an analytical connection between classical and quantum formalisms, overcoming the apparent discontinuity between classical and quantum pictures. Nevertheless, we always have to assume first quantum operators to obtain semi-classical results, while at the same time, quantum operators (and specially quantum Hamiltonian) are themselves derived from the correspondence principle. So, quantum operators are in fact deduced from classical ones by some ''pure algebraic rule.'' Then, at a logical level, the relationship between classical and quantum mechanics remains not so clear, since we need both of them at the same time, although only quantum mechanics is assumed in principle to be the ''true theory.''

This shows that the logical relationship between quantum mechanics and classical mechanics is more complicated than, for example, the relationship between classical mechanics and special relativity; while quantum mechanics only needs a new constant ''$\hbar$,'' exactly as special relativity needs the new constant ''c.'' We mean that classical and relativistic mechanics are formulated on the same mathematical ground (basic mathematical objects) in such a way that taking the limit $c\to\infty$ into any relativistic formula, we obtain the standard classical result. But this cannot be done directly in the same way ($\hbar\to 0$) in the case of quantum mechanics because the Hilbert space formalism is not the mathematical formalism of classical mechanics.

For the same reason, in special relativity we do not need a general procedure to lift up a classical quantity into the relativistic framework, while in quantum mechanics, we need the correspondence principle.

Of course, different studies have been led, not on a purely analytical level, but on a logical level, to find an *a priori* justification of the quantum picture and these attempts go back to von Neumann.[9]

More recently, in the 1960s, Mackey[10,11] has presented a general mathematical description of a statistical system based on an abstract structure called ''orthocomplemented lattice'' that unifies classical and quantum statistics: adding an *ad hoc* postulate to the basic lattice picture allows us to recover either classical formalism or a quantum one.

This shows that the mathematical representations of classical and quantum theories share some general common structure, but this does not explain the special realization leading to quantum mechanics, namely the choice of the Hilbert space as $L^2(\mathbf{R}^n)$ with $\mathbf{p}=-i\hbar\nabla$ and the free Hamiltonian $\mathbf{H}=-\hbar^2\Delta/2m$. In fact, different studies show that these special realizations are connected to group theory, namely Euclidean invariance and Galilean invariance.[11,12]

Among the contributions to these ''first level'' foundations of quantum mechanics (see Ref. 13 for a nonexhaustive list of references), we shall give some details about the results obtained by Prugovečki[6,14] that are in direct relation with the present article.

The common structure shared by classical and quantum theories suggests that it may exist a possible unified mathematical framework based on L^2-spaces over classical phase space, and the work of Prugovečki in Refs. 14 and 6 (Chaps. 1 and 3) deals with this problem. In fact, this unification is obtained by a change of representation of quantum mechanics and a recasting of classical statistical mechanics. Coherent states obtained from the Galilei group allows us to formulate quantum mechanics into a subspace of the Hilbert space $L^2(\Gamma)$ on the phase space Γ, while classical statistical mechanics can be also formulated in the Hilbert space $L^2(\Gamma)$. Moreover, as indicated in Ref. 14 ''the classical theory emerges as an approximation to the first order of $\hbar$ of the

quantum theory once both of these theories are formulated in terms of superoperators acting in the Liouville space over $L^2(\Gamma)$.''

Now, let us situate our article and its goals.

As noticed previously, the difficulty to connect classical and quantum mechanics on both logical and analytical levels is essentially due to the great difference of mathematical language that confuses physical intuition. In this article, we develop a precise mathematical ground based on some axiomatics, in which classical mechanics and quantum mechanics can be expressed using the same tools. Our goal is not only to unify classical and quantum formalism, but also to rebuild quantum mechanics only starting with classical mechanics, using physical ideas and logical arguments instead of ''simple algebraic rules.'' Moreover, we want to obtain a precise status (classical or quantum) for each ingredient of quantum mechanics.

This question of the classical or purely quantum nature of the ingredients of quantum mechanics is legitimate by at least two arguments:

(i) First, most of quantum operators are deduced from classical quantities (correspondence principle).

(ii) Second, taking the limit $\hbar \to 0$, quantum mechanics must degenerate into classical mechanics. Unfortunately, this limit only says that $\mathbf{p}$ and $\mathbf{q}$ are now commuting operators: the general quantum formalism with wave functions, operators, and so on remains unchanged.

The only possible explanation of this last result is that quantum formalism with commuting operators describes the ideas of classical statistical mechanics as well as the usual formalism in phase space. This means that we have in fact two possible mathematical formalisms to represent the same physical ideas of classical statistical mechanics. Then it must be possible to formulate the ideas and the equations of standard classical statistical mechanics using only the general quantum formalism (axiomatics) and then the question of the true quantization with $\hbar$ must be seen as an independent problem not directly related with the formalism.

In this article, we present such a ''nonstandard axiomatic formulation'' of classical statistical mechanics and we show how (and why) it is equivalent to the usual one. Of course this new picture is not a true quantum theory, since it represents always classical ideas, but it works with general quantum formalism. The use of Hilbert space techniques into classical mechanics is not new and goes back to Koopman.[15] Even the concept of ''classical amplitude'' is not new and has been introduced by Schönberg.[16] But in this article we do not look at these techniques with the same point of view: we consider the Hilbert space formalism as a true logical and analytical representation of classical mechanics, and not only as a mathematical trick. Of course, even if our starting point is different, we recover most of the formula obtained by Prugovečki in Refs. 14 and 6 (Chap. 3).

Then, we show that our nonstandard formalism exhibits a new operation (projection) that has no classical counterpart: this operation is related to the ''quantization process,'' and we show why quantization physically depends on group theory (Galilei group). We cross again the results obtained in Ref. 6, since the procedure of projection gives a subspace of $L^2(\Gamma)$ where quantum mechanics can be formulated, and then many results are common.

But the important result is that this procedure of projection replaces the correspondence principle and allows us to recover all operators of quantum mechanics and the Schrödinger equation.

The great advantage of this point of view is that now, quantization is explicitly based on concrete physical arguments and not derived from some ''pure algebraic rule.'' Moreover, spins for particles are naturally generated, including an approximation of their interaction with magnetic fields. We also recover the natural semi-classical formalism due to coherent states of Galilei group: some exact quantum results are obtained with classicallike formula.

As indicated, many formulas obtained in this article can be found in the previous works of Prugovečki, but they are obtained from another point of view (and our formalism does not use superoperators and Liouville space). The necessary parallels are done in the remainder of the text.

To conclude this introduction, let us specify two points.

First, we do not situate our article in the framework of the question: why does the macroscopic world appear essentially classical, while the microscopic world is quantum? It is well known that this effect is due to decoherence (for details see the nonexhaustive list of references in Ref. 17). Our article is not any more in the field of ''consistent interpretations of quantum mechanics'' or ''consistent histories'' that looks for the logical problems raised by quantum mechanics (Omnès,[18] Gell-Mann–Hartle,[19] Griffiths[20]), even if our article contains consequences on the interpretation of quantization.

Second, there exists one important aspect of our point of view that is not developed in this article: this concerns our previous remark on the equivalence of quantum formalism with commuting operators and the usual classical formalism. If this equivalence is true, this means that any one of these formalisms can be (logically and physically) rebuilt from the other one, and more specially that the full general quantum framework (axiomatics) can be found (as a change of mathematical language) only starting with classical formalism. Of course, on a logical level, it should be more enlightening to recover first general quantum formalism, before any further development. But this would be too long for a single article. So, this special point will be published later in an article devoted to this question.

II. CLASSICAL MECHANICS IN PHASE SPACE (ONE PARTICLE)

A. Phase space structure and Poisson brackets

We only present in this section the main features that we need. For more details, see Ref. 21.

Phase space represents configuration space and it is the set of pairs $(\vec{p},\vec{q})$ of momenta and positions, where $(\vec{p},\vec{q})$ represents the (pure) state of the system. Physical observables are functions $f(\vec{p},\vec{q})$ on phase space.

Now, from a mathematical point of view, if we call M the $\mathbf{R}^3$ space manifold, phase space is the cotangent bundle TM^*. It possesses a natural geometry (namely, a symplectic geometry) that allows us to define the Poisson brackets (PB), $\{f,g\}$ of two functions by

$$\{f,g\}=\vec{\nabla}_p f\cdot\vec{\nabla}_q g-\vec{\nabla}_p g\cdot\vec{\nabla}_q f. \tag{1}$$

The PB is the basic algebraic component of classical mechanics and the physical content of PBs can be related to group theory. Namely, any classical observable f can be seen as the generator of a one-parameter group of transformations acting on observables. Any g is transformed into g_α through

$$\frac{\partial g_\alpha}{\partial\alpha}=\{f,g_\alpha\}. \tag{2}$$

Equivalently, we have trajectories of states $(\vec{p_\alpha},\vec{q_\alpha})$ generated by f following the equations

$$\begin{aligned}\frac{\partial}{\partial\alpha}\vec{q_\alpha}&=\vec{\nabla}_p f(\vec{q_\alpha},\vec{p_\alpha}),\\ \frac{\partial}{\partial\alpha}\vec{p_\alpha}&=-\vec{\nabla}_q f(\vec{q_\alpha},\vec{p_\alpha}).\end{aligned} \tag{3}$$

Then, on a mathematical level, all classical observables play the same role and this role is summarized by the algebra due to Poisson brackets.

