The quantized Hall conductance in a plateau is related to the index of a Fredholm operator. In this paper we describe the generic ''phase diagram'' of Fredholm indices associated with bounded and Toeplitz operators. We discuss the possible relevance of our results to the phase diagram of disordered integer quantum Hall systems. © *2001 American Institute of Physics.* [DOI: 10.1063/1.1331317]

The Hall conductance of integer quantum Hall systems is described mathematically by the index of Fredholm operators. (For precise definitions, see below.) In this paper we investigate the phase diagram of the Fredholm index for a few classes of operators. For the algebra of bounded operators, little can be said beyond the fact that the phase diagrams can be arbitrarily complicated. But for the algebra of Toeplitz operators, and other related classes of operators, we establish a kind of a Gibbs phase rule.[1] Typical of our results is the statement that if the system is governed by two parameters, then one should expect jumps by one at phase boundaries and jumps by up to 2 at triple points, while jumps by more than two should never be observed.

We relate this behavior to experimental results, conjectures and open problems that arise in the context of the quantum Hall effect (QHE).[2]

In Sec. I we define Fredholm operators and their indices, and explore the different sorts of phase diagrams that can arise. In Sec. II we recall how Fredholm indices are related to the conductance of Quantum Hall systems. In Sec. III we consider phase diagrams for general bounded operators. In Sec. IV we describe the phase diagram for linear combination of shift operators, and in Sec. V we consider general Toeplitz operators. In Sec. VI we discuss the phase diagrams of soluble models related to the quantum Hall effect, and how they might be modified by disorder. We also discuss the relevance of Toeplitz operators to the quantum Hall effect and present some open problems.

I. FREDHOLM INDICES

A. Basic notions

The following is a brief description of Fredholm operators. For more details, see Refs. 3–5.

Definition 1: A bounded operator F on a separable Hilbert space is Fredholm if there exists a bounded operator B such that $1-FB$ and $1-BF$ are compact. The Fredholm index is defined by

$$\mathrm{Index}(F)=\dim \mathrm{Ker}(F)-\dim \mathrm{Ker}(F^{\dagger}). \tag{1}$$

The simplest example of a Fredholm operator with nonzero index is the unilateral shift operator: Let $e_0,e_1,e_2,\ldots$ be the canonical basis for the Hilbert space $l^2(\mathbb{N})$, and let the operator a act by

$$a(e_n)=\begin{cases} e_{n-1} & \text{if } n>0, \\ 0 & \text{if } n=0. \end{cases} \tag{2}$$

[a)]On leave from the Department of Mathematics, University of Texas, Austin, TX 78712.

The reason for denoting the unilateral shift operator by a is its similarity to the harmonic oscillator lowering operator. The adjoint of a acts by

$$a^\dagger(e_n)=e_{n+1}. \tag{3}$$

Since $1=aa^\dagger=a^\dagger a+|e_0\rangle\langle e_0|$, a is Fredholm. The kernel of a is one dimensional and the kernel of $a^\dagger$ is zero dimensional. Thus $\mathrm{Index}(a)=1$ and $\mathrm{Index}(a^\dagger)=-1$.

Although neither the dimension of $\mathrm{Ker}\,F$ nor that of $\mathrm{Ker}\,F^\dagger$ is stable under deformations of F, the index *is* stable. For any compact operator C, for any bounded operator B, and for ϵ sufficiently small:[4,5]

$$\mathrm{Index}(F)=\mathrm{Index}(F+\epsilon B+C). \tag{4}$$

The following theorem is standard.

Theorem 1: If $A_1,\ldots A_n$ are Fredholm operators, then the product $A_1A_2\cdots A_n$ is also Fredholm, and $\mathrm{Index}\,(A_1\cdots A_n)=\Sigma_{i=1}^n\mathrm{Index}(A_i)$.

If F and F' are Fredholm operators on the same Hilbert space, then there is a continuous path of Fredholm operators from F to F' if and only if $\mathrm{Index}(F)=\mathrm{Index}(F')$. (By continuous, we mean relative to the operator norm.) Put another way, the path components of $\mathrm{Fred}(H)$, the space of Fredholm operators on H, are indexed by the integers. The nth path component is precisely the set of Fredholm operators of index n.[4]

B. Phase diagrams

Our main concern in this paper is the following problem: Suppose one interpolates between Fredholm operators with different indices. What can one say about the way the indices change? Another way of phrasing this is: What is the phase diagram of Fredholm indices?

The answer to this question depends on the choice of the embedding space. In the space of bounded operators, the ''phases''—each labeled by its index—are open sets. But the boundary between phases, as we shall explain, is rather wild: A point on the boundary of one phase is also on the boundary of *every other* phase. This behavior is difficult to visualize.

Another class of embedding spaces that we consider is associated with Toeplitz operators with various regularity assumptions on a class of functions. Here, at least if the functions are sufficiently smooth, the boundaries between phases have a simple structure and the phase diagrams satisfy simple rules that have the flavor of Gibbs' phase rule.[1] Typical of our results is the statement that under appropriate conditions, phases whose indices differ by one have a common boundary whose codimension is one, and phases whose indices differ by two meet on a set of codimension two, etc. Figure 1 is an example of one of the phase diagrams we obtain.

II. THE HALL CONDUCTANCE AS A FREDHOLM INDEX

Theories of the quantum Hall effect are roughly of two kinds: those that focus on the bulk of the Hall and those that focus on the edge.[2] It was pointed out by Ref. 6 that the bulk-edge duality is an illustration of the *holographic principle*. In either approach, the quantized Hall conductance can be related to a Fredholm index.

A. Theories of the bulk

It is common knowledge that the Hall conductance can be identified with a Chern number.[7] For noninteracting electrons in two dimensions, this result is a special case of the fact that the Hall conductance is a Fredholm index. Since this is not common knowledge, we recall how Chern numbers and Fredholm indices are related.

For noninteracting electrons in two dimensions with the Fermi energy in a gap, TKN[2], showed that the Hall conductance for Landau Hamiltonians with *periodic* potential, is related to a Chern number.[8] The (magnetic) Brillouin zone associated with the periodicity plays a role in this theory. Because of this, the interpretation of the Hall conductance as a Chern number does not

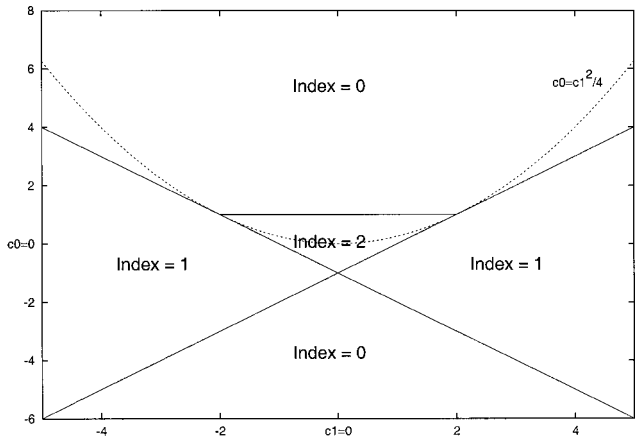

FIG. 1. A phase diagram for the Fredholm index of $F=a^2+c_1a+c_0$.

carry over to random or even quasiperiodic potentials nor to ''irrational magnetic fields,'' all of which have no (classical) Brillouin zone. Although the quantization of the Hall conductance can be established in these cases by a limiting argument,[9,7] the interpretation as a Chern number does not survive.

Bellissard,[10] in a work that had impact on noncommutative geometry,[11,12] showed that the Hall conductance with *ergodic* potential, be it periodic, quasiperiodic or random, and real magnetic field, rational or not, is a Fredholm index. This result was derived in Ref. 13 without using noncommutative geometry.

More precisely, consider the (infinite dimensional) spectral projection P on the states below the Fermi energy E_F for the one particle Hamiltonian in the plane. Let U be the multiplication operator $e^{i\theta}$, where θ is the usual polar angle in the plane. U is a singular gauge transformation that introduces an Aharonov–Bohm flux tube at the origin of the Euclidean plane. The Hall conductance is the Fredholm index of PUP thought of as an operator on the range of P.[14] Since the Fredholm index does not need a Brillouin zone, this approach offers a natural framework that accounts for the quantization and stability of the Hall conductance.

B. Theories of the edge

Finite quantum Hall systems have chiral edge currents.[15,16] Consider the case that the boundary is a circle of circumference L. The dispersion relation of the edge states is approximately linear in a small neighborhood of the Fermi energy and the Hamiltonian for a single edge channel, with velocity v_F, is

$$H=-i\frac{v_F}{L}\partial_\theta. \tag{5}$$

Now, the projection P is associated with the occupied edge states, $e^{-im\theta}$ with $m\geqslant m_0$. Introducing a flux tube into the system is associated with the unitary $U=e^{i\theta}$ and sends $H\to UHU^\dagger$. This leads to the spectral flow of the edge states. PUP is the unilateral shift operator a and the number of edge states that cross the Fermi energy is Index $PUP=1$. By an argument of Halperin[15] this is also the Hall conductance.

An extension of this idea to Harper models with an edge is described in Ref. 17.

III. THE PHASE DIAGRAM FOR BOUNDED OPERATORS

We begin with the space of bounded operators with the topology defined by the operator norm, and we wish to understand the phase diagram of a generic family of such operators. As we shall explain, the phase diagram in the entire space is quite wild: Any point on the boundary of the ''index=k'' phase is also on the boundary of every other phase.

To understand this bizarre behavior, recall that the zero operator (which is *not* a Fredholm operator) is on the boundary of every phase: Zero is the limit, as $\varepsilon \to 0$, of εa^n, with a of Eq. (2), for any n. The point of the theorem is that similar behavior occurs at all boundary points.

Theorem 2: Let U_n be the set of Fredholm operators of index n. Every point on the boundary of U_n is also on the boundary of U_m, for every integer m.

Proof: Let A be a (not Fredholm) operator on the boundary of U_n. Given $\epsilon > 0$, we must find an operator in U_m within a distance ϵ of A.

Suppose that the kernel and cokernel of A are infinite dimensional, and that there is a gap in the spectrum of $A^\dagger A$ at zero. (If this is not the case, we may perturb A by an arbitrarily small amount to make it so.) Now let B be a unitary map from the kernel of A to the cokernel. Let P (P'), be the orthogonal projection onto $\ker(A)$ [$\mathrm{coker}(A)$], and let a be a shift operator on $\ker(A)$. For each $m \geqslant 0$, $A(\epsilon) = A + \epsilon B a^m P$ has a bounded right inverse

$$A^\dagger \frac{1}{P' + AA^\dagger} P'_\perp + \frac{1}{\epsilon} (a^\dagger)^m B^\dagger P'. \tag{6}$$

It follows that the cokernel of $A(\epsilon)$ is empty. It is easy to see that the kernel of $A(\epsilon)$ is m dimensional hence $\mathrm{Index}(A(\epsilon)) = m$. Similarly, $A + \epsilon B (a^\dagger)^m P$ has index $-m$. ■

IV. LINEAR COMBINATIONS OF SHIFTS

In this section and the next we show that there are interesting and simple ''generic'' phase diagrams of Fredholm indices in some finite-dimensional spaces, and in some infinite-dimensional spaces with sufficiently fine topologies. We shall also see how control is lost as the space is enlarged and the topology is coarsened.

A. Shift by one

We begin by considering linear combinations of the shift operator a and the identity operator 1. That is, we consider the operator

$$A = c_1 a + c_0,$$

where c_1 and c_0 are constants.

Theorem 3: If $|c_1| \neq |c_0|$, then A is Fredholm. The index of A is 1 if $|c_1| > |c_0|$ and zero if $|c_1| < |c_0|$. If $|c_1| = |c_0|$, then A is not Fredholm.

Proof: First suppose $|c_0| > |c_1|$. Then A is invertible:

$$A^{-1} = c_0^{-1}(1 + (c_1/c_0)a)^{-1} = \sum_{n=0}^{\infty} \frac{(-1)^n c_1^n}{c_0^{n+1}} a^n,$$

as the sum converges absolutely. Thus A has neither kernel nor cokernel, and has index zero.

If $|c_1| > |c_0|$, then the kernel of A is one dimensional, namely all multiples of $|\psi\rangle = \Sigma_{n=0}^{\infty} z_0^n e_n$, where $z_0 = -c_0/c_1$. Notice how the norm of $|\psi\rangle$ goes to infinity as $|z_0| \to 1$. However, $A^\dagger$ has no kernel, since for any unit vector $|\phi\rangle$, $\|A^\dagger|\phi\rangle\| = \|\overline{c_1} a^\dagger |\phi\rangle + \overline{c_0}|\phi\rangle\| \geqslant \|\overline{c_1} a^\dagger |\phi\rangle\| - \|\overline{c_0}|\phi\rangle\| = |c_1| - |c_0|$. Thus the index of A is 1.

If $|c_1| = |c_0|$, then A is at the boundary between index 1 and index 0, and so cannot be Fredholm. ■

B. Finite linear combinations of shifts

Next we consider linear combinations of $1,a,a^2,\ldots$ up to some fixed a^n. That is, we consider operators of the form

$$A=c_n a^n+c_{n-1}a^{n-1}+\cdots+c_0. \tag{7}$$

This is closely related to the polynomial

$$p(z)=c_n z^n+\cdots+c_0. \tag{8}$$

Theorem 4: If none of the roots of p lie on the unit circle, then A is Fredholm, and the index of A equals the number of roots of p inside the unit circle, counted with multiplicity. If any of the roots of p lie on the unit circle, then A is not Fredholm.

Proof: The polynomial $p(z)$ factorizes as $p(z)=c_k\Pi_{i=1}^{k}(z-\zeta_i)$, where k is the degree of p (typically $k=n$, but it may happen that $c_n=0$). But then $A=c_k\Pi_{i=1}^{k}(a-\zeta_i)$. If none of the roots ζ_i lie on the unit circle, then each term in the product is Fredholm, so the product is Fredholm, and the index of the product is the sum of the indices of the factors. By Theorem 3, this exactly equals the number of roots ζ_i inside the unit circle.

If any of the roots lie on the unit circle, then a small perturbation can push those roots in or out, yielding Fredholm operators with different indices. This borderline operator therefore cannot be Fredholm. ■

The last theorem easily generalizes to linear combination of left shifts and right shifts. The index of an operator

$$A=c_n a^n+\cdots+c_1 a+c_0+c_{-1}a^\dagger+\cdots+c_{-m}(a^\dagger)^m \tag{9}$$

equals the number of roots of

$$p(z)=\sum_{i=-m}^{n} c_i z^i \tag{10}$$

inside the unit circle, minus the degree of the pole at $z=0$ (that is m, unless $c_{-m}=0$). This follows from the fact that

$$A=\left(\sum_{i=-m}^{n} c_i a^{i+m}\right)(a^\dagger)^m. \tag{11}$$

Since there is no qualitative difference between combinations of left shifts and combinations of both left and right shifts, we restrict our attention to left shifts only, and consider families of operators of the form (7).

Theorem 5: In the space of complex linear combinations of $1,a,\ldots,a^n$, almost every operator is Fredholm. For every $k\leqslant n$, the points where the index can jump by k (by which we mean the common boundaries of regions of Fredholm operators whose indices differ by k) is a set of real codimension k.

In the space of real linear combinations of $1,a,\ldots,a^n$, almost every operator is Fredholm. For every $k\leqslant n$, the points where the index jumps by k is a stratified space, the largest stratum of which has real codimension $\lfloor (k+1)/2\rfloor$, where $\lfloor x\rfloor$ denotes the integer part of x.

Proof: Our parameter space is the space of coefficients c_i, or equivalently the space of polynomials of degree $\leqslant n$. This is either $\mathbb{R}^{n+1}$ or $\mathbb{C}^{n+1}$, depending on whether we allow real or complex coefficients. In either case, the set U_k of Fredholm operators of index k is identical to the set of polynomials with k roots inside the unit circle and the remaining $n-k$ roots outside. (If $c_n=0$, we say there is a root at infinity; if $c_n=c_{n-1}=0$, there is a double root at infinity, and so on. Counting these roots at infinity, there are always exactly n roots in all.) The boundary of U_k is the set of polynomials with at most k roots inside the unit circle, at most $n-k$ outside the unit

circle, and at least one root on the unit circle. (Strictly speaking, the zero polynomial is also on this boundary. This is of such high codimension that it has no effect on the phase portrait we are developing.) We consider the common boundary of U_k and $U_{k'}$. If $k<k'$, a nonvanishing polynomial is on the boundary of both U_k and $U_{k'}$ if it has at most k roots inside the unit circle and at most $n-k'$ roots outside. It must therefore have at least $k'-k$ roots on the unit circle.

If we are working with complex coefficients, this is a set of codimension $k'-k$. The roots themselves, together with an overall scale c_n, can be used to parametrize the space of polynomials. For each root, being on the unit circle is codimension 1, while being inside or outside are open conditions. Since the roots are independent, placing $k'-k$ roots on the unit circle is codimension $k'-k$.

If we are working with real coefficients, the roots are not independent, as nonreal roots come in complex conjugate pairs. Thus, the common boundary of U_k and $U_{k'}$ breaks into several strata, depending on how many real roots and how many complex conjugate pairs lie on the unit circle. If $k'-k$ is even, the biggest stratum consists of having $(k'-k)/2$ pairs, and has codimension $(k'-k)/2$. If $k'-k$ is odd, the biggest stratum consists of having $(k'-k-1)/2$ pairs and one real root on the unit circle, and has codimension $(k'+1-k)/2$. ■

Theorem 5 is illustrated in Fig. 1, where the phase portrait is shown for $n=2$ with real coefficients, with c_2 fixed to equal 1. The points above the parabola $c_0=c_1^2/4$ have complex conjugate roots, while points below have real roots. Notice that the transition from index 2 to index 0 occurs at an isolated point when the roots are real, but on an interval when the roots come in complex-conjugate pairs.

It is clear that an almost identical theorem applies to linear combinations of left shifts up to a^n and right shifts up to $(a^\dagger)^m$. The results are essentially independent of n and m (their only effect being to limit the size of possible jumps to $n+m$). We can therefore extend the results to the space of all (finite) linear combinations of left and right shifts, which is topologized as the union over all n and m of the spaces considered above. Our result, restated for that space, is

Theorem 6: In the space of finite complex linear combinations of left and right shifts of arbitrary degree, almost every operator is Fredholm. For every integer $k\geqslant 1$, the points where the index can jump by k (by which we mean the common boundaries of regions of Fredholm operators whose indices differ by k) is a set of real codimension k.

If we restrict the coefficients to be real, then, for every $k\leqslant n$, the points where the index jumps by k is a stratified space, the largest stratum of which has real codimension $\lfloor (k+1)/2 \rfloor$.

V. TOEPLITZ OPERATORS

Although Theorem 6 refers to an infinite-dimensional space, this space is still extremely small—each point is a *finite* linear combination of shifts. In this section we consider *infinite* linear combinations of shifts. This is equivalent to studying Toeplitz operators.

Definition 2: The Hardy space H is the subspace of $L^2(S^1)$ consisting of functions whose Fourier transforms have no negative frequency terms. Equivalently, if we give $L^2(S^1)$ a basis of Fourier modes $e_n=e^{in\theta}$, where the integer n ranges from $-\infty$ to ∞, then H is the closed linear span of $e_0, e_1, e_2, \ldots$.

We think of S^1 as sitting in the complex plane, with $z=e^{i\theta}$. Now let $f(z)$ be a bounded, measurable function on S^1, and let P be the orthogonal projection from $L^2(S^1)$ to H. If $|\psi\rangle \in H$, then $|f\psi\rangle$ (pointwise product) is in $L^2(S^1)$, and $P|f\psi\rangle \in H$. We define the operator T_f by

$$T_f|\psi\rangle = P|f\psi\rangle. \tag{12}$$

Definition 3: An operator of the form (12) is called a Toeplitz operator. We call a Toeplitz operator T_f continuous if the underlying function f is continuous, and apply the terms ''differentiable,'' ''smooth,'' and ''analytic'' similarly.

Remark: Toeplitz operators can be represented by semi-infinite matrices that have constant entries on diagonals, and the various classes we have defined correspond to the decay away from the main diagonal.

Notice that

$$T_{e_m} e_n = \begin{cases} e_{n+m} & \text{if } n+m \geqslant 0, \\ 0 & \text{otherwise,} \end{cases} \tag{13}$$

so T_{e_m} is simply a shift by m, a right shift if $m>0$ and a left shift if $m<0$. All our results about shifts can therefore be understood in the context of Toeplitz operators. Theorem 5 refers to operators T_f, where f is a polynomial in z^{-1} of limited degree. Theorem 6 considers polynomials or arbitrary degree in z and z^{-1}. We will see that the results carry over to analytic functions on an annulus around S^1, and to a lesser extent to C^k Toeplitz operators, but with results that weaken as k is decreased.

Here are some standard results about Toeplitz operators. For details, see Ref. 4.

Theorem 7: A C^1 Toeplitz operator T_f is Fredholm if and only if f is everywhere nonzero on the unit circle. In that case the index of T_f is minus the winding number of f around the origin, namely

$$\text{Index}(T_f) = -\text{Winding}(f) = \frac{-1}{2\pi i} \int_{S^1} \frac{df}{f}. \tag{14}$$

Given the first half of the theorem, the equality of index and winding number is easy to understand. We simply deform f to a function of the form $f(z)=z^n$, while keeping f nonzero on all of S^1 throughout the deformation (this is always possible, see e.g., Ref. 18). In the process of deformation, neither the index of T_f nor the winding number of f can change, as they are topological invariants. Since the winding number of z^n is n, and since $T_{z^n}=(a^\dagger)^n$ (if $n\geqslant 0$, a^{-n} otherwise), which has index $-n$, the result follows.

We now consider functions f on S^1 that can be analytically continued (without singularities) to an annulus $r_0 \leqslant |z| \leqslant r_1$, where the radii $r_0<1$ and $r_1>1$ are fixed. This is equivalent to requiring that the Fourier coefficients $\hat{f}_n$ decay exponentially fast, i.e., that the sum

$$\sum_{n=-\infty}^{\infty} |\hat{f}_n|(r_0^n + r_1^n) \tag{15}$$

converges. For now we do not impose any reality constraints or other symmetries on the coefficients $\hat{f}_n$. This space of functions is a Banach space, with norm given by the sup norm on the annulus. This norm is stronger than any Sobolev norm on the circle itself.

The analysis of the corresponding Toeplitz operators is straightforward and similar to the proof of Theorem 5. Since f has no poles in the annulus, we just have to keep track of the zeroes of f. For the index of T_f to change, a zero of f must cross the unit circle. For the index to jump from k to k', $|k-k'|$ zeroes must cross simultaneously. In the absence of symmetry, the locations of the zeroes are independent and can be freely varied, so this is a codimension-$|k-k'|$ event.

If we impose a reality condition: $f(\overline{z})=\overline{f(z)}$, then zeroes appear only on the real axis or in complex conjugate pairs. In that case, changing the index by 2 is merely a codimension-1 event. Combining these observations we obtain the following theorem.

Theorem 8: In the space of Toeplitz operators that are analytic in a (fixed) annulus containing S^1, almost every operator is Fredholm. For every integer $k\geqslant 1$, the points where the index can jump by k is a set of real codimension k.

If we impose a reality condition $f(\overline{z})=\overline{f(z)}$ then, for every $k\leqslant n$, the points where the index jumps by k is a stratified space, the largest stratum of which has real codimension $\lfloor (k+1)/2 \rfloor$.

Finally we consider Toeplitz operators that are not necessarily analytic, but are merely l times differentiable, and we use the C^l norm. Our result is the following.

Theorem 9: In the space of Toeplitz C^l operators, almost every operator is Fredholm. For every integer k with $1 \leqslant k \leqslant 2l+1$, the points where the index can jump by k is a set of real codimension k. For every integer $k \geqslant 2l+1$, the points where the index can jump by k is a set of real codimension $2l+1$.

In other words, our familiar results hold up to codimension $2l+1$, at which point we lose all control of the change in index.

Proof: As long as f is everywhere nonzero, T_f is Fredholm. To get a change in index, therefore, we need one or more points where f, and possibly some derivatives of f with respect to θ, vanish. Suppose then that for some angle θ_0, $f(\theta_0)=f'(\theta_0)=\cdots=f^{(n-1)}(\theta_0)=0$ for some $n \leqslant l$, but that the nth derivative $f^{(n)}(\theta_0) \neq 0$. This is a codimension $2n-1$ event, since we are setting the real and imaginary parts of n variables to zero, but have a 1-parameter choice of points where this can occur. Without loss of generality, we suppose that this nth derivative is real and positive. By making a C^l-small perturbation of f, we can make the value of f highly oscillatory near θ_0, thereby wrapping around the origin a number of times. However, since a C^l-small perturbation does not change the nth derivative by much, the sign of the real part of f can change at most n times near θ_0, so the argument of f can only increase or decrease by $n\pi$ or less. The difference between these two extremes is $2n\pi$, or a change in winding number of n.

To change the index by an integer m, therefore, we must have the function vanish to various orders at several points, with the sum of the orders of vanishing adding to m. The generic event is for f (but not f') to vanish at m different points—this is a codimension m event, analogous to having m zeroes of a polynomial cross the unit circle simultaneously at m different points. All other scenarios have higher codimension and are analogous to having two or more zeroes of the m zeroes crossing the unit circle at the same point.

The situation is different, however, when the function f and the first l derivatives all vanish at a point θ_0. Then the higher-order derivatives are not protected from C^l-small perturbations and, by making such a perturbation, we can change f into a function that is identically zero on a small neighborhood of $\theta=\theta_0$. By making a further small perturbation, we can make f wrap around the origin as many times as we like near $\theta=\theta_0$. More specifically, if f is zero on an interval of size δ, then, for small ϵ, $\tilde{f}(\theta)=f(\theta)+\epsilon e^{iN\theta}$ will wrap around the origin approximately $N\delta/2\pi$ times near θ_0. By picking N as large (positive or negative) as we wish, we can obtain arbitrarily positive or negative indices. As long as we take $\epsilon \ll N^{-l}$, this perturbation will remain small in the C^l norm. ■

The results of this section can be extended, with minor modifications, to the algebra of matrix valued Toeplitz operators[4] where the index is related to the winding of the determinant of a matrix.

VI. QUANTUM HALL SYSTEMS

A. Phase diagrams of soluble models

Phase diagrams of the quantum Hall system describe the dependence of the Hall conductance on parameters such as the magnetic field B and the Fermi energy E. There are three idealized models where the phase diagram can be computed explicitly: The Landau Hamiltonian in the Euclidean plane, whose phase diagram is shown in Fig. 2; The Landau Hamiltonian for the hyperbolic plane, whose phase diagram is shown in Fig. 3 and Harper models in the plane,[19,8] whose phase diagram is associated with the Hofstadter butterfly, shown in Fig. 4 for the case of a tight binding model on a square lattice.

These are not models of Toeplitz operators, and none of these models are generic, especially insofar as all of them have symmetries. However, we consider the extent to which they follow the generic phase rules of (smooth, complex) Toeplitz operators anyway. Where these rules are not followed, we consider how a small generic perturbation might restore the rules.

The phase diagram for the Euclidean plane, Fig. 2 satisfies the generic phase rules away from the line $B=0$. On the line $B=0$, however, the index takes an infinitely large jump, while at the origin infinitely many phases meet. Both are forbidden by the phase rules.

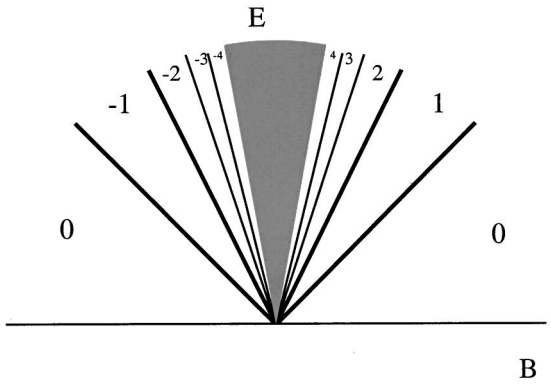

FIG. 2. The phase diagram for the Landau Hamiltonian in the Euclidean plane. The shaded wedge contains infinitely many, thinner and thinner, wedges, with indices that go to $\pm\infty$ and accumulate at the B axis.

The phase diagram in the hyperbolic plane, Fig. 3, satisfies the generic phase rules outside the shaded parabolic region. In the shaded region, the operator is not Fredholm and the index is not defined. This is contrary to the phase rules since not being Fredholm is expected to be a codimension 1 event.

The phase diagram of the Harper model, Fig. 4, is in serious conflict with the phase rule for (smooth, complex) Toeplitz operators: It is known,[20] that for a full measure of values of the magnetic field (irrational, of course), the spectrum is a Cantor set. Since the boundary between phases is contained in the spectrum, this suggests that any point on the boundary between any two phases can also be on the boundary between infinitely many other phases. This is the sort of behavior we observed for bounded operators with no restrictions. However, even in this wildness there is some regularity. For example, the center of the figure is on the boundary of all phases with *odd* indices while Theorem 2 allows for even indices as well.

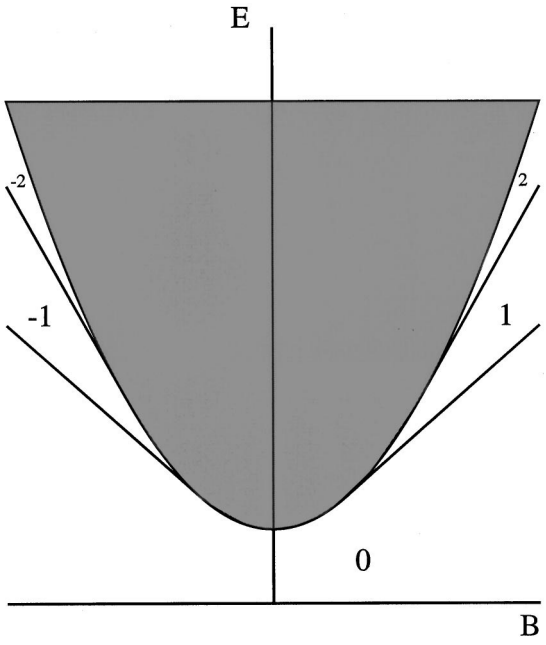

FIG. 3. The phase diagram for the Landau Hamiltonian in the hyperbolic plane. In the shaded parabolic region the operator is not Fredholm and the index is not defined.

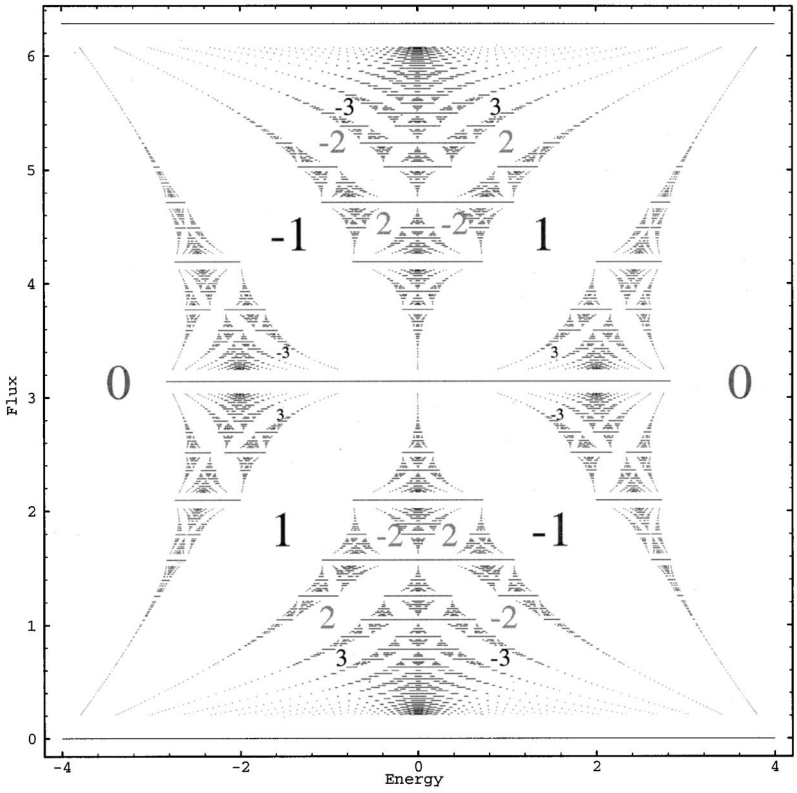

FIG. 4. The phase diagram for the Harper model associated with tight binding model on a square lattice the plane. Every point on the boundary between two phases appears to be a point of accumulation of infinitely many phases. Figure taken, with permission, from Ref. 31.

Remark: To see how Fig. 4 is obtained, we recall that for a tight-binding model with flux p/q through a unit cell, the Hall conductance, σ_j associated with the jth gap, (provided all gaps below it are open) satisfies the diophantine equation[8,21]

$$p\sigma_j = j \bmod q. \tag{16}$$

A similar equation holds for gaps counted from above. In the Harper model it is known[22] that all gaps except possibly for the central gap, are open.

Finally, consider the phase diagram of the Harper model with a disordered potential. This is not soluble in the same sense that the previous models are, but there are numerical results for it. Figure 5, which we borrowed from Ref. 23, shows the phase diagram for a split Landau level in the Harper model with disorder. More precisely, the diagram describes a Harper model with fractional flux $\frac{8}{5}$ through a unit cell.

Without disorder the conductance σ of each isolated band satisfies the Diophantine equation similar to Eq. (16), except that for a split Landau band p and q are interchanged. For flux $\frac{8}{5}$ the Diophantine equation fixes the conductances $(2,-3,2)$ of the bands at the flanks and -1 at the center. Zero disorder is, of course, not generic, and, indeed, there are bands on the E axis where the index is not defined, something that the phase rules for Toeplitz forbid. Under perturbation the diagram should deform so that these bands where the index is not defined disappear. This is indeed the case. The diagram in Ref. 23 is obtained by drawing n lines emanating from each band where n is its Hall conductance.

In summary, the wild character of the phase diagram of the Harper model is tamed by disorder and one finds, remarkably, a phase diagram compatible with the phase rules for Toeplitz operators.

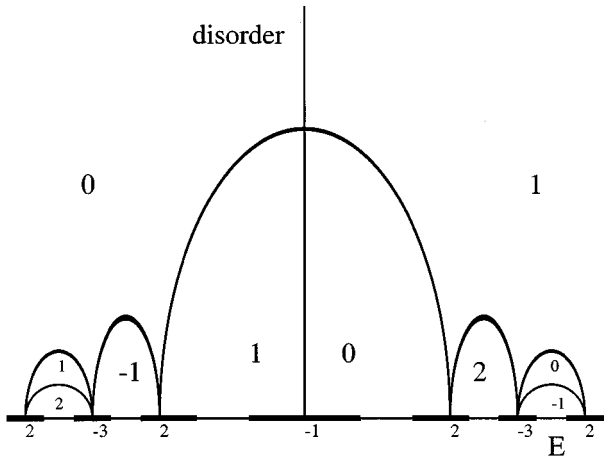

FIG. 5. The phase diagram for the Hall conductance of a split Landau level in Harper model with disorder after Ref. 23.

B. Perturbations of Landau Hamiltonians

Motivated by the effect of disorder on the Harper model phase portrait, we next consider the effect of perturbations on the phase portraits of Landau Hamiltonians. Such perturbations will modify the phase diagram near phase boundaries. As a consequence one expects a phase diagram to be qualitatively modified near points of accumulation of phases, even if the perturbation is small.

Figures 2 and 3 satisfy the phase rules in the region of large magnetic fields, but fail to do so for small magnetic fields. We now examine how the two figures might be modified to satisfy the phase rules everywhere.

The phase diagram of the Landau Hamiltonian in the plane, Fig. 2, will be significantly modified near the line $B=0$ which, by symmetry, must lie in a region with index 0. A schematic phase diagram that is generic and close to the Landau phase diagram is shown in Fig. 6.

The phase diagram in Fig. 3 has a region of full measure, the shaded parabola, where the operator is not Fredholm. This is nongeneric, and unstable. A perturbation might produce a phase diagram like Fig. 7. Note that the two perturbed diagrams, Figs. 6 and 7 are topologically identical.

How do the phase diagrams, Figs. 6 and 7, compare with what one finds in experiments on the quantum Hall effect? For large magnetic fields one finds phase diagrams that resemble both Figs.

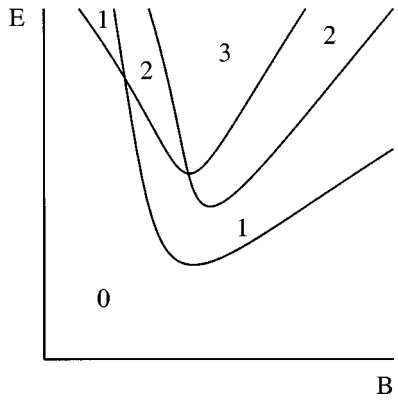

FIG. 6. A phase diagram that satisfies the phase rules of Toeplitz operators and is a perturbation of the phase diagram of Landau Hamiltonian in the plane.

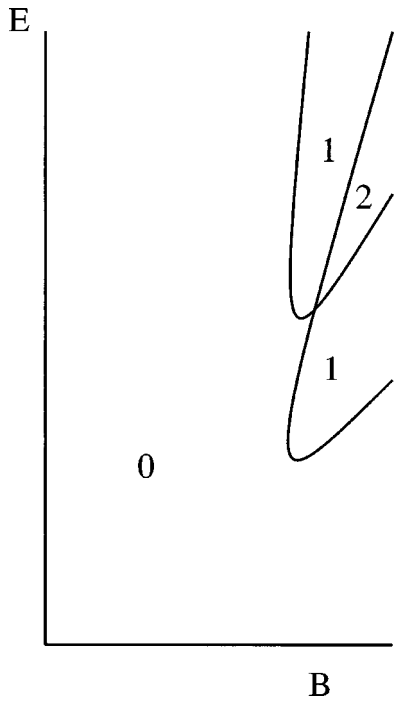

FIG. 7. A phase diagram that satisfies the rules of Toeplitz operators and is a perturbation of the phase diagram of Landau Hamiltonian in the hyperbolic plane.

2 and 6 and satisfy the phase rules. For weak magnetic fields one observes a transition to an insulating phase. The emergence of an insulating phase (with index 0) for small magnetic fields is in agreement with the phase rule and Fig. 6. However, some experiments[24] and numerical simulations[25] have been interpreted as giving evidence to direct transitions from a Hall conductance of 2 and 3 to the insulating phase. Taken literally, such transitions would violate the phase rule. However, these results may merely indicate that, for B small, the phase boundaries of Fig. 6 are too closely spaced to be distinguished numerically and experimentally.

C. Toeplitz operators

The main gap in our analysis is that we have not established a direct relation between the algebra of Toeplitz operators, where our phase rules are proven, and the class of operators relevant to (disordered) quantum Hall systems.

At the minimum, Toeplitz operators serve as a natural mathematical laboratory. However, there is a more direct justification for considering Toeplitz operators. The most elementary paradigm for a quantum Hall system is the Landau Hamiltonian, in which case one has the following.

Theorem 10: Let P be a projection on the lowest Landau level in $\mathbb{R}^2$, and let U be the gauge transformation associated with an Aharonov–Bohm flux tube at the origin. Then PUP, acting on the range of P, differs from a Toeplitz operator by a compact operator.

Proof: A basis for the lowest Landau level is

$$|n\rangle = \frac{1}{\sqrt{\pi\, n!}} z^n\, e^{-|z|^2/2}, \quad n \geqslant 0. \tag{17}$$

As a consequence

$$\langle n|U|m\rangle = \delta_{n,m+1}\frac{(m+1/2)!}{m!\sqrt{m+1}} \approx \delta_{n,m+1}\left(1-\frac{1}{8m}\right). \tag{18}$$

■

In this case, a compact perturbation of PUP is not only a Toeplitz operator; it is a simple shift. However, if the flux tube is placed at a different point, or if the magnetic field is spread out over a finite region, then we obtain a more general Toeplitz operator. If P is a projection on a higher Landau level, the same results hold but the calculation is more involved. If P is a projection onto multiple Landau levels, then PUP is a compact perturbation of a direct sum of Toeplitz operators, one for each Landau level.

This is not to say that Toeplitz operators apply directly to all systems, only that they apply to many. There are basic models where PUP fails to be Toeplitz. Indeed, an elementary model for localization is a random multiplication operator, i.e., $H=V_\omega$ on $l(\mathbb{Z}^d)$. This is a caricature of strong disorder. The eigenfunctions are now concentrated at lattice points. The projection P (below a Fermi energy) is

$$P=\sum |n\rangle\langle n|, \tag{19}$$

where the sum is over a random set of lattice points with, $V_\omega(n)<E$, in $\mathbb{Z}^d$. PUP is now a multiplication by a phase. It is an invertible operator and has Fredholm index zero. It is, however, not Toeplitz.

D. Open problems

It is tempting to directly study the index of PUP, for spectral projections P and unitary operators U, rather than rely on generic results based on Toeplitz operators. There are, however, several technical obstacles. The first is that PUP is thought of as acting on Range P, which is a Hilbert space in its own right. This means that a deformation of the parameters of the system leads to a deformation of the space Range P. In contrast, our strategy so far is formulated on a fixed space. The second obstacle is that our results depend on continuity properties while spectral projections tend to have bad continuity properties that come from a discontinuity at the Fermi energy.

To overcome the first problem one can replace PUP by an operator F defined on the entire Hilbert space with coinciding index. There is large arbitrariness in choosing F, but a natural choice is

$$F=PUP+P_\perp=PUP+P_\perp^2=1+P(U-1)P, \tag{20}$$

where $P_\perp=1-P$.

To overcome the second problem one may want to replace P by a Fermi function. That is, replace P by a smooth version

$$P(\beta,B,E_F)=\frac{1}{\exp(\beta(H(B)-E_F))+1}. \tag{21}$$

In that case, however, P^2 is no longer equal to P, and the different expressions for F in Eq. (20) are no longer equivalent. For each choice, it would be interesting to derive a phase portrait for index (F) as the temperature, Fermi energy, magnetic field and degree of randomness are varied.

E. Concluding remark

In this paper we explored what can be said about generic phase diagrams of indices of Fredholm operators. We did not use the fact that the Fredholm operators relevant to the quantum

Hall effect are of the form PUP, with P a spectral projection of an ergodic Schrödinger operator. Rather, we considered the index of several natural classes (and algebras) of operators. The weakness of this strategy is that we cannot say much that is definitive about quantum Hall systems. In its defense, we recall that replacing the particular by the generic proved to be useful in quantum physics in the hands of Wigner, von Neuman, and Dyson.[26–28] Whether it will turn out to be useful for quantum Hall effect remains to be seen.

JOURNAL OF MATHEMATICAL PHYSICS VOLUME 42, NUMBER 1 JANUARY 2001

One-dimensional crystal with a complex periodic potential

John K. Boyd
Lawrence Livermore National Laboratory, P.O. Box 808 L-095, Livermore, California 94551

(Received 8 September 2000; accepted for publication 26 September 2000)

A one-dimensional crystal model is constructed with a complex periodic potential. A wave function solution for the crystal model is derived without relying on Bloch functions. The new wave function solution of this model is shown to correspond to the solution for the probability amplitude of a two-level system. The energy discriminant is evaluated using an analytic formula derived from the probability amplitude solution, and based on an expansion parameter related to the energy and potential amplitude. From the wave function energy discriminant the crystal band structure is derived and related to standard energy bands and gaps. It is also shown that several of the properties of the two-level system apply to the one-dimensional crystal model. The two-level system solution which evolves in time is shown to manifest as a spatial configuration of the one-dimensional crystal model. The sensitivity of the wave function probability density is interpreted in the context of the new solution. The spatial configuration of the wave function, and the appearance of a long wavelength in the wave function probability density is explained in terms of the properties of Bessel functions. I. INTRODUCTION

In solid-state physics one-dimensional systems can be realized in several ways. First, a geometric shaping of a material may be fabricated to restrict the width in the perpendicular direction, and elongate the size in the longitudinal direction. This is the wire or strand model of a one-dimensional system, and such configurations have been observed experimentally.[1] Nearly one-dimensional electronic systems can be produced from silicon or gallium arsenide by lithographic techniques.[2] There are also materials that tend to naturally have a one-dimensional structure, such as polycarbyne[3] or cumulene.[4,5] Second, the anisotropy of a material can result in one-dimensional behavior. An example would be a Krogmann salt or a KCP compound.[6] There is also an abundance of research on quasione-dimensional crystals for x-ray emission,[7] sound propagation,[8] and various kinds of flow.[9] The experimentation on one-dimensional systems is widespread and the theoretical understanding of one-dimensional systems has great practical importance.

Typically, analysis of one-dimensional systems relies on the use of Bloch functions.[10] This is a result of the fact that to a very good approximation, crystals have potentials that are nearly invariant under translation and thus periodic. In practice, impurities and surfaces can alter the periodicity. The Bloch function solution can be obtained from Floquet's theorem, which has been previously applied to many areas[11,12] of research, including transition state dynamics.[13–17]

In this work, a complex potential[18–23] is permitted, and the wave function needed to determine the energy band structure is derived, from the Schrödinger equation, without using Bloch functions. The form of the wave function solution is expressed as a sine or cosine of a new dependent variable, and two related functions. In Sec. III, a transformation is used to obtain a new perspective on the wave function solution. An exact analytic expression for the wave function is obtained for a one-dimensional crystal in terms of two functions which are determined in several limits. In one limit the two functions are derived for the case of small potential compared to energy. The wave function solution based on this limit is used to obtain the energy discriminant. The energy discriminant is then used to study the crystal band structure. In the other limit when the potential

amplitude is large the form of the wave function solution is used to explain the expected occurrence of wave number harmonics.

The crystal energy band spectrum, is investigated in Sec. IV. The form of the wave function solution for this application is shown to manifest coefficients that are integer order Bessel functions. The zeros of the Bessel functions point to parameter values where the wave function solution can be substantially altered. The parameter values relate to the energy, potential amplitude, and the wave number periodicity associated with the potential. Regions around several zeros are numerically studied to show the dependence of the wave function probability density on the selection of parameter values near Bessel function zeros.

II. THEORETICAL BASIS FOR THE ONE-DIMENSIONAL CRYSTAL MODEL

The derivation of the equation governing the one-dimensional crystal uses a change of variables to make contact with the two-level system solution. An equivalence between the Schrödinger equation for the crystal, and the transition amplitude equation for a two-level system is demonstrated. As a result of the correspondence, the wave function solution can be derived from the two-level solution.

A. General time dependent wave equation

The basic time dependent wave equation is discussed to clarify the physical significance of a potential with a real and imaginary part. However, only the time independent wave equation derived in Sec. II B is needed for the one-dimensional crystal model. The derivation of the time independent wave equation begins with the statement of the time dependent Schrödinger equation,

$$i\hbar\frac{\partial\Phi}{\partial t}=-\frac{\hbar^2}{2m}\nabla^2\Phi+V\Phi, \tag{1}$$

where $i\cdot i=-1$, m is the electron mass, and $2\pi\hbar$ is Planck's constant. Typically the potential, V, is real to permit a correspondence of the dynamics of a wave packet with the motion of a particle described by classical mechanics. However, in this derivation a more general complex V is allowed. To interpret the imaginary part of the potential, decompose the potential $V=V_r+iV_i$, and take the time derivative of the probability density $\mathcal{P}=\Phi\Phi^*$.

$$\begin{aligned}\frac{\partial\mathcal{P}}{\partial t}&=\Phi^*\frac{\partial\Phi}{\partial t}+\frac{\partial\Phi^*}{\partial t}\Phi\\&=\Phi^*\left[-\frac{\hbar}{2im}\nabla^2\Phi+\frac{V}{i\hbar}\Phi\right]+\left[\frac{\hbar}{2im}\nabla^2\Phi^*-\frac{V^*}{i\hbar}\Phi^*\right]\Phi.\end{aligned} \tag{2}$$

A volume integral of Eq. (2) followed by an application of the divergence theorem gives

$$\frac{\partial\mathcal{P}}{\partial t}+\nabla\cdot S_{\mathrm{cur}}=\frac{2}{\hbar}V_i\mathcal{P}, \tag{3}$$

where probability current density $S_{\mathrm{cur}}=\hbar[\Phi^*\nabla\Phi-(\nabla\Phi^*)\Phi]/(2im)$. From Eq. (3), it is clear that the right side acts as a probability source when V_i is positive, and as a probability sink when it is negative. A complex potential has been used in the past to model neutron absorption[24,25] and thus the imaginary potential represents emission or absorption. Thus, in the crystal model the complex potential is viewed as representing a ''prepared'' material. The material is assumed to be capable of absorption or emission.

B. Time independent wave equation

Assuming an exponential time variation, the wave function $\Phi=\Psi(x)e^{-iEt/\hbar}$ for the one-dimensional crystal, is substituted into Eq. (1) to obtain the time independent Schrödinger equation,

$$-\frac{\hbar^2}{2m}\frac{d^2\Psi}{dx^2}+V(x)\Psi=E\Psi. \tag{4}$$

The energy is written as $E=\hbar^2K^2/(2m)$ and the chosen form of the potential function is

$$V(x)=\frac{\hbar^2}{2m}\left[-\frac{\beta^2}{4}\cos^2\alpha x+\frac{i\alpha\beta}{2}\sin\alpha x\right], \tag{5}$$

with variable parameters α and β and thus,

$$\frac{d^2\Psi}{dx^2}+\left[K^2+\frac{\beta^2}{4}\cos^2\alpha x-\frac{i\alpha\beta}{2}\sin\alpha x\right]\Psi=0. \tag{6}$$

The real part of the potential has amplitude $-\hbar^2\beta^2/(8m)$, and the imaginary part has amplitude $\hbar^2\alpha\beta/(4m)$. Thus, the amplitude of the real and imaginary part are related. Furthermore, the amplitude of the imaginary part of the potential is linearly related to the inverse of the period of the potential $\omega=2\pi/\alpha$. Note also that $V(x)=[V(-x)]^*$, and consequently the potential has parity and time reversal symmetry.

To facilitate the solution for Ψ, an exponential variation is factored, $\Psi=c_+e^{-i(\beta/2\alpha)\sin\alpha x}$ and after substituting into Eq. (6),

$$\frac{d^2c_+}{dx^2}-i\beta\frac{dc_+}{dx}\cos\alpha x+K^2c_+=0. \tag{7}$$

The following two coupled first-order differential equations can also be used to derive Eq. (7),

$$\frac{dc_+}{dx}=-iKc_-e^{i(\beta/\alpha)\sin\alpha x}, \tag{8a}$$

$$\frac{dc_-}{dx}=-iKc_+e^{-i(\beta/\alpha)\sin\alpha x}, \tag{8b}$$

since the derivative of Eq. (8a) with respect to x results in Eq. (7). Comparing with previous work[26] it can be seen that c_+ is closely related to the coupled equations governing the two-level probability amplitude dynamics. When K is set to one in Eq. (8) the equations are identical to the governing equations for the probability amplitude of a two-level system. A direct correspondence is obtained if distance x is scaled by K in Eq. (6), however this normalization is not convenient for the later energy band discussion.

III. FORMULATION OF THE WAVE FUNCTION SOLUTION WITH A NEW DEPENDENT VARIABLE

The x variable used in Eq. (8) is replaced with a new variable s, in order to gain insight into the wave function solution dependence on the α and β parameters, and to avoid the need for the use of Bloch functions. The objective is to use a variable that is more natural to Eq. (8) and also contains as much of the characteristic behavior as possible.

A. The wave function solution based on variable *s*

The previously derived solution[26] of the two-level probability amplitude problem relied on the introduction of a new variable s. In the crystal model wave function solution the variable s is modified by a scale factor, K. The s coordinate originally was proposed as a generalization to arbitrary wave number of a variable used previously for a strictly resonance solution.[27] In this work, for the purpose of deriving the crystal solution,

$$s = K\int_0^x dy\, e^{i\,(\beta/\alpha)\,\sin\alpha y}$$

$$= Kx\mathcal{J}_0 + \frac{K}{\alpha}\sum_{n=1}^{\infty}\mathcal{J}_{2n}\frac{\sin(2n\alpha x)}{n} - \frac{2iK}{\alpha}\sum_{n=0}^{\infty}\mathcal{J}_{2n+1}\frac{\cos[(2n+1)\alpha x]-1}{2n+1}, \tag{9}$$

where $\mathcal{J}_n = J_n(\beta/\alpha)$ is the order n Bessel function evaluated at β/α. The integral required to determine the s variable is obtained using the Eq. (A1a) and Eq. (A1b) Bessel generating function relations[28] written in the appendix.

Starting with the unscaled c_+, the K scaled solution for c_+, needed for the wave function can be readily derived from a Riccati equation as previously detailed:[26]

$$\Psi = \left\{ C_{11}\cos\left[\frac{(s+s^*)}{2}+p\right]e^{Q} + C_{12}\sin\left[\frac{(s+s^*)}{2}+p^*\right]e^{Q^*}\right\} e^{-i(\beta/2\alpha)\sin\alpha x}, \tag{10}$$

where C_{11} and C_{12} are constants depending on initial conditions and the p and Q functions are both the solution of a first-order differential equation,

$$\frac{dp}{dx} = -iK\sin\left[\left(\frac{\beta}{\alpha}\right)\sin(\alpha x)\right]\cos(s+s^*+2p), \tag{11}$$

$$\frac{dQ}{dx} = -iK\sin\left[\left(\frac{\beta}{\alpha}\right)\sin(\alpha x)\right]\sin(s+s^*+2p). \tag{12}$$

For the time independent wave function solution the time variable of the two-level probability amplitude solution has been switched to the spatial coordinate x. The complete time history of the two-level probability amplitude solution is simultaneously manifested in the spatial configuration of the time independent wave function solution.

As can be seen from Eq. (9) for s and Eqs. (10)–(12), the ratio β/α has a substantial influence on the solution of c_+ and thus Ψ, since β/α is fundamental to the variable s and the solution of the p and Q functions. Any wave number content that enters p appears in the argument of the Eq. (10) solution and any wave number content entering Q appears in the exponential. The strong β/α influence is a result of dp/dx and dQ/dx, having a factor of $K\sin[(\beta/\alpha)\sin(\alpha x)]$. This factor common to both Eqs. (11) and (12) can also be written in terms of s,

$$\frac{1}{2i}\frac{d(s-s^*)}{dx} = K\sin[(\beta/\alpha)\sin(\alpha x)]. \tag{13}$$

In selecting the potential, the choice of β/α may be large or small. When it is small corresponding to a weak potential, the maximum value of $\sin[(\beta/\alpha)\sin\alpha x]$ only achieves a value less than the possible maximum of one. However, under this condition it reflects the wave number selected by the choice of α. At small values $\sin[(\beta/\alpha)\sin\alpha x]\approx(\beta/\alpha)\sin\alpha x$, and α has the character of a wave number. The parameter β has the character of an amplitude, which is consistent with the relationship of β to the potential amplitude. When $\beta/\alpha=\pi/2$, the outer sinusoid achieves its maximum value of one and the inner and outer sinusoids closely track each other as shown in Fig. 1(a). The curve in Fig. 1(a) is calculated with $\alpha=2$. For β/α somewhat greater than $\pi/2$, a new phenom-

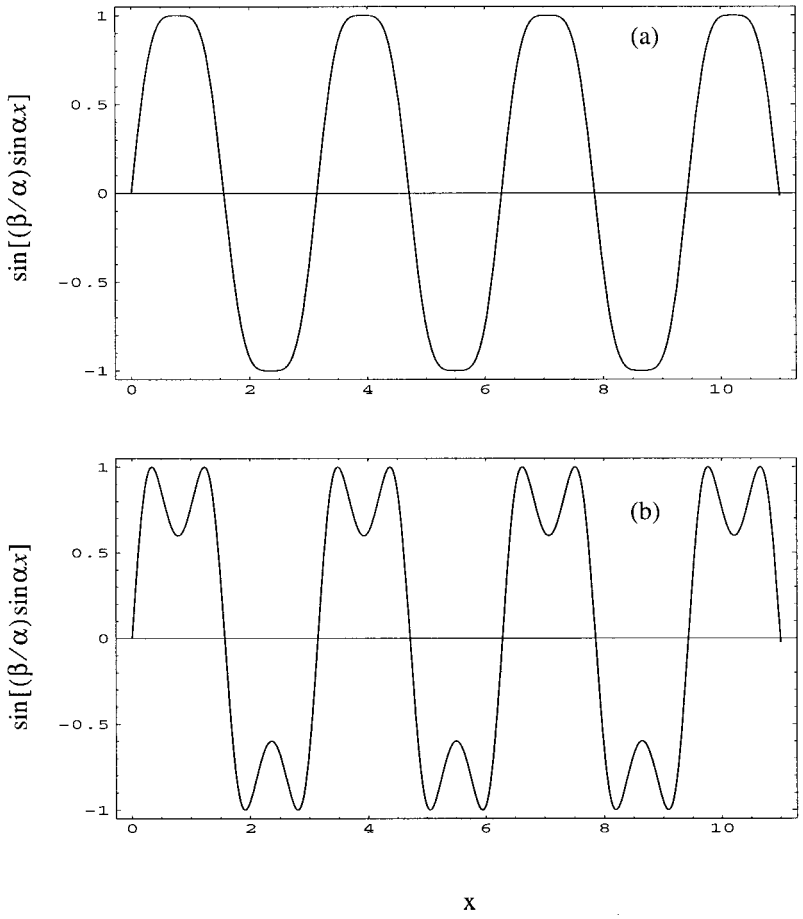

FIG. 1. The function $\sin[(\beta/\alpha)\sin \alpha x]$ is compared for $\alpha=2$ with two values: (a) $\beta/\alpha=\pi/2$, (b) $\beta/\alpha=5$.

enon begins to occur. This is illustrated in Fig. 1(b) where now $\beta/\alpha=5$ and $\alpha=2$. The outer sinusoid achieves its maximum before $\alpha x=\pi/2$, and at the peak value of one for the inner sinusoid, the outer sinusoid has an argument beyond $\pi/2$ and thus it has a value less than one. The effect is to begin to cause a ripple structure on the peaks of $\sin[(\beta/\alpha)\sin \alpha x]$. The ripple is a new wave number related to the magnitude of β/α, and thus β/α takes on the character of a wave number that is greater than α. This behavior causes harmonics of the fundamental wave number to enter the solution.

An advantage of the Eq. (10) solution compared to Bloch functions is that it is completely determined once the p and Q functions are specified. Additionally, the form of the solution provides considerable information about the spatial nature of the wave function. The key point is that the Bessel functions of integer order evident in the s variable are all oscillatory. The zero-order Bessel function is one at zero and all other orders vanish at zero. The arguments of the Bessel functions scale like the ratio of the amplitude of the real part of the potential to the imaginary part. This ratio can be small and then the solution is described in the region near zero by the approximate expression,

$$\Psi=(C_{11}\cos[\mathcal{J}_0 Kx]+C_{12}\sin[\mathcal{J}_0 Kx])e^{-i(\beta/2\alpha)\sin \alpha x}. \tag{14}$$

Equation (14) result shows in the small β/α limit that the coefficient of Kx is the zero-order Bessel function. Because $\mathcal{J}_0 Kx$ is the first term of the real part of s, it persists as the β/α argument is increased. At $\beta/\alpha=2.4048$ the zero-order Bessel function has its first zero. This

means that the character of the spatial variation contributed by $s+s^*$ dramatically changes at this location in parameter space. In other words, selecting $\beta/\alpha=2.4048$ switches off the linear spatial variation contribution of $s+s^*$. There are an infinite number of zero-order Bessel function nodes where this occurs. The other terms of $s+s^*$ are even harmonic sines with even-order Bessel functions as coefficients. Thus, it is equally possible to switch off any particular even harmonic contribution from $s+s^*$, and this may be done at any of the infinite set of available zeros. Because the nodes of the integer-order Bessel functions are interlaced, the selection of the term to switch on or off can be done while leaving all other terms at a finite value. Another interesting feature is that as the order of the Bessel function increases the first zero appears at a larger value. For large β/α, the asymptotic form

$$\mathcal{J}_n \approx \left(\frac{2\alpha}{\pi\beta}\right)^{1/2} \cos\left[\frac{\beta}{\alpha} - \frac{\pi n}{2} - \frac{\pi}{4}\right], \tag{15}$$

shows an increasing density of nodes contributed by ever larger Bessel function orders. The spacing between nodes is approximately π.

From Eqs. (11) and (12) it is clear each of these functions is similar since a $\pi/4$ shift in the p function in the argument of the sine on the right side of dQ/dx gives $dQ/dx(p+\pi/4)=dp/dx$. Additionally, both dp/dx and dQ/dx are proportional to $\sin[(\beta/\alpha)\sin(\alpha x)]$, which by using Eq. (A1b), can be expanded as

$$\sin\left[\frac{\beta}{\alpha}\sin(\alpha x)\right] = 2\sum_{n=0}^{\infty} \mathcal{J}_{2n+1} \sin[(2n+1)\alpha x]. \tag{16}$$

The form of this result reveals that p and Q can be controlled to some degree by selecting β/α to coincide with a zero of any odd integer-order Bessel function. For example, to eliminate the $\sin(\alpha x)$ term, β/α could be set to the first zero, 3.832, of $\mathcal{J}_1$ or a zero at a larger value of β/α. The odd-order Bessel functions, as also in the case of the even-order Bessel functions, are nearly zero until the argument is comparable or greater than the order. Thus, it should be expected that the higher-order harmonics of Eq. (16) have a minuscule effect unless the β/α argument is comparable or greater than the order. In the vicinity of the first peak, there is dominance over the magnitude of all other Bessel functions.

Each integer-order Bessel function has an infinite number of nodes. The primary parameter, β/α is a ratio and thus, there are two ways to select any particular Bessel zero. First, the potential period which corresponds to α can be set, and then the real potential amplitude which corresponds to β can be scanned. Second, β can be set and then α can be scanned. As α gets small, the ratio β/α can be made large. The method of selecting β/α determines the weighting between the real and imaginary part of the potential. It is also possible to diminish the influence of a Bessel function, and consequently its associated harmonic by setting β/α less than the order. The oscillatory behavior of a Bessel function with an approximate π period does not begin to be significant until the argument of the Bessel function exceeds the order.

B. Analytic solutions for the *p* and *Q* functions

The function p has a nonlinear dependence since p appears as an argument of the cosine in Eq. (11). However, an analytic solution can be obtained for this equation assuming $K\beta/\alpha \ll 1$. This is possible because dp/dx scales like $K\beta/\alpha$ when $K\beta/\alpha \ll 1$. From Eq. (9) at small β/α, it is found $s+s^* \approx 2Kx\mathcal{J}_0$. Under these conditions, Eq. (11) becomes

$$\frac{dp}{dx} = -iK \sin\left[\left(\frac{\beta}{\alpha}\right)\sin(\alpha x)\right] \cos(2Kx\mathcal{J}_0). \tag{17}$$

If α is chosen such that $\alpha=2K\mathcal{J}_0$, then Eq. (17) is a perfect derivative and

$$p=\frac{iK}{\beta}\cos\left[\left(\frac{\beta}{2K\mathcal{J}_0}\right)\sin(2Kx\mathcal{J}_0)\right]-\frac{iK}{\beta}. \tag{18}$$

For the situation where $\alpha\neq 2K\mathcal{J}_0$,

$$p=iK\mathcal{J}_1\left[\frac{\cos(\alpha+2K\mathcal{J}_0)x-1}{\alpha+2K\mathcal{J}_0}+\frac{\cos(\alpha-2K\mathcal{J}_0)x-1}{\alpha-2K\mathcal{J}_0}\right]. \tag{19}$$

Also, to lowest order in β/α, Eq. (12) becomes for $\alpha=2K\mathcal{J}_0$,

$$\begin{aligned}Q&=-2iK\mathcal{J}_1\int \sin(2Kx\mathcal{J}_0)\sin(2Kx\mathcal{J}_0)dx\\&=-iK\mathcal{J}_1\left[x-\frac{\sin(4Kx\mathcal{J}_0)}{4K\mathcal{J}_0}\right],\end{aligned} \tag{20}$$

and for $\alpha\neq 2K\mathcal{J}_0$,

$$\begin{aligned}Q&=-2iK\mathcal{J}_1\int \sin(\alpha x)\sin(2Kx\mathcal{J}_0)dx\\&=-iK\mathcal{J}_1\left[\frac{\sin(\alpha-2K\mathcal{J}_0)x}{\alpha-2K\mathcal{J}_0}-\frac{\sin(\alpha+2K\mathcal{J}_0)x}{\alpha+2K\mathcal{J}_0}\right].\end{aligned} \tag{21}$$

IV. RESULTS AND DISCUSSION

An interesting aspect of a periodic potential is the advent of forbidden energy regions. The approximate p and Q functions of Sec. III B are used to determine the energy band structure with a fully complex potential. A numerical solution is calculated and the formula of Eq. (10) is used to explain the observed wave number behavior of the probability density.

A. Energy band structure results from the analytic solution

In past research where the Schrödinger equation potential is periodic, energy band conditions have been derived from wave function boundary conditions[29] or the properties of the wave equation solutions.[30] In this work the energy discriminant, based on properties of the wave equation, as described by Bender[31] is used:

$$\Delta E=\Psi_1(\omega)+\Psi_2'(\omega), \tag{22}$$

where ω is the period of the potential. For allowed energy regions (energy bands) the constraint satisfied by the discriminant is $|\Delta E|\leqslant 2$, and for disallowed regions (energy gaps) $|\Delta E|>2$. The wave functions in the energy discriminant formula must satisfy specific conditions. For Ψ_1, at $x=0$, $\Psi_1(0)=1$, $d\Psi_1/dx(0)=0$, and applying these conditions to the Eq. (10) solution,

$$\Psi_1=\left\{\cos\left[\frac{(s+s^*)}{2}+p\right]e^{Q}+\frac{i\beta}{2K}\sin\left[\frac{(s+s^*)}{2}+p^*\right]e^{Q^*}\right\}e^{-i(\beta/(2\alpha))\sin\alpha x}, \tag{23}$$

and for Ψ_2, at $x=0$ the conditions are $\Psi_2(0)=0$, $d\Psi_2/dx(0)=1$,

$$\Psi_2=\frac{1}{K}\sin\left[\frac{(s+s^*)}{2}+p^*\right]e^{Q^*}e^{-i(\beta/(2\alpha))\sin\alpha x}. \tag{24}$$

Substituting the Eqs. (23)–(24) wave functions into the Eq. (22) formula for the discriminant,

$$\Delta E = 2\ \mathrm{Re}[\cos(K\omega\mathcal{J}_0 + p(\omega))e^{Q(\omega)}]. \tag{25}$$

The final form of the energy discriminant is intended to use the strictly imaginary Sec. III B formulas and in that case Eq. (25) becomes

$$\Delta E = 2\cos(K\omega\mathcal{J}_0)\cosh[p_i(\omega)]\cos[Q_i(\omega)] - 2\sin(K\omega\mathcal{J}_0)\sinh[p_i(\omega)]\sin[Q_i(\omega)], \tag{26}$$

where subscript ''i'' denotes the imaginary part. The restriction on the application of Eq. (26) is that $K\beta/\alpha \ll 1$.

As an example, consider the discriminant plotted in Fig. 2(a) for $\alpha = 4.$ and $\beta = 0.01$. The dashed lines are placed for reference at the critical values of ± 2. The regions where $|\Delta E| > 2$ are forbidden and this condition defines the energy gaps. As can be seen there is a local minimum around $K = 2,6,10$ and local maximum around $K = 4,8,12$. This is expected since $\mathcal{J}_0 \approx 1$ when $\beta/\alpha \ll 1$ and the argument of the cosine in Eq. (25) is nearly $K2\pi/4$. The local maximums are greater than 2 and the local minimums are less than -2. This means the solution Ψ has both periodic $\Psi(x) = \Psi(x+\omega)$ and antiperiodic solutions $\Psi(x) = -\Psi(x+\omega)$. This behavior is quite different than a potential such as $i\sin^{2N+1}(x)$ $(N = 0,1,2\ldots)$, where Bender[31] found no antiperiodic solutions existed.

Since the discriminant variation near 2 is difficult to see in the full plot of Fig. 2(a), an additional two enlarged plots are shown in Figs. 2(b) and 2(c). In Fig. 2(b) the abscissa is restricted to $3.7 < K < 4.1$ and the energy gap region of $3.8 < K < 4$ is clearly visible. The maximum value is $\Delta E = 2.027\,82$ at $K = 3.897$. In Fig. 2(c) the abscissa is restricted to $7.7 < K < 8.1$ and the energy gap region is $7.855 < K < 8$. The maximum value is $\Delta E = 2.0100$ at $K = 7.937$. These two gaps illustrate the diminishing gap width as K or energy increases and also the diminishing amplitude of $\Delta E - 2$. To go to larger K using the approximate Sec. III B formulas it is necessary to reduce β or increase α, in order to maintain $K\beta/\alpha \ll 1$. In the limit the Eq. (25) result indicates that the ΔE function oscillates between ± 2.

B. Numerical results

It is not apparent from Eq. (7) that there are any special values of α and β which would cause substantial changes to the solution. However, when the wave function is written in the form of Eq. (10), it is clear the s variable is fundamental to the solution. As discussed earlier the s variable has drastically different behavior which depends on the properties of Bessel functions. The same situation is also true of the p and Q functions. The first place a very different behavior occurs is at the first zero of $\mathcal{J}_0$ where $\beta/\alpha = 2.4048$. At this value the linear term of s, $Kx\mathcal{J}_0$ vanishes and s becomes a bounded function. For this condition the results of Sec. III B are still valid if $K \ll 1/2.4048$,

$$p = 2iK\mathcal{J}_1(\cos\alpha x - 1)/\alpha, \tag{27a}$$

$$Q = 0. \tag{27b}$$

To recover a finite value for Q, a somewhat less restrictive requirement of small K/α can be imposed. The differential equation for Q, Eq. (12) can be directly integrated if p is known. The differential equation for p, Eq. (11) can be viewed as

$$\frac{dp}{d(s^* - s)} = \frac{1}{2}\cos(s + s^* + 2p), \tag{28}$$

which may be formally written

$$\int \frac{dp}{\cos(s + s^* + 2p)} = \frac{s^* - s}{2}. \tag{29}$$

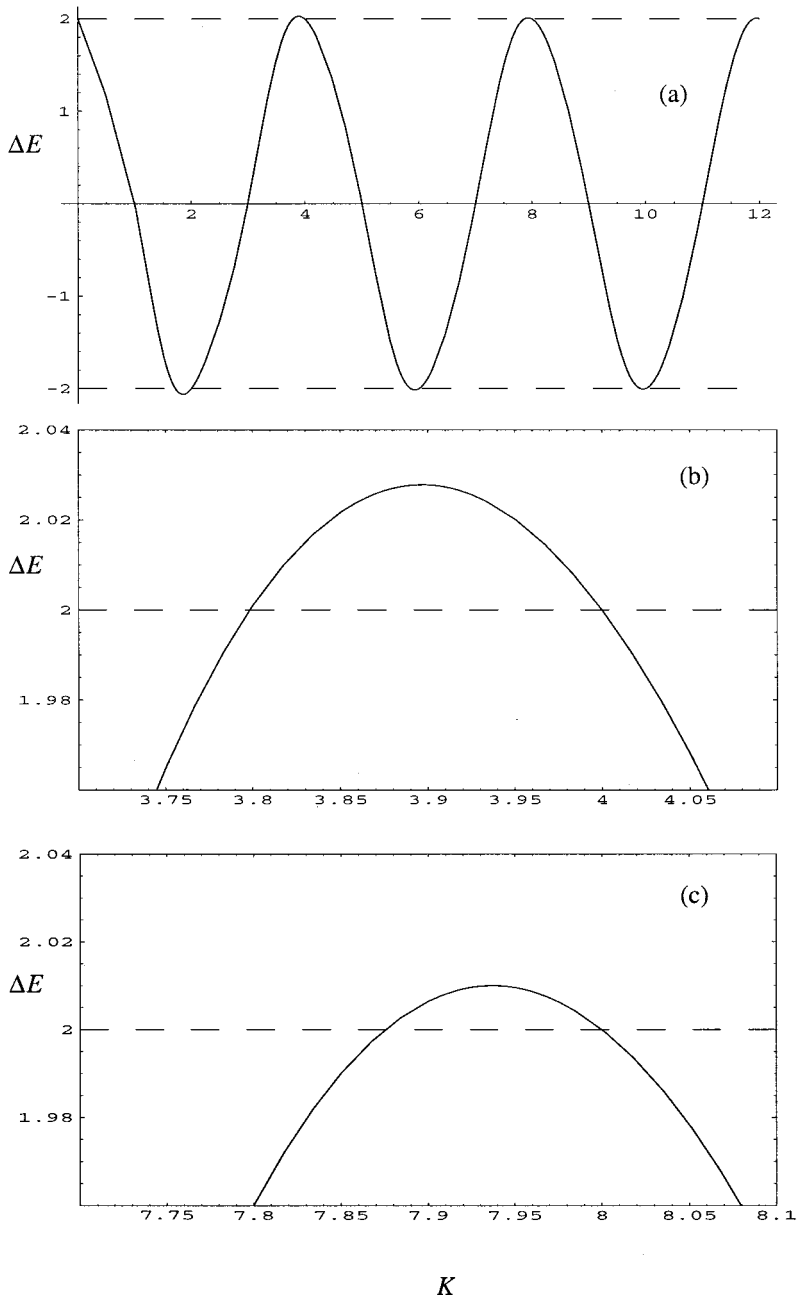

FIG. 2. The energy discriminant is displayed for $\alpha=4$, and $\beta=0.01$ with three energy parameter ranges: (a) $0<K<12$, (b) $3.7<K<4.1$, (c) $7.7<K<8.1$.

In the event $s+s^*$ is precisely constant, Eq. (29) can be immediately integrated without approximation. When $K/\alpha \ll 1$ and β/α is set to the value of a $\mathcal{J}_0$ zero, then $s+s^*$ is small and nearly constant. On the basis of these properties of the s variable an analytic solution, referred to in past work as the dwell point solution,[26] has been derived. It is most accurate when α is large and β/α is near a zero of $\mathcal{J}_0$. The dwell point solution gives the expectation that the wave function is very different, depending on whether or not $s+s^*$ is approximately constant.

For general values of K/α and β/α needed to explore the implications of the constancy of $s+s^*$, it is necessary to resort to numerical calculations to obtain the wave function. A useful function to illustrate the spatial behavior is the probability density. Using Eq. (10) it follows the probability density can be expressed in terms of c_+ as $\mathcal{P}=c_+c_+^*$, and thus it is only necessary to calculate c_+. Applying the boundary conditions, $\Psi_1(0)=1$, $d\Psi_1/dx(0)=0$, to the Eq. (10) solution,

$$c_+=\cos\left[\frac{(s+s^*)}{2}+p\right]e^Q+\frac{i\beta}{2K}\sin\left[\frac{(s+s^*)}{2}+p^*\right]e^{Q^*}. \tag{30}$$

From Eq. (7) it is clear that the $\cos\alpha x$ coefficient of dc_+/dx is expected to result in harmonics of wave number α in the solution. The source of other wave numbers unrelated to α are revealed by the form of Eq. (30). As an illustration the probability density (for a convenient ordinate scale the normalized Ψ has been multiplied by 100) is plotted in Fig. 3 for $\alpha=2$ and $K=0.4$, which adequately satisfies the $K/\alpha\ll 1$ criteria. In Fig. 3(a), $\beta=16.9$ and it is seen that there is a dominant small wave number evidenced. The probability density plot is observed to have a period of approximately 153, which is far greater than the expected fundamental length of $2\pi/(2\alpha)=1.57$. This can be understood by considering the formula for variable s. In Eq. (9) the formula shows that the argument $(s+s^*)/2$ in Eq. (30) has a linear term of $K\mathcal{J}_0x=0.022\,23x$. There is also a linear contribution from $p_r\approx-0.002\,254x$. The associated wavelength $2\pi/(2(K\mathcal{J}_0+p_r))=157$ which is very close to the period of 153 plotted in Fig. 3(a). The wavelength is almost completely determined by s, since $|p_r/x|\ll K\mathcal{J}_0$. The period is about half the wavelength associated with the smallest wave number in the solution since it appears as a square in $\mathcal{P}$. The large thickness of the curve in Fig. 3(a) is due to the comparatively rapid oscillations related to the expected α wave number and its harmonics. In Fig. 3(b), $\beta=17.1$ and $K\mathcal{J}_0x=0.011\,31x$. There is also a linear contribution from $p_r\approx-0.002\,136x$. The associated wavelength is $2\pi/(2(K\mathcal{J}_0+p_r))=342$ which agrees well with the plotted result of 340. Again the large curve thickness is due to the expected α wave number and its harmonics. For a modest change in β the long wavelength evident in $\Psi\Psi^*$ is changed by approximately a factor of two. The large change is caused by the dependence of the sinusoids in Eq. (30) on $(s+s^*)/2$ and the linear contribution from p_r. In Fig. 3(c), $\beta=17.307$ to emphasize the role of the Bessel functions in the probability density. For this value $\beta/\alpha=8.653\,73$, which results in $\mathcal{J}_0\approx 0$. As a consequence the wavelength associated with $K\mathcal{J}_0=0$ becomes infinite, and it may be assumed that a flat probability function would result. However, as shown by Fig. 3(c) there is still a very long wavelength present. Referring back to Eq. (30) this feature is explained by the presence of the real part p_r in the argument of the sinusoids. The equation for p_r,

$$\frac{dp_r}{dx}=-K\sin[(\beta/\alpha)\sin\alpha x]\sin(s+s^*+2p_r)\sinh(2p_i), \tag{31}$$

includes the factor $\sin[(\beta/\alpha)\sin\alpha x]$ which can be expanded in odd harmonics, $\sin(2n+1)\alpha x$, as shown in Eq. (16). The presence of $\sin(s+s^*+2p_r)$ on the right side of Eq. (31) causes wave number feedback in a nonlinear manner. Because of the product rules of trigonometric functions,

$$\begin{aligned}
2\sin\theta_1\sin\theta_2&=\cos(\theta_1-\theta_2)-\cos(\theta_1+\theta_2),\\
2\sin\theta_1\cos\theta_2&=\sin(\theta_1+\theta_2)+\sin(\theta_1-\theta_2),\\
2\cos\theta_1\cos\theta_2&=\cos(\theta_1-\theta_2)+\cos(\theta_1+\theta_2),
\end{aligned} \tag{32}$$

the right side of Eq. (31) contains sum and difference wave numbers. The result is that p_r attains a linear term. For the example of Fig. 3(c), the linear term of p_r is $-0.0021x$ which corresponds

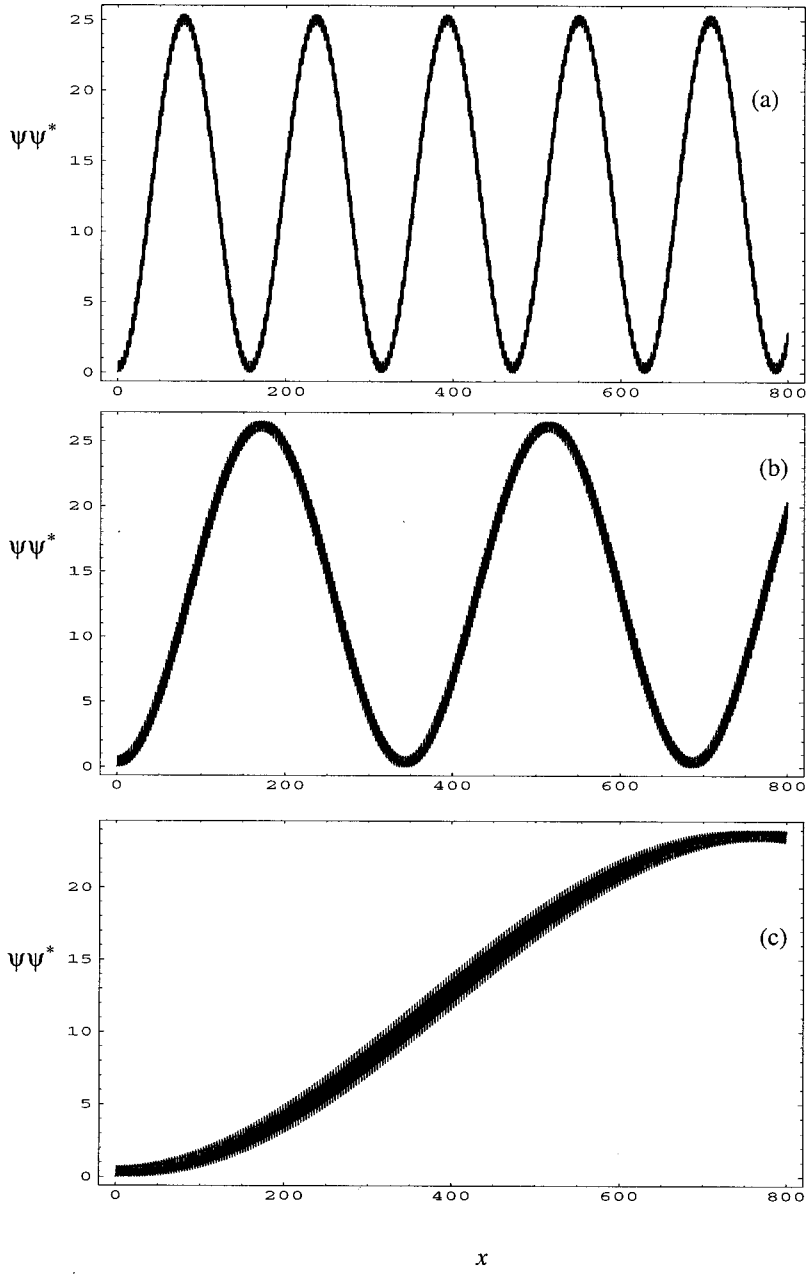

FIG. 3. The probability density for $\alpha=2$, $K=0.4$, and three β values: (a) $\beta=16.9$, (b) $\beta=17.1$, (c) $\beta=17.307$.

to a wavelength of $2\pi/(2\times 0.0021)=1495$. This agrees with the half wavelength of 750 plotted in Fig. 3(c). Thus, even though there is no linear contribution from $s+s^*$ the linear part of p_r causes a very small wave number in the probability density.

In the example of Fig. 3, β varied from 16.9 to 17.3 and the change of $\mathcal{P}$ was observed with K constant. In most instances of a physical system the potential is given and the energy can be varied. This amounts to a fixed α and β, with a variable K. The Q function is obtained from Eq. (12) and does not appear on the right side. Thus, the differential equation for Q is not nonlinear

and therefore Q is known as soon as p is determined. The most important consideration is then the dependence of p on K. To assess in a qualitative manner how K influences p, introduce a variable $u=Kx$. The s variable then becomes

$$s(u)=u\mathcal{J}_0+\frac{K}{\alpha}\sum_{n=1}^{\infty}\mathcal{J}_{2n}\frac{\sin(2n\alpha u/K)}{n}-\frac{2iK}{\alpha}\sum_{n=0}^{\infty}\mathcal{J}_{2n+1}\frac{\cos[(2n+1)\alpha u/K]-1}{2n+1}. \tag{33}$$

Now K does not appear in the linear term, however it behaves as a scale factor for α. The p_r differential equation is no longer proportional to K, though K scales α in the sine argument, and appears in $s(u)$

$$\frac{dp_r}{du}=-\sin[(\beta/\alpha)\sin(\alpha u/K)]\sin(s(u)+s^*(u)+2p_r)\sinh(2p_i). \tag{34}$$

As K increases the effective wave numbers, α/K decrease in the $s(u)$ variable and also in the $\sin[(\beta/\alpha)\sin(\alpha u/K)]$ term. The net effect is that at larger K the linear part of p_r gets larger. As an example, consider the probability density at $\alpha=2$, and $\beta=16.9$. In this example there is no concern for smallness of any parameter as required in Sec. III B or the dwell point solution. In Fig. 4(a), the probability density (for a convenient ordinate scale the normalized Ψ has been multiplied by 100) is plotted for $K=1.1$, showing the probability density is rich in structure at the α wave number and its harmonics. There is also a much longer wavelength visible. For this example $K\mathcal{J}_0=0.061\,1352$ and $p_r\approx-0.044\,2756x$. Combining these two contributions produces a wavelength $2\pi/2(0.061\,1352-0.044\,2756)=186$, which is in good agreement with the wavelength of 185 displayed in Fig. 4(a). Likewise in Fig. 4(b), for $K=1.2$, $K\mathcal{J}_0=0.066\,6929$ and $p_r\approx-0.057\,0173x$. Combining these two linear contributions produces a wavelength $2\pi/2(0.066\,6929-0.057\,0173)=325$. This is within 5% of the wavelength of 343 in Fig. 4(b). A small 9% change of K from 1.1 to 1.2 causes about a factor of two wavelength change. Note that as K increases $|p_r/x|$ increases more rapidly than $K\mathcal{J}_0$. This phenomenon admits the possibility that the linear contribution from p_r can, at a particular K value, equal $K\mathcal{J}_0$. Because the signs of these terms are opposite in this example, at $K=1.3005$ they cancel, and as shown in Fig. 4(c), there is no longer a long wavelength evidenced. Actually, $K\mathcal{J}_0=0.072\,2785$ and $p_r\approx-0.072\,2661x$ which results in a wavelength of 2.5×10^5, which is only visible after calculating out to about $x=25\,000$. At higher $K>1.3005$ the long wavelength returns. The abscissa in Fig. 4(c) is only plotted out to 100 to keep the short wavelength from producing a black rectangle filling the plot area. The curve shows a set of periodic major peaks with three minor peaks in the top third of the amplitude.

V. SUMMARY AND CONCLUSIONS

The wave function for a one-dimensional system, having a complex periodic potential has been analytically derived in terms of a variable c_+ which is the weighted sum of the familiar two-level system probability amplitude. The analytic solution has the form displayed in Eq. (10) with a dependence on complex variable s, and functions p and Q. The formulation of the analytic solution relied on the use of the variable s, which contains a substantial portion of the trigonometric argument of the solution. The variable s has a linear term in x with Bessel function coefficient $\mathcal{J}_0$, and a sum of even harmonics of the potential wave number with even integer-order $\mathcal{J}_{2n}$ Bessel coefficients and a complex sum of odd harmonics with odd-order $\mathcal{J}_{2n+1}$ Bessel coefficients. The solution in Eq. (10) is exact when p is known precisely and Q can be precisely determined from p analytically or determined to high accuracy through numerical integration. In general, the number of terms used to specify s and the degree of approximation of p and Q determines the precision of Ψ. The wave function solution was shown to correspond to a medium which exhibits absorption or emission. This is viewed as a prepared medium and thus is a special material or state.

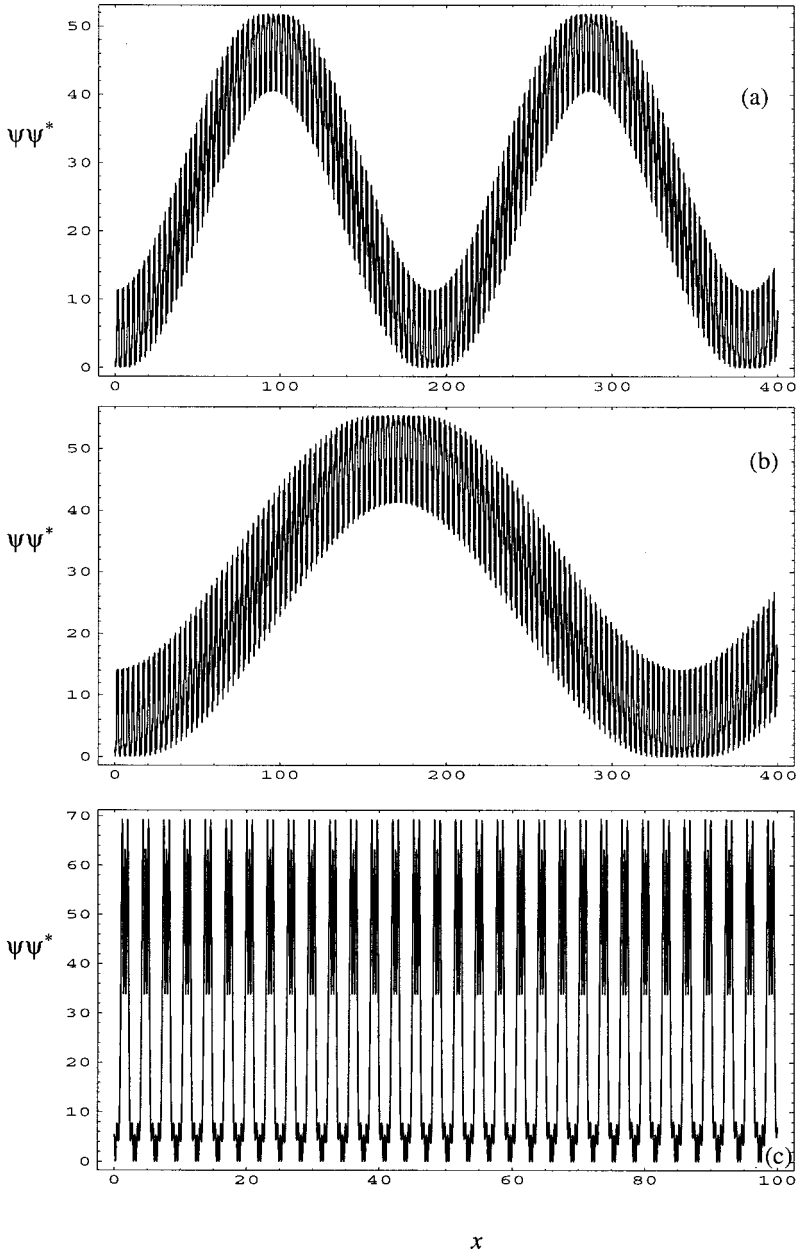

FIG. 4. The probability density for $\alpha=2$, $\beta=16.9$, and three K values: (a) $K=1.1000$, (b) $K=1.2000$, (c) $K=1.3005$.

The equation solved by Ψ in Eq. (6) has also been solved in the past using series of Bloch functions. Obviously the Bloch function solution contains all the same information of the Eq. (10) solution, however the Bloch function solution does not provide a method of understanding the dependence of the solution on α and β parameters. On the other hand the role of α and β is clear in the s variable. The s variable also points out the importance of zeros in the Bessel functions with respect to selecting interesting values of α and β. In addition the basic functions p and Q each have a differential equation with a factor of $\sin[(\beta/\alpha)\sin\alpha x]$. It was shown that for $\beta/\alpha < \pi/2$ the ratio β/α has the character of an amplitude. However, for $\beta/\alpha > \pi/2$, the ratio β/α has the character of a wave number. Consequently, as β/α is increased there is harmonic generation of the fundamental wave number contained in the solution.

The new wave function solution requires the determination of just two functions, p and Q. The form of the solution based on these two functions displays integer-order Bessel functions. The Bloch function series solves the same equation and thus it is possible to expand the Eq. (10) solution and derive the Bloch function series. The expansion procedure uses the Eq. (32) relations and the Eq. (A1) relations in the appendix. The resulting procedure produces a series with coefficients that are products of Bessel functions. Thus, the coefficients of the Bloch function series must also be products of Bessel functions that depend on α and β.

For $\beta/\alpha \ll 1$, $\mathcal{J}_{2n} \approx 0$, $\mathcal{J}_{2n+1} \approx 0$ and then s is real and $s \approx xK\mathcal{J}_0$. Using this approximation and restricting $K\beta/\alpha \ll 1$, analytic solutions for p and Q were derived. The analytic solutions were then applied to form wave functions used to determine the energy discriminant. The energy discriminant, which becomes a completely analytic function in this limit, was used to map the energy bands and gaps. The diminishing amplitude of $\Delta E - 2$ was illustrated as well as the reduction in the energy gap width as K increases.

As discussed earlier, the solution derived for p and Q in Sec. III B requires $K\beta/\alpha \ll 1$. This restriction must be imposed on the solution because as $\beta/\alpha \sim 1$ the couplings between p_r and p_i cannot be ignored and the solution requires the calculation of several difficult integrals. This difficulty can be overcome for a restricted parameter range. The solution can be extended based on an analysis of the behavior of the s variable. The main property of s that is useful in the construction of a large β/α solution is the highly nonuniform behavior of $ds/dx(\alpha,\beta)$. As x changes uniformly, s only changes uniformly when β/α is small. As β/α is increased beyond 1, ds/dx can be positive, negative, or very small. When it is very small the c_+ function tends to be approximately constant. Consequently, the solution under this condition is referred to as the dwell point solution. The dwell point solution relies on the validity of the issue of locality of $s+s^*$. For the circumstance of precisely constant $s+s^*$, Eq. (29) can be immediately integrated. Over a spatial region in which the s-plane trajectory is localized, $s+s^*$ is approximately constant, and thus separability of Eq. (28) is a good approximation. The best locality is attained near a zero of $\mathcal{J}_0$ with α large.

An interesting property of the integer-order Bessel functions is the oscillatory nature with regularly spaced zeros. The zeros of the Bessel functions point out interesting values of α and β where the character of the solution can be substantially altered. Regions around several zeros were numerically studied in Sec. IV B to show the dependence of the probability density on the selection of parameter values near Bessel function zeros. At fixed K, with $\alpha = 2$, the potential amplitude β was scanned from 16.9 to 17.3. It was shown that the appearance of the long wavelength in the probability density depends on the size of $\mathcal{J}_0$ and any low frequency contribution from p_r. Furthermore, even when $\mathcal{J}_0$ was identically zero there remained a long wavelength. The long wavelength in $\mathcal{P}$ for this case was demonstrated to be caused by the part of p_r linear in x.

Normally in a physical system the potential is given and the energy can be varied. To study the probability density under this condition β was set to 16.9 with $\alpha = 2$ and then K was varied from 1.1 to 1.3. It was found as in the previous example that the long wavelength in the probability density depends on the size of $\mathcal{J}_0$ and any low frequency contribution from p_r, except at $K = 1.3005$. At this particular value the linear part of p_r is equal and opposite to the linear part of $(s+s^*)/2$ and consequently the probability density does not have a long wavelength. Instead it is spatially distributed in very short wavelength peaks. The great difference between the spatial configuration with and without a long wavelength present hints at the possibility of a new semiconductor device. The switching action between the two modes occurs for a specific energy at fixed α and β.

ACKNOWLEDGMENTS

The advice provided by Dr. A. E. Schach von Wittenau concerning energy bands is greatly appreciated. This work was performed under the auspices of the U.S. Department of Energy by the University of California Lawrence Livermore National Laboratory under Contract no. W-7405-Eng-48.

(Received 26 January 2000; accepted for publication 2 May 2000)

We discuss spectral and resonance properties of exactly solvable Dirac Hamiltonians corresponding to a surface δ and δ' interactions. First, we study spectral properties for δ-sphere and δ'-sphere models. Next, we analyze the resonance phenomena for the same models with specific boundary conditions. © *2001 American Institute of Physics.* [DOI: 10.1063/1.1316060]

I. INTRODUCTION

The solvable models play a fundamental role in many areas of physics as they are simple and lead to much insight into the structure and properties of more complicated phenomena. Popular examples of such models are represented by the δ and δ'-sphere interactions which have been used in the recent past to describe various physical properties related as well to scattering theory as to spectral properties (see Ref. 1 and the references therein).

While these interactions have been deeper studied in nonrelativistic quantum mechanics, their profound analysis in relativistic theory was still missing. Some recent works[2–7] aim at extending our knowledge to δ and δ' interactions in relativistic quantum mechanics.

We pursue here the same objective and provide a systematic analysis of spectral and resonance properties of δ and δ'-type interactions for the Dirac operator with boundary conditions of the first and second type.[5]

The paper is organized as follows. In Sec. II, basic spectral properties are presented and analyzed. In Sec. III, we discuss the resonance properties. Section IV is devoted to some final remarks.

II. BASIC SPECTRAL PROPERTIES OF δ- AND δ'-SPHERE INTERACTIONS

A. The models

The expressions describing formally the models are of the type[2–7]

$$H = H_{\mathrm{D}} + V(|\underline{x}|), \quad \underline{x} \in \mathbb{R}^3, \tag{2.1}$$

where H_{D} is the free Dirac Hamiltonian:

$$H_{\mathrm{D}} \equiv -ic\alpha\nabla + \beta Mc^2, \tag{2.2}$$

M being the Dirac particle mass, i the complex imaginary ($i^2 = -1$), c the velocity of the light, ∇ the standard nabla operator while α and β are the Dirac matrices,

$$\alpha = \begin{pmatrix} \mathbf{0} & \sigma \\ \sigma & \mathbf{0} \end{pmatrix}, \quad \beta = \begin{pmatrix} \mathbf{1} & \mathbf{0} \\ \mathbf{0} & -\mathbf{1} \end{pmatrix}, \tag{2.3}$$

[a]Electronic mail: hounkon@syfed.bj.refer.org
[b]Electronic mail: avossevou@yahoo.fr

$\sigma \equiv \sigma^{\iota}$ ($\iota = 1,2,3$) are the 2×2 Pauli matrices:

$$\sigma^1 = \begin{pmatrix} 0 & 1 \\ 1 & 0 \end{pmatrix}, \quad \sigma^2 = \begin{pmatrix} 0 & -i \\ i & 0 \end{pmatrix}, \quad \sigma^3 = \begin{pmatrix} 1 & 0 \\ 0 & -1 \end{pmatrix}. \tag{2.4}$$

$V(|\underline{x}|)$ represents the potential that could be expressed as

$$V(|\underline{x}|) = \begin{cases} \sum_{m=1}^{N} \alpha_m \delta(|\underline{x}| - R_m), \\ \qquad \text{or} \\ \sum_{m=1}^{N} \beta_m \delta'(|\underline{x}| - R_m), \quad N \in \mathbb{N}^*, \quad N < \infty; \end{cases} \tag{2.5}$$

$\alpha_m, \beta_m \in \mathbb{R}$ and m stands for the number of concentric spheres of radii R_m.
The method adopted for the study of these singular interactions is based on the von Neumann theory of self-adjoint extensions of closed symmetric operators in Hilbert spaces.[8–11]

Let us consider the closed symmetric operator,

$$\dot{H} \equiv H_{\mathrm{D}}, \tag{2.6}$$

with the domain

$$\mathcal{D}(\dot{H}) = \{\psi \in H^{1,2}(\mathbb{R}^3) \otimes \mathbb{C}^4, \ \ \psi(S_{R_m}) = 0\}, \tag{2.7}$$

where $S_{R_m} = \{x \in \mathbb{R}^3, |x| = R_m\}$ is the closed ball of radius R_m centered at the origin in $\mathbb{R}^3$, and $H^{k,p}(\Omega)$ is the Sobolev space of indices (k,p).
The state Hilbert space $\mathcal{H}$ is decomposed as follows.[2–7]

$$\mathcal{H} = \bigoplus_{j=(1/2)}^{\infty} \bigoplus_{l=j-(1/2)}^{j+(1/2)} \bigoplus_{\mu=-j}^{j} \mathcal{H}_{jl\mu} = \bigoplus_{j=(1/2)}^{\infty} \bigoplus_{l=j-(1/2)}^{j+(1/2)} \mathcal{H}_{jl} \otimes [\Omega_{jl\mu}], \tag{2.8}$$

$\mathcal{H}_{jl}$ is the radial space:

$$\mathcal{H}_{jl} = \left\{ \psi(r) \in L^2((0,\infty)) \otimes \mathbb{C}^2; \ \ \psi(r) = \begin{pmatrix} f(r) \\ g(r) \end{pmatrix}; \ \ f,g \in L^2((0,\infty), r^2\, dr) \right\}, \tag{2.9}$$

and $[\Omega_{jl\mu}(\theta,\varphi)]$ is a space generated by the spherical spinors,

$$\Omega_{jl\mu}(\theta,\varphi) = \begin{pmatrix} \sqrt{\dfrac{j+\mu}{2l+1}} & Y_{l,\mu-(1/2)}(\theta,\varphi) \\ \sqrt{\dfrac{j-\mu}{2l+1}} & Y_{l,\mu+(1/2)}(\theta,\varphi) \end{pmatrix}, \quad \text{for } \ l = j - \frac{1}{2}, \tag{2.10}$$

$$\Omega_{jl\mu}(\theta,\varphi) = \begin{pmatrix} -\sqrt{\dfrac{j-\mu+1}{2l+1}} & Y_{l,\mu-(1/2)}(\theta,\varphi) \\ \sqrt{\dfrac{j+\mu+1}{2l+1}} & Y_{l,\mu+(1/2)}(\theta,\varphi) \end{pmatrix}, \quad \text{for } \ l = j + \frac{1}{2}, \tag{2.11}$$

where the spherical harmonics provide a basis for $L^2(S^2)$ (S^2 is the unit sphere in $\mathbb{R}^3$) and denote the linear span of vectors in $L^2(S^2)$. j,l,μ are the quantum numbers that characterize the total

angular momentum, its orbital and third (magnetic) components, respectively. Next, the following isomorphism is introduced in order to separate in each subspace $\mathcal{H}_{jl\mu}$, the radial part of the operator H and to remove the weight factor r^2 from the measure:[3,4]

$$\begin{aligned} U_{jl}:\quad & \mathcal{H}_{jl}\to L^2((0,\infty),dr)\otimes\mathbb{C}^2, \\ \psi\mapsto(U_{jl}\psi)(r)=&\begin{pmatrix} rf(r) \\ (-1)^{j-l-(1/2)}rg(r)\end{pmatrix}. \end{aligned} \tag{2.12}$$

This yields the following decomposition of $\mathcal{H}$:

$$\mathcal{H}=\bigoplus_{j=(1/2)}^{\infty}\bigoplus_{l=j-(1/2)}^{j+(1/2)}U_{jl}^{-1}[L^2((0,\infty),dr)\otimes\mathbb{C}^2]\bigotimes[\Omega_{jl-j},\ldots,\Omega_{jlj}]. \tag{2.13}$$

Provided the decomposition (2.13), one defines $\dot{H}$ as

$$\dot{H}=\bigoplus_{j=(1/2)}^{\infty}\bigoplus_{l=j-(1/2)}^{j+(1/2)}U_{jl}^{-1}\dot{h}_{jl}U_{jl}\bigotimes\mathbf{1}, \tag{2.14}$$

where ''the component operator'' $\dot{h}_{jl}$ is self-adjoint and represents the radial quantum Hamiltonian,

$$\dot{h}_{jl}=\begin{pmatrix} Mc^2 & c\left(-\dfrac{d}{dr}+\dfrac{K_{jl}}{r}\right) \\ c\left(\dfrac{d}{dr}+\dfrac{K_{jl}}{r}\right) & -Mc^2 \end{pmatrix}:=\tau, \tag{2.15}$$

with the domain

$$\begin{aligned} \mathcal{D}(\dot{h}_{jl})=&\{\psi\in L^2((0,\infty))\otimes\mathbb{C}^2;\ \ \psi,\psi'\in AC_{\mathrm{loc}}((0,\infty)-\{R\});\dot{h}_{jl}\psi\in L^2((0,\infty))\otimes\mathbb{C}^2\}, \\ &\{R\}:=\{R_1,R_2,\ldots,R_N\} \end{aligned} \tag{2.16}$$

and the physical constant $K_{jl}=(-1)^{j-l+(1/2)}(j+\frac{1}{2})$.

From this point, it remains only to characterize the deficiency subspace which should lead to a rigorous mathematical definition of the formal expression (2.1). Indeed,[4–7] one can easily show that $\mathrm{def}(\dot{h}_{jl})=(2N,2N)$ and that all self-adjoint extensions are characterized by a $4N^2$- parameter family. However, two special families of restricted number of parameters must be considered in accordance with the boundary conditions. An account of the method of obtaining the two families of boundary conditions can be found in Refs. 5, 6.

B. Basic spectral properties with boundary conditions of the first type

1. The δ-sphere models

We analyze the spectral properties for the δ-sphere interaction, for a finitely many δ-sphere interactions and for a δ-sphere coupled with a Coulomb type potential, respectively.

(i) The formal expression describing the one δ-sphere model is[7]

$$H=H_{\mathrm{D}}+\alpha\delta(|\underline{x}|-R),\quad \alpha\in\mathbb{R},\quad \underline{x}\in\mathbb{R}^3. \tag{2.17}$$

The boundary conditions which characterize each of the two special one-parameter families of self-adjoint extensions (s.a.e.) of the free Dirac Hamiltonian H_{D} are

$$g(k,R_+)-g(k,R_-)=\frac{\alpha}{c}f(k,R)+A,$$
$$f(k,R_+)=f(k,R_-)\equiv f(k,R), \tag{2.18}$$

or

$$f(k,R_+)-f(k,R_-)=-\frac{\theta}{c}g(k,R)+B,$$
$$g(k,R_+)=g(k,R_-)\equiv g(k,R); \tag{2.19}$$

$f(k,r)$ and $g(k,r)$ are the first and second components of the wave function, respectively; k, α, θ, A and B are nonvanishing constants; c is the velocity of the light.

The first family of s.a.e. labeled by α reads as

$$h_{jl,\alpha_{jl}}\equiv\tau,$$
$$\mathcal{D}(h_{jl,\alpha_{jl}})=\{\psi(r)\in L^2((0,\infty))\otimes\mathbb{C}^2;\ \ f_{jl}\in AC_{\mathrm{loc}}((0,\infty));$$
$$g_{jl}\in AC_{\mathrm{loc}}((0,\infty)-\{R\});\ \ g_{jl}(R_+)-g_{jl}(R_-)=\frac{\alpha}{c}f_{jl}(R)+A;$$
$$h_{jl,\alpha_{jl}}\psi\in L^2((0,\infty))\otimes\mathbb{C}^2\}. \tag{2.20}$$

The second family of s.a.e. is defined by

$$h_{jl,\theta_{jl}}\equiv\tau,$$
$$\mathcal{D}(h_{jl,\theta_{jl}})=\{\psi(r)\in L^2((0,\infty))\otimes\mathbb{C}^2;\ \ f_{jl}\in AC_{\mathrm{loc}}((0,\infty)-\{R\});$$
$$g_{jl}\in AC_{\mathrm{loc}}((0,\infty));\ \ f_{jl}(R_+)-f_{jl}(R_-)=-\frac{\theta}{c}g_{jl}(R)+B;$$
$$h_{jl,\theta_{jl}}\psi\in L^2((0,\infty))\otimes\mathbb{C}^2\}. \tag{2.21}$$

The resolvent is of a great help for the deduction of relevant physical properties as the scattering elements, the resonances and the spectra. The resolvent of $h_{jl,\alpha_{jl}}$ and H_α are given by the following Theorem.

Theorem II.1: *If $\alpha_{jl}\neq 0$, then the following holds.*

(i) The resolvent of $h_{jl,\alpha_{jl}}$ is given by

$$(h_{jl,\alpha_{jl}}-k^2)^{-1}=(h_{jl,0}-k^2)^{-1}+\frac{-\alpha_{jl}/c}{1+(\alpha_{jl}/c)[F_{jl}^{(0)}(k,R)G_{jl}^{(0)}(k,R)]}$$
$$\times\begin{pmatrix}1&0\\0&1\end{pmatrix}(\psi_{jl}(-\overline{k}),.)\psi_{jl}(k);\ \ k^2\in\rho(h_{jl,\alpha_{jl}}),\ \ \mathrm{Im}\,k>0. \tag{2.22}$$

$G_{jl,0}=(h_{jl,0}-k^2)^{-1}$, $\mathrm{Im}\,k>0$, *is the free resolvent kernel:*

$$G_{jl,0}(k',r,r')=\begin{bmatrix}\tilde{g}_{jl0}^{(I)}(k',r,r')&\tilde{g}_{jl0}^{(I)}(k',r,r')\\ \tilde{g}_{jl0}^{(II)}(k',r,r')&\tilde{g}_{jl0}^{(II)}(k',r,r')\end{bmatrix}, \tag{2.23}$$

where

$$\tilde{g}^{(I)}_{jl0}(k',r,r')=\begin{cases} G^{(0)}_{jl}(k',r)F^{(0)}_{jl}(k',r'); & r'<r,\\ F^{(0)}_{jl}(k',r)G^{(0)}_{jl}(k',r'); & r'>r, \end{cases} \tag{2.24}$$

and

$$\tilde{g}^{(II)}_{jl0}(k',r,r')=\begin{cases} \tilde{G}^{(0)}_{jl}(k',r)\tilde{F}^{(0)}_{jl}(k',r'); & r'<r,\\ \tilde{F}^{(0)}_{jl}(k',r)\tilde{G}^{(0)}_{jl}(k',r'); & r'>r. \end{cases} \tag{2.25}$$

$F^{(0)}_{jl}$, $\tilde{F}^{(0)}_{jl}$, $G^{(0)}_{jl}$ *and* $\tilde{G}^{(0)}_{jl}$ *are given by*

$$\begin{aligned} F^{(0)}_{jl}(k',r)&=\left(\frac{k'}{2}\right)^{-K_{jl}-(1/2)}\Gamma\left(K_{jl}+\frac{3}{2}\right)r^{1/2}J_{K_{jl}+(1/2)}(k'r),\\ G^{(0)}_{jl}(k',r)&=-\frac{i\pi}{2}\frac{1}{\Gamma(K_{jl}+(3/2))}\left(\frac{k'}{2}\right)^{K_{jl}+(1/2)}r^{1/2}H^{(2)}_{K_{jl}+(1/2)}(k'r),\\ \tilde{F}^{(0)}_{jl}(k',r)&=\left(\frac{k'}{2}\right)^{-K_{jl}+(1/2)}\Gamma\left(K_{jl}+\frac{1}{2}\right)r^{1/2}J_{K_{jl}-(1/2)}(k'r),\\ \tilde{G}^{(0)}_{jl}(k',r)&=-\frac{i\pi}{2}\frac{1}{\Gamma(K_{jl}+(1/2))}\left(\frac{k'}{2}\right)^{K_{jl}-(1/2)}r^{1/2}H^{(2)}_{K_{jl}-(1/2)}(k'r), \end{aligned} \tag{2.26}$$

where $k'^2=c^{-2}(k^4-M^2c^4)$, $J_\nu(z)$ *and* $H^{(2)}_\nu(z)$ *are*[13,14] *the Bessel function and the Hankel function of the second type of order* ν, *respectively.* $\psi_{jl}(k',r)$ *is given by*

$$\psi_{jl}(k',r)=\begin{pmatrix} F^{(0)}_{jl}(k',r)G^{(0)}_{jl}(k',R)+F^{(0)}_{jl}(k',R)G^{(0)}_{jl}(k',r)\\ \tilde{F}^{(0)}_{jl}(k',r)G^{(0)}_{jl}(k',R)+F^{(0)}_{jl}(k',R)\tilde{G}^{(0)}_{jl}(k',r)\end{pmatrix}. \tag{2.27}$$

(ii) The resolvent of H_α *is given by*

$$\begin{aligned}(H_\alpha-k^2)^{-1}=(H_0-k^2)^{-1}+\bigoplus_{j=1/2}^{\infty}\bigoplus_{l=j-1/2}^{j+1/2}\bigoplus_{m=-l}^{+l}\frac{-\alpha_{jl}/c}{1+(\alpha_{jl}/c)[F^{(0)}_{jl}(k,R)G^{(0)}_{jl}(k,R)]}\\ \times[|\cdot|^{-1}(\psi_{jl}(-\overline{k})\otimes\Omega_{jlm}),.]|\cdot|^{-1}\psi_{jl}(k)\otimes\Omega_{jlm},\ \ k^2\in\rho(H_\alpha),\end{aligned} \tag{2.28}$$

with the notation

$$\psi_{jl}(k)\otimes\Omega_{jlm}=\begin{pmatrix}\psi_{(jl)_1}\Omega_{(jlm)_1}\\ \psi_{(jl)_2}\Omega_{(jlm)_2}\end{pmatrix},\quad \psi_{jl}=\begin{pmatrix}\psi_{(jl)_1}\\ \psi_{(jl)_2}\end{pmatrix},\ \ \Omega_{(jlm)}=\begin{pmatrix}\Omega_{(jlm)_1}\\ \Omega_{(jlm)_2}\end{pmatrix},$$

$\rho(\cdot)$ *is the resolvent set,* H_α:=H [*see Eq. (2.1)*].

Proof: By means of Krein's formula[10] and after a straightforward computation performed as in Ref. 4, the resolvent (2.22) is deduced. Expression (2.28) follows from the decomposition (2.13). ■

Theorem II.2: *All self-adjoint extensions of the extended Dirac operator* $H=H_D+V(|\underline{x}|)$ *with deficiency indices* (2,2) *have the same continuous spectrum as that of the free Dirac operator* H_D; *this spectrum is purely and absolutely continuous and equals* $]-\infty,-Mc^2]\cup[Mc^2,+\infty[$.

Proof: The first part of this statement follows immediately from the fact that all s.a.e. of an operator with equal and finite deficiency indices have the same continuous spectrum (see Ref. 10, Theorem 1, p. 365).

Next, in Refs. 2, 12, it has been proved that the continuous spectrum of the free Dirac operator is known to be purely and absolutely continuous and equals $]-\infty,-Mc^2]\cup[Mc^2,+\infty[$ taking into account the following radial equation (in Ref. 2, $c=1$):

$$Mc^2 f - c\frac{d}{dr}g + c\frac{K_{jl}}{r}g = \lambda f,$$

$$c\frac{d}{dr}f + c\frac{K_{jl}}{r}f - Mc^2 = \lambda g, \quad \lambda \in \mathbb{R}. \tag{2.29}$$

Finally, the spectral kernel of the extended Dirac operator coincides with the spectrum of this operator. Moreover, the spectral kernel of $h_{jl,\alpha_{jl}}$ contains the spectral kernel of $h_{jl,0}$ as the former stands for the s.a.e. of the latter. So, each part of the spectral kernel of $h_{jl,\alpha_{jl}}$ contains the corresponding part of the spectral kernel of $h_{jl,0}$. As the deficiency indices of the operator $h_{jl,0}$ is finite $(\mathrm{def}(h_{jl,0})=(2,2))$, the continuous part of its spectral kernel is invariant for its symmetric extensions.[10] Hence, the free Dirac operator $h_{jl,0}$ and its s.a.e. have the same continuous spectrum.

Besides, by the von Neumann formula,[10] the manifold $(h_{jl,\alpha_{jl}}-k^2)\mathcal{D}(h_{jl,\alpha_{jl}})$ contains the manifold $(h_{jl,0}-k^2)\mathcal{D}(h_{jl,0})$ and the difference in dimensions is finite. Therefore, the operator $(h_{jl,\alpha_{jl}}-k^2)^{-1}$ is bounded along with the operator $(h_{jl,0}-k^2)^{-1}$.

Theorem II.3: *The singularly continuous and residual spectra of the extended Dirac operator $h_{jl,\alpha_{jl}}$ are empty.*

Proof: One can follow step by step the development given in Ref. 2 to show that the singularly continuous spectrum is empty. The fact that the residual spectrum is empty results from the self-adjointness of the operator. ■

The above development trivially generalizes for $N>2$ $(\mathrm{def}(h_{jl,0})=(N,N))$. Henceforth, we shall restrict ourselves to the study of the bound state equations that are different for different models as the boundary conditions characterizing these models change.

The bound state equations for the model (2.17) provide elements for its point spectrum and their solutions are the negative eigenvalues of the singular radial Hamiltonian $h_{jl,\alpha_{jl}}$. These equations are obtained from the following Theorem.

Theorem II.4: *The bound state equations relative to the first and second families of s.a.e. read as*

$$\frac{\alpha_{jl}}{c} = \frac{\pm \tilde{T}^{(0)}_{jl}(\tilde{E},R)\tilde{L}^{(0)}_{jl}(\tilde{E},R)}{T^{(0)}_{jl}(\tilde{E},R)L^{(0)}_{jl}(\tilde{E},R)+A_1}, \quad A=\frac{\alpha_{jl}}{c}A_1 \tag{2.30}$$

and

$$\frac{\theta_{jl}}{c} = \frac{\pm T^{(0)}_{jl}(\tilde{E},R)L^{(0)}_{jl}(\tilde{E},R)}{\tilde{T}^{(0)}_{jl}(\tilde{E},R)\tilde{L}^{(0)}_{jl}(\tilde{E},R)-B_1}, \quad B=\frac{\theta_{jl}}{c}B_1, \tag{2.31}$$

respectively, where

$$
\begin{aligned}
L_{jl}^{(0)}(\tilde{E},r) &= \Gamma\left(K_{jl}+\frac{3}{2}\right)\left(\frac{\sqrt{-\tilde{E}}}{2}\right)^{-K_{jl}-(1/2)} r^{1/2} I_{K_{jl}+(1/2)}(\sqrt{-\tilde{E}}r),\\
T_{jl}^{(0)}(\tilde{E},r) &= \frac{2}{\Gamma(K_{jl}+(3/2))}\left(\frac{\sqrt{-\tilde{E}}}{2}\right)^{K_{jl}+(1/2)} r^{1/2} K_{K_{jl}+(1/2)}(\sqrt{-\tilde{E}}r),\\
\tilde{L}_{jl}^{(0)}(\tilde{E},r) &= \Gamma\left(K_{jl}+\frac{1}{2}\right)\left(\frac{\sqrt{-\tilde{E}}}{2}\right)^{-K_{jl}+(1/2)} r^{1/2} I_{K_{jl}-(1/2)}(\sqrt{-\tilde{E}}r),\\
\tilde{T}_{jl}^{(0)}(\tilde{E},r) &= \frac{2}{\Gamma(K_{jl}+(1/2))}\left(\frac{\sqrt{-\tilde{E}}}{2}\right)^{K_{jl}-(1/2)} r^{1/2} K_{K_{jl}-(1/2)}(\sqrt{-\tilde{E}}r).
\end{aligned}
\tag{2.32}
$$

I_ν and K_ν are the modified Bessel functions of the first and second type of order ν, respectively.[13]

Proof: These equations stem from the following eigenvalue equations:

$$
\begin{pmatrix} Mc^2 & c\left(-\frac{d}{dr}+\frac{K_{jl}}{r}\right) \\ c\left(\frac{d}{dr}+\frac{K_{jl}}{r}\right) & -Mc^2 \end{pmatrix}
\begin{pmatrix} f_{jl}(E,r) \\ g_{jl}(E,r) \end{pmatrix} = E\begin{pmatrix} f_{jl}(E,r) \\ g_{jl}(E,r) \end{pmatrix}, \quad E<0, \tag{2.33}
$$

that split into

$$
f''(E,r)+\left[\frac{E^2-M^2c^4}{c^2}-\frac{1}{r^2}K_{jl}(K_{jl}+1)\right]f(E,r)=0, \tag{2.34}
$$

$$
g''(E,r)+\left[\frac{E^2-M^2c^4}{c^2}-\frac{1}{r^2}K_{jl}(K_{jl}-1)\right]g(E,r)=0. \tag{2.35}
$$

A supplementary condition (physically admitted) is $E^2<M^2c^4$. This yields $\tilde{E}=(E^2-M^2c^4)/c^2<0$ and the corresponding separated equations provide the solutions (2.32). Besides, using the modified Bessel functions (2.32), the implementation of the boundary conditions (2.18) and (2.19) gives the bound state equations (2.30) and (2.31). ■

Let us discuss some solutions.

Using relations (2.32), Eq. (2.30) reduces to the equation

$$
1+\bar{\alpha}_{jl}RK_{K_{jl}+(1/2)}(\sqrt{-\tilde{E}}R)I_{K_{jl}+(1/2)}(\sqrt{-\tilde{E}}R)=0, \tag{2.36}
$$

with $\bar{\alpha}_{jl}=(2/A)(\alpha_{jl}/c\pm b)$, $\alpha_{jl}\in\mathbb{R}$, $b\in\mathbb{R}$, for the first family characterized by the parameters α_{jl}; an analogous equation with adequate parameters is obtained for the second family from (2.31).

This equation is similar to that analyzed in Ref. 1 [Eq. 2.39)], using the monotonicity properties of $K(\cdot)I(\cdot)$. For each family of s.a.e., we have two solutions $\tilde{E}_{1,2}<0$ for $\bar{\alpha}_{jl}R<-(K_{jl}+1/2)$ and no solution for $\bar{\alpha}_{jl}R\geqslant-(K_{jl}+1/2)$. Obviously, the two solutions stem from the two possibilities $\pm b$ in the expression of $\bar{\alpha}_{jl}$ occurring in Eq. (2.36).

This result is in good accordance with the wording of Proposition 6.1 given in Ref. 2. Compared with the nonrelativistic case,[1] this result is predictable since two special one parameter families of s.a.e. are defined in the relativistic case instead of one in the nonrelativistic case because of the matrix structure of the Dirac equation.

(ii) Concerning the finitely many δ-sphere interactions case, the model is formally expressed as[5]

$$H_{\{R\}}=H_{\mathrm{D}}+\sum_{m=1}^{N}\alpha_m\delta(|\underline{x}|-R_m);\quad \underline{x}\in\mathbb{R}^3, \tag{2.37}$$

where H_{D} is the free Dirac operator; $\alpha_m\neq 0$, $1\leqslant m\leqslant N$. Two special N-parameter families of s.a.e. are defined. The first family characterized by the parameters α_m, $m=1,\ldots,N$ reads as

$$h_{jl,\alpha_{jl}\{R\}}\equiv\begin{pmatrix} Mc^2 & c\left(-\dfrac{d}{dr}+\dfrac{K_{jl}}{r}\right)\\ c\left(\dfrac{d}{dr}+\dfrac{K_{jl}}{r}\right) & -Mc^2\end{pmatrix},$$

$$\mathcal{D}(h_{jl,\alpha_{jl}\{R\}})=\{\psi(r)\in L^2((0,\infty))\otimes\mathbb{C}^2;\ \ f_{jl}\in AC_{\mathrm{loc}}((0,\infty));$$

$$g_{jl}\in AC_{\mathrm{loc}}((0,\infty)-\{R\});g_{jl}(R_{m+})-g_{jl}(R_{m-})=\frac{\alpha_m}{c}f_{jl}(R_m)+A_m;$$

$$h_{jl,\alpha_{jl}\{R\}}\psi\in L^2((0,\infty))\otimes\mathbb{C}^2\},\{R\}:=\{R_1,R_2,\ldots,R_N\}. \tag{2.38}$$

So, for all $m=1,\ldots,N$, assuming $\alpha_{jl}\in\mathbb{R}$, the negative eigenvalues of the radial extended Hamiltonian are given by the bound state equations

$$\frac{\alpha_m}{c}=\frac{\pm\tilde{T}_{jl}^{(0)}(\tilde{E},R_m)\tilde{L}_{jl}^{(0)}(\tilde{E},R_m)}{T_{jl}^{(0)}(\tilde{E},R_m)L_{jl}^{(0)}(\tilde{E},R_m)+A_1^m},\quad A_1^m=\frac{\alpha_m}{c}A_m. \tag{2.39}$$

The second family is defined by

$$\mathcal{D}(h_{jl,\theta_{jl}\{R\}})=\{\psi(r)\in L^2((0,\infty))\otimes\mathbb{C}^2;\ \ g_{jl}\in AC_{\mathrm{loc}}((0,\infty));$$

$$f_{jl}\in AC_{\mathrm{loc}}((0,\infty)\backslash\{R\});\ \ f_{jl}(R_{m+})-f_{jl}(R_{m-})=-\frac{\theta_m}{c}g_{jl}(R_m)+B_m;$$

$$h_{jl,\gamma_{jl}\{R\}}\psi\in L^2((0,\infty))\otimes\mathbb{C}^2\},\{R\}:=\{R_1,R_2,\ldots,R_N\}. \tag{2.40}$$

The corresponding bound state equations are

$$\frac{\theta_{jl}}{c}=\frac{\pm T_{jl}^{(0)}(\tilde{E},R_m)L_{jl}^{(0)}(\tilde{E},R_m)}{\tilde{T}_{jl}^{(0)}(\tilde{E},R_m)\tilde{L}_{jl}^{(0)}(\tilde{E},R_m)-B_1^m},\quad \text{with}\quad B_m=\frac{\theta_{jl}}{c}B_1^m. \tag{2.41}$$

The discussion is similar to that of the one δ-sphere model. Thus, if for each equation we get n solutions, we can hope to obtain for each family at most $2nN$ negative eigenvalues by analogy to the δ-sphere case replacing R by R_m.

(iii) In the model of one δ-sphere interaction coupled with a Coulomb potential, the formal expression describing the interaction Hamiltonian reads as[4,6,7,11]

$$H=H_{\mathrm{D}}+\frac{\gamma_0}{r}+\alpha\delta(r-R), \tag{2.42}$$

where H_{D} represents the free Dirac Hamiltonian, γ_0 and α are nonvanishing physical constants. We can define two special one-parameter families of s.a.e. according to the boundary conditions (2.18) and (2.19). For the bound state equations, we state the following Theorem.

Theorem II.5: *The negative eigenvalues $\tilde{E}$ are solutions of the equations*

$$\frac{\alpha_{jl\gamma_0}}{c}=\frac{\pm\tilde{T}^{(0)}_{jl\gamma_0}(\tilde{E},R)\tilde{L}^{(0)}_{jl\gamma_0}(\tilde{E},R)}{T^{(0)}_{jl\gamma_0}(\tilde{E},R)L^{(0)}_{jl\gamma_0}(\tilde{E},R)+A_{\gamma_0 1}},\quad A_{\gamma_0}=\frac{\alpha_{jl\gamma_0}}{c}A_{\gamma_0 1},\tag{2.43}$$

for the first family and

$$\frac{\theta_{jl\gamma_0}}{c}=\frac{\pm T^{(0)}_{jl\gamma_0}(\tilde{E},R)L^{(0)}_{jl\gamma_0}(\tilde{E},R)}{\tilde{T}^{(0)}_{jl\gamma_0}(\tilde{E},R)\tilde{L}^{(0)}_{jl\gamma_0}(\tilde{E},R)-B_{\gamma_0 1}},\quad B_{\gamma_0}=\frac{\theta_{jl\gamma_0}}{c}B_{\gamma_0 1},\tag{2.44}$$

for the second family, respectively, where

$$\begin{aligned}L_{jl\gamma_0}(\tilde{E},r)&=\left(\frac{\gamma_0}{2\epsilon(K_{jl}-\epsilon)}p_1-\frac{1}{2\epsilon}q_1\right);\ r<R,\\ T_{jl\gamma_0}(\tilde{E},r)&=\left(\frac{\gamma_0}{2\epsilon(K_{jl}-\epsilon)}p_2-\frac{1}{2\epsilon}q_2\right);\ r>R,\end{aligned}\tag{2.45}$$

and

$$\begin{aligned}\tilde{L}^{(0)}_{jl\gamma_0}(\tilde{E},r)&=\left(-\frac{1}{2\epsilon}p_1+\frac{\gamma_0}{2\epsilon(K_{jl}-\epsilon)}q_1\right);\ r<R\\ \tilde{T}^{(0)}_{jl\gamma_0}(\tilde{E},r)&=\left(-\frac{1}{2\epsilon}p_2+\frac{\gamma_0}{2\epsilon(K_{jl}-\epsilon)}q_2\right);\ r>R,\end{aligned}\tag{2.46}$$

with

$$p_1(\tilde{E},r)=r^{\mu+1}\exp(\sqrt{-\tilde{E}}r)\,{}_1F_1\left(1+\mu-\frac{\gamma_0 E}{c^2\sqrt{-\tilde{E}}};2(\mu+1);-2\sqrt{-\tilde{E}}r\right),\tag{2.47}$$

$$p_2(\tilde{E},r)=\Gamma[2(\mu+1)]^{-1}\Gamma\left[\left(1+\mu-\frac{\gamma_0 E}{c^2\sqrt{-\tilde{E}}}\right)\right](-2\sqrt{-\tilde{E}})^{2\mu+1}r^{\mu+1}\exp(\sqrt{-\tilde{E}}r)$$

$$\times U\left(1+\mu-\frac{\gamma_0 E}{c^2\sqrt{-\tilde{E}}};2(\mu+1);-2\sqrt{-\tilde{E}}r\right),$$

$$q_1(\tilde{E},r)=r^{\mu}\exp(\sqrt{-\tilde{E}}r)\,{}_1F_1\left(\mu-\frac{\gamma_0 E}{c^2\sqrt{-\tilde{E}}};2\mu;-2\sqrt{-\tilde{E}}r\right),\tag{2.48}$$

$$q_2(\tilde{E},r)=\Gamma(2\mu)^{-1}\Gamma\left(\mu-\frac{\gamma_0 E}{c^2\sqrt{-\tilde{E}}}\right)(-2\sqrt{-\tilde{E}})^{2\mu-1}r^{\mu}\exp(\sqrt{-\tilde{E}}r)$$

$$\times U\left(\mu-\frac{\gamma_0 E}{c^2\sqrt{-\tilde{E}}};2\mu;-2\sqrt{-\tilde{E}}r\right),$$

$\tilde{E}=c^{-2}(E^2-M^2c^4)<0$, $\epsilon=\sqrt{c^2K_{jl}^2-\gamma_0^2}$, $\mu=\epsilon/c$. ${}_1F_1(z)$ *and* $U(z)$ *are the hypergeometric functions of the first and second type, respectively.*[13,14]

Proof: The method of solving the bound state equations [a matrix differential equation analogous of Eq. (2.33)] can be found in Ref. 14. Besides, the implementation of the boundary conditions (2.18) and (2.19) using the obtained solutions, gives the equations (2.43) and (2.44). ■

Next, one can easily apply the technique previously used to carry out a systematic study of this model.

2. The δ'-sphere models

Here, we only sketch some important facts and merely provide a collection of relevant formulas without explicit proofs, since the whole analysis can be carried through as in the previous subsection.

For the one δ'-sphere model, we have[6]

$$H=H_{\mathrm{D}}+\tilde{\alpha}\,\delta'(|\underline{x}|-R),\quad \tilde{\alpha}\in\mathbb{R},\quad \underline{x}\in\mathbb{R}^3. \tag{2.49}$$

The boundary conditions of the first type which characterize each of the two special one-parameter families of s.a.e. of the free Dirac Hamiltonian H_{D} are given by

$$\begin{aligned} g(k,R_+)-g(k,R_-)&=-\frac{\tilde{\alpha}}{c}\frac{1}{2}[f'(k,R_+)+f'(k,R_-)]+\tilde{A},\\ f(k,R_+)&=f(k,R_-)\equiv f(k,R), \end{aligned} \tag{2.50}$$

or

$$\begin{aligned} f(k,R_+)-f(k,R_-)&=\frac{\tilde{\theta}}{c}\frac{1}{2}[g'(k,R_+)+g'(k,R_-)]-\tilde{B},\\ g(k,R_+)&=g(k,R_-)\equiv g(k,R), \end{aligned} \tag{2.51}$$

where $f(k,r)$ and $g(k,r)$ are as usual the components of the wave function; k, $\tilde{\alpha}$, $\tilde{\theta}$, $\tilde{A}$ and $\tilde{B}$ are nonvanishing constants. We can easily define two families of s.a.e. accordingly with the above boundary conditions (see Ref. 7).

The bound state equations for the first family are

$$\frac{\tilde{\alpha}_{jl}}{c}=\frac{\pm 2\tilde{T}_{jl}^{(0)}(\tilde{E},R)\tilde{L}_{jl}^{(0)}(\tilde{E},R)}{T_{jl}^{(0)}(\tilde{E},R)L_{jl}^{(0)}(\tilde{E},R)-2\tilde{A}_1},\quad \tilde{A}=\frac{\tilde{\alpha}_{jl}}{c}\tilde{A}_1. \tag{2.52}$$

For the second family of s.a.e., we have

$$\frac{\tilde{\theta}_{jl}}{2c}=\frac{\pm T_{jl}^{(0)}(\tilde{E},R)L_{jl}^{(0)}(\tilde{E},R)}{\tilde{T}_{jl}^{(0)}(\tilde{E},R)\tilde{L}_{jl}^{(0)}(\tilde{E},R)-2\tilde{B}_1},\quad \text{with}\quad \tilde{B}=\frac{\tilde{\theta}_{jl}}{c}\tilde{B}_1. \tag{2.53}$$

The same procedure as that of the previous subsection applied here, yields

$$1+\bar{\tilde{\alpha}}_{jl}RK_{K_{jl}+(1/2)}(\sqrt{-\tilde{E}}R)I_{K_{jl}+(1/2)}(\sqrt{-\tilde{E}}R)=0, \tag{2.54}$$

with $\bar{\tilde{\alpha}}_{jl}=(1/2\tilde{A})(\tilde{\alpha}_{jl}/c\pm 2\tilde{b})$, $\tilde{\beta}_{jl}\in\mathbb{R}$, $\tilde{b}\in\mathbb{R}$, for the first family characterized by the parameters $\tilde{\alpha}_{jl}$ and an analogous equation with appropriate parameters for the second family.

From this, two solutions are possible for each family of s.a.e.: For $\tilde{\bar{\alpha}}_{jl}R<-(2K_{jl}+1)$, we have one solution with $\tilde{\bar{\alpha}}_{jl}=(\tilde{\alpha}_{jl}/c+2\tilde{b})$ and another with $\tilde{\bar{\alpha}}_{jl}=(\tilde{\alpha}_{jl}/c-2\tilde{b})$, while for $\tilde{\bar{\alpha}}_{jl}R \geqslant -(2K_{jl}+1)$ there is no solution in the both cases.

Concerning the finitely many sphere case, we hope at most $2N$ eigenvalues of the above types for each extended radial operator.

Finally, for the case of one δ'-sphere interaction coupled with a Coulomb potential, the formal model is[6,7]

$$H=H_{\mathrm{D}}+\frac{\gamma_0}{r}+\tilde{\alpha}\,\delta'(r-R). \tag{2.55}$$

The corresponding extended radial operators are

$$h_{jl\gamma_0,\tilde{\alpha}_{jl}}\equiv\begin{pmatrix} Mc^2+\dfrac{\gamma_0}{r} & c\left(-\dfrac{d}{dr}+\dfrac{K_{jl}}{r}\right) \\ c\left(\dfrac{d}{dr}+\dfrac{K_{jl}}{r}\right) & -Mc^2+\dfrac{\gamma_0}{r}\end{pmatrix}:=\tau_{\gamma_0}, \tag{2.56}$$

$$\begin{aligned}\mathcal{D}(h_{jl\gamma_0,\tilde{\alpha}_{jl}})=\Big\{ & \psi(r)\in L^2((0,\infty))\otimes\mathbb{C}^2;\ ;f_{jl}\in AC_{\mathrm{loc}}((0,\infty));\\ & f'_{jl}\in AC_{\mathrm{loc}}((0,\infty)\backslash\{R\});\ g_{jl},g'_{jl}\in AC_{\mathrm{loc}}((0,\infty)\backslash\{R\});\\ & g_{jl}(k,R_+)-g_{jl}(k,R_-)=-\frac{1}{2}\frac{\tilde{\alpha}_{jl}}{c}[f'_{jl}(k,R_+)+f'_{jl}(k,R_-)]+\tilde{A};\\ & h_{jl\gamma_0,\tilde{\alpha}_{jl}}\psi\in L^2((0,\infty))\otimes\mathbb{C}^2;\ \tilde{A}\neq 0;\ -\infty<\tilde{\alpha}_{jl}<+\infty\Big\},\end{aligned} \tag{2.57}$$

for the first family and

$$h_{jl\gamma_0,\tilde{\theta}_{jl}}\equiv\tau_{\gamma_0},$$

$$\begin{aligned}\mathcal{D}(h_{jl\gamma_0,\tilde{\theta}_{jl}})=\Big\{ & \psi(r)\in L^2((0,\infty))\otimes\mathbb{C}^2;\ g_{jl},g'_{jl}\in AC_{\mathrm{loc}}((0,\infty)\backslash\{R\});\\ & f_{jl},f'_{jl}\in AC_{\mathrm{loc}}((0,\infty)\backslash\{R\});\ g_{jl}(k,R_+)=g_{jl}(k,R_-);\\ & f_{jl}(k,R_+)-f_{jl}(k,R_-)=\frac{\tilde{\gamma}_{jl}}{c}\frac{1}{2}[g'_{jl}(k,R_+)+g'_{jl}(k,R_-)]-\tilde{B};\\ & h_{jl\gamma_0,\tilde{\theta}_{jl}}\psi\in L^2((0,\infty))\otimes\mathbb{C}^2;\\ & \tilde{B}\neq 0;\ -\infty<\tilde{\theta}_{jl}<+\infty\Big\},\end{aligned} \tag{2.58}$$

for the second family.

The negative eigenvalues are solutions of the equations

$$\frac{\tilde{\alpha}_{jl\gamma_0}}{2c}=\frac{\pm\tilde{T}^{(0)}_{jl\gamma_0}(\tilde{E},R)\tilde{L}^{(0)}_{jl\gamma_0}(\tilde{E},R)}{T^{(0)}_{jl\gamma_0}(\tilde{E},R)L^{(0)}_{jl\gamma_0}(\tilde{E},R)-2\tilde{A}_{\gamma_0 1}},\quad \tilde{A}_{\gamma_0}=\frac{\alpha_{jl\gamma_0}}{c}\tilde{A}_{\gamma_0 1}, \tag{2.59}$$

for the first family and

$$\frac{\tilde{\theta}_{jl\gamma_0}}{2c}=\frac{\pm T^{(0)}_{jl\gamma_0}(\tilde{E},R)L^{(0)}_{jl\gamma_0}(\tilde{E},R)}{\tilde{T}^{(0)}_{jl\gamma_0}(\tilde{E},R)\tilde{L}^{(0)}_{jl\gamma_0}(\tilde{E},R)-2\tilde{B}_{\gamma_0 1}},\quad \tilde{B}_{\gamma_0}=\frac{\theta_{jl\gamma_0}}{c}\tilde{B}_{\gamma_0 1}, \tag{2.60}$$

for the second family.

C. Basic spectral properties with boundary conditions of second type

1. The δ-sphere models

Turning back to the one-sphere interaction, the second type boundary conditions are obtained from (2.18) and (2.19) by interchanging formally f and f' (g and g'). We have[4]

$$\begin{aligned} g'(k,R_+)-g'(k,R_-)&=\frac{\beta}{c}f'(k,R)+A,\\ f'(k,R_+)&=f'(k,R_-)\equiv f'(k,R), \end{aligned} \tag{2.61}$$

or

$$\begin{aligned} f'(k,R_+)-f'(k,R_-)&=-\frac{\gamma}{c}g'(k,R)+B,\\ g'(k,R_+)&=g'(k,R_-)\equiv g'(k,R). \end{aligned} \tag{2.62}$$

Following Ref. 4, two special one-parameter families of s.a.e. have been defined accordingly with the above boundary conditions and the bound state equations read, respectively, for the first and second families,

$$\frac{\beta_{jl}}{c}=\frac{\pm\tilde{T}^{(0)'}_{jl}(\tilde{E},R)\tilde{L}^{(0)'}_{jl}(\tilde{E},R)}{T^{(0)'}_{jl}(\tilde{E},R)L^{(0)'}_{jl}(\tilde{E},R)+A_1},\quad A=\frac{\beta_{jl}}{c}A_1, \tag{2.63}$$

$$\frac{\gamma_{jl}}{c}=\frac{\pm T^{(0)'}_{jl}(\tilde{E},R)L^{(0)'}_{jl}(\tilde{E},R)}{\tilde{T}^{(0)'}_{jl}(\tilde{E},R)\tilde{L}^{(0)'}_{jl}(\tilde{E},R)-B_1},\quad B=\frac{\gamma_{jl}}{c}B_1. \tag{2.64}$$

The generalization to finitely many concentric sphere interactions and to the one-sphere coupled with a Coulomb potential follows the same way as previously and the equations express with the derivatives of the special functions (2.32), (2.45) and (2.46).

2. The δ'-sphere models

The one-sphere model is formally expressed by Eq. (2.49). Here again, the boundary conditions of the second type are obtained from (2.50) and (2.51) by interchanging formally f and f', g and g' with the labels $\tilde{\beta}$ and $\tilde{\gamma}$ instead of β and γ in (2.61) and (2.62), that explicitly writes

$$\begin{aligned} g'(k,R_+)-g'(k,R_-)&=-\frac{\tilde{\beta}}{c}\frac{1}{2}[f(k,R_+)+f(k,R_-)]+\tilde{A},\\ f'(k,R_+)&=f'(k,R_-)\equiv f'(k,R), \end{aligned} \tag{2.65}$$

and

$$f'(k,R_+)-f'(k,R_-)=\frac{\tilde{\gamma}}{c}\frac{1}{2}[g(k,R_+)+g(k,R_-)]-\tilde{B},$$

$$g'(k,R_+)=g'(k,R_-)\equiv g'(k,R), \tag{2.66}$$

where $f(k,r)$ and $g(k,r)$ are as usual the components of the wave function; k, $\tilde{\beta}$, $\tilde{\gamma}$, $\tilde{A}$ and $\tilde{B}$ are nonvanishing constants.

The eigenvalues of the bound states are solutions of the equations

$$\frac{\tilde{\beta}_{jl}}{2c}=\frac{\pm\tilde{T}_{jl}^{(0)'}(\tilde{E},R)\tilde{L}_{jl}^{(0)'}(\tilde{E},R)}{T_{jl}^{(0)'}(\tilde{E},R)L_{jl}^{(0)'}(\tilde{E},R)-2\tilde{A}_1}, \quad \tilde{A}=\frac{\tilde{\beta}_{jl}}{c}\tilde{A}_1, \tag{2.67}$$

$$\frac{\tilde{\gamma}_{jl}}{2c}=\frac{\pm T_{jl}^{(0)'}(\tilde{E},R)L_{jl}^{(0)'}(\tilde{E},R)}{\tilde{T}_{jl}^{(0)'}(\tilde{E},R)\tilde{L}_{jl}^{(0)'}(\tilde{E},R)-2\tilde{B}_1}, \quad \tilde{B}=\frac{\tilde{\gamma}_{jl}}{c}\tilde{B}_1. \tag{2.68}$$

The generalization is now standard and we omit it since the technique is the same.

III. ANALYSIS OF RESONANCE PHENOMENA

A. The δ-sphere models

We deal now with the resonance phenomena for the extended operators. As usual,[15] resonances are defined as poles of the resolvents in the unphysical sheet $\mathrm{Im}\,k'<0$. The resolvent of $h_{jl,\beta_{jl}}$ using the boundary conditions of the second type (2.61) for a one δ-sphere interaction is given by[4]

$$(h_{jl,\beta_{jl}}-k^2)^{-1}=(h_{jl,0}-k^2)^{-1}+\frac{\beta_{jl}/c}{1-(\beta_{jl}/c)F_{jl}^{(0)'}(k,R)G_{jl}^{(0)'}(k,R)} \times\begin{pmatrix}1 & 0\\ 0 & 1\end{pmatrix}(\psi_{jl}(-\overline{k}),.)\psi_{jl}(k); \quad k^2\in\rho(h_{jl,\beta_{jl}}), \quad \mathrm{Im}\,k>0. \tag{3.1}$$

$G_{jl,0}=(h_{jl,0}-k^2)^{-1}$, $\mathrm{Im}\,k>0$, is the free resolvent kernel,

$$G_{jl,0}(k',r,r')=\begin{bmatrix}\tilde{g}_{jl0}^{(I)}(k',r,r') & \tilde{g}_{jl0}^{(I)}(k',r,r')\\ \tilde{g}_{jl0}^{(II)}(k',r,r') & \tilde{g}_{jl0}^{(II)}(k',r,r')\end{bmatrix}, \tag{3.2}$$

where $\tilde{g}_{jl0}^{(I)}(k',r,r')$ and $\tilde{g}_{jl0}^{(II)}(k',r,r')$ were previously defined by (2.24) and (2.25). $\psi_{jl}(k',r)$ is given by

$$\psi_{jl}(k',r)=\begin{pmatrix}F_{jl}^{(0)}(k',r)G_{jl}^{(0)'}(k',R)+F_{jl}^{(0)'}(k',R)G_{jl}^{(0)}(k',r)\\ \tilde{F}_{jl}^{(0)}(k',r)G_{jl}^{(0)'}(k',R)+F_{jl}^{(0)'}(k',R)\tilde{G}_{jl}^{(0)}(k',r)\end{pmatrix}. \tag{3.3}$$

The resonance equation is then

$$1-\frac{\beta_{jl}}{c}F_{jl}^{(0)'}(k',R)G_{jl}^{(0)'}(k',R)=0, \quad \mathrm{Im}\,k'<0, \tag{3.4}$$

i.e.,

$$1-\frac{\beta_{jl}}{c}\left[\frac{d}{dr}F_{jl}^{(0)}(k',r)\right]_{r=R}\times\left[\frac{d}{dr}G_{jl}^{(0)}(k',r)\right]_{r=R}=0, \quad \mathrm{Im}\,k'<0. \tag{3.5}$$

For the boundary conditions of the first type and for the same interaction, we obtain [see the resolvent equation (2.22)]

$$1+\frac{\alpha_{jl}}{c}F_{jl}^{(0)}(k',R)G_{jl}^{(0)}(k',R)=0, \quad \mathrm{Im}\,k'<0, \tag{3.6}$$

that is similar to the result obtained in Ref. 1. In this case, for the poles located on the negative imaginary k' axis, let $k'=-ix$, $x>0$. Then using analytic continuation of Bessel functions, the equation (3.6) transforms as follows:

$$1+\frac{\alpha_{jl}}{c}RI_{K_{jl}+(1/2)}(xR)K_{K_{jl}+(1/2)}(xR)=0. \tag{3.7}$$

Next,[1] using as usual the monotonicity properties of the modified Bessel functions and the bound

$$I_\nu(x)K_\nu(x)\leqslant(2\nu)^{-1}, \quad \nu>0, \quad x\geqslant 0, \tag{3.8}$$

in each partial wave (jl), the equation (3.7) has exactly one solution $x_1>0$ if $(\alpha_{jl}/c)R>-(2K_{jl}+1)$. The case $(\alpha_{jl}/c)R=-(2K_{jl}+1)$ gives a zero energy resonance $x_0=0$.

Let us now investigate the solutions located off the imaginary axis.

To make clear our analysis in this context, let us illustrate our study on the first partial waves corresponding to $j=1/2$, $l=0$ or 1. In the particular case of $j=1/2$ and $l=0$, $K_{jl}=-1$ and the special functions $F_{jl}^{(0)}$ and $G_{jl}^{(0)}$ in (2.26) expressed in terms of Bessel and Hankel functions of index $-1/2$. So, the resonance equation (3.6) becomes

$$1-\frac{i\pi\alpha_0 R}{2c}J_{-1/2}(k'R)H_{-1/2}^{(2)}(k'R)=0, \tag{3.9}$$

that reduces to

$$1-i\frac{\alpha_0}{ck'}\cos(k'R)\exp(-ik'R)=0, \tag{3.10}$$

using[13]

$$J_{-1/2}(k'R)=\sqrt{\frac{2}{\pi k'R}}\cos(k'R), \quad H_{-1/2}^{(2)}(k'R)=\sqrt{\frac{2}{\pi k'R}}\exp(-ik'R).$$

Here, α_0 stands for $\alpha_{jl}\,(j=1/2,\, l=0)$. Setting $k'=y-ix$, $x>0$ and $c=R=1$ for simplicity, we get

$$2y-\alpha_0\exp(-2x)\sin 2y-i[2x+\alpha_0+\alpha_0\exp(-2x)\cos 2y=0], \tag{3.11}$$

that splits into the following system:

$$\begin{aligned} 2y-\alpha_0\exp(-2x)\sin 2y&=0,\\ -2x-\alpha_0-\alpha_0\exp(-2x)\cos 2y&=0, \end{aligned} \tag{3.12}$$

or, equivalently,

$$\begin{aligned} -2x&=\ln\left[\frac{2y}{\alpha_0\sin 2y}\right],\\ \ln\left[\frac{2y}{\alpha_0\sin 2y}\right]-\alpha_0-\frac{2y\cos 2y}{\sin 2y}&=0, \quad 2\alpha_0 y\sin 2y>0. \end{aligned} \tag{3.13}$$

Theorem III.1: *The equation (3.13) has an infinity of solutions. Hence, for the partial waves corresponding to* $jl(j=1/2,\ l=0)$, $h_{jl,\alpha_{jl}}$ *has an infinite number of resonances off the imaginary axis characterized by their energies.*

Proof: To prove the first part of this Theorem, it suffices to show that the function

$$Z(y)=\ln\left[\frac{2y}{\alpha_0\sin 2y}\right]-\alpha_0-\frac{2y\cos 2y}{\sin 2y} \tag{3.14}$$

is continuous and changes signs on each part of its domain. First of all, remark that the function $Z(y)$ is even and, consequently, its graphic representation is symmetric with respect to the Z axis. So, we restrict our analysis to the positive part of the y axis, the whole picture being symmetric with respect to the Z axis for a given α_0. This domain reads as

$$\mathcal{D}_Z=\begin{cases}\cup_{n\in\mathbb{Z}_+}]n\pi,(2n+1)\dfrac{\pi}{2}[, & \forall\,\alpha_0>0, y>0,\\[2ex] \cup_{n\in\mathbb{Z}_+}](2n+1)\dfrac{\pi}{2},(n+1)\pi[, & \forall\,\alpha_0<0, y>0.\end{cases} \tag{3.15}$$

First, let us consider the case $\alpha_0>0$. The continuity property is evident. A straightforward treatment shows that

$$\lim_{\substack{y\to 0\\ y>0}} Z(y)=-\alpha_0-1<0,\quad \lim_{\substack{y\to \pi/2\\ y<\pi/2}} Z(y)=+\infty,\ \ \forall\,\alpha_0>0, \tag{3.16}$$

$$\lim_{\substack{y\to n\pi\\ y>n\pi\\ n\in\mathbb{Z}_+^\star}} Z(y)=-\infty,\qquad \lim_{\substack{y\to (2n+1)\,\pi/2\\ y<(2n+1)\,\pi/2\\ n\in\mathbb{Z}_+^\star}} Z(y)=+\infty,\ \ \forall\,\alpha_0>0. \tag{3.17}$$

A similar analysis can be easily conducted for the case $\alpha_0<0$. We have

$$\lim_{\substack{y\to (2n+1)\,\pi/2\\ y>(2n+1)\,\pi/2\\ n\in\mathbb{Z}_+}} Z(y)=-\infty,\qquad \lim_{\substack{y\to (n+1)\pi\\ y<(n+1)\pi\\ n\in\mathbb{Z}_+}} Z(y)=+\infty,\ \ \forall\,\alpha_0<0. \tag{3.18}$$

Hence, the first part of the Theorem results.

The second part of the Theorem is a consequence of the former. ■

The statements of the Theorem III.1 are well illustrated by numerical explorations. Figures 1(a)–1(d) show the function $Z(y)$ versus y for $\alpha_0>0$. The case $\alpha_0<0$ is represented in Figs. 2(a)–2(d).

The wording of Theorem III.1 can be extended to the general equation (3.6) with the same conclusion on the infinite set of resonances off the imaginary axis for $h_{jl,\alpha_{jl}}$, whatever the partial wave characterized by the quantum numbers j, l and α_{jl}. So doing, the only difficulties one encounters arise from the complexity of mathematical expressions that appear more and more less treatable analytically as the quantum numbers j and l raise. Taking just $j=1/2$ and $l=1$ leads to an intricate nonlinear system in x and y. Numerical computations allow us to go around these difficulties.

The generalization to finitely many δ-sphere interactions using for example the boundary conditions (2.61) provide the following resolvent equation:[5]

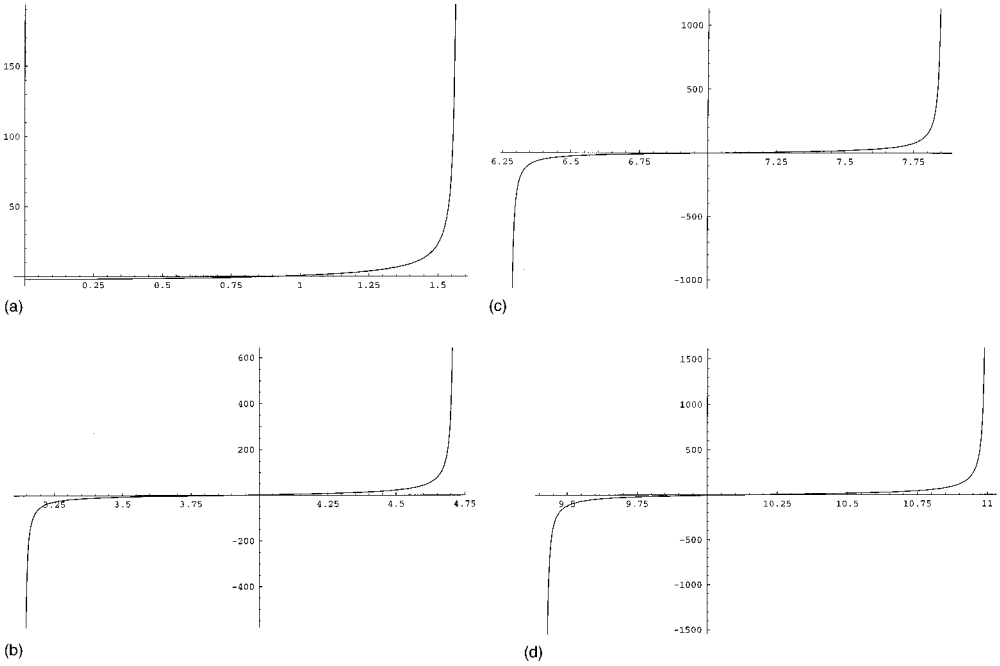

FIG. 1. (a) Curve $Z(y)$ versus $y \in]0,\pi/2[$, $\alpha_0 = 1$. (b) Curve $Z(y)$ versus $y \in]\pi,3\pi/2[$, $\alpha_0 = 1$. (c) Curve $Z(y)$ versus $y \in]2\pi,5\pi/2[$, $\alpha_0 = 1$. (d) Curve $Z(y)$ versus $y \in]3\pi,7\pi/2[$, $\alpha_0 = 1$.

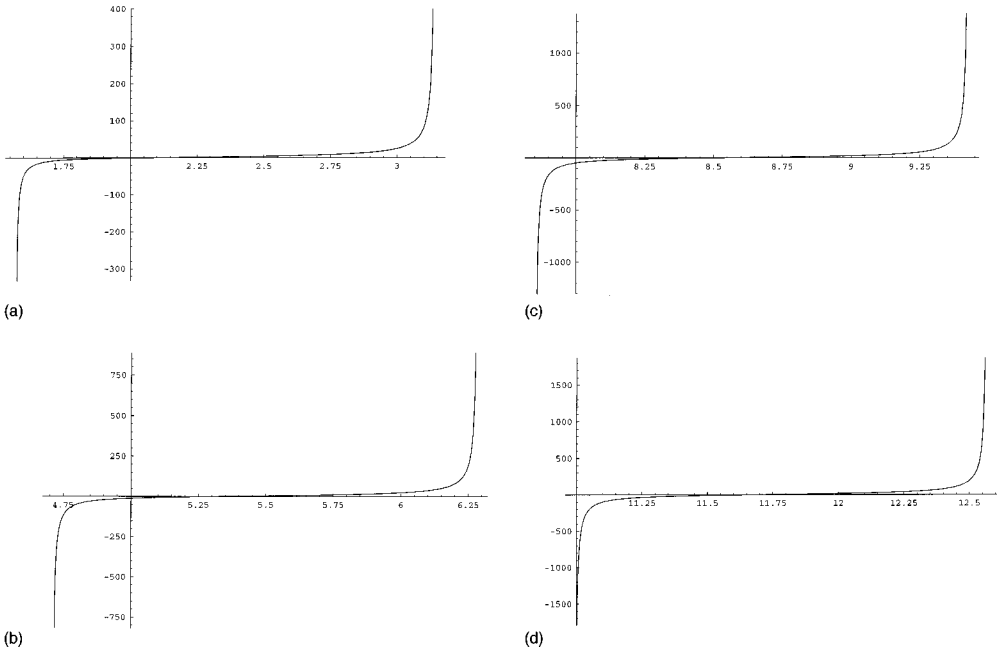

FIG. 2. (a) Curve $Z(y)$ versus $y \in]\pi/2,\pi[$, $\alpha_0 = -1$. (b) Curve $Z(y)$ versus $y \in]3\pi/2,2\pi[$, $\alpha_0 = -1$. (c) Curve $Z(y)$ versus $y \in]5\pi/2,3\pi[$, $\alpha_0 = -1$. (d) Curve $Z(y)$ versus $y \in]7\pi/2,4\pi[$, $\alpha_0 = -1$.

$$(h_{jl,\beta_{jl}\{R\}}-k^2)^{-1}=(h_{jlo}-k^2)^{-1}+\sum_{m,m'=1}^{N}\kappa_{jl}^{mm'}(k)(\psi_{jl}^{(m)}(-\overline{k}),.)\psi_{jl}^{(m')}(k),$$
$$k^2\in\rho(h_{jl,\beta_{jl}\{R\}});\quad \mathrm{Im}\,k>0, \tag{3.19}$$

with

$$\kappa_{jl}^{mm'}(k)=\frac{\beta_{jl}^{m}/c}{\delta_{mm'}-(\beta_{jl}^{m}/c)\tilde{g}_{jl}^{(I)'}(k,R_m,R_{m'})}\begin{pmatrix}1&0\\0&1\end{pmatrix},\quad \delta_{mm'}=\begin{cases}0; & m\neq m',\\ 1; & m=m',\end{cases}$$

$$\psi_{jl}^{(m)}(k)=\begin{pmatrix}F_{jl}^{(o)}(k,r)G_{jl}^{(o)'}(k,R_m)+F_{jl}^{(o)'}(k,R_m)G_{jl}^{(o)}(k,r)\\ \tilde{F}_{jl}^{(o)}(k,r)G_{jl}^{(o)'}(k,R_m)+F_{jl}^{(o)'}(k,R_m)\tilde{G}_{jl}^{(o)}(k,r)\end{pmatrix}, \tag{3.20}$$

$$\tilde{g}_{jl}^{(I)'}(k,R_m,R_{m'})=F_{jl}^{(o)'}(k,R_m)G_{jl}^{(o)'}(k,R'_m).$$

For this model, the resonance phenomena could be more complicated, mixing the resonances of a specific sphere with the resonance arising from the whole system.

Concerning the Dirac–Coulomb case, Krein's formula provides us with the following resolvent equation:

$$(h_{jl\gamma_0,\alpha_{jl}}-k^2)^{-1}=(h_{jl\gamma_0,0}-k^2)^{-1}-\frac{\alpha_{jl}}{cD}\begin{pmatrix}1&0\\0&1\end{pmatrix}(\psi_{jl\gamma_0}(-\overline{k}),.)\psi_{jl\gamma_0}(k); \tag{3.21}$$

$$k^2\in\rho(h_{jl\gamma_0,\alpha_{jl}}),\quad \mathrm{Im}\,k>0,$$

$$D=F_{jl\gamma_0}^{(0)}(k',R)\tilde{G}_{jl\gamma_0}^{(0)}(k',R)-\tilde{F}_{jl\gamma_0}^{(0)}(k',R)G_{jl\gamma_0}^{(0)}(k',R)+\frac{\alpha_{jl}}{c}F_{jl\gamma_0}^{(0)}(k',R)G_{jl\gamma_0}^{(0)}(k',R), \tag{3.22}$$

$G_{jl\gamma_0}=(h_{jl\gamma_0,0}-k^2)^{-1}$, $\mathrm{Im}\,k>0$, is the free resolvent kernel:

$$G_{jl\gamma_0}(k',r,r')=\begin{bmatrix}\tilde{g}_{jl\gamma_0}^{(I)}(k',r,r') & \tilde{g}_{jl\gamma_0}^{(I)}(k',r,r')\\ \tilde{g}_{jl\gamma_0}^{(II)}(k',r,r') & \tilde{g}_{jl\gamma_0}^{(II)}(k',r,r')\end{bmatrix}, \tag{3.23}$$

where

$$\tilde{g}_{jl\gamma_0}^{(I)}(k',r,r')=\begin{cases}G_{jl\gamma_0}^{(0)}(k',r)F_{jl\gamma_0}^{(0)}(k',r'); & r'<r,\\ F_{jl\gamma_0}^{(0)}(k',r)G_{jl\gamma_0}^{(0)}(k',r'); & r'>r,\end{cases} \tag{3.24}$$

and

$$\tilde{g}_{jl0}^{(II)}(k',r,r')=\begin{cases}\tilde{G}_{jl\gamma_0}^{(0)}(k',r)\tilde{F}_{jl\gamma_0}^{(0)}(k',r'); & r'<r,\\ \tilde{F}_{jl\gamma_0}^{(0)}(k',r)\tilde{G}_{jl\gamma_0}^{(0)}(k',r'); & r'>r,\end{cases} \tag{3.25}$$

with

$$F_{jl\gamma_0}^{(0)}(k',r)=\frac{\gamma_0}{2\epsilon(K_{jl}-\epsilon)}u_1-\frac{1}{2\epsilon}v_1;\quad r<R,$$

$$G^{(0)}_{jl\gamma_0}(k',r)=\frac{\gamma_0}{2\epsilon(K_{jl}-\epsilon)}u_2-\frac{1}{2\epsilon}v_2;\quad r>R, \tag{3.26}$$

$$\tilde{F}^{(0)}_{jl\gamma_0}(k',r)=-\frac{1}{2\epsilon}u_1+\frac{\gamma_0}{2\epsilon(K_{jl}-\epsilon)}v_1;\quad r<R,$$

$$\tilde{G}^{(0)}_{jl\gamma_0}(k',r)=-\frac{1}{2\epsilon}u_2+\frac{\gamma_0}{2\epsilon(K_{jl}-\epsilon)}v_2;\quad r>R, \tag{3.27}$$

and

$$u_1(k',r)=r^{\mu+1}\exp(-ik'r)\,{}_1F_1\left(1+\mu-i\frac{k^2\gamma_0}{c^2k'};2(\mu+1);2ik'r\right),$$

$$u_2(k',r)=\Gamma[2(\mu+1)]^{-1}\Gamma\left[\left(1+\mu-i\frac{k^2\gamma_0}{c^2k'}\right)\right](2ik')^{2\mu+1}r^{\mu+1}\exp(-ik'r) \tag{3.28}$$

$$\times U\left(1+\mu-i\frac{k^2\gamma_0}{c^2k'};2(\mu+1);2ik'r\right),$$

$$v_1(k',r)=r^{\mu}\exp(-ik'r)\,{}_1F_1\left(\mu-i\frac{k^2\gamma_0}{c^2k'};2\mu;2ik'r\right), \tag{3.29}$$

$$v_2(k',r)=\Gamma(2\mu)^{-1}\Gamma\left(\mu-i\frac{k^2\gamma_0}{c^2k'}\right)(2ik')^{2\mu-1}r^{\mu}\exp(-ik'r)U\left(\mu-i\frac{k^2\gamma_0}{c^2k'};2\mu;2ik'r\right),$$

where $k'^2=(k^4-M^2c^4)/c^2$, $\epsilon=\sqrt{c^2K_{jl}^2-\gamma_0^2}$, $\mu=\epsilon/c=\sqrt{K_{jl}^2-(\gamma_0/c)^2}$, ${}_1F_1(z)$ and $U(z)$ are the hypergeometric functions of the first and second type, respectively.

$\psi_{jl\gamma_0}(k',r)$ is given by

$$\psi_{jl\gamma_0}(k',r)=\begin{pmatrix} F^{(0)}_{jl\gamma_0}(k',r)G^{(0)}_{jl\gamma_0}(k',R)+F^{(0)}_{jl\gamma_0}(k',R)G^{(0)}_{jl\gamma_0}(k',r)\\ \tilde{F}^{(0)}_{jl\gamma_0}(k',r)G^{(0)}_{jl\gamma_0}(k',R)+F^{(0)}_{jl\gamma_0}(k',R)\tilde{G}^{(0)}_{jl\gamma_0}(k',r)\end{pmatrix}. \tag{3.30}$$

The resonance equation is then

$$F^{(0)}_{jl\gamma_0}(k',R)\tilde{G}^{(0)}_{jl\gamma_0}(k',R)-\tilde{F}^{(0)}_{jl\gamma_0}(k',R)G^{(0)}_{jl\gamma_0}(k',R)+\frac{\alpha_{jl}}{c}F^{(0)}_{jl\gamma_0}(k',R)G^{(0)}_{jl\gamma_0}(k',R)=0,\ \ \mathrm{Im}\,k'<0. \tag{3.31}$$

Using the boundary conditions of the second type the resonances could be obtained from the resolvent equation computed in Ref. 4. We have

$$F^{(0)'}_{jl\gamma_0}(k',R)\tilde{G}^{(0)'}_{jl\gamma_0}(k',R)-\tilde{F}^{(0)'}_{jl\gamma_0}(k',R)G^{(0)'}_{jl\gamma_0}(k',R)-\frac{\beta_{jl}}{c}F^{(0)'}_{jl\gamma_0}(k',R)G^{(0)'}_{jl\gamma_0}(k',R)=0,\ \ \mathrm{Im}\,k'<0. \tag{3.32}$$

A systematic study of this model can be conducted using the same machinery. The physics being the same, the only difficulties are of a technical order related to the mathematical expressions that present here a more complicated form.

B. The δ' models

We analyze the one-sphere case, its generalization to finitely many concentric spheres and the δ'-Coulomb case with the boundary conditions of the second type.

The resolvent of the δ'-sphere model is[6]

$$(h_{jl,\tilde{\beta}_{jl}\{R\}}-k^2)^{-1}=(h_{jlo}-k^2)^{-1}+\Theta_{jl}(k)(\psi_{jl}(-\overline{k}),.)\psi_{jl}^{(\Delta)}(k),$$

$$k^2\in\rho(h_{jl,\tilde{\beta}_{jl}});\ \ \mathrm{Im}\,k>0, \tag{3.33}$$

with

$$\Theta_{jl}(k')=\frac{-2(\tilde{\beta}_{jl}/c)}{2+(\tilde{\beta}_{jl}/c)g'_{jl}(k',R,R)}\begin{pmatrix}1 & 0\\ 0 & 1\end{pmatrix}, \tag{3.34}$$

$$\psi_{jl}(k')=\begin{pmatrix}F_{jl}^{(o)}(k',r)G_{jl}^{(o)}(k',R)+F_{jl}^{(o)}(k',R)G_{jl}^{(o)}(k',r)\\ \tilde{F}_{jl}^{(o)}(k',r)G_{jl}^{(o)}(k',R)+F_{jl}^{(o)}(k',R)\tilde{G}_{jl}^{(o)}(k',r)\end{pmatrix}, \tag{3.35}$$

$$\psi_{jl}^{(\Delta)}(k')=\begin{pmatrix}F_{jl}^{(o)}(k',r)G_{jl}^{(o)'}(k',R)+F_{jl}^{(o)'}(k',R)G_{jl}^{(o)}(k',r)\\ \tilde{F}_{jl}^{(o)}(k',r)G_{jl}^{(o)'}(k',R)+F_{jl}^{(o)'}(k',R)\tilde{G}_{jl}^{(o)}(k',r)\end{pmatrix}, \tag{3.36}$$

$$g'_{jl}(k',R,R)=F_{jl}^{(o)}(k',R)G_{jl}^{(o)'}(k',R)+G_{jl}^{(o)}(k',R)F_{jl}^{(o)'}(k',R)=\frac{d}{dr}[F_{jl}^{(o)}(k',r)G_{jl}^{(o)}(k',r)]_{r=R}. \tag{3.37}$$

The resulting resonance energies are given by

$$2+\frac{\tilde{\beta}_{jl}}{c}g'_{jl}(k',R,R)=0,\ \ \mathrm{Im}\,k'<0. \tag{3.38}$$

Setting $k'=-ix$, this equation transforms as follows:

$$-\frac{2c}{\tilde{\beta}_{jl}}=\frac{d}{dr}[rI_{K_{jl}+1/2}(xr)K_{K_{jl}+1/2}(xr)]_{r=R}. \tag{3.39}$$

In each partial wave (jl), the Eq. (3.39) has one solution $x>0$ if $\tilde{\beta}_{jl}/c<2(2K_{jl}+1)$. The case $\tilde{\beta}_{jl}/c=2(2K_{jl}+1)$ gives a zero energy resonance, i.e., $x_0=0$ and there is an infinite number of resonances off the imaginary axis.

The generalization to finitely many spheres cases is immediate.

Concerning the δ'-Coulomb case, the resolvent is[6]

$$(h_{jl\gamma_0,\tilde{\beta}_{jl}}-k^2)^{-1}=(h_{jl\gamma_0,0}-k^2)^{-1}+-2\frac{\tilde{\beta}_{jl}}{cD}\begin{pmatrix}1 & 0\\ 0 & 1\end{pmatrix}(\psi_{jl\gamma_0}(-\overline{k}),.)\psi_{jl\gamma_0}^{(\triangle)}(k); \tag{3.40}$$

$$k^2\in\rho(h_{jl\gamma_0,\tilde{\beta}_{jl}}),\ \ \mathrm{Im}\,k>0,$$

$$D=2[F_{jl\gamma_0}^{(0)'}(k',R)\tilde{G}_{jl\gamma_0}^{(0)'}(k',R)-\tilde{F}_{jl\gamma_0}^{(0)'}(k',R)G_{jl\gamma_0}^{(0)'}(k',R)]$$

$$+\frac{\tilde{\beta}_{jl}}{c}[F_{jl\gamma_0}^{(0)'}(k',R)G_{jl\gamma_0}^{(0)}(k',R)+F_{jl\gamma_0}^{(0)}(k',R)G_{jl\gamma_0}^{(0)'}(k',R)]. \tag{3.41}$$

The following equation gives the resonance energies:

$$0=2[F^{(0)'}_{jl\gamma_0}(k',R)\tilde{G}^{(0)'}_{jl\gamma_0}(k',R)-\tilde{F}^{(0)'}_{jl\gamma_0}(k',R)G^{(0)'}_{jl\gamma_0}(k',R)]$$

$$+\frac{\tilde{\beta}_{jl}}{c}[F^{(0)'}_{jl\gamma_0}(k',R)G^{(0)}_{jl\gamma_0}(k',R)+F^{(0)}_{jl\gamma_0}(k',R)G^{(0)'}_{jl\gamma_0}(k',R)],\quad \mathrm{Im}\,k'<0. \tag{3.42}$$

IV. FINAL REMARKS

Our results are very similar to those obtained with singular Schrödinger Hamiltonians[1] for the same interactions; the only difference lies in the interchanging between the free Schrödinger Hamiltonian $H_0=-\Delta$ and the free Dirac one H_{D}.

Moreover, as in the nonrelativistic case where the results for δ-sphere and δ-point interactions are similar,[1,8] the results of our study compared with those obtained for point interactions in relativistic quantum mechanics studied by Gesztesy and Šeba are the same.[4,16] That is the most interesting information we get from this study. This is predictable since it has been shown that the δ-sphere interaction H_α converges to the δ-point interaction H_η of strength η centered at the origin, as the radius of the sphere shrinks to zero with adequate normalization of the coupling constant α (Ref. 1, Lemma 2.2). The results concerning a systematic study of δ- and δ'-point interactions including the scattering theory in relativistic quantum mechanics is thus predictable.

Let us now discuss briefly the nonrelativistic limit $c\to\infty$. Following Ref. 14 (Chap. V, Sec. 25, 3), the spinors

$$\psi(k,r)=\begin{pmatrix} f(k,r)\\ g(k,r)\end{pmatrix},$$

the solution of the indicial equation $\dot{h}_{jl}\psi=k^2\psi$, $\mathrm{Im}\,k>0$, reduce to $f(k,r)$ as $c\to\infty$, i.e., $|g(k,r)|\ll|f(k,r)|$. This latter coincides exactly with the special functions which span the deficiency subspace in the Schrödinger case with respect to the same normalization. On the other hand, the strategy used in Ref. 16 and the references therein for point interactions using the resolvents to discuss the nonrelativistic limit applies here since the results are the same.

Finally, let us point out the fact (so far implicit) that the Hamiltonians perturbed by singular δ and δ' interactions are in fact local interactions both in nonrelativistic and relativistic mechanics. This gives us some additional information on the domains of the radial extended Hamiltonians.

Using the resolvent equation, the proof is easy. The δ- and δ'-sphere interactions in nonrelativistic quantum mechanics are treated in Refs. 1, 17. For the relativistic case, we restrict our study with an explicit proof to the δ- and δ'-sphere models using the boundary conditions of the second type, by stating the following Theorem.

Theorem IV.1: *For $\psi_{jl,o}(k,r)$ belonging to $\mathcal{D}(h_{jl,o})$ which is the domain of the free radial Dirac Hamiltonian, the domain $\mathcal{D}(h_{jl,\beta_{jl}})$ of the extended radial operator consists of spinors of the type*

$$\psi_{jl,\beta_{jl}}(k,r)=\psi_{jl,o}(k,r)+K(k,R)\begin{pmatrix}1&0\\0&1\end{pmatrix}\Phi_{jl}(k,r,R), \tag{4.1}$$

with

$$K(k,R)=\frac{(\beta_{jl}/c)[F^{(o)'}_{jl}(k,R)+A_1]}{1-(\beta_{jl}/c)F^{(o)'}_{jl}(k,R)G^{(o)'}_{jl}(k,R)}, \tag{4.2}$$

$$A_1 = G_{jl}^{(o)'}(k',R)\int_0^R [\tilde{F}_{jl}^{(o)}(k',r') - F_{jl}^{(o)}(k',r')]\tilde{F}_{jl}^{(o)}(k',r')dr'$$

$$+ F_{jl}^{(o)'}(k',R)\int_R^\infty [\tilde{G}_{jl}^{(o)}(k',r') - G_{jl}^{(o)}(k',r')]\tilde{G}_{jl}^{(o)}(k',r')dr', \tag{4.3}$$

$$\Phi_{jl}(k,r,R) = \begin{pmatrix} F_{jl}^{(o)}(k,r)G_{jl}^{(o)'}(k,R) + F_{jl}^{(o)'}(k,R)G_{jl}^{(o)}(k,r) \\ \tilde{F}_{jl}^{(o)}(k,r)G_{jl}^{(o)'}(k,R) + F_{jl}^{(o)'}(k,R)\tilde{G}_{jl}^{(o)}(k,r) \end{pmatrix}, \tag{4.4}$$

$k^2 \in \rho(h_{jl,\beta_{jl}})$, $\rho(\cdot)$ *is the resolvent set.*

Furthermore, the decomposition (4.1) is unique and we are allowed to write

$$(h_{jl,\beta_{jl}} - k^2)^{-1}\psi_{jl,\beta_{jl}}(k,r) = (h_{jl,o} - k^2)^{-1}\psi_{jl,o}(k,r). \tag{4.5}$$

Besides, if $\psi_{jl,\beta_{jl}}(k,r) \in \mathcal{D}(h_{jl,\beta_{jl}})$ *and* $\psi_{jl,\beta_{jl}} = 0$ *in an open subset of* $(0,\infty)$, *then* $h_{jl,\beta_{jl}}\psi_{jl,\beta_{jl}} = 0$ *in this subset.*

Proof: One may follow step by step Ref. 8, where a similar result has been obtained for point interactions. However, using the resolvent equation we can show how (4.1) is obtained.
We know that

$$(h_{jl,o} - k^2)^{-1}: \; L^2((0,\infty)) \otimes \mathbb{C}^2 \to \mathcal{D}(h_{jl,o}),$$

$$(h_{jl,\beta_{jl}} - k^2)^{-1}: \; L^2((0,\infty)) \otimes \mathbb{C}^2 \to \mathcal{D}(h_{jl,\beta_{jl}})$$

and

$$\mathcal{D}(h_{jl,\beta_{jl}}) = (h_{jl,\beta_{jl}} - k^2)^{-1}(h_{jl,o} - k^2)\mathcal{D}(h_{jl,o}). \tag{4.6}$$

Then for

$$\psi_{jl,o}(k,r) = \begin{pmatrix} F_{jl}^{(o)}(k,r) \\ \tilde{F}_{jl}^{(o)}(k,r) \end{pmatrix} \in \mathcal{D}(h_{jl,o}),$$

we have

$$\psi_{jl,\beta_{jl}}(k,r) = (h_{jl,\beta_{jl}} - k^2)^{-1}(h_{jl,o} - k^2)\psi_{jl,o}(k,r); \quad \psi_{jl,\beta_{jl}}(k,r) \in \mathcal{D}(h_{jl,\beta_{jl}}). \tag{4.7}$$

Inserting the resolvent equation (3.1) into (4.7), we obtain

$$\psi_{jl,\beta_{jl}}(k,r) = \begin{pmatrix} F_{jl}^{(o)}(k,r) \\ \tilde{F}_{jl}^{(o)}(k,r) \end{pmatrix} + \begin{pmatrix} K & 0 \\ 0 & K \end{pmatrix} \begin{pmatrix} F_{jl}^{(o)}(k,r)G_{jl}^{(o)'}(k,R) + F_{jl}^{(o)'}(k,R)G_{jl}^{(o)}(k,r) \\ \tilde{F}_{jl}^{(o)}(k,r)G_{jl}^{(o)'}(k,R) + F_{jl}^{(o)'}(k,R)\tilde{G}_{jl}^{(o)}(k,r) \end{pmatrix}. \tag{4.8}$$

The implementation of the boundary conditions (2.61) gives the value of the coefficient K. Thus (4.1) results. ■

Turning to the δ'-sphere case and using (3.33), the elements of the first family of s.a.e. satisfy the following decomposition:

$$\psi_{jl,\tilde{\beta}_{jl}}(k,r) = \psi_{jl,o}(k,r) + \tilde{K}(k,R)\begin{pmatrix} 1 & 0 \\ 0 & 1 \end{pmatrix}\Phi_{jl}(k,r,R), \tag{4.9}$$

with

$$\tilde{K}(k,R)=\frac{-2(\tilde{\beta}_{jl}/c)[F_{jl}^{(o)\prime}(k,R)+A_1]}{2+(\tilde{\beta}_{jl}/c)[F_{jl}^{(o)}(k,R)G_{jl}^{(o)\prime}(k,R)+F_{jl}^{(o)\prime}(k,R)G_{jl}^{(o)}(k,R)]}, \tag{4.10}$$

$$A_1=G_{jl}^{(o)\prime}(k',R)\int_0^R[F_{jl}^{(o)}(k',r')-\tilde{F}_{jl}^{(o)}(k',r')]\tilde{F}_{jl}^{(o)}(k',r')dr'$$

$$+F_{jl}^{(o)\prime}(k',R)\int_R^\infty[G_{jl}^{(o)}(k',r')-\tilde{G}_{jl}^{(o)}(k',r')]\tilde{G}_{jl}^{(o)}(k',r')dr', \tag{4.11}$$

$$\Phi_{jl}(k,r,R)=\begin{pmatrix} F_{jl}^{(o)}(k,r)G_{jl}^{(o)\prime}(k,R)+F_{jl}^{(o)\prime}(k,R)G_{jl}^{(o)}(k,r) \\ \tilde{F}_{jl}^{(o)}(k,r)G_{jl}^{(o)\prime}(k,R)+F_{jl}^{(o)\prime}(k,R)\tilde{G}_{jl}^{(o)}(k,r)\end{pmatrix}, \tag{4.12}$$

$k^2\in\rho(h_{jl,\tilde{\beta}_{jl}})$. (4.9) is also unique and if $\psi_{jl,\tilde{\beta}_{jl}}\in\mathcal{D}(h_{jl,\tilde{\beta}_{jl}})$ and $\psi_{jl,\tilde{\beta}_{jl}}=0$ in an open set $\mathcal{O}\subset(0,\infty)$, then $h_{jl,\tilde{\beta}_{jl}}\psi_{jl,\tilde{\beta}_{jl}}=0$ in $\mathcal{O}$ which means that the δ'-sphere interaction is a local interaction in relativistic quantum mechanics.

Fast-convergent resummation algorithm and critical exponents of ϕ^4-theory in three dimensions

(Received 24 March 2000; accepted for publication 27 April 2000)

We develop an efficient algorithm for evaluating divergent perturbation expansions of field theories in the bare coupling constant g_B for which we possess a finite number L of expansion coefficients plus two more information: the knowledge of the large-order behavior proportional to $(-\alpha)^k k! k^\beta g_B^k$, with a known growth parameter α, and the knowledge of the approach to scaling of the type $c+c'/g_B^\omega$, with constants c,c' and a critical exponent of approach ω. The latter information leads to an increase in the speed of convergence and a high accuracy of the results. The algorithm is applied to the six- and seven-loop expansions for the critical exponents of $O(N)$-symmetric ϕ^4-theories, and the result for the critical exponent α is compared with a recent satellite experiment. © *2001 American Institute of Physics.* [DOI: 10.1063/1.1289377]

I. INTRODUCTION

The field-theoretic approach to critical phenomena provides us with power series expansions for the critical exponents of a wide variety of universality classes. For ϕ^4-theories with $O(N)$ symmetry in three dimensions, these expansions have been calculated numerically as power series in the renormalized coupling constant up to seven loops for[1] the critical exponents ν and η and up to six loops for the exponent ω governing the approach to scaling. In 4-ϵ dimensions, exact ϵ-expansions are available up to five loops for all critical exponents with $O(N)$ symmetry,[2] cubic symmetry, and mixtures of these.[3] When inserted into the renormalization group equations, these expansions are supposed to determine the critical exponents via their values at an infrared-stable fixed point $g=g^*$. The latter step is nontrivial since the expansions are divergent and require resummation, for which sophisticated methods have been developed, summarized and applied most recently in Ref. 4. The resummation methods use the information from the known large-order behavior $(-\alpha)^k k! k^\beta g_B^k$ of the expansions and analytic mapping techniques to obtain quite accurate results.

A completely different resummation procedure was developed recently on the basis of variational perturbation theory[5] to the expansions in powers of the *bare coupling constant*, which goes to infinity at the critical point. The resulting *strong-coupling theory*[6] was successfully applied in three[8,9] and $4-\epsilon$ dimensions,[10] and rendered for the first time an interpolation between expansions of $4-\epsilon$ and $2+\epsilon$-dimensional theories. This method converges as fast as the previous ones, even though it does not take into account the information on the large-order behavior of the expansions. Instead, it uses the fact that the power series for the critical exponents approach their constant critical value in the form $c+c'/g_B^\omega$, where c,c' are constants, and ω is the critical exponent of the approach to scaling. The results show that the latter information is just as efficient in increasing the speed of convergence as the information on the large-order behavior.

We may therefore expect that a resummation method which incorporates both informations should lead to results with an even higher accuracy, and it is the purpose of this paper to present such a method in the form of a simple algorithm.

II. STRONG-COUPLING

The development of our resummation algorithm is based on an improvement of the problem formulated in Refs. 6 and 7 and solved via variational perturbation theory.[5] Mathematically, the problem we want to solve is the following: Let

$$f_L(g_B)=\sum_{k=0}^{L} f_k g_B^k \tag{1}$$

be the first L terms of a divergent asymptotic expansion

$$f(g_B)=\sum_{k=0}^{\infty} f_k g_B^k \tag{2}$$

of a function $f(g_B)$, which possesses a strong-coupling expansion of the type

$$f(g_B)=g_B^s\sum_{k=0}^{\infty} b_k g_B^{-k\omega}, \tag{3}$$

which is assumed to have some finite convergence radius $|g_B|\geqslant g_B^{\mathrm{conv}}$. Suppose that the function is analytic in the complex g_B-plane with a cut along the negative real axis, with a discontinuity known from instanton calculations[11,12] to have near the tip of the cut the generic form

$$\mathrm{disc}\, f(-g_B)\equiv 2\pi i\ \gamma\,(\alpha|g_B|)^{-\beta-1}e^{-1/\alpha|g_B|}. \tag{4}$$

Via a dispersion relation,

$$f(g_B)=\frac{1}{2\pi i}\int_0^{\infty} dg_B'\,\frac{\mathrm{disc}\, f(-g_B)}{g_B'+g_B}, \tag{5}$$

or a sufficiently subtracted version of it, this discontinuity corresponds to the large-order behavior of the expansion coefficients f_k

$$f_k \overset{k\to\infty}{=} \gamma k!(-\alpha)^k k^{\beta}[1+\mathcal{O}(1/k)]. \tag{6}$$

The constant α is given by the inverse action of the radially symmetric solution to the classical field equations. The parameter β counts the number of zero modes in the fluctuation determinant around this solution. The absolute normalization γ of the large-order behavior requires the calculation of the fluctuation determinant.[11]

As far as the leading strong-coupling coefficient b_0 is concerned, this problem has been attacked before by Parisi[13] using a resummation method based on Borel transformations in combination with analytic mapping techniques. However, when applied to the asymptotic expansions of the ground state energy of the anharmonic oscillator, his method converges very slowly, too slow to lead to reliable critical exponents, where only five to seven expansion coefficients f_k known. The reason is that in Parisi's approach, the corrections to the leading power behavior fail to match the true irrational powers of the strong-coupling expansion (3).

This deficiency was cured by the strong-coupling theory of one of the authors (H.K.) in Ref. 6, and the subsequent application to critical exponents in Refs. 8, 9, and 10, which showed a surprisingly rapid convergence. However, that theory did not take advantage of the knowledge of the large-order behavior (6), which can lead to an increase in the speed of convergence and thus of the accuracy of theoretical values for the critical exponents. This will be achieved in the present improved resummation method.

III. BOREL METHODS

Basis for this method is the development of a more general Borel-type transformation which will automatically guarantee the form of the strong-coupling expansion (3) for each approximant $f_L(g_B)$. Let us first recall briefly the important properties of an ordinary Borel transformation: it is a function $B(t)$ associated with $f(g_B)$ which is defined by the Taylor series

$$B(t)=\sum_{k=0}^{\infty} B_k t^k \equiv \sum_{k=0}^{\infty} \frac{f_k}{k!} t^k. \tag{7}$$

By dividing the expansion coefficients f_k by $k!$, the factorial growth of f_k is reduced to a power growth, thus giving $B(t)$ a finite convergence radius.

An alternative definition of the Borel transform is given by the contour integral

$$B(t)\equiv \frac{1}{2\pi i} \oint_C \frac{dz}{z} e^z f(t/z), \tag{8}$$

where the contour C encloses anticlockwise the negative real axis. Indeed, inserting (1) and performing the integral we obtain (7).

If $f(g_B)$ is an analytic function in the sector

$$S^R_{\pi/2+\delta} \equiv \{g_B \mid |g_B|<R, |\arg(g_B)|<\pi/2+\delta\} \tag{9}$$

of a circle, and satisfies the so-called strong asymptotic condition

$$\left| f(g_B) - \sum_{k=0}^{L} f_k g_B^k \right| < A g_B^{L+1} \alpha^{L+1} (L+1)! \quad \text{with} \quad \alpha, A>0, \tag{10}$$

then $B(t)$ is analytic in S^{∞}_{δ}, with a finite radius of convergence $t<1/\alpha$. The original function $f(g_B)$ can be recovered from $B(t)$ by the inverse Borel transformation

$$f(g_B)=\int_0^{\infty} e^{-t} B(t g_B) dt. \tag{11}$$

Obviously, the inverse transformation can only be performed if $B(t)$ is known on the entire positive real t-axis. The Taylor series (7) for $B(t)$, however, converges only inside the circle of radius $1/\alpha$. Before we can do the integral in (11), we must therefore perform a suitable analytic continuation of (7).[14] This can be done by re-expanding $B(t)$ in powers of the function $\kappa(t)$ defined implicitly by

$$t=\frac{1}{\sigma} \frac{\kappa(t)}{[1-\kappa(t)]^p}. \tag{12}$$

This function maps the interval $[0,\infty]$ of the t-axis to the interval $[0,1]$ of the κ-plane. By a proper choice of σ it is possible to make the unit circle free of singularities. Then we may use the re-expansion $B(t)$ in powers of $\kappa(t)$ truncated after κ^L,

$$B_L(t)\equiv \sum_{k=0}^{L} v_k \kappa^k(t), \tag{13}$$

as an approximation to $B_L(t)$ on the entire positive real t axis. Inserting this into the inverse transformation formula (11), we obtain an approximation $f^a_L(g_B)$ for $f(g_B)$, which has the same first L expansion coefficients as $f_L(g_B)$ and, in addition, the correct large-order behavior (6).

How can we incorporate the strong-coupling expansion (3) of $f(g_B)$ into the approximation $f_L^a(g_B)$? In the Borel transform $B(t)$, the strong-coupling expansion (3) amounts to a large-t expansion

$$B(t)=t^s\sum_{k=0}^{\infty}\frac{\sin\pi(k\omega-s)}{\pi}\Gamma(k\omega-s)b_k t^{-k\omega}. \tag{14}$$

This follows directly by inserting (3) into (8) and integrating each term. Here and in the sequel, C denotes a path of integration which encloses anticlockwise the negative real axis in the complex plane.

If the series (3) has a finite radius of convergence, the large-t expansion of $B(t)$ is a divergent asymptotic one, because of the factor $\Gamma(k\omega-s)$ in the kth expansion coefficient.

It should be stressed, that the relation between the coefficients of the strong-coupling expansion (3) and the coefficients of expansion (14) is not generally invertible, because of the factor $\sin\pi(k\omega-s)$ which causes the coefficients of negative integer powers of t to vanish.

Note that, in general, an expansion in the Borel-plane with a power sequence in t as in (14) is not sufficient to ensure an expansion in the same powers in the g_B-plane as in (3), because of the appearance of extra integer powers in g_B. This is illustrated by the simple function $B(t)=(1+t)^s$, which possesses a strong-coupling expansion in the powers t^{s-k}. If s is noninteger the expansion of the corresponding function $f(g_B)$ reads

$$f(g_B)=\int_0^{\infty}dt\,e^{-t}(1+g_B t)^s=e^{1/g_B}\Gamma(s+1)g_B^s+e^{1/g_B}\sum_{k=0}^{\infty}\frac{(-1)^k}{(k+s+1)k!}g_B^{-k-1}, \tag{15}$$

and expanding the exponential we see that the sum contains integer powers which are not contained in the strong-coupling expansion of $B(t)$.

It is advantageous to perform a further analytic continuation of the re-expansion (13) which enforces automatically the leading power behavior t^s of $B(t)$. For this we change (13) to

$$B_L(t)\equiv[1-\kappa(t)]^{-ps}\sum_{k=0}^{L}h_k\kappa^k(t). \tag{16}$$

The coefficients h_k are determined by using (12) to expand $\kappa(t)$ in powers of t, inserting this into (16), re-expanding in powers of t, and comparing the final coefficients with those in (7). When the approximation (16) is inserted into (11), we obtain $f_L^a(g_B)$ with the correct leading power behavior g_B^s for large g_B.

Unfortunately, the simple prefactor does not produce the correct subleading powers $(g_B)^{s-k\omega}$ of the strong-coupling expansion (3), and we have not been able to find another simple analytic continuation of $B(t)$ which would achieve this.

IV. HYPER-BOREL TRANSFORMATION

A solution of this problem is, however, possible with the help of a generalization of the Borel–Leroy transformation to what we shall call a *hyper-Borel transformation*[15]

$$\tilde{B}(y)=\sum_{k=0}^{\infty}\tilde{B}_k y^k, \tag{17}$$

with coefficients

$$\tilde{B}_k\equiv\omega\frac{\Gamma(k(1/\omega-1)+\beta_0)}{\Gamma(k/\omega-s/\omega)\Gamma(\beta_0)}f_k. \tag{18}$$

A. General properties

The inverse transformation is given by the double integral

$$f(g_B)=\frac{\Gamma(\beta_0)}{2\pi i}\oint_C dt\, e^t t^{-\beta_0}\int_0^\infty \frac{dy}{y}\left[\frac{g_B}{yt^{(1-\omega)/\omega}}\right]^s \exp\left[\frac{yt^{(1-\omega)/\omega}}{g_B}\right]^\omega \tilde{B}(y), \tag{19}$$

as can easily be shown with the help of the integral representation of the inverse Gamma function

$$\frac{1}{\Gamma(z)}=\frac{1}{2\pi i}\int_C dt\, e^t t^{-z}. \tag{20}$$

The transformation possesses a free parameter β_0 which will be used to optimize the approximation $f_L(g_B)$ at each order L. The power ω of the strong-coupling expansion is assumed to lie in the interval $0<\omega<1$, as it does in the upcoming physical applications.

The hyper-Borel transformation has the desired property of allowing for a resummation of $f_L(g_B)$ with the full sequence of powers of g_B in the strong-coupling expansion (3). To show this we first observe that as in the ordinary Borel transform (7), the large-argument behavior of the gamma function known from Stirling's formula

$$\Gamma(pk+q)\overset{k\to\infty}{=}\sqrt{2\pi}^{1-p}p^{q-1/2}k^{-1/2+q-p/2}p^{pk}(k!)^p[1+\mathcal{O}(1/k)], \tag{21}$$

removes the factorial growth (6) from the expansion coefficients f_k, and leads to a simple power behavior of the coefficients $\tilde{B}_k$:

$$\tilde{B}_k\overset{k\to\infty}{=}\text{const}\times[\alpha\omega(1-\omega)^{1/\omega-1}]^k k^{\beta+\beta_0+1/2+s/\omega}[1+\mathcal{O}(1/k)]. \tag{22}$$

Thus our transform $\tilde{B}(y)$ shares with the ordinary Borel transform $B(t)$ the property of being analytic at the origin. Its radius of convergence is determined by the singularity on the negative real axis at

$$y_s=-\frac{1}{\sigma}\equiv-\frac{1}{\alpha}\frac{1}{\omega(1-\omega)^{1/\omega-1}}. \tag{23}$$

B. Resummation procedure

A resummation procedure can now be set up on the basis of the transform $\tilde{B}(y)$ as before. The inverse transformation (19) contains an integral over the entire positive axis, requiring again an analytic continuation of the Taylor expansion of $\tilde{B}(y)$ beyond the convergence radius.

The reason for introducing the transform $\tilde{B}(y)$ was to allow us to reproduce the complete power sequence in the strong-coupling expansion (3), with a leading power g_B^s and a subleading sequence of powers $g_B^{s-k\omega}$, $k=1,2,3,\ldots$. This is achieved by removing a factor $e^{-\rho\sigma y}$ with $\rho,\sigma>0$ from the truncated series (18) of our transform $\tilde{B}(y)$. Furthermore by removing a second simple prefactor of the form $(1+\sigma y)^{-\delta}$ we weaken the leading singularity in the hyper-Borel complex y-plane, which determines the large order behavior (6). The remaining series has still a finite radius of convergence. To achieve convergence on the entire positive y axis for which we must do the integral (19), we re-expand the remaining series of y in powers of $\kappa(y)$ which is related to y by an equation like Eq. (12). For simplicity we choose the parameter $p=1$, i.e.,

$$y=\frac{1}{\sigma}\frac{\kappa(y)}{1-\kappa(y)}, \tag{24}$$

which maps a shifted right half of the complex y-plane with $\mathrm{Re}[y] \geqslant -1/2\sigma$ onto the unit circle in the complex κ-plane. Thus we re-expand $\tilde{B}(y)$ in the following way:

$$\tilde{B}(y) \equiv \sum_{k=0}^{\infty} \tilde{B}_k y^k = e^{-\rho\sigma y}[1+\sigma y]^{-\delta} \sum_{k=0}^{\infty} h_k \kappa^k(y) = e^{-\rho\sigma y} \sum_{k=0}^{\infty} h_k \frac{(\sigma y)^k}{(1+\sigma y)^{k+\delta}}. \tag{25}$$

The inverse hyper-Borel transform of $\tilde{B}(y)$ is now found by forming the integrals of the expansion functions in (25):

$$I_n(g_B) = \frac{\Gamma(\beta_0)}{2\pi i} \oint_C dt\, e^t t^{-\beta_0} \int_0^{\infty} \frac{dy}{y} \left[\frac{g_B}{y t^{1/\omega - 1}} \right]^s \exp\left[\frac{y t^{1/\omega - 1}}{g_B} \right]^{\omega} e^{-\rho\sigma y} \frac{(\sigma y)^n}{(1+\sigma y)^{n+\delta}}, \tag{26}$$

so that the approximants $f_L^a(g_B)$ may be written as

$$f_L^a(g_B) = \sum_{n=0}^{L} h_n I_n(g_B). \tag{27}$$

The same functions $I_n(g_B)$ may be used as basis functions for a wide variety of divergent truncated perturbation expansions $f_L(g_B)$. The complete list of parameters on which they depend reads as follows:

$$I_n(g_B) = I_n(g_B, \omega, s, \rho, \sigma, \delta, \beta_0) = I_n(\sigma g_B, \omega, s, \rho, 1, \delta, \beta_0), \tag{28}$$

but in the following we shall mostly use the shorter notation $I_n(g_B)$. The integral representation of $I_n(g_B)$ breaks down at $s=n$, requiring an analytical continuation. For the upcoming applications in the large-g_B regime it will be sufficient to perform this continuation only in the convergent strong-coupling expansion of $I_n(g_B)$. This is obtained by performing a Taylor series expansion of the exponential function in (26), which is an expansion in powers of $1/g_B^{\omega}$. After integrating over t and y using (20), we obtain an expansion

$$I_n(g_B) = g_B^s \sum_{k=0}^{\infty} b_k^{(n)} g_B^{-k\omega}, \tag{29}$$

which has indeed the same power sequence as the strong-coupling expansion (3) of the function $f(g_B)$ to be resummed.

The expansion coefficients are

$$b_k^{(n)} = \frac{(-1)^k}{k!} \frac{\sigma^{s-k\omega}\Gamma(\beta_0)}{\Gamma[(\omega-1)k + \beta_0 + (1/\omega - 1)s]} i_k^{(n)}, \tag{30}$$

where $i_k^{(n)}$ denotes the integral

$$i_k^{(n)} = \int_0^{\infty} dy\, e^{-\rho y} (1+y)^{-\delta-n} y^{k\omega+n-s-1}. \tag{31}$$

This integral is seen to coincide with the Kummer function

$$U(\alpha, \gamma, z) \equiv \frac{1}{\Gamma(\alpha)} \int_0^{\infty} dy\, e^{-zy} y^{\alpha-1} (1+y)^{\gamma-\alpha-1}, \tag{32}$$

in terms of which we can write

$$i_k^{(n)} = \Gamma(k\omega + n - s) U(k\omega + n - s, k\omega - s - \delta + 1, \rho). \tag{33}$$

The latter expression is useful since in some applications the integral (31) may diverge, and requires an analytic continuation by deforming the contour of integration. Such deformations are automatically supplied by choosing other representations for the Kummer function, for instance,

$$U(\alpha,\gamma,z)=\frac{\pi}{\sin\pi\gamma}\left[\frac{M(\alpha,\gamma,z)}{\Gamma(1+\alpha-\gamma)\Gamma(\gamma)}-z^{1-\gamma}\frac{M(1+\alpha-\gamma,2-\gamma,z)}{\Gamma(\alpha)\Gamma(2-\gamma)}\right], \tag{34}$$

where $M(\alpha,\gamma,z)$ is the confluent hypergeometric function with a Taylor expansion

$$M(\alpha,\gamma,z)=1+\frac{\alpha}{\gamma}\frac{z}{1!}+\frac{\alpha(\alpha-1)}{\gamma(\gamma-1)}\frac{z^2}{2!}+\cdots. \tag{35}$$

The alternative expression (33) for $i_k^{(n)}$, with (34) and (35), is useful for resumming various asymptotic expansions, for example, that of the ground state energy of the anharmonic oscillator, in which case the leading strong-coupling power s has the value 1/3. There, the integral representation (31) would have to be evaluated for values $n=0, k=0$, where the integral does not exist, whereas formula (33) with (34) and (35) is well defined.

For large k, the integral on the right-hand side of (31) can be estimated with the help of the saddle point approximation. The saddle point lies at

$$y_s\approx\frac{k\omega}{\rho}, \tag{36}$$

leading to the asymptotic estimate

$$\begin{aligned} i_k^{(n)} &\overset{k\to\infty}{=} \left(\frac{k\omega}{\rho}\right)^{-\delta-n}\int_0^\infty dy\, e^{-\rho y}y^{\omega k+n-s-1}[1+\mathcal{O}(1/k)] \\ &= \left(\frac{\omega k}{\rho}\right)^{-\delta-n}\rho^{-k\omega-n+s}\Gamma(k\omega+n-s)[1+\mathcal{O}(1/k)]. \end{aligned} \tag{37}$$

The behavior of the strong-coupling coefficients $b_k^{(n)}$ for large k is obtained with the help of the identity

$$\Gamma(z)\Gamma(1-z)=\frac{\pi}{\sin\pi z} \tag{38}$$

and Stirling's formula (21), yielding

$$b_k^{(n)} \overset{k\to\infty}{=} \gamma\sin\pi[k(\omega-1)+\beta_0+(1/\omega-1)s]\left[-\frac{(1-\omega)^{(1-\omega)}}{(\sigma\rho)^\omega}\right]^k k^{\gamma_1}[1+\mathcal{O}(1/k)]. \tag{39}$$

The values of the real constants γ, γ_1 will not be needed in the upcoming discussions, and are therefore not calculated explicitly.

Equation (39) shows that the strong-coupling expansion (3) has a convergence radius

$$|g_B|\geqslant\frac{(\rho\sigma)^\omega}{(1-\omega)^{1-\omega}}, \tag{40}$$

which means that the basis functions $I_n(g_B)$, and certainly also $f(g_B)$ itself, possess additional singularities beside $g_B=0$. The parameter ρ will be optimally adjusted to match the positions of these singularities.

C. Taylor series of basis functions

For re-expanding $f_L(g_B)$ in terms of the basis functions $I_n(g_B)$, we must know their Taylor series. These are obtained by substituting into (26) the variable y by $g_B y'$, and expanding the integrand of (26) in powers of g_B. After performing the integrals over y' and t, we find

$$I_n(g_B)=\sum_{k=n}^{\infty} f_k^{(n)} g_B^k, \tag{41}$$

with the coefficients

$$f_k^{(n)}=\frac{1}{\omega}\frac{\Gamma(\beta_0)\Gamma(k/\omega-s/\omega)}{\Gamma(k(1/\omega-1)+\beta_0)}\sum_{j=0}^{k-n}\binom{-\delta-n}{j}\frac{(-\rho)^{k-n-j}}{(k-n-j)!}\sigma^k. \tag{42}$$

The coefficients in the last sum arise from the t-integral:

$$\sum_{j=0}^{k-n}\binom{-n-\delta}{j}\frac{(-\rho)^{k-n-j}}{(k-n-j)!}=\frac{(-1)^{k-n}}{\Gamma(k-n+1)\Gamma(n+\delta)}\int_0^\infty dt\, e^{-t}t^{\delta+n-1}(\rho+t)^{k-n}. \tag{43}$$

For large k, the integral may be evaluated with the help of the saddle-point approximation. Using this and Stirling's formula (21), we find

$$\sum_{j=0}^{k-n}\binom{-n-\delta}{j}\frac{(-\rho)^{k-n-j}}{(k-n-j)!}\overset{k\to\infty}{=}\frac{(-1)^{k-n}e^{\rho}}{\Gamma(\delta+n)}k^{\delta+n-1}[1+\mathcal{O}(1/k)]. \tag{44}$$

Inserting this into (42) and using once more Stirling's formula, we obtain for the expansion coefficients $f_k^{(n)}$ the following factorial growth

$$f_k^{(n)}\overset{k\to\infty}{=}\frac{(-1)^n e^{\rho}\Gamma(\beta_0)}{\sqrt{2\pi}\Gamma(\delta+n)}(1-\omega)^{1/2-\beta_0}\omega^{\beta_0-1+s/\omega}k^{\delta-\beta_0+n-3/2-s/\omega}$$
$$\times\left[\frac{\sigma}{\omega(1-\omega)^{1/\omega-1}}\right]^k k![1+\mathcal{O}(1/k)]. \tag{45}$$

For an optimal re-expansion (27), we shall choose the free parameters of the basis functions $I_n(g_B,\omega,s,\rho,\sigma,\delta,\beta_0)$ to match the large-order behavior of the coefficients f_k in (6).

D. Convergence properties of resummed series

We shall now discuss the speed of convergence of the resummation procedure. For this it will be sufficient to estimate the convergence of the strong-coupling coefficients b_k^L of the approximations $f_L(g_B)$ against the true strong-coupling coefficients b_k in (3). The convergence for arbitrary values of g_B will always be better than that. Such an estimate is possible by looking at the large-n behavior of the expansion coefficients $b_k^{(n)}$ in the strong-coupling expansion of $I_n(g_B)$ in (29). This is determined by the saddle point approximation to the integral $i_k^{(n)}$ in Eq. (31), which we rewrite as

$$i_k^{(n)}=\int_0^\infty dy\, e^{-\rho y-n\ln(1+1/y)}(1+y)^{-\delta}y^{k\omega-s-1}. \tag{46}$$

The saddle point lies at

$$y_s=\sqrt{\frac{n}{\rho}}\,[1+\mathcal{O}(1/\sqrt{n})]. \tag{47}$$

At this point, the total exponent in the integrand is

$$-\rho y_s - n \ln\left(1+\frac{1}{y_s}\right) = -2\sqrt{\rho n}[1+\mathcal{O}(1/\sqrt{n})], \tag{48}$$

implying the large-n behavior

$$b_k^{(n)} \overset{n\to\infty}{=} \text{const}\times n^{k\omega-s-1-\delta} e^{-2\sqrt{\rho n}}[1+\mathcal{O}(1/\sqrt{n})]. \tag{49}$$

The strong-coupling coefficients b_k^L of the approximations $f_L^a(g_B)$ are linear combinations of the coefficients $b_k^{(n)}$ of the basis functions $I_n(g_B)$:

$$b_k^L = \sum_{n=0}^{L} b_k^{(n)} h_n . \tag{50}$$

The speed of convergence with which the b_k^L's approach b_k as the number L goes to infinity is governed by the growth with n of the re-expansion coefficients h_n and of the coefficients $b_k^{(n)}$ in Eq. (49). We shall see that for the series to be resummed, the re-expansion coefficients h_n will grow at most like some power n^r, implying that the approximations b_k^L approach their $L\to\infty$ -limit b_k with an error proportional to

$$b_k^L - b_k \sim L^{r+k\omega-s-\delta-1/2}\times e^{-2\sqrt{\rho L}}. \tag{51}$$

The leading exponential falloff of the error $e^{-2\sqrt{\rho L}}$ is independent of the other parameters in the basis functions $I_n(g_B,\omega,p,\rho,\sigma,\delta,\beta_0)$ which still need adjustment. This is the important advantage of the present resummation method with respect to variational perturbation theory[5,8] where the error decreases merely like $e^{-\text{const}\times L^{1-\omega}}$ with $1-\omega$ close to 1/4.

The nonexponential prefactor in Eq. (51) depends on the parameters in $I_n(g_B,\omega,p,\rho,\sigma,\delta,\beta_0)$. Some of them are related to observables, others are free and may be chosen to optimize the convergence.

1. Parameters s and ω

The perturbation expansions for the critical exponents are power series in the bare coupling constant g_B whose strong-coupling limit is a constant.[8,9] The same is true for the series expressing the renormalized coupling constant g in powers of the bare coupling constant. This implies that the growth parameter s for the basis functions $I_n(g_B)$ is equal to zero in all cases. The constant asymptotic values are approached with the subleading powers $1/g_B^{k\omega-s}$, where ω is a universal experimentally measurable critical exponent.

2. Parameter σ

In the ordinary Borel transformation, the parameter α in the large-order behavior of the expansion coefficients f_k in Eq. (6), which is determined directly by the inverse value of the reduced action of the classical solution to the field equations, specifies also the position of the singularity on the negative t axis in $B(t)$. In our transform $\tilde{B}(y)$, the singularity position of the singularity is proportional to α, with an ω-dependent prefactor. It lies at [see Eq. (23)]

$$\sigma = \alpha\omega(1-\omega)^{1/\omega-1}. \tag{52}$$

This value of σ ensures that the expansion coefficients f_k^n of the basis functions $I_n(g_B)$ in Eq. (45) grow for large k with the same factor $(-\alpha)^k$ as the expansion coefficients for $f(g_B)$ in Eq. (6).

The conformal mapping (24) maps the singularity at $t=-1/\sigma$ to $\kappa=\infty$, and converts the cut along the negative into a cut in the κ-plane from 1 to ∞. The growth of the re-expansion coefficients h_n with n is therefore determined by the nature of the singularity of $\tilde{B}(y)$ at ∞.

In the upcoming applications to critical exponents it will turn out that the value (52) following from the inverse action of the solution to the classical field equations and ω will not yield the fastest convergence of the approximations $f^L(g_B)$ towards $f(g_B)$, but that a slightly smaller value gives better results. This seems to be due to the fact that the classical solution gives only the nearest singularity in the hyper-Borel transform $\tilde{B}(y)$ of $f(g_B)$. In reality, there are many additional cuts from other fluctuating field configurations which determine the size of the expansion coefficients f_k at pre-asymptotic orders k. Since the few known f_k's are always pre-asymptotic, they are best accounted for by an effective shift of the position of the singularity into the direction of the additional cuts at larger negative y, corresponding to a smaller σ.

3. Parameter ρ

According to Eq. (40), the parameter ρ determines the radius of convergence of the strong-coupling expansion of the basis functions $I_n(g_B)$. It should therefore be adjusted to fit optimally the corresponding radius of the original function $f(g_B)$. Since we do not know this radius, this adjustment will be done phenomenologically by varying ρ to optimize the speed of convergence. Specifically, we shall search at each order L for a vanishing highest re-expansion coefficient h_L or, if it does not vanish anywhere, for a vanishing derivative with respect to ρ:

$$h_L(\rho)=0 \quad \text{or} \quad \frac{dh_L(\rho)}{d\rho}=0. \tag{53}$$

4. Parameter δ

From Eq. (45) we see that the parameter δ influences the power k^β in the large-order behavior (6). By comparing the two equations, we identify the growth parameter β of $I_n(g_B)$ as being

$$\beta=\delta-\beta_0-3/2-s/\omega+n. \tag{54}$$

At first it appears to be impossible to give *all* basis functions $I_n(g_B)$ the same growth power β in (45) by simply letting δ depend on the order n as required by (54). If we were to do this, we would have to assign to δ the value

$$\delta=\delta_n\equiv\beta+\beta_0+3/2+s/\omega-n, \tag{55}$$

which depends on the index n of the function $I_n(g_B)$, and this means that we perform an analytical continuation of the power series expansion of $\tilde{B}(y)$ by re-expanding it as follows:

$$\tilde{B}(y)=\sum_{k=0}^{\infty}\tilde{B}_k y^k=e^{-\rho\sigma y}(1+\sigma y)^{-\delta}\sum_{k=0}^{\infty}h_k(\sigma y)^k. \tag{56}$$

But the series in this formula which is obtained from the series of $\tilde{B}(y)$ by removing a simple factor still has the same finite radius of convergence and could not be used to estimate $\tilde{B}(y)$ for large values of y needed to perform the back transform (19). It is, however, possible to sidetrack this problem by letting ρ grow linearly with the order L. Then the exponential factor of (56) suppresses the integrals over y for large y sufficiently to make the divergence of the re-expanded series (56) at large y irrelevant. If we determine ρ from the condition (53), the growth of ρ with L turns out to emerge by itself.

5. Parameter β_0

The parameter β_0 has two effects. From Eq. (30) we see that for

$$k>k_c\equiv\frac{\beta_0+(1/\omega-1)s}{1-\omega} \tag{57}$$

the signs of the strong-coupling expansion coefficients start to alternate irregularly. This irregularity weakens the convergence of the higher strong-coupling coefficients b_k^L with $k>k_c$ against b_k. The convergence can therefore be improved by choosing a β_0 which grows proportionally to the order L of the approximation.

In addition, β_0 appears in the power of k in (45), which is a consequence of the fact that it determines the nature of the cut in $\widetilde{B}(y)$ in the complex y-plane starting at $y=-1/\sigma$ [see Eq. (25)].

If we expand both sides of (25) in powers of $\kappa=\sigma y/(1+\sigma y)$ and compare the coefficients of powers of κ, it is easy to write down an explicit formula for the re-expansion coefficients h_n in terms of the coefficients $\widetilde{B}_j$ of $\widetilde{B}(y)$ by

$$h_n=\sum_{k=0}^{n}\sum_{j=0}^{k}\frac{\widetilde{B}_j\sigma^{-j}\rho^{k-j}}{(k-j)!}\binom{\delta+n-1}{n-k}, \tag{58}$$

where $\widetilde{B}_j$ are obtained from the original expansion coefficients f_k of $f(g_B)$ by relation (18).

Before beginning with the resummation of the perturbation expansions for the critical exponents of ϕ^4-field theories, it will be useful to obtain a feeling for the quality of the above-developed resummation procedure, in particular for the significance of the parameters upon the speed of convergence. We do this by resumming the often-used example of an asymptotic series, the perturbation expansion of the ground state energy of the anharmonic oscillator.

E. Resummation of ground state energy of anharmonic oscillator

Consider the one-dimensional anharmonic oscillator with the Hamiltonian

$$H=\frac{p^2}{2}+m^2\frac{x^2}{2}+g_Bx^4. \tag{59}$$

In this quantum mechanical system, there is no need to distinguish bare and renormalized coupling constants, but since the previous resummation formulas were all formulated in terms of g_B we shall keep this notation also here. The ground state energy has a perturbation expansion

$$E^{(0)}(g_B)=\sum_{k}^{\infty} f_kg_B^k, \tag{60}$$

whose coefficients can be calculated via the Bender–Wu recursion relation[16] to arbitrarily high orders, with a large-order behavior

$$f_k=-\sqrt{\frac{6}{\pi^3}}k!(-3)^kk^{-1/2}[1+\mathcal{O}(1/k)]. \tag{61}$$

By comparison with (6) we identify the growth parameters

$$\alpha=3,\quad \beta=-1/2. \tag{62}$$

A scale transformation $x\to g^{1/6}x$ applied to the Hamiltonian (59) reveals the scaling property[17] for the energy as a function of g_B and m^2:

$$E(m^2,g_B)=g_B^{1/3}E(g_B^{-2/3}m^2,1). \tag{63}$$

Combining this with the knowledge[17] that $E(m^2,1)$ is an analytic function at $m^2=0$, we see that $E(1,g_B)$ possesses a power series expansion of the form (3), with the parameters

$$s=1/3,\quad \omega=2/3. \tag{64}$$

Inserting the latter number together with α from Eq. (62) into (52), we identify

$$\sigma = \frac{2}{\sqrt{3}}. \tag{65}$$

The ground state energy $E^{(0)}(g_B)$ obeys a once-subtracted dispersion relation:[17]

$$E^{(0)}(g_B) = \frac{1}{2} + \frac{g_B}{\pi}\int_0^\infty \frac{dg_B'}{g_B'}\,\frac{\mathrm{Im}\,E^{(0)}(-g_B')}{g_B'+g_B}. \tag{66}$$

The perturbation expansion (60) is obtained from this by expanding $1/(g_B'+g_B)$ in powers of g_B, and performing the integral term by term. This shows explicitly that the large-order behavior (61) is caused by an imaginary part

$$\mathrm{Im}\,E^{(0)}(-|g_B|) = \sqrt{\frac{6}{\pi}}\sqrt{\frac{1}{3|g_B|}}e^{-1/3|g_B|}[1+\mathcal{O}(|g_B|)] \tag{67}$$

near the tip of the left-hand cut in the complex g_B-plane, in agreement with the general form (5) associated with the large-order behavior (6).

Let us now specify the parameter δ. We shall do this here in an n-dependent way using Eq. (55), which now reads with (64):

$$\delta = \delta_n \equiv \beta_0 + 3/2 - n. \tag{68}$$

The corresponding basis functions

$$I_n(g_B, 2/3, 1/3, \rho, 2/\sqrt{3}, \beta_0 + 3/2 - n, \beta_0), \tag{69}$$

have then all the same large-order growth parameter β in (6).

The two parameters ρ and β_0 are still arbitrary. The first is determined by an order-dependent optimization of the approximations via the conditions (53). The best choice of β_0 will be made differently depending on the regions of g_B.

Let us test the convergence of our algorithm at small negative coupling constants g_B, i.e., near the tip of the left-hand cut in the complex g_B-plane. We do this by calculating the prefactor γ in the large-order behavior (6). In this case the convergence turns out to be fastest by giving the parameter β_0 a small value, i.e., $\beta_0 = 2$. With the large-order behavior (45) of the basis functions $I_n(g_B)$, we find the resummed functions $f_L(g_B)$ of Lth order $\Sigma_{n=0}^L h_n I_n(g_B)$ to have a large-order behavior (6) with a prefactor

$$\gamma_L = \frac{e^\rho \Gamma(\beta_0)}{\sqrt{2\pi}\Gamma(\delta)}\sum_{k=0}^{L}(-1)^k h_k. \tag{70}$$

The values of these sums for increasing L are shown in Fig. 1. They converge exponentially fast against the exact limiting value

$$\gamma = \sqrt{\frac{6}{\pi^3}}, \tag{71}$$

with superimposed oscillations. The oscillations are of the same kind as those observed in variational perturbation theory for the convergence of the approximations to the strong-coupling coefficients b_k (see Figs. 5.19 and 5.20 in Ref. 5) Also here, the strong-coupling coefficients b_k^L

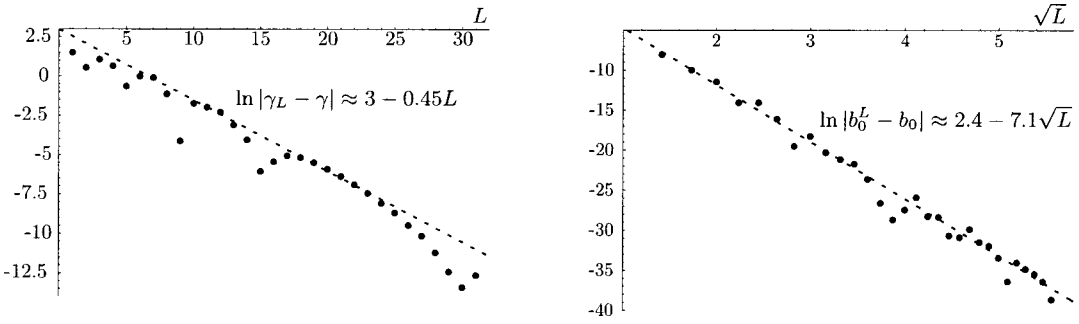

FIG. 1. Logarithmic plot of the convergence behavior of the successive approximations to the prefactor γ^L in the large-order behavior (87), and of the leading strong-coupling coefficient b_0^L.

converge exponentially fast towards b_k, but with a larger power of L in the exponent of the last term $\approx e^{-\text{const}\times\sqrt{L}}$ [see Eq. (51)], rather than $\approx e^{-\text{const}\times L^{1/3}}$ for variational perturbation theory [see Eq. (5.199) in Ref. 5]. This is seen on the right-hand side of Fig. 1.

We have applied our resummation method to the first 10 strong-coupling coefficients using the expansion coefficients f_k up to order 70. The results are shown in Table I. Comparison with a similar table in Refs. 18 and 5 shows that the new resummation method yields in 70th order the same accuracy as variational perturbation theory did in 251st order. In all cases the optimal parameter ρ turns out to be a slowly growing function with L.

In the strong-coupling regime, the convergence is fastest by choosing for β_0 an L-dependent value

$$\beta_0 = L. \tag{72}$$

Note that this choice of β_0 ruins the convergence to the imaginary part for small negative g_B which was resummed best with $\beta_0 = 2$.

F. Resummation of critical exponents

Having convinced ourselves of the fast convergence of our new resummation method, let us now turn to the perturbation expansions of the $O(N)$-symmetric ϕ^4 theories in powers of the bare coupling constant $\overline{g_B}$, defined by the Euclidean action

TABLE I. Strong-coupling coefficients b_n of the 70th order approximants $E^0_{70}(g)=\Sigma_{n=0}^{70}h_nI_n(g)$ to the ground state energy $E^0(g)$ of the anharmonic oscillator. They have the same accuracy as the variational perturbation–theoretic calculations up to order 251 in Refs. 18 and 5.

$$\mathcal{A}=\int d^D x\{\tfrac{1}{2}[\partial\phi_0(x)]^2+\tfrac{1}{2}m_0^2\phi_0^2(x)+2\pi\lambda_B[\phi_0^2(x)]^2\} \tag{73}$$

in $D=3$ dimensions. The field ϕ_0 is an N-component vector $\phi_0=(\phi_0^1,\phi_0^2,\ldots,\phi_0^N)$, and the action is $O(N)$-symmetric. We define renormalized mass m and field strength by parametrizing the behavior of the connected two point function $G^{(2)}$ in momentum space near zero momentum as

$$G^{(2)}(p,\alpha;-p,\beta)=Z_\phi\frac{\delta_{\alpha\beta}}{m^2+p^2+\mathcal{O}(p^4)}. \tag{74}$$

The renormalized coupling constant g is defined by the value of the connected four-point function at zero momenta:

$$G^{(4)}(0,\alpha;0,\beta;0,\gamma;0,\delta)=m^{-4-D}Z_\phi^2 g(\delta_{\alpha\beta}\delta_{\gamma\delta}+\delta_{\alpha\gamma}\delta_{\beta\delta}+\delta_{\alpha\delta}\delta_{\beta\gamma}). \tag{75}$$

If we introduce the dimensionless bare coupling constant $g_B\equiv\lambda_B/m$, the critical exponents are defined by

$$\begin{aligned}\eta(g_B)&=g_B\frac{d}{dg_B}\log Z_\phi,\\ 2-\nu(g_B)^{-1}&=g_B\frac{d}{dg_B}\log\frac{m_0^2}{m^2}.\end{aligned} \tag{76}$$

The following expansions for the critical indices in the bare dimensionless coupling constant are available[19] in the literature for all $O(N)$:

$$\begin{aligned}\eta(g_B)=&(16/27+8N/27)g_B^2+(-9.086\,537\,459-5.679\,085\,912N-0.567\,908\,591\,2N^2)g_B^3\\ &+(127.491\,6153+94.773\,205\,34N+17.134\,775\,5N^2+0.810\,538\,322\,1N^3)g_B^4\\ &+(-1843.491\,99-1576.466\,76N-395.267\,835\,8N^2-36.006\,602\,42N^3\\ &-1.026\,437\,849N^4)g_B^5+(28\,108.603\,98+26\,995.879\,62N+8461.481\,806N^2\\ &+1116.246\,863N^3+62.887\,906\,8N^4+1.218\,861\,532N^5)g_B^6,\end{aligned} \tag{77}$$

$$\begin{aligned}2-\nu^{-1}(g_B)=&g_B(2+N)+(523/27+316N/27+N^2)g_B^2+(229.374\,4544+162.847\,4234N\\ &+26.080\,098\,09N^2+N^3)g_B^3+(-309\,099\,6037-2520.848\,751N\\ &-572.328\,2893N^2-44.326\,461\,41N^3-N^4)g_B^4+(45\,970.718\,39\\ &+42\,170.327\,07N+12\,152.706\,75N^2+1408.064\,008N^3+65.976\,301\,08N^4+N^5)g_B^5\\ &+(-740\,843.1985-751\,333.064N-258\,945.0037N^2-39\,575.570\,37N^3\\ &-2842.8966N^4-90.714\,5582N^5-N^6)g_B^6.\end{aligned} \tag{78}$$

In addition, seventh order coefficients have been calculated for $N=0,1,2,3$:[1]

$$\eta^{(7)}=\left\{\begin{array}{r}-45\,387.489\,27\\-114\,574.4876\\-241\,0424.7646\\-454\,761.4731\end{array}\right\}g_B^7,\ \nu^{-1(7)}=\left\{\begin{array}{r}-127\,922\,69.773\\-337\,114\,16.972\\-737\,808\,09.849\\-143\,831\,857.01\end{array}\right\}g_B^7\ \text{for}\left\{\begin{array}{l}N=0\\N=1\\N=2\\N=3\end{array}\right\}. \tag{79}$$

When approaching the critical point, the renormalized mass m tends to zero, so that the problem is to find the strong-coupling limit of these expansions. In order to have the critical exponents approach a constant value, the power s in Eq. (3) must be set equal to zero.

In contrast to the quantum-mechanical discussion in the last section, the exponent ω governing the approach to the scaling limit is now unknown, and must also be determined from the available perturbation expansions. As in Refs. 8 and 9, we solve this problem by using the fact that the existence of a critical point implies the renormalized coupling constant g in powers of g_B to converge against a constant renormalized coupling g^* for $m\to 0$. The expansion of $g(g_B)$ is known up to six loops[19] for all $O(N)$:

$$\begin{aligned}g(g_B)=&\,g_B+(-8-N)g_B^2+(2108/27+514/27N+N^2)g_B^3\\&+(-878.793\,7193-312.634\,446\,71N-32.548\,413\,03N^2-N^3)g_B^4\\&+(11\,068.061\,83+5100.403\,285N+786.366\,569\,9N^2+48.213\,867\,44N^3+N^4)g_B^5\\&+(-153\,102.850\,23-85\,611.919\,96N-17\,317.7025N^2-1585.114\,189N^3\\&-65.820\,362\,03N^4-N^5)g_B^6\\&+(2297\,647.148+149\,5703.313N+371\,103.0896N^2+44\,914.04\,8\,18N^3\\&+2797.291\,579N^4+85.213\,105\,01N^5+N^6)g_B^7.\end{aligned} \tag{80}$$

The convergence against a fixed coupling g^* occurs only for the correct value of ω in the resummation functions $I_n(g_B,\omega,s,\rho,\sigma,\delta,\beta_0)$. At different values, $g(g_B)$ has some strong-coupling power behavior g_B^s with $s\neq 0$. We may therefore determine ω by forming from (80) a series for the power s,

$$s=\frac{d\log g(g_B)}{d\log g_B}=\frac{g_B}{g}g'(g_B), \tag{81}$$

resumming this for various values of ω in the basis functions, and finding the critical exponent ω from the zero of s. Alternatively, since $g(g_B)\to g^*$, we can just as well resum the series for $-gs$, which coincides with the β-function of renormalization group theory [not to be confused with the growth parameter β in (6)]

$$\beta(g_B)\equiv -g_B\frac{dg(g_B)}{dg_B}. \tag{82}$$

If we denote its strong-coupling limit by β^*,

$$\beta^*\equiv\beta(g_B)\big|_{g_B\to\infty}, \tag{83}$$

we resum the expansion for $\beta(g_B)$ to form the approximations

$$\beta_L(g_B)=\sum_{n=0}^{L}h_nI_n(g_B,\omega), \tag{84}$$

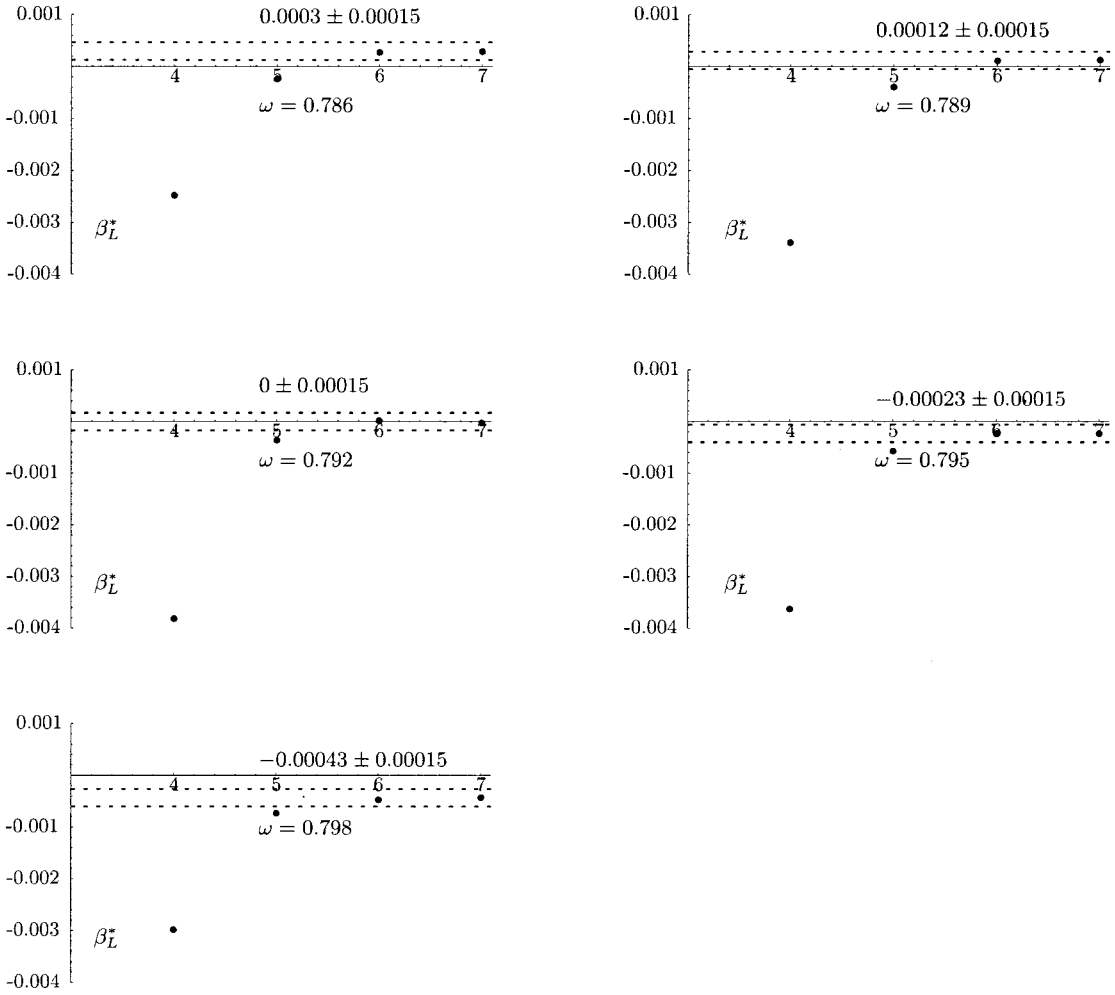

FIG. 2. Convergence of strong-coupling limits of the β-function (82) for $N=1$ and different values of ω. The upper and lower dashed lines denote the range of the $L\to\infty$ limit of β_L^* from which the value of ω is deduced in Fig. 3.

and plot the strong-coupling limits of the Lth approximations β_L^* for various values of ω. This is shown in Fig. 2. From these plots we extract the critical exponent ω by finding the ω-value for which the approximations β_L^* extrapolate best to zero for $L\to\infty$, taking into account that the convergence is exponentially fast with superimposed oscillations. These ω-values are called ω_L.

For these resummations, we must of course specify the remaining parameters in the basis functions $I_n(g_B,\omega,0,\rho,\sigma,\delta,\beta_0)$. This can, in principle, proceed as in the case of the anharmonic oscillator. The parameter α is determined from the action of a classical instanton solution $\phi_c(x)$ of the field equations, and has for all expansions the N-independent value[11]

$$\alpha=\frac{32\pi}{I_4}=1.329\,97, \tag{85}$$

where $I_p\equiv\int d^Dx[\phi_c(x)]^p$ are integrals over powers of $\phi_c(x)$.

To determine the parameter δ, we recall the remaining growth parameters β and γ of the large-order behavior (6) of the perturbative series for the critical exponents. The growth parameter β is given by the number of zero modes in the fluctuation spectrum around this classical solution:

TABLE II. First six perturbative coefficients in the expansions of the β-function in powers of the bare coupling constant g_B, divided by their asymptotic large-order estimates $(-\alpha)^k k! k^{\beta_\beta}$. The ratios increase quite slowly towards the theoretically predicted normalization constant γ_β in the asymptotic regime given in the lowest row.

N	0	1	2	3
k	$f_k^\beta / f_k^{\beta\,\mathrm{as}}$	$f_k^\beta / f_k^{\beta\,\mathrm{as}}$	$f_k^\beta / f_k^{\beta\,\mathrm{as}}$	$f_k^\beta / f_k^{\beta\,\mathrm{as}}$
2	0.57	0.45	0.35	0.27
3	0.61	0.45	0.32	0.22
4	0.73	0.51	0.34	0.22
5	0.89	0.61	0.40	0.25
6	1.07	0.73	0.47	0.29
7	1.26	0.88	0.56	0.34
⋮	⋮	⋮	⋮	⋮
γ_β	110.0	97.0	75.5	53.2

$$\begin{Bmatrix} \beta_\eta \\ \beta_{\nu^{-1}} \\ \beta_\beta \end{Bmatrix} = \begin{Bmatrix} 3+N/2 \\ 4+N/2 \\ 4+N/2 \end{Bmatrix}. \tag{86}$$

The prefactors γ in (6) requires the calculation of the fluctuation determinants around the classical solution, which yields in the case of the β-function

$$\gamma_\beta = \frac{2^{N/2+2} 3^{-3/2} \pi^{-2}}{\Gamma(N/2+2)} \left(\frac{I_1^2}{I_4}\right)^2 \left(\frac{I_6}{I_4} - 1\right)^{3/2} D_L^{-1/2} D_T^{-(N-1)/2}, \tag{87}$$

where D_L and D_T are characteristic quantities of the longitudinal and transverse parts of the fluctuation determinant, respectively. Their numerical values are[11]

D_L	D_T	I_1	I_4	I_6	H_3
10.544 ± 0.004	1.4571 ± 0.0001	31.691 522	75.589 005	659.868 352	13.563 312

(88)

The parameters γ_η, $\gamma_{\nu^{-1}}$ are obtained from γ_β by

$$\gamma_\eta = \gamma_\beta \frac{2H_3}{I_1 D(4-D)}, \quad \gamma_{\nu^{-1}} = \gamma_\beta \frac{N+2}{N+8} (D-1) 4\pi \frac{I_2}{I_1^2}, \tag{89}$$

where $I_2 = (1 - D/4) I_4$ and H_3 is listed in (88). Note that the expansions in powers of the renormalized coupling constant g have the same parameters α and β, but different parameters γ_R. These differ from the above α's by a common factor:

$$\gamma_R = \gamma e^{-(N+8)/\alpha}. \tag{90}$$

From Eq. (85), the parameter σ is found using relation (52). It turns out, however, that this value does not lead to an optimal convergence. This can be understood qualitatively by observing that the large-order behavior of the expansion coefficients of the critical exponents and of the β-function in powers of the bare coupling constant g_B is not nearly as precocious in reaching the large-order form (6) as the corresponding expansions in powers of the renormalized coupling constant g (see Fig. 1 in Ref. 9). The lack of precocity here is illustrated for the expansion coefficients f_k^β of the β-function in Table II, which gives the ratios of f_k^β and their leading asymptotic estimates $f_k^{\beta\,\mathrm{as}}$:

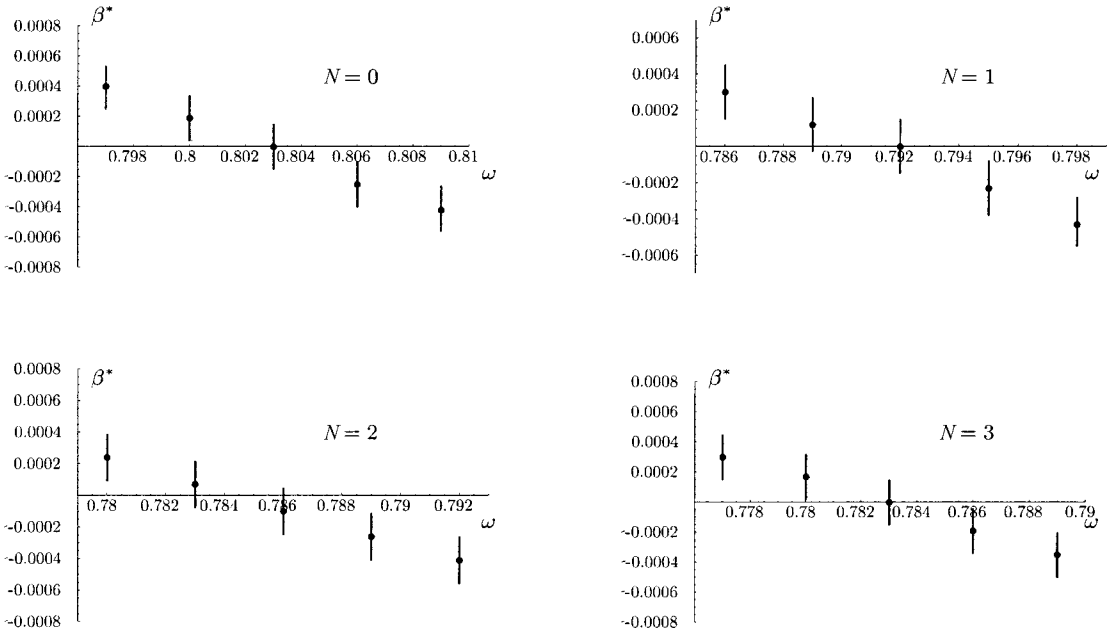

FIG. 3. Plot of resummed values of β^* against ω. The true value of ω is deduced from the condition $\beta^*=0$ and the errors are determined from the range of ω where the error bars from the resummation of β^* intersect with the x-axis.

$$f_k^\beta / f_k^{\beta\,\mathrm{as}} \equiv f_k^\beta / k!(-\alpha)^k k^\beta. \tag{91}$$

The first six approach their large-order limits quite slowly. For this reason we prefer to adapt σ not from α by Eq. (52), but by an optimization of the convergence. Since the re-expanded series converges for fixed values of δ and σ it is reasonable to determine these parameters by searching for a point of least dependence in largest available order L. This is done by imposing the conditions

$$\frac{d\kappa_L}{d\sigma}=0 \quad \text{and} \quad \frac{d^2\kappa_L}{d\sigma^2}=0 \tag{92}$$

to determine *both* parameters δ, σ, where κ_L denotes the Lth approximation to any exponent γ, ν or η. In accordance with the discussions in Sec. II A 2 this procedure provides a value of σ which is smaller than that given by (52).

After trying out a few choices, we have given the parameters β and ρ the fixed values 1 and 10, respectively, to accelerate the convergence.

The results for the critical exponents of all $O(N)$-symmetries are shown in Figs. 2–6 and Table III.

The total error is indicated in the square brackets. It is deduced from the error of resummation of the critical exponent at a fixed value of ω indicated in the parentheses, and from the error $\Delta\omega$ of ω, using the derivative of the exponent with respect to ω given in curly brackets. Symbolically, the relation between these errors is

$$[\cdots]=(\cdots)+\Delta\omega\{\cdots\}. \tag{93}$$

The accuracy of our results can be judged by comparison with the most accurately measured critical exponent α parametrizing the divergence of the specific heat of superfluid helium at the λ-transition by $|T_c-T|^{-\alpha}$. By going into a vicinity of the critical temperature with $\Delta T\approx 10^{-8}$ K, a recent satellite experiment has provided us with the value[20]

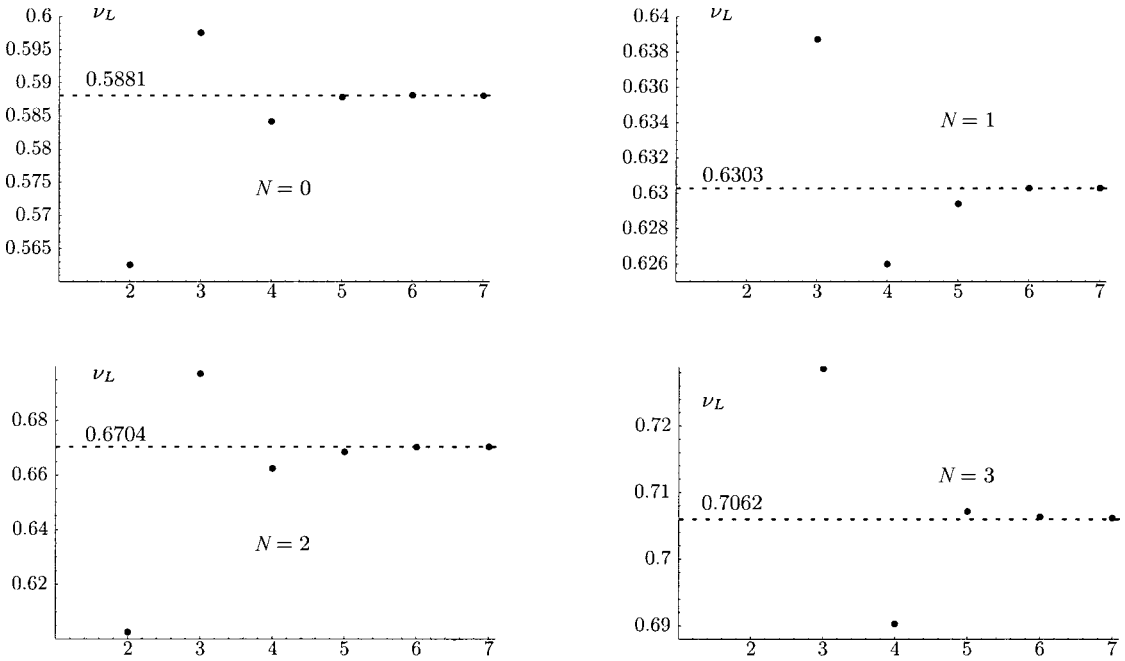

FIG. 4. Convergence of the approximations ν_L to the critical exponent ν for different values of N.

$$\alpha = -0.010\,56 \pm 0.000\,38. \tag{94}$$

Our value for ν in Table III is

$$\nu = -0.6704 \pm 0.007. \tag{95}$$

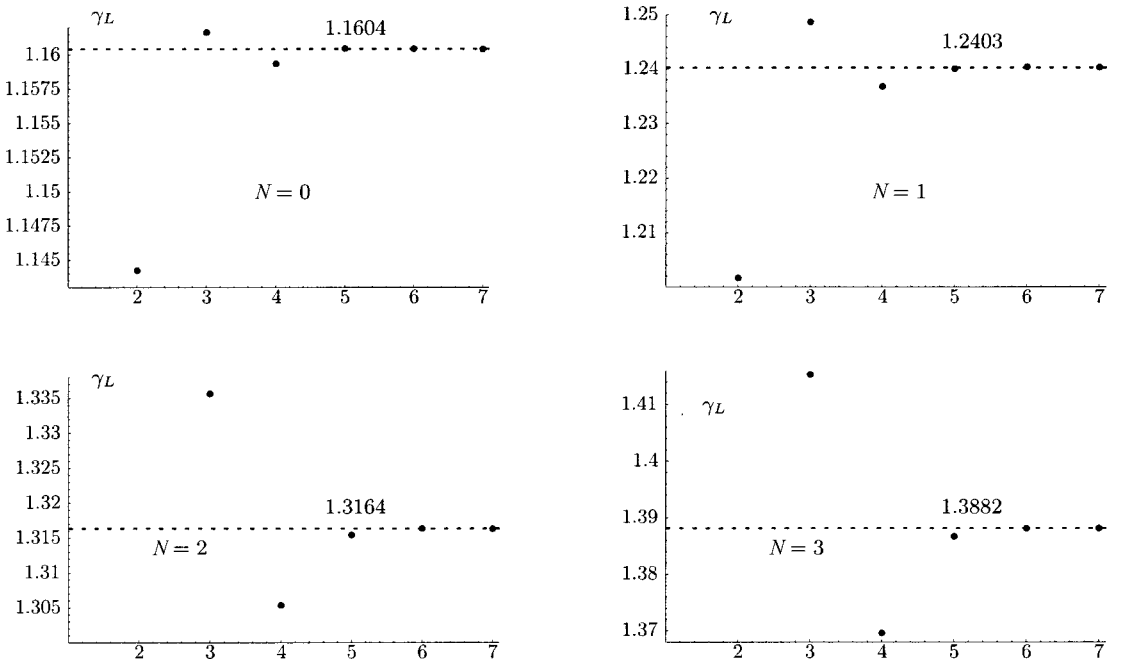

FIG. 5. Convergence of the approximations γ_L to the critical exponent γ for different values of N.

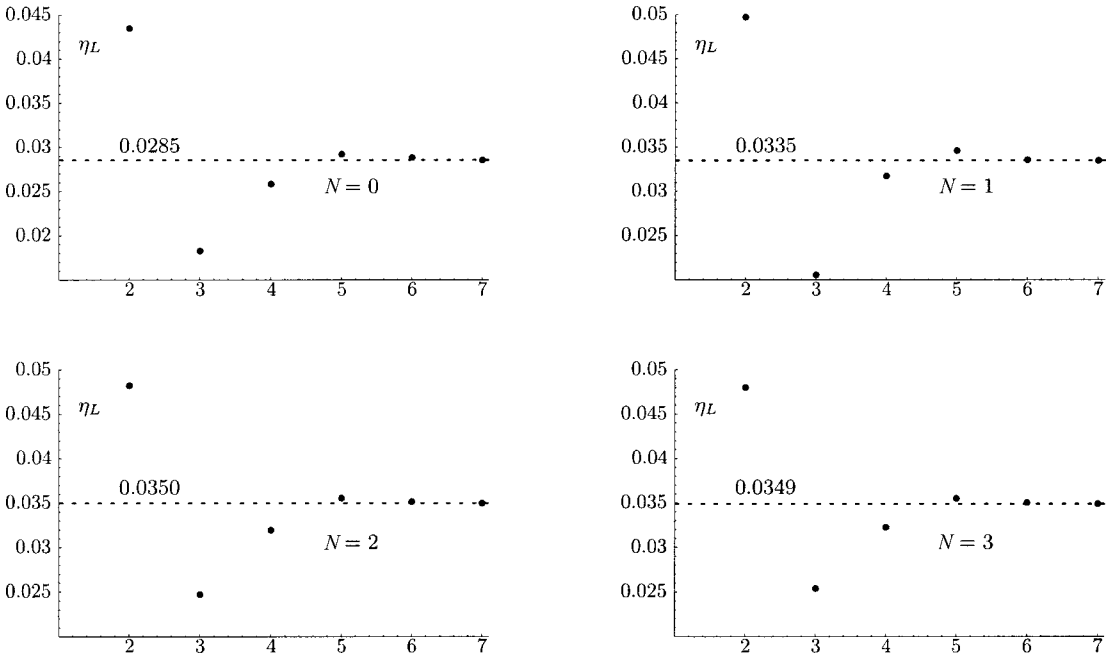

FIG. 6. Convergence of the approximations η_L to the critical exponent η for different values of N.

TABLE III. Critical exponents of the $O(N)$-symmetric ϕ^4-theory from our new resummation method. The numbers in square brackets indicate the total errors. They arise from the error of the resummation at fixed values of ω indicated in parentheses, and the errors coming from the inaccurate knowledge of ω. The former are estimated from the scattering of the approximants around the graphically determined large-L limit, the latter follow from the errors in ω and the derivatives of the critical exponents with respect to changes of ω indicated in the curly brackets.

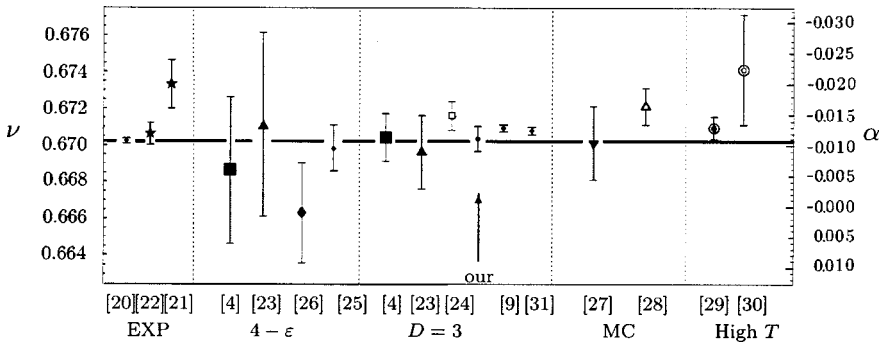

FIG. 7. Comparison of our result (96) for critical exponents α of superfluid helium with experiments and other theories.

and yields via the scaling relation $\alpha = 2 - 3\nu$:

$$\alpha = -0.0112 \pm 0.0021, \tag{96}$$

in good agreement with the experimental number (94). A comparison with other experiments and theories is shown in Fig. 7, showing that our result is among the more accurate ones.

A remark is necessary concerning the errors quoted in this paper. We do not know how to estimate precisely the errors which can appear in an involved numerical approximation scheme such as the one presented here. Our estimates are based on the range of critical exponents which can be reached by reasonably modifying the parameters in the calculations. What may be considered as reasonable is a somewhat subjective procedure. As such, our error estimates follow the rule of maximal optimism, and are probably underestimated. This is, however, not uncommon in resummations of divergent power series of critical exponents.[21–31]

[5] For a detailed description of this theory in quantum mechanics see the textbook H. Kleinert, *Path Integrals in Quantum Mechanics Statistics and Polymer Physics* (World Scientific, Singapore, 1995) (http://www.physik.fu-berlin.de/~kleinert/b3). The extension to quantum field theory is described in Chap. 19 of the textbook H. Kleinert and V. Schulte-Frohlinde, *Critical Properties of ϕ^4-Theories* (World Scientific, Singapore, 2000) (http://www.physik.fu-berlin.de/~kleinert/b8). There were two main predecessors to variational perturbation theory coming from two different directions. From the mathematical side, the seminal paper was by R. Seznec and J. Zinn-Justin, J. Math. Phys. **20**, 1398 (1979). From the physical side, inspiration came from R. P. Feynman and H. Kleinert, Phys. Rev. A **34**, 5080 (1986) (http://www.physik.fu-berlin.de/~kleinert/159), and its systematic extension in H. Kleinert, Phys. Lett. A **173**, 332 (1993). For the contributions of numerous other authors see Notes and References of Chaps. 5 and 17 in the first textbook. A small excerpt is given below. The crucial breakthrough which opened up the previous quantum mechanical variational approaches to quantum field theory came in three steps. First, still in quantum mechanics, by exploiting previously unused even approximants which do not have an extremum, as explained in Chap. 5 of the textbook. For applications to quantum field theory, two more ingredients were important, as pointed out in Refs. 8 and 9: the determination of the exponent ω by the leading power behavior in the strong-coupling limit, and an extrapolation procedure to infinite order on the basis of the theoretically known analytic order dependence. These developments were essential in obtaining accurate critical exponents rivaling the powerful combination of renormalization group and Borel-type resummation methods. Variational perturbation theory also yields directly ϵ-expansions for the critical exponents without the renormalization group formalism, as shown in Ref. 10. A selected list of historic contributions is T. Barnes and G. I. Ghandour, Phys. Rev. D **22**, 924 (1980); B. S. Shaverdyan and A. D. Usherveridze, Phys. Lett. B **123**, 316 (1983); P. M. Stevenson, Phys. Rev. D **30**, 1712 (1985); **32**, 1389 (1985); P. M. Stevenson and R. Tarrach, Phys. Lett. B **176**, 436 (1986); A. Okopinska, Phys. Rev. D **35**, 1835 (1987); **36**, 2415 (1987); W. Namgung, P. M. Stevenson, and J. F. Reed, Z. Phys. C **45**, 47 (1989); U. Ritschel, Phys. Lett. B **227**, 44 (1989); Z. Phys. C **51**, 469 (1991); M. H. Thoma, *ibid.* **44**, 343 (1991); I. Stancu and P. M. Stevenson, Phys. Rev. D **42**, 2710 (1991); R. Tarrach, Phys. Lett. B **262**, 294 (1991); H. Haugerud and F. Raunda, Phys. Rev. D **43**, 2736 (1991); A. N. Sissakian, I. L. Solivtosv, and O. Y. Sheychenko, Phys. Lett. B **313**, 367 (1993). A. Duncan and H. F. Jones, Phys. Rev. D **47**, 2560 (1993). For the anharmonic oscillator, the highest accuracy in the strong-coupling limit was reached with exponentially fast convergence in Ref. 18. That paper contains references to earlier less accurate calculations of strong-coupling expansion coefficients from weak-coupling perturbation theory, in particular F. M. Fernández and R. Guardiola, J. Phys. A **26**, 7169 (1993); F. M. Fernńdez, Phys. Lett. A **166**, 173 (1992); R. Guardiola, M. A. Solís, and J. Ros, Nuovo Cimento **107**, 713 (1992); A. V. Turbiner and A. G. Ushveridze, J. Math. Phys. **29**, 2053 (1988); B. Bonnier, M. Hontebeyrie, and E. H. Ticembal, *ibid.* **26**, 3048 (1985). Those works were unable to extract the exponential law of convergence from their data. This was shown to be related to the convergence radius of the strong-coupling expansion by H. Kleinert and W. Janke, Phys. Lett. A **206**, 283 (1995) and in the second paper in Ref. 7. Predecessors of these works which did not yet explain the exponentially fast convergence in the strong-couplings limit are I. R. C. Buckley, A. Duncan, and H. F. Jones, Phys. Rev. D **47**, 2554 (1993); C. M. Bender, A. Duncan, and H. F. Jones, *ibid.* **49**, 4219 (1994); A. Duncan and H. F. Jones, *ibid.* **47**, 2560 (1993); C. Arvanitis, H. F. Jones, and C. S. Institut für Theoretische Physik, FU Berlin, Germany

(Received 27 June 2000; accepted for publication 27 June 2000)

In this letter we construct a representation of the 3+1-dimensional Poincaré group by modular groups of von Neumann algebras lying in a specified modular position with respect to each other. Combining this new result with an old one of Bisognano–Wichmann [J. Math. Phys. **16**, 985 (1975)] we obtain a net of local observables of a 3+1-dimensional quantum field theory out of a finite set of algebras. © *2001 American Institute of Physics.* [DOI: 10.1063/1.1327597]

I. INTRODUCTION

In this article we continue our investigation on classifying quantum field theories by a finite set of algebras lying in a specified modular position relative to each other, see Ref. 1.

Our framework will be the algebraic approach to quantum field theory, in which the physical system is described by a net of bounded operators, see Ref. 2. As a fundamental feature we have the Reeh–Schlieder property of the vacuum.[3] Intuitively speaking this property reflects the vacuum fluctuations of local quantum field theories. Mathematically it enables one to apply the modular theory of operator algebras as developed by Tomita and Takesaki[4] to each local algebra. As has been realized by Bisognano and Wichmann[5] this rather general structure has a very beautiful interpretation in terms of space–time symmetries of the underlying quantum field theory. We will subsequently review some of these results in Sec. II.

In 1992 Borchers[6] gave an abstract version of this observation which motivated one of the authors (Wiesbrock) to investigate a special type of inclusions of algebras, so called modular inclusions.[7]

They show a rich symmetry structure. Out of such inclusions he constructed a net of algebras fulfilling the assumptions of algebraic quantum field theory in $1+1$ dimensions.[8]

In order to generalize this result to higher dimensions he introduced the notion of modular intersections of von Neumann algebras.[9] Starting with a set of 3 modular intersections and one additional modular inclusion he constructed a representation of the Poincaré group in $2+1$ dimensions. Exploiting the result of Ref. 5 these data give rise to a $2+1$-dimensional quantum field theory.[1]

In this article we will generalize this result to $3+1$ dimensions.

II. PRELIMINARIES

For the convenience of the reader we recall the notion of modular inclusion and modular intersection.

Definition 1 (Ref. 7):

(a) Let $\mathcal{N}\subset\mathcal{M}$ be von Neumann algebras acting on a Hilbert space $\mathcal{H}$, and let $\Omega\in\mathcal{H}$ be a common cyclic and separating vector. $(\mathcal{N}\subset\mathcal{M},\Omega)$ is called a $\pm$ **half-sided modular inclusion** (abbreviated by $\pm$hsm), if $\Delta_{\mathcal{M}}^{it}\mathcal{N}\Delta_{\mathcal{M}}^{-it}\subset\mathcal{N}$ for all $\pm t>0$.

[a)]Electronic mail: kaehler@physik.fu-berlin.de
[b)]Electronic mail: wiesbroc@physik.fu-berlin.de

(b) Let $\mathcal{N}$ and $\mathcal{M}$ be von Neumann algebras acting on a Hilbert space $\mathcal{H}$, which have a common cyclic and separating vector $\Omega\in\mathcal{H}$. In addition let Ω also be cyclic for $\mathcal{N}\cap\mathcal{M}$. If

I. $((\mathcal{N}\cap\mathcal{M})\subset\mathcal{N},\Omega)$ and $((\mathcal{N}\cap\mathcal{M})\subset\mathcal{M},\Omega)$ are $\pm$hsm inclusions,

II. $J_{\mathcal{N}}(s-\lim_{t\to\mp\infty}\Delta_{\mathcal{N}}^{it}\Delta_{\mathcal{M}}^{-it})J_{\mathcal{N}}=s-\lim_{t\to\mp\infty}\Delta_{\mathcal{M}}^{it}\Delta_{\mathcal{N}}^{-it}$, then the triple $(\mathcal{N},\mathcal{M},\Omega)$ is called a $\pm$ **modular intersection** (abbreviated by $\pm$mi).

The fundamental Theorem in this context is:

Theorem 1 (Ref. 1): *Let $\mathcal{N}$ and $\mathcal{M}$ fulfill one of the conditions (a) or (b) in Definition 1. Then*

(a) $\ln(\Delta_{\mathcal{N}})-\ln(\Delta_{\mathcal{M}})$ *is essentially self-adjoint (for modular inclusions even positive).*

Denote by $U_{\mathcal{M},\mathcal{N}}(a),a\in\mathbf{R}$ *the unitary group on* $\mathcal{H}$ *with the generator* $\mp(1/2\pi)(\ln(\Delta_{\mathcal{N}})-\ln(\Delta_{\mathcal{M}}))$. *Then,*

(b) $\Delta_{\mathcal{M}}^{it}U_{\mathcal{M},\mathcal{N}}(a)\Delta_{\mathcal{M}}^{-it}=\Delta_{\mathcal{N}}^{it}U_{\mathcal{M},\mathcal{N}}(a)\Delta_{\mathcal{N}}^{-it}=U_{\mathcal{M},\mathcal{N}}(e^{\pm 2\pi t}a)$ *for* $t,a\in\mathbf{R}$,

(c) $J_{\mathcal{M}}U_{\mathcal{M},\mathcal{N}}(a)J_{\mathcal{M}}=J_{\mathcal{N}}U_{\mathcal{M},\mathcal{N}}(a)J_{\mathcal{N}}=U_{\mathcal{M},\mathcal{N}}(-a)$ *for all* $a\in\mathbf{R}$,

(d) $\Delta_{\mathcal{N}}^{it}\mathcal{M}\Delta_{\mathcal{N}}^{-it}\subset\mathcal{M}$ *for all* $\mp t>0$,

(e) $\mathcal{N}=U_{\mathcal{M},\mathcal{N}}(1)\mathcal{M}U_{\mathcal{M},\mathcal{N}}(-1)$,

(f) $\Delta_{\mathcal{M}}^{it}\Delta_{\mathcal{N}}^{-it}=U_{\mathcal{M},\mathcal{N}}(-1+e^{\pm 2\pi t})$,

(g) $J_{\mathcal{M}}J_{\mathcal{N}}=U_{\mathcal{M},\mathcal{N}}(-2)$,

(h) $(\mathcal{N},\mathcal{M},\Omega)$ *is* $\pm$mi (hsm)$\Leftrightarrow(\mathcal{N}',\mathcal{M}',\Omega)$ *is* $\mp$mi(hsm),

(i) $U_{\mathcal{M}',\mathcal{N}'}(a)=U_{\mathcal{M},\mathcal{N}}(a)$ *for all* $a\in\mathbf{R}$.

(There was an error in the original proof of statement (a) for the case of hsm-inclusions, which was noticed by Araki and Zsido. They also provided a way of filling the gap.[10] For an alternate proof, see Ref. 11.) It is convenient to sign the various algebras occurring in the following by two integers, f. e. by $\mathcal{M}_{12}$. (This notation is closely related to the labeling of wedge regions by two light vectors, see Sec. III.) Further Δ_{12} and J_{12} will denote the modular objects belonging to $(\mathcal{M}_{12},\Omega)$ and $U_{12,13}(a)$ is the one-parameter group mapping $\mathcal{M}_{12}$ onto $\mathcal{M}_{13}$ (see Theorem 1).

Starting with a set of 3 algebras with $\pm$mi properties, Theorem 1 provides commutation relations between their modular groups. One finds that these groups build a three-dimensional Lie group (3 generators, 3 commutation relations). It turns out to be a representation of the Lorentz group in 2+1 dimensions (for details see Ref. 9):

Theorem 2: (Ref. 9): *Let $\mathcal{M}_{12}$, $\mathcal{M}_{13}$, and $\mathcal{M}_{23}$ be von Neumann algebras acting on a Hilbert space $\mathcal{H}$ and let $\Omega\in\mathcal{H}$ be a common cyclic and separating vector. Further assume the following modular intersection properties:*

$$(\mathcal{M}_{12},\mathcal{M}_{13},\Omega)\ \text{has the}-\text{mi-property},$$

$$(\mathcal{M}_{23},\mathcal{M}_{13},\Omega)\ \text{has the}+\text{mi-property},$$

$$(\mathcal{M}_{23},\mathcal{M}_{12}',\Omega)\ \text{has the}-\text{mi-property}.$$

Then the one-parameter groups

$$\Delta_{12}^{ir},\Delta_{13}^{is},\Delta_{23}^{it}\quad for\ r,s,t\in\mathbf{R}$$

generate a representation of the group SO(2,1).

The main problem in proving this Theorem is to show that the representation of the rotation by an angle of 2π equals 1, see Ref. 9. A relation obtained in this investigation and needed in the following, is given by

Lemma 1 (Ref. 9): Let the assumptions of Theorem 2 be fulfilled. Then the following relations hold:

$$(a)\quad Ad\,U_{13,12}(1)J_{13}(\mathcal{M}_{23})=\mathcal{M}_{23},$$

$$(b)\quad Ad\,U_{12,32}(1)J_{12}(\mathcal{M}_{31})=\mathcal{M}_{31}.$$

At this point it is reasonable to ask how translations arise in this context. For this we assume the existence of another modular inclusion. Applying the symmetry on it we get several unitary groups. To achieve commutativity some more assumptions have to be satisfied. Finally, one obtains a representation of the whole Poincaré group in $2+1$ dimensions.

Theorem 3 (Ref. 1): *Let $\mathcal{M}_{12}$, $\mathcal{M}_{13}$ and $\mathcal{M}_{23}$ be von Neumann algebras fulfilling the assumptions of Theorem 2. Further let $\mathcal{N}$ be another von Neumann algebra with the following properties:*

(a) $(\mathcal{N}\subset\mathcal{M}_{12},\Omega)$ *is* $-hsm$ *inclusion,*

(b) $\mathrm{Ad}\, J_{13}(J_{\mathcal{N}}J_{12})=J_{12}J_{\mathcal{N}}$,

(c) $[\mathrm{Ad}\, J_{23}(J_{\mathcal{N}}J_{12}),J_{\mathcal{N}}J_{12}]=0$. *Then one obtains a faithful, unitary representation $\mathcal{U}_{Trans}$ of the translation group $\mathbf{R}^{2,1}$. If*

(d) for all $\alpha\in\mathbf{R}^{2,1}$ there exists a $\beta\in\mathbf{R}^{2,1}$, so that the relation

$$\mathrm{Ad}\, J_{12}(\mathcal{U}_{\mathrm{Trans}}(\alpha))=\mathcal{U}_{\mathrm{Trans}}(\beta)$$

holds, then the modular groups $\Delta_{12}^{ir},\Delta_{13}^{is},\Delta_{23}^{it}$ and $\Delta_{\mathcal{N}}^{iu}$ generate a representation of the Poincaré group in $2+1$ dimensions. This representation fulfills the spectrum condition.

One explicit commutation relation obtained in the proof of this Theorem (see lemma 12 in Ref. 1) is

$$\mathrm{Ad}\, U_{12,13}(1)(U_{\mathcal{N},12}(a))=U_{\mathcal{N},12}(a)\quad \text{for } a\in\mathbf{R}. \tag{1}$$

We will need this result several times later on.

One might think that the assumptions of Theorem 3 are rather artificial. But using the result of Ref. 12 one finds that 2 wedge-algebras with one lightray in common fulfill the requirement for having a modular intersection with respect to the vacuum (for more details, see Ref. 1, and Sec. III). Furthermore, a wedge algebra and its translation in lightray direction provide an example of a half-sided modular inclusion. We will elaborate on this in the next section.

The topic of this article is an extension of Theorem 2 and Theorem 3 to $3+1$ dimensions. In order to do this let us first review some important facts concerning $3+1$-dimensional quantum field theory.

III. MODULAR INTERSECTIONS OF von NEUMANN ALGEBRAS IN 3+1 DIMENSIONAL QUANTUM FIELD THEORY

Our framework will be the description of quantum field theory in terms of nets of local algebras, see Ref. 2. In this algebraic approach the physical system is characterized by algebras of bounded operators acting on a Hilbert space $\mathcal{H}$, indexed by space–time regions,

$$\mathcal{O}\subset\mathbf{R}^{3,1}\mapsto\mathcal{A}(\mathcal{O}).$$

They might be interpreted as bounded functions of the observables localized in that region. This net is assumed to fulfill the following physically motivated assumptions:[2]

(A) $\mathcal{A}(\mathcal{O}_1)\subset\mathcal{A}(\mathcal{O}_2)$ if $\mathcal{O}_1\subset\mathcal{O}_2$ (isotony),

(B) $\mathcal{A}(\mathcal{O}_1)\subset\mathcal{A}(\mathcal{O}_2)'$ if $\mathcal{O}_1\subset\mathcal{O}_2'$, where $\mathcal{A}(\mathcal{O})'$ denotes the commutant of $\mathcal{A}(\mathcal{O})$, $\mathcal{O}'\in\mathbf{R}^{3,1}$ the causal complement of $\mathcal{O}$ (locality),

(C) There exists a unitary representation of the Poincaré group,

$$\mathcal{U}:\mathcal{P}^{\uparrow}\mapsto\mathcal{B}(\mathcal{H})$$

acting covariantly on the net (Poincaré covariance).

(D) There exists a unique vector $\Omega\in\mathcal{H}$, which is invariant under this representation (vacuum).

Such a net describes a $3+1$-dimensional quantum field theory in the algebraic approach.

The famous Reeh–Schlieder[3] property of the vacuum now states that due to locality and vacuum fluctuations any local algebra is cyclic and separating with respect to the vacuum vector.

This enables one to apply the modular theory to each $(\mathcal{A}(\mathcal{O}),\Omega)$. For some special regions in Minkowski space, namely, wedge regions, these abstract mathematical structures have a direct physically interpretation.

A wedge region is determined by two linearly independent lightlike vectors l_1 and l_2 belonging to the forward lightcone. With a convenient notation introduced by Borchers,[12] it is defined by

$$\mathcal{W}[l_1,l_2] := \{\alpha l_1+\beta l_2+L^{\perp} \mid \alpha>0,\beta<0, l\in L^{\perp}\}.$$

$L^{\perp}$ denotes the set of all vectors lying orthogonal to l_1 and l_2 with respect to the Minkowski metric.

Bisognano and Wichmann[5] showed that if the net is generated by bounded functions of Wightman fields, then the modular groups associated with algebras of wedge regions act as Lorentz boosts. More precisely one obtains the one parameter group of boosts $\Lambda_{l_1,l_2}(t)$ leaving the set $\mathcal{W}[l_1,l_2]$ invariant,

$$\Delta^{it}_{\mathcal{A}(\mathcal{W}[l_1,l_2])}=\mathcal{U}(\Lambda_{l_1,l_2}(-2\pi t)).$$

The reader may consult Ref. 13 for an excellent review about recent results obtained in the application of modular theory in quantum field theory.

For the following we will consider such a net and fix four lightlike vectors:

$$l_1=(1,1,0,0),$$

$$l_2=(1,-(1/3),2\sqrt{2}/3,0),$$

$$l_3=(1,-(1/3),-(\sqrt{2}/3),-(\sqrt{6}/3)),$$

$$l_4=(1,-(1/3),-(\sqrt{2}/3),(\sqrt{6}/3)).$$

The spacelike components of these vectors build a tetrahedron (we thank Schmidt for the idea to this choice). Lemmas 2, 3, and 4 do not depend on the special choice of vectors, as long as they are linearly independent and belong to the forward lightcone. But in this very symmetric case the combination of some special Lorentz transformations implementing some permutations of the four vectors is much simpler than for the general case. The subgroup of $S(4)$, the permutation group of 4 elements, we have in mind, is built by elements of the form $(i)(jkl)=(jkl)(i)$ and $(ij)\times(kl)$ for pairwise different $i,j,k,l\in\{1,2,3,4\}$. Its representation by modular objects will be important in the next section.

These lightlike vectors define wedge regions $\mathcal{W}[l_i,l_j]$ for $i\neq j\in\{1,2,3,4\}$. Let the associated algebras be denoted by $\mathcal{A}(\mathcal{W}[l_i,l_j])$. Now, as already mentioned in the last section, modular intersections occur in a natural way. Analogously to Ref. 12, Lemma 6 and Ref. 1, Proposition 7, one shows

Lemma 2: Let $\mathcal{A}(\mathcal{O})$, $\mathcal{O}\subset\mathbf{R}^{3,1}$, be a net fulfilling the assumptions of the Theorem of Bisognano and Wichmann.[1] Then,

$$(\mathcal{A}(\mathcal{W}[l_i,l_j]),\mathcal{A}(\mathcal{W}[l_i,l_k]),\Omega) \textit{has the} -\text{mi property}$$

for pairwise different i,j,k $\in\{1,2,3,4\}$.

To see how $\pm$hsm-inclusions arise in this context we have to look at wedge regions translated by vectors $a\in\mathbf{R}^{3,1}$,

$$\mathcal{W}[l_i,l_j,a] := \{x\in\mathbf{R}^{3,1} \mid (x-a)\in\mathcal{W}[l_i,l_j]\}.$$

Then we have (analogously to Refs. 12 and 1),

Lemma 3: Let the assumptions be the same as in lemma 2. Then for all $\alpha>0$ and $i\neq j\in\{1,2,3,4\}$,

$$(\mathcal{A}(\mathcal{W}[l_i,l_j,\alpha l_i])\subset\mathcal{A}(\mathcal{W}[l_i,l_j]),\Omega) \text{is a } -\text{hsm}-\text{inclusion.}$$

In particular the one-parameter group that belongs to this inclusion (see Theorem 1) is equal to the representation of the translation in l_i-direction.

Furthermore in a given basis of $\mathbf{R}^{3,1}$ one easily verifies

Lemma 4: Let the assumptions be the same as in lemma 2. Then the 6 modular groups $\Delta^{it}_{\mathcal{A}(\mathcal{W}[l_i,l_j])}$ *generate a representation of the group* SO(3,1).

It is not surprising that the modular groups in Lemma 4 and another ''lightlike'' translated group together generate a representation of the whole Poincaré group.

In the next sections we will in a way invert this observation. Starting with a set of 7 algebras lying in a specific modular position we will construct a unitary representation of the Poincaré group in 3+1 dimensions.

IV. REPRESENTATION OF SO(3,1)

First we will focus our attention to the Lorentz group. Motivated by Lemma 2 we want to construct a representation of it by 6 modular groups of von Neumann algebras.

From our experience in algebraic quantum field theory the simplest Ansatz in this context is:

Assumption I: Let $\mathcal{M}_{ij}$, $1\leqslant i<j\leqslant 4$, be von Neumann algebras acting on a Hilbert space $\mathcal{H}$ with a common cyclic and separating vector $\Omega\in\mathcal{H}$. Further assume that the triple $(\mathcal{M}_{ij},\mathcal{M}_{ik},\Omega)$ has the $-$mi property for pairwise different $i,j,k\in\{1,2,3,4\}$.

In analogy to the case of ''Bisognano–Wichmann''-nets, in this abstract situation we also denote the commutants of $\mathcal{M}_{ij}$ by $\mathcal{M}_{ji}:=\mathcal{M}'_{ij}$. (Notice that Lemma 1h) states that $(\mathcal{M}_{ji},\mathcal{M}_{ki},\Omega)=(\mathcal{M}'_{ij},\mathcal{M}'_{ik},\Omega)$ has the $+$mi property.) Assumption I already fixes two subgroups of the group SO(3,1). (The authors thank Schroer for the remark of relation B):

Lemma 5: (A) The one parameter groups $\Delta^{ia}_{12},\Delta^{ib}_{13}$, *and* Δ^{ic}_{23} *for* $a,b,c\in\mathbf{R}$, *generate a representation of* SO(2,1).

(B) $[U_{14,24}(a),U_{14,34}(b)]=0$ *for all a,b in* $\mathbf{R}$.

(C) The one parameter groups Δ^{ia}_{14}, Δ^{ib}_{24} *and* Δ^{ic}_{34} *for* $a,b,c\in\mathbf{R}$, *span a three-dimensional Lie group.*

Proof: Property (A) follows directly from Theorem 2. For (B) notice that Theorem 1 implies

$$\begin{aligned}
&U_{14,24}(-1+e^{2\pi a})U_{14,34}(-1+e^{2\pi b})\\
&\quad=\Delta^{ia}_{14}(\Delta^{-ia}_{24}\Delta^{ib}_{14})\Delta^{-ib}_{34}\\
&\quad=\Delta^{i(b+(1/2\pi)\,(\ln(e^{-2\pi b}(-1+e^{2\pi a})+1)}_{14}\Delta^{-i(1/2\pi)\,\ln(e^{-2\pi b}(-1+e^{2\pi a})+1)}_{24}\Delta^{-ib}_{34}.
\end{aligned}$$

We used (1f) in the first step and then (1b) to pull the Δ_{14}-factor in front. Commuting the factors Δ_{34} and Δ_{14} as well as Δ_{24} and Δ_{34} and also using the abbreviation $c=-(1/2\pi)\ln(e^{-2\pi a}(e^{2\pi b}-1)+1)$ one similarly gets

$$\begin{aligned}
&U_{14,34}(-1+e^{2\pi b})U_{14,24}(-1+e^{2\pi a})\\
&\quad=\Delta^{i(a+(1/2\pi)\,ln(e^{-2\pi a}(-1+e^{2\pi b})+1)}_{14}\Delta^{i(c-a+(1/2\pi)\ln(e^{2\pi a}(-1+e^{-2\pi c})+1))}_{24}\\
&\qquad\times\Delta^{-i(1/2\pi)\ln(e^{2\pi a}(-1+e^{-2\pi c})+1)}_{34}.
\end{aligned}$$

An easy algebraic transformation shows that the exponents of the modular groups in both equations are equal.

Property (C) follows from property (B). □

Notice that the two commuting groups in (B) are isomorphic to the translations belonging to the isotropy group of the lightray l_4, see Sec. III. The Lie group in (C) consists of these translations and the dilatation in the l_4-direction.

Simple combinatorics show that we obtain 12 commutation relations out of Assumption I. In order to fix a group generated by 6 one-parameter groups one needs 15 relations. As it turns out the Jacobi identities will roughly lead to the three missing ones.

Let us first assume that the algebras are chosen symmetrically. For this we define

Definition 2:

$$\Gamma_{(132)(4)} := U_{21,23}(1)J_{12}U_{13,12}(1)J_{13} = U_{21,23}(1)U_{13,12}(1)$$

and those equations obtained from this by permuting the indices. Using Theorem (1i) one can also write $\Gamma_{(132)(4)} := U_{12,32}(1)J_{12}U_{13,12}(1)J_{13}$. We now state

Assumption II:

$$\text{(a) } \mathrm{Ad}\,\Gamma_{(132)(4)}(\mathcal{M}_{14}) = \mathcal{M}_{34},\ \mathrm{Ad}\,\Gamma_{(132)(4)}(\mathcal{M}_{24}) = \mathcal{M}_{14},$$

$$\text{(b) } \mathrm{Ad}\,\Gamma_{(134)(2)}(\mathcal{M}_{12}) = \mathcal{M}_{32},\ \mathrm{Ad}\,\Gamma_{(134)(2)}(\mathcal{M}_{42}) = \mathcal{M}_{12}.$$

This situation is given in Sec. III (due to the symmetric choice of the vectors $l_1,\ldots,l_4$ and the result of Bisognano and Wichmann[5]).

Lemma 6: Products of $\Gamma_{(132)(4)}$ *and* $\Gamma_{(134)(2)}$ *generate a representation of a subgroup of* S(4)*, the permutation group of 4 elements. This subgroup is built by elements of the form (ijk)(l),(ij)(kl) with pairwise different* $i,j,k,l \in \{1,2,3,4.\}$ The representation acts on the algebras by permuting their indices in the denoted way.

Proof: Using Theorem 1 and Lemma 1 it is an easy exercise to show that $\Gamma_{(132)(4)}$ and $\Gamma_{(134)(2)}$ act in the right way on the algebras $\mathcal{M}_{ij}$ for $i,j \in \{1,2,3\}, i \neq j$, since it is the same situation as in the three-dimensional case.

We will sketch the proof for $\Gamma_{(132)(4)}$ and $\mathcal{M}_{13}$,

$$\begin{aligned}\mathrm{Ad}\,\Gamma_{(132)(4)}(\mathcal{M}_{13}) &= \mathrm{Ad}\,U_{21,23}(1)J_{12}U_{13,12}(1)J_{13}(\mathcal{M}_{13})\\ &= \mathrm{Ad}\,U_{21,23}(1)J_{12}(\mathcal{M}_{21})\\ &= \mathrm{Ad}\,U_{21,23}(1)(\mathcal{M}_{12}) = \mathcal{M}_{32}.\end{aligned}$$

Therefore this is also true for their modular objects. For algebras with indices i or $j = 4$ we need the following observations:

$$\begin{aligned}\Gamma_{(132)(4)} &= \mathrm{Ad}\,\Gamma_{(132)(4)}(\Gamma_{(132)(4)})\\ &= \mathrm{Ad}\,\Gamma_{(132)(4)}(U_{21,23}(1)J_{12}U_{13,12}(1)J_{13})\\ &= U_{13,12}(1)J_{31}U_{32,31}(1)J_{32}. \qquad (2)\end{aligned}$$

Analogously one gets

$$\Gamma_{(132)(4)} = U_{32,31}(1)J_{23}U_{21,23}(1)J_{21}.$$

Combined with (2) and Theorem (1c) this leads to the relation

$$\begin{aligned}\Gamma^3_{(132)(4)} &= (U_{21,23}(1)J_{12}U_{13,12}(1)J_{13})(U_{13,12}(1)J_{31}U_{32,31}(1)J_{32})U_{32,31}(1)J_{23}U_{21,23}(1)J_{21}\\ &= U_{21,23}(1)J_{12}(U_{13,12}(1)U_{13,12}(-1))(U_{32,31}(1)U_{32,31}(-1))U_{21,23}(1)J_{21}\\ &= U_{21,23}(1)(J_{12}U_{21,23}(1)J_{12}) = 1.\end{aligned}$$

Using Assumption (IIa) this implies

$$\mathrm{Ad}\,\Gamma_{(132)(4)}(\mathcal{M}_{34}) = \mathrm{Ad}\,\Gamma^2_{(132)(4)}(\mathcal{M}_{14}) = \mathrm{Ad}\,\Gamma^{-1}_{(132)(4)}(\mathcal{M}_{14}) = \mathcal{M}_{24}.$$

Analogous relations hold for $\Gamma_{(134)(2)}$. Taking products of $\Gamma_{(134)(2)}$ and $\Gamma_{(132)(4)}$ one obtains all permutations of the form $(ijk)(l)$ and $(ij)(kl)$ for pairwise different $i,j,k,l \in \{1,2,3,4\}$. □

Assuming that the modular groups generate a 6 dimensional Lie group we use these symmetries and the Jacobi identities to obtain the missing commutation relations. At the end of this section we will give a formulation of this additional Assumption using only modular data (see Assumption III and Propositon 2).

Proposition 1: Let Assumptions I and II be fulfilled. Further assume that the modular groups Δ_{kl}^{ia} *for* $k,l \in \{1,2,3,4\}$ *generate a six-dimensional Lie group. Then this Lie group is a representation of the group* SO(3,1).

Proof: Let $\lambda_{kl} := (i/2\pi)(d/dt)\Delta_{kl}^{it}|_{t=0}$ denote the generators. Theorem (1b) and $\Delta_{kl}^{it} = \Delta_{lk}^{-it}$ give the relations

$$[\lambda_{ij},\lambda_{ik}] = \lambda_{ij} - \lambda_{ik}, \tag{3}$$

$$\lambda_{ij} = -\lambda_{ji}. \tag{4}$$

It remains to prove the right commutation relations $[\lambda_{ij},\lambda_{kl}]$ for pairwise different indices. Starting with linear combinations summing to zero and taking Lie-products according to (3) it is a lengthy but easy exercise to show the linear independence of 5 generators assuming that the algebras $\mathcal{M}_{ij}$ are not identic. We further need the following observation:

Lemma 7: The real linear subspace formed by the elements λ_{ij} *commuting with* λ_{12} *is at least two-dimensional.*

Proof: Rewriting the Jacobi identity one obtains

$$[\lambda_{12},[\lambda_{12}-\lambda_{14},\lambda_{12}-\lambda_{32}]] = 0.$$

Assume

$$[\lambda_{12}-\lambda_{14},\lambda_{12}-\lambda_{32}] = \alpha\lambda_{12}$$

for $\alpha \in \mathbf{R}$. By (3) this is equivalent to

$$[\lambda_{14},\lambda_{32}] = (\alpha-2)\lambda_{12} + \lambda_{32} + \lambda_{14}. \tag{5}$$

Applying on both sides the ''permutation'' $\Gamma_{(14)(32)}$ gives

$$[\lambda_{41},\lambda_{23}] = [\lambda_{14},\lambda_{32}] = (\alpha-2)\lambda_{43} + \lambda_{23} + \lambda_{41}. \tag{6}$$

But (5) and (6) imply

$$(\alpha-2)(\lambda_{43}-\lambda_{12}) + 2\lambda_{23} + 2\lambda_{41} = 0,$$

leading to a contradiction to the linear independence of 4 generators. □

We now take such a commuting element

$$\lambda = \left(\sum_{j=2}^{4} \alpha_{1j}\lambda_{1j}\right) + \left(\sum_{j=3}^{4} \alpha_{j2}\lambda_{j2}\right) + \alpha_{34}\lambda_{34}$$

with real α_{ij}. According to the linear independence and the commutation relation (3) it is easy to see that $\alpha_{34} \neq 0$ holds. The relation $[\lambda_{12},\lambda] = 0$ implies

$$-\alpha_{34}[\lambda_{12},\lambda_{34}] = \sum_{j=3}^{4} (\alpha_{1j}-\alpha_{j2})\lambda_{12} - \alpha_{13}\lambda_{13} - \alpha_{14}\lambda_{14} + \alpha_{32}\lambda_{32} + \alpha_{42}\lambda_{42}. \tag{7}$$

Applying $\mathrm{Ad}\,\Gamma_{(12)(34)}$ to this equation the left-hand side is invariant and the right-hand side gives $\Sigma_{j=3}^{4}(\alpha_{1j}-\alpha_{j2})\lambda_{21}-\alpha_{13}\lambda_{24}-\alpha_{14}\lambda_{23}+\alpha_{32}\lambda_{41}+\alpha_{42}\lambda_{31}$. A subtraction of these two equations gives

$$0=2(\alpha_{13}-\alpha_{32}+\alpha_{14}-\alpha_{42})\lambda_{12}+(\alpha_{42}-\alpha_{13})\lambda_{13}+(\alpha_{32}-\alpha_{14})\lambda_{14}+(\alpha_{14}-\alpha_{32})\lambda_{23}$$
$$+(\alpha_{13}-\alpha_{42})\lambda_{24}$$

and the linear independence of the generators implies $\alpha_{42}=\alpha_{13}$ and $\alpha_{14}=\alpha_{32}$. Hence (7) may be rewritten as

$$[\lambda_{12},\lambda_{34}]=\alpha(\lambda_{13}-\lambda_{42})+\beta(\lambda_{14}-\lambda_{32}) \tag{8}$$

with $\alpha:=\alpha_{13}/\alpha_{34}$ and $\beta:=\alpha_{14}/\alpha_{34}$. Using a second time the Jacobi identity we obtain

$$[[\lambda_{12},\lambda_{34}],\lambda_{14}]=\lambda_{12}-\lambda_{34}. \tag{9}$$

Next we insert relation (8) into (9) and ''permute'' the result by $\Gamma_{(1)(234)}$. This leads to

$$\beta[\lambda_{12},\lambda_{34}]=-(\lambda_{13}-\lambda_{42})+\alpha(\lambda_{14}-\lambda_{32}). \tag{10}$$

The comparison of the coefficients in (8) and (10) gives the missing relation

$$[\lambda_{12},\lambda_{34}]=\lambda_{13}-\lambda_{42}-\lambda_{14}+\lambda_{32}. \tag{11}$$

The rest follows from symmetry.

Now all 15 commutations relations are fixed. In order to make sure that the modular groups $\Delta_{14}^{it_{14}},\ldots,\Delta_{34}^{it_{34}}$ generate a representation of SO(3,1) one has to investigate the effect of the rotation by an angle 2π. But this is the identity, as shown in the proof of Theorem 2 and Lemma 1 (for details, see Ref. 9). □

Let us next propose an assumption leading to the premise of Proposition 1:

Assumption III: There exists an $\epsilon'>0$ and two strict monotone, continuous mappings $\delta:]0,\epsilon'[\mapsto R^{+}$ and $\delta':]0,\epsilon'[\mapsto R^{+}$ so that for all $0<\epsilon<\epsilon'$ the relation

$$\mathrm{Ad}\,J_{12}(\mathcal{P}_{\epsilon})\subset\mathcal{P}_{\delta(\epsilon)}\mathcal{S}_{\delta'(\epsilon)}$$

holds, where

$$\mathcal{P}_{\epsilon}:=\{\Delta_{14}^{ir}\Delta_{24}^{is}\Delta_{34}^{it}\,|\,|(r,s,t)|:=\sqrt{r^2+s^2+t^2}<\epsilon\},$$

and

$$\mathcal{S}_{\epsilon}:=\{\Delta_{12}^{ir}\Delta_{13}^{is}\Delta_{23}^{it}\,|\,|(r,s,t)|<\epsilon\}$$

denote neighborhoods of the Lie groups introduced in Lemma 5.

Proposition 2: Assumptions I, II, and III imply that the 6 modular groups $\Delta_{12}^{it_{12}},\ldots,\Delta_{34}^{it_{34}}$ *for* $t_{12},\ldots,t_{34}\in\mathbf{R}$ *generate a six-dimensional Lie group.*

Proof: We show that products of the modular groups $\Delta_{12}^{it_{12}},\ldots,\Delta_{34}^{it_{34}}$ can be commuted into a determined order in a neighborhood of the identity. For this notice that Assumption III and the symmetry imply that $\mathrm{Ad}\,J_{ij}(\mathcal{P}_{\epsilon})\subset\mathcal{P}_{\delta(\epsilon)}\mathcal{S}_{\delta(\epsilon)}$ holds for $i,j\in\{1,2,3\}$. (For convenience we choose a sloppy notation in this proof using the same δ for all functions of type δ, δ'.) Now Theorem (1g) states

$$\mathrm{Ad}\,U_{13,12}(2)(\mathcal{P}_{\epsilon})=\mathrm{Ad}\,J_{12}J_{13}(\mathcal{P}_{\epsilon})\subset\mathcal{P}_{\delta(\epsilon)}\mathcal{S}_{\delta(\epsilon)}. \tag{12}$$

With help of Theorem 1 one further shows for all $r\in\mathbf{R}$,

$$U_{13,12}(2)\Delta_{14}^{ir}=\Delta_{14}^{ir}U_{13,12}(2e^{2\pi r}).$$

Together with relation (12) this implies

$$\mathrm{Ad}\, U_{13,12}(2-2e^{2\pi r})(\mathcal{P}_\epsilon)\subset\mathcal{P}_{\delta(\epsilon)}\mathcal{S}_{\delta(\epsilon)}$$

for r in a neighborhood of zero. Due to the permutation symmetry $\Gamma_{(123)(4)}$ this also holds for $U_{12,32}, U_{13,23}$. For $U_{14,24}$, $U_{14,34}$, and $U_{24,34}$ analogous relations follow directly from Lemma 5, because they are elements of the Lie group $\mathcal{P}$. Now Theorem (1f) finishes the proof. □

Combining Proposition 1 and 2, we finally arrive at

Theorem 4: *Let* $\mathcal{M}_{ij}$, $1\leqslant i<j\leqslant 4$ *be 6 von Neumann algebras fulfilling Assumptions I, II, and III. Then their modular groups generate a representation of* SO(3,1).

A model fulfilling the assumptions of Theorem 4 was given in Sec. III. In that case the 6 algebras are realized by algebras belonging to wedge-regions in 3+1-dimensional Minkowski space.

V. REPRESENTATION OF THE TRANSLATIONS

In this section we extend the representation given by Theorem 4 to a representation of the whole Poincaré group in 3+1 dimensions. Motivated by Lemma 3 we make the following assumption (in addition to the assumptions I to III):

Assumption (A): Let $\mathcal{N}$ be another von Neumann algebra, so that the triple $(\mathcal{N}\subset\mathcal{M}_{12},\Omega)$ is a $-$hsm inclusion.

As a candidate for the translation in direction of l_1 we take

$$\mathcal{U}_{l_1}(a):=U_{12,\mathcal{N}}(a).$$

Choosing a basis in $\mathbf{R}^{3,1}$, see Sec. III, one easily verifies

$$\Lambda_{l_1,l_3}(-\ln 2)\Lambda_{l_2,l_3}(\ln 2)l_1=l_2.$$

Therefore a candidate to define the translations in l_2-direction is given by

$$\mathcal{U}_{l_2}(a):=\mathrm{Ad}\,\mathcal{U}_{Lor}(\Lambda_{l_1,l_3}(-\ln 2)\Lambda_{l_2,l_3}(\ln 2))(\mathcal{U}_{l_1}(a))=\mathrm{Ad}\, U_{13,23}(1)(\mathcal{U}_{l_1}(a)),$$

and analogously,

$$\mathcal{U}_{l_3}(a):=\mathrm{Ad}\, U_{12,32}(1)(\mathcal{U}_{l_1}(a)),$$

$$\mathcal{U}_{l_4}(a)=\mathrm{Ad}\, U_{12,42}(1)(\mathcal{U}_{l_1}(a)),$$

for all $a\in\mathbf{R}$. But there is an alternative way to these choices. We also have

$$\Lambda_{l_1,l_4}(-\ln 2)\Lambda_{l_2,l_4}(\ln 2)l_1=l_2. \tag{13}$$

Hence it is also reasonable to set

$$\tilde{\mathcal{U}}_{l_2}(a)=\mathrm{Ad}\, U_{14,24}(1)(\mathcal{U}_{l_1}(a))$$

and similarly for the others. The following assumption implies the equivalence of both definitions. Furthermore it makes sure that they are compatible with respect to the permutations defined in the last section.

Assumption (B): $\mathrm{Ad}\,\Gamma_{(1)(234)}(J_{\mathcal{N}}J_{12})=J_{\mathcal{N}}J_{12}$.

This is motivated by the observations made in Sec. III. Because of Theorem (1g) $J_{\mathcal{N}}J_{12}$ can be interpreted as a discrete translation in l_1-direction. So it should be left invariant by $\Gamma_{(1)(234)}$.

Notice that Assumption (b) of Theorem 3 can now be derived from Assumptions (A) and (B):

$$\mathrm{Ad}\, J_{13}(J_{12}J_{\mathcal{N}}) = \mathrm{Ad}\, \Gamma_{(1)(234)} J_{12}(J_{12}J_{\mathcal{N}}) = J_{\mathcal{N}}J_{12}\,. \tag{14}$$

Analogously one obtains

$$\mathrm{Ad}\, J_{14}(J_{12}J_{\mathcal{N}}) = J_{\mathcal{N}}J_{12}\,. \tag{15}$$

Next we prove the equivalence of both definitions:

Lemma 8: Assume (A) and (B). Then,

$$\mathcal{U}_{l_i}(a) = \tilde{\mathcal{U}}_{l_i}(a)$$

for all $a \in \mathbf{R}$ *and* $i \in \{2,3,4\}$.

Proof: Using (1) and Assumption B, then

$$[U_{12,14}(1), U_{12,\mathcal{N}}(2)] = [U_{12,14}(1), J_{\mathcal{N}}J_{12}] = 0 \tag{16}$$

holds. Combining this with Assumption B one gets

$$[\Gamma_{(1)(234)} U_{12,14}(1), J_{\mathcal{N}}J_{12}] = 0. \tag{17}$$

Using Theorem (1c) it is easy to see, that

$$[\Gamma_{(1)(234)} U_{12,14}(1), J_{12}] = 0 \tag{18}$$

is fulfilled. Together with (17) we have

$$[\Gamma_{(1)(234)} U_{12,14}(1), J_{\mathcal{N}}] = 0. \tag{19}$$

This implies that the modular conjugation to $(\mathrm{Ad}\, \Gamma_{(1)(234)} U_{12,14}(1)(\mathcal{N}), \Omega)$ is the modular conjugation $J_{\mathcal{N}}$ of $\mathcal{N}$. Furthermore,

$$\mathrm{Ad}\, \Gamma_{(1)(234)} U_{12,14}(1)(\mathcal{N}) \subset \mathcal{M}_{12}$$

holds, which shows that Ω is separating for

$$(\mathcal{N} \cup \mathrm{Ad}\, \Gamma_{(1)(234)} U_{12,14}(1)(\mathcal{N})) \subset \mathcal{M}_{12}$$

again with the same conjugation. So modular theory tells us

$$\mathcal{N} = \mathrm{Ad}\, \Gamma_{(1)(234)} U_{12,14}(1)(\mathcal{N}).$$

In particular we have

$$[\Delta_{\mathcal{N}}^{it}, \Gamma_{(1)(234)} U_{12,14}(1)] = 0 \tag{20}$$

for all $t \in \mathbf{R}$. Completely analogous to (1) the relation

$$[U_{12,14}(a), \mathcal{U}_{l_1}(b)] = [U_{12,14}(a), U_{12,\mathcal{N}}(b)] \quad \text{for all} \quad a,b \in \mathbf{R} \tag{21}$$

holds (for details see Lemma 12 in Ref. 1). Now using (20) and Theorem (1f) this gives

$$\mathrm{Ad}\, \Gamma_{(1)(234)}(\mathcal{U}_{l_1}(a)) = \mathcal{U}_{l_1}(a). \tag{22}$$

With $\Gamma_{(1)(234)} = \Gamma_{(123)(4)}\Gamma_{(134)(2)}$ it follows that

$$\mathrm{Ad}\, \Gamma_{(123)(4)}^{-1}(\mathcal{U}_{l_1}(a)) = \mathrm{Ad}\, \Gamma_{(134)(2)}(\mathcal{U}_{l_1}(a)) \tag{23}$$

holds. Definition 2 and Theorem 1 imply

$$\Gamma_{(134)(2)} = U_{14,34}(1)U_{13,14}(1), \tag{24}$$

$$\Gamma_{(132)(4)} = \Gamma^{-1}_{(123)(4)} = U_{12,32}(1)U_{13,12}(1). \tag{25}$$

Using relations (1) and (22) we obtain

$$\mathrm{Ad}\, U_{13,14}(1)(\mathcal{U}_{l_1}(a)) = \mathrm{Ad}\, \Gamma_{(1)(234)} U_{12,13}(1)(\mathcal{U}_{l_1}(a)) = \mathcal{U}_{l_1}(a). \tag{26}$$

Inserting (1) and (26) into (23), one finally sees

$$\tilde{\mathcal{U}}_{l_3}(a) = \mathrm{Ad}\, U_{14,34}(1)(\mathcal{U}_{l_1}(a)) = \mathrm{Ad}\, U_{12,32}(1)(\mathcal{U}_{l_1}(a)) = \mathcal{U}_{l_3}(a).$$

The remaining relations follow by symmetry. □

So finally we get the following ''candidates'' for the representators of translations in $\mathbf{R}^{3,1}$:

Definition 3:

$$\text{(a)}\ \mathcal{U}_{l_1}(a) := U_{12,\mathcal{N}}(a),$$

$$\text{(b)}\ \mathcal{U}_{l_2}(a) := \mathrm{Ad}\, U_{13,23}(1)(\mathcal{U}_{l_1}(a)) = \mathrm{Ad}\, U_{14,24}(1)(\mathcal{U}_{l_1}(a)),$$

$$\text{(c)}\ \mathcal{U}_{l_3}(a) := \mathrm{Ad}\, U_{12,32}(1)(\mathcal{U}_{l_1}(a)) = \mathrm{Ad}\, U_{14,34}(1)(\mathcal{U}_{l_1}(a)),$$

$$\text{(d)}\ \mathcal{U}_{l_4}(a) := \mathrm{Ad}\, U_{12,42}(1)(\mathcal{U}_{l_1}(a)) = \mathrm{Ad}\, U_{13,43}(1)(\mathcal{U}_{l_1}(a)),$$

for all $a \in \mathbf{R}$.

Using relations (1), (22), Definition 2 and Theorem 1 it is a straightforward calculation to verify that this definition respects the symmetries introduced in the last section. To make sure that these unitary groups commute, we state analogously to Theorem (3c):

Assumption (C): $[\mathrm{Ad}\, J_{23}(J_{\mathcal{N}} J_{12}), J_{\mathcal{N}} J_{12}] = 0$.

This is again motivated by the discussion in Sec. III. In the case of Bisognano–Wichmann-fields J_{23} acts, up to a spatial rotation, like CTP. So it maps $J_{\mathcal{N}} J_{12}$ upon another translation.

From relation (14) and Assumption (C) it follows that the groups $\mathcal{U}_{l_i}$ commute and that they fulfill the spectrum condition. For details the reader may consult the proof of Proposition 11 in Ref. 1. Hence,

Definition 4: $\mathcal{U}_{\mathrm{Trans}} : \mathbf{R}^{3,1} \to \mathcal{U}(H)$ with

$$\alpha = \left(\sum_{i=1}^{4} \alpha_i l_i \right) \to \mathcal{U}_{\mathrm{Trans}}(\alpha) := \mathcal{U}_{l_1}(\alpha_1)\mathcal{U}_{l_2}(\alpha_2)\mathcal{U}_{l_3}(\alpha_3)\mathcal{U}_{l_4}(\alpha_4)$$

defines a representation of $\mathbf{R}^{3,1}$. It remains to show that these translations have the right commutation relations with the representation $\mathcal{U}_{\mathrm{Lor}}$ of the Lorentz group. As in Theorem (3d) we need

Assumption (D): For all $\alpha \in \mathbf{R}^{3,1}$, there exists a $\beta \in \mathbf{R}^{3,1}$, so that

$$\mathrm{Ad}\, J_{12}(\mathcal{U}_{\mathrm{Trans}}(\alpha)) = \mathcal{U}_{\mathrm{Trans}}(\beta).$$

This is very similar to Assumption III. It makes sure that the whole representation $\mathcal{U}_{\mathrm{Lor}}$ maps translations upon translations. To see this, notice that the relation

$$\mathrm{Ad}\, \mathcal{U}_{\mathrm{Lor}}(\Lambda_{l_i, l_j}(2\pi t))(\mathcal{U}_{l_i}(a)) = \mathcal{U}_{l_i}(e^{2\pi t} a) \tag{27}$$

holds. Using Theorem 1 and Definition 2 one finds that $\mathcal{U}_{\mathrm{Lor}}(\Lambda_{l_i, l_j}(z \ln 2))$ maps translations upon translations for all $z \in \mathbf{Z}$. But these elements form a dense subset of SO(3,1) and so the claim follows from continuity.

So together $\mathcal{U}_{\mathrm{Lor}}$ and $\mathcal{U}_{\mathrm{Trans}}$ form a Lie group. The next Proposition states, that they have the correct commutation relations with each other.

Proposition 3: Assume (A)–(D). Then $\mathcal{U}_{\mathrm{Lor}}$ and $\mathcal{U}_{\mathrm{Trans}}$ generate a representation of the Poincaré group in 3+1 dimensions satisfying the spectrum condition.

Proof: Denote by $t_i := -(d/da)\mathcal{U}_{l_i}(a)_{|a=0}$ the generators of the translations. Relation (27) implies

$$[\lambda_{ij}, t_i] = -t_i . \tag{28}$$

With help of the Jacobi identities, one finds

$$[\lambda_{12}, [t_1, \lambda_{32}]] = -t_1 , \tag{29}$$

$$[\lambda_{13}, [t_1, \lambda_{32}]] = t_1 . \tag{30}$$

As already mentioned above $\mathcal{U}_{\mathrm{Lor}}$ maps translations upon translations, so

$$[t_1, \lambda_{32}] = \sum_{i=1}^{4} \alpha_i t_i \quad \text{with} \quad \alpha_i \in \mathbf{R} \tag{31}$$

holds. Inserting relation (31) into (29) one gets

$$-\alpha_1 t_1 + \alpha_2 t_2 + \alpha_3 [\lambda_{12}, t_3] + \alpha_4 [\lambda_{12}, t_4] = -t_1 .$$

Analogously the substitution of (31) into (30) gives

$$-\alpha_1 t_1 + \alpha_2 [\lambda_{13}, t_2] + \alpha_3 t_3 + \alpha_4 [\lambda_{13}, t_4] = t_1 .$$

Using the symmetries a summation of these two equations leads to

$$(\alpha_2 - \alpha_3)[t_3, \lambda_{12}] = (1 + \alpha_1 - \alpha_2) t_2 + (\alpha_1 - \alpha_3 - 1) t_1 . \tag{32}$$

$\alpha_2 - \alpha_3 \neq 0$ holds because of the linear independence of t_1 and t_2 (which is easy to see by commutation of $\alpha t_1 + \beta t_2 = 0$ with λ_{12}). So we obtain

$$[\lambda_{12}, t_3] = -\frac{(\alpha_1 - \alpha_3 - 1)}{(\alpha_2 - \alpha_3)} t_1 - \frac{(1 + \alpha_1 - \alpha_2)}{(\alpha_2 - \alpha_3)} t_2 =: \xi_1 t_1 + \xi_2 t_2 . \tag{33}$$

$t_1, \ldots, t_4$ are linearly independent. This can be shown analogously to the linear independence of the boost-generators and it is an easy but lengthy computation of the same type. For details one may look at Ref. 14.

Applying $\mathrm{Ad}\,\Gamma_{(123)(4)}$ to (33) the comparison with (31) gives two sets of solutions for α_2 and α_3,

$$\{\alpha_2 = -1; \alpha_3 = 1\} \quad \text{and} \quad \{\alpha_2 = \alpha_3 + 1\}.$$

Using the Jacobi identities another time the second case again leads to contradiction. See Ref. 14 for more details. Therefore we obtain the remaining relation

$$[\lambda_{12}, t_3] = t_2 - t_1$$

and again the rest follows from symmetry. □

Combining Theorem 4 and Proposition 3 we finally arrive at

Theorem 5: *Let $\mathcal{M}_{ij}, i<j \in \{1,2,3,4\}$ be von Neumann algebras fulfilling Assumptions I, II, III and A to D. Then their modular groups generate a representation of the Poincaré group in 3+1 dimensions, which fulfills the spectrum condition.*

We can use Theorem 5 in order to construct a $3+1$-dimensional quantum field theory starting from a set of seven algebras $\mathcal{M}_{ij}$ for $i,j<\{1,2,3,4\}$ and $\mathcal{N}$ fulfilling Assumptions I, II, III and A to D. For this one further needs the assumption that Ω is also cyclic for the local algebras to be constructed. We start by interpreting $\mathcal{M}_{ij}$ as the local algebras associated with the wedge regions $\mathcal{W}[l_i,l_j]$. But this is not unique due to the invariance of the wedge regions under special Poincaré group elements. Therefore we use the minimal definition by taking the intersection of all possible choices. Analogously we define local algebras associated to double cone. As already mentioned above Ω is assumed to be cyclic for these algebras and therefore modular theory implies

$$\mathcal{A}(\mathcal{W}[l_i,l_j])=\mathcal{M}_{ij}.$$

For details one may look up,[5] where the construction sketched here is carried out in detail.

VI. OPEN QUESTIONS

We conclude this article by mentioning some problems that are left open.

Looking at the requirements we assumed a symmetric situation, see Assumption II. But it seems plausible that the assumption of a special symmetric situation is not fundamental. Such a situation may be achieved by applying suitable unitary transformations on more general sets of algebras. So we expect that this assumption might be omitted.

Furthermore Assumption III, used to be able to apply the Jacobi identity, calls for nicer criteria. In the given form it is hard to verify. Therefore, it is desirable to have a formulation which is manageable. The presented one was only made for technical purposes and should be formulated in a less technical way.

(Received 16 May 2000; accepted for publication 15 September 2000)

The capacity of a quantum channel for transmission of classical information depends in principle on whether product states or entangled states are used at the input, and whether product or entangled measurements are used at the output. We show that when *product measurements* are used, the capacity of the channel is achieved with *product input states*, so that entangled inputs do not increase capacity. We show that this result continues to hold if sequential measurements are allowed, whereby the choice of successive measurements may depend on the results of previous measurements. We also present a new simplified expression which gives an upper bound for the Shannon capacity of a channel, and which bears a striking resemblance to the well-known Holevo bound. © *2001 American Institute of Physics.* [DOI: 10.1063/1.1327598]

I. INTRODUCTION

A. Overview

Bennett and Shor[1] note that there are, in principle, four basic types of channel capacities for ''classical'' communication using quantum signals, i.e., communications in which signals are sent using an ''alphabet'' of pure states of quantum systems and decoded using measurements on the (possibly mixed state) signals which arrive. The mixed states are the result of noise which is represented by a *stochastic* or completely positive, trace-preserving map Φ. The four possible capacities correspond to using product or entangled states at the input, and using product or entangled measurements at the output. These are denoted as follows: C_{PP}, product signals and product measurements; C_{PE}, product signals and entangled measurements; C_{EP}, entangled signals and product measurements; C_{EE}, entangled signals and entangled measurements. In more precise language ''using product'' means restricting to products and ''using entangled'' means using arbitrary (product or entangled) states or measurements. Hence, it is evident that $C_{\mathrm{PP}} \leqslant \{C_{\mathrm{EP}}, C_{\mathrm{PE}}\} \leqslant C_{\mathrm{EE}}$. The main purpose of this note is to show that $C_{\mathrm{PP}} = C_{\mathrm{EP}}$, i.e., that if one is restricted to using product measurements, then using entangled inputs does not increase the capacity. Thus $C_{\mathrm{PP}} = C_{\mathrm{EP}} \leqslant C_{\mathrm{PE}} \leqslant C_{\mathrm{EE}}$. It is known[2–4] that one can have strict inequality in $C_{\mathrm{PP}} < C_{\mathrm{PE}}$ for certain non-unital channels. The question of whether or not one can have strict inequality in $C_{\mathrm{PE}} \leqslant C_{\mathrm{EE}}$ is open, although numerical evidence[5,6] suggests equality.

B. Notation and definitions

To give precise definitions, we use relatively standard notation[7,8] in which $\mathcal{M} = \{E_b\}$ denotes a ''positive operator valued measurement'' (POVM) i.e., $E_b \geqslant 0$ and $\Sigma_b E_b = I$. Let ρ_j denote a set (or alphabet) of pure state density matrices, π_j a discrete probability vector, and $\rho = \Sigma_j \pi_j \rho_j$. We

[a)]Dedicated to Robert Schrader and Ruedi Seiler on the occasion of their 60th birthdays.

[c)]Electronic mail: bruskai@cs.uml.edu

let $\mathcal{E}=\{\pi_j,\rho_j\}$ denote this ensemble of input states. Both E_b and ρ_j are operators on a Hilbert space $\mathcal{H}$, so that the stochastic map Φ (representing the noise in the channel) acts on $B(\mathcal{H})$, the algebra of bounded operators on $\mathcal{H}$. We will write $\tilde{\mathcal{E}}=\{\pi_j,\Phi(\rho_j)\}$ for the ensemble of output states emerging from the channel.

We write the dual of Φ (or adjoint with respect to the Hilbert–Schmidt inner product) as $\widehat{\Phi}$ so that $\mathrm{Tr}[\Phi(\rho)\,E]=\mathrm{Tr}[\rho\,\widehat{\Phi}(E)]$. The adjoint of a stochastic map takes a POVM $\mathcal{M}=\{E_b\}$ to another POVM $\hat{\mathcal{M}}=\{\hat{E}_b\}$ since the trace-preserving condition on Φ is equivalent to $\widehat{\Phi}(I)=I$.

The information content of a noiseless quantum channel with a fixed input ensemble and a fixed POVM can be described using the standard Shannon formula of classical information theory.

Definition 1: For a fixed ensemble $\mathcal{E}=\{\pi_j,\rho_j\}$ and a POVM $\mathcal{M}=\{E_b\}$ on a Hilbert space $\mathcal{H}$, the quantum mutual information is given by

$$I^q(\mathcal{E};\mathcal{M})=S(\mathrm{Tr}[\rho E_b])-\sum_j \pi_j S(\mathrm{Tr}[\rho_j E_b]), \tag{1}$$

where $S(\mathrm{Tr}[\rho E_b])$ denotes the Shannon entropy $-\Sigma_b p_b\log p_b$ of the probability vector with elements $p_b=\mathrm{Tr}[\rho E_b]$ [and similarly for $S(\mathrm{Tr}[\rho_j E_b])$].

The information content of a noisy channel defined by the stochastic map Φ is obtained from (1) by replacing $\mathcal{E}$ by the output ensemble $\tilde{\mathcal{E}}=\{\pi_j,\Phi(\rho_j)\}$. Alternatively, since $\mathrm{Tr}[\Phi(\rho_j)\,E]=\mathrm{Tr}[\rho_j\,\widehat{\Phi}(E)]$, we could instead choose to regard the ''noise'' as acting on the POVM, and obtain the capacity from (1) by replacing $\mathcal{M}$ by $\hat{\mathcal{M}}$. Although this viewpoint is atypical, it can be useful, as we will see in Sec. IV.

Definition 2: For a stochastic map Φ, an input ensemble $\mathcal{E}=\{\pi_j,\rho_j\}$ and a POVM $\mathcal{M}=\{E_b\}$, the quantum information content is given by

$$I^q_\Phi(\mathcal{E};\mathcal{M})=I^q(\tilde{\mathcal{E}};\mathcal{M})=I^q(\mathcal{E};\hat{\mathcal{M}})=S(\mathrm{Tr}[\Phi(\rho)E_b])-\sum_j \pi_j S(\mathrm{Tr}[\Phi(\rho_j)E_b]). \tag{2}$$

We consider memoryless channels in which multiple uses of the channel are described by the n-fold tensor product $\Phi\otimes\Phi\cdots\otimes\Phi$ acting on the tensor product Hilbert space $\mathcal{H}\otimes\mathcal{H}\cdots\otimes\mathcal{H}$ which we denote by $\Phi^{\otimes n}$ and $\mathcal{H}^{\otimes n}$, respectively. This allows us to define the ''ultimate'' information capacity of the channel as the asymptotic rate achievable when entangled inputs and measurements are used.

Definition 3: The entangled signals/entangled measurements capacity of a quantum channel is defined as

$$C_{\mathrm{EE}}(\Phi)=\lim_{n\to\infty}\frac{1}{n}\sup_{\mathcal{E},\mathcal{M}} I^q_{\Phi^{\otimes n}}(\mathcal{E};\mathcal{M}), \tag{3}$$

where the supremum is taken over all possible (product or entangled) signals and measurements on $\mathcal{H}^{\otimes n}$.

To define capacity restricted to product measurements, we write $\mathcal{M}^{\otimes n}$ for a product POVM of the form $\{E_{b_1}\otimes E_{b_2}\cdots\otimes E_{b_n}\}$.

Definition 4: The entangled signals/product measurements capacity of a quantum channel is defined as

$$C_{\mathrm{EP}}(\Phi)=\lim_{n\to\infty}\frac{1}{n}\sup_{\mathcal{E},\mathcal{M}^{\otimes n}} I^q_{\Phi^{\otimes n}}(\mathcal{E};\mathcal{M}^{\otimes n}). \tag{4}$$

Note that the existence of the limits follows from superadditivity of the classical capacity.

The capacities C_{PP} and C_{PE} can be similarly defined. We write $\mathcal{E}^{\otimes n}$ to denote an ensemble of the form $\{\pi_{j_1,\ldots,j_n},\rho_{j_1}\otimes\cdots\otimes\rho_{j_n}\}$, where $\{\rho_j\}$ is a fixed collection of states, and $\{\pi_{j_1,\ldots,j_n}\}$ is some joint probability distribution.

Definition 5: The product signals/entangled measurements capacity of a quantum channel is defined as

$$C_{\mathrm{PE}}(\Phi)=\lim_{n\to\infty}\frac{1}{n}\sup_{\mathcal{E}^{\otimes n},\mathcal{M}} I^q_{\Phi^{\otimes n}}(\mathcal{E}^{\otimes n};\mathcal{M}). \tag{5}$$

Definition 6: The product signals/product measurements capacity of a quantum channel is defined as

$$C_{\mathrm{PP}}(\Phi)=\lim_{n\to\infty}\frac{1}{n}\sup_{\mathcal{E}^{\otimes n},\mathcal{M}^{\otimes n}} I^q_{\Phi^{\otimes n}}(\mathcal{E}^{\otimes n};\mathcal{M}^{\otimes n}). \tag{6}$$

The additivity of classical information capacity immediately implies the following result.

Theorem 7: *The product signals/product measurements capacity of a quantum channel is given by*

$$C_{\mathrm{PP}}(\Phi)=C_{\mathrm{Shan}}(\Phi)=\sup_{\mathcal{E},\mathcal{M}} I^q_{\Phi}(\mathcal{E};\mathcal{M}), \tag{7}$$

which we call the Shannon capacity.

A far deeper result is that $C_{\mathrm{PE}}(\Phi)$ can be re-expressed in terms of the well-known Holevo bound.[9,3,10] This result was proved independently in Refs. 3 and 11, building on earlier work in Refs. 4 and 12.

Theorem 8: *(Holevo–Schumacher–Westmoreland): The product signals/entangled measurements capacity of a quantum channel is given by*

$$C_{\mathrm{PE}}(\Phi)=C_{\mathrm{Holv}}(\Phi)=\sup_{\mathcal{E}}\left(S[\Phi(\rho)]-\sum_j \pi_j S[\Phi(\rho_j)]\right), \tag{8}$$

where $S(P)=-\mathrm{Tr}(P\log P)$ denotes the von Neumann entropy of the density matrix P. We call this the Holevo capacity of the channel.

C. Summary of results

Our main result, that using entangled inputs with product measurements does not increase the capacity of a channel, can be stated as

Theorem 9: *For any stochastic map, $C_{EP}(\Phi)=C_{\mathrm{Shan}}(\Phi)$.*

There is another implementation of product measurements which has the potential for a greater capacity. It involves a sequence of POVM's on the product spaces $\mathcal{H}^{\otimes n}$, whereby the POVM for the second measurement depends on the result of the first measurement, the POVM for the third measurement depends on the results of the first two measurements, and so on. The idea is that ''Bob'' can choose his successive POVM's based on the results of previous measurements. We write $C^{\mathrm{cond}}_{\mathrm{EP}}(\Phi)$ for the maximum asymptotic rate achievable for such a sequence of conditional POVM's, with entangled inputs allowed. [The precise definition of a conditional POVM is postponed to Sec. IV and the capacity is given by (34).] Our next result shows that using such conditional POVM's with entangled inputs again does not increase the channel capacity.

Theorem 10: *For any stochastic map, $C^{\mathrm{cond}}_{EP}(\Phi)=C_{\mathrm{Shan}}(\Phi)$.*

Theorem 10 was proved independently (and simultaneously), using different methods, by Shor,[13] and also later proved independently by Holevo.[14] A conditional POVM is not the most

general situation involving product measurements, which would be a POVM in which each measurement can be written as a tensor product. Except for the obvious bounds, we know of no results for the capacity associated with such POVM's.

The capacity of a classical channel can be written as the (suitably restricted) supremum of the classical mutual information. We extend this observation to the quantum case, using a tensor product formulation whereby the first two (and possibly all four) of these basic capacities are realized using mutual information in the form of the relative entropy of a density matrix and the product of its reduced density matrices. This leads to the following upper bound:

Theorem 11: *For any stochastic map,*

$$C_{\mathrm{EP}}(\Phi) \leqslant \sup_{\mathcal{M},\rho} \left[S(\rho) - \sum_b S(\sqrt{\rho}\,\hat{\Phi}(E_b)\sqrt{\rho}) + S(\tau) \right],$$

where $\tau_b = \mathrm{Tr}\,\Phi(\rho)E_b = \mathrm{Tr}\,\rho\widehat{\Phi}(E_b)$.

We call the quantity on the right U_{EP}, and we conjecture that it is equal to C_{EP}, i.e., that equality holds in Theorem 11 above. We motivate and study U_{EP} in Sec. II C, where we show that it can be rewritten in a form similar to the Holevo capacity. Combined with Theorem I C above, this conjectured equality would provide a simplified expression for the Shannon capacity of any channel, whereby the sup over both input ensemble and POVM is replaced by a sup over *one* average input state and the POVM.

Although the proof of Theorem 10 does not depend on our tensor product reformulation, we present this material first, in the following section, because we feel it gives some useful insights. Section II is largely pedagogical and provides the motivation for our conjectured expression for C_{EP}. Section III is also primarily pedagogical; it introduces the reader to Holevo's $C-Q$ and $Q-C$ channels.[3] This leads to a short proof of both the well-known Holevo bound and the new bound in Theorem 11. Moreover, the additivity of $Q-C$ channels implies Theorem 9 and motivates our proof of Theorem 10. The reader primarily interested in this proof can skip directly to Sec. IV.

II. CAPACITY FROM MUTUAL INFORMATION

A. Classical background

The *classical mutual information of two* random variables X and Y measures how much information they have in common and is given by

$$I^c(X;Y) \equiv \sum_{x,y} p(x,y)\log\frac{p(x,y)}{p(x)p(y)}. \tag{9}$$

If X and Y represent the input and output distributions of a channel, then the classical Shannon capacity is the supremum of $I^c(X;Y)$ taken over all possible joint distributions allowed by the channel.

The Shannon capacity of a quantum channel can also be obtained in this way provided that the joint distribution arises from a quantum communication process $(\Phi,\mathcal{E},\mathcal{M})$ as

$$p(j,b) = \pi_j\,\mathrm{Tr}[\Phi(\rho_j)E_b] = \pi_j\,\mathrm{Tr}[\rho_j\widehat{\Phi}(E_b)]. \tag{10}$$

Although the stochastic map Φ is usually regarded as noise acting on the signals ρ_j, it is important to recognize that it has another interpretation corresponding to the second expression for $p(j,b)$ in (10) above. In the second case, the channel transmits signals faithfully, but the ''noise'' distorts the measurement process by converting the POVM $\{E_b\}$ to a modified POVM $\{\hat{E}_b = \widehat{\Phi}(E_b)\}$ implemented by the action of the dual of Φ.

In order to make the transition from classical to quantum communication, it is sometimes useful to consider a classical probability vector $p(x)$ as the diagonal of a matrix P. We can then write the *relative entropy*,

$$H(P,Q)=\mathrm{Tr}[P\log P-P\log Q] \tag{11}$$

in a form which reduces to the usual classical expression when P and Q are diagonal, but is also valid when P and Q are density matrices representing mixed quantum states. In this notation (9) becomes

$$I^c(X;Y)=H[P_{12},P_1\otimes P_2], \tag{12}$$

where P_{12},P_1, and P_2 are diagonal matrices with nonzero entries $p(x,y),p(x)$ and $p(y)$, respectively.

B. Tensor product reformulation

A reformulation and generalization of mutual information and capacity can be made using *formal* tensor products. It should be emphasized that this is done for convenience of notation and is *distinct* from the tensor products used in describing multiple uses of the channel. Let $\mathcal{H}_{ABQR}=\mathbf{C}^J\otimes\mathbf{C}^M\otimes\mathcal{H}\otimes\mathcal{H}$, where $j=1...J$, $b=1...M$, and $\mathcal{H}_Q=\mathcal{H}_R=\mathcal{H}$ is the original Hilbert space on which ρ and E_b act. The partial traces then correspond to $T_A=\Sigma_j$, $T_B=\Sigma_b$, $T_Q=\mathrm{Tr}$, and $T_R=\mathrm{Tr}$.

Let P_{ABQ} be the block diagonal matrix with blocks $\pi_j\sqrt{\Phi(\rho_j)}E_b\sqrt{\Phi(\rho_j)}$ and $\hat{P}_{ABQ}$ the block diagonal matrix with blocks $\pi_j\sqrt{\rho_j}\,\widehat{\Phi}\,(E_b)\sqrt{\rho_j}$.

Then $P_{AB}\equiv T_QP_{ABQ}=T_Q\hat{P}_{ABQ}\equiv\hat{P}_{AB}$ and P_{AB} is a diagonal matrix with (nonzero) elements $p(j,b)=\pi_j\,\mathrm{Tr}[\Phi(\rho_j)\,E_b]$, $P_A\equiv T_{BC}P_{ABQ}=T_BP_{AB}$ is a diagonal matrix with elements $\delta_{ij}\pi_j$, $P_B\equiv T_{AQ}P_{ABQ}=T_AP_{AB}$ is a diagonal matrix with elements $\delta_{ab}\tau_b$ where $\tau_b=\mathrm{Tr}\,\Phi(\rho)E_b=\mathrm{Tr}\,\rho\widehat{\Phi}(E_b)$ as in Theorem 11.

It is straightforward to verify that

$$\begin{aligned}C_{\mathrm{PP}}\equiv C_{\mathrm{Shan}}(\Phi)&=\sup_{\mathcal{E},\mathcal{M}}[S(P_B)-S(P_{AB})+S(P_A)] &(13)\\&=\sup_{\mathcal{E},\mathcal{M}}H(P_{AB},P_A\otimes P_B)=\sup_{\mathcal{E},\mathcal{M}}I^q_\Phi(\mathcal{E};\mathcal{M})\\&=\sup_{\mathcal{E},\mathcal{M}}I^q(\tilde{\mathcal{E}};\mathcal{M})=\sup_{\mathcal{E},\mathcal{M}}I^q(\mathcal{E};\hat{\mathcal{M}}), &(14)\end{aligned}$$

where the last line in (14), although redundant is included to emphasize the fact that we can suppress the explicit dependence on Φ by using either a restricted ensemble with $\tilde{\rho}_j=\Phi(\rho_j)$ or a restricted POVM of the form $\widehat{\Phi}(E_b)$.

Note that all the matrices in (13) above are diagonal and could be replaced by probability vectors. The quantum character of the channel is hidden in the fact that P_{AB} must be the reduced density matrix of a P_{ABQ} of the form above with quantum blocks. Thus we might have replaced $\sup_{\mathcal{E},\mathcal{M}}$ above by either $\sup_{P_{ABQ}}H(P_{AB},P_A\otimes P_B)$ or $\sup_{\hat{P}_{ABQ}}H(P_{AB},P_A\otimes P_B)$ with the understanding that the supremum was to be taken over those P_{ABQ} or $\hat{P}_{ABQ}$ with the block diagonal form given above.

We can find a similar expression for the Holevo capacity by noting that $P_{AQ}\equiv T_BP_{ABQ}$ is a block diagonal matrix with blocks $\pi_j\Phi(\rho_j)$, and $P_Q\equiv T_{AB}P_{ABQ}=T_AP_{AQ}=\Phi(\rho)$.

It is again straightforward to verify that

$$C_{\mathrm{PE}}\equiv C_{\mathrm{Holv}}(\Phi)=\sup_{\mathcal{E}}[S(P_Q)-S(P_{AQ})+S(P_A)]=\sup_{\mathcal{E}}H(P_{AQ},P_A\otimes P_Q). \tag{15}$$

We can interpret this as a classical to quantum mutual information between the classical probability distribution π_j of the input alphabet and the average quantum distribution $\Phi(\rho)$ which emerges from the channel.

We conclude by observing that the entanglement assisted capacity of Ref. 15 can be written in a similar way as

$$\sup\{H(\rho_{QR},\rho_Q\otimes\rho_R):\rho_{QR}=(\Phi\otimes I)(|\Psi\rangle\langle\Psi|)\} \tag{16}$$

with $\Psi\in\mathbf{C}^2\otimes\mathbf{C}^2$. This differs slightly from Eq. (4) of Ref. 15. However, because $|\Psi\rangle\langle\Psi|$ is pure, their $S(\rho)=S[T_2(|\Psi\rangle\langle\Psi|)]=S[T_1(|\Psi\rangle\langle\Psi|)]=S(\rho_R)$ in our notation. Thus the expression in (16) above is equivalent to Eq. (4) of Ref. 15. This is a form of quantum to quantum mutual information between the subsystems of an entangled pair, one of which is subjected to noise via transmission through the channel.

We also expect that the capacity C_{EE} can be expressed as a (different) quantum to quantum mutual information. Unfortunately the precise form has eluded us. This approach does, however, lead in a natural way to a new expression related to C_{EP}.

C. Proposed expression for C_{EP}

To motivate our new candidate for C_{EP}, we let P_{BR} be the block diagonal matrix with blocks $\sqrt{\rho}\,\widehat{\Phi}(E_b)\sqrt{\rho}$. Then, $P_B\equiv T_R P_{BR}$ is a diagonal matrix with elements τ_b, $P_R\equiv T_B P_{BR}=\rho$, and define

$$U_{\mathrm{EP}}(\Phi)=\sup_{\mathcal{M},\rho}[S(P_R)+S(P_B)-S(P_{BR})]=\sup_{\mathcal{M},\rho}H(P_{BR},P_R\otimes P_B) \tag{17}$$

$$=\sup_{\mathcal{M},\rho}\left[S(\rho)-\sum_b\, S(\sqrt{\rho}\,\widehat{\Phi}(E_b)\sqrt{\rho})+S(\tau)\right]=\sup_{\tau_b,\gamma_b}\left[S(\gamma)-\sum_b\,\tau_b S(\gamma_b)\right], \tag{18}$$

where $\gamma_b=(1/\tau_b)\sqrt{\rho}\,\widehat{\Phi}(E_b)\sqrt{\rho}$ and $\gamma=\Sigma_b\tau_b\gamma_b=\rho$. The last form (18), looks like the Holevo capacity with the input ensemble $\mathcal{E}=\{\pi_j,\rho_j\}$ replaced by a new ''output measurement ensemble'' $\{\tau_b,\gamma_b\}$. How can we characterize this ensemble? Using Kraus operators we can write $\Phi(\rho)=\Sigma_k A_k^\dagger\rho A_k$, where $\Sigma_k A_k A_k^\dagger=I$. It follows that $\gamma_b=(1/\tau_b)\,\Sigma_k B_k^\dagger E_b B_k$ with $B_k=A_k^\dagger\sqrt{\rho}$. Hence γ_b is a density matrix in the range of a completely positive map which, rather than being trace-preserving or unital, satisfies $\Sigma_k B_k B_k^\dagger=\Phi(\rho)$. If we define $\Gamma_\rho(P)=\sqrt{\rho}\,\widehat{\Phi}(P)\sqrt{\rho}$ we can write

$$U_{\mathrm{EP}}(\Phi)=\sup_{\mathcal{M},\rho}\left(S[\Gamma_\rho(I)]-\sum_b\,S[\Gamma_\rho(E_b)]\right). \tag{19}$$

A different characterization is given in the next section as a condition on P_{BR}.

We can interpret (17) as a quantum to classical mutual information between the average input ρ and the classical probability vector τ_b associated with the correspondingly averaged output measurements $\mathrm{Tr}\,\rho\widehat{\Phi}(E_b)$.

We conjecture that $U_{\mathrm{EP}}=C_{\mathrm{EP}}$ although we can only show $U_{\mathrm{EP}}\geqslant C_{\mathrm{EP}}$, which is proved in the next section. Note if Φ is the completely noisy channel which maps every density matrix to the identity, then $P_{BR}=P_B\otimes P_R$ so that $H(P_{BR},P_B\otimes P_R)=0$ as expected. This also holds if ρ is a one-dimensional projection.

D. Optimization constraints

We can rewrite all of these expressions for capacity as the suitably constrained supremum of an ''Input–Output'' mutual information, $H(\rho_{\mathcal{IO}},\rho_{\mathcal{I}}\otimes\rho_{\mathcal{O}})$, i.e.,

$$\sup\{H(\rho_{\mathcal{IO}},\rho_{\mathcal{I}}\otimes\rho_{\mathcal{O}}):\rho_{\mathcal{IO}}\ \text{is a density matrix in}\ X_{\mathcal{IO}}\}, \tag{20}$$

where the subset $X_{\mathcal{IO}}$ lies in $\mathcal{A}_{\mathcal{I}}\otimes\mathcal{A}_{\mathcal{O}}$ and the algebra $\mathcal{A}$ is either $\mathbf{C}^{n\times n}$ or $\mathbf{D}^n$, the algebra of diagonal $n\times n$ matrices. We will let $\mathcal{G}=\{E:0\leqslant E\leqslant I\}$ denote the set of positive semidefinite operators less than or equal to the identity, $\mathcal{D}$ the set of density matrices, and $\leqslant\mathcal{D}$ the set of positive semi-definite matrices with trace $\leqslant 1$, i.e., the set of matrices λP, where P is a density matrix and $0\leqslant\lambda\leqslant 1$,

$$C_{\mathrm{PP}}:\ X_{\mathcal{IO}}=\{\rho_{AB}=\mathrm{Tr}_Q\,\rho_{ABQ}:\rho_{AQ}^{-1/2}\,\rho_{ABQ}\,\rho_{AQ}^{-1/2}\in\mathbf{D}^n\otimes\mathbf{D}^n\otimes\widehat{\Phi}(\mathcal{G})\}.$$

In the case of maps on $\mathbf{C}^{2\times 2}$ we expect this to be a subset of $\mathbf{D}^2\otimes\mathbf{D}^2$ although, in principle, it could be a subset of $\mathbf{D}^4\otimes\mathbf{D}^4$,

$$C_{\mathrm{PE}}:\ X_{\mathcal{IO}}=\{\rho_{AQ}:\rho_{AQ}\in\mathbf{D}^n\otimes\Phi(\leqslant\mathcal{D})\},$$

$$U_{\mathrm{EP}}:\ X_{\mathcal{IO}}=\{\rho_{BR}:\rho_B^{-1/2}\,\rho_{BR}\,\rho_B^{-1/2}\in\mathbf{D}^n\otimes\widehat{\Phi}(\mathcal{G})\},$$

$$C_{\mathrm{EE}}:\ \text{We know only that } X_{\mathcal{IO}}\subset\mathbf{C}^{n\times n}\otimes\mathbf{C}^{n\times n}.$$

In order to conclude that these expressions are equivalent to those given previously, we need to verify that when $\rho_{\mathcal{IO}}$ is in the indicated set, one can always find a corresponding ensemble $\mathcal{E}$ and/or POVM $\mathcal{M}$. The block diagonal conditions implicit in the notation above and the fact that Φ and $\widehat{\Phi}$ are trace-preserving and identity preserving respectively, makes this quite straightforward.

When $n=2$, we can describe $\mathcal{G}$ explictly by writing $E=w_0I+\mathbf{w}\cdot\sigma$ where $\sigma=(\sigma_x,\sigma_y,\sigma_z)$ denotes the formal vector of Pauli matrices and $\mathbf{w}$ in $\mathbf{R}^3$. Then $0\leqslant E\leqslant I$ if and only if $|\mathbf{w}|\leqslant\min\{w_0,1-w_0\}$ so that

$$\mathcal{G}=\bigcup_{w_0\in[0,1]}\{E=w_0I+\mathbf{w}\cdot\sigma:|\mathbf{w}|\leqslant\min\{w_0,1-w_0\}\}.$$

III. BOUNDS VIA $Q-C$ CHANNELS

Holevo[16] introduced an extremely useful family of stochastic maps of the form,

$$\Omega(P)=\sum_k R_k\,\mathrm{Tr}(PX_k),\tag{21}$$

where R_k is a family of density matrices, X_k is a POVM. He also distinguished two important subclasses of these channels

Ω_{QC}: Quantum-classical channels in which $R_k=|e_k\rangle\langle e_k|$ so that each density matrix is a one-dimensional projection from an orthonormal basis $\{e_k\}$;

Ω_{CQ}: Classical-quantum channels in which $X_k=|e_k\rangle\langle e_k|$ so that the POVM is a partition of unity arising from an orthonormal basis $\{e_k\}$.

Holevo[16] showed that the quantum capacity of such channels is additive, i.e.,

$$C_{\mathrm{PE}}(\Phi_{\mathrm{QC}}\otimes\Phi_{\mathrm{QC}}\cdots\otimes\Phi_{\mathrm{QC}})=C_{\mathrm{PE}}(\Phi_{\mathrm{QC}}^{\otimes n})=n\,C_{\mathrm{PE}}(\Phi_{\mathrm{QC}}),$$

and similarly for $C_{\mathrm{PE}}(\Phi_{\mathrm{CQ}}^{\otimes n})=n\,C_{\mathrm{PE}}(\Phi_{\mathrm{CQ}})$. In the next section, we use Holevo's strategy for proving additivity for Φ_{CQ} to prove Theorem 10.

We now show that both the celebrated ''Holevo bound'' $C_{\mathrm{PP}}(\Phi)\leqslant C_{\mathrm{PE}}(\Phi)$ and the new bound $C_{\mathrm{PP}}(\Phi)\leqslant U_{\mathrm{EP}}(\Phi)$ follow easily from the monotonicity of relative entropy under Ω_{QC} channels. Our strategy is similar to one used earlier by Yuen and Ozawa.[17]

In the first case, we let Ω_{QB} be a $Q-C$ map of the form (21) with $X_b=E_b$ and $R_b=|e_b\rangle\langle e_b|$. Then,

$$H(P_{AB},P_A\otimes P_B)=H[\Omega_{QB}(P_{AQ}),\Omega_{QB}(P_A\otimes P_Q)]\leqslant H(P_{AQ},P_A\otimes P_Q),\tag{22}$$

where P_{AQ} and P_{AB} are as in Sec. II and we have suppressed the identity in $I\otimes\Omega_{QB}$. Taking the supremum over $\mathcal{E}$ yields $C_{\mathrm{PP}}(\Phi)\leqslant C_{\mathrm{PE}}(\Phi)$.

For the new bound, let Ω_{RA} be a $Q-C$ map of the form (21) with $X_j=\pi_j\rho^{-1/2}\rho_j\,\rho^{-1/2}$ and $R_j=|e_j\rangle\langle e_j|$, so that $\Omega_{RA}(P_{BR})=P_{AB}$. Then,

$$H(P_{AB},P_A\otimes P_B)=H[\Omega_{RA}(P_{BR}),\Omega_{RA}(P_B\otimes P_R)]\leqslant H(P_{BR},P_B\otimes P_R)$$

from which it follows that $C_{\mathrm{PP}}(\Phi)\leqslant U_{\mathrm{EP}}(\Phi)$.

Remark: It may appear that the argument in (22) above yields a simple proof of the Holevo bound without using the strong subadditivity (SSA) of relative entropy[18] as in Ref. 19. However, Lindblad[20] made the useful observation that any stochastic map can be represented as the partial trace after interaction with an auxiliary system, i.e., $\Phi(P)=T_B[U_{AB}P\otimes E_BU_{AB}^\dagger]$. In fact, he used this representation to obtain monotonicity as a corollary of SSA. Thus, the arguments used to obtain the Holevo bound via monotonicity (as above or in Ref. 17) and via SSA (as in Ref. 19) are essentially equivalent. In the latter approach, an auxiliary system is added explicitly and then discarded; in the former, this is done implicitly via Lindblad's representation theorem. Further discussion of the history of the closely connected properties of SSA, monotonicity of relative entropy and the joint convexity of relative entropy is given in Refs. 21–23.

IV. PROOF OF ADDITIVITY USING $Q-C$ CHANNELS

Theorem 9 can be obtained from Holevo's result[16] that $C_{\mathrm{Holv}}(\Omega_{\mathrm{QC}})$ is additive, i.e., if Γ is a $Q-C$ channel of the form following (21), then $C_{\mathrm{Holv}}(\Gamma)$ is additive. To show how this follows, we define

$$\Gamma_{\Phi,\mathcal{M}}(P)=\sum_b\ |e_b\rangle\langle e_b|\ \mathrm{Tr}[P\widehat{\Phi}(E_b)]. \tag{23}$$

Then $\Gamma_{\Phi,\mathcal{M}}(P)$ is a $Q-C$ channel with $X_n=\widehat{\Phi}(E_b)$. Moreover, $\sup_{\mathcal{E}}I_\Phi^q(\mathcal{E};\mathcal{M})=C_{\mathrm{Holv}}(\Gamma_{\Phi,\mathcal{M}})$, and the additivity of $C_{\mathrm{Holv}}(\Gamma_{\Phi,\mathcal{M}})$ implies $\sup_{\mathcal{E}}I_{\Phi^{\otimes n}}^q(\mathcal{E};\mathcal{M}^{\otimes n})=C_{\mathrm{Holv}}(\Gamma_{\Phi,\mathcal{M}}^{\otimes n})=nC_{\mathrm{Holv}}(\Gamma_{\Phi,\mathcal{M}})$. Then Theorem 9 follows from

$$C_{\mathrm{Shan}}(\Phi)=\sup_{\mathcal{E},\mathcal{M}}I_\Phi^q(\mathcal{E};\mathcal{M})=\sup_{\mathcal{M}}C_{\mathrm{Holv}}(\Gamma_{\Phi,\mathcal{M}})=C_{\mathrm{EP}}(\Phi).$$

In order to prove Theorem 10, we will need to extend Holevo's result. Our extension, which we present below, follows Holevo's strategy[16] with the identity (27) replacing subadditivity. This also provides a self-contained proof of Theorem 9, since a product measurement is a special case of a conditional measurement.

First consider a product channel with Hilbert space $\mathcal{H}_1\otimes\mathcal{H}_2$ and noise operator $\Phi_1\otimes\Phi_2$. Let $\mathcal{E}_{12}=\{\pi_j,\rho_j\}$ be an ensemble of possibly entangled input states on $\mathcal{H}_1\otimes\mathcal{H}_2$. Let $\mathcal{M}_1=\{E_b\}$ denote the POVM on $\mathcal{H}_1$ which implements the first measurement, and for each b let $\mathcal{M}_2(b)=\{E_c^{(b)}\}$ denote the POVM on $\mathcal{H}_2$ which implements the second measurement. We then define a joint POVM $\mathcal{M}_{12}$ on $\mathcal{H}_1\otimes\mathcal{H}_2$, namely $\{E_b\otimes E_c^{(b)}\}$. Note that although each element of $\mathcal{M}_{12}$ is a product, the joint measurement need not be the product of independent measurements $\mathcal{M}_1\otimes\mathcal{M}_2$. This is the result of the fact that the second measurement may be conditioned on the results of the first. Nevertheless, it is easy to verify that $\mathcal{M}_{12}$ is a POVM since

$$\sum_{b,c}\ E_b\otimes E_c^{(b)}=\sum_b\ E_b\otimes\left(\sum_c\ E_c^{(b)}\right)=\sum_b\ E_b\otimes I.$$

The information content of a channel using such conditioned measurements is

$$I_{\Phi_1\otimes\Phi_2}^q(\mathcal{E}_{12};\mathcal{M}_{12})=I^q(\mathcal{E}_{12};\hat{\mathcal{M}}_{12})=I^q(\tilde{\mathcal{E}}_{12};\mathcal{M}_{12}), \tag{24}$$

where $\hat{\mathcal{M}}_1, \hat{\mathcal{M}}_2(b)$, and $\hat{\mathcal{M}}_{12}$ denote the POVM's in which E_b is replaced by $F_b = \widehat{\Phi_1}(E_b)$ and $E_c^{(b)}$ is replaced by $F_c^{(b)} = \widehat{\Phi_2}(E_c^{(b)})$, and we have used the notation defined in (1) and (2). Because we are interested in studying the capacity for a fixed set of POVM's, we use the form $I^q(\mathcal{E}_{12}; \hat{\mathcal{M}}_{12})$ and proceed as if we were considering a noiseless channel with a restricted POVM of the above form. Although this viewpoint is useful, it is not essential. The argument would work equally well if we explicitly included the stochastic maps or used the form $I^q(\tilde{\mathcal{E}}_{12}; \mathcal{M}_{12})$ and defined reduced density matrices using partial traces acting on, e.g., $(\Phi_1 \otimes \Phi_2)(\rho_j)$.

For any input ensemble $\mathcal{E}_{12}$ we now define a pair of associated input ensembles on $\mathcal{H}_1$ and $\mathcal{H}_2$, respectively. For this purpose it is useful to let T_j denote the partial trace over $\mathcal{H}_j$. First, let $\rho_j^{(1)} = T_2[\rho_j]$ be the indicated reduced density matrix and $\mathcal{E}_1 = \{\pi_j, \rho_j^{(1)}\}$. This is our ensemble on $\mathcal{H}_1$. Second, for each j and b, define a state on $\mathcal{H}_2$ by

$$\rho_{j,b}^{(2)} = p(b|j)^{-1} T_1[(\rho_j)(F_b \otimes I)], \tag{25}$$

where $p(b|j) = \mathrm{Tr}[\rho_j (F_b \otimes I)]$. Then the corresponding input ensemble on $\mathcal{H}_2$ is $\mathcal{E}_2(b) = \{p(j|b), \rho_{j,b}^{(2)}\}$, where $p(j|b) = p(b|j)\pi_j / p(b)$ and

$$p(b) = \sum_j \pi_j p(b|j) = \mathrm{Tr}\left[\left(\sum_j \pi_j \rho_j\right)(F_b \otimes I)\right]. \tag{26}$$

We claim that

$$I^q(\mathcal{E}_{12}; \hat{\mathcal{M}}_{12}) = I^q(\mathcal{E}_1; \hat{\mathcal{M}}_1) + \sum_b p(b)\, I^q[\mathcal{E}_2(b); \hat{\mathcal{M}}_2(b)]. \tag{27}$$

Since

$$I^q[\mathcal{E}_2(b); \hat{\mathcal{M}}_2(b)] = I^q_{\Phi_2}[\mathcal{E}_2(b); \mathcal{M}_2(b)] \leqslant C_{\mathrm{Shan}}(\Phi_2), \tag{28}$$

it follows immediately from (27) that

$$I^q(\mathcal{E}_{12}; \hat{\mathcal{M}}_{12}) \leqslant I^q(\mathcal{E}_1; \hat{\mathcal{M}}_1) + \sum_b p(b)\, C_{\mathrm{Shan}}(\Phi_2) = I^q(\mathcal{E}_1; \hat{\mathcal{M}}_1) + C_{\mathrm{Shan}}(\Phi_2). \tag{29}$$

Taking the supremum over channels of this type, which we now emphasize by writing $\mathcal{M}_{12}^{\mathrm{cond}}$, gives

$$\sup_{\mathcal{E}_{12}, \mathcal{M}_{12}^{\mathrm{cond}}} I^q_{\Phi_1 \otimes \Phi_2}(\mathcal{E}_{12}; \mathcal{M}_{12}^{\mathrm{cond}}) = \sup_{\mathcal{E}_{12}, \hat{\mathcal{M}}_{12}^{\mathrm{cond}}} I^q(\mathcal{E}_{12}; \hat{\mathcal{M}}_{12}^{\mathrm{cond}}) \leqslant C_{\mathrm{Shan}}(\Phi_1) + C_{\mathrm{Shan}}(\Phi_2). \tag{30}$$

However by restricting to product ensembles and product POVM's in the sup on the left-hand side of (30), and using additivity of the classical capacity (7), we deduce

$$\sup_{\mathcal{E}_{12}, \mathcal{M}_{12}^{\mathrm{cond}}} I^q_{\Phi_1 \otimes \Phi_2}(\mathcal{E}_{12}; \mathcal{M}_{12}^{\mathrm{cond}}) \geqslant C_{\mathrm{Shan}}(\Phi_1) + C_{\mathrm{Shan}}(\Phi_2). \tag{31}$$

Hence we have an equality in (30).

Now consider the n-fold product channel $\Phi_1 \otimes \cdots \otimes \Phi_n$. Let $\mathcal{M}^{\mathrm{cond}}$ be a conditional POVM on $\mathcal{H}_1 \otimes \cdots \otimes \mathcal{H}_n$. By assumption, every operator in this POVM has the form $E_b \otimes E_c^{(b)}$, where $\{E_b\}$ is a conditional POVM $\mathcal{N}^{\mathrm{cond}}$ on $\mathcal{H}_1 \otimes \cdots \otimes \mathcal{H}_{n-1}$, and for each b, $E_c^{(b)}$ constitute a POVM on $\mathcal{H}_n$. Also, for any input ensemble $\mathcal{E}$ on $\mathcal{H}_1 \otimes \cdots \otimes \mathcal{H}_n$, let $\mathcal{E}'$ be the ensemble of reduced density matrices on $\mathcal{H}_1 \otimes \cdots \otimes \mathcal{H}_{n-1}$. Then (29) implies

$$\sup_{\mathcal{E},\mathcal{M}^{\rm cond}} I^q_{\Phi_1\otimes\Phi_2\otimes\cdots\otimes\Phi_n}(\mathcal{E};\mathcal{M}^{\rm cond}) \leq \sup_{\mathcal{E}',\mathcal{N}^{\rm cond}} I^q_{\Phi_1\otimes\Phi_2\otimes\cdots\otimes\Phi_{n-1}}(\mathcal{E}';\mathcal{N}^{\rm cond}) + C_{\rm Shan}(\Phi_n). \quad (32)$$

Iterating (32) gives

$$\sup_{\mathcal{E},\mathcal{M}^{\rm cond}} I^q_{\Phi_1\otimes\Phi_2\otimes\cdots\otimes\Phi_n}(\mathcal{E};\mathcal{M}^{\rm cond}) \leq \sum_{k=1}^{n} C_{\rm Shan}(\Phi_k). \quad (33)$$

The definition of conditional capacity is

$$C^{\rm cond}_{\rm EP}(\Phi) = \lim_{n\to\infty}\frac{1}{n}\sup_{\mathcal{E},\mathcal{M}^{\rm cond}} I^q_{\Phi^{\otimes n}}(\mathcal{E};\mathcal{M}^{\rm cond}). \quad (34)$$

Hence if we let $\Phi_k=\Phi$, $(k=1,2,\ldots)$ it follows immediately from (33) that

$$C^{\rm cond}_{\rm EP}(\Phi) \leq C_{\rm Shan}(\Phi). \quad (35)$$

Since the capacity of the product channel is never less than the sum of the channel capacities, i.e, $C^{\rm cond}_{EP}(\Phi)\geq C_{\rm Shan}(\Phi)$ we must have equality in (35) which proves Theorem 10.

It is worth noting that our argument can be used to prove a somewhat stronger result, namely, that $\sup_{\mathcal{E}} I^q_{\Phi}(\mathcal{E};\mathcal{M}^{\rm cond})$ is additive in Φ for any fixed conditional measurement $\mathcal{M}^{\rm cond}$.

All that remains is to verify (27) which is, except for notation, equivalent to the following result from classical information theory: for any random variables J,B,C,

$$I^c(J;B,C) = I^c(J;B) + I^c(J;C|B). \quad (36)$$

Although the derivation of (36) is quite elementary (see, for example, Refs. 24 and 10), for completeness we include it in the Appendix, where we also show its equivalence to (27).

Shor for communicating his independent proof of Theorem 10. We are also grateful to the referee for an extremely careful reading of the manuscript.

APPENDIX: A USEFUL INFORMATION IDENTITY

First we relate (27) to an expression involving classical mutual information. The input alphabet of the product channel can be described by a classical discrete random variable J, whose distribution is given by the input ensemble $\mathcal{E}_{12}$, that is, $P(J=j)=\pi_j$. The output alphabet can be described similarly by a pair of random variables B,C, corresponding to the joint POVM $\hat{\mathcal{M}}_{12}$. The joint distribution of J,B,C is given by application of formula (10), namely,

$$P(J=j,B=b,C=c) = p(j,b,c) = \pi_j \,{\rm Tr}[\,(\rho_j)\, F_b\otimes F^{(b)}_c]. \quad (A1)$$

Applying the definitions in (1), (9), and (10) gives directly

$$I^c(J;B,C) = I^q(\mathcal{E}_{12};\hat{\mathcal{M}}_{12}). \quad (A2)$$

Furthermore, by summing over c in (A1) and conditioning on j, it follows that

$$p(b|j)=\mathrm{Tr}[\,(\rho_j)\,F_b\otimes I\,]=\mathrm{Tr}[\,(\rho_j)^{(1)}\,F_b]. \tag{A3}$$

Comparing with the definition of the ensemble $\mathcal{E}_1$, it follows that

$$I^c(J;B)=I^q(\mathcal{E}_1;\hat{\mathcal{M}}_1). \tag{A4}$$

For the second term on the right-hand side of (36), recall that by definition,

$$I^c(J;C\,|\,B)=\sum_b\, p(b)I^c(J;C\,|\,\{B=b\}). \tag{A5}$$

Also,

$$p(c|j,b)=\frac{p(j,b,c)}{p(j,b)}=\mathrm{Tr}[\,(\rho_{j,b})^{(2)}\,F_c^{(b)}\,] \tag{A6}$$

and $p(j|b)=p(j,b)/p(b)=p(b|j)\pi_j/p(b)$, so therefore

$$I^c(J;C\,|\,\{B=b\})=I^q(\mathcal{E}_2(b);\hat{\mathcal{M}}_2(b)). \tag{A7}$$

Hence Eqs. (27) and (36) are identical.

As noted before, (36) is a standard result in information theory. We include its derivation for completeness. The left-hand side can be rewritten as

$$I(J;B,C)=H(J)+H(B,C)-H(J,B,C), \tag{A8}$$

where $H(X)$ is the classical entropy of the random variable X. The two terms on the right-hand side are, respectively,

$$I(J;B)=H(J)+H(B)-H(J,B), \tag{A9}$$

$$I(J;C\,|\,B)=H(J|B)+H(C|B)-H(J,C|B). \tag{A10}$$

Further, for any random variables X and Y,

$$H(X|Y)=H(X,Y)-H(Y), \tag{A11}$$

and therefore (A10) can be written as

$$I(J;C\,|\,B)=H(J,B)-H(B)+H(C,B)-H(B)-H(J,C,B)+H(B). \tag{A12}$$

Adding (A9) and (A12) gives the right-hand side of (A8), which proves the result.

This paper addresses the following problem of relativistic quantum field theory: Given a relativistic quantum field, construct a net of local observable algebras over space–time with ''natural'' properties. A few years ago we started a project which suggests to look at this problem in the framework of relativistic quantum field theory in terms of Fourier hyperfunctions. Accordingly we present the relevant analyticity results, some modular aspects of our theory for the Bisognano–Wichman argument, and a concrete suggestion for the definition of the local observable algebras. Finally, we construct a class of models of hyperfunction quantum fields for which the algebras of bounded operators assigned to nonempty regions in space–time are not trivial. It is remarkable that our models are not tempered quantum fields and do not admit ''test functions'' of compact support.
 [DOI: 10.1063/1.1326460]

I. INTRODUCTION

The problem of defining and of constructing a causal net of operator algebras for general relativistic quantum field theory has attracted considerable attention in the last 15 years (see Refs. 1–6). Typically additional (mainly technical) assumptions are involved to define causal nets of operators algebras for a standard quantum field theory, i.e., a relativistic quantum field theory in the sense of Gårding and Wightman.[7] Ultimately the goal is to construct an algebraic quantum field theory in the sense of Haag and Kastler.[4] However, at the moment it is still open what the most appropriate way of defining these local algebras is though there have been a number of promising suggestions.[1,6] And the problem of nontriviality of the operator *-algebras assigned to an open nonempty region of space–time is also not settled in these suggestions.

Accordingly we found it attractive to look for another framework to address these problems. Here we suggest to use the framework of Fourier hyperfunctions which is weaker than that of tempered distributions. Thus we have to choose quite a different route to proceed.

Our attempt is also motivated by the fact that the question of which type of generalized functions one should use in the formulation of relativistic quantum field theory, has not yet found a final answer. From the construction of models[8] and from general considerations there are strong indications that in the framework of hyperfunction quantum field theory (HFQFT for short), i.e., relativistic quantum field theory in terms of Fourier hyperfunctions,[9,10] one can do better with regard to these problems in so far that the additional assumptions can be dropped (or at least be weakened considerably). Other reasons for why it is attractive to study quantum field theory in terms of Fourier hyperfunctions are given in Refs. 11 and 12.

For the convenience of readers who are not too familiar with HFQFT and its motivation we

[a)]Electronic mail: shigeaki@pm.tokushima-u.ac.jp
[b)]Electronic mail: ebruning@pixie.udw.ac.za

recall the main points. (1) The fact that in four-dimensional space–time no nontrivial standard quantum fields have been constructed indicates that the axioms of QFT in terms of tempered distributions might be too strong. (2) On p. 425 of Ref. 11 one finds the following:

In conclusion we remark that Jaffe's formulation of the problem is not the most general. One might try [in the spirit of the work of Martineau (1963), for example] to define local properties of generalized functions (in particular the notion of support of a generalized function) even when the space of test functions does not include functions of compact support. The hope is that in this general framework one might arrive at a class of generalized functions satisfying weaker conditions than (15.53)–(15.54); in particular, the generalized functions which increase at infinity no faster than any linear exponential $|f(p)| \leqslant C_\epsilon \exp \epsilon|p|$ *for all* $\epsilon > 0$ *might be included.*

We point out that all this is realized in HFQFT. (3) In HFQFT there is a more natural relation between Wightman distributions and Schwinger functions.[13] (4) The two point function $D_m^{(-)}(x-y) = \langle \phi(x)\phi(y) \rangle$ has a local singularity of the form

$$\frac{1}{[(x-y)^2]^{(s-1)/2}}$$

in $s > 1$ space dimension. Thus an infinite power series in this quantity will have an essential singularity at the origin, and therefore not be tempered. But if $s = 1$ the local singularity in $D_m^{(-)}(x-y)$ is $\log(x-y)^2$ and so an infinite sum can define a tempered distribution. This is the reason why in the case of $s = 1$ Wick power series can converge in a framework of tempered fields, whereas in the case of $s > 1$ only Wick polynomials are defined in the framework of tempered fields. Thus (Wick ordered) entire functions of free fields find a natural formulation in HFQFT and thus provide a huge class of additional explicit models of quantum fields which are far more complex than the class of explicit models in standard QFT. (5) Certain ''formally interacting'' models can be treated rigorously in HFQFT but not in standard QFT.[8]

Since the system of axioms for HFQFT is weaker than that of standard QFT, the construction of a causal net is more difficult in HFQFT. In fact, if we look at the works quoted above we see that the existence of compactly supported test functions plays a fundamental role in all approaches to this problem in the framework of standard QFT. Thus at first it seems very questionable whether this problem can be addressed in HFQFT at all where there are no test functions of compact support available. But these doubts are based on the understanding that localization can only be achieved through localized test functions. In HFQFT localization is achieved through the main objects of the theory, namely through the fields (as operator-valued Fourier hyperfunctions) and their localization properties. Naturally, the concept of localization is more subtle in the theory of (Fourier) hyperfunctions than in Schwartz' distribution theory. (Localization of Fourier hyperfunctions is for instance explained in Sec. 2 of Ref. 10 and for hyperfunctions in Secs. 9.1 and 9.2 of Ref. 14).

In this paper we intend to show that it is sensible and promising to address the problem of defining and constructing local nets of operator algebras in the framework of Fourier hyperfunction quantum field theory by providing the following: (1) The basic ingredients for the Bisognano–Wichmann approach to this problem [existence and standard properties of the CPT-operator; HFQFT version of the Reeh–Schlieder theorem; analytic continuation over spatial wedges $W_\pm$; identification of the concrete action of the operator J of Eq. (24) and its main properties] and (2) A concrete proposal for the assignment of *-algebras of bounded operators to open nonempty domains of space–time (which is shown to be local for double cones). (3) A construction of a simple class of models of hyperfunction quantum fields (which are not standard quantum fields) for which the local algebras according to our suggestion are not trivial.

Standard quantum field theory uses the space $\mathcal{S}(\mathbf{R}^4)$ of rapidly decreasing C^∞-functions as a test function space, i.e., the field Φ is an operator-valued tempered distribution, more precisely $\Phi(f)$ is an unbounded operator defined on a dense subset $\mathcal{D}$ of a Hilbert space $\mathcal{H}$ for all $f \in \mathcal{S}(\mathbf{R}^4)$. On the other hand hyperfunction quantum field theory uses as a test function space the space $\mathcal{Q}(\mathbf{D}^4)$ of rapidly decreasing analytic functions defined below.

An element μ of the dual space $\mathcal{Q}(\mathbf{D}^n)'$ of $\mathcal{Q}(\mathbf{D}^n)$ is called a Fourier hyperfunction and an element ν of the space $\mathcal{L}(\mathcal{Q}(\mathbf{D}^n),\mathcal{H})$ of continuous linear mappings from $\mathcal{Q}(\mathbf{D}^n)$ to $\mathcal{H}$ is called a vector-valued Fourier hyperfunction. Though there are no functions of compact support in $\mathcal{Q}(\mathbf{D}^n)$, we can define the support of a Fourier hyperfunction as follows:

Let S_∞^{n-1} be the $(n-1)$-dimensional sphere at infinity, which is homeomorphic to the unit sphere $S^{n-1}=\{x\in\mathbf{R}^n;|x|=1\}$ by the mapping $x\to x_\infty$, where the point $x_\infty\in S_\infty^{n-1}$ lies on the ray connecting the origin with the point $x\in S^{n-1}$. The set $\mathbf{R}^n\cup S_\infty^{n-1}$, equipped with its natural topology [a fundamental system of neighborhoods of x_∞ is the set of all the sets $O_{\Omega,R}(x_\infty)$ given by

$$O_{\Omega,R}(x_\infty)=\{\xi\in\mathbf{R}^n;\xi/|\xi|\in\Omega,\ \ |\xi|>R\}\cup\{\xi_\infty;\xi\in\Omega\}$$

for every neighborhood Ω of x in S^{n-1} and $R>0$], is denoted by $\mathbf{D}^n$, called the radial compactification of $\mathbf{R}^n$. Let $Q^n=\mathbf{D}^n\times i\mathbf{R}^n$ and give it the product topology. Naturally, $\mathbf{C}^n=\mathbf{R}^n\times i\mathbf{R}^n$ is embedded in Q^n. Let K be a compact set in $\mathbf{D}^n$, $\{U_m\}$ a fundamental system of neighborhoods of K in Q^n and $\mathcal{O}_c^m(U_m)$ the Banach space of functions f analytic in $U_m\cap\mathbf{C}^n$ and continuous on $\overline{U_m}\cap\mathbf{C}^n$ which satisfy

$$\|f\|_m=\sup_{z\in U_m\cap\mathbf{C}^n}|f(z)|e^{|z|/m}<\infty.$$

Next we introduce the space

$$\mathcal{Q}(K)=\operatorname{ind}\lim_{m\to\infty}\mathcal{O}_c^m(U_m).$$

Observe that $\mathcal{Q}(\mathbf{D}^n)$ is dense in $\mathcal{Q}(K)$ (see for instance Ref. 15). Therefore continuous extensions are unique if they exist at all. We say that the *support* of $\mu\in\mathcal{Q}(\mathbf{D}^n)'$ is contained in K if μ has a continuous extension to $\mathcal{Q}(K)$. The localization of Fourier hyperfunctions can be summarized by recalling that Fourier hyperfunctions form a (flabby) sheaf over space–time.[16]

There are two main approaches to construct a net of local algebras from tempered quantum fields (see Refs. 1, 6, 17 for a survey of these and other attempts). One way to define local algebras $\{\mathcal{M}(O)\}$ for bounded open sets O in $\mathbf{R}^4$ is to define $\mathcal{M}(O)$ as the set of all 'bounded functions' of $\Phi(f)$ for $f\in\mathcal{S}(\mathbf{R}^4)$ with $\operatorname{supp}f\subset O$. Since the test functions of the Fourier hyperfunctions are analytic functions, there are no nonzero functions with compact supports. Therefore we cannot define local algebras for hyperfunction quantum fields by this method. Another definition of local algebras is that $\mathcal{M}(O)$ is the set of all bounded operators which commute weakly with all field operators $\Phi(f)$ with $\operatorname{supp}f\subset O'$ where $O'=\operatorname{int}\{x\in\mathbf{R}^4;(x-y)^2<0,\ \forall y\in O\}$. This definition has a counterpart in hyperfunction quantum field theory as we indicate now. Let $\mathcal{D}$ be a dense subset of the Hilbert space $\mathcal{H}$ such that $\Phi(f)\mathcal{D}\subset\mathcal{D}$ for all test functions $f\in\mathcal{Q}(\mathbf{D}^4)$. Then the mapping $(f_1,\ldots,f_n)\to\Phi(f_1)\cdots\Phi(f_n)u$ for $u\in\mathcal{D}$ defines a vector-valued Fourier hyperfunction $\Phi(x_1)\cdots\Phi(x_n)u$ (see Ref. 15). Since there are no nontrivial test functions with compact supports, we do not use smeared quantities $\Phi(f_1)\cdots\Phi(f_n)u$ but instead we use the vector-valued Fourier hyperfunctions $\Phi(x_1)\cdots\Phi(x_n)u$ directly. Since we can define the supports of Fourier hyperfunctions, we define the following set:

$$\mathcal{L}_w'(O)=\{X\in\mathcal{B}(\mathcal{H});\ \ \forall n\in\mathbb{N},\forall u\in\mathcal{D},\forall v\in\mathcal{D},$$

$$\operatorname{supp}[(X^*u,\Phi(x_1)\cdots\Phi(x_n)v)-(\Phi(x_n)^*\cdots\Phi(x_1)^*u,Xv)]\subset\mathbf{D}^{4n}\setminus O^n\}.$$

$\mathcal{L}_w'(O)$ is the set of all bounded operators which commute weakly with $\Phi(x_1)\cdots\Phi(x_n)$ for all $x_k\in O$. Since $\mathcal{L}_w'(O)$ is not necessarily an algebra, we propose to define an algebra $\mathcal{M}(O)$, for double cones O, as a subset of $\mathcal{L}_w'(O')$.

Questions of prime importance are: Is the net $\{\mathcal{M}(O)\}$ is local? Is $\{\mathcal{M}(O)\}$ not trivial? In this paper we give an affirmative answer to the first question for the family of double cones using the Bisognano–Wichmann argument (see Refs. 1, 5, 17).

In Sec. II, we study the vector-valued Fourier hyperfunctions $\Phi(x_1)\cdots\Phi(x_n)\Phi_0$, where Φ_0 is the vacuum vector, especially the analytic properties of these Fourier hyperfunctions. As a counter part of the well-known Reeh–Schlieder theorem of standard QFT we prove Proposition II.1. In Sec. II B we study the analytic properties of n-point functions $\mathcal{W}_n(x_1,\ldots,x_n) = (\Phi_0,\Phi(x_1)\cdots\Phi(x_n)\Phi_0)$ and prove the existence of the CPT-operator θ in hyperfunction quantum field theory. Next, in Sec. II C we study again analytic properties of

$$\Phi(x_1)\cdots\Phi(x_n)\Phi_0.$$

In particular we prove Proposition II.7 which is the crucial tool for the following development. As a preparation, in Sec. III, modular aspects of the theory for sets of operators over the spatial wedges $W_{\pm}$ are considered. Compared to standard QFT an additional domain problem has to be addressed (Sec. III B). This then allows us in Sec. IV to derive suitable characterizations of weak commutants of field operators localized on wedges. Then, besides a domain problem, we have prepared the ground for the Bisognano–Wichman route to causality for weak commutants over wedges and then over double-cones (Sec. V).

We want to stress that all the results and proofs are valid also in tempered quantum field theory because tempered quantum fields can be considered to be (Fourier) hyperfunction quantum fields.

As it is well known in the case of tempered quantum fields[1,3,2] the nontriviality of the local observable algebras is a difficult problem which has not yet found a general solution. Our above remarks indicate considerable additional difficulties in the case of hyperfunction quantum fields. So, instead of proving the existence of nontrivial local observable algebras in the general case, we present in Sec. VI a class of examples of hyperfunction quantum fields which have nontrivial local observable algebras. We proceed as follows.

We construct a hyperfunction quantum field as a Wick power series of a free field which is not a standard quantum field. We construct the local algebras for this field according to our suggestion. The nontriviality of these local algebras is shown as follows: A standard construction gives the local algebras for this free field. And it is shown that these local algebras for the free field are contained in the corresponding local algebras constructed for the hyperfunction quantum field. This amounts to the statement that the free field we start with and the hyperfunction quantum field constructed out of it are local relative to each other, in some sense. (We think that these hyperfunction quantum fields are in Borchers class of the free field, in the sense of HFQFT; but the Borchers class, in the sense of HFQFT, of a free field has not yet been determined.)

II. HYPERFUNCTION QUANTUM FIELD THEORY: ANALYTICITY RESULTS

Naturally we begin by specifying the framework in which we will be working.

By definition hyperfunction quantum fields are (relativistic) quantum fields over the test function space $E=\mathcal{Q}(\mathbf{D}^4)$ as discussed in Ref. 10. Here we address only the theory of a neutral scalar hyperfunction quantum field. For convenience we recall the basic defining assumptions $H_1,\ldots,H_5$. A quadruple $(\mathcal{H},U,\mathcal{D},\Phi)$ is called a *hyperfunction quantum field theory* iff the following conditions are satisfied:

H_1 *Quantum fields as operator valued Fourier hyperfunctions:* The field Φ is a linear map from $\mathcal{Q}(\mathbf{D}^4)$ into the algebra $L(\mathcal{D},\mathcal{D})$ of linear operators defined on the dense subset $\mathcal{D}$ of a separable complex Hilbert space $\mathcal{H}$. For all $u,v\in\mathcal{D}$, $f\to(u,\Phi(f)v)$ is a Fourier hyperfunction and one has $\Phi(f^*)\subset\Phi(f)^*$, where $\Phi(f)^*$ is the adjoint of the densely defined linear operator $\Phi(f)$ and $f^*(z)=\overline{f(\bar{z})}$ (Φ is Hermitian).

H_2 *Relativistic covariance:* U is a unitary representation of (the universal covering group of) the proper Poincaré group G on $\mathcal{H}$ which satisfies

$$U(g)\mathcal{D}=\mathcal{D},\ \ U(g)\Phi(f)U(g)^{-1}=\Phi(f_g),$$

for all $g\in G$ and all $f\in\mathcal{Q}(\mathbf{D}^4)$, where $f_g(x)=f(g^{-1}x)$.

H_3 *Spectral condition:* The spectrum of the energy-momentum operator P (i.e., the generator of the time–space translations in the representation U) is contained in the closed forward light cone $\overline{V}_+$, where

$$V_\pm=\{(p^0,\mathbf{p});\ \ \pm p^0>|\mathbf{p}|\}.$$

H_4 *Causality or local commutativity:* If x_1 and x_2 are spacelike separated then $\Phi(x_1)\Phi(x_2)u=\Phi(x_2)\Phi(x_1)u$ for every $u\in\mathcal{D}$.

H_5 *Uniqueness of the vacuum:* The subspace $\mathcal{H}_0$ of translation invariant vectors in $\mathcal{H}$ is one-dimensional and generated by a unit vector $\Phi_0\in\mathcal{D}$. This vacuum vector Φ_0 is also invariant under the Lorentz transformations $U(\Lambda)$ and cyclic for the field operators $\Phi(f)$, $f\in\mathcal{Q}(\mathbf{D}^4)$, i.e.,

$$\mathcal{D}_0=\text{lin span}\{\Phi_0,\ \ \Phi(f_1)\cdots\Phi(f_n)\Phi_0;f_k\in\mathcal{Q}(\mathbf{D}^4),\ \ n=1,2,\ldots\}$$

is dense in $\mathcal{H}$.

Remark: It follows from the first axiom that for every $u\in\mathcal{D}$ the mapping

$$\mathcal{Q}(\mathbf{D}^4)^n\ni(f_1,\ldots,f_n)\to\Phi(f_1)\cdots\Phi(f_n)u\in\mathcal{D} \tag{1}$$

defines a unique vector-valued Fourier hyperfunction $\Phi(x_1)\cdots\Phi(x_n)u$ (see Ref. 15). Therefore we are dealing with well defined vector valued Fourier hyperfunctions in condition H_4.

A. Basic analyticity results

Introduce the vector-valued Fourier hyperfunction

$$\Phi_n(x_1,\ldots,x_n)=\Phi(x_1)\cdots\Phi(x_n)\Phi_0 \tag{2}$$

and denote the Fourier transform of $\Phi_n(x_1,\ldots,x_n)$ by $\tilde{\Phi}_n(p_1,\ldots,p_n)$. Now, in appropriately chosen variables

$$(q_1,\ldots,q_n)=\chi^{-1}(p_1,\ldots,p_n),\ \ q_k=\sum_{j=k}^{n}p_j,$$

the Fourier hyperfunction $\tilde{\Phi}_n$ has convenient support properties. Consider

$$\tilde{Z}_n=\tilde{\Phi}_n\circ\chi_n. \tag{3}$$

Then we have (see Ref. 10)

$$\text{supp}\,\tilde{Z}_n(q_1,\ldots,q_n)\subset\overline{V}_+^n. \tag{4}$$

If $\text{Im}\,\zeta_k\in V_+$, then

$$q\to\exp\left(i\sum_{k=1}^{n}\langle\zeta_k,q_k\rangle\right)=\psi_{\zeta_1,\ldots,\zeta_n}(q_1,\ldots,q_n)$$

belongs to the space $\mathcal{Q}(\overline{V}_+^n)$ and therefore

$$Z_n(\zeta_1,\ldots,\zeta_n)=\tilde{Z}_n(\psi_{\zeta_1,\ldots,\zeta_n}) \tag{5}$$

is holomorphic in $\mathcal{T}_+^n$, where $\mathcal{T}_+^n=\{(\zeta_1,\ldots,\zeta_n);\ \text{Im}\,\zeta_k\in V_+,\ \text{for}\ \ k=1,\ldots,n\}$ and

$$\Phi_n(x_1,\ldots,x_n)=Z_n(x_1,x_2-x_1,\ldots,x_n-x_{n-1})=Z_n(\xi_1,\ldots,\xi_n). \tag{6}$$

$Z_n(\xi_1,\ldots,\xi_n)$ is the Fourier hyperfunction which is defined as the boundary value of $Z_n(\zeta_1,\ldots,\zeta_n)$ on $\mathcal{T}_+^n$. It is also the Fourier transform of the Fourier hyperfunction $\tilde{Z}_n$ introduced above. It follows that the Fourier hyperfunction (2) is the boundary value of the analytic function,

$$\Phi_n(z_1,\ldots,z_n)=Z_n(z_1,z_2-z_1,\ldots,z_n-z_{n-1})=Z_n(\zeta_1,\ldots,\zeta_n) \tag{7}$$

in $\{(z_1,\ldots,z_n)\in\mathbf{C}^{4n};(z_1,z_2-z_1,\ldots,z_n-z_{n-1})\in\mathcal{T}_+^n\}$. The condition H_2 of Lorentz covariance implies for any Lorentz transformation Λ,

$$U(\Lambda)\Phi_n(z_1,\ldots,z_n)=\Phi_n(\Lambda z_1,\ldots,\Lambda z_n)=Z_n(\Lambda\zeta_1,\ldots,\Lambda\zeta_n) \tag{8}$$

for all $(z_1,\ldots,z_n)$ such that $(z_1,z_2-z_1,\ldots,z_n-z_{n-1})\in\mathcal{T}_+^n$.

Remark: For $z=(z^0,\ldots,z^3)\in(\mathbf{C}\backslash\mathbf{R})^4$ introduce the function $h_z\in\mathcal{Q}(\mathbf{D}^4)$ defined by $h_z(t)=\Pi_{k=0}^3 e^{-(t^k-z^k)^2}/2\pi i(t^k-z^k)$. Then we have

$$f(t)=\int_{\Gamma^4}h_z(t)f(z)dz$$

for $f\in\mathcal{Q}(\mathbf{D}^4)$, where $\Gamma=\Gamma^+-\Gamma^-$, $\Gamma^\pm=\{z;z=\pm x\pm i\delta,-\infty<x<\infty\}$ is a suitable path in $(\mathbf{C}\backslash\mathbf{R})$.

For $u\in\mathcal{D}$ define a function F by $F(z_1,\ldots,z_n)=\Phi(h_{z_1})\cdots\Phi(h_{z_n})u$. Then $F(z_1,\ldots,z_n)$ is holomorphic in $(\mathbf{C}\backslash\mathbf{R})^{4n}$ and represents the vector-valued Fourier hyperfunction $\Phi(x_1)\cdots\Phi(x_n)u$ as follows:

$$\Phi(f_1)\cdots\Phi(f_n)u=\int_{\Gamma^{4n}}F(z_1,\ldots,z_n)f_1(z_1)\cdots f_n(z_n)\prod_{j=1}^{n}\prod_{k=0}^{3}dz_j^k. \tag{9}$$

And we say that $\Phi(x_1)\cdots\Phi(x_n)u$ is the boundary value of $\underline{F(z_1,\ldots,z_n)}$. Since $\Phi(h_{z_1})^*\cdots\Phi(h_{z_n})^*u=\Phi(h_{z_1}^*)\cdots\Phi(h_{z_n}^*)u=F(\overline{z_1},\ldots,\overline{z_n})$ [where $h_z^*(t)=h_z(\overline{t})=h_{\overline{z}}(t)$], hence $F(\overline{z_1},\ldots,\overline{z_n})$ represents the vector-valued Fourier hyperfunction $\Phi(x_1)^*\cdots\Phi(x_n)^*u$, we write

$$\Phi(x_1)^*\cdots\Phi(x_n)^*u=\Phi(\overline{x_1})\cdots\Phi(\overline{x_n})u \tag{10}$$

and have

$$\int_{\overline{\Gamma}^{4n}}F(\overline{z_1},\ldots,\overline{z_n})\overline{f_1(z_1)}\cdots\overline{f_n(z_n)}dz_1\cdots dz_n=\int_{\Gamma^{4n}}F(w_1,\ldots,w_n)f_1^*(w_1)\cdots f_n^*(w_n)dw_1\cdots dw_n.$$

In this notation we have in particular

$$\Phi(x_1)^*\cdots\Phi(x_n)^*\Phi_0=\Phi(\overline{x_1})\cdots\Phi(\overline{x_n})\Phi_0=\Phi(\overline{x_1},\ldots,\overline{x_n}). \tag{11}$$

With these basic analyticity properties we are well prepared to derive the main result of this section, an analogue of the much used Reeh–Schlieder theorem of standard QFT.

Proposition II.1 (HFQFT Reeh–Schlieder): Let U_n $(n=1,2,\ldots)$ be open nonempty sets in $\mathbf{R}^{4n}$ and u a vector of $\mathcal{H}$. If $(u,Z_n(\xi_1,\ldots,\xi_n))=0$ [respectively $(Z_n(\overline{\xi_1},\ldots,\overline{\xi_n}),u)=0$] in U_n as Fourier hyperfunctions for $n=0,1,2,\ldots$ (we use here $Z_0=\Phi_0$), then $u=0$.

Proof: Since $(u,Z_n(\zeta_1,\ldots,\zeta_n))$ [resp. $(Z_n(\overline{\zeta_1},\ldots,\overline{\zeta_n}),u)$] is holomorphic in $\mathcal{T}_+^n$ (respectively, in $\mathcal{T}_-^n$) and U_n is open in $\mathbf{R}^{4n}$ we get $(u,Z_n(\zeta_1,\ldots,\zeta_n))=0$ [respectively $(Z_n(\overline{\zeta_1},\ldots,\overline{\zeta_n}),u)=0$] in $\mathcal{T}_+^n$ (respectively, in $\mathcal{T}_-^n$) by edge of the wedge theorem (see Theorem 5.1 of Nagamachi and Nishimura[18]). Therefore $(u,\Phi(f_1)\cdots\Phi(f_n)\Phi_0)=0$ (respectively, $(\Phi(f_1)\cdots\Phi(f_n)\Phi_0,u)=0$) for any $f_k\in\mathcal{Q}(\mathbf{D}^4)$ for $n=0,1,2,\ldots$. By condition H_5 this implies $u=0$. □

B. Existence of a CPT-operator

There are several useful representations of the n-point functions $\mathcal{W}_n$ of the theory,

$$\mathcal{W}_n(z_1,\ldots,z_n)=(\Phi_k(\overline{z_k},\ldots,\overline{z_1}),\Phi_{n-k}(z_{k+1},\ldots,z_n))$$
$$=(\Phi_0,\Phi_n(z_1,\ldots,z_n)). \tag{12}$$

By translation invariance expressed in the form (7) the last term is equal to

$$(\Phi_0,Z_n(z_1,z_2-z_1,\ldots,z_n-z_{n-1}))$$

and thus it follows from the translation invariance of the vector Φ_0 that this quantity does not depend on z_1 when $\zeta_k=z_k-z_{k-1}$ is fixed for $k=2,\ldots,n$, and is denoted by W_{n-1}, i.e.,

$$\mathcal{W}_n(z_1,\ldots,z_n)=W_{n-1}(\zeta_2,\ldots,\zeta_n). \tag{13}$$

The function W_{n-1} is holomorphic in $\mathcal{T}_+^{n-1}$ and invariant under the proper Lorentz group $L_+^{\uparrow}$ since the vector Φ_0 is invariant under this group. We recall now some well-known results from standard QFT about the analytic continuation of the n-point functions. Since these results are based purely on analyticity arguments they apply in our context too. Accordingly the function W_{n-1} is analytically continued to a single valued $L_+(\mathbf{C})$-invariant function $\hat{W}_{n-1}$ which is analytic in the extended tube

$$\mathcal{T}'_{n-1}=\cup_{A\in L_+(\mathbf{C})}A\mathcal{T}_+^{n-1}$$

by the Bargmann–Hall–Wightman theorem.[19] $\mathcal{T}'_{n-1}$ contains real points called Jost points.[19] The Jost theorem[19] says that a real point $(\rho_2,\ldots,\rho_n)$ belongs to $\mathcal{T}'_{n-1}$ if, and only if, the convex cone $C(\rho_2,\ldots,\rho_n)$ generated by $\rho_2,\ldots,\rho_n$ contains only spacelike points. According to these results the n-point function $\mathcal{W}_n$ is analytically continued to a function $\hat{\mathcal{W}}_n$ which is analytic in

$$\mathcal{S}'_n=\{(z_1,\ldots,z_n)\in\mathbf{C}^{4n};z_k-z_{k-1}=\zeta_k\in\mathcal{T}'_{n-1}\}.$$

Condition H_4 (local commutativity) implies that $\hat{\mathcal{W}}_n$ is analytically continued to a function $\mathcal{W}_n^P$ which is symmetric and analytic in $\mathcal{S}_n^P$, the union of all domains generated from $\mathcal{S}'_n$ by arbitrary permutation of variables $z_1,\ldots,z_n$.

A certain weaker version of the locality condition H_4 called weak locality has found a number of successful applications in standard QFT because it can be characterized by a simple symmetry property (14) of the n-point functions. Since the proof of this characterization relies on analyticity arguments only it applies to HFQFT too, as we are going to show. First we recall that a hyperfunction quantum field is called *weakly local* iff for all n and all real points $(r_1,\ldots,r_n)$ in $\mathcal{S}'_n$ the relation $\hat{\mathcal{W}}_n(r_1,\ldots,r_n)=\hat{\mathcal{W}}_n(r_n,\ldots,r_1)$ holds. The announced characterization of weak locality is given by the following theorem:

Theorem II.2: *In a theory characterized by conditions H_1-H_3 and H_5 weak locality is equivalent to the following symmetry* (14) *for the n-point hyperfunctions $\mathcal{W}_n$, for all $n=2,3,\ldots$,*

$$\mathcal{W}_n(x_1,\ldots,x_n)=\mathcal{W}_n(-x_n,\ldots,-x_1)=\overline{\mathcal{W}_n(-x_1,\ldots,-x_n)}. \tag{14}$$

Proof: The arguments of Chap. V of Ref. 19 apply. □

Corollary II.3: The n-point functions of a hyperfunction quantum field theory satisfy the symmetry relations (14).

Proof: The condition H_4 of local commutativity implies weak locality. □

Theorem II.4 (TCP-Theorem): *A theory $(\mathcal{H},U,\mathcal{D},\Phi)$ characterized by conditions H_1-H_3 and H_5 is weakly local if, and only if, there is an antiunitary operator θ on $\mathcal{H}$ with the properties*

$$\theta\Phi_0=\Phi_0,\quad \theta\Phi(f_1)\cdots\Phi(f_n)\Phi_0=\Phi(f_1^-)\cdots\Phi(f_n^-)\Phi_0, \tag{15}$$

where $f_k^-(z)=\overline{f_k(-\bar{z})}$. *This antiunitary operator* θ *is called TCP-operator. It satisfies*

$$\theta^2=I,\quad \theta U(a,\Lambda)\theta=U(-a,\Lambda)\ \text{ on }\ \mathcal{H}, \tag{16}$$

$$\theta\Phi(f)\theta=\Phi(f^-)\ \text{ on }\ \mathcal{D}. \tag{17}$$

Proof: Since Theorem II.2 is established, the standard proof[19] applies. □

Corollary II.5: A hyperfunction quantum field theory has a TCP-operator θ.

Proof: Use Corollary II.3 and Theorem II.4. □

C. Analytic continuation over spatial wedges (Bisognano–Wichmann analyticity)

In the following we assume that a hyperfunction quantum field theory $(\mathcal{H},U,\mathcal{D},\Phi)$ is given as specified at the beginning of this section. We use the notation and the results from the previous sections without referring to them explicitly. Consider the following 1-parameter subgroup of the Lorentz group

$$v_t=\begin{pmatrix}\cosh t & \sinh t & 0 & 0\\ \sinh t & \cosh t & 0 & 0\\ 0 & 0 & 1 & 0\\ 0 & 0 & 0 & 1\end{pmatrix}\in G$$

and

$$g_-=v_{i\pi}=v_{-i\pi}=\begin{pmatrix}-1 & 0 & 0 & 0\\ 0 & -1 & 0 & 0\\ 0 & 0 & 1 & 0\\ 0 & 0 & 0 & 1\end{pmatrix}.$$

Then

$$V(t)=U(v_t)$$

is a 1-parameter group of unitary operators in the Hilbert space $\mathcal{H}$ which has a self-adjoint generator L. Thus, by functional calculus, we have an analytic continuation of $V(t)$ to $V(\tau)$, $\tau\in\mathbf{C}$. Clearly, when τ does not belong to $\mathbf{R}$, the linear operators $V(\tau)$ are unbounded. Following Bisognano–Wichmann[17] we will be able to give suitable domains for these unbounded operators and to identify their action. Relation (8) implies

$$V(t)Z_n(\zeta_1,\ldots,\zeta_n)=Z_n(\zeta_1(t),\ldots,\zeta_n(t)), \tag{18}$$

where $\zeta(t)=v_t\zeta$, for all $t\in\mathbf{R}$ and all $(\zeta_1,\ldots,\zeta_n)\in\mathcal{T}_+^n$. Recall that Z_n is holomorphic on $\mathcal{T}_+^n$. For $\tau=i\lambda,\lambda\in\mathbf{R}$ we calculate

$$\operatorname{Im}\zeta(i\lambda)^0=\operatorname{Im}\zeta^0\cos\lambda+\operatorname{Re}\zeta^1\sin\lambda,$$

$$\operatorname{Im}\zeta(i\lambda)^1=\operatorname{Im}\zeta^1\cos\lambda+\operatorname{Re}\zeta^0\sin\lambda,$$

and introduce the spatial wedges

$$W_\pm=\{x\in\mathbf{R}^4;\pm x^1>|x^0|\}, \tag{19}$$

and the following subcone of the forward light-cone V_+,

$$V_+^0=\{(\eta^0,\eta^1,\eta^2,\eta^3)\in V_+;\ \ \eta^2=\eta^3=0\}.$$

Then, for $\zeta_k=\xi_k+i\eta_k$ such that $\mathrm{Re}\,\zeta_k\in W_\pm$ and $\mathrm{Im}\,\zeta_k\in V_+^0$ we have $\mathrm{Im}\,\zeta_k(i\lambda)\in V_+^0\subset V_+$ for $\pm\lambda\in[0,\pi/2]$ and thus $Z_n(\zeta_1(i\lambda),\ldots,\zeta_n(i\lambda))$ is well defined. This allows to deduce the following lemma.

Lemma II.6: (a) Let $\zeta_k\in\mathcal{T}_+$ be such that $\zeta_k(i\lambda)\in\mathcal{T}_+$ for $\pm\lambda\in[0,\pi/2]$ and $k=1,...,n$, then $Z_n(\zeta_1,\ldots,\zeta_n)\in\mathrm{dom}\,V(i\lambda)$ and

$$V(i\lambda)Z_n(\zeta_1,\ldots,\zeta_n)=Z_n(\zeta_1(i\lambda),\ldots,\zeta_n(i\lambda)) \tag{20}$$

as an identity between vector-valued analytic functions.

(b) When $\mathrm{Im}\,\zeta_k\in V_+^0$ and $\mathrm{Re}\,\zeta_k\in W_\pm$, then $\zeta_k(i\lambda)\in\mathcal{T}_+$ for $\pm\lambda\in[0,\pi/2]$ and the conclusion of (a) applies.

Proof: The proof of the Lemma 8 of Ref. 17 works without modification. □

Now, the main results of this subsection are given in the following proposition.

Proposition II.7: As identities between analytic functions in $\xi=(\xi_1,\ldots,\xi_n)\in W_\pm^n$ the following holds:

(a) If $\Phi\in\mathrm{dom}\,\mathrm{V}(\pm i\pi/2)$, then

$$(V(\pm i\pi/2)\Phi,Z_n(\xi_1,\ldots,\xi_n))=(\Phi,Z_n(\xi_1(\pm i\pi/2),\ldots,\xi_n(\pm i\pi/2)), \tag{21}$$

and

$$(\Phi,Z_n(g_-\xi_1,\ldots,g_-\xi_n))=(V(\pm i\pi/2)\Phi,Z_n(\xi_1(\pm i\pi/2),\ldots,\xi_n(\pm i\pi/2)). \tag{22}$$

(b) If $\Psi\in\mathrm{dom}\,V(\pm i\pi)$, then

$$(V(\pm i\pi)\Psi,Z_n(\xi_1,\ldots,\xi_n))=(\Psi,Z_n(g_-\xi_1,\ldots,g_-\xi_n)). \tag{23}$$

(c) Define

$$J=U(0,R)\theta, \tag{24}$$

where θ is the CPT-operator of Theorem II.4 and R the Euclidean rotation by π around the x^1-axis. If $\Psi\in\mathrm{dom}\,V(\pm i\pi)$, then

$$(V(\pm i\pi)\Psi,Z_n(\xi_1,\ldots,\xi_n))=(\Psi,JZ_n(\overline{\xi_1},\ldots,\overline{\xi_n})). \tag{25}$$

Proof: For $\mathrm{Im}\,\zeta_k\in V_+^0$ and $\xi_k=\mathrm{Re}\,\zeta_k\in W_\pm$ we know by Lemma II.6,

$$(V(\pm i\pi/2)\Phi,Z_n(\zeta_1,\ldots,\zeta_n))=(\Phi,Z_n(\zeta_1(\pm i\pi/2),\ldots,\zeta_n(\pm i\pi/2)). \tag{26}$$

The left-hand side of (26) is holomorphic in $\mathbf{R}^{4n}+iV_+^n$ and it defines a hyperfunction on $\mathbf{R}^{4n}$. There exists a neighborhood U of $\xi=(\xi_1,\ldots,\xi_n)$ in $W_\pm^n$ and $\delta>0$ such that the right-hand side of (26) is holomorphic in $U+iV_{+,\delta}^n$ and $U-iV_{+,\delta}^n$, where $V_{+,\delta}=\{\eta\in V_+;\eta^0<\delta\}$, and it defines a hyperfunction on U (see Theorem 4.4 of Ref. 18). Since both sides of (26) coincide in $U+iV_{+,\delta}^n$, they define the same hyperfunction in U. Since $\xi\in W_\pm^n$ is arbitrary, by the localization (sheaf) property of hyperfunctions, Eq. (21) holds in $W_\pm^n$ as an identity for hyperfunctions.

The left-hand side of (21) is a boundary value from $\mathbf{R}^{4n}+iV_+^n$, and the right-hand side a boundary value from both $U+iV_{+,\delta}^n$ and $U-iV_{+,\delta}^n$. Hence, by the edge of the wedge theorem, both sides are analytic in U. Again, since $\xi\in W_\pm^n$ is arbitrary, we deduce that Eq. (21) holds as an identity for analytic functions.

Now Eq. (22) follows from (21) and the following chain of identities:

$$(\Phi, Z_n(g_-\xi_1,\ldots,g_-\xi_n)) = (V(\pm i\pi/2)\Phi, Z_n(g_-\xi_1(\mp i\pi/2),\ldots,g_-\xi_n(\mp i\pi/2))$$
$$= (V(\pm i\pi/2)\Phi, Z_n(\xi_1(\pm i\pi/2),\ldots,\xi_n(\pm i\pi/2)).$$

From spectral calculus we know that if $\Psi \in \operatorname{dom} V(\pm i\pi)$ then $V(\pm i\pi/2)\Psi \in \operatorname{dom} V(\pm i\pi/2)$ and $V(\pm i\pi/2)V(\pm i\pi/2)\Psi = V(\pm i\pi)\Psi$. Thus Eqs. (21) and (22) apply and yield

$$(V(\pm i\pi)\Psi, Z_n(\xi_1,\ldots,\xi_n)) = (V(\pm i\pi/2)\Psi, Z_n(\xi_1(\pm i\pi/2),\ldots,\xi_n(\pm i\pi/2))$$
$$= (\Psi, Z_n(g_-\xi_1,\ldots,g_-\xi_n)).$$

Thus part (b) follows.

According to Sec. II B, the operator $J = U(0,R)\theta$ has the following properties:

$$J^2 = I, \quad J\Phi_0 = \Phi_0, \quad J\Phi(\overline{x})J = \Phi(g_-x), \tag{27}$$

$$JU(a,\Lambda)J = U(g_-a, g_-\Lambda g_-), \quad JV(t)J = V(t) \tag{28}$$

for all $t \in \mathbf{R}$. Now it follows from (23), for all $(\xi_1,\ldots,\xi_n) \in W_\pm^n$,

$$(V(\pm i\pi)\Psi, Z_n(\xi_1,\ldots,\xi_n)) = (\Psi, Z_n(g_-\xi_1,\ldots,g_-\xi_n))$$
$$= (\Psi, J\Phi(\overline{x_1})\cdots\Phi(\overline{x_n})\Phi_0) = (\Psi, JZ_n(\overline{\xi_1},\ldots,\overline{\xi_n})),$$

and we conclude (c). □

III. MODULAR ASPECTS

In standard QFT the modular theory for the O^*-algebra $\mathcal{P}(W_\pm)$ on $\mathcal{D}$ generated by the field operators $\Phi(f)$, $f \in \mathcal{S}(\mathbf{R}^4)$, $\operatorname{supp} f \subset W_\pm$, is fully developed. The maps

$$X\Phi_0 \to X^*\Phi_0, \quad X \in \mathcal{P}(W_\pm)$$

are closable and their closures $S_\pm$ satisfy

$$S_+ = S_-^* = JV(i\pi)$$

(see Theorem 4.52 in Inoue[20]).

Here, in HFQFT we develop certain aspects of this theory, needed for the proof of locality of our assignment of *-algebras of bounded operators to the wedges $W_\pm$. We are going to show that in our case too these maps are implemented as above.

A. Modular relation

For $\lambda \in \mathbf{R}$ introduce the subspace

$$\mathcal{D}_V(\lambda) = (1 + V(i\lambda))^{-1}\mathcal{H}$$

and observe that for $\lambda > 0$ (resp. $\lambda < 0$), $\mathcal{D}_V(\lambda)$ is a core for all $V(\tau)$ with $0 \leqslant \operatorname{Im}\tau \leqslant \lambda$ (resp. $0 \geqslant \operatorname{Im}\tau \geqslant \lambda$). For all $u \in \mathcal{D}_V(\lambda)$ the function $\tau \to V(\tau)u$ is strongly continuous and bounded in $0 \leqslant \operatorname{Im}\tau \leqslant \lambda$ (resp. $0 \geqslant \operatorname{Im}\tau \geqslant \lambda$) and analytic in the interior of this set. The operators $V(\tau)$, τ as above, are transformed under the operator J of Eq. (28) as follows:

$$J\mathcal{D}_V(\lambda) = \mathcal{D}_V(-\lambda), \quad JV(\tau)J = V(\overline{\tau}),$$

and

$$J\mathcal{V}(W_\pm)J = \mathcal{V}(W_\mp).$$

Denote $\mathcal{D}_\pm = \mathcal{D}_V(\pm\pi)$ and define

$$\mathcal{A}_\pm = \{X \in \mathcal{B}(\mathcal{H});\ \ X\Phi_0 \in \mathcal{D}_\pm\},$$

$$\mathcal{V}(W_\pm) = \{X \in \mathcal{A}_\pm;\ \ V(\pm i\pi)X\Phi_0 = JX^*\Phi_0\}. \tag{29}$$

The following two propositions provide important details about these sets of operators.

Proposition III.1: (a) $\mathcal{V}(W_\pm)\Phi_0 = \mathcal{D}_\pm$.

(b) Whenever $X_1, X_2 \in \mathcal{V}(W_\pm)$ *satisfy the condition* $X_1 V(t) X_2^* V(t)^* \in \mathcal{V}(W_\pm)$ *for all* $t \in \mathbf{R}$, *then*

$$X_1(JX_2J)\Phi_0 = (JX_2J)X_1\Phi_0. \tag{30}$$

Proof: For $u \in \mathcal{D}_\pm$ define, for all $v \in \mathcal{H}$,

$$Z_\pm(u)v = u(\Phi_0, v) + \Phi_0(JV(\pm i\pi)u, v) - (\Phi_0, u)(\Phi_0, v)\Phi_0.$$

Clearly, $Z_\pm(u)$ are bounded linear operators on $\mathcal{H}$, and for $v = \Phi_0$ we have

$$Z_\pm(u)\Phi_0 = u(\Phi_0, \Phi_0) + \Phi_0(JV(\pm i\pi)u, \Phi_0) - (\Phi_0, u)(\Phi_0, \Phi_0)\Phi_0 = u.$$

In order to determine the adjoints of the operators $Z_\pm(u)$ we calculate for all $w,\ v \in \mathcal{H}$,

$$\begin{aligned}(Z_\pm(u)^*w, v) &= (w, Z_\pm(u)v)\\ &= (w, u(\Phi_0, v) + \Phi_0(JV(\pm i\pi)u, v) - (\Phi_0, u)(\Phi_0, v)\Phi_0)\\ &= (w, u)(\Phi_0, v) + (w, \Phi_0)(JV(\pm i\pi)u, v) - (w, \Phi_0)(\Phi_0, u)(\Phi_0, v)\\ &= (\overline{(w, u)}\Phi_0, v) + (\overline{(w, \Phi_0)}JV(\pm i\pi)u, v) - (\overline{(w, \Phi_0)(\Phi_0, u)}\Phi_0, v)\end{aligned}$$

It follows, for all $w \in \mathcal{H}$,

$$Z_\pm(u)^*w = \overline{(w, u)}\Phi_0 + \overline{(w, \Phi_0)}JV(\pm i\pi)u - \overline{(w, \Phi_0)(\Phi_0, u)}\Phi_0,$$

and therefore

$$Z_\pm(u)^*\Phi_0 = \overline{(\Phi_0, u)}\Phi_0 + \overline{(\Phi_0, \Phi_0)}JV(\pm i\pi)u - \overline{(\Phi_0, \Phi_0)(\Phi_0, u)}\Phi_0 = JV(\pm i\pi)u.$$

This shows that $Z_\pm(u) \in \mathcal{V}(W_\pm)$ and $\mathcal{V}(W_\pm)\Phi_0 = \mathcal{D}_\pm$ and thus proves part (a).

In order to prove part (b) let $X_1,\ X_2 \in \mathcal{V}(W_\pm)$ be given which satisfy the hypothesis of part (b). Then we know, with $X = X_1 V(t) X_2^* V(t)^*,\ t \in \mathbf{R}$, that $V(\pm i\pi)X\Phi_0 = JX^*\Phi_0$ holds. Thus we have

$$V(\pm i\pi)X_1 V(t)X_2^*\Phi_0 = JV(t)X_2 V(t)^* X_1^*\Phi_0.$$

By the same argument for $X = X_1$ and $X = X_2$ we deduce

$$V(\pm i\pi)X_1 V(t)JV(\pm i\pi)X_2\Phi_0 = JV(t)X_2 V(t)^* JV(\pm i\pi)X_1\Phi_0.$$

Finally we employ the relations of Sec. II C between J and $V(t)$ and the group properties of $V(\tau)$ for complex τ and get

$$V(\pm i\pi)X_1 JV(t \pm i\pi)X_2 J\Phi_0 = V(t)JX_2 JV(\pm i\pi - t)X_1\Phi_0$$

and

$$V(\pm i\pi - t)X_1 JV(t \pm i\pi)X_2\Phi_0 = JX_2 JV(\pm i\pi - t)X_1\Phi_0. \tag{31}$$

Now take any $\Psi \in \mathcal{H}$ and a cutoff function $c \in \mathcal{D}(\mathbf{R})$ and consider the three vector-valued functions with complex variable τ,

$$X_1 JV(\overline{\tau} \pm i\pi) X_2 \Phi_0, \quad JX_2 JV(\pm i\pi - \tau) X_1 \Phi_0, \quad V(\overline{\tau} \pm i\pi) c(L)\Psi.$$

These functions are strongly continuous on the closed strip $0 \leqslant \pm \operatorname{Im} \tau \leqslant \pi$. The first two functions are analytic in $0 < \pm \operatorname{Im} \tau < \pi$ and the third is entire analytic in $\overline{\tau}$. Therefore the function

$$f(\tau) = (V(\overline{\tau} \pm i\pi) c(L)\Psi, \quad X_1 JV(\overline{\tau} \pm i\pi) X_2 \Phi_0) - (c(L)\Psi, JX_2 JV(\pm i\pi - \tau) X_1 \Phi_0)$$

is continuous in $0 \leqslant \pm \operatorname{Im} \tau \leqslant \pi$ and analytic in $0 < \pm \operatorname{Im} \tau < \pi$. By Eq. (31) we know $f(\tau) = 0$ for all real τ; it follows $f(\pm i\pi) = 0$, i.e.,

$$(c(L)\Psi, \quad X_1 JX_2 \Phi_0) = (c(L)\Psi, JX_2 JX_1 \Phi_0).$$

Since $\Psi \in \mathcal{H}$ and $c \in \mathcal{D}(\mathbf{R})$ are arbitrary, we have $X_1 JX_2 J\Phi_0 = JX_2 JX_1 \Phi_0$. This proves part (b). □

Proposition III.2: An operator $X \in \mathcal{A}_\pm$ belongs to the set $\mathcal{V}(W_\pm)$, i.e., it satisfies the equation

$$V(\pm i\pi) X\Phi_0 = JX^*\Phi_0$$

if, and only if, for all $n = 1,2,\ldots$,

$$(X^*\Phi_0, Z_n(\xi_1, \ldots, \xi_n))_{|W^n_\mp} = (Z_n(\overline{\xi_1}, \ldots, \overline{\xi_n}), X\Phi_0)_{|W^n_\mp}. \tag{32}$$

Proof: Assume first that $X \in \mathcal{V}(W_\pm)$ is given. For all $\xi = (\xi_1, \ldots, \xi_n) \in W^n_\mp$ we obtain, using $V(\pm i\pi) X\Phi_0 = JX^*\Phi_0$, and the relations for J from above,

$$(X^*\Phi_0, Z_n(\xi)) = (JV(\pm i\pi) X\Phi_0, Z_n(\xi)) = (V(\mp i\pi) JX\Phi_0, Z_n(\xi)).$$

Now Eq. (25) implies that this equals

$$(JX\Phi_0, JZ_n(\overline{\xi})) = (Z_n(\overline{\xi}), \quad X\Phi_0).$$

Hence relation (32) is necessary.

Conversely assume that X is a bounded linear operator on $\mathcal{H}$ for which relation (32) holds. Since $X\Phi_0 \in \mathcal{D}_\pm$ we can use (25) and get from relation (32)

$$\begin{aligned}(X^*\Phi_0, Z_n(\xi_1, \ldots, \xi_n))_{|W^n_\mp} &= (Z_n(\overline{\xi_1}, \ldots, \overline{\xi_n}), X\Phi_0)_{W^n_\mp} \\ &= (JX\Phi_0, JZ_n(\overline{\xi}))_{|W^n_\mp} = (V(\mp i\pi) JX\Phi_0, Z_n(\xi))_{|W^n_\mp}.\end{aligned}$$

Hence Proposition II.1 implies

$$X^*\Phi_0 = V(\mp i\pi) JX\Phi_0 = JV(\pm i\pi) X\Phi_0.$$

Therefore condition (32) is sufficient. □

B. Growth restriction and the domain problem

The temperedness of the distributions allows to show in standard QFT that the condition $X\Phi_0 \in \operatorname{dom} V(\pm i\pi)$ follows from condition (32). The proof relies on the fact that compactly supported testfunctions are available.

Compared to tempered distributions Fourier hyperfunctions can grow much stronger. Accordingly we impose a (mild) growth restriction on our theory. This growth condition [see Eq. (37)]

allows us to control the domains of the operators $V(\pm i\pi)$ and then we are able to prove $\mathcal{L}'_w(W_\mp)\subset\mathcal{A}_\pm$. This control of the domain is achieved by using a suitable rapidly decreasing cut-off function,

$$f(t)=c\exp(-\cosh t), \tag{33}$$

where $c>0$ is a number such that

$$\int_{-\infty}^{\infty} f(t)dt=1.$$

For $\mu>0$ denote

$$f_\mu(t)=\mu f(\mu t).$$

Lemma III.3: Let $0<\epsilon<\pi/2\mu$. Then the Fourier transform

$$\tilde{f}_\mu(p)=\int e^{ipt}f_\mu(t)dt$$

of f_μ is an entire function which satisfies the estimate

$$|\tilde{f}_\mu(p)|\leqslant M(\epsilon,\mu)e^{-\epsilon|p|} \tag{34}$$

for some $M(\epsilon,\mu)>0$, and

$$\tilde{f}_\mu(p)\to 1$$

as $\mu\to\infty$ for every p.

Proof: The identity

$$|f_\mu(t+is)|=c\mu\exp(-\cosh\mu t\cos\mu s)$$

follows from the equality

$$f_\mu(t+is)=c\mu\exp(-\cosh\mu t\cos\mu s-i\sinh\mu t\sin\mu s).$$

If $|s|<\pi/2\mu$ then $f_\mu(t+is)\to 0$ decays faster than exponentially as $t\to\pm\infty$. Therefore $\tilde{f}_\mu(p)$ is an entire function of p. Since $f_\mu(t)\to\delta(t)$ as $\mu\to\infty$,

$$\tilde{f}_\mu(p)\to 1$$

as $\mu\to\infty$ for every p.

Let $0<\epsilon<\pi/2\mu$. Then

$$\begin{aligned}|e^{\pm\epsilon p}\tilde{f}_\mu(p)|&=(2\pi)^{-1/2}\left|\int e^{ip(t\pm i\epsilon)}f_\mu(t)dt\right|\\&=(2\pi)^{-1/2}\left|\int e^{ipt}f_\mu(t\mp i\epsilon)dt\right|<\infty\end{aligned}$$

and we have

$$|\tilde{f}_\mu(p)|\leqslant M(\epsilon,\mu)e^{-\epsilon|p|}$$

for some $M(\epsilon,\mu)>0$. □

Lemma III.4: Let $V(t)=e^{itL}$. *Then, for all* $\mu>0$, $V(\pm i\epsilon)\tilde{f}_\mu(L)$ *is a bounded operator for* $\epsilon<\pi/2\mu$.

Proof: It follows from (34) that $|e^{\pm\epsilon p}\tilde{f}_\mu(p)|\leqslant M(\epsilon,\mu)$. Therefore, by spectral calculus, $\tilde{f}_\mu(L)$ maps $\mathcal{H}$ into the domain of $V(\pm i\epsilon)$ and

$$V(\pm i\epsilon)\tilde{f}_\mu(L)=\int_{-\infty}^{\infty}e^{\pm\epsilon p}\tilde{f}_\mu(p)dE(p)$$

is a bounded operator, where $E(p)$ is the spectral measure of the self-adjoint operator L. □

Recall the definition of the vector-valued Fourier hyperfunctions,

$$Z_n(\xi_1,\ldots,\xi_n)=\Phi(x_0)\Phi(x_1)\cdots\Phi(x_n)\Phi_0$$

with $\xi_j=x_j-x_{j-1}$ for $j=1,\ldots,n$. It is the boundary value of a slowly increasing vector-valued holomorphic function $Z_n(\zeta)$ in the forward tube, $\zeta=(\zeta_1,\ldots,\zeta_n)\in\mathcal{T}_+^n$ which, by Lorentz covariance, satisfies the relation

$$V(t)Z_n(\zeta)=Z_n(\zeta(t)) \tag{35}$$

for $\zeta\in\mathcal{T}_+^n$ and $\zeta(t)=v_t\zeta$. Both sides of Eq. (35) are holomorphic functions on $\mathcal{T}_+^n$, thus they define the same Fourier hyperfunctions. So, we denote

$$V(t)Z_n(\xi)=Z_n(\xi(t))$$

with $\zeta(t)=v_t\zeta$.

Lemma III.5: Suppose X *is a bounded operator on* $\mathcal{H}$ *for which the two Fourier hyperfunctions* $(X^*\Phi_0,Z_n(\xi))$ *and* $(Z_n(\overline{\xi}),X\Phi_0)$ *coincide on some open nonempty set* O *in* $\mathbf{R}^{4n}$. *Then both Fourier hyperfunctions are actually analytic functions in* O *and coincide there as analytic functions.*

Proof: $Z_n(\overline{\zeta})$ is a vector-valued slowly increasing holomorphic function in the backward tube $\mathcal{T}_-^n$ and defines a Fourier hyperfunction $Z_n(\overline{\xi})$ on $\mathbf{R}^{4n}$. From our assumption it follows that the two Fourier hyperfunctions $(X^*\Phi_0,Z_n(\xi))$ and $(Z(\overline{\xi}),X\Phi_0)$ coincide in O. By the Edge of the Wedge theorem for Fourier hyperfunction[18] we conclude. □

With the notation introduced in Sec. III A we define

$$\mathcal{V}(W_\pm)=\{X\in\mathcal{B}(\mathcal{H});X\Phi_0\in\mathcal{D}_\pm \text{ and } V(\pm i\pi)X\Phi_0=JX^*\Phi_0\}$$

and formulate the main result of this section.

Theorem III.6: *If for a bounded operator* X *on* $\mathcal{H}$ *one knows for all* n,

$$(X^*\Phi_0,Z_n(\xi))_{|W_\mp^n}=(Z_n(\overline{\xi}),X\Phi_0)_{|W_\mp^n}, \tag{36}$$

and if for every n *there are non-negative constants* M_n *and* K_n *such that*

$$|(X^*\Phi_0,Z_n(\xi(t)))|=|(Z_n(\overline{\xi}(t)),X\Phi_0)|\leqslant M_ne^{K_n\cosh t}, \tag{37}$$

then $X\in\mathcal{V}(W_\pm)$.

Proof: According to the preceding lemma we know that the growth restriction (37) for analytic functions is meaningful even if the coincidence relation (36) is originally assumed in the sense of Fourier hyperfunctions.

We employ the cut-off functions f_μ introduced above and show in a first step

$$(\tilde{f}_\mu(L)X^*\Phi_0,Z_n(\xi))_{|W_\mp^n}=(Z_n(\overline{\xi}),\tilde{f}_\mu(L)X\Phi_0)_{|W_\mp^n}$$

for large μ. To begin, observe that the properties of the cut-off function and the growth restriction (37) imply that the integrals

$$\int f_\mu(t)(X^*\Phi_0, Z_n(\xi(t)))dt \quad \text{and} \quad \int f_\mu(t)(Z_n(\overline{\xi}(t)), X\Phi_0)dt$$

exist if $\mu > 1$, and we have

$$\begin{aligned}(\tilde{f}_\mu(L)X^*\Phi_0, Z_n(\xi)) &= \int f_\mu(t)(V(t)X^*\Phi_0, Z_n(\xi))dt \\ &= \int f_\mu(t)(X^*\Phi_0, Z_n(\xi(t)))dt \\ &= \int f_\mu(t)(Z(\overline{\xi}(t)), X\Phi_0)dt \\ &= \int f_\mu(t)(Z(\overline{\xi}), V(t)X\Phi_0)dt = (Z_n(\overline{\xi}), \tilde{f}_\mu(L)X\Phi_0),\end{aligned}$$

where we used the coincidence relation (36) in the third equation.

In a second step we show that

$$(\tilde{f}_\mu(L)X^*\Phi_0, Z_n(\xi(t))) \quad \text{and} \quad (Z_n(\overline{\xi}(t)), \tilde{f}_\mu(L)X\Phi_0)$$

are bounded functions of $t \in \mathbf{R}$: It follows from Lemma III.4 that the vectors $\tilde{f}_\mu(L)X^*\Phi_0$ and $\tilde{f}_\mu(L)X\Phi_0$ belong to the domain of the operators $V(\pm i\epsilon)$ for $0 < \epsilon < \pi/2\mu$. Since $\xi(\mp i\epsilon) \in \mathcal{T}_+^n$ if $\xi \in W_\mp^n$, $Z_n(\xi(\mp i\epsilon))$ is a well defined vector in $\mathcal{H}$. By part (b) of Lemma II.6 the following is known: If $\zeta_j = \xi_j + i\eta_j \in W_\pm + iV_+^0$ for $j = 1,...,n$ then, for all $t \in \mathbf{R}$, $Z_n(\zeta(t)) \in \operatorname{dom} V(\mp i\epsilon)$ and $V(\mp i\epsilon)Z_n(\zeta(t)) = Z_n(\zeta(t \mp i\epsilon)) = V(t)Z_n(\zeta(\mp i\epsilon))$. Thus it follows

$$\begin{aligned}(V(\pm i\epsilon)\tilde{f}_\mu(L)X^*\Phi_0, V(t)Z_n(\zeta(\mp i\epsilon))) &= (V(\pm i\epsilon)\tilde{f}_\mu(L)X^*\Phi_0, V(\mp i\epsilon)Z_n(\zeta(t))) \\ &= (\tilde{f}_\mu(L)X^*\Phi_0, Z_n(\zeta(t))).\end{aligned}$$

Observing Lemma III.5 we can take the limit $\eta \to 0$ and get the identity

$$(\tilde{f}_\mu(L)X^*\Phi_0, Z_n(\xi(t))) = (V(\pm i\epsilon)\tilde{f}_\mu(L)X^*\Phi_0, V(t)Z_n(\xi(\mp i\epsilon)))$$

and hence

$$|(\tilde{f}_\mu(L)X^*\Phi_0, Z_n(\xi(t))| \leq \|V(\pm i\epsilon)\tilde{f}_\mu(L)X^*\Phi_0\| \|Z_n(\xi(\mp i\epsilon)\|$$

for all $t \in \mathbf{R}$. Similarly one proves the boundedness of the second function $(Z_n(\overline{\xi}(t)), \tilde{f}_\mu(L)X\Phi_0)$.

In a third step we use another cut-off function $c(p) \in \mathcal{D}_{\mathbf{R}}(\mathbf{R})$, i.e., a real valued C^∞-function with compact support, and show

$$(c(L)\tilde{f}_\mu(L)X^*\Phi_0, Z_n(\xi)) = (JV(\pm i\pi)c(-L)J\tilde{f}_\mu(L)X\Phi_0, Z_n(\xi)).$$

Let

$$\check{c}(t) = (2\pi)^{-1}\int_{\mathbf{R}} e^{-itp}c(p)dp \in \mathcal{S}(\mathbf{R})$$

be the inverse Fourier transform of $c(p)$. Then $c(L)J\tilde{f}_\mu(L)X\Phi_0 \in \mathrm{dom}\, V(\mp i\pi)$ and, by the previous step, the integrals

$$\int_{\mathbf{R}} \check{c}(t)(\tilde{f}_\mu(L)X^*\Phi_0, Z_n(\xi(t))dt \quad \text{and} \quad \int_{\mathbf{R}} \check{c}(t)(Z_n(\overline{\xi}(t)), \tilde{f}_\mu(L)X\Phi_0)dt$$

exist. Thus we have for all $\xi \in W^n_{\mp}$,

$$\begin{aligned}
(c(L)\tilde{f}_\mu(L)X^*\Phi_0, Z_n(\xi)) &= \int_{\mathbf{R}} (\check{c}(-t)V(-t)\tilde{f}_\mu(L)X^*\Phi_0, Z_n(\xi))dt \\
&= \int_{\mathbf{R}} \check{c}(t)(\tilde{f}_\mu(L)X^*\Phi_0, V(t)Z_n(\xi))dt \\
&= \int_{\mathbf{R}} \check{c}(t)(\tilde{f}_\mu(L)X^*\Phi_0, Z_n(\xi(t))dt \\
&= \int_{\mathbf{R}} \check{c}(t)(Z_n(\overline{\xi}(t)), \tilde{f}_\mu(L)X\Phi_0)dt \\
&= \int_{\mathbf{R}} \check{c}(t)(Z_n(\overline{\xi}), V(-t)\tilde{f}_\mu(L)X\Phi_0)dt \\
&= (Z_n(\overline{\xi}), c(-L)\tilde{f}_\mu(L)X\Phi_0) = (Jc(-L)\tilde{f}_\mu(L)X\Phi_0, JZ_n(\overline{\xi})) \\
&= (V(\mp i\pi)Jc(-L)\tilde{f}_\mu(L)X\Phi_0, Z_n(\xi)) \\
&= (JV(\pm i\pi)c(-L)\tilde{f}_\mu(L)X\Phi_0, Z_n(\xi)),
\end{aligned}$$

where we used the relations $V(\mp i\pi)J = JV(\pm i\pi)$ and

$$(\Psi, JZ_n(\overline{\xi})) = (V(\mp i\pi)\Psi, Z_n(\xi))$$

for $\Psi \in \mathrm{dom}\, V(\mp i\pi)$ (see Proposition II.7). By the Reeh–Schlieder theorem for hyperfunction quantum fields (Proposition II.1) we have

$$c(L)\tilde{f}_\mu(L)X^*\Phi_0 = JV(\pm i\pi)c(-L)\tilde{f}_\mu(L)X\Phi_0.$$

The final step removes the cut-offs. Let $c(p) \in \mathcal{D}_{\mathbf{R}}(\mathbf{R})$ such that $c(p)=1$ for $|p| \leqslant 1$ and introduce $c_\mu(p) = c(p/\mu)$ for $\mu > 0$. Then we have, as $\mu \to \infty$,

$$c_\mu(L)\tilde{f}_\mu(L)X^*\Phi_0 \to X^*\Phi_0, \quad c_\mu(-L)\tilde{f}_\mu(L)X\Phi_0 \to X\Phi_0.$$

Thus the relation

$$Jc_\mu(L)\tilde{f}_\mu(L)X^*\Phi_0 = V(\pm i\pi)c_\mu(-L)\tilde{f}_\mu(L)X\Phi_0$$

for all sufficiently large μ and the closedness of the self-adjoint operators $V(\pm i\pi)$ imply $X\Phi_0 \in \mathrm{dom}\, V(\pm i\pi)$ and $V(\pm i\pi)X\Phi_0 = JX^*\Phi_0$. □

IV. WEAK COMMUTANTS OF FIELD OPERATORS

Let $(\mathcal{H}, U, \mathcal{D}, \Phi)$ be a hyperfunction quantum field theory. For $u, v \in \mathcal{D}_0$, $n = 1,2,\ldots$, and $X \in \mathcal{B}(\mathcal{H})$ define the Fourier hyperfunction

$$\Psi_{X;n,u,v}(x_1,\ldots,x_n) = (X^*u, \Phi(x_1)\cdots\Phi(x_n)v) - (\Phi(\overline{x_n})\cdots\Phi(\overline{x_1})u, Xv). \tag{38}$$

If this Fourier hyperfunction vanishes on an open set O^n, $O\subset\mathbf{D}^4$, i.e., if $\Psi_{X;n,u,v}|O^n=0$, then this means intuitively that the operator X commutes weakly with the field operators localized on O.

To any open nonempty set O in $\mathbf{D}^4$ we assign the following set of bounded linear operators on the state space $\mathcal{H}$:

$$\begin{aligned}\mathcal{L}'_w(O)&=\{X\in\mathcal{B}(\mathcal{H});\ \ \Psi_{X;n,u,v}|O^n=0,\ \ \forall u,v\in\mathcal{D}_0,\ \ \forall n\in\mathbb{N}\}\\&=\{X\in\mathcal{B}(\mathcal{H});\ \ \operatorname{supp}\Psi_{X;n,u,v}\subset\mathbf{D}^{4n}\setminus O^n,\ \ \forall n\in\mathbb{N},\ \ \forall u,v\in\mathcal{D}_0\}.\end{aligned}\tag{39}$$

These sets $\mathcal{L}'_w(O)$ will be our starting point for the assignment of algebras $\mathcal{M}(O)$ to nonempty sets of space–time. In case O is a wedge $W_{\pm}$ or a double cone we will be able to show the locality of this assignment.

Clearly, a much simpler and more natural definition would be to consider all those bounded operators on $\mathcal{H}$ which commute weakly with $\Phi(x)$, $x\in O$ as it is done in standard QFT. In this section, by relying on some recent progress in the theory of Fourier hyperfunctions we show that actually the two definitions agree. To this end we introduce

$$\begin{aligned}L'(O)=\{&X\in\mathcal{B}(\mathcal{H});\forall u\in\mathcal{D}_0,\forall v\in\mathcal{D}_0,\\&\operatorname{supp}[(X^*u,\Phi(x)v)-(\Phi(x)^*u,Xv)]\subset\mathbf{D}^4\setminus O\}\end{aligned}$$

and show $\mathcal{L}'_w(O)=L'(O)$.

Recall the following general form of Schwartz' kernel theorem for Fourier hyperfunctions (Theorem 3.2 of Ref. 21):

Theorem IV.1: *Let K_i be a closed subset of $\mathbf{D}^{k_i}$ for $i=1,2,\ldots,N$. Then, for every separately continuous N-linear form B on $G=\mathcal{Q}(K_1)\times\cdots\times\mathcal{Q}(K_N)$ there is a unique Fourier hyperfunction F_B on $K_1\times\cdots\times K_N$, i.e., $F_B\in\mathcal{Q}(K_1\times\cdots\times K_N)'$ such that for all $(g_1,\ldots,g_N)\in G$,*

$$B(g_1,\ldots,g_N)=F_B(g_1\otimes\cdots\otimes g_N).$$

We have to comment on this result. $K_1\times\cdots\times K_N$ is a subset of $\mathbf{D}^{k_1}\times\cdots\times\mathbf{D}^{k_N}$, but not of $\mathbf{D}^n$, $n=\Sigma_{i=1}^N k_i$, in general. Accordingly elements $\mu\in\mathcal{Q}(K_1\times\cdots\times K_N)'$ have to be considered as elements of $\mathcal{Q}(\Pi_{i=1}^N\mathbf{D}^{k_i})'$ with support in $K_1\times\cdots\times K_N$. But hyperfunctions in n variables are defined on $\mathbf{D}^n$, the radial compactification of $\mathbf{R}^n$; and in this sense we need the above result. However we can choose a fundamental sequence of neighborhoods $\{U_m\}$ (resp. $\{V_m\}$) of $\mathbf{D}^n$ (resp. $\Pi_{i=1}^N\mathbf{D}^{k_i}$) such that $U_m\cap\mathbf{C}^n=V_m\cap\mathbf{C}^n=\{z\in\mathbf{C}^n;|\operatorname{Im}z|<1/m\}$. Thus we deduce $\mathcal{Q}(\mathbf{D}^n)=\mathcal{Q}(\Pi_{i=1}^N\mathbf{D}^{k_i})$ and consequently, $\mathcal{Q}(\mathbf{D}^n)'=\mathcal{Q}(\Pi_{i=1}^N\mathbf{D}^{k_i})'$ though $\mathbf{D}^n\neq\Pi_{i=1}^N\mathbf{D}^{k_i}$.

As a further preparation we prove

Lemma IV.2: Let O be an open set in $\mathbf{R}^4$. Then,

$$\mathcal{Q}(\mathbf{D}^{4n}\setminus O^n)=\mathcal{Q}((\mathbf{D}^4)^n\setminus O^n).\tag{40}$$

Proof: Let

$$O_m=\{x\in O;\operatorname{dist}(x,\partial O)>1/m\}.$$

Then $\mathbf{R}^{4n}\setminus O_m^n$ $(m=1,\ldots)$ is a fundamental system of neighborhoods of $\mathbf{R}^{4n}\setminus O^n$ in $\mathbf{R}^{4n}$. Since $\mathbf{D}^{4n}\setminus\mathbf{R}^{4n}=S_\infty^{4n-1}$, we can choose a fundamental system of neighborhoods U_m $(m=1,\ldots)$ of $\mathbf{D}^{4n}\setminus O^n$ in $\mathbf{Q}^{4n}$ such that

$$U_m\cap\mathbf{C}^{4n}=\{x\in\mathbf{R}^{4n};\|x\|>m\}\cup\mathbf{R}^{4n}\setminus O_m^n+i\{y\in\mathbf{R}^{4n};\|y\|<1/m\}.$$

Since $(\mathbf{D}^4)^n\setminus\mathbf{R}^{4n}=\cup_{j=1}^n(\mathbf{D}^4)^{j-1}\times S_\infty^3\times(\mathbf{D}^4)^{n-j}$, we can choose a fundamental system of neighborhoods V_m $(m=1,\ldots)$ of $(\mathbf{D}^4)^n\setminus O^n$ in $(\mathbf{Q}^4)^n$ such that

$$V_m\cap\mathbf{C}^{4n}=\cup_{j=1}^n\mathbf{R}^{4(j-1)}\times\{x\in\mathbf{R}^4;\|x\|>m\}\times\mathbf{R}^{4(n-j)}\cup\mathbf{R}^{4n}\setminus O_m^n+i\{y\in\mathbf{R}^4;\|y\|<1/m\}^n.$$

Since for any m_1 there exists m_2 such that $U_{m_1}\supset V_{m_2}$ (resp. $V_{m_1}\supset U_{m_2}$), we have (40). □

Corollary IV.3: A Fourier hyperfunction $\mu(\in\mathcal{Q}(\mathbf{D}^{4n})'=\mathcal{Q}((\mathbf{D}^4)^n)')$ *which vanishes in* O^n *belongs to* $\mathcal{Q}(\mathbf{D}^{4n}\setminus O^n)'=\mathcal{Q}((\mathbf{D}^4)^n\setminus O^n)'$. *Thus we have the following interpretation of the support of* μ*:*

$$\operatorname{supp}\mu\subset\mathbf{D}^{4n}\setminus O^n \quad\text{and}\quad \operatorname{supp}\mu\subset(\mathbf{D}^4)^n\setminus O^n.$$

Proposition IV.4: Suppose $j\in\{1,\ldots,n\}$ *and* t_j *is a separately continuous n-linear form on* $\mathcal{Q}(\mathbf{D}^4)^{(j-1)}\times\mathcal{Q}(\mathbf{D}^4)\times\mathcal{Q}(\mathbf{D}^4)^{(n-j)}$ *which, for fixed* $f_i\in\mathcal{Q}(\mathbf{D}^4)$, $i\neq j$ *has a continuous linear extension* $T_{\{f_i;i\neq j\}}(f_j)$ *to* $f_j\in\mathcal{Q}(K_j)$, $K_j\subset\mathbf{D}^4$ *closed. Then* t_j *has an extension to a separately continuous n-linear form* T_j *on* $\mathcal{Q}(\mathbf{D}^4)^{(j-1)}\times\mathcal{Q}(K_j)\times\mathcal{Q}(\mathbf{D}^4)^{(n-j)}$.

Proof: We have to show that for fixed $f_j\in\mathcal{Q}(K_j)$,

$$\{f_i;i\neq j\}\to T_{\{f_i;i\neq j\}}(f_j)$$

is a separately continuous $(n-1)$-linear form on $\mathcal{Q}(\mathbf{D}^4)^{(n-1)}$. By Theorem 2.7 of Ref. 10, $f_j\in\mathcal{Q}(K_j)$ is the limit in $\mathcal{Q}(K_j)$ of a sequence $\{g_k\}_{k\in\mathbb{N}}$ in $\mathcal{Q}(\mathbf{D}^4)$. Thus we get the following limit representation of the above functional,

$$T_{\{f_i;i\neq j\}}(f_j)=\lim_{k\to\infty}t_j(f_1\otimes\cdots\otimes f_{j-1}\otimes g_k\otimes f_{j+1}\otimes\cdots\otimes f_n).$$

For each k, by assumption, $t_j(f_1\otimes\cdots\otimes f_{j-1}\otimes g_k\otimes f_{j+1}\otimes\cdots\otimes f_n)$ depends continuously on $f_i\in\mathcal{Q}(\mathbf{D}^4)$ for each $i\neq j$; and $\mathcal{Q}(\mathbf{D}^4)$ is known to be a barreled space, hence by the Banach–Steinhaus theorem the above limit depends continuously on $f_i\in\mathcal{Q}(\mathbf{D}^4)$, $i\neq j$. □

Now we are prepared to prove the main result of this section.

Theorem IV.5: *If* O *is an open nonempty set of* $\mathbf{R}^4$, *then* $\mathcal{L}'_w(O)=L'(O)$.

Proof: In the notation introduced in (38) the set $L'(O)$ is characterized by

$$\begin{aligned}L'(O)&=\{X\in\mathcal{B}(\mathcal{H});\ \ \Psi_{X;1,u,v}|O=0,\ \ \forall u,v\in\mathcal{D}_0\}\\&=\{X\in\mathcal{B}(\mathcal{H});\ \ \operatorname{supp}\Psi_{X;1,u,v}\subset\mathbf{D}^4\setminus O,\ \ \forall u,v\in\mathcal{D}_0\}.\end{aligned}\tag{41}$$

Thus it suffices to show for a bounded operator X on $\mathcal{H}$: If

$$\operatorname{supp}\Psi_{X;1,u,v}\subset\mathbf{D}^4\setminus O,\ \ \forall u,v\in\mathcal{D}_0,$$

then

$$\operatorname{supp}\Psi_{X;n,u,v}\subset\mathbf{D}^{4n}\setminus O^n,\ \ \forall n\in\mathbb{N},\ \ \forall u,v\in\mathcal{D}_0.$$

Observe first that for all $f_j\in\mathcal{Q}(\mathbf{D}^4)$ the following relation holds:

$$\begin{aligned}\Psi_{X;n,u,v}(f_1\otimes\cdots\otimes f_n)&=\Psi_{X;1,u,\Phi(f_2)\cdots\Phi(f_n)v}(f_1)+\Psi_{X;1,\Phi(f_{n-1})*\cdots\Phi(f_1)*u,v}(f_n)\\&\quad+\sum_{j=2}^{n-1}\Psi_{X;1,\Phi(f_{j-1})*\cdots\Phi(f_1)*u,\Phi(f_{j+1})\cdots\Phi(f_n)v}(f_j).\end{aligned}\tag{42}$$

Clearly, the summands of this relation are separately continuous n-linear forms on $\mathcal{Q}(\mathbf{D}^4)^{(j-1)}\times\mathcal{Q}(\mathbf{D}^4)\times\mathcal{Q}(\mathbf{D}^4)^{(n-j)}$ and by Proposition IV.4, if $X\in L'(O)$, have extensions to separately continuous n-linear forms on $\mathcal{Q}(\mathbf{D}^4)^{(j-1)}\times\mathcal{Q}(K_j)\times\mathcal{Q}(\mathbf{D}^4)^{(n-j)}$, where $K_j=\mathbf{D}^4\setminus O$. Now we can apply the kernel theorem to conclude

$$\Psi_{X;n,u,v}(f_1\otimes\cdots\otimes f_n)=\sum_{j=1}^{n}T_j(f_1\otimes\cdots\otimes f_n)\tag{43}$$

with

$$T_j \in \mathcal{Q}(\mathbf{D}^{4n})' \quad \text{and} \quad \operatorname{supp} T_j \subset \mathbf{D}^{4(j-1)} \times K_j \times \mathbf{D}^{4(n-j)}. \tag{44}$$

It follows

$$\operatorname{supp} \Psi_{X;n,u,v}(x_1,\ldots,x_n) \subset \bigcup_{j=1}^{n} (\mathbf{D}^4)^{j-1} \times (\mathbf{D}^4 \backslash O) \times (\mathbf{D}^4)^{n-j}$$

$$= (\mathbf{D}^4)^n \backslash \bigcap_{j=1}^{n} (\mathbf{D}^4)^{j-1} \times O \times (\mathbf{D}^4)^{n-j} = (\mathbf{D}^4)^n \backslash O^n.$$

Finally we apply Corollary IV.3 to conclude

$$\operatorname{supp} \Psi_{X;n,u,v}(x_1,\ldots,x_n) \subset \mathbf{D}^{4n} \backslash O^n,$$

and thus $X \in \mathcal{L}'_w(O)$. □

*Corollary IV.6: (a) For any open nonempty subset O in $\mathbf{D}^4$, $\mathcal{L}'_w(O)$ is a *-invariant linear subspace of the *-algebra $\mathcal{B}(\mathcal{H})$ of bounded linear operators on the Hilbert space $\mathcal{H}$. It contains the identity of $\mathcal{B}(\mathcal{H})$.*

(b) The assignment $O \to \mathcal{L}'_w(O)$ is antimonotone, i.e., if $O_1 \subset O_2$ then $\mathcal{L}'_w(O_2) \subset \mathcal{L}'_w(O_1)$, and it is

(c) Poincaré covariant, i.e.,

$$U(g)\mathcal{L}'_w(O)U(g)^* = \mathcal{L}'_w(g \cdot O),$$

for all $g \in G$ and all open nonempty subsets $O \subset \mathbf{D}^4$.

(d) For any open nonempty subsets O_j of $\mathbf{D}^4$ one has $\mathcal{L}'_w(O_1) \cap \mathcal{L}'_w(O_2) = \mathcal{L}'_w(O_1 \cup O_2)$.

Proof: The Fourier hyperfunction $\Psi_{X;n,u,v}$ depends linearly on $X \in \mathcal{B}(\mathcal{H})$, therefore $\mathcal{L}'_w(O)$ is a linear subspace. By Hermiticity of the field we know $\Psi_{I;n,u,v} = 0$, hence this subspace contains the identity $I \in \mathcal{B}(\mathcal{H})$. A straightforward calculation shows $\Psi_{X^*;n,u,v}(x_1,\ldots,x_n) = \overline{\Psi_{X;n,u,v}(\overline{x_1},\ldots,\overline{x_n})}$. Since a Fourier hyperfunction μ and its complex conjugate $\overline{\mu}$, defined by $\overline{\mu}(f) = \overline{\mu(f^*)}$, have the same support it follows that $\Psi_{X^*;n,u,v}$ vanishes on O^n whenever $\Psi_{X;n,u,v}$ does. This proves part (a).

Part (b) is obvious from the definition.

Concerning Poincaré covariance we observe first

$$\Psi_{U(g)XU(g)^*;n,u,v}(x_1,\ldots,x_n) = \Psi_{X;n,u_g,v_g}(g^{-1}x_1,\ldots,g^{-1}x_n)$$

and note that with u, v also $u_g = U(g^{-1})u$ and $v_g = U(g^{-1})v$ belong to $\mathcal{D}_0$.

Part (d) follows from the identity $\mathcal{L}'_w(O) = L'(O)$ and the relation $L'(O_1) \cap L'(O_2) = L'(O_1 \cup O_2)$ which is obvious from the definition. Thus we conclude. □

V. CAUSALITY FOR WEDGES AND DOUBLE-CONES

As the above corollary shows the weak commutants $\mathcal{L}'_w(O)$ are known to be just *-invariant linear subspaces of the *-algebra $\mathcal{B}(\mathcal{H})$ of bounded linear operators on the Hilbert space $\mathcal{H}$ of our theory. For the wedges $W_\pm$ we will introduce a certain class of ''admissible'' *-algebras $\mathcal{M}(W_\pm)$ on $\mathcal{H}$ and for a certain subclass, relying on the results concerning modular aspects, we will be able to show locality. This then is used in the second subsection to derive locality for double cones.

A. Causality for wedges

At first we study in some detail the sets $\mathcal{L}'_w(W_\mp)$, and relate them in particular to the sets $\mathcal{V}(W_\pm)$ of Sec. III. If the growth restriction (37) of Theorem III.6 is taken into account we get results which are analogous to standard QFT.

Proposition V.1: In a hyperfunction quantum field theory $(\mathcal{H},U,\mathcal{D},\Phi)$ *the following relations hold for the spaces introduced above:*

(a) $\mathcal{L}'_w(W_\mp)\cap\mathcal{A}_\pm\subset\mathcal{V}(W_\pm)$,

(b) $J\mathcal{L}'_w(W_\pm)J=\mathcal{L}'_w(W_\mp)$,

(c) $V(t)\mathcal{L}'_w(W_\pm)V(t)^*=\mathcal{L}'_w(W_\pm)$ *for all* $t\in\mathbf{R}$,

(d) Under the assumption of the growth condition (37) of Theorem III.6, (a) can be sharpened to $\mathcal{L}'_w(W_\mp)\subset\mathcal{V}(W_\pm)$.

Proof: We denote $O_\mp=\{(x_1,\ldots,x_n)\in W^n_\mp\,;\,\xi_k=x_{k+1}-x_k\in W_\mp\}$. Observe the fact that $x_k-x_j=\Sigma_{i=j+1}^k\xi_i\in W_\mp$ for $k>j$ and that x_k and x_j are spacelike separated. For any $X\in\mathcal{L}'_w(W_\mp)$ one has

$$\begin{aligned}(X^*\Phi_0,Z_n(\xi_1,\ldots,\xi_n))_{|W^n_\mp}&=(X^*\Phi_0,\Phi(x_1)\cdots\Phi(x_n)\Phi_0)_{|O_\mp}\\&=(\Phi(x_n)^*\cdots\Phi(x_1)^*\Phi_0,X\Phi_0)_{|O_\mp}\\&=(\Phi(\overline{x_1})\cdots\Phi(\overline{x_n})\Phi_0,X\Phi_0)_{|O_\mp}\\&=(Z_n(\overline{\xi_1},\ldots,\overline{\xi_n}),X\Phi_0)_{|W^n_\mp}.\end{aligned}$$

By Proposition III.2 we deduce $X\in\mathcal{V}(W_\pm)$. This proves part (a).

Antiunitarity of the operator J implies $(JXJ)^*=JX^*J$ and thus, using the known transformation properties of the field under the operator J we calculate

$$\Psi_{JXJ;n,u,v}(x_1,\ldots,x_n)=-\Psi_{X^*;n,Jv,Ju}(g_-x_1,\ldots,g_-x_n).$$

Since the domain $\mathcal{D}_0$ is invariant under the TCP-operator θ it follows that this domain is also invariant under the operator $J=U(0,R)\theta$. Since $g_-W_\pm=W_\mp$ we see that $\Psi_{JXJ;n,u,v}$ vanishes on $W^n_\mp$ for all $u,v\in\mathcal{D}_0$ and $n=1,2,\ldots$ whenever $X\in\mathcal{L}'_w(W_\pm)$. We conclude $J\mathcal{L}'_w(W_\pm)J\subset\mathcal{L}'_w(W_\mp)$, and therefore $\mathcal{L}'_w(W_\pm)\subset J\mathcal{L}'_w(W_\mp)J$. This implies the identity stated in part (b).

In a similar way we prove part (c). Using the covariance properties of the field we calculate

$$\Psi_{V(t)XV(t)^*;n,u,v}(x_1,\ldots,x_n)=\Psi_{X;n,V(-t)u,V(-t)v}(v_{-t}x_1,\ldots,v_{-t}x_n).$$

Since $v_tW_\pm=W_\pm$ and since the domain $\mathcal{D}_0$ is invariant under $V(t)$, $t\in\mathbf{R}$, it follows, for all $t\in\mathbf{R}$, $V(t)\mathcal{L}'_w(W_\pm)V(t)^*\subset\mathcal{L}'_w(W_\pm)$, and therefore $\mathcal{L}'_w(W_\pm)\subset V(-t)\mathcal{L}'_w(W_\pm)V(-t)^*$. This proves the identity of part (c).

If the growth condition is assumed then by Theorem III.6 we know $\mathcal{L}'_w(W_\mp)\subset\mathcal{A}_\pm$ and thus (d) follows from (a). □

In general, $\mathcal{L}'_w(O)\cap\mathcal{A}_\pm\cap\mathcal{A}^*_\pm$ is only a *-invariant subspace but not a *-algebra of bounded operators on the state space $\mathcal{H}$. For the special case $O=W_\pm$ we will propose some choices for such a *-algebra which will finally enable us to assign *-algebras of bounded operators $\mathcal{M}(O)$ on $\mathcal{H}$ to all double cones O and this assignment will satisfy the condition of locality.

For $O=W_\pm$ we proceed as follows. First we introduce a certain class of *-algebras on $\mathcal{H}$ which we call ''admissible.'' Then for a certain subclass of these admissible *-algebras assigned to $W_\pm$ the locality condition will be shown.

Definition V.2: Let $(\mathcal{H},U,\mathcal{D},\Phi)$ *be a hyperfunction quantum field theory. A pair* $\mathcal{M}(W_\pm)$ *of* *-*algebras of bounded operators on the state space* $\mathcal{H}$ *is called* **admissible** *if it has the following properties:*

(A_1) $\mathcal{M}(W_\pm)\subset\mathcal{L}'_w(W_\mp)\cap\mathcal{A}_\pm\cap\mathcal{A}^*_\pm$,

(A_2) $J\mathcal{M}(W_\pm)J=\mathcal{M}(W_\mp)$,

(A_3) $V(t)\mathcal{M}(W_\pm)V(t)^*=\mathcal{M}(W_\pm)$ *for all* $t\in\mathbf{R}$.

Under the growth condition (37) *the right-hand side of* (A_1) *is* $\mathcal{L}'_w(W_\mp)$.

Since the identity operator belongs to $\mathcal{L}'_w(W_\mp)\cap\mathcal{A}_\pm\cap\mathcal{A}_\pm^*$ the trivial *-algebra is always admissible in this sense. We will see later (Proposition V.5) there is another construction to obtain admissible *-algebras.

As the following theorem shows an admissible pair of *-algebras satisfies the condition of locality, under the assumption of a strong technical condition, as in standard QFT.

Theorem V.3: *If in a hyperfunction quantum field theory* $(\mathcal{H},U,\mathcal{D},\Phi)$ *the space* $\mathcal{M}(W_\pm)\Phi_0$ *is dense in the state space* $\mathcal{H}$*, then the following assignment*

$$W_\pm\to\mathcal{M}(W_\pm)$$

is local, i.e.,

$$\mathcal{M}(W_\pm)\subset\mathcal{M}(W_\mp)'.$$

Proof: Because of property A_3 and since $\mathcal{M}(W_\pm)$ are *-algebras we know for any triple X_1, X_2, X_3 of its elements and for all $t\in\mathbf{R}$,

$$X_2V(t)X_3^*V(t)^*\in\mathcal{M}(W_\pm)\quad\text{and}\quad X_1X_3V(t)X_2^*V(t)^*\in\mathcal{M}(W_\pm).$$

By Property A_1 we know $\mathcal{M}(W_\pm)\subset\mathcal{V}(W_\mp)$ and thus Proposition III.1 applies. Part (b) of this proposition therefore implies the following chain of identities:

$$JX_2JX_1X_3\Phi_0=X_1X_3JX_2\Phi_0=(X_1J)JX_3JX_2\Phi_0=X_1JX_2JX_3\Phi_0.$$

Since $\{X_3\Phi_0;\ X_3\in\mathcal{M}(W_\pm)\}$ is dense, this equation implies $[X_1,JX_2J]=0$ for any X_1, $X_2\in\mathcal{M}(W_\pm)$, thus $\mathcal{M}(W_\pm)\subset(J\mathcal{M}(W_\pm)J)'$. Now we conclude by Property A_2. □

We prepare our discussion of a special way to obtain an admissible pair *-algebra $\mathcal{M}_0(W_\pm)$ by proving some properties of the set $\mathcal{A}_\pm=\{X\in\mathcal{B}(\mathcal{H});\ X\Phi_0\in\mathcal{D}_\pm\}$ introduced earlier.

Lemma V.4: (a) $J\mathcal{A}_\pm J=\mathcal{A}_\mp$ *and* $J\mathcal{A}_\pm^*J=\mathcal{A}_\mp^*$.

(b) $V(t)\mathcal{A}_\pm V(t)^*=\mathcal{A}_\pm$ *and* $V(t)\mathcal{A}_\pm^*V(t)^*=\mathcal{A}_\pm^*$ *for all* $t\in\mathbf{R}$.

Proof: (a) For $X\in\mathcal{A}_\pm$ we know $X\Phi_0\in\mathcal{D}_\pm$. Since $J\mathcal{D}_\pm=\mathcal{D}_\mp$ it follows $JXJ\Phi_0=JX\Phi_0\in J\mathcal{D}_\pm=\mathcal{D}_\mp$, hence $JXJ\in\mathcal{A}_\mp$, and therefore $J\mathcal{A}_\pm J\subset\mathcal{A}_\mp$; $JJ=I$ implies $\mathcal{A}_\pm\subset J\mathcal{A}_\pm J\subset\mathcal{A}_\pm$, and we get the first identity. The relation $JX^*J=(JXJ)^*$ implies now the second identity: $J\mathcal{A}_\pm J=(J\mathcal{A}_\pm J)^*=\mathcal{A}_\pm^*$.

For (b) we observe that the self-adjoint operators $V(\pm i\pi)$ commute with the unitary operators $V(t)$, $t\in\mathbf{R}$, therefore $V(t)\mathcal{D}_\pm=\mathcal{D}_\pm$. Since $V(t)\Phi_0=\Phi_0$ it follows easily $V(t)\mathcal{A}_\pm V(t)^*\subset\mathcal{A}_\pm$ for all $t\in\mathbf{R}$. Using the group properties of $V(t)$ we deduce $\mathcal{A}_\pm\subset V(-t)\mathcal{A}_\pm V(-t)^*$ for all $t\in\mathbf{R}$ and we conclude that the first identity holds. Taking adjoints the second identity follows. □

Proposition V.5: Introduce the *-*subspace,*

$$\mathcal{K}_\pm=\mathcal{K}(W_\pm)=\mathcal{L}'_w(W_\mp)\cap\mathcal{A}_\pm\cap\mathcal{A}_\pm^*,$$

respectively,

$$\mathcal{K}_\pm=\mathcal{K}(W_\pm)=\mathcal{L}'_w(W_\mp)$$

if the growth condition (37) is assumed and define

$$\mathcal{M}_0(W_\pm)=\mathcal{K}_{\text{alg}}(W_\pm)=\{C\in\mathcal{K}_\pm;C\mathcal{K}_\pm\subset\mathcal{K}_\pm,\mathcal{K}_\pm C\subset\mathcal{K}_\pm\}.\tag{45}$$

Then $\mathcal{M}_0(W_\pm)$ *are a pair of admissible* *-*algebras of bounded operators on the state space* $\mathcal{H}$.

Proof: By definition $\mathcal{M}_0(W_\pm)$ are *-algebras of bounded operators on $\mathcal{H}$ which are contained in $\mathcal{K}_\pm$. Hence condition A_1 is satisfied.

Next, by part (b) of Proposition V.1 and part (a) of Lemma V.4 we know $J\mathcal{K}_\pm J\subset\mathcal{K}_\mp$. Now, for any $Y\in\mathcal{M}_0(W_\pm)$ one has by definition, $Y\mathcal{K}_\pm\subset\mathcal{K}_\pm$ and $\mathcal{K}_\pm Y\subset\mathcal{K}_\pm$. It follows $JYJ\mathcal{K}_\pm$

$=JYJ\mathcal{K}_{\pm}JJ\subset JY\mathcal{K}_{\mp}J\subset J\mathcal{K}_{\mp}J\subset\mathcal{K}_{\pm}$ and similarly $\mathcal{K}_{\pm}JYJ\subset\mathcal{K}_{\pm}$, hence $J\mathcal{M}_0(W_{\pm})J\subset\mathcal{M}_0(W_{\mp})$ and thus, by $JJ=I$, $J\mathcal{M}_0(W_{\pm})J=\mathcal{M}_0(W_{\mp})$; therefore condition A_2 is satisfied.

Finally, by part (c) of Proposition V.1 and part (b) of Lemma V.4, $V(t)\mathcal{K}_{\mp}V(t)^*=\mathcal{K}_{\mp}$ is known for all $t\in\mathbf{R}$. Then we can proceed as for the second condition and conclude that condition A_3 is satisfied too. □

B. Causality for double-cones

Let G be the proper Poincaré group. We define

$$G_{\pm}=\{g\in G;g\cdot W_{+}=W_{\pm}\}$$

as the subset of G consisting of those elements which leave the wedge W_{+} invariant, respectively map it onto the wedge W_{-}. The following lemma determines the general form of an element in G_{+} explicitly and provides an elementary property of $G_{\pm}$. We omit the straight forward proof.

Lemma V.6: (a) G_{+} is the subgroup of G consisting of elements g of the Poincaré group G of the form $g=(a,\Lambda)$ with $a=(0,0,a^2,a^3)$ and

$$\Lambda=\begin{pmatrix}\cosh t & \sinh t & 0 & 0\\ \sinh t & \cosh t & 0 & 0\\ 0 & 0 & \cos\theta & -\sin\theta\\ 0 & 0 & \sin\theta & \cos\theta\end{pmatrix} \tag{46}$$

with $t\in\mathbf{R}$ and $\theta\in\mathbf{R}$.

(b) For $g\in G_{\pm}$ and v_t as introduced in Sec. II C, the following relation holds:

$$gv_tg^{-1}=v_{\pm t}. \tag{47}$$

Lemma V.7: For the set $G_{\pm}=\{g\in G;g\cdot W_{+}=W_{\pm}\}$ the following holds:
(a) $U(g)\mathcal{A}_{\pm}U(g)^{-1}=\mathcal{A}_{\pm}$ for all $g\in G_{+}$.
(b) $U(g)\mathcal{A}_{\pm}U(g)^{-1}=\mathcal{A}_{\mp}$ for all $g\in G_{-}$.

Proof: Lemma V.6 implies $U(g)V(t)U(g)^{-1}=V(t)$ for all $g\in G_{+}$ and all $t\in\mathbf{R}$. Using functional calculus we deduce by analytic continuation $U(g)V(\pm i\pi)=V(\pm i\pi)U(g)$ for all $g\in G_{+}$, in particular $U(g)\mathcal{D}_{\pm}=\mathcal{D}_{\pm}$. Now, since $U(g)\Phi_0=\Phi_0$ for all $g\in G$, statement (a) follows easily.

For $g\in G_{-}$ we know $g\cdot W_{+}=W_{-}$ and by Lemma V.6, for all $t\in\mathbf{R}$, $U(g)V(t)=V(-t)U(g)$. Again using functional calculus and analytic continuation we deduce $U(g)V(\pm i\pi)=V(\mp i\pi)U(g)$, in particular, $U(g)\mathcal{D}_{\pm}=\mathcal{D}_{\mp}$ for all $g\in G_{-}$. Now statement (b) follows as in the previous case. □

*Definition V.8: A pair $\mathcal{M}(W_{\pm})$ of admissible *-algebras of bounded operators on $\mathcal{H}$ is called covariant if, and only if, it satisfies the following identity:*

$$U(g)\mathcal{M}(W_{+})U(g)^{-1}=\mathcal{M}(W_{\pm})\ \forall g\in G_{\pm}. \tag{48}$$

The following lemma shows that there is at least one pair of covariant admissible *-algebras.

*Lemma V.9: The special pair $\mathcal{M}_0(W_{\pm})$ $\mathcal{H}$ of admissible *-algebras of bounded operators on $\mathcal{H}$ which was introduced in Proposition V.5 is covariant, i.e.,*

$$U(g)\mathcal{M}_0(W_{+})U(g)^{-1}=\mathcal{M}_0(W_{\pm})\ \forall g\in G_{\pm}. \tag{49}$$

Proof: On the basis of Lemma V.6–V.7 we can proceed in more or less the same way as in the proof of Proposition V.5 starting with the observation

$$U(g)\mathcal{L}'_w(W_{-})\cap\mathcal{A}_{+}\cap\mathcal{A}_{+}^{*}U(g)^{-1}=\mathcal{L}'_w(W_{\mp})\cap\mathcal{A}_{\pm}\cap\mathcal{A}_{\pm}^{*}\ \forall g\in G_{\pm}$$

which follows from part (c) of Corollary IV.6 and part (a) of Lemma V.7. □

Next consider the set of all wedgelike regions,

$$\mathcal{W}=\{W\subset\mathbf{R}^4;\ \ W=g\cdot W_+,\ \ g\in G\}=G\cdot W_+.$$

Clearly, two elements $g_1, g_2\in G$ define the same wedge, i.e., $g_1\cdot W_+=g_2\cdot W_+$, if, and only if, $g_1^{-1}g_2\in G_+$. Thus the elements of $\mathcal{W}$ are distinguished by the elements $[g]$ of the quotient G/G_+.

Now, given any pair of admissible *-algebras $\mathcal{M}(W_\pm)$ which are covariant in the sense of the identities (48), we assign to the wedge $W\in\mathcal{W}$ the set of operators $\mathcal{M}(W)$ defined by

$$\mathcal{M}(W)=U(g)\mathcal{M}(W_+)U(g)^{-1} \tag{50}$$

with any representative $g\in G$ of the equivalence class $[g]$ which characterizes W. $\mathcal{M}(W)$ is well defined: Whenever $W=g_1\cdot W_+=g_2\cdot W_+$ there is $g_0\in G_+$ such that $g_2=g_1\cdot g_0$ and therefore, by Lemma V.9, $U(g_2)\mathcal{M}(W_+)U(g_2)^{-1}=U(g_1)U(g_0)\mathcal{M}(W_+)U(g_0)^{-1}U(g_1)^{-1}$ $=U(g_1)\mathcal{M}(W_+)U(g_1)^{-1}$. This lemma also shows that for $W=W_\pm$ the above definition of $\mathcal{M}(W)$ is consistent, in particular $U(R)\mathcal{M}(W_+)U(R)^{-1}=\mathcal{M}(W_-)$ since $R\cdot W_+=W_-$, where R is the Euclidean rotation by π around the x^3-axis.

*Proposition V.10: The assignment of operator *-algebras $\mathcal{M}(W)$ to wedges $W\in\mathcal{W}$ is causal in the sense that*

$$\mathcal{M}(W)\subset\mathcal{M}(W')' \tag{51}$$

for all wedges $W\in\mathcal{W}$.

Proof: The causal complement W' of a wedge $W=g\cdot W_+\in\mathcal{W}$ again belongs to $\mathcal{W}$ since $W'=g\cdot(W_+)'=g\cdot W_-=g\cdot R\cdot W_+\in\mathcal{W}$. Now consider any pair of operators $X_1\in\mathcal{M}(W)$ and $X_2\in\mathcal{M}(W')$. There exists $Y_1\in\mathcal{M}(W_+)$ and $Y_3\in\mathcal{M}(W_+)$ such that $X_1=U(g)Y_1U(g)^{-1}$ and $X_2=U(gR)Y_3U(gR)^{-1}=U(g)U(R)Y_3U(R)^{-1}U(g)^{-1}=U(g)Y_2U(g)^{-1}$ with Y_2 $Y_2=U(R)Y_3U(R)^{-1}\in\mathcal{M}(W_-)$. By Theorem V.3 we know that the operators Y_1 and Y_2 commute. Therefore the operators X_1 and X_2 commute since

$$[X_1,X_2]=U(g)[Y_1,Y_2]U(g)^{-1}=0.$$

Thus we conclude. □

Finally recall that a double cone in Minkowski space is the intersection of all wedges that contain it. Accordingly we assign a *-algebra $\mathcal{M}(D)$ of bounded operators on $\mathcal{H}$ to a double cone D and a *-algebra $\mathcal{M}(D')$ to the spacelike complement D' of D according to the following formulas:

$$\mathcal{M}(D)=\bigcap_{D\subset W\in\mathcal{W}}\mathcal{M}(W),\quad \mathcal{M}(D')=\Big\{\bigcup_{D'\supset W\in\mathcal{W}}\mathcal{M}(W)\Big\}''. \tag{52}$$

Then by definition we have

$$\mathcal{M}(D_1)\subset\mathcal{M}(W)\subset\mathcal{M}(D_2') \tag{53}$$

for any triplet (D_1,D_2,W), with $W\in\mathcal{W}$ and where D_1, D_2 are double cones such that $D_1\subset W\subset D_2'$.

Theorem V.11: *Let a hyperfunction quantum field theory $(\mathcal{H},U,\mathcal{D},\Phi)$ be given. If $\mathcal{M}(W_+)\Phi_0$ is dense in the state space $\mathcal{H}$, then the net $\{\mathcal{M}(D)\}$ assigned to double cones D satisfies the condition of causality (local commutativity) in the sense that for any pair of double cones D_1, D_2 with $D_1\subset D_2'$ the operator algebra $\mathcal{M}(D_1)$ is contained in the commutant of the operator algebra $\mathcal{M}(D_2)$,*

$$\mathcal{M}(D_1)\subset\mathcal{M}(D_2)'. \tag{54}$$

Proof: Though we are not in the setting of standard QFT the proofs of Theorem 13.3.7 of Ref. 1 and/or Theorem 5 of Ref. 17 apply since the necessary background has been provided. □

VI. NONTRIVIALITY OF LOCAL ALGEBRAS

In this section we show that our suggestion for the assignment of local *-algebras $\mathcal{M}(O)$ to open nonempty subsets O of space–time is not vacuous by constructing a simple class of models of hyperfunction quantum fields (which are not standard quantum fields) for which it is easy to show that the algebras $\mathcal{M}(O)$ of our construction are not trivial. The first subsection gives the construction of this model while the second proves the nontriviality of these algebras.

A. Power series of free fields

A class of hyperfunction quantum fields $\rho(x)$ will be constructed as Wick power series of a free field $\phi(x)$. We begin with a brief discussion of power series of two-point functions.

The two-point Wightman function of a free neutral scalar field in four-dimensional space–time is

$$D_m^{(-)}(x)=(2\pi)^{-3}\int_{\mathbf{R}^4} e^{-ik\cdot x}\delta(k\cdot k-m^2)\,\theta(k^0)\,dk$$

$$=(2\pi)^{-3}\int_{\mathbf{R}^3}[2\omega(\mathbf{k})]^{-1}e^{-i\omega(\mathbf{k})x^0}e^{i\mathbf{k}\cdot\mathbf{x}}d\mathbf{k}, \tag{55}$$

where $k\cdot x=k^0x^0-\mathbf{k}\cdot\mathbf{x}$, $\omega(\mathbf{k})=\sqrt{\mathbf{k}^2+m^2}$.

The identity (55) shows that $D_m^{(-)}(x)$ is the Fourier transform of a distribution whose support is contained in the forward light cone. Therefore $D_m^{(-)}(x)$ is the boundary value of the function $D_m^{(-)}(z)$ which is holomorphic in the backward tube $\mathcal{T}_-=\{x+iy\in\mathbf{C}^4; y\in V_-\}$, where $V_-=\{y\in\mathbf{R}^4; y^0<-|\mathbf{y}|\}$ is a backward light cone. Moreover, we have, for any $\epsilon>0$,

$$|D_m^{(-)}(x^0-i\epsilon,\mathbf{x})|\leqslant\frac{1}{(2\pi)^3}\int_{\mathbf{R}^3}\frac{e^{-\omega(\mathbf{k})\epsilon}}{2\omega(\mathbf{k})}d\mathbf{k}=D_m^{(-)}(-i\epsilon,\mathbf{0})=g(\epsilon), \tag{56}$$

where $g(\epsilon)$ is a decreasing function of $\epsilon>0$ [$g(\epsilon_1)\geqslant g(\epsilon_2)$ for $\epsilon_1<\epsilon_2$] and $\epsilon^2 g(\epsilon)\to(2\pi)^{-1}$ as $\epsilon\to 0$. By Lorentz invariance, $D_m^{(-)}(z)$ can be analytically continued to a function which is analytic in the extended tube $\mathcal{T}_1=\{\zeta\in\mathbf{C}^4;\zeta\cdot\zeta\notin\mathbf{R}_+\}$ and invariant under complex Lorentz transformations.

Since $D_m^{(-)}(x)$ is a boundary value of $D_m^{(-)}(z)$ which is holomorphic in the backward tube, the n-fold product $D_m^{(-)}(x)^n$ of $D_m^{(-)}(x)$ is also a boundary value of the holomorphic function $D_m^{(-)}(z)^n$ and defines a hyperfunction; moreover it is a distribution since the order of growth is ϵ^{-2n} when the boundary is approached. But

$$\sum_{n=0}^{\infty} b_n D_m^{(-)}(x)^n \tag{57}$$

is a distribution if, and only if, all except finitely many of the coefficients b_n's vanish (see Ref. 22). On the other hand, if

$$F(z)=\sum_{n=0}^{\infty} b_n z^n \tag{58}$$

is not a polynomial but an entire function, then (57) is a hyperfunction. Moreover it is a Fourier hyperfunction because $D_m^{(-)}(x-i\epsilon,x)$ for ϵ fixed is a bounded function by (56). The power series (58) determines an entire function if, and only if, its coefficients b_n satisfy the condition

$$\limsup_{n\to\infty}|b_n|^{1/n}=0.$$

If the entire function (58) is not too rapidly increasing, i.e., $F(z)=\exp z$, then (57) defines an ultradistribution of Gevrey class but if (58) is rapidly increasing, e.g., $F(z)=\exp\exp z$, then (57) does not define even an ultradistribution of Gevrey class. It defines a generalized function whose test-function space has no nontrivial functions with compact supports since it consists of quasi-analytic functions. The above statement is proved by similar arguments to those in Refs. 23 and 24. We will prove it in a forthcoming paper.

The Wick monomials $:\phi^l:(x)$ of a free field ϕ are defined by Wightman and Gårding in Ref. 25.

Now let $\{a_n^{(i)}\}$ be sequences satisfying $\lim_{n\to\infty}[|a_n^{(i)}|^2/n!]^{1/n}=0$ and define $\rho^{(i)}(x)$ by

$$\rho^{(i)}(x)=\sum_{n=0}^{\infty}a_n^{(i)}\frac{:\phi(x)^n:}{n!}. \tag{59}$$

Then Nagamachi and Mugibayashi have shown in Ref. 8 that the above series converges and defines a hyperfunction quantum field defined in the Fock space of $\phi(x)$ using the basic relation between Schwinger functions and Wightman functions for a hyperfunction quantum field which was established in Ref. 13. We give here a new direct proof which does not rely on the relation between Wightman and Schwinger functions.

To begin we recall:

Theorem VI.1 (Theorem A.1 of Ref. 26): *As a formal power series we have*

$$(\Omega,\rho^{(1)}(x_1)\cdots\rho^{(n)}(x_n)\Omega)=\sum_{r_{ij}=0;1\leqslant i<j\leqslant n}^{\infty}\frac{A(R)T^R}{R!}, \tag{60}$$

where

$$r_{ij}=r_{ji},\ \ r_{ii}=0,\ \ R_i=\sum_{j=1}^{n}r_{ij},\ \ t_{ij}=D_m^{(-)}(x_i-x_j),$$

$$R!=\prod_{1\leqslant i<j\leqslant n}(r_{ij})!,\quad T^R=\prod_{1\leqslant i<j\leqslant n}(t_{ij})^{r_{ij}},\ \ A(R)=\prod_{j=1}^{n}a_{R_j}^{(j)}.$$

From the above theorem one easily gets

Theorem VI.2 (Theorem 3.3 of Ref. 8): *If*

$$\lim_{n\to\infty}[|a_n^{(i)}|^2/n!]^{1/n}=0, \tag{61}$$

then the right-hand side of (60) is an entire function of the variables t_{ij}.

Now, if the coefficients $a_n^{(i)}$ of $\rho^{(i)}(x)$ according to (59) satisfy the condition (61), then, by the above results, the right-hand side of (59) defines a (Fourier) hyperfunction quantum field (of type I).

We indicate briefly the proof of this observation. In fact, if $z_j-z_i\in\mathcal{T}_+=\mathbf{R}^4+iV_+$ (V_+ denotes the forward light cone), then $D_m^{(-)}(z_i-z_j)$ is holomorphic there and $D_m^{(-)}(x_i-x_j)$ is the boundary value of $D_m^{(-)}(z_i-z_j)$. Therefore, if $\mathrm{Im}(z_{i+1}-z_i)\in V_+$ $(i=1,2,\ldots,n-1)$, then $(\Omega,\rho^{(1)}(z_1)\cdots\rho^{(n)}(z_n)\Omega)$ is holomorphic and $(\Omega,\rho^{(1)}(x_1)\cdots\rho^{(n)}(x_n)\Omega)$ is the boundary value of $(\Omega,\rho^{(1)}(z_1)\cdots\rho^{(n)}(z_n)\Omega)$. Since

$$|D_m^{(-)}(x^0-i\epsilon,\mathbf{x})|\leqslant[2(2\pi)^3]^{-1}\int\omega(\mathbf{k})^{-1}e^{-\omega(\mathbf{k})\epsilon}d\mathbf{k}$$

(60) defines a Fourier hyperfunction.

In order to show that (59) defines a hyperfunction quantum field (see Refs. 10, 27, 28, 9, and 13), we show that the system of Fourier hyperfunctions $\mathcal{W}_n$ of (60) satisfies the (modified) Wightman axioms, as formulated by Nagamachi and Mugibayashi in Ref. 9:

R_0 Fourier hyperfunction property:

$$\mathcal{W}_n \in \mathcal{Q}(\mathbf{D}^{4n})', \quad \mathcal{W}_n(f) = \mathcal{W}_n(\overline{f}),$$

where $\overline{f}(x_1,\ldots,x_n) = \overline{f(x_n,\ldots,x_1)}$.

R_1 Relativistic covariance: For every $(\Lambda,a) \in G$ and $n=1,2,\ldots$ we have

$$\mathcal{W}_n(\Lambda x_1 + a,\ldots,\Lambda x_n + a) = \mathcal{W}_n(x_1,\ldots,x_n)$$

as an identity for Fourier hyperfunctions on $\mathbf{R}^{4n}$. Here G denotes the proper Poincaré group.

R_2 Positivity:

$$\sum_{m,n=0}^{k} \mathcal{W}_{m+n}(\overline{f}_m \otimes f_n) \geqslant 0,$$

for any choice of $f_n \in \mathcal{Q}(\mathbf{D}^{4n})$ and any k.

R_3 Local commutativity:

$$\mathcal{W}_n(x_1,\ldots,x_j,x_{j+1},\ldots,x_n) = \mathcal{W}_n(x_1,\ldots,x_{j+1},x_j,\ldots,x_n)$$

if $(x_j - x_{j+1})^2 < 0$ as an identity for Fourier hyperfunctions on $\mathbf{R}^{4n}$, for $n=2,3,\ldots$.

R_4 Spectral condition: For $n=2,3,\ldots$ there exists a $\mu_{n-1} \in \mathcal{Q}(\overline{V_+^{n-1}})'$ such that

$$\mathcal{W}_n(x_1,\ldots,x_n) = W_{n-1}(x_2 - x_1,\ldots,x_n - x_{n-1}),$$

where W_{n-1} is the Fourier transform of μ_{n-1}.

R_5 Cluster property: If a is spacelike,

$$\mathcal{W}_n(x_1,\ldots,x_j,x_{j+1}+\lambda a,\ldots,x_n+\lambda a) \to \mathcal{W}_n(x_1,\ldots,x_j)\mathcal{W}_n(x_{j+1},\ldots,x_n)$$

as $\lambda \to \infty$.

R_1 is obviously satisfied. R_5 follows from the fact that $D_m^{(-)}(z-\lambda a) \to 0$ Im $z \in V_+$, $a^2 < 0$ and $\lambda \to \infty$. In fact, let $y_i = z_i$ for $i \leqslant k$ and $y_i = z_i + \lambda a$ for $k < i$. Then $t_{ij} = D_m^{(-)}(y_i - y_j)$, $1 \leqslant i \leqslant k < j \leqslant n$ vanishes as $\lambda \to \infty$. Therefore,

$$T^R = \prod_{1 \leqslant i < j \leqslant n} (t_{ij})^{r_{ij}} \to 0$$

unless all r_{ij} for $1 \leqslant i \leqslant k < j \leqslant n$ are zero. Thus we have

$$T^R \to \left[\prod_{1 \leqslant i < j \leqslant k} (t_{ij})^{r_{ij}} \right] \left[\prod_{k < i < j \leqslant n} (t_{ij})^{r_{ij}} \right]$$

which shows the cluster property.

In order to show R_0 and R_2, a Wick polynomial $\rho_N^{(i)}(x)$ is introduced as a truncation of $\rho^{(i)}(x)$,

$$\rho_N^{(i)}(x) = \sum_{n=0}^{N} a_n^{(i)} : \phi(x)^n : /n!.$$

Then the Wightman functions for $\rho_N^{(i)}(x)$ satisfy all the (unmodified) Wightman axioms (see Ref. 25). Since the right-hand side of (60) is an absolutely convergent series of the variables t_{ij}, $(\Omega,\rho_N^{(1)}(x_1)\cdots\rho_N^{(n)}(x_n)\Omega)$ converges to $(\Omega,\rho^{(1)}(x_1)\cdots\rho^{(n)}(x_n)\Omega)$ as $N\to\infty$ in the sense of Fourier hyperfunctions. Thus we easily see Hermiticity and the positivity. However, such limit does not necessarily preserve the support (see Theorem 4.1.14 of Ref. 16), and it is unknown whether the spectral condition and the local commutativity can be verified in this manner. But as written in Note 4.1 of Ref. 16, ''if you want to use topology, use it at the level of holomorphic functions.''

In order to simplify notations we denote here and in the remainder of this section the analytic function whose boundary value is the vacuum expectation value $(\Omega,\rho^{(1)}(x_1)\cdots\rho^{(n)}(x_n)\Omega)$ of the fields $\rho^{(i)}$ with $(\Omega,\rho^{(1)}(z_1)\cdots\rho^{(n)}(z_n)\Omega)$ and similarly for the fields $\rho_N^{(i)}$. Then the holomorphic function $(\Omega,\rho^{(1)}(z_1)\cdots\rho^{(n)}(z_n)\Omega)$ is the limit of the holomorphic functions $(\Omega,\rho_N^{(1)}(z_1)\cdots\rho_N^{(n)}(z_n)\Omega)$, and this will give us the necessary information. Our proof of the spectral condition relies the following two results from the general theory of Fourier hyperfunctions.

Theorem VI.3 (Theorem 3.3.1 of Ref. 29): *Let Γ be a closed and strictly convex cone with vertex at the origin and satisfy $\Gamma\setminus\{0\}\subset\{x_1>0\}$ and K be its closure in $\mathbf{D}^n$. Let $\Gamma^0=\{\xi;\langle x,\xi\rangle\geqslant 0,\forall x\in\Gamma\}$. Then every $\mu\in\mathcal{O}(K)'$ has the following properties: The Fourier transform $\langle\mu,e^{i\langle\cdot,\zeta\rangle}\rangle$ of μ is holomorphic in $\mathbf{R}^n\times i(\Gamma^0)^i$ and satisfies the following growth condition. For every $\Gamma'\subset\subset\Gamma^0$ (the closure of Γ' has a compact neighborhood in the closure of Γ^0 with respect to the topology of $\mathbf{D}^n$) and $\epsilon>0$,*

$$|\langle\mu,e^{i\langle\cdot,\zeta\rangle}\rangle|\leqslant C_\epsilon\exp(\epsilon|\mathrm{Re}\,\zeta|+\chi_{\Gamma,\epsilon}(\mathrm{Im}\,\zeta)),\quad \zeta\in\mathbf{R}^n\times i\Gamma', \tag{$*$}$$

where

$$\chi_{\Gamma,\epsilon}(\eta)=\sup_{x\in\Gamma-\epsilon(1,0,\ldots,0)}(-\langle x,\eta\rangle+\epsilon|x|).$$

Theorem VI.4 (Theorem 3.3.2 of Ref. 29): *Let $F(\zeta)$ be holomorphic in $\mathbf{R}^n\times i(\Gamma^0)^i$ and satisfies the growth condition (*). Then there exists a unique $\mu\in\mathcal{O}(K)'$ such that $F(\zeta)=\langle\mu,e^{i\langle\cdot,\zeta\rangle}\rangle$.*

Since $D_m^{(-)}(z)$ is a bounded holomorphic function in $\mathbf{R}^4\times i\Gamma'$ for any $\Gamma'\subset\subset V_-$, $(\Omega,\rho^{(1)}(z_1)\cdots\rho^{(n)}(z_n)\Omega)$ satisfies the estimate (*) for $\zeta_j=z_{j+1}-z_j$ and $\Gamma=\overline{V_+^{n-1}}$. Thus we deduce the spectral condition R_4. For the proof of the local commutativity, we use the following theorem on p. 83 of Ref. 19.

Theorem VI.5: *If $\mathcal{W}_n(z_1,\ldots,z_n)$ has all the properties of a Wightman function except the ones derived from locality and if in addition $\mathcal{W}_n(z_1,\ldots,z_n)$ is symmetric in $z_1,\ldots,z_n$, then it satisfies also the requirements of locality.*

This theorem is proved for hyperfunction quantum field theory in the same way as in standard tempered quantum field theory. Since $(\Omega,\rho_N^{(1)}(z_1)\cdots\rho_N^{(n)}(z_n)\Omega)$ is symmetric in $z_1,\ldots,z_n$ in the extended tube, the function $(\Omega,\rho^{(1)}(z_1)\cdots\rho^{(n)}(z_n)\Omega)$ is also symmetric there. Thus we deduce the locality condition R_3.

By the reconstruction theorem (see Ref. 9), we have a Hilbert space $\mathcal{H}$, field operators $\rho^i(f)$ for $f\in\mathcal{O}(\mathbf{D}^4)$, and a unitary representation of the Poincaré group $U(a,\Lambda)$ on $\mathcal{H}$.

The Hilbert space $\mathcal{H}$ can be assumed to be contained in the Fock space $\mathcal{H}_F$ of the free field. In fact, the vectors $\Phi_N=\rho_N^{(1)}(f_1)\cdots\rho_N^{(n)}(f_n)\Omega$ for $f_j\in\mathcal{O}(\mathbf{D}^4)$ are contained in $\mathcal{H}_F$ and

$$\|\Phi_N-\Phi_M\|^2=(\Phi_N,\Phi_N)-(\Phi_N,\Phi_M)-(\Phi_M,\Phi_N)+(\Phi_M,\Phi_M)\to 0$$

as $N,M\to\infty$. Thus $\rho^{(1)}(f_1)\cdots\rho^{(n)}(f_n)\Omega=\lim_{N\to\infty}\rho_N^{(1)}(f_1)\cdots\rho_N^{(n)}(f_n)\Omega$ belongs to $\mathcal{H}_F$.

Let $\{a_n\}_{n\in\mathbb{N}}$ be a sequence satisfying

$$\lim_{n\to\infty}[|a_n|^2/n!]^{1/n}=0$$

and define $\rho(x)$ by

$$\rho(x)=\sum_{n=0}^{\infty} a_n \frac{:\phi(x)^n:}{n!}.$$

Let $\rho^{(i)}(x)$ of (59) be either $\phi(x)$ or $\rho(x)$. Then we have the system

$$(\mathcal{H},\Omega,\phi(x),\rho(x),U(a,\Lambda)),$$

which satisfies the defining conditions $H_1,\ldots,H_5$ of a hyperfunction quantum field (see Ref. 10). Since the vectors $\phi(f_1)\cdots\phi(f_n)\Omega$ span the Fock space $\mathcal{H}_F$ we have $\mathcal{H}=\mathcal{H}_F$.

Thus we arrive at the main result of this section.

Theorem VI.6: *Let ϕ be a free massive neutral scalar field and $\{a_n\}_{n\in\mathbb{N}}$ a sequence of real numbers satisfying* $\lim_{n\to\infty}[|a_n|^2/n!]^{1/n}=0$. *Then the (Wick) power series ρ of ϕ formed with the coefficients a_n according to Eq. (59) is a hyperfunction quantum field (but not a standard quantum field if infinitely many of the coefficients a_n are nonzero*).

B. A Model with nontrivial local algebras

The power series ρ of a free scalar field ϕ provide a class of hyperfunctions quantum fields (under technical restrictions discussed in the previous section).

The main focus of our discussion now is to show, for the class of models ρ constructed above, that $\mathcal{L}'_w(O)=L'(O)$ contains indeed a nontrivial *-algebra of observables. Clearly in the proof of this statement we will use the explicit definition of the hyperfunction quantum fields ρ in an essential way.

For a free neutral scalar field $\phi(x)$ of mass m the field operators $\phi(f)$, for real $f\in\mathcal{S}(\mathbf{R}^4)$, are known to be essentially self-adjoint on

$$\mathcal{D}_0=\text{lin span}\{\Omega,\phi(f_1)\cdots\phi(f_n)\Omega;\ \ f_k\in\mathcal{S}(\mathbf{R}^4),n=1,2,\ldots\}.$$

Denote the self-adjoint closure of $\phi(f)$ by $\Phi(f)$. Then,

$$e^{i\Phi(f)}\psi=\sum_{n=0}^{\infty}\frac{i^n\phi(f)^n}{n!}\psi$$

converges for $\psi\in\mathcal{D}_0$, and defines a unitary operator $e^{i\Phi(f)}$ (see Theorem X.41 of Ref. 30).

To an open set O in $\mathbf{R}^4$ assign the *-algebra $\mathcal{M}(O)$ generated by elements $e^{i\Phi(f)}$ for $f\in\mathcal{S}(\mathbf{R}^4)$ with $\text{supp}\, f\subset O$. This defines a net of nontrivial *-algebras of bounded operators on $\mathcal{H}$. Using the relation

$$e^{i\Phi(f)}e^{i\Phi(g)}=e^{D_m^{(-)}(f,g)/2}e^{i\Phi(f+g)}, \tag{62}$$

we have $e^{i\Phi(f_1)}\cdots e^{i\Phi(f_n)}=ce^{i\Phi(f_1+\cdots+f_n)}$ for some $c\in\mathbf{C}$. Thus, locality of the net $\{\mathcal{M}(O)\}$ is evident from (62) since $D_m^{(-)}(f,g)=D_m^{(-)}(g,f)$ if the supports of f and g are spacelike separated. Define $\Psi(g)$ by

$$\Psi(g)=:\exp i\phi(g):=\sum_{n=0}^{\infty} i^n\frac{:\phi(g)^n:}{n!}.$$

Let S be a subset of $\{1,2,\ldots,n\}$ and $\psi^{(i)}=\Psi(g)$ if $i\in S$ otherwise $\psi^{(i)}=\rho(x_i)$. Then we have

$$(\Omega,\psi^{(1)}\cdots\psi^{(n)}\Omega)=\sum_{r_{ij}=0,1\leqslant i<j\leqslant n}^{\infty}\frac{A(R)T^R}{R!}, \tag{63}$$

where

$$t_{ij}=D_m^{(-)}(x_i-x_j) \quad \text{if } i,j\notin S,$$

$$t_{ij}=\int D_m^{(-)}(x_i-x_j)g_i(x_i)g_j(x_j)dx_i dx_j\in\mathbf{C} \quad \text{if } i,j\in S,$$

$$t_{ij}=D_m^{(-)}(x_i,g_j)=\int D_m^{(-)}(x_i-x_j)g_j(x_j)dx_j \quad \text{if } i\notin S \text{ and } j\in S,$$

$$t_{ij}=D_m^{(-)}(g_i,x_j)=\int D_m^{(-)}(x_i-x_j)g_i(x_i)dx_i \quad \text{if } i\in S \text{ and } j\notin S.$$

Fix $j\in\{1,\ldots,n\}$ and consider points $z_i\in\mathbf{C}^4$ which satisfy the following conditions: $\mathrm{Im}(z_{i+1}-z_i)\in V_+$, $i=1,\ldots,j-1$ and $i=j+2,\ldots,n-1$; $\mathrm{Im}\,z_{j+2}\in V_+$, $\mathrm{Im}\,z_j=0$.

Now we apply the identity (63) to

$$(\Omega,\rho(z_1)\cdots\rho(z_{j-1})\rho(x_j)\Psi(g)\rho(z_{j+2})\cdots\rho(z_n)\Omega)$$

and look at the effect of the exchange of j and $j+1$, e.g., of $t_{i,j}\to t_{i,j+1}$. We find

$$(\Omega,\rho(z_1)\cdots\rho(z_{j-1})\Psi(g)\rho(x_j)\rho(z_{j+2})\cdots\rho(z_n)\Omega).$$

If x_j and $\mathrm{supp}\,g$ are spacelike separated, then $t_{j,j+1}=D_m^{(-)}(x_j,g)=D_m^{(-)}(g,x_j)=t_{j+1,j}$. Thus we get

$$\begin{aligned}&(\Omega,\rho(z_1)\cdots\rho(z_{j-1})\rho(x_j)\Psi(g)\rho(z_{j+2})\cdots\rho(z_n)\Omega)\\&\quad=(\Omega,\rho(z_1)\cdots\rho(z_{j-1})\Psi(g)\rho(x_j)\rho(z_{j+2})\cdots\rho(z_n)\Omega)\end{aligned}$$

and therefore

$$\begin{aligned}&(\Omega,\rho(x_1)\cdots\rho(x_{j-1})\rho(x_j)\Psi(g)\rho(x_{j+1})\cdots\rho(x_n)\Omega)\\&\quad=(\Omega,\rho(x_1)\cdots\rho(x_{j-1})\Psi(g)\rho(x_j)\rho(x_{j+1})\cdots\rho(x_n)\Omega)\end{aligned}\tag{64}$$

as an identity between Fourier hyperfunctions.

Now assume that O is an open bounded nonempty subset of space–time and that $g\in\mathcal{S}(\mathbf{R}^4)$ has its support in O. Then, for all x_j in the causal complement O' of O we deduce from (64)

$$(\Psi(g)^*u,\rho(x_j)v)=(\rho(x_j)u,\Psi(g)v)\tag{65}$$

for all $u=\rho(\overline{f}_{j-1})\cdots\rho(\overline{f}_1)\Omega$ and all $v=\rho(f_{j+2})\cdots\rho(f_n)\Omega$ in $\mathcal{D}_0$, where

$$\mathcal{D}_0=\mathrm{lin\,span}\{\Omega,\rho(f_1)\cdots\rho(f_n)\Omega;\ f_j\in\mathcal{Q}(\mathbf{D}^4),\ n=1,2,\ldots\}.$$

For the hyperfunction quantum field ρ recall the definition of the set of bounded operators localized in an open set $O\subset\mathbf{R}^4$ according to Sec. IV,

$$L'(O')=\{X\in\mathcal{B}(\mathcal{H});\mathrm{supp}[(X^*u,\rho(x)v)-(\rho(x)^*u,Xv)]\subset\mathbf{D}^4\setminus O',\forall u,v\in\mathcal{D}_0\},$$

where $\mathcal{D}_0=\mathrm{lin\,span}\{\Omega,\rho(f_1)\cdots\rho(f_n)\Omega;\ f_j\in\mathcal{Q}(\mathbf{D}^4),\ n=1,2,\ldots\}$. Hence Eq. (65) shows

$$\Psi(g)\in L'(O')$$

if $\mathrm{supp}\,g\subset O$. Since

$$:\exp i\phi(g):=e^{-D_m^{(-)}(g,g)/2}\exp i\Phi(g),$$

we have $\exp i\Phi(g)\in L'(O')$, and therefore

$$\mathcal{M}(O)\subset L'(O').$$

This shows

Theorem VI.7: *Consider a free neutral scalar field ϕ and assign to open bounded nonempty sets $O\subset\mathbf{R}^4$ the *-algebras $\mathcal{M}(O)$ introduced above. For the power series ρ of ϕ according to Theorem VI.6 form the spaces $L'(O')$ of bounded operators on the state space of ρ which are localized in open bounded nonempty sets $O\subset\mathbf{R}^4$ according to Sec. III. Then,*

$$\mathcal{M}(O)\subset L'(O')=\mathcal{L}'_w(O').$$

VII. CONCLUSION

In this paper the old problem of how to assign, in a relativistic quantum field theory, local *-algebras of observables to open bounded nonempty subsets $O\subset\mathbf{R}^4$ has been addressed in the context of hyperfunction quantum field theory. Since the localization properties of hyperfunction quantum fields are considerably more subtle than standard (Wightman) quantum fields the established routes to this problem do not apply. Thus a major step in addressing this problem ''correctly'' is our suggestion of the sets $\mathcal{L}'_w(O)$ of the set of those bounded operators on the state space of the field Φ which commute weakly with all products of fields $\Phi(x_1)\cdots\Phi(x_n)$ for all $x_k\in O$, $n=1,2,\ldots$. The local *-algebras of observables $\mathcal{M}(O)$ are then defined as suitable subspaces of $\mathcal{L}'_w(O')$.

In order to enable this construction, the proof of three important structural results in hyperfunction quantum field theory which are all well known in standard QFT: existence of a CPT-operator, Reeh–Schlieder theorem, Bisognano–Wichmann analyticity had to be given. This then prepares the ground for the proof of some structural results for the weak commutants $\mathcal{L}'_w(O)$ and a suggestion for $\mathcal{M}(O)\subset\mathcal{L}'_w(O')$. Following basically a modification of the Bisognano–Wichmann strategy the locality of the net $\{\mathcal{M}(O)\}$ is established for double cones. We conclude that the Bisognano–Wichmann theory does not really rely on the existence of compactly supported test functions.

Since hyperfunctions can grow much faster than tempered distributions, a domain problem in the definition of $\mathcal{L}'_w(O)$ (which does not occur in standard QFT) has to be addressed, and a mild growth restriction for the hyperfunction quantum field is offered which allows us to solve the domain problem. Then, relying on recent results in the theory of Fourier hyperfunctions (the kernel theorem in full generality) a simplifying and more intuitive characterization of the weak commutants $\mathcal{L}'_w(O)$ is derived in

$$\mathcal{L}'_w(O)=L'(O),$$

where $L'(O)$ is the space of all bounded operators on the state space of the field which commute weakly with the field $\Phi(x)$ for $x\in O$.

It seems to us that it is expected too much to be able to prove the nontriviality of the suggested *-algebras in full generality without any further specification of the hyperfunction quantum field under consideration (as in the case of standard quantum fields). Thus we address the problem of the existence of nontrivial *-algebras $\mathcal{M}(O)$ in the context of a class of concrete models: Wick powers series of free fields (in general they are hyperfunction quantum fields but not standard quantum fields). For this class of models the existence of a nontrivial *-algebra $\mathcal{M}(O)\subset L'(O')$ is shown explicitly. It is remarkable that these models of hyperfunction quantum fields do not admit test-functions with compact support.

ACKNOWLEDGMENTS

Most of the work for this paper was done during S. Nagamachi's visit to the Department of Mathematics and Applied Mathematics, University of Durban-Westville and during E. Brüning's

sabbatical leave visiting among others the University of Tokushima. We are very grateful to the National Research Foundation of South Africa, in particular to the International Liaison and Open Research Program Departments, and the University of Tokushima who enabled these visits through their generous financial support. The suggestions of the referee were quite valuable for the presentation of our results. We are very grateful for his constructive criticism.

We show that a partition function of topological twisted $N=4$ Yang–Mills theory is given by Seiberg–Witten invariants on a Riemannian four manifolds under the condition that the sum of the Euler number and the signature of the four manifolds vanishes. The partition function is the sum of the Euler number of instanton moduli space when it is possible to apply the vanishing theorem. Also we obtain a relation of the Euler number labeled by the instanton number k with Seiberg–Witten invariants. All calculations in this article are done without assuming duality. [DOI: 10.1063/1.1331319]

I. INTRODUCTION

The aim of this article is to obtain a relation of the partition function of topological twisted $N=4$ gauge theory with Seiberg–Witten invariants in four manifolds. The partition function is given by the Euler number of instanton moduli space in some conditions. We will show that the Euler number labeled by instanton number k is expressed by Seiberg–Witten invariants when the sum of the Euler number and the signature of the base four manifolds vanishes. This result gives us the formulas to obtain the partition function of the twisted $N=4$ gauge theory by Seiberg–Witten invariants.

The partition functions of the $N=4$ Yang–Mills theories on some four manifolds are calculated by Vafa and Witten with topological field theory.[1,2] It is an SL(2,Z) modular form. SL(2,Z) transformation is understood as an extension of Montonen–Olive duality.[3] So the duality relation is apparent in that partition function.

This duality is deeply connected with the Hilbert scheme picture of instanton moduli space.[4] However, in general, instanton moduli space has variety compactification and the sum of the Euler number of any compactified moduli space is not necessarily a modular form. Actually, in our calculus, the partition function is not a modular form with no contrivance. On the other hand, $N=4$ gauge theory is given by the toroidal compactification of 10-dim $N=1$ gauge theory on a 4-dim manifold. (Note that ''compactification'' is used two ways.) So the theory is interpreted as a low-energy theory of the heterotic or type I string theory. Recent developments in string theory show us much evidence of duality relation in field theory. In our case, Vafa shows us one method to link the compactified instanton moduli space with the Hilbert scheme.[5] This fact implies that a choice of compactification is understood in string theory better than field theory. We discuss the problem of compactification and duality later.

For our purpose we use a tool similar to topological QCD constructed by S. Hyun, J. Park, and J-S. Park (H-P-P).[6] They used the non-Abelian monopole theory and related the Donaldson invariants to Seiberg–Witten invariants without using duality.[7,8] We also calculate the partition function in the low-energy limit of cohomological field theory[9] and there is no request of S-duality. This is the most different point from Dijkgraaf, Park, and Schroers.[10] They have deter-

[a)]Electronic mail: sako@math.sci.hiroshima-u.ac.jp
[b)]Electronic mail: sasaki@particle.sci.hokudai.ac.jp

mined the partition function of $N=4$ supersymmetric Yang–Mills theory on a Kähler surface, using S-duality. Their result is given by Seiberg–Witten invariants, too. So, it is interesting to compare our results with theirs.

What we do first is to extend the instanton moduli space to non-Abelian monopole moduli. In usual cohomological field theory, it was done by H-P-P[11] and Labastida and Mariño.[12] Vafa–Witten theory is constructed as a balanced topological field theory (we denote it as BTFT in the following).[13] BTFT has no ghost number anomaly, and its partition function is a sum of the Euler numbers of given zero-section space under the vanishing theorem. In Sec. II, we will construct the non-Abelian monopole theory as BTFT and investigate some characteristics of the theory. The vanishing theorem is an obstruction to constructing the partition function as the sum of the Euler numbers of the monopole moduli, and to get a relation with Vafa–Witten theory. We do not study this case closer in this article.

In Sec. III, we obtain the formulas between the partition function of a twisted $N=4$ Yang–Mills theory and Seiberg–Witten invariants. To obtain them, we break the balance of topological charge. The tools in this article were used in obtaining a relation of Donaldson invariants and Seiberg–Witten invariants.[6] We use a model which has a gauge multiplet that is balanced and a hypermultiplet that is not balanced. We call the model unbalanced topological QCD. The vacuum expectation value (VEV) of an observable is calculated and the relation between the Euler number of instanton moduli space and Seiberg-Witten invariants is obtained if the vanishing theorem is applicable and the sum of the Euler number and the signature of the four manifolds vanishes. The comparison with the papers of Vafa and Witten[1] and Dijkgraaf, Park, and Schroers[10] is also made in this section. In the last section, we discuss some remaining problems and the possibility of extension.

II. BALANCED TOPOLOGICAL QCD

In this section, we construct a balanced topological QCD (BTQCD), which is a twisted $N=4$ Yang–Mills theory coupled with massive hypermultiplets in the fundamental representation.[10,11,6]

A. Balanced topological QCD

Let X be a compact Riemannian four manifold and E be an SU(2)-bundle over X. The bundle E is classified by the instanton number

$$k=\frac{1}{8\pi^2}\int_X \mathrm{Tr}\, F\wedge F, \tag{2.1}$$

where Tr is the trace in the fundamental representation of SU(2) and $F\in\Omega^2_X(\mathcal{G}_E)$ is the adjoint valued curvature two-form on X. We denote the group of gauge transformation by $\mathcal{G}$, i.e., elements of $\mathcal{G}$ are sections of P, where P is the associated principal SU(2)-bundle over X. We pick a spin^c structure c on X and consider the associated spin^c bundle $W_c^{\pm}$. Let $\mathcal{A}$ be the space of all connections on P and $\Gamma(W_c^+\otimes E)(\Gamma(W_c^-\otimes E))$ be the space of the sections of the spin^c bundle twisted by the vector bundle E. After twisting, the complex boson in the hypermultiplet becomes a section of $\Gamma(W_c^+\otimes E)(\Gamma(W_c^-\otimes E))$:

$$\begin{aligned} &q\in\Gamma(W_c^+\otimes E), \quad q^\dagger\in\Gamma(\overline{W}_c^+\otimes\tilde{E}),\\ &B\in\Gamma(W_c^-\otimes E), \quad B^\dagger\in\Gamma(\overline{W}_c^-\otimes\tilde{E}), \end{aligned} \tag{2.2}$$

where $\tilde{E}$ denotes the vector bundle conjugate to E. The spin^c Dirac operator

$$\sigma^\mu D_\mu:\Gamma(W_c^+\otimes E)\to\Gamma(W_c^-\otimes E) \tag{2.3}$$

is the Dirac operator for the spin^c bundle twisted by E. We will sometimes denote $\sigma^\mu D_\mu$ by $\not{D}$ or $\not{D}_c^E$.

Throughout this article, we restrict our attention to the case that the gauge group is SU(2) and the theory is coupled with hypermultiplets in the fundamental representation.

1. Algebra of BTQCD

In this section, the algebra of BTQCD is given.

We introduce two global supercharges $Q_\pm$ carrying an additive quantum number (ghost number) $U=\pm 1$. When they act on fields in the adjoint representation, they satisfy the following commutation relations:

$$Q_+^2=\delta_\theta^g,\ \{Q_+,Q_-\}=-\delta_c^g,\quad Q_-^2=-\delta_{\bar\theta}^g, \tag{2.4}$$

where δ_θ^g denotes the gauge transformation generated by adjoint scalar field $\theta\in\Omega_\chi^0(\mathcal{G}_E)$ and we adopt $\delta_\theta^g A_\mu=D_\mu\theta$, $\delta_\theta^g B_{+\mu\nu}=i[B_{+\mu\nu},\theta]$, and $\delta_\theta^g c=i[c,\theta]$. When they act on fields in the fundamental representation, they satisfy the following commutation relations:

$$Q_+^2=-\delta_\theta^g,\quad \{Q_+,Q_-\}=\delta_c^g,\quad Q_-^2=\delta_{\bar\theta}^g, \tag{2.5}$$

where we also introduce U(1) global transformation generated by $m\in iR$ and we adopt $\delta_\theta^g q=(i\theta+m)q$, $\delta_\theta^g q^\dagger=q^\dagger(-i\theta-m)$, $\delta_\theta^g B=(i\theta+m)B$, and $\delta_\theta^g B^\dagger=B^\dagger(-i\theta-m)$. The relative sign difference between (2.4) and (2.5) is simply the difference of representations. A simple explanation is the following. One can construct a field J^a in the adjoint representation with a pair of fields $q,q^\dagger$ in the fundamental representation,

$$J^a\equiv q^\dagger T^a q. \tag{2.6}$$

Using the above transformations, one can check (2.4) follows from (2.5):

$$Q_+^2 J^a=Q_+^2(q^\dagger T^a q)=(-\delta_\theta^g q^\dagger)T^a q+q^\dagger T^a(-\delta_\theta^g q)=i[q^\dagger Tq,\theta]^a=\delta_\theta^g J^a. \tag{2.7}$$

Note that the relative sign difference between (2.4) and (2.5) is consistent with this derivation. The recipe for giving mass to fields in the fundamental representation by global symmetry is considered by H-P-P.[6]

We define $\delta_\pm$ transformations $\delta_\pm\equiv[Q_\pm,*\}$. $\delta_\pm$ transformations are given in Appendix A. See also Refs. 13 and 6.

2. Action of BTQCD

Using the previous fields and transformations, we define the action of BTQCD as

$$h^2 S=\int\sqrt{g}\mathcal{L}, \tag{2.8}$$

where

$$\mathcal{L}=\delta_+\delta_-\mathcal{F}. \tag{2.9}$$

Here $\mathcal{F}$ is described with fields in the previous paragraph and has ghost number 0. The general recipe for constructing a balanced topological field theory is given by Moore *et al.*[13]

Here $\mathcal{F}$ is explicitly given by

$$\mathcal{F}=(B_+^{\mu\nu a}s^a_{+\mu\nu})-(\chi_+^{I\mu\nu a}\psi^a_{B\mu\nu})-(\chi^{IIa}_{B\mu}\psi^{\mu a})+(-i\tfrac{1}{3}B_+^{\mu\nu a}[B_{+\mu\rho},B_{+\nu\sigma}]^a g^{\rho\sigma})$$
$$+(B^{\dagger\alpha}s_\alpha)-(\chi_q^{I\dagger\alpha}\psi_{B\alpha})-(\chi^{II\dagger}_{B\dot\alpha}\psi_q^{\dot\alpha})+(s^{\dagger\alpha}B_\alpha)+(\psi_B^{\dagger\alpha}\chi^1_{q\alpha})+(\psi^\dagger_{q\dot\alpha}\chi_B^{II\dot\alpha})+(\xi^a\eta^a), \tag{2.10}$$

where

$$s_+^{\mu\nu}=F_+^{\mu\nu}+q^\dagger\bar\sigma^{\mu\nu}q, \tag{2.11}$$

$$s_\alpha=(\not{D}q)_\alpha. \tag{2.12}$$

Finally, the full Lagrangian is given by

$$\mathcal{L}^{\text{full}}=\delta_+\delta_-\mathcal{F}. \tag{2.13}$$

Explicit expression of this Lagrangian is given in Appendix A. This Lagrangian [(A18)] is different from Vafa–Witten[1] in matter fields (q, B, etc.) and also different from H-P-P[6] in dual fields ($B_+^{\mu\nu}$, c, B, etc.). However, due to its construction, it is balanced.

B. Fixed point

In this subsection, we study the nature of the action given in Sec. II A. Here in particular we investigate the fixed points and vanishing theorem.[1]

1. Fixed point

To check the nature of the Lagrangian, we decompose the bosonic part of Lagrangian (A18)

$$\mathcal{L}^{\text{full}}_{\text{boson}}=\mathcal{L}^{\text{eq}}_{\text{boson}}+\mathcal{L}^{\text{pro}}_{\text{boson}}, \tag{2.14}$$

where

$$\begin{aligned}\mathcal{L}^{\text{eq}}_{\text{boson}}=&-H_+^{I\mu\nu a}\{H^a_{+\mu\nu}-(s^a_{+\mu\nu}-i[B_{+\mu\rho},B_{+\nu\sigma}]^a g^{\rho\sigma}-i[B_{+\mu\nu},c]^a)\}\\&-H_B^{II\rho a}\{H^{IIa}_{B\rho}-(-2D^\mu B^a_{+\mu\rho}+iB^\dagger\sigma_\rho T^a q-iq^\dagger\bar\sigma_\rho T^aB-D_\rho c^a)\}\\&-H_q^{I\dagger\alpha}\{H^I_{q\alpha}-(s_\alpha+icB_\alpha+m_cB_\alpha)\}+(\text{h.c.})\\&-H^{II\dagger}_{B\dot\alpha}\{H_B^{II\dot\alpha}-(-(\not{D}B)^{\dot\alpha}+(\bar\sigma^{\mu\nu}B_{+\mu\nu}q)^{\dot\alpha}+icq^{\dot\alpha}+m_cq^{\dot\alpha})\}+(\text{h.c.})\end{aligned} \tag{2.15}$$

and

$$\begin{aligned}\mathcal{L}^{\text{pro}}_{\text{boson}}=&-\{[\theta,\bar\theta]^a[\bar\theta,\theta]^a-[c,\theta]^a[c,\bar\theta]^a+[B_+^{\mu\nu},\bar\theta]^a[B_{+\mu\nu},\theta]^a\}+D_\mu\bar\theta^aD^\mu\theta^a\\&+(-iq^\dagger\bar\theta-q^\dagger\bar m)(i\theta q+mq)+(-iq^\dagger\theta-q^\dagger m)(i\bar\theta q+\bar mq)\\&+(-iB^\dagger\bar\theta-B^\dagger\bar m)(i\theta B+mB)+(-iB^\dagger\theta-B^\dagger m)(i\bar\theta B+\bar mB).\end{aligned} \tag{2.16}$$

Here $\mathcal{L}^{\text{eq}}_{\text{boson}}$ is defining the moduli space that we want to consider and $\mathcal{L}^{\text{pro}}_{\text{boson}}$ is induced for the projection to gauge normal direction. Lagrangian (2.15) is rewritten as

$$\begin{aligned}\mathcal{L}^{\text{eq}}_{\text{boson}}=&H\ \text{ square terms}+\tfrac{1}{4}(s^a_{+\mu\nu}-i[B_{+\mu\rho},B_{+\nu\sigma}]^a g^{\rho\sigma})^2-\tfrac{1}{4}([B_{+\mu\nu},c]^a)^2\\&+\tfrac{1}{4}(-2D^\mu B^a_{+\mu\rho}+iB^\dagger\sigma_\rho T^aq-iq^\dagger\bar\sigma_\rho T^aB)^2+\tfrac{1}{4}(D_\rho c^a)^2+\tfrac{1}{2}|s|^2\\&+\tfrac{1}{2}|icB+m_cB|^2+\tfrac{1}{2}|-(\not{D}^\dagger B)^{\dot\alpha}+(\bar\sigma^{\mu\nu}B_{+\mu\nu}q)^{\dot\alpha}|^2+\tfrac{1}{2}|icq+m_cq|^2.\end{aligned} \tag{2.17}$$

Thus we have the following fixed point equations:

$$
\begin{gathered}
F_{+\mu\nu}+q^{\dagger}\bar{\sigma}_{\mu\nu}q-i[B_{+\mu\rho},B_{+\nu\sigma}]g^{\rho\sigma}=0,\\
-2D_{\mu}B_{+}^{\mu\nu}+iB^{\dagger}\sigma^{\nu}q-iq^{\dagger}\bar{\sigma}^{\nu}B=0,\\
s=\not{D}q=0,\\
-\not{D}^{\dagger}B+\bar{\sigma}_{\mu\nu}B_{+}^{\mu\nu}q=0,\\
D_{\nu}\theta=D_{\nu}c=D_{\nu}\bar{\theta}=0,\\
[\theta,\bar{\theta}]=[c,\theta]=[c,\bar{\theta}]=[B_{+}^{\mu\nu},\theta]=[B_{+}^{\mu\nu},\bar{\theta}]=[B_{+}^{\mu\nu},c]=0,\\
(i\theta+m)q=(i\bar{\theta}+\bar{m})q=(ic+m_{c})q=0,\\
q^{\dagger}(-i\theta-m)=q^{\dagger}(-i\bar{\theta}-\bar{m})=q^{\dagger}(-ic-m_{c})=0,\\
(i\theta+m)B=(i\bar{\theta}+\bar{m})B=(ic+m_{c})B=0,\\
B^{\dagger}(-i\theta-m)=B^{\dagger}(-i\bar{\theta}-\bar{m})=B^{\dagger}(-ic-m_{c})=0.
\end{gathered}
\tag{2.18}
$$

If hypermultiplet fields are set to zero ($q=q^{\dagger}=B=B^{\dagger}=0$), then the above equations are Vafa–Witten equations.[1,10] Thus we call the above equations extended Vafa–Witten equations.

2. Problem

In the previous paragraph, we have obtained fixed point equations of BTQCD. The equations for fermionic zero-modes are just the linearization of the fixed point equation and the condition that they are orthogonal to gauge orbits. Due to the balanced structure each fermionic zero-mode has a partner with the opposite U number. Thus there is no ghost number anomaly and the partition function is well defined, i.e., there is no need to insert observables. We want to compute the partition function of BTQCD. According to Vafa–Witten, if an appropriate vanishing theorem holds, the partition function becomes the sum of the Euler numbers of moduli space which we want to calculate. Roughly speaking, the vanishing theorem is understood as the condition that dual fields ($B_{+\mu\nu},c,B,B^{\dagger}$, etc.) are to be zero and the dimensions of their moduli space become zero, when we choose an appropriate metric.[1] However, we could not verify that the vanishing theorem holds in this model. To compare the result of this section to that of the next section, we give the only result to compute the partition function of BTQCD on the condition that the vanishing theorem holds.

C. Result

In this subsection, we give the result of computing the path integral of BTQCD. We define partition function of BTQCD as

$$
Z=\frac{1}{\mathrm{Vol}\,\mathcal{G}(2\pi)^{\Omega}}\int \mathcal{D}W\mathcal{D}\psi_{W}\mathcal{D}Q^{\dagger}\mathcal{D}\psi_{Q}^{\dagger}\mathcal{D}Q\mathcal{D}\psi_{Q}e^{-S},
\tag{2.19}
$$

where

$$
\begin{gathered}
W=A_{\mu},B_{+}^{\mu\nu},H_{B}^{\mu},H_{+}^{\mu\nu},\theta,c,\bar{\theta},\\
\psi_{W}=\psi_{\mu},\psi_{B}^{\mu\nu},\chi_{B}^{II\mu},\chi_{+}^{I\mu\nu},\xi,\eta,\\
Q=q,B,H_{q}^{I},H_{B}^{II},
\end{gathered}
\tag{2.20}
$$

$$\psi_Q = \psi_q, \psi_B, \chi_q^I, \chi_B^{II},$$

$$\Omega = \text{dim of } H\text{'s}.$$

Here we denote auxiliary fields as $H_B^\mu, H_+^{\mu\nu}, H_q^I, H_B^{II}$, and we call auxiliary fields for Y as H's of Y in the following, dim of H's is the number of the auxiliary fields.

After path integrations of the transverse part we get the partition function as the sum of two branches, according to the methods of the next section,

$$Z = Z^{\mathrm{V-W}} + Z^{B-U(1)S-W}. \tag{2.21}$$

$Z^{\mathrm{V-W}}$ is a contribution from branch 1 (gauge symmetry is unbroken), and corresponds to a Vafa–Witten partition function. $Z^{B-U(1)S-W}$ is a contribution from branch 2 [gauge symmetry is broken to U(1)], and corresponds to balanced U(1) monopole theory. The fixed point equations of the balanced U(1) monopole theory are

$$\begin{gathered} F^3_{+\mu\nu} + \tfrac{1}{2} q_1^\dagger \overline{\sigma}_{\mu\nu} q_1 = 0, \\ -2\nabla_\mu B_+^{\mu\nu 3} + i\,\tfrac{1}{2} B_1^\dagger \sigma^\nu q_1 - i\,\tfrac{1}{2} q_1^\dagger \overline{\sigma}^\nu B_1 = 0, \\ \not{D}^3 q_1 = 0, \\ -\not{D}^{\dagger 3} B_1 + \tfrac{1}{2}\,\overline{\sigma}_{\mu\nu} B_+^{\mu\nu 3} q_1 = 0, \end{gathered} \tag{2.22}$$

where $F^3_{+\mu\nu}$ is a curvature of U(1) left symmetry after breaking SU(2) and the labels of q_1 and B_1 are the ones of color. Since we do not know the vanishing theorem for dual fields $(B^3_{+\mu\nu}, B_1, B_1^\dagger)$ from (2.22), we stop to investigate this model further in this article.

III. UNBALANCED TOPOLOGICAL QCD

In this section, we compute a correlation function of an appropriate BRS exact operator (the BRS operator is defined in Appendix A) in the unbalanced topological QCD. As a result, we can describe the Euler number of instanton moduli space with Seiberg–Witten invariants. We have a similar but not the same expression to Dijkgraaf *et al.*,[10] because we treat a different theory from theirs. We discuss this point at the end of this section.

A. Unbalanced topological QCD

Here we construct the unbalanced topological QCD, which is a twisted $N=4$ Yang–Mills theory coupled with only one massive hypermultiplet in the fundamental representation (we denote it as UBTQCD in the following). Alternatively, one obtains a UBTQCD, when one sets one massive hypermultiplet $(B, \psi_B, \chi_B^{II}, H_B^{II})$ of BTQCD in the previous section to zero (we call this process breaking balanced structure).

1. Algebra of UBTQCD

The algebra of UBTQCD is given as a part of the BTQCD algebra. Contrary to the previous section, we only consider the global supercharge Q_+. When it acts on adjoint (fundamental) fields, it satisfies the following commutation relation:

$$Q_+^2 = \delta_\theta^g(-\delta_\theta^g). \tag{3.1}$$

We adopt the same δ_+ transformations as in the previous section and in Appendix A (A7)–(A14).

2. Action of UBTQCD

We define the action of UBTQCD as

$$h^2 S = \int d^4x \sqrt{g}\mathcal{L}, \tag{3.2}$$

where

$$\mathcal{L} = \delta_+ \Psi. \tag{3.3}$$

We explicitly give Ψ as

$$\begin{aligned}
\Psi = & -\chi_+^{I\mu\nu a}\{H_{+\mu\nu}^{Ia} - (s_{+\mu\nu}^a - i[B_{+\mu\rho}, B_{+\nu\sigma}]^a g^{\rho\sigma} - i[B_{+\mu\nu}, c]^a)\} \\
& - \chi^{II\rho a}\{H_{B\rho}^{IIa} - (-2D^\mu B_{+\mu\rho}^a - D_\rho c^a)\} - \chi_q^{I\dagger\alpha}\{H_{q\alpha}^I - s_\alpha\} - \{H_q^{I\dagger\alpha} - s^{\dagger\alpha}\}\chi_{q\alpha}^I \\
& + \{i[\theta, \overline{\theta}]^a \eta^a - i\xi^a [c, \overline{\theta}]^a\} + i[B_+^{\mu\nu}, \overline{\theta}]^a \psi_{B\mu\nu}^a + D_\mu \overline{\theta}^a \psi^{\mu a} \\
& - (-iq_{\dot\alpha}^\dagger \overline{\theta} - \overline{m} q_{\dot\alpha}^\dagger)\psi_q^{\dot\alpha} - \psi_{q\dot\alpha}^\dagger (i\overline{\theta} q^{\dot\alpha} + \overline{m} q^{\dot\alpha}),
\end{aligned} \tag{3.4}$$

where

$$s_+^{\mu\nu a} = F_+^{\mu\nu a} + q^\dagger \overline{\sigma}^{\mu\nu} T^a q, \tag{3.5}$$

$$s^\alpha = (\not{D} q)^\alpha. \tag{3.6}$$

Finally, the full Lagrangian is given by

$$\mathcal{L}^{\text{full}} = \delta_+ \Psi \tag{3.7}$$

$$\begin{aligned}
= & -H_+^{I\mu\nu a}\{H_{+\mu\nu}^{Ia} - (s_{+\mu\nu}^a - i[B_{+\mu\rho}, B_{+\nu\sigma}]^a g^{\rho\sigma} - i[B_{+\mu\nu}, c]^a)\} \\
& - \chi_+^{I\mu\nu a}\{-i[\chi_{+\mu\nu}^I, \theta]^a + 2D_\mu \psi_\nu^a + \psi_q^\dagger \overline{\sigma}_{\mu\nu} T^a q + q^\dagger \overline{\sigma}_{\mu\nu} T^a \psi_q - 2i[B_{+\mu\rho}, \psi_{B\nu\sigma}]^a g^{\rho\sigma} \\
& - i[\psi_{B\mu\nu}, c]^a - i[B_{+\mu\nu}, \xi]^a\} - H_B^{II\rho a}\{H_{B\rho}^{IIa} - (-2D^\mu B_{+\mu\rho}^a - D_\rho c^a)\} \\
& - \chi_B^{II\rho a}\{-i[\chi_{B\rho}^{II}, \theta]^a - 2D^\mu \psi_{B\mu\rho}^a - 2i[\psi^\mu, B_{+\mu\rho}]^a - D_\rho \xi^a - i[\psi_\rho, c]^a\} \\
& - H_q^{I\dagger\alpha}\{H_{q\alpha}^I - s_\alpha\} - \chi_q^{I\dagger}\{\not{D}\psi_q + \sigma_\rho i\psi^\rho q\} + (\text{h.c. previous two terms}) \\
& - \{[\theta, \overline{\theta}]^a [\overline{\theta}, \theta]^a - [c, \theta]^a [c, \overline{\theta}]^a + [B_+^{\mu\nu}, \overline{\theta}]^a [B_{+\mu\nu}, \theta]^a\} + D_\mu \overline{\theta}^\alpha D^\mu \theta^\alpha i[\theta, \eta]^a \eta^a \\
& + i\xi^a [\xi, \overline{\theta}]^a + i\xi^a [c, \eta]^a + i[\psi_B^{\mu\nu}, \overline{\theta}]^a \psi_{B\mu\nu}^a + i[B_+^{\mu\nu}, \eta]^a \psi_{B\mu\nu}^a + D_\mu \eta^a \psi^{\mu a} \\
& + i[\psi_\mu, \overline{\theta}]^a \psi^{\mu a} + (-iq^\dagger \overline{\theta} - q^\dagger \overline{m})(i\theta q + mq) + (-iq^\dagger \theta - q^\dagger m)(i\overline{\theta} q + \overline{m} q) \\
& + 2\psi_q^\dagger (i\overline{\theta} + \overline{m})\psi_q - 2\chi_q^{I\dagger}(i\theta + m)\chi_q^I - (-iq^\dagger \eta - q^\dagger \eta_m)\psi_q + \psi_q^\dagger (i\eta q + \eta_m q).
\end{aligned} \tag{3.8}$$

Notice that Lagrangian (3.8) is given by Lagrangian (A18) of the previous section if $(B, \psi_B, H_B^{II}, \chi_B^{II})$ is set to zero.

B. Fixed point

In this subsection, we study the nature of the action given in Sec. III A. Here in particular we investigate the fixed points and some observables to insert.

1. Fixed point

To check the nature of the Lagrangian, we decompose the bosonic part of Lagrangian (3.8):

$$\mathcal{L}^{\text{full}}_{\text{boson}}=\mathcal{L}^{\text{eq}}_{\text{boson}}+\mathcal{L}^{\text{pro}}_{\text{boson}}, \tag{3.9}$$

where

$$\begin{aligned}\mathcal{L}^{\text{eq}}_{\text{boson}}=&-H_{+}^{I\mu\nu a}\{H^{Ia}_{+\mu\nu}-(s^{a}_{+\mu\nu}-i[B_{+\mu\rho},B_{+\nu\sigma}]^{a}g^{\rho\sigma}-i[B_{+\mu\nu},c]^{a})\}\\&-H_{B}^{II\rho a}\{H^{IIa}_{B\rho}-(-2D^{\mu}B^{a}_{+\mu\rho}-D_{\rho}c^{a})\}-H_{q}^{I\dagger\alpha}\{H^{I}_{q\alpha}-s_{\alpha}\}+(\text{h.c.})\end{aligned} \tag{3.10}$$

and

$$\begin{aligned}\mathcal{L}^{\text{pro}}_{\text{boson}}=&-\{[\theta,\overline{\theta}]^{a}[\overline{\theta},\theta]^{a}-[c,\theta]^{a}+[B_{+}^{\mu\nu},\overline{\theta}]^{a}[B_{+\mu\nu},\theta]^{a}\}+D_{\mu}\overline{\theta}^{a}D^{\mu}\theta^{a}+(-iq^{\dagger}\overline{\theta}-q^{\dagger}\overline{m})\\&+(i\theta q+mq)+(-iq^{\dagger}\theta-q^{\dagger}m)(i\overline{\theta}q+\overline{m}q).\end{aligned} \tag{3.11}$$

Here $\mathcal{L}^{\text{eq}}_{\text{boson}}$ is defining the moduli space that we want to consider and $\mathcal{L}^{\text{pro}}_{\text{boson}}$ is induced for the projection to gauge normal direction. Lagrangian (3.10) is transformed into

$$\begin{aligned}\mathcal{L}^{\text{eq}}_{\text{boson}}=&-\{H^{Ia}_{+\mu\nu}-\tfrac{1}{2}(s^{a}_{+\mu\nu}-i[B_{+\mu\rho},B_{+\nu\sigma}]^{a}g^{\rho\sigma}-i[B_{+\mu\nu},c]^{a})\}^{2}\\&-\{H^{IIa}_{B\rho}-\tfrac{1}{2}(-2D^{\mu}B^{a}_{+\mu\rho}-D_{\rho}c^{a})\}^{2}-2|H^{I}_{q\alpha}-\tfrac{1}{2}s_{\alpha}|^{2}\\&+\tfrac{1}{4}(s^{a}_{+\mu\nu}-i[B_{+\mu\rho},B_{+\nu\sigma}]^{a}g^{\rho\sigma}-i[B_{+\mu\nu},c]^{a})^{2}+\tfrac{1}{4}(-2D^{\mu}B^{a}_{+\mu\rho}-D_{\rho}c^{a})^{2}+\tfrac{1}{2}|s_{\alpha}|^{2}.\end{aligned} \tag{3.12}$$

Thus we have the following fixed point equations:

$$\begin{gathered}F_{+\mu\nu}+q^{\dagger}\overline{\sigma}_{\mu\nu}q-i[B_{+\mu\rho},B_{+\nu\sigma}]g^{\rho\sigma}-i[B_{+\mu\nu},c]=0,\\-2D_{\mu}B_{+}^{\mu\nu}-D^{\nu}c=0,\\s=\not{D}q=0,\\D_{\nu}\theta=D_{\nu}\overline{\theta}=0,\\[\theta,\overline{\theta}]=[c,\theta]=[c,\overline{\theta}]=[B_{+}^{\mu\nu},\theta]=[B_{+}^{\mu\nu},\overline{\theta}]=0,\\(i\theta+m)q=(i\overline{\theta}+\overline{m})q=0,\\q^{\dagger}(-i\theta-m)=q^{\dagger}(-i\overline{\theta}-\overline{m})=0.\end{gathered} \tag{3.13}$$

2. Problem

In the previous paragraph, we have obtained the fixed point equations of UBTQCD. In the same way as in the previous section, the equations for fermionic zero-modes are just the linearization of the fixed point equations and the conditions that they are orthogonal to gauge orbits. Compared with the previous section, UBTQCD does not have balanced structure. In particular, the hypermultiplet does not have balanced structure, while adjoint representation fields still have balanced structure. The partition function of unbalanced theory becomes zero due to its ghost number anomaly when the moduli space dimension of the matter field is nonzero. Thus to get a well-defined path integral, we have to insert some observables. One can think of an observable

$$I=\int d^4x\,(q^\dagger(i\theta+m)q+\psi_q^\dagger\psi_q). \tag{3.14}$$

Note that this observable itself is BRS exact, i.e.,

$$I=\delta_+\frac{1}{2}\int d^4x\,(-\psi_q^\dagger q+q^\dagger\psi_q). \tag{3.15}$$

Thus the expectation value of I is zero according to the Ward–Takahashi identity, and the expectation value of e^I becomes zero when this theory has a ghost number anomaly. However, as we will see, we obtain nontrivial results.

C. Branch

In this subsection, we will show that the fixed point equations are decomposed to two branches. We cite H-P-P.[6]

Equations

$$D_\nu\theta=D_\nu\overline{\theta}=0,\quad [\theta,\overline{\theta}]=0 \tag{3.16}$$

imply that θ, $\overline{\theta}$ can be diagonalized in the fixed points. If connections A_μ are irreducible, θ, $\overline{\theta}$ should be zero (the gauge symmetry is unbroken). If connections A_μ are reducible, θ, $\overline{\theta}$ can be nonzero [the gauge symmetry is broken down to U(1)]. When these solutions are applied to

$$\begin{gathered}(i\theta+m)q=(i\overline{\theta}+\overline{m})q=0,\\ q^\dagger(-i\theta-m)=q^\dagger(-i\overline{\theta})-\overline{m})=0,\end{gathered} \tag{3.17}$$

we have two branches:

branch 1 $\theta=\overline{\theta}=0$ and $q=q^\dagger=0$

or

branch 2 $\theta=\theta^3T^3\neq 0$, $\overline{\theta}=\overline{\theta}^3T^3\neq 0$ and $q\neq 0$, $q^\dagger\neq 0$.

Note that in branch 2 we choose unbroken U(1) as T^3 direction without a loss of generality.

Branch 1: $\theta=\overline{\theta}=0$ and $q=q^\dagger=0$, i.e., the gauge symmetry is unbroken. The remaining fixed point equations are

$$\begin{gathered}F_+^{\mu\nu}-i[B_{+\mu\rho},B_{+\nu\sigma}]g^{\rho\sigma}=0,\quad -2D_\mu B_+^{\mu\nu}=0,\quad D_\mu c=0,\\ [B_+^{\mu\nu},c]=0.\end{gathered} \tag{3.18}$$

Here one may apply the same condition as Vafa–Witten[1] to induce the vanishing theorem, and obtain the moduli space of

$$F_+^{\mu\nu}=0. \tag{3.19}$$

Branch 2: $\theta=\theta^3T^3\neq 0$, $\overline{\theta}=\overline{\theta}^3T^3\neq 0$ and $q\neq 0$, $q^\dagger\neq 0$, i.e., the gauge symmetry is broken to U(1). Thus the bundle E splits into line bundles, $E=L\oplus L^{-1}$ with $L\cdot L=-k$. Then Eqs. (3.17) are

$$(i\theta^3T^3+m)q=\begin{pmatrix}\frac{i}{2}\theta^3+m & 0\\ 0 & -\frac{i}{2}\theta^3+m\end{pmatrix}\begin{pmatrix}q_1\\ q_2\end{pmatrix}=0,$$

$$
\begin{aligned}
(i\overline{\theta^3}T^3+\overline{m})q&=\begin{pmatrix}\frac{i}{2}\overline{\theta^3}+\overline{m} & 0\\ 0 & -\frac{i}{2}\overline{\theta^3}+\overline{m}\end{pmatrix}\begin{pmatrix}q_1\\ q_2\end{pmatrix}=0,\\
q^\dagger(-i\theta^3T^3-m)&=(q_1^\dagger \quad q_2^\dagger)\begin{pmatrix}-\frac{i}{2}\theta^3-m & 0\\ 0 & \frac{i}{2}\theta^3+m\end{pmatrix}=0,\\
q^\dagger(-i\overline{\theta^3}T^3-\overline{m})&=(q_1^\dagger \quad q_2^\dagger)\begin{pmatrix}-\frac{i}{2}\overline{\theta^3}-\overline{m} & 0\\ 0 & \frac{i}{2}\overline{\theta^3}+\overline{m}\end{pmatrix}=0.
\end{aligned}
\tag{3.20}
$$

Thus the only nontrivial solutions for q are either

$$
q=\begin{pmatrix}q_1\\ 0\end{pmatrix},\quad q^\dagger=(q_1^\dagger \quad 0),\quad \text{and}\quad \frac{i}{2}\theta^3+m=\frac{i}{2}\overline{\theta^3}+\overline{m}=0 \tag{3.21}
$$

or

$$
q=\begin{pmatrix}0\\ q_2\end{pmatrix},\quad q^\dagger=(0 \quad q_2^\dagger),\quad \text{and}\quad -\frac{i}{2}\theta^3+m=-\frac{i}{2}\overline{\theta^3}+\overline{m}=0. \tag{3.22}
$$

Throughout this article we pick the nontrivial solutions for q as $q_1\neq 0$ and $\theta^3=2im$. In this branch the equations

$$
[c,\theta]=[c,\overline{\theta}]=[B_+^{\mu\nu},\theta]=[B_+^{\mu\nu},\overline{\theta}]=0 \tag{3.23}
$$

imply that nonzero solutions of $B_+^{\mu\nu}$, c have the same direction T^3 as θ. Finally, we obtain the remaining equations

$$
\begin{aligned}
&F^3_{+\mu\nu}+\tfrac{1}{2}q_1^\dagger\overline{\sigma}_{\mu\nu}q_1=0,\\
&-2\nabla^\mu B^3_{+\mu\nu}=\partial^\mu c^3=0,\\
&\sigma^\mu\mathcal{D}_\mu q_1=0,
\end{aligned}
\tag{3.24}
$$

where ∇^μ is the covariant derivative with respect to the Levi-Civita connection of background metric $g^{\mu\nu}$. Here we reinterpret U(1)⊗U(1) [gauge U(1) and spin^{c}U(1)] as a new U(1) [spin$^{c'}$U(1)], or alternately we redefine $W_c^+\otimes\zeta=W_{c'}^+$ as a different spin^c structure $c'=c+2\zeta$, i.e., $\det(W_c^+\otimes\zeta)=L_c\otimes\zeta^2$. As a result, (3.24) can be interpreted as a perturbed Seiberg–Witten monopole equation for the spin^c structure c' as well as H-P-P[6] and B_+, c equations for the T^3 direction.

D. Gaussian integral

In this subsection we compute the path integral of UBTQCD. According to Appendix B, we could evaluate the exact path integral of this theory. In this subsection, we only denote the diagonal part of the big matrix (see Appendix B) to read the right contribution easily. As we have

already mentioned in Sec. III B, we have to insert some observables of fundamental fields to get a well-defined path integral. Thus we define the expectation value of e^I as

$$\langle e^I \rangle_{m,c,k} = \frac{1}{\mathrm{Vol}\,\mathcal{G}(2\pi)^\Omega} \int \mathcal{D}W \mathcal{D}\psi_W \mathcal{D}Q^\dagger \mathcal{D}\psi_Q^\dagger \mathcal{D}Q \mathcal{D}\psi_Q e^{-S+I}, \tag{3.25}$$

where

$$\begin{aligned} W &= A_\mu, B_+^{\mu\nu}, H_B^\mu, H_+^{\mu\nu}, \theta, c, \overline{\theta}, \\ \psi_W &= \psi_\mu, \psi_B^{\mu\nu}, \chi_B^{II\mu}, \chi_+^{I\mu\nu}, \xi, \eta, \\ Q &= q, H_q^I, \\ \psi_Q &= \psi_q, \chi_q^I, \\ I &= \int d^4x (q^\dagger (i\theta + m) q + \psi_q^\dagger \psi_q), \\ \Omega &= \text{dim of } H's. \end{aligned} \tag{3.26}$$

In a general computation of the path integral of topological field theory (TFT), it is sufficient to keep only quadratic terms for the transverse degrees and compute the one-loop approximations which give a result exactly.[9] Now let us see what are transverse degrees of freedom in each branch. Picking a Riemannian metric g, we rescale $g \to tg$ and take the $t \to \infty$ limit. In branch 1, the gauge symmetry is unbroken and the matter fields decouple as the transverse degrees of freedom. In branch 2, the gauge symmetry is broken down to U(1) and the hypermultiplet reduces to one of its color. The suppressed color degrees of freedom for the hypermultiplet and the components of the $N=4$ vector multiplet which do not belong to the Cartan subalgebra part become the transverse degrees of freedom.

On the other hand, the path integrals for the nontransverse degrees should be computed exactly. These path integrals correspond to the path integral of Vafa–Witten theory in branch 1 and the path integral of U(1) monopole theory and U(1)B_+, c theory in branch 2.

We will use the notation $\langle O \rangle_{m,c,k}$ for the VEV evaluated in the massive UBTQCD for a given spin^c and instanton number k.

1. Result of branch 1

In this branch, the degrees of freedom for the hypermultiplet become the transverse degrees of freedom. One can decompose the Lagrangian (3.8) into two parts:

$$\mathcal{L} \approx \mathcal{L}^{\mathrm{V-W}}(1) + \mathcal{L}^t(1), \tag{3.27}$$

where the Vafa–Witten part is

$$\begin{aligned} \mathcal{L}^{\mathrm{V-W}}(1) = & -H_+^{I\mu\nu a}\{H_{+\mu\nu}^{Ia} - (F_{+\mu\nu}^a - i[B_{+\mu\rho}, B_{+\nu\sigma}]^a g^{\rho\sigma} - i[B_{+\mu\nu}, c]^a)\} \\ & - \chi_+^{I\mu\nu a}\{-i[\chi_{+\mu\nu}^I, \theta]^a + 2D_\mu \psi_\nu^\sigma - 2i[B_{+\mu\rho}, \psi_{B\nu\sigma}]^a g^{\rho\sigma} - i[\psi_{B\mu\nu}, c]^a \\ & - i[B_{+\mu\nu}, \xi]^a\} - H_B^{II\rho a}\{H_{B\rho}^{IIa} - (-2D^\mu B_{+\mu\rho}^a - D_\rho c^a)\} \\ & - \chi_B^{II\rho a}\{-i[\chi_{B\rho}^{II}, \theta]^a - 2D^\mu \psi_{B\mu\rho}^a - 2i[\psi^\mu, B_{+\mu\rho}]^a - D_\rho \xi^a - i[\psi_\rho, c]^a\} \\ & - \{[\theta, \overline{\theta}]^a [\overline{\theta}, \theta]^a - [c, \theta]^a [c, \overline{\theta}]^a + [B_+^{\mu\nu}, \overline{\theta}]^a [B_{+\mu\nu}, \theta]^a\} \\ & + D_\mu \overline{\theta}^a D^\mu \theta^a + i[\theta, \eta]^a \eta^a + i\xi^a [\xi, \overline{\theta}]^a + i\xi^a [c, \eta]^a \end{aligned}$$

$$+i[\psi_B^{\mu\nu},\overline{\theta}]^a\psi^a_{B\mu\nu}+i[B_+^{\mu\nu},\eta]^a\psi^a_{V\mu\nu}+D_\mu\eta^a\psi^{\mu a}+i[\psi_\mu,\overline{\theta}]^a\psi^{\mu a} \tag{3.28}$$

and a quadratic Lagrangian due to the transverse degrees is

$$\begin{aligned}\mathcal{L}^t(1)&=-H_q^{I\dagger\alpha}\{H^I_{q\alpha}-s_\alpha\}-\chi_q^{I\dagger}\not{D}\psi_q+(\text{h.c. previous two terms})-2q^\dagger\overline{m}mq+2\psi_1^\dagger\overline{m}\psi_q-2\chi_q^{I\dagger}m\chi_q^I\\&=-2|H_q^I+\cdots|^2-2m|\chi_q^I+\cdots|^2-\frac{1}{2}q^\dagger(\not{D}^\dagger\not{D}+4m\overline{m})q+\frac{1}{2m}\psi_q^\dagger(\not{D}^\dagger\not{D}+4m\overline{m})\psi_q.\end{aligned} \tag{3.29}$$

One can rewrite the path integral (3.25) in this branch as

$$\langle e^I\rangle_{m,c,k}(1)=\underbrace{\frac{1}{Vol\mathcal{G}(2\pi)^{\Omega'}}\int\mathcal{D}W\mathcal{D}\psi_W e^{-S^{V-W}(1)}}_{\equiv Z^{V-W}_{m,c,k}(1)}\cdot\underbrace{\frac{1}{(2\pi)^{\Omega''}}\int\mathcal{D}Q^\dagger\mathcal{D}\psi_Q^\dagger\mathcal{D}Q\mathcal{D}\psi_Q e^{-S^t(1)+I(1)}}_{\equiv Z^t_{m,c,k}(1)}, \tag{3.30}$$

where

$$\begin{aligned}h^2S^{\mathrm{V-W}}(1)&=\int d^4x\,\sqrt{g}\mathcal{L}^{\mathrm{V-M}}(1),\\h^2S^t(1)&=\int d^4x\,\sqrt{g}\mathcal{L}^t(1),\\I(1)&=\int d^4x\,\sqrt{g}(q^\dagger mq+\psi_q^\dagger\psi_q),\\\Omega'&=\dim\ \text{of adjoint}\ H's,\\\Omega''&=\dim\ \text{of fundamental}\ H's.\end{aligned} \tag{3.31}$$

For the Vafa–Witten part $Z^{\mathrm{V-W}}_{m,c,k}(1)$, we completely follow Vafa–Witten.[1] Thus we have

$$Z^{\mathrm{V-M}}_{m,c,k}(1)\doteq\chi_k, \tag{3.32}$$

where χ_k stands for the Euler number of instanton moduli space with instanton number k and $\doteq$ means equality under keeping the vanishing theorem as shown in Vafa–Witten. Note that the existence of the vanishing theorem in the previous section is unknown, but, in this case, we have some examples to which we apply the vanishing theorem.[1] When the vanishing theorem is not applicable, we denote this part as $Z^{\mathrm{V-W}}_{m,c,k}(1)$ itself. We discuss the problem of compactification of moduli space later.

For the transverse part $Z^t_{m,c,k}(1)$, we first perform H_q^I,χ_q^I integral and obtain

$$\frac{1}{(2\pi)^{\Omega''}}\frac{[\det(-2m)]_{(\chi_q^{I\dagger},\chi_q^I)}}{[\det(-1/\pi)]_{(H_q^{I\dagger},H_q^I)}}=\left[\det\left(\frac{m}{2\pi}\right)\right]_{\Gamma^-}=\left(\frac{m}{2\pi}\right)^{\dim(\Gamma^-_{\lambda>0}\oplus\mathrm{Ker}(\not{D}^\dagger))}. \tag{3.33}$$

Second, we perform q,ψ_q integral for zero and nonzero modes, respectively, and obtain

$$\frac{[\det(-\not{D}^2/2m)]_{(\psi_q^\dagger,\psi_q)\text{non }0}}{[\det(-\not{D}^2/4\pi)]_{(q^\dagger,q)\text{non }0}}\cdot\frac{[\det(-1)]_{(\psi_q^\dagger,\psi_q)0}}{[\det(-m/2\pi)]_{(q^\dagger,q)0}}=\left(\frac{2\pi}{m}\right)^{\dim(\Gamma^+_{\lambda>0}\oplus\mathrm{Ker}\not{D})}. \tag{3.34}$$

Note that this expression is not exact, but is sufficient to get the right contribution (see Appendix B).

Collecting (3.33) and (3.34), one can obtain

$$Z^t_{m,c,k}(1)=\left(\frac{m}{2\pi}\right)^{\dim((\Gamma^-_{\lambda>0}\oplus\mathrm{Ker}\,\not{D}^\dagger))}\left(\frac{2\pi}{m}\right)^{\dim(\Gamma^+_{\lambda>0}\oplus\mathrm{Ker}(\not{D}))}=\left(\frac{2\pi}{m}\right)^{\mathrm{index}\,(\not{D}^E_c)}. \tag{3.35}$$

Finally, for $\langle e^{\hat{v}}\rangle_{m,c,k}(1)$, one can obtain

$$\langle e^{\hat{v}}\rangle_{m,c,k}(1)=Z^{\mathrm{V-W}}_{m,c,k}(1)\cdot Z^t_{m,c,k}(1)=Z^{\mathrm{V-W}}_{m,c,k}(1)\cdot\left(\frac{2\pi}{m}\right)^{\mathrm{index}\,(\not{D}^E_c)}\doteq\chi_k\cdot\left(\frac{2\pi}{m}\right)^{\mathrm{index}\,(\not{D}^E_c)}, \tag{3.36}$$

where $\doteq$ stands for results in the vanishing theorem case.

2. Result of branch 2

In this branch, the gauge symmetry is broken down to U(1). The components of any field which do not belong to the Cartan subalgebra part become the transverse variables, that is, the $\pm$ components of adjoint fields, i.e., $T_\pm=T_1\pm iT_2$, and the components of the hypermultiplet with the suppressed color index become the transverse variable. One can decompose the Lagrangian (3.8) into two parts

$$\mathcal{L}\approx\mathcal{L}^{U(1)}(2)+\mathcal{L}^t(2), \tag{3.37}$$

where $\mathcal{L}^{U(1)}(2)$ is the Lagrangian of U(1) UBTQCD, and $\mathcal{L}^t(2)$ is the quadratic Lagrangian due to the transverse degrees.

The U(1) part $\mathcal{L}^{U(1)}(2)$ can be further decomposed into two parts,

$$\mathcal{L}^{U(1)}(2)=\mathcal{L}^{U(1)}_{\mathrm{mono}}(2)+\mathcal{L}^{U(1)}_{B_+,c}(2), \tag{3.38}$$

$$\begin{aligned}\mathcal{L}^{U(1)}_{\mathrm{mono}}(2)=&-H^{I3\mu\nu}_+\{H^{I3}_{+\mu\nu}-(F^3_{+\mu\nu}+\tfrac{1}{2}q_1^\dagger\overline{\sigma}_{\mu\nu}q_1)\}-\chi^{I3\mu\nu}_+\{2\nabla_\mu\psi^3_\nu+\tfrac{1}{2}\psi^\dagger_{q_1}\overline{\sigma}_{\mu\nu}q_1+\tfrac{1}{2}q_1^\dagger\overline{\sigma}_{\mu\nu}\psi_{q_1}\}\\&-H^{I\dagger}_q\{H^I_{q_1}-\not{D}q_1\}-\chi^{I\dagger}_{q_1}\not{D}\psi_{q_1}+(\text{h.c. previous two terms})+\partial_\mu\overline{\theta^3}\partial^\mu\theta^3+\partial_\mu\eta^3\psi^{3\mu}\\&+2(-i\tfrac{1}{2}q_1^\dagger\overline{\theta^3}-q_1^\dagger\overline{m})(i\tfrac{1}{2}\theta^3_{q_1}+mq_1)+2\psi^\dagger_{q_1}(i\tfrac{1}{2}\overline{\theta^3}+\overline{m})\psi_{q_1}-2\chi^{I\dagger}_{q_1}(i\tfrac{1}{2}\theta^3+m)\chi^I_{q_1}\\&-(-i\tfrac{1}{2}q_1^\dagger\eta^3-q_1^\dagger\eta_m)\psi_{q_1}+\psi^\dagger_{q_1}(i\tfrac{1}{2}\eta^3q_1+\eta_mq_1),\end{aligned} \tag{3.39}$$

and

$$\mathcal{L}^{U(1)}_{B_+,c}(2)=-H^{II3\rho}_B\{H^{II3}_{B\rho}-(-2\nabla^\mu B^3_{+\mu\rho}-\partial_\rho c^3)\}-\chi^{II3\rho}_B\{-2\nabla^\mu\psi^3_{B\mu\rho}-\partial_\rho\xi^3\}, \tag{3.40}$$

where the first part $\mathcal{L}^{U(1)}_{\mathrm{mono}}(2)$ is $U(1)$ monopole theory, and the second part $\mathcal{L}^{U(1)}_{B_+,c}(2)$ is $U(1)B_+,c$ theory.

The quadratic Lagrangian due to the transverse degrees $\mathcal{L}^t(2)$ is

$$\begin{aligned}\mathcal{L}^t(2)=&-4|H^{I+}_{+\mu\nu}+\cdots|^2-8m|\chi^{I+}_{+\mu\nu}+\cdots|^2+16m^2|\overline{\theta}^+\cdots|^2-8m|\eta^+\cdots|^2\\&-A^+_\mu\Big\{(D^{3+}{*}D^{3+})^{\mu\nu}+(D^3D^{3*})^{\mu\nu}-\widetilde{B}^{3\mu\rho}_+\widetilde{B}^{3\nu}_{+\rho}-\frac{1}{2}\widetilde{q}_1^\dagger\overline{\sigma}^\mu\sigma^\nu\widetilde{q}_1+(-(\widetilde{c}^3)^2\\&+16m\overline{m})g^{\mu\nu}\Big\}A^-_\nu+\frac{1}{2m}\psi^+_\mu\Big\{(D^{3+}{*}D^{3+})^{\mu\nu}+(D^3D^{3*})^{\mu\nu}-\widetilde{B}^{3\mu\rho}_+\widetilde{B}^{3\nu}_{+\rho}\\&-\frac{1}{2}\widetilde{q}_1^\dagger\overline{\sigma}^\mu\sigma^\nu\widetilde{q}_1+(-(\widetilde{c}^3)^2+16m\overline{m})g^{\mu\nu}\Big\}\psi^-_\nu-4|H^{II+}_B+\cdots|^2-8m|\chi^{II+}_B+\cdots|^2\end{aligned}$$

$$
\begin{aligned}
&-B_{+\mu\nu}\{(D^{3+}D^{3+}*)^{\mu\rho}g^{\nu\sigma}-4\tilde{B}_{+}^{3\mu\nu}\tilde{B}_{+}^{3\rho\sigma}+(-(\tilde{c}^{3})^{2}+16m\bar{m})g^{\mu\rho}g^{\nu\sigma}\}B_{+\rho\sigma}\\
&+\frac{1}{2m}\psi_{B\mu\nu}\{(D^{3+}D^{3+}*)^{\mu\rho}g^{\nu\sigma}-4\tilde{B}_{+}^{3\mu\nu}\tilde{B}_{+}^{3\rho\sigma}+(-(\tilde{c}^{3})^{2}+16m\bar{m})g^{\mu\rho}g^{\nu\sigma}\}\psi_{B\rho\sigma}\\
&-c^{+}\{D^{3}*D^{3}-\tilde{B}_{+}^{3\mu\nu}\tilde{B}_{+\mu\nu}^{3}-(\tilde{c}^{3})^{2}-16m\bar{m}\}c^{-}+\frac{1}{2m}\xi^{+}\{D^{3}*D^{3}-\tilde{B}_{+}^{3\mu\nu}\tilde{B}_{+\mu\nu}^{3}\\
&-(\tilde{c}^{3})^{2}-16m\bar{m}\}\xi^{-}-2|H_{q_2}^{I}+\cdots|^{2}-4m|\chi_{q_2}^{I}+\cdots|^{2}-\tfrac{1}{2}q_{2}^{\dagger}\{\not{D}^{3\dagger}\not{D}^{3}-2\bar{\sigma}_{\mu\nu}\tilde{q}_{1}\tilde{q}_{1}^{\dagger}\bar{\sigma}^{\mu\nu}\\
&+16m\bar{m}\}q_{2}+\frac{1}{4m}\psi_{q_2}^{\dagger}\{\not{D}^{3\dagger}\not{D}^{3}+2\bar{\sigma}_{\mu\nu}\tilde{q}_{1}\tilde{q}_{1}^{\dagger}\bar{\sigma}^{\mu\nu}+16m\bar{m}\}\psi_{q_2}+(\text{cross terms}). \qquad (3.41)
\end{aligned}
$$

One can rewrite the path integral (3.25) in this branch as

$$
\begin{aligned}
\langle e^{I}\rangle_{m,c,k}(2)=&\underbrace{\frac{1}{Vol\mathcal{G}^{3}(2\pi)^{\Omega'}}\int \mathcal{D}W^{3}\mathcal{D}\psi_{W}^{3}\mathcal{D}Q_{1}^{\dagger}\mathcal{D}\psi_{Q1}^{\dagger}\mathcal{D}Q_{1}\mathcal{D}\psi_{Q1}e^{-S^{U(1)}(2)}}_{\equiv Z_{m,c,k}^{U(1)}(2)}\\
&\cdot\underbrace{\frac{1}{Vol\mathcal{G}^{\pm}(2\pi)^{\Omega''}}\int \mathcal{D}W^{\pm}\mathcal{D}\psi_{W}^{\pm}\mathcal{D}Q_{2}^{\dagger}\mathcal{D}\psi_{Q2}^{\dagger}\mathcal{D}Q_{2}\mathcal{D}\psi_{Q2}e^{-S^{t}(2)+J(2)}}_{\equiv Z_{m,c,k}^{t}(2)}
\end{aligned}
\qquad (3.42)
$$

where

$$
\begin{aligned}
h^{2}S^{\mathrm{U}(1)}(2)&=\int d^{4}x\,\sqrt{g}\mathcal{L}^{\mathrm{U}(1)}(2),\\
h^{2}S^{t}(2)&=\int d^{4}x\,\sqrt{g}\mathcal{L}^{t}(2),\\
I(2)&=\int d^{4}x\,\sqrt{g}(q_{2}^{\dagger}2mq_{2}+\psi_{q_2}^{\dagger}\psi_{q_2}),
\end{aligned}
\qquad (3.43)
$$

$\Omega'=$ dim of H's of nontransverse degrees,

$\Omega''=$ dim of H's of transverse degrees.

For the U(1) monopole part, we have

$$
Z_{\mathrm{mono}}^{\mathrm{U}(1)}=\frac{1}{\mathrm{Vol}\,\mathcal{G}^{3}(2\pi)^{\Omega'''}}\int \mathcal{D}W_{A}^{3}\mathcal{D}\psi_{W_A^3}\mathcal{D}Q_{1}^{\dagger}\mathcal{D}\psi_{Q1}^{\dagger}\mathcal{D}Q_{1}\mathcal{D}\psi_{Q1}e^{-S_{\mathrm{mono}}^{\mathrm{U}(1)}(2)}, \qquad (3.44)
$$

where

$$
\begin{aligned}
&W_{A}^{3}=A^{\mu 3},H_{+\mu\nu}^{3},\theta^{3},\bar{\theta^{3}},q_{1},H_{q1}^{I},\\
&\psi_{W_A}^{3}=\psi_{A}^{\mu 3},\chi_{+\mu\nu}^{3},\eta^{3},\psi_{q1},\chi_{q1}^{I},\\
&h^{2}S_{\mathrm{mono}}^{\mathrm{U}(1)}(2)=\int d^{4}x\,\sqrt{g}\mathcal{L}_{\mathrm{mono}}^{\mathrm{U}(1)}(2)
\end{aligned}
\qquad (3.45)
$$

$$\Omega''' = \text{dim of } H\text{'s of U(1) S}-\text{W part.}$$

For this part we follow H-P-P.[6] In a simple type manifold we only need to consider the zero-dimensional moduli space of the Seiberg–Witten monopoles [we call them $\mathcal{M}(x)$]. Here we denote spin^c structure c' that we have already mentioned in Sec. III C by $2x$ if c' satisfies the condition of the zero-dimensional moduli space [$\dim \mathcal{M}(c') = (c' \cdot c')/4 - (2\chi + 3\sigma)/4 = 0$], and we call this spin^c structure x the Seiberg–Witten basic class. The moduli space $\mathcal{M}(x)$ consists of a finite set of points. First, for the contributions of the zero-dimensional moduli space $\mathcal{M}(x)$, we have

$$\mathcal{N} n_x, \tag{3.46}$$

where $\mathcal{N}$ is the standard renormalization due to the local operators constructed from metric and depends only on χ and σ.[8] n_x is the sum of the number of points counted with a sign and is called the Seiberg–Witten invariant. For the total contribution to U(1) monopole part (3.44), we have to sum (3.46) with all basic classes x and obtain

$$Z^{\mathrm{U}(1)}_{\mathrm{mono}} = \mathcal{N} \sum_x n_x. \tag{3.47}$$

For U(1) B_+, c part we have

$$Z^{\mathrm{U}(1)}_{B_+} = \frac{1}{(2\pi)^{\Omega'''}} \int \mathcal{D} W^3_{B_+,c} \mathcal{D} \psi^3_{W_{B_+,c}} e^{-S^1_{B_+,c}(2)}, \tag{3.48}$$

where

$$\begin{aligned} W^3_{B_+,c} &= B^{\mu\nu 3}_+, H^{\mu 3}_B, c^3, \\ \psi^3_{W_{B_+,c}} &= \psi^{\mu\nu 3}_B, \chi^{II\mu 3}_B, \xi^3, \\ h^2 S^{U(1)\, B_+,c}(2) &= \int d^4x \sqrt{g} \mathcal{L}^{U(1) B_+,c}(2), \\ \Omega'''' &= \text{dim of } H\text{'s of U(1) } B_+, c \text{ part.} \end{aligned} \tag{3.49}$$

$Z^{\mathrm{U}(1)}_{B_+}$ is the partition function of the cohomological field theory with the fixed point

$$\nabla^\mu B^3_{+\mu\nu} = 0, \quad \partial_\nu c^3 = 0. \tag{3.50}$$

This partition function is sum of the ± 1 when there are only isolated solutions as usual. The condition that the $Z^{\mathrm{U}(1)}_{B_+}$ is nonzero is that the dimensions of the moduli space of the 0 section defined by (3.50) become zero. In fact, the virtual dimension of this moduli space is calculated to be

$$\Delta = \mathrm{index}\,(d^{*+} + d) = \tfrac{1}{2}(\chi + \sigma), \tag{3.51}$$

where χ and σ are the Euler number and signature of X, respectively. Thus $\Delta = 0$ is a condition that we get nontrivial results. We discuss this point later.

Finally, we obtain

$$Z^{\mathrm{U}(1)}_{m,c,k}(2) = \mathcal{N} Z^{\mathrm{U}(1)}_{B_+} \sum_x n_x. \tag{3.52}$$

Now we evaluate the transverse integral $Z^t_{m,c,k}(2)$. Following H-P-P,[6] we choose a unitary gauge in which

$$\theta_{\pm}=0, \tag{3.53}$$

where

$$\theta=\theta^3T^3+\theta^+T^++\theta^-T^-. \tag{3.54}$$

In this gauge θ has values on the maximal torus (Cartan subalgebra). By following the standard Faddeev–Povov gauge fixing procedure, we introduce a new nilpotent BRST operator δ with the algebra

$$\delta\theta_{\pm}=\pm iC_{\pm}\theta_3, \quad \delta C_{\pm}=0, \quad \delta\theta_3=0, \quad \delta\overline{C}_{\pm}=b_{\pm}, \quad \delta b_{\pm}=0, \tag{3.55}$$

where $C_{\pm}$ and $\overline{C}_{\pm}$ are anticommuting ghosts and antighosts, respectively, and $b_{\pm}$ are commuting auxiliary fields. The action for gauge fixing terms reads

$$\begin{aligned} S_{m,\text{gauge}}(2)&=\delta\frac{1}{mh^2}\int d^4x\,\sqrt{g}(\theta_+\overline{C}_-+\overline{C}_+\theta_-)\\ &=\frac{1}{mh^2}\int d^4x\,\sqrt{g}\{\theta_+b_-+b_+\theta_-+iC_+\theta_3\overline{C}_-+i\overline{C}_+\theta_3C_-\}\\ &=\frac{1}{mh^2}\int d^4x\,\sqrt{g}\{\theta_+b_-+b_+\theta_--C_+2m\overline{C}_--\overline{C}_+2mC_-\}. \end{aligned} \tag{3.56}$$

From the second line to the third line, we take a weak coupling limit and replace θ^3 with $2im$. Note that this action has ghost number 0.

Now consider the transverse part involving adjoint fields. We perform $b_{\pm},C_{\pm},\overline{C}_{\pm},\overline{\theta^{\pm}},\eta^{\pm}$ integral and obtain

$$\begin{aligned} &[\det(im)]^{(1/2)2}_{\Omega^0}[\det(-2)]^{(1/2)2}_{\Omega^0}\left[\det\left(\frac{16m^2}{\pi}\right)\right]^{-1/2}_{\Omega^0}[\det(-8m)]^{1/2}_{\Omega^0}\\ &=[\det(2\pi m)]^{1/2}_{\Omega^0}=(2\pi m)^{(1/2)\,\dim\,(\Omega^0_{\lambda>0}\oplus\mathrm{Ker}\,(D^3))}. \end{aligned} \tag{3.57}$$

(i) $H^{\pm}_+,\chi^{\pm}_+$ integral:

$$[\det(2\pi m)]^{1/2}_{\Omega^{2+}}=(2\pi m)^{(1/2)\,\dim\,(\Omega^{2+}_{\lambda>0}\oplus\mathrm{Ker}\,(D^{3+}*))}. \tag{3.58}$$

(ii) $H^{\pm}_B,\chi^{\pm}_B$ integral:

$$[\det(2\pi m)]^{1/2}_{\Omega^1}=(2\pi m)^{(1/2)\,\dim\,(\Omega^1_{\lambda>0}\oplus\mathrm{Ker}\,(D^{3+}+D^3*))}. \tag{3.59}$$

(iii) $A^{\pm},\psi^{\pm}$ integral for nonzero mode:

$$\frac{[\det(-(D^3D^3*+D^{3+}*D^{3+})/m)]^{1/2}_{\psi^{\pm}_{\text{non }0}}}{[\det(-(D^3D^3*+D^{3+}*D^{3+})/2\pi)]^{1/2}_{A^{\pm}_{\text{non }0}}}=\left[\det\left(\frac{2\pi}{m}\right)\right]^{1/2}_{\Omega^1_{\text{non }0}}=\left(\frac{2\pi}{m}\right)^{(1/2)\,\dim\,(\Omega^1_{\lambda>0})}. \tag{3.60}$$

(iv) $B^{\pm}_+,\psi^{\pm}_B$ integral for nonzero mode:

$$\frac{[\det(-(D^{3+}D^{3+}*)/m)]^{1/2}_{\chi^{\pm}_{B\text{non }0}}}{[\det(-(D^{3+}D^{3+}*)/2\pi)]^{1/2}_{B^{\pm}_{+\text{non }0}}}=\left[\det\left(\frac{2\pi}{m}\right)\right]^{1/2}_{\Omega^{2+}_{\text{non }0}}=\left(\frac{2\pi}{m}\right)^{(1/2)\dim(\Omega^{2+}_{\lambda>0})}. \tag{3.61}$$

(v) $c^{\pm},\xi^{\pm}$ integral for nonzero mode:

$$\frac{[\det(-(D^{3}*D^{3})/m)]^{1/2}_{\xi^{\pm}_{\text{non }0}}}{[\det(-(D^{3}*D^{3})/2\pi)]^{1/2}_{c^{\pm}_{\text{non }0}}}=\left[\det\left(\frac{2\pi}{m}\right)\right]^{1/2}_{\Omega^{0}_{\text{non }0}}=\left(\frac{2\pi}{m}\right)^{(1/2)\dim(\Omega^{0}_{\lambda>0})}. \tag{3.62}$$

Now we collect all the contributions of the adjoint transverse part and obtain

$$\begin{aligned}&\frac{1}{(2\pi)^{\Omega''_{\text{ado}}}}(2\pi m)^{(1/2)\dim(\Omega^{0}_{\lambda>0}\oplus\mathrm{Ker}\,(D^{3}))}(2\pi m)^{(1/2)\dim(\Omega^{2+}_{\lambda>0}\oplus\mathrm{Ker}\,(D^{3+}*))}\\&\quad\times(2\pi m)^{(1/2)\dim(\Omega^{1}_{\lambda>o}\oplus\mathrm{Ker}\,(D^{3+}+D^{3}*))}\cdot\left(\frac{2\pi}{m}\right)^{(1/2)\dim(\Omega^{1}_{\lambda>0})}\left(\frac{2\pi}{m}\right)^{(1/2)\dim(\Omega^{2+}_{\lambda>0})}\\&\quad\times\left(\frac{2\pi}{m}\right)^{(1/2)\dim(\Omega^{0}_{\lambda>0})}=1.\end{aligned} \tag{3.63}$$

The remaining transverse integral is a fundamental part. First we perform the H^{I}_{q2},χ^{I}_{q2} integral and obtain

$$\frac{1}{(2\pi)^{\Omega''_{\text{fun}}}}\frac{[\det(-4m)]_{(\chi^{\dagger}_{q2},\chi_{q2})}}{[\det(-1/\pi)]_{(H^{\dagger}_{q2},H^{2}_{q})}}=\left[\det\left(\frac{m}{\pi}\right)\right]_{\Gamma^{-}}=\left(\frac{m}{\pi}\right)^{\dim(\Gamma^{-}_{\lambda>0}\oplus\mathrm{Ker}\,((\not{D}^{3})^{\dagger}))}. \tag{3.64}$$

Next we perform the q_2,ψ_{q_2} integral for nonzero and zero modes, respectively, and obtain

$$\frac{[\det(-\not{D}^{\dagger}\not{D}/4m)]_{(\psi^{\dagger}_{q_2},\psi_{q_2})_{\text{non }0}}}{[\det(-\not{D}^{\dagger}\not{D}/4\pi)]_{(q^{\dagger}_{2},q_2)_{\text{non }0}}}\frac{[\det(-1)]_{(\psi^{\dagger}_{q_2},\psi_{q_2})_{0}}}{[\det(-m/\pi)]_{(q^{\dagger}_{2},q_2)_{0}}}=\left[\det\left(\frac{\pi}{m}\right)\right]_{\Gamma^{+}}=\left(\frac{\pi}{m}\right)^{\dim(\Gamma^{+}_{\lambda>0}\oplus\mathrm{Ker}\,(\not{D}^{3}))}. \tag{3.65}$$

Collecting (3.64) and (3.65), one can obtain

$$\left(\frac{m}{\pi}\right)^{\dim(\Gamma^{-}_{\lambda>0}\oplus\mathrm{Ker}((\not{D}^{3})^{\dagger}))}\left(\frac{\pi}{m}\right)^{\dim(\Gamma^{+}_{\lambda>0}\oplus\mathrm{Ker}\,(\not{D}^{3}))}=\left(\frac{\pi}{m}\right)^{\text{index}\,(\not{D}^{3})} \tag{3.66}$$

From (3.63) and (3.66) we obtain

$$Z^{t}_{m,c,k}(2)=\left(\frac{\pi}{m}\right)^{\text{index}\,(\not{D}^{3})}. \tag{3.67}$$

Finally for $\langle e^{I}\rangle_{m,c,k}$ (2) we obtain

$$\langle e^{I}\rangle_{m,c,k}(2)=Z^{U(1)}_{m,c,k}(2)\cdot Z^{2}_{m,c,k}(2)=\mathcal{N}\left(\frac{\pi}{m}\right)^{\text{index}\,(\not{D}^{3})}Z^{U(1)}_{B_{+}}\sum_{x}n_{x}. \tag{3.68}$$

3. Synthesis

As we have already mentioned, $\langle e^{I}\rangle_{m,c,k}$ itself is zero. However, from the previous two paragraphs, each branch has nontrivial contributions. Thus we have finally

$$0 = Z^{\mathrm{V-W}}_{m,c,k} \cdot \left(\frac{2\pi}{m}\right)^{\text{index } \not{D}_c^E} + \mathcal{N} Z_{B_+} \sum_x n_x \cdot \left(\frac{\pi}{m}\right)^{\text{index } \not{D}^3} \doteq \chi_k \cdot \left(\frac{2\pi}{m}\right)^{\text{index } \not{D}_c^E} + \mathcal{N} Z_{B_+} \sum_x n_x \cdot \left(\frac{\pi}{m}\right)^{\text{index } \not{D}^3}, \tag{3.69}$$

where the last expression is valid in the vanishing theorem case.

In general index $\not{D}_c^E$ is calculated to be

$$\text{index } \not{D}_c^E = -k + \frac{\text{rank}\,(E)}{8}(c\cdot c - \sigma). \tag{3.70}$$

In this case,

$$c\cdot\zeta = -\text{index } \not{D}_c^E + 2\Delta. \tag{3.71}$$

The Dirac operator $\not{D}^3$, which operates on q_2, ψ_{q_2}, and so on is necessary to be understood as the Dirac operator with the connection given by $c-2\zeta$. Then,

$$\text{index } \not{D}_c^3 = 0 + \tfrac{1}{8}((c-2\zeta)\cdot(c-2\zeta) - \sigma) \tag{3.72}$$

$$= \tfrac{1}{8}(c\cdot c - 4k + 4\ \text{index } \not{D}_c^E - 8\Delta - \sigma). \tag{3.73}$$

Thus we obtain a relation

$$\text{index } \not{D}^3 = \text{index } \not{D}_c^E - \Delta. \tag{3.74}$$

Inserting (3.74) into (3.69), since m is a free parameter, we get a nontrivial result only in the case $\Delta = 0$. Remember that Δ is also the dimension of the moduli space of U(1) B_+, c theory. Thus the condition $\Delta = 0$ is consistent with defining $Z^{\mathrm{U}(1)}_{B_+}$ in (3.48). $\Delta = 0$ is also consistent with geographic condition, for example, simple type condition ($b_2^+ \geqslant 3$), Furuta theory ($b_2 \geqslant 5/4|\sigma| + 2$) and 11/8 conjecture ($b_2 \geqslant 11/8|\sigma|$).[14,15]

Finally, under the condition $\Delta = 0$, from (3.69) we have

$$\chi_k \doteq Z^{\mathrm{V-W}}_{m,c,k} = -\mathcal{N} Z_{B_+} \sum_x n_x \left(\frac{1}{2}\right)^{\text{index } \not{D}_c^E}. \tag{3.75}$$

Note that above x satisfies that $x\cdot x = (2\chi + 3\sigma)/4$ and $x = (c + 2\zeta)/2$.

We think of the Vafa–Witten partition as the sum of (3.75) with weight $e^{\tau k}$, where τ is a parameter. But the sum of this partition function does not clarify modular invariance since $\Delta = 0$ is a special case which does not depend on the coupling τ in the topological twisted model.[1] Additionally, we do not assume duality. Then there is no guarantee that our partition function has modular invariance and is the same as Vafa–Witten's. We suppose that the difference comes from compactification of the moduli space. We do not use the duality relation and our model is not an asymptotic-free theory. So, there is a possibility that compactification in our theory is not the same as the one in the Hilbert scheme. Thus we can describe the twisted $N = 4$ Yang–Mills partition function that may not be the same as Vafa–Witten's partition function with Seiberg–Witten invariants. Our expression is similar to Dijkgraaf *et al.*[10] The most significant difference is τ dependence. Theirs is τ dependent, while ours is τ independent. The reason why their partition function depends on τ is that they treat the physical $N = 4$ Yang–Mills theory itself. According to Labastida,[13] the $N = 4$ Yang–Mills theory depends on τ. On the other hand, we treat UBTQCD, which is the twisted $N = 4$ Yang–Mills theory coupled with a fundamental hypermultiplet. As we mention earlier, this difference may cause breaking of the modular invariance. In other words, our theory is not conformal invariant, and τ is not possible to be a good parameter. However, our

computation is done without an assumption like duality relation. If there is a difference we have to interpret that the origin of the difference occurred from compactification.[16]

IV. CONCLUSION

We have studied the balanced topological QCD and its broken balance theory and obtained relations of the partition function of twisted $N=4$ SU(2) Yang–Mills theory with the partition function of twisted Abelian QCD. This relation is understood in several ways. For example, the sum of Euler numbers of instanton moduli space, which is invariant under SL(2,Z) transformation, is described by Seiberg–Witten invariants when $\Delta=0$ and the vanishing theorem is valid. In other cases there is no vanishing theorem like §5.4 in Ref. 1; we obtained similar but not the same formulas under the condition of $\Delta=0$. There is no other reason to understand the difference from the result of Vafa, Witten and Dijkgraaf *et al.*[1,10] than the difference of compactification.

Some problems are left for our future work. When $\Delta\neq 0$, can we obtain any similar nontrivial results without assumption of duality relation? We may obtain them by simple reformation. However, it is difficult to expect that the partition function has the nature of modular invariance in naive reformation. We are interested in a connection with the duality and a compactification. How can we obtain the modular invariant partition function with no assumption of duality? We have some hints of this question but no answer.

As we saw in Sec. II, the vanishing theorem of BTQCD is not studied in this article. If the theorem exists, we get the sum of Euler numbers of non-Abelian monopole moduli space as the partition function of the BTQCD. It is interesting work to investigate the nature of the partition function because the theory has the branches that contain both Vafa–Witten theory and Seiberg–Witten theory.

APPENDIX A: THE BRS ALGEBRA AND THE BTQCD ACTION

We give the BRS algebra and the Lagrangian of BTQCD explicitly in this appendix.

1. Algebra

The δ_+ transformations are as follows:

$$\begin{aligned}
\delta_- A_\mu &= \chi^{\mathrm{II}}_\mu,\\
\delta_- \chi^{\mathrm{II}}_\mu &= -\delta^{\bar\theta}_g A_\mu = -D_\mu \bar\theta,\\
\delta_- \psi_\mu &= -\delta^c_g A_\mu - H^{\mathrm{II}}_{B_\mu} = -D_\mu c - H^{\mathrm{II}}_{B_\mu},\\
\delta_- H^{\mathrm{II}}_{B_\mu} &= -\delta^c_g \chi^{II}_{B_\mu} + \delta_+ \delta^{\bar\theta}_g A_\mu = -i[\chi^{\mathrm{II}}_{B_\mu}, c] + \delta_+ \delta^{\bar\theta}_g A_\mu;
\end{aligned} \tag{A1}$$

$$\begin{aligned}
\delta_- B^{\mu\nu}_+ &= \chi^{I\mu\nu}_+,\\
\delta_- \chi^{I\mu\nu}_+ &= -\delta^{\bar\theta}_g B^{\mu\nu}_+ = -i[B^{\mu\nu}_+, \bar\theta],\\
\delta_- \psi^{\mu\nu}_B &= -\delta^c_g B^{\mu\nu}_+ - H^{\mathrm{I}\mu\nu}_+ = -i[B^{\mu\nu}_+, c] - H^{\mathrm{I}\mu\nu}_+,\\
\delta_- H^{\mathrm{I}\mu\nu} &= -\delta^c_g \chi^{\mathrm{I}\mu\nu}_+ + \delta_+ \delta^{\bar\theta}_g B^{\mu\nu}_+ = -i[\chi^{\mathrm{I}\mu\nu}_+, c] + \delta_+ \delta^{\bar\theta}_g B^{\mu\nu}_+;
\end{aligned} \tag{A2}$$

$$\begin{aligned}
&\delta_- q^{\dot\alpha} = \chi_B^{\mathrm{II}\dot\alpha},\\
&\delta_- \chi_B^{\mathrm{II}\dot\alpha} = \delta_g^{\theta} q^{\dot\alpha} = i\bar\theta q^{\dot\alpha} + \bar m q^{\dot\alpha},\\
&\delta_- \psi_q^{\dot\alpha} = \delta_g^c q^{\dot\alpha} - H_B^{II\dot\alpha} = icq^{\dot\alpha} + m_c q^{\dot\alpha} - H_B^{\mathrm{II}\dot\alpha},\\
&\delta_- H_B^{\mathrm{II}\dot\alpha} = \delta_g^c \chi_B^{\mathrm{II}\dot\alpha} - \delta_+ \delta_g^{\theta} q^{\dot\alpha} = ic\chi_B^{\mathrm{II}\dot\alpha} + m_c - \delta_+ \delta_g^{\theta} q^{\dot\alpha};
\end{aligned} \tag{A3}$$

$$\begin{aligned}
&\delta_- B_\alpha = \chi_{q\alpha}^I,\\
&\delta_- \chi_{q\alpha}^{\mathrm{I}} = \delta_g^{\theta} B_\alpha = i\bar\theta B_\alpha + \bar m B_\alpha,\\
&\delta_- \psi_{B\alpha} = \delta_g^c B_\alpha - H_{q\alpha}^{\mathrm{I}} = icB_\alpha + m_c B_\alpha - H_{q\alpha}^{\mathrm{I}},\\
&\delta_- H_{q\alpha}^{\mathrm{I}} = \delta_g^c \chi_{q\alpha}^I - \delta_+ \delta_g^{\theta} B_\alpha = ic\chi_{q\alpha}^I + m_c \chi_{q\alpha}^{\mathrm{I}} - \delta_+ \delta_g^{\theta} B_\alpha;
\end{aligned} \tag{A4}$$

$$\begin{aligned}

\tag{A14}
$$

2. Action of BTQCD

We write down the Lagrangian of BTQCD explicitly in this paragraph. Here $\delta_-\mathcal{F}$ is given as

$$
\begin{aligned}
\delta_-\mathcal{F}=&\delta_-(B_+^{\mu\nu a}s_{+\mu\nu}^a)-\delta_-(\chi_+^{I\mu\nu a}\psi_{B\mu\nu}^a)-\delta_-(\chi_{B\mu}^{IIa}\psi^{\mu a})+\delta_-(-i\tfrac{1}{3}B_+^{\mu\nu a}[B_{+\mu\rho},B_{+\nu\sigma}]^a g^{\rho\sigma})\\
&+\delta_-(B^{\dagger\alpha}s_\alpha)-\delta_-(\chi_q^{I\dagger\alpha}\psi_{B\alpha})-\delta_-(\chi_{B\dot\alpha}^{II\dagger}\psi_q^{\dot\alpha})+\delta_-(s^{\dagger\alpha}B_\alpha)+\delta_-(\psi_B^{\dagger\alpha}\chi_{q\alpha}^I)\\
&+\delta_-(\psi_{q\dot\alpha}^\dagger\chi_B^{II\dot\alpha})+\delta_-(\xi^a\eta^a)
\end{aligned}
\tag{A15}
$$

$$
\begin{aligned}
=&-\chi_+^{I\mu\nu a}\{H_{+\mu\nu}^{Ia}-(s_{+\mu\nu}^a-i[B_{+\mu\rho},B_{+\nu\sigma}]^a g^{\rho\sigma}-i[B_{+\mu\nu},c]^a)\}\\
&-\chi_+^{II\rho a}\{H_{B\rho}^{IIa}-(2D^\mu B_{+\mu\rho}^a+iB^\dagger\sigma_\rho T^a q-iq^\dagger\overline{\sigma}_\rho T^a B-D_\rho c^a)\}\\
&-\chi^{I\dagger\alpha}\{H_{q\alpha}^I-(s_\alpha+icB_\alpha+m_cB_\alpha)\}-\chi_{B\dot\alpha}^{II\dagger}\{H_B^{II\dot\alpha}-(-(\not{D}^\dagger B)^{\dot\alpha}+(\overline{\sigma}^{\mu\nu}B_{+\mu\nu}q)^{\dot\alpha}\\
&+icq^{\dot\alpha}+m_cq^{\dot\alpha})\}-\{H_q^{I\dagger\alpha}-(s^{\dagger\alpha}-iB^{\dagger\alpha}c-m_cB^{\dagger\alpha})\}\chi_{q\alpha}^I-\{H_{B\dot\alpha}^{II\dagger}-(-(\not{D}^\dagger B)_\alpha^\dagger\\
&+(q^\dagger B_{+\mu\nu}\overline{\sigma}^{\mu\nu})_{\dot\alpha}-iq_{\dot\alpha}^\dagger c-m_cq_{\dot\alpha}^\dagger)\}\chi_B^{II\dot\alpha}+\{i[\theta,\overline{\theta}]^a\eta^a-i\xi^a[c,\overline{\theta}]^a\}+i[B_+^{\mu\nu},\overline{\theta}]^a\psi_{B\mu\nu}^a\\
&+D_\mu\overline{\theta}^a\psi^{\mu a}-(-iB^{\dagger\alpha}\overline{\theta}-\overline{m}B^{\dagger\alpha})\psi_{B\alpha}-(-iq_{\dot\alpha}^\dagger\overline{\theta}-\overline{m}q_{\dot\alpha}^\dagger)\psi_q^{\dot\alpha}\\
&-\psi_B^{\dagger\alpha}(i\overline{\theta}B_\alpha+\overline{m}B_\alpha)-\psi_{a\dot\alpha}^\dagger(i\overline{\theta}q^{\dot\alpha}+\overline{m}q^{\dot\alpha}).
\end{aligned}
\tag{A16}
$$

The full Lagrangian is given as

$$\mathcal{L}^{\text{full}}=\delta_+\delta_-\mathcal{F} \tag{A17}$$

$$\begin{aligned}
&=-H_+^{I\mu\nu a}\{H_{+\mu\nu}^{Ia}-(s_{+\mu\nu}^a-i[B_{+\mu\rho},B_{+\nu\sigma}]^a g^{\rho\sigma}-i[B_{+\mu\nu},c]^a)\}-\chi_+^{I\mu\nu a}\{-i[\chi_{+\mu\nu}^I,\theta]^a\\

\end{aligned} \tag{A18}$$

APPENDIX B: THE PATH INTEGRAL OF THE TRANSVERSE PART

As we have mentioned in the first part of Sec. III D, the path integral in Sec. III D is not exact, but it amounts to the right result that we will derive in this section. In computation, we take the weak coupling limit. When we replace the nontransverse fields with the fixed point values, we denote Y_{nontrans} by $\tilde{Y}_{\text{nontrans}}$. In particular, the fixed points of θ, $\overline{\theta}$ are given as $\theta=\overline{\theta}=0$ in branch 1 and $\theta^3=2im$, $\overline{\theta}=2i\overline{m}$ in branch 2. We also discuss the different treatment of the path integral in III D at the end of this section. See Ref. 17, too.

1. Branch 1 and its big matrix

In branch 1, the path integral of the transverse part is

$$Z_{m,c,k}^t(1)=\frac{1}{(2\pi)^{\Omega''}}\int\mathcal{D}Q^\dagger\mathcal{D}\psi_Q^\dagger\mathcal{D}Q\mathcal{D}\psi_Q e^{-S^t(1)+I(1)}, \tag{B1}$$

where

$$h^2S^t(1)=\int d^4x\,\sqrt{g}\mathcal{L}^t(1),$$

$$I(1)=\int d^4x\,\sqrt{g}(q^\dagger mq+\psi_q^\dagger\psi_q).$$

$$\Omega''=\text{dim of fundamental } H's. \tag{B2}$$

For $\mathcal{L}^t(1)(3.29)$, we denote

$$\mathcal{L}^t(1) = -2|H_q^I + \cdots|^2 - 2m|\chi_q^I + \cdots|^2 - \frac{1}{2} q^\dagger M^b(1) q + \frac{1}{2m} \psi_q^\dagger M^f(1) \psi_q, \tag{B3}$$

where

$$M^b(1) = M^f(1) = \not{D}^\dagger \not{D} + 4m\overline{m}. \tag{B4}$$

In general, $M^b(M^f)$ is a matrix and is not necessarily diagonalized. M^b and M^f may not be the same as we will see soon. We call $M^b(1)$ the big matrix of branch 1.

Before computing (B1), we briefly review the notion of index $\not{D}$.

One can decompose $q \in \Gamma^+$, $H_q^I \in \Gamma^-$ into

$$\begin{aligned} \not{D}^\dagger \not{D} q^\lambda &= \lambda q^\lambda, \\ \not{D} \not{D}^\dagger H_q^{I^\lambda} &= \lambda H_q^{I^\lambda}. \end{aligned} \tag{B5}$$

This decomposition is called spectra decomposition. Note that if $\lambda > 0$, then q^λ and $H_q^{I^\lambda}$ are isomorphic. However, if $\lambda = 0$, then q^λ and $H_q^{I^\lambda}$ are not isomorphic. The index $\not{D}$ measures the difference between $\Gamma^+_{\lambda=0}$ and $\Gamma^-_{\lambda=0}$, and is defined as

$$\begin{aligned} \text{index}\, \not{D} &= \dim\ \Gamma^+_{\lambda=0} - \dim\ \Gamma^-_{\lambda=0} \\ &= \dim\ \text{Ker}\, \not{D} - \dim\ \text{Ker}\, \not{D}^\dagger, \end{aligned} \tag{B6}$$

where we denote $\Gamma^+_{\lambda=0} = \text{Ker}\, \not{D}$, $\Gamma^+_{\lambda=0} = \text{Ker}\, \not{D}^\dagger$.

In computing (B1), (B6) emerges when the nonkinetic part and the off-diagonal part of M are able to be ignored [in this branch, simply $m\overline{m}$ terms in (B4)]. This process is achieved by diagonalization and field redefinition. Then we obtain the expression (B1) as index $\not{D}$. Conversely, it is enough to obtain this expression that we consider only the kinetic diagonal part of M in the path integral.

Now we perform the path integral of the transverse part of branch 1 explicitly. First, for the H_q^I, χ_q^I integral,

$$\frac{1}{(2\pi)^{\Omega''}} \frac{[\det(-2m)]_{(\chi_q^{I\dagger}, \chi_q^I)}}{\left[\det\left(-\frac{1}{\pi}\right)\right]_{(H_q^{I\dagger}, H_q^I)}} = \left[\det\left(\frac{m}{2\pi}\right)\right]_{\Gamma^-} = \left(\frac{m}{2\pi}\right)^{\dim(\Gamma^-_{\lambda>0} \oplus \text{Ker}(\not{D}^\dagger))}. \tag{B7}$$

Note that the transformation at the second equality is necessary to derive index $\not{D}$.

For the q, ψ_q integral for nonzero-mode,

$$\frac{[\det(-\not{D}^2/2m)]_{(\psi_q^\dagger, \psi_q)_{\text{non } 0}}}{[\det(-\not{D}^2/4\pi)]_{(q^\dagger, q)_{\text{non } 0}}} = \left(\frac{2\pi}{m}\right)^{\dim(\Gamma^+_{\lambda>0})}. \tag{B8}$$

For the q, ψ_q integral for zero-mode, we consider that the integrant of this path integral comes only from observable $I(1)$ and we obtain

$$\frac{[\det(-1)]_{(\psi_q^\dagger, \psi_q)_0}}{[\det(-m/2\pi)]_{(q^\dagger, q)_0}} = \left(\frac{2\pi}{m}\right)^{\dim\ \text{Ker}\,(\not{D})}. \tag{B9}$$

From (B8) and (B9)

$$\left(\frac{2\pi}{m}\right)^{\dim(\Gamma^{+}_{\lambda>0}\oplus \mathrm{Ker}\,(\not{D}))}. \tag{B10}$$

Collecting (B7) and (B10),

$$Z^{t}_{m,c,k}=\left(\frac{m}{2\pi}\right)^{\dim(\Gamma^{-}_{\lambda>0}\oplus \mathrm{Ker}\,(\not{D}^{\dagger}))}\left(\frac{2\pi}{m}\right)^{\dim(\Gamma^{+}_{\lambda>0}\oplus \mathrm{Ker}\,(\not{D}))}=\left(\frac{2\pi}{m}\right)^{\mathrm{index}\,\not{D}}. \tag{B11}$$

Note that $\dim(\Gamma^{+}_{\lambda>0})$ and $\dim(\Gamma^{-}_{\lambda>0})$ cancel each other.

2. Branch 2 and its big matrix

In branch 2, the path integral of the transverse part is

$$Z^{t}_{m,c,k}(2)=\frac{1}{\mathrm{Vol}\;\mathcal{G}^{\pm}(2\pi)^{\Omega''}}\int \mathcal{D}W^{\pm}\mathcal{D}\psi^{\pm}_{W}\mathcal{D}Q^{\dagger}_{2}\mathcal{D}\psi^{\dagger}_{Q2}\mathcal{D}Q_{2}\mathcal{D}\psi_{Q2}e^{-S^{t}(2)+I(2)}, \tag{B12}$$

where

$$\begin{aligned} h^{2}S^{t}(2)&=\int d^{4}x\,\sqrt{g}\,\mathcal{L}^{t}(2),\\ I(2)&=\int d^{4}x\sqrt{g}(q^{\dagger}_{2}2mq_{2}+\psi^{\dagger}_{q_{2}}\psi_{q_{2}}),\\ \Omega''&=\text{dim of } H\text{'s of transverse degrees.}\end{aligned} \tag{B13}$$

For $\mathcal{L}^{t}(2)$ in (3.41), we denote

$$\begin{aligned}\mathcal{L}^{t}(2)=&-4|H^{I+}_{+\mu\nu}+\cdots|^{2}-8m|\chi^{I+}_{+\mu\nu}+\cdots|^{2}+16m^{2}|\overline{\theta}^{+}+\cdots|^{2}-8m|\eta^{+}+\cdots|^{2}-4|H^{II+}_{B}+\cdots|^{2}\\&-8m|\chi^{II+}_{B}+\cdots|^{2}-2|H^{I}_{q2}+\cdots|^{2}-4m|\chi^{I}_{q_{2}}+\cdots|^{2}-Y^{T}M^{b}(2)Y+\frac{1}{2m}\Psi^{T}_{Y}M^{f}(2)\Psi_{Y},\end{aligned} \tag{B14}$$

where Y^{T} and Ψ^{T}_{Y} are raw vectors,

$$Y^{T}=(A^{+}_{\mu},B^{+}_{+\nu\rho},c^{+},q^{\dagger}_{2}), \tag{B15}$$

$$\Psi^{T}_{Y}=(\psi^{+}_{\mu},\psi^{+}_{B\nu\rho},\xi^{+},\psi^{\dagger}_{q_{2}}), \tag{B16}$$

and Y and Ψ_{Y} are column vectors,

$$Y=(A^{-}_{\sigma},B^{-}_{+\gamma\delta},c^{-},q_{2}), \tag{B17}$$

$$\Psi_{Y}=(\psi^{-}_{\sigma},\psi^{-}_{B\gamma\delta},\xi^{-},\psi_{q_{2}}). \tag{B18}$$

To derive the result (3.67) from (B12) and (B14), we can neglect the nonkinetic terms and off-diagonal part of $M(2)$ (we will give these explicitly later). There is the contribution from the Faddeev–Popov determinant of $\theta^{\pm}=0$ gauge and it is possible to discard the path integral of $Y^{\pm}$ for zero-mode according to the balanced structure of adjoint fields.

In this remaining subsection, we concentrate on giving $M(2)$ explicitly. $M^{b}(2)(M^{f}(2))$ can be decomposed into

$$M^b(2)=\begin{pmatrix} M^b_{AA} & M^b_{Aq} \\ M^b_{q^\dagger A} & M^b_{q^\dagger q}\end{pmatrix}. \tag{B19}$$

We denote the matrix element of $M^b(2)$ (or $M^b_{AA},M^b_{Aq},M^b_{q^\dagger A},M^b_{q^\dagger q}$) by $\{M^b(2)\}^{A^+\mu B^-_+\gamma\delta}$,$\{M^b_{Aq}\}^{A^+\mu}{}_q$, etc.

a. Diagonal part of $M^b(2)(M^f(2))$

$$\begin{aligned}\{M^b_{AA}\}^{A^+\mu A^-\sigma}&=\{M^f_{AA}\}^{A^+\mu A^-\sigma}\\ &=(D^{3+}{*}D^{3+})^{\mu\sigma}+(D^3D^3{*})^{\mu\sigma}-\tilde B^{3\mu\rho}_+\tilde B^{3\sigma}_{+\rho}\\ &\quad-\tfrac12\tilde q_1^\dagger\bar\sigma^\mu\sigma^\sigma\tilde q_1+(-(\tilde c^3)^2+16m\bar m)g^{\mu\sigma}.\end{aligned} \tag{B20}$$

$$\begin{aligned}\{M^b_{AA}\}^{B^+_+\nu\rho B^-_+\gamma\delta}&=\{M^f_{AA}\}^{B^+_+\nu\rho B^-_+\gamma\delta}\\ &=(D^{3+}D^{3+}{*})^{\nu\rho}g^{\gamma\delta}-4\tilde B^{3\nu\rho}_+\tilde B^{3\gamma\delta}_+ +(-(\tilde c^3)^2+16m\bar m)g^{\nu\rho}g^{\gamma\delta}.\end{aligned} \tag{B21}$$

$$\{M^b_{AA}\}^{c^+c^-}=\{M^f_{AA}\}^{c^+c^-}=D^3{*}D^3-\tilde B^{3\mu\nu}_+\tilde B^3_{+\mu\nu}-(\tilde c^3)^2-16m\bar m. \tag{B22}$$

$$\{M^b_{q^\dagger q}\}^{q^\dagger q}=\not D^{3\dagger}\not D^3-2\bar\sigma_{\mu\nu}\tilde q_1\tilde q_1^\dagger\bar\sigma^{\mu\nu}+16m\bar m. \tag{B23}$$

$$\{M^f_{q^\dagger q}\}^{q^\dagger q}=\not D^{3\dagger}\not D^3+2\bar\sigma_{\mu\nu}\tilde q_1\tilde q_1^\dagger\bar\sigma^{\mu\nu}+16m\bar m. \tag{B24}$$

Note that $\{M^b_{q^\dagger q}\}^{q^\dagger q}$ and $\{M^f_{q^\dagger q}\}^{q^\dagger q}$ are different.

b. Off-diagonal part of $M^b_{AA}(M^f_{AA})$

$$\begin{aligned}\{M^b_{AA}\}^{A^+\mu B^-_+\rho\sigma}&=\{M^b_{AA}\}^{A^+\mu B^-_+\rho\sigma}\\ &=i(\overleftarrow{D^{3+}})_\nu\tilde c^3g^{\mu\rho}g^{\nu\sigma}-2i\tilde B^{3\mu\rho}_+(D^{3+}{*})^\rho\\ &\quad-i(\overleftarrow{D^{3*}})^\mu\tilde B^{3\rho\sigma}_+-2i(\overleftarrow{D^{3+}})_\nu\tilde B^{3\mu\rho}_+g^{\nu\sigma}.\end{aligned} \tag{B25}$$

$$\{M^b_{AA}\}^{A^+\mu c^-}=\{M^b_{AA}\}^{A^+\mu}{}_{c^-}=-i(\overleftarrow{D^{3+}})_\nu\tilde B^{3\mu\nu}_+-2i\tilde B^{3\mu\rho}_+(D^3)_\rho+i(\overleftarrow{D^{3*}})^\mu\tilde c^3. \tag{B26}$$

$$\{M^b_{AA}\}^{B^+_+\nu\rho c^-}=\{M^b_{AA}\}^{B^+_+\nu\rho}{}_{c^-}=(\overleftarrow{D^{3+}{*}})^\nu(D^3)^\rho-2\tilde c^3\tilde B^{3\nu\rho}_+. \tag{B27}$$

c. Off-diagonal part of $M^b_{Aq}(M^f_{Aq})$

Here using

$$Y^\pm=\tfrac12(Y^1\mp iY^2), \tag{B28}$$

we denote $\{M^b_{Aq}\}^{Y^1q}$,$\{M^b_{Aq}\}^{Y^2q}$ and $\{M^f_{Aq}\}^{Y^1q}$,$\{M^f_{Aq}\}^{Y^2q}$ instead of $\{M^b_{Aq}\}^{Y^+q}$,$\{M^f_{Aq}\}^{Y^+q}$. The reason why we cannot denote $\{M^b_{Aq}\}^{Y^+q}$,$\{M^f_{Aq}\}^{Y^+q}$ is that there are terms $(D^3_\mu A^+_\nu-D^3_\nu A^+_\mu)_+q_2^\dagger\bar\sigma^{\mu\nu}\tilde q_1$ and $i(\not D^3q_2)^\dagger\not A^-\tilde q_1$ that exist simultaneously in $\mathcal{L}^t(2)$ in (B14). The remaining elements of this matrix are

$$\{M^b_{Aq}\}^{A^1\mu}{}_q=-\tfrac12(\overleftarrow{D^{3+}})^\nu\tilde q_1^\dagger\bar\sigma_{\mu\nu}-i\tfrac14\tilde q_1^\dagger\bar\sigma_\mu\not D^3-i\tfrac14(\overleftarrow{D^{3+}})^\mu\tilde q_1^\dagger, \tag{B29}$$

$$\{M_{Aq}^{b}\}^{A^2\mu_q} = -i\,\tfrac{1}{2}(\overleftarrow{D^{3+}})^{\nu}\tilde{q}_1^{\dagger}\overline{\sigma}_{\mu\nu} - \tfrac{1}{4}\tilde{q}_1^{\dagger}\overline{\sigma}_{\mu}\not{D}^3 - \tfrac{1}{4}(\overleftarrow{D^{3+}})^{\mu}\tilde{q}_1^{\dagger}, \tag{B30}$$

$$\{M_{Aq}^{f}\}^{A^1\mu_q} = \tfrac{1}{2}(\overleftarrow{D^{3+}})^{\nu}\tilde{q}_1^{\dagger}\overline{\sigma}_{\mu\nu} - i\,\tfrac{1}{4}\tilde{q}_1^{\dagger}\overline{\sigma}_{\mu}\not{D}^3 - i\,\tfrac{1}{4}(\overleftarrow{D^{3+}})^{\mu}\tilde{q}_1^{\dagger}, \tag{B31}$$

$$\{M_{Aq}^{b}\}^{A^2\mu_q} = i\,\tfrac{1}{2}(\overleftarrow{D^{3+}})^{\nu}\tilde{q}_1^{\dagger}\overline{\sigma}_{\mu\nu} - \tfrac{1}{4}\tilde{q}_1^{\dagger}\overline{\sigma}_{\mu}\not{D}^3 - \tfrac{1}{4}(\overleftarrow{D^{3+}})^{\mu}\tilde{q}_1^{\dagger}, \tag{B32}$$

$$\{M_{Aq}^{b}\}^{B^1\nu\rho_q} = -i\,\tfrac{1}{2}\tilde{c}^3\tilde{q}_1^{\dagger}\overline{\sigma}^{\nu\rho} + \tfrac{1}{4}\tilde{B}^{3\nu\rho}\tilde{q}_1^{\dagger} + \tilde{B}^{3\rho}_{+\mu}\overline{\sigma}^{\mu\nu}\tilde{q}_1^{\dagger}, \tag{B33}$$

$$\{M_{Aq}^{b}\}^{B^2\nu\rho_q} = \tfrac{1}{2}\tilde{c}^3\tilde{q}_1^{\dagger}\overline{\sigma}^{\nu\rho} - i\,\tfrac{1}{4}\tilde{B}^{3\nu\rho}\tilde{q}_1^{\dagger} - \tilde{B}^{3}_{+\mu}{}^{\rho}\overline{\sigma}^{\mu\nu}\tilde{q}_1^{\dagger}, \tag{B34}$$

$$\{M_{Aq}^{f}\}^{B^1\nu\rho_q} = i\,\tfrac{1}{2}\tilde{c}^3\tilde{q}_1^{\dagger}\overline{\sigma}^{\nu\rho} + \tfrac{1}{4}\tilde{B}^{3\nu\rho}\tilde{q}_1^{\dagger} - i\tilde{B}^{3}_{+\mu}{}^{\rho}\overline{\sigma}^{\mu\nu}\tilde{q}_1^{\dagger}, \tag{B35}$$

$$\{M_{Aq}^{f}\}^{B^2\nu\rho_q} = -\tfrac{1}{2}\tilde{c}^3\tilde{q}_1^{\dagger}\overline{\sigma}^{\nu\rho} - i\,\tfrac{1}{4}\tilde{B}^{3\nu\rho}\tilde{q}_1^{\dagger} + \tilde{B}^{3}_{+\mu}{}^{\rho}\overline{\sigma}^{\mu\nu}\tilde{q}_1^{\dagger}, \tag{B36}$$

$$\{M_{Aq}^{b}\}^{c^1q} = i\,\tfrac{1}{2}\tilde{B}^{3\mu\nu}_{+}\overline{\sigma}_{\mu\nu}\tilde{q}_1^{\dagger} - \tfrac{1}{4}\tilde{c}^3\tilde{q}_1^{\dagger}, \tag{B37}$$

$$\{M_{Aq}^{b}\}^{c^2q} = -\tfrac{1}{2}\tilde{B}^{3\mu\nu}_{+}\overline{\sigma}_{\mu\nu}\tilde{q}_1^{\dagger} + i\,\tfrac{1}{4}\tilde{c}^3\tilde{q}_1^{\dagger}, \tag{B38}$$

$$\{M_{Aq}^{f}\}^{c^1q} = -i\,\tfrac{1}{2}\tilde{B}^{3\mu\nu}_{+}\overline{\sigma}_{\mu\nu}\tilde{q}_1^{\dagger} - \tfrac{1}{4}\tilde{c}^3\tilde{q}_1^{\dagger}, \tag{B39}$$

$$\{M_{Aq}^{f}\}^{c^2q} = \tfrac{1}{2}\tilde{B}^{3\mu\nu}_{+}\overline{\sigma}_{\mu\nu}\tilde{q}_1^{\dagger} + i\,\tfrac{1}{4}\tilde{c}^3\tilde{q}_1^{\dagger}. \tag{B40}$$

For (B29)–(B40), one can find the relation

$$\begin{pmatrix}\{M_{Aq}^{f}\}^{Y^1q}\\ \{M_{Aq}^{f}\}^{Y^2q}\end{pmatrix} = \begin{pmatrix}0 & i\\ -i & 0\end{pmatrix}\begin{pmatrix}\{M_{Aq}^{b}\}^{Y^1q}\\ \{M_{Aq}^{b}\}^{Y^2q}\end{pmatrix}. \tag{B41}$$

Using the explicit matrix elements (B20)–(B40), we can perform the path integral (B12) directly, instead of neglecting the nonkinetic off-diagonal part of $M^b(2)(M^f(2))$. Then we have a crucial obstacle from the difference between (B23) and (B24), while the obstacle from (B29)–(B40) is resolved by the relation (B41). This obstacle tells us that the contributions from (B23) and (B24) is not 1 and that the result (3.67) is effective up to order of square of $\tilde{q}_1$. (In fact, this problem does not appear when we treat adjoint matter instead of fundamental matter. Thus we think that this problem comes from the choice of the representation of matter fields.) However, the contributions from (B23) and (B24) becomes 1 in the $\tilde{q}_1 \to 0$ limit after path integration. Thus we estimate the contributions from (B23) and (B24) to be 1 in the case that the result $Z^t_{m,c,k}(2)$ in (3.67) is topological. This is why it is enough to estimate the path integral with the indices that only the kinetic terms in the diagonal block are counted from the big matrices in Sec. III.

In this article the inverse scattering problem of reconstructing the energy dependent potential $i\sqrt{E^2-m^2}\,P(x)+Q(x)$ of a Schrödinger equation on the line from its reflection coefficients and bound state data (i.e., poles of the transmission coefficients and associated norming constants) is solved using the Marchenko integral equation approach. © *2001 American Institute of Physics.*

I. INTRODUCTION

In this article we study the inverse scattering problem for the generalized 1-D Schrödinger equation,

$$\psi''(k,x)+[k^2+m^2]\psi(k,x)=[ikP(x)+Q(x)]\psi(k,x), \quad x\in\mathbb{R}, \tag{1.1}$$

where the prime denotes the derivative with respect to the spatial coordinate x, k is the wavenumber, m is a positive mass parameter, $P(x)$ describes the energy absorption or generation, and $Q(x)$ represents the restoring force density. The quantity $E=\sqrt{k^2+m^2}$ stands for the energy.

Letting $\mathbb{C}^+$ and $\mathbb{C}^-$ stand for the open upper and lower complex half-planes and defining the regions $\Omega^+=\mathbb{C}^+\backslash i\,[0,m]$ and $\Omega^-=\mathbb{C}^-\backslash i\,[-m,0]$, for a suitable choice of the square root one can use the mapping $E=\sqrt{k^2+m^2}$ to transform either of the regions $\Omega^\pm$ conformally and bijectively into either of the regions $\mathbb{C}^\pm$, thus yielding four transformations. Using the inverse transformation $k(E)=\sqrt{E^2-m^2}$ we obtain the two-fold Riemann surface with branch cuts along the real line from m to $+\infty$ and from $-m$ to $-\infty$. As we are interested primarily in the domain $E\in\mathbb{C}^+\cup\mathbb{R}$, it is natural to define $k(E)=\sqrt{E^2-m^2}$ as a single-valued continuous function of $E\in\mathbb{C}^+\cup\mathbb{R}$ with $(k(E)/E)>0$ for $E\in\mathbb{R}\backslash[-m,m]$, so that $\mathrm{Im}\,k(E)>0$ for $E\in(-m,m)$. We then write (1.1) in the equivalent form

$$\psi^\pm{}''(E,x)+E^2\psi^\pm(E,x)=[\pm i\,k(E)P(x)+Q(x)]\psi^\pm(E,x), \tag{1.2}$$

where $x\in\mathbb{R}$ and $E\in\overline{\mathbb{C}^+}$.

Let us define the Jost solutions $f_l^\pm(E,x)$ and $f_r^\pm(E,x)$ as the solutions of (1.2) with the $\pm$ sign in the first term of the right-hand side that satisfy the boundary conditions

$$\begin{aligned} f_l^\pm(E,x)&=e^{iEx}+o(1), \quad x\to+\infty,\\ f_r^\pm(E,x)&=e^{-iEx}+o(1), \quad x\to-\infty. \end{aligned} \tag{1.3}$$

b)Electronic mail: v.pivovarchik@paco.net, vnp.@dtp.odessa.ua Research supported in part by INDAM-GNFM.

In terms of the Jost solutions, the scattering coefficients $a_l^{\pm}(E)$, $a_r^{\pm}(E)$, $b_l^{\pm}(E)$, and $b_r^{\pm}(E)$ are defined by

$$\begin{aligned} f_l^{\pm}(E,x) &= a_l^{\pm}(E)e^{iEx} + b_l^{\pm}(E)e^{-iEx} + o(1), \quad x \to -\infty, \\ f_r^{\pm}(E,x) &= a_r^{\pm}(E)e^{-iEx} + b_r^{\pm}(E)e^{iEx} + o(1), \quad x \to +\infty. \end{aligned} \tag{1.4}$$

In this article a fundamental role is played by the transformation

$$g_1(E) = \frac{g^+(E) + g^-(E)}{2}, \quad g_2(E) = \frac{g^+(E) - g^-(E)}{2ik(E)}, \tag{1.5}$$

between pairs of functions of E. This transformation allows one to convert the pair of uncoupled differential equations (1.2) into the coupled system of differential equations,

$$\begin{bmatrix} \psi_1''(E,x) \\ \psi_2''(E,x) \end{bmatrix} + E^2 \begin{bmatrix} \psi_1(E,x) \\ \psi_2(E,x) \end{bmatrix} = \Xi(E,x) \begin{bmatrix} \psi_1(E,x) \\ \psi_2(E,x) \end{bmatrix}, \tag{1.6}$$

where

$$\Xi(E,x) = \begin{bmatrix} Q(x) & -k(E)^2 P(x) \\ P(x) & Q(x) \end{bmatrix} \tag{1.7}$$

and $k(E)^2 = E^2 - m^2$. Transforming the Jost solutions as in (1.5), we obtain from (1.3) and (1.4),

$$\begin{aligned} f_{l1}(E,x) &= e^{iEx} + o(1), \quad f_{l2}(E,x) = o(1), \quad x \to +\infty, \\ f_{r1}(E,x) &= e^{-iEx} + o(1), \quad f_{r2}(E,x) = o(1), \quad x \to -\infty, \end{aligned} \tag{1.8}$$

$$\begin{aligned} f_{ls}(E,x) &= a_{ls}(E)e^{iEx} + b_{ls}(E)e^{-iEx} + o(1), \quad x \to -\infty, \\ f_{rs}(E,x) &= a_{rs}(E)e^{-iEx} + b_{rs}(E)e^{iEx} + o(1), \quad x \to +\infty, \end{aligned} \tag{1.9}$$

where $s = 1,2$.

The direct and inverse scattering problems for Schrödinger equations of the type (1.1) have been studied extensively. Jaulent and Jean[1–3] studied (1.1) with $m = 0$, imaginary $P(x)$ and real $Q(x)$, both on the half-line and on the full line (problems leading to unitary scattering data), and established the unique solvability of their Marchenko equations. Jaulent[4] derived Marchenko integral equations leading to the solution of the inverse problem for (1.1) with $m = 0$ and real potentials $P(x)$ and $Q(x)$. Sattinger and Szmigielski[5] studied (1.1) with $m = 0$, imaginary $P(x)$ and real $Q(x)$ and applied the results to solve a nonlinear evolution equation. Aktosun *et al.*[6,7] studied in detail the direct and inverse scattering problems for (1.2) for $m = 0$, obtained many results on the discrete eigenvalues, and gave sufficient conditions for the unique solvability of the Marchenko equations.

The more interesting case where $m > 0$, was taken up by Kaup[8,9] in connection with a nonlinear evolution equation (a long-wave water equation resembling the Boussinesq equation). In Ref. 9 a pair of coupled Marchenko integral equations was given to solve the inverse scattering problem. Under the assumption that $\int_{-\infty}^{\infty} dx\, P(x) = 0$, Sattinger and Szmigielski[10] considered the direct and inverse problems for (1.1) with $m = 1$ and C^{∞} potentials and applied their results to a nonlinear evolution equation. Equation (1.1), with $k^2 + m^2$ and $ikP(x)$ replaced by $k^2 - m^2$ and $kP(x)$, respectively, for real potentials $P(x)$ and $Q(x)$, is the 1-D Klein–Gordon equation. For this equation and on the half-line, Corinaldesi,[11] Degasperis,[12] and Weiss and Scharf[13] studied the inverse scattering problem and Pivovarchik[14] studied the number of bound states.

When $P,Q\in L^1(\mathbb{R})$, the Schrödinger operators in (1.2) have very different properties depending on whether $m=0$ or $m>0$, since for $m=0$ their essential spectrum is the set of $k\in\mathbb{R}$ whereas for $m>0$ it is the set of $k\in\mathbb{R}\cup i[-m,m]$. Moreover, as observed in Refs. 8 and 9, the $m>0$ equation is important for solving a certain system of nonlinear evolution equations by the inverse scattering transform, whereas no such connection is apparent for $m=0$.

In this article we analyze the inverse scattering problem for (1.2) by the Marchenko method. Essentially, although most of the scattering solutions and scattering coefficients are defined as in Refs. 6 and 7 where the $m=0$ case was treated, we differ from these papers in one important aspect: We also define the scattering solutions and scattering coefficients as if (1.6) were the equation of interest rather than (1.2). The Riemann–Hilbert problem relating the usual Faddeev solutions, as studied since the seminal papers by Faddeev[15] and Deift and Trubowitz,[16] and the Marchenko integral equations obtained by Fourier transformation are derived for quantities that are primarily connected with (1.6). The relationships between the two approaches are explained in detail. The advantage of the new approach lies in the behavior as $E\to\pm m$. In this case, (1.2) approaches two copies of the 1-D Schrödinger equation on the line with real potential $Q(x)$, whereas (1.6) tends to a nonselfadjoint matrix Schrödinger equation that also involves $P(x)$. In principle, this new approach could also have been applied to the case $m=0$, a possibility not observed before. It might then be comparatively easy to study the behavior of the solutions of (1.2) as $m\to 0^+$.