B. Classical dynamics

1. Equations of motion for a pure state

Dynamics on phase space is defined by the Hamiltonian equations that are a special case of (3):

$$\frac{d}{dt}\vec{q}=\vec{\nabla}_p H(\vec{q},\vec{p},t),$$
$$\frac{d}{dt}\vec{p}=-\vec{\nabla}_q H(\vec{q},\vec{p},t), \tag{4}$$

where H is the Hamiltonian (eventually time dependent).

2. Dynamics and statistics

These equations (4) correspond to the ideal case of a particle perfectly localized in phase space and we can represent this situation by the probability density $\rho(\vec{p},\vec{q},t)=\delta(\vec{p}-\vec{p_0}(t))\delta(\vec{q}-\vec{q_0}(t))$. Now, if we build a general density ρ as superpositions of "δ" as $\rho=\Sigma_i p_i \delta_{\vec{p_i}(t),\vec{q_i}(t)}$, we find that ρ verifies the Liouville equation:

$$\frac{\partial\rho}{\partial t}=-\{H,\rho\}. \tag{5}$$

So we say classically that (5) describes the evolution of any probability density ρ.

Now, starting from a density ρ that verifies (5), we can look at the evolution of the expectation value $\langle f\rangle_t$ of an observable $f(\vec{p},\vec{q},t)$ defined as $\langle f\rangle_t=\int d^3\vec{p}\,d^3\vec{q}\,\rho(\vec{q},\vec{p},t)\ f(\vec{p},\vec{q},t)$. We find

$$\frac{d}{dt}\langle f\rangle_t=\left\langle\frac{\partial f}{\partial t}\right\rangle_t+\langle\{H,f\}\rangle_t. \tag{6}$$

Applied to the special case of the two fundamental observables $\vec{p}$ and $\vec{q}$, Eq. (6) gives

$$\frac{d}{dt}\langle\vec{q}\rangle_t=\langle\vec{\nabla}_p H\rangle_t,$$
$$\frac{d}{dt}\langle\vec{p}\rangle_t=-\langle\vec{\nabla}_q H\rangle_t. \tag{7}$$

3. Strong and weak dynamical equations

In this section we want to point out some important remarks on the dynamical equations in the framework of statistical mechanics.

Let us assume that the evolution of the probability density $\rho(\vec{p},\vec{q},t)$ is unknown, and that we only know the evolution of expectation values of $\vec{p}$ and $\vec{q}$ through the equations (7). We want to see if it is possible to rebuild the equations (4) on pure states and to find the Liouville equation, only starting with (7).

Basically, if we assume that "δ" densities are allowed such as $\rho(\vec{p},\vec{q},t)=\delta(\vec{p}-\vec{p_0}(t))\delta(\vec{q}-\vec{q_0}(t))$, we find that the equations (7) on expectation values imply that the trajectory $(\vec{p_0}(t),\vec{q_0}(t))$ follows the Hamiltonian equations (4), then we deduce in the same way that a general density must verify the Liouville equation.

But if "δ" densities are not allowed, we cannot directly deduce the evolution of states only starting with expectation value equations, and then we cannot recover Liouville equation. This means that we can find other possible laws of evolution for the density $\rho(\vec{q},\vec{p},t)$ that are compatible with the equations (7) on expectation values.

So we call Eqs. (4) on states "*strong dynamical equations*" and Eqs. (7) on expectation values "*weak dynamical equations*."

Now, as argued by Born,[22] the true mathematical representation of any physical measure is an expectation value associated with some probability density, because a real result of a physical

experiment always contains some uncertainty. Therefore, physical observables (classical or quantum) are always stochastic. This important remark is also the starting point of Prugovečki's monograph.[6]

So weak dynamical equations (7) are a better mathematical description of our physical knowledge about classical dynamics. When we say that strong dynamical equations (4) are realized, in fact we extrapolate our real knowledge by assuming that we can use "δ" densities. Of course this procedure is natural, but not logically necessary. We will use this remark in Sec. V A.

C. Physical symmetries in phase space

We will see later in Sec. VI that our quantization principle is based on the representation of symmetries. Symmetries are defined as the set of physical transformations allowing us to look at the same system from different but equivalent frames. Then let us specify in this section the symmetries involved in phase space.

At first sight, the Poisson brackets defined previously seem to prove that each observable defines a generator of such a symmetry, so the set of symmetries is generated by the full set of classical observables.

But this is only true on a mathematical level: it is false on a physical point of view, because any of these transformations cannot be realized in practice as a real change of frame. The only real continuous transformations that can be realized are space translations, space rotations and Galilean transformations. They constitute the Galilei group. We can also add two discrete transformations: parity and time reversal.

So the true set of classical symmetries can be divided as follows:

(i) the space transformations: translations, rotations and parity,
(ii) the kinematical transformations: Galilei boosts, and
(iii) time reversal.

III. NEW FRAMEWORK FOR CLASSICAL MECHANICS

As indicated in the Introduction, our point of view is to use standard quantum formalism applied to the case of classical mechanics.

So, we introduce the "continuous orthonormal basis" $\{|\vec{p},\vec{q}\rangle\}$ that diagonalizes at the same time the operators $\vec{\mathbf{p}}$ and $\vec{\mathbf{q}}$ ($[\vec{\mathbf{p}},\vec{\mathbf{q}}]=0$). In the remainder of the text, we often use this notation $|\vec{p},\vec{q}\rangle$, but only in circumstances that do not introduce mathematical ambiguity.

It is well known that these $|\vec{p},\vec{q}\rangle$ vectors do not belong to the Hilbert space defined later, but rather to corresponding rigged or equipped Hilbert space.[23]

Now we list the basic axioms[24] (since we do not try to obtain a minimal list, some axioms can be redundant).

A. The basic elements

1. Primary axioms

(i) The mathematical framework is the Hilbert space $\mathcal{H}=L^2(\mathbf{R}^6)$ over classical phase space with the inner product: $(\phi|\psi)=\int d^3\vec{p}\,d^3\vec{q}\,\phi^*(\vec{p},\vec{q})\,\psi(\vec{p},\vec{q})$.
(ii) A particle is represented at a given time by a normalized vector ϕ_t in $\mathcal{H}$ called the state of the system.
(iii) An observable $\mathbf{F}$ is a self-adjoint operator on $\mathcal{H}$ and the possible values of this observable are the eigenvalues of $\mathbf{F}$.

Remarks: Orthogonal projectors are special observables with eigenvalues 0 and 1, corresponding to experiments of the true–false type, and by the spectral theorem[25] we know that general observables are related to orthogonal projectors thanks to projection valued measures (pvm).

2. Statistical axioms

(i) A statistical situation is described by a density operator **D** (a positive trace class operator with $\mathrm{Tr}\mathbf{D}=1$); in particular a system in the state ϕ is statistically represented by the density $\mathbf{D}=|\phi\rangle\langle\phi|$.

(ii) The expectation value of an observable **F** is given by $\langle\mathbf{F}\rangle=\mathrm{Tr}(\mathbf{D}.\mathbf{F})$; the standard error ΔF is given by $\Delta F^2=\langle\mathbf{F}^2\rangle-\langle\mathbf{F}\rangle^2$.

3. Collapse axiom

• Let a system be in a situation described by the density **D** and consider a measure of the observable **F** associated with its projection valued measure **P**. Now, assume that a measure of the observable specifies that the numerical outcomes f are in the range $f\in A$, where A is some interval. Then after the experiment, the system is described by the new density operator $\mathbf{D}'$ with

$$\mathbf{D}'=\frac{1}{\mathrm{Tr}(\mathbf{DP}(A))}\mathbf{P}(A)\mathbf{DP}(A). \tag{8}$$

More precisely, if the system is initially in the state $|\phi\rangle$, after the experiment the system is in the state $|\phi'\rangle$:

$$|\phi'\rangle=\frac{1}{\sqrt{\langle\phi|\mathbf{P}(A)|\phi\rangle}}\mathbf{P}(A)|\phi\rangle. \tag{9}$$

This means that after the experiment, the system is in a state that belongs to the subspace of $\mathcal{H}$ associated with the orthogonal projector $\mathbf{P}(A)$.

4. Axiom of evolution

• The evolution of a state ϕ_t is given by a unitary operator $\mathbf{U}_{t_1,t_2}$ such that $\phi_t=\mathbf{U}_{t,t_0}(\phi_{t_0})$.