Let us discuss briefly some of the differences between Ref. 10 and the present paper. In Refs. 9 and 10 the E and k variables are transformed into the complex z variable by the conformal mapping $z=E+k=m^2/(E-k)$, where $m=1$ in Ref. 10. The complex z-plane is then divided into the regions $\mathcal{U}_+=\{z\in\mathbb{C}:|z|>m$ and $\mathrm{Im}\,z>0\}\cup\{z\in C:|z|<m$ and $\mathrm{Im}\,z<0\}$ and $\mathcal{U}_-=\{z\in\mathbb{C}:|z|>m$ and $\mathrm{Im}\,z<0\}\cup\{z\in C:|z|<m$ and $\mathrm{Im}\,z>0\}$, separated by $\Sigma=\{z\in\mathbb{C}:|z|=m\}\cup(\mathbb{R}\backslash\{0\})$. The inverse scattering problem is then posed as a vector Riemann–Hilbert problem on the curve Σ that relates vector functions analytic in $\mathcal{U}_-$ to vector functions analytic in $\mathcal{U}_+$. The unfamiliarity of the curve Σ, however, makes it hard to replace these Riemann–Hilbert problems by equivalent integral equations. For this reason we have decided not to use the z variable.

Let us now discuss the contents of this article. In Sec. II we introduce and study the scattering solutions and their asymptotic properties as $|E|\to\infty$. We also derive the continuity of the scattering solutions for (1.6) as $E\to\pm m$. In Sec. III we introduce and study the scattering coefficients and their asymptotics as $|E|\to\infty$. Their behavior as $E\to\pm m$ is also obtained. Their asymptotics as $E\to 0$ is found using the recent results in Ref. 17. It follows in particular that the scattering matrix is unitary if $E\in[-m,m]$, something that can also be derived from results in Ref. 10, and has certain contractivity and expansivity properties if $E\in\mathbb{R}\backslash[-m,m]$ and $P(x)$ does not change sign. In Sec. IV an idea by Weiss and Scharf[13] is employed to derive Marchenko integral equations for (1.6), both in the absence and in the presence of (finitely many) discrete eigenvalues. Any solution of one of the two coupled systems of two Marchenko integral equations allows one to uniquely determine the potentials $P(x)$ and $Q(x)$, provided the second one of the pair of functions being a solution has its values in $(-1,1)$. In Sec. V we relate, as in Ref. 7, the unique solvability of either of the systems of Marchenko equations to the existence of a canonical Wiener–Hopf factorization of a 2×2 matrix function on the line.

II. JOST SOLUTIONS AND FADDEEV FUNCTIONS

In this section we introduce various scattering solutions for (1.2) and (1.6) and study their symmetry and asymptotic properties.

A. Analyticity and symmetry properties

Let $P,Q\in L^1(\mathbb{R})$. Then the Jost solutions $f_l^{\pm}(E,x)$ and $f_r^{\pm}(E,x)$ satisfy the integral equations

$$f_l^{\pm}(E,x)=e^{iEx}+\frac{1}{E}\int_x^{\infty}dy\,\sin\{E(y-x)\}[\pm i\,k(E)P(y)+Q(y)]f_l^{\pm}(E,x); \tag{2.1}$$

$$f_r^{\pm}(E,x)=e^{-iEx}+\frac{1}{E}\int_{-\infty}^{x}dy\,\sin\{E(x-y)\}[\pm i\,k(E)P(y)+Q(y)]f_r^{\pm}(E,x). \tag{2.2}$$

Using the 2×2 matrix $\Xi(E,x)$ introduced in (1.7), these integral equations are easily transformed into the pairs of coupled integral equations,

$$\begin{bmatrix} f_{l1}(E,x)\\ f_{l2}(E,x)\end{bmatrix}=\begin{bmatrix}\cos(Ex)\\ \dfrac{\sin(Ex)}{k(E)}\end{bmatrix}+\int_x^{\infty}dy\,\frac{\sin\{E(y-x)\}}{E}\,\Xi(E,y)\begin{bmatrix} f_{l1}(E,y)\\ f_{l2}(E,y)\end{bmatrix};$$

$$\begin{bmatrix} f_{r1}(E,x)\\ f_{r2}(E,x)\end{bmatrix}=\begin{bmatrix}\cos(Ex)\\ \dfrac{\sin(Ex)}{k(E)}\end{bmatrix}+\int_{-\infty}^{x}dy\,\frac{\sin\{E(x-y)\}}{E}\,\Xi(E,y)\begin{bmatrix} f_{r1}(E,y)\\ f_{r2}(E,y)\end{bmatrix}.$$

Defining the Faddeev functions $m_l^{\pm}(E,x)$ and $m_r^{\pm}(E,x)$ by

$$m_l^{\pm}(E,x)=e^{-iEx}f_l^{\pm}(E,x),\quad m_r^{\pm}(E,x)=e^{iEx}f_r^{\pm}(E,x), \tag{2.3}$$

we get from (2.1) and (2.2) the Volterra integral equations,

$$m_l^{\pm}(E,x)=1+\int_x^{\infty}dy\,\frac{e^{2iE(y-x)}-1}{2iE}[\pm i\,k(E)P(y)+Q(y)]m_l^{\pm}(E,y); \tag{2.4}$$

$$m_r^{\pm}(E,x)=1+\int_{-\infty}^{x}dy\,\frac{e^{2iE(x-y)}-1}{2iE}[\pm i\,k(E)P(y)+Q(y)]m_r^{\pm}(E,y). \tag{2.5}$$

Using (1.5), these are transformed into the pairs of coupled integral equations:

$$\begin{bmatrix} m_{l1}(E,x)\\ m_{l2}(E,x)\end{bmatrix}=\begin{bmatrix}1\\0\end{bmatrix}+\int_x^{\infty}dy\,\frac{e^{2iE(y-x)}-1}{2iE}\,\Xi(E,y)\begin{bmatrix} m_{l1}(E,y)\\ m_{l2}(E,y)\end{bmatrix}; \tag{2.6}$$

$$\begin{bmatrix} m_{r1}(E,x)\\ m_{r2}(E,x)\end{bmatrix}=\begin{bmatrix}1\\0\end{bmatrix}+\int_{-\infty}^{x}dy\,\frac{e^{2iE(x-y)}-1}{2iE}\,\Xi(E,y)\begin{bmatrix} m_{r1}(E,y)\\ m_{r2}(E,y)\end{bmatrix}. \tag{2.7}$$

By differentiation with respect to x we obtain

$$\begin{bmatrix} m'_{l1}(E,x)\\ m'_{l2}(E,x)\end{bmatrix}=-\int_x^{\infty}dy\,e^{2iE(y-x)}\,\Xi(E,y)\begin{bmatrix} m_{l1}(E,y)\\ m_{l2}(E,y)\end{bmatrix}; \tag{2.8}$$

$$\begin{bmatrix} m'_{r1}(E,x)\\ m'_{r2}(E,x)\end{bmatrix}=\int_{-\infty}^{x}dy\,e^{2iE(x-y)}\,\Xi(E,y)\begin{bmatrix} m_{r1}(E,y)\\ m_{r2}(E,y)\end{bmatrix}. \tag{2.9}$$

In the next theorem we state the analyticity and continuity properties of $m_{ls}(E,x)$, $m_{rs}(E,x)$, $f_{ls}(E,x)$, $f_{rs}(E,s)$ and their derivatives ($s=1,2$). Such results will then also hold for $m_l^{\pm}(E,x)$, $m_r^{\pm}(E,x)$, $f_l^{\pm}(E,x)$, $f_r^{\pm}(E,x)$ and their derivatives.

Theorem 2.1: *Assume $P,Q\in L^1(\mathbb{R})$. Then the following is true.*

(1) For $x\in\mathbb{R}$ and $s=1,2$, the functions $m_{ls}(E,x)$, $m_{rs}(E,x)$, $m'_{ls}(E,x)$ and $m'_{rs}(E,x)$ are analytic in $\mathbb{C}^+$ and continuous in $\overline{\mathbb{C}^+}\backslash\{0\}$. Consequently, for each $x\in\mathbb{R}$ and $s=1,2$ the transformed Jost solutions $f_{ls}(E,x)$ and $f_{rs}(E,x)$ and their derivatives $f'_{ls}(E,x)$ and $f'_{rs}(E,x)$ are analytic in $\mathbb{C}^+$ and continuous in $\overline{\mathbb{C}^+}\backslash\{0\}$.

(2) If $P,Q\in L^1_1(\mathbb{R})$, the continuity of the functions in (i) *extends to $\overline{\mathbb{C}^+}$.*

Proof: Let $E \in \overline{\mathbb{C}^+}$. For large $|E|$ it is expedient to iterate the four integral equations (2.4) and (2.5) for $m_l^{\pm}(E,x)$ and $m_r^{\pm}(E,x)$, while it is more convenient to iterate the two systems (2.6) and (2.7) as $E \to \pm m$.

First, using the estimate

$$\sqrt{||E|^2-m^2|} \leqslant |k(E)| \leqslant \sqrt{|E|^2+m^2},$$

one obtains the auxiliary upper bounds:

$$\left|\frac{e^{2iE|y-x|}-1}{2iE}[\pm i\,k(E)P(y)+Q(y)]\right| \leqslant \begin{cases} 2|P(y)|+\dfrac{1}{m}|Q(y)|, & |E| \geqslant m, \\ (m\sqrt{2}\,|P(y)|+|Q(y)|)/|E|, & |E| \leqslant m, \\ |y-x|[m\sqrt{2}\,|P(y)|+|Q(y)|], & |E| \leqslant m. \end{cases}$$

In analogy with Refs. 15 and 16 we obtain the estimates

$$|m_l^{\pm}(E,x)| \leqslant \begin{cases} \exp\left(2\|P\|_1+\dfrac{1}{m}\|Q\|_1\right), & |E| \geqslant m, \\ \exp((m\sqrt{2}\,\|P\|_1+\|Q\|_1)/|E|), & |E| \leqslant m, \\ [1+\max(0,-x)]\exp(m\sqrt{2}\,\|P\|_{1,1}+\|Q\|_{1,1}), & |E| \leqslant m, \end{cases}$$

and hence

$$\max(|m_l^{\pm}(E,x)|,|m_r^{\pm}(E,x)) \leqslant c_2;$$

$$\max(|m_l^{\pm\prime}(E,x)|,|m_r^{\pm\prime}(E,x)|) \leqslant c_1c_2(\|P\|_1+\|Q\|_1)[1+|E|],$$

where $c_2 = e^{c_1(\|P\|_1+\|Q\|_1)/\min(1,|E|)}$ and $c_1 = \max(2,m\sqrt{2},1/m)$, as well as

$$|m_l^{\pm}(E,x)| \leqslant [1+\max(0,-x)]e^{c_1(\|P\|_{1,1}+\|Q\|_{1,1})}; \tag{2.10}$$

$$|m_l^{\pm\prime}(E,x)| \leqslant c_1c_3(\|P\|_1+\|Q\|_1)[1+|E|][1+\max(0,-x)], \tag{2.11}$$

where $c_3 = e^{c_1(\|P\|_{1,1}+\|Q\|_{1,1})}$. The proof for $m_r^{\pm}(E,x)$ and $m_r^{\pm\prime}(E,x)$, where (2.10) and (2.11) hold with $\max(0,-x)$ replaced by $\max(0,x)$, is similar.

Next, the derivation of the analyticity of $m_{ls}(E,x)$ and $m_{rs}(E,x)$ and their derivatives in a neighborhood of $\pm m$ in $\overline{\mathbb{C}^+}$ for $s=1,2$ is analogous. Here one employs the following estimate for the Euclidean norm of the matrix $\Xi(E,x)$:

$$\|\Xi(E,x)\| \leqslant 2|Q(x)|+(1+|k(E)|^2)|P(x)|,$$

which completes the proof. □

When $P,Q \in L_1^1(\mathbb{R})$, we find as $E \to 0$,

$$m_l^{\pm}(0,x) = 1+\int_x^{\infty} dy\,(y-x)[Q(y)\mp mP(y)]m_l^{\pm}(0,y); \tag{2.12}$$

$$m_r^{\pm}(0,x) = 1+\int_{-\infty}^{x} dy\,(x-y)[Q(y)\mp mP(y)]m_r^{\pm}(0,y). \tag{2.13}$$

Then (2.12) and (2.13) are the integral equations for the zero energy Jost functions of the usual 1-D Schrödinger equation with potential $Q(x)\mp mP(x)$. We will call $Q\mp mP$ an *exceptional* potential (for the usual Schrödinger equation) if there exists a nonzero (real) constant $\gamma^{\pm}$ such that

$$\gamma^{\pm}=\frac{m_l^{\pm}(0,x)}{m_r^{\pm}(0,x)}=\frac{f_l^{\pm}(0,x)}{f_r^{\pm}(0,x)}. \tag{2.14}$$

Otherwise $Q\mp mP$ is called a *generic* potential. Obviously, (2.12) and (2.13) can be transformed into the pairs of coupled integral equations

$$\begin{bmatrix} m_{l1}(0,x) \\ m_{l2}(0,x) \end{bmatrix}=\begin{bmatrix} 1 \\ 0 \end{bmatrix}+\int_x^{\infty} dy\,(y-x)\begin{bmatrix} Q(y) & m^2P(y) \\ P(y) & Q(y) \end{bmatrix}\begin{bmatrix} m_{l1}(0,y) \\ m_{l2}(0,y) \end{bmatrix};$$

$$\begin{bmatrix} m_{r1}(0,x) \\ m_{r2}(0,x) \end{bmatrix}=\begin{bmatrix} 1 \\ 0 \end{bmatrix}+\int_{-\infty}^{x} dy\,(x-y)\begin{bmatrix} Q(y) & m^2P(y) \\ P(y) & Q(y) \end{bmatrix}\begin{bmatrix} m_{r1}(0,y) \\ m_{r2}(0,y) \end{bmatrix}.$$

The complicated conjugation symmetry properties of $k(E)$ make it hazardous to state conjugation symmetry properties for $f_l^{\pm}(E,x)$, $f_r^{\pm}(E,x)$, $m_l^{\pm}(E,x)$, and $m_r^{\pm}(E,x)$ directly. However, since $k(-\overline{E})^2=\overline{k(E)^2}$, we immediately have for $s=1,2$,

$$\overline{f_{ls}(-\overline{E},x)}=f_{ls}(E,x), \quad \overline{f_{rs}(-\overline{E},x)}=f_{rs}(E,x), \tag{2.15}$$

and similarly for $m_{ls}(E,x)$ and $m_{rs}(E,x)$ where $s=1,2$. Now note that $(k(E)/E)>0$ for $E\in\mathbb{R}\backslash[-m,m]$ and $k(E)$ is positive imaginary for $E\in(-m,m)$. Thus $\overline{k(-\overline{E})}=-k(E)$ for $E\in\overline{\mathbb{C}^+}$. Using the identities $f_l^{\pm}(E,x)=f_{l1}(E,x)\pm ik(E)f_{l2}(E,x)$ and similarly for $f_r^{\pm}(E,x)$, we obtain

$$\overline{f_l^{\pm}(-\overline{E},x)}=f_l^{\pm}(E,x), \quad \overline{f_r^{\pm}(-\overline{E},x)}=f_r^{\pm}(E,x). \tag{2.16}$$

Similar relations hold for $m_l^{\pm}(E,x)$ and $m_r^{\pm}(E,x)$.

B. Large-*E* asymptotics

To study the large-E asymptotics of the Jost solutions, we define

$$\eta_l^{\pm}(E,x)=e^{\pm\zeta(x)}m_l^{\pm}(E,x)=e^{-iEx\pm\zeta(x)}f_l^{\pm}(E,x); \tag{2.17}$$

$$\eta_r^{\pm}(E,x)=e^{\pm p\mp\zeta(x)}m_l^{\pm}(E,x)=e^{iEx\pm p\mp\zeta(x)}f_r^{\pm}(E,x), \tag{2.18}$$

where

$$\zeta(x)=\frac{1}{2}\int_x^{\infty} dz\,P(z), \quad p=\frac{1}{2}\int_{-\infty}^{\infty} dz\,P(z). \tag{2.19}$$

Theorem 2.2: *Let $P,Q\in L^1(\mathbb{R})$. Then the following statements are true.*

(i) For each $x\in\mathbb{R}$, the functions $\eta_l^{\pm}(E,x)$ and $\eta_r^{\pm}(E,x)$ are analytic in $\mathbb{C}^+$, are continuous in $\overline{\mathbb{C}^+}\backslash\{0\}$, and we have for some constant C not depending on k and x,

$$|\eta_l^{\pm}(E,x)|\leq Ce^{C/|E|}, \quad |\eta_r^{\pm}(E,x)|\leq Ce^{C/|E|}, \quad E\in\overline{\mathbb{C}^+}\backslash\{0\}. \tag{2.20}$$

Further, as $|E|\to\infty$ in $\overline{\mathbb{C}^+}$ we have

$$\eta_l^{\pm}(E,x)=1+o(1), \quad \eta_r^{\pm}(E,x)=1+o(1); \tag{2.21}$$

$$\eta_l^{\pm\prime}(E,x)=o(E), \quad \eta_r^{\pm\prime}(E,x)=o(E). \tag{2.22}$$

(ii) If $P,Q\in L_1^1(\mathbb{R})$, the continuity of the functions in (i) *extends to $\overline{\mathbb{C}^+}$. Moreover, for $E\in\overline{\mathbb{C}^+}$ we have*

$$|\eta_l^{\pm}(E,x)|\leqslant C[1+\max(0,-x)],\quad |\eta_r^{\pm}(E,x)|\leqslant C[1+\max(0,x)].$$

Proof: Letting $z(E,x)=\eta_l^{\pm}(E,x)-1$, we obtain

$$z(E,x)=z_0(E,x)+\int_x^{\infty}dy\,\frac{e^{2iE(y-x)}-1}{2iE}e^{\pm[\zeta(x)-\zeta(y)]}[\pm i\,k(E)P(y)+Q(y)]z(E,y), \tag{2.23}$$

where

$$z_0(E,x)=\int_x^{\infty}dy\,\frac{e^{2iE(y-x)}-1}{2iE}e^{\pm[\zeta(x)-\zeta(y)]}Q(y)$$
$$\pm\frac{k(E)}{2E}\int_x^{\infty}dy\,e^{2iE(y-x)}e^{\pm[\zeta(x)-\zeta(y)]}P(y)+\left(1-\frac{k(E)}{E}\right)[e^{\pm\zeta(x)}-1].$$

Then the Riemann–Lebesgue lemma implies that $\sup_{t\geqslant x}|z_0(E,t)|$ vanishes as $E\to\pm\infty$. Iterating (2.23) we now see that $z(E,x)$ is uniformly bounded in $\overline{\mathbb{C}^+}$ for $|E|\geqslant a>0$ for each $x\in\mathbb{R}$ and $a>0$. Using a Phragmen–Lindelöf theorem (cf. Ref. 18) we conclude that $z(E,x)$ vanishes as $E\to\infty$ in $\overline{\mathbb{C}^+}$.

To prove (2.22) we introduce the function

$$\xi_l^{\pm}(E,x)=\frac{1}{iE}m_l^{\pm\prime}(E,x)e^{\pm\zeta(x)}=\frac{1}{2iE}[\pm P(x)\,\eta_l^{\pm}(E,x)+2\,\eta_l^{\pm\prime}(E,x)].$$

From (2.8) and (2.17) we get

$$\xi_l^{\pm}(E,x)=\int_x^{\infty}dy\,e^{2iE(y-x)}\left[\mp\frac{k(E)}{E}P(y)+\frac{i}{E}Q(y)\right]e^{\pm[\zeta(x)-\zeta(y)]}\eta_l^{\pm}(E,y). \tag{2.24}$$

Thus, using (2.20), we see that the integrand on the right-hand side of (2.24) is bounded by the integrable function $C_a[|P(y)|+|Q(y)|]$, uniformly in $x\in\mathbb{R}$ and $E\in\overline{\mathbb{C}^+}$ for $|E|\geqslant a>0$ and each $a>0$, where the constant C_a does not depend on x and E. By the Riemann–Lebesgue lemma, we conclude that the right-hand side of (2.24) is $o(1)$ as $E\to\pm\infty$, so that by a Phragmen–Lindelöf theorem (cf. Ref. 18) we see that the left-hand side of (2.24) is $o(1)$ as $E\to\infty$ in $\overline{\mathbb{C}^+}$. Consequently, $\xi_l^{\pm}(E,x)=o(1)$ as $E\to\infty$ in $\overline{\mathbb{C}^+}$, which implies (2.22) for $\eta_l^{\pm\prime}(E,x)$. The proof for $\eta_r^{\pm}(E,x)$ and $\eta_r^{\pm\prime}(E,x)$ is similar. □

To study the inverse scattering problem for (1.2), as in Ref. 7 we strengthen Theorem 2.2 by making additional assumptions on P and Q. In fact, we assume that P is absolutely continuous, and define the two auxiliary potential functions,

$$W^{\pm}(x)=Q(x)\mp\tfrac{1}{2}P'(x)-\tfrac{1}{4}P(x)^2. \tag{2.25}$$

Using (1.2)–(1.4) we obtain for $x\in\mathbb{R}$,

$$\eta_l^{\pm\prime\prime}(E,x)+[2iE\pm P(x)]\eta_l^{\pm\prime}(E,x)=[W^{\pm}(x)\mp i(E-k(E))P(x)]\eta_l^{\pm}(E,x), \tag{2.26}$$

$$\eta_l^{\pm}(E,+\infty)=1,\quad \eta_l^{\pm\prime}(E,+\infty)=0, \tag{2.27}$$

where $W^{\pm}(x)$ is given by (2.25). Multiplying (2.26) by $\mu_l^{\pm}(E,x)=e^{2iEx\mp 2\zeta(x)}$, we obtain for $x\in\mathbb{R}$,

$$[\mu_l^{\pm}(E,x)\ \eta_l^{\pm\prime}(E,x)]'=\mu_l^{\pm}(E,x)\,[W^{\pm}(x)\mp i(E-k(E))P(x)]\,\eta_l^{\pm}(E,x). \tag{2.28}$$

Integrating (2.28) and using (2.27) we get

$$\eta_l^{\pm\prime}(E,x)=-\int_x^{\infty}dy\,e^{2iE(y-x)\pm\int_x^y d\hat{z}\,P(\hat{z})}[W^{\pm}(y)\mp i(E-k(E))P(y)]\,\eta_l^{\pm}(E,y). \tag{2.29}$$

Integrating (2.29), using (2.27) once again and changing the order of integration, we find

$$\eta_l^{\pm}(E,x)=1+\int_x^{\infty}dy\,G_l^{\pm}(E;x,y)[W^{\pm}(y)\mp i(E-k(E))P(y)]\,\eta_l^{\pm}(E,y), \tag{2.30}$$

where we have defined

$$\begin{aligned}G_l^{\pm}(E;x,y)&=\int_x^y dz\,e^{2iE(y-z)\pm\int_z^y d\hat{z}\,P(\hat{z})}\\&=\frac{1}{2iE}[e^{2iE(y-x)\pm\int_x^y d\hat{z}\,P(\hat{z})}-1]\mp\frac{1}{2iE}\int_x^y dz\,P(z)\,e^{2iE(y-z)\pm\int_z^y d\hat{z}\,P(\hat{z})}.\end{aligned} \tag{2.31}$$

Similarly, using (1.2)–(1.4), (2.17)–(2.19), and (2.25) we obtain

$$\eta_r^{\pm\prime\prime}(E,x)-[2iE\pm P(x)]\,\eta_r^{\pm\prime}(E,x)=[W^{\mp}(x)\pm i(E-k(E))P(x)]\,\eta_r^{\pm}(E,x), \tag{2.32}$$

$$\eta_r^{\pm}(E,-\infty)=1,\quad \eta_r^{\pm\prime}(E,-\infty)=0. \tag{2.33}$$

Integrating (2.32) twice and using (2.33) we first get

$$\eta_r^{\pm\prime}(E,x)=\int_{-\infty}^x dy\,e^{2iE(x-y)\pm\int_y^x d\hat{z}\,P(\hat{z})}[W^{\mp}(y)\pm i(E-k(E))P(y)]\,\eta_r^{\pm}(E,y),$$

and subsequently

$$\eta_r^{\pm}(E,x)=1+\int_{-\infty}^x dy\,G_r^{\pm}(E;x,y)\,[W^{\mp}(y)\pm i(E-k(E))P(y)]\,\eta_r^{\pm}(E,y), \tag{2.34}$$

where we have defined

$$\begin{aligned}G_r^{\pm}(E;x,y)&=\int_y^x dz\,e^{2iE(z-y)\pm\int_y^z d\hat{z}\,P(\hat{z})}\\&=\frac{1}{2iE}[e^{2iE(x-y)\pm\int_y^x P(z)dz}-1]\pm\frac{1}{2iE}\int_y^x dz\,P(z)\,e^{2iE(z-y)\pm\int_y^z d\hat{z}\,P(\hat{z})}.\end{aligned}$$

Let us now employ the integral equations (2.30) and (2.34) to derive asymptotic expressions for $\eta_l^{\pm}(E,x)$ and $\eta_r^{\pm}(E,x)$ as $E\to\infty$ in $\overline{\mathbb{C}^+}$.

Theorem 2.3: *(1) Assume $P\in L^1(\mathbb{R})$ and $Q\in L_1^1(\mathbb{R})$. Then, for each fixed $x\in\mathbb{R}$, the functions $\eta_l^{\pm}(E,x)$ and $\eta_r^{\pm}(E,x)$ are analytic in $\mathbb{C}^+$ and continuous in $\overline{\mathbb{C}^+}$, and*

$$\eta_l^{\pm}(E,x)=1+o(1),\quad \eta_r^{\pm}(E,x)=1+o(1),\quad E\to\infty \text{ in } \overline{\mathbb{C}^+}.$$

(2) Assume that $W^+,W^-\in L^1(\mathbb{R})$. Then as $E\to\infty$ in $\overline{\mathbb{C}^+}$ we have

$$\eta_l^{\pm}(E,x)=1+O(1/|E|),\quad \eta_r^{\pm}(E,x)=1+O(1/|E|). \tag{2.35}$$

(3) If further we assume $P \in L_1^1(\mathbb{R})$, $Q \in L_2^1(\mathbb{R})$ *and* $W^{\pm} \in L_1^1(\mathbb{R})$, *then*

$$\eta_l^{\pm}(E,x) = 1 - \frac{\int_x^{\infty} dz\, W^{\pm}(z)}{2iE} + O(1/|E|^2), \quad E \to \infty \text{ in } \overline{\mathbb{C}^+}, \tag{2.36}$$

$$\eta_r^{\pm}(E,x) = 1 - \frac{\int_{-\infty}^{x} dz\, W^{\mp}(z)}{2iE} + O(1/|E|^2), \quad E \to \infty \text{ in } \overline{\mathbb{C}^+}. \tag{2.37}$$

Proof: We only prove (2.35), (2.36) and (2.37), because the rest of the proof is given in Theorem 3.1 of Ref. 6. Note that (2.31) implies for $y \geqslant x$,

$$|G_l^{\pm}(E;x,y)| \leqslant \frac{C}{|E|}, \quad E \in \overline{\mathbb{C}^+} \backslash \{0\}, \tag{2.38}$$

where $C = \frac{1}{2}(1 + (1 + ||P||_1)e^{||P||_1})$. Thus, iterating (2.30) and using (2.38) we obtain

$$|\eta_l^{\pm}(E,x) - 1| \leqslant \frac{C}{|E|}\left[\int_x^{\infty} dt\, (|W^{\pm}(t)| + m|P(t)|)\right] \exp\left(\int_x^{\infty} dz\, (|W^{\pm}(z)| + m|P(z)|)\right),$$

where $E \in \overline{\mathbb{C}^+} \backslash \{0\}$ and $|E| \geqslant m$. This implies (2.35) for $\eta_l^{\pm}(E,x)$ whenever $W^{\pm} \in L^1(\mathbb{R})$. The proof of (2.35) for $\eta_r^{\pm}(E,x)$ is obtained in a similar manner. To prove (2.36) we obtain from (2.30),

$$\begin{aligned}\eta_l^{\pm}(E,x) = 1 &+ \int_x^{\infty} dy\, G_l^{\pm}(E;x,y)[W^{\pm}(y) \mp i(E - k(E))P(y)] \\ &+ \int_x^{\infty} dy\, G_l^{\pm}(E;x,y)[W^{\pm}(y) \mp i(E - k(E))P(y)] \\ &\times \int_y^{\infty} dz\, G_l^{\pm}(E;y,z)[W^{\pm}(z) \mp i(E - k(E))P(z)]\eta_l^{\pm}(E,z).\end{aligned} \tag{2.39}$$

Using (2.36) and the inequality

$$|E - k(E)| \leqslant \frac{m^2}{|E|}, \quad |E| \geqslant m,$$

we obtain from (2.39),

$$\eta_l^{\pm}(E,x) = 1 + \int_x^{\infty} dy\, G_l^{\pm}(E;x,y)W^{\pm}(y) + O\left(\frac{1}{|E|^2}\right), \tag{2.40}$$

as $E \to \infty$ in $\overline{\mathbb{C}^+}$. Substituting (2.31) into (2.40) and integrating by parts we obtain (2.36). The proof of (2.37) is analogous. □

III. SCATTERING COEFFICIENTS

In this section we introduce various scattering coefficients as well as the scattering matrix for (1.2) and (1.6) and study their symmetry, asymptotic and unitarity and contractivity properties.

A. Wronskian relations and symmetry properties

Let $[f;g] = fg' - f'g$ denote the Wronskian. Then from (1.3) and (1.4) as $x \to \pm\infty$ we get

$$[f_l^{\pm}(E,x); f_r^{\pm}(E,x)] = -2iEa_l^{\pm}(E) = -2iEa_r^{\pm}(E), \tag{3.1}$$

where (3.1) holds for $E\in\overline{\mathbb{C}^+}$. Consequently, $a_l^{\pm}(E)=a_r^{\pm}(E)$, which we now denote by $a^{\pm}(E)$. From (1.8) and (1.9) we now easily obtain

$$\overline{a_s(-\overline{E})}=a_s(E),\quad E\in\overline{\mathbb{C}^+};\tag{3.2}$$

$$\overline{b_{ls}(-E)}=b_{ls}(E),\quad \overline{b_{rs}(-E)}=b_{rs}(E),\quad E\in\mathbb{R},\tag{3.3}$$

where $s=1,2$. Using (1.3), (1.4), and (2.16) we easily obtain

$$\overline{a^{\pm}(-\overline{E})}=a^{\pm}(E),\quad E\in\overline{\mathbb{C}^+};\tag{3.4}$$

$$\overline{b_l^{\pm}(-E)}=b_l^{\pm}(E),\quad \overline{b_r^{\pm}(-E)}=b_r^{\pm}(E),\quad E\in\mathbb{R}.\tag{3.5}$$

Next, if one assumes that $a^{\pm}(E)\neq 0$ and defines the transmission coefficients by $T^{\pm}(E)=a^{\pm}(E)^{-1}$, the reflection coefficients from the left by $L^{\pm}(E)=b_l^{\pm}(E)/a^{\pm}(E)$, and the reflection coefficients from the right by $R^{\pm}(E)=b_r^{\pm}(E)/a^{\pm}(E)$, then, if $P,Q\in L^1(\mathbb{R})$ [$P,Q\in L_1^1(\mathbb{R})$, respectively], the function $Ea^{\pm}(E)=E/T^{\pm}(E)$ is analytic in $\mathbb{C}^+$ and continuous in $\overline{\mathbb{C}^+}\backslash\{0\}$ [$\overline{\mathbb{C}^+}$, respectively] and the functions $Eb_l^{\pm}(E)=EL^{\pm}(E)/T^{\pm}(E)$ and $Eb_r^{\pm}(E)=ER^{\pm}(E)/T^{\pm}(E)$ are continuous in $\mathbb{R}\backslash\{0\}$ [$\mathbb{R}$, respectively]. In terms of the reflection and transmission coefficients we define the scattering matrix by

$$\mathbf{S}^{\pm}(E)=\begin{bmatrix}T^{\pm}(E) & R^{\pm}(E)\\ L^{\pm}(E) & T^{\pm}(E)\end{bmatrix}.\tag{3.6}$$

Let $E\in\mathbb{R}\backslash[-m,m]$. Then $k(-E)=-k(E)$ is real. Thus $f_l^{\pm}(E,x)$, $f_r^{\pm}(E,x)$, $f_l^{\mp}(-E,x)$ and $f_r^{\mp}(-E,x)$ all satisfy (1.2) and hence their Wronskians are independent of x. Using (1.3) and (1.4) we get

$$[f_l^{\pm}(E,x);f_l^{\mp}(-E,x)]=-2iE=-2iE[a_l^{\pm}(E)a_l^{\mp}(-E)-b_l^{\pm}(E)b_l^{\mp}(-E)],$$

$$[f_l^{\pm}(E,x);f_r^{\mp}(-E,x)]=-2iEb_r^{\mp}(-E)=2iEb_l^{\pm}(E),$$

$$[f_r^{\pm}(E,x);f_l^{\mp}(-E,x)]=-2iEb_r^{\pm}(E)=2iEb_l^{\mp}(-E),$$

$$[f_r^{\pm}(E,x);f_r^{\mp}(-E,x)]=2iE[a_r^{\pm}(E)a_r^{\mp}(-E)-b_r^{\pm}(E)b_r^{\mp}(-E)]=2iE,$$

where the behavior as $x\to+\infty$ is given first and then the behavior as $x\to-\infty$. As a result, we get

$$\mathbf{S}^{\pm}(E)^{-1}=\mathbf{S}^{\mp}(-E).\tag{3.7}$$

From (1.3), (1.4), and (3.6) we obtain

$$\begin{bmatrix}f_l^{\mp}(-E,x)\\ -f_r^{\mp}(-E,x)\end{bmatrix}=\mathbf{S}^{\pm}(E)\begin{bmatrix}f_r^{\pm}(E,x)\\ -f_l^{\pm}(E,x)\end{bmatrix}.\tag{3.8}$$

Let $E\in(-m,m)$. Then $k(-E)=k(E)$ is positive imaginary. Thus $f_l^{\pm}(E,x)$, $f_r^{\pm}(E,x)$, $f_l^{\pm}(-E,x)$ and $f_r^{\pm}(-E,x)$ all satisfy (1.2) and hence their Wronskians are independent of x. Using (1.3) and (1.4) we get

$$[f_l^{\pm}(E,x);f_l^{\pm}(-E,x)]=-2iE=-2iE[a_l^{\pm}(E)a_l^{\pm}(-E)-b_l^{\pm}(E)b_l^{\pm}(-E)],$$

$$[f_l^{\pm}(E,x);f_r^{\pm}(-E,x)]=-2iEb_r^{\pm}(-E)=2iEb_l^{\pm}(E),$$

$$[f_r^{\pm}(E,x);f_l^{\pm}(-E,x)]=-2iEb_r^{\pm}(E)=2iEb_l^{\pm}(-E),$$

$$[f_r^{\pm}(E,x);f_r^{\pm}(-E,x)]=2iE[a_r^{\pm}(E)a_r^{\pm}(-E)-b_r^{\pm}(E)b_r^{\pm}(-E)]=2iE,$$

where the behavior as $x\to+\infty$ is given first and then the behavior as $x\to-\infty$. As a result, we get

$$\mathbf{S}^{\pm}(E)^{-1}=\mathbf{S}^{\pm}(-E). \tag{3.9}$$

From (1.3), (1.4), and (3.6) we obtain

$$\begin{bmatrix} f_l^{\pm}(-E,x) \\ -f_r^{\pm}(-E,x) \end{bmatrix}=\mathbf{S}^{\pm}(E)\begin{bmatrix} f_r^{\pm}(E,x) \\ -f_l^{\pm}(E,x) \end{bmatrix}. \tag{3.10}$$

When $E\in\{-m,m\}$, the $\pm$ equations (1.2) are identical and the boundary conditions (1.3) do not distinguish between the $\pm$ versions of (1.2). It then follows that

$$f_{l1}(m,x)=f_l^{+}(m,x)=f_l^{-}(m,x),\quad f_{l1}(-m,x)=f_l^{+}(-m,x)=f_l^{-}(-m,x),$$

$$f_{r1}(m,x)=f_r^{+}(m,x)=f_r^{-}(m,x),\quad f_{r1}(-m,x)=f_r^{+}(-m,x)=f_r^{-}(-m,x),$$

which implies

$$a_1(m)=a^{+}(m)=a^{-}(m),\quad a_1(-m)=a^{+}(-m)=a^{-}(-m),$$

$$b_{l1}(m)=b_l^{+}(m)=b_l^{-}(m),\quad b_{l1}(-m)=b_l^{+}(-m)=b_l^{-}(-m),$$

$$b_{r1}(m)=b_r^{+}(m)=b_r^{-}(m),\quad b_{r1}(-m)=b_r^{+}(-m)=b_r^{-}(-m).$$

Hence, $\mathbf{S}^{+}(m)=\mathbf{S}^{-}(m)$ and $\mathbf{S}^{+}(-m)=\mathbf{S}^{-}(-m)$ are both unitary matrices, provided $a_1(m)=\overline{a_1(-m)}\neq 0$. The behavior of $a_2(E)$, $b_{l2}(E)$, and $b_{r2}(E)$ as $E\to\pm m$ will be given by (3.20).

Finally, for $E\in\mathbb{R}\backslash\{-m,m\}$ and under the assumption that $a^{\pm}(E)\neq 0$ for every $E\in\mathbb{R}$, we introduce the modified scattering matrix,

$$\tilde{\mathbf{S}}(E)=\tilde{\mathbf{M}}(E)[\mathbf{S}^{+}(E)\oplus\mathbf{S}^{-}(E)]\tilde{\mathbf{M}}(E)^{-1}, \tag{3.11}$$

where

$$\tilde{\mathbf{M}}(E)=\frac{1}{2ik(E)}\begin{bmatrix} ik(E) & 0 & ik(E) & 0 \\ 0 & ik(E) & 0 & ik(E) \\ 1 & 0 & -1 & 0 \\ 0 & 1 & 0 & -1 \end{bmatrix};$$

$$\tilde{\mathbf{M}}(E)^{-1}=\begin{bmatrix} 1 & 0 & ik(E) & 0 \\ 0 & 1 & 0 & ik(E) \\ 1 & 0 & -ik(E) & 0 \\ 0 & 1 & 0 & -ik(E) \end{bmatrix}.$$

Using that

$$\tilde{\mathbf{S}}(E)=\begin{bmatrix} T_1(E) & R_1(E) & -k(E)^2T_2(E) & -k(E)^2R_2(E) \\ L_1(E) & T_1(E) & -k(E)^2L_2(E) & -k(E)^2T_2(E) \\ T_2(E) & R_2(E) & T_1(E) & R_1(E) \\ L_2(E) & T_2(E) & L_1(E) & T_1(E) \end{bmatrix}, \tag{3.12}$$

we obtain from (3.8) and (3.10) the following Riemann–Hilbert problem valid for both $E\in\mathbb{R}\backslash[-m,m]$ and $E\in(-m,m)$:

$$\begin{bmatrix} f_{l1}(-E,x) \\ -f_{r1}(-E,x) \\ f_{l2}(-E,x) \\ -f_{r2}(-E,x) \end{bmatrix} = \tilde{\mathbf{S}}(E) \begin{bmatrix} f_{r1}(E,x) \\ -f_{l1}(E,x) \\ f_{r2}(E,x) \\ -f_{l2}(E,x) \end{bmatrix}. \tag{3.13}$$

One easily proves that $\tilde{\mathbf{S}}(E)^{-1} = \tilde{\mathbf{S}}(-E)$, both for $E \in (-m,m)$ and for $E \in \mathbb{R}\backslash[-m,m]$.

B. Various asymptotic properties

Theorem 3.1: *Let $P,Q \in L^1(\mathbb{R})$. Then*

$$a^{\pm}(E)e^{\pm p} = 1 + O\left(\frac{1}{|E|}\right), \quad E \to \infty \ \text{ in } \ \overline{\mathbb{C}^+}; \tag{3.14}$$

$$b_r^{\pm}(E) = O\left(\frac{1}{|E|}\right), \quad b_l^{\pm}(E) = O\left(\frac{1}{|E|}\right), \quad E \to \pm\infty, \tag{3.15}$$

where p is defined by (2.19).

Proof: From (3.1) we obtain

$$2iEa^{\pm}(E)e^{\pm p} = [2iE \pm P(x)]\eta_l^{\pm}(E,x)\eta_r^{\pm}(E,x) + \eta_l^{\pm\prime}(E,x)\eta_r^{\pm}(E,x) - \eta_l^{\pm}(E,x)\eta_r^{\pm\prime}(E,x). \tag{3.16}$$

Now (3.14) follows from (2.21), (2.22), and (3.16). Similarly, (3.15) follows with the help of

$$-2iEb_r^{\pm}(E) = e^{-2iEx \mp p \pm 2\zeta(x)}[\eta_l^{\pm}(E,x); \eta_l^{\mp}(-E,x)], \tag{3.17}$$

and the analogous expression involving $b_l^{\pm}(E)$. □

Let us now consider the low energy asymptotics of the scattering coefficients. From Ref. 17 we get the following result, depending on whether we are in the generic or in the exceptional case. We let $f_l^{\pm}(0,x)$ and $f_r^{\pm}(0,x)$ stand for the zero energy Jost functions of the usual 1-D Schrödinger equation with potential $Q(x) \mp mP(x)$ and $\gamma^{\pm}$ for the quantity given by (2.14).

Using Theorem 2.2 of Ref. 17, with $F(k) = k^2 + m^2$, $k_0 = im$, $\mathcal{S} = \{k \in \overline{\mathbb{C}^+} : |k - im| \leqslant m\}$ and $\mathcal{P}(k_0) = i[0,m]$, we easily obtain the following result.

Proposition 3.2: Suppose $P,Q \in L_1^1(\mathbb{R})$.

(i) In the generic case we have

$$\begin{aligned} T^{\pm}(E) &= -\frac{2iE}{[f_l^{\pm}(0,\cdot); f_r^{\pm}(0,\cdot)]} + o(E), \quad E \to 0 \ \text{ in } \ \overline{\mathbb{C}^+}, \\ L^{\pm}(E) &= -1 + o(1), \ R^{\pm}(E) = -1 + o(1), \quad E \to 0 \ \text{ in } \ \mathbb{R}. \end{aligned} \tag{3.18}$$

(ii) In the exceptional case we have

$$T^{\pm}(0) = \frac{2\gamma^{\pm}}{\gamma^{\pm 2} + 1}, \quad L^{\pm}(0) = \frac{\gamma^{\pm 2} - 1}{\gamma^{\pm 2} + 1}, \quad R^{\pm}(0) = \frac{1 - \gamma^{\pm 2}}{\gamma^{\pm 2} + 1}. \tag{3.19}$$

Finally, we consider the behavior of the scattering coefficients as $E \to \pm m$ in $\overline{\mathbb{C}^+}$.

Propositon 3.3: Let $P \in L_1^1(\mathbb{R})$ and $Q \in L_2^1(\mathbb{R})$. Then the expressions

$$\frac{a^+(E) - a^-(E)}{k(E)}, \quad \frac{b_l^+(E) - b_l^-(E)}{k(E)}, \quad \frac{b_r^+(E) - b_r^-(E)}{k(E)}, \tag{3.20}$$

have finite limits as $E\to\pm m$, $E\in\overline{\mathbb{C}^+}$.

Proof: From (1.4), (2.3), (2.6), and (2.7) we have

$$\begin{bmatrix}a_1(E)\\ a_2(E)\end{bmatrix}=\begin{bmatrix}1\\0\end{bmatrix}-\frac{1}{2iE}\int_{-\infty}^{\infty}dy\,\Xi(E,y)\begin{bmatrix}m_{l1}(E,y)\\ m_{l2}(E,y)\end{bmatrix}$$

$$=\begin{bmatrix}1\\0\end{bmatrix}-\frac{1}{2iE}\int_{-\infty}^{\infty}dy\,\Xi(E,y)\begin{bmatrix}m_{r1}(E,y)\\ m_{r2}(E,y)\end{bmatrix};$$

$$\begin{bmatrix}b_{l1}(E)\\ b_{l2}(E)\end{bmatrix}=\frac{1}{2iE}\int_{-\infty}^{\infty}dy\,e^{2iEy}\Xi(E,y)\begin{bmatrix}m_{l1}(E,y)\\ m_{l2}(E,y)\end{bmatrix};$$

$$\begin{bmatrix}b_{r1}(E)\\ b_{r2}(E)\end{bmatrix}=\frac{1}{2iE}\int_{-\infty}^{\infty}dy\,e^{-2iEy}\Xi(E,y)\begin{bmatrix}m_{r1}(E,y)\\ m_{r2}(E,y)\end{bmatrix},$$

where the limits as $E\to\pm m$ from $\overline{\mathbb{C}^+}$ exist. □

When $1/T^+(E)$ and $1/T^-(E)$ have a (necessarily common) nonzero limit as $E\to\pm m$, the next corollary is a restatement of Proposition 3.3.

Corollary 3.4: Let $P\in L_1^1(\mathbb{R})$ *and* $Q\in L_2^1(\mathbb{R})$ *and suppose* $1/T^+(E)$ *and* $1/T^-(E)$ *have a nonzero limit as* $E\to\pm m$ *in* $\overline{\mathbb{C}^+}$. *Then the expressions*

$$\frac{T^+(E)-T^-(E)}{k(E)},\quad \frac{L^+(E)-L^-(E)}{k(E)},\quad \frac{R^+(E)-R^-(E)}{k(E)},$$

have finite limits. Hence, $T_2(E)=[T^+(E)-T^-(E)]/2ik(E)$ *and the analogous quantities* $R_2(E)$ *and* $L_2(E)$ *are continuous in* $E\in\mathbb{R}$ *if* $T^\pm(E)$ *is continuous in* $E\in\mathbb{R}$.

Proposition 3.5: Assume $P\in L_1^1(\mathbb{R})$, $Q\in L_2^1(\mathbb{R})$, *and* $W^\pm\in L_1^1(\mathbb{R})$, *and let* $T^+(E)$ *and* $T^-(E)$ *be continuous in* $E\in\mathbb{R}$. *Then the functions* $L_1(E)$, $L_2(E)$, $k(E)^2L_2(E)$, $R_1(E)$, $R_2(E)$, *and* $k(E)^2R_2(E)$ *belong to* $L^2(\mathbb{R})$.

Proof: In view of Corollary 3.4 and the continuity of $T^\pm(E)$ in $E\in\mathbb{R}$, it suffices to study the asymptotic behavior of the above functions as $E\to\pm\infty$. From (2.36) and (2.37) we have as $E\to\pm\infty$,

$$\eta_l^{\pm\prime}(E,x)=\frac{W^\pm(x)}{2iE}+O\left(\frac{1}{|E|^2}\right),\quad \eta_r^{\pm\prime}(E,x)=-\frac{W^\mp(x)}{2iE}+O\left(\frac{1}{|E|^2}\right).$$

Using (3.17) we find

$$b_r^\pm(E)=\frac{R^\pm(E)}{T^\pm(E)}=O\left(\frac{1}{|E|^2}\right),$$

and similarly for $L^\pm(E)/T^\pm(E)$. On the other hand, using (3.16) we get

$$T^\pm(E)=e^{\pm p}\left\{1+\frac{\int_{-\infty}^{\infty}dz\,W^\pm(z)}{2iE}+O\left(\frac{1}{|E|^2}\right)\right\},$$

whence

$$R^\pm(E)=O\left(\frac{1}{|E|^2}\right).$$

A similar asymptotic expression can be derived for $L^\pm(E)$. This expression implies that $L_1(E)$, $L_2(E)$, and $k(E)^2L_2(E)$ belong to $L^2(\mathbb{R})$. □

C. Unitarity and contractivity properties

Let $E\in(-m,m)$. Then (1.2) is a pair of 1-D Schrödinger equations with real potentials and hence the scattering matrix $\mathbf{S}^{\pm}(E)$ is unitary (cf. Refs. 15 and 16). As a result, the reflection and transmission coefficients $R^{\pm}(E)$, $L^{\pm}(E)$, and $T^{\pm}(E)$ are continuous in $E\in(-m,m)$.

Let $E\in\mathbb{R}\backslash[-m,m]$. Observe that if $\psi(E,x)$ is a solution of the $\pm$ version of (1.2) and $\varphi(E,x)$ of the $\mp$ version of (1.2), then

$$\frac{d}{dx}[\psi(E,x);\varphi(E,x)]=\mp 2ik(E)P(x)\psi(E,x)\varphi(E,x). \tag{3.21}$$

Hence two expressions of the Wronskian of $\psi(E,x)$ and $\varphi(E,x)$ can be found by examining their value as $x\to\pm\infty$ and integrating with respect to x. Using (2.16), (3.4), (3.5), and (3.21) we get

$$[f_l^{\pm}(E,x);f_l^{\pm}(-E,x)] =\begin{cases} -2iE\pm 2ik(E)\displaystyle\int_x^{\infty} dy\, P(y)|f_l^{\pm}(E,y)|^2; \\ -2iE[|a^{\pm}(E)|^2-|b_l^{\pm}(E)|^2]\mp 2ik(E)\displaystyle\int_{-\infty}^{x} dy\, P(y)|f_l^{\pm}(E,y)|^2, \end{cases} \tag{3.22}$$

$$[f_l^{\pm}(E,x);f_r^{\pm}(-E,x)]=\begin{cases} 2iEb_l^{\pm}(E)\mp 2ik(E)\displaystyle\int_{-\infty}^{x} dy\, P(y)f_l^{\pm}(E,y)\overline{f_r^{\pm}(E,y)}; \\ -2iE\overline{b_r^{\pm}(E)}\pm 2ik(E)\displaystyle\int_x^{\infty} dy\, P(y)f_l^{\pm}(E,y)\overline{f_r^{\pm}(E,y)}, \end{cases} \tag{3.23}$$

$$[f_r^{\pm}(E,x);f_r^{\pm}(-E,x)] =\begin{cases} 2iE\mp 2ik(E)\displaystyle\int_{-\infty}^{x} dy\, P(y)|f_r^{\pm}(E,y)|^2; \\ 2iE[|a^{\pm}(E)|^2-|b_r^{\pm}(E)|^2]\pm 2ik(E)\displaystyle\int_x^{\infty} dy\, P(y)|f_r^{\pm}(E,y)|^2. \end{cases} \tag{3.24}$$

Subtracting the two right-hand sides of each of (3.22)–(3.24), we get

$$-1+|a^{\pm}(E)|^2-|b_l^{\pm}(E)|^2=\mp\frac{k(E)}{E}\int_{-\infty}^{\infty} dy\, P(y)|f_l^{\pm}(E,y)|^2; \tag{3.25}$$

$$-b_l^{\pm}(E)-\overline{b_r^{\pm}(E)}=\mp\frac{k(E)}{E}\int_{-\infty}^{\infty} dy\, P(y)f_l^{\pm}(E,y)\overline{f_r^{\pm}(E,y)}, \tag{3.26}$$

$$-1+|a^{\pm}(E)|^2-|b_r^{\pm}(E)|^2=\mp\frac{k(E)}{E}\int_{-\infty}^{\infty} dy\, P(y)|f_r^{\pm}(E,y)|^2. \tag{3.27}$$

From (3.25) and (3.27) it is clear that $a^{\pm}(E)\neq 0$ when $(\mp P(x))\geqslant 0$. In that case we define the matrix

$$\mathbf{W}^{\pm}(E)=\mp\begin{bmatrix} \displaystyle\int_{-\infty}^{\infty} dyP(y)|f_l^{\pm}(E,y)|^2 & \displaystyle\int_{-\infty}^{\infty} dyP(y)f_r^{\pm}(E,y)\overline{f_l^{\pm}(E,y)} \\ \displaystyle\int_{-\infty}^{\infty} dyP(y)\overline{f_r^{\pm}(E,y)}f_l^{\pm}(E,y) & \displaystyle\int_{-\infty}^{\infty} dyP(y)|f_r^{\pm}(E,y)|^2 \end{bmatrix},$$

and, provided $a^{\pm}(E)\neq 0$, derive the identity

$$\frac{k(E)}{E}|T^{\pm}(E)|^2\mathbf{W}^{\pm}(E)=\begin{bmatrix}1 & 0\\ 0 & 1\end{bmatrix}-\mathbf{S}^{\pm}(E)^{\dagger}\mathbf{S}^{\pm}(E),$$

which is nonnegative selfadjoint if $(\mp P(x))\geqslant 0$. Here $\dagger$ denotes the conjugate transpose. Similarly, one proves that if $(\mp P(x))\leqslant 0$ and the transmission coefficient $T^{\pm}(E)$ is well-defined, the scattering matrix $\mathbf{S}^{\pm}(E)$ has a contractive inverse.

D. Discrete eigenvalues

The discrete eigenvalues of the pair of modified Schrödinger equations (1.2) coincide with those of the system (1.6). They form a finite or countably infinite subset of $\mathbb{C}^+$ of eigenvalues of finite algebraic multiplicity. The geometric multiplicity of the eigenvalues of either of the equations (1.2) is one, while that of (1.6) is at most two. They can only accumulate in a bounded interval of the real line, but not at points of $(-m,m)$. Accumulation as $E\to\infty$ is impossible because of (3.14). Accumulation at points of $(-m,m)$ is impossible, because the scattering matrix $\mathbf{S}^{\pm}(E)$ is unitary if $E\in(-m,m)$.

The discrete eigenvalues are symmetrically located with respect to the imaginary axis, where the geometric and algebraic multiplicities of an eigenvalue at E_0 coincide with those at $-\overline{E_0}$. This follows directly from (3.4)–(3.5). The net result is that the residues of $iT^{\pm}(E)$ at E_0 and $-\overline{E_0}$ are complex conjugates.

For the problem (1.2) with $m=0$, the properties of the discrete spectrum have been discussed in detail in Ref. 6. Many of these results also follow from spectral properties of certain operator pencils (cf. Ref. 19). If $m>0$, most of those results are expected to go through, albeit in a slightly different form.

IV. MARCHENKO EQUATIONS

In this section we derive the Marchenko integral equations leading to the solution of the inverse scattering problem.

A. Fourier transformation properties

Let us apply the method of Ref. 13 to derive Marchenko integral equations to solve the inverse scattering problem. We begin by deriving some integral representations for the (transformed) Jost solutions.

Theorem 4.1: *Assume* $P\in L^1_1(\mathbb{R})$, $Q\in L^1_2(\mathbb{R})$, *and* $W^{\pm}\in L^1_1(\mathbb{R})$. *Then the Jost solutions* $f_{rs}(E,x)$ *and* $f_{ls}(E,s)$ $(s=1,2)$ *can be represented as follows:*

$$f_{r1}(E,x)=e^{-iEx}\cosh(p-\zeta(x))+\int_{-\infty}^{x}dt\,K_{r1}(x,t)e^{-iEt},\tag{4.1}$$

$$f_{r2}(E,x)=\int_{-\infty}^{x}dt\,K_{r2}(x,t)e^{-iEt},\tag{4.2}$$

$$f_{l1}(E,x)=e^{iEx}\cosh(\zeta(x))+\int_{x}^{\infty}dt\,K_{l1}(x,t)e^{iEt},\tag{4.3}$$

$$f_{l2}(E,x)=\int_{x}^{\infty}dt\,K_{l2}(x,t)e^{iEt},\tag{4.4}$$

where $K^{\pm}_{rs}(x,t)$ *and* $K^{\pm}_{ls}(x,t)$ $(s=1,2)$ *are independent of* E *and belong to* $L^2(\mathbb{R})$ *as functions of* t *when* $x\in\mathbb{R}$ *is fixed.*

Proof: Using (2.17), (2.18), (2.36), and (2.37) it follows that $\tilde{f}_{l1}(E,x)=f_{l1}(E,x)-e^{iEx}\cosh(\zeta(x))$ and $\tilde{f}_{r1}(E,x)=f_{r1}(E,x)-e^{-iEx}\cosh(p-\zeta(x))$, as well as $\tilde{f}_{l2}(E,x)=f_{l2}(E,x)$ and $\tilde{f}_{r2}(E,x)=f_{r2}(E,x)$ belong to $L^2(\mathbb{R})$ as functions of E for fixed $x\in\mathbb{R}$. Further, these functions multiplied by $(\log(|E|+2))^{1/2}$ belong to $L^2(\mathbb{R})$. So Plancherel's theorem (cf. Ref. 20, Theorems 48 and 63) implies the existence of the integrals,

$$K_{rs}(x,t)\overset{l.i.m.}{=\!=\!=}_{a\to+\infty}\frac{1}{2\pi}\int_{-a}^{a}dE\,\tilde{f}_{rs}(E,x)e^{iEt},\quad s=1,2,$$

$$K_{ls}(x,t)\overset{l.i.m.}{=\!=\!=}_{a\to+\infty}\frac{1}{2\pi}\int_{-a}^{a}dE\,\tilde{f}_{ls}(E,x)e^{-iEt},\quad s=1,2.$$

It is clear that $K_{rs}(x,t)$ and $K_{ls}(x,t)$ $(s=1,2)$ belong to $L^2(\mathbb{R})$ as functions of t for every $x\in\mathbb{R}$ (cf. Ref. 20, Theorems 48 and 63).

Due to (1.7) and Theorem 2.1, the functions $f_{rs}(E,x)$ and $f_{ls}(E,x)$ $(s=1,2)$ are analytic in $E\in\mathbb{C}^+$. Moreover, there exists $C>0$ (depending on $x\in\mathbb{R}$) such that for $s=1,2$,

$$|f_{rs}(E,x)|\leqslant Ce^{x\,\mathrm{Im}\,E},\quad |f_{ls}(E,x)|\leqslant Ce^{-x\,\mathrm{Im}\,E},$$

for all $x\in\mathbb{R}$. From (2.37) we obtain

$$\int_{-\infty}^{\infty}dt\,|\tilde{f}_{r1}(t+i\,\mathrm{Im}\,E,x)|^2=O(e^{-2x\,\mathrm{Im}\,E}).$$

Similar estimates hold for $K_{r2}(E,x)$ and for $K_{ls}(E,x)$ $(s=1,2)$. Hence we may apply Titchmarsh's theorem (cf. Ref. 20, Theorem 96) and obtain

$$K_{r1}(x,t)=K_{r2}(x,t)=0,\quad t>x,$$

$$K_{l1}(x,t)=K_{l2}(x,t)=0,\quad t<x.$$

This proves the representations (4.1)–(4.4). □

Using (2.18), (2.19), and (2.37), we obtain

$$\begin{aligned}\tilde{f}_{r1}(E,x)&=\frac{ie^{-iEx}}{4E}\left(e^{-p+\zeta(x)}\int_{-\infty}^{x}dz\,W^+(z)+e^{p-\zeta(x)}\int_{-\infty}^{x}dz\,W^-(z)\right)+O\left(\frac{1}{|E|^2}\right)\\&=\frac{ie^{-iEx}}{4(E+i\chi)}\left(e^{-p+\zeta(x)}\int_{-\infty}^{x}dz\,W^+(z)+e^{p-\zeta(x)}\int_{-\infty}^{x}dz\,W^-(z)\right)+O\left(\frac{1}{|E|^2}\right),\end{aligned}$$

where χ is an arbitrary positive number. Its Fourier transform is of the form

$$K_{r1}(x,t)=\left[\frac{e^{-p+\zeta(x)}}{4}\int_{-\infty}^{x}dz\,W^+(z)+\frac{e^{p-\zeta(x)}}{4}\int_{-\infty}^{x}dz\,W^-(z)\right]e^{-\chi(x-t)}\theta(x-t)+M_{r1}(x,t),$$

where $\theta(z)$ is the Heaviside function given by

$$\theta(z)=\begin{cases}0, & \text{for } z<0,\\ 1, & \text{for } z>0,\end{cases}$$

$M_{r1}(x,t)$ is continuous in $t\in\mathbb{R}$ for fixed $x\in\mathbb{R}$ and there exists the partial derivative $(\partial M_{r1}(x,t)/\partial t)\in L^2(\mathbb{R})$ (cf. Ref. 20, the beginning of Sec. 6.13, before Theorem 128). Hence, $K_{r1}(x,t)$ has a jump discontinuity at $x=t$. Taking into account the identity $K_{r1}(x,x+0)=0$, we obtain

$$K_{r1}(x,x-0)=\frac{1}{4}\left(e^{-p+\zeta(x)}\int_{-\infty}^{x}dz\,W^{+}(z)+e^{p-\zeta(x)}\int_{-\infty}^{x}dz\,W^{-}(z)\right). \tag{4.5}$$

In the same way we obtain

$$K_{r2}(x,x-0)=\sinh(p-\zeta(x)). \tag{4.6}$$

Using (4.5) and (4.6) we now compute $Q(x)$ and $P(x)$ from $K_{r1}(x,x-0)$ and $K_{r2}(x,x-0)$. In fact, we obtain

$$P(x)=2\frac{d}{dx}\log(K_{r2}(x,x-0)+(K_{r2}(x,x-0)^2+1)^{1/2}), \tag{4.7}$$

$$Q(x)=2\frac{d}{dx}\left(\frac{K_{r1}(x,x-0)}{\cosh\frac{1}{2}\int_{-\infty}^{x}dz\,P(z)}-\frac{P(x)}{4}\tanh\left(\frac{1}{2}\int_{-\infty}^{x}dz\,P(z)\right)\right)+\frac{P(x)^2}{4}. \tag{4.8}$$

In the same way we derive

$$K_{l2}(x,x+0)=\sinh(\zeta(x)),$$

$$P(x)=-2\frac{d}{dx}\log(K_{l2}(x,x-0)+(K_{l2}(x,x-0)^2+1)^{1/2}), \tag{4.9}$$

$$Q(x)=-2\frac{d}{dx}\left(\frac{K_{l1}(x,x+0)}{\cosh\frac{1}{2}\int_{x}^{\infty}dz\,P(z)}-\frac{P(x)}{4}\tanh\left(\frac{1}{2}\int_{x}^{\infty}dz\,P(z)\right)\right)+\frac{P(x)^2}{4}. \tag{4.10}$$

B. Marchenko equations without bound states

Let us assume that $T^{+}(E)$ and $T^{-}(E)$ are both continuous in $E\in\mathbb{R}$. Before deriving the two pairs of Marchenko integral equations, we introduce the two sets of integral kernels as follows:

$$F_{l1}(x)=\frac{1}{2\pi}\int_{-\infty}^{\infty}dE\,L_1(E)e^{iEx}=\int_{-\infty}^{\infty}\frac{dE}{4\pi}[L^{+}(E)+L^{-}(E)]e^{iEx}, \tag{4.11}$$

$$F_{l2}(x)=\frac{1}{2\pi}\int_{-\infty}^{\infty}dE\,L_2(E)e^{iEx}=\int_{-\infty}^{\infty}\frac{dE}{4\pi}\frac{L^{+}(E)-L^{-}(E)}{i\,k(E)}e^{iEx}, \tag{4.12}$$

$$\begin{aligned}F_{l3}(x)&=-\frac{1}{2\pi}\int_{-\infty}^{\infty}dE\,k(E)^2L_2(E)e^{iEx}\\&=i\int_{-\infty}^{\infty}\frac{dE}{4\pi}k(E)[L^{+}(E)-L^{-}(E)]e^{iEx},\end{aligned} \tag{4.13}$$

as well as

$$F_{r1}(x)=\frac{1}{2\pi}\int_{-\infty}^{\infty}dE\,R_1(E)e^{iEx}=\int_{-\infty}^{\infty}\frac{dE}{4\pi}[R^{+}(E)+R^{-}(E)]e^{iEx}, \tag{4.14}$$

$$F_{r2}(x)=\frac{1}{2\pi}\int_{-\infty}^{\infty}dE\,R_2(E)e^{iEx}=\int_{-\infty}^{\infty}\frac{dE}{4\pi}\,\frac{R^+(E)-R^-(E)}{i\,k(E)}e^{iEx}, \tag{4.15}$$

$$\begin{aligned}F_{r3}(x)&=-\frac{1}{2\pi}\int_{-\infty}^{\infty}dE\,k(E)^2R_2(E)e^{iEx}\\&=i\int_{-\infty}^{\infty}\frac{dE}{4\pi}k(E)[R^+(E)-R^-(E)]e^{iEx}.\end{aligned} \tag{4.16}$$

Then the integrals (4.11)–(4.13) and (4.14)–(4.16) exist as a result of Proposition 3.5 and the continuity of $T^+(E)$ and $T^-(E)$ in $E\in\mathbb{R}$.

Next, we introduce the unknown functions $B_{rs}(x,y)$ and $B_{ls}(x,y)$ $(x\in\mathbb{R},\ y>0,\ s=1,2)$ by

$$B_{rs}(x,y)=\frac{K_{rs}(x,x-y)}{\cosh(p-\zeta(x))},\quad B_{ls}(x,y)=\frac{K_{ls}(x,x+y)}{\cosh(\zeta(x))}, \tag{4.17}$$

and write (4.1)–(4.4) in the form

$$f_{rs}(E,x)=e^{-iEx}\cosh(p-\zeta(x))\left[\delta_{s,1}+\int_0^{\infty}dy\,e^{iEy}B_{rs}(x,y)\right],$$

$$f_{ls}(E,x)=e^{iEx}\cosh(\zeta(x))\left[\delta_{s,1}+\int_0^{\infty}dy\,e^{iEy}B_{ls}(x,y)\right],$$

where $s=1,2$.

Starting from the two pairs of equations [cf. (3.13)],

$$\begin{aligned}&f_{r1}(-E,x)+L_1(E)f_{r1}(E,x)-k(E)^2L_2(E)f_{r2}(E,x)\\&\quad=T_1(E)f_{l1}(E,x)-k(E)^2T_2(E)f_{l2}(E,x),\end{aligned} \tag{4.18}$$

$$\begin{aligned}&f_{r2}(-E,x)+L_2(E)f_{r1}(E,x)+L_1(E)f_{r2}(E,x)\\&\quad=T_2(E)f_{l1}(E,x)+T_1(E)f_{l2}(E,x),\end{aligned} \tag{4.19}$$

and

$$\begin{aligned}&f_{l1}(-E,x)+R_1(E)f_{l1}(E,x)-k(E)^2R_2(E)f_{l2}(E,x)\\&\quad=T_1(E)f_{r1}(E,x)-k(E)^2T_2(E)f_{r2}(E,x),\end{aligned} \tag{4.20}$$

$$\begin{aligned}&f_{l2}(-E,x)+R_2(E)f_{l1}(E,x)+R_1(E)f_{l2}(E,x)\\&\quad=T_2(E)f_{r1}(E,x)+T_1(E)f_{r2}(E,x),\end{aligned} \tag{4.21}$$

and Fourier transforming the contributions to these equations that are analytic in $\mathbb{C}^-$ and vanish at infinity while taking into account (4.11)–(4.17), we obtain the two pairs of coupled Marchenko equations,

$$\begin{aligned}&B_{r1}(x,y)+\int_0^{\infty}dz\,[F_{l1}(y+z-2x)B_{r1}(x,z)+F_{l3}(y+z-2x)B_{r2}(x,z)]\\&\quad=-F_{l1}(y-2x),\end{aligned} \tag{4.22}$$

$$B_{r2}(x,y)+\int_0^\infty dz\,[F_{l2}(y+z-2x)B_{r1}(x,z)+F_{l1}(y+z-2x)B_{r2}(x,z)]$$
$$=-F_{l2}(y-2x), \tag{4.23}$$

and

$$B_{l1}(x,y)+\int_0^\infty dz\,[F_{r1}(y+z+2x)B_{l1}(x,z)+F_{r3}(y+z+2x)B_{l2}(x,z)]$$
$$=-F_{l1}(y+2x), \tag{4.24}$$

$$B_{l2}(x,y)+\int_0^\infty dz\,[F_{r2}(y+z+2x)B_{l1}(x,z)+F_{r1}(y+z+2x)B_{l2}(x,z)]$$
$$=-F_{r2}(y+2x). \tag{4.25}$$

In deriving (4.22)–(4.25), we have assumed the absence of the discrete spectrum of the two equations (1.2) and hence the analyticity of $T_1(E)$ and $T_2(E)$ in $\mathbb{C}^+$.

C. Marchenko equations with bound states

When one of the two equations (1.2) has a discrete spectrum, the derivation of the Marchenko equations (4.22)–(4.25) should be modified, since the right-hand sides of (4.18)–(4.21) may no longer vanish. To simplify the discussion, we make the following assumptions.

(1) $T^+(E)$ and $T^-(E)$ are continuous in $E\in\mathbb{R}$.
(2) The number of poles of $T^+(E)$ and $T^-(E)$ in $\mathbb{C}^+$ is finite [denote the poles of either of $T^\pm(E)$ in $\mathbb{C}^+$ by E_j, where $j=1,\ldots,\mathcal{N}$].
(3) The poles of $T^+(E)$ and $T^-(E)$ in $\mathbb{C}^+$ are simple; we write $it_j^\pm$ for the residue of $T^\pm(E)$ at $E=E_j$ ($j=1,\ldots,\mathcal{N}$). We put $t_{j1}=[t_j^+ + t_j^-]/2$ and $t_{j2}=[t_j^+ - t_j^-]/2ik(E_j)$.
(4) We remark that $t_j^\pm$, t_{j1}, t_{j2}, and $ik(E_j)$ are real if E_j is imaginary. Quantities $t_j^\pm$, t_{j1}, t_{j2}, and $ik(E_j)$ corresponding to eigenvalues symmetrically located with respect to the imaginary axis are complex conjugates. These properties are immediate from the observations made in Sec. III D.
(5) Using the terminology of Ref. 16 and recalling that the eigenvalues of either of (1.2) have geometric multiplicity one, we first introduce the norming constants,

$$C_j^\pm=\frac{f_l^\pm(E_j,x)}{f_r^\pm(E_j,x)},\quad j=1,\ldots,\mathcal{N}_j^\pm.$$

Then one easily verifies that

$$f_{l1}(E_j,x)=C_{j1}f_{r1}(E_j,x)-k_j^2C_{j2}f_{r2}(E_j,x),$$
$$f_{l2}(E_j,x)=C_{j2}f_{r1}(E_j,x)+C_{j1}f_{r2}(E_j,x),$$

where $k_j=k(E_j)$ and

$$C_{j1}=\frac{C_j^+ + C_j^-}{2},\quad C_{j2}=\frac{C_j^+ - C_j^-}{2ik_j}.$$

Calculating the residues of the expressions on the right-hand sides of (4.18)–(4.21) at $E=E_j$ in $\mathbb{C}^+$, we obtain

$$[t_{j1}C_{j1}-k_j^2 t_{j2}C_{j2}]f_{r1}(E_j,x)-k_j^2[t_{j1}C_{j2}+t_{j2}C_{j1}]f_{r2}(E_j,x), \tag{4.26}$$

$$[t_{j2}C_{j1}+t_{j1}C_{j2}]f_{r1}(E_j,x)+[-k_j^2 t_{j2}C_{j2}+t_{j1}C_{j1}]f_{r2}(E_j,x), \tag{4.27}$$

$$[t_{j1}D_{j1}-k_j^2 t_{j2}D_{j2}]f_{r1}(E_j,x)-k_j^2[t_{j1}D_{j2}+t_{j2}D_{j1}]f_{r2}(E_j,x), \tag{4.28}$$

$$[t_{j2}D_{j1}+t_{j1}D_{j2}]f_{r1}(E_j,x)+[-k_j^2 t_{j2}D_{j2}+t_{j1}D_{j1}]f_{r2}(E_j,x), \tag{4.29}$$

multiplied by the imaginary unit i. Here

$$f_{r1}(E_j,x)=D_{j1}f_{l1}(E_j,x)-k_j^2 D_{j2}f_{l2}(E_j,x),$$

$$f_{r2}(E_j,x)=D_{j2}f_{l1}(E_j,x)+D_{j1}f_{l2}(E_j,x),$$

where we note that

$$\begin{bmatrix} D_{j1} & -k_j^2 D_{j2} \\ D_{j2} & D_{j1} \end{bmatrix}=\begin{bmatrix} C_{j1} & -k_j^2 C_{j2} \\ C_{j2} & C_{j1} \end{bmatrix}^{-1}.$$

We remark that $C_j^{\pm}$, C_{j1}, C_{j2}, D_{j1}, D_{j2} and ik_j are real if E_j is imaginary. Quantities $t_j^{\pm}$, C_{j1}, C_{j2}, D_{j1}, D_{j2}, and ik_j corresponding to eigenvalues symmetrically located with respect to the imaginary axis are complex conjugates. These properties are immediate from (2.16).

We now recall that in order to compute the left-hand side minus the right-hand side of (4.22) and (4.23), we have to single out the contributions to (4.18) and (4.19) that are analytic in $\mathbb{C}^-$ and vanish at infinity and apply the operation $1/2\pi\int_{-\infty}^{\infty}dE\,e^{iE(y-x)}[\cosh(p-\zeta(x))]^{-1}$ to them. Applying the same procedure to the right-hand sides of (4.18) and (4.19) and using (4.17), (4.26), and (4.27), we obtain

$$-\sum_{j=1}^{\mathcal{N}} e^{iE_j(y-2x)}\left(A_{lj1}+\int_0^{\infty}dz\,e^{iE_j z}[A_{lj1}B_{r1}(x,z)-k_j^2 A_{lj2}B_{r2}(x,z)]\right),$$

$$-\sum_{j=1}^{\mathcal{N}} e^{iE_j(y-2x)}\left(A_{lj2}+\int_0^{\infty}dz\,e^{iE_j z}[A_{lj2}B_{r1}(x,z)-k_j^2 A_{lj1}B_{r2}(x,z)]\right),$$

where

$$A_{lj1}=t_{j1}C_{j1}-k_j^2 t_{j2}C_{j2},\quad A_{lj2}=t_{j1}C_{j2}+t_{j2}C_{j1}.$$

Introducing the modified Marchenko kernel functions,

$$\tilde{F}_{ls}(x)=F_{ls}(x)+\sum_{j=1}^{\mathcal{N}} A_{ljs}e^{iE_j x},\quad s=1,2,3,$$

where $A_{lj3}=-k_j^2 A_{lj2}$, we arrive at the coupled Marchenko integral equations,

$$B_{r1}(x,y)+\int_0^{\infty}dz\,[\tilde{F}_{l1}(y+z-2x)B_{r1}(x,z)+\tilde{F}_{l3}(y+z-2x)B_{r2}(x,z)]$$

$$=-\tilde{F}_{l1}(y-2x), \tag{4.30}$$

$$B_{r2}(x,y)+\int_0^\infty dz\,[\tilde{F}_{l2}(y+z-2x)B_{r1}(x,z)+\tilde{F}_{l1}(y+z-2x)B_{r2}(x,z)]$$
$$=-\tilde{F}_{l2}(y-2x). \tag{4.31}$$

In an analogous way we obtain the coupled Marchenko integral equations

$$B_{l1}(x,y)+\int_0^\infty dz\,[\tilde{F}_{r1}(y+z+2x)B_{l1}(x,z)+\tilde{F}_{r3}(y+z+2x)B_{l2}(x,z)]$$
$$=-\tilde{F}_{r1}(y+2x), \tag{4.32}$$

$$B_{l2}(x,y)+\int_0^\infty dz\,[\tilde{F}_{r2}(y+z+2x)B_{l1}(x,z)+\tilde{F}_{r1}(y+z+2x)B_{l2}(x,z)]$$
$$=-\tilde{F}_{r2}(y+2x), \tag{4.33}$$

where

$$\tilde{F}_{rs}(x)=F_{rs}(x)+\sum_{j=1}^{\mathcal{N}} A_{rjs}e^{iE_jx},\quad s=1,2,3,$$

$$A_{rj1}=t_{j1}D_{j1}-k_j^2t_{j2}D_{j2},\quad A_{rj2}=t_{j1}D_{j2}+t_{j2}D_{j1},$$

and $A_{rj3}=-k_j^2A_{rj2}$. Using the symmetry statements made before in this subsection, one easily proves that $\tilde{F}_{ls}(x)$ and $\tilde{F}_{rs}(x)$ $(s=1,2,3)$ are real functions.

When $T^+(E)$ and $T^-(E)$ both have a finite number of poles and some of them are multiple poles (but otherwise the first assumption is fulfilled), (4.30)–(4.33) can be derived using a generalization of the notion of norming constant given in Ref. 7, but with more complicated auxiliary kernel functions $\tilde{F}_{ls}(y)$ and $\tilde{F}_{rs}(y)$ $(s=1,2,3)$.

We now state the main result. The first part is immediate from (4.7)–(4.8) and (4.17). The second part follows from the second (4.17) and expressions involving $K_{ls}(x,t)$ and $B_{ls}(x,y)$ $(s=1,2)$ analogous to (4.7)–(4.8).

Theorem 4.2: *Suppose* $P\in L_1^1(\mathbb{R})$, $Q\in L_2^1(\mathbb{R})$, *and* $W^\pm\in L_1^1(\mathbb{R})$, *and let conditions (1)–(3) stated at the beginning of Sec. IV C be fulfilled. Then if* $B_{rs}(x,\cdot)$ $(s=1,2)$ *are the solutions of the Marchenko equations (4.30) and (4.31) and* $B_{r2}(x,0^+)\in(-1,1)$, *the potentials* $Q(x)$ *and* $P(x)$ *are given by*

$$P(x)=\frac{d}{dx}\log\frac{1+B_{r2}(x,0^+)}{1-B_{r2}(x,0^+)}; \tag{4.34}$$

$$Q(x)=2\frac{d}{dx}\left[B_{r1}(x,0^+)-\frac{P(x)}{4}\tanh\left(\frac{1}{2}\int_{-\infty}^x dz\,P(z)\right)\right]+\frac{P(x)^2}{4}. \tag{4.35}$$

Similarly, if $B_{ls}(x,\cdot)$ $(s=1,2)$ *are the solutions of the Marchenko equations (4.32) and (4.33) and* $B_{l2}(x,0^+)\in(-1,1)$, *then the potentials* $Q(x)$ *and* $P(x)$ *are given by*

$$P(x)=\frac{d}{dx}\log\frac{1-B_{l2}(x,0^+)}{1+B_{l2}(x,0^+)}; \tag{4.36}$$

$$Q(x)=-2\frac{d}{dx}\left[B_{l1}(x,0^+)-\frac{P(x)}{4}\tanh\left(\frac{1}{2}\int_x^\infty dz\,P(z)\right)\right]+\frac{P(x)^2}{4}. \tag{4.37}$$

V. SOLVABILITY OF THE MARCHENKO EQUATIONS

In this section we establish the compactness of the Marchenko integral operators and relate the unique solvability of the (pairs of) Marchenko integral equations to the canonical factorizability of a matrix function.

Theorem 5.1: *Suppose* $P \in L_1^1(\mathbb{R})$, $Q \in L_2^1(\mathbb{R})$, *and* $W^{\pm} \in L_1^1(\mathbb{R})$, *and let conditions (1)–(3) stated at the beginning of Sec. IV C be fulfilled. Then the integral operators arising from the Marchenko integral equations (4.30)–(4.33) are compact on* $L^2(\mathbb{R}^+)$.

Proof: All of these integral operators have the form

$$(Kg)(y) = \int_0^\infty dz\, F(y+z)g(z), \quad y>0,$$

where

$$F(x) = \frac{1}{2\pi}\int_{-\infty}^{\infty} dE\, \Phi(E)e^{iEx},$$

for some function $\Phi(E)$ that is continuous in $E \in \mathbb{R}$ and vanishes as $E \to \pm\infty$. Such integral operators are Hankel operators with continuous symbol and as such compact on $L^2(\mathbb{R})$ (cf. Refs. 21 and 22). □

In order to derive sufficient conditions for the unique solvability of the Marchenko equations (4.30)–(4.31) or the Marchenko equations (4.32)–(4.33), we define the quantities

$$\hat{R}_s(E) = \int_{-\infty}^{\infty} dz\, e^{-iEz}\tilde{F}_{rs}(z), \quad \hat{L}_s(E) = \int_{-\infty}^{\infty} dz\, e^{-iEz}\tilde{F}_{ls}(z),$$

where $s=1,2,3$. If neither of (1.2) has any eigenvalues, we have

$$\hat{R}_1(E) = R_1(E), \quad \hat{R}_2(E) = R_2(E), \quad \hat{R}_3(E) = -k(E)^2 R_2(E),$$

$$\hat{L}_1(E) = L_1(E), \quad \hat{L}_2(E) = L_2(E), \quad \hat{L}_3(E) = -k(E)^2 L_2(E).$$

Introducing the functions

$$B_{rs}^{\pm}(E,x) = \pm\int_0^{\pm\infty} dy\, B_{rs}(x,y)e^{iEy}, \quad B_{ls}^{\pm}(E,x) = \pm\int_0^{\pm\infty} dy\, B_{ls}(x,y)e^{iEy},$$

where $s=1,2$, by Fourier transformation we obtain from (4.30)–(4.31) the Riemann–Hilbert problem,

$$\begin{bmatrix} I & 0 \\ \mathbf{F}_l(-E,x) & I \end{bmatrix}\begin{bmatrix} \mathbf{X}^+(E,x) \\ \mathbf{X}^-(-E,x) \end{bmatrix} + \begin{bmatrix} I & \mathbf{F}_l(E,x) \\ 0 & I \end{bmatrix}\begin{bmatrix} \mathbf{X}^-(E,x) \\ \mathbf{X}^+(-E,x) \end{bmatrix} = \begin{bmatrix} \mathbf{Y}(-E,x) \\ \mathbf{Y}(E,x) \end{bmatrix}, \tag{5.1}$$

where I denotes the 2×2 identity matrix and

$$\mathbf{X}^{\pm}(E,x) = \begin{bmatrix} B_{r1}^{\pm}(E,x) \\ B_{r2}^{\pm}(E,x) \end{bmatrix}, \quad \mathbf{Y}(E,x) = -e^{-2iEx}\begin{bmatrix} \hat{L}_1(E) \\ \hat{L}_2(E) \end{bmatrix},$$

$$\mathbf{F}_l(E,x) = e^{-2iEx}\begin{bmatrix} \hat{L}_1(E) & \hat{L}_3(E) \\ \hat{L}_2(E) & \hat{L}_1(E) \end{bmatrix}.$$

In the same way we define

$$\mathbf{F}_r(E,x)=e^{2iEx}\begin{bmatrix}\hat{R}_1(E) & \hat{R}_3(E)\\ \hat{R}_2(E) & \hat{R}_1(E)\end{bmatrix}.$$

In analogy with (5.1), we derive the Riemann–Hilbert problem,

$$\begin{bmatrix} I & 0\\ \mathbf{F}_l(-E,x) & I\end{bmatrix}\begin{bmatrix}\mathbf{X}^+(E,x)\\ -\mathbf{X}^-(-E,x)\end{bmatrix}+\begin{bmatrix} I & \mathbf{F}_l(E,x)\\ 0 & I\end{bmatrix}\begin{bmatrix}\mathbf{X}^-(E,x)\\ -\mathbf{X}^+(-E,x)\end{bmatrix}=\begin{bmatrix}\mathbf{Y}(-E,x)\\ -\mathbf{Y}(E,x)\end{bmatrix},$$

from the system of integral equations obtained from (4.30) and (4.31) by replacing the kernels $\hat{F}_{ls}$ with $-\hat{F}_{ls}$.

Next, by a (right) *canonical factorization* of a matrix function $W(E)$ defined for $E\in\mathbb{R}$ we mean a factorization of the form

$$W(E)=W^-(E)W^+(E), \tag{5.2}$$

where both $W^{\pm}(E)$ and $W^{\pm}(E)^{-1}$ are continuous in $E\in\overline{\mathbb{C}^{\pm}}$, are analytic in $E\in\mathbb{C}^{\pm}$, and have a limit as $E\to\infty$ in $\overline{\mathbb{C}^{\pm}}$. Replacing (5.2) with $W(E)=W^+(E)W^-(E)$, we get the definition of a left canonical factorization.

The following theorem easily follows using the methods employed in Refs. 23 and 24. Such methods were applied to inverse scattering before in Ref. 7.

Theorem 5.2: *Suppose $P\in L^1_1(\mathbb{R})$, $Q\in L^1_2(\mathbb{R})$ and $W^{\pm}\in L^1_1(\mathbb{R})$, and let conditions (1)–(3) stated at the beginning of Sec. IV C be fulfilled. Then, for fixed $x\in\mathbb{R}$, the system of Marchenko integral equations (4.30) and (4.31) and the system of integral equations obtained from them by replacing the kernels $\tilde{F}_{ls}$ with $-\tilde{F}_{ls}$ both have a unique solution if and only if the 4×4 matrix function*

$$\begin{bmatrix} I-\mathbf{F}_l(E,x)\mathbf{F}_l(-E,x) & -\mathbf{F}_l(E,x)\\ \mathbf{F}_l(-E,x) & I\end{bmatrix} \tag{5.3}$$

has a (right) canonical factorization. Similarly, for fixed $x\in\mathbb{R}$, the system of Marchenko integral equations (4.32) and (4.33) and the system of integral equations obtained from them by replacing the kernels $\tilde{F}_{rs}$ with $-\tilde{F}_{rs}$ both have a unique solution if and only if the 4×4 matrix function

$$\begin{bmatrix} I-\mathbf{F}_r(E,x)\mathbf{F}_r(-E,x) & -\mathbf{F}_r(E,x)\\ \mathbf{F}_r(-E,x) & I\end{bmatrix} \tag{5.4}$$

has a (right) canonical factorization.

In Ref. 7 the Marchenko equations are simple enough to allow for a representation of the 4×4 matrix functions in (5.3) and (5.4) as the direct sum of two 2×2 matrix functions (one being the adjoint of the other) multiplied on either side by constant nonsingular matrices. As a result, in Ref. 7 the analog of the present Theorem 5.2 involves the equivalence of the simultaneous unique solvability of two pairs of Marchenko equations to the existence of both a left and a right canonical factorization of a 2×2 matrix function. No such simplification has been found for the present problem.

We conclude this article by giving a sufficient condition for the canonical factorizability of the matrix function in (5.3) and hence of the unique solvability of the solution of the Marchenko equations (4.30)–(4.31).

Corollary 5.3: Suppose $P\in L^1_1(\mathbb{R})$, $Q\in L^1_2(\mathbb{R})$ and $W^{\pm}\in L^1_1(\mathbb{R})$, and let conditions (1)–(3) stated at the beginning of Sec. IV C be fulfilled. Then, for fixed $x\in\mathbb{R}$, the system of Marchenko integral equations (4.30) and (4.31) are uniquely solvable if

$$\sup_{E\in\mathbb{R}}\|\mathbf{F}_l(E,x)\|<1. \tag{5.5}$$

Analogously, for fixed $x \in \mathbb{R}$, the system of Marchenko integral equations (4.32) and (4.33) are uniquely solvable if

$$\sup_{E \in \mathbb{R}} \|\mathbf{F}_r(E,x)\| < 1. \tag{5.6}$$

In (5.5) and (5.6) the norm is defined as the largest singular value of the matrix.

Proof: This corollary is immediate from Theorem 5.2 by observing that (5.5) implies that $\mathbf{F}_l(E,x)$ has a canonical factorization (cf. Ref. 25, Sec. III A). □

(Received 29 June 2000; accepted for publication 19 September 2000)

Static vortices close together are studied for two different models in two-dimensional Euclidean space. In a simple model for one complex field, an expansion in the parameters describing the relative position of two vortices can be given in terms of trigonometric and exponential functions. The results are then compared to those of the Ginzburg–Landau theory of a superconductor in a magnetic field at the point between type-I and type-II superconductivity. For the angular dependence a similar pattern emerges in both models. The differences for the radial functions are studied up to third order. © *2001 American Institute of Physics.*

I. INTRODUCTION

Ever since t'Hooft[1] and Polyakov[2] found a monopole solution in the SU(2) Yang–Mills–Higgs theory, solitons in field theories have been studied extensively. Our understanding of monopole solutions has been greatly enhanced by an existence proof for static solutions by Taubes[3] and the construction of monopole solutions started by Ward.[4] This process was not matched by quite the same progress in our understanding of the Abrikosov solutions of the Ginzburg–Landau theory, although one might have expected that the Abelian Higgs theory in $2+1$ dimensions is actually simpler than the SU(2) Yang–Mills–Higgs theory in $3+1$ dimensions. Again an existence proof was given by Taubes.[5] However, only superimposed vortices can be described explicitly and no explicit construction of separated vortices is known. In this article, we want to give the solution for two vortices close together in terms of an expansion in the parameters which describe the relative location.

In Secs. II and III, we study a model for one complex field. Here the calculations are simpler than in the Ginzburg–Landau theory which is our second model. The first model has, however, some peculiar (unphysical) features. Assuming the most symmetric form in terms of angular dependence, only two smooth vortices can be superimposed, and when ''pulled apart,'' they develop a singularity at third order. In the Ginzburg–Landau model this does not happen. In fact, delicate cancellations take place to make the expansion smooth, at least up to third order. In this model the radial functions are given as solutions of certain linear ordinary differential equations. This is discussed in Sec. IV.

II. VORTEX SOLUTIONS AND ZERO MODES IN A SIMPLE MODEL

Our first model is a model[6,7] for a pair of real fields $\phi^a(\vec{x})$, $a,b=1,2$, or equivalently, for a complex field $\phi=\phi_1+\imath\phi_2$. The Lagrangian density of the model reads

$$\mathcal{L}=\partial_{[i}\phi^a\partial_{j]}\phi^b\partial^{[i}\phi_a\partial^{j]}\phi_b+(1-|\phi|^2)^2|\phi|^2, \tag{2.1}$$

where $a,b=1,2$ labels the components of the Higgs field and $i,j=1,2$ are the space indices. The square brackets mean antisymmetrization,

$$\partial_{[i}\phi^a\partial_{j]}\phi^b=(\partial_i\phi^a)(\partial_j\phi^b)-(\partial_j\phi^a)(\partial_i\phi^b). \tag{2.2}$$

We are working in two-dimensional Euclidean space, i.e., the space indices can be raised and lowered without any change in the formulas. The indices which label the components of the Higgs field can also be raised and lowered without any change. In terms of the complex field ϕ, the Euler–Lagrange equation reads

$$\partial_i\phi^*\partial_j(\partial^{[i}\phi\partial^{j]}\phi^*)=(1-|\phi|^2)|\phi|\frac{\partial}{\partial\phi}(1-|\phi|^2)|\phi|. \tag{2.3}$$

Any solution of the equation,

$$2\det\left(\frac{\partial\phi^a}{\partial x^i}\right)=\pm(1-|\phi|^2)|\phi|, \tag{2.4}$$

solves the equation of motion (2.3). Note that Eq. (2.4) is a first-order equation whereas Eq. (2.3) is of second order. So we would expect that (2.4) is somewhat easier to solve than (2.3). For different types of models, this reduction of order was first introduced by Bogomolnyi.[8] That is why we call Eq. (2.4) the Bogomolnyi equation here. Any solution of (2.4) also attains the lower bound in the following inequality:

$$A=\int_{\mathbf{R}^2}\mathcal{L}\ \ d^2x\geqslant\frac{16\pi}{15}|Q|, \tag{2.5}$$

where

$$Q=\frac{15}{8\pi}\int_{\mathbf{R}^2}\imath\epsilon_{ij}(1-|\phi|^2)|\phi|(\partial^i\phi)(\partial^j\phi^*)d^2x \tag{2.6}$$

is the winding number. Finally, all finite-action solutions actually solve the Bogomolnyi equation, so we do not miss out on any by concentrating on the first-order equation.

We now seek to attain a smooth finite-action solution of Eq. (2.4). For

$$\phi=f(r)e^{\imath n\theta}, \tag{2.7}$$

Eq. (2.4) reduces to

$$\frac{nf(r)f'(r)}{r}=\frac{1}{2}(1-f^2)f. \tag{2.8}$$

Since $f\to 0$ as $r\to 0$ [otherwise ϕ in (2.7) is not defined at the origin], we have

$$f=\tanh\frac{r^2}{4n}. \tag{2.9}$$

The solution ϕ in (2.7) with $f(r)$ given by (2.9) is defined in the whole of $\mathbf{R}^2$ and is clearly a C^∞ function in $\mathbf{R}^2\backslash\{0\}$. Since

$$f\approx 1-2\exp\frac{r^2}{2n}\ \text{as}\ r\to\infty, \tag{2.10}$$

ϕ has the right asymptotic behavior for a solution with winding number n. We still have to ensure that ϕ is C^∞ at the origin. There we use the Taylor expansion of f,

$$f=\sum_{K=1}^{\infty}\frac{2^{2k}(2^{2k}-1)B_{2k}}{(2k)!}\left(\frac{r^2}{4n}\right)^{2k-1}=\frac{r^2}{4n}-\frac{1}{3}\left(\frac{r^2}{4n}\right)^3+\ldots\ , \tag{2.11}$$

where B_k is the kth Bernoulli number. We see that for $n=2$ and only for $n=2$, ϕ is a polynomial in x^i. In this model, we have the (somewhat peculiar) situation that within the most natural ansatz (2.7), smooth finite action solutions exist only for $n=2$, i.e., we only have a solution of the form (2.7) for two vortices.

We have found the solution for two vortices sitting on top of each other, which we now denote by $\hat{\phi}$. To extend our study to two vortices slightly apart we consider $\phi=\hat{\phi}+\gamma$, where γ is very small, and we solve the Bogomolyni equation, linearized in γ. Equation (2.4) becomes

$$\begin{aligned}&\left(f'\cos\theta\cos2\theta+\frac{2}{r}f\sin\theta\sin2\theta\right)\frac{\partial\gamma^2}{\partial x^2}+\left(f'\sin\theta\sin2\theta+\frac{2}{r}f\cos\theta\cos2\theta\right)\frac{\partial\gamma^1}{\partial x^1}\\&-\left(f'\sin\theta\cos2\theta-\frac{2}{r}f\cos\theta\sin2\theta\right)\frac{\partial\gamma^2}{\partial x^1}-\left(f'\cos\theta\sin2\theta-\frac{2}{r}f\sin\theta\cos2\theta\right)\frac{\partial\gamma^1}{\partial x^2}\\&=\frac{1}{2}(1-3f^2)(\gamma^1\cos2\theta+\gamma^2\sin2\theta).\end{aligned} \tag{2.12}$$

We find a two-parameter family of zero modes,

$$\gamma(r)=[\alpha+\beta+\imath(\alpha-\beta)]h(r)\quad\text{with}\ \ h(r)=\frac{\sinh\frac{r^2}{8}}{\cosh^3\frac{r^2}{8}}. \tag{2.13}$$

These zero modes are C^∞ functions which vanish exponentially at infinity. By a rotation, one of the parameters could be removed and the vortices could be positioned, say, on the x-axis. Since this does not simplify the calculations significantly, we will retain both parameters. Retaining the two parameters would also be necessary for a study of vortex scattering in the slow-motion approximation. This study is not done in this work.

III. THE QUADRATIC AND CUBIC TERMS

We now consider $\phi=\hat{\phi}+\gamma+\delta$, and equate the second-order terms in the Bogomolyni Eq. (2.4). This leads to the equation,

$$\begin{aligned}&\frac{2}{r}\left(f'\cos2\theta\frac{\partial\delta^2}{\partial\theta}+2f\sin2\theta\frac{\partial\delta^2}{\partial r}-f'\sin2\theta\frac{\partial\delta^1}{\partial\theta}+2f\cos2\theta\frac{\partial\delta^1}{\partial r}\right)=(\alpha^2+\beta^2)fh^2\left(\frac{1}{f^2}-3\right)\\&-\frac{1}{2}fh^2\left(3+\frac{1}{f^2}\right)\ [\alpha^2(\cos2\theta+\sin2\theta)^2+2\alpha\beta(\cos^22\theta-\sin^22\theta)+\beta^2(\cos2\theta-\sin2\theta)^2]\\&+(1-3f^2)(\delta^1\cos2\theta+\delta^2\sin2\theta),\end{aligned} \tag{3.1}$$

with $f(r)$ given in (2.9) and $h(r)$ given in (2.13).

With δ of the form

$$\delta=\alpha^2F(r,\theta)+2\alpha\beta G(r,\theta)+\beta^2H(r,\theta), \tag{3.2}$$

we obtain the following equation for $F(r,\theta)$:

$$\frac{2}{r}\left(f'\cos 2\theta\frac{\partial F^2}{\partial\theta}+2f\sin 2\theta\frac{\partial F^2}{\partial r}-f'\sin 2\theta\frac{\partial F^1}{\partial\theta}+2f\cos 2\theta\frac{\partial F^1}{\partial r}\right)$$
$$=h^2\left(\frac{1}{f}-3f\right)-\frac{h^2}{2}\left(3f+\frac{1}{f}\right)(\cos 2\theta+\sin 2\theta)^2+(1-3f^2)(F^1\cos 2\theta+F^2\sin 2\theta). \tag{3.3}$$

To solve this equation we seek a solution of the form

$$F=f_1(r)\exp^{\imath 2\theta}-\imath f_2(r)\exp^{-\imath 2\theta}. \tag{3.4}$$

The ansatz (3.4) leads to two decoupled equations for f_1 and f_2. In terms of the variable $\xi=r^2/8$, they read

$$\frac{df_1}{d\xi}+\frac{1}{f}\left(3f^2-1-\frac{df}{d\xi}\right)f_1=\frac{h^2}{2f^2}(1-9f^2), \tag{3.5}$$

$$\frac{df_2}{d\xi}+\frac{1}{f}\left(3f^2-1+\frac{df}{d\xi}\right)f_2=-\frac{h^2}{2f}(1+3f^2). \tag{3.6}$$

The general solution to Eq. (3.5) is

$$f_1=\frac{1}{\cosh^2\xi}\left(\frac{3\sinh\xi}{2\cosh^3\xi}-\frac{\sinh\xi}{\cosh\xi}+C_1\right). \tag{3.7}$$

The function f_1 is a C^∞ function for $0<\xi<\infty$. For $\xi\to 0$, $f_1\to C_1$ holds. This implies that $C_1=0$; otherwise F in (3.4) is not defined at the origin. Therefore, f_1 reads

$$f_1=\frac{3\sinh\xi}{2\cosh^5\xi}-\frac{\sinh\xi}{\cosh^3\xi}. \tag{3.8}$$

The expansion of f_1 near the origin is of the form

$$f_1=\sum_{k=1}^{\infty}a_k\xi^k=\sum_{k=1}^{\infty}a_k\left(\frac{r^2}{8}\right)^k. \tag{3.9}$$

Hence, the first term in (3.4) is a C^∞ function of x^1 and x^2 at the origin. We also see that f_1 vanishes exponentially at infinity. So its contribution to ϕ does not change the winding number (2.6) which is a multiple of the action.

A similar calculation yields a one-parameter family of solutions to Eq. (3.6), namely

$$f_2=\frac{\sinh\xi}{2\cosh^3\xi}-\frac{3\sinh^3\xi}{2\cosh^5\xi}+C_2\frac{\sinh^2\xi}{\cosh^4\xi}. \tag{3.10}$$

In contrast to f_1, all the solutions f_2 are acceptable. In fact, for all C_2, f_2 is of the form

$$f_2=\sum_{k=1}^{\infty}b_k\xi^k=\sum_{k=1}^{\infty}b_k\left(\frac{r^2}{8}\right)^k \tag{3.11}$$

near the origin, and therefore the second term in (3.4) is in $C^\infty(\mathbf{R}^2)$. The winding number and the action are also not altered because f_2 decays exponentially at infinity.

The functions G and H in (3.2) can be found in the same way. If we put all results together, we obtain the second-order terms,

$$\delta=(\alpha^2+\beta^2)f_1(r)\exp^{\imath 2\theta}+\imath(\alpha-\imath\beta)^2 f_2(r)\exp^{-\imath 2\theta}, \tag{3.12}$$

where f_1 and f_2 are given by (3.8) and (3.10), respectively.

To find the cubic terms, we consider $\phi=\hat{\phi}+\gamma+\delta+\epsilon$, with γ given in (2.13) and δ given by (3.12). We set $\beta=0$ and concentrate on

$$\epsilon=\alpha^3 I(r,\theta). \tag{3.13}$$

For the Bogomolnyi equation to hold, I must satisfy

$$\begin{aligned}
&\frac{2}{r}\Bigg(f'\cos 2\theta\frac{\partial I^2}{\partial\theta}+2f\sin 2\theta\frac{\partial I^2}{\partial r}-f'\sin 2\theta\frac{\partial I^1}{\partial\theta}+2f\cos 2\theta\frac{\partial I^1}{\partial r}\\
&\quad+h'(2f_1\cos 2\theta+2f_2\sin 2\theta)+h'(2f_1\sin 2\theta+2f_2\cos 2\theta)\Bigg)\\
&=-3f^2(I^1\cos 2\theta+I^2\sin 2\theta)-3hf(f_1-f_2)(\cos 2\theta+\sin 2\theta)\\
&\quad-3fh(\cos 2\theta+\sin 2\theta)(2f_1-f_2-2f_2\cos 2\theta\sin 2\theta)-3(\cos 2\theta+\sin 2\theta)h^3\\
&\quad+I^1\cos 2\theta+I^2\sin 2\theta+\frac{h}{2}[f_1(\cos 2\theta+\sin 2\theta)-f_2(\cos 2\theta+\sin 2\theta)]\\
&\quad+\frac{h^3}{2}(\cos 2\theta+\sin 2\theta)^3-\frac{h^3}{f^2}(\cos 2\theta+\sin 2\theta)\\
&\quad-\frac{h}{f}(\cos 2\theta+\sin 2\theta)(f_1-2f_2\cos 2\theta\sin 2\theta)+\frac{h}{2f^2}(\cos 2\theta+\sin 2\theta)^3.
\end{aligned} \tag{3.14}$$

To solve Eq. (3.14) we seek a solution of the form

$$\begin{aligned}
I^1&=g_1(\xi)+g_2(\xi)(\cos 4\theta-\sin 4\theta),\\
I^2&=g_1(\xi)-g_2(\xi)(\cos 4\theta+\sin 4\theta).
\end{aligned} \tag{3.15}$$

This implies that g_1 and g_2 must satisfy the equations

$$\frac{dg_1}{d\xi}+\left(3f-\frac{1}{f}\right)g_1=-\frac{f_1+f_2}{f}\frac{dh}{d\xi}-6hf_1+\frac{9}{2}hf_2-\frac{hf_2}{2f^2}-\frac{h^3}{4f^3}-\frac{9h^3}{4f}, \tag{3.16}$$

$$\frac{dg_2}{d\xi}-\left(\frac{1}{f}-3f+\frac{2}{f}\frac{df}{d\xi}\right)g_2=-\frac{hf_2}{2f^2}-\frac{3hf_2}{2}-\frac{h^3}{4f^3}-\frac{h^3}{4f}. \tag{3.17}$$

The general solution to Eq. (3.17) is

$$g_2=\frac{\sinh\xi}{4\cosh^5\xi}-\frac{5\sinh^3\xi}{4\cosh^7\xi}+C_2\left(\frac{\sinh^2\xi}{2\cosh^4\xi}-\frac{3\sinh^4\xi}{2\cosh^6\xi}\right)+C_3\frac{\sinh^3\xi}{\cosh^5\xi}. \tag{3.18}$$

All solutions (3.18) decay exponentially at infinity. For $r\to 0$, however,

$$g_2(r)=\frac{1}{24}r^2+\ldots\ . \tag{3.19}$$

Hence, I in (3.15) is not a C^∞ function on $\mathbf{R}^2$. Our expansion gets singular at third order for the ansatz (3.15). In the next section we will discuss a realistic model in which a similar pattern emerges but no singularities occur.

IV. ABRIKOSOV VORTICES

The Ginzburg–Landau theory of a superconductor in a magnetic field in direction z is given by the Lagrangian density

$$\mathcal{L}=\frac{1}{4}F_{ij}F^{ij}+\frac{1}{2}(D_i\phi)(D^i\phi)^*+\frac{\lambda}{8}(|\phi|^2-1)^2, \tag{4.1}$$

where ϕ is the complex Higgs field, and $D_i\phi=\partial_i\phi-\imath A_i\phi$ and $F_{ij}=\partial_iA_j-\partial_jA_i$ in terms of the gauge potentials A_i, $i=1,2$. The Euler–Lagrange equations are

$$D_iD^i\phi=\frac{\lambda}{2}\phi(1-|\phi|^2),\quad \partial_iF^{ij}=\frac{\imath}{2}[\phi(D^j\phi)^*-\phi^*D^j\phi]. \tag{4.2}$$

In the special case $\lambda=1$, it can be shown[9] that all finite action solutions of Eq. (4.2) satisfy the first-order Bogmolnyi equations,[8]

$$F_{12}=\tfrac{1}{2}(1-|\phi|^2),\quad D_1\phi=-iD_2\phi. \tag{4.3}$$

It has also been shown[9] that a $2n$-parameter family of solution of (4.3) exists with winding number

$$n=\frac{1}{2\pi}\int_{\mathbf{R}^2}F_{12}\ d^2x. \tag{4.4}$$

This family describes n vortices sitting at n position in space.

Even for n vortices sitting on top of each other, the solution is not known explicitly in terms of elementary functions. It is known,[10] however, that this solution is of the form

$$\phi=f(r)e^{\imath n\theta},\quad A_i=-\frac{na(r)}{r^2}\varepsilon_{ij}x^j, \tag{4.5}$$

where f and a satisfy

$$rf'-n(1-a)f=(2n/r)a'+f^2-1=0 \tag{4.6}$$

and

$$f(0)=a(0)=0,\quad \lim_{r\to\infty}f(r)=\lim_{r\to\infty}a(r)=1. \tag{4.7}$$

In the following, we restrict our attention to $n=2$ and use the solution (4.5) as the zero-order term in an expansion in the separation parameters. The first-order terms are given by the two zero modes describing the separation of the vortices. These were found by Weinberg.[11] Using his results we can write, up to quadratic terms,

$$\phi=fe^{2\imath\theta}+2(\alpha+\imath\beta)kf+\alpha^2\psi+\alpha\beta\phi+\beta^2\chi+\cdots, \tag{4.8}$$

$$A_1+\imath A_2=\imath\frac{2a}{r}e^{\imath\theta}-2\imath(\alpha+\imath\beta)\left(k'+\frac{2k}{r}\right)e^{-\imath\theta}$$
$$+\alpha^2(B_1+\imath B_2)+\alpha\beta(C_1+\imath C_2)+\beta^2(D_1+\imath D_2)+\cdots . \tag{4.9}$$

Here the radial function $k(r)$ satisfies

$$k''+\frac{1}{r}k'-\left(f^2+\frac{4}{r^2}\right)k=0, \tag{4.10}$$

with

$$\lim_{r\to 0} r^2k=1, \quad \lim_{r\to\infty} k(r)=0. \tag{4.11}$$

Our task is to determine $\psi,\phi,\chi,B_i,C_i,D_i$, which are functions of r and θ.

Equating the α^2-terms in the Bogomolnyi Eqs. (4.3), we obtain

$$(\partial_1+\imath\partial_2)\psi+\frac{2a}{r}\psi e^{\imath\theta}-\imath f(B_1+\imath B_2)e^{2\imath\theta}=4kf\left(k'+\frac{2k}{r}\right)e^{-\imath\theta}, \tag{4.12}$$

$$\partial_1B_2-\partial_2B_1+\tfrac{1}{2}(f\psi e^{-2\imath\theta}+f\psi e^{2\imath\theta})=-2k^2f^2. \tag{4.13}$$

A Fourier expansion with the minimal number of nonzero terms leads to the ansatz

$$\psi=g(r)f(r)e^{2\imath\theta}+\tilde{g}(r)e^{-2\imath\theta},$$
$$B_1+\imath B_2=\tilde{b}(r)e^{\imath\theta}+\imath b(r)f(r)e^{-3\imath\theta}, \tag{4.14}$$

and to equations for $g(r),\tilde{g}(r),b(r)$, and $\tilde{b}(r)$. The equations for $\tilde{g}(r)$ and $\tilde{b}(r)$ read

$$\tilde{g}=\frac{1+2a}{r}b-b', \quad \tilde{b}=-\imath h'. \tag{4.15}$$

The functions $g(r)$ and $b(r)$ must satisfy the equations

$$g''+\frac{1}{r}g'-f^2g=2k^2f^2, \tag{4.16}$$

$$b''+\frac{1}{r}b'-\left(\frac{1+f^2}{2}+\frac{1+4a+4a^2}{r^2}\right)b=-4kf\left(k'+\frac{2k}{r}\right). \tag{4.17}$$

Equating the $\alpha\beta$-terms and the β^2-terms in the Bogonolnyi Eq. (4.3), we obtain equations for ϕ and C_i, and for χ and D_i, respectively. These equations, which are very similar to Eqs. (4.12) and (4.13), can again be solved by functions with the same θ-dependence as in (4.14) but with slightly different radial functions. Collecting all results, we can write the solution, up to quadratic terms, in the form

$$\phi=fe^{2\imath\theta}+2(\alpha+\imath\beta)kf+(\alpha^2+\beta^2)gfe^{2\imath\theta}+(\alpha+\imath\beta)^2\left(\frac{1+2a}{r}b-b'\right)e^{-2\imath\theta}+\cdots,$$
$$A_1+\imath A_2=\imath\frac{2a}{r}e^{\imath\theta}-2\imath(\alpha+\imath\beta)\left(k'+\frac{2k}{r}\right)e^{-\imath\theta}-\imath(\alpha^2+\beta^2)g'e^{\imath\theta}+\imath(\alpha+\imath\beta)^2bfe^{-3\imath\theta}+\ldots . \tag{4.18}$$

It remains to be shown that the quadratic terms in (4.18) are C^∞ functions on $\mathbf{R}^2$ which do not change the action (and the winding number). To this end we use the power series expansions of $f, a,$ and r^2k at the origin (where the series converge),[12]

$$f(r)=f_1r^2+\tfrac{1}{8}f_1r^4+\ldots, \quad a(r)=\tfrac{1}{8}r^2-\tfrac{1}{24}f_1^2r^6+\ldots,$$
$$k(r)=r^{-2}+k_1r^2+\ldots \quad . \tag{4.19}$$

Here $f_1=0.236$ and $k_1=-0.025$ from the numerical analysis. We find that the solutions of (4.16) and (4.17) have the following expansions at the origin:

$$g(r)=g_{-1}\log r+g_1+\tfrac{1}{2}f_1^2r^2+\cdots,$$
$$b(r)=b_{-1}r^{-1}+b_1r+(\tfrac{1}{8}b_1-2f_1k_1)r^3+\ldots \quad . \tag{4.20}$$

The higher-order terms in $g(r)$ are even powers of r, whereas the higher-order terms in $b(r)$ are odd powers of r. Hence, the quadratic terms in (4.18) are C^∞ near the origin if and only if $h_{-1}=b_{-1}=0$. So far, the constants g_1 and b_1 are arbitrary.

For large r the functions $f, a,$ and k can be written as convergent series whose leading terms are[12]

$$f(r)=1+\tilde{f}_1(r)e^{-r}+\cdots,$$
$$a(r)=1+\tilde{a}_1(r)e^{-r}+\cdots, \tag{4.21}$$
$$k(r)=\tilde{k}_1(r)e^{-r}+\cdots,$$

with coefficient functions which are polynomially bounded. This leads to the existence of exponentially decaying solutions which asymptotically are of the form

$$g(r)=\tilde{g}_1(r)e^{-r}+\cdots, \quad b(r)=\tilde{b}_1(r)e^{-r}+\cdots. \tag{4.22}$$

Here $\tilde{g}_1$ and $\tilde{b}_1$ are polynomially bounded.

By numerical integration, the coefficients g_1 and b_1 which lead to an exponential falloff at infinity, are found to be $g_1=-0.144$ and $b_1=-0.026$. The existence of such functions can be explained analytically as follows: Eq. (4.16) shows that for positive g_1, g cannot have a maximum for any r. So the function diverges exponentially. For very small g_1, the term on the right-hand side of (4.16) will force the function to cross the r-axis, and then, as before, diverge exponentially. For very large negative g_1, the third term in (4.16) will force g to go through a maximum for large r. After that, the function cannot have a minimum and must go to minus infinity. Because of the continuous dependence on the initial data, we have an open set of data for which g crosses the r-axis, and an open set of data for which g goes through a maximum below the r-axis. Therefore, we have at least one value of g_1 for which the function does neither. This function must converge and does so to zero, exponentially.

A similar argument explains the existence of an acceptable solution $b(r)$ to Eq. (4.17). The right-hand side of that equation is positive. So again b cannot have a maximum above the r-axis. Also, for very small negative b_1, the right-hand side will force b to go through a minimum and then cross the r-axis. For very large negative b_1, the third term in (4.17) prevents b from going through a minimum. In between these two possibilities we find the desired solution which goes through a minimum but does not cross the r-axis. Such a solution must decay exponentially.

The cubic terms can be calculated in the same manner. We find, at third order,

$$\begin{aligned}\phi &= \ldots + (\alpha+\imath\beta)(\alpha^2+\beta^2)fh + (\alpha+\imath\beta)^3\left(-c' + \frac{3+2a}{r}c\right)e^{-4\imath\theta} + \cdots,\\ A_1 + \imath A_2 &= \cdots + \imath(\alpha+\imath\beta)(\alpha^2+\beta^2)\left[-h' - \frac{2}{r}h + 2g\left(k' + \frac{2k}{r}\right) + 2kg'\right]e^{-\imath\theta}\\ &\quad + \imath(\alpha+\imath\beta)^3 fc e^{-5\imath\theta} + \cdots.\end{aligned} \tag{4.23}$$

The new radial functions, $h(r)$ and $c(r)$, satisfy the equations,

$$h'' + \frac{1}{r}h' - \left(f^2 + \frac{4}{r^2}\right)h = 4k'g' + 2fk\left(2fk^2 + 3fg + \frac{1+2a}{r}b - b'\right), \tag{4.24}$$

$$c'' + \frac{1}{r}c' - \left(\frac{1+f^2}{2} + \frac{9+12a+4a^2}{r^2}\right)c = 2kf^2 b - 2\left(k' + \frac{2k}{r}\right)\left(\frac{1+2a}{r}b - b'\right). \tag{4.25}$$

Near the origin, Eq. (4.25) has a series solution in powers of r^2 of the form

$$h(r) = f_1^2 + h_1 r^2 + h_2 r^4 + \cdots. \tag{4.26}$$

The constant term is given in terms of the coefficient f_1 of the leading term in the expansion (4.19) of $f(r)$. The form of this term leads to the cancellation of the r^{-1}-terms in the radial function multiplying $e^{-\imath\theta}$ in (4.23), and thus ensures that this term in (4.23) is C^∞ on $\mathbf{R}^2$. The series in odd powers of r for $c(r)$ which solves Eq. (4.25) near the origin, is

$$c(r) = c_1 r^3 + c_2 r^5 + \cdots. \tag{4.27}$$

The form of the series solutions at the origin guarantees that the cubic terms in (4.23) are C^∞ functions on $\mathbf{R}^2$. For large r, Eqs. (4.24) and (4.25) have exponentially decaying solutions.

V. CONCLUSIONS

Our expansions show a simple θ-dependence in terms of trigonometric functions. In both models, the expansion of ϕ exhibits the following pattern:

$$\begin{array}{cccccccc}
 & & & & & & e^{2\imath\theta} & \\
 & & & & & e^{0\imath\theta} & & \\
 & & & & e^{-2\imath\theta} & & e^{2\imath\theta} & \\
 & & & e^{-4\imath\theta} & & e^{0\imath\theta} & & \\
 & & e^{-6\imath\theta} & & e^{-2\imath\theta} & & e^{2\imath\theta} & \\
 & e^{-8\imath\theta} & & e^{-4\imath\theta} & & e^{0\imath\theta} & & \\
\ldots & & \ldots & & \ldots & & \ldots &
\end{array}$$

Here the first line gives the θ dependence of the zero order term; the second line gives the first order term, and so on. We get a similar triangular pattern for the θ dependence of $A_1 + \imath A_2$ at any order. For the radial functions we find differences between the two models. In the model for one complex field, the radial functions can be given explicitly in terms of exponential functions. However, for the angular dependence (3.15), a singularity occurs at the origin. [We have found no solution to (3.14) which is not of the form (3.15); we have no proof that there is none.]

For the Ginzburg–Landau theory on the other hand, the expansion is smooth, at least up to the order to which we carried out our calculations. In this model the radial functions are not given in terms of well-known functions. Having used the technique to calculate the terms up to third order,

it is quite clear how to proceed to any order, and also how to proceed in the case of more than two vortices. We expect these expansions to converge for small separation parameters in the physical Ginzburg–Landau model. However, we do not have an estimate of the radius of convergence.

Energy estimates for the von Kármán model of thin-film blistering

Weimin Jin and Peter Sternberg[a)]
Department of Mathematics, Indiana University, Bloomington, Indiana 47405

(Received 12 May 2000; accepted for publication 26 July 2000)

We consider the behavior of buckling driven thin-film blisterings using von Kármán's plate theory. Our focus is on the setting where the blistered region is the unit square with clamped boundary conditions at the vertical sides and periodic ones along the horizontal sides. In this setting, we prove rigorous upper and lower bounds for the elastic energy which are of the same order as the film thickness. We also present a convincing argument for the necessity of branching of folds near the boundary as has been observed in experiments. © *2001 American Institute of Physics.* [DOI: 10.1063/1.1316058]

I. INTRODUCTION

In this sequel to Ref. 1, we continue our investigation of thin-film blistering via the von Kármán model. These blisters are formed when a thin film in a state of residual compression decoheres and buckles away from its substrate. The goal is to better understand the nature of the complex folding and branching patterns observed in experiments.[2–7] Our focus here is on the incorporation of in-plane displacements in the model.

Given a blistered region Ω, we shall denote by u the out-of-plane displacement of the film and let (w_1,w_2) denote the in-plane displacements. Then in our scaling, the von Kármán model takes the form

$$\min_{\substack{w=0,u=0,\\ \partial u/\partial n=0, \text{ at } \partial\Omega}} \int_\Omega [(w_{\alpha,\beta}+w_{\beta,\alpha})/2+u_{,\alpha}u_{,\beta}/2-\delta_{\alpha\beta}]^2+\varepsilon^2|\nabla\nabla u|^2, \tag{1}$$

where ε is the normalized film thickness. The formulation above corresponds to the choice of zero Poisson's ratio, though we note that this choice does not affect the essential features of the problem. See Ref. 1 for a more detailed discussion of the model and, for example, Refs. 8–11 for a derivation.

In this article, we choose to study the setting where Ω is the unit square. What is more, we will take clamped boundary conditions at $x=0$ and $x=1$, but replace the clamped conditions by periodic ones along $y=0$ and $y=1$. To be more specific, our problem is formulated as

$$\min_{\substack{u=0,u_x=0, \text{ at } x=0,1\\ w_1=0,w_2=0, \text{ at } x=0,1\\ w_1,w_2,u,\nabla u, \text{ periodic in } y}} \int_0^1\int_0^1 [(w_{\alpha,\beta}+w_{\beta,\alpha})/2+u_{,\alpha}u_{,\beta}/2-\delta_{\alpha\beta}]^2+\varepsilon^2|\nabla\nabla u|^2\,dx\,dy. \tag{2}$$

Here α and β run between 1 and 2. We will henceforth refer to the first term above as the membrane energy and we refer to the singular perturbation term as the bending energy.

A primary motivation in our choice of boundary conditions is to focus our attention on perhaps the simplest geometry in which the behavior of the film near the clamped boundary can be successfully analyzed. A secondary rationale is our belief that through a local curvilinear coordi-

a)Electronic mail: sternber@indiana.edu

nate change, the folding patterns of an arbitary smooth blistered domain might be understood through a study of the annular setting. Physically, our choice of domains is also motivated by earlier studies of instabilities of straight delamination blisters (Refs. 4, 12). By analyzing carefully the structure of solutions for a straight blister, our hope here is to gain insight into the nature of the stress distribution near the boundary which is ultimately responsible for the observed instabilities of such a blister region.

Various simplifications have been carried out on (1). If one completely ignores all in-plane displacements ($w_1=w_2=0$), then one is left with an energy of the form

$$|\Omega|+\int_\Omega\left(1-\frac{1}{2}|\nabla u|^2\right)^2+\varepsilon^2|\nabla\nabla u|^2$$

whose infimum is clearly $\mathcal{O}(1)$. This functional has been studied extensively; see, e.g., Refs. 13–17.

Another possible simplication of (1) comes from assuming a one-dimensional folding pattern, sometimes referred to as an ''Euler column.''[4] That is, one takes $u=u(x)$, $w_1=w_1(x)$ and $w_2\equiv 0$. This again yields an order 1 infimum to the energy.

In Ref. 1 we took a less drastic simplication by only assuming a one-dimensional in-plane displacement [i.e., $w_1=w_1(x)$, $w_2\equiv 0$] while allowing u to depend on x and y. Within this class of deformations, we obtained rigorous upper and lower bounds on the energy of order $\varepsilon^{2/3}$. The construction of a minimizing sequence achieving the asymptotic upper bound involved complicated branching patterns near the clamped boundaries of the unit square. This construction was reminiscent of branching sequences used in Ref. 18.

In this paper, we do not impose any restrictions on (w_1,w_2,u) and we then prove rigorous upper and lower bounds for the full von Kármán energy (1) which are of order ε. In light of these bounds, one obtains a convincing argument for the necessity of branching near the boundary. We make this argument formally at the outset of the next section. The folding patterns we obtain lend rigorous support to earlier observations made in the physics literature (Refs. 12, 19). In Ref. 19 one finds a prediction of branching near the boundary based on energetic scaling arguments while Ref. 12 contains a stability analysis of the von Kármán equations linearized about the one-dimensional ''Euler column'' solution for a straight-edged blister—an analysis which predicts the instability of this solution. Our assertion here is that the oscillatory profile near the boundary predicted by our construction imposes nonuniform stresses along the boundary which in turn indicate the instability of the delamination front as is depicted, for example, in Ref. 12, Fig. 4. The resultant wavy boundary of the blistered region would then resemble the often observed ''telephone cord'' pattern for such films.

Finally, we should note that our formulation (1) arose through a choice of eigenstrain $e^*_{\alpha\beta}=\delta_{\alpha\beta}$. In reality, the eigenstrains involved are much smaller. Alternatively, one could have taken, say, $e^*_{\alpha\beta}=k\delta_{\alpha\beta}$, with k a second small parameter (in addition to the thickness ε). Then, with a rescaling of $u\to\sqrt{k}u$ and $(w_1,w_2)\to k(w_1,w_2)$, one would arrive at an energy of order $k^{3/2}\varepsilon$. (See Remark 2.)

Note: After submission of this paper, we learned of a similar result for arbitrary smooth domains just completed in Ref. 20.

II. MAIN RESULTS

Before presenting the main theorem and its proof, we wish to give a feel for the ingredients leading to the lower and upper bounds on the minimal energy. Thus, for the moment, we proceed formally.

Much of the argument relies on the obvious requirement to keep the membrane energy as small as possible. In particular, one would expect a minimizer (or minimizing sequence) to satisfy the condition

$$\int_0^1 \left(w_{2,y}(x,y) + \frac{1}{2} u_y^2(x,y) - 1 \right)^2 dy \approx 0,$$

for x away from $x=0$ or $x=1$. In light of the periodicity of w_2 in y, this suggests that

$$\int_0^1 \frac{1}{2} u_y^2(x,y)\, dy \approx 1, \tag{3}$$

for such x. However, the boundary conditions for u imply that $\int_0^1 u_y^2(0,y)dy = \int_0^1 u_y^2(1,y)dy = 0$, necessitating a boundary layer along the two vertical sides of the unit square. Let us introduce a boundary layer width δ and note that in light of (3), the integrand in the membrane energy will be $\mathcal{O}(1)$ within this layer, yielding a contribution to the total energy of order $\mathcal{O}(\delta)$.

On the other hand, turning to the bending energy in such a boundary layer, we see that since u_y must make an $\mathcal{O}(1)$ change over an x-interval of size δ, we find

$$\varepsilon^2 \int \int_{\text{boundary layer}} u_{xy}^2 dx\, dy \sim \frac{\varepsilon^2}{\delta}. \tag{4}$$

Hence, the total energy is at least of order $\mathcal{O}(\delta + \varepsilon^2/\delta)$, which immediately indicates the lower bound of ε and a boundary layer width $\delta \sim \varepsilon$.

To motivate our construction leading to an upper bound of order ε, we must look at the other terms in the bending energy. To analyze these, we formally introduce a quantity $\gamma(x)$ representing the wavelength of oscillations of u in the y-direction for x away from the boundary. In view of (3), however, one can equivalently think of $\gamma(x)$ as measuring the amplitude of u along vertical segments. For example, one might think of $\gamma(x) = (\int_0^1 u^2(x,y)dy)^{1/2}$.

With this notion in hand, we can estimate

$$\varepsilon^2 \int \int_{\text{boundary layer}} u_{xx}^2 dx\, dy \sim \varepsilon^2 \left(\frac{\gamma(\delta)}{\delta^2} \right)^2 \delta = \frac{\varepsilon^2 \gamma(\delta)^2}{\delta^3}.$$

Since we previously found that $\delta \sim \varepsilon$, the above estimate shows that $\gamma(\delta) \sim \varepsilon$ as well if we are to achieve the upper bound of order ε. On the other hand, using the standard inequality

$$\int_0^1 u^2 dy \int_0^1 u_{yy}^2 dy \geqslant \left(\int_0^1 u_y^2 dy \right)^2,$$

we see through (3) that

$$\int_0^1 u_{yy}^2(x,y)dy \geqslant \frac{1}{\gamma(x)^2},$$

for x in the interior of the square. Consequently, the total bending energy behaves like $\varepsilon^2 \int [1/\gamma(x)^2]\, dx$. This suggests that we must increase $\gamma(x)$ from $\mathcal{O}(\varepsilon)$ to at least $\mathcal{O}(\sqrt{\varepsilon})$ as we move into the interior of the square.

In our particular construction, we achieve this transition incrementally by successively doubling the wavelengths as we move towards the interior of the square.

So far we have neglected the contribution from the membrane energy in the interior. Ideally, one might seek to eliminate this contribution entirely, leading to the conditions

$$w_{1,x} + \tfrac{1}{2} u_x^2 - 1 = 0, \tag{5}$$

$$w_{2,y} + \tfrac{1}{2} u_y^2 - 1 = 0, \tag{6}$$

$$w_{2,x}+w_{1,y}+u_x u_y=0. \tag{7}$$

Taking the sum of the second y-derivative of (5) and the second x-derivative of (6) and then subtracting the mixed second derivative of (7), one arrives at a consistency condition,

$$u_{xx}u_{yy}-u_{xy}^2=0. \tag{8}$$

That is, ideally, the graph of u should be a developable surface (see Ref. 21). In particular, one can satisfy this condition by taking $u=u(x+y)$. Our particular choice for u below involving cosine functions is motivated by these considerations and by the exact solution in the one-dimensional example found in Ref. 1.

These heuristics are now made rigorous through the following theorem.

Theorem 1: *There exist positive constants C_1 and C_2 independent of ε such that the minimal energy E_ε of (2) satisfies the bounds*

$$C_1\varepsilon\leqslant E_\varepsilon\leqslant C_2\varepsilon,$$

for ε sufficiently small.

Proof: (i) Lower bound. Suppressing the ε-dependence, we denote a minimizer to (2) by (u,w_1,w_2). Then denote by δ the positive number satisfying

$$\delta=\max_{x\in[0,1]}\left\{x:\int_0^1 u_y(x',y)^2dy\leqslant 1,\quad \forall x'\in[0,x]\right\}.$$

Certainly $0<\delta\leqslant 1$ since the boundary conditions imply that $u_y(0,y)=0$ for $y\in[0,1]$.

Then, using the periodicity of w_2 in y, we estimate the membrane energy on $[0,\delta]\times[0,1]$ as follows:

$$\int_0^\delta\int_0^1\left(w_{2,y}+\frac{1}{2}u_y^2-1\right)^2dydx\geqslant\int_0^\delta\left(\int_0^1 w_{2,y}+\frac{1}{2}u_y^2-1dy\right)^2dx=\int_0^\delta\left(\int_0^1\frac{1}{2}u_y^2-1dy\right)^2dx\geqslant\frac{1}{4}\delta. \tag{9}$$

If $\delta=1$, then the desired lower bound is immediate. If, on the other hand, $\delta<1$, then $\int_0^1 u_y(\delta,y)^2dy=1$ and one can estimate the bending energy in this strip from below by

$$\varepsilon^2\int_0^1\int_0^\delta u_{xy}^2dx\,dy\geqslant\varepsilon^2\int_0^1\frac{1}{\delta}\left(\int_0^\delta u_{xy}dx\right)^2dy=\frac{\varepsilon^2}{\delta}. \tag{10}$$

Hence, we find

$$E_\varepsilon\geqslant\frac{1}{4}\delta+\frac{\varepsilon^2}{\delta}\geqslant\varepsilon. \tag{11}$$

(ii) Upper bound. We begin by constructing a sequence of functions (u,w_1,w_2) on the unit square which will satisfy the boundary conditions at $x=0$. Again, we will suppress the ε-dependence in referring to our constructed sequence. Then through some straight-forward reflections and rescalings, we will modify the construction to satisfy the boundary conditions at $x=1$ as well.

Making the definition

$$b_n=\left(\frac{1}{2^{3/2}}\right)^n, \tag{12}$$

we will denote the strip $[b_{n+1},b_n]\times[0,1]$ by I_n for $n=0,1,2,\ldots,N$ where N will be specified later. Then for any $\varepsilon>0$ we define a positive number $a<1$ by the condition

$$\frac{1}{a\varepsilon^{1/3}} = 2k\pi, \text{ for some integer } k, \tag{13}$$

and we let

$$a_n = \frac{a\varepsilon^{1/3}}{2^n}. \tag{14}$$

We also introduce $f:[0,1]\to\mathbf{R}$ and $g:[0,1]\to\mathbf{R}$ as any two functions satisfying the conditions

$$0\leqslant f(x)\leqslant 1,\ 0\leqslant g(x)\leqslant 1, \text{ for } x\in[0,1], \tag{15}$$

$$f(1)=1,\ f'(1)=f(0)=f'(0)=0, \tag{16}$$

$$g(0)=1,\ g'(0)=g(1)=g'(1)=0, \tag{17}$$

$$f(x)^2+g(x)^2=1, \text{ for } x\in[0,1]. \tag{18}$$

We are now prepared to define the function u in our construction via the formula

$$u(x,y)=2a_n\left[\cos\left(\frac{x+y}{a_n}\right)+1\right]f_n(x)+2a_{n+1}\left[\cos\left(\frac{x+y}{a_{n+1}}\right)+1\right]g_n(x), \tag{19}$$

for $x\in I_n$ and $y\in[0,1]$, $n=0,1,2,\ldots,N$ where we have introduced

$$f_n(x)=f\left(\frac{x-b_{n+1}}{b_n-b_{n+1}}\right) \tag{20}$$

and

$$g_n(x)=g\left(\frac{x-b_{n+1}}{b_n-b_{n+1}}\right). \tag{21}$$

Note that u so defined will satisfy the periodic boundary conditions at $y=0$ and $y=1$ in light of (13) and will be sufficiently smooth in light of (16)–(17).

Next we turn to the definition of w_2. In order to eliminate one of the terms in the membrane energy completely, we will choose this function so that

$$w_{2,y}=1-\frac{u_y^2}{2}. \tag{22}$$

This leads after an integration and a use of (18) to the formula

$$\begin{aligned} w_2(x,y)=&\frac{a_n}{2}f_n(x)^2\sin\left[2\left(\frac{x+y}{a_n}\right)\right]+\frac{a_{n+1}}{2}g_n(x)^2\sin\left[2\left(\frac{x+y}{a_{n+1}}\right)\right]-2a_nf_n(x)g_n(x)\sin\left[\left(\frac{x+y}{a_n}\right)\right]\\ &+\frac{2}{3}a_nf_n(x)g_n(x)\sin\left[3\left(\frac{x+y}{a_n}\right)\right]+h_2(x), \end{aligned} \tag{23}$$

where h_2 will be specified shortly.

We turn now to the definition of w_1, where one goal will be to completely eliminate the contribution to the membrane energy from the cross-term

$$(\tfrac{1}{2}w_{1,y}+\tfrac{1}{2}w_{2,x}+\tfrac{1}{2}u_xu_y)^2.$$

This can be accomplished by choosing $h_2(x)=-2x$ and then seeking w_1 of the form

$$w_1(x,y)=w_2(x,y)+h_1(x,y)+2x,$$

where, in order to kill the cross-term, we are led to take

$$\begin{aligned}h_{1,y}(x,y)=&-a_n f_n(x)f_n'(x)\sin\left[2\left(\frac{x+y}{a_n}\right)\right]-a_{n+1}g_n(x)g_n'(x)\sin\left[2\left(\frac{x+y}{a_{n+1}}\right)\right]\\&+(f_n(x)g_n'(x)+f_n'(x)g_n(x))\left(2a_n\sin\left[\left(\frac{x+y}{a_n}\right)\right]-\frac{2}{3}a_n\sin\left[3\left(\frac{x+y}{a_n}\right)\right]\right)\\&-2u_y(x,y)\left(a_n f_n'(x)\left[\cos\left(\frac{x+y}{a_n}\right)+1\right]+a_{n+1}g_n'(x)\left[\cos\left(\frac{x+y}{a_{n+1}}\right)+1\right]\right).\end{aligned}\tag{24}$$

Integrating in y we see that each term in h_1 is a product of functions of $x+y$ and either f_nf_n', g_ng_n', f_ng_n' or g_nf_n', along with a factor that is quadratic in a_n and a_{n+1}. We take the arbitrary function of x arising through the integration to be zero.

With this choice, one can compute $h_{1,x}$ to find that $h_{1,x}=h_{1,y}$ plus terms involving products of quadratic expressions in a_n and a_{n+1} with expressions involving either $(f_n')^2,(g_n')^2,f_n'',g_n''$ or $f_n'g_n'$ multiplied against $\mathcal{O}(1)$ quantitites. Hence,

$$h_{1,x}=h_{1,y}+\mathcal{O}\left(\frac{a_n^2}{b_n^2}\right).\tag{25}$$

To clarify our construction, note from (19) that $u_x=u_y+A$ where $|A|$ is of order $\mathcal{O}(a_n/b_n)$ while $w_{2,x}$ takes the form $w_{2,x}=w_{2,y}+B-2$ where our choice of h_1 yields the condition

$$h_{1,y}+B+Au_y=0.\tag{26}$$

Turning then to the remaining term in the membrane energy, we find through (22), (25), and (26) that

$$\begin{aligned}w_{1,x}+\tfrac{1}{2}u_x^2-1&=w_{2,y}+B+h_{1,x}+\tfrac{1}{2}(u_y+A)^2-1\\&=\left(w_{2,y}+\frac{1}{2}u_y^2-1\right)+B+h_{1,y}+Au_y+\mathcal{O}\left(\frac{a_n^2}{b_n^2}\right)=\mathcal{O}\left(\frac{a_n^2}{b_n^2}\right).\end{aligned}\tag{27}$$

Estimating the bending energy is much simpler. Indeed, a view of (19), along with the fact that $a_n\leqslant b_n$, immediately yields the estimate

$$|\nabla\nabla u|=\mathcal{O}\left(\frac{1}{a_n}\right),\ \text{ in }\ I_n.\tag{28}$$

Consequently, recalling (12) and (14), we arrive at the estimate

$$\begin{aligned}\int\int_{I_n}&\left\{\left[\left(w_{1,x}+\frac{1}{2}u_x^2-1\right)^2+\left(w_{2,y}+\frac{1}{2}u_y^2-1\right)^2\right.\right.\\&\left.\left.+2\left(\frac{1}{2}(w_{1,y}+w_{2,x})+\frac{1}{2}u_xu_y\right)^2\right]+\varepsilon^2|\nabla\nabla u|^2\right\}dxdy\\&=\mathcal{O}\left(\frac{a_n^4}{b_n^3}\right)+\varepsilon^2\mathcal{O}\left(\frac{b_n}{a_n^2}\right)\leqslant C\varepsilon^{4/3}(\sqrt{2})^n,\end{aligned}\tag{29}$$

where C is a positive constant independent of ε and n.

We wish to continue the iteration on n until the function u is decreased to $\mathcal{O}(\varepsilon)$, leading us to select N so that

$$\frac{1}{2^N} \sim \varepsilon^{2/3} \quad \text{and} \quad b_{N+1} = \varepsilon. \tag{30}$$

We should point out here that this choice of N is consistent with our condition that $a_n \leqslant b_n$. Summing over n we that find that the total energy over the set $[\varepsilon,1]\times[0,1]$ is bounded from above by

$$\varepsilon^{4/3} \sum_{n=0}^{N} (\sqrt{2})^n \sim \varepsilon^{4/3} (\sqrt{2})^N = \mathcal{O}(\varepsilon). \tag{31}$$

Our next task is to match the clamped boundary conditions at $x=0$. To accomplish this, we will interpolate as was done in Ref. 1. For completeness, we present the construction below. In the strip $[0,\varepsilon]\times[0,1]$, we set $u=P$ where

$$P(x,y) = \left(\frac{u_x}{\varepsilon^2} - \frac{2u}{\varepsilon^3} \right) x^3 + \left(\frac{3u}{\varepsilon^2} - \frac{u_x}{\varepsilon} \right) x^2. \tag{32}$$

Here u and u_x are evaluated at (ε,y). Note that P and ∇P so defined agree with u and ∇u at $x=\varepsilon$ while $P(0,y)=0$ and $\nabla P(0,y)=(0,0)$.

For the functions w_1 and w_2 in this strip $[0,\varepsilon]\times[0,1]$, we simply linearly interpolate in x between the functions $w_\alpha(\varepsilon,y)$ and 0 for $\alpha=1,2$.

To estimate the energy in this boundary layer, we first note that $|\nabla P| = \mathcal{O}(1)$ while $|\nabla\nabla P| = \mathcal{O}(1/\varepsilon)$ and $|\nabla w_\alpha| = \mathcal{O}(1)$ since $|w_\alpha(\varepsilon,y)| = \mathcal{O}(\varepsilon)$ for $\alpha=1,2$ and $y\in[0,1]$. Hence, the total energy in the layer $[0,\varepsilon]\times[0,1]$ is $\mathcal{O}(\varepsilon)$.

It remains to alter our construction so as to satisfy the boundary conditions at $x=1$ as well. At first glance, one might be tempted to simply compress our construction to the interval $[0,1/2]\times[0,1]$ and then reflect u evenly in x. However, in view of the term

$$\left(w_{1,x} + \frac{1}{2} u_x^2 - 1 \right)^2$$

in the membrane energy, this would require an odd reflection in w_1 leading to a discontinuity since $w_1(1,y)\neq 0$. What is more, such an even reflection of u would lead to a jump in u_x since $u_x(1,y)\neq 0$.

Instead we will take a different tack. Using almost the same construction as we used on $[0,1]\times[0,1]$, we can work on the strips $[2-b_n,2-b_{n+1}]\times[0,1]$ for $n=0,1,2,\ldots,N$ and an interpolation layer $[2-\varepsilon,2]\times[0,1]$ to obtain the boundary values

$$u(2,y) = u_x(2,y) = w_1(2,y) = 0, \quad \text{for } y\in[0,1]. \tag{33}$$

Noticing that w_2 is the sum of $-2x$ and an oscillatory function [cf. (23)], we use the interpolation layer to eliminate the oscillation, leaving the boundary values

$$w_2(2,y) = -4.$$

In light of (33), we can now take an odd reflection in x for w_1 and even reflections for u and w_2 so as to obtain a construction on $[0,4]\times[0,1]$ whose energy is $\mathcal{O}(\varepsilon)$. Rescaling $x\to x/4$, $y\to y/4$ and $(u,w_1,w_2)\to 1/4(u,w_1,w_2)$, and using the periodicity of our original construction in y, we obtain the desired construction on the unit square. □

Remark 1: In our heuristics preceeding the proof we indicated that an interior lengthscale for oscillations in u of order $\varepsilon^{1/2}$ would suffice. In fact, there is some freedom, in that any scale between $\varepsilon^{1/2}$ and $\varepsilon^{1/3}$ will do, and we have chosen the latter in our construction.

Remark 2: When the von Kármán model is derived, it is assumed that the derivatives of the in-plane displacements (w_1, w_2) are small and, therefore, quadratic terms in these derivatives can be neglected; see, e.g., Refs. 8–11. We note that in our construction, the first derivatives of (w_1, w_2) are of order $\mathcal{O}(1)$. However, in reality, for thin-film blistering problems, the eigenstrains are smaller, e.g., $e^*_{\alpha\beta} = k\delta_{\alpha\beta}$, where $k = o(1)$. Had we taken such eigenstrains, then, with a rescaling of $u \to \sqrt{k}u$ and $(w_1, w_2) \to k(w_1, w_2)$, it is obvious that the derivatives of (w_1, w_2) would have been of order $\mathcal{O}(k)$. Consequently, our construction is consistent with the assumption in the von Kármán model.

(Received 8 November 1999; accepted for publication 31 July 2000)

The Fokker–Planck equation has been very useful for studying dynamic behavior of stochastic differential equations driven by Gaussian noises. However, there are both theoretical and empirical reasons to consider similar equations driven by strongly non-Gaussian noises. In particular, they yield strongly non-Gaussian anomalous diffusion which seems to be relevant in different domains of Physics. In this paper, we therefore derive a fractional Fokker–Planck equation for the probability distribution of particles whose motion is governed by a *nonlinear* Langevin-type equation, which is driven by a Lévy stable noise rather than a Gaussian. We obtain in fact a general result for a Markovian forcing. We also discuss the existence and uniqueness of the solution of the fractional Fokker–Planck equation. [DOI: 10.1063/1.1318734]

I. INTRODUCTION AND MOTIVATION

The Fokker–Planck equation is one of the most celebrated equations in Physics, since it has been very useful for studying[1] the dynamic behavior of stochastic differential equations driven by Gaussian noises. However, it turns out that many physical phenomena are outside of this framework. For instance, it has been argued that diffusion by geophysical turbulence[2–7] corresponds, loosely speaking, to a series of sticking (pauses), when the particle is trapped by a coherent structure, and (fast) flights, when the particle moves in the jet flow. A similar phenomenology is observed for zoo plankton grazing.[8,9]

Although there have been some attempts[6] to analyze and quantify this behavior with the help of the classical Fokker–Planck equation, i.e., assuming finite moments of all orders, some laboratory experiments[3–5] or numerical simulations of geostrophic turbulence[10] show that this phenomenology could be rather a consequence of the presence of heavy tails (i.e., power law falloff) for the probability distribution and a strong anisotropy with a clearly preferred direction of diffusion. One can conclude[11] that if the processes are additive, the corresponding walks are Lévy motions.

[a]Author to whom correspondence should be addressed. Electronic mail: schertze@ccr.jussieu.fr

Let us recall that indeed stable Lévy motions $L(t)$ generalize the Brownian motion $B(t)$ in the sense that first they are also motions (e.g., Refs. 12 and 13) whose increments $\Delta L(t,\Delta t)=L(t+\Delta t)-L(t)$ are stationary (therefore ΔL has no statistical dependence on t) and independent for any nonoverlapping time lags Δt. Therefore, $L(t)$ corresponds to the sum of independent, identically distributed Lévy stable variables.[14–18] The second common property is that these increments satisfy a ''stability property:'' up to a rescaling and recentring, the sum of different steps has the same probability distribution as one of the steps. Lévy stable variables are precisely defined by this property. The stability property implies in both cases a property of attraction: under rather general conditions a renormalized sum of independent identically distributed variables converge to a stable law. Furthermore, there are no other attractive laws. This explains why the stable property is so important. The attraction property corresponds to a broad generalization of the central limit theorem, with the important difference that whereas the classical theorem (Gaussian case) is satisfied with the condition that the variance is finite, the convergence towards a Lévy law is obtained with the condition that *not only* the variance of the summands X_i is infinite, but also that all their moments of order q equal to or larger than a critical order α $(0<\alpha<2)$ are infinite. This critical order α is called the Lévy stability index and corresponds to the exponent of the power law of probability distribution tails:

$$\text{any } s\gg 1\text{: } \Pr(|\Delta L|>s)\approx s^{-\alpha}\Leftrightarrow\text{any } q\geqslant\alpha\text{: } E(|X|^q)=\infty, \tag{1}$$

where Pr denotes the probability, $E(\,)$ is the mathematical expectation, and s is a given (large) non-negative threshold. This statistical divergence of a Lévy motion is due to jumps, whereas a Brownian motion is almost surely continuous.

This index is the most important of the four parameters defining a Lévy stable law. The second one is the skewness β $(-1\leqslant\beta\leqslant 1)$ which defines the degree of asymmetry of the law, which is maximal for $\beta=-1$ or $\beta=+1$, and the law is symmetric when $\beta=0$. In spite of its name and some common properties, β nevertheless does not correspond to the classical skewness of a quasi-Gaussian law. The latter is indeed undefined for a stable Lévy law due to the above-mentioned statistical divergences. The center γ corresponds to the statistical mean when defined (i.e., $\alpha>1$) and/or to the median when symmetric (i.e., $\beta=0$). The scale parameter $D(D\geqslant 0)$ corresponds to a generalization of the variance of the Gaussian case. More precisely, as discussed below, it corresponds to the intensity scale of the cumulant of (possibly noninteger) order α. It yields an anomalous[19] generalization of the classical Einstein relation: $\mathrm{Var}[X(t)-X(t_0)]=2D(t-t_0)$, where Var( ) denotes the variance. Finally, let us emphasize that the Gaussian case corresponds to the limit case $\alpha=2$, which also implies $\beta=0$, i.e., no asymmetry.

Further comments are now in order on the relevance of Lévy motions in Physics. On the one hand, claims in favor of the relevance of Lévy motions have been made on many physical phenomena ranging from subrecoil laser cooling[20,21] to diffusion by flows in porous media,[22,23] including finance fluctuations,[24,25] see Refs. 26 and 27 for other examples. Many systems indeed display a phenomenology rather similar to that we reported above on geostrophic turbulence.

On the other hand, important questions have been raised. In particular, Ref. 28 questioned the resulting infinite variance of the advecting field for porous media. Indeed, it turns out that recent estimates[29] of the power law of the probability distributions of the hydraulic conductivity yields an exponent $\alpha\approx 3.5$. The question of finite variance might apply to other examples, in particular for atmospheric turbulence where different studies[30] yield a critical exponent $\alpha\approx 7$ for the wind field. Therefore, in spite of their clear phenomenological interest, the relevance of pure Lévy motions could be questioned.

The main goal of this paper is to clarify and define a framework adequate for handling motions more general than pure Lévy motions and which are nevertheless generated by the latter. We will do it by building upon a series of rather recent works[31–37,19,38] which show that the probability density of particles moving with a Lévy motion satisfies a generalized Fokker–Planck equation involving fractional orders of differentiation. Indeed, it could be first argued in a ''very formal and phenomenological'' manner[31] that a fractional power of the Laplacian yields an anomalous scaling for the corresponding diffusion.

A fractional Fokker–Planck equation was obtained in a less formal manner by Refs. 32 and 35 in the framework of the continuous time random walks (CTRWs) model of anomalous diffusion.[33] However, this method does not involve directly a stable Lévy process, but a walk sharing some behavior common with the latter, without being equivalent to it. A different fractional Fokker–Planck equation was introduced[37] with the help of a phenomenological and interesting transformation of the classical Fick law into a fractional Fick law. However, it is not clear that its solution corresponds to a (non-negative) probability distribution. A rather distinct approach was followed by Refs. 34 and 19 since it starts with a *linear* Langevin-type equation with random forces which are *exact* stable Lévy processes, which can be symmetric as well as asymmetric, and with no limitation on the possible values of the Lévy index α. The fundamental mathematical tool which is used is the second characteristic (or cumulant generating) function of the motion defined by this Langevin-type equation. The particular case of symmetric processes correspond to what was previously inferred by Refs. 31, 32, 35, and 37. However, it was shown that in the more general case of asymmetric processes, a new nontrivial advective–diffusive term appears. This is confirmed with the help of a reinterpretation of the characteristic function of a Lévy motion.[38]

We already discussed that theoretically and empirically the nonfiniteness of the variance could be questioned. There are two more general questions: the inhomogeneities of the medium, which are first emphasized for the introduction of the Lévy motions, are finally reduced to a (homogeneous) distribution of times when the particle is strongly kicked. As soon as this representation is granted, the medium (and its properties) does not intervene any longer. This is very restrictive and for instance incompatible with the multifractality of the medium[39,8] (or of the diffusion) when observed. The second reason is that the underlying processes are thought to be strongly nonlinear, whereas the transport is modeled with the help of a (stochastic) linear equation.

Both the successes and limitations of the previous results plead in favor of investigating a local and nonlinear modeling with the help of Lévy motions. This is the reason that we investigate the properties of *nonlinear* Langevin-type equation forced by a Lévy stable motion.

II. STATEMENT OF THE PROBLEM

Further to our above discussion, we consider the following *nonlinear* Langevin-type equation for a stochastic (real) quantity $X(t)$ (e.g., location of a particle):

$$dX(t)=m(X(t),t)dt+\sigma(X(t),t)dL, \tag{2}$$

where the driving source is a Lévy stable motion $L(t)$ instead of Brownian motion $B(t)$. The latter case corresponds to the basis of stochastic calculus (e.g., Ref. 40) and the corresponding differential equation is often called the Ito–Skorokhod equation. The extension to Lévy stable motion $L(t)$ is rather natural and straightforward (e.g., Ref. 41) due to the common properties of $L(t)$ and $B(t)$ that we discussed in Sec. I, i.e., their infinitesimal increments are independent identically distributed and furthermore stable.

More precisely the Ito stochastic calculus corresponds to consider that the dL is, similarly to dB, a forward increment in time [it should be understood as $dL(t,dt)=L(t+dt)-L(t)$]. This means that the value of X at time t is determined by events prior to the application of the stochastic force $dL(t)$, which acts only from time t to $t+dt$.

The Eq. (2) can also be understood under its integral form

$$X(t)=X(t_0)+\int m(X(t),t)dt+\int \sigma(X(t),t)dL, \tag{3}$$

where the last term corresponds to a stochastic integration of a stochastic process. The integration of a stochastic process $\Phi(t)$ [in the case of Eq. (2): $\Phi(t)=\sigma(X(t),t)$] with respect to the Lévy motion L, is rather straightforward in the case of step processes:[42]

$$\Phi(t)=\Phi_n, \quad \text{for } t\in(t_n,t_{n+1}),\ n=0,1,...,N-1; \int \Phi(t)dL=\sum_{n=0}^{N-1}\Phi_n(L(t_{n+1})-L(t_n)) \tag{4}$$

and this rather suggestive definition is naturally extended to functional spaces in which the step processes are dense.

In order to establish local properties, for instance the time evolution of the probability of the particles, we will use the differential form [Eq. (2)], whereas Refs. 34 and 19 rather used the integral form [Eq. (4)] which becomes cumbersome in the nonlinear case and is in fact useful only to establish global properties (Sec. IX).

After having emphasized the similarities between $L(t)$ and $B(t)$, it is important to underline the nontrivial consequences due to the fact, contrary to the Gaussian case which has all its moments finite, Lévy motions have a finite critical order of divergence of statistical moments $(0<\alpha<2)$. These include the fact that the mathematical techniques which could be used can be rather distinct. For instance, our derivation will rely on the use of the second characteristic function of the increments, Sec. III, instead of probabilities of the increments as done usually for the derivation of the classical Fokker–Planck equation. An obvious reason is that the former are relatively simple (see Sec. VII), while the latter are not, with the only exception of the three following cases: $\alpha=2$, $\beta=0$; $\alpha=1$, $\beta=0$; $\alpha=1/2$, $\beta=1$. The fundamental reason is that both the stability property and the divergence of moments are related to the presence of a cumulant of noninteger order α. In relation to this problem, the convenient L^2 Hilbert structure of Gaussian processes is reduced to a L^α Banach structure for stable Lévy processes. This is particularly important for the integral equation (3), when defining functional spaces where step processes are dense.

The linear case, which is the hitherto studied case, corresponds to

$$m(X(t),t)\equiv m=\text{const}; \quad \sigma(X(t),t)\equiv\sigma=\text{const}. \tag{5}$$

$X(t)-X(t_0)$ is also a Lévy motion which has the same Lévy stability index α as its increments, but with a different center or trend and scale or amplitude.

In the nonlinear case, $m(X(t),t)$ and $\sigma(X(t),t)$ are (possibly nonlinear) functions of $X(t)$ and t, which satisfy certain regularity constraints to be discussed later (Sec. IX). They correspond to inhomogeneities of the medium, which were ignored in the linear case. As a possibly important, but simple example, let us mention the Lévy extension of the so-called geometric Brownian motion, which is rather ubiquitous and for instance is at the core of the Black–Scholes model for option pricing: $m(X(t),t)=mX(t)$ and $\sigma(X(t),t)=\sigma X(t)$, where σ is the votality constant of the price $X(t)$ of a given stock share.

We will demonstrate the following proposition:

Proposition 1: The transition probability density:

$$\forall t\geqslant t_0: \;\; p(x,t|x_0,t_0)=\Pr(X(t)=x|X(t_0)=x_0) \tag{6}$$

corresponding to the nonlinear stochastic differential equation (2), with a Lévy forcing of parameters $\alpha\neq 1$ or $\beta=0$, γ, $D\geqslant 0$, is solution of the following fractional Fokker–Planck equation:

$$\begin{aligned}\frac{\partial}{\partial t}p(x,t|x_0,t_0)=&-\frac{\partial}{\partial x}(\gamma\sigma(x,t)+m(x,t))p(x,t|x_0,t_0)\\&-D\Big[(-\Delta)^{\alpha/2}(|\sigma(x,t)|^\alpha p(x,t|x_0,t_0))\\&+\beta\omega(\alpha)\frac{\partial}{\partial x}(-\Delta)^{(\alpha-1)/2}(|\sigma(x,t)|^{\alpha-1}\sigma(x,t)p(x,t|x_0,t_0))\Big]\end{aligned} \tag{7}$$

with the initial condition

$$p(x,t_0|x_0,t_0)=\delta(x-x_0), \tag{8}$$

where $\delta(x-x_0)$ is the degenerate Dirac measure in x_0 and $\omega(\alpha)$ is defined by

$$\alpha \neq 1: \quad \omega(\alpha) = \tan \frac{\pi \alpha}{2} \tag{9}$$

and where the fractional powers of the Laplacian Δ will be discussed in Sec. VI. Proposition 1 and Eq. (7) are for scalar processes (i.e., $\Delta \equiv \partial^2/\partial x^2$) and their extension to vector processes will be discussed and presented in Sec. VIII. One may note that the fractional diffusive isotropic operator $-(-\Delta)^{\alpha/2}$ applies via a fractional diffusivity $|\sigma(x,t)|^{\alpha}$, whereas the advective–diffusive term corresponds to a conjugate action of a fractional diffusive term $-(-\Delta)^{(\alpha-1)/2}|\sigma(x,t)|^{\alpha-1}$ and a convective term $(\partial/\partial x)\sigma(x,t)$ on the transition probability.

This fractional Fokker–Planck equation will be established with the help of the much more general proposition.

Proposition 2: The inverse Fourier transform of the second characteristic function or cumulant generating function of the increments of a Markov process $X(t)$ generates by convolution the Fokker–Planck equation of evolution of its transition probability $p(x,t|x_0,t_0)$.

We will demonstrate this proposition in a straightforward, yet rigorous way. More precisely, we will establish the following:

$$\frac{\partial p}{\partial t}(x,t|x_0,t_0) = \int dy \, \frac{\partial \tilde{K}}{\partial t}(x-y|y,t) p(y,t|x_0,t_0), \tag{10}$$

where $\tilde{K}$ is the inverse Fourier transform of the cumulant generating function of the increments. The $\tilde{K}$ arguments will become explicit in Sec. III.

Equation (10) not only holds for processes with stationary and independent increments, as in the linear case [Eq. (5)] but also for any Markov process, including those defined by the nonlinear Langevin-type equation [Eq. (2) with $m \neq \text{const}$, $\sigma \neq \text{const}$]. As a consequence of Eq. (10), we will demonstrate the following.

Proposition 3: When the increment's cumulant generating function of a Markov process $X(t)$ is defined by its expansion in cumulants C_n, its Fokker–Planck equation is

$$\frac{\partial p}{\partial t}(x,t|x_0,t_0) = \sum_{n \in J} \frac{(-1)^n}{n!} \frac{\partial^n}{\partial x^n}[C_n(x,t) p(x,t|x_0,t_0)]. \tag{11}$$

An obviously sufficient condition of convergence is obtained when the set J of the orders of differentiation n is finite. This is true in particular for Gaussian forcing: $J=\{1,2\}$. It corresponds to the classical Fokker–Planck equation. On the other hand, $J=\mathbf{N}$ would correspond to an analytic expansion of cumulants. In spite of its interest, we will not discuss the latter case in this paper, nor its relationship to the classical Kramers–Moyal expansion (e.g., Ref. 43).

Below, we concentrate on the case of a finite, but nonanalytic expansion: $J=\{1,\alpha\}$ (noninteger α, $0<\alpha<2$), since it corresponds to the Lévy extension (Sec. VII and yields Proposition 1 with the help of fractional derivatives, as discussed in Sec. VI.

III. THE CUMULANT GENERATING FUNCTION OF THE INCREMENTS

The first and second (conditional) characteristic functions are, respectively, the moment generating function $Z_X(k,t-t_0|x_0,t_0)$ and the cumulant generating function $K_X(k,t-t_0|x_0,t_0)$, associated with the transition probability $p(x,t|x_0,t_0)$ of a process $X(t)$. These are defined by the Fourier transform of the latter, with k being the conjugate variable of $x-x_0$:

$$F[p(x,t|x_0,t_0)] \equiv Z_X(k,t-t_0|x_0,t_0) \tag{12}$$

$$\equiv \exp(K_X(k,t-t_0|x_0,t_0)) \tag{13}$$

$$\equiv E[\exp(ik(X(t)-X(t_0))|X(t_0)=x_0], \tag{14}$$

where $E[\cdot|\cdot]$ denote the conditional mathematical expectation, F and F^{-1}, respectively, the Fourier transform and its inverse:

$$F[f]=\hat{f}(k)=\int_{-\infty}^{\infty} dx \exp(ikx)f(x), \tag{15}$$

$$F^{-1}[\hat{f}]=f(x)=\int_{-\infty}^{\infty}\frac{dk}{2\pi}\exp(-ikx)\hat{f}(k). \tag{16}$$

The corresponding quantities for increments $\delta X(\delta t)=X(t+\delta t)-X(t)$, corresponding to a given time lag $\delta t>0$, are defined in a similar way:

$$F[p(x+\delta x,t+\delta t|x,t)]=\delta Z_X(k,\delta t|x,t) \tag{17}$$

$$\equiv \exp(\delta K_X(k,\delta t|x,t)) \tag{18}$$

$$=E[\exp(ik(X(t+\delta t)-X(t))|X(t)=x], \tag{19}$$

where k is the conjugate variable of δx. The cumulants of the increments C_n are the coefficients of the Taylor expansion of δK_X:

$$\delta K_X(k,\delta t|x,t)=\delta t\sum_{n\in J}\frac{(ik)^n}{n!}C_n(x,t)+o(\delta t). \tag{20}$$

As already mentioned, the classical case corresponds to an analytic expansion of δK_X, i.e., $J\subseteq\mathbf{N}$, whereas we will be interested by a finite but nonanalytic expansion $J=\{1,\alpha\}$ (noninteger α, $0<\alpha<2$).

IV. PROCESSES WITH STATIONARY AND INDEPENDENT INCREMENTS

Let us first consider the simple subcase of a process with stationary and independent increments. It corresponds to $C_n(x,t)\equiv C_n=\text{const}$ in Eqs. (11) and (20) and as already discussed in Sec. I, it includes the linear case [Eq. (5)] of the Langevin-type equation (2).

However, we believe that the following derivation is not only somewhat pedagogical on the role of the characteristic functions for the nonlinear case, but also terser than derivations previously presented for the linear case.

The stationarity of the increments implies that the transition probability depends only on the time and space lags, i.e.,

$$p(x,t|x_0,t_0)=p(x-x_0,t-t_0) \tag{21}$$

and similarly, the characteristic functions of the increments are no longer conditioned, for instance,

$$Z_X(k,t-t_0|x_0,t_0)\equiv Z_X(k,t-t_0), \tag{22}$$

$$K_X(k,t-t_0|x_0,t_0)\equiv K_X(k,t-t_0). \tag{23}$$

On the other hand, the independence of the increments implies that the transition probabilities satisfy a convolution (over any possible intermediate position y) for any given time lag δt:

$$\forall\,\delta t>0:\ \ p(x-x_0,t+\delta t-t_0)=\int dy\, p(x-y,\delta t)(y-x_0,t-t_0) \tag{24}$$

and the corresponding characteristic functions merely factor (respectively, add). Therefore, we have,

$$Z_X(k,t+\delta t-t_0)-Z_X(k,t-t_0)=Z_X(k,t-t_0)(\delta Z_X(k,\delta t)-1). \tag{25}$$

This in turn leads to

$$Z_X(k,t+\delta t-t_0)-Z_X(k,t-t_0)=Z_X(k,t-t_0)\,\delta K_X(k,\delta t)+o(\delta t). \tag{26}$$

Its inverse Fourier transform yields

$$p(x,t+\delta t|x_0,t_0)-p(x,t|x_0,t_0)=\int dy\, F^{-1}[\,\delta K_X(k,\delta t)]p(y-x_0,t-t_0)+o(\delta t). \tag{27}$$

This demonstrates (in the limit $\delta t\to 0$) Proposition 2 and Eq. (10), as well as Proposition 3, since Eq. (27) corresponds, with the help of Eq. (20), to

$$p(x,t+\delta t|x_0,t_0)-p(x,t|x_0,t_0)=\delta t\sum_{n\in J}\frac{(-1)^n}{n!}\left[C_n\int dy\,\delta^{(n)}_{x-y}p(y,t|x_0,t_0)\right]+o(\delta t), \tag{28}$$

where δ^n_x denotes the nth derivative of the Dirac function. Therefore, we obtain

$$\frac{\partial}{\partial t}p(x,t|x_0,t_0)=\sum_{n\in J}\frac{(-1)^n}{n!}C_n\frac{\partial^n}{\partial x^n}p(x,t|x_0,t_0) \tag{29}$$

which corresponds to the linear case of Eq. (11).

V. MORE GENERAL MARKOV PROCESSES

In the case of a Markov process which does not have stationary and independent increments, there is no longer a simple convolution equation [Eq. (24)] of the transition probabilities, nor a simple factorization of characteristic functions [Eq. (25)]. However, the former satisfies a generalized convolution equation which corresponds to the Chapman–Kolmogorov identity[17] valid for any Markov process $X(t)$:

$$\forall\,\delta t>0:\ \ p(x,t+\delta t|x_0,t_0))=\int dy\,p(x,t+\delta t|y,t)p(y,t|x_0,t_0) \tag{30}$$

which indeed reduces to a mere convolution [Eq. (24)] in the case of processes with stationary and independent increments. This identity can be written under the equivalent form:

$$p(x,t+\delta t|x_0,t_0)=\int dy\int\frac{dk}{2\pi}e^{-iky+\delta K_X(k,\delta t|y,t)}p(y,t|x_0,t_0). \tag{31}$$

Noting that we have

$$p(x,t|x_0,t_0)=\int dy\,p(y,t|x_0,t_0)\int\frac{dk}{2\pi}e^{-iky}, \tag{32}$$

we obtain

$$p(x,t+\delta t|x_0,t_0)-p(x,t|x_0,t_0)=\delta t\int dy\,F^{-1}[\,\delta K_X(k,\delta t|y,t)]p(y,t|x_0,t_0)+o(\delta t). \tag{33}$$

In the limit $\delta t\to 0$, this corresponds to Proposition 2 and Eq. (10). When $J\subseteq\mathbf{N}$, it yields with the help of Eq. (20):

$$\delta p(x,t|x_0,t_0)=\delta t\sum_{n\in J}\int dy\ \delta^{(n)}_{x-y}\left[\frac{(-1)^n}{n!}C_n(y,t)p(y,t|x_0,t_0)\right]+o(\delta t). \tag{34}$$

The limit $\delta t\to 0$ corresponds to Eq. (11) and demonstrates Proposition 3 for a Markow process.

VI. EXTENSION TO FRACTIONAL ORDERS

In the two preceding sections (Secs. IV and V), the fact that the indices $n\in J$ should be integers intervened at best only in the correspondence between (integer order) differentiation $\partial^n/\partial x^n$ [in Eq. (11)] and powers of the conjugate variable k^n [in Eq. (20)]. However, by the very definition of fractional differentiation (e.g., Ref. 44), this correspondence holds also for noninteger orders. However, there is not a unique definition of fractional differentiation and therefore, as discussed in some details in Ref. 19, we cannot expect to have a unique expression of the fractional Fokker–Planck equation.

Since in the following it will be sufficient to consider an expansion of the characteristic function involving fractional powers of only the wave number $|k|$, it is interesting to consider Riesz's definition of a fractional differentiation. Indeed, the latter corresponds to consider fractional powers of the Laplacian:

$$-(-\Delta)^{\alpha/2}f(x)=F^{-1}[|k|^{\alpha}\hat{f}(k)] \tag{35}$$

which has furthermore the advantage of being valid for the vector cases. However, we will see in Sec. VIII that in general it does not apply in a straightforward manner for vector stable Lévy motions. Indeed the latter introduces rather (one-dimensional) directional Laplacians, i.e., (one-dimensional) Laplacians along a given direction $\underline{u}(|\underline{u}|=1)$:

$$-(-\Delta_{\underline{u}})^{\alpha/2}f(x)=F^{-1}[|(\underline{k},\underline{u})|^{\alpha}\hat{f}(k)], \tag{36}$$

where (.,.) denotes the scalar product. On the other hand, it will be useful to consider the fractional power of the contraction of the Laplacian tensor $\underline{\underline{\Delta}}$:

$$\Delta_{i,j}=\frac{\partial}{\partial x_i}\frac{\partial}{\partial x_j} \tag{37}$$

by a tensor $\underline{\underline{\sigma}}$ ($\underline{\underline{\sigma}}^*$ denotes its transpose), with the following definition:

$$-(-\underline{\underline{\Delta}}:\underline{\underline{\sigma}}.\underline{\underline{\sigma}}^*)^{\alpha/2}\equiv F^{-1}[|(\underline{k},\underline{\underline{\sigma}}.\underline{\underline{\sigma}}^*.\underline{k}|^{\alpha/2}]=F^{-1}[|\underline{\underline{\sigma}}^*.\underline{k}|^{\alpha}]. \tag{38}$$

VII. LÉVY CASE

The second characteristic function of the increments δL of the (scalar) Lévy forcing is the following:

$$\delta K_L(k,\delta t)=\delta t\left[ik\gamma-D|k|^{\alpha}\left(1-i\beta\frac{k}{|k|}\right)\omega(k,\alpha)\right]+o(\delta t), \tag{39}$$

where $\omega(k,\alpha)$ is defined by

$$\alpha\neq 1:\quad \omega(k,\alpha)\equiv\omega(\alpha)=\tan\frac{\pi\alpha}{2},\quad \alpha=1:\quad \omega(k,\alpha)=\frac{\pi}{2}\log|k|. \tag{40}$$

Considering an Ito-type forward integration of Eq. (2), the increments δL generates the following (first) characteristic function for the increments δX of the motion $X(t)$:

$$\delta Z_X(k,\delta t|x-\delta x,t)=E(e^{ikm(X,t)})\,\delta Z_{\sigma L}(k,\delta t|x,t)+o(\delta t) \tag{41}$$

which yields the following elementary cumulant generating function δK_X:

$$\delta K_X(k,\delta t|x,t)=\delta t\left[ikm(x,t)+ik\gamma\sigma(x,t)-D|k|^{\alpha}|\sigma(x,t)|^{\alpha}\left(1-i\beta\frac{k\sigma(x,t)}{|k||\sigma(x,t)|}\omega(k,\alpha)\right)\right]+o(\delta t) \tag{42}$$

and which is of the same type as Eq. (20), with $J=\{1,\alpha\}$. Therefore, as discussed in Sec. VI, we have fractional differentiations in the corresponding Eq. (11), which will precisely correspond to Eq. (7), and therefore establishes Proposition 1.

VIII. EXTENSION TO VECTOR PROCESSES

With but one important exception, the extension of the previous results to higher dimensions is rather straightforward. The starting point of this extension is the following nonlinear stochastic equation ($\underline{X}(t)\in R^d$):

$$d\underline{X}(t)=\underline{m}(\underline{X}(t),t)dt+\underline{\underline{\sigma}}(\underline{X}(t),t).d\underline{L}, \tag{43}$$

where $\underline{m}$ is the natural d-dimensional vector extension of the deterministic-like trend, $\underline{\underline{\sigma}}$ is the $d\times d'$-dimensional tensor extension of the modulation of the random driving force, and $\underline{L}$ is a d'-dimensional Lévy stable motion. As discussed below, the expression of the characteristic function of the latter corresponds to the source of the difficulty in extending the scalar results to higher dimensions. On the contrary, it is straightforward to check that Propositions 2 and 3 are valid in the vector case, with the following extensions ($\underline{x}\in R^d$) for Eq. (10):

$$\frac{\partial p}{\partial t}(\underline{x},t|\underline{x}_0,t_0)=\int d\underline{y}\frac{\partial\tilde{K}}{\partial t}(\underline{x}-\underline{y}|\underline{y},t)p(\underline{y},t|\underline{x}_0,t_0) \tag{44}$$

and for Eq. (11) ($\underline{n}\in J\subseteq\mathbf{N}^d,|\underline{n}|=\Sigma_{i=1}^d n_i$):

$$\frac{\partial p}{\partial t}(\underline{x},t|\underline{x}_0,t_0)=\sum_{\underline{n}\in J}\frac{(-1)^{|\underline{n}|}}{(n_1)!(n_2)!..(n_d)!}\frac{\partial^{|\underline{n}|}}{\partial x_1^{n_1}\partial x_2^{n_2}..\partial x_d^{n_d}}[C_{\underline{n}}(\underline{x},t)p(\underline{x},t|\underline{x}_0,t_0)]. \tag{45}$$

On the other hand, Eq. (43) yields the following extension to Eq. (41):

$$\delta Z_{\underline{X}}(\underline{k},\delta t|\underline{x},t)=e^{i\,\underline{k}.\underline{m}(\underline{x},t)}\,\delta Z_{\underline{\underline{\sigma}}.\underline{L}}(\underline{k},\delta t|\underline{x},t) \tag{46}$$

and therefore we have

$$\delta K_{\underline{X}}(\underline{k},\delta t|\underline{x},t)=i\,\underline{k}.\underline{m}(\underline{x},t)+\delta K_{\underline{L}}(\underline{\underline{\sigma}}^*.\underline{k},\delta t|\underline{x},t)+o(\delta t). \tag{47}$$

Let us recall that a stable Lévy vector in the classical sense[14,45,46] (see Ref. 47 for a discussion on a rather straightforward generalization, or Refs. 48, 49, and 50 for a more abstract generalization) corresponds to the limit of a sum of jumps, with a power-law distribution, along random directions $\underline{u}\in\partial B_1$, B_1 being the unit ball, distributed according to a (positive) measure $d\Sigma(\underline{u})$. The latter, which generalizes the scale parameter D of the scalar case, is the source of the difficulty since in general the probability distribution of a stable Lévy vector depends on this measure, and therefore is a nonparametric distribution. However, as discussed below, there is at least a trivial exception: the case of isotropic stable Lévy vectors.

Corresponding to our previous remarks, a (classical) stable Lévy vector has the following (Fourier) cumulant generating function:

$$K_{\underline{L}}(\underline{k})=\delta t\left[i(\underline{k},\underline{\gamma})-\int_{\underline{u}\in\partial B_1}(i\underline{k},\underline{u})^{\alpha}\,d\Sigma(\underline{u})\right]+o(\delta t) \tag{48}$$

which yields with the help of Eq. (47):

$$\frac{\partial}{\partial t}\tilde{K}_{\underline{X}}(\underline{k})=-\operatorname{div}(\underline{m}+\underline{\underline{\sigma}}.\underline{\gamma})-F^{-1}\left[\int_{\underline{u}\in\partial B_1}(i\underline{\underline{\sigma}}^{*}(\underline{x},t).\underline{k},\underline{u})^{\alpha}\,d\Sigma(\underline{u})\right]. \tag{49}$$

The scalar case [Eq. (39)] corresponds to

$$0\leqslant p\leqslant 1:\ \ \beta=2p-1,\ \ d\Sigma(u)=D\cos\left(\frac{\pi\alpha}{2}\right)[p\,\delta_{(u-1)}+(1-p)\,\delta_{(u+1)}]. \tag{50}$$

For any dimension d, the second term on the right-hand side of Eq. (49) corresponds to a fractional differentiation operator of order α. This operator can be slightly rearranged. With the help of the odd $d\Sigma^{-}(\underline{u})$ and even $d\Sigma^{+}(\underline{u})$ parts of the measure $d\Sigma(\underline{u})$:

$$2\,d\Sigma^{+}(\underline{u})=d\Sigma(\underline{u})+d\Sigma(-\underline{u}),\quad 2\,d\Sigma^{-}(\underline{u})=d\Sigma(\underline{u})-d\Sigma(-\underline{u}) \tag{51}$$

and the identity (θ being the Heaviside function):

$$(ik)^{\alpha}=|k|^{\alpha}[\,\theta(k)e^{i(\alpha\pi/2)}+\theta(-k)e^{-i(\alpha\pi/2)}] \tag{52}$$

one can write the extension of Eq. (7) under the following form:

$$\begin{aligned}\frac{\partial}{\partial t}p(\underline{x},t|\underline{x}_0,t_0)=&-\operatorname{div}[\underline{m}(\underline{x},t)+\underline{\underline{\sigma}}(\underline{x},t).\underline{\gamma})]p(\underline{x},t|\underline{x}_0,t_0)\\&-[\langle(-\underline{\underline{\Delta}}:\underline{\underline{\sigma}}.\underline{\underline{\sigma}}^{*})^{\alpha/2}\rangle_{\Sigma^{+}}-\langle(\underline{\nabla}.\underline{\underline{\sigma}}^{*}).(-\underline{\underline{\Delta}}:\underline{\underline{\sigma}}.\underline{\underline{\sigma}}^{*})^{\alpha-1/2}\rangle_{\Sigma^{-}}]\\&\times p(\underline{x},t|\underline{x}_0,t_0),\end{aligned} \tag{53}$$

where the symmetric fractional diffusive and, respectively, the antisymmetric advective–diffusive terms are defined, similarly to Eq. (38), in the following manner:

$$-\langle(-\underline{\underline{\Delta}}:\underline{\underline{\sigma}}.\underline{\underline{\sigma}}^{*})^{\alpha/2}\rangle_{\Sigma^{+}}=\int_{\underline{u}\in\partial B_1}d\Sigma^{+}(\underline{u})F^{-1}[|(\underline{\underline{\sigma}}^{*}(\underline{x},t).\underline{k},\underline{u})|^{\alpha}] \tag{54}$$

$$-\langle(\underline{\nabla}.\underline{\underline{\sigma}}^{*}).(-\underline{\underline{\Delta}}:\underline{\underline{\sigma}}.\underline{\underline{\sigma}}^{*})^{\alpha-1/2}\rangle_{\Sigma^{-}}=\int_{\underline{u}\in\partial B_1}d\Sigma^{-}(\underline{u})F^{-1}[(-i\underline{\underline{\sigma}}^{*}(\underline{x},t).\underline{k},\underline{u})|(\underline{\underline{\sigma}}^{*}(\underline{x},t).\underline{k},\overline{u})|^{\alpha-1}]. \tag{55}$$

In general, each term corresponds to a rather complex integration (which is indicated by the symbol $\langle.\rangle_{\Sigma}$) by the measure $d\Sigma$ of directional fractional Laplacians [Eq. (36)]. However, the symmetric term becomes simpler as soon as the even part $d\Sigma^{+}$ of the measure $d\Sigma$ is isotropic. Indeed, the integration over directions yields only a prefactor D:

$$\langle-(\underline{\underline{\Delta}}:\underline{\underline{\sigma}}.\underline{\underline{\sigma}}^{*})^{\alpha/2}\rangle_{\Sigma^{+}}=D(-\underline{\underline{\Delta}}:\underline{\underline{\sigma}}.\underline{\underline{\sigma}}^{*})^{\alpha/2}D=\int_{\underline{u}\in\partial B_1}d\Sigma^{+}(\underline{u})|(\underline{u}_1,\underline{u})|^{\alpha} \tag{56}$$

and for $\alpha=2$ this corresponds to the classical term $(\underline{\underline{\Delta}}:\underline{\underline{\sigma}}.\underline{\underline{\sigma}}^{*})$ of the standard d-dimensional Fokker–Planck equation. If $d\Sigma$ itself is rotation invariant, then the asymmetric operator vanishes, since $d\Sigma^{-}=0$. If furthermore, $\underline{\underline{\sigma}}$ is scalar, i.e., $\underline{\underline{\sigma}}=\sigma\underline{\underline{1}}$, then one obtains the following Fractional Fokker–Planck equation:

$$\frac{\partial}{\partial t}p(\underline{x},t|\underline{x}_0,t_0)=-\mathrm{div}[\underline{\underline{\sigma}}.\underline{\gamma}(\underline{x},t)+\underline{m}(\underline{x},t)]p(\underline{x},t|\underline{x}_0,t_0) \tag{57}$$

$$-D[(-\Delta)^{\alpha/2}]|\sigma(x,t)|^{\alpha}p(\underline{x},t|\underline{x}_0,t_0). \tag{58}$$

Therefore, as one might expect the rotation symmetries yield a rather trivial extension of the standard Gaussian case: a fractional power α of the d-dimensional Laplacian, as in the pure scalar case [Eq. (7)]. Obviously, the integration performed in Eq. (53) is also greatly simplified as soon as $d\Sigma(\underline{u})$ is discrete, i.e. its support corresponds to a discrete set of directions $\underline{u}_i$.

On the other hand, let us note that the framework of generalized stable Lévy vectors,[47–50] allows one to introduce a much stronger anisotropy than the measure $d\Sigma$ allows for classical stable Lévy vectors. This therefore diminishes the importance of the asymmetry of the latter. Indeed, the components of a generalized stable Lévy vector do not necessarily have the same Lévy stability index, the latter being generalized into a second rank tensor. Similarly, the differential operators involved in the corresponding fractional Fokker–Planck equation no longer have a unique order of differentiation. This is rather easy to check in case of a discrete measure $d\Sigma(\underline{u})$ and we will explore the general case elsewhere.

IX. EXISTENCE AND UNIQUENESS OF THE SOLUTION

The preceding sections established a generalization of the Fokker–Planck equation for the evolution of the probability distribution of nonlinear stochastic differential equations driven by Lévy stable noises. This is the main goal of this paper. Naturally, one would also like to have if possible a theorem of existence and uniqueness of the solution of this equation. Due to its origin, such a theorem will also imply that the solution will remain positive and normalized, as required for a transition probability. In this section we argue that the general results obtained[51] in the classical Gaussian case ($\alpha=2$) are also relevant for the Lévy extension, whereas up until now existence and uniqueness conditions of partial fractional differential equations have been scarcely explored (see however Refs. 52 and 53) and therefore we cannot rely on general results.

The classical Fokker–Planck equation belongs to the well-explored domain of parabolic equations. Existence and uniqueness of the solution fundamentally result[54] from the fact that the linear operator $A=-\Delta$ is a (self-adjoint) positive generator of a semigroup of contraction operators $T(t)=e^{-tA}$, $t\geqslant 0$. In the case of constant coefficients (linear Langevin equation), the solution is directly obtained with the help of $T(t)$ and this ensures its existence, uniqueness, and positiveness. Note that in our case, the semigroup action corresponds to the equation of convolution [Eq. (24)].

Similar results hold for a Lipschitz variation of the coefficients, i.e.,

$$|m(x,t)-m(y,t)|+|\sigma(x,t)-\sigma(y,t)|\leqslant D|x-y| \tag{59}$$

as well as a condition of slow growth in time of the coefficients $m(X(t),t)$ and $\sigma(X(t),t)$, e.g.,

$$|m(x,t)|+|\sigma(x,t)|\leqslant C|1+x|, \tag{60}$$

where D and C are given positive constants.

These conditions have been extensively used for the classical Fokker–Planck equation with non constant coefficients (e.g., Ref. 43). Considering now the fractional generalization, it is important to note that the fractional power of the Laplacian $-(-\Delta)^{\alpha/2}$ remains positive, since its definition Eq. (35) corresponds to replacing the eigenvalues k^2 by eigenvalues having as real part $|k|^{\alpha}$. Therefore, we remain inside of the previous framework of contraction semigroup and the previous results should hold.

This could also be seen from the integral form of the differential equation. Indeed, in the classical case, the Lipschitz condition is classical for the Brownian forcing,[55,41] as well as for the

more general case of martingale and semimartingale forcing.[56–58] The latest case is relevant for the stable Lévy forcing. The Lipschitz condition can be rather understood as a condition of convergence of the Picard iteration method towards a fixed point:

$$X^{n+1}(t)=X(t_0)+\int m(X^n(t),t)dt+\int \sigma(X^n(t),t)dL;X^0(t)=X(t_0). \tag{61}$$

On the other hand, the condition of slow growth (60) in time prevents a finite explosion time, i.e., $X(t)$ remains finite for any given finite time t: this condition is rather general, since it is already required by the deterministic part of the Langevin-type equation.

X. CONCLUSION

We have derived a fractional Fokker–Planck equation, i.e., a kinetic equation which involves fractional derivatives, for the evolution of the probability distribution of nonlinear stochastic differential equations driven by non-Gaussian Lévy stable noises. We first established this equation in the scalar case, where it has a rather compact expression with the help of fractional powers of the Laplacian, and then discussed and presented its extension to the vector case. This fractional Fokker–Planck equation generalizes broadly previous results obtained for a linear Langevin-type equation with a Lévy forcing, as well as the standard Fokker–Planck equation for a nonlinear Langevin equation with a Gaussian forcing. As suggested in Ref. 36 and in the comments of Ref. 19 on Refs. 32 and 35, we will show elsewhere, that the present results could be extended to include fractional time derivative in the Langevin equation and in the corresponding Fokker–Planck equation. This is particularly important for multifractal modeling, since the generators of dynamic universal multifractals[30] are defined by this type of equations.

Hamiltonians and zero-curvature equations for integrable partial differential equations

Malcolm R. Adams[a] and Saša Krešić-Jurić
University of Georgia, Department of Mathematics, Athens, Georgia 30602

(Received 26 June 2000; accepted for publication 31 July 2000)

We discuss the relationship between two approaches to integrable partial differential equations, one using formal affine Lie algebras and the other Banach–Lie groups. In the first approach integrability of the equations follows from commutativity of Hamiltonian flows on the Lie algebra, while in the second it follows from commutativity of certain flows induced by an action on the Banach–Lie group. We show that these two methods are essentially equivalent since one can calculate one type of the flows from the other. The classes of solutions encompassed by the two methods, however, vary significantly. We demonstrate this relationship specifically with the nonlinear Schrödinger equation. © *2001 American Institute of Physics.* [DOI: 10.1063/1.1312197]

I. INTRODUCTION

Integrable partial differential equations (PDE's), such as the Korteweg de Vries (KdV) equation or the cubically nonlinear Schrödinger (NLS) equation, have been studied in the context of infinite dimensional Lie groups or their Lie algebras for many years now. One approach, originated by the Kyoto school,[1] considers flows of an Abelian group on an infinite dimensional Grassmannian. The partial differential equations then arise in Hirota form as the Plücker equations for a projective embedding of the Grassmannian. On the other hand integrable PDE's are often studied in the zero-curvature form. This expression arises from modeling the Grassmannian by G/G_+ where G is a certain infinite dimensional Lie group with subgroups G_-, G_+ such that G_-G_+ is dense in G, and $G_-\cap G_+=\{I\}$. Commuting flows on G/G_+ are constructed as flows $g_-(\mathbf{t})$, $\mathbf{t}\in\mathbb{R}^n$, on G_- whose commutativity leads to matrix PDE's in the zero-curvature form which are equivalent to scalar PDE's for matrix coefficients, such as the NLS or the KdV equation. The equivalence of the Hirota approach to the zero-curvature method was given by Segal and Wilson[2] for the KP hierarchy, and was recently generalized by Bergvelt and ten Kroode.[3]

The zero-curvature equation is actually a partial differential equation on elements of $\mathfrak{g}$, the Lie algebra of G. In Ref. 4, Flaschka, Newell and Ratiu observed that this equation is also related to commutativity of certain Lax pair flows on the Lie algebra $\mathfrak{g}_-$, and that these flows have a Hamiltonian interpretation in terms of the natural Lie–Poisson structure on $\mathfrak{g}_+^*$, the dual of $\mathfrak{g}_+$. This approach leads to an understanding of the integrability of the original PDE's in terms of the Liouville integrability of the flows in $\mathfrak{g}_+^*$, as given by the Adler–Kostant–Symes theorem.

Our purpose in this paper is to describe the relation between the Lax pair flows on $\mathfrak{g}_-$ and the Abelian flows on G/G_+. The literature often treats the two approaches as equivalent but we have been unable to find a published proof of this fact. Indeed, if one takes care to distinguish which spaces of solutions are discussed in the two approaches it becomes apparent that they are not exactly equivalent. We remark in Sec. II that the Lie algebraic approach provides all regular solutions for the the NLS equation, while it is generally known that the Lie group approach leads to rather obscure subspaces of solutions due to the necessity of a Banach–Lie group structure of G (see Refs. 2 and 5). In Sec. III we describe how to construct the Banach–Lie group G and the

[a]Electronic mail: adams@math.uga.edu

Abelian flows on G/G_+ whose commutativity gives rise to integrable PDE's. This is illustrated with the NLS example.

In Sec. IV we provide a computational proof of the equivalence of the two approaches to integrable PDE's. If one begins with a suitable Abelian flow $g(\mathbf{t})$ in G, then one obtains $g_-(\mathbf{t}) \in G_-$ by a Riemann–Hilbert type splitting on G, and the solution $X(\mathbf{t})$ to the Lax equations on the Lie algebra $\mathfrak{g}_-$ is given by conjugating $X(0)$ with $g_-(\mathbf{t})$. On the other hand if we start with a solution $X(\mathbf{t})$ to the Lax equations, then producing the solution $g_-(\mathbf{t})$ to the Riemann–Hilbert problem is a little more complicated. It involves solving a differential equation on the group G_- which is determined from the Lax equations for $X(\mathbf{t})$. The first half of this argument, presented in Proposition 1, is well known (and perhaps accounts for the general notion that the two methods are entirely equivalent), but the second half, Proposition 2, is somewhat more obscure. Examining the relationship of $g_-(\mathbf{t})$ to $X(\mathbf{t})$ helps provide an understanding of the relationship between the different classes of solutions given by these two approaches. To pass from $X(\mathbf{t})$ to $g_-(\mathbf{t})$ one must solve a differential equation in some Banach–Lie group, and this requires that $X(\mathbf{t})$ lies in a particular Banach–Lie algebra. In Sec. V we present a geometric interpretation of the relationship between the two approaches. This is basically just an application of the general setting provided by Guillemin and Sternberg in Ref. 6.

II. THE ADLER–KOSTANT–SYMES METHOD OF FLASCHKA, NEWELL AND RATIU

Let $\mathfrak{g}$ be a Lie algebra and let $\mathfrak{g}^*$ denote its dual which is (weakly) paired via $\langle\,,\rangle:\mathfrak{g}^*\times\mathfrak{g}\to\mathbb{C}$. The space $\mathfrak{g}^*$ admits the structure of a Poisson manifold with the Lie–Poisson bracket defined by

$$\{F,G\}(\alpha)=\left\langle \alpha,\left[\frac{\delta F}{\delta\alpha},\frac{\delta G}{\delta\alpha}\right]\right\rangle,\quad \alpha\in\mathfrak{g}^*,\quad F,G\in C^\infty(\mathfrak{g}^*). \tag{1}$$

Here $\delta F/\delta\alpha$ is the functional derivative of F, i.e., it is the element of $\mathfrak{g}$ satisfying

$$\left\langle \beta,\frac{\delta F}{\delta\alpha}\right\rangle=\left.\frac{d}{dt}\right|_{t=0} F(\alpha+t\beta),\quad \text{for all}\quad \beta\in\mathfrak{g}^*.$$

Bracket (1) plays an important role in the description of many finite and infinite dimensional Hamiltonian systems (see Ref. 7). We shall briefly describe this in the following. If $\mathfrak{g}$ is infinite dimensional and the pairing $\langle\,,\rangle$ is weak, we must restrict this bracket to an appropriate class of functions so that $\delta F/\delta\alpha$ makes sense, i.e., it defines an element of $\mathfrak{g}$. Details of the problems that can arise may be found in Ref. 8.

A Hamiltonian $H\in C^\infty(\mathfrak{g}^*)$ generates the vector field X_H on $\mathfrak{g}^*$ by the relation $X_H[F]=\{F,H\}$ where $X_H[F]$ is the Lie derivative of F along X_H, $X_H[F](\alpha)=dF(\alpha)X_H(\alpha)$ for any $\alpha\in\mathfrak{g}^*$. It follows from (1) that the flow of X_H satisfies the generalized Lax equation,

$$\frac{d\alpha}{dt}=-\mathrm{ad}^*\left(\frac{\delta H}{\delta\alpha}\right)\alpha,$$

where $\mathrm{ad}^*(X)$ is the dual of $\mathrm{ad}(X)$ defined by $\langle\mathrm{ad}^*(X)\alpha,Y\rangle=\langle\alpha,\mathrm{ad}(X)Y\rangle$.

Now, let $\mathrm{I}(\mathfrak{g}^*)$ denote the space of all ad*-invariant functions on $\mathfrak{g}^*$:

$$\mathrm{I}(\mathfrak{g}^*)=\{F\,|\,dF(\alpha)(\mathrm{ad}^*(X)\alpha)=0,\quad \text{for all}\quad X\in\mathfrak{g},\ \alpha\in\mathfrak{g}^*\}.$$

If the Lie algebra $\mathfrak{g}$ has a Lie group G, then functions satisfying $F\circ\mathrm{Ad}^*(g^{-1})=F$ for all $g\in G$ are ad*-invariant. Here $\mathrm{Ad}^*(g)$ is the dual of $\mathrm{Ad}(g)$, $\langle\mathrm{Ad}^*(g)\alpha,X\rangle=\langle\alpha,\mathrm{Ad}(g)X\rangle$. One easily shows from the definition of the Lie–Poisson bracket that $\mathrm{I}(\mathfrak{g}^*)$ is in the center of $C^\infty(\mathfrak{g}^*)$, i.e., if $F\in I(\mathfrak{g}^*)$ then $\{F,H\}=0$ for all $H\in C^\infty(\mathfrak{g}^*)$. Thus ad*-invariant functions are integrals of the

motion for any Hamiltonian H. Unfortunately, their vector fields vanish identically so they generate only trivial flows. In order to construct nontrivial Poisson-commuting flows, one needs an additional structure on $\mathfrak{g}$.

Suppose that $\mathfrak{g}$ splits into the vector space direct sum of subalgebras,

$$\mathfrak{g}=\mathfrak{g}_-\oplus\mathfrak{g}_+,$$

and let $\Pi_+:\mathfrak{g}\to\mathfrak{g}_+$ denote the projection with kernel $\mathfrak{g}_-$. Then its dual also splits into

$$\mathfrak{g}^*=\mathfrak{g}_-^*\oplus\mathfrak{g}_+^*,$$

where $\mathfrak{g}_\pm^*=\mathrm{Ann}(\mathfrak{g}_\mp)$ is the annihilator of $\mathfrak{g}_\mp$. Since $\mathfrak{g}_+$ is a Lie subalgebra, the space $\mathfrak{g}_+^*$ is also equipped with the Lie–Poisson structure (1). Now suppose that $H_1\in \mathrm{I}(\mathfrak{g}^*)$, and let $\tilde{H}_1$ denote the restriction of H_1 to $\mathfrak{g}_+^*$. Then $\tilde{H}_1$ is generally not in the center of $C^\infty(\mathfrak{g}_+^*)$, hence $\tilde{H}_1$ generates nontrivial flows on $\mathfrak{g}_+^*$. But if H_2 is another invariant function on $\mathfrak{g}^*$, then the celebrated result of Adler, Kostant and Symes (see Refs. 9, 10, and 11) states that $\tilde{H}_1$ and $\tilde{H}_2$ Poisson commute. More precisely, $\{\tilde{H}_1,\tilde{H}_2\}=0$ where

$$\{\tilde{H}_1,\tilde{H}_2\}(\alpha)=\left\langle \alpha,\left[\Pi_+\left(\frac{\delta H_1}{\delta\alpha}\right),\Pi_+\left(\frac{\delta H_2}{\delta\alpha}\right)\right]\right\rangle,\quad \alpha\in\mathfrak{g}_+^*.$$

Thus $\tilde{H}_1$ and $\tilde{H}_2$ generate commuting Hamiltonian flows on $\mathfrak{g}_+^*$ which are given by

$$\frac{d\alpha}{dt_i}=-\mathrm{ad}^*\left(\Pi_+\left(\frac{\delta H_i}{\delta\alpha}\right)\right)\alpha,\quad \alpha\in\mathfrak{g}_+^*. \tag{2}$$

Equation (2) takes the usual Lax form if $\mathfrak{g}$ is self-dual, i.e., if we can identify $\mathfrak{g}^*$ with $\mathfrak{g}$ by a nondegenerate symmetric bilinear form on $\mathfrak{g}$ which is ad-invariant:

$$(\mathrm{ad}(Z)X,Y)=-(X,\mathrm{ad}(Z)Y). \tag{3}$$

In this case the coadjoint representation of $\mathfrak{g}$ on $\mathfrak{g}^*$ is identified with the adjoint representation of $\mathfrak{g}$ on itself, and $\mathfrak{g}_\pm^*$ is identified with $\mathfrak{g}_\mp^\perp$, the perpendicular complement of $\mathfrak{g}_\mp$ with respect to the bilinear form (3). Equation (2) then becomes

$$\frac{\partial X}{\partial t_i}=\left[\Pi_+\left(\frac{\delta H_i}{\delta X}\right),X\right],\quad X\in\mathfrak{g}_-^\perp. \tag{4}$$

Hence the Adler–Kostant–Symes theorem provides a systematic method for searching for integrals of the motion of a system described by the Lax equation (4).

Flaschka, Newell and Ratiu[4] apply the Adler–Kostant–Symes result to the loop algebra $\widetilde{sl}(2)$ of formal series $X=\Sigma_{i=-\infty}^{m}X_iz^i$, $X_i\in sl(2,\mathbb{C})$, $m<\infty$. They show that the Ablowitz–Kaup–Newell–Segur (AKNS) equations,

$$\frac{\partial Q}{\partial t_k}=[Q^{(k)},Q],\quad k\geqslant 1, \tag{5}$$

where $Q=\Sigma_{i=0}^{\infty}Q_iz^{-i}$ and $Q^{(k)}=\Sigma_{i=0}^{k}Q_iz^{k-i}$ arise as commuting Hamiltonian flows on $\widetilde{sl}(2)_+^*$. Their theory is outlined below.

Let $\mathfrak{g}$ denote the loop algebra $\widetilde{sl}(2)$ with the commutator bracket. This algebra admits a natural splitting $\mathfrak{g}=\mathfrak{g}_-\oplus\mathfrak{g}_+$ into subalgebras where

$$\mathfrak{g}_+=\left\{X=\sum_{i\geqslant 0}X_iz^i\,\middle|\,X_i\in sl(2,\mathbb{C})\right\},$$

$$\mathfrak{g}_- = \left\{ X = \sum_{i=1}^{\infty} X_i z^{-i} \,\middle|\, X_i \in sl(2,\mathbb{C}) \right\}.$$

We can identify $\mathfrak{g}^*$ with $\mathfrak{g}$ by the nondegenerate symmetric bilinear form,

$$(X,Y) = \mathrm{res}_{z=0}\,\mathrm{Tr}(X(z)Y(z)), \tag{6}$$

which is ad-invariant. The perpendicular complement of $\mathfrak{g}_-$ is $\mathfrak{g}_-^{\perp} = \mathfrak{g}_-$, so $\mathfrak{g}_+^*$ is identified with $\mathfrak{g}_-$. Now consider a family of Hamiltonian functions on $\mathfrak{g}^* \simeq \mathfrak{g}$,

$$H_k(X) = \tfrac{1}{2}\mathrm{res}_{z=0}\,\mathrm{Tr}(z^{k+1}X^2(z)), \quad k \geqslant 1. \tag{7}$$

One easily checks that the Hamiltonians H_k are ad-invariant, hence their restrictions to $\mathfrak{g}_-$ give rise to a hierarchy of commuting flows given by Eq. (4). Furthermore, if $X = \Sigma_{i=1}^{\infty} X_i z^{-i} \in \mathfrak{g}_-$, then

$$\Pi_+\left(\frac{\delta H_k}{\delta X}\right) = \Pi_+(z^{k+1}X) = \sum_{i=0}^{k} X_{i+1} z^{k-i} = M_k.$$

Therefore, for this choice of Hamiltonian functions the system of equations (4) is equivalent with the AKNS equations (5), with X standing for Q and M_k for $Q^{(k)}$.

It is generally stated that the commutativity of the flows of type (5) gives rise to the ''zero curvature'' equation,

$$\frac{\partial M_k}{\partial t_l} - \frac{\partial M_l}{\partial t_k} + [M_k, M_l] = 0. \tag{8}$$

However, if one compares $X_{t_k t_l}$ to $X_{t_l t_k}$, it only follows that the left hand side of Eq. (8) commutes with X. To see that it is actually zero requires more work. Suppose without loss of generality that $k = l + p$ for some $p \geqslant 1$. Observing that

$$M_k = z^p M_l + \sum_{i=1}^{p} X_{l+i+1} z^{p-i}, \tag{9}$$

a lengthy but straighforward computation yields

$$\frac{\partial M_k}{\partial t_l} - \frac{\partial M_l}{\partial t_k} + [M_k, M_l] = z^l \left[z^p \sum_{i=0}^{k} \frac{\partial X_{i+1}}{\partial t_l} z^{-i} - \sum_{i=0}^{l} \frac{\partial X_{i+1}}{\partial t_k} z^{-i} - \sum_{i=0}^{l} \sum_{j=1}^{p} [X_{i+1}, X_{l+j+1}] z^{p-i-j} \right]. \tag{10}$$

Since X satisfies

$$\frac{\partial X}{\partial t_k} = [M_k, X] \quad \text{and} \quad \frac{\partial X}{\partial t_l} = [M_l, X], \tag{11}$$

substituting (9) into the first equation above and making use of the second, one obtains

$$z^p \sum_{i=0}^{\infty} \frac{\partial X_{i+1}}{\partial t_l} z^{-i} = \sum_{i=0}^{\infty} \frac{\partial X_{i+1}}{\partial t_k} z^{-i} + \sum_{i=0}^{\infty} \sum_{j=1}^{p} [X_{i+1}, X_{l+j+1}] z^{p-i-j}.$$

Multiplying this equation by z^l and taking the polynomial part of both sides yields

$$0 = z^k \sum_{i=0}^{k} \frac{\partial X_{i+1}}{\partial t_l} z^{-i} - z^l \sum_{i=0}^{l} \frac{\partial X_{i+1}}{\partial t_k} z^{-i} - \sum_{j=1}^{p} \sum_{i=0}^{k-j} [X_{i+1}, X_{l+j+1}] z^{k-i-j}. \tag{12}$$

The difference between the right hand sides of Eqs. (12) and (10) is given by

$$\sum_{j=1}^{p}\sum_{i=l+1}^{k-j}[X_{i+1},X_{l+j+1}]z^{k-i-j}=\sum_{j=1}^{p}\sum_{i=1}^{p-j}[X_{i+l+1},X_{l+j+1}]z^{p-i-j}$$

$$=\sum_{s=2}^{p}\sum_{\substack{i+j=s,\\ 1\leqslant i\leqslant p-j\\ 1\leqslant j\leqslant p-1}}[X_{i+l+1},X_{l+j+1}]z^{p-i-j}$$

$$=\sum_{s=2}^{p}\sum_{\substack{i+j=s,\\ 1\leqslant i,j\leqslant p}}[X_{i+l+1},X_{l+j+1}]z^{p-i-j},$$

which is zero by skew symmetry. Thus, if X satisfies the system of equations (11), then the matrix elements of X are solutions to a hierarchy of PDE's obtained from the zero-curvature equation (8).

To illustrate the point, let $l=1$, $k=2$, and consider the subset $\mathcal{S}\subset\mathfrak{g}_-$ which consists of all $X\in\mathfrak{g}_-$ such that the first three Fourier coefficients have the form

$$X_1=\begin{pmatrix} i & 0\\ 0 & -i\end{pmatrix},\quad X_2=2\begin{pmatrix} 0 & iu\\ -\overline{iu} & 0\end{pmatrix},\quad X_3=2\begin{pmatrix} -i|u|^2 & h\\ -\overline{h} & i|u|^2\end{pmatrix},$$

for some complex valued functions $u(t_1,t_2)$ and $h(t_1,t_2)$. One easily checks that $\mathcal{S}$ is invariant under the flows (11) (see Ref. 12 for a geometric explanation of this). Then Eq. (8) with $M_1=X_1z+X_2$ and $M_2=X_1z^2+X_2z+X_3$ implies that $h=\frac{1}{2}u_x$ and u satisfies the NLS equation

$$iu_t-\tfrac{1}{2}u_{xx}-4u|u|^2=0, \tag{13}$$

where $x=t_1$ and $t=t_2$.

One should remark that any regular solution of the NLS equation can be studied in this framework. Indeed, suppose that $u(x,t)$ satisfies (13), and form X_1,X_2 and X_3 as above with this particular u and $h=\frac{1}{2}u_x$. Then X_n, $n\geqslant 4$, can be found so that for $X=\Sigma_{i=1}^{\infty}X_iz^{-i}$ we get

$$\frac{\partial X}{\partial x}=[X_1z+X_2,X]\quad\text{and}\quad\frac{\partial X}{\partial t}=[X_1z^2+X_2z+X_3,X]. \tag{14}$$

To find X_n notice that (14) implies

$$\frac{\partial X_1}{\partial x}=0,\quad\frac{\partial X_1}{\partial t}=0,$$

$$\frac{\partial X_2}{\partial x}=[X_1,X_3],\quad\frac{\partial X_2}{\partial t}=[X_1,X_4],$$

$$\frac{\partial X_3}{\partial x}=[X_2,X_3]+[X_1,X_4],\quad\frac{\partial X_3}{\partial t}=[X_1,X_5]+[X_2,X_4],$$

and generally

$$\frac{\partial X_n}{\partial x}=[X_2,X_n]+[X_1,X_{n+1}],\quad\frac{\partial X_n}{\partial t}=[X_3,X_n]+[X_2,X_{n+1}]+[X_1,X_{n+2}].$$

Now let us notice that if we ignore the t-dependence and simply consider the system of ordinary differential equations (ODE's) given by the variable x, then we can solve recursively for X_n by noting first that the off-diagonal part of X_4 is determined from $[X_1,X_4]=(X_3)_x-[X_2,X_3]$, and

that the diagonal part is determined up to an integration constant by $(X_4)_x=[X_2,X_4]+[X_1,X_5]$. Meanwhile, this last equation determines the off-diagonal part of X_5, while the next equation will determine the diagonal part, and so on.

Since the t-equations are three term recursion it is a little more complicated to see that they are not overdetermined. First, we get the off-diagonal part of X_4 from the equation for $(X_2)_t$. Then, using the equation for $(X_3)_t$ we can write the off-diagonal part of X_5 in terms of X_4 and lower terms. Finally, the diagonal part of $(X_4)_t$ involves only the off-diagonal part of X_5, and so we get an ODE for the diagonal part of X_4. Meanwhile, the off-diagonal part of $(X_4)_t$ determines the off-diagonal part of X_6 in terms of X_5 and lower terms, and the diagonal part of $(X_5)_t$ involves only the off-diagonal part of X_6. Thus the argument continues.

Finally, in order to check that we can solve these two ODE's simultaneously in order to get $X(x,t)$, we must check that the mixed partials are equal. But this just amounts to checking that zero-curvature expression is zero for our particular M_1 and M_2. As noted above, this is guaranteed by Eq. (13).

III. THE ZERO-CURVATURE METHOD AND THE RIEMANN–HILBERT PROBLEM

In this section we describe the zero-curvature approach[13] to systems of integrable PDE's, and examine its connection with the Adler–Kostant–Symes method of Flaschka, Newell and Ratiu. In the zero-curvature method one uses commutativity of certain flows on a Banach-Lie group G to derive a hierarchy of integrable nonlinear PDE's on the Lie algebra of G. The flows are generated by an action of the translation group $\mathbb{R}^n$ on G as outlined in the following.

Suppose that G is a Banach–Lie group which contains closed subgroups G_-, G_+ such that $G_-\cap G_+=\{I\}$ and G_-G_+ is open (and usually dense) in G. Then the Lie algebra of G splits into the vector space direct sum of subalgebras $\mathfrak{g}=\mathfrak{g}_-\oplus\mathfrak{g}_+$. Consider the differentiable action $\mathbb{R}^n\times G\to G$ given by

$$\mathbf{t}g=\exp\left(\sum_{i=1}^{n} t_iP_i\right)g, \tag{15}$$

where $\{P_1,\ldots,P_n\}$ is contained in an Abelian subalgebra of $\mathfrak{g}_+$. Note that the action (15) descends to an action of $\mathbb{R}^n$ on the quotient space G/G_+ by

$$\mathbf{t}(gG_+)=(\mathbf{t}g)G_+. \tag{16}$$

Now let $g\in G_-G_+$. Then $\mathbf{t}g\in G_-G_+$ for all $\mathbf{t}$ in a neighborhood U of $0\in\mathbb{R}^n$. Hence $\mathbf{t}g$ can be written in a unique way as the product

$$\mathbf{t}g=g_-(\mathbf{t})g_+(\mathbf{t}),\quad \mathbf{t}\in U, \tag{17}$$

where $g_\pm\in G_\pm$. We shall refer to (17) as the Riemann–Hilbert factorization of $\mathbf{t}g$. Combining this with Eq. (16) it follows that the action of $\mathbb{R}^n$ on the Grassmannian G/G_+ induces the flow $g_-(\mathbf{t})G_+$ on G/G_+. Since $[P_i,P_j]=0$, the t_i and t_j flows commute. Next we will show that $g_-(\mathbf{t})$ is a ''solution'' to a hierarchy of nonlinear PDE's which live on the Lie algebra of G_+. By differentiating Eq. (17) and using (15) one obtains

$$g_-^{-1}P_ig_-=g_-^{-1}\frac{\partial g_-}{\partial t_i}+\frac{\partial g_+}{\partial t_i}g_+^{-1}.$$

By taking the projection $\Pi_+:\mathfrak{g}\to\mathfrak{g}_+$ along $\mathfrak{g}_-$ it follows that

$$\Pi_+(g_-^{-1}P_ig_-)=\frac{\partial g_+}{\partial t_i}g_+^{-1}.$$

Denote $M_i(\mathbf{t})=\Pi_+(g_-^{-1}(\mathbf{t})P_ig_-(\mathbf{t}))$. Since the flows commute, the system of equations,

$$\frac{\partial g_+}{\partial t_i} = M_i g_+, \quad i=1,\ldots,n,$$

satisfies the compatibility condition $(g_+)_{t_k t_l} = (g_+)_{t_l t_k}$ which yields the zero-curvature equation,

$$\frac{\partial M_k}{\partial t_l} - \frac{\partial M_l}{\partial t_k} + [M_k, M_l] = 0. \tag{18}$$

We can think of (18) as an abstract partial differential equation on $\mathfrak{g}_+$. In practice G is usually the loop group of a linear group, and the zero-curvature condition is equivalent to a nonlinear PDE satisfied by a matrix element $u(\mathbf{t})$ of M_k and M_l. Since $u(\mathbf{t})$ can be explicitly calculated in terms of $g_-(\mathbf{t})$ we have the mappings

$$g \mapsto g_-(\mathbf{t}) \mapsto u(\mathbf{t}).$$

The function $u(\mathbf{t})$ simultaneously solves all equations of the form (18) for different values of k and l, and the Riemann–Hilbert factorization establishes the local existence of $u(\mathbf{t})$. Moreover, it linearizes the equations for $u(\mathbf{t})$ since a multiplication of g by $\exp(\Delta t_i P_i)$ corresponds to $u(\mathbf{t})$ flowing in the t_i-direction by the amount Δt_i. Since the map $g \mapsto g_-(\mathbf{t})$ is invariant under the right multiplication of g by an element of G_+, we may assume that $g \in G_-$. Then by uniqueness of the splitting we have $g = g_-(0)$, so g encodes the initial values of $u(\mathbf{t})$.

A convenient analytical structure of G which suffices to describe a number of integrable systems can be constructed as follows (see Ref. 5). Let $\mathcal{A}$ denote the Banach algebra of functions $f: S^1 \to \mathbb{C}$, $f(z) = \Sigma_{n\in\mathbb{Z}} a_n z^n$, with pointwise addition and multiplication, relative to the norm $\|f\|_1 = \Sigma_{n\in\mathbb{Z}} |a_n|$. $\mathcal{A}$ consists of continuous functions on S^1 which have an absolutely convergent Fourier series. Consider the set $GL(n,\mathcal{A})$ of all invertible elements in $M(n,\mathcal{A})$. Here $M(n,\mathcal{A})$ is the matrix Banach algebra with the norm $\|A\| = \Sigma_{i,j=1}^n \|A_{ij}\|_1$. By Wiener's Lemma[14] $f(z)^{-1} \in \mathcal{A}$ if and only if $f(z)$ vanishes nowhere on S^1, hence $GL(n,\mathcal{A})$ is the set of all elements A such that $\det(A(z)) \neq 0$ for all $z \in S^1$. Thus $GL(n,\mathcal{A})$ is a Banach–Lie group as an open submanifold of $M(n,\mathcal{A})$. Let σ be a norm preserving involution on the algebra $M(n,\mathcal{A})$, and define

$$G = \{g \in GL(n,\mathcal{A}) \,|\, g g^\sigma = I\}. \tag{19}$$

A standard result from the theory of Banach manifolds[15] asserts that the group G is a closed submanifold of $M(n,\mathcal{A})$, and hence a Banach–Lie group with Lie algebra,

$$\mathfrak{g} = \{X \in M(n,\mathcal{A}) \,|\, X + X^\sigma = 0\}.$$

Associated with the loop group G we introduce the subgroups

$$G_+ = \left\{ g \in G \,\middle|\, g(z) = \sum_{i\geqslant 0} C_i z^i \right\}, \quad G_- = \left\{ g \in G \,\middle|\, g(z) = I + \sum_{i<0} C_i z^i \right\}.$$

The Lie algebras of G_- and G_+ are closed subalgebras of $\mathfrak{g}$ which they decompose into the direct sum of vector spaces, $\mathfrak{g} = \mathfrak{g}_- \oplus \mathfrak{g}_+$. Thus the set $G_- G_+$ is open in G. A particular choice of σ and the action of $\mathbb{R}^n$ on G determines the hierarchy of differential equations represented by (18). Note that the above construction also includes twisted loop algebras related to systems such as the mKdV equation[12] and the Neumann oscillator.[16] We emphasize that there is a major difference between this method and that of Flaschka, Newell and Ratiu: *the flows are given directly from a group action and there is no use of a Hamiltonian structure.*

To illustrate these remarks let the involution σ on $M(2,\mathcal{A})$ be given by $g^\sigma(z) = \overline{g}^\tau(z)$ where the bar conjugates the Fourier coefficients of $g(z)$, but not the parameter z. Define the action of $\mathbb{R}^2$ on G by

$$\mathbf{t}g = \exp(t_1 i\sigma_3 z + t_2 i\sigma_3 z^2)g,$$

where $\sigma_3 = \left(\begin{smallmatrix} 1 & 0 \\ 0 & -1 \end{smallmatrix}\right)$. Suppose that $g_-(\mathbf{t})$ is the solution of the Riemann–Hilbert factorization of $\mathbf{t}g$ such that $g_-(0,0) = g$. If $g_- = I + A_1 z^{-1} + A_2 z^{-2} + \cdots$ is the Fourier expansion of $g_-(\mathbf{t})$, then $g_-^{-1} = I - A_1 z^{-1} + (A_1^2 - A_2) z^{-2} + \cdots$. Substituting this into $M_k = \Pi_+(g_-^{-1} i\sigma_3 z^k g_-)$ we obtain

$$M_1 = i\sigma_3 z + [i\sigma_3, A_1],$$

$$M_2 = i\sigma_3 z^2 + [i\sigma_3, A_1]z + [i\sigma_3, A_2] - A_1[i\sigma_3, A_1].$$

Denote

$$A_1 = \begin{pmatrix} ia & u \\ -\overline{u} & ib \end{pmatrix} \quad \text{and} \quad A_2 = \begin{pmatrix} p & r \\ s & q \end{pmatrix},$$

where a and b are real-valued functions of t_1 and t_2 (note that the group law in G implies that A_1 has the form specified above). We then have

$$M_1 = i\sigma_3 z + 2\begin{pmatrix} 0 & iu \\ -\overline{iu} & 0 \end{pmatrix}, \quad M_2 = zM_1 + 2\begin{pmatrix} -i|u|^2 & h \\ -\overline{h} & i|u|^2 \end{pmatrix}$$

where $h = au + ir$. Now it is straightforward to verify that the zero-curvature condition (18) implies that $h = \frac{1}{2}u_x$ and u satisfies the NLS equation (13) where $x = t_1$ and $t = t_2$.

IV. RELATING THE TWO METHODS

In this section we give a direct proof of the equivalence of the Flaschka–Newell–Ratiu method and the zero-curvature approach. We shall consider a slightly more general type of AKNS equations of which (5) is a special case. In the following it is assumed that G is a given Banach–Lie group defined by Eq. (19) whose Lie algebra admits the ad-invariant bilinear form (6), and $\mathfrak{g}_-$ satisfies $\mathfrak{g}_-^{\perp} = \mathfrak{g}_-$.

Consider the Riemann-Hilbert splitting on G,

$$\exp\left(\sum_{i=1}^{n} t_i R^p z^i\right) g = g_-(\mathbf{t}) g_+(\mathbf{t}), \quad g \in G_-, \tag{20}$$

where we assume that $R \in GL(n,\mathbb{C})$ is chosen so that $R^p z^i \in \mathfrak{g}_+$ for some $p \in \mathbb{N}$. We associate to splitting (20) the generalized AKNS equations on the Lie algebra of G_-:

$$\frac{\partial X}{\partial t_k} = [\Pi_+(z^{k+p} X^p), X], \quad X \in \mathfrak{g}_-. \tag{21}$$

Note that (21) is equivalent with (5) when $p = 1$ because Π_+ is the projection containing only non-negative powers of z. According to Flaschka–Newell–Ratiu theory, the Lax equations (21) are commuting flows of ad-invariant Hamiltonians,

$$H_k^{(p)}(X) = \frac{1}{p+1} \operatorname{res}_{z=0} \operatorname{Tr}(z^{k+p} X^{p+1}), \quad 1 \leqslant k \leqslant n.$$

Proposition 1: *If the flow $g_-(\mathbf{t}) \in G_-$ is obtained by solving the Riemann–Hilbert problem (20), then $X(\mathbf{t}) = g_-^{-1}(\mathbf{t}) R z^{-1} g_-(\mathbf{t})$ is the integral curve of (21) with initial value $X(0) = g^{-1} R z^{-1} g$.*

Proof: Define $X(\mathbf{t}) = g_-^{-1}(\mathbf{t}) R z^{-1} g_-(\mathbf{t})$. Then it readily follows that

$$\frac{\partial X}{\partial t_k}=\left[X,g_-^{-1}\frac{\partial g_-}{\partial t_k}\right]. \tag{22}$$

On the other hand, by differentiating Eq. (20) we obtain

$$z^{k+p}X^p=g_-^{-1}\frac{\partial g_-}{\partial t_k}+\frac{\partial g_+}{\partial t_k}g_+^{-1}, \tag{23}$$

which yields

$$\frac{\partial g_+}{\partial t_k}g_+^{-1}=\Pi_+(z^{k+p}X^p).$$

Substituting this back into Eq. (23) and using Eq. (22) we conclude that $X(\mathbf{t})$ is a solution of the Lax equations (21) with initial value $X(0)=g^{-1}Rz^{-1}g$. ■

Thus, by solving the Riemann–Hilbert problem one obtains solutions of the AKNS equations. This is not surprising, but one can show that the converse is also true. Namely, if one is given a solution of the AKNS system (21), then it is possible to construct the flows $g_\pm(\mathbf{t})\in G_\pm$ without actually solving the Riemann–Hilbert problem (20).

Proposition 2: *Suppose that $X(\mathbf{t})\in\mathfrak{g}_-$ is the integral curve of (21) with initial value $X(0)=g^{-1}Rz^{-1}g$ for some $g\in G_-$. Then $X(\mathbf{t})$ induces Abelian flows $g_\pm(\mathbf{t})\in G_\pm$ which represent solutions of the Riemann–Hilbert problem (20). Furthermore, the evolution of $X(\mathbf{t})$ is given by $X(\mathbf{t})=g_-^{-1}(\mathbf{t})Rz^{-1}g_-(\mathbf{t})$.*

Proof: Define $M_k^{(p)}=\Pi_+(z^{k+p}X^p)$ and $N_k^{(p)}=\Pi_-(z^{k+p}X^p)$. For fixed k, solve the following differential equations for $g_\pm\in G_\pm$:

$$\frac{\partial g_+}{\partial t_k}=M_k^{(p)}g_+,\quad \frac{\partial g_-}{\partial t_k}=g_-N_k^{(p)}, \tag{24}$$

with $g_+(0)=I$ and $g_-(0)=g$. Using the decomposition $z^{k+p}X^p=N_k^{(p)}+M_k^{(p)}$ and Eq. (21) we have

$$\frac{\partial X}{\partial t_k}=-[N_k^{(p)},X].$$

This implies

$$\frac{\partial}{\partial t_k}(g_-Xg_-^{-1})=\left(\frac{\partial X}{\partial t_k}+[N_k^{(p)},X]\right)g_-^{-1}=0.$$

Hence $g_-(\mathbf{t})X(\mathbf{t})g_-^{-1}(\mathbf{t})$ is a constant loop. But $X(0)=g^{-1}Rz^{-1}g$ and $g_-(0)=g$, so it follows that

$$X(\mathbf{t})=g_-^{-1}(\mathbf{t})Rz^{-1}g_-(\mathbf{t}). \tag{25}$$

Furthermore, in view of Eqs. (25) and (24) the identity $z^{k+p}X^p=N_k^{(p)}+M_k^{(p)}$ implies that the product g_-g_+ satisfies

$$\frac{\partial}{\partial t_k}(g_-g_+)=R^pz^kg_-g_+,\quad k=1,2,\ldots,n.$$

This equation has a unique solution $g_-(\mathbf{t})g_+(\mathbf{t})=\exp(\Sigma_{k=1}^n t_kR^pz^k)g_-(0)\,g_+(0)$ with initial value $g_-(0)\,g_+(0)=g$. Hence the flows $g_-(\mathbf{t})$ and $g_+(\mathbf{t})$ are solutions of the Riemann–Hilbert problem (20). ■

V. THE GEOMETRIC PICTURE

In Ref. 6, Guillemin and Sternberg showed that the flows in $\mathfrak{g}_+^*$ obtained from the Adler–Kostant–Symes method are given by projecting certain flows on the cotangent bundle T^*G to T^*G_+, and then identifying T^*G_+ with $G_+\times\mathfrak{g}_+^*$ via left multiplication. This geometric description of the Adler–Kostant–Symes flows is as follows.

Let $H\in I(\mathfrak{g}^*)$. Identify T^*G with $G\times\mathfrak{g}^*$ via left multiplication, and use this identification to consider H as a Hamiltonian function on T^*G. It is shown in Ref. 6 that this generates the flow through $(g,\mu)\in G\times\mathfrak{g}^*$ given by

$$(g,\mu)\mapsto(g\exp(-tX),\mu), \tag{26}$$

where $X=dH(-\mu)$. In this section we shall identify $dH(-\mu)$ with $\delta H/\delta(-\mu)\in\mathfrak{g}$.

Notice that under this flow, the space $G\times\mathfrak{g}_+^*$ is invariant. Right multiplication by the inverse induces the action of G_- on $G\times\mathfrak{g}_+^*$ given by

$$h(g,\mu)=(gh^{-1},\mathrm{Ad}^*(h^{-1})\mu).$$

Thus, on the open dense subspace $G_+G_-\times\mathfrak{g}_+^*\subset G\times\mathfrak{g}_+^*$ we have the projection

$$\pi: G_+G_-\times\mathfrak{g}_+^*\to G_+\times\mathfrak{g}_+^*,$$

$$\pi((g_+g_-,\mu))=(g_+,\mathrm{Ad}^*(g_-^{-1})\mu),$$

given by quotienting by the action.

Guillemin and Sternberg show that the Adler–Kostant–Symes flows for $H\in I(\mathfrak{g}^*)$ in $\mathfrak{g}_+^*$ are given by the $\mathfrak{g}_+^*$ component of the projection of the flow (26). Namely, if we write

$$g\exp(-tX)=g_+(t)g_-(t),$$

then this flow is given by

$$\mu(t)=\mathrm{Ad}^*(g_-^{-1}(t))\mu_0,\quad \mu_0\in\mathfrak{g}_+^*. \tag{27}$$

Now, let H_1 and H_2 be Hamiltonians in $I(\mathfrak{g}_+^*)$ whose flows are parametrized by x and t variables, respectively. Fix $\mu_0\in\mathfrak{g}_+^*$, and let

$$P_1=dH_1(-\mu_0),\quad P_2=dH_2(-\mu_0).$$

Since x and t flows commute we can write

$$g\exp(-xP_1)\exp(-tP_2)=g_+(x,t)g_-(x,t). \tag{28}$$

Hence Eq. (27) gives the flow

$$\mu(x,t)=\mathrm{Ad}^*(g_-^{-1}(x,t))\mu_0.$$

On the other hand, identifying $\mathfrak{g}_+^*$ with $\mathfrak{g}_-^{\perp}=\mathfrak{g}_-$ we have

$$\mu(x,t)=\mathrm{Ad}(g_-(x,t))\mu_0,\quad \mu_0\in\mathfrak{g}_-. \tag{29}$$

From the Adler–Kostant–Symes theorem μ satisfies the differential equations

$$\frac{\partial\mu}{\partial x}=[\Pi_+(dH_1(-\mu)),\mu], \tag{30}$$

$$\frac{\partial \mu}{\partial t} = [\Pi_+(dH_2(-\mu)), \mu]. \tag{31}$$

As in Sec. II, the PDE follows from the commutation relation for

$$\Pi_+(dH_1(-\mu)) \text{ and } \Pi_+(dH_2(-\mu)).$$

From Eq. (28) we have

$$\exp(tP_2)\exp(xP_1)g^{-1} = g_-^{-1}(x,t)g_+^{-1}(x,t).$$

Comparing this with the Riemann–Hilbert splitting of the flow $\exp(xP_1+tP_2)g^{-1}$ we conclude that M_k in Eq. (18) is given by

$$M_k = -\Pi_+(g_- P_k g_-^{-1}) = -\Pi_+[\mathrm{Ad}(g_-)dH_k(-\mu_0)] = -\Pi_+[dH_k(\mathrm{Ad}(g_-)(-\mu_0))],$$

because H_k is ad-invariant. In view of Eq. (29) it follows that the commutation relations for M_k are equivalent to those for $\Pi_+[(dH_k(-\mu))]$. Note also that the initial conditions, exemplified by $\mathcal{S}$ for the NLS example in the Flaschka–Newell–Ratiu approach, are determined by the G_- orbit through μ_0.

Notice that in order to produce the Lax pairs (30)–(31) on $\mathfrak{g}_-$ we have reduced the flows on T^*G to $T^*G_+ \subset T^*(G/G_-)$. Hence, these flows are directly related to Hamiltonian flows on the cotangent bundle of the Grassmannian G/G_-, while the zero-curvature formalism starts with flows on G/G_+. The Grassmannian G/G_- is the ''dual Grassmannian'' to G/G_+. If one identifies G/G_+ to the Grassmannian of subspaces of vectors in $L^2(S^1)$ which are in the G orbit of the Hardy space $L^2_+(S^1)$, then the G orbit of $L^2_-(S^1)$ is the collection of dual spaces to G/G_+ because the negative frequency space $L^2_-(S^1)$ is dual to $L^2_+(S^1)$. This duality gives a map from G/G_+ to G/G_- by sending a subspace in G/G_+ to its dual in G/G_-. Since the big cell of G/G_+ is identified with G_- (and likewise the big cell of G/G_- with G_+) this map can be considered as a map from G_- to G_+. However, it is not the case that the flows g_- and g_+ are related by that map. These flows are simply related by the fact that they are projections of the flow through g in G.

We now show how this works in the NLS example. Here we choose $\mu_0 \in \mathfrak{g}_-^{\perp} = \mathfrak{g}_-$ to be

$$\mu_0 = -z^{-1} i\sigma_3, \quad \sigma_3 = \begin{pmatrix} 1 & 0 \\ 0 & -1 \end{pmatrix}.$$

Using H_1 and H_2 from Eq. (7) we have that $dH_k(-\mu_0) = P_k$ with $P_1 = zi\sigma_3$, $P_2 = z^2 i\sigma_3$. Finally, taking $g_- = I + z^{-1}A_1 + z^{-2}A_2 + \cdots$ yields

$$M_k = \Pi_+[dH_k(-\mathrm{Ad}(g_-)\mu_0)].$$

JOURNAL OF MATHEMATICAL PHYSICS VOLUME 42, NUMBER 1 JANUARY 2001

Lie algebraic approach to the construction of (2+1)-dimensional lattice-field and field integrable Hamiltonian equations

Maciej Błaszak[a] and Andrzej Szum
Physics Department, A. Mickiewicz University, Umultowska 85, 61-614 Poznan, Poland

(Received 13 December 1999; accepted for publication 11 September 2000)

Two different methods for the construction of $(2+1)$-dimensional integrable lattice-field and field Hamiltonian dynamical systems are presented. The first method is based on the so-called central extension procedure applied to the Lie algebra of shift operators and the Lie algebra of pseudodifferential operators. The second method is the so-called operand formalism. Both methods allow a construction of some new integrable nonlinear Hamiltonian lattice-field and field equations in $(2+1)$-dimensional space. © *2001 American Institute of Physics.*

I. INTRODUCTION

For the last 20 years algebraic tools, basically the $\mathcal{R}$-matrix approach, have been widely applied for the construction of nonlinear integrable Hamiltonian dynamical systems. This approach was proposed in pioneer works by Adler,[1] Reyman and Semenov-Tian-Shansky,[2] and also by Gelfand and Dikii[3] and led finally to the celebrated Adler–Gelfand–Dikii (AGD) scheme. On the other hand, the notion of bi-Hamiltonicity, introduced by Magri,[4] revealed an important feature of integrable Hamiltonian systems. Actually, it allows a construction of a whole hierarchy of commuting vector fields (symmetries) and related gradients (co-symmetries) of conserved quantities in involution with respect to two Poisson brackets which ''decode'' the notion of bi-Hamiltonicity. In his famous paper this notion was illustrated on the Harry–Dym, nonlinear Schrödinger, mKdV, and KdV equations, and their bi-Hamiltonian structures were found, i.e., a pair of compatible Poisson (implectic) operators, where compatibility means that a linear combination of two Poisson operators is itself a Poisson operator. On the other hand, working in a frame of the AGD scheme one can quite readily construct bi-Hamiltonian structures of the above-mentioned dynamical systems and many others. We only need to start from a suitable Lax operator which defines a specific dynamical system. This approach was successfully applied to integrable field $(1+1)$-dimensional dynamical systems. In later papers[5–7] this formalism was applied to the construction of integrable lattice dynamical systems.

The next task was to develop this formalism for $(2+1)$-dimensional dynamics. However, as shown by Zakharov and Konopelchenko,[8] the regular recursion operator Φ for symmetries (or, respectively, Ψ one for co-symmetries) which admits an implectic–symplectic factorization, i.e., can be presented in the form $\Phi=\theta_2\cdot\theta_1^{-1}$ ($\Psi=\theta_1^{-1}\cdot\theta_2$), where $(\theta_1,\ \theta_2)$ is a pair of compatible implectic operators, constructed from a bi-Hamiltonian formulation of the dynamics, is a pure one-dimensional phenomenon. Nevertheless, as was shown in Refs. 9 and 10, equations in $(2+1)$-dimensions, and in particular the Kadomtsev–Petviashvili equation, admit a new type of bi-Hamiltonian formulation and thus the result of Ref. 8 is not violated. This generalized bi-Hamiltonian formulation was given as a kernel representation by Fokas and Santini[9,11,12] and also by introducing the Lenard bi-complex scheme in Refs. 13 and 14. In later works[11,15,16] the so-

[a]Electronic mail: blaszakm@main.amu.edu.pl

called operand formalism was introduced, i.e., the AGD scheme over the noncommutative ring of formal integro-differential operators with respect to ∂_y. The particular realization of operator value fields is formally equivalent to the central extension approach with additional space variable y, which allows a construction of a hierarchy of symmetries and a Hamiltonian formulation (Poisson tensor) of the $(2+1)$-dimensional dynamical systems. The central extension method was considered in early works by Reiman and Semenov-Tian-Shansky[2,17] and also by Prikarpatsky.[18,19] The well-known Sato approach[20,21] also allows a construction of a hierarchy of commuting vector fields, but it does not contain a systematic way for the construction of a Hamiltonian formulation of $(2+1)$-dimensional dynamics. Magnano and Magri[22] showed how to extend the Lenard bicomplex scheme onto n-field manifold and developed a method for the construction of Poisson structures for the Sato hierarchy using n-fold Hamiltonian formalism. Thus the results of previous papers[9–13,16] were extended onto n-field manifold in the $(2+1)$-dimensional case and the problem of the extension of the AGD scheme onto $(2+1)$-dimensional space for the field dynamical systems was completely solved.

Here we would like to stress that when we work with more then one-field dynamics and apply the operand formalism, we are not able to construct a whole hierarchy of commuting vector fields which can be fully presented by the central extension approach.

The basic aim of the present paper is to apply the operand formalism for the construction of lattice-field dynamics in $(2+1)$ dimensions, i.e., dynamics with one discrete and one continuous space variable. The results of this approach were given in Ref. 23 and here we present a more detailed theory including many examples. We also present the results of the operand approach, applied to the field dynamical systems. Although this formalism is not as complete as the one proposed by Magri and Magnano, nevertheless it allows some new results which we present here. As it seems to us nowadays, the Magnano–Magri approach cannot be applied for the construction of the lattice-field two-dimensional dynamics because the Lie algebra of shift operators has specific, non-derivative-like' features of the shifts. Here we develop and generalize the results of Refs. 9–13, and 16 and work in the frames of the operand formalism. In Sec. II we recall the $\mathcal{R}$-matrix formalism and the AGD scheme. In Sec. III we formulate the central extension procedure and apply it to the Lie algebras of shift and pseudodifferential (PDO) operators, respectively. We illustrate the results of our approach by many examples of known and new $(2+1)$-dimensional systems of lattice-field and field types, putting them into one unified scheme. Section IV contains the so-called operand approach to the construction of the extended bi-Hamiltonian formalism for dynamical systems in $(2+1)$-dimensions. We recall the basic notions of the operand approach, proposed in earlier works by Magri, Morosi, and Tondo,[13] and also by Athorne and Dorfman[16] and Fokas and Santini[10] and propose some generalizations of this formalism. The examples considered coincide with those from the previous section but due to the operand formalism approach the $(2+1)$-dimensional dynamical systems are endowed now with a generalized bi-Hamiltonian structure. In conclusion we discuss basic results of this work and some open problems.

II. LIE ALGEBRAIC APPROACH TO THE HAMILTONIAN DYNAMICAL SYSTEMS: $\mathcal{R}$-MATRIX FORMALISM

As mentioned in Sec. I, integrable dynamical systems may be constructed using Lie algebra techniques, and the Lax equation $L_t=[A,L]$ itself can be considered as some Hamiltonian dynamical system on a suitable Lie algebra. Here we recall basic notions of Lie algebra construction.[24]

Let g be a Lie algebra, g^* the dual algebra related to g by the *duality map* $\langle\cdot,\cdot\rangle_g\to\mathbb{R}$,

$$g^*\times g\to\mathbb{R}: \quad (\alpha,a)\to\langle\alpha,a\rangle_g, \quad a\in g, \quad \alpha\in g^*, \tag{1}$$

and $\mathcal{D}(g^*):=C^\infty(g^*)$ be a space of C^∞-functions on g^*. Then, let

$$\mathrm{ad}:g\times g\to g: \quad (a,b)\mapsto \mathrm{ad}_a b, \quad a,b\in g, \tag{2}$$

be the adjoint action of g on g, i.e., the Lie product, and

$$\mathrm{ad}^*: g\times g^*\to g^*: \quad (a,\alpha)\mapsto \mathrm{ad}_a^*\alpha, \quad a\in g, \quad \alpha\in g^* \tag{3}$$

be the co-adjoint action of g on g^*. For arbitrary $a,b\in g$ and $\alpha\in g^*$ the following relations hold:

$$\mathrm{ad}_a b=[a,b], \quad \langle \mathrm{ad}_a^*\alpha,b\rangle_g=-\langle \alpha,\mathrm{ad}_a b\rangle_g=-\langle \alpha,[a,b]\rangle_g, \tag{4}$$

where $[\cdot,\cdot]$ is a Lie bracket on g. The Lie bracket is:

(i) skew-symmetric

$$[a,b]=-[b,a] \tag{5}$$

and

(ii) satisfies the Jacobi identity

$$[[a,b],c]+[[c,a],b]+[[b,c],a]=0. \tag{6}$$

There exists a natural *Lie–Poisson bracket* on g^*, discovered by Lie[25] and rediscovered by Kirillov,[26] Kostant,[27] Souriau,[28] and Berezin.[29] Let $L\in g^*$, functions H_i, H_j belong to the space of functions on g^*: $\mathcal{D}(g^*)$, and their gradients ∇H_i, $\nabla H_j\in g$, then the Lie–Poisson bracket reads

$$\{H_i,H_j\}(L):=\langle L,[\nabla H_j,\nabla H_i]\rangle_g. \tag{7}$$

Consider next a dynamical system defined by

$$L_t=\{H,L\}. \tag{8}$$

So according to relations (4) and (7), a Hamiltonian dynamical system on g^* can be written down in the following form:

$$L_t=-\mathrm{ad}^*_{\nabla H}L=\Theta(L)\circ\nabla H, \quad L\in g^*, \quad \nabla H\in g, \tag{9}$$

where $\Theta(L): g\to g^*$ is a Poisson tensor.

We confine our further considerations to such algebras for which g^* can be identified with g. So, we assume the existence of an invariant metric, i.e., nondegenerate symmetric product on g,

$$(a,b)_g=(b,a)_g, \quad a,b\in g, \tag{10}$$

invariant under the adjoint action

$$(\mathrm{ad}_a b,c)_g+(b,\mathrm{ad}_a c)_g=0\Leftrightarrow([a,b],c)_g=(a,[b,c])_g, \quad a,b,c\in g. \tag{11}$$

In our particular realizations it will be a *trace form* $\mathrm{tr}: g\to\mathbb{R}$,

$$(a,b)_g=\mathrm{tr}(a\cdot b)=\mathrm{tr}(b\cdot a)=(b,a)_g, \tag{12}$$

where "$\cdot$" means some multiplication of the elements $a,b\in g$. For example, if g is a Lie algebra of shift operators (17), then, for $a=\Sigma_i a_i(n)\mathcal{E}^i$ and $b=\Sigma_j b_j(n)\mathcal{E}^j$ we have $a\cdot b=\Sigma_{i,j} a_i(n)b_j(n+i)\mathcal{E}^{i+j}$. For the PDO Lie algebra (21) if $a=\Sigma_i a_i(x)\partial_x^i$ and $b=\Sigma_j b_j(x)\partial_x^j$ we have $a\cdot b=\Sigma_{i,j} a_i(x)\partial_x^i b_j(x)\partial_x^j$, where $\partial_x^i b_j(x)\partial_x^j$ can be calculated using (22). Then, we can identify g^* with g, $(g^*\cong g)$ by setting

$$\langle \alpha,b\rangle_g=(a,b)_g, \quad a,b\in g, \alpha\in g^*, \tag{13}$$

where α is identified with $a\in g$. Thus, now we can write the Lie–Poisson bracket as

$$\begin{aligned}\{H_i,H_j\}(L)&=\langle L,[\nabla H_j,\nabla H_i]\rangle_g\\&=(L,[\nabla H_j,\nabla H_i])_g\\&=(\nabla H_j,[\nabla H_i,L])_g\equiv(\nabla H_j,\Theta(L)\circ\nabla H_i)_g,\end{aligned}\tag{14}$$

where ''$\circ$'' means an action of the Poisson operator on the gradient ∇H. Hence, equation of motion (9) takes the form

$$L_t=-\mathrm{ad}^*_{\nabla H}L=\Theta(L)\circ\nabla H=[\nabla H,L]=\mathrm{ad}_{\nabla H}L.\tag{15}$$

We notice that under the above-mentioned identification $g^*\cong g$, the co-adjoint action goes over into the minus adjoint one.

Now, we can identify the dynamic equation (15) and the Lax equation with a natural Hamiltonian structure

$$L_t=[A,L]=[\nabla H,L]=\Theta(L)\circ\nabla H.\tag{16}$$

This abstract approach to integrable systems profits with a deeper understanding of the nature of integrability as well as equips us with a very general and efficient tool for the construction of multi-Hamiltonian systems from a scratch. Working with the Lie algebra formalism we will apply it to the construction of finite field dynamical systems. We pick up the Lie algebra of shift operators of the form

$$g=\left\{L=\sum\nolimits_{i\ll\infty}u_i(n)\mathcal{E}^i\right\},\tag{17}$$

where $\mathcal{E}$ is a shift operator, which satisfies the simple commutation rule

$$\mathcal{E}^iu(n)=(E^iu(n))\mathcal{E}^i=u(n+i)\mathcal{E}^i,\tag{18}$$

E acts on $u(n)$ as a unit shift: $Eu(n):=u(n+1)$, $i\in\mathbb{Z}$ and $u(n)$ are discrete functions with space variable $n\in\mathbb{Z}$. For the Lie algebra g of shift operators (18) a *trace* form (12) takes the form

$$\mathrm{tr}(a)=\mathrm{tr}\left(\sum\nolimits_i a_i(n)\mathcal{E}^i\right)=\sum\nolimits_{-\infty}^{\infty}a_0(n).\tag{19}$$

The vector fields L_t and gradients ∇H are conveniently parametrized by

$$L_t=\sum\nolimits_{i<\infty}(u_i)_t\mathcal{E}^i,\quad \nabla H=\sum\nolimits_i\mathcal{E}^{-i}\frac{\delta H}{\delta u_i},\tag{20}$$

where $\delta H/\delta u_i$ is variational derivative of a functional $H=\Sigma_{n=-\infty}^{+\infty}h[u(n)]$ and $h[u(n)]:=h(u(n),u(n\pm1),u(n\pm2),\dots)$. The PDO Lie algebra is given by

$$g=\left\{L=\sum\nolimits_{i\ll\infty}u_i(x)\partial_x^i\right\},\tag{21}$$

where ∂_x^k acts on $a(x)$ according to the general Leibniz rule

$$\partial_x^ka=\sum\nolimits_{i\geqslant0}C_i^k(D_x^ia)\partial_x^{k-i},\tag{22}$$

where $D_x=\mathrm{ad}_{\partial_x}$, $D_xa=a_x$,

$$C_i^k=\left\{\begin{array}{ll}\binom{k}{i} & \text{for} \quad k\geqslant i\geqslant 0\\ 0 & \text{for} \quad i\geqslant k\geqslant 0 \ \text{ or } \ i<0\\ \binom{|k|+i-1}{i}(-1)^i & \text{for} \quad k<0, i\geqslant 0\end{array}\right\}$$

and

$$\binom{k}{i}=\frac{k!}{i!(k-i)!}.$$

Then the trace form of g (12) is

$$\mathrm{tr}(L)=\mathrm{tr}\left(\sum\nolimits_{i\ll\infty}u_i(x)\partial_x^i\right)=\int_{\mathbb{R}}\mathrm{res}\left(\sum\nolimits_{i\ll\infty}u_i(x)\partial_x^i\right)dx=\int_{\mathbb{R}}u_{-1}(x)dx, \tag{23}$$

and allows us to identify g^* with g. As a consequence, vector fields L_t and gradients ∇H are conveniently parametrized by

$$L_t=\sum\nolimits_{i\ll\infty}(u_i)_t\partial_x^i, \quad \nabla H(L)=\sum\nolimits_{i\ll\infty}\partial_x^{-1-i}\frac{\delta H}{\delta u_i}, \tag{24}$$

where $\delta H/\delta u_i$ is the usual variational derivative of the functional $H=\int_{\mathbb{R}}h[u(x)]dx$ and $h[u]$ $:=h(u, u_x, u_{xx}, \ldots)$. Both Lie algebras contain an infinite number of fields so, because we are interested in dynamical systems with finite number of fields, we have to reduce the Lie–Poisson bracket (14) onto a suitable submanifold $\overline{M}$. This procedure can be successfully done using the $\mathcal{R}$-matrix formalism.

Although all considerations in this paper are performed on the algebraic level, one has to pay much attention to the admissible classes of functions, i.e., such that the action of all constructed objects on them do make sense. At least in one space dimension it is obvious that the basic manifold M can be considered as a topological linear space of complex-valued, C^∞-functions f of a real variable $x\in\mathbb{R}$ such that $D^{-1}f$ is well defined and $\int_\Omega f\,dx<\infty$. In the case of lattice functions, the continuous space variable $x\in\mathbb{R}$ is replaced by a discrete integer variable $n\in\mathbb{Z}$. In such a case, we assume that the series $\Sigma_{n=-\infty}^{n=+\infty}f(n)$ must be absolutely convergent. In two space dimensions the situation is even more delicate as all equations are nonlocal, but the nonlocality is of a special form. For field systems, for example, operators D_x^{-1}, D_y^{-1} never appear alone but always in pairs $D_x^{-1}D_y$ or $D_y^{-1}D_x$. That is, the hierarchies of symmetries and conservation laws belong to a field of so-called quasilocal functions.[30] Of course M should be choosen as carefully as in the one-dimensional case.

Let us consider a nonlinear dynamical system

$$u_t=K[u] \tag{25}$$

on a Poisson manifold M, i.e., a manifold endowed with a Poisson structure, $u\in M$ is n-component field ($n\geqslant 1$), $K\in TM$ is a vector field from the tangent bundle of M. Let $\tilde{g}$ be an Abelian Lie algebra of Hamiltonian symmetries of (25). Then consider another Lie algebra g such that $\tilde{g}$ is isomorphic to its some subalgebra. So, for a given $\tilde{a}\in\tilde{g}$ we denote by a its counterpart from g. Finally, we assume the existence of some ''momentum mapping'' $L:M\to g^*$ such that

$$\begin{array}{ccc} M & \overset{L}{\rightarrow} & g^* \\ \phi^{\tilde{a}} \downarrow & & \downarrow \mathrm{ad}_a^* \\ M & \overset{L}{\rightarrow} & g^* \end{array}$$

is commuting for any $\tilde{a} \in \tilde{g}$. Here $\phi^{\tilde{a}}$ denotes a Hamiltonian Poisson action with infinitesimal generator $\tilde{a}$. Additionally we assume the existence of a trace form $\mathrm{tr}: g \to \mathbb{R}$ (12) allowing us to identify g^* with g. As a result of the above assumptions one can represent the Poisson structure on the manifold M as a standard reduction on M of the canonical Lie–Poisson structure on the $g^* \cong g$:

$$\{h_i, h_j\}(u) \equiv \{H_i, H_j\}(L) := (L, [\nabla H_j, \nabla H_i])_g, \tag{27}$$

where the functionals h_i, h_j belong to the functional space $\mathcal{D}(g)$. The main reason for such a construction is that *a priori* we do not know the explicit form of the dynamics (25) and the related Poisson structure. On the other hand, choosing an appropriate algebra g, we select the admissible maps L, and for each L first we construct a respective Hamiltonian subalgebra on g and then we reconstruct the related subalgebra $\tilde{g}$ on M. Hence, as regards the integrable Poissonian flows (25) on M, we intend to construct a hierarchy of Poisson commuting functionals $H_i := h_i \in \mathcal{D}(M)$, $i \in \mathbb{Z}_+$, which can be produced first on g via the standard $\mathcal{R}$-martix approach.[25,31]

We will consider a Casimir functional C of the Lie–Poisson bracket (27), satisfying

$$[\nabla C(L), L] = 0. \tag{28}$$

The role of the Casimir functionals in the $\mathcal{R}$-matrix formalism will be cleared in the following.

As we are interested in finite field dynamical systems, we have to construct an invariant with respect to ad-operation submanifold $\overline{M}$. Assume that the Lie algebra g admits a standard $\mathcal{R}$-structure, that is the new Lie bracket[32]

$$[a,b]_{\mathcal{R}} := [a, \mathcal{R}b] + [\mathcal{R}a, b] \tag{29}$$

defined by some linear homomorphism $\mathcal{R}: g \to g$. The $\mathrm{ad}^{\mathcal{R}}$-operation must be associative with respect to this bracket, i.e.,

$$\mathrm{ad}_a^{\mathcal{R}}[b,c]_{\mathcal{R}} = [\mathrm{ad}_a^{\mathcal{R}} b, c]_{\mathcal{R}} + [b, \mathrm{ad}_c^{\mathcal{R}}]_{\mathcal{R}}, \tag{30}$$

where now

$$\mathrm{ad}_a^{\mathcal{R}} b = [a,b]_{\mathcal{R}}, \tag{31}$$

or, in other words, the new Lie bracket must satisfy the Jacobi identity or sufficiently the following modified Yang–Baxter $[\mathrm{mYB}(q)]$ equation

$$[\mathcal{R}a, \mathcal{R}b] - \mathcal{R}([a,b]_{\mathcal{R}}) = -q[a,b] \tag{32}$$

for any $a, b \in g$ and constant q.[32]

Consider the following Poisson structures on the double Lie algebra $(\mathcal{R}, g)$:[33,7]

$$\{H_i, H_j\}_1(L) := (\nabla H_j, \Theta_1(L) \circ \nabla H_i)_g, \tag{33}$$

$$\{H_i, H_j\}_2(L) := (\nabla H_j, \Theta_2(L) \circ \nabla H_i)_g, \tag{34}$$

where $L \in g^* \simeq g$ is a Hill's type (scalar) Lax operator and the respective Poisson tensors are

$$\Theta_1(L)\circ\nabla H:=[\mathcal{R}\nabla H,L]+\mathcal{R}^*[\nabla H,L], \tag{35}$$

$$\Theta_2(L)\circ\nabla H:=A_1(L\nabla H)L-LA_2(\nabla HL)+S(\nabla HL)L-LS^*(L\nabla H), \tag{36}$$

where for the second Poisson structure

$$A_1+S=A_2+S^*=\mathcal{R}, \tag{37}$$

the linear maps $A_{1,2}:g\to g$ are skew-symmetric ($A_{1,2}^*=-A_{1,2}$) with respect to the trace duality and the linear map $S:g\to g$ with the adjoint S^* satisfies

$$\begin{gathered} S[A_2(a),b]+[a,A_2(b)]=[S(a),S(b)],\\ S^*[A_1(a),b]+[a,A_1(b)]=[S^*(a),S^*(b)],\quad a,b\in g. \end{gathered} \tag{38}$$

These are the most general, linear, and quadratic in L, Poisson tensors on g which are compatible as it is not difficult to check that $\Theta_2(L+\varepsilon\mathbf{1})=\Theta_2(L)+\varepsilon\Theta_1(L)$. We recall that two Poisson tensors are called compatible if their linear combination is also a Poisson tensor. The compatibility condition is needed for the construction of recursion operator and a hierarchy of commuting vector fields. The reader can find more detailed information in Ref. 24. Besides, one can verify that for solutions of Eq. (28): $\nabla H=\nabla C(L)$, we get

$$\begin{gathered} \Theta_1(L)\circ\nabla C=[\mathcal{R}\nabla C,L],\\ \Theta_2(L)\circ\nabla C=[\mathcal{R}(L\cdot\nabla C),L], \end{gathered} \tag{39}$$

which are in the form of Lie–Poisson bracket.

Theorem 1 (Ref. 31): *Given a set of Casimir functionals $C_i\in\mathcal{D}(g^*), i\in\mathbb{Z}_+$ solving Eq. (28), all the reduced on $\overline{M}$ functionals $C_i:=c_i[u]$ $u\in\overline{M}$ are in involution with respect to the Poisson brackets*

$$\{c_i,c_j\}_{\theta_s}(u)\equiv\{C_i,C_j\}_{\Theta_s}(L)=(\nabla C_j,\Theta_s(L)\circ\nabla C_i)_g=0,\quad s=1,2, \tag{40}$$

reduced from g^* on $\overline{M}$ according to the diagram (26), where $\Theta_s(L)$ are Poisson tensors on g^* and $\theta_s(u)$ are respective Poisson tensors on $\overline{M}$. Moreover the momentum mapping $L:M\to g^*$ and Hamiltonian functionals $C_i(L)$ satisfy the following evolution equations on $g^*\cong g$:

$$L_{t_i}=\mathrm{ad}_{\mathcal{R}(L^{s-1}\cdot\nabla C_i)}L=[\mathcal{R}(L^{s-1}\cdot\nabla C_i),L]=\Theta_s(L)\circ\nabla C_i,\quad s=1,2, \tag{41}$$

which is just a Lax representation of the dynamical system (25), i.e., $A=\mathcal{R}(L^{s-1}\cdot\nabla C_i)$.

To construct the simplest $\mathcal{R}$-structure let us assume that the Lie algebra g can be split into a direct sum of Lie subalgebras g_+ and g_-, i.e.,

$$g=g_+\oplus g_-,\ [g_\pm,g_\pm]\subset g_\pm. \tag{42}$$

Denoting the projections onto these subalgebras by $P_\pm$: $P_\pm g:=g_\pm$, it is easy to verify that

$$\mathcal{R}=\tfrac{1}{2}(P_+-P_-) \tag{43}$$

solves the mYB($\frac{1}{4}$) and hence defines an $\mathcal{R}$-structure on g. For both Lie algebras considered:

$$\mathcal{R}=\tfrac{1}{2}(P_{\geqslant k}-P_{<k}), \tag{44}$$

where for the Lie algebra of shift operators

$$P_{\geqslant k}g := g_{\geqslant k} = \sum_{i\geqslant k} u_i(n)\mathcal{E}^i, \quad P_{<k}g := g_{<k} = \sum_{i<k} u_i(n)\mathcal{E}^i,$$
$$P^*_{\geqslant k} = P_{\leqslant -k}, \quad P^*_{<k} = P_{>-k}, \quad k = 0,1. \tag{45}$$

and for the PDO Lie algebra

$$P_{\geqslant k}g = g_{\geqslant k} = \left\{\sum_{i\geqslant k}(u_i)\partial_x^i\right\}, \quad P_{<k}g = g_{<k} = \left\{\sum_{i<k}(u_i)\partial_x^i\right\},$$
$$P^*_{\geqslant k} = P_{<-k}, \quad P^*_{<k} = P_{\geqslant -k}, \quad k = 0,1,2. \tag{46}$$

Notice that from (28) and the fact that $P_{\geqslant k} + P_{<k} = 1$ we have

$$[\mathcal{R}(L^{s-1}\cdot\nabla C_i), L] = [P_{\geqslant k}(L^{s-1}\cdot\nabla C_i), L], \quad s = 1,2. \tag{47}$$

Thus, the introduction of an $\mathcal{R}$-matrix on g turns the algebra into a Hamiltonian phase space. With the results of this section we have demonstrated that the $\mathcal{R}$-matrix approach is a powerful tool for constructing multi-Hamiltonian formulation (41) of dynamical systems in $(1+1)$ dimensions. The details of multi-Hamiltonian dynamics in the case $k=0$ for the Lie algebra of shift operators (17) and in the case $k=0,1$ for the PDO Lie algebra (21) the reader can find in literature (see, e.g., Refs. 7, 24, 31, 34–36). Here we will use this formalism in further considerations, i.e., for the construction of $(2+1)$ dimensional dynamics.

III. CENTRAL EXTENSION APPROACH

Assume now that the Lie algebra g (PDO or shift operators) depends effectively on an independent parameter $y \in S^1$, which naturally generates the corresponding current operator Lie algebra $C(g) = C^\infty(S^1; g)$ with the following modified Tr-operation:

$$\mathrm{Tr}\, a := \int_{S^1} \mathrm{tr}(a)\, dy, \tag{48}$$

where tr operation is defined by (19) for the Lie algebra of shift operators and by (23) for the PDO Lie algebra. The scalar product reads

$$(a,b)_{C(g)} := \mathrm{Tr}(a\cdot b) \tag{49}$$

for a and $b \in C(g)$. The current Lie algebra $C(g)$ can be naturally extended via the central extension procedure: $C(g) \to \overline{C}(g) = C(g) \oplus \mathbf{C}$ with the following Lie product:

$$[(a,\alpha),(b,\beta)] := ([a,b], \omega_2(a,b)), \tag{50}$$

where $\alpha,\beta \in \mathbf{C}$ and $\omega_2 : C(g)\times C(g) \to \mathbf{C}$ is the standard Maurer-Cartan two-cocycle on $C(g)$:

$$\omega_2(a,b) := \int_{S^1} dy\,(a, D_y b)_g = \mathrm{Tr}\left(a\cdot\frac{db}{dy}\right), \quad a,b \in C(g). \tag{51}$$

The appropriate momentum map:

$$\overline{L} : M \to \overline{C}(g^*) \tag{52}$$

is associated with the corresponding current Lie algebra action of $\overline{C}(g)$ on M.

Let us repeat the $\mathcal{R}$-matrix approach for the current Lie algebra $\overline{C}(g)$.

Casimir functionals $C \in \mathcal{D}(\overline{C}(g))$ satisfy now the so-called Novikov–Lax equation

$$[\nabla C,L]+D_y\nabla C=0, \tag{53}$$

for all $\overline{L}:=(L,1)\in\overline{C}(g^*)\cong\overline{C}(g)$. The $\mathcal{R}$-structure $\overline{\mathcal{R}}\in\mathrm{Hom}(\overline{C}(g))$ is defined as follows:

$$[(a,\alpha),(b,\beta)]_{\overline{\mathcal{R}}}:=([a,b]_{\mathcal{R}},\omega_2^{\mathcal{R}}(a,b)), \tag{54}$$

where $\omega_2^{\mathcal{R}}(a,b):=\omega_2(\mathcal{R}\,a,b)+\omega_2(a,\mathcal{R}b)$.

Theorem 2 (Ref. 17): *Given a set of Casimir functionals $C_i\in\mathcal{D}(\overline{C}(g))$ solving Eq. (53), all the reduced on M functionals $C_i:=c_i(u)$, $u\in\overline{M}$, are in involution with respect to the Poisson bracket*

$$\begin{aligned}\{c_i,c_j\}(u)&\equiv\{C_i,C_j\}_{\overline{\mathcal{R}}}(L)\\&=(L,[\nabla C_j,\nabla C_i]_{\mathcal{R}})_{C(g)}+\omega_2^{\mathcal{R}}(\nabla C_i,\nabla C_j) \qquad (55)\\&=(\nabla C_j,\Theta_1(L)\circ\nabla C_i)_{C(g)}+\omega_2^{\mathcal{R}}(\nabla C_i,\nabla C_j)=0 \qquad (56)\end{aligned}$$

reduced from $\overline{C}(g)$ on M with respect to the diagram (26). Moreover, the momentum map $\overline{L}:M\to\overline{C}(g)$ and Casimir functionals C_i, satisfy the following hierarchy of evolution equations:

$$\begin{aligned}L_{t_i}&=[\mathcal{R}\nabla C_i,L]+D_y(\mathcal{R}\nabla C_i)\\&=(\Theta_1(L)+D_y\mathcal{R})\circ\nabla C_i\\&=[\mathcal{R}\nabla C_i,L-\partial_y]:=\Theta_1(L,\partial_y)\circ\nabla C_i,\quad i\in\mathbb{Z}.\end{aligned} \tag{57}$$

The quadratic structure $\Theta_2(L,\partial_y)=\Theta_2(L)+D_y\mathcal{R}$ does not survive the central extension as it fails the property of Jacobi identity. Thus, the second Poisson structure should be essentially modified. We use in the last part of this article the so-called operand approach to derive the second Poisson structures of $(2+1)$-dimensional systems in a generalized sense. In the following section we illustrate the cental extension approach for Lie algebra of shift operators and for the PDO Lie algebra.

A. Extended Lie algebra of shift operators

Here we will consider the central extension for the Lie algebra of shift operators.[23] The restricted finite field Lax operator reads

$$k=0:L=\mathcal{E}^{n+\alpha}+u_{n+\alpha-1}\mathcal{E}^{n+\alpha-1}+\cdots+u_\alpha\mathcal{E}^\alpha,\quad -n<\alpha\leqslant 0, \tag{58}$$

and the case $\alpha=0$ is also included. Lax dynamics for $\alpha=0$ are purely $(2+1)$-dimensional effect and they cannot be reduced onto $(1+1)$-dimensional space.

The Poisson structure (57) linear with respect to the restricted Lax operator (58), related to $\mathcal{R}=\frac{1}{2}(P_{\geqslant 0}-P_{<0})$ and the relations (45), follows from the centrally extended $(L\to L-\partial_y)$ linear Poisson structure $\Theta_1(L)$ (35) for $(1+1)$-lattice systems:[23]

$$\begin{aligned}L_t&=\Theta_1(L,\partial_y)\circ\nabla H\\&=[\mathcal{R}\nabla H,L-\partial_y]+\mathcal{R}^*[\nabla H,L-\partial_y]\\&=-\mathrm{ad}_L(\nabla H)_{\geqslant 0}+(\mathrm{ad}_L\nabla H)_{>0}-(D_y\nabla H)_{>0}+D_y(\nabla H)_{\geqslant 0},\end{aligned} \tag{59}$$

when substitute $H\equiv C$ with the condition $[\nabla C,L-\partial_y]=0$ (53). On the other hand, from the relation $P_{\geqslant 0}+P_{<0}=1$ the hierarchy (57) takes the form

$$L_{t_i}=[P_{\geqslant 0}\nabla C_i,L-\partial_y]. \tag{60}$$

Equation (53) for Casimir functionals can be solved putting

$$\nabla C_i(L) := \sum_{j \leqslant i} a_j \mathcal{E}^j, \quad i = 1,2,\ldots, \tag{61}$$

where the function parameters a_j are obtained from (53) succesively via the recurrent procedure. Notice that although the solutions (61) are in the form of infinite series, in fact we need only their finite parts $P_{\geqslant 0}\nabla C_i$. In the following we present $(2+1)$-dimensional generalizations of some known lattice systems as well as some new examples of lattice-field systems.

Examples. We illustrate in detail the presented formalism on the first example.

(1) The lattice-field Benjamin–Ono equation: $n=1, \alpha = 0$.

This case does not exist in the one-dimensional lattice case. The Lax operator has the form[14,37]

$$L = \mathcal{E} + u. \tag{62}$$

Using (20) for the above Lax operator we get

$$\nabla H = \frac{\delta H}{\delta u} \tag{63}$$

and substituting it in (59) we get the Poisson tensor for this system in the form

$$\theta_1 = D_y. \tag{64}$$

To construct a hierarchy of vector fields we use (61) for $i = 1,2,3,\ldots$ and find

$$\begin{aligned} P_{\geqslant 0}\nabla C_1 &= \mathcal{E} + u, \\ P_{\geqslant 0}\nabla C_2 &= \mathcal{E}^2 + [u(n+1) + u(n)]\mathcal{E} + u^2(n) + \mathcal{H}u(n)_y, \\ P_{\geqslant 0}\nabla C_3 &= \mathcal{E}^3 + [u(n+2) + u(n+1) + u(n)]\mathcal{E}^2 \\ &\quad \times [u^2(n+1) + u(n+1)u(n) + u^2(n) + \tfrac{1}{4}(E-1)(u(n)_y + 3\mathcal{H}^2 u(n)_y)]\mathcal{E} \\ &\quad + \tfrac{1}{4}u(n)_{yy} + u(n)^3 + \tfrac{2}{4}\mathcal{H}u(n)u(n)_y + \tfrac{2}{3}u(n)\mathcal{H}u(n)_y + \tfrac{3}{4}\mathcal{H}^2 u(n)_{yy}, \ldots. \end{aligned} \tag{65}$$

Then, substituting the results to Eq. (60), we get the first equations of the hierarchy

$$\begin{aligned} u(n)_{t_1} &= u_y, \\ u(n)_{t_2} &= 2uu_y + \mathcal{H}u_{yy}, \\ u(n)_{t_3} &= \tfrac{1}{4}u_{yyy} + 3u^2 u_y + \tfrac{3}{2}\mathcal{H}(uu_y)_y + \tfrac{3}{2}(u\mathcal{H}u_y)_y + \tfrac{3}{4}\mathcal{H}^2 u_{yyy}, \\ &\vdots, \end{aligned} \tag{66}$$

where $\mathcal{H} = (E+1)/(E-1)$.

(2) The lattice-field Toda equation: $n=2, \alpha = 1$.

The Lax operator takes the form[23]

$$L = \mathcal{E} + p + v\mathcal{E}^{-1}. \tag{67}$$

Poisson tensor for the lattice-field Toda equation is given by

$$\theta_1=\begin{pmatrix} 0 & v(1-E^{-1}) \\ (E-1)v & D_y \end{pmatrix} \tag{68}$$

and the first equations from the hierarchy read:

$$\begin{pmatrix} v(n) \\ p(n) \end{pmatrix}_{t_1}=\begin{pmatrix} v(n)[p(n)-p(n-1)] \\ v(n+1)-v(n)+p(n)_y \end{pmatrix},$$

$$\begin{aligned} v(n)_{t_2}&=v(n)[p^2(n)-p^2(n-1)+v(n+1)-v(n-1)+p(n)_y+p(n-1)_y], \\ p(n)_{t_2}&=v(n+1)[p(n+1)+p(n)]-v(n)[p(n-1)+p(n)]+v(n)_y \\ &\quad +v(n+1)_y+\mathcal{H}p(n)_{yy}+2p(n)p(n)_y, \\ &\vdots . \end{aligned} \tag{69}$$

The first equation from this hierarchy was derived for the first time in a different representation by Mikhailov[38,39] and in the Lagrange form was given in Ref. 40. Here we present a Hamiltonian representation of the $(2+1)$-dimensional Toda equation and its hierarchy.

(3) The case: $n=2,\alpha=0$.

This case does not exist in the one-dimensional lattice. The Lax operator takes the form

$$L=\mathcal{E}^2+u\mathcal{E}+w. \tag{70}$$

The Poisson tensor for this case is given by

$$\theta_1=\begin{pmatrix} D_y & 0 \\ 0 & E-E^{-1} \end{pmatrix} \tag{71}$$

and the first equation from the hierarchy is

$$\begin{pmatrix} u(n) \\ w(n) \end{pmatrix}_{t_1}=\begin{pmatrix} u(n)\mathcal{H}^{-1}u(n)-w(n+1)+w(n) \\ -(E+1)^{-1}u(n)_y \end{pmatrix},\ldots . \tag{72}$$

Notice that eliminating the w variables we get

$$u(n)_{tt}=\mathcal{H}^{-1}u_y+(u\mathcal{H}^{-1}u)_t \tag{73}$$

and then interchanging the variables $y\leftrightarrow t$ and putting $\mathcal{H}^{-1}u:=v$,

$$v(n)_t=\mathcal{H}v_{yy}-(v\mathcal{H}v)_y. \tag{74}$$

This is the lattice-field equation unknown so far (at least to the knowledge of the authors).

(4) The case: $n=3,\alpha=-1$.

The Lax operator takes the form

$$L=\mathcal{E}^2+p\mathcal{E}+v+u\mathcal{E}^{-1}. \tag{75}$$

The Poisson tensor for this case is given by

$$\theta_1=\begin{pmatrix} 0 & u(1-E^{-1}) & 0 \\ (E-1)u & D_y & 0 \\ 0 & 0 & E-E^{-1} \end{pmatrix} \tag{76}$$

and the first equations from the hierarchy read

$$\begin{pmatrix} u(n) \\ v(n) \\ p(n) \end{pmatrix}_{t_1} = \begin{pmatrix} u(n)\mathcal{H}^{-1}p(n-1) \\ u(n+1)-u(n)+(E+1)^{-1}p(n)_y \\ v(n+1)-v(n)-p(n)\mathcal{H}^{-1}p(n) \end{pmatrix},$$

$$\begin{pmatrix} u(n) \\ v(n) \\ p(n) \end{pmatrix}_{t_2} = \begin{pmatrix} u(n)[v(n)-v(n-1)] \\ p(n)u(n+1)-p(n-1)u(n)+v(n)_y \\ u(n+2)-u(n)+p(n)_y \end{pmatrix}, \tag{77}$$

$$\vdots .$$

This is the lattice-field hierarchy unknown so far.

B. Extended PDO Lie algebra

The Poisson bracket on the extended current PDO Lie algebra admits only a linear Poisson structure related to

$$\mathcal{R}=\tfrac{1}{2}(P_{\geqslant k}-P_{<k}), \quad k=0,1. \tag{78}$$

The new Poisson structure coming from (46) and (35) is

$$\begin{aligned} L_t &= \Theta_1(L,\partial_y)\circ\nabla H \\ &= [\mathcal{R}\nabla H, L-\partial_y]+\mathcal{R}^*[\nabla H, L-\partial_y] \\ &= -\mathrm{ad}_L(\nabla H)_{\geqslant k}+(\mathrm{ad}_L\nabla H)_{>-k}-(D_y\nabla H)_{>-k}+D_y(\nabla H)_{\geqslant k}. \end{aligned} \tag{79}$$

The quadratic structure, as was mentioned earlier, does not survive the central extension as it fails the property of the Jacobi identity. Again Eq. (53) for Casimir functionals can be solved putting

$$\nabla C_i(L) := \sum_{j\leqslant i} a_j\partial_x^j, \quad i=1,2,\ldots, \tag{80}$$

where the function parameters a_j are obtained from (53) successively via the recurrent procedure. Here we will use restricted Lax operators,

$$k=0: L=\partial_x^N+u_{N-2}\partial_x^{N-2}+\ldots+u_1\partial_x^1+u_0, \tag{81}$$

$$k=1: L=\partial_x^N+u_{N-1}\partial_x^{N-1}+\cdots+u_0+\partial_x^{-1}u_{-1}. \tag{82}$$

Here again the choice $H\equiv C$ leads from Eq. (79) to Eq. (57) and finally to the form

$$L_{t_i}=[P_{\geqslant k}\nabla C_i, L-\partial_y] \tag{83}$$

as $P_{\geqslant k}+P_{<k}=1$ and hence $\mathcal{R}=P_{\geqslant k}-\frac{1}{2}$. We will ilustrate this formalism in a few examples.

Examples. We illustrate the above formalism for the PDO Lie algebra on the first example.

(1) The KP equation: $k=0, N=2$.

The KP equation is a $(2+1)$-dimensional extension of the KdV equation. The Lax operator for the KP equation has the form[17,37]

$$L=\partial_x^2+u. \tag{84}$$

Using (24) for this Lax operator we get

$$\nabla H=\partial_x^{-1}\frac{\delta H}{\delta u} \tag{85}$$

and subsituting this gradient and the Lax operator in (79) we derive the Poisson tensor for the KP equation

$$\theta_1=2D_x. \tag{86}$$

Applying formula (80) for $i=1,2,3,\ldots$, etc., and subsituting the respective projections of gradients $P_{\geqslant 0}\nabla C_i$ into (83), we derive the KP hierarchy

$$\begin{aligned}
u_{t_1}&=u_x,\\
u_{t_2}&=u_y,\\
u_{t_3}&=u_{xxx}+6uu_x+3D_x^{-1}u_{yy},\\
u_{t_4}&=u_{xxy}+4uu_y+2u_xD_x^{-1}u_y+D_x^{-2}u_{yyy},\\
u_{t_5}&=u_{5x}+10uu_{xxx}+20u_xu_{xx}+30u^2u_x+10u_{xyy}+10u_xD_x^{-2}u_{yy}\\
&\quad+D_x^{-1}(5D_x^{-2}u_{4y}+30u_y^2+30uu_{yy}+20u_{xy}D_x^{-1}u_y+20u_xD_x^{-1}u_{yy}),\\
&\vdots.
\end{aligned} \tag{87}$$

(2) The $(2+1)$*-Boussinesq equation:* $k=0, N=3$.
The Lax operator is given by[23]

$$L=\partial_x^3+u\partial_x+v. \tag{88}$$

Poisson tensor for the Boussinesq equation takes the form

$$\theta_1=\begin{pmatrix}0 & 3D_x\\ 3D_x & 0\end{pmatrix}. \tag{89}$$

Applying formulas (80) and (83) we get the hierarchy

$$\begin{aligned}
\begin{pmatrix}u\\ v\end{pmatrix}_{t_1}&=\begin{pmatrix}u_x\\ v_x\end{pmatrix},\\
\begin{pmatrix}u\\ v\end{pmatrix}_{t_2}&=\begin{pmatrix}u_{2x}-2v_x\\ \frac{2}{3}(u_{3x}+uu_x-u_y)-v_{xx}\end{pmatrix}.
\end{aligned} \tag{90}$$

Elliminating the field v from this equation we can derive the $(2+1)$-dimensional Boussinesq equation

$$u_{tt}=-\tfrac{1}{3}u_{4x}-\tfrac{2}{3}(u^2)_{xx}-\tfrac{4}{3}u_{xy}. \tag{91}$$

This equation coincides with the KP equation after the replacement $t\leftrightarrow y$,

$$\begin{pmatrix} u \\ v \end{pmatrix}_{t_3} = \begin{pmatrix} u_y \\ v_y \end{pmatrix}, \tag{92}$$

$$u_{t_4} = 2v_{xxx} + 4(uv)_x - u_{4x} - (u^2)_{xx} - 2u_{xy} + 4v_y,$$

$$v_{t_4} = v_{4x} + 2uv_{xx} + 2(v_2)_x - 2v_{xy} + 2u_x v_x - \tfrac{2}{3}(u_{5x} + 3uu_{xxx} + 6u_x u_{xx} + 2u^2 u_x) + \tfrac{4}{3} D_x^{-1} u_{yy} - \tfrac{2}{3} u_{xxy},$$

$$u_{t_5} = u_{5x} + 5(uu_{xx})_x + 5u^2 u_x + 5(u_x v)_x - 10vv_x + 5u_{xxy} + 5uu_y + 5u_x D_x^{-1} u_y - 5D_x^{-1} u_{yy},$$

$$v_{t_5} = v_{5x} + 5(uv)_{xxx} + 5(u_{xx} v)_x + 5(u^2 v)_x - 5(v^2)_{xx} + 5v_{xxy} + 10u_y v + 5uv_y + 5v_x D_x^{-1} u_y - 5D_x^{-1} v_{yy},$$

$$u_{t_6} = 6u_{3xy} + 4v_{xxy} - 6uu_{xy} + 4uv_y + 6u_y v - 5u_{yy} - 2D_x^{-1} v_{yy} - 2u_{xx} D_x^{-1} u_y + 4v_x D_x^{-1} u_y + 2u_x D_x^{-1} v_y,$$

$$v_{t_6} = 8u_{4xy} + 6v_{3xy} + 4uu_{xxy} + 8u_{xyy} - 12(u_x u_y)_x - 4u^2 u_y + 6uv_{xy} + 24u_y v_x + 18vv_y - 3v_{yy} - 4u_{xxx} D_x^{-1} u_y - 4uu_x D_x^{-1} u_y + 6v_{xx} D_x^{-1} u_y + 6v_x D_x^{-1} v_y - 4(uD_x^{-1} u_y)_y,$$

$$\vdots.$$

3 The case: $k=0,\ N=4$.
The Lax operator is

$$L = \partial_x^4 + u\partial_x^2 + v\partial_x + w. \tag{93}$$

The Poisson tensor is given by

$$\theta_1 = \begin{pmatrix} 0 & 0 & 4D_x \\ 0 & 4D_x & 2D_x^2 \\ 4D_x & -2D_x^2 & 2D_x^3 + uD_x + D_x u \end{pmatrix}. \tag{94}$$

Applying formulas (80) and (83) we get the hierarchy of commuting vector fields

$$\begin{pmatrix} u \\ v \\ w \end{pmatrix}_{t_1} = \begin{pmatrix} u_x \\ v_x \\ w_x \end{pmatrix},$$

$$\begin{pmatrix} u \\ v \\ w \end{pmatrix}_{t_2} = \begin{pmatrix} -2u_{xx}+2v_x \\ 2w_x+v_{xx}-2u_{xxx}-uu_x \\ w_{xx}-\frac{1}{2}(u_{4x}+uu_{xx}+vu_x+u_y) \end{pmatrix},$$

$$\begin{aligned} u_{t_3} &= 2u_{5x}-20v_{4x}+40w_{xxx}+40(uw)_x-40u_{xx}v-20uv_{xx} \\ &\quad +20(v_x)^2-45u_xv_x-10uu_{xxx}-15u^2u_x+32u_{xy}-40v_y, \end{aligned}$$

$$\begin{aligned} v_{t_3} &= 10u_{6x}-28v_{5x}+40w_{4x}+40(vw)_x-40uv_{xxx}+40(uw_x)_x \\ &\quad -100u_xv_{xx}-110u_{xx}v_x+5(u^2)_{4x}-15(u^2v)_x-20v_{xy}-40w_y+30u_{xxy}+10uu_y, \\ w_{t_3} &= 5u_{7x}-12v_{6x}+12w_{5x}+20(w_x)^2+20v_xw_x+20vw_{xx} \\ &\quad +20uw_{xxx}+12u_xw_{xx}+5uu_{5x}+5(uu_x)_{4x}-10(uv)_{4x} \\ &\quad +5u^2w_x-10u(uv)_{xx}+5v(uu_x)_x-10v(uv)_x+5u(uu_x)_{xx} \\ &\quad +2u_{xx}w_x-20w_{xy}+15u_{3xy}-10v_{xxy}+10D_x^{-1}u_{yy}+15uu_{xy}+5u_xu_y-10uv_y, \\ &\vdots . \end{aligned} \tag{95}$$

(4). The case: $k=1, N=0$.

This case does not exist in $(1+1)$-dimensions. The Lax operator reads[23]

$$L=u+\partial_x^{-1}w. \tag{96}$$

For this Lax operator we get the Poisson tensor

$$\theta_1=\begin{pmatrix} 0 & -D_y \\ -D_y & 0 \end{pmatrix} \tag{97}$$

and applying formulas (80) and (83) we find the hierarchy

$$\begin{pmatrix} u \\ w \end{pmatrix}_{t_1} = \begin{pmatrix} u_x \\ w_x \end{pmatrix},$$

$$\begin{pmatrix} u \\ w \end{pmatrix}_{t_2} = \begin{pmatrix} u_{xx}+2w_x-2u_xD_y^{-1}u_x \\ -w_{xx}-2(wD_y^{-1}u_x)_x \end{pmatrix},$$

$$\begin{aligned} u_{t_3} &= u_{xxx}-3(u_xD_y^{-1}u_x)_x-3u_xD_y^{-1}w_x-3(wD_y^{-1}u_x)_x-3w_xD_y^{-1}u_x \\ &\quad +6u_xD_y^{-1}u_xD_y^{-1}u_x, \\ w_{t_3} &= w_{xxx}+3(w_xD_y^{-1}u_x)_x-3(wD_y^{-1}w_x)_x+6(wD_y^{-1}u_xD_y^{-1}u_x)_x, \\ &\vdots . \end{aligned} \tag{98}$$

(5). The case: $k=1, N=2$.
The Lax operator has the form

$$L=\partial_x^2+u\partial_x+v+\partial_x^{-1}w. \tag{99}$$

For this Lax operator we get the Poisson tensor

$$\theta_1=\begin{pmatrix} 0 & 0 & 2D_x \\ 0 & 2D_x & D_x^2-D_y+uD_x \\ 2D_x & -D_x^2-D_y+D_xu & 0 \end{pmatrix} \tag{100}$$

and applying formulas (80) and (83) we find the hierarchy

$$\begin{pmatrix} u \\ v \\ w \end{pmatrix}_{t_1}=\begin{pmatrix} u_x \\ v_x \\ w_x \end{pmatrix},$$

$$\begin{pmatrix} u \\ v \\ w \end{pmatrix}_{t_2}=\begin{pmatrix} 2v_x+u_y \\ 2w_x+v_{xx}+uv_x \\ -w_{xx}+(wu)_x \end{pmatrix},$$

$$\begin{aligned} u_{t_3}&=u_{xxx}-\tfrac{3}{2}u^2u_x+6(uv)_x+6v_{xx}+12w_x+6v_y+3D_x^{-1}u_{yy}\\ &\quad+3u_xD_x^{-1}u_y,\\ v_{t_3}&=v_{xxx}+\tfrac{3}{2}(wu)_x+\tfrac{3}{2}uv_{xx}+\tfrac{3}{2}uw_x+\tfrac{3}{4}u_xv_x+\tfrac{3}{2}vv_x+\tfrac{3}{8}u^2v_x\\ &\quad+\tfrac{3}{4}v_xD_x^{-1}u_y,\\ w_{t_3}&=w_{xxx}-\tfrac{3}{2}(wu)_{xx}+\tfrac{3}{4}(wu_x)_x+\tfrac{3}{2}(wv)_x+\tfrac{3}{8}(u^2w)_x+\tfrac{3}{4}wu_y\\ &\quad+\tfrac{3}{4}w_xD_x^{-1}u_y,\\ &\vdots. \end{aligned} \tag{101}$$

The reduction $v=w=0$ gives the mKP equation

$$u_{t_3}=u_{xxx}-\tfrac{3}{2}u^2u_x+3D_x^{-1}u_{yy}+3u_xD_x^{-1}u_y. \tag{102}$$

The Poisson tensor (100) after the Dirac reduction procedure takes the form

$$\theta_1=8(D_x-D_yD_x^{-1}+u)^{-1}D_x(u-D_x-D_x^{-1}D_y)^{-1} \tag{103}$$

and the respective symplectic operator

$$J=\theta_1^{-1}=\tfrac{1}{8}(u-D_x-D_x^{-1}D_y)D_x^{-1}(D_x-D_yD_x^{-1}+u). \tag{104}$$

IV. THE OPERAND APPROACH

In this section we implement the ideas of Magri–Morosi–Tondo[13,14] and Athorne–Dorfman–Fokas[11,15,16] of the so-called *operand approach* in the frames of the $\mathcal{R}$-matrix formalism. This gives us a powerful tool for the construction of multi-Hamiltonian bilocal for-

malism of integrable systems in $(2+1)$-dimensions.

The basic idea of the operand approach is the assumption that the element u satisfies the condition: $u \equiv \hat{u} \in \hat{M} \subset C^{(\infty)}(\mathbb{Z} \times (\mathbb{R}/2\pi\mathbb{Z}); \mathcal{B})$ with $\mathcal{B}$ being some associative algebra, for instance, the algebra of pseudodifferential operators. Thus, we pass from field variables to operator variables. All considerations for the $(1+1)$-dimensional case can be extended over the operator level with the only modification related to noncommutativity of $\hat{u}$ elements. As $\hat{M}$ is some operator manifold, we produce bi-Hamiltonian operator vector fields with two Poisson operands (operators acting in the space of operators).

To compare the results with the central extension approach let us consider the following case:

$$\hat{L} = \sum_{i \leqslant \infty} \hat{u}_i \mathcal{T}^i, \quad \mathcal{T} = \{\mathcal{E} \text{ or } \partial_x\}, \quad \hat{u}_i = u_i \ \ i \neq 0, \quad \hat{u}_0 = u_0 - \partial_y, \tag{105}$$

where the operator ∂_y is such that $\mathrm{ad}_{\partial_y} = D_y$, so we have $\hat{L} = L - \partial_y$. On the operator-field Lie algebra $\hat{g}$ we define an invariant nondegenerate scalar product

$$(\hat{a}, \hat{b})_{\hat{g}} = (\hat{b}, \hat{a}) = \mathrm{Tr}(\hat{a} \cdot \hat{b}) = \int_{-\infty}^{+\infty} \int_0^{2\pi} \hat{\mathrm{Sp}}(\hat{a} \cdot \hat{b}) dx\, dy, \quad \hat{a}, \hat{b} \in \hat{g}, \tag{106}$$

where $\hat{\mathrm{Sp}}(\hat{a} \cdot \hat{b} \cdot \hat{c}) := \mathrm{tr}(\hat{a} \cdot \hat{b} \cdot \hat{c})$, and $\hat{\mathrm{Sp}}(\hat{a} \cdot \hat{b} \cdot \hat{c}) = \hat{\mathrm{Sp}}(\hat{c} \cdot \hat{a} \cdot \hat{b}) = \hat{\mathrm{Sp}}(\hat{b} \cdot \hat{c} \cdot \hat{a})$ for any $\hat{a}, \hat{b}, \hat{c} \in \hat{g}$. The bi-Hamiltonian formalism on $\hat{M}$ produces, of course, hierarchies of commuting operator vector fields $\hat{K}[\hat{u}]$, i.e., the vector fields which are polynomials in ∂_y operator

$$\hat{K}[\hat{u}] = \sum\nolimits_{i \geqslant 0} K_i[u] \partial_y^i. \tag{107}$$

What we have to do, is to find through appropriate linear combinations, ∂_y-free vector fields, i.e., ''physical'' objects.

Here we show how to calculate gradients of operator Hamiltonians and commutator of two vector operator fields in the PDO case. Let

$$\hat{H}[\hat{u}] = \int_{-\infty}^{+\infty} \hat{h}[\hat{u}] dx = \int_{-\infty}^{+\infty} (\hat{u}^2 - (\hat{u}_x)^2) dx \tag{108}$$

and take a realization of the field $\hat{u}$ in terms of ∂_y in the form

$$\hat{u} = u + \partial_y, \tag{109}$$

where now

$$\begin{aligned}
\hat{H}[u, \partial_y] &= \int_{-\infty}^{+\infty} \int_0^{2\pi} ((u + \partial_y)^2 - (u_x)^2) dx\, dy \\
&= \int_{-\infty}^{+\infty} \int_0^{2\pi} (u^2 + u_y + 2u\partial_y + \partial_y^2 - (u_x)^2) dx\, dy \\
&= \int_{-\infty}^{+\infty} \int_0^{2\pi} (u^2 + u_y - (u_x)^2) dx\, dy + \left\{ \int_{-\infty}^{+\infty} \int_0^{2\pi} 2u\, dx\, dy \right\} \partial_y \\
&\quad + \left\{ \int_{-\infty}^{+\infty} \int_0^{2\pi} 1\, dx\, dy \right\} \partial_y^2.
\end{aligned} \tag{110}$$

The gradient of $\hat{H}[u, \partial_y]$ is given by

$$\delta\hat{H}[u,\partial_y]=\langle\nabla\hat{h}[u,\partial_y],\delta u\rangle, \tag{111}$$

$$\nabla\hat{H}[u,\partial_y]=2u+2u_{xx}+2\partial_y, \tag{112}$$

where $\langle .,. \rangle$ is a dual map on $\hat{M}$.

Let us take two vector operator fields,

$$\hat{K}_1[\hat{u}]=\hat{u}, \quad \hat{K}_2[\hat{u}]=\hat{u}\hat{u}_x \tag{113}$$

which are presented using the realization (109) in the form

$$\hat{K}_1[\hat{u}]=u+\partial_y, \quad \hat{K}_2[\hat{u}]=(u+\partial_y)u_x=uu_x+u_{xy}+u_x\partial_y$$

and their commutator

$$[\hat{K}_1[\hat{u}],\hat{K}_2[\hat{u}]]=\hat{K}_1'[\hat{u}][\hat{K}_2[\hat{u}]]-\hat{K}_2'[\hat{u}][\hat{K}_1[\hat{u}]], \tag{114}$$

where ''prim'' means a Frechet derivative which is calculated in the following way:

$$\hat{K}'[\hat{u}][\hat{V}]=\left(\sum\nolimits_{i\geqslant 0} K_i'[u]\partial_y^i\right)[\hat{V}]=\sum\nolimits_{i\geqslant 0} K_i'[u][\hat{V}]\partial_y^i=\sum\nolimits_{i\geqslant 0}\lim_{\varepsilon\to 0}\frac{dK_i[u+\epsilon\hat{V}]}{d\epsilon}\partial_y^i.$$

Calculating the commutator (114) we get

$$\begin{aligned}[\hat{K}_1[\hat{u}],\hat{K}_2[\hat{u}]]&=1\cdot[uu_x+u_{xy}+u_x\partial_y]\\&\quad-(u_x+uD_x+D_xD_y)[u+\partial_y]+D_x[u+\partial_y]\partial_y\\&=-uu_x-u_{xy}-u_x\partial_y.\end{aligned} \tag{115}$$

In a similar way one can perform these calculations for the shift operator algebra just changing the integral over x by the infinite summation over n.

Theorem 3 (Ref. 41): *Let $\hat{\theta}_1$ and $\hat{\theta}_2$ be two compatible Poisson operands such that $\hat{\theta}_1$ is f-type (i.e., ∂_y free) and $\hat{\theta}_2=\overline{\theta}-\epsilon R_{\partial_y}\hat{\theta}_1=\widetilde{\theta}-\epsilon\hat{\theta}_1 R_{\partial_y}$, where R_{∂_y} stands for the right multiplication by ∂_y, $\overline{\theta}$, $\widetilde{\theta}$ are f-type operators and $\epsilon=$ const. Let $\nabla h_0=\text{const}\in\ker\hat{\theta}_1$, then*

$$K_n:=\hat{\theta}_1\circ\sum_{k=0}^{n}\epsilon^k\binom{n}{k}\hat{\Psi}^{n-k}R_{\partial_y}^k\nabla h_0:=\hat{\theta}_1\circ\hat{Q}_n\nabla h_0, \tag{116}$$

where $\hat{\Psi}=\hat{\theta}_1^{-1}\hat{\theta}_2=\widetilde{\Psi}-\epsilon R_{\partial_y}$ is a recursion operand for covector fields on $\hat{M}$, are f-type vector fields.

Proof: From the property of binomial coefficients

$$\binom{n+1}{k}=\binom{n}{k}+\binom{n}{k-1} \tag{117}$$

it is easy to verify that

$$\begin{aligned}K_{n+1}&=\hat{\theta}_1\circ\sum_{k=0}^{n}\epsilon^k\binom{n}{k}\hat{\Psi}^{n-k+1}R_{\partial_y}^k\nabla h_0\\&\quad+\hat{\theta}_1\circ\sum_{k=0}^{n}\epsilon^{k+1}\binom{n}{k}\hat{\Psi}^{n-k}R_{\partial_y}^{k+1}\nabla h_0\end{aligned}$$

$$= \hat{\theta}_1 \circ (\hat{\Psi} \hat{Q}_n + \epsilon \hat{Q}_n R_{\partial_y}) \nabla h_0 = \hat{\theta}_1 \circ (\tilde{\Psi} \hat{Q}_n \nabla h_0 + \epsilon [\hat{Q}_n, R_{\partial_y}] \nabla h_0). \tag{118}$$

If $\tilde{\Psi}$ and $\hat{Q}_n \nabla h_0$ are f-type, then $[\hat{Q}_n, R_{\partial_y}] \nabla h_0$ and K_{n+1} are f-type too, and hence $K_n(\nabla h_0)$ are f-type vector fields.

Lemma 1: If basic operator vector fields $\hat{\theta}_2 \circ \nabla h_0 \partial_y^k$ commute

$$[\hat{\theta}_2 \circ \nabla h_0 \partial_y^k, \hat{\theta}_2 \circ \nabla h_0 \partial_y^l] = 0 \tag{119}$$

and leave the recursion operand invariant with respect to a Lie derivative $\mathcal{L}$:

$$\mathcal{L}_{\hat{\theta}_2 \circ \nabla h_0 \partial_x^k} \hat{\Phi} = 0, \tag{120}$$

where $\hat{\Phi} = \hat{\theta}_2 \hat{\theta}_1^{-1} = \overline{\Phi} - \epsilon R_{\partial_y}$, then K_n constitute a commuting hierarchy of Hamiltonian vector fields.

There are two special cases of the general formula (116):

Lemma 2: Take the assumptions from Theorem 3.

(i) *If $\nabla h_0 \partial_x^k \in \ker\ \hat{\theta}_1$, $k = 0,1,2,\ldots$, then*[16]

$$K_n := \sum_{k=0}^{n} \epsilon^k \binom{n}{k} \hat{\Phi}^{n-k} \circ \hat{\theta}_2 \nabla h_0 \partial_y^k. \tag{121}$$

(ii) *If $\nabla h_0 \in \ker\ \hat{\theta}_1, \hat{\theta}_2$ then $\hat{\theta}_2 \circ \nabla h_0 \partial_y^k \equiv \hat{\Phi} \hat{\theta}_1 \circ \nabla h_0 \partial_y^k$ and*[13,14]

$$K_n := \sum_{k=1}^{n} \epsilon^k \binom{n}{k} \hat{\Phi}^{n-k} \circ \hat{\theta}_1 \nabla h_0 \partial_y^k. \tag{122}$$

The formula (121) was derived by Athorne and Dorfman.[16] In their article they applied the operand formalism for the construction of the KP hierarchy.

Lemma 3: If $\hat{L} = L - \partial_y$ then

(i) *$\hat{\theta}_1$ is of f type,*

(ii) *and $\hat{\theta}_2 = \overline{\theta} - R_{\partial_y} \hat{\theta}_1$,* where *$\overline{\theta}$ is of f-type.*

Proof of this lemma follows immediately from the fact that $\mathrm{ad}_{\hat{L}} \Leftrightarrow f$-type operator and $\mathrm{ad}_{\hat{L}}^{+} \Leftrightarrow f$-type $-2R_{\partial_y}$. Notice that $\hat{\theta}_1$ operand when applied to the f-type covectors (i.e., when reduce to $M \subset \hat{M}$), is equal to θ_1 constructed via the central extension.

Let us consider the operand formalism for the Lie algebra of shift operators and for the PDO Lie algebra.

A. Lie algebra of shift operators with operator-valued fields

The Lax operator for operator valued variables have the following form:

$$k = 0: \hat{L} = \mathcal{E}^{n+\alpha} + \hat{u}_{n+\alpha-1} \mathcal{E}^{n+\alpha-1} + \cdots + \hat{u}_\alpha \mathcal{E}^\alpha, \quad -n < \alpha \leqslant 0, \quad \alpha \in \mathbb{Z}. \tag{123}$$

As a consequence, from (106) and (19), vector fields L_t and gradients ∇H are conveniently parametrized by

$$\hat{L}_t = \sum_i (\hat{u}_i)_t \mathcal{E}^i, \quad \widehat{\nabla H} = \sum_i \mathcal{E}^{-i} \frac{\delta \hat{H}}{\delta u_i}, \tag{124}$$

where $\delta\hat{H}/\delta u_i$ is the variational derivative of an operator-valued functional $\hat{H}[u,\partial_y]$. The linear and quadratic Poisson tensors are

$$\hat{L}_t=\hat{\Theta}_1(\hat{L})\circ\nabla\hat{H}=-\mathrm{ad}_{\hat{L}}(\nabla\hat{H})_{\geqslant 0}+(\mathrm{ad}_{\hat{L}}\nabla\hat{H})_{>0}, \tag{125}$$

$$\begin{aligned}\hat{L}_t=\hat{\Theta}_2(\hat{L})\circ\nabla\hat{H}=&-\tfrac{1}{2}\mathrm{ad}_{\hat{L}}(\mathrm{ad}^{+}_{\hat{L}}\nabla\hat{H})_{\geqslant 0}+\tfrac{1}{2}\mathrm{ad}^{+}_{\hat{L}}(\mathrm{ad}_{\hat{L}}\nabla\hat{H})_{>0}\\&+\tfrac{1}{2}\mathrm{ad}_{\hat{L}}\Pi_{n+\alpha}(\mathrm{ad}_{\hat{L}}\nabla\hat{H})_0,\end{aligned} \tag{126}$$

where

$$\Pi_{n+\alpha}=(E^{n+\alpha}+1)(E^{n+\alpha}-1)^{-1}. \tag{127}$$

The $\Theta_2(L)$ for commuting fields, derived in Ref. 7, is just the (36) one, where now

$$\begin{aligned}A_1&=P_{\geqslant 1}-P_{<0}-\Pi_{n+\alpha}P_0,\\A_2&=P_{\geqslant 1}-P_{<0}+\Pi_{n+\alpha}P_0,\\S&=P_0+\Pi_{n+\alpha}P_0,\\S^*&=P_0-\Pi_{n+\alpha}P_0.\end{aligned} \tag{128}$$

Examples. Here, with the help of the operand formalism, we reconstruct the results of central extension approach applied to the algebra of shift operators.

(1) The case of $n=1$, $\alpha=0$*:*

The Lax operator reads

$$\hat{L}=\mathcal{E}+u-\partial_y. \tag{129}$$

For this Lax operator, using (124), we get the following gradient:

$$\widehat{\nabla H}=\frac{\delta\hat{H}}{\delta u}. \tag{130}$$

Substituting this Lax operator and gradient into (125), (126), we derive the first Poisson operand

$$\hat{\theta}_1=-\mathrm{ad}_u+D_y, \tag{131}$$

and the second Poisson operand

$$\begin{aligned}\hat{\theta}_2=&-\tfrac{1}{2}\mathrm{ad}^{+}_u\mathrm{ad}_u+\tfrac{1}{2}\mathrm{ad}^{+}_u D_y+\tfrac{1}{2}D_y\mathrm{ad}_u-\tfrac{1}{2}D_y^2+\tfrac{1}{2}\mathrm{ad}_u\mathcal{H}\,\mathrm{ad}_u\\&-\tfrac{1}{2}D_y\mathcal{H}\,\mathrm{ad}_u-\tfrac{1}{2}\mathrm{ad}_u\,\mathcal{H}D_y+\tfrac{1}{2}\mathcal{H}D_x^2+R_{u_y}+(ad_u-D_y)R_{\partial_y}.\end{aligned} \tag{132}$$

The recursion operand is given by

$$\hat{\Phi}=\tfrac{1}{2}\mathrm{ad}^{+}_u-\tfrac{1}{2}D_y-\tfrac{1}{2}\mathrm{ad}_u\,\mathcal{H}+\tfrac{1}{2}\mathcal{H}D_y-R_{\partial_y}, \tag{133}$$

deduced for the first time by Morosi and Tondo[14] via a completely different approach. Taking $\nabla h_0=1\in\ker\,\hat{\theta}_1,\ \hat{\theta}_2$ and applying the reduced formula (122) we get the hierarchy

$$u(n)_{t_1}=u_y,$$

$$u(n)_{t_2}=2uu_y+\mathcal{H}u_{yy},$$
$$u(n)_{t_3}=\tfrac{1}{4}u_{yyy}+3u^2u_y+\tfrac{3}{2}\mathcal{H}(uu_y)_y+\tfrac{3}{2}(u\mathcal{H}u_y)_y+\tfrac{3}{4}\mathcal{H}^2u_{yyy}, \tag{134}$$
$$\vdots,$$

where $\mathcal{H}=(E+1)/(E-1)$.

(2) The lattice-field Toda (Ref. 41): $n=2$, $\alpha=-1$.