Now, to specify the situation of classical mechanics, we must add a new axiom of "classicity."

5. Axiom of classicity

• The true physical observables are always "diagonal in the $|\vec{p},\vec{q}\rangle$ basis," and then a classical observable **f** can be written

$$\forall\,\phi\in\mathcal{H},\mathbf{f}(\phi)(\vec{p},\vec{q})=f(\vec{p},\vec{q})\,\phi(\vec{p},\vec{q}), \tag{10}$$

or $\mathbf{f}=f(\vec{\mathbf{p}},\vec{\mathbf{q}})$ as a function of operators.

This axiom is equivalent to the classical hypothesis specifying that all observables are functions of $\vec{p}$ and $\vec{q}$.

Remark: Density operators **D** are not considered as observables, so they do not need to be "diagonal in the $\{|\vec{p},\vec{q}\rangle\}$ basis" (in fact this is impossible for a trace class operator).

Now, we claim that this new mathematical framework constitutes a complete alternative formulation of classical statistical mechanics.

B. Equivalence of the new framework with the standard formalism

1. The mathematical basis of statistical mechanics

Classical statistical mechanics is based on ordinary probability theory[26] that employs a sample space $\mathcal{C}$. An event is a set of sample points, and the events, under the operations on sets form a Boolean algebra. The set $\mathcal{E}$ of events is a σ-field, and a probability law μ on $\mathcal{C}$ is a positive function acting on events as prescribed by the mathematical theory of measure.[27]

In our case, the sample space $\mathcal{C}$ is phase space and a sample point is a state $(\vec{p},\vec{q})$. The set $\mathcal{E}$ of events is given by the family $\mathcal{B}(\mathcal{C})$ of Borel sets in $\mathcal{C}$. Each probability law μ is associated with a positive density $\rho(\vec{p},\vec{q})$ such that $\mu(A)=\int_A \rho d^3\vec{p}\, d^3\vec{q}$.

2. Equivalence of primary axioms

(i) Now let us call Ω the set of orthogonal projectors of $\mathcal{H}=L^2(\mathcal{C})$ and define the mapping Π from the set of events $\mathcal{E}$ to Ω by

$$\forall \phi \in \mathcal{H}, \forall A \in \mathcal{E}, \Pi(A)(\phi)(\vec{p},\vec{q}) = \chi_A(\vec{p},\vec{q})\phi(\vec{p},\vec{q}), \tag{11}$$

where $\chi_A(\vec{p},\vec{q})$ is the characteristic function of the set A.

The family $\{\Pi(A)\}_{A\in\mathcal{E}}$ gives a representation of the Boolean algebra of events in the quantum mathematical framework as an Abelian algebra of orthogonal projectors [and the $\Pi(A)$ become classical observables according to our previous definition].

(ii) In the ordinary formalism a particle is assumed to be represented by a point $(\vec{p},\vec{q})$ at a given time; but as remarked previously, a true physical experiment always has some uncertainty, so the mathematical representation of a physical result is an expectation value associated with some probability density ρ. Of course in principle, ρ can be as close as possible to a "δ," but "δ" is never reached. This means that we can never really know that a particle is at the point $(\vec{p},\vec{q})$. It is much more realistic to say that a single particle is represented by a true (sharp) density ρ. In the language of statistical sets, this means that we look at a single particle as an element of the class of all particles "prepared" in the same way, the preparation being such that the uncertainty on $\vec{p}$ and $\vec{q}$ can be reduced, but cannot be cancelled.

If we start with this new hypothesis, this means that now, a single particle always exhibits some uncertainty. Moreover, this hypothesis allows us to associate to each particle the object $\phi(\vec{p},\vec{q})=\sqrt{\rho(\vec{p},\vec{q})}$ that defines a normalized wave function of $\mathcal{H}$.

This result can also be found using some extremum property. In the ordinary formalism, the one-point sets $\{(\vec{p},\vec{q})\}$ can be seen as the smallest (more precise) events for the ordering relation "$\subset$" on sets. Using the mapping Π on events, we see that $A\subset B \Leftrightarrow \Pi(A)\leqslant\Pi(B)$ where "$\leqslant$" is the inegality between self-adjoint operators. So a new representation of points can be given by using Π directly or using the extremum property. Since the projector associated to a point x is $\Pi(\{x\})=0$, a point x cannot be associated with a true projector, and then we can only use the extremum property to look for the minimal orthogonal projectors. Of course these minimal projectors are given by $|\phi\rangle\langle\phi|$, where ϕ is a normalized vector in $\mathcal{H}$. So we recover that the most precise events are associated with a normalized vector ϕ in $\mathcal{H}$, and then a particle must be described by ϕ. We remark that the real equivalent of the point $(\vec{p},\vec{q})$ is the unbounded state $|\vec{p},\vec{q}\rangle$ or pseudo-projector $|\vec{p},\vec{q}\rangle\langle\vec{p},\vec{q}|$ that cannot be seen as a "true state" in this formalism.

To finish, let us say that we recover through $\rho(\vec{p},\vec{q})=|\phi(\vec{p},\vec{q})|^2$ the idea of "confidence measures" introduced by Prugovecki[6] in order to build the "stochastic phase space."

(iii) Now if we look at observables, each classical quantity $f(\vec{p},\vec{q})$ can be approximated by step functions $\Sigma_i f_i \chi_{A_i}$ where χ_{A_i} are characteristic functions of sets A_i. So we can extend by linearity the mapping Π to lift up any classical observable into its quantum representation as

$$\forall \phi \in \mathcal{H}, \mathbf{f}(\phi)(\vec{p},\vec{q}) = f(\vec{p},\vec{q})\phi(\vec{p},\vec{q}). \tag{12}$$

Of course we recover the "axiom of classicity" and the fact that the possible values of the observable are its eigenvalues.

3. Equivalence of statistical axioms

(i) A probability law on the ordinary framework is given by a mapping μ acting on events following some precise rules. If we look for a mapping μ_Q acting on the representation of events (that is, on orthogonal projectors) with the same rules, a theorem due to Gleason[28] proves that μ_Q

is given by a density operator $\mathbf{D}$ such that $\mu_Q(\Pi(A))=\mathrm{Tr}(\mathbf{D}\cdot\Pi(A))$. This means that we can associate to each classical probability law μ a density operator $\mathbf{D}$ such that $\mu(A)=\mathrm{Tr}(\mathbf{D}\cdot\Pi(A))$. If we develop this formula, we find

$$\mu(A)=\mathrm{Tr}(\mathbf{D}\cdot\Pi(A))=\int_A d^3\vec{p}\,d^3\vec{q}\,\langle\vec{p},\vec{q}|\mathbf{D}|\vec{p},\vec{q}\rangle. \tag{13}$$

So the classical density $\rho(\vec{p},\vec{q})$ is given by the diagonal element $\rho(\vec{p},\vec{q})=\langle\vec{p},\vec{q}|\mathbf{D}|\vec{p},\vec{q}\rangle$ (this quantity is positive since $\mathbf{D}$ is a positive operator).

Now for a particle "in the state ϕ," if we assume that $\mathbf{D}=|\phi\rangle\langle\phi|$, the corresponding classical density ρ is given by

$$\rho(\vec{p},\vec{q})=\langle\vec{p},\vec{q}|\mathbf{D}|\vec{p},\vec{q}\rangle=|\langle\vec{p},\vec{q}|\phi\rangle|^2. \tag{14}$$

So we recover the formula introduced for justifying the existence of states.

(ii) Now, if we use the relation $\rho(\vec{p},\vec{q})=\langle\vec{p},\vec{q}|\mathbf{D}|\vec{p},\vec{q}\rangle$ for computing classical expectation value, we find

$$\langle f\rangle=\int d^3\vec{p}\,d^3\vec{q}\,\rho f=\mathrm{Tr}(\mathbf{D}\cdot\mathbf{f}). \tag{15}$$

Remark: We see that it is impossible to distinguish the statistical effects due to a general density $\mathbf{D}$ from those due to a pure state, because only the diagonal elements $\langle\vec{p},\vec{q}|\mathbf{D}|\vec{p},\vec{q}\rangle$ are relevant in our case: the pure state $\langle\vec{p},\vec{q}|\phi\rangle=\sqrt{\langle\vec{p},\vec{q}|\mathbf{D}|\vec{p},\vec{q}\rangle}$ gives exactly the same results as $\mathbf{D}$ (in our classical framework). So pure states and general densities $\mathbf{D}$ are different on a logical level, but they are physically undistinguishable. Physical results only depend on an equivalence class of densities $\mathbf{D}$ such that $\langle\vec{p},\vec{q}|\mathbf{D}|\vec{p},\vec{q}\rangle=\rho(\vec{p},\vec{q})$ for a given density ρ. We also find this remark in Prugovečki's monograph[6] (p. 154).