The Lax operator has the form

$$\hat{L}=\mathcal{E}+p-\partial_y+v\mathcal{E}^{-1}. \tag{135}$$

For this Lax operator, using (124), we get the following gradient

$$\widehat{\nabla H}=\frac{\delta\hat{H}}{\delta p}+\mathcal{E}\frac{\delta\hat{H}}{\delta v}. \tag{136}$$

Substituting this Lax operator and gradient into (125), (126), we derive the first Poisson operand

$$\hat{\theta}_1=\begin{pmatrix}0 & R_v-vE^{-1}\\ ER_v-v & -(\mathrm{ad}_p-D_y)\end{pmatrix} \tag{137}$$

and the second Poisson operand

$$\hat{\theta}_2=\overline{\theta}-R_{\partial_y}\hat{\theta}_1, \tag{138}$$

where

$$\overline{\theta}_{11}=(R_vE-vE^{-1})(E-1)^{-1}(ER_v-v),$$
$$\overline{\theta}_{12}=(R_v-vE^{-1})(E-1)^{-1}(ER_p-p+D_y)+R_{v_y},$$
$$\overline{\theta}_{21}=(R_pE-p+D_y)(E-1)^{-1}(ER_v-v),$$
$$\overline{\theta}_{22}=ER_v-vE^{-1}-(R_pE-p+D_y)(E-1)^{-1}(\mathrm{ad}_p-D_y).$$

The recursion operand is given by

$$\hat{\Phi}=\hat{\theta}_2\hat{\theta}_1^{-1}=\overline{\Phi}-R_{\partial_y}I, \tag{139}$$

where

$$\begin{aligned}\overline{\Phi}_{11}=&[R_vE^1-vE^{-1}][E^1-1]^{-1}[\mathrm{ad}_p-D_y][R_v-vE^{-1}]^{-1}\\ &+[vE^{-1}-R_v][E^1-1]^{-1}[E^1R_p-p+D_y][vE^{-1}-R_v]^{-1}\\ &-R_{v_x}[vE^{-1}-R_v]^{-1},\end{aligned}$$
$$\overline{\Phi}_{12}=[R_vE^1-vE^{-1}][E^1-1]^{-1},$$
$$\overline{\Phi}_{21}=[vE^{-1}-E^1R_v][vE^{-1}-R_v]^{-1},$$

$$\overline{\Phi}_{22}=[R_pE^1-p+D_y][E^1-1]^{-1}$$

and I is a unit matrix. Taking

$$\nabla h_0=\begin{pmatrix}0\\1\end{pmatrix}\in\ker\hat{\theta}_1,$$

the general formula (116) gives the hierarchy

$$\begin{pmatrix}v(n)\\p(n)\end{pmatrix}_{t_1}=\begin{pmatrix}v(n)[p(n)-p(n-1)]\\v(n+1)-v(n)+p(n)_y\end{pmatrix},$$

$$v(n)_{t_2}=v(n)[p^2(n)-p^2(n-1)+v(n+1)-v(n-1)+p(n)_y+p(n-1)_y]$$

$$\begin{aligned}p(n)_{t_2}=&v(n+1)[p(n+1)+p(n)]-v(n)[p(n-1)+p(n)]+v(n)_y\\&+v(n+1)_y+\mathcal{H}p(n)_{yy}+2p(n)p(n)_y,\end{aligned}\tag{140}$$

$$\vdots.$$

(3) The case of $n=2$, $\alpha=0$*:*
The Lax operator has the form

$$\hat{L}=\mathcal{E}^2+u\mathcal{E}+w-\partial_y.\tag{141}$$

For this Lax operator, using (124), we get the following gradient:

$$\widehat{\nabla H}=\mathcal{E}^{-1}\frac{\delta\hat{H}}{\delta u}+\mathcal{E}\frac{\delta\hat{H}}{\delta w}.\tag{142}$$

Substituting this Lax operator and gradient into (125), (126), we derive the first Poisson operand

$$\hat{\theta}_1=\begin{pmatrix}-(\mathrm{ad}_w-D_y) & 0\\0 & E-E^{-1}\end{pmatrix},\tag{143}$$

and the second Poissson operand

$$\hat{\theta}_2=\frac{1}{2}\overline{\theta}-R_{\partial_y}\hat{\theta}_1,\tag{144}$$

where

$$\overline{\theta}_{11}=(\mathrm{ad}_w-D_y)\Pi(\mathrm{ad}_w-D_y)-\mathrm{ad}_{(w^2-w_y)}-D_y^2+2wD_y,$$

$$\overline{\theta}_{12}=(\mathrm{ad}_w-D_y)((\Pi-1)u-(\Pi+1)E^{-1}R_u),$$

$$\overline{\theta}_{21}=(uE(\Pi-1)-R_u(\Pi+1))(\mathrm{ad}_w-D_y),$$

$$\overline{\theta}_{22}=2(ER_w-wE^{-1})+2D_yE^{-1}+uE(\Pi-1)u+R_u(\Pi+1)E^{-1}R_u$$
$$-u\Pi R_u-R_u\Pi u.$$

The recursion operand is given by

$$\hat{\Phi}=\begin{pmatrix}\overline{\Phi}_{11} & \overline{\Phi}_{12}\\ \overline{\Phi}_{21} & \overline{\Phi}_{22}\end{pmatrix}-R_{\partial_y}I, \tag{145}$$

where

$$\Phi_{11}=\mathrm{ad}_w^+-D_y-(\mathrm{ad}_w-D_x)\Pi,$$

$$\Phi_{12}=(\mathrm{ad}_w-D_y)((\Pi-1)u-(\Pi+1)E^{-1}R_u)(E-E^{-1})^{-1},$$

$$\Phi_{21}=R_u(\Pi+1)-uE(\Pi-1),$$

$$\Phi_{22}=\{2(ER_w-wE^{-1})+2D_yE^{-1}+uE(\Pi-1)u$$
$$+R_u(\Pi+1)E^{-1}R_u-u\Pi R_u-R_u\Pi u\}\times(E-E^{-1})^{-1}$$

and $\Pi\equiv\Pi_2=(E^2+1)/(E^2-1)$. Taking $\nabla h_0=\binom{0}{1}\in\ker\hat{\theta}_1$, the general formula (116) gives the hierarchy

$$\begin{pmatrix}u(n)\\ w(n)\end{pmatrix}_{t_1}=\begin{pmatrix}u(n)\mathcal{H}^{-1}u(n)-w(n+1)+w(n)\\ -(E+1)^{-1}u(n)_y\end{pmatrix},$$
$$\vdots. \tag{146}$$

(4) The case of $n=3,\alpha=-1$*:*
The Lax operator is of the form

$$\hat{L}=\mathcal{E}^2+p\mathcal{E}+v-\partial_y+u\mathcal{E}^{-1}. \tag{147}$$

For this Lax operator, using (124), we get the following gradient:

$$\widehat{\nabla H}=\mathcal{E}^{-1}\frac{\delta\hat{H}}{\delta p}+\frac{\delta\hat{H}}{\delta v}+\mathcal{E}\frac{\delta\hat{H}}{\delta u}. \tag{148}$$

Substituting this Lax operator and gradient into (125), (126), we derive the first Poisson operand

$$\hat{\theta}_1=\begin{pmatrix}0 & R_u-uE^{-1} & 0\\ ER_u-u & -\mathrm{ad}_v+D_y & 0\\ 0 & 0 & E-E^{-1}\end{pmatrix} \tag{149}$$

and the second Poisson operand is given by

$$\hat{\theta}_2=\begin{pmatrix} \overline{\theta}_{11} & \overline{\theta}_{12} & \overline{\theta}_{13} \\ \overline{\theta}_{21} & \overline{\theta}_{22} & \overline{\theta}_{23} \\ \overline{\theta}_{31} & \overline{\theta}_{32} & \overline{\theta}_{33} \end{pmatrix} - R_{\partial_y}\hat{\theta}_1, \tag{150}$$

where

$$\overline{\theta}_{11}=R_uER_u-uE^{-1}u+R_u\Pi_2[ER_u-u]+u\Pi_2[E^{-1}u-R_u],$$

$$\overline{\theta}_{12}=(v-D_y)R_u+R_uR_v-uE^{-1}(\mathrm{ad}_v^+-D_y)+(uE^{-1}-R_u)\Pi_2(\mathrm{ad}_v-D_y)+R_{u_y},$$

$$\overline{\theta}_{13}=pR_u-uE^{-2}(\Pi_2+1)R_p+uE^{-1}(\Pi_2-1)p+R_uE^{-1}(\Pi_2+1)R_p-R_u\Pi_2p,$$

$$\overline{\theta}_{21}=-uR_v-(v-D_y)u+(\mathrm{ad}_v^+-D_y)ER_u+(\mathrm{ad}_v-D_y)\Pi_2(u-ER_u)+ER_{u_y},$$

$$\overline{\theta}_{22}=2pER_u-2uE^{-1}R_p+(\mathrm{ad}_v-D_y)\Pi_2(\mathrm{ad}_v-D_y)-\mathrm{ad}_{v^2}+\mathrm{ad}_{v_y}+2vD_y-D_y^2+2R_{v_y},$$

$$\overline{\theta}_{23}=2ER_u+pR_v-(v-D_y)p-2uE^{-2}-(\mathrm{ad}_v-D_y)E^{-1}R_p+(\mathrm{ad}_v-D_y)\Pi_2(p-E^{-1}R_p),$$

$$\overline{\theta}_{31}=-uR_p+pE(ER_u-u)+R_pER_u+R_p\Pi_2(ER_u-u)+p\Pi_2E(u-ER_u),$$

$$\overline{\theta}_{32}=2E^2R_u-2uE^{-1}-pE(\mathrm{ad}_v-D_y)-(v-D_y)R_p+R_pR_v+(pE-R_p)\Pi_2(\mathrm{ad}_v-D_y)-R_{p_y},$$

$$\overline{\theta}_{33}=2ER_v-2(v-D_y)E^{-1}-pEp+R_pE^{-1}R_p+p\Pi_2(Ep-R_p)+R_p\Pi_2(E^{-1}R_p-p).$$

Taking

$$\nabla h_0=\begin{pmatrix} 0 \\ 1 \\ 0 \end{pmatrix}\in\ker\hat{\theta}_1,$$

and applying the general formula (116) we get the first hierarchy

$$\begin{pmatrix} u(n) \\ v(n) \\ p(n) \end{pmatrix}_{t_2}=\begin{pmatrix} u(n)[v(n)-v(n-1)] \\ p(n)u(n+1)-p(n-1)u(n)+v(n)_y \\ u(n+2)-u(n)+p(n)_y \end{pmatrix}, \tag{151}$$

$$\vdots.$$

Taking

$$\nabla h_0 = \begin{pmatrix} 0 \\ 0 \\ 1 \end{pmatrix} \in \ker \hat{\theta}_1,$$

and applying the formula (116) we get the second hierarchy

$$\begin{pmatrix} u(n) \\ v(n) \\ p(n) \end{pmatrix}_{t_1} = \begin{pmatrix} u(n)\mathcal{H}^{-1}p(n-1) \\ u(n+1)-u(n)+(E+1)^{-1}p(n)_y \\ v(n+1)-v(n)-p(n)\mathcal{H}^{-1}p(n) \end{pmatrix}, \tag{152}$$

$$\vdots .$$

B. PDO Lie algebra with operator valued fields

Lax operators for operator valued variables have the following form:

$$k=0: \hat{L} = \partial_x^N + \hat{u}_{N-2}\partial_x^{N-2} + \cdots + \hat{u}_1\partial_x^1 + \hat{u}_0, \tag{153}$$

$$k=1: \hat{L} = \hat{u}_N\partial_x^N + \hat{u}_{N-1}\partial_x^{N-1} + \cdots + \hat{u}_0 + \partial_x^{-1}\hat{u}_{-1}. \tag{154}$$

As a consequence, from (106) and (23), vector fields $\hat{L}_t$ and gradients $\widehat{\nabla H}$ are conveniently parametrized by

$$\hat{L}_t = \sum_i (\hat{u}_i)_t \partial_x^i, \quad \widehat{\nabla H} = \sum_i \partial_x^{-1-i} \frac{\delta \hat{H}}{\delta u_i}, \tag{155}$$

where $\delta\hat{H}/\delta u_i$ is the variational derivative of an operator-valued functional $\hat{H}[u, \partial_y]$. The linear Poisson tensors are

$$\hat{L}_t = \hat{\Theta}_1(\hat{L}) \circ \widehat{\nabla H} = -\operatorname{ad}_{\hat{L}}(\widehat{\nabla H})_{\geqslant k} + (\operatorname{ad}_{\hat{L}}\widehat{\nabla H})_{\geqslant -k}, \quad k=0,1. \tag{156}$$

and quadratic Poisson tensors take the form

$$\begin{aligned} k=0: \hat{L}_t = \hat{\Theta}_2(\hat{L}) \circ \widehat{\nabla H} &= (\hat{L}\widehat{\nabla H})_{\geqslant 0}\hat{L} - \hat{L}(\widehat{\nabla H}\hat{L})_{\geqslant 0} \\ &+ \frac{1}{N}[D_x^{-1}\operatorname{res}([\widehat{\nabla H}, \hat{L}]), \hat{L}], \end{aligned} \tag{157}$$

$$\begin{aligned} k=1: \hat{L}_t = \hat{\Theta}_2(\hat{L}) \circ \widehat{\nabla H} &= (\hat{L}\widehat{\nabla H})_{\geqslant 1}\hat{L} - \hat{L}(\widehat{\nabla H}\hat{L})_{\geqslant 0} + \hat{L}(\hat{L}\widehat{\nabla H})_0 \\ &- \partial_x^{-1}\operatorname{res}([\widehat{\nabla H}, \hat{L}])\hat{L} + [D_x^{-1}\operatorname{res}([\widehat{\nabla H}, \hat{L}]), \hat{L}]. \end{aligned} \tag{158}$$

Both quadratic Poisson tensors for commuting fields were derived in Ref. 36 and are the special cases of (36), where for $k=0$,

$$\begin{aligned} A_1 &= P_{\geqslant 0} - P_{<0} - \frac{1}{N}D_x^{-1}P_{-1}, \\ A_2 &= P_{\geqslant 0} - P_{<0} + \frac{1}{N}D_x^{-1}P_{-1}, \\ S &= \frac{1}{N}D_x^{-1}P_{-1}, \end{aligned} \tag{159}$$

$$S^*=-\frac{1}{N}D_x^{-1}P_{-1},$$

and for $k=1$,

$$\begin{aligned}
A_1&=P_{\geqslant 1}-P_0+\partial_x^{-1}P_{-1}-P_{<-1}-2D_x^{-1}P_{-1},\\
A_2&=P_{\geqslant 0}-P_{<0}+2D_x^{-1}P_{-1},\\
S&=-2\partial_x^{-1}P_{-1}+2D_x^{-1}P_{-1},\\
S^*&=-2P_0-2D_x^{-1}P_{-1}.
\end{aligned}\tag{160}$$

Examples. Here, with the help of the operand formalism, we reconstruct the results of central extension approach applied to the PDO algebra.

(1) The KP equation: $k=0$, $N=2$.

The Lax operator is given by

$$\hat{L}=\partial_x^2+u-\partial_y.\tag{161}$$

For this Lax operator we get the following gradient, using (155),

$$\widehat{\nabla H}=\partial_x^{-1}\frac{\delta\hat{H}}{\delta u}.\tag{162}$$

Substituting this Lax operator and gradient into (156), (157) we get[15] the first

$$\hat{\theta}_1=2D_x,\tag{163}$$

and the second

$$\begin{aligned}
\hat{\theta}_2=\tfrac{1}{2}(&D_x^3+D_x\,\mathrm{ad}_u^+ +\mathrm{ad}_u^+\,D_x-2D_xD_y+\mathrm{ad}_u\,D_x^{-1}\,\mathrm{ad}_u\\
&-D_x^{-1}D_y\,\mathrm{ad}_u-\mathrm{ad}_uD_x^{-1}D_y+D_x^{-1}D_y^2)-R_{\partial_y}\hat{\theta}_1,
\end{aligned}\tag{164}$$

Poisson operands and recursion operand

$$\begin{aligned}
\hat{\Phi}=\hat{\theta}_2\hat{\theta}_1^{-1}=\tfrac{1}{4}(&D_x^2+D_x\,\mathrm{ad}_u^+\,D_x^{-1}+\mathrm{ad}_u^+-2D_y+\mathrm{ad}_u\,D_x^{-1}\,\mathrm{ad}_u\,D_x^{-1}\\
&-D_x^{-1}D_y\,\mathrm{ad}_u\,D_x^{-1}-\mathrm{ad}_u\,D_x^{-2}D_y+D_x^{-2}D_y^2)-R_{\partial_y}.
\end{aligned}\tag{165}$$

Taking $\nabla h_0=1\in\ker\hat{\theta}_1$, and applying formula (121) we get the KP hierarchy

$$\begin{aligned}
u_{t_1}&=u_x,\\
u_{t_3}&=u_{3x}+6uu_x+3D_x^{-1}u_{yy},\\
u_{t_5}&=u_{5x}+10uu_{3x}+20u_xu_{xx}+30u^2u_x+10u_{xyy}+10u_xD_x^{-2}u_{yy}\\
&\quad+D_x^{-1}(5D_x^{-2}u_{4y}++30u_y^2+30uu_{yy}+20u_{xy}D_x^{-1}u_y+20u_xD_x^{-1}u_{yy}),\ldots.
\end{aligned}\tag{166}$$

The central extension approach gives us additional equations for this hierarchy (87), i.e.,

$$u_{t_2}=u_y,\tag{167}$$

$$u_{t_4}=u_{xxy}+4uu_y+2u_xD_x^{-1}u_y+D_x^{-2}u_{3y},\ldots.$$

These equations are purely $(2+1)$-dimensional, because they reduce to zero by the dimension reduction from $(2+1)$ to $(1+1)$.

(2) The $(2+1)$*-Boussinesq equation:* $k=0$, $N=3$.

For the $(2+1)$-Boussinesq equation the Lax operator is

$$\hat{L}=\partial_x^3+u\partial_x+v-\partial_y. \tag{168}$$

From Eq. (155) we get the following gradient

$$\widehat{\nabla H}=\partial_x^{-2}\frac{\delta\hat{H}}{\delta u}+\partial_x^{-1}\frac{\delta\hat{H}}{\delta v}. \tag{169}$$

Substituting this Lax operator and gradient into (156), (157) we get the first Poisson operand

$$\hat{\theta}_1=\begin{pmatrix}0 & 3D_x\\ 3D_x & \mathrm{ad}_u\end{pmatrix},\quad \hat{\theta}_1^{-1}=\frac{1}{3}\begin{pmatrix}-\frac{1}{3}D_x^{-1}\,\mathrm{ad}_u\,D_x^{-1} & D_x^{-1}\\ D_x^{-1} & 0\end{pmatrix}, \tag{170}$$

and the second one

$$\hat{\theta}_2=\begin{pmatrix}\overline{\theta}_{11} & \overline{\theta}_{12}\\ \overline{\theta}_{21} & \overline{\theta}_{22}\end{pmatrix}-R_{\partial_y}\hat{\theta}_1, \tag{171}$$

where

$$\overline{\theta}_{11}=2D_x^3+D_xu+R_uD_x-\mathrm{ad}_v+D_y+\tfrac{1}{3}\mathrm{ad}_u\,D_x^{-1}\,\mathrm{ad}_u,$$

$$\begin{aligned}\overline{\theta}_{12}=&-D_x^4-D_x^2R_u+vD_x+D_x\,\mathrm{ad}_v^+-2D_xD_y\\&+\tfrac{1}{3}(\mathrm{ad}_u\,D_x^{-1}\,\mathrm{ad}_v+\mathrm{ad}_u\,D_x^2+\mathrm{ad}_u\,R_u-\mathrm{ad}_u\,D_x^{-1}D_y),\end{aligned}$$

$$\begin{aligned}\overline{\theta}_{21}=&D_x^4+uD_x^2+D_xR_v+\mathrm{ad}_v^+\,D_x-D_xD_y\\&+\tfrac{1}{3}(D_x^2\,\mathrm{ad}_u+u\,\mathrm{ad}_u-D_x^{-1}D_y\,\mathrm{ad}_u+\mathrm{ad}_vD_x^{-1}\,\mathrm{ad}_u),\end{aligned}$$

$$\begin{aligned}\overline{\theta}_{22}=&\tfrac{2}{3}(D_x^2R_v-vD_x^2-D_x^5-D_x^3R_u-uD_x^3-uD_xR_u+D_yR_u+uR_v-vR_u)\\&+\tfrac{1}{3}(D_x^2v-R_vD_x^2+D_x^2D_y+uv-uD_y-R_vR_u\\&+\mathrm{ad}_v\,D_x^{-1}\,\mathrm{ad}_v-\mathrm{ad}_v\,D_x^{-1}D_y-D_x^{-1}D_y\,\mathrm{ad}_v+D_x^{-1}D_y^2).\end{aligned}$$

Taking

$$\nabla h_0=\begin{pmatrix}1\\0\end{pmatrix}\in\ker\hat{\theta}_1,$$

and applying formula (116) we get the first hierarchy of vector fields

$$\begin{pmatrix}u\\v\end{pmatrix}_{t_1}=\begin{pmatrix}u_x\\v_x\end{pmatrix},$$

$$u_{t_3}=2v_{3x}+4(uv)_x-u_{4x}-(u^2)_{2x}-2u_{xy}+4v_y, \tag{172}$$

$$v_{t_3}=v_{4x}+2uv_{2x}+2(v^2)_x+2v_{xy}+2u_xv_x-\tfrac{2}{3}(u_{5x}+3uu_{3x}+6u_xu_{2x}$$
$$+2u^2u_x)+\tfrac{4}{3}D_x^{-1}u_{2y}-\tfrac{2}{3}u_{y2x},\ldots.$$

Taking

$$\nabla h_0\begin{pmatrix}0\\1\end{pmatrix}\in\ker\hat{\theta}_1,$$

and applying formula (116) we get the first equation from the second hierarchy

$$\begin{pmatrix}u\\v\end{pmatrix}_{t_2}=\begin{pmatrix}u_{2x}-2v_x\\ \dfrac{2}{3}(u_{3x}+uu_x-u_y)-v_{xx}\end{pmatrix},\ldots. \tag{173}$$

(3) The case: $k=0$, $N=4$.
The Lax operator has the form

$$\hat{L}=\partial_x^4+u\partial_x^2+v\partial_x+w-\partial_y. \tag{174}$$

For this Lax operator we get from (155) the following gradient:

$$\widehat{\nabla H}=\partial_x^{-3}\frac{\delta\hat{H}}{\delta u}+\partial_x^{-2}\frac{\delta\hat{H}}{\delta v}+\partial_x^{-1}\frac{\delta\hat{H}}{\delta w}. \tag{175}$$

Substituting the Lax operator and the gradient in (156), (157) we get the first Poisson operand and its inverse

$$\hat{\theta}_1=\begin{pmatrix}0&0&4D_x\\0&4D_x&2D_x^2+\mathrm{ad}_u\\4D_x&-2D_x^2+\mathrm{ad}_u&2D_x^3+uD_x+D_xR_u+\mathrm{ad}_v\end{pmatrix}, \tag{176}$$

$$\hat{\theta}_1^{-1}=-\frac{1}{64}\begin{pmatrix}\hat{\theta}_{11}&4D_x^{-1}(-2D_x^2+\mathrm{ad}_u)D_x^{-1}&-16D_x^{-1}\\4D_x^{-1}(2D_x^2+\mathrm{ad}_u)D_x^{-1}&-16D_x^{-1}&0\\-16D_x^{-1}&0&0\end{pmatrix}, \tag{177}$$

where

$$\hat{\theta}_{11}=4D_x^{-1}(2D_x^3+uD_x+D_xR_u+\mathrm{ad}_v)D_x^{-1}-D_x^{-1}(-2D_x^2+\mathrm{ad}_u)D_x^{-1}(2D_x^2+\mathrm{ad}_u)D_x^{-1}$$

and the second Poisson operand

$$\hat{\theta}_2=\begin{pmatrix}\overline{\theta}_{11}&\overline{\theta}_{12}&\overline{\theta}_{13}\\\overline{\theta}_{21}&\overline{\theta}_{22}&\overline{\theta}_{23}\\\overline{\theta}_{31}&\overline{\theta}_{32}&\overline{\theta}_{33}\end{pmatrix}-R_{\partial_y}\hat{\theta}_1, \tag{178}$$

where

$$\overline{\theta}_{11}=5D_x^3-\mathrm{ad}_v+\tfrac{1}{4}(\mathrm{ad}_u D_x^{-1}\mathrm{ad}_u+6D_xu+6R_uD_x-2uD_x-2D_xR_u),$$

$$\overline{\theta}_{12}=vD_x-\mathrm{ad}_w+D_y-5D_x^4+\mathrm{ad}_u D_x^2-2D_x^2R_u$$
$$+\tfrac{1}{4}(\mathrm{ad}_u D_x^{-1}\mathrm{ad}_v+2\,\mathrm{ad}_u R_u+2D_xR_v+6D_xv),$$

$$\overline{\theta}_{13}=wD_x+\tfrac{1}{4}(\mathrm{ad}_u D_x^{-1}\mathrm{ad}_w-\mathrm{ad}_u D_x^{-1}D_y-\mathrm{ad}_u D_x^3-\mathrm{ad}_u D_xR_u$$
$$+6D_x\,\mathrm{ad}_w^+ +\mathrm{ad}_u R_v-6D_xD_y+6D_x^5+6D_x^3R_u-6D_x^2R_v),$$

$$\overline{\theta}_{21}=D_xR_v-\mathrm{ad}_w+D_y+5D_x^4+D_x^2\,\mathrm{ad}_u+2uD_x^2$$
$$+\tfrac{1}{4}(\mathrm{ad}_v D_x^{-1}\mathrm{ad}_u+2u\,\mathrm{ad}_u+6R_vD_x+2vD_x),$$

$$\overline{\theta}_{22}=2D_xR_w+2wD_x-2D_xD_y-6D_x^5-R_vD_x^2+D_x^2v-2D_x^3R_u$$
$$-2uD_x^3-uD_xR_u+\tfrac{1}{4}(\mathrm{ad}_v D_x^{-1}\mathrm{ad}_v+2u\,\mathrm{ad}_v^+-2\,\mathrm{ad}_v^+ R_u),$$

$$\overline{\theta}_{23}=2D_x^2R_w-wD_x^2-wR_u+D_yR_u-2D_x^3R_v+2D_x^4R_u+2D_x^6$$
$$+D_x^2w+\tfrac{1}{4}(\mathrm{ad}_v D_x^{-1}\mathrm{ad}_w-\mathrm{ad}_v D_x^{-1}D_y-\mathrm{ad}_v D_x^3+2uD_x^4+2uD_x^2R_u$$
$$-\mathrm{ad}_v D_xR_u-2uD_xR_v+2u\,\mathrm{ad}_w^+-2uD_y+\mathrm{ad}_v R_v),$$

$$\overline{\theta}_{31}=D_xR_w+\tfrac{1}{4}(\mathrm{ad}_w D_x^{-1}\mathrm{ad}_u-D_x^{-1}D_y\,\mathrm{ad}_u+D_x^3\,\mathrm{ad}_u+6D_x^5+6\,\mathrm{ad}_w^+ D_x$$
$$-6D_xD_y+uD_x\,\mathrm{ad}_u+6uD_x^3+6vD_x^2+v\,\mathrm{ad}_u),$$

$$\overline{\theta}_{32}=D_x^2R_w-2D_x^6-2uD_x^4-2vD_x^3-2wD_x^2+2D_x^2D_y+uR_w-R_wD_x^2$$
$$+\tfrac{1}{4}(\mathrm{ad}_w D_x^{-1}\mathrm{ad}_v-D_x^{-1}D_y\,\mathrm{ad}_v+D_x^3\,\mathrm{ad}_v-2D_x^4R_u-2uD_x^2R_u$$
$$+uD_x\,\mathrm{ad}_v-2vD_xR_u-2\,\mathrm{ad}_w^+ R_u+2D_yR_u+v\,\mathrm{ad}_v),$$

$$\overline{\theta}_{33}=\tfrac{1}{4}(\mathrm{ad}_w D_x^{-1}\mathrm{ad}_w-D_x^{-1}D_y\,\mathrm{ad}_w-\mathrm{ad}_w D_x^{-1}D_y+D_x^{-1}D_y^2+R_wD_x^3$$
$$+D_x^3w-D_x^3D_y+R_wD_xR_u+uD_xw-uD_xD_y+3D_x^3R_w+3wD_x^3$$
$$-3D_x^3D_y+3D_x^5R_u+3uD_x^5+3D_x^7-3D_x^4R_v+3vD_x^4+3uD_x^3R_u$$
$$-3uD_x^2R_v+3vD_x^2R_u+3uD_xR_w+3wD_xR_u-3D_xD_yR_u-3vD_xR_v$$
$$+vw-vD_y-R_wR_v+3vR_w-3wR_v+3D_yR_v).$$

Taking

$$\nabla h_0=\begin{pmatrix}1\\0\\0\end{pmatrix}\in\ker\hat{\theta}_1$$

and applying formula (116) we get the first hierarchy of commuting vector fields

$$\begin{pmatrix}u\\v\\w\end{pmatrix}_{t_1}=\begin{pmatrix}u_x\\v_x\\w_x\end{pmatrix},$$

$$
\begin{aligned}
u_{t_3} &= 2u_{5x} - 20v_{4x} + 40w_{3x} + 40(uw)_x - 40u_{xx}v - 20uv_{xx} \\
&\quad + 20(v_x)^2 - 45u_xv_x - 10uu_{xxx} - 15u^2u_x + 32u_{xy} - 40v_y, \\
v_{t_3} &= 10u_{6x} - 28v_{5x} + 40w_{4x} + 40(vw)_x - 40uv_{xxx} + 40(uw_x)_x \\
&\quad - 100u_xv_{xx} - 110u_{xx}v_x + 5(u^2)_{4x} - 15(u^2v)_x - 20v_{xy} \\
&\quad - 40w_y + 30u_{xxy} + 10uu_y, \qquad (179) \\
w_{t_3} &= 5u_{7x} - 12v_{6x} + 12w_{5x} + 20(w_x)^2 + 20v_xw_x + 20vw_{xx} \\
&\quad + 20uw_{xxx} + 12u_xw_{xx} + 5uu_{5x} + 5(uu_x)_{4x} - 10(uv)_{4x} \\
&\quad + 5u^2w_x - 10u(uv)_{xx} + 5v(uu_x)_x - 10v(uv)_x + 5u(uu_x)_{xx} \\
&\quad + 2u_{xx}w_x - 20w_{xy} + 15u_{3xy} - 10v_{xxy} + 10D_x^{-1}u_{yy} + 15uu_{xy} + 5u_xu_y - 10uv_y, \\
&\quad \vdots .
\end{aligned}
$$

Taking

$$
\nabla h_0 = \begin{pmatrix} 0 \\ 1 \\ 0 \end{pmatrix} \in \ker \hat{\theta}_1
$$

and applying formula (116) we get the firts equation of the second hierarchy

$$
\begin{pmatrix} u \\ v \\ w \end{pmatrix}_{t_2} = \begin{pmatrix} -2u_{xx} + 2v_x \\ 2w_x + v_{xx} - 2u_{3x} - uu_x \\ w_{xx} - \frac{1}{2}(u_{4x} + uu_{xx} + vu_x + u_y) \end{pmatrix}, \qquad (180)
$$

$$
\vdots .
$$

(4) The case: $k=1$, $N=0$.
The Lax operator is of the form

$$
\hat{L} = u + \partial_x^{-1}w - \partial_y . \qquad (181)
$$

For this Lax operator we get from (155) the following gradient:

$$
\widehat{\nabla H} = \partial_x^{-2}\frac{\delta \hat{H}}{\delta w} + \partial_x^{-1}\frac{\delta \hat{H}}{\delta u}. \qquad (182)
$$

Substituting the Lax operator and the gradient in (156), (158) we get the first Poisson operand

$$
\hat{\theta}_1 = \begin{pmatrix} 0 & \mathrm{ad}_u - D_y \\ \mathrm{ad}_u - D_y & \mathrm{ad}_w \end{pmatrix}, \qquad (183)
$$

and the second Poisson operand

$$
\hat{\theta}_2 = \begin{pmatrix} \overline{\theta_{11}} & \overline{\theta_{12}} \\ \overline{\theta_{21}} & \overline{\theta_{22}} \end{pmatrix} - R_{\partial_y}\hat{\theta}_1, \qquad (184)
$$

where

$$\overline{\theta}_{11}=(\mathrm{ad}_u-D_y)D_x^{-1}(\mathrm{ad}_u-D_y),$$

$$\overline{\theta}_{12}=(u-D_y)(\mathrm{ad}_u-D_y)+(\mathrm{ad}_u-D_y)D_x^{-1}\,\mathrm{ad}_w,$$

$$\overline{\theta}_{21}=(\mathrm{ad}_u-D_y)R_u+\mathrm{ad}_w\,D_x^{-1}(\mathrm{ad}_u-D_y)+R_{u_y},$$

$$\overline{\theta}_{22}=w(u-D_y)-R_uR_w+\mathrm{ad}_w\,D_x^{-1}\,\mathrm{ad}_w.$$

The recursion operand is given by

$$\hat{\Phi}=\begin{pmatrix} u-D_y & (\mathrm{ad}_u-D_y)D_x^{-1} \\ w & R_u+\mathrm{ad}_w\,D_x^{-1}\end{pmatrix}-R_{\partial_y}I. \tag{185}$$

Taking

$$\nabla h_0=\begin{pmatrix}0\\1\end{pmatrix}\in\ker\hat{\theta}_1,\hat{\theta}_2$$

and applying formula (122) we get the hierarchy

$$\begin{pmatrix}u\\w\end{pmatrix}_{t_1}=\begin{pmatrix}u_x\\w_x\end{pmatrix},$$

$$\begin{pmatrix}u\\w\end{pmatrix}_{t_2}=\begin{pmatrix}u_{2y}-2uu_y+2D_x^{-1}w_{2y}\\ -w_{2y}-2(wu)_y\end{pmatrix},$$

$$u_{t_3}=\tfrac{1}{2}(u^2)_{2y}-u^2u_y-\tfrac{1}{3}u_{3y}+uD_x^{-1}w_{2y}+D_x^{-1}(uw)_{2y}+u_yD_x^{-1}w_y, \tag{186}$$

$$w_{t_3}=-2uwu_y-u^2w_y-uw_{2y}-u_yw_y-\tfrac{1}{3}w_{3y}+wD_x^{-1}w_{2y}+w_yD_x^{-1}w_y,\ldots.$$

Interestingly, for $N=0$ the central extension approach gives another hierarchy of commuting vector fields, i.e.,

$$\begin{pmatrix}u\\w\end{pmatrix}_{t_1}=\begin{pmatrix}u_x\\w_x\end{pmatrix},$$

$$\begin{pmatrix}u\\w\end{pmatrix}_{t_2}=\begin{pmatrix}u_{xx}+2w_x-2u_xD_y^{-1}u_x\\ -w_{xx}-2(wD_y^{-1}u_x)_x\end{pmatrix},$$

$$\begin{aligned}u_{t_3}=&u_{3x}-3(wD_y^{-1}u_x)_x-3(u_xD_y^{-1}u_x)_x-3w_xD_y^{-1}u_x\\&-3u_xD_y^{-1}w_x+6u_xD_y^{-1}u_xD_y^{-1}u_x,\end{aligned} \tag{187}$$

$$w_{t_3}=w_{3x}+3(w_xD_y^{-1}u_x)_x-3(wD_y^{-1}w_x)_x+6(wD_y^{-1}u_xD_y^{-1}u_x)_x,\ldots.$$

We can transform this hierarchy to the (186) one through the following transformation: $D_y^{-1}u_x\to u$, $w\to w$, $x\leftrightarrow y$.

(5) The case: $k=1$, $N=2$.

The Lax operator takes the form

$$\hat{L}=\partial_x^2+u\partial_x+v-\partial_y+\partial_x^{-1}w. \tag{188}$$

For this Lax operator we get from (155) the following gradient:

$$\widehat{\nabla H}=\partial_x^{-2}\frac{\delta\hat{H}}{\delta u}+\partial_x^{-1}\frac{\delta\hat{H}}{\delta v}+\frac{\delta\hat{H}}{\delta w}. \tag{189}$$

Substituting the Lax operator and the gradient in (156), (158) we get the first Poisson operand and its inverse

$$\hat{\theta}_1=\begin{pmatrix} 0 & 0 & 2D_x+\mathrm{ad}_u \\ 0 & 2D_x+\mathrm{ad}_u & D_x^2-D_y+uD_x+\mathrm{ad}_v \\ 2D_x+\mathrm{ad}_u & -D_x^2-D_y+D_xR_u+\mathrm{ad}_v & \mathrm{ad}_w \end{pmatrix}, \tag{190}$$

$$\hat{\theta}_1^{-1}=\begin{pmatrix} \hat{\theta}_{11} & \hat{\theta}_{12} & (2D_x+\mathrm{ad}_u)^{-1} \\ \hat{\theta}_{21} & (2D_x+\mathrm{ad}_u)^{-1} & 0 \\ (2D_x+\mathrm{ad}_u)^{-1} & 0 & 0 \end{pmatrix}, \tag{191}$$

where

$$\begin{aligned}\hat{\theta}_{11}=&-(2D_x+\mathrm{ad}_u)^{-1}\mathrm{ad}_w(2D_x+\mathrm{ad}_u)^{-1}\\ &+(2D_x+\mathrm{ad}_u)^{-1}(-D_x^2-D_y+D_xR_u+\mathrm{ad}_v)(2D_x+\mathrm{ad}_u)^{-1}\\ &\times(D_x^2-D_y+uD_x+\mathrm{ad}_v)(2D_x+\mathrm{ad}_u)^{-1},\end{aligned}$$

$$\hat{\theta}_{12}=-(2D_x+\mathrm{ad}_u)^{-1}(-D_x^2-D_y+D_xR_u+\mathrm{ad}_v)(2D_x+\mathrm{ad}_u)^{-1},$$

$$\hat{\theta}_{21}=-(2D_x+\mathrm{ad}_u)^{-1}(D_x^2-D_y+uD_x+\mathrm{ad}_v)(2D_x+\mathrm{ad}_u)^{-1}.$$

and the second Poisson operand

$$\hat{\theta}_2=\begin{pmatrix} \overline{\theta}_{11} & \overline{\theta}_{12} & \overline{\theta}_{13} \\ \overline{\theta}_{21} & \overline{\theta}_{22} & \overline{\theta}_{23} \\ \overline{\theta}_{31} & \overline{\theta}_{32} & \overline{\theta}_{33} \end{pmatrix}-R_{\partial_y}\hat{\theta}_1, \tag{192}$$

where

$$\overline{\theta}_{11}=6D_x+5\mathrm{ad}_u+\mathrm{ad}_u D_x^{-1}\mathrm{ad}_u,$$

$$\overline{\theta}_{12}=2D_x\,\mathrm{ad}_u^+ +2\,\mathrm{ad}_v+\mathrm{ad}_{u^2}+\mathrm{ad}_u D_x^{-1}\mathrm{ad}_v-2D_y-\mathrm{ad}_u D_x^{-1}D_y,$$

$$\begin{aligned}\overline{\theta}_{13}=&2D_x^3+\mathrm{ad}_u D_x^2+u\,\mathrm{ad}_u D_x+2D_xuD_x+2D_xv+\mathrm{ad}_u v+2\,\mathrm{ad}_w\\ &+\mathrm{ad}_u D_x^{-1}\mathrm{ad}_w-2D_xD_y-\mathrm{ad}_u D_y+R_{u_y},\end{aligned}$$

$$\overline{\theta}_{21}=2\,\mathrm{ad}_u^+ D_x+2\,\mathrm{ad}_v-2D_y+\mathrm{ad}_{u^2}+\mathrm{ad}_v D_x^{-1}\mathrm{ad}_u-D_yD_x^{-1}\mathrm{ad}_u,$$

$$\begin{aligned}\overline{\theta}_{22}=&2D_x^3+\mathrm{ad}_u D_x^2+D_x^2\,\mathrm{ad}_u+vD_x-D_yD_x+D_xR_v-\mathrm{ad}_w+uD_xu\\ &+R_uD_xR_u+v\,\mathrm{ad}_u^+ -D_y\,\mathrm{ad}_u^+ +uv-uD_y-R_vR_u-\mathrm{ad}_u^+ R_v\end{aligned}$$

$$+(\mathrm{ad}_v-D_y)D_x^{-1}(\mathrm{ad}_v-D_y)+R_{u_y},$$

$$\begin{aligned}\overline{\theta}_{23}=&D_x^4+uD_x^3+D_x^2uD_x+D_x^2v-D_x^2D_y+\mathrm{ad}_v D_x^2-D_yD_x^2+R_wD_x\\&+D_x\,\mathrm{ad}_w^+ +uD_xuD_x+vuD_x-D_yuD_x+uD_xv-uD_xD_y-uR_vD_x\\&+(v-D_y)(\mathrm{ad}_v-D_y)+uw-R_uR_w+\mathrm{ad}_v D_x^{-1}\,\mathrm{ad}_w-D_yD_x^{-1}\,\mathrm{ad}_w,\end{aligned}$$

$$\begin{aligned}\overline{\theta}_{31}=&2D_x^3+D_x^2\,\mathrm{ad}_u-D_x\,\mathrm{ad}_u R_u-2D_xR_uD_x+2R_vD_x+R_v\,\mathrm{ad}_u\\&+2\,\mathrm{ad}_w+\mathrm{ad}_w D_x^{-1}\,\mathrm{ad}_u,\end{aligned}$$

$$\begin{aligned}\overline{\theta}_{32}=&-D_x^4+D_x^3R_u+D_xR_uD_x^2-R_vD_x^2+D_x^2\,\mathrm{ad}_v-D_x^2D_y+D_xw\\&+\mathrm{ad}_w^+ D_x-D_xR_uD_xR_u+D_xR_uR_v+R_vD_xR_u-D_xvR_u\\&+D_xD_yR_u+\mathrm{ad}_v R_v-D_yR_v+wu-R_wR_u+\mathrm{ad}_w D_x^{-1}\,\mathrm{ad}_v\\&-\mathrm{ad}_w D_x^{-1}D_y-D_xR_{u_y}+R_{v_y},\end{aligned}$$

$$\overline{\theta}_{33}=wD_x^2-D_x^2R_w+wuD_x+D_xR_uR_w+wv-wD_y-R_vR_w+\mathrm{ad}_w D_x^{-1}\,\mathrm{ad}_w.$$

Taking

$$\nabla h_0=\begin{pmatrix}0\\0\\1\end{pmatrix}\in\ker\hat{\theta}_1$$

and applying formula (116) we get the hierarchy

$$\begin{pmatrix}u\\v\\w\end{pmatrix}_{t_1}=\begin{pmatrix}u_x\\v_x\\w_x\end{pmatrix},$$

$$\begin{pmatrix}u\\v\\w\end{pmatrix}_{t_2}=\begin{pmatrix}2v_x+u_y\\2w_x+v_{xx}+uv_x\\-w_{xx}+(wu)_x\end{pmatrix},$$

$$\begin{aligned}u_{t_3}&=u_{xxx}-\tfrac{3}{2}u^2u_x+6(uv)_x+6v_{xx}+12w_x+6v_y+3D_x^{-1}u_{yy}+3u_xD_x^{-1}u_y,\\v_{t_3}&=v_{xxx}+\tfrac{3}{2}(wu)_x+\tfrac{3}{2}uv_{xx}+\tfrac{3}{2}uw_x+\tfrac{3}{4}u_xv_x+\tfrac{3}{2}vv_x+\tfrac{3}{8}u^2v_x+\tfrac{3}{4}v_xD_x^{-1}u_y,\\w_{t_3}&=w_{xxx}-\tfrac{3}{2}(wu)_{xx}+\tfrac{3}{4}(wu_x)_x+\tfrac{3}{2}(wv)_x+\tfrac{3}{8}(u^2w)_x+\tfrac{3}{4}wu_y+\frac{3}{4}w_xD_x^{-1}u_y,\\&\vdots.\end{aligned}\tag{193}$$

The reduction $v=w=0$ gives the mKP equation

$$u_{t_3}=u_{xxx}-\tfrac{3}{2}u^2u_x+3D_x^{-1}u_{yy}+3u_xD_x^{-1}u_y.\tag{194}$$

V. CONCLUSIONS

In this paper we illustrated two different methods for the construction of a bi-Hamiltonian representation of the lattice-field and field dynamical system in $(2+1)$-dimension. The first method is based on the central extension approach and allows a construction of a hierarchy of commuting vector fields and a Hamiltonian representation of dynamical system. The second method is the so-called operand approach. This method allows a construction of a bi-Hamiltonian representation for dynamical systems in $(2+1)$-dimension. This bi-Hamiltonian representation is related to the so-called operand Poisson tensors. Inverting the first Poisson tensor we can construct a recursion operand and applying Theorem 3 and the Lemmas 1,2 to produce a whole hierarchy of commuting vector fields. The general idea was to extend the known methods for the construction integrable nonlinear Hamiltonian dynamical systems, which are based on the $\mathcal{R}$-matrix formalism, and to derive new dynamical systems in $(2+1)$-dimensions. We used the central extension procedure for the construction of $(2+1)$-dimensional lattice-field and field dynamical systems and their Hamiltonian formulation and derived hierarchies of vector fields of the $(2+1)$–Benjamin–Ono, $(2+1)$–Toda and some new equations. The $(2+1)$-dimensional systems which do not survive a reduction onto $(1+1)$-dimensional space are also derived. We developed operand formalism and extended theorems proposed by Magri, Morosi, and Tondo[13,14] and by Athorne, Dorfman, and Fokas,[11,15,16] unified them into one and also derived, using the proposed theorem, a bi-Hamiltonian formulation of well-known and some new dynamical systems of lattice-field and field types in $(2+1)$-dimensions. The operand formalism in the majority of the cases considered gives the same result as central extension approach, but we still do not have a general formula for the construction of hierarchies of commuting vector fields and each time we have to find a ''right'' starting symmetry. This problem is still open.

(Received 7 December 1998; accepted for publication 12 October 2000)

We study a family of fermionic extensions of the Camassa–Holm equation. Within this family we identify three interesting classes: (a) equations, which are inherently Hamiltonian, describing geodesic flow with respect to an H^1 metric on the group of superconformal transformations in two dimensions, (b) equations which are Hamiltonian with respect to a different Hamiltonian structure and (c) supersymmetric equations. Classes (a) and (b) have no intersection, but the intersection of classes (a) and (c) gives a system with interesting integrability properties. We demonstrate the Painlevé property for some simple but nontrivial reductions of this system, and also discuss peakon-type solutions. © *2001 American Institute of Physics.*

I. INTRODUCTION

Recently there has been substantial interest in the Camassa–Holm (CH) equation:[1,2]

$$u_t - \nu u_{xxt} = \kappa u_x - 3uu_x + \nu(uu_{xxx} + 2u_x u_{xx}). \tag{1}$$

This equation has been proposed as a model for shallow water waves. It is believed to be integrable, having a bi-Hamiltonian structure, as was first observed by Fokas and Fuchssteiner[3] 12 years prior to Camassa's and Holm's work. Due to the nonlinear dispersion term, uu_{xxx}, it exhibits more general wave phenomena than other integrable water wave equations such as KdV. In particular, when $\kappa = 0$ it admits a class of nonanalytic weak solutions known as *peakons*, as well as finite time blow-up of classical solutions.[1]

Geometrically, the relationship of CH to KdV is rather deeper: Both are regularizations of the Euler equation for a one dimensional compressible fluid (Monge or inviscid Burgers equation),

$$u_t = -3uu_x. \tag{2}$$

A solution to this equation describes a geodesic on the group of diffeomorphisms of the circle $\mathrm{Diff}(S^1)$[4] with respect to a right-invariant metric induced by an L^2 norm, $\int u^2\,dx$, on the associated Lie algebra. If the group is centrally extended to the Bott–Virasoro group, the KdV equation arises.[5–8] On the other hand, if the metric is changed to one induced by an H^1 norm, $\int(u^2 + \nu u_x^2)dx$, the CH equation arises.[9–11] Both these ''deformations'' have a regularizing effect on solutions of (2), which exhibit discontinuous shocks.

Thus KdV and CH arise in a unified geometric setting; both are geodesic flows which are integrable systems. (Here, and henceforth in this paper, when we refer to a ''geodesic flow'' we

a)Electronic mail: devchand@mpim-bonn.mpg.de
b)Electronic mail: schiff@math.biu.ac.il

mean the evolutionary PDE which can be formally associated—in the manner we will see in Sec. II—with any inner product on the Lie algebra of a diffeomorphism group, and which, at least in the cases mentioned above, is known to describe geodesic flow, in the usual sense of the phrase, with respect to the correpsonding right-invariant metric on the group. In the case of a general inner product, the existence of the corresponding geodesic flow, in the usual sense of the phrase, is highly nontrivial.) The following important question arises: What features of the underlying geometry give rise to integrability? In general, geodesic flows are *not* integrable: the Euler equation for fluid flow in more than one spatial dimension is an example.[4] Indeed, for the latter, Arnold has suggested a relationship between negative sectional curvatures and nonpredictability of the flow. We feel that it ought to be possible to identify some other geometric property that ''causes'' integrability. In a remarkable recent paper,[12] Fringer and Holm have shown that certain features usually considered to be hallmarks of integrable systems, such as elastic scattering and asymptotic sorting according to height, in fact, appear in geodesic flows on $\mathrm{Diff}(S^1)$ with respect to a large class of metrics. Thus, there may well be a hierarchy of geometric structures corresponding to various degrees of integrability.

One further example of an integrable bi-Hamiltonian system arising as a geodesic flow has been discussed by Ovsienko and Khesin.[5] Using the superconformal group with an L^2 type metric, they obtained the so-called kuper-KdV system of Kupershmidt.[13] This is a fermionic extension of KdV: it describes evolution of functions valued in (the odd or even parts of) a Grassmann algebra. In fact, as we will see below, taking a general L^2 type metric on the superconformal group gives rise to a one parameter family of fermionic extensions of KdV, which includes not only kuper-KdV, but also the super-KdV system of Mathieu and Manin–Radul.[14,15] The latter is integrable: it has only a single Hamiltonian structure, but unlike kuper-KdV it is supersymmetric, a property which is widely believed to contribute to integrability. It remains a mystery as to why, of the one parameter family of geodesic flows associated with L^2 type metrics on the superconformal group, only two specific choices of the parameter give rise to integrable systems.

Our main purpose in this paper is to investigate geodesic flows obtained from H^1 type norms on the superconformal group; more generally we consider the following family of fermionic extensions of CH:

$$\begin{aligned} u_t-\nu u_{xxt}&=\kappa_1 u_x+\kappa_2 u_{xxx}+\beta_1 uu_x+\beta_2 u_x u_{xx}+\beta_3 uu_{xxx}+\gamma_1\xi\xi_{xx}+\gamma_2\xi_x\xi_{xxx}+\gamma_3\xi\xi_{xxxx}, \\ \xi_t-\mu\xi_{xxt}&=\sigma_1\xi_x+\sigma_2\xi_{xxx}+\epsilon_1 u_x\xi+\epsilon_2 u\xi_x+\rho_1 u\xi_{xxx}+\rho_2 u_x\xi_{xx}+\rho_3 u_{xx}\xi_x+\rho_4 u_{xxx}\xi. \end{aligned} \tag{3}$$

Here $u(x,t)$ and $\xi(x,t)$ are fields valued, respectively, in the even and odd parts of a Grassmann algebra, and $\{\nu,\mu,\kappa_1,\kappa_2,\beta_1,\beta_2,\beta_3,\gamma_1,\gamma_2,\gamma_3,\sigma_1,\sigma_2,\epsilon_1,\epsilon_2,\rho_1,\rho_2,\rho_3,\rho_4\}$ are parameters. By rescaling u and ξ it is possible to set $\beta_1=-3$ and $\gamma_1=2$ (assuming that they are nonzero), and we shall do this throughout. In addition it is possible to eliminate up to two further parameters by rescaling the coordinates x,t.

We derive three interesting classes of systems of the form (3). In Sec. II, we consider geodesic flows on the superconformal group with an H^1 type metric; the resulting systems have a natural Hamiltonian structure, or more precisely, since the fields are Grassmann algebra valued, a graded Hamiltonian structure. In Sec. III we identify a class of systems having a different Hamiltonian structure. Unfortunately the latter has no intersection with the class of Sec. II, so there does not seem to be a bi-Hamiltonian fermionic extension of CH. In Sec. IV we consider systems of the form (3) that are invariant under supersymmetry transformations between u and ξ. This class has nontrivial intersections with both the classes of Secs. II and III. In particular there is a unique supersymmetric geodesic flow which is a candidate for being a new integrable system. We call this equation *super-CH*. In Sec. V we show that two reductions of super-CH have the Painlevé property, which is positive evidence for integrability. In Sec. VI we look for peakon-type solutions of super-CH; as for CH, multipeakon solutions arise from the solutions of a system of ODEs, but the integrability of this unfortunately remains unclear.

Super-CH is a supersymmetric geodesic flow whose bosonic part is integrable. While in this paper we do not fully establish integrability of super-CH, we regard it as an interesting test case to determine whether in general supersymmetric geodesic flows with integrable bosonic parts must be integrable.

A trivial integrable CH system of the form (3), which is not incorporated in the classes of Secs. II, III, and IV, and which we shall not discuss further, is the odd linearization of the bosonic CH system (1):

$$\begin{aligned} u_t-\nu u_{xxt}&=\kappa u_x-3uu_x+\nu(uu_{xxx}+2u_xu_{xx}),\\ \xi_t-\nu\xi_{xxt}&=\kappa\xi_x-3(\xi u)_x+\nu(\xi u_{xxx}+u\xi_{xxx}+2(\xi_xu_x)_x). \end{aligned} \tag{4}$$

Replacing u by $u+\kappa/3$ and considering the limit $\nu\to 0$, $\kappa\to\infty$, with $\nu\kappa=3$, yields the system

$$\begin{aligned} u_t&=-3uu_x+u_{xxx},\\ \xi_t&=-3(\xi u)_x+\xi_{xxx}. \end{aligned} \tag{5}$$

This trivial fermionic extension of KdV has appeared often in the literature (see, e.g., Ref. 14).

II. GEODESIC FLOWS ON THE SUPERCONFORMAL GROUP

An inner product $\langle\cdot\,,\cdot\rangle$ on a Lie algebra $\mathfrak{g}$ determines a right- (or a left-) invariant metric on the corresponding Lie group G. The equation of geodesic motion on G with respect to this metric is determined as follows.[4] Define a bilinear operator $B\colon \mathfrak{g}\times\mathfrak{g}\to\mathfrak{g}$ by

$$\langle[V,W],U\rangle=\langle W,B(U,V)\rangle,\quad \forall\ \ W\in\mathfrak{g}. \tag{6}$$

Then geodesics are determined by solutions of the ''geodesic flow,''

$$U_t=B(U,U). \tag{7}$$

In our case, $\mathfrak{g}$ is the NSR superconformal algebra, consisting of triples $(u(x),\varphi(x),a)$, where u is a bosonic field, φ is a fermionic field and a is a constant. The Lie bracket is given by

$$\begin{aligned} [(u,\varphi,a)\,,(v,\psi,b)]=\Big(&uv_x-u_xv+\frac{1}{2}\varphi\psi\,,\,u\psi_x-\frac{1}{2}u_x\psi-\varphi_xv+\frac{1}{2}\varphi v_x\,,\\ &\int dx\Big(c_1u_xv_{xx}+c_2uv_x+c_1\varphi_x\psi_x+\frac{c_2}{4}\varphi\psi\Big)\Big), \end{aligned} \tag{8}$$

where c_1,c_2 are constants. On this algebra, an H^1 type inner product is given by

$$\begin{aligned} \langle(u,\varphi,a)\,,(v,\psi,b)\rangle&=\int dx(uv+\nu u_xv_x+\alpha\varphi\,\partial_x^{-1}\psi+\alpha\mu\varphi_x\psi)+ab\\ &=\int dx(u\Delta_0v+\varphi\Delta_1\psi)+ab, \end{aligned} \tag{9}$$

where

$$\Delta_0=1-\nu\partial_x^2,\quad \Delta_1=\alpha(\partial_x^{-1}-\mu\partial_x), \tag{10}$$

and μ,ν,α are further constants, all assumed nonzero. (See Ref. 5 for the definition of the natural fermionic extension of the standard L^2 inner product, to which the above reduces if $\mu=\nu=0$. The natural fermionic extension of the standard H^1 inner product is constructed, as for pure bosonic

systems, by taking the sum of the L^2 inner product for the functions involved with the L^2 inner product for the derivatives of the functions involved.) Writing $U=(u,\varphi,a)$, $V=(v,\psi,b)$, we find $B(U,V)=(B_0,B_1,0)$, where

$$\begin{aligned}\Delta_0 B_0(U,V)&=-(2v_x\Delta_0 u+v\,\Delta_0 u_x+\tfrac{3}{2}\psi_x\Delta_1\varphi+\tfrac{1}{2}\psi\Delta_1\varphi_x)-+a(c_1v_{xxx}-c_2v_x),\\ \Delta_1 B_1(U,V)&=-\left(\frac{3}{2}v_x\Delta_1\varphi+v\,\Delta_1\varphi_x+\frac{1}{2}\psi\Delta_0 u\right)+a\left(c_1\psi_{xx}-\frac{c_2}{4}\psi\right).\end{aligned}\tag{11}$$

The geodesic flows are therefore conveniently written in the form

$$\begin{aligned}\Delta_0 u_t&=\Delta_0 B_0(U,U),\\ \Delta_0\varphi_t&=\Delta_1 B_1(U,U),\\ a_t&=0.\end{aligned}\tag{12}$$

Writing $\varphi=\lambda\xi_x$, where λ is a constant satisfying $\lambda^2=4/3\alpha$, this yields the system

$$\begin{aligned}u_t-\nu u_{xxt}&=\kappa_1 u_x+\kappa_2 u_{xxx}-3uu_x+\nu(uu_{xxx}+2u_xu_{xx})+2\xi\xi_{xx}+\frac{2\mu}{3}\xi_x\xi_{xxx},\\ \xi_t-\mu\xi_{xxt}&=\frac{\kappa_1}{4\alpha}\xi_x+\frac{\kappa_2}{\alpha}\xi_{xxx}-\frac{3}{2}u_x\xi-\left(1+\frac{1}{2\alpha}\right)u\xi_x+\mu u\xi_{xxx}+\frac{3\mu}{2}u_x\xi_{xx}+\frac{\nu}{2\alpha}u_{xx}\xi_x.\end{aligned}\tag{13}$$

Here κ_1,κ_2 are independent parameters determined by a,c_1,c_2. This is evidently a 5 parameter class of systems of type (3).

Setting ξ to zero in (13) yields the CH result of Refs. 9–11. If instead we choose μ,ν to vanish, the H^1 norm becomes an L^2 norm; then choosing κ_1 to be zero and rescaling κ_2 to 1 we obtain the following 1 parameter fermionic extension of KdV:

$$\begin{aligned}u_t&=u_{xxx}-3uu_x+2\xi\xi_{xx},\\ \xi_t&=\frac{1}{\alpha}\xi_{xxx}-\frac{3}{2}u_x\xi-\left(1+\frac{1}{2\alpha}\right)u\xi_x.\end{aligned}\tag{14}$$

Modulo rescalings, the super-KdV of Mathieu and Manin–Radul is obtained by taking $\alpha=1$. The kuper-KdV system arises by taking $\alpha=\frac{1}{4}$, the choice made in Ref. 5. Other values of the parameters give systems which are not believed to be integrable (see however Ref. 16).

III. HAMILTONIAN EQUATIONS

Like KdV, CH has a bi-Hamiltonian structure, and this accounts for its integrability. We might hope that for some choices of parameters the system (13) should also have a bi-Hamiltonian structure. One Hamiltonian structure follows automatically from the geometric origins of the system.[4] Explicitly, introducing new variables, $m=u-\nu u_{xx}$ and $\eta=\xi-\mu\xi_{xx}$, (13) takes the form

$$\begin{pmatrix}m_t\\ \eta_t\end{pmatrix}=\mathcal{P}_2\begin{pmatrix}\dfrac{\delta\mathcal{H}_2}{\delta m}\\ \dfrac{\delta\mathcal{H}_2}{\delta\eta}\end{pmatrix},\tag{15}$$

where

$$\mathcal{P}_2=\begin{pmatrix} \kappa_2\partial_x^3+\kappa_1\partial_x-\partial_x m-m\partial_x & \frac{1}{2}\partial_x\eta+\eta\partial_x \\ -\partial_x\eta-\frac{1}{2}\eta\partial_x & \frac{3}{4\alpha}\left(\frac{\kappa_1}{4}+\kappa_2\partial_x^2\right)-\frac{3}{8\alpha}m \end{pmatrix}, \tag{16}$$

and the Hamiltonian functional is given succinctly by the H^1 inner product on the algebra,

$$\mathcal{H}_2=\tfrac{1}{2}\langle U\,,\,U\rangle=\tfrac{1}{2}\int dx(u^2+\nu u_x^2+\tfrac{4}{3}(\xi_x\xi+\mu\xi_{xx}\xi_x)). \tag{17}$$

This generalizes the so-called *second Hamiltonian structure* of KdV and its fermionic extensions.[13,14] Checking (15) is straightforward: the Euler–Lagrange derivatives $\delta\mathcal{H}_2/\delta m$, $\delta\mathcal{H}_2/\delta\eta$ are defined by

$$\delta\mathcal{H}_2=\int dx\left(\frac{\delta\mathcal{H}_2}{\delta m}\,\delta m+\frac{\delta\mathcal{H}_2}{\delta\eta}\,\delta\eta\right), \tag{18}$$

from which it follows immediately that $\delta\mathcal{H}_2/\delta m=u$ and $\delta\mathcal{H}_2/\delta\eta=\frac{4}{3}\xi_x$.

To investigate the possibility of systems amongst (13) having another Hamiltonian form, we look at systems of the form

$$\begin{pmatrix} m_t \\ \eta_t \end{pmatrix}=\mathcal{P}_1\begin{pmatrix} \dfrac{\delta\mathcal{H}_1}{\delta m} \\ \dfrac{\delta\mathcal{H}_1}{\delta\eta} \end{pmatrix}, \tag{19}$$

where

$$\mathcal{P}_1=\begin{pmatrix} \partial_x(1-\nu\partial_x^2) & 0 \\ 0 & -\dfrac{\epsilon_1}{2}(1-\mu\partial_x^2) \end{pmatrix}. \tag{20}$$

Here ϵ_1 is a constant and $\mathcal{H}_1$ is a functional generalizing the KdV *first Hamiltonian*,

$$\begin{aligned}\mathcal{H}_1=\int dx\Big(&-\frac{1}{2}u^3-\frac{\beta_3}{2}uu_x^2-\frac{\kappa_2}{2}u_x^2+\frac{\kappa_1}{2}u^2+\frac{\sigma_1}{\epsilon_1}\xi\xi_x+\frac{\sigma_2}{\epsilon_1}\xi\xi_{xxx}\\&+2u\xi\xi_x+(\gamma_2-\gamma_3)u\xi_x\xi_{xx}+\gamma_3u\xi\xi_{xxx}\Big).\end{aligned} \tag{21}$$

This is the most general functional of this type, up to rescalings of u and ξ. Since $\delta m=(1-\nu\partial_x^2)\delta u$, we have $(1-\nu\partial_x^2)(\delta\mathcal{H}_1/\delta m)=(\delta\mathcal{H}_1/\delta u)$, and similarly $(1-\mu\partial_x^2)(\delta\mathcal{H}_1/\delta\eta)=(\delta\mathcal{H}_1/\delta\xi)$. Thus Eqs. (19) take the simple form

$$\begin{aligned} u_t-\nu u_{xxt}&=\partial_x\left(\frac{\delta\mathcal{H}_1}{\delta u}\right)=\kappa_1u_x+\kappa_2u_{xxx}-3uu_x+\beta_3(2u_xu_{xx}+uu_{xxx})\\&\quad+2\xi\xi_{xx}+\gamma_2\xi_x\xi_{xxx}+\gamma_3\xi\xi_{xxxx},\\ \xi_t-\mu\xi_{xxt}&=\epsilon_1\left(\frac{\delta\mathcal{H}_1}{\delta\xi}\right)=\sigma_1\xi_x+\sigma_2\xi_{xxx}+\epsilon_1(u_x\xi+2u\xi_x)+\epsilon_1(2\gamma_3-\gamma_2)u\xi_{xxx}\\&\quad+\frac{3}{2}\epsilon_1(2\gamma_3-\gamma_2)u_x\xi_{xx}+\frac{1}{2}\epsilon_1(4\gamma_3-\gamma_2)u_{xx}\xi_x+\frac{1}{2}\epsilon_1\gamma_3u_{xxx}\xi.\end{aligned} \tag{22}$$

This is a 10 parameter class of systems of the form (3). Comparing with (13), we see that the only bi-Hamiltonian systems occur when $\{\mu=\nu=\beta_3=\gamma_2=\gamma_3=0,\ \epsilon_1=-\frac{3}{2},\ \sigma_1=\kappa_1,\ \sigma_2=4\kappa_2\}$, which is equivalent to (13) with $\{\mu=\nu=0\,,\ \alpha=\frac{1}{4}\}$, i.e., the kuper-KdV system. Thus, no new bi-Hamiltonian systems arise.

We note that the systems (22) can be obtained from a Lagrangian. Introducing a potential f defined by $u=f_x$, they are Euler–Lagrange equations for the functional

$$\mathcal{L}=\int dx\Big(\frac{1}{2}(f_x-\nu f_{xxx})f_t+\frac{1}{\epsilon_1}(\xi-\mu\xi_{xx})\xi_t+\frac{1}{2}f_x^3+\frac{\beta_3}{2}f_xf_{xx}^2+\frac{\kappa_2}{2}f_{xx}^2-\frac{\kappa_1}{2}f_x^2-\frac{\sigma_1}{\epsilon_1}\xi\xi_x$$
$$-\frac{\sigma_2}{\epsilon_1}\xi\xi_{xxx}-2\,f_x\xi\xi_x+(\gamma_3-\gamma_2)f_x\xi_x\xi_{xx}-\gamma_3f_x\xi\xi_{xxx}\Big). \tag{23}$$

IV. SUPERSYMMETRIC EQUATIONS

Define a fermionic superfield $\Phi(x,\vartheta)=s\xi+\vartheta u$ and superderivative $D=\partial/\partial\vartheta+\vartheta\partial_x$, where s is a nonzero parameter and ϑ is an odd coordinate. The most general superfield equation having a component content of the form (3) is the 8 parameter system,

$$(1-\nu D^4)\Phi_t=\kappa_1D^2\Phi+\kappa_2D^6\Phi-\frac{2}{s^2}\Phi D^3\Phi+\Big(\frac{2}{s^2}-3\Big)D\Phi D^2\Phi+\Big(\frac{\gamma_3}{s^2}+\beta_3\Big)D\Phi D^6\Phi$$
$$-\frac{\gamma_3}{s^2}\Phi D^7\Phi+\Big(\beta_3+\frac{\gamma_3-\gamma_2}{s^2}\Big)D^2\Phi D^5\Phi+\Big(\beta_2-\beta_3+\frac{\gamma_2-\gamma_3}{s^2}\Big)D^3\Phi D^4\Phi, \tag{24}$$

where $\{\nu,s,\kappa_1,\kappa_2,\beta_2,\beta_3,\gamma_2,\gamma_3\}$ are parameters. The component equations are

$$u_t-\nu u_{xxt}=\kappa_1u_x+\kappa_2u_{xxx}-3uu_x+\beta_2u_xu_{xx}+\beta_3uu_{xxx}+2\xi\xi_{xx}+\gamma_2\xi_x\xi_{xxx}+\gamma_3\xi\xi_{xxxx},$$
$$\xi_t-\nu\xi_{xxt}=\kappa_1\xi_x+\kappa_2\xi_{xxx}-\frac{2}{s^2}u_x\xi+\Big(\frac{2}{s^2}-3\Big)u\xi_x+\Big(\frac{\gamma_3}{s^2}+\beta_3\Big)u\xi_{xxx}$$
$$+\Big(\beta_2-\beta_3+\frac{\gamma_2-\gamma_3}{s^2}\Big)u_x\xi_{xx}+\Big(\frac{\gamma_3-\gamma_2}{s^2}+\beta_3\Big)u_{xx}\xi_x-\frac{\gamma_3}{s^2}u_{xxx}\xi. \tag{25}$$

These systems are by construction invariant under the supersymmetry transformations,

$$\delta u=\tau\xi_x,\quad \delta\xi=\frac{\tau u}{s^2}, \tag{26}$$

where τ is an odd parameter. The super-KdV limit, namely $\{\nu,\beta_2,\beta_3,\gamma_2,\gamma_3,\kappa_1\}$ all zero, yields, modulo rescalings, the one-parameter family of systems studied by Mathieu.[14]

By comparing (25) and (22) it is straightforward to extract systems which are both supersymmetric and have Hamiltonian form (19), (20). Taking $s^2=2$ in (25), $\{\nu=\mu,\ \sigma_1=\kappa_1,\ \sigma_2=\kappa_2,\ \epsilon=-1\}$ in (22), and $\{\beta_2=2\beta_3,\ \beta_3=\gamma_2-\frac{5}{2}\gamma_3\}$ in both, we obtain the systems,

$$u_t-\nu u_{xxt}=\kappa_1u_x+\kappa_2u_{xxx}-3uu_x+(\gamma_2-\tfrac{5}{2}\gamma_3)(2u_xu_{xx}+uu_{xxx})$$
$$+2\xi\xi_{xx}+\gamma_2\xi_x\xi_{xxx}+\gamma_3\xi\xi_{xxxx},$$
$$\xi_t-\nu\xi_{xxt}=\kappa_1\xi_x+\kappa_2\xi_{xxx}-u_x\xi-2u\xi_x+(\gamma_2-2\gamma_3)u\xi_{xxx}$$
$$+\tfrac{3}{2}(\gamma_2-2\gamma_3)u_x\xi_{xx}+\tfrac{1}{2}(\gamma_2-4\gamma_3)u_{xx}\xi_x-\tfrac{1}{2}\gamma_3u_{xxx}\xi. \tag{27}$$

These may be expressed in superfield form (24) with the above choice of parameters. The manifestly supersymmetric Hamiltonian form is given by

$$M_t=\hat{\mathcal{P}}_1\frac{\delta\hat{\mathcal{H}}_1}{\delta M},\quad M=\Phi-\nu D^4\Phi, \tag{28}$$

with

$$\hat{\mathcal{P}}_1=D(1-\nu D^4), \tag{29}$$

$$\hat{\mathcal{H}}_1=\int dx\,d\vartheta\left(\frac{\kappa_1}{2}\Phi D\Phi-\frac{\kappa_2}{2}D^2\Phi D^3\Phi-\frac{1}{2}\Phi(D\Phi)^2+\frac{1}{4}\gamma_3\Phi(D^3\Phi)^2+\frac{1}{4}(\gamma_2-2\gamma_3)(D\Phi)^2D^4\Phi\right). \tag{30}$$

Since the KdV reduction of (27) (with $\kappa_1=\gamma_2=\gamma_3=0$) is not believed to be integrable, we have not explored this class of systems further.

In a similar fashion, we may look for choices of parameter sets for which the geodesic flows of Sec. II are also supersymmetric. Comparing (13) with (25), we see that the choice $\{\mu=\nu,\ \alpha=1\ ,\ \kappa_1=0\}$ in the former and $\{s^2=\frac{4}{3},\ \beta_2=2\nu,\ \beta_3=\nu,\ \gamma_2=2\nu/3,\ \gamma_3=\kappa_1=0\}$ in the latter, yields the two-parameter system of supersymmetric geodesic flows:

$$\begin{aligned}u_t-\nu u_{xxt}&=\kappa_2u_{xxx}-3uu_x+2\xi\xi_{xx}+\nu(uu_{xxx}+2u_xu_{xx})+\frac{2\nu}{3}\xi_x\xi_{xxx},\\ \xi_t-\nu\xi_{xxt}&=\kappa_2\xi_{xxx}-\frac{3}{2}(u\xi)_x+\nu\left(u\xi_{xxx}+\frac{3}{2}u_x\xi_{xx}+\frac{1}{2}u_{xx}\xi_x\right).\end{aligned} \tag{31}$$

We shall call this system, with $\kappa_2=0$ and $\nu\neq0$, the *supersymmetric Camassa–Holm equation* (super-CH). The system (31) reduces to super-KdV, upon setting ν to zero, and to CH, upon setting ξ to zero and translating u.

Not surprisingly, the systems (31) arise as geodesic flows precisely when the metric (9) on the NSR superconformal algebra is supersymmetric. Then, the calculations of Sec. II can be performed using superfields. Specifically, writing $\mathcal{U}=u+\vartheta\phi$ and $\mathcal{V}=v+\vartheta\psi$, the bracket (8) takes the form

$$[(\mathcal{U},a)\,,(\mathcal{V},b)]=\left(\mathcal{U}D^2\mathcal{V}-\mathcal{V}D^2\mathcal{U}+\frac{1}{2}D\mathcal{U}D\mathcal{V},c_1\int dx\,d\vartheta\,D^2\mathcal{U}D^3\mathcal{V}\right), \tag{32}$$

and the inner product (9) may be written as

$$\langle(\mathcal{U},a)\,,(\mathcal{V},b)\rangle=\int dx\,d\vartheta(\mathcal{U}D^{-1}\mathcal{V}+\nu D^2\mathcal{U}D\mathcal{V})+ab. \tag{33}$$

The superspace bilinear operator $\hat{B}$ is given by $\hat{B}((\mathcal{U},a),(\mathcal{V},b))=(\hat{B}_0,0)$, where $\hat{B}_0$ satisfies

$$(1-\nu D^4)D^{-1}\hat{B}_0=c_1aD^5\mathcal{V}-\tfrac{3}{2}D^2\mathcal{V}(1-\nu D^4)D^{-1}\mathcal{U}-\tfrac{1}{2}D\mathcal{V}(1-\nu D^4)\mathcal{U}-\mathcal{V}(1-\nu D^4)D\mathcal{U}. \tag{34}$$

Writing $c_1a=\kappa_2$ and $\mathcal{U}=D\Phi$, the geodesic flows $(\mathcal{U}_t,a_t)=\hat{B}((\mathcal{U},a),(\mathcal{U},a))$ yield

$$(1-\nu D^4)\Phi_t=\kappa_2D^6\Phi-\tfrac{3}{2}(\Phi D^3\Phi+D\Phi D^2\Phi)+\nu(D\Phi D^6\Phi+\tfrac{1}{2}D^2\Phi D^5\Phi+\tfrac{3}{2}D^3\Phi D^4\Phi). \tag{35}$$

We thus recover the subsystem of (24) having component content (31). Equation (35) has a superfield Hamiltonian formulation,

$$M_t=\hat{\mathcal{P}}_2\frac{\delta\hat{\mathcal{H}}_2}{\delta M},\quad M=\Phi-\nu D^4\Phi, \tag{36}$$

with

$$\hat{\mathcal{P}}_2=\kappa_2 D^5-\tfrac{1}{2}DMD-D^2M-MD^2, \tag{37}$$

$$\hat{\mathcal{H}}_2=\frac{1}{2}\langle(D\Phi,0)\,,(D\Phi,0)\rangle=\frac{1}{2}\int dx\,d\vartheta\Phi DM. \tag{38}$$

V. PAINLEVÉ INTEGRABILITY OF SUPER-CH SYSTEMS

In this section we investigate, in more detail, the supersymmetric geodesic flow (31) with $\nu=1$ and $\kappa_2=0$,

$$\begin{aligned} m_t&=-2mu_x-um_x+2\eta\xi+\tfrac{2}{3}\eta_x\xi_x,\quad m=u-u_{xx},\\ \eta_t&=-\tfrac{3}{2}\eta u_x-\tfrac{1}{2}m\xi_x-u\eta_x,\quad \eta=\xi-\xi_{xx}. \end{aligned} \tag{39}$$

We shall consider the two simplest possible choices for the Grassmann algebra in which the fields are valued, viz. algebras with one or two odd generators. Taking the algebra to be finite dimensional is a very convenient tool for preliminary investigations of systems with Grassmann algebra-valued fields. Manton[17] recently studied some simple supersymmetric classical mechanical systems in this way and he introduced the term ''deconstruction'' to denote a component expansion in a Grassmann algebra basis. In Ref. 18 we investigate fermionic extensions of KdV in a similar fashion.

A. First deconstruction of super-CH

We first consider the super-CH system (39) with fields taking values in the simplest Grassmann algebra with basis $\{1,\tau\}$, where τ is a single fermionic generator. In this case the fermionic fields may be expressed as $\xi=\tau\xi_1$, $\eta=\tau\eta_1$, where ξ_1 and η_1 are standard (i.e., commuting, c-number) functions, as are u and m in this simple case. Since $\tau^2=0$, the fermionic bilinear terms do not contribute and we are left with the system

$$\begin{aligned} m_t&=-2mu_x-um_x,\quad m=u-u_{xx},\\ \eta_{1t}&=-\tfrac{3}{2}\eta_1u_x-\tfrac{1}{2}m\xi_{1x}-u\eta_{1x},\quad \eta_1=\xi_1-\xi_{1xx}. \end{aligned} \tag{40}$$

Further analysis is simplified by changing coordinates as described in Ref. 19. Writing $m=p^2$, the first equation of (40) takes the form $p_t=(-pu)_x$, which suggests new coordinates y_0,y_1 defined via

$$dy_0=p\,dx-pu\,dt,\quad dy_1=dt, \tag{41}$$

or dually, via

$$\frac{\partial}{\partial x}=p\frac{\partial}{\partial y_0},\quad \frac{\partial}{\partial t}=\frac{\partial}{\partial y_1}-pu\frac{\partial}{\partial y_0}. \tag{42}$$

Implementing this coordinate change and eliminating the functions u and ξ_1, the remaining equations for p and $q\equiv\eta_1$ are

$$p^2\dot{p}''-p(\dot{p}p''+\dot{p}'p')+\dot{p}p'^2-2p^3p'-\dot{p}=0, \tag{43}$$

$$\dot{q}''-\frac{3p'}{p}\dot{q}'-\frac{3\dot{p}}{2p}q''+\left(\frac{4p'^2}{p^2}-\frac{2p''}{p}-\frac{1}{p^2}\right)\dot{q}+\left(\frac{15p'\dot{p}}{2p^2}-\frac{3\dot{p}'}{p}-\frac{p}{2}\right)q'$$
$$+3\left(\frac{\dot{p}p''+2p'\dot{p}'}{p^2}-\frac{4\dot{p}p'^2}{p^3}-p'\right)q=0. \tag{44}$$

Here the dot and prime denote differentiations with respect to y_1 and y_0, respectively. We note: (a) thanks to supersymmetry (26), if p is a solution of (43), then $q=p^2$ is a solution of (44); and (b) under the substitution $q=p^{3/2}r$, (44) takes the substantially simpler form

$$\dot{r}''+\left(\frac{p'^2}{4p^2}-\frac{p''}{2p}-\frac{1}{p^2}\right)\dot{r}-\frac{p}{2}r'-\frac{3p'}{4}r=0. \tag{45}$$

The system (43), (44) passes the WTC Painlevé test.

Proof: Equation (43) is a rescaled version of the Associated Camassa–Holm equation of Ref. 19. The consideration of solutions with $p(y_0,y_1)\sim p_0(y_0,y_1)\phi(y_0,y_1)^n$ near $\phi(y_0,y_1)=0$, for some $n\neq 0$, yields $n=-2$ or $n=1$ as the possible leading orders of Laurent series solutions. We need to perform the WTC Painlevé test[20] for both these types of series. The first type, namely, Laurent series solutions exhibiting double poles on the singular manifold $\phi(y_0,y_1)=0$, have already been considered in Ref. 21. These take the form

$$p=\frac{2\phi'\dot{\phi}}{\phi^2}-\frac{\dot{\phi}'}{\phi}+p_2+p_3\phi+p_4\phi^2+\ldots, \tag{46}$$

where ϕ,p_2,p_4 are arbitrary functions of y_0,y_1, and

$$p_3=\frac{-1}{2\phi'^2\dot{\phi}^2}(\phi'^2\dot{\phi}\dot{p}_2+\phi'\dot{\phi}^2p_2'-(\phi'^2\ddot{\phi}-2\phi'\dot{\phi}\dot{\phi}'+\phi''\dot{\phi}^2)p_2$$
$$-(\phi'\dot{\phi}\ddot{\phi}''-\phi'\ddot{\phi}\dot{\phi}''-\dot{\phi}\phi''\ddot{\phi}'+\ddot{\phi}\phi''\dot{\phi}')). \tag{47}$$

We have, at present, no explanation of the remarkable symmetry of these expressions under interchange of the independent variables. The second type of solutions have a simple zero on the singular manifold $\phi(y_0,y_1)=0$. They take the form

$$p=\pm\frac{\phi}{\phi'}+p_2\phi^2+p_3\phi^3+\ldots, \tag{48}$$

where ϕ,p_2,p_3 are arbitrary functions. The verification of the consistency of both these types of expansions is straightforward. This completes the WTC test for Eq. (43).

It remains to look at Eq. (44). Although linear in q, it is *not* automatically Painlevé. The movable poles and zeros in p give rise to movable poles in the coefficient functions of the linear equation for q, and we need to examine the resulting singularities of q. If p has a pole on $\phi=0$, then near $\phi=0$ we have $p\sim 2\dot{\phi}\phi'/\phi^2$, and Eq. (44) takes the form

$$\dot{q}''+\left(\frac{6\phi'}{\phi}+\ldots\right)\dot{q}'+\left(\frac{3\dot{\phi}}{\phi}+\ldots\right)q''+\left(\frac{4\phi'^2}{\phi^2}+\ldots\right)\dot{q}+\left(\frac{11\phi'\dot{\phi}}{\phi^2}+\ldots\right)q'+\left(O\left(\frac{1}{\phi^2}\right)\right)q=0.$$

Thus the equation has a solution with $q\sim\phi^n$ if $n(n-1)(n-2)+9n(n-1)+15n=0$, giving $n=-4,-2,0$. It follows that in the case when p is given by the series (46), no inconsistencies will arise near the double poles of p if (44) has a series solution of the form

$$q=\frac{q_0}{\phi^4}+\frac{q_1}{\phi^3}+\frac{q_2}{\phi^2}+\frac{q_3}{\phi}+q_4+\ldots, \tag{49}$$

with q_0, q_2, q_4 arbitrary. The consistency of such a solution can easilly be verified using a symbolic manipulator. Using MAPLE we find that

$$q_1 = \frac{2\phi'' q_0 - \phi' q_0'}{\phi'^2}. \tag{50}$$

The explicit expression for q_3 is too lengthy to be given here.

Suppose now that p has a zero on $\phi = 0$. Near this, $p \sim \pm \phi/\phi'$ and Eq. (44) has the structure

$$\dot{q}'' - \left(\frac{3\phi'}{\phi} + \ldots\right)\dot{q}' - \left(\frac{3\dot{\phi}}{2\phi} + \ldots\right)q'' + \left(\frac{3\phi'^2}{\phi^2} + \ldots\right)\dot{q} + \left(\frac{15\phi'\dot{\phi}}{2\phi^2} + \ldots\right)q' - \left(\frac{12\phi'^2\dot{\phi}}{\phi^3} + \ldots\right)q = 0.$$

Thus (44) has a solution with $q \sim \phi^n$ if $n(n-1)(n-2) - \frac{9}{2}n(n-1) + \frac{21}{2}n - 12 = 0$, giving $n = \frac{3}{2}, 2, 4$. The appearance of a half-integer here is not considered a violation of the Painlevé test (see, e.g., Ref. 22). The half-integer value of n gives rise to a series solution of (44), near a zero of p, of the form

$$q = q_0\phi^{3/2} + q_1\phi^{5/2} + q_2\phi^{7/2} + \ldots, \tag{51}$$

with q_0 arbitrary, and $q_1, q_2, \ldots$ determined by q_0 [and the arbitrary functions arising in the series (48) for p]. The two integer values of n tell us that we need to check the consistency of solutions of (44) taking the form

$$q = Q_0\phi^2 + Q_1\phi^3 + Q_2\phi^4 + \ldots, \tag{52}$$

with two arbitrary functions Q_0 and Q_2. This is indeed consistent; using MAPLE we obtain

$$Q_1 = \pm 2\phi' Q_0 p_2 - \frac{1}{3\phi'^2\dot{\phi}}(2\phi'^2\dot{Q}_0 + 2\phi''\dot{\phi}Q_0 + \phi'\dot{\phi}Q_0' + 4\phi'\dot{\phi}'Q_0), \tag{53}$$

with the choice of $\pm$ depending on the choice in (48). The general solution of (44) near a zero of p, with three arbitrary functions, is a linear combination of the series (51) and (52). Thus the system (43), (44) passes the WTC test. □

The WTC test is evidence for the complete integrability of the system (43), (44). This in turn suggests that super-CH indeed has some integrable content.

B. Second deconstruction of super-CH

We now consider the system (39) with fields taking values in a Grassmann algebra with two anticommuting fermionic generators, τ_1, τ_2. Expanding in the basis $\{1, \tau_1, \tau_2, \tau_1\tau_2\}$,

$$\begin{aligned} u &= u_0 + \tau_1\tau_2 u_1, \quad \xi = \tau_1\xi_1 + \tau_2\xi_2, \\ m &= m_0 + \tau_1\tau_2 m_1, \quad \eta = \tau_1\eta_1 + \tau_2\eta_2, \end{aligned} \tag{54}$$

where the functions $u_0, u_1, m_0, m_1, \xi_1, \xi_2, \eta_1, \eta_2$ are all standard, we obtain the system

$$m_{0t} = -2m_0u_{0x} - u_0m_{0x}, \quad m_0 = u_0 - u_{0xx}, \tag{55}$$

$$\eta_{it} = -\tfrac{3}{2}u_{0x}\eta_i - \tfrac{1}{2}m_0\xi_{ix} - u_0\eta_{ix}, \quad \eta_i = \xi_i - \xi_{ixx}, \quad i = 1,2, \tag{56}$$

$$\begin{aligned} m_{1t} = &-2m_1u_{0x} - 2m_0u_{1x} - u_0m_{1x} - u_1m_{0x} \\ &+ 2(\eta_1\xi_2 - \eta_2\xi_1) + \tfrac{2}{3}(\eta_{1x}\xi_{2x} - \eta_{2x}\xi_{1x}), \quad m_1 = u_1 - u_{1xx}. \end{aligned} \tag{57}$$

Supersymmetry (26) tells us that given a solution u_0, m_0 of (55), we can solve the remaining equations by taking $\xi_i = \alpha_i u_0$, $\eta_i = \alpha_i m_0$ $(i=1,2)$, $u_1 = \beta u_{0x}$ and $m_1 = \beta m_{0x}$, where $\alpha_1, \alpha_2, \beta$ are arbitrary constants.

We handle the system (55)–(57) following the procedure of the previous section. Writing $m_0 = p^2$ and changing coordinates to y_0, y_1, the system can be written as

$$u_0' = \left(\frac{1}{p}\right)^{\cdot}, \quad u_0 = p^2 - p\left(\frac{\dot{p}}{p}\right)', \tag{58}$$

$$\xi_i' = \frac{3\eta_i \dot{p}}{p^4} - \frac{2\dot{\eta}_i}{p^3}, \quad \xi_i = \eta_i + p\left(\frac{3\eta_i \dot{p}}{p^3} - \frac{2\dot{\eta}_i}{p^2}\right)', \quad i=1,2, \tag{59}$$

$$\left(\frac{m_1}{p^2}\right)^{\cdot} = -(2u_1 p)' + \left(\frac{8(\dot{\eta}_1\eta_2 - \dot{\eta}_2\eta_1)}{3p^3}\right)' + \left(\frac{4(\eta_1'\eta_2 - \eta_2'\eta_1)}{3p^3}\right)^{\cdot},$$
$$m_1 = u_1 - p(pu_1')'. \tag{60}$$

Applying the WTC Painlevé test to this is a mammoth task, so instead we consider the Galilean-invariant reduction and apply the Painlevé test at this level. The Galilean-invariant reduction is obtained, as usual, by restricting all functions to depend on the single variable $z = y_0 - v y_1$ alone. Evidently the first equations of both (58) and (60) can be integrated once immediately. Then eliminating u_0 from (58), ξ_i from (59) and m_1 from (60), we obtain

$$\left(\frac{p'}{p}\right)' = -\frac{p}{v} + \frac{c_1}{p} - \frac{1}{p^2}, \tag{61}$$

$$\eta_i''' - \frac{9p'}{2p}\eta_i'' + \left(\frac{11p}{2v} - \frac{5c_1}{p} + \frac{4}{p^2} + \frac{13p'^2}{2p^2}\right)\eta_i' - \frac{3p'}{p}\left(\frac{2p}{v} - \frac{3c_1}{p} + \frac{3}{p^2} + \frac{p'^2}{p^2}\right)\eta_i = 0, \quad i=1,2, \tag{62}$$

$$u_1'' + \frac{p'}{p}u_1' + \left(\frac{2p}{v} - \frac{1}{p^2}\right)u_1 = d_1 + \frac{4}{p^3}(\eta_1\eta_2' - \eta_2\eta_1'), \tag{63}$$

where c_1, d_1 are integration constants. The equation for $p(z)$ may be integrated again after multiplying both sides by p'/p; this gives

$$p'^2 = 1 - 2c_1 p + c_2 p^2 - \frac{2}{v}p^3, \tag{64}$$

where c_2 is another integration constant. This equation is well known in KdV theory. Its general solution can be written in terms of the Weierstrass $\wp$-function,

$$p(z) = -2v\wp(z) + \tfrac{1}{6}c_2 v, \tag{65}$$

where the periods of $\wp$ are determined by the coefficients c_1, c_2, v. Using (64), the coefficients in (62) can be simplified. Further, we know from supersymmetry that this equation has a solution $\eta_i = p^2$. Substituting $\eta_i = p^2 q_i$ the equation becomes a second order equation for q_i':

$$q_i''' + \frac{3p'}{2p}q_i'' + \left(-\frac{3p}{2v} - \frac{3}{2p^2} + \frac{c_2}{2}\right)q_i' = 0, \quad i=1,2. \tag{66}$$

Supersymmetry (26) allows a reduction of the order of (63) as well. It implies that $u_1 = p'/p$, $\eta_i = p^2$ is a solution. So, writing $u_1 = rp'/p, \eta_i = p^2 q_i$ in (63) yields a first order equation for r':

$$r'' + \left(c_2 p - \frac{4p^2}{v} - \frac{1}{p}\right)\frac{r'}{p'} = \frac{p}{p'}(d_1 + 4p(q_1 q_2' - q_2 q_1')). \tag{67}$$

Multiplying by the integrating factor p'^2/p and integrating, we obtain

$$r' = \frac{p}{p'^2}\left(d_1 p + d_2 + 4\int (q_1 q_2' - q_2 q_1')pp'\, dz \right), \tag{68}$$

where d_2 is a further constant of integration.

Thus the Galilean-invariant reduction of the second deconstruction of super-CH takes the form of the three equations (64), (66), (68), to which we now apply the Painlevé test. All substitutions hitherto have been ones which do not interfere with the test. Equation (64) has movable double poles and movable simple zeros. Near a double pole at z_0, the series solution contains only even powers of $(z-z_0)$,

$$p(z) = -\frac{2v}{(z-z_0)^2} + \frac{c_2 v}{6} + \frac{12c_1 - c_2^2 v}{120}(z-z_0)^2 + \frac{\dfrac{54}{v} + c_2^3 v - 18c_1 c_2}{3024}(z-z_0)^4 + \ldots, \tag{69}$$

and near a simple zero at z_0,

$$p(z) = \pm(z-z_0) - \frac{1}{2}c_1(z-z_0)^2 \pm \frac{1}{6}c_2(z-z_0)^3 - \frac{1}{24}\left(\frac{6}{v} + c_1 c_2\right)(z-z_0)^4 + \ldots . \tag{70}$$

At both the zeros and poles of p, Eq. (66), which is just a linear third order ODE, has regular singular points. Checking the Painlevé property for this reduces to doing the necessary Frobenius–Fuchs analysis at these regular singular points to check that no logarithmic singularities in the solutions q_i arise. Finally, Eq. (68) gives an explicit formula for r involving two quadratures. Here the necessary analysis involves writing series expansions for the integrands near the zeros and poles of p, and checking for the absence of $1/(z-z_0)$ terms, which would give rise to logarithms on integration. We do not present all these calculations in detail; with the aid of a symbolic manipulator they are quite straightforward. We conclude that the Galilean-invariant reduction of the second deconstruction of super-CH has the Painlevé property.

We note, in conclusion, that two of the equations we have encountered are interesting variants of the Lamé equation: In (66), the substitution $q_i' = p^{-3/4}h_i$ yields

$$h_i'' + \frac{3}{8}\left(\frac{p}{v} - \frac{c_2}{6} + \frac{c_1}{p} - \frac{7}{2p^2}\right)h_i = 0, \tag{71}$$

and similarly, on writing $u_1 = p^{-1/2}k$, the homogeneous part of (63) takes the form

$$k'' + \left(\frac{3p}{v} - \frac{c_2}{4} - \frac{3}{4p^2}\right)k = 0. \tag{72}$$

By the arguments above, the latter is integrable by quadratures.

VI. SUPERPEAKON SOLUTIONS

As mentioned in the Introduction, one of the intriguing features of the CH equation is the existence of peakon solutions. One would hope that super-CH shares this property. However, peakon solutions are weak solutions, with a discontinuity in the first derivative; and the action of supersymmetry on such functions, for a general underlying Grassmann algebra, yields objects which are not regular enough to be considered as weak solutions. So, CH peakon solutions do not admit a general supersymmetrization. The above argument does not hold in the first deconstruction, because if there is only one fermionic generator, the supersymmetry transformation (26) does not involve an x-derivative. So such supersymmetrized peakon solutions of the super-CH system (39) do exist if the fields are restricted to take values in a Grassmann algebra with only one fermionic generator.

Consider Eqs. (40) of the first deconstruction. Supersymmetry implies that if (u,m) is a solution of the first equation in (40), then $\xi_1=cu$, $\eta_1=cm$ (where c is a constant) gives a solution of the second equation. Thus, for example, the speed v traveling-wave peakon solution of CH, $u=v\exp(-|x-vt|)$, can be supersymmetrized, as can any multipeakon solution. In fact, there also exist more general superpeakons. The superposition ansatz,

$$u(x,t)=\sum_{i=1}^{N} p_i(t)\exp(-|x-q_i(t)|), \tag{73}$$

$$\xi_1(x,t)=\sum_{i=1}^{N} r_i(t)\exp(-|x-q_i(t)|), \tag{74}$$

gives a solution of the system (40) provided the functions $q_i(t),p_i(t),r_i(t)$ $(i=1,\ldots,N)$ satisfy the ODE system,

$$q_{it}=\sum_{j=1}^{N} p_j\exp(-|q_i-q_j|), \tag{75}$$

$$p_{it}=\sum_{j=1}^{N}{}' \operatorname{sgn}(q_i-q_j)p_ip_j\exp(-|q_i-q_j|), \tag{76}$$

$$r_{it}=\frac{1}{2}\sum_{j=1}^{N}{}' \operatorname{sgn}(q_i-q_j)(p_ir_j+p_jr_i)\exp(-|q_i-q_j|), \tag{77}$$

where the primed sums range over values of $j\neq i$. Equations (75) and (76) are the conditions which determine u of the form (73) to be a multipeakon solution of CH. They describe geodesic motion on an N-dimensional surface with coordinates $q_i{}^1$ and form an integrable Hamiltonian system.[23] The further equations (77) are linear equations for the functions r_i. Clearly, taking the $r_i=cp_i$ for some constant c gives a solution, these being the supersymmetrized multipeakon solutions discussed before. *More general solutions certainly exist.* Since the system (75)–(76) is integrable, integrability of the additional N linear equations (77) depends on the existence of $N-1$ independent conserved quantities depending on the r_i. We have not settled this question in general, but we note that $\Sigma_{i=1}^{N}r_i$ is a conserved quantity, just as the total momentum $\Sigma_{i=1}^{N}p_i$ is also conserved. This suffices for integrability when $N=2$, in which case the remaining equation for r_1-r_2 can be integrated explicitly. Note that unlike the existence of the superpeakons which arise in virtue of supersymmetry transformations of CH peakons, the existence of this extra conserved quantity depends critically on the coefficients of the η_1 evolution equation in (40). Even if the full superpeakon system (77) proves not to be fully integrable, the geodesy and supersymmetry conditions have certainly picked out an equation with some integrability properties (cf. Ref. 12).

VII. OUTLOOK

In this paper we have examined fermionic extensions of the Camassa–Holm equation. In particular we have identified the super-CH system (39), which, for low dimensional Grassmann algebras displays some integrability properties and has peakon-type solutions. Further investigation is needed to determine whether the super-CH system is fully integrable.

Our work provides a further instance of integrability properties arising in the context of geodesic flows on a group manifold, and in particular provides some evidence that supersymmetric geodesic flows whose bosonic part is integrable must also be integrable.

We note in closing that the KP (and super-KP) systems have yet to be presented as geodesic flows. If such a presentation exists, it would have a bearing on the question of whether there is a KP-type higher dimensional generalization of Camassa–Holm (arising in a way similar to that in which KP generalizes KdV).

(Received 10 January 2000; accepted for publication 5 September 2000)

A soliton cellular automaton associated with crystals of symmetric tensor representations of the quantum affine algebra $U_q'(A_M^{(1)})$ is introduced. It is a crystal theoretic formulation of the generalized box–ball system in which capacities of boxes and carriers are arbitrary and inhomogeneous. Scattering matrices of two solitons coincide with the combinatorial R matrices of $U_q'(A_{M-1}^{(1)})$. A piecewise linear evolution equation of the automaton is identified with an ultradiscrete limit of the nonautonomous discrete Kadomtsev–Petviashivili equation. A class of N soliton solutions is obtained through the ultradiscretization of soliton solutions of the latter. [DOI: 10.1063/1.1322077]

I. INTRODUCTION

The box–ball system invented by Takahashi and Satsuma[1] is an important example of soliton cellular automata. It is a discrete dynamical system in which finitely many balls move along the one-dimensional array of boxes under a certain rule. Its integrability has been proved in Ref. 2 by making a connection to the difference analog of the Lotka–Volterra equation[3] through the limiting procedure called *ultradiscretization*.

By now the original box–ball system has been generalized into several directions. First, one can introduce the balls distinguished by the index from the set $\{1,2,\ldots,M\}$. Second, one lets the box at site n accommodate up to θ_n balls, where the capacity θ_n may depend on n. Third, one can introduce a *carrier* with capacity κ_t to redefine the time evolution at time t. The carrier comes from the left and proceeds to the right, picking up the balls in a box and dropping them into another under a certain rule. While it goes through the array of boxes, the successive loading–unloading process induces the motion of balls over the boxes, hence the time evolution of the system. These generalizations of the Takahashi–Satsuma box–ball system are characterized by the parameters (M,θ_n,κ_t). ($n,\ t\in\mathbb{Z}$ play the role of space and time coordinates as in the diagram in Sec. II C.) The original one[1] corresponds to the choice $(M,\forall\,\theta_n,\forall\,\kappa_t)=(1,1,\infty)$. The case $(M,\forall\,\theta_n=1,\forall\,\kappa_t=\infty)$ was introduced in Ref. 4 and studied in Ref. 5. Similarly, the cases

a)Electronic mail: atsuo@gokutan.c.u-tokyo.ac.jp

$(M=1, \forall\theta_n=\theta, \forall\kappa=\kappa)$ with $\kappa>\theta$ and $(M,\theta_n,\forall\kappa_t=\infty)$ were treated in Refs. 6 and 7, respectively. These works have been done mainly from the viewpoint of the ultradiscretization.

The purpose of this paper is to study the general (M,θ_n,κ_t) case. In Sec. II we formulate the corresponding generalization of the box–ball system in terms of the crystal theory.[8–10] The latter is a representation theory of quantum groups at $q=0$. The unexpected link between the crystals and the box–ball systems has also been exploited in Refs. 11 and 12 through a crystal theoretic interpretation of the L-operator approach.[13] The idea is to regard the box–ball system as a solvable vertex model[14] at $q=0$ under a ''ferromagnetic'' boundary condition. More concretely, the box–ball system corresponding to the data (M,θ_n,κ_t) is naturally related to the $U_q'(A_M^{(1)})$ vertex model at $q=0$ whose inhomogeneity in the quantum and auxiliary spaces is parametrized by θ_n's and κ_t's, respectively.

Let B_l be the classical crystal of $U_q'(A_M^{(1)})$ in the sense of Ref. 9 corresponding to the l-fold symmetric tensor representation of $U_q(A_M)$. Then the array of boxes and the ball configurations are identified with the elements from $\cdots\otimes B_{\theta_n}\otimes B_{\theta_{n+1}}\otimes\cdots$. The time evolution by the carrier with capacity κ_t is realized as the action of the $q=0$ row transfer matrix acting on $\cdots\otimes B_{\theta_n}\otimes B_{\theta_{n+1}}\otimes\cdots$ with the auxiliary space corresponding to B_{κ_t}. We call the resulting dynamical system the $A_M^{(1)}$ automaton. It is the most general one in the $A_M^{(1)}$ case as far as the crystals for symmetric tensors are concerned. For generalizations to other root systems, see Ref. 15 for a supersymmetric one and Ref. 11 for the nonexceptional series other than $A_M^{(1)}$.

In Sec. III we introduce solitons and study the two-soliton scattering. As in Refs. 11 and 12 we label the solitons in terms of the elements of the $U_q'(A_{M-1}^{(1)})$-crystal B_l, where l plays the role of the amplitude of a soliton. In the collisions of two solitons associated with B_l and B_k, the scattering matrix is shown to coincide with the combinatorial R matrix giving the isomorphism $B_l\otimes B_k\simeq B_k\otimes B_l$ of the $U_q'(A_{M-1}^{(1)})$ crystals. These features are essentially the same with the $\forall\theta_n=1$ case.[5,11,12] A new aspect here is that depending on the amplitudes l, k and the parameters θ_n, κ_t, the smaller soliton can overtake the larger one. This is most transparently understood by viewing the scattering from the cross channel. By interchanging θ_n and κ_t, one can swap the role of the space and time and thereby the boxes and carriers. Then the curious scattering mentioned previously reduces to the ''usual'' one in the cross channel where the larger soliton overtakes the smaller one. In Sec. III D we also give a brief sketch of the conserved quantities of our automaton following Ref. 12.

In Sec. IV we set up a piecewise linear equation for the relevant combinatorial R matrix[16] and the resulting evolution equation for the $A_M^{(1)}$ automaton. Extending the earlier result,[7] we identify the evolution equation with an ultradiscrete limit of the nonautonomous discrete Kadomtsev–Petviashivili (ndKP) equation. A class of N soliton solutions is obtained through an ultradiscretization of the τ functions. As in the previous case[7] one needs to make a fine adjustment of the fermion momenta entering the vacuum expectation value expression of the τ functions. Each soliton in the automaton is obtained by letting M solitons in the ndKP merge together in the ultradiscrete limit.

Section V is a summary. Appendices A and B contain the details of the proofs of Proposition 3.8 and Theorem 4.5, respectively.

II. AUTOMATA FROM CRYSTALS

A. $U_q'(A_M^{(1)})$ crystals

Let B_k be the classical crystal of $U_q'(A_M^{(1)})$ corresponding to the k-fold symmetric tensor representation. As a set it consists of the single row semistandard tableaux of length k on letters $\{1,2,\ldots,M+1\}$:

$$B_k=\{\boxed{m_1\cdots m_k}\mid m_i\in\{1,\ldots,M+1\}, m_1\le\cdots\le m_k\},$$

where we have omitted the $k-1$ vertical lines separating the entries. We also represent the elements by the multiplicities of their contents. Namely,

$$b = \boxed{m_1 \cdots m_k} \in B_k$$

is also denoted by $b=(x_1,x_2,\ldots,x_{M+1})$ with $x_i=\#\{l|m_l=i\}$.

Denote the Kashiwara operators of B_k by $\tilde{f}_i$ and $\tilde{e}_i$ for $i=0,1,\ldots,M$. The actions of $\tilde{e}_i$, $\tilde{f}_i$ on B_k are defined as follows: for $b=(x_1,x_2,\ldots,x_{M+1})\in B_k$,

$$\begin{cases} \tilde{e}_0 b=(x_1-1,x_2,\ldots,x_{M+1}+1), \\ \tilde{f}_0 b=(x_1+1,x_2,\ldots,x_{M+1}-1), \\ \tilde{e}_i b=(x_1,\ldots,x_i+1,x_{i+1}-1,\ldots,x_{M+1}) \quad \text{for } i=1,\ldots,M, \\ \tilde{f}_i b=(x_1,\ldots,x_i-1,x_{i+1}+1,\ldots,x_{M+1}) \quad \text{for } i=1,\ldots,M. \end{cases} \tag{1}$$

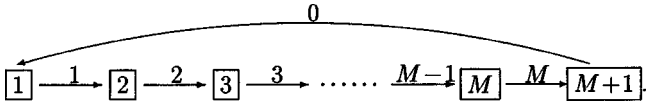
In Eq. (1), the right-hand sides are to be understood as 0 if they are not in B_k. A crystal can be regarded as a colored oriented graph called a ''crystal graph'' by defining

$$b \overset{i}{\longrightarrow} b' \leftrightarrow \tilde{f}_i b = b'.$$

Thus, for example,

$$B_1 = \{\boxed{1},\ldots,\boxed{M+1}\}$$

has the crystal graph:



Setting $\varepsilon_i(b)=\max_l\{\tilde{e}_i^{\,l}b\neq 0|l\geq 0\}$ and $\varphi_i(b)=\max_l\{\tilde{f}_i^{\,l}b\neq 0|l\geq 0\}$ for $b\in B_k$, one has

$$\varepsilon_0(b)=x_1, \quad \varepsilon_i(b)=x_{i+1} \quad \text{for } i=1,\ldots,M,$$

$$\varphi_0(b)=x_{M+1}, \quad \varphi_i(b)=x_i \quad \text{for } i=1,\ldots,M.$$

The data are necessary when we treat tensor products of the crystals. For two crystals B and B', the tensor product $B\otimes B'$ is defined. As a set,

$$B\otimes B'=\{b_1\otimes b_2|b_1\in B, b_2\in B'\}.$$

The actions of $\tilde{e}_i$ and $\tilde{f}_i$ are defined by

$$\tilde{e}_i(b_1\otimes b_2)=\begin{cases} \tilde{e}_i b_1\otimes b_2 & \text{if } \varphi_i(b_1)\geq\varepsilon_i(b_2) \\ b_1\otimes\tilde{e}_i b_2 & \text{if } \varphi_i(b_1)<\varepsilon_i(b_2) \end{cases}, \tag{2}$$

$$\tilde{f}_i(b_1\otimes b_2)=\begin{cases} \tilde{f}_i b_1\otimes b_2 & \text{if } \varphi_i(b_1)>\varepsilon_i(b_2) \\ b_1\otimes\tilde{f}_i b_2 & \text{if } \varphi_i(b_1)\leq\varepsilon_i(b_2) \end{cases}. \tag{3}$$

Here $0\otimes b$ and $b\otimes 0$ are understood to be 0. For two crystals B and B', the tensor products $B'\otimes B$ and $B\otimes B'$ constructed as shown previously are again crystals which are canonically isomorphic. The isomorphism R: $B'\otimes B\xrightarrow{\sim} B\otimes B'$ is called the combinatorial R matrix.[9,16] By the definition R commutes with $\tilde{f}_i$, $\tilde{e}_i$ for any $i=0,1,\ldots,M$. (More precisely one introduces affine crystals and the associated energy function, but in this paper we shall exclusively treat classical crystals and concern the energy function only in connection with the conserved quantities in Sec. III D).

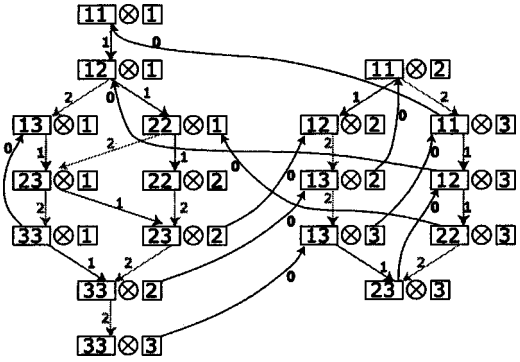


FIG. 1. Crystal graph of $U_q'(A_2^{(1)})$-crystal $B_2 \otimes B_1$.

Example 2.1: Figures 1 and 2 are the crystal graphs of $U_q'(A_2^{(1)})$-crystals $B_2 \otimes B_1$ and $B_1 \otimes B_2$, respectively.

Example 2.2: Let $B' = B_2$, $B = B_1$ of $U_q'(A_2^{(1)})$ crystals.

$$\text{(i)}\ R : \boxed{13} \otimes \boxed{2} \mapsto \boxed{1} \otimes \boxed{23},$$
$$\text{(ii)}\ R : \boxed{23} \otimes \boxed{2} \mapsto \boxed{3} \otimes \boxed{22}.$$

These are obtained by comparing the crystal graphs in Example 2.1.

We write the highest weight element in B_k with respect to $U_q(A_M)$ as u_k:

$$u_k = \overbrace{\boxed{11\ldots1}}^{k} = (k, 0, \cdots, 0) \in B_k. \tag{4}$$

B. Isomorphism

Here we give an explicit procedure to obtain the isomorphism R: $B_k \otimes B_l \to B_l \otimes B_k$ without drawing the whole crystal graphs of $B_k \otimes B_l$ and $B_l \otimes B_k$.

Let $b_1 \otimes b_2$ be an element in $B_k \otimes B_l$ such as $b_1 = (x_1, \ldots, x_{M+1})$ and $b_2 = (y_1, \ldots, y_{M+1})$. We represent $b_1 \otimes b_2$ by the two-column diagram. Each column has $M+1$ rows, enumerated as 1 to $M+1$ from the top to the bottom. We put x_i (respectively y_i) dots $\bullet$ in the ith row of the left

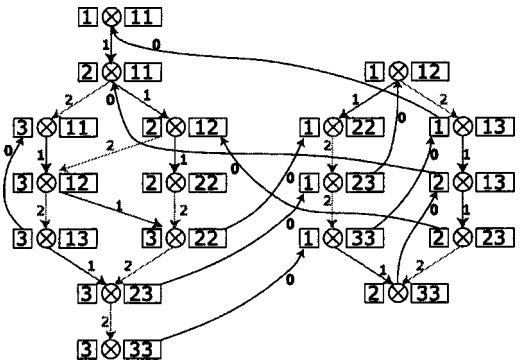

FIG. 2. Crystal graph of $U_q'(A_2^{(1)})$-crystal $B_1 \otimes B_2$.

(respectively right) column.

$b_1 \otimes b_2 =$ 
Proposition 2.3: The rule to obtain the isomorphism R is as follows.

(1) Assume $k \geqslant l$ (respectively, $k \leqslant l$). Pick any dot, say $\bullet_a$, in the right (respectively, left) column and find its partner $\bullet'_a$ in the left (respectively, right) column. The $\bullet'_a$ is chosen from the dots which are in the lowest (respectively, highest) row among all dots whose positions are higher (respectively, lower) than that of $\bullet_a$. If there is no such dot, we return to the bottom (respectively, top) and the partner $\bullet'_a$ is chosen from the dots in the lowest (respectively, highest) row among all dots. Connect $\bullet_a$ and $\bullet'_a$ by a line. We call the lines in the latter case winding and in the former case unwinding.

(2) Repeat procedure (1) for the remaining unconnected dots $(l-1)$ times [respectively, $(k-1)$ times].

(3) The isomorphism R is obtained by sliding the remaining $(k-l)$ [respectively, $(l-k)$] unpaired dots in the left (respectively, right) column to the right (respectively, left).

The *R* obtained by this rule has the correct property as the isomorphism. This fact has been proved in Sec. III of Ref. 16. We will write the relation *R*: $u \otimes v \mapsto v' \otimes u'$ also as $u \otimes v \simeq v' \otimes u'$. Obviously one has

$$u_k \otimes u_l \simeq u_l \otimes u_k \tag{5}$$

for the element (4).

Example 2.4: Let $M=2$, $k=2$, $l=1$. Examples 2.2 (i) and 2.2 (ii) are obtained by the following diagrams:

(i)  , (ii)  .

The line in (i) is unwinding and that in (ii) is winding.

Suppose $b \otimes b' \in B \otimes B'$ is mapped to $\tilde{b}' \otimes \tilde{b} \in B' \otimes B$ under the isomorphism $B \otimes B' \simeq B' \otimes B$ of $U'_q(A_M^{(1)})$ crystals. A $\mathbb{Z}$-valued function H on $B \otimes B'$ is called an *energy function* if for any i and $b \otimes b' \in B \otimes B'$ such that $\tilde{e}_i(b \otimes b') \neq 0$, it satisfies

$$\begin{aligned} H(\tilde{e}_i(b \otimes b')) &= H(b \otimes b') + 1 \quad \text{if } i=0, \varphi_0(b) \geqslant \varepsilon_0(b'), \varphi_0(\tilde{b}') \geqslant \varepsilon_0(\tilde{b}) \\ &= H(b \otimes b') - 1 \quad \text{if } i=0, \varphi_0(b) < \varepsilon_0(b'), \varphi_0(\tilde{b}') < \varepsilon_0(\tilde{b}) \\ &= H(b \otimes b') \quad \text{otherwise.} \end{aligned} \tag{6}$$

When we want to emphasize $B \otimes B'$, we write $H_{BB'}$ for H. This definition of the energy function is due to (3. 4. e) of Ref. 16, that is a generalization of the definition for the $B=B'$ case in Ref. 9. The energy function is unique up to additive constant, since $B \otimes B'$ is connected. By definition, $H_{BB'}(b \otimes b') = H_{B'B}(\tilde{b}' \otimes \tilde{b})$. Throughout this paper we normalize it as

$$H_{B_l B_k}(u_l \otimes u_k) = 0, \tag{7}$$

irrespective of $l<k$ or $l\geqslant k$. Then it is the result of Ref. 16 that the energy function is (-1) times the number of unwinding lines in the sense of Example 2.4.

With a successive application of R's, one interchanges the order of tensor product pairwise and obtains the isomorphism of $B_{k_1}\otimes\cdots\otimes B_{k_n}$ and $B_{k_{P_1}}\otimes\cdots\otimes B_{k_{P_n}}$ for any permutation P. The compatibility of this construction is guaranteed by the Yang–Baxter equation obeyed by R. The following assertion follows easily from Proposition 2.3.

Proposition 2.5: Let $k_1,k_2,\ldots\in\mathbb{Z}_{\geqslant 1}$ be any sequence. Suppose $b\otimes u_{k_1}\otimes\cdots\otimes u_{k_n}\simeq c_1\otimes\cdots\otimes c_n\otimes b'$ is valid for some b' and c_i's under the isomorphism $B_l\otimes B_{k_1}\otimes\cdots\otimes B_{k_n}\simeq B_{k_1}\otimes\cdots\otimes B_{k_n}\otimes B_l$. For any $b\in B_l$, there exists n_0 such that $b'=u_l$ for all $n\geqslant n_0$.

This property will be needed in constructing the automation in Sec. II C.

C. Automaton

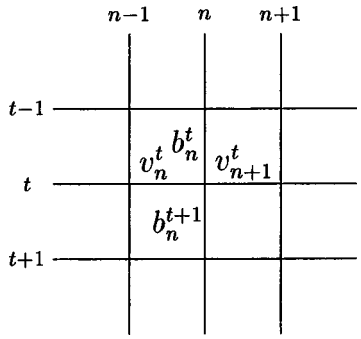
Let $\ldots,\theta_{-1},\theta_0,\theta_1,\ldots$ and $\ldots,\kappa_{-1},\kappa_0,\kappa_1,\ldots$ be two sequences of positive integers. Denote the former indices by n, and the latter indices by t. Consider the two-dimensional lattice with n and t directions,

$$n \text{ direction} \quad \cdots\otimes B_{\theta_{n-1}}\otimes B_{\theta_n}\otimes B_{\theta_{n+1}}\otimes\cdots,$$

$$t \text{ direction} \quad \cdots\otimes B_{\kappa_{t-1}}\otimes B_{\kappa_t}\otimes B_{\kappa_{t+1}}\otimes\cdots.$$

In terms of the box–ball systems, θ_n is the capacity of the nth box, and κ_t is the capacity of the tth carrier.

Draw t-constant lines horizontally, and n-constant lines vertically. Number the former downward, and the latter to the right. At any horizontal or vertical line segment of the lattice, we inscribe an element of the crystals in the following way. At the point labeled by (t, n), we put $b_n^t\in B_{\theta_n}$ on the upper line segment and $v_n^t\in B_{\kappa_t}$ on the left line segment. Thus we have $b_n^{t+1}\in B_{\theta_n}$ on the lower line segment and $v_{n+1}^t\in B_{\kappa_t}$ on the right line segment.



We impose the condition that they are related by the combinatorial R matrix,

$$R: v_n^t\otimes b_n^t\tilde{\mapsto} b_n^{t+1}\otimes v_{n+1}^t. \tag{8}$$

In the following sections, we consider the time evolution of the system downward. In view of Proposition 2.5 we can and will exclusively consider the case where for any t, $b_n^t\neq u_{\theta_n}$ only for finitely many n's and similarly for any n, $v_n^t\neq u_{\kappa_t}$ only for finitely many t's. Sometimes we ignore v_n^t's and display the time evolution of the system only with the arrays

$$\cdots\ b_{-2}^0\ b_{-1}^0\ b_0^0\ b_1^0\ b_2^0\ \cdots,$$

$$\cdots\ b_{-2}^1\ b_{-1}^1\ b_0^1\ b_1^1\ b_2^1\ \cdots,$$

$$\cdots\ b_{-2}^2\ b_{-1}^2\ b_0^2\ b_1^2\ b_2^2\ \cdots.$$

In short, the evolution of the array $\{b_n^t\}$ to $\{b_n^{t+1}\}$ is determined by

$$B_{\kappa_t}\otimes(\cdots\otimes B_{\theta_n}\otimes B_{\theta_{n+1}}\otimes\cdots)\simeq(\cdots\otimes B_{\theta_n}\otimes B_{\theta_{n+1}}\otimes\cdots)\otimes B_{\kappa_t},$$

$$u_{\kappa_t}\otimes(\cdots\otimes b_n^t\otimes b_{n+1}^t\otimes\cdots)\simeq(\cdots\otimes b_n^{t+1}\otimes b_{n+1}^{t+1}\otimes\cdots)\otimes u_{\kappa_t},$$

under the successive applications of the combinatorial R matrices R: $B_{\kappa_t}\otimes B_{\theta_j}\overset{\sim}{\mapsto}B_{\theta_j}\otimes B_{\kappa_t}$.

Setting $\mathbf{p}=\cdots\otimes b_n^t\otimes b_{n+1}^t\otimes\cdots$, we denote the time evolution induced by u_{κ_t} as above by $T_{\kappa_t}(\mathbf{p})=\cdots\otimes b_n^{t+1}\otimes b_{n+1}^{t+1}\otimes\cdots$. Obviously the time evolutions are invertible, and due to (5) they are commutative,

$$T_\kappa T_{\kappa'}=T_{\kappa'}T_\kappa. \tag{9}$$

In the rest of the paper, the two-dimensional lattice on which the automaton is defined should be appropriately understood either as large but finite or formally infinite depending on the situation.

The following observation will turn out to be useful in the sequel.

Remark 2.6: Interchanging the role of ''space'' and ''time,'' one can view (8) *as the evolution of the array* $\cdots\otimes v_{n+1}^{t+1}\otimes v_{n+1}^t\otimes v_{n+1}^{t-1}\otimes\cdots$ *to the left as*

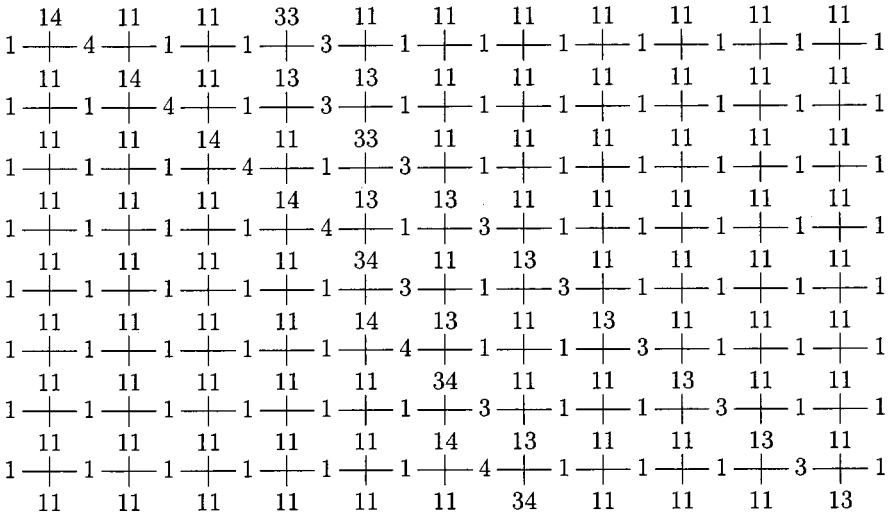
$$T_{\theta_n}(\cdots\otimes v_{n+1}^{t+1}\otimes v_{n+1}^t\otimes v_{n+1}^{t-1}\otimes\cdots)=\cdots\otimes v_n^{t+1}\otimes v_n^t\otimes v_n^{t-1}\otimes\cdots.$$

Example 2.7: Let $M=3$, $\forall\,\theta_n=1$, and $\forall\,\kappa_t=\infty$,

$$\begin{aligned}
&\cdots11114211311111111111\cdots\\
&\cdots11111142131111111111\cdots\\
&\cdots11111114231111111111\cdots\\
&\cdots11111111124311111111\cdots\\
&\cdots11111111112143111111\cdots\\
&\cdots11111111111211431111\cdots
\end{aligned}$$

where i denotes $\boxed{i}$. This is a typical two-soliton scattering. One can see that a soliton with amplitude l moves to the right with velocity l if separated sufficiently. Hence the larger solitons overtake the smaller ones. (See Sec. III A for the precise definition of the solitons and their amplitude.)

Example 2.8: Let $M=3$, $\forall\,\theta_n=2$, and $\forall\,\kappa_t=1$.



Here i and ij denote $\boxed{i}$ and $\boxed{ij}$, respectively. We have depicted both variables $\{b^t_n\}$ and $\{v^t_n\}$. This time 14 on the top left is the smaller soliton and 33 or $13\otimes 13$ is the larger soliton. Thus in terms of the $\{b^t_n\}$ variable, the smaller one overtakes the larger one as we go down the figure ending with the solitons 34 and 13. This is an opposite feature from the previous example. However in the space–time interchanged picture (Remark 2.6), it reduces to the situation similar to Example 2.7. Namely, in terms of the $\{v^t_n\}$ variable, the larger soliton overtakes the small one as $\ldots 43\ldots 3\ldots \to \ldots 4\ldots 33$, as we trace the diagram from the right to the left.

D. Equivalence with box–ball systems

Our $A^{(1)}_M$ automaton can be viewed as a generalized box–ball system. One interprets the letter 1 in the tableaux as an empty space and the other letters $2\leqslant i\leqslant M+1$ as the balls with index $M+2-i$. The element b^t_n signifies the balls contained in the nth box with capacity θ_n at time t. Similarly v^t_n stands for the carrier with capacity κ_t. Then (8) tells that through the loading–unloading process, the box and the carrier change into b^{t+1}_n and v^t_{n+1}, respectively. Sending the carrier through to the left, one has the time evolution of the box–ball state $\cdots\otimes b^t_n\otimes b^t_{n+1}\otimes\cdots$ into $\cdots\otimes b^{t+1}_n\otimes b^{t+1}_{n+1}\otimes\cdots$. For a concrete rule describing (8) in terms of the box–ball terminology, see the *BBS scattering rule* in Ref. 5. Relation (8) will also be expressed as a piecewise linear equation in Proposition 4.1.

When $\forall\,\kappa_t=\infty$ we claim that the evolution of $\{b^t_n\}$ in our $A^{(1)}_M$ automaton is equivalent to the box–ball system studied in Ref. 7 under the above-stated translation. In the latter the one-dimensional array of boxes with capacities $\ldots,\theta_{n-1},\theta_n,\theta_{n+1},\ldots$ accommodate the balls with an index from the set $\{1,\ldots,M\}$. The dynamics of the balls in each time step is governed by the following rules.[7]

(1) Move every ball only once.
(2) Move the leftmost ball with index 1 to the nearest right box with space.
(3) Move the leftmost ball with index 1 among the rest to its nearest right box with space.
(4) Repeat this procedure until all of the balls with index 1 are moved.
(5) Do the same procedure (2)–(4) for the balls with index 2.
(6) Repeat this procedure successively until all of the balls with index M are moved.

If the ball with some index is absent, one just proceeds to those with the next index. A box with space means the one that contains strictly fewer balls than its capacity. If a box contains more than one ball with the same index and they are not yet moved at an instant during the procedure, one

may pick any one of them when looking for the leftmost one. The equivalence to our automaton with $\forall \kappa_t \to \infty$ is shown by the fact that both lead to the same evolution equation, which is given from Proposition 4.1 under the said limit.

The above-mentioned rule tells that the time evolution T_∞ in our automation admits the following factorization:

$$T_\infty = \tilde{T}_M \cdots \tilde{T}_2 \tilde{T}_1, \tag{10}$$

where $\tilde{T}_j$ moves the balls with index j only, and we identify the left-hand side with the corresponding operator acting on the box–ball systems.

For later convenience we introduce the *canonical system* following Ref. 5. We keep assuming $\forall \kappa_t = \infty$ and stay in the description in terms of the box–ball system rather than crystals until the end of this section. Thus we identify $b \in B_\theta$ with the capacity θ box containing the balls as specified before. Suppose a state $\mathbf{p} = \cdots \otimes b_n \otimes b_{n+1} \otimes \cdots$ contains J balls in total. Then the action of $\tilde{T}_M \cdots \tilde{T}_2 \tilde{T}_1$ consists of J steps, each of which is to move a certain ball. To a ball to be moved in the jth step ($1 \leqslant j \leqslant J$), we assign a *signature* j. The assignment is unique up to the trivial freedom among the commonly indexed balls within the same boxes. Let $c(\mathbf{p})$ be the ball configurations obtained from $\mathbf{p}$ just by regarding the signatures as new indices. It consists of the same array of the boxes and J balls as before but with the new distinct index from 1 to J. One can still let $c(\mathbf{p})$ evolve under the previously stated rules (1)–(6) by replacing M therein with J. The resulting new box–ball system is called the canonical system. By a close inspection of rules (1)–(6), it is not difficult to confirm the commutativity:

$$c(\tilde{T}_M \cdots \tilde{T}_2 \tilde{T}_1(\mathbf{p})) = \tilde{T}_J \cdots \tilde{T}_2 \tilde{T}_1(c(\mathbf{p})). \tag{11}$$

In this sense the canonical system essentially grasps the time development pattern of the original one. This fact, first recognized in Ref. 5 for $\forall \theta_n = 1$, will be utilized in Appendix A.

III. COMBINATORIAL *R* MATRIX AS SCATTERING MATRIX OF ULTRADISCRETE SOLITONS

Here we prove Theorem 3.10, which identifies the scattering matrix of the ultradiscrete solitons with the combinatorial R matrix of $U'_q(A^{(1)}_{M-1})$.

A. Solitons

Let B'_k be the classical crystal of $U'_q(A^{(1)}_{M-1})$ corresponding to the k-fold symmetric tensor representation:

$$B'_k = \{\boxed{m_1 \cdots m_k} \mid m_i \in \{1, \ldots, M\}, m_1 \leq \cdots \leq m_k\}.$$

Denote the Kashiwara operators of B'_k by $\tilde{f}'_i$ and $\tilde{e}'_i$ for $i = 0,1, \ldots, M-1$. For distinction, from now on we use the notation $B_k, \tilde{f}_i, \tilde{e}_i$ for $U'_q(A^{(1)}_M)$ crystals and $B'_k, \tilde{f}'_i, \tilde{e}'_i$ for $U'_q(A^{(1)}_{M-1})$ crystals. Let R and R' be the combinatorial R matrices for $U'_q(A^{(1)}_M)$ and $U'_q(A^{(1)}_{M-1})$, respectively. Thus $R\tilde{f}_i = \tilde{f}_i R$ and $R'\tilde{f}'_i = \tilde{f}'_i R'$ hold when they act on the tensor product of two crystals, and similarly for $\tilde{e}_i, \tilde{e}'_i$. (We will specify the crystals that they act on each time.)

Remark 3.1: When $M = 1$ we still define B'_k as above, which is the set with the single element

$$u_k = \boxed{1 \ldots 1}.$$

We further understand that the "$U'_q(A^{(1)}_0)$" combinatorial R matrix $R' : B'_l \otimes B'_k \to B'_k \otimes B'_l$ is given by $R'(u_l \otimes u_k) = u_k \otimes u_l$.

For each $k \in \mathbb{Z}_{\geqslant 1}$ define a map $\imath_k$ by

$$\begin{array}{rccc} \imath_k: & B'_k & \longrightarrow & (B_1)^{\otimes k} \\ & \boxed{m_1 \cdots m_k} & \mapsto & \boxed{m_k+1} \otimes \cdots \otimes \boxed{m_1+1}. \end{array}$$

Let $k_1, \ldots, k_N \in \mathbb{Z}_{\geqslant 1}$ and $L_0, \ldots, L_N \in \mathbb{Z}_{\geqslant 0}$ for some $N \in \mathbb{Z}_{\geqslant 1}$. In terms of $\imath_k$ we further introduce a map

$$\imath^{(L_0,\ldots,L_N)}_{k_1,\ldots,k_N}: B'_{k_1} \otimes \cdots \otimes B'_{k_N} \to (B_1)^{\otimes L_0+\cdots+L_N+k_1+\cdots+k_N}$$

by

$$\begin{aligned} &\imath^{(L_0,\ldots,L_N)}_{k_1,\ldots,k_N}(b_1 \otimes b_2 \otimes \cdots \otimes b_N) \\ &= \boxed{1}^{\otimes L_0} \otimes \imath_{k_1}(b_1) \otimes \boxed{1}^{\otimes L_1} \otimes \imath_{k_2}(b_2) \otimes \cdots \otimes \boxed{1}^{\otimes L_{N-1}} \otimes \imath_{k_N}(b_N) \otimes \boxed{1}^{\otimes L_N}. \end{aligned}$$

In particular $\imath_k = \imath^{(0,0)}_k$. The map $\imath^{(L_0,\ldots,L_N)}_{k_1,\ldots,k_N}$ is injective. For each $k \in \mathbb{Z}_{\geqslant 1}$ let ς_k denote the map

$$\begin{array}{rccc} \varsigma_k: & (B_1)^{\otimes k} & \longrightarrow & B_k \\ & \boxed{m_1} \otimes \cdots \otimes \boxed{m_k} & \mapsto & \boxed{m'_1 \ldots m'_k} \end{array}$$

where $1 \leqslant m'_1 \leqslant \cdots \leqslant m'_k \leqslant M+1$ are just the reordering of $m_1, \ldots, m_k$ into the weakly increasing order. We assume that $\mathcal{L} := \Sigma_n \theta_n$ is sufficiently large. We set

$$\hat{\theta} = (\cdots \otimes \varsigma_{\theta_n} \otimes \varsigma_{\theta_{n+1}} \otimes \cdots): B_1^{\otimes \mathcal{L}} \to \cdots \otimes B_{\theta_n} \otimes B_{\theta_{n+1}} \otimes \cdots. \tag{12}$$

For non-negative integers $L_0, \ldots, L_N$ such that $\mathcal{L} = L_0 + \cdots + L_N + k_1 + \cdots + k_N$, denote by $\iota^{(L_0,\ldots,L_N)}_{k_1,\ldots,k_N}$ the composition $\hat{\theta} \circ \imath^{(L_0,\ldots,L_N)}_{k_1,\ldots,k_N}$, i.e.,

$$\iota^{(L_0,\ldots,L_N)}_{k_1,\ldots,k_N}: B'_{k_1} \otimes \cdots \otimes B'_{k_N} \xrightarrow{\imath^{(L_0,\ldots,L_N)}_{k_1,\ldots,k_N}} B_1^{\otimes \mathcal{L}} \xrightarrow{\hat{\theta}} \cdots \otimes B_{\theta_n} \otimes B_{\theta_{n+1}} \otimes \cdots. \tag{13}$$

Suppose that the image is obtained from the element $\cdots \otimes u_{\theta_n} \otimes u_{\theta_{n+1}} \otimes \cdots$ by replacing only the isolated segments $u_{\theta_{n_i}} \otimes u_{\theta_{n_i+1}} \otimes \cdots \otimes u_{\theta_{n'_i}} (n_i \leqslant n'_i)$ with some $b_{\theta_{n_i}} \otimes \cdots \otimes b_{\theta_{n'_i}} \in B_{\theta_{n_i}} \otimes \cdots \otimes B_{\theta_{n'_i}}$ for $1 \leqslant i \leqslant N$. Assume further that the interval is sufficiently large, namely, $n_i - n'_{i-1} \gg \max(k_1, \ldots, k_N)$ for any $2 \leqslant i \leqslant N$. In such a case we call the image of (13) an *asymptotic N soliton state*. Each soliton is essentially associated with an element in B'_k, and we call k the *amplitude* of the corresponding soliton. States obtained from an asymptotic N soliton state under arbitrary time evolutions $T_\kappa \cdots T_{\kappa'}$ will be called N soliton states. This definition will naturally be justified from the consideration on the conserved quantities in Section III D. Note that $\iota^{(L_0,\ldots,L_N)}_{k_1,\ldots,k_N}$ is not injective since $\hat{\theta}$ is not. Consequently, the result of the application of $\iota^{(L'_0,\ldots,L'_N)}_{k_1,\ldots,k_N}$ is not necessarily an ''overall translation'' of (13) in a naive sense even when $L'_i - L_i$ is i independent for $i < N$ or $i > 0$. See Example 3.2 in the following.

First we consider the $N=1$ case. As it turns out in Proposition 3.3, there is no distinction between an asymptotic one-soliton state and a one-soliton state. Moreover one can check that the definition of the one-soliton state here agrees with the one-soliton solution that will be given later in (B1). Given a one-soliton state

$$\mathbf{p} = \cdots \otimes b_{n-1} \otimes b_n \otimes b_{n+1} \otimes \cdots \in \cdots \otimes B_{\theta_{n-1}} \otimes B_{\theta_n} \otimes B_{\theta_{n+1}} \otimes \cdots,$$

one can unambiguously specify integers $n,k(\geqslant 1),s,t$ by the conditions:

$$
\begin{aligned}
&b_j = u_{\theta_j} \quad \text{if } j < n \text{ or } j > n+k,\\
&b_n = \boxed{1\cdots 1 m_1 \cdots m_t} \quad 1 \leq t \leq \theta_n,\ 2 \leq m_1 \leq \cdots \leq m_t \leq M+1,\\
&b_{n+k} = \boxed{1\cdots 1 m_1' \cdots m_s'} \quad 0 \leq s \leq \theta_{n+k}-1,\ 2 \leq m_1' \leq \cdots \leq m_s' \leq M+1,\\
&b_{n+1},\ldots,b_{n+k-1} \text{ do not contain 1 in their tableaux.}
\end{aligned}
$$

Note that ''if'' in the first condition is not ''only if'' in that $b_{n+k}=u_{\theta_{n+k}}$ is allowed as $s=0$. The amplitude of the soliton according to the above-mentioned definition equals $t+\theta_{n+1}+\cdots+\theta_{n+k-1}+s$. We set

$$
x(\mathbf{p})=\sum_{j\leqslant n}\theta_j - t, \quad y(\mathbf{p})=t+\theta_{n+1}+\cdots+\theta_{n+k-1}
$$

and call $x(\mathbf{p})$ the *coordinate* of the soliton. $y(\mathbf{p})$ should not be confused with the amplitude of the soliton.

Example 3.2: Consider $B_{\theta_1}\otimes\cdots\otimes B_{\theta_6}$ with $\theta_1=\theta_3=1$, $\theta_2=\theta_4=\theta_6=2$, and $\theta_5=3$, hence $\mathcal{L}=11$.

(i) Take

$$
b=\boxed{1}\in B_1'.
$$

Then $\iota_1^{(L_0,L_1)}(b)$ with $L_0+L_1=10$ are examples of one-soliton states with amplitude 1. One has $\iota_1^{(1,9)}(b)=\iota_1^{(2,8)}(b)$, $\iota_1^{(4,6)}(b)=\iota_1^{(5,5)}(b)$, and $\iota_1^{(6,4)}(b)=\iota_1^{(7,3)}(b)=\iota_1^{(8,2)}(b)$. For $L_0\leqslant 8$ they look as

$\boldsymbol{p}$	n	$n+k$	$x(\boldsymbol{p})$	$y(\boldsymbol{p})$
$\iota_1^{(0,10)}(b)=\boxed{2}\otimes\boxed{11}\otimes\boxed{1}\otimes\boxed{11}\otimes\boxed{111}\otimes\boxed{11}$	1	2	0	1,
$\iota_1^{(2,8)}(b)=\boxed{1}\otimes\boxed{12}\otimes\boxed{1}\otimes\boxed{11}\otimes\boxed{111}\otimes\boxed{11}$	2	3	2	1,
$\iota_1^{(3,7)}(b)=\boxed{1}\otimes\boxed{11}\otimes\boxed{2}\otimes\boxed{11}\otimes\boxed{111}\otimes\boxed{11}$	3	4	3	1,
$\iota_1^{(5,5)}(b)=\boxed{1}\otimes\boxed{11}\otimes\boxed{1}\otimes\boxed{12}\otimes\boxed{111}\otimes\boxed{11}$	4	5	5	1,
$\iota_1^{(8,2)}(b)=\boxed{1}\otimes\boxed{11}\otimes\boxed{1}\otimes\boxed{11}\otimes\boxed{112}\otimes\boxed{11}$	5	6	8	1,

where we have also listed, n, $n+k$, $x(\mathbf{p})$ and $y(\mathbf{p})$.

(ii) Take

$$
c=\boxed{11223}\in B_5'.
$$

Then $\iota_1^{(L_0,L_1)}(b)$ with $L_0+L_1=6$ are examples of one-soliton states with amplitude 5. For $L_0\leqslant 5$ they look as

$\boldsymbol{p}$	n	$n+k$	$x(\boldsymbol{p})$	$y(\boldsymbol{p})$
$\iota_5^{(0,6)}(c)=\boxed{4}\otimes\boxed{33}\otimes\boxed{2}\otimes\boxed{12}\otimes\boxed{111}\otimes\boxed{11}$	1	4	0	4,
$\iota_5^{(1,5)}(c)=\boxed{1}\otimes\boxed{34}\otimes\boxed{3}\otimes\boxed{22}\otimes\boxed{111}\otimes\boxed{11}$	2	5	1	5,
$\iota_5^{(2,4)}(c)=\boxed{1}\otimes\boxed{14}\otimes\boxed{3}\otimes\boxed{23}\otimes\boxed{112}\otimes\boxed{11}$	2	5	2	4,
$\iota_5^{(3,3)}(c)=\boxed{1}\otimes\boxed{11}\otimes\boxed{4}\otimes\boxed{33}\otimes\boxed{122}\otimes\boxed{11}$	3	5	3	3,
$\iota_5^{(4,2)}(c)=\boxed{1}\otimes\boxed{11}\otimes\boxed{1}\otimes\boxed{34}\otimes\boxed{223}\otimes\boxed{11}$	4	6	4	5,
$\iota_5^{(5,1)}(c)=\boxed{1}\otimes\boxed{11}\otimes\boxed{1}\otimes\boxed{14}\otimes\boxed{233}\otimes\boxed{12}$	4	6	5	4.

In Sec. III C we will make use of

Proposition 3.3: Let $\mathbf{p}=\iota_l^{(L_0,L_1)}(b)$ *be the one soliton of amplitude* l *associated with* $b \in B_l'$. *Then its time evolution* $T_\kappa(\mathbf{p})$ *is again one soliton and expressible as* $T_\kappa(\mathbf{p})=\iota_l^{(L_0',L_1')}(b)$ *for some* L_0', L_1' $(L_0'+L_1'=L_0+L_1)$ *but with the same* $b \in B_l'$. *The difference of their coordinates* (*velocity under* T_κ) *is given by*

$$x(T_\kappa(\mathbf{p}))-x(\mathbf{p})=\begin{cases}\kappa, & \kappa<y(\mathbf{p})\\ \min(\kappa,l)+\max(\theta_{n+k}-l,0), & \kappa\geqslant y(\mathbf{p}).\end{cases}$$

The proof is done by a cumbersome case study. When $\forall\,\theta_n=1$, the above result simplifies to $x(T_\kappa(\mathbf{p}))-x(\mathbf{p})=\min(\kappa,l)$ in agreement with Ref. 12. In general, the velocity varies locally depending on the data $\{\theta_n\}$. In Example 3.2 (i) one has $T_\kappa(\iota_1^{(0,10)}(b))=\iota_1^{(2,8)}(b)$, $T_\kappa(\iota_1^{(2,8)}(b))=\iota_1^{(3,7)}(b)$, $T_\kappa(\iota_1^{(3,7)}(b))=\iota_1^{(5,5)}(b)$, $T_\kappa(\iota_1^{(5,5)}(b))=\iota_1^{(8,2)}(b)$ for any $\kappa\geqslant 1$. Similarly in (ii) one has $T_\kappa(\iota_5^{(0,6)}(c))=\iota_5^{(\kappa',6-\kappa')}(c)$ for any $\kappa\geqslant 1$, where $\kappa'=\min(\kappa,5)$. These results agree with Proposition 3.3

Let $\iota_{k_1,\ldots,k_N}^{(L_0,\ldots,L_N)}(c_1\otimes\cdots\otimes c_N)(c_i\in B_{k_i}')$ be an asymptotic N soliton state and

$$\cdots\otimes b_n^t\otimes b_{n+1}^t\otimes\cdots=T_{\kappa_t}T_{\kappa_{t-1}}\cdots(\iota_{k_1,\ldots k_N}^{(L_0,\ldots,L_N)}(c_1\otimes\cdots\otimes c_N))$$

be its time evolution. Assume that the solitons are sufficiently separated without an interaction throughout the time interval under consideration. Let $\{v_n^t\}$ be the associated variables on the vertical edges as in (8). Then in the space–time interchanged picture, the state $\cdots\otimes v_n^{t+1}\otimes v_n^t\otimes\cdots$ is also an asymptotic N soliton state associated with the same $c_1\otimes\cdots\otimes c_N$. Namely,

$$\cdots\otimes v_n^{t+1}\otimes v_n^t\otimes\cdots=\hat\kappa\circ\iota_{k_1,\ldots,k_N}^{(L_0',\ldots,L_N')}(c_1\otimes\cdots\otimes c_N)$$

for some $L_0',\ldots,L_N'$. Here

$$\hat\kappa=(\cdots\otimes\varsigma_{\kappa_{t+1}}\otimes\varsigma_{\kappa_t}\otimes\cdots):B_1^{\otimes\mathcal{M}}\to\cdots\otimes B_{\kappa_{t+1}}\otimes B_{\kappa_t}\otimes\cdots,$$

is an analog of $\hat\theta$ in (12), and we have set $\mathcal{M}=\Sigma_t\,\kappa_t$. The figure in Example 2.8 will be of help to understand this fact. In a sense one can employ either picture to describe the scattering process. Indeed our discussion at the end of Sec. III C will rely on this observation.

B. Scattering of two solitons: A typical case

Our aim here is to show Theorem 3.9 which is valid in the ''typical'' situation (19).

Lemma 3.4: For each $i=1,\ldots,M-1$, *we have a commutative diagram:*

$$\begin{array}{ccc} B_k' & \xrightarrow{\iota_k} & (B_1)^{\otimes k} \\ {\scriptstyle\tilde e_i'}\downarrow & & \downarrow{\scriptstyle\tilde e_{i+1}} \\ B_k'\sqcup\{0\} & \xrightarrow{\iota_k} & (B_1)^{\otimes k}\sqcup\{0\}, \end{array}$$

where $\iota_k(0)=0$. *The same relation also holds between* $\tilde f_i'$ and $\tilde f_{i+1}'$.

Combining Lemma 3.4 with the realization of B_θ in $B_1^{\otimes\theta}$ as a $U_q(A_M)$ crystal (cf. Ref. 17), one can derive the following lemmas.

Lemma 3.5: In the diagram

$$\begin{array}{ccc} B'_l \otimes B'_k & \xrightarrow{\iota_{l,k}^{(L_0,L_1,L_2)}} & (\cdots \otimes B_{\theta_n} \otimes B_{\theta_{n+1}} \otimes \cdots) \\ \downarrow{\scriptstyle \tilde{e}'_i} & & \downarrow{\scriptstyle \tilde{e}_{i+1}} \\ (B'_l \otimes B'_k) \sqcup \{0\} & \xrightarrow{\iota_{l,k}^{(L_0,L_1,L_2)}} & (\cdots \otimes B_{\theta_n} \otimes B_{\theta_{n+1}} \otimes \cdots) \sqcup \{0\}, \end{array}$$

suppose that the image of $\iota_{l,k}^{(L_0,L_1,L_2)}$ *is an asymptotic two-soliton state. Then the diagram is commutative for any* $i=1,\ldots,M-1$. *The same relation holds also between* $\tilde{f}'_i$ *and* $\tilde{f}_{i+1}$

Actually, the commutativity of the above diagram holds under a milder condition than being an asymptotic two-soliton state.

Lemma 3.6: Let $p_1,\ldots,p_m$ *be the subsequence of* $a_1,\ldots,a_L (a_n \in B_{\theta_n})$ *consisting of all the elements such that* $a_n \neq u_{\theta_n}$. *Assume the same relation between* $p'_1,\ldots,p'_m$ *and* $a'_1,\ldots,a'_L$. *Then for any* $t, t' \in \mathbb{Z}_{\geqslant 0}$ *and* $\kappa \in \mathbb{Z}_{\geqslant 1}$, *the two relations*

$$\tilde{f}_{i+1}(p_1 \otimes \cdots \otimes p_m) = p'_1 \otimes \cdots \otimes p'_m,$$

$$\tilde{f}_{i+1}(u_\kappa^{\otimes t} \otimes a_1 \otimes \cdots \otimes a_L \otimes u_\kappa^{\otimes t'}) = u_\kappa^{\otimes t} \otimes a'_1 \otimes \cdots \otimes a'_L \otimes u_\kappa^{\otimes t'}$$

are equivalent for each $i=1,\ldots,M-1$. *The equivalence persists even when the right-hand sides are both 0. The same is true also for* $\tilde{e}_{i+1}$.

Proposition 3.7: Suppose an asymptotic two-soliton state has evolved into another as

$$T_k^t(\iota_{l,k}^{(L_0,L_1,L_2)}(b \otimes c)) = \iota_{k,l}^{(L'_0,L'_1,L'_2)}(c' \otimes b') \tag{14}$$

for some $\kappa, t, L_i, L'_i > 0, b, b' \in B'_l$ *and* $c, c' \in B'_k$. *Then* (14) *is also valid under the replacement of* $b \otimes c$ (*respectively,* $c' \otimes b'$) *by* $\tilde{f}'_i(b \otimes c)$ [*respectively,* $\tilde{f}'_i(c' \otimes b')$] *for any* $i=1,\ldots,M-1$ *such that* $\tilde{f}'_i(b \otimes c) \neq 0$.

Proof: (14) is equivalent to

$$u_\kappa^{\otimes t} \otimes \iota_{l,k}^{(L_0,L_1,L_2)}(b \otimes c) \simeq \iota_{k,l}^{(L'_0,L'_1,L'_2)}(c' \otimes b') \otimes u_\kappa^{\otimes t}.$$

Apply $\tilde{f}_{i+1}$ to both sides. Due to Lemmas 3.5 and 3.6, the result becomes

$$u_\kappa^{\otimes t} \otimes \iota_{l,k}^{(L_0,L_1,L_2)}(\tilde{f}'_i(b \otimes c)) \simeq \iota_{k,l}^{(L'_0,L'_1,L'_2)}(\tilde{f}'_i(c' \otimes b')) \otimes u_\kappa^{\otimes t}.$$

□

Proposition 3.8: Let $l > k$ *and assume that* $\iota_{l,k}^{(L_0,L_1,L_2)}(b_1 \otimes b_2)$ *is an asymptotic two-soliton state with*

$$b_1 = (l,0,\ldots,0) \in B'_l, \quad b_2 = (h,k-h,0,\ldots,0) \in B'_k \tag{15}$$

with $0 \leqslant h \leqslant k$ *in the notation of* (1). *Assume further that* $l > \theta_n$ *for all but finitely many n's. Then if* $\kappa \gg l$, *there exists* $t > 0$ *such that the result of the time evolution* T_κ^t *also becomes the asymptotic two-soliton state as*

$$T_\kappa^t(\iota_{l,k}^{(L_0,L_1,L_2)}(b_1 \otimes b_2)) = \iota_{k,l}^{(L'_0,L'_1,L'_2)}(c_2 \otimes c_1), \tag{16}$$

where c_1, c_2 *are given by*

$$c_2=(k,0,\ldots,0)\in B'_k, \quad c_1=(l-k+h,k-h,0,\ldots,0)\in B'_l. \tag{17}$$

The proof is given in Appendix A. In fact both $b_1\otimes b_2$ and $c_2\otimes c_1$ are $U_q(A_{M-1})$ highest element, i.e., $\tilde{e}'_i(b_1\otimes b_2)=\tilde{e}'_i(c_2\otimes c_1)=0$ for all $1\leqslant i\leqslant M-1$. Combining this property with the conservation of weights (number of the letters) and the soliton content (cf. Sec. III D), one can argue that the outgoing state should necessarily correspond to $c_2\otimes c_1$ if it is an asymptotic two-soliton state at all. However, to establish the separation into two solitons asymptotically is not a trivial task for inhomogeneous θ_n's only bounded by the condition $l\geqslant\theta_n$ for all but finitely many n's. So far we have not managed it without recourse to the actual two-soliton solution as in Appendix A.

As a $U_q(A_{M-1})$ crystal, the $U'_q(A^{(1)}_{M-1})$-crystal $B'_l\otimes B'_k$ decomposes into the connected components. Each component is parametrized with the $U_q(A_{M-1})$ highest elements $b_1\otimes b_2$ (15), and is generated by applying $\tilde{f}'_i$ operators $(1\leqslant i\leqslant M-1)$ to it. The decomposition of the same pattern takes place also for $B'_k\otimes B'_l$ according to the highest elements $c_2\otimes c_1$. Combining this fact with Propositions 3.7 and 3.8, we conclude that there exists a map S' (S matrix) uniquely defined by

$$\begin{gathered} S':B'_l\otimes B'_k\to B'_k\otimes B'_l, \\ T^t_\kappa(\iota^{(L_0,L_1,L_2)}_{l,k}(b\otimes c))=\iota^{(L'_0,L'_1,L'_2)}_{k,l}(S'(b\otimes c)), \end{gathered} \tag{18}$$

under the condition

$$\kappa\gg l>k, \quad l>\theta_n \quad \text{for all but finitely many } n\text{'s}. \tag{19}$$

It describes the two-soliton scattering.

Theorem 3.9: *Under the assumption* (19), *we have* $R'=S'$ *on the* $U'_q(A^{(1)}_{M-1})$*-crystal* $B'_l\otimes B'_k$.

Proof: By the definition and Proposition 3.7, both R' and S' commute with $\tilde{f}'_i$ for any $1\leqslant i\leqslant M-1$. Moreover, for any $U_q(A_{M-1})$ highest elements $b_1\otimes b_2$ given by (15), their actions are the same, i.e., $S'(b_1\otimes b_2)=c_2\otimes c_1=R'(b_1\otimes b_2)$, where the latter can be verified from Proposition 2.3. □

Thus in situation (19) the larger soliton overtakes the smaller soliton and the scattering matrix coincides with the combinatorial R matrix of the $U'_q(A^{(1)}_{M-1})$ crystal. For instance Example 2.7 tells that

$$S':\boxed{13}\otimes\boxed{2}\mapsto\boxed{1}\otimes\boxed{23}.$$

This agrees with Example 2.2(i).

C. Scattering of two solitons: General case

First let us consider the homogeneous case $\forall\theta_n=\theta, \forall\kappa_t=\kappa$. Fix positive integers $l>k$. We study the scattering of two solitons in $\cdots\otimes B_\theta\otimes B_\theta\otimes\cdots$ with amplitudes l and k under the time evolution T^t_κ. The qualitative feature of the scattering depends on the following cases:

(i) $l>k\geqslant\max(\theta,\kappa)$, $v_l=v_k=\kappa$,

(ii) $\min(\theta,\kappa)\geqslant l>k$, $v_l=v_k=\theta$,

(iii) $l\geqslant\kappa>k\geqslant\theta$, $v_l=\kappa>v_k=k$,

(iv) $\kappa\geqslant l>k\geqslant\theta$, $v_l=l>v_k=k$,

(v) $l\geqslant\kappa>\theta\geqslant k$, $v_l=\kappa>v_k=\theta$,

(vi) $\kappa \geqslant l > \theta \geqslant k, \quad v_l = l > v_k = \theta,$

(vii) $l \geqslant \theta > k \geqslant \kappa,$

(viii) $\theta \geqslant l > k \geqslant \kappa,$

(ix) $l \geqslant \theta > \kappa \geqslant k,$

(x) $\theta \geqslant l > \kappa \geqslant k.$

Here the classification has been done so that

$$\{(\mathrm{i}) \amalg (\mathrm{ii})\} \amalg \{(\mathrm{iii}) \cup (\mathrm{iv}) \cup (\mathrm{v}) \cup (\mathrm{vi})\} \amalg \{(\mathrm{vii}) \cup (\mathrm{viii}) \cup (\mathrm{ix}) \cup (\mathrm{x})\}.$$

For example, cases (iii) and (iv) share the $l = \kappa > k \geqslant \theta$ case. However the three groups are mutually disjoint and correspond to distinct features of the scattering as we will see in the following. The v_l and v_k are the velocities of the solitons with amplitude l and k, respectively. For each soliton it has been calculated by using Proposition 3.3 by assuming no effect from the other soliton. In cases (vi) and (x) we have excluded $l = \theta$ and $l = \kappa$, respectively, since they both lead to $v_l = v_k = \theta$ and hence no scattering. For the same reason, cases (i) and (ii) are out of question. Via the space–time interchange $\theta \leftrightarrow \kappa$, cases (vii), (viii), (ix), and (x) are mapped to (iii), (iv), (v), and (vi), respectively. [See the argument before Theorem 3.10 on the velocities in cases (vii)–(x).] Thus we are left with cases (iii)–(vi), where $l > \theta$ and $v_l > v_k$ are always valid. Following Ref. 12, we utilize the commutativity (9) and consider the two-soliton scattering under T^t_κ as

$$T^t_\kappa = T^{-t'}_\infty T^t_\kappa T^{t'}_\infty .$$

The scatterings are thus divided into three stages. In the first stage, we let solitons evolve under $T^{t'}_\infty$ for sufficiently large t'. Since $l > \theta$ matches condition (19), Theorem 3.9 tells us that the larger soliton overtakes the smaller one with the scattering rule described by $S' = R'$. In the second stage corresponding to T^t_κ, the larger soliton goes further ahead than the smaller one with no interaction because of $v_l > v_k$. Therefore in the last stage $T^{-t'}_\infty$, the two remain isolated even though they are drawn back and get relatively closer. Thus we conclude that in all the cases (iii)–(vi), the qualitative feature is the same as the one in Theorem 3.9. Namely, the larger soliton overtakes the smaller one and the scattering rule is given by the combinatorial R matrix $R' : B'_l \otimes B'_k \to B'_k \otimes B'_l$. Through the space–time interchange argument, this implies the opposite feature of scattering in cases (vii)–(x). Namely, the smaller one overtakes the larger one with the scattering rule given by the combinatorial R matrix $R' : B'_k \otimes B'_l \to B'_l \otimes B'_k$.

We note that in cases (vii)–(x) one does not necessarily have $v_l < v_k$ at any time. It actually depends on whether $\kappa \gtrless y(\mathbf{p})$ when Proposition 3.3 is applied. Nevertheless $v_l < v_k$ should be valid ''on average'' and the above-mentioned feature of the scattering should hold due to the reduction to cases (iii)–(vi) where the strict inequality $v_l > v_k$ is always valid. To summarize, we have shown

Theorem 3.10: *Let $l > k$ be the amplitude of two solitons in $\cdots \otimes B_\theta \otimes B_\theta \otimes \cdots$. Under the time evolution T_κ, the scattering matrix of the collision (if any) in the sense of (18) or $(18)_{l \leftrightarrow k}$ is given by $S' = R'$, where R' is the combinatorial R matrix of the $U'_q(A^{(1)}_{M-1})$ crystals for*

(I) $B'_l \otimes B'_k \tilde{\mapsto} B'_k \otimes B'_l \quad if \min(l, \kappa) > \max(k, \theta),$

(II) $B'_k \otimes B'_l \tilde{\mapsto} B'_l \otimes B'_k \quad if \min(l, \theta) > \max(k, \kappa),$

(III) *no scattering* (*same velocity*) *otherwise.*

Example 2.8 corresponds to the choice $l=\theta=2, k=\kappa=1$, hence to (II) in the theorem. The scattering matrix is read off the figure,

$$S' : \boxed{3} \otimes \boxed{22} \mapsto \boxed{23} \otimes \boxed{2}.$$

This agrees with the inverse of the R matrix in Example 2.2(ii).

Let us comment on the inhomogeneous case where θ_n's and κ_t's actually depend on the indices. In view of (19), the qualitative feature of the scattering remains the same as Theorem 3.10 even if we slightly relax the conditions therein. For instance the larger soliton still overtakes the smaller one with the rule $S'=R'$ if $\min(l,\kappa_t)>\max(k,\theta_n)$ holds for almost all n and t that are relevant during the scattering in question. In such cases we expect that the asymptotic N soliton state in the sense of Sec. III A undergoes the scattering which is essentially factorized into the two-body ones studied here. On the other hand, if θ_n's and κ_t's are not bounded by the condition as noted previously and indeed are far from being homogeneous, even two solitons can collide many times in general depending on the local velocities. In such a case we do not have a simple picture of the scattering.

Example 3.11: Let $M=3$.

$$\begin{aligned}
0&:\cdots 14\cdot 3\cdot 123\cdot 111\cdot 24\cdot 1\cdot 1\cdot 111\cdot 11\cdot 1\cdot 1111\cdot 1111\cdot 11111\cdot 11111\cdot 111\cdot 1111\cdots\\
1&:\cdots 11\cdot 1\cdot 114\cdot 233\cdot 11\cdot 4\cdot 2\cdot 111\cdot 11\cdot 1\cdot 1111\cdot 1111\cdot 11111\cdot 11111\cdot 111\cdot 1111\cdots\\
2&:\cdots 11\cdot 1\cdot 111\cdot 111\cdot 34\cdot 3\cdot 1\cdot 224\cdot 11\cdot 1\cdot 1111\cdot 1111\cdot 11111\cdot 11111\cdot 111\cdot 1111\cdots\\
3&:\cdots 11\cdot 1\cdot 111\cdot 111\cdot 11\cdot 1\cdot 4\cdot 113\cdot 34\cdot 2\cdot 1112\cdot 1111\cdot 11111\cdot 11111\cdot 111\cdot 1111\cdots\\
4&:\cdots 11\cdot 1\cdot 111\cdot 111\cdot 11\cdot 1\cdot 1\cdot 114\cdot 13\cdot 1\cdot 1234\cdot 1112\cdot 11111\cdot 11111\cdot 111\cdot 1111\cdots\\
5&:\cdots 11\cdot 1\cdot 111\cdot 111\cdot 11\cdot 1\cdot 1\cdot 111\cdot 14\cdot 3\cdot 1114\cdot 1223\cdot 11111\cdot 11111\cdot 111\cdot 1111\cdots\\
6&:\cdots 11\cdot 1\cdot 111\cdot 111\cdot 11\cdot 1\cdot 1\cdot 111\cdot 11\cdot 1\cdot 1134\cdot 1234\cdot 11112\cdot 11111\cdot 111\cdot 1111\cdots\\
7&:\cdots 11\cdot 1\cdot 111\cdot 111\cdot 11\cdot 1\cdot 1\cdot 111\cdot 11\cdot 1\cdot 1111\cdot 2334\cdot 11114\cdot 11112\cdot 111\cdot 1111\cdots\\
8&:\cdots 11\cdot 1\cdot 111\cdot 111\cdot 11\cdot 1\cdot 1\cdot 111\cdot 11\cdot 1\cdot 1111\cdot 1134\cdot 11123\cdot 11114\cdot 112\cdot 1111\cdots\\
9&:\cdots 11\cdot 1\cdot 111\cdot 111\cdot 11\cdot 1\cdot 1\cdot 111\cdot 11\cdot 1\cdot 1111\cdot 1111\cdot 12334\cdot 11111\cdot 114\cdot 1112\cdots
\end{aligned}$$

where $\cdot$ denotes $\otimes$, and 14 for example does

$$\boxed{14} \in B_2.$$

Not only θ_n's but also κ_t are inhomogeneous here so that the relevant time evolutions are T_5 for the process $0\to1\to2\to3\to4$, whereas they are T_2 for $4\to5\to6\to7\to8\to9$. This is an example of the double scattering of two solitons caused by the inhomogeneity. The larger soliton once overtakes the smaller one, but after the collision it gets slower due to the environmental change and is eventually passed by the smaller one again. This is easily understood from the classification (I)–(III) in Theorem 3.10 for the homogeneous case. In the first stage we have $l=4$, $\kappa=5$, $k=2$, $\theta_n\leqslant 3$ so that the larger soliton overtakes the smaller as in (I). On the other hand we have $\kappa=2$, $\theta_n\geqslant 3$ in the second stage; hence the smaller one passes the larger one as in (II). Following the time evolution downward, one finds the scattering matrices for the successive collisions:

$$\boxed{1223} \otimes \boxed{13} \mapsto \boxed{23} \otimes \boxed{1123} \mapsto \boxed{1223} \otimes \boxed{13}$$

in terms of the soliton labels with the $U_q'(A_2^{(1)})$-crystal elements. They agree with the combinatorial R matrices $B_4'\otimes B_2' \simeq B_2'\otimes B_4'$ calculated from Proposition 2.3.

D. Conserved quantities

Let us give a class of conserved quantities in the $A_M^{(1)}$ automaton. Since our construction here is based on Ref. 12 and the result is quite parallel, we will only present a brief sketch. Given an automaton state $\mathbf{p}=\cdots\otimes b_n\otimes b_{n+1}\otimes\cdots$ ($b_n=u_{\theta_n}$ for $|n|\gg 1$,), let

$$u_\kappa \otimes \mathbf{p} \simeq \cdots \otimes b'_{n-1} \otimes b'_n \otimes v_n \otimes b_{n+1} \otimes b_{n+2} \otimes \cdots$$

for some $b'_i \in B_{\theta_i}$ and $v_n \in B_\kappa$. Set

$$E_\kappa(\mathbf{p}) = -\sum_n H_{B_\kappa B_{\theta_{n+1}}}(v_n \otimes b_{n+1}),$$

which is well defined owing to the normalization (7). By the same argument as in Ref. 12 we get

$$E_\kappa(T_{\kappa'}(\mathbf{p})) = E_\kappa(\mathbf{p}) \quad \text{for any } \kappa, \kappa'.$$

Thus $E_\kappa(\mathbf{p})$, $\kappa \in \mathbb{Z}_{\geqslant 1}$ form a family of conserved quantities. If $\mathbf{p}$ is an asymptotic N soliton state in the sense of Sec. III A, it is straightforward to derive

$$E_\kappa(\mathbf{p}) = \sum_{l \geqslant 1} \min(l, \kappa) N_l, \tag{20}$$

where N_l is the number of solitons with amplitude l. Therefore if a state with the soliton content $\{N_l\}$ scatters into another state with the content $\{N'_l\}$, $N_l = N'_l$ must be valid for any l due to the conservation of all E_κ's. In both Examples 2.7 and 2.8 we have $E_1 = 2$, $E_l = 3$ for $l \geqslant 3$, in agreement with $N_1 = N_2 = 1$, $N_l = 0$ for $l \geqslant 3$. In Example 3.11, we have $E_1 = 2$, $E_2 = 4$, $E_3 = 5$, and $E_l = 6$ for $l \geqslant 4$, in agreement with $N_l = \delta_{l2} + \delta_{l4}$.

When $\forall \theta_n = 1$, (20) is obtained in proposition 4.4 in Ref. 12. An equivalent family of the conserved quantities has also been given in Ref. 5.

Another conserved quantity is the semistandard Young tableau, which can be constructed as follows. Given an automaton state $\mathbf{p} = \cdots \otimes b_n \otimes b_{n+1} \otimes \cdots$, let $c_s \cdots c_2 c_1$ be the subsequence of $\cdots b_{n-1} b_n b_{n+1} \cdots$ obtained by dropping all the b_j's such that $b_j = u_{\theta_j}$. Each c_j has the form

$$c_j = \boxed{1 \ldots 1 m_1 \ldots m_k} \quad 2 \leq m_1 \leq \cdots \leq m_k \leq M+1 \ \text{ for some } k \geq 1,$$

for which we set

$$\bar{c}_j = \boxed{m_1 - 1 \ldots m_k - 1} \in B'_k.$$

Let $\mathcal{T}(\mathbf{p}) := (((\bar{c}_1 \cdot \bar{c}_2) \cdot \bar{c}_3) \cdot \cdots \cdot \bar{c}_s)$ be the semistandard tableau constructed from the successive products of $\bar{c}_j$'s defined via the row insertion as in Ref. 18, p. 11. By virtue of the $U'_q(A_{M-1})$ invariance,[12] it is a conserved quantity under any time evolution T_κ, i.e., $\mathcal{T}(\mathbf{p}) = \mathcal{T}(T_\kappa(\mathbf{p}))$. In the context of the Robinson–Schensted–Knuth correspondence, $\mathcal{T}(\mathbf{p})$ stands for the P symbol. For any one-soliton state $\mathbf{p} = \iota_k^{(L_0, L_1)}(b)$, $b \in B'_k$, one has $\mathcal{T}(\mathbf{p}) = b$. One can also check that $\mathcal{T}(\mathbf{p})$ equals

$$\begin{array}{|c|c|}\hline 1 & 3 \\ \hline 2 \\ \cline{1-1}\end{array} \qquad \begin{array}{|c|c|c|}\hline 2 & 2 & 3 \\ \hline\end{array} \qquad \begin{array}{|c|c|c|c|c|}\hline 1 & 1 & 2 & 2 & 3 \\ \hline 3 \\ \cline{1-1}\end{array}$$

in Examples 2.7, 2.8, and 3.11, respectively, throughout the scattering.

IV. $A_M^{(1)}$ AUTOMATON AS AN ULTRADISCRETE KP EQUATION

Here we investigate the $A_M^{(1)}$ automaton constructed in Sec. II C from the viewpoint of ultradiscretization.[2,19] With the same notations as (1) we define $u_{n,j}^t$ and $v_{n,j}^t$ to be the multiplicities of the $(M+2-j)$th content of b_n^t and v_n^t, i.e.,

$$b_n^t = (u_{n,M+1}^t, u_{n,M}^t, \ldots, u_{n,1}^t),$$

$$v_n^t=(v_{n,M+1}^t v_{n,M}^t,\ldots,v_{n,1}^t),$$

Proposition 4.1: The map

$$R:v_n^t\otimes b_n^t\tilde{\mapsto}b_n^{t+1}\otimes v_{n+1}^t, \tag{21}$$

is expressed by $(1\leqslant j\leqslant M)$

$$\begin{aligned}u_{n,j}^{t+1}-v_{n,j}^t=&\max[X_1-\theta_n,X_2-\theta_n,\ldots,X_{j-1}-\theta_n,X_j-\kappa_t,\ldots,X_M-\kappa_t,0]\\&-\max[X_1-\theta_n,X_2-\theta_n,\ldots,X_j-\theta_n,X_{j+1}-\kappa_t,\ldots,X_M-\kappa_t,0],\end{aligned} \tag{22}$$

$$v_{n+1,j}^t=u_{n,j}^t+v_{n,j}^t-u_{n,j}^{t+1}, \tag{23}$$

where

$$X_\ell=X_{n;\ell}^t:=\sum_{i=\ell}^{M}u_{n,i}^t+\sum_{i=1}^{\ell}v_{n,i}^t.$$

Actually (23) is also valid for $j=M+1$.

Proof: In the present proof, we abbreviate $u_{n,j}^t$ and $v_{n,j}^t$ to u_j and v_j, respectively. We also put $u_{j+M+1}=u_j$, $v_{j+M+1}=v_j$, etc., i.e., each suffix is defined modulo $M+1$.

We define $u_j^{(k)},v_j^{(k)}$ $(j=1,2,\ldots,M+1,\ k=1,2,\ldots,M+1)$ as follows.

(1) Let $\Delta u_j=\Delta v_{j+1}:=\min[u_j,v_{j+1}]$, and $u_j^{(1)}:=u_j-\Delta u_j, v_j^{(1)}:=v_j-\Delta v_j$ for $j=1,2,\ldots,M+1$.
(2) For $\forall j$, we define $\Delta u_j^{(1)}=\Delta v_{j+2}^{(1)}:=\min[u_j^{(1)},v_{j+2}^{(1)}]$, and $u_j^{(2)}:=u_j^{(1)}-\Delta u_j^{(1)}$, $v_j^{(2)}:=v_j^{(1)}-\Delta v_j^{(1)}$.
(3) Similar to step (2), we recursively define $\Delta u_j^{(\ell-1)}=\Delta v_{j+\ell}^{(\ell-1)}:=\min[u_j^{(\ell-1)},v_{j+\ell}^{(\ell-1)}]$, $u_j^{(\ell)}:=u_j^{(\ell-1)}-\Delta u_j^{(\ell-1)}$ and $v_j^{(\ell)}:=v_j^{(\ell-1)}-\Delta v_j^{(\ell-1)}$ for $\ell=2,3,\ldots,M+1$.

From Proposition 2.3, we see that $u_j^{(M+1)}$ and $v_j^{(M+1)}$ are the number of *unconnected* dots in the $(M+2-j)$th box in the column diagrams for b_n^t and v_n^t, respectively. See Example 2.4. Noting that $\Delta u_j^{(M)}=\Delta v_j^{(M)}$ we have

$$u_{n,j}^{t+1}=v_j+u_j^{(M+1)}-v_j^{(M+1)}=v_j+u_j^{(M)}-v_j^{(M)} \tag{24}$$

for $1\leqslant j\leqslant M+1$. The following formulas are easily shown by induction:

$$\begin{aligned}u_j^{(\ell)}=&\max\left[\sum_{i=0}^{\ell-1}u_{j+i},\sum_{i=1}^{\ell-1}u_{j+i}+v_{j+1},\sum_{i=2}^{\ell-1}u_{j+i}+\sum_{i=1}^{2}v_{j+i},\ldots,u_{j+\ell-1}+\sum_{i=1}^{\ell-1}v_{j+i},\sum_{i=1}^{\ell}v_{j+i}\right]\\&-v_{j+1}-\max\left[\sum_{i=1}^{\ell-1}u_{j+i},\sum_{i=2}^{\ell-1}u_{j+i}+v_{j+2},\ldots,u_{j+\ell-1}+\sum_{i=2}^{\ell-1}v_{j+i},\sum_{i=2}^{\ell}v_{j+i}\right],\end{aligned} \tag{25}$$

$$\begin{aligned}v_j^{(\ell)}=&\max\left[\sum_{i=0}^{\ell-1}v_{j-i},\sum_{i=1}^{\ell-1}v_{j-i}+u_{j-1},\sum_{i=2}^{\ell-1}v_{j-i}+\sum_{i=1}^{2}u_{j-i},\ldots,v_{j-\ell+1}+\sum_{i=1}^{\ell-1}u_{j-i},\sum_{i=1}^{\ell}u_{j-i}\right]\\&-u_{j-1}-\max\left[\sum_{i=1}^{\ell-1}v_{j-i},\sum_{i=2}^{\ell-1}v_{j-i}+u_{j-2},\ldots,v_{j-\ell+1}+\sum_{i=2}^{\ell-1}u_{j-i},\sum_{i=2}^{\ell}u_{j-i}\right].\end{aligned} \tag{26}$$

Noticing $u_{j-1}=u_{j+M}$, $v_{j+1}=v_{j-M}$, we find

$$u_j^{(M)}-v_j^{(M)}=\max\left[\sum_{i=0}^{M}u_{j+i},\sum_{i=1}^{M}u_{j+i}+v_{j+1},\sum_{i=2}^{M}u_{j+i}+\sum_{i=1}^{2}v_{j+i},\ldots,\sum_{i=M-1}^{M}u_{j+i}+\sum_{i=1}^{M-1}v_{j+i},u_{j+M}+\sum_{i=1}^{M}v_{j+i}\right]-\max\left[\sum_{i=0}^{M}v_{j-i},\sum_{i=1}^{M}v_{j-i}+u_{j-1},\sum_{i=2}^{M}v_{j-i}+\sum_{i=1}^{2}u_{j-i},\ldots,\sum_{i=M-1}^{M}v_{j-i}+\sum_{i=1}^{M-1}u_{j-i},v_{j-M}+\sum_{i=1}^{M}u_{j-i}\right]. \tag{27}$$

Subtracting

$$\sum_{i=0}^{j-1}u_i+\sum_{i=j+1}^{M+1}v_i$$

from both max[$\cdots$] terms on the right-hand side of the equation and using the relations:

$$u_{M+1}=\theta_n-\sum_{j=1}^{M}u_j,\quad v_{M+1}=\kappa_t-\sum_{j=1}^{M}v_j,$$

we get (22) from (24). Noticing that the number of dots of two column diagrams is preserved in the rule, we obtain (23). □

Our goal in this section is to show that (22) and (23) are ultradiscrete limits of the (one-constrained) nonautonomous discrete KP equation (ndKP equation):

$$(b_{n+1}-c_{j+1})\tau(t,n,j)\tau(t+1,n+1,j+1)+(c_{j+1}-a_{t+1})\tau(t+1,n+1,j)\tau(t,n,j+1)+(a_{t+1}-b_{n+1})\tau(t,n+1,j)\tau(t+1,n,j+1)=0. \tag{28}$$

Here a_t,b_n,c_j are arbitrary complex parameters. The ndKP equation (28), which is sometimes called the (nonautonomous) Hirota–Miwa equation, is equivalent to the generating formulas of the KP hierarchy.[20,21] Its soliton solutions, Lax operators, Darboux transformations, etc., have been investigated in Ref. 22. We set $a_{t+1}=1+\delta_t$ and $b_{n+1}=1+\gamma_n$. We also assume that $c_1=1$, $c_2=c_3=\cdots=c_{M+1}=0$, and

$$\tau(t,n,j+M+1)=\tau(t,n,j). \tag{29}$$

The constraint (29) is an analog of M-reduction of the KP hierarchy which restricts the space of transformation group of τ functions to the subgroup generated by $A_M^{(1)}$.[21] Let

$$U_{n,j}^t:=\frac{\tau(t,n+1,j)\tau(t,n,j+1)}{\tau(t,n,j)\tau(t,n+1,j+1)},\qquad V_{n,j}^t:=\frac{\tau(t+1,n,j+1)\tau(t,n,j)}{\tau(t+1,n,j)\tau(t,n,j+1)}, \tag{30}$$

for $1\leqslant j\leqslant M$. We also introduce a small positive parameter ε, and put $\delta_t=\exp[-\kappa_t/\varepsilon]$ and $\gamma_n=\exp[-\theta_n/\varepsilon]$. Then we have

Theorem 4.2: Let

$$u_{n,j}^t=\lim_{\varepsilon\to+0}\varepsilon\log U_{n,j}^t,$$

$$v_{n,j}^t=\lim_{\varepsilon\to+0}\varepsilon\log V_{n,j}^t$$

be the ultradiscrete limits for $1 \leqslant j \leqslant M$, *and specify* $u^t_{n,M+1}$ *and* $v^t_{n,M+1}$ *by* $\Sigma_{j=1}^{M+1} u^t_{n,j} = \theta_n$ *and* $\Sigma_{j=1}^{M+1} v^t_{n,j} = \kappa_t$. *Then* $\{u^t_{n,j}\}$ *and* $\{v^t_{n,j}\}$ *satisfy (22) and (23).*

Proof: We use abbreviations: $\tau_j := \tau(t,n,j)$, $\tau^t_j := \tau(t+1,n,j)$, $\tau_{n,j} := \tau(t,n+1,j)$, $\tau^t_{n,j} := \tau(t+1,n+1,j)$. The ndKP equation (28) with the constraint (29) is rewritten as the following $M+1$ simultaneous equations:

$$
\begin{aligned}
&(1+\gamma_n)\tau_1\tau^t_{n,2} - (1+\delta_t)\tau^t_{n,1}\tau_2 + (\delta_t - \gamma_n)\tau_{n,1}\tau^t_2 = 0,\\
&(1+\gamma_n)\tau_2\tau^t_{n,3} - (1+\delta_t)\tau^t_{n,2}\tau_3 + (\delta_t - \gamma_n)\tau_{n,2}\tau^t_3 = 0,\\
&\cdots\\
&(1+\gamma_n)\tau_M\tau^t_{n,M+1} - (1+\delta_t)\tau^t_{n,M}\tau_{M+1} + (\delta_t - \gamma_n)\tau_{n,M}\tau^t_{M+1} = 0,\\
&\gamma_n\tau_{M+1}\tau^t_{n,1} - \delta_t\tau^t_{n,M+1}\tau_1 + (\delta_t - \gamma_n)\tau_{n,M+1}\tau^t_1 = 0.
\end{aligned}
\tag{31}
$$

Defining

$$
\begin{aligned}
&x_1 := \tau^t_{n,1}\tau_2\tau_3\cdots\tau_{M+1}, \quad y_1 := \tau_{n,1}\tau^t_2\tau_3\tau_4\cdots\tau_{M+1},\\
&x_2 := \tau_1\tau^t_{n,2}\tau_3\cdots\tau_{M+1}, \quad y_2 := \tau_1\tau_{n,2}\tau^t_3\tau_4\cdots\tau_{M+1},\\
&\cdots \quad \cdots\\
&x_{M+1} := \tau_1\tau_2\tau_3\cdots\tau^t_{n,M+1}, \quad y_{M+1} := \tau^t_1\tau_2\tau_3\tau_4\cdots\tau_{n,M+1},\\
&\vec{x} := (x_1, x_2, \ldots, x_{M+1})^T, \quad \vec{y} := (y_1, y_2, \ldots, y_{M+1})^T,
\end{aligned}
$$

we obtain

$$
\mathbf{L}\vec{x} = (\delta_t - \gamma_n)\vec{y},
$$

where

$$
\mathbf{L} = \begin{pmatrix}
(1+\delta_t) & -(1+\gamma_n) & 0 & \cdots & 0 & 0\\
0 & (1+\delta_t) & -(1+\gamma_n) & 0 & \cdots & 0\\
\vdots & \vdots & \ddots & \ddots & \ddots & \vdots\\
0 & 0 & 0 & \cdots & (1+\delta_t) & -(1+\gamma_n)\\
-\gamma_n & 0 & 0 & \cdots & 0 & \delta_t
\end{pmatrix}.
$$

Its inverse matrix is easily calculated as

$$
\mathbf{L}^{-1} = \mathbf{D}/((1+\delta_t)^M\delta_t - (1+\gamma_n)^M\gamma_n),
$$

$$
(\mathbf{D})_{i,j} = \begin{cases}
(1+\gamma_n)^{M+1-i}(1+\delta_t)^{i-1} & j = M+1\\
\delta_t(1+\delta_t)^{M+i-j-1}(1+\gamma_n)^{j-i} & j \geqslant i\ (j \neq M+1)\\
\gamma_n(1+\gamma_n)^{M-i+j}(1+\delta_t)^{i-j-1}, & j \leqslant i-1\ (j \neq M+1).
\end{cases}
$$

Thus, for $0 < \delta_t,\ \gamma_n \ll 1$, we have

$$(\delta_t-\gamma_n)\mathbf{L}^{-1}\sim\begin{pmatrix}\delta_t & \delta_t & \delta_t & \cdots & \delta_t & 1\\ \gamma_n & \delta_t & \delta_t & \cdots & \delta_t & 1\\ \gamma_n & \gamma_n & \delta_t & \cdots & \delta_t & 1\\ \vdots & \vdots & \vdots & \ddots & \vdots & \vdots\\ \gamma_n & \gamma_n & \gamma_n & \cdots & \gamma_n & 1\end{pmatrix}.$$

Precisely speaking, $A\sim B$ means $\lim_{\varepsilon\to+0}\varepsilon\log A(\varepsilon)=\lim_{\varepsilon\to+0}\varepsilon\log B(\varepsilon)$. Since

$$x_j\sim\gamma_n\sum_{i=1}^{j-1}y_i+\delta_t\sum_{i=j}^{M}y_i+y_{M+1}, \tag{32}$$

$$x_{j+1}\sim\gamma_n\sum_{i=1}^{j}y_i+\delta_t\sum_{i=j+1}^{M}y_i+y_{M+1}, \tag{33}$$

we have

$$\frac{x_j}{x_{j+1}}\sim\frac{\gamma_n\Sigma_{i=1}^{j-1}(y_i/y_{M+1})+\delta_t\Sigma_{i=j}^{M}(y_i/y_{M+1})+1}{\gamma_n\Sigma_{i=1}^{j}(y_i/y_{M+1})+\delta_t\Sigma_{i=j+1}^{M}(y_i/y_{M+1})+1}. \tag{34}$$

From the definition of $U_{n,j}^t$ and $V_{n,j}^t$, we find that the left-hand side of (34) is equal to $U_{n,j}^{t+1}/V_{n,j}^t$ and that

$$(y_j/y_{M+1})=\prod_{i=j}^{M}U_{n,i}^t\prod_{i=1}^{j}V_{n,i}^t.$$

Since it holds that

$$\lim_{\varepsilon\to+0}\varepsilon\log\left(\frac{x_j}{x_{j+1}}\right)=\lim_{\varepsilon\to+0}\varepsilon\log[\text{the right-hand side of (34)}]$$

we have (22) by putting

$$u_{n,j}^t=\lim_{\varepsilon\to+0}\varepsilon\log U_{n,j}^t,$$

$$v_{n,j}^t=\lim_{\varepsilon\to+0}\varepsilon\log V_{n,j}^t.$$

From the definitions (30), we have

$$\frac{U_{n,j}^{t+1}}{U_{n,j}^t}=\frac{V_{n,j}^t}{V_{n+1,j}^t},$$

which gives (23) in the ultradiscrete limit. □

Next, we consider soliton solutions to the $A_M^{(1)}$ automaton. It is obvious that if the limit

$$Y_{n,j}^t:=\lim_{\varepsilon\to+0}\varepsilon\log\tau(t,n,j) \tag{35}$$

exists, then from (30) we have for $1\leqslant j\leqslant M$,

$$u_{n,j}^t = Y_{n+1,j}^t + Y_{n,j+1}^t - Y_{n,j}^t - Y_{n+1,j+1}^t,$$
$$v_{n,j}^t = Y_{n,j+1}^{t+1} + Y_{n,j}^t - Y_{n,j}^{t+1} - Y_{n,j+1}^t. \tag{36}$$

From Theorem 4.2, they satisfy (22) and (23). Hence we have only to know $Y_{n,j}^t$ to get solutions to (22) and (23). We will call $Y_{n,j}^t$ an N soliton solution to the $A_M^{(1)}$ automaton when it is an ultradiscrete limit of one parameter (ε) family of certain $M\times N$ soliton solutions $\tau(t,n,j)$ to the ndKP equation (28) as explained in Appendix B. It indeed corresponds to an N soliton state in the sense of Sec. III A.

The following fact is well known.[21,22]

Proposition 4.3: The N soliton solution to (28) is given by the vacuum expectation value:

$$\tau(t,n,j) = \langle \mathrm{vac}|g(\mathbf{t})|\mathrm{vac}\rangle, \tag{37}$$

$$g(\mathbf{t}) = \prod_{k=1}^{N} (1+\alpha_k \psi(p_k,\mathbf{t})\psi^*(q_k,\mathbf{t})). \tag{38}$$

Here $\mathbf{t}=(t,n,j)$ *and* $\alpha_k (k=1,2,\ldots,N)$ *are arbitrary complex constants,*

$$\psi(p,\mathbf{t}) = \left[\prod_{t'}^{t} (a_{t'}-p)\prod_{n'}^{n} (b_{n'}-p)^{-1}\prod_{j'=1}^{j} (-c_{j'}+p)^{-1}\right]\psi(p),$$

$$\psi^*(q,\mathbf{t}) = \left[\prod_{t'}^{t} (a_{t'}-q)^{-1}\prod_{n'}^{n} (b_{n'}-q)\prod_{j'=1}^{j} (-c_{j'}+q)\right]\psi^*(q),$$

with

$$\prod_{n'}^{n} X_{n'} := \begin{cases} \Pi_{n'=1}^{n} X_{n'}, & 1\leqslant n \\ 1, & n=0 \\ \Pi_{n'=n+1}^{0} X_{n'}^{-1}, & n\leqslant -1, \end{cases}$$

and $\psi(p),\psi^*(q)$ *are fermionic field operators which satisfy*

$$\{\psi(p),\psi(p')\}_+ := \psi(p)\psi(p')+\psi(p')\psi(p)=0,$$

$$\{\psi^*(q),\psi^*(q')\}_+ = 0, \quad \{\psi(p),\psi^*(q)\}_+ = 0 \ \text{ for } \ (p\neq q),$$

$$\langle \mathrm{vac}|\psi(p_1)\psi(p_2)\cdots\psi(p_r)\psi^*(q_r)\psi^*(q_{r-1})\cdots\psi^*(q_1)|\mathrm{vac}\rangle$$
$$= \det\left(\frac{1}{p_i-q_j}\right)_{1\leqslant i,j\leqslant r} = \frac{\Pi_{i<j}(p_i-p_j)(q_j-q_i)}{\Pi_{i,j}(p_i-q_j)}.$$

The N soliton solution (38) is also a solution to (31) when it satisfies the constraint (29). We can easily show

Proposition 4.4: The constraint (29) is achieved if it holds that

$$\left(\frac{q_k}{p_k}\right)^M \left(\frac{1-q_k}{1-p_k}\right) = 1 \quad (k=1,2,\cdots,N). \tag{39}$$

Note that, for a given p_k, there are M q_k's which satisfy (39) and $q_k\neq p_k$. We use this fact to construct explicit solutions.

From Propositions 4.3 and 4.4, we can construct a class of N soliton solutions to the $A_M^{(1)}$ automaton. The result is summarized as

Theorem 4.5:

$$Y_{n+1,j+1}^{t+1}=\max_{\vec{\mu}}\left[\sum_{i=1}^{N}\mu_i K^{(i)}(t,n,j)-A(\vec{\mu};j)\right] \tag{40}$$

is an N soliton solution to the $A_M^{(1)}$ automaton. Here $\vec{\mu}=(\mu_1,\mu_2,\ldots,\mu_N)$ $(\mu_i=0,1)$ and $\max_{\vec{\mu}}[\cdots]$ denotes the maximum among the 2^N values obtained by putting $\mu_i=0$ or 1 for $i=1,2,\ldots,N$,

$$K^{(i)}(t,n,j)=K_0^{(i)}-\sum_{j'=1}^{j}\nu_{j'}^{(i)}-\sum_{t'}^{t}\min[\kappa_{t'},L^{(i)}]+\sum_{n'}^{n}\min[\theta_{n'},L^{(i)}],$$

where the sums here are generally defined by

$$\sum_{n'}^{n}X_{n'}:=\begin{cases}\Sigma_{n'=1}^{n}X_{n'}, & 1\leqslant n\\ 0, & n=0\\ -\Sigma_{n'=n+1}^{0}X_{n'}, & n\leqslant -1.\end{cases}$$

$L^{(i)}$, $\nu_j^{(i)}$ $(1\leqslant i\leqslant N,1\leqslant j\leqslant M)$ are non-negative integers which satisfy $L^{(i)}=\Sigma_{j=1}^{M}\nu_j^{(i)}$,

$$L^{(1)}\geqslant L^{(2)}\geqslant\cdots\geqslant L^{(N)},$$

$$\nu_j^{(1)}\geqslant\nu_j^{(2)}\geqslant\cdots\geqslant\nu_j^{(N)}\quad(j=1,2,\ldots,M),$$

and $K_0^{(i)}$ is an arbitrary integer. In the case:

$$\left\{\begin{array}{ll}\mu_i=1 & \text{for } i=i_1,i_2,\ldots,i_p\\ \mu_i=0 & \text{otherwise}\end{array}\right\}$$

the phase factor $A(\vec{\mu};j)$ is given by

$$A(\vec{\mu};j)=\sum_{k=1}^{p}(k-1)L^{(i_k)}+\sum_{k=1}^{p}(X^{(i_k)}(j+k-1)-X^{(i_k)}(j)),$$

where $X^{(i)}(j)=\Sigma_{j'=1}^{j}\nu_{j'}^{(i)}$ with $\nu_{j+M}^{(i)}=\nu_j^{(i)}$.

The proof of this theorem is parallel to that in Ref. 7. We give the detail in Appendix B. For $N=1$ it is the general solution, and we conjecture that it is also so for $M=1$. Except for these cases the above-mentioned result does not cover the arbitrary initial condition. There is some freedom to employ different ''phase factors'' $A(\vec{\mu};j)$ than the above-mentioned one depending on the way in taking the ultradiscrete limit.

V. SUMMARY

In this paper we have introduced the $A_M^{(1)}$ automaton, which is a crystal theoretic formulation of the generalized box–ball systems. In terms of the box–ball systems, it corresponds to the dynamics of M kinds of balls, where the carriers and boxes have arbitrary and inhomogeneous capacities. We have introduced the solitons labeled with the crystals B_k' of $U_q'(A_{M-1}^{(1)})$. Scattering matrices of two solitons are identified with the combinatorial R matrices of $U_q'(A_{M-1}^{(1)})$ crystals. Piecewise linear evolution equations are obtained and identified with an ultradiscrete limit of the nonautonomous discrete KP equation. It allowed us to construct a class of N soliton solutions. We have left the studies of phase shifts in the scattering and construction of N soliton solutions corresponding to arbitrary initial conditions for $N\geqslant 2$ as future problems. The interplay between

the ultradiscrete limit of the classical integrable systems and the $q \to 0$ limit of the quantum integrable systems elucidated in this paper deserves further investigation.

ACKNOWLEDGMENTS

APPENDIX A: PROOF OF PROPOSITION 3.8

First we show that it suffices to prove Proposition 3.8 for $M=1$ and $h=k$. Without a loss of generality we may set $M=2$ and consider the time evolution $T_{\kappa=\infty}$. We find it convenient to adopt the equivalent box–ball system picture explained in Sec. II D. Thus the elements in $B_1^{\otimes \mathcal{L}}$ in (13) will be represented as ... 131..2 ... for example. It stands for the array of the balls with the indices 1, 3, 1 and 2 and . denotes an empty box. (So they do *not* correspond to the letters in the semistandard tableaux in the crystal notation.) We keep the same notation $\hat{\theta}$ to denote the map corresponding to (12) in the box–ball picture. It groups the array of balls and empty boxes locally together into the boxes with capacities $\ldots, \theta_n, \theta_{n+1}, \ldots$. Then the assertion of Proposition 3.8 is that the scattering

$$\hat{\theta}(\ldots \overbrace{2\cdots 2}^{l} \ldots \overbrace{1\cdots 1}^{k-h}\overbrace{2\cdots 2}^{h}\ldots) \xrightarrow{(\tilde{T}_2\tilde{T}_1)^t} \hat{\theta}(\ldots \overbrace{2\cdots 2}^{k} \ldots \overbrace{1\cdots 1}^{k-h}\overbrace{2\cdots 2}^{l+h-k}\ldots) \tag{A1}$$

takes place for sufficiently large t. Here $\tilde{T}_1, \tilde{T}_2$ are the ball-moving operators defined in Sec. II D, and we have used $T_\infty^t = (\tilde{T}_2\tilde{T}_1)^t$ in view of (10) and the fact that the balls with index $\geqslant 3$ are absent. In (A1) the sequences ... of the empty boxes are sufficiently long since both sides are to represent the asymptotic two-soliton states in the sense of Sec. III A. Now we make use of the relation $(\tilde{T}_2\tilde{T}_1)^t = \tilde{T}_2(\tilde{T}_1\tilde{T}_2)^{t-1}\tilde{T}_1$. From the definition of the operators $\tilde{T}_i$'s and the assumption that the two solitons are sufficiently separated, (A1) is equivalent to

$$\hat{\theta}(\ldots \overbrace{2\cdots 2}^{l} \ldots \overbrace{2\cdots 2}^{h}\overbrace{1\cdots 1}^{k-h}\ldots) \xrightarrow{(\tilde{T}_1\tilde{T}_2)^{t-1}} \hat{\theta}(\ldots \overbrace{2\cdots 2}^{k} \ldots \overbrace{2\cdots 2}^{l+h-k}\overbrace{1\cdots 1}^{k-h}\ldots). \tag{A2}$$

But this is justified once one establishes

$$\hat{\theta}(\ldots \overbrace{1\cdots 1}^{l} \ldots \overbrace{1\cdots 1}^{k}\ldots) \xrightarrow{\tilde{T}_1^{t-1}} \hat{\theta}(\ldots \overbrace{1\cdots 1}^{k} \ldots \overbrace{1\cdots 1}^{l}\ldots), \tag{A3}$$

because (A2) and (A3) correspond to the same canonical system $\hat{\theta}(\ldots 12\cdots l \ldots . l+1\cdots l+k \ldots)$ in the sense of Sec. II D with respect to the relevant time evolutions and therefore they possess the parallel time evolution pattern owing to (11). In this way the proof of Proposition 3.8 is reduced to (A3), which is equivalent to the case $M=1$ and $h=k$.

Now setting $L^{(1)}=l$ and $L^{(2)}=k$, we are to show

Proposition A.1: Set $M=1$, assume that $\kappa_t \geqslant L^{(1)}(\forall t)$ and $\theta_n < L^{(1)}$ for all but finitely many n's. Then two solitons with amplitudes $L^{(1)}$ and $L^{(2)}(L^{(1)}>L^{(2)})$ scatter into two solitons with amplitudes $L^{(2)}$ and $L^{(1)}$, respectively.

Namely, the amplitudes of two solitons do not change after the collision. To prove the proposition, we need several lemmas. The following two lemmas are obvious.

Lemma A.2: For given integers K_1 and K_2, if there exists an integer n_0 such that

$$K_1+\sum_{n'}^{n_0}\ \min[\,\theta_{n'},L^{(1)}]\geqslant 0\geqslant K_2+\sum_{n'}^{n_0}\ \min[\,\theta_{n'},L^{(2)}],$$

then, for $n\geqslant n_0$,

$$K_1+\sum_{n'}^{n}\ \min[\,\theta_{n'},L^{(1)}]\geqslant K_2+\sum_{n'}^{n}\ \min[\,\theta_{n'},L^{(2)}],$$

and for $n<n_0$,

$$0>K_2+\sum_{n'}^{n}\ \min[\,\theta_{n'},L^{(2)}].$$

Lemma A.3: For given integers K_1' *and* K_2', *if there exists an integer* n_0 *such that*

$$K_2'+\sum_{n'}^{n_0}\ \min[\,\theta_{n'},L^{(2)}]\geqslant 2L^{(2)}>0\geqslant K_1'+\sum_{n'}^{n_0}\ \min[\,\theta_{n'},L^{(1)}],$$

then, for $n\geqslant n_0$,

$$K_1'+K_2'+\sum_{n'}^{n}\ \min[\,\theta_{n'},L^{(1)}]+\sum_{n'}^{n}\ \min[\,\theta_{n'},L^{(2)}]-2L^{(2)}\geqslant K_1'+\sum_{n'}^{n}\ \min[\,\theta_{n'},L^{(1)}],$$

and for $n<n_0$,

$$0>K_1'+\sum_{n'}^{n}\ \min[\,\theta_{n'},L^{(1)}].$$

Now we define an integer $N_0(t)$ for given integers K_2 and t as

$$K_2-L^{(2)}t+\sum_{n'}^{N_0(t)}\ \min[\,\theta_{n'},L^{(2)}]\geqslant 2L^{(2)}>K_2-L^{(2)}t+\sum_{n'}^{N_0(t)-1}\ \min[\,\theta_{n'},L^{(2)}].$$

With this $N_0(t)$ we can show

Lemma A.4: For any integers K_1 *and* K_2, *we have*

$$\lim_{T\to\infty}\left(K_2-L^{(2)}T+\sum_{n'}^{N_0(T)}\ \min[\,\theta_{n'},L^{(2)}]-K_1+L^{(1)}T-\sum_{n'}^{N_0(T)}\ \min[\,\theta_{n'},L^{(1)}]\right)=+\infty.$$

Proof: From the definition of $N_0(t)$, we have

$$-L^{(2)}<-tL^{(2)}+\sum_{n'=N_0(0)+1}^{N_0(t)}\ \min[\,\theta_{n'},L^{(2)}]<L^{(2)}. \tag{A4}$$

Hence we have

$$\Delta(t) := -L^{(2)}t + \sum_{n'=N_0(0)+1}^{N_0(t)} \min[\theta_{n'}, L^{(2)}] - \left(-L^{(1)}t + \sum_{n'=N_0(0)+1}^{N_0(t)} \min[\theta_{n'}, L^{(1)}] \right)$$

$$= t(L^{(1)} - L^{(2)}) - \sum_{n'=N_0(0)+1}^{N_0(t)} (\min[\theta_{n'}, L^{(1)}] - \min[\theta_{n'}, L^{(2)}]) \geqslant t(L^{(1)} - L^{(2)})$$

$$- \sum_{n'=N_0(0)+1}^{N_0(t)} (\theta_{n'} - \min[\theta_{n'}, L^{(2)}]) > tL^{(1)} - L^{(2)} - \sum_{n'=N_0(0)+1}^{N_0(t)} \theta_{n'}. \tag{A5}$$

From (A4), we obtain an inequality:

$$t > -1 + \frac{1}{L^{(2)}} \sum_{n'=N_0(0)+1}^{N_0(t)} \min[\theta_{n'}, L^{(2)}].$$

Thus, from (A5), we find

$$\Delta(t) > -(L^{(1)} + L^{(2)}) + \sum_{n'=N_0(0)+1}^{N_0(t)} \min\left[\frac{L^{(1)} - L^{(2)}}{L^{(2)}} \theta_{n'}, L^{(1)} - \theta_{n'} \right]. \tag{A6}$$

Since $L^{(1)} > L^{(2)}, L^{(1)} > \theta_n$ for all but finitely many n's and $\lim_{t \to +\infty} N_0(t) = +\infty$ which is seen from (A4), we find

$$\lim_{t \to +\infty} \Delta(t) = +\infty. \tag{A7}$$

This suffices to prove the lemma. □

Now we prove Proposition A.1. From (36) we have

$$u_n^t := u_{n,j=1}^{t+1} = Y_{n+1,1}^{t+1} - Y_{n+1,2}^{t+1} - Y_{n,1}^{t+1} + Y_{n,2}^{t+1}. \tag{A8}$$

Specializing Theorem 4.5 to a two-soliton solution with $M = 1$ and $\kappa_t = +\infty$, we have

$$Y_{n+1,1}^{t+1} = \max[0, K_1(n,t), K_2(n,t), K_1(n,t) + K_2(n,t) - 2L^{(2)}],$$

$$Y_{n+1,2}^{t+1} = \max[0, K_1(n,t) - L^{(1)}, K_2(n,t) - L^{(2)}, K_1(n,t) + K_2(n,t) - L^{(1)} - 3L^{(2)}],$$

$$K_i(n,t) = K_i + \sum_{n'}^{n} \min[\theta_{n'}, L^{(i)}] - tL^{(i)} \quad (i = 1,2).$$

Note that $Y_{n,2}^t = Y_{n,1}^{t+1}$ due to the last equation in (31) and the condition $\delta_t = \exp[-\kappa_t/\varepsilon] = 0$. Given $L^{(1)} > L^{(2)}$, there exist integers n_1, n_2, j, r_1, r_2 that satisfy

$$n_1 \leqslant n_1 + j \leqslant n_2, \quad 1 \leqslant r_1 \leqslant \min(L^{(1)}, \theta_{n_1}), \quad 1 \leqslant r_2 \leqslant \min(L^{(2)}, \theta_{n_2}),$$

$$K_1 + \sum_{n'}^{n_1} \min[\theta_{n'}, L^{(1)}] > 0 \geqslant K_2 + \sum_{n'}^{n_1} \min[\theta_{n'}, L^{(2)}],$$

$$K_1 - L^{(1)} + \sum_{n'}^{n_1+j} \min[\theta_{n'}, L^{(1)}] > 0 \geqslant K_2 - L^{(2)} + \sum_{n'}^{n_1+j} \min[\theta_{n'}, L^{(2)}],$$

where $K_i (i=1,2)$ is defined by

$$K_1 = r_1 - \sum_{n'}^{n_1} \min[\theta_{n'}, L^{(1)}],$$

$$K_2 = r_2 + 2L^{(2)} - \sum_{n'}^{n_2} \min[\theta_{n'}, L^{(2)}].$$

From Lemma A.2, we find at $t=0$ that

$$\begin{aligned} Y^1_{n+1,1} &= \max[0, K_1(n,0), K_1(n,0) + K_2(n,0) - 2L^{(2)}], \\ Y^1_{n+1,2} &= \max[0, K_1(n,0) - L^{(1)}, K_1(n,0) + K_2(n,0) - L^{(1)} - 3L^{(2)}]. \end{aligned} \tag{A9}$$

Substituting (A9) into Eq. (A8), we obtain

$$u^0_n = \begin{cases} 0 & \text{for } n < n_1 \\ r_1 & \text{for } n = n_1 \\ \theta_n & \text{for } n_1 < n < n'_1 \\ L^{(1)} - \sum_{n'=n_1+1}^{n'_1-1} \theta_{n'} - r_1 & \text{for } n = n'_1 \\ 0 & \text{for } n'_1 < n < n_2 \\ r_2 & \text{for } n = n_2 \\ \theta_n & \text{for } n_2 < n < n'_2 \\ L^{(2)} - \sum_{n'=n_2+1}^{n'_2-1} \theta_{n'} - r_2 & \text{for } n = n'_2 \\ 0 & \text{for } n'_2 < n, \end{cases} \tag{A10}$$

where $n'_i (i=1,2)$ are defined by $n'_i = n_i + 1$ if $r_i = L^{(i)}$, and otherwise by

$$L^{(i)} - \sum_{n'=n_i+1}^{n'_i} \theta_{n'} - r_i \leqslant 0 < L^{(i)} - \sum_{n'=n_i+1}^{n'_i-1} \theta_{n'} - r_i .$$

Thus we see that the two-soliton solution can correspond to any initial configuration in which $L^{(1)}$ soliton is situated to the left-hand side of $L^{(2)}$ soliton with sufficient spacing. Hence, to prove the proposition, we have only to show that the solution u^t_n describes the two-soliton state in which $L^{(2)}$ soliton is the left-hand side of $L^{(1)}$ soliton for $t \gg 1$.

From the definition of $N_0(t)$ and Lemma A.4, there exists T and j such that

$$K_2 - L^{(2)}T + \sum_{n'}^{N_0(T)} \min[\theta_{n'}, L^{(2)}] > 0 \geqslant K_1 - L^{(1)}T + \sum_{n'}^{N_0(T)} \min[\theta_{n'}, L^{(1)}],$$

$$K_2 - L^{(2)}T - L^{(2)} + \sum_{n'}^{N_0(T)+j} \min[\theta_{n'}, L^{(2)}] > 0 \geqslant K_1 - L^{(1)}T - L^{(1)} + \sum_{n'}^{N_0(T)+j} \min[\theta_{n'}, L^{(1)}].$$

Thus, from Lemma A.3, we have at $t=T$ that

$$Y_{n+1,1}^{T+1}=\max[0,K_2(n,T),K_1(n,T)+K_2(n,T)-2L^{(2)}],$$

$$Y_{n+1,2}^{T+1}=\max[0,K_2(n,T)-L^{(2)},K_1(n,T)+K_2(n,T)-L^{(1)}-3L^{(2)}].$$

Substituting these into Eq. (A8), we find that u_n^T describes a configuration in which $L^{(2)}$ soliton locates around $n=N_0(T)$ and $L^{(1)}$ soliton does around $n\gg N_0(T)$. This completes the proof.

APPENDIX B: DERIVATION OF *N* SOLITON SOLUTIONS

Here we explain the derivation of the N soliton solution in Theorem 4.5 along the simple cases $N=1$ and $N=2$. First we consider one-soliton solution. We will show that it has the form:

$$Y_{n,j}^t=\max\left[0,K_0-\sum_{i=1}^{j-1}\ell_i-\sum_{t'}^{t-1}\min[\kappa_{t'},L]+\sum_{n'}^{n-1}\min[\theta_{n'},L]\right], \tag{B1}$$

where L is the amplitude, K_0 is an integer which is related to the phase of the soliton, and ℓ_i $(i=1,2,\ldots,M)$ are the non-negative integers which correspond to the number of ith balls in the soliton and $\Sigma_{i=1}^M\ell_i=L$. We give some details of its derivation, because similar technical difficulties in obtaining multisoliton solutions are resolved in the same way.

To obtain (B1), we take $g(\mathbf{t})$ in (38) as

$$g(\mathbf{t})=\prod_{\ell=0}^{M-1}(1+c_\ell(p)\psi(p,\mathbf{t})\psi^*(q_\ell,\mathbf{t}))=1+\psi(p,\mathbf{t})\phi^*(p,\mathbf{t}),$$
$$\phi^*(p,\mathbf{t}):=\sum_{\ell=0}^{M-1}c_\ell(p)\psi^*(q_\ell,\mathbf{t}), \tag{B2}$$

where q_ℓ $(\ell=0,1,\ldots,M-1)$ are the roots of the algebraic equation:

$$\frac{x^M(1-x)-p^M(1-p)}{x-p}=0,\quad (x\neq p) \tag{B3}$$

for a given real number $p[(1+M^{-1})^{-1}<p<1]$, and $c_\ell(p)$ $(0\leqslant\ell\leqslant M-1)$ are complex coefficients which will be determined later. Since (B3) has one real positive root, we assume that q_0 is positive and we put $\eta=q_0/p$. Then p and q_0 satisfy

$$p=\frac{1-\eta^M}{1-\eta^{M+1}}, \tag{B4}$$

$$1-p=\eta^M\left(\frac{1-\eta}{1-\eta^{M+1}}\right), \tag{B5}$$

$$q_0=\eta\left(\frac{1-\eta^M}{1-\eta^{M+1}}\right). \tag{B6}$$

The τ function $\tau(t,n,j)$ is given by vacuum expectation value as

$$\tau(t,n,j)=\langle \mathrm{vac}|g(\mathbf{t})|\mathrm{vac}\rangle$$
$$=1+\sum_{\ell=0}^{M-1} c_\ell(p)\frac{1}{p-q_\ell}\left(\frac{q_\ell}{p}\right)^{j-M-1}\left(\frac{1-p/(1+\delta_0)}{1-q_\ell/(1+\delta_0)}\right)\left(\frac{1-q_\ell/(1+\gamma_0)}{1-p/(1+\gamma_0)}\right)$$
$$\times\prod_{t'}^{t-1}\left(\frac{1-p/(1+\delta_{t'})}{1-q_\ell/(1+\delta_{t'})}\right)\prod_{n'}^{n-1}\left(\frac{1-q_\ell/(1+\gamma_{n'})}{1-p/(1+\gamma_{n'})}\right). \tag{B7}$$

We introduce a small positive parameter ε and put $\eta=\exp[-L/(M\varepsilon)]$. We also put

$$\tilde{c}_\ell(p):=\frac{c_\ell(p)}{p-q_\ell}\left(\frac{q_\ell}{p}\right)^{-M-1}\left(\frac{1-p/(1+\delta_0)}{1-q_\ell/(1+\delta_0)}\right)\left(\frac{1-q_\ell/(1+\gamma_0)}{1-p/(1+\gamma_0)}\right)$$
$$\times\prod_{t'=-T_0}^{0}(1-q_\ell/(1+\delta_{t'}))\prod_{n'=1}^{N_0}(1-q_\ell/(1+\gamma_{n'})), \tag{B8}$$

$$\chi_p(s):=\sum_{\ell=0}^{M-1}\tilde{c}_\ell(p)\left(\frac{q_\ell}{p}\right)^s \quad (s\in\mathbb{Z}), \tag{B9}$$

where $T_0=T_0(\varepsilon)$ and $N_0=N_0(\varepsilon)$ are positive integers which satisfy $T_0\simeq N_0\simeq 1/\varepsilon$. Hence,

$$\lim_{\varepsilon\to+0}T_0=\lim_{\varepsilon\to+0}N_0=+\infty.$$

Since

$$\chi_p(s+M)=\sum_{\ell=0}^{M-1}\tilde{c}_\ell(p)\left(\frac{q_\ell}{p}\right)^{s+M}$$
$$=\sum_{\ell=0}^{M-1}\tilde{c}_\ell(p)\left(\frac{q_\ell}{p}\right)^{s}\left(\frac{1-p}{1-q_\ell}\right)$$
$$=(1-p)\sum_{i=0}^{\infty}p^i\sum_{\ell=0}^{M-1}\tilde{c}_\ell(p)\left(\frac{q_\ell}{p}\right)^{s+i}$$
$$=(1-p)\sum_{i=0}^{\infty}p^i\chi_p(s+i),$$

we have

$$\chi_p(s+M)=\sum_{i=0}^{M-1}\left(\sum_{\ell=0}^{\infty}(1-p)^{\ell+1}p^{M\ell}\varrho_\ell(i)\right)p^i\chi_p(s+i), \tag{B10}$$

where $\varrho_0(i)=1$, $\varrho_1(i)=i+1$, and

$$\varrho_\ell(i)=\sum_{k_1=(\ell-1)M}^{(\ell-1)M+i}\ \sum_{k_2=(\ell-2)M}^{k_1}\cdots\sum_{k_\ell=0}^{k_{\ell-1}}1$$
$$=\frac{(i+1)}{\ell!}\prod_{j=1}^{\ell-1}(\ell M+i+j+1),$$

for $\ell \geqslant 2$. Note that $\chi_p(s)$ is a real function when $\chi_p(j)$ $(0 \leqslant j \leqslant M-1)$ are real. The ratio $\varrho_{\ell+1}(i)/\varrho_\ell(i)$ $(\ell \geqslant 1, 0 \leqslant i \leqslant M-1)$ is calculated as

$$\frac{\varrho_{\ell+1}(i)}{\varrho_\ell(i)} = \frac{(\ell+1)(M+1)+i}{\ell+1} \prod_{k=2}^{\ell} \left(1+\frac{M}{\ell M+i+k}\right) < (M+1)\left(1+\frac{1}{\ell}\right)^{\ell} < (M+1)e.$$

Hence, if it holds that $(1-p)p^M < (M+1)^{-1}e^{-1}$, we obtain

$$|\chi_p(s+M)| \leqslant (1-p)\sum_{i=0}^{M-1} \left(1+(i+1)\frac{(1-p)p^M}{1-(1-p)p^M(M+1)e}\right)|\chi_p(s+i)|. \tag{B11}$$

Thus we find

$$\chi_p(s+M) \sim \eta^M \sum_{i=0}^{M-1} \chi_p(s+i)$$

for sufficiently small η.

We assume the following for $\chi_p(j)$:

$$\begin{aligned} \chi_p(1) &= \chi_0, \\ \chi_p(2) &= N_1 y^{\ell_1} \chi_p(1), \\ \chi_p(3) &= N_2 y^{\ell_2} \chi_p(2), \\ &\cdots \\ \chi_p(M) &= N_{M-1} y^{\ell_{M-1}} \chi_p(M-1). \end{aligned} \tag{B12}$$

Here χ_0 is a positive number which is related to the initial phase of soliton, $y = \exp[-1/\varepsilon]$, ℓ_j and $N_j = N_j(\varepsilon)$ $(j = 1,2,\ldots,M-1)$ are non-negative integers and positive numbers, respectively. They are also supposed to satisfy

$$\begin{aligned} &\ell_M := L - \sum_{j=1}^{M-1} \ell_j \geqslant 0, \\ &\lim_{\varepsilon \to 0} \varepsilon \log N_j(\varepsilon) = 0, \\ &N_j y^{\ell_j} \leqslant \varepsilon^{N^*}, \end{aligned} \tag{B13}$$

for a sufficiently large positive integer N^*. From these conditions, $\tilde{c}_\ell(p)$ $(0 \leqslant \ell \leqslant M-1)$ are uniquely determined by

$$\begin{pmatrix} q_0 & q_1 & \cdots & q_{M-1} \\ q_0^2 & q_1^2 & \cdots & q_{M-1}^2 \\ \vdots & \vdots & \ddots & \vdots \\ q_0^M & q_1^M & \cdots & q_{M-1}^M \end{pmatrix} \begin{pmatrix} \tilde{c}_0(p) \\ \tilde{c}_1(p) \\ \vdots \\ \tilde{c}_{M-1}(p) \end{pmatrix} = \begin{pmatrix} p\chi_p(1) \\ p^2\chi_p(2) \\ \vdots \\ p^M\chi_p(M) \end{pmatrix}. \tag{B14}$$

Note that the determinant of the $M \times M$ matrix on the left-hand side is equal to

$$\left(\prod_{i=0}^{M-1} q_i\right)\left(\prod_{j>i} (q_j - q_i)\right) \neq 0.$$

It should be also noted from (B11) to (B13) that

$$\chi_p(i) \geqslant \varepsilon^{-N^*}\chi_p(i+1) \quad \text{for } \forall i,$$
$$\chi_p(i) \geqslant C\exp[L/\varepsilon]\chi_p(i+M) \quad \text{for } \forall i \text{ and } \exists C>0. \tag{B15}$$

From (B7), we have

$$\tau(t,n,j) = 1 + \sum_{\ell=0}^{M-1} \tilde{c}_\ell(p)\left(\frac{q_\ell}{p}\right)^i \prod_{t'=-T_0}^{t-1}\left(1-\frac{q_\ell}{1+\delta_{t'}}\right)^{-1}\prod_{t'}^{t-1}\left(1-\frac{p}{1+\delta_{t'}}\right)$$
$$\times \prod_{n'}^{n-1}\left(1-\frac{p}{1+\gamma_{n'}}\right)^{-1}\prod_{n'=n}^{N_0}\left(1-\frac{q_\ell}{1+\gamma_{n'}}\right)^{-1}. \tag{B16}$$

Hereafter we restrict ourselves to the region: $|n| \leqslant N_0$ and $|t| \leqslant T_0$. Noticing that

$$\prod_{t'=T_0}^{t-1}\left(1-\frac{q_\ell}{1+\delta_{t'}}\right)^{-1}\prod_{n'=n}^{N_0}\left(1-\frac{q_\ell}{1+\gamma_{n'}}\right)^{-1}$$
$$= 1 + \left(\sum_{t=-T_0}^{t-1}\left(\frac{1}{1+\delta_{t'}}\right) + \sum_{n'=n}^{N_0}\left(\frac{1}{1+\gamma_{n'}}\right)\right)q_\ell + \cdots$$
$$=: 1 + a_1\left(\frac{q_\ell}{p}\right) + a_2\left(\frac{q_\ell}{p}\right)^2 + a_3\left(\frac{q_\ell}{p}\right)^3 + \cdots,$$

we find

$$\tau(t,n,j) = 1 + \prod_{t'}^{t-1}\left(1-\frac{p}{1+\delta_{t'}}\right)\prod_{n'}^{n-1}\left(1-\frac{p}{1+\gamma_{n'}}\right)^{-1}\sum_{i=0}^{\infty} a_i\chi_p(j+i), \tag{B17}$$

where $a_0 = 1$ and $a_{i+1}/a_i \sim \varepsilon^{-1}$. From (B15), we have

$$0 < \sum_{i=1}^{\infty} a_i\chi_p(j+i) < \chi_p(j)$$

for sufficiently small ε. Putting $\chi_0 = \exp[K_0/\varepsilon]$ and noticing the relations:

$$\lim_{\varepsilon\to+0} \varepsilon\log(1-p) = -L,$$

$$\lim_{\varepsilon\to+0} \varepsilon\log\chi_p(j) = K_0 - \sum_{i=1}^{j-1}\ell_i,$$

$$\lim_{\varepsilon\to+0} \varepsilon\log\left(1-\frac{p}{1+\gamma_n}\right)^{-1} = \min[L,\theta_n],$$

$$\lim_{\varepsilon\to+0} \varepsilon\log\left(1-\frac{p}{1+\delta_t}\right) = -\min[L,\kappa_t],$$

we obtain

$$\lim_{\varepsilon\to+0}\ \varepsilon\log\tau(t,n,j)=\max\left[0,K_0-\sum_{i=1}^{j-1}\ell_i-\sum_{t'}^{t-1}\min[\kappa_{t'},L]+\sum_{n'}^{n-1}\min[\theta_{n'},L]\right]. \tag{B18}$$

Since

$$\lim_{\varepsilon\to+0}\ N_0(\varepsilon)=\lim_{\varepsilon\to+0}\ T_0(\varepsilon)=+\infty,$$

we have shown that (B1) is a one-soliton solution to the $A_M^{(1)}$ automaton.

Next we consider two-soliton solutions. From the previous arguments about one-soliton solution, we see that the field operators $\psi(p)$ and $\phi^*(p)$ are essentially determined by L, ℓ_j $(j=1,2,\ldots,M)$ and K_0. Therefore we denote these operators by

$$\psi(p)=\psi(L:\varepsilon),\quad \phi^*(p)=\phi^*(L;\{\ell_j\};K_0:\varepsilon). \tag{B19}$$

Then we take

$$g(\mathbf{t})=(1+\psi(p_1,\mathbf{t})\phi^*(p_1,\mathbf{t}))(1+\psi(p_2,\mathbf{t})\phi^*(p_2,\mathbf{t})), \tag{B20}$$

where

$$\psi(p_i)=\psi(L^{(i)}:\varepsilon),\quad \phi^*(p_i)=\phi^*(L^{(i)};\{\ell_j^{(i)}\};K_0^{(i)}:\varepsilon)\quad (i=1,2). \tag{B21}$$

We also assume $L^{(1)}\geqslant L^{(2)}$ and $\ell_j^{(1)}\geqslant\ell_j^{(2)}$ $(j=1,2,\ldots,M)$. As we shall see in the following, the latter condition turns out to be a natural constraint for soliton solutions. Using similar notations as given previously, we have

$$\begin{aligned}\tau(t,n,j)&=\langle\mathrm{vac}|(1+\psi(p_1,\mathbf{t})\phi^*(p_1,\mathbf{t}))(1+\psi(p_2,\mathbf{t})\phi^*(p_2,\mathbf{t}))|\mathrm{vac}\rangle\\&=1+\langle\mathrm{vac}|\psi(p_1,\mathbf{t})\phi^*(p_1,\mathbf{t})|\mathrm{vac}\rangle+\langle\mathrm{vac}|\psi(p_2,\mathbf{t}))\phi^*(p_2,\mathbf{t})|\mathrm{vac}\rangle\\&\quad+\langle\mathrm{vac}|\psi(p_1,\mathbf{t})\psi^*(p_1,\mathbf{t})\psi(p_2,\mathbf{t})\phi^*(p_2,\mathbf{t})|\mathrm{vac}\rangle.\end{aligned} \tag{B22}$$

The second and third terms are calculated in the same way as above. The fourth term is evaluated as

$$\begin{aligned}&\langle\mathrm{vac}|\psi(p_1,\mathbf{t})\phi^*(p_1,\mathbf{t})\psi(p_2,\mathbf{t})\phi^*(p_2,\mathbf{t})|\mathrm{vac}\rangle\\&=\sum_{\ell_1=0}^{M-1}\sum_{\ell_2=0}^{M-1}\tilde{c}_{\ell_1}(p_1)\tilde{c}_{\ell_2}(p_2)\left(\frac{(p_1-p_2)(q_{\ell_2}^{(2)}-q_{\ell_1}^{(1)})}{(p_1-q_{\ell_2}^{(2)})(p_2-q_{\ell_1}^{(1)})}\right)\prod_{i=1,2}\left(\frac{q_{\ell_i}^{(i)}}{p_i}\right)^j\prod_{t'=-T_0}^{t-1}\\&\quad\times\left(1-\frac{q_{\ell_i}^{(i)}}{1+\delta_{t'}}\right)^{-1}\prod_{t'}^{t-1}\left(1-\frac{p_i}{1+\delta_{t'}}\right)\prod_{n'}^{n-1}\left(1-\frac{p_i}{1+\gamma_{n'}}\right)^{-1}\prod_{n'=n}^{N_0}\left(1-\frac{q_{\ell_i}^{(i)}}{1+\gamma_{n'}}\right)^{-1}.\end{aligned} \tag{B23}$$

We define $\chi_{p_i}(s)$ by

$$\chi_{p_i}(s):=\sum_{\ell=0}^{M-1}\tilde{c}_{\ell}(p_i)\left(\frac{q_{\ell}^{(i)}}{p_i}\right)^s\quad (i=1,2), \tag{B24}$$

and suppose

$$\chi_{p_i}(1)=\chi_0^{(i)},$$

$$\begin{aligned}
\chi_{p_i}(2) &= N_1^{(i)} y^{\ell_1^{(i)}} \chi_{p_i}(1), \\
\chi_{p_i}(3) &= N_2^{(i)} y^{\ell_2^{(i)}} \chi_{p_i}(2), \\
&\cdots \\
\chi_{p_i}(M) &= N_{M-1}^{(i)} y^{\ell_{M-1}^{(i)}} \chi_{p_i}(M-1),
\end{aligned} \tag{B25}$$

where positive numbers $N_j^{(i)}$ satisfy similar inequalities to (B13). From the assumption: $\ell_j^{(1)} \geqslant \ell_j^{(2)}$ $(j=1,2,\ldots,M)$, it is always possible to choose $N_j^{(i)}$ such that

$$\frac{\chi_{p_2}(j+1)}{\chi_{p_2}(j)} \gg \frac{\chi_{p_1}(j+1)}{\chi_{p_1}(j)}. \tag{B26}$$

Then (B23) is expanded as

$$\begin{aligned}
(\mathrm{B23}) = {} & \frac{(p_1-p_2)}{p_1 p_2} \prod_{k=1}^{2} \prod_{t'}^{t-1} \prod_{n'}^{n-1} \left(1-\frac{p_k}{1+\delta_{t'}}\right)\left(1-\frac{p_k}{1+\gamma_{n'}}\right)^{-1} \\
& \times \sum_{i=0}^{\infty} \sum_{i'=0}^{\infty} \left(a_{i,i'} \chi_{p_1}(j+i)\chi_{p_2}(j+1+i') - b_{i,i'} \chi_{p_2}(j+i)\chi_{p_1}(j+1+i')\right),
\end{aligned}$$

where the coefficients $a_{i,i'}$ are defined by

$$\begin{aligned}
& \left(\frac{p_1 p_2^2}{(p_1-q_{\ell_2}^{(2)})(p_2-q_{\ell_1}^{(1)})}\right) \prod_{k=1,2} \prod_{t'=-T_0}^{t-1} \left(1-\frac{q_{\ell_k}^{(k)}}{1+\delta_{t'}}\right)^{-1} \prod_{n'=n}^{N_0} \left(1-\frac{q_{\ell_k}^{(k)}}{1+\gamma_{n'}}\right)^{-1} \\
& \quad = \sum_{i=0}^{\infty} \sum_{i'=0}^{\infty} a_{i,i'} \left(\frac{q_{\ell_1}^{(1)}}{p_{\ell_1}}\right)^{i} \left(\frac{q_{\ell_2}^{(2)}}{p_{\ell_2}}\right)^{i'},
\end{aligned}$$

and

$$b_{i,i'} = \left(\frac{p_1}{p_2}\right) a_{i',i}.$$

From (B15), we evaluate

$$a_{0,0}\chi_{p_1}(j)\chi_{p_2}(j+1) \gg \sum_{i=0}^{\infty} \sum_{\substack{i'=0 \\ i+i'\neq 0}}^{\infty} a_{i,i'} \chi_{p_1}(j+i)\chi_{p_2}(j+1+i')$$

$$b_{0,0}\chi_{p_2}(j)\chi_{p_1}(j+1) \gg \sum_{i=0}^{\infty} \sum_{\substack{i'=0 \\ i+i'\neq 0}}^{\infty} b_{i,i'} \chi_{p_2}(j+i)\chi_{p_1}(j+1+i').$$

Then, noticing $a_{0,0}=p_2$, $b_{0,0}=p_1$ and using (B26), we find

$$\begin{aligned}
& \lim_{\varepsilon \to +0} \varepsilon \log \tau(t+1,n+1,j+1) \\
& \quad = \max[0, K^{(1)}(t,n,j), K^{(2)}(t,n,j), K^{(1)}(t,n,j)+K^{(2)}(t,n,j)-A(j)],
\end{aligned} \tag{B27}$$

$$K^{(i)}(t,n,j) := K_0^{(i)} - \sum_{j'=1}^{j} \mathcal{L}_{j'}^{(i)} - \sum_{t'}^{t} \min[\kappa_{t'}, L^{(i)}] + \sum_{n'}^{n} \min[\theta_{n'}, L^{(i)}] \quad (i=1,2), \tag{B28}$$

$$A(j) := L^{(2)} + \mathcal{L}_{j+1}^{(2)} \quad (0 \leqslant j \leqslant M-1). \tag{B29}$$

This gives a two-soliton solution. For the scattering where the larger soliton overtakes the smaller one like (I) in Theorem 3.10, the integer $\mathcal{L}_j^{(1)}$ $(1 \leqslant j \leqslant M)$ corresponds to the number of jth balls in the larger soliton at $t \to -\infty$, and $\mathcal{L}_j^{(2)}$ corresponds to that of the smaller soliton at $t \to +\infty$. Since the balls in the smaller soliton at $t \to +\infty$ must be included in the larger soliton at $t \to -\infty$, the condition $\mathcal{L}_j^{(1)} \geqslant \mathcal{L}_j^{(2)}$ must hold for soliton solutions. Similarly, for the scattering where the smaller soliton overtakes the larger one like (II) in Theorem 3.10, the integer $\mathcal{L}_j^{(2)}$ $(1 \leqslant j \leqslant M)$ corresponds to the number of jth balls in the smaller soliton at $t \to -\infty$, and $\mathcal{L}_j^{(1)}$ corresponds to that of the larger soliton at $t \to +\infty$. We should also note that there are several freedoms to choose the ''phase'' $A(j)$ in taking the ultradiscrete limit. However we conjecture that the above-mentioned choice will cover all the canonical systems, hence essentially all the time development patterns for $N=2$.

The N soliton solution (40) is obtained in the same way. The key in the construction is to evaluate the expansion:

$$\begin{aligned}
&\langle \mathrm{vac} | \psi(p_1)\psi^*(q_1)\psi(p_2)\psi^*(q_2)\cdots\psi(p_r)\psi^*(q_r) | \mathrm{vac} \rangle \\
&\quad = \langle \mathrm{vac} | \psi(p_1)\psi(p_2)\cdots\psi(p_r)\psi^*(q_r)\psi^*(q_{r-1})\cdots\psi^*(q_1) | \mathrm{vac} \rangle \\
&\quad = \frac{\Pi_{1 \leqslant i < j \leqslant r}(p_i - p_j)(q_j - q_i)}{\Pi_{1 \leqslant i,j \leqslant r}(p_i - q_j)} \\
&\quad = \frac{\Pi_{1 \leqslant i < j \leqslant r}(p_i - p_j)}{\Pi_{i=1}^{r} p_i^r} (q_r^{r-1} q_{r-1}^{r-2} \cdots q_2 + \text{other terms})
\end{aligned}$$

and show that this term gives the phase factor $A(\vec{\mu}; j)$ and the ''other terms'' do not contribute to the final results. This can be done in the same manner as in the case of two soliton solutions. We take

$$g(\mathbf{t}) = \prod_{i=1}^{N} (1 + \psi(p_i, \mathbf{t})\phi^*(p_i, \mathbf{t})), \tag{B30}$$

where

$$\psi(p_i) = \psi(L^{(i)}:\varepsilon), \quad \phi^*(p_i) = \phi^*(L^{(i)}; \{\mathcal{L}_j^{(i)}\}; K_0^{(i)}:\varepsilon) \quad (i=1,2,\ldots,N). \tag{B31}$$

We suppose

$$L^{(1)} \geqslant L^{(2)} \geqslant \cdots \geqslant L^{(N)},$$

and

$$\mathcal{L}_j^{(1)} \geqslant \mathcal{L}_j^{(2)} \geqslant \cdots \geqslant \mathcal{L}_j^{(N)} \quad (j=1,2,\ldots,M).$$

Note that this implies: $p_1 > p_2 > \cdots > p_N$. The latter condition is also a natural constraint for N soliton solutions as in the case of two-soliton solutions. Finally we find that the result is given by (40).

(Received 22 May 2000; accepted for publication 14 September 2000)

It is shown that a Lagrangian system whose Legendre transformation degenerates along a hypersurface behaves in a strange manner by jumping from time to time without any ''visible cause.'' In such a jump the system changes instantaneously its coordinates as well as its momenta. Necessary elements of the general theory of such systems are reported and a detailed description of a postrelativistic oscillator showing such a behavior is given. © *2001 American Institute of Physics.*

I. INTRODUCTION

In Lagrangian mechanics two, in a sense, extremal situations were widely studied. One of them, classical, corresponds to systems with nowhere degenerated Legendre map. In this situation the Legendre map identifies the Lagrangian dynamics with the corresponding Hamiltonian one. On the contrary, in the second case the Legendre transformation is supposed to be everywhere degenerated (and of constant rank). Such a situation is common in gauge theories and for this reason was studied in many works, starting with the pioneering paper by Dirac.[1] But in a generic, in the sense of singularity theory, situation the Legendre map $\mathcal{L}$ is almost everywhere nondegenerated except for a critical hypersurface S. Examples of this kind of Lagrangians can be found, for instance, in the literature dedicated to the motion of relativistic particles and the Einstein equations in the post-Newtonian approximation.[2–5] However, the dynamics of these systems has not been analyzed in a satisfactory way up to now, due to the difficulty of studying the behavior of trajectories near S. For reasons explained in Ref. 6 such difficulties cannot be overcome by applying the standard variational principles. Instead, a new principle is needed, which does not determine *a priori* the nature of the singularities of motion and takes into account the natural geometrical structure of the singular hypersurface. Such a prescription, the *Lagrangian transition principle*, has been proposed for the first time in Ref. 6. According to the transition principle, if a trajectory of the system reaches S at a folding point x of the Legendre map, then it makes a jump to another precisely prescribed singular point belonging to the same characteristic curve. From there the motion continues smoothly according to Euler–Lagrange equations up to a possible subsequent jump.

The Lagrangian transition principle was suggested by an analogous principle[7] describing impact and refraction phenomena for Hamiltonian discontinuous systems. We want to stress that the analogy between these two cases is purely geometrical, whereas the physical situations are *completely different*. In this sense, the Lagrangian transition principle cannot be reduced to the Hamiltonian one, and the corresponding physical context is new.

[b)]Electronic mail: vinograd@unisa.it

The aim of this paper is to illustrate the Lagrangian transition principle with an example of a certain physical flavor, a relativistic oscillator in the post-Galilean approximation. This system is a special case of a class of singular Lagrangians proposed in Ref. 4 and was partially studied in Ref. 8. We have chosen it because it is ''completely integrable'' in the sense that it admits a complete analytical description. We think that its self-consistency is an argument in favor of the reasonableness of the proposed principle.

The paper is structured as follows. In Sec. II the Hamiltonian transition principle is briefly recalled, and then it is applied to deduce the classic laws of reflection and refraction in geometrical optics. This application, together with those given in Refs. 6 and 7, represents strong evidence in favor of the principle. In Sec. III we recall the Lagrangian transition principle and some of the main results on Lagrangians with folds found in Ref. 6. The last section is dedicated to a very detailed analysis of the above-mentioned relativistic oscillator.

II. TRANSITION PRINCIPLE

The transition principle is a universal, in a sense, prescription of how a physical system admitting a natural Hamiltonian (symplectic) description should react when an instant drastic change of some of its basic ''parameters'' happens. The last ones could be its Hamiltonian function, phase or configuration space, various types of constraints imposed, charge, etc. In this sense the transition principle is rather general and, for instance, describes various types of collisions between rigid bodies[6] as well as refraction and reflection phenomena in geometric optics (see the example at the end of this section). At present it seems hardly possible to derive the transition principle in its full generality from more fundamental physical laws with such commonly used tricks as the passage to the limit, conservation law arguments, etc. For instance, for Lagrangian systems with fold singularities considered in this paper the limit arguments cannot be applied because that type of singularities is stable and as such cannot be approximated by regular Lagrangians. Conservation law arguments are not, generally, sufficient for this kind of Lagrangian. Darwin's two-electron model[3] gives an example of that. By these and other similar reasons we call this prescription ''principle'' in order to stress its flavor, if not the status, of a physical law. In a subsequent paper[9] we will apply it to describe nonelastic collisions and a number of other of its particular applications are on the agenda. In last years the interest to problems of the so-called nonsmooth mechanics was growing and the recent book[10] by Brogliato gives an account of the recent developments in this field and also contains a rich bibliography. It is recommended as an alternative approach. But we would like to emphasize that the transition principle covers a larger area of physical phenomena and, in particular, those that can be mathematically interpreted as propagation of singularities of solutions of (nonlinear) PDEs, say, geometrical optics (see Refs. 11 and 12).

Below we illustrate the principle in its original and simplest version (see Refs. 6 and 7 for further details) and give in addition a remarkable application to geometrical optics.

Let (Φ,Ω) be the phase space of a dynamical system with $\Omega=\Sigma_i\, dp_i/\backslash dq_i$ being a symplectic two form on Φ. Suppose then that Φ is divided by a hypersurface Γ into two closed domains Φ_+, Φ_-, having Γ as their common boundary, i.e., $\partial\Phi_+=\Gamma=\partial\Phi_-$. Suppose also that the Hamiltonian of the system is smooth on $\Phi_\pm$. In other words, if $H_\pm=H|_{\Phi_\pm}$, then $H_\pm\in C^\infty(\Phi_\pm)$. This, in particular, means that $H_\pm|_\Gamma\in C^\infty(\Gamma)$, but it is not supposed that $H_+|_\Gamma$ coincides with $H_-|_\Gamma$. So H, and consequently the Hamiltonian field X_H associated with it, are well defined on $\Phi\backslash\Gamma$ and is bi-valued on Γ.

As is well known, the local coordinate expression of $X_{H_\pm}$ is

$$X_{H_\pm}=\sum_i\left(\frac{\partial H_\pm}{\partial p_i}\frac{\partial}{\partial q_i}-\frac{\partial H_\pm}{\partial q_i}\frac{\partial}{\partial p_i}\right).$$

The corresponding canonical equations:

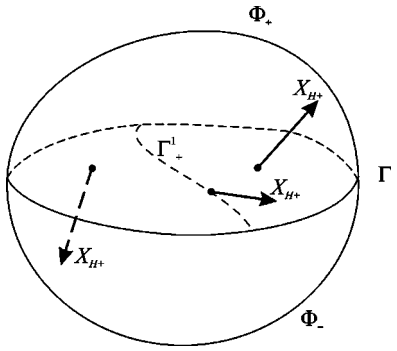

FIG. 1. In- and out-points (for H_+).

$$\dot{q}_i=\frac{\partial H_\pm}{\partial p_i}, \quad \dot{p}_i=-\frac{\partial H_\pm}{\partial q_i},$$

describe the motion of the system *inside* $\Phi_\pm$. But when the phase trajectory arrives at Γ it must ''decide'' under control of which Hamiltonian to proceed on. The *Transition Principle* prescribes how this decision should be taken.

First, recall[7] that on Γ is defined the one-dimensional *characteristic distribution* $x\mapsto l_x$, given by

$$l_x=\{\xi\in T_x(\Phi)|\Omega_x(\xi,\eta)=0 \quad \forall\,\eta\in T_x(\Gamma)\}.$$

Its integral curves are called *characteristics* of Γ.

Remark: A case of particular interest is when $\Gamma=\pi^{-1}(S)$, with $\pi:T^*(M)\to M$ being the cotangent bundle on a manifold M and $S\subset M$ being a hypersurface in the base. In this case characteristics of Γ are straight lines contained in the fibers $T^*_q(M)$, $q\in S$. In fact, if $q_n=0$ is the equation of S in a certain local chart, then the characteristic directions are given by the vector field $\partial/\partial p_n$.

Coming back to the general situation, let $x\in\Gamma$. We say that x is a $+$*-in-point* (respectively, a $+$*-out-point*) if $X_{H_+}|_x$ is directed toward Φ_+ (respectively, Φ_-). Similarly, we say that x is a $-$*-in-point* (respectively, a $-$*-out-point*) if $X_{H_-}|_x$ is directed toward Φ_- (respectively Φ_+) (see Fig. 1). In and out points of $H_\pm$ are separated by a hypersurface $\Gamma^1_\pm\subset\Gamma$ along which $X_{H_\pm}$ is tangent to Γ.

Suppose now that the phase trajectory, starting from a point inside of Φ_+ (respectively, Φ_-), reaches a point $x\in\Gamma$ at an instant $\bar{t}$, and let E be the constant value of H_+ (respectively, H_-) along the phase trajectory for $t\leqslant\bar{t}$. Denote by γ_x the characteristic curve of Γ passing through x, and by Σ^+_E (respectively, Σ^-_E) the hypersurface $\{H_+=E\}$ (respectively, $\{H_-=E\}$) of $\bar{\Phi}_+$ (respectively, $\bar{\Phi}_-$). A point $y\in\gamma_x\cap\Sigma^+_E$ (respectively, $\gamma_x\cap\Sigma^-_E$) is called *decisive* for x if it is a $+$-in-point (respectively, a $-$-in-point). Now we can state the following.

Transition principle: When a moving point reaches the separation hypersurface Γ *at a point* x *with energy* E*, then it continues its motion from all* x*-decisive points* $y\in\Sigma^\pm_E$ *simultaneously under control of corresponding Hamiltonians* $H_\pm$*. The passage of the phase point from* x *to the* y*'s is assumed to be instantaneous.*

The transition principle is illustrated in Fig. 2.

In Ref. 7 some examples illustrating this principle in mechanics and in geometrical optics are given. To these we will now add the following one.

Example (laws of reflection and refraction): Following the previous remark for notations, suppose M to be a region of the ordinary Euclidean space filled with two inhomogeneous isotropic

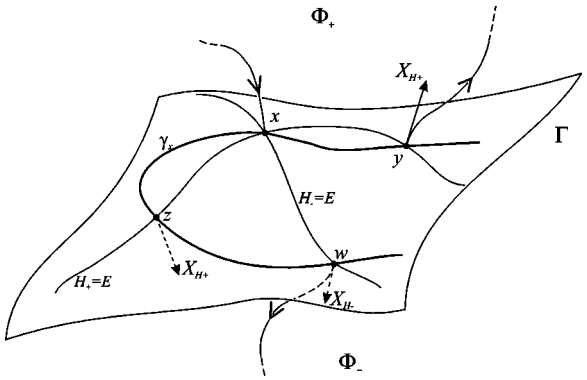

FIG. 2. The Hamiltonian transition principle (y and w are decisive for x).

optical media M_+, M_- separated by the surface S. Denote the light velocity in $M_\pm$ by $V_\pm(q)$, with (q_1,q_2,q_3) being Cartesian orthogonal coordinates in M. Then in each medium the propagation of light rays is described by the canonical system:[13]

$$\dot{q}_i=\frac{\partial H_\pm}{\partial p_i}, \quad \dot{p}_i=-\frac{\partial H_\pm}{\partial q_i}, \quad i=1,2,3$$

with

$$H_\pm(q,p)=V_\pm(q)\|p\|, \tag{1}$$

where $\|p\|=\sqrt{\Sigma_i p_i^2}$.

Suppose that a ray starting from M_+ reaches S at a point $\overline{q}\equiv(\overline{q_1},\overline{q_2},\overline{q_3})$ with an impulse $\overline{p}\equiv(\overline{p_1},\overline{p_2},\overline{p_3})$. The corresponding velocity is $\overline{v}=V_+(\overline{q})\overline{p}/\|\overline{p}\|$. In $\Phi=T^*(M)$ the phase trajectory of the ray reaches $\Gamma=\pi^{-1}(S)$ at the point $\overline{x}\equiv(\overline{q},\overline{p})$. By the previous remark the characteristic curve $\gamma_{\overline{x}}$ of Γ passing through x is a straight line contained in the fiber $T^*_{\overline{q}}(M)$. Let us choose coordinates (q_1,q_2,q_3) in such a way that S is tangent at $\overline{q}$ to the hyperplane $\{q_3=\overline{q_3}\}$ and the q_3 axis is directed toward M_-. Then the parametric equations of $\gamma_{\overline{x}}$ are

$$q_i(t)=\overline{q_i}$$

$$p_i(t)=\overline{p_i}+\delta_{i3}t, \quad t\in\mathbf{R}, \quad i=1,2,3. \tag{2}$$

If $E=H_+(\overline{q},\overline{p})$, then, in view of (2) and (1), the intersection $\gamma_{\overline{x}}\cap\Sigma_E^+$ is composed of the two points $\overline{x}$ and $x^*\equiv(\overline{q},p^*)$ with $p^*=(\overline{p_1},\overline{p_2},-\overline{p_3})$ It is easy to check that x^* is decisive for $\overline{x}$. Therefore, the transition principle tells that the reflected ray does always exist, and starts from the same point $\overline{q}\in S$ in the direction $v^*=V_+(\overline{q})p^*/\|p^*\|$ corresponding to p^*. Further, $\overline{v}$, v^* are coplanar with the normal to S at $\overline{q}$ and form with it equal angles ϕ,ψ_+, respectively (*reflection law*).

On the other hand, the intersection of $\gamma_{\overline{x}}$ with the circle $C_E^-=\Sigma_E^-\cap T^*_{\overline{q}}(M)$: (1) is empty if $\sin\phi=\sqrt{1-\overline{v_3}^2/V_+(\overline{q})^2}>\overline{n}$, with $\overline{n}=V_+(\overline{q})/V_-(\overline{q})$; (2) consists of the two points $\tilde{x}\equiv(\overline{q},\overline{p_1},\overline{p_2},\tilde{p}_3)$, $\hat{x}\equiv(\overline{q},\overline{p_1},\overline{p_2},-\tilde{p}_3)$, with $\tilde{p}_3=\|\overline{p}\|\sqrt{\overline{p_3}/\|\overline{p}\|+\overline{n}^2-1}$, if $\sin\phi\leqslant\overline{n}$. But only $\tilde{x}$ is decisive for $\overline{x}$. Hence, by the transition principle, in case (1) there is no refracted ray (*total reflection*), while in case (2) there is one refracted ray whose initial direction $\tilde{p}=(\overline{p_1},\overline{p_2},\tilde{p}_3)$ is coplanar with the incident ray and the normal to S at $\overline{q}$, and forms with this an angle ψ_- such that (*Snellius' law*):

$$\frac{\sin\phi}{\sin\psi_-}=\frac{\sqrt{1-\dfrac{\overline{p}_3^2}{\|\overline{p}\|^2}}}{\sqrt{1-\dfrac{\tilde{p}_3^2}{\|\tilde{p}\|^2}}}=\overline{n}.$$

III. LAGRANGIANS WITH SINGULAR HYPERSURFACES

In this section we briefly recall the notion of relative Hamiltonian vector field and the Lagrangian principle of transition, proposed for the first time in Ref. 6. As was mentioned in Sec. I, this principle was suggested by the *geometrical* analogy between discontinuous Hamiltonian systems considered in Sec. II and singular Lagrangians with fold-type singularities. We stress that this analogy is only geometrical, but that the two situations are totally different from the physical point of view. However, as in the Hamiltonian case, the Lagrangian transition principle allows one to completely describe discontinuities of motion that occur when the phase point of the system reaches the singular hypersurface.

A. The relative Hamiltonian vector field

As was pointed out in Ref. 6 the basic tool necessary for extending the transition principle to the Lagrangian case is the *relative Hamiltonian vector field*, whose definition we now briefly recall. Let M, $\dim M=n$, be the configuration space of a dynamical system described by a Lagrangian $L\in C^\infty(T(M))$, and let $\mathcal{L}:T(M)\to T^*(M)$ be the corresponding Legendre mapping. Recall that, in a fixed local chart $(q_1,\ldots,q_n)$ on M, $\mathcal{L}$ is represented by

$$\begin{aligned} q_i&=q_i, \quad i=1,\ldots,n,\\ p_i&=L_{v_i}(q,v), \quad i=1,\ldots,n, \end{aligned} \tag{3}$$

where (q,v), (q,p) are the natural coordinates on $T(M)$ and $T^*(M)$, respectively, associated with $(q_1,\ldots,q_n)$.

Now, one can associate with L the following vector field along $\mathcal{L}$:

$$X_L\overset{\text{def}}{=}\sum_i v_i\frac{\partial}{\partial q_i}+\sum_i L_{q_i}(q,v)\frac{\partial}{\partial p_i}. \tag{4}$$

The main properties of this operator were shown in Ref. 6. Here we limit ourselves to recalling why X_L was called Hamiltonian. In fact, it is easy to check that it satisfies the fundamental relation

$$X_L\lrcorner\Omega=-dE, \tag{5}$$

with $\Omega=\Sigma_i dp_i\wedge dq_i$ being the canonical two-form on $T^*(M)$ and

$$E(q,v)\overset{\text{def}}{=}\sum_i v_iL_{v_i}(q,v)-L(q,v)$$

being the energy function associated with L. Now, if L is regular, i.e., $\mathcal{L}$ is a diffeomorphism, then the Hamiltonian function $H=(\mathcal{L}^{-1})^*(E)$ is uniquely determined and, denoting by X_H the corresponding Hamiltonian vector field on $T^*(M)$, one immediately gets from (5) that

$$X_L=\mathcal{L}^*\circ X_H.$$

To our knowledge, the relative vector field (4) was proposed for the first time in Ref. 14. Later on some applications of it were found, especially in the study of constrained systems (see Ref. 6

for further references). However, the important role of X_L in the analysis of Lagrangian systems with singular hypersurfaces was indicated only recently in Ref. 6. In the next section we will recall briefly the main result of that work, the Lagrangian transition principle.

B. Legendre maps with folds. The Lagrangian transition principle

Referring to Sec. III A for the notations, suppose that L is non-regular and let S be the singular points locus of the Legendre map:

$$S=\{x\in T(M)|\text{rank } d_x\mathcal{L}<2n\}.$$

According to the standard-procedure, the motion of the system outside S can be described by Euler–Lagrange equations:

$$\begin{cases} \dot{q}_i=v_i, \\ \dfrac{d}{dt}(L_{v_i})-L_{q_i}=0, \end{cases} \tag{6}$$

$i=1,\ldots,n$. Equation $(6)_2$ can be rewritten in the normal form:

$$\dot{v}_i=f_i(q,v) \tag{7}$$

in a neighborhood of any point $(q,v)\in T(M)\setminus S$. So, outside of S the motions of the system coincide with the integral curves of the vector field

$$Z_L=\sum_i \left(v_i\frac{\partial}{\partial q_i}+f_i(q,v)\frac{\partial}{\partial v_i}\right).$$

On the other hand, this standard description is no longer possible if $(q,v)\in S$. Namely, accelerations become undetermined on S and velocities may have discontinuities.

As has been remarked in Sec. I for a generic Lagrangian S is a hypersurface (possibly with singularities). Its equation is

$$\mathcal{H}(q,v)=0,$$

with $\mathcal{H}:=\det\|L_{v_iv_j}\|$. We assume S to be a regular hypersurface of $T(M)$, i.e.,

$$d_x\mathcal{H}\neq 0, \quad \forall x\in S. \tag{8}$$

Further, we assume the following transversality condition

$$\text{Ker}\, d_x\mathcal{L}\cap T_x(S)=\{0\}, \quad \forall x\in S. \tag{9}$$

As was shown in Ref. 6, assumptions (8) and (9) guarantee $\mathcal{L}$ to be a *submersion with folds*.[15] Then, for any point $\overline{x}\in S$ there exist coordinates $(x_1,\ldots,x_{2n})$ on $T(M)$ and $(y_1,\ldots,y_{2n})$ on $T^*(M)$, centered at $\overline{x}$ and $\mathcal{L}(\overline{x})$, respectively, in terms of which $\mathcal{L}$ takes the form

$$\begin{aligned} y_1&=x_1\\ &\vdots\\ y_{2n-1}&=x_{2n-1}\\ y_{2n}&=x_{2n}^2. \end{aligned} \tag{10}$$

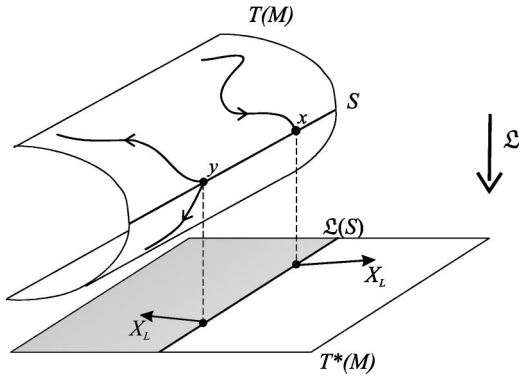

FIG. 3. The Lagrangian transition principle (y is decisive for x).

From (10) it easily follows that the range of $\mathcal{L}$ locally belongs to the half-space $y_{2n} \geqslant 0$. This allows us to extend the definition of in- and out-points and the corresponding transition principle to the Lagrangian case. Namely, a point $x \in S$ is called an *in-point* if $X_L|_x$ is directed toward the range of $\mathcal{L}$, $X_L|_x(y_{2n}) > 0$, while it is called an *out-point* if $X_L|_x$ is directed outside of it, $X_L|_x(y_{2n}) < 0$.

Let us note that the pullback $\mathcal{L}^*(\Omega)$ of the canonical symplectic form on $T^*(M)$ along the Legendre map is degenerated on S and is of rank $2n-2$ at any fold point. The restriction $\Omega_S \overset{\text{def}}{=} \mathcal{L}^*(\Omega)|_S$ continues to be of rank $2n-2$ due to (9). This means that the kernel l_x of Ω_S at a fold point $x \in S$ is one dimensional. This way one gets a one-dimensional distribution on S. *Characteristic curves* are integral curves of it. Denote by γ_x the characteristic curve passing through $x \in S$.

Now it is clear how to extend the transition principle to the Lagrangian case. Namely, calling *decisive* for $x \in S$ any in-point $y \in \gamma_x$ belonging to the same level Σ_E of energy of x, the principle can be stated as follows.

Transition Principle (Lagrangian case): When a phase point moving along Z_L reaches at an instant a point $x \in S$, it then continues its motion along all trajectories of Z_L issuing from points decisive for x. Moreover, the passage from x to a decisive point is instantaneous.

The principle is illustrated in Fig. 3.

Remark 1: According to the principle there are in general as many possible phase trajectories after the impact with S at a point x as are the points decisive for x. This is analogous to the splitting of light rays in reflection and refraction phenomena considered in Sec. II.

Remark 2: Note that, in order to define in- and out-points in the Lagrangian case, it is essential that the singularities of $\mathcal{L}$ be fold points. In Sec. IV we will see that the Lagrangian of the post-Galilean oscillator also exhibits some irregular singularities, which can be studied as well.

IV. RELATIVISTIC OSCILLATOR

In this section the behavior of a relativistic oscillator whose Lagrangian possesses fold singularities is analyzed on the basis of transition principle. We have chosen this example to show the above-mentioned theory in action mainly because of its relative simplicity: its phase trajectories and characteristics can be described analytically without difficulties. However, we will see that even in this simple case the behavior of phase trajectories with respect to the singular surface is rather interesting, at least from a geometrical point of view.

By applying the transition principle to describe the discontinuities of motion of relativistic oscillator we discover a rather remarkable phenomenon. Namely, if the energy exceeds a certain level and at the same time the velocity is not too high, the oscillator starts jumping. In other words, after a smooth motion it instantaneously changes its position (as well as velocity). In the classical

example of reflection and refraction of light, or elastic collision of bodies and particles, there is no discontinuity of position. It is worth noting that the ''jumping'' motions of the oscillator are in a good consistency with the smooth ones.

Finally, we note that the relativistic oscillator also possesses singularities of nonfold type. These are very degenerated and the phase portrait in this region is rather curious.

A. Relativistic oscillator

Recall that there were proposed various relativistic generalizations of the standard harmonic oscillator (see for instance Ref. 8). Some of them possess singularities, while others do not. In the following we study the two-dimensional post-Galilean oscillator[8] of tensor rank 2, possessing both fold and not fold type singularities:

$$L=L(r,x)=-mc^2[\sqrt{1-x}+(r/r_0)^2(1+x/2)]. \tag{11}$$

Here m,r_0 are the mass and the characteristic length of the oscillator, respectively, linked by the relation $r_0=\sqrt{m/k}\,c$ (with k being the elastic constant); r is the distance between the oscillating mass and the elastic force center; $x=v^2/c^2$ is the square of oscillator velocity, measured with respect to the light velocity c. If we fix in the plane of motion a system of orthogonal coordinates (q_1,q_2) with the origin at the center of the force, then obviously:

$$r=\sqrt{q_1^2+q_2^2}, \quad x=\frac{v_1^2+v_2^2}{c^2}.$$

Note that

$$0\leqslant x<1, \tag{12}$$

due to the fact that $v^2<c^2$. In the following we refer to $M=\mathbf{R}^2=\{(q_1,q_2)\}$ as the configuration space. So the Lagrangian (11) is defined in the domain $\mathcal{U}\subset T(M)=\{(q,v)\}=\mathbf{R}^2\times\mathbf{R}^2$, defined as

$$\mathcal{U}=\{(q,v)\in T(M)\,|\,q\in M,\|v\|<c\}.$$

However we will often not distinguish between $\mathcal{U}$ and $T(M)$. A similar convention will be adopted also for the cotangent bundle $T^*(M)$).

In the following we will systematically use in $\mathcal{U}$ the system of coordinates (r,ϕ,x,θ) [or equivalently (r,ϕ,x,u), with $u=\theta-\phi$] where ϕ and ϑ are the angle between q_1 axis and $\mathbf{r}\equiv(q_1,q_2)$, and the angle between $\mathbf{r}$ and the velocity vector $\mathbf{v}\equiv(v_1,v_2)$, respectively.

To simplify general considerations concerning Lagrangian (11) it is convenient to work with a generic Lagrangian of the form

$$L=L(r,x). \tag{13}$$

The energy function

$$E=v_1L_{v_1}+v_2L_{v_2}-L \tag{14}$$

takes the following form for Lagrangian (13):

$$E(r,x)=2xL_x-L, \tag{15}$$

which in the case of oscillator (11) becomes

$$E(r,x)=mc^2\left[\frac{1}{\sqrt{1-x}}+\left(\frac{r}{r_0}\right)^2\left(1-\frac{x}{2}\right)\right].$$

Lagrangian (13) also admits another integral of motion, namely the *angular momentum*:

$$I(r,x,u)=\frac{2}{c^2}L_x(r,x)(q_1v_2-q_2v_1)=\frac{2}{c}r\sqrt{x}L_x(r,x)\sin u. \tag{16}$$

For Lagrangian (11) it is specified as:

$$I(r,x,u)=mcr\sqrt{x}\left[\frac{1}{\sqrt{1-x}}-\left(\frac{r}{r_0}\right)^2\right]\sin u.$$

The integral I corresponds, via Noether's theorem, to the infinitesimal symmetry:

$$X=-q_2\frac{\partial}{\partial q_1}+q_1\frac{\partial}{\partial q_2}=\frac{\partial}{\partial\phi},$$

of Lagrangian (13).

B. Singular hypersurface of relativistic oscillator

The Legendre map $\mathcal{L}$ associated with Lagrangian (13) is given by

$$\begin{aligned} q_i&=q_i,\\ p_i&=L_{v_i}=\frac{2}{c^2}L_xv_i, \quad i=1,2. \end{aligned} \tag{17}$$

The corresponding Jacobian matrix in terms of standard coordinates (q,v) and (q,p) in $T(M)$ and $T^*(M)$, respectively, has the entries:

$$L_{v_iq_j}=\frac{2}{c^2}\frac{L_{xr}}{r}v_iq_j, \quad L_{v_iv_j}=\frac{2}{c^2}L_x\delta_{ij}+\frac{4}{c^4}L_{xx}v_iv_j, \quad i,j=1,2.$$

So, the corresponding Hessian is

$$\mathcal{H}(q,v)=L_{v_1v_1}L_{v_2v_2}-L_{v_1v_2}^2=\frac{4}{c^4}L_x(L_x+2xL_{xx})=\mathcal{H}(r,x)$$

It is easy to see that

$$L_x+2xL_{xx}=E_x, \tag{18}$$

and, therefore,

$$\mathcal{H}(r,x)=\frac{4}{c^4}L_xE_x.$$

Hence,

$$E_xL_x=0$$

is the equation of the singular hypersurface S. In other words

$$S=S_1\cup S_2,$$

with $S_1=\{E_x=0\},S_2=\{L_x=0\}$. Each of these hypersurfaces is fibered in tori (ϕ,θ), some of which may reduce to circles or to a point, depending on L. The bases of these ''fibrations'' are

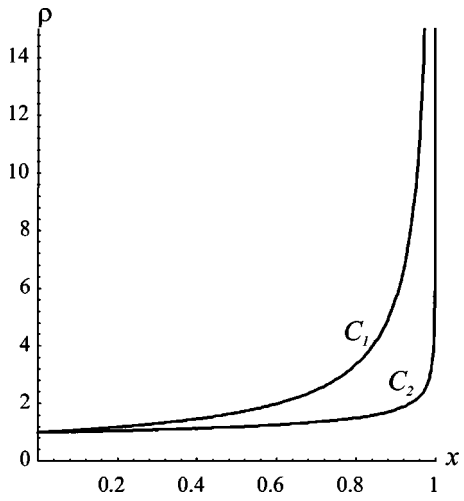

FIG. 4. Singular surface of the oscillator ($\rho = r/r_0$).

curves C_1, C_2 in the (x,r) plane, given by equations $E_x(r,x)=0$ and $L_x(r,x)=0$, respectively. These curves for the oscillator (11) are shown in Fig. 4. In this case the intersection $\gamma = S_1 \cap S_2$ is the circle $\{r=r_0, x=0\}$ included in the null section $M \subset T(M)$. γ is the locus $\operatorname{Sing} S$ of singular points of S. This follows easily from

$$\mathcal{H}_{q_i} = \frac{q_i}{r}\mathcal{H}_r = \frac{q_i}{r}(L_{xr}E_x + L_x E_{xr}),$$

$$\mathcal{H}_{v_i} = 2\frac{v_i}{c^2}\mathcal{H}_x = 2\frac{v_i}{c^2}(L_{xx}E_x + L_x E_{xx}),$$

and from the fact that $S_1 \setminus \gamma$ and $S_2 \setminus \gamma$ are regular.

Now we pass to describe how the kernel of the Legendre map behaves along the singular hypersurface S. A vector

$$\xi = \sum_{i=1}^{2}\left(a_i\frac{\partial}{\partial q_i} + b_i\frac{\partial}{\partial v_i}\right)$$

belongs to the kernel of $d\mathcal{L}$ iff

$$a_1 = a_2 = 0, \quad L_{vv}\begin{pmatrix} b_1 \\ b_2 \end{pmatrix} = \begin{pmatrix} 0 \\ 0 \end{pmatrix}. \tag{19}$$

In full details, the second of condition of (19) looks as

$$\left(L_x + \frac{2}{c^2}L_{xx}v_1^2\right)b_1 + \frac{2}{c^2}L_{xx}v_1v_2b_2 = 0, \tag{20}$$

$$\frac{2}{c^2}L_{xx}v_1v_2b_1 + \left(L_x + \frac{2}{c^2}L_{xx}v_2^2\right)b_2 = 0.$$

By construction these equations are linearly dependent at any point of S.

For a point $(q,v) \in S_2 \setminus S_1$ there are two possibilities: $L_{xx}(q,v)=0$ or $L_{xx}(q,v)\neq 0$. In the first case the system becomes trivial and $\operatorname{Ker} d_{(q,v)}\mathcal{L}$ is two dimensional. This never happens for the oscillator (11). In the second case system (20) reduces to the linear equation:

$$v_1 b_1 + v_2 b_2 = 0.$$

Except for the points $(v_1 = v_2 = 0)$, $\operatorname{Ker} d_{(q,v)}\mathcal{L}$ is one dimensional. It is generated by the vector

$$v_2 \frac{\partial}{\partial v_1} - v_1 \frac{\partial}{\partial v_2},$$

which coincides with $-\partial/\partial u$ in coordinates (r,ϕ,x,u). This shows that in both cases $\operatorname{Ker} d_{(q,v)}\mathcal{L}$ is tangent to S_2. So fold type singularities do not belong to S_2 and $\dim \mathcal{L}(S_2) < 3$. For the oscillator (11) $\mathcal{L}(S_2)$ is two-dimensional and coincides with the null section of $T^*(M)$.

Now we go to describe fold points belonging to $S_1 \backslash S_2$. These form an open domain $S_1^{\text{fold}} \subset S_1$ everywhere dense in S_1.

If $(q,v) \in S_1 \backslash S_2$, it follows from (18) that $L_x = -2xL_{xx}$, hence $(20)_2$ becomes

$$v_2 b_1 - v_1 b_2 = 0.$$

Therefore we have that

$$\operatorname{Ker} d_{(q,v)}\mathcal{L} = \operatorname{Span}\left(v_1 \frac{\partial}{\partial v_1} + v_2 \frac{\partial}{\partial v_2} \right) = \operatorname{Span}\left(\frac{\partial}{\partial x} \right) \quad \text{on} \quad S_1 \backslash S_2.$$

Thus, singularities of $\mathcal{L}$ along S_1 are of a substantially different nature from those along S_2. Namely, the kernel of $d\mathcal{L}$ is *transversal* to $S_1 \backslash S_2$ (due to the fact that $E_{xx} \neq 0$ on it) and is *tangent* to S_2, since $\partial L_x / \partial u = 0$ on it. Hence, $\dim \mathcal{L}(S_2) < 3$ and the transition principle cannot be applied to S_2. In the Sec. IV C we shall see that even characteristic directions are undetermined on S_2.

C. Characteristic curves on *S*

To simplify computations we will make use of coordinates (r,x,ϕ,ϑ) (or, equivalently, (r,x,u,ϕ)). Let

$$\rho = \sum_i p_i dq_i$$

be the universal one-form[7] on $T^*(M)$. Then

$$\mathcal{L}^*(\rho) = L_{v_1} dq_1 + L_{v_2} dq_2 = \frac{2}{c}\sqrt{x} L_x(r,x)(\cos u\, dr + r \sin u\, d\phi). \tag{21}$$

It follows from (21) that $\mathcal{L}^*(\rho)|_{S_2} = 0$. Hence

$$\mathcal{L}^*(\Omega)|_{S_2} = 0.$$

Therefore, $\mathcal{L}(S_2)$ is a Lagrangian submanifold in $T^*(M)$ (with possible singularities) and characteristic directions on S_2 are undetermined.

Now we pass to describe characteristics on S_1^{fold}. Since $\operatorname{grad} \mathcal{H} \neq 0$ on it, the equation $E_x(r,x) = 0$ of S_1 can be solved with respect to one of the variables, say r:

$$r = r_1(x) \quad \text{on} \quad S_1^{\text{fold}}.$$

In the case of the oscillator (11):

$$r_1(x) = \frac{r_0}{(1-x)^{3/4}}.$$

So (x,u,ϕ) can be taken as local coordinates on S_1^{fold}. Then from (21) we get:

$$\mathcal{L}^*(\rho)|_{S_1}=\frac{2}{c}\sqrt{x}L_x(r_1(x),x)[r_1'(x)\cos u\,dx+r_1(x)\sin u\,d\phi],$$

so that

$$\mathcal{L}^*(\Omega)|_{S_1}=d\mathcal{L}^*(\rho)|_{S_1}=\frac{2}{c}[\alpha(x,u)dx\wedge du+\beta(x,u)dx\wedge d\phi+\gamma(x,u)du\wedge d\phi], \tag{22}$$

with

$$\alpha(x,u)=\sqrt{x}L_x(r_1(x),x)r_1'(x)\sin u,$$

$$\beta(x,u)=\frac{d}{dx}[r_1(x)\sqrt{x}L_x(r_1(x),x)]\sin u,$$

$$\gamma(x,u)=r_1(x)\sqrt{x}L_x(r_1(x),x)\cos u.$$

Characteristic directions on S_1 are described by a characteristic vector field $X\in\mathcal{D}(S_1)$, i.e., such that

$$\mathcal{L}^*(\Omega)|_{S_1}(X,\bullet)=0. \tag{23}$$

If

$$X=a\frac{\partial}{\partial x}+b\frac{\partial}{\partial u}+c\frac{\partial}{\partial\phi},\quad a,b,c\in C^\infty(S_1),$$

then (23) is equivalent, in view of (22), to

$$\begin{pmatrix}0&-\alpha&-\beta\\ \alpha&0&-\gamma\\ \beta&\gamma&0\end{pmatrix}\begin{pmatrix}a\\b\\c\end{pmatrix}=\begin{pmatrix}0\\0\\0\end{pmatrix}.$$

This system is of rank 2 on S_1^{fold}, and its fundamental solution is

$$(a,b,c)=(\gamma,-\beta,\alpha).$$

Therefore,

$$X=\gamma\frac{\partial}{\partial x}-\beta\frac{\partial}{\partial u}+\alpha\frac{\partial}{\partial\phi}=q(x)\cos u\frac{\partial}{\partial x}-q'(x)\sin u\frac{\partial}{\partial u}+r_1'(x)\sqrt{x}L_x(r_1(x),x)\sin u\frac{\partial}{\partial\phi},$$

with $q(x)=r_1(x)\sqrt{x}L_x(r_1(x),x)$ and characteristic curves are solutions of the system:

$$\dot{x}=q(x)\cos u,$$

$$\dot{u}=-q'(x)\sin u, \tag{24}$$

$$\dot{\phi}=q(x)\frac{r_1'(x)}{r_1(x)}\sin u.$$

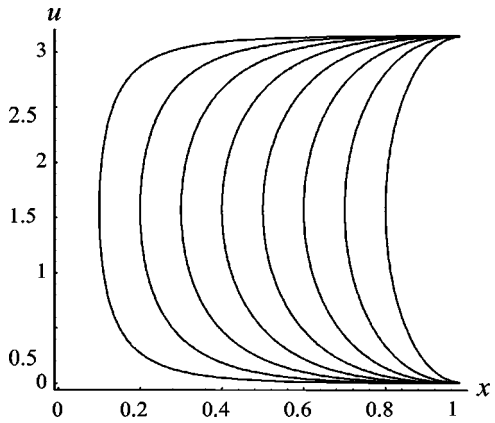

FIG. 5. Characteristic curves on S_1.

Integration of system (24) is reduced, obviously, to its subsystem $(24)_{1,2}$, whose solutions are to be described in the rectangle $[0,1[\times[-\pi,\pi]$ due to the cyclicity of u.

It follows from $(24)_{1,2}$ that

$$\frac{du}{dx}=-\frac{q'(x)}{q(x)}\tan u, \tag{25}$$

and, consequently,

$$\int \frac{du}{\tan u}=\ln|\sin u|=-\int\frac{q'(x)}{q(x)}dx=-\int\frac{dq}{q}=-\ln|q(x)|+\text{const}=\ln\frac{c}{|q(x)|},\quad c>0.$$

Hence the general integral of (25) is

$$\sin u=\frac{a}{q(x)},\quad a\in\mathbf{R}. \tag{26}$$

For the oscillator (11) it is specified as

$$\sin u=-\frac{2a}{mc^2r_0}\frac{(1-x)^{9/4}}{x^{3/2}}.$$

Let us remark that $q(x)\sin u=(c/2)\,I|_{S_1}$. So (26) shows that I is constant along characteristic curves of S_1. Therefore, by the transition principle, angular momentum (as well as energy) *does not change after the impact with* S_1.

The curves (26), denote them by γ_a, for the oscillator are shown in Fig. 5. Since the variable u is cyclic $\bmod 2\pi$ and γ_a and γ_{-a} are symmetric with respect to the x axis we can limit ourselves to dealing with the curves in the rectangle $(x,u)\in[0,1[\times[0,\pi]$.

Let $\overline{P}\equiv(\overline{x},\overline{u},\overline{\phi})\in S_1$ and let $\gamma_{\overline{a}}$ be the characteristic passing through $\overline{P}$, $\overline{E}=E(\overline{P})$. The intersection between the energy level surface $\Sigma_{\overline{E}}$ and S_1 is the torus $T_{\overline{E}}=\{r=r_1(\overline{x}),x=\overline{x}\}$. The projection of $T_{\overline{E}}$ onto the (x,u) plane is the line $x=\overline{x}$. For the oscillator (11) this is shown, together with the projection of $\gamma_{\overline{a}}$, in Fig. 6.

Therefore, assuming $\overline{u}\in[0,\pi]$, $\gamma_{\overline{a}}$ intersects $T_{\overline{E}}$ at $\overline{P}$ and at $\tilde{P}\equiv(\overline{x},\pi-\overline{u},\tilde{\phi})$. In order to determine $\tilde{\phi}$ notice that

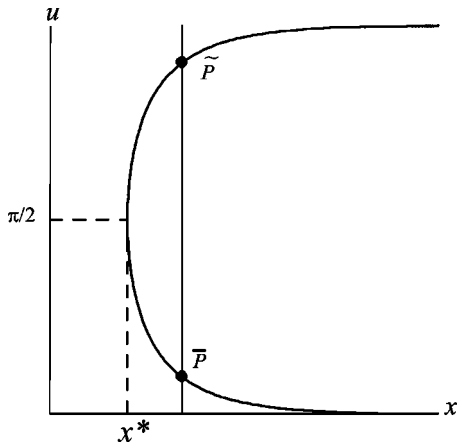

FIG. 6. Intersection between a characteristic curve and the energy level surface.

$$\frac{d\phi}{dx}=\frac{r_1'(x)}{r_1(x)}\tan u=\pm\frac{r_1'(x)}{r_1(x)}\frac{\sin u}{\sqrt{1-\sin^2 u}}=\pm|\overline{a}|\frac{r_1'(x)}{r_1(x)\sqrt{q^2(x)-\overline{a}^2}}, \tag{27}$$

as it results directly from $(24)_{1,2}$ and (26). In (27) the choice of ''+'' (respectively, ''−'') corresponds to $u\in[0,\pi/2[$ (respectively, $u\in]\pi/2,\pi]$). Hence, the possible position jump is described by

$$\tilde{\phi}-\bar{\phi}=\Delta\phi(\bar{x},\bar{u})=\pm 2|\overline{a}|\int_{x^*}^{\bar{x}}\frac{r_1'(x)}{r_1(x)\sqrt{q^2(x)-\overline{a}^2}}dx, \tag{28}$$

where x^* (see Fig. 6) is the root of

$$|q(x)|=|\overline{a}|, \tag{29}$$

and the sign + (respectively, −) corresponds to $\bar{u}\in[\pi/2,\pi]$ (respectively, $\bar{u}\in[0,\pi/2]$). In the case of the oscillator equation (29) becomes

$$x^2=\left(\frac{2|\overline{a}|}{mc^2r_0}\right)^{4/3}(1-x)^3,$$

which has only one root x^* in the interval $[0,1[$. Relation (27) remains valid also for $\bar{u}\in[-\pi,0]$. In this case the sign + (respectively, −) corresponds to $\bar{u}\in[-\pi,-\pi/2]$ (respectively, $\bar{u}\in[-\pi/2,0]$).

Since on a given characteristic only two points lie, $\bar{P}$ and $\tilde{P}$, belonging to the same energy level, a jump from $\bar{P}$ to $\tilde{P}$ or vice versa may happen only if one of these points is ''in'' while the other is ''out.'' This occurs iff the function $X_L(g)$, $g(q,p)=0$, being the equation of $\mathcal{L}(S_1)$, takes opposite signs at points $\bar{P}$, $\tilde{P}$, and we go to analyze when such is the case.

It follows from (4) that for Lagrangian (13)

$$X_L=v_1\frac{\partial}{\partial q_1}+v_2\frac{\partial}{\partial q_2}+\frac{L_r}{r}\left(q_1\frac{\partial}{\partial p_1}+q_2\frac{\partial}{\partial p_2}\right). \tag{30}$$

In the following we work with the local chart (r,ϕ,y,α), $y=(p_1^2+p_2^2)/m^2c^2$, $\alpha=\arctan p_2/p_1$, on $T^*(M)$. In terms of these coordinates the Legendre map (17) is given as follows:

$$y=\psi(r,x),\quad \alpha=\theta, \tag{31}$$

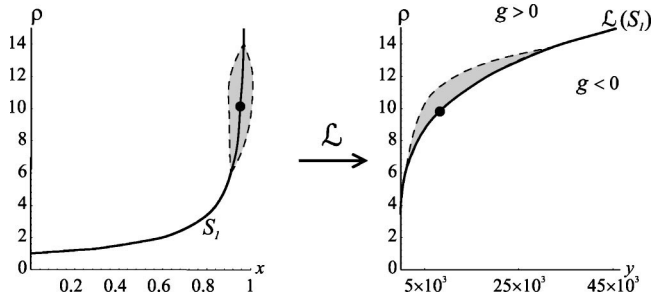

FIG. 7. Legendre map for the oscillator ($\rho = r/r_0$).

with $\psi(r,x) = (4/m^2c^4)\, xL_x^2(r,x)$, and the expression (30) takes the form

$$X_L = c\sqrt{x}\left(\cos u\,\frac{\partial}{\partial r} + \frac{\sin u}{r}\,\frac{\partial}{\partial \phi}\right) + \frac{\sqrt{\psi}}{mc} L_r\left(2\cos u\,\frac{\partial}{\partial y} - \frac{\sin u}{\psi}\,\frac{\partial}{\partial \alpha}\right). \tag{32}$$

Due to $(31)_1$ hypersurface $\mathcal{L}(S_1)$ is given by

$$g(r,y) = 0,$$

with

$$g(r,y) = \frac{4}{m^2c^4} x_1(r)\tilde{L}_x^2(r) - y, \tag{33}$$

where $x = x_1(r)$ is the function implicitly defined by equation $E_x(r,x) = 0$, and $\tilde{L}_x(r) = L_x(r,x_1(r))$. For the oscillator (11) the Legendre mapping $\mathcal{L}$ is illustrated in Fig. 7. In this case, as is easy to see from (31) and (33), the image with respect to $\mathcal{L}$ of a sufficiently small neighborhood of a point $(q,v) \in S_1$ is contained in the region $\{g > 0\}$.
From (32) we get:

$$X_L(g) = \cos u\left(c\sqrt{x} g_r + \frac{2\sqrt{\psi}}{mc} L_r g_y\right).$$

But from (18), (33) and $\mathcal{L}(S_1)$'s equation follows:

$$g_r = \frac{4}{m^2c^4}[x_1'\tilde{L}_x^2 + 2x_1\tilde{L}_x(\tilde{L}_{xr} + x_1'\tilde{L}_{xx})] = \frac{4\tilde{L}_x}{m^2c^4}(x_1'\tilde{E}_x + 2x_1\tilde{L}_{xr}) = \frac{8}{m^2c^4} x_1\tilde{L}_x\tilde{L}_{xr},$$

where, as before, $\tilde{f}(r)$ means $f(r,x_1(r))$. Hence, we obtain

$$X_L(g) = \frac{4}{m^2c^3}\sqrt{x}\cos u(2x_1\tilde{L}_x\tilde{L}_{xr} - L_xL_r). \tag{34}$$

Since $2xL_{xr} - L_r = E_r$ the restriction of (34) to S_1 is

$$\widetilde{X_L(g)} = \frac{4}{m^2c^3}\sqrt{x_1}\cos u\tilde{L}_x\tilde{E}_r. \tag{35}$$

In the case of the oscillator we have $\tilde{L}_x < 0$, $\tilde{E}_r > 0$. Therefore (35) shows that $\widetilde{X_L(g)}$ is:

(1) positive in the region S_1^+ corresponding to $u \in [\pi/2,\pi] \cup [-\pi,-\pi/2]$;
(2) negative in the region S_1^- corresponding to $u \in [-\pi/2,\pi/2]$;

(3) null on the bidimensional surface $W=S_1\cap\{u=\pm\pi/2\}$.

Hence, keeping in mind what was said previously about the range of $\mathcal{L}$ and applying the transition principle, we see the following.

(1) If $\overline{P}\in S_1^+$, then $\overline{P}$ is an in-point, while $\tilde{P}$ is an out-point. Therefore, if the phase point, starting from outside S_1, reaches it at $\tilde{P}$, its trajectory can be prolongated starting from $\overline{P}$ (jump from $\tilde{P}$ to $\overline{P}$).

(2) If $\overline{P}\in S_1^-$, then $\overline{P}$ is an out-point, while $\tilde{P}$ is an in-point. Therefore, if the phase point, starting from outside S_1, reaches it at $\overline{P}$, its trajectory can be prolongated starting from $\tilde{P}$ (jump from $\overline{P}$ to $\tilde{P}$).

(3) If $\overline{P}\in W$, i.e., if $\overline{u}=\pm\pi/2$, then $\overline{P}\equiv\tilde{P}$. In this case the jump becomes infinitesimal and its direction is indicated by the Hamiltonian vector field. In fact $\mathcal{L}(W)$ is described in terms of coordinates (r,ϕ,y,α) by

$$g(r,y)=0,$$

$$\cos u=0.$$

But it follows from (32) that on W

$$X_L(\cos u)=-\frac{L_r}{mc\sqrt{\psi}}\sin u=\pm\frac{L_r}{mc\sqrt{\psi}},$$

which is different from zero on S_1. More precisely, it is positive for $u=\pi/2$ and negative for $u=-\pi/2$; in both cases X_L is directed toward the region S_1^- in which singular trajectories end.

Finally note that, for the oscillator (11),

$$X_L(p_i)=\frac{q_i}{r}L_r\neq 0 \quad \text{on } S_2\backslash S_1.$$

Since $\mathcal{L}(S_2)$ coincides with the null section of $T^*(M)$, this shows that X_H is transversal to $\mathcal{L}(S_2)$.

D. Phase trajectories of the oscillator

In this section we will study phase trajectories of the oscillator outside S. It will be shown that their behavior depends strongly on their position with respect to the singular surface. Trajectories arriving at S have discontinuities, described by the transition principle, and together with others form a perfectly self-consistent dynamical model.

In this section coordinates (r,x,u,ϕ) are used. Let, as before,

$$Z_L=\dot{r}\frac{\partial}{\partial r}+\dot{\phi}\frac{\partial}{\partial\phi}+\dot{x}\frac{\partial}{\partial x}+\dot{u}\frac{\partial}{\partial u}$$

be the vector field on $T(M)$ corresponding to the Lagrangian L. Since I,E are first integrals, then

$$Z_L(I)=Z_L(E)=0,$$

or, equivalently

$$\begin{pmatrix} I_r & I_x & I_u \\ E_r & E_x & 0 \end{pmatrix}\begin{pmatrix} \dot{r} \\ \dot{x} \\ \dot{u} \end{pmatrix}=\begin{pmatrix} 0 \\ 0 \\ 0 \end{pmatrix}.$$

Therefore

$$\dot{r}=-kI_uE_x, \quad \dot{x}=kI_uE_r, \quad \dot{u}=k(I_rE_x-I_xE_r). \tag{36}$$

On the other hand,

$$\dot{r}=\frac{d}{dt}(\sqrt{q_1^2+q_2^2})=\frac{q_1v_1+q_2v_2}{r}=c\sqrt{x}\cos u.$$

So that

$$k=-\frac{c\sqrt{x}\cos u}{E_xI_u}=-\frac{c\sqrt{x}\sin u}{IE_x}=-\frac{c^2}{2rL_xE_x}. \tag{37}$$

Notice also

$$I_rE_x-I_xE_r=\frac{E_x}{c\sqrt{x}}\sin u(2xL_x+rL_r), \tag{38}$$

which follows directly from (15), (18), (16), and

$$\frac{\partial}{\partial x}(\sqrt{x}L_x)=\frac{E_x}{2\sqrt{x}}.$$

This way one gets the first three Euler–Lagrange equations:

$$\dot{r}=c\sqrt{x}\cos u$$

$$\dot{x}=-c\frac{E_r}{E_x}\sqrt{x}\cos u \tag{39}$$

$$\dot{u}=-\frac{c\sin u}{2r\sqrt{x}L_x}(2xL_x+rL_r),$$

which form a closed subsystem of the whole system.

Denote by $\tilde{Z}_L$ the projection of Z_L onto the (x,r,u) space. Then, solutions of (39) are identified with trajectories of $\tilde{Z}_L$. Due to obvious symmetry with respect to the (x,r) plane it is sufficient to consider those of them for which $u\in[0,\pi]$ (i.e., counterclockwise motions around the center of the elastic force).

The fourth Euler–Lagrange equation,

$$\dot{\phi}=\frac{c\sqrt{x}}{r}\sin u, \tag{40}$$

can be found directly from

$$\tan\phi=\frac{q_2}{q_1},$$

so that

$$\phi(t)=c\int_0^t\frac{\sqrt{x(\tau)}}{r(\tau)}\sin u(\tau)d\tau+\text{const}, \tag{41}$$

with $(x(t),r(t),u(t))$ being a solution of (39).

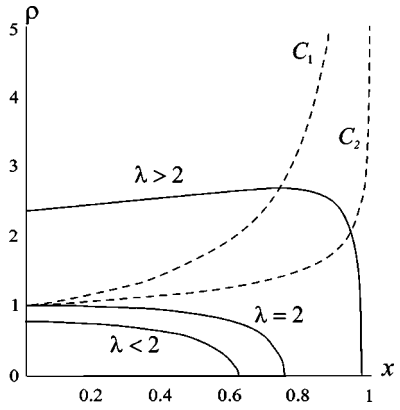

FIG. 8. Energy level surfaces of the oscillator.

Let

$$\Xi_{\lambda,\mu}=\{E=\lambda mc^2\}\cap\{I=\mu mcr_0\}. \tag{42}$$

Obviously,

$$\Xi_{\lambda,\mu}=\Gamma_{\lambda,\mu}\times S^1,$$

where $\Gamma_{\lambda,\mu}$ is the projection of $\Xi_{\lambda,\mu}$ into (r,x,u) space, while the circle S^1 corresponds to the cyclic coordinate ϕ. In their turn surfaces $\Xi_{\lambda,\mu}$ foliate the energy level three-fold,

$$\Sigma_\lambda=\{E=\lambda mc^2\}.$$

In the case of oscillator (11) Σ_λ is not empty for $\lambda\in[1,+\infty]$.
Let $\tilde{\Sigma}_\lambda$ be the projection of Σ_λ onto the (r,x,u) space. Obviously

$$\tilde{\Sigma}_\lambda=\Gamma_\lambda\times S^1,$$

where Γ_λ is the curve in (r,x) plane given by equation $E(r,x)=\lambda mc^2$ and S^1 is the circle corresponding to the cyclic coordinate u. Curves Γ_λ are shown in Fig. 8. One can see that Γ_λ intersects the projections C_1,C_2, of S_1,S_2, respectively, as follows: (i) at two different points P_1,P_2, if $\lambda>2$; (ii) at the single point Q, if $\lambda=2$; (iii) nowhere, if $1\leqslant\lambda<2$. Therefore Σ_λ intersects S_1 and S_2:

(1) along two tori $T_i=\Sigma_\lambda\cap S_i$, $i=1,2$, if $\lambda>2$. These tori project onto P_i's and have (ϕ,u) as cyclic coordinates.
(2) along the circle $\gamma=S_1\cap S_2$, with the cyclic coordinate ϕ, if $\lambda=2$.
(3) nowhere if $\lambda<2$.

Therefore, $\Sigma_\lambda\backslash S$ has three connected components, if $\lambda>2$ and is connected, if $\lambda\leqslant 2$.

In the case $\lambda>2$ the behavior of phase trajectories depends strongly on the connected component of $\Sigma_\lambda\backslash S$ they belong to. Due to (41) it is sufficient to study trajectories of (39), i.e., connected components of curves $\Gamma_{\lambda,\mu}\backslash\tilde{S}$, with $\tilde{S}$ being the projection of S onto the (r,x,u) space. In Fig. 9 the projections into the (x,u) plane of three different kinds of such trajectories contained in $\tilde{\Sigma}_\lambda$ for a fixed λ are shown. As before we limit ourselves to $0\leqslant u\leqslant\pi$. The three vertical lines correspond to the projections $\tilde{T}_i$ of tori T_i's (in fact they are circles, due to the cyclicity of coordinate u). Passing to further details, denote by $x_i=x_i(\lambda)$ the constant value of x along T_i. Connected components $\Sigma_\lambda^1,\Sigma_\lambda^2,\Sigma_\lambda^3$ of $\Sigma_\lambda\backslash S$ correspond to $x<x_1$, $x_1<x<x_2$ and $x_2<x$, respec-

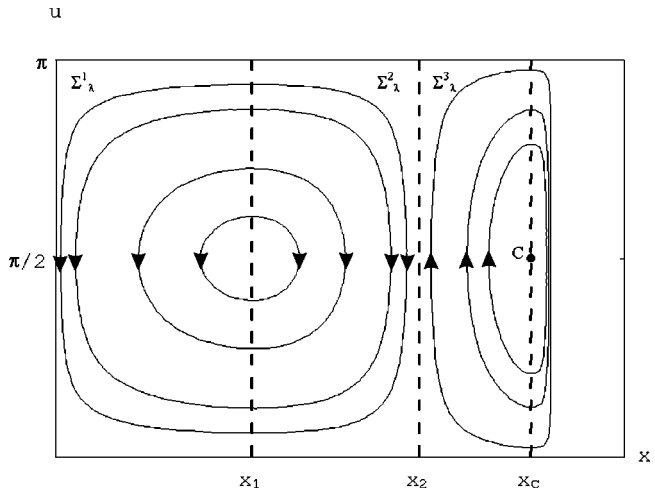

FIG. 9. Phase portrait of the oscillator for a fixed value of energy ($\lambda > 2$).

tively. The trajectories belonging to Σ^1_λ and Σ^2_λ are discontinuous in the sense that they end on S_1 and then jump, according to the transition principle, at another point of S_1. More exactly, in the situation shown in the figure, such a trajectory starts from a point of $T_1^+ = T_1 \cap \{\pi/2 \leqslant u \leqslant \pi\}$ and reaches a point in $T_1^- = T_1 \cap \{0 \leqslant u \leqslant \pi/2\}$ in a finite time. Trajectories γ_1 and γ_2, whose projections $\tilde{\gamma}_1$ and $\tilde{\gamma}_2$ are shown in Fig. 10, correspond to the same value of λ and of μ. Denote by $P_{\text{start}} \equiv (\overline{x}, \overline{r}, \pi - \overline{u}) \in \tilde{T}_1^+$ and $P_{\text{end}} \equiv (\overline{x}, \overline{r}, \overline{u}) \in \tilde{T}_1^-$ the common starting and ending points of $\tilde{\gamma}_1$ and $\tilde{\gamma}_2$. When a phase point starts from $(P_{\text{start}}, \phi_0) \equiv (\overline{x}, \overline{r}, \pi - \overline{u}, \phi_0)$ and then goes along γ_1 (or, alternatively, γ_2) it arrives at the point $(P_{\text{end}}, \overline{\phi}) \equiv (\overline{x}, \overline{r}, \overline{u}, \overline{\phi})$ with $\overline{\phi}$ given by (28) and then proceeds along the trajectory whose projection is $\tilde{\gamma}_1$ or, alternatively, $\tilde{\gamma}_2$, and so on.

In Fig. 11 the situation in the configuration space $M = \{(q_1, q_2)\} = \{(r, \phi)\}$ is shown. The oscillating particle, starting from the point $(r = \overline{r}, \phi = 0)$, moves along the projection $\hat{\gamma}_1$ of γ_1 onto

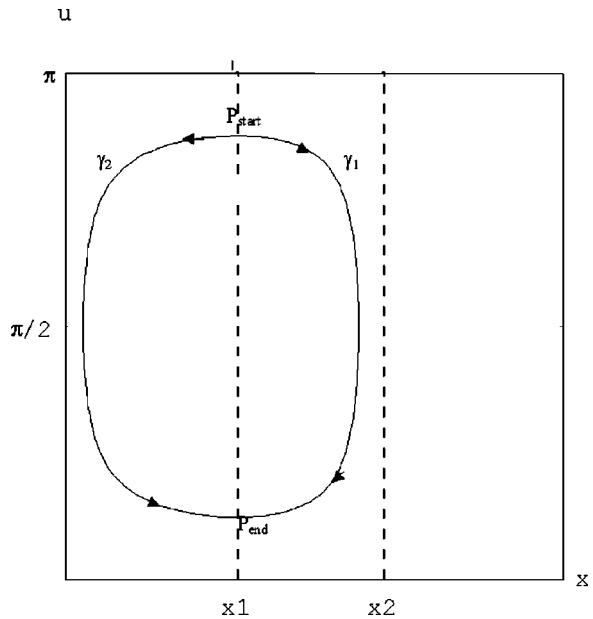

FIG. 10. Jumping phase trajectories.

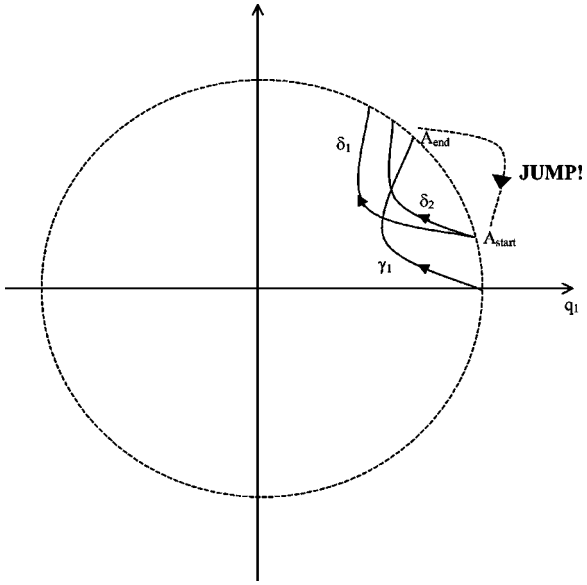

FIG. 11. Jumping oscillator.

M until it reaches the point $A_{\text{end}} \equiv (r=\overline{r}, \phi=\overline{\phi})$. From there it jumps to the point $A_{\text{start}} \equiv (r=\overline{r}, \phi=\tilde{\phi})$, where $\tilde{\phi}$ is given by (28). Then it splits into the two trajectories δ_1, δ_2, both with initial velocity

$$(x=\overline{x}, u=\tilde{u}=\pi-\overline{u}).$$

Consider now the trajectories of (39) contained in Σ^3_λ. These are regular closed trajectories winding around the center $C=C(\lambda) \equiv (x=x_C, u=\pi/2)$, where $x_C=x_C(\lambda)$ is the zero of the equation $2xL_x(r_{en}(x,\lambda),x)+rL_r(r_{en}(x,\lambda),x)=0$, and $r=r_{en}(x,\lambda)$ is implicitly defined by the equation $E(r,x)=\lambda mc^2$. The corresponding trajectories in the configuration space are shown in Fig. 12. They are precessions around the force center.

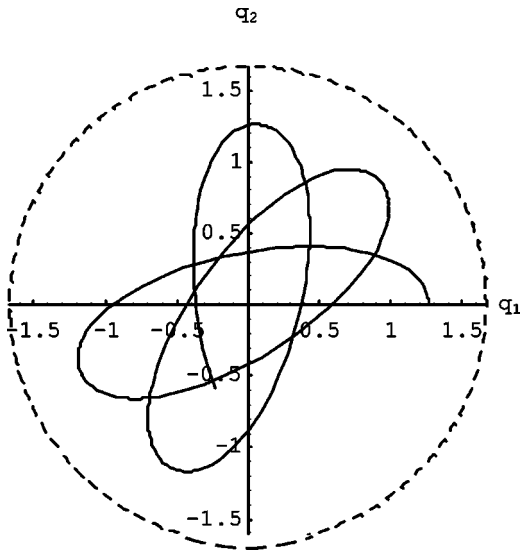

FIG. 12. Regular precessions of the oscillator.

Note that both the discontinuous trajectories in Σ^2_λ and the regular ones in Σ^3_λ near S_2 tend to be parallel to it, so that this component of the singular hypersurface is never reached by the phase point, at least for trajectories with nonzero angular momentum.

V. CONCLUSIONS

The self-consistency of the example discussed in this paper shows that the transition principle is natural not only from the geometrical but also from the dynamical point of view. The following question should, however, be answered: whether the existence of the singular hypersurface is merely due to approximation procedures or, on the contrary, it has a substantial physical meaning. So, it would be very interesting to look for singular Lagrangians which could be directly experimentally tested.

(Received 17 April 2000; accepted for publication 26 May 2000)

An eigenvalue problem and the associated hierarchy of nonlinear soliton equations are proposed in this paper. In particular, a representative system of generalized AKNS soliton equations in the hierarchy is given, namely, $q_t=-\frac{1}{2}q_{xx}+q^2r-2\mu q^2r_x-2\mu rqq_x+2\mu^2q^3r^2$, $r_t=\frac{1}{2}r_{xx}-qr^2-2\mu r^2q_x-2\mu qrr_x+2\mu^2q^2r^3$. *N*-Hamiltonian structures are also established for all the hirarchy of generalized AKNS soliton equations based on $N+1$ pairs of Hamiltonian pairs. And then the eigenvalue problem is nonlinear as a finite-dimensional completely integrable Hamiltonian system under the Bargmann constraint between the potentials and the eigenvalue functions, and its involutive system is also given. Finally, the involutive solutions of the hierarchy of generalized AKNS soliton equations are found, in particular, the involutive solutions of the system of generalized Schrödinger equations are given. © *2001 American Institute of Physics.*

I. INTRODUCTION

As is well known, it plays important roles in the soliton theory and dynamical integrable system to find many new nonlinear evolution equations and to further consider their algebraic properties and geometrical structures, such as the Hamiltonian structure, conserved density, symmetry, and Liouville integrable property.[1–36] In 1983, Tu[5] developed a simple approach to Hamiltonian structures of integrable systems. The essence of the method was the use of the chain rule of variational derivatives. It was improved further by Chowdhury and Swapna.[6] Recently, Tu[9] proposed a so-called loop algebra scheme to generate the hierarchy of Liouville sense integrable evolution equations and their Hamiltonian structures from the eigenvalue problem. This approach has been applied to find many new important nonlinear evolution equations hierarchies, such as the AKNS hierarchy,[1–4] TA hierarchy,[5] TB hierarchy,[7] TC hierarchy,[8] BTP hierarchy,[10] Kaup–Newell hierarchy,[11] WKI hierarchy,[12] Benjamin–Ono hierarchy,[13] Dirac hierarchy,[14] coupled KdV hierarchy,[15] Harry-Dym hierarchy,[16] coupled Burgers hierarchy,[18,24] Kupershmidt hierarchy,[19] coupled MKdV hierarchy,[25] and AKNS–Kaup–Newell hierarchy,[20] and so on, and the associated Hamiltonian structures can also be derived by virtue of the trace identity. In addition, the bi-Hamiltonian structure[17,21,22] and tri-Hamiltonian structure[20,23] had been also presented and applied to some soliton hierarchies by using the recursion operators.

In order to find many finite-dimensional integrable Hamiltonian systems (FDIHS), Cao *et al.*[26–28] proposed an effective skill, nonlinearization technique, to find new FDIHS, in which the well-known Bargmann constraint and Neumann constraint are contained. Many FDIHS have been obtained through using the approach (see Refs. 26–30). But this method has its disadvantages. Only lower order constraint flows could be found. In order to obtain higher order constraint flows, more recently, Zeng[31,32] presented a powerful approach, which contains Cao's method, by introducing so-called Jacobi–Ostrogradsky coordinates. It can easily prove that these higher constraint

[a]Electronic mail: zhanghq@dlut.edu.cn

flows are Liouville sense integrable by virtue of the r-matrix and Poisson structure.[31–34]

In this paper, we would like to introduce an eigenvalue problem

$$\phi_x = U(\lambda,u)\phi = U\phi, \quad U\begin{pmatrix} -\lambda-\mu qr & q \\ r & \lambda+\mu qr \end{pmatrix}, \quad \phi=\begin{pmatrix}\phi_1\\ \phi_2\end{pmatrix}, \quad u=\begin{pmatrix} q\\ r\end{pmatrix}, \tag{1}$$

where q and r are two scalar potentials, λ being a constant spectral parameter, and μ being an arbitrary constant, which is a simple extension of the AKNS eigenvalue problem,[1–4]

$$\phi_x = U(\lambda,u)\phi = U\phi, \quad U\begin{pmatrix} -\lambda & q \\ r & \lambda \end{pmatrix}, \quad \phi=\begin{pmatrix}\phi_1\\ \phi_2\end{pmatrix}. \tag{2}$$

As $\mu=0$, the eigenvalue problem (1) reduces to the AKNS eigenvalue problem (2).

This paper is organized as follows. In Sec. II, we give a generalized AKNS soliton hierarchy and its N-Hamiltonian structure by introducing the auxiliary problem of (1), trace identity and Hamiltonian pairs. As the special case of (1), the N-Hamiltonian structure of the AKNS hierarchy is about (2). In Sec. III, we first obtain $N+1$ pairs of Lennard's operators pairs. Then a system of constraint conditions are proposed; (1) is nonlinearized to a finite-dimensional completely integrable system in the Liouville sense under the first constraint condition. In Sec. IV, the involutive solutions of the hierarchy of generalized AKNS soliton equations are obtained. Finally, some summaries and conclusions are given in Sec. V.

II. THE HIERARCHY OF GENERALIZED AKNS EQUATIONS ASSOCIATED WITH EQ. (1) AND *N*-HAMILTONIAN STRUCTURES

It is clear that the adjoint equation of Eq. (1) can be written as

$$V_x=[U,V]\equiv UV-VU, \quad V=V(\lambda,u)=\begin{pmatrix} a & b\\ c & -a\end{pmatrix}=\sum_{i=0}^{\infty}\begin{pmatrix} a_i & b_i\\ c_i & -a_i\end{pmatrix}\lambda^{-i}, \tag{3}$$

where $a_i, b_i, c_i (i=0,1,2,...)$ are all functions of q and r to be determined later. Equation (3) leads to

$$a_{n,x}=qc_n-rb_n, \quad b_{n,x}=-2b_{n+1}-2qa_n-2\mu qrb_n, \quad c_{n,x}=2c_{n+1}-2ra_n+2\mu qrc_n. \tag{4}$$

The following recursion formulas are obtained from Eq. (4):

$$\begin{pmatrix} c_{n+1}\\ b_{n+1}\end{pmatrix}=L\begin{pmatrix} c_n\\ b_n\end{pmatrix}, \quad L=\begin{pmatrix} \frac{1}{2}\partial-r\partial^{-1}q-\mu qr & r\partial^{-1}r\\ -q\partial^{-1}q & -\frac{1}{2}\partial+q\partial^{-1}r-\mu qr\end{pmatrix}, \tag{5a}$$

$$a_{n+1}=\tfrac{1}{2}(rb_{n,x}+qc_{n,x})-\mu qra_{n,x}, n=1,2,..., \tag{5b}$$

where $\partial=\partial/\partial x$, $\partial\partial^{-1}=1$. If we take the values $a_0=-1$, $b_0=c_0=0$, then, Eqs. (5a) and (5b) imply the following results:

$$a_1=0, \quad b_1=q, \quad c_1=r, a_2=\tfrac{1}{2}qr, \quad b_2=-\tfrac{1}{2}qx-\mu q^2r,$$

$$c_2=\tfrac{1}{2}r_x-\mu qr^2, \quad a_3=\tfrac{1}{4}(qr_x-rq_x)-\mu q^2r^2,$$

$$b_3=\tfrac{1}{4}q_{xx}+\tfrac{1}{2}\mu(q^2r)_x-\tfrac{1}{2}q^2r+\tfrac{1}{2}\mu rqq_x+\mu^2q^3r^2,$$

$$c_3=\tfrac{1}{4}q_{xx}+\tfrac{1}{2}\mu(qr^2)_x-\tfrac{1}{2}qr^2-\tfrac{1}{2}\mu qrr_x+\mu^2q^2r^3,$$

$$a_4=\tfrac{1}{8}(rq_{xx}-qr_{xx}-q_xr_x)-\tfrac{3}{8}q^2r^2+\tfrac{3}{4}\mu(r^2qq_x-q^2rr_x).$$

In order to deduce a hierarchy of nonlinear evolution equations from Eq. (1), we introduce the auxiliary problem of Eq. (1), namely,

$$\phi_{t_n}=V^{(n)}\phi=V^{(n)}(\lambda,u)\phi, \tag{6}$$

$$V^{(n)}=(\lambda^n V)^+ +\Delta_n=\sum_{i=0}^{n}\begin{pmatrix} a_i & b_i \\ c_i & -a_i \end{pmatrix}\lambda^{n-i}+\begin{pmatrix} \delta_{1n} & 0 \\ 0 & \delta_{2n} \end{pmatrix}, \tag{7}$$

where δ_{1n},delta$_{2n}$ are functions to be determined later. Therefore it is easy to prove that the compatibility condition $\phi_{xt}=\phi_{tx}$ of Eqs. (1) and (6) generates the zero curvature equation $U_{t_n}-V^{(n)}+[U,V^{(n)}]=0$, namely,

$$\delta_{1n,x}=-\mu(qr_t+rq_t), \quad \delta_{1n}=-\delta_{2n}, \tag{8}$$

$$q_t=-2b_{n+1}+2q\delta_{1n}, \tag{9}$$

$$r_t=2c_{n+1}+2r\delta_{2n}. \tag{10}$$

From Eqs. (8)–(10), we have

$$\delta_{1n}=-\mu\partial^{-1}(qr_t+rq_t)=\mu\partial^{-1}(2rb_{n+1}-2qc_{n+1}). \tag{11}$$

Substituting Eq. (11) into Eqs. (9) and (10), we deduce the following hierarchy of nonlinear evolution equations:

$$u_t=\begin{pmatrix} q_{t_n} \\ r_{t_n} \end{pmatrix}=K_n=\begin{pmatrix} -4\mu q\partial^{-1}q & -2+4\mu q\partial^{-1}r \\ 2+4\mu r\partial^{-1}q & -4\mu r\partial r \end{pmatrix}\begin{pmatrix} c_{n+1} \\ b_{n+1} \end{pmatrix}$$

$$=M\begin{pmatrix} c_{n+1} \\ b_{n+1} \end{pmatrix}=ML^nN\begin{pmatrix} r \\ q \end{pmatrix}. \tag{12}$$

In order to consider and N-Hamiltonian structures and the integrability of Eq. (12) under the Liouville's sense. We need to introduce new variables, namely,

$$G_{n+1}=\begin{pmatrix} G_{n+1}^{(1)} \\ G_{n+1}^{(2)} \end{pmatrix}=\begin{pmatrix} c_{n+1}-2\mu ra_{n+1} \\ b_{n+1}-2\mu qa_{n+1} \end{pmatrix}. \tag{13}$$

According to Eqs. (4) and (13), we get

$$\begin{pmatrix} c_{n+1} \\ b_{n+1} \end{pmatrix}=\begin{pmatrix} 1+2\mu r\partial^{-1}q & -2\mu r\partial^{-1}r \\ 2\mu q\partial^{-1}q & 1-2\mu q\partial^{-1}r \end{pmatrix}\begin{pmatrix} c_{n+1}-2\mu ra_{n+1} \\ b_{n+1}-2\mu qa_{n+1} \end{pmatrix}=N\begin{pmatrix} c_{n+1}-2\mu ra_{n+1} \\ b_{n+1}-2\mu qa_{n+1} \end{pmatrix}. \tag{14}$$

Therefore we have the following recursion relation:

$$G_{n+1}=\begin{pmatrix} c_{n+1}-2\mu ra_{n+1} \\ b_{n+1}-2\mu qa_{n+1} \end{pmatrix}=N^{-1}LN\begin{pmatrix} c_n-2\mu ra_n \\ b_n-2\mu qa_n \end{pmatrix}=\Psi G_n, \quad n=1,2,..., \tag{15}$$

where

$$N^{-1}=\begin{pmatrix} 1-2\mu r\partial^{-1}q & 2\mu r\partial^{-1}r \\ -2\mu q\partial^{-1}q & 1+2\mu q\partial^{-1}r \end{pmatrix},$$

and $\Psi=N^{-1}LN$ is a recursion operator.