4. Equivalence of the collapse axiom with conditional probability

In ordinary probability theory, we use conditional probability to take into account new results to modify a probability law. Namely, if we have a probability law μ and if we know that some event E is realized, the new probability law μ_E is

$$\mu_E(A)=\frac{\mu(A\cap E)}{\mu(E)}. \tag{16}$$

In our case, if μ is associated with a density $\mathbf{D}$, we have

$$\mu_E(A)=\frac{\mathrm{Tr}(\mathbf{D}\cdot\Pi(A\cap E))}{\mathrm{Tr}(\mathbf{D}\cdot\Pi(E))}. \tag{17}$$

If we use the fact that $\Pi(A\cap E)=\Pi(A)\cdot\Pi(E)=\Pi(E)\cdot\Pi(A)$, we find

$$\mu_E(A)=\frac{\mathrm{Tr}(\Pi(E)\cdot\mathbf{D}\cdot\Pi(E)\Pi(A))}{\mathrm{Tr}(\mathbf{D}\cdot\Pi(E))}. \tag{18}$$

If we introduce the operator $\mathbf{D}_E$ defined as

$$\mathbf{D}_E=\frac{1}{\mathrm{Tr}(\mathbf{D}\cdot\Pi(E))}\Pi(E)\cdot\mathbf{D}\cdot\Pi(E), \tag{19}$$

$\mathbf{D}_E$ is a true density operator and $\mu_E(A)=\mathrm{Tr}(\mathbf{D}_E\cdot\Pi(A))$. So $\mathbf{D}_E$ is the density operator associated with μ_E.

So, we find that conditional probability is implemented in the quantum framework with the formula of the ''collapse axiom.'' Now, let us apply this result to the case of some measure of a classical observable $F(\vec{p},\vec{q})$ that specifies that the possible numerical outcomes f belong to a set $V\subset\mathbf{R}$. This means that after the measure, we know that the particle ''is'' in the region $F^{-1}(V)$ of phase space. This means that we know that the event $F^{-1}(V)$ is realized. So the initial probability law μ associated with the density $\mathbf{D}$ must be changed and the new density $\mathbf{D}'$ is

$$\mathbf{D}'=\frac{1}{\mathrm{Tr}(\mathbf{D}\cdot\mathbf{P}(V))}\mathbf{P}(V)\cdot\mathbf{D}\cdot\mathbf{P}(V) \quad \text{with} \quad \mathbf{P}=\Pi\circ F^{-1}. \tag{20}$$

It is not hard to see that $\mathbf{P}=\Pi\circ F^{-1}$ is exactly the projection valued measure associated with the quantum version $\mathbf{F}$ of the classical observable F. This shows that the collapse axiom is (in our case) a translation of conditional probability.

5. Axiom of evolution

We will see in the following that this axiom allows us to recover classical dynamics.

C. Conclusion

This new mathematical framework for classical mechanics is completely equivalent to the ordinary one. But, while the usual framework is mathematically and physically closed (all things that you can write possess a classical meaning), now this new formalism can be extended by removing some axiom, more specially the ''axiom of classicity,'' by assuming that, perhaps, some unclassical observables also have a physical meaning. As we will see later, quantization corresponds to such a process. We finish with some remarks.

(i) Interference effect: Usually, interferences are seen as one of the main consequences of quantum formalism. We want to point out that they cannot be observed in our case, thanks to our ''axiom of classicity.'' Actually, to see interferences, we need at least two physical observables that are not diagonal in the same basis, and this case is excluded by our axiom. This can be seen also by the fact that pure states cannot be distinguished from general densities.

(ii) Delocalization of states: We have introduced the state ϕ that describes a particle by assuming that $\rho(\vec{p},\vec{q})=|\langle\vec{p},\vec{q}|\phi\rangle|^2$ is a sharp density in phase space. But nothing forbids ϕ to be very delocalized, and, in principle, we must look at this delocalization as being intrinsic (not due to a lack of information as in the case of a general density $\mathbf{D}$). So the question that arises is: why do classical objects have to be described in practice with only very sharp densities? The answer to this question is contained in our previous remark on the physical impossibility (in this framework) to distinguish states from general densities (the physical effects of a density can always be represented by a state). So, it is only a matter of convenience (and consistency) to decide that ''true states'' correspond to very small delocalization. Of course, it must also be possible to develop some argumentation based on ''decoherence.''

(iii) Equivalence-class of densities: We have seen that physical results only depend on some equivalence class of densities $\mathbf{D}$. At first sight, this can be thought as a weakness of our formalism, since this introduces some degeneracy into the representation. But this is in fact a richness of the formalism, because breaking the degeneracy we can recover quantum mechanics.

(iv) Local $U(1)$ invariance: Since the computation of any physical quantity only depends on $\rho(\vec{p},\vec{q})=|\langle\vec{p},\vec{q}|\phi\rangle|^2$, we can modify the state $\phi(\vec{p},\vec{q})$ by any phase factor $\exp(i\,\theta(\vec{p},\vec{q}))$ without changing physical results.

Now, we can analyze how the classical structure of Poisson brackets can be implemented in this new framework, and how we can recover classical dynamics.

IV. REPRESENTATION OF POISSON BRACKETS IN THE NEW FRAMEWORK

Let $f(\vec{p},\vec{q})$ be an observable (real function). We associate to f a self-adjoint operator $\mathbf{X}_f$ acting on states $\phi \in \mathcal{H}$ by

$$\mathbf{X}_f \phi = -i\{f,\phi\}. \tag{21}$$

Here $\mathbf{X}_f$ defines a generator of a one-parameter unitary group $\mathbf{U}_\alpha$ with

$$\mathbf{U}_\alpha = \exp[-i\alpha \mathbf{X}_f]. \tag{22}$$

Furthermore, if we define the state $|\phi_\alpha\rangle = \mathbf{U}_\alpha |\phi\rangle$, we have

$$i\frac{\partial}{\partial \alpha}|\phi_\alpha\rangle = \mathbf{X}_f|\phi_\alpha\rangle \quad \text{or} \quad \frac{\partial}{\partial \alpha}\phi_\alpha = -\{f,\phi_\alpha\}. \tag{23}$$

Now it is obvious that $\mathbf{U}_\alpha$ acts on unbounded states $|\vec{p},\vec{q}\rangle$ exactly as the classical transformation (3):

$$\mathbf{U}_\alpha |\vec{p},\vec{q}\rangle = |\vec{p_\alpha},\vec{q_\alpha}\rangle, \tag{24}$$

where $(\vec{p_\alpha},\vec{q_\alpha})$ is the trajectory with initial conditions $(\vec{p},\vec{q})$.

So $\mathbf{U}_\alpha$ maps states into states.

For a classical observable g, and the associated operator $\mathbf{g}$, the transformed operator $\mathbf{g}_\alpha$ is $\mathbf{U}_\alpha^\dagger \mathbf{g} \mathbf{U}_\alpha$.

Due to (24), $\mathbf{g}_\alpha$ is also a self-adjoint operator associated with a classical observable g_α and

$$\frac{\partial}{\partial \alpha}\mathbf{g}_\alpha = i[\mathbf{X}_f,\mathbf{g}_\alpha] \quad \text{or} \quad \frac{\partial}{\partial \alpha} g_\alpha = \{f,g_\alpha\}. \tag{25}$$

Moreover, the commutator $[\mathbf{X}_f,\mathbf{X}_g]$ of two operators $\mathbf{X}_f$ and $\mathbf{X}_g$ is given by

$$i[\mathbf{X}_f,\mathbf{X}_g] = \mathbf{X}_{\{f,g\}}. \tag{26}$$

So the linear mapping $f \to \mathbf{X}_f$ is a representation of the action induced by f through Poisson brackets. The equation (26) shows that $i[\cdot,\cdot]$ is a representation of $\{\cdot,\cdot\}$.

Nevertheless, since $\mathbf{X}_f = 0$ for $f = \text{const}$, we cannot recover the special value $\{p_i,q_j\} = \delta_{ij}$.

Remark on the "active" and "passive" representations of observables: From general quantum axiomatics, each $\mathbf{X}_f$ as a self-adjoint operator defines mathematically a possible observable (even if physically $\mathbf{X}_f$ is not a classical object because of our axiom of classicity). Then, on a purely mathematical point of view, we have two possible self-adjoint operators deducible from the classical quantity $f(x)$:

(i) $\mathbf{f} = \int dx\ f(x)|x\rangle\langle x|$,
(ii) $\mathbf{X}_f$.

Here $\mathbf{f}$ defines the observable as a ''passive object,'' which is a datum, while $\mathbf{X}_f$ is the ''active version'' of f as the action induced by f through Poisson brackets. Moreover $\mathbf{f}$ and $\mathbf{X}_f$ are independent, because $[\mathbf{f},\mathbf{X}_f] = 0$.