According to Eqs. (12) and (14), we easily derive

$$u_{t_n}=\begin{pmatrix} q_{t_n} \\ r_{t_n} \end{pmatrix}=K_n=J_0G_{n+1}=J_1G_n=J_2G_{n-1}=\cdots=J_nG_1=J_{n+1}G_0, \tag{16}$$

where $J_n=ML^nN=J_0(N^{-1}LN)^n$, $n=0,1,2,...$ and

$$J_0=MN=\begin{pmatrix} -8\mu q\partial^{-1}q & -2+8\mu q\partial^{-1}r \\ 2+8\mu r\partial^{-1}q & -8\mu r\partial^{-1}r \end{pmatrix}.$$

Proposition 1: The 2×2 matrix integrodifferential operator J_0 defined by the above equation is a Hamiltonian operator for the arbitrary constant μ.

Proof: Because it is a skew symmetry operator, i.e., $J_0^*=-J_0$ and it is easy to prove that J_0 satisfies the Jacobi identity, that is,

$$\langle Z,J_0'(u([J_0X]Y\rangle+\text{cycle}(X,Y,Z)\equiv0(\text{mod}\,\partial),$$

with $X=(X_1,X_2)^T$, $Y=(Y_1,Y_2)^T$, $Z=(Z_1,Z_2)^T$, and $J_0'(u)[f]$ denotes the Frechet derivative of J_0,

$$J_0'(u)[f]=\frac{d}{d\epsilon}J_0(u+\epsilon f)|_{\epsilon=0}.$$

Hence, J_0 is Hamiltonian (or symplectic) operator.

According to the same theory, we can also prove that other operators $J_i(i=1,2,...)$ are also all Hamiltonian operators.

Through using the same as the notion applied in Refs. 8 and 9, the Killing–Cartan standard form is defined by $\langle X,Y\rangle=\text{const.}\cdot\text{tr}(XY)$. In order to calculation conveniently, we take const. $=1$. Hence we have from Eqs. (1) and (3),

$$\left\langle V,\frac{\partial U}{\partial q}\right\rangle=c-2\mu ra,\quad \left\langle V,\frac{\partial U}{\partial r}\right\rangle=c-2\mu qb,\quad \left\langle V,\frac{\partial U}{\partial\lambda}\right\rangle=-2a. \tag{17}$$

According to definition of the trace identity,[8,9] yields

$$\frac{\delta}{\delta u}\left(\left\langle V,\frac{\partial U}{\partial\lambda}\right\rangle\right)=\lambda^{-\beta}\frac{\partial}{\partial\lambda}\lambda^{\beta}\left(\left\langle V,\frac{\partial U}{\partial q}\right\rangle,\left\langle V,\frac{\partial U}{\partial r}\right\rangle\right)^T, \tag{18}$$

where β is constant to be determined later. Substituting Eq. (17) into (18) and combining these conditions

$$a=\sum_{i\geqslant0}a_n\lambda^{-i},\quad b=\sum_{i\geqslant0}b_n\lambda^{-i},\quad c=\sum_{i\geqslant0}c_n\lambda^{-i},$$

we get through comparing the coefficients of λ^{-n-2} of two sides of Eq. (18), yields

$$\frac{\delta}{\delta u}(-2a_{n+2})=(\beta-n-1)(c_{n+1}-2\mu ra_{n+1},b_{n+1}-2\mu qa_{n+1})^T. \tag{19}$$

In order to get the value of β, we take $n=-1$ in Eq. (19) and obtain $\beta=0$. Therefore we have

$$G_{n+1}=\begin{pmatrix} c_{n+1}-2\mu ra_{n+1} \\ b_{n+1}-2\mu qa_{n+1} \end{pmatrix}=\frac{\delta H_{n+1}}{\delta u}=\Psi\frac{\delta H_n}{\delta u}=\Psi G_n, \tag{20}$$

with the Hamiltonian functions satisfying

$$H_0=2\mu rq, \quad H_n=\frac{2a_{n+1}}{n}, \quad n=1,2,\ldots. \tag{21}$$

Therefore the hierarchy of the nonlinear evolution Eq. (16) possesses the following formal N-Hamiltonian structures from Eqs. (16) and (20):

$$u_{t_n}=\begin{pmatrix} q_{t_n} \\ r_{t_n} \end{pmatrix}=K_n=J_0\frac{\delta H_{n+1}}{\delta u}=J_1\frac{\delta H_n}{\delta u}=J_2\frac{\delta H_{n-1}}{\delta u}=\cdots=J_{n+1}\frac{\delta H_0}{\delta u}. \tag{22}$$

In fact, we can easily show that the Hamiltonian functions $\{H_n\}_n^\infty=0$ satisfying $\delta H_{n+1}/\delta u=\Psi(\delta H_n/\delta u)$, $n\geqslant 0$ are all common conserved densities for the whole generalized AKNS hierarchy. And they are commute with each other under the $n+2$ Poisson brackets associated with the Hamiltonian operators $J_i=J_0\Psi^i$, $i=0,1,2,...$, because a direct calculation can show that

$$\begin{aligned}\{H_n,H_m\}J_i&=\int\left\langle\frac{\delta H_n}{\delta u},J_i\frac{\delta H_m}{\delta u}\right\rangle dx=\int\left\langle\frac{\delta H_n}{\delta u},J_i\Psi\frac{\delta H_{m-1}}{\delta u}\right\rangle dx\\&=\int\left\langle\frac{\delta H_n}{\delta u},\Psi^*J_i\frac{\delta H_m}{\delta u}\right\rangle dx=\int\left\langle\Psi\frac{\delta H_n}{\delta u},J_i\frac{\delta H_m}{\delta u}\right\rangle dx\\&=\{H_{n+1},H_{m-1}\}_{J_i}=\cdots=\{H_m,H_n\}_{J_i},n,m\geqslant 0.\end{aligned} \tag{23}$$

Therefore we get $\{H_n,H_m\}_{J_i}=0$. During the course of the proof of Eq. (23), we use the following formula obtained from $J_i^*=-J_i$:

$$J_i\Psi=J_0\Psi^{i+1}=J_{i+1}=-J_{i+1}^*=-(J_i\Psi)^*=-\Psi^*J_i^*=\Psi^*J_i.$$

And we can also derive

$$[K_n,K_m]=\left[J_i\frac{\delta H_n}{\delta u},J_i\frac{\delta H_m}{\delta u}\right]=J_i\frac{\delta}{\delta u}\{H_n,H_m\}=0,n,m\geqslant 0, \tag{24}$$

which shows that every system generalize AKNS equations posses infinitely many commuting symmetries $\{K_n\}_{n=0}^\infty$.

Remark 1: Taking $n=2$, Eq. (16) becomes a new system of the generalized ANKS soliton equations,

$$q_t=-\tfrac{1}{2}q_{xx}+q^2r-2\mu q^2r_x-2\mu rqq_x+2\mu^2q^3r^2, \tag{25a}$$

$$r_t=\tfrac{1}{2}r_{xx}-qr^2-2\mu r^2q_x-2\mu qrr_x+2\mu^2q^2r^3. \tag{25b}$$

If setting $\mu=0$, then Eqs. (25) reduce to the AKNS equation.[1–4] Equations (25) possess the flowing quadr-Hamiltonian structures,

$$u_t=\begin{pmatrix} q_t \\ r_t \end{pmatrix}=J_0\frac{\delta H_3}{\delta u}=J_1\frac{\delta H_2}{\delta u}=J_2\frac{\delta H_1}{\delta u}=J_3\frac{\delta H_0}{\delta u},$$

where the Hamiltonian functions H_i, $(i=0,1,2,3)$ are

$$H_0=2\mu qr, \quad H_1=qr, \quad H_2=\tfrac{1}{4}(qr_x-rq_x)-\mu q^2r^2,$$

$$H_3=\tfrac{1}{12}(rq_{xx}-qr_{xx}-q_xr_x)-\tfrac{1}{4}q^2r^2+\tfrac{1}{2}\mu(r^2qq_x-q^2rr_x).$$

Remark 2: Equation (2) is a special case of Eq. (1) with $\mu=0$, so according to the above results, we can come to some conclusions about the hierarchy of the AKNS equations,

$$u_t=\begin{pmatrix} q_{t_n} \\ r_{t_n} \end{pmatrix}=K_n=\begin{pmatrix} 0 & -2 \\ 2 & 0 \end{pmatrix}\begin{pmatrix} c_{n+1} \\ b_{n+1} \end{pmatrix}=M\begin{pmatrix} c_{n+1} \\ b_{n+1} \end{pmatrix}=ML^nN\begin{pmatrix} r \\ q \end{pmatrix}, \tag{26}$$

where

$$L=\begin{pmatrix} \frac{1}{2}\partial-r\partial^{-1}q & r\partial^{-1}r \\ -q\partial^{-1}q & -\frac{1}{2}\partial+q\partial^{-1}r \end{pmatrix},\ M=\begin{pmatrix} 0 & -2 \\ 2 & 0 \end{pmatrix},\ N=\begin{pmatrix} 1 & 0 \\ 0 & 1 \end{pmatrix}.$$

Therefore, we have

$$J_0=MN=M=\begin{pmatrix} 0 & -2 \\ 2 & 0 \end{pmatrix},$$

$$J_1=MLN=ML=\begin{pmatrix} 2q\partial^{-1}q & \partial-2r\partial^{-1}q \\ \partial-2r\partial^{-1}q & 2r\partial^{-1}r \end{pmatrix},\ J_i=ML^iN=ML^i, i=2,3,\ldots.$$

It is clear that J_0 and J_1 are both Hamiltonian operators and we can also derive that J_i, $i=2,3,\ldots$ are also Hamiltonian operators. The hierarchy of the AKNS equation (23) also possesses the following N-Hamiltonian structures:

$$u_t=\begin{pmatrix} q_t \\ r_t \end{pmatrix}=K_n=J_0\frac{\delta H_{n+1}}{\delta u}=J_1\frac{\delta H_n}{\delta u}=J_2\frac{\delta H_{n-1}}{\delta u}=\cdots=J_{n+1}\frac{\delta H_0}{\delta u}$$

with the Hamiltonian functions satisfy Eq. (21). They are all common conserved densities for the hierarchy of AKNS equations and commute with each other under these Poisson brackets associated with the Hamiltonian operators J_i, $i=0,1,2,\ldots$. In addition, there exists many commuting symmetries $\{K_n=J_i\,\delta H_{n-i+1}/\delta u\}_{n=0}^{\infty}$ for every system of AKNS equations.

III. FINITE-DIMENSIONAL INVOLUTIVE SYSTEMS

Let $\lambda_i(i=1,2,\ldots,N)$ be N different eigenvalues of problem (1), and $\phi_i=(\phi_{1i},\phi_{2i})^T$ be the corresponding solutions of problem (1), then (1) can become

$$\begin{pmatrix} \phi_{1i} \\ \phi_{2i} \end{pmatrix}_x=\begin{pmatrix} -\lambda_i-\mu qr & q \\ r & \lambda_i+\mu qr \end{pmatrix}\begin{pmatrix} \phi_{1i} \\ \phi_{2i} \end{pmatrix},\ u=\begin{pmatrix} q \\ r \end{pmatrix}. \tag{27}$$

Through the direct calculation, we get the spectral gradient $\nabla\lambda_i$ of the spectral value λ_i with respect to the potentials q and r,

$$\nabla\lambda_i=\frac{\delta\lambda_i}{\delta u}=\left(\frac{\delta\lambda_i}{\delta q},\frac{\delta\lambda_i}{\delta r}\right)^T=\left(-2\int \phi_{1i}\phi_{2i}dx\right)^{-1}\begin{pmatrix} \phi_{2i}^2+2\mu r\phi_{1i}\phi_{2i} \\ -\phi_{1i}^2+2\mu r\phi_{1i}\phi_{2i} \end{pmatrix}.$$

Proposition 2: The Hamiltonian operators J_k and J_{k+1} are all the pairs of Lennard's operators for $k=0,1,2,\ldots$.

Proof: Through the direct calculation, we easily find

$$J_{k+1}\nabla\lambda_i=\lambda_iJ_k\nabla\lambda_i.\ \ k=0,1,2,\ldots, \tag{28}$$

which shows that the proposition is true. In fact, we can prove that they are also Hamiltonian pairs.[23]

Next, we consider the following formal constraint conditions:

$$\frac{\delta H_{k+1}}{\delta u}-\gamma\sum_{i=1}^{N}\frac{\delta\lambda_{k+1}}{\delta u}=\frac{\delta H_{k+1}}{\delta u}-\gamma\begin{pmatrix}\langle\Phi_2,\Phi_2\rangle+2\mu r\langle\Phi_1,\Phi_2\rangle\\-\langle\Phi_1,\Phi_1\rangle+2\mu q\langle\Phi_1,\Phi_2\rangle\end{pmatrix}=0, \tag{29}$$

where $\Phi_j=(\phi_{j1},\phi_{j2},\ldots,\phi_{jN})$, $j=1,2$ and $\langle\cdot,\cdot\rangle$ denotes the standard inner product in R^N.

Taking $k=0$, $\gamma=\frac{1}{2}$ in Eq. (29), yields the first explicit constraint condition,

$$q=-\frac{\langle\Phi_1,\Phi_1\rangle}{2(1-2-\mu\langle\Phi_1,\Phi_2\rangle)},\quad r=\frac{\langle\Phi_2,\Phi_2\rangle}{2(1-2-\mu\langle\Phi_1,\Phi_2\rangle)}. \tag{30a}$$

In fact, this being the Bargmann constraint, that is

$$G_1=\begin{pmatrix}r\\q\end{pmatrix}=\sum_{i=1}^{N}\nabla\lambda_i=\begin{pmatrix}\langle\Phi_2,\Phi_2\rangle+2-\mu r\langle\Phi_1,\Phi_2\rangle\\-\langle\Phi_1,\Phi_1\rangle+2-\mu q\langle\Phi_1,\Phi_2\rangle\end{pmatrix}. \tag{30b}$$

Hence, (27) reduces to the following finite-dimensional Hamiltonian system under the Bargmann constraint (30a),

$$\Phi_{1x}=-\Lambda\Phi_1-\frac{\Phi_2\langle\Phi_1,\Phi_1\rangle}{2(1-2-\mu\langle\Phi_1,\Phi_2\rangle)}+\frac{-\mu\Phi_1\langle\Phi_1,\Phi_1\rangle\langle\Phi_2,\Phi_2\rangle}{4(1-2-\mu\langle\Phi_1,\Phi_2\rangle)^2}=\frac{\partial H_1}{\partial\Phi_2}, \tag{31a}$$

$$\Phi_{2x}=\Lambda\Phi_2+\frac{\Phi_1\langle\Phi_2,\Phi_2\rangle}{2(1-2-\mu\langle\Phi_1,\Phi_2\rangle)}-\frac{-\mu\Phi_2\langle\Phi_1,\Phi_1\rangle\langle\Phi_2,\Phi_2\rangle}{4(1-2-\mu\langle\Phi_1,\Phi_2\rangle)^2}=-\frac{\partial H_1}{\partial\Phi_1}, \tag{31b}$$

with the Hamiltonian function H_1 being

$$H_1=-\langle\Lambda\Phi_1,\Phi_2\rangle-\frac{\langle\Phi_1,\Phi_1\rangle\langle\Phi_2,\Phi_2\rangle}{4(1+2\mu\langle\Phi_1,\Phi_2\rangle)},$$

where $\Lambda=\mathrm{diag}(\lambda_1,\lambda_2,\ldots,\lambda_N)$. For other constraint conditions ($k\geqslant 0$), we can reduce problem (27) to other finite-dimensional Hamiltonian systems.

Theorem 1: Let (Φ_1,Φ_2) satisfy Eq. (31), then

$$q=-\frac{\langle\Phi_1,\Phi_1\rangle}{2(1-2\mu\langle\Phi_1,\Phi_2\rangle)},\quad r=\frac{\langle\Phi_2,\Phi_2\rangle}{2(1-2\mu\langle\Phi_1,\Phi_2\rangle)}$$

is a solution of the stationary generalized AKNS equations,

$$K_N+d_1K_{N-1}+\cdots+d_NK_0=0. \tag{32}$$

Proof: Letting the operator $J_0^{-1}J_1$ act upon Eq. (30b) for m times and noting $G_{n+1}=J_0-1J_1G_n$ and Eq. (28), we have

$$G_m+\alpha_2G_{m-2}+\cdots+\alpha_mG_0+\alpha_{m+1}G_{-1}=\begin{pmatrix}\langle\Lambda^m\Phi_2,\Phi_2\rangle+2-\mu r\langle\Lambda^m\Phi_1,\Phi_2\rangle\\-\langle\Lambda^m\Phi_1,\Phi_1\rangle+2-\mu q\langle\Lambda^m\Phi_1,\Phi_2\rangle\end{pmatrix}, \tag{33}$$

where $\alpha_j(j=2,3,\ldots,m+1)$ are arbitrary constants and $G_{-1}\in\mathrm{Ker}\,J_0$. Introducing the following polynomial:

$$P(y):=\Pi_{i=1}^{N}(y-\lambda_i)=y^N+p_1y^{N-1}+\cdots+p_N=\sum_{k=0}^{N}p_{N-k}y^k.$$

And then let the operator $J_0\Sigma_{k=0}^{N}p_{N-k}y^k$ act upon Eq. (33) and noting $K_n=J_0G_n$, we can derive Eq. (32). Where $d_i(i=1,2,\ldots,N)$ are determined by $\alpha_i(i=2,3,\ldots,m+1)$ and $p_i(i=1,2,\ldots,N)$.

The standard Poisson bracket containing two functions in the symplectic space $(R^{2N}, d\Phi_1 \Lambda d\Phi_2)$ is defined by

$$(F,G)=\sum_{i=1}^{N}\left(\frac{\partial F}{\partial \Phi_{1i}}\frac{\partial G}{\partial \Phi_{2i}}-\frac{\partial F}{\partial \Phi_{2i}}\frac{\partial G}{\partial \Phi_{1i}}\right)=\langle F_{\Phi_1}, G_{\Phi_2}\rangle-\langle F_{\Phi_2}, G_{\Phi_1}\rangle.$$

F, G are involutive, if $(F,G)=0$. Next, we would like to construct a set of functions $\{F_n\}$ as follows:

$$\begin{aligned} F_n=&-\langle \Lambda^{n+1}\Phi_1, \Phi_2\rangle(1-2-\mu\langle \Phi_1, \Phi_2\rangle) \\ &+\frac{1}{2}\sum_{i=0}^{n}\begin{vmatrix}\langle \Lambda^{i-1}\Phi_1, \Phi_1\rangle & \langle \Lambda^{i-1}\Phi_1, \Phi_2\rangle \\ \langle \Lambda^{n-i}\Phi_1, \Phi_2\rangle & \langle \Lambda^{i-1}\Phi_2, \Phi_2\rangle\end{vmatrix} n \\ &=0,1,2,\ldots . \end{aligned} \tag{34}$$

Proposition 3: For the functions F_n defined by Eq. (34), there exist the relation for arbitrary n, $m \in Z^+$,

$$\langle F_{n,\Phi_1}, F_{m,\Phi_2}\rangle=\langle F_{m,\Phi_1}, F_{n,\Phi_2}\rangle.$$

Proposition 4: The functions $\{F_n\}$ determined by Eq. (34) are involutive, i.e., $(F_n, F_m)=0$ under the Poisson bracket in symplectic space $(R^{2N}, d\Phi_1 \Lambda d\Phi_2)$.

Proof: According to Proposition 4, it yields

$$\begin{aligned}(F_n, F_m)&=\langle F_{n,\Phi_1}, F_{m,\Phi_2}\rangle-\langle F_{n,\Phi_2}, F_{m,\Phi_1}\rangle \\ &=\langle F_{m,\Phi_1}, F_{n,\Phi_2}\rangle-\langle F_{m,\Phi_1}, F_{n,\Phi_2}\rangle=(F_m, F_n)=-(F_n, F_m).\end{aligned}$$

Hence $(F_n, F_m)=0$ and we complete the proof of the proposition.

Theorem 2: The Hamiltonian systems (F_n),

$$(F_n): \Phi_{1t_n}=\frac{\partial F_n}{\partial \Phi_2}, \quad \Phi_{2t_n}=-\frac{\partial F_n}{\partial \Phi_1}, \quad n=0,1,2,\ldots \tag{35}$$

with Hamiltonian functions F_n determined by Eq. (34) are completely integrable in the Liouville sense.

Proof: According to Proposition 4, we know that the conclusion is true.

Theorem 3: The Hamiltonian system (31) is completely integrable in Liouville sense in the symplectic manifold $(R^{2N}, d\Phi_1 \Lambda d\Phi_2)$ and its involutive system is $\{F_n\}$, i.e., $(H_1, F_n)=0$.

Proof: According to Eqs. (31) and (33) and Propositions 4–6, we can prove that H_1 and $F_n (n=0,1,2,\ldots)$ are involutive under the Poisson bracket in symplectic space $(R^{2N}, d\phi_1 \Lambda d\phi_2)$ by a direct calculation, that is

$$(H_1, F_n)=\langle H_{1,\Phi_1}, F_{n,\Phi_2}\rangle-\langle H_{1,\Phi_2}, F_{n,\Phi_1}\rangle=0, \quad n=0,1,2,\ldots .$$

Therefore we complete the proof of the theorem.

IV. THE INVOLUTIVE SOLUTIONS OF THE HIERARCHY OF THE SOLITON EQUATION (16)

Denote the solution operators of the initial-value problems of the integrable Hamiltonian systems (15) and (F_n) by f_0^x and $f_n^{t_n}$, respectively. $(H_1, F_n)=0$ implies that any two canonical systems (15) and (F_n) are compatible, then their own flows f_0^x and $f_n^{t_n}$ commute. Therefore the involutive solution of the consistent Eq. (15) and (F_n) is[35]

$$\begin{pmatrix} \Phi_1(x,t_n) \\ \Phi_2(x,t_n) \end{pmatrix} = f_0^x f_n^{t_n} \begin{pmatrix} \Phi_1(0,0) \\ \Phi_2(0,0) \end{pmatrix}$$

and a smooth function of (x,t_n).

Proposition 5: Let $(\Phi_1(x,t_n),\Phi_2(x,t_n))$ be an involutive solution of the consistent system (15) and (F_n), then the Bagmann constraints (30a),

$$q(x,t_n) = -\frac{\langle \Phi_1,\Phi_1\rangle}{2(1-2-\mu\langle \Phi_1,\Phi_2\rangle)}, \quad r(x,t_n) = \frac{\langle \Phi_2,\Phi_2\rangle}{2(1-2-\mu\langle \Phi_1,\Phi_2\rangle)} \tag{36}$$

satisfy the soliton hierarchy of the generalized AKNS equations,

$$u_{t_n} = \begin{pmatrix} q_{t_n} \\ r_{t_n} \end{pmatrix} = K_n = J_0 G_{n+1} = J_n G_1 = J_0 \Psi^n G_1. \tag{37}$$

Proof: Through a direct differential calculation with respect to t_n for Eq. (36) and combining (35), we can derive that Eq. (37) holds.

According to Proposition 5, we can derive the following conclusion:

Proposition 6: Let $(\Phi_1(x,t_2),\Phi_2(x,t_2))$ be an involutive solution of the consistent systems (15) and (F_2), then the Bagmann constraint (30a),

$$q(x,t_2) = -\frac{\langle \Phi_1(x,t_2),\Phi_1(x,t_2)\rangle}{2(1-2-\mu\langle \Phi_1(x,t_2),\Phi_2(x,t_2)\rangle)},$$

$$r(x,t_2) = \frac{\langle \Phi_2(x,t_2),\Phi_2(x,t_2)\rangle}{2(1-2-\mu\langle \Phi_1(x,t_2),\Phi_2(x,t_2)\rangle)}, \tag{38}$$

satisfy the system of generalized AKNS soliton equations (25).

V. SUMMARY AND CONCLUSION

By introducing the associated auxiliary problem of problem (1), we derive a hierarchy of the generalized AKNS soliton equations, which contains the known AKNS soliton hierarchy. Its finite-dimensional *N*-Hamiltonian structures are obtained by virtue of the trace identity and a recursion operator and are shown to be Liouville sense integrable. Here, we propose the notation, *N*-Hamiltonian structure, which is natural extension of bi-Hamiltonian structure[18,21,22] and tri-Hamiltonian structure.[20,23] In addition, for the contained condition (29), we only consider the case $k=0$, under which (27) is nonlinearized into finite-dimensional Hamiltonian system. For other cases $k \geqslant 1$, (27) can also be nonlinearized into higher order constrained flows by introducing so-called Jacobi–Ostrogradsky coordinates. If introducing the Lax matrix and *r*-matrix again,[31–34] we can study the separation of variables[31,34] for these finite-dimensional integrable Hamiltonian systems (FDIHS). Then the separability of the FDIHS will give rise to the Jacobi inverse problem for the associated soliton hierarchies. The soliton hierarchies can be solved in terms of Riemann theta function by a standard Jacobi inverse technique.[36] These problems need to be further considered.

Unimodular relativity and cosmological constant

David R. Finkelstein, Andrei A. Galiautdinov, and James E. Baugh
School of Physics, Georgia Institute of Technology, Atlanta, Georgia 30332-0430

(Received 21 August 2000; accepted for publication 27 September 2000)

Unimodular relativity is a theory of gravity and space–time with a fixed absolute space–time volume element, the *modulus*, which we suppose is proportional to the number of microscopic modules in that volume element. In general relativity an arbitrary fixed measure can be imposed as a gauge condition, while in unimodular relativity it is determined by the events in the volume. Since this seems to break general covariance, some have suggested that it permits a nonzero covariant divergence of the material stress-energy tensor and a variable cosmological ''constant.'' In Lagrangian unimodular relativity, however, even with higher derivatives of the gravitational field in the dynamics, the usual covariant continuity holds and the cosmological constant is still a constant of integration of the gravitational field equations. © *2001 American Institute of Physics.* [DOI: 10.1063/1.1328077]

I. INTRODUCTION TO UNIMODULAR RELATIVITY

Unimodular relativity is an alternative theory of gravity considered by Einstein in 1919[1] without a Lagrangian and put into Lagrangian form by Anderson and Finkelstein.[2] The space–time of unimodular relativity is a measure manifold, a manifold provided by nature with a fixed absolute physical measure field $\mu(x)$ to be found by direct measurement, subject to no dynamical development. The sole structural variable is a conformal metric tensor $f_{\mu\nu}$, subject to dynamical equations. The measure of a space–time region may be regarded as indirectly counting the modules of which it is composed, in the way that the volume of a lake indirectly counts its water molecules. Both space–time measure and liquid measure indicate a modular structure below the limit of resolution of the present measuring instruments.

The conformal metric field $f_{\mu\nu}(x)$ is a symmetric relative tensor of weight 1/2, signature 1–3, and determinant -1 in all coordinate systems, with nine independent components, operationally defined by the system of light paths, whose tangent vectors dx^μ obey $f_{\mu\nu}\,dx^\mu dx^\nu=0$.

The unimodular space–time structure also defines a metric tensor

$$g_{\mu\nu}=\sqrt{\mu}f_{\mu\nu}(x), \tag{1}$$

but the determinant

$$-g:=\det g_{\mu\nu}=-\mu^2 \tag{2}$$

is not a dynamical variable. The conformal metric f is the sole gravitational variable of unimodular relativity.

We assume that the metric tensor field $g_{\mu\nu}$ found by measuring the proper times $d\tau^2=g_{\mu\nu}\,dx^\mu\,dx^\nu$ for a sufficiently fine network of intervals dx^μ, also determines the measure field μ by the usual relation (2).

Once the measure μ has been experimentally determined it establishes a class of admissible metrics obeying (2). Metrics violating (2) are unphysical according to unimodular relativity.

The variable of general relativity is a compound of a light-cone field f and a measure field μ, and the group of general relativity is a nonsimple group of diffeomorphisms, with an invariant subgroup of unimodular coordinate transformations, those with Jacobian $\det(\partial x'/\partial x)=1$. Unimodular relativity has a simple group and a simple variable.

Originally we proposed unimodular relativity because there is indeed an experimental atomic standard of length near each point of space–time, not built into general relativity.[2] This suggests that the macroscopic structure of space–time is a smoothed description of an underlying atomic space–time microstructure, which seems necessary for other reasons.

Since the actual value of the cosmological constant is so finely tuned, it is natural to attempt to derive its value from physical principles. A theory in which it is variable would be a useful starting point for any such attempt. Recently the difference in symmetry between unimodular and general relativity led some to hope that they might differ on the constancy of this parameter.[3]

On the other hand, many authors have already argued that the difference is only a gauge condition, which has no physical consequences.[4] However, some authors do not share this point of view. In particular, van der Bij *et al.*[5] stated very clearly the physical difference between the usual formulation of gravity and the unimodular theory. Also, an interesting and somewhat alternative approach is presented in Ref. 6.

We examine the gauge-condition argument more carefully here. In its usual form it omits several relevant features special to this problem. Usually gauge conditions are applied to Lagrangians that are already physically well defined in their absence; the unimodularity condition is not a gauge condition of this kind.

One should also take into account the possibility of higher-order derivatives in the gravitational equations, of the kind that might arise from renormalization in some hypothetical quantum field theory of gravity.

We show here that any gravitational theory of classical unimodular relativity with a Lagrangian density that is invariant under the unimodular coordinate group is equivalent in its experimental predictions to a theory of classical general relativity. Higher-order corrections do not disturb this equivalence.

II. THE METRIC TENSOR OF UNIMODULAR RELATIVITY

In deriving the field equations from a variational principle (on which our approach is based), the measure μ is not varied but is treated as if it were a fixed external field. This disturbs general covariance. The law of nature may take a simpler form in *unimodular coordinates*, where $\mu(x) \equiv 1$. Unimodular coordinate systems are related by unimodular transformations.

Let R be the Riemann scalar computed from the metric tensor $g_{\mu\nu}$ of (1). Let L_M be the Lagrangian density of the matter field in the presence of $g_{\mu\nu}=\sqrt{\mu} f_{\mu\nu}$. Then

$$S=\int d^4x\left(\frac{\Gamma}{2}R+L_M\right) \tag{3}$$

is a possible action functional for unimodular relativity in a unimodular coordinate system. The constant $\Gamma=1/4\pi G$ is the inverse rationalized gravitational constant, the reciprocal square of the rationalized Planck length, in units with $\hbar=c=1$.

In unimodular relativity, there is initially no way to vary all 10 components of $g_{\mu\nu}$ independently. The action is in principle defined only for $g=\mu^2$. Only derivatives with respect to the nine-dimensional conformal metric field f are defined.

A cosmological constant term $\Lambda\sqrt{g}$ in the action function would be an ineffectual additive constant since $\sqrt{g}=\mu$ is not varied.

This action can be transformed to any other coordinate system under the general diffeomorphism group, but is not generally invariant in functional form, since the fixed measure μ sets an absolute scale at each event.

The derivative with respect to the conformal metric f requires special care. Since infinitesimal variations δf are subject to the unimodular condition (2), they obey

$$f^{\mu\nu}\delta f_{\mu\nu}=0. \tag{4}$$

If $W:\mathcal{F}\to\mathcal{W}$, $f\mapsto W(f)$ is a functional from the function manifold $\mathcal{F}$ of conformal metrics on a region $\mathcal{R}$ to some value-manifold $\mathcal{W}$, we define the functional derivative $W_f=\delta W/\delta f$ as the linear operator

$$W_f: d\mathcal{F}\to\mathcal{W} \tag{5}$$

such that for any $\delta f\in d\mathcal{F}$ vanishing on the boundary $\partial\mathcal{R}$ the tangent space to $\mathcal{F}$ at f,

$$\delta W = W_f\cdot\delta f = \int d^4x\,\frac{\delta W}{\delta f_{\mu\nu}(x)}\,\delta f_{\mu\nu}(x). \tag{6}$$

Then the dynamical equation that follows from the action principle for any space–time region $\mathcal{R}$ is

$$\delta S(\mathcal{R}) = \int_{\partial\mathcal{R}} d\sigma_\mu\,\pi^\mu\cdot\delta f \tag{7}$$

with a boundary term that is linear in δf on the boundary $\partial\mathcal{R}$ and vanishes for variations that vanish on the boundary. The tensor field π^μ canonically conjugate to $f(x)$ is defined by these relations.

III. FIELD EQUATIONS AND THE COSMOLOGICAL CONSTANT

It is often inconvenient to work with a field variable subject to non-linear conditions like the conformal metric. One may reformulate unimodular relativity with an unconstrained variable $g_{\mu\nu}(x)$ and take the unimodular condition (2) into account through Lagrange's method of undetermined multipliers.

To do this, however, we must give values to the Lagrangian density for metric tensors that have $g\neq\mu$[22,4,7] and hence are unphysical. One way to do this is to replace μ by $\sqrt{g}$ and $f_{\mu\nu}$ by $g_{\mu\nu}/g^{1/4}$ at all their ''appearances'' in the action S, so that S is defined in a 10-dimensional neighborhood $\mathcal{F}'\supset\mathcal{F}$ in a smooth way consistent with the values on $\mathcal{F}$. Then in addition one adds a Lagrangian-multiplier term expressing the unimodular condition. We call the resulting extension of S to $\mathcal{F}'$ the *extended action function* S'.

But this prescription is ambiguous, since it depends on ''appearances,'' on how S is written, on matters of notation. The extended action S' is arbitrary up to a correction term $\Delta_M S$ depending on the matter variables and the metric $g_{\mu\nu}$, subject only to the condition that $\Delta_M L$ and its derivative with respect to λ vanish in the unimodular sector (2):

$$S' = S+\Delta_M S+\int d^4x\sqrt{g}\lambda(x)\left[\frac{\mu}{\sqrt{g(x)}}-1\right], \tag{8}$$

$\Delta_M S=\int d^4x\sqrt{g}\Delta_M L$ is the *unimodular ambiguity* in the action. No physical results may depend on the choice of $\Delta_M L$, and so no physical experiments can determine $\Delta_M L$.

In mechanical theories sometimes we impose a constraint and thereby reduce an already well-defined system to a system of lower dimensionality. For example, we reduce a free particle to a spherical pendulum by constraining it to a sphere. Then there is a well-defined unconstrained Lagrangian, found by removing the constraint, and the ambiguity $\Delta_M L$ does not arise.

But according to unimodular relativity we have no way of actually removing the unimodular condition (2). In this sense it is not a constraint, so we call it a condition. While the proper time $d\tau$ of a coordinate interval dx^μ at x depends on the gravitational field at x, each coordinate cell d^4x at x comes with its own intrinsic measure $\mu(x)d^4x$, independent of gravity. The unimodular ambiguity $\Delta_M L$ acknowledges that as a matter of principle we cannot know how the system would evolve absent the unimodular condition.

The admissible infinitesimal variations df within the neghborhood $\mathcal{F}'$ are those that obey (4) for all $x \in \mathcal{R}$. That is, they all belong to the null space of the inverse conformal metric tensor $f^{\mu\nu}$.

The action principle states that for any physical field $f=(f_{\mu\nu}(x))$, and for any variations $\delta f=(\delta f_{\mu\nu}(x))$ about f,

$$S_f \cdot \delta f := \int_{\mathcal{R}} d^4x\, S_f(x)\, \delta f(x) = \int_{\partial\mathcal{R}} S^{\mu\nu}\delta f_{\mu\nu}. \tag{9}$$

That is, any vector $\delta f(x)$ in the null space of $f^{-1}(x)$ is in the null space of $S_f(x)$. It follows that $S_f(x)$ is in the ray of $f^{-1}(x)$:

$$\frac{\delta S}{\delta f_{\mu\nu}(x)} = \lambda(x) f^{\mu\nu}(x). \tag{10}$$

The multiplier $\lambda(x)$ is then fixed by the unimodular condition.

This implies that the augmented action (8) is stationary up to boundary terms when we vary $\lambda(x)$ and the 10 components $g_{\mu\nu}(x)$ independently.

The unimodular condition makes the stress tensor ambiguous as well as the dynamical equations. In unimodular relativity the general relativistic concept of the stress tensor

$$T^{\mu\nu} = \frac{1}{\sqrt{g}} \frac{\delta(\sqrt{g} L_M)}{\delta g_{\mu\nu}} \tag{11}$$

has no principled meaning at first, since it involves breaking the unimodular condition, nor has the statement of covariant continuity, $T^{\mu\nu}{}_{;\nu}=0$.

We may suppose that $\Delta_M L$ has the form

$$\Delta_M L = \left[\frac{\mu(x)}{\sqrt{g(x)}} - 1 \right] l_M, \tag{12}$$

where l_M is any function of the matter variables and $g_{\mu\nu}$. We write $L'_M := L_M + \Delta_M L$ for the sum.

From any general-relativity action principle S we obtain in this way an ambiguous unimodular-relativity action principle

$$S' = \int \sqrt{g(x)}\, d^4x \left\{ \frac{\Gamma}{2} R(x) + \frac{\Gamma}{2} \lambda(x) \left[\frac{\mu(x)}{\sqrt{g(x)}} - 1 \right] + L_M + \Delta_M L \right\}. \tag{13}$$

The second term in S' expresses the unimodular condition and breaks general covariance. The fourth term expresses the unimodular ambiguity. We vary the 10 $g_{\mu\nu}(x)$ and the Lagrange multiplier $\lambda(x)$ independently. We have written the λ term in a form that makes λ a scalar field under the general group.

Variation of λ in S' recovers the condition

$$\sqrt{g(x)} = \mu(x). \tag{14}$$

The unimodular ambiguity $\Delta_M L$ does not affect this result, since it vanishes when the unimodular condition holds.

Variation of $g_{\mu\nu}$ gives the equation of motion

$$\delta S' = \int \sqrt{g}\, d^4x \{\Gamma(\tfrac{1}{2} g^{\mu\nu} R - R^{\mu\nu}) + \tfrac{1}{2}\Gamma\lambda g^{\mu\nu}\}\delta g_{\mu\nu} + \int \sqrt{g}\, d^4x \left\{ \frac{1}{\sqrt{g}} \frac{\delta}{\delta g_{\mu\nu}} (\sqrt{g} L_M + \sqrt{g}\Delta_M L) \right\} \delta g_{\mu\nu} = 0, \tag{15}$$

or

$$R^{\mu\nu} - \tfrac{1}{2} g^{\mu\nu} R - \tfrac{1}{2}\lambda g^{\mu\nu} = 8\pi G T'^{\mu\nu}, \tag{16}$$

where $G := 1/\Gamma$ is a rationalized gravitational coupling strength and

$$T'^{\mu\nu} := \frac{1}{\sqrt{g}} \frac{\delta}{\delta g_{\mu\nu}} (\sqrt{g} L_M + \sqrt{g}\Delta_M L). \tag{17}$$

Tracing (16) gives the Lagrange multiplier:

$$\lambda = -\tfrac{1}{2}(8\pi G T' + R). \tag{18}$$

The field equation then simplifies to

$$R^{\mu\nu} - \tfrac{1}{2} R g^{\mu\nu} = 8\pi G T'^{\mu\nu} - \tfrac{1}{4} g^{\mu\nu}(8\pi G T' + R), \tag{19}$$

or equivalently

$$R_{\mu\nu} - \tfrac{1}{4} R g_{\mu\nu} = 8\pi G T'^{\mathrm{T}}_{\mu\nu}, \tag{20}$$

where

$$T'^{\mathrm{T}}_{\mu\nu} := T'_{\mu\nu} - \tfrac{1}{4} g_{\mu\nu} T' \tag{21}$$

is the traceless (part of the) stress tensor, or the *sess tensor* (note that the tr has been removed). The covariant divergence of (19) is

$$8\pi G T'^{\mu\nu}{}_{;\nu} = \tfrac{1}{4} g^{\mu\nu}(8\pi G T' + R)_{,\nu} \equiv -\tfrac{1}{2} g^{\mu\nu}\lambda, \tag{22}$$

which was suggested as a ''modified covariant divergence law'' by Tiwari.[3]

In general relativity, general invariance of the action function implies that the covariant divergence $T'^{\mu\nu}{}_{;\nu}$ vanishes in virtue of the field equations for matter.[8,9] Then it follows that

$$-\tfrac{1}{2}(8\pi G T' + R) = \lambda = \text{constant}. \tag{23}$$

If the stress tensor of unimodular relativity were covariantly continuous too, then the undetermined multiplier λ could be identified with a cosmological constant Λ, though now a constant of the motion determined by the initial data, rather than a fixed absolute constant as supposed in general relativity.

In unimodular relativity however, $T'^{\mu\nu}$ is not covariantly continuous because the action S' is not generally covariant, which seems to justify Tiwari's suggestion. $T'^{\mu\nu}$ is ambiguous by an additive term

$$\Delta T^{\mu\nu} = -\tfrac{1}{2} g^{\mu\nu} l_M \tag{24}$$

and its trace is correspondingly ambiguous by

$$\Delta T = -2l_{\mathrm{M}}. \tag{25}$$

However substitution of these expressions into (20) immediately leads to

$$R_{\mu\nu} - \tfrac{1}{4}Rg_{\mu\nu} = 8\pi G T^{\mathrm{T}}_{\mu\nu}, \tag{26}$$

with

$$T^{\mathrm{T}}_{\mu\nu} := T_{\mu\nu} - \tfrac{1}{4}g_{\mu\nu}T, \tag{27}$$

where $T_{\mu\nu}$ is the usual covariantly continuous stress-energy tensor (11) of the matter field. The gravitational field equations *do not* depend on the ambiguity in the matter field Lagrangian. The cosmological constant again arises as a constant of integration.

Einstein's law of gravity is a second-order differential equation for the metric field. In quantum field theories higher-order derivatives arise from renormalization. One might hope that in higher-order theories, the unimodular relativity differs in content from general relativity, and allows the cosmological constant to vary. In such theories the cosmological constant may be defined as $\lambda = S(h)/\mu$ where $S(h)$ is the value of the gravitational action density for the case of the Minkowski metric.

It easily follows from the generalized (contracted) Bianchi identities of the higher order theory (see, for example, Refs. 10 and 11) that even in higher-order unimodular relativity, where the gravitational part of the action is an arbitrary generally invariant functional of the curvature scalar, the cosmological constant also arises as the constant of integration.

IV. CONCLUSIONS

We have shown that in Lagrangian unimodular relativity the usual covariant continuity equation holds for the source stress tensor, and the cosmological constant is a constant of integration of the gravitational field equations. Higher derivatives of the gravitational field may appear in the Lagrangian without disturbing these conclusions. The essential point is that the stress tensor have no covariant divergence. This follows from either unimodular or general covariance.

There are several reasons not to be quite certain that these classical conclusions will still hold in the quantum domain.

The fact remains that unimodular relativity forces us to allow many values as possibilities for the cosmologcal constant, while general relativity fixes on one value. In quantum theories, possibilities affect actualities. In a quantum theory of sufficient scope, these many possibilities for the cosmological constant of unimodular relativity might influence the actual experimental situation.[7]

Furthermore, quantum field theories often lack symmetries and conservation laws present in the classical Lagrangian from which they stem, due to divergences inherent in the limiting process used to define the quantum theory. This results in quantum anomalies, for example. Similar effects may permit the cosmological constant—the vacuum rest-energy-density—to vary in some quantum version of unimodular relativity.

Perhaps the most basic weakness in the deduction is the postulate of strong locality. This is implicit in general covariance and is required to deduce the covariant continuity of stress. If there is a fundamental quantum time, a limit to locality, as some suggest, then the cosmological constant can vary.

(Received 31 May 2000; accepted for publication 27 September 2000)

A discussion of projective symmetry in general relativity is given. Techniques are developed and used to show that null Einstein–Maxwell fields in general relativity cannot admit any proper projective symmetry. © *2001 American Institute of Physics.* [DOI: 10.1063/1.1332121]

I. INTRODUCTION

In spite of much recent interest in the study of symmetry in general relativity theory, projective symmetry seems to be ignored. This may be largely to do with the difficulties involved although, following Ref. 1, some progress was made in Ref. 2. The results of this latter paper suggested that examples of space-times admitting proper projective symmetries would not be plentiful (see also Refs. 3 and 4) and this present paper continues by demonstrating their absence in space-times of the null Einstein–Maxwell type. Non-null Einstein–Maxwell fields will be considered in a future paper.

Let M be a smooth space-time with smooth Lorentz metric g of signature $(-\ +\ +\ +)$ and associated curvature tensor components R_{abcd}. The Ricci tensor components are $R_{ab}\equiv R^{c}{}_{acb}$, the Ricci scalar is $R\equiv R_{ab}g^{ab}$ and the Weyl tensor components are C_{abcd}. A Lie (respectively, a covariant and a partial) derivative is denoted by $\mathcal{L}$ (respectively, a semicolon and a comma). A smooth vector field X on M may be decomposed uniquely in any coordinate system on M according to

$$X_{a;b}=\tfrac{1}{2}h_{ab}+F_{ab}\quad (h_{ab}=h_{ba},\quad F_{ab}=-F_{ba}), \tag{1}$$

where $h(=\mathcal{L}_X g)$ is symmetric and F (the *projective bivector*) is skew-symmetric. Such a vector field X is called *projective* if the local diffeomorphisms ψ_t (for appropriate t) associated with X map geodesics into geodesics. This is equivalent to the condition that h satisfies

$$h_{ab;c}=2g_{ab}\phi_c+g_{ac}\phi_b+g_{bc}\phi_a \tag{2}$$

for some smooth closed 1-form on M with local components ϕ_a. Thus ϕ_a is locally a gradient and will, where appropriate, be written as $\phi_a=\phi_{,a}$ for some function ϕ on some open subset of M. The function ϕ may be taken as a global function on M if M is simply connected.[5] The statement that h is covariantly constant on M is, from (2), equivalent to ϕ_a being zero on M and is, in turn, equivalent to X being an *affine* vector field on M (so that the local diffeomorphisms ψ_t preserve not only geodesics but also their affine parameters). If X is projective but not affine it is called *proper projective*. If X is affine and $h=cg(c\in\mathbb{R})$ then X is *homothetic* (otherwise proper affine). If X is homothetic and $c\neq 0$ it is *proper homothetic* while if $c=0$ it is *Killing*.

II. PROJECTIVE SYMMETRY

Let X be a projective vector field on M. Then (1) and (2) hold and also (cf. Ref. 1)

$$\mathcal{L}_X R^{a}{}_{bcd}=\delta^{a}_{d}\phi_{b;c}-\delta^{a}_{c}\phi_{b;d},\quad \mathcal{L}_X R_{ab}=-3\phi_{a;b}. \tag{3}$$

Also the Ricci identity on h gives[2]

$$h_{ae}R^{e}{}_{bcd}+h_{be}R^{e}{}_{acd}=g_{ac}\phi_{b;d}-g_{ad}\phi_{b;c}+g_{bc}\phi_{a;d}-g_{bd}\phi_{a;c}. \tag{4}$$

The difficulty with projective vector fields is the complicated relationship (2) satisfied jointly by h_{ab} and ϕ_a. However, the following result is useful in obtaining prior algebraic information on h_{ab} and $\phi_{a;b}$ and follows from (4). The first parts were given in Ref. 6 following a special case in Ref. 2 and the other part is a straightforward extension. A prior definition is required. Let $m \in M$ and let G be a (real or complex) bivector at m. Then G is called a *curvature eigenbivector* with eigenvalue $\lambda \in \mathbb{C}$ if, at m, $R^{ab}{}_{cd}G^{cd}=\lambda G^{ab}$.

Theorem 1: Let X be a projective vector field on M so that (1) and (2) hold and let G be a curvature eigenbivector at $m \in M$ with eigenvalue $\lambda \in \mathbb{C}$.

(i) If G (and hence λ) are real and G is simple (i.e., $G^{ab}=2p^{[a}q^{b]}$ for p and q in the tangent space T_mM to M at m) then each vector in the span of p and q (the *blade* of G) is an eigenvector of the symmetric tensor at m given by

$$P_{ab}=\lambda h_{ab}+2\phi_{a;b} \tag{5}$$

with the same eigenvalue α.

(ii) If G is real and non simple then G uniquely determines a timelike–spacelike orthogonal pair of two-dimensional subspaces of T_mM [i.e., there exists a real null tetrad (l,n,x,y) at m with $l^an_a=x^ax_a=y^ay_a=1$ and all other inner products of tetrad members zero such that $G^{ab}=2Al^{[a}n^{b]}+2Bx^{[a}y^{b]}$ with A and B real and nonzero]. These subspaces spanned, respectively, by the vector pairs (l,n) and (x,y) are eigenspaces of P in (5).

(iii) If G and λ are not real then similar, if a little more complicated, information is available and this is, perhaps, best discussed when it arises.

III. PROJECTIVE SYMMETRY AND NULL EINSTEIN–MAXWELL FIELDS

Let (M,g) represent a null Einstein–Maxwell field. Then it is assumed that M admits a global, nowhere zero, smooth, null vector field l such that the Ricci tensor satisfies $R_{ab}=\psi l_a l_b$ for some smooth, nowhere zero function ψ. Also, the contracted Bianchi identity shows that l is geodesic and, henceforth, l will be assumed to be affinely parametrized ($l_{a;b}l^b=0$) in each coordinate system considered. Finally the Goldberg–Sachs theorem[7,8] shows that the Petrov type at each point of M is algebraically special with l as a repeated principle null direction. In fact, M may then be decomposed as a *disjoint* union

$$M=II\cup \operatorname{int} D\cup \operatorname{int} III\cup \operatorname{int} N\cup \operatorname{int} O\cup M', \tag{6}$$

where *II*, *III*, *D*, *N*, and *O* are the subsets of M at each point of which the Petrov type is the same as the subset label (and *I* is empty), where int denotes the interior of a subset in the manifold topology of M and where M' is a closed subset of M defined by the disjointness of the decomposition and with no interior.[9] Since *I* is empty the ''rank'' theorem together with a minimal polynomial argument given in Ref. 9 shows that *II* is open and so $II=\operatorname{int} II$. The idea is to let X be a projective vector field on M and to consider the regions in the decomposition (6) separately. If m is a point in any of the open regions of constant Petrov type in (6) then one may introduce a local real null tetrad (l,n,x,y) of vector fields in some open region about m [but still within the particular chosen open subset in (6)] (see, e.g., Ref. 10). Then one constructs bivectors in this region given by (and using the abbreviation $x\wedge y=2x^{[a}y^{b]}$, etc.)

$$V=l\wedge x, \quad \overset{*}{V}=-l\wedge y, \quad M=l\wedge n, \quad \overset{*}{M}=x\wedge y,$$

$$U=n\wedge x, \quad \overset{*}{U}=n\wedge y, \tag{7}$$

where $*$ denotes the usual dual. One can now choose the null tetrad so that the curvature tensor takes the form

$$R_{abcd}=A(V_{ab}V_{cd}+\overset{*}{V}_{ab}\overset{*}{V}_{cd})+C_{abcd}, \tag{8}$$

where A is some nowhere zero function on M, and the first term on the right-hand side is the Maxwell term. Thus for each Petrov type one substitutes for C an appropriate canonical form (e.g., as in Refs. 11, 12, and 8) and then one is ready to apply Theorem 1. So let X be a projective vector field on M.

Region int O. Here, the Weyl tensor is zero and so from (8) the curvature tensor, considered as a 6×6 matrix, is of rank 2 and satisfies $R_{abcd}l^d=0$. It now follows (Ref. 2, theorem 4) that, in $\operatorname{int} O$, $\phi_a=0$ and so from (2) $h_{ab;c}=0$. Thus the restriction of X to $\operatorname{int} O$ is affine on each connected and simply connected open subset of $\operatorname{int} O$. If the restriction over a particular component U is proper affine then it is easily checked that the holonomy group of U (with the latter regarded as a space-time) is of the type R_8 (see e.g. Ref. 13) and that l is covariantly constant on U. If X is not proper affine on U it is homothetic (possibly *Killing*) on U.

Region int N. Here the Petrov type is N and use of the appropriate canonical form for the Weyl tensor shows that $R_{abcd}l^d=0$ and that

$$R_{abcd}=A_1V_{ab}V_{cd}+A_2\overset{*}{V}_{ab}\overset{*}{V}_{cd} \tag{9}$$

with A_1 and A_2 functions on $\operatorname{int} N$ satisfying $A_1^2+A_2^2\neq 0$ at each point of $\operatorname{int} N$. However, one cannot guarantee that A_1 and A_2 are each nonzero at each $m\in\operatorname{int} N$ and so the Riemann rank may vary over $\operatorname{int} N$. Let $W_1\subset\operatorname{int} N$ be the (necessarily open) subset of M consisting of those points at which A_1 *and* A_2 are not zero (i.e., the open subset of $\operatorname{int} N$ where the curvature rank is 2) and let W_2 be the interior of the subset $\operatorname{int} N\backslash W_1$ (the latter subset being the subset of $\operatorname{int} N$ where exactly one of A_1 and A_2 is zero and hence where the curvature rank is 1). Then $\operatorname{int} N$ has the disjoint decomposition $\operatorname{int} N=W_1\cup W_2\cup E$ where E is defined by the disjointness. It is easily checked that E has no interior. Then over W_1 one may, as in the previous case, appeal to Theorem 4 in Ref. 2 to see that $\phi_a=0$ on W_1 and make similar remarks about when the various restrictions of X are proper affine or not. Over W_2 the curvature rank is 1 and, from (7) and (9) one sees that $V,\overset{*}{V}$, M, and $\overset{*}{M}$ are curvature eigenbivectors with eigenvalue zero. It follows from Theorem 1 that l, n, x, and y are eigenvectors of $\phi_{a;b}$ with zero eigenvalue at each point of W_2 and hence that $\phi_{a;b}=0$ on W_2. If one now appeals to holonomy considerations on each connected and simply connected open subset of W_2 then it follows from Theorem 5 in Ref. 13 and Theorems 7, 8, and 9 in Ref. 2 that on each such open subset either $\phi_a=0$ or the holonomy group is type R_{10}. But if on some such open subset ϕ_a is not identically zero (but still satisfies $\phi_{a;b}=0$) the holonomy type R_{10} conditions allow the choice of the local null tetrad (l,n,x,y) (depending on which open region of W_2 one is on, i.e., where $A_1\neq 0$ and $A_2=0$, or vice versa) such that (7) and (9) hold and such that $\phi_a=Cy_a$ for some $C\in\mathbb{R}$. Also (4) gives

$$h_{ae}R^e{}_{bcd}+h_{be}R^e{}_{acd}=0. \tag{10}$$

Now (10) implies that (Ref. 14)

$$h_{ab}=\alpha g_{ab}+\beta y_ay_b+\gamma l_al_b+2\,\delta l_{(a}y_{b)} \tag{11}$$

for appropriate functions α, β, γ, and δ. Then on substituting (11) and the relation $\phi_a=Cy_a$ into (2) and contracting with x^ax^b one finds that $\alpha_{,c}=2Cy_c$. On substituting this back into (2) and contracting with l^a one immediately finds $C=0$ and so $\phi_a=0$ on the region considered and hence on W_2. Thus $\phi_a=0$ (and $h_{ab;c}=0$) on $W_1\cup W_2$. Now put $W=W_1\cup W_2$ and note that $\operatorname{int}(\operatorname{int} N\backslash W)=\emptyset$. This follows since if $\emptyset\neq V\subseteq\operatorname{int} N\backslash W$ with V open then $V\cap W=\emptyset$ and so on

$V\cap W_1=0$ and hence $V\subseteq \text{int}\, N\backslash W_1$. Since V is open this gives $V\subseteq \text{int}(\text{int}\, N\backslash W_1)=W_2$ and hence the contradiction that $V\cap W\neq\emptyset$. From this one can see that if $m\in \text{int}\, N\backslash W$ then any open neighborhood V' of m intersects W nontrivially (otherwise $V'\cap \text{int}\, N$ would be open, nonempty and contained in $\text{int}\, N\backslash W$). Thus since $\phi_a\equiv 0$ on W, $\phi_a\equiv 0$ on $\text{int}\, N$ by continuity.

It is remarked that over connected and simply connected open subsets of $\text{int}\, N$ whose holonomy group is of type R_3, R_8 or R_{10}, X could restrict to a proper affine vector field and elsewhere only to a homothetic vector field.[13,15]

Region int III. In this case, Eq. (8) and an appeal to the Petrov canonical forms show that

$$R_{abcd}=A(V_{ab}V_{cd}+\overset{*}{V}_{ab}\overset{*}{V}_{cd})+B(V_{ab}M_{cd}+M_{ab}V_{cd}-\overset{*}{V}_{ab}\overset{*}{M}_{cd}-\overset{*}{M}_{ab}\overset{*}{V}_{cd}) \tag{12}$$

on $\text{int}\, III$ with A and B nowhere zero functions on $\text{int}\, III$. It follows from (7) (and using an obvious abbreviated notation where $R_{abcd}V^{cd}$ is written as RV, etc.) that

$$RV=0,\quad \overset{*}{R}V=0,$$

$$RM=-2BV,\quad \overset{*}{R}M=-2B\overset{*}{V},$$

$$RU=2AV+2BM,\quad \overset{*}{R}U=-2A\overset{*}{V}+2B\overset{*}{M}. \tag{13}$$

Now (13) and Theorem 1 show that on $\text{int}\, III$

$$\phi_{a;b}=\alpha g_{ab}+\beta l_a l_b \tag{14}$$

and (4) and (14) then give, on $\text{int}\, III$,

$$h_{ae}R^e{}_{bcd}+h_{be}R^e{}_{acd}=\beta(g_{ac}l_b l_d-g_{ad}l_b l_c+g_{bc}l_a l_d-g_{bd}l_a l_c). \tag{15}$$

Contracting (15) successively with M^{cd} and $\overset{*}{M}{}^{cd}$ gives

$$h_{ae}V^e{}_b+h_{bc}V^e{}_a=-2\beta B^{-1}l_a l_b,\quad h_{ae}\overset{*}{V}{}^e{}_b+h_{be}\overset{*}{V}{}^e{}_a=0 \tag{16}$$

and the second of (16) yields, by an argument similar to one used earlier[14]

$$h_{ab}=\lambda g_{ab}+\mu l_a l_b+\nu x_a x_b+2\rho l_{(a}x_{b)}. \tag{17}$$

A substitution of (17) into the first of (16) shows that $\nu\equiv 0$ on $\text{int}\, III$.

Next, substitute (17) with $\nu=0$ into (15) and contract first with U^{cd} and then with $\overset{*}{U}{}^{cd}$, using (13). The resulting equations show (since A and B are nowhere zero on $\text{int}\, III$) that $\rho=\mu=\beta=0$ on $\text{int}\, III$. Hence $h_{ab}=\lambda g_{ab}$ and on substituting this into (2) and contracting at each $m\in \text{int}\, III$ with $k\in T_m M$ satisfying $\phi_a k^a=0$, $k_a k^a\neq 0$, one finds that $\lambda_{,a}=2\phi_a$. A back substitution into (2) and a further contraction with k^a then shows that $\phi_a=0$ at m and hence that $\phi_a\equiv 0$ and $\lambda=$ constant on $\text{int}\, III$. Thus the restriction of X to any component of $\text{int}III$ is affine and, since the curvature tensor has rank 4 [from (13)], the restriction of X to any component of $\text{int}\, III$ is homothetic.[15]

Region II. In this case, Eq. (8) and the canonical Petrov type *II* form allow the null tetrad to be chosen locally in this region so that

$$R_{abcd}=A_1(V_{ab}V_{cd})+A_2(\overset{*}{V}_{ab}\overset{*}{V}_{cd})+C(U_{ab}V_{cd}+V_{ab}U_{cd}-\overset{*}{U}_{ab}\overset{*}{V}_{cd}$$
$$-\overset{*}{V}_{ab}\overset{*}{U}_{cd}+2M_{ab}M_{cd}-2\overset{*}{M}_{ab}\overset{*}{M}_{cd})-D(U_{ab}\overset{*}{V}_{cd}+\overset{*}{U}_{ab}V_{cd}$$
$$+V_{ab}\overset{*}{U}_{cd}+\overset{*}{V}_{ab}U_{cd}+2M_{ab}\overset{*}{M}_{cd}+2\overset{*}{M}_{ab}M_{cd}), \tag{18}$$

where A_1, A_2, C, and D are real functions and $A_1^2+A_2^2$ is nowhere zero on II. It is convenient to disjointly decompose II as $II=W_1\cup W_2\cup E$ where W_1 is the necessarily open subset of II consisting of exactly those points of II where D is not zero and where $W_2=\mathrm{int}(II\backslash W_1)$. Then E is well defined by disjointness and has no interior.

One finds from (18), using the same abbreviated notation, that

$$RV=2CV-2D\overset{*}{V},\quad \overset{*}{R}V=2C\overset{*}{V}+2DV,$$
$$RM=-4CM+4D\overset{*}{M},\quad \overset{*}{R}M=-4C\overset{*}{M}-4DM, \tag{19}$$
$$RU=2CU-2D\overset{*}{U}+2A_1V,\quad \overset{*}{R}U=2C\overset{*}{U}+2DU-2A_2\overset{*}{V}.$$

From this it is easily checked that $V+i\overset{*}{V}$ and $M+i\overset{*}{M}$ are complex curvature eigenbivectors with eigenvalues $2(C+iD)$ and $-4(C+iD)$ and so the region W_1 is that part of II where these eigenvalues are not real. Then the appropriate contractions of (4) and use of (19) gives the equations

$$P_{ad}V^d{}_b+P_{bd}V^d{}_a-Q_{ad}\overset{*}{V}{}^d{}_b-Q_{bd}\overset{*}{V}{}^d{}_a=0,$$
$$P_{ad}\overset{*}{V}{}^d{}_b+P_{bd}\overset{*}{V}{}^d{}_a+Q_{ad}V^d{}_b+Q_{bd}V^d{}_a=0, \tag{20}$$
$$(P_{ab}=2Ch_{ab}+2\phi_{a;b,}\quad Q_{ab}=2Dh_{ab})$$

and

$$P'_{ad}M^d{}_b+P'_{bd}M^d{}_a-Q'_{ad}\overset{*}{M}{}^d{}_b-Q'_{bd}\overset{*}{M}{}^d{}_a=0,$$
$$P'_{ad}\overset{*}{M}{}^d{}_b+P'_{bd}\overset{*}{M}{}^d{}_a+Q'_{ad}M^d{}_a+Q'_{bd}M^d{}_a=0, \tag{21}$$
$$(P'_{ab}=-4Ch_{ab}+2\phi_{a;b,}\quad Q'_{ab}=-4Dh_{ab}).$$

First consider the subset W_1 on which D is nowhere zero. Then (20) holds and algebraic information on h_{ab} and $\phi_{a;b}$ can be obtained by substituting for V and $\overset{*}{V}$ into each of (20) from (7). If one performs these substitutions and then contracts over the indices a and b with all combinations of the basis vectors l, n, x and y one finds [using the abbreviation $P(l,n)$ for $P_{ab}l^an^b$, etc.] that

$$
\begin{gathered}
P(l,l)=Q(l,l)=P(l,x)=P(l,y)=Q(l,x)=Q(l,y)=0,\\
P(n,x)=-Q(n,y)\quad P(n,y)=Q(n,x),\\
Q(l,n)=Q(x,x)-P(x,y)=Q(y,y)+P(x,y),\\
P(l,n)=P(x,x)+Q(x,y)=P(y,y)-Q(x,y).
\end{gathered}
\tag{22}
$$

A similar procedure using (21) yields

$$
\begin{gathered}
P'(l,l)=P'(n,n)=Q'(l,l)=Q'(n,n)=P'(x,y)=Q'(x,y)=0,\\
P'(x,x)=P'(y,y)\quad Q'(x,x)=Q'(y,y),\\
P'(l,x)=-Q'(l,y)\quad P'(l,y)=Q'(l,x),\\
P'(n,x)=Q'(n,y)\quad P'(n,y)=-Q'(n,x).
\end{gathered}
\tag{23}
$$

Since D is nowhere zero on W_1, h_{ab} is a multiple of Q and Q' (and $Q'=-2Q$). Then (22) and (23) show that $Q(x,x)=Q(y,y)$ and then $P(x,y)=0$. This implies that $Q(l,n)=Q(x,x)=Q(y,y)$ and the information accumulated on h in the above null tetrad shows that

$$
h_{ab}=\alpha g_{ab}+2\lambda l_{(a}x_{b)}+2\mu l_{(a}y_{b)} \tag{24}
$$

for functions α, λ, and μ on W_1. The information on h in (24) gives rise to similar information on Q and Q' which can then be transmitted to P and P' through (22) and (23), respectively. One finds that $P(l,l)=P(l,x)=P(l,y)=P(x,y)=0$, $P(l,n)=P(x,x)=P(y,y)$ and that $P'(l,l)=P'(n,n)=P'(l,x)=P'(l,y)=P'(x,y)=0$, $P'(x,x)=P'(y,y)$. Thus

$$
P_{ab}=\beta g_{ab}+\gamma l_a l_b+2\delta l_{(a}x_{b)}+2\epsilon l_{(a}y_{b)}, \tag{25}
$$

$$
P'_{ab}=\beta' g_{ab}+2\gamma' l_{(a}n_{b)}+2\delta' l_{(a}x_{b)}+2\epsilon' l_{(a}y_{b)} \tag{26}
$$

for functions $\beta,\gamma,\ldots,\epsilon'$ on W_1. But the defining Eqs. (20) and (21) for P and P' show that $P-P'=6Ch$ and then (24)–(26) show that $\gamma\equiv\gamma'\equiv 0$ on W_1. Thus, on W_1,

$$
\phi_{a;b}=\sigma g_{ab}+2\nu l_{(a}x_{b)}+2\rho l_{(a}y_{b)} \tag{27}
$$

for functions σ, ν, and ρ on W_1. Now one substitutes (24) and (27) into (4), noting that the terms containing α and σ immediately cancel. Then since one of A_1 and A_2 is not zero at each point of *II*, and hence W_1, suppose that at $m\in W_1$, $A_1(m)\neq 0$. A contraction of (4) with U^{cd} (after making the above substitutions and cancellations) and comparison of the independent symmetric tensors on either side of the resulting equation yields $\lambda=\mu=\nu=\rho=0$ at m. If $A_2(m)\neq 0$ a contraction with $\overset{*}{U}{}^{cd}$ (or an appeal to symmetry) gives the same conclusion. So $\lambda\equiv\mu\equiv\nu\equiv\rho\equiv 0$ and $h_{ab}=\alpha g_{ab}$ and $\phi_{a;b}=\sigma g_{ab}$ on W_1. Finally, just as in the conclusion of the type *III* discussion, one then finds from (2) that $\phi_a\equiv 0$ on W_1 and λ is constant on each component of U. Hence any restriction of X to some connected open subset of W_1 is homothetic.

Now consider the subset W_2 of *II*. Here, D is zero and the curvature eigenbivectors and eigenvalues introduced earlier are real and from (19) are V and $\overset{*}{V}$ (with eigenvalue $2C$) and M and $\overset{*}{M}$ (with eigenvalue $-4C$). Also, the given Petrov type shows that C is nowhere zero on W_2. Then Theorem 1 shows that in this case

$$2Ch_{ab}+2\phi_{a;b}=\mu g_{ab}+\nu l_a l_b$$
$$-4Ch_{ab}+2\phi_{a;b}=\mu' g_{ab}+2\nu' l_{(a}n_{b)} \tag{28}$$

for functions μ, ν, μ', and ν' on W_2. From this one finds

$$h_{ab}=\alpha g_{ab}+\beta l_a l_b+2\gamma l_{(a}n_{b)},$$
$$\phi_{a;b}=\alpha' g_{ab}+\beta' l_a l_b+2\gamma' l_{(a}n_{b)} \tag{29}$$

for functions $\alpha,\beta,\ldots,\gamma'$ on W_2. Now return to the second equation in (3) and recall the expression $R_{ab}=\psi l_a l_b$ for a nowhere zero function ψ on W_2. First note that from (1) and the first of (29),

$$\mathcal{L}_X(l^a)=l^a{}_{;b}X^b-X^a{}_{;b}l^b \Rightarrow l_a(\mathcal{L}_X l^a)=0$$
$$\Rightarrow(\text{since}\ \ \mathcal{L}_X(l^a l_a)=0)\ \ l^a(\mathcal{L}_X l_a)=0. \tag{30}$$

So (3) and the second equation of (29) gives

$$\mathcal{L}_X(\psi l_a l_b)=-3\alpha' g_{ab}-3\beta' l_a l_b-6\gamma' l_{(a}n_{b)}. \tag{31}$$

On expanding the left-hand side of (31) and contracting with $x^a x^b$ one finds $\alpha'\equiv 0$ on W_2 and a back substitution of this result into (31) and a contraction with l^a, using (30), gives $\gamma'\equiv 0$ on W_2. Thus $\phi_{a;b}=\beta' l_a l_b$. The Ricci identity $\phi_{a;[bc]}=\phi^d R_{dabc}$ on contraction with l^a then gives

$$R_{abcd}H^{cd}=0, \quad H_{ab}=2l_{[a}\phi_{b]}. \tag{32}$$

But from (19) the curvature tensor has rank 6 and so no nonzero bivector H could satisfy (32). Hence $H\equiv 0$ and so $\phi_a=\chi l_a$ for some function χ on W_2. Then the second equation of (29) with $\alpha'\equiv\gamma'\equiv 0$ shows that $\chi l_{a;b}=l_a r_b$ for some covector field r on W_2 and hence that l is recurrent on any open subset of W_2 on which χ does not vanish. But this recurrency of l would force a curvature rank of 4 or less on that subset[13,15] and thus $\chi\equiv 0$ and $\phi_a\equiv 0$ on W_2. Hence $\phi_a\equiv 0$ on $W_1\cup W_2$ and hence (by a similar argument to that in the type N case) $\phi_a\equiv 0$ on II.

Region D. In this case the curvature tensor takes the form (18) with $A_1=A_2=A$ and with A nowhere zero on D and the argument is essentially identical to that on region II. Thus one finds that $\phi_a\equiv 0$ on $\text{int}\,D$.

In summary the above analysis has shown that if X is a projective vector field on a null Einstein–Maxwell space-time M then $\phi_a\equiv 0$ on $\text{int}\,O$, $\text{int}\,N$, $\text{int}\,III$, $\text{int}\,D$ and II and hence, from (6), on $M\backslash M'$. Since $\text{int}\,M'=\emptyset$ it then follows by continuity that $\phi_a\equiv 0$ on M. Thus X is not proper projective. The following theorem has been established.

Theorem 2: If M is a null Einstein–Maxwell space-time and if X is a projective vector field on M then X is not proper.

It should be remarked that one could have considered separate null Einstein–Maxwell space-times of the constant Petrov types O, N, III, D, and II and established the lack of proper projective vector fields in each case. These results, of course, follow from the above although not conversely, since there is an extra patching procedure to be considered. Also one can add a little more to the theorem by noting from (8), (9), (13), and (19) that the curvature tensor has rank$\geqslant 4$ for Petrov types III, D, and II. Hence from Refs. 3 and 15 and the above theorem any projective vector field X on a null Einstein–Maxwell space-time of one of these Petrov types (or a region of one of these types in such a space-time where the Petrov type is not constant) cannot be proper affine and so must be homothetic. However, X could be proper affine for a null Einstein–Maxwell space-time (or a region of such a space-time) of Petrov type N or O.

The situation for non-null Einstein–Maxwell and other fields will be considered elsewhere.

JOURNAL OF MATHEMATICAL PHYSICS VOLUME 42, NUMBER 1 JANUARY 2001

Rotating Bianchi type *V* dust models generalizing the $k=-1$ Friedmann model

Andrzej Krasiński[a)]
N. Copernicus Astronomical Center, Polish Academy of Sciences, Bartycka 18, 00 716 Warszawa, Poland

(Received 31 May 2000; accepted for publication 12 October 2000)

The Einstein equations are investigated for a rotating Bianchi type *V* dust model in which one of the Killing fields is spanned on velocity and rotation (case 1.2.2.2 in the classification scheme of the earlier papers). A first integral of the field equations is found, and with a special value of this integral coordinate transformations are used to eliminate two components of the metric. The $k=-1$ Friedmann model is shown to be contained among the solutions in the limit of zero rotation. The field equations for the simplified metric are reduced to 3 second-order ordinary differential equations that determine 3 metric components plus a first integral that algebraically determines the fourth component. First derivatives of the metric components are subject to a constraint (a second-degree polynomial with coefficients depending on the functions). It is shown that the set does not follow from a Lagrangian of the Hilbert type. The group of Lie point-symmetries of the set is found, it is two-dimensional noncommutative. Finally, a method of searching for first integrals (for sets of differential equations) that are polynomials of degree 1 or 2 in the first derivatives is applied. No such first integrals exist. The method is used to find a constraint (of degree 1 in first derivatives) that could be imposed on the metric, but it leads to a vacuum solution, and so is of no interest for cosmology.
 [DOI: 10.1063/1.1330197]

I. STATEMENT OF THE PROBLEM AND SUMMARY OF THE PAPER

This paper is a continuation of a series of papers on rotating dust models in relativity.[1–3] The initial motivation for this research was the desire to find a rotating generalization of the Friedmann models. In spite of much effort spent on investigating solutions of Einstein equations with a rotating matter source, no such generalization has been found so far; see literature surveys in Refs. 3 and 4. References 1, 2 and 3 provided a complete classification scheme for hypersurface–homogeneous rotating perfect fluid models with zero acceleration. Unlike previous approaches, the classification includes also timelike and null symmetry orbits, and so it is the farthest-reaching application of the Bianchi classification to rotating and nonaccelerating perfect fluid models in relativity. The models split into 3 general classes: I, in which two of the Killing fields are everywhere spanned on the vector fields of velocity u^α and rotation w^α (Ref. 1); II, in which only one Killing field is spanned on u^α and w^α (Ref. 2); and III, in which all Killing fields are linearly independent of u^α and w^α (Ref. 3). The many particular cases arise because of several possible alignments or misalignments among the 3 Killing fields and u^α and w^α.

By the Bianchi type of the symmetry algebra and by the relation of the velocity field to the symmetry orbits it can be recognized in which cases generalizations of the Friedmann models can be expected. Two such candidate cases were found in class II, and five more in class III. Those of class III were prohibitively complicated, but one of the cases of class II allowed for some progress, and this one is presented in the present paper. It is the Bianchi type *V* subcase of the case 1.2.2.2, given by Eq. (5.19) in Ref. 2. For the other candidate case found in class II, Eq. (5.10) in Ref. 2,

a)Electronic mail: akr@camk.edu.pl

the $k=0$ Friedmann limit is calculated in a much more complicated way, this will be a subject of another paper.

In Sec. II, the metric is simplified by a coordinate transformation, and a first integral of the Einstein equations is found. With a zero value of this integral, coordinate transformations can be used to eliminate two components of the metric tensor, and the number of nontrivial Einstein equations is reduced to 7. Although there are only 4 functions+matter density to be determined by these 7 equations, the set later turns out to be self-consistent. In Sec. III, it is shown that the $k=-1$ Friedmann models are contained among the metrics that result in the limit of zero rotation. In Sec. IV, the Einstein equations are reduced to a set S of 3 second-order equations to determine 3 metric components+a quadrature Q to determine the fourth component (g_{33}). Of the Einstein equations derived in Sec. II, one is fulfilled identically in consequence of the set $\{S\cup Q\}$, one turns out to be a constraint imposed on the initial data, and the one that determines the matter-density turns out to provide a first integral. The first integral determines g_{33} algebraically in terms of the other components, and so it is a replacement for the quadrature Q. It is also shown that the set S cannot be obtained as the Euler–Lagrange equations from a variational principle of the Hilbert type. Finally, it is shown in Sec. IV how the set $\{S\cup Q\}$ reproduces the Friedmann equations in the limit of zero rotation and zero shear. In Sec. V, the two-dimensional (non-Abelian) group of Lie point-symmetries of the set is found. In Sec. VI, a method of systematic search for polynomial first-order first integrals of a set of ordinary differential equations is applied to the set S of Sec. IV. It is shown that no first integrals that are polynomials of degree 1 or 2 in the first derivatives exist. The same method is used to reveal the existence of a possible constraint on initial data, which is of degree 1 in first derivatives, that is preserved by the set S. However, the constraint necessarily implies zero matter-density, and so it is not interesting for cosmology.

Equations that are of secondary importance for the main text, but are difficult to reproduce, can be found in the preprint version of this paper.[5] They have been deleted from this text at the request of the referee.

II. THE EINSTEIN EQUATIONS, THEIR FIRST INTEGRAL AND IMPLICATIONS OF THE ZERO VALUE OF THIS INTEGRAL

The subject of the present paper are the Einstein equations for the Bianchi type V subcase of case 1.2.2.2 of Ref. 2. For reference, the initial formulas are recalled in their original notation.

The Bianchi type V symmetry results when $c=0$ in Eqs. (5.19) of Ref. 2 and when, in addition, $j=-a$ in Eqs. (5.16). Hence, the metric is

$$\begin{aligned} ds^2 = {} & dt^2 + 2y\,dt\,dx + y^2 h_{11}\,dx^2 + 2h_{12}\,dx\,dy + 2y^2 h_{13}\,dx\,dz \\ & + (h_{22}/y^2)dy^2 + 2h_{23}\,dy\,dz + y^2 h_{33}\,dz^2, \end{aligned} \tag{2.1}$$

where the coordinates are $\{x^\alpha\}=\{x^0,x^1,x^2,x^3\}=\{t,x,y,z\}$, and $h_{ij}, i,j=1,2,3$ are unknown functions of the variable

$$v = e^t y^{C_2/a}, \tag{2.2}$$

a and C_2 being arbitrary constants. The velocity field u^α, the rotation field w^α and the Killing fields $k_{(i)}{}^\alpha$, $i=1,2,3$ are given by

$$\begin{gathered} u^\alpha = \delta^\alpha{}_0, \quad w^\alpha = (\rho/y)\,\delta^\alpha{}_0, \quad k_{(1)}{}^\alpha = \delta^\alpha{}_1, \quad k_{(3)}{}^\alpha = \delta^\alpha{}_3, \\ k_{(2)}{}^\alpha = C_2\,\delta^\alpha{}_0 + a(x\,\delta^\alpha{}_1 - y\,\delta^\alpha{}_2 + z\,\delta^\alpha{}_3), \end{gathered} \tag{2.3}$$

where ρ is the matter-density of dust. The rotation tensor $\omega_{\alpha\beta}$ has only one algebraically independent nonzero component:

$$\omega_{12} = \tfrac{1}{2}, \tag{2.4}$$

and therefore the coordinates used here are ill-suited for considering the limit $\omega\to 0$.

As shown in Ref. 1, it follows from the equations of motion and from the equation of conservation of the number of particles that

$$g:=\det(g_{\alpha\beta})=-(y/\rho)^2. \tag{2.5}$$

This is the form in which the metric resulted from the Killing equations in Ref. 2. It is advantageous to transform the coordinates as follows:

$$t=t'-(C_2/a)\ln y', \quad x=x'-C_2/(ay'), \quad (y,z)=(y',z'). \tag{2.6}$$

The result is equivalent to substituting $C_2=0$ and $a=1$ in Eqs. (2.1)–(2.4), i.e., the forms of the metric (2.1), of the vector fields u^α, w^α, ${k_{(1)}}^\alpha$ and ${k_{(3)}}^\alpha$ in (2.3) and of the rotation tensor $\omega_{\alpha\beta}$ in (2.4) do not change [although the new h'_{ij} in (2.1) will be linear combinations of the old h_{ij}], while the new ${k_{(2)}}^\alpha$ basis vector will be

$${k_{(2)}}^\alpha=x\,{\delta^\alpha}_1-y\,{\delta^\alpha}_2+z\,{\delta^\alpha}_3, \tag{2.7}$$

and the argument of h_{ij} will now be $v=\mathrm{e}^{t'}$, i.e., the h_{ij} are from now on unknown functions of the time-coordinate t.

It is convenient to parametrize the metric as follows:

$$\mathrm{d}s^2=(\mathrm{d}t+y\,\mathrm{d}x)^2-(yK_{11}\,\mathrm{d}x)^2-(K/y)^2(\mathrm{d}y+y^2h\,\mathrm{d}x)^2-{K_{33}}^2[yg\,\mathrm{d}x+(f/y)\mathrm{d}y+y\,\mathrm{d}z]^2, \tag{2.8}$$

where K_{11}, K, K_{33}, h, f and g are unknown functions of t. The components of the Einstein tensor referred to below are tetrad components $G_{IJ}={e^\alpha}_I{e^\beta}_J G_{\alpha\beta}$, i.e., projections of the coordinate components $G_{\alpha\beta}$ onto the orthonormal tetrad $e^I:={e^I}_\alpha\,\mathrm{d}x^\alpha$ implied by (2.8):

$$e^0=\mathrm{d}t+y\,\mathrm{d}x, \quad e^1=yK_{11}\,\mathrm{d}x, \quad e^2=(K/y)(\mathrm{d}y+y^2h\,\mathrm{d}x),$$

$$e^3=K_{33}[yg\,\mathrm{d}x+(f/y)\mathrm{d}y+y\,\mathrm{d}z], \tag{2.9}$$

where ${e^\alpha}_I$ is the inverse matrix to ${e^I}_\alpha$, i.e., ${e^\alpha}_I{e^I}_\beta={\delta^\alpha}_\beta$, ${e^\alpha}_J{e^I}_\alpha={\delta^I}_J$. In the parametrization (2.8), the determinant of the metric is

$$g=-(yK_{11}KK_{33})^2. \tag{2.10}$$

The tetrad components of the Einstein tensor corresponding to the metric (2.8) are given in Appendix A of Ref. 5. As seen from there, two combinations of those equations are of first order, they are $K_{11}G_{03}+G_{13}=0$, i.e.,

$$\left(\tfrac{3}{2}K_{33}/K_{11}\right)[({K_{11}}^2-1)K^{-2}f_{,t}+h(hf_{,t}-g_{,t})]=0, \tag{2.11}$$

and $K_{11}G_{02}+G_{12}=0$, i.e.,

$$(K_{11}K)^{-1}[-\tfrac{3}{2}K^2hh_{,t}+\tfrac{1}{2}h-K_{11}K_{11,t}+({K_{11}}^2-1)(2K_{,t}/K-K_{33,t}/K_{33})]=0. \tag{2.12}$$

As shown in Appendix B of Ref. 5, the case $h=0$ does not lead to interesting developments, so we shall proceed further under the assumption

$$h\neq 0. \tag{2.13}$$

Then, Eq. (2.11) implies

$$g_{,t}=[h+(K_{11}{}^2-1)/(hK^2)]f_{,t}. \tag{2.14}$$

With this, the equations $G_{03}=G_{13}=G_{23}=0$ turn out to be equivalent, and they can be written as follows:

$$-\frac{1}{2}\left(\frac{K_{11}{}^2-1}{h}\cdot\frac{K_{33}{}^3 f_{,t}}{K_{11}K}\right)_{,t}+\frac{K_{33}{}^3 f_{,t}}{K_{11}K}=0. \tag{2.15}$$

This invites the introduction of the new variable $u(t)$ by $u_{,t}=h/(K_{11}{}^2-1)$, and then (2.15) becomes

$$\left(\frac{K_{33}{}^3 f_{,u}}{K_{11}K}\right)_{,u}-2\frac{K_{33}{}^3 f_{,u}}{K_{11}K}=0, \tag{2.16}$$

which has the first integral $K_{33}{}^3 f_{,u}/(K_{11}K)=C\mathrm{e}^{2u}$, $C=\text{const}$, i.e.,

$$f_{,t}=C\mathrm{e}^{2u}hK_{11}K/[K_{33}{}^3(K_{11}{}^2-1)]. \tag{2.17}$$

From here on, we shall follow only the special case $C=0$, which is a solution of the Einstein equations, but not a general one: it is a subcase chosen *ad hoc* for further progress with integration. Then, from (2.17) and (2.14) $f=\text{const}$, $g=\text{const}$, and from (2.9) the coordinate transformation $z'=z+f/y+gx$ leads to

$$f=g=0, \tag{2.18}$$

without changing any of the other formulas for $g_{\alpha\beta}$, u^α, w^α, $\omega_{\alpha\beta}$ or $k_{(i)}{}^\alpha$.

The Einstein equations $G_{03}=G_{13}=G_{23}=0$ are now fulfilled identically. We are left with 7 equations that should determine the 4 functions K_{11}, K, K_{33} and h, and the matter density ρ in addition. It will turn out in Sec. IV that the 7 equations are dependent just in the way needed to make the problem self-consistent and determinate.

III. THE FRIEDMANN LIMIT OF THE METRIC

As already stated, the coordinates used in Sec. II are ill-suited for considering the limit $\omega\to 0$. This limit can be calculated after a coordinate transformation and a reparametrization of the metric.

Since $\omega_{12}=-\omega_{21}=\frac{1}{2}$ are the only nonzero components of the rotation tensor, a natural coordinate transformation to consider is

$$y=\omega_0 y', \tag{3.1}$$

where ω_0 is a constant. After the transformation

$$\omega'_{12}=\tfrac{1}{2}\omega_0=-\omega'_{21} \tag{3.2}$$

(all other $\omega_{\alpha\beta}=0$), and the limit of zero rotation is $\omega_0\to 0$. However, before this limit is taken, the metric functions in (2.8) must be reparametrized or else the limit will be singular. The following reparametrizations will do the job:

$$K_{11}=\tilde{K}_{11}/\omega_0,\quad K_{33}=\tilde{K}_{33}/\omega_0,\quad f=\tilde{f}\omega_0. \tag{3.3}$$

The transformation (3.1) and the reparatmetrization (3.3) result in a metric whose limit $\omega_0\to 0$ (with primes and tildes omitted) is

$$\mathrm{d}s^2=\mathrm{d}t^2-(yK_{11}\,\mathrm{d}x)^2-(K/y)^2\,\mathrm{d}y^2-K_{33}{}^2[yg\,\mathrm{d}x+(f/y)\mathrm{d}y+y\,\mathrm{d}z]^2. \tag{3.4}$$

The $k=-1$ Friedmann model results when $g=f=0$ and $K_{11}=K=K_{33}:=R(t)$, where $R(t)$ is the Friedmann scale factor. The resulting coordinates are none of the standard ones, but are related by $y=e^u$ to one of the sets used in the literature [see Eq. (1.3.15) in Ref. 6].

The fact that (3.4), the limit $\omega_0\to 0$ of (2.8), is still more general than the Friedmann metric means that shear survives the transition $\omega\to 0$.

It will be shown at the end of Sec. IV that the explicitly written out Einstein equations do allow a continuous limiting transition $\omega\to 0$, $\sigma\to 0$, and in the limit they reproduce exactly the Friedmann equations.

IV. THE INDEPENDENT EINSTEIN EQUATIONS

We shall now proceed with the subcase (2.18). Equation (2.11) is then fulfilled identically. Equation (2.12) does not change, and it can be more conveniently rewritten if K_{11} is parametrized as follows:

$$K_{11}=\cosh(F). \tag{4.1}$$

Then, from (2.12),

$$K_{33},_t=K_{33}[-\tfrac{3}{2}K^2hh,_t/\sinh^2(F)+\tfrac{1}{2}h/\sinh^2(F)+2K,_t/K-\cosh(F)F,_t/\sinh(F)]. \tag{4.2}$$

When this is substituted into the remaining Einstein equations [(A.1)–(A.10) in Ref. 5], the function K_{33} disappears from the set completely, i.e., we are left with 6 equations to determine h, K, F and the matter-density plus the quadrature implied by (4.2) that allows one to calculate K_{33} once $h(t)$, $K(t)$ and $F(t)$ are known.

Since (2.12) is now satisfied, the equations $G_{02}=0$ and $G_{12}=0$ are equivalent, and they can be written as

$$\begin{aligned} h,_{tt}=&\tfrac{3}{2}K^2hh,_t^2/\sinh^2(F)-5K,_th,_t/K+(2\cosh^2(F)-1)F,_th,_t/\sinh(F)\cosh(F)\\ &+hh,_t/\sinh^2(F)+K,_t/K^3+F,_t/K^2\cosh(F)\sinh(F)-\tfrac{1}{2}h/(K\sinh(F))^2. \end{aligned} \tag{4.3}$$

This is used to eliminate $h,_{tt}$ from the other Einstein equations. The equation $G_{01}=0$ can then be solved for $F,_{tt}$ (see Appendix C in Ref. 5) and this is used to eliminate $F,_{tt}$ from the diagonal components of the Einstein tensor (all the nondiagonal Einstein equations have been used up at this point). After such a substitution, the following identity is fulfilled:

$$G_{11}+G_{33}-2G_{22}\equiv 0, \tag{4.4}$$

i.e., one of the three equations $G_{11}=G_{22}=G_{33}=\Lambda$ can be discarded because it is a consequence of the remaining two. We choose to discard $G_{33}=\Lambda$.

Then, $K,_{tt}$ can be calculated from $G_{22}-G_{11}=0$. The result is

$$\begin{aligned} K,_{tt}=&\tfrac{1}{4}K^3\sinh^{-2}(F)h,_t^2-\tfrac{3}{2}K^3h\cosh(F)\sinh^{-3}(F)F,_th,_t\\ &-\cosh^{-1}(F)\sinh^{-1}(F)K,_tF,_t+2\cosh(F)\sinh^{-1}(F)K,_tF,_t-K\cosh^2(F)\sinh^{-2}(F)F,_t^2\\ &-\tfrac{3}{4}Kh,_t+\tfrac{3}{2}K^3h^2\sinh^{-4}(F)h,_t+\tfrac{3}{4}K^3h^2\sinh^{-2}(F)h,_t\\ &-\tfrac{3}{2}hK,_t-h\sinh^{-2}(F)K,_t-Kh\cosh^{-1}(F)\sinh^{-1}(F)F,_t+\tfrac{3}{2}Kh\cosh^3(F)\sinh^{-3}(F)F,_t\\ &-\tfrac{1}{4}K^{-1}\cosh^2(F)\sinh^{-2}(F)-\tfrac{1}{2}Kh^2\sinh^{-4}(F)-\tfrac{1}{4}Kh^2\sinh^{-2}(F). \end{aligned} \tag{4.5}$$

This is used to eliminate $K,_{tt}$ from the right-hand side of the equation determining $F,_{tt}$ (see Appendix C in Ref. 5), and the result is

$$
\begin{aligned}
F_{,tt} = &-\tfrac{3}{4}K^2\cosh^{-1}(F)\sinh^{-1}(F)h_{,t}^2-\tfrac{3}{2}Kh\cosh^{-1}(F)\sinh^{-1}(F)K_{,t}h_{,t}\\
&+2K^{-2}\cosh^{-1}(F)\sinh(F)K_{,t}^2-K^{-1}K_{,t}F_{,t}-\cosh(F)\sinh^{-1}(F)F_{,t}^2\\
&+\tfrac{3}{4}K^2h^2\cosh^{-1}(F)\sinh^{-1}(F)h_{,t}+\tfrac{3}{2}K^2h^2\cosh^{-1}(F)\sinh^{-3}(F)h_{,t}\\
&+\tfrac{1}{2}\cosh^{-1}(F)\sinh^{-1}(F)h_{,t}-\tfrac{3}{4}\cosh^{-1}(F)\sinh(F)h_{,t}-\tfrac{3}{2}K^{-1}h\cosh^{-1}(F)\sinh^{-1}(F)K_{,t}\\
&-\tfrac{3}{2}K^{-1}h\cosh^{-1}(F)\sinh(F)K_{,t}+h\sinh^{-2}(F)F_{,t}+\tfrac{5}{2}hF_{,t}-\tfrac{1}{4}K^{-2}\cosh^{-1}(F)\sinh(F)\\
&-\tfrac{3}{4}K^{-2}\cosh^{-1}(F)\sinh^{-1}(F)-\tfrac{1}{2}h^2\cosh^{-1}(F)\sinh^{-3}(F)-\tfrac{1}{4}h^2\cosh^{-1}(F)\sinh^{-1}(F).
\end{aligned}
\tag{4.6}
$$

With (4.2), (4.3), (4.5) and (4.6) all substituted, the equation $G_{11}=\Lambda$ reduces to the following form:

$$
\begin{aligned}
G_{11} = &\tfrac{1}{4}K^2\cosh^{-2}(F)h_{,t}^2+\tfrac{3}{2}Kh\cosh^{-2}(F)K_{,t}h_{,t}+\tfrac{3}{2}K^2h\cosh^{-1}(F)\sinh^{-1}(F)F_{,t}h_{,t}\\
&-2K^{-2}\cosh^{-2}(F)\sinh^2(F)K_{,t}^2-2K^{-1}\cosh^{-1}(F)\sinh(F)F_{,t}K_{,t}+F_{,t}^2\\
&+\tfrac{3}{2}K^2h^2\cosh^{-2}(F)h_{,t}-3K^2h^2\sinh^{-2}(F)h_{,t}-\tfrac{1}{2}\cosh^{-2}(F)h_{,t}+\tfrac{3}{2}h_{,t}\\
&+\tfrac{5}{2}K^{-1}h\cosh^{-2}(F)K_{,t}+3K^{-1}hK_{,t}-\tfrac{5}{2}h\cosh^{-1}(F)\sinh^{-1}(F)F_{,t}\\
&-3h\cosh^{-1}(F)\sinh(F)F_{,t}+\tfrac{1}{4}K^{-2}\cosh^{-2}(F)+\tfrac{3}{2}K^{-2}+\tfrac{1}{2}h^2\cosh^{-2}(F)+h^2\sinh^{-2}(F)\\
=&\,\Lambda.
\end{aligned}
\tag{4.7}
$$

Now it may be verified that $G_{11}=\text{const}$ is preserved by Eqs. (4.3), (4.5) and (4.6). This is done as follows. The derivative $(\mathrm{d}/\mathrm{d}t)\,G_{11}$ is calculated, and $h_{,tt}$, $K_{,tt}$ and F_{tt} that reappear are eliminated using (4.3), (4.5) and (4.6). Then, $K_{,t}^2$ is found from (4.7) and used to eliminate $K_{,t}^3$ and $K_{,t}^2$ from $(\mathrm{d}/\mathrm{d}t)\,G_{11}$. The result is the identity $(\mathrm{d}/\mathrm{d}t)\,G_{11}\equiv 0$. This means that, in virtue of the other field equations, if $G_{11}=\Lambda$ holds at any given time, it will remain constant at all other times. Hence, $G_{11}=\Lambda$ is a limitation imposed by the Einstein equations on the initial data for Eqs. (4.3), (4.5), (4.6), and it defines the cosmological constant in terms of the other constants that will appear after (4.3), (4.5) and (4.6) are solved. If $\Lambda=0$, then $G_{11}=0$ reduces the number of arbitrary constants by 1.

Hence, with (4.4), we are left with only four equations: (4.2), (4.7) and any two equations from the set $S=\{(4.3),(4.5),(4.6)\}$, to determine the four functions K_{33}, h, K and F. The third equation in S is implied by the remaining two together with (4.7). The only field equation that has not yet been used up is

$$G_{00}=(8\pi G/c^4)\rho-\Lambda. \tag{4.8}$$

This may be expected to simply define the matter-density in terms of the metric functions. However, in the formulation used in this paper, matter-density enters the equations in two ways: as a source term in G_{00} above, and also through (2.5). From (2.5) and (2.10) it follows that ρ must be related to the other functions by

$$\rho=(K_{11}KK_{33})^{-1}. \tag{4.9}$$

Together with (4.8) and (4.1) this implies that the following must hold:

$$[(G_{00}+\Lambda)\cosh(F)KK_{33}]_{,t}\equiv 0. \tag{4.10}$$

Indeed, this is an identity. This is verified as follows. First, (4.1), (4.2), (4.3), (4.5) and (4.6) are substituted into G_{00} (with $f=g=0$) to eliminate all second derivatives. Then, (4.10) is calculated, and (4.2), (4.3), (4.5) and (4.6) are used to eliminate $K_{33},_t$ and all second derivatives again. Finally, (4.7) is used to eliminate $K,_t^3$ and $K,_t^2$ from the left-hand side of (4.10). In the end, the identity (4.10) results. Hence, (2.5) and (4.8) are consistent in virtue of the other field equations, and moreover $(G_{00}+\Lambda)\cosh(F)KK_{33}=C=\text{const}$ [with second derivatives of h, K and F eliminated by (4.3), (4.5) and (4.6) and with $K,_t^2$ eliminated by (4.7)] is the following first integral of the Einstein equations:

$$K_{33}\Big[-3Kh\sinh(F)F,_t-\frac{3}{2}Kh^2\cosh^{-1}(F)+\frac{3}{2}K\cosh^{-1}(F)\sinh^2(F)h,_t$$
$$+3h\cosh^{-1}(F)\sinh^2(F)K,_t-\frac{3}{2}K^{-1}\sinh^2(F)\cosh^{-1}(F)-\frac{3}{2}K^3h^2\cosh^{-1}(F)h,_t\Big]=C. \tag{4.11}$$

Note that, from (4.8) and (4.9), $C=8\pi G/c^4\neq 0$, and so (4.11) determines K_{33} algebraically. Hence, (4.11) can replace (4.2) as the definition of K_{33}. Thereby, the problem of this paper was reduced to the following procedure.

(1) Find the most general solution of the set $\{(4.3),(4.5),(4.6)\}$. It will contain 6 arbitrary constants $\{C_1,\ldots,C_6\}$.

(2) Impose (4.7) on the $\{h,K,F\}$ found in the previous step. This will be just a definition of Λ in terms of $\{C_1,\ldots,C_6\}$ or, when $\Lambda=0$, an additional constraint imposed on $\{C_1,\ldots,C_6\}$.

(3) Calculate K_{33} from (4.11), with $C=8\pi G/c^4$.

(4) Calculate the matter-density from (4.9).

As shown in Ref. 7, an efficient method to find first integrals of a set of equations exists if the set can be obtained from a Lagrangian. Unfortunately, the problem of determining whether a given set of equations is derivable from a Lagrangian is rather complicated and unsolved in general.[8] It is known that the Einstein equations for class B Bianchi metrics may not admit a Lagrangian, even though the general Einstein equations do (see Ref. 9 for an explanation). It is shown in Appendix A that Eqs. (4.3), (4.5), (4.6) do not follow from the most natural Lagrangian conceivable in this case: a second-degree polynomial in the first derivatives of h, K and F, with coefficients being functions of h, K and F.

For further reference, let us consider the limit of zero rotation in (4.2)–(4.3) and (4.5)–(4.7). After the reparametrization (3.3) we have

$$\cosh(F)=\tilde{K}_{11}/\omega_0,\quad \sinh(F)=\sqrt{\tilde{K}_{11}{}^2/\omega_0^2-1},$$
$$F,_t=\tilde{K}_{11,t}/\sqrt{\tilde{K}_{11}{}^2-\omega_0^2}, \tag{4.12}$$

and then (4.2) in the limit $\omega_0\to 0$ becomes

$$\tilde{K}_{33,t}=\tilde{K}_{33}(2K,_t/K-\tilde{K}_{11,t}/\tilde{K}_{11}), \tag{4.13}$$

which is an identity in the Friedmann limit $\tilde{K}_{11}=K=\tilde{K}_{33}=R(t)$.

The limiting form of (4.3) is

$$h,_{tt}=-5h,_tK,_t/K+2\tilde{K}_{11,t}h,_t/\tilde{K}_{11}+K,_t/K^3. \tag{4.14}$$

The limit $\omega_0\to 0$ of (4.5) is

$$K_{,tt}=-K\tilde{K}_{11,t}{}^2/\tilde{K}_{11}{}^2-\tfrac{3}{4}Kh_{,t}-\tfrac{3}{2}hK_{,t}$$
$$+\tfrac{3}{2}Kh\tilde{K}_{11,t}/\tilde{K}_{11}-1/(4K)+2K_{,t}\tilde{K}_{11,t}/\tilde{K}_{11}. \tag{4.15}$$

The same limit of (4.6) is

$$\tilde{K}_{11,tt}/\tilde{K}_{11}=2K_{,t}^2/K^2-K_{,t}\tilde{K}_{11,t}/(K\tilde{K}_{11})+\tfrac{3}{2}h\tilde{K}_{11,t}/\tilde{K}_{11}-\tfrac{3}{2}h_{,t}-\tfrac{3}{2}hK_{,t}/K-1/(4K^2). \tag{4.16}$$

In the Friedmann limit $\tilde{K}_{11}=K=R(t)$, Eqs. (4.15) and (4.16) become identical:

$$R_{,tt}/R=R_{,t}^2/R^2-\tfrac{3}{4}h_{,t}-1/(4R^2). \tag{4.17}$$

Finally, the limit $\omega_0\to 0$ of (4.7) is

$$-2K_{,t}^2/K^2-2K_{,t}\tilde{K}_{11,t}/(K\tilde{K}_{11})+\tilde{K}_{11,t}{}^2/\tilde{K}_{11}{}^2+\tfrac{3}{2}h_{,t}+3hK_{,t}/K-3h\tilde{K}_{11,t}/\tilde{K}_{11}+3/(2K^2)=\Lambda. \tag{4.18}$$

The Friedmann limit of this is

$$-3R_{,t}^2/R^2+\tfrac{3}{2}h_{,t}+3/(2R^2)=\Lambda. \tag{4.19}$$

Finding $h_{,t}$ from (4.19) and substituting it in (4.17) we obtain

$$R_{,tt}/R=-R_{,t}^2/(2R^2)+1/(2R^2)-\Lambda/2, \tag{4.20}$$

which is exactly one of the Friedmann equations. Incidentally, the $h_{,t}$ found from (4.19), if substituted in (4.14), leads to (4.20) again. Hence, in the Friedmann limit, (4.14) follows from (4.19) and (4.17). The function h, as seen from (3.4), does not enter the limiting metric $\omega\to 0$ at all because, after the reparametrization (3.3), it is multiplied by ω_0.

Note that also (4.11) has a meaningful Friedmann limit. In order to make this limit finite, it must be assumed that

$$C=\tilde{C}/\omega_0^2, \tag{4.21}$$

and then the limit $\omega_0\to 0$ of (4.11) is

$$K_{33}[\Lambda K\tilde{K}_{11}+2K_{,t}^2\tilde{K}_{11}/K+2K_{,t}\tilde{K}_{11,t}-K\tilde{K}_{11,t}{}^2/\tilde{K}_{11}-3\tilde{K}_{11}/K]=\tilde{C}. \tag{4.22}$$

In the Friedmann limit this becomes

$$R(\Lambda R^2+3R_{,t}^2-3)=\tilde{C}. \tag{4.23}$$

Recalling the Friedmann formula for the mass-density, with $k=-1$:

$$3R_{,t}^2/R^2-3/R^2+\Lambda=(8\pi G/c^2)\rho, \tag{4.24}$$

we recognize in (4.23) the familiar mass-conservation formula of the Friedmann model, $\rho R^3=c^2\tilde{C}/(8\pi G)=\text{const}$.

V. THE LIE POINT-SYMMETRIES OF THE EQUATIONS (4.3), (4.5) AND (4.6)

The basic definitions and theorems concerning point-symmetries are presented in detail in Refs. 7 and 8.

Equations (4.3), (4.5) and (4.6) are of the following form:

$$\frac{d^2z^i}{dt^2}=W^i{}_{jk}\frac{dz^j}{dt}\frac{dz^k}{dt}+V^i{}_j\frac{dz^j}{dt}+U^i, \tag{5.1}$$

where $i=0,1,2$; $(z^0,z^1,z^2)=(h,K,F)$ and $W^i{}_{jk}$, $V^i{}_j$ and U^i are functions of the z^i, but not of t. (Incidentally, the independence of t of all these coefficients immediately implies one group of symmetries, $t\to t'=t+s$, where s is the group parameter.) Let the following be a one-dimensional group of point transformations:

$$t'=t'(t,\{z^j\},\tau),\quad z'^i=z'^i(t,\{z^j\},\tau), \tag{5.2}$$

where τ is the group parameter and $\tau=\tau_0$ corresponds to the identity [so that $t'(t,\{z^j\},\tau_0)\equiv t$, etc.]. The generators of this group [the field of vectors tangent to the orbits of the group (5.2)] are then

$$X=\xi\frac{\partial}{\partial t}+\eta^j\frac{\partial}{\partial z^j}, \tag{5.3}$$

where

$$\begin{bmatrix}\xi\\ \eta^j\end{bmatrix}=\frac{d}{d\tau}\begin{bmatrix}t'\\ z'^j\end{bmatrix}_{\tau=\tau_0}. \tag{5.4}$$

The generator X is extended to arbitrary derivatives $d^kz/dt^k:=\overset{(k)}{z}$ by the recursive formulas

$$\overset{(0)j}{\eta}=\eta^j,\qquad \overset{(k)j}{\eta}=\frac{d\overset{(k-1)j}{\eta}}{dt}-\frac{d^kz^j}{dt^k}\frac{d\xi}{dt}, \tag{5.5}$$

$$\overset{(k)}{X}=\xi\frac{\partial}{\partial t}+\eta^j\frac{\partial}{\partial z^j}+\overset{(1)j}{\eta}\frac{\partial}{\partial\overset{(1)j}{z}}+\cdots+\overset{(k)j}{\eta}\frac{\partial}{\partial\overset{(k)j}{z}}. \tag{5.6}$$

The derivatives d/dt in (5.5) are total derivatives, i.e.,

$$\frac{d}{dt}f(t,\{z^i\},\{\overset{(1)i}{z}\},\ldots,\{\overset{(k)i}{z}\})=\frac{\partial f}{\partial t}+\frac{dz^j}{dt}\frac{\partial f}{\partial z^j}+\sum_{p=1}^{k}\overset{(p+1)j}{z}\frac{\partial}{\partial\overset{(p)j}{z}},$$

and the order n to which the generator X has to be extended is equal to the highest order of derivatives in the set (5.1) ($n=2$ in our case). A generator of a point-symmetry obeys then

$$\overset{(n-1)}{X}\ \Omega^i=\frac{d\overset{(n-1)i}{\eta}}{dt}-\Omega^i\frac{d\xi}{dt}, \tag{5.7}$$

where Ω^i is the right-hand side of (5.1). Equations (5.7) must be identities in all the derivatives $\overset{(1)i}{z},\ldots,\overset{(n-1)i}{z}$, and so they imply several separate equations to be obeyed by the ξ and η^i.

For our equations (5.1), Eqs. (5.7) imply the following four relations:

$$\xi_{,kl}+W^j{}_{kl}\xi_{,j}=0, \tag{5.8}$$

$$\eta^i{}_{,kl}=W^i{}_{kl,s}\eta^s+2W^i{}_{s(l}\eta^s{}_{,k)}-W^s{}_{kl}\eta^i{}_{,s}+\delta^i{}_{(l}V^s{}_{k)}\xi_{,s}+V^i{}_{,(l}\xi_{,k)}+2\frac{\partial^2\xi}{\partial t\,\partial z^{(k}}\delta^i{}_{l)}, \tag{5.9}$$

where parentheses on indices denote symmetrization,

$$\frac{\partial^2 \eta^i}{\partial t\,\partial z^k} = W^i{}_{ks}\frac{\partial \eta^s}{\partial t} + \frac{1}{2}V^i{}_{k,s}\eta^s + \frac{1}{2}V^i{}_s\eta^s{}_{,k} - \frac{1}{2}V^s{}_k\eta^i{}_{,s} + \frac{1}{2}V^i{}_k\frac{\partial \xi}{\partial t} + U^i\xi_{,k} + \frac{1}{2}\delta^i{}_k U^s\xi_{,s} + \frac{1}{2}\delta^i{}_k\frac{\partial^2 \xi}{\partial t^2}, \tag{5.10}$$

$$\frac{\partial^2 \eta^i}{\partial t^2} = V^i{}_s\frac{\partial \eta^s}{\partial t} + U^i{}_{,s}\eta^s - U^s\eta^i{}_{,s} + 2U^i\frac{\partial \xi}{\partial t}. \tag{5.11}$$

The general solution of these equations [with $W^i{}_{kl}$, $V^i{}_k$ and U^i read off from (4.3), (4.5) and (4.6)] is

$$X = A\frac{\partial}{\partial t} + B\left(t\frac{\partial}{\partial t} - h\frac{\partial}{\partial h} + K\frac{\partial}{\partial K}\right), \tag{5.12}$$

where A and B are arbitrary constants. The proof that this is the most general solution is laborious but straightforward, it is given in Appendix E of Ref. 5. Hence, our set of equations has a two-dimensional symmetry group whose generators are

$$X_{(1)} = \frac{\partial}{\partial t}, \quad X_{(2)} = t\frac{\partial}{\partial t} - h\frac{\partial}{\partial h} + K\frac{\partial}{\partial K}, \tag{5.13}$$

and the corresponding finite symmetry transformations are

$$t' = t + \tau_1, \quad (h', K', F') = (h, K, F);$$

$$t' = \mathrm{e}^{\tau_2}t, \quad h' = \mathrm{e}^{-\tau_2}h, \quad K' = \mathrm{e}^{\tau_2}K, \quad F' = F, \tag{5.14}$$

where τ_1 and τ_2 are the group parameters.

Unfortunately, these symmetries do not lead to any discernible simplification of the set $S = \{(4.3),(4.5),(4.6)\}$. In variables adapted to the generator $X_{(1)}$, the independent variable is K, and $t(K)$ is one of the functions. The set (5.1) thus transformed is of first order in $\phi(K) := dt/dK$, but the first-order equation is still a member of a complicated set and none of the equations separate out. Moreover, after the transformed set is algebraically solved for $t_{,KK}$, $h_{,KK}$ and $F_{,KK}$, the right-hand sides become polynomials of *third* degree in $t_{,K}$, $h_{,K}$ and $F_{,K}$.

The variables adapted to the generator $X_{(2)}$ are (t', h', K'), where

$$t = \mathrm{e}^{K'}t', \quad K = \mathrm{e}^{K'}, \quad h = \mathrm{e}^{-K'}h'. \tag{5.15}$$

In these variables, the set (5.1) becomes of first order in $\psi(t') = K'_{,t'}$. However, after it is solved for $h'_{,t't'}$, $K'_{,t't'}$ and $F_{,t't'}$, the right-hand sides of $h'_{,t't'}$ and $F_{,t't'}$ contain rational functions of the form $W/(1 + t'K'_{,t'})$, where W is a monomial of second degree in some of the $h'_{,t'}$, $K'_{,t'}$ and $F_{,t'}$. Neither equation separates out. It is not possible to adapt the variables to both the generators simultaneously because the group is nonabelian. This author was not able to make any use of the new variables.

VI. FIRST INTEGRALS THAT ARE POLYNOMIALS IN $(h_{,t}, K_{,t}, F_{,t})$

Suppose that the set $\tilde{S} = \{(4.3),(4.5),(4.6),(4.7)\}$ has a first integral of the form

$$I := Q_{ij}\dot{z}^i\dot{z}^j + L_i\dot{z}^i + E = C = \text{const}, \tag{6.1}$$

where C is an arbitrary constant, $Q_{ij} = Q_{ji}$, L_i and E are unknown functions of (h, K, F), $i, j = 1,2,3$, $z^1 = h, z^2 = K, z^3 = F$. Then $\mathrm{d}I/\mathrm{d}t \equiv 0$ in virtue of $\tilde{S}$, i.e., using (5.1) to eliminate $\dot{z}^i$:

$$(2Q_{ij}\dot{z}^j+L_i)(W^i{}_{kl}\dot{z}^k\dot{z}^l+V^i{}_k\dot{z}^k+U^i)+Q_{ij,k}\dot{z}^i\dot{z}^j\dot{z}^k+L_{i,j}\dot{z}^i\dot{z}^j+E_{,i}\dot{z}^i\equiv 0. \tag{6.2}$$

It can be verified that first integrals of the form (6.1) do not exist for our set $\tilde{S}$. The calculations are conceptually straightforward, but lead through horrible intermediate expressions, so they are not reported here. The hypothesis that (6.1) is a first integral uniquely leads to an equation that is equivalent to (4.7).

The same method may be used to test whether our set of equations admits a constraint that would be a polynomial of degree 1 or 2 in the first derivatives. The only difference with respect to the procedure of looking for a first integral is that in verifying whether (6.2) is zero, Eq. (6.1) is used, too. If a nontrivial solution of (6.2) with this additional simplification is found, then it means that the derivative of (6.1) by t is zero if (6.1) holds for any fixed t. Then, such (6.1) is a constraint preserved by the set $\tilde{S}$. However, even this attempt has not led to useful results. Constraints of degree 2, i.e., those with $Q_{ij}\neq 0$, lead to prohibitively complicated equations and could not be investigated. One constraint of the form (6.1) with $Q_{ij}=0$ was found, but it is equivalent to the square bracket in (4.11) being zero, and so implies zero matter density. Again, the details are not reported because they contain complicated equations, but no ingenious ideas. This result proves the usefulness of the method—a sensible constraint was revealed—but the solution with zero density is not interesting for cosmology, and thus not necessarily worth investigating.

The zero-density constraint was found without using Eq. (4.7). Equation (4.7) would reduce the number of unknown functions by one, but the resulting set of equations is prohibitively complicated and no progress was achieved.

VII. SUMMARY OF RESULTS

It was shown that the Einstein equations for the metric (2.8) with $f=g=0$ are self-consistent and solvable. They reduce to the set $S=\{(4.3),(4.5),(4.6)\}$ to determine h, K and $K_{11}=\cosh(F)$, and (4.11) to determine K_{33} (where $C=8\pi G/c^4$). The matter density is found from (4.9). The first derivatives of the functions obeying the set S must obey (4.7).

The Friedmann solution with $k=-1$ is contained among the solutions of this set, as shown in Eqs. (4.12)–(4.24). Unfortunately, no explicit example of a more general solution could be found. Attempts to follow *ad hoc* Ansatzes produced uninteresting results. The Ansatz $K=K_{33}$ led to the deSitter solution in disguise, in which the t-lines had nonzero rotation. The Ansatz $K_{11}=K/C$ ($C=\text{const}$), which is consistent with the Friedmann limit, led to such complicated equations that it could not even be verified if they are not contradictory. The assumption of zero shear implies zero expansion, in virtue of the theorem $(\sigma=0)\Rightarrow(\omega\theta=0)$ that holds for dust (see Ref. 10).

The set S was shown to have a two-dimensional group of point-symmetries, given by (5.14), and to admit no Lagrangian of the Hilbert type. It was also verified that no first integrals of the form (6.1) exist.

The progress achieved in this paper was the reduction of the problem of existence of a rotating generalization of the $k=-1$ Friedmann model to the technical problem of finding an explicit solution of the set S. The solvability of the set S may be taken for granted because the Friedmann model itself was shown to be one of its solutions. It is still unknown, though, whether a continuous family of solutions exists labeled by the parameter ω (rotation) such that the limit $\omega\to 0$ taken in the explicit solution leads to the $k=-1$ Friedmann model.

A similar analysis as done here should be done for the other promising cases identified in Ref. 3.

ACKNOWLEDGMENTS

The algebraic manipulations for this paper were carried out using the computer algebra system Ortocartan[11,12] that was for this purpose extended by several new programs.[12,13] The author is

APPENDIX A: NONEXISTENCE OF A HILBERT-TYPE LAGRANGIAN FOR THE SET {(4.3), (4.5), (4.6)}

Equations (4.3), (4.5) and (4.6) can be written in the form

$$\frac{\mathrm{d}^2 z^i}{\mathrm{d}t^2} = W^i{}_{jk}\frac{\mathrm{d}z^j}{\mathrm{d}t}\frac{\mathrm{d}z^k}{\mathrm{d}t} + V^i{}_j\frac{\mathrm{d}z^j}{\mathrm{d}t} + U^i, \tag{A1}$$

where $i=0,1,2$; $z^0=h$, $z^1=K$, $z^2=F$ and $W^i{}_{jk}$, $V^i{}_j$ and U^i are functions of (h,K,F) (but not of t). Note that the set (A.1) is covariant with respect to arbitrary transformations $z^i \to z'^i = f^i(\{z^j\})$: the first derivatives $\mathrm{d}z^j/\mathrm{d}t$ transform then like a contravariant vector, and so do the terms U^i, the coefficients $V^i{}_j$ transform like a mixed tensor, and the coefficients $(-W^i{}_{jk})$ transform like components of an affine connection. [The nontensorial terms in the transformed $(-W^i{}_{jk})$ arise from $\mathrm{d}^2 z^i/\mathrm{d}t^2$.] The most natural Ansatz for a Lagrangian for (A1) is

$$L = Q_{ij}\frac{\mathrm{d}z^i}{\mathrm{d}t}\frac{\mathrm{d}z^j}{\mathrm{d}t} + L_i\frac{\mathrm{d}z^i}{\mathrm{d}t} + \Phi, \tag{A2}$$

where Q_{ij}, L_i and Φ are functions of (h,K,F). Such a Lagrangian would result from the Hilbert Lagrangian by taking out a complete divergence and integrating the result with respect to the spatial variables. The Euler–Lagrange equations implied by (A2) are

$$Q_{is}\frac{\mathrm{d}^2 z^s}{\mathrm{d}t^2} = -\left(Q_{ki,l} - \frac{1}{2}Q_{kl,i}\right)\frac{\mathrm{d}z^k}{\mathrm{d}t}\frac{\mathrm{d}z^l}{\mathrm{d}t} + \frac{1}{2}(L_{k,i} - L_{i,k})\frac{\mathrm{d}z^k}{\mathrm{d}t} + \frac{1}{2}\Phi_{,i}. \tag{A3}$$

If these are to be equivalent to (A1), then the following must hold:

$$Q_{is}W^s{}_{kl} = -\tfrac{1}{2}(Q_{ki,l} + Q_{li,k} - Q_{kl,i}), \tag{A4}$$

$$Q_{is}V^s{}_k = \tfrac{1}{2}(L_{k,i} - L_{i,k}), \tag{A5}$$

$$Q_{is}U^s = \tfrac{1}{2}\Phi_{,i}. \tag{A6}$$

Equation (A4) implies that $(-W^i{}_{jk})$ must be Christoffel symbols constructed from the metric Q_{ij}, Eq. (A5) implies that $\frac{1}{2}L_i$ must be a vector potential for the tensor field $Q_{is}V^s{}_k$, and Eq. (A6) implies that $\Phi/2$ must be a scalar potential for the vector field $Q_{is}U^s$. All of these are strong conditions and they may be impossible to fulfill in many cases.

Indeed, for our equations (4.3), (4.5), (4.6), the solution of (A4) turns out to be $Q_{ij} \equiv 0$, i.e., the Lagrangian (A2) does not exist. An outline of the proof is given in Appendix D of Ref. 5.

Since the Euler–Lagrange equations (A4) are covariant with respect to arbitrary transformations of the Lagrangian variables [in our case $h \to h'(h,K,F)$, etc.], and equations of the form (A1) are covariant, too, the conclusion that a Lagrangian of the form (A2) exists (or does not exist) is coordinate-independent, i.e., having shown that Eqs. (4.3),(4.5),(4.6) do not follow from a Lagrangian (A2) in our variables $\{h,K,F\}$, we know that no such Lagrangian will exist in any other variables.

Since in all the type-D solutions of the Einstein vacuum field equations with a cosmological term each maximal spin-weighted component of the electromagnetic spinor field satisfies a decoupled equation and there exists a two-index Killing spinor field; we show, via the adjoint operators method, that a symmetry operator for the Maxwell equations can be constructed. © *2001 American Institute of Physics.* [DOI: 10.1063/1.1319515]

I. INTRODUCTION

In a recent paper[1] we showed that the symmetry operator for the Maxwell equations obtained when the space–time is a type-D solution of the Einstein vacuum field equations with a cosmological constant in Ref. 2 (without an explicit derivation) can be obtained under the conditions that the background space–time admits an algebraically general two-index Killing spinor field and that *each component* of the electromagnetic spinor field satisfies a decoupled equation. Our aim in the present paper is to obtain, via the method of adjoint operators, the same result but under the condition that *each maximal spin-weighted* component satisfies a decoupled equation. We think that the approach described in this work, to obtain the main result, offers hope of an improved understanding of the analogous problem for the gravitational perturbation equations. Thus, in Sec. II we review the adjoint operators method originally introduced by Wald[3] and in Sec. III we apply it to the Maxwell equations in order to obtain the symmetry operator for the Maxwell equations. In this work, the spinor formalism and the Newman–Penrose notation are used throughout; see Refs. 4, 5 for all relevant notation and definitions.

II. THE METHOD OF ADJOINT OPERATORS

Let f be a tensor or spinor field (its components representing unknown variables) that satisfies a coupled system of homogeneous linear partial differential equations given by

$$\mathcal{E}(f)=0, \tag{1}$$

where $\mathcal{E}$ is a linear differential operator that maps tensor or spinor fields like f into tensor or spinor fields, possibly of a type different from that of f. If by performing linear combinations of Eqs. (1) and their derivatives, one can obtain a decoupled equation of the form

$$\mathcal{O}(\chi)=0, \tag{2}$$

where χ is a function made out (linearly) of the components of f and their derivatives and $\mathcal{O}$ is a linear differential operator that maps scalar fields into scalar fields. Then, there exists a linear operator $\mathcal{T}$ such that $\chi=\mathcal{T}(f)$ and the fact that Eq. (2) is obtained by linear combinations of Eqs.

a)Electronic mail: gsilva@fcfm.buap.mx; gsilva@phyast.pitt.edu

(1) and their derivatives means that there must exist a linear differential operator $\mathcal{S}$ [representing the manipulations that one must perform on Eq. (1) to derive Eq. (2)] such that $\mathcal{SE}(f)=\mathcal{O}(\chi)=\mathcal{OT}(f)$. Hence

$$\mathcal{SE}=\mathcal{OT}, \tag{3}$$

must hold as an operator identity, so that when both sides of Eq. (3) are applied to a solution f of Eq. (1) one gets the decoupled equation (2).

By defining the adjoint, $\mathcal{A}^\dagger$, of a linear differential operator $\mathcal{A}$ in such a way that $\mathcal{A}^\dagger$ is also a linear operator and

$$(\mathcal{AB})^\dagger=\mathcal{B}^\dagger\mathcal{A}^\dagger, \tag{4}$$

for any pair of linear operators $\mathcal{A}$ and $\mathcal{B}$ whose composition is well defined, then using this property one can establish the (main result of the adjoint operators method) following.

Theorem 1: Suppose the identity $\mathcal{SE}=\mathcal{OT}$ holds for the linear partial differential operators $\mathcal{S}$, $\mathcal{E}$, $\mathcal{O}$ and $\mathcal{T}$ and that ψ satisfies $\mathcal{O}^\dagger(\psi)=0$. Then $\mathcal{S}^\dagger(\psi)$ satisfies $\mathcal{E}^\dagger(\mathcal{S}^\dagger(\psi))=0$.

Proof: Taking the adjoint of $\mathcal{SE}=\mathcal{OT}$ we have $\mathcal{E}^\dagger\mathcal{S}^\dagger=\mathcal{T}^\dagger\mathcal{O}^\dagger$, applying these operators to ψ, we obtain

$$\mathcal{E}^\dagger(\mathcal{S}^\dagger(\psi))=0, \tag{5}$$

which is the desired result. Thus, in particular, if $\mathcal{E}^\dagger=\pm\mathcal{E}$, then $\mathcal{S}^\dagger(\psi)$ is a solution of $\mathcal{E}(f)=0$.

Remark 1: If ψ satisfies $\mathcal{O}^\dagger(\psi)=0$ then, $\mathcal{E}^\dagger\mathcal{S}^\dagger(\psi)=0$, and hence if $\mathcal{E}^\dagger=\pm\mathcal{E}$, then $0=\mathcal{SES}^\dagger(\psi)=\mathcal{OTS}^\dagger(\psi)$. *Therefore, if $\mathcal{E}^\dagger=\pm\mathcal{E}$, the operator $\mathcal{TS}^\dagger$ maps solutions of the adjoint equation $\mathcal{O}^\dagger(\psi)=0$ into solutions of the equation $\mathcal{O}(\chi)=0$.*

Observe that to prove Theorem 1 the important property is that given by Eq. (4). In particular if the adjoint of a linear operator $\mathcal{A}$, that maps tensor or spinor fields into tensor or spinor fields, is defined as that linear operator $\mathcal{A}^\dagger$ such that

$$g\cdot\mathcal{A}(f)-[\mathcal{A}^\dagger(g)]\cdot f=\nabla_\alpha s^\alpha, \tag{6}$$

for every pair of tensor or spinor fields f and g for which the full contraction of g and $\mathcal{A}(f)$ denoted by $g\cdot\mathcal{A}(f)$, yields a scalar field, where s^α is some vector field (which depends on f and g), then it follows that Eq. (4) holds. For example for the derivative operators $(D,\Delta,\delta,\overline{\delta})$ one finds that[6]

$$\begin{aligned}
D^\dagger&=-(D+\varepsilon+\overline{\varepsilon}-\rho-\overline{\rho}),\\
\Delta^\dagger&=-(\Delta-\gamma-\overline{\gamma}+\mu+\overline{\mu}),\\
\delta^\dagger&=-(\delta+\beta-\overline{\alpha}-\tau+\overline{\pi}),\\
\overline{\delta}^\dagger&=-(\overline{\delta}-\alpha+\overline{\beta}+\pi-\overline{\tau}).
\end{aligned} \tag{7}$$

III. THE SOLUTION OF THE MAXWELL EQUATIONS AND THE SYMMETRY OPERATOR

It is well-known that the (source-free) Maxwell equations in a space–time solution of the Einstein vacuum field equations in terms of the electromagnetic potential are given by

$$\nabla^{\dot{A}}{}_{B}\nabla^{\dot{C}(A}\epsilon^{B)C}\Phi_{\dot{C}C}=0. \tag{8}$$

Comparing Eqs. (1) and (8) we see that for the electromagnetic case, the components of the spinor field f are $\Phi^{B}{}_{\dot{C}}$, while the components of the operator $\mathcal{E}$ are given by

$$[\mathcal{E}]^{\dot{A}A\dot{C}C}=\nabla^{\dot{A}}{}_{B}\nabla^{\dot{C}(A}\epsilon^{B)C}. \tag{9}$$

If $H_{A\dot{A}}$ and $W_{A\dot{A}}$ are two complex vector fields, then from the above expression we have

$$H\cdot\mathcal{E}(W)\equiv H_{A\dot{A}}\nabla^{\dot{A}}{}_{B}\nabla^{\dot{C}(A}W^{B)}{}_{\dot{C}}=\nabla^{\dot{A}}{}_{B}[H_{A\dot{A}}\nabla^{\dot{C}(A}W^{B)}{}_{\dot{C}}]-[\nabla^{\dot{C}(A}W^{B)}{}_{\dot{C}}][\nabla^{\dot{A}}{}_{B}H_{A\dot{A}}], \tag{10}$$

from this follows that

$$H\cdot\mathcal{E}(W)-[\mathcal{E}(H)]\cdot W=\nabla_{A\dot{A}}s^{A\dot{A}}, \tag{11}$$

where

$$s_{A}{}^{\dot{B}}=H_{A\dot{A}}\nabla^{\dot{C}(A}W^{B)}{}_{\dot{C}}-W_{A\dot{A}}\nabla^{\dot{C}(A}H^{B)}{}_{\dot{C}}. \tag{12}$$

Therefore, $\mathcal{E}^{\dagger}=\mathcal{E}$.

Since the Maxwell equations in terms of the electromagnetic spinor field can be written in the following form:

$$\nabla^{\dot{A}}{}_{B}\varphi^{AB}=0, \tag{13}$$

where

$$\varphi^{AB}=\nabla^{\dot{C}(A}\Phi^{B)}{}_{\dot{C}}, \tag{14}$$

then from these equations we obtain that, in this case, the components of the field χ are given by φ^{AB} and the components of the operator $\mathcal{T}$ are given by

$$[\mathcal{T}]^{AB\dot{C}C}=\nabla^{\dot{C}(A}\epsilon^{B)C}. \tag{15}$$

The hardest part in applying the method of adjoint operators to solve a coupled system of homogeneous linear partial differential equations is to obtain one decoupled equation. For the electromagnetic case, it is well-known that when the space–time is a type-D solution of the Einstein vacuum field equations with a possible nonvanishing cosmological term, each component of the electromagnetic spinor field φ_{AB} satisfies a decoupled equation. This means that there must exist three different operators $\mathcal{S}_{(i)}$ (with $i=0,1,2$) such that when they are applied to the Maxwell equations one obtains the decoupled equations for the components of the electromagnetic spinor field. Here we present one way of obtaining these three operators which is useful in writing the decoupled equations in a covariant way. For this end we write the Maxwell equations with sources in terms of the electromagnetic spinor field, i.e.,

$$J_{B\dot{M}}=\nabla_{\dot{M}}{}^{A}\varphi_{AB}, \tag{16}$$

and we assume that the operators $\mathcal{S}_{(i)}$ are first-order differential operators that can be written as

$$\mathcal{S}_{(i)}^{B\dot{M}}=gH_{(i)}^{AB}\nabla_{A}^{\dot{M}}f, \tag{17}$$

where g and f are scalar fields and $H_{(i)}^{AB}$, for each value of i, is a two-index symmetric spinor field, which will be determined from the condition that when $\mathcal{S}_{(i)}$ is applied to the Maxwell equations one obtains a decoupled equation for the φ_i component of the electromagnetic spinor field. (i.e., for $\varphi_0=o_Ao_B\varphi^{AB}$, $\varphi_1=o_{(A}\iota_{B)}\varphi^{AB}$ or $\varphi_2=\iota_A\iota_B\varphi^{AB}$; where $\{o^A,\iota^A\}$ is a spin frame such that $o_A\iota^A=1$.) In other words, we require that

$$\mathcal{S}_{(i)}^{B\dot{M}}J_{B\dot{M}}=\mathcal{O}_i\varphi_i \tag{18}$$

(here and in what follows the repeated index i does not mean summation convention) where $\mathcal{O}_i$, for each value of i, is a second-order differential operator that maps scalar fields into scalar fields. Observe that Eq. (18) is Eq. (3) for the electromagnetic case applied to the electromagnetic potential vector field. This means that in this way we not only are going to obtain the operators $\mathcal{S}_{(i)}$ but also the operators $\mathcal{O}_i$, which is equivalent to obtain the decoupled equations.

Using the Newman–Penrose notation we have that Eq. (18) is equivalent to

$$\begin{aligned}\mathcal{S}^{B\dot{M}}_{(i)}J_{B\dot{M}} = fg\{&H^{00}_{(i)}[(\delta-\overline{\alpha}-\beta+\overline{\pi}+\delta\ln f)J_{0\dot{0}}-(D-\varepsilon+\overline{\varepsilon}-\overline{\rho}+D\ln f)J_{0\dot{1}}+\sigma J_{1\dot{0}}-\kappa J_{1\dot{1}}]\\&+H^{10}_{(i)}[(\delta+\beta-\overline{\alpha}+\overline{\pi}+\tau+\delta\ln f)J_{1\dot{0}}-(D+\varepsilon+\overline{\varepsilon}-\overline{\rho}+\rho+D\ln f)J_{1\dot{1}}\\&+(\Delta-\gamma-\overline{\gamma}-\mu+\overline{\mu}+\Delta\ln f)J_{0\dot{0}}-(\overline{\delta}-\alpha+\overline{\beta}-\overline{\tau}-\pi+\overline{\delta}\ln f)J_{0\dot{1}}]\\&+H^{11}_{(i)}[(\Delta+\gamma-\overline{\gamma}+\overline{\mu}+\Delta\ln f)J_{1\dot{0}}-(\overline{\delta}+\alpha+\overline{\beta}-\overline{\tau}+\overline{\delta}\ln f)J_{1\dot{1}}-\nu J_{0\dot{0}}+\lambda J_{0\dot{1}}]\},\end{aligned} \tag{19}$$

where

$$\begin{aligned}J_{0\dot{0}}&=[(\overline{\delta}-2\alpha+\pi)\varphi_0-(D-2\rho)\varphi_1-\kappa\varphi_2],\\J_{0\dot{1}}&=[(\Delta-2\gamma+\mu)\varphi_0-(\delta-2\tau)\varphi_1-\sigma\varphi_2],\\J_{1\dot{0}}&=[(\overline{\delta}+2\pi)\varphi_1-(D+2\varepsilon-\rho)\varphi_2-\lambda\varphi_0],\\J_{1\dot{1}}&=[(\Delta+2\mu)\varphi_1-(\delta+2\beta-\tau)\varphi_2-\nu\varphi_0].\end{aligned} \tag{20}$$

Now we impose the conditions that $i=0$ and that the only component different from zero of $H^{AB}_{(0)}$ is $H^{00}_{(0)}$. Under these conditions Eq. (19) can be written in the following form $\mathcal{S}^{B\dot{M}}_{(0)}J_{B\dot{M}}=\mathcal{O}_0\varphi_0+\mathcal{P}_1\varphi_1+\mathcal{P}_2\varphi_2$, where $\mathcal{P}_1$ and $\mathcal{P}_2$ are differential operators such that when the commutator between D and δ and the Ricci identities are used they can be rewritten in the following form:

$$\begin{aligned}&[(\Delta-3\gamma-\overline{\gamma}+\overline{\mu})(-2\kappa)+(\overline{\delta}-3\alpha+\overline{\beta}-\overline{\tau})(2\sigma)+2\rho\delta\ln f-2\tau D\ln f\\&\quad+(2\rho+D\ln f)\delta-(2\tau+\delta\ln f)D-4\Psi_1],\end{aligned} \tag{21}$$

and

$$[(2\rho+D\ln f)\sigma-(2\tau+\delta\ln f)\kappa+\Psi_0], \tag{22}$$

respectively. From these expressions we observe that $\mathcal{P}_1$ and $\mathcal{P}_2$ are identically to the zero operator if

$$\kappa=\sigma=\Psi_0=\Psi_1=0,\quad \delta\ln f=-2\tau \text{ and } D\ln f=-2\rho. \tag{23}$$

It is important to remark that the integrability conditions on these equations are identically satisfied. Actually they are the conditions such that the background space-time admits a shear-free congruence of null geodesics, i.e., the space-time is algebraically special. In this case one can choose the spin frame $\{o^A,\iota^A\}$ with o^A being the repeated principal null spinor of the conformal curvature. From Eq. (23) we have that Eq. (19) reduces to

$$\mathcal{S}^{B\dot{M}}_{(0)}J_{B\dot{M}}=gfH^{00}_{(0)}[(\delta-\beta-\overline{\alpha}+\overline{\pi}-2\tau)(\overline{\delta}-2\alpha+\pi)-(D-\varepsilon+\overline{\epsilon}-\overline{\rho}-2\rho)(\Delta-2\gamma+\mu)]\varphi_0. \tag{24}$$

Therefore, we observe that when $\Phi_A{}^{\dot{B}}$ satisfies the Maxwell equations without sources and the space-time is algebraically special then the operator $\mathcal{S}_{(0)}$ engenders a decoupled equation for φ_0 (with $H^{AB}_{(0)}=o^A o^B$ and $g=f^{-1}$) given by

$$\mathcal{O}_0\varphi_0\equiv[(\delta-\beta-\overline{\alpha}+\overline{\pi}-2\tau)(\overline{\delta}-2\alpha+\pi)-(D-\varepsilon+\overline{\varepsilon}-\overline{\rho}-2\rho)(\Delta-2\gamma+\mu)]\varphi_0=0. \quad (25)$$

If now we impose the conditions that $i=2$ and that the only component different from zero of $H^{AB}_{(2)}$ is $H^{11}_{(2)}$, then after using the commutator of Δ and $\overline{\delta}$ and the Ricci identities we obtain that the differential operators acting on φ_0 and φ_1 can be rewritten in the following form:

$$[(D+3\varepsilon+\overline{\varepsilon}-\overline{\rho})(2\nu)-(\delta+3\beta-\overline{\alpha}+\overline{\pi})(2\lambda)-2\mu\overline{\delta}\ln f$$
$$+2\pi\Delta\ln f+(\Delta\ln f-2\mu)\overline{\delta}-(\overline{\delta}\ln f-2\pi)\Delta-4\Psi_3], \quad (26)$$

and

$$[(2\mu-\Delta\ln f)\lambda-(2\pi-\overline{\delta}\ln f)\nu+\Psi_4], \quad (27)$$

respectively. Therefore, in this case the conditions to obtain a decoupled equation for φ_2 are

$$\lambda=\nu=\Psi_3=\Psi_4=0, \quad \Delta\ln f=2\mu \ \text{ and } \ \overline{\delta}\ln f=2\pi. \quad (28)$$

The integrability conditions on these equations are identically satisfied. As in the previous case they are equivalent to say that the space-time admits a shear-free congruence of null geodesics. Therefore, if in addition to the decoupled equation for φ_0 we want to obtain a decoupled equation for φ_2, then the background space–time must be of type-D. With $H^{AB}_{(2)}=\iota^A\iota^B$, where ι^A is the other repeated principal null spinor field of the conformal curvature, and using Eq. (28) we find that when $J_{B\dot{M}}=0$ Eq. (19) reduces to

$$\mathcal{O}_2\varphi_2\equiv[(\Delta+\gamma-\overline{\gamma}+\overline{\mu}+2\mu)(D+2\varepsilon-\rho)-(\overline{\delta}+\alpha+\overline{\beta}-\overline{\tau}+2\pi)(\delta+2\beta-\tau)]\varphi_2=0. \quad (29)$$

Finally, assuming that $i=1$ and that the only component different from zero of the spinor field $H^{AB}_{(1)}$ is $H^{10}_{(1)}$, then using the commutators between D and δ, Δ and $\overline{\delta}$ and the Ricci identities we find that the differential operators acting on φ_0 and φ_2, can be rewritten in a such a way that they are identically to the zero operator under the conditions (23) and (28). In this case the decoupled equation for φ_1 is given by

$$\mathcal{O}_1\varphi_1\equiv[(\delta+\beta-\overline{\alpha}+\overline{\pi}-\tau)(\overline{\delta}+2\pi)-(D+\varepsilon+\overline{\varepsilon}-\overline{\rho}-\rho)(\Delta+2\mu)$$
$$-(\Delta-\gamma-\overline{\gamma}+\overline{\mu}+\mu)(D-2\rho)+(\overline{\delta}-\alpha+\overline{\beta}-\overline{\tau}+\pi)(\delta-2\tau)]\varphi_1=0. \quad (30)$$

Remark 2: The conditions given by Eqs. (23) and (28) are equivalent to say that the background space–time admits a two-index Killing spinor field. That is, a symmetric spinor field L_{AB} that satisfies $\nabla_{\dot{A}(B}L_{CD)}=0$,[7] in this case $L_{AB}=-2\phi^{-1}o_{(A}\iota_{B)}$, where $\phi=\sqrt{f}$. This means that the existence of decoupled equations for the components of the electromagnetic spinor field is very close related to the two-index Killing spinor field admitted by all the type-D metrics. We will see that the Killing spinor is also crucial for the construction of a differential operator that maps the space of solutions of the Maxwell equations without sources into itself.

From the computations presented above we have that the expressions for the $\mathcal{S}_{(i)}$ operators are given by

$$\mathcal{S}^{B\dot{M}}_{(0)}=\phi^2 o^A o^B\nabla_A{}^{\dot{M}}\phi^{-2}, \quad \mathcal{S}^{B\dot{M}}_{(1)}=\phi^2 o^{(A}\iota^{B)}\nabla_A{}^{\dot{M}}\phi^{-2}, \quad \mathcal{S}^{B\dot{M}}_{(2)}=\phi^2\iota^A\iota^B\nabla_A{}^{\dot{M}}\phi^{-2}. \quad (31)$$

Therefore, the decoupled equations in a covariant way can be written as

$$\phi^2\nabla_{(A}{}^{\dot{M}}\phi^{-2}\nabla_{|\dot{M}|}{}^{C}\varphi_{B)C}=0. \tag{32}$$

(Parentheses denote symmetrization on the indices enclosed and the indices between bars are excluded from the symmetrization.) Observe that Eq. (32) is equivalent to $\mathcal{O}_i\varphi_i=0$. Using Eq. (7), from Eqs. (25), (29) and (30) we obtain $\mathcal{O}_i^\dagger$. The corresponding adjoint equations are given by

$$\begin{aligned}
\mathcal{O}_0^\dagger\psi_2 &\equiv [(\overline{\delta}+\alpha+\overline{\beta}-\overline{\tau})(\delta+2\beta+\tau)-(\Delta+\gamma-\overline{\gamma}+\overline{\mu})(D+2\varepsilon+\rho)]\psi_2=0,\\
\mathcal{O}_1^\dagger\psi_1 &\equiv [(\overline{\delta}+\overline{\beta}-\alpha-\overline{\tau})\delta-(\Delta-\gamma-\overline{\gamma}-\mu+\overline{\mu})D+(\delta+\beta-\overline{\alpha}+\tau+\overline{\pi})\overline{\delta}\\
&\quad -(D+\varepsilon+\overline{\varepsilon}-\overline{\rho}+\rho)\Delta]\psi_1=0,\\
\mathcal{O}_2^\dagger\psi_0 &\equiv [(D+\varepsilon+\overline{\varepsilon}-\overline{\rho})(\Delta-2\gamma-\mu)-(\delta-\beta-\overline{\alpha}+\overline{\pi})(\overline{\delta}-2\alpha-\pi)]\psi_0=0.
\end{aligned} \tag{33}$$

The covariant version of these equations is obtained from Eq. (32) by applying property (4) to the differential operator appearing in Eq. (32). Thus Eqs. (33) are equivalent to

$$\nabla_{\dot{R}(A}\phi^{-2}\nabla^{S\dot{R}}\phi^2\psi_{C)S}=0. \tag{34}$$

Since in this case we have a decoupled equation for each component of the electromagnetic spinor field then, in accordance with Theorem 1, we can construct three solutions to the Maxwell equations without sources. Using property (4) to obtain $\mathcal{S}_{(i)}^\dagger$ from Eqs. (31), we find that these three solutions are given by

$$\Phi_{(0)}^{B\dot{M}}=\phi^{-2}\nabla_A{}^{\dot{M}}\phi^2 o^A o^B\psi_2, \tag{35}$$

$$\Phi_{(1)}^{B\dot{M}}=\phi^{-2}\nabla_A{}^{\dot{M}}\phi^2 o^{(A}\iota^{B)}\psi_1, \tag{36}$$

$$\Phi_{(2)}^{B\dot{M}}=\phi^{-2}\nabla_A{}^{\dot{M}}\phi^2 \iota^A\iota^B\psi_0. \tag{37}$$

After some computations one can show that these solutions are equivalent each other. Since the $\Phi_{(i)}$'s are solutions of the Maxwell equations then

$$\Phi^{B\dot{M}}=\phi^{-2}\nabla_A{}^{\dot{M}}\phi^2\psi^{AB}, \tag{38}$$

where ψ_{AB} is a solution of Eq. (34), is also a solution of the Maxwell equations. It is important to remark that if the background space-time is not of type-D, but algebraically special, then we only can obtain a decoupled equation (for φ_1 or φ_2) and in this case the solution to the Maxwell equations without sources is given by Eq. (35) or Eq. (37) and therefore, we cannot write it in a covariant way.

That $\Phi^{B\dot{M}}$ given by Eq. (38) satisfies the Maxwell equations is guaranteed by Theorem 1. Then this means that

$$\varphi_{AB}=\nabla^{\dot{C}}{}_{(A}\Phi_{B)\dot{C}}, \tag{39}$$

and

$$G_{\dot{A}\dot{B}}=\nabla^B{}_{(\dot{R}}\Phi_{\dot{S})B}, \tag{40}$$

are solutions of the Maxwell equations. From Remark 1 we have that if ψ_i is a solution of $\mathcal{O}_i^\dagger\psi_i=0$ then $\varphi_i=[\mathcal{T}\mathcal{S}^\dagger(\psi)]_i$ is a solution of $\mathcal{O}_i\varphi_i=0$. Using $\mathcal{T}$ given by Eq. (15) and computing

$\mathcal{S}^{\dagger}_{(i)}$ from Eqs. (31) and (4), one finds that the statement of Remark 1, in a covariant way, is equivalent to $\varphi_i=\varphi_{AB}=0$, the last equality is obtained from the fact that ψ_{AB} satisfies Eq. (34). Therefore, the operator $\mathcal{TS}^{\dagger}$ maps solutions of Eqs. (33), into the trivial solution of Eqs. (25), (29) and (30). This is equivalent to say that the vector potential given by Eq. (38) is a vector potential of a self-dual electromagnetic field given by $G_{A\dot{A}}$ in Eq. (40).

Remark 3: A straightforward computation shows that if φ_0,φ_1 and φ_2 satisfy Eqs. (25), (30) and (29), respectively, then $\psi_0=\phi^{-2}\varphi_0,\psi_1=-\phi^{-2}\varphi_1$ and $\psi=\phi^{-2}\psi_2$ satisfy Eqs. (33), recall that $\phi=\sqrt{f}$. In a covariant way this means that if φ_{AB} is a solution of Eq. (32) then $\psi_{AB}=L_{AC}L_{BD}\varphi^{CD}$ is a solution of Eq. (34). Using this fact and Eqs. (38) and (40) one finds that if φ_{AB} is a solution of the Maxwell equations without sources in a type-D solution of the Einstein vacuum field equations with a cosmological term then $G_{\dot{R}\dot{S}}=\nabla^{B}{}_{(\dot{R}}\phi^{-2}\nabla^{S}{}_{\dot{S})}\phi^{2}L_{BD}L_{SE}\varphi^{DE}$ is also a solution of the Maxwell equations.[1,2,8]

Observe that the result established in the previous remark was obtained analyzing the relationship between the solutions to the scalar equations $\mathcal{O}_i\varphi_i=0$ and $\mathcal{O}_i^{\dagger}\psi_i=0$. It turns out that the connection between the two sets of solutions is given by the two-index Killing spinor admitted by all the type-D metrics. It seems that this result is also a direct consequence of the existence of decoupled equations for *each component* of the electromagnetic spinor field, but in what follows we are going to show that we can obtain the same result without assuming a decoupled equation for φ_1. For this end, we rewrite $G_{A\dot{B}}$ in the following form:

$$
\begin{aligned}
G_{\dot{0}}&=2\phi^{-2}[(\overline{\delta}-\alpha-\overline{\beta}+3\pi)(\overline{\delta}-2\alpha+\pi)\varphi_0+(D+\varepsilon-\overline{\varepsilon}-3\rho)(D+2\varepsilon-\rho)\varphi_2],\\
G_{\dot{1}}&=\phi^{-2}\{[(\Delta-\gamma-\overline{\gamma}+3\mu-\overline{\mu})(\overline{\delta}-2\alpha+\pi)+(\overline{\delta}-\alpha+\overline{\beta}+3\pi+\overline{\tau})(\Delta-2\gamma+\mu)]\varphi_0\\
&\quad+[(D+\varepsilon+\overline{\varepsilon}-3\rho+\overline{\rho})(\delta+2\beta-\tau)+(\delta+\beta-\overline{\alpha}-3\tau-\overline{\pi})(D+2\varepsilon-\rho)]\varphi_2\},\\
G_{\dot{2}}&=2\phi^{-2}[(\Delta-\gamma+\overline{\gamma}+3\mu)(\Delta-2\gamma+\mu)\varphi_0+(\delta+\beta+\overline{\alpha}-3\tau)(\delta+2\beta-\tau)\varphi_2].
\end{aligned}
\tag{41}
$$

In doing this we only have used the Maxwell equations and the facts that when the background space-time is of type-D the following commutation relations hold[9] (in a spin frame such that the only non-vanishing component of the Weyl spinor is Ψ_2):

$$
\begin{aligned}
&[D+(p+1)\varepsilon+\overline{\varepsilon}+q\rho-\overline{\rho}](\delta+p\beta+q\tau)=[\delta+(p-1)\beta-\overline{\alpha}+q\tau+\overline{\pi}](D+p\varepsilon+q\rho),\\
&[\Delta-(p-1)\gamma-\overline{\gamma}-q\mu+\overline{\mu}](\overline{\delta}-p\alpha-q\pi)=[\overline{\delta}-(p-1)\alpha+\overline{\beta}-q\pi-\overline{\tau}](\Delta-p\gamma-q\mu),
\end{aligned}
\tag{42}
$$

where p and q are arbitrary constants.

The remarkable thing is that Eqs. (41) can be written in a covariant way using the two-index Killing spinor admitted by all the type-D space–times, which was our desired aim. In fact one direct computation, using a spin frame such that Ψ_2 is the only component different from zero of the Weyl spinor curvature, shows that Eqs. (41) are equivalent to

$$
T_{\dot{R}\dot{S}}=\nabla^{B}{}_{(\dot{R}}\phi^{-2}\nabla^{S}{}_{\dot{S})}\phi^{2}Y_{BS},
\tag{43}
$$

where

$$
Y_{AB}=\tfrac{1}{2}[L_{AC}L_{BD}\varphi^{CD}+L^{D}{}_{C}L^{C}{}_{(A}\varphi_{B)D}].
\tag{44}
$$

Observe that since $\varphi_{AB}=0$, this operator maps solutions with indices without dots of the Maxwell equations into solutions with dotted indices of the Maxwell equations.

IV. CONCLUDING REMARKS

Remember that Eqs. (41) were obtained using the Maxwell equations, in a spin frame such that the only component different from zero of the Weyl spinor curvature is Ψ_2 and the identities

(42), which are equivalent to the Teukolsky–Starobinsky identities[8,9] for the electromagnetic case. From this, it seems that the fact that Eqs. (41) can be rewritten in a covariant way by using the two-index Killing spinor is because there exist some kind of ''equivalence'' between the Teukolsky-Starobinsky identities and the two-index Killing spinor admitted by all the type-D space-times.

From the result obtained above we hope that an analogous program can be applied to the Weyl spinor perturbations of type-D vacuum backgrounds where one can only obtain decoupled equations for the maximal spin-weighted components of the Weyl spinor perturbations. In this case there exist also the Teukolsky-Starobinsky identities.[10,11]

Finally we point out that it could be interesting to study in detail the relationship between the result obtained here and the result obtained from a generalization of the Killing-Yano equation point of view.[12]

(Received 18 July 2000; accepted for publication 31 August 2000)

We suggest a new approach to the problem of dimensional reduction of initial/boundary value problems for evolution equations in one spatial variable. The approach is based on higher-order (generalized) conditional symmetries of the equations involved. It is shown that reducibility of an initial value problem for an evolution equation to a Cauchy problem for a system of ordinary differential equations can be fully characterized in terms of conditional symmetries which leave invariant the equation in question. We also give some examples of the solution of initial value problems for second- and third-order nonlinear differential equations by reduction by their conditional symmetries. We give a systematic classification of general second-order partial differential equations admitting second-order conditional symmetries, based on Lie's classification of invariant second-order ordinary differential equations. This yields five classes of principally new initial value problems for nonlinear evolution equations which admit no Lie symmetries and are reducible via second-order conditional symmetries. © *2001 American Institute of Physics.* [DOI: 10.1063/1.1330199]

I. INTRODUCTION

As is well-known, the basic idea of the classical Lie approach to solving partial differential equations (PDEs) is to use symmetries to reduce the number of independent variables in order to get an ordinary differential equation. If one can then solve the resulting ordinary differential equation, the whole procedure yields particular solutions of the initial PDE. This procedure of dimensional reduction is referred to in the literature as symmetry reduction, and it has proved to be a very efficient tool for constructing exact solutions of many linear and nonlinear differential equations arising in different areas of applied mathematics (see, e.g., Refs. 1–3 and the references therein).

On the other hand, the problem of the application of the symmetry approach to the analysis of boundary and initial value problems still remains a great challenge for mathematicians. The main difficulty is that the symmetry groups admitted by boundary and initial value problems arising in applications are not sufficiently rich to allow for the effective use of the technique of symmetry reduction. It would be natural to attempt to exploit conditional (nonclassical) symmetries of PDEs in order to extend the range of the initial/boundary value problems that can be handled within the framework of the symmetry approach.

Our aim in the present paper is to present our view of the problem of dimensional reduction of initial value problems for evolution equations in two independent variables t, x:

$$u_t = F(t,x,u,u_1,u_2,\ldots,u_n), \tag{1}$$

[a)]Electronic mail: pehor@mai.liu.se
[b)]Electronic mail: renat@imath.kiev.ua

where $u \in C^n(\mathbf{R^2},\mathbf{R^1})$, $u_k=\partial^k u/\partial x^k$, $1\leqslant k\leqslant n$. The approach we give below is based on higher-order conditional symmetries of PDEs of the form (1). The concept of higher-order conditional symmetry was introduced by Fushchych and Zhdanov,[4] and independently by Fokas and Liu.[5] It was proved in Ref. 4 that it is higher-order conditional symmetries that are responsible for the ''nonlinear separation of variables'' introduced by Galaktionov[6] (see also the related papers addressing this problem[7–9]).

The structure of the paper is as follows. In Sec. II we give some necessary notations, definitions and theorems. In Sec. III, we formulate the principal theorem on the reduction of the initial value problem for a PDE of the form (1) to a Cauchy problem for some system of ordinary differential equations. In addition, we give two illustrative examples of applications of the theorem to the reduction of initial value problems for the second- and third-order nonlinear evolution equations. Section IV is devoted to the systematic classification of second-order evolutionary PDEs using their second-order conditional symmetries. The results of this classification are used to describe the initial value problems for second-order PDEs that admit dimensional reductions to Cauchy problems for some systems of ordinary differential equations.

II. BASIC NOTATIONS AND DEFINITIONS

It is known that reducibility of any PDE in two variables to a single ordinary differential equation is in one-to-one correspondence with its Q-conditional symmetry[10,11] (see also Refs. 12–17). We have proved in Ref. 18 that reducibility of (1) to a system of several ordinary differential equations is in one-to-one correspondence with its invariance under a nonpoint group of infinitesimal transformations,

$$\begin{aligned} u' &= u+\epsilon\eta(t,x,u,u_1,\ldots,u_N),\\ u_1' &= u_1+\epsilon D_x\eta(t,x,u,u_1,\ldots,u_N),\ldots, \end{aligned} \tag{2}$$

provided some smoothness requirements are satisfied. The above group is generated by the Lie–Bäcklund vector field,

$$Q=\sum_{k=0}^{\infty}(D_x^k\eta)\frac{\partial}{\partial u_k}\equiv\eta\frac{\partial}{\partial u}+(D_x\eta)\frac{\partial}{\partial u_1}+(D_x^2\eta)\frac{\partial}{\partial u_2}+\cdots. \tag{3}$$

In formulas (1), (3) we use the following notation:

$$D_x=\frac{\partial}{\partial x}+\sum_{k=0}^{\infty}u_{k+1}\frac{\partial}{\partial u_k},\quad D_x^{j+1}=D_x(D_x^j),\quad D_x^0=1.$$

Remark 1: In general, the function η in (3) may also depend on derivatives of the function u with respect to t. However, on the solution manifold of PDE (1) we can express all the derivatives of u with respect to t in terms of $t,x,u,u_1,u_2,\ldots$, and thus eliminate derivatives with respect to the variable t.

Remark 2: If the function η has the structure

$$\eta=\tilde{\eta}(t,x,u)-\xi_0(t,x,u)u_t-\xi_1(t,x,u)u_1, \tag{4}$$

then the Lie–Bäcklund vector field (3) is equivalent to a Lie vector field and can be represented in the standard form (*see, e.g., Refs. 2, 19*):

$$Q=\xi_0(t,x,u)\frac{\partial}{\partial t}+\xi_1(t,x,u)\frac{\partial}{\partial x}+\tilde{\eta}(t,x,u)\frac{\partial}{\partial u}.$$

As the form of a Lie–Bäcklund vector field is fully defined by the form of the coefficient η of $\partial/\partial u$ we will use the notation

$$Q=\eta\frac{\partial}{\partial u}+\ldots,$$

instead of (3).

Definition 1: PDE (1) is invariant under the Lie–Bäcklund vector field (3) if the condition

$$Q(u_t-F)\big|_M=0 \tag{5}$$

holds, where M is the set of all differential consequences of the equation $u_t-F=0$, that is $D_x^jD_t^k(u_t-F)=0, j,k=0,1,2,\ldots$.

Definition 2: PDE (1) is conditionally-invariant under the Lie–Bäcklund vector field (3) if the following condition holds:

$$Q(u_t-F)\big|_{M\cap L_x}=0. \tag{6}$$

Here the symbol L_x stands for the set of all differential consequences of the equation $\eta=0$ with respect to x, that is $D_x^j\eta=0, j=0,1,2,\ldots,$.

The procedure for constructing Lie–Bäcklund vector fields is, in fact, encoded in the above definitions. If one considers the problem of finding Lie–Bäcklund symmetries in the sense of Definition 1, then the first thing to do is to act with the operator Q on the expression u_t-F, considered as a function of the independent variables $t,x,u,u_t,u_1,\ldots,u_n$. The next step is to eliminate the derivatives $u_{tj}, j=0,1,2,\ldots,$ with the use of the equation $u_t-F=0$ and its differential consequences $D_x^j(u_t-F)=0, j=1,2,\ldots,$. Equating the resulting expression to zero yields a system of linear PDEs called the system of determining equations. Solving this system yields the most general form of the Lie–Bäcklund vector field (3) admitted by Eq. (1). Further details about the procedure for calculating higher symmetries of PDEs and numerous examples of equations possessing these symmetries can be found in Refs. 2, 19, 20. The procedure for calculating higher conditional symmetries is essentially the same. The only difference is the necessity of taking into account not only the differential consequences of Eq. (1) but also the differential consequences $D_x^j\eta=0, j=1,2,\ldots,$ of the invariance condition $\eta=0$. This additional restriction, on the one hand, extends considerably the scope of invariant equations (as the number of variables to be split, decreases) but, on the other hand, yields a nonlinear system of determining equations.

Clearly, if PDE (1) is invariant under the Lie–Bäcklund vector field (3), then it is conditionally invariant under it; however, the converse is not true. Consequently, this means that Definition 2 is a generalization of the standard definition of invariance of a partial differential equation with respect to the Lie–Bäcklund vector field.

If we consider the nonlinear PDE,

$$\eta(t,x,u,u_1,\ldots,u_N)=0, \tag{7}$$

as an N-th-order ordinary differential equation with respect to variable x, then its general integral can be given (locally) in the form

$$u(t,x)=U(t,x,\varphi_1(t),\varphi_2(t),\ldots,\varphi_N(t)), \tag{8}$$

where $\varphi_j(t)$, $(j=1,\ldots,N)$ are arbitrary smooth functions. In the following, we call expression (8) the *ansatz* invariant under the Lie–Bäcklund vector field (3). The following result (see Ref. 18) establishes the connection between reducibility of a given PDE (1) to ordinary differential equations and its higher-order conditional symmetry.

Theorem 1: *Let Eq. (1) with $F\in C^{N+1}(\mathcal{D})$, where $\mathcal{D}$ is an open domain in $\mathbf{R}^{n+3}$, be conditionally invariant under Lie–Bäcklund vector field (3) with $\eta\in C^2(\mathcal{D}')$, where $\mathcal{D}'$ is an open*

domain in $\mathbf{R}^{N+3}$ *and* $\partial\eta/\partial u_N \neq 0$ *on* $\mathcal{D}'$. *Then ansatz (8) invariant under the Lie–Bäcklund vector field (3) reduces PDE (1) to a system of N ordinary differential equations for some functions* $\varphi_j(t)$ $(j=1,\ldots,N)$,

$$\dot{\varphi}_j = F_j(t,\varphi_1,\ldots,\varphi_N), \quad j=1,\ldots,N. \tag{9}$$

Now suppose the converse. Namely, that ansatz (8), where the function U and its derivatives $\partial U^{k+1}/\partial\varphi_j\partial x^k$, $(j=1,\ldots,N,\ k=0,\ldots,N)$ *exist and are continuous on an open domain* $\mathcal{D}_1$ *in* $\mathbf{R}^{N+2}$, *reduces (1) to a system of ordinary differential equations (9) with* $F_i \in C^1(\mathcal{D}_1')$, *where* $\mathcal{D}_1'$ *is an open domain in* $\mathbf{R}^{N+2}$. *Then there exists a Lie–Bäcklund vector field (3) such that Eq. (1) is conditionally-invariant with respect to it.*

The principal reason for the existence of the phenomenon of nonlinear separation of variables in nonintegrable evolution equations is their higher-order conditional symmetry. Of course, the usual Lie and higher-order Lie symmetries can be also used to reduce nonlinear PDEs that have the necessary algebraic properties, but there exist equations that admit no Lie symmetries but are nonetheless reducible to one or several ordinary differential equations due to their (first- or higher-order) conditional symmetry. As an example we give the following nonlinear PDE:

$$u_t = u_{xx} + f_1(t, r(u_x)-x)u_x + f_2(t, r(u_x)-x) - \frac{1}{r'(u_x)}, \tag{10}$$

where f_1, f_2, r are arbitrary smooth functions of their arguments with $r'(u_x)\neq 0$. This equation admits neither first- nor higher-order Lie symmetries (except for the trivial one-parameter translation group by u). However, it can be reduced to a system of two ordinary differential equations due to the fact that Eq. (10) is conditionally invariant with respect to the Lie–Bäcklund field,

$$Q = (r'(u_x)u_{xx} - 1)\frac{\partial}{\partial u} + \cdots.$$

III. REDUCTION OF INITIAL VALUES PROBLEMS FOR EVOLUTION PDES

Consider the following initial value problem for the evolution equation (1):

$$\begin{aligned} u_t &= F(t,x,u,u_1,u_2,\ldots,u_n), \\ (\alpha(x)u_1 + \beta(x)u)\big|_{t=t_0} &= \gamma(x), \end{aligned} \tag{11}$$

where $\alpha(x)$, $\beta(x)$, $\gamma(x)$ are smooth functions.

If the problem (11) is invariant under a one-parameter transformation group, then it is possible to reduce it by symmetry reduction. However, this approach is too restrictive, since a choice of initial conditions that are invariant with respect to a Lie group can be very limited. Indeed, the transformation group in question must leave invariant the initial surface at $t=t_0$, and this imposes rather strong limitations on the exploitation of symmetry reduction in its classical setting. For instance, even such a simple symmetry as invariance under t-translations violates the symmetry of problem (11).

We will show that using higher-order conditional symmetries enables us to overcome this difficulty. The principal idea is to rewrite the generator of a one-parameter transformation group,

$$Q = \xi_0(t,x,u)\frac{\partial}{\partial t} + \xi_1(t,x,u)\frac{\partial}{\partial x} + \tilde{\eta}(t,x,u)\frac{\partial}{\partial u},$$

as a canonical generator of a Lie–Bäcklund field of the form (3), with $\eta = \tilde{\eta}(t,x,u) - \xi_0(t,x,u)u_t - \xi_1(t,x,u)u_1$, and then to eliminate all t derivatives with the use of Eq. (1). Since the vector field (3) generates an infinitesimal transformation group of the form (2), the initial

surface at $t=t_0$, as well as any boundary surface $X(x)=0$, is invariant with respect to it, and an *arbitrary* Lie symmetry can, in principle, be used for dimensional reduction of the initial value problem (11)! However, the price for this is that the order of the symmetry operator is no longer equal to one, and the standard procedure of symmetry reduction has to be modified in order to be applicable to the case under investigation. To this end we will use Theorem 1.

One of the immediate conclusions is that higher-order conditional symmetry is not just one more exotic concept, but the natural and efficient tool for handling initial value problems (11) within the framework of the symmetry approach.

It is natural to expect that, provided PDE (1) admits higher-order conditional symmetry (and some reasonable restrictions are satisfied), there exist functions $\alpha(x)$, $\beta(x)$, $\gamma(x)$ such that the initial value problem (11) reduces [by virtue of the ansatz (8)] to the Cauchy problem for the functions $\varphi_j(t)$, $(j=1,\ldots,N)$. This means that PDE (1) should reduce to a system of ordinary differential equations (9), and the initial condition given in (11) should reduce to a set of algebraic relations prescribing the values of the functions $\varphi_j(t)$, $(j=1,\ldots,N)$ at $t=t_0$.

To make the above procedure meaningful one has to give a formal definition of what is meant by a reduction of the initial-value problem,

$$(\alpha(x)u_1+\beta(x)u)\big|_{t=t_0}=\gamma(x). \tag{12}$$

Definition 3: We say that ansatz (8) reduces the initial-value condition (12) if substituting it into (12) yields an expression that vanishes identically when

$$\varphi_i(t_0)=C_i, \quad i=1,2,\ldots,N,$$

where $C_1,\ldots,C_N$ are some constants.

We prove the following assertion.

Theorem 2: *Ansatz (8), invariant with respect to the Lie–Bäcklund field (3), reduces the initial-value condition (12) if and only if*

(a) the system of two PDEs,

$$\eta(t,x,u,u_1,\ldots,u_N)=0, \;\; a(t,x)u_1+b(t,x)u-c(t,x)=0, \tag{13}$$

is compatible, and

(b) its solution is obtained from the general integral (8) of equation $\eta=0$ considered as an ordinary differential equation with respect to x.

Proof: The implication *reduction* $\Rightarrow$ *compatibility* is evident. We prove the converse assertion.

Suppose that conditions *a* and *b* of the theorem hold. Then, substituting ansatz (8) into the left-hand side of the second equation of (13) yields an expression of the form $R(t,x,\varphi_1(t),\varphi_1(t),\ldots,\varphi_N(t))$.

As the solution of system (13) exists (by assumption) and belongs to the family (8), there are constants $C_1,C_2,\ldots,C_N$ such that the relation

$$R(t,x,C_1,C_2,\ldots,C_N)=0$$

holds. This means that ansatz (8) reduces the initial-value condition. This establishes the theorem.

Definition 4: We say that the equation

$$\eta(t,x,u,u_1,\ldots,u_N)=0, \tag{14}$$

considered as an ordinary differential equation with respect to x, is conditionally invariant under the operator

$$X=\xi(t,x,u)\frac{\partial}{\partial x}+\zeta(t,x,u)\frac{\partial}{\partial u}, \tag{15}$$

with $\xi \neq 0$ *if the following relation holds:*

$$\tilde{X}\,\eta|_{\mathcal{M}} = 0. \tag{16}$$

Here, $\tilde{X}$ *is the* N*th prolongation of the operator* X*. The symbol* $\mathcal{M}$ *stands for the intersection of the surface defined in the space* $\mathbf{R}^{N+3}$ *of the variables* t, x, u, u_t, u_x,..., u_N *by the equation* $\eta = 0$ *and differential consequences* (*with respect to* x) *of the equation* $\xi(t,x,u)u_1 - \zeta(t,x,u) = 0$ *up to the order* $N-1$*. When* $\xi = 0$*, we say that (14) is conditionally invariant under the operator (15), if solving the relation* $\zeta(t,x,u) = 0$ *with respect to* u *yields an exact solution of (14).*

Theorem 3: *Ansatz (8), invariant with respect to the Lie–Bäcklund field (3), reduces the initial value condition (12) if and only if*

(a) Eq. (9) is conditionally invariant under the operator (15) with $\xi = \alpha(x)$, $\zeta = -\beta(x)u + \gamma(x)$, *and*

(b) the solution of the corresponding system (13) exists and is obtained from the general integral (8) of the equation $\eta = 0$*, considered as an ordinary differential equation with respect to* x.

Proof: To prove the theorem it is sufficient to show that, given condition b, then condition a of Theorem 3 is equivalent to condition a of Theorem 2.

Since the assertion to be proved is evident for the case $\alpha = 0$, we will concentrate on the case when $\alpha \neq 0$.

When $\alpha \neq 0$, we can make a change of variables,

$$\tilde{x} = X(t,x), \quad \tilde{u} = U_1(t,x)u + U_2(t,x),$$

so that the operator (15) takes the form $\tilde{X} = \partial/\partial\tilde{x}$ (to simplify notations, we omit the tilde in the sequel). Now, system (13) reads as follows:

$$\tilde{\eta}(t,x,u,u_1,\ldots,u_N) = 0, \;\; u_1 = 0. \tag{17}$$

Compatibility of this system means that the function $\tilde{\eta}(t,x,u,0,\ldots,0)$ is independent of x, whence we find that there exist smooth functions

$$a_0(t,u,u_1,\ldots,u_N), \;\; a_i(t,x,u,u_1,\ldots,u_N), \;\; i = 1,2,\ldots,N,$$

such that

$$\tilde{\eta}(t,x,u,u_1,\ldots,u_N) = a_0(t,u,u_1,\ldots,u_N) + \sum_{i=1}^{N} a_i(t,x,u,u_1,\ldots,u_N)u_i\,.$$

Hence, we conclude that the equation $\tilde{\eta} = 0$ is conditionally invariant with respect to the operator $\partial/\partial x$. Reversing this argument completes the proof of the equivalence of conditions a of Theorems 2 and 3. This proves Theorem 3.

As an immediate consequence of Theorem 3, we see that a necessary condition for the reducibility of a Cauchy problem by solutions invariant under some Lie–Bäcklund field (3) is the conditional invariance of the equation $\eta = 0$ with respect to the operator (15) with $\xi = \alpha(x)$, $\zeta = -\beta(x)u + \gamma(x)$. In view of this fact, we can formulate the following symmetry approach to the reduction of initial value problems (11) for the case when the corresponding evolution equation admits first- or higher-order conditional symmetry:

(i) rewrite the symmetry operator in the canonical form (3),

(ii) calculate the classical or conditional symmetry of the equation $\eta = 0$ within the class of operators,

$$X = \alpha(x)\frac{\partial}{\partial x} + (-\beta(x)u + \gamma(x))\frac{\partial}{\partial u}, \tag{18}$$

(iii) carry out the reduction of the initial value problem (11) to a Cauchy problem for a system of ordinary differential equations using ansatz (8), invariant with respect to the Lie–Bäcklund vector field (3).

Note that condition b of Theorem 3 cannot be neglected, since conditional invariance alone cannot guarantee reducibility of the corresponding initial value problem. As an example, consider the Lie–Bäcklund vector field,

$$Q=(u_x+u^2-1)\frac{\partial}{\partial u}+\dots .$$

The equation $u_x+u^2-1=0$ is evidently invariant under translations by x. Furthermore, system

$$u_x+u^2-1=0,\ \ u_1=0$$

is compatible [it has the solution $u(t,x)=1$]. However, the ansatz,

$$u(t,x)=\tanh(x+\varphi(t)), \tag{19}$$

which is invariant under Q, does not reduce the initial condition $u_1|_{t=t_0}=0$. The reason for this is that the function $u(t,x)=1$ does not belong to the family (19), and thus the condition b of Theorem 3 fails to hold.

Let us now proceed to giving examples which illustrate the main features of the whole procedure. As the first example, we consider the nonlinear heat-conduction equation,

$$u_t=u_x^{-1}u_{xx},\ \ u_x\neq 0. \tag{20}$$

It is evidently invariant with respect to the one-parameter transformation group having the generator $Q=\partial/\partial t+a\,(\partial/\partial u)$ with a being an arbitrary constant. Our aim is to describe the initial value problems,

$$\begin{gathered} u_t=u_x^{-1}u_{xx}, \\ (\alpha(x)u_x+\beta(x)u)|_{t=t_0}=\gamma(x), \end{gathered} \tag{21}$$

that are reducible to Cauchy problems for some first-order systems of ordinary differential equations. First we note that, since the initial surface at $t=t_0$ is not invariant with respect to the group generated by the operator Q, we cannot apply the symmetry reduction method in its standard form. However, if we rewrite Q in the canonical form (3) and eliminate the t derivative on the solution manifold of PDE (20), then the resulting Lie–Bäcklund vector field,

$$\tilde{Q}=(u_x^{-1}u_{xx}-a)\frac{\partial}{\partial u}+\dots,$$

generates an infinitesimal transformation group leaving invariant the initial surface $t=t_0$. Consequently, we can apply the procedure developed above and based on Theorem 3. Solving the invariance condition $u_x^{-1}u_{xx}-a=0$ gives the ansatz for $u=u(t,x)$,

$$u(t,x)=\varphi_1(t)\exp(ax)+\varphi_2(t), \tag{22}$$

which reduces the initial PDE (20) to a system of two ordinary differential equations for φ_1, φ_2 (Theorem 1).

In order to exploit Theorem 3, we calculate the Lie symmetry of equation $u_{xx}-au_x=0$ and obtain the five-dimensional invariance algebra with basis elements,

$$e_1=\frac{\partial}{\partial x},\quad e_2=\exp(ax)\left(\frac{\partial}{\partial x}+au\frac{\partial}{\partial u}\right),$$

$$e_3=u\frac{\partial}{\partial u},\quad e_4=\exp(ax)\frac{\partial}{\partial u},\quad \frac{\partial}{\partial u}.$$

In other words, the most general form of the Lie vector field admitted by PDE $u_{xx}-au_x=0$ reads as

$$C_1\frac{\partial}{\partial x}+C_2\exp(ax)\left(\frac{\partial}{\partial x}+au\frac{\partial}{\partial u}\right)+C_3u\frac{\partial}{\partial u}+C_4\exp(ax)\frac{\partial}{\partial u}+C_5\frac{\partial}{\partial u},$$

where C_1, C_2,..., C_5 are arbitrary real constants. Hence, using Theorem 3, we find the form of the unknown functions $\alpha(x)$, $\beta(x)$, $\gamma(x)$ to be

$$\alpha(x)=(C_1+C_2\exp(ax)),\quad \beta(x)=-C_3-aC_2\exp(ax),$$

$$\gamma(x)=C_4+C_5\exp(ax).$$

Direct verification shows that the initial value problem,

$$\begin{gathered}u_t=u_x^{-1}u_{xx},\\ ((C_1+C_2\exp(ax))u_x-(C_3+aC_2\exp(ax))u)|_{t=t_0}=C_4+C_5\exp(ax),\end{gathered}\tag{23}$$

under $C_2(aC_1-C_3)\neq 0$ fulfills the conditions of Theorem 3 and, consequently, can be reduced to a Cauchy problem for a system of ordinary differential equations. Indeed, inserting ansatz (22) into (23) yields

$$\varphi_1'(t)=0,\quad \varphi_2'(t)=a,$$

$$\varphi_1(t_0)=\frac{aC_5+C_4}{aC_1-C_3},\quad \varphi_2(t_0)=\frac{C_5}{C_2},\quad C_2(aC_1-C_3)\neq 0.$$

Finally, solving the above Cauchy problem gives the following unique solution of the initial value problem (23):

$$u(t,x)=\frac{aC_5+C_4}{aC_1-C_3}\exp(ax)+a(t-t_0)+\frac{C_5}{C_2}.$$

Next, we apply the above scheme for reduction of the initial value problem for the third-order nonlinear PDE,

$$u_t=u_{xxx}+u_x^2-4auu_x+4a^2u^2,\tag{24}$$

where a is an arbitrary real parameter. Note that when $a\neq 0$, Eq. (24) cannot be solved by the methods of soliton theory, and in this sense it is nonintegrable. When $a=0$, (24) is reduced to the KdV equation by the (nonpoint) change of dependent variable $v(t,x)=u_x(t,x)$. In what follows we suppose that $a\neq 0$.

Direct calculation shows that Eq. (24) is conditionally invariant with respect to the Lie–Bäcklund vector field (3) with $\eta=u_{xxx}-3au_{xx}+2a^2u_x$. On calculating the Lie symmetry of the equation $\eta=u_{xxx}-3au_{xx}+2a^2u_x=0$, and taking into account Theorem 3, we get the following initial value problem for PDE (24):

$$
\begin{aligned}
&u_t = u_{xxx} + u_x^2 - 4auu_x + 4a^2u^2,\\
&((C_1 + C_2\exp(ax) + C_3\exp(-ax))u_x + (C_4 - 2aC_2\exp(ax))u)\big|_{t=t_0}\\
&\quad = C_5 + C_6\exp(ax) + C_7\exp(2ax).
\end{aligned}
\tag{25}
$$

Integrating the equation $\eta = 0$ and substituting its general solution,

$$
u(t,x) = \varphi(t) + \varphi_2(t)\exp(ax) + \varphi_3(t)\exp(2ax) \tag{26}
$$

into (25) give the following Cauchy problem:

$$
\vec{\varphi}\,'(t) = \mathcal{F}(\vec{\varphi}(t)),
$$

$$
\mathcal{C}\vec{\varphi}(t_0) = \vec{C},
$$

where

$$
\vec{\varphi}(t) = \begin{pmatrix} \varphi_1(t) \\ \varphi_2(t) \\ \varphi_3(t) \end{pmatrix}, \quad \mathcal{F}(\vec{\varphi}) = \begin{pmatrix} 4a^2\varphi_1^2 \\ a^3\varphi_2 + 4a^2\varphi_1\varphi_2 \\ 8a^3\varphi_3 + a^2\varphi_2^2 \end{pmatrix},
$$

$$
\mathcal{C} = \begin{pmatrix} C_4 & aC_3 & 0 \\ -2aC_2 & aC_1 + C_4 & 2aC_3 \\ 0 & -aC_2 & C_4 + 2aC_1 \end{pmatrix}, \quad \vec{C} = \begin{pmatrix} C_5 \\ C_6 \\ C_7 \end{pmatrix}.
$$

Thus, using higher-order conditional symmetries of the nonlinear PDE (24), we reduce the initial value problem (25) to the Cauchy problem for a system of three first-order ordinary differential equations for the functions $\varphi_1(t), \varphi_2(t), \varphi_3(t)$. The general solution of the system in question reads as

$$
\varphi_1(t) = (\kappa_1 - 4a^2t)^{-1},
$$

$$
\varphi_2(t) = \kappa_2\exp(a^3t)(\kappa_1 - 4a^2t)^{-1},
$$

$$
\varphi_3(t) = \exp(8a^3t)\left(\kappa_3 + a^2\kappa_2^2\int_{t_0}^{t}\exp(-6a^3z)(\kappa_1 - 4a^2z)^{-2}dz\right),
$$

where $\kappa_1, \kappa_2, \kappa_3$ are arbitrary real parameters (integration constants).

We emphasize that the exact analytic solution of the nonlinear PDE (24) that is obtained via substitution of the corresponding expressions for the functions $\varphi_1(t), \varphi_2(t), \varphi_3(t)$ into (26) cannot be constructed within the standard symmetry reduction approach. The reason for this is that the solution is not invariant with respect to the two-parameter displacement group defined by $\partial/\partial t$, $\partial/\partial x$, which is the maximal Lie symmetry algebra of (24).

Specifying $\kappa_1, \kappa_2, \kappa_3$ appropriately, we can solve any representative of the seven-parameter family of initial value problems given in (25). Consider, for example, the case $C_1 = C_2 = C_3 = C_7 = 0$ and $C_4 = 1$, $C_5 = k_1$, $C_6 = k_2$. Then the unique solution of the corresponding initial value problem,

$$
u_t = u_{xxx} + u_x^2 - 4auu_x + 4a^2u^2,
$$

$$
u(t_0,x) = k_1 + k_2\exp(ax),
$$

is given by

IV. CONDITIONALLY-INVARIANT SECOND-ORDER PDES

An analysis of the examples given in the previous section reveals an evident restriction on the scope of applicability of the reduction techniques based on higher conditional symmetries. It comes from a necessity to integrate a nonlinear high-order ordinary differential equation (7). Moreover, in order to use Theorem 3, we need to ensure that the ordinary differential equation $\eta=0$ has a nontrivial Lie symmetry. These observations suggest the idea of using Lie's classification of invariant second-order ordinary differential equations as the source of the functions η. With this choice of the conditional symmetry we are guaranteed that differential equation $\eta=0$ admits two-, three- or eight-parameter transformation group and, consequently, is integrable by quadratures. Surprisingly, it is possible to implement this approach to classifying second-order PDEs (1) by their second-order conditional symmetries in full generality.

In Table I we present the complete list of invariant real second-order ordinary differential equations together with their maximal invariance algebras, obtained by Lie (Refs. 21, 22). Note that a,k are arbitrary real parameters and f is an arbitrary function. As classification has been done

to within an arbitrary reversible transformation of the variables x,y, the equations given in Table I are representatives of the conjugacy classes of invariant ordinary differential equations.

We exclude from further consideration case 1 of Table I, since the corresponding ordinary differential equation is not integrable by quadratures. Next, since our final aim is to exploit conditional symmetries for the description and reduction of initial value problems, it makes no sense to consider case 4. This is because the symmetry group admitted by the corresponding ordinary differential equation within the class (18) is the same as that of the more general equation given in case 3 of Table I. The same argument applies to case 8. Consequently, we will deal only with the remaining cases 2, 3, 5–7, 9.

We take as the function η in operator (3) the expressions $y''-f(x,y,y')$, where f is one of the right-hand sides of equations listed in the second column of Table I and make the replacements $y\to u$, $y'\to u_x$ and $y''\to u_{xx}$. We classify PDEs of the form

$$u_t=u_{xx}+F(t,x,u,u_x), \tag{27}$$

admitting the corresponding Lie–Bäcklund vector fields. As we have already mentioned, this program can be realized in full generality. Indeed, given the above choice of higher conditional symmetry operators, we are able to describe the most general PDEs (27) admitting these symmetries. The form of the function F is the same for all the cases, namely,

$$F(t,x,u,u_x)=rF_1(t,\omega_1,\omega_2)+pF_2(t,\omega_1,\omega_2)+q.$$

Here F_1,F_2 are arbitrary smooth functions of the indicated variables and the forms of the coefficients r,p,q and of the ''invariants'' ω_1,ω_2 are presented in Table II.

As an example, we consider the case of the Lie–Bäcklund field $Q=(u_{xx}-a\exp(-u_x))(\partial/\partial u)+\cdots$. Inserting this operator into the invariance condition (6) yields the second-order PDE for the function $F=F(t,x,u,u_x)$ (we have generated it using MATHEMATICA),

$$a^3\exp(-3u_x)+a^2\exp(-2u_x)F_{u_xu_x}+a\exp(-u_x)(u_x+1)F_u+2au_x\exp(-u_x)F_{uu_x}$$
$$+u_x^2F_{uu}+a\exp(-u_x)F_x+2a\exp(-u_x)F_{xu_x}+2u_xF_{xu}+F_{xx}=0.$$

The equation obtained looks rather fearsome. However, it simplifies radically with the change of variables $F=\tilde F(t,x,\omega_1,\omega_2)$, where ω_1,ω_2 are the integrals of the ordinary differential equation $u_{xx}-a\exp(-u_x)=0$. As a result, we find that the function $\tilde F$ satisfies the following PDE:

$$a^3\exp(-3u_x)+a\exp(-u_x)\tilde F_x+\tilde F_{xx}=0.$$

Now, we eliminate u_x, using the second invariant $\omega_2=-ax+\exp(u_x)$, and thus get an ordinary differential equation with respect to x. Solving it yields formulas 6 from Table II. The other cases are dealt with in an analogous way.

Now we proceed to calculating the initial conditions (12) such that the initial value problems for conditionally invariant PDEs (27) given in Table II are reducible to Cauchy problems for systems of two ordinary differential equations. To this end we exploit Theorem 3. First of all we note that for Eqs. 2, 3 of Table II, the condition b of Theorem 3 fails to hold. For this reason, the corresponding initial value problem is not reduced to a Cauchy problem within the framework of our approach. For the remaining cases 5, 6, 7.1, 7.2 and 9 we get the following initial conditions.

Case 5: $(C_1+2C_2x+C_3x^2)u_x(t_0,x)-(C_2+C_3x)u(t_0,x)=0$,
$C_3\neq 0$, $C_1C_3\neq C_2^2$;

Case 6: $(C_1+C_3x)u_x(t_0,x)-C_3u(t_0,x)=C_2+C_3x$, $C_3\neq 0$;

Case 7.1: $(C_1+C_3x)u_x(t_0,x)-kC_3u(t_0,x)=C_2$, $C_3\neq 0$;

Case 7.2: $(C_1+C_3x)u_x(t_0,x)=C_2$, $C_2\neq 0$;

TABLE II. Conditionally-invariant PDEs (27).

No.	Coefficients r,p,q	Functions ω_1,ω_2
2	$r=1$ $p=u_x$ $q=-(f'(u_x))^{-1}$	$\omega_1=u-\int^{f(u_x)} g(z)dz$ $\omega_2=f(u_x)-x$
3	$r=1$ $p=xu_x-u$ $q=-(xf'(u_x))^{-1}$	$\omega_1=u-x\exp(-f(u_x))\times\int^{f(u_x)} g(z)\exp(z)dz$ $\omega_2=f(u_x)-\ln x$
5	$r=u^{-1}u_x(a+u^2u_x^2)^{1/2}$ $p=u^3(2xu_x-u)(a+u^2u_x^2)^{-3/2}$ $q=-au^{-3}$	$\omega_1=2u^3u_x(a+u^2u_x^2)^{-1}-2x$ $\omega_2=u^{-2}(u_x^2u^2-a)$
6	$r=1$ $p=u_x$ $q=-a\exp(-u_x)$	$\omega_1=au+(1-u_x)\exp(u_x)$ $\omega_2=-ax+\exp(u_x)$
7.1	$r=1$ $p=u_x$ $q=-au_x^{(k-2)/(k-1)},\ k\neq 0,1,2$	$\omega_1=u+\dfrac{1-k}{ak}u_x^{k/(k-1)}$ $\omega_2=\dfrac{ax}{1-k}+u_x^{1/(k-1)}$
7.2	$r=1$ $p=u_x$ $q=-au_x^2$	$\omega_1=u-a^{-1}\ln(u_x)$ $\omega_2=ax+(u_x)^{-1}$
9	$r=1$ $p=x$ $q=0$	$\omega_1=xu_x-u$ $\omega_2=u_x$

Case 9: $(C_1+C_4x+C_6x^2)u_x(t_0,x)-(C_5+C_6x)u(t_0,x)=C_2+C_3x$,
$\Delta=C_1C_6+C_5(C_5-C_4)\neq 0$, $\Delta_1=C_2(C_4-C_5)-C_1C_3$,
$\Delta_2=C_2C_6-C_3C_5$.

In the above formulas $C_1,C_2,\ldots,C_6$ are arbitrary real constants satisfying the given constraints. These constraints ensure that the corresponding initial value problem fulfills both the conditions of Theorem 3.

The last step of the reduction algorithm is the construction of ansatzes for the function $u(t,x)$ and the reduction of both the invariant equation and initial conditions to systems of ordinary differential equations and algebraic equations, correspondingly. We present the list of obtained results in Table III, where $F_i=F_i(t,\varphi_1(t),\varphi_2(t)),i=1,2$, the functions $\varphi_1(t),\varphi_2(t)$ are new dependent variables and the symbol g stands for the converse of the function $f(u_x)$, i.e., $g(f(u_x))\equiv u_x$.

Let us emphasize that the nonlinear evolution equations constructed above, for arbitrary functions F_1,F_2, admit no Lie symmetry. Consequently, the symmetry reduction algorithm cannot be applied to perform dimensional reductions of these equations. This means that the reductions obtained in this section (both for PDEs and initial value problems) are purely non-Lie reductions and cannot be obtained within the framework of the standard Lie's approach.

V. CONCLUSIONS

In our work we show that higher-order conditional symmetry is a useful and efficient concept in handling initial-value problems. In fact, in view of Theorem 3, one may claim that the method of conditional symmetries is the most appropriate tool for reductions of initial-value problems for evolution type equations. It extends the scope of applicability of symmetry methods to the analysis of initial value problems via dimensional reductions.

TABLE III. Ansatzes and reduced equations.

No.	Ansatz for $u(t,x)$	ODEs	Cauchy data
2	$\varphi_1(t)+g(x+\varphi_2(t))$	$\varphi_1'=F_1$ $\varphi_1'=F_2$	No reduction
3	$\varphi_1(t)+\exp(-\varphi_2(t))$ $\times\int^{\ln(x)+\varphi_2(t)}\exp(y)g(y)dy$	$\varphi_1'=F_1$ $-\varphi_1F_2$ $\varphi_2'=F_2$	No reduction
5	$\frac{1}{2\sqrt{\varphi_2(t)}}(4a+\varphi_2^2(t)$ $\times(2x+\varphi_1(t))^2)^{1/2}$	$\varphi_1'=2\varphi_1^{1/2}F_1$ $-2\varphi_1\varphi_2^{1/2}F_2$ $\varphi_2'=2\varphi_2^{1/2}F_2$	$\varphi_1(t_0)=\frac{2C_2}{C_3}$ $\varphi_2(t_0)=\frac{C_3\sqrt{a}}{\sqrt{C_1C_3-C_2^2}}$
6	$\varphi_1(t)+a^{-1}(ax+\varphi_2(t))$ $\times(\ln(ax+\varphi_2(t))-1)$	$\varphi_1'=F_1$ $\varphi_2'=aF_2$	$\varphi_1(t_0)=\frac{C_2-C_1}{C_3}$ $\varphi_2(t_0)=\frac{aC_1}{C_3}$
7.1	$\varphi_1(t)+\frac{k-1}{ak}\left(\frac{ax}{k-1}+\varphi_2(t)\right)^k$	$\varphi_1'=F_1$ $\varphi_2'=\frac{a}{k-1}F_2$	$\varphi_1(t_0)=\frac{C_2}{kC_3}$ $\varphi_2(t_0)=\frac{aC_1}{(k-1)C_3}$
7.2	$\varphi_1(t)-a^{-1}\ln(\varphi_2(t)-ax)$	$\varphi_1'=F_1$ $\varphi_2'=-aF_2$	$C_3=-aC_2$ $\varphi_2(t_0)=\frac{C_1}{C_2}$
9	$\varphi_1(t)+\varphi_2(t)x$	$\varphi_1'=F_1$ $\varphi_1'=F_2$	$\varphi_1(t_0)=\frac{\Delta_1}{\Delta}$ $\varphi_2(t_0)=\frac{\Delta_2}{\Delta}$

Furthermore, the technique developed in this paper can be applied to boundary value problems as well, provided the PDE under study admits some higher-order Lie–Bäcklund vector field. Indeed, inserting ansatz (8) into the boundary condition,

$$U(t,u,u_1,\ldots,u_M)|_{x=x_0}=0,\quad M<N,$$

yields an algebraic relation for the functions $\varphi_i, i=1,2,\ldots,N$. This means that, if we are given a reducible initial value problem, then we can add *any* boundary condition, so that the resulting problem remains reducible. However, the problem of compatibility of initial and boundary conditions must be investigated separately (see also the paper in Ref. 23 and the references therein).

We consider in the present paper the case of one dependent variable. However, all our arguments can be directly applied to the analysis of systems of evolution equations in one spatial dimension. One final point is that it seems to be possible to apply the same technique for the reduction of multi-dimensional evolution equations admitting classical or nonclassical symmetries. These and related problems are under study now and will be reported on in future publications.

We apply methods of symmetry groups to heat equations on $\mathbb{R}$ with drift terms and to heat equations for Lie groups. In particular, we are able to characterize those functions f for which equations of the form $(\partial^2 u/\partial x^2)+f(x)u_x=u_t$ have a point symmetry which takes a constant solution to the fundamental solution. Further, we apply symmetry methods to the heat equation of the $ax+b$ group. © *2001 American Institute of Physics.* [DOI: 10.1063/1.1316763]

I. INTRODUCTION

From the point of view of harmonic analysis, one of the more intriguing remarks to be found in Olver's book[1] is that the fundamental solution of the one-dimensional heat equation may be obtained from the constant solution by acting with an element of the symmetry group. It is the purpose of this paper to explore some extensions and ramifications of this remark.

We will discuss three aspects of the problem. In Sec. II we introduce the basic techniques involved with symmetry group calculations, and their application to heat kernels. We then use ideas from Refs. 2 and 3, applying the method of group representations to the problem of exponentiating generalized symmetries. Although, at the level of generalized vector fields, this can be a forbiddingly difficult process, the technique of introducing a suitable group representation, exponentiating in the appropriate representation space, and transforming back, often yields rather simple formulas.

The essential observation is that at the level of group representations, the difference between point symmetries and generalized symmetries disappears. As the culmination of this section, we are able to show that for any simply connected nilpotent Lie group, the heat equation corresponding to any sub-Laplacian satisfying the Hörmander condition has a generalized symmetry taking a constant solution to the heat kernel. In Sec. III we show how symmetry calculations yield the fundamental solutions for certain equations on the real line.

In Sec. IV, we are able to characterize those functions $f(x)$ for which the equation

$$\frac{\partial^2 u}{\partial x^2}+f(x)\frac{\partial u}{\partial x}=\frac{\partial u}{\partial t}$$

has an ordinary symmetry taking a constant solution to the fundamental solution. It turns out that f must satisfy one of several Ricatti equations. We are able also to give some explicit formulas for the heat kernel in these cases. Section V extends the results of Sec. IV to the two other finite-dimensional Lie algebras of vector fields on $\mathbb{R}$, viz. those spanned by $\partial/\partial x$ and $x(\partial/\partial x)$ and by $\partial/\partial x$, $x(\partial/\partial x)$, and $x^2(\partial/\partial x)$, respectively.

In the final section, a different approach is considered. We apply symmetry methods to the heat kernel on the $ax+b$ group, obtaining new information about its behavior.

We believe that the idea of applying the symmetry methods of Lie to the study of heat kernels on Lie groups to be a novel one which will require further investigation.

II. SYMMETRIES: GENERALIZED SYMMETRIES

Let us recall the notion of a symmetry of a system of differential equations.

Consider the system

$$P_\nu(x,D^\alpha u)=0, \quad \nu=1,...p, \tag{2.1}$$

α a multi-index, $D^\alpha=\partial^{|\alpha|}/\partial x_1^{\alpha_1}\cdots\partial x_n^{\alpha_n}$.

A symmetry of (2.1) is a mapping defined on the space of solutions, $\mathcal{H}$, i.e.,

$$B:\ \mathcal{H}\to\mathcal{H}.$$

So if u is a solution of (2.1) then Bu is also a solution. That is, symmetries map solutions to new solutions. Symmetry methods are important because they allow us to construct complex solutions to a differential equation from simple solutions. (See the heat equation example below.) Lie developed a technique for computing *groups* of symmetries. An excellent modern account is contained in Ref. 1.

We consider P to be an operator on the manifold $X\times U$ where the independent variables are elements of X and the dependent variables elements of U. The first-order differential operator

$$v=\sum_{i=1}^{n}\xi_i(a,u)\frac{\partial}{\partial x_i}+\sum_{j=1}^{p}\phi^j(x,u)\frac{\partial}{\partial u^j} \tag{2.2}$$

generates a local group of transformations on $X\times U$. The n jet bundle of $X\times U$, is denoted by $J^n(X,U)$. $J^n(X,U)$ is a C^∞ manifold which may be thought of as consisting of $X\times U$ together with the derivatives of the u variables up to order n.

The theory of jet bundles is developed extensively in Ref. 4. Briefly, the construction involves considering $C^\infty(X,U)$ and taking the equivalence relation defined by *$f\sim g$ if f and g have identical Taylor polynomial to nth order*.

In Ref. 4 it is shown that under this equivalence relation $C^\infty(X,U)$ can be given the structure of a smooth manifold, denoted $J^n(X,U)$. Local coordinates on $J^n(X,U)$ are viewed as consisting of the x variables, the u variables, and the derivatives of u up to order n. We may then consider (2.1) as an algebraic equation on $J^n(X,U)$.

The flow generated by v is a symmetry group of (2.1) if the extension of v to $J^n(X,U)$ (called the nth prolongation of v, denoted $\mathrm{pr}^n v$), satisfies Lie's condition (see Theorem 2.1). $\mathrm{pr}^n v$ may be calculated from v by essentially requiring that the chain rule hold. An explicit formula for $\mathrm{pr}^n v$ was found by Olver and is given in Ref. 1 (pp. 108–117).

Lie's condition that v generate a symmetry of (2.1) may be stated as follows.

Theorem 2.1 (Lie): *A vector field v of the form (2.2) generates a local group of symmetries of (2.1) if and only if*

$$\mathrm{pr}^n v[P_\nu(x,D^\alpha)u]=0,$$

whenever u is a solution of (2.1).

Proof: See Ref. 1, Chap. 2.

Remark: In Craddock's thesis and in Refs. 2, 3 and 5, a new approach to the study of group symmetries was developed. This approach demonstrates that the local groups of symmetries which Lie's prolongation method yields may often be extended to global group actions by methods of representation theory.

Calculation of the flow associated with v is called exponentiating v; v generates a transformation that moves x and u to $\tilde{x}(x,u,\epsilon)$ and $\tilde{u}(x,u,\epsilon)$, respectively. The process of exponentiating v is straightforward. Given v of the form (2.2), we solve the first-order system of differential equations

$$\frac{d\tilde{x}_i}{d\epsilon}=\xi_i(\tilde{x},\tilde{u}),\quad \tilde{x}_i(0)=x_i,\quad i=1,2,...,n,$$

$$\frac{d\tilde{u}_j}{d\epsilon}=\phi^j(\tilde{x},\tilde{u}),\quad \tilde{u}^j(0)=u^j,\quad j=1,...,p.$$

Then the new solution is $\tilde{u}(\tilde{x})$. A convenient shorthand for this notation is to write

$$\rho(\exp \epsilon v)(u(x))=\tilde{u}(\tilde{x}).$$

Example 1: The one-dimensional heat equation

$$u_t=u_{xx} \tag{2.3}$$

was shown by Lie to have a six-dimensional Lie algebra of symmetries (cf. Ref. 1, p. 120ff).

A basis for this Lie algebra is

$$v_1=\frac{\partial}{\partial x},\quad v_2=\frac{\partial}{\partial t},\quad v_3=u\frac{\partial}{\partial u},\quad v_4=x\frac{\partial}{\partial x}+2t\frac{\partial}{\partial t}-\frac{1}{2}u\frac{\partial}{\partial u},$$

$$v_5=2t\frac{\partial}{\partial x}-xu\frac{\partial}{\partial u},\quad v_6=4xt\frac{\partial}{\partial x}+4t^2\frac{\partial}{\partial t}-(x^2+2t)u\frac{\partial}{\partial u}.$$

It is easy to show that v_6 exponentiates to produce an action on solutions given by

$$\rho(\exp \epsilon v_6)u(x,t)=\frac{1}{\sqrt{1+4\epsilon t}}\exp\left\{\frac{-\epsilon x^2}{1+4\epsilon t}\right\}u\left(\frac{x}{1+4\epsilon t},\frac{t}{1+4\epsilon t}\right).$$

Thus if u solves (2.3), so does $\rho(\exp \epsilon v_6)u$, at least for ϵ sufficiently small.

Note that $u=1$ solves (2.3). Therefore by symmetry so does

$$u=\frac{1}{\sqrt{1+4\epsilon t}}\exp\left\{\frac{-\epsilon x^2}{1+4\epsilon t}\right\}.$$

Translating t by $-(1/4\epsilon)$ and choosing $\epsilon=\pi$ gives the new solution

$$k_t(x)=\frac{1}{\sqrt{4\pi t}}\exp\left\{\frac{-x^2}{4t}\right\}.$$

Thus we have found the heat kernel for (2.3) by using a group transformation applied to the trivial solution $u=1$. This leads to an obvious question: Can we use symmetries to construct fundamental solutions from trivial solutions in some systematic manner for other equations? This question motivates the rest of this paper.

Symmetries generated by a vector field of the form (2.2) are known as point symmetries. We may also study generalized symmetries by considering generalized vector fields of the form

$$v=\sum_{i=1}^{n}\xi_i(x,u,D^\alpha u)\frac{\partial}{\partial x_i}+\sum_j \phi^J(x,u,D^\alpha u)\frac{\partial^{|J|}}{\partial u_{x_j}}, \tag{2.4}$$

where J ranges over a set of multi-indices and the derivatives in the second sum are with respect to u and with respect to the partial derivatives of u with respect to the x variables. The order of a generalized symmetry is the order of the highest derivative appearing in (2.4). For example,

$$v = xu_x \frac{\partial}{\partial x} + u_{xx} \frac{\partial}{\partial u} \tag{2.5}$$

is a generalized vector field of the second order.

When dealing with generalized symmetries it is convenient to employ the so-called evolutionary form of (2.4). One can replace v by a vector field of the form

$$v_Q = \sum_J Q_J(x, D^\alpha u) \frac{\partial}{\partial u_J}, \tag{2.6}$$

where

$$Q_J(x, D^\alpha) = \phi^J(x, u, D^\alpha u) - \sum_{i=1}^{n} \xi_i(x, u, D^\alpha u) u_i^J \tag{2.7}$$

in which $u_i^J = \partial u^J / \partial x_i$.

For example,

$$v = x \frac{\partial}{\partial x} + 2t \frac{\partial}{\partial t} \tag{2.8}$$

is equivalent to the evolutionary form

$$v_Q = -(xu_x + 2tu_t) \frac{\partial}{\partial u}. \tag{2.9}$$

Chapter 5 of Ref. 1 contains a detailed analysis of such symmetries. The *infinite* prolongation of v (denoted pr$v$) to an infinite jet bundle may be defined and a group of transformations associated with v constructed. The following theorem holds.

Theorem 2.2: *Let v be a generalized vector field of the form (2.4). Then the group of transformations associated with (2.4) is a local group of symmetries of (2.1) if and only if*

$$\mathrm{pr}v[P_\nu(x, D^\alpha u)] = 0,$$

whenever

$$P_\nu(x, D^\alpha) u = 0.$$

Proof: See Ref. 1, Chap. 5.

For the remainder of this work we restrict to the case where there is only one dependent variable u.

A major difficulty with generalized symmetries is that the group action arising from a generalized vector field may be very hard to calculate. Theoretically, one solves the initial value problem

$$\frac{\partial \tilde{u}}{\partial \epsilon} = Q(\tilde{x}, D^\alpha \tilde{u}) \tag{2.10}$$

with $\tilde{u}(\tilde{x}, 0) = u(x)$. For example, to determine the group action associated with $-u_x \partial / \partial u$, we solve

$$\frac{\partial \tilde{u}}{\partial \epsilon} = -\tilde{u}_{\tilde{x}} \tag{2.11}$$

with $\tilde{u}(\tilde{x},0)=u(x)$. In this instance we have $\tilde{u}(\tilde{x},\epsilon)=u(x-\epsilon)$.

However, the initial value problem (2.10) may be ill posed. Consequently many results on generalized symmetries are of a rather theoretical nature. One aim of this paper is to promote interest in such symmetries and introduce an approach to dealing with certain of these problems. We make the blanket assumption that (2.10) is well posed.

Computation of generalized symmetries, by which we shall mean vector fields satisfying the Lie condition of Theorem 2.2, is itself a rather difficult task. Techniques involving, for example, recursion operators are available. In addition if the order of the generalized symmetry is predetermined, one can find all generalized symmetries of that order for a given equation, though this may be computationally intensive. Nevertheless the general problem remains unsolved.

In Refs. 2 and 3, a new method of studying group symmetries was introduced and applied *inter alia* to the heat equation on $\mathbb{R}^n$, and to a number of other examples. The essence of this method is to observe that the groups determined by Lie's prolongation algorithm are very often equivalent to the action of a representation of the corresponding Lie group on some space of functions (or possibly distributions).

To explain this remark, consider an evolution equation of the form

$$Pu = \frac{\partial u}{\partial t}, \tag{2.12}$$

where u is a function on $\mathbb{R}^n \times \mathbb{R}$ and P is a polynomial in $\{\partial/\partial x_i : i=1\cdots n\}$. Suppose that we can find a heat kernel for such an equation, that is a kernel K on $\mathbb{R}^n \times \mathbb{R}$ so that the integral

$$u(x,t) = \int_{\mathbb{R}^n} f(y)K(x-y,t)dy = (Af)(x,t)$$

converges for all $f \in L^2(\mathbb{R}^n)$ to a solution of (2.12). Then given any group S which admits a continuous representation π on $L^2(\mathbb{R}^n)$, the equation

$$\begin{aligned}(\sigma(s)u)(x,t) &= \int_{\mathbb{R}^n} (\pi(s)f)(y)K(x-y,t)dy \\ &= A(\pi(s)f)(x,t) \quad (s \in S)\end{aligned} \tag{2.13}$$

defines a symmetry of (2.12).

The content of Refs. 2 and 3 is essentially that the symmetries one computes by Lie's method are very often equivalent to representations of the underlying Lie group via the equivalence relation (2.13). That is, Lie's prolongation algorithm in a fundamental sense, constructs representations of a Lie group on some vector space of solutions of a (linear) PDE. Precisely how far the relation between Lie's method and representations of the underlying group goes will be the subject of a forthcoming paper.

A part of the value in using (2.13) to study symmetries lies in the fact that properties which may be somewhat difficult to understand on the left-hand side of (2.13) may be utterly transparent on the right-hand side. See the comments following Theorem 2.3 for an example.

In Ref. 2 it is shown that the group $G=H_3 \times \mathrm{SL}(2,\mathbb{R})$ is a global group of symmetries for the one-dimensional heat equation $u_{xx}=u_t$, and that the symmetries generated by the vector fields $\{v_1,\ldots,v_6\}$ of example 1 are intertwined by this method with an analytic continuation of the Segal–Shale–Weil representation of G. In this case, every Segal–Shale–Weil induced symmetry is a point symmetry. (The one arising from the Weyl element maps the constant solution of the heat equation to the fundamental solution.)

However, for other equations and for other representations on $L^2(\mathbb{R}^n)$, the symmetries induced in this way will typically be generalized symmetries. We also remark that since they are presented in ''exponentiated form,'' this suggests an approach to finding the exponentials of generalized symmetries.

Before considering the case of a general Lie group, let us exemplify the concluding remarks of the previous paragraph. Consider the linearized KdV equation

$$u_{xxx}=u_t. \tag{2.14}$$

Lie's prolongation algorithm may be applied to find a basis of four vector fields for the Lie algebra of point symmetries; $v_1=\partial/\partial x$, $v_2=\partial/\partial t$, $v_3=x(\partial/\partial x)+3(\partial/\partial t)$, $v_4=u(\partial/\partial u)$. Thus, if u solves (2.2), so do $u(x-\epsilon,t),u(x,t-\epsilon),u(e^{\epsilon},e^{3\epsilon}t),e^{\epsilon}u(x,t)$.

Standard Fourier transform methods allow us to write the solution of (2.14) as

$$Af(x,t)=\frac{1}{2\pi}\int_{-\infty}^{\infty} f(\xi)\exp\{-i\xi^3t+i\xi x\}d\xi.$$

This integral can be shown to converge for $f\in L^1(\mathbb{R})$ and can also be extended by a density argument to $L^2(\mathbb{R})$.

We now construct the symmetry that translation on $L^2(\mathbb{R})$ yields. Let $(\pi(\epsilon)f)(y)=f(y-\epsilon)$. Then

$$(\sigma(\epsilon)u)(x,t)=\frac{1}{2\pi}\int_{-\infty}^{\infty}(\pi(\epsilon))f(y)\exp\{-iy^3t+iyx\}dy$$

$$=\frac{1}{2\pi}e^{i\epsilon x-i\epsilon^3t}\int_{-\infty}^{\infty}(f(s)e^{3it\epsilon s^2-is^3t})e^{isz}\,ds,$$

where $z=x-3\epsilon^2t$. Thus

$$(\sigma(\epsilon)u)(x,t)=e^{i\epsilon x-i\epsilon^3t}\int_{-\infty}^{\infty}u(x-3\epsilon^2t-y,t)K_{3i\epsilon t}(y)dy,$$

where

$$\int_{-\infty}^{\infty}e^{3it\epsilon s^2+ix}\,ds=\frac{1}{\sqrt{12\epsilon it}}\exp\left\{\frac{ix^2}{12\epsilon t}\right\}=K_{3\epsilon it}(x).$$

Differentiating with respect to ϵ and setting $\epsilon=0$, gives the characteristic for the evolutionary form of the vector field, v_Q generating this symmetry,

$$\left.\frac{d}{d\epsilon}(\sigma(\epsilon)u)(x,t)\right|_{\epsilon=0}=ixu+3it\frac{\partial^2u}{\partial x^2}.$$

Thus, the vector field generating the symmetry $\sigma(\epsilon)$ has evolutionary form $v_Q=i(xu+3tu_{xx})\times(\partial/\partial u)$. This does not reduce to a standard vector field. It is therefore a generalized symmetry.

This example suggests two things. First, at the level of group representations, there seems to be no difference between a point symmetry and a generalized symmetry. Second, since the group representation method gives us symmetries in exponentiated form, we may hope to use it to exponentiate generalized symmetries. As an example take the heat equation $u_t=u_{xx}$. We have a generalized symmetry

$$v_Q = u_{xxx}\frac{\partial}{\partial u}.$$

If

$$u(x,t) = \int_{-\infty}^{\infty} \phi(y) e^{-y^2 t + iyx}\, dy \quad \text{for } \phi \in L^2(\mathbb{R}),$$

then

$$\frac{\partial^3 u}{\partial x^3} = -i \int_{-\infty}^{\infty} y^3 \phi(y) e^{-y^2 t + iyx}\, dy.$$

Now if

$$\rho(\exp \epsilon v_Q) u(x,t) = \int_{-\infty}^{\infty} (R(\epsilon)\phi)(y) e^{-y^2 t + iyx}\, dy,$$

where $R(\epsilon)$ is a representation of a one parameter group, and v_Q generates this one parameter group, then we have

$$u_{xxx} = \frac{d}{d\epsilon}\rho(\epsilon)u(x,t)\bigg|_{\epsilon=0} = \int_{-\infty}^{\infty} \left(\frac{dR(\epsilon)}{d\epsilon}\phi\right)(y) e^{-y^2 t + iyx}\, dy \bigg|_{\epsilon=0}$$

$$= -i \int_{-\infty}^{\infty} y^3 \phi(y) e^{-y^2 t + iyx}\, dy.$$

If we take $(R(\epsilon)\phi)(y) = e^{-i\epsilon y^3}\phi(y)$, then we have effectively exponentiated v_Q:

$$\rho(\exp \epsilon v_Q) u(x,t) = \int_{-\infty}^{\infty} e^{-i\epsilon y^3} \phi(y) e^{-y^2 t + iyx}\, dy$$

$$= \frac{1}{(3\epsilon)^{1/3}} \int_{-\infty}^{\infty} u(x-y,t)\, \mathrm{Ai}\left(\frac{y}{(3\epsilon)^{1/3}}\right) dy,$$

where Ai is an Airy function of the first kind.

Obviously one might have obtained this result by standard techniques, and our method is certainly not completely rigorous or general, but it offers an interesting way to study the problem.

We now set up a version of the group representation approach which holds for equations more general than the heat equation on $\mathbb{R}$, and in particular applies to a range of sub-Laplacians on Lie groups.

Theorem 2.3: *Let X and U be manifolds, and suppose that*

$$P(x, u, u_{x_1}, \ldots, u_{x_1 x_1}, \ldots) = 0 \tag{2.15}$$

is a differential equation on $J^n(X,U)$. Suppose further that there exists a connected submanifold $X_1 \subset X$ a measure μ on X_1 and a kernel function $K(x,y)$ so that for all $f \in L^2(X_1, \mu)$, the integral $Af(x) = \int_{X_1} K(x,y) f(y)\, d\mu(y)$ converges to a solution of (2.15).

Let G be a Lie group which possesses a representation $\{\pi, L^2(X_1, \mu)\}$. Then G is a global group of symmetries for (2.15).

Proof: The proof is little more than an observation. Since $(\pi(g)f)(y) \in L^2(X_1, \mu)$ whenever $f \in L^2(X_1, \mu)$, then we may define a symmetry of (2.15) as we did above, i.e.,

$$(\sigma(g)u)(y)=(A\pi(g)f)(y).$$

■

Remark: This result immediately implies that any equation for which we may compute solutions by $u(x)=Af(x)$, $f\in L^2(\mu)$, $A\in\mathcal{B}(L^2(\mu))$ must have infinitely many group symmetries, since there are obviously infinitely many group actions on $L^2(\mu)$ which can be used to construct symmetries. In practice, usually all but finitely many are generalized symmetries, though equations with infinitely many point symmetries exist. The two-dimensional Laplace equation is the best known example (see Ref. 3). We remark that the existence of an infinite-dimensional symmetry group is closely related to the linearization of a partial differential equation. See Ref. 6, Chap. 6, for more on this important topic. In fact this result is more general. Any PDE which is integrable in the sense that it possesses a mapping from some vector space of functions (or distributions) into its solution space, will have infinitely many symmetries by the above construction. Conversely, any equation which does not have infinitely many symmetries cannot be integrable in this particular sense. These symmetries, generalized and otherwise can be explicitly constructed by Lie's prolongation algorithm. This illustrates how the group representation approach can make certain symmetry properties transparent. The existence of infinitely many group symmetries for a PDE satisfying the given conditions is far from clear with the prolongation approach, but it is obvious if we use the representation theory method.

We now let G be a Lie group with Lie algebra $\mathfrak{g}$. Suppose that $X_1,\ldots,X_n\in\mathfrak{g}$ are left invariant vector fields which generate the Lie algebra in the sense that their successive brackets span $\mathfrak{g}$. The operator $\mathcal{L}=\Sigma_{i=1}^n X_i^2$ is then a sub-Laplacian and satisfies the Hörmander condition on G. The associated heat equation

$$\left(\frac{\partial}{\partial t}-\mathcal{L}\right)u(x,t)=0,\quad (x,t)\in G\times(0,\infty) \tag{2.16}$$

has been the object of intensive study, starting from Hunt's paper[7]—see also Refs. 8, 9, and 10. In fact, Folland[11] shows that there exists a unique function $h\in C^\infty(G\times(0,\infty))$ such that

$$\text{(a)}\quad \int_G h_t(x)dx=1,\quad \text{(b)}\quad h(x,t)\geqslant 0,\quad \text{(c)}\quad h(x,t)=h(x^{-1},t),$$

and (d) for all $f\in L^p(1\leqslant p<\infty)$, the function $u(x,t)=h_t*f(x)$ solves (2.16) with initial condition $u(x,0)=f(x)$. As usual, $h_t(x)=h(x,t)$; we shall refer to h_t as the heat kernel for $\mathcal{L}$.

Now consider the group acting by the left regular representations on say $\mathcal{S}(G)$ (assuming G has a well-defined Schwartz space and the left regular action preserves it). Since the left regular action commutes with convolution, we see that if $u(x,t)=(h_t*f)(x)$ is a solution, then so is $(\sigma(g)u)$ given by $h_t*\lambda(g)f(x)=\Delta(g)^{-1}u(g^{-1}x,t)$ where Δ is the modular function of G. Obviously many interesting symmetries may be constructed in this way as the example of the linearized KdV equation, presented above, demonstrates. Since $h_t\in C^\infty$, we may also obtain distributional solutions of (2.16) by allowing u to be defined by $h_t*\phi$, where ϕ is a distribution of compact support. Substituting in the Dirac delta for ϕ gives us h_t as a distributional solution. On the other hand, any continuous mapping $\mathcal{S}'(G)\to\mathcal{S}'(G)$ gives a (possibly generalized) symmetry of (2.16). Thus, if there is a continuous invertible mapping ψ: $\mathcal{S}'(G)\to\mathcal{S}'(G)$ so that $\psi(\delta_a)=1$, the symmetry $\sigma_{\psi^{-1}}$ necessarily maps the constant to the fundamental solution. In the case where $G=\mathbb{R}^n$, the Fourier transform provides such a transformation.

In fact, since the topology of $S(G)$ is defined only by the topological nature of G and not by its group structure, such an operator will exist whenever G is homeomorphic to $\mathbb{R}^n$. In particular, this holds if G is a simply connected nilpotent Lie group: in this case, the exponential map is a bijection of $\mathfrak{g}$ onto G. Thus, we can state

Theorem 2.4: *Let G be a simply connected nilpotent Lie group, and let $\mathcal{L}$ be a sub-Laplacian on G satisfying the Hörmander condition. Then there exists a generalized vector field v generating a symmetry of $\mathcal{L}-(\partial/\partial t)$ which carries the constant solution to the heat kernel.*

Proof: The preceding remarks clearly justify the result. However, let us explicitly exhibit such a generalized vector field arising from a specific action of $\mathrm{SL}_2(\mathbb{R})$. The calculation will be useful in what follows. Let H be a simply connected nilpotent Lie group homeomorphic to $\mathbb{R}^n$ and let the heat kernel be $h_t(x)$. Set

$$u(x,t)=\int_H f(y)h_t(y^{-1}x)dy. \tag{2.17}$$

Now consider a basis for the Lie algebra $\mathfrak{sl}_2$

$$k_1=\begin{pmatrix}0 & 2\\ 0 & 0\end{pmatrix},\quad k_2=\begin{pmatrix}1 & 0\\ 0 & -1\end{pmatrix},\quad k_3=\begin{pmatrix}0 & 0\\ -2 & 0\end{pmatrix}$$

and a representation of $\mathrm{SL}_2(\mathbb{R})$ on $L^2(H)$ identified with $L^2(\mathbb{R}^n)$ defined by

$$R\begin{pmatrix}1 & b\\ 0 & 1\end{pmatrix}f(y)=e^{-ib|y|^2}f(y), \tag{2.18}$$

$$R\begin{pmatrix}a & 0\\ 0 & a^{-1}\end{pmatrix}f(y)=a^{n/2}f(ay), \tag{2.19}$$

$$R\begin{pmatrix}0 & 1\\ -1 & 0\end{pmatrix}f(y)=\hat{f}(y), \tag{2.20}$$

where $a>0$ and $\hat{f}$ is the Fourier transform of f. [In (2.19) we are assuming that there is a well-defined action of $\mathbb{R}^+$ on H.] R defines the so-called Segal–Shale–Weil representation of $\mathrm{SL}_2(\mathbb{R})$. In fact it is a projective representation if n is odd. Usually one thinks of it as a representation of the *double cover* of $\mathrm{SL}_2(\mathbb{R})$. See Ref. 2 for more details.

Consider the one parameter subgroup of $\mathrm{SL}_2(\mathbb{R})$ generated by (k_1+k_3). This is actually the subgroup of rotations about the origin. We define a symmetry of the heat equation by

$$\sigma\begin{pmatrix}\cos 2\epsilon & \sin 2\epsilon\\ -\sin 2\epsilon & \cos 2\epsilon\end{pmatrix}u(x,t)=\int_H R(\exp(\epsilon(k_1+k_3))f(y)h_t(y^{-1}x)dy. \tag{2.21}$$

Setting $\epsilon=\pi/4$, we obtain

$$\sigma\begin{pmatrix}0 & 1\\ -1 & 0\end{pmatrix}u(x,t)=\int_H \hat{f}(y)h_t(y^{-1}x)dy. \tag{2.22}$$

Thus if we take the solution with initial condition $u(x,0)=1$ this symmetry ''rotates'' (in some sense) the solution to one with initial condition $u(x,0)=\delta(x)$. That is, it takes the constant solution to the fundamental solution. If we assume suitable smoothness properties for f and differentiate both sides of (2.21) with respect to ϵ and set $\epsilon=0$ we obtain

$$v(u)=\int_H (k_1+k_3)(f)(y)h_t(y^{-1}x)dy \tag{2.23}$$

in which v is an operator acting on u which corresponds to k_1+k_3 acting on f. In local coordinates we may write

$$v(u)=Q(x,D^{\alpha}u)\frac{\partial}{\partial u}u \tag{2.24}$$

for some function Q. v is then the evolutionary representative of a generalized symmetry which maps the constant solution to the fundamental solution for $\epsilon=\pi/4$.

The question of when there is a point symmetry with this property has motivated the remainder of the paper.

Remark 1: Theorem 2.4 guarantees for a large class of equations the existence of a symmetry that maps the constant solution of some heat equation to the heat kernel. Obviously it would be useful to know what the particular symmetry is for a given equation. Then one could identify the heat kernel by a group transformation of the constant solution. Unfortunately this result does not tell us whether or not the symmetry is a point symmetry, as is the case for the heat equation on $\mathbb{R}$, or whether it is a generalized symmetry.

Remark 2: Theorem 2.4 may be extended to equations other than the heat equation. All that is required is a suitable integral kernel for an operator $Pu=0$. We will not however consider such equations.

The proof of Theorem 2.4 suggests that if we wish to obtain the heat kernel from the constant solution by symmetry we should try to find an element of the Lie algebra of symmetries which corresponds to the element k_1+k_3 in $\mathfrak{sl}_2$. Below we will do precisely this for a class of heat equations with drift on the real line, and we will show that for these equations, the element corresponding to k_1+k_3 of $\mathfrak{sl}_2$ does indeed produce the heat kernel. The symmetries accomplishing the transformation will turn out to be point symmetries.

III. HEAT KERNELS ON $\mathbb{R}^n$

Let us now present some examples of how the heat kernel may sometimes be obtained by the method described above. We study the following equations.

(1) The heat equation

$$\frac{\partial u}{\partial t}=\Delta u \quad \text{on } \mathbb{R}^n.$$

(2) The Fokker–Planck equation

$$\frac{\partial u}{\partial t}=\frac{\partial^2 u}{\partial x^2}+\frac{\partial}{\partial x}(xu).$$

(3) The harmonic oscillator

$$-\frac{\partial u}{\partial t}=-\frac{1}{2}\frac{\partial^2 u}{\partial x^2}+\frac{1}{2}(x^2-1)u.$$

The heat kernel for the harmonic oscillator is given by Mehler's formula.[12] We will derive Mehler's formula by an elegant symmetry group calculation which should illustrate how effective Lie group techniques can be for determining fundamental solutions.

(1) The heat equation

$$\frac{\partial u}{\partial t}=\Delta u$$

has symmetry group $G=H_{2n+1}\rtimes(\mathrm{SL}(2,\mathbb{R})\times\mathrm{SO}(n))$ (see Craddock[2]). A basis for the Lie algebra of symmetries was found by Goff.[13] Details of the calculation of symmetries in the $n=1$ case may be found in Ref. 1. It can be shown that the vector fields

$$v_1=\frac{\partial}{\partial t} \quad \text{and} \quad v_2=4\sum_{i=1}^{n} x_i t\frac{\partial}{\partial x_i}+4t^2\frac{\partial}{\partial t}-\left(\sum_{i=1}^{n} x_i^2+2nt\right)u\frac{\partial}{\partial u}$$

generate symmetries, and further, by examining the commutator tables we establish the existence of a Lie algebra isomorphism taking k_1+k_3 to v_1+v_2. Thus exponentiating v_1+v_2 and setting $\epsilon=\pi/4$ should produce a symmetry which maps the solution of the heat equation with $u(x,0)=f(x)$ to the solution with $u(x,0)=\hat{f}(x)$.

Let us exhibit the $n=1$ case, and leave the general case to the interested reader. We need to exponentiate

$$v=4xt\frac{\partial}{\partial x}+(1+4t^2)\frac{\partial}{\partial t}-(x^2+2t)u\frac{\partial}{\partial u}.$$

Elementary calculations show that the action generated by the above vector field is

$$\sigma(\exp \epsilon v)u(x,t)=\sqrt{\frac{\sec(\tan^{-1}(2t)-2\epsilon)}{\sec(\tan^{-1}(2t))}}\exp\left[-\frac{x^2(2t-\tan(\tan^{-1}(2t)-2\epsilon))}{2(1+4t^2)}\right]$$
$$\times u\left(\frac{x\sec(\tan^{-1}(2t)-2\epsilon)}{\sqrt{1+4t^2}},\frac{1}{2}\tan(\tan^{-1}(2t)-2\epsilon)\right). \tag{3.1}$$

To obtain the solution of the one-dimensional heat equation with initial data $u(x,0)=\hat{f}(x)$ from the solution with $u(x,0)=f(x)$ we must set $\epsilon=\pi/4$. This gives

$$\sigma\left(\exp\frac{\pi}{4}v\right)u(x,t)=\frac{1}{\sqrt{2t}}\exp\left(-\frac{x^2}{4t}\right)u\left(\frac{x}{2t},-\frac{1}{4t}\right). \tag{3.2}$$

Using (3.2) and taking $u(x,t)=1/\sqrt{2\pi}$ we find the solution with initial data $u(x,0)=\delta(x)$ to be

$$k(x,t)=\frac{1}{\sqrt{4\pi t}}e^{-(x^2/4t)},$$

which is of course the fundamental solution of the heat equation.

It is not difficult to see that this result may also be obtained by applying first the group action arising from v_2 and then the group action arising from v_1 as described in the introduction. In fact it is frequently computationally easier to do this. With experience, one can often see from the form of the vector fields and their corresponding group actions, which ones will lead to the fundamental solution. To determine the heat kernel we simply perform the group translation $x\to x-y$ which arises from the vector field $\partial/\partial x$.

(2) Next we consider the Fokker–Planck equation

$$\frac{\partial u}{\partial t}=\frac{\partial^2}{\partial x^2}+x\frac{\partial u}{\partial x}+u. \tag{3.3}$$

Bluman and Cole[14] calculated the group of symmetries for the Fokker–Planck equation. This equation, and the harmonic oscillator equation which follow, lie somewhat outside the methodology which we have so far described. This is because they do not possess constant solutions. Nevertheless, we can perform the symmetry analysis and obtain the fundamental solution and heat kernel from ''time independent'' solutions. We may once more obtain the heat kernel by identifying an element of the Lie algebra of symmetries corresponding to the element k_1+k_3 of $\mathfrak{sl}_2$. However, it is quicker to use successive transformations by appropriate symmetries.

We use the fact that

$$v_1 = e^{-t}\partial/\partial x \quad \text{and} \quad v_5 = -xe^{-2t}\frac{\partial}{\partial x} + e^{-2t}\frac{\partial}{\partial y} + e^{-2t}u\frac{\partial}{\partial u}$$

generate symmetries. So if $u(x,t)$ is a solution of the Fokker–Planck equation then so are

$$\rho(\exp \epsilon v_1)u(x,t) = u(x - \epsilon e^{-t}, t)$$

and

$$\rho(\exp \epsilon v_5)u(x,t) = \frac{e^t}{\sqrt{e^{2t} - 2\epsilon}} u\left(\frac{x}{1 - 2\epsilon e^{-2t}}, \frac{1}{2}\log(e^{2t} - 2\epsilon) \right).$$

A solution of

$$\frac{\partial^2}{\partial x^2} + x\frac{\partial u}{\partial x} + u = 0$$

is $u_0(x) = e^{-x/2}$. Thus

$$\rho(\exp \epsilon v_5)u_0 = \frac{e^t}{\sqrt{e^{2t} - 2\epsilon}} \exp\left\{ \frac{-x^2}{2(1 - 2\epsilon e^{-2t})} \right\}$$

$$= \frac{e^t}{\sqrt{e^{2t} - 2\epsilon}} \exp\left\{ \frac{-x^2 e^{2t}}{2(e^{2t} - 2\epsilon)} \right\}$$

is also a solution of the Fokker–Planck equation. Setting $\epsilon = 1/2$, we obtain the solution

$$K(t,x,0) = \frac{e^t}{\sqrt{e^{2t} - 1}} \exp\left\{ \frac{-x^2 e^{2t}}{2(e^{2t} - 1)} \right\}.$$

We now wish to obtain the full heat kernel. Below we will explain how this is done in more detail. For now, we remark that letting $x \to x - ye^{-t}$ yields the new solution

$$K(t,x,y) = \frac{e^t}{\sqrt{e^{2t} - 1}} \exp\left\{ \frac{-(x - ye^{-t})^2 e^{2t}}{2(e^{2t} - 1)} \right\}.$$

This is, up to a multiplicative constant, the desired heat kernel. A fact which may be readily checked by a Fourier transform calculation, which converts the Fokker–Plank equation into a simple first-order linear PDE.

(3) As our final example, we show how to derive Mehler's formula for the harmonic oscillator. The equation

$$-\frac{\partial u}{\partial t} = -\frac{1}{2}\frac{\partial^2 u}{\partial x^2} + \frac{1}{2}(x^2 - 1)u \tag{3.4}$$

is known to have heat kernel given by Mehler's formula (see Ref. 12, p. 113):

$$K(t,x,y) = \{\pi(1 - e^{-2t})\}^{-1/2} \exp\left\{ \frac{4xye^{-t} - (x^2 + y^2)(1 + e^{-2t})}{2(1 - e^{-2t})} \right\}.$$

Equation (3.4) does not have a constant solution. Nevertheless it has the stationary solution $u_0(x)=e^{-(x^2/2)}$. We will show that there exists a point symmetry taking $u_0(x)$ to $K(t,x,0)$.

Following the usual procedure for computing symmetry groups, we find that if

$$v=\xi(x,t,u)\partial/\partial x+\tau(x,t,u)\partial/\partial t+\phi(x,t,u)\partial/\partial u$$

generates a symmetry then

$$\begin{aligned}-(\phi_t-\xi_t)u_x+(\phi_u-\tau_t)(-\tfrac{1}{2}u_{xx}+\tfrac{1}{2}(x^2-1)u)\\ =-\tfrac{1}{2}(\phi_{xx}+(2\phi_{xu}-\xi_{xx})u_x-\tau_{xx}u_t+(\phi_{uu}-2\xi_{xu})u\\ -2\tau_x u_{xt}+(\phi_u-2\xi_x)u_{xx})+\tfrac{1}{2}(x^2-1)\phi+xu\xi,\end{aligned}$$

where we may take $\tau_u=\xi_u=0$ since (3.4) is linear.

A straightforward calculation shows that a basis for the Lie algebra of symmetries is

$$v_1=xe^{2t}\partial/\partial x+e^{-2t}\partial/\partial t+(x^2-1)e^{-2t}u\partial/\partial u,$$

$$v_2=-xe^{2t}\frac{\partial}{\partial x}+e^{2t}\frac{\partial}{\partial t}+x^2e^{2t}u\frac{\partial}{\partial u},$$

$$v_3=\frac{\partial}{\partial t},$$

$$v_4=e^{-t}\frac{\partial}{\partial x}+xe^{-t}u\frac{\partial}{\partial u},$$

$$v_5=e^{t}\frac{\partial}{\partial x}-xe^{t}u\frac{\partial}{\partial u},$$

$$v_6=u\frac{\partial}{\partial u}.$$

It is not hard to show that these vector fields form a basis for the Lie algebra $\mathfrak{h}_3\oplus\mathfrak{sl}_2$, where $\mathfrak{h}_3$ is the Lie algebra of the three-dimensional Heisenberg group. Exponentiating $\{v_1,\ldots,v_6\}$ we find that if $u(x,t)$ is a solution of (3.3) then so are

$$\rho(\exp\epsilon v_1)u(x,t)=\frac{1}{\sqrt{1+2\epsilon e^{-2t}}}\exp\left\{\frac{\epsilon e^{-2t}x^2}{1+2\epsilon e^{-2t}}\right\}u\left(\frac{x}{\sqrt{1+2\epsilon e^{-2t}}},\frac{1}{2}\ln\left(\frac{e^{-2t}}{1+2\epsilon e^{-2t}}\right)\right),$$

$$\rho(\exp\epsilon v_2)u(x,t)=\exp\left\{\frac{\epsilon x^2}{e^{-2t}-2\epsilon}\right\}u\left(\frac{xe^t}{\sqrt{e^{-2t}-2\epsilon}},\frac{1}{2}\ln(e^{-2t}-2\epsilon)\right),$$

$$\rho(\exp\epsilon v_3)u(x,t)=u(x,t-\epsilon),$$

$$\rho(\exp\epsilon v_4)u(x,t)=\exp\left\{\epsilon xe^{-t}-\frac{\epsilon^2}{2}e^{-2t}\right\}u(x,\epsilon e^{-t},t),$$

$$\rho(\exp\epsilon v_5)u(x,t)=\exp\left\{-\epsilon xe^{t}+\frac{\epsilon^2}{2}e^{2t}\right\}u(x-\epsilon e^{t},t),$$

$$\rho(\exp\epsilon v_6)u(x,t)=e^{\epsilon}u(x,t).$$

The element of the Lie algebra of symmetries which corresponds to k_1+k_3 is v_2+v_1. However we really only need the action of v_1. Observe that

$$\rho(\exp \epsilon v_1)u_0=\frac{1}{\sqrt{1+2\epsilon e^{-2t}}}\exp\left\{\frac{\epsilon e^{-2t}x^2}{1+2\epsilon e^{-2t}}\right\}\exp\left(\frac{-x^2}{2(1+2\epsilon e^{-2t})}\right)$$

$$=\frac{1}{\sqrt{1+2\epsilon e^{-2t}}}\exp\left\{\frac{-x^2(1-2\epsilon e^{-2t})}{2(1+2\epsilon e^{-2t})}\right\}, \quad \text{put } 2\epsilon=-1$$

$$=\frac{1}{\sqrt{1-e^{-2t}}}\exp\left\{\frac{-x^2(1+e^{-2t})}{2(1-e^{-2t})}\right\}$$

which is Mehler's formula for $y=0$.

The question remains as to how we translate $K(t,x,0)$ to give $K(t,x,y)$. Let us look at the problem in a more general setting. Consider an elliptic operator H, such that the semigroup e^{-tH} has a convolution kernel $K(t,x,y)$. If $f\in L^2(\mathbb{R}^n)$, then

$$u(x,t)=\int_{\mathbb{R}^n} f(y)K(t,x,y)dy$$

is a solution of

$$\frac{\partial u}{\partial t}=-Hu \tag{3.5}$$

with $u(x,0)=f(x)$.

We know that we can define symmetries of (3.5) by considering a group G with a continuous representation $\{\pi,L^2(\mathbb{R}^n)\}$, and setting

$$(\rho(g)u)(x,t)=\int_{\mathbb{R}^n}(\pi(g)f)(y)K(t,x,y)dy.$$

Let us assume that we have a symmetry $\rho(g)$ such that if u_0 is a solution of

$$Hu=0,$$

then

$$(\rho(g)u_0)(x,t)=K(t,x,0).$$

Now consider the representation of $\mathbb{R}^n$ on $L^2(\mathbb{R}^n)$ given by

$$(\sigma(a)f)(y)=f(y-a).$$

If

$$u_0(x)=\int_{\mathbb{R}^n} f(y)K(t,x,y)dy,$$

and

$$(\rho(g)u_0)(x)=\int_{\mathbb{R}^n}(\pi(g)f)(y)K(t,x,y)dy=K(t,x,0),$$

then

$$(\pi(g)f)(y)=\delta(y).$$

Then, if we apply σ to $\rho(g)u$ we have

$$\begin{aligned}(\sigma(a)\rho(g)u_0)(x,t)&=\int_{\mathbb{R}^n}(\sigma(a)\delta)(y)K(t,x,y)dy\\&=\int_{\mathbb{R}^n}\delta(y-a)K(t,x,y)dy\\&=K(t,x,a).\end{aligned}$$

Clearly, the symmetry that takes $K(t,x,0)$ to $K(t,x,y)$ is the one that is equivalent to the translation representation σ of $\mathbb{R}^n$.

If we look at the heat equation on $\mathbb{R}$ we see that the constant solution is mapped to $K(t,x)=(1/\sqrt{4\pi t})\exp\{-x^2/4t\}$ and that the convolution kernel is given by translating x by y. That is

$$K(t,x,y)=\rho(\exp yv_1)K(t,x,0),$$

where $v_1=\partial/\partial x$ generates the translational symmetry of the heat equation.

For the Fokker–Planck equation we see that a solution of $Hu=0$ can be mapped to $K(t,x,0)$ and

$$\rho(\exp yv_1)K(t,x,0)=K(t,x,y),$$

where $v_1=e^{-t}\partial/\partial x$ generates the symmetry $x\to x-\epsilon e^{-t}$. Now the Lie algebra of point symmetries of the heat equation and the Fokker–Planck equation are isomorphic (see Ref. 2). At the level of the Lie algebra $e^{-t}\partial/\partial x$ is equivalent to $\partial/\partial x$. That is $v_1=e^{-t}\partial/\partial x$, generates the symmetry which is equivalent to translation on $\mathbb{R}$.

We now need to determine which element of the symmetry algebra for the harmonic oscillator is equivalent to translation. The easiest way to do this is to compute the commutator table and compare with the table for the Lie algebra $\mathfrak{h}_3\oplus\mathfrak{sl}_2$. In this way it can be shown that the desired element of the symmetry algebra is $\frac{1}{2}(v_5-v_4)=v$. If we use ρ to denote the action of v on solutions then

$$\rho(\exp yv)u(x,t)=\exp\left\{\frac{-yxe^{t}+yxe^{-t}}{2}-\frac{y^2}{8}(e^{2t}-e^{-2t})\right\}u\left(x-\frac{1}{2}y(e^{t}+e^{-t}),t\right).$$

Applying $\rho(\exp yv)$ to the function $K(t,x,0)$ calculated above must give $K(t,x,y)$. A straightforward calculation yields

$$\rho(\exp yv)K(t,x,0)=\frac{1}{\sqrt{1-e^{-2t}}}\exp\left(\frac{4xye^{-t}-(x^2+y^2)(1+e^{-2t})}{2(1-e^{-2t})}\right).\tag{3.6}$$

Up to a multiplicative constant, this is indeed the heat kernel. Thus we have obtained Mehler's formula for the harmonic oscillator by group translation of a stationary solution.

The process of computing the heat kernel for $\partial u/\partial t=Hu$ from a point symmetry calculation should now be clear. We begin by finding solutions of

$$Hu=0.\tag{3.7}$$

We determine the symmetry which takes a solution u_0 of (3.7) to $K(t,x,0)$. $K(t,x,0)$ is then shifted to $K(t,x,y)$ by an appropriate group translation. We encapsulate this result in the following.

Theorem 3.5: *Let*

$$\frac{\partial u}{\partial t} = Hu \tag{3.8}$$

have heat kernel $K(t,x,y)$ such that for $f \in L^2(\mathbb{R}^n)$,

$$u(x,t) = \int_{\mathbb{R}^n} f(y)K(t,x,y)dy$$

solves (3.8) with $u(x,0) = f(x)$.

Assume that there exists a symmetry group G of (3.8) acting by ρ, such that if $u_0(x)$ is a solution of

$$Hu_0 = 0$$

then $\rho(g)u_0 = K(t,x,0)$.

Then $K(t,x,y)$ may be obtained by a further symmetry operation where the symmetry is defined by

$$\pi(a)u(x,t) = \int_{\mathbb{R}^n} f(y-a)K(t,x,y)dy$$

$$= \int_{\mathbb{R}^n} (\sigma(a)f)(y)K(t,x,y)dy.$$

So

$$(\pi(y)\rho(g)u_0)(x,t) = K(t,x,y).$$

Comment: We may of course relax the condition that $f \in L^2(\mathbb{R}^n)$. In fact it is frequently *necessary* to do so. The heat equation is an example of this, as described in Ref. 2.

Proof: If

$$(\rho(g)u_0)(x,t) = \int_{\mathbb{R}^n} f(y)K(t,x,y)dy$$

$$= K(t,x,0).$$

Then

$$(\pi(a)\rho(g)u)(x,t) = \int_{\mathbb{R}^n} f(y-a)K(t,x,y)dy$$

$$= \int_{\mathbb{R}^n} f(y)K(t,x,y+a)dy$$

$$= K(t,x,a).$$

Hence $(\pi(y)\rho(g)u)(x,t) = K(t,x,y)$. ■

Obviously the most important aspect of this problem is the existence of a symmetry taking a solution of $Hu=0$ to $K(t,x,0)$. Equations where this may be effected with a point symmetry are clearly of interest.

In the next section we will characterize the functions $f(x)$ so that there exists a point symmetry of

$$\frac{\partial u}{\partial t}=\frac{\partial^2 u}{\partial x^2}+f(x)\frac{\partial u}{\partial x}$$

taking the constant solution of $u_{xx}+f(x)u_x=0$ to $K(t,x,0)$.

IV. ONE-DIMENSIONAL HEAT KERNELS WITH DRIFT

In this section, we will give a characterization of one-dimensional heat equations with a drift term for which there exists a point symmetry taking the constant solution **1** to the fundamental solution. The equations we shall consider have the form

$$\frac{\partial^2 u}{\partial x^2}+f(x)\frac{\partial u}{\partial x}=\frac{\partial u}{\partial t}. \tag{4.1}$$

In the preceding sections we made use of the construction (2.13). If u is a solution of (4.1) and $K(t,x,y)$ is a kernel function such that for all $f\in L^2(\mathbb{R})\int_{\mathbb{R}}f(y)K(t,x,y)dy$ defines a solution of (4.1) then the relation

$$\sigma(g)u(x,t)=\int_{\mathbb{R}}\pi(g)f(y)K\,dy \tag{4.2}$$

with g in some appropriate locally compact group, defines symmetries of (4.1). $K(t,x,y)$ will typically be the heat kernel. We shall characterize those equations of the form (4.1) such that the kernel function $K(t,x,y)$ or at least $K(t,x,0)$ may be obtained by a point symmetry acting on the constant solution. To be clear, by ''heat kernel,'' we mean the kernel function K of (4.2). We should note that it is possible that the technique we develop here may work for similar equations. For example, those of the form $u_t=\mathcal{H}(u)$, where $\mathcal{H}$ is a formally self-adjoint differential operator.

We shall prove the following theorem.

Theorem 4.1: *There exists a point symmetry of (4.1) taking* **1** *to the fundamental solution if and only if f satisfies one of the following Ricatti equations:*

$$\text{(i)}\quad f'+\frac{1}{2}f^2=\frac{A}{x^2}-\frac{a}{2},$$

$$\text{(ii)}\quad f'+\frac{1}{2}f^2=\frac{1}{8}x^2+\frac{C}{x^2},$$

$$\text{(iii)}\quad f'+\frac{1}{2}f^2=\frac{C}{(x+2)^2},$$

$$\text{(iv)}\quad f'+\tfrac{1}{2}f^2=\tfrac{2}{3}Cx,$$

$$\text{(v)}\quad f'+\tfrac{1}{2}f^2=\tfrac{1}{2}Cx^2+D,$$

where A, C, D, a are arbitrary real numbers.

Before proving the result let us make the observation that these Ricatti equations have arisen in other contexts. Bluman derived conditions under which the fundamental solutions of certain Fokker–Plank equations on a finite interval may be obtained as *group invariant* solutions of

related boundary value problems, and obtained Ricatti equations similar to those listed in Theorem 4.1. The details may be found in Ref. 14. The interested reader may wish to compare our results with his.

Proof of the theorem: The point symmetry algebra of (4.1) is generated by

$$v=\xi\frac{\partial}{\partial x}+\tau\frac{\partial}{\partial t}+\phi\frac{\partial}{\partial u},$$

where

$$\mathrm{pr}^2 v[u_{xx}+f(x)u_x-u_t]=0.$$

This gives immediately, using the prolongation formula, the defining equations for ϕ, ξ, τ:

$$\phi^{xx}+f(x)\phi^x+f'(x)u_x\xi-\phi^t=0.$$

Now (4.1) is linear, so $\xi_u=\tau_u=0$. Hence we find

$$\begin{aligned}&\phi_{xx}+(2\phi_{xu}-\xi_{xx})u_x-\tau_{xx}(u_{xx}+f(x)u_x)+\phi_{uu}u_x^2+(\phi_u-2\xi_x)u_{xx}-2\tau_x u_{xt}\\&\quad+f(x)(\phi_x+(\phi_u-\xi_x)u_x-\tau_x(u_{xx}+f(x)u_x))+f'(x)u_x\xi\\&\quad=\phi_t-\xi_t u_x+(\phi_u-\tau_t)(u_{xx}+f(x)u_x),\end{aligned}$$

where we have used $u_t=u_{xx}+f(x)u_x$.

Thus we have the system of defining equations

$$\phi_{xx}+f(x)\phi_x=\phi_t,$$

$$2\phi_{xu}-\xi_{xx}-f(x)\tau_{xx}+f(x)(\phi_u-\xi_x)-f^2(x)\tau_x+f'(x)\xi=-\xi_t+f'(x)(\phi_u-\tau_t),$$

$$-\tau_{xx}+(\phi_u-2\xi_x)-f(x)\tau_x=(\phi_u-\tau_t),$$

$$-2\tau_x=0,$$

$$\phi_{uu}=0.$$

Now, if τ is constant, it is clear that the fundamental solution cannot arise from exponentiation of v. If τ is constant the symmetry only generates translations in time, so it clearly cannot map a constant, time independent solution to a time dependent solution. Hence, we seek conditions of f which yield a nontrivial τ.

From the equation $\phi_{uu}=0$, we see that $\phi=\alpha u+\beta$ where α and β both satisfy (4.1). Furthermore, the fact that $\tau_x=0$ tells us that $2\xi_x=\tau_t$, and hence we deduce that

$$\xi=\frac{x}{2}\tau_t+\rho(t)\quad\text{for some function}\quad\rho.$$

Now $\phi_{xu}=\alpha_x$, so we obtain from the second equation

$$2\alpha_x-f(x)\xi_x+f'(x)\xi=-\xi_t-f(x)\tau_t,$$

and substituting $\xi_x=\frac{1}{2}\tau_t$, we obtain

$$\begin{aligned}2\alpha_x&=\tfrac{1}{2}f(x)\tau_t-f'(x)(\tfrac{1}{2}x\tau_t+\rho(t))-\tfrac{1}{2}x\tau_{tt}-\rho'(t)-f(x)\tau_t\\&=-\tfrac{1}{2}f(x)\tau_t-\tfrac{1}{2}xf'(x)\tau_t-f'(x)\rho(t)-\tfrac{1}{2}x\tau_{tt}-\rho'(t).\end{aligned}$$

From this it follows that

$$2\alpha = -\tfrac{1}{2}xf(x)\tau_t - f(x)\rho(t) - \tfrac{1}{4}x^2\tau_{tt} - x\rho'(t) + \sigma(t)$$

for a suitable function σ, and hence

$$2\alpha_t = -\tfrac{1}{2}xf(x)\tau_{tt} - f(x)\rho'(t) - \tfrac{1}{4}x^2\tau_{ttt} - x\rho''(t) + \sigma'(t).$$

Since $2\alpha_{xx} + 2f(x)\alpha_x = 2\alpha_t$, and

$$2\alpha_{xx} = -\frac{1}{2}\frac{d^2}{dx^2}(xf(x))\tau_t - f''(x)\rho - \frac{1}{2}\tau_{tt}.$$

We must therefore have

$$-\frac{\tau_t}{2}(xf(x))'' - f''(x)\rho - \frac{1}{2}\tau_{tt} + f(x)\left(-\frac{1}{2}f(x)\tau_t - \frac{1}{2}xf'(x)\tau_t - f'(x)\rho(t) - \frac{1}{2}x\tau_{tt} - \rho'(t)\right)$$
$$= -\frac{1}{2}xf(x)\tau_{tt} - f(x)\rho'(t) - \frac{1}{4}x^2\tau_{ttt} - x\rho''(t) + \sigma'(t).$$

This equation gives a limited number of possibilities for f if we wish to have τ nontrivial. In fact, collecting terms in τ_t gives the coefficient

$$-\tfrac{1}{2}(xf)'' - \tfrac{1}{2}f^2 - \tfrac{1}{2}xff'(x)$$

since we can eliminate the $-\tfrac{1}{2}xf(x)\tau_{tt}$ from each side of the equation.

Careful examination shows that, τ will only be nontrivial if one of the following five cases occur: Clearly either (i) $\tau_{ttt}=0$ or (ii) $\tau_{ttt}\neq 0$. There are several subcases in (ii) viz: (a) $\rho=0$; (b) $\tau_t=\rho$, $\rho\neq 0$; (c) $\rho_{tt}=C\tau_t$; (d) $\tau_{ttt}=C\tau_t$, $\rho_{tt}=C\rho$, $\sigma_t=-D\tau_t-\tfrac{1}{2}\tau_{tt}$. Here C and D are constants. Determining the admissible equations for f is now straightforward. See the following cases for example.

Case (i) leads to the condition

$$-\tfrac{1}{2}(xf)'' - \tfrac{1}{2}f^2(x) - \tfrac{1}{2}xff' = a, \quad a \text{ constant.} \tag{4.3}$$

Case (ii)(a) gives

$$-\tfrac{1}{2}(xf)'' - \tfrac{1}{2}f^2 - \tfrac{1}{2}xff' = -\tfrac{1}{4}x^2. \tag{4.4}$$

We will analyze these two cases. Let us deal first with Eq. (4.3), which we may rewrite as

$$xf'' + xf'f + 2f' + f^2 = -2a.$$

Substituting $u = f' + \tfrac{1}{2}f^2$ we have $u' = f'' + f'f$, and the equation becomes $x(du/dx) + 2u = -2a$, which has solution $u = (A/x^2) - a$. Thus we obtain the Ricatti equation for f

$$f' + \frac{1}{2}f^2 = \frac{A}{x^2} - a.$$

In the case of Eq. (4.4), the substitution $u = f' + \tfrac{1}{2}f^2$ reduces the equation to $(d/dx)(x^2u) = x^3$, which has solution $u = \tfrac{1}{4}x^2 + (C/x^2)$, and so f satisfies

$$f' + \frac{1}{2}f^2 = \frac{1}{8}x^2 + \frac{C}{x^2}.$$

The remaining three cases may be dealt with similarly and are left to the reader. This completes the ''only if'' part of the proof.

We now proceed to prove the other direction. In order to achieve this, we need to show that if f satisfies the given Ricatti equations, then a point symmetry exists taking a constant solution to the fundamental solution. Detailing all possible cases would be a lengthy procedure. For brevity, we treat equation (i); the details of Eqs. (ii)–(v) are essentially identical and are left to the reader.

In case (i) we have $\tau_{ttt}=0$. So $\tau(t)$ has the form $\tau=c_2+2c_4t+4c_6t^2$. We thus have $\sigma_t'=-\frac{1}{2}\tau_{tt}+a\tau_t$ giving $\sigma=-4c_6(t-at^2)+2ac_4t$.

We need to determine ξ and ρ. If $f''+ff'=x$ then we must have $\rho=0$. Hence

$$\xi=\tfrac{1}{2}x(2c_4+8c_6t)=c_4x+4c_6xt$$

and

$$\begin{aligned}\alpha&=-\tfrac{1}{4}(xf)\tau_t-\tfrac{1}{8}\tau_{tt}+\tfrac{1}{2}\sigma\\&=-\tfrac{1}{4}(xf)(2c_4+8c_0t)-\tfrac{1}{8}x^2(8c_6)+ac_4t-2c_6(t-at^2)+c_3.\end{aligned}$$

Thus a basis for the Lie algebra of symmetries is

$$v_2=\partial/\partial t,\quad v_3=u\partial/\partial u,\quad v_4=x\partial/\partial x+2t\partial/\partial t-(\tfrac{1}{2}xf+at)u\partial/\partial u,$$

$$v_6=4xt\partial/\partial x+4t^2\partial/\partial t-(2xft+x^2+2t+2at^2)u\partial/\partial u.$$

It can easily be shown that v_2, v_4, v_6 generate a copy of $\mathfrak{sl}_2$ and that v_2+v_6 corresponds to the action of the subgroup of rotations about the origin. We will show that exponentiating v_2+v_6 gives the ''heat kernel'' at $y=0$ for (4.1), i.e., takes $u=1$ to $K_t(x,0)$.

To exponentiate v_2+v_6 we solve

$$\frac{d\tilde{x}}{d\epsilon}=4xt,\quad \frac{d\tilde{t}}{d\epsilon}=1+4\tilde{t}^2,\quad \frac{d\tilde{u}}{d\epsilon}=-(2xft+x^2+2t+2at^2)\tilde{u},$$

$$\tilde{x}(0)=x,\quad \tilde{t}(0)=t,\quad \tilde{u}(0)=u.$$

We obtain immediately

$$\tilde{x}=\frac{x\sec(2\epsilon+\tan^{-1}(2t))}{\sqrt{1+4t^2}},\quad \tilde{t}=\frac{1}{2}\tan(2\epsilon+\tan^{-1}(2t)).$$

Hence

$$\begin{aligned}\frac{d\tilde{u}}{\tilde{u}}=-\Bigg(&\frac{x\sec(2\epsilon+\tan^{-1}(2t))}{\sqrt{1+4t^2}}f\Bigg(\frac{x\sec(2\epsilon+\tan^{-1}(2t))}{\sqrt{1+4t^2}}\Bigg)\tan(2\epsilon+\tan^{-1}(2t))\\&+\frac{x^2\sec^2(2\epsilon+\tan^{-1}(2t))}{1+4t^2}+\tan(2\epsilon+\tan^{-1}(2t))+\frac{a}{2}\tan^2(2\epsilon+\tan^{-1}(2t))\Bigg)d\epsilon.\end{aligned}$$

Introduce the function F, such that $F'=f$. Elementary integration produces the function $\tilde{u}$ in terms of x, t, u, and ϵ. We rewrite this function in terms of $\tilde{x}$ and $\tilde{t}$ to conclude that if u is a solution of (4.1) for the given f, then so is

$$\tilde{u}=\exp\left(-\frac{1}{2}\left(F(x)-F\left(\frac{x\sec(\tan^{-1}(2t)-2\epsilon)}{\sqrt{1+4t^2}}\right)\right)-\frac{x^2[2t-\tan(\tan^{-1}(2t)-2\epsilon)]}{2(1+4t^2)}\right.$$
$$\left.-\frac{1}{2}\ln\left(\frac{\sqrt{1+4t^2}}{\sec(\tan^{-1}(2t)-2\epsilon)}\right)-\frac{a}{4}(2t-\tan(\tan^{-1}(2t)-2\epsilon)-2\epsilon)\right)$$
$$\times u\left(\frac{x\sec(\tan^{-1}(2t)-2\epsilon)}{\sqrt{1+4t^2}},\frac{1}{2}\tan(\tan^{-1}(2t)-2\epsilon)\right).$$

We now put $\epsilon=\pi/4$ and set $u=1/\sqrt{2\pi}$. We use the identities

$$\sec\left(\tan^{-1}(2t)-\frac{\pi}{2}\right)=\frac{\sqrt{1+4t^2}}{2t},\quad \tan\left(\tan^{-1}(2t)-\frac{\pi}{2}\right)=-\frac{1}{2t}.$$

The solution $u=1/\sqrt{2\pi}$ is mapped to the new solution

$$K_t(x)=\frac{1}{\sqrt{4\pi t}}\exp\left\{-\frac{1}{2}\left(F(x)-F\left(\frac{x}{2t}\right)\right)-\frac{x^2}{4t}-\frac{a(1+4t^2)}{8t}+\frac{a\pi}{8}\right\}.$$

The function $K_t(x)$ is the heat kernel at $y=0$ as may be readily checked. The case $\rho\neq 0$ is similar.

This proves the theorem for (i). The other cases proceed in a similar way. ■

The Ricatti equations of Theorem 4.1 may be linearized by introducing the substitution $f=2y'/y$. This allows the general solutions to be determined.

The Ricatti equations of Theorem 4.1 may be rewritten as

$$\text{(i)}\quad y''=\frac{1}{2}\left(\frac{A}{x^2}-\frac{a}{2}\right)y,$$

$$\text{(ii)}\quad y''=\frac{1}{2}\left(\frac{1}{8}x^2+\frac{C}{x^2}\right)y,$$

$$\text{(iii)}\quad y''=\frac{1}{2}\left(\frac{C}{(x+2)^2}\right)y,$$

$$\text{(iv)}\quad y''=\tfrac{1}{3}Cxy,$$

$$\text{(v)}\quad y''=\tfrac{1}{2}(\tfrac{1}{2}Cx^2+D)y.$$

We now list the general solutions:

$$\text{(i)}\quad y=B_1\sqrt{x}J_{-\sqrt{4+8A}/4}\left(\frac{\sqrt{\alpha}x}{2}\right)+B_2\sqrt{x}J_{\sqrt{4+8A}/4}\left(\frac{\sqrt{\alpha}x}{2}\right),$$

$$\text{(ii)}\quad y=B_1\sqrt{x}I_{-\frac{1}{8}\sqrt{4+8C}}\left(\frac{x^2}{8}\right)+B_2\sqrt{x}I_{\frac{1}{8}\sqrt{4+8C}}\left(\frac{x^2}{8}\right),$$

$$\text{(iii)}\quad y=B_1(8+8x+2x^2)^{1-\sqrt{1+2C}/4}+B_2(8+8x+2x^2)^{1+\sqrt{1+2C}/4},$$

$$\text{(iv)}\quad y=B_1\,\mathrm{Ai}\left(\frac{x}{(3C)^{\frac{1}{3}}}\right)+D_1B_i\left(\frac{x}{(3C)^{\frac{1}{3}}}\right),$$

$$\begin{aligned}\text{(v)}\quad y=\exp\Bigg\{&-\frac{1}{4}\Bigg(\frac{D+\sqrt{D^2-C(-2Dx^2-Cx^4)}}{\sqrt{C}}-\ln(-16C^2D\\&-16C^2\sqrt{D^2-C(-2Cx^2-Cx^4)})\Bigg)\Bigg\}(D\\&+\sqrt{D^2-C(-2Dx^2-Cx^4)})^{1/4}\\&\times\Bigg(B_1M\left(\frac{3}{4}-\frac{D}{4\sqrt{C}},\frac{3}{2},\frac{1}{2\sqrt{C}}(D+\sqrt{D^2-C(-2Cx-Cx^4)})\right)\\&+B_2U\left(\frac{3}{4}-\frac{D}{4\sqrt{C}},\frac{3}{2},\frac{1}{2\sqrt{C}}(D+\sqrt{D^2-C(-2Cx-Cx^4)})\right)\Bigg).\end{aligned}$$

Here, B_1, B_2, D_1 are constants. $J_a(z)$ and $I_a(z)$ are Bessel functions of the first kind; Ai and Bi are Airy functions; and $M(a,b,z)$, $U(a,b,z)$ are the hypergeometric functions as described in Abramowitz and Stegun (Ref. 15, Chap. 15). From these solutions we may determine all possible forms for f. An exhaustive analysis of these functions and the heat kernels to which they give rise is beyond the scope of this paper.

In fact we may solve the Ricatti equations in (i) through (v) for various cases to obtain easy derivations for heat kernels of many interesting equations of the form (4.1).

Consider (i) with $a=0$.

Then

$$f'+\frac{1}{2}f^2=\frac{A}{x^2}.$$

If $A=0$ then $f(x)=2/(x+c)$, $c=$constant. In this case $\tau_{tt}=0$ and in addition to $\{v_2,v_3,v_4,v_6\}$ given in the proof of the theorem we also have

$$v_1=\frac{\partial}{\partial x}-\frac{u}{x+c}\frac{\partial}{\partial u},$$

$$v_5=2t\frac{\partial}{\partial x}-\left(x+\frac{2t}{x+c}\right)u\frac{\partial}{\partial u}.$$

We can also solve for $A\neq 0$, provided $A=\frac{1}{2}a^2-a$, a is a constant. We obtain the following possibilities for f:

$$\text{(i)}\quad f=\frac{2}{x+c},$$

$$\text{(ii)}\quad f=\frac{a}{x},$$

$$\text{(iii)}\quad f=\frac{a}{x}+\frac{2(1-a)}{x+2c(1-a)x^{a}},\quad a\neq 1,\quad c \text{ constant},$$

$$\text{(iv)}\quad f=\frac{1}{x}+\frac{2}{2cx+x\ln x},\quad c \text{ constant}.$$

Let us collect some results together.

Corollary 4.2: For equation (4.1) and for each given $f(x)$, we have the following heat kernels:

$$\text{(i)}\quad f=\frac{2}{x+c},\quad K(t,x,0)=\frac{x}{(x+c)(4\pi t)^{3/2}}\exp\left\{\frac{-x^2}{4t}\right\},$$

$$\text{(ii)}\quad f=\frac{a}{x},\quad K(t,x,0)=\frac{1}{(4\pi t)^{(a+1)/2}}\exp\left\{\frac{-x^2}{4t}\right\},$$

$$\text{(iii)}\quad f=\frac{a}{x}+\frac{2(1-a)}{x(1+2c(1-a)x^{a-1})},\quad a\neq 1,$$

$$K(t,x,0)=\frac{1}{(4\pi t)^{(a+1)/2}}\left[1+\frac{x^{1-a}}{2x(1-a)}\right]\exp\left\{\frac{-x^2}{4t}\right\},$$

$$\text{(iv)}\quad f=\frac{1}{x}+\frac{2}{2cx+x\ln x},\quad K(t,x,0)=\frac{1}{4\pi t}\left[1-\frac{\ln(4\pi t)}{2c+\ln x}\right]\exp\left\{\frac{-x^2}{4t}\right\},$$

$$\text{(v)}\quad f=\frac{-\sqrt{\alpha}(1-Ae^{\sqrt{\alpha}x})}{1+Ae^{\sqrt{\alpha}x}},\quad \alpha>0,\quad A \text{ constant},$$

$$K(t,x,0)=\frac{1}{\sqrt{4\pi t}}\left(\frac{1+A\exp\sqrt{\alpha}x}{1+A\exp\left(\dfrac{\sqrt{\alpha}x}{4\pi t}\right)}\right)\exp\left\{\frac{-x^2}{4t}+\frac{\sqrt{\alpha}x}{2}-\frac{\sqrt{\alpha}x}{8\pi t}-\frac{\alpha\left(t-\dfrac{1}{4\pi}\right)^2}{2t}\right\}.$$

In some cases we can translate $K(t,x,0)$ to obtain $K(t,x,y)$ by picking an appropriate group translation. For example, for $f=2/(x+c)$,

$$K(t,x,y)=\left(1-\frac{y}{x+c}\right)K(t,x-y,0).$$

So, for example, $u_{xx}+(2/x)u_x=u_t$ has ''heat kernel''

$$K(t,x,y)=\frac{1}{(4\pi t)^{3/2}}(1-y/x)\exp\left\{\frac{-(x-y)^2}{4t}\right\}.$$

For $f=[-\sqrt{\alpha}(1-Ae^{\sqrt{\alpha}x})/(1+Ae^{\sqrt{\alpha}x})]$,

$$K(t,x,y)=e^{-\sqrt{\alpha}y/2}\left(\frac{1+Ae^{\sqrt{\alpha}x}}{1+Ae^{\sqrt{\alpha}(x-y)}}\right)K(t,x-y,0).$$

In cases where no such simple group translation exists as a point symmetry, we would need to seek a generalized symmetry to translate $K(t,x,0)$ to $K(t,x,y)$. We have not attempted to do this.

The interested reader may attempt to find other heat kernels by finding different solutions to (i) through (v).

V. HEAT KERNELS FOR OTHER FINITE-DIMENSIONAL LIE ALGEBRAS ON $\mathbb{R}$

In the preceding section, we considered those drift terms for which $(\partial^2/\partial x^2)+f(x)(\partial/\partial x)$ had a fundamental solution obtained from a point symmetry.

Notice that $\partial^2/\partial x^2$ may be thought of as the Laplacian generated by the one-dimensional Lie algebra of differential operators on $\mathbb{R}$ generated by $\partial/\partial x$. Recall that this is one of three finite-dimensional Lie algebras of first-order differential operators on $\mathbb{R}$. The other two are spanned by $\partial/\partial x$ together with $x(\partial/\partial x)$, and by $\partial/\partial x$, $x(\partial/\partial x)$, and $x^2(\partial/\partial x)$.

These generate the Lie algebra of the $ax+b$ group and of SL $(2,\mathbb{R})$, respectively. In this section, we consider sums-of-squares Laplacians, with drift terms, for these two algebras.

The Laplacian generated by $\partial/\partial x$ together with $x(\partial/\partial x)$ has the form $\Delta=(1+x^2)(\partial^2/\partial x^2)+x(\partial/\partial x)$.

We study equations of the form

$$\Delta u+f(x)\frac{\partial u}{\partial x}=\frac{\partial u}{\partial t},$$

which may be written

$$(1+x^2)\frac{\partial^2 u}{\partial x^2}+(x+f(x))\frac{\partial u}{\partial x}=\frac{\partial u}{\partial t}.$$

Observe that if we put $x=\sinh\xi$ in this equation, we have $\partial u/\partial x=(1/(\partial/\cosh\xi)\partial\xi)$ and $\partial^2 u/\partial x^2=(1/\cosh^2\xi)(\partial^2/\partial\xi^2)-(\sinh\xi/\cosh\xi)(\partial/\partial\xi)$. Hence, the equation is transformed into

$$\frac{\partial^2 u}{\partial\xi^2}+h(\xi)\frac{\partial u}{\partial\xi}=\frac{\partial u}{\partial t}, \tag{5.1}$$

where $h(\xi)=\tanh\xi f(\sinh\xi)$.

This is exactly of the form (4.1). We find again that (5.1) has a point symmetry generating the fundamental solution if and only if h satisfies one of the Ricatti equations of Theorem 4.1.

Thus, for example, applying Corollary 4.2, we see that when

$$h(\xi)=\left(\frac{a}{\xi}+\frac{2(1-a)c}{\xi+2(1-a)c\xi^a}\right),$$

$$f(\sinh\xi)=\frac{1}{\tanh\xi}\left(\frac{a}{\xi}+\frac{2(1-a)c}{\xi+2(1-a)c\xi^a}\right),\quad a\neq 1.$$

Putting $x=\sinh\xi$ gives

$$f(x)=\frac{\sqrt{1+x^2}}{x}\left(\frac{a}{\sinh^{-1}x}+\frac{2(1-a)c}{\sinh^{-1}x+2(1-a)c(\sinh^{-1}x)^a}\right).$$

Thus, we obtain the following.

Corollary 5.1:

$$(1+x^2)\frac{\partial^2 u}{\partial x^2}+\left(x+\frac{\sqrt{1+x^2}}{x}\left(\frac{a}{\sinh^{-1}x}+\frac{2(1-a)c}{\sinh^{-1}\xi+2(1-a)c(\sinh^{-1}x)^a}\right)\right)\frac{\partial u}{\partial x}=\frac{\partial u}{\partial t},$$

$a\neq 1$, *has heat kernel*

$$k(t,x,0)=\frac{1}{(4\pi)^{(a+1)/2}}\left[1+\frac{(\sinh^{-1}x)^{1-a}}{2c(1-a)}\right]\exp\left\{-\frac{(\sinh^{-1}x)^2}{4t}\right\}.$$

The other case we want to consider here is the Lie algebra spanned by $\partial/\partial x$, $x(\partial/\partial x)$, and $x^2(\partial/\partial x)$.

The appropriate sums-of-squares Laplacian for this basis is

$$\Delta=(1+x^2+x^4)\frac{\partial^2}{\partial x^2}+(x+2x^3)\frac{\partial}{\partial x},$$

and we consider the equation

$$\Delta u+f(x)\frac{\partial u}{\partial x}=\frac{\partial u}{\partial t},$$

which we may rewrite as

$$(1+x^2+x^4)\frac{\partial^2 u}{\partial x^2}+(x+2x^3+f(x))\frac{\partial u}{\partial x}=\frac{\partial u}{\partial t}.$$

If we put $k^{-1}(x)=\int dx/\sqrt{1+x^2+x^4}$, which is a higher analogue of the inverse tanh function, then the substitution $x=k(\xi)$ reduces the equation to

$$\frac{\partial^2 u}{\partial^2 \xi}+\frac{k(\xi)}{k'(\xi)}f(k(\xi))\frac{\partial u}{\partial \xi}=\frac{\partial u}{\partial t}.$$

Putting $[k(\xi)/k'(\xi)]f(k(\xi))=h(\xi)$, there are a limited number of possibilities for f, and using Corollary 4.2 we see, for example, that the heat kernel for

$$\frac{\partial u}{\partial t}=(1+x^2+x^4)\frac{\partial^2 u}{\partial x^2}+\left(x+2x^2+\frac{\sqrt{1+x+x^2}}{x}\left(\frac{a}{k^{-1}(x)}+\frac{2(1-c)a}{k^{-1}(x)+2(1-c)a(k^{-1}(x))^a}\right)\right)\frac{\partial u}{\partial x}$$

is

$$k(t,x,0)=\frac{1}{(4\pi t)^{(a+1)/2}}\left[1+\frac{(k^{-1}x)^{1-a}}{2c(1-a)}\right]\exp\left\{\frac{-k^{-1}(x)^2}{4t}\right\}.$$

Similar formulas may be found whenever we have an explicit solution for the Ricatti equations of Theorem 4.1.

VI. THE $ax+b$ GROUP

In this section we apply another aspect of group symmetry techniques to the study of properties heat kernels. The study of the asymptotic behavior of heat kernels is an important area of harmonic analysis. In this final section we will illustrate how quite simple group symmetry methods may be used to derive some new and unusual integrals of the heat kernel of the $ax+b$ group. Such integrals may be useful in studying the heat kernel's asymptotics, as well as having intrinsic interest. We believe that further investigation of these ideas will be useful for other equations.

In the remainder of this section, we consider the $ax+b$ group, given in matrix presentation by

$$G=\left\{\begin{pmatrix} a & b \\ 0 & 1 \end{pmatrix}: a>0, b\in\mathbb{R}\right\}.$$

It is known[9,16] that the heat equation for G may be written as

$$y^2\left(\frac{\partial^2 u}{\partial x^2}+\frac{\partial^2 y}{\partial y^2}\right)+y\frac{\partial u}{\partial y}=\frac{\partial u}{\partial t} \tag{6.1}$$

with $y>0$, $x\in\mathbb{R}$. Further, the heat kernel is

$$\rho_t(y,x)=\frac{\sqrt{y}}{\sqrt{4\pi^3 t}}\int_0^\infty \frac{e^{-[(r^2/2t)-\pi^2]}\sinh r\sin\dfrac{\pi r}{t}}{(1+x^2+y^2+2y\cosh r)^{1/2}}dr,$$

where $r=(x^2+y^2)^{1/2}$. This integral cannot be done explicitly, and a great deal of effort has gone into estimating its asymptotics—see, for example, Ref. 9.

A basis for the symmetry algebra of point symmetries is easily shown to consist of

$$v_1=\frac{\partial}{\partial x},\quad v_2=\frac{\partial}{\partial t},\quad v_3=u\frac{\partial}{\partial u},\quad v_4=x\frac{\partial}{\partial x}+y\frac{\partial}{\partial y}-\frac{1}{2}u\frac{\partial}{\partial u},$$

$$v_5=(x^2-y^2)\frac{\partial}{\partial x}+2xy\frac{\partial}{\partial y}-ux\frac{\partial}{\partial u}.$$

Calculation of the commutator table shows that these vector fields generate the Lie algebra of $\mathrm{SL}(2,\mathbb{R})\oplus\mathbb{R}^2$.

We wish to determine solutions of (6.1) which are invariant under the symmetries generated by one of the vector fields above. We shall see that different choices of vector field give different information about the heat kernel.

Let us first use v_4, which generates the scaling symmetry

$$\sigma(\exp\epsilon v_4)u(x,y,t)=e^{1/2\epsilon}u(e^\epsilon y,e^\epsilon x,t).$$

Since scalar multiplication of u is also a symmetry, we may drop the factor of $e^{1/2\epsilon}$. According to the method of Ref. 1, Chap. 3, we now note that $r=x/y$ is an invariant of v_4 and hence we may obtain a group invariant solution of (6.1) by solving the reduced equation.

$$(1+r^2)\frac{\partial u^2}{\partial r^2}+r\frac{\partial u}{\partial r}=\frac{\partial u}{\partial t}.$$

As in Sec. V, this may be solved by setting $r=\sinh\xi$ to obtain

$$\frac{\partial^2 u}{\partial \xi^2}=\frac{\partial u}{\partial t},$$

the heat equation on $\mathbb{R}$. Thus, Eq. (6.1), with an initial condition of the form $u(y,x,0)=h(x/y)$, has a solution

$$u(u,x,t)=\int_{-\infty}^{\infty}h(\sinh\xi)K_t(\sinh^{-1}(x/y)-\xi)d\xi,$$

where K_t is the heat kernel on $\mathbb{R}$. Replacing ξ by $\sinh^{-1}\omega$, this becomes

$$u(y,x,t)=\int_{-\infty}^{\infty}h(\omega)K_t(\sinh^{-1}(x/y)-\sinh^{-1}/\omega)\,\frac{d\omega}{\sqrt{1+\omega^2}}.$$

It is amusing to compare this with the solution found via the usual heat kernel p_t, viz.

$$u(y,x,t)=\int_{-\infty}^{\infty}\int_{0}^{\infty}h(\xi/\eta)p_t((\eta,\xi)^{-1}(y,x))\,\frac{d\eta}{\eta}d\xi.$$

Putting $\omega=\xi/\eta$ and $z=\eta$, this becomes

$$u(y,x,t)=\int_{-\infty}^{\infty}h(\omega)\left(\int_{0}^{\infty}p_t\left(\frac{y}{z},\frac{x-z\omega}{z}\right)dz\right)d\omega,$$

whence we obtain

$$\int_{0}^{\infty}p_t\left(\frac{y}{z},\frac{x-z\omega}{z}\right)dz=\frac{K_t\left(\sinh^{-1}\left(\frac{x}{y}\right)-\sinh^{-1}\omega\right)}{\sqrt{1+\omega^2}}.$$

This may be regarded as some kind of new estimate on the asymptotic behavior of p_t.

In fact, using the machinery developed in Sec. V, we may use the preceding sequence of changes of variables to solve the heat equation with drift on the $ax+b$ group provided that the drift term is of the form $f(x/y)$, where f is one of the functions of the form in Theorem (4.1). The result is as follows. We leave the detailed verification to the reader.

Proposition 6.1: Consider the equation

$$y^2\left(\frac{\partial^2u}{\partial x^2}+\frac{\partial^2u}{\partial y^2}\right)+y\frac{\partial u}{\partial y}+\frac{y}{\cosh\left(\frac{x}{y}\right)}f\left(\sinh\left(\frac{x}{y}\right)\right)\frac{\partial u}{\partial x}=\frac{\partial u}{\partial t},$$

$$u(x,y,0)=h\left(\frac{x}{y}\right),$$

where f is given by one of the functions of Corollary 4.2. This equation has solution

$$u(y,x,t)=\int_{-\infty}^{\infty}h(\omega)K\left(\sinh^{-1}\frac{x}{y}-\sinh^{-1}\omega,t\right)\frac{d\omega}{\sqrt{1+\omega^2}},$$

where $K(x,t)$ is the given heat kernel for $(\partial^2u/\partial x^2)+f(x)(\partial u/\partial x)=\partial u/\partial t$.

In the preceding section we used the v_4 symmetry reduction to obtain an integral of the heat kernel p_t. We now repeat the exercise using the v_1 symmetry and the v_5 symmetry. The results are contained in the following theorem. Our methods may be applied to heat kernels of other Lie groups as well.

Proposition 6.2: Let p_t be the heat kernel on G and K_t the heat kernel of $\mathbb{R}$. Then

$$\text{(i)}\quad \int_0^\infty p_t\left(\frac{y}{z}, \frac{x-z\omega}{z}\right)dz = \frac{K_t\left(\sinh^{-1}\frac{x}{y} - \sinh^{-1}\omega\right)}{\sqrt{1+\omega^2}}$$

$$\text{(ii)}\quad \int_{-\infty}^\infty p_t((\eta,\xi)^{-1}(y,x))d\xi = K_t(\log y - \log \eta),$$

$$\text{(iii)}\quad \int_0^\infty p_t(ye^{-z}(e^{2z}+s^2), e^{-z}x(e^{2z}+s^2) - e^{-z}s)e^{-z/2}\frac{ds}{\sqrt{e^{2z+s}}} = \frac{e^{t/4}}{\sqrt{y}}K_t\left(\log\frac{y}{x^2+y^2} - t - z\right).$$

Proof: (i) was proved above.

For the proof of (ii), note that $v_1 = \partial/\partial x$ generates the symmetry

$$\sigma(\exp \epsilon v_1)u(x,y,t) = u(y, x-\epsilon, t);$$

an invariant of this is $r = y$. This yields the reduced equation

$$y^2 u_{yy} + y u_y = u_t, \quad y > 0.$$

Putting $y = e^s$, we find the equation

$$u_{ss} = u_t, \quad -\infty < s < \infty$$

and hence, as above, the boundary value problem

$$y^2(u_{yy} + u_{xx}) + y u_y = u_t,$$

$$u(y,x,0) = f(y)$$

has the solution

$$u(y,x,t) = \int_0^\infty f(\eta)K_t(\log y - \log \eta)\frac{d\eta}{\eta}.$$

Comparing as above with the solution coming directly from p_t, we obtain (ii).

To prove (iii) note that v_5 generates the symmetry

$$\sigma(\exp \epsilon v_5)u(x,y,t) = \frac{1}{\sqrt{(1+\epsilon x)^2 + \epsilon^2 y^2}}u\left(\frac{y}{(1+\epsilon x)^2+\epsilon^2 y^2}, \frac{x+\epsilon(x^2+y^2)}{(1+\epsilon x)^2+\epsilon^2 y^2}, t\right),$$

invariants being $r = \log[y/(x^2+y^2)]$ and $v = \sqrt{y}u$.

Substituting these new parameters into our equation, it reduces to

$$v_{rr} - v_r + \tfrac{1}{4}v = v_t, \quad -\infty < r < \infty.$$

This may be solved by standard Fourier transform techniques to obtain

$$v(r,t) = e^{t/4}\int_{-\infty}^\infty f(\lambda)K_t(r - t - \lambda)d\lambda.$$

Thus, the solution of the initial value problem

$$y^2(u_{xx}+u_{yy})+yu_y=u_t,$$

$$u(y,x,0)=\frac{1}{\sqrt{y}}h\left(\frac{y}{x^2+y^2}\right)$$

is

$$u(y,x,t)=\frac{e^{t/4}}{\sqrt{y}}\int_{-\infty}^{\infty}f(\xi)K_t\left(\log\frac{y}{x^2+y^2}-t-\xi\right)d\xi. \tag{6.2}$$

In order to compare this with the solution coming directly from p_t, viz,

$$u(y,x,t)=\int_{-\infty}^{\infty}\int_0^{\infty}\frac{1}{\eta}f\left(\log\frac{\eta}{\xi^2+\eta^2}\right)p_t((\eta,\xi)^{-1}(y,x))\frac{d\eta}{\eta}d\xi,$$

we set $r=\eta/(\xi^2+\eta^2)$, $s=\xi/(\xi^2+\eta^2)$, to obtain

$$u(y,x,t)=\int_{-\infty}^{\infty}\int_0^{r}f(\log r)p_t\left(y\frac{(r^2+s^2)}{r},\frac{x(r^2+s^2)-s}{r}\right)\frac{dr\,ds}{r^{3/2}\sqrt{r^2+s^2}}.$$

Finally, substituting $z=\log r$ and comparing this expression with (6.2), we obtain (iii). ■

(Received 20 June 2000; accepted for publication 24 July 2000)

This paper deals with the striking fact that there is an essentially canonical path from the ith Lie algebra cohomology cocycle, $i=1,2,\ldots,l$, of a simple compact Lie algebra $\mathfrak{g}$ of rank l to the definition of its primitive Casimir operators $C^{(i)}$ of order m_i. Thus one obtains a complete set of Racah–Casimir operators $C^{(i)}$ for each $\mathfrak{g}$ and nothing else. The paper then goes on to develop a general formula for the eigenvalue $c^{(i)}$ of each $C^{(i)}$ valid for any representation of $\mathfrak{g}$, and thereby to relate $c^{(i)}$ to a suitably defined generalized Dynkin index. The form of the formula for $c^{(i)}$ for su(n) is known sufficiently explicitly to make clear some interesting and important features. For the purposes of illustration, detailed results are displayed for some classes of representation of su(n), including all the fundamental ones and the adjoint representation. © *2001 American Institute of Physics.*

I. INTRODUCTION

It is well-known (see, e.g., Refs. 1–3 for lists of references and further details) that the l basis elements of the Lie algebra cohomology of a simple compact Lie algebra $\mathfrak{g}$ define, up to a constant, l totally antisymmetric tensors. In fact, these may also be understood as the coordinates of the different invariant $(2m-1)$-forms on the manifold of the compact group G associated with $\mathfrak{g}$ that, in the Chevalley–Eilenberg version of the Lie algebra cohomology,[4] characterize the $(2m-1)$-cocycles. Given a simple compact $\mathfrak{g}$, we shall refer to these l tensors as the Omega tensors $\Omega^{(2m_s-1)}$ of $\mathfrak{g}$. They have orders $2m_s-1$, $s=1,2,\ldots,l$, where m_s are the orders of the primitive Casimir–Racah operators of $\mathfrak{g}$ (see also Refs. 1–3 for lists of references). For su(n), $m_s\in\{2,3,\ldots,n\}$, and hence the Omega tensors are of orders $3,5,\ldots(2l+1)$. There is an essentially canonical path from the Omega tensors of a given $\mathfrak{g}$ that leads to the set of its l *primitive* Racah–Casimir operators $C^{(m_s)}$. Following this path,[2] the resulting set of Racah–Casimir operators $C^{(m_s)}$ [represented by invariant symmetric tensors $t^{(m_s)}$ of order m_s] is optimally defined in the sense that it contains one member for each required order m_s and nothing else. The procedure allows for the appearance of no $C^{(m_s)}$ other the l primitive ones; any formal attempt to define $C^{(m)}$ for, say, su(n) for $m>n$ simply produces a vanishing result. Since this paper concentrates on su(n), we shall not worry about the refinements that are needed to deal explicitly with all the invariants of the even orthogonal algebras $\mathfrak{g}=D_l$, where the Pfaffian enters the picture. Nor will the subsequent discussion make explicit the qualifications that may be needed to cover the exceptional algebras.

The paper proceeds from the definition of a complete set of primitive Racah–Casimir operators for $\mathfrak{g}$ to a new general result for the eigenvalues $c^{(m_s)}(D)$ of $C^{(m_s)}(D)$ for a generic representation D,

$$X_i \mapsto D(X_i) \tag{1}$$

of the Lie algebra

$$[X_i, X_j] = i f_{ijk} X_k \tag{2}$$

of $\mathfrak{g}$. We have here written f_{ijk} for the structure constants of $\mathfrak{g}=\mathrm{su}(n)$. For this algebra, almost all of the technical machinery is at hand[2,5] to enable us to display explicitly the key features of our general result for $c^{(m)}(D)$. Obvious analogues of these results are applicable to all other $\mathfrak{g}$.

Our main result states that, for any representation D,

$$(\dim D)\, c^{(m_s)}(D) = 2^{1-m_s} (gdi)^{(m_s)}(D) \Omega^{(2m_s-1)^2}, \tag{3}$$

where

$$\Omega^{(2m_s-1)^2} \equiv \Omega_{i_1 \cdots i_{2m_s-1}} \Omega_{i_1 \cdots i_{2m_s-1}}, \tag{4}$$

and $(gdi)^{(m_s)}(D)$ is a number dependent on the order m_s of the Racah–Casimir operators, the representation D considered and $\mathfrak{g}$, or rather in the case of $\mathrm{su}(n)$, on n. For the representation considered, $(gdi)^{(m_s)}(D)$, $s=1,\ldots,l$, is an acronym for the sth *generalized Dynkin index* for the representation D considered and its use in (3) is discussed below. What is special about $\mathrm{su}(n)$ is that $\Omega^{(2m_s-1)^2}$ is known explicitly for all n and for all $2 \leqslant m \leqslant n$ (from now on, we drop the subindex $s=1,\ldots,l$ in m_s). From Ref. 5 we quote

$$\Omega^{(2m-1)^2} = \frac{2^{2m-3}}{(2m-2)!}\, n \prod_{r=1}^{m-1} (n^2 - r^2) \tag{5}$$

$$= \frac{4}{(2m-2)(2m-3)}\, \Omega^{(2m-3)^2}. \tag{6}$$

Equation (5) exhibits features of (3) which we believe apply equally well to all other $\mathfrak{g}$. Equation (5) shows that $\Omega^{(2m-1)^2} \neq 0$ and hence $\Omega^{(2m-1)}$ is nonvanishing only of $m \leqslant n$. In other words the primitive $(2m-1)$-cocycle exists only for $m \leqslant n$ as known from Lie algebra cohomology, and (3) gives a null result for $c^{(m)}(D)$ only when $n < m$. The power of two in (3) has been chosen, as far as we know it to be necessary, to ensure that, as is customary for an index, $(gdi)^{(m)}(D)$ takes on only integral values. In the case of $m=2$ and the familiar Dynkin index itself,[6] (3) takes on its standard form (see, e.g., Ref. 7),

$$(gdi)^{(2)}(D) = \frac{2 \dim D}{n \dim \mathfrak{g}}\, c^{(2)}(D), \tag{7}$$

using $f_{ijk} f_{ijk} = \Omega^{(3)^2} = n(n^2-1) = n.\dim(\mathrm{su}(n))$. The factor n in the denominator of (7) reflects the fact that for uniformity (in m) of our definitions of the various $C^{(m)}$ for $\mathrm{su}(n)$, we have defined the quadratic Casimir operator of $\mathrm{su}(n)$ as

$$C^{(2)} = n X_i X_i, \quad i = 1, \ldots, n-1, \tag{8}$$

see Sec. II C. For higher values of m there is less agreement as to how the Casimir operators $C^{(m)}$, and hence the $(gdi)^{(m)}(D)$, should be defined. We have argued that our definition of the former is optimal, featuring as it does t-tensors[2] and Omega tensors that are in one-to-one correspondence with the cohomology cocycles of $\mathrm{su}(n)$. This is tantamount to asserting that the Omega tensors are the fundamental entities (in fact, Ω^3 is given by the structure constants of the algebra themselves), and our definition of Casimir operators follows from this and reflects it too. A good recent account

of the role of, and of one way of defining, generalized Dynkin indices, which were originally introduced in Ref. 8, is Ref. 9, which refers to earlier papers.[10,11] The paper[9] also emphasizes the role of ''orthogonal'' tensors—in essence our t-tensors—making reference to Ref. 2 in this context, and attributing the recognition of the importance of orthogonality to the definition of generalized Dynkin indices to Ref. 8. Reference 9 contains extensive tabulations of generalized Dynkin indices, as does Ref. 12. Another useful discussion of indices is contained in Ref. 13, which aims, as we do here, at getting results for all su(n) valid for all n, using procedures—Cvitanovic's bird-track methods—that are there also applied to other $\mathfrak{g}$. Our work differs from that of the papers just cited in that it emphasizes the central role of the Omega-tensors, and employs a definition of indices that follows from this viewpoint. In view of (5) we believe that a significant amount of new information is contained in our work. We would further wish to advocate that (3)—the formula for the eigenvualue $c^{(m)}(D)$ of the Racah–Casimir operator of order m—be seen as the result of primary importance. The $(gdi)^{(m)}(D)$ are merely numbers, knowledge of which is required to complete the determination of the $c^{(m)}(D)$. Thus while the number $(gdi)^{(m)}(D)$ in some sense characterizes the eigenvalue $c^{(m)}(D)$, general su(n) formulas for $(gdi)^{(m)}(D)$ do not automatically exhibit the restrictions on n necessary for their applicability. Thus, for the adjoint represention ad, see below, of su(n),

$$(gdi)^{(4)}(\mathrm{ad}) = 2n. \tag{9}$$

But this applies *only* when $n \geqslant 4$, since (3)–(5) show that $c^{(4)}(D)$ equals zero for any D for $n = 2,3$, as it should do, since $\mathcal{C}^{(4)}$ is absent for these n-values. See also comments following (70) and (103) below.

The paper turns next to providing some illustrations of the results that are contained within (3). We wish to deduce the values of $(gdi)^{(m)}(D)$ for various m and representations D, obtaining results from a single computation that are valid for all n. For this purpose we consider the following classes of representations of su(n). We will use the notation $\mathcal{F}^s$ for $s = 1,2 \ldots, l$, for the fundamental representations of su(n) of rank $l = n-1$ (writing also $\mathcal{F} \equiv \mathcal{F}^1$ for the defining representation), and denote the adjoint representation of the algebra by ad.

A. The defining representation of su(n), $\mathcal{F}$

$\mathcal{F} = (1,0,\ldots,0)$ and is given by

$$X_i \mapsto \tfrac{1}{2}\lambda_i \equiv \mathcal{F}_i, \tag{10}$$

where the λ_i are the standard Gell–Mann matrices of su(n).[14] Using results from Ref. 5, we can show by a single calculation that

$$(gdi)^{(m)}(\mathcal{F}) = 1 \tag{11}$$

for all n and for all $m \leqslant n$. This simple general result offers some indication of the appropriateness of our definition of $(gdi)^{(m)}$.

B. The adjoint representation ad of su(n)

In Dynkin coordinates $\mathrm{ad} = (1,0,\ldots,1)$ (see, e.g., Ref. 7) and it is given by

$$X_i \mapsto \mathrm{ad}(X_i) \equiv \mathrm{ad}_i, \quad (\mathrm{ad}_i)_{jk} = -if_{ijk}. \tag{12}$$

We show that $(gdi)^{(m)}(\mathcal{F}) = 0$ for all odd m for all n, and give results for $m = 2,4$ and 6, on the basis of one calculation for each of these three m values.

C. The representation $\mathcal{D}$ of $\mathfrak{g} = $ su(n)

Let $\mathcal{D}$ denote the representation of $\mathfrak{g}$ built[15,16] using the set of Hermitian Dirac matrices of a euclidean space of dimension $\dim \mathfrak{g} = r$. The representation $\mathcal{D}$ is defined by means of

$$X_i \mapsto \mathcal{D}(X_i) \equiv S_i = -\tfrac{1}{4} i f_{ijk} \gamma_j \gamma_k , \tag{13}$$

in terms of Dirac matrices such that

$$\{\gamma_i , \gamma_j\} = 2\delta_{ij} ; \tag{14}$$

hence, $\mathcal{D}$ has dimension $2^{[r/2]}$ ($[x]$ denotes the integral part of x). Unlike all the other representations that we treat $\mathcal{D}$ is reducible; it describes the direct sum of a number of copies of the irreducible representation of $\mathfrak{g}$ whose highest weight is the principal Weyl vector $\delta = \frac{1}{2}\Sigma_{\alpha>0}\alpha$, i.e., half the sum of the positive roots of su(n), given by $\delta = (1, \ldots, 1)$ in Dynkin coordinates. This representation has dimension $2^{(r-l)/2}$. The actual number of copies of δ in $\mathcal{D}$ is $2^{[l/2]}$. It follows that $\dim \mathcal{D} = 2^{[l/2]} 2^{(r-l)/2} = 2^{[r/2]}$. We restrict to $\mathfrak{g} = \mathrm{su}(n)$, for which $l = n-1$ and $r = n^2 - 1$. We show that $(gdi)^{(m)}(\mathcal{D})$ is zero for all odd m for all su(n), and give explicit results for $m = 2$ and $m = 4$ only.

D. The *l* fundamental representations $\mathcal{F}^s$ and the irrep $\mathcal{S}_p = (p,0,\ldots,0)$

By dealing with the completely symmetrized and also the completely antisymmetrized direct products of p copies of the defining representation $\mathcal{F}$, we derive results for the representations of su(n) with Dynkin coordinates $(p,0,\ldots,0)$, and for the fundamental representations $\mathcal{F}^s$, $s = 1,2,\ldots,n-1$. For the latter, we give all indices for all $\mathcal{F}^s$ for $n = 3,4,5$, and 6. Bird-track methods[13] are employed here.

The material of this paper is organized as follows. Section II gives a brief description of the various families of su(n) tensors, including the Omega tensors, that are involved in the build up to the definition of Casimir operators. To some extent this reviews our earlier paper,[2] where detailed references to previous studies of Casimir operators may be found. In Sec. III, we derive and discuss the key result (3). In Sec. IV, we turn to the illustration of (3) for the classes of su(n) representations just listed.

The interest of this paper in the eigenvalues of Casimir operators has been in the context of generalized Dynkin indices, because our approach brings these in completely naturally. There are however other sources of information on the subject. There is Ref. 17 where valuable explicit formulas are given for all Casimir operators of all classical algebras and also for g_2, while Ref. 18 addresses the problem for other exceptional algebras.

II. DEFINITIONS OF TENSORS AND RACAH–CASIMIR OPERATORS

A. The *d*-tensors

This is a family of symmetric tensors first defined by Sudbery.[19] The definition sets out from the standard Gell–Mann totally symmetric third order tensor d_{ijk} that exists for all $n \geqslant 3$ and is traceless $d_{ijk}\delta_{ij} = 0$. Higher order tensors in the family

$$d^{(r)}_{(i_1,\ldots,i_r)} , \tag{15}$$

are defined recursively by symmetrizing

$$d^{(r)}_{i_1,\ldots,i_r} = d^{(r-1)}_{i_1,\ldots,i_{r-2}j} d^{(3)}_{ji_{r-1}i_r} , \tag{16}$$

over all its $i_1, \ldots, i_r$ indices. Round brackets here denote symmetrization with unit weight. Thus

$$d^{(3)}_{(ijk)} = d_{ijk} ,$$

$$d^{(4)}_{(ijkl)} = \tfrac{1}{3}(d_{ijp}d_{pkl} + d_{jkp}d_{pil} + d_{kip}d_{pjl}). \tag{17}$$

Sometimes it is useful to refer to $d^{(2)}_{ij} = \delta_{ij}$ as the rank two member of the family.

B. The Omega tensors

Using the mentioned correspondence between $(2m-1)$-cocycles and $\Omega^{(2m-1)}$ tensors, we have (see, e.g., Refs. 1, 2 for the structure of these expressions)

$$\Omega^{(3)}_{ijk}=f_{ijk}=f_{aij}d^{(2)}_{(ak)}, \tag{18}$$

$$\Omega^{(5)}_{ijkpq}=f_{a[ij}f^{b}{}_{kp]}d^{(3)}_{(abq)}, \tag{19}$$

$$\Omega^{(7)}_{ijkpqrs}=f_{a[ij}f^{b}{}_{kp}f^{c}{}_{qr]}d^{(4)}_{(abcs)}, \tag{20}$$

and in general

$$\Omega^{(2m-1)}_{i_1j_i\cdots\, i_{m-1}j_{m-1}k}=f^{k_1}{}_{[i_1j_1}\cdots\ f^{k_{m-1}}{}_{i_{m-1}j_{m-1}]}d^{(m)}_{(k_1\cdots\ k_m)}. \tag{21}$$

Here square brackets indicate unit weight antisymmetrization over all the surrounded indices. The structure of $\Omega^{(2m-1)}$ above is general for any $\mathfrak{g}$; what makes it specific to su(n) are the orders $(3,5,\ldots,(2l+1))$, and of course the fact that the f's are the su(n) ones. One may check explicitly that $\Omega^{(2m-1)}$ tensor is fully antisymmetric in all its $(2m-1)$ indices $(i_1j_1i_2j_2\cdots\ i_{m-1}j_{m-1}k)$, even if only the first $(2m-2)$ indices are antisymmetrized by actual square brackets. The position of the indices in this paper is without metric significance. Since $\mathfrak{g}$ is compact and its generators are Hermitian, we may take the Killing metric as the unit matrix, and so the raising of indices may just serve to remove them from the sets of indices that are subject to antisymmetrization (or symmetrization).

A detailed account of the properties of Omega tensors has recently been prepared.[5] The extensive compilation of results contained in Ref. 5 includes the important formula (5), together with its derivation. As noted above, (5) makes clear that $\Omega^{(2m-1)}$ is absent for su(n) whenever $m>n$.

C. The *t*-tensors

Following Ref. 2 we review some properties of this family of totally symmetric and totally tracelsss tensors $t^{(m)}$ for su(n). The definitions are

$$t^{(2)}_{ak}=\Omega^{(3)}_{ijk}f_{ija}, \tag{22}$$

$$t^{(3)}_{abm}=\Omega^{(5)}_{ijklm}f_{ija}f_{klb}, \tag{23}$$

$$t^{(4)}_{abcq}=\Omega^{(7)}_{ijklmpq}f_{ija}f_{klb}f_{mpc}, \tag{24}$$

$$t^{(5)}_{abcds}=\Omega^{(9)}_{ijklmpqrs}f_{ija}f_{klb}f_{mpc}f_{qrd}, \tag{25}$$

and in general

$$t^{(m)}_{k_1\cdots\ k_m}=\Omega^{(2m-1)}_{i_1j_1\cdots\, i_{m-1}j_{m-1}k}f_{i_1j_1k_1}\cdots\ f_{i_{m-1}j_{m-1}k_{m-1}}. \tag{26}$$

It follows from definition (26) that the tensor $t^{(m)}$ is fully symmetric (Ref. 2, lemma 3.2).

We do not make extensive use of explicit expressions for the t-tensors, but it is useful to note results from[2,5]

$$t^{(2)}_{ij}=n\,\delta_{ij}, \tag{27}$$

$$t^{(3)}_{ijk}=\tfrac{1}{3}n^2d_{ijk}, \tag{28}$$

$$t^{(4)}_{ijkl}=\tfrac{1}{15}(n(n^2+1)d^{(4)}_{(ijkl)}-2(n^2-4)\,\delta_{(ij}\delta_{kl)}), \tag{29}$$

$$t^{(5)}_{ijklm}=\frac{n}{105}((n(n^2+5)d^{(5)}_{(ijklm)}-2(3n^2-20)d_{(ijk}\delta_{lm)}). \tag{30}$$

We have adjusted the normalizations in (27)–(30) by excluding some powers of two present in (6.12)–(6.14) of Ref. 2. The t-tensors are ''orthogonal'' among themselves, which means that the maximal contraction of a $t^{(m)}$ with a tensor $t^{(m')}$ of different order yields zero. This implies, in particular, that $t^{(m)}$ is traceless with respect any two indices. In the simplest, third order case, Eq. (28), this is just the well known property $d_{ikk}=0$. For order four, $t^{(4)}$, this means that

$$t^{(4)}_{ijkl}\delta_{ij}=0, \quad t^{(4)}_{ijkl}d_{ijk}=0. \tag{31}$$

But, since the trace formulas for d-tensors give

$$d^{(4)}_{(ijkl)}d_{ijm}=\frac{2}{3}\,\frac{(n^2-8)}{n}d_{klm}, \tag{32}$$

we learn that the nontrivial result for the nonmaximal contraction

$$t^{(4)}_{ijkl}d_{ijm}=\tfrac{2}{45}n^2(n^2-9)d_{klm}, \tag{33}$$

holds, although it collapses to zero, as it ought, for $n=3$. Also (33) yields the second part of (31) when one makes the contraction $k=m$. For order five, the orthogonality of the t-tensors means that

$$t^{(5)}_{ijklm}t^{(2)}{}_{ij}=0, \quad t^{(5)}_{ijklm}t^{(3)}_{ijk}=0, \quad t^{(5)}_{ijklm}t^{(4)}{}_{ijkl}=0, \tag{34}$$

and so on.

One way to see that the t-tensors, like the Omega tensors, are absent for $m>n$ is to consider the fully contracted square of a generic t-tensor,

$$t^{(m)^2}=t^{(m)}_{k_1\cdots\ k_m}t^{(m)}_{k_1\cdots\ k_m}. \tag{35}$$

This scalar quantity can be seen to contain the same product of factors as is seen in (5). Thus it is a polynomial in n that has factors which vanish whenever $n<m$. Actually the proof of this claim for the t-tensors was achieved for $m\leqslant 5$ in Ref. 2, whereas (5) is proved in full generality in Ref. 5, relatively speaking rather easily.

The d-tensors are less convenient than the t-tensors in that for su(n) they are well-defined for any order m, but are present as nonprimitive tensors for $m>n$. However,[19,2,20] the unwanted or rather inessential d-tensors of higher orders can always be expressed in terms of the primitive set with $m\leqslant n$. For example, for su(3) we have

$$d^{(4)}_{(ijkl)}=\tfrac{1}{3}\,\delta_{(ij}\delta_{kl)}, \tag{36}$$

$$d^{(5)}_{(ijklm)}=\tfrac{1}{3}\,\delta_{(ij}d_{klm)}, \tag{37}$$

and, for su(4),

$$d^{(5)}_{(ijklm)}=\tfrac{2}{3}\,\delta_{(ij}d_{klm)}. \tag{38}$$

The above expressions exhibit the nonprimitive character of the symmetric tensors on their left-hand sides. It becomes increasingly hard to supply such results for su(n) at higher n. Fortunately this is unnecessary. Further, as Ref. 5 shows, the d-tensors serve perfectly well for the definition of Omega tensors. If non-primitive d-tensors like (36)–(38) are employed in the definition of

tensors like those of Sec. II B, when we know that no Omega tensor is allowed (Ref. 2, Corollary 3.1), a vanishing result is obtained.[5] It follows that symmetric invariant tensors differing in nonprimitive parts lead to the same Omega tensors.

D. The Racah–Casimir operators

Given the t-tensor of Eq. (26), we define, for su(n), the generalized Casimir operator of rank m by means of

$$C^{(m)}=t^{(m)}_{i_1 i_2 \cdots\ i_m} X_{i_i} X_{i_2} \cdots\ X_{i_m}, \tag{39}$$

where the X_i are the generators of the Lie algebra (2) of su(n). The definition (39) produces each of the primitive su(n) Casimir operators of orders $m \in \{2,3,\ldots,n\}$, and nothing else. This is so because the l su(n) Lie algebra cohomology cocycles and their associated Omega tensors are in one-to-one correspondence with the t-tensors and hence with the $C^{(m)}$. Had we used the d-tensors in (39) instead of the t-tensors, we would always thereby obtain commuting su(n) invariant operators, but of all orders for all su(n) so that all but l of them are nonprimitive. For low enough n, we can derive results which show explicitly how some of the nonprimitive operators so obtained can be written in terms of primitive ones. But, in the context of the present work, this is not important; use of (39) bypasses the problem entirely.

We should point out one consequence of the uniformity in m of the definitions (27)–(30) of t-tensors. Equation (27) implies

$$C^{(2)}=t^{(2)}_{ij} X_i X_j = n X_i X_i\,, \tag{40}$$

with a possibly unexpected, but harmless, factor n. For example, for the su(3) representation (λ,μ) in Dynkin coordinates, Eq. (40) gives the eigenvalue

$$c^{(2)}(\lambda,\mu)=(\lambda^2+\lambda\mu+\mu^2+3\lambda+3\mu), \tag{41}$$

and, for the representation (λ,μ,ν) (cf. Ref. 7) of su(4),

$$c^{(2)}(\lambda,\mu,\nu)=\tfrac{1}{2}(3\lambda^2+4\mu^2+3\nu^2+4\lambda\mu+2\lambda\nu+4\mu\nu+12\lambda+6\mu+12\nu). \tag{42}$$

It may also be worth mentioning the result[21] for the eigenvalue of the cubic Casimir operator of su(3),

$$c^{(3)}(\lambda,\mu)=\tfrac{1}{6}(\lambda+2\mu+3)(2\lambda+\mu+3)(\lambda-\mu). \tag{43}$$

One may use the defining representations of su(3) and su(4) to check that the normalizations of (41)–(43) give agreement with (39), (27), and (28).

III. THE EIGENVALUES OF THE HIGHER CASIMIR OPERATORS

For su(n) for large enough n, $n \geqslant m$, we defined the mth order Casimir operator by means of (39), where the X_i are the su(n) generators. This yields an invariant operator $C^{(m)}(D)$ with eigenvalue $c^{(m)}(D)$ in any representation $X_i \mapsto D_i$ so that

$$C^{(m)}(D)=c^{(m)}(D)\, I_{\dim D}\,. \tag{44}$$

Then, using (26), we find

$$
\begin{aligned}
c^{(m)}(D)\dim D &= \mathrm{Tr}\, C^{(m)}(D) \\
&= \Omega^{(2m-1)}_{i_1 j_1 \cdots\, i_{m-1} j_{m-1} k_m} f_{i_1 j_1 k_1} \cdots\; f_{i_{m-1} j_{m-1} k_{m-1}}\, \mathrm{Tr}\, D_{k_1 \cdots\, k_m} \\
&= (-i)^{m-1}\, \Omega^{(2m-1)}_{i_1 j_1 \cdots\, i_{m-1} j_{m-1} k_m}\, \mathrm{Tr}\,([D_{i_1}, D_{j_1}] \cdots\; [D_{i_{m-1}}, D_{j_{m-1}}] D_{k_m}) \\
&= (-2i)^{m-1}\, \Omega^{(2m-1)}_{i_1 j_1 \cdots\, i_{m-1} j_{m-1} k_m}\, \mathrm{Tr}\, D_{[i_1 j_1 \cdots\, i_{m-1} j_{m-1} k_m]}\,. \qquad (45)
\end{aligned}
$$

The first trace in (45), $\mathrm{Tr}\, D_{k_1 \cdots\, k_m}$ is in practice a unit weight symmetric trace $\mathrm{Tr}\, D_{(k_1} \cdots\; D_{k_m)}$ since $t^{(m)}$ is symmetric and $C^{(m)}(D)$ is given by (39) with $X = D$. For the last one we have written

$$
D_{[ij \cdots\, s]} = D_{[i} D_j \cdots\; D_{s]}\,. \qquad (46)
$$

We note here the transfer of the total antisymmetry from the Omega tensor to the trace of a product of $(2m-1)$ D's. This enables a crucial development since, as stated, $\mathrm{Tr}(D_{[i_1 j_1 \cdots\, i_{m-1} j_{m-1} k_m]})$ must belong to the $(2m-1)$-cocycle space and, hence, has to be proportional to the only primitive, SU(n)-invariant, skew symmetric, $(2m-1)$-Omega tensor.

Hence (see also Sec. III A) for any representation D, we may write

$$
\mathrm{Tr}\, D_{[i_1 j_1 \cdots\, i_{m-1} j_{m-1} k_m]} = \left(\frac{1}{4} i\right)^{m-1} (gdi)^{(m)}(D)\, \Omega^{(2m-1)}_{i_1 j_i \cdots\, i_{m-1} j_{m-1} k_m}\,, \qquad (47)
$$

thereby defining a quantity $(gdi)^{(m)}(D)$ which depends on m and D and in general on the Lie algebra $\mathfrak{g}$ in question. Since $\mathfrak{g} = \mathrm{su}(n)$ here, $(gdi)^{(m)}(D)$ depends also on n. As noted above (gdi) is an acronym for generalized Dynkin index. Insertion of (47) into (45) immediately gives rise to one of the main results of this paper,

$$
\dim D\, c^{(m)}(D) = 2^{(1-m)} (gdi)^{(m)}(D)\, \Omega^{(2m-1)2}. \qquad (48)
$$

The importance of (48) is enhanced for su(n) by the availability of the explicit result (5), valid for all n and for all m relevant to that n value, $m \leqslant n$. The relationship of our discussion of $c^{(m)}(D)$ and $(gdi)^{(m)}(D)$ to the work of previous authors is reviewed in the introduction. Our presentation conforms fully to this for $m = 2$. Otherwise our approach differs from that of others in view of the primary role in it that is played by the Omega tensors. This feature is inherited from Ref. 2, but (5) was not known when Ref. 2 was written.

We believe the analysis described here for the A_l family of Lie algebras extends to other classical compact simple algebras, exhibiting similar attractive features, and in some fashion to the exceptional algebras. For example, the crucial property of ''orthogonality'' among two t-tensors of different order follows from their general definition in terms of their respective Ω cocycle tensors, and does not depend on the specific simple $\mathfrak{g}$ being considered.[2] However the corresponding tensor calculus, and the analogue of the su(n) λ-matrix machinery is not yet developed sufficiently to produce simple expressions and formulas for all simple algebras.

A. Another approach to (47)

We sketch here another means of justifying our use of (47).

We have by now familiar steps

$$
\mathrm{Tr}\, D_{[i_1 j_1 \cdots\, i_{m-1} j_{m-1} k_m]} = \left(\frac{1}{2} i\right)^{m-1} f^{k_1}{}_{[i_1 j_1} \cdots\; f^{k_{m-1}}{}_{i_{m-1} j_{m-1}]}\, \mathrm{Tr}\, D_{k_1 \cdots\, k_m}. \qquad (49)
$$

It is legitimate to insert round brackets first to enclose the set $k_1 \cdots\, k_{m-1}$ of indices, and then by use of the cyclic property of the trace to extend them to enclose the full set $k_1 \cdots\, k_m$. Now we may refer to the discussion in Ref. 2 for the construction of a basis for the vector space of su(n)-invariant symmetric tensors like $\mathrm{Tr}\, D_{(k_1 \cdots\, k_m)}$. The term in the expansion of $\mathrm{Tr}\, D_{(k_1 \cdots\, k_m)}$ with respect to this basis which involves $d^{(m)}_{(k_1 \cdots\, k_m)}$ is the significant one for our argument. Use of it immediately gives rise to a result for $\mathrm{Tr}\, D_{[i_1 j_1 \cdots\, i_{m-1} j_{m-1} k_m]}$ of the form (47). All the other

terms of the expansion are made up of symmetrized products of lower order d-tensors, and give rise to vanishing contributions to (47) in view of Jacobi identities, as shown in Ref. 5.

IV. APPLICATION TO CERTAIN CLASSES OF REPRESENTATIONS OF su(n)

We consider here several important classes of representations of su(n), including the fundamental ones, for which one may provide a definition that applies uniformly for all n.

A. The fundamental defining representation $\mathcal{F}$ of su(n)

The representation $\mathcal{F}$ is defined by (10) where the Gell–Mann lambda-matrices[14] are subject to

$$\mathrm{Tr}\,\lambda_i=0, \quad \mathrm{Tr}\,\lambda_i\lambda_j=2\delta_{ij}, \quad \lambda_i^\dagger=\lambda_i, \tag{50}$$

$$\lambda_i\lambda_j=\frac{2}{n}\delta_{ij}+(d+if)_{ijk}\lambda_k, \tag{51}$$

valid for all su(n), $n\geqslant 3$.

Using notation like that defined by (46), we quote from Ref. 5 the result for the trace of the fully antisymmetric product of an *odd* number of $(2m-1)$ lambda matrices,

$$\mathrm{Tr}\,\lambda_{[i_1j_1\cdots\, i_{m-1}j_{m-1}k]}=2i^{m-1}\Omega_{[i_1j_1\cdots\, i_{m-1}j_{m-1}k]}. \tag{52}$$

We may now use (10) to substitute $\mathcal{F}_i$ for λ_i in (52), and deduce from (45), that

$$nc^{(m)}(\mathcal{F})=2^{(-m+1)}\Omega^{(2m-1)2}, \tag{53}$$

so that (48) gives

$$(gdi)^{(m)}(\mathcal{F})=1, \tag{54}$$

which also follows by comparing (52) and (47).

This result applies to all su(n) and for any $m\leqslant n$. Equation (53) and the explicit expression (5) for $\Omega^{(2m-1)^2}$ show that $(gdi)^{(m)}(\mathcal{F})$ is zero otherwise. Equation (54) does not itself provide new information (see Table II in Ref. 9) but (53) presents its information in a way that perhaps is. In this context, it may be worthwhile to display some formulas for eigenvalues in full detail,

$$c^{(2)}(\mathcal{F})=\tfrac{1}{2}(n^2-1), \tag{55}$$

$$c^{(3)}(\mathcal{F})=\tfrac{1}{12}(n^2-1)(n^2-4), \tag{56}$$

$$c^{(4)}(\mathcal{F})=\tfrac{1}{180}(n^2-1)(n^2-4)(n^2-9), \tag{57}$$

$$c^{(5)}(\mathcal{F})=\tfrac{1}{1680}(n^2-1)(n^2-4)(n^2-9)(n^2-16). \tag{58}$$

The factors that make $c^{(m)}(\mathcal{F})$ vanish when $m>n$ are visible here; the last factor above is $(n^2-(m-1)^2)$, and a nonzero result requires $n\geqslant m$.

B. The adjoint representation ad of su(n)

The adjoint representation ad of the su(n) algebra is defined by means of

$$X_i\mapsto ad_i, \quad (\mathrm{ad}_i)_{jk}=-if_{ijk}. \tag{59}$$

We do not possess a general formula for the factor μ that occurs in

$$\mathrm{Tr}\,\mathrm{ad}_{[i_1\cdots\ i_{2m-1}]}=\mu\,\Omega_{[i_1\cdots\ i_{2m-1}]}. \tag{60}$$

However it is easy to prove that for *m odd* the trace in (60) vanishes, so that $c^{(m)}(\mathrm{ad})=0$ for all odd m. Since the matrices of the adjoint representation of any simple Lie algebra are antisymmetric, we find, e.g., that

$$\mathrm{Tr}\,\mathrm{ad}_{[ijkpq]}=\mathrm{Tr}\,(\mathrm{ad}_{[ijkpq]})^T=-\mathrm{Tr}\,\mathrm{ad}_{[qpkji]}=-\mathrm{Tr}\,\mathrm{ad}_{[ijkpq]}=0. \tag{61}$$

For *m even* no such conclusion follows: the same steps applied to, say, the sevenfold trace do not give zero, because now an odd permutation is required at the last step to restore the indices to their original order.

It remains to look at the even cases $m=2,4$ and $m=6$, each by a separate calculation to get explicit formulas for $c^{(m)}(\mathrm{ad})$ for su(n). The results are

$$c^{(2)}(\mathrm{ad})=n^2, \tag{62}$$

$$c^{(4)}(\mathrm{ad})=\frac{2^3}{6!}n^2(n^2-4)(n^2-9), \tag{63}$$

$$c^{(6)}(\mathrm{ad})=\frac{2^5}{10!}n^2\prod_{k=2}^{5}(n^2-k^2), \tag{64}$$

from which we may conjecture that, for arbitrary *even* p,

$$c^{(p)}(\mathrm{ad})=\frac{2^{p-1}}{[2(p-1)]!}n^2\prod_{k=2}^{p-1}(n^2-k^2), \tag{65}$$

whereas $c^{(\mathrm{odd})}(\mathrm{ad})=0$.

The generalized Dynkin indices are then

$$(gdi)^{(2)}(\mathrm{ad})=2n, \tag{66}$$

$$(gdi)^{(3)}(\mathrm{ad})=0, \tag{67}$$

$$(gdi)^{(4)}(\mathrm{ad})=2n, \tag{68}$$

$$(gdi)^{(5)}(\mathrm{ad})=0, \tag{69}$$

$$(gdi)^{(6)}(\mathrm{ad})=2n, \tag{70}$$

etc. We recall that $\mathcal{C}^{(6)}$ is absent for $n<6$ [Eq. (64) contains explicit factors that reflect this], and hence note that (70) really only applies when $n\geqslant 6$. See also remarks that follow (103). Results (66) and (68) agree with results in Ref. 13.

The proof of (62) is easy. To obtain (63) we use

$$\mathrm{Tr}\,\mathrm{ad}_{[ijklpqr]}=\left(\frac{1}{2}i\right)^3 f^a{}_{[ij}f^b{}_{kl}f^c{}_{pq]}\,\mathrm{Tr}(\mathrm{ad}_r\,\mathrm{ad}_{(abc)})=\left(\frac{1}{4}i\right)^3 2n\,\Omega_{ijklpqr}. \tag{71}$$

To perform the last step, a result from Ref. 2 is employed,

$$\mathrm{Tr}\,(\mathrm{ad}_r\,\mathrm{ad}_{(abc)})=\frac{n}{4}d^{(4)}_{(abcr)}+2\,\delta_{(ab}\delta_{cr)}. \tag{72}$$

In fact the second term of (72) does not contribute to (71) because it is nonprimitive.

The proof of (64) similarly requires the formula

$$\mathrm{Tr}\,\mathrm{ad}_{(abcder)}=\frac{n}{16}d^{(6)}_{(abcder)}+\cdots\ , \tag{73}$$

where the dots denote terms which do not contribute to (64). One obtains this result by a method similar to that sketched in Ref. 2 to derive (A21) there. This requires a preliminary result,

$$\mathrm{Tr}\,\mathrm{ad}_{(abcd}D_{e)}=\frac{n}{8}d^{(5)}_{(abcde)}+\delta_{(ab}d_{cde)}\,, \tag{74}$$

where $(D_i)_{jk}=d_{ijk}$. The deduction of each of the last two results entails a considerable amount of effort, making liberal use of identities found in the Appendix to Ref. 2.

C. The reducible representation $\mathcal{D}$

The representation $\mathcal{D}$ of $\mathfrak{g}=\mathrm{su}(n)$, of dimension $2^{[\dim \mathfrak{g}/2]}=2^{[(n^2-1)/2]}$, has been described in the Introduction. However in this case again, we lack an explicit analog of (52). Again too the odd order Casimir operators have zero eigenvalues. To show this is true, we note there exists a matrix C such that

$$C\gamma_iC^{-1}=\pm\gamma_i^T\,, \tag{75}$$

with the sign depending on $\dim \mathfrak{g}$. Hence in general ($S_i\equiv\mathcal{D}(X_i)$),

$$S_i=-\tfrac{1}{4}i\,f_{ijk}\gamma_j\gamma_k\,,\quad [S_i\,,S_j]=if_{ijk}S_k\,, \tag{76}$$

obeys

$$S_i^T=-CS_iC^{-1}. \tag{77}$$

This is sufficient to allow steps like those used in (60) to complete the demonstration, since the matrix C is invisible within the trace. To get nonvanishing results we look at m even, this time confining ourselves to the cases $m=2$ and $m=4$. We have

$$c^{(2)}(\mathcal{D})=\frac{n}{8}\Omega^{(3)^2}, \tag{78}$$

$$c^{(3)}(\mathcal{D})=0, \tag{79}$$

$$c^{(4)}(\mathcal{D})=-\frac{n}{64}\Omega^{(7)^2}, \tag{80}$$

and hence

$$(gdi)^{(2)}(\mathcal{D})=\frac{n}{4}(\dim\mathcal{D}), \tag{81}$$

$$(gdi)^{(3)}(\mathcal{D})=0, \tag{82}$$

$$(gdi)^{(4)}(\mathcal{D})=-\frac{n}{8}(\dim\mathcal{D}). \tag{83}$$

We have already noted that $\mathcal{D}$ is a direct sum of $2^{[(n-1)/2]}$ copies of the irreducible representation $\delta=(1,\ldots,1)$ of su(n),[16] and that $\dim \mathcal{D}=2^{[(n^2-1)/2]}$. It follows that the indices given by (81) and (83) are in all cases integers.

We remark also that the results (78)–(80) apply also to the representation δ of su(n) since $\mathcal{D}$ is a direct sum of copies of δ.

For su(3), for which δ coincides with the adjoint representation, $\mathcal{D}$ comprises two copies of ad, $c^{(2)}(\mathcal{D})=c^{(2)}(\delta)=c^{(2)}(\mathrm{ad})=9$ [Eq. (62)], but

$$(gdi)^{(2)}(\mathcal{D})=2(gdi)^{(2)}(\mathrm{ad}), \tag{84}$$

as is to be expected since by Eq. (47) the dimension of the representation enters into the definition of the Dynkin index.

The easier of the proofs known to us for (80) follows the same lines as the proof of (62). It therefore requires the result

$$\mathrm{Tr}\,(S_d S_{(abc)})=-\frac{n}{64}d^{(4)}_{(abcd)}(\dim \mathcal{D})+\frac{3n^2-8}{64}\delta_{(ab}\delta_{cd)}(\dim \mathcal{D}), \tag{85}$$

which is proven in much the same way as (A11) in Ref. 2 is proven. Some nontrivial work on traces of gamma matrices is involved. Also, as for (72), the second term of (85) does not contribute to the derivation of (83). The minus sign in (83) may be noted. It is not exceptional: the tables of Ref. 9 have plenty of negative entries.

D. The representations $\mathcal{S}_p$ of highest weight $(p,0,\ldots,0)$

The representations $\mathcal{S}_p$ carried by totally symmetric su(n) tensors of rank p, the defining representation $\mathcal{F}$ being the case with $p=1$, i.e., $\mathcal{S}_1=\mathcal{F}=\mathcal{F}^1$. We can extend the results obtained for $\mathcal{F}=(1,0,\ldots,0)$ easily to $\mathcal{S}_2$ for which we define matrices

$$(M_i)_{a_1a_2,b_1b_2}=\delta_{(a_1}{}^{(b_1}\lambda_{i_{a_2})}{}^{b_2)}. \tag{86}$$

It is easy to check that (86) satisfies (2). As previous sections indicate, what one needs for the calculation of generalized Dynkin indices in our approach is the evaluation of traces

$$\mathrm{Tr}\,D_{(a}D_b\cdots D_{s)}. \tag{87}$$

It is easy to use (86) to compute

$$\mathrm{Tr}\,M_iM_j=\tfrac{1}{2}(n+2)\,\delta_{ij}, \tag{88}$$

$$\mathrm{Tr}\,M_{(i}M_jM_{k)}=\tfrac{1}{4}(n+4)d_{ijk}, \tag{89}$$

$$\mathrm{Tr}\,M_{(i}M_jM_kM_{l)}=\tfrac{1}{8}(n+8)d^{(4)}_{(ijkl)}+\cdots, \tag{90}$$

where the dots indicate lower order terms known but known also, because of Jacobi identities, not to contribute to the calculation of the eigenvalues $c^{(4)}(\mathcal{S}_2)$. Thus we find that all results agree with

$$(gdi)^{(m)}(\mathcal{S}_2)=n+2^{m-1}. \tag{91}$$

To proceed further it is advisable to use heavier duty methods. Bird-track methods allow us to subsume the calculations just done into the treatment of the general p case, by dealing with the totally symmetrized p-fold direct products of defining representations.

Our results include the following:

$$(gdi)^{(m)}(\mathcal{S}_p)=\frac{(n+p)!}{(p-1)!(n+1)!},\quad m=2; \tag{92}$$

$$=\frac{(n+p)!}{(p-1)!(n+2)!}(n+2p),\quad m=3; \tag{93}$$

$$=\frac{(n+p)!}{(p-1)!(n+3)!}(n^2-n+6pn+6p^2),\quad m=4. \tag{94}$$

The result (91) for $\mathcal{S}_2$ of course conforms to these results. To derive these expressions, we employ results for totally symmetrized traces that appear in Ref. 13 as Eqs. (12.69)–(12.71). We note also from Ref. 13 the diagram (12.64) used to define the matrices of $(p,0,\ldots,0)$, and the essential results (5.19) and (5.23) given in the valuable chapter in Ref. 13 on permutations.

E. The *l* fundamental representations $\mathcal{F}^s$ of su(n)

The representation $\mathcal{F}^2=(0,1,0,\ldots,0)$ of su(n) is the antisymmetric part of the direct product $\mathcal{F}\otimes\mathcal{F}$, where $\mathcal{F}=\mathcal{F}^1$ is the defining representation of su(n). Thus we define for $\mathcal{F}^2$ the matrices,

$$(N_i)_{a_1a_2,b_1b_2}=\delta_{[a_1}{}^{[b_1}\lambda_{i\,a_2]}{}^{b_2]}. \tag{95}$$

This differs from (86) only in that round symmetrization brackets are replaced by square antisymmetrization brackets. We find the following results:

$$\mathrm{Tr}\,N_iN_j=\tfrac{1}{2}(n-2)\,\delta_{ij}, \tag{96}$$

$$\mathrm{Tr}\,N_{(i}N_jN_{k)}=\tfrac{1}{4}(n-4)d_{ijk}, \tag{97}$$

$$\mathrm{Tr}\,N_{(i}N_jN_kN_{l)}=\tfrac{1}{8}(n-8)d^{(4)}_{(ijkl)}+\cdots\ . \tag{98}$$

Again all these results agree with the general statement

$$(gdi)^{(m)}(\mathcal{F}^2)=n-2^{m-1}. \tag{99}$$

It is of clear interest to proceed further down the antisymmetrization path. For su(n), the totally antisymmetrized parts of the s-fold products of defining representations correspond to the fundamental representations $\mathcal{F}^s$ of su(n) for $s=1,2,\ldots,l=(n-1)$, i.e., $\mathcal{F}^s$ has a one in the sth place of its Dynkin coordinate description and zeros elsewhere; its highest weight is the sth fundamental dominant weight.

Using bird-track methods, we find

$$(gdi)^{(m)}(\mathcal{F}^s)=\frac{(n-2)!}{(s-1)!(n-s-1)!},\quad m=2; \tag{100}$$

$$=\frac{(n-3)!}{(s-1)!(n-s-1)!}(n-2s),\quad m=3; \tag{101}$$

$$=\frac{(n-4)!}{(s-1)!(n-s-1)!}(n^2+n-6sn+6s^2),\quad m=4. \tag{102}$$

The result (99) for $s=2$ conforms to these results; for $s=1$ we get $(gdi)^{(m)}(\mathcal{F}^1)=1$, which also follows from (92)–(94) for $p=1$ as it should. Results analogous to (100)–(102) for $m=5$ and $m=6$ have also been computed. For $s=2$ they each agree with (99). When $s=3$ we have

$$(gdi)^{(5)}(\mathcal{F}_3)=\tfrac{1}{2}(n-6)(n-27). \tag{103}$$

Since su(n) has a fifth order Casimir operator only for $n \geqslant 5$, (103) applies only for such n. It gives 11 for $n=5$ and vanishes for $n=6$, but is nonzero for all larger n except $n=27$. In other words $c^{(5)}(\mathcal{F}_3)$ vanishes when $n=6$ in virtue of its (gdi) factor rather than its Ω factor.

To obtain these results we have followed methods for the antisymmetric case analogous to those of the previous section for the symmetric case. Permutation lemmas (5.19) and (5.23) of Ref. 13 expedite the work.

The results of this section permit the evaluation of all the indices of all the fundamental representations of su(n) for all $n \leqslant 6$. These are presented in Tables I–IV in Sec. V.

The results of (92)–(94) are very closely related to results to be found in Chap. 16 of Ref. 13. Although no such statement holds for (100)–(102), all the tools needed to derive them were found in Ref. 13 polished and ready for use.

V. TABLES OF INDICES FOR su(n) FOR $n \leqslant 6$

The (gdi) indices presented in Tables I–IV that follow have been deduced from (99)–(103), where one easy check is available. If $X_i \mapsto D_i$ defines the representation D of su(n), then

$$X_i \mapsto \overline{D}_i = -D_i^T \tag{104}$$

defines the representation $\overline{D}$ of su(n). It then follows that

$$c^{(m)}(D) = \pm c^{(m)}(\overline{D}), \tag{105}$$

where the plus applies to even m and the minus to m odd. The data in the accompanying tables conforms to this. Further some entries for su(4) and su(6) agree with the consequence of (105) that odd Casimir operators have zero eigenvalues for self-conjugate representations.

TABLE I. Indices for su(3).

	Generalized Dynkin indices of su(3)

(Received 26 March 1999; accepted for publication 28 September 1999)

We consider smeared zeta functions and heat-kernel coefficients on the bounded, generalized cone in arbitrary dimensions. The specific case of a ball is analyzed in detail and used to restrict the form of the heat-kernel coefficients A_n on smooth manifolds with boundary. Supplemented by conformal transformation techniques, it is used to provide an effective scheme for the calculation of the A_n. As an application, the complete $A_{5/2}$ coefficient is given. © *2001 American Institute of Physics.* [DOI: 10.1063/1.1285969]

I. INTRODUCTION

The coefficients A_n in the small-time asymptotic expansion of the heat-kernel corresponding to a Laplacian-like operator on smooth manifolds (possibly with a boundary) play important roles both in quantum field theory and pure mathematics.

Many schemes for their evaluation have been developed, which may be divided roughly into ''direct''[1–7] and ''indirect.''[8–12] For manifolds without boundary, the A_n are determined by algebraic equations and their computation can be, and has been, done by computer. In principle, the only things needed are the coincidence limits of the geodesic distance and of its derivatives at two points. Methods employing one or another variation on this scheme can be termed direct. The ''indirect'' method has been developed most systematically by Branson and Gilkey.[8] Conformal transformation techniques give relations between the numerical multipliers in the heat-kernel coefficients. However, on its own, this method is unable to determine the coefficients fully. Additional information is needed, coming from other functorial relations or special case calculations.[8] Given a subset of numerical coefficients, the method then provides all required information with relative ease. Our aim in the present article is to give a special case calculation containing enough information, which, when supplemented by the methods of Ref. 8, leads to a very effective scheme for the evaluation of at least a substantial part of any A_n.

In a previous article[13] (see also Ref. 14) we considered the nonsmeared heat kernel of the Laplacian with Dirichlet or Robin boundary conditions on the $(d+1)$-dimensional bounded cone. Here we generalize this work to include a smearing function. This is an essential step in elucidating the form of the coefficients in the presence of boundaries and is also vital when conformal properties are being analyzed, particularly those of the functional determinant.

The resulting restrictions are more informative than others available and are used to determine the first few heat-kernel coefficients on an arbitrary smooth manifold with a boundary. The complete pure boundary coefficient $A_{5/2}$ is given, showing the practicability of our approach for high orders.[15]

The paper is organized as follows. In Sec. II a method is developed for the calculation of the smeared heat-kernel coefficients on the generalized cone. Both Dirichlet and Robin boundary

conditions are treated. This information is used in Sec. III to put restrictions on the general form of the coefficients. Supplemented by additional relations,[8] the coefficients $A_0,\ldots,A_{5/2}$, are (re)considered and fully determined. In the Conclusion we summarize our main results and suggest extensions.

II. SMEARED ζ FUNCTION ON THE GENERALIZED CONE

Our immediate objective is the determination of the smeared heat-kernel coefficients on the $(d+1)$-dimensional bounded generalized cone $\mathcal{M}=I\times\mathcal{N}$ with the hyperspherical metric, cf. Ref. 16,

$$ds^2=dr^2+r^2d\Sigma^2, \tag{1}$$

where $d\Sigma^2$ is the metric on the manifold $\mathcal{N}$, and r runs from 0 to 1. $\mathcal{N}$ will be referred to as the base of the cone. If it has no boundary, then it is the boundary of $\mathcal{M}$ with extrinsic curvature $K^a_b=\delta^a_b$.

We consider the Laplacian on $\mathcal{M}$,

$$\Delta_{\mathcal{M}}=\frac{\partial^2}{\partial r^2}+\frac{d}{r}\frac{\partial}{\partial r}+\frac{1}{r^2}\Delta_{\mathcal{N}}, \tag{2}$$

with Dirichlet or Robin boundary conditions. The nonzero eigenmodes of $\Delta_{\mathcal{M}}$ that are finite at the origin have eigenvalues $-\alpha^2$ and are of the form

$$\frac{J_\nu(\alpha r)}{r^{(d-1)/2}}Y(\Omega), \tag{3}$$

where the harmonics on $\mathcal{N}$ satisfy

$$\Delta_{\mathcal{N}}Y(\Omega)=-\lambda^2Y(\Omega) \tag{4}$$

and

$$\nu^2=\lambda^2+(d-1)^2/4. \tag{5}$$

One can also add the coupling $-\xi R$ to $\Delta_{\mathcal{M}}$, changing the following analysis slightly.[13]

In order to deal with the smeared ζ function, we parallel the analysis presented in Ref. 13 and refer to it for further details. We consider both Dirichlet,

$$J_\nu(\alpha)=0, \tag{6}$$

and Robin boundary conditions,

$$\left(1-\frac{D}{2}-S\right)J_\nu(\alpha)+\alpha J'_\nu(\alpha)=0, \tag{7}$$

where $D=d+1$. Pure Neumann conditions correspond to $S=0$.

Our main interest is in the calculation of the boundary terms of the heat-kernel expansion. A convenient way of handling these is to introduce smeared, integrated quantities, e.g., the heat kernel,

$$K(F;\tau)=\int dx\,F(x)K(x,x,\tau), \tag{8}$$

and its Mellin transform, the ζ function,

$$\zeta(F;s)=\sum_{\alpha}\int dx\,F(x)\phi(x)\phi^{*}(x)\frac{1}{\alpha^{2s}}, \tag{9}$$

in terms of eigenfunctions, ϕ, and eigenvalues, $-\alpha^2$. In addition, the base ζ function,

$$\zeta_{\mathcal{N}}(s)=\sum_{\nu}d(\nu)\nu^{-2s}, \tag{10}$$

will turn out to be very useful. Here, $d(\nu)$ is the (''angular'') degeneracy.

On the generalized cone, the eigenfunctions (3) are products of Bessel functions and ''spherical,'' i.e., base, harmonics. If we smear in the radial coordinate only, then in (9) the integration over the base yields exactly the same degeneracies as in the unsmeared case, i.e., the $d(\nu)$, and the contour expression for the ζ function on $\mathcal{M}$ reads (we treat Dirichlet scalars first) as

$$\zeta(F;s)=\sum\int_{\gamma}\frac{dk}{2\pi i}k^{-2s}\int_0^1 dr\,F(r)\overline{J}_{\nu}^2(kr)rd(\nu)\frac{\partial}{\partial k}\ln J_{\nu}(k), \tag{11}$$

where the overbar stands for normalized, $\overline{J}_{\nu}(\alpha r)=\sqrt{2}J_{\nu}(\alpha r)/J_{\nu}'(\alpha)$.

The boundary parts of the coefficients contain normal derivatives, $F_{r\cdots r}$, of F and we choose for F a polynomial in r^2 (why r^2 will be clear soon) that contains sufficient independent derivatives to pick out the relevant contributions. For example, in A_1, since there is only one normal derivative F_r, it is sufficient to take

$$F(r)=f_0+f_1r^2 \tag{12}$$

and to use

$$F(1)=f_0+f_1,\quad F_r(1)=2f_1, \tag{13}$$

in order to identify the boundary terms.

To explain our method more precisely, we continue with this simple example, (12), and afterward generalize to an arbitrary polynomial. Using

$$\int_0^1 dr\,r^3\overline{J}_{\nu}^2(\alpha r)=\frac{2}{3}\frac{\nu^2-1}{\alpha^2}+\frac{1}{3}, \tag{14}$$

and substituting (12) into (11), we obtain two contributions:

$$\zeta_{\mathcal{M}}(F;s)=(f_0+\tfrac{1}{3}f_1)\zeta_{\mathcal{M}}(s)+\frac{2}{3}f_1\sum(\nu^2-1)d(\nu)\int_{\gamma}\frac{dk}{2\pi i}k^{-2(s+1)}\frac{\partial}{\partial k}\ln J_{\nu}(k). \tag{15}$$

Here, $\zeta_{\mathcal{M}}(s)$ is defined to be $\zeta_{\mathcal{M}}(1;s)$ and is known from our previous analysis.[13] Also, the second line in (15) may be immediately given by direct comparison with our previous calculation. The contour integral is the same as previously apart from replacing $s\to s+1$. For the second term this is already all we need. The first term contains a factor ν^2, raising the argument of the base zeta function by one. [See Eq. (20)].

In order to describe the method further, it is necessary to use some notation introduced in Ref. 13. For the calculation of the heat-kernel coefficients, a split of the zeta function into two parts is very useful. One part contains all the relevant contributions and comes from the uniform asymptotic expansion of the Bessel function $I_{\nu}(k)$. As has been shown in Ref. 13, these are the only contributions to the heat-kernel coefficients. Explicitly, for $\nu\to\infty$ with $z=k/\nu$ fixed, one has

$$I_\nu(\nu z)\sim\frac{1}{\sqrt{2\pi\nu}}\frac{e^{\nu\eta}}{(1+z^2)^{1/4}}\left[1+\sum_{k=1}^{\infty}\frac{u_k(t)}{\nu^k}\right], \tag{16}$$

with $t=1/\sqrt{1+z^2}$ and $\eta=\sqrt{1+z^2}+\ln(z/(1+\sqrt{1+z^2}))$. Any required number of $u_k(t)$ polynomials can be obtained via the recursion relation given in Ref. 17 and 18. In addition, we need the cumulant expansion

$$\ln\left[1+\sum_{k=1}^{\infty}\frac{u_k(t)}{\nu^k}\right]\sim\sum_{n=1}^{\infty}\frac{D_n(t)}{\nu^n}, \tag{17}$$

where the D_n have the polynomial structure

$$D_n(t)=\sum_{b=0}^{n}x_{n,b}t^{n+2b}. \tag{18}$$

The second part of the split, named $Z(s)$ in Ref. 13 and accordingly $Z(F;s)$ here, is analytic and is of no relevance to the construction of the coefficients.

By adding and subtracting L leading terms of the asymptotic expansion, (17), and performing the same steps as described in Ref. 13 one finds the aforementioned split,

$$\zeta_{\mathcal{M}}(F;s)=Z(F;s)+\sum_{i=-1}^{L}A_i(F;s), \tag{19}$$

with the definitions

$$A_{-1}(F;s)=\frac{1}{4\sqrt{\pi}}\frac{\Gamma\left(s-\frac{1}{2}\right)}{\Gamma(s+1)}\zeta_{\mathcal{N}}(s-1/2)\left[f_0+\frac{1}{3}f_1+\frac{2}{3}f_1\frac{s-1/2}{s+1}\right]$$
$$-\frac{2}{3}f_1\frac{1}{4\sqrt{\pi}}\frac{\Gamma\left(s+\frac{1}{2}\right)}{\Gamma(s+2)}\zeta_{\mathcal{N}}(s+1/2),$$

$$A_0(F;s)=-\tfrac{1}{4}\zeta_{\mathcal{N}}(s)[f_0+f_1]-\tfrac{1}{4}\zeta_{\mathcal{N}}(s+1)f_1, \tag{20}$$

$$A_i(F;s)=-\frac{1}{\Gamma(s)}\zeta_{\mathcal{N}}(s+i/2)\sum_{b=0}^{i}x_{i,b}\frac{\Gamma(s+b+i/2)}{\Gamma(b+i/2)}\left[f_0+\frac{1}{3}f_1+\frac{2}{3}f_1\frac{s+b+i/2}{s}\right]$$
$$-\frac{2}{3}f_1\zeta_{\mathcal{N}}(s+1+i/2)\sum_{b=0}^{i}x_{i,b}\frac{\Gamma(s+1+b+i/2)}{\Gamma(s+1)\Gamma(b+i/2)}.$$

As is apparent in (20), base contributions are separated from radial ones. This enables the heat-kernel coefficients of the Laplacian on the manifold $\mathcal{M}$ to be written in terms of those on $\mathcal{N}$.

In the next section we discuss the restrictions our calculation places on the general form of the heat-kernel coefficients. It is known, for example, that the coefficient A_2 contains the third normal derivative of the smearing function F and the higher coefficients involve correspondingly higher derivatives. It is thus obvious that the $F(r)$ employed earlier (12) will not be general enough to discuss coefficients beyond $A_{3/2}$. In order to apply our technique to all higher coefficients, at least in principle, we consider the polynomial

$$F(r)=\sum_{n=0}^{N} f_n r^{2n}. \tag{21}$$

This leads to normalization integrals of the type

$$S[1+2p]=\int_0^1 dr\, \overline{J}_\nu^2(\alpha r) r^{1+2p}, \tag{22}$$

which can be treated using Schafheitlin's reduction formula.[19] Writing this formula for the case when α is a zero of the Bessel function, $J_\nu(\alpha)=0$, one has

$$\int_0^1 dr\, \overline{J}_\nu^2(\alpha r) r^{\mu+2}=\frac{\mu+1}{\mu+2}\,\frac{(\nu^2-(\mu+1)^2/4)}{\alpha^2}\int_0^1 dr\, \overline{J}_\nu^2(\alpha r) r^{\mu}+\frac{1}{\mu+2}. \tag{23}$$

This can be iterated down to the standard normalization value, $\mu=1$, and is the origin of (14). In order to use this formula, which is our essential technical novelty, we see that it is necessary to have a polynomial in r^2.

Schafheitlin's formula gives the recursion for the normalization integrals (22),

$$S[1+2p]=\frac{2p}{2p+1}\,\frac{\nu^2-p^2}{\alpha^2}S[2p-1]+\frac{1}{2p+1}, \tag{24}$$

so that $S[1+2p]$ has the following form:

$$S[1+2p]=\sum_{m=0}^{p}\left(\frac{\nu}{\alpha}\right)^{2m}\sum_{l=0}^{m}\gamma_{ml}^{p}\nu^{-2l}, \tag{25}$$

with the numerical coefficients γ_{ml}^{p} being easily determined recursively.

As seen in the treatment of the function $F(r)$ in Eq. (12), using the same rules of replacement, the $A_i(s)$ read, after some rearrangement, as

$$A_{-1}(F;s)=\frac{1}{4\sqrt{\pi}}\sum_{l=0}^{N}\left[\sum_{m=l}^{N}L_{m,l}^{(N)}\frac{\Gamma(s-1/2+m)}{\Gamma(s+1+m)}\right]\zeta_{\mathcal{N}}(s-1/2+l),$$

$$A_0(F;s)=-\frac{1}{4}\sum_{l=0}^{N}\left[\sum_{m=l}^{N}L_{m,l}^{(N)}\right]\zeta_{\mathcal{N}}(s+l), \tag{26}$$

$$A_i(F;s)=-\sum_{l=0}^{N}\left[\sum_{m=l}^{N}L_{m,l}^{(N)}\sum_{b=0}^{i}x_{i,b}\frac{\Gamma(s+b+i/2+m)}{\Gamma(s+m)\Gamma(b+i/2)}\right]\zeta_{\mathcal{N}}(s+l+i/2),$$

where the linear form in the f_p is defined by

$$L_{m,l}^{(N)}=\sum_{p=m}^{N}\gamma_{ml}^{p}f_p.$$

For Dirichlet boundary conditions, these formulas provide the generalization of our formalism[13] to the radially smeared case. This is enough for our purposes because the general forms of the heat-kernel coefficients contain only normal derivatives, and these are radial derivatives on the generalized cone.

In the special case of the D ball, the residues of the poles of the base (i.e., sphere) ζ function are given in terms of Bernoulli polynomials and the ball coefficients are then efficiently evaluated by machine.[13] One could equally well take the torus as the base manifold, but the information obtained differs only slightly.

We now turn to Robin boundary conditions. It is possible to proceed in the same way as for Dirichlet, but complications arise and the situation is sufficiently different so as to warrant a separate treatment.

Write the Robin condition (7) as

$$G_\nu(\alpha)=\alpha J'_\nu(\alpha)+uJ_\nu(\alpha)=0.$$

The normalization is

$$\int_0^1 J_\nu^2(\alpha r)r\,dr=\frac{1}{2\alpha^2}(\alpha^2-\nu^2+u^2)J_\nu^2(\alpha), \tag{27}$$

and the normalized Schafheitlin formula reads as

$$\int_0^1 dr\overline{J}_\nu^2(\alpha r)r^{\mu+2}=\frac{\mu+1}{\mu+2}\,\frac{(\nu^2-(\mu+1)^2/4)}{\alpha^2}\int_0^1 dr\,\overline{J}_\nu^2(\alpha r)r^\mu + \frac{1}{\mu+2}\left(1+\frac{(\mu+1)\left(u+\frac{1}{2}(\mu+1)\right)}{\alpha^2-\nu^2+u^2}\right). \tag{28}$$

Continuing as in the Dirichlet case, and defining $S[1+2p]$ as in (22), we find the reduction formula,

$$S[1+2p]=\frac{2p}{2p+1}\,\frac{\nu^2-p^2}{\alpha^2}S[2p-1]+\frac{1}{2p+1}\left(1+\frac{2p(u+p)}{\alpha^2+u^2-\nu^2}\right). \tag{29}$$

Explicitly, this gives the following form:

$$S[1+2p]=\sum_{m=0}^{p}\left(\frac{\nu}{\alpha}\right)^{2m}\sum_{l=0}^{m}\gamma_{ml}^p\nu^{-2l}+\frac{1}{\alpha^2+u^2-\nu^2}\sum_{m=0}^{p-1}\left(\frac{\nu}{\alpha}\right)^{2m}\sum_{l=0}^{n}\delta_{ml}^p\nu^{-2l}, \tag{30}$$

where the γ_{ml}^p are the same as in (25) and the δ_{ml}^p are also easily determined by machine.

For the ζ function we have

$$\zeta^{\mathrm{Rob}}(F;s)=\sum\int_\gamma\frac{dk}{2\pi i}k^{-2s}\int_0^1 dr\,F(r)\overline{J}_\nu^2(kr)rd(\nu)\,\frac{\partial}{\partial k}\ln G_\nu(k), \tag{31}$$

where the contour γ has to be chosen so as to enclose the zeros of *only* $G_\nu(k)$. Thus the poles of $S[1+2p]$, located at $k=\pm\sqrt{\nu^2-u^2}$ must be outside the contour. It is important to locate the contour properly because, when deforming it to the imaginary axis, contributions from the pole at $k=\sqrt{\nu^2-u^2}$ arise.

As a result, apart from contributions identical to (26), with the usual changes between Dirichlet and Robin boundary conditions,[13] we have the extra pieces

$$\zeta^p_\delta(F;s)=\frac{\sin\pi s}{\pi}\sum\ d(\nu)\sum_{m=0}^{p-1}\sum_{l=0}^{m}\delta^p_{ml}\nu^{-2l}$$
$$\times\int_{m/\nu}^{\infty}dz\,\frac{[(z\nu)^2-m^2]^{-s}}{u^2-\nu^2(1+z^2)}z^{-2m}\frac{\partial}{\partial z}\ln(uI_\nu(z\nu)+z\nu I'_\nu(\nu z)), \tag{32}$$

$$\zeta^p_{\rm shift}(F;s)=-\frac{1}{2}\sum_{m=0}^{p-1}\sum_{l=0}^{m}\delta^p_{ml}\sum\ d(\nu)\,\nu^{2m-2l}(\nu^2-u^2)^{-s-m-1/2}$$
$$\times\frac{\partial}{\partial k}\ln(kJ'_\nu(k)+uJ_\nu(k))|_{k=\sqrt{\nu^2-u^2}}, \tag{33}$$

the last one arising on moving the contour over the pole at $k=\sqrt{\nu^2-u^2}$. These are the contributions additional to those in the Dirichlet case. The index p refers to the fact that these are the contributions coming from the power r^p in (21). In order to obtain the full zeta function, the $\Sigma_{p=0}^{N}f_p\zeta^p$ has to be done.

Looking at (32), we first define the asymptotic contributions $A^p_{i,\delta}(F;s)$ in the same manner as before by taking the different terms in the asymptotic expansion of the argument of the logarithm. We illustrate the calculation by dealing with

$$A^p_{-1,\delta}(F;s)=\frac{\sin\pi s}{\pi}\sum\ d(\nu)\sum_{m=0}^{p-1}\sum_{l=0}^{m}(-1)^m\delta^p_{ml}\nu^{1-2l}$$
$$\times\int_{m/\nu}^{\infty}dz\,\frac{[(z\nu)^2-m^2]^{-s}}{u^2-\nu^2(1+z^2)z^{2m+1}}(1+z^2)^{1/2}. \tag{34}$$

Using the expansion for small u,

$$\frac{1}{u^2-\nu^2(1+z^2)}=-\sum_{i=0}^{\infty}\frac{u^{2i}}{(\nu^2)^{i+1}(1+z^2)^{i+1}},$$

one arrives at

$$A^p_{-1,\delta}(F;s)=-\frac{\sin\pi s}{\pi}\sum_{i=0}^{\infty}u^{2i}\sum\ d(\nu)\sum_{m=0}^{p-1}\sum_{l=0}^{m}(-1)^m\delta^p_{ml}\nu^{-1-2i-2l}$$
$$\times\int_{m/\nu}^{\infty}dz\,\frac{[(z\nu)^2-m^2]^{-s}}{(1+z^2)^{i+1/2}z^{2m+1}}. \tag{35}$$

At this point we can continue as in previous articles by realizing that the above integrals are representations of a hypergeometric function.[20] With the help of their Mellin–Barnes representation,[20] the ν summation can be done, yielding the base ζ function, and in the massless case our final result reads as

$$A^p_{-1,\delta}(F;s)=\frac{1}{2\Gamma(s)}\sum_{i=0}^{\infty}u^{2i}\sum_{m=0}^{p-1}\sum_{l=0}^{m}\delta^p_{ml}$$
$$\times\frac{\Gamma(-s-m)\Gamma(s+i+m+1/2)}{\Gamma(-s+1)\Gamma(i+1/2)}\zeta_{\mathcal{M}}(s+l+i+1/2). \tag{36}$$

In the same way one obtains for the other $A^p_{i,\delta}(s)$,

$$A^p_{0,\delta}(F;s) = -\frac{1}{4\Gamma(s)}\sum_{i=0}^{\infty}\frac{u^{2i}}{\Gamma(i+2)}\sum_{m=0}^{p-1}\sum_{l=0}^{m}(-1)^m\delta^p_{ml} \times\frac{\Gamma(s+i+m+1)\Gamma(1-s-m)}{\Gamma(1-s)}\zeta_{\mathcal{N}}(s+i+l+1), \tag{37}$$

$$A^p_{n,\delta}(F;s) = \frac{1}{2\Gamma(s)}\sum_{i=0}^{\infty}u^{2i}\sum_{m=0}^{n-1}\sum_{l=0}^{m}(-1)^m\delta^p_{ml}\sum_{b=0}^{n}x_{n,b}(n+2b) \times\frac{\Gamma(1-s-m)\Gamma(s+i+n/2+b+m+1)}{\Gamma(1-s)\Gamma(i+n/2+b+2)}\zeta_{\mathcal{N}}(s+i+l+1+n/2). \tag{38}$$

These forms are well suited for machine evaluation and the residues relevant for the heat-kernel expansion are thereby quickly determined.

The remaining task is to deal with $\zeta^p_{\text{shift}}(F;s)$ defined in (33). To get the relevant residues we need the asymptotic behavior of J_ν, information that can be found in Abramowitz and Stegun.[17] Ultimately, as a practical application, we want to restrict the general form of the $A_{5/2}$ coefficient, and so, restricting the calculation to the order necessary for this coefficient, we arrive at

$$\zeta^p_{\text{shift}}(F;s) = -\frac{1}{2}\sum_{m=0}^{p-1}\sum_{l=0}^{m}\delta^p_{ml} \times(u\zeta_{\mathcal{N}}(s+l+1)+u^3(s+m+1)\zeta_{\mathcal{N}}(s+l+2)+\cdots), \tag{39}$$

after some algebra. As mentioned, the dots indicate contributions having their rightmost pole to the left of $s=(D-5)/2$.

All the relevant results for the calculation up to the $A_{5/2}$ coefficient are now on hand. It would be possible to go further, if desired. (But see our cautionary note at the end.)

III. HEAT-KERNEL COEFFICIENTS ON GENERAL MANIFOLDS

In this section we describe the restrictions placed on the general form of the heat-kernel coefficients by our special case evaluation. Because the case we treat has a vanishing Riemann tensor and constant extrinsic curvature, it cannot, in general, determine the complete coefficient. However, supplemented by a lemma on product manifolds and using relations of the heat-kernel coefficients under conformal rescalings,[8] we will develop a very effective scheme for their calculation. Although for Dirichlet and Robin conditions the coefficients are already completely known up to A_2, we will describe our procedure by starting with these low coefficients. We will see that the lower the coefficient the more restrictive is the special case; a ball calculation. This opens up for future applications the possibility of applying our approach to spectral boundary conditions[21–23] and to boundary conditions involving tangential derivatives discussed recently in the context of the quantization of gauge fields in the presence of boundaries.[24–27]

In what follows we will take the standpoint that the volume part of the coefficients is known. This is motivated by the fact that its calculation is purely algebraic and very effective schemes already exist.[1,2,7] In contrast, the boundary contributions are not determined purely algebraically, and their evaluation turns out to be much more involved. It is here that our special case evaluation of the smeared coefficients on the ball gives the additional information necessary for the complete calculation of the coefficients. We will show the effectiveness of the scheme by giving all of $A_{5/2}$, but we first explain things in detail, starting from the lower coefficients.

Some notation is needed. Here and in the following $F[\mathcal{M}]=\int_{\mathcal{M}}dx\,F(x)$ and $F[\partial\mathcal{M}]=\int_{\partial\mathcal{M}}dy\,F(y)$, with dx and dy being the Riemannian volume elements of $\mathcal{M}$ and $\partial\mathcal{M}$. In addition, '';'' denotes differentiation with respect to the Levi-Civita connection of $\mathcal{M}$ and '':'' covariant differentiation tangentially with respect to the Levi-Civita connection of the boundary.

Finally, our sign convention is $R^i_{jkl}=-\Gamma^i_{jk,l}+\Gamma^i_{jl,k}+\Gamma^i_{nk}\Gamma^n_{jl}-\Gamma^i_{nl}\Gamma^n_{jk}$ (see, for example Ref. 28). To state the general form of the coefficients define the partial differential operator,

$$P=-\Delta-E,$$

together with Dirichlet or Robin boundary conditions,

$$\mathcal{B}^-\phi\equiv\phi|_{\partial\mathcal{M}} \quad \text{and} \quad \mathcal{B}^+_S\phi\equiv(\phi_{;m}-S\phi)|_{\partial\mathcal{M}}.$$

To have a uniform notation we set $S=0$ for Dirichlet boundary conditions and write $B^{\mp}_S$. Let $D_{\mathcal{B}}$ be the operator defined by the appropriate boundary conditions.

If F is a smooth function on $\mathcal{M}$, there is an asymptotic series as $t\to 0$ of the form

$$\mathrm{Tr}_{L^2}(Fe^{-tP_{\mathcal{B}}})\approx\sum_{n\geqslant 0} t^{(n-D)/2}a_n(F,P_{\mathcal{B}}),$$

where the $a_n(F,P_{\mathcal{B}})$ are locally computable.[29]

We now state, one by one, the general form of the coefficients and compare them with our special case evaluation. For convenience we will drop the index $\mathcal{B}$ of the operator P. The coefficient A_0 is, by normalization,

$$A_0(F,P)=(4\pi)^{-D/2}F[\mathcal{M}].$$

The next one is

$$A_{1/2}(F,P)=\delta(4\pi)^{-d/2}F[\partial\mathcal{M}].$$

For the ball this means

$$A_{1/2}(F,P)=\delta(4\pi)^{-d/2}F(1)\mathrm{vol}(S^d).$$

Using the relations (26) and (36)–(39) we can immediately determine δ,

$$\delta=\left(-\frac{1^-}{4},\frac{1^+}{4}\right).$$

The coefficient $A_{1/2}$ is thus given for a general manifold from the result on the ball (which was clear, of course). Passing on to A_1, the general form is

$$A_1(F,P)=(4\pi)^{-D/2}6^{-1}\{(6FE+FR)[\mathcal{M}]+(b_0FK+b_1F_{;m}+b_2FS)[\partial\mathcal{M}]\}.$$

In our special case on the ball, $K^b_a=\delta^b_a$, and thus

$$A_1(F,P)=(4\pi)^{-D/2}6^{-1}\,\mathrm{vol}(S^d)\{b_0F(1)d+b_1F'(1)+b_2F(1)S\}.$$

Comparing with the results given in the previous section, one finds

$$b_0=2;\quad b_1=(3^-,-3^+);\quad b_2=12.$$

Thus, our special case also gives the entire A_1 coefficient without any further information being needed. It is very important that the calculation can be performed for an arbitrary ball dimension, D, and also for a smearing function $F(r)$. This allows one just to compare polynomials in d with the associated extrinsic curvature terms in the general expression and simply to read off the universal constants in this expression.

The idea is now clear and in the following we will state only the general expression and the restrictions found from the special case presented in the previous section. We continue with the next higher coefficient, with the general form

$$A_{3/2}(F,P)=\frac{\delta}{96(4\pi)^{d/2}}(F(c_0E+c_1R+c_2R_{mm}+c_3K^2+c_4K_{ab}K^{ab}+c_7SK+c_8S^2)$$
$$+F_{;m}(c_5K+c_9S)+c_6F_{;mm})[\partial\mathcal{M}].$$

The ball calculation immediately gives seven of the ten unknowns,

$$c_3=(7^-,13^+),\quad c_4=(-10^-,2^+),\quad c_5=(30^-,-6^+),$$

$$c_6=24,\quad c_7=96,\quad c_8=192,\quad c_9=-96.$$

We next apply the lemma on product manifolds mentioned above.[8] Let $N^\nu(F)=F_{;m\ldots}$ be the νth normal covariant derivative. There exist local formulas $a_n(x,P)$ and $a_{n,\nu}(y,D)$, so that

$$A_n(F,P,\mathcal{B}_S^{\mp})=\{FA_n(x,P)\}[\mathcal{M}]+\left\{\sum_{\nu=0}^{2n-1}N^\nu(F)A_{n,\nu}(y,P,\mathcal{B}_S^{\mp})\right\}[\partial\mathcal{M}].$$

Let $\mathcal{M}=\mathcal{M}_1\times\mathcal{M}_2$ and $P=P_1\otimes 1+1\otimes P_2$ and $\partial\mathcal{M}_2=\varnothing$. Then

$$A_{n,\nu}(y,P,\mathcal{B}_S^{\mp})=\sum_{p+q=n}A_{p,\nu}(y_1,P_1,\mathcal{B}_S^{\mp})A_q(x_2,P_2).$$

For $A_{3/2}$ this means

$$A_{3/2}(y,P)=A_{3/2}(y_1,P_1)A_0(x_2,P_2)+A_{1/2}(y_1,P_1)A_1(x_2,P_2).$$

We will choose $P_1=-\Delta_1$ and $P_2=-\Delta_2-E(x_2)$ with obvious notation to obtain

$$\delta 96^{-1}(c_0E+c_1R(\mathcal{M}_2))=\delta 6^{-1}(6E+R(\mathcal{M}_2)),$$

where we used, in addition, $R(\mathcal{M}_1\times\mathcal{M}_2)=R(\mathcal{M}_1)+R(\mathcal{M}_2)$. This gives

$$c_0=96,\quad c_1=16.$$

It is seen that the determination of $A_{3/2}$ is relatively simple, once the ball result is on hand. The lemma on product manifolds is also very easily applied and already only one of the universal constants c_i, namely c_2, is missing.

The remaining information is obtained using the relations between the heat-kernel coefficients under conformal rescaling,[8]

$$\left.\frac{d}{d\epsilon}\right|_{\epsilon=0}a_n(1,e^{-2\epsilon F}P)-(D-2n)a_n(F,P)=0. \tag{40}$$

Setting to zero the coefficients of all terms in (40) gives several relations between the universal constant c_i. We will need only one of them. Thus, setting to zero the coefficient of $F_{;mm}$ gives

$$\tfrac{1}{2}(D-2)c_0-2(D-1)c_1-(D-1)c_2-(D-3)c_6=0,$$

and so $c_2=-8$ for Dirichlet and Robin boundary conditions. This completes the calculation of $A_{3/2}$.

We continue with the treatment of A_2. Its general form is[8]

$$
\begin{aligned}
A_2(F,P)=(4\pi)^{-D/2}360^{-1}\{&F(60\Delta E+60RE+180E^2+12\Delta R+5R^2-2R_{ij}R^{ij}\\
&+2R_{ijkl}R^{ijkl})[\mathcal{M}]+[F(d_1E_{;m}+d_2R_{;m}+d_3K^a_{:a}+d_4K_{ab:}{}^{ab}+d_5EK\\
&+d_6RK+d_7R_{mm}K+d_8R_{ambm}K^{ab}+d_9R_{abc}{}^bK^{ac}+d_{10}K^3\\
&+d_{11}K_{ab}K^{ab}K+d_{12}K_{ab}K^b_cK^{ac}+d_{13}SE+d_{14}SR+d_{15}SR_{mm}\\
&+d_{16}SK^2+d_{17}SK_{ab}K^{ab}+d_{18}KS^2+d_{19}S^3+d_{20}S^a_{:a})\\
&+F_{;m}(e_1E+e_2R+e_3R_{mm}+e_4K^2+e_5K_{ab}K^{ab}+e_8SK+e_9S^2)\\
&+F_{;mm}(e_6K+e_{10}S)+e_7(\Delta F)_{;m}][\partial\mathcal{M}]\}. \qquad (41)
\end{aligned}
$$

The ball calculation gives

$$
\begin{gathered}
d_{10}=(40/21^-,40/3^+),\quad d_{11}=(-88/7^-,8^+),\quad d_{12}=(320/21^-,32/3^+),\\
d_{16}=144,\quad d_{17}=48,\quad d_{18}=480,\quad d_{19}=480,\\
e_4=(180/7^-,-12^+),\quad e_5=(-60/7^-,-12^+),\quad e_6=24,\\
e_7=(30^-,-30^+),\quad e_8=-72,\quad e_9=-240,\quad e_{10}=120. \qquad (42)
\end{gathered}
$$

The product formula here reads as

$$
A_2(y,P)=A_2(y_1,P_1)A_0(x_2,P_2)-A_0(y_1,P_1)A_2(x_2,P_2)+A_1(y_1,P_1)A_1(x_2,P_2),
$$

and leads to the universal constants,

$$
\begin{gathered}
d_5=120,\quad d_6=20,\quad d_{13}=720,\quad d_{14}=120,\\
e_1=(180^-,-180^+)\quad e_2=(30^-,-30^+). \qquad (43)
\end{gathered}
$$

These two inputs already give 20 of the 30 unknowns; the remaining 10 are determined by the conformal rescaling (40),

$$
\left.\frac{d}{d\epsilon}\right|_{\epsilon=0} a_2(1,e^{-2\epsilon F}P)-(D-4)a_2(F,P)=0. \qquad (44)
$$

Having already evaluated many of the constants only a few more relations are required to fix the remaining ones. In the following list, we give, on the left, the term in (44) whose coefficient is equated to zero.

Term	Coefficient
$EF_{;m}$	$0=-2d_1+60(D-6)+d_5(D-1)-(D-4)e_1-\frac{1}{2}(D-2)d_{13}$
$(\Delta F)_{;m}$	$0=6(D-6)+\frac{1}{2}(D-2)d_1-2(D-1)d_2-(D-4)e_7$
$F_{:a}K^a_:$	$0=-4(D-6)+(D-4)d_3-\frac{1}{2}(D-2)d_5+2(D-1)d_6+d_7+d_9$
$KF_{;mm}$	$0=\frac{1}{2}(D-2)d_5-2(D-1)d_6-(D-1)d_7-d_8-(D-4)e_6$
$K_{ab:}{}^bF^a_:$	$0=(D-4)d_4+d_8+(D-3)d_9+4(D-6)$
$R_{mm}F_{;m}$	$0=(D-1)d_7+d_8-2d_9+e_3+4(D-6)-\frac{1}{2}(D-2)d_{15}$

$$F_{:a}S^{a}_{:} \qquad 0=-\tfrac{1}{2}(D-2)d_{13}+2(D-1)d_{14}+d_{15}+(D-4)d_{20}. \tag{45}$$

From here one finds the universal constants,

$$\begin{gathered} d_1=(120^-,-240^+), \quad d_2=(18^-,-42^+), \quad d_3=24, \quad d_4=0, \\ d_7=-4, \quad d_8=12, \quad d_9=-4, \quad d_{15}=0, \quad d_{20}=120, \quad e_3=0. \end{gathered} \tag{46}$$

This completes the evaluation of A_2 and we finally come to the calculation of $A_{5/2}$, which, for an arbitrary smearing function F, has been calculated only for a totally geodesic boundary $\partial\mathcal{M}$. When $F=1$, it has been determined for $\mathcal{M}$ a domain of $\mathbb{R}^m$.

It has been shown that for a smooth, but not necessarily totally geodesic, boundary there exist universal constants such that

$$\begin{aligned} A_{5/2}(F,P)=&\mp 5760^{-1}(4\pi)^{-d/2}\{F\{g_1E_{;mm}+g_2E_{;m}S+g_3E^2+g_4E_{:a}{}^{a}+g_5RE+120\Omega_{ab}\Omega^{ab} \\ &+g_6\Delta R+g_7R^2+g_8R_{ij}R^{ij}+g_9R_{ijkl}R^{ijkl}+g_{10}R_{mm}E+g_{11}R_{mm}R+g_{12}RS^2 \\ &+(-360^-,90^+)\Omega_{am}\Omega^{a}{}_{m}+g_{13}R_{;mm}+g_{14}R_{mm:a}{}^{a}+g_{15}R_{mm;mm}+g_{16}R_{;m}S \\ &+g_{17}R_{mm}S^2+g_{18}SS_{:a}{}^{a}+g_{19}S_{:a}S^{a}_{:}+g_{20}R_{ammb}R^{ab}+g_{21}R_{mm}R_{mm}+g_{22}R_{ammb}R^{a}{}_{mb}{}^{a} \\ &+g_{23}ES^2+g_{24}S^4\}+F_{;m}\{g_{25}R_{;m}+g_{26}RS+g_{27}R_{mm}S+g_{28}S_{:a}{}^{a}+g_{29}E_{;m}+g_{30}ES \\ &+g_{31}S^3\}+F_{;mm}\{g_{32}R+g_{33}R_{mm}+g_{34}E+g_{35}S^2\}+g_{36}SF_{;mmm}+g_{37}F_{;mmmm} \\ &+F\{d_1KE_{;m}+d_2KR_{;m}+d_3K^{ab}R_{ammb;m}+d_4KS_{:b}{}^{b}+d_5K_{ab}S^{ab}_{:}+d_6K_{:b}S^{b}_{:} \\ &+d_7K_{ab:}{}^{a}S^{b}_{:}+d_8K_{:b}{}^{b}S+d_9K_{ab:}{}^{ab}S+d_{10}K_{:b}K^{b}_{:}+d_{11}K_{ab:}{}^{a}K^{b}_{:}+d_{12}K_{ab:}{}^{a}K^{bc}{}_{:c} \\ &+d_{13}K_{ab:c}K^{ab}{}_{:}{}^{c}+d_{14}K_{ab:c}K^{ac}{}_{:}{}^{b}+d_{15}K_{:b}{}^{b}K+d_{16}K_{ab:}{}^{ab}K+d_{17}K_{ab:}{}^{a}{}_{c}K^{bc} \\ &+d_{18}K_{:bc}K^{bc}+d_{19}K_{bc:a}{}^{a}K^{bc}+g_{38}KSE+d_{20}KSR_{mm}+g_{39}KSR+d_{21}K_{ab}R^{ab}S \\ &+d_{22}K^{ab}SR_{ammb}+g_{40}K^2E+g_{41}K_{ab}K^{ab}E+g_{42}K^2R+g_{43}K_{ab}K^{ab}R+d_{23}K^2R_{mm} \\ &+d_{24}K_{ab}K^{ab}R_{mm}+d_{25}KK_{ab}R^{ab}+d_{26}KK^{ab}R_{ammb}+d_{27}K_{ab}K^{ac}R^{b}_{c}+d_{28}K^{b}_{a}K^{ac}R_{bmmc} \\ &+d_{29}K_{ab}K_{cd}R^{acbd}+d_{30}KS^3+d_{31}K^2S^2+d_{32}K_{ab}K^{ab}S^2+d_{33}K^3S+d_{34}KK_{ab}K^{ab}S \\ &+d_{35}K_{ab}K^{bc}K^{a}_{c}S+d_{36}K^4+d_{37}K^2K_{ab}K^{ab}+d_{38}K_{ab}K^{ab}K_{cd}K^{cd}+d_{39}KK_{ab}K^{bc}K^{a}_{c} \\ &+d_{40}K_{ab}K^{bc}K_{cd}K^{da}\}+F_{;m}\{g_{44}KE+d_{41}KR_{mm}+g_{45}KR+d_{42}KS^2+d_{43}K_{:b}{}^{b} \\ &+d_{44}K_{ab:}{}^{ab}+d_{45}K_{ab}R^{ab}+d_{46}K^{ab}R_{ammb}+d_{47}K^2S+d_{48}K_{ab}K^{ab}S+d_{49}K^3 \\ &+d_{50}KK_{ab}K^{ab}+d_{51}K_{ab}K^{bc}K^{a}_{c}\}+F_{;mm}\{d_{52}KS+d_{53}K^2+d_{54}K_{ab}K^{ab}\}+d_{55}KF_{;mmm}\} \\ &[\partial\mathcal{M}]. \end{aligned} \tag{47}$$

In this case, specializing to the ball gives

$$g_{24}=1440,\quad g_{31}=-720,$$
$$g_{35}=360,\quad g_{36}=-180,$$
$$g_{37}=45,\quad d_{30}=2160,$$
$$d_{31}=1080,\quad d_{32}=360,$$
$$d_{33}=885/4,\quad d_{34}=315/2,$$
$$d_{35}=150,\quad d_{36}=(-65/128^{-},2041/128^{+}),$$
$$d_{37}=(-141/32^{-},417/32^{+}),\quad d_{40}=(-327/8^{-},231/8^{+}),$$
$$d_{42}=-600,\quad d_{47}=-705/4,$$
$$d_{48}=75/2,\quad d_{49}=(495/32^{-},-459/32^{+}),$$
$$d_{50}=(-1485/16^{-},-267/16^{+}),\quad d_{51}=(225/2^{-},54^{+}),$$
$$d_{52}=30,\quad d_{53}=(1215/16^{-},315/16^{+}),$$
$$d_{54}=(-954/8^{-},-645/8^{+}),\quad d_{55}=(105^{-},30^{+}),$$

and $d_{38}+d_{39}=(1049/32^{-},1175/32^{+})$.

The product formula explicitly reads as

$$A_{5/2}(y,P)=A_{5/2}(y_1,P_1)A_0(x_2,P_2)+A_{3/2}(y_1,P_1)A_1(x_2,P_2)+A_{1/2}(y_1,P_1)A_2(x_2,P_2),$$

which gives the 22 universal constants,

$$g_3=720,\quad g_5=240,\quad g_6=48,\quad g_7=20,$$
$$g_8=-8,\quad g_9=8,\quad g_{10}=-120,\quad g_{11}=-20,$$
$$g_{12}=480,\quad g_{23}=2880,\quad g_{26}=-240,\quad g_{30}=-1440,$$
$$g_{32}=60,\quad g_{34}=360,\quad g_{38}=1440,\quad g_{39}=240,$$
$$g_{40}=(105^{-},195^{+}),\quad g_{41}=(-150^{-},30^{+}),\quad g_{42}=(105/6^{-},195/6^{+}),$$
$$g_{43}=(-25^{-},5^{+}),\quad g_{44}=(450^{-},-90^{+}),\quad g_{45}=(75^{-},-15^{+})$$

All this information puts us in a very good position to use the relations between the heat-kernel coefficients that result from conformal rescalings. The relevant relation reads as

$$\left.\frac{d}{d\epsilon}\right|_{\epsilon=0} A_{5/2}(1,e^{-2\epsilon F}P)-(D-5)A_{5/2}(F,P)=0. \tag{48}$$

Setting to zero the coefficients of all terms in (48), we obtain the equations given in (50). (They are ordered in such a way that nearly every equation immediately yields a universal constant. This was the main motivation for the given ordering.) Using the relation (50), we find

$$g_1=360,\quad g_2=-1440,\quad g_4=240,$$
$$g_{13}=12,\quad g_{14}=24,\quad g_{15}=15,$$
$$g_{16}=-270,\quad g_{17}=120,\quad g_{18}=960,$$
$$g_{19}=600,\quad g_{20}=-16,\quad g_{21}=-17,$$
$$g_{22}=-10,\quad g_{25}=(60^{-},195/2^{+}),\quad g_{27}=90,$$

$$g_{28}=-270, \quad g_{29}=(450^{-},630^{+}), \quad g_{33}=-90,$$

$$d_1=(450^{-},-90^{+}), \quad d_2=(42^{-},-111/2^{+}), \quad d_3=(0^{-},30^{+}),$$

$$d_4=240, \quad d_5=420, \quad d_6=390,$$

$$d_7=480, \quad d_8=420, \quad d_9=60,$$

$$d_{20}=30, \quad d_{21}=-60, \quad d_{22}=-180.$$

Thus, the equations given up to this point allow for the determination of the universal constants apart from two groups. The first group is $d_{23},\ldots,d_{29},d_{38},d_{39},d_{41},d_{45},d_{46}$ and the second one, $d_{10},\ldots,d_{19},d_{43},d_{44}$. The first group is completely determined using the relations given in (51). One finds

$$d_{23}=(-215/16^{-},-275/16^{+}), \quad d_{24}=(-215/8^{-},-275/8^{+}),$$

$$d_{25}=(14^{-},-1^{+}), \quad d_{26}=(-49/4^{-},-109/4^{+}),$$

$$d_{27}=16, \quad d_{28}=(47/2^{-},-133/2^{+}),$$

$$d_{29}=32, \quad d_{38}=(777/32^{-},375/32^{+}),$$

$$d_{39}=(17/2^{-},25^{+}), \quad d_{41}=(-255/8^{-},165/8^{+}),$$

$$d_{45}=(-30^{-},-15^{+}), \quad d_{46}=(-465/4^{-},-165/4^{+}).$$

Finally, we consider the second group mentioned above. As we will see, one needs just one more relation in addition to those obtained from Eq. (48), which are presented in (52). They yield

$$d_{11}=(58^{-},238^{+}), \quad d_{15}=(6^{-},111^{+}),$$

$$d_{16}=(-30^{-},-15^{+}), \quad d_{19}=(54^{-},114^{+}),$$

together with the relations

$$2d_{10}+d_{43}=-91, \quad 2d_{10}-d_{18}=(-983/8^{-},-1403/8^{+}),$$

$$2d_{14}-3d_{18}=(-913/4^{-},-2533/4^{+}), \quad d_{13}+d_{14}=(297/8^{-},837/8^{+}),$$

$$d_{18}-d_{44}=(60^{-},225^{+}), \quad 2d_{12}-2d_{17}-d_{18}=(-7/4^{-},-787/4^{+}),$$

$$2d_{12}-d_{17}=32.$$

This is all we can get with the relation (48). It is seen that, given d_{43} or d_{44}, for example, the remaining constants can be determined. This is achieved with the equation (8)

$$\left.\frac{d}{d\epsilon}\right|_{\epsilon=0} A_{5/2}(e^{-2\epsilon f}F,e^{-2\epsilon f}P)=0, \quad \text{for } D=7. \tag{49}$$

Thus, finally, one gets

$$d_{10}=(-413/16^{-},487/16^{+}), \quad d_{12}=(-11/4^{-},49/4^{+}),$$

$$d_{13}=(355/8^{-},535/8^{+}), \quad d_{14}=(-29/4^{-},151/4^{+}),$$

$$d_{17}=(-75/2^{-},-15/2^{+}),\quad d_{18}=(285/4^{-},945/4^{+}),$$

$$d_{43}=(-315/8^{-},-1215/8^{+}),\quad d_{44}=45/4,$$

which concludes the calculation of the complete $A_{5/2}$ coefficient on a smooth manifold with a boundary. All terms not displayed in the above lists have been used as checks on the computed universal constants.

IV. CONCLUSIONS

In this article we have developed a technique for the calculation of smeared heat-kernel coefficients on the generalized cone. This is a generalization of our previous work,[13] where we treated the $F=1$ case only. All technical and aesthetic advantages emphasized previously are still present for arbitrary F. Namely, by restricting attention to the ball, and using a function F as general as needed, the coefficients can be found as polynomials in the dimension of the ball. This has the advantage that the special case evaluation can easily be used to put restrictions on the general form of the heat-kernel coefficients. This idea was applied to the coefficients $A_0,\ldots,A_{5/2}$ for Dirichlet and Robin boundary conditions. Supplemented by a lemma on product manifolds and relations from conformal rescalings, we have shown that starting with the results of the special case, treated here for the first time, the complete coefficients are obtained very effectively.

The method is clearly capable of being applied to other situations. An example of even more complexity is the generalized boundary condition involving tangential derivatives of the field.[24–27] Up to now, for this case, we have applied the technique of special case evaluation only to the four-dimensional ball.[30] The treatment of the D-dimensional ball is under consideration with the aim of finding the general form of the coefficients using the ideas presented here. Another situation of interest is the spectral boundary condition applied to spinor fields. These conditions are nonlocal and it is known that the relations obtained with conformal techniques are not sufficient for the determination of the entire coefficient.[31] However, supplemented by the ball calculation, it is possible to find at least the lower coefficients in this case too. We reserve exposition of these extensions for later.

A general word of caution, however. The evaluation of higher and higher coefficients quickly becomes prodigiously complicated, even for just the volume terms, and there is the danger of it becoming an end in itself. The question is whether there is any value in displaying an impenetrable profusion of terms, without some strong motivation. As far as the boundary terms go, we feel that with $A_{5/2}$ we probably have reached the limit of what can sensibly be calculated and displayed. Already the expressions are becoming unwieldy. Further progress in this area should, we think, be limited to extending the class of manifolds, say to those with nonsmooth boundaries, and to the consideration of other fields and boundary conditions as indicated in the preceding paragraph.

ACKNOWLEDGMENTS

We are indebted to Peter Gilkey for providing results on conformal rescalings. They have served as a very good check of the calculation and have been of invaluable help. Furthermore, we wish to thank Giampiero Esposito and Michael Bordag for interesting discussions. This investigation has been partly supported by the DFG under Contract No. ber BO1112/4-2 and partly by the EPSRC under Grant No. GR/D75708.

APPENDIX

In this appendix we list the relations resulting from the conformal property (48).
The first group of relations is

Term	Coefficient
$EF_{;mm}$	$0=-2g_1+(D-2)g_3-2(D-1)g_5-(D-1)g_{10}-(D-5)g_{34}$

$$ESF_{;m} \quad 0=-2g_2-(D-2)g_{23}+(D-1)g_{38}-(D-5)g_{30}$$

$$FK_{:a}{}^{a}S \quad 0=\tfrac{1}{2}(D-2)g_2+2(D-1)g_{16}-d_4+d_6-(D-4)d_8$$
$$+\tfrac{1}{2}(D-2)g_{38}-d_{20}-2(D-1)g_{39}-d_{21}$$

$$FK_{ab}S^{ab}_{:} \quad 0=-(D-2)g_2+4(D-1)g_{16}+3d_5-(D-2)d_7+(D-2)d_9$$
$$-(D-2)d_{21}+d_{22}$$

$$FK_{ab:}{}^{ab}S \quad 0=-d_5+d_7-(D-4)d_9-(D-2)d_{21}+d_{22}$$

$$F_{;m}S_{:a}{}^{a} \quad 0=\tfrac{1}{2}(D-2)g_2-2(D-1)g_{16}-(D-2)g_{18}+(D-2)g_{19}+(D-1)d_4 +d_5-(D-1)d_6-d_7+(D-1)d_8+d_9-(D-5)g_{28}. \tag{A1}$$

For the second one we have the following.

Term	Coefficient
$F_{;mm}K_{ab}K^{ab}$	$0=-(D-2)g_1+4(D-1)g_6+4(D-1)g_{13}+2g_{15}+d_3+\tfrac{1}{2}(D-2)g_{41} -2(D-1)g_{43}-(D-1)d_{24}-d_{27}+d_{28}-(D-5)d_{54}$
$F_{;mm}K^2$	$0=-2(D-1)g_6+\tfrac{1}{2}(D-2)d_1-2(D-1)d_2+(D-2)g_{40} -2(D-1)g_{42}-(D-1)d_{23}-d_{25}+d_{26}-(D-5)d_{53}$
$F_{;m}KR$	$0=\tfrac{1}{2}(D-2)g_5-2g_6-4(D-1)g_7-2g_8-g_{11}-2d_2-\tfrac{1}{2}(m-2)g_{39} +2(D-1)g_{42}+2g_{43}+d_{25}-(D-5)g_{45}$
$F_{;m}KR_{mm}$	$0=\tfrac{1}{2}(D-2)g_1+\tfrac{1}{2}(D-2)g_{10}-2(D-1)g_{11}-2(D-1)g_{13}+4g_{15} +g_{20}-2g_{21}-\tfrac{1}{2}(D-2)d_1+2(D-1)d_2+d_3-\tfrac{1}{2}(D-2)d_{20} +2(D-1)d_{23}+2d_{24}-d_{25}-d_{26}-(D-5)d_{41}$
$F_{;m}K_{ab}R^{ab}$	$0=-\tfrac{1}{2}(D-2)g_1+2(D-1)g_6-2(D-2)g_8-8g_9+2(D-1)g_{13} -4g_{15}+g_{20}-d_3-\tfrac{1}{2}(D-2)d_{21}+(D-1)d_{25}+2d_{27}+2d_{29}-(D-5)d_{45}$
$F_{;m}K^{ab}R_{ammb}$	$0=-(D-2)g_1+4(D-1)g_6+4(D-1)g_{13}+2g_{15}-(D-2)g_{20} +2g_{22}-d_3-\tfrac{1}{2}(D-2)d_{22}+(D-1)d_{26}+2d_{28}+2d_{29}-(D-5)d_{46}$
$F_{;m}K_{ab}K^{bc}K_c^a$	$0=(D-2)g_1-4(D-1)g_6-4(D-1)g_{13}-2g_{15}-d_3-(D-2)d_{27} +d_{28}+2d_{29}-\tfrac{1}{2}(D-2)d_{35}+(D-1)d_{39}+4d_{40}-(D-5)d_{51}$
$FR_{ac}K_b^cK^{ab}$	$0=-2(D-2)g_8-8g_9+4g_{15}+g_{20}+2d_3+4d_{13}+4d_{14}-4d_{19} -(D-2)d_{27}+d_{28}+2d_{29}.$

(A2)

Finally, the third group:

Term	Cofficient
$FK_{:b}K^{:b}$	$0=2(D-1)g_6-4g_{15}-(D-2)g_{20}+2g_{22}-\tfrac{1}{2}(D-2)d_1 +2(D-1)d_2+2d_{10}+d_{11}-(D-3)d_{15}-d_{16}-d_{18}+(D-2)g_{40} -4(D-1)g_{42}-2d_{23}-2d_{25}$
$FK_{ab:}{}^{a}K_{:}^{b}$	$0=2(D-2)g_1-4(D-1)g_6-8(D-1)g_{13}+(4D-6)g_{20}-8g_{22} -(D-2)d_1+4(D-1)d_2-(D-3)d_{11}+2d_{12}-2d_{14}+2d_{16} -2d_{17}+2d_{18}-2(D-2)d_{25}+2d_{26}-4d_{29}$

$$
\begin{aligned}
FK_{ab:c}K^{ab\ c}_{\ :} \quad 0 &= (D-2)g_1 - 4(D-1)g_6 - 4(D-1)g_{13} - 2g_{15} + (D-2)g_{20} \\
&\quad - 2g_{22} - 3d_3 + 2d_{13} + 2d_{14} - (D-3)d_{19} + (D-2)g_{41} \\
&\quad - 4(D-1)g_{43} - 2d_{24} - 2d_{27} \\
FKK_{ab:}^{\ \ ab} \quad 0 &= 4(D-2)g_8 + 16g_9 - 4g_{15} - Dg_{20} + 2g_{22} + d_{11} + 2d_{12} - (D-4)d_{16} \\

F_{:m}K_{:a}^{\ \ a} \quad 0 &= -\tfrac{3}{2}(D-2)g_1 + 4(D-1)g_6 - 4(D-2)g_8 - 16g_9 + 6(D-1)g_{13} \\
&\quad + \tfrac{1}{2}(D-2)d_1 - 2(D-1)d_2 - d_3 - \tfrac{1}{2}(D-2)d_4 + \tfrac{1}{2}(D-2)d_6 \\
&\quad - \tfrac{1}{2}(D-2)d_8 - 2(D-1)d_{10} \\
&\quad - d_{11} - 2d_{13} + 2(D-1)d_{15} + d_{16} + d_{18} + 2d_{19} - (D-5)d_{43} \\
F_{:m}K_{ab:}^{\ \ \ ab} \quad 0 &= \tfrac{1}{2}(D-2)g_1 - 2(D-1)g_6 + 4(D-2)g_8 + 16g_9 - 2(D-1)g_{13} \\
&\quad + 2g_{15} + 2d_3 - \tfrac{1}{2}(D-2)d_5 + \tfrac{1}{2}(D-2)d_7 - \tfrac{1}{2}(D-2)d_9 \\
&\quad - (D-1)d_{11} - 2d_{12} - 2d_{14} + (D-1)d_{16} + 2d_{17} + (D-1)d_{18} \\
&\quad - (D-5)d_{44} \\
FK_{ab:}^{\ \ \ a}K^{bc}_{\ \ :c} \quad 0 &= (4-3D)g_{20} + 6g_{22} - 2d_3 - 2(D-2)d_{12} - 4d_{13} - 2d_{14} \\
&\quad + (D+1)d_{17} + 4d_{19} - (D-2)d_{27} + d_{28} + 2d_{29} \\
FK_{:ab}K^{ab} \quad 0 &= 2(D-2)g_1 - 4(D-1)g_6 - 2(D-2)g_8 - 8g_9 - 8(D-1)g_{13} \\
&\quad + (4D-5)g_{20} - 8g_{22} - (D-2)d_1 + 4(D-1)d_2 - (D-2)d_{11} \\
&\quad - 2d_{14} + (D-2)d_{16} + 3d_{18} - (D-2)d_{25} + d_{26} - 2d_{29}.
\end{aligned} \tag{A3}
$$

This completes the list of relations used for the calculation of the $A_{5/2}$ coefficient.

Note added in proof. As suggested in the Conclusions the method has now been applied to generalized boundary conditions involving tangential derivatives and to spectral boundary conditions. Details can be found in Refs. 32 and 33.

The general solution to the complex Bateman equation in a space of arbitrary dimensions is constructed.
[DOI: 10.1063/1.1286230]

I. INTRODUCTION

We define the complex Bateman equation in n-dimensional space by analogy with the so-called universal field equation[1] as

$$\det\begin{vmatrix} 0 & \frac{\partial\phi}{\partial\bar{y}_1} & \cdots & \frac{\partial\phi}{\partial\bar{y}_n} \\ \frac{\partial\phi}{\partial y_1} & \frac{\partial^2\phi}{\partial y_1\partial\bar{y}_1} & \cdots & \frac{\partial^2\phi}{\partial x_1\partial\bar{y}_n} \\ \vdots & \vdots & \ddots & \vdots \\ \frac{\partial\phi}{\partial y_n} & \frac{\partial^2\phi}{\partial y_n\partial\bar{y}_1} & \cdots & \frac{\partial^2\phi}{\partial y_n\partial\bar{y}_n} \end{vmatrix} = 0. \tag{1}$$

Recently it was shown that the general solution to this equation, in the case where $n=2$ is given implicitly, by equating two arbitrary functions of three variables, $F(\phi,y_1,y_2)$ and $G(\phi,\bar{y}_1,\bar{y}_2)$ and solving the resulting equation

$$F(\phi,y_1,y_2)=G(\phi,\bar{y}_1,\bar{y}_2) \tag{2}$$

for $\phi(y_1,y_2,\bar{y}_1,\bar{y}_2)$.[2] After we found this solution, we were astonished to find it set as an exercise as Problem (8) (ii) on page 328 of Chaundy's *The Differential Calculus*, Oxford University Press (1935)![3] This assertion may be readily verified by partial differentiation. The corresponding result for (1) is the subject of this article.

II. EQUIVALENT FIRST-ORDER EQUATIONS

The complex Bateman equation, (1), is the eliminant of $(n+1)$ linear equations which may be written as

$$\sum_{i=1}^{n}\alpha^i\phi_{\bar{y}_i}=0, \quad \phi_{y_s}=\sum_{1}^{n}\alpha^i_{y_s}\phi_{\bar{y}_i}, \tag{3}$$

a)Electronic mail: david.fairlie@durham.ac.uk

where ϕ_{y_i} denotes $\partial\phi/\partial y_i$, etc. Similarly, it is also the eliminant of the equations

$$\sum_{i=1}^{n} \beta^i \phi_{y_i} = 0, \quad \phi_{\bar{y}_s} = \sum_{1}^{n} \beta^i_{\bar{y}_s} \phi_{y_i}. \tag{4}$$

From (3) and (4) it follows that

$$\sum_{s} \alpha^s_{y_i} \beta^k_{\bar{y}_s} = \delta^k_i, \tag{5}$$

or in other words, the above-introduced Jacobian matrices $\alpha^s_{y_i}$ and $\beta^k_{\bar{y}_s}$ are inverses of one another. Let us multiply and sum each equation of the first system (3) by β^s [and carry out a similar operation for system (4)]. We obtain

$$\sum_{i=1}^{n} \beta^s \alpha^i_{y_s} \phi_{\bar{y}_i} = 0, \quad \sum_{1}^{n} \alpha^s \beta^i_{\bar{y}_s} \phi_{y_i} = 0. \tag{6}$$

Now we come to a crucial step; Eq. (6) cannot contain any new information, but will only repeat those equations already quoted. In other words,

$$\sum_{i} \beta^i \alpha^s_{y_i} = \theta \alpha^s \tag{7}$$

for some θ. It follows immediately (taking into account the inverse properties of the above-introduced matrices) in symmetrical fashion that

$$\sum_{i} \alpha^i \beta^s_{\bar{y}_i} = \theta^{-1} \beta^s, \tag{8}$$

which is consistent with the other set of equations. We shall show that in fact θ is unity, as a requirement that this linear system is equivalent to the complex Bateman equation Sec. III.

Dividing these last equations, respectively, by α^s, β^s and introducing the notation $v^\nu = \alpha^\nu/\alpha^n$, $u^\mu = \beta^\mu/\beta^n$ with the convention that Greek indices take values from 1 up to $n-1$ we can eliminate θ by subtracting the last equation to arrive at the following system:

$$-v^\nu_{y_n} = \sum u^\mu v^\nu_{y_\mu}, \quad -u^\mu_{\bar{y}_n} = \sum v^\nu u^\mu_{\bar{y}_\nu}. \tag{9}$$

In the familiar case of two-dimensional space this system takes the form

$$-v_{y_1} = u v_{y_2}, \quad -u_{\bar{y}_1} = v u_{\bar{y}_2}, \tag{10}$$

the general solution of which is connected with

$$G(\phi; y_1, y_2) = F(\phi; \bar{y}_1, \bar{y}_2). \tag{11}$$

We therefore expect that in the general case of n dimensions the general solution of the complex Bateman equation (1) is connected in some way to a system of $n-1$ equations for $n-1$ unknown functions ψ^μ:

$$Q^\nu(\psi^\mu; y_1, \ldots, y_n) = P^\nu(\psi^\mu; \bar{y}_1, \ldots, \bar{y}_n), \quad \nu = 1 \cdots n-1. \tag{12}$$

III. CONDITIONS OF SELF-CONSISTENCY

As a direct corollary of (3) and (4) it follows that the functions ψ can be thought of as either dependent upon the set of variables $(u^\mu;y_i)$, or else $(v^\nu;\overline{y_j})$,

$$\psi(v^\nu;\overline{y_i})=\psi(u^\mu;y_j). \tag{13}$$

This result is equivalent to using two equations from (3) and (4). The remaining $2n$ equations, taking into account (13), may be transformed in the following way:

$$\psi_{y_s}=\sum\ \alpha^i_{y_s}\sum\ \psi_{u^\mu}u^\mu_{\overline{y_i}}=\sum\ \psi_{u^\mu}\sum\ \alpha^i_{y_s}\left(\frac{\beta^\mu_{\overline{y_i}}}{\beta^n}-\frac{\beta^\mu\beta^n_{\overline{y_i}}}{(\beta^n)^2}\right)=\frac{1}{\beta^n}\sum\ \psi_{u^\mu}(\delta_{s\mu}-u^\mu\delta_{sn}). \tag{14}$$

Or finally,

$$\psi_{y_\mu}=\frac{1}{\beta^n}\psi_{u^\mu}(u^\mu;y_i),\quad \psi_{y_n}=-\frac{1}{\beta^n}\sum\ u^\mu\psi_{u^\mu}, \tag{15}$$

$$\psi_{\overline{y_\nu}}=\frac{1}{\alpha^n}\psi_{v^\nu}(v^\nu;\overline{y_i}),\quad \psi_{\overline{y_n}}=-\frac{1}{\alpha^n}\sum\ v^\nu\psi_{v^\nu}. \tag{16}$$

(The reader can compare these equations with the analogous equations in the paper on the real universal equation.) Now let us use the integrability conditions of self-consistency of the second-order mixed derivatives. Using the conditions of self-consistency for Greek barred and unbarred indices, which read

$$\left(\frac{\psi_{v^\nu}}{\alpha^n}\right)_{y_\mu}=\left(\frac{\psi_{u^\mu}}{\beta^n}\right)_{\overline{y}_\nu}, \tag{17}$$

we consider what follows from the conditions of self-consistency for the other pairs $(y_\mu,\overline{y_n})$, $(\overline{y}_\nu,y_n)$, and $(y_n,\overline{y_n})$. We have in consequence (for the first pair of variables)

$$\frac{\partial}{\partial y_\mu}\frac{\partial\psi}{\partial\overline{y_n}}=-\frac{\partial}{\partial y_\mu}\sum\ v^\nu\frac{\psi_{v^\nu}}{\alpha^n}=-\frac{\psi_{y_\mu}}{\alpha^n}-\sum\ v^\nu\left(\frac{\psi_{v^\nu}}{\alpha^n}\right)_{y_\mu}=-\frac{\psi_{y_\mu}}{\alpha^n}-\sum\ v^\nu\left(\frac{\psi_{u^\mu}}{\beta^n}\right)_{\overline{y}_\nu}=\frac{\partial}{\partial\overline{y}_n}\left(\frac{\psi_{u^\mu}}{\beta^n}\right). \tag{18}$$

The last row of this equality can been transformed into

$$\sum_\alpha\ \psi_{u^\mu,u^\alpha}\left(u^\alpha_{\overline{y}_n}+\sum\ v^\nu u^\alpha_{\overline{y}_\nu}\right)+\left(\frac{\psi_{u^\mu}}{\alpha^n}\right)\left(1-\frac{\Sigma_i\alpha^i\beta^n_{\overline{y}_i}}{\beta^n}\right)=0. \tag{19}$$

Rewriting the previous equality,

$$\psi_{\overline{y_n}}+\sum\ v^\nu\psi_{\overline{y}_\nu}=0, \tag{20}$$

in terms of the variables (u,y) to give

$$\sum\ \psi_{u^\alpha}\left(u^\alpha_{\overline{y}_n}+\sum\ v^\nu u^\alpha_{\overline{y}_\nu}\right)=0, \tag{21}$$

we arrive at a linear system of n equations for the n unknowns:

$$\left(u^{\alpha}_{\overline{y}_n}+\sum v^{\nu}u^{\alpha}_{\overline{y}_\nu}\right),\quad \alpha^n\left(1-\frac{\Sigma_i\alpha^i\beta^n_{\overline{y}_i}}{\beta^n}\right),$$

and assuming that the determinant of the corresponding universal equation in the $(n-1)$ dimensional space u^{α} is different from zero (the degenerate case, when it is equal to zero demands special consideration):

$$\sum_i \alpha^i\beta^n_{\overline{y}_i}=\beta^n,\quad u^{\mu}_{\overline{y}_n}+\sum v^{\nu}u^{\mu}_{\overline{y}_\nu}=0, \tag{22}$$

$$\sum_i \beta^i\alpha^n_{y_i}=\alpha^n,\quad v^{\nu}_{y_n}+\sum u^{\mu}v^{\nu}_{y_\mu}=0, \tag{23}$$

which proves that $\theta=1$ in (8) and (9) and shows that the hydrodynamical system (9) is the direct corollary of the main equations. The equivalence of the second mixed partial derivatives $(\psi_{\overline{y}_n})_{y_n}$ in both orders leads to equivalent expressions. They are not essential for what follows and are omitted here.

IV. THE SYSTEM OF HYDRODYNAMIC TYPE

We understand by a system of hydrodynamic type the system (9) rewritten in the following:

$$v^{\nu}_{y_n}+\sum u^{\mu}v^{\nu}_{y_\mu}=0,\quad u^{\mu}_{\overline{y}_n}+\sum v^{\nu}u^{\mu}_{\overline{y}_\nu}=0. \tag{24}$$

Two propositions with respect to this system will be required in the following.[3]

Proposition 1: The conditions that the pair of operators

$$D=\frac{\partial}{\partial y_n}+\sum u^{\mu}\frac{\partial}{\partial y_\mu},\quad \overline{D}=\frac{\partial}{\partial\overline{y}_n}+\sum v^{\nu}\frac{\partial}{\partial\overline{y}_\nu} \tag{25}$$

are commutative are that the functions (u^{μ},v^{ν}) are solutions of system (24).

Acting with the help of operators $(D,\overline{D})$ on the second and the first equations of (24), respectively, we further conclude that the $2(n-1)$ functions

$$\overline{D}(v^{\nu})=v^{\nu}_{\overline{y}_n}+\sum v^{\mu}v^{\nu}_{\overline{y}_\mu},\quad D(u^{\mu})=u^{\mu}_{y_n}+\sum u^{\nu}u^{\mu}_{y_\nu} \tag{26}$$

are also solutions of the first and the second system of Eq. (24).

As a corollary we obtain the following

Proposition 2: Suppose the following notation for the above-mentioned expressions is introduced:

$$v^{\nu}_{\overline{y}_n}+\sum v^{\mu}v^{\nu}_{\overline{y}_\mu}=Q^{\nu}(v;\overline{y}),\quad u^{\mu}_{y_n}+\sum u^{\nu}u^{\mu}_{y_\nu}=P^{\mu}(u;y). \tag{27}$$

Then, as has been anticipated in the notation, Q^{μ} depends upon y_j, $\overline{y_j}$ through the variables v^j and $\overline{y_j}$, and P^{μ} through u^j, y_j. Indeed, the n sets of variables $(1,u)$, satisfy a linear system of $n-1$ matrix equations arising from the first equation of (24) and the fact that Q^{μ} is a solution, for each $\mu=1\cdots n-1$, namely

$$\begin{pmatrix} v^1_{y_1} & \cdots & v^1_{y_{n-1}} & v^1_{y_n} \\ \vdots & \ddots & \vdots & \vdots \\ v^{n-1}_{y_1} & \cdots & v^{n-1}_{y_n} & v^{n-1}_{y_n} \\ Q^\nu_{y_1} & \cdots & Q^\nu_{y_{n-1}} & Q^\nu_{y_n} \end{pmatrix} \begin{pmatrix} u^1 \\ \vdots \\ u^{n-1} \\ 1 \end{pmatrix} = 0. \tag{28}$$

The condition for the existence of a solution is that the determinant of the Jacobian matrix should vanish, which implies that each Q^μ is a function of the variables y only through the functions v. The corresponding result holds for P^μ in a similar manner, so Proposition 2 is proved.

Compared with (24) and (27) is an inhomogeneous system of hydrodynamic equations separated into functions (u,v). Now we are able to find solutions of the primary equations (22) and (23). To this end, let us rewrite them in the terms of operators D, $\overline{D}$:

$$\overline{D}\left(\frac{1}{\beta^n}\right) = -\frac{1}{\alpha^n\beta^n} = D\left(\frac{1}{\alpha^n}\right). \tag{29}$$

We have in consequence the result that there must exist a function Θ such that

$$\frac{1}{\beta^n} = D\Theta, \quad \frac{1}{\alpha^n} = \overline{D}\Theta, \quad (\overline{D}\Theta)(D\Theta) = -\overline{D}D\Theta. \tag{30}$$

The solution of Eq. (30) follows the pattern for the solution to the complex variable equation $f_z f_{\bar{z}} + f_{z\bar{z}} = 0$ and takes the form

$$\exp\Theta = -g(u;y) + \overline{g}(v;\overline{y}). \tag{31}$$

V. GENERAL SOLUTION OF THE HYDRODYNAMIC SYSTEM

Suppose we have the following system of equations defining implicitly $(n-1)$ unknown functions (ψ) in $(2n)$ dimensional space $(y,\overline{y})$:

$$Q^\nu(\psi;y) = P^\nu(\psi;\overline{y}) \tag{32}$$

with the convention that all Greek indices take values between 1 and $(n-1)$. The number of equations in (32) coincides with the number of unknown functions ψ^α.

With the help of the usual rules of differentiation of implicit functions we find from (32):

$$\psi_y = (P_\psi - Q_\psi)^{-1} Q_y, \quad \psi_{\overline{y}} = -(P_\psi - Q_\psi)^{-1} P_{\overline{y}}. \tag{33}$$

Let us assume that between n derivatives with respect to barred and unbarred variables the following linear dependencies obtain:

$$\sum_1^n c_i \psi^\alpha_{y_i} = 0, \quad \sum_1^n d_i \psi^\alpha_{\overline{y}_i} = 0 \tag{34}$$

and analyze the consequences of these facts.

Assuming that $c_n \neq 0$, $d_n \neq 0$, dividing them into each equation of the left and right systems, respectively, and introducing the notation $u^\alpha = c_\alpha / c_n$, $v^\alpha = d_\alpha / d_n$ we may rewrite the last set in the following form:

$$\psi^\alpha_{y_n} + \sum_1^{n-1} u^\nu \psi^\alpha_{y_\nu} = 0, \quad \psi^\alpha_{\overline{y}_n} + \sum_1^{n-1} v^\nu \psi^\alpha_{\overline{y}_\nu} = 0. \tag{35}$$

Substituting values of the derivatives from (33) and multiplying the result by the matrix $(P_\psi - Q_\psi)$ from the left we obtain

$$Q^\alpha_{y_n} + \sum_1^{n-1} u^\nu Q^\alpha_{y_\nu} = 0, \quad P^\alpha_{\bar{y}_n} + \sum_1^{n-1} v^\nu P^\alpha_{\bar{y}_\nu} = 0. \tag{36}$$

From these last equations it immediately follows that

$$u^\nu = -(Q_{y_\nu})^{-1} Q_{y_n}, \quad v^\nu = -(P_{\bar{y}_\nu})^{-1} P_{\bar{y}_n}. \tag{37}$$

We see that if we augment the initial system (32) by $(n-1)$ vector functions (u,v) defined by (37), then the differential operators D, $\bar{D}$ defined by (5) in connection with (35) annihilate each ψ either as a Q or a P function:

$$D\psi = \bar{D}\psi = DQ = DP = \bar{D}Q = \bar{D}P = 0. \tag{38}$$

This means that $D\bar{f}(\psi,\bar{y}) = \bar{D}f(\psi,y) = 0$. As a direct corollary of this fact, $Dv = \bar{D}u = 0$ and the generators D, $\bar{D}$ constructed in this way mutually commute. Thus we have found the general solution of the hydrodynamic system and a concrete realization of the manifold with the properties of Sec. IV.

With respect to the generators D, $\bar{D}$ all functions of $2n$ dimensional space may be divided into the following subclasses: functions of general position F, $DF \neq 0$, $\bar{D}F \neq 0$, holomorphic functions f, $\bar{D}f = 0$, $Df \neq 0$, antiholomorphic ones $\bar{f}$, $D\bar{f} = 0$, $\bar{D}\bar{f} \neq 0$, and f^0 ''central'' functions, both holomorphic and antiholomorphic simultaneously; $\bar{D}f^0 = Df^0 = 0$. Each central function may be represented in the following form:

$$f^0 = f^0(Q) = f^0(P) = g^0(\phi).$$

VI. EQUATIONS FOLLOWING FROM THE OTHER RESTRICTIONS

Formula (37) together with (32) give the general solution of the hydrodynamic system (24). Indeed this solution depends upon $2(n-1)$ arbitrary functions (32) each of $(2n-1)$ independent arguments, which are sufficient for the statement of Cauchy or Goursat initial value problems. The general solution of the complex Bateman equation (1) depends upon only two arbitrary functions each of $(2n-1)$ arguments. Thus all other restrictions arising on the way must reduce the $2(n-1)$ arbitrary functions of (32) to only two.

For this purpose it is necessary to calculate derivatives of the functions u,v defined by (37). We have in consequence, suppressing the index ν,

$$\begin{aligned} u_{y_\alpha} &= -Q_y^{-1}\left(Q_{y_n,y_\alpha} + \sum Q_{y_n,\psi^\beta}\psi^\beta_{y_\alpha} - Q_{y,y_\alpha}Q_y^{-1}Q_{y_n} - \sum Q_{y,\psi^\beta}\phi^\beta_{y_\alpha}Q_y^{-1}Q_{y_n}\right) \\ &\equiv -Q_y^{-1}(DQ_{y_\alpha}) + Q_y^{-1}(DQ_\psi)(P_\psi - Q_\psi)^{-1}Q_{y_\alpha}. \end{aligned} \tag{39}$$

By the same technique we can calculate $u_{\bar{y}}, v_y$ using

$$u_{\bar{y}} = Q_y^{-1}(DQ_\psi)(P_\psi - Q_\psi)^{-1}P_{\bar{y}}, \quad v_y = -P_{\bar{y}}^{-1}(DP_\psi)(P_\psi - Q_\psi)^{-1}Q_y. \tag{40}$$

Comparing (13) with results of Sec. V we conclude that the function ψ is central and so depends only on $(n-1)$ arguments. For us it will be more convenient to go back directly to the linear systems (3) and (4) and investigate their properties. We have in consequence

$$\sum \phi_{\psi^\alpha}\psi^\alpha_{y_s} = \sum \phi_{\psi^\alpha} \sum \psi^\alpha_{\bar{y}_i}\alpha^i_{y_s}.$$

Further evaluation of the last equality is connected with the substitution of the explicit expressions for the derivatives of the functions ψ (33). The results of the further calculations we present in the form of multiplication of the row ϕ_ψ by the corresponding matrix:

$$\phi_\psi(P_\psi-Q_\psi)^{-1}\left(Q_{y_s}+\sum\ \alpha^i_{y_s}Q_{\bar{y}_i}\right)=\phi_\psi(P_\psi-Q_\psi)^{-1}\left(Q_{y_s}+\sum\ v^\nu_{y_s}Q_{\bar{y}_\nu}\right)$$
$$=\phi_\psi(I-\alpha^n(P_\psi-Q_\psi)^{-1}\bar{D}P_\psi)(P_\psi-Q_\psi)^{-1}Q_{y_s}=0. \tag{41}$$

In the process of the above evaluation we have used the equalities $\bar{D}Q=0$ and the explicit expression for the derivatives of the functions v with respect to the unbarred coordinates (40).

Equation (41) for $s=n$ is a direct corollary of the equations with Greek indices as a consequence of the equality $DQ=0$. Assuming that $\det Q^\mu_{y_\nu}\neq 0$, $\det(P_\psi-Q_\psi)\neq 0$, we may rewrite Eq. (41) with Greek indices in the final form:

$$\sum\ \phi_{\psi^\alpha}(I-\alpha^n(P_\psi-Q_\psi)^{-1}\bar{D}P_\psi)^\alpha_\nu=0. \tag{42}$$

A similar equation follows from (4):

$$\sum\ \phi_{\psi^\alpha}(I-\beta^n(P_\psi-Q_\psi)^{-1}DQ_\psi)^\alpha_\nu=0. \tag{43}$$

Now we assume that only one from the set of the functions ψ^α satisfies the complex Bateman equation. Suppose it is ψ^1 and that the solution may be chosen in the form $\phi(\psi^1)$. Of course, this suggestion must be confirmed by the detailed investigations of all results following from (42) and (43). We omit here this consideration, replacing it by checking the final result. Under this assumption, Eqs. (42) and (43) are equivalent to the following $2(n-1)$ equalities:

$$(I-\beta^n(P_\psi-Q_\psi)^{-1}DQ_\psi)^1_\nu=0,\quad (I-\alpha^n(P_\psi-Q_\psi)^{-1}\bar{D}P_\psi)^1_\nu=0,$$

which after substituting into them the explicit expressions for $1/\alpha^n=\bar{D}\Theta$, $1/\beta^n=D\Theta$ from (31) it will be convenient to rewrite in the form of multiplication of the row by the matrix $(P_\psi-Q_\psi)=\delta$:

$$(\bar{D}\Theta,0\cdots0)=(1,0\cdots0)\delta^{-1}\bar{D}\delta,$$

multiplying the last equality with the matrix δ^{-1} on the right we obtain

$$(D\Theta,0\cdots0)\delta^{-1}=-(1,0\cdots0)D\delta^{-1},\quad (\bar{D}\Theta,0\cdots0)\delta^{-1}=-(1,0\cdots0)\bar{D}\delta^{-1}. \tag{44}$$

The integration of the last system is straightforward with the following result:

$$(\delta^{-1})_{1,\beta}=\rho(\psi)_\beta\exp\Theta=\rho(\psi)_\beta(\bar{g}-g). \tag{45}$$

We consider in the following the simplest examples of solutions of the last system for functions Q,P from which the situation in the general case of arbitrary n will be clarified.

A. The case $n=2$

In this case there is only one Greek index and two scalar equations (44) lead to the result

$$\exp\Theta=\rho(\psi^1)(P_{\psi^1}-Q_{\psi^1})=\bar{g}-g.$$

The last equality may be considered as the definition of the functions $g,\bar{g}$ in terms of P,Q:

$$\overline{g}=\rho(\psi^1)P_{\psi^1}(\psi^1;\overline{y_1},\overline{y_2}),\quad g=\rho(\psi^1)Q_{\psi^1}(\psi^1,y_1,y_2)$$

with the correct dependence upon their independent arguments.

B. The case $n=3$

This case is more illustrative of the general situation. Using the explicit form of the matrix δ,

$$\delta=\begin{pmatrix}\Delta^1_{\psi^1} & \Delta^2_{\psi^1}\\ \Delta^1_{\psi^2} & \Delta^1_{\psi^1}\end{pmatrix},$$

we can invert it explicitly and after substitution into (45) it leads to

$$\begin{aligned}(P^1_{\psi^2}-Q^1_{\psi^2})+\frac{\rho_2}{\rho_1}(P^2_{\psi^2}-Q^2_{\psi^2})=0,\\ (P^1_{\psi^1}-Q^1_{\psi^1})+\frac{\rho_2}{\rho_1}(P^2_{\psi^1}-Q^2_{\psi^1})=\overline{g}-g.\end{aligned}\tag{46}$$

Taking into account the explicit dependence of P,Q functions upon their arguments we separate the last system into two systems of equations for Q,P, respectively ($\rho_2/\rho_1=\rho$):

$$Q^1_{\psi^1}+\rho Q^2_{\psi^1}=g,\quad Q^1_{\psi^2}+\rho Q^2_{\psi^2}=0.$$

The condition of self-consistency of the last two equations (equality of second mixed derivatives of the function Q^1) leads to

$$\rho_{\psi^2}Q^2_{\psi^1}-\rho_{\psi^1}Q^2_{\psi^2}=g_{\psi^2},$$

a single equation for the determination of the function Q^2. Let us consider in the last equation Q^1 as an arbitrary given function $p=p(\psi;y)$. Then the equation for it may be considered as a definition of the function g, which for what follows it is better to rewrite in the form

$$\rho p_{\psi^1}-\left(\int d\psi^2\,\rho p_{\psi^2}\right)_{\psi^1}=g.$$

Substituting this expression into the first initial equation we obtain for Q^1:

$$Q^1=\int d\psi^2\,\rho p_{\psi^2}=\rho p-\int d\psi^2\,p\rho_{\psi^2}.$$

Introducing the new function $F=\int d\psi^2 p\nu_{\psi^2}$ we are now able with its help to represent both functions Q^1,Q^2 in a local form:

$$Q^2=\frac{F_{\psi^2}}{\rho_{\psi^2}},\quad Q^1=\rho Q^2-F.$$

The same procedure may be used with a similar result for the functions P^1,P^2:

$$P^2=\frac{\overline{F}_{\psi^2}}{\rho_{\psi^2}},\quad P^1=\rho P^2-\overline{F}.$$

Equating $P^{1,2}=Q^{1,2}$ and taking into account that all factors depending upon functions ψ may be canceled, we arrive at the following system:

$$F=\overline{F},\quad F_{\psi^2}=\overline{F}_{\psi^2}, \tag{47}$$

which determine implicitly two functions ψ, one of which, ψ^1, is the solution of the complex Bateman equation in three dimensions.

C. The general case of arbitrary *n*

Let us denote the minors of $(n-2)$th order of the first column of the matrix δ, $\Delta^1_{\psi^\beta}$ by M^β and introduce the notation $\rho^\beta=M^\beta/M^1$. Then the systems (44) and (45) may be solved in the following way:

$$\sum \rho^\alpha \Delta^\alpha_{\psi^1}=\overline{g}-g,\quad \rho^\alpha=\rho^\alpha(\psi) \tag{48}$$

and rewrite the definition of the functions ρ^α in the form

$$M^\alpha=\rho^\alpha M^1.$$

Multiplying the last equalities by elements of each (given) column (except for the first one) with further summation of the results we always obtain zero on the left-hand sides of the equalities arising (determinants with equal columns). Thus we may rewrite (48) in the equivalent form

$$\sum \rho^\alpha \Delta^\alpha_{\psi^1}=\overline{q}-q,\quad \sum \rho^\alpha \Delta^\alpha_{\psi^A}=0,\quad 2\neq A\neq(n-1).$$

Keeping in mind that $\Delta^\alpha_{\psi^\beta}=P^\alpha_{\psi^\beta}-Q^\alpha_{\psi^\beta}$ and recalling the definition of (anti) holomorphic functions of Sec. V, we separate the last system into two independent ones:

$$\sum \rho^\alpha Q^\alpha_{\psi^1}=g,\quad \sum \rho^\alpha Q^\alpha_{\psi^A}=0,\quad \sum \rho^\alpha P^\alpha_{\psi^1}=\overline{g},\quad \sum \rho^\alpha P^\alpha_{\psi^A}=0.$$

Further transformations of both barred and unbarred systems are similar and so we will follow through the evaluation of the first one.

Introducing a new function $F=\Sigma\rho^\alpha Q^\alpha$ we obtain

$$\sum \rho^\alpha_{\psi^1} Q^\alpha=-g+F_{\psi^A},\quad \sum \rho^\alpha_{\psi^A} Q^\alpha=F_{\psi^A}. \tag{49}$$

In particular, we recall that $\rho^1=1$ and so each equation on its left-hand side contains only $(n-2)$ terms. Thus between $(n-1)$ equations above at least one linear dependence exists. Denoting the coefficients of it by $d^A=D^A(\psi)$ we rewrite the condition of self-consistency of the last system in the form of a single equation relating the function F in terms of the function g:

$$g=F_{\psi^1}+\sum d^A F_{\psi^A}.$$

Inverting the problem we can consider the last equality as a definition of the function g in terms of the given F. Solving the last $(n-2)$ equations of the system (49) and adding to them Q^1 obtained from the definition of the function F, we obtain finally

$$Q^B=\sum (\rho^{-1}_\psi)^B_A F_{\psi^A},\quad Q^1=F-\sum \rho^A Q^A.$$

Completely similar calculations lead to the following expressions for the functions P:

$$P^B=\sum\ (\rho_{\psi}^{-1})^B_A\overline{F}_{\psi^A},\quad P^1=\overline{F}-\sum\ \rho^A P^A.$$

We especially emphasize that all coefficient functions in the above-mentioned expressions determining functions Q,P in terms of two arbitrary functions $F,\overline{F}$ are functions only of the arguments ψ (central functions) and are the same in both cases.

Equating $P^\beta=Q^\beta$ after the obvious cancellation of all (scalar, matrix) factors depending only upon the functions ψ we reach the final system of equations implicitly determining all functions ψ:

$$F=\overline{F},\quad F_{\psi^A}=\overline{F}_{\psi^A}. \tag{50}$$

The function ψ^1 is the solution of the Complex Bateman equation (1) in the space of n dimensions.

VII. THE MAIN THEOREM

Theorem: The general solution of the complex Bateman equation (1) is defined by the function ψ^1, which is implicitly determined from the following system of $(n-1)$ equations for $(n-1)$ functions ψ^ν:

$$F(\psi;y)=\overline{F}(\psi;\overline{y}),\quad F_{\psi^A}=\overline{F}_{\psi^A},\quad 2\leqslant A\leqslant(n-1).$$

VIII. OUTLOOK

The principal concrete results of the present paper are concentrated in the theorem of Sec. VII, giving the explicit general solution (in implicit form) of the complex Bateman equation (1) in n dimensional space.

But a no less important hydrodynamic type system with two times $(y_n,\overline{y_n})$ was discovered and solved. A reduction of its general solution leads to the general solution of complex Bateman equation. We cannot exclude the possibility that there exist other reductions leading to no less interesting systems and equations.[4]

Nevertheless, the majority of these results were obtained more on the basis of intuitive calculations. We think that the algebraic-geometrical form of the answer tells us of the necessity to consider the group of motions (the symmetry structure) of the manifold (32) determining the general solution of hydrodynamic system (24). The properties of the group of inner symmetry of it must explain more precisely and directly the proposed way of integration of the systems under consideration (hydrodynamic and complex Bateman) as the uniquely possible one.

We have a feeling that in these problems algebraic-geometrical methods are more appropriate and effective. Unfortunately, they are not within our area of expertise.

(Received 14 July 2000; accepted for publication 18 August 2000)

Braided differential calculuses on the quantized braided groups are constructed and their braided bialgebra (Hopf algebra) structures are demonstrated. These are a kind of generalization and unification of the differential calculuses on quantum groups, braided groups, quantum supergroups, etc., and contain the latter ones as special cases. Moreover, it is shown that some quantum differential (co)vector algebras are covariant under the braided ''local'' coactions of the obtained braided differential bialgebras (Hopf algebras). Some examples are also given. © *2001 American Institute of Physics.* [DOI: 10.1063/1.1328742]

I. INTRODUCTION

In the last few years the differential calculuses on the quantum groups, braided groups, and other quantum spaces have attracted increasing attention owing to their great importance in mathematics and physics (see, e.g., Refs. 1–7, and references therein). In this paper we construct differential calculuses on some more general algebraic systems: the quantized braided groups (QBGs). The QBGs were proposed by Hlavaty years ago,[8] and contain the usual quantum groups,[9,10] braided groups,[11] quantum supergroups,[12] quantum anyonic groups,[13] μ-braided GL_q,[14] etc., as special cases. Thus, the theory of QBGs has, among other features, a remarkable advantage that enables us to study the two quite different kinds of noncommutativities (associated, respectively, with quantization and general braid statistics) in a unified way. Some properties and applications of the QBGs have been discussed recently.[15,16]

The main aim of the present paper is to construct quantized braided differential calculuses on the QBGs. Then the braided ''local'' coactions of the obtained quantized braided differential bialgebras (Hopf algebras) on some quantum differential (co)vector spaces are also considered. These are a kind of generalization and unification of the differential calculuses and coactions for the usual quantum groups, braided groups, quantum supergroups, etc., and the latter ones can be obtained as special cases.

In Sec. II, we recall some related results of QBGs, which are useful for later discussions. In Sec. III, differential calculuses on the QBGs are constructed and their braided bialgebra (Hopf algebra) structures are demonstrated in some detail. Some examples are also given for illustrating the formulas obtained. Section IV shows the covariance of some quantum differential vector algebras under braided ''local'' coactions of the braided differential bialgebras (Hopf algebras) given in Sec. III. Finally, Sec. V contains some conclusions and discussions.

II. QUANTIZED BRAIDED GROUPS

For later use, here we recall some related results of the QBGs.[8,16] Let $T=\{T^i_j\}^N_{i,j=1}$ be a matrix of N^2 elements T^i_j and $R,Z\in M_N(\mathbf{C})\otimes M_N(\mathbf{C})$ be an R-matrix pair satisfying the following set of quantum Yang–Baxter-type equations:[8]

[a)]Electronic mail: gaoyaj@netease.com

$$R_{12}R_{13}R_{23}=R_{23}R_{13}R_{12},\quad Z_{12}Z_{13}Z_{23}=Z_{23}Z_{13}Z_{12},$$
$$R_{12}Z_{13}Z_{23}=Z_{23}Z_{13}R_{12},\quad Z_{12}Z_{13}R_{23}=R_{23}Z_{13}Z_{12}. \tag{2.1}$$

Then the quantized braided (matrix) group $A(R,Z)$ is defined as follows.

(i) $A(R,Z)$ is generated by $\{T_j^i, 1\}$ with the algebra relations

$$R_{12}Z_{12}^{-1}T_1Z_{12}T_2=Z_{21}^{-1}T_2Z_{21}T_1R_{12}, \tag{2.2}$$

the coproduct and counit

$$\Delta(T_j^i)=T_k^i\otimes T_j^k,\quad \varepsilon(T_j^i)=\delta_j^i, \tag{2.3}$$

and the braiding

$$\Psi(Z_{12}^{-1}T_1\otimes Z_{12}T_2)=T_2Z_{12}^{-1}\otimes T_1Z_{12}. \tag{2.4}$$

(ii) There is an antipode S obeying usual axioms such as

$$S(T)T=TS(T)=I,\quad S(1)=1 \tag{2.5}$$

and extending to the whole algebra by the rule

$$S\cdot=\cdot\Psi(S\otimes S). \tag{2.6}$$

If $A(R,Z)$ satisfies condition (i) only, we call it a quantized braided (matrix) bialgebra. Moreover, for $a\otimes b$, $c\otimes d\in A(R,Z)\otimes A(R,Z)$, the product in the (braided) tensor product algebra is given by (as in Ref. 11)

$$(a\otimes b)(c\otimes d)=a\Psi(b\otimes c)d. \tag{2.7}$$

Similar to Ref. 11, sometimes we also use the notations with a prime ($'$) to denote the second factor of $A(R,Z)\otimes A(R,Z)$ and omit writing the tensor product $\otimes$. Thus the braiding relation (2.4) can also be written simply as $Z_{12}^{-1}T_1'Z_{12}T_2=T_2Z_{12}^{-1}T_1'Z_{12}$.

We mention some special cases of QBGs: When $Z=R$ or $Z=I$ while R is any regular solution of the quantum Yang–Baxter equation (QYBE), then $A(R,Z)$ is reduced to the ordinary braided group[11] or quantum group,[9,10] respectively. If Z is diagonal and R is some specified $R(q)$,[14] then $A(R(q),Z)$ gives the μ-braided GL_q considered in Ref. 14, etc.

In this paper, R, Z are always assumed to be invertible. A matrix solution R of QYBE is being called Hecke type if it satisfies

$$(PR-q)(PR+q^{-1})=0,$$

or

$$PRPR=1+\lambda PR \tag{2.8}$$

for a suitable q and $\lambda=q-q^{-1}$, where P is the usual permutation matrix.

Proposition 2.1:[16] Defining $R^{(n)}\equiv(ZP)^nR(Z^{-1}P)^n$, if (R,Z) is an R-matrix pair satisfying (2.1), then $(R^{(n)},Z)$ satisfies (2.1), too, for each integer $n=0,\pm1,\pm2,\ldots$. Moreover, if R is Hecke type, then so is $R^{(n)}$.

III. DIFFERENTIAL CALCULUSES ON THE QBGS

In this section, we construct quantized braided differential (matrix) bialgebras on the QBGs and show that if some suitable braided antipode is introduced, we can obtain braided differential Hopf algebras.

Consider $\{T^i_j\}$ and their differential forms $\{dT^i_j\}$, and let the external differentiation d obey $d^2=0$ and the usual (graded) Leibnitz rule, then we have the following.

Theorem 3.1: Let (R,Z) obey (2.1), R be Hecke type, and Z have the second inverse $\tilde{Z} \equiv((Z^{t_2})^{-1})^{t_2}$ (t_2 denotes transposition in the second factor). Then the element set $\{T^i_j, dT^i_j, 1\}$ generates a braided differential bialgebra, denoted by $\Omega_{A(R,Z)}$, with the following algebra relations:

$$R_{12}Z^{-1}_{12}T_1Z_{12}T_2=Z^{-1}_{21}T_2Z_{21}T_1R_{12}, \tag{3.1a}$$

$$R^{-1}_{21}Z^{-1}_{12}T_1Z_{12}dT_2=Z^{-1}_{21}dT_2Z_{21}T_1R_{12}, \tag{3.1b}$$

$$R^{-1}_{21}Z^{-1}_{12}dT_1Z_{12}dT_2=-Z^{-1}_{21}dT_2Z_{21}dT_1R_{12}, \tag{3.1c}$$

coproduct and counit

$$\Delta T=T\otimes T\equiv TT', \quad \Delta(dT)=dTT'+TdT', \qquad \varepsilon(T)=I, \quad \varepsilon(dT)=0, \tag{3.2}$$

and braidings

$$\begin{aligned} &Z^{-1}_{12}T'_1Z_{12}T_2=T_2Z^{-1}_{12}T'_1Z_{12}, \quad Z^{-1}_{12}dT'_1Z_{12}T_2=T_2Z^{-1}_{12}dT'_1Z_{12},\\ &Z^{-1}_{12}T'_1Z_{12}dT_2=dT_2Z^{-1}_{12}T'_1Z_{12}, \quad Z^{-1}_{12}dT'_1Z_{12}dT_2=-dT_2Z^{-1}_{12}dT'_1Z_{12}. \end{aligned} \tag{3.3}$$

If we also introduce a braided antipode S: $S(T)\equiv T^{-1}$ as in (2.5) and $S(dT)\equiv dT^{-1}=-T^{-1}TT^{-1}$, then $\Omega_{A(R,Z)}$ forms a braided Hopf algebra.

Proof: By definition, $\Omega_{A(R,Z)}$ is an associative algebra. For simplifying notations, we denote $\hat{R}_{12}=Z_{12}R_{21}Z^{-1}_{21}$ in the following. Consider, e.g., the expression containing triples of the generators as

$$T_1Z_{12}dT_2Z_{13}Z_{23}T_3. \tag{3.4}$$

We involve Z in (3.4) in order that the algebra relations (3.1) can be conveniently used, and this does not lose the generality because of the existence of $\tilde{Z}$. Transposing (3.4) in two ways, from (3.1) we obtain

$$\begin{aligned} \underline{T_1Z_{12}dT_2}Z_{13}Z_{23}T_3&=\hat{R}_{12}dT_2Z_{21}\underline{T_1R_{12}Z_{13}Z_{23}T_3}\\ &=\hat{R}_{12}\underline{dT_2Z_{21}Z_{23}\hat{R}^{-1}_{31}T_3}Z_{31}T_1R_{13}R_{12}\\ &=\hat{R}_{12}\hat{R}^{-1}_{31}\hat{R}^{-1}_{32}T_3Z_{32}dT_2R^{-1}_{32}Z_{21}Z_{31}T_1R_{13}R_{12}, \end{aligned}$$

$$\begin{aligned} T_1Z_{12}\underline{dT_2Z_{13}Z_{23}T_3}&=\underline{T_1Z_{12}Z_{13}\hat{R}^{-1}_{32}T_3}Z_{32}dT_2R^{-1}_{32}\\ &=\hat{R}^{-1}_{32}\hat{R}^{-1}_{31}T_3Z_{31}\underline{T_1R_{13}Z_{12}Z_{32}dT_2}R^{-1}_{32}\\ &=\hat{R}^{-1}_{32}\hat{R}^{-1}_{31}T_3Z_{31}Z_{32}\hat{R}_{12}dT_2Z_{21}T_1R_{12}R_{13}R^{-1}_{32}. \end{aligned}$$

The two right-hand side results are equal from (2.1) and Proposition 2.1. In the above-given calculations we have used (2.1) and (3.1) many times to the underlined parts in each expression to obtain the next expression. For other triples of generators, the calculations are similar. So these do not impose any additional relation on T, dT.

Now we check that Ψ, Δ, S are well defined when extended to products. First, we calculate that, e.g., from (3.1b),

$$\begin{aligned}
&\Psi(R_{21}^{-1}Z_{12}^{-1}T_1Z_{12}dT_2\otimes Z_{13}Z_{23}dT_3)\\
&\quad=(\mathrm{id}\otimes\cdot)\Psi[(R_{21}^{-1}Z_{12}^{-1}T_1\otimes Z_{12}dT_2)\otimes Z_{13}Z_{23}dT_3]\\
&\quad=-R_{21}^{-1}Z_{12}^{-1}Z_{23}Z_{13}dT_3\otimes Z_{13}^{-1}T_1Z_{13}Z_{12}Z_{23}^{-1}dT_2Z_{23}\\
&\quad=-Z_{23}Z_{13}R_{21}^{-1}Z_{12}^{-1}dT_3\otimes Z_{13}^{-1}Z_{23}^{-1}T_1Z_{12}dT_2Z_{13}Z_{23}\\
&\quad=-Z_{23}Z_{13}dT_3\otimes Z_{13}^{-1}Z_{23}^{-1}R_{21}^{-1}Z_{12}^{-1}T_1Z_{12}dT_2Z_{13}Z_{23}.
\end{aligned}$$

On the other hand,

$$\begin{aligned}
&\Psi(Z_{21}^{-1}dT_2Z_{21}T_1R_{12}\otimes Z_{13}Z_{23}dT_3)\\
&\quad=(\mathrm{id}\otimes\cdot)\Psi[(Z_{21}^{-1}dT_2\otimes Z_{21}T_1R_{12})\otimes Z_{13}Z_{23}dT_3]\\
&\quad=-Z_{21}^{-1}Z_{13}Z_{23}dT_3\otimes Z_{23}^{-1}dT_2Z_{23}Z_{21}Z_{13}^{-1}T_1Z_{13}R_{12}\\
&\quad=-Z_{23}Z_{13}dT_3\otimes Z_{21}^{-1}Z_{23}^{-1}Z_{13}^{-1}dT_2Z_{21}T_1Z_{23}Z_{13}R_{12}\\
&\quad=-Z_{23}Z_{13}dT_3\otimes Z_{13}^{-1}Z_{23}^{-1}Z_{21}^{-1}dT_2Z_{21}T_1R_{12}Z_{13}Z_{23}.
\end{aligned}$$

These two results are equal by using (3.1b) once again. The consistency of Ψ with other algebra relations and with high order products of generators T, dT can be verified similarly. Hence the braiding Ψ is well defined on $\Omega_{A(R,Z)}$ and is functorial with respect to the product.

Next we extend Δ to products in such a way that it is a homomorphism to the braided tensor product (2.7), this is consistent because, e.g., for (3.1c), from (3.1) to (3.3) we have

$$\begin{aligned}
&\Delta(R_{21}^{-1}Z_{12}^{-1}dT_1Z_{12}dT_2)\\
&\quad=R_{21}^{-1}Z_{12}^{-1}(dT_1T_1'+T_1dT_1')Z_{12}(dT_2T_2'+T_2dT_2')\\
&\quad=R_{21}^{-1}Z_{12}^{-1}dT_1\underline{T_1'Z_{12}dT_2}T_2'+R_{21}^{-1}Z_{12}^{-1}dT_1\underline{T_1'Z_{12}T_2}dT_2'+R_{21}^{-1}Z_{12}^{-1}T_1\underline{dT_1'Z_{12}dT_2}T_2'\\
&\qquad+R_{21}^{-1}Z_{12}^{-1}T_1\underline{dT_1'Z_{12}T_2}dT_2'\\
&\quad=\underline{R_{21}^{-1}Z_{12}^{-1}dT_1Z_{12}dT_2}Z_{12}^{-1}T_1'Z_{12}T_2'+R_{21}^{-1}\underline{Z_{12}^{-1}dT_1Z_{12}T_2}Z_{12}^{-1}T_1'Z_{12}dT_2'\\
&\qquad-\underline{R_{21}^{-1}Z_{12}^{-1}T_1Z_{12}dT_2}Z_{12}^{-1}dT_1'Z_{12}T_2'+\underline{R_{21}^{-1}Z_{12}^{-1}T_1Z_{12}T_2}Z_{12}^{-1}dT_1'Z_{12}dT_2'\\
&\quad=-Z_{21}^{-1}dT_2Z_{21}dT_1\underline{R_{12}Z_{12}^{-1}T_1'Z_{12}T_2'}+R_{21}^{-1}R_{12}^{-1}Z_{21}^{-1}T_2Z_{21}dT_1\underline{R_{21}^{-1}Z_{12}^{-1}T_1'Z_{12}dT_2'}\\
&\qquad-Z_{21}^{-1}dT_2Z_{21}T_1\underline{R_{12}Z_{12}^{-1}dT_1'Z_{12}T_2'}+Z_{21}^{-1}T_2Z_{21}T_1\underline{R_{21}^{-1}Z_{12}^{-1}dT_1'Z_{12}dT_2'}\\
&\quad=-Z_{21}^{-1}dT_2Z_{21}dT_1Z_{21}^{-1}T_2'Z_{21}T_1'R_{12}+R_{21}^{-1}R_{12}^{-1}Z_{21}^{-1}T_2Z_{21}dT_1Z_{21}^{-1}dT_2'Z_{21}T_1'R_{12}\\
&\qquad-Z_{21}^{-1}dT_2Z_{21}T_1Z_{21}^{-1}T_2'Z_{21}dT_1'R_{21}^{-1}-Z_{21}^{-1}T_2Z_{21}T_1Z_{21}^{-1}dT_2'Z_{21}dT_1'R_{12},\\
&\qquad\Delta(-Z_{21}^{-1}dT_2Z_{21}dT_1R_{12})=-Z_{21}^{-1}(dT_2T_2'+T_2dT_2')Z_{21}(dT_1T_1'+T_1dT_1')R_{12}\\
&\quad=-Z_{21}^{-1}dT_2\underline{T_2'Z_{21}dT_1}T_1'R_{12}-Z_{21}^{-1}dT_2\underline{T_2'Z_{21}T_1}dT_1'R_{12}-Z_{21}^{-1}T_2\underline{dT_2'Z_{21}dT_1}T_1'R_{12}\\
&\qquad-Z_{21}^{-1}T_2\underline{dT_2'Z_{21}T_1}dT_1'R_{12}\\
&\quad=-Z_{21}^{-1}dT_2Z_{21}dT_1Z_{21}^{-1}T_2'Z_{21}T_1'R_{12}-Z_{21}^{-1}dT_2Z_{21}T_1Z_{21}^{-1}T_2'Z_{21}dT_1'R_{21}^{-1}R_{21}R_{12}\\
&\qquad+Z_{21}^{-1}T_2Z_{21}dT_1Z_{21}^{-1}dT_2'Z_{21}T_1'R_{12}-Z_{21}^{-1}T_2Z_{21}T_1Z_{21}^{-1}dT_2'Z_{21}dT_1'R_{12}.
\end{aligned}$$

The two results are equal because of the Hecke property of R and relation (3.1). For relations (3.1b) and (3.1a), the calculations are similar. So the coproduct Δ is well-defined. The functoriality of Ψ with respect to Δ can also be easily verified.

Finally, for the antipode S, from (2.6), (3.3), and the functoriality of Ψ we have, e.g., for (3.1b),

$$\begin{aligned} S(R_{21}^{-1}Z_{12}^{-1}T_1Z_{12}dT_2) &= R_{21}^{-1}dT_2^{-1}Z_{12}^{-1}T_1^{-1}Z_{12} \\ &= -R_{21}^{-1}T_2^{-1}dT_2\underline{T_2^{-1}Z_{12}^{-1}T_1^{-1}Z_{12}} \\ &= -R_{21}^{-1}T_2^{-1}\underline{dT_2R_{12}^{-1}T_1^{-1}Z_{21}^{-1}}T_2^{-1}Z_{21}R_{12} \\ &= -\underline{R_{21}^{-1}T_2^{-1}Z_{12}^{-1}T_1^{-1}Z_{12}R_{21}Z_{21}^{-1}}dT_2T_2^{-1}Z_{21}R_{12} \\ &= -T_1^{-1}Z_{21}^{-1}T_2^{-1}dT_2T_2^{-1}Z_{21}R_{12}, \end{aligned}$$

$$S(Z_{21}^{-1}dT_2Z_{21}T_1R_{12}) = T_1^{-1}Z_{21}^{-1}dT_2^{-1}Z_{21}R_{12}.$$

So $S(R_{21}^{-1}Z_{12}^{-1}T_1Z_{12}dT_2)=S(Z_{21}^{-1}dT_2Z_{21}T_1R_{12})$. For the other relations in (3.1) and high orders of products the calculations are similar. Thus S is well defined.

Other braided Hopf algebra axioms such as $\cdot(S\otimes\mathrm{id})\Delta=\cdot(\mathrm{id}\otimes S)\Delta=\eta\varepsilon$, etc., can be easily verified. □

When $Z=I$, while R is any solution of QYBE with Hecke property, the $\Omega_{A(R,Z)}$ reduces to $\Omega_{A(R)}$, the differential bialgebra (or Hopf algebra) on the quantum group $A(R)$.[2,3,5] When $Z=R$, the $\Omega_{A(R,Z)}$ reduces to $\Omega_{B(R)}$, the braided differential bialgebra (or Hopf algebra) on the braided group $B(R)$.[6] Moreover, the $\Omega_{A(R,Z)}$ also contains the differential calculuses on the quantum supergroups, on the quantum anionic groups, etc., as special cases provided that the R-matrix pair (R,Z) is suitably chosen.

To illustrate the above-mentioned formulas, we give a simple example. Taking

$$R=\begin{pmatrix} q & 0 & 0 & 0 \\ 0 & 1 & \lambda & 0 \\ 0 & 0 & 1 & 0 \\ 0 & 0 & 0 & q \end{pmatrix}, \quad Z=\begin{pmatrix} r & 0 & 0 & 0 \\ 0 & u & 0 & 0 \\ 0 & 0 & v & 0 \\ 0 & 0 & 0 & w \end{pmatrix}, \qquad T=\begin{pmatrix} \alpha & \beta \\ \gamma & \delta \end{pmatrix}, \quad q\neq\pm i, \quad ruvw\neq 0, \tag{3.5}$$

then from (3.1), the corresponding braided differential bialgebra (Hopf algebra), denoted by $\Omega_{A_2(R,Z)}$, has the following algebra relations:

$$v\beta\alpha=qr\alpha\beta, \quad r\gamma\alpha=qv\alpha\gamma, \quad ur\gamma\beta=vw\beta\gamma, \quad u\delta\beta=qw\beta\delta,$$

$$w\delta\gamma=qu\gamma\delta, \quad \delta\alpha=\alpha\delta+\lambda v^{-1}r\gamma\beta, \quad \alpha d\alpha=q^2d\alpha\alpha, \quad r\alpha d\beta=qvd\beta\alpha,$$

$$v\beta d\alpha=qrd\alpha\beta+q\lambda vd\beta\alpha, \quad \beta d\beta=q^2d\beta\beta, \quad v\alpha d\gamma=qrd\gamma\alpha, \quad \alpha d\delta=d\delta\alpha,$$

$$wv\beta d\gamma=urd\gamma\beta+\lambda uvd\delta\alpha, \quad w\beta d\delta=qud\delta\beta, \quad r\gamma d\alpha-\lambda v\alpha d\gamma=qvd\alpha\gamma,$$

$$u\delta d\beta-\lambda w\beta d\delta=qwd\beta\delta, \quad \gamma d\gamma=q^2d\gamma\gamma, \quad u\gamma d\delta=qwd\delta\gamma, \quad w\delta d\gamma=qud\gamma\delta+\lambda qwd\delta\gamma,$$

$$\delta d\delta=q^2d\delta\delta, \quad (d\alpha)^2=0, \quad (d\beta)^2=0, \quad (d\gamma)^2=0, \quad (d\delta)^2=0,$$

$$rd\alpha d\beta=-qvd\beta d\alpha, \quad vd\beta d\alpha=-qrd\alpha d\beta-q\lambda vd\beta d\alpha, \quad vd\alpha d\gamma=-qrd\gamma d\alpha,$$

$$d\alpha d\delta=-d\delta d\alpha,\quad wvd\beta d\gamma=-urd\gamma d\beta-\lambda uvd\delta d\alpha,\quad wd\beta d\delta=-qud\delta d\beta,$$

$$rd\gamma d\alpha-\lambda vd\alpha d\gamma=-qvd\alpha d\gamma,\quad rud\gamma d\beta-\lambda uvd\alpha d\delta=-vwd\beta d\gamma,$$

$$ud\delta d\alpha-\lambda wd\beta d\gamma=-ud\alpha d\delta-\lambda wd\beta d\gamma,\quad ud\delta d\beta-\lambda wd\beta d\delta=-qwd\beta d\delta,$$

$$ud\gamma d\delta=-qwd\delta d\gamma,\quad wd\delta d\gamma=-qud\gamma d\delta-\lambda qwd\delta d\gamma.$$

Defining the degree of the generators of $\Omega_{A_2(R,Z)}$ as $|\alpha|=|\beta|=|\gamma|=|\delta|=0$, $|d\alpha|=|d\beta|=|d\gamma|=|d\delta|=1$; $|ab|=|a|+|b| \bmod 2$, $a, b\in\Omega_{A_2(R,Z)}$, then from (3.3) the braiding relations are

$$\Psi(\mu\otimes\nu)=(-1)^{|\mu||\nu|}\nu\otimes\mu,\qquad \Psi(\nu\otimes\mu)=(-1)^{|\nu||\mu|}\mu\otimes\nu,$$
$$\text{if } \mu\in\{\alpha,\delta,d\alpha,d\delta\},\ \nu\in\{\alpha,\beta,\gamma,\delta,d\alpha,d\beta,d\gamma,d\delta\}$$

$$\Psi(\beta\otimes\beta)=\frac{rw}{uv}\beta\otimes\beta,\quad \Psi(\beta\otimes\gamma)=\frac{uv}{rw}\gamma\otimes\beta,\quad \Psi(\gamma\otimes\beta)=\frac{uv}{rw}\beta\otimes\gamma,$$

$$\Psi(\gamma\otimes\gamma)=\frac{rw}{uv}\gamma\otimes\gamma,\quad \Psi(d\beta\otimes\beta)=\frac{rw}{uv}\beta\otimes d\beta,\quad \Psi(d\beta\otimes\gamma)=\frac{uv}{rw}\gamma\otimes d\beta,$$

$$\Psi(d\gamma\otimes\beta)=\frac{uv}{rw}\beta\otimes d\gamma,\quad \Psi(d\gamma\otimes\gamma)=\frac{rw}{uv}\gamma\otimes d\gamma,\quad \Psi(\beta\otimes d\beta)=\frac{rw}{uv}d\beta\otimes\beta,$$

$$\Psi(\beta\otimes d\gamma)=\frac{uv}{rw}d\gamma\otimes\beta,\quad \Psi(\gamma\otimes d\beta)=\frac{uv}{rw}d\beta\otimes\gamma,\quad \Psi(\gamma\otimes d\gamma)=\frac{rw}{uv}d\gamma\otimes\gamma,$$

$$\Psi(d\beta\otimes d\beta)=-\frac{rw}{uv}d\beta\otimes d\beta,\quad \Psi(d\beta\otimes d\gamma)=-\frac{uv}{rw}d\gamma\otimes d\beta,\quad \Psi(d\gamma\otimes d\beta)=-\frac{uv}{rw}d\beta\otimes d\gamma,$$

$$\Psi(d\gamma\otimes d\gamma)=-\frac{rw}{uv}d\gamma\otimes d\gamma.$$

IV. BRAIDED ''LOCAL'' COACTIONS ON SOME QUANTUM DIFFERENTIAL ALGEBRAS

In this section, we show that the braided differential Hopf algebra $\Omega_{A(R,Z)}$ given in Theorem 3.1 can coact on some quantum differential algebras covariantly. Since the calculations involve the differentials and braidings, we call the coaction braided ''local'' coaction. Here are two typical examples.

Proposition 4.1: Let $\Omega_{V^*(R)}$ denote the quantum differential algebra on the quantum (co)vector space $V^*(R)$. $\Omega_{V^*(R)}$ is generated by $\{x=(x_i),\ dx=(dx_i),$ (written as row vectors), $1\}$ with the relations[4] (use the tensor notation)

$$x_2x_1R_{12}=qx_1x_2,\quad qdx_2x_1R_{12}=x_1dx_2,\quad qdx_2dx_1R_{12}=-dx_1dx_2. \tag{4.1}$$

Then $\Omega_{V^*(R)}$ is covariant under the braided ''local'' coaction β of the braided differential bialgebras $\Omega_{A(R,Z)}$,

$$\beta: x\mapsto xT,\quad dx\mapsto dxT+xdT \tag{4.2}$$

with the braidings

$$T_1'x_2=x_2Z_{12}^{-1}T_1'Z_{12},\quad T_1'dx_2=dx_2Z_{12}^{-1}T_1'Z_{12},$$
$$dT_1'x_2=x_2Z_{12}^{-1}dT_1'Z_{12},\quad dT_1'dx_2=-dx_2Z_{12}^{-1}dT_1'Z_{12}. \tag{4.3}$$

Proof: For simplifying the notations, in (4.2) we have omitted writing the tensor product $\otimes$. Moreover, since $x, dx \in \Omega_{V^*(R)}$ and $T, dT \in \Omega_{A(R,Z)}$ live in different algebras, in the following calculations, we shall also omit the primes on T, dT when using braidings such as (4.3).

The covariance properties of the first relation in (4.1) have been pointed out in Refs. 8 and 16, here we consider the second and third. For the second relation, we have

$$\begin{aligned} q(dx_2T_2+x_2dT_2)x_1T_1R_{12} &= q\underline{dx_2T_2x_1}T_1R_{12}+qx_2\underline{dT_2x_1}T_1R_{12} \\ &= qdx_2x_1\underline{Z_{21}^{-1}T_2Z_{21}T_1R_{12}}+qx_2x_1\underline{Z_{21}^{-1}dT_2Z_{21}T_1R_{12}} \\ &= \underline{qdx_2x_1R_{12}}Z_{12}^{-1}T_1Z_{12}T_2+\underline{qx_2x_1R_{21}^{-1}}Z_{12}^{-1}T_1Z_{12}dT_2 \\ &= x_1\underline{dx_2Z_{12}^{-1}T_1Z_{12}}T_2+x_1\underline{x_2Z_{12}^{-1}T_1Z_{12}}dT_2 \\ &= x_1T_1dx_2T_2+x_1T_1x_2dT_2=x_1T_1(dx_2T_2+x_2dT_2), \end{aligned}$$

where we have used relations (3.1), (4.1), and (4.3). Similarly, for the third relation we have

$$\begin{aligned} &q(dx_2T_2+x_2dT_2)(dx_1T_1+x_1dT_1)R_{12} \\ &\quad= qdx_2dx_1\underline{Z_{21}^{-1}T_2Z_{21}T_1R_{12}}-qx_2dx_1Z_{21}^{-1}dT_2Z_{21}T_1R_{12} \\ &\qquad+qdx_2x_1\underline{Z_{21}^{-1}T_2Z_{21}dT_1}R_{12}+qx_2x_1\underline{Z_{21}^{-1}dT_2Z_{21}dT_1R_{12}} \\ &\quad= \underline{qdx_2dx_1R_{12}}Z_{12}^{-1}T_1Z_{12}T_2-qx_2dx_1Z_{21}^{-1}dT_2Z_{21}T_1R_{12} \\ &\qquad+\underline{qdx_2x_1R_{12}}Z_{12}^{-1}dT_1Z_{12}T_2(1+\lambda R_{21}P_{12})-\underline{qx_2x_1R_{21}^{-1}}Z_{12}^{-1}dT_1Z_{12}dT_2 \\ &\quad= -dx_1\underline{dx_2Z_{12}^{-1}T_1Z_{12}}T_2+x_1\underline{dx_2Z_{12}^{-1}dT_1Z_{12}}T_2-\underline{q^{-1}x_2dx_1R_{21}^{-1}Z_{12}^{-1}T_1Z_{12}}dT_2 \\ &\qquad-x_1\underline{x_2Z_{12}^{-1}dT_1Z_{12}}dT_2 \\ &\quad= -dx_1T_1dx_2T_2-x_1dT_1dx_2T_2-dx_1T_1x_2dT_2-x_1dT_1x_2dT_2 \\ &\quad= -(dx_1T_1+x_1dT_1)(dx_2T_2+x_2dT_2). \end{aligned}$$

So the transformed quantum covectors and their differentials obey the same relations as that of the original quantities. Here we have used (3.1), (4.1), (4.3) and the Hecke property of R. □

Proposition 4.2: Let $\Omega_{V(R)}$ denote the quantum differential algebra on the quantum vector algebra $V(R)$. $\Omega_{V(R)}$ is generated by $\{v=(v^i), dv=(dv^i)$, (written as column vectors), $1\}$ with the relations[5]

$$R_{12}v_2v_1=qv_1v_2, \quad qR_{21}v_1dv_2=dv_2v_1, \quad qR_{12}dv_2dv_1=-dv_1dv_2. \tag{4.4}$$

Then $\Omega_{V(R)}$ is covariant under the braided ''local'' coaction β of the braided differential Hopf algebra $\Omega_{A(R,Z)}$,

$$\beta: v\mapsto T^{-1}v, \quad dv\mapsto dT^{-1}v+T^{-1}dv \tag{4.5}$$

with the braidings

$$\begin{gathered} Z_{12}^{-1}T_1'^{-1}Z_{12}v_2=v_2T_1'^{-1}, \quad Z_{12}^{-1}dT_1'^{-1}Z_{12}v_2=v_2dT_1'^{-1}, \\ Z_{12}^{-1}T_1'^{-1}Z_{12}dv_2=dv_2T_1'^{-1}, \quad Z_{12}^{-1}dT_1'^{-1}Z_{12}dv_2=-dv_2dT_1'^{-1}. \end{gathered} \tag{4.6}$$

Proof: Similar to the explanations in Refs. 17 and 16, here the meanings of $T^{-1}v$ and $dT^{-1}v+T^{-1}dv$ are precisely $\Psi(T^{-1}v)$ and $\Psi(dT^{-1}v)+\Psi(T^{-1}dv)$ by definition as elements of the braided tensor-product algebra $\Omega_{V(R)}\otimes\Omega_{A(R,Z)}$. We write $T^{-1}v$, etc., with T^{-1}, etc., on the left for convenience with regard to their matrix structure. In practice, it is convenient to write the braiding relations in the implicit forms as in (4.6). Moreover, we omit the primes on T^{-1} and dT^{-1} as in the proof of Proposition 4.1. The covariance of the first relation in (4.4) has been pointed out in Refs. 8 and 16, now we consider the second and the third relations. For the second, we have

$$
\begin{aligned}
&qR_{21}T_1^{-1}v_1(dT_2^{-1}v_2+T_2^{-1}dv_2)\\
&\quad=qR_{21}T_1^{-1}\underline{v_1dT_2^{-1}}v_2+qR_{21}T_1^{-1}\underline{v_1T_2^{-1}}dv_2\\
&\quad=q\underline{R_{21}T_1^{-1}Z_{21}^{-1}dT_2^{-1}Z_{21}}v_1v_2+q\underline{R_{21}T_1^{-1}Z_{21}^{-1}T_2^{-1}Z_{21}}v_1dv_2\\
&\quad=dT_2^{-1}Z_{12}^{-1}T_1^{-1}Z_{12}\underline{qR_{12}^{-1}v_1v_2}+T_2^{-1}Z_{12}^{-1}T_1^{-1}Z_{12}\underline{qR_{21}v_1dv_2}\\
&\quad=dT_2^{-1}\underline{Z_{12}^{-1}T_1^{-1}Z_{12}v_2}v_1+T_2^{-1}\underline{Z_{12}^{-1}T_1^{-1}Z_{12}dv_2}v_1\\
&\quad=dT_2^{-1}v_2T_1^{-1}v_1+T_2^{-1}dv_2T_1^{-1}v_1\\
&\quad=(dT_2^{-1}v_2+T_2^{-1}dv_2)T_1^{-1}v_1.
\end{aligned}
$$

Similarly, for the third relation we have

$$
\begin{aligned}
&qR_{12}(dT_2^{-1}v_2+T_2^{-1}dv_2)(dT_1^{-1}v_1+T_1^{-1}dv_1)\\
&\quad=qR_{12}dT_2^{-1}\underline{v_2dT_1^{-1}}v_1+qR_{12}dT_2^{-1}\underline{v_2T_1^{-1}}dv_1+qR_{12}T_2^{-1}\underline{dv_2dT_1^{-1}}v_1+qR_{12}T_2^{-1}\underline{dv_2T_1^{-1}}dv_1\\
&\quad=q\underline{R_{12}dT_2^{-1}Z_{12}^{-1}dT_1^{-1}Z_{12}}v_2v_1+qR_{12}\underline{dT_2^{-1}Z_{12}^{-1}T_1^{-1}Z_{12}}v_2dv_1-qR_{12}T_2^{-1}Z_{12}^{-1}dT_1^{-1}Z_{12}dv_2v_1\\
&\qquad+q\underline{R_{12}T_2^{-1}Z_{12}^{-1}T_1^{-1}Z_{12}}dv_2dv_1\\
&\quad=-dT_1^{-1}Z_{21}^{-1}dT_2^{-1}Z_{21}\underline{qR_{21}^{-1}v_2v_1}+(1+\lambda P_{12}R_{21})T^{-1}Z_{21}^{-1}dT_2^{-1}Z_{21}\underline{qR_{12}v_2dv_1}\\
&\qquad-qR_{12}T_2^{-1}Z_{12}^{-1}dT_1^{-1}Z_{12}dv_2v_1+T_1^{-1}Z_{21}^{-1}T_2^{-1}Z_{21}\underline{qR_{12}dv_2dv_1}\\
&\quad=-dT_1^{-1}\underline{Z_{21}^{-1}dT_2^{-1}Z_{21}v_1}v_2+T_1^{-1}\underline{Z_{21}^{-1}dT_2^{-1}Z_{21}dv_1}v_2-dT_1^{-1}\underline{Z_{21}^{-1}T_2^{-1}Z_{21}q^{-1}R_{21}^{-1}dv_2v_1}\\
&\qquad-T_1^{-1}\underline{Z_{21}^{-1}T_2^{-1}Z_{21}dv_1}dv_2\\
&\quad=-dT_1^{-1}v_1dT_2^{-1}v_2-T_1^{-1}dv_1dT_2^{-1}v_2-dT_1^{-1}v_1T_2^{-1}dv_2-T_1^{-1}dv_1T_2^{-1}dv_2\\
&\quad=-(dT_1^{-1}v_1+T_1^{-1}dv_1)(dT_2^{-1}v_2+T_2^{-1}dv_2).
\end{aligned}
$$

In the above-mentioned calculations, we have used the relations for $\Omega_{A(R,Z)}$ in a form obtained by applying the braided antipode S to (3.1), and also used (4.4), (4.6) and the Hecke property of R.□

As some important special cases of Propositions 4.1 and 4.2, we mention that, when $Z=I$, R is a regular solution of QYBE, we obtain the braided ''locally'' covariant coactions of $\Omega_{A(R)}$ on $\Omega_{V^*(R)}$ and $\Omega_{V(R)}$, which were given in Refs. 2 and 5 for different purposes. When $Z=R$, we obtain the braided ''local'' coactions of $\Omega_{B(R)}$ on $\Omega_{V^*(R)}$ and $\Omega_{V(R)}$, etc. However, here we use the ''right-hand'' notations.

V. CONCLUSIONS AND DISCUSSIONS

We have constructed the braided differential bialgebras (Hopf algebras) $\Omega_{A(R,Z)}$ on the quantized braided groups $A(R,Z)$. The $\Omega_{A(R,Z)}$ is a kind of generalization of the differential calculuses on the quantum groups, braided groups, quantum supergroups, etc., and unifies them into a single

algebraic system. When some further restrictions are imposed on the R-matrix pair (R,Z), the quantum differential bialgebras (Hopf algebras) $\Omega_{A(R)}$,[2,3,5] the braided differential bialgebras (Hopf algebras) $\Omega_{B(R)}$,[6] etc., can be obtained as special cases of $\Omega_{A(R,Z)}$.

The covariance properties of the quantum differential (co)vector algebras $\Omega_{V^*(R)}$ and $\Omega_{V(R)}$ under the braided ''local'' coactions of $\Omega_{A(R,Z)}$ are also considered. These can be taken as the bases of $A(R,Z)$ gauge theories, which will be discussed in further work.

On the classification of irreducible finite-dimensional representations of $U_q'(so_3)$ algebra

M. Havlíček[a] and S. Pošta
Department of Mathematics and Doppler Institute, FNSPE, Czech Technical University, Trojanova 13, CZ-120 00 Prague 2, Czech Republic

(Received 3 August 2000; accepted for publication 27 September 2000)

In an earlier work [M. Havlíček *et al.*, J. Math. Phys. **40**, 2135 (1999)] we defined for any finite dimension five nonequivalent irreducible representations of the nonstandard deformation $U_q'(so_3)$ of the Lie algebra so_3 where q is not a root of unity [for each dimension only one of them (called classical) admits limit $q\to 1$]. In the first part of this paper we show that any finite-dimensional irreducible representation is equivalent to some of these representations. In the case $q^n=1$ we derive new Casimir elements of $U_q'(so_3)$ and show that a dimension of any irreducible representation is not higher than n. These elements are Casimir elements of $U_q'(so_m)$ for all m and even of $U_q'(iso_{m+1})$ due to Inönu–Wigner contraction. According to the spectrum of one of the generators, the representations are found to belong to two main disjoint sets. We give full classification and explicit formulas for all representations from the first set (we call them nonsingular representations). If n is odd, we have full classification also for the remaining singular case with the exception of a finite number of representations. © *2001 American Institute of Physics.*

I. INTRODUCTION

Quantum orthogonal and Lorentz groups and their corresponding q-deformed algebras are of special interest for modern physics. M. Jimbo and V. Drinfeld defined q-deformations $U_q(g)$ for all simple complex Lie algebras g by means of Cartan subalgebras and root subspaces. Reshetikhin, Takhtajan, and Faddeev defined quantum algebras $U_q(g)$ in terms of the universal R-matrix. These approaches do not give a satisfactory presentation of the quantum algebra $U_q(so(n,\mathbb{C}))$ because these definitions of algebras do not allow inclusions $U_q(so(n+1,\mathbb{C}))\supset U_q(so(n,\mathbb{C}))$. These reductions are easy to explore if we take q-deformations of the Lie algebra $so(n,\mathbb{C})$ defined in terms of the generators $I_{k,k-1}=E_{k,k-1}-E_{k-1,k}$ [where E_{is} is the matrix with elements $(E_{is})_{rt}=\delta_{ir}\delta_{st}$] rather than by means of Cartan subalgebras and root elements [for definition see Ref. 1 or (81)–(83)]. As a result we obtain the associative algebra denoted by $U_q'(so(n,\mathbb{C}))$.

In this article we are interested in algebra $U_q'(so(3,\mathbb{C}))$ [for convenience we write $U_q'(so_3)$]. This algebra turns out to be of great importance for quantum gravity when considering the quantum algebra of gauge invariant quantities (see Ref. 2). This article is a prolongation of Ref. 3 where we presented for any finite dimension five nonequivalent irreducible representations of the algebra $U_q'(so_3)$.

The first main result of this article is a proof that any finite-dimensional irreducible representation of $U_q'(so_3)$ is equivalent to some of the described ones when q is not a root of unity [Secs. III and IV]. The considerations are based on an important fact that number $2\varepsilon(q-q^{-1})^{-1}$, $\varepsilon=\pm 1$, can never be an eigenvalue of generators of $U_q'(so_3)$ in irreducible finite-dimensional representation if q is not a root of unity (see Theorem 2). This simply formulated assertion is a consequence of Lemma 14, which represents deep insight in the algebraical structure of $U_q'(so_3)$.

[a]Electronic mail: havlicek@km1.fjfi.cvut.cz

As a corollary we obtain that the generators are diagonalizable in any finite-dimensional irreducible representation when q is not a root of unity (the same situation as in classical case $q=1$). If the dimension of irreducible representation is greater than one, there exist two weight vectors—analogs of highest and lowest weight in the classical case $q=1$.

Irreducible finite-dimensional representations in the case $q^n=1$ are studied in Secs. V–VII. The basic tools are three new Casimir elements (Lemma 2) in the polynomial form in one of the generators. The proof that these Casimir elements commute is based on nontrivial combinatorial identities (see Lemma 12 in Appendix A). First we show that any irreducible representation of $U_q'(so_3)$ is finite-dimensional. According to the spectrum of one choosen generator (say I_3) we define two types of representations: nonsingular and singular ones (spectrum of I_3 contains value $-i[\nu]_q$ with $q^\nu=i\varepsilon q^{-k/2}$ for some $k\in\mathbb{Z}$, $\varepsilon\in\{-1,1\}$).

For nonsingular irreducible representations we give their full classification with explicit form for any n. It consists of a three-parameter set of n-dimensional nonequivalent irreducible representations presented earlier in Ref. 3 and one k-dimensional irreducible representation, where $k=1,2,...,n-1$ if n is odd, $k=1,2,...,n/2$ if n is even. If n is even, there is, moreover, one one-parameter set of nonequivalent $n/2$-dimensional irreducible representations (see Table II).

The structure of singular representations is much more complicated and we give a final result only for the case where n is odd. There are four nonequivalent irreducible representations for dimensions $1,2,...,(n+1)/2$ and two families of n-dimensional nonequivalent irreducible representations: one- and two-parameter ones. With the exception of the mentioned one-parameter family we also give explicit formulas. As to dimensions $(n+3)/2,...,n-1$ we have uncertainty: there are at most four irreducible representations for each dimension, but we did not prove their existence for $n\geqq 7$ (see Table III).

The simple consequence of our considerations is the assertion that singular n-dimensional irreducible representation generator I_3 is diagonalizable iff Casimir C has a special value (Note 12). With only one exception, the explicit forms of all irreducible representations having I_3 diagonalizable are presented. The systematic study of representations and corresponding problems of $U_q'(so_3)$ in full detail presented in this article could be useful as illustrations of possible complications considering deformations of Lie algebras. We hope that similar techniques can be applied in the other cases of various deformations.

II. BASIC DEFINITIONS AND FACTS

We suppose through the whole article that q is fixed complex number, $q\notin\{0,1,-1\}$.

Definition 1: $U_q'(so_3)$ is a complex associative algebra generated by three elements I_1, I_2, I_3 and relations (square roots of q is convention only)

$$q^{1/2}I_1I_2-q^{-1/2}I_2I_1=I_3, \tag{1}$$

$$q^{1/2}I_2I_3-q^{-1/2}I_3I_2=I_1, \tag{2}$$

$$q^{1/2}I_3I_1-q^{-1/2}I_1I_3=I_2. \tag{3}$$

Theorem 1: The set $\{I_1^kI_2^mI_3^n|k,m,n\in\mathbb{N}\cup\{0\}\}$ forms a basis of the linear space $U_q'(so_3)$.

Proof: Theorem 1 is proven by means of the diamond lemma (see Ref. 4, subsection 4.1.5).

Note 1: The algebra defined by the relations (1)–(3) is distinctive among others in the following sense: although we can assume more general deformation of the Lie algebra o(3) defined by relations

$$\alpha_1I_1I_2-\alpha_2I_2I_1=\alpha_3I_3,$$

$$\alpha_4I_2I_3-\alpha_5I_3I_2=\alpha_6I_1,$$

$$\alpha_7I_3I_1-\alpha_8I_1I_3=\alpha_9I_2$$

$(\alpha_1,\ldots,\alpha_9\in\mathbb{C}-\{0\})$, it can be proven that (very important) Theorem 1 is valid if and only if the deformation has the form (1)–(3) (up to an isomorphism).

Lemma 1: An element

$$C=q^2I_1^2+I_2^2+q^2I_3^2-(q^{5/2}-q^{1/2})I_1I_2I_3 \tag{4}$$

is a Casimir element of $U_q'(\mathrm{so}_3)$.

Proof: Clearly from the defining relations $[C,I_1]=[C,I_2]=[C,I_3]=0$ (the brackets denote the usual commutator $[x,y]=xy-yx$).

Lemma 2: Let $q^n=1$. Then the element

$$C^{(n)}(I_1)=\sum_{j=0}^{[(n-1)/2]}\binom{n-j}{j}\frac{1}{n-j}\left(\frac{i}{q-q^{-1}}\right)^{2j}I_1^{n-2j} \tag{5}$$

is a Casimir element of $U_q'(\mathrm{so}_3)$; $[x]$ for $x\in\mathbb{R}$ denotes the integral part of x.

Proof: Because $C^{(n)}(I_1)$ is a polynomial in I_1 and because of (3) it is sufficient to show $[C^{(n)}(I_1),I_3]=0$, i.e. (see Lemma 13),

$$\sum_{j=0}^{[(n-1)/2]}\binom{n-j}{j}\frac{1}{n-j}\left(\frac{i}{q-q^{-1}}\right)^{2j}(p_{n-2j}(I_1)I_2+q_{n-2j}(I_1)I_3-I_1^{n-2j}I_3)=0.$$

Thus we have to prove that two polynomials with complex coefficients

$$P_n(x):=\sum_{j=0}^{[(n-1)/2]}\binom{n-j}{j}\frac{1}{n-j}\left(\frac{i}{q-q^{-1}}\right)^{2j}p_{n-2j}(x),$$

$$Q_n(x):=\sum_{j=0}^{[(n-1)/2]}\binom{n-j}{j}\frac{1}{n-j}\left(\frac{i}{q-q^{-1}}\right)^{2j}(q_{n-2j}(x)-x^{n-2j})$$

are zero polynomials. Let us consider first polynomial P_n. Using Lemma 13 [we use the property $\binom{u}{v}=0$ for $u,v\in\mathbb{Z}$, $v<0$ or $0\leqq u<v$ to change bounds of various sums advantageously, for example to make inner summations independent] we have

$$P_n(x)=q^{-1/2}\sum_{c=0}^{[(n-1)/2]}\left(\frac{q+q^{-1}}{q-q^{-1}}\right)^{-2[(n-1)/2]+2c}(-1)^c\pi_{n,c}(q)\left(\frac{x(q+q^{-1})}{2}\right)^{n-1-2c},$$

where

$$\pi_{n,c}(q)=p_{n,c}((q-q^{-1})^{-2}),$$

$$p_{n,c}(y)=\sum_{j=0}^{[(n-1)/2]}\sum_{t=0}^{[(n-1)/2]-j}\binom{n-j}{j}\frac{1}{n-j}\binom{n-2j}{2t+1}\binom{t}{c-j}y^j(1+4y)^{[(n-1)/2]-(t+j)}.$$

Then we find a better form for polynomial $p_{n,c}$:

$$p_{n,c}(y)=\sum_{d=0}^{[(n-1)/2]}p_{n,c,d}y^d,$$

where

$$p_{n,c,d}=4^d\sum_{j=0}^{[(n-1)/2]}\binom{n-j}{j}\frac{1}{4^j(n-j)}\sum_{t=0}^{[(n-1)/2]-j}\binom{n-2j}{2t+1}\binom{t}{c-j}\binom{\left[\frac{n-1}{2}\right]-j-t}{d-j}.$$

Now we use formula (A1) (see Lemma 12; we take $N=n-2j$, $M=c-j$, $H=[(n-1)/2]-d$ and fact that it is sufficient to compute outer sum over $j=0...\min\{c,d\}$):

$$p_{n,c,d}=\sum_{j=0}^{\min\{c,d\}}\binom{n-j}{j}\frac{4^{[(n-1)/2]-c}}{n-j}\binom{\left[\frac{n-1}{2}\right]-d}{c-j}(-2j+2d+1+(n-2d-1)^{n'})$$

$$\cdot\frac{(2[n/2]-2j)!(n-1-c-d)!([n/2]-c)!}{([n/2]-j)!(d-j+1-n')!(2[n/2]-2c)!(n-2d+n'-1)!},$$

where $n'=n \bmod 2$. Now we can apply directly (A2) and have

$$p_{n,c,d}=\frac{4^{[(n-1)/2]-c}\binom{n-1-d}{d}\binom{n-1-c}{c}}{(n/2)^{1-n'}(n-2d)^{n'}}.$$

We come back to polynomial $p_{n,c}$:

$$p_{n,c}(y)=\frac{4^{[(n-1)/2]-c}\binom{n-1-c}{c}}{(n/2)^{1-n'}}\sum_{d=0}^{[(n-1)/2]}\frac{\binom{n-1-d}{d}}{(n-2d)^{n'}}y^d.$$

If n is even, then $n'=0$ and we can apply the formula [see Ref. 5, (5.74)]

$$\sum_{k=0}^{[n/2]}\binom{n-k}{k}z^k=\frac{1}{\sqrt{1+4z}}\left(\left(\frac{1+\sqrt{1+4z}}{2}\right)^{n+1}-\left(\frac{1-\sqrt{1+4z}}{2}\right)^{n+1}\right),$$

$$n\in\mathbb{N},\quad z\in\mathbb{C}-\{-\tfrac{1}{4}\}. \tag{6}$$

Then, after returning to $y\to(q-q^{-1})^{-2}$, we have directly $p_{n,c}((q-q^{-1})^{-2})=0$ using the fact $q^n=1$ for all $c\leqq n/2-1$.

If n is odd, then $n'=1$ and we apply the formula [see Ref. 5, (5.75)]

$$\sum_{k=0}^{[n/2]}\binom{n-k}{k}\frac{n}{n-k}z^k=\left(\frac{1+\sqrt{1+4z}}{2}\right)^n+\left(\frac{1-\sqrt{1+4z}}{2}\right)^n,\quad n\in\mathbb{N},\quad z\in\mathbb{C}. \tag{7}$$

Again we have directly $p_{n,c}((q-q^{-1})^{-2})=0$ using the fact $q^n=1$ for all $c\leqq(n-1)/2$.

Let us now examine the polynomial Q_n. Using (B3) we can transform Q_n into two parts. The first part is zero because it is a multiple of P_n. Using (7) and the fact that $q^n=1$ we get directly that the second part is equal to zero, too.

Corollary 1: The same assertion as in Lemma 2 is valid for the generators I_2 and I_3.

Proof: Use the automorphism $\rho:U_q'(so_3)\to U_q'(so_3)$ defined by relations

$$\rho(I_1)=I_2,\quad \rho(I_2)=I_3,\quad \rho(I_3)=I_1. \tag{8}$$

□

Definition 2: Let $\nu\in\mathbb{C}$. We denote by O_ν and R_ν these special linear combinations:

$$O_\nu:=iI_2+q^{-\nu+1/2}I_1,$$

$$R_\nu := iI_2 - q^{\nu+1/2} I_1 .$$

Lemma 3: Let $R: U_q'(\mathrm{so}_3) \to L(V)$ be a linear representation of $U_q'(\mathrm{so}_3)$ on (not necessarily finite-dimensional) vector space V [through the whole article we will usually denote the operators $R(I_1)$, $R(I_2)$ and $R(I_3)$ acting on vectors from the representation space V by the same symbols I_1, I_2, I_3, so there can be no misunderstanding]. Let $x \in \mathrm{Ker}\,(I_3 + i[\nu+k]_q)$ for some fixed $k \in \mathbb{Z}$ and $\nu \in \mathbb{C}$ [we denote $\mathrm{Ker} A = \{v \in V | Av = 0\}$ and $[a]_q := (q^a - q^{-a})/(q - q^{-1})$ for $a \in \mathbb{C}$]. Then

$$I_3(O_{\nu+k} x) = -i[\nu+k+1]_q (O_{\nu+k} x), \tag{9}$$

$$I_3(R_{\nu+k} x) = -i[\nu+k-1]_q (R_{\nu+k} x), \tag{10}$$

$$O_{\nu+k-1} R_{\nu+k} x = -(C + q[\nu+k-1]_q [\nu+k]_q) x, \tag{11}$$

$$R_{\nu+k+1} O_{\nu+k} x = -(C + q[\nu+k]_q [\nu+k+1]_q) x, \tag{12}$$

where C denotes Casimir element (4).

Proof: By inspection using the defining relations (1)–(3).

Note 2: The system of linear equations ($x, y, z \in V$)

$$O_\nu x = y, \quad \text{i.e.,} \quad iI_2 x + q^{-\nu+1/2} I_1 x = y,$$

$$R_\nu x = z, \quad \text{i.e.,} \quad iI_2 x - q^{\nu+1/2} I_1 x = z$$

has a unique solution for the vectors $I_1 x$ and $I_2 x$ for given y, z if and only if $q^\nu \neq i\varepsilon$ for both $\varepsilon \in \{-1, 1\}$.

Note 3: Let $R^{(1,1)}$ be a representation of $U_q'(\mathrm{so}_3)$. Then $R^{(\eta_1, \eta_2)}$, $\eta_1, \eta_2 \in \{1, -1\}$, where

$$R^{(1,-1)}(I_1) = -R^{(1,1)}(I_1), \quad R^{(1,-1)}(I_2) = -R^{(1,1)}(I_2), \quad R^{(1,-1)}(I_3) = R^{(1,1)}(I_3),$$

$$R^{(-1,1)}(I_1) = -R^{(1,1)}(I_1), \quad R^{(-1,1)}(I_2) = R^{(1,1)}(I_2), \quad R^{(-1,1)}(I_3) = -R^{(1,1)}(I_3),$$

$$R^{(-1,-1)}(I_1) = R^{(1,1)}(I_1), \quad R^{(-1,-1)}(I_2) = -R^{(1,1)}(I_2), \quad R^{(-1,-1)}(I_3) = -R^{(1,1)}(I_3)$$

form four representations of $U_q'(\mathrm{so}_3)$. If the dimension of representation is odd and at least two of the three operators $R^{(1,1)}(I_j)$, $j = 1,2,3$, are bijective, these four representations are nonequivalent (the determinants of the operators have different signs).

III. BASIS CONSTRUCTION AND SPECTRAL PROPERTIES WHEN q IS NOT A ROOT OF UNITY

The following theorem plays an important simplifying role in our considerations.

Theorem 2: If q is not a root of unity, then $\mathrm{Ker}\,(I_3 - (2\varepsilon/(q - q^{-1}))) = \{0\}$ for both $\varepsilon \in \{-1, 1\}$ in any irreducible finite-dimensional representation of $U_q'(\mathrm{so}_3)$.

Proof: See Appendix B.

Corollary 2: The same assertion as in Theorem 2 is valid for generators I_2 and I_1.

Proof: Use the automorphism (8).

Theorem 3: Let R be an irreducible representation of $U_q'(\mathrm{so}_3)$ on vector space V, $\dim V = r$, and let q not be a root of unity. Then there exist $\nu \in \mathbb{C}$ and vector $0 \neq x_0 \in \mathrm{Ker}\,(I_3 + i[\nu]_q)$ such that $O_\nu x_0 = 0$ and

$$V = \mathbb{C}\{x_0, x_{-1,\ldots}, x_{-r+1}\}_{\mathrm{lin}}, \quad x_{-j-1} := R_{\nu-j} x_{-j}, \quad j = 0,1,\ldots,r-2.$$

Proof: Let $0 \neq y_0 \in \mathrm{Ker}\,(I_3 + i[\mu]_q)$ for some $[\mu]_q$, where q^μ is choosen such that numbers $-i[\mu]_q, -i[\mu+1]_q, \ldots$ are mutually different (see Lemma 10). Let us define vectors

$$y_{j+1} := O_{\mu+j} y_j, \quad j \geqq 0 \tag{13}$$

and let $l \in \mathbb{N}$ such that vectors $y_0,\ldots,y_{l-1}$ are linearly independent and $y_l \in \mathbb{C}\{y_0,\ldots,y_{l-1}\}_{\text{lin}}$ (such l exists, it is the consequence of the finite dimension of V). Equation (9) shows that all vectors $y_0,\ldots,y_{l-1},y_l$ fulfill eigenequation $I_3 y_j = -i[\mu+j]_q y_j$ with different eigenvalues and, therefore, the only possibility for y_l is

$$y_l = 0. \tag{14}$$

Denote $x_0 := y_{l-1}$, $\nu := \mu + l - 1$ and define similarly vectors

$$x_{-j-1} := R_{\nu-j} x_{-j}, \quad j \geqq 0.$$

Again from (10) follows

$$I_3 x_{-j} = -i[\nu - j]_q x_{-j}, \quad j \geqq 0. \tag{15}$$

Let $k \in \mathbb{N}$ be such that vectors $x_0,\ldots,x_{-k+1}$ are linearly independent and $x_{-k} \in \mathbb{C}\{x_0,\ldots,x_{-k+1}\}_{\text{lin}}$. Equation (11) then implies for $j = 1,2,\ldots,k-1$

$$O_{\nu-j} x_{-j} = O_{\nu-j} R_{\nu-j+1} x_{-j+i} = -(C + q[\nu-j+1]_q[\nu-j]_q) x_{-j+1},$$

and for Eqs. (13) and (14)

$$O_\nu x_0 = 0. \tag{16}$$

Since representation R is irreducible, Casimir operator C [see (4)] equals a multiple of the identity and we will denote this complex constant by the same symbol $C \in \mathbb{C}$. Equation (16) together with (12) implies $0 = R_{\nu+1} O_\nu x_0 = -(C + q[\nu+1]_q[\nu]_q) x_0$, which gives for C value $C = -q[\nu+1]_q[\nu]_q$. We have (put $x_1 := 0$) for all $j \in \{0,\ldots,k-1\}$

$$R_{\nu-j} x_{-j} = x_{-j-1}, \tag{17}$$

$$O_{\nu-j} x_{-j} = -(C + q[\nu-j+1]_q[\nu-j]_q) x_{-j+1}. \tag{18}$$

According to Note 2 this system has solution $I_1 x_{-j}$ and $I_2 x_{-j}$ iff $q^{\nu-j} \neq i\varepsilon$ for both $\varepsilon \in \{-1,1\}$. This condition is fulfilled: in the opposite case $-i[\nu-j]_q = 2\varepsilon/(q-q^{-1})$ and it is an eigenvalue of the vector x_{-j}. Theorem 2 excludes such eigenvalues for I_3 in finite-dimensional representation if q is not a root of unity. Vectors $I_1 x_{-j}$ and $I_2 x_{-j}$ are expressed by means of $x_0,\ldots,x_{-k+1}$; therefore $\mathbb{C}\{x_0,x_{-1},\ldots,x_{-k+1}\}_{\text{lin}}$ is an invariant subspace and, due to the irreducibility of R, this subspace equals to V, i.e., $k = r$. □

Corollary 3: If q is not a root of unity, then in any irreducible representation generator I_3 is diagonalizable. The same assertion holds for the generators I_1 and I_2.

Proof: Vectors $x_0,\ldots,x_{-r+1}$ are eigenvectors of generator I_3. The second assertion follows from Corollary 2. □

IV. EXPLICIT FORMULAS WHEN *q* IS NOT A ROOT OF UNITY

Let us prolongate considerations of Theorem 3. Solving (17) and (18) we obtain

$$I_1 x_{-j} = \frac{-q^{-1/2}}{q^{\nu-j} + q^{-\nu+j}} (D_j x_{-j+1} + x_{-j-1}), \quad 0 \leqq j \leqq r-1, \tag{19}$$

$$I_2 x_{-j} = \frac{i}{q^{\nu-j}+q^{-\nu+j}}(q^{\nu-j}D_j x_{-j+1} - q^{-\nu+j}x_{-j-1}),$$
$$D_j := C + q[\nu-j+1]_q[\nu-j]_q = -q[j]_q[2\nu-j+1]_q, \tag{20}$$

where $x_1 := 0$ and x_{-r} is some vector from V. As $x_{-r} \in \mathrm{Ker}\,(I_3 + i[\nu-r]_q)$ [see (15)] and q-number $-i[\nu-r]_q$ can be equal to at most one of the numbers $-i[\nu]_q, \ldots, -i[\nu-r+1]_q$, say $-i[\nu-p]_q$, $0 \leqq p \leqq r-1$ (see Lemma 10), there exists $\alpha \in \mathbb{C}$ such that $x_{-r} = \alpha x_{-p}$ (reason: linear-dependent vectors have the same eigenvalue) and $\alpha = 0$ or $\alpha \neq 0$ covers both cases.

Calculating $(q^{1/2}I_1I_2 - q^{-1/2}I_2I_1 - I_3)x_{-r+1} = 0$ [see (1)] we obtain

$$\frac{-iq^{-1}D_r}{q^{\nu-r+1}+q^{-\nu+r-1}}x_{-r+1} + \frac{\alpha i D_p(q^{-\nu+r-1}+q^{-\nu-p-1})}{(q^{\nu-r+1}+q^{-\nu+r-1})(q^{\nu-p}+q^{-\nu+p})}x_{-p+1}$$
$$+ \frac{i\alpha q^{-\nu-1}(q^r - q^p)}{(q^{\nu-r+1}+q^{-\nu+r-1})(q^{\nu-p}+q^{-\nu+p})}x_{-p-1} = 0. \tag{21}$$

Now we distinguish two cases $\alpha = 0$ and $\alpha \neq 0$.

A. Classical case $\alpha = 0$

Equation (21) gives now $D_r = 0$, i.e., $q^{2r} = 1$ or $q^{4\nu} = q^{2r-2}$. Because q is not a root of unity, thus $q^\nu = \varepsilon q^{(r-1)/2}$ or $q^\nu = i\varepsilon q^{(r-1)/2}$ for some $\varepsilon \in \{-1,1\}$.

If r is odd, then the case $q^\nu = i\varepsilon q^{(r-1)/2}$ is not allowed: we have $-i[\nu-(r-1)/2]_q = 2\varepsilon/(q - q^{-1})$ in the spectrum of I_3, which contradicts Theorem 2. It can be directly verified that in all remaining cases relations (1)–(3) are fulfilled and relations (19) and (20) take the following form:

$$I_3 x_{-j} = -i\frac{c_1 q^{-j+(r-1)/2} - c_1^{-1}q^{j-(r-1)/2}}{q-q^{-1}}x_{-j}, \quad 0 = \leqq j \leqq r-1, \quad x_1 = x_{-r} = 0, \tag{22}$$

$$I_1 x_{-j} = \frac{-q^{-1/2}}{c_1 q^{-j+(r-1)/2} + c_1^{-1}q^{j-(r-1)/2}}(c_1^2 q[j]_q[j-r]_q x_{-j+1} + x_{-j-1}), \tag{23}$$

$$I_2 x_{-j} = \frac{ic_1^3 q^{1/2}}{c_1 q^{-j+(r-1)/2} + c_1^{-1}q^{j-(r-1)/2}}(q^{r/2-j}[j]_q[j-r]_q x_{-j+1} - q^{-r/2+j}x_{-j-1}), \tag{24}$$

$c_1 = \varepsilon$ or $c_1 = i\varepsilon$. Possibility $c_1 = i\varepsilon$ is excluded also in the case when r is even: in Ref. 3 (Sec. IV) reducible representations $R_l^{(\pm i)}$, $l = (r-1)/2$, were defined on r-dimensional space $V = \mathbb{C}\{|m\rangle | m = -l, \ldots, l\}_{\mathrm{lin}}$ and representations (22)–(24) are equivalent to $R_l^{(-\varepsilon i)}$ through mapping

$$Tx_{-j} = \prod_{k=1}^{j} q^{1/2}[r-k]_q |-l+j\rangle, \quad j = 0,\ldots,2l = r-1.$$

In the only allowed case $c_1 = \varepsilon$ the representations are equivalent to irreducible representations $R_l^{(\varepsilon)}$ defined in Ref. 3 on the same space V through mapping

$$Tx_{-j} = \prod_{k=1}^{j} (-q^{1/2})[r-k]_q |-l+j\rangle, \quad j = 0,\ldots,2l = r-1.$$

It is shown in Ref. 3 that representations $R_l^{(1)}$ and $R_l^{(-1)}$ are equivalent. We see that formulas (22)–(24) admit limit $q \to 1$ and pass to usual formulas for irreducible representation of the Lie algebra o(3).

Note 4: Formulas (22)–(24) (from now we always assume $c_1=1$) define irreducible representation also for some roots of unity. If $q^k=-1$ for some $k\in\{r-1,r-3,...\}$, matrix I_1 is not defined. If $q^k=-1$ for some $k\in\{r-2,r-4,...\}$ or $q^k=1$ for some $k\in\{r-1,r-2,...\}$, representations (22)–(24) are reducible (some element of I_1 below diagonal is equal to zero). Therefore, we have the following.

(a) Let $q^n=1$, n odd. Then $q^j\neq -1$ for any $j\in\mathbb{N}$ (see Note 6) and (22)–(24) form irreducible representation for $n\geqq r$.
(b) Let $q^n=1$, n even (this implies $q^{n/2}=-1$). Then
  (i) we have irreducible representation if $n/2\geqq r$; and
  (ii) formulas lead to irreducible representation also for $n/2=r-1$. If $q^{r-1}\neq -1$, the diagonal matrix T,

$$Tx_0=(q^{(r-1)/2}+q^{-(r-1)/2})x_0,\quad Tx_{-j}=x_{-j},\quad j=1,2,...,r-1,$$

  is bijective, and equivalent representation TI_iT^{-1}, $i=1,2,3$, does not have singularity at $q^{r-1}=-1$ after continuous prolongation.

B. Nonclassical case $\alpha\neq 0$

In this case $q^\nu=i\varepsilon q^{(r+p)/2}$ for some $p\in\{0,1,...,r-1\}$ and $x_{-r}=\alpha x_{-p}$. Equation (21) has now the form

$$\frac{\varepsilon q^{-1}D_r}{q^{(r-p)/2-1}-q^{-(r-p)/2+1}}x_{-r+1}+\frac{\alpha\varepsilon q^{-1}}{q^{(r-p)/2-1}-q^{-(r-p)/2+1}}x_{-p-1}=0. \tag{25}$$

This equation can be satisfied only in two cases:

(a) $p+1=r-1$ but now $q^\nu=i\varepsilon q^{r-1}$, and again $2\varepsilon/(q-q^{-1})=-i[\nu-r+1]_q$ would be in the spectrum of generator I_3 which contradicts Theorem 2.
(b) $p+1=r$, which implies $x_{-p-1}=x_{-r}=\alpha x_{-r+1}$. Substituting into (25) we obtain

$$\alpha=i\varepsilon' q^{1/2}[r]_q \quad \text{for some} \quad \varepsilon'\in\{-1,1\}.$$

The final form of relations (19) and (20) in this case is

$$I_3x_{-j}=\varepsilon\frac{q^{1/2-r+j}+q^{-1/2+r-j}}{q-q^{-1}}x_{-j},\quad 0\leqq j\leqq r-1,\quad x_1=0,\quad x_{-r}=i\varepsilon' q^{1/2}[r]_q x_{-r+1}, \tag{26}$$

$$I_1x_{-j}=\frac{-i\varepsilon q^{-1/2}}{q^{1/2-r+j}-q^{-1/2+r-j}}(q[j]_q[2r-j]_q x_{-j+1}+x_{-j-1}), \tag{27}$$

$$I_2x_{-j}=\frac{-iq^{1/2}}{q^{1/2-r+j}-q^{-1/2+r-j}}([j]_q[2r-j]_q q^{r-j}x_{-j+1}+q^{-r+j}x_{-j-1}). \tag{28}$$

Similarly, these four representations are equivalent to irreducible representations $R_r^{(-i\varepsilon,\varepsilon')}$ from Ref. 3 acting on the space $V=\mathbb{C}\{|k\rangle|k=1,...,r\}_{\text{lin}}$ through mapping

$$Tx_{-j}=\prod_{k=1}^{j}(-q^{1/2})[2r-k]_q|r-j\rangle,\quad j=0,...,r-1.$$

All five constructed representations were described in Ref. 3 where their mutual nonequivalence and irreducibility were proved. So we have the following.

TABLE I. Finite-dimensional representations when q is not a root of unity.

Representation characteristic	Corresponding formulas	Dimension	No./each dimension
Classical (admit limit $q\to 1$)	(22)–(24), $c_1=1$	any	1
Nonclassical (does not admit limit $q\to 1$)	(26)–(28), $\epsilon,\epsilon'\in\{-1,1\}$	any	4

Theorem 4 (Main result): Any r-dimensional irreducible representation of $U_q'(\mathrm{so}_3)$ when q is not a root of unity is equivalent to one of five nonequivalent irreducible representations defined either by (22)–(24) where $c_1=1$ or by (26)–(28) where ε, $\varepsilon'\in\{-1,1\}$ (see Table I).

Note 5: If $q^k=1$, $k\in\{3,5,...,2r-1\}$, then matrix I_1 given by (27) is not defined. If $q^k=-1$ and $k\in\{2,...,r-1,r+1,...,2r-1\}$ or $q^k=1$ and $k\in\{4,6,...,2r-2\}$, matrices (26)–(28) form reducible representation. Therefore we have the following.

(a) Let $q^n=1$, n odd. Then $q^j\neq -1$ for any $j\in\mathbb{N}$ and
  (i) for $n>2r-1$ we have irreducible representation, and
  (ii) similarly as in Note 4, formulas lead to irreducible representation also in the case $n=2r-1$. The equivalence matrix T which removes singularity from I_1 now has form

$$Tx_0=(q^{1/2-r}-q^{-1/2+r})x_0;\quad Tx_{-j}=x_{-j},\quad j=1,2,...,r-1.$$

(b) Let $q^n=1$, n even ($\Rightarrow q^{n/2}=-1$). Then (26)–(28) define representation which is irreducible only if $n\subset\{4,6,...,2r-2,2r+2,...,2(2r-1)\}$, i.e., if $n\geqq 4r$ or $n=2r$.

V. REPRESENTATIONS WHEN q IS A ROOT OF UNITY

Note 6: Through Secs. V–VII we assume that q is a root of unity, i.e., $q^n=1$ for some fixed $n\in\mathbb{N}$, $q^j\neq 1$ for $j<n$.

Lemma 4: $U_q'(\mathrm{so}_3)$ is at most a $3n(n-1)+1$-dimensional module over the center.

Proof: Because the Casimir elements $C^{(n)}(I_j)$, $j\in\{1,2,3\}$ [see (5)], belong to the center of $U_q'(\mathrm{so}_3)$, any element $A=I_1^{j_0}I_2^{k_0}I_3^{l_0}\in U_q'(\mathrm{so}_3)$, where $j_0,k_0,l_0\geqq 0$, can be expressed as linear combination

$$A=\sum_{j,k,l=0}^{n-1} Z_{j,k,l}I_1^jI_2^kI_3^l, \tag{29}$$

where $Z_{j,k,l}$ belong to the center. Similarly, due to Casimir element C [see (4)] we can remove from sum (29) all operators $I_1^jI_2^kI_3^l$ where product $jkl>0$ because all such operators can be expressed as a linear combination with coefficients from the center of elements $I_1^jI_2^k$, $I_2^jI_3^k$ and $I_1^jI_3^k$, $0\leqq j,k\leqq n-1$. Therefore, we have

$$A=\sum_{j,k=1}^{n-1} Z_{j,k}^{(1)}I_1^jI_2^k+\sum_{j,k=1}^{n-1} Z_{j,k}^{(2)}I_1^jI_3^k+\sum_{j,k=1}^{n-1} Z_{j,k}^{(3)}I_2^jI_3^k+\sum_{j=1}^{n-1} Z_j^{(4)}I_1^j+\sum_{j=1}^{n-1} Z_j^{(5)}I_2^j+\sum_{j=1}^{n-1} Z_j^{(6)}I_3^j+Z^{(7)}I,$$

where I denotes identity element and $Z_{\cdots}^{(\cdot)}$ are from center. The number of elements on right-hand side is $3(n-1)^2+3(n-1)+1=3n(n-1)+1$. □

Corollary 4: When q is a root of unity, any irreducible representation of $U_q'(\mathrm{so}_3)$ has finite dimension $\leqq[\sqrt{3n(n-1)+1}]$.

Proof: Let $\rho:U_q'(\mathrm{so}_3)\to L(V)$ be any nontrivial irreducible representation. Choose any $0\neq x\in V$. Then $V'=\mathbb{C}\{\rho(I_1^jI_2^kI_3^l)x|j,k,l\geqq 0\}_{\mathrm{lin}}$ is clearly an invariant subspace with at most countable basis. Because ρ is irreducible, we have $V'=V$. Now we can use Schur's lemma (see Ref. 6, section 8.2), which states that Casimir operators (4) and (5) are equal to a multiple of the identity. A previous lemma says that $\dim\mathbb{C}\{\rho(I_1^jI_2^kI_3^l)|j,k,l\geqq 0\}_{\mathrm{lin}}\leqq 3n(n-1)+1$. From the Burnside theo-

rem (see Ref. 7) follows that $\mathbb{C}\{\rho(I_1^j I_2^k I_3^l)|j,k,l\geqq 0\}_{\text{lin}}=L(V)$, i.e., $\dim L(V)\leqq 3n(n-1)+1$, which means that irreducible representation has finite dimension $\dim V\leqq[\sqrt{3n(n-1)+1}]$.

Definition 3: Representation is called having *weight vector* x_0 if there exist $x_0\neq 0$ and $\nu,\mu\in\mathbb{C}$ such that

$$I_3x_0=-i[\nu]_q x_0 \quad \text{and} \quad (O_\nu x_0=\mu x_0 \ \text{ or } \ R_\nu x_0=\mu x_0).$$

Note 7: It can be easily seen [taking $\nu'=-\nu+\pi i(\ln q)^{-1}$] that we can always assume $O_\nu x_0=\mu x_0$ in previous definition, i.e., representation has weight vector x_0 if there exist $x_0\neq 0$ and $\nu,\mu\in\mathbb{C}$ such that

$$I_3x_0=-i[\nu]_q x_0 \quad \text{and} \quad O_\nu x_0=\mu x_0. \tag{30}$$

Lemma 5: Let us assume (30). Then

$$q^\nu=i\varepsilon q^{-1/2} \ \text{ for some } \ \varepsilon\in\{-1,1\} \quad \text{and} \quad \mu^2=-C+q\left(\frac{q^{1/2}+q^{-1/2}}{q-q^{-1}}\right)^2 \tag{31}$$

or

$$\mu=0 \quad \text{and} \quad C=-q[\nu]_q[\nu+1]_q. \tag{32}$$

Proof: Applying I_3 on (30) [see (9)] we have $-i[\nu+1]_q O_\nu x_0=-i[\nu+1]_q\mu x_0=\mu(-i[\nu]_q)x_0$, so that either $\mu=0$ or $-i[\nu+1]_q=-i[\nu]_q\Rightarrow q^\nu=i\varepsilon q^{-1/2}$. Using (12) we obtain $-(C+q[\nu]_q[\nu+1]_q)x_0=\mu R_{\nu+1}x_0$. If $\mu=0$, we have $C=-q[\nu]_q[\nu+1]_q$. If $\mu\neq 0$, then $R_{\nu+1}=O_\nu$ (due to $q^\nu=i\varepsilon q^{-1/2}$) and therefore $-(C+q[\nu]_q[\nu+1]_q)x_0=\mu(\mu x_0)\Rightarrow\mu^2=-C+q((q^{1/2}+q^{-1/2})(q-q^{-1})^{-1})^2$. □

Note 8: Sign convention. Assume (31) in (30). Then we have

$$I_3x_0=\varepsilon\frac{q^{1/2}+q^{-1/2}}{q-q^{-1}}x_0, \quad O_\nu x_0=\tilde{\varepsilon}\sqrt{-C+q\left(\frac{q^{1/2}+q^{-1/2}}{q-q^{-1}}\right)^2}\,x_0,$$

where $\varepsilon,\tilde{\varepsilon}\in\{-1,1\}$. Turning to representation

$$I_1\to\varepsilon\tilde{\varepsilon}I_1, \quad I_2\to\tilde{\varepsilon}I_2, \quad I_3\to\varepsilon I_3,$$

we can, without loss of generality, assume $\varepsilon=\tilde{\varepsilon}=1$ and obtain three other possibilities using Note 3.

Lemma 6: Let us have irreducible representation with weight vector x_0 on a vector space V. Then $V=\mathbb{C}\{I_1^m x_0|m=0,1,...,n-1\}_{\text{lin}}$ and therefore $\dim V\leqq n$.

Proof: Let us assume (30). We use the formula $I_3I_1^m=p_m(I_1)I_2+q_m(I_1)I_3$ from Lemma 13. We have $I_2x_0=-i\mu x_0+q^{-\nu+1/2}I_1x_0$ so that

$$I_3(I_1^m x_0)=p_m(I_1)(-i\mu x_0+q^{-\nu+1/2}I_1x_0)+-i[\nu]_q q_m(I_1)x_0.$$

Therefore subspace $\mathbb{C}\{x_0,I_1x_0,I_1^2x_0,...\}_{\text{lin}}$ is invariant not only with respect to I_1, but also with respect to I_3 and, due to (3), also with respect to I_2.

Because $q^n=1$, we have an irreducible representation [see (5)]

$$I_1^n=\alpha_{n-2}I_1^{n-2}+\alpha_{n-4}I_1^{n-4}+\cdots,$$

where α_j are some complex constants [they depend on q and can be read out from (5) but we do not need it here]. Thus $\mathbb{C}\{x_0,I_1x_0,I_1^2x_0,...\}_{\text{lin}}=\mathbb{C}\{x_0,I_1x_0,...,I_1^{n-1}x_0\}_{\text{lin}}=V$. □

Definition 4: Representation is called *nonsingular* if there exist $x_0\neq 0$ and $\nu\in\mathbb{C}$ such that

$$I_3 x_0 = -i[\nu]_q x_0 \quad \text{and} \quad q^{\nu} \notin \{i\varepsilon q^{-k/2} | k=0,...,n-1; \varepsilon = \pm 1\}. \tag{33}$$

Otherwise, i.e., if x_0 has eigenvalue $-i[\nu]_q$ such that

$$q^{\nu} = i\varepsilon q^{-k/2} \quad \text{for some} \quad k \in \{0,...,n-1\} \quad \text{and} \quad \varepsilon \in \{-1,1\}, \tag{34}$$

we call the representation *singular*.

Note 9: In the nonsingular case the sequence $[\nu]_q, [\nu+1]_q, \ldots, [\nu+n-1]_q$ contains mutually different numbers (see Lemma 11) and it does not contain $2i\varepsilon/(q-q^{-1}), \varepsilon = \pm 1$; equations from Note 2 are therefore solvable.

Lemma 7: Consider the nonsingular irreducible representation of $U_q'(\mathrm{so}_3)$ on the vector space V [i.e., assume (33)]. Then either it is a representation having weight vector or

$$V = \mathbb{C}\{x_0, O_{\nu} x_0, O_{\nu+1} O_{\nu} x_0, \ldots, O_{\nu+n-2} \ldots O_{\nu} x_0\}_{\mathrm{lin}}, \quad \dim V = n.$$

Proof: Take x_0 from (33) and consider the set

$$\{x_0, x_1, \ldots, x_{m-1}\}, \quad x_i := O_{\nu+i-1} x_{i-1}, \quad i = 1,...,m-1,$$

where m is chosen such that this set consists of linear-independent vectors, $\dim \mathbb{C}\{x_0, x_1, \ldots, x_{m-1}\}_{\mathrm{lin}} = m$, and simultaneously, $x_m = O_{\nu+m-1} x_{m-1} \in \mathbb{C}\{x_0, x_1, \ldots, x_{m-1}\}_{\mathrm{lin}}$.

If $m = 1,...,n-1$, then the last condition is equivalent (due to the nondegeneracy of the spectrum of I_3) to the equality $O_{\nu+m-1} x_{m-1} = 0$ and we have representation with weight vector x_{m-1}.

If $m = n, \ldots, 2n-1$, the mentioned condition is equivalent to the equality $O_{\nu+m-1} x_{m-1} = \alpha x_{m-n}$. For $m > n$ we have $x_{m-n} = O_{\nu+m-n-1} x_{m-n-1} = O_{\nu+m-1} x_{m-n-1}$ so that $O_{\nu+m-1}(x_{m-1} - \alpha x_{m-n-1}) = 0$ and we have again representation with weight vector.

If $m = n$, then this argument cannot be used and we proceed as follows. Consider the vectors $x_{-1}, x_{-2}, \ldots, x_{-m'+1}$ defined by $x_{-i} := R_{\nu-i+1} x_{-i+1}$, where m' is chosen such that the set $\{x_{-m'+1}, x_{-m'+2}, \ldots, x_{-1}, x_0, x_1, \ldots, x_{n-1}\}$ is linear independent and $x_{-m'} = R_{\nu-m'+1} x_{-m'+1} \in \mathbb{C}\{x_{-m'+1}, \ldots, x_{n-1}\}_{\mathrm{lin}}$.

Due to Corollary 4, $m' < n-1$ and therefore there exists $\beta \in \mathbb{C}$ such that

$$x_{-m'} = R_{\nu-m'+1} x_{-m'+1} = \beta x_{n-m'}. \tag{35}$$

Now, if $m' \in \{2,3,...,n-2\}$, then [see (12)]

$$R_{\nu-m'+1} O_{\nu+n-m'} x_{n-m'} = R_{\nu-m'+1} x_{n-m'+1} = -(C + q[\nu-m'][\nu-m'+1]_q) x_{n-m'}. \tag{36}$$

For $C \neq -q[\nu-m'][\nu-m'+1]_q$ we may calculate $x_{n-m'}$ and, substituting into (35), we again have

$$R_{\nu-m'+1}\left(x_{-m'+1} + \frac{\beta}{(C + [\nu-m'][\nu-m'+1]_q)} x_{n-m'+1} \right) = 0,$$

i.e., representation has a weight vector.

If $C = -q[\nu-m'][\nu-m'+1]_q$, we have representation with weight vector $x_{n-m'+1}$ [see (36)]. The only open case is $m' = 1$, i.e.,

$$O_{\nu+n-1} x_{n-1} = \alpha x_0, \quad R_{\nu} x_0 = \beta x_{n-1} \tag{37}$$

(where $\alpha, \beta \in \mathbb{C}$) and $\dim \mathbb{C}\{x_0, \ldots, x_{n-1}\}_{\mathrm{lin}} = n$. The subspace $\mathbb{C}\{x_0, \ldots, x_{n-1}\}_{\mathrm{lin}}$ is invariant with respect to $2n$ operators $O_{\nu}, O_{\nu+1}, \ldots, O_{\nu+n-1}, R_{\nu}, R_{\nu+1}, \ldots, R_{\nu+n-1}$ [see (9)–(12) and (37)]:

$$(iI_2 + q^{-\nu-k+1/2} I_1) x_k = O_{\nu+k} x_k = x_{k+1}, \quad 0 \leqq k \leqq n-2, \tag{38}$$

$$(iI_2+q^{-\nu-n+k/2}I_1)x_{n-1}=O_{\nu+n-1}x_{n-1}=\alpha x_0, \tag{39}$$

$$(iI_2-q^{\nu+k+3/2}I_1)x_k=R_{\nu+k}x_k=-(C+q[\nu+k-1]_q[\nu+k]_q)x_{k-1}, \quad 1\leqq k\leqq n-1, \tag{40}$$

$$(iI_2-q^{\nu+1/2}I_1)x_0=R_\nu x_0=\beta x_{n-1}. \tag{41}$$

This system can be solved for the vectors I_1x_k and I_2x_k (see Note 9). For I_3 we have $I_3x_k=-i[\nu+k]_qx_k$, $k=0,...,n-1$. Thus invariance of $\mathbb{C}\{x_0,\ldots,x_{n-1}\}_{\text{lin}}$ is proved and, due to assumed irreducibility, the proof is finished. □

Lemma 8: Any irreducible representation of $U_q'(so_3)$ such that $\text{Ker}\,(I_3-\varepsilon\,(q^{1/2}+q^{-1/2})/(q-q^{-1}))\neq\{0\}$ for some $\varepsilon\in\{1,-1\}$ has a weight vector from this subspace.

Proof: Let ν fulfill the equation $q^\nu=i\varepsilon q^{-1/2}$. Consider vectors $0\neq x_0\in\text{Ker}\,(I_3-\varepsilon(q^{1/2}+q^{-1/2})/(q-q^{-1}))$ and $x_1:=O_\nu x_0$. If $O_\nu x_0=\alpha x_0$ for some $\alpha\in\mathbb{C}$, the representation has a weight vector, so let x_1 and x_0 be linearly independent. Equation (9) shows that x_1 has the same eigenvalue as x_0. Following (12) we have

$$R_{\nu+1}x_1=R_{\nu+1}O_\nu x_0=-(C+q[\nu]_q[\nu+1]_q)x_0,$$

but $R_{\nu+1}=O_\nu$ so that subspace $\mathbb{C}\{x_0,x_1\}_{\text{lin}}$ is invariant with respect to O_ν. The weight vector is therefore any eigenvector of restriction O_ν to the subspace $\mathbb{C}\{x_0,x_1\}_{\text{lin}}$. □

Lemma 9: A singular irreducible representation has a weight vector with the exception that n is even and vectors $x_0,O_\nu x_0,\ldots,O_{\nu+n/2}O_{\nu+n/2-1},\ldots,O_\nu x_0$, where $0\neq x_0\in\text{Ker}\,(I_3-2\varepsilon/(q-q^{-1}))$ for some $\varepsilon\in\{1,-1\}$, are linear independent.

Proof: Let $0\neq x_0\in\text{Ker}\,(I_3+i[\nu]_q)$ and $q^\nu\in\{i\varepsilon q^{-k/2}|k=0,1,...,n-1\}$ if n is odd and $q^\nu\in\{i\varepsilon q^{-k/2}|k=1,3,...,n-1\}$ if n is even. In these cases the sequence $[\nu]_q,\ldots,[\nu+n-1]_q$ contains value $i\varepsilon(q^{1/2}+q^{-1/2})/(q-q^{-1})$. Consider the vectors

$$x_0,O_\nu x_0,\ldots,O_{\nu+n-2},\ldots,O_\nu x_0 \tag{42}$$

for which we have $O_{\nu+j},\ldots,O_\nu x_0\in\text{Ker}\,(I_3+i[\nu+j+1]_q)$. If any of these vectors is equal to zero, then the representation has a weight vector; if all vectors are nonzero, then $\text{Ker}\,(I_3+\varepsilon(q^{1/2}+q^{-1/2})/(q-q^{-1}))\neq\{0\}$ and we use Lemma 8.

In the remaining case (i.e., $q^\nu\in\{i\varepsilon q^{-k/2}|k=0,2,...,n-2\}$, n is even) we have

$$\{[\nu]_q,\ldots,[\nu+n-1]_q\}=\left\{\pm\frac{2i}{q-q^{-1}},\pm i\,\frac{q+q^{-1}}{q-q^{-1}},\ldots,\pm i\,\frac{q^{[n/4]}+q^{-[n/4]}}{q-q^{-1}}\right\},$$

and if all vectors (42) are nonzero, then they are eigenvectors of I_3 with $n/2+1$ different eigenvalues

$$\frac{2\varepsilon}{q-q^{-1}},\varepsilon\,\frac{q+q^{-1}}{q-q^{-1}},\ldots,\varepsilon\,\frac{q^{[n/4]}+q^{-[n/4]}}{q-q^{-1}},-\varepsilon\,\frac{q^{[n/4]}+q^{-[n/4]}}{q-q^{-1}},\ldots,-\frac{2\varepsilon}{q-q^{-1}}.$$

Taking vector $\tilde{x}_0\in\text{Ker}\,(I_3-2\varepsilon/(q-q^{-1}))$ instead of x_0 we obtain the set $\{\tilde{x}_0,O_\nu\tilde{x}_0,\ldots,O_{\nu+n/2-1},\ldots O_\nu\tilde{x}_0\}$ of $n/2+1$ linear-independent vectors. □

Thus we can now state the following theorem.

Theorem 5: Let n be odd and R be any irreducible representation of $U_q'(so_3)$. Then either (a) or (b) is true, where we have the following.

(a) Representation R has weight vector x_0 [see Definition 3, Eq. (30)] and for representation space V we have

$$V=\mathbb{C}\{I_1^mx_0|m=0,1,...,n-1\}_{\text{lin}}, \quad \dim V\leqq n. \tag{43}$$

(b) The representation is nonsingular [see (33) for definition of vector x_0] and for representation space V we have

$$V=\mathbb{C}\{x_i|i=0,...,n-1\}_{\rm lin},\quad x_i:=O_{\nu+i-1}x_{i-1},\quad i=1,...,n-1,\quad \dim V=n. \tag{44}$$

Now it remains to consider the last case when n is even, the representation does not have any weight vector, and I_3 has an eigenvector with eigenvalue $2\varepsilon/(q-q^{-1})$.

Theorem 6: Let n be even and R be any irreducible representation of $U_q'(\mathrm{so}_3)$. Then either (a), (b), or (c) is true, where (a) and (b) are from Theorem 5 and (c) is as follows.

(c) For the representation space V we have

$$V=\mathbb{C}\{x_0,\ldots,x_{n/2},I_1x_0,\ldots,I_1^{n/2-1}x_0\}_{\rm lin},\quad 0\neq x_0\in\mathrm{Ker}\left(I_3-\frac{2\varepsilon}{(q-q^{-1})}\right),$$

$$x_i:=O_{\nu+i-1}x_{i-1},\quad \dim V=n.$$

Proof: Let us suppose that neither case (a) nor (b) takes place. Then we have (see Lemma 9) $0\neq x_0\in\mathrm{Ker}\,(I_3-2\varepsilon/(q-q^{-1}))$ for some $\epsilon\in\{-1,1\}$ and vectors $x_0,x_1,\ldots,x_{n/2}$, where $x_i:=O_{\nu+i-1}x_{i-1}$, $i=1,...,n/2$, are linear-independent eigenvectors of I_3. Therefore, Corollary 5 $(v_0\to x_0,\eta\to\varepsilon)$ implies linear independence of the set $\{w_1,\ldots,w_{n/2-1},x_0,x_1,\ldots,x_{n/2}\}$, because vector w_s is the principal vector corresponding to the eigenvalue $\varepsilon\,(q^s+q^{-s})/(q-q^{-1})$.

Since $b_{n/2}^{(n/2)}=0$, the vector $w_{n/2}$ fulfills eigenvalue equation $(I_3-\varepsilon(q^{n/2}+q^{-n/2})/(q-q^{-1}))w_{n/2}=0$. Because n is even, we have $q^{n/2}=-1$ (see Note 6) and therefore $\varepsilon\,(q^{n/2}+q^{-n/2})/(q-q^{-1})=-2\varepsilon/(q-q^{-1})$ (vector $x_{n/2}$ has the same eigenvalue). We distinguish two cases:

(a) the vectors $w_{n/2}$ and $x_{n/2}$ are linearly independent, and
(b) $w_{n/2}=\gamma x_{n/2}$ for some $\gamma\in\mathbb{C}$.

Let us consider the case (a). We will show that it is not possible. Consider the vectors

$$\tilde{x}_{n/2}=w_{n/2},\tilde{x}_{n/2-1},\ldots,\tilde{x}_0,\quad \tilde{x}_i:=R_{\tilde{\nu}+i+1}\tilde{x}_{i+1},\quad i=0,...,n/2-1,\quad q^{\tilde{\nu}}=-i\varepsilon.$$

Since the representation does not have a weight vector, the above vectors are (nonzero) eigenvectors with mutually different eigenvalues; $\tilde{x}_k$ and x_k belong to the same eigenvalue $\varepsilon(q^k+q^{-k})/(q-q^{-1})$.

Let us show now that the set of vectors $\{\tilde{x}_{n/2},\ldots,\tilde{x}_0,w_1,\ldots,w_{n/2-1},x_{n/2},\ldots,x_0\}$ is linearly independent. First define the following projective operators,

$$P_0=c_0\prod_{l=1}^{n/2-1}\left(I_3-\varepsilon\frac{q^l+q^{-l}}{q-q^{-1}}\right)^2\left(I_3-\frac{-2\varepsilon}{q-q^{-1}}\right),$$

$$P_k=c_k\left(I_3-\frac{2\varepsilon}{q-q^{-1}}\right)\prod_{\substack{l=1\\ l\neq k}}^{n/2-1}\left(I_3-\varepsilon\frac{q^l+q^{-l}}{q-q^{-1}}\right)^2\left(I_3-\frac{-2\varepsilon}{q-q^{-1}}\right),\quad 0<k<\frac{n}{2},$$

$$P_{n/2}=c_{n/2}\left(I_3-\frac{2\varepsilon}{q-q^{-1}}\right)\prod_{l=1}^{n/2-1}\left(I_3-\varepsilon\frac{q^l+q^{-l}}{q-q^{-1}}\right)^2,$$

where

$$c_0^{-1}=\prod_{l=1}^{n/2-1}\left(\frac{2\varepsilon}{q-q^{-1}}-\varepsilon\frac{q^l+q^{-l}}{q-q^{-1}}\right)^2\left(\frac{2\varepsilon}{q-q^{-1}}-\frac{2\varepsilon}{q-q^{-l}}\right),$$

$$c_k^{-1}=\left(\varepsilon\frac{q^k+q^{-k}}{q-q^{-1}}-\frac{2\varepsilon}{q-q^{-1}}\right)\prod_{\substack{l=1\\ l\neq k}}^{n/2-1}\left(\varepsilon\frac{q^k+q^{-k}}{q-q^{-1}}-\varepsilon\frac{q^l+q^{-l}}{q-q^{-1}}\right)^2\left(\varepsilon\frac{q^k+q^{-k}}{q-q^{-1}}-\frac{2\varepsilon}{q-q^{-1}}\right),$$

$$0<k<\frac{n}{2},$$

$$c_{n/2}^{-1}=\left(\frac{-2\varepsilon}{q-q^{-1}}-\frac{2\varepsilon}{q-q^{-1}}\right)\prod_{l=1}^{n/2-1}\left(\frac{-2\varepsilon}{q-q^{-1}}-\varepsilon\frac{q^l+q^{-l}}{q-q^{-1}}\right)^2.$$

Assume, on the contrary, that

$$\tilde{x}_k=\alpha_{k-1}\tilde{x}_{k-1}+\cdots+\alpha_0\tilde{x}_0+\beta_1 w_1+\cdots+\beta_{n/2-1}+\omega_{n/2-1}+\gamma_{n/2}x_{n/2}+\cdots+\gamma_0 x_0. \tag{45}$$

If $k=0$ or $k=n/2$, we apply P_0 or $P_{n/2}$, respectively, and we obtain

$$\tilde{x}_0=\gamma_0 x_0, \quad (\text{resp.} \quad \tilde{x}_{n/2}=\gamma_{n/2}x_{n/2}).$$

Application of the operator $O_{\nu+n/2-1}\cdots O_{\nu+1}O_\nu$ to the first equation leads to linear dependence

$$\text{const}(\tilde{x}_{n/2}-\gamma_0 x_{n/2})=0,$$

where const$\neq 0$ [see (11)]. Thus both cases are in contradiction with the assumption.

If $0<k<n/2$, we use the operator $(I_3-\varepsilon(q^k+q^{-k})/(q-q^{-1}))P_k$ and we have $b_k^{(k)}w_k=0$, i.e., $b_k^{(k)}=0$. Then, using operator P_k acting on Eq. (45) we come to linear dependence,

$$\tilde{x}_k=\gamma_k x_k,$$

and, using further operator $O_{\nu+n/2-1}\cdots O_{\nu+k+1}O_{\nu+k}$, we come to the linear dependence of vectors $x_{n/2}$ and $\tilde{x}_{n/2}$ (contradiction).

Let us now construct principal vectors $\tilde{w}_1,\ldots,\tilde{w}_{n/2-1}$ using eigenvectors $\tilde{x}_0,\ldots,\tilde{x}_{n/2}$ in the same way as the vectors $w_1,\ldots,w_{n/2-1}$ were constructed by means of the vectors $x_0,\ldots,x_{n/2}$. Due to Lemma 4 we have

$$\begin{aligned}\tilde{w}_k=&\alpha_{k-1}\tilde{w}_{k-1}+\cdots+\alpha_1\tilde{w}_1+\beta_{n/2}\tilde{x}_{n/2}+\cdots+\beta_0\tilde{x}_0\\&+\gamma_{n/2-1}w_{n/2-1}+\cdots+\gamma_1 w_1+\delta_0 x_0+\cdots+\delta_{n/2}x_{n/2}\end{aligned}$$

for some $k<n/2-1$. Using again the operator $(I_3-\epsilon(q^k+q^{-k})/(q-q^{-1}))P_k$ we come to the linear dependence of eigenvectors $\tilde{x}_k$ and x_k, which is the contradiction. Thus the case (a) is not possible.

The case (b) therefore takes place, thus we have an n-dimensional subspace, spanned by vectors $x_0,\ldots,x_{n/2},w_1,\ldots,w_{n/2-1}$ in the representation space of the considered irreducible representation. This subspace is invariant with respect to the operator I_3, but it may not be invariant with respect to the operator I_1: we have no information about the vector $I_1x_{n/2}$. However, assertion of Lemma 14 is valid if we use it for vector $x_{n/2}$, i.e., we can put $v_0\to x_{n/2}$ and $\eta\to-\epsilon$ and construct similarly vectors $\tilde{w}_s$ for $s\in\{1,...,n/2-1\}$ fulfilling modified (B18), and we obtain $\tilde{w}_{n/2}=\tilde{\gamma}x_0$ for some $\tilde{\gamma}\in\mathbb{C}$.

Therefore, the subspace

$$\mathbb{C}\{\tilde{w}_{n/2-1},\ldots,\tilde{w}_1,x_0,\ldots,x_{n/2},w_1,\ldots,w_{n/2-1}\}_{\text{lin}}$$

is invariant with respect to the operators I_3 and I_1 (and therefore it is invariant with respect to the operator I_2, too).

Lemma 17 used on the characteristic polynomial of operator I_3 [because the representation is n-dimensional we know its explicit form (5)] implies that each eigenvalue has multiplicity at most equal to 2, i.e., principal vectors w_k and $\tilde{w}_k$ may differ at most by an eigenvector corresponding to the eigenvalue $\varepsilon(q^k+q^{-k})/(q-q^{-1})$, which, in our case, means $\tilde{w}_k-w_k=\text{const}\,x_k$. □

VI. EXPLICIT FORMULAS FOR NONSINGULAR IRREDUCIBLE REPRESENTATIONS WHEN $q^n=1$

When q is a root of unity, $q^n=1$ with n odd or even, according to Theorems 5 and 6 we must distinguish two, resp. three, cases: (a), (b), and (c). This section covers for all n the case (b) (the representation is nonsingular) and partly the case (a) (the representation has a weight vector and is in addition nonsingular). The following section finishes the case (a) (a singular representation having a weight vector) for odd n.

(1) Let us first assume the case (b) [see (44)]. From (38)–(41) we have

$$I_3x_j=-i[\nu+j]_qx_j,\quad 0\leqq j\leqq n-1, x_n=\alpha x_0, \tag{46}$$

$$I_1x_0=\frac{q^{-1/2}}{q^{\nu}+q^{-\nu}}x_1-\frac{\beta q^{-1/2}}{q^{\nu}+q^{-\nu}}x_{n-1}, \tag{47}$$

$$I_1x_j=\frac{q^{-1/2}(C+q[\nu+j-1]_q[\nu+j]_q)}{q^{\nu+j}+q^{-(\nu+j)}}x_{j-1}+\frac{q^{-1/2}}{q^{\nu+j}+q^{-(\nu+j)}}x_{j+1},\quad 1\leqq j\leqq n-1, \tag{48}$$

$$I_2x_0=\frac{-iq^{\nu}}{q^{\nu}+q^{-\nu}}x_1-\frac{i\beta q^{-\nu}}{q^{\nu}+q^{-\nu}}x_{n-1}, \tag{49}$$

$$I_2x_j=\frac{iq^{-\nu-j}(C+q[\nu+j-1]_q[\nu+j]_q)}{q^{\nu+j}+q^{-(\nu+j)}}x_{j-1}-\frac{iq^{\nu+j}}{q^{\nu+j}+q^{-(\nu+j)}}x_{j+1},\quad 1\leqq j\leqq n-1. \tag{50}$$

From $(q^{1/2}I_1I_2-q^{-1/2}I_2I_1-I_3)x_0=0$ we obtain the value of Casimir element $C=-\alpha\beta-q[\nu]_q[\nu-1]_q$. After substituting into (46)–(50) we easily check that these relations form representation of $U_q'(\mathrm{so}_3)$. Let us put

$$T|j\rangle=q^{-j/2}(-1)^jx_j,\quad j=0,...,n-1,\quad \lambda=-iq^{-\nu},\quad a=\beta(-1)^{n-1}q^{n/2-1},\quad b=\alpha(-1)^nq^{-n/2}.$$

Using this equivalence matrix T, representation $R_{ab\lambda}$ defined in Ref. 3 by (46)–(49) is found to be equivalent with our considered representation. In Ref. 3 it is proven that this representation is irreducible if $q^{\nu}\neq\pm iq^{-n/2+1}$; however, this is fulfilled in our case.

Note 10: (*i*) Equations (46)–(50) form an irreducible representation also if $\alpha=0$ or $\beta=0$. In this case it is a representation with one or two weight vectors.

(*ii*) Equations (46)–(50) form an irreducible representation also in the case $q^{2n}=1$ (which implies $q^n=-1$, see Note 6), $\alpha=\beta=0$. This can be immediately verified.

(2) Let us now assume that the representation is nonsingular and fulfills the case (a), [see (43)]. Consider the set of vectors in representation space

$$\{x_0,x_{-1},...,x_{-k+1}\},\quad x_{-j-1}:=R_{\nu-j}x_{-j}, \tag{51}$$

such that

$$\dim\mathbb{C}\{x_0,x_{-1},...,x_{-k+1}\}_{\mathrm{lin}}=k\quad\text{and}\quad x_{-k}\equiv R_{\nu-k+1}x_{-k+1}\in\mathbb{C}\{x_0,x_{-1},...,x_{-k+1}\}_{\mathrm{lin}}. \tag{52}$$

Because the representation is nonsingular, Lemma 5 gives

$$O_{\nu}x_0=0,\quad C=-q[\nu+1]_q[\nu]_q. \tag{53}$$

If $k=1$, we obtain a trivial one-dimensional representation.

If $k=n$, then $x_{-k}=\alpha x_0$ for some $\alpha\in\mathbb{C}$ and we obtain the special case of nonsingular representation (46)–(50) studied above.

If $1<k<n$, then $x_{-k}=0$ (different eigenvalues) and, using (11), we obtain another condition for *C:*

TABLE II. Nonsingular representations, $q^n=1$.

(46)–(50), $\alpha,\beta,\nu\in\mathbb{C},\nu$ fulfilling (33)	n	3 parameters
(22)–(24) (see Note 4)	$1\leqq$dimension$<n$ if n is odd $1\leqq$dimension$\leqq n/2$ if n is even	1/each dimension
(46)–(50), $\alpha,\beta=0$, $\nu\in\mathbb{C}$, ν fulfilling (33), $n\to n/2$ (this possibility can take place only if n is even)	$n/2$	1 parameter

$$0=O_{\nu-k}x_{-k}=O_{\nu-k}R_{\nu-k+1}x_{-k+1}=-(C+q[\nu-k]_q[\nu-k+1]_q)x_{-k+1}. \tag{54}$$

Comparing with (53) we obtain $C=-q[\nu+1]_q[\nu]_q=-q[\nu-k]_q[\nu-k+1]_q$, thus $q^{2k}=1$ or $q^\nu=\varepsilon\sqrt{\varepsilon'}q^{(k-1)/2}$ for some $\varepsilon,\varepsilon'\in\{-1,1\}$.

(i) If $q^\nu=\varepsilon\sqrt{\varepsilon'}q^{(k-1)/2}$, then $\varepsilon'=1$ because the representation is assumed to be nonsingular. Solving (51) and (11) we obtain explicit forms of matrices I_1 and I_2. This representation is equivalent to the one defined by (22)–(24). Representations with $\varepsilon=\pm1$ are equivalent. According to Note 4 we have if n is odd, the representation is irreducible. If n is even, we have an irreducible representation if $1<k\leqq n/2$ and a reducible representation if $n/2<k<n$.

(ii) If $q^{2k}=1$, then $n=2k$ (because $1<k<n$), $q^k=-1$, and ν is independent. We obtain again formulas (46)–(50), which give an irreducible representation (see Note 10). Furthermore, for special $\nu=n/2-1$ we obtain an equivalent representation to the $n/2$-dimensional representation from (*i*).

Theorem 7: Let $q^n=1$ and let R be an irreducible nonsingular representation. Then R is equivalent to one of the representations given in Table II.

VII. EXPLICIT FORMULAS FOR SINGULAR IRREDUCIBLE REPRESENTATIONS WHEN $q^n=1$, n ODD

To obtain explicit formulas of singular representations, let us write first $\{i\varepsilon q^{-k/2}|k=0,\ldots,n-1;\varepsilon=\pm1\}=M_n\cup M_n'$, where $M_n=\{i\varepsilon q^{-1/2-m}|m=0,1,\ldots,(n-1)/2;\varepsilon=\pm1\}$, and $M_n'=\{i\varepsilon q^{-m}|m=1,2,\ldots,(n-1)/2;\varepsilon=\pm1\}$.

Possible eigenvalues of generator I_3 in singular representation are

$$\varepsilon\frac{q^{1/2}+q^{-1/2}}{q-q^{-1}},\varepsilon\frac{q^{3/2}+q^{-3/2}}{q-q^{-1}},\ldots,\varepsilon\frac{q^{n/2-1}+q^{-n/2+1}}{q-q^{-1}},\frac{2\varepsilon\tilde{\varepsilon}}{q-q^{-1}},$$

where $\tilde{\varepsilon}\equiv q^{n/2}\in\{-1,1\}$ (we use this abbreviation through the whole section).

Let $q^\nu\in M_n\cup M_n'$ and let

$$I_3x_0=-i[\nu]_qx_0,\quad O_\nu x_0=\mu x_0. \tag{55}$$

We distinguish five cases.

Case 1: $q^\nu\in M_n'$, i.e., $q^\nu=i\varepsilon q^{-m}$ for some $m\in\{1,2,\ldots,(n-1)/2\}$. Take the set (51) such that (52) holds. If $1\leqq k\leqq(n-1)/2-m$, then $x_{-k}=0$ (reason: mutually different eigenvalues) and similarly as in (53) and (54) we have

$$C=-q[\nu+1]_q[\nu]_q=-q[\nu-k]_q[\nu-k+1]_q. \tag{56}$$

This condition implies $q^{2k}=1$ or $q^{2(k+2m-1)})=1$. However, none of these possibilities can be fulfilled (see Note 6).

If $k>(n-1)/2-m$, then there exist nonzero vector $x_{-(n-1)/2+m}$ with eigenvalue $\varepsilon\tilde{\varepsilon}(q^{1/2}+q^{-1/2})/(q-q^{-1})$. According to Lemma 8, there exists a new weight vector x_0' with this eigenvalue and the rest of this case is covered by case 3, resp. 5.

Case 2: $\mathrm{Ker}(I_3-2\varepsilon\tilde{\varepsilon}/(q-q^{-1}))=\{0\}$ and $q^\nu\in M_n$, $q^\nu\neq\pm iq^{-1/2}$. Let $q^\nu=i\varepsilon q^{-1/2-m}$, $m\in\{1,2,\ldots,(n-3)/2\}$ and take the set (51) such that (52) and $k\leqq(n-1)/2-m$. Similarly as in (54) we have again (56), which cannot be satisfied.

Case 3: $\mathrm{Ker}(I_3-2\varepsilon\tilde{\varepsilon}/(q-q^{-1}))=\{0\}$ and $q^\nu=i\varepsilon q^{-1/2}$ for some $\varepsilon\in\{-1,1\}$. Take $q^\nu=i\varepsilon q^{-1/2}$ and consider (51) and (52). We now have $1\leqq k\leqq(n-1)/2$ and from (54)

$$C=-q[\nu-k+1]_q[\nu-k]_q=q\frac{(q^{1/2-k}+q^{-1/2+k})(q^{-1/2-k}+q^{1/2+k})}{(q-q^{-1})^2}.$$

Similarly as in Lemma 5 we have

$$\mu=i\tilde{\tilde{\varepsilon}}q^{1/2}[k]_q,\quad \tilde{\tilde{\varepsilon}}\in\{-1,1\}.$$

We have the same situation as in Sec. IV, nonclassical case B. Therefore we obtain formulas (26)–(28) [see Note 5(a)(i)].

Case 4: $\mathrm{Ker}\,(I_3-2\epsilon\tilde{\epsilon}/(q-q^{-1}))\neq\{0\}$ and $q^\nu\in M_n$, $q^\nu\neq\pm iq^{-1/2}$. In this case $q^\nu=i\varepsilon q^{-1/2-m}$, $m\in\{1,2,...,(n-1)/2\}$. For C we have

$$C=-q[\nu]_q[\nu+1]_q=q\frac{(q^{1/2-m}+q^{-1/2+m})(q^{-1/2-m}+q^{1/2+m})}{(q-q^{-1})^2}. \tag{57}$$

Value m can be assumed the lowest one in the sense that no weight vector with eigenvalue $\varepsilon(q^{-1/2-m'}+q^{1/2+m'})/(q-q^{-1}),m'<m$ exists. In the set

$$\{x_0,x_{-1,\ldots},x_{-(n-1)/2+m}\},\quad x_{-j-1}:=R_{\nu-j}x_{-j}$$

the vector $y_0\equiv x_{-(n-1)/2+m}\in\mathrm{Ker}\,(I_3-2\epsilon\tilde{\epsilon}/(q-q^{-1}))\neq\{0\}$ and we can use it as v_0 in Lemma 14 and Corollary 5 ($\epsilon\tilde{\epsilon}\to\eta$). Let us define vectors w_s, $s=1,...,n$, as in (B18).

For $y_j=O_{\tilde{\nu}+j-1}y_{j-1}=O_{\tilde{\nu}+j-1}O_{\tilde{\nu}+j-2}\cdots O_{\tilde{\nu}}y_0$, $j=1,2,...,q^{\tilde{\nu}}=i\epsilon\tilde{\epsilon}$ we have [using (11)]

$$y_j=\prod_{l=0}^{j-1}(-(C+q[\nu-(n-1)/2+m+l]_q[\nu-(n-1)/2+m+l+1]_q))x_{-(n-1)/2+m+j}. \tag{58}$$

Due to fixed value of Casimir operator (57), $y_j=0$ for all $j\geqq(n-1)/2-m+1$ while $y_0,\ldots,y_{(n-1)/2-m}$ are eigenvectors of generator I_3. Corollary 5 then implies the following.

(i) The set

$$\{x_0,x_{-1},\ldots,x_{-(n-1)/2+m}\equiv y_0,w_1,\ldots,w_{(n-1)/2-m}\}$$

contains $n-2m$ linear-independent vectors, and vector w_k is principal vector to eigenvector $x_{(n-1)/2+m+k}$.

(ii) Since $y_{(n-1)/2-m+1}=y_{(n-1)/2-m+2}=0,w_{(n-1)/2-m+1}\in\mathrm{Ker}\,(I_3-\varepsilon q^{-1/2-m+1}+q^{1/2+m-1}/q-q^{-1})=\{0\}$ and $w_{(n-1)/2-m+2}\in\mathrm{Ker}\,(I_3-\varepsilon q^{-1/2-m+2}+q^{1/2+m-2}/q-q^{-1})=\{0\}$, i.e.,

$$I_1^s y_0+\cdots+\frac{2\varepsilon\tilde{\varepsilon}b_s^{(s)}[s-2]_q^2}{q^{s-1}-q^{-s+1}}\tilde{D}_1y_{s-2}=0, \tag{59}$$

$$I_1^{s+1}y_0+\cdots+\frac{2\varepsilon\tilde{\varepsilon}b_{s+1}^{(s+1)}[s-1]_q^2}{q^s-q^{-s}}\tilde{D}_1y_{s-1}=0, \tag{60}$$

$s=(n-1)/2-m+1$. Vectors y_{s-2} and y_{s-1} are multiples of x_{-1} and x_0, respectively, and relations

$$R_{\nu-1}x_{-1}=x_{-2}, \quad O_{\nu-1}x_{-1}=-(C+q[\nu-1]_q[\nu]_q)x_0$$

give

$$I_1x_{-1}=\frac{i\varepsilon\tilde{\varepsilon}q^{-1/2}}{q^{s-2}-q^{-s+2}}(x_{-2}+(C+q[\nu-1]_q[\nu]_q)x_0).$$

Subtracting the I_1 ''multiple'' of (59) from (60) and comparing the coefficient by vector x_0 we obtain the relation

$$\frac{2\varepsilon\tilde{\varepsilon}b_s^{(s)}[s-2]_q^2\tilde{D}_1}{q^{s-1}-q^{-s+1}}\cdot\frac{i\varepsilon\tilde{\varepsilon}q^{-1/2}}{q^{s-2}-q^{-s+2}}+\frac{2\varepsilon\tilde{\varepsilon}b_{s+1}^{(s+1)}[s-1]_q^2\tilde{D}_1}{q^s-q^{-s}}=0,$$

which leads to condition $q^{4m}=1$. Because $4\leqq 4m\leqq 2n-2$, we must have $4m=n$, but this is a contradiction (n is odd).

Case 5: $\mathrm{Ker}\,(I_3-2\varepsilon\tilde{\varepsilon}/(q-q^{-1}))\neq\{0\}$ and $q^\nu=i\varepsilon q^{-1/2}$ for some $\varepsilon\in\{-1,1\}$. According to Note 8, put $\varepsilon=1$ and, in Lemma 5, assume

$$\mu=+\sqrt{-C+q\left(\frac{q^{1/2}+q^{-1/2}}{q-q^{-1}}\right)^2}. \tag{61}$$

Consider (51) where $k=(n+1)/2$. Again, we can use $y_0\equiv x_{-(n-1)/2}$ as v_0 in Lemma 14 and Corollary 5. Let us again put $y_j=O_{\tilde{\nu}+j-1}y_{j-1}=O_{\tilde{\nu}+j-1}O_{\tilde{\nu}+j-2}\cdots O_{\tilde{\nu}}y_0$ for $j=1,2,...,q^{\tilde{\nu}}=i\tilde{\varepsilon}$ and let us define vectors w_s, $s=1,...,n$, as in (B18). We have

$$y_j=\prod_{l=0}^{j-1}\left(-\left(C-q\frac{(q^l+q^{-l})(q^{l+1}+q^{-l-1})}{(q-q^{-1})^2}\right)\right)x_{-(n-1)/2+j}. \tag{62}$$

Consider the set

$$V'=\mathbb{C}\{x_0,x_{-1},...,x_{-(n-3)/2},x_{-(n-1)/2},w_1,...,w_{m-1}\}_{\mathrm{lin}}, \tag{63}$$

such that $\dim V'=(n+1)/2+m-1$, $w_m\in V'$ and $m\leqq(n+1)/2$ (such m exists because $\dim V'\leqq n$). V' is invariant with respect to I_3 and also I_1.

We distinguish two cases:

(i) $m\leqq(n-1)/2$. Assumption $w_m\in V'$ and (B17) give

$$w_m=\alpha x_{-(n-1)/2+m} \quad \text{for some} \quad \alpha\in\mathbb{C}, \tag{64}$$

$$\prod_{l=0}^{m-1}\left(-\left(C-q\frac{(q^l+q^{-l})(q^{l+1}+q^{-l-1})}{(q-q^{-1})^2}\right)\right)=0 \tag{65}$$

[see (62)]. Because $w_{m+1}\in V'$, the last equation (giving $y_{m+1}=0$) implies further ($x_1:=x_0$)

$$w_{m+1}=\beta x_{-(n-1)/2+m+1} \quad \text{for some} \quad \beta\in\mathbb{C}. \tag{66}$$

Explicit forms of (64) and (66) are

$$I_1^m y_0+\frac{a_{m-2}^{(m)}}{q^{m-1}-q^{-m+1}}I_1^{m-2}y_0+\cdots+\frac{2b_m^{(m)}[m-2]_q^2\tilde{D}_1}{q^{m-1}-q^{-m+1}}y_{m-2}=\alpha x_{-(n-1)/2+m},$$

$$I_1^{m+1}y_0+\frac{a_{m-1}^{(m+1)}}{q^m-q^{-m}}I_1^{m-1}y_0+\cdots+\frac{2b_{m+1}^{(m+1)}[m-1]_q^2\tilde{D}_1}{q^m-q^{-m}}y_{m-1}=\beta x_{-(n-1)/2+m+1}.$$

Subtracting the I_1 multiple of the first equation from the second, we obtain the relation among linearly independent vectors which can be fulfilled only if

$$\frac{a_{m-2}^{(m)}}{q^{m-1}-q^{-m+1}}=\frac{a_{m-1}^{(m+1)}}{q^m-q^{-m}},$$

which fixes the value of the Casimir operator

$$C=q\frac{(q^{m-1}+q^{-m+1})(q^m+q^{-m})}{(q-q^{-1})^2}.$$

It shows that vectors $y_1,\ldots,y_{m-1}$ are nonzero, i.e., $w_1,\ldots,w_{m-1}$ are principal vectors.

Further, using relations (19) with $q^\nu=i\varepsilon q^{-1/2}$ and $j=(n-1)/2-m$, $j=(n-1)/2-m+2$ and comparing coefficients of vector $x_{-(n-1)/2+m-1}$ we obtain the equation determining $\alpha\in\mathbb{C}$.

Note that for $m=1$ it is clear (because there is no other such representation with that dimension) that we must obtain the same representation as in Sec. IV, nonclassical case B, formulas (26)–(28) [see Note 5(a)(ii)].

(ii) $m=(n+1)/2$: from (B17) we have

$$\left(I_3-\tilde{\varepsilon}\frac{q^{1/2}+q^{-1/2}}{q-q^{-1}}\right)w_{(n+1)/2}=\text{const}\,x_0, \tag{67}$$

thus vector $w_{(n+1)/2}$ fulfills the same principal equation as $w_{(n-1)/2}$ [const can be read out from (62) and (67)]. Because the dimension of Jordan blocks in matrix I_3 is at most 2, there exists $\alpha\in\mathbb{C}$ such that

$$w_{(n+1)/2}=\alpha x_0+\text{const}'\,w_{(n-1)/2} \tag{68}$$

(again, const′ can be easily computed, α is unknown).

Therefore we get two-parameter set of operators

$$\{(I_3^{(C,\alpha)},I_1^{(C,\alpha)})\,|\,(C,\alpha)\in\mathbb{C}\times\mathbb{C}\}. \tag{69}$$

Matrix I_1 is defined through Eqs. (19), (55), (B18), and (68), matrix I_3 through Eqs. (15), (B17), and (62).

We will now show that matrices (69) form representation of $U_q'(\mathrm{so}_3)$ for all $(C,\alpha)\in\mathbb{C}^2$ and that almost all are irreducible.

We can easily prove that for each $(C,\alpha)\in\mathbb{C}^2$

$$(q^2I_1^{(C,\alpha)^2}+I_2^{(C,\alpha)^2}+q^2I_3^{(C,\alpha)^2}-(q^{5/2}-q^{1/2})I_1^{(C,\alpha)}I_2^{(C,\alpha)}I_3^{(C,\alpha)})e_1=Ce_1,$$

where $I_2^{(C,\alpha)}:=q^{1/2}I_3^{(C,\alpha)}I_1^{(C,\alpha)}-q^{-1/2}I_1^{(C,\alpha)}I_3^{(C,\alpha)}$ and $e_1=(1,0,\ldots,0)\in\mathbb{C}^n$. This means that the value of parameter C is really the value of the Casimir operator.

Further, rewriting operator $I_1^{(C,\alpha)}$ in basis

$$V'=\mathbb{C}\{x_0,x_{-1},\ldots,x_{-(n-3)/2},y_0=x_{-(n-1)/2},I_1y_0,\ldots,I_1^{m-1}y_0\}_{\text{lin}}, \tag{70}$$

we can achieve the result

$$\det I_1^{(C,\alpha)}=\det I_1^{(C,0)}+\alpha\prod_{j=0}^{(n-3)/2}\frac{iq^{-1/2}}{q^{-j+1/2}-q^{j-1/2}}, \tag{71}$$

i.e., $\det I_1^{(C,\alpha)}$ depends on α so that parameter α cannot be removed by change of basis.

Let $M=\{(C,\alpha)\in\mathbb{C}^2|\text{matrices } I_3^{(C,\alpha)}, I_1^{(C,\alpha)} \text{ define an irreducible representation of } U_q'(so_3)\}$. Let us show now that there exists $M_1\subset\mathbb{C}^2$ of Lebesgue measure zero such that $M=\mathbb{C}-M_1$.

Consider irreducible n-dimensional representation (46)–(50) after automorphism ρ from Corollary 1:

$$I_1x_j=-i[\nu+j]_qx_j,\quad 0\leqq j\leqq n-1,\ x_n=\tilde{\alpha}x_0, \tag{72}$$

$$I_3x_0=\frac{-iq^{\nu}}{q^{\nu}+q^{-\nu}}x_1-\frac{i\tilde{\beta}q^{-\nu}}{q^{\nu}+q^{-\nu}}x_{n-1}, \tag{73}$$

$$I_3x_j=\frac{iq^{-\nu-j}(C+q[\nu+j-1]_q[\nu+j]_q)}{q^{\nu+j}+q^{-(\nu+j)}}x_{j-1}-\frac{iq^{\nu+j}}{q^{\nu+j}+q^{-(\nu+j)}}x_{j+1},\quad 1\leqq j\leqq n-1, \tag{74}$$

where

$$C=-\tilde{\alpha}\tilde{\beta}-q[\nu]_q[\nu-1]_q \quad\text{and}\quad (\tilde{\alpha},\tilde{\beta},q^{\nu})\in\mathbb{C}^2\times(\mathbb{C}-\{i\varepsilon q^{-i}|j=0,\ldots,n-1,\varepsilon=\pm1\}). \tag{75}$$

Due to irreducibility, Casimir element $C^{(n)}$ in this representation is equal to a multiple of the identity:

$$C^{(n)}(I_3)=-\det I_3=-\tilde{\alpha}\prod_{k=0}^{n-1}\frac{q^{-1/2}}{q^{\nu+k}+q^{-\nu-k}}+\tilde{\beta}\frac{q^{-1/2}}{q^{\nu}+q^{-\nu}}\prod_{k=0}^{n-2}\frac{q^{-1/2}(C+q[\nu+k]_q[\nu+k-1]_q)}{q^{\nu+k+1}+q^{-\nu-k-1}}.$$

If we choose constants $\tilde{\alpha}$ and $\tilde{\beta}$ such that

$$\det I_3=\frac{2\tilde{\varepsilon}}{n(q-q^{-1})^n}, \tag{76}$$

representation (72)–(74) is singular. Condition (76) is equivalent to

$$\tilde{\alpha}-\tilde{\beta}\prod_{k=0}^{n-2}(C+q[\nu+k]_q[\nu+k+1]_q)=\frac{2}{(q-q^{-1})^n}\prod_{k=0}^{n-1}(q^{\nu+k}+q^{-\nu-k}). \tag{77}$$

Using (75) we have

$$\tilde{\beta}^2\prod_{k=0}^{n-2}(C+q[\nu+k]_q[\nu+k+1]_q)-\tilde{\beta}\frac{2}{(q-q^{-1})^n}\prod_{k=0}^{n-1}(q^{\nu+k}+q^{-\nu-k})+C+q[\nu-1]_q[\nu]_q=0$$

having at least one solution $\tilde{\beta}$ for any pair $(C,q^{\nu})\in\mathbb{C}\times(\mathbb{C}-\{i\varepsilon q^{-j}|j=0,\ldots,n-1,\varepsilon=\pm1\})$. For given $\alpha\in\mathbb{C}$ we choose $q^{\nu}\in\mathbb{C}$ such that $\det I_1^{(C,\alpha)}=\det I_1$, i.e.,

$$\prod_{j=0}^{n-1}(-i[\nu+j]_q)=\det I_1^{(C,0)}+\alpha\prod_{j=0}^{(n-3)/2}\frac{iq^{-1/2}}{q^{-j+1/2}-q^{j-1/2}}. \tag{78}$$

If q^{ν} is a solution of (78), then this equation is solved also by $q^{\nu+1},\ldots,q^{\nu+n-1}$. However, if constants (C,α) fulfill the condition

$$\varepsilon\prod_{j=0}^{n-1}\frac{q^j+q^{-j}}{q-q^{-1}}=\det I_1^{(C,0)}+\alpha\prod_{j=0}^{(n-3)/2}\frac{iq^{-1/2}}{q^{-j+1/2}-q^{j-1/2}} \tag{79}$$

solutions q^{ν} of (78) are bad—they belong to the set $\{i\varepsilon q^{-j}|j=0,\ldots,n-1,\varepsilon=\pm1\}$.

TABLE III. Singular representations, $q^n=1$, n odd.

Corresponding formulas	Dimension	No./each dimension
(26)–(28) (I_3 diagonal)	$1\leqq k\leqq(n+1)/2$	4
explicit formulas not computed, I_3 not diagonalizable	$(n+1)/2<k\leqq n-1$	at most 4
(72)–(74), $C,\tilde{\alpha},\tilde{\beta},\nu\in C$, fulfilling (75) and (77)	n	2 parameters
(69), $(C,\alpha)\in M_1$ (see Theorem 8)	n	1 parameter

Therefore we can state the following.

Theorem 8: Let n be odd. Then the following assertions are true:

(i) If R is a singular n-dimensional irreducible representation of $U_q'(\mathrm{so}_3)$, then there exists at most one pair $(C,\alpha)\in\mathbb{C}^2$ and $\eta_1,\eta_2\in\{-1,1\}$ such that R is equivalent to some of the four representations generated from representation (69) using Note 3.

(ii) If M_1 is the set of all pairs (C,α) satisfying condition (79), then the Lebesgue measure of M_1 is equal to zero. If $(C,\alpha)\in\mathbb{C}^2-M_1$, then matrices (69) form a representation equivalent to some of four representations generated from representation (72)–(74) using Note 3.

Note 11: Matrices (69) form a representation for all $(C,\alpha)\in\mathbb{C}^2$. When $(C,\alpha)\in\mathbb{C}^2-M_1$ it follows from the previous theorem. When $(C,\alpha)\in M_1$, then we have $(C,\alpha_1)\notin M_1$ for all $\alpha_1\neq\alpha$ [condition (79) is linear in α]. Clearly

$$\lim_{\alpha_1\to\alpha} I_j^{(C,\alpha_1)}=I_j^{(C,\alpha)},\quad j=1,2,3,$$

which follows from the fact that only one of the n^2 matrix coefficients of $I_1^{(C,\alpha)}$ [see (68)] depends (linearly) on α, and matrix coefficients of $I_3^{(C,\alpha)}$ do not depend on α at all. Using this continuity argument on relations (1)–(3) we obtain the desired result. Note we do not know if representations from M_1 are irreducible.

Theorem 9: Let $q^n=1$ for n odd. If R is an irreducible singular representation, then R is equivalent to one of the representations given in Table III.

Note 12: In the two last cases described in Table III we know also matrix I_3 is written in basis (63) $[m=(n+1)/2]$. Relations (62) and (B17) show that this matrix is diagonalizable iff

$$C=C_{\mathrm{diag}}\equiv\frac{2q(q+q^{-1})}{(q-q^{-1})^2}. \tag{80}$$

Comparing Tables II [see also (46)] and III we see that in the case n odd we have full classification and explicit formulas of all irreducible representations with diagonalizable I_3 with only one exception—point $(C_{\mathrm{diag}},\alpha)\in M_1$ [Theorem 8 (ii)].

VIII. CONCLUSION AND REMARKS

(i) In Lemma 2 we give a proof that $C^{(n)}(I_1)$ is a Casimir element of $U_q'(\mathrm{so}_3)$ when q is a root of unity, $q^n=1$. This interesting polynomial seems to be of great importance for algebras $U_q'(\mathrm{so}_m)$, $m\geqq 3$.

Let us recall that $U_q'(\mathrm{so}_m)$ is an associative algebra generated by elements $I_{i,i-1}$, $i\in\{2,\ldots,m\}$ and relations

$$I_{i,i-1}I_{i-1,i-2}^2-(q+q^{-1})I_{i-1,i-2}I_{i,i-1}I_{i-1,i-2}+I_{i-1,i-2}^2I_{i,i-1}=-I_{i,i-1}, \tag{81}$$

$$I_{i,i-1}^2I_{i-1,i-2}-(q+q^{-1})I_{i,i-1}I_{i-1,i-2}I_{i,i-1}+I_{i-1,i-2}I_{i,i-1}^2=-I_{i-1,i-2}, \tag{82}$$

$$[I_{i,i-1},I_{j,j-1}]=0, \quad |i-j|>1, \tag{83}$$

where $[\cdot,\cdot]$ denotes the usual commutator. One can also give an equivalent definition of $U'_q(\mathrm{so}_m)$ in terms of generators I_{ij}, $i\in\{2,...,m\}$, $j\in\{1,...,i-1\}$, fulfilling these commutation relations:

$$I_{ij}=[I_{j+1,j},I_{i,j+1}]_q\equiv q^{1/2}I_{j+1,j}I_{i,j+1}-q^{-1/2}I_{i,j+1}I_{j+1,j} \quad \text{for } i>j+1,$$

$$[I_{jk},I_{ij}]_q=I_{ik}, \quad [I_{ij},I_{ik}]_q=I_{jk}, \quad [I_{ik},I_{jk}]_q=I_{ij} \quad \text{for } i>j>k,$$

$$[I_{ij},I_{kl}]=0, \quad \text{for } i>j>k>l \text{ and } i>k>l>j,$$

$$[I_{ij},I_{kl}]_q=(q-q^{-1})(I_{jl}I_{ik}-I_{il}I_{kj}) \quad \text{for } i>k>j>l.$$

Using this definition we can formulate the following statement:

Theorem 10: $C^{(n)}(I_{ij})$, $i\in\{2,...,m\}$, $j\in\{1,...,i-1\}$ is a Casimir element of $U'_q(\mathrm{so}_m)$ when $q^n=1$.

Proof: Let us give the proof for $m=4$. One can find a more detailed proof in Ref. 8. We can consider generator I_{21} as an element of $U'_q(\mathrm{so}_3)$ subalgebra of $U'_q(\mathrm{so}_4)$ generated by two elements I_{21} and I_{32}. It implies $[C^{(n)}(I_{21}),I_{32}]=0$. The second commutator $[C^{(n)}(I_{21}),I_{43}]=0$ follows from (83). The commutators with elements I_{31}, I_{41}, and I_{42} are then trivially equal to zero because these three elements can be expressed in terms of I_{21}, I_{32}, and I_{43}. The same arguments can be used for $C^{(n)}(I_{32})$ with generator I_{41} used instead of I_{43}. □

As algebra $U_q(\mathrm{iso}_{m+1})$ can be obtained from $U'_q(\mathrm{so}_{m+1})$ by Inönu–Wigner contraction $[I_{m+1,i}\to\varepsilon I_{m+1,i}, U'_q(\mathrm{so}_m)$ fixed]; polynoms $C^{(n)}(I_{ij})$ with $I_{ij}\in U'_q(\mathrm{so}_m)$ remain Casimir operators also for $U_q(\mathrm{iso}_{m+1})$.

(ii) By doing classification of singular irreducible representations in the first nontrivial case when n is even, i.e., $q^4=1$, one can see that it is richer in comparison with cases when n is odd. The same result can be assumed in other cases $n=6,8,...$.

(iii) In Ref. 9 irreducible star representations (that is, such that $I_1^*=-I_1$ and $I_3^*=-I_3$) with diagonal generator I_3 are presented. These irreducible representations are equivalent to irreducible representations described by formulas (72)–(74) with $C=C_{\mathrm{diag}}$ [see (80)] and suitable $\nu\in\mathbb{C}$.

APPENDIX A: COMBINATORIAL IDENTITIES

Here we present basic properties of q-numbers and some combinatorial identities.

Lemma 10: Let q be not root of unity (i.e., $q^j\neq 1$ for all $j\in\mathbb{N}$).

(a) For given $\lambda\in\mathbb{C}$ we can choose $\nu\in\mathbb{C}$ such that $\lambda=[\nu]_q$, $[\nu+1]_q$, $[\nu+2]_q,\ldots$ are mutually different.

(b) if $q^\nu=i\varepsilon q^{-k/2}$ for some $k\in\mathbb{Z},\varepsilon\in\{-1,1\}$, then (1) $[\nu+k-j]_q=[\nu+j]_q$ for all $j\in\mathbb{Z}$, and (2) the equation $[\nu+j_1]_q=[\nu+j_2]_q$ for some $j_1,j_2\in\mathbb{Z},j_1\neq j_2$ implies $j_1=k-j_2$.

(c) If $[\nu]_q\notin\{i\varepsilon(q^{k/2}+q^{-k/2})/(q-q^{-1})|k=0,1,...,\varepsilon=\pm 1\}$, then q-numbers $[\nu]_q,[\nu\pm 1]_q,\ldots$ are mutually different. □

Proof: Straightforward.

Lemma 11: Let $q^n=1$ for some $n\in\mathbb{N},q^j\neq 1$ for $j\in\mathbb{N},j<n$. Then

(a) $q^\nu\notin\{i\varepsilon q^{-k/2}|k=0,1,...,n-1;\varepsilon=\pm 1\}$ implies q-numbers $[\nu]_q,[\nu+1]_q,\ldots,[\nu+n-1]_q$ are mutually different.

(b) If $q^\nu=i\varepsilon q^{-k/2}$ for some $k\in\{0,1,...,n-1\}$, $\varepsilon\in\{1,-1\}$, then

$$[\nu+j]_q=[\nu+k-j]_q, \quad j=0,1,...,[k/2],$$

$$[\nu+k+j]_q=[\nu+n-j]_q, \quad j=1,...,[(n-k)/2],$$

and no other equalities of the numbers $[\nu]_q,\ldots,[\nu+n-1]_q$ can be found.

Proof: Straightforward. □

Lemma 12: Some useful combinatorial identities. The following formulas hold (we take $0^0=1$):

(1) Let $N\in\mathbb{N}$, $0\leqq H\leqq[(N-1)/2]$, $0\leqq M\leqq[(N-1)/2]$. Let us denote $N'=N \bmod 2$, i.e., $N'=1$ when N is odd and zero otherwise. Then

$$\sum_{t=0}^{[(N-1)/2]}\binom{N}{2t+1}\binom{\left[\frac{N-1}{2}\right]-t}{\left[\frac{N-1}{2}\right]-H}\binom{t}{M}$$
$$=4^{H-M}\binom{H}{M}(N-2H(1-N'))\frac{(2[N/2])!([N/2]+H-M)!([N/2]-M)!}{[N/2]!(2H+1)!(2[N/2]-2M)!([N/2]-H)!}. \tag{A1}$$

(2) Let $n\in\mathbb{N}$, $0\leqq c\leqq[(n-1)/2]$, $0\leqq d\leqq[(n-1)/2]$. Put $n'=n \bmod 2$. Then

$$\sum_{j=0}^{d}\binom{n-j}{j}\frac{2d-2j+1+(n-2d-1)^{n'}}{n-j}$$
$$\times\binom{\left[\frac{n-1}{2}\right]-d}{c-j}\cdot\frac{(2[n/2]-2j)!(n-1-c-d)!([n/2]-c)!}{([n/2]-j)!(d-j+1-n')!(2[n/2]-2c)!(n-2d+n'-1)!}$$
$$=\frac{\binom{n-1-d}{d}\binom{n-1-c}{c}}{(n/2)^{1-n'}(n-2d)^{n'}}. \tag{A2}$$

Proof: We prove both formulas for odd and even N (resp. n) separately.

(1) Let N be even, $N=2K$, $K\in N$. Then we have

$$\sum_{t=0}^{K-1}\binom{2K}{2t+1}\binom{K-1-t}{K-1-H}\binom{t}{M}=\frac{\mathrm{d}^M}{\mathrm{d}z^M}\left(\frac{1}{M!}\sum_{t=0}^{K-1}\binom{2K}{2t+1}\binom{K-1-t}{K-1-H}z^t\right)\Bigg|_{z=1}.$$

To compute the inner sum we express it in terms of hypergeometric functions and use M times formula [see Ref. 5, (5.106)]

$$\frac{\mathrm{d}}{\mathrm{d}z}F(a,b;c;z)=\frac{ab}{c}F(a+1,b+1;c+1;z). \tag{A3}$$

Then, using formula [see Ref. 5, (5.92)]

$$F(a,-n;c;1)=\frac{\Gamma(c-a+n)\Gamma(c)}{\Gamma(c-a)\Gamma(c+n)}, \quad n\in\mathbb{N}\cup\{0\}, \quad \mathrm{Re}(c-a)\geqq 0, \quad \mathrm{Re}\,c\geqq 0, \tag{A4}$$

we find the closed form of the sum:

$$\sum_{t=0}^{K-1}\binom{2K}{2t+1}\binom{K-1-t}{K-1-H}\binom{t}{M}=4^{H-M}\binom{H}{M}(2K-2H)\frac{(2K)!(K+H-M)!(K-M)!}{K!(2H+1)!(2K-2M)!(K-H)!},$$

$$K\in\mathbb{N},\quad 0\leqq M\leqq K,\quad 0\leqq H\leqq K.$$

We use exactly the same approach to find the closed form for N odd, $N=2K-1$:

$$\sum_{t=0}^{K-1}\binom{2K-1}{2t+1}\binom{K-1-t}{K-1-H}\binom{t}{M}$$

$$=4^{H-M}\binom{H}{M}(2K-1)\frac{(2K-2)!(K+H-M-1)!(K-M-1)!}{(K-1)!(2H+1)!(2K-2M-2)!(K-1-H)!},$$

$$K\in\mathbb{N},\quad 0\leqq M\leqq K-1,\quad 0\leqq H\leqq K-1.$$

(2) Let n be even, $n=2k$. First express the sum in terms of hypergeometric functions and then use the formula [see Ref. 5, (5.97)]:

$$F(a,b,-n;c,a+b-c-n+1;1)=\frac{\Gamma(c-a+n)\Gamma(c-b+n)\Gamma(c)\Gamma(c-a-b)}{\Gamma(c-a)\Gamma(c-b)\Gamma(c+n)\Gamma(c-a-b+n)},\tag{A5}$$

$$n\in\mathbb{N}\cup\{0\},\quad \mathrm{Re}\,c\geqq 0,\quad \mathrm{Re}\,(c-a)\geqq 0,\quad \mathrm{Re}(c-b)\geqq 0,\quad \mathrm{Re}\,(c-a-b)\geqq 0$$

to obtain the closed form:

$$\sum_{j=0}^{d}\binom{2k-j}{j}\frac{2d+2-2j}{2k-j}\binom{k-1-d}{c-j}\frac{(2k-2j)!(2k-1-c-d)!(k-c)!}{(k-j)!(1+d-j)!(2k-2c)!(2k-2d-1)!}$$

$$=\frac{1}{k}\binom{2k-1-d}{d}\binom{2k-1-c}{d},$$

$$k\in\mathbb{N},\quad 0\leqq c\leqq k-1,\quad 0\leqq d\leqq k-1.$$

For odd $n=2k-1$ we have

$$\sum_{j=0}^{d}\binom{2k-1-j}{j}\frac{2k-2j-1}{2k-j-1}\binom{k-1-d}{c-j}\frac{(2k-2j-2)!(2k-2-c-d)!(k-c-1)!}{(k-j-1)!(d-j)!(2k-2c-2)!(2k-2d-1)!}$$

$$=\frac{1}{2k-2d-1}\binom{2k-2-d}{d}\binom{2k-2-c}{c},\quad k\in\mathbb{N},\quad 0\leqq c\leqq k-1,\quad 0\leqq d\leqq k-1.$$

Composing the results we obtain the required formulas. □

APPENDIX B: PROOF OF THE THEOREM 2

Here we present necessary theorems and lemmas used in the proof of Theorem 2.

Lemma 13: Let $n\in\mathbb{N}$. Then

$$I_3I_1^n=p_n(I_1)I_2+q_n(I_1)I_3,$$

where

$$p_n(x)=q^{-1/2}\left(\frac{x(q+q^{-1})}{2}\right)^{n-1}\sum_{t=0}^{[(n-1)/2]}\binom{n}{2t+1}\left(\left(\frac{q-q^{-1}}{q+q^{-1}}\right)^2-\left(\frac{2}{x(q+q^{-})}\right)^2\right)^t,\tag{B1}$$

$$q_n(x)=-q^{1/2}\frac{x(q-q^{-1})}{2}p_n(x)+\left(\frac{x(q+q^{-1})}{2}\right)^{n}\sum_{t=0}^{[n/2]}\binom{n}{2t}\left(\left(\frac{q-q^{-1}}{q+q^{-1}}\right)^2-\left(\frac{2}{x(q+q^{-})}\right)^2\right)^t. \tag{B2}$$

Furthermore, we have

$$q_n(x)=-q^{1/2}\frac{x(q+q^{-1})}{2}\left(\frac{q-q^{-1}}{q+q^{-1}}+\sqrt{\left(\frac{q-q^{-1}}{q+q^{-1}}\right)^2-\left(\frac{2}{x(q+q^{-1})}\right)^2}\right)p_n(x)$$
$$+\left(\frac{x(q+q^{-1})}{2}\right)^{n}\left(1+\sqrt{\left(\frac{q-q^{-1}}{q+q^{-1}}\right)^2-\left(\frac{2}{x(q+q^{-1})}\right)^2}\right)^{n}. \tag{B3}$$

Proof: Equations (1)–(3) give us system of difference equations

$$p_{n+1}(x)=qxp_n(x)+q^{-1/2}q_n(x),$$

$$q_{n+1}(x)=q^{1/2}p_n(x)+q^{-1}xq_n(x),$$

which can be separated to the form

$$p_{n+2}(x)=(q+q^{-1})xp_{n+1}(x)-(x^2+1)p_n(x), \tag{B4}$$

$$q_{n+2}(x)=(q+q^{-1})xq_{n+1}(x)-(x^2+1)q_n(x). \tag{B5}$$

The initial conditions are

$$p_1(x)=q^{-1/2},\quad p_2(x)=(q^{1/2}+q^{-3/2})x,\quad q_1(x)=q^{-1}x,\quad q_2(x)=q^{-2}x^2-1.$$

We find the solution of (B4) and (B5) in the form $q_n(x)=C_1\lambda_1^n+C_2\lambda_2^n$ (and similarly for p_n) where C_i are constants easily derived from initial conditions and λ_i are roots of characteristic polynomial

$$\lambda^2-(q+q^{-1})x\lambda+(x^2+1)=0.$$

Note 13: Let us remark that formulas (B1) [resp. (B2)] are of course easily summable using formulas

$$\sum_{t=0}^{[(n-1)/2]}\binom{n}{2t+1}z^t=\frac{1}{2}z^{-1/2}((1+z^{1/2})^n-(1-z^{1/2})^n),\quad \sum_{t=0}^{[n/2]}\binom{n}{2t}z^t=\frac{1}{2}((1+z^{1/2})^n+(1-z^{1/2})^n).$$

Lemma 14: Let us have some irreducible representation of $U_q'(\mathrm{so}_3)$, let $\eta\in\{-1,1\}$, $q^{\xi}=i\eta$, $0\neq v_0\in\mathrm{Ker}(I_3+i[\xi]_q)$. Define vectors

$$v_{j+1}:=O_{\xi+j}v_j,\quad j\geqq 0. \tag{B6}$$

Then for each $s,1\geqq s<s_q+2$, there exist unique complex constants (depending on q and C) $a_s^{(s)},a_{s-2}^{(s)},a_{s-4}^{(s)},\ldots,a_2^{(s)}$ (resp. $a_1^{(s)}$ if s is odd) and $b_s^{(s)},b_{s-2}^{(s)},\ldots,b_0^{(s)}$ (resp $b_1^{(s)}$) such that

$$I_3I_1^sv_0=a_s^{(s)}I_1^sv_0+a_{s-2}^{(s)}I_1^{s-2}v_0+a_{s-4}^{(s)}I_1^{s-4}v_0+\cdots+\cdots+b_{s-4}^{(s)}v_{s-4}+b_{s-2}^{(s)}v_{s-2}+b_s^{(s)}v_s, \tag{B7}$$

and for each $s,1\geqq s<s_q+1$, there exist constants $c_{s+1}^{(s)},c_{s-1}^{(s)},c_{s-3}^{(s)},\ldots,c_1^{(s)}$ (resp. $c_2^{(s)}$ if s is odd) and $d_{s+1}^{(s)},d_{s-1}^{(s)},\ldots,d_1^{(s)}$ (resp. $d_0^{(s)}$) such that

$$I_2I_1^sv_0=c_{s+1}^{(s)}I_1^{s+1}v_0+c_{s-1}^{(s)}I_1^{s-1}v_0+c_{s-3}^{(s)}I_1^{s-3}v_0+\cdots+\cdots+d_{s-3}^{(s)}v_{s-3}+d_{s-1}^{(s)}v_{s-1}+d_{s+1}^{(s)}v_{s+1}, \tag{B8}$$

where $s_q=+\infty$ if q is not the root of unity, $s_q=n-1$ if $q^n=1$ and n is odd, and $s_q=n/2-1$ if $q^n=1$ and n is even.

Furthermore, we have

$$a_s^{(s)}=\eta\frac{q^s+q^{-s}}{q-q^{-1}},\quad c_{s+1}^{(s)}=\eta q^{s+1/2},\quad d_{s+1}^{(s)}=-i\left(\frac{-i\eta q^{1/2}}{q-q^{-1}}\right)^s([s]_q!)^{-1}, \tag{B9}$$

$$b_s^{(s)}=\eta\left(\frac{-i\eta q^{-1/2}}{q-q^{-1}}\right)^s([s-1]_q!)^{-1}(q^s-q^{-s}),\quad c_{s-1}^{(s)}=\frac{-\eta q^{-1/2}}{q-q^{-1}}([s-1]_q+q^s(1+s+\tilde{D}_1)), \tag{B10}$$

$$a_{s-2}^{(s)}=\frac{-\eta q^{-1}}{(q-q^{-1})^2}((q^s-q^{-s})\tilde{D}_1+sq(q^{s-1}-q^{-s+1})), \tag{B11}$$

$$b_0^{(2)}=\frac{-\eta(-8+Cq^{-1}(q-q^{-1})^2(q+q^{-1}))}{(q-q^{-1})^3}, \tag{B12}$$

$$b_{s-2}^{(s)}=\eta\left(\frac{-i\eta q^{-1/2}}{q-q^{-1}}\right)^s\frac{[s-2]_q^2}{[s-1]_q!}\left((q^s-q^{-s})C+\frac{q^{1-s}}{(q-q^{-1})}F_s\right),\quad s>2, \tag{B13}$$

$$d_0^{(1)}=\frac{-\eta(2-6q^2+Cq^2(q-q^{-1})^2)}{q^{3/2}(q-q^{-1})^3}, \tag{B14}$$

$$d_{s-1}^{(s)}=\frac{b_{s-1}^{(s-1)}}{(q-q^{-1})(q^s-q^{-s})}\left(-Cq^{s-1/2}+\frac{q^{1/2}}{(q-q^{-1})^2(q^{s-1}-q^{-s+1})}G_s\right),\quad s>1, \tag{B15}$$

$$\tilde{D}_1:=C-q\frac{2(q+q^{-1})}{(q-q^{-1})^2},$$

$$F_s:=-sq^s(q-q^{-1})(q^{s-1}-q^{-s+1})-2q^s[s]_q(q+q^{-1}),$$

$$G_s:=-s-sq^{-4}+(2s-1)q^{-2}-3q^2+(2+s+sq^{-4}-2(s-1)q^{-2})q^{2s}+q^{-2s}(q-q^{-1})^2,$$

where we denote $[j]_q!:=[j]_q\cdot[j-1]_q\cdot\cdots\cdot[1]_q$.

Proof: From the definition of vectors v_j and from (12) we have

$$O_{\xi+j}v_j=v_{j+1},\quad j\geqq 0,$$

$$R_{\xi+j}v_j=R_{\xi+j}O_{\xi+j-1}v_{j-1}=-(C+q[\xi+j-1]_q[\xi+j]_q)v_{j-1},\quad j\geqq 1. \tag{B16}$$

Since $O_{\xi+j}=iI_2-i\eta q^{1/2-j}I_1$ and $R_{\xi+j}=iI_2-i\eta q^{j+1/2}I_1$ we can find vectors I_1v_j and I_2v_j, $j=1,\ldots,s_q$ from these equations:

$$I_1v_j=\frac{-i\eta q^{-1/2}}{q^j-q^{-j}}(\tilde{D}_jv_{j-1}+v_{j+1}),\quad I_2v_j=\frac{-i}{q^j-q^{-j}}(\tilde{D}_jq^{-j}v_{j-1}+q^jv_{j+1}),$$

$$\tilde{D}_j:=C-q\frac{(q^{j-1}+q^{-j+1})(q^j+q^{-j})}{(q-q^{-1})^2}.$$

Lemma can be proved by induction using these relations. □

Note 14: Consider all coefficients from Lemma 14 as functions of complex variable $C\in\mathbb{C}$ (q fixed):

$$a_j^{(i)}=a_j^{(i)}(C),\quad b_j^{(i)}=b_j^{(i)}(C),\ldots,\text{etc.}$$

Then it can be easily proved by induction that for each $C_0\in\mathbb{C}$ we have

$$\lim_{C\to C_0} a_j^{(i)}(C)=a_j^{(i)}(C_0),\ldots,$$

i.e., that they are continuous functions on $\mathbb{C}$.

Corollary 5: Let us assume the same as in Lemma 14. Then for all $s\in\{1,...,s_q+1\}$ there exist unique complex constants (depending on q and C) $\hat{a}_{s-4}^{(s)},\ldots,\hat{a}_2^{(s)}$ (or $\hat{a}_1^{(s)}$ if s is odd) and $\hat{b}_{s-4}^{(s)},\hat{b}_{s-6}^{(s)},\ldots,\hat{b}_0^{(s)}$ (or $\hat{b}_1^{(s)}$) such that

$$\left(I_3-\eta\frac{q^s+q^{-s}}{q-q^{-1}}\right)w_s=b_s^{(s)}v_s, \tag{B17}$$

where

$$w_2=I_1^2v_0+\frac{\eta b_0^{(2)}}{q-q^{-1}}v_0,$$

$$w_s=I_1^sv_0+\frac{\eta a_{s-2}^{(s)}}{q^{s-1}-q^{-s+1}}I_1^{s-2}v_0+\hat{a}_{s-4}^{(s)}I_1^{s-4}v_0+\cdots+\hat{b}_{s-4}^{(s)}v_{s-4}+\frac{2\eta b_s^{(s)}[s-2]_q^2}{q^{s-1}-q^{-s+1}}\tilde{D}_1v_{s-2},$$

$$s>2. \tag{B18}$$

Proof: Assume $s>2$. Taking (B7) for s and $s-2$,

$$(I_3-a_s^{(s)})(I_1^sv_0)=a_{s-2}^{(s)}I_1^{s-2}v_0+a_{s-4}^{(s)}I_1^{s-4}v_0+\cdots+b_{s-2}^{(s)}v_{s-2}+b_s^{(s)}v_s,$$

$$(I_3-a_{s-2}^{(s-2)})(I_1^{s-2}v_0)=a_{s-4}^{(s-2)}I_1^{s-4}v_0+\cdots+b_{s-2}^{(s-2)}v_{s-2},$$

we obtain

$$(I_3-a_s^{(s)})\left(I_1^sv_0+\frac{a_{s-2}^{(s)}}{a_{s-2}^{(s-2)}-a_s^{(s)}}I_1^{s-2}v_0-\frac{b_{s-2}^{(s)}(a_{s-2}^{(s-2)}-a_s^{(s)})-a_{s-2}^{(s)}b_{s-2}^{(s-2)}}{(a_{s-2}^{(s-2)}-a_s^{(s)})^2}v_{s-2}\right)=w_{s-4}+b_s^{(s)}v_s,$$

where $w_{s-4}\in W_{s-4}\equiv\mathbb{C}\{I_1^{s-4}v_0,I_1^{s-6}v_0,\ldots,v_{s-6},v_{s-4}\}_{\text{lin}}$.

Using (B7) for $s-4$, $s-6$, ..., 2 (or 1 if s is odd) we easily show that

$$w_{s-4}=(I_3-a_s^{(s)})w'_{s-4}$$

for some $w_{s-4}^l\in W_{s-4}$. □

Note 15: As in Note 14 coefficients $\hat{a}_j^{(i)},\hat{b}_j^{(i)}$ are continuous functions of $C\in\mathbb{C}$.

Lemma 15: Same assumptions as in Lemma 14. Let vectors $v_0,v_1,\ldots$ are nonzero and $v_m=0$ for some $m\in\{0,...,s_q\}$. Then the vectors $v_0,\ldots,v_{m-1}$ are linear-independent eigenvectors of I_3 with different eigenvalues. Equation (B17) shows that $w_1,\ldots,w_{m-1}$ [see (B18)] are their principal vectors to the eigenvalues $\eta(q^s+q^{-s})/(q-q^{-1}),s\in\{1,...,m-1\}$. From (B17) we also have that if $w_m\neq0$, then w_m is an eigenvector of I_3 with eigenvalue $\eta(q^m+q^{-m})/(q-q^{-1})$.

Proof: Clear.

Lemma 16: Let q not be a root of unity. Let us have some finite-dimensional irreducible representation of $U_q'(\text{so}_3)$, and let $\eta\in\{-1,1\}$, $q^\xi=i\eta$, $\text{Ker}(I_3+i[\xi]_q)\neq\{0\}$. Then for each $v_0\in\text{Ker}(I_3+i[\xi]_q)$ there exists $m\in\mathbb{N}$ such that $w_m=0$ [for definition of w_j, see (B18)].

Proof: For each $v_0\in\text{Ker}(I_3+i[\xi]_q)$ consider (B6). Since the representation is finite-dimensional and the vectors $v_0,v_1,\ldots$ belong to different eigenvalues, there exists $m(v_0)\in\mathbb{N}$ such

that $v_{m(v_0)-1}\neq 0$ and $v_{m(v_0)}=0$. Since $v_{m(v_0)}\equiv O_{\xi+m(v_0)-1}v_{m(v_0)-1}$, (12) fixes the value of the Casimir operator: $C+q[\xi+m(v_0)-1]_q[\xi+m(v_0)]_q=0$. We will show that $w_{m\equiv m(v_0)}=0$.

Assume, on the contrary, that $w_m\neq 0$. Then w_m is eigenvector of I_3 with eigenvalue $\eta(q^m+q^{-m})/(q-q^{-1})$. Consider the vectors

$$\tilde{v}_m\equiv w_m,\quad \tilde{v}_{m+1}=O_{\xi+m}\tilde{v}_m,\quad \ldots,\quad \tilde{v}_{m+k}=O_{\xi+m+k-1}\tilde{v}_{\xi+m+k-1},\quad \ldots.$$

All these vectors are nonzero {in the opposite case, i.e., if $\tilde{v}_{m+k}=0$, (12) would give for the Casimir operator another value $C+q[\xi+m+k-1]_q[\xi+m+k]_q=0$} and therefore eigenvectors of operator I_3 with mutually different eigenvalues. It is in contradiction with assumed finite dimension of representation. □

Proof of Theorem 2: Let us assume the opposite case: let ν fulfill the equation $q^\nu=i\varepsilon$ for some $\varepsilon\in\{-1,1\}$ and let $x_0\in V$ such that $I_3x_0=-i[\nu]_qx_0=2\varepsilon(q-q^{-1})^{-1}x_0$. Let us define vectors

$$x_{j+1}:=O_{\nu+j}x_j,\quad j\geqq 0. \tag{B19}$$

Then from Lemma 16 ($v_i\to x_i$) it follows that there exists $m\in\mathbb{N}$ such that $w_m=0$ [see (B18)] from which we have

$$I_1^mx_0=-\frac{\eta\alpha_{m-2}^{(m)}}{q^{m-1}-q^{-m+1}}I_1^{m-2}x_0-\hat{a}_{m-4}^{(m)}I_1^{m-4}v_0-\cdots-\hat{b}_{m-4}^{(m)}v_{m-4}-\frac{2\eta b_m^{(m)}[m-2]_q^2}{q^{m-1}-q^{-m+1}}\tilde{D}_1x_{m-2}.$$

Applying $q^{1/2}I_1$ to Eq. (B8) (with $s\to m-1, v_i\to x_i$) and subtracting the $q^{-1/2}I_2$-multiple of this equation we obtain vector $I_3I_1^{m-1}x_0$ [see (1)]. Comparing with Eq. (B7), especially the coefficient by vector x_{m-1}, we obtain the condition which can be fulfilled only if q is a root of unity. □

Lemma 17: (a) Let $q^{2m}=1$, $q^j\neq 1$ for $j<2m$ and $\varepsilon\in\{-1,1\}$. Then

$$\begin{aligned}\sum_{j=0}^{m}\binom{2m-j}{j}\frac{2m}{2m-j}\frac{(-1)^j}{(q-q^{-1})^{2j}}x^{2m-2j}-\frac{2}{(q-q^{-1})^{2m}}&\\ =\prod_{j=0}^{2m-1}\left(x-\varepsilon\frac{q^j+q^{-j}}{q-q^{-1}}\right)&\\ =\left(x-\frac{2\varepsilon}{q-q^{-1}}\right)\left(x-\frac{-2\varepsilon}{q-q^{-1}}\right)\prod_{j=1}^{m-1}\left(x-\varepsilon\frac{q^j+q^{-j}}{q-q^{-1}}\right)^2.&\end{aligned}$$

(b) Let $q^{2m+1}=1$, $q^j\neq 1$ for $j<2m+1$ and $\varepsilon\in\{-1,1\}$. Put $q^{m+1/2}\equiv\tilde{\varepsilon}$. Then

$$\begin{aligned}\sum_{j=0}^{m}\binom{2m+1-j}{j}\frac{2m+1}{2m+1-j}\frac{(-1)^j}{(q-q^{-1})^{2j}}x^{2m+1-2j}-\frac{2\varepsilon\tilde{\varepsilon}}{(q-q^{-1})^{2m+1}}&\\ =\left(x-\frac{2\varepsilon\tilde{\varepsilon}}{q-q^{-1}}\right)\prod_{j=0}^{m-1}\left(x-\varepsilon\frac{q^{1/2+j}+q^{-1/2-j}}{q-q^{-1}}\right)^2.&\end{aligned}$$

Proof: (a) We will use the formula (7). Let

$$p(x)=\sum_{j=0}^{m}\binom{2m-j}{j}\frac{2m}{2m-j}\frac{(-1)^j}{(q-q^{-1})^{2j}}x^{2m-2j}-\frac{2}{(q-q^{-1})^{2m}}. \tag{B20}$$

Then we have directly $p(\varepsilon(q^j+q^{-j})/(q-q^{-1}))=0$. It means that numbers $\varepsilon(q^j+q^{-j})/(q-q^{-1}), j\in\{0,\ldots,m\}$, are roots of polynomial p. However, not all of these roots are mutually different:

$$\varepsilon\frac{q^k+q^{-k}}{q-q^{-1}}=\varepsilon\frac{q^j+q^{-j}}{q-q^{-1}}\Leftrightarrow k+j=2m,$$

so we have to prove that p' (the first derivative of the polynomial p) has as roots the numbers $\varepsilon(q^j+q^{-j})/(q-q^{-1}), j\in\{1,...,m-1\}$. If $\varepsilon(q^j+q^{-j})/(q-q^{-1})=0$ we see immediately from the left-hand side of (7) that $p'(0)=0$. Otherwise we compute $p'(x)$ by differentiating the right-hand side of (7) and see that $p'(\varepsilon(q^j+q^{-j})/(q-q^{-1}))=0$.

Thus the roots $\varepsilon(q^k+q^{-k})/(q-q^{-1}), k\in\{1,...,m-1\}$, have multiplicity 2 and the theorem holds.

Formula (b) is proved similarly. □

Improved results on convergence of the Magnus expansion are reported. Consequences are discussed for exponential perturbation theory, construction of numerical methods, control theory or, in general, for problems where time-ordered integrals are involved. © *2001 American Institute of Physics.*

I. INTRODUCTION

Consider the linear differential equation,

$$\frac{\mathrm{d}}{\mathrm{d}t}Z(t)=A(t)Z(t), \quad Z(0)=I, \tag{1}$$

where $A(t)$ is a bounded family of operators in some Banach space equipped with the norm $\|\cdot\|$. Time-ordered integrals are central when dealing with such initial value problems. One instance in physics is provided by the so-called Dyson time-ordered exponential widely used in both quantum mechanics and high energy physics. Most systems of interest have some small parameter, ϵ, such that $Z'=\epsilon A(t)Z$, and the traditional way of approximating the solution of these is some perturbative expansion of the solution $Z(t)$ in powers of ϵ.

Less known, and used, are nonlinear methods of approximation of linear systems. At first sight it may sound complicated to treat a linear system by nonlinear means, but in some cases such an approach has some clear advantages over the standard approaches. A particular consequence is that certain constants of motion and other geometric features of the exact solution can be preserved exactly in approximate solutions.

One such approach which has become increasingly more popular is the Magnus expansion[1] whose applications are expanding continuously, and accordingly it has been reinvented an extraordinary number of times with new names.[2–7] Sometimes referred to as *exponential perturbation theory* in quantum mechanics,[8] *exponential Lie series associated with the Chen–Fliess expansion* in control theory,[2,4,9] or just *Lie integral*,[6] the Magnus expansion has been found useful in a large variety of problems. A formulation of the expansion in terms of Lie operators can also be applied to nonlinear systems of ODEs.[5,10] Even more general, it has been applied in the analysis of noncommutative stochastic differential equations.[11–13] Examples of a different nature are encountered in numerical analysis with the development of geometric integration.[14,15] It has also been used in a variety of time-dependent problems in physics: infrared divergences in QED,[16] spectral line broadening,[17] high-resolution NMR spectroscopy in terms of average Hamiltonians,[18–20] Coulomb excitations in nuclei,[21] multi-photon excitation of molecules,[22] multilevel Landau–Zener effect[23] and neutrino oscillations in matter,[24] to quote just a few. Recently the Magnus expansion has been used as a tool to show the exponential smallness of effects in relation to conservative numerical integration algorithms. In that case the radius of convergence for a bounded operator

a)Electronic mail: oteo@uv.es

equation relates directly with the smallness of the unremovable remainder in the averaging procedure. The crucial property of the Magnus expansion is that truncations provide asymptotic approximations to differential equations.

In essence, Magnus expansion yields the solution of the linear operator equation (1) in exponential form,

$$Z(t)=\exp[\Omega(t)]Z(0). \tag{2}$$

It is now worth mentioning two ways of viewing (2) that motivate most of the applications of the Magnus expansion. First, (2) gives the solution of (1) at time t. Second, and more importantly, one can view (2) as the solution of the differential equation,

$$\frac{\mathrm{d}}{\mathrm{d}s}X(s)=\Omega(t)X(s),\quad X(0)=Z(0), \tag{3}$$

at $s=1$. The latter way can be utilized as a means to *average* out rapid oscillations in $A(t)$ making the problem more suited for, e.g., numerical calculations. Such approaches have led to particularly efficient methods for stochastic differential equations.[11]

Of course, if $A(t)$ commutes with itself at different times then the solution is well known, and $\Omega(t)$ collapses into $\int_0^t A(s)\mathrm{d}s$. Otherwise, the Magnus operator $\Omega(t)$ can be obtained by solving[1,25]

$$\dot{\Omega}=\frac{\mathrm{ad}_\Omega}{\exp(\mathrm{ad}_\Omega)-1}A=\sum_{j=0}^{\infty}\frac{B_j}{j!}\mathrm{ad}_\Omega^j A,\quad \mathrm{ad}_\Omega^0 A=A, \tag{4}$$

as a series expansion,

$$\Omega(t)=\sum_{k=1}^{\infty}\Omega_k(t),\quad \Omega_k(0)=0. \tag{5}$$

Equation (4) is written in terms of the adjoint operator $\mathrm{ad}_\Omega A\equiv[\Omega,A]\equiv\Omega A-A\Omega$, and Bernoulli numbers[26] $\{B_j\}$. Clearly this construction leads to Ω_k's that are elements in the Lie algebra determined by the family $A(t)$. More importantly, an approximate solution $\tilde{\Omega}(t)$ residing in the same Lie algebra is obtained by truncating (5). Magnus approximations, $\tilde{\Omega}(t)=\Sigma_{k=1}^{n}\Omega_k(t)$, are then written in terms of multiple integrals of nested commutators of A evaluated at different times. Thus, replacing the linear equation (1) with the nonlinear one (4) is the crux of this approach, and leads directly to the aforementioned favorable properties for the approximate solution $\tilde{Z}(t)=\exp[\tilde{\Omega}(t)]$, at the cost of the finite radius of convergence of the expansion which has caused problems in some applications.[27–30] The re-summation of the fundamental solution is also concomitant with the amount of work needed to obtain a given order of approximation. It is therefore central to understand as fully as possible the causes of the observed divergences, and give conditions when one safely can apply the Magnus expansion to obtain meaningful approximations.

In the present paper we present results on the convergence properties of the Magnus expansion on which two studies may be found in recent issues of this journal.[7,31] Due to the many possible ways of writing down the expansion, it becomes central in a convergence analysis to find a form of the expansion that is simple to state and has as few redundancies or nontrivial cancellations as possible. The expansion found by solving (4) iteratively does not have a structure malleable enough for a very good bound. Explicitly stated the question we address is therefore the following: *For a given $A(t)$ what is the maximum value of t such that Magnus series (5) converges*?

In the original paper by Magnus no explicit result for convergence in terms of $A(t)$ is stated, though it is mentioned that the expansion converges provided t is sufficiently small. Some lower

bounds for the absolute convergence of Magnus expansion may be found in the literature.[8,14,31] The largest one to date[32,33] states that the convergence is guaranteed provided

$$\int_0^t \|A(s)\| \mathrm{d}s \leqslant 1.086869. \tag{6}$$

Since the goal of providing the bound is to explain practical applications of Magnus series we choose to continue to work with norms of A in our statements, even though more refined bounds involving eigenvalues of Ω could tighten our results somewhat. It is noteworthy that the result above has been obtained in two different ways albeit both strategies are based on the Magnus operator equation (4). Arguably one may deduce from this coincidence that the bounding procedures underpinning both procedures has reached some natural barrier.

In the present work we develop a new method showing that as a matter of fact the domain of convergence of Magnus expansion can be further enlarged. It is the Lie algebraic nature of (4) that gives rise to complications, mainly due to the rather intricate nature of Lie algebra bases. More specifically, it is not clear at this moment how to simplify Ω_k generated by (4) to a form amenable to good bounds due to the complexity of the algebra of iterated integrals and commutators.[34]

We shall resort to a form of the expansion that avoids dealing explicitly with commutators since the bound $\|[\Omega,A]\| \leqslant 2\|\Omega\|\|A\|$ induces a geometrically growing factor when applied to nested commutators, which together with the complications of Lie algebra bases is hard to reduce. Certainly the absence of multiple commutators might surprise the reader acquainted with the subject. However from Dynkin's theorem[35] the nested commutator structure is readily recovered. We shall base our computations on a particular combinatorial approach to Magnus series given in Refs. 3 and 36, later rediscovered in Ref. 5. In Sec. II we collect these formulas and outline our approach for estimating the convergence domain. Furthermore the material related to absolute convergence of the series is developed. Section II A contains a proof of the convergence result, while Sec. II B contains numerical evidence of the sharpness of the bound in Sec. II A. The final Sec. III contains our conclusions.

II. THE METHOD

The usual ways of solving (4) with (5) results in the expressions

$$\Omega_1 = \int_0^t \mathrm{d}t_1 A(t_1), \quad \Omega_2 = \frac{1}{2}\int_0^t \mathrm{d}t_1 \int_0^{t_1} \mathrm{d}t_2 [A(t_1),A(t_2)], \tag{7}$$

$$\Omega_3 = \frac{1}{4}\int_0^t \left[\int_0^\kappa \left[\int_0^\xi A(\nu)\,d\nu, A(\xi) \right] d\xi, A(\kappa) \right] d\kappa + \frac{1}{12}\int_0^t \left[\int_0^\kappa A(\nu)\,d\nu, \left[\int_0^\kappa A(\xi)\,d\xi, A(\kappa) \right] \right] d\kappa, \tag{8}$$

$$= \frac{1}{6}\int_0^t \mathrm{d}t_1 \int_0^{t_1} \mathrm{d}t_2 \int_0^{t_2} \mathrm{d}t_3 ([A(t_1),[A(t_2),A(t_3)]] + [A(t_3),[A(t_2),A(t_1)]]). \tag{9}$$

Higher order terms may be obtained, for instance, from either recurrence relations[37] or binary trees techniques.[14] Equations (7)–(9) illustrate the structure of nested commutators and time-ordered integrals in Ω_n of increasing complexity, as well as the nonuniqueness of explicit formulas due to Jacobi identity.

Mielnik and Plebański[36] devised an algorithm for direct formal construction of $\Sigma_{k=1}^{\infty}\Omega_k$. According to them,

$$\Omega(t) = \sum_{n=1}^{\infty} \int_0^t \cdots \int_0^t \mathrm{d}t_n \cdots \mathrm{d}t_1 L_n(t_n,\cdots,t_1) A(t_n)\cdots A(t_1). \tag{10}$$

The point to notice is that $L_n(t_n,\ldots,t_1)$ admits the representation

$$L_n(t_n,\ldots,t_1)=\frac{\Theta_n!(n-1-\Theta_n)!}{n!}(-1)^{n-1-\Theta_n}, \tag{11}$$

with the definition $\Theta_n:=\theta_{n-1,n-2}+\cdots+\theta_{2,1}$, where the step function $\theta_{b,a}=1$ if $t_b>t_a$ and 0 otherwise.

Accordingly we have $n!$ sectors defined by inequalities $t_{i_n}>t_{i_{n-1}}\cdots>t_{i_1}$. For the proper chronological sector $(i_n=n,i_{n-1}=n-1,\ldots,i_1=1)$ we get the maximal value $\Theta_n=n-1$, while the anti-chronological sector $(i_n=1,i_{n-1}=2,\ldots,i_1=n)$ gives the minimal $\Theta_n=0$. For mixed sectors $0<\Theta_n<n-1$. Thus, the main result of Refs. 3, 36 is that

$$\Omega(t)=\sum_{n=1}^{\infty}\int_0^t\cdots\int_0^t \mathrm{d}t_n\cdots\mathrm{d}t_1\frac{\Theta_n!(n-1-\Theta_n)!}{n!}(-1)^{n-1-\Theta_n}A(t_n)\cdots A(t_1). \tag{12}$$

Every monomial $A(t_n)\cdots A(t_1)$ in (12) may be replaced by the fully nested commutator $(1/n)\,[A(t_n),\ldots,[A(t_2),A(t_1)]]$ in order to recover the commutator structure[35] giving an expansion in a Lie algebra. However, as already pointed out above, such a structure will be avoided in the following and we will stay with (12).

Now, consider

$$\left\|\int_0^t\cdots\int_0^t \mathrm{d}t_n\cdots\mathrm{d}t_1 L_n A(t_n)\cdots A(t_1)\right\|\leqslant(\|A\|^*)^n\int_0^t\cdots\int_0^t \mathrm{d}t_n\cdots\mathrm{d}t_1|L_n|, \tag{13}$$

where $\|A\|^*=\sup_{s\in[0,t]}\|A(s)\|$. Hence the convergence of the series (12) follows from an appropriate bound on $\int_0^t\cdots\int_0^t \mathrm{d}t_n\cdots\mathrm{d}t_1|L_n|$. Observe that L_n has the same constant value on sections of the n-cube $[0,t]^n$ corresponding to constant $\Theta_n=:k$. Thus by computing the fraction of the volume of $[0,1]^n$ corresponding to a given k $(0\leqslant k\leqslant n-1)$ we arrive at a bound for the terms of the expansion. Denote this fraction V_n^k; then

$$\|\Omega_n\|\leqslant(t\|A\|^*)^n\sum_{k=0}^{n-1}V_n^k\frac{k!(n-1-k)!}{n!}, \tag{14}$$

after using (12) and the fact that the fraction of the n-cube $[0,t]^n$ scales as t^n times the same fraction of the n-cube $[0,1]^n$. Now to compute the fraction V_n^k we consider the representation

$$V_n^k=\sum_{k_1+k_2+\cdots+k_{n-1}=k}\int_0^1\int_{\gamma_{k_1}}\int_{\gamma_{k_2}}\cdots\int_{\gamma_{k_{n-1}}}\mathrm{d}t_n\cdots\mathrm{d}t_2\mathrm{d}t_1, \tag{15}$$

where $\int_{\gamma_{k_i}}=\int_0^{t_i}$ if $k_i=1$, $\int_{\gamma_{k_i}}=\int_{t_i}^1$ when $k_i=0$ and the sum is taken over all combinations with $k_i=1$ or 0. For example, the chronological ordering corresponds to $k_i=1$ for $i=1,\ldots,n-1$ with $V_n^{n-1}=1/n!$, whereas the anti-chronological ordering has $k_i=0$ for $i=1,\ldots,n-1$ with $V_n^0=1/n!$. In order to find V_n^k for all n and k we introduce instead the functions $P_n^k(x)$ given by

$$P_n^k(t_1)=\sum_{k_1+k_2+\cdots+k_{n-1}=k}\int_{\gamma_{k_1}}\int_{\gamma_{k_2}}\cdots\int_{\gamma_{k_{n-1}}}dt_n\cdots dt_2. \tag{16}$$

Clearly we have $V_n^k=\int_0^1 P_n^k(x)dx$, and it is straightforward to see that the following two-index recurrence relation holds:

$$P_n^k(x)=\int_0^x P_{n-1}^k(s)\mathrm{d}s+\int_x^1 P_{n-1}^{k-1}(s)\mathrm{d}s,\quad (n\geqslant 1,\ k=1,\ldots,n-1),$$
$$P_n^0(x)=\frac{x^{n-1}}{(n-1)!},\quad P_n^{n-1}(x)=\frac{(1-x)^{n-1}}{(n-1)!},\tag{17}$$

and $P_n^k(x)=0$ for any other value of the indices. By multiplying $P_n^k(x)$ by $a^n b^k$ and summing over the appropriate domain we have

$$G(a,b,x):=\sum_{n=3}^{\infty}\sum_{k=1}^{n-2} a^n b^k P_n^k(x)=\sum_{n=3}^{\infty}\sum_{k=1}^{n-2} a^n b^k\int_0^x P_{n-1}^k(s)\mathrm{d}s+\sum_{n=3}^{\infty}\sum_{k=1}^{n-2} a^n b^k\int_x^1 P_{n-1}^{k-1}(s)\mathrm{d}s.\tag{18}$$

Taking the boundary values into account we find that the generating function G satisfies

$$\frac{\partial G}{\partial x}=(a-ab)G+a^2(\mathbf{e}^{ab(1-x)}-1)-a^2b(\mathbf{e}^{ax}-1),\tag{19}$$

whose solution is easily found to be

$$G(a,b,x)=\frac{1}{b-1}[(ab-a)\mathbf{e}^{(ab(1-x))}+a+ab(\mathbf{e}^{ax}-1)+\mathbf{e}^{ax(b-1)}(1-b)G(a,b,0)].\tag{20}$$

From this, and the fact that $G(a,b,0)=ab\int_0^1 G(a,b,x)dx+ab(\mathbf{e}^a-a)$ it follows that

$$\sum_{n=1}^{\infty}\sum_{k=0}^{n} a^n b^k V_n^k=\frac{1-\exp(a(1-b))}{b\exp(a(1-b))-1}.\tag{21}$$

By differentiating (21) we find the recursion

$$V_n^k=\frac{(n-k)}{n}V_{n-1}^{k-1}+\frac{(k+1)}{n}V_{n-1}^k\quad (n\geqslant 1,\ k=0,\ldots,n-1),\tag{22}$$

which together with the values $V_n^{n-1}=1/n!$ and $V_n^0=1/n!$ greatly facilitates the computation of V_n^k when numerical values are sought.

A. Analytic estimate of the convergence radius

In order to give a rigorous bound on the convergence domain let us introduce the related value,

$$U_n^k:=\frac{(n-k-1)!k!}{n!}V_n^k;\tag{23}$$

hence the bound (14) becomes

$$\|\Omega_n\|\leqslant(t\|A\|^*)^n\sum_{k=0}^{n-1} V_n^k\frac{k!(n-1-k)!}{n!}=(t\|A\|^*)^n\sum_{k=0}^{n-1} U_n^k.\tag{24}$$

Using the recursion (22) we find that

$$\sum_{k=0}^{n-1} U_n^k=2\sum_{k=0}^{n-2}\frac{(n-k-1)(k+1)}{n^2}U_{n-1}^k\leqslant\frac{1}{2}\sum_{k=0}^{n-2} U_{n-1}^k,\tag{25}$$

since $(n-k-1)(k+1)\leqslant n^2/4$ for $k=0,\ldots,n-2$; thus $\Sigma_{k=0}^{n-1}U_n^k\leqslant C2^{-n}$ where an easy calculation shows that we can choose $C=2$. From this it follows that the expansion (5) converges provided

$$\|A\|^*t<2. \tag{26}$$

Recall that $\|A\|^*$ denotes the maximum value of $\|A(s)\|$ for $s\in[0,t]$. Hence, a comparison with (6) is only pertinent provided $A(t)$ does not vary very much so as

$$\int_0^t\|A(s)\|\mathrm{d}s\sim\|A(s)\|^*t \tag{27}$$

can be allowed, in which case one can argue that the new domain of convergence defined by (26) is almost twice the preceding one (6).

B. Numerical estimate of the convergence radius

Our determination of absolute convergence of $\Sigma_{k=1}^{\infty}\Omega_k(t)$ was based on the bound (14), i.e.,

$$\|\Omega(t)\|\leqslant\sum_{n=1}^{\infty}\|\Omega_n(t)\|\leqslant\sum_{n=1}^{\infty}\|A\|^{*n}t^n\sum_{k=0}^{n-1}\frac{(n-1-k)!k!}{n!}V_n^k=:\sum_{n=1}^{\infty}\|A\|^{*n}t^nc_n. \tag{28}$$

D'Alembert's criterium for convergence applied to the above series leads to a lower bound estimate for absolute convergence of Magnus expansion. Let $r_n:=c_{n+1}/c_n$ with $n>1$; thus the domain of convergence is given by the value $\lim_{n\to\infty}r_n$.