Then, while in the ''passive representation,'' all classical observables $\mathbf{f}$ commute; in the ''active representation'' commutators are related to Poisson brackets [Eq. (26)].

So, from the mathematical point of view, $\mathbf{X}_f$ is an alternative representation of the classical quantity $f(x)$. Unfortunately, on a physical level, $\mathbf{f}$ and $\mathbf{X}_f$ do not have the same homogeneity: $\mathbf{X}_f$ is homogeneous to $\mathbf{f}$ divided by an action. So, as long as we do not have a specific unit of action, we cannot follow up this process.

To end this remark, we want to indicate that this idea of representing classical observables by a pair of operators has already been used by George and Prigogine[29] using the superoperator formalism.

V. CLASSICAL DYNAMICS IN THE NEW FRAMEWORK

A. New formulation of equations of motion

From the general axioms, we know that the evolution of states is given by the unitary operators $\mathbf{U}_{t,t_0}$ such that $\phi_t=\mathbf{U}_{t,t_0}(\phi_{t_0})$. Moreover, Sec. II B 1 specifies that dynamics is defined by the data of the classical Hamiltonian H (eventually time dependent), and we have seen in Secs. II B 2 and 3 that ''weak dynamical equations'' (7) are a more general formula to specify dynamics. So, we assume in the following that Eqs. (7) are our basic equations of motion.

Since we have seen in Sec. III B 3 the equivalence between quantum and classical formula for expectation values of classical observables using the classical density $\rho(\vec{p},\vec{q},t)=|\langle\vec{p},\vec{q}|\phi_t\rangle|^2$, equations (7) can be written

$$\frac{d}{dt}\langle\phi_t|\vec{\mathbf{q}}|\phi_t\rangle=\langle\phi_t|\overrightarrow{\nabla}_p H(\vec{\mathbf{p}},\vec{\mathbf{q}},t)|\phi_t\rangle,$$

$$\frac{d}{dt}\langle\phi_t|\vec{\mathbf{p}}|\phi_t\rangle=-\langle\phi_t|\overrightarrow{\nabla}_q H(\vec{\mathbf{p}},\vec{\mathbf{q}},t)|\phi_t\rangle, \tag{27}$$

where $\overrightarrow{\nabla}_p H$ and $\overrightarrow{\nabla}_q H$ can be seen as functions of the operators $\vec{\mathbf{p}}$ and $\vec{\mathbf{q}}$, since $\vec{\mathbf{p}}$ and $\vec{\mathbf{q}}$ commute.

Equations (27) are our new basic dynamical equations.

B. Classical dynamics

1. Primary equations

Any operator $\mathbf{f}$ associated with the classical observable $f(\vec{p},\vec{q})$ can be written as $\mathbf{f}=f(\vec{\mathbf{p}},\vec{\mathbf{q}})$, since $\vec{\mathbf{p}}$ and $\vec{\mathbf{q}}$ commute. So the expectation value $\langle\mathbf{f}\rangle_t$ verifies

$$\langle\mathbf{f}\rangle_t=\langle\phi_t|f(\vec{\mathbf{p}},\vec{\mathbf{q}})|\phi_t\rangle=\langle\phi_0|f(U^\dagger_{t,t_0}\vec{\mathbf{p}}U_{t,t_0},U^\dagger_{t,t_0}\vec{\mathbf{q}}U_{t,t_0})|\phi_0\rangle. \tag{28}$$

Now we introduce the operators $\vec{\mathbf{q}}(t)$ and $\vec{\mathbf{p}}(t)$ defined as

$$\begin{aligned}\vec{\mathbf{q}}(t)&=U^\dagger_{t,t_0}\vec{\mathbf{q}}U_{t,t_0},\\ \vec{\mathbf{p}}(t)&=U^\dagger_{t,t_0}\vec{\mathbf{p}}U_{t,t_0}.\end{aligned} \tag{29}$$

Equations for expectation values (27) become

$$\begin{aligned}\langle\phi_0|\frac{d}{dt}\vec{\mathbf{q}}(t)|\phi_0\rangle&=\langle\phi_0|\overrightarrow{\nabla}_p H(\vec{\mathbf{p}}(t),\vec{\mathbf{q}}(t),t)|\phi_0\rangle,\\ \langle\phi_0|\frac{d}{dt}\vec{\mathbf{p}}(t)|\phi_0\rangle&=-\langle\phi_0|\overrightarrow{\nabla}_q H(\vec{\mathbf{p}}(t),\vec{\mathbf{q}}(t),t)|\phi_0\rangle.\end{aligned} \tag{30}$$

Since Eqs. (30) **must be valid for any state** ϕ_0, we deduce the following equations of evolution for the operators $\vec{\mathbf{q}}(t)$ and $\vec{\mathbf{p}}(t)$:

$$\begin{aligned}\frac{d}{dt}\vec{\mathbf{q}}(t)&=\overrightarrow{\nabla}_p H(\vec{\mathbf{p}}(t),\vec{\mathbf{q}}(t),t),\\ \frac{d}{dt}\vec{\mathbf{p}}(t)&=-\overrightarrow{\nabla}_q H(\vec{\mathbf{p}}(t),\vec{\mathbf{q}}(t),t),\end{aligned} \tag{31}$$

which are the natural formulation of the equations of motion in the new framework, and they can be symbolically identified with the Hamiltonian equations (4).

2. Operator of evolution and Liouville equation

Now if we look at the operator $\mathbf{X}_H(t)$ as defined in Sec. III C,

$$\mathbf{X}_H(t) = -i(\overrightarrow{\nabla}_p H \cdot \overrightarrow{\nabla}_q - \overrightarrow{\nabla}_q H \cdot \overrightarrow{\nabla}_p). \tag{32}$$

We have

$$\begin{aligned} [\mathbf{X}_H(t), \vec{\mathbf{q}}] &= -i\overrightarrow{\nabla}_p H(\vec{\mathbf{p}}, \vec{\mathbf{q}}, t), \\ [\mathbf{X}_H(t), \vec{\mathbf{p}}] &= i\overrightarrow{\nabla}_q H(\vec{\mathbf{p}}, \vec{\mathbf{q}}, t). \end{aligned} \tag{33}$$

Let us define $\mathbf{U}_{t,t_0}$ as the unitary operator generated by $\mathbf{X}_H(t)$:

$$\begin{aligned} i\frac{d}{dt}\mathbf{U}_{t,t_0} &= \mathbf{X}_H(t)\mathbf{U}_{t,t_0}, \\ \mathbf{U}_{t_0,t_0} &= \mathbf{1}. \end{aligned} \tag{34}$$

A simple checking shows that now the operators $\vec{\mathbf{q}}(t)$ and $\vec{\mathbf{p}}(t)$ defined by (29) verify Eqs. (31) and then $\mathbf{U}_{t,t_0}$ is the operator of evolution. We deduce that for any state ϕ_0 at time t_0 we have

$$\phi(t) = \mathbf{U}_{t,t_0}(\phi_0). \tag{35}$$

Then using the definition of $\mathbf{U}_{t,t_0}$, the wave function $\phi(\vec{p},\vec{q},t)$ verifies the Liouville equation:

$$\frac{\partial \phi}{\partial t} = -\{H, \phi\}. \tag{36}$$

Because this differential equation is of order one with real coefficients, we recover that the probability density $\rho(\vec{p},\vec{q},t) = |\phi(\vec{p},\vec{q},t)|^2$ must also verify the Liouville equation. Now, since any density operator $\mathbf{D}$ can be split as $\mathbf{D} = \Sigma_n p_n |\phi_n\rangle\langle\phi_n|$, we recover that any classical density $\rho(\vec{p},\vec{q},t) = \langle \vec{p},\vec{q}|D_t|\vec{p},\vec{q}\rangle$ must verify also the Liouville equation. Prugovečki also finds equation (36) in his monograph Ref. 6, (Chap. 3) for a ''classical wave function,'' but our procedure based on ''weak dynamical equations'' is completely different.

We see that starting only from equations for expectation values, and even if ''δ'' densities are excluded, we recover completely the equations of standard classical mechanics. This result is due to the fact that we can find densities as close as possible to ''δ.''

VI. THE QUANTIZATION PROCESS

A. The problem of unclassical observables: What is quantization?

Our framework of classical mechanics is based on the ''axiom of classicity'' that limits the range of physical observables. We analyze here the possibility of giving a physical meaning to some unclassical observable (and then breaking down our axiom).