In order to test the tightness of the inequality (25) we will carry out some numerical experiments. Numerical evaluation of $\{r_n\}$ shows slow convergence of the sequence, thus some procedure of convergence acceleration is in order. Since the growth of $\{r_n\}$ is seemingly monotonous beyond the first few values we choose to fit r_n in some range $n=n_0\cdots N$ with $n_0>1$ and N sufficiently large. An accurate way of extrapolating to the value at the limit $n\to+\infty$ is by rational Padé approximants. A direct fit of a rational function to a set of points can be performed iteratively as a linear problem,[38] but is in general a delicate task, highly sensitive to numerical errors. Instead, we choose to use a *Thiele continued fraction*[26,39] which provides us with a simple and efficient algorithm. The calculation is carried out using the stable reciprocal difference method, with a recursive formula for the needed coefficients.

The values obtained using the Thiele extrapolation show a rapid convergence to the rational value $r_\infty=1/2$. Consequently, our analytic bound (26) agrees with the numerical one and no accuracy was lost in the bound (25).

III. CONCLUSIONS

We have seen that, apart form the bounding procedure, the ordering of the elements in the Magnus expansion is critical with regards to the radius of convergence one can prove for the series. It is worth mentioning which effects could be taken into account in order to further improve the bound. The only inequality applied to find the bound was (13), hence any improvement in this can enlarge the bound (26). Inequality (13) subsumes the effect of different ordering of Ω_n and any relation between products like $A(t_1)A(t_2)\cdots A(t_n)$ when integrated over a chronological sector. We now believe it is the latter effect that is most significant if one seeks to further improve upon the convergence result.

The result in (26) may be of particular significance for numerical integrators based on Magnus expansion, since the approximation (27) is most likely accurate. Together with bounds on other discretization errors our result can give improved error bounds for such methods.

Also, this result is significant in the context of nonlinear ODE where Magnus expansion considered as an exponential Lie series allows one to study the effects of nonautonomous, periodic perturbations to, e.g., Hamiltonian systems. It indicates that the constants of bounds found in the literature are rather pessimistic. To transfer the result developed here to the nonlinear case it is

sufficient to endow our procedure with norms of vector fields and their compositions. This gives rise to a *Gevrey*-1 asymptotic sum whose optimal truncation gives rise to approximations that are exponentially accurate in the period of the perturbation.

With regards to applications of the Magnus expansion to quantum problems some particular results on convergence are known[27–30] albeit they are different in nature to that reported here. They refer to the situation when the Hermitian Hamiltonian $H=-i\hbar A$, is split into two parts, namely $H(t)=H_0+\epsilon H_1(t)$, with $0\leqslant\epsilon\ll 1$, and state the domain of convergence after a unitary transformation leading to the Dirac interaction picture. In this case the Hamiltonian is given by $H_{\mathrm{Int}}(t)=\epsilon\exp(i\hbar H_0 t)H_1(t)\exp(-i\hbar H_0 t)$, hence our bound on the convergence domain becomes $\|H_{\mathrm{Int}}\|^* t=\epsilon\|H_1\|^* t<2$, provided the operator norm $\|\cdot\|^*$ is unitary invariant. Thus the convergence domain in the interaction picture is significantly enlarged.

(Received 28 May 1998; accepted for publication 11 August 1998)

We carry out a construction of nonstandard matrix quantum groups comodules through a generalization of the coaction on tensor powers of a comodule. This generalization amounts to consider the situation where quantum space coordinates and its endomorphism matrix entries belong to a noncommutative quadratic algebra. © *2001 American Institute of Physics.* [DOI: 10.1063/1.1285814]

I. INTRODUCTION

Quantum Groups arise as the abstract structure underlying the symmetries of integrable systems in $(1+1)$ dimensions.[1] There, the theory of quantum inverse scattering give rise to some deformed algebraic structures which were first explained by Drinfel'd as deformations of classical Lie algebras.[2,3] An analog structure was obtained by Woronowicz in the context of noncommutative C^*-algebras.[4] There is a third approach, due to Manin, where Quantum Groups are interpreted as the endomorphisms of certain non commutative algebraic varieties defined by quadratic algebras, called quantum linear spaces (QLS).[5] Faddeev *et al.* had also interpreted the Quantum Groups from the point of view of corepresentations and quantum spaces, furnishing a connection with the quantum deformations of the universal enveloping algebras and the quantum double of Hopf algebras.[6,7]

From the algebraic point of view, quantum groups are Hopf algebras and the relation with the endomorphism algebra of QLS come from their corepresentations on tensor product spaces. The usual construction of the coaction on the tensor product space involves the flip operator interchanging factors of the tensor product of the QLS with the bialgebra. This fact implies the commutativity between the matrix elements of a representation of the endomorphism and the coordinates of the QLS. Moreover, the flip operator for the tensor product is also involved in many steps of the construction of Quantum Groups. In the braided approach to q-deformations, the flip operator is replaced by a braiding giving rise to the quasitensor category of k-modules, where a natural braided coaction appears.[8]

In the present work, we introduce a deformed coaction over the tensor product space, thus admitting noncommutative relations between endomorphism matrix entries and quantum linear space coordinates, however this has nothing to do with the braided approach mentioned above. We find the conditions under which the general algebraic framework of multiplicative quantum groups still holds. It is also shown that the bialgebras arising from this context may be regarded as a partial twisting of usual quantum groups and the connections with integrable systems is analyzed after the introduction of the spectral parameter. This twisted coaction allow us to introduce new deformation parameters in the endomorphism bialgebra of the QLS, as it is shown in the quantum plane example where a four parameters deformation is obtained, although the Yang–Baxter condition is relaxed. Also, we find a noncentral object playing the role of (q,p,r,s)-deformed deter-

minant. In the undeformed limit for the parameters (r,s) we recover the biparametric deformation $GL_{q,p}(2)$ described in Ref. 13.

We present a brief description of the corepresentations of bialgebras in Sec. II and develop our approach to nonstandard comodules in Sec. III. In Sec. IV we present the result of the previous section as twisted bialgebras. The connection with integrable systems is discussed in Sec. V and, finally, we work out the quantum plane example in Sec. VII.

II. QUANTUM ALGEBRAS AND COREPRESENTATIONS

Let V be a vector space of dimension n, $\{e_i\}$ a basis for V and H_0 the trivial bialgebra of functions over $GL(n,\mathbf{C})$. This bialgebra is freely generated by the identity and the coordinates functions T_i^j, in the basis $\{e_i\}$, defined by

$$T_i^j : GL(n,C) \to C,$$

$$T_i^j : g \to g_i^j$$

for $g \in GL(n,\mathbf{C})$. The T_i^j are group like, hence their coproduct and counit are given by

$$\Delta T_i^j = T_i^k \otimes T_k^i, \tag{1}$$

$$\varepsilon(T_i^j) = \delta_j^i. \tag{2}$$

From now on, summation over the repeated index is assumed. The comodule (δ,V), with

$$\begin{aligned} &\delta : V \to H_0 \otimes V, \\ &\delta(e_i) = T_i^j \otimes e_j, \end{aligned} \tag{3}$$

provides a representation of $GL(n,\mathbf{C})$ in V, through the g_i^j in the basis b of V. It has the coassociativity property and preserves the counit, which is expressed by the relations

$$(I_{H_0} \otimes \delta_V)\delta_V = (\Delta \otimes I_V), \tag{4}$$

$$(\epsilon \otimes I_{H_0})\delta_V = I_V. \tag{5}$$

In order to extend the comodule to the tensor product algebra $V^{\otimes}$, one can introduce the coaction on $V \otimes V$,

$$\begin{aligned} &\delta_{V\otimes V} : V \otimes V \to H_0 \otimes V \otimes V, \\ &\delta_{V\otimes V} = (m \otimes I_{V\otimes V})(I_{H_0} \otimes \tau \otimes I_V)(\delta_V \otimes \delta_V). \end{aligned} \tag{6}$$

The extension to $V^{\otimes N}$ is achieved via the recursive relations

$$\begin{aligned} &\delta_{V^{\otimes N}} : V^{\otimes N} \to H_0 \otimes V^{\otimes N}, \\ &\delta_{V^{\otimes N}} = (m \otimes I_{V^{\otimes N}})(I_{H_0} \otimes \tau_{V^{\otimes N},H_0} \otimes I_V)(\delta_{V^{\otimes (N-1)}} \otimes \delta_V), \end{aligned} \tag{7}$$

where $\tau_{V^{\otimes N},H_0}$ is the flip operator mapping $\tau_{V^{\otimes N},H_0} : V^{\otimes N} \otimes H_0 \to H_0 \otimes V^{\otimes N}$. This definition satisfies the coassociativity and counit properties described in relations (4) and (5). It is also worth to remark that the appearance of the flip operator in (7) leads to the commutativity between the coordinates of the quantum space and its endomorphism matrix entries, as it is assumed for the quantum plane and $GL_q(2)$.[5]

Building up corepresentations for objects with more structure than $V^{\otimes}$, as quadratic algebras for example, requires some extra conditions that we sketch below.

Let A denote the quadratic algebra generated by the ideal $I(\mathfrak{B})$, where $\mathfrak{B}: V\otimes V\rightarrow V\otimes V$, then

$$A(\mathfrak{B})=\frac{V^{\otimes}}{I(\mathfrak{B})}, \tag{8}$$

and $V^{\otimes}$ is a tensor algebra on V. In general we consider $\mathfrak{B}$ with the form

$$\mathfrak{B}=(I_{V\otimes V}-B), \tag{9}$$

$$e_i e_j - B_{ij}^{kl} e_k e_l . \tag{10}$$

$\delta_{V\otimes V}$ must be an homomorphism of quadratic algebra, i.e.,

$$(I_{H_0}\otimes\mathfrak{B})\,\delta_{V\otimes V}=\delta_{V\otimes V}\mathfrak{B}. \tag{11}$$

This is satisfied if H is the bialgebra arising from the quotient of the free algebra generated by the objects T_i^j and the ideal $I(\mathfrak{B},H_0)$ generated by the quadratic relation

$$B_{ij}^{kl}T_k^r T_l^a - T_i^k T_j^l B_{kl}^{rs}, \tag{12}$$

i.e.,

$$H=\frac{H_0}{I(\mathfrak{B},H_0)}. \tag{13}$$

Since $I(\mathfrak{B},H_0)$ is a coideal with relation to Δ, H becomes a bialgebra, namely an *FRT bialgebra*. Equation (12) is a central object in the so-called FRT construction.[6] In this way, $A(\mathfrak{B})$ becomes in a H-algebra comodule.

Indeed, in the strict context of Quantum Groups additional conditions are imposed on the bitensor B. These constraints stem from the categorical setting of these structures; quantum linear spaces belongs to the monoidal category of $A(\mathfrak{B})$-comodules. In fact, if the coaction defined in (6) can be extended to the module $V\otimes W$, for W another $A(\mathfrak{B})$-comodule, so that $V\otimes W$ is also an $A(\mathfrak{B})$-comodule, then the category is monoidal. Moreover, it is relevant to supply this category with an additional structure on the monoidal product, namely, a representation of the braid group. This turns the category into a quasitensor or braided category, where its main property is the existence of a natural isomorphism Ψ: $V\otimes W\rightarrow W\otimes V$, for V and W two arbitrary $A(\mathfrak{B})$-comodules, satisfying the McLane's hexagon conditions. For the kind of quadratic bialgebras we are concerned, this is achieved by requiring $A(\mathfrak{B})$ be dual-quasitriangular[2,8] (see Sec. IV) from which arises the celebrated Quantum Yang–Baxter equation,

$$B_{12}B_{23}B_{12}=B_{23}B_{12}B_{23}.$$

However, it is worth remarking that in the case of general bialgebras or Hopf algebras the $A(\mathfrak{B})$-comodules $V\otimes W$ and $W\otimes V$ may be quite unrelated.

III. GENERALIZED FRT COMODULES

The main aim of this section is to build up the mathematical framework encoding the situation in which entries of the endomorphism matrix may not commute with the coordinates of the quantum linear space defined in (8). We will reach it by means of a modification in the corepresentation theory, obtained by substituting the flip map τ in the standard definition of the coaction on $V\otimes V$ by a nontrivial map γ.

As described in the previous section, supplying the quantum linear space with a comodule structure requires a right definition of a coaction on the tensor product space, and the standard definition of $\delta_{V\otimes V}$, Eq. (6), provides both $V\otimes V$ with a H_0-comodule structure and $A=V^{\otimes}/I(\mathfrak{B})$ with an H-comodule structure.

Then, let us introduce the map γ, defined by

$$\gamma: V\otimes H\to H\otimes V, \tag{14}$$

$$\gamma(e_i\otimes T_j^k)=\gamma_{ijn}^{klm}T_l^n\otimes e_m, \tag{15}$$

and our proposal of generalized or noncommutative coaction on tensor product space is

$$\delta_{V\otimes V}^{\gamma}=(m\otimes I_{V\otimes V})(I_{H_\gamma}\otimes\gamma\otimes I_V)(\delta_V\otimes\delta_V). \tag{16}$$

Then, we shall see that a H_γ-comodule structure there it is possible, for some H_γ to be constructed and provided γ satisfying some requirements. The first question is finding the condition under which $\delta_{V\otimes V}^{\gamma}$ is actually a coaction. It is addressed in the following proposition:

Proposition 1: The map $\delta_{V\otimes V}^{\gamma}: V\otimes V\to H_0\otimes V\otimes V$ *is a coaction turning* $V\otimes V$ *into a* H_0*-comodule iff* $\gamma: V\otimes H_0\to H_0\otimes V$ *satisfies the following conditions:*

$$\gamma_{ijn}^{klm}=\delta_i^m\theta_{jn}^{kl}, \tag{17}$$

$$\theta_{ij}^{pl}\theta_{pk}^{rs}-\delta_j^s\theta_{ik}^{rl}=0, \tag{18}$$

$$\theta_{jn}^{kn}=\delta_j^k. \tag{19}$$

Proof: These properties for γ are readily derived from the coassociativity and counit conditions,

$$\begin{gathered}(\Delta\otimes I_{V\otimes V})\circ\delta_{V\otimes V}^{\gamma}=(I_{H_\gamma}\otimes\delta_{V\otimes V}^{\gamma})\circ\delta_{V\otimes V}^{\gamma},\\ (\epsilon\otimes I_{V\otimes V})\circ\delta_{V\otimes}^{\gamma}=I_{V\otimes V}.\end{gathered} \tag{20}$$

□

A mapping γ satisfying the conditions (17)–(19) leads to a comodule over $V^{\otimes N}$ as stated in the following proposition.

Proposition 2: Let $\delta_{V^{\otimes N}}: V^{\otimes N}\to H_0\otimes V^{\otimes N}$ *be defined by,*

$$\begin{gathered}\delta_V^{\gamma}e_i=\delta_V\ \ e_i=T_i^k\otimes e_k,\\ \delta_{V^{\otimes N}}^{\gamma}=(m_{H_0}\otimes I_{V^{\otimes N}})(I_{H_0}\otimes\gamma_{V^{\otimes(N-1)},H_0}\otimes I_V)(\delta_{V^{\otimes(N-1)}}\otimes\delta_V),\end{gathered} \tag{21}$$

for $N\geqslant 1$, *where*

$$\gamma V^{\otimes N},H_0(e_{i_1}\otimes\ldots e_{i_N}\otimes T_j^k)=\gamma_{V,H_0}\otimes I_{V\otimes(N-1)}(e_{i_1}\otimes\gamma_{V\otimes(N-1),H_0}(e_{i_2}\otimes\cdots\otimes e_{i_N}\otimes T_j^k))$$

and

$$\gamma_{V,H_0}=\gamma,$$

then $(V^{\otimes},\{\delta_{V\otimes N}^{\gamma}\})$ *is a left* H_o*-comodule.*

The proof runs as the previous one, just with a more complicated algebra.

Recalling the bijection between comodules and multiplicative matrices,[5] let us consider the multiplicative matrix M in $V\otimes V$ with coefficients in H_o corresponding to the comodule $\delta_{V\otimes V}^{\gamma}$, i.e.,

$$\delta^{\gamma}_{V\otimes V}\equiv M\in \mathrm{End}(V\otimes V,H_0),$$
$$\delta^{\gamma}_{\otimes V}(e_i\otimes e_j)=M^{rs}_{ij}\otimes e_r\otimes e_s, \tag{22}$$

hence M is

$$M^{kl}_{ij}=T^k_i\theta^{lm}_{jn}T^n_m. \tag{23}$$

Let us adopt the following convention: for A^{kl}_{ij} and D^{kl}_{ij} being any pair of four-tensors, we write $(A\times B)^{rs}_{ij}=A^{kl}_{ij}\times D^{rs}_{kl}$, where $\times$ stands for any kind of product (tensor, algebraic, etc.), and sum over repeated index is also assumed.

With this notation, conditions (18) and (19) are

$$\Delta M=M\otimes M,$$
$$\epsilon(M)=I. \tag{24}$$

The next step is to consider a quadratic structure on $V\otimes V$ giving rise to a QLS. Now, the bialgebra H_o is no longer in the endomorphism algebra of the QLS. Let us consider a QLS generated by the quotient algebra

$$A(\mathfrak{B})=\frac{V^{\otimes}}{I(\mathfrak{B})}, \tag{25}$$

where $\mathfrak{B}$ means the relations defining the quadratic algebra. Associated with it we now introduce a new bialgebra structure on the free algebra generated by the $\{T^k_i\}$.

Proposition 3: Let H_0 the free algebra generated by the $\{T^k_i\}$, γ as in the previous proposition and $I(\mathfrak{B}M-M\mathfrak{B})$ is the ideal generated by the quadratic relation,

$$(\mathfrak{B}M-M\mathfrak{B})^{kl}_{ij}\equiv B^{ab}_{ij}T^k_a\theta^{lm}_{bn}T^n_m-T^a_i\theta^{bm}_{jn}T^n_mB^{kl}_{ab}, \tag{26}$$

then, the quotient algebra H_γ defined as

$$H_\gamma=\frac{H_0}{I(\mathfrak{B}M-M\mathfrak{B})} \tag{27}$$

is a bialgebra.

Proof: A necessary and sufficient condition for H_γ to be a bialgebra is that $I(\mathfrak{B}M-M\mathfrak{B})$ be a coideal, i.e.,

$$\Delta I\subset I\otimes H_0+H_0\otimes I.$$

Then, taking into account the relation (24), one gets

$$\Delta(\mathfrak{B}M-M\mathfrak{B})=\mathfrak{B}\Delta M-\Delta M\mathfrak{B}=\mathfrak{B}(M\otimes M)-(M\otimes M)\mathfrak{B}$$
$$=(\mathfrak{B}M-M\mathfrak{B})\otimes M-M\otimes(\mathfrak{B}M-M\mathfrak{B})$$

and

$$\epsilon(\mathfrak{B}M-M\mathfrak{B})=\mathfrak{B}\epsilon(M)-\epsilon(M)\mathfrak{B}=0,$$

hence H_γ is a bialgebra. □

The main result of this section is expressed in the following proposition:

Proposition 4: $\{\delta^{\gamma}_{V\otimes N}\}$ *supplies* $A(\mathfrak{B})=V^{\otimes}/I(\mathfrak{B})$ *with a left* H_{γ}*-comodule structure. Moreover, if* H' *is another bialgebra coacting on* $A(\mathfrak{B})$ *via the coaction* $\{\delta'^{\gamma}_{V\otimes N}\}$*, with the same* γ*, then there exists a unique map* $f:H_{\gamma}\rightarrow H'$ *such that* $\delta'^{\gamma}_{V\otimes N}=(f\otimes id_{V\otimes N})\delta^{\gamma}_{V\otimes N}$*. Then,* H_{γ} *is unique up to isomorphism.*

Proof: This assertion means the map $\delta^{\gamma}_{V\otimes V}:A(\mathfrak{B})\rightarrow H^{\gamma}\otimes A(\mathfrak{B})$ is an homomorphism of quadratic algebras, as in Eq. (11). This fact is realized by the communication relation

$$(I_{H_{\gamma}}\otimes\mathfrak{B})\circ\delta^{\gamma}_{V\otimes V}=\gamma^{\gamma}_{V\otimes V}\circ\mathfrak{B},$$

which is immediately satisfied by virtue of the ideal defining H_{γ}, i.e., the condition

$$\mathfrak{B}M=M\mathfrak{B}.$$

The universality property follows on the same steps as in Proposition VIII.6.1 of Ref. 7, just taking into account the coaction (16) and (21), and that θ is a linear map. □

Resuming, we can make the following assertion: given a quadratic algebra $A(\mathfrak{B})$ and a map γ satisfying the relations (17)–(19), then $H_{\gamma}=H_0/I(\mathfrak{B}M-M\mathfrak{B})$ is a bialgebra and $\{\delta^{\gamma}_{V\otimes N}\}$ renders $A(\mathfrak{B})$ into a H_{γ}-comodule (a similar quadratic algebra arise in the context of quantum braided group[9]). This may be understood because of the bijection between all the structures of left comodule on $V=\mathbf{C}^n$ and the multiplicative matrix $\mathbf{M}(n,H_{\gamma})$,[5] since $M\in H_{\gamma}$ satisfy $\Delta M=M\otimes M$ and $\epsilon(M)=I_{V\otimes V}$, for $M\in H_{\gamma}$.

In some physical applications of Quantum Groups comodules are also equipped with an algebra structure, i.e., they are QG comodules-algebras. Let us analyze how this works in the framework of the $\{\delta^{\gamma}_{V\otimes N}\}$ coaction. A *H_{γ}-comodule algebra* $(V^{\otimes}(m_V,\eta_V),\{\delta^{\gamma}_{V\otimes N}\})$ is a *H_{γ}-comodule* $(V^{\otimes},\{\delta^{\gamma}_{V\otimes N}\})$ such that the product in V extended to $V^{\otimes}$, $m_V:V\otimes V\rightarrow V$, and the unit $\eta_V:k\rightarrow V$ are H_{γ}-comodule homomorphisms. Equivalently, it can be shown that $V^{\otimes}(m_V,\eta_V)$ is a *H_{γ}-comodule algebra* iff $\{\delta^{\gamma}_{V\otimes N}\}$ are algebra homomorphisms. It means that the following constraint must hold:

$$(I_{H_{\gamma}}\otimes m_V)\circ\delta^{\gamma}_{V\otimes V}=\delta_V\circ m_V, \tag{28}$$

$$\delta^{\gamma}_{V\otimes N}\circ\eta_{V\otimes N}=\eta_{H_{\gamma}}\otimes\eta_{V\otimes N}. \tag{29}$$

Observe that the first relation can be written as

$$(I_{H_{\gamma}}\otimes m_V)\circ\delta^{\gamma}_{V\otimes V}=m_{H_{\gamma}\otimes V}\circ(\delta_V\otimes\delta_V), \tag{30}$$

so, in order to compensate the γ appearing in the left hand side we must redefine $m_{H_{\gamma}\otimes V}$. Thus we get now

$$m_{H_{\gamma}\otimes V}=(m_{H_{\gamma}}\otimes m_V)(I_{H_{\gamma}}\otimes\gamma\otimes I_V). \tag{31}$$

The question now is if $m_{H_{\gamma\otimes V}}$ is an associative product. Due to Proposition 2, $\gamma=(\theta\otimes I_V)\circ\tau$. There are two possibilities to fulfill this constraint:

(1) $\theta:H_{\gamma}\rightarrow H_{\gamma}$ is an algebra homomorphism.
(2) $\theta\circ m=m\circ(\theta\otimes I_V)$.

On the other side, the unit constraint, Eq. (29) imposes that

$$\theta\circ\eta_{H_{\gamma}}=\eta_{H_{\gamma}}. \tag{32}$$

The existence of an antipode is not involved in the comodule structure, so the above construction still holds when H_γ is a Hopf algebra, giving rise to nonstandard comodules of Quantum Groups.

As it was remarked at the end of the previous section, without the quasintriangularity constraints, $\otimes$ stands just for a monoidal product, i.e., the $A(\mathfrak{B})$-comodules $V\otimes W$ and $W\otimes V$ may be quite unrelated. In the next section we discuss the question of quasitriangularity and the Yang–Baxter constraint on the bialgebra H_γ.

In the last section, we describe an explicit example enjoying all these properties presented above, namely a multiparameter deformed version of the endomorphism of the quantum plane. In this example the first possibility for fulfilling the associativity of the $m_{H_\gamma\otimes V}$ product is realized.

IV. RELATION WITH TWISTED BIALGEBRAS

Let us introduce a bialgebra structure on $\mathrm{Hom}(H_0^{\otimes 2},k)$ by means the convolution product $*$ of linear forms, defined as $(f*g)(T)=(f\otimes g)(\Delta T)$ for $f,g\in \mathrm{Hom}(H_0^{\otimes 2},k)$ and $T\in H_0^{\otimes 2}$. The coproduct is $(\Delta h)(T\otimes T')=(h\circ m)(T\otimes T')$ for $h\in \mathrm{Hom}(H_0^{\otimes 2},k)$ and $T,T'\in H_0$. The unit is ϵ, the counit of the H_0, namely, $(\epsilon * f)(T)=f(T)$.

In this framework,[2,8,7] H defined in Eq. (13) can be presented as the bialgebra $H(m,\Delta,\eta,\epsilon,R)$, with $R:H_0^{\otimes 2}\to k$ being an invertible linear form, related to $\mathfrak{B}$ of the previous section by

$$R(T_i^k\otimes T_j^l)=R_{ij}^{kl}\equiv B_{ji}^{kl}, \tag{33}$$

and defined by the quadratic ideal generated by the relation

$$m^{0p}=R*m*\overline{R}. \tag{34}$$

Here, $m^{op}=m\circ\tau$ and $R*\overline{R}=\overline{R}*R=\epsilon$. Moreover, H is said to be *dual quasitriangular*[8] provided R satisfies

$$R\circ(I_H\otimes m)=R_{13}*R_{12}\quad R\circ(m\otimes I_H)=R_{13}*R_{23}. \tag{35}$$

Here, $R_{12}=R\otimes\epsilon$, $R_{23}=\epsilon\otimes R$, $R_{13}=(\epsilon\otimes R)\circ R)\otimes(\tau\otimes I_H)$. This last relations implies R is a solution of the *Quantum Yang–Baxter equation*,

$$R_{12}*R_{13}*R_{23}=R_{23}*R_{13}*R_{12}. \tag{36}$$

Coming back to our problem, let us work out the bialgebra structure H_γ, Eq.(27), derived from noncommutative corepresentations of the previous section. The following characterization of the γ map drives to a different interpretation of the bialgebra H_γ.

Let θ be the linear map,

$$\begin{gathered}\theta:H_0\to H_0,\\ \theta(T_i^j)=\theta_{im}^{jn}T_n^m=\tilde{T}_i^j,\end{gathered} \tag{37}$$

with the properties

$$\begin{gathered}\theta_{ij}^{pl}\theta_{pk}^{rs}-\delta_j^s\theta_{ik}^{rl}=0,\\ \theta_{jn}^{kn}=\delta_j^k.\end{gathered} \tag{38}$$

Proposition 5: θ is a coalgebra homomorphism, such that

$$\Delta \tilde{T}_i^j = \tilde{T}_i^k \otimes \tilde{T}_k^j ,$$
$$\epsilon(\tilde{T}_i^j) = \delta_i^j . \tag{39}$$

Proof: The properties (38) implies that $\tilde{T}$ are group like elements, then satisfying the coassociativity and counit properties.

With this notation, the twisting γ, Eq. (14) can now be expressed as

$$\gamma(e_i \otimes T_j^k) = \theta(T_j^k) \otimes e_i = \tilde{T}_j^k \otimes e_i$$

and the quadratic relation (26) can be written more explicitly as

$$R_{ij}^{ab} T_a^k \tilde{T}_b^l = T_j^a \tilde{T}_i^b R_{ba}^{kl} . \tag{40}$$

This relation generates the ideal which give rise to the quadratic algebra $H_\gamma(m, \Delta, \eta, \epsilon)$.

Now we address the question of quasitriangularity. Let us introduce the deformed product

$$m_\theta = m \circ (I_H \otimes \theta) \tag{41}$$

with θ such that m_θ is a well defined product. Hence, in addition to Eqs. (35), the relation

$$R * m_\theta = m_\theta^{0p} * R \tag{42}$$

allows us to cast the bialgebra $H_\gamma(m, \Delta, \eta, \epsilon)$ into a standard FRT bialgebra $H(m_\theta, \Delta, \eta, \epsilon, R)$, with deformed product m_θ and supplied with the two-form R. This form is close to dual-quasitriangularity. To get a well defined m_θ, i.e., θ such that m_θ satisfies $m_\theta(m_\theta \otimes I_H) = m_\theta(I_H \otimes m_\theta)$ and $m_\theta(\eta \otimes I_H) = m_\theta(I_H \otimes \eta) = I_H$, one may choose for instance $\theta \circ m = m \otimes (\theta \otimes I_H)$.

An easy way to construct a product m_θ satisfying the requirements of Proposition 1 is to consider it as the twisting of the usual product by a 2-cocycle. This will also allow to relate the above construction with twisted bialgebras. The twisting by 2-cocyles of quasitriangular Hopf algebras is due to Drinfel'd[10] who has shown that starting from a quasitriangular Hopf algebra, a new quasitriangular Hopf algebra is obtained twisting by a 2-cocycle the coproduct and the quasitriangular structure $\mathcal{R}$. In our case, we shall use in a partial twisting; we shall need just a twisting of the product or a twisting of the dual-quasitriangular structure. We shall show that the deformation introduced by the noncommutative coaction boils down to a partial twisting of the usual FRT bialgebras, which in general do not preserves dual-quasitriangularity. To this end, we extract some dual results from the Drinfeld analysis.

Following Ref. 8, we introduce a 2-cocycle on the bialgebra $\mathrm{Hom}(H^{\otimes 2}, k)$ as being an invertible element of $H^{\otimes 2}$, in the sense of the product $*$, satisfying the condition $\phi_{23} * ((I_H \otimes \Delta) \circ \phi) = \phi_{12} * ((\Delta \otimes I_H) \circ \phi)$.

The maps $\phi : H^{\otimes 2} \to k$ being a 2-cocycle give rise to a new bialgebra structure on H_0, namely $H_\phi(m_\phi, \Delta, \eta, \epsilon)$, with a twisted product m_ϕ,

$$m_\phi : H_0^{\otimes 2} \to H_0 ,$$
$$m_\phi = \phi * m * \overline{\phi}. \tag{43}$$

Moreover, if ϕ is a bialgebra bicharacter, i.e.,

$$\phi(m \otimes I_H) = \phi_{13} * \phi_{23} ,$$
$$\phi(I_H \otimes m) = \phi_{13} * \phi_{12} , \tag{44}$$

then the 2-cocycle condition leads to the Quantum Yang–Baxter equation,

$$\phi_{12}*\phi_{13}*\phi_{23}=\phi_{23}*\phi_{13}*\phi_{12}. \tag{45}$$

The above proposition provides the framework to interpret the bialgebra H_γ as a twisted one. In fact, let us assume the map θ, introduced in Eq. (37), can be written as

$$\theta(T_j^k)=\theta_{jn}^{km}T_m^n=\rho_j^m T_m^n\overline{\rho}_n^k, \tag{46}$$

i.e., the map θ admits the factorization,

$$\theta_{ij}^{kl}=\rho_i^l\overline{\rho}_j^k. \tag{47}$$

Then, we may introduce the bialgebra bicharacter $\phi:H_0^{\otimes 2}\to k$, inherited from the associativity constraint, defined by the relations

$$\begin{gathered}\phi(T_i^k\otimes T_j^l)=(\epsilon\otimes\rho)(T_i^k\otimes T_j^l),\\ \rho(T_i^k)=\rho_i^k,\\ \phi(T_i^k\otimes e)=\phi(e\otimes T_i^k)=1,\\ \phi(m\otimes I_H)=\phi_{13}*\phi_{23},\\ \phi(I_H\otimes m)=\phi_{13}*\phi_{12},\end{gathered} \tag{48}$$

with $\rho:H_0\to k$ an invertible map, i.e., there exist $\overline{\rho}$ such that $\overline{\rho}*\rho=\rho*\overline{\rho}=\epsilon$, and e is unit of the algebra H_0. Then ϕ is a 2-cocycle, giving rise to the twisted product on H_0,

$$\begin{gathered}m_\phi(T_i^k\otimes T_j^l)=T_i^k\tilde{T}_j^l,\\ \tilde{T}_i^j=\rho_i^m T_m^n\overline{\rho}_n^j.\end{gathered} \tag{49}$$

Observe that condition (18) is trivially fulfilled. Then, the bialgebra $H_\gamma(m,\Delta,\eta,\epsilon,R)$, Eq. (27), is isomorphic to a partial twisting by the 2-cocycle ϕ, (48), of the standard FRT bialgebra $H(m,\Delta,\eta,\epsilon,R)$, (40). The twisting can be performed on the product, thus obtaining the bialgebra isomorphism $H_\gamma(m,\Delta,\eta,\epsilon,R)=H(m_\phi,\Delta,\eta,\epsilon,R)$, with the quadratic ideal $\mathfrak{B}M-M\mathfrak{B}$ being expressed as

$$m_\phi^{op}(T_i^k\otimes T_j^l)=(R*m_\phi*\overline{R})(T_i^k\otimes T_j^l), \tag{50}$$

or, alternatively, one may leaves the product untwisted, but applying the twisting onto the R map,

$$R^\phi=\overline{\phi}_{21}*R*\phi$$

and, again, $H_\gamma(m,\Delta,\eta,\epsilon,R)=H(m,\Delta,\eta,\epsilon,R^\phi)$ with the ideal of Eq. (40), expressed as

$$m^{op}(T_i^k\otimes T_j^l)=(R^\phi*m*\overline{R}^\phi)(T_i^k\otimes T_j^l). \tag{51}$$

In general, both schemes may spoil out dual-quasitriangularity. However, it is important to recover the strict context of Quantum Groups, i.e., the quasitensor structure on the monoidal category of $H_\gamma(m,\Delta,\eta,\epsilon,R)$-comodules. This leaves open the connection with statistical systems. In fact, in these systems the R^ϕ matrix plays the role of Boltzmann weight, and the monodromy matrix are the T_i^k. All this works if R^ϕ provides a representation of the bialgebra H_γ, as it happens with dual-quasitriangular bialgebras. This is achieved if R^ϕ satisfy the relations

$$R^{\phi}(m\otimes I_H)=R^{\phi}_{13}*R^{\phi}_{23},$$
$$R^{\phi}(I_H\otimes m)=R^{\phi}_{13}*R^{\phi}_{12}, \tag{52}$$

so that R^{ϕ} is a solution of the Quantum Yang–Baxter equation. In this way, those quantum bialgebras arising from noncommutative corepresentations with factorizable θ-map, can be mapped into standard FRT bialgebras by a twisting of the original R. In this way, independently of whether the original R is quasitriangular or not, the quasitriangularity of R^{ϕ} means that it is a solution of the quantum Yang–Baxter equation,

$$R^{\phi}_{12}*R^{\phi}_{13}*R^{\phi}_{23}=R^{\phi}_{23}*R^{\phi}_{13}*R^{\phi}_{12},$$

and the monoidal category of H_{γ}-comodules, with $\delta^{\gamma}_{V\otimes V}$, becomes into a quasitensorial one.

V. INTEGRABILITY

The deep relation between Hopf algebras and two dimensional physical systems stems from the integrability condition. As we saw in the previous section, for bialgebras arising from noncommutative corepresentations with a factorizable θ-map it is possible to arrive to dual quasitriangularity structure, then connection goes as usual. We shall see in this section in which way a general bialgebra H_{γ} may be associated to some integrable systems. The main question is the introduction of the spectral parameter, which is related to the coupling constant of the physical system. In doing so, we proceed as in Ref. 2 by regarding a collection of vector spaces $V(\lambda)=\mathbf{C}^n$ for every $\lambda\in\mathbf{C}$, with basis $b(\lambda)=\{e_i(\lambda), i=1,...,n\}$.

For each value of the spectral parameter λ the coordinate functions T^j_i generates a bialgebra $H_0(\lambda)$ with coproduct $\Delta T^j_i(\lambda)=T^k_i(\lambda)\otimes T^j_k(\lambda)$ and counit $\epsilon(T^j_i(\lambda))=\delta^j_i$. Furthermore, the union of the $H_0(\lambda)$ of these bialgebras for all values of λ, i.e., $\mathcal{H}_0=U_{\lambda}H_0(\lambda)$, is also a bialgebra with the same coproduct and counit. Also, a $\mathcal{H}_0$-comodule structure on $V(\lambda)$ is obtained by the coaction $\delta_{V(\lambda)}e_i(\lambda)=T^k_i(\lambda)\otimes e_i(\lambda)$.

Now, let us consider the map

$$\mathfrak{B}(\lambda,\mu): V(\lambda)\otimes V(\mu)\to V(\mu)\otimes V(\lambda),$$
$$e_i(\lambda)\otimes e_j(\mu)\to B^{kl}_{ij}(\lambda,\mu)e_k(\mu)\otimes e_l(\lambda), \tag{53}$$

and the QLS defined by the quadratic algebra,

$$A=\frac{\oplus_{\lambda}V^{\otimes}(\lambda)}{R}, \tag{54}$$

where

$$\mathcal{R}=U_{\lambda,\mu}[1\otimes 1-B(\lambda,\mu)]V(\lambda)\otimes V(\mu).$$

In order to obtain a structure of $\mathcal{H}_0$ comodule on A, we define, following the previous section, the map γ as

$$\gamma: V(\lambda)\otimes\mathcal{H}_0\to\mathcal{H}_0\otimes V(\lambda),$$
$$\gamma(e_i(\lambda)\otimes T^k_j(\mu))=\gamma^{klm}_{ijn}(\lambda,\mu)T^n_l(\mu)\otimes e_m(\lambda), \tag{55}$$

and the coaction on the tensor product space $V(\lambda)\otimes V(\mu)$,

$$\delta^{\gamma}_{V\otimes V}=(m\otimes I_{V(\mu)})(I_{H_{\gamma}}\otimes\gamma(\lambda,\mu)\otimes I_{V(\mu)})(\delta_{V(\lambda)}\otimes\delta_{V(\mu)}). \tag{56}$$

In analogy with Proposition 2, this can be extended to a map,

$$\delta^{\gamma}: A \to \mathcal{H}_0 \otimes A$$

supplying A with a left $\mathcal{H}_0$-comodule structure.

The results analogous to those ones of Propositions 1–3 of Sec. II are still valid provided the replacements

$$\gamma_{ijn}^{klm}(\lambda,\mu) = \delta_i^m \theta_{jn}^{kl}(\lambda,\mu),$$

$$\theta_{ij}^{pl}(\lambda,\mu)\,\theta_{pk}^{rs}(\lambda,\mu) - \delta_j^s \theta_{ik}^{rl}(\lambda,\mu) = 0, \tag{57}$$

$$\theta_{jn}^{kn}(\lambda,\mu) = \delta_j^k,$$

and

$$M_{ij}^{kl}(\lambda,\mu) = T_i^k(\lambda)\,\theta_{jn}^{km}(\lambda,\mu)\,T_m^n(\mu). \tag{58}$$

So that, the ideal $\mathfrak{B}M - M\mathfrak{B}$ of Proposition 2 becomes in

$$B_{ij}^{mn}(\lambda,\mu)M_{mn}^{kl}(\lambda,\mu) - M_{ij}^{mn}(\mu,\lambda)B_{mn}^{kl}(\lambda,\mu). \tag{59}$$

In order to study integrability, we analyze this equation, Eq. (59). In general, a γ map just satisfying the condition of Proposition 1, does not lead to integrability making it necessary to impose additional conditions on it. In the following we study some options.

Our first ansatz is to require that

$$\gamma_{imj}^{mkl}(\lambda,\mu) \equiv \delta_i^l \theta_{mj}^{mk} = \delta_i^l \delta_j^k. \tag{60}$$

In this way, assuming B to be invertible, one can multiply (59) by the inverse of B and then make the contraction of the free index of both B and B^{-1}, thus reaching the integrability condition,

$$T(\lambda)T(\mu) = T(\mu)T(\lambda). \tag{61}$$

Here, $T(\lambda)$ means the trace $T_m^m(\lambda)$.

There is a less obvious way to recover integrability. Condition (59) in terms of θ is

$$B_{ij}^{kl}(\lambda,\mu)T_k^m(\lambda)\,\theta_{lv}^{nu}(\lambda,\mu)T_u^v(\mu) = T_i^k(\lambda)\,\theta_{jv}^{lu}(\lambda,\mu)T_u^v(\mu)B_{kl}^{mn}(\lambda,\mu). \tag{62}$$

If the following nontrivial commutation holds,

$$B_{ij}^{rk}(\lambda,\mu)\,\theta_{sr}^{sl}(\lambda,\mu) = \theta_{si}^{sr}(\lambda,\mu)B_{rj}^{lk}(\lambda,\mu), \tag{63}$$

we may now contract (62) with $\theta_{ar}^{ai}(\lambda,\mu)$ and, after using (63), we get

$$B_{rj}^{il}(\lambda,\mu)\,\theta_{si}^{sk}(\lambda,\mu)T_k^m(\lambda)\,\theta_{lv}^{nu}(\lambda,\mu)T_u^v(\mu) = \theta_{sr}^{si}(\lambda,\mu)T_i^k(\lambda)\,\theta_{jv}^{lu}(\lambda,\mu)T_u^v(\mu)B_{kl}^{mn}(\lambda,\mu), \tag{64}$$

and now we proceed as in the previous case; multiplying by $(B^{-1})_{ab}^{rj}$, and then performing the contractions (a,m), (b,n), thus getting

$$\theta_{sa}^{sk}(\lambda,\mu)T_k^a(\lambda)\,\theta_{bv}^{bu}(\lambda,\mu)T_u^v(\mu) = \theta_{sk}^{si}(\lambda,\mu)T_i^k(\lambda)\,\theta_{lv}^{lu}(\lambda,\mu)T_u^v(\mu). \tag{65}$$

Introducing the quantum matrix $\tilde{T}$ of the final of the previous section, the new integrability condition is written as

$$\tilde{T}(\lambda)\tilde{T}(\mu) = \tilde{T}(\mu)\tilde{T}(\lambda). \tag{66}$$

This last approach to integrability may have an interpretation in the framework of statistical models through their monodromy matrices $T_i^k(\lambda)$. In those models, periodic boundary conditions drive to the transfer matrix by taking the trace over the auxiliary space of the monodromy matrix, which means a sum over all the edge states (see, for example Ref. 11). The objects $\tilde{T}(\lambda)$ means a weighted sum over these edge states, so that θ seems to behave as a twisting factor on the boundary conditions. The periodic ones correspond to the trivial choice $\theta_{ij}^{kl}=\delta_i^l\delta_j^k$. Also, we speculate that many other kind of boundary conditions would be reached by a suitable choice of θ.[14]

As a matter of fact, in Ref. 15, a spin chain model was constructed from the R-matrix of the twisted version of $GL_q(2)$, namely $GL_{p,q}(2)$ (we shall see in the next section that this biparametric deformation of $GL(2)$ coacts also on the standard quantum plane through a twisted coaction). There one may observe that the local twist of the Boltzmann weight can be regarded as some operators coacting through δ^γ on some QLS associated to the inner space at each site, also showing that the effect on the full chain boils down to a twist of the boundary conditions.

We would also like to emphasize that the present construction of nonstandard corepresentationes could be nontrivially realized in conformal field theories. In this respect it is noteworthy that the vertex operators in these theories satisfy a QLS algebra and therefore transform covariantly under the action of a QG. For example, in the WZW model the algebra of vertex operators transforms covariantly under $U_q(\mathrm{sl}(2))$.

In the next section we present a multiparametric example constructed from the quantum plane and fulfilling the first integrability condition.

VI. THE QUANTUM PLANE

Let us consider the quantum plane $A_q^{2|0}$ described by

$$e_1e_2=qe_2e_1. \tag{67}$$

In the basis $\{e_1\otimes e_1, e_1\otimes e_2, e_2\otimes e_1, e_2\otimes e_1\}$, this relation can be expressed by means of the quadratic form B as

$$B=\begin{bmatrix} 1 & 0 & 0 & 0 \\ 0 & 0 & q & 0 \\ 0 & q & 1-q^2 & 0 \\ 0 & 0 & 0 & 1 \end{bmatrix}, \tag{68}$$

which is a solution of the Yang–Baxter equation,

$$B_{12}B_{23}B_{12}=B_{23}B_{12}B_{23}. \tag{69}$$

It is worth remarking that the following construction leads to the same structure for other choice of B, as the symmetric and idempotent B',

$$B'=\frac{1}{q+q^{-1}}\begin{bmatrix} q+q^{-1} & 0 & 0 & 0 \\ 0 & q-q^{-1} & 2 & 0 \\ 0 & 2 & q^{-1}-q & 0 \\ 0 & 0 & 0 & q+q^{-1} \end{bmatrix}. \tag{70}$$

This B' is not a solution of the Yang–Baxter equation but, in the Manin construction for pseudo-symmetric quantum space,[5] it enables us to characterize all the endomorphisms of the quantum plane by the relation $B'M-MB'$ as the only solution to the master relation $(I-B')M(I+B')$.

The endomorphism matrix T is

$$T=\begin{bmatrix} a & b \\ c & d \end{bmatrix}. \tag{71}$$

We find a multiparametric $\theta(r,p,s)$, solution of the coassociativity, counity, and the integrability condition, Eqs. (18), (19), (60), that it is factorizable

$$\theta_{ij}^{kl}=\rho_i^l\overline{\rho}_j^k, \tag{72}$$

with

$$\rho=\begin{bmatrix} 1 & r/s \\ -s/p & (1-r)/p \end{bmatrix}, \tag{73}$$

and $\overline{\rho}$ is it inverse.

This means that the induced map $\phi=\epsilon\otimes\rho$ is a 2-cocycle whenever $s\neq 0$, hence there is an obstruction in to obtain the undeformed limit $s\to 0$. In this sense, this $\phi(r,p,s)$ is not a 2-cocycle for the whole spectrum of its parameters and the twisting arising from it does not yields a continuous deformation of the algebra H_0.

From this matrix we obtain the rules to commute e and T,

$$\gamma(e_i\otimes T_j^k)=\theta_{jp}^{ks}T_s^p\otimes e_i. \tag{74}$$

As we see, there are now three new deformation parameters (p,r,s) besides q, which was introduced by the quadratic algebra of the quantum plane (67).

The relations $BM-MB$ can be written in a compact form by introducing the objects $\tilde{T}_i^j=\theta_{ir}^{js}T_s^r$, such that

$$\tilde{T}=\begin{bmatrix} \tilde{a} & \tilde{b} \\ \tilde{c} & \tilde{d} \end{bmatrix}, \tag{75}$$

so that we get

$$\begin{gathered} a\tilde{c}-qc\tilde{a}=0, \\ a\tilde{b}-qb\tilde{a}=0, \\ b\tilde{c}-c\tilde{b}=0, \\ c\tilde{d}-qd\tilde{c}=0, \\ b\tilde{d}-qd\tilde{b}=0, \\ a\tilde{d}-d\tilde{a}+(q^{-1}-q)c\tilde{b}=0, \end{gathered} \tag{76}$$

and

$$\begin{gathered} \gamma(e_i\otimes\tilde{a})=\tilde{a}\otimes e_i, \\ \gamma(e_i\otimes\tilde{d})=\tilde{d}\otimes e_i, \\ \gamma(e_i\otimes\tilde{b})=p\tilde{b}\otimes e_i, \\ \gamma(e_i\otimes\tilde{c})=p^{-1}\tilde{c}\otimes e_i. \end{gathered} \tag{77}$$

Relations (76) acquire a highly nontrivial form in terms of the T_i^k. In this way, one can define a four parameter deformation of the $M(2)$, namely, $M_{q,p,r,s}(2)$,

$$M_{q,p,r,s}(2)=\frac{k[T_i^j]}{I(BM-MB)}. \tag{78}$$

Also, the Grassmannian plane $A_q^{0/2}(\xi_1,\xi_2)$, defined by the relation

$$\xi_1\xi_2=-\frac{1}{q}\xi_2\xi_1$$

is naturally a $M_{q,p,r,s}(2)$-comodule.[12] This allows us to define a determinant for this $M_{q,p,r,s}(2)$ from the coaction $\delta^{\gamma}_{V\otimes V}$ on the object $\xi_1\xi_2$,

$$\delta^{\gamma}_{V\otimes V}(\xi_1\xi_2)=D\otimes\xi_1\xi_2. \tag{79}$$

Thus we get

$$D=M_{12}^{12}-qM_{12}^{21}=a\tilde{d}-qb\tilde{c}=ad-\frac{q}{p}(1-r)bc-\frac{r}{s}ac-q\frac{s}{p}bd. \tag{80}$$

As was explained above, this is a nonperturbative deformation; the limit to the undeformed case cannot be taken simultaneously. However, there is a sequential limit leading to another 3 and 2 parameters deformation. In fact, if we take first the limit $r\to 0$ we get $M_{q,p,s}(2)$ and now the remaining $\phi(p,s)$ is now a genuine 2-cocycle, so that the twisting is well defined in the whole spectrum of p and s. Taking now a second undeformed limit, we set $s\to 0$, then we recover the biparametric $M_{q,p}(2)$ obtained by Manin *et al.*,[13] as nonstandard quantum groups. In these limits θ becomes

$$\theta(p)=\begin{bmatrix} 1 & 0 & 0 & 0 \\ 0 & 0 & p & 0 \\ 0 & \frac{1}{p} & 0 & 0 \\ 0 & 0 & 0 & 1 \end{bmatrix}, \tag{81}$$

and now, the 2-cocycle $\phi=\epsilon\otimes\rho$ becomes

$$\rho=\begin{bmatrix} 1 & 0 \\ 0 & 1/p \end{bmatrix}, \tag{82}$$

and the relations $BM-MB$, or $R^{\phi}*m=m^{op}*R^{\phi}$, reduce to

$$\begin{gathered} ac-pqca=0, \\ ab-p^{-1}qba=0, \\ bc-p^2cb=0, \\ cd-p^{-1}qdc=0, \\ bd-pqdb=0, \\ ad-da+p(q^{-1}-q)cb=0, \end{gathered} \tag{83}$$

which define a two parametric $M_{q,p}(2)$ as the quotient algebra,[13]

$$M_{q,p}(2)=\frac{k[T_i^j]}{I(BM-MB)} \tag{84}$$

for i and j from 1 to 2. It is worth remarking that $R^{\phi}(q,p)=\overline{\phi}_{21}(p)*R(q)*R(q)*\phi(p)$ is a solution of the Quantum Yang–Baxter equation, and assuming R^{ϕ} is a bialgebra bicharacter, it supplies $M_{q,p}(2)$ with a dual-quasitriangular structure.

This γ gives rise to the following relations between matrix entries and the coordinates of the quantum plane:

$$\begin{aligned}
\gamma(e_i\otimes a)&=a\otimes e_i,\\
\gamma(e_i\otimes d)&=d\otimes e_i,\\
\gamma(e_i\otimes b)&=pb\otimes e_i,\\
\gamma(e_i\otimes c)&=p^{-1}c\otimes e_i.
\end{aligned} \tag{85}$$

Defining $\tilde{T}_i^j=\theta_{il}^{jk}T_k^l$ we get

$$\tilde{T}=\begin{bmatrix} a & pc \\ \dfrac{b}{p} & d \end{bmatrix}, \tag{86}$$

and with the coproduct

$$\Delta\tilde{T}_i^j=\tilde{T}_i^k\otimes\tilde{T}_k^j. \tag{87}$$

The determinant becomes in

$$D=\det{}_{q,p}=ad-p^{-1}qbc,$$

that satisfy the following commutation relations:

$$\begin{aligned}
Da\mp aD&=0,\\
Db-p^{-2}bD&=0,\\
Dc-p^{2}cD&=0,\\
Dd-dD&=0.
\end{aligned}$$

With these properties, and assuming that D is an invertible element of $M_{q,p}(2)$, the antipode can be defined

$$S\begin{bmatrix} a & b \\ c & d \end{bmatrix}=D^{-1}\begin{bmatrix} d & -(pq)^{-1}b \\ -pqc & a \end{bmatrix}, \tag{88}$$

and, consequently, the quasitriangular Hopf algebra $GL_{qp}(2)$ is obtained.[13] This means that through the noncommutative coaction,

$$\delta^{\gamma}(e_1\otimes e_1)=aa\otimes e_1\otimes e_1+pab\otimes e_1\otimes e_2+ba\otimes e_2\otimes e_1+pbb\otimes e_2\otimes e_2,$$

$$\delta^{\gamma}(e_1\otimes e_2)=\frac{1}{p}ac\otimes e_1\otimes e_1+ac\otimes e_1\otimes e_2+\frac{1}{p}bc\otimes e_2\otimes e_1+cd\otimes e_2\otimes e,$$

$$\delta^{\gamma}(e_2\otimes e_1)=ca\otimes e_1\otimes e_1+pcb\otimes e_1\otimes e_2+da\otimes e_2\otimes e_1+pdb\otimes e_2\otimes e_2,$$

$$\delta^{\gamma}(e_1\otimes e_2)=\frac{1}{p}cc\otimes e_1\otimes e_1+cd\otimes e_1\otimes e_2+\frac{1}{p}dc\otimes e_2\otimes e_1+dd\otimes e_2\otimes e,$$

with $\gamma(e_k\otimes T^l_j)$ defined in Eq. (85), the standard Quantum Planes $A_q^{2/0}$ and $A_q^{0/2}$ appears also as $GL_{p,q}(2)$-comodules, this result can be obtained by completely different means as in Ref. 16.

VII. CONCLUDING REMARKS

We have introduced a new ingredient in the construction of comodules of Quantum (semi) Groups admitting noncommutativity between endomorphism matrix entries and quantum space coordinates. This feature give rise to an extra deformation of all the involved structures. Our approach is not a full braiding as those obtained from the quasitensor category of *k*-modules.[8] In a less ambitious project, we have just redefined the coaction showing that it is possible to introduce a nontrivial map $\gamma: V\otimes H_\gamma\rightarrow H_\gamma\otimes V$ without spoiling out the Hopf algebra and the comodule structures provided that γ turns H_γ into a Quantum Matrix Group. No additional modification were introduced in the usual structure of bialgebras, preserving the product and coproduct untouched. However, provided a factorizable γ, this generalization of the coaction boils down to a twisting of the algebra structure or a twist of the *R*-matrix, and in some cases it is possible to recover a quasitriangular FRT bialgebra.

Although the map γ seems too constrained, we have found nontrivial solutions introducing many new deformation parameters, still under the additional condition of integrability. This last point was also analyzed, showing that integrability can be reached at least in two independent ways. Working on the Quantum Planes as examples, it was shown that the biparametric deformation of $GL(2,\mathbf{C})$, namely, $GL_{p,q}(2)$, can be regarded as coacting in a twisted way over the standard quantum plane.

A spinor-like representation of the contact superconformal algebra $K'(4)$

Elena Poletaeva[a)]
Centre for Mathematical Sciences, Mathematics, Lund University, Box 118, S-221 00 Lund, Sweden

(Received 10 July 2000; accepted for publication 27 September 2000)

In this work we construct an embedding of a nontrivial central extension of the contact superconformal algebra $K'(4)$ into the Lie superalgebra of pseudodifferential symbols on the supercircle $S^{1/2}$. Associated with this embedding is a one-parameter family of spinor-like tiny irreducible representations of $K'(4)$ realized just on 4 fields instead of the usual 16. © *2001 American Institute of Physics.* [DOI: 10.1063/1.1326920]

I. INTRODUCTION

Recall that a *superconformal algebra* is a simple complex Lie superalgebra such that it contains the centerless Virasoro algebra (i.e., the Witt algebra) $\mathrm{Witt}=\oplus_{n\in\mathbb{Z}}\mathbb{C}L_n$ as a subalgebra, and has growth 1. The $\mathbb{Z}$-graded superconformal algebras are ones for which $\mathrm{ad}L_0$ is diagonalizable with finite-dimensional eigenspaces; see Ref. 1. In general, a superconformal algebra is a subalgebra of the Lie superalgebra of all derivations of $\mathbb{C}[t,t^{-1}]\otimes\Lambda(N)$, where $\Lambda(N)$ is the Grassmann algebra in N odd variables.

The Lie superalgebra $K(N)$ of contact vector fields with Laurent polynomials as coefficients is characterized by its action on a contact 1-form (Refs. 1, 2 and 3); it is isomorphic to the $SO(N)$ *superconformal algebra* (Ref. 4). $K(N)$ is simple except when $N=4$. In this case $K'(4)=[K(4),K(4)]$ is simple. Note that $K'(N)$ is spanned by 2^N fields. It was discovered in Refs. 5, 6 and 7 that the Lie superalgebra of contact vector fields with polynomial coefficients in 1 even and 6 odd variables contains an exceptional simple Lie superalgebra (see also Refs. 2 and 3). It was shown in Ref. 3 that the derived Lie superalgebra of divergence-free derivations of $\mathbb{C}[t,t^{-1}]\otimes\Lambda(2)$, which is spanned by 8 fields, can be realized inside $K(4)$ using the construction of the exceptional superconformal algebra inside $K(6)$.

Note that a Lie algebra of contact vector fields can be realized as a subalgebra of Poisson algebra; see Ref. 8. The Poisson algebra of formal Laurent series on $\dot{T}^*S^1=T^*S^1\backslash S^1$ has a well-known deformation, that is the Lie algebra R of pseudodifferential symbols on the circle. The Poisson algebra can be considered to be the semiclassical limit of R; see Refs. 9, 10, 11 and 12.

In this work we define a family $R_h(N)$ of Lie superalgebras of pseudodifferential symbols on the supercircle $S^{1/N}$, where $h\in]0,1]$, which contracts to the Poisson superalgebra.

For each h we construct an embedding of a central extension $\hat{K}'(4)$ into $R_h(2)$. These central extensions are isomorphic to one of 3 independent central extensions, which are known for $K'(4)$ (Refs. 1, 2, 13 and 14). The corresponding central element is $h\in R_h(2)$. The elements of embeddings of $\hat{K}'(4)$ are power series in h; considering their limits as $h\to 0$, we obtain an embedding of $K'(4)$ into the Poisson superalgebra.

The idea of our construction is as follows. We consider the Schwimmer–Seiberg's deformation $S(2,\alpha)$ of the Lie superalgebra of divergence-free derivations of $\mathbb{C}[t,t^{-1}]\otimes\Lambda(2)$ (Refs. 15 and 1) and observe that the exterior derivations of $S'(2,\alpha)$ form an $\mathfrak{sl}(2)$ if $\alpha\in\mathbb{Z}$. The exterior derivations of $S'(2,\alpha)$ for all $\alpha\in\mathbb{Z}$ generate a subalgebra of the Poisson superalgebra isomorphic

a)Electronic mail: elena@maths.lth.se

to the loop algebra $\tilde{\mathfrak{sl}}(2)$ [$\mathfrak{sl}(2)$ corresponds to $\alpha=1$]. We prove that the family $S'(2,\alpha)$ for all $\alpha\in\mathbb{Z}$ and $\tilde{\mathfrak{sl}}(2)$ generate a Lie superalgebra isomorphic to $K'(4)$. The similar construction for each $h\in]0,1]$ gives an embedding of a nontrivial central extension of $K'(4)$:

$$\hat{K}'(4)\subset R_h(2). \tag{1.1}$$

It is known that the Lie algebra R has two independent central extensions; see Refs. 9, 10 and 11. Accordingly, there exist, up to equivalence, two nontrivial 2-cocycles on its superanalog $R_{h=1}(N)$. The 2-cocycle on $K'(4)$, which corresponds to the central extension $\hat{K}'(4)$ is equivalent to the restriction of one of the 2-cocycles on $R_{h=1}(2)$.

Finally, the embedding (1.1) for $h=1$ allows us to define a new one-parameter family of tiny irreducible representations of $\hat{K}'(4)$. Recall that there exists a two-parameter family of representations of $K'(N)$ in the superspace spanned by 2^N fields. These representations are defined by the natural action of $K'(N)$ in the spaces of ''densities;'' see Ref. 1.

We obtain representations of $\hat{K}'(4)$, where the value of the central charge is equal to 1, realized on just 4 fields, instead of the usual 16.

II. SUPERCONFORMAL ALGEBRAS

In this section we review the notion of a superconformal algebra and give the necessary definitions.

A *superconformal algebra* is a complex Lie superalgebra $\mathfrak{g}$ such that

(1) $\mathfrak{g}$ is simple,
(2) $\mathfrak{g}$ contains the Witt algebra $\mathrm{Witt}=\mathrm{der}\,\mathbb{C}[t,t^{-1}]=\oplus_{n\in\mathbb{Z}}\mathbb{C}L_n$ with the well-known commutation relations

$$[L_n,L_m]=(n-m)L_{n+m} \tag{2.1}$$

as a subalgebra,
(3) adL_0 is diagonalizable with finite-dimensional eigenspaces:

$$\mathfrak{g}=\oplus_j\mathfrak{g}_j,\mathfrak{g}_j=\{x\in\mathfrak{g}|[L_0,x]=jx\}, \tag{2.2}$$

so that $\dim\mathfrak{g}_j<C$, where C is a constant independent of j; see Ref. 1. The main series of superconformal algebras are $W(N)(N\geqslant 0)$, $S'(N,\alpha)(N\geqslant 2)$ and $K'(N)$ $(N\geqslant 1)$. The corresponding central extensions were classified in Ref. 1; see also Refs. 2, 13, 14 and 16.

The superalgebras $W(N)$. Consider the superalgebra $\mathbb{C}[t,t^{-1}]\otimes\Lambda(N)$, where $\Lambda(N)$ is the Grassmann algebra in N variables $\theta_1,\ldots,\theta_N$. Let p be the parity of the homogeneous element. Let $p(t)=\overline{0}$ and $p(\theta_i)=\overline{1}$ for $i=1,...,N$. By definition $W(N)$ is the Lie superalgebra of all derivations of $\mathbb{C}[t,t^{-1}]\otimes\Lambda(N)$. Let ∂_i stand for $\partial/\partial\theta_i$ and ∂_t stand for $\partial/\partial t$. Every $D\in W(N)$ is represented by a differential operator,

$$D=f\partial_t+\sum_{i=1}^{N} f_i\partial_i, \tag{2.3}$$

where f, $f_i\in\mathbb{C}[t,t^{-1}]\otimes\Lambda(N)$. $W(N)$ has no nontrivial 2-cocycles if $N>2$. If $N=1$ or 2, then there exists, up to equivalence, one nontrivial 2-cocycle on $W(N)$.

The superalgebras $S(N,\alpha)$. The Lie superalgebra $W(N)$ contains a one-parameter family of Lie superalgebras $S(N,\alpha)$; see Refs. 15 and 1. By definition

$$S(N,\alpha)=\{D\in W(N)|\mathrm{Div}(t^\alpha D)=0\},\quad \text{for } \alpha\in\mathbb{C}. \tag{2.4}$$

Recall that

$$\mathrm{Div}(D)=\partial_t f+\sum_{i=1}^{N}(-1)^{p(f_i)}\partial_i(f_i) \tag{2.5}$$

and

$$\mathrm{Div}(fD)=Df+f\,\mathrm{Div}\,D, \tag{2.6}$$

where f is an even function. Let $S'(N,\alpha)=[S(N,\alpha),S(N,\alpha)]$ be the derived superalgebra. Assume that $N>1$. If $\alpha\notin\mathbb{Z}$, then $S(N,\alpha)$ is simple, and if $\alpha\in\mathbb{Z}$, then $S'(N,\alpha)$ is a simple ideal of $S(N,\alpha)$ of codimension one defined from the exact sequence,

$$0\to S'(N,\alpha)\to S(N,\alpha)\to\mathbb{C}t^{-\alpha}\theta_1\cdots\theta_N\partial_t\to 0. \tag{2.7}$$

Notice that

$$S(N,\alpha)\cong S(N,\alpha+n),\quad \text{for } n\in\mathbb{Z}. \tag{2.8}$$

There exists, up to equivalence, one nontrivial 2-cocycle on $S'(N,\alpha)$ if and only if $N=2$; see Ref. 1. Let $\hat{S}'(2,\alpha)$ be the corresponding central extension of $S'(2,\alpha)$. Note that $S'(2,\alpha)$ is spanned by 4 even fields and 4 odd fields. Sometimes the name ''$N=4$ superconformal algebra'' is used for $\hat{S}'(2,0)$; see Refs. 4 and 3.

The superalgebras $K(N)$. By definition,

$$K(N)=\{D\in W(N)\,|\,D\Omega=f\Omega,\quad \text{for some } f\in\mathbb{C}[t,t^{-1}]\otimes\Lambda(N)\}, \tag{2.9}$$

where

$$\Omega=dt-\sum_{i=1}^{N}\theta_i\,d\theta_i \tag{2.10}$$

is a contact 1-form; see Refs. 1, 2 and 3. Every differential operator $D\in K(N)$ can be represented by a single function,

$$f\in\mathbb{C}[t,t^{-1}]\otimes\Lambda(N): f\to D_f. \tag{2.11}$$

Let

$$\Delta(f)=2f-\sum_{i=1}^{N}\theta_i\partial_i(f). \tag{2.12}$$

Then

$$D_f=\Delta(f)\partial_t+\partial_t(f)\sum_{i=1}^{N}\theta_i\partial_i+(-1)^{p(f)}\sum_{i=1}^{N}\partial_i(f)\partial_i. \tag{2.13}$$

Notice that

$$\begin{aligned} D_{f+g}&=D_f+D_g,\\ [D_f,D_g]&=D_{\{f,g\}}, \end{aligned} \tag{2.14}$$

where

$$\{f,g\}=\Delta(f)\partial_t(g)-\partial_t(f)\Delta(g)+(-1)^{p(f)}\sum_{i=1}^{N}\partial_i(f)\partial_i(g). \tag{2.15}$$

The superalgebras $K(N)$ are simple, except when $N=4$. If $N=4$, then the derived superalgebra $K'(4)=[K(4),K(4)]$ is a simple ideal in $K(4)$ of codimension one defined from the exact sequence

$$0\to K'(4)\to K(4)\to \mathbb{C}D_{t^{-1}\theta_1\theta_2\theta_3\theta_4}\to 0. \tag{2.16}$$

There exists no nontrivial 2-cocycles on $K(N)$ if $N>4$. If $N\leqslant 3$, then there exists, up to equivalence, one nontrivial 2-cocycle. Let $\hat{K}(N)$ be the corresponding central extension of $K(N)$. Notice that $\hat{K}(1)$ is isomorphic to the Neveu–Schwarz algebra (Ref. 17), and $\hat{K}(2)\cong\hat{W}(1)$ is isomorphic to the so-called $N=2$ superconformal algebra; see Ref. 18. The superalgebra $K'(4)$ has 3 independent central extensions (Refs. 1, 2, 13 and 14), which is important for our task.

III. LIE SUPERALGEBRAS OF PSEUDODIFFERENTIAL SYMBOLS

Recall that the ring R of pseudodifferential symbols is the ring of the formal series,

$$A(t,\xi)=\sum_{-\infty}^{n}a_i(t)\xi^i, \tag{3.1}$$

where $a_i(t)\in\mathbb{C}[t,t^{-1}]$, and the variable ξ corresponds to $\partial/\partial t$; see Refs. 9, 10, 11 and 12. The multiplication rule in R is determined as follows:

$$A(t,\xi)\circ B(t,\xi)=\sum_{n\geqslant 0}\frac{1}{n!}\partial_\xi^n A(t,\xi)\partial_t^n B(t,\xi). \tag{3.2}$$

Notice that R is a generalization of the associative algebra of the regular differential operators on the circle, and the multiplication rule in R, when restricted to the polynomials in ξ, coincides with the multiplication rule for the differential operators. The Lie algebra structure on R is given by

$$[A,B]=A\circ B-B\circ A, \tag{3.3}$$

where $A,\ B\in R$.

The Poisson algebra P of pseudodifferential symbols has the same underlying vector space. The multiplication in P is naturally defined. The Poisson bracket is defined as follows:

$$\{A(t,\xi),B(t,\xi)\}=\partial_\xi A(t,\xi)\partial_t B(t,\xi)-\partial_t A(t,\xi)\partial_\xi B(t,\xi) \tag{3.4}$$

(Refs. 12 and 19). One can construct the contraction of the Lie algebra R to P using the linear isomorphisms:

$$\varphi_h: R\to R, \tag{3.5}$$

defined by

$$\varphi_h(a_i(t)\xi^i)=a_i(t)h^i\xi^i,\ \text{ where }\ h\in\,]0,1]; \tag{3.6}$$

see Ref. 12. The new multiplication in R is defined by

$$A\circ_h B=\varphi_h^{-1}(\varphi_h(A)\circ\varphi_h(B)). \tag{3.7}$$

Correspondingly, the commutator is

$$[A,B]_h = A\circ_h B - B\circ_h A. \tag{3.8}$$

Thus

$$[A,B]_h = h\{A,B\} + hO(h). \tag{3.9}$$

Hence

$$\lim_{h\to 0}\frac{1}{h}[A,B]_h = \{A,B\}. \tag{3.10}$$

To construct a superanalog of R, consider an associative superalgebra $\Theta_h(N)$ with generators $\theta_1,\dots,\theta_N,\partial_1,\dots,\partial_N$ and relations

$$\begin{aligned} \theta_i\theta_j &= -\theta_j\theta_i, \\ \partial_i\partial_j &= -\partial_j\partial_i, \\ \partial_i\theta_j &= h\delta_{i,j} - \theta_j\partial_i, \end{aligned} \tag{3.11}$$

where $h\in\,]0,1]$. Define an associative superalgebra,

$$R_h(N) = R\otimes\Theta_h(N), \tag{3.12}$$

such that

$$(A\otimes X)(B\otimes Y) = \frac{1}{h}(A\circ_h B)\otimes(XY), \tag{3.13}$$

where $A, B\in R$, and $X, Y\in\Theta_h(N)$. The product in $R_h(N)$ determines the natural Lie superalgebra structure on this space:

$$[(A\otimes X),(B\otimes Y)]_h = \frac{1}{h}(A\circ_h B)\otimes(XY) - (-1)^{p(X)p(Y)}\frac{1}{h}(B\circ_h A)\otimes(YX). \tag{3.14}$$

For each $h\in\,]0,1]$ there exists an embedding,

$$W(N)\subset R_h(N), \tag{3.15}$$

such that the commutation relations in $R_h(N)$, when restricted to $W(N)$, coincide with the commutation relations in $W(N)$. In particular, when $h=1$, we obtain the superanalog $R(N) := R_{h=1}(N)$ of the Lie algebra of pseudodifferential symbols on the circle.

The Poisson superalgebra $P(N)$ has the underlying vector space $P\otimes\Theta(N)$, where $\Theta(N) := \Theta_{h=0}(N)$ is the Grassman algebra with generators $\theta_1,\dots,\theta_N,\overline{\theta_1},\dots,\overline{\theta_N}$, where $\overline{\theta_i}=\partial_i$ for $i=1,\dots,N$. The Poisson bracket is defined as follows:

$$\{A,B\} = \partial_\xi A\partial_t B - \partial_t A\partial_\xi B - (-1)^{p(A)}\left(\sum_{i=1}^{N}\partial_{\theta_i}A\partial_{\overline{\theta_i}}B + \partial_{\overline{\theta_i}}A\partial_{\theta_i}B\right), \tag{3.16}$$

where $A, B\in P(N)$; cf. Refs. 2, 5. Thus

$$\lim_{h\to 0}[A,B]_h = \{A,B\}. \tag{3.17}$$

Correspondingly, we have the embedding

$$W(N)\subset P(N). \tag{3.18}$$

Remark 3.1: Recall that there exist, up to equivalence, two nontrivial 2-cocycles on R (Refs. 9, 10 and 11). Analogously, one can define two 2-cocycles, c_ξ and c_t, on $R(N)$; cf. Ref. 20. Let $A, B \in R$, and $X, Y \in \Theta_{h=1}(N)$. Then

$$c_\xi(A\otimes X, B\otimes Y) = \text{the coefficient of } t^{-1}\xi^{-1}\theta_1\dots\theta_N\partial_1\dots\partial_N \text{ in } ([\log\xi, A]\circ B)\otimes(XY), \tag{3.19}$$

where

$$[\log\xi, A(t,\xi)] = \Sigma_{k\geq 1}\frac{(-1)^{k+1}}{k}\partial_t^k A(t,\xi)\xi^{-k}, \tag{3.20}$$

and

$$c_t(A\otimes X, B\otimes Y) = \text{the coefficient of } t^{-1}\xi^{-1}\theta_1\dots\theta_N\partial_1\dots\partial_N \text{ in } ([\log t, A]\circ B)\otimes(XY), \tag{3.21}$$

where

$$[\log t, A(t,\xi)] = \Sigma_{k\geq 1}\frac{(-1)^{k+1}}{k}t^{-k}\partial_\xi^k A(t,\xi). \tag{3.22}$$

IV. THE CONSTRUCTION OF EMBEDDING

Let $\mathrm{Der}\, S'(2,\alpha)$ be the Lie superalgebra of all derivations of $S'(2,\alpha)$.

Lemma 4.1: The exterior derivations $\mathrm{Der}_{\mathrm{ext}} S'(2,\alpha)$ for all $\alpha\in\mathbb{Z}$ generate the loop algebra,

$$\tilde{\mathfrak{sl}}(2)\subset P(2). \tag{4.1}$$

Proof: In Ref. 21 we observed that the exterior derivations of $S'(2,0)$ form an $\mathfrak{sl}(2)$. Let

$$\{\mathcal{L}_n^\alpha, E_n, H_n, F_n, h_n^\alpha, p_n^0, x_n^0, y_n^\alpha\}_{n\in\mathbb{Z}} \tag{4.2}$$

be a basis of $S'(2,\alpha)$ defined as follows:

$$\begin{aligned}
\mathcal{L}_n^\alpha &= -t^n(t\xi + \tfrac{1}{2}(n+\alpha+1)(\theta_1\partial_1+\theta_2\partial_2)),\\
E_n &= t^n\theta_2\partial_1,\\
H_n &= t^n(\theta_2\partial_2-\theta_1\partial_1),\\
F_n &= t^n\theta_1\partial_2,\\
h_n^\alpha &= t^n\xi\theta_2-(n+\alpha)t^{n-1}\theta_1\theta_2\partial_1,\\
p_n^0 &= -t^{n+1}\partial_2,\\
x_n^0 &= t^{n+1}\partial_1,\\
y_n^\alpha &= t^n\xi\theta_1+(n+\alpha)t^{n-1}\theta_1\theta_2\partial_2.
\end{aligned} \tag{4.3}$$

Let us show that if $\alpha\in\mathbb{Z}$, then $\mathrm{Der}_{\mathrm{ext}} S'(2,\alpha)\cong\mathfrak{sl}(2)=\langle \boldsymbol{\mathcal{E}}, \boldsymbol{\mathcal{H}}, \boldsymbol{\mathcal{F}}\rangle$, where

$$[\boldsymbol{\mathcal{H}}, \boldsymbol{\mathcal{E}}] = 2\boldsymbol{\mathcal{E}}, \quad [\boldsymbol{\mathcal{H}}, \boldsymbol{\mathcal{F}}] = -2\boldsymbol{\mathcal{F}}, \quad [\boldsymbol{\mathcal{E}}, \boldsymbol{\mathcal{F}}] = \boldsymbol{\mathcal{H}}, \tag{4.4}$$

and the action of $\mathfrak{sl}(2)$ is given as follows:

$$[\boldsymbol{\mathcal{E}}, h_n^\alpha] = x_{n-1+\alpha}, \quad [\boldsymbol{\mathcal{E}}, y_n^\alpha] = p^0_{n-1+\alpha}, \quad [\boldsymbol{\mathcal{F}}, x_n] = h^\alpha_{n+1-\alpha}, \quad [\boldsymbol{\mathcal{F}}, p_n^0] = y^\alpha_{n+1-\alpha},$$
$$[\boldsymbol{\mathcal{H}}, x_n^0] = x_n^0, \quad [\boldsymbol{\mathcal{H}}, h_n^\alpha] = -h_n^\alpha, \quad [\boldsymbol{\mathcal{H}}, p_n^0] = p_n^0, \quad [\boldsymbol{\mathcal{H}}, y_n^\alpha] = -y_n^\alpha. \tag{4.5}$$

Notice that

$$\mathrm{Der}_{\mathrm{ext}} S'(2,\alpha) \cong H^1(S'(2,\alpha), S'(2,\alpha)); \tag{4.6}$$

see Ref. 22. Consider the following $\mathbb{Z}$-grading deg of $S'(2,\alpha)$:

$$\deg \mathcal{L}_n^\alpha = n, \quad \deg E_n = n+1-\alpha, \quad \deg F_n = n-1+\alpha, \quad \deg H_n = n,$$
$$\deg h_n^\alpha = n, \quad \deg p_n = n, \quad \deg x_n = n+1-\alpha, \quad \deg y_n^\alpha = n-1+\alpha. \tag{4.7}$$

Let

$$L_0^\alpha = -\mathcal{L}_0^\alpha + \tfrac{1}{2}(1-\alpha)H_0. \tag{4.8}$$

Then

$$[L_0^\alpha, s] = (\deg s)s, \tag{4.9}$$

for a homogeneous $s \in S'(2,\alpha)$. Accordingly,

$$[L_0^\alpha, D] = (\deg D)D, \tag{4.10}$$

for a homogeneous $D \in \mathrm{Der}_{\mathrm{ext}} S'(2,\alpha)$. On the other hand, since the action of a Lie superalgebra on its cohomology is trivial, then one must have

$$[L_0^\alpha, D] = 0. \tag{4.11}$$

Hence the nonzero elements of $\mathrm{Der}_{\mathrm{ext}} S'(2,\alpha)$ have deg=0, and they preserve the superalgebra $S'(2,\alpha)_{\deg=0}$. One can check that the exterior derivations of $S'(2,\alpha)_{\deg=0}$ form an $\mathfrak{sl}(2)$, and extend them to the exterior derivations of $S'(2,\alpha)$ as in (4.5). One should also note that if the restriction of a derivation of $S'(2,\alpha)$ to $S'(2,\alpha)_{\deg=0}$ is zero, then this derivation is inner. We can identify the exterior derivation $t^{-\alpha}\xi\theta_1\theta_2$ [see (2.7)] with $-\boldsymbol{\mathcal{F}}$. We cannot realize all the exterior derivations as regular differential operators on the supercircle, but can do this using the symbols of pseudodifferential operators. In fact, let $\alpha = 1$. Then

$$\mathrm{Der}_{\mathrm{ext}} S'(2,1) = \mathfrak{sl}(2) = \langle \boldsymbol{\mathcal{F}}, \boldsymbol{\mathcal{H}}, \boldsymbol{\mathcal{E}} \rangle \subset P(2), \tag{4.12}$$

where

$$\boldsymbol{\mathcal{F}} = -t^{-1}\xi\theta_1\theta_2, \quad \boldsymbol{\mathcal{H}} = -\theta_1\partial_1 - \theta_2\partial_2, \quad \boldsymbol{\mathcal{E}} = t\xi^{-1}\partial_1\partial_2. \tag{4.13}$$

One can then construct the loop algebra of $\mathfrak{sl}(2)$ as follows:

$$\tilde{\mathfrak{sl}}(2) = \langle \boldsymbol{\mathcal{F}}_n, \boldsymbol{\mathcal{H}}_n, \boldsymbol{\mathcal{E}}_n \rangle_{n \in \mathbb{Z}}, \tag{4.14}$$

where

$$\boldsymbol{\mathcal{F}}_n = -t^{n-1}\xi\theta_1\theta_2,$$
$$\boldsymbol{\mathcal{H}}_n = nt^{n-1}\xi^{-1}\theta_1\theta_2\partial_1\partial_2 - t^n(\theta_1\partial_1 + \theta_2\partial_2), \tag{4.15}$$

$$\boldsymbol{\mathcal{E}}_n = t^{n+1}\xi^{-1}\partial_1\partial_2 .$$

The nonvanishing commutation relations are

$$[\boldsymbol{\mathcal{H}}_n, \boldsymbol{\mathcal{E}}_k] = 2\boldsymbol{\mathcal{E}}_{n+k}, \quad [\boldsymbol{\mathcal{H}}_n, \boldsymbol{\mathcal{F}}_k] = -2\boldsymbol{\mathcal{F}}_{n+k}, \quad [\boldsymbol{\mathcal{E}}_n, \boldsymbol{\mathcal{F}}_k] = \boldsymbol{\mathcal{H}}_{n+k}. \tag{4.16}$$

Let $\alpha \in \mathbb{Z}$. Then

$$\mathrm{Der}_{\mathrm{ext}} S'(2,\alpha) \cong \langle \boldsymbol{\mathcal{F}}_{-\alpha+1}, \boldsymbol{\mathcal{H}}_0, \boldsymbol{\mathcal{E}}_{\alpha-1} \rangle. \tag{4.17}$$

□

Theorem 4.1: The superalgebras $S'(2,\alpha)$ for all $\alpha \in \mathbb{Z}$ together with $\tilde{\mathfrak{sl}}(2)$ generate a Lie superalgebra isomorphic to $K'(4)$.

Proof: Let

$$\begin{aligned} I_n^0 &= t^n(\theta_1\partial_1 + \theta_2\partial_2), \\ \mathfrak{r}_n &= t^{n-1}\theta_1\theta_2\partial_1, \\ \mathfrak{s}_n &= t^{n-1}\theta_1\theta_2\partial_2 . \end{aligned} \tag{4.18}$$

Then according to (4.3),

$$\begin{aligned} \mathcal{L}_n^\alpha &= \mathcal{L}_n^0 - \tfrac{1}{2}\alpha I_n^0, \\ h_n^\alpha &= h_n^0 - \alpha\mathfrak{r}_n, \\ y_n^\alpha &= y_n^0 + \alpha\mathfrak{s}_n . \end{aligned} \tag{4.19}$$

One can easily check that the superalgebras $S'(2,\alpha)$, where $\alpha \in \mathbb{Z}$, generate $W(2) \subset P(2)$. In fact, $W(2)$ is spanned by 8 fields defined in Eq. (4.3), where $\alpha = 0$, together with 3 fields defined in Eq. (4.18) and the field $\boldsymbol{\mathcal{F}}_n$. If we include two even fields, $\boldsymbol{\mathcal{E}}_n$ and $\boldsymbol{\mathcal{H}}_n$, into the picture, then from the commutation relations, we obtain two additional odd fields:

$$\begin{aligned} \mathfrak{q}_n &= t^n\xi^{-1}\theta_2\partial_1\partial_2, \\ \mathfrak{t}_n &= -t^n\xi^{-1}\theta_1\partial_1\partial_2 . \end{aligned} \tag{4.20}$$

Let $\mathfrak{g} \subset P(2)$ be the Lie superalgebra generated by the superalgebras $S'(2,\alpha)$ for all $\alpha \in \mathbb{Z}$ and $\tilde{\mathfrak{sl}}(2)$. We will show that there exists an isomorphism:

$$\psi : K'(4) \to \mathfrak{g}. \tag{4.21}$$

Let

$$\begin{aligned} \mathcal{L}_n &= \mathcal{L}_n^0 + \boldsymbol{\mathcal{H}}_n + \tfrac{1}{2} I_n^0, \\ I_n &= I_n^0 + \boldsymbol{\mathcal{H}}_n, \\ p_n &= p_n^0 + \mathfrak{t}_n, \\ x_n &= x_n^0 - \mathfrak{q}_n . \end{aligned} \tag{4.22}$$

Set

$$h_n = h_n^0, \quad y_n = y_n^0. \tag{4.23}$$

Then $\mathfrak{g} = \mathfrak{g}_0^- \oplus \mathfrak{g}_1^-$, where

$$\begin{gathered}\mathfrak{g}_0^- = \langle \mathcal{L}_n, I_n, E_n, H_n, F_n, \boldsymbol{\mathcal{E}}_n, \boldsymbol{\mathcal{H}}_n, \boldsymbol{\mathcal{F}}_n \rangle, \\ \mathfrak{g}_1^- = \langle h_n, p_n, x_n, y_n, \mathfrak{r}_n, \mathfrak{s}_n, \mathfrak{q}_n, \mathfrak{t}_n \rangle.\end{gathered} \tag{4.24}$$

We will describe the nonvanishing commutation relations in $\mathfrak{g}$ with respect to this basis.

For $[\mathfrak{g}_0^-, \mathfrak{g}_0^-]$ the relations are

$$\begin{gathered}[\mathcal{L}_n, \mathcal{L}_k] = (n-k)\mathcal{L}_{n+k}; \\ [H_n, E_k] = 2E_{n+k}, [H_n, F_k] = -2F_{n+k}, \quad [E_n, F_k] = H_{n+k}; \\ [\boldsymbol{\mathcal{H}}_n, \boldsymbol{\mathcal{E}}_k] = 2\boldsymbol{\mathcal{E}}_{n+k}, [\boldsymbol{\mathcal{H}}_n, \boldsymbol{\mathcal{F}}_k] = -2\boldsymbol{\mathcal{F}}_{n+k}, \quad [\boldsymbol{\mathcal{E}}_n, \boldsymbol{\mathcal{F}}_k] = \boldsymbol{\mathcal{H}}_{n+k}; \\ [\mathcal{L}_n, X_k] = -kX_{n+k}, \quad \text{where } X_k = I_k, E_k, H_k, F_k, \boldsymbol{\mathcal{E}}_k, \boldsymbol{\mathcal{H}}_k, \boldsymbol{\mathcal{F}}_k.\end{gathered} \tag{4.25}$$

For $[\mathfrak{g}_0^-, \mathfrak{g}_1^-]$ the relations are

$$[\mathcal{L}_n, X_k] = \left(-k + \frac{n}{2}\right) X_{n+k}, \quad \text{where } X_k = h_k, p_k, x_k, y_k;$$

$$[\mathcal{L}_n, X_k] = \left(-k - \frac{n}{2}\right) X_{n+k}, \quad \text{where } X_k = \mathfrak{r}_k, \mathfrak{s}_k, \mathfrak{q}_k, \mathfrak{t}_k;$$

$$[I_n, X_k] = nY_{n+k}, \quad \text{where } X_k = h_k, p_k, x_k, y_k, \quad \text{and } Y_k = \mathfrak{r}_k, \mathfrak{t}_k, -\mathfrak{q}_k, -\mathfrak{s}_k, \quad \text{respectively;}$$

$$[H_n, X_k] = X_{n+k}, \quad \text{where } X_k = h_k, x_k, \mathfrak{q}_k, \mathfrak{r}_k;$$

$$[H_n, X_k] = -X_{n+k}, \quad \text{where } X_k = y_k, p_k, \mathfrak{s}_k, \mathfrak{t}_k; \tag{4.26}$$

$$[E_n, X_k] = Y_{n+k}, [F_n, Y_k] = X_{n+k}, \quad \text{where } X_k = y_k, p_k, \mathfrak{s}_k, \mathfrak{t}_k,$$
$$\text{and } Y_k = h_k, x_k, -\mathfrak{r}_k, -\mathfrak{q}_k, \quad \text{respectively;}$$

$$[\boldsymbol{\mathcal{H}}_n, X_k] = X_{n+k} + nY_{n+k}, \quad \text{where } X_k = p_k, x_k, \mathfrak{q}_k, \mathfrak{t}_k \quad \text{and } Y_k = \mathfrak{t}_k, -\mathfrak{q}_k, 0, 0, \quad \text{respectively;}$$

$$[\boldsymbol{\mathcal{H}}_n, X_k] = -X_{n+k} - nY_{n+k}, \quad \text{where } X_k = h_k, y_k, \mathfrak{r}_k, \mathfrak{s}_k, \quad \text{and } Y_k = \mathfrak{r}_k, -\mathfrak{s}_k, 0, 0, \quad \text{respectively;}$$

$$[\boldsymbol{\mathcal{E}}_n, X_k] = Y_{n+k} - nZ_{n+k}, \quad [\boldsymbol{\mathcal{F}}_n, Y_k] = X_{n+k} - n\overline{Z}_{n+k}, \quad \text{where } X_k = h_k, y_k, \mathfrak{r}_k, \mathfrak{s}_k,$$

$$Y_k = x_k, p_k, -\mathfrak{q}_k, -\mathfrak{t}_k, Z_k = \mathfrak{q}_k, -\mathfrak{t}_k, 0, 0, \quad \text{and } \overline{Z}_k = -\mathfrak{r}_k, \mathfrak{s}_k, 0, 0, \quad \text{respectively.}$$

Finally, for $[\mathfrak{g}_1^-, \mathfrak{g}_1^-]$ the relations are

$$\begin{gathered}[h_n, x_k] = (k-n)E_{n+k}, [p_n, y_k] = (k-n)F_{n+k}, \\ [h_n, p_k] = \mathcal{L}_{n+k} - \tfrac{1}{2}(k-n)H_{n+k}, [x_n, y_k] = -\mathcal{L}_{n+k} + \tfrac{1}{2}(k-n)H_{n+k}, \\ [h_n, \mathfrak{q}_k] = E_{n+k}, [x_n, \mathfrak{r}_k] = E_{n+k}, [p_n, \mathfrak{s}_k] = F_{n+k}, [y_n, \mathfrak{t}_k] = F_{n+k}, \\ [p_n, \mathfrak{q}_k] = -\boldsymbol{\mathcal{E}}_{n+k}, [x_n, \mathfrak{t}_k] = -\boldsymbol{\mathcal{E}}_{n+k}, [h_n, \mathfrak{s}_k] = -\boldsymbol{\mathcal{F}}_{n+k}, [y_n, \mathfrak{r}_k] = -\boldsymbol{\mathcal{F}}_{n+k},\end{gathered} \tag{4.27}$$

$$[p_n,\mathfrak{r}_k]=\tfrac{1}{2}I_{n+k}-\tfrac{1}{2}(H_{n+k}+\boldsymbol{\mathcal{H}}_{n+k}),[x_n,\mathfrak{s}_k]=\tfrac{1}{2}I_{n+k}+\tfrac{1}{2}(H_{n+k}-\boldsymbol{\mathcal{H}}_{n+k}),$$

$$[h_n,\mathfrak{t}_k]=\tfrac{1}{2}I_{n+k}+\tfrac{1}{2}(H_{n+k}+\boldsymbol{\mathcal{H}}_{n+k}),[y_n,\mathfrak{q}_k]=\tfrac{1}{2}I_{n+k}-\tfrac{1}{2}(H_{n+k}-\boldsymbol{\mathcal{H}}_{n+k}).$$

Recall that the elements of $K(4)$ can be identified with the functions from $\mathbb{C}[t,t^{-1}]\otimes\Lambda(4)$. Let

$$\breve{\theta}_1=\theta_2\theta_3\theta_4,\quad \breve{\theta}_2=\theta_1\theta_3\theta_4,\quad \breve{\theta}_3=\theta_1\theta_2\theta_4,\quad \breve{\theta}_4=\theta_1\theta_2\theta_3. \tag{4.28}$$

The following 16 series of functions together with $t^{-1}\theta_1\theta_2\theta_3\theta_4$ span $\mathbb{C}[t,t^{-1}]\otimes\Lambda(4)$:

$$\begin{gathered}
f_n^1=2nt^{n-1}\theta_1\theta_2\theta_3\theta_4,\\
f_n^2=-\tfrac{1}{2}t^{n+1}+\tfrac{1}{2}it^n(\theta_2\theta_3-\theta_1\theta_4)-\tfrac{1}{2}n(n+1)t^{n-1}\theta_1\theta_2\theta_3\theta_4,\\
f_n^k=\tfrac{1}{2}t^{n\mp1}(\pm\theta_1\theta_2\mp\theta_3\theta_4-i\theta_1\theta_3-i\theta_2\theta_4),\quad k=3,4,\\
f_n^5=it^n(\theta_1\theta_4-\theta_2\theta_3),\\
f_n^k=\tfrac{1}{2}t^n(\mp\theta_1\theta_4\mp\theta_2\theta_3+i\theta_2\theta_4-i\theta_1\theta_3),\quad k=6,7,\\
f_n^8=-it^n(\theta_1\theta_2+\theta_3\theta_4),\\
f_n^k=\frac{(i)^{p(k)}}{\sqrt{8}}(t^n(\theta_1\mp i\theta_2\mp\theta_3+i\theta_4)-nt^{n-1}(\breve{\theta}_1\pm i\breve{\theta}_2\mp\breve{\theta}_3-i\breve{\theta}_4)),\quad k=9,10,\\
f_n^k=\frac{(i)^{p(k)}}{\sqrt{8}}(t^{n+1}(\theta_1\pm i\theta_2\mp\theta_3-i\theta_4)-(n+1)t^n(\breve{\theta}_1\mp i\breve{\theta}_2\mp\breve{\theta}_3+i\breve{\theta}_4)),\quad k=11,12,\\
f_n^k=\frac{(-i)^{p(k)}}{\sqrt{2}}t^{n-1}(\breve{\theta}_1\pm i\breve{\theta}_2\mp\breve{\theta}_3-i\breve{\theta}_4),\quad k=13,14,\\
f_n^k=\frac{(-i)^{p(k)}}{\sqrt{2}}t^n(\breve{\theta}_1\mp i\breve{\theta}_2\mp\breve{\theta}_3+i\breve{\theta}_4),\quad k=15,16,
\end{gathered} \tag{4.29}$$

where $p(k)=0$ if k is even, and $p(k)=1$ if k is odd.

The 16 series of the corresponding differential operators $\{D_{f_n^i}\}_{i=1,\ldots,16}$ span $K'(4)$. Set

$$\begin{gathered}
\psi(D_{f_n^1})=I_n,\quad \psi(D_{f_n^2})=\mathcal{L}_n,\\
\psi(D_{f_n^3})=E_n,\quad \psi(D_{f_n^4})=F_n,\quad \psi(D_{f_n^5})=H_n,\\
\psi(D_{f_n^6})=\boldsymbol{\mathcal{E}}_n,\quad \psi(D_{f_n^7})=\boldsymbol{\mathcal{F}}_n,\quad \psi(D_{f_n^8})=\boldsymbol{\mathcal{H}}_n,\\
\psi(D_{f_n^9})=x_n,\quad \psi(D_{f_n^{10}})=h_n,\quad \psi(D_{f_n^{11}})=y_n,\quad \psi(D_{f_n^{12}})=p_n,\\
\psi(D_{f_n^{13}})=\mathfrak{q}_n,\quad \psi(D_{f_n^{14}})=\mathfrak{r}_n,\quad \psi(D_{f_n^{15}})=\mathfrak{s}_n,\quad \psi(D_{f_n^{16}})=\mathfrak{t}_n.
\end{gathered} \tag{4.30}$$

Notice that $f_n^1=0$, if $n=0$. This corresponds to the fact that $D_{t^{-1}\theta_1\theta_2\theta_3\theta_4}\notin K'(4)$. One can verify that ψ is an isomorphism from $K'(4)$ onto $\mathfrak{g}$. □

Remark 4.2: We have obtained an embedding,

$$K'(4)\subset P(2). \tag{4.31}$$

In general, a Lie algebra of contact vector fields can be realized as a subalgebra of Poisson algebra; see Ref. 8. We will explain this from the geometrical point of view in application to our case. Recall that the Lie algebra Vect(S^1) of smooth vector fields on the circle has a natural embedding into the Poisson algebra of functions on the cylinder $\dot{T}^*S^1=T^*S^1\backslash S^1$ with the removed zero section; see Refs. 11, 12 and 19. One can introduce the Darboux coordinates $(q,p)=(t,\xi)$ on this manifold. The symbols of differential operators are functions on $\dot{T}^*S^1$ which are formal Laurent series in p with coefficients periodic in q. Correspondingly, they define Hamiltonian vector fields on $\dot{T}^*S^1$:

$$A(q,p)\to H_A=\partial_p A\partial_q-\partial_q A\partial_p. \tag{4.32}$$

The embedding of Vect(S^1) into the Lie algebra of Hamiltonian vector fields on $\dot{T}^*S^1$ is given by

$$f(q)\partial_q\to H_{f(q)p}. \tag{4.33}$$

Notice that we obtain a subalgebra of Hamiltonian vector fields with Hamiltonians which are homogeneous of degree 1. (This condition holds in general, if one considers the *symplectification* of a contact manifold; see Ref. 8.) In other words, we obtain a subalgebra of Hamiltonian vector fields, which commute with the (semi-) Euler vector field:

$$[H_A,p\partial_p]=0. \tag{4.34}$$

We will show that for $N\geqslant 0$ there exists the analogous embedding:

$$K(2N)\subset P(N). \tag{4.35}$$

The analog of the formula (4.32) in the supercase is as follows (Refs. 2, 5):

$$A(q,p,\theta_i,\overline{\theta_i})\to H_A=\partial_p A\partial_q-\partial_q A\partial_p-(-1)^{p(A)}\sum_{i=1}^{N}(\partial_{\theta_i}A\partial_{\overline{\theta_i}}+\partial_{\overline{\theta_i}}A\partial_{\theta_i}). \tag{4.36}$$

Then $K(2N)$ is defined as the set of all (Hamiltonian) functions $A(q,p,\theta_i,\overline{\theta_i})\in P(N)$ such that

$$\left[H_A,p\partial_p+\sum_{i=1}^{N}\overline{\theta_i}\partial_{\overline{\theta_i}}\right]=0. \tag{4.37}$$

Equivalently, we have the following characterization of the embedding (4.35). Consider a $\mathbb{Z}$-grading of the (associative) superalgebra $P(N)=\oplus_{j\in\mathbb{Z}}P_j(N)$ defined by

$$\begin{aligned}&\deg p=\deg\overline{\theta_i}=1,\quad \text{for } i=1,...,N,\\ &\deg q=\deg\theta_i=0,\quad \text{for } i=1,...,N.\end{aligned} \tag{4.38}$$

Thus with respect to the Poisson bracket,

$$\{P_j(N),P_k(N)\}\subset P_{j+k-1}(N). \tag{4.39}$$

Then

$$K(2N)=P_1(N). \tag{4.40}$$

Theorem 4.2: There exists an embedding,

$$\hat{K}'(4)\subset R_h(2), \tag{4.41}$$

for each $h\in]0,1]$, such that the central element in $\hat{K}'(4)$ is $h\in R_h(2)$, and

$$\lim_{h\to 0}\hat{K}'(4)=K'(4)\subset P(2). \tag{4.42}$$

Proof: For each $h\in]0,1]$ and $\alpha\in\mathbb{Z}$ we have an embedding,

$$\mathrm{Der}\,S'(2,\alpha)\subset R_h(2). \tag{4.43}$$

The exterior derivations $\mathrm{Der}_{\mathrm{ext}}S'(2,\alpha)$ for all $\alpha\in\mathbb{Z}$ generate the loop algebra,

$$\tilde{\mathfrak{sl}}(2)=\langle \boldsymbol{\mathcal{F}}_n,\boldsymbol{\mathcal{H}}_n,\boldsymbol{\mathcal{E}}_n\rangle_{n\in\mathbb{Z}}\subset R_h(2), \tag{4.44}$$

where

$$\boldsymbol{\mathcal{F}}_n=-t^{n-1}\xi\theta_1\theta_2,$$

$$\boldsymbol{\mathcal{H}}_n=\frac{1}{h}((\xi^{-1}\circ_h t^n\xi)(h^2-h\theta_1\partial_1-h\theta_2\partial_2-\theta_1\theta_2\partial_1\partial_2)+t^n\theta_1\theta_2\partial_1\partial_2), \tag{4.45}$$

$$\boldsymbol{\mathcal{E}}_n=(\xi^{-1}\circ_h t^{n+1})\partial_1\partial_2,$$

so that Eqs. (4.16)–(4.17) hold. Let $\mathfrak{g}\subset R_h(2)$ be the Lie superalgebra generated by $S'(2,\alpha)$ for all $\alpha\in\mathbb{Z}$ and $\tilde{\mathfrak{sl}}(2)$. Set

$$\begin{aligned}\mathfrak{q}_n&=(\xi^{-1}\circ_h t^n)(h\partial_1+\theta_2\partial_1\partial_2),\\ \mathfrak{t}_n&=(\xi^{-1}\circ_h t^n)(h\partial_2-\theta_1\partial_1\partial_2).\end{aligned} \tag{4.46}$$

The basis (4.24) in $\mathfrak{g}$ is defined by Eqs. (4.3), (4.18), (4.22)–(4.23) and (4.45)–(4.46). The commutation relations in $\mathfrak{g}$ with respect to this basis are given by Eqs. (4.25)–(4.27). The Lie superalgebra $\mathfrak{g}$ is isomorphic to a central extension,

$$\hat{K}'(4)=K'(4)\oplus\mathbb{C}C, \tag{4.47}$$

of $K'(4)$. The corresponding 2-cocycle (up to equivalence) is

$$\begin{aligned}c(t^{n+1},t^{k+1}\theta_1\theta_2\theta_3\theta_4)&=\delta_{n+k+2,0},\\ c(t^{n+1}\theta_i,t^{k+1}\partial_i(\theta_1\theta_2\theta_3\theta_4))&=\tfrac{1}{2}\,\delta_{n+k+2,0},\quad \text{for } i=1,\ldots,4.\end{aligned} \tag{4.48}$$

The isomorphism,

$$\psi:\hat{K}'(4)\to\mathfrak{g}, \tag{4.49}$$

is defined by Eq. (4.30) and the equation

$$\psi(C)=I_0=h\in R_h(2). \tag{4.50}$$

The corresponding 2-cocycle in the basis (4.24) is

$$c(p_n,\mathfrak{r}_k)=\tfrac{1}{2}\,\delta_{n,-k},$$

$$
\begin{aligned}
c(x_n,\mathfrak{s}_k)&=\tfrac{1}{2}\,\delta_{n,-k},\\
c(h_n,\mathfrak{t}_k)&=\tfrac{1}{2}\,\delta_{n,-k},\\
c(y_n,\mathfrak{q}_k)&=\tfrac{1}{2}\,\delta_{n,-k},\\
c(\mathcal{L}_n,I_k)&=n\,\delta_{n,-k}.
\end{aligned}
\tag{4.51}
$$

Note that in the realization of $K'(4)$ inside $P(2)$, obtained in Theorem 4.1, we have $I_0=0$. □

Remark 4.3: The 2-cocycle c is one of three nontrivial 2-cocycles on $K'(4)$; see Refs. 1 and 2. [In Ref. 1 this cocycle is defined by Eq. (4.22), where $d=0$, $e=1$]. Note that the cocycle c is equivalent to the restriction of the 2-cocycle c_t on $R(2)$; see Eqs. (3.21), (3.22).

V. ONE-PARAMETER FAMILY OF REPRESENTATIONS OF $\hat{K}'(4)$

Theorem 5.1: There exists a one-parameter family of irreducible representations of $\hat{K}'(4)$ depending on parameter $\mu\in\mathbb{C}$ in the superspace spanned by 2 even fields and 2 odd fields where the value of the central charge is equal to one.

Proof: Let $g\in t^{\mu}\mathbb{C}[t,t^{-1}]$, where $\mu\in\mathbb{R}\backslash\mathbb{Z}$. One can think of ξ^{-1} as the anti-derivative,

$$
\xi^{-1}g(t)=\int g(t)dt. \tag{5.1}
$$

Let $f(t)\in\mathbb{C}[t,t^{-1}]$. According to (3.2),

$$
\xi^{-1}\circ f=\sum_{n=0}^{\infty}(-1)^n(\xi^n f)\xi^{-n-1}. \tag{5.2}
$$

Notice that this formula, when applied to a function g, corresponds to the formula of integration by parts. Let

$$
V^{\mu}=t^{\mu}\mathbb{C}[t,t^{-1}]\otimes\Lambda(2)=t^{\mu}\mathbb{C}[t,t^{-1}]\otimes\langle 1,\theta_1,\theta_2,\theta_1\theta_2\rangle,\mu\in\mathbb{R}\backslash\mathbb{Z}. \tag{5.3}
$$

Using the realization of $\hat{K}'(4)$ inside $R(2)$ (see Theorem 4.2 for $h=1$) we obtain a representation of $\hat{K}'(4)$ in V^{μ}. A central element in $\hat{K}'(4)$ is $I_0=1\in R(2)$; the 2-cocycle is defined by Eq. (4.51). Let $\{v_m^i\}$, where $m\in\mathbb{Z}$ and $i=0,1,2,3$, be the following basis in V^{μ}:

$$
\begin{aligned}
v_m^0&=\frac{1}{m+\mu}\,t^{m+\mu},\\
v_m^1&=t^{m+\mu}\theta_1,\\
v_m^2&=t^{m+\mu}\theta_2,\\
v_m^3&=t^{m+\mu}\theta_1\theta_2.
\end{aligned}
\tag{5.4}
$$

The action of $\hat{K}'(4)$ is given as follows:

$$
\mathcal{L}_n(v_m^0)=-(m+n+\mu-1)v_{m+n}^0,
$$

$$
\mathcal{L}_n(v_m^i)=-(m+\tfrac{1}{2}n+\mu)v_{m+n}^i,\quad i=1,2,
$$

$$
\begin{gathered}
\mathcal{L}_n(v^3_m)=-(m+n+\mu+1)v^3_{m+n},\\
E_n(v^1_m)=v^2_{m+n},\quad F_n(v^2_m)=v^1_{m+n},\\
\boldsymbol{\mathcal{E}}_n(v^3_m)=v^0_{m+n+2},\quad \boldsymbol{\mathcal{F}}_n(v^0_m)=-v^3_{m+n-2},\\
H_n(v^i_m)=\mp v^i_{m+n},\quad i=1,2,\\
\boldsymbol{\mathcal{H}}_n(v^i_m)=\pm v^i_{m+n},\quad i=0,3,\\
h_n(v^1_m)=-(m+n+\mu)v^3_{m+n-1},\quad y_n(v^2_m)=(m+n+\mu)v^3_{m+n-1},\\
h_n(v^0_m)=v^2_{m+n-1},\quad y_n(v^0_m)=v^1_{m+n-1},\\
x_n(v^1_m)=(m+n+\mu)v^0_{m+n+1},\quad p_n(v^2_m)=-(m+n+\mu)v^0_{m+n+1},\\
x_n(v^3_m)=v^2_{m+n+1},\quad p_n(v^3_m)=v^1_{m+n+1},\\
\mathfrak{r}_n(v^1_m)=v^3_{m+n-1},\quad \mathfrak{s}_n(v^2_m)=v^3_{m+n-1},\\
\mathfrak{q}_n(v^1_m)=v^0_{m+n+1},\quad \mathfrak{t}_n(v^2_m)=v^0_{m+n+1},\\
I_n(v^i_m)=v^i_{m+n},\quad i=0,1,2,3.
\end{gathered}
\tag{5.5}
$$

Note that I_0 acts by the identity operator. One can then define a one-parameter family of representations of $\hat{K}'(4)$ depending on parameter $\mu\in\mathbb{C}$ in the superspace $V=\langle v^0_m,v^3_m,v^1_m,v^2_m\rangle_{m\in\mathbb{Z}}$, where $p(v^i_m)=\overline{0}$, for $i=0$, 3, and $p(v^i_m)=\overline{1}$ for $i=1$, 2, according to the formulas (5.5).

□

Remark 5.1: The elements $\{\mathcal{L}_n,H_n,h_n,p_n\}_{n\in\mathbb{Z}}$ span a subalgebra of $K'(4)$ isomorphic to $K(2)$. Note that V decomposes into the direct sum of two submodules over this superalgebra:

$$
V=\langle v^0_m,v^2_m\rangle_{m\in\mathbb{Z}}\oplus\langle v^3_m,v^1_m\rangle_{m\in\mathbb{Z}}. \tag{5.6}
$$

Remark 5.2: We conjecture that there exists a *two*-parameter family of representations of $\hat{K}'(4)$ in the superspace spanned by 4 fields. In order to define it, instead of the superspace of functions, V^μ, one should consider the superspace of ''densities.''

ACKNOWLEDGMENTS

JOURNAL OF MATHEMATICAL PHYSICS VOLUME 42, NUMBER 2 FEBRUARY 2001

On solvable potentials related to SO(2,2)

S. A. Baran, A. Dalgic, and G. A. Kerimov
International Centre for Physics and Applied Mathematics, Trakya University, P.O. Box 126, Edirne, Turkey

(Received 2 October 2000; accepted for publication 31 October 2000)

Scattering problems in one dimension associated with the SO(2,2) group are studied. The *S* matrices for the systems under consideration are calculated by using the theory of intertwining operators for semisimple Lie groups. The wave functions are expressed in terms of matrix elements of principal series representation of the SO(2,1) group. © *2001 American Institute of Physics.*

I. INTRODUCTION

The group theoretical studies of dynamical systems in nonrelativistic quantum mechanics has a long history. The first study in this direction was made by Pauli,[1] before Schrödinger's equation was published. In that pioneering work, Pauli showed that the bound-state spectrum of the quantum-mechanical nonrelativistic Coulomb problem could be obtained by studying the abstract algebra generated by angular momentum and the Runge–Lenz vector. Following that, Fock and Bargmann[2,3] have recognized that this algebra is isomorphic to the $\mathfrak{so}(4)$ Lie algebra. Moreover, it was realized that the ''accidental'' degeneracies, i.e., degeneracies not connected with geometrical SO(3) symmetries of the Hamiltonian, are due to the dynamical invariance group SO(4). Ever since dynamical invariance groups have been determined for many quantum mechanical systems. This is a situation in which the Hamiltonian H of the system belongs to the center of the enveloping algebra of some group G, i.e., $H=f(C)$, where C is the Casimir operator of dynamical symmetry group G. For example, in the Coulomb bound-state problem, $H=\alpha/2(C-1)$, where C is the second-order Casimir operator of symmetric tensor representations of SO(4).

Since the work of Zwanzinger[4] it has become clear that group theoretical methods can be successfully applied to the solution of scattering problems. In that paper Zwanzinger showed how the symmetry group SO(3.1) allows for an algebraic determination of the Coulomb *S* matrix. However, this method, which at the beginning has been developed only for Coulomb problem, cannot be generalized to other scattering problems and for this reason, the Coulomb problem was the only known example for a long time.

Important results have been obtained in this respect by the Yale group and others.[5–10] It appears that knowledge of the interrelation between dynamical algebra, which describes the scattering problem, and an Euclidean algebra, which describes the problem in the absence of interactions, allow in principle, pure algebraic calculation of *S* matrices. This technique, which is called the Euclidean connection, essentially uses the theory of group expansions or deformations.[11] However, due to the absence of a general procedure for the descriptions of such connection formulas, it is rather difficult to derive the *S* matrix using the above-mentioned method. (Note that the general expansion problem is not yet solved.)

Since knowledge of the dynamic group is sufficient to solve the bound state problems, it is quite suggestive to ask whether or not one can use information on the dynamic group directly to obtain stringent restrictions upon the structure of the scattering matrices, or even to determine it completely. The answer is in the affirmative.[12] It has been discovered that the *S* matrices for systems under consideration are related to intertwining operators between Weyl equivalent principal series representations of the dynamical group *G*. In other words, *S* matrices for systems under consideration are constrained to satisfy

$$\mathrm{SU}^{\chi}(g)=U^{\tilde{\chi}}(g)S \quad \text{for all} \quad g\in G \tag{1.1}$$

or

$$SdU^{\chi}(b)=dU^{\tilde{\chi}}(b)S \quad \text{for all} \quad b\in \mathfrak{g}, \tag{1.2}$$

where U^{χ} and $U^{\tilde{\chi}}$ are the Weyl equivalent unitary irreducible representations (UIRs) of principal series of G, while dU^{χ} and $dU^{\tilde{\chi}}$ are the corresponding representations of the algebra $\mathfrak{g}$ of G. Thus, one can in principle evaluate the S matrix from (1.1) or (1.2) without ever writing a Shrödinger equation, or wave functions, or ever mentioning the concepts of space and time.

Moreover, it follows from Eq. (1.1) or (1.2) that if the matrix of representation operator U is diagonal in some basis then the matrix of the intertwining operator is also diagonal. This fact leads to the suggestion that there might exist a class of one-dimensional potentials for which the scattering matrix is determined by diagonal elements of the intertwining operator. This is exactly what happens in the Olshanetsky–Perelomov approach[13] to one-dimensional many-body problems related to Lie algebras (where the Hamiltonians of systems are described in terms of the ''radial part'' of the Casimir operator) or in the ''potential group'' approach to scattering problems.[5–10] Thus, the number of subgroup chains provided by representation theory necessarily correspond to the number of class of quantum-mechanical systems. Therefore the problem of classification of all one-dimensional many-body systems with dynamic group G may be reduced to the more tractable problem of the enumeration of all subgroup chains of G. Moreover the well-developed theory of intertwining operators for the semisimple Lie group[14,15] led to the hope that one may determine explicitly the scattering matrices for all systems related to semisimple Lie groups.

This paper is the first of two devoted to the study of scattering problems for solvable potentials related to the SO(2.2) group. In the present paper we consider one-dimensional potential scattering of a system with a SO(2.2) ''potential group.'' [5] We hence illustrated the method in the simple case of the most degenerate representation of SO(2.2). Our other purpose here is to prepare all the necessary background for the second paper in the series, devoted to the Natanzon-type potentials. The content of the paper is arranged as follows. In Sec. II, we describe the construction of S matrices corresponding to the $\mathrm{SO(2,2)}\supset\mathrm{SO(2)}\times\mathrm{SO(2)}$, $\mathrm{SO(2,2)}\supset\mathrm{SO(2)}\times\mathrm{E(1)}$, $\mathrm{SO(2,2)}\supset\mathrm{SO(2)}\times\mathrm{SO(1,1)}$, $\mathrm{SO(2,2)}\supset\mathrm{SO(1,1)}\times\mathrm{E(1)}$, and $\mathrm{SO(2,2)}\supset\mathrm{E(1)}\times\mathrm{E(1)}$ reductions. The reason for the restriction to these reductions is that the basis functions on the symmetric space SO(2,2)/SO(2.1) are expressed in terms of matrix elements of the SO(2,1) group for all these reductions. In Sec. III we discuss a class of quantum scattering problems governed by Hamiltonian $H=-(C+1)/8$. Finally, we have included in Appendices A and B some technical of the calculation that for clarity were omitted from the main text.

II. GROUP THEORETICAL CONSTRUCTION OF THE *S* MATRIX

Let $R^{2,2}$ be a four-dimensional pseudo-Euclidean space with the bilinear form

$$[x,y]=x_1y_1+x_2y_2-x_3y_3-x_4y_4. \tag{2.1}$$

By SO(2,2) we denote the connected component of the group of linear transformation of $R^{2,2}$ preserving the form (2.1). We consider SO(2,2) as acting on $R^{2,2}$ on the right. In accordance with this we shall write the vector in the row form $x=(x_1,x_2,x_3,x_4)$

Let us denote $\{g_{ij}(\theta)\}$ $i<j$, $i,j=1,2,3,4$ the one-parameter subgroups of SO(2,2) consisting of rotations or pseudorotations in the x_i-x_j planes, that is, of transformations of the form

$$x_k'=x_k, \quad k\neq i,j, \quad x_i'=x_i\cos\theta+x_j\sin\theta, \quad x_j'=-x_i\sin\theta+x_j\cos\theta \tag{2.2}$$

or

$$x_k'=x_k, \quad k\neq i,j, \quad x_i'=x_i\cosh\theta+x_j\sinh\theta, \quad x_j'=x_i\sinh\theta+x_j\cosh\theta, \tag{2.3}$$

respectively. The matrices

$$a_{ij}=\frac{\mathrm{d}}{\mathrm{d}\theta}g_{ij}(\theta)\big|_{\theta=0},\quad i<j \tag{2.4}$$

form a basis of the Lie algebra $\mathfrak{so}(2,2)$ of the group SO(2,2). Defining

$$\begin{aligned} a_1&=(a_{13}+a_{24})/2,\quad b_1=(a_{13}-a_{24})/2,\\ a_2&=(a_{23}-a_{14})/2,\quad b_2=(a_{23}+a_{14})/2,\\ a_3&=(a_{34}-a_{12})/2,\quad b_3=-(a_{12}+a_{34})/2, \end{aligned} \tag{2.5}$$

one has

$$\begin{aligned} &[a_1,a_2]=a_3,\quad [b_1,b_2]=b_3,\\ &[a_2,a_3]=-a_1,\quad [b_2,b_3]=-b_1,\\ &[a_3,a_1]=-a_2,\quad [b_3,b_1]=-b_2. \end{aligned} \tag{2.6}$$

The generators a_i and b_i separately form a Lie algebra of SO(2,1). In other words SO(2,2) is the product group of two SO(2,1) groups, i.e., SO(2,2)=SO(2,1)×SO(2,1).

Let us note at this point that the group SO(2,1) has three subgroups SO(2), SO(1,1), and E(1) generated, for example, by a_3, a_1 and a_2+a_3, respectively, where E(1) is an Euclidean group in one dimension. It is also worth noting that each UIR of SO(1.1) is doubly degenerate in principal series of UIR of SO(2.1).

We want to deal only with single particle scattering by one-dimensional potential related to the SO(2,2) group. For this case the theory of most degenerate (or, class I) representations[16–18] of SO(2,2) is helpful.

The most degenerate representations of SO(2,2) are known to form three series: principal, supplementary, and discrete. It is also known that only the principal series of SO(2,2) describe scattering states. Consequently, the relevant unitary representations will be the principal series and we restrict the discussion to it.

The principal series of the most degenerate representation of SO(2,2) are characterized by the pair $\chi=(\rho,\epsilon)$, where ϵ is equal to 0 or 1, while $0\leqslant\rho<\infty$. The representations specified by labels $\chi=(\rho,\epsilon)$ and $\tilde{\chi}=(-\rho,\epsilon)$ are equivalent. For the sake of simplicity, we consider the representations with $\epsilon=0$, although the case $\epsilon=1$ can also be easily treated. Hence, we are interested in examining the intertwining operator of U^{χ}, $\chi=(\rho,0)$, in different subgroup bases.

The calculation of these can be performed by two different methods. If the principal series of the algebra $\mathfrak{so}(2,2)$ in some basis is known, we can get recurrence relations for the intertwining operator by applying both sides of Eq. (1.2) to the basis vectors. By solving the recurrence relations, one can find its explicit form. An alternative way employs Eq. (1.1). By realizing the principal series of SO(2,2) on suitable Hilbert spaces of some functions we can derive from Eq. (1.1) the functional relations for the kernel of the intertwining operator. This global approach, which is complimentary to the infinitesimal treatment, allows one to obtain integral representations for the matrix elements of the intertwining operator.

In Appendix A, we calculate the matrix form of the intertwining operator in the basis corresponding to the reductions with respect to SO(2)×SO(2), SO(2)×E(1), SO(2)×SO(1,1), SO(1,1)×E(1), and E(1)×E(1). As a result we come to following conclusion: The S matrices of the one-dimensional system described by $(\rho,0)$ representation of SO(2,2) in the above-mentioned subgroup basis have the following form.

(i) The SO(2,2)⊃SO(2)×SO(2) reduction. The S matrix for this class of potentials is given by

$$S=\begin{pmatrix} R(m,k) & 0 \\ 0 & R(m,k) \end{pmatrix}, \tag{2.7}$$

where

$$R(m,k)=c\,\frac{\Gamma\left(\frac{1}{2}-\frac{i\rho}{2}+m\right)\Gamma\left(\frac{1}{2}-\frac{i\rho}{2}+k\right)}{\Gamma\left(\frac{1}{2}+\frac{i\rho}{2}+m\right)\Gamma\left(\frac{1}{2}+\frac{i\rho}{2}+k\right)}$$

with the notation as in Appendix A. The energy-dependent parameter ρ is determined by the relation between the Hamiltonian and the Casimir invariant.

(ii) The SO(2,2)⊃SO(2)×E(1) reduction. In this case

$$S=\begin{pmatrix} R(\lambda,m) & 0 \\ 0 & R(\lambda,m) \end{pmatrix}, \tag{2.8}$$

where

$$R(\lambda,m)=c\lambda^{-i\rho}\frac{\Gamma\left(\frac{1}{2}-\frac{i\rho}{2}+m\right)}{\Gamma\left(\frac{1}{2}+\frac{i\rho}{2}+m\right)}.$$

(iii) The SO(2,2)⊃SO(2)×SO(1,1) reduction. Now, we have

$$S=\begin{pmatrix} R(\mu,m) & T(\mu,m) \\ T(\mu,m) & R(\mu,m) \end{pmatrix}, \tag{2.9}$$

$$R(\mu,m)=\frac{c}{\pi}\cosh\pi\mu\,\Gamma\left(\frac{1}{2}-\frac{i\rho}{2}+i\mu\right)\Gamma\left(\frac{1}{2}-\frac{i\rho}{2}-i\mu\right)\frac{\Gamma\left(\frac{1}{2}-\frac{i\rho}{2}+m\right)}{\Gamma\left(\frac{1}{2}+\frac{i\rho}{2}+m\right)},$$

$$T(\mu,m)=i\,\frac{c}{\pi}\sinh\frac{\pi\rho}{2}\,\Gamma\left(\frac{1}{2}-\frac{i\rho}{2}+i\mu\right)\Gamma\left(\frac{1}{2}-\frac{i\rho}{2}-i\mu\right)\frac{\Gamma\left(\frac{1}{2}-\frac{i\rho}{2}+m\right)}{\Gamma\left(\frac{1}{2}+\frac{i\rho}{2}+m\right)}.$$

(iv) The SO(2,2)⊃SO(1,1)×E(1) reduction. The corresponding S matrix is given by

$$S=\begin{pmatrix} R(\mu,\lambda) & T(\mu,\lambda) \\ T(\mu,\lambda) & R(\mu,\lambda) \end{pmatrix}, \tag{2.10}$$

$$R(\mu,\lambda)=\frac{c}{\pi}\lambda^{-i\rho}\cosh\pi\mu\,\Gamma\left(\frac{1}{2}-\frac{i\rho}{2}+i\mu\right)\Gamma\left(\frac{1}{2}-\frac{i\rho}{2}-i\mu\right),$$

$$T(\mu,\lambda)=i\,\frac{c}{\pi}\lambda^{-i\rho}\sinh\pi\frac{\rho}{2}\,\Gamma\left(\frac{1}{2}-\frac{i\rho}{2}+i\mu\right)\Gamma\left(\frac{1}{2}-\frac{i\rho}{2}-i\mu\right).$$

(v) The SO(2,2)⊃E(1)×E(1) reduction. For this class of the potentials

$$S=\begin{pmatrix} R(\lambda,\mu) & 0 \\ 0 & R(\lambda,\mu) \end{pmatrix}, \tag{2.11}$$

where $R(\lambda,\mu)=c|\lambda\mu|^{-i\rho}$.

It should be noted that the potential functions of the third and fourth classes admit a double degeneracy of the wave function for every positive value of energy. [The twofold degeneracy corresponds to the fact that each UIR of SO(1,1) is twofold degenerate in principal series of UIR of SO(2,1).] Therefore, one may construct wave packets which are partly transmitted and partly reflected by the potential. According to (2.9) and (2.10), in both cases, the reflection and transmission coefficients are

$$|R|^2=\frac{\cosh^2 \pi\mu}{\cosh^2 \pi\mu+\sinh^2 \pi\dfrac{\rho}{2}},$$

$$|T|^2=\frac{\sinh^2 \pi\dfrac{\rho}{2}}{\cosh^2 \pi\mu+\sinh^2 \pi\dfrac{\rho}{2}},$$

respectively. It is also worth nothing that the reflection coefficient $|R|^2=1$ for all potentials of first, second, and fifth classes; hence the reflection is total. This is a result of very general properties, shared by all one-dimensional Hamiltonians which have continuous nondegenerate spectrum.

III. CLASS OF POTENTIALS RELATED TO THE SO(2,2) GROUP

In this section we give a simple example of how the inverse problem can be solved. By the inverse problem we mean the determination of potentials from a given dynamical group. For the sake of simplicity, we suppose that the Hamiltonian of a quantum-mechanical system is a linear function of the Casimir operator. In this study of such a system, we can, without loss of generality, limit ourselves to the case where $H=-(C+1)/8$.

Let us consider a reducible representation of SO(2,2), which contains the irreducible subrepresentation $(\rho,0)$. For example, let $T(g)$ be a quasiregular representation of SO(2,2). This representation can be realized in the Hilbert space of square-integrable functions $f(x)$ on hyperboloid X,

$$x_1^2+x_2^2-x_3^2-x_4^2=1, \tag{3.1}$$

with an invariant measure $dx=dx_1\,dx_2\,dx_3/|x_4|$. The representation $T(g)$ is defined by

$$T(g)f(x)=f(xg). \tag{3.2}$$

The (Hermitian) infinitesimal operators $A_{ij}=-i(d/d\theta)T(g_{ij}(\theta))|_{\theta=0}$ of the representation $T(g)$ corresponding to the one-parameter subgroups $g_{ij}(\theta)$ are given by

$$\begin{aligned} A_{12}&=-i\left(x_2\frac{\partial}{\partial x_1}-x_1\frac{\partial}{\partial x_2}\right), \quad A_{23}=-i\left(x_3\frac{\partial}{\partial x_2}+x_2\frac{\partial}{\partial x_3}\right), \\ A_{13}&=-i\left(x_3\frac{\partial}{\partial x_1}-x_1\frac{\partial}{\partial x_3}\right), \quad A_{24}=-ix_4\frac{\partial}{\partial x_2}. \end{aligned} \tag{3.3}$$

Then, the Casimir operator $C=A_{12}^2+A_{34}^2-A_{13}^2-A_{14}^2-A_{23}^2-A_{24}^2$ has the form

$$C=-\frac{\partial^2}{\partial x_1^2}-\frac{\partial^2}{\partial x_2^2}-\frac{\partial^2}{\partial x_3^2}+I(I+2), \tag{3.4}$$

where $I=x_1\partial/\partial x_1+x_2\partial/\partial x_2+x_3\partial/\partial x_3$.

We now require the representation space to be irreducible. [We note that representation (3.2) is decomposed onto principal and discrete series representations.][17,19] Such a restriction is obtained if all functions are eigenfunctions of the Casimir operator

$$Cf=j(j+2)f. \tag{3.5}$$

Since we are interested only in continuous spectrum, we will put $j=-1-i\rho$.

The coordinate independent solutions to this equation are given by

$$e_{p,n}(x)=|[x,n]|^{-2-j} \tag{3.6}$$

with

$$\int\int\int_X |[x,n]|^{-1+i\rho}\overline{|[x,n']|^{-1+i\rho'}}\,\mathrm{d}x=\frac{16\pi^2}{\rho^2\tanh^2\pi\rho/2}\,\delta(\rho-\rho')\,\delta(n-n'),$$

where $x\in X$, n, $n'\in\Gamma$ and Γ is a contour on the cone $C=\{n\in R^{2,2}|n_1^2+n_2^2-n_3^2-n_4^2=0\}$ intersecting each generator. The case when Γ is the section of the cone by the Euclidean sphere of radius $\sqrt{2}$ with center at origin is described in Refs. 16 and 17. In this case Γ is the direct product of two circles of unit radius (see Appendix A).

The structure (3.3) of A_{ij} has the consequence that the two commuting SO(2,1) subgroups generated by a_i and b_i share the same Casimir operator. In fact, we have

$$C_a=C_b=\tfrac{1}{4}C,$$

where $C_a=A_1^2+A_2^2-A_3^2$, $C_b=B_1^2+B_2^2-B_3^2$ and $\dot{A}_i,B_i$ are infinitesimal operators corresponding to generators a_i,b_i, respectively. In other words, the operator C is essentially the Casimir operator of regular representation of $\mathrm{SO}(2,1)\simeq\mathrm{SL}(2,R)$. For this reason, the solution to Eq. (3.5) is related to matrix elements of $\mathrm{SL}(2,R)$. This should be no surprise because the group $\mathrm{SL}(2,R)\simeq\mathrm{SO}(2,1)$ can be realized as the hyperboloid X,

$$\mathrm{SL}(2,R)\ni g(x)=\begin{pmatrix} x_1+x_3 & x_4+x_2 \\ x_4-x_2 & x_1-x_3 \end{pmatrix},\quad x\in R^{2,2}, x_1^2+x_2^2-x_3^2-x_4^2=1. \tag{3.7}$$

We are now prepared to obtain the explicit form of Hamiltonians $H=-(C+1)/8$ for all subgroup reductions mentioned in Sec. II.

(i) The reduction $\mathrm{SO}(2,2)\supset\mathrm{SO}(2)\times\mathrm{SO}(2)$. We want to diagonalize the $\mathrm{SO}(2)\times\mathrm{SO}(2)$ subgroup. Then, the reduction conditions are

$$A_3f_{mk}^{(1)}=mf_{mk}^{(1)},\quad B_3f_{mk}^{(1)}=kf_{mk}^{(1)}.$$

The parametrization that we have seen for hyperboloid (3.1) must be such as to make A_3,B_3 particularly simple. The appropriate parametrization of $\mathrm{SL}(2,R)$ will be the Cartan parametrization

$$g=\begin{pmatrix} \cos\frac{\varphi}{2} & \sin\frac{\varphi}{2} \\ -\sin\frac{\varphi}{2} & \cos\frac{\varphi}{2} \end{pmatrix}\begin{pmatrix} e^{\alpha/2} & 0 \\ 0 & e^{-\alpha/2} \end{pmatrix}\begin{pmatrix} \cos\frac{\psi}{2} & \sin\frac{\psi}{2} \\ -\sin\frac{\psi}{2} & \cos\frac{\psi}{2} \end{pmatrix}, \tag{3.8}$$

$$0\leqslant\varphi\leqslant2\pi,\quad 0\leqslant\psi\leqslant2\pi,\quad 0<\alpha<\infty.$$

By equating the element $g(x)$ to (3.8), we get the equations relating $x_i, i=1,...,4$, to new variables φ, α, ψ,

$$x_1=\cosh\frac{\alpha}{2}\cos\frac{\psi+\varphi}{2},\quad x_3=\sinh\frac{\alpha}{2}\cos\frac{\psi-\varphi}{2},$$
$$x_2=\cosh\frac{\alpha}{2}\sin\frac{\psi+\varphi}{2},\quad x_4=\sinh\frac{\alpha}{2}\sin\frac{\psi-\varphi}{2}. \tag{3.9}$$

Then $A_3=-i(\partial/\partial\varphi)$ and $B_3=-i(\partial/\partial\psi)$ as we expected. If we compute the Casimir operator C for this parametrization, it becomes

$$\frac{1}{4}C=\frac{\partial^2}{\partial\alpha^2}+\coth\alpha\frac{\partial}{\partial\alpha}+\frac{1}{\sinh^2\alpha}\left(\frac{\partial^2}{\partial\varphi^2}-2\cosh\alpha\frac{\partial^2}{\partial\varphi\partial\psi}+\frac{\partial^2}{\partial\psi^2}\right). \tag{3.10}$$

Thus, the basis functions $f^{(1)}_{mk}$ corresponding to the considered reduction can be written as $\Phi(\alpha)e^{im\varphi}e^{in\psi}$, where $\Phi(\alpha)$ satisfies

$$4\left(-\frac{\mathrm{d}^2}{\mathrm{d}\alpha^2}-\coth\alpha\frac{\mathrm{d}}{\mathrm{d}\alpha}+\frac{m^2-2mk\cosh\alpha+k^2}{\sinh^2\alpha}\right)\Phi(\alpha)=-j(j+2)\Phi(\alpha).$$

Now we redefine the function $\Phi(\alpha)$ to absorb the weight function in the hyperboloid measure $\mathrm{d}x=\sinh\alpha\,\mathrm{d}\varphi\,\mathrm{d}\psi$, $\Phi(\alpha)=[\sinh\alpha]^{-1/2}\Psi(\alpha)$. Then this equation reduces to the Schrödinger one,

$$\left(-\frac{\mathrm{d}^2}{\mathrm{d}\alpha^2}+\frac{(m-k)^2-\frac{1}{4}}{4\sinh^2\alpha/2}-\frac{(m+k)^2-\frac{1}{4}}{4\cosh^2\alpha/2}\right)\Psi(\alpha)=2E\Psi(\alpha), \tag{3.11}$$

where $E=\rho^2/8$.

Thus, the knowledge of the interwining operator in SO(2)×SO(2) basis solves the scattering problem for the Pöschl–Teller potential. Among other, things the group structure provides the integral representation of the basis function

$$f^{(1)}_{mk}(x)=\varkappa\int_0^{2\pi}\int_0^{2\pi}|[x,n]|^{-2-j}\exp(im\varphi'+ik\psi')\mathrm{d}\varphi'\,\mathrm{d}\psi', \tag{3.12}$$

where x and n are given by Eqs. (3.9) and (A3), respectively. The normalization constant $\varkappa$ is chosen as in Appendix A, i.e.,

$$\varkappa=2^j\pi^{-1}\Gamma^2\left(\frac{2+j}{2}\right)\Gamma^{-2}\left(\frac{-1-j}{2}\right).$$

The explicit expression for $f^{(1)}_{mk}$ is given in Appendix A. As a result, for the scattering solutions of the Schrödinger equation with the Poschl–Teller potential we have

$$\Phi(\alpha)=\frac{2^{j+2}\pi^{1/2}\Gamma\left(\frac{2+j}{2}\right)\Gamma\left(\frac{j}{2}+m+1\right)}{\Gamma\left(\frac{-1-j}{2}\right)\Gamma\left(-\frac{j}{2}+m\right)}(\sinh\alpha)^{1/2}\mathfrak{P}^{(-2-j)/2}_{km}(\cosh\alpha), \tag{3.13}$$

where $\mathfrak{P}^j_{mn}(z)$ is the generalized Legendre function (of the first kind) as defined by Vilenkin.[20]

(ii) The reduction SO(2,2)⊃SO(2)×E(1). It is easy to see that geometrically the Iwasawa decomposition of SL(2,R),

$$g=\begin{pmatrix} \cos\varphi/2 & \sin\varphi/2 \\ -\sin\varphi/2 & \cos\varphi/2 \end{pmatrix}\begin{pmatrix} e^{\alpha/2} & 0 \\ 0 & e^{-\alpha/2} \end{pmatrix}\begin{pmatrix} 1 & t \\ 0 & 1 \end{pmatrix}, \tag{3.14}$$

$$0<\alpha<\infty, \quad 0<\varphi<2\pi, \quad -\infty<t<\infty,$$

is merely telling us that the appropriate parametrization of hyperboloid (3.1) is given by

$$x_1=\cosh\frac{\alpha}{2}\cos\frac{\varphi}{2}-\frac{t}{2}e^{\alpha/2}\sin\frac{\varphi}{2}, \quad x_3=\sinh\frac{\alpha}{2}\cos\frac{\varphi}{2}+\frac{t}{2}e^{\alpha/2}\sin\frac{\varphi}{2},$$

$$x_2=\cosh\frac{\alpha}{2}\sin\frac{\varphi}{2}+\frac{t}{2}e^{\alpha/2}\cos\frac{\varphi}{2}, \quad x_4=-\sinh\frac{\alpha}{2}\sin\frac{\varphi}{2}+\frac{t}{2}e^{\alpha/2}\cos\frac{\varphi}{2}$$

with $\mathrm{d}x=\frac{1}{8}e^{\alpha}\mathrm{d}\alpha\,\mathrm{d}\varphi\,\mathrm{d}t$. Then $A_3=i(\partial/\partial\varphi)$, $B_2+B_3=-i(\partial/\partial t)$, and

$$C=4\frac{d\partial^2}{\partial\alpha^2}+4\frac{\partial}{\partial\alpha}-8e^{-\alpha}\frac{\partial^2}{\partial\varphi\partial t}+4e^{-2\alpha}\frac{\partial^2}{\partial t^2}. \tag{3.15}$$

The basis functions in this reduction are the eigenfunctions of the set of operators C, A_3, and B_2+B_3, with

$$A_3 f^{(2)}_{m\lambda}=m f^{(2)}_{m\lambda} \quad (B_2+B_3)f^{(2)}_{m\lambda}=\lambda f^{(2)}_{m\lambda}.$$

Substitution of $f^{(2)}_{m\lambda}(x)$ by $e^{-\alpha/2}\Psi(\alpha)\exp(im\varphi+i\lambda t)$ transforms the Casimir equation into the Schrödinger equation

$$\left(-\frac{\mathrm{d}^2}{\mathrm{d}\alpha^2}+\lambda^2e^{-2\alpha}-2m\lambda e^{-\alpha}\right)\Psi(\alpha)=2E\Psi(\alpha) \tag{3.16}$$

with $E=\rho^2/8$. Thus, the S matrix for the scattering on the Morse potential is given by (2.8), where $\rho=2\sqrt{2E}$. Finally, for the scattering solutions of the Schrödinger equation we obtain

$$\Psi(\alpha)=\begin{cases} \dfrac{2^{1+j}\Gamma\left(\dfrac{j}{2}-m+1\right)}{\Gamma(-1-j)}(2\lambda)^{1/2}\exp(\alpha/2)W_{m,-(1+j)/2}(2e^{-\alpha}\lambda) & \text{if } \lambda>0 \\ \dfrac{2^{1+j}\Gamma\left(\dfrac{j}{2}+m+1\right)}{\Gamma(-1-j)}(-2\lambda)^{1/2}\exp(\alpha/2)W_{-m,-(1+j)/2}(-2e^{-\alpha}\lambda) & \text{if } \lambda<0 \end{cases}.$$

(iii) The reduction $\mathrm{SO}(2,2)\supset\mathrm{SO}(2)\times\mathrm{SO}(1,1)$. The basis functions corresponding to the considered reduction are the eigenfunctions of C, A_1, and B_3 with

$$A_1 f^{(3)}_{m\mu\tau}=\mu f^{(3)}_{m\mu\tau}, \quad B_3 f^{(3)}_{m\mu\tau}=m f^{(3)}_{m\mu\tau},$$

where $\tau=\pm1$ is the multiplicity label. Since the operators B_3 and A_1 generate rotations and pseudorotations, respectively, the appropriate parametrization for $\mathrm{SL}(2,R)$ in these circumstances is

$$g=\begin{pmatrix} e^{\beta/2} & 0 \\ 0 & e^{-\beta/2} \end{pmatrix}\begin{pmatrix} \cosh\dfrac{\alpha}{2} & \sinh\dfrac{\alpha}{2} \\ \sinh\dfrac{\alpha}{2} & \cosh\dfrac{\alpha}{2} \end{pmatrix}\begin{pmatrix} \cos\dfrac{\varphi}{2} & \sin\dfrac{\varphi}{2} \\ -\sin\dfrac{\varphi}{2} & \cos\dfrac{\varphi}{2} \end{pmatrix},$$

$$-\infty<\beta<\infty, \quad -\infty<\alpha<\infty, \quad -2\pi<\beta<2\pi.$$

According to this, we choose the following coordinate systems on the hyperboloid:

$$\begin{aligned}
x_1&=\cosh\frac{\alpha}{2}\cosh\frac{\beta}{2}\cos\frac{\varphi}{2}-\sinh\frac{\alpha}{2}\sinh\frac{\beta}{2}\sin\frac{\varphi}{2},\\
x_2&=\sinh\frac{\alpha}{2}\sinh\frac{\beta}{2}\cos\frac{\varphi}{2}+\cosh\frac{\alpha}{2}\cosh\frac{\beta}{2}\sin\frac{\varphi}{2},\\
x_3&=\cosh\frac{\alpha}{2}\sinh\frac{\beta}{2}\cos\frac{\varphi}{2}-\sinh\frac{\alpha}{2}\cosh\frac{\beta}{2}\sin\frac{\varphi}{2},\\
x_4&=\sinh\frac{\alpha}{2}\cosh\frac{\beta}{2}\cos\frac{\varphi}{2}+\cosh\frac{\alpha}{2}\sinh\frac{\beta}{2}\sin\frac{\varphi}{2}
\end{aligned} \tag{3.17}$$

with $\mathrm{d}x=\frac{1}{8}\cosh\alpha\mathrm{d}\alpha\,\mathrm{d}\beta\,\mathrm{d}\varphi$. Then $A_1=-i(\partial/\partial\beta)$, $B_3=-i(\partial/\partial\varphi)$, and

$$C=4\frac{\partial^2}{\partial\alpha^2}+4\frac{\sinh\alpha}{\cosh\alpha}\frac{\partial}{\partial\alpha}-8\frac{\sinh\alpha}{\cosh^2\alpha}\frac{\partial^2}{\partial\beta\partial\varphi}+\frac{1}{\cosh^2\alpha}\left(\frac{\partial^2}{\partial\beta^2}-\frac{\partial^2}{\partial\varphi^2}\right). \tag{3.18}$$

Now, the Casimir equation in these coordinates after substitution of the $f^{(3)}_{m\mu\tau}(x)$ by $(\cosh\alpha)^{-1/2}\Psi_\tau(\alpha)e^{i\mu\beta+im\varphi}$ is transformed into the Schrödinger equation

$$\left(-\frac{\mathrm{d}^2}{\mathrm{d}\alpha^2}+\frac{\mu^2-m^2-2m\mu\sinh\alpha}{\cosh^2\alpha}\right)\Psi_\tau(\alpha)=2E\Psi_\tau(\alpha) \tag{3.19}$$

with $E=\rho^2/8$.

Thus, knowing the intertwining operator for the SO(2,2) group in the SO(2)×SO(1.1) basis solves the scattering problem for the Pöschl–Teller type potential

$$2V(\alpha)=\frac{\mu^2-m^2-2m\mu\sinh\alpha}{\cosh^2\alpha}. \tag{3.20}$$

Moreover, we have (see Appendix B)

$$\begin{aligned}
\Psi_\tau(\alpha)=&\frac{\Gamma\left(1+\frac{j}{2}+m\right)\Gamma\left(1+\frac{j}{2}-i\tau\mu\right)\exp[i\pi(m+1)(\tau+1)/2]}{\pi\Gamma(-1-j)}\\
&\times(\cosh\alpha)^{1/2}\mathfrak{Q}^{j/2}_{i\tau\mu,m}(i\tau\sinh\alpha),
\end{aligned} \tag{3.21}$$

where $\mathfrak{Q}^j_{\mu\nu}(z)$ is the generalized Legendre function of the second kind as defined by Azimov.[21]

The two functions Ψ_{+1} and Ψ_{-1} are finite everywhere, both are admissible solutions. The first of these represents a wave incident from the left. Reflection occurs at the potential barrier (3.20), but there is also transmission to the right. A similar interpretation of Ψ_{-1} can be made. It represents a wave incident from the right, and transmitted through the barrier to the left. According to (2.9), the reflection and transmission coefficients are

$$|R|^2=\frac{\cosh^2 \pi\mu}{\cosh^2 \pi\mu+\sinh^2 \pi\sqrt{2E}},$$
$$|T|^2=\frac{\sinh^2 \pi\sqrt{2E}}{\cosh^2 \pi\mu+\sinh^2 \pi\sqrt{2E}}, \tag{3.22}$$

respectively.

(iv) The reduction $SO(2,2)\supset SO(1,1)\times E(1)$. The reduction conditions are

$$A_2 f^{(4)}_{\lambda\mu\tau}=\mu f^{(4)}_{\lambda\mu\tau}, \quad (B_2+B_3) f^{(4)}_{\lambda\mu\tau}=\lambda f^{(4)}_{\lambda\mu\tau},$$

where $\tau=\pm 1$ is the multiplicity label. The corresponding parametrization of $SL(2,R)$ is then of the form

$$g=\begin{pmatrix} \cosh\frac{\beta}{2} & \sinh\frac{\beta}{2} \\ \sinh\frac{\beta}{2} & \cosh\frac{\beta}{2} \end{pmatrix} \begin{pmatrix} e^{\alpha/2} & 0 \\ 0 & e^{-\alpha/2} \end{pmatrix} \begin{pmatrix} 0 & 1 \\ -1 & 0 \end{pmatrix}^{\sigma} \begin{pmatrix} 1 & t \\ 0 & 1 \end{pmatrix},$$

where $\sigma=0,1$. Now, on the basis of the above-mentioned parametrization for $SL(2,R)$, we have divided the hyperboloid X into two subregions. So then the passage from x_i to new variables β,α,t gives the following:

$$X^+: \quad (\sigma=0),$$

$$x_1=\cosh\frac{\alpha}{2}\cosh\frac{\beta}{2}+\frac{t}{2}e^{\alpha/2}\sinh\frac{\beta}{2}, \quad x_3=\sinh\frac{\alpha}{2}\cosh\frac{\beta}{2}-\frac{t}{2}e^{\alpha/2}\sinh\frac{\beta}{2},$$

$$x_2=-\sinh\frac{\alpha}{2}\sinh\frac{\beta}{2}+\frac{t}{2}e^{\alpha/2}\cosh\frac{\beta}{2}, \quad x_4=\cosh\frac{\alpha}{2}\sinh\frac{\beta}{2}+\frac{t}{2}e^{\alpha/2}\cosh\frac{\beta}{2}$$

with $dx=\frac{1}{8}e^{\alpha}d\alpha\, d\beta\, dt$ and

$$X^-: \quad (\sigma=1),$$

$$x_1=\sinh\frac{\alpha}{2}\sinh\frac{\beta}{2}-\frac{t}{2}e^{-\alpha/2}\cosh\frac{\beta}{2}, \quad x_3=-\cosh\frac{\alpha}{2}\sinh\frac{\beta}{2}+\frac{t}{2}e^{-\alpha/2}\cosh\frac{\beta}{2},$$

$$x_2=\cosh\frac{\alpha}{2}\cosh\frac{\beta}{2}-\frac{t}{2}e^{-\alpha/2}\sinh\frac{\beta}{2}, \quad x_4=\sinh\frac{\alpha}{2}\cosh\frac{\beta}{2}-\frac{t}{2}e^{-\alpha/2}\sinh\frac{\beta}{2}$$

with $dx=\frac{1}{8}e^{\alpha}d\alpha\, d\beta\, dt$.

Now the expressions for A_2 and B_2+B_3 are uniformly given in both regions by $A_2=-i(\partial/\partial\beta)$, $B_2+B_3=-i(\partial/\partial t)$ while C is given as

$$C=+4\frac{\partial^2}{\partial\alpha^2}+4\frac{\partial}{\partial\alpha}+8e^{-\alpha}\frac{\partial^2}{\partial\beta\partial t}-4e^{-2\alpha}\frac{\partial^2}{\partial t^2} \tag{3.23}$$

and

$$C=4\frac{\partial^2}{\partial\alpha^2}-4\frac{\partial}{\partial\alpha}-8e^{\alpha}\frac{\partial^2}{\partial\beta\partial t}-4e^{2\alpha}\frac{\partial^2}{\partial t^2} \tag{3.24}$$

in X^+ and X^-, respectively. The potentials gained for $\mathrm{SO}(2,2)\supset\mathrm{SO}(1,1)\times\mathrm{E}(1)$ reduction is

$$2V(\alpha)=\begin{cases}\lambda^2 e^{-2\alpha}-2\lambda\mu e^{-\alpha} & \text{if } \alpha>0\\ \lambda^2 e^{2\alpha}+2\lambda\mu e^{\alpha} & \text{if } \alpha<0\end{cases}. \tag{3.25}$$

Hence formula (2.50) with $\rho=2\sqrt{2E}$ is determined as the S matrix for this potential.

(v) The reduction $\mathrm{SO}(2,2)\supset\mathrm{E}(1)\times\mathrm{E}(1)$. The basis functions in this reduction will be the eigenfunctions of C, A_2+A_3 and B_2+B_3 with

$$(A_2+A_3)f^{(5)}_{\lambda\mu}=\mu f^{(5)}_{\lambda\mu},\quad (B_2+B_3)f^{(5)}_{\lambda\mu}=\lambda f^{(5)}_{\lambda\mu}.$$

Therefore, we choose Gauss parametrization for $\mathrm{SL}(2,R)$

$$g=\begin{pmatrix}1 & 0\\ t & 1\end{pmatrix}\begin{pmatrix}e^{\alpha/2} & 0\\ 0 & e^{-\alpha/2}\end{pmatrix}\begin{pmatrix}1 & y\\ 0 & 1\end{pmatrix},$$

$$-\infty<t<\infty,\quad 0<\alpha<\infty,\quad -\infty<y<\infty.$$

According to this, one has to choose the following coordinate system on hyperboloid X:

$$x_1=\cosh\frac{\alpha}{2}+\frac{yt}{2}e^{\alpha/2},\quad x_3=\sinh\frac{\alpha}{2}-\frac{yt}{2}e^{\alpha/2},$$

$$x_2=\tfrac{1}{2}e^{\alpha/2}(y-t),\quad x_4=\tfrac{1}{2}e^{\alpha/2}(y+t)$$

with $dx=\frac{1}{4}e^{\alpha}\mathrm{d}\alpha\,\mathrm{d}t\,\mathrm{d}y$. Then $A_2+A_3=-i(\partial/\partial t)$ and $B_2+B_3=-i(\partial/\partial y)$. The Casimir operator in these coordinates is

$$C=4\left(\frac{\partial^2}{\partial\alpha^2}+\frac{\partial}{\partial\alpha}+e^{-\alpha}\frac{\partial^2}{\partial t\,\partial y}\right). \tag{3.26}$$

By arguments very similar to those used to obtain (3.11) we can show that the Casimir invariant is related to the group Hamiltonian $H=(-\mathrm{d}^2/\mathrm{d}\alpha^2+\mu\lambda e^{-\alpha})/2$ by $H=-(C+1)/8$. Therefore, formula (2.11) at $\rho=2\sqrt{2E}$ determines the scattering matrices for the system with Toda potential $V=\mu\lambda e^{-\alpha}/2$. Moreover, one has

$$\Psi(\alpha)=\frac{2^{-1-j}}{\Gamma\left(\dfrac{-1-j}{2}\right)}(\lambda\mu)^{(i+j)/2}K_{-1-j}(e^{-\alpha/2}\sqrt{\lambda\mu}),\quad \text{if } \lambda\mu>0, \tag{3.27}$$

where $K_j(z)$ is the modified Bessel function of the third kind.

ACKNOWLEDGMENT

Support for the research from TURF is gratefully acknowledged.

APPENDIX A: THE INTERTWINING OPERATORS OF SO(2,2)

The principal series of the most degenerate representation of SO(2,2) is characterized by the pair $\chi=(\rho,\epsilon)$ where ϵ is equal to 0 or 1, while $0\leqslant\rho<\infty$ can be realized in the space of infinitely differentiable functions $f(\zeta)$ on the cone $[\zeta,\zeta]=0$, homogeneous of degree $j=-1-i\rho$ and with parity ϵ,

$$f(t\zeta)=|t|^j\,\mathrm{sign}^{\epsilon}t\,f(\zeta). \tag{A1}$$

A representation operator U^χ of the group SO(2,2) is defined by

$$U^\chi(g)f(\zeta)=f(\zeta g). \tag{A2}$$

For the purposes of this paper, we are interested in examining the interwining operator of $U^\chi, \chi=(\rho,0)$, in different bases.

Generally we may choose a large number of different coordinate systems on the cone. The different choices of separable orthogonal coordinate systems lead to different subgroup reductions.

(i) The $SO(2,2)\supset SO(2)\times SO(2)$ reduction. This chain of group reduction corresponds to an introduction of spherical coordinates on the cone, so that

$$\zeta=\omega n, \quad n=\left(\cos\frac{\psi+\varphi}{2},\ \sin\frac{\psi+\varphi}{2},\ \cos\frac{\psi-\varphi}{2},\ \sin\frac{\psi-\varphi}{2}\right), \tag{A3}$$

$$0\leqslant\omega<\infty, \quad 0<\psi\leqslant 2\pi, \quad 0<\varphi\leqslant 2\pi.$$

Indeed, in these coordinates the infinitesimal operators A_3 and B_3 of the representation (A2) are diagonal

$$A_3=-i\frac{\partial}{\partial\varphi}, \quad B_3=-i\frac{\partial}{\partial\psi}. \tag{A4}$$

Here and in the following infinitesimal operators corresponding to generators a_i, b_i are denoted by A_i, B_i respectively.

Due to homogeneity condition (A1) we obtain the following realization of U^χ:

$$U^\chi(g)f(n)=\left(\frac{\omega}{\omega_g}\right)^j f(n_g), \tag{A5}$$

where ω_g and n_g are determined from the parametrization (A3) of $\zeta_g=\zeta g$. Consequently, the representation $U^\chi, \chi=(\rho,0)$ of SO(2,2) can be realized on the Hilbert space $L^2(S^1\times S^1)$ of even functions $f(n)$ on the direct product of two circles $S^1\times S^1$, with inner product

$$(f,f')=\frac{1}{(2\pi)^2}\int_{S^1\times S^1}\int \overline{f(n)}f'(n)\mathrm{d}n, \tag{A6}$$

where $\mathrm{d}n=\mathrm{d}\varphi\,\mathrm{d}\psi$ is the invariant measure on $S^1\times S^1$. The intertwining operator A between the representations U^χ and $U^{\tilde\chi}$ is defined by

$$(Af)(n)=\int_{S^1\times S^1}\int K(n,n')f(n')\mathrm{d}n' \tag{A7}$$

with

$$AU^\chi(g)=U^{\tilde\chi}(g)A. \tag{A8}$$

Thus, Eq. (A8) will serve to fix the dependence of the kernel $K(n,n')$ on n and n'. Equality (A8) implies that

$$(AU^\chi(g)f)(n)=(U^{\tilde\chi}(g)Af)(n). \tag{A9}$$

So the kernel $K(n,n')$ is constrained to satisfy the functional equation

$$K(n_g,n'_g)=\left(\frac{\omega_g}{\omega}\right)^{2+j}\left(\frac{\omega'_g}{\omega}\right)^{2+j}K(n,n'). \tag{A10}$$

The kernel K is, up to a constant $\varkappa(j)$ uniquely determined and is given by

$$K(n,n')=\varkappa(j)|[n,n']|^{-2-j}. \tag{A11}$$

The verification of Eq. (A11) is based on the relation

$$[n_g,n'_g]=\left(\frac{\omega_g}{\omega}\right)^{-1}\left(\frac{\omega'_g}{\omega}\right)^{-1}[n,n'], \tag{A12}$$

which is an obvious consequence of the relation $[\zeta g,\zeta' g]=[\zeta,\zeta']$ where $[.,.]$ is defined by (2.1). The module of constant $\varkappa$ is fixed by the normalization, which gives

$$|\varkappa|^2=\pi^{-2}2^{-4}\rho^2\tan^2(\pi\rho/2). \tag{A13}$$

Therefore, we put

$$\varkappa=\frac{2^j}{\pi}\frac{\Gamma^2\left(\frac{2+j}{2}\right)}{\Gamma^2\left(\frac{-1-j}{2}\right)}c, \tag{A14}$$

where c is the phase factor. Thus we obtain

$$Af(\varphi,\psi)=\varkappa\int_0^{2\pi}\int_0^{2\pi}\left|\sin\frac{\varphi-\varphi'}{2}\sin\frac{\psi-\psi'}{2}\right|^{-2-j}f(\varphi',\psi')\mathrm{d}\varphi'\,\mathrm{d}\psi. \tag{A15}$$

For the sake of brevity the value of function f at n is denoted by $f(\varphi,\psi)$. Taking into account the fact that the function $|mn\rangle=\exp(im\varphi+ik\psi)$ forms SO(2)×SO(2) bases in $L^2(S^1\times S^1)$, we have

$$\langle m'k'|A|mk\rangle=\delta_{mm'}\delta_{kk'}S(m,k), \tag{A16}$$

where

$$\begin{aligned}S(m,k)&=\varkappa\int_0^{2\pi}\int_0^{2\pi}\left|\sin\frac{\varphi}{2}\sin\frac{\psi}{2}\right|^{-2-j}\exp(im\varphi+ik\psi)\mathrm{d}\varphi\,\mathrm{d}\psi\\&=c\frac{\Gamma\left(\frac{1}{2}-\frac{i\rho}{2}+m\right)\Gamma\left(\frac{1}{2}-\frac{i\rho}{2}+k\right)}{\Gamma\left(\frac{1}{2}+\frac{i\rho}{2}+m\right)\Gamma\left(\frac{1}{2}+\frac{i\rho}{2}+k\right)}.\end{aligned} \tag{A17}$$

(ii) The SO(2,2)⊃SO(2)×E(1) reduction. Since A_3 and B_2+B_3 are sought to be diagonal, we introduce new coordinates in cone as follows $\zeta=\omega n,\ \omega>0$, where now

$$n=\left(\cos\frac{\varphi}{2}-t\sin\frac{\varphi}{2},\sin\frac{\varphi}{2}+t\cos\frac{\varphi}{2},\cos\frac{\varphi}{2}+t\sin\frac{\varphi}{2},-\sin\frac{\varphi}{2}+t\cos\frac{\varphi}{2}\right), \tag{A18}$$

$$0<\varphi\leqslant 2\pi,\quad -\infty<t<\infty.$$

Then the operators A_3 *and* B_2+B_3 have the forms

$$A_3=-i\frac{\partial}{\partial\varphi},\quad B_2+B_3=-i\frac{\partial}{\partial t}. \tag{A19}$$

The intertwining operator A in this realization is given by

$$Af(\varphi,t)=\varkappa\int_0^{2\pi}\int_{-\infty}^{+\infty}\left|(t-t')\sin\frac{\varphi-\varphi'}{2}\right|^{-2-j}f(\varphi',t')\mathrm{d}\varphi'\,\mathrm{d}t', \tag{A20}$$

where $f(\varphi,t)\equiv f(n)$. Taking into account that $|m\lambda\rangle=\exp(im\varphi+i\lambda t)$, we have

$$\langle m'\lambda'|A|m\lambda\rangle=\delta_{mm'}\delta(\lambda-\lambda')S(m,\lambda), \tag{A21}$$

where

$$S(m,\lambda)=c|\lambda|^{-i\rho}\frac{\Gamma\left(\frac{1}{2}-\frac{i\rho}{2}+m\right)}{\Gamma\left(\frac{1}{2}+\frac{i\rho}{2}+m\right)}. \tag{A22}$$

(iii) The $SO(2,2)\supset SO(2)\times SO(1,1)$ reduction. This case is somewhat more complicated than the previous one. We find that the parametrization $\zeta=\omega n$, $n>0$ covers only with two choices of n,

$$n^\tau=\Big(\cosh\frac{\beta}{2}\cos\frac{\varphi}{2}-\tau\sinh\frac{\beta}{2}\sin\frac{\varphi}{2},\tau\sinh\frac{\beta}{2}\cos\frac{\varphi}{2}+\cosh\frac{\beta}{2}\sin\frac{\varphi}{2},$$
$$\sinh\frac{\beta}{2}\cos\frac{\varphi}{2}-\tau\cosh\frac{\beta}{2}\sin\frac{\varphi}{2},\tau\cosh\frac{\beta}{2}\cos\frac{\varphi}{2}+\sinh\frac{\beta}{2}\sin\frac{\varphi}{2}\Big), \tag{A23}$$

where $\tau=\pm1$, $-\infty<\beta<\infty$, $0<\varphi\leqslant2\pi$. Observe that the operators A_1 and B_3 are diagonal,

$$A_1=-i\frac{\partial}{\partial\beta},\quad B_3=-i\frac{\partial}{\partial\varphi}. \tag{A24}$$

Then, a function $f(x)$ on the cone has to be thought of as a pair, expressed by $f(x)=\{f(\omega n^+),f(\omega n^-)\}$, and we have

$$Af^\tau(\beta,\varphi)=\varkappa\sum_{\tau'=\pm1}\int_0^{2\pi}\int_{-\infty}^{+\infty}|[1-\tau\tau'\cos(\varphi-\varphi')]$$
$$\times[1-\tau\tau' ch(\beta-\beta')]|^{-2-j}f(\beta,\varphi)\mathrm{d}\varphi'\,\mathrm{d}\beta', \tag{A25}$$

where $f^\tau(\beta,\varphi)\equiv f(n^\tau)$. This then gives the integral representation of the matrix elements of S in the $SO(2)\times SO_0(1,1)$ basis. Taking into account that

$$|m\mu+\rangle=\begin{pmatrix}1\\0\end{pmatrix}\exp(im\varphi+i\mu\beta),\quad |m\mu+\rangle=\begin{pmatrix}0\\1\end{pmatrix}\exp(im\varphi+i\mu\beta), \tag{A26}$$

we have

$$\langle m'\mu'\tau'|A|m\mu\tau\rangle=\delta(\mu-\mu')\delta_{mm'}S_{\tau\tau'}(\mu,m), \tag{A27}$$

where

$$S_{++}=S_{+-}=\frac{c}{\pi}\cos\pi\mu\,\Gamma\left(\frac{1}{2}-\frac{i\rho}{2}+i\mu\right)\Gamma\left(\frac{1}{2}-i\frac{\rho}{2}-i\mu\right)\frac{\Gamma\left(\frac{1}{2}-\frac{i\rho}{2}+m\right)}{\Gamma\left(\frac{1}{2}+\frac{i\rho}{2}+m\right)},$$

$$S_{-+}=S_{+-}=i\frac{c}{\pi}\sinh\pi\frac{\rho}{2}\,\Gamma\left(\frac{1}{2}-\frac{i\rho}{2}+i\mu\right)\Gamma\left(\frac{1}{2}-i\frac{\rho}{2}-i\mu\right)\frac{\Gamma\left(\frac{1}{2}-\frac{i\rho}{2}+m\right)}{\Gamma\left(\frac{1}{2}+\frac{i\rho}{2}+m\right)}.$$

(iv) The $SO(2,2)\supset SO(1,1)\times E(1)$ reduction. This subgroup reduction corresponds to a coordinate system on the cone, in which $\zeta=\omega n^{\tau},\omega>0,\tau=\pm1$, where

$$n^{-}=\left(\cosh\frac{\beta}{2}+t\sinh\frac{\beta}{2},-\sinh\frac{\beta}{2}+t\cosh\frac{\beta}{2},\cosh\frac{\beta}{2}-t\sinh\frac{\beta}{2},\sinh\frac{\beta}{2}+t\cosh\frac{\beta}{2}\right) \quad \text{(A28)}$$

and

$$n^{+}=\left(-\sinh\frac{\beta}{2}-t\cosh\frac{\beta}{2},\cosh\frac{\beta}{2}-t\sinh\frac{\beta}{2},-\sinh\frac{\beta}{2}+t\cosh\frac{\beta}{2},-\cosh\frac{\beta}{2}-t\sinh\frac{\beta}{2}\right) \quad \text{(A29)}$$

with $-\infty<\beta<\infty$, $-\infty<t<\infty$. Observe that, in this case, operators A_2 and B_2+B_3 are diagonal

$$A_2=-i\frac{\partial}{\partial\beta},\quad B_2+B_3=-i\frac{\partial}{\partial t}. \quad \text{(A30)}$$

Thus we obtain

$$Af^{\tau}(\beta,t)=\varkappa\sum_{\tau'=\pm1}\int_{-\infty}^{+\infty}\int_{-\infty}^{+\infty}|[\cosh(\beta-\beta')-\tau\tau'](t-t')|^{-2-j}f^{\tau}(\beta',t')\mathrm{d}\beta'\,\mathrm{d}t', \quad \text{(A31)}$$

where we have taken $f^{\tau}(\beta,t)=f(n^{\tau})$ for n^{τ} given by (A28) and (A29). This then gives the integral representation of the matrix element of A in the $SO_0(1,1)\times E(1)$ basis. As a result

$$\langle\lambda'\mu'\tau'|A|\lambda\mu\tau\rangle=\delta(\mu-\mu')\,\delta(\lambda-\lambda')S_{\tau\tau'}(\mu,\lambda), \quad \text{(A32)}$$

where

$$S_{++}=S_{--}=\frac{c}{\pi}|\lambda|^{-i\rho}\cosh\pi\mu\,\Gamma\left(\frac{1}{2}-\frac{i\rho}{2}+i\mu\right)\Gamma\left(\frac{1}{2}-\frac{i\rho}{2}-i\mu\right),$$

$$S_{-+}=S_{+-}=i\frac{c}{\pi}|\lambda|^{-i\rho}\sinh\pi\frac{\rho}{2}\,\Gamma\left(\frac{1}{2}-\frac{i\rho}{2}+i\mu\right)\Gamma\left(\frac{1}{2}-\frac{i\rho}{2}-i\mu\right).$$

(v) The $SO(2,2)\supset E(1)\times E(1)$ reduction. Let us now introduce coordinates on the cone by putting

$$\zeta=\omega n,\quad n=(1+yt,y-t,1-yt,y+t),$$

where $\omega>0,-\infty<t<\infty,-\infty<y<\infty$. Clearly we have diagonalized the operators A_2+A_3 and B_2+B_3:

$$A_2+A_3=-i\frac{\partial}{\partial t},\quad B_2+B_3=-i\frac{\partial}{\partial y}. \tag{A33}$$

In this realization the intertwining operator A is given by

$$Af(t,y)=\varkappa\int_{-\infty}^{+\infty}\int_{-\infty}^{+\infty}|(t-t')(y-y')|^{-2-j}f(t',y')\mathrm{d}t'\,\mathrm{d}y'. \tag{A34}$$

Therefore, the matrix element of A in the E(1)×E(1) basis $|\mu,\lambda\rangle$ is given by

$$\langle\mu'\lambda'|A|\mu\lambda\rangle=\delta(\mu-\mu')\,\delta(\lambda-\lambda')S(\mu,\lambda), \tag{A35}$$

where $S(\mu,\lambda)=c(\mu\lambda)^{-i\rho},\ \mu\lambda>0$.

APPENDIX B: BASIS FUNCTIONS ON THE HYPERBOLOID *X*

In this section we calculate basis functions corresponding to the reduction considered in Sec. III.

(i) The SO(2,2)⊃SO(2)×SO(2) reduction. The basis functions in this reduction are defined as (3.12)

$$f^{(1)}_{mk}(x)=\varkappa\int_0^{2\pi}\int_0^{2\pi}\left|\cosh\frac{\alpha}{2}\cos\frac{\psi'-\psi+\varphi'-\varphi}{2}-\sinh\frac{\alpha}{2}\cos\frac{\psi'-\psi-\varphi'+\varphi}{2}\right|^{-2-j}$$
$$\times\exp(im\varphi'+ik\psi')\mathrm{d}\psi'\,\mathrm{d}\varphi'. \tag{B1}$$

For the explicit calculation we rewrite (B1) in the following form:

$$f^{(1)}_{mk}(x)=\varkappa\exp(im\varphi+ik\psi)\int_0^{2\pi}\int_0^{2\pi}(\cosh\alpha-\sinh\alpha\cos\psi')^{-(2+j)/2}\left|\cos\left(\frac{\varphi'+\varphi_0}{2}\right)\right|^{-2-j}$$
$$\times\exp(im\varphi'+ik\psi')\mathrm{d}\psi'\,\mathrm{d}\varphi', \tag{B2}$$

where

$$\cos\varphi_0=\frac{\cosh\alpha\cos\psi'-\sinh\alpha}{\cosh\alpha-\sinh\alpha\cos\psi'},\quad \sin\varphi_0=\frac{\sin\psi'}{\cosh\alpha-\sinh\alpha\cos\psi'}.$$

After integration over the angle φ' expression (B2) reduces to the well-known integral representation for the matrix elements of the SO(2,1) group in the SO(2) basis.[20] As a result we find

$$f^{(1)}_{mk}(x)=\frac{2^{j+2}\pi^{1/2}\Gamma\left(\frac{2+j}{2}\right)\Gamma\left(\frac{j}{2}+m+1\right)}{\Gamma\left(\frac{-1-j}{2}\right)\Gamma\left(\frac{-j}{2}+m\right)}\exp(im\varphi+ik\psi)\mathfrak{P}^{-(2+j)/2}_{k,m}(\cosh\alpha), \tag{B3}$$

where $\mathfrak{P}^{j}_{mn}(z)$ is the generalized Legendre function as defined by Vilenkin.[20]

(ii) SO(2,2)⊃SO(2)×E(1). The basis functions in this reduction are defined as

$$f^{(2)}_{m\lambda}(x)=\varkappa\int_0^{2\pi}\int_{-\infty}^{+\infty}\left|e^{-\alpha/2}\cos\frac{\varphi'-\varphi}{2}-e^{-\alpha/2}(t'-t)\sin\frac{\varphi'-\varphi}{2}\right|^{-2-j}e^{im\varphi'+i\lambda t'}\mathrm{d}\varphi'\,\mathrm{d}t'. \tag{B4}$$

The explicit calculation is achieved by writing (B4) in the form

$$f^{(2)}_{m\lambda}(x)=\varkappa\exp(im\varphi+i\lambda t)\int_0^{2\pi}\int_{-\infty}^{+\infty}(e^{-\alpha}+e^{\alpha}t'^2)^{-(2+j)/2}\left|\cos\frac{\varphi'-\varphi_0}{2}\right|^{-2-j}$$
$$\times\exp(im\varphi'+i\lambda t')\mathrm{d}\varphi'\,\mathrm{d}t', \tag{B5}$$

where

$$\cos\varphi_0=\frac{e^{-\alpha}-e^{\alpha}t'^2}{e^{-\alpha}+e^{\alpha}t'^2},\quad \sin\varphi_0=\frac{2t'}{e^{-\alpha}+e^{\alpha}t'^2}.$$

We then have that

$$f^{(2)}_{m\lambda}(x)=\begin{cases}\dfrac{2^{1+j}\Gamma\left(\dfrac{j}{2}-m+1\right)}{\Gamma(-1-j)}(2\lambda)^{j/2}\exp(im\varphi+i\lambda t)W_{m,-(1+j)/2}(2e^{-\alpha}\lambda) & \text{if } \lambda>0\\ \dfrac{-2^{1+j}\Gamma\left(\dfrac{j}{2}+m+1\right)}{\Gamma(-1-j)}(-2\lambda)^{j/2}\exp(im\varphi+i\lambda t)W_{-m,-(1+j)/2}(-2e^{-\alpha}\lambda) & \text{if } \lambda<0,\end{cases} \tag{B6}$$

where $W_{\mu\nu}(z)$ is the Whittaker function.[22] Furthermore we can check that the basis function $f^{(2)}_{m\lambda}$ is indeed related to the SO(2)−E(1) mixed basis matrix elements of the principal series representation of SO(2,1).[23]

(iii) SO(2,2)⊃SO(2)×SO(1,1). The basis function $f^{(3)}_{m\mu\tau}$ may be calculated from the formula

$$f^{(3)}_{m\mu\tau}(x)=\varkappa\int_0^{2\pi}\int_{-\infty}^{+\infty}\left|e^{-\alpha\tau/2}\cosh\frac{\beta'-\beta}{2}\cos\frac{\varphi'-\varphi}{2}-\tau e^{\alpha\tau/2}\sinh\frac{\beta'-\beta}{2}\right.$$
$$\left.\times\sin\frac{\varphi'-\varphi}{2}\right|^{-2-j}\exp(i\mu\beta'+im\varphi')\mathrm{d}\varphi'\,\mathrm{d}\beta'. \tag{B7}$$

The explicit calculation is achieved by writing (B7) in the form

$$f^{(3)}_{m\mu\tau}(\beta,\alpha,\varphi)=\exp(i\mu\beta+im\varphi)\int_0^{2\pi}\int_{-\infty}^{+\infty}|\cosh\alpha\cosh\beta'-\tau\sinh\alpha|^{(-2-j)/2}$$
$$\times[1-\tau\cos(\varphi'-\varphi_0)]^{(-2-j)/2}\exp(i\mu\beta'+im\varphi')\mathrm{d}\varphi'\,\mathrm{d}\beta',$$

where

$$\cos\varphi_0=\frac{\sinh\alpha\cosh\beta'-\tau\cosh\alpha}{\cosh\alpha\cosh\beta'-\tau\sinh\alpha},\quad \sin\varphi_0=\frac{\sinh\beta'}{\cosh\alpha\cosh\beta'-\tau\sinh\alpha}.$$

We then obtain

$$f^{(3)}_{m\mu\tau}(\beta,\alpha,\varphi)=\frac{\Gamma\left(1+\dfrac{j}{2}+m\right)\Gamma\left(1+\dfrac{j}{2}-i\tau\mu\right)\exp[i\pi(m+1)(\tau+1)/2]}{\pi\Gamma(-1-j)}$$
$$\times\exp(i\mu\beta+im\varphi-\pi\tau\mu)\mathfrak{Q}^{j/2}_{i\tau\mu,m}(i\tau\sinh\alpha), \tag{B8}$$

where $\mathfrak{Q}^{j}_{\mu\nu}(z)$ is the generalized Legendre function of the second kind as defined by Azimov.[21] Observe that the basis function $f^{(3)}_{m\mu\tau}$ is related to SO(2)–SO(1,1) mixed basis matrix elements of SO(2,1).[23]

(iv) The SO(2,2)⊃SO(1,1)×E(1) reduction. The basis functions in this reduction are given by

$$f^{(4)}_{\lambda\mu\tau}(x)=\varkappa\int_{-\infty}^{+\infty}\int_{-\infty}^{+\infty}|[x,n^{\tau}]|^{-2-j}\exp(i\mu\beta'+i\lambda t')\mathrm{d}\beta'\,\mathrm{d}t', \tag{B9}$$

where n^{τ} are given by (A28) and (A29). After integration over t', expression (B9) reduces to the integral representations for SO(1,1)−E(1) mixed basis matrix elements of SO(2,1).[23] As result

$$f^{(4)}_{\lambda\mu+}(x)=\pi^{1/2}(2\lambda)^{1+j}\frac{\Gamma\left(\frac{2+j}{2}\right)}{\Gamma\left(\frac{-1-j}{2}\right)}e^{i\mu\beta+i\lambda t}\left[\Gamma\left(\frac{j}{2}-i\mu+1\right)(-2i\lambda)^{-(2+j)/2}\right.$$

$$\left.\times W_{i\mu,(1+j)/2}(-2i\lambda e^{\alpha})+\Gamma\left(\frac{j}{2}+i\mu+1\right)(2i\lambda)^{-(2+j)/2}W_{-i\mu,(1+j)/2}(2i\lambda e^{\alpha})\right],$$

$$f^{(4)}_{\lambda\mu-}(x)=\pi^{1/2}(2\lambda)^{1+j}e^{-i\lambda e^{\alpha}}\frac{\Gamma\left(\frac{2+j}{2}\right)}{\Gamma\left(\frac{-1-j}{2}\right)}e^{\alpha(2+j)/2}$$

$$\times B\left(\frac{j}{2}-i\mu+1,\frac{j}{2}+i\mu+1\right)e^{i\mu\beta+i\lambda t}\,{}_1F_1\left(\frac{j}{2}+i\mu+1,2+j;2i\lambda e^{\alpha}\right)$$

with $x\in X^{-}$, $B(a,b)=\Gamma(a)\Gamma(b)/\Gamma(a+b)$ and

$$f^{(4)}_{\lambda\mu+}(x)=\pi^{1/2}(2\lambda)^{1+j}e^{i\lambda e^{-\alpha}}\frac{\Gamma\left(\frac{2+j}{2}\right)}{\Gamma\left(\frac{-1-j}{2}\right)}e^{-\alpha(2+j)/2}$$

$$\times B\left(\frac{j}{2}-i\mu+1,\frac{j}{2}+i\mu+1\right)e^{i\mu\beta+i\lambda t}\,{}_1F_1\left(\frac{j}{2}+i\mu+1,2+j;-2i\lambda e^{-\alpha}\right)$$

$$f^{(4)}_{\lambda\mu-}(x)=\pi^{1/2}(2\lambda)^{1+j}\frac{\Gamma\left(\frac{2+j}{2}\right)}{\Gamma\left(\frac{-1-j}{2}\right)}e^{i\mu\beta+i\lambda t}\left[\Gamma\left(\frac{j}{2}+i\mu+1\right)(-2i\lambda)^{(-2-j)/2}\right.$$

$$\left.\times W_{-i\mu,(1+j)/2}(-2i\lambda e^{-\alpha})+\Gamma\left(\frac{j}{2}-i\mu+1\right)(2i\lambda)^{(-2-j)/2}W_{i\mu,(1+j)/2}(2i\lambda e^{-\alpha})\right]$$

with $x\in X^{+}$.

(v) The SO(2,2)⊃E(1)×E(1) reduction. The basis function in this reduction may be calculated from

$$f^{(5)}_{\lambda\mu}(x)=\varkappa\int_{-\infty}^{+\infty}\int_{-\infty}^{+\infty}|e^{-\alpha/2}+(y'-y)(t'-t)e^{\alpha/2}|^{-2-j}\exp(i\lambda\xi'+i\mu t')\mathrm{d}y'\,\mathrm{d}t'.$$

We obtain

$$f^{(5)}_{\lambda\mu}(x)=\frac{2^{-1-j}}{\Gamma(-1-j)}(\lambda\mu)^{(1+j)/2}\exp\left(i\lambda y+i\mu t-\frac{\alpha}{2}\right)K_{-1-j}(e^{-\alpha/2}\sqrt{\lambda\mu}),\lambda\mu>0,$$

where $K_j(z)$ is the modified Bessel function of the third kind.

(Received 24 July 2000; accepted for publication 26 October 2000)

Using the zeta function regularization method we calculate the ground state energy of scalar massive field inside a spherical region in the space–time of a pointlike global monopole. Two cases are investigated: (i) First, we calculate the Casimir energy inside a sphere of radius R and analyze the obtained result. We observe that this energy may be positive or negative depending on metric coefficient α and nonconformal coupling ξ. In the limit $R\to\infty$, this energy vanishes: (ii) In the second model, we surround the monopole by an additional sphere of radius $r_0 < R$ and consider the scalar field confined in the region between these two spheres. In this case, the ground state energy presents an additional contribution due to boundary at r_0 which is divergent for small radius. Additional comments about renormalization are considered. © *2001 American Institute of Physics.*

I. INTRODUCTION

Different types of topological objects may have been formed during Universe expansion, among them we have domain walls, cosmic strings and monopoles.[1] These topological defects appear as a consequence of breakdown of local or global gauge symmetries of a system composed by self-coupling iso-scalar Higgs fields Φ^a. Global monopoles are created due to phase transition when a global gauge symmetry is spontaneously broken and they may have an important role in cosmology and astrophysics. The process of global monopole creation is accompanied by particle production.[2] Grand unified theory predicts great number of these objects in the Universe,[3] but this problem can be avoided using inflationary models. From an astrophysical point of view, there is at most one global monopole in the local group of galaxies.[4]

The space–time of a global monopole in an $O(3)$ broken symmetry model has been investigated by Barriola and Vilenkin.[5] They have shown that far from the compact monopole's core the space–time is approximately described by a spherical symmetric metric with an additional deficit solid angle. It is also possible to find solution for the Einstein equation coupled with an energy-momentum tensor associated with a pointlike global monopole. For simplicity we shall consider in this article this singular configuration. In Ref. 6 a simplified model is presented in order to consider some internal structure for the global monopole.

The analysis of quantum fields on the global monopole background has been considered in Refs. 7–9. It was shown, taking into account only dimensional and conformal considerations,[7] that the vacuum expectation value of the energy-momentum tensor associated with a collection of conformal massless quantum fields of arbitrary spin in this background has the following general structure,

$$\langle T_k^i \rangle = S_k^i \frac{\hbar c}{r^4},$$

[a]Electronic mail: emello@fisica.ufpb.br
[b]Electronic mail: valdir@fisica.ufpb.br

where the quantities S_k^i depend only on the solid angle deficit and spin of the fields. For a scalar field this tensor was investigated more carefully by Mazzitelli and Lousto[8] and for a massless spinor field by the authors of Ref. 9 in detail.

The above energy-momentum tensor has nonintegrable singularity at the origin, therefore the ground state energy cannot be found by integrating the energy density. The same problem also appears for cosmic string space–time[10] and in the Minkowski one with a boundary condition on the dihedral angle.[11] The calculation of ground state energy for the cosmic string space–time was considered in Refs. 12 and 13, using different approaches. For an infinitely thin cosmic string, a specific global effect appears which leads to additional surface renormalization.[12] The ground state energy of the massive scalar field in the background of a cosmic string with internal nonsingular structure has been considered in Ref. 13. It has been found that it is zero, independently of the transverse diameter of the string.

The nontrivial topology of space–time, as well as its curvature, leads to a number of interesting effects which are not presented in a flat space. For example, there appear self-interacting forces on massive pointlike particles at rest. These forces have been investigated in Refs. 14 and 15 for cosmic string and global monopole space–times.

In the framework of the zeta function regularization method[16] (see also Ref. 17), the ground state energy of a scalar massive field can be obtained from

$$E(s)=\tfrac{1}{2}M^{2s}\zeta_A(s-\tfrac{1}{2}), \tag{1}$$

which is expressed in terms of the zeta function ζ_A associated with the Laplace operator $\hat{A}=-\Delta+\xi\mathcal{R}+m^2$ defined in the three-dimensional spatial section of the space–time. Here, the parameter M, with dimension of mass, has been introduced in order to have the correct dimension for the energy. In order to calculate the renormalized ground state energy we shall use the approach which was suggested and developed in Refs. 18–21.

In this article we would like to discuss the ground state energy of a scalar massive field in the background of a pointlike global monopole space–time inside a spherical region, considering an arbitrary nonminimal coupling of this field with the geometry. Because the energy-momentum tensor has nonintegrable singularity at the origin we would like to investigate two cases: (i) In the first we consider a pointlike global monopole and calculate the ground state energy using the zeta function approach; and (ii) in the second one, we consider a sphere surrounding the monopole and cut out internal part of it by an appropriate boundary condition for the radial functions. This procedure permits us to show up the role of the singularity. In the limit of zero radius of the inner sphere, this model corresponds to a topological defect, because, in this case, there is no internal structure.

The zeta function of the Laplace operator on the pointlike global monopole background has been considered by Bordag, Kirsten and Dowker in Ref. 22, using the method given in Refs. 18–21. There, the general mathematical structure of the zeta function and the heat kernel coefficients on the generalized cone have been obtained. Because the main emphasis of the present article is on the ground state energy, we shall rederive in Sec. III some specific formulas for our case which was not considered in Ref. 22.

The organization of this article is as follows. In Sec. II we briefly review some geometrical properties about global monopole space–time which will be needed. In Sec. III, the zeta function of the Laplace operator on the three-dimensional section of a pointlike global monopole space–time is given. In Sec. IV we consider the zeta function for global monopole space–time, cutting out the interior of the sphere around the origin. In Sec. V, the ground state energy of the massive scalar field with arbitrary nonconformal coupling on the global monopole background is considered for both cases. In Sec. VI, we discuss our results. The signature of the space–time, the sign of the Riemann and Ricci tensors, is the same as in Christensen's paper.[23] We use units $\hbar=c=G=1$.

II. THE GEOMETRY

Global monopoles are heavy objects probably formed in the early Universe by a phase transition which occurred in a system composed by a scalar self-coupling triplet field ϕ^a whose original global symmetry $O(3)$ is spontaneously broken to $U(1)$.

The simplest model which gives rise a global monopole is described by the Lagrangian density

$$L=\frac{1}{2}(\partial_l\phi^a)(\partial^l\phi^a)-\frac{\lambda}{4}(\phi^a\phi^a-\eta^2)^2.$$

Coupling this matter field with Einstein equations, Barriola and Vilenkin[5] have shown that the effect produced by this configuration, from the geometrical point of view, can be approximately represented by a deficit solid angle in the $(3+1)$-dimensional space–time, whose line element is given by

$$ds^2=-dt^2+\alpha^{-2}dr^2+r^2(d\theta^2+\sin^2\theta d\varphi^2), \tag{2}$$

where the parameter $\alpha^2=1-8\pi\eta^2$ is smaller than unity and depends on the symmetry breaking energy scale η. The solid angle in the geometry defined by (2) is $4\pi\alpha^2$, consequently smaller than 4π. So this space–time presents a deficit solid angle given by $\delta\Omega=32\pi^2\eta^2$. We also can note that it is not flat. The nonzero components of the Riemann and Ricci tensors, and the scalar curvature are given by

$$\mathcal{R}^{\theta\varphi}_{\ .\theta\varphi}=\mathcal{R}^{\theta}_{\ \theta}=\mathcal{R}^{\varphi}_{\ \varphi}=\frac{1-\alpha^2}{r^2},\quad \mathcal{R}=\frac{2(1-\alpha^2)}{r^2}.$$

For further application, let us consider an extrinsic curvature tensor on the sphere of radius R around the origin:

$$K_{ij}=\nabla_i N_j.$$

Here N_j is the outward unit normal vector with coordinates $N_j=(0,\alpha,0,0)$. This tensor has two nonzero components,

$$K^{\theta}_{\theta}=K^{\varphi}_{\varphi}=\frac{\alpha}{R}.$$

III. ZETA FUNCTION FOR POINTLIKE GLOBAL MONOPOLE SPACE–TIME

In order to calculate the ground state energy given by Eq. (1) we have to obtain the zeta function of the operator $\hat{A}$ in the neighborhood of the point $s=-\frac{1}{2}$. To do the calculation of the zeta function we follow Refs. 19, 20, and 22. The zeta function of the operator $\hat{A}=-\triangle+\xi\mathcal{R}+m^2$ is defined in terms of the sum over all eigenvalues of this operator by

$$\zeta_A\left(s-\frac{1}{2}\right)=\sum_{(n)}(\lambda^2_{(n)}+m^2)^{1/2-s}.$$

Here $\lambda^2_{(n)}$ is the eigenvalue of the operator $\hat{B}=\hat{A}-m^2$. The eigenfunctions of the operator $\hat{A}$ defined on the background (2), which are regular at the origin, have the form

$$\Phi(\mathbf{r})=\sqrt{\frac{\lambda}{\alpha r}}Y_{lm}(\theta,\varphi)J_{\mu}\left(\frac{\lambda}{\alpha}r\right), \tag{3}$$

where Y_{lm} are the spherical harmonics and J_{μ} is the Bessel function of the first kind with index

$$\mu=\frac{1}{\alpha}\sqrt{\left(l+\frac{1}{2}\right)^2+2(1-\alpha^2)\left(\xi-\frac{1}{8}\right)}. \tag{4}$$

A discrete set of eigenvalues $\lambda_{l,j}$ can be found by imposing some boundary condition on this function. Let us consider the Dirichlet boundary condition at the surface of a sphere of radius R concentric with the pointlike monopole:

$$\sqrt{\lambda_{l,j}}J_\mu\left(\frac{\lambda_{l,j}}{\alpha}R\right)=0. \tag{5}$$

Then, the zeta function reads

$$\zeta_A^R\left(s-\frac{1}{2}\right)=\sum_{l=0}^{\infty}\sum_{j=0}^{\infty}(2l+1)(\lambda_{l,j}^2+m^2)^{1/2-s},$$

where the label R in the zeta function was introduced to indicate this kind of boundary condition. The solutions $\lambda_{l,j}$ of Eq. (5) cannot be found in closed form. For this reason we use the method suggested in Refs. 18–20, which allows us to express the zeta function in terms of the eigenfunctions. According to this approach, the sum over j may be converted into a contour integral in a complex λ-plane using the principal of argument, namely

$$\zeta_A^R\left(s-\frac{1}{2}\right)=\sum_{l=0}^{\infty}(2l+1)\int_\gamma d\lambda^2(\lambda^2+m^2)^{1/2-s}\frac{\partial}{\partial\lambda}\ln\lambda^{-\mu}J_\mu\left(\frac{\lambda}{\alpha}R\right),$$

where the contour γ runs counterclockwise and must enclose all solutions of Eq. (5) on the positive real axis. Shifting the contour to the imaginary axis, we obtain the following formula for the zeta function (see Ref. 19 for details):

$$\zeta_A^R\left(s-\frac{1}{2}\right)=-\frac{\cos\pi s}{\pi}\sum_{l=0}^{\infty}(2l+1)\int_m^\infty dk(k^2-m^2)^{1/2-s}\frac{\partial}{\partial k}\ln k^{-\mu}I_\mu\left(\frac{k}{\alpha}R\right). \tag{6}$$

Here I_μ is the modified Bessel function. In what follows, we will use the uniform expansion for the Bessel function $I_\mu(\mu z)$ as

$$I_\mu(\mu z)=\sqrt{\frac{t}{2\pi\mu}}e^{\mu\eta(z)}\left\{1+\sum_{k=1}^{\infty}\frac{u_k(t)}{\mu^k}\right\}, \tag{7}$$

where $t=1/\sqrt{1+z^2}$, $\eta(z)=\sqrt{1+z^2}+\ln(z/(1+\sqrt{1+z^2}))$ and $z=kR/\mu\alpha$. The first coefficients $u_k(t)$ and the recursion relations for the higher ones are listed in Ref. 24 This uniform expansion leads to the power series in m, and the term u_N gives the contribution $\sim 1/m^{3-N}$. We shall make the calculations up to $N=3$. In this case we obtain the following formula for uniform expansion of the logarithm of Bessel function:

$$\ln\left(k^{-\mu}I_\mu\left(\frac{k}{\alpha}R\right)\right)=\mu(\eta(z)-z)-\frac{1}{4}\ln(1+z^2)+\frac{1}{\mu}D_1(t)+\frac{1}{\mu^2}D_2(t)+\frac{1}{\mu^3}D_3(t), \tag{8}$$

where

$$D_1(t)=\sum_{a=0}^{1} x_{1,a}t^{1+2a}=\frac{1}{8}t-\frac{5}{24}t^3,$$

$$D_2(t)=\sum_{a=0}^{2} x_{2,a}t^{2+2a}=\frac{1}{16}t^2-\frac{3}{8}t^4+\frac{5}{16}t^6, \tag{9}$$

$$D_3(t)=\sum_{a=0}^{3} x_{3,a}t^{3+2a}=\frac{25}{384}t^3-\frac{531}{640}t^5+\frac{221}{128}t^7-\frac{1105}{1152}t^9.$$

In the above expression we omit all constants which are not important for calculation of the zeta function. Adding and subtracting uniform expansion (8) in the integrand of formula (6), we may represent the zeta function in the form

$$\zeta_A^R\left(s-\frac{1}{2}\right)=N^R(s)+\frac{m^{-2s}}{(4\pi)^{3/2}\Gamma(s-\frac{1}{2})}\sum_{k=-1}^{3} A_k(s,R), \tag{10}$$

where

$$N^R(s)=-\frac{\cos\pi s}{\pi R}\sum_{l=0}^{\infty}(2l+1)\mu\alpha\int_{\beta/\mu\alpha}^{\infty}dx\left\{x^2-\left(\frac{\beta}{\mu\alpha}\right)^2\right\}^{1/2-s}$$
$$\times\frac{\partial}{\partial x}\left\{\ln I_\mu(\mu x)-\mu\eta(x)+\frac{1}{4}\ln(1+x^2)-\frac{1}{\mu}D_1(t)-\frac{1}{\mu^2}D_2(t)-\frac{1}{\mu^3}D_3(t)\right\}, \tag{11}$$

$$A_{-1}(s,R)=\frac{4\pi^{3/2}m\beta}{\alpha}\sum_{l=0}^{\infty}(2l+1)\left[\frac{\Gamma(s-1)}{\sqrt{\pi}}{}_2F_1-\frac{\alpha\mu}{\beta}\Gamma\left(s-\frac{1}{2}\right)\right], \tag{12}$$

$$A_0(s,R)=-2\pi^{3/2}m\mathcal{Z}(0,s-\tfrac{1}{2}), \tag{13}$$

$$A_1(s,R)=-\frac{\pi m\alpha}{\beta}\left[\mathcal{Z}(0,s)-\frac{10}{3}\mathcal{Z}(2,s+1)\right], \tag{14}$$

$$A_2(s,R)=-\frac{\pi^{3/2}m\alpha^2}{2\beta^2}\left[\mathcal{Z}\left(0,s+\frac{1}{2}\right)-6\mathcal{Z}\left(2,s+\frac{3}{2}\right)+\frac{5}{2}\mathcal{Z}\left(4,s+\frac{5}{2}\right)\right], \tag{15}$$

$$A_3(s,R)=-\frac{\pi m\alpha^3}{24\beta^3}\left[25\mathcal{Z}(0,s+1)-\frac{1062}{5}\mathcal{Z}(2,s+2)\right.$$
$$\left.+\frac{884}{5}\mathcal{Z}(4,s+3)-\frac{1768}{63}\mathcal{Z}(6,s+4)\right]. \tag{16}$$

Here ${}_2F_1={}_2F_1(-\frac{1}{2},s-1;\frac{1}{2};-(\mu\alpha/\beta))^2$ is the hypergeometric function, $\beta=mR$ and

$$\mathcal{Z}(p,s)=\Gamma(q)\sum_{l=0}^{\infty}\frac{2l+1}{(1+\alpha^2\mu^2/\beta^2)^s}\left(\frac{\alpha\mu}{\beta}\right)^p. \tag{17}$$

The series in Eq. (12),

$$T(s)=\sum_{l=0}^{\infty}(2l+1)\left[\frac{\Gamma(s-1)}{\sqrt{\pi}}{}_2F_1-\frac{\alpha\mu}{\beta}\Gamma\left(s-\frac{1}{2}\right)\right], \tag{18}$$

can be expressed in terms of the same function given in Eq. (17). Indeed, one can use analytical continuation of the hypergeometrical function [24]

$$
{}_2F_1\left(-\frac{1}{2},s-1;\frac{1}{2};-\left(\frac{\alpha\mu}{\beta}\right)^2\right)=\frac{\alpha\mu}{\beta}\frac{\Gamma\frac{1}{2}\Gamma(s-\frac{1}{2})}{\Gamma(s-1)}+\frac{\Gamma(\frac{1}{2})\Gamma(\frac{1}{2}-s)}{\Gamma(-\frac{1}{2})\Gamma(\frac{3}{2}-s)}
$$

$$
\times\left(1+\left(\frac{\alpha\mu}{\beta}\right)^2\right)^{1-s}{}_2F_1\left(1,s-1;s+\frac{1}{2};\frac{1}{1+(\alpha\mu/\beta)^2}\right).
$$

So, the first term on the rhs of the above equation cancels the second divergent term in the sum (18) which is due to term $k^{-\mu}$ in (6) (see Ref. 13). Now, one can use power series expansion for the hypergeometric function because its argument $1/(1+(\alpha\mu/\beta)^2)$ is always smaller than unity. Then, we get

$$
T(s)=\frac{1}{2\sqrt{\pi}}\Gamma\left(s-\frac{1}{2}\right)\sum_{l=0}^{\infty}\frac{\mathcal{Z}(0,n+s-1)}{\Gamma(n+s+\frac{1}{2})}. \tag{19}
$$

Therefore, in order to calculate the zeta function, we have to obtain an analytical continuation of the series $\mathcal{Z}(p,q)$. In fact, we may consider just

$$
\mathcal{Z}(0,s)=\Gamma(q)\sum_{l=0}^{\infty}\frac{2l+1}{(1+\alpha^2\mu^2/\beta^2)^s}, \tag{20}
$$

because the other functions with $p=2,4,6,...$ can be expressed in terms of $\mathcal{Z}(0,q)$. Substituting the value for μ given in Eq. (4) into Eq. (20), we obtain

$$
\mathcal{Z}(0,s)=2\Gamma(q)\beta^{2s}\sum_{l=0}^{\infty}\frac{l+\frac{1}{2}}{((l+\frac{1}{2})^2+b^2)^s}, \tag{21}
$$

where $b^2=\beta^2+2(1-\alpha^2)(\xi-1/8)$. This series is convergent for $\Re q>1$. It is not difficult to obtain the analytical continuation of this series for a small value of parameter b. Indeed, expanding $\mathcal{Z}$ in powers of b we have

$$
\mathcal{Z}(0,s)=2\beta^{2s}\sum_{k=0}^{\infty}\frac{(-1)^k}{k!}\Gamma(k+s)b^{2k}\zeta_H\left(2k+2s-1,\frac{1}{2}\right). \tag{22}
$$

In order to consider the analytical continuation of this function in the domain $\Re q\leqslant 1$ and for a large value of b, let us take the series

$$
F(s,a,b^2)=\sum_{l=0}^{\infty}\frac{1}{((l+a)^2+b^2)^s}.
$$

This series, which has been considered in great detail by Elizalde,[25] presents the following analytical continuation for great b:

$$
F(s,a,b^2)\simeq\frac{b^{-2s}}{\Gamma(s)}\sum_{l=0}^{\infty}\frac{(-1)^l\Gamma(l+s)}{l!}b^{-2l}\zeta_H(-2l,a)+\frac{\sqrt{\pi}\Gamma(s-\frac{1}{2})}{2\Gamma(s)}b^{1-2s}
$$

$$
-\frac{2\pi b^{-1/2-s}}{\Gamma(s)}\sum_{n=1}^{\infty}n^{s-1/2}\cos(2\pi na)K_{s-1/2}(2\pi nb).
$$

Here ζ_H is the Hurwitz zeta function and K_n is the modified Bessel function. Differentiating this series with respect to a and putting $a=1/2$ we obtain the analytical continuation that we need, which is the following:

$$\sum_{l=0}^{\infty}\frac{l+\frac{1}{2}}{((l+\frac{1}{2})^2+b^2)^s}\simeq\frac{b^{2-2s}}{2(s-1)}+\sum_{l=0}^{\infty}\frac{(-1)^l\Gamma(l+s)}{l!\Gamma(s)}b^{-2s-2l}\zeta_H(-1-2l,\tfrac{1}{2}).$$

Taking into account this expression we obtain the analytical continuation for $\mathcal{Z}(0,q)$, which is given by the expression

$$\mathcal{Z}(0,s)\simeq\left(\frac{b^2}{\beta^2}\right)^{-s}\left\{b^2\Gamma(s-1)+2\sum_{l=0}^{\infty}\frac{(-1)^l}{l!}\Gamma(l+s)b^{-2l}\zeta_H(-1-2l,\tfrac{1}{2})\right\},\tag{23}$$

where $b^2/\beta^2=1+2(1-\alpha^2)(\xi-\frac{1}{8})/\beta^2$. This function has simple poles for integer numbers $q=1,0,-1,-2,\ldots$. In order to obtain a renormalized value for the ground state energy we have to extract from our expression for zeta function (10) the part which survives in the limit $m\to\infty$. Moreover, to calculate the zeta function up to degree m^0 we need only two terms from series (23) in which $\zeta_H(-1,\frac{1}{2})=\frac{1}{24}$, and $\zeta_H(-3,\frac{1}{2})=-7/960$, and three terms of $T(s)$ which are obtained from Eq. (19).

Putting this expression into Eqs. (19) and (12)–(16), expanding in powers of $1/\beta=1/mR\ll 1$ and s, and collecting terms with similar degree on the mass m up to m^0 (here we cannot collect terms with higher orders in m because we used uniform expansion up to this power), we obtain

$$\begin{aligned}\zeta_A^R\left(s-\frac{1}{2}\right)=\frac{m^{-2s}}{(4\pi)^{3/2}}\Bigg\{&\left[\frac{4\pi R^3}{3\alpha}\right]m^4\frac{\Gamma(s-2)}{\Gamma(s-\frac{1}{2})}+[-2\pi^{3/2}R^2]m^3\frac{\Gamma(s-\frac{3}{2})}{\Gamma(s-\frac{1}{2})}\\&+\left[\frac{7}{3}\pi\alpha R-\frac{4\pi R}{\alpha}\left(\Delta-\frac{1}{12}\right)\right]m^2\frac{\Gamma(s-1)}{\Gamma(s-\frac{1}{2})}+\left[2\pi^{3/2}\left(\Delta-\frac{1}{12}\right)\right]m\\&+\left[\frac{\pi\alpha}{R}\left(\Delta-\frac{1}{12}+\frac{229}{2520}\alpha^2\right)-\frac{2\pi}{\alpha R}\left(\Delta^2-\frac{1}{6}\Delta+\frac{7}{240}\right)\right]\frac{\Gamma(s)}{\Gamma(s-\frac{1}{2})}+\ldots\Bigg\},\end{aligned}\tag{24}$$

where $\Delta=2(1-\alpha^2)(\xi-\frac{1}{8})$. All these terms are pole contributions to the zeta function and all next terms will be finite for $s\to 0$. Comparing the above expression with that obtained by the Mellin transformation taking the trace of heat kernel (in three dimensions),

$$\begin{aligned}\zeta_A^R\left(s-\frac{1}{2}\right)&=\frac{1}{\Gamma(s-\frac{1}{2})}\int_0^{\infty}dt\,t^{s-3/2}K(t)\\&=\frac{m^{-2s}}{(4\pi)^{3/2}}\Bigg\{B_0^Rm^4\frac{\Gamma(s-2)}{\Gamma(s-\frac{1}{2})}+B_{1/2}^Rm^3\frac{\Gamma(s-\frac{3}{2})}{\Gamma(s-\frac{1}{2})}\\&\quad+B_1^Rm^2\frac{\Gamma(s-1)}{\Gamma(s-\frac{1}{2})}+B_{3/2}^Rm+B_2^R\frac{\Gamma(s)}{\Gamma(s-\frac{1}{2})}+\ldots\Bigg\},\end{aligned}\tag{25}$$

we obtain the heat kernel coefficients:

$$B_0^R=\frac{4\pi R^3}{3\alpha},\quad B_{1/2}^R=-2\pi^{3/2}R^2,\quad B_1^R=\frac{7}{3}\pi\alpha R-\frac{4\pi R}{\alpha}\left(\Delta-\frac{1}{12}\right),$$

$$B_{3/2}^R=2\pi^{3/2}\left(\Delta-\frac{1}{12}\right),\quad B_2^R=\frac{\pi\alpha}{R}\left(\Delta-\frac{1}{12}+\frac{229}{2520}\alpha^2\right)-\frac{2\pi}{\alpha R}\left(\Delta^2-\frac{1}{6}\Delta+\frac{7}{240}\right). \tag{26}$$

Those terms which are proportional to the inverse degree of α come from the exponential part of the uniform expansion given by (7), which gives $T(s)$ (19). The terms which are linear in α^1 or α^0 come from the series $\Sigma u_k/\mu^k$ in (7).

Now we may compare our results with well-known formulas given in Refs. 26, 22, 17, and 27. The coefficients B_0^R, $B_{1/2}^R$, B_1^R, $B_{3/2}^R$ coincide with general formulas in three dimensions (note the necessary geometrical quantities to perform the calculations are given at the end of Sec. II):

$$\begin{aligned}
B_0^R&=\frac{4\pi R^3}{3\alpha}=\int_V dV,\\
B_{1/2}^R&=-2\pi^{3/2}R^2=-\frac{\sqrt{\pi}}{2}\int_{\partial V}dS,\\
B_1^R&=\frac{7}{3}\pi\alpha R-\frac{4\pi R}{\alpha}\left(\Delta-\frac{1}{12}\right)=\left(\frac{1}{6}-\xi\right)\int_V\mathcal{R}\,dV+\frac{1}{3}\int_{\partial V}(\mathrm{tr}\,K)dS,\\
B_{3/2}^R&=2\pi^{3/2}\left(\Delta-\frac{1}{12}\right)\\
&=-\frac{\sqrt{\pi}}{192}\int_{\partial V}(-96\xi\mathcal{R}+16\mathcal{R}+8\mathcal{R}_{ik}N^iN^k+7(\mathrm{tr}\,K)^2-10(\mathrm{tr}\,K)^2)dS.
\end{aligned} \tag{27}$$

As we will see, there are some problems connected with the term B_2. The general structure of this term is the following (see Refs. 23 and 27):

$$B_2^R=\int_V b_2\,dV+\int_{\partial V}c_2\,dS, \tag{28}$$

where

$$b_2=-\tfrac{1}{180}\mathcal{R}^{ik}\mathcal{R}_{ik}+\tfrac{1}{180}\mathcal{R}^{iklj}\mathcal{R}_{iklj}+\tfrac{1}{6}(\tfrac{1}{5}-\xi)\Box\mathcal{R}+\tfrac{1}{2}(\tfrac{1}{6}-\xi)^2\mathcal{R}^2 \tag{29}$$

is the volume part, and

$$\begin{aligned}
c_2=&\tfrac{1}{3}(\tfrac{1}{6}-\xi)\mathcal{R}(\mathrm{tr}\,K)+\tfrac{1}{3}(3/20-\xi)\mathcal{R}_{;l}N^l-\tfrac{1}{90}\mathcal{R}_{lk}N^lN^k(\mathrm{tr}\,K)+\tfrac{1}{30}\mathcal{R}_{iljk}N^lN^kK^{ij}\\
&-\tfrac{1}{90}\mathcal{R}_{il}K^{il}+\tfrac{1}{315}[\tfrac{5}{3}(\mathrm{tr}\,K)^3-11(\mathrm{tr}\,K)(\mathrm{tr}\,K^2)+\tfrac{40}{3}(\mathrm{tr}\,K^3)]+\tfrac{1}{15}\Box(\mathrm{tr}\,K)
\end{aligned} \tag{30}$$

is the boundary contribution. Taking into account the results obtained in Sec. II we have

$$b_2=-\frac{1}{r^4}\frac{\alpha}{4\pi}\left\{\pi\alpha\left(\Delta-\frac{1}{12}+\frac{17}{120}\alpha^2\right)-\frac{2\pi}{\alpha}\left(\Delta^2-\frac{1}{6}\Delta+\frac{7}{240}\right)\right\}, \tag{31}$$

$$c_2=-\frac{4\alpha^3}{315R^3}. \tag{32}$$

We observe that b_2 is proportional to $1/r^4$ and the integral over volume in Eq. (28) will diverge at the origin. This problem has already been discussed by Cheeger,[28] Brüning and Seeley,[29] and Bordag, Kirsten and Dowker[22] using *partie finite* of the integral. We regularize the expression for B_2 by restricting the domain of radial integration:

$$B_2=-\int_{\varepsilon}^{R}\frac{dr}{r^2}\left\{\pi\alpha\left(\Delta-\frac{1}{12}+\frac{17}{120}\alpha^2\right)-\frac{2\pi}{\alpha}\left(\Delta^2-\frac{1}{6}\Delta+\frac{7}{240}\right)\right\}-\frac{16\pi\alpha^3}{315R}. \tag{33}$$

After integration we take its finite remainder parts as $\varepsilon\to 0$, and the expression obtained in this way coincides with that given in Eq. (26).

Our expressions for the heat kernel coefficients also agree with those obtained in Ref. 22. In that article the heat kernel coefficients have been calculated for the conformal case ($\xi=1/8$, in three dimensions). In order to compare both results we have to set $\xi=1/8(\triangle=0)$ in Eq. (26) and use the formulas of Appendix A from Ref. 22 for the three-dimensional case $d=2$.

To proceed with the renormalization, which we shall discuss later, we have to subtract from zeta function (10) the asymptotic expansion (24). Because all divergences at $s\to 0$ are contained in (24), we set $s=0$ in the remained part. After a long calculation we arrive at the following formula for the zeta function:

$$\zeta_A^R\left(s-\frac{1}{2}\right)=-\frac{m}{16\pi^2\beta}\{B^R(\beta)\ln\beta^2+\Omega^R(\beta)\}+\frac{m^{-2s}}{(4\pi)^{3/2}}\left\{B_0^R m^4\frac{\Gamma(s-2)}{\Gamma(s-\frac{1}{2})}\right.$$
$$\left.+B_{1/2}^R m^3\frac{\Gamma(s-\frac{3}{2})}{\Gamma(s-\frac{1}{2})}+B_1^R m^2\frac{\Gamma(s-1)}{\Gamma(s-\frac{1}{2})}+B_{3/2}^R m+B_2^R\frac{\Gamma(s)}{\Gamma(s-\frac{1}{2})}\right\}, \tag{34}$$

where

$$B^R(\beta)=\tfrac{1}{2}Rm^4B_0^R-Rm^2B_1^R+RB_2^R=\tfrac{1}{2}\beta^4b_0^R-\beta^2b_1^R+b_2^R. \tag{35}$$

In order to exhibit the dependence on the mass m and on the radius of sphere R, we have introduced in the formula above the dimensionless heat kernel coefficients, which are given by relations

$$b_0^R=B_0^R/R^3=\frac{4\pi}{3\alpha},\quad b_1^R=B_1^R/R=\frac{7}{3}\pi\alpha-\frac{4\pi}{\alpha}\left(\Delta-\frac{1}{12}\right), \tag{36}$$

$$b_2^R=B_2^RR=\pi\alpha\left(\Delta-\frac{1}{12}+\frac{229}{2520}\alpha^2\right)-\frac{2\pi}{\alpha}\left(\Delta^2-\frac{1}{6}\Delta+\frac{7}{240}\right). \tag{37}$$

The function $\Omega^R(\beta)$ tends to a constant for $\beta\to 0$ and $\Omega^R(\beta)=-B^R(\beta)\ln\beta^2+\sqrt{\pi}b_{5/2}^R/\beta+O(1/\beta^2)$ for $\beta\to\infty$. The details of calculation and a closed form for $\Omega^R(\beta)$ are outlined in the Appendix.

At this point we would like to make a comment. The origin of the term $B^R\ln\beta^2$ is the following: In the limit $m\to\infty$ the singular part of the zeta function has the structure given by Eq. (25). For a small value of m it has the same pole structure multiplied by β^{2s}. This is because all functions $\mathcal{Z}(p,s)$ are proportional to this degree of β as it may be seen from Eq. (22). The difference between them in the limit $s\to 0$ is $s\ln\beta^2$ multiplied by Eq. (25). Obviously, in this limit, only B_0^R, B_1^R, B_2^R survive and give the logarithm contribution to Eq. (34).

IV. THE MODEL

Because the geometrical characteristics of global monopole space–time are divergent at the origin we consider the following model: The center of the monopole is surrounded by a sphere

with radius r_0 whose interior region is cut out. It means that in our model there is no internal structure for the global monopole. The present model reflects this peculiarity of a topological defect.

In the context of this model, we have to take into account both solutions of the radial equation of the Laplace operator, instead of only that given in Eq. (3), which is regular at the origin. The eigenfunctions now have the following form:

$$\Phi(\mathbf{r})=\sqrt{\frac{\lambda}{\alpha r}}Y_{lm}(\theta,\varphi)\left\{C_1 J_\mu\left(\frac{\lambda}{\alpha}r\right)+C_2 N_\mu\left(\frac{\lambda}{\alpha}r\right)\right\}, \tag{38}$$

where N_μ is the Bessel function of the second kind.

In this case we have two boundaries and one has to impose two boundary conditions. Let us again choose the Dirichlet boundary condition for the radial functions at spheres of radii R and r_0, which implies the following relations:

$$C_1 J_\mu\left(\frac{\lambda}{\alpha}R\right)+C_2 N_\mu\left(\frac{\lambda}{\alpha}R\right)=0 \tag{39}$$

and

$$C_1 J_\mu\left(\frac{\lambda}{\alpha}r_0\right)+C_2 N_\mu\left(\frac{\lambda}{\alpha}r_0\right)=0. \tag{40}$$

The set of discrete eigenvalues $\lambda_{l,j}$ can be found from the equation

$$J_\mu\left(\frac{\lambda_{l,j}}{\alpha}r_0\right)N_\mu\left(\frac{\lambda_{l,j}}{\alpha}R\right)-N_\mu\left(\frac{\lambda_{l,j}}{\alpha}r_0\right)J_\mu\left(\frac{\lambda_{l,j}}{\alpha}R\right)=0, \tag{41}$$

which is, in fact, the condition for existence of the solution (38). Therefore, instead of Eq. (6) we obtain the following formula for the zeta function:

$$\zeta_A\left(s-\frac{1}{2}\right)=-\frac{\cos\pi s}{\pi}\sum_{l=0}^{\infty}(2l+1)\int_m^\infty dk(k^2-m^2)^{1/2-s} \times\frac{\partial}{\partial k}\ln\left(I_\mu\left(\frac{kR}{\alpha}\right)K_\mu\left(\frac{kr_0}{\alpha}\right)-K_\mu\left(\frac{kR}{\alpha}\right)I_\mu\left(\frac{kr_0}{\alpha}\right)\right). \tag{42}$$

This general expression may be essentially simplified in the limit $R/r_0\to\infty$ which we are interested in. Taking into account that in this limit the ratio $K_\mu(kR/\alpha)/I_\mu(kR/\alpha)<\pi\exp(-2mR/\alpha)$ is exponentially small, we may divide the expression for zeta function (42) in two parts,

$$\zeta_A(s-\tfrac{1}{2})=\zeta_A^R(s-\tfrac{1}{2})+\zeta_A^{r_0}(s-\tfrac{1}{2}), \tag{43}$$

where

$$\zeta_A^R\left(s-\frac{1}{2}\right)=-\frac{\cos\pi s}{\pi}\sum_{l=0}^{\infty}(2l+1)\int_m^\infty dk(k^2-m^2)^{1/2-s}\frac{\partial}{\partial k}\ln\left(k^{-\mu}I_\mu\left(\frac{k}{\alpha}R\right)\right) \tag{44}$$

and

$$\zeta_A^{r_0}\left(s-\frac{1}{2}\right)=-\frac{\cos\pi s}{\pi}\sum_{l=0}^{\infty}(2l+1)\int_m^\infty dk(k^2-m^2)^{1/2-s}\frac{\partial}{\partial k}\ln\left(k^{\mu}K_\mu\left(\frac{k}{\alpha}r_0\right)\right). \tag{45}$$

The first part is the zeta function for a pointlike global monopole which we have already calculated in the previous section. It depends only on the boundary condition on the sphere of radius R. The second part depends on the boundary condition on the inner sphere of radius r_0. This kind of division of the zeta function has been used in the case of thick cosmic strings in Ref. 13. It is also in qualitative agreement with Ref. 20. Indeed, according with Ref. 20, the internal solution gives Bessel function I_μ and the external solution gives the function K_μ in the expression for the zeta function. The first part of zeta function (44) depends on the solutions inside the sphere of radius R, and the second part of zeta function (45) depends on the solutions outside the sphere of radius r_0.

Let us consider now the second expression (45). To calculate $\zeta_A^{r_0}$ we use the same approach which we have used in the previous section. We have to take into account the uniform expansion for the modified Bessel function of second kind $K_\mu(\mu x)$ which has the form

$$K_\mu(\mu z)=\sqrt{\frac{\pi t}{2\mu}}e^{-\mu\eta(z)}\left\{1+\sum_{k=1}^{\infty}(-1)^k\frac{u_k(t)}{\mu^k}\right\}. \tag{46}$$

Different from the uniform expansion of the Bessel function of the first kind given by Eq. (7), the odd degrees of μ in the above formula have the opposite sign. This fact leads to the change of sign of the heat kernel coefficients with integer index, also with respect of the heat kernel coefficients which were considered in last section. Using this uniform expansion we arrive at the following formulas for the zeta function $\zeta_A^{r_0}$:

$$\zeta_A^{r_0}\left(s-\frac{1}{2}\right)=N^{r_0}(s)+\frac{m^{-2s}}{(4\pi)^{3/2}\Gamma(s-\frac{1}{2})}\sum_{k=-1}^{3}(-1)^k A_k(s,r_0), \tag{47}$$

where

$$N^{r_0}(s)=-\frac{\cos\pi s}{\pi R}\sum_{l=0}^{\infty}(2l+1)\mu\alpha\int_{\beta/\mu\alpha}^{\infty}dx\left\{x^2-\left(\frac{\beta}{\mu\alpha}\right)^2\right\}^{1/2-s}$$
$$\times\frac{\partial}{\partial x}\left\{\ln(K_\mu(\mu x))+\mu\eta(x)+\frac{1}{4}\ln(1+x^2)+\frac{1}{\mu}D_1(t)-\frac{1}{\mu^2}D_2(t)+\frac{1}{\mu^3}D_3(t)\right\}, \tag{48}$$

and the functions $A_k(s,r_0)$ are the same as in Eqs. (12)–(16), but now they depend on the radius r_0. Proceeding in the same way as it was done in the previous section, we obtain the following expression for the second part of zeta function $\zeta_A^{r_0}$:

$$\zeta_A^{r_0}\left(s-\frac{1}{2}\right)=-\frac{m}{16\pi^2\beta_0}\{B^{r_0}(\beta_0)\ln\beta_0^2+\Omega^{r_0}(\beta_0)\}+\frac{m^{-2s}}{(4\pi)^{3/2}}\left\{B_0^{r_0}m^4\frac{\Gamma(s-2)}{\Gamma(s-\frac{1}{2})}\right.$$
$$\left.+B_{1/2}^{r_0}m^3\frac{\Gamma(s-\frac{3}{2})}{\Gamma(s-\frac{1}{2})}+B_1^{r_0}m^2\frac{\Gamma(s-1)}{\Gamma(s-\frac{1}{2})}+B_{3/2}^{r_0}m+B_2^{r_0}\frac{\Gamma(s)}{\Gamma(s-\frac{1}{2})}\right\}, \tag{49}$$

where $\beta_0=mr_0$ and

$$B^{r_0}(\beta_0)=\tfrac{1}{2}r_0m^4B_0^{r_0}-r_0m^2B_1^{r_0}+r_0B_2^{r_0}=\tfrac{1}{2}\beta_0^4b_0^{r_0}-\beta_0^2b_1^{r_0}+b_2^{r_0}. \tag{50}$$

Contrary to the previous section, the heat kernel coefficients with integer number have changed sign and they are

$$b_0^{r_0}=B_0^{r_0}/r_0^3=-\frac{4\pi}{3\alpha},\quad b_1^{r_0}=r_0/B_1^{r_0}=-\frac{7}{3}\pi\alpha+\frac{4\pi}{\alpha}\left(\Delta-\frac{1}{12}\right), \tag{51}$$

$$b_2^{r_0}=B_2^{r_0}r_0=-\pi\alpha\left(\Delta-\frac{1}{12}+\frac{229}{2520}\alpha^2\right)+\frac{2\pi}{\alpha}\left(\Delta^2-\frac{1}{6}\Delta+\frac{7}{240}\right). \tag{52}$$

The heat kernel coefficients, according to Eq. (43), are the sum of B_n^R and $B_n^{r_0}$ and they are in agreement with general formulas. We have to take into account that normal vectors for spheres of radius R and r_0 have opposite directions and that the boundaries consist now of two spheres. It is easy to understand the division of the zeta function in two parts given by Eq. (43), and the opposite sign of the heat kernel coefficients B^R and B^{r_0} with integer indexes, by calculating B_0 and $B_{1/2}$. For the space between two spheres we have

$$B_0=\int_V dV=\frac{4\pi}{\alpha}\int_{r_0}^{R}r^2\,dr=\frac{4\pi}{3\alpha}R^3-\frac{4\pi}{3\alpha}r_0^3=B_0^R+B_0^{r_0}, \tag{53}$$

$$B_{1/2}=-\frac{\sqrt{\pi}}{2}\int_R dS-\frac{\sqrt{\pi}}{2}\int_{r_0}dS=-2\pi^{3/2}R^2-2\pi^{3/2}r_0^2=B_{1/2}^R+B_{1/2}^{r_0}. \tag{54}$$

Therefore, the full zeta function in this case has the following form:

$$\begin{aligned}\zeta_A\left(s-\frac{1}{2}\right)=&-\frac{m}{16\pi^2\beta_0}\{B^{r_0}(\beta_0)\ln\beta_0^2+\Omega^{r_0}(\beta_0)\}-\frac{m}{16\pi^2\beta}\{B^R(\beta)\ln\beta^2+\Omega^R(\beta)\}\\&+\frac{m^{-2s}}{(4\pi)^{3/2}}\left\{B_0m^4\frac{\Gamma(s-2)}{\Gamma(s-\frac{1}{2})}+B_{1/2}m^3\frac{\Gamma(s-\frac{3}{2})}{\Gamma(s-\frac{1}{2})}+B_1m^2\frac{\Gamma(s-1)}{\Gamma(s-\frac{1}{2})}\right.\\&\left.+B_{3/2}m+B_2\frac{\Gamma(s)}{\Gamma(s-\frac{1}{2})}\right\}.\end{aligned} \tag{55}$$

The close expression for Ω^{r_0} is given in the Appendix.

V. THE GROUND STATE ENERGY

In the framework of the zeta function approach the ground state energy is proportional to the zeta function of the Laplace operator and is given by Eq. (1). In order to analyze this energy, let us first of all consider the ground state energy for a pointlike global monopole. The full energy of the system consists of two parts, namely, the classical part due to the boundary and monopole background, and the quantum one due to loop corrections. The general expression for boundary contributions has been considered in Refs. 16 and 20 and it has the following form:

$$E_{cl}^R=p_RV_R+\sigma_RS_R+F_RR+\Lambda_R+\frac{h_R}{R}. \tag{56}$$

Here $V_R=4\pi R^3/3\alpha$ and $S_R=4\pi R^2$ are the volume and area of the spherical surface. Parameters p_R and σ_R have simple physical means as pressure and surface tension. The constant contribution described by parameter Λ_R may be explained by the cosmological constant.[30] The other two parameters, F_R, and h_R, do not have special names.

The energy in the monopole background can be obtained by integrating the (t,t) component of the energy-momentum tensor:[7]

$$E_{cl}^{gm}=-\int_0^R \frac{\eta^2\alpha^2}{r^2}dV=-4\pi\eta^2\alpha R. \tag{57}$$

The quantum correction, using Eq. (34), is

$$E_q^R=\frac{1}{2}M^{2s}\zeta_A^R\left(s-\frac{1}{2}\right)_{s\to 0}=-\frac{m}{32\pi^2\beta}\{B^R(\beta)\ln\beta^2+\Omega^R(\beta)\}+\left(\frac{M}{m}\right)^{2s}\frac{1}{16\pi^{3/2}}$$
$$\times\left\{B_0^R m^4\frac{\Gamma(s-2)}{\Gamma(s-\frac{1}{2})}-\frac{2}{3}B_{1/2}^R m^3+B_1^R m^2\frac{\Gamma(s-1)}{\Gamma(s-\frac{1}{2})}+B_{3/2}^R m+B_2^R\frac{\Gamma(s)}{\Gamma(s-\frac{1}{2})}\right\}_{s\to 0}, \tag{58}$$

where the heat kernel coefficients B_k^R and B^R are given by Eqs. (26) and (35), respectively.

In order to obtain a well defined result for the full energy, we have to renormalize the parameters of the classical part (56) according to the rules

$$p_R\to p_R-\left(\frac{M}{m}\right)^{2s}\frac{3m^4b_0^R}{64\pi^{5/2}}\frac{\Gamma(s-2)}{\Gamma(s-\frac{1}{2})},\quad \sigma_R\to\sigma_R+\frac{m^3b_{1/2}^R}{96\pi^{5/2}},$$

$$F_R\to F_R-\left(\frac{M}{m}\right)^{2s}\frac{m^2b_1^R}{16\pi^{3/2}}\frac{\Gamma(s-1)}{\Gamma(s-\frac{1}{2})},\quad \Lambda_R\to\Lambda_R-\frac{mb_{3/2}^B}{16\pi^{3/2}}, \tag{59}$$

$$h_R\to h_R-\left(\frac{M}{m}\right)^{2s}\frac{b_2^R}{16\pi^{3/2}}\frac{\Gamma(s)}{\Gamma(s-\frac{1}{2})}.$$

After this procedure we obtain the following expression for ground state energy:

$$E_q^R=-\frac{m}{32\pi^2\beta}\{B^R(\beta)\ln\beta^2+\Omega^R(\beta)\}. \tag{60}$$

A similar general structure for the ground state energy in the massless case has been obtained by Blau, Visser and Wipf[16] using dimensional considerations only. For the massive case we find the same structure. If we used another scale for mass as, for example, like $M\to M/\chi$, in renormalization rules (59), the above logarithmic term $\ln\beta^2$ would be replaced by $\ln(\chi\beta)^2$.

The expression (60) is, in fact, the Casimir energy for the internal part of the spherical bag in the global monopole background. For the small radius of the bag, this energy tends to infinity as $\ln R/R$:

$$E_q^R\sim-\frac{m}{16\pi^2\beta}b_2^R\ln\beta, \tag{61}$$

and for the large radius of the bag $R\to\infty$ it tends to zero:

$$E_q^R\sim-\frac{mb_{5/2}^R}{16\pi^{3/2}\beta^2}. \tag{62}$$

Using these two limits we may analyze qualitatively the dependence of the Casimir energy of the internal part of the bag on its radius. The behavior of energy is defined by two heat kernel coefficients b_2^R and $b_{5/2}^R$. Both of these coefficients are the functions of nonminimal coupling parameter ξ and metric coefficient α. In general, three kinds of different behaviors exist, which are plotted in Fig. 1. It is possible to analyze the energy in the general case, however we shall discuss only the cases $\xi=\frac{1}{6}, \frac{1}{8}, 0$.

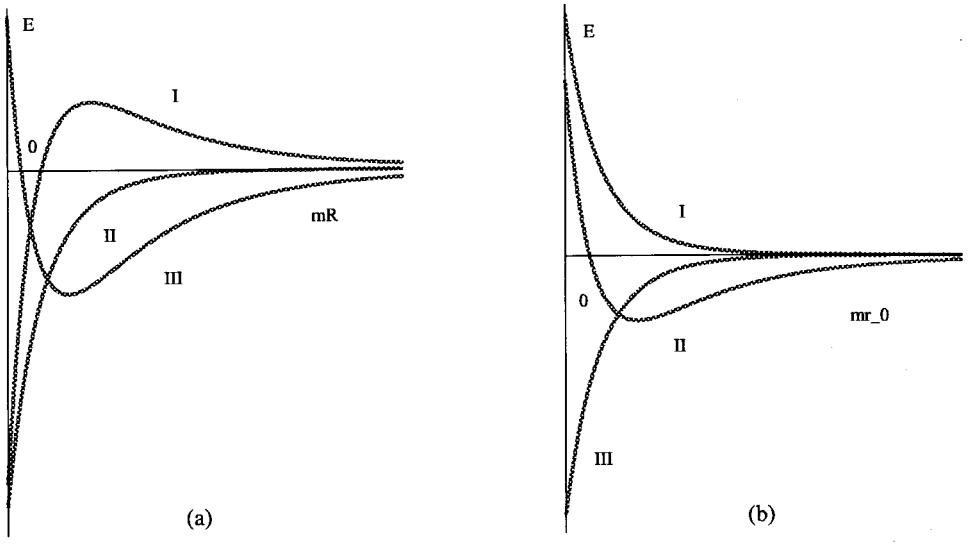

FIG. 1. Three types of dependence of the ground state energy for the field (a) inside the sphere of radius R and (b) outside the sphere of radius r_0.

(1) $\xi=\frac{1}{6}$. In this case the behavior may be of kinds I and II, namely, the first kind for $\alpha<1.24$ and the second one for $\alpha>1.24$. The coefficient b_2^R does not change its sign, but $b_{5/2}^R$ does for $\alpha=1.24$.
(2) $\xi=\frac{1}{8}$. The behavior of energy may be of kinds I, II and III. The first kind is for $\alpha<1.045$; the second kind is in the region $1.045<\alpha<1.17$ and the third one is for $\alpha>1.17$. At the point $\alpha=1.045$ the coefficient $b_{5/2}^R$ changes the sign, but b_2^R does not up to $\alpha=1.17$ where it changes the sign, too.
(3) $\xi=0$. This case is similar to the previous one: it is of the first kind for $\alpha<1.016$, of the second for region $1.016<\alpha<1.054$, and of the third for $\alpha>1.054$.

For $\alpha\leqslant 1$ and $\xi=\frac{1}{6},\frac{1}{8},0$, only the first kind of behavior is possible. In the case when $\alpha=1$, the energy was calculated numerically in Ref. 20 and our results are in agreement with that calculation. In this case $b_2^R=-\pi^2 16/315$, $b_{5/2}^R=-\pi^{3/2}/120$ and the dependence may be of the first kind only.

In the limit $R\to\infty$, the quantum correction tends to zero and the full energy contains only the classical part which is due to boundary and background.

Let us now proceed in our model. We surround the monopole origin by spheres of radii r_0 and $R>r_0$ and consider the bosonic matter field in the space between them. We do not take into account the interior of the sphere of radius r_0 because there is nothing inside it. We impose the Dirichlet boundary condition on this sphere which means that there is no flux into this region. The full energy in this case consists of five parts,

$$E=E_{cl}^R+E_{cl}^{r_0}+E_{cl}^{gm}+E_q^R+E_q^{r_0}, \tag{63}$$

where

$$E_{cl}^R=p_R V_R+\sigma_R S_R+F_R R+\Lambda_R+\frac{h_R}{R}, \tag{64}$$

$$E_{cl}^{r_0}=p_{r_0} V_{r_0}+\sigma_{r_0} S_{r_0}+F_{r_0} r_0+\Lambda_{r_0}+\frac{h_{r_0}}{r_0}, \tag{65}$$

$$E_{cl}^{gm}=-4\pi\eta^2\alpha(R-r_0) \tag{66}$$

are the classical parts of energy due to the boundaries and global monopole background, and

$$E_q^R=\frac{1}{2}M^{2s}\zeta_A^R\left(s-\frac{1}{2}\right)_{s\to 0}=-\frac{m}{32\pi^2\beta}\{B^R(\beta)\ln\beta^2+\Omega^R(\beta)\}+\left(\frac{M}{m}\right)^{2s}\frac{1}{16\pi^{3/2}}$$
$$\times\left\{B_0^R m^4\frac{\Gamma(s-2)}{\Gamma(s-\frac{1}{2})}-\frac{2}{3}B_{1/2}^R m^3+B_1^R m^2\frac{\Gamma(s-1)}{\Gamma(s-\frac{1}{2})}+B_{3/2}^R m+B_2^R\frac{\Gamma(s)}{\Gamma(s-\frac{1}{2})}\right\}_{s\to 0}, \tag{67}$$

$$E_q^{r_0}=\frac{1}{2}M^{2s}\zeta_A^{r_0}\left(s-\frac{1}{2}\right)_{s\to 0}=-\frac{m}{32\pi^2\beta_0}\{B^{r_0}(\beta_0)\ln\beta_0^2+\Omega^{r_0}(\beta_0)\}+\left(\frac{M}{m}\right)^{2s}\frac{1}{16\pi^{3/2}}$$
$$\times\left\{B_0^{r_0} m^4\frac{\Gamma(s-2)}{\Gamma(s-\frac{1}{2})}-\frac{2}{3}B_{1/2}^{r_0} m^3+B_1^{r_0} m^2\frac{\Gamma(s-1)}{\Gamma(s-\frac{1}{2})}+B_{3/2}^{r_0} m+B_2^{r_0}\frac{\Gamma(s)}{\Gamma(s-\frac{1}{2})}\right\}_{s\to 0} \tag{68}$$

are the quantum corrections. Adopting the same renormalization prescription for parameters in E_{cl}^R and $E_{cl}^{r_0}$ as in Eq. (59), one arrives at the following expressions for renormalized quantum corrections:

$$E_q^R=-\frac{m}{32\pi^2\beta}\{B^R(\beta)\ln\beta^2+\Omega^R(\beta)\} \tag{69}$$

and

$$E_q^{r_0}=-\frac{m}{32\pi^2\beta_0}\{B^{r_0}(\beta_0)\ln\beta_0^2+\Omega^{r_0}(\beta_0)\}. \tag{70}$$

The sum of these terms gives the Casimir energy of the field in space between the two spheres in the global monopole background. The first part we have already discussed. We may consider the second part in the same way. For the small radius of the sphere, $r_0\to 0$, it tends to infinity,

$$E_q^{r_0}\sim-\frac{m}{16\pi^2\beta_0}b_2^{r_0}\ln\beta_0, \tag{71}$$

and for the large radius of the sphere $r_0\to\infty$ it tends to zero,

$$E_q^{r_0}\sim-\frac{m b_{5/2}^{r_0}}{16\pi^{3/2}\beta_0^2}. \tag{72}$$

Due to the fact that $b_2^{r_0}=-b_2^R$ and $b_{5/2}^{r_0}=b_{5/2}^R$, the energy $E_q^{r_0}$ has different behavior at small radius r_0. The sum of b_n^R and $b_n^{r_0}$ constitutes the whole heat kernel coefficients for this space. For this reason three kinds of dependence of $E_q^{r_0}$ on the radius are possible, and these are displayed in Fig. 1. The same results are available for $E_q^{r_0}$ as it was obtained above for E_q^R for $\xi=\frac{1}{6},\frac{1}{8},0$; we have to change only the left plot to the right one in Fig. 1. The case $b_2=0$ has to be analyzed numerically; however, this discussion is out of the scope of the present article.

For any nonzero radius of the inner cavity r_0 we have a finite result. In this case the Casimir energy may be positive or negative, depending on the parameters of the theory. The main problem now is with the limit $r_0\to 0$, which has to reproduce the topological defect itself. The energy $E_q^{r_0}$ presents divergence in this limit as $\ln r_0/r_0$. This is in contradiction with earlier considerations about the pointlike monopole. If we set the radius $r_0=0$ at the beginning, as it was done in Sec.

III, we obtain zero ground state energy for $R\to\infty$. From the point of view of heat kernel coefficients we have already thrown away the divergent part of B_2 using *partie finite* of integral (33). In the framework of our model this part is divergent at the origin and the additional renormalization is needed.

In order to do the renormalization we may use the last term h_{r_0}/r_0 in the classical part of the energy which is due to the boundary (65). We define a parameter M_0 with dimension of mass by the relation $h_{r_0}=GM_0^2$, where G is gravitational constant. With this definition, the divergent contribution for small radius r_0 may be canceled by the renormalization rule

$$M_0^2\to M_0^2+\frac{m_{\mathrm{Pl}}^2}{32\pi^2}\{2B^{r_0}\ln(mr_0)+\Omega^{r_0}(mr_0)\}, \tag{73}$$

where m_{Pl}^2 is the Plank mass, and then ground state energy is zero.

VI. CONCLUSION

In this article we have considered the ground state energy of a quantum scalar field in the background of global monopole space–time, with a line element given by Eq. (2), in the framework of zeta function approach. In order to point out the role of singularity, we investigated two cases: In the first, we calculated the ground state energy for a pointlike global monopole. We surrounded the origin by a sphere of radius R and obtained the ground state energy of the field inside. It has the form (60) and tends to zero in the limit $R\to\infty$ and to infinity when $R\to 0$. The behavior of this Casimir energy in these cases is determined by the heat kernel coefficients b_2^R and $b_{5/2}^R$. The qualitative plots of the ground state energy for different values of the parameters $\xi=\frac{1}{6},\ \frac{1}{8},0$ and α are given in Fig. 1(a). For these values of ξ and $\alpha\leqslant 1$ it is of the first kind only.

In order to avoid the problem with singularity at origin, we investigated as a second case, in Sec. IV, the following model: We surrounded the origin by a sphere of radius $r_0<R$ and considered the scalar field in the region between these two spheres using the Dirichlet boundary condition on the wave function associated with the massive scalar field on these surfaces. This boundary condition guarantees that there is no flux of particles through the spherical surfaces. The Casimir energy in this case consists of two parts given in Eqs. (69) and (70). The first part is the same as for the pointlike monopole case and the second one is due to the inner sphere of radius r_0 around the origin. The structure of the second part of the ground state energy (70) is similar: there is a logarithmic divergence at origin which tends to zero for infinite radius. The sign of energy for a small distance is opposite. For this reason we have the three kinds of dependence of energy displayed in Fig. 1(b).

In the limit $R\to\infty$ and finite $r_0\neq 0$ only one contribution to the ground state energy survives (69). In the limit $r_0\to 0$, it is divergent and additional renormalization is needed which is given by Eq. (73). After this renormalization, the ground state energy of a global monopole will be zero. This is in agreement with the ground state energy of a pointlike global monopole.

If one fills up this cavity around the origin with matter, the situation becomes different. We may expect the same kind of divergence for additional energy from the interior of the monopole but with opposite sign. We have already seen that the internal and external contributions have opposite signs: $b_2^R=-b_2^{r_0}$. For this reason we may expect that this kind of divergence will cancel. However, we cannot say anything analytically about the divergence of $\Omega(mr_0)/r_0$. In flat space-time[20] it cancels, too, because the ground state energy is zero for zero radius of the bag. The same cancellation takes place in the case of a thick cosmic string background considered in Ref. 13. All of these aspects will be discussed in a separate paper.

NK would like to thank Dr. M. Bordag for many helpful discussions. NK is also grateful to Departamento de Física, Universidade Federal da Paraiba (Brazil), where this work was done, for hospitality. His work was supported in part by CAPES and in part by the Russian Found for Basic

Research, Grant No. 99-02-17941. ERBM and VBB also would like to thank the Conselho Nacional de Desenvolvimento Cientifico e Tecnológico (CNPq) for partial financial support.

APPENDIX: FORMULAS FOR ZETA-FUNCTION

In this appendix we want to give a brief explanation about the most important results we found. First of all, we represent the expressions for A_k as a series in powers of $\beta=mr_0$, regarding for a moment $b,\beta<1$ and $\Delta>-\frac{1}{4}$ in order to have convergence of series. They are

$$A_{-1}(s,R)=\frac{m}{\beta}\beta^{2s}\frac{4\pi}{\alpha}\sum_{n=0}^{\infty}\frac{(-1)^n}{n!}\beta^{2n}\frac{\Gamma(s-1+n)}{s+n-\frac{1}{2}}\sum_{l=0}^{\infty}\frac{\nu_l}{(\nu_l^2+\Delta)^{s+n-1}}, \tag{A1}$$

$$A_0(s,R)=-\frac{m}{\beta}\beta^{2s}4\pi^{3/2}\sum_{n=0}^{\infty}\frac{(-1)^n}{n!}b^{2n}\Gamma\left(s+n-\frac{1}{2}\right)\zeta_H\left(2s+2n-2,\frac{1}{2}\right), \tag{A2}$$

$$A_k(s,R)=-\frac{m}{\beta}\beta^{2s}16\pi^{3/2}\alpha^k\sum_{n=0}^{\infty}\frac{(-1)^n}{n!}b^{2n}\sum_{a=0}^{k}x_{k,a}\frac{\Gamma(s+k/2+a+n-\frac{1}{2})}{\Gamma(k/2+a)}\times\sum_{l=0}^{\infty}\frac{(\nu_l^2+\Delta)^a}{\nu_l^{2s+k+2a+2n-2}}. \tag{A3}$$

In the above formulas we have used the following notations: $\nu_l=l+\frac{1}{2}$, $\Delta=2(1-\alpha^2)(\xi-\frac{1}{8})$ and $b^2=\beta^2+\Delta$. As we can see, only the first three terms in the expression for A_{-1}, with $n=0,1,2$, two terms in A_0, A_1, A_2, and one term in A_3 are divergent in the limit $s\to 0$. Extracting these terms we may set $s=0$ in the remaining series and we get the following result:

$$\begin{aligned}\zeta_A^R\left(s-\frac{1}{2}\right)&=N^R(s,\beta)+\frac{m^{-2s}}{(4\pi)^{3/2}\Gamma(s-\frac{1}{2})}\sum_{k=-1}^{3}A_k(s,R)\\&=\frac{m^{-2s}}{(4\pi)^{3/2}\Gamma\left(s-\frac{1}{2}\right)}\beta^{2s}\left\{m^4B_0^R\Gamma(s-2)+m^3B_{1/2}^R\Gamma\left(s-\frac{3}{2}\right)+m^2B_1^R\Gamma(s-1)\right.\\&\quad\left.+mB_{3/2}^R\Gamma\left(s-\frac{1}{2}\right)+B_2^R\Gamma(s)\right\}-\frac{1}{16\pi^2R}\left\{\sum_{k=-1}^{3}\omega_k(\beta)+\omega_f^R(\beta)\right\},\end{aligned} \tag{A4}$$

where

$$\begin{aligned}\omega_f^R(\beta)&=32\pi\sum_{l=0}^{\infty}\nu_l\sqrt{\nu_l^2+\Delta}\int_{\beta/\sqrt{\nu_l^2+\Delta}}^{\infty}dx\sqrt{x^2-\frac{\beta^2}{\nu_l^2+\Delta}}\\&\quad\times\frac{\partial}{\partial x}\left\{\ln I_\mu(\mu x)-\mu\eta(x)+\frac{1}{4}\ln(1+x^2)-\frac{1}{\mu}D_1-\frac{1}{\mu^2}D_2-\frac{1}{\mu^3}D_3\right\},\end{aligned} \tag{A5}$$

$$\begin{aligned}\omega_{-1}(\beta)&=-\frac{4\pi}{\alpha}\left\{\left[-\frac{7}{2}\zeta'(-3)-\frac{7}{160}+\frac{1}{240}\ln 2+\Delta\left(-2\zeta'(-1)+\frac{1}{6}-\frac{1}{6}\ln 2\right)\right]\right.\\&\quad+\beta^2\left[2\zeta'(-1)+\frac{1}{4}+\frac{1}{6}\ln 2+\Delta(2\gamma+4\ln 2-3)\right]+\beta^4\left[\frac{1}{3}\gamma+\frac{2}{3}\ln 2-\frac{13}{36}\right]\\&\quad\left.-\sum_{n=3}^{\infty}\frac{(-1)^n}{n!}\Gamma(n-1)\Delta^n\zeta_H\left(2n-3,\frac{1}{2}\right)-2\beta^2\sum_{n=2}^{\infty}\frac{(-1)^n}{n!}\Delta^n\Gamma(n)\zeta(2n-1)\right\}\end{aligned}$$

$$+\frac{1}{3}\beta^4 Y_{1,1}(\Delta)+\sum_{n=3}^{\infty}\frac{(-1)^n}{n!}\frac{\Gamma(n-1)}{n-\frac{1}{2}}\beta^{2n}\sum_{l=0}^{\infty}\frac{\nu_l}{(\nu_l^2+\Delta)^{n-1}}\Bigg\}, \tag{A6}$$

$$\omega_0(\beta)=-2\pi^2\sum_{n=2}^{\infty}\frac{(-1)^n}{n!}\frac{\Gamma(n-\frac{1}{2})}{\Gamma(\frac{3}{2})}b^{2n}\zeta_H\left(2n-2,\frac{1}{2}\right), \tag{A7}$$

$$\omega_1(\beta)=-2\pi\alpha\Bigg\{\left[-\zeta'(-1)-\frac{5}{36}-\frac{1}{12}\ln 2+\Delta\left(-\gamma-2\ln 2+\frac{5}{3}\right)\right]+\beta^2\left[\frac{7}{3}\gamma+\frac{1}{2}+\frac{14}{3}\ln 2\right]$$
$$+\sum_{n=2}^{\infty}\frac{(-1)^n}{n!}\left(\Gamma(n)-\frac{10}{3}\Gamma(n+1)\right)b^{2n}\zeta_H\left(2n-1,\frac{1}{2}\right)-\frac{10}{3}\Delta Y_{1,1}(b)\Bigg\}, \tag{A8}$$

$$\omega_2(\beta)=-2\pi^2\alpha^2\Bigg\{\frac{3}{16}\pi^2\Delta+\frac{5}{32}\pi^2\Delta^2+\frac{1}{2}Y_{1/2,0}(b)-\frac{3}{2}Y_{3/2,0}(b)+\frac{15}{16}Y_{5/2,0}(b)$$
$$+\Delta\left[-\frac{3}{2}Y_{3/2,2}(b)+\frac{15}{8}Y_{5/2,2}(b)\right]+\Delta^2\frac{15}{16}Y_{5/2,4}(b)\Bigg\}, \tag{A9}$$

$$\omega_3(\beta)=-2\pi\alpha^3\Bigg\{\frac{293}{1512}-\frac{22}{2520}\gamma-\frac{229}{1260}\ln 2+\left[\frac{25}{24}X_{1,1}(b)-\frac{177}{20}X_{2,1}(b)\right.$$
$$\left.+\frac{221}{15}X_{3,1}(b)-\frac{442}{63}X_{4,1}(b)\right]+\Delta\left[-\frac{177}{20}Y_{2,3}(b)+\frac{442}{15}Y_{3,3}(b)-\frac{442}{21}Y_{4,3}(b)\right]$$
$$+\Delta^2\left[\frac{221}{15}Y_{3,5}(b)-\frac{442}{21}Y_{4,5}(b)\right]-\Delta^3\frac{442}{63}Y_{4,7}(b)\Bigg\}, \tag{A10}$$

$$X_{p,q}(b)=\sum_{n=0}^{\infty}\frac{(-1)^n}{n!}\frac{\Gamma(n+p)}{\Gamma(p)}b^{2n}\zeta_H\left(2n+q,\frac{1}{2}\right), \tag{A11}$$

$$Y_{p,q}(b)=\sum_{n=1}^{\infty}\frac{(-1)^n}{n!}\frac{\Gamma(n+p)}{\Gamma(p)}b^{2n}\zeta_H\left(2n+q,\frac{1}{2}\right). \tag{A12}$$

Each of the above series may be analytically continued in terms of digamma function Ψ for arbitrary values of b and Δ. For example,

$$\sum_{n=3}^{\infty}\frac{(-1)^n}{n!}\frac{\Gamma(n-1)}{n-\frac{1}{2}}\beta^{2n}\sum_{l=0}^{\infty}\frac{\nu_l}{(\nu_l^2+\Delta)^{n-1}}=-2\beta^4\int_0^1 dx x(1-x)^2$$
$$\times\left\{\Psi\left[\frac{1}{2}-i\sqrt{\Delta+\beta^2x^2}\right]+\Psi\left[\frac{1}{2}+i\sqrt{\Delta+\beta^2x^2}\right]-\Psi\left[\frac{1}{2}-i\sqrt{\Delta}\right]-\Psi\left[\frac{1}{2}+i\sqrt{\Delta}\right]\right\}, \tag{A13}$$

$$\sum_{n=3}^{\infty}\frac{(-1)^n}{n!}\Gamma(n-1)\Delta^n\zeta_H\left(2n-3,\frac{1}{2}\right)$$
$$=-\Delta^2\int_0^1 dx x(1-x^2)\left\{\Psi\left[\frac{1}{2}-i\sqrt{\Delta}\right]+\Psi\left[\frac{1}{2}+i\sqrt{\Delta}\right]-2\Psi\left[\frac{1}{2}\right]\right\}. \tag{A14}$$

This kind of representation is suitable for numerical calculations.

Adding and subtracting the asymptotic expansion of zeta function (25) we obtain the following formula:

$$\zeta_A^R\left(s-\frac{1}{2}\right)=-\frac{m}{16\pi^2\beta}\{B^R(\beta)\ln\beta^2+\Omega^B(\beta)\}+\frac{m^{-2s}}{(4\pi)^{3/2}}\left\{B_0^R m^4\frac{\Gamma(s-2)}{\Gamma(s-\frac{1}{2})}\right.$$
$$\left.+B_{1/2}^R m^3\frac{\Gamma(s-\frac{3}{2})}{\Gamma(s-\frac{1}{2})}+B_1^R m^2\frac{\Gamma(s-1)}{\Gamma(s-\frac{1}{2})}+B_{3/2}^R m+B_2^R\frac{\Gamma(s)}{\Gamma(s-\frac{1}{2})}\right\},\qquad\text{(A15)}$$

where $\Omega^B(\beta)=\Sigma_{k=-1}^3\omega_k(\beta)+\omega_f^R(\beta)$. It is easy to see that the function $\Omega^B(\beta)$ tends to a constant which may be calculated using the above formulas. Indeed, in the limit $\beta\to\infty$ we have to obtain asymptotic expansion of zeta function. Because one has already extracted the first five terms, the next will be $B_{5/2}$. For this reason we get the following behavior for great β: $\Omega^B(\beta)\sim -B^R\ln\beta^2+\sqrt{\pi}b_{5/2}^R/\beta+\cdots$. The coefficient $b_{5/2}^R$ may be found in the same way and it has the following form:

$$b_{5/2}^R=\frac{R}{m}B_{5/2}^R=\pi^{3/2}\{\tfrac{1}{16}\alpha^4+\tfrac{1}{2}(\Delta-\tfrac{1}{12})\alpha^2-(\Delta^2-\tfrac{1}{6}\Delta+\tfrac{7}{240})\}.\qquad\text{(A16)}$$

It is not difficult to obtain the formulas for zeta function $\zeta_A^{r_0}$ from the above expressions. The index k in A_k corresponds to a term which is proportional to μ^{-k} in uniform expansion of the Bessel function in Eq. (8). The uniform expansion of the modified Bessel function of the second kind given in Eq. (46) may be obtained from uniform expansion of the modified Bessel function of the first kind in (7) by replacing the index μ by $-\mu$. For this reason, in order to obtain the formulas for the zeta function $\zeta_A^{r_0}$, we must do the replacements $R\to r_0$, $\beta\to\beta_0$ and $A_k(s,R)\to(-1)^kA_k(s,r_0)$ in the above formulas for zeta function ζ_A^R. As the odd degrees of μ give contributions to heat kernel coefficients with integer index, they will change the sign. Therefore we have the following formula for zeta function $\zeta_A^{r_0}$:

$$\zeta_A^{r_0}\left(s-\frac{1}{2}\right)=-\frac{m}{16\pi^2\beta_0}\{B^{r_0}(\beta_0)\ln\beta_0^2+\Omega^{r_0}(\beta_0)\}+\frac{m^{-2s}}{(4\pi)^{3/2}}\left\{B_0^{r_0}m^4\frac{\Gamma(s-2)}{\Gamma(s-\frac{1}{2})}\right.$$
$$\left.+B_{1/2}^{r_0}m^3\frac{\Gamma(s-\frac{3}{2})}{\Gamma(s-\frac{1}{2})}+B_1^{r_0}m^2\frac{\Gamma(s-1)}{\Gamma(s-\frac{1}{2})}+B_{3/2}^{r_0}m+B_2^{r_0}\frac{\Gamma(s)}{\Gamma(s-\frac{1}{2})}\right\},\qquad\text{(A17)}$$

where $\Omega^{r_0}(\beta_0)=\Sigma_{k=-1}^3(-1)^k\omega_k(\beta_0)+\omega_f^{r_0}(\beta_0)$ and

$$\omega_f^R(\beta)=32\pi\sum_{l=0}^{\infty}\nu_l\sqrt{\nu_l^2+\Delta}\int_{\beta/\sqrt{\nu_l^2+\Delta}}^{\infty}dx\sqrt{x^2-\frac{\beta^2}{\nu_l^2+\Delta}}$$
$$\times\frac{\partial}{\partial x}\left\{\ln K_\mu(\mu x)+\mu\eta(x)+\frac{1}{4}\ln(1+x^2)+\frac{1}{\mu}D_1-\frac{1}{\mu^2}D_2+\frac{1}{\mu^3}D_3\right\}.\qquad\text{(A18)}$$

Maximal subalgebras of vector fields for equivariant quantizations

F. Boniver[a] and P. Mathonet[b]
Institute of Mathematics, B37, University of Liège, B-4000 Sart Tilman, Belgium

(Received 1 March 2000; accepted for publication 20 October 2000)

The elaboration of new quantization methods has recently developed the interest in the study of subalgebras of the Lie algebra of polynomial vector fields over a Euclidean space. In this framework, these subalgebras define maximal equivariance conditions that one can impose on a linear bijection between observables that are polynomial in the momenta and differential operators. Here, we determine which finite dimensional graded Lie subalgebras are maximal. In order to characterize these, we make use of results of Guillemin, Singer, and Sternberg and Kobayashi and Nagano. © *2001 American Institute of Physics.* [DOI: 10.1063/1.1332782]

I. INTRODUCTION

Our interest in the present study comes from recent works about new equivariant quantizations (Refs. 1 and 2).

One can define quantization maps as linear bijections $\mathcal{Q}$ from the space $\mathrm{Pol}(T^*M)$ of functions on the cotangent bundle of a smooth manifold M, that are polynomial on the fibre, to a space $D_\lambda(M)$ of differential operators acting on tensor densities of weight λ over M.

It is known that a quantization map $\mathcal{Q}$ cannot be equivariant with respect to all diffeomorphisms of M. From the infinitesimal point of view, this means that such a map does not commute with the action on these spaces of the Lie algebra $\mathrm{Vect}(M)$ of vector fields over M. In other words, differential operators and polynomials are inequivalent modules of $\mathrm{Vect}(M)$.

However, when M is endowed with an additional structure, some particular subalgebras of $\mathrm{Vect}(M)$ naturally deserve consideration, because they are made up of infinitesimal transformations preserving the structure.

The authors of Refs. 1 and 2 considered the case of infinitesimal projective or conformal transformations of M. In suitable charts, these can be realized in polynomial vector fields over a Euclidean space. For instance, if M is endowed with a projective structure (i.e., M is locally identified with a real projective space, say of dimension n) then in appropriate charts, the Lie algebra of infinitesimal projective transformations—isomorphic to $\mathrm{sl}(n+1,\mathbb{R})$—is generated by the vector fields,

$$\frac{d}{dx^j}, x^j\frac{d}{dx^k}, x^j\sum_{l=1}^{n} x^l\frac{d}{dx^l}, \quad \forall j,k\leqslant n. \tag{1}$$

In this setting, those conformal and projective subalgebras share the property of being maximal in the algebra of polynomial vector fields: they are not contained in any larger proper subalgebra. The reader may refer to Refs. 2 and 3 for proofs.

Now, it was proved in Refs. 1 and 2 that one could construct a quantization map equivariant with respect to those subalgebras. This quantization is unique up to normalization.

In this framework, our concern in the present paper is to determine all finite dimensional graded subalgebras of polynomial vector fields over a given Euclidean space that are maximal.

[a]Electronic mail: f.boniver@ulg.ac.be
[b]Electronic mail: p.mathonet@ulg.ac.be

Independently of quantization purposes, other maximality conditions have also been studied.

In Ref. 4, Kantor classified irreducible transitively differential groups. This notion gives rise, from the Lie algebraic point of view, to the class of finite dimensional graded Lie subalgebras of polynomial vector fields containing all constant vector fields. The author then seeks for irreducible (see Ref. 4, p. 1405 or below) subalgebras being maximal in this class.

Another more recent study is that of Post (Ref. 5). In this paper, a stronger grading requirement is imposed in order to define a class of finite dimensional Lie algebras containing all constant vector fields. All maximal subalgebras of this class are then identified.

We point out two differences between the maximality conditions examined here and in these studies.

On the one hand, we impose fewer conditions on the subalgebras we consider, keeping only the requirements for a subalgebra to be graded and finite dimensional. On the other hand, the maximality property is not investigated inside a particular class of subalgebras, but in the general class of all subalgebras of polynomial vector fields.

Before giving our main result and a brief description of the tools we shall use, let us fix some notations.

Throughout this note, we assume that E is an n-dimensional vector space over $\mathbb{K}$, which is taken to be $\mathbb{R}$ or $\mathbb{C}$. We shall deal with polynomial vector fields over E.

We denote by $\mathrm{Vect}_*(E)$ the space of these vector fields, i.e., the space of polynomial maps from E to E. It is worth noticing that the vector fields considered when E is complex are thus holomorphic. Let $\{e_j, j=1,...,n\}$ be a basis of E. Assume that $X, Y \in \mathrm{Vect}_*(E)$ are written $X=\Sigma_{j=1}^n X^j e_j$ and $Y=\Sigma_{j=1}^n Y^j e_j$. We denote as usual by $[X, Y]$ the Lie bracket

$$\sum_{j,k} X^j \partial_j Y^k e_k - Y^j \partial_j X^k e_k,$$

where ∂_j represents the derivation d/dx^j along the jth axis. For the sake of convenience, we shall also use this notation to designate the jth vector of a basis of E. We denote by $\mathrm{ad}(X)$ the map $Y \mapsto [X,Y]$.

We name Euler vector field the identity transformation of E. In a basis $\{\partial_j\}$, it reads

$$\mathcal{E}(x)=\sum x^j \partial_j .$$

It defines a natural grading on $\mathrm{Vect}_*(E)$,

$$\mathrm{Vect}_*(E)=\bigoplus_{p \geqslant -1} \mathrm{Vect}_p(E),$$

where $\mathrm{Vect}_p(E)$ denotes the space of eigenvectors of $\mathrm{ad}(\mathcal{E})$ associated with the eigenvalue p, i.e., vector fields with homogeneous coefficients of degree $p+1$.

We are interested in these graded subalgebras L,

$$L=\bigoplus_{-1 \leqslant p \leqslant r} L_p \quad \text{with} \quad L_p=\mathrm{Vect}_p(E) \cap L,$$

which are maximal in $\mathrm{Vect}_*(E)$. As mentioned above, the notion of maximality has been used in various senses. Therefore, it is worth emphasizing the following definition.

Definition 1: A subalgebra L of $\mathrm{Vect}_*(E)$ is maximal if

$$L \subset L' \Rightarrow L'=L \quad \text{or} \quad L'=\mathrm{Vect}_*(E),$$

whenever L' is a subalgebra of $\mathrm{Vect}_*(E)$.

II. MAIN RESULT

Definition 2: (See, for instance, Ref. 6, p. 682.) A graded subalgebra $L=L_{-1}\oplus\cdots\oplus L_k$ of $\mathrm{Vect}_*(E)$ is said to be irreducible if the representation $(L_{-1},\mathrm{ad}_{|L_0})$ is irreducible.

Theorem 1: *Let $L=L_{-1}\oplus\cdots\oplus L_k$ be a graded subalgebra of $\mathrm{Vect}_*(E)$. Then L is maximal if and only if*

(1) $L_{-1}=\mathrm{Vect}_{-1}(E)$;

(2) L is irreducible;

(3) $L_1\neq 0$;

(4) when $\mathbb{K}=\mathbb{R}$, the representation $(L_{-1},\mathrm{ad}_{|L_0})$ admits no complex structure.

The text below is organized as follows. In Sec. III, we prove the necessity of the first three conditions above. Then, in Sec. IV, we consider polynomial vector fields from a slightly modified point of view, in order to prove, in Sec. V, the fourth condition given above. We expose in Sec. VI how the graded maximal subalgebras relate to the irreducible filtered Lie algebras of finite type, which were classified in Ref. 7. Using the classification of all irreducible infinite dimensional subalgebras of polynomial vector fields (see, for instance, Refs. 8, 9, 10, 6, and references therein), we show in Sec. VII that all these algebras give rise to a canonical graded maximal subalgebra of polynomial vector fields.

III. CONSTANT VECTOR FIELDS AND IRREDUCIBILITY

Lemma 1: Let L be a maximal subalgebra of $\mathrm{Vect}_*(E)$. Then $\mathcal{E}\in L$ if and only if L is graded.

Proof: The sufficiency of the condition follows from the fact that

$$\mathbb{K}\mathcal{E}+L$$

is a Lie subalgebra when L is graded. In order to check the necessity of the condition, notice that

$$\mathrm{ad}(\mathcal{E})^k L\subset L,\quad \forall k\in\mathbb{N},$$

gives a Vandermonde system allowing to compute the homogeneous components of a vector field $X\in L$. □

This proof is similar to the proof by Koecher (see Ref. 11, p. 354) that any ideal of $\mathrm{Vect}_*(E)$ is graded. We therefore state the following remark:

Remark 1: If L is a subalgebra of $\mathrm{Vect}_*(E)$ that contains $\mathcal{E}$, then any ideal of L is graded.

Lemma 2: Let L_{-1}, L_0, and L_+ be vector subspaces of $\mathrm{Vect}_{-1}(E)$, $\mathrm{Vect}_0(E)$, and $\oplus_{i\geqslant 1}\mathrm{Vect}_i(E)$, respectively, such that

(1) $L_{-1}\oplus L_0$ is a Lie subalgebra;

(2) $[L_{-1},L_+]\subset L_0\oplus L_+$, and $[L_0,L_+]\subset L_+$.

Set $c^0(L_+)=L_+$ and $c^{k+1}(L_+)=[L_+,c^k(L_+)]$, $(k\in\mathbb{N})$.

Then the smallest Lie subalgebra containing

$$L_{-1}\oplus L_0\oplus L_+$$

is

$$L_{-1}\oplus L_0\oplus\sum_{k\in\mathbb{N}} c^k(L_+).$$

In particular, if $L_+\subset\mathrm{Vect}_1(E)$, the latter subalgebra is graded.

Proof: Using Jacobi identity, we check that $[L_0,c^k(L_+)]\subset c^k(L_+)$ and consequently $[L_{-1},c^k(L_+)]\subset\Sigma_{i=0}^k c^k(L_+)$ by induction on $k\geqslant 1$. By definition, $[c^0(L_+),c^k(L_+)]=c^{k+1}(L_+)$ for all $k\in\mathbb{N}$. Then, we check, by induction on $j\geqslant 0$, that $[c^j(L_+),c^k(L_+)]\subset c^{j+k+1}(L_+)$.

Therefore, $L_{-1}\oplus L_0\oplus\Sigma_{k\in\mathbb{N}}c^k(L_+)$ is a Lie subalgebra. It is trivially the smallest one to contain the subspaces L_{-1}, L_0 and L_+. □

Definition 3: Let F be a vector subspace of $\mathrm{Vect}_{-1}(E)$. We set

$$\mathcal{N}^i(F)=\{X\in\mathrm{Vect}_i(E):\mathrm{ad}(F)^{i+1}X\subset F\}$$

and

$$\mathcal{N}(F)=\oplus_{i\geqslant -1}\mathcal{N}^i(F).$$

Notice that $\mathcal{N}^{-1}(F)=F$ and that $\mathcal{N}^0(F)$ is the intersection of the normalizer of F and the subspace of linear vector fields.

Proposition 2: Let $L=\oplus_{i\geqslant -1}L_i$ be a graded subalgebra of $\mathrm{Vect}_*(E)$. Then $\mathcal{N}(L_{-1})$ is an infinite dimensional graded subalgebra containing L. Moreover, $\mathcal{N}(L_{-1})=\mathrm{Vect}_*(E)$ if and only if $L_{-1}=\mathrm{Vect}_{-1}(E)$.

Proof: It is obvious that $[\mathcal{N}^i(L_{-1}),\mathcal{N}^j(L_{-1})]\subset\mathcal{N}^{i+j}(L_{-1})$. Furthermore, if $L_{-1}=0$ or $L_{-1}=\mathrm{Vect}_{-1}(E)$,

$$\mathcal{N}(L_{-1})=L_{-1}\oplus\bigoplus_{i\geqslant 0}\mathrm{Vect}_i(E).$$

Now, if $h\in L_{-1}$, then, for every polynomial function $p:E\to\mathbb{K}$, the field $x\mapsto p(x)h$ belongs to $\mathcal{N}(L_{-1})$. □

Corollary 3: Let L be a finite dimensional graded maximal subalgebra of $\mathrm{Vect}_*(E)$. Then $\mathrm{Vect}_{-1}(E)\subset L$.

Corollary 4: Let L be a finite dimensional graded maximalsubalgebra of $\mathrm{Vect}_*(E)$. Then $L_1\neq 0$.

Proof: Notice that L cannot be made only of constant and linear vector fields. Indeed, it would then be included in the maximal subalgebra (1) presented in the introduction, for instance. Therefore, $L_k\neq 0$ for some $k>0$. The conclusion follows from Corollary 3. □

Proposition 5: Let L be a finite dimensional graded maximal subalgebra of $\mathrm{Vect}_*(E)$. Then

$$(L_{-1}=\mathrm{Vect}_{-1}(E),\mathrm{ad}_{|L_0})$$

is an irreducible representation of L_0. It follows that any nontrivial ideal of L contains every constant vector field.

Proof: Let $F\neq\{0\}$ be a stable subspace of L_{-1} under the action of L_0.

The space

$$L_{-1}\oplus\mathcal{N}^0(F)\oplus\bigoplus_{i\geqslant 1}\{X\in\mathrm{Vect}_i(E):\mathrm{ad}(L_{-1})^iX\subset\mathcal{N}^0(F)\}$$

satisfies the hypotheses of Lemma 2. Its algebraic closure is an infinite dimensional proper subalgebra containg L properly, hence a contradiction.

Let now I be a nontrivial ideal of L. It contains at least one constant vector field since $[\mathrm{Vect}_{-1}(E),I]\subset I$. It contains all of them since $I\cap L_{-1}$ is a stable subspace of L_{-1}. □

IV. A CONVENIENT MODEL FOR POLYNOMIAL VECTOR FIELDS

It will be useful to consider the spaces of multilinear symmetric mappings from $E\times\cdots\times E$ to E instead of those of homogeneous polynomial vector fields. We shall write

$$\mathcal{T}_i(E)=S^{i+1}E^*\otimes E,\quad\text{and}\quad\mathcal{T}_*(E)=\bigoplus_{i\geqslant -1}\mathcal{T}_i(E).$$

To turn $\mathcal{T}_*(E)$ into a Lie algebra, we define as in Ref. 6 the following bracket operation. If $t\in\mathcal{T}_p(E)$ and $t'\in\mathcal{T}_q(E)$ then $[t,t']\in\mathcal{T}_{p+q}(E)$ and

$$[t,t'](x_0,x_1,\ldots,x_{p+q})=\frac{1}{p!(q+1)!}\sum_j t(t'(x_{j_0},x_{j_1},\ldots,x_{j_q}),x_{j_{q+1}},\ldots,x_{j_{p+q}})$$
$$-\frac{1}{(p+1)!q!}\sum_k t'(t(x_{k_0},x_{k_1},\ldots,x_{k_p}),x_{k_{p+1}},\ldots,x_{k_{p+q}}),$$

where both j and k run over all possible permutations of the $p+q+1$ first natural numbers.

Proposition 6: The map $T:\mathcal{T}_*(E)\to\mathrm{Vect}_*(E)$ *defined by*

$$T(M):x\in E\mapsto-\frac{1}{(p+1)!}M(x,\ldots,x),\quad\forall M\in\mathcal{T}_p(E)$$

is an isomorphism of Lie algebras.

V. ABSENCE OF COMPLEX STRUCTURE

We now assume $\mathbb{K}=\mathbb{R}$ and prove, in Lemma 3, the fourth condition of maximality of our main result.

Let E be a real vector space of even dimension and J a complex structure of E, i.e., an endomorphism of E such that $J^2=-id$. We denote by E_J the complex vector space defined by E with the structure of $\mathbb{C}$-module defined by

$$(a+ib)e:=ae+bJe,\quad\forall a,b\in\mathbb{R},\quad\forall e\in E.$$

Define

$$\mathcal{T}_p^J(E)=\{M\in\mathcal{T}_p(E)\,|\,J(M(x_0,\ldots,x_p))=M(Jx_0,x_1\ldots,x_p),\forall x_0,\ldots,x_p\in E\}$$

for all $p\geqslant-1$. Then the subalgebra $\mathcal{T}_*^J(E)=\oplus_{i\geqslant-1}\mathcal{T}_p^J(E)$ of $\mathcal{T}_*(E)$ is isomorphic to $\mathcal{T}_*(E_J)$ as a real Lie algebra. Indeed, the condition defining $\mathcal{T}_*^J(E)$ means that an application $M\in\mathcal{T}_*(E)$ is $\mathbb{C}$-multilinear on E_J.

Lemma 3: Let E be a real vector space and $L=\mathcal{T}_{-1}(E)\oplus\oplus_{j=0}^k L_j$ *a graded subalgebra of* $\mathcal{T}_*(E)$. *Assume that J is a complex structure of* $(L_{-1},ad_{|L_0})$, *i.e.,*

$$[x_0,Jx_{-1}]=J[x_0,x_{-1}],\quad\forall x_0\in L_0,\forall x_{-1}\in L_{-1}$$

and

$$J^2=-id.$$

Then,

$$L\subset\mathcal{T}_*^J(L_{-1})\subset\mathcal{T}_*(L_{-1}),$$

where both inclusions are strict.

Proof: Indeed, $L_{-1}=\mathcal{T}_{-1}^J(E)=\mathcal{T}_{-1}(E)$. The requirement for J to intertwine the action of L_0 on L_{-1} precisely means that $L_0\subset\mathcal{T}_0^J(E)$. If $L_{k-1}\subset\mathcal{T}_{k-1}^J(E)$ and $M\in L_k$, the equalities

$$J\circ M(x_0,\ldots,x_k)=J([M,x_1](x_0,x_2,\ldots,x_k))=M(x_1,Jx_0,x_2,\ldots,x_k)=M(Jx_0,x_1,\ldots,x_k)$$

show that $M\in\mathcal{T}_k^J(E)$.

The inclusions are strict because the dimension of $\mathcal{T}_*^J(L_{-1})$ is infinite and because the dimension of $\mathcal{T}_p^J(L_{-1})$, for all $p\geqslant0$, is strictly less than that of $\mathcal{T}_p(L_{-1})$. □

This lemma generalizes the construction used in Ref. 3 to show that a subalgebra of infinitesimal conformal transformations, isomorphic to so(3, 1, $\mathbb{R}$), is not maximal in $\mathrm{Vect}_*(\mathbb{R}^2)$.

VI. IRREDUCIBLE FILTERED ALGEBRAS OF FINITE TYPE

Let $L=\oplus_{j=-1}^{k}L_j$ be a graded maximal subalgebra of polynomial vector fields. In the last section, we have shown that L possesses interesting properties. It actually belongs to a broader class of Lie algebras studied in Ref. 7, Theorem 1, p. 875.

This theorem describes the structure of some filtered finite dimensional Lie algebras together with a group of automorphisms.

We shall only associate the trivial group $\{id\}$ to such an algebra. Furthermore, the reader may find worth noticing that the algebras we consider carry the filtration which is naturally associated to their grading and that the other hypotheses of the theorem are satisfied in view of the first three conditions required in our main result for a subalgebra to be maximal.

For the sake of simplicity, we shall name algebras described by this theorem *Irreducible filtered algebras of finite type*, as it was done in Ref. 6, or simply write IFFT-algebras.

As a consequence of the mentioned result, we know that L is simple and is of order two, i.e., $L=L_{-1}\oplus L_0\oplus L_1$. Moreover, there exists a unique element $e\in L$ such that L_p is the eigenspace of $\mathrm{ad}(e)$ associated with the eigenvalue p. This element is thus in the center of L_0. We shall name it the Euler element of L. Finally, L_{-1} and L_1 are dual to each other as modules over L_0 with respect to the Killing form of L.

On the one hand, Kobayashi and Nagano gave a list of the admissible algebras and detailed in each case the associated grading. The pairs (L,e) where L is a real IFFT-algebra and e its Euler element are classified in Ref. 7, pp. 892–895. On the other hand, to any graded algebra $L=\oplus_{k\geqslant -1}L_k$, they associated in a natural way a graded subalgebra of $\mathcal{T}_*(L_{-1})$ (see Ref. 6, p. 683). The reader may compare this construction with that of Gradl (Ref. 12). In the case of $L=L_{-1}\oplus L_0\oplus L_1$, this is done by the following monomorphism $\phi: L\to\mathcal{T}_*(L_{-1})$,

$$\begin{cases}\phi_{|L_{-1}}=id,\\ \phi_{|L_0}=\mathrm{ad}_{|L_0},\\ \phi(M)=(x,y)\mapsto[[M,x],y]. \quad \forall M\in L_1,\forall x,y\in L_{-1}.\end{cases}$$

Notice that this is the only way to proceed provided the value of ϕ on L_{-1} is set to *id.*

VII. IFFT-ALGEBRAS ARE MAXIMAL

In this section, we prove the sufficiency of the conditions given in our main result for a subalgebra of polynomial vector fields to be maximal.

We first assume that E is a complex vector space and $L=L_{-1}\oplus L_0\oplus L_1$ an irreducible graded subalgebra of $\mathcal{T}_*(E)$ such that $L_{-1}=\mathcal{T}_{-1}(E)$ and $L_1\neq 0$. Then we shall show how the proof adapts to the real case.

Let L' be a subalgebra of $\mathcal{T}_*(E)$ such that $L'\supset L$. Then L' is graded and irreducible, since L is.

If L' is finite dimensional, one sees, by using the description of the IFFT-algebras (see Sec. VI), that $L'_1=L_1$, that L' is simple and eventually that $L=L'$, since $[L'_{-1},L'_1]=L_0$.

Therefore, if L' contains properly L, then it must be infinite dimensional. It possesses two additional properties, consequences of the following result.

Proposition 7 (Ref. 6, p. 688): *Let $\oplus_{p\geqslant -1}G_p$ be an irreducible graded Lie algebra of infinite type or finite type of order $\geqslant 2$ over a field of characteristic 0. Then G_0 is reductive and $[G_{-1},G_1]$ contains the semisimple part of G_0.*

(a) L'_0 is reductive and has a nontrivial center (the multiples of the identity transformation of L_{-1});

(b) L' is still simple. Indeed, if I is an ideal of L' then $I \supset L$ (see Proposition 5), which implies that I contains the multiples of the identity transformation of L_{-1} and in turn that $I \supset L'_j$ for all $j \neq 0$. Since $[L'_{-1}, L'_1]$ contains the semisimple part of L'_0, the conclusion follows.

In order to prove the maximality of L, the remaining point is to ensure that $L' = \mathcal{T}_*(E)$. The key result is due to Cartan. We refer the reader to the works of Guillemin, Quillen, Singer, Sternberg, Kobayashi, and Nagano (Refs. 8, 9, 10, 6).

This result states that the only irreducible infinite dimensional graded subalgebras of $\mathrm{Vect}_*(E)$ are

(1) $\mathrm{Vect}_*(E)$ itself;
(2) the divergence-free vector fields;
(3) the Hamiltonian vector fields with respect to a symplectic form given on E, provided E is even dimensional;
(4) the last two subalgebras supplemented with the multiples of the Euler vector field.

But the subalgebras described in (4) are not simple, and those in (2) and (3) have a simple linear part.

Hence the proof.

Now, when E is a real vector space and L and L' as above, one proceeds in the same way to prove the simplicity of L', noticing that both L_0 and L'_0 still have a one dimensional center.

Indeed, if x_0 is central in one of these two subalgebras, then $\mathrm{ad}(x_0)$ intertwines the action of L_0 on L_{-1}. Since the representation $(L_{-1}, \mathrm{ad}_{|L_0})$ admits no complex structure, Schur's lemma ensures that $\mathrm{ad}(x_0)_{|L_{-1}}$ is a multiple of the identity transformation of L_{-1}. Therefore, $\dim Z(L_0) = 1$.

The description of irreducible infinite dimensional graded subalgebras of $\mathrm{Vect}_*(E)$ is essentially due to Matsushima. It can be found in Refs. 6 and 13.

Two cases arise whether $L'_0 \otimes \mathbb{C}$ acts irreducibly on $E \otimes \mathbb{C}$ or not. In the first case, L' should be one of the real analogs of the Cartan algebras listed above. But in the second, E admits a complex structure as a L_0 module, which contradicts the hypotheses.

Theorem 1 is proved.

In order to complete our search for maximal subalgebras of polynomial vector fields over a given *real* vector space, we need to be able to identify in the tables given in Ref. 7, pp. 892–895, the algebras such that the representation $(L_{-1}, \mathrm{ad}_{|L_0})$ admits a complex structure.

Proposition 8: Let L_{-1} be a real vector space and $L = L_{-1} \oplus L_0 \oplus L_1$ an IFFT-algebra. Then $(L_{-1}, \mathrm{ad}_{|L_0})$ admits a complex structure if and only if the algebra L admits a complex structure.

Proof: The sufficiency of the condition is obvious. Notice that a complex structure on L stabilizes the eigenspaces of e.

Let J_{-1} be a complex structure on $(L_{-1}, \mathrm{ad}_{|L_0})$. Let $J_1 : L_1 \to L_1$ be the adjoint of J_{-1} with respect to the Killing form β of L, i.e.,

$$\beta(J_1 x_1, x_{-1}) = \beta(x_1, J_{-1} x_{-1}), \quad \forall x_{-1} \in L_{-1}, \forall x_1 \in L_1.$$

The so defined J_1 intertwines the action of L_0 on L_1. Moreover,

$$[J_1 x_1, x_{-1}] = [x_1, J_{-1} x_{-1}], \quad \forall x_{-1} \in L_{-1}, \forall x_1 \in L_1.$$

Indeed, for all $x_{-1}, y_{-1} \in L_{-1}$ and $x_1, y_1 \in L_1$,

$$\begin{aligned} \beta([[x_1, J_{-1} x_{-1}], y_{-1}], y_1) &= \beta(J_{-1} x_{-1}, [x_1, [y_1, y_{-1}]]) \\ &= \beta(x_{-1}, [J_1 x_1, [y_1, y_{-1}]]) \\ &= \beta([[J_1 x_1, x_{-1}], y_{-1}], y_1). \end{aligned}$$

Define

$$J_0: L_0 \to \mathcal{T}_0(L_{-1}): A \mapsto A \circ J_{-1}.$$

This map is actually valued in L_0 since

$$\begin{aligned}(J_0[x_1, x_{-1}])y_{-1} &= [[x_1, x_{-1}], J_{-1}y_{-1}] = [[x_1, J_{-1}y_{-1}], x_{-1}] \\ &= [[J_1 x_1, y_{-1}], x_{-1}] = [J_1 x_1, x_{-1}]y_{-1}\end{aligned}$$

for all $y_{-1} \in L_{-1}$.

The map $J: L \to L$ defined by its restrictions J_i to $L_i (i = -1, ..., 1)$ is then a complex structure of L as a Lie algebra. □

The statement ''IFFT-algebras are maximal'' should be taken in the following sense. In the tables given in Ref. 7, one can distinguish complex algebras from real ones admitting no complex structure. The latter give rise to maximal subalgebras of the real algebra $\mathcal{T}_*(L_{-1})$. One may consider the former as Lie subalgebras of the real Lie algebra $\mathcal{T}_*(L_{-1})$, in which case Lemma 3 shows that they are not maximal. They are maximal when regarded in their natural position of complex subalgebras of the complex Lie algebra $\mathcal{T}_*(L_{-1})$.

(Received 7 August 2000; accepted for publication 27 October 2000)

The factorization method for Schrödinger operators with magnetic fields on a two-dimensional surface M^2 with nontrivial metric is investigated. This leads to the new integrable examples of such operators and brings a new look at some classical problems such as the Dirac magnetic monopole and the Landau problem. The global geometric aspects and related spectral properties of the operators from the factorization chains are discussed in detail. We also consider the Laplace transformations on a curved surface and extend the class of Schrödinger operators with two integrable levels introduced in the flat case by S. P. Novikov and one of the authors.
 [DOI: 10.1063/1.1334903]

I. INTRODUCTION

In spite of the fact that some important examples of integrable Schrödinger equations with magnetic fields were known since the 1930s (Landau problem, Dirac magnetic monopole), the general problem of integrability for such equations is still far from being understood.

In two dimensions probably the first important step in this direction has been taken by Dubrovin, Krichever and Novikov in 1976, who introduced a very important class of Schrödinger operators with magnetic fields integrable (''finite-gap'') on one energy level.[1] The coefficients of the corresponding operators are periodic (or quasiperiodic) so that the total magnetic flux is zero.

The case of periodic magnetic fields with nonzero flux has been considered by Dubrovin and Novikov[2] following the Aharonov–Casher observation[3] that the Pauli operators for spin $\frac{1}{2}$ particles in a magnetic field are related to the factorizable Schrödinger operators. This allowed one to describe explicitly the ground states of the corresponding operators (see Refs. 4 and 5 for the details).

In Ref. 6 Novikov and one of the authors found a class of operators with magnetic fields which are integrable on two different energy levels including the ground state. In Sec. V of this article we present some generalizations of this result, but our main goal here is to investigate what the factorization method can give for the theory of Schrödinger operators L with magnetic fields on a curved two-dimensional surface M^2.

Although some ideas have been developed already in the 19th century by Darboux, and Moutard *et al.* (see, e.g., Ref. 7), it was probably Schrödinger who first used the factorization method in quantum mechanics[8] (see also Ref. 9). The idea of this method is very simple: if a given operator L can be factorized as

$$L = D_1 D_2,$$

then the new operator

$$\tilde{L} = D_2 D_1$$

[a]Electronic mail: E.V.Ferapontov@lboro.ac.uk
[b]Electronic mail: A.P.Veselov@lboro.ac.uk

has the same spectrum as L (provided the operators are good enough), except possibly $\lambda=0$, and if one knows the eigenfunctions ψ of L, then the formula

$$\tilde{\psi}=D_2\psi$$

gives the eigenfunctions of $\tilde{L}$. One can obviously include a shift into the factorization scheme:

$$L=D_1D_2+c\rightarrow\tilde{L}=D_2D_1+c,$$

where c is a constant. In one dimension it is always possible to factorize the Schrödinger operator and continue this procedure to construct an infinite chain of operators related by this transformation usually called the *factorization chain* (or dressing chain). In the case when this chain is periodic with an odd period the spectrum and eigenfunctions of all these operators can be described explicitly (see Ref. 10). The classical example is a harmonic oscillator when $\tilde{L}=L+\text{const}$.

In two dimensions the factorization of the general Schrödinger operator L with magnetic field on a curved surface M^2 is possible only in the special case when the potential is equal up to a sign to the magnetic field (see Theorem 1). A simple but important calculation shows that the transformation

$$L=D^*D\rightarrow\tilde{L}=DD^*$$

changes the magnetic field B by the Gaussian curvature K of M^2:

$$\tilde{B}=B+K.$$

In contrast to the one-dimensional, case in two dimensions one cannot, in general, continue the factorization procedure. We give a complete classification of all possible factorization chains on a curved surface M^2 (Theorem 2), which in particular says that infinite factorization chain exists only on the surfaces with constant Gaussian curvature. The magnetic field and the potential of the corresponding operators must also be constant.

In Sec. III we discuss the global geometric aspects of the factorization chains. The index theorem and the classical Gauss–Bonnet formula play a crucial role here. They explain a big difference between positive and negative curvature cases. In the positive constant curvature case, when $M^2=S^2$ is the standard round sphere, we have the *Dirac magnetic monopole*.[11–13] We show how the factorization method leads to the complete description of the spectrum of the corresponding Schrödinger operator L in the same way as Schrödinger did for the harmonic oscillator in Ref. 8. For the flat torus we have the standard *Landau problem*.[14] We also discuss what the factorization method gives for the analog of the Landau problem on a surface of constant negative curvature with genus more than 1.

In Sec. IV we present some new examples of integrable Schrödinger operators with magnetic fields related to the two-term factorization chains on the surfaces with nonconstant curvature. The main observation here is that if the Laplace–Beltrami operator on M^2 is integrable, then the same is true for the operator with the additional magnetic field $B=\pm K$ and the potential $U=K$, K being the Gaussian curvature.

In the last section we consider the quasi-cyclic chains of the Schrödinger operators with magnetic fields on a curved surface related by Laplace transformations generalizing the constructions from Ref. 6. This leads to a class of operators with two known energy levels, one of which is the ground state.

II. FACTORIZATION METHOD ON CURVED SURFACES: LOCAL THEORY

Consider an oriented analytic surface M^2 with a Riemannian metric ds^2. It is known that M^2 has a complex structure such that the metric is conformal. In any complex chart $z=x+iy$, $\overline{z}=x-iy$ the metric has the form

$$ds^2=\frac{dzd\overline{z}}{h^2(z,\overline{z})}=\frac{dx^2+dy^2}{h^2(z,\overline{z})}.$$

The Laplace–Beltrami operator Δ_h can be defined locally as

$$\Delta_h=4h^2\partial\overline{\partial}=h^2(\partial_x^2+\partial_y^2),$$

where $\partial=\partial_z=\frac{1}{2}(\partial_x-i\partial_y)$ and $\overline{\partial}=\partial_{\overline{z}}=\frac{1}{2}(\partial_x+i\partial_y)$. To introduce the magnetic field one should replace the usual derivatives by their covariant counterparts:

$$\begin{gathered}\nabla_x=\partial_x-ia, \quad \nabla_y=\partial_y-ib,\\ \nabla=\partial-iA, \quad \overline{\nabla}=\overline{\partial}-i\overline{A},\\ A=\tfrac{1}{2}(a-ib), \quad \overline{A}=\tfrac{1}{2}(a+ib).\end{gathered} \tag{1}$$

The corresponding Schrödinger operator

$$L_A=-h^2[(\partial_x-ia)^2+(\partial_y-ib)^2]$$

can be rewritten as

$$L_A=-4h^2\nabla\overline{\nabla}+h^2H=-4h^2\overline{\nabla}\nabla-h^2H=-2h^2(\nabla\overline{\nabla}+\overline{\nabla}\nabla), \tag{2}$$

where

$$H=\partial_x b-\partial_y a=i[\nabla_x,\nabla y]=2[\nabla,\overline{\nabla}].$$

Geometrically, we have a complex $U(1)$-bundle over M^2 with the connection form

$$\alpha=i(adx+bdy) \tag{3}$$

and the curvature

$$\Omega=d\alpha=iHdx\wedge dy=-\frac{H}{2}dz\wedge d\overline{z} \tag{4}$$

(see the next section for further discussion of the geometric aspects). Let us define magnetic field B by the relation

$$\Omega=iBd\sigma, \tag{5}$$

where $d\sigma=(1/h^2)\,dx\wedge dy$ is the area element of the surface. By definition we have

$$B=h^2H. \tag{6}$$

The most general Schrödinger operator on M^2 has the form

$$L=-h^2[(\partial_x-ia)^2+(\partial_y-ib)^2]+U, \tag{7}$$

where the potential $U(x,y)$ is a real function on M^2.

Consider the following *factorization problem* for (7): when L can be represented locally as

$$L=(\alpha_1\partial+\alpha_0)(\alpha_1^*\overline{\partial}+\alpha_0^*) \tag{8}$$

(α-factorization) or

$$L=(\beta_1\overline{\partial}+\beta_0)(\beta_1^*\partial+\beta_0^*) \tag{9}$$

(β-factorization) for some functions α, α^*, β, β^* ? In the Euclidean case such factorizations appeared in the theory of Pauli operators for spin 1/2 particles (see Refs. 3 and 4). On a curved surface the situation is pretty similar.

Theorem 1: *The α-factorization for the Schrödinger operator (7) exists iff $U=-B$. Similarly, the necessary and sufficient condition for the β-factorization is $U=B$.*

The sufficiency readily follows from formulas (2):

$$\text{If } U=-B, \text{ then } L=-4h^2\nabla\overline{\nabla}.$$

$$\text{If } U=B, \text{ then } L=-4h^2\overline{\nabla}\nabla.$$

The factorization is not unique: if $L=D_1D_2$ is any factorization, then $L=(D_1f^{-1})(fD_2)$ is another one for an arbitrary function f. This actually gives all such factorizations.

Having a factorized operator $L=D_1D_2$ one can consider the new operator

$$\tilde{L}=D_2D_1.$$

Notice that the change of factorization $D_1\to D_1f^{-1}$ and $D_2\to fD_2$ corresponds to the gauge transformation of $\tilde{L}$:

$$\tilde{L}\to fD_2D_1f^{-1}=f\tilde{L}f^{-1}.$$

The magnetic field and the potential do not depend on the gauge and are defined correctly. Let us compute them for α-factorized L. We can assume that $D_2=\overline{\nabla}$ and $D_1=-4h^2\nabla$, so that

$$\tilde{L}=D_2D_1=-4\overline{\nabla}(h^2\nabla)=-4h^2\overline{\nabla}\nabla-2h_{\bar{z}}h\nabla=-4h^2(\overline{\nabla}+2h_{\bar{z}}h^{-1})\nabla=-4h^2\tilde{\overline{\nabla}}\tilde{\nabla}, \tag{10}$$

where $\tilde{\overline{\nabla}}=\overline{\nabla}+2h_{\bar{z}}h^{-1}$, $\tilde{\nabla}=\nabla$.

Remark: The nonsymmetry between $\tilde{\nabla}$ and $\tilde{\overline{\nabla}}$ can be easily corrected by a suitable gauge transformation: $\tilde{\nabla}\to h\tilde{\nabla}h^{-1}=\nabla-h_zh^{-1}$ and $\tilde{\overline{\nabla}}\to h\tilde{\overline{\nabla}}h^{-1}=\overline{\nabla}+h_{\bar{z}}h^{-1}$. In the future we will not worry about such a nonsymmetry provided the corresponding magnetic field is real.

The new magnetic field is

$$\begin{aligned}\tilde{B}&=2h^2[\tilde{\nabla},\tilde{\overline{\nabla}}]=2h^2[\nabla,\overline{\nabla}+2h_{\bar{z}}h^{-1}]=B+4h^2(h_{\bar{z}}h^{-1})_z\\&=B+4h^2(\ln h)_{z\bar{z}}=B+h^2\triangle\ln h=B+K,\end{aligned}$$

where K is the *Gaussian curvature* of the surface. Here we have used the standard formula for K in the conformal coordinates

$$K=h^2\triangle\ln h \tag{11}$$

(see, e.g., Ref. 15). Thus the new magnetic field is

$$\tilde{B}=B+K. \tag{12}$$

According to Theorem 1 the new potential is

$$\tilde{U}=\tilde{B}=B+K. \tag{13}$$

Similarly, for β-factorization the new magnetic field and the new potential are

$$\tilde{B}=B-K, \quad \tilde{U}=K-B.$$

Let us introduce the notation (B,U) for the gauge class of Schrödinger operators (7) with given magnetic field B and potential U. Then we have the following two-term factorization chains:

$$(B,-B)\overset{\alpha}{\to}(B+K,B+K) \tag{14}$$

and

$$(B,B)\overset{\beta}{\to}(B-K,K-B). \tag{15}$$

Notice that $\alpha\circ\beta=\beta\circ\alpha=Id$:

$$(B,-B)\overset{\alpha}{\to}(B+K,B+K)\overset{\beta}{\to}(B,-B),$$

$$(B,B)\overset{\beta}{\to}(B-K,K-B)\overset{\alpha}{\to}(B,B).$$

The question is: can we continue the α-chain allowing a shift by a constant? The answer is simple: in order to have α-factorization for an operator from the class $(B+K,B+K-2c)$, $c=\text{const}$ we should require $B+K-2c=-(B+K)$ or $B+K=c$. In this case we have the following three-term chains with an arbitrary constant c:

$$(c-K,K-c)\overset{\alpha}{\to}(c,c)=(c,-c)+2c\overset{\alpha}{\to}(c+K,c+K)+2c=(c+K,3c+K) \tag{16}$$

and similarly

$$(c+K,c+K)\overset{\beta}{\to}(c,-c)=(c,c)-2c\overset{\beta}{\to}(c-K,K-c)-2c=(c-K,K-3c). \tag{17}$$

Here by $(B,U)+c$ with constant c we denote the class of operators $L+c$ with $L\in(B,U)$. Of course $(B,U)+c=(B,U+c)$, but it is convenient for us to use this notation to explain the procedure. Notice that the operators with constant magnetic field and constant potential can be considered as the natural analog of the *Landau operators* on a curved surface M^2. One more step in the factorization procedure is possible only if the Gaussian curvature is constant: $K=K_0$. In that case we actually can perform infinitely many steps:

$$(c-K_0,\ K_0-c)\overset{\alpha}{\to}(c,c)\overset{\alpha}{\to}(c+K_0,\ 3c+K_0)\overset{\alpha}{\to}\ldots\overset{\alpha}{\to}(c+mK_0,\ (2m+1)c+m^2K_0)\overset{\alpha}{\to}\ldots \tag{18}$$

for any $m\in\mathbf{Z}_+$ and similarly

$$(c+K_0,\ c+K_0)\overset{\beta}{\to}(c,-c)\overset{\beta}{\to}(c-K_0,\ K_0-3c)$$

$$\overset{\beta}{\to}\ldots\overset{\beta}{\to}(c-mK_0,-(2m+1)c+m^2K_0)\overset{\beta}{\to}\ldots \tag{19}$$

Summarizing all this we have the following.

Theorem 2: *All possible factorization chains on a surface M^2 with Gaussian curvature K are given by*

(1) two-term chains (14) and (15) with an arbitrary magnetic field B;

(2) three-term chains (16) and (17) of the operators on M^2 with constant magnetic fields. If a surface M^2 has a constant Gaussian curvature then we have also

(3) infinite chains (18) and (19) with constant magnetic fields.

III. GLOBAL GEOMETRY AND SPECTRAL PROPERTIES OF *L*

Let us assume now that M^2 is a closed surface of genus g with given Riemannian metric, ξ is a complex $U(1)$-bundle over M^2, α is a connection on ξ, and $\Omega=iBd\sigma$ is its curvature form. Here as above $d\sigma$ is the area element of the surface determined by the metric and B is a function on M^2 called magnetic field.

Remark: We should mention that for a given magnetic field B the corresponding connection α is defined uniquely modulo natural gauge transformations only when M^2 is a topological sphere. For a surface of genus g one can always add to α a closed one-form without changing B. Modulo exact forms corresponding to the gauge transformations the connections form the first cohomology group $H^1(M^2,\mathbf{R})\simeq\mathbf{R}^{2g}$. These additional $2g$ parameters are called the *Aharonov–Bohm* fluxes (see Refs. 16 and 17). All the spectra we consider in general depend not only on the magnetic field B but also on the choice of the connection α and therefore on these parameters. When $g=1$ (i.e., when M^2 is a torus) this corresponds to the choice of two *Bloch quasi-momenta*.

Notice that the total magnetic flux is an integer multiple of 2π:

$$\frac{1}{2\pi}\int_{M^2}Bd\sigma=b,\quad b\in\mathbf{Z}. \tag{20}$$

The integer b is actually the first Chern class of ξ:

$$b=c_1(\xi)\in H^2(M^2,\mathbf{Z})\simeq\mathbf{Z} \tag{21}$$

(see, e.g., Ref. 15). Having all this plus a potential U which is a function on M^2 one can define the Schrödinger operator L in (7) as explained in the previous section. This operator is acting on the sections $S(\xi)$ of the bundle ξ and is self-adjoint with respect to the natural Hermitian structure with the norm

$$\|\psi\|^2=\int_{M^2}|\psi|^2d\sigma.$$

Let us analyze now what happens when we apply the factorization procedure. Consider first the two-term chain (14):

$$(B,-B)\overset{\alpha}{\to}(B+K,B+K)$$

or, in the local coordinates,

$$L=D^*D\to DD^*=\tilde{L},$$

where $D=2\overline{\nabla}$ and $D^*=-2h^2\nabla$. Here we have used the complex structure on M^2 uniquely determined by the Riemannian metric, which exists according to the classical results (see, e.g., Ref. 15).

Notice, first of all, that the operator D maps the sections $S(\xi)$ of ξ into the sections $S(\eta)$ of the bundle $\eta=\xi\otimes T^{0,1}(M^2)$ which are the antiholomorphic one-forms on M^2 with the values in ξ of the form $\psi d\overline{z},\psi\in S(\xi)$. This space also has the natural Hermitian structure induced by the Hermitian structure on ξ and the metric on M^2. It is easy to check that $D^*=-2h^2\nabla$ is indeed operator adjoint to $D=2\overline{\nabla}$ with respect to these structures, so the operator $L=D^*D$ is nonnegative and $\mathrm{Ker}\,L=\mathrm{Ker}\,D$.

The new operator $\tilde{L}=DD^*$ is acting on the sections $S(\eta)$ of the bundle η and in the local coordinates has the form (10):

$$\tilde{L}=-4\overline{\nabla}(h^2\nabla)=-4h^2(\overline{\nabla}+2h_{\bar{z}}h^{-1})\nabla.$$

The new covariant derivatives $\tilde{\overline{\nabla}}=\overline{\nabla}+2h_{\bar{z}}h^{-1}$, $\tilde{\nabla}=\nabla$, correspond to the natural connection on η induced by the connection α on ξ and the natural Hermitian connection on the antiholomorphic cotangent bundle $T^{0,1}(M^2)$ (see Ref. 18). The curvature of this connection is

$$\tilde{\Omega}=i(B+K)d\sigma,$$

where K is the Gaussian curvature of the metric. Notice that the total flux of the new magnetic field $\tilde{B}=B+K$ (or, equivalently, the first Chern class of the bundle η) is

$$c_1(\eta)=\tilde{b}=\frac{1}{2\pi}\int_{M^2}\tilde{B}d\sigma=b+\chi=b+(2-2g), \tag{22}$$

where $\chi=2-2g$ is the *Euler characteristics* of M^2 because of the *Gauss–Bonnet formula*:

$$\int_{M^2}Kd\sigma=2\pi\chi. \tag{23}$$

The operator D is an elliptic operator from $S(\xi)$ into $S(\eta)$. Its index can be determined by the index theorem and is given by the Riemann–Roch formula

$$\mathrm{ind}\,D=\dim\mathrm{Ker}\,D-\dim\mathrm{Ker}\,D^*=b-g+1. \tag{24}$$

When the magnetic field is large enough, more precisely when $b>2g-2$, we have

$$\dim\mathrm{Ker}\,D^*=0,\quad \dim\mathrm{Ker}\,D=b-g+1. \tag{25}$$

In that case the ground state of the operator L is degenerate:

$$\dim\mathrm{Ker}L=\dim\mathrm{Ker}\,D=b-g+1,$$

while $\tilde{L}$ is positive operator:

$$\dim\mathrm{Ker}\tilde{L}=\dim\mathrm{Ker}\,D^*=0.$$

The rest of the spectrum (which is discrete according to general theory) is the same for L and $\tilde{L}$: the intertwining operators D and D^* establish the isomorphism of the corresponding eigenspaces. Notice that if $b=g-1$, then, according to the Riemann–Roch formula (24), $\dim\mathrm{Ker}\,L=\dim\mathrm{Ker}\,\tilde{L}$ so that L and $\tilde{L}$ are isospectral everywhere (not just for $\lambda>0$). Now for the general factorization chain one should only take into account the additional shift of the spectrum.

For the β-factorization chains (15) the analysis is similar, one should simply replace the holomorphic structure by the antiholomorphic one.

Let us consider now some examples.

Example 1: Dirac magnetic monopole on a sphere. Let M^2 be a sphere $S^2 \subset R^3$ with the standard metric of constant Gaussian curvature K. The Hamiltonian of the Dirac monopole with a charge $q \in \mathbf{Z}$ in our notations is a Schrödinger operator H_q from the gauge class $(B,0)$, where B is a constant satisfying the quantization relation

$$\frac{1}{2\pi}\int_{S^2} B d\sigma = \frac{B}{2\pi}\int_{S^2} d\sigma = 2B = q,$$

i.e., $B = q/2$ must be integer or half-integer. It is acting on the sections of the U(1)-bundle with the first Chern class q. As we have seen earlier, such an operator can be included in the infinite factorization chain:

$$\begin{aligned}(B,0) &= (B,-B)+B \to (B+K,\ B+K)+B \\ &= (B+K,\ 2B+K) \\ &= (B+K,\ -(B+K))+3B+2K \to (B+2K,B+2K)+3B+2K \\ &= (B+2K,4B+4K) \to \ldots \to (B+mK,\ 2mB+m^2K) \to \ldots, \end{aligned} \tag{26}$$

$m \in \mathbf{Z}_+$. If $B = q/2 > 0$, then the operator $(B,-B)$ is positive and, according to index theorem (25),

$$\dim \mathrm{Ker}(B,-B) = q - g + 1 = q + 1$$

since $g = 0$ and $q \geqslant 2g - 1 = -1$. Therefore the ground state of H_q has the energy $\lambda = B = q/2$ and the corresponding eigenspace has dimension $q + 1 = 2B + 1$. The second operator $(B+K,2B+K)$ in the chain has the same spectrum as $(B,0)$, except the ground state. By the same reasons its ground state has energy $\lambda = 3B + 2K$ which is degenerate:

$$\dim \mathrm{Ker}[(B+K,2B+K)-(3B+2K)] = \dim \mathrm{Ker}[B+K,-(B+K)] = 2B+2+1 = 2B+3.$$

Thus the second eigenvalue of H_q is $\lambda_2 = 3B + 2K$ with degeneracy $2B + 3$. On the mth step we will have the operator $(B+mK,2mB+m^2K) = (B+mK,-B-mK)+(2m+1)B+(m^2+m)K$ which leads to the eigenvalue

$$\lambda_m = (2m+1)B + m(m+1)K$$

with degeneracy $2B + 2m + 1$. Thus we arrived at the well-known result about the spectrum of the Dirac monopole (see, e.g., Ref. 13):

$$\mathrm{Spec} H_q = \left\{ \lambda_n = (2m+1)\frac{q}{2} + m(m+1)K \text{ with degeneracy } \quad q + 2m + 1 \right\},$$

$m = 0,1,2,\ldots$.