The starting point of our procedure is the representation of classical events given by our mapping Π. As we can verify easily, for each classical event ''A'' that gives a nonzero projector $\Pi(A)$, $\Pi(A)$ corresponds in fact to an infinite dimensional subspace of $\mathcal{H}$. This means that the one-dimensional projectors $\boldsymbol{\pi}_\phi = |\phi\rangle\langle\phi|$ that represent the ''minimal events'' and define states are not classical events. Since we only possess the projectors $\Pi(A)$ to select particles, we can never decide if a particle is in a given state ϕ (this is because we cannot distinguish states from general densities). So in this classical picture, a particle is described by a mathematical object that cannot be completely specified from experiment (exactly as points in phase space that cannot be experi-

mently reached). But this means that we cannot specify any more what is really the full space $\mathcal{S}$ of all ϕ. So we can imagine two different situations:

(i) The space $\mathcal{S}=\mathcal{H}$, and then all states are possible.
(ii) The space $\mathcal{S}$ is only a proper subspace of $\mathcal{H}$.

In the latter case, we can define the orthogonal projector $\boldsymbol{\pi}_{\mathcal{S}}$ on $\mathcal{S}$. By definition $\boldsymbol{\pi}_{\mathcal{S}}$ cannot be a classical event, but nevertheless $\boldsymbol{\pi}_{\mathcal{S}}$ has a physical meaning as the projector on all physical states. So we can give a physical meaning to an unclassical object and, moreover this ''unclassical event'' must always be realized since all physical states ϕ must verify $\boldsymbol{\pi}_{\mathcal{S}}\phi=\phi$.

Another way to present the problem is to look at the full set of orthogonal projectors as the set of all symbolic logical questions on a system. In the framework of classical mechanics, only a subset of questions [the projectors $\Pi(A)$] possesses a physical answer (true or false). The remainder must be either unphysical questions, or *undecidable* questions. The ''question $\boldsymbol{\pi}_{\mathcal{S}}$'' is undecidable.

So we have the opportunity of ''creating'' a new logical framework by postulating that some ''question $\boldsymbol{\pi}_{\mathcal{S}}$'' has a positive answer. Of course, we need physical arguments to choose $\boldsymbol{\pi}_{\mathcal{S}}$ in order to preserve basic physical results. In our point of view, quantization corresponds to this kind of postulate.

In the following, we assume that some proper subspace $\mathcal{S}$ of $\mathcal{H}$ (represented by $\boldsymbol{\pi}_{\mathcal{S}}$) contains all possible states.

We analyze first the consequences of this postulate and then we give the arguments to choose $\boldsymbol{\pi}_{\mathcal{S}}$.

B. Consequences of a quantization

Of course, we must assume that all general axioms listed in Secs. III A 1–4 are always valid, but on the Hilbert space $\mathcal{S}$. Moreover, we must analyze separately how to take into account our axiom of classicity.

First of all, since the basic objects of our formalism are now operators on $\mathcal{S}$ which is a subspace of $\mathcal{H}$, we want to specify the relation between self-adjoint operators on $\mathcal{H}$ and self-adjoint operators on $\mathcal{S}$. Since $\boldsymbol{\pi}_{\mathcal{S}}$ is a projector, a self-adjoint operator $\mathbf{a}$ on $\mathcal{H}$ corresponds to a self-adjoint operator on $\mathcal{S}$ if and only if

$$\boldsymbol{\pi}_{\mathcal{S}}\cdot\mathbf{a}\cdot\boldsymbol{\pi}_{\mathcal{S}}=\mathbf{a}. \tag{37}$$

So this relation (37) must now be verified for both observables and densities. Now we analyze how classical observables are modified.

1. The "correspondence principle"

Let f be a classical observable and $\mathbf{f}=\int f(x)|x\rangle\langle x|dx$ be the corresponding operator. For any density $\mathbf{D}$, we have seen that the expectation value of f is given by $\langle f\rangle=\mathrm{Tr}(\mathbf{D}\cdot\mathbf{f})$. But now the only possible densities verify Eq. (37) and then $\langle f\rangle$ can be written as $\langle f\rangle=\mathrm{Tr}(\mathbf{D}\cdot\boldsymbol{\pi}_{\mathcal{S}}\cdot\mathbf{f}\cdot\boldsymbol{\pi}_{\mathcal{S}})$. So in any physical situation, we only need the self-adjoint operator $\mathbf{f}_{\mathcal{S}}=\pi_{\mathcal{S}}\mathbf{f}\pi_{\mathcal{S}}$, and by construction $\mathbf{f}_{\mathcal{S}}$ defines a true observable on the physical Hilbert space $\mathcal{S}$.

So it is natural to assume that the operator $\mathbf{f}_{\mathcal{S}}=\boldsymbol{\pi}_{\mathcal{S}}\cdot\mathbf{f}\cdot\boldsymbol{\pi}_{\mathcal{S}}$ *defines the new version of the classical observable* **f:** *we call* $\mathbf{f}_{\mathcal{S}}$ *the quantized observable associated with* **f**.

This allows us to justify and not to postulate the famous ''correspondence principle'' that gives quantized version of classical observable. We will see later that *almost* all these quantized observables correspond effectively to the usual quantum operators.

2. Remarks on quantized observables

Of course, the simplest quantized observables are $\boldsymbol{\pi}_{\mathcal{S}}\vec{\mathbf{p}}\boldsymbol{\pi}_{\mathcal{S}}$ and $\boldsymbol{\pi}_{\mathcal{S}}\vec{\mathbf{q}}\boldsymbol{\pi}_{\mathcal{S}}$. Since $\vec{\mathbf{p}}$ and $\vec{\mathbf{q}}$ are the basic objects of our classical framework, $\boldsymbol{\pi}_{\mathcal{S}}\vec{\mathbf{p}}\boldsymbol{\pi}_{\mathcal{S}}$ and $\boldsymbol{\pi}_{\mathcal{S}}\vec{\mathbf{q}}\boldsymbol{\pi}_{\mathcal{S}}$ must become the new fundamental observables; and these new operators do not commute in general.

In the case of more complex classical observables, some ambiguity may exist in the definition of the quantized version.

For example, if we look at the quantized observable $\vec{\mathbf{L}}$ associated with the classical orbital momentum $\vec{l}=\vec{p}\wedge\vec{q}$, we can say that $\vec{\mathbf{L}}=\overrightarrow{\mathbf{L_1}}=\boldsymbol{\pi}_{\mathcal{S}}\vec{\mathbf{p}}\wedge\vec{\mathbf{q}}\boldsymbol{\pi}_{\mathcal{S}}$ according to our procedure, but we can also define $\vec{\mathbf{L}}=\overrightarrow{\mathbf{L}_2}=1/2(\boldsymbol{\pi}_{\mathcal{S}}\vec{\mathbf{p}}\boldsymbol{\pi}_{\mathcal{S}}\wedge\boldsymbol{\pi}_{\mathcal{S}}\vec{\mathbf{q}}\boldsymbol{\pi}_{\mathcal{S}}-\boldsymbol{\pi}_{\mathcal{S}}\vec{\mathbf{q}}\boldsymbol{\pi}_{\mathcal{S}}\wedge\boldsymbol{\pi}_{\mathcal{S}}\vec{\mathbf{p}}\boldsymbol{\pi}_{\mathcal{S}})$. In both cases we have a well-defined self-adjoint operator, and then a possible observable associated with the classical quantity $\vec{l}$ (in general $\overrightarrow{\mathbf{L_1}}$ and $\overrightarrow{\mathbf{L_2}}$ define two different operators). Of course only $\overrightarrow{\mathbf{L_1}}$ is a direct quantization (according to our procedure); but it is not sufficient to prove that $\overrightarrow{\mathbf{L_1}}$ is the right answer, because orbital momentum is classically the generator of rotations and we can demand that this general physical property remains unchanged. This means that, for complex observables, we need generally some external arguments on the physical role played by the observable (for example, as generator of symmetry) to decide which is the right quantized object. We will see in Sec. X B, precisely in the case of $\vec{l}=\vec{p}\wedge\vec{q}$, that we must examine carefully different possible observables to deduce the right one.

3. Quantization of classical events

As seen before, classical events are represented by the projectors $\Pi(A)$. Our quantization transforms $\Pi(A)$ into $\Pi_{\mathcal{S}}(A)=\boldsymbol{\pi}_{\mathcal{S}}\Pi(A)\boldsymbol{\pi}_{\mathcal{S}}$. But now $\Pi_{\mathcal{S}}(A)$ is no longer an orthogonal projector and cannot be associated with a ''true-false type question.'' $\Pi_{\mathcal{S}}(A)$ must be interpreted as a ''semi-classical event'' or as a quasiprojector. This label becomes more obvious if we remark that

$$\Pi_{\mathcal{S}}(A)=\int_A d^3\vec{p}\,d^3\vec{q}\,\boldsymbol{\pi}_{\mathcal{S}}|\vec{p},\vec{q}\rangle\langle\vec{p},\vec{q}|\,\boldsymbol{\pi}_{\mathcal{S}}, \tag{38}$$

while

$$\mathbf{1}_{\mathcal{S}}=\boldsymbol{\pi}_{\mathcal{S}}=\int d^3\vec{p}\,d^3\vec{q}\,\boldsymbol{\pi}_{\mathcal{S}}|\vec{p},\vec{q}\rangle\langle\vec{p},\vec{q}|\,\boldsymbol{\pi}_{\mathcal{S}}. \tag{39}$$

The states $\{|\xi_{\vec{p},\vec{q}}\rangle=\boldsymbol{\pi}_{\mathcal{S}}|\vec{p},\vec{q}\rangle\}$ are no longer a ''continuous orthogonal basis,'' but they verify the previous closure relation on the physical Hilbert space $\mathcal{S}$. So, these states define in fact an overcomplete basis and can be seen as ''semi-classical states.'' In Sec. XI, we detail this point in direct connection with Prugovečki's work.

Now, we can analyze what kind of arguments can be used to specify the projector $\boldsymbol{\pi}_{\mathcal{S}}$.

C. Our arguments to choose a quantization

Our arguments for quantization are based on the physical existence of a fundamental group of transformations acting on phase space, namely the symmetry group. As indicated in Sec. II C, the symmetry group is the Galilei group G (up to some discrete transformations). So we look for a representation of the group G on the Hilbert space $\mathcal{H}$ in such a way that classical objects are always transformed in the same way.

1. How to represent the Galilei group

Classically an observable $f(\vec{p},\vec{q})$ is transformed into $f_u=f\circ u^{-1}$ in a symmetry $u\in G$. Now, the operator associated with f_u is

$$\mathbf{f}_u=\int d^3\vec{p}\,d^3\vec{q}\,(f\circ u^{-1})(\vec{p},\vec{q})|\vec{p},\vec{q}\rangle\langle\vec{p},\vec{q}|. \tag{40}$$

Since any symmetry u preserves the element of volume in phase space, we have

$$\mathbf{f}_u=\int d^3\vec{p}\,d^3\vec{q}\,f(\vec{p},\vec{q})|u(\vec{p},\vec{q})\rangle\langle u(\vec{p},\vec{q})|. \tag{41}$$

Then we can write

$$\mathbf{f}_u = \mathbf{T}_u \cdot \mathbf{f} \cdot \mathbf{T}_u^{\dagger} \tag{42}$$

if we define the action of the operator $\mathbf{T}_u$ on $\mathcal{H}$ as

$$\mathbf{T}_u |\vec{p},\vec{q}\rangle = \exp(i\theta_u(\vec{p},\vec{q}))|u(\vec{p},\vec{q})\rangle, \tag{43}$$

where $\theta_u(\vec{p},\vec{q})$ is an unspecified phase factor [in fact we use the local $U(1)$ invariance].

This means that any projective representation of G preserves classical properties. Of course the choice $\theta_u = 0$ gives a right representation, but this solution is not necessarily the unique one. Moreover, if there exist different nonequivalent representations, we have to make a choice: if this picture is really the right mathematical framework, we must say that only one of these representations is realized.

In the following, we assume that this choice has been done, and then the functions θ_u are specified.

Now, we are ready to develop our arguments for quantization.

2. Arguments for quantization

We remark first that "*phase space is connected by symmetries*": given two points x_0 and x_1 in phase space, we can always find some symmetry $u \in G$ such that $x_1 = u(x_0)$ (the group G is transitive). So, starting from any point x_0, the action of the full symmetry group G generates phase space. This means that the set of physical states is generated by the symmetry group: to specify dynamical properties of a particle, we do not need a larger space than a space generated by G.

Now in the new framework, the points x of phase space are used to build the "continuous orthogonal basis" $\{|x\rangle\}$, so this complete orthogonal basis of $\mathcal{H}$ is generated by the action G (or its representation) on some ket $|x_0\rangle$. But, in general, we can build other (orthogonal) bases with this property: we can find orthogonal basis $\{|y,n\rangle\}$ (where y specifies continuous variables and n is an integer parameter) such that the action of the representation $\{\mathbf{T}_u\}$ on some ket $|y_0,n\rangle$ generates the full set $\{|y,n\rangle\}$ for a fixed n. So each subspace $\mathcal{H}_n$ associated with the projector $\Pi_n = \int dy |y,n\rangle\langle y,n|$ possesses exactly the same property as the initial Hilbert space $\mathcal{H}$. Moreover, two states ϕ_0 and ϕ_1 belonging to two different subspaces $\mathcal{H}_{n_0}$ and $\mathcal{H}_{n_1}$ can never be connected by a symmetry $\mathbf{T}_u$. So it is logical to assume that only one of these subspaces $\mathcal{H}_n$ is sufficient to specify the dynamical properties of a particle.

3. Conclusion

If we demand that the Hilbert space of states verifies the same property as classical phase space, then it is sufficient to assume that the physical Hilbert space $\mathcal{S}$ is a subspace of irreducible representation of the $\{\mathbf{T}_u\}$: this specifies our quantization.

So, logically, we must first analyze all possible projective representations of the Galilei group, before looking for quantization. Nevertheless, since in this article we want to focus on the "right choice," we only develop in the following paragraphs the intuitive arguments leading to the "right" representation compatible with quantum mechanics (there is no mathematical reason to choose this special representation).

VII. REPRESENTATIONS OF THE GALILEI GROUP

The quantum phase space representation of the Galilei group developed in this section can be found in Prugovečki's monograph (Ref. 6 Chap. 1). This representation has been obtained in the context of positive operator value (POV) measures that constitute a "system of covariance" for the Galilei group, and the method was originally developed in the configuration representation.[30]

But, as indicated at the end of the last section, we have no mathematical reason to choose a special representation, starting from our point of view. So we will prove in the following that

assuming the physical existence of some "unit of action" implies the existence of some new symmetry with no classical equivalent, and taking into account this new symmetry, we can guess the representation we look for.

To begin, we look first at the classical situation corresponding to a cancellation of all the coefficients $\theta_u(x)$ introduced in Sec. VI.

A. The classical representation

We can use the generators $\mathbf{X}_f$ induced by Poisson brackets (Sec. IV) to build this classical representation of the Galilei group.

The continuous transformations of the group are space translations, Galilei boosts and rotations that are respectively associated with the observables $\vec{p}$, $\vec{q}$ and $\vec{l}=\vec{q}\wedge\vec{p}$. Namely, using the notations of Sec. IV,

$$\begin{aligned}\exp[-i\vec{q_0}\cdot\mathbf{X}_{\vec{p}}]|\vec{p},\vec{q}\rangle&=|\vec{p},\vec{q}+\vec{q_0}\rangle,\\ \exp[i\vec{p_0}\cdot\mathbf{X}_{\vec{q}}]|\vec{p},\vec{q}\rangle&=|\vec{p}+\vec{p_0},\vec{q}\rangle,\\ \exp[-i\vec{\omega}\cdot\mathbf{X}_{\vec{l}}]|\vec{p},\vec{q}\rangle&=|\mathcal{R}_{\vec{\omega}}(\vec{p}),\mathcal{R}_{\vec{\omega}}(\vec{q})\rangle,\end{aligned}\tag{44}$$

where $\mathcal{R}_{\vec{\omega}}$ is the geometrical rotation.

B. First consequences of a unit of action

In the remainder, we assume that there exists some natural unit of action, namely, the Planck constant h (or the reduced value $\hbar=h/2\pi$), and we are interested in the consequences of this hypothesis for the objects defined on $\mathcal{H}$.

1. New physical symmetry: The symplectic transform

Taking into account the data of $\hbar$, we can define a set of linear operators $\{\mathbf{K}_S(\alpha)\}_{\alpha\in\mathbf{R}}$ (symplectic involutions) depending on the undimensional real parameter α by

$$\langle\vec{p},\vec{q}|\mathbf{K}_S(\alpha)|\vec{p_1},\vec{q_1}\rangle=(\alpha/h)^3\exp[(i\alpha/\hbar)(\vec{q}\cdot\vec{p_1}-\vec{p}\cdot\vec{q_1})].\tag{45}$$

A simple checking proves that

$$\mathbf{K}_S^\dagger(\alpha)=\mathbf{K}_S(\alpha)\quad\text{and}\quad\mathbf{K}_S(\alpha)^2=\mathbf{1}_{\mathcal{H}}.\tag{46}$$

So each $\mathbf{K}_S(\alpha)$ is a self-adjoint unitary operator, that is, an involution, and $\mathbf{K}_S(\alpha)$ depends on the symplectic product $\vec{q}\cdot\vec{p_1}-\vec{p}\cdot\vec{q_1}$.