We can make all this explicit (including the calculation of the corresponding eigenfunctions) using the stereographic coordinate $z = x + iy$. Assume for simplicity that the radius of the sphere $R = 1$, so that the Gaussian curvature $K = 1/R^2 = 1$. The metric has the form

$$ds^2 = \frac{4}{(1+z\overline{z})^2} dz d\overline{z}.$$

The corresponding chain of operators in a suitable gauge has the form

$$L_N = -(1+z\bar{z})^2\partial\bar{\partial} - Nz(1+z\bar{z})\partial + N\bar{z}(1+z\bar{z})\bar{\partial} + N^2(1+z\bar{z})$$
$$= D_N^* D_N + N(N+1) = D_{N-1}D_{N-1}^* + N(N-1), \tag{27}$$

$$D_N = (1+z\bar{z})\bar{\partial} + Nz; \quad D_N^* = -(1+z\bar{z})\partial + (N+1)\bar{z}.$$

Here $L_N = H_{2N} + N^2$, where H_{2N} is the Dirac monopole operator with the charge $q=2N$, $B=N$. We obviously have the intertwining relations

$$L_{N+1}D_N = D_N L_N, \quad L_N D_N^* = D_N^* L_{N+1}. \tag{28}$$

To find the ground state of $L_N : L_N\psi = N(N+1)\psi$ one should solve the equation $D_N\psi = 0$:

$$(1+z\bar{z})\bar{\partial}\psi + Nz\psi = 0, \quad \text{or} \quad \bar{\partial}\ln\psi = -\frac{Nz}{1+z\bar{z}}.$$

The solutions are easy to find:

$$\psi = \frac{f(z)}{(1+z\bar{z})^N},$$

where f is any holomorphic function of z. Because of the condition

$$\int |\psi|^2 d\sigma = \int\int_{R^2} \frac{|\psi|^2 dz d\bar{z}}{(1+z\bar{z})^2} < \infty,$$

the function $f(z)$ must be a polynomial of order $\leqslant 2N$. This gives us the space of dimension $2N+1$. Applying to this space the ''lowering'' operators $D_{N-1}^*, D_{N-2}^*, \ldots$ we will construct all eigenfunctions of the operators $L_{N-1}, L_{N-2}, \ldots$ with the eigenvalue $\lambda = N(N+1)$. This gives the following description of the eigenfunctions of the Dirac monopole operator H_q.

Theorem 3: *The eigenfunctions of the Dirac magnetic monopole operator with the charge q on a unit sphere corresponding to the eigenvalue*

$$\lambda = (2m+1)\frac{q}{2} + m(m+1), \quad m \in Z_+, \tag{29}$$

form the space of dimension $q+2m+1$ *which can be described as*

$$\psi = D_{N-m}^* \ldots D_{N-2}^* D_{N-1}^* \frac{f(z)}{(1+z\bar{z})^N}, \tag{30}$$

where $N = m + q/2$ *and* $f(z)$ *is an arbitrary polynomial of degree* $\deg f \leqslant 2N = 2m+q$.

One can check that the formulas for ψ we have given actually determine the smooth sections of the corresponding line bundles over the sphere S^2.

The eigenfunctions of the Dirac magnetic monopole are known as *monopole harmonics* and have been investigated by Wu and Yang,[13] who were probably the first to identify them explicitly as the sections. Our derivation is different and closer to the one of the paper[19] by D'Hoker and Vinet who discovered the supersymmetry of the corresponding Pauli equation in the presence of a magnetic monopole (see also Ref. 20).

Remark: If $q=2N$ is an even integer, then $H_{2N} = L_N - N^2$ can be intertwined with the shifted standard Laplace–Beltrami operator $L_0 = -\Delta_g$ on the sphere S^2:

$$H_{2N}D = D(L_0 - N^2), \quad D = D_{N-1}\cdots D_1 D_0,$$

so that one can use the well-known eigenfunctions of L_0 (spherical harmonics) to construct the eigenfunctions of H_q. Notice that we have given an alternative description of spherical harmonics using the factorization chain. The explicit form of the intertwining operator D is

$$D=\frac{1}{(1+z\overline{z})^{N-2}}\overline{\partial}(1+z\overline{z})^2\overline{\partial}(1+z\overline{z})^2\overline{\partial}\cdots\overline{\partial}(1+z\overline{z})^2\overline{\partial},$$

which is of the order N in $\overline{\partial}$.

It is interesting to compare the Dirac monopole problem on a sphere with the Landau problem on the surfaces of genus $g\geqslant 2$ with the constant negative Gaussian curvature $K<0$ which we analyze later. The corresponding classical problems behave very differently so one should expect the same for the quantum problems as well.

For the investigation of the intermediate case of flat torus which is the classical Landau problem we refer to Refs. 14 and 5. In that case $K=0$ and our formula (26) leads to the usual Landau spectrum

$$\lambda_m=\{(2m+1)B,\quad m=0,1,\dots\},$$

where B is assumed positive and quantized. The corresponding eigenfunctions can be expressed in terms of the classical elliptic σ-functions (see Refs. 5 and 2 for the details).

Example 2: Landau problem on a surface of genus $g\geqslant 2$. Let M^2 be any analytic surface with the metric ds^2 of constant curvature $K=-1$. Such surface M^2 can be considered as a quotient of the Lobachevsky plane $\mathcal{L}$ by an infinite discrete group G:

$$M^2=\mathcal{L}/G.$$

Here $\mathcal{L}$ can be realized as an open disc $|z|<1$ with the metric

$$ds^2=\frac{4}{(1-z\overline{z})^2}dzd\overline{z}.$$

The Schrödinger operator on $\mathcal{L}$ with constant magnetic field B (Landau operator) can be written as $L_B^{\mathcal{L}}=-(1-z\overline{z})^2(\nabla\overline{\nabla}+\overline{\nabla}\nabla)$, where

$$\nabla=\partial-B\frac{\overline{z}}{1-z\overline{z}},\quad \overline{\nabla}=\overline{\partial}+B\frac{z}{1-z\overline{z}},$$

or, explicitly,

$$L_B^{\mathcal{L}}=-(1-z\overline{z})^2\partial\overline{\partial}+B\overline{z}(1-z\overline{z})\overline{\partial}-Bz(1-z\overline{z})\partial+B^2z\overline{z}. \tag{31}$$

In order to define the corresponding operator L_B acting on the sections of some $U(1)$-bundle over M^2 one needs the quantization condition

$$\frac{1}{2\pi}\int_{M^2}Bd\sigma=\frac{1}{2\pi}B\int_{M^2}d\sigma=(2g-2)B\in\mathbf{Z} \tag{32}$$

to be satisfied. Here we have again used the Gauss–Bonnet formula

$$\frac{1}{2\pi}\int_{M^2}Kd\sigma=-\frac{1}{2\pi}\int_{M^2}d\sigma=\chi=2-2g.$$

Notice that to define L_B one also needs to choose a connection α which depends on $2g$ Aharonov–Bohm fluxes (see the remark at the beginning of this section).

Let us see what the factorization chain (18) gives us for the calculation of the spectrum of L_B. We have the chain (26) with $K=-1$:

$$\begin{aligned}(B,0)&\to(B,-B)+B\to(B-1,B-1)+B\\&=(B-1,2B-1)\to\ldots\to(B-m,2mB-m^2)\\&=(B-m,m-B)+(2m+1)B-(m^2+m).\end{aligned}$$

Let us assume that $B>0$. By Riemann–Roch formula (24) the index of the operator $(B-m,m-B)$ is $(2g-2)(B-m)-g+1=(2g-2)(B-m-\frac{1}{2})$, so it is positive if

$$m<B-\tfrac{1}{2}.$$

Using the same arguments as in the previous example we can claim that the first $[B-\frac{1}{2}]+1$ eigenvalues of the operator L_B have the form

$$\lambda_m=(2m+1)B-m(m+1),\quad m=0,1,2,\ldots,[B-\tfrac{1}{2}]. \tag{33}$$

Let us remember that B has the form $k/(2g-2)$ for some positive integer k. Moreover, we can say that if $(2g-2)(B-m)>2g-2$, i.e., if

$$m<B-1,$$

then the corresponding eigenspace has the dimension

$$\dim \mathrm{Ker}(L_B-\lambda_m)=(2g-2)(B-m-\tfrac{1}{2}). \tag{34}$$

Notice that the spectrum (33) depends only on the magnetic field B but not on the Aharonov–Bohm fluxes. It is related to the discrete part of the spectrum of the Landau operator $L_B^{\mathcal{L}}$ on the whole Lobachevsky plane (see, e.g. Ref. 21). It would be interesting to find an effective representation for the corresponding eigenfunctions on a surface M^2 given explicitly as an algebraic curve in $\mathbf{C}^2$.

From these considerations we have nothing to say about the rest of the spectrum of L_B [which in fact depends both on Aharonov–Bohm fluxes and on $(3g-3)$ complex parameters (*moduli*) determining the conformal structure on M^2]. In particular, we can not say anything about the spectrum of the pure Laplace–Beltrami operator L_0 on M^2. This is a reflection of the fact that the corresponding classical geodesics problem on M^2 is nonintegrable. In this relation we would like to mention an interesting paper[22] where the both classical and quantum problems with a constant magnetic field are considered on a surface which is a (noncompact) quotient of the Lobachevsky plane by a subgroup of the modular group.

IV. NEW EXAMPLES OF THE INTEGRABLE QUANTUM PROBLEMS WITH MAGNETIC FIELD

Let us consider any surface M^2 with integrable quantum geodesic problem

$$L\psi=\lambda\psi,$$

where $L=-\Delta_h$ and Δ_h is the Laplace–Beltrami operator on M^2. By definition the integrability means that there exists an integral, which is another differential operator F commuting with L: $[F,L]=0$ and having an independent highest symbol. We have shown [see (16)] that L can be factorized $L=D^*D$ and the new operator $\tilde{L}=DD^*$ has the magnetic field $B=\pm K$ (K is the Gaussian curvature) and the potential $U=K$. We claim that this new operator is also integrable. Indeed, consider the differential operator

$$\tilde{F}=DFD^*, \tag{35}$$

Then

$$\tilde{L}\tilde{F}=DD^*DFD^*=DLFD^*=DFLD^*=DFD^*DD^*=\tilde{F}\tilde{L},$$

i.e., $\tilde{F}$ commutes with $\tilde{L}$. It is easy to check that if the highest symbol of F is independent of the highest symbol of L, then the same is true for $\tilde{F}$ and $\tilde{L}$. The intertwining relations

$$\tilde{L}D=DL \quad \text{and} \quad D^*\tilde{L}=LD^*$$

establish isomorphism between the two spectral problems

$$L\psi=\lambda\psi \quad \text{and} \quad \tilde{L}\tilde{\psi}=\lambda\tilde{\psi}$$

for any $\lambda\neq 0$: $\tilde{\psi}=D\psi$, $\psi=D^*\tilde{\psi}$. For $\lambda=0$ the situation is described by the Riemann–Roch formula:

$$\dim \mathrm{Ker}\, L-\dim \mathrm{Ker}\ \tilde{L}=1-g. \tag{36}$$

In particular, for the sphere S^2 we have $g=0$,

$$\dim \mathrm{Ker}\, L=1, \quad \dim \mathrm{Ker}\, \tilde{L}=0.$$

This means that the ground state of $\tilde{L}$ has the energy which is equal to the minimal positive eigenvalue of L: if Spec $L=\{\lambda_0=0, \lambda_1,\lambda_2,\dots\}$, then Spec $\tilde{L}=\{\lambda_1,\lambda_2,\dots\}$.

For the torus T^2 we have $g=1$ and

$$\dim \mathrm{Ker}\, L=\dim \mathrm{Ker}\, \tilde{L}=1$$

so that

$$\mathrm{Spec\,L}=\mathrm{Spec}\,\tilde{L}.$$

This is true for all the values of quasi-momenta, i.e., for the whole Bloch spectrum. Notice for the torus the total magnetic flux of $\tilde{L}$ is zero.

We do not know any integrable Laplace–Beltrami operators on a surface of genus $g\geqslant 2$. For the corresponding classical problem about geodesics on M^2 there exists a rigorous proof that there are no such metrics (see Ref. 23).

Theorem 4: *Let M^2 be any surface such that the corresponding quantum geodesic problem $-\Delta_h\psi=\lambda\psi$ is integrable. Then the Schrödinger operator $\tilde{L}$ on M^2 with magnetic field $B=\pm K$ and potential $U=K$, K is the Gaussian curvature of M^2, is integrable, too, and has the same spectrum as $L=-\Delta_h$ with the only possible exception at $\lambda=0$.*

Example: Consider an ellipsoid M^2,

$$\frac{x^2}{a^2}+\frac{y^2}{b^2}+\frac{z^2}{c^2}=1,$$

with the metric induced from $\mathbf{R}^3$. The geodesic problem on M^2 has been solved by Jacobi who showed that it can be integrated by separation of variables. The same is true for the corresponding quantum problem. Gaussian curvature of M^2 has the form

$$K=(abc)^{-2}\left(\frac{x^2}{a^4}+\frac{y^2}{b^4}+\frac{z^2}{c^4}\right)^{-2},$$

so we can claim that the Schrödinger operator $\tilde{L}$ on M^2 with the magnetic field

$$B=(abc)^{-2}\left(\frac{x^2}{a^4}+\frac{y^2}{b^4}+\frac{z^2}{c^4}\right)^{-2}$$

and the potential

$$U=-(abc)^{-2}\left(\frac{x^2}{a^4}+\frac{y^2}{b^4}+\frac{z^2}{c^4}\right)^{-2}$$

is integrable and $\mathrm{Spec}\, L=\mathrm{Spec}\,\tilde{L}\cup\{0\}$. Notice that the order of the additional quantum integral $\tilde{F}=DFD^*$ is 4, since the order of F is known to be 2.

Remark: We do not claim that that the minimal order of the additional integral is 4. On the contrary, in this case one can show that there exists an additional integral of order 2. It would be interesting to investigate the corresponding classical mechanical problem of motion on the ellipsoid in this special magnetic field. We conjecture that it is nonintegrable.

This example can be generalized in the following way. Consider any surface M^2 with the Liouville metric

$$ds^2=g_{11}du^2+g_{22}dv^2,\quad g_{11}=\frac{u-v}{f},\quad g_{22}=\frac{v-u}{g},$$

where $f(u)$ and $g(v)$ are arbitrary functions of the specified arguments. Its Gaussian curvature is expressed by the formula

$$K=\frac{f-g}{2(u-v)^3}-\frac{f'+g'}{4(u-v)^2}.$$

The corresponding Laplace–Beltrami operator

$$\Delta_h=\sqrt{g^{11}g^{22}}\partial_u\frac{g^{11}}{\sqrt{g^{11}g^{22}}}\partial_u+\sqrt{g^{11}g^{22}}\partial_v\frac{g^{22}}{\sqrt{g^{11}g^{22}}}\partial_v$$

commutes with the second-order operator

$$F=v\sqrt{g^{11}g^{22}}\partial_u\frac{g^{11}}{\sqrt{g^{11}g^{22}}}\partial_u+u\sqrt{g^{11}g^{22}}\partial_v\frac{g^{22}}{\sqrt{g^{11}g^{22}}}\partial_v,$$

so that variables can be separated both in the classical and quantum cases. So, we can claim that the Schrödinger operator with magnetic field $B=\pm K$ and the potential $U=K$ is integrable on any Liouville surface.

As a degenerate case of this construction one can get the surfaces of revolution in R^3 with the metric

$$ds^2=\rho(z)^2d\varphi^2+(1+\rho'(z)^2)dz^2.$$

In that case the Gaussian curvature is given by the formula

$$K=\frac{\rho'\rho''}{\rho(1+(\rho')^2)^2}.$$

We would like to mention that there exist the intertwining relations between two Schrödinger operators which are not related to any factorization of the operators (see Ref. 24 for some examples). We will present here another example of this type modifying the previous analysis ofthe Dirac monopole. Recall that the operator L_N of the Dirac monopole on the unit sphere given by (27),

$$L_N=-(1+z\overline{z})^2\partial\overline{\partial}-Nz(1+z\overline{z})\partial+N\overline{z}(1+z\overline{z})\overline{\partial}+N^2(1+z\overline{z}),$$

satisfies the interwining relations (28),

$$L_{N+1}D_N=D_NL_N,$$

where

$$D_N=(1+z\overline{z})\overline{\partial}+Nz.$$

It can be readily verified that the modified operators $\tilde{L}_N$ given by

$$\tilde{L}_N=L_N-\tfrac{1}{4}P^2-(N+1)P,\quad \tilde{L}_{N+1}=L_{N+1}-\tfrac{1}{4}P^2-NP$$

satisfy the same intertwining relations

$$\tilde{L}_{N+1}\tilde{D}_N=\tilde{D}_N\tilde{L}_N,$$

where the modified intertwining operator $\tilde{D}_N$ is of the form

$$\tilde{D}_N=D_N+\frac{\varphi}{1+z\overline{z}},$$

Here φ is a quadratic polynomial in z:

$$\varphi=q+pz-\overline{q}z^2,\quad p\in R,\quad q,\overline{q}\in C,$$

and P is given by the formula

$$P=\varphi'-\frac{2\overline{z}\varphi}{1+z\overline{z}}=p\frac{1-z\overline{z}}{1+z\overline{z}}-2\frac{\overline{q}z+q\overline{z}}{1+z\overline{z}}.$$

Geometrically, P represents the restriction to the sphere S^2 of an arbitrary linear function from the ambient space R^3. Without any loss of generality we may assume $q=\overline{q}=0$ (by appropriately choosing the axis of stereographic projection), so $P=p\,(1-z\overline{z})/(1+z\overline{z})$.

In particular, for $N=-1$ we have the intertwining relation between the Dirac monopole operator with charge 2 in the potential $U=-\frac{1}{4}P^2$ and the usual Laplace–Beltrami operator with the additional potential $V=-\frac{1}{4}P^2+P$.

One can show that this construction actually gives all the potential deformations of the intertwining relations (28).

V. LAPLACE TRANSFORMATIONS ON A CURVED SURFACE AND QUASI-CYCLIC CHAINS

Let L be any Schrödinger operator with magnetic field B and potential U:

$$L=-4h^2\nabla\overline{\nabla}+(U+B)=-4h^2\overline{\nabla}\nabla+(U-B).$$

In general none of these forms is pure factorizable but on the level $\lambda=0$: $L\psi=0$ we still can do the transformation

$$\tilde{\psi}=\nabla\psi \quad \text{or} \quad \tilde{\psi}=\overline{\nabla}\psi.$$

In particular, if

$$L\psi=[-4h^2\overline{\nabla}\nabla+(U-B)]\psi=0$$

and $\tilde{\psi}=\nabla\psi$, we have

$$\overline{\nabla}\tilde{\psi}=\frac{U-B}{4h^2}\psi$$

and therefore

$$\tilde{\nabla}\overline{\nabla}\tilde{\psi}=\frac{U-B}{4h^2}\tilde{\psi},$$

where $\tilde{\nabla}$ satisfies the relation

$$\tilde{\nabla}\frac{U-B}{4h^2}=\frac{U-B}{4h^2}\nabla$$

implying

$$\tilde{\nabla}=\nabla-\ln(U-B)_z+(\ln h^2)_z. \tag{37}$$

Thus $\tilde{\psi}=\nabla\psi$ satisfies the new Schrödinger equation $\tilde{L}\tilde{\psi}=0$, where

$$\tilde{L}=-4h^2\tilde{\nabla}\overline{\nabla}+(U-B)=-4h^2\tilde{\nabla}\overline{\nabla}+(\tilde{U}+\tilde{B}). \tag{38}$$

The new magnetic field is

$$\tilde{B}=2h^2[\tilde{\nabla},\overline{\nabla}]=B+2h^2(\ln(U-B))_{z\bar{z}}-4h^2(\ln h)_{z\bar{z}}=B+\tfrac{1}{2}\Delta_h(\ln(U-B))-K, \tag{39}$$

where $\Delta_h=4h^2\partial\overline{\partial}$ is the Laplace–Beltrami operator on M^2, and K is the Gaussian curvature. The new potential is

$$\tilde{U}=U-B-\tilde{B}=U-[2B+\tfrac{1}{2}\Delta_h(\ln(U-B))-K]. \tag{40}$$

The formulas (37)–(40) define correctly the Laplace transformation for the Schrödinger operators on a curved surface. The only difference with the standard formulas in the flat case (see, e.g., Ref. 6) is the additional Gaussian curvature term.

Following Ref. 6 let us call the chain of Laplace transformations

$$\begin{aligned} B_{k+1}&=B_k+\tfrac{1}{2}\Delta_h(\ln(U_k-B_k))-K,\\ U_{k+1}&=U_k-B_k-B_{k+1}=U_k-\Big[2B_k+\tfrac{1}{2}\Delta_h(\ln(U_k-B_k))-K\Big], \end{aligned} \tag{41}$$

$k=0,\ldots,N$, *quasi-cyclic* if both the initial and final Schrödinger operators are factorizable, possibly at the different energy levels:

$$U_0+B_0=0, \quad U_N+B_N=U_{N-1}-B_{N-1}=-c, \tag{42}$$

where $c>0$ is a constant.

As well as in the flat case,[6] the last operator L_N has two ''integrable'' levels: $L_N\psi_0=0$ and $L_N\psi_c=-c\psi_c$. Indeed, ψ_0 can be found as the result

$$\psi_0=\nabla_{N-1}\nabla_{N-2}\ldots\nabla_0\psi$$

of the Laplace transformations applied to the solutions of the initial equation $L_0\psi=0$, which is equivalent to

$$\overline{\nabla}_0\psi=0, \tag{43}$$

while ψ_c are the ground states of the operator $L_N=-4h^2\nabla_N\overline{\nabla}_N-c$ satisfying the equation

$$\overline{\nabla}_N\psi=0. \tag{44}$$

Obviously we should assume that solutions of both (43) and (44) do exist, which imposes some global assumptions on the magnetic field. Let us discuss these assumptions.

First of all, let us notice that the magnetic charge $b=(1/2\pi)\int_{M^2}Bd\sigma$ (which should be integer because of the quantization condition) changes under Laplace transformations according to the formula

$$\tilde{b}=b+2g-2$$

as it follows from (39) and the Gauss–Bonnet formula. After N steps we have $b_N=b_0+2N(g-1)$. Also from (41) we have

$$\int_{M^2}(U_k+B_k)d\sigma=\int_{M^2}(U_{k-1}-B_{k-1})d\sigma=\int_{M^2}(U_{k-1}+B_{k-1})d\sigma-4\pi b_{k-1}.$$

Since $U_0+B_0=0$ it follows that

$$\frac{1}{2\pi}\int_{M^2}(U_N+B_N)d\sigma=-\frac{1}{2\pi}\int_{M^2}cd\sigma=-2Nb-N(N-1)(2g-2),$$

so we have the relation

$$c\frac{A(M^2)}{2\pi}=2Nb_0+N(N-1)(2g-2), \tag{45}$$

where $A(M^2)=\int_{M^2}d\sigma$ is the area of M^2. For the sphere we have $c=Nb_0-N(N-1)$, for the torus $cA(M^2)=4\pi Nb_0$, and for a surface of genus $g>1$ the relation $c(2g-2)=2Nb_0+N(N-1)(2g-2)$.

This determines the constant c in the quasi-cyclic chain if we know the magnetic charge b_0 of the first operator and therefore imposes a quantization condition on c since b_0 is an integer. In terms of this integer b_0 the sufficient conditions for the equations (43) and (44) to have a solution have the form (see Sec. III)

$$b_0>g-1, \quad b_0+2N(g-1)>g-1.$$

For the topological sphere S^2 this is equivalent to the inequality $b_0>2N-1$, for the torus this simply means that b_0 is positive, and for a surface of genus $g>1$ we have just the first inequality $b_0>g-1$.

Theorem 5: *Let $U_k, B_k, k=0,1,\ldots,N$, satisfy the quasi-cyclic chain (41) on a curved surface M^2 and let the magnetic charge of the first operator b_0 satisfy the conditions described above. Then the last operator of the chain L_N has two known energy levels independent of the Aharonov–*

Bohm fluxes: the ground state $\lambda=-c$ *and* $\lambda=0$. *The corresponding eigenfunctions can be found from the solutions of the first order equations (43) and (44) and for a large* b_0 *form the spaces of the dimensions* $b_0+(2N-1)(g-1)$ *for* $\lambda=-c$ *and* b_0-g+1 *for* $\lambda=0$ *respectively*.

Example 1: Quasi-cyclic chains of length $N=1$:

$$U_0+B_0=0,$$

$$U_1+B_1=U_0-B_0=-c$$

implies that $U_0=-B_0=-c/2$ are constants, so that L_0 is the Landau operator on a curved surface M^2. Notice that

$$B_1=B_0+\tfrac{1}{2}\Delta_h(\ln(-c))-K=B_0-K,$$

$$U_1=U_0-2B_0+K=K-3B_0,$$

so that in this case the Laplace transformation coincides with one step of the factorization procedure (17): $(B_0,-B_0)\to(B_0-K,K-3B_0),B_0=c/2$. Thus in this case we claim that the Schrödinger operator with the magnetic field $B=c/2-K$ and the potential $U=K-3c/2$ has two lowest energy levels known: $\lambda=-c$ and $\lambda=0$ provided the quantization and positivity conditions for c are satisfied.

Example 2: Quasi-cyclic chains with $N=2$:

$$U_0+B_0=0\Leftrightarrow U_0=-B_0;$$

$$B_1=B_0+\tfrac{1}{2}\Delta_h(\ln B_0)-K,\quad U_1=U_0-B_0-B_1=-2B_0-B_1;$$

$$U_2+B_2=U_1-B_1=-2B_0-2B_1=-c.$$

Thus we have the following relation for the magnetic field B_0:

$$2B_0+\frac{1}{2}\Delta_h(\ln B_0)-K=\frac{c}{2}$$

or

$$\Delta_h(\ln B_0)=c+2K-4B_0,$$

which, after introducing $\varphi=\ln B_0$, takes the form

$$\Delta_h\varphi=c+2K-4e^{\varphi}. \tag{46}$$

When $K=0$ this reduces to the equation from Ref. 6.

As well as in the flat case, any solution of (46) determines a Schrödinger operator in the magnetic field with two integrable levels.

Remark: When $c=0$, Eq. (46) reduces to

$$\Delta_h\varphi=2K-4e^{\varphi},$$

which is a natural analog of the well-known Liouville equation for a curved surface. It can be transformed into the standard Liouville equation $\tilde{\varphi}_{z\bar{z}}=-e^{\tilde{\varphi}}$ by a substitution $\varphi=\tilde{\varphi}+2\ln h$. When $c\neq 0$ the equation (46) is probably nonintegrable already in the flat case.

ACKNOWLEDGMENTS

Our interest to the quantum problems with magnetic fields was initiated by S. P. Novikov to whom we would like to express a special gratitude. We are grateful also to Nick Manton and John Samson for useful and stimulating discussions and to A. Macfarlane, R. Seiler, and F. Williams for sending us the copies of their papers which appeared to be very helpful. Finally we would like to thank the referee for the very useful comments. This research has been partially supported by EPSRC (Grants Nos. GR/M69548 and GR/N30941).

JOURNAL OF MATHEMATICAL PHYSICS VOLUME 42, NUMBER 2 FEBRUARY 2001

Borel summable solutions to one-dimensional Schrödinger equation

Stefan Giller[a] and Piotr Milczarski[b]
Theoretical Physics Department II, University of Łódź, Pomorska 149/153, 90-236 Łódź, Poland

(Received 7 December 1999; accepted for publication 12 October 2000)

It is shown that so called fundamental solutions the semiclassical expansions of which have been established earlier to be Borel summable to the solutions themselves appear also to be the unique solutions to the one-dimensional (1D) Schrödinger equation having this property. Namely, it is shown in this paper that for the polynomial potentials the Borel function defined by the fundamental solutions can be considered as the canonical one. The latter means that any Borel summable solution can be obtained by the Borel transformation of this unique canonical Borel function multiplied by some $\hbar$-dependent and Borel summable constant. This justifies the exceptional role the fundamental solutions play in 1D quantum mechanics and completes the relevant semiclassical theory relied on the Borel resummation technique and developed in our other papers. © *2001 American Institute of Physics.* [DOI: 10.1063/1.1331099]

I. INTRODUCTION

The semiclassical approximation is one of the most widely used approximate methods in physics, particularly, in quantum mechanics. In fact it is not limited only to pure power series expansions in the Planck constant $\hbar$ but it is used also in all problems which can be formulated semiclassically. The method can be applied in this way to, say, the quartic oscillator perturbation theory from the one hand[1,2] and to a variety of problems with so called large-N expansions from the other.[3–5] Therefore, independently of the expansion parameter we shall consider all such asymptotic series expansions as semiclassical.

The method can be stated in the Schrödinger wave function formulation of quantum mechanics[6,7] as well as in the Feynman path inegral form of the latter.[8,9] Its main ingredient as the approximation method is to represent considered quantities by a limited number of first terms of the corresponding infinite series expansions, knowing usually that the series is typically asymptotic, i.e., divergent. Therefore, contrary to the case of convergent series, such a representation of the expanded quantities is of a rather limited value.

First, it cannot be done arbitrarily accurate by enlarging a number of kept terms, i.e., such an approximation can be only the best one in which the case a finite rest is exponentially small (in the parameter of the expansion) in comparison with the main contribution.

Second, it is just these exponentially small differences which can become dominating in other domains of the expansion parameter being arbitrarily close to the original one, i.e., such a finite representation of quantities by their corresponding asymptotic series are strongly limited to the original domain and it cannot give any information about the analytic properties of the quantities considered as functions of the expansion parameter. In particular this finite sum cannot be continued analytically outside the original domain of obtaining it.

The latter means that the considered quantities cannot be recovered in some simple way by the knowledge of a finite number of terms of their semiclassical expansions even if the series are

[a]Electronic mail: sgiller@krysia.uni.lodz.pl
[b]Electronic mail: jezykmil@krysia.uni.lodz.pl

abbreviated at their least terms. (In the latter case the approximation is considered to be best.) In fact these analytic properties are determined rather by the behavior of so called large order terms of the series. It is just the properties of these large order terms (considered as functions of their order) which allow us actually to reconstruct quantities represented by such semiclassical series. In particular if these terms grow with their order not faster than factorially then the Borel method of summation of the diverging series can be used in such cases. We shall call such semiclassical series Borel summable.

In the case of the Borel summable semiclassical expansions the Borel method of summation can be used in the following way.

First the Borel function is determined approximately after the knowledge of a limited number of first terms of the asymptotic series expansion of the considered quantity. Namely, by its definition the approximate Borel function is obtained as a sum of these known first terms divided by the corresponding factorials. The sum represents in this way the abbreviated Taylor series expansion corresponding to the exact Borel function. (The latter is obtained if all the terms of the asymptotic series are used to construct the Taylor series in the above way.) The last series has a finite radius of convergence and therefore an additional knowledge even approximate of the singularity structure of the corresponding Borel function is still necessary for an approximate recovery of this function from its abbreviated Taylor series. This knowledge can be extracted to the known extent from the detailed knowledge of the large order behavior of the considered semiclassical series. Having (or assuming) however this knowledge a function with the desired singularity structure can be constructed and its Taylor series expansion can be compared with the known abbreviated Taylor series so that the free parameters of the assumed singularities can be determined. Finally by the Borel transformation of the Borel function the original quantity is reproduced approximately in this way.[4]

The above reproduction can still be performed in the spirit of asymptotic expansions and on different levels of accuracy. The lowest level is obtained when the Borel integral is substituted by its best asymptotics. It means that the quantity considered is represented again by a finite sum a definite number of first terms of which coincide exactly with the original terms used to construct the (approximate) Borel function. However this sum can now contain many more terms since it ends on the least term of the asymptotic series corresponding to the Borel integral. Therefore it can approximate the considered quantity much better than the sum of the original terms with which the method has started.

However, since the method contains still additional information about the singularity structure of the Borel function then one step further can be done in getting a still better level of accuracy by extracting from the Borel integral so called exponentially small contributions. Such computations are known as the hyperasymptotic ones.[10,11] The finite semiclassical sum is then completed by the exponentially small contributions the forms and numbers of which are determined by the known (assumed) singularity structure of the Borel function.[12] The latter means that the Borel summability allows us to realize the *principle of resurgence*, i.e., to recover the information contained in the divergent tails of the semiclassical series.[10,12–17]

It should be noted also, however, that the exponentially small contributions are of their own importance since in many cases of quantities considered these contributions are dominant. Among the latter cases the most well known one is the difference between the energy levels of different parities in the symmetric double well.[6] But these are also the cases of transition probabilities in the tunnelling phenomena[6] or their adiabatic limits in the time-dependent problem of transitions between two (or more) energy levels (see Refs. 18, 19 and references cited therein) or the exponential decaying of resonances in the weak electric field (see Refs. 20, 21 and references cited therein).

The applicability of the Borel resummation to the semiclassical expansions in quantum mechanics has been proved by many authors.[22–24] Particularly, the 1D quantum mechanics offers a possibility of constructing a full semiclassical theory relied on the Borel resummation.[1,12,25] Namely, several years ago one of the authors of the present paper discovered[1] that for a large family of analytical potentials including all the polynomial ones there are solutions to a 1D

stationary Schrödinger equation for which their well defined semiclassical expansions are Borel summable to the solutions themselves. These solutions appearing for polynomial potentials in a finite number were called fundamental because of their completeness for solving any one-dimensional problem.[5] Their Borel summability property played an essential role in many of their applications.[1] In particular this property allowed us to prove the Borel summability of energy levels for most of the polynomial potentials.

On the other hand it is easy to construct solutions to the Schrödinger equation (in fact, infinitely many of them) with well defined Borel summable semiclassical expansions but with results of such Borel resummations not coinciding with the initial solutions generating the series. However the results of the Borel resummations are again solutions to the Schrödinger equation since in general each successful Borel resummation of any semiclassical series always leads to some solution to the Schrödinger equation.

In this paper we want to demonstrate an exceptional role the fundamental solutions mentioned above play with respect to the Borel summability property showing that they provide a general scheme for a construction of Borel summable solutions to the 1D stationary Schrödinger equation at least for polynomial potentials. A main ingredient of such a scheme is an observation that the Borel function of some fundamental solution is not only such a function for any other fundamental solution but it is also a Borel function allowing us to construct any Borel summable solution to a given 1D Schrödinger equation with polynomial potential.

The latter conclusion means that in all the semiclassical problems in 1D quantum mechanics in which the Borel resummation method is to be applied the fundamental solutions should be used preferably.

Our way of considering the problem of the Borel summability in 1D quantum mechanics makes use of the global features of the fundamental solutions and the Stokes graphs related to them and as such is to some extent complementary to the way utilized by Delabaere *et al.*[13,14] making use of rather local properties of the considered quantities.

Our method can be also used to analyze the adiabatic limits considered by Joye *et al.*[18] at least in the case of two energy levels.[26] The cases of several levels need, however, a generalization of our method since these cases are described by systems of the linear equations in numbers larger than two.

To make the original results of our paper more transparent we have formulated them in many places in the forms of theorems or lemmas equipped with the corresponding proofs. However we do not consider our paper to pretend to a full formal mathematical rigor supposing most of the presented ideas to be sufficiently obvious and clear by presented proofs or when confronted with our earlier papers or with the papers of other authors mentioned.

The paper is organized as follows.

In the next section we remind a construction and basic properties of the fundamental solutions and Borel functions corresponding to them as well.

In Sec. III we show that the Borel functions corresponding to different fundamental solutions are only different branches of the same unique Borel function and can be recovered by the Borel transformations performed along suitably chosen paths on the ''Borel plane.'' We show also here that there are two ways of integrations in the Borel plane providing us with the Borel summable solutions to the Schrödinger equation which, on their own, coincide each, up to $\hbar$-dependent multiplicative constants, with the corresponding fundamental solutions.

In Sec. IV we consider in some detail a general expression for the semiclassical expansions to the Schrödinger equation and introduce there also their standardized forms. We point out in this section an essential difference between the forms of the latter for the Borel summable and non-summable quantities.

In Sec. V we show the existence almost at each point of the x-plane two pairs of the base solutions to the Schrödinger equation with well defined Borel summable semiclassical asymptotic but not summed to the solutions themselves. The semiclassical expansions of the solutions considered in this section and their Borel resummations are a particular illustration of our main thesis that a result of any such a resummation is always some fundamental solution.

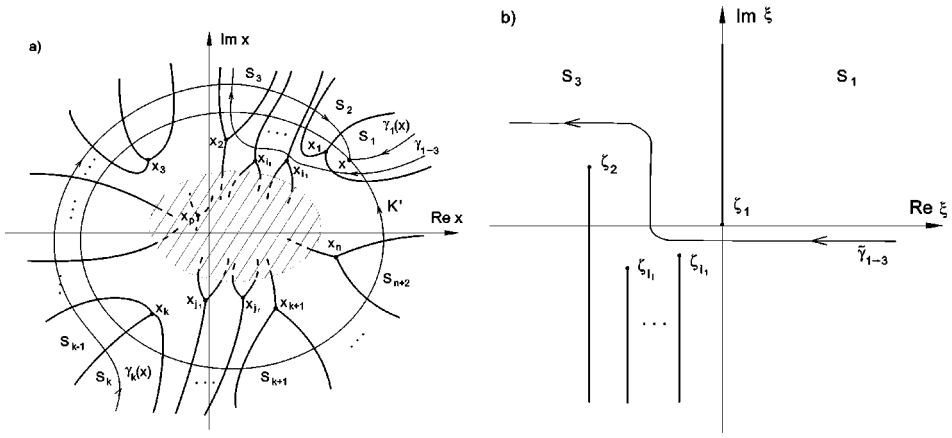

FIG. 1. (a) A general form of the Stokes graph for the polynomial potential discussed in Sec. II. (b) The ξ-variable map of the Stokes graph of (a) containing the sectors S_1 and S_3.

In Sec. VI we generalize the results of Sec. IV and show that the Borel function defined by the fundamental solutions can be considered as canonical in a sense that up to a multiplicative $\hbar$-dependent constant any Borel summable solution to the Schrödinger equation can be obtained by the Borel transformation of this canonical Borel function. This means that each Borel summable solution has to be essentially some of the fundamental solutions.

Section VII is a discussion of the results of the paper.

II. FUNDAMENTAL SOLUTIONS TO 1D STATIONARY SCHRÖDINGER EQUATION

Let us remind shortly basic lines in defining fundamental solutions.[1,5]

A set of fundamental solutions is attached in a unique way to a so called Stokes graph corresponding to a given polynomial potential $V(x)$ of the nth degree. Each Stokes graph is a collection of lines (Stokes lines) in the complex x-plane which are a loci of points where the real parts of action functions defined by the following n integrals:

$$W_i(x,E)=\int_{x_i}^{x}\sqrt{q(y,E)}dy,$$
$$q(x,E)=2V(x)-2E, \tag{1}$$

vanish. In (1) E is the energy of the system and x_i, $i=1,2,\ldots,n$, are roots of $q(x)$.

The fundamental solutions are defined in infinite connected domains called sectors with boundaries of the latter consisting of Stokes lines and x_i's; see Fig. 1(a).

In a sector S_k a corresponding fundamental solution ψ_k to the Schrödinger equation:

$$\psi''(x)-\hbar^{-2}q(x)\psi(x)=0, \tag{2}$$

has Dirac's form

$$\psi_k(x)=q^{-1/4}(x)\cdot e^{(\sigma_k/\hbar)\,W_k(x)}\cdot\chi_k(x), \tag{3}$$

with x_k lying at the boundary of S_k and with a sign $\sigma_k(=\pm 1)$ [which we shall call a *signature* of the solution (3)], chosen in such a way as to have

$$\Re(\sigma_k W_k(x))<0. \tag{4}$$

The amplitude factor $\chi_k(x,\hbar)$ in (3) has the following Fröman and Fröman's form:[27]

$$\chi_k(x,\hbar)=1+\sum_{n\geqslant 1}\left(\frac{\sigma_k\hbar}{2}\right)^n\int_{\infty_k}^{x}dy_1\int_{\infty_k}^{y_1}dy_2\ldots\int_{\infty_k}^{y_{n-1}}dy_n\omega(y_1)\omega(y_2)\ldots\omega(y_n)$$
$$\times(1-e^{-(2\sigma_k/\hbar)(W_k(x)-W_k(y_1))})(1-e^{(-2\sigma_k/\hbar)(W_k(y_1)-W_k(y_2))})$$
$$\cdots(1-e^{(-2\sigma_k/\hbar)(W_k(y_{n-1})-W_k(y_n))}), \tag{5}$$

with

$$\omega(x)=\frac{1}{4}\frac{q''(x)}{q^{3/2}(x)}-\frac{5}{16}\frac{q'^2(x)}{q^{5/2}(x)}=-q^{-1/4}(x)(q^{-1/4}(x))'', \tag{6}$$

and with integration paths in (5) chosen to be canonical,[1,5] i.e., on such paths the following condition is satisfied:

$$\sigma_k\Re(W_k(y_j)-W_k(y_{j+1}))\geqslant 0, \tag{7}$$

for any ordered pair of integration variables (with $y_0=x$). The condition (7) ensures the solution (3) to vanish at the infinity ∞_k of the sector S_k.

A domain $D_k(\supset S_k)$ where $\chi_k(x)$ can be represented by (5) with the canonical integration paths is called canonical. In each D_k the following semiclassical expansion for $\chi_k(x)$ can be deduced from (5) by standard methods (see also the next section):

$$\chi_k(x,\hbar)\sim\chi_k^{\mathrm{as}}(x,\hbar)=\sum_{n\geqslant 0}\left(\frac{\sigma_k\hbar}{2}\right)^n\chi_{k,n}(x),$$

$$\chi_{k,n}(x)=\int_{\infty_k}^{x}dy\,q^{-1/4}(y)(q^{(-1/4)(y)}\chi_{k,n-1}(y))''$$
$$=\int_{\infty_k}^{x}dy_n\,q^{-1/4}(y_n)\times\left(q^{-1/4}(y_n)\int_{\infty_k}^{y_n}dy_{n-1}\,q^{-1/4}(y_{n-1})\right.$$
$$\left.\times\left(\ldots q^{-1/4}(y_2)\int_{\infty_k}^{y_2}dy_1\,q^{-1/4}(y_1)(q^{-1/4}(y_1))''\ldots\right)''\right)'', \tag{8}$$

$$n=1,2,\ldots,\quad \chi_{k,0}(x)\equiv 1.$$

What has been said above assumed a real and positive value of $\lambda\equiv\hbar^{-1}$ (we prefer to use rather λ as a more convenient variable). However when considering Borel summability properties of $\chi_k(x,\lambda)$ it is unavoidable to complexify λ. If it is done the only change in the above descriptions of properties of Fröman and Fröman solutions to the Schrödinger equation is to substitute $W(x,E)$ in the conditions (4) and (7) by $e^{i\phi}W(x,E)$ where $\phi=\arg\lambda$. Of course, the domains D_k as well as the Stokes graph itself depend then on ϕ. In particular, all the Stokes lines rotate then around the corresponding turning points x_i, $i=1,2,\ldots,n$, they emanate from by the angle $-2\phi/3$. For $\phi=\pm\pi$ the Stokes graph comes back to its initial position, i.e., a dependence of the Stokes graph on ϕ is periodic with π as its period. Such a full rotation of Stokes graph we shall call *cyclic*. We can use the cyclic rotations to enumerate all the sectors according to the order they come into each other by the subsequent cyclic rotations starting from the one chosen arbitrarily. We shall assume from now on such a convention for the sector ordering with the numbers attached to sectors increasing anticlockwise.

By a cyclic rotation a solution $\psi_k(x,\lambda)$ from a sector S_k transforms into a solution $\psi_{k-1}(x,\lambda)$ or $\psi_{k+1}(x,\lambda)$ (modulo $n+2$, the last number being the total number of sectors for a polynomial potential of the nth degree) according to whether the rotation of the Stokes graph is clockwise or anticlockwise, respectively. Of course, for a fixed x after at most two subsequent cyclic rotations

(in the same direction) the path of integration in (5) stops to be canonical if it was as such before the rotation operations. Let us note also that making, say clockwise, $n+2$ subsequent cyclic rotations a solution $\psi_k(x,\lambda)$ does not come back exactly to its initial form (3) but acquires rather an additional phase factor which in the case of even n is equal to $(-\imath)^n \exp(\lambda \sigma_k \oint_{K'} \sqrt{q(x,E)}dx)$ where the (closed) contour K' encloses (anticlockwise) all n roots of the potential $V(x)$ [see Fig. 1(a)]. In the case of odd n one needs to surround all the roots twice as much to close the corresponding path of analytical continuation of $\chi_k(x,\lambda)$ in the x-plane with the result analogous with the even case. It means of course that as a function of λ a solution $\psi_k(x,\lambda)$ branches infinitely around the points $\lambda=0,\infty$ of the λ-plane.[1]

As we have mentioned earlier it was shown in Ref. 1 that in sector S_k the series (8) can be Borel summed to $\chi_k(x,\lambda)$ itself. To be a little bit detailed it was shown in Ref. 1 that when $x \in S_k$,

(1) the size of a sector in the λ-plane where the expansion (8) is valid is larger than 2π; and

(2) the rate of grow of $\chi_{k,n}(x)$ in (8) with n is factorial.

The last property which was established by an application of the Bender–Wu formula[2] ensured that the following Borel series:

$$\sum_{n\geqslant 0} \chi_{k,n}(x) \frac{(-s)^n}{n!}, \tag{9}$$

was convergent in a circle: $|s|<|W_k(x,E)|$.

On its turn the property (1) above ensured that the series (9) define Borel functions $\tilde{\chi}_k(x,s)$ holomorphic in the half-plane: $\Re s<-\sigma_k \Re W_k(x,E)$ allowing us to recover $\chi_k(x,\lambda)$ from the series (8) by the following Borel transformation of $\tilde{\chi}_k(x,s)$:

$$\chi_k(x,\lambda)=2\lambda \int_{C_\phi} e^{2\lambda s}\tilde{\chi}_k(x,s)ds, \tag{10}$$

where C_ϕ is a half-line in the Borel half-plane $\Re s<-\sigma_k \Re W_k(x,E)$ starting at infinity and ending at $s=0$ with ϕ as its declination angle ($\pi/2\leqslant\phi\leqslant 3\pi/2$).

However, for the latter transformations to exist it is neccessary for the functions $\tilde{\chi}_k(x,s)$ to be holomorphic only in some vicinity of a ray $\arg s=\phi_0$ along which the transformation (10) can be taken.[28] Such a limiting situation appears when $\chi_k(x,\lambda)$ is continued from the sector S_k to other domains of the Stokes graph so that such a continuation generates singularities of $\tilde{\chi}_k(x,s)$ in the half-plane $\Re s<0$ close to the ray $\arg s=\phi_0$. A mechanism of such singularity generations has been described by one of the present authors.[12] Some of these singularities are fixed and the others are moving with their positions in the s-plane depending on x. The possibility to perform the Borel transformation (10) of $\tilde{\chi}_k(x,s)$ along the ray $\arg s=\phi_0$ to get $\chi_k(x,\lambda)$ disappears at the moment when two of the moving singularities which are localized close to the ray $\arg s=\phi_0$ pinch the latter. It is clear that such cases depend continuously on x, i.e., for a given ϕ_0 in the domain $D_k(\phi_0)$ of the x-plane there is a maximal domain $B_k(\phi_0)$ $(D_k(\phi_0)\supset B_k(\phi_0)\supset S_k(\phi_0))$ inside which the series (8) for $\chi_k(x,\lambda)$ is Borel summable along C_{ϕ_0} to $\chi_k(x,\lambda)$ itself. To find a boundary of $B_k(\phi_0)$ one can use Voros' technique[24] of rotating of the reduced Stokes graph (i.e., the one obtained in the limit $|\lambda|\to\infty$) with changing of $\arg\lambda$ (see also Ref. 1): when $x \in \partial B_k(\phi_0)$ the total change of $\arg\lambda$ preserving the canonicness of the integration path in (5) running from $\infty_k(\phi_0)$ to x cannot be greater than π. Let us note also that for $x\in B_k(\phi_0)$ but close to $x_0\in\partial B_k(\phi_0)$ the Borel transformation of $\tilde{\chi}_k(x,s)$ along the ray $\arg s=\phi_0$ provides us with $\chi_k(x,\lambda)$ defined for $\pi/2-\phi_0\leqslant\arg\lambda\leqslant 3\pi/2-\phi_0$.

III. PROPERTIES OF THE BOREL FUNCTIONS $\tilde{\chi}_K(x,s)$

In this section we shall establish properties of the fundamental solutions and their corresponding Borel functions not discussed in our papers quoted in the previous sections.

First let us note that we can drop the subscribe k at the Borel functions $\tilde{\chi}_k(x,s)$ because in fact all these functions define one and the same Borel function. This property is the subject of the following theorem.

Theorem 1: *Let* $\tilde{\chi}(x,s)$ *coincide with* $\tilde{\chi}_1(x,s)$ *when* $x \in S_1$ *and* $|s|<|\xi(x)|$ *and where* $\xi(x) \equiv -\sigma_1 W_1(x,E)$. *Then*

(a) $\tilde{\chi}(x,s)$ *coincides with the Borel functions* $\tilde{\chi}_k(x,s)$, $k=2,\ldots,n+2$, *corresponding to the remaining fundamental solutions*;

(b) each fundamental solution can be obtained from $\tilde{\chi}(x,s)$ *when* $x \in S_1$ *by the Borel transformation with the integration path obtained by a suitable homotopic deformation of the path* C_1 *used to recover* $\chi_1(x,\lambda)$.

Proof: The part (a) of the theorem follows directly from the definitions of the Borel functions $\tilde{\chi}_k(x,s)$ by (9). Namely, for $x \in K' \cap S_1$ while $|s|<|\xi(x)|$, we can transform the coefficients $\chi_{1,n}(x)$ defining $\tilde{\chi}(x,s)$ by the series (9) into the corresponding coefficients $\chi_{k,n}(x)$. To do it, it is enough to continue analytically the infinite limit ∞_1 of all the integrations in (8) from the sector S_1 to the sector S_k to achieve the infinity ∞_k of the sector S_k. Of course this is a deformation of the integration path $\gamma_1(x)$ in (8) into the $\gamma_k(x)$ one but this does not affect the integrations if *none* of the turning points is touched by the deformed path which is assumed and seen in Fig. 1(a). In other words such a deformation should be homotopic. Due to this operation we have, of course, $\chi_{1,n}(x) \equiv \chi_{k,n}(x), n \geqslant 1$ and, by (9) $\tilde{\chi}_k(x,s) \equiv \tilde{\chi}(x,s)$, $k=2,\ldots,n+2$.

Before going to the proof of the part (b) of the theorem let us make the following comments to the proof done so far.

First let us call as the standard paths the integration paths $\gamma_k(x)$ which appear in this way in (8) linking the infinity ∞_k, $k=2,\ldots,n+2$, with the point x, $x \in K' \cap S_1$.

Let us note further that continuing the infinite tail of the standard path by moving by the subsequent sectors around the *closed* contour K' (to close the contour K' in the case of the odd n it is necessary to round the infinity point two times) we have to come back again to the sector S_1 when crossing the ''last'' S_{n+2} one. The consistency condition which follows then from (8) demands that the integral $\oint_{K'} q^{-1/4}(x)(q^{-1/4}(x)\chi_{1,n}(x))'' dx$ should then vanish for each $n \geqslant 0$. One can easily check that it happens indeed for all the polynomial potentials.

For the factor $\chi_k(x,\lambda)$, however, as given by (5) if $k \neq 2, n+2$ the standard path is of course noncanonical [see Fig. 1(a)]. But this means merely that $\chi_k(x,\lambda)$ obtained in this way is an effect of its analytical continuation along K' from the sector S_k, where it could be initially defined, to the sector S_1. This of course means also that $\chi_k(x,\lambda)$ cannot be obtained from (10) by the integration along a half-line but rather by the corresponding integration along some more complicated path described below.

To restore, however, the Borel function corresponding to $\chi_k(x,\lambda)$ when $x \in S_k$ it is necessary only to continue $\tilde{\chi}(x,s)$ analytically by moving the point x from the sector S_1 to S_k along the contour K'. Of course at the end of this continuation the standard path linking ∞_k with the continued x is then found completely in the sector S_k being there a typical canonical path for the integrations in (5) and (8).

On the Borel plane the latter analytical continuation of $\tilde{\chi}(x,s)$ corresponds to a motion of the branch point of at $s=\xi(x)=-\sigma_1 \int_{x_1}^{x} \sqrt{q(y,E)}\,dy$ shown in Fig. 3 along the line $\tilde{K}'$ which is the image of K' on the s-Riemann surface given by the map $s=\xi(x)$. During this motion the argument of this branch point changes by $(k-1)\pi$.

Let us finish these comments of the part (a) of the theorem by noticing that this part can be proved also using the results of the discussion performed in Appendix A and Theorem 6.

The validity of the part (b) follows easily just from Theorem 6 of Appendix A. Namely, to prove this part consider first $\tilde{\chi}(x,s)$ when x is continued from the sector S_1 to the sector S_3 along the contour K' shown in Fig. 1(a) while s is kept fixed. A pattern of the first sheet of the s-Riemann surface is then shown in Fig. 10(b). To recover $\chi_3(x,\lambda)$ by (10) we have to integrate $\tilde{\chi}(x,s)$ over the negative real half-axis. Let us now move all the branch points shown in Fig. 10(b) back according to moving back the point x on the contour K' to its original position in the sector S_1. The point $s=0$ of this sheet is then left from the right. This motion causes the integration path

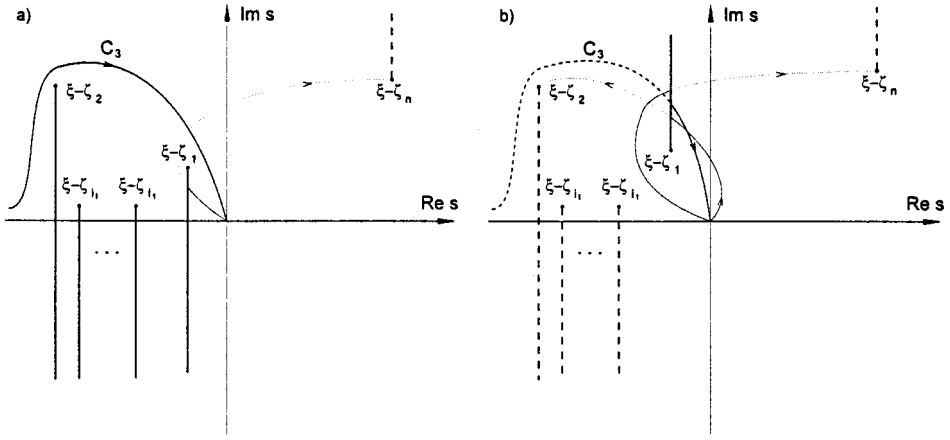

FIG. 2. (a) The position of the branch points at $\xi-\zeta_1,\ldots,\xi-\zeta_2$ and of the contour C_3 for $\tilde{\chi}(x,s)$ when $x\in K'\cap S_2$. (b) The same as in (a) after uprighting the cut emerging from the point $\xi-\zeta_1$.

just mentioned to be deformed into the one shown in Fig. 2(a). If we apply now to the cut emerging from the branch point $\xi-\zeta_1$ an operation of rotating it clockwise by π which is reversed to the unscreening operation described in Theorem 6 of Appendix A we obtain the situation drawn in Fig. 2(b). This figure shows in detail why in these positions of the considered cuts the integration in (10) along the path C_3 provides us with the factor $\chi_3(x,\lambda)$ which corresponds to the sector S_3 [i.e., the infinite integration limit in (5) coincides with ∞_3], but is continued on the x-plane to the sector S_1 along the contour K'.

Let us note further that in the positions of the cuts shown in Fig. 2(b) we can obtain the factors $\chi_1(x,\lambda)$ and $\chi_2(x,\lambda)$ as well integrating along the left and right real half-axes.

We can repeat the above analysis starting from the cut pattern shown in Fig. 11(b) and corresponding to the Borel function $\tilde{\Phi}(\xi(x),s)(\equiv\tilde{\chi}(x,s))$ continued to the sector S_k along the contour K'. In this position of ξ the factor $\chi_k(x,\lambda)$ is recovered by (10) by integrating $\tilde{\Phi}(\xi,s)$ along, say, the negative real half-axis (assuming k is odd). Next, moving the point x back to its original position in the sector S_1 and applying to the consecutive cuts emerging from the branch points at $\xi-\zeta_{i_{k-1}}$, $\xi-\zeta_{i_{k-2}},\ldots,\ \xi-\zeta_2,\ \xi-\zeta_1$ the operations reversed to the uprighting ones described in Theorem 6 of Appendix A we achieve the pattern of Fig. 3. It follows from the figure that the above operations deform merely homotopically the integration contour C_k from its original position when it coincides with the negative real half-axis to the one shown in this figure where it has a spiral form allows it to avoid all the branch points.

Let us note that as it follows from the analysis performed in Appendix A the *fixed* branch points lie on the lower sheets of the s-Riemann surface beeing *always* screened by the moving ones and therefore *not* participating in the deformation of the contour C_k.

Note also that this deformation of the contour C_k does not affect the convergence of the integral (10) since as we have shown in Ref. 12 and mentioned in Appendix A on *each* sheet of the s-Riemann surface the divergence of $\tilde{\Phi}(\xi,s)$ at infinity is at most exponential.

In this way we have however completed the proof of the theorem. QED.

It is certainly worth stressing that a net result which follows from Theorem 1 is that to obtain the subsequent $\chi_k(x,\lambda)$'s, $k=2,3,\ldots,n+2$ it is enough (according to our enumeration convention) to deform C_1 homotopically anticlockwise by making its infinite tail to rotate by the angles $\pi,2\pi,\ldots,(n+1)\pi$ so that to coincide eventually with the real half-axes, positive or negative, on the corresponding sheets, see Fig. 3. We get in this way the sequence of paths $C_2,\ C_3,\ldots,\ C_{n+2}$ integrations on which according to the formula (10) provide us with the corresponding $\chi_k(x,\lambda)$'s, $k=2,\ldots,n+2$. But these latter χ-factors are exactly the ones which were obtained in Sec. II by applying to $\chi_1(x,\lambda)$ the subsequent cyclic rotations since the latter correspond to (opposite) rotations on the λ-Riemann surface by the angles $-\pi,-2\pi,\ldots,-(n+1)\pi$. It follows however

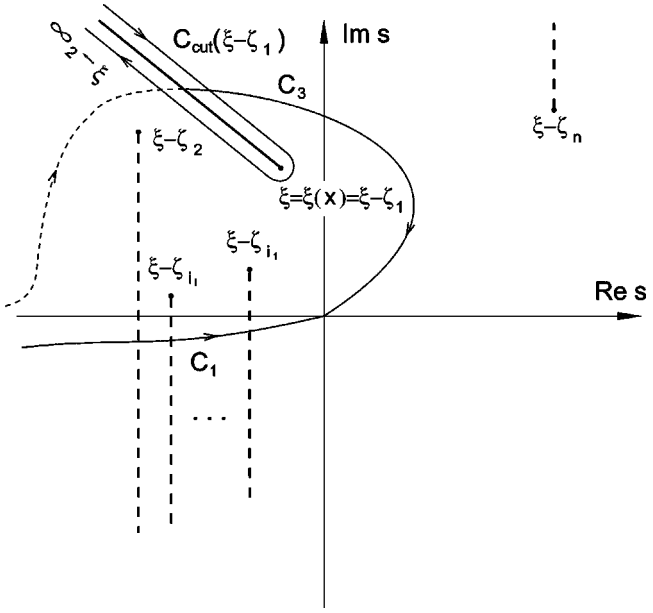

FIG. 3. The corresponding integration paths C_1, $C_2,\ldots,C_k$ in the formula (10) when $x\in K'\cap S_2$.

from the formula (10) that such cyclic rotations have to be accompanied then by the compensating rotations of the integration path on the s-Riemann surface to maintain the convergence of the formula.

We see therefore that the cyclic rotation property of transforming the fundamental solution $\psi_1(x,\lambda)$ into $\psi_k(x,\lambda)$ can be realized in the following two equivalent ways.

(1) On the x-plane by deforming the integration path $\gamma_1(x)$ in the formula (5) [when it defines the solution $\psi_1(x,\lambda)$, with $x\in S_1$] into the corresponding standard path linking the sector S_1 with the sector S_k.
(2) On the Borel plane by deforming the the path C_1 in the way described above.

We know however that after such $n+2$ cyclic rotations we do not come back to exactly the same factor $\chi_1(x,\lambda)$ but the latter acquires rather an additional phase factor which for the even degree polynomials is equal to $(-\imath)^n\exp(-\lambda\sigma_1\oint_{K'}\sqrt{q(x,E)}dx)$. Therefore deforming the path C_{n+2} once more in the above way to a path C_{n+3} and integrating $\tilde{\Phi}(\xi,s)$ along this path we get as a result again $\chi_1(x,\lambda)$ but multiplied by the phase factor just mentioned, i.e., for the even degree polynomials we have

$$\int_{C_{n+3}} e^{2\lambda s}\tilde{\chi}(x,s)ds = e^{-\lambda\sigma_1\oint_{K'}\sqrt{q(y,E)}dy-\imath n(\pi/2)}\int_{C_1} e^{2\lambda s}\tilde{\chi}(x,s)ds. \tag{11}$$

Deforming C_1 appropriately clockwise we obtain of course the corresponding integration paths $C'_{k'}$, $k'=2,3,\ldots$, providing us with $\chi_k(x,\lambda)$'s ordered in the opposite way, i.e., with $k=n-k'+4=n+2,n+1,\ldots,2$. For the path C'_{n+3} we get an identity similar to (11) but with the opposite sign at the exponent of the proportionality coefficient. This confirms that the s-Riemann surface of $\tilde{\chi}(x,s)$ is in general infinitely sheeted. The only obvious case with the finite six sheeted s-Riemann surface is provided by the linear potential.[12]

Let us discuss still in some detail the deformation procedure of the path C_1 described above.

The singularity pattern of Fig. 3 which corresponds to $x\in S_1$ shows that to fall on the corresponding sheets in order to approach eventually the chosen direction of the real axis the paths C_k

have to avoid in general the existing singularities of $\tilde{\chi}(x,s)$ on its s-Riemann surface. According to Fig. 3 such necessary deformations have to be applied for example to the path C_3 and to the subsequent ones but not to C_2.

The integration in (10) along C_3 provides us with $\chi_3(x,\lambda)$ but since $x \in S_1$ the corresponding integration path in (5) cannot then be canonical, i.e., if $|\lambda| \to \infty$ then $\psi_3(x,\lambda)$ does not behave according to its JWKB factor in (3). The obvious reason for that is just the (branch point) singularity of $\tilde{\chi}(x,s)$ at $s=\xi$ (with $\Re\xi>0$) which causes $\chi_3(x,\lambda)$ calculated in this way to diverge as $e^{2\lambda\xi}$ in the semiclassical limit.

To restore, therefore, the proper canonical behavior of $\chi_3(x,\lambda)$ in this limit given by (8) we would have to move the singularity at $s=\xi$ to the left half-plane of Fig. 3, i.e., to move the corresponding variable x from the sector S_1 to S_2 along the contour K'. This is just the procedure described in the course of the proof of the theorem.

Earlier we have distinguished the canonical paths of integrations in (5) as the ones which ensured that the χ-factors in (3) had well defined semiclassical expansions given by (8). A part of these paths penetrating the domains B_k's mentioned in the previous section ensured also that the fundamental solutions defined by them were Borel summable and these resummations were achieved by the Borel transforms of the Borel function $\tilde{\chi}(x,s)$ along half-lines running from the infinity of the Borel ''plane'' and ending at its center. Let us call *canonical* also these latter paths on the Borel ''plane.''

However we could notice above that it is possible to generalize substantially the notion of the Borel transformation by integrating in the Borel ''plane'' along the paths C_k described above and recovering in this way the fundamental solutions obtained by the deformations of the canonical paths in the formulas (5) due to the cyclic rotations of the Stokes graph.

It is therefore worthwhile distinguishing also these new types of the Borel transformation paths and these noncanonical paths in the x-''plane'' as well which appear as a result of the homotopic deformations of the canonical paths by the cyclic rotations. Namely, we shall call further such paths both on the s- and on the x-''plane'' as the *standard* paths in common.

Although it should be obvious that the Borel transformation of the Borel function $\tilde{\chi}(x,s)$ along any standard path should always provide us with the corresponding χ-factor of the Dirac form (3) of the fundamental solutions we show this fact explicitly in Appendix B.

It is a good moment of our discussion to mention an old problem of the semiclassical theory known as the connection problem.[29–32] In the context of our considerations it arises when we are interested in the semiclassical behavior of $\psi_3(x,\lambda)$ while x is kept in S_1 (i.e., $x \in S_1$). In such a case we can deform the standard path C_3 into two paths, a path C_3' surrounding the cut generated by the singularity at $s=\xi$ (see Fig. 4) and again the canonical path C_1. By multiplying (10) (with C_3 as the integration path) by $q^{-1/4}e^{-\lambda\xi}$ we obtain $\psi_3(x,\lambda)$ to be represented in this way by the following linear combination of two solutions to the Schrödinger equation (2):

$$\psi_3(x,\lambda)=\psi_1(x,\lambda)+C(\lambda)\psi_2(x,\lambda). \tag{12}$$

Of course, $\psi_1(x,\lambda)$ is generated by the C_1 part of C_3. The fact that the cut integration part of $\psi_3(x,\lambda)$ is just proportional to $\psi_2(x,\lambda)$ can be easily seen by pushing ξ to infinity along the cut which corresponds to approaching by $x(\xi)$ the infinity of the sector S_2. The cut integral (multiplied by $q^{-1/4}e^{-\lambda\xi}$) vanishes however in this limit (since $\Re\xi \to -\infty$) which proves our assertion. In other words we have

$$q^{-1/4}(x,E)e^{-\lambda\int_{x_1}^{x}\sqrt{q(y,E)}dy}2\lambda\int_{C_{\mathrm{cut}}(\xi)}e^{2\lambda s}\tilde{\chi}(x,s)ds=C(\lambda)\psi_2(x,\lambda). \tag{13}$$

It is easily seen that the last relation is independent of such critical forms of the Stokes graph as the ones corresponding to the coinciding of two (or more) turning points. However, when the

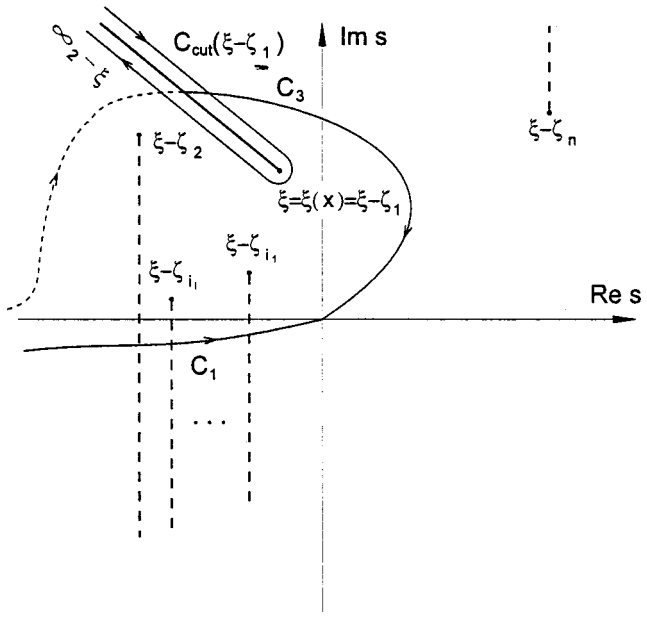

FIG. 4. The path C_3 splitted into the paths C_1 and $C_{\text{cut}}(\xi-\zeta_1)$.

Stokes graph is built only by the simple turning points then this relation can be established by the standard methods, i.e., by continuing the fundamental solutions along the canonical paths on the x-''plane,'' which gives[1,5]

$$C(\lambda)=-\imath\chi_{3\to 1}(\lambda), \tag{14}$$

where $\chi_{3\to 1}(\lambda)=\lim_{x\to\infty_1}\chi_3(x,\lambda)=\chi_{1\to 3}(\lambda)$ is calculated by (5) along the canonical path $\gamma_{1\to 3}$ [see Fig. 1(b)].

Writing further $\psi_2(x,\lambda)$ in Dirac's form (3) we get

$$\begin{aligned}\chi_2(x,\lambda)&=\imath\chi_{3\to 1}^{-1}(\lambda)e^{-2\lambda\xi}2\lambda\int_{C_{\text{cut}}(\xi)}e^{2\lambda s}\tilde{\chi}(x,s)ds\\&=\imath\chi_{3\to 1}^{-1}(\lambda)2\lambda\int_{C_{\text{cut}}(0)}e^{2\lambda s}\tilde{\chi}(x,s+\xi)ds.\end{aligned} \tag{15}$$

Taking now into account that $\chi_2(x,\lambda)$ is given by the Borel transformation along the canonical path C_2 in Fig. 4 while $\chi_{3\to 1}(\lambda)[\equiv\chi_{1\to 3}(\lambda)]$ can be obtained analogously by the integration $\tilde{\chi}_{\text{can}}(\infty_3,s)[\equiv\lim_{x\to\infty_3}\tilde{\chi}(x,s)]$ along C_1 when $\xi(x)$ in Fig. 1(b) goes from the sector S_1 to ∞_3 of the sector S_3 along the canonical path we get the following relation for $\tilde{\chi}(x,s)$ and its jump $\Delta_{s_0}\tilde{\chi}(x,s)$ through the cut emerging from the branch point $s=s_0=\xi(x)$:

$$\tilde{\chi}(x,s)=\imath\tilde{\chi}_{\text{can}}{}^{*-1}(\infty_3,s)*\Delta_0\tilde{\chi}(x,-s+\xi(x)). \tag{16}$$

The ''*'' symbols in (16) denote the convolution operations [see Appendix C, formula (56)].

One easily recognizes in (16) the fundamental solution version of the analytical bootstrap property of the Borel function $\tilde{\chi}(x,s)$ discovered by Voros.[24] It is our aim in this paper, however, to show that in the case of the polynomial potentials there are *no* other versions of the realization of the analytical bootstrap idea since in this case the Borel function $\tilde{\chi}(x,s)$ is unique (up to an irrelevant constant) being uniquely defined by the fundamental solutions.

The same comments as above are valid of course with respect to the results of the integrations along the subsequent standard paths C_k, $k=4,5,\ldots$, i.e., these paths provide us with the corresponding $\chi_k(x,\lambda)$'s calculated along the noncanonical standard paths on the x-''plane'' obtained by the continuation of the variable x from S_k to S_1 along the contour K'. Such a form does not allow us to estimate easily its semiclassical limit. To recover this limit properly we have to deform C_k's keeping its infinite tail along the appropriate real half-axis. This deformation splits C_k into C_1 or C_2 (the latter choice depends on a sign of $\Re\lambda$) and into a number of paths surrounding some cuts (the cuts have to run to the left half-planes for $\Re\lambda>0$ or to the right ones in the opposite case). Each such cut contribution represents a solution to the Schrödinger equation (see Appendix B) being proportional to some fundamental solution. The identification of these solutions can be performed by considering the limit of the latter when $\xi\to\infty$ along the appropriate cuts (or their elongations) (the solutions have to vanish in this limit) and following parallelly the corresponding paths drawn by $x(\xi)$ on the Stokes graph. Again, if the Stokes graph considered is determined only by simple turning points then a total number of the fundamental solutions engaged in the above splitting operation is limited only to those of them which can contact canonically with the sector S_1 where the variable x/ξ ($\xi=\xi(x)$) actually is and the proportionality coefficients of the cut contributions to appropriate fundamental solutions can be calculated by the standard methods.[1,5]

Let x be fixed somewhere on K' [see Fig. 1(a)].

We shall call a cut path each path surrounding a half-line cut of the s-Riemann surface running from its infinity and ending at some of its moving or fixed branch points.

Together with the result of Appendix B the net results of the above discussion can be summarized as the following two theorems.

Theorem 2: *(a) The Borel function $\tilde{\chi}(x,s)$ when Borel transformed along a standard or a cut path and multiplied by the JWKB factor always provides us with a solution to the Schrödinger equation (2) having the Dirac form (3).*

(b) The solutions we get in this way are always proportional to fundamental solutions.

(c) If a solution defined by a cut path is generated by the deformation of the standard path then if it is proportional to the fundamental solution $\psi_k(x,\lambda)$ with a proportionality constant $C_k(\lambda)$ then a jump $\Delta_{s_0}\tilde{\Phi}(\xi(x),s)$ of $\tilde{\Phi}(\xi(x),s)(\equiv\tilde{\chi}(x,s))$ through the cut generated by the branch point at $s=s_0$ is related in the following way with $\tilde{\Phi}(\xi,s)$ itself (a case of the analytic bootstrap of Voros[24]):

$$\tilde{\Phi}((-1)^{k-1}\xi(x'),s)=\tilde{C}_k(s,s_0)*\Delta_{s_0}\tilde{\Phi}(\xi,\pm s+s_0), \tag{17}$$

where the rhs of (17) is the convolution of $\tilde{C}_k(s,s_0)$ which is the Borel function corresponding to the inverse of the constant $C_k(\lambda)$ multiplied by $e^{2\lambda s_0}$ and of $\tilde{\Phi}(\xi,s)$ shifted, respectively, while $\tilde{\Phi}((-1)^{k-1}\xi(x'),s)$ denotes $\tilde{\chi}(x,s)$ continued analytically along K' from the point $x\in K'\cap S_1$ to the point $x'\in K'\cap S_k$ such that $\xi(x)=(-1)^{k-1}\xi(x')$. The ''$\pm$'' signs at the variable s in (17) takes into account that Borel integrations along the cut and the canonical path C_k^{can} to recover $\chi_k(x,\lambda)$ can go to the same (''$+$'' sign) or to the opposite (''$-$'' sign) infinities of $\Re$'s.

The existence of $\tilde{C}_k(s,s_0)$ and the holomorphicity of $\Delta_{s_0}\tilde{\Phi}(\xi(x),\pm s+s_0)$, at $s=0$, is assumed.

Proof of the theorem: The part (a) of the theorem is obvious by noticing that any Borel transformation along the standard/cut path with the Borel function $\tilde{\chi}(x,\lambda)$ defined by (9) satisfies the linear differential equation defining $\chi(x,\lambda)$'s (see Appendix B).

The part (b) of the theorem when concerning the standard paths is a repetition of the corresponding result of Theorem 1. With respect, however, to the cut paths it follows as a conclusion summarizing the discussion preceding the formulation of this theorem.

The part (c) is the direct consequence of the hypothesis of this part of the theorem written explicitly as

$$q^{-1/4}(x')e^{\sigma_k\lambda\xi(x')}2\lambda\int_{C_{\mathrm{cut}}(s_0)}e^{2\sigma\lambda s}\tilde{\Phi}(\xi(x),s)ds$$
$$=C(\lambda)q^{-1/4}(x')e^{\sigma_k\lambda\xi(x')}\chi_k(x',\lambda)$$
$$=C(\lambda)q^{-1/4}(x')e^{\sigma_k\lambda\xi(x')}2\lambda\int_{C_k^{\mathrm{can}}}e^{-2\sigma_k\lambda s}\tilde{\Phi}(\xi,s)ds, \tag{18}$$

where C_k^{can} denotes the canonical path on the Borel ''plane'' used for recovering $\chi_k(x,\lambda)$, σ_k is a signature of the latter and $\sigma=\pm 1$ is taken as $+1$ for the integration along the cut $C_{\mathrm{cut}}(s_0)$ to $-\infty$ of $\Re s$ and as -1 in the opposite case.

Since $\chi_k(x',\lambda)$ in (18) is recovered by the integration $\tilde{\Phi}(\xi(x'),s)$ along the *canonical* path C_k^{can} then it means that this latter function results as its analytical continuation from the first sheet where it determines $\chi_1(x,\lambda)$ (by the integration along a canonical path C_1 on this sheet) to the sheet considered. This continuation has to be performed along the path $\tilde{K}'$, the image of K' on the Borel ''plane,'' as long as ξ acquires the argument equal to $(k-1)\pi$ which put ξ in the position $(-1)^{k-1}\xi$ on the final sheet. This corresponds of course to a point x' on K' such that $\xi(x)=(-1)^{k-1}\xi(x')$.

Now, if $\sigma_k=\sigma$ (this case is the only one possible when s_0 is the fixed branch point) then we get the relation (17) with ''+'' at the variable s and with ''−'' in the opposite case.

This latter conclusion ends, however, the proof of the theorem. QED.

Let us note, as a comment to the part (b) of the above theorem, that the proportionality constants can be always calculated independently when all turning points of considered polynomial problems are simple. We can use then the powerful method of analytical continuation of the fundamental solutions along the canonical paths which guarantees the full control of the semiclassical properties of calculated quantities at each stage of such calculations. The considerations preceding the above theorem are the good illustration of the possibilities of the method.

Theorem 3: *The connection problem, i.e., the analytical continuation of the fundamental solutions throughout the x-plane along the contour K′ of Fig. 1(a) can be solved by performing this continuation on the Borel plane. By such a continuation the original Borel integration along the deformed path has to be split into integrations along standard and cut paths the latter emerging from the branch points of $\tilde{\chi}(x,s)$ pinching the deformed path.*

Proof: The validity of the theorem follows directly from the preceding discussion.

Another important property of the fundamental solutions which distinguishes these solutions among other possible Borel summable solutions can be formulated as the following theorem.

Theorem 4: *Let x_0 $[=x(\xi_0)]$ be an arbitrary point of the x-plane not coinciding with a root of $q(x,E)$. Then there is a (nonempty) subset $N(x_0)$ of fundamental solutions of both signatures with the following properties.*

(1) The point x_0 is canonical for every member of $N(x_0)$.
(2) Every element of $N(x_0)$ can be obtained by the formula (10) integrating along a corresponding standard path.

We shall assume $N(x_0)$ to collect all such fundamental solutions.

Proof of the theorem: The validity of this theorem can be easily seen by considering the topology of sectors with respect to the chosen x on the Riemann surface of the action variable $\xi(\equiv\xi(x))$ substituting the variable x (see Fig. 5 and Ref. 1). For real λ the Stokes lines on the surface are now parallel to imaginary axes and the sectors are left and right half-planes not containing (the images of) turning points on each sheet of the surface.[1] The λ-rotations of the Stokes graph make Stokes lines on the ξ-Riemann surface rotating around the images of the turning points preserving their parallelness.

We shall distinguish the following four cases for the position of x_0 for real λ.

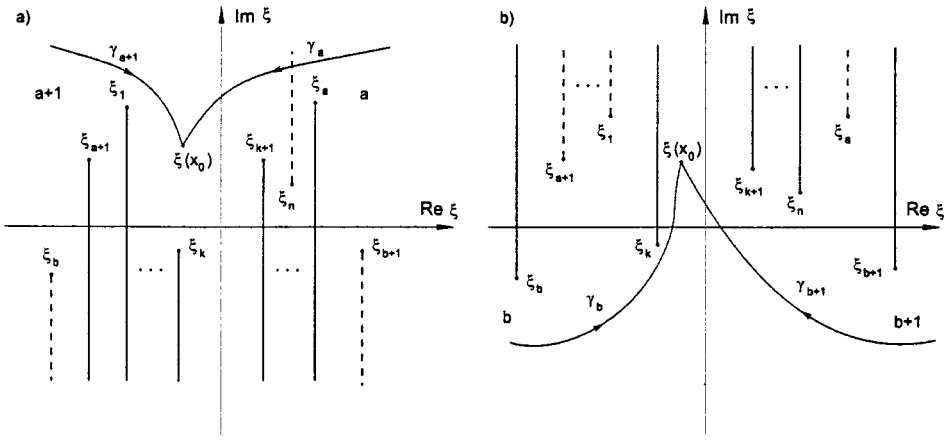

FIG. 5. (a) The sectors S_{a+1} and S_a the fundamental solutions of which communicate canonically with the point $\xi(x_0)$. (b) The sectors S_b and S_{b+1} the fundamental solutions of which communicate canonically with the *same* point $\xi(x_0)$.

(1) x_0 does not lie on any Stokes line but
   (a) x_0 belongs to some sector,
   (b) x_0 does not belong to any sector;
(2) x_0 lies on some Stokes line and
   (c) this Stokes line is finite, i.e., it emerges from some turning point and ends on the other,
   (d) this Stokes line is infinite, i.e., it emerges from some turning point and runs to infinity of the $x(\xi)$-plane.

The above possibilities exhaust of course all the possible positions of x_0 with respect to the Stokes lines.

Consider case (a) of (1).

First let us note that for real λ the Stokes lines are parallel to the imaginary axis as it is shown in Fig. 5. If x_0 is in some sector, say S_a, then obviously the fundamental solution ψ_a defined in this sector belongs to $N(x_0)$. There are however another two fundamental solutions which belong to $N(x_0)$ too. Namely, these are the two neighbors of ψ_a, i.e., ψ_{a+1} and ψ_{a-1} (according to our enumeration convention). Both of them have their signatures opposite to ψ_a. Depending on a position of x_0 in S_a there is always one of these two neighbor solutions which is Borel summable at x_0 simultaneously with ψ_a and at the same time can communicate with it canonically.

Consider next case (b) of (1).

In this case x_0 is in some infinite vertical strip on the ξ-Riemann surface (see Fig. 5) bounded from each side by two chains of Stokes lines parallel to each other. Following each of these chains of lines while keeping on the strip we find on them their extremal turning points, i.e., the ones from which Stokes lines emerge running to imaginary infinities, positive or negative. Consider such a Stokes line which bounds the strip from the right and runs to positive imaginary infinity. This Stokes line bounds simultaneously from the left a strip neighbor to the one just considered. This new strip is again bounded from the right by a chain of Stokes lines whose structure is similar to the Stokes line chains already considered. So there is again in this chain a Stokes line ending it and running to positive imaginary infinity. We can repeat this procedure of moving to the right of the ξ-''plane'' to finish eventually with a ''strip'' which is a right half-plane of the ξ-plane sheet considered. This procedure has to be finite since there is a finite number of extremal turning points met in this way due to the polynomial potential. It is clear also that this half-plane corresponds to a sector, say S_a, of the Stokes graph. The way of its finding proves that the fundamental solution ψ_a defined in it belongs to the set $N(x_0)$. Mutatis mutandis to this set belongs also the solution ψ_{a+1} corresponding to the sector S_{a+1}, the next one to S_a and having an opposite signature. By the same reasoning but moving down the ξ-sheet we find two others sectors, call them S_b and S_{b+1}, the fundamental solutions of which are both Borel summable at x_0 having of course

opposite signatures. Therefore there are at least four fundamental solutions in $N(x_0)$ for this case. Besides, within the pairs ψ_a, ψ_b and ψ_{a+1}, ψ_{b+1} both the fundamental solutions can communicate with themselves canonically and can be simultaneously Borel summable. This last result is a conclusion from the fact that these pairs of fundamental solutions are related by the cyclic rotations.

Consider now the case (c) of (2).

In this case we can consider both the sides of the Stokes line on which x_0 is placed as pieces of two strips for which this line is their bound. The strips can be identified as the wholes by the procedure similar to the one used previously. Namely, we move along a chain of Stokes lines directing to, say, the positive imaginary infinity choosing the most right Stokes line each time we meet some turning point. Continuing this motion we meet finally the last such turning point from which the most right Stokes line emerges running directly to the positive imaginary infinity. From this moment we can repeat the arguments of the previous point when concluding that we can find in the right half-plane on a certain ξ-sheet a sector, call it S_a again, a fundamental solution of which is Borel summable at x_0, i.e., this solution belongs to $N(x_0)$.

However, this case differs a little bit from the previous one by the fact that the neighbor sector ψ_{a+1} is *not* Borel summable at x_0 in the actual position of this variable. Nevertheless, if we rotate the variable λ anticlockwise by an arbitrary small angle we immediately satisfy the Watson–Sokal–Nevanlinna conditions for the Borel resummation of ψ_{a+1}. Making a cyclic rotation in the same direction we transform the last solution into ψ_a and this rotation can still be continued a little bit further. This proves that ψ_a indeed satisfies the conditions mentioned above to be Borel summable at x_0 in its actual position.

Again mutatis mutandis we can prove moving down the ξ-sheet the existence of another fundamental solution in the right half of the sheet which is Borel summable at x_0. Let us call it ψ_b.

Repeating the procedure and keeping the most left Stokes lines while moving to the imaginary infinities in both directions, positive and negative, we find still another two respective solutions ψ_d and ψ_c. Collecting them into the following pairs ψ_a, ψ_c and ψ_b, ψ_d we find that the solutions in each pair communicate canonically with each other and are Borel summable simultaneously at x_0.

In this way we have proved however our theorem. QED.

Theorem 4 is, to some extent, a generalization of Theorem 1. Namely, we have the following.

Corollary: In the assertion (b) *of Theorem 1 we can take any regular point of the* x*-plane in which we want to obtain any fundamental solution continued to this point by the cyclic rotation operations defined in Sec. II.*

Proof: Our reasoning is the following.

Theorem 4 tells us that for a given (regular) x_0 there is *always* a fundamental solution, say $\psi_a(x,\lambda)$, Borel summable at this point. This means however that the χ-factor of this solution is recovered from the Borel function $\tilde{\chi}(x,s)$ by the Borel transformation along the path C_a coinciding with the left/right real half-axis of the Borel plane. The latter plane is of course a sheet of the s-Riemann surface obtained from the one in Fig. 7 by the unscreening operation. Depending on the actual position of x_0 the representation of branch points on this sheet can be richer than in the cases considered in Theorem 1 because of the closest environment of x_0 which can be richer in turning points. This structure can be analyzed in a way similar to that in Appendix A giving a typical branch point pattern with both moving and fixed branch points on this sheet lying above or below the path C_a but allowing us to perfom the Borel transformation along the path.

We can now start to deform homotopically the path C_a exactly in the same way as we did with the path C_1 in Theorem 1 taking its infinite end and rotating it by the angles $\pm\pi$, $\pm 2\pi, \ldots,$ to appropriate positions along the left/right half-axis on the sheets corresponding to subsequent fundamental solutions starting from $\psi_{a+1}(x,\lambda)$ in the clockwise direction of the deformation or from $\psi_{a-1}(x,\lambda)$ in the opposite case. This procedure could be disturbed only when the deformed path C_a met on its way a chain of branch points elongating to infinity. This is *not* possible however since such possible chains of branch points are always screened by the moving

cuts. A good illustration of the described situation is provided by the harmonic oscillator case (see Ref. 12).

We have already mentioned in the course of the proof of Theorem 1 that the suitable deformations of the path C_1 to $C_2,\ldots,C_{n+2}$ described in this theorem restore all the fundamental solutions when $x\in S_1$ strictly corresponded to the recovering these solutions from $\psi_1(x,\lambda)$ defined in S_1 by the cyclic rotations. Exactly the same relation connects the above deformations of the path C_a with the cyclic rotations of the Stokes graph from its position just considered.

The last conclusion finishes the proof of the corollary. QED.

IV. GENERAL FORM OF SEMICLASSICAL EXPANSION FOR χ-FACTORS

Let us note that the χ-factors entering the Dirac forms (3) are the solutions of the following two second order linear differential equations obtained by the substitution (3) into the Schrödinger equation:

$$-q^{-1/4}(x)(q^{-1/4}(x)\chi(x))''+2\sigma\lambda\chi'(x)=0. \tag{19}$$

The equations (19) provide us with a general form of semiclassical expansions for the χ-factors if such expansions exists. Namely, assuming the latter we can substitute into (19) the semiclassical expansion for χ:

$$\chi(x,\lambda)\sim\sum_{n\geqslant 0}\left(\frac{\sigma}{2\lambda}\right)^n\chi_n(x), \tag{20}$$

to get the following recurrent relations for $\chi_n(x)$:

$$\begin{gathered}\chi_n(x)=C_n+\int_{x_n}^{x}q^{-1/4}(y)(q^{-1/4}(y)\chi_{n-1}(y))''dy,\quad n\geqslant 1,\\ \chi_0(x)\equiv C_0,\end{gathered} \tag{21}$$

where x_n, $n\geqslant 1$, are arbitrary chosen regular points of $\omega(x)$ and C_n, $n\geqslant 0$, are arbitrary constants. It is, however, easy to show that choosing all the points x_n to be the same, say x_0, merely redefines the constants C_n. Assuming this we get for $\chi_n(x)$,

$$\begin{gathered}\chi_n(x)=\sum_{k=0}^{n}C_{n-k}I_k(x,x_0),\\ I_0(x,x_0)\equiv 1,\\ I_k(x,x_0)=\int_{x_0}^{x}d\xi_k\,q^{-1/4}(\xi_k)\Bigg(q^{-1/4}(\xi_k)\int_{x_0}^{\xi_k}d\xi_{k-1}\,q^{-1/4}(\xi_{k-1})\\ \times\Bigg(q^{-1/4}(\xi_{k-1})\int_{x_0}^{\xi_{k-2}}d\xi_{k-2}\cdots\Bigg(q^{-1/4}(\xi_2)\int_{x_0}^{\xi_2}d\xi_1\,q^{-1/4}(\xi_1)(q^{-1/4}(\xi_1))''\Bigg)''\cdots\Bigg)''\Bigg)'',\\ k=1,2,\ldots.\end{gathered} \tag{22}$$

Substituting (22) into (20) we get finally for the expansion:

$$\chi(x,\lambda)\sim\sum_{n\geqslant 0}\left(\frac{\sigma}{2\lambda}\right)^n C_n\sum_{k\geqslant 0}\left(\frac{\sigma}{2\lambda}\right)^k I_k(x,x_0). \tag{23}$$

In this way we have proven the following lemma.

Lemma 1: An arbitrary semiclassical expansion (20) which follows from (19) can be given the form (23) with an arbitrarily chosen regular point x_0 *and arbitrary constants* C_n, $n \geqslant 0$.

We shall call (23) the standard form of the expansion (20).

Of course, for a given χ the choice of x_0 determines the constants, i.e., the latter depend on it. However, if such a χ is given a choice of x_0 cannot be arbitrary. The reasons for that are that if χ considered can be semiclassically expanded then a domain of the x-plane for such an expansion is strictly determined. Good examples of the latter statement are provided just by the fundamental solutions. Each of the latter possesses as we have discussed it in Sec. II its allowed canonical domain of the semiclassical expansion (23). Therefore each χ possesses its own domain D_χ of the existence of the corresponding semiclassical expansion χ^{as}. Such a domain can however also be empty.

Suppose D_χ is not empty and let $x, x_0 \in D_\chi$. Then we can expand χ semiclassically and this expansion has the form (23). Let us assume a little bit more about χ, namely that there is a domain $B_\chi \subset D_\chi$ in which χ is Borel summable and let $x, x_0 \in B_\chi$. Then both $\chi(x,\lambda)$ and $\chi(x_0,\lambda)$ can be restored by the Borel transformation of the corresponding Borel functions and, respectively, along the negative real half-axis (by assumption) of the Borel plane. Their semiclassical expansions (23) can be obtained then by substituting simply into the Borel integral the Borel series (9) with the respective arguments x and x_0. But it means, of course, that we can obtain $\chi^{\mathrm{as}}(x_0,\lambda)$ simply from $\chi^{\mathrm{as}}(x,\lambda)$ by putting $x = x_0$ in the latter. Doing this in (23) we see that it takes in this case the following form:

$$\chi(x,\lambda) \sim \chi^{\mathrm{as}}(x,\lambda) = \chi^{\mathrm{as}}(x_0,\lambda) \sum_{k \geqslant 0} \left(\frac{\sigma}{2\lambda} \right)^k I_k(x,x_0). \tag{24}$$

Therefore the following lemma has been proven.

Lemma 2: If $\psi(x,\lambda)$ *is a solution to the Schrödinger equation (2) given in some domain B in the Dirac form (3) with the corresponding factor* $\chi(x,\lambda)$ *having in B the standard semiclassical expansion (23) which is Borel summable in B to the factor* $\chi(x,\lambda)$ *itself then this semiclassical expansions takes in B the form (24) where* $x_0 \in B$.

The above formula shows explicitly the way of determining the series of the constants C_n in the case just discussed. However, we shall show below that in general the form (24) can not be valid, i.e., the series of constants in (23) *is not* a semiclassical expansion of $\chi(x,\lambda)$ at $x = x_0$ even if the corresponding semiclassical expansions exist in both of the points.

Nevertheless, the formula (24) can be certainly applied to the fundamental solution χ-factors $\chi_k(x,\lambda)$ with $\chi_k^{\mathrm{as}}(x,\lambda)$ and $\chi_k^{\mathrm{as}}(x_0,\lambda)$ defined by (8) when $x, x_0 \in B_k \subset D_k$, with D_k being the canonical domain of $\chi_k(x,\lambda)$. In these latter cases the formula (24) can be derived directly from (8) by noticing that

$$\chi_{k,n}(x) = \sum_{p=0}^{n} \chi_{k,p}(x_0) I_{n-p}(x,x_0), \tag{25}$$

and by multiplying both sides of (25) by $(2\sigma\lambda)^{-n}$ and summing over n (from 0 to ∞).

V. OTHER SOLUTIONS WITH WELL DEFINED BOREL SUMMABLE SEMICLASSICAL ASYMPTOTICS

In this section we shall show that at each point of the x-plane not coinciding with the root of $q(x,E)$ there are two pairs of base solutions to (19) each of which can be expanded semiclassically in some well defined domain. These expansions are Borel summable in corresponding domains although not to the solutions themselves.

A. Fröman and Fröman construction of solutions to Schrödinger equation

A construction of the solutions just mentioned is the following.[27,25]

In the x-plane we choose any point x_0 [not being a root of $q(x)$ however]. The point distinguishes a line $\Re W_k(x,E)=\Re W_k(x_0,E)$ (it is independent of $k=1,2,\ldots,n$) on which it lies so that $\Re W_k(x,E)$ increases on one side of the line and decreases on the other. On each side of the line we can define two independent solutions each having the form (3) with the following formulas for the χ-factors:[27,25]

$$\chi_1^{\sigma}(x,x_0)=1+\sum_{n\geqslant 1}\left(\frac{\sigma}{2\lambda}\right)^n\int_{x_0}^{x}d\xi_1\int_{x_0}^{\xi_1}d\xi_2\ldots\int_{x_0}^{\xi_{n-1}}d\xi_n\,\omega(\xi_1)\omega(\xi_2)\ldots\omega(\xi_n)$$
$$\times(1-e^{-2\sigma\lambda(W_k(x)-W_k(\xi_1))})(1-e^{-2\sigma\lambda(W_k(\xi_1)-W_k(\xi_2))})\cdots(1-e^{-2\sigma\lambda(W_k(\xi_{n-1})-W_k(\xi_n))}) \tag{26}$$

and

$$\chi_2^{\sigma}(x,x_0)=\frac{\sigma}{2\lambda}\frac{1}{q^{1/2}(x_0)}\Bigg[1-e^{-2\sigma\lambda(W_k(x)-W_k(x_0))}+\sum_{n\geqslant 1}\left(\frac{\sigma}{2\lambda}\right)^n\int_{x_0}^{x}d\xi_1\int_{x_0}^{\xi_1}d\xi_2$$
$$\ldots\int_{x_0}^{\xi_{n-1}}d\xi_n\,\omega(\xi_1)\omega(\xi_2)\ldots\omega(\xi_n)(1-e^{-2\sigma\lambda(W_k(x)-W_k(\xi_1))})$$
$$\times(1-e^{-2\sigma\lambda(\mathbf{W}_k(\xi_1)-W_k(\xi_2))})\ldots(1-e^{-2\sigma\lambda(W_k(\xi_n)-W_k(x_0))})\Bigg], \tag{27}$$

where $\sigma=+1$ for x on the side of increasing $\Re W_k(x,E)$ and $\sigma=-1$ in the opposite case so that all integrations in (26) and (27) run from x_0 to x along the canonical paths, finite this time. Due to that both the solutions to the Schrödinger equation obtained by multiplying the χ-factors (26) and (27) by the corresponding WKB-factors increase exponentially in the semiclassical limit.

The χ-factors of (26) and (27) satisfy the following ''initial'' conditions:

$$\chi_1^{\sigma}(x_0,x_0)=\chi_2^{\sigma'}(x_0,x_0)=1 \quad \text{and} \quad \chi_1^{\sigma'}(x_0,x_0)=\chi_2^{\sigma}(x_0,x_0)=0. \tag{28}$$

B. Semiclassical expansions for $\chi_1(x,\lambda)$ and $\chi_2(x,\lambda)$

Consider now the solutions (26) and (27) defined at a vicinity of some point x_0. We shall show below that if x can be linked with x_0 by a canonical path the solutions can be expanded semiclassically having the corresponding forms (23) where x_0 means now the ''initial'' point for the solutions.

To formulate the corresponding lemma let us first invoke Theorem 4 of the previous section to note that when x_0 is chosen then there are always at least two fundamental solutions of opposite signatures belonging to $N(x_0)$ which are Borel summable at the point x_0 and communicate with themselves canonically. Let us choose these two fundamental solutions to be $\psi_a(x,\lambda)$ and $\psi_b(x,\lambda)$.

For the solution $\psi_1(x,\lambda)$ to the Schrödinger equation (2) defined by $\chi_1(x,\lambda)$ and the fundamental solutions $\psi_a(x,\lambda)$ and $\psi_b(x,\lambda)$ we have

$$\psi_1(x,\lambda)=\alpha(x_0,\lambda)\psi_a(x,\lambda)+\beta(x_0,\lambda)\psi_b(x,\lambda), \tag{29}$$

due to the linear independence of the latter. For definiteness we shall assume further that $\sigma_{1,2}=\sigma_a=-\sigma_b=-1$ in the corresponding formulas for the solutions so that $\Re\xi(x)<\Re\xi(x_0)$ if x can be linked with x_0 by a canonical path. The coefficients α and β in (29) can be easily calculated according to the general rules described in Refs. 1 and 5, for example. We have

$$\alpha(x_0,\lambda)=\frac{\chi_b(x_0,\lambda)}{\chi_{a\to b}(\lambda)}\exp\left(\lambda\int_{x_a}^{x_0}\sqrt{q(x,E)}dx\right),$$
$$\beta(x_0,\lambda)=\frac{1}{\chi_b(x_0,\lambda)}\left(1-\frac{\chi_a(x_0,\lambda)\chi_b(x_0,\lambda)}{\chi_{a\to b}(\lambda)}\right)\exp\left(-\lambda\int_{x_b}^{x_0}\sqrt{q(x,E)}dx\right), \tag{30}$$

where the condition (28) for $\chi_1(x,\lambda)$ has been used as well as the following relation:

$$\chi_1(\infty_b,\lambda)=\chi_b(x_0,\lambda). \tag{31}$$

The last relation generalizes a little bit a relation $\chi_{i\to j}=\chi_{j\to i}$ valid for any pair of fundamental solutions communicating canonically.[5]

We shall prove the following lemma.

Lemma 3: (a) The factors $\chi_{1,2}$ given by (26) and (27), respectively, can be expanded in corresponding domains $D_{1,2}=\{x:\Re\xi(x)<\Re\xi(x_0)\}$ into the semiclassical series determined by the following formulas:

$$\chi_1^{\mathrm{as}}(x,\lambda)=\frac{\chi_b^{\mathrm{as}}(x_0,\lambda)\chi_a^{\mathrm{as}}(x,\lambda)}{\chi_{a\to b}^{\mathrm{as}}(\lambda)}=\frac{\chi_a^{\mathrm{as}}(x_0,\lambda)\chi_b^{\mathrm{as}}(x_0,\lambda)}{\chi_{a\to b}^{\mathrm{as}}(\lambda)}\sum_{n\geqslant 0}\left(\frac{\sigma}{2\lambda}\right)^n I_n(x,x_0) \tag{32}$$

and

$$\chi_2^{\mathrm{as}}(x,\lambda)=\left(1-\frac{\chi_a^{\mathrm{as}}(x_0,\lambda)\chi_b^{\mathrm{as}}(x_0,\lambda)}{\chi_{a\to b}^{\mathrm{as}}(\lambda)}\right)\frac{\chi_a^{\mathrm{as}}(x_0,\lambda)}{\chi_a'^{\mathrm{as}}(x_0,\lambda)}\sum_{n\geqslant 0}\left(\frac{\sigma}{2\lambda}\right)^n I_n(x,x_0). \tag{33}$$

(b) The domains $D_{1,2}$ are maximal for the above expansions to be valid and are contained in the canonical domain D_a of the fundamental solution χ_a.

(c) The asymptotic series (32) and (33) can be Borel summed with the following results:

$$[\chi_1^{\mathrm{as}}(x,x_0,\lambda)]_a^{\mathrm{BS}}=C_a(x_0,\lambda)\frac{\chi_a(x,\lambda)}{\chi_a(x_0,\lambda)} \tag{34}$$

and

$$[\chi_2^{\mathrm{as}}(x,x_0,\lambda)]_a^{\mathrm{BS}}=(1-C_a(x_0,\lambda))\frac{\chi_a(x,\lambda)}{\chi_a'(x_0,\lambda)}, \tag{35}$$

where the Borel sum $C_a(x_0,\lambda)\equiv[\chi_a^{\mathrm{as}}(x_0,\lambda)\chi_b^{\mathrm{as}}(x_0,\lambda)/\chi_{a\to b}^{\mathrm{as}}(\lambda)]^{\mathrm{BS}}$ is defined below.

(d) The representations (34) and (35) are not unique.

Proof of the lemma: To prove the part (a) of the lemma let us first divide both the sides of (29) by $q^{-1/4}(x)\exp(-\lambda\int_{x_a}^{x}\sqrt{q(y)}dy)$ to get

$$\chi_1(x,\lambda)=\frac{\chi_b(x_0,\lambda)}{\chi_{a\to b}(\lambda)}\chi_a(x,\lambda)+\left(1-\frac{\chi_a(x_0,\lambda)\chi_b(x_0,\lambda)}{\chi_{a\to b}(\lambda)}\right)\exp\left(2\lambda\int_{x_0}^{x}\sqrt{q(y)}dy\right)\frac{\chi_b(x,\lambda)}{\chi_b(x_0,\lambda)}. \tag{36}$$

Next we note that the term in (36) proportional to $\chi_b(x,\lambda)$ is exponentially small in the semiclassical limit when compared with the first one. Therefore pushing λ to infinity in (36) we get (32).

It is now easy to find the semiclassical series (33) for $\chi_1(x,\lambda)$. To this end let us note that $\chi_{1,2}(x,x_0)$ are linear independent solutions of (19) satisfying the conditions (28) so that we can write for $\chi_a(x,\lambda)$:

$$\chi_a(x,\lambda)=\chi_a(x_0,\lambda)\chi_1(x,x_0,\lambda)+\chi_a'(x_0,\lambda)\chi_2(x,x_0,\lambda). \tag{37}$$

Getting asymptotics of both the sides of (37) and solving the obtained equation with respect to $\chi_2^{\mathrm{as}}(x,\lambda)$ we obtain (33).

The thesis (b) of the lemma follows from the fact that both the solutions $\chi_{1,2}(x,\lambda)$ diverge exponentially for $\Re x>\Re x_0$ when $\lambda\to\infty$ [the property which follows directly when the considered pair of solutions is expressed by the second pair of them defined by (26) and (27) with the opposite signature] and from the fact that the condition $\Re x<\Re x_0$ defines also a (proper) part of the canonical domain D_a of the fundamental solution χ_a.

To prove the part (c) of the lemma it is necessary to invoke the exponential representation of the fundamental solution χ-factors.[5] By this representation the following is meant:

$$\chi_{a,b}(x,\lambda)=\exp\left(\mp\int_{\infty_{a,b}}^{x}\rho^{-}(y,\lambda)dy+\int_{\infty}^{x}\rho^{+}(y,\lambda)dy\right),$$

$$\chi_{a,b}^{\mathrm{as}}(x,\lambda)=\exp\left(\mp\int_{\infty_{a,b}}^{x}\rho_{\mathrm{as}}^{-}(y,\lambda)dy+\int_{\infty}^{x}\rho_{\mathrm{as}}^{+}(y,\lambda)dy\right), \tag{38}$$

$$\rho_{\mathrm{as}}^{-}(y,\lambda)=\sum_{n\geqslant 0}\frac{\rho_{2n}^{-}(y)}{\lambda^{2n+1}},\quad \rho_{\mathrm{as}}^{+}(y,\lambda)=\sum_{n\geqslant 0}\frac{\rho_{2n+1}^{+}(y)}{\lambda^{2n+2}},$$

where the coefficients $\rho_n^{\pm}(y)$, $n\geqslant 0$, have been calculated explicitly in Ref. 5 [see Sec. 2.3 of this reference, where the roles of $\rho^{\pm}(x,\lambda)$ are played by the corresponding $\chi^{\pm}(x,E,\lambda)$-functions]. The important properties of the coefficients as well as of the asymptotic series in (38) they constitute are in Refs. 1, 5 (see Appendix 2 in Ref. 5).

(a) They are point (path-independent) functions of y, i.e., they are universal, sector independent functions.
(b) $\rho_n^{-}(y)$ have square root singularities at every turning point.
(c) $\rho_n^{+}(y)$ are meromorphic at each turning point with vanishing residues at the points [i.e., $\oint\rho_n^{+}(y)dy=0$ around any turning point].
(d) Both the series in (38) are Borel summable.

This is the property (c) which causes the ρ_{as}^{+}-integral in (38) to be again the point function of y, i.e., it is sector independent.

The property (d) which follows from the corresponding property of fundamental solutions[1] generates two Borel functions $\rho^{\pm}(x,s)$:

$$\tilde{\rho}^{-}(x,s)=\sum_{n\geqslant 0}\frac{\rho_n^{-}(x)}{(2n)!}s^{2n},\quad \tilde{\rho}^{+}(x,s)=-\sum_{n\geqslant 0}\frac{\rho_n^{+}(x)}{(2n+1)!}s^{2n+1}, \tag{39}$$

which can be Borel transformed along any standard path $\tilde{C}$ in the Borel plane providing us each time with the corresponding Borel sums $\rho_{\tilde{C}}^{\pm}(x,\lambda)$ of the series in (39). If we performed a Borel resummation of the first formula in (39) along such a path $\tilde{C}$ we get

$$\chi_C(x,\lambda)=e^{\int_{\infty_C}^{x}(-\rho_C^{-}(y,\lambda)+\rho_C^{+}(y,\lambda))dy}, \tag{40}$$

where $\chi_C(x,\lambda)$ is a χ-function of some fundamental solution, rotated possibly in the λ-plane. The minus sign in (40) has been chosen for definiteness.

Noticing further, that

$$\chi_b^{\mathrm{as}}(x_0,\lambda)\chi_a^{\mathrm{as}}(x_0,\lambda)=e^{2\int_{\infty}^{x_0}\rho_{\mathrm{as}}^{+}(x,\lambda)dx}\chi_{a\to b}^{\mathrm{as}}(\lambda), \tag{41}$$

we can sum à là Borel both the equations (32) and (33) along the path $\tilde{C}_a$ recovering the factor $\chi_a(x,\lambda)$ to obtain the formulas (34) and (35). In these formulas $C_a(x_0,\lambda)$ is therefore the following Borel sum:

$$C_a(x_0,\lambda)=\exp\left(2\int_{\infty_a}^{x_0}\rho_a^+(y,\lambda)dy\right). \tag{42}$$

The representations (34) and (35) are not unique since, in general, there can be other fundamental solutions in $N(x_0)$ with the same signature as the solutions $\chi_{1,2}$ have which can substitute the solution χ_a in our considerations. However, having the same signatures these other fundamental solutions can provide us with the representations (34) and (35) which, in this case, differ between themselves only by exponentially small contributions.

The last statements end our proof of Lemma 3. QED.

One can easily identify the coefficients in front of the sum on the rhs' of (32) and (33) as the corresponding series of constants in the standard expansions (23). It is important to note that *none* of them is equal to the asymptotic series corresponding to $\chi_1(x_0,\lambda)\equiv 1$ and $\chi_2(x_0,\lambda)\equiv 0$, respectively. This confirms of course our earlier statement that the semiclassical series (32) and (33) cannot be Borel summed to the respective factors $\chi_1(x,\lambda)$ and $\chi_2(x,\lambda)$. A reason for that is the presence of exponential terms $e^{-2\lambda\sigma(W_k(x)-W_k(x_0))}$ in the asymptotic formulas for (26) and (27) [when $\Re(W_k(x)-W_k(x_0))=0$] which breaks the necessary conditions for the Watson–Sokal theorem[28] to be applied. Note that these exponential terms are absent in the case of fundamental solutions which are obtained in the limit $x_0\to\infty_k$ taken along a canonical path, for any $k=1,2,\ldots,2n+2$.

VI. UNIQUENESS OF FUNDAMENTAL SOLUTIONS AS BOREL SUMMABLE SOLUTIONS

Let $\psi(x,\lambda)$ be any solution to the Schrödinger equation (2) given at some domain D of the x-plane. Let us choose in D a point x_0 which is not a root of $q(x,E)$ [i.e., which is regular for $\omega(x)$ as given by (6)]. The solution $\psi(x,\lambda)$ can always be given each of the two Dirac forms (3) with the corresponding χ-factors satisfying the equation (19). Let us write these forms in the following way:

$$\psi(x,\lambda)=C_\pm(\lambda)q^{-1/4}(x)e^{\pm\lambda\int_{x_0}^{x}\sqrt{q(y)}dy}\chi_\pm(x,\lambda). \tag{43}$$

We shall say that $\psi(x,\lambda)$ has *well defined* semiclassical expansion in D if there is a choice of a sign in (43) and an accompanied constant $C_\pm(\lambda)$ such that the χ-factor $\chi_\pm(x,\lambda)$ corresponding to this choice can be expanded semiclassically in the standard way given by (23).

It follows directly from the above definition that only one of the two possible choices can satisfy it.

We shall also say that $\psi(x,\lambda)$ is Borel summable in D if it has well defined semiclassical expansion there and the corresponding series (23) is Borel summable to the uniquely chosen χ-factor $\chi(x,\lambda)$ of $\psi(x,\lambda)$.

We shall prove below the following main theorem of this paper.

Theorem 5: *Let a solution $\psi(x,\lambda)$ given at some vicinity D of x_0 (x_0 does not coincide with any turning point) be Borel summable in D. Then this solution must coincide with one of the fundamental solutions up to some λ-dependent constant.*

Proof: To prove the theorem we could utilize the solutions (26) and (27) and all their properties which we have established in Lemma 3 of the previous section. It can however be quite instructive to prove the theorem not invoking for the latter solutions since it makes the main arguments supporting the theorem (which have worked implicitly also in proving Lemma 3 of the previous section) to be more transparent.

According to Theorem 4 of Sec. III, for x_0 chosen we can always find in the set $N(x_0)$ a number of fundamental solutions of the same signatures as the respective $\chi(x,\lambda)$ corresponding to $\psi(x,\lambda)$ has. Let $\chi_a(x,\lambda)$ be one of them. It is Borel summable at x_0 and in some of its vicinity. Then using (24) both for $\chi(x,\lambda)$ and $\chi_a(x,\lambda)$ we have

$$\frac{\chi^{\mathrm{as}}(x,\lambda)}{\chi^{\mathrm{as}}(x_0,\lambda)}=\sum_{n\geqslant 0}\left(\frac{\sigma}{2\lambda}\right)^n I_n(x,x_0)=\frac{\chi_a^{\mathrm{as}}(x,\lambda)}{\chi_a^{\mathrm{as}}(x_0,\lambda)}. \tag{44}$$

It follows from (44) that the outer parts of this equality having the same semiclassical expansions have to have also the same Borel function. Since $\chi^{\mathrm{as}}(x,\lambda)$ and $\chi^{\mathrm{as}}(x_0,\lambda)$ are both Borel summable in D they can be summed along the same standard path $\tilde{C}$ on their corresponding Borel planes if x is chosen to be sufficiently close to x_0. It is, however, easy to check (see Appendix C) that under the latter condition the same standard path $\tilde{C}$ can be chosen to sum the quotient on the lhs of (44) since its corresponding Borel function is holomorphic around this path. However, the same must be true for the rhs quotient, i.e., the corresponding Borel functions of its two factors can be integrated also along $\tilde{C}$ lying in their Borel planes. Let us sum therefore à là Borel both the outer sides of (44) along this path. We get

$$\chi(x,\lambda)=\chi(x_0,\lambda)\frac{2\lambda\int_{\tilde{C}}e^{2\lambda s}\tilde{\chi}_a(x,s)ds}{2\lambda\int_{\tilde{C}}e^{2\lambda s}\tilde{\chi}_a(x_0,s)ds}. \tag{45}$$

The last equation, however, ends the proof of the theorem. QED.

As a comment to the last theorem we would like to stress that it summarizes a particular property of the semiclassical theory of the 1D Schrödinger equation with the polynomial potentials. Namely, this is that the standard semiclassical expansion (23) is constructed basically by the series $\Sigma_{n\geqslant 0}(\sigma/2\lambda)^n I_n(x,x_0)$ which can be Borel summable and the Borel function of which, by (44), coincides up to a λ-dependent multiplicative constant with the one of the fundamental solutions and, also by (44), with the Borel function of any Borel summable solution. This means that we can consider the Borel function of the fundamental solutions as the canonical one. The latter can be uniquely defined by the condition of being equal to unity at $s=0$ on the ''first sheet'' of the corresponding Riemann surface which the condition actually satisfies.

VII. CONCLUSIONS AND DISCUSSION

Theorem 5 of the previous section shows that in the case of the Schrödinger equation with the polynomial potentials its Borel summable solutions are the fundamental ones. The Borel function generated by these solutions is, up to analytical continuation, the unique one. This property justifies our earlier use of the fundamental solutions to investigate the problem of the Borel summability of energy levels and matrix elements in 1D quantum mechanics.[1] It also shows that only the fundamental solutions can be invoked when *any* problem connected with the Borel resummation is considered and conditions for such resummations are satisfied.[28]

The latter objection is important since not all the results we obtain for the case of polynomial potentials can be immediately extended to other cases of potentials. These are, for example, the rational potentials being the next class of potentials of modeling importance. In particular, the universality of the Borel function in the later case of potentials seems not to be satisfied.[33]

Nevertheless, the role of the corresponding fundamental solutions as the unique Borel summable ones seems to be maintained not only in the case of rational potentials but also in the case of other meromorphic potentials such as the Pöschl–Teller one, for example.

The fundamental solutions we have discussed in Sec. II can be given another form when each of the factors in (3) becomes a complicated function of λ.[34] These generalized representations however preserve all the Borel summing features of the original fundamental solutions being only a partial Borel resummation of the latter.[25]

Finally, we would like to note that the result obtained in the present paper completes the ones obtained in our other papers.[1,12,25] Namely, all these results show that the semiclassical theory in 1D quantum mechanics can be completely formulated on the basis of the Borel method of resummation. This is certainly true in the case of the polynomial potentials and it seems to be true with some modifications for meromorphic potentials as well.[33] In the formulation of such a theory the essential role as we have shown in the present paper is played by the fundamental solutions (see also Refs. 1, 12, 25). The theory allows us to construct the simplest semiclassical approximations as well as to complete the latter by the exponentially small contributions up to a desired level of accuracy.[12] In such a theory even a change of variable in the Schrödinger equation the procedure which is used very frequently as a way of improving the semiclassical approximations is also a result of the proper Borel resummation operation.[25,34]

APPENDIX A

Here we would like to draw some basic conclusions which follow for the Borel function $\tilde{\chi}(x,s)$ from its representation given by the topological expansion developed in our recent paper (see Ref. 12) and not dicussed there.

First of all let us recapitulate shortly basic elements of this representation. Namely, we have shown in Ref. 12 that the Borel function defined originally in some sector, say can be represented in this sector as the following series $[\xi=\xi(x)=\int_{x_1}^{x}\sqrt{q(y,E)}dy]$:

$$\tilde{\Phi}_1(\xi,s)=\sum_{q\geqslant 0}\tilde{\Phi}_1^{(q)}(\xi,s), \tag{A1}$$

where $\tilde{\Phi}_1(\xi(x),s)\equiv\tilde{\chi}(x,s)$ and the terms $\tilde{\Phi}^{(q)}(\xi,s),q\geqslant 0$ of the series are given by the formulas

$$\tilde{\Phi}_1^{(0)}(\xi,s)=I_0(\sqrt{4s\Omega(\xi)}),$$

$$\tilde{\Phi}_1^{(2q)}(\xi,s)=\int_{\tilde{C}(s)}d\eta_1\int_{\tilde{C}(\eta_1)}d\eta_2\ldots\int_{\tilde{C}(\eta_{q-1})}d\eta_q\int_{\infty_1}^{\xi-\eta_1}d\xi_1\int_{\infty_1}^{\xi_1}d\xi_2\ldots\int_{\infty_1}^{\xi_{q-1}}d\xi_q,$$

$$\tilde{\omega}(\xi_1+\eta_1)\tilde{\omega}(\xi_1+\eta_2)\cdot\ldots\cdot\tilde{\omega}(\xi_q+\eta_q)\tilde{\omega}(\xi_q)(2s-2\eta_1)^{2q}\frac{I_{2q}(z_{2q}^{1/2})}{z_{2q}^{q}},$$

$$z_{2q}=4(s-\eta_1)\Omega(\xi)+8(s-\eta_1)\sum_{p=1}^{q}(\Omega(\xi_p+\eta_{p+1})-\Omega(\xi_q+\eta_p)),$$

$$\eta_{q+1}\equiv 0,\quad q=1,2,\ldots, \tag{A2}$$

$$\tilde{\Phi}_1^{(2q+1)}(\xi,s)=\int_{\tilde{C}(s)}d\eta_1\ldots\int_{\tilde{C}(\eta_q)}d\eta_{q+1}\,\tilde{\omega}(\xi-\eta_1+\eta_2)\int_{\infty_1}^{\xi-\eta_1}d\xi_1\ldots\int_{\infty_1}^{\xi_{q-1}}d\xi_q\tilde{\omega}(\xi_1+\eta_2)$$

$$\times\tilde{\omega}(\xi_1+\eta_3)\cdot\cdots\cdot\tilde{\omega}(\xi_q+\eta_{q+1})\tilde{\omega}(\xi_q)(2s-2\eta_1)^{2q+1}\frac{I_{2q+1}(z_{2q+1}^{1/2})}{z_{2q+1}^{(2q+1/2)}},$$

$$z_{2q+1}=4(s-\eta_1)\Omega(\xi)+8(s-\eta_1)\sum_{p=0}^{q}(\Omega(\xi_p+\eta_{p+2})-\Omega(\xi_p+\eta_{p+1})),$$

$$\xi_0\equiv\xi,\quad \eta_{q+2}\equiv 0,\quad q=0,1,2,\ldots,$$

where $\tilde{\omega}(\xi(x))\equiv\omega(x)q^{-1/2}(x),\Omega=\int_{\infty_1}^{\xi}\tilde{\omega}(\eta)d\eta$ and the functions $I_q(x),q\geqslant 0$, in (A2) are the modified Bessel functions [of the first kind, Ref. 35, p. 5, formula (12)].

The formulas (A2) can be obtained from the following recurrences:

$$\tilde{\Phi}_1^{(2q+2)}(\xi,s)=-\int_{\tilde{C}(s)}d\eta\int_{\tilde{C}(\eta)}d\eta'\int_{\infty_1}^{\xi}d\xi_1\,\tilde{\omega}(\xi_1)\tilde{\omega}(\xi_1-\eta')(2s-2\eta)$$
$$\times\tilde{\Phi}_1^{(2q)}(\xi_1-\eta',\eta-\eta')\frac{I_1(\sqrt{4(s-\eta)(\Omega(\xi)-2\Omega(\xi_1)+\Omega(\xi_1-\eta'))})}{\sqrt{4(s-\eta)(\Omega(\xi)-2\Omega(\xi_1)+\Omega(\xi_1-\eta'))}},\tag{A3}$$

$$\tilde{\Phi}_1^{(2q+1)}(\xi,s)=-\int_{\tilde{C}(s)}d\eta\int_{\tilde{C}(\eta)}d\eta'\,\tilde{\omega}(\xi-\eta')$$
$$\times\tilde{\Phi}_1^{(2q)}(\xi-\eta',\eta-\eta')I_0(\sqrt{-4(s-\eta)(\Omega(\xi)-\Omega(\xi-\eta'))}),$$
$$q=0,1,2,\ldots,$$

where $\tilde{\Phi}_1^{(0)}(\xi,s)$ is given by (A2).

Note that (A3) can be obtained from (A2) and vice versa by applying the following relations:

$$\int_0^1 dx\,I_m(\sqrt{\alpha x})I_m(\sqrt{\beta(1-x)})(\alpha x)^{1/2\,m}(\beta(1-x))^{(1/2)\,n}$$
$$=2\alpha^m\beta^n\frac{I_{m+n+1}(\sqrt{\alpha+\beta})}{(\sqrt{\alpha+\beta})^{m+n+1}}\frac{1}{(k-1)!(n-k)!}\int_\eta^s d\eta'(s-\eta')^{k-1}(\eta'-\eta)^{n-k}=\frac{(s-\eta)^n}{n!}.\tag{A4}$$

The ξ-integrations in (A2) and (A3) run over some ξ-Riemann surfaces of the subintegral functions starting from the infinite points of these surfaces which are the corresponding images of the infinite point of the sector S_1. The η-integrations, contrary to the ξ-ones, are finite and run over the s-Riemann surfaces. All the latter integrations end at $s=0$.

For these integrations the most important are the branch point structures of the Riemann surfaces corresponding to the functions $\tilde{\omega}(\xi)$ and $\Omega(\xi)$ and the shifts of these surfaces by some complex number η. The two latter surfaces corresponds to the functions $\tilde{\omega}(\xi-\eta)$ and $\Omega(\xi-\eta)$.

Since every of these four surfaces has complicated topology (defined by its branch points) we decided not trying to sew them suitably together when these functions are integrated simultaneously but rather to consider them, for safeness, separately. These topologies are determined, of course, by the singularities of the respective functions $\tilde{\omega}(\xi)$ and $\Omega(\xi)$. Besides, since the latter of these two functions is defined as the integral over the former then the corresponding Riemann surface on which $\Omega(\xi)$ is defined is a map of the surface corresponding to $\tilde{\omega}(\xi)$, i.e., there is a well defined relation between these two surfaces.

For the polynomial potentials with simple roots all singularities of $\tilde{\omega}(\xi)$ and $\Omega(\xi)$ are cubic root branch points corresponding to turning points. Therefore, the four surfaces discussed above acquires a suitable cut pattern each. The corresponding ξ-integration runs over the sheets of these

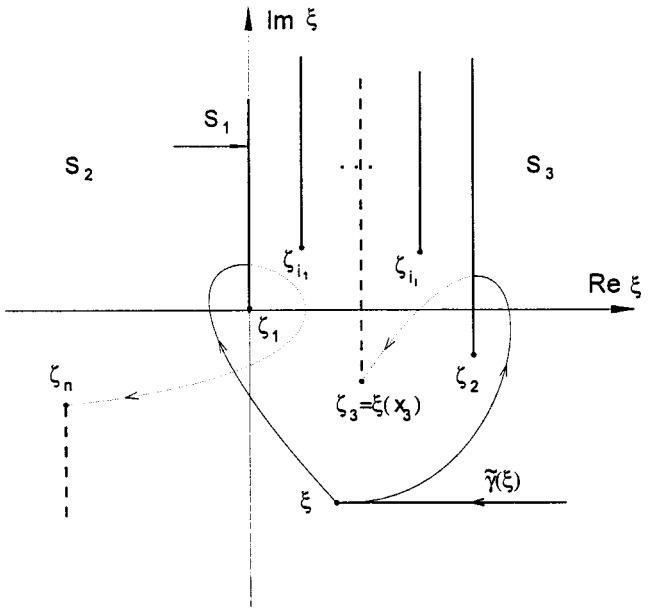

FIG. 6. The branch point structure of the ξ-Riemann surface sheet for $\tilde{\Phi}(\xi,s)$ containing the sectors S_2 and S_3 when $x \in K' \cap S_3$.

surfaces which are unambiguously related to each others (by the above shift or by a map) so that the integration paths on this sheets look the *same* running from ∞_1 to some finite point, the *same* on each sheet.

It is necessary to stress that every subsequent integration in (A2) or every subsequent step in the recurrent formulas (A3) changes the structure of the Riemann surfaces corresponding to functions resulting from these integrations. Namely, these surfaces become still more complicated preserving all the branch points of the previous stage and acquiring new ones as a result of the last integration(s).

Nevertheless, these structures look relatively simple if we consider them on definite sheets of the Riemann surfaces we want to stay considering the properties of the Borel functions $\tilde{\Phi}(\xi,s)$. Namely, starting from the sheets corresponding to the sector S_1 we shall keep the variable x [or $\xi(x)$] changing along the contour K' of Fig. 1(a). This corresponds to a path $\gamma_1(x)$ on the x-plane which begins in the sector S_1 and crosses on its way all the Stokes lines running to the infinity of the plane (but each line only once) penetrating subsequent sectors in their cyclic (clockwise or anticlockwise) ordering introduced in Sec. II. We shall call such a path the outer path.

Under the above condition the final pattern of the branch points of $\tilde{\Phi}(\xi,s)$ viewed from the relevant sheets is quite simple. First let us note that, as it follows from (A2) and (A3), under the above circumstances we can deform homotopically the infinite end of the outer path γ from the sector S_1 to any of the subsequent sectors $S_2,\ldots,S_{n+1}$ (in this or in the reversed orders). This is the consequence of the fact that the initial condition (7) put on the path γ to make it canonical is no longer valid since all the dangerous exponentials in the formula (5) enforcing this condition disappeared on the way of passing to the formulas (A2) and (A3). Figure 6 shows the corresponding result of such an operation for $x \in K' \cap S_3$. This proves that under the above condition (A2) and (A3) define the *same* unique Borel function $\tilde{\Phi}(\xi,s)$ for all the $n+1$ fundamental solutions (3). This deformation can be done keeping the end point x $(\xi(x))$ of the outer path γ in *any* of the sectors $S_1,\ldots,S_{n+1}$. The latter property means, of course, that if ξ is in S_k and the infinite end of γ is in S_l then $\tilde{\Phi}(\xi,s)$ represents the Borel function of the fundamental solution ψ_k (defined in S_k) analytically continued to the sector S_l and the formulas (A2) and (A3) define then this continuation explicitly.

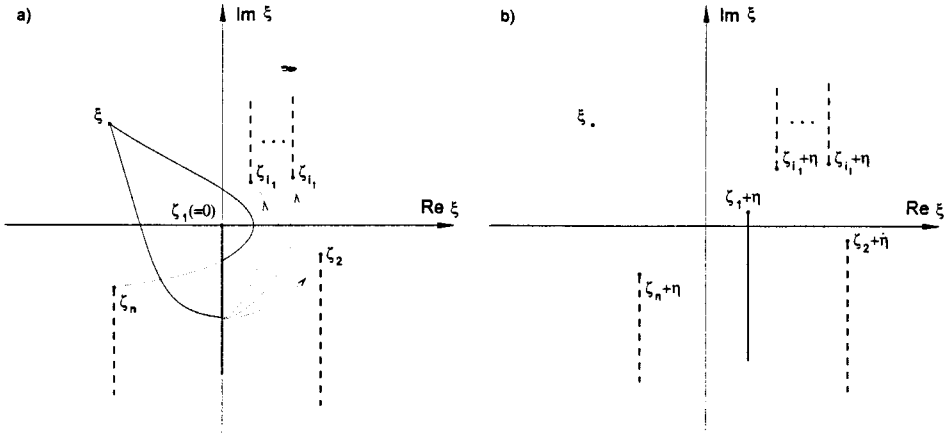

FIG. 7. (a) The 'first' sheet of the ξ-Riemann surface corresponding to $\tilde{\Phi}^{(0)}(\xi,s)$ when $x\in K'\cap S_3$. (b) The 'first' sheet of the ξ-Riemann surface corresponding to $\tilde{\Phi}^{(0)}(\xi-\eta,s)$ when $x\in K'\cap S_3$.

Theorem 6: *Let the end point x go around the contour K' of Fig. 1(a) starting from the sector S_1 and passing consecutively by the sectors $S_2,\ldots,S_{n+1}$. Then the sheets from which the χ-factors corresponding to the subsequent sectors are recovered by the Borel transformations over the Borel function $\tilde{\chi}(x,s)$ along the suitable real half-axes have the branch point structures shown in Fig. 11.*

Proof: Let us consider first a sheet of the s-Riemann surface corresponding to the sector S_1 and let the point x be then on K' in the sector S_1 so that $\Re\xi(x)>0$.

Consider $\tilde{\Phi}^{(0)}(\xi,s)$. Since $I_0(\sqrt{4s\Omega(\xi)})$ is the holomorphic function of its argument then $\tilde{\Phi}^{(0)}(\xi,s)$ is an entire function of s (i.e., holomorphic in the whole s-plane) so that its corresponding s-Riemann surface coincides with the s-plane. What concerns its ξ-Riemann surface structure it coincides with the one of $\Omega(\xi)$ since for each natural power of the latter its ξ-Riemann structure is the same and $I_0(\sqrt{4s\Omega(\xi)})$ determines $\tilde{\Phi}^{(0)}(\xi,s)$ as the holomorphic function of ξ in each nonsingular point of $\Omega(\xi)$. Therefore $\tilde{\Phi}^{(0)}(\xi,s)$ has on the corresponding first sheet in the ξ-plane a unique branch point at ζ_1, as it is shown in Fig. 7(a), if the corresponding cut emerges from this branch point vertically down. There are no other branch points visible then on the sheet. These other branch points, however, are on the sheets lying *below* the first sheet and the closest ones at $\zeta_2,\zeta_{i_1},\ldots,\zeta_{i_l}$ and ζ_n are shown in Fig. 7(a) with the dashed lines of cuts emerging from them. The full thin paths on the figure emerging from the point ξ show us how to approach these last branch points starting from ξ. We shall adopt this convention for the remaining figures too.

Figure 7(b) shows the ξ-Riemann surface for the shifted function $\tilde{\Phi}^{(0)}(\xi-\eta,s)$.

Next consider $\tilde{\Phi}^{(1)}(\xi,s)$. It is given by the second of the formulas (A3) for $q=0$. In this formula we have to integrate first over the variable η'. As it follows from the formula the branch point structure of the η'-Riemann surface is determined by the functions $\tilde{\omega}(\xi-\eta')$, $\Omega(\xi-\eta')$ and $\tilde{\Phi}^{(0)}(\xi-\eta',\eta'-\eta)$ and its first and second sheets are shown in Fig. 8(a).

The integration over η' leads us to a function defined on the ξ-Riemann surface shown in Fig. 7(b). The cuts shown there are a result of the end point (EP) mechanism of the singularity produced (Ref. 12, see also Ref. 36). Namely, the η'-integration is perturbed if the moving branch points of Fig. 8(a) can approach the fixed end points $\eta'=0$ and $\eta'=\eta$ of the integration path $C(\eta)$. For example, to generate the branch point at $\zeta_1(=0)$ we simply move the branch point $\xi-\zeta_1$ against the end point $\eta'=0$ of $C(\eta)$ to touch it finally. To produce the branch point at ζ_2 in Fig. 8(b) we have to move $\xi-\zeta_1$ down avoiding the end point η' from the left and below and next moving it to the right in such a way as to make the screened branch point at $\xi-\zeta_2$ coinciding with the end point η'.

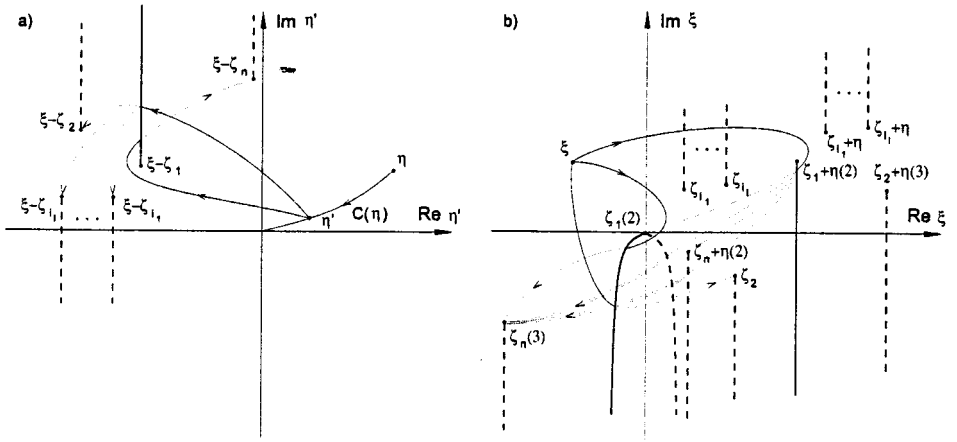

FIG. 8. (a) The singularity structure of the integrand in the second formula (48) for $q=0$ and the integration path $C(\eta)$. (b) The resulting ξ-singularity structure of $\tilde{\Phi}^{(1)}(\xi,s)$.

In the way described above we can generate the branch points at the position shown in Fig. 8(b). A convention adopted in this figure for the cut designing is to draw a full thin path emerging from the point ξ and if the path crosses a cut it becomes dotted. If it crosses the next appropriate cut it is doubly dotted and so on. This way of designing cuts allows us to establish the sheets on which they are distributed. The figure in parentheses at the different branch points indicates the multiplicity of the latter, i.e., their appearing on *different* sheets at the *same* positions. However, for the sake of transparency of the figures not all paths showing the distributions of the branch points on the sheets have been shown.

It is worth noting that this multiplication of branch points with the same coordinates but lying on different sheets in this figure is necessary to keep fixed the relative distribution of the branch points Fig. 8(a) when the moving ones in Fig. 8(b) change their positions. In fact the branch points in this figure with the same coordinate substitute each other during such a motion. This is because the branch point $\xi-\zeta_1$ in Fig. 8(a) has to be always accompanied by the branch points at $\xi-\zeta_2$ and $\xi-\zeta_n$ lying on the next two lower sheets. For example, if the branch points $\zeta_1+\eta$ and $\zeta_2+\eta$ move to the left so that they pass the branch point at $\zeta_1(=0)$ having it between themselves then the point $\zeta_2+\eta$ on the sheet opened by the first of these moving points is screened in some moment by the cut emerging from $\zeta_1=0$ lying on the first sheet in Fig. 8(b). But then the branch point at $\zeta_2+\eta$ on the sheet opened just by this latter cut becomes unscreened substituting its copy on the sheet we started with. Of course, all three copies of the branch points at $\zeta_2+\eta$ are mapped by the relation $\xi-\eta=\zeta_k$, $k=1,2,3$, into the one copy of them at $\xi-\zeta_2$ on the η'-plane of Fig. 8(a).

The final integration over η repeats only the steps done earlier introducing nothing new to the distribution of the branch ponts on the first sheet not modifying the lower sheets as well so that the final branch point structures of the first sheets look again as in Figs. 8(a) and 8(b) where we have to substitute η' and η by s on both the figures.

Consider next $\tilde{\Phi}^{(2)}(\xi,s)$. It is given by the first of the formulas (A3) for $q=0$. The initial ξ-Riemann surface structure is similar to that shown in Fig. 7 and look as in Figs. 9(a) and 9(b). The first ξ_1-integration in the corresponding formula (A3) provides us this time with both the types of singularities on the η'-Riemann surface, i.e., generated by the E-mechanism, which makes a replica of the branch point structures of Fig. 8(a), and by the pinch (P) mechanisms (discussed in Ref. 12; see also Ref. 36). A singularity generated by the second mechanism arises when, for example, the branch point at $\zeta_1+\eta'$ in Fig. 9(b) moves against the one at $\zeta_1=0$ of Fig. 9(a) pinching the integration path $\tilde{\gamma}(\xi)$. It can be done by making a tour around the end ξ of the path $\tilde{\gamma}(\xi)$ in both the directions, i.e., clockwise or anticlockwise. In this example we will produce branch point singularities on both the lower sheets of the η'-Riemann surface shown if Fig. 9(c)

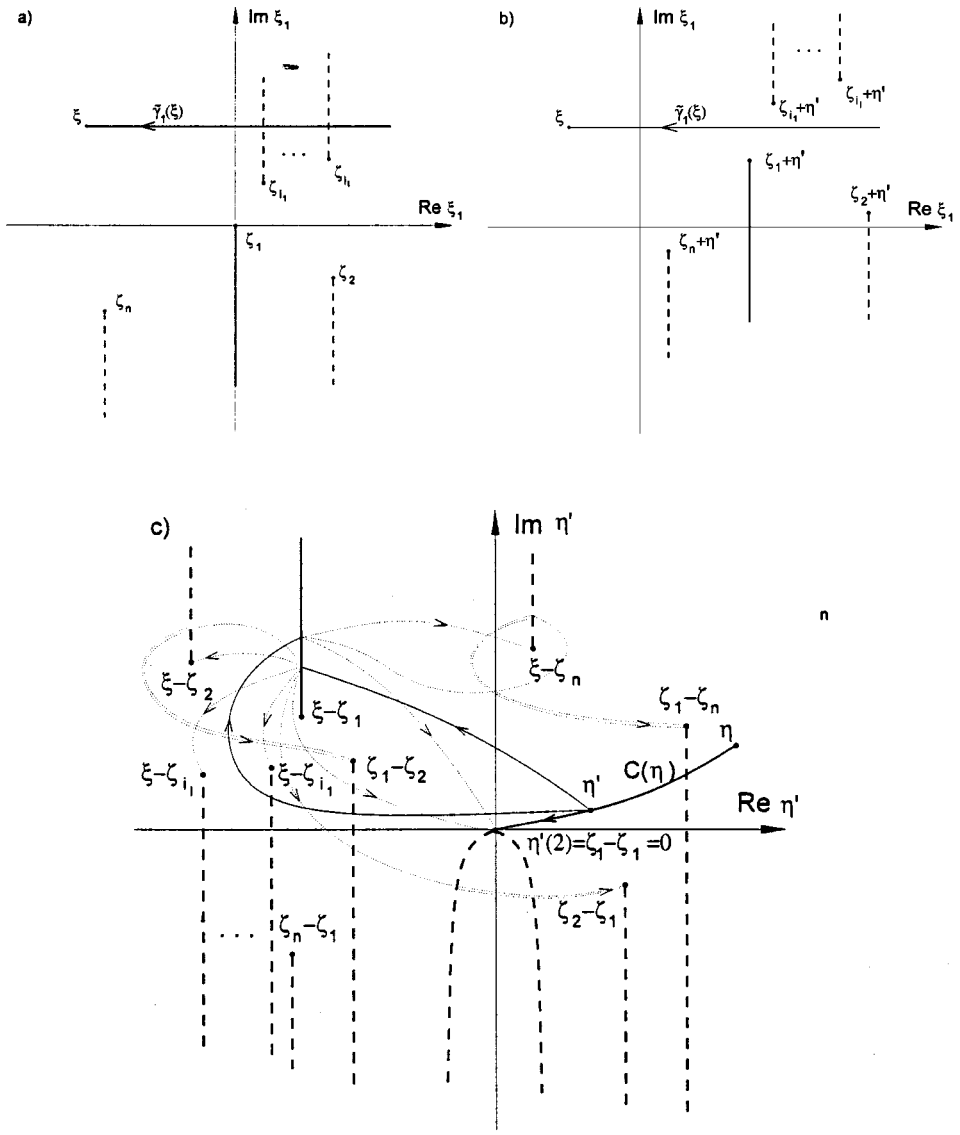

FIG. 9. (a) The ξ_1-singularity structure of the only ξ_1-dependent factors of the integrand in the first formula (48) for $q=0$. (b) The ξ_1-singularity structure of the η'-dependent factors of the integrand in the first formula (48) for $q=0$. (c) The η'-singularity structure of the first formula (48) for $q=0$ after the ξ_1-integration.

at $\eta'=0$. We can pinch the path $\tilde{\gamma}(\xi)$ by $\xi_1+\eta'$ also in this way but against the branch points at ζ_2 and ζ_n. This needs only to cross the cut emerging from $\zeta_1(=0)$ to reach the points mentioned, i.e., the first one by crossing this cut from the left while the second—from the right. It means that η' itself has to do the same in Fig. 9(c) crossing the cuts emerging from $\eta'=0$ on the corresponding sheets. The positions of the branch points generated in this way are shown in Fig. 9(c) where only a closest part of them is shown. It follows from the figure that some of the closest fixed branch points are at η' on the two sheets opened by the branch point at $\xi-\zeta_1$. The other ones lie on the sheets opened by the the branch points at $\xi-\zeta_2,\xi-\zeta_{i_1},\ldots,\xi-\zeta_{i_l}$ and $\xi-\zeta_n$ and by the fixed branch points generated in this way, i.e., still on the lower sheets.

A discussion of the remaining two η'- and η-inegrations goes along the same lines as in the previous discussion on calculating $\tilde{\Phi}^{(1)}(\xi,s)$ with the similar results obtained accordingly to Fig. 9(c). The only appearing difference is that in both these integrations the P-mechanism of the

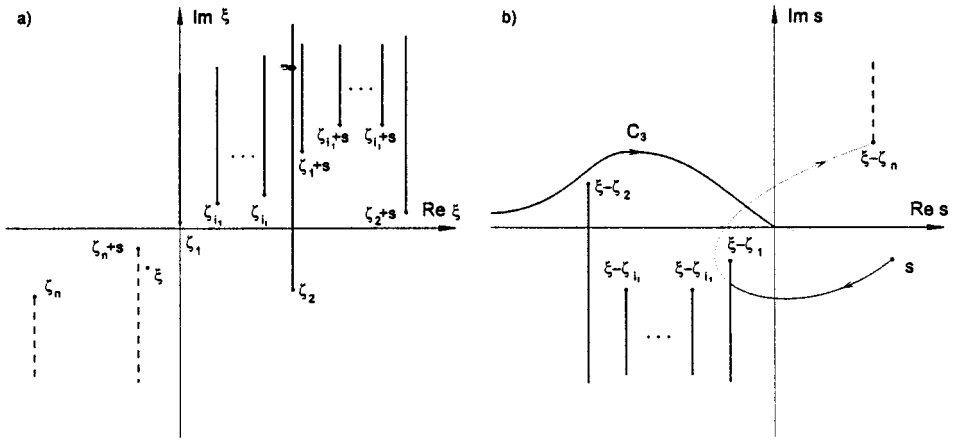

FIG. 10. (a) The ξ-singulalrity structure of $\tilde{\Phi}(\xi,s)$ for $x\in K'\cap S_3$. (b) The s-singularity structure of $\tilde{\Phi}(\xi,s)$ for $x\in K'\cap S_3$.

moving branch point singularity generation on the ξ-Riemann surface becomes active since, except for the moving singularities, there are also the fixed ones on the corresponding sheets of the η'- and η-Riemann surfaces [see Fig. 9(c)]. Therefore, the final first sheet structures are again a replica of those shown in Fig. 8(b) for the ξ-Riemann surface and in Fig. 9(c) for the s-Riemann one (with the η-, η'-variables substituted suitably by the s-one). Of course, because of the reason of transparency only the branch points on the first three sheets are shown in the figures. A comment made previously on the proliferation of the moving branch points with the same coordinates but lying on different sheets is also still valid and Fig. 8(b) reproduces this fact correctly.

Now consider the cases $\tilde{\Phi}^{(2q+1)}(\xi,s)$ and $\tilde{\Phi}^{(2q+2)}(\xi,s)$ assuming that the first sheets of the ξ-, s-Riemann surface structure of $\tilde{\Phi}^{(2q)}(\xi,s)$ is given by Fig. 8(b) and Fig. 9(c) (with the suitable $\eta,\ \eta'\to s$ substitutions on the figures). It is clear that we can repeat all the previous analyses and conclusions without any changes if the considered structure is limited only to the sheets defined by the formulas (A3) and the branch points shown in Figs. 8(a) and 9(c), i.e., the structure in these figures is reproduced also for the functions $\tilde{\Phi}^{(2q+1)}(\xi,s)$ and $\tilde{\Phi}^{(2q+2)}(\xi,s)$. Since the series (A2) is convergent this structure is the same also for $\tilde{\Phi}(\xi,s)$ itself.

It is important to note that the *fixed* branch points on the s-Riemann surface are generated in the scheme of the topological expansion (A2) on *lower* sheets.

Having $\tilde{\Phi}(\xi,s)$ defined in the above way we can restore the χ-factors defined in the sectors S_1 or S_2 by the Borel transformations of $\tilde{\Phi}(\xi,s)$ along the left half-axis to get $\chi_1(x,\lambda)$ or along the right one to get $\chi_2(x,\lambda)$. Clearly, the signs of λ in both these integrations are different.

To prove the assertion of the theorem about the structure of the ξ-, s-Riemann surface for $\tilde{\Phi}(\xi,s)$ continued to the sector S_k along the contour K' in Fig. 1(a) we should perform this continuation on the ξ-, s-Riemann surface corresponding to $\tilde{\Phi}(\xi,s)$ changing ξ, respectively, and drawing cuts properly. Such an operation, however, needs the detailed knowledge of the structure of many lower sheets of the ξ-, s-Riemann surface, a task which seems to be in general hopeless. However, we have already noticed that such a continuation can be easily performed with the help of the formulas (A2)–(A3) by changing the infinite ends of the ξ-integrations in these formulas, i.e., moving them to the appropriate sectors when the variable $\xi(=\xi(x))$ itself is continued to these sectors when x changes along the contour K'. For definitness let ξ be continued to the sector S_3. Then we can continue the mentioned infinite ends to the same sector. According to the Stokes graph in Fig. 1(a) the corresponding pattern of the sheets on which $\tilde{\omega}(\xi)$ and $\Omega(\xi)$ are defined are shown in Fig. 6. Therefore, taking this figure as the original one and using again the formulas (A3) we can repeat once again the analyses done above. The only difference are introduced by addi-

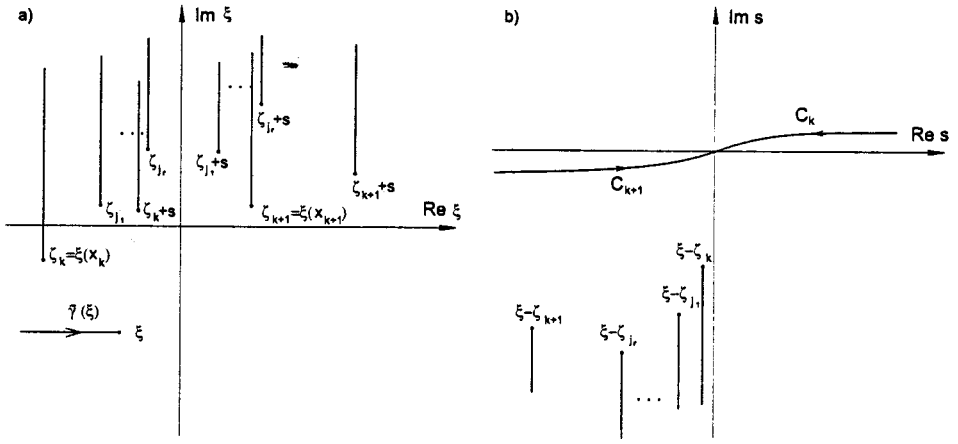

FIG. 11. (a) The ξ-singularity structure of $\tilde{\Phi}(\xi,s)$ for $x\in K'\cap S_k$. (b) The s-singularity structure of $\tilde{\Phi}(\xi,s)$ for $x\in K'\cap S_k$.

tional branch points which can appear according to the Stokes graph in Fig. 1(a). Then forgetting about the branch points which lie on the lower sheets in Fig. 6 (such as ζ_3) we get as the final structure of the first sheets for $\tilde{\Phi}(\xi,s)$ the one shown in Fig. 10.

The pattern in Fig. 10 is the one which has also to follow if we would continue the pattern of Fig. 8(b) (with the $\eta\to s$ substitution) by moving anticlockwise the variable ξ around the branch point ζ_1 and uprighting the cut emerging from this point by rotating it in the same anticlockwise direction. Then the cut emerging from ζ_2 on the figure is unscreened and uprighting it again anticlockwise as well as all the other consecutive cuts met by ξ on its way to the sector S_3 we have to reveal by these *uprighting operations* of the cuts the pattern of Fig. 10(a). Compairing the latter with Fig. 8(b) we see that these operations do their job properly. The proliferation of the branch points with the same coordinates on different sheets plays an essential role in this operation allowing us to recover the cuts which are screened by the uprighting operations made over the cuts emerging from $\xi=\zeta_1$ and $\xi=\zeta_2$.

On the s-Riemann surface of $\tilde{\Phi}(\xi,s)$ shown in Fig. 9(c) (with $\eta'\to s$ on the axes) the corresponding operation with cuts are of course reversed, i.e., each consecutive cut which is unscreened by the anticlockwise upside-down rotation of its predecessor originating by the cut emerging from the branch point $\xi-\zeta_1$ in Fig. 9(c) has also to be rotated in the same way. This process stops on the cut emerging from the last branch point at $\xi-\zeta_2$ being unscreened. We can then move this new pattern first down leaving the origin of the first sheet to the right and next move to the right leaving the origin of the sheet above all the moved branch points. The final position has to coincide then with that shown in Fig. 10(b).

We shall call the above operations with cuts leadind us to uncovering the desired sheets of the ξ-, s-Riemann surface the *unscreening operations*.

It is now clear that we can follow the above way considering the ξ-, s-Riemann surface structure corresponding to $\tilde{\Phi}(\xi,s)$ when ξ is in S_k being continued along the contour K' in Fig. 1(a). The tour along the contour K' is mapped properly on the ξ-Riemann surface of $\tilde{\Phi}(\xi,s)$ where ξ moves anticlockwise avoiding all met branch points from the left and putting upside-down the crossed cuts emerging from them realizing in this way the unscreening operation. The same unscreening operations of putting the properly chosen cuts upside-down are applied on the s-Riemann surface. We start from the pattern of Fig. 9(b) and repeat the procedure described above k times. The final pattern has to have the form shown in Figs. 11(a) and 11(b). Its detailed structure shown in the figure can be obtained from the formulas (A3) by the analyses described above.

Borel transforming along the left half-axis of Fig. 11(b) we recover the χ-factor corresponding to the sector S_k (if k is odd) or the one corresponding to the sector S_{k+1} when the Borel transformation is performed along the right half-axis. QED.

To finish the above discussion let us note yet that as it follows from our estimation of the convergence of the series (A2) made in Ref. 12 (see Appendix A.3 there) its *divergence* on each sheet of its s-Riemann surface (when ξ is fixed) is no faster than the exponential one.

APPENDIX B

We shall show here that the Borel transformation (10) of $\tilde{\chi}(x,s)$ [as given by (9) with $\chi_{k,n}(x)$ in the latter satisfying the reccurent relations (21) (in its differential form)] along any standard path satisfies the differential equation (19).

To this end write (21) in its differential form:

$$\chi'_{n+1}(x)=q^{-1/4}(x)(q^{-1/4}(x)\chi_n(x))'', \quad n\geqslant 0. \tag{B1}$$

Next multiply both the sides of (B1) by $(-s)^n/n!$ and sum them over n $(n\geqslant 0)$ to get

$$\frac{\partial^2\tilde{\chi}(x,s)}{\partial s\,\partial x}+q^{-1/4}(x)\frac{\partial^2}{\partial x^2}(q^{-1/4}(x)\tilde{\chi}(x,s))=0. \tag{B2}$$

Finally, multiply (B2) by $2\lambda e^{2\sigma\lambda s}$ and integrate (by parts) along a standard/cut path C to have

$$2\sigma\lambda\left(2\lambda\int_C ds\, e^{2\sigma\lambda s}\tilde{\chi}(x,s)\right)'+q^{-1/4}(x)\left(q^{-1/4}(x)2\lambda\int_C ds\, e^{2\sigma\lambda s}\tilde{\chi}(x,s)\right)''=0,$$

$$\lambda>0,\ \sigma=\begin{cases}+1, & \text{for infinity of } \Re C<0\\ -1, & \text{for infinity of } \Re C>0.\end{cases} \tag{B3}$$

According to (10) the equation (B3) coincides with (19).

APPENDIX C

We shall show here that if x is sufficiently close to x_0 then the Borel function of the quotient of $\chi^{as}(x,\lambda)$ and $\chi^{as}(x_0,\lambda)$ [with its factors corresponding to $\chi(x,\lambda)$ and $\chi(x_0,\lambda)$, respectively] can be integrated along the same standard path $\tilde{C}$ along which both the factors of the quotient can be summed too. It means that all the three Borel functions, the quotient and its two factors, are holomorphic in a common strip containing $\tilde{C}$.

To show this let us note that it is certainly true for the Borel fuctions $\tilde{\chi}(x,s)$ and $\tilde{\chi}(x_0,s)$ of the two quotient factors considered separately from the Borel function of the quotient itself. This is the result of the analytical dependence on x of singularities of the Borel functions of both these factors.[12] Therefore there is a strip $\tilde{S}$ on the Borel planes of $\tilde{\chi}(x,s)$ and $\tilde{\chi}(x_0,s)$ containing a standard path $\tilde{C}$ along which these functions can be integrated to reproduce the corresponding χ-factors $\chi(x,\lambda)$ and $\chi(x_0,\lambda)$. It is now elementary to show that if $\tilde{\chi}(x_0,s)$ is holomorphic in $\tilde{S}$ then the Borel function of $\chi^{-1}(x_0,\lambda)$ is also. This latter conclusion follows from the semiclassical expansion of $\chi^{-1}(x_0,\lambda)$. Namely, we have for this expansion,

$$\left(\frac{1}{\chi(x_0,\lambda)}\right)^{as}=\frac{1}{\chi^{as}(x_0,\lambda)}=\sum_{n\geqslant 0}\frac{1}{C_0^{n+1}}(C_0-\chi^{as}(x_0,\lambda))^n, \tag{C1}$$

where for $\chi^{as}(x_0,\lambda)$ we have assumed

$$\chi^{as}(x_0,\lambda)=\sum_{n\geqslant 0}\frac{C_n}{(2\lambda)^n}. \tag{C2}$$

The expansion (C1) follows of course from the identical (in form) expansion of $\chi^{-1}(x_0,\lambda)$ itself valid for $|\arg|\leqslant\pi/2$ when λ is sufficiently large.

The Borel function corresponding to the expansion (C1) is therefore

$$\begin{aligned}\frac{\tilde{1}}{\chi(x,\lambda)} &= C_0+\sum_{n\geqslant 1}\frac{(C_0-\tilde{\chi}(x,\lambda))^n}{C_0^{n+1}}\\ &= C_0+\sum_{n\geqslant 1}\frac{(C_0-\tilde{\chi})^{*n}(x,s)}{C_0^{n+1}}\\ &= C_0+\sum_{n\geqslant 1}\frac{(-1)^{n+1}}{C_0^{n+1}}\int_0^s ds_1(C_0-\tilde{\chi}(x,s-s_1))\\ &\quad\times\int_0^{s_1} ds_2\,\tilde{\chi}'(x,s_1-s_2)\cdots\int_0^{s_{n-3}} ds_{n-2}\,\tilde{\chi}'(x,s_{n-3}-s_{n-2})\\ &\quad\times\int_0^{s_{n-2}} ds_{n-1}\,\tilde{\chi}'(x,s_{n-2}-s_{n-1}),\end{aligned}\tag{C3}$$

where the prime at $\tilde{\chi}'(x,s)$ means the differentiation over s and where the following definition of the star (convolution) operation has been used:

$$(\tilde{f}*\tilde{g})(s)=\frac{d}{ds}\int_0^s\tilde{f}(s)\tilde{g}(s-s')ds'.\tag{C4}$$

From the representation (C4) it follows easily that the strip $\tilde{S}$ of the holomorphicity of $\tilde{\chi}(x,s)$ is also such a strip for the Borel function of $\chi^{-1}(x,\lambda)$ since the series in (C4) is uniformly convergent in $\tilde{S}$.

The perturbation theory around the soliton fields of the sin-Gordon model is developed in the coset space. It is shown by explicit calculations that all corrections to the topological soliton contribution are canceled exactly. © *2001 American Institute of Physics.* [DOI: 10.1063/1.1337613]

I. INTRODUCTION

The problem of quantization of the extended objects was formulated mainly in the middle of the 1970s, see the review paper[1] and references cited therein. One starts from the classical Lagrange equation:

$$\frac{\delta S(u)}{\delta u(x,t)}=0, \tag{1}$$

where, for simplicity, $u(x,t)$ is the real scalar field.[2] If this equation has nontrivial solution $u_c(x,t)$ then the problem of its quantization will arise. One of the first attempts to construct the perturbation theory was based on the WKB expansion in the vicinity of u_c.[3,4]

The Born–Oppenheimer method was adopted also.[5,6] First of all, to construct the quantum mechanics, the structure of Hilbert space $\mathcal{H}$ is postulated. So, it is assumed that the Fock column consists from the vacuum state $|0\rangle$ and from the multiple meson states $|p_1,p_2,\ldots,p_n\rangle$, $n\geqslant 1$. The ordinary perturbation theory operates just with this meson sector only. The *anzats* $|P_1,P_2,\ldots,P_l\rangle$[5] for the l-soliton state, $l\geqslant 1$, is introduced also.

It is postulated that the quantum excitations in the soliton sector are described by the excitation of the meson field.[5] Therefore, to construct the perturbation theory, there should also be the mixed states:

$$|P_1,\ldots,P_l;p_1,\ldots,p_n\rangle,\quad l\geqslant 1,\ n\geqslant 1, \tag{2}$$

but, at the same time,

$$\langle P_1,\ldots,P_l;p_1,\ldots,p_n|p_1,\ldots,p_{n'}\rangle\equiv 0,\ l\geqslant 1,\ n+n'\geqslant 0, \tag{3}$$

i.e., it is assumed that the solitons are the absolutely stable field configurations.[1]

The present paper in a definite sense completes the picture in Refs. 5 and 6, The $(1+1)$-dimensional exactly integrable sin-Gordon model will be considered to illustrate our result. We will investigate the multiple production of mesons by soliton and the truth of (3) will be shown at the end of explicit calculations. In other words, it will be shown that the postulate in

a)Electronic mail: joseph@nu.jinr.ru
b)Electronic mail: sisakian@jinr.ru

Refs. 5 and 6 concerning orthogonality of the meson $\mathcal{H}_m$ and soliton $\mathcal{H}_s$ Hilbert spaces can be proved. We will see that this conclusion follows from exactness of the semiclassical approximation for the sin-Gordon model.

It should be noted that the exactness of the semiclassical approximation in the topological soliton sector of the sin-Gordon model is not beyond the realm.[3] It is well known also that the integrable Coulomb problem is exactly semiclassical. We have the same for the quantum rigid rotator,[7] which is the isomorphic to the Poshle–Teller model. The general discussion of the exactness of the semiclassical approximation from a geometrical point of view was given in Ref. 8.

It will be crucial for us in many respects to follow the WKB ideology. So, we will consider the meson production amplitudes

$$a_{nm}(p,q)=\langle p_1,\ldots,p_n|q_1,\ldots,q_m\rangle_c, \quad n,m=1,2,\ldots. \tag{4}$$

The index c means that the calculations are performed in the soliton sector and p_i and q_i are the meson momenta. By definition,

$$p_i^2=q_i^2=m^2, \tag{5}$$

since the quantum uncertainty principle leads to the impossibility of mass-shell observation of the field.[9] The ordinary reduction formalism will be used to calculate a_{nm}. This means that we will construct the *phenomenological S*-matrix of the meson interaction through the soliton fields, i.e., we will start from the assumption that the states (2) exist, and it will be shown at the end of the calculations that such *S*-matrix is trivial:

$$a_{nm}(p,q)\equiv 0, \quad n+m>0. \tag{6}$$

The formalism allows to prove (6). For this purpose we will build the perturbation theory expansion over $1/g$, where g is the interaction constant.[10] This perturbation theory is dual to the theory described in Ref. 1, over g, i.e., one cannot decompose the definite order over g contribution in terms of the $1/g$ expansion, and vice versa. So, only the summary results of both expansion may be compared.

Following to WKB ideology, to find the corrections to the semiclassical approximation in the vicinity of the extremum $u_c(x,t)$, one should find the solution of the equation for the Green function:

$$(\partial^2+v''(u_c))G(x,t;x',t')=\delta(x-x')\,\delta(t-t'),$$

where $v''(u)$ is the second derivative of the potential function $v(u)$. This Green function describes propagation of a particle in the time dependent inhomogeneous and anisotropic external field $u_c(x,t)$. Generally, this problem has no closed solution. So, for instance, the attempt to solve the problem using the momentum decomposition[11] leads to the hardly handling double-parametric perturbation theory. To avoid this problem we will build a new perturbation theory over $1/g$.

Imagining particle coordinates as the elements of the Lee group, the classical particle motion may be described mapping the trajectory on group manifold. Roughly speaking, this means that the group combination law creates the particles classical trajectory.[12]

Moreover, this program was realized for description of the particle quantum motion.[13] It was shown for essentially nonlinear Lagrangian $L=\frac{1}{2}g_{\mu\nu}(x)\dot{x}^\mu\dot{x}^\nu$ that the semiclassical approximation is exact on the (semi)simple Lee group manifold. But this slender solution of quantum problems is destructed in presence of the interaction potential $v(x)=O(x^n)$, $n>2$, since the last one breaks the isotropy and homogeneity of the Lee group manifolds.[10] The developed perturbation theory will describe the quantum perturbations breaking isotropy and homogeneity of the group manifold.

Developed formalism contains the following steps.[10,14] (i) We will introduce the manifold W_G of trajectories u_c, solving the Eq. (1). The manifold W_G will be labeled by the local coordinates

(ξ,η), i.e., we will consider $u_c=u_c(x;\xi,\eta)$ since u_c should belong to W_G *completely*. (ii) The numbers (ξ,η) are interpreted as the generalized coordinates of the particle. Then $u_c(x;\xi,\eta)$ will define the external potential for it. The quantum motion of the particle may be described noting that W_G is the homogeneous and isotropic manifold, since this case is a rather quantum mechanical problem in the flat space.

It was shown in Ref. 14 that the WKB model,[5] where the field excitations in vicinity of u_c are decomposed over the meson states, and our model quantum mechanics of the particle in the external potential defined by u_c, are isomorphic. In other words, we know that the quantum trajectory of the particle covers the phase space $(\xi,\eta)\in W_G$ densely. But it should be noted also that the model described in Ref. 5 presents the expansion over the interaction constant λ and our perturbation theory describes expansion over the $(1/\lambda)$.

In the classical limit (labeled by the index 0) the motion of our particle must be free,[14] i.e., its velocity should be a constant,

$$\dot{\xi}_0=\text{const}, \quad \dot{\eta}_0=0. \tag{7}$$

This may be achieved expressing the set $\{\eta\}$ through the set of generators of the subgroup broken by u_c.[15] It is evident, such choice of the particles coordinate gives the same effect as in the above discussed transformation to the homogeneous and isotropic (semi)simple Lee group manifold,[10] see also Ref. 16. Moreover, we will see that even in the case of nontrivial potential function, one can get to the free particles motion, rescaling the quantum sources.[10,14]

Thus, the necessary invariant subspace W_G would be chosen equal to the coset space G/G_c:

$$W_G=G/G_c, \tag{8}$$

where G is the symmetry group and $G_c\subset G$ is the classical solutions u_c symmetry group. The problem of quantization of the coset space have a reach history, see, e.g., Ref. 17. As described in Refs. 10 and 14, the formalism presents one possible realization of the coset spaces quantization scheme.

The last one means that we will realize the transformation generated by the classical trajectory:[14]

$$u_c:\ (u,p)(x,t)\rightarrow(\xi,\eta). \tag{9}$$

Such construction of perturbation theory in the W_G space requires the additional effort noting that the dimension of the original phase space $(u,p)\in T^*V$ is infinite. Therefore, Eq. (9) assumes the infinite reduction since the dimension of coset space W_G is finite.[18] The crucial reduction scheme was formulated in Ref. 14.

In other words, quantizing the sin-Gordon soliton fields, the space coordinate would be an irrelevant variable. This is the well-known fact, e.g., Ref. 4, and it leads to the Lorentz noncovariant perturbation theory. It is the consequence of the solitary profile of considered field configurations and its absolute stability, i.e., of conservation of the topological charge. The necessary information concerning this question will be given in Sec. III.

Having the complete theory, one can analyze the perturbations. The crucial point of the new perturbation theory is the statement[10] that the quantum corrections are accumulated strictly on the boundaries ∂W_G (bifurcation manifolds[19,20,15]) of the W_G space. Therefore, if

$$\partial u_c\cap\partial W_G=\varnothing, \tag{10}$$

then the problem is exactly semiclassical. On other hand, Eq. (10) means conservation of the topological charge: ∂u_c is the flow induced by the quantum perturbations in W_G and if (10) is not satisfied, then one should exist a flow into the forbidden, separated by the bifurcation boundary, domain with other topological charge. So, Eq. (10) is the topological charge conservation.

On the other hand, Eq. (10) leads to (6) since particle production is the pure quantum effect. This will be shown in Sec. IV.

The paper is organized as follows. In Sec. II we will (i) formulate the necessary boundary conditions to derive the LSZ reduction formula, (ii) find the explicit expression for a_{nm}, (iii) formulate the mapping into the coset space W_G. In Sec. III we (i) consider the sin-Gordon model, (ii) discuss the coset space boundary condition, (iii) remind the structure of the new perturbation theory,[14] (iv) describe meson multiple production to show (6).

II. DENSITY MATRIX ON THE DIRAC MEASURE

The main point of this section is the attempt to generalize the ordinary for field theory boundary condition

$$u(x\in\sigma_\infty)=0,$$

where σ_∞ is the remote hypersurface. This boundary condition is used to remove the surface term, and it is necessary to formulate the reduction formalism. We would like to introduce the new boundary condition to have a possibility to include the nonvanishing on σ_∞ field configurations and, at the same time, throw off the surface term.

The $(n+m)$-point Green functions G_{nm} are introduced through the generating functional Z_j:[21]

$$G_{nm}(x,y)=(-i)^{n+m}\prod_{k=1}^{n}\hat{j}(x_k)\prod_{k=1}^{m}\hat{j}(y_k)Z_j, \tag{11}$$

where $\hat{j}(x)=\delta/\delta j(x)$ and the generating functional

$$Z_j=\int Du\, e^{iS_j(u)}. \tag{12}$$

The action

$$S_j(u)=S(u)-V(u)+\int \mathrm{d}x\,\mathrm{d}t\, j(x,t)u(x,t), \tag{13}$$

where

$$S(u)=\int \mathrm{d}x\,\mathrm{d}t\left(\tfrac{1}{2}(\partial u)^2-m^2u^2\right),\quad m^2\geqslant 0, \tag{14}$$

is the free part and $V(u)$ describes the interactions. At the end of the calculations one should put $j=0$.

To provide convergence, the integral (12) will be defined on the Mills complex time contour C_+.[22] For example,

$$C_\pm:\quad t\to t+i\varepsilon,\varepsilon\to+0,\ -\infty\leqslant t\leqslant+\infty \tag{15}$$

and after all calculations, one should return the time contour on the real axis putting $\varepsilon=0$.

In a 'meson' sector the integration in (12) is performed over all field configurations with standard vacuum boundary condition:

$$\int \mathrm{d}^2x\,\partial_\mu(u\partial^\mu u)=\int_{\sigma_\infty}\mathrm{d}\sigma_\mu\, u\partial^\mu u=0. \tag{16}$$

It follows from this conditions that

$$u(x\in\sigma_\infty)=0,\quad pa_\mu u(x\in\sigma_\infty)=0. \tag{17}$$

It excludes a contribution from the surface term, since it assumes that field disappeared on the remote hypersurface σ_∞. Considering the soliton sector this boundary condition requires the modification since there is in the $(x-t)$ space such direction along which the soliton field does not disappear. The integral (12) would have a formal meaning until this boundary condition will not be specified.

Let us introduce now the field φ through the equation

$$-\frac{\delta S(\varphi)}{\delta\varphi(x,t)}=j(x,t). \tag{18}$$

It is assumed that we can formulate such boundary condition that the surface term may be neglected calculating the variational derivative in (18). Then we perform the ordinary shift $u\to u+\varphi$ in integral (12). Considering φ as the probe field created by the source:

$$\varphi(x)=\int \mathrm{d}^2x'\, G_0(x-x')j(x'),\quad (\partial^2+m^2)G_0(x-x')=\delta(x-x'), \tag{19}$$

the connected Green function G^c_{nm} will only be interesting for us,

$$G^c_{nm}(x,y)=(-i)^{n+m}\prod_{k=1}^{n}\hat{j}(x_k)\prod_{k=1}^{m}\hat{j}(y_k)Z(\varphi), \tag{20}$$

where

$$Z(\varphi)=\int Du\, e^{iS(u)-iV(u+\varphi)} \tag{21}$$

is the new generating functional.

To calculate the nontrivial elements of the S matrix we must put the external particles on the mass shell. Formally this procedure means amputation of the external legs of G^c_{nm} and further multiplication on the free particle wave functions. In result the amplitude of n into m particle transition a_{nm} in the momentum representation has the form

$$a_{nm}(q,p)=(-i)^{n+m}\prod_{k=1}^{n}\hat{\varphi}(q_k)\prod_{k=1}^{m}\hat{\varphi}^*(p_k)Z(\varphi). \tag{22}$$

Here the particles creation operator

$$\hat{\phi}^*(q)=\int \mathrm{d}^2x\, e^{iqx}\hat{\phi}(x),\quad \hat{\phi}(x)=\frac{\delta}{\delta\phi(x)}. \tag{23}$$

was introduced. The Eq. (22) is the ordinary LSZ reduction formulas. But one should remember that the boundary condition (16) should be generalized to have permission for inclusion of the soliton contributions calculating $Z(\varphi)$.

Describing the particles multiple production it is enough to consider the generating functional

$$\rho(\alpha,z)=\exp\Big\{-\int \mathrm{d}\Omega_1(p)(\hat{\varphi}^*_+(p)\hat{\varphi}_-(p)e^{i\alpha_+p}z_+(p) + \hat{\varphi}^*_-(p)\hat{\varphi}_+(p)e^{i\alpha_-p}z_-(p))\Big\}Z(\varphi_+)Z^*(\varphi_-), \tag{24}$$

where

$$d\Omega_n(p)=\prod_{k=1}^{n}\frac{d^1p_k}{(2\pi)2\epsilon(p_k)}=\prod_{k=1}^{n}d\Omega_1(p_k),\quad \epsilon(p)=(p^2+m^2)^{1/2}.$$

Let us calculate

$$\int\frac{d^2\alpha_+}{(2\pi)^2}e^{-iP\alpha_+}\frac{d^2\alpha_-}{(2\pi)^2}e^{-iP\alpha_-}\prod_{k=1}^{n}\frac{\delta}{\delta z_+(p_k)}\prod_{k=1}^{m}\frac{\delta}{\delta z_-(q_k)}\rho(\alpha,z)|_{z_+=z_-=0}.$$

Inserting here the definition (24), one can find that this expression gives

$$\delta\left(P-\sum_{k=1}^{n}p_k\right)\delta\left(P-\sum_{k=1}^{m}q_k\right)|a_{nm}(p,q)|^2,$$

where the δ functions are the result of integration over $\alpha_\pm$. So, the factors $e^{i\alpha_\pm p}$ in (24) permit to introduce the energy-momentum shell and the δ function defines the restriction on the shell. Both restrictions

$$P=\sum_{k=1}^{m}q_k,\quad P=\sum_{k=1}^{n}p_k$$

are compatible since the amplitude a_{nm} is translationally invariant. The integration over P gives energy-momentum conservation law.

Notice now that $\rho(\alpha,z)$ is defined through the generating functional

$$\rho_0(\varphi)=Z(\varphi_+)Z^*(-\varphi_-)=\int Du_+\,Du_-\,e^{iS_+(u_+)-iS_-(u_-)}e^{-iV_+(u_++\varphi_+)+iV_-(u_--\varphi_-)}. \quad (25)$$

Then, we can consider the closed-path boundary condition

$$\int_{\sigma_\infty}d\sigma_\mu\,u_+\partial^\mu u_+=\int_{\sigma_\infty}d\sigma_\mu\,u_-\partial^\mu u_-, \quad (26)$$

instead of (16) and (17). The natural solution of this boundary condition is

$$u_+(x\in\sigma_\infty)=u_-(x\in\sigma_\infty)=u(x\in\sigma_\infty). \quad (27)$$

It provides cancellation of the surface term on the remote hypersurface σ_∞ independently on the value of the field $u(x\in\sigma_\infty)$.

Considering the system with the large number of particles, we can simplify calculations choosing the center-of-mass (c.m.) frame $P=(P_0=E,\vec{0})$. It is useful also[23] to rotate the contours of integration over

$$\alpha_{0,k}:\ \alpha_{0,k}=-i\beta_k,\ \mathrm{Im}\,\beta_k=0,\quad k=1,2.$$

Then $\rho(\beta,z)$ have a meaning of the density matrix, where β would have, in the some definite case,[24] meaning of the inverse temperature and z is the activity.[25]

It was shown in Ref. 14 that the unitarity condition unambiguously determines contributions in the path integrals for ρ. Exist the statement:

S1. The density matrix $\rho(\alpha,z)$ has the following representation:

$$\rho(\alpha,z)=e^{-i\hat{K}(je)}\int DM(u)e^{iS_O(u)-iU(u,e)}e^{N(\alpha,z;u)}\equiv\mathcal{O}(u)e^{N(\alpha,z;u)}. \quad (28)$$

It should be underlined that this representation is strict and is valid for arbitrary Lagrange theory of arbitrary dimensions. The derivation of (28) is given in the Appendix.

Expansion over the operator

$$\hat{K}(je)=\frac{1}{2}\,\mathrm{Re}\int_{C_+}\mathrm{d}x\,\mathrm{d}t\,\frac{\delta}{\delta j(x,t)}\,\frac{\delta}{\delta e(x,t)}\equiv\frac{1}{2}\,\mathrm{Re}\int_{C_+}\mathrm{d}x\,\mathrm{d}t\,\hat{j}(x,t)\hat{e}(x,t) \tag{29}$$

generates the perturbation series. We will assume that this series exist (at least in the Borel sense). The variational derivatives in (29) are defined as follows:

$$\frac{\delta\phi(x,t\in C_i)}{\delta\phi(x',t'\in C_j)}=\delta_{ij}\delta(x-x')\,\delta(t-t')\quad i,j=+,-,$$

where C_i is the Mills time contour. The auxiliary variables (j,e) must be taken equal to zero at the very end of the calculations.

The functionals $U(u,e)$ and $S_O(u)$ are defined by the equalities

$$S_O(u)=(S(u+e)-S(u-e))+2\ \mathrm{Re}\int_{C_+}\mathrm{d}x\,\mathrm{d}t\,e(x,t)(\partial^2+m^2)u(x,t), \tag{30}$$

$$U(u,e)=V(u+e)-V(u-e)-2\ \mathrm{Re}\int_{C_+}\mathrm{d}x\,\mathrm{d}t\,e(x,t)v'(u), \tag{31}$$

where $S(u)$ is the free part of the Lagrangian and $V(u)$ describes interactions. The phase $S_O(u)$ is not equal to zero if u have the nontrivial topological charge.[14] We will discuss carefully this question later.

The measure $DM(u,p)$ has the form

$$DM(u)=\prod_{x,t}\mathrm{d}u(x,t)\,\delta\left(\frac{\delta(S(u)-V(u))}{\delta u(x,t)}+j(x,t)\right). \tag{32}$$

The functional δ function in the measure means that the necessary and sufficient set of contributions in the integral over $u(x,t)$ is defined by the classical equation

$$-\frac{\delta(S(u)-V(u))}{\delta u(x,t)}=j(x,t), \tag{33}$$

disturbed by the quantum source $j(x,t)$.

For further calculation another representation will be useful. If we insert into the integral (28)

$$1=\int\prod_{x,t}\mathrm{d}p(x,t)\,\delta(p(x,t)-\dot{u}(x,t))$$

then the measure DM takes the form

$$DM(u,p)=\prod_{x,t}\mathrm{d}u(x,t)\mathrm{d}p(x,t)\,\delta\left(\dot{u}(x,t)-\frac{\delta H_j(u,p)}{\delta p(x,t)}\right)\delta\left(\dot{p}(x,t)+\frac{\delta H_j(u,p)}{\delta u(x,t)}\right) \tag{34}$$

with the total Hamiltonian

$$H_j(u,p)=\int\mathrm{d}x\left\{\frac{1}{2}p^2+\frac{1}{2}\,(\nabla u)^2+v(u)-ju\right\}. \tag{35}$$

The last one includes the energy ju of quantum fluctuations. The measure (34) describes motion in the symplectic space $(u,p)\in V$. But it should be underlined that the used expansion is not the Lagrange transformation. So, generally, it is quite possible, considering x as the index of the space shell, that not all of $p(x,t)$ are the independent variables. For this reason the measure (34) has mostly a Lagrange meaning.

The measure (34) contains the following information.[10,14]

(a) *Only the strict solutions of equations*

$$\dot{u}-\frac{\delta H_j(u,p)}{\delta p}=0,\quad \dot{p}+\frac{\delta H_j(u;p)}{\delta u}=0 \tag{36}$$

at $j=0$ *should be taken into account*. This rigidness means absence in the formalism of the pseudo-solution (similar to multi-instanton, or multikink) contributions.

(b) $\rho(\alpha,z)$ *is described by the sum of all solutions of Eq. (36), independently from their nearness in the functional space*.

(c) *The field disturbed by* $j(x)$ *belongs to the same manifold (topology class) as the classical field defined by (36).*[10]

(d) *The consequence of properties b. and c. is the selection rule: quantum dynamics is realized in the coset space of highest dimension.*[10] This, excluding from consideration the pure meson sector.

The particle density

$$N(\alpha,z;u)=N_+(\alpha_+,z_+;u)+N_-(\alpha_-,z_-;u), \tag{37}$$

where

$$N_\pm(\alpha_\pm,z_\pm;u)=\int \mathrm{d}\Omega_1(q)e^{i\alpha_\pm q}z_\pm(q)|\Gamma(q;u)|^2. \tag{38}$$

The vertex $\Gamma(q;u)$ is the function of the external particle momentum q and is the linear functional of $u(x)$:

$$\Gamma(q;u)=-\int \mathrm{d}x\, e^{iqx}\frac{\delta S(u)}{\delta u(x)}=\int \mathrm{d}x\, e^{iqx}(\partial^2+m^2)u(x),\quad q^2=m^2, \tag{39}$$

for the mass m field. This parameter presents the momentum distribution of the interacting field $u(x)$ on the remote hypersurface σ_∞ *if* $u(x)$ is the regular function. Notice, the operator cancels the mass-shell states of $u(x)$.

Generally $\Gamma(q;u)$ is connected directly with *external* particles properties and sensitive to the symmetry of the interacting fields system.[26]

The construction (39) means, because of the operator (∂^2+m^2) and remembering that the external states should be mass shell by definition,[9] the solution $\rho(\alpha,z)=0$ is actually possible for particular topology (compactness and analytic properties) of *quantum* field $u(x)$. So, $\Gamma(q;u)$ carry remarkable properties: (i) it directly defines the observables, (ii) is defined by the topology of $u(x)$. Notice that the space-time topology of $u(x,t)$ becomes important calculating integral (39) by parts. This procedure is available if $u(x,t)$ is the regular function. But the *quantum* fields are always singular. Therefore, the solution $\Gamma(q;u)=0$ is valid iff the semiclassical approximation is exact, i.e., the particle production is the pure quantum effect. Just this situation is realized in the soliton sector of the sin-Gordon model.

Let G be the symmetry of the problem and let G_c be the symmetry of the solution u_c. Then

S2. The measure (34) admits the transformation:

$$u_c:(u,p)\to(\xi,\eta)\in W=G/G_c \tag{40}$$

and transformed measure has the form

$$DM(u,p)=\prod_{x,tC} \mathrm{d}\xi(t)\mathrm{d}\eta(t)\,\delta\left(\dot{\xi}-\frac{\delta h_j(\xi,\eta)}{\delta\eta}\right)\delta\left(\dot{\eta}+\frac{\delta h_j(\xi,\eta)}{\delta\xi}\right), \tag{41}$$

where $h_j(\xi,\eta)=H_j(u_c,p_c)$ *is the transformed Hamiltonian*

$$h_j(\xi,\eta;t)=h(\eta)-\int \mathrm{d}x\, j(x,t)u_c(x;\xi,\eta) \tag{42}$$

and $u_c(x;\xi,\eta)$ *is the soliton solution parametrized by* (ξ,η).

The proof of Eq. (41) is the same as for the Coulomb problem considered in Ref. 14. But the case of the $(1+1)$-dimensional model needs the additional explanations. First of all, one must introduce the functional

$$\Delta(u,p)=\int \prod_t \mathrm{d}^N\xi(t)\mathrm{d}^N\eta(t)\prod_{x,t}\delta(u(x,t)-u_c(x;\xi,\eta))\,\delta(p(x,t)-p_c(x;\xi,\eta)). \tag{43}$$

The equalities

$$u(x,t)=u_c(x;\xi,\eta),\quad p(x,t)=p_c(x;\xi,\eta) \tag{44}$$

assume that for given $u(x,t)$ and $p(x,t)$ one can hide the t dependence into the N functions $\xi=\xi(t)$ and $\eta=\eta(t)$. It is assumed that this procedure can be done for arbitrary x. In other respects, functions $u(x,t)$ and $p(x,t)$, and therefore, $u_c(x;\xi,\eta)$ and $p(x;\xi,\eta)$, are arbitrary.

For more confidence, one may divide the space onto the N cells and to each $(u,p)_x$ we may adjust $(\xi,\eta)_x$. It is possible that (ξ,η) are x independent. In this degenerate case $\Delta\sim(\delta(0))^k$, where $k\leqslant N$ is the degree of the degeneracy. We will omit the index x considering $(\xi,\eta)_x$ as the vector of the necessary dimension.

If (ξ,η) are the solutions of (44), then

$$\Delta(u,p)=\int \prod_t \mathrm{d}\xi'(t)\mathrm{d}\eta'(t)\,\delta(u_c^{\xi}\xi'+u_c^{\eta}\eta')\,\delta(p_c^{\xi}\xi'+p_c^{\eta}\eta')=\Delta_c(\xi,\eta)\neq 0, \tag{45}$$

where, for instance, $u_c^X=\partial u_c(x;\xi,\eta)/\partial X$, $X=\xi,\eta$. Notice the importance of the last condition. If it is fulfilled, then one may insert into (28), with measure (41),

$$1=\frac{\Delta(u,p)}{\Delta_c(\xi,\eta)} \tag{46}$$

and integrate over $u(x,t)$ and $p(x,t)$. Notice that the possible infinite factor $(\delta(0))^k$ would be canceled in the ratio (46).

The Jacobian of transformation

$$J=\int \frac{Du\,Dp}{\Delta_c(\xi,\eta)}\prod_{x,t}\delta\left(\dot{u}-\frac{\delta H_j(u,p)}{\delta p}\right)\delta\left(\dot{p}+\frac{\delta H_j(u,p)}{\delta u}\right)$$
$$\times\,\delta(u(x,t)-u_c(x;\xi,\eta))\,\delta(p(x,t)-p_c(x;\xi,\eta)), \tag{47}$$

is proportional to functional δ-functions again. To have the transformation, we should use the last two δ functions. Notice, if the first two δ functions are used to calculate J, then the last two δ functions realize the constraints. In result,

$$J=\frac{1}{\Delta_c(\xi,\eta)}\prod_{x,t}\delta\left(\dot{u}_c-\frac{\delta H_j(u_c,p_c)}{\delta p_c}\right)\delta\left(\dot{p}_c+\frac{\delta H_j(u_c,p_c)}{\delta u_c}\right). \tag{48}$$

It should be underlined that u_c and p_c are *arbitrary* functions of ξ and η, i.e., on this stage we make the transformation of arbitrary functions $u(x,t)$ and $p(x,t)$ on the new arbitrary functions $u_c(x;\xi,\eta)$ and $p_c(x;\xi,\eta)$, where, generally speaking, $\xi=\xi(x,t)$ and $\eta=\eta(x,t)$. Then Δ_c is the corresponding determinant.

The expression (48) can be rewritten identically to the form

$$J=\frac{1}{\Delta_c(\xi,\eta)}\int\prod_{x,t}\mathrm{d}\xi'(t)\mathrm{d}\eta'(t)\,\delta\left(\dot\xi'-\left(\dot\xi-\frac{\delta h_j(\xi,\eta;t)}{\delta\eta}\right)\right)\delta\left(\dot\eta'-\left(\dot\eta+\frac{\delta h_j(\xi,\eta;t)}{\delta\xi}\right)\right)$$
$$\times\,\delta\left(u_c^\xi\xi'+u_c^\eta\eta'+\{u_c,h_j\}-\frac{\delta H_j}{\delta p_c(x,t)}\right)\delta\left(p_c^\xi\xi'+p_c^\eta\eta'-\{p_c,h_j\}+\frac{\delta H_j}{\delta u_c(x,t)}\right),\qquad(49)$$

where $\{,\}$ is the Poisson bracket.

Let us assume now that the auxiliary function $h_j(\xi,\eta;t)$ is chosen so that the equalities

$$\{u_c,h_j\}=\frac{\delta H_j}{\delta p_c(x,t)},\quad \{p_c,h_j\}=-\frac{\delta H_j}{\delta u_c(x,t)}\qquad(50)$$

are satisfied identically. Then, taking into account the condition (45), one can find

$$J=\delta\left(\dot\xi-\frac{\delta h_j(\xi,\eta;t)}{\delta\eta}\right)\delta\left(\dot\eta+\frac{\delta h_j(\xi,\eta;t)}{\delta\xi}\right).\qquad(51)$$

This ends the transformation. Notice that the determinant Δ_c was canceled identically.

The transformation specify by the Eqs. (50) the function h_j. It assumes that one can find such functions $u_c=u_c(x;\xi,\eta)$ and $p_c=p_c(x;\xi,\eta)$, with property (45), that (50) has unique solution $h_j(\xi,\eta;t)$.

Let us convert the problem assuming that just h_j is known. It is natural to assume that

$$h_j(\xi,\eta;t)=H_j(u_c,p_c),\qquad(52)$$

then u_c and p_c are defined by Eqs. (50) and

$$\dot\xi=\frac{\delta h_j(\xi,\eta;t)}{\delta\eta},\quad \dot\eta=-\frac{\delta h_j(\xi,\eta;t)}{\delta\xi}.\qquad(53)$$

It is not hard to see that (50) together with (53) are equivalent to incident equations (36). This is seen from the following chain of equalities:

$$\dot u_c(x;\xi\eta)=u_c^\xi\dot\xi+u_c^\eta\dot\eta=u_c^\xi\frac{\partial h_j(\xi,\eta;t)}{\partial\eta}-u_c^\eta\frac{\partial h_j(\xi,\eta;t)}{\partial\xi}$$
$$=\{u_c,h_j\}=\frac{\delta H_j}{\delta p_c(x,t)}$$

and the same we have for p_c. Therefore (u_c,p_c) is the classical phase space flow and the space W_G, labeled by (ξ,η), is the coset space G/G_c.

In result, the new measure takes the form (41), i.e., ξ and η should obey the equations (53):

$$\dot\xi=\omega(\eta)-\int\mathrm{d}x\,j(x,t)\frac{\partial u_N(x;\xi,\eta)}{\partial\eta},\quad \dot\eta=\int\mathrm{d}x\,j(x,t)\frac{\partial u_N(\xi,\eta)}{\partial\xi},\qquad(54)$$

where $\omega(\eta)\equiv\partial h(\eta)/\partial\eta$. Hence the source of quantum perturbations are proportional to the time-local tangent vectors

$$\int \mathrm{d}x\, \partial u_N(x;\xi,\eta)/\partial\eta, \quad \int \mathrm{d}x\, \partial u_N(x;\xi,\eta)/\partial\xi$$

to the soliton configurations. It suggests the idea in Ref. 14 to split the Lagrange sources

$$j(x,t)\to(j_\xi,j_\eta)(t).$$

The mechanism of splitting was described in Ref. 10. The resulting operator $\mathcal{O}(u_c)$, defined in (28), has the same structure. But new perturbations of the generating operator

$$\hat{K}(e_\xi,e_\eta;j_\xi,j_\eta)=\tfrac{1}{2}\mathrm{Re}\int_{C_+}\mathrm{d}t\{\hat{j}_\xi(t)\cdot\hat{e}_\xi(t)+\hat{j}_\eta(t)\cdot\hat{e}_\eta(t)\}. \tag{55}$$

The measure takes the form

$$DM(\xi,\eta)=\prod_t \mathrm{d}\xi(t)\mathrm{d}\eta(t)\,\delta(\dot{\xi}-\omega(\eta)-j_\xi(t))\,\delta(\dot{\eta}-j_\eta(t)). \tag{56}$$

The effective potential $U=U(u_c;e_c)$ with

$$e_c(x,t)=e_\xi(t)\cdot\frac{\partial u_N(x;\xi,\eta)}{\partial\eta(t)}-e_\eta(t)\cdot\frac{\partial u_N(x;\xi,\eta)}{\partial\xi(t)}. \tag{57}$$

Notice that the space degree of freedom is disappeared from our consideration.

III. MULTIPLE PRODUCTION IN SIN-GORDON MODEL

We would consider the theory with the Lagrangian

$$L=\frac{1}{2}(\partial_\mu u)^2+\frac{m^2}{\lambda^2}[\cos(\lambda u)-1]. \tag{58}$$

It is well known that this field model possesses the soliton excitations in the $(1+1)$ dimension.

Formally nothing prevents to linearize partly our problem considering the Lagrangian

$$L=\frac{1}{2}[(\partial_\mu u)^2-\alpha m^2u^2]+\frac{m^2}{\lambda^2}\left[\cos(\lambda u)-1+\alpha\frac{\lambda^2}{2}u^2\right]\equiv S(u)-v(u). \tag{59}$$

The last term $v(u)=O(u^4)$ describes interactions. The corresponding vertex function is

$$\Gamma(q;u)=\int \mathrm{d}x\,\mathrm{d}t\, e^{iqx}(\partial^2+m^2)u(x,t), \quad q^2=m^2. \tag{60}$$

It should be noted here that the division chosen in (59) onto the free and interaction parts did not affect the equation of motion, see (33), and effective potential, see (31), i.e., in this sense α may be chosen arbitrary. But α will arise in the definition of the mass: one should change $m^2\to\alpha m^2$ in (60). This means that our S-matrix approach requires additional, external, normalization condition for the mass shell. We will choose $\alpha=1$ assuming that m is the measured mass of the meson.

We assume that $u(x,t)$ belongs to Schwarz space:

$$u(x,t)|_{|x|=\infty}=0\left(\mathrm{mod}\frac{2\pi}{\lambda}\right). \tag{61}$$

This means that $u(x,t)$ tends to zero $[\mathrm{mod}\,(2\pi/\lambda)]$ at $|x|\to\infty$ faster then any power of $1/|x|$.

The ν-soliton classical Hamiltonian h_ν is the sum

$$h_\nu(\eta)=\int \mathrm{d}r\ \sigma(r)\sqrt{r^2+m^2}+\sum_{i=1}^{\nu} h(\eta_i), \tag{62}$$

where $\sigma(r)$ is the continuous spectrum and $h(\eta)$ is the soliton energy. Notice absence of the energy of soliton interactions.

The ν-soliton solution u_ν depends on the 2ν parameters. Half of the ν can be considered as the position of the solitons and the other ν as the solitons momentum. Generally, at $|t|\to\infty$ the u_ν solution decomposed on the single solitons u_s and on the double soliton bound states u_b:

$$u_\nu(x,t)=\sum_{j=1}^{n_1} u_{s,j}(x,t)+\sum_{k=1}^{n_2} u_{b,k}(x,t)+O(e^{-|t|}). \tag{63}$$

For this reason the one soliton u_s and two-soliton bound state u_b would be the main elements of our formalism. Its (ξ,η) parametrizations, i.e., the solution of Eq. (50), has the form:[27]

$$u_s(x;\xi,\eta)=-\frac{4}{\lambda}\arctan\{\exp(mx\cosh\beta\eta-\xi)\},\quad \beta=\frac{\lambda^2}{8} \tag{64}$$

and

$$u_b(x;\xi,\eta)=-\frac{4}{\lambda}\arctan\left\{\tan\frac{\beta\eta_2}{2}\,\frac{mx\sinh\dfrac{\beta\eta_1}{2}\cos\dfrac{\beta\eta_2}{2}-\xi_2}{mx\cosh\dfrac{\beta\eta_1}{2}\sin\dfrac{\beta\eta_2}{2}-\xi_1}\right\}. \tag{65}$$

The (ξ,η) parametrization of soliton individual energies $h(\eta)$ takes the form

$$h_s(\eta)=\frac{m}{\beta}\cosh\beta\eta,\quad h_b(\eta)=\frac{2m}{\beta}\cosh\frac{\beta\eta_1}{2}\sin\frac{\beta\eta_2}{2}\geqslant 0.$$

The bound-state energy h_b depends on η_2 amd η_1. First one defines the inner motion of two bounded solitons and the second one defines the bound states center of mass motion. Correspondingly we will call these parameters as the internal and external ones. Note that the inner motion is periodic, see (65).

Following the definition of the Dirac measure one should sum over all solutions of the Lagrange equation, see the property (b). In Sec. II. As follows from the equality:

$$\sum_{\{u_c\}}=\int_{W_G}\mathrm{d}\xi_0\,\mathrm{d}\eta_0\sigma(u;\xi_0,\eta_0),$$

we should define the density $\sigma(u;\xi_0,\eta_0)$ of states in the element of the coset space W_G. The Faddeev–Popov *ansatz* is used for this purpose.[4]

In our approach, performing the transformation into the coset space W_G, we define the density $\sigma(u;\xi_0,\eta_0)$. Indeed, using the definition

$$\int Dx\prod_t \delta(\dot{x})=\int \mathrm{d}x(0)=\int \mathrm{d}x_0$$

the functional integrals with measure (56) are reduced to the ordinary ones over the initial data $(\xi,\eta)_0$.

But it is important here to trace on the following question. One can note that, at first glance, integration over $(\xi,\eta)_0$ may only give $\rho\sim V_0^1$, where V_0 is the zero modes volume, i.e., is a volume of the W_G space. On other hand, as follows from definition of $\rho\sim|a_{nm}|^2$, one may expect that $\rho\sim V_0^2$. This discrepancy should have an explanation.

Remembering definition of ρ as the square of the amplitudes, we should define the contributions on the whole time contour $C=C_+ + C_-$, see (15), to take into account the input condition that the trajectories $u_+(t\in C_+)$ and $u_-(t\in C_-)$ are absolutely independent in the frame of the closed-path boundary condition (27):

$$u_c(x,t\in\partial C_+)=u_c(x,t\in\partial C_-), \tag{66}$$

where $\partial C_\pm$ is the boundary of $C_\pm$. Other directions to the $\sigma_{|}infty$ are not important here.

Then, if we introduce $(\xi,\eta)(t\in C_\pm)|_0\equiv(\xi_0,\eta_0)_\pm$, one should have in mind that, generally speaking, $(\xi_0,\eta_0)_+\neq(\xi_0,\eta_0)_-$ and the integration over them should be performed independently. This may explain the above discrepancy and one should have $\rho\sim V_0^2$.

It is not hard to see that for our topological solitons the condition (66) leads to the equalities

$$(\xi_0,\eta_0)_+=(\xi_0,\eta_0)_-=(\xi_0,\eta_0). \tag{67}$$

To see this it is enough to insert (64), or (65), into (66) and take into account that at $t\in\partial C_\pm$ the estimation (63) is right.

Solution (67) means that, for arbitrary functional $F(\xi,\eta)$,

$$\int\prod_{t\in C_++C_-}\mathrm{d}\xi\mathrm{d}\eta\,\delta(\dot\xi)\delta(\dot\eta)F(\xi,\eta)=\int\mathrm{d}\xi_{0+}\mathrm{d}\eta_{0+}\int\mathrm{d}\xi_0 d\,\eta_0F(\xi_0,\eta_0). \tag{68}$$

Therefore, $\rho\sim V_0^2$. We will put out the integrals over inessential variables ξ_{0+} and η_{0+}.

It should be underlined that (67) is the consequence of the conservation of the topological charge: the solitons by this reason are the stable formation and, therefore, to satisfy the closed path boundary condition, one should have (67).

Performing the shifts

$$\xi_i(t)\to\xi_i(t)+\int\mathrm{d}t'\,g(t-t')j_{\xi,i}(t')\equiv\xi_i(t)+\xi_i'(t),$$

$$\eta_i(t)\to\eta_i(t)+\int\mathrm{d}t'\,g(t-t')j_{\eta,i}(t')\equiv\eta_i(t)+\eta_i'(t),$$

we can get the Green function $g(t-t')$ into the operator exponent

$$\hat K(ej)=\frac{1}{2}\int\mathrm{d}t\,\mathrm{d}t'\Theta(t-t')\{\hat\xi'(t')\cdot\hat e_\xi(t)+\hat\eta'(t')\cdot\hat e_\eta(t)\}, \tag{69}$$

since the Green function $g(t-t')$ of the transformed theory is the step function[10]

$$g(t-t')=\Theta(t-t'). \tag{70}$$

Such Green function allows to shift $C_\pm$ on the real-time axis. This, noting (67), excludes doubling of the degrees of freedom.

Notice the Lorentz noncovariantness of our perturbation theory with Green function (70).

The measure takes the form

$$D^\nu M(\xi,\eta)=\prod_{i=1}^{\nu}\prod_t\mathrm{d}\xi_i(t)\mathrm{d}\eta_i(t)\,\delta(\dot\xi_i-\omega(\eta+\eta'))\delta(\dot\eta_i). \tag{71}$$

The interactions are described by

$$U(u_\nu;e_c)=-\frac{2m^2}{\lambda^2}\int \mathrm{d}x\,\mathrm{d}t\,\sin\lambda u_\nu(\sin\lambda e_c-\lambda e_c) \tag{72}$$

with

$$u_\nu=u_\nu(x;\xi+\xi',\eta+\eta') \tag{73}$$

and e_c was defined in (57).

The equation

$$\dot{\xi}_i=\omega(\eta_i+\eta_i') \tag{74}$$

is trivially integrable. In the quantum case $\eta_i'\neq 0$ this equation describes motion in the nonhomogeneous and anisotropic manifold. So, the expansion over $(\hat{\xi}',\hat{e}_\xi,\hat{\eta}',\hat{e}_\eta)$ generates the local in time fluctuations of W_G manifold. The weight of these fluctuations is defined by $U(u_\nu;e_c)$.

Expansion of $\exp\{\hat{K}(je)\}$ gives the strong coupling perturbation series. The analyses show that[14]

S3. Action of the integro-differential operator $\hat{\mathcal{O}}$ leads to the following representation:

$$\rho(\alpha,z)=\int_{W_G}\left\{\mathrm{d}\xi(o)\cdot\frac{\partial}{\partial\xi(0)}R^\xi(\alpha,z)+\mathrm{d}\eta(0)\cdot\frac{\partial}{\partial\eta(0)}R^\eta(\alpha,z)\right\}. \tag{75}$$

This means that the contributions into ρ are accumulated strictly on the boundary bifurcation manifold ∂W_G. The proof of this important result was given in Refs. 10 and 14 and we will use it without comments.

We would divide calculations on two parts. First of all, we would consider the semiclassical approximation and then we will show that this approximation is exact.

Performing the last integration we find

$$\rho(\alpha,z)=\int\prod_{i=1}^{\nu}\{\mathrm{d}\xi_0\,\mathrm{d}\eta_0\}_i e^{-i\hat{K}}e^{iS_O(u_\nu)}e^{-iU(u_\nu;e_c)}e^{N(\alpha,z;u_\nu)}, \tag{76}$$

where

$$u_\nu=u_\nu(\eta_0+\eta',\xi_0+\omega(t)+\xi') \tag{77}$$

and

$$\omega(t)=\int \mathrm{d}t'\,\Theta(t-t')\omega(\eta_0+\eta')(t'). \tag{78}$$

In the semiclassical approximation $\xi'=\eta'=0$ we have

$$u_\nu=u_\nu(x;\eta_0,\xi_0+\omega(\eta_0)t). \tag{79}$$

Notice that the surface term

$$\int \mathrm{d}x^\mu\,\partial_\mu(e^{iqx}u_\nu)=0. \tag{80}$$

Then

$$\int \mathrm{d}^2x\, e^{iqx}(\partial^2+m^2)u_\nu(x,t)=-(q^2-m^2)\int \mathrm{d}^2x\, e^{iqx}u_\nu(x,t)=0, \tag{81}$$

since q^2 belongs to the mass shell by definition. The condition (80) is satisfied for all $q_\mu\neq 0$ since u_ν belongs to the Schwarz space. Therefore, in the semiclassical approximation $R^c(\alpha,z)$ is the trivial function of z: $\partial R^c(\alpha,z)/\partial z=0$.

Expending the operator exponent in (76), we find that action of the operators $\hat{\xi}'$, $\hat{\eta}'$ create the terms

$$\sim \int \mathrm{d}^2x\, e^{iqx}\theta(t-t')(\partial^2+m^2)u_\nu(x,t)\neq 0. \tag{82}$$

So, generally $R(\alpha,z)$ is the nontrivial function of z.

Now we will show that the semiclassical approximation is exact in the soliton sector of the sin-Gordon model. The structure of the perturbation theory is readily seen in the normal-product form

$$R(\alpha,z)=\sum_\nu \int \prod_{i=1}^{N}\{\mathrm{d}\xi_0\mathrm{d}\eta_0\}_i :e^{-iU(u_\nu;\hat{J}/2i)}e^{iS_O(u_\nu)}e^{N(\alpha,z;u_\nu)}:, \tag{83}$$

where

$$\hat{J}=\hat{J}_\xi\cdot\frac{\partial u_\nu}{\partial\eta}-\hat{J}_\eta\cdot\frac{\partial u_\nu}{\partial\xi}=\Omega\hat{J}_X\frac{\partial u_\nu}{\partial X} \tag{84}$$

and

$$\hat{J}_X=\int \mathrm{d}t'\,\Theta(t-t')\hat{X}(t') \tag{85}$$

with the $2N$-dimensional vector $X=(\xi,\eta)$. In Eq. (84) Ω is the ordinary symplectic matrix.

The colons in (83) mean that the operator $\hat{J}$ should stay to the left of all functions. The structure (84) shows that each order over $\hat{J}_{X_i}$ is proportional at least to the first order derivative of u_ν over conjugate to X_i variable.

The expansion of (83) over $\hat{J}_X$ can be written using the form

$$\rho(\alpha,z)=\sum_\nu \int \prod_{i=1}^{\nu}\{\mathrm{d}\xi_0\,\mathrm{d}\eta_0\}_i\left\{\sum_{i=1}^{2\nu}\frac{\partial}{\partial X_{0i}}P_{X_i}(u_\nu)\right\}, \tag{86}$$

where $P_{X_i}(u_\nu)$ is the infinite sum of the time-ordered polynomial over u_ν and its derivatives.[14] The explicit form of $P_{X_i}(u_\nu)$ is unimportant, it is enough to know, see (84), that

$$P_{X_i}(u_\nu)\sim\Omega_{ij}\frac{\partial u_\nu}{\partial X_{0j}}. \tag{87}$$

Therefore,

$$\frac{\partial}{\partial z}R(\alpha,z)=0 \tag{88}$$

since (i) each term in (86) is the total derivative, (ii) we have (87), and (iii) u_ν belongs to Schwarz space.

IV. CONCLUSION

We would like to conclude this paper noting the role of the coset space G/G_c topology. It was shown that if

(i) $W_G=G/G_c\neq\varnothing$,
(ii) $W_G=T^*V$ is the simplectic manifold,
(iii) ∂u_c is the phase space flow [see (87)],
(iv) $\partial u_c\cap\partial W_G=\varnothing$,

then the semiclassical approximation is exact.

For this reason, being absolutely stable, topological solitons are unable to describe the multiple production processes. This property of the exactly integrable models was formulated also as the absence of stochastization in the integrable systems.[28] The $O(4)\times O(2)$-invariant solution of $O(4,2)$-invariant theories[29] is noticeably more interesting from this point of view.[30]

ACKNOWLEDGMENTS

We acknowledged to members of the seminar 'Symmetries and integrable systems' of the N.N. Bogolyubov Laboratory of theoretical physics (JINR) for important discussions. We would like to thank V.G. Kadyshevski for fruitful interest to described technique and underling idea. One of us (J.M.) was partially supported by the Georgian Academy of Sciences.

APPENDIX: DERIVATION OF EQ. (29)

The generating functional (24) can be written in the form

$$\rho(\beta,z)=e^{-\overline{n}(s)(\beta,z;\varphi)}\rho_0(\varphi), \tag{A1}$$

where the particles number operator

$$\overline{n}(s)(\beta,z;\varphi)=\overline{n}(s)(\beta_+,z_+;\varphi)+\overline{n}(s)^*(\beta_-,z_-;\varphi) \tag{A2}$$

and

$$\overline{n}(s)(\beta_+,z_+;\varphi_+)=\int \mathrm{d}\Omega_1(q)\hat{\varphi}_+^*(q)\hat{\varphi}_-(q)e^{-\beta_+\epsilon(q)}z_+(q) \tag{A3}$$

is the produced particle number operator.

The functional ρ_0 was introduced in (25):

$$\begin{aligned}\rho_0(\varphi)&=Z(\varphi_+)Z^*(-\varphi_-)\\&=\int Du_+\,Du_-e^{iS_+(u_+)-iS_-(u_-)}e^{-iV_+(u_++\varphi_+)+iV_-(u_--\varphi_-)}.\end{aligned} \tag{A4}$$

So, the integration over u_+ and u_- is not performed independently: one should take into account the boundary condition (27). We can perform in this integral the linear transformation

$$u_\pm(x)=u(x)\pm\phi(x). \tag{A5}$$

Then the boundary condition (27) leads to the equality

$$\phi(x\in\sigma_\infty)=0, \tag{A6}$$

leaving $u(x\in\sigma_\infty)$ arbitrary. Last one means that the integration over this turning-point field $u(x\in\sigma_\infty)$ should be performed, see Sec. III.

Let us extract in the exponents (A4) the linear term over $(\phi+\varphi)$:

$$V_+(u+(\phi+\varphi))-V_-(u-(\phi+\varphi))$$
$$=U(u,\phi+\varphi)+2\,\mathrm{Re}\int_{C_+}\mathrm{d}x(\phi(x)+\varphi(x))v'(u) \tag{A7}$$

and

$$S_+(u+\varphi)-S_-(u-\varphi)=S_O(u)-2i\,\mathrm{Re}\int_{C_+}\mathrm{d}x\,\varphi(x)(\partial_\mu^2+m^2)u(x), \tag{A8}$$

where

$$2\,\mathrm{Re}\int_{C_+}=\int_{C_+}+\int_{C_-}.$$

Notice that generally speaking, $S_O(u)\neq 0$, if the topology of the field $u(x)$ is nontrivial, see Sec. III.

The expansion over $(\phi+\varphi)$ can be written in the form

$$e^{-iU(u,\phi+\varphi)}=e^{(1/2i)\,\mathrm{Re}\int_{C_+}\mathrm{d}x\,\hat{j}(x)\widehat{\varphi'}(x)}e^{i2\,\mathrm{Re}\int_{C_+}\mathrm{d}x\,\mathrm{d}t\,j(x)(\phi(x)+\varphi(x))}e^{-iU(u,\varphi')}, \tag{A9}$$

where $\hat{j}(x)$, $\widehat{\varphi'}(x)$ are the variational derivatives. The auxiliary variables (j,φ') must be taken equal to zero at the very end of the calculations.

In result,

$$\rho_0(\phi)=e^{(1/2i)\mathrm{Re}\int_{C_+}\mathrm{d}x\,\hat{j}(x)\hat{\varphi}(x)}\int Du\,e^{is_0(u)}e^{-iU(u,\varphi)}e^{i2\,\mathrm{Re}\int_{C_+}\mathrm{d}x(j(x)-v'(u))\phi(x)}$$
$$\times\prod_x\,\delta(\partial_\mu^2u+m^2u+v'(u)-j), \tag{A10}$$

where the functional δ function was defined by the equality

$$\prod_x\,\delta(\partial_\mu^2u+m^2u+v'(u)-j)=\int D'\phi\,e^{-2i\,\mathrm{Re}\int_{C_+}\mathrm{d}x(\partial_\mu^2u+m^2u+v'(u)-j)\varphi(x)}, \tag{A11}$$

where the prime means that $D'\phi$ does not includes the integration over $\phi(x\in\sigma_\infty)$. This condition is not seen in the functional δ function because of the definition

$$\int\,\prod_x\,\mathrm{d}u(x)\,\delta(\partial_\mu u(x))=\int\mathrm{d}u(x_\mu\in\sigma_\infty).$$

Equation (A10) can be rewritten in the equivalent form

$$\rho_0(\phi)=e^{-i\hat{K}(j,\varphi)}\int DM(u)e^{is_0(u)-iU(u,\varphi)}e^{i2\,\mathrm{Re}\int_{C_+}\mathrm{d}x\,\phi(x)(\partial_\mu^2+m^2)u(x)} \tag{A12}$$

because of the δ functional measure

$$DM(u)=\prod_x\,\mathrm{d}u(x)\,\delta(\partial_\mu^2u+m^2u+v'(u)-j), \tag{A13}$$

with

$$\hat{K}(j\varphi)=\frac{1}{2}\mathrm{Re}\int_{C_+}\mathrm{d}x\hat{j}(x)\hat{\varphi}(x). \tag{A14}$$

Notice at the end that the contour C_+ in (A14) cannot be shifted on the real time axis since the Green function of the equation

$$\partial_\mu^2 u + m^2 u + v'(u) = j$$

is singular on the light cone.

The action of operator $\mathbf{N}(\beta, z; \hat{\phi})$ maps the interacting fields system on the physical states. Last ones are marked by $z_\pm$ and $\beta_\pm$. The operator exponent is the linear functional over ϕ and this allows easily find (28).

[2] The developed formalism is not manifestly Lorentz covariant. By this reason we decouple the space component x and time t. But, if the expression contains the x dependence only, then in this expression x is the two-dimensional vector.
[3] It was noted in the papers of R. Dashen, B. Hasslacher, and A. Neveu, Phys. Rev. D **10**, 4114 (1974); **10**, 4130 (1974) that the semiclassical bound states mass spectrum of sin-Gordon model coincide with strict one, defined using the isomorphysm among the Thirring fermion fields model and soliton sector of the sin-Gordon model, S. Coleman, *ibid.* **11**, 2088 (1975). This result may be explained as the consequence of stabilizing the quantum perturbations effect of the infinite number of hidden conservation laws in involution presence in the sin-Gordon model, J. L. Gervais and A. Neveu, Phys. Rep. **23**, 237 (1976). One may note also that the factorization of soliton S-matrix, see, e.g., R. Rajaraman, *Solitons and Instantons* (North-Holland, Amsterdam, 1982), and absence of multiple production, A. B. Zamolodchikov and A. B. Zamolodchikov, Phys. Lett. **72B**, 503 (1978), is peculiar for the exactly integrable models. This seems natural since if the soliton may produce the meson, then the soliton S-matrix cannot be factorizable, as well as the mesons may produce the solitons.

I. INTRODUCTION

In classical mechanics a Hamiltonian system with n degrees of freedom is called ''integrable,'' or ''Liouville integrable,'' if it allows n functionally independent integrals of motion in involution that are well-defined functions on phase space.[1] The same concept is used in nonrelativistic quantum mechanics. There a system is integrable if it allows a set of n pairwise commuting linearly independent linear operators, including the Hamiltonian.

A system in classical, or quantum, mechanics is ''superintegrable'' if it allows more than n integrals of motion. A classical system with n degrees of freedom can allow up to $2n-1$ functionally independent integrals of motion. We shall call such a system ''maximally superintegrable.'' The best known maximally superintegrable systems in an n-dimensional Euclidean space E_n correspond to two spherically symmetric potentials, namely the Kepler (or Coulomb) potential $V=\alpha r^{-1}$ and the harmonic oscillator $V=\omega^2 r^2$. These are also the only spherically symmetric potentials in E_3 in which all finite trajectories are closed.[1,2] It is well known[3–5] that in quantum mechanics the corresponding operators, commuting with the Hamiltonian, form an $o(4)$ algebra for the hydrogen atom and a $su(3)$ algebra for the harmonic oscillator.

A systematic search for superintegrable systems in classical and quantum mechanics was started some time ago[6–8] and by now a sizable literature on this topic exists (see, e.g., Refs. 3–31 and references therein).

In quantum mechanics, the usual restriction is to consider linear operators that are polynomials in the momenta and require that they should commute with the Hamiltonian. Thus, in Euclidean space $E_n$we write the stationary Schrödinger equation as

$$H\psi=E\psi, \quad H=-\tfrac{1}{2}\Delta+V(\vec{r}) \tag{1.1}$$

and require

$$[H,\hat{X}_i]=0, \tag{1.2}$$

[a)]Electronic mail: sheftel@gursey.gov.tr
[b)]Electronic mail: tempesta@le.infn.it
[c)]Electronic mail: wintern@crm.umontreal.ca

where $\hat{X}_i$ are some polynomials in the momenta.

In a two-dimensional space E_2 it was shown[6,7] that one first-order operator $\hat{X}$ satisfying Eq. (1.2) implies that the potential has a geometric symmetry. This means that it is invariant either under rotations, $V(x,y)=V(r)$, or under translations, $V=V(x)$.

One second-order operator $\hat{X}$ implies that the Schrödinger equation (1.1) allows the separation of variables in one of the following coordinate systems: Cartesian, polar, parabolic, or elliptic. If two linearly independent operators commute with H, then H is (maximally) superintegrable. All finite classical trajectories are closed, the quantum energy levels are degenerate, and the Schrödinger equation can be solved in terms of known special functions.

The purpose of this article is to consider the problem of the integrability and superintegrability of the Schrödinger equation from a different point of view. Namely, we relate integrability and superintegrability to similar concepts in soliton theory.[32] There one is dealing with infinite dimensional Hamiltonian systems, with infinitely many integrals of motion. An indication of integrability is the existence of infinitely many ''generalized'' symmetries,[33] sometimes called ''Lie-Bäcklund'' symmetries,[34] i.e., symmetries depending on derivatives of the dependent variables. Another basic feature of soliton systems is the existence of a recursion operator that generates higher symmetries from lower ones.

Thus, we shall consider the Schrödinger equation (1.1) in two dimensions and establish conditions on the potential $V(x,y)$ for it to have one or more symmetries depending on first and second derivatives of the wave function ψ. We shall show that the same conditions imply the existence of a recursion operator.

In Sec. II we formulate the problem of finding Lie point symmetries and generalized symmetries of the linear Schrödinger equation in E_2 with an arbitrary potential. We use the formalism of evolutionary vector fields[33] and their prolongations. Section III is devoted to first-order symmetries, i.e., Lie transformations depending only on x,y,u,u_x,u_y. They turn out to be point symmetries and exist only if the potential is invariant under rotations about some point, or translations in some direction. In Sec. IV we find all second-order generalized symmetries. Generalized symmetries in classical and quantum mechanics were already introduced by Anderson *et al.*[31,34] and Fokas *et al.*[28–30] Here we perform a systematic study and in particular show that second-order symmetries exist if and only if the Schrödinger equation allows the separation of variables. The simplest superintegrable systems are introduced in Sec. V. They are required to have one first-order and one second-order symmetry. It turns out that four such systems exist with potential $\alpha r^{-1}, \omega^2 r^2, \alpha x^{-2}$, and αx, respectively. The study of superintegrable systems is completed in Sec. VI, where all potentials allowing two second-order symmetries are obtained. Four classes of such Schrödinger equations exist, each allowing separation of variables in at least two coordinate systems. Finally, in Sec. VII we show that a recursion operator, generating new symmetries from known ones can be identified with a linear operator commuting with the Hamiltonian.

II. FORMULATION OF THE PROBLEM

Our aim is to study the Lie point symmetries and generalized symmetries of the two-dimensional Schrödinger equation (1.1). First of all we notice that the stationary Schrödinger equation can be treated as a real equation since the real and imaginary parts of the wave function ψ satisfy the same equation. On the other hand, it is sometimes convenient to use complex independent variables. Thus, we rewrite Eq. (1.1) as

$$-\tfrac{1}{2}(u_{xx}+u_{yy})+(V-E)u=0, \quad \psi=u=u_1+iu_2, \tag{2.1}$$

or

$$S=u_{z\bar{z}}-Ru=0, \quad R=\tfrac{1}{2}(V(z,\bar{z})-E)$$
$$z=x+iy, \quad \bar{z}=x-iy. \tag{2.2}$$

The function $u(z,\bar{z})=\overline{u(z,\bar{z})}$ represents both the real and imaginary parts of ψ.

To find symmetries we shall use the formalism of evolutionary vector fields.[33] This allows us to treat Lie point symmetries, and generalized symmetries, on the same footing. An nth order symmetry is given by a vector field

$$\hat{W}=Q(z,\bar{z},u,u_z,u_{\bar{z}},u_{zz},u_{z\bar{z}},u_{\bar{z}\bar{z}},\ldots)\partial_u, \tag{2.3}$$

where the characteristic Q of the symmetry depends on derivatives up to order n. The condition for $\hat{W}$ to generate a symmetry of the equation, i.e., generate transformations taking solutions into solutions, is

$$pr^{(2)}\hat{W}S|_{S=0}=0 \tag{2.4}$$

with S given in Eq. (2.2). The vector field $\hat{W}$ acts only on functions of u, its second prolongation acts on functions of $u,u_z,u_{\bar{z}},u_{zz},u_{z\bar{z}}$ and $u_{\bar{z}\bar{z}}$. The part of the prolongation needed to act on Eq. (2.2) is

$$pr^{(2)}\hat{W}=\hat{W}+D_zD_{\bar{z}}Q\partial_{u_{z\bar{z}}}, \tag{2.5}$$

where D_z is the total derivative. The vector field $\hat{W}$ will generate point symmetries if it is of first order and moreover satisfies

$$Q=\phi(z,\bar{z},u)-\xi(z,\bar{z},u)u_z-\overline{\xi}(z,\bar{z},u)u_{\bar{z}},\quad \phi(z,\bar{z},u)=\overline{\phi}(z,\bar{z},u). \tag{2.6}$$

Equation (2.4) provides a set of determining equations for the function Q. Indeed, Q depends on derivatives up to order n. The prolongations introduce derivatives of order $n+1$ and $n+2$. All mixed derivatives like $u_{z\bar{z}},u_{zz\bar{z}},u_{z\bar{z}\bar{z}},\ldots$ must be eliminated, using Eq. (2.2) and its differential consequences. The coefficients of terms involving $u_{(n+1)z},u_{(n+1)\bar{z}},u_{(n+2)z},u_{(n+2)\bar{z}}$ must vanish separately. This will determine the dependence of Q on the highest derivatives. Proceeding in this manner we obtain an overdetermined system of linear partial differential equations for the function Q. Once Q is determined we obtain a flow

$$\frac{d}{d\lambda}\begin{pmatrix}u_1\\u_2\end{pmatrix}=\begin{pmatrix}Q_1\\Q_2\end{pmatrix} \tag{2.7}$$

that is compatible with the Schrödinger equation. In Eq. (2.7) λ is a group parameter and Q_1 and Q_2 are general solutions of the same determining equations, i.e., they differ only by possibly different choices of integration constants. The condition $Q_1=Q_2=0$ will provide us with invariant solutions of the Schrödinger equation. More generally, we can solve Eq. (2.7) together with the Schrödinger equation. Each flow (2.7) will provide us with a one-parameter family of solutions of the Schrödinger equation.

Some obvious symmetries exist for any (real) potential $V(x,y)$. They are

$$\begin{pmatrix}Q_1\\Q_2\end{pmatrix}=\begin{pmatrix}a&b\\c&d\end{pmatrix}\begin{pmatrix}u_1\\u_2\end{pmatrix}+\begin{pmatrix}h_1(x,y)\\h_2(x,y)\end{pmatrix}, \tag{2.8}$$

where a, b, c and d are arbitrary constants and h_1 and h_2 are real solutions of the Schrödinger equation. The constant matrix expresses the fact that u_1 and u_2 solve the same linear homogeneous equation, the functions $h_{1,2}$ express the linear superposition formula.

Our aim in this article is to find all first- and second-order Lie symmetries and the potentials that allow them. We shall classify the potentials under the Euclidean group $E(2)$, which leaves the Schrödinger equation form invariant. We shall need the Euclidean Lie algebra $e(2)$ with basis

$$L_3=y\partial_x-x\partial_y,\quad P_1=\partial_x,\quad P_2=\partial_y. \tag{2.9}$$

At an intermediate stage we shall use complex variables, in which the Schrödinger equation is Eq. (2.2). The determining equation (2.4) can be rewritten as

$$D_{z\bar{z}}Q - RQ|_{u_{z\bar{z}}=Ru} = 0. \tag{2.10}$$

The type of Lie symmetries that we obtain from Eq. (2.10) depends on the restrictions we impose on the characteristic functions Q_1 and Q_2. In this article we impose the following restrictions:

(1) Q_1 and Q_2 depend on derivatives up to second order only.
(2) The symmetries are energy independent, i.e., Q_1 and Q_2 are the same for all energies E.

The second condition is in keeping with the general philosophy of quantum mechanics. The Schrödinger equation is viewed as an eigenvalue problem and symmetries depend on the Hamiltonian, but not on the individual energy level.

We shall see in the following, that the functions Q_1 and Q_2 are linear in u_1 and u_2 and their derivatives. This makes it possible to write

$$\begin{pmatrix} Q_1 \\ Q_2 \end{pmatrix} = M_1 \hat{X} \begin{pmatrix} u_1 \\ u_2 \end{pmatrix} + M_2 \begin{pmatrix} u_1 \\ u_2 \end{pmatrix} + \begin{pmatrix} h_1(x,y) \\ h_2(x,y) \end{pmatrix}, \tag{2.11}$$

where M_1 and M_2 are arbitrary constant matrices, h_1 and h_2 are arbitrary real solutions of the Schrödinger equation, and $\hat{X}$ is a differential operator (to be determined in the following). Moreover, we shall show that the operator $\hat{X}$ commutes with the Hamiltonian

$$[H, \hat{X}] = 0. \tag{2.12}$$

III. FIRST-ORDER SYMMETRIES

Let us now consider the determining equation (2.10) with

$$Q = Q(z, \bar{z}, u, u_z, u_{\bar{z}}). \tag{3.1}$$

The expression $D_{z\bar{z}}Q$ will involve third-order terms $u_{zz\bar{z}}$ and $u_{z\bar{z}\bar{z}}$, but those are reduced to first-order ones, using the Schrödinger equation (2.2). From the coefficients of u_{zz} $u_{\bar{z}\bar{z}}$, u_{zz} and $u_{\bar{z}\bar{z}}$ we obtain

$$Q = \alpha(z) u_z + \bar{\alpha}(\bar{z}) u_{\bar{z}} + \phi(z, \bar{z}, u) \tag{3.2}$$

with ϕ real. The dependence on the first derivatives is thus linear. From the coefficients of u_z $u_{\bar{z}}$, u_z and $u_{\bar{z}}$ in Eq. (2.10) we now obtain

$$Q = \alpha(z) u_z + \bar{\alpha}(\bar{z}) u_{\bar{z}} + \gamma u + h(z, \bar{z}), \tag{3.3}$$

where $\gamma = \bar{\gamma}$ is a constant and h is a real function. Putting (3.3) back into Eq. (2.10) we obtain

$$\alpha_z R + \alpha R_z + \bar{\alpha}_{\bar{z}} R + \bar{\alpha} R_{\bar{z}} = 0, \tag{3.4}$$

$$h_{z\bar{z}} - Rh = 0. \tag{3.5}$$

Thus, $h(z, \bar{z}) = h(x,y)$ is an arbitrary (real) solution of the Schrödinger equation [see Eq. (2.11)].

In real variables Eq. (3.4) with the analyticity conditions $\alpha_{\bar{z}} = 0$, $\bar{\alpha}_z = 0$ implies

$$(\alpha_{1x} + \alpha_{2y})(V - E) + \alpha_1 V_x + \alpha_2 V_y = 0, \tag{3.6}$$

$$\alpha_{1x} - \alpha_{2y} = 0, \quad \alpha_{2x} + \alpha_{1y} = 0, \tag{3.7}$$

where

$$\alpha_1(x,y)=\mathrm{Re}\,\alpha, \quad \alpha_2(x,y)=\mathrm{Im}\,\alpha.$$

Up to now the symmetry Q and hence the functions α_1 and α_2 were allowed to depend on the energy E. Now, in keeping with the philosophy of quantum mechanics, we request that the symmetries be the same for all energies. This implies

$$\alpha_{1x}+\alpha_{2y}=0 \tag{3.8}$$

in Eq. (3.6). Together with the Cauchy–Riemann equations (3.7) this allows us to solve the system (3.6)–(3.8) completely. We obtain

$$\alpha_1=\alpha y+\beta, \quad \alpha_2=-\alpha x+\gamma, \tag{3.9}$$

where α, β, and γ are real constants and the potential $V(x,y)$ satisfies

$$[\alpha(y\partial_x-x\partial_y)+\beta\partial_x+\gamma\partial_y]V(x,y)=0. \tag{3.10}$$

The solution of Eq. (3.10) is

$$V=V(\xi), \quad \xi=\tfrac{1}{2}\alpha(x^2+y^2)-\gamma x+\beta y. \tag{3.11}$$

For $\alpha\neq 0$ we use a translation to annul β and γ. For $\alpha=0$ we rotate to put $\beta=0$.

We can sum up the results as a theorem.

Theorem 1: *First-order energy independent Lie symmetries of the Schrödinger equation (1.1) exist if and only if the potential allows a geometric symmetry, i.e., satisfies Eq. (3.10). The flow corresponding to this symmetry is*

$$\begin{pmatrix} u_1 \\ u_2 \end{pmatrix}_\lambda = (M_1\hat{X}+M_2)\begin{pmatrix} u_1 \\ u_2 \end{pmatrix}+\begin{pmatrix} h_1(x,y) \\ h_2(x,y) \end{pmatrix} \tag{3.12}$$

with

$$\hat{X}=\alpha L_3+\beta P_1+\gamma P_2, \quad \psi=u_1+iu_2. \tag{3.13}$$

$\alpha,\beta,\gamma\in R$, $M_1,M_2\in R^{(2\times 2)}$, and h_1, h_2 are real solutions of the Schrödinger equation.

Theorem 1 states that all first-order symmetries are hydrodynamic type[35,36] symmetries. It gives the precise relation between Lie symmetries of the Schrödinger equation and first-order operators, commuting with the Hamiltonian. Both are just manifestations of rotational, or translational symmetry of the potential. Equations (3.12) and (3.13) define Lie point symmetries if M_1 and M_2 are diagonal.

IV. SECOND-ORDER SYMMETRIES

A. The determining equations and general form of the symmetry

We again start from Eq. (2.10), this time with

$$Q=Q(z,\bar{z},u,u_z,u_{\bar{z}},u_{zz},u_{\bar{z}\bar{z}}) \tag{4.1}$$

[the term $u_{z\bar{z}}$ can be eliminated using the Schrödinger equation (2.2)]. The vanishing of the coefficients of $u_{zzz}u_{\bar{z}\bar{z}\bar{z}}$, u_{zzz}, and $u_{\bar{z}\bar{z}\bar{z}}$ implies that Q must be linear in u_{zz} and $u_{\bar{z}\bar{z}}$. The coefficients of $u_{zz}u_{\bar{z}\bar{z}}$, u_{zz}, and $u_{\bar{z}\bar{z}}$ must also vanish and we obtain that Q is linear in all derivatives. Substituting back into (2.10) we require that the coefficients of $u_zu_{\bar{z}}$, u_z, $u_{\bar{z}}$ and 1 must vanish separately. Finally, we obtain

$$Q=A(z)u_{zz}+\overline{A}(\overline{z})u_{\overline{z}\overline{z}}+B(z)u_z+\overline{B}(\overline{z})u_{\overline{z}}+C(z,\overline{z})u+h(z,\overline{z}),$$
$$C(z,\overline{z})=\overline{C(z,\overline{z})},\quad h(z,\overline{z})=\overline{h(z,\overline{z})} \tag{4.2}$$

with

$$RA_z+2AR_z+C_{\overline{z}}=0,$$
$$R\overline{A}_{\overline{z}}+2\overline{A}R_{\overline{z}}+C_z=0, \tag{4.3}$$

$$C_{z\overline{z}}+(B_z+\overline{B}_{\overline{z}})R+BR_z+\overline{B}R_{\overline{z}}+A_zR_z+\overline{A}_{\overline{z}}R_{\overline{z}}+AR_{zz}+\overline{A}R_{\overline{z}\overline{z}}=0, \tag{4.4}$$

$$h_{z\overline{z}}-Rh=0. \tag{4.5}$$

The function h just represents the linear superposition principle. Equations (4.3) and (4.4) must be solved. To do this we return to real variables, putting

$$\mathrm{Re}\,A=2a_1,\quad \mathrm{Im}\,A=2a_2,\quad \mathrm{Re}\,B=b_1,\quad \mathrm{Im}\,B=b_2.$$

We now have

$$Q=a_1(u_{xx}-u_{yy})+2a_2u_{xy}+b_1u_x+b_2u_y+C(x,y)u+h(x,y). \tag{4.6}$$

Analyticity imposes the Cauchy–Riemann conditions on the functions (a_1,a_2) and (b_1,b_2), i.e.,

$$a_{1,x}=a_{2,y},\quad a_{1y}=-a_{2,x}, \tag{4.7}$$

$$b_{1,x}=b_{2,y},\quad b_{1y}=-b_{2,x}. \tag{4.8}$$

The function $C(x,y)$ is determined by Eq. (4.3),

$$C_x=-(V-E)(a_{1x}+a_{2y})-2a_1V_x-2a_2V_y,$$
$$C_y=-(V-E)(a_{1y}-a_{2x})-2a_2V_x+2a_1V_y. \tag{4.9}$$

The compatibility condition for Eq. (4.9) is

$$2[(V-E)a_1]_{xy}-(a_2V_x)_x+(a_2V_y)_y=0. \tag{4.10}$$

We now request that a_1 and a_2 be energy independent. This implies

$$a_{1,x\,y}=0. \tag{4.11}$$

Combining Eqs. (4.11) and (4.7), we obtain

$$a_1=-\tfrac{1}{2}a(x^2-y^2)+by+cx+d,$$
$$a_2=-axy-bx+cy+e, \tag{4.12}$$

where $a,\ldots,e$ are real constants.

In Eq. (4.4) we eliminate $C_{z\overline{z}}$ using Eq. (4.3). We set the energy-dependent and energy-independent parts equal to zero separately and obtain

$$b_1=-ax+\alpha y+\beta+c,$$
$$b_2=-ay-\alpha x+\gamma-b, \tag{4.13}$$

where α, β, and γ are constants and

$$[\alpha(y\partial_x - x\partial_y) + \beta\partial_x + \gamma\partial_y]V = 0. \tag{4.14}$$

Equation (4.14) is precisely the condition (3.10) for a first-order symmetry to exist. We are interested in the most general potential for which one second-order symmetry exists. Hence, we require Eq. (4.14) to be satisfied trivially, and put

$$\alpha = \beta = \gamma = 0. \tag{4.15}$$

We now rewrite Eq. (4.2) for Q as

$$\begin{aligned} Q = \{&aL_3^2 + b(L_3P_1 + P_1L_3) + c(L_3P_2 + P_2L_3) + d(P_1^2 - P_2^2) \\ &+ 2eP_1P_2 + \phi(x,y)\}u + h(x,y) \end{aligned} \tag{4.16}$$

with

$$\begin{aligned} \phi_x &= -2(ay^2 + 2by + d)V_x + 2(axy + bx - cy - e)V_y, \\ \phi_y &= 2(axy + bx - cy - e)V_x + 2(-ax^2 + 2cx + d)V_y. \end{aligned} \tag{4.17}$$

The compatibility condition for Eq. (4.17) gives us the condition on the potential, necessary and sufficient for a second-order symmetry to exist, namely

$$\begin{aligned} &(-axy - bx + cy + e)(V_{xx} - V_{yy}) + [a(x^2 - y^2) - 2by - 2cx - 2d]V_{xy} \\ &\quad - 3(ay + b)V_x + 3(ax - c)V_y = 0. \end{aligned} \tag{4.18}$$

Now let us consider a second-order operator $\hat{X}$, the differential part of which lies in the enveloping algebra of the Euclidean Lie algebra $e(2)$:

$$\begin{aligned} \hat{X} = &aL_3^2 + b(L_3P_1 + P_1L_3) + c(L_3P_2 + P_2L_3) + d(P_1^2 - P_2^2) \\ &+ 2eP_1P_2 + \alpha L_3 + \beta P_1 + \gamma P_2 + \phi(x,y). \end{aligned} \tag{4.19}$$

Let us require that it should commute with the Hamiltonian:

$$[H, \hat{X}] = 0. \tag{4.20}$$

This will be the case if and only if the function ϕ and the potential are related by Eq. (4.17) and the potential satisfies Eq. (4.14) [and the compatibility condition (4.18)].

We have obtained the following theorem.

Theorem 2: *A second-order Lie symmetry (4.1) of the Schrödinger equation (2.1) exists if and only if there exists a second-order operator $\hat{X}$ of the form (4.19) that commutes with the Hamiltonian.*

Finding the operator $\hat{X}$ and the symmetry characteristic Q is thus reduced to solving Eq. (4.18) for the potential and (4.17) for $\phi(x,y)$. This task was already solved in Refs. 6 and 7. For completeness, we review the results in the following.

B. Classification of second-order symmetries

In Sec. IV A we have reduced the set of determining equations for the characteristic Q of a second-order symmetry to Eq. (4.18) for the potential $V(x,y)$.

To solve this equation, we first classify the operators $\hat{X}$ into orbits under the action of the Euclidean group $E(2)$. We also allow linear combinations of $\hat{X}$ with H to ensure that only $P_1^2 - P_2^2$ enters in $\hat{X}$, not P_1^2 and P_2^2 separately.

The result is that the operator $\hat{X}$ can be transformed into precisely one of the following operators.

(1) $a=0$, $b=0$, $c=0$, $d^2+e^2\neq 0$:

$$\hat{X}_C=-\tfrac{1}{2}(P_1^2-P_2^2)+\phi_C(x,y). \tag{4.21}$$

(2) $a\neq 0$, $l^2=(1/a^3)[(2a^2d+b^2-c^2)^2+4(a^2e+bc)^2]^{1/2}=0$:

$$\hat{X}_R=L_3^2+\phi_R(x,y). \tag{4.22}$$

(3) $a=0$, $b^2+c^2\neq 0$:

$$\hat{X}_P=L_3P_2+P_2L_3+\phi_P(x,y). \tag{4.23}$$

(4) $a\neq 0$, $l^2\neq 0$:

$$\hat{X}_E=L_3^2+\frac{l^2}{2}(P_1^2-P_2^2)+\phi_E(x,y), \tag{4.24}$$

where l^2 is given above Eq. (4.22).

We shall call $\hat{X}_C$, $\hat{X}_R$, $\hat{X}_P$ and $\hat{X}_E$ Cartesian, polar, parabolic, and elliptic operators, respectively.

C. Solution of the determining equations

Let us now run through the four representative cases (4.21)–(4.24).

(1) *The Cartesian operator* $\hat{X}_C$. We have $a=b=c=e=0$ in Eqs. (4.16)–(4.19), and also $\alpha=\beta=\gamma=0$. Equation (4.18) reduces to $V_{xy}=0$ and we obtain

$$V=f(x)+g(y), \quad \phi_C=f(x)-g(y), \tag{4.25}$$

where $f(x)$ and $g(y)$ are arbitrary functions.

This is the most general potential that allows the separation of variables in Cartesian coordinates.

(2) *The polar operator* $\hat{X}_R$. We have $a=1$, $b=c=d=e=\alpha=\beta=\gamma=0$. Equation (4.18) simplifies greatly in polar coordinates

$$x=r\cos\vartheta, \quad y=r\sin\vartheta \tag{4.26}$$

and we obtain

$$V=f(r)+\frac{1}{r^2}g(\vartheta), \quad \phi_R=-2g(\vartheta). \tag{4.27}$$

This is the most general potential that allows the separation of variables in polar coordinates.

(3) *The parabolic operator* $\hat{X}_P$. We have $a=b=d=e=\alpha=\beta=\gamma=0, c=1$ in Eqs. (4.16)–(4.19). Equation (4.18) simplifies in parabolic coordinates

$$x=\tfrac{1}{2}(\xi^2-\eta^2), \quad y=\xi\eta \tag{4.28}$$

and we can solve to obtain

$$V=\frac{f(\xi)+g(\eta)}{\xi^2+\eta^2}, \quad \phi_P=\frac{g(\eta)\xi^2-f(\xi)\eta^2}{\xi^2+\eta^2}. \tag{4.29}$$

This is the most general potential that allows separation in parabolic coordinates.

(4) *The elliptic operator* $\hat{X}_E$. We have $a=1, b=c=\alpha=\beta=\gamma=0, d=l^2/2$.

To solve Eq. (4.18) in this case we introduce elliptic coordinates

$$x=l\cosh\rho\cos\sigma, \quad y=l\sinh\rho\sin\sigma \tag{4.30}$$

and obtain

$$V=\frac{f(\sigma)+g(\rho)}{\cos^2\sigma-\cosh^2\rho},$$
$$\phi_E=-l^2\frac{\cosh 2\rho f(\sigma)+\cos 2\sigma g(\rho)}{\cos^2\sigma-\cosh^2\rho}. \tag{4.31}$$

This is the most general potential that allows separation of variables in elliptic coordinates, where l is one half of the interfocal distance.

We have again obtained a general result.

Theorem 3: *A second-order Lie symmetry exists if and only if the potential V(x,y) is such that the Schrödinger equation (1.1) allows the separation of variables in Cartesian, polar, parabolic, or elliptic coordinates.*

The flow corresponding to such a symmetry has the form (2.11) with $\hat{X}$ as in (4.19) with $\alpha=\beta=\gamma=0$. The presence of the constant matrix M_1 in (2.11) indicates that we can choose separation constants differently for the real and imaginary part of the wave function ψ.

V. SUPERINTEGRABLE SYSTEMS WITH ONE FIRST-ORDER AND ONE SECOND-ORDER LIE SYMMETRY

In Sec. III we showed that a first-order symmetry exists if the potential allows a geometric symmetry: rotations or translations. Let us consider the two cases separately and request that a further symmetry, a second-order one, should exist.

A. Potentials invariant under rotations

The potential has the form $V=V(r)$. The first-order symmetry is given by Eq. (3.12), with $\hat{X}=L_3$, i.e., angular momentum. To find a second-order symmetry we must find a nontrivial and independent solution of Eq. (4.18). For $V=V(r)$ Eq. (4.18) reduces to

$$(-cy-bx)\left[V_{rr}+\frac{2}{r}V_r\right]+[-2dxy+e(x^2-y^2)]\frac{1}{r^2}\left(V_{rr}-\frac{1}{r}V_r\right)=0. \tag{5.1}$$

Since V depends only on r and the coefficients in Eq. (5.1) are not rotationally invariant, only two solutions exist, namely

$$\text{(i)} \quad d=e=0, \quad V=\frac{\alpha}{r}, \tag{5.2}$$

$$\text{(ii)} \quad b=c=0, \quad V=\omega^2 r^2. \tag{5.3}$$

For the Coulomb potential we obtain two second-order symmetries, given by

$$\hat{X}_1^C=P_1L_3+L_3P_1-\frac{2\alpha y}{r}, \tag{5.4}$$

$$\hat{X}_2^C=P_2L_3+L_3P_2+\frac{2\alpha x}{r}. \tag{5.5}$$

We have

$$[\hat{X}_1^C,\hat{X}_2^C]=8HL_3,\quad [L_3,\hat{X}_1^C]=\hat{X}_2^C,\quad [L_3,\hat{X}_2^C]=-\hat{X}_1^C. \tag{5.6}$$

The operators (5.4) and (5.5) correspond to the fact that the Schrödinger equation separates in parabolic coordinates with an arbitrary orientation of the axes. Moreover, $\hat{X}_1$ and $\hat{X}_2$ are simply the two components of the Laplace–Runge–Lenz vector.

For the harmonic oscillator we also obtain two second-order symmetries. The corresponding operators are

$$\hat{X}_1^h=-\tfrac{1}{2}P_1^2+\omega^2x^2+\tfrac{1}{2}P_2^2-\omega^2y^2, \tag{5.7}$$

$$\hat{X}_2^h=-P_1P_2+2\omega^2xy, \tag{5.8}$$

satisfying

$$[\hat{X}_1^h,\hat{X}_2^h]=-4\omega^2L_3,\quad [L_3,\hat{X}_1^h]=-2\hat{X}_2^h,\quad [L_3,\hat{X}_2^h]=-2\hat{X}_1^h. \tag{5.9}$$

This result is in full agreement with the Bertrand theorem: The only rotationally invariant potentials in which all finite trajectories are closed are precisely $V=\alpha/r$ and $V=\omega^2r^2$.

B. Potentials invariant under a translation

We have $V=V(x)$ and the first-order Lie symmetry is given by taking $\hat{X}=P_2$. Equation (4.18) for a second-order symmetry reduces to

$$y[-a(xV_{xx}+3V_x)+cV_{xx}]+[-b(xV_{xx}+3V_x)+eV_{xx}]=0. \tag{5.10}$$

The term proportional to y must vanish separately, since V depends only on x.

For $a\neq 0$ we translate x to annul c and obtain

$$V=\frac{\alpha}{x^2},\quad c=e=0. \tag{5.11}$$

The second-order symmetries correspond to a, b, and d and are given by

$$\begin{gathered}\hat{X}_1=L_3^2-2\alpha\frac{y^2}{x^2},\quad \hat{X}_2=L_3P_1+P_1L_3-4\alpha\frac{y}{x^2},\\ \hat{X}_3=-\frac{1}{2}\,P_1^2+\frac{\alpha}{x^2}=H+\frac{1}{2}\,P_2^2.\end{gathered} \tag{5.12}$$

We have the following commutation relations:

$$[P_2,\hat{X}_1]=\hat{X}_2,\quad [P_2,\hat{X}_2]=-4\hat{X}_3,\quad [P_2,\hat{X}_3]=0. \tag{5.13}$$

However, $[\hat{X}_2,\hat{X}_3]=Y$, where Y is a third-order operator. Commuting $\hat{X}_2$ and $\hat{X}_3$ with Y we obtain higher order operators and the Lie algebra is infinite dimensional.

For $a=0$, $c\neq 0$ we obtain

$$V=\alpha x,\quad a=b=0. \tag{5.14}$$

The second-order symmetries correspond to c, d, and e. They are given by the operators

$$\begin{gathered}\hat{X}_1=L_3P_2+P_2L_3+\alpha y^2,\quad \hat{X}_2=P_1P_2+\alpha y,\\ \hat{X}_3=-\tfrac{1}{2}P_1^2+\alpha x=H+\tfrac{1}{2}P_2^2.\end{gathered} \tag{5.15}$$

The commutation relations are

$$[P_2,\hat{X}_1]=2\hat{X}_2,\quad [P_2,\hat{X}_2]=\alpha I,\quad [P_2,\hat{X}_3]=0. \tag{5.16}$$

However $[\hat{X}_1,\hat{X}_3]$ is again a third-order operator and the Lie algebra is infinite dimensional. Let us sum up the results.

Theorem 4: *Precisely four $E(2)$ classes of potentials exist, allowing one first-order Lie symmetry and at least one second-order one. For $V=\omega^2 r^2$ the symmetries $\{L_3,\hat{X}_1,\hat{X}_2,H\}$ form a $u(2)$ algebra. For $V(r)=\alpha/r$, L_3, $\hat{X}_1$ and $\hat{X}_2$ form an $o(3)$, $o(2,1)$ or $e(2)$ algebra for a fixed energy $E<0$, $E>0$, and $E=0$, respectively. For $V=\alpha x^{-2}$ and $V=\alpha x$ the second-order Lie symmetries generate infinite-dimensional Lie algebras.*

VI. SUPERINTEGRABLE SYSTEMS WITH TWO SECOND-ORDER LIE SYMMETRIES

Our starting point will be Theorem 3 of Sec. IV. We will assume that one second-order Lie symmetry is already known. The potential $V(x,y)$ is thus specified up to two functions of one variable each. A second-order operator $\hat{X}_1$ is also specified. We must solve Eq. (4.18) to find a second operator $\hat{X}_2$. The operator $\hat{X}_2$ can be simplified by linear combinations with $\hat{X}_1$ and H. We assume that no first-order symmetry exists, i.e., we have $\alpha=\beta=\gamma=0$ in Eq. (4.19).

We have four cases to consider.

A. A Cartesian operator $\hat{X}_1$

We have $\hat{X}_1=\hat{X}_c$ as in Eq. (4.21). We substitute $V(x,y)=f(x)+g(y)$ into Eq. (4.18) and obtain an equation for X_2, namely:

$$\begin{aligned} &a[xy(f_{xx}-g_{yy})+3(yf_x-xg_y)]+b[x(f_{xx}-g_{yy})+3f_x]\\ &\quad+c[-y(f_{xx}-g_{yy})+3g_y]-e(f_{xx}-g_{yy})=0. \end{aligned} \tag{6.1}$$

Translations do not change the form of $\hat{X}_1$, nor of the potential, so we can use them to simplify Eq. (6.1). Two cases must be distinguished.

(a) $a\neq 0$. We normalize a to $a=1$ and transform $b\to 0, c\to 0$ by translations. The general solution of Eq. (6.1) then yields (for $e=0$)

$$\begin{aligned} V_I&=\omega^2(x^2+y^2)+\frac{\alpha}{x^2}+\frac{\beta}{y^2},\\ \hat{X}_2&=\hat{X}_R=L_3^2-2\left(\frac{\alpha}{\cos^2\phi}+\frac{\beta}{\sin^2\phi}\right). \end{aligned} \tag{6.2}$$

For $e\neq 0$ we would have $\alpha=\beta=0$ in (6.2) and a first-order symmetry exists. The potential V_{I} is the most general one that allows separation of variables in Cartesian and polar coordinates. Moreover, the operator $\hat{X}_2+(l^2/2)\hat{X}_1$ also provides a second-order symmetry. Hence the potential V_{I} also allows separation of variables in elliptic coordinates with an arbitrary focal distance.

(b) $a=0, b^2+c^2\neq 0$. By a translation we set $e=0$. The remaining equation is

$$b[x(f_{xx}-g_{yy})+3f_x]+c[-y(f_{xx}-g_{yy})+3g_y]=0. \tag{6.3}$$

For $b\neq 0, c\neq 0$ the potential V must be linear and hence allows a first-order symmetry.

For $b=0$, $c=1$ we obtain

$$V_{\mathrm{II}}=\omega^2(4x^2+y^2)+\frac{\alpha}{y^2}+\beta x,$$
$$\hat{X}_2=L_3P_2+P_2L_3-4\omega^2xy^2+4\frac{\alpha x}{y^2}-\beta y^2. \tag{6.4}$$

For $b=1$, $c=0$ we obtain an equivalent result [i.e., (6.4)] with x and y interchanged). The potential V_{II} is the most general one that allows separation in Cartesian and (properly oriented) parabolic coordinates.

B. A polar operator $\hat{X}_1$

We have $\hat{X}_1=\hat{X}_R$ as in Eq. (4.22). We substitute the potential (4.27) into Eq. (4.18) and obtain, in polar coordinates,

$$\begin{aligned}&(b\cos\vartheta+c\sin\vartheta)\left[-r^4\left(f_{rr}+\frac{2}{r}f_r\right)+g_{\vartheta\vartheta}-2g\right]+[-b\sin\vartheta+c\cos\vartheta]3g_\vartheta\\&+[-d\sin 2\vartheta+e\cos 2\vartheta]\frac{1}{r}\left[r^4\left(f_{rr}-\frac{1}{r}f_r\right)-(g_{\vartheta\vartheta}-8g)\right]\\&+[d\cos 2\vartheta+e\sin 2\vartheta]\frac{6}{r}g_\vartheta=0.\end{aligned} \tag{6.5}$$

For $b=c=0$ we reobtain the result of Eq. (6.2). Hence we take $b^2+c^2\neq 0$.

The form of the potential and operator X_R is invariant under rotations, so we use them to simplify Eq. (6.5), i.e., to arrange $b=0$, $c=1$.

For $d^2+e^2\neq 0$ we obtain only $V=\mathrm{const}$, so we put $d=e=0$. In this case we obtain

$$V_{\mathrm{III}}=\frac{\alpha}{r}+\frac{1}{r^2}\left(\frac{\beta+\gamma\cos\vartheta}{\sin^2\vartheta}\right)$$
$$\hat{X}_2=L_3P_2+P_2L_3+2\alpha(\cos\vartheta)+2\frac{\gamma(\cos^2\vartheta+1)+2\beta\cos\vartheta}{r\sin^2\vartheta}. \tag{6.6}$$

The potential V_{III} is the most general one for which the Schrödinger equation separates in polar and parabolic coordinates.

C. A parabolic operator $\hat{X}_1$

We have $\hat{X}_1=\hat{X}_P$ as in Eq. (4.23) and the potential is as in Eq. (4.29). Substituting into Eq. (4.18) we obtain an equation for $\hat{X}_2$, namely

$$\begin{aligned}&(\xi^2+\eta^2)^4\{-a[\xi\eta(f''-g'')+3(\eta f'-\xi g')]-2b(f''-g'')\}\\&-8d\{(\xi^2+\eta^2)[+\xi\eta(\xi^2+\eta^2)(f''-g'')-3\eta(3\xi^2-\eta^2)f'-3\xi(\xi^2-3\eta^2)g']\\&-24\xi\eta(\xi^2-\eta^2)(f+g)\}+4e\{(\xi^2+\eta^2)[(\xi^4-\eta^4)(f''-g'')\\&-6\xi(\xi^2-3\eta^2)f'+6\eta(3\xi^2-\eta^2)g']+12(\xi^4-6\xi^2\eta^2+\eta^4)(f+g)\}=0.\end{aligned} \tag{6.7}$$

For $a\neq 0$, or $b\neq 0$ we differentiate Eq. (6.7) nine times with respect to both ξ and η. We find that both f and g must be polynomials of at most order 9.

Substituting back into Eq. (6.7) we find that for $a\neq 0$, $b\neq 0$, we obtain a new potential and invariant

$$V_{\mathrm{IV}}=\frac{2\alpha+\beta\xi+\gamma\eta}{\xi^2+\eta^2}=\frac{\alpha}{r}+\frac{1}{\sqrt{2r}}\left(\beta\cos\frac{\vartheta}{2}+\gamma\sin\frac{\vartheta}{2}\right),$$
$$\hat{X}_2=P_1L_3+L_3P_1+\frac{\beta\eta(\eta^2-\xi^2)+\gamma\xi(\xi^2-\eta^2)-4\alpha\eta\xi}{(\eta^2+\xi^2)}. \tag{6.8}$$

For $a=0$, $b=0$, $(d,e)\neq(0,0)$ we reobtain the result of Eq. (6.4).

D. An elliptic operator X_1

The potential has the form of Eq. (4.31) and $\hat{X}_1=\hat{X}_E$ is given in Eq. (4.24). The second operator $\hat{X}_2$ must also be of elliptic type, otherwise we would have obtained the corresponding system in Secs. VI A, VI B, or VI C. However, if $\hat{X}_1$ and $\hat{X}_2$ are of elliptic type, their difference is of Cartesian type and we reobtain the potential V_{I}. So this case need not be considered.

We have obtained the following result.

Theorem 5: *Precisely four superintegrable systems with two second-order Lie symmetries exist in the Euclidean space E_2. Each of them corresponds to a Schrödinger equation allowing the separation of variables in at least two coordinate systems. They are*

(1)

$$V_{\mathrm{I}}=\omega^2(x^2+y^2)+\frac{\alpha}{x^2}+\frac{\beta}{y^2},$$
$$\hat{X}_1=P_1^2-P_2^2-2\left[\omega^2(x^2-y^2)+\frac{\alpha}{x^2}-\frac{\beta}{y^2}\right],$$
$$\hat{X}_2=L_3^2-2\left(\frac{\alpha}{\cos^2\phi}+\frac{\beta}{\sin^2\phi}\right).$$

The equation separates in Cartesian, polar, and also elliptic coordinates.

(2)

$$V_{\mathrm{II}}=\omega^2(4x^2+y^2)+\frac{\alpha}{y^2}+\beta x,$$
$$\hat{X}_1=P_1^2-P_2^2-2\left[\omega^2(4x^2-y^2)+\beta x-\frac{\alpha}{y^2}\right],$$
$$\hat{X}_2=L_3P_2+P_2L_3-4\,\omega^2 x y^2+\frac{4\alpha x}{y^2}-\beta y^2.$$

The equation separates in Cartesian and parabolic coordinates.

(3)

$$V_{\mathrm{III}}=\frac{\alpha}{r}+\frac{1}{r^2}\left(\frac{\beta+\gamma\cos\vartheta}{\sin^2\vartheta}\right),$$
$$\hat{X}_1=L_3^2-2\left(\frac{\beta+\gamma\cos\vartheta}{\sin^2\vartheta}\right),$$
$$\hat{X}_2=L_3P_2+P_2L_3+2\alpha\cos\vartheta+2\frac{\gamma(\cos^2\vartheta+1)+2\beta\cos\vartheta}{r\sin^2\vartheta}.$$

The equation separates in polar and parabolic coordinates.

(4)

$$V_{\mathrm{IV}}=\frac{2\alpha+\beta\xi+\gamma\eta}{\xi^2+\eta^2}=\frac{\alpha}{r}+\frac{1}{\sqrt{2r}}\left(\beta\cos\frac{\vartheta}{2}+\gamma\sin\frac{\vartheta}{2}\right),$$

$$\hat{X}_1=L_3P_1+P_1L_3+\frac{\beta\eta(\eta^2-\xi^2)+\gamma\xi(\xi^2-\eta^2)-4\alpha\eta\xi}{(\xi^2+\eta^2)},$$

$$\hat{X}_2=L_3P_2+P_2L_3+2\frac{\alpha(\xi^2-\eta^2)+\eta\xi(\gamma\xi-\beta\eta)}{(\xi^2+\eta^2)}.$$

The equation separates in two different parabolic coordinate systems (and in any parabolic system of coordinates).

In other words, a consistent application of second-order Lie symmetries leads to the same result as was obtained 35 years ago in Ref. 6.

VII. RECURSION OPERATORS

In soliton theory, recursion operators are used to obtain infinitely many higher symmetries from one known symmetry. Generally speaking, they exist only for integrable, or linearizable nonlinear equations. A recursion operator L for a differential equation can be defined as a linear operator that takes evolutionary symmetries into new evolutionary symmetries.[33] Thus, consider an equation and an evolutionary symmetry

$$\hat{W}=Q\partial_u. \tag{7.1}$$

The operator L is a recursion operator if

$$\hat{\tilde{W}}=(LQ)\partial_u \tag{7.2}$$

is also a symmetry of the same equation for any given symmetry characteristic Q.

In general, for nonlinear equations, recursion operators are very useful, but are hard to find.

Now let us consider the case of the Schrödinger equation (2.2) and let Q be a characteristic of a symmetry. The operator L will be a recursion operator if we have

$$D_{z\bar{z}}(LQ)-R(LQ)|_{u_{z\bar{z}}=Ru}=0. \tag{7.3}$$

Any linear operator L satisfying the commutation relation

$$[\Sigma,L]=\lambda\Sigma,\quad \Sigma=\partial_{z\bar{z}}-R \tag{7.4}$$

will also satisfy Eq. (7.3) and vice versa. Here λ can be a function of z and $\bar{z}$, or a linear operator.

In order to determine the operator L from Eq. (7.4), we must impose some restrictions, in particular as to the order of the linear operator L.

Let us first consider first-order recursion operators

$$L=A(z,\bar{z})D_z+\bar{A}(z,\bar{z})D_{\bar{z}}+C(z,\bar{z}). \tag{7.5}$$

In keeping with the spirit of this article, we must require that L be the same for all energies E. This implies $\lambda=0$ in Eq. (7.4). But this simply means that L commutes with the Hamiltonian and we find that the recursion operator L coincides with the linear operator $\hat{X}$ of Eqs. (2.11), (2.12) and more specifically (3.13).

A second-order recursion operator will have the form

$$L=A(z,\bar{z})D_z^2+2B(z,\bar{z})D_zD_{\bar{z}}+\bar{A}(z,\bar{z})D_{\bar{z}}^2+C(z,\bar{z})D_z+\bar{C}(z,\bar{z})D_{\bar{z}}+F(z,\bar{z}). \tag{7.6}$$

Condition (7.4), combined with the requirement that L be energy independent, requires $\lambda=0$. Thus, we again find that the recursion operator L satisfies $[H,L]=0$, i.e, coincides with the operator $\hat{X}$ of Eq. (4.19).

VIII. CONCLUSIONS

We have established the exact relation between generalized Lie symmetries of the Schrödinger equation in the Euclidian plane E_2, separability of the Schrödinger equation in configuration space, superintegrable systems in quantum mechanics, and recursion operators in quantum mechanics. More specifically, in this article we have restricted ourselves to second-order symmetries. Work is in progress on nth order energy independent symmetries and on the integrability properties of Schrödinger equation with higher order Lie symmetries. We are also investigating the possibility of obtaining and utilizing symmetries that do depend on the energy.

Three formulas for the off-diagonal density matrix of a dirac spinor, with an application[a)]

A. S. Wightman
Department of Physics, Princeton University, Princeton, New Jersey 08544

(Received 2 October 2000; accepted for publication 19 October 2000)

Expressions for the off-diagonal density matrix of a Dirac spinor in space–time dimensions 2, 3, and 4 are derived. They are used to obtain formulas for the dual potential of a free Dirac current in two, three, and four dimensions of space–time.
 [DOI: 10.1063/1.1332784]

I. INTRODUCTION

In 1954, Louis Michel and I, seeking to describe massive, polarized, spin-$\frac{1}{2}$ particles in terms of solutions of the Dirac equation, derived the following formula for the diagonal density matrix:[1]

$$u(p,s)\otimes u(p,s)^{+}=\tfrac{1}{4}[1+\gamma^5\not{s}][m+\not{p}]\operatorname{sgn}p^0. \tag{1.1}$$

Here, $u(p,s)$ is the solution of the Dirac equation

$$(\not{p}-m)u(p,s)=0 \tag{1.2}$$

of energy momentum, p, and polarization, s, normalized so that

$$u(p,s)^{+}u(p,s)=m\ \operatorname{sgn}p^0. \tag{1.3}$$

The energy momentum, p, satisfies

$$p^2=p\cdot p=(p^0)^2-\vec{p}^2=m^2, \tag{1.4}$$

and the polarization, s, satisfies

$$s\cdot p=0,\quad s^2=-1. \tag{1.5}$$

The notation for the 4×4 Dirac matrices, γ^μ, $\mu=0,1,2,3$, is such that

$$\gamma^\mu\gamma^\nu+\gamma^\nu\gamma^\mu=2g^{\mu\nu};\quad g^{00}=1=-g^{ii},\quad i=1,2,3;\quad g^{ij}=0,\quad i\neq j, \tag{1.6}$$

and

$$\not{a}=a^0\gamma^0-\vec{a}\cdot\vec{\gamma};\quad \gamma^5=i\gamma^0\gamma^1\gamma^2\gamma^3, \tag{1.7}$$

$$(u(p,s)^{+})_\alpha=\sum_{\beta=1}^{4}\overline{(u(p,s))_\beta}A_{\beta\alpha}, \tag{1.8}$$

where A is a Hermitian matrix satisfying

$$A\gamma^\mu A^{-1}=(\gamma^\mu)^*. \tag{1.9}$$

[a)]In memoriam Louis Michel (1923–1999).

An overbar means complex conjugate, and a star means Hermitian adjoint. In the following, specific representations of the γ's will sometimes be used for space–times of dimensions 2, 3, and 4, but the results are independent of the choice of γ's.

Michel and I were attempting to express all physically significant matrix elements of the $u(p,s)$ in terms of the momenta and polarization observables of the particles. For such purposes, it is natural to ask for an off-diagonal version of (1.1), an expression for $u(q,t)\otimes u(p,s)^+$ in terms of the momenta p and q and the corresponding polarization vectors s and t. We found such a formula:

$$u(q,t)\oplus u(p,s)^+ = x\left|\mathrm{tr}\, P(q,t)P(p,s)\right|^{-1/2} P(q,t)P(p,s), \tag{1.10}$$

where

$$P(p,s) = \mathrm{sgn}\, p^0 [1+\gamma^5 \not{s}][m+\not{p}] \tag{1.11}$$

and x is a phase factor. This formula implies immediately

$$u(p,s)^+ u(q,t) = x\left|\mathrm{tr}\, P(q,t)P(p,s)\right|^{-1/2} \mathrm{tr}\,(P(q,t)(P(p,s)) \tag{1.12}$$

and consequently

$$u(q,t)\otimes u(p,s)^+ = u(p,s)^+ u(q,t)[\mathrm{tr}\,[P(q,t)P(p,s)]]^{-1} P(q,t)P(p,s). \tag{1.13}$$

What follows in this article can be regarded as an extended discussion of this formula, (1.13), together with an application arising in quantum field theory. A different line was taken by Jean Nuyts.[2] He fixed the phase of $u(q,t)$ by writing it as a Lorentz transform of $u(p,s)$. His Appendix D contains many of the formulas used in Sec. IV of the present article.

II. TWO-DIMENSIONAL SPACE–TIME

In two-dimensional space–time, the Dirac matrices are 2×2 matrices satisfying

$$\gamma^\mu\gamma^\nu + \gamma^\nu\gamma^\mu = 2g^{\mu\nu}, \quad \mu,\nu = 0,1; \quad g^{00} = +1 = -g^{11}, \quad g^{01} = 0, \tag{2.1}$$

and the Dirac equation reads

$$(-\not{p}+m)u(p) = 0, \tag{2.2}$$

where m is positive and

$$\not{p} = p^0\gamma^0 - p^1\gamma^1. \tag{2.3}$$

The adjoint

$$u(p)^+ = \overline{u(p)}A$$

satisfies

$$u(p)^+(\not{p}+m) = 0. \tag{2.4}$$

To compute $u(q)\otimes u(p)^+$, consider first the special choice of Dirac matrices

$$\gamma^0 = \begin{pmatrix} 0 & 1 \\ 1 & 0 \end{pmatrix}, \quad \gamma^1 = \begin{pmatrix} 0 & -1 \\ 1 & 0 \end{pmatrix}, \quad \gamma^5 = \gamma^0\gamma^1 = \begin{pmatrix} 1 & 0 \\ 0 & -1 \end{pmatrix}. \tag{2.5}$$

The Dirac equation then says that $u(p)$ lies in the null space of the matrix

$$\begin{Bmatrix} m & -(p^0+p^1) \\ -(p^0-p^1) & m \end{Bmatrix} \tag{2.6}$$

and $u(p)$ is proportional to

$$\begin{pmatrix} p^0+p^1 \\ m \end{pmatrix}. \tag{2.7}$$

A may be chosen as γ^0. The relation $(p^0-p^1)(p^0+p^1)=m^2$ implies that $u(p)$, normalized so that $u(p)^+\gamma^0 u(p)=|p^0|$, may be chosen as

$$u(p)=\frac{1}{\sqrt{2}}\begin{pmatrix} |p^0+p^1|^{1/2} \\ |p^0-p^1|^{1/2}\operatorname{sgn} p^0 \end{pmatrix}. \tag{2.8}$$

Consequently,

$$\begin{aligned} u(q)\otimes u(p)^+ &= \frac{1}{2}\begin{Bmatrix} |(q^0+q^1)(p^0-p^1)^{1/2}\operatorname{sgn} p^0 & |(p^0+p^1)(q^0+q^1)|^{1/2} \\ |(q^0-q^1)(p^0-p^1)|^{1/2}\operatorname{sgn} p^0\operatorname{sgn} q^0 & |(q^0-q^1)(p^0+p^1)|^{1/2}\operatorname{sgn} q^0 \end{Bmatrix} \\ &= \frac{1}{2}\left\{\begin{pmatrix} 1 & 0 \\ 0 & 1 \end{pmatrix} u(p)^+u(q)+\begin{pmatrix} 1 & 0 \\ 0 & -1 \end{pmatrix} u(p)^+\gamma^5 u(q)+\gamma^0 u(p)^+\gamma^0 u(q)\right. \\ &\quad \left. -\gamma^1 u(p)^+\gamma^1 u(q)\right\}, \end{aligned} \tag{2.9}$$

where

$$\begin{aligned} u(p)^+u(q) &= \tfrac{1}{2}[|(q^0+q^1)(p^0-p^1)|^{1/2}\operatorname{sgn} p^0+|(q^0-q^1)(p^0+p^1)|^{1/2}\operatorname{sgn} q^0], \\ u(p)^+\gamma^5 u(q) &= \tfrac{1}{2}[|(q^0+q^1)(p^0-p^1)|^{1/2}\operatorname{sgn} p^0-|(q^0-q^1)(p^0+p^1)|^{1/2}\operatorname{sgn} q^0], \\ u(p)^+\gamma^0 u(q) &= \tfrac{1}{2}[|(q^0+q^1)(p^0+p^1)|^{1/2}+|(q^0-q^1)(p^0-p^1)|^{1/2}\operatorname{sgn} p^0\operatorname{sgn} q^0], \\ u(p)^+\gamma^1 u(q) &= \tfrac{1}{2}[|(q^0+q^1)(p^0+p^1)|^{1/2}-|(q^0-q^1)(p^0-p^1)|^{1/2}\operatorname{sgn} p^0\operatorname{sgn} q^0]. \end{aligned}$$

Notice that $u(p)^+u(q)$ is invariant under restricted Lorentz transformations because

$$\begin{aligned} (q^0+q^1)(p^0-p^1) &= q\cdot p+\det\{p,q\}, \\ (q^0-q^1)(p^0+p^1) &= q\cdot p-\det\{p,q\}. \end{aligned} \tag{2.10}$$

This is evident for $u(p)^+u(q)$, up to a sign, because

$$(u(p)^+u(q))^2=\tfrac{1}{4}\operatorname{sgn} p^0\operatorname{sgn} q^0[(p+q)\cdot(p+q)].$$

From (2.9), one gets expressions for the ratios

$$\left[\frac{u(p)^+\gamma^5 u(q)}{u(p)^+u(q)}\right], \quad \left[\frac{u(p)^+\gamma^0 u(q)}{u(p)^+u(q)}\right], \quad \left[\frac{u(p)^+\gamma^1 u(q)}{u(p)^+u(q)}\right],$$

which reduce to tensors in p and q. Consider first

$$\frac{u(p)^+\gamma^5 u(q)}{u(p)^+u(q)}=\frac{[|(q^0+q^1)(p^0-p^1)|^{1/2}\operatorname{sgn}p^0-|(q^0-q^1)(p^0+p^1)|^{1/2}\operatorname{sgn}q^0]}{[|(q^0+q^0)(p^0-p^1)|^{1/2}\operatorname{sgn}p^0+|(q^0-q^1)(p^0+p^1)|^{1/2}\operatorname{sgn}q_0]}.$$

Multiplying numerator and denominator by the numerator one gets for the denominator

$$2\operatorname{sgn}p^0\operatorname{sgn}q^0(q^1p^0-q^0p^1)$$

and for the numerator

$$2\operatorname{sgn}p^0\operatorname{sgn}q^0(p\cdot q-m^2),$$

so

$$\frac{u(p)^+\gamma^5 u(q)}{u(p)^+u(q)}=\frac{(p\cdot q-m^2)}{q^1p^0-q^0p^1}=\frac{(q^1p^0-q^0p^1)}{(p\cdot q+m^2)}. \tag{2.11}$$

The last identity is most easily derived by recognizing that $\det\{p,q\}=q^1p^0-q^0p^1$ and using the multiplication law for determinants. Similar manipulations yield

$$\frac{u(p)^+\gamma^\mu u(q)}{u(p)^+u(q)}=\frac{2m(p+q)^\mu}{(p+q)^2}, \tag{2.12}$$

and hence the desired analog of (1.13) is

$$u(q)\otimes u(p)^+=\frac{u(p)^+u(q)}{2}\left[1+\gamma^5\frac{2\det\{p,q\}}{(p+q)^2}+(\not{p}+\not{q})\frac{2m}{(p+q)^2}\right]. \tag{2.13}$$

When $p=q$, the coefficient of γ^5 vanishes and the formula reduces to the following analog of (1.1):

$$u(p)\otimes u(p)^+=\tfrac{1}{2}[m+\not{p}]\operatorname{sgn}p^0.$$

Equation (2.13) is the main result of this section.

It is easy to see that if one had chosen a different irreducible set of γ^μ, say $\hat{\gamma}^\mu$, and the appropriate corresponding $\hat{A}$, the result (2.13) would have been the same. The argument is standard. Any two irreducible sets of γ's satisfying (2.1) are related by a nonsingular matrix T:

$$\hat{\gamma}^\mu=T^{-1}\gamma^\mu T.$$

Then

$$(\hat{\gamma}^\mu)^*=\hat{A}\hat{\gamma}^\mu\hat{A}^{-1},$$

if $\hat{A}$ is chosen as

$$\hat{A}=T^*AT.$$

The quantity

$$\hat{\mu}(p)=Tu(p)$$

satisfies the Dirac equation in the hatted γ's, and the formula for $\hat{u}(q)\otimes\hat{u}(p)^+$ in the hatted γ's is a consequence of that in the unhatted γ's.

Of course, (2.13) can also be derived directly from the analog of (1.13):

$$u(q)\otimes u(p)^+=u(p)^+u(q)[\operatorname{tr}(P(q)P(p))]^{-1}P(q)P(p) \tag{2.14}$$

where

$$P(p)=[m+\not{p}],$$

because

$$P(q)P(p)=[m^2+m(\not{p}+\not{q})+\not{q}\not{p}]$$

and

$$\not{q}\not{p}=q\cdot p+\gamma^5\det\{p,q\}.$$

There is an additional useful formula for the axial vector, which connects it with the pseudoscalar

$$\begin{aligned} u(p)^+\gamma^5\gamma^\mu u(q)&=\varepsilon^{\mu\nu}u(p)^+\gamma_\nu u(q)\\ &=-\begin{Bmatrix}u(p)^+\gamma^1u(q)\\ u(p)^+\gamma^0u(q)\end{Bmatrix}\\ &=\frac{-2m}{(p-q)^2}u(p)^+\gamma^5u(q)(p^\mu-q^\mu). \end{aligned}\tag{2.15}$$

The proof can be based on (2.9):

$$\frac{u(p)^+\gamma^1u(q)}{u(p)^+\gamma^5u(q)}=\frac{[|(p^0+p^1)(q^0+q^1)|^{1/2}-|(p^0-p^1)(q^0-q^1)|^{1/2}\operatorname{sgn}p^0\operatorname{sgn}q^0]}{[|(q^0+q^1)(p^0-p^1)|^{1/2}\operatorname{sgn}p^0-|(q^0-q^1)(p^0+p^1)|^{1/2}\operatorname{sgn}q^0]}.$$

Multiplying numerator and denominator by

$$[|(q^0+q^1)(p^0-p^1)|^{1/2}\operatorname{sgn}p^0+|(q^0-q^1)p^0-p^1|^{1/2}\operatorname{sgn}q^0],$$

one gets for the denominator

$$2\operatorname{sgn}p^0\operatorname{sgn}q^0(q^1p^0-q^0p^1),$$

while the numerator turns out to be

$$2m\operatorname{sgn}p^0\operatorname{sgn}q^0(p^1+q^1).$$

When the numerator and denominator are multiplied by p^0-q^0, the denominator produces a factor p^1+q^1, leaving

$$\frac{u(p)^+\gamma^1u(q)}{u(p)^+\gamma^5u(q)}=\frac{2m(p^0-q^0)}{(p-q)^2}$$

as required. The argument for

$$\frac{u(p)^+\gamma^0u(q)}{u(p)^+\gamma^5u(q)}=\frac{2m(p^1-q^1)}{(p-q)^2}$$

is similar.

III. THREE-DIMENSIONAL SPACE–TIME

In three-dimensional space–time, as in all linear spaces of odd dimension, the Clifford algebra has two inequivalent irreducible representations. They can be taken as

$$\gamma^0=\begin{Bmatrix}0 & 1\\ 1 & 0\end{Bmatrix},\quad \gamma^1=\begin{Bmatrix}0 & -1\\ 1 & 0\end{Bmatrix},\quad \gamma^2=\begin{Bmatrix}i & 0\\ 0 & -i\end{Bmatrix} \tag{3.1}$$

and the negatives of these. The analog of γ^5 distinguishes these two representations,

$$\tilde{\gamma}^5=-i\gamma^0\gamma^1\gamma^2=\pm 1, \tag{3.2}$$

respectively. In the following, I will work with (3.1) but will indicate the effect of using $-\gamma^\mu$ instead of γ^μ by inserting $\tilde{\gamma}^5$ in appropriate places in the final result.

The solution of the Dirac equation, $u(p)$, lies in the null space of the matrix

$$(-\not{p}+m)=\begin{pmatrix} m+ip^2 & -(p^0+p^1)\\ -(p^0-p^1) & m-ip^2\end{pmatrix}, \tag{3.3}$$

so $u(p)$ is proportional to

$$\begin{pmatrix} p^0+p^1\\ m+ip^2\end{pmatrix}. \tag{3.4}$$

Since

$$|p^0+p^1|^2+|m+ip^2|^2=2p^0(p^0+p^1)=2|p^0||p^0+p^1|,$$

the normalization of (3.3) goes as before, and yields

$$u(p)=\frac{1}{\sqrt{2}}\begin{Bmatrix} |p^0+p^1|^{1/2}\\ |p^0-p^1|^{1/2}\dfrac{(m+ip^2)}{|m+ip^2|}\operatorname{sgn}p^0\end{Bmatrix}. \tag{3.5}$$

The definition of the adjoint spinor is the same as in two dimensions, so

$$\begin{aligned} u(q)\otimes u(p)^+=\frac{1}{2}\Bigg[&\begin{pmatrix}1 & 0\\ 0 & 1\end{pmatrix}u(p)^+u(q)+\gamma^0u(p)^+\gamma^0u(q)\\ &-\gamma^1u(p)^+\gamma^1u(q)-\gamma^2u(p)^+\gamma^2u(q)\Bigg],\end{aligned} \tag{3.6}$$

where

$$\begin{aligned} u(p)^+u(q)=\frac{1}{2}\Bigg[&|(q^0+q^1)(p^0-p^1)|^{1/2}\frac{(m-ip^2)}{|m-ip^2|}\operatorname{sgn}p^0\\ &+|(q^0-q^1)(p^0+p^1)|^{1/2}\frac{(m+iq^2)}{|m+iq^2|}\operatorname{sgn}q^0\Bigg],\end{aligned}$$

$$\begin{aligned} u(p)^+\gamma^0u(q)=\frac{1}{2}\Bigg[&|(q^0+q^1)(p^0+p^1)|^{1/2}\\ &+|(q^0-q^1)|^{1/2}\frac{(m-ip^2)}{|m-ip^2|}\,\frac{(m+iq^2)}{|m+iq^2|}\operatorname{sgn}p^0\operatorname{sgn}q^0\Bigg],\end{aligned} \tag{3.7}$$

$$u(p)^+\gamma^1 u(q)=\frac{1}{2}\Bigg[|(q^0+q^1)(p^0+p^1)|^{1/2} -|(q^0-q^1)(p^0-p^1)|^{1/2}\frac{(m-ip^2)}{|m-ip^2|}\,\frac{(m+iq^2)}{|m+iq^2|}\operatorname{sgn}p^0\operatorname{sgn}q^0\Bigg],$$

$$u(p)^+\gamma^2 u(q)=\frac{i}{2}\Bigg[|(q^0+q^1)(p^0-p^1)|^{1/2}\frac{(m-ip^2)}{|m-ip^2|}\operatorname{sgn}p^0 -|(q^0-q^1)(p^0+p^1)|^{1/2}\frac{(m+iq^2)}{|m+iq^2|}\operatorname{sgn}q^0\Bigg].$$

Since

$$|u(p)^+u(q)|^2=\frac{|(p+q)^2|}{4}, \tag{3.8}$$

$u(p)^+u(q)$ is Lorentz invariant in absolute value, but its phase is not, in contrast to the situation in two dimensions.

The computation of the ratios $u(p)^+\gamma^\mu u(q)[u(p)^+u(q)]^{-1}$ is rather tedious in this special choice of basis, but eventually yields the simple result

$$\frac{u(p)^+\gamma^\mu u(q)}{u(p)^+u(q)}=\frac{2m[p^\mu+q^\mu+(i/m)\tilde{\gamma}^5\epsilon^{\mu\kappa\lambda}q_\kappa p_\lambda]}{(p+q)^2}, \tag{3.9}$$

so

$$u(q)\otimes u(p)^+=\frac{u(p)^+u(q)}{2}\left[1+\frac{2m}{(p+q)^2}\,\gamma_\mu\left(p^\mu+q^\mu+\frac{i}{m}\tilde{\gamma}^5\epsilon^{\mu\kappa\lambda}q_\kappa p_\lambda\right)\right]. \tag{3.10}$$

Here $\epsilon^{\kappa\lambda\mu}$ is totally antisymmetric under permutation of indices and $\epsilon^{012}=1$. Equation (3.9) is the main result of this section.

This result can also be obtained directly from (2.14) with the altered definition $\not{p}=p^0\gamma^0-p^1\gamma^1-p^2\gamma^2$, since,

$$[m+\not{q}][m+\not{p}]=m^2+m(\not{q}+\not{p})+\not{q}\not{p}$$

and

$$\operatorname{tr}P(q)P(p)=2(q\cdot p+m^2)=(p+q)^2$$

as before, but now

$$\not{q}\not{p}=q\cdot p+i\tilde{\gamma}^5\gamma_\mu\epsilon^{\mu\kappa\lambda}q_\kappa p_\lambda\,.$$

IV. FOUR-DIMENSIONAL SPACE–TIME

Here there is only one irreducible representation of the Clifford algebra,

$$\gamma^\mu\gamma^\nu+\gamma^\mu\gamma^\mu=2g^{\mu\nu},\quad \mu,\nu=0,1,2,3,$$

up to equivalence. A standard choice of the γ's is the set of 4×4 matrices:

$$\gamma^0=\begin{pmatrix}0&1\\1&0\end{pmatrix},\quad \vec{\gamma}=\begin{pmatrix}0&-\vec{\tau}\\\vec{\tau}&0\end{pmatrix},\quad \gamma^5=i\gamma^0\gamma^1\gamma^2\gamma^3=\begin{pmatrix}1&0\\0&-1\end{pmatrix}. \tag{4.1}$$

Then the matrix A that appears in Eq. (1.4) may be taken to be γ^0.

The desired expansion of $u(q,t)\otimes u(p,s)^+$ may be written

$$u(q,t)\otimes u(p,s)^+ = \tfrac{1}{4}[\mathbf{1}u(p,s)^+u(q,t)+\gamma^5 u(p,s)^+\gamma^5 u(q,t)+\gamma_\mu u(p,s)^+\gamma^\mu u(q,t) - \gamma^5\gamma_\mu u(p,s)^+\gamma^5\gamma^\mu u(q,t)+\tfrac{1}{2}\sigma_{\kappa\lambda}u(p,s)^+\sigma^{\kappa\lambda}u(q,t)], \tag{4.2}$$

and, according to Eq. (1.7), the ratios of the coefficients to the first coefficient may be obtained by multiplying out the matrix product $P(q,t)P(p,s)$ and dividing by $\mathrm{tr}(P(q,t)P(p,s))$. This requires a number of identities. For example,

$$P(q,t)=[1+\gamma^5\not{t}][m+\not{q}]=[m+\not{q}+m\gamma^5\not{t}-i\gamma^5\sigma_{\kappa\lambda}t^\kappa q^\lambda] \tag{4.3}$$

because

$$\not{a}\not{b}=a\cdot b-i\sigma_{\mu\nu}a^\mu b^\nu, \tag{4.4}$$

where

$$\sigma_{\mu\nu}=\frac{i}{2}(\gamma_\mu\gamma_\nu-\gamma_\mu\gamma_\nu).$$

On the other hand, to get the product

$$\begin{aligned}P(q,t)P(p,s)=[&m^2+m\not{p}+m^2\gamma^5\not{s}-im\gamma^5\sigma_{\kappa\lambda}s^\mu p^\nu\\ &+m\not{q}+\not{q}\not{p}-\gamma^5\not{q}\not{s}m+i\gamma^5\not{q}\sigma_{\mu\nu}s^\mu p^\nu+m^2\gamma^5\not{t}+m\gamma^5\not{t}\not{p}-m^2\not{t}\not{s}\\ &+im\not{t}\sigma_{\mu\nu}s^\mu p^\nu-im\gamma^5\sigma_{\kappa\lambda}t^\kappa q^\lambda-i\gamma^5\sigma_{\kappa\lambda}\not{p}t^\kappa q^\lambda\\ &-im\sigma_{\kappa\lambda}\not{s}t^\kappa q^\lambda-\sigma_{\kappa\lambda}\sigma_{\mu\nu}t^\kappa q^\lambda s^\mu p^\nu]\end{aligned} \tag{4.5}$$

into the form (4.2) we need the identities

$$\begin{aligned}\gamma_\lambda\sigma_{\mu\nu}&=ig_{\lambda\mu}\gamma_\nu-ig_{\lambda\nu}\gamma_\mu+\epsilon_{\lambda\mu\nu\rho}\gamma^5\gamma^\rho,\\ \sigma_{\kappa\lambda}\gamma_\mu&=ig_{\lambda\mu}\gamma_\kappa-ig_{\kappa\mu}\gamma_\lambda+\epsilon_{\kappa\lambda\mu\rho}\gamma^5\gamma^\rho,\\ \sigma_{\kappa\lambda}\sigma_{\mu\nu}&=g_{\kappa\mu}g_{\lambda\nu}-g_{\kappa\nu}g_{\lambda\mu}+i\epsilon_{\kappa\lambda\mu\nu}\gamma^5-i(g_{\kappa\mu}\sigma_{\lambda\nu}+g_{\lambda\nu}\sigma_{\kappa\mu}-g_{\kappa\nu}\sigma_{\lambda\mu}-g_{\lambda\mu}\sigma_{\kappa\nu}),\\ \gamma^5\sigma_{\kappa\lambda}&=\frac{i}{2}\epsilon_{\kappa\lambda\mu\nu}\sigma^{\mu\nu}.\end{aligned} \tag{4.6}$$

They imply

$$\begin{aligned}i\gamma^5\not{q}\sigma_{\mu\nu}s^\mu p^\nu&=(q\cdot p)\gamma^5\not{s}-(q\cdot s)\gamma^5\not{p}+iq^\lambda s^\mu p^\nu\epsilon_{\lambda\mu\nu\rho}\gamma^\rho,\\ im\not{t}\sigma_{\mu\nu}s^\mu p^\nu&=m[(t\cdot p)\not{s}-(t\cdot s)\not{p}+it^\lambda s^\mu p^\nu\epsilon_{\lambda\mu\nu\rho}\gamma^5\gamma^\rho],\\ -i\gamma^5\sigma_{\kappa\lambda}\not{p}t^\kappa q^\lambda&=(q\cdot p)\gamma^5\not{t}-(t\cdot p)\gamma^5\not{q}-it^\kappa q^\lambda p^\mu\epsilon_{\kappa\lambda\mu\rho}\gamma^\rho,\\ -imt^\kappa q^\lambda s^\mu\sigma_{\kappa\lambda}\gamma_\mu&=m[(s\cdot q)\not{t}-(s\cdot t)\not{q}-it^\kappa q^\lambda s^\mu\epsilon_{\kappa\lambda\mu\rho}\gamma^5\gamma^\rho],\\ \sigma_{\kappa\lambda}\sigma_{\mu\nu}t^\kappa q^\lambda s^\mu p^\nu&=(s\cdot t)(p\cdot q)-(p\cdot t)(s\cdot q)+i\gamma^5\epsilon_{\kappa\lambda\mu\nu}t^\kappa q^\lambda s^\mu p^\nu-i(s\cdot t)\sigma_{\lambda\nu}q^\lambda p^\nu\\ &\quad-i(q\cdot p)\sigma_{\kappa\mu}t^\kappa s^\mu+i(p\cdot t)\sigma_{\lambda\mu}q^\lambda s^\mu+i(q\cdot s)\sigma_{\kappa\nu}t^\kappa p^\nu,\end{aligned} \tag{4.7}$$

so

$$P(q,t)P(p,s)=[(m^2+q\cdot p)(1-s\cdot t)+(t\cdot p)(q\cdot s)]+\gamma^5[-m(q\cdot s)+m(p\cdot t)-i\epsilon_{\kappa\lambda\mu\nu}t^\kappa q^\lambda s^\mu p^\nu]$$
$$+\gamma_\mu[m(p^\mu+q^\mu)(1-s\cdot t)+m((t\cdot p)s^\mu+(s\cdot q)t^\mu)+i\epsilon^\mu_{\rho\sigma\tau}(s+t)^\rho q^\sigma p^\tau]$$
$$+\gamma^5\gamma_\mu[(m^2+(q\cdot p))(s^\mu+t^\mu)-(q\cdot s)p^\mu-(t\cdot p)q^\mu-i\epsilon^\mu_{\rho\sigma\tau}(p+q)^\rho t^\sigma s^\tau]$$
$$+\tfrac{1}{2}\sigma_{\mu\nu}[m\epsilon^{\mu\nu}_{\kappa\lambda}(s^\kappa+t^\kappa)(p^\lambda+q^\lambda)+2i((s\cdot t)q^\mu p^\nu+(m^2+q\cdot p)t^\mu s^\nu-(t\cdot p)q^\mu s^\nu$$
$$+(q\cdot s)p^\mu t^\nu)]. \tag{4.8}$$

Thus

$$u(q,t)\otimes u(p,s)^+=u(p,s)^+u(q,t)\{1+[4((m^2+q\cdot p)(1-s\cdot t)+(t\cdot p)(q\cdot s))]^{-1}$$
$$\times[\gamma^5[-m((q\cdot s)-(p\cdot t))-i\epsilon_{\kappa\lambda\mu\nu}t^\kappa q^\lambda s^\mu p^\nu]+\gamma_\mu[m[(1-s\cdot t)(p^\mu+q^\mu)$$
$$+(t\cdot p)s^\mu+(s\cdot q)t^\mu]+(i\epsilon^\mu_{\rho\sigma\tau}(s+t)^\rho q^\sigma p^\tau)]+\gamma^5\gamma_\mu[(m^2+q\cdot p)(s^\mu+t^\mu)$$
$$-(q\cdot s)p^\mu-(t\cdot p)q^\mu-i(\epsilon^\mu_{\rho\sigma\tau}(s^\rho+t^\rho)q^\sigma p^\tau)]+\tfrac{1}{2}\sigma_{\mu\nu}[m\epsilon^{\mu\nu}_{\kappa\lambda}(s^\kappa+t^\kappa)(p^\lambda+q^\lambda)$$
$$+2i((s\cdot t)q^\mu p^\nu+(m^2+q\cdot p)t^\mu s^\nu-(p\cdot t)q^\mu s^\nu+(q\cdot s)p^\mu t^\nu)]]\}. \tag{4.9}$$

This rather formidable expression, the analog in four dimensions of (2.13) in two-dimensional space–time and (3.9) in three-dimensional space-time, is the main result of this section.

V. AN APPLICATION TO QUANTUM FIELD THEORY

A current, j, in a space–time of n dimensions has a dual, J, which is a totally antisymmetric tensor of rank $n-1$:

$$J_{\mu_1\cdots\mu_{n-1}}=\epsilon_{\mu_1\cdots\mu_n}j^{\mu_n}.$$

In turn, such a J has a dual which is the first rank tensor j:

$$j^{\mu_1}=\frac{1}{(n-1)!}\epsilon^{\mu_1\cdots\mu_n}J_{\mu_2\cdots\mu_n}.$$

When j is conserved

$$\partial_\mu j^\mu=0,$$

J satisfies the differential equation

$$\partial_{\mu_1}\epsilon^{\mu_1\cdots\mu_n}J_{\mu_2\cdots\mu_n}=0. \tag{5.1}$$

In the language of differential forms $J_{\mu_1\cdots\mu_{n-1}}$ defines a differential form

$$J=\sum_{\mu_1\cdots\mu_{n-1}}J_{\mu_1\cdots\mu_{n-1}}dx^{\mu_1}\wedge\cdots\wedge dx^{\mu_{n-1}},$$

and the differential equation (5.1) says that

$$dJ=0, \tag{5.2}$$

i.e., the differential form J is closed. If it happens that $J=dK$, where K is a monomial $n-2$ form, J is then said to be exact. If J is exact, it is automatically closed since $d^2=0$. For brevity, such a form K will be referred to as a dual potential.

In quantum field theory, it is of interest to prove the existence and determine the properties of dual potentials for Dirac currents.[3] Such currents have Fourier representations in which the factor $\exp i(p-q)\cdot x$ is accompanied by the matrix element

$$u(p)^+\gamma^\mu u(q)$$

in two- or three-dimensional space–time and

$$u(p,s)^+\gamma^\mu u(q,t)$$

in four dimensions. The duals of these currents have similar Fourier representations in which the matrix elements

$$\epsilon_{\kappa\mu}u(p)^+\gamma^\mu u(q), \quad \epsilon_{\kappa\lambda\mu}u(p)^+\gamma^\mu u(q),$$

and

$$\epsilon_{\kappa\lambda\mu\nu}u(p,s)^+\gamma^\nu u(q,t)$$

appear, respectively.

For two dimensions, from (2.15) we get

$$\epsilon_{\kappa\lambda}u(p)^+\gamma^\lambda u(q)=-2m[(p-q)^2]^{-1}u(p)^+\gamma^5 u(q)(p-q)_\kappa=K(p,q)i(p-q)_\kappa \tag{5.3}$$

with

$$K(p,q)=2mi[(p-q)^2]^{-1}u(p)^+\gamma^5 u(q).$$

In three dimensions, using (3.10) we get

$$\epsilon_{\kappa\lambda\mu}u(p)^+\gamma^\mu u(q)=2mu(p)^+u(q)[(p+q)^2]^{-1}\left[\epsilon_{\kappa\lambda\mu}(p^\mu+q^\mu)+\frac{i}{m}\tilde{\gamma}^5\epsilon_{\kappa\lambda\mu}\epsilon^\mu_{\rho\sigma}q^\rho p^\sigma\right]. \tag{5.4}$$

Since

$$\epsilon_{\kappa\lambda\mu}\epsilon^\mu_{\rho\sigma}=g_{\kappa\rho}g_{\sigma\lambda}-g_{\kappa\sigma}g_{\lambda\rho} \tag{5.5}$$

and

$$(p^\rho q^\sigma-q^\rho p^\sigma)=\tfrac{1}{2}[(p^\rho-q^\rho)(p^\sigma+q^\sigma)-(p^\sigma-q^\sigma)(p^\rho+q^\rho)], \tag{5.6}$$

the second term in the square brackets can be written as the monomial

$$-\frac{i\tilde{\gamma}^5}{2m}[(p-q)_\kappa(p+q)_\lambda-(p-q)_\lambda(p+q)_\kappa],$$

which is of the form required to make

$$\epsilon_{\kappa\lambda\mu}u(p)^+\gamma^\mu u(q)=(p-q)_\kappa K_\lambda(p,q)-(p-q)_\lambda K_\kappa(p,q). \tag{5.7}$$

The first term, $\epsilon_{\kappa\lambda\mu}(p+q)^\mu$, is the dual of vector $p+q$; it is a bivector describing the two planes perpendicular to $p+q$. [The dual of any monomial p-vector is a monomial $(m-p)$-vector,

if n is the dimension of the vector space.] Since $(p-q)$ is orthogonal to $(p+q)$, because $p^2=q^2=m^2$, we can pick any vector, r, orthogonal to $p+q$ and linearly independent of $p-q$ and write

$$\epsilon_{\kappa\lambda\mu}(p+q)^{\mu}\propto(p-q)_{\kappa}r_{\lambda}-(p-q)_{\lambda}r_{\kappa}.$$

To fix the normalization of r, set the two sides equal and form the scalar product with $(p-q)^{\lambda}$. The result is

$$r_{\kappa}=-\frac{\epsilon_{\kappa\lambda\mu}(p-q)^{\lambda}(p+q)^{\mu}}{(p-q)^2}+b(p-q)_{\kappa}, \tag{5.8}$$

where b is any real-valued function of p and q. The choice $b=0$ makes r orthogonal to both $(p+q)$ and $(p-q)$. Thus

$$K_{\lambda}(p,q)=\frac{i}{(p+q)^2}u(p)^{+}u(q)\left[-\tilde{\gamma}^5(p+q)_{\lambda}+\frac{2mi}{(p-q)^2}\epsilon_{\lambda\rho\sigma}(p-q)^{\rho}(p+q)^{\sigma}\right] \tag{5.9}$$

with the square bracket determined uniquely up to the addition of an arbitrary multiple of $(p-q)$.

In four dimensions we have from (4.9)

$$\epsilon_{\kappa\lambda\mu\nu}u(p,s)^{+}\gamma^{\nu}u(q,t)=\frac{u(p,s)^{+}u(q,t)}{4[(m^2+q\cdot p)(1-s\cdot t)+(t\cdot p)(q\cdot s)]}[m\epsilon_{\kappa\lambda\mu\nu}(1-s\cdot t)(p^{\nu}+q^{\nu})$$
$$+(t\cdot p)s^{\nu}+(s\cdot q)t^{\nu}+i\epsilon_{\kappa\lambda\mu\nu}\epsilon^{\nu}_{\rho\sigma\tau}(s+t)^{\rho}q^{\sigma}p^{\tau}]. \tag{5.10}$$

The last term may be written with the use of the identity

$$\epsilon_{\kappa\lambda\mu\nu}\epsilon^{\nu}_{\rho\sigma\tau}=g_{\kappa\rho}g_{\lambda\sigma}g_{\mu\tau}-g_{\kappa\rho}g_{\lambda\tau}g_{\mu\sigma}$$
$$+g_{\kappa\sigma}g_{\lambda\tau}g_{\mu\rho}-g_{\kappa\sigma}g_{\lambda\rho}g_{\mu\tau}+g_{\kappa\tau}g_{\lambda\rho}g_{\mu\sigma}-g_{\kappa\tau}g_{\lambda\sigma}g_{\mu\rho} \tag{5.11}$$

as

$$i[(s+t)_{\kappa}q_{\lambda}p_{\mu}-(s+t)_{\kappa}q_{\mu}p_{\lambda}+(s+t)_{\lambda}q_{\mu}p_{\kappa}-(s+t)_{\lambda}q_{\kappa}p_{\mu}+(s+t)_{\mu}q_{\kappa}p_{\lambda}-(s+t)_{\mu}q_{\lambda}p_{\kappa}],$$

which is just the trivector $i(s+t)\wedge q\wedge p$ written in components. Since, by (5.6), $q\wedge p=\frac{1}{2}(p+q)\wedge(p-q)$, we have the result that the last term of the square bracket in (5.10) is

$$\frac{i}{2}(p-q)\wedge(s+t)\wedge(p+q).$$

The simplification of the remaining term in (5.10) proceeds analogously to that for (5.4). Note first that $(p-q)$ is orthogonal to $v=(1-s\cdot t)(p+q)+(t\cdot p)s+(s\cdot q)t$. Thus, the trivector $m\epsilon_{\kappa\lambda\mu\nu}[(1-s\cdot t)(p^{\nu}+q^{\nu})+(s\cdot t)^{\nu}+(q\cdot s)t^{\nu}]$ is of the form $(p-q)\wedge r_1\wedge r_2$ where r_1 and r_2 are orthogonal to $(p-q)$ and to $(1-s\cdot t)(p+q)+(t\cdot p)s+(s\cdot q)t$. The bivector $r_1\wedge r_2$ is up to a constant factor just the dual of the bivector $(p-q)\wedge[(1-s\cdot t)(p+q)+(t\cdot p)s+(s\cdot q)t]$ uniquely determined up to the addition of a multiple of that bivector. The constant of proportionality, a, is fixed by contracting the two sides of the identity

$$m\epsilon_{\kappa\lambda\mu\nu}v^{\nu}=a[(p-q)_{\kappa}\tfrac{1}{2}\epsilon_{\lambda\mu\rho\sigma}(p-q)^{\rho}v^{\sigma}$$
$$+(p-q)_{\lambda}\tfrac{1}{2}\epsilon_{\mu\kappa\rho\sigma}(p-q)^{\rho}v^{\sigma}+(p-q)_{\mu}\tfrac{1}{2}\epsilon_{\kappa\lambda p\sigma}(p-q)^{\rho}v^{\sigma}]$$

with $(p-q)^{\kappa}$. The result is

$$a=\frac{2m}{(p-q)^2},$$

so, finally, we have

$$\epsilon_{\kappa\lambda\mu\nu}u(p)^{+}\lambda^{\nu}u(q)=(p-q)_{\kappa}K_{\lambda\mu}+(p-q)_{\lambda}K_{\mu\kappa}+(p-q)_{\mu}K_{\kappa\lambda},$$

where

$$K_{\kappa\lambda}=\frac{u(p,s)^{+}u(q,t)}{4[(m^2+q\cdot p)(1-s\cdot t)+(t\cdot p)(q\cdot s)]}$$
$$\times\left[\frac{i}{2}((s+t)_{\kappa}(p+q)_{\lambda}-(s+t)_{\lambda}(p+q)_{\kappa})+\frac{m}{(p-q)^2}\right.$$
$$\left.\times\epsilon_{\kappa\lambda\rho\sigma}(p-q)^{\rho}((1-s\cdot t)(p+q)+(t\cdot p)s+(s\cdot q)t)^{\sigma}\right]. \tag{5.12}$$

Equations (5.3), (5.9), and (5.12) are the basic input for the quantum field theories described in Ref. 3.

ACKNOWLEDGMENTS

The original version of this article was presented, under the title ''A Few Additional Pages for the Black Book,'' at a Symposium (Lyon, 8–12 June 1992) in honor of Louis Michel on the occasion of his retirement from the Institut des Hautes Études Scientifiques. The paper was submitted to the proceedings of the symposium but they never were published. The Black Book in question was a compendium of information concerning the solutions of the Dirac equation in four-dimensional space–time prepared by Michel and me in 1954–1956 with an eye to a review of the theory of the weak interactions. We were later joined in this enterprise by Val Telegdi. Alas, the contemplated review was never finished and published; we were overtaken by events—the parity revolution. The present article can be regarded as the promised paper quoted in Ref. 4.