On the other hand, we can also define the unitary gauge transforms $\mathbf{U}_G(\xi)$ depending on the undimensional real parameter ξ as

$$\mathbf{U}_G(\xi)|\vec{p},\vec{q}\rangle=\exp[-(i\xi/\hbar)\vec{p}\cdot\vec{q}]|\vec{p},\vec{q}\rangle,\tag{47}$$

or

$$\mathbf{U}_G(\xi)=\exp[-(i\xi/\hbar)\vec{\mathbf{p}}\cdot\vec{\mathbf{q}}].\tag{48}$$

These operators $\mathbf{K}_S(\alpha)$ and $\mathbf{U}_G(\xi)$ are the simplest "new symmetries" induced by the existence of $\hbar$.

Combining $\mathbf{K}_S(\alpha)$ and $\mathbf{U}_G(\xi)$, we extend the set $\{\mathbf{K}_S(\alpha)\}_{\alpha\in\mathbf{R}}$ of involutions (unitary self-adjoint operators) to $\{\mathbf{K}_S(\alpha,\xi)\}_{(\alpha,\xi)\in\mathbf{R}^2}$ with

$$\mathbf{K}_S(\alpha,\xi)=\mathbf{U}_G(\xi)^\dagger\mathbf{K}_S(\alpha)\mathbf{U}_G(\xi).\tag{49}$$

Now, each $\mathbf{K}_S(\alpha,\xi)$ is mathematically a new symmetry. But is it really possible that different nonequivalent $\mathbf{K}_S(\alpha,\xi)$ physically exist at the same time?

In fact, we see that modifying α and ξ corresponds to a scaling on $\hbar$. If we say that there exists a **unique** unit of action, only one of these $\mathbf{K}_S(\alpha,\xi)$ must be taken as fundamental. Of course, this is not sufficient to specify the value of α and ξ, so we have to make a choice.

a. Conclusion. We postulate in all the following that **the fundamental symplectic transform** is $\mathbf{K}_S$ defined as

$$\mathbf{K}_S=\mathbf{K}_S(\tfrac{1}{2},\tfrac{1}{2}) \tag{50}$$

or

$$\langle\vec{p},\vec{q}|\mathbf{K}_S|\vec{p_1},\vec{q_1}\rangle=(1/2h)^3\exp[(i/2\hbar)(\vec{q}-\vec{q_1})\cdot(\vec{p}+\vec{p_1})]. \tag{51}$$

(Of course this choice contains some arbitrariness due to other possible unitary equivalent possibilities.)

Now, $\mathbf{K}_S$ must be seen as a new physical symmetry (unclassical) induced by the existence of "h," and then it must be added to the Galilei group.

2. "Passive" and "active" representations of observables

We have seen in Sec. IV that we can mathematically associate to each classical observable f two self-adjoint operators $\mathbf{f}$ and $\mathbf{X}_f$, $\mathbf{X}_f$ being homogeneous to f divided by an action.

So $\mathbf{f}$ and $\hbar\mathbf{X}_f$ are now two possible representations of f with the same physical homogeneity, but $\hbar\mathbf{X}_f$ is a nonclassical observable. Moreover, $\mathbf{f}$ and $\hbar\mathbf{X}_f$ are independent since $[\mathbf{f},\hbar\mathbf{X}_f]=0$. Then, introducing $\hbar$ generates some apparent mathematical ambiguity into the representation of observables: each observable can be defined as a datum or as a generator of a one-parameter group.

We will see in the remainder that our procedure of quantization allows us to remove this ambiguity.

C. New representation of the Galilei group

Now, we consider $\mathbf{K}_S$ as a new physical symmetry, but without any classical equivalent. So it is natural to assume that $\mathbf{K}_S$ does not interfere with the unitary operators $\mathbf{U}_\beta$ that represent the Galilei group, in other words $[\mathbf{K}_S,\mathbf{U}_\beta]=0$. This means that the (self-adjoint) generators $\mathbf{Y}\alpha$ of the Galilei group must verify $[\mathbf{K}_S,\mathbf{Y}\alpha]=0$. Since $\mathbf{K}_S$ is an involution, this last requirement can be written as

$$\mathbf{K}_S\mathbf{Y}\alpha\mathbf{K}_S=\mathbf{Y}\alpha \quad\text{or}\quad \mathbf{Y}\alpha=\tfrac{1}{2}(\mathbf{Y}\alpha+\mathbf{K}_S\mathbf{Y}\alpha\mathbf{K}_S). \tag{52}$$

Now, as seen in Sec. VII A, the classical generators of the Galilei group are $\mathbf{X}_{\vec{p}}=-i\overrightarrow{\nabla}_q$, $\mathbf{X}_{\vec{q}}=i\overrightarrow{\nabla}_p$ and $\mathbf{X}_{\vec{q}\wedge\vec{p}}=(-i)(\vec{q}\wedge\overrightarrow{\nabla}_q+\vec{p}\wedge\overrightarrow{\nabla}_p)$. Using (51) and the fact that $\mathbf{K}_S$ is an involution, we find, after some algebra,

$$\begin{aligned}
\mathbf{K}_S\mathbf{X}_{\vec{p}}\mathbf{K}_S&=(1/2\hbar)(\vec{\mathbf{p}}+\mathbf{K}_S\vec{\mathbf{p}}\mathbf{K}_S)=\mathbf{X}_{\vec{p}},\\
\mathbf{K}_S\mathbf{X}_{\vec{q}}\mathbf{K}_S&=(1/2\hbar)(\vec{\mathbf{q}}-\mathbf{K}_S\vec{\mathbf{q}}\mathbf{K}_S)=-\mathbf{X}_{\vec{q}},\\
\mathbf{K}_S\mathbf{X}_{\vec{q}\wedge\vec{p}}\mathbf{K}_S&=\mathbf{X}_{\vec{q}\wedge\vec{p}}.
\end{aligned} \tag{53}$$

So, $\mathbf{X}_{\vec{p}}$ and $\mathbf{X}_{\vec{q}\wedge\vec{p}}$ (generators of translation and rotations) are effectively invariant under $\mathbf{K}_S$, but not $\mathbf{X}_{\vec{q}}$ (generator of Galilei boosts). So we must modify $\mathbf{X}_{\vec{q}}$ and we define the new generator $\mathbf{X}^{(1)}_{\vec{q}}$ of Galilei boosts as

$$\mathbf{X}_{\vec{q}}^{(1)}=(1/2\hbar)(\vec{\mathbf{q}}+\mathbf{K}_S\vec{\mathbf{q}}\mathbf{K}_S)=\hbar^{-1}\vec{\mathbf{q}}+\mathbf{X}_{\vec{q}}. \tag{54}$$

Now we have

$$\mathbf{K}_S\mathbf{X}_{\vec{q}}^{(1)}\mathbf{K}_S=\mathbf{X}_{\vec{q}}^{(1)}. \tag{55}$$

This new generator $\mathbf{X}_{\vec{q}}^{(1)}$ is invariant under $\mathbf{K}_S$ and the new representation of Galilei boosts becomes

$$\exp[i\vec{p_0}\cdot\mathbf{X}_{\vec{q}}^{(1)}]|\vec{p},\vec{q}\rangle=\exp[(i/\hbar)\vec{p_0}\cdot\vec{q}]|\vec{p}+\vec{p_0},\vec{q}\rangle. \tag{56}$$

As expected from the general arguments of Sec. VI C, we find a supplementary phase factor $\theta=(i/\hbar)\vec{p_0}\cdot\vec{q}$ that modifies the classical representation, but only for Galilei boosts. The representation of translations and rotations is unchanged.

To conclude, taking into account the remarks of Sec. VII B 2 on the representation of observables, we introduce the ''prequantum'' operators $\overrightarrow{\mathbf{P}_*}$, $\overrightarrow{\mathbf{Q}_*}$ and $\overrightarrow{\mathbf{J}_*}$, homogeneous, respectively, to $\vec{p}$, $\vec{q}$ and $\vec{q}\wedge\vec{p}=\vec{l}$:

$$\begin{aligned}
\overrightarrow{\mathbf{P}_*}&=\hbar\mathbf{X}_{\vec{p}}=-i\hbar\overrightarrow{\nabla}_q=(\tfrac{1}{2})(\vec{\mathbf{p}}+\mathbf{K}_S\vec{\mathbf{p}}\mathbf{K}_S),\\
\overrightarrow{\mathbf{Q}_*}&=\hbar\mathbf{X}_{\vec{q}}^{(1)}=\vec{q}+i\hbar\overrightarrow{\nabla}_p=(\tfrac{1}{2})(\vec{\mathbf{q}}+\mathbf{K}_S\vec{\mathbf{q}}\ \ \mathbf{K}_S),\\
\overrightarrow{\mathbf{J}_*}&=\hbar\mathbf{X}_{\vec{l}}=-i\hbar(\vec{q}\wedge\overrightarrow{\nabla}_q+\vec{p}\wedge\overrightarrow{\nabla}_p).
\end{aligned} \tag{57}$$

These operators are the generators of the new representation of the Galilei group through the equations
